About the pagination of this eBook

This eBook contains a multi-volume set.

To navigate this eBook by page number, you will need to use the volume number and the page number, separated by a hyphen.

For example, to go to page 5 of volume 1, type “1-5” in the Go box at the bottom of the screen and click "Go."

To go to page 5 of volume 2, type “2-5”… and so forth.

Notices

Knowledge and best practice in this field are constantly changing. As new research and experience broaden our understanding, changes in research methods, professional practices, or medical treatment may become necessary.

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds, or experiments described herein. In using such information or methods they should be mindful of their own safety and the safety of others, including parties for whom they have a professional responsibility.

With respect to any drug or pharmaceutical products identified, readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered, to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of practitioners, relying on their own experience and knowledge of their patients, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions.

To the fullest extent of the law, neither the Publisher nor the authors, contributors, or editors, assume any liability for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein.

To Chester, Lady, Cheerio, Moxie, Domino, Sasha, Tuxedo, Chairman Meow, Zoey, Apollo, Ayla, Annabelle, and Atticus for enriching our lives.

Raymond J. Fonseca

To Aubrey, Cam, and Katharine—it is wonderful to be your Dad.
To Dr. Raymond J. Fonseca, a tremendous mentor, educator, surgeon, and friend.
To Dr. Hans Bosker, an exceptional intellect, surgeon, gardener, and friend.
To Dr. David Frost, a superb humanitarian, surgeon, and friend.
And to Jennifer, with love.

Michael P. Powers

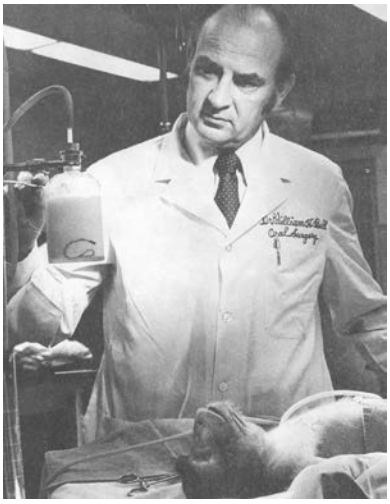
I dedicate my portion of this work to Travis A. "Bz" Witherington who saw something in me, encouraged me, and made everything else possible. He is one of the best teachers anywhere. To my mentors: Ray Fonseca, Bob Bays, John Gregg, Tim Turvey, and Khursheed Moos—they are teachers, researchers, mentors, confidants, and friends. Thank you all.

David E. Frost

To my wife Nancie for her unconditional support and my children Andrew, Dharma, Dana, and Bodhi, who inspire me and make me so proud.

Bach Le

In Memoriam



William H. Bell, DDS

We respectfully dedicate this edition of *Oral and Maxillofacial Surgery* to the memory of Dr. William "Bill" Harrison Bell. Matchless among his peers, Dr. Bell was an inimitable leader in surgery and medicine throughout his career.

In the early 1970s, Dr. Bell revolutionized oral and maxillofacial surgery through his landmark research on the biologic basis and clinical rationale for the Le Fort I osteotomy. In subsequent decades, he guided the hands of generations of surgeons, whether in academic medical centers across the world or through his meticulously detailed textbooks. It is a testament to Dr. Bell's always-passionate and always-persistent pursuit of excellence that his textbooks still remain contemporary decades after their publication.

While Dr. Bell was a revolutionary in our field, it is not simply in this spirit that we dedicate this book. Dr. Bell also served as an inspiration and mentor to us throughout our careers and lives, showing us always a readiness to inspire and a passion to change lives however he could. We are, quite simply, not alone in this feeling. It was this passion that compelled him to devote his life to improving patient care. It was this passion that affected so many others in our field. And it was this passion that also characterized so many areas of his vibrant and rich life—a life very well-lived.

It was an honor to learn from and know Bill. He was unwavering and uncompromising, and his love was unconditional. We know that the passion that burned in him to help others will continue to ignite the spirits of generations of surgeons to come. It will guide our hands and our actions as well.

Preface

We are excited to present the third edition of *Oral and Maxillofacial Surgery*. This three-volume text is the result of the collaboration of multiple contributors. The first edition, published in 2000, and the second edition, published in 2009, were very well-received. However, with all the advances in our profession, we felt it was time for a new edition. The section editors have done an excellent job recruiting the most knowledgeable individuals in their specific areas of expertise. The authors have submitted chapters that reflect the state of the art in their areas of responsibility.

This text is a comprehensive resource on oral and maxillofacial surgery. Every area in our specialty has been addressed. It defines the scope of the specialty. Every surgical procedure performed by an oral surgeon is covered in this text. This multi-volume text provides coverage of a wide range of issues related to surgical care, such as anesthesia, diagnostic imaging treatment planning, rehabilitation, physical therapy, and psychological considerations.

After an analysis of the changing field of oral and maxillofacial surgery, we strove to present a comprehensive, current book that covers the complete scope of our specialty. We hope that the reader appreciates and agrees with our efforts. We stated in the preface of the first edition that we hoped that our future attempts will present an even broader scope of oral and maxillofacial surgery. The fact that this edition has succeeded in that regard is a testament to the individuals who are constantly expanding the envelope.

Acknowledgments

The third edition of *Oral and Maxillofacial Surgery* is a team approach. The section editors—Michael P. Powers, David E. Frost, and Bach Le—were invaluable contributors to the success of this effort. They diligently pestered authors so that deadlines were almost met. This edition, like the last two, attempts to define the scope of oral and maxillofacial surgery and could not have come to fruition without these contributors.

Residents are the lifeblood of our specialty. Many have helped to contribute portions of chapters in this book. They have also provided us with friendship, dedication, intellectual stimulation, and humility, without which this book would not have been written.

Last, I would like to thank all the staff who helped to prepare these manuscripts and the editorial staff at Elsevier, who were so patient with our procrastination and meticulous in their development and editing of this book. Additionally, I would like to thank my staff—Laynee Adams, Sally Brown, Heather Early, Patty Martin, Sarah Merrill, Josie Ray, and Ashley Wood—who collectively and individually make my life so enjoyable.

Raymond J. Fonseca, DMD

1 Professionalism and Ethics

LEE D. POLLAN

Oral and maxillofacial surgery (OMS) training is an intense educational process that requires 4 to 6 years of residency beyond the traditional 4-year predoctoral dental educational curriculum. The OMS residency includes exposure and training to competency in the following disciplines: dento-alveolar surgery and implants, medicine, general surgery, anesthesiology, critical and intensive care, pathology, trauma management and reconstruction, cleft and craniofacial surgery, temporomandibular dysfunction, orthognathics, and cosmetic surgery. The Commission on Dental Accreditation also requires each resident to participate in scholarly activity and to be educated in coding and practice management.

The oral and maxillofacial surgeon enjoys a unique position among the dental specialties in that the educational process is longer and more intense, and it straddles the fence between medicine and dentistry. The OMS is often seen as the "go-to" person in dentistry and is often called on to assist in the diagnosis and treatment of patients who present with unique and perplexing problems in dental practice. Physicians will also refer patients who present with unusual problems of the head and neck. It is implied that as a health care provider, the OMS is given the privilege to provide care for patients, but also must demonstrate the responsibility to patients who place their trust in the OMS to care for them and their families. It is for these reasons that the OMS must function in a highly professional and ethical manner. It is this author's belief that the OMS curriculum is deficient in teaching and mentoring in the areas of professionalism and ethics.

What is the Definition of "Professionalism"?

The American Board of Medical Specialties (ABMS) states that *professionalism* is a belief system in which group members (professionals) declare to each other and to the public the shared competency standards and ethical values they promise to uphold in their work and what the public and individual patients can and should expect from medical (dental) professionals. At the heart of this concept is a three-part promise to acquire, maintain, and advance:

- An ethical value system grounded in the conviction that the professions exist to serve the patients' and the public's best interests.
- The knowledge and technical skills required for good practice.
- The interpersonal skills necessary to work together with patients.

There is a shared view that the members of a profession should work together, are committed to maintaining the standards and values that govern their practice, and monitor each others' adherence to their standards on behalf of the public. These standards are vetted through a process of internal debate and then are declared to the public to encourage open dialogue and ensure that the standards meet social needs and at the same time uphold core professional values. These standards are distributed to all stakeholders to ensure they are understood as part of the professional's contract with society, and then they must be enforced by the profession.[1]

Alan Norton, in a blog post published in 2010 at www.techrepublic.com, discusses 10 things that define a true professional. These are:

1. ***Put the customer (patient) first.*** Understanding and satisfying your patient's needs is the cornerstone of being a successful professional. Do what is necessary to meet those needs. Consider putting first the satisfaction of your co-workers.
2. ***Make expertise your specialty.*** The very word professional implies that you are an expert. Technical competence is essential.
   - Become an expert in the skills and tools necessary to do your job
   - Always perform to the best of your abilities
   - Keep your knowledge up to date
3. ***Do more than expected.*** Professionals aren't bound by a clock and have the ability to self manage their time. Professionals are expected to efficiently manage

their workload and frequently must work well beyond the standard 40 hour workweek. The professional is expected to produce results and meet or exceed expectations.

4. ***Do what you say and say what you can do.*** Professionals must walk the walk to back up talking the talk. To do less erodes the trust that patients have in their doctor.
5. ***Communicate effectively.*** A patient will go out of their way to seek out a doctor who has excellent communication skills. The professional takes time to explain treatment options, make recommendations, clearly state financial arrangements, and predict expected completion of treatment. This in turn empowers the patient to accept treatment plans and make appropriate treatment decisions.
6. ***Follow exceptional guiding principles.*** Professionals demonstrate appreciation of their employees, practice proper etiquette, and have high ethical and moral standards. Professionals are honest and fair in their dealings with others.
7. ***Praise your peers not yourself.*** Demonstrate respect for your peers. While you may not always agree with another provider's treatment, a professional should not denigrate the care provided by others.
8. ***Share your knowledge.*** If you believe in hoarding information and have the opinion that your knowledge is greater than that of others and will ensure your success, think again—no one is irreplaceable. Professionals should help their peers and are respected for doing so.
9. ***Say thank you (and don't be afraid to say I'm sorry).*** A simple "thank you" to a co-worker, employee, assistant, patient or referral source goes a long way to state your gratitude. Saying "I'm sorry" doesn't make you appear weak or imply a sense of guilt. It merely expresses your admission that you (and perhaps an outcome) are less than perfect. It expresses your humanity and a willingness to admit that a professional isn't always perfect.
10. ***Keep a smile on your face and the right attitude in your heart.*** Being pleasant and cheerful can be difficult when you are feeling unpleasant at times. Sharing the misery is not the mark of a professional.[2]

A Little History

Dental (and medical) education historically upheld the notion of professionalism. Numerous institutions hold "white coat ceremonies" inducting the student into the professional arena. Students in the early stages of clinical exposure to patients were called "doctor." Students were mandated to wear professional attire, act in a certain manner, and act respectfully toward peers and patients. But it wasn't until the mid-1990s that the concept of teaching professionalism began to emerge into health care and medical and dental education. The health care professions and the commitment to the patient were being challenged by external forces of change in society (e.g., managed care, health care financing challenges, governmental pressures). Numerous print and broadcast news segments have raised concerns about unprofessional and unethical behavior. It is the public's perception of dishonesty and a lack of professional integrity by physicians and dentists, and the resulting erosion of public trust, that forced health care into a renewed sense of professionalism.

The Physicians' Charter, published in *Lancet* in 2002, was a product of the American College of Physicians, the American Society of Internal Medicine, the American Board of Internal Medicine Foundation, and the European Federation of Internal Medicine. The Charter outlines three fundamental principles underlying professionalism:

- Primacy of patients' welfare
- Patients' autonomy
- Social justice

The Charter goes on to establish a set of 10 professional commitments to:

1. Professional competence
2. Honesty with patients
3. Patient confidentiality
4. Maintaining appropriate relationships with patients
5. Improving quality of care
6. Improving access to care
7. Just distribution of finite resources
8. Scientific knowledge
9. Maintaining trust by managing conflicts of interest
10. Professional responsibilities

The expanded definition of the Physician Charter commitments are a set of professional responsibilities that inform the public and the profession of the fundamental principles that help to ensure patient welfare and autonomy.

1. **Commitment to professional excellence.** Physicians must be committed to lifelong learning and be responsible for maintaining the medical knowledge and clinical and team skills necessary for the provision of quality health care. More broadly, the profession as a whole must strive to see that all of its members are competent and must ensure that appropriate mechanisms are available for physicians to accomplish this goal.
2. **Commitment to honesty with patients.** Physicians must ensure that patients are completely and honestly informed before the patient has consented to treatment and after treatment has occurred. This expectation does not mean that patients should be involved in every minute decision about medical care; rather, they must be empowered to decide on the course of therapy. Physicians should also acknowledge that in health care, medical errors that injure patients do sometimes occur. Whenever patients are injured as a consequence of medical care, patients should be informed promptly because failure to do so seriously compromises patient and societal trust. Reporting and analyzing medical mistakes provide the basis for appropriate prevention and improvement strategies and for appropriate compensation to injured parties.

3. **Commitment to patient confidentiality.** Earning the trust and confidence of patients requires that appropriate confidentiality safeguards be applied to disclosure of patient information. This commitment extends to discussions with persons acting on a patient's behalf when obtaining the patient's own consent is not feasible. Fulfilling the commitment to confidentiality is more pressing now than ever before, given the widespread use of electronic information systems for compiling patient data such as electronic medical records (EMRs) and an increasing availability of genetic information. Physicians recognize, however, that their commitment to doctor-patient confidentiality must occasionally yield to overriding considerations in the public interest (for example, when patients endanger others).
4. **Commitment to maintaining appropriate relations with patients.** Given the inherent vulnerability and dependency of patients, certain relationships between physicians and patients must be avoided. In particular, physicians should never exploit patients for any sexual advantage, personal financial gain, or other private purpose.
5. **Commitment to improving quality of care.** Physicians must be dedicated to continuous improvement in quality health care. This commitment entails not only maintaining clinical competence but also working collaboratively with other professionals to reduce medical error, increase patient safety, minimize overuse of health care resources, and optimize the outcomes of care. Physicians must actively participate in the development of better measures of quality of care and the application of quality measures to assess routinely the performance of all health care professionals, institutions, and systems. Physicians, both individually and through their professional associations, must take responsibility for assisting in the creation and implementation of mechanisms designed to encourage continuous improvement in the quality of care.
6. **Commitment to improving access to care.** Medical professionalism demands that the objective of all health care systems be the availability of a uniform and adequate standard of care. Physicians must individually and collectively strive to reduce barriers to equitable health care. Within each system, the physician should work to eliminate barriers to access based on education, laws, finances, geography, and social discrimination. A commitment to equity entails the promotion of public health and preventive medicine, as well as public advocacy on the part of each physician, without concern for the self-interest of the physician or the profession.
7. **Commitment to a just distribution of finite resources.** While meeting the needs of individual patients, physicians are required to provide health care that is based on the wise and cost-effective management of limited clinical resources. They should be committed to working with other physicians, hospitals, and payers to develop guidelines for cost effective care. The physician's professional responsibility for appropriate allocation of resources requires scrupulous avoidance of superfluous tests and procedures. The provision of unnecessary services not only exposes one's patients to avoidable harm and expense but also diminishes the resources available for others.
8. **Commitment to scientific knowledge.** Much of medicine's contract with society is based on the integrity and appropriate use of scientific knowledge and technology. Physicians have a duty to uphold scientific standards, to promote research, and to create new knowledge and ensure its appropriate use. The profession is responsible for the integrity of this knowledge, which is based on scientific evidence and physician experience.
9. **Commitment to maintaining trust by managing conflicts of interest.** Medical professionals and their organizations have many opportunities to compromise their professional responsibilities by pursuing private gain or personal advantage. Such compromises are especially threatening in the pursuit of personal or organizational interactions with for-profit industries, including medical equipment manufacturers, insurance companies, and pharmaceutical firms. Physicians have an obligation to recognize, disclose to the general public, and deal with conflicts of interest that arise in the course of their professional duties and activities. Relationships between industry and opinion leaders should be disclosed, especially when the latter determine the criteria for conducting and reporting clinical trials, writing editorials or therapeutic guidelines, or serving as an editor of a scientific journal.
10. **Commitment to professional responsibilities.** As members of a profession, physicians are expected to work collaboratively to maximize patient care, be respectful of one another, and participate in the processes of self-regulation, including the remediation and discipline of members who have failed to meet professional standards. The profession should also define and organize the educational and standard-setting process for current and future members. Physicians have both individual and collective obligations to participate in these processes. These obligations include engaging in internal assessment and accepting external scrutiny of all aspects of their professional performance.[3]

It is difficult to define professionalism in the style of a dictionary. Many individuals have made the tongue-in-cheek comment that pornography and professionalism have two similarities—they may be hard to define, but people know it when they see it. Defining professionalism becomes a little easier when one recognizes that there are common characteristics that define all professions. Autonomy is granted to the profession only if the profession meets the responsibilities placed on it by patients, third-party payers, state regulatory bodies, peers, and the institutions that grant privileges to the health care provider. In particular, the health care professions serve as guardians of social values and the professionals are

expected to articulate and hold these values publically. Professionalism is grounded within a series of behavioral patterns, moral values, honesty, integrity, and judgment. The profession then becomes a way of life with a moral value.[4]

In his article on defining medical professionalism, Swick states that medical professionalism comprises a series of behaviors. He says that health care providers:

- Subordinate their own interests to the interests of others.
- Adhere to high ethical and moral standards.
- Respond to societal needs, and their behaviors reflect a social contract with the community served.
- Project core humanistic values, including honesty and integrity, caring and compassion, altruism and empathy, respect for others, and trustworthiness.
- Exercise accountability for themselves and for their colleagues.
- Demonstrate a continuing commitment to excellence.
- Exhibit a commitment to scholarship and to advancing their field.
- Deal with high levels of complexity and uncertainty.
- Reflect upon their actions and decisions.[4]

This chapter has discussed many attributes of professional behavior, teaching of professionalism, the responsibilities of being a professional, and the expectations placed on the health care professional by society and regulatory bodies. Patrick Duff, MD, has enumerated several examples of unprofessional behavior in students. These include:

- Intellectual or personal dishonesty: a fabrication of research results or lab data, failure to follow through on assignments and cheating on examinations
- Arrogance and disrespectfulness: a student's inappropriate sense of entitlement
- Prejudice on the basis of gender, ethnicity, age, or sexual orientation
- Abrasive interactions with patients and co-workers: a student's exaggerated sense of self importance
- Lack of accountability for medical errors and administrative over sights; lack of student investment in a patient's outcome
- Fiscal irresponsibility: ordering expensive and unnecessary lab tests; receiving kick-backs for referrals or use of materials
- Lack of commitment to lifelong learning: failing to explore new technologies or seeking continuing education
- Lack of due diligence: carelessness, laziness, inattention to detail, and failure to follow through
- Personal excesses: substance abuse, high-stakes gambling, and high-risk behaviors
- Sexual misconduct: inappropriate advances or relationships with patients, co-workers, and students[5]

The trigger for professionalism in medical education initiatives was the Physicians' Charter. Professionalism has been identified as a core competency that needs to be evaluated in students and residents. The Group on Educational Affairs (GEA), the Association of American Medical Colleges (AAMC), and the Accreditation Council for Graduate Medical Education (ACGME) as well as many specialty boards have identified professionalism education as a priority.

Can Professionalism be Taught?

The oral and maxillofacial surgeon who is involved in predoctoral or residency education must decide: can professionalism be taught using the traditional Socratic method, or should it be taught by role modeling?

If professionalism is taught by role modeling, the mentor should answer the following:

- Am I modeling teamwork?
- Am I a role model for lifelong learning?
- Can the student see that I am honest and compassionate?
- Do I make the student aware of my advocacy efforts?

If professionalism is taught by conventional didactic means, the mentor might ask:

- Can I teach the student to be compassionate or respectful?
- Can I teach the student to self-monitor honesty and goals for excellence?
- Can I teach teamwork?[6]

Even though the concept of professionalism can be nebulous and very difficult to define, several organizations have elucidated constructs to assist with this definition. The ACGME has stated that professionalism is a core competency for all residents. The competencies expected are that "residents must demonstrate a commitment to carrying out professional responsibilities and an adherence to ethical principles. Residents are expected to demonstrate:

- Compassion, integrity, and respect for others
- Responsiveness to patient needs that supersedes self-interest
- Respect for patient privacy and autonomy
- Accountability to patients, society, and the profession
- Sensitivity and responsiveness to a diverse patient population, including but not limited to diversity in gender, age, culture, race, religion, disabilities, and sexual orientation

The Gold Humanism Foundation promotes the concept of a humanistic doctor as one who demonstrates integrity, excellence, compassion, altruism, respect, and service.

The University of Texas Medical Branch Professionalism Charter outlines a set of commitments that is expected of *every* employee: commitment to responsibility, service, diversity, competence, confidentiality, honesty, responsible use of resources, improving access to education and health care, quality, maintaining appropriate relations, managing conflicts of interest, and knowledge. It is incomprehensible that UTMB is the only institution that states these expectations.[7]

Evaluation of the Student (Resident) and Adherence to Professional Behavior

Since the ACCME and other accrediting bodies state that teaching of professionalism is a core competency as part

of residency education, what is the appropriate method of evaluating the resident and providing feedback to the resident?

All faculty at the predoctoral and postgraduate levels in dentistry must adhere to the standards of the Commission on Dental Accreditation (CODA). These standards include regular evaluation of the performance of the resident. The standards also allow for evaluation of the faculty by the resident.

If one subscribes to the foregoing discussion, it is clear that one of the major tenets of professionalism is *honesty*. It is not unusual for the mentor to question whether or not a specific resident evaluation is warranted. (Maybe I was ineffective as a teacher—maybe my evaluation was too harsh. Perhaps the student who receives a poor evaluation will recognize that I was the one who gave that bad evaluation and I will in turn receive a poor evaluation myself.) The simple answer is that honesty is one of the most important characteristics in solving this problem. If we are dishonest in our evaluations, are we, in turn, being truly unprofessional?

To demonstrate true professionalism, we must be able to be critical when reflecting on our own behaviors, regardless if we are the resident or the mentor. As the resident, it is appropriate to ask:

- How did I behave in that critical situation?
- If I had it to do over, would I do anything differently?
- What aspect of professionalism was challenging for me today?

As the mentor, it is appropriate to pose the following questions to the resident:

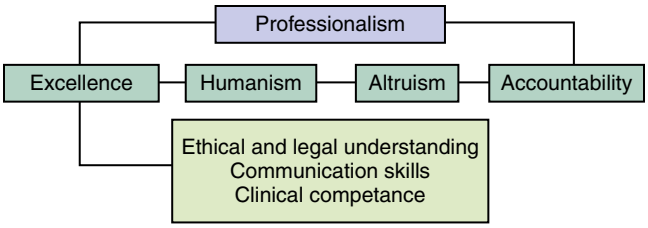
- How did you think you did in that difficult situation?
- If you had it to do over, would you do anything differently?
- What aspect of professionalism was challenging for you today?

As a professional, it is expected that one demonstrate CHARACTER:

C ompassion
H onesty
A ltruism
R esponsibility
A iming for excellence
C onfidentiality
T eamwork
E thical approach
R espect[8]

Paul S. Mueller, in his paper presented to the Keio Medical Society in Tokyo in 2008, lists eight reasons for teaching and assessing professionalism.[9]

1. Teaching and assessing professionalism does not occur by chance alone. The elements of the framework of professionalism should intentionally be taught (Figure 1-1).
2. Patients expect doctors to be professional. Patients expect the doctor to be confident, empathetic, personal, forthright, respectful, and thorough.



• **Figure 1-1** A framework for defining medical professionalism.

3. Medical and dental professional societies expect professionalism to be taught and assessed. Accrediting organizations such as the ACGME and the Joint Commission recommend that professionalism be included as a core competency in graduate medical education and accreditation of institutions. CODA has standards that require education in practice management and professionalism.
4. Professionalism is associated with improved medical outcomes. These are related to increased patient trust, better compliance, fewer patient complaints, and less patient litigation.
5. Unprofessional behavior is associated with adverse medical outcomes. These are related to reduced employee morale and productivity, reduced communication, burnout and depression.
6. Accrediting bodies require that professionalism be taught and assessed.
7. Professionalism can be taught and learned. Formal and informal curricula can influence values and beliefs about moral and ethical reasoning and behavior.
8. Informal educational processes (the hidden curriculum) that include conversations during rounds, hallways, call rooms, etc. can be powerful influences on trainees provided by role models and mentors.

There are several concepts for teaching professionalism that must be considered. According to Epstein and Hundert, these concepts include identifying the challenges of teaching professionalism, transitioning from measuring values to predicting behaviors, methodologies for teaching professionalism, and the importance of imparting the concept of professional behavior to the student.[10]

Today's students face pressures that seem daunting to them. Merely trying to understand the expectations of what professionalism encompasses is difficult for the student. Numerous students have negative role models based on their exposure to the print and broadcast media. Newspaper articles about health care professionals who have committed egregious acts are prominent. Many television shows portray health care professionals in a very unprofessional light.

A student's values can be very difficult to observe and measure. Providing feedback to a student about values can be threatening and imply character defects. Discussing deviations from expected behavior is less threatening and usually, more readily accepted. While educators generally have an easier time assessing cognitive skills, there often is greater

difficulty in discussing non-cognitive skills such as communication, integrity, and honesty.

Several steps are involved in teaching professionalism: setting expectations, performing assessments, remediating inappropriate behaviors, preventing inappropriate behaviors, and implementing cultural change.

Initially, expected behaviors must be defined. These expectations can be variable based on the culture of a particular institution. In addition, institutional processes such as reporting channels, due process, remediation processes, and lack of retaliation against those who report behavior issues may vary.

Educators, especially those who are involved in predoctoral education, must have the tools to provide uniform, consistent, and unbiased evaluation of students. The institution must provide this information to the faculty in order to make the evaluation process effective.

Last, the institution must provide the educators with the tools to remediate the student who does not comply with accepted defined patterns of professional behavior. The student must have information about the consequences of noncompliance with regard to faculty and institutional expectations for professional behavior.[11]

Causes of Unprofessional Behavior

Types of unprofessional behavior were previously discussed. It is important to note that unprofessional behavior does not necessarily indicate a character flaw or lack of a moral compass. It is generally believed that all medical and/or dental students enter professional school intending to become respected, successful, and contributory members of their respective professional communities. What happens that leads to an alteration in behavior within the individual who is deemed to be unprofessional?

According to Liselotte N. Dyrbye and her colleagues, there is a direct relationship between self-reported unprofessional conduct and burnout among medical students.[12] Of students who responded to a survey, 52.8% were experiencing burnout. Students with burnout were significantly more likely to have engaged in cheating and dishonest clinical behaviors. These students were less likely to hold altruistic values regarding a physician's responsibility to society, including serving underserved patient populations.

A study by Shalini T. Reddy published in the *Journal of Hospital Medicine* identified causes of unprofessional behavior among hospitalists.[13] Four key factors or patterns of unprofessional behavior included making fun of others, conduct in the learning environment (texting during conferences), workload management (celebrating transfer of a patient), and time pressures (signing out early). The most common unprofessional behaviors were having nonmedical, personal conversations in patient corridors, ordering a routine test as urgent to expedite patient care, signing out a patient by phone when it could have been done in person, and ridiculing physicians to colleagues.

According to a blog post published by Kaiser Health News on June 14, 2012, two thirds of doctors surveyed at three Chicago hospitals admit to having personal conversations within earshot of patients. Sixty-two percent have characterized a lab test as urgent in order to obtain the result faster. Forty percent mocked another physician. The same number made disparaging remarks about emergency room doctors for missing part of a patient's medical problems. Thirty percent made disparaging remarks about patients on rounds. Twenty-nine percent of respondents stated they had attended a dinner or social event sponsored by a drug or medical device manufacturer that stood to gain from a doctor's decision. The good news is that egregious behaviors such as falsifying patient records (6.4%) and performing procedures beyond the provider's skill level (2.6%) were much less common.[14]

The Link between Disciplinary Actions and Prior Behavior in Professional School

Maxine Papadakis and co-workers published a paper in the *New England Journal of Medicine* in 2005 that looked at the correlation between disciplinary action by state medical boards and prior behavior in medical school.[15] This case-controlled study investigated disciplinary actions against medical school graduates and the types of behavior that might be predictive of disciplinary action by state boards. The methodology evaluated physicians who were graduates of three respected, high-profile medical schools since 1990. The actions ranged from public reprimand to revocation of the medical license. The control group consisted of graduates who graduated within 1 year of the disciplined graduates and had no disciplinary actions on their record. The measurements used were admission applications, course grades, evaluation narratives, and scores from licensing examinations, administrative correspondence, and a dean's letter of recommendation to residency programs. Other predictor variables included undergraduate GPA, MCAT scores, and scores on the National Board of Medical Examiners or the USMLE Step 1. (See Table 1-1 for the results.)

TABLE 1-1 Comparison between Disciplined and Non-disciplined Physicians Based on Prior Academic Performance

Variable	Non-disciplined Physicians	Disciplined Physicians
Undergraduate GPA	Somewhat higher	Somewhat lower
MCAT scores	Slightly higher	Slightly lower
NBME/USMLE Step 1	Slightly higher	Slightly lower
Repeated course in medical school	Most likely did not fail a course	Twice as likely to have failed a course

What were the Types of Unprofessional Behavior?

- Irresponsibility
- Diminished capacity for self-improvement
- Poor initiative
- Impaired relationships with fellow students, residents, and faculty
- Impaired relationships with nurses and other non-physician health care workers
- Behaviors associated with being anxious, insecure, or nervous
- Unreliable attendance in clinic and poor follow-up related to patient care
- Failure to accept constructive criticism
- Argumentativeness
- Poor attitude with lack of motivation and enthusiasm, or passive affect

The two types of unprofessional behavior most likely to predict disciplinary actions were irresponsibility and diminished capacity for self-improvement.

What can be Done about this Problem?

- Standards for professional school admission and outcome objectives for graduation should be reviewed so that they contain specific language about professional behavior.
- Professionalism can be taught and modeled.
- Students should be provided with feedback that can motivate them and assist in remediating unprofessional patterns of behavior.

Without question, identifying students who exhibit a tendency toward unprofessional behavior early in their career can help them to minimize the likelihood of unprofessional behavior and possibly future disciplinary actions by administrators and state boards.

Based on the material discussed in this chapter, it is relatively easy to identify and enumerate the behavioral patterns that are unprofessional: putting one's self-interest above the interests of the patient, lack of honesty and integrity, and ignoring the consequences of actions that are not socially acceptable. In this author's opinion, a significant contributory influence in unprofessional activities is *greed*—maximizing income for the least amount of work. Being the consummate professional does not mean having the best clothes, driving the nicest car, giving the most lavish parties, or belonging to the most exclusive country club. A true professional is a caring, compassionate, and honest person. It is the true professional who gives back to the patients who seek care, contributes to the good of the local community, and earns the admiration of peers.

The financial gains from greed often result in penalties imposed by state boards, loss of reputation, erosion of the referral base, and generally being perceived as unprofessional and unethical.

The news media is laden with reports of fines, suspension or revocation of license, expulsion from professional societies or associations, or even incarceration. For example:

- An orthodontist was forced to repay $800,000 in a Medicaid fraud case for improper billing of claims. He was forced to resign as a Medicaid provider and not see any new patients.
- A New York dentist was found guilty of larceny charges for fraudulent billing and up-coding services for Medicaid-covered patients. A criminal and civil settlement was reached in excess of $480,000. He was sentenced to full restitution and community service for his felony conviction.
- A New York dentist was sentenced to 1 to 3 years in jail and will have to repay $700,000 in restitution for fraudulent Medicaid practices.
- The Board for Professional Medical Misconduct of the New York State Health Department recently barred a physician from practicing in New York after he was found guilty of harassing, abusing, or intimidating a patient, moral unfitness, and fraudulent practice.
- FORBA Holdings LLC, the management of FORBA, and several dentists who operated and owned numerous dental facilities in many states have been the target of legal and regulatory actions. The clinical facilities were operated as "Small Smiles Dental Centers." The dentists who owned, were employed by, and treated patients in these centers were charged with performing unnecessary procedures, failing to obtain proper informed consent, performing substandard care, and fraudulent billing practices. Some of the dentists were incarcerated. Some paid hundreds of thousands or, in some cases, millions of dollars to settle civil claims and repay financial gains from fraudulent billing practices. Some were required to inactivate and/or surrender their state dental licenses.
- A New Jersey oral and maxillofacial surgeon was found guilty of illegally selling human body parts obtained from funeral homes without the consent of the deceased person's family. The tissues harvested were used for tendon replacement, bone grafts, and other reconstructive surgical procedures. He was sentenced to 18 to 54 years' imprisonment and died in prison in July 2013.

How does this Information Relate to Oral and Maxillofacial Surgery?

In 2006, The American Association of Oral and Maxillofacial Surgeons published a DVD about professionalism and ethics. The intent was to distribute the DVD to first-year residents so that the door to teaching of professionalism could be opened. As previously stated, the teaching of professionalism has been identified as part of the core curriculum in predoctoral professional education in medicine, and should be a portion of the core curriculum in dental education. This concept is endorsed

and mandated by ACGME and CODA. The producers of the DVD identified four major aspects of professionalism that are germane to the OMS resident as well as the practitioner, regardless of experience or length of time in practice. These are:

- Ethics
- Giving back to the specialty
- Contributing to the community
- Contributing to education and research efforts

The late Dr. Robert V. Walker made several statements that speak volumes concerning the type of behavior, dedication, and personality of the consummate professional. Those who knew Dr. Walker understand that he was speaking to every person who has the title "Doctor." He stated,

> *Professionalism requires that you provide excellence in every conceivable way in the care of your patients. We should have a sense of excellence in giving back to our specialty that can be in many ways: monetarily, to contributing to research of the highest quality, commitment to your community, your church, the schools that you attended (both undergraduate and professional). You have to support them. . . . They provided the ticket for what I am. We are not an island unto ourselves. We all have had help to get where we are and if we don't give back to the institutions that have helped us, well then, we are being selfish to the institutions. Professionalism is a feeling that one has a debt to those who have gone before us.*

Dr. Rocco R. Addante, former chair of the AAOMS Commission on Professional Conduct, has stated that "ethics and professional behavior speaks volumes to your colleagues and patients. This includes the way one manages his practice to how one conducts himself in everyday life." Dr. Addante says, "We must take the high road and be honest while maintaining integrity. Patients are very perceptive of how the doctor treats the staff and what type of rapport the staff has with the doctor and how they support the doctor." Is the atmosphere in the office professionally respectful of the staff and patients? Does the staff look and speak to each other and to the patient in a respectful, caring manner? Referring doctors are also able to perceive that the office has a professional atmosphere that spawns a close, confident working relationship while caring for patients. This type of atmosphere goes a long way to positively promote the practice and generate referrals from other doctors as well as other patients. This type of perception and behavior is far more influential than print or Internet advertising.

How does a young professional new to practice get started? According to Dr. Robert M. Brandjord, Past President of the American Dental Association, involvement occurs early in one's career, and it begins on the local level. Early involvement in county and district dental associations is an important step in promoting your practice. More importantly, you develop a sense of community involvement, not only within dentistry, but also in the local community. It is not uncommon for a health care provider to be looked on as a "go-to" person or leader in the community. Demonstrating professional behavior enhances one's perceived standing in the community.

Dr. Brandjord says, "Involvement in local dental community activities gives one insight into the political process in achieving goals related to the needs of your specialty. Local involvement helps to build coalitions." He further believes that "the dental specialties should be involved in American Dental Association activities to share ideas, discuss common concerns, and gain better understanding of common concerns and issues."

Dr. Michael A. Menis, former chair of the Oral and Maxillofacial Surgery Political Action Committee, discusses the importance of professional association involvement and the establishment of relationships with local, state, and federal representatives. Fostering such relationships can allow the OMS to be proactive in discussing issues that may have an effect on the care of patients and the ability to practice the scope of our profession. Association involvement provides the knowledge base to enable the OMS to advocate for patients who may be affected by legislative measures adopted by local, state, and federal representative bodies.

Dr. David E. Frost, former chair of the Oral and Maxillofacial Surgery Foundation, believes that involvement in activities of the OMS Foundation makes the oral and maxillofacial surgeon aware of the mechanisms of fund raising and funding of the many research activities that lead to improved instrumentation and procedures that enhance the care of patients. Doctors Frost, J. Thomas Soliday, and Steven R. Nelson all have stated that volunteerism, locally and internationally, reinforces the sense of social responsibility and giving back to the communities that support the practice of the local OMS. We all have the ability to make a difference in the lives of those in the community who are economically, developmentally, and physically challenged. Caring for the disadvantaged has the capability to enhance the visibility of the OMS in the community and foster the professional outlook of the allied staff in the practitioner's office.

While CODA mandates specific criteria and minimal standards for accreditation of residency programs in oral and maxillofacial surgery, it is understood that many OMS program graduates do not practice the full scope of their education and training. Dr. Mark W. Ochs, Chair of Oral and Maxillofacial Surgery at the University of Pittsburgh Medical Center, believes that OMSs who have completed an accredited residency program have the skills to provide care in significant aspects of the core of oral and maxillofacial surgery. He has stated that "trauma management is a core of OMS training and when orthognathic surgery and trauma management is abandoned, you really narrow your scope and that at that point, you are not a strong player."

Dr. Steven Feinberg, a highly visible and respected research and academic oral and maxillofacial surgeon, states, "The true professional has the obligation to thank those who have served as our mentors by mentoring the young OMS."[16]

How are Ethics and Professionalism Linked?

Ethics is defined as a branch of philosophy and theology that is the systematic study of what is right and good with respect to character and conduct. Ethics seeks to answer two fundamental questions:

- What should we do?
- Why should we do it?

Ethics are the moral principles or virtues that govern the character and conduct of an individual group. The object of ethics is to emphasize the spirit (or intent) rather than law. Dental ethics applies the moral principles and virtues to the practice of dentistry. Ethics deal with moral conduct, duty, and judgment. Ethics are concerned with standards for determining whether actions are right or wrong. These are voluntary controls, not laws, and serve as a method of self-policing within the profession. Ethics deal with moral conduct, right and wrong, good and evil. The difference between ethics and the law is that legal issues are settled with the use of laws and court decisions. Ethical issues are subject to individual interpretation with regard to the right and wrong of a particular situation. Laws are very specific and written by people with the authority to write them. Laws are "black or white," whereas ethics are less specific and have more gray areas. Laws set the minimum standard of behavior; ethics set the highest standards of behavior.[17]

As a general rule, most professional associations, academies, colleges, and boards have written and adopted principles of ethics or codes of professional conduct. Members and fellows of such organizations are expected and mandated to adhere to the stipulations set forth is these types of documents. Fellows and members of the American Association of Oral and Maxillofacial Surgeons are responsible to adhere to the Code of Professional Conduct as written and overseen by the Commission on Professional Conduct (CPC). In addition, individuals who are also members of the American Dental Association (ADA) or the American Medical Association (AMA) must follow the mandates as put forth in the documents pertaining to principles of ethics and the code of professional conduct for those respective organizations. These documents have many similarities, but for the purposes of this chapter, the focus will be on the AAOMS CPC document and the Principles of Ethics as published by the ADA. In the case where the practitioner is not a fellow or member of any professional organization, complaints about unprofessional or unethical behavior are referred to state dental or medical boards.

The ADA Principles of Ethics and Code of Professional Conduct state that there are five basic principles that form the aspirational goals of the profession:

- The principle of patient autonomy (self-governance)
- The principle of non-malfeasance (do no harm)
- The principle of beneficence (do good)
- The principle of justice (fairness)
- The principle of veracity (truthfulness)

The Principle of Autonomy

The dentist has the obligation to respect the patient's rights to self-determination and confidentiality. The dentist is obligated to inform the patient of the proposed treatment plan as well as reasonable alternatives, which allows the patient to become involved in the treatment. The dentist is also obligated to safeguard the confidentiality of the patient records. The dentist has the ethical obligation upon request of the patient or the patient's new dentist to provide a copy of the record health history information, treatment performed, and copies of all pertinent imaging regardless of the patient's financial standing within the practice.

The Principle of Non-malfeasance

The dentist has the duty and responsibility to protect the patient from harm. This principle includes the responsibility to keep one's skills and education current. Especially important is the responsibility to know one's limitations and to seek consultation as well as referral of the patient to a specialist when appropriate. The specialist has the responsibility to send the patient back to the referring dentist for care that is not within the realm of the specialist. The dentist must protect the patient by delegating care by auxiliary personnel only to the extent of those duties that can be legally delegated. It is unethical for the dentist to practice while impaired by substance abuse. The dentist has the responsibility to inform any patient who may have been exposed to a blood-borne pathogen or other infectious materials. The dentist also must not discontinue treatment of a patient without adequate notice so as to give the patient the opportunity to seek care from another provider (abandonment of the patient).

The Principle of Beneficence

The dentist has the responsibility and duty to promote the welfare of the patient by using his or her skills, knowledge, and experience for the improvement of the dental health of the public. This responsibility also serves as encouragement for dentists to be leaders in their communities. Furthermore, the dental profession owes society the responsibility to regulate itself. Dentists are obligated to become familiar with the signs of abuse and

neglect and to report suspected cases to proper authorities as consistent with state law.

The Principle of Justice

The dentist has a duty to treat people fairly. Dentists may exercise reasonable discretion in selecting patients for their practice, but the dentist cannot refuse to provide services for a patient based on race, creed, color, sex, or national origin. Dentists are obligated to provide reasonable arrangements for emergency care for a patient of record when the dentist is not available to provide that care himself. The dentist is obligated to report to appropriate reviewing agencies instances of grossly negligent or continually faulty treatment by other dentists.

The Principle of Veracity

The dentist has the duty to communicate truthfully and to be honest as well as trustworthy in their dealings with people. The dentist shall not represent care being rendered to patients in a false or misleading manner. A dentist is deemed to be providing care unethically in instances where treatment is not based on accepted scientific knowledge or research. It is also unethical for a dentist to perform unnecessary services or procedures. Dentists must not misrepresent their training and competence in a manner that is false or misleading in any material respect.

The American Dental Association recognizes the following specialties. These specialties all have certifying boards that require successful completion of both an accredited educational program and a certifying examination:

- Dental Public Health
- Endodontics
- Oral and Maxillofacial Pathology
- Oral and Maxillofacial Radiology
- Oral and Maxillofacial Surgery
- Orthodontics and Dentofacial Orthopedics
- Periodontics
- Prosthodontics

Dentists are allowed to announce limitation of their practice to areas of special interest (non-ADA-recognized specialties) as long as they avoid any communication that implies or expresses specialization.[18]

The American Association of Oral and Maxillofacial Surgeons also has written a Code of Professional Conduct. The AAOMS Commission on Professional Conduct developed the code. The Commission (CPC) has the responsibility to review complaints brought by a member, fellow, or provisional member or fellow against another OMS, to refer complaints or violations of the code to state boards when appropriate, rule on violations of the code and provide appropriate sanctions, recommend changes to the code to reflect changing circumstances, and assist the AAOMS membership in interpretation of the code. The CPC's jurisdiction is limited to AAOMS fellows and members and their relationships with and privileges within the AAOMS.

The AAOMS Code of Professional Conduct and the ADA Code of Ethics mirror each other on many levels. Areas of parallelism include:

- Patient autonomy, self-determination, and confidentiality
- Ensuring proper professional education, training, and competence
- Avoiding personal impairment
- Promoting welfare of patients and the community
- Fairness and non-discrimination
- Patient abandonment
- Fairness in dealing with colleagues
- Honesty and truthfulness
- Advertising

Areas of the AAOMS Code of Professional Conduct that differ slightly from the ADA Code of Ethics include:

- Itinerant surgery
- Expert witness testimony
- Insurance consultants

Itinerant surgery is defined as elective oral and maxillofacial surgery performed in non-accredited surgical facilities other than the facility or facilities owned and/or leased by the oral and maxillofacial surgery practice employing the OMS. Fellows and members are strongly discouraged from making itinerant surgery a major part of their practice.

- It is unethical if the patient is unfamiliar with the surgeon who performs their surgery.
- It is unethical for the surgeon to delegate their primary patient responsibility.
- It is unethical for the surgeon to perform surgery in an unsafe or unsuitably equipped facility.
- It is unethical for the surgeon to perform surgery in an unsafe or unsuitably staffed facility.
- It is unethical for the surgeon to delegate postoperative care to a person who is not similarly qualified to recognize, treat, and manage all surgical complications.

These provisions of the code do not apply to the occasional performance by a fellow or member from performing surgery in a facility for the purposes of teaching or charity patient benefit.

Oral and maxillofacial surgeons are encouraged to serve as expert witnesses in legal proceedings to assist in finding the truth in matters under consideration. The qualifications for the Oral and Maxillofacial Surgeon expert witness include:

- The OMS expert witness must have direct clinical experience in the specific area of oral and maxillofacial surgery in question.
- The OMS expert witness should be a diplomate of the American Board of Oral and Maxillofacial Surgery.
- The OMS expert witness who is still engaged in private practice demonstrates enough familiarity with present practices to warrant designation as an expert witness.
- The OMS expert witness must have a current valid and unrestricted license to practice in the state in which he or she practices.
- The OMS expert witness must not serve as such in cases where they also served as one of the patient's treating doctors.

Oral and maxillofacial surgeons who serve as insurance consultants are expected to promote the best interests of the patient and fair claims practices by third-party payers.

- An insurance consultant must be currently engaged in the practice of oral and maxillofacial surgery or have enough familiarity with present practices to evaluate treatment on which he or she gives an insurance consultation.
- An insurance consultant must have a current and unrestricted license to practice; however, he or she need not have a valid license in every state in which he or she renders an insurance consultation.
- An insurance consultant should be a diplomate of the American Board of Oral and Maxillofacial Surgery.
- An insurance consultant has the duty to be fair in dealings with patients and providers.
- The consultant must avoid any conflict of interest that would compromise or influence decisions rendered by the consultant.
- The consultant must not prejudge any claim and must render decisions based solely on facts, merits, and clinical circumstances.
- The consultant must be able to explain the decision based on experience, clinical references, and generally accepted opinion in the specialty field.

The CPC also has the authority to rule on areas of advertising, as well as use of the AAOMS seal and the AAOMS slogan, "Saving Faces/Changing Lives." The CPC will respond to written complaints and written request for information submitted by AAOMS fellows and members.[19]

Ethical Dilemmas

This section of the chapter deals with ethical dilemmas that a practitioner may be faced with in the daily activities of a private or academic institution faculty practice. These dilemmas are modified to fit the oral and maxillofacial surgery model and are based on ethical dilemmas as published in various past ADA journals.

What are the ethics concerning a patient's request for you to refer him to a new general dentist? As the treating dentist, you are obligated to put the welfare of the patient first. Yet, you also must respect the patient's right to self-determination and confidentiality. It is fair to ask the patient why he is making this request. Has there been some problem with the other dentist's office, care, or other reason? Is this request due to a financial situation? Is this request merely a desire on the part of the patient to try another dentist? You have the obligation to encourage the patient to return to the referring dentist and discuss the concerns. Even if you, as the treating dentist, agree that there are issues with the treatment provided by the referring dentist, you must avoid making any disparaging remarks that could lead to a liability action or bring allegations of defamation against you. It is also appropriate to notify the dentist of the patient's request and relay the concerns brought up by the patient.

Who is ethically responsible for patient care in a corporate practice where you are an employee dentist? The doctor-patient relationship begins when you agree to treat the patient. You alone are responsible ethically and legally for the care and treatment of the patient, not the corporate entity. While corporate employment may alleviate day-to-day operational stress, the doctor-patient relationship exists between you and the patient. As part of a corporate practice, you must not allow potential performance pressure and production incentives to influence or coerce you into performing unnecessary procedures or up-coding the procedures you do perform.

While you are attending a local seminar, a member dentist shares with you information about behavior you believe may be unethical. The obligation of self-governance requires that the dentist be made aware of your ethical concerns. If the dentist informs you that he is able to maximize production by up-coding, billing for procedures not performed, or performing incomplete or ineffective treatment, you should inform him that these practices are fraudulent. It is also appropriate to inform him that these types of practices can lead to expulsion from participation with insurance carriers, charges of insurance fraud, and loss of his license to practice. You also have the ability to request that the dentist discontinue such practices. You have the responsibility to contact the ethics committee of the dental society to file a formal complaint.

What are the ethical implications of using social coupons to expand patient or referral base? This relatively new concept raises many ethical and legal issues. Many companies that provide discount coupons to patients collect the fee charged, keep a portion of the fee as part of their costs, and remit a portion to the dentist (the concept behind Groupon). This may be viewed as fee splitting. A better arrangement of this would be for the coupon company to pay the dentist the full fee and then have the dentist remit the promotional fee to the coupon company. This does not constitute fee splitting. Another ethical issue concerning discounting of fees has to do with billing the insurance company the discounted fee and not the usual and customary fee for a service. This practice constitutes insurance fraud and potentially violates the Stark law. This provision of CMS mandates that Medicare and Medicaid patients must be offered the same discounts as patients not covered by Medicare or Medicaid. If after a clinical examination, appropriate and necessary procedures are required that are not included as part of the coupon offer, the dentist is obligated to inform that patient before performing the procedures. The patient may view this practice as "bait and switch" and outside of informed consent for treatment.

A patient undergoes a procedure requiring antibiotic prophylaxis. The patient refuses to comply, and you dismiss him from your practice. The patient seeks care from another dentist but does not intend to inform the new dentist of this medical necessity, and states he would lie about it on a health history. Should I inform the new dentist of this? This is a conflict between ethical and legal issues. The patient has the responsibility to provide accurate, honest, and complete health history information.

The patient also has the right to accept, defer, or decline treatment recommendations. Health history information is confidential and privileged between the dentist and the patient. The privilege belongs solely to the patient and not the dentist, and violation of this privilege may subject to dentist to legal prosecution. Therefore, the patient has the right to refuse the premedication and the treatment.

The dentist has the duty and obligation to promote the welfare of the patient and to do no harm. The dentist can comply with the wishes of the patient by requiring a written signed request by the patient to send part or all of the record. This constitutes authorization to release confidential information. A signed release to transfer the record supersedes the oral request for confidentiality. As an alternative, the dentist can consider sending the entire record to the patient with a note suggesting that he provide all information to the new dentist.

What are the ethical obligations of a dentist who suspects his partner is impaired by addiction and substance abuse? A dentist has the duty to refrain from harming a patient. A dentist with an addiction has an ethical responsibility to refrain from practice that may adversely affect patients. All dentists have an ethical obligation to urge chemically impaired colleagues to seek treatment. All dentists are ethically responsible to report the colleague to the professional assistance committee of the appropriate dental society. The impaired dentist is not required to disclose his impairment to patients. The intent of these requirements is to protect the patient, the public, the practitioner, the partner, and the profession.

What are the ethical obligations of an OMS who places implants for patients in the office of a general dentist? It is considered itinerant practice of oral and maxillofacial surgery when the OMS provides care for patients outside of his or her own office location. In this instance, the OMS must adhere to the provisions of the Code of Professional Conduct as related to itinerant practice. The operating OMS has an obligation to the patient to discuss fully the treatment plan for that patient. The OMS must make records of treatment accessible to the patient, the restorative dentist, and other involved providers, and also make provisions for follow-up so as not to abandon the patient. If the OMS becomes unavailable to provide the continuity of care discussed in this section, this can be interpreted as meaning that the OMS did not have the best interests of the patient at heart, did not communicate truthfully with the patient in reference to the treatment plan (including procedures and costs), and may be abandoning the patient. These behaviors not only are unprofessional, but also can be construed as unethical.

The Politics of Town and Gown

The concept of town and gown is rooted in the Middle Ages and had to do with the competition between the students and faculty of the local universities and the citizens of the community directly adjacent to those universities. The gowns worn by the students and faculty of the university were originally designed to provide warmth and comfort for those who worked and studied in the cold and drafty rooms of the universities. These gowns often were adorned with the colors of the university and signified the scholar's affiliation with it. Ultimately, the gowns served as a social symbol that set apart and distinguished the student or faculty from the townspeople. This social interaction often became adversarial because of economic issues between the towns and the universities, as the universities often were financially independent of the town and were not under its civil authority. The confrontations between town and gown became violent on many occasions. Examples include the Battle of St. Scholastica Day at the University of Oxford in the 1300s, a confrontation between the students of Yale and the citizens of New Haven in the 1800s, and the infamous events at Kent State University in the 1970s. Fortunately, these types of confrontations have become less prevalent as universities in crisis have been "rescued" by the urban dynamics surrounding them. Universities and the communities surrounding them have an incentive to cooperate with each other, as the universities depend on the cities for services and approval for long-range plans, and the towns benefit from public services provided by the universities.[20,21]

The town-gown "confrontation" in medicine (and dentistry) is largely driven by competitive forces within the community that have a number of contributing factors:

1. Competition for the same patient population.
2. Concern that patients referred from the community will be absorbed by the university.
3. The shift from salaried "hard money" positions to fee-for-service models where the academic faculty is expected to generate patient care revenue as their primary income source.
4. The perception by the university providers that the community providers are "cherry picking" by referring underinsured or uninsured patients to university providers for care that could be rendered by community-based providers. This practice is often couched in terms stating that a particular case provides an excellent resident educational opportunity.[22]

These factors and the historical interaction between town and gown have the potential to create a level of mistrust and an adversarial relationship between community-based providers and providers affiliated with an academic institution. Almost all oral and maxillofacial surgeons who have completed a CODA-accredited residency program have met the same criteria of education, training, and experience to perform the procedures that were included in the clinical curriculum as part of their residency training programs. The community-based OMSs all have the ability to gain hospital privileges, provide care based on their residency experiences, and perform the same procedures for the same patient population as the university-based OMSs. The argument against this premise is that significant numbers of OMSs choose to perform only the procedures that are more lucrative and primarily office based. They see it as inconvenient to admit

patients to the hospital and burdensome to take hospital call, which disrupts the functioning of their offices. This practice has the potential to perpetuate the adversarial relationship between town and gown and further drive a wedge between the academic institution and the community-based providers. The reality is that both parties can and should work together for mutual benefit for private practitioners, academic practitioners, and patients from the community. Anything less may be interpreted as being unprofessional and unethical.

This chapter is unusual in that it does not contain strong evidence-based information that relies on years of laboratory research or numerous clinical trials. It does not contain the newest techniques for performance of a recently developed surgical procedure or reporting of a newly discovered disease or pathologic entity. It does contain several abstract ideas, philosophies, and moral and ethical issues that will test the OMS daily as he or she practices. It is designed to make one think about how one conducts themselves regularly within their communities, specialty, and the health care professions. It is this author's hope that the reader will reflect on this information and apply it to make him or her a better provider, a better teacher, a better mentor, and more importantly, a better person.

2

The Philosophical Basis of a Successful Surgical Practice

TRAVIS A. WITHERINGTON

It had long since come to my attention that people of accomplishment rarely sat back and let things happen to them. They went out and happened to things.

—Leonardo da Vinci

A successful surgical practice is not encountered as a random fortunate occurrence. It is created by intentional design, and it is sustained by active engagement of the owners. The design of the successful practice starts not at the architectural level with bricks and paint, but at the philosophical level with personal introspection and worldly study.

The Definition of Success

Beauty lies in the eyes of the beholder.

—PLATO

The variation among surgical practices is in the emphasis placed on the functional aspects of the practice (goals) and in the ownership arrangement of the company (business models). These goals and business models define the philosophy of the practice. They determine success, relative success, or failure.

A logical and systematic approach to creating a successful practice is to first investigate the goals of the owners. The second step should be to study the business models to determine which is most likely to allow fulfillment of the goals. After these two underlying fundamentals are in place, the efforts of the owners should be channeled toward achieving the identified success.

Goals

If you wish to converse with me, define your terms.

—VOLTAIRE

Goals are the deep, personal driving traits of the owners of the practice. They are the motivations that brought us first to advanced education, second to dentistry as a profession, and finally to surgery as a specialty.

These driving elements began at a very young age when we were asked, "What do you want to do with your life?" They matured and grew in college as we encountered social settings and academic courses that taught us what we found resonant in our hearts and souls. They became clearer during dental school, and they neared maturation in our surgical residencies as we finally envisioned a more singular professional lifestyle for our productive years.

These goals are particular to the individual, and variation is the norm. Understanding this fact is critical to the success of a practice, because a mismatch of goals among surgeons can lead to disharmony if it is not addressed.

Our profession of oral and maxillofacial surgery (OMS) is wonderfully positioned to allow us to realize many different professional and personal goals. We must carefully study these goals to determine their relative position in our hierarchy of assessment. Introspection and reevaluation should continue throughout one's career to correct its course and give it more resonance.

The following categories of goals influence the surgeon:

- Service to humankind
- Profits
- Working in a challenging professional atmosphere
- Freedom of choice
- Working alongside peers
- Education
- Diversity

Service to Humankind

Whenever the art of medicine is loved, there is also love of humanity.

—HIPPOCRATES

Service to humankind is the strongest driving force of OMS doctors. The desire to help others emerges early in life and becomes much stronger once an individual realizes that he or she has the capacity to enact that help. Relieving pain and suffering is a particularly strong motivator for those attracted to surgery, because the profession allows us to be effective quickly. This particular goal is satisfied every day in a surgical practice, but many surgeons are inclined to devote even more time, energy, and resources through donated service. This donated time taken away from a financially productive practice must be reconciled.

Profits

> *Lay not up for yourselves treasures upon earth, where moth and rust doth corrupt, and where thieves break through and steal: But lay up for yourselves treasures in heaven, where neither moth nor rust doth corrupt, and where thieves do not break through nor steal: For where your treasure is, there will your heart be also. No man can serve two masters: for either he will hate the one, and love the other; or else he will hold to the one, and despise the other. Ye cannot serve God and mammon.*
>
> **—MATTHEW 6:19-21, 24 (KJV)**

There is nothing wrong with making money unless the money is an object of worship. Most professionals incur significant loans to underwrite their education, and the surgical practice must make profits to retire those loans. Profits are also needed to support a surgeon's family, employees, and all of their dependents. Profits are needed to prepare for disabilities and life after surgery. Profits are needed in order to devote time and resources to donated surgical service. Clearly, profits are an appropriate key element in most surgeons' goals.

Working in a Challenging Professional Atmosphere

> *Life is either a daring adventure or nothing at all.*
>
> **—HELEN KELLER**

The opportunity to come to the aid of the sick, injured, or disfigured patient and perform healing surgery in a difficult environment is a significant driver for many surgeons. Trauma, academics, orthognathic surgery, pathology, and cosmetics are exciting and challenging sectors of our profession, and they can be strong attractors. Major surgeries or difficult cases inspire us to succeed because surgeons, in particular, rise to a challenge. Deep satisfaction can also be gained by understanding the complicated anatomy, physiology, pathology, and pharmacology that tip us toward difficult surgeries. It is common for a recently minted surgeon to embrace these complicated surgeries but then experience waning enthusiasm in later years in the face of diminished capacity to endure stress and long hours.

Freedom of Choice

> *Choose a job you love, and you will never have to work a day in your life.*
>
> **—CONFUCIUS**

Having been constrained by our parents, administrators, teachers, and attending staff for many years, the thought of being in charge of our lives becomes very attractive. The flexibility of being an owner allows a surgeon to adjust both personal and professional schedules to fit a desired lifestyle. That lifestyle might include a family, travel, donated service, sports, education, or avocation. Private practice ownership gives one much more control over life than the other business models, but it comes at a heavy price. That price is substantially increased responsibility.

Working Alongside Peers

> *Coming together is a beginning, keeping together is progress, working together is success.*
>
> **—HENRY FORD**

The opportunity to share the ups and downs of a professional life with another surgeon is attractive. Surgeons who work together can supply a network of support to endure difficulties and to celebrate successes. Building a surgical team of support staff can go a long way toward this goal, but sharing with a respected peer, and then gaining his or her trust and admiration, is a satisfying experience.

Education

> *Tell me and I forget. Teach me and I remember. Involve me and I learn.*
>
> **—BENJAMIN FRANKLIN**

Participation in academics runs deep in surgeons, and we embrace this endeavor as participants throughout our career. We must realize that a primary requirement to give rather than receive in education is a capacity to teach. A teacher's heart is a giving and sharing one. A teacher's mind is one that distills complicated issues and then presents them so they can be understood by students. As we think back on the professors that we have known in our lengthy education, we recall those who were gifted, and others who meant well but did not inspire. Before pursuing formal participation in academics, we must honestly gauge our capacity to teach as well as our motivation. Are we motivated by the potential growth of the student or by the glory of being called teacher?

Whether it is working as a full-time academic professor or as a visiting lecturer, sharing in the educational experience can be rewarding. Opportunities to participate in education exist at levels other than surgical residency. Cardiopulmonary resuscitation (CPR) instruction, lecturing at a community college, and presenting at a professional society are other ways to satisfy this goal.

Diversity

There is no such thing as a single goal in a surgical practice. Rather, there are composites of goals, some given more emphasis than others. A practice might emphasize delivering a diversity of procedures, or it might wish to limit certain

ones. A practice might emphasize profitability, or it might embrace OMS education at a local residency program. It might limit exposure to major hospital surgeries such as trauma, cancer, and orthognathics, or it might emphasize recruiting those types of patients. The owners might desire a flexible or reduced patient schedule to incorporate personal, professional, and family life outside the practice.

The desires and relative emphasis of the individual owners will define the practice. Consequently, each owner must consider these factors carefully before a practice is designed. Significant variation in emphasis should be expected among doctors, and that diversity should be celebrated and accommodated. The owners must be meticulously honest with themselves and with each other during this design process.

The ranking of these goals should be expected to change as the individual ages, so they should be revisited as time progresses. The cultivation of a successful practice is an ongoing task that does not end with the initial design.

Business Models

The majority of oral surgery practices are for-profit, closely held private companies of limited geographic scope, but there are major differences. Most depend on favorable relationships with patient-referring sources and employ a small number of managerial, clerical, and clinical employees. They typically have a single main office and might have a secondary one that serves a different geographic sector on a more limited basis.

The business models are legal and financial entities whose functions are governed by state law and binding agreements. During the design phase, significant time must be spent in conversation with experts in accounting, human resources, and the law.

The ownership arrangements or business models include variations on these themes:

- Solo
- True partnership
- Entrepreneurial
- Expense sharing

The development of the business model will have a direct impact on the ability of the practice to attain the goals of the owners. Sometimes the model will facilitate the goal. In other cases it will be an impediment.

Solo

The solo surgeon wears all hats. Although the greatest benefit of a solo practice is that issues never need to be brought to a vote, the greatest detriment is the isolation in which those same decisions are made. Taking emergency calls, deciding which insurance plans to enroll in, hiring and firing employees, and buying equipment and office space are all decisions that weigh on the shoulders of the solo owner. In order to succeed, the solo doctor must be adequately versed in all phases of clinical, administrative, financial, and legal business activities.

A solo practice gives the individual owner infinite freedom to select and modify his or her goals initially and in the future. The solo doctor has the most ability to design a practice that maximizes profits.

This business model, at first glance, gives the owner the ability to attain almost all goals because there is no opposition to the owner's choices. The downside is that the surgeon will be professionally isolated except for traveling to other locales and visiting with non-competing surgeons. It can be a lonely existence, but there will be no boardroom arguments over decisions, and the pace of the practice is firmly in the owner's control.

The single goal that is missing is the opportunity to work alongside a peer. However, even that goal might be satisfied when two surgeons share a complicated set of cases. There are work-with-others benefits that might be reaped from building a surgical and administrative employee team in a family atmosphere. The solo surgeon must be a fiercely independent person but will be most likely to succeed when surrounded with competent office staff and advisors.

True Partnership

In this model, the owners have a binding legal agreement that gives voting rights on the functional decisions of the company to each owner and that outlines expectations of performance. In most issues needing a decision, the majority of votes rule, but in major decisions, such as the acceptance or dismissal of a partner, the partnership agreement might require that a vote be unanimous or by a supermajority. The partnership agreement outlines these rights and obligations, and it deserves close analysis by an independent trusted advisor.

In the true partnership model, the ability of the individual owner to pick and choose among the goals is significantly limited by the vote of the other partners. Owners need to obtain permission from their partners to make changes that might conflict with another owner's goals. Consequently, freedom of choice is more limited than with the solo model.

Profitability is typically less in a practice with a true partnership than in a solo practice. The owners in a partnership tend to focus on enjoyable procedures and pursuits rather than on financially productive ones. A partnership also spends more on staff, equipment, and expenses, probably because of a false feeling of having diluted the expense.

The potential for conflict among the owners is so high that it should be expected, and resources should be gathered for conflict resolution.

Entrepreneurial

The entrepreneurial model is a blend of the other models. In this model, there is an owner of the company, and salaried associate doctors are hired to produce professional care. The owner has the right to make the decisions relevant to the practice; an associate doctor has only the rights of an employee.

In this model, the owner is well able to attain goals, but that ability is low for the salaried associate employee-doctors. The burden of responsibility is greater for the owner because of the number and class of employees and the greater amount of time involved in management issues.

Expense Sharing

The expense sharing model is a blend of other ownership models. It is a business relationship between multiple solo or true partnership practices, and the focus is on money. Because the relationship between the practices might be competitive, the only goal that is truly applicable is the one dealing with profits.

As the name implies, this business model focuses on expenses, not income. The intent is to increase profits by reducing expenses through economies of scale. Many financial advisors argue that profits are more readily increased by increasing production rather than by decreasing expense. As with all business models, expert advice is most appropriate before entry into this legal relationship.

Interpersonal Relationships for Success

Our society is based on interpersonal relationships, and our personal lives and our business practices are subsets of the world's society. A successful practice is an extension of a successful person who is fluent in interpersonal relationships.

The Relationship between the Surgeon and the World

> *We are what we repeatedly do. Excellence, then, is not an act, but a habit.*
>
> —ARISTOTLE

In descending order of importance, a simple list of the daily chores of a successful surgeon would be to:

- do excellent work,
- enjoy each day, and
- then do everything else.

> *To improve is to change; to be perfect is to change often.*
>
> —WINSTON CHURCHILL

First and foremost, a successful surgeon strives for surgical excellence. Obviously there is no such thing as a perfect procedure, but a surgeon can have a mindset of constantly striving for perfection. From the first day of practice to the day of retirement, the successful surgeon seeks to practice his craft with less pain, less swelling, less fear, quicker healing, more predictable outcomes, faster times, and less expense. His handwriting will be on each wound, his signature will be on each op note, and his name will be on each patient's mind. All movements and interactions move toward or away from the path to perfection.

Healthy and rewarding relationships allow a surgeon to enjoy each day. These relationships begin at home and follow the surgeon to the office, and to peers, staff, advisors, patients, and their families. All of these relationships are founded on trust, honesty, and communication. Associations of relationships are based on inference, love, solidarity, social commitment, or business interactions. Law, custom, or mutual agreement regulates these associations.

All else follows the first two chores. For the surgeon, there is nothing more important than performing excellent surgery while striving to enjoy professional life.

Relationships between Owners

The owners determine the philosophy of a practice. Only the owner is capable of formulating policy that affects the operational heart of the practice that all others follow. Even when the owner abdicates a role in decision making, that action is in itself a policy decision.

Solo

> *Most people do not really want freedom, because freedom involves responsibility, and most people are frightened of responsibility.*
>
> —SIGMUND FREUD

The solo surgeon must be a fiercely independent and resourceful person. He or she is more likely to succeed if surrounded by competent staff and advisors. This extended family will support the surgeon in daily activities and represent him in his absence.

Although not necessarily a loner, the solo surgeon must be comfortable with working in a relative vacuum of professional interaction. Often, a solo surgeon will miss critical information affecting decisions of the practice, and will need to scramble to catch up or stay abreast of trends.

True Partnership

> *More important than the deal is the person in the deal.*
>
> —RICHARD COLLIER

A successful partnership is based on trust, sharing, and communication. It is not necessarily based on money, but money has an important place in a business, and if there is not enough of it, this will become a divisive issue for the owners.

Sharing is the foundation on which all partnership decisions are made, and communication is a means to develop and maintain rewarding relationships and to reconcile conflicts. A good partner will have a sharing heart and seek the participation of others in professional affairs of education, management, marketing, and human resources. He will have a developed sense of communication and be sensitive to others as he speaks.

> *Relationships of trust depend on our willingness to look not only to our own interests, but also the interests of others.*
>
> —PETER FARQUAHARSON

Before signing the partnership agreement, each potential partner's goals must be carefully explored and stated. Conflicting goals should be discovered, and methods of compensation should then be determined to reconcile those conflicting forces. There are ways to make a partnership successful even in the face of conflicting goals. The

compensation might be in the form of differentially assigned duties, modification of pay and vacation days, a change in work hours, or differing loads of on-call.

Management

Dr. W., there is more to pulling teeth than pulling teeth.

—ANDREW C. CHEUNG

Although a group of partners might assume that the success of their business will be the sum of individual production of the owners, final success will be brought about by decision making and implementation of policy promulgated by the collective ownership. The management side of a partnership is a complex and difficult area for doctors to master, because they have had little or no formal business education. Yet, the business side dictates financial success, harmony with the employees, and the long-term momentum of the practice.

Management by a doctor requires a significant expenditure of time and energy, yet it has no quantification that can be referenced when it comes to allocating compensation among the partners. Whereas the value of surgeries can be quantified by dollars produced, the time spent in business affairs cannot be so readily identified and compensated. For this reason, some sort of division of management responsibilities among the doctors is appropriate. If a partner does not participate in this uncompensated managerial work, the others will resent it.

Management styles that are available to the partnership include:

- Rotation of management assignments among the owners
- Management by committees of owners
- A compensated managing partner (who is a surgeon)
- Salaried professional practice manager
- Chaos

Decision Making

Every man builds his world in his own image. He has the power to choose, but no power to escape the necessity of choice.

—AYN RAND

Even when no decision is made, that is still a decision, and it has its consequential impact. Owners will encounter difficult problems that are not readily solved, but that cannot be ignored or postponed indefinitely. In these cases, some decision must be made in order for the practice to move forward.

Although unanimous decisions are desirable, this is rarely the case. Unanimity should not be expected, and polite negotiations must be undertaken to arrive at a decision. A cautious eye should be kept for any individual who bullies or forces his opinion on the group. A referee or an advisor is appropriate to help in arriving at a decision in the presence of a bully.

Small partnerships allow more fluid decision making. However, the greater the number of individuals with voting authority, the more appropriate it becomes to formally conduct the business with *Robert's Rules of Order*.

Communication

Much unhappiness has come into the world because of bewilderment and things left unsaid.

—DOSTOYEVSKY

This critical trait of a partnership must be cultivated and planned and not left to chance. It is not enough to ask that partners speak to each other. The forum and time must be allocated and respected to allow that communication to occur. Without definite planning, communication will occur sporadically and at the whim of chance. It is too important for that.

The best way to provide a forum for communication is a regularly scheduled doctors' meeting. These meetings should be considered sacrosanct, and no conflicts should be allowed. These meetings are chances to explain and opportunities to apologize. Texting, phone calls, faxing, and emails are appropriate for transferring information, but face-to-face meetings are for communication.

The eyes are windows to the soul.

—CICERO

Doctors' meetings should follow a businesslike format with a chairman who collects the agenda, encourages a timely flow of business, brings issues to a vote, and records the decisions for the archive of minutes. This formality will provide fairness to each owner, help position the partnership in decision making, and leave a store of information for future reference.

Good doctor's meetings will serve many functions, including:

- Analysis of and decision making regarding business issues
- Consultation with partners about challenging cases and conundrums
- Sharing of information gleaned from journals, seminars, or educational meetings

Internal Competition

Competition within the partnership tends to occur because a posted schedule of daily procedures is readily available. Partners will compare their productivity, and this should provoke some healthy competition among friends and peers. However, if viewed in the wrong light, this can lead to resentment of the productive partner or suspicion of favoritism by clerical personnel. The true competition is outside the walls of the practice, and a reminder is occasionally needed to turn the focus outward.

Conflict Resolution

I've always believed that a lot of troubles in the world would disappear if we were talking to each other instead of about each other.

—RONALD REAGAN

An eye for an eye will only make the whole world blind.

—MAHATMA GANDHI

Pick your battles. In a partnership, there will be enough material to start a war. Life is a continuous confrontation with conflict, and a surgical partnership is a microcosm of life with all of the characteristics of a marriage except the intimacy. Either relationship can be destroyed by the same mechanisms.

The first step in conflict resolution among the partners is to create an opportunity to explain circumstances and offer apologies. If that opportunity is not made available, the chance of resolving the conflict is slim. All of us are subject to misunderstanding or mistaken beliefs about behavior, and a time and place must be made available for a clear dialogue to dispel the misunderstandings.

The End of a Partnership and Succession Planning

In this world, nothing can be certain, except death and taxes.

—BEN FRANKLIN

All partnerships come to an end. The ending mechanism is death, disability, or dissolution, and the ending should be carefully designed at the beginning of the company. This ending should be scripted for logic, fairness, and ease, because it will be used.

This true partnership model is the most common model among OMS practices, and it is the one with the most frequent failures. Common sources of acrimonious dissolution are a failure to reconcile the different goals among the owners and a failure to communicate.

A natural progression in a surgeon's career is retirement after a long and successful professional life. Planning for the next generation starts early in order to search for an individual with like-minded goals to assume the practice.

Entrepreneurial

The owner relationships in the entrepreneurial model are variations of the solo or true partnership designs. All decisions, including those affecting employees, will fall to the owners either as a solo owner or a partnership of owners.

While a doctor serving as an employee of a business entity will have a significant effect on the relationships within the practice, the owners will define the true practice philosophy. Many surgeons opt for serving as a salaried associate for a period of time, but because the associate is an employee and not an owner, he will be severely limited in his ability to attain any of his goals.

Expense Sharing Association

The expense sharing business model is strictly a financial arrangement and has little to do with sharing professional relationships. In fact, the owners involved are in competition with each other for business. This practice model should not be confused with a partnership. Although the word "sharing" is used in this title, the only sharing that comes about is in the sharing of money spent for production of income.

A key element in an expense sharing model is communication. The rules for this relationship must be clearly delineated. The rules can be negotiated by a third party, because they have nothing to do with friendship or personal relations.

The Relationship between Owners and Employees

Take care of your people, and they will take care of your customers.

—JOHN WILLIARD MARRIOTT

The surgeon will spend more time with staff than any other group of humans other than family. It follows then that surgeons should surround themselves with wonderful people and devote the time and energy to cultivate those relationships. The staff is a surgeons' extended family, but chosen by the surgeon—unlike his own family.

The success of a company is predicated on hiring the right people, but that process starts with owners who are actively engaged in recruiting, hiring, training, and managing. If owners take a passive role, the outcome may be unpredictable. The task of managing human resources in a surgical practice represents the most challenging, potentially vexing, and time-consuming job of ownership.

Start with good people, lay out the rules, communicate with your employees, motivate them and reward them. If you do all those things effectively, you can't miss.

—LEE IACOCCA

The practice owners must identify the company's mission and become actively involved in the human resources to match that mission. They must:

- Hire the best people and pay them well
- Empower their employees through education and support
- Give them the authority to do their jobs
- Expect good results
- Constantly evaluate their performance and provide feedback

Hiring

A surgeon's practice is a home away from home, and patients are to be greeted as if they were invited to that home. To provide this aura of welcome, the practice needs outwardly focused employees who have genuine smiles and truly care for people. The clinical staff must be gentle and nurturing to bring calm to those in pain and fear.

Those employees who answer the phone and greet the arriving patient have a unique opportunity to make a good first impression for the practice. There is only one chance to make a good first impression, and if that chance is lost, the remaining portion of the relationship with the patient may be difficult.

Team function is an important aspect of OMS practice, and the combination of the right people is a powerful tool for the delivery of expert, caring surgical services. All individuals have strengths and weaknesses. Some employees are masterful at interaction with children and the elderly, while others excel at organization. Some have extraordinary manual dexterity. For a team to function well, an effort must be made to match the assets of the members to cover all needed roles of the team.

Training

Owners are responsible for training an employee about expectations for job performance. The employee must be provided with feedback, because surgery is a continually changing profession. The owners should use outside resources such as seminars and conventions for education, but they should not hesitate to provide education solely for the individual employee. Education is an investment, and it will provide a return.

Assigning Value

All humans are inspired by expressions of appreciation and value. Words of affirmation, acts of service, and rewards are good ways to show employees that hard work and talent are noticed and valued.

For greater impact, give gifts in a public forum and positive feedback in front of patients and professionals. The employee review is an opportunity to foster meaningful dialogue for methods for improvement on both sides of the paycheck.

Autonomy

Trust, but verify.

—RONALD REAGAN

After acceptable performance standards have been outlined, employees should be given the autonomy to complete their tasks. The practice should verify compliance with the performance parameters by audits, and feedback should be provided to the employee.

Discipline

All humans make mistakes, and even reliable employees can make errors of judgment. Documentation and timely discussion allows the properly engaged employee an opportunity to learn, to grow, and to modify his behavior. If this does not happen, then the owners have a clear path to follow.

The Relationships between Owners and Referral Sources

Depending on the business model, referral sources might be located within the company, generated by external marketing, or made up of local professionals, especially family dentists. The fruitfulness of attempts to develop productive relationships with referring doctors varies, but communication and excellent service are always key elements of enduring relationships. Gifts and promotions can generate some good will, but once begun, the gift giving will be expected to continue, and it is subject to a competitor supplying a fancier prize.

A hard fact of life is the realization that these relationships are based on "What have you done for me lately?" Performing great work, communicating effectively, and promptly seeing emergencies are expected to continue throughout the lifetime of the relationship.

To refer a patient to a specific surgeon is an act of trust. If the patient has a good experience and the surgery is successful, then the referring doctor is rewarded with having made a good decision in his choice of specialist. Conversely, a poor experience or surgical result can taint the referring doctor as well as the surgeon.

Personal Communications

The most important thing in communication is hearing what isn't said.

—PETER DRUCKER

Personal time with a referring doctor is directly proportional to the volume of referred business. Texting, letters, and email are informational, a phone call is conversational, and a personal meeting is true communication. Do not underestimate the need for face-to-face meetings in order to communicate sincerity.

A surgeon may encounter a patient who is unhappy with his or her family dentist and asks the surgeon for a referral to another dentist. The surgeon should decline this opportunity. After the patient is dismissed, the surgeon should call the affected referring doctor to explain the circumstance and ask for advice on how to handle this delicate issue. This approach will help build a strong professional relationship with that referring doctor.

Educational Opportunities

A rising tide lifts all boats.

—JOHN F. KENNEDY

Because most referring doctors embrace education, presentations at professional societies and study clubs appeal to those interested in bettering themselves. Study clubs are particularly fertile for developing enduring relationships with referring doctors. All professionals enjoy interaction to compare cases and learn from others, so an educationally based club also offers all its members an opportunity to improve their professional care. This rising tide of knowledge brings with it the camaraderie of learning together. The employees of this subset of doctors will also enjoy this educational emphasis, and they will readily participate in a club for staff.

The Relationship between the Surgeon and the Patient

The practice of OMS is an uphill battle. We must entice patients to our business when they would rather be anywhere else. We frighten them. We hurt them. Then, we

make them pay us. After all of that, some of us believe we can make the patients like us.

Obligation to Educate

Only the educated are free.

—EPICTETUS

Although trained to cut and sew, surgeons have a most important secondary task, and that is to educate their patients and their families. The surgeon must clearly explain findings from examinations, treatment alternatives, consequences of the avoidance of treatment, outcome predictions, potential complications of treatment, and costs of each treatment option in terms of time, money, and morbidity. Finally, he should state how he would treat the condition if it were found in his own family member. All of this discussion takes time and produces no income, but it is critical to the development of a strong professional relationship with the patient.

Fear and Its Manifestations

Apprehension, uncertainty, waiting, expectation, fear of surprise, do a patient more harm than any exertion.

—FLORENCE NIGHTINGALE

Patients manifest fear and apprehension in different ways, and most manifestations are obvious and easily attended. For instance, fear can manifest as anger. Some individuals may assume an aggressive, verbally abusive attitude with clerical and clinical staff, but once face-to-face with the doctor, they become much more reasonable and compliant. The staff should be educated to recognize this aggression, understand its cause, handle it professionally, and not take it personally.

Just Say No

A surgeon will encounter patients who harbor unrealistic expectations of professional care. Ideally the surgeon will realize this during the initial patient encounter and before any treatment. If the surgeon explains that those expectations cannot be met and the patient continues to hold unrealistic beliefs, the patient should be gently but firmly released from the practice. The surgeon should say, "Ms. Jones, you need to find another surgeon." If the patient repeats her needs, the same dismissal phrase should be used. If the patient asks for a referral to another surgeon, the surgeon should decline that request. An unrealistic patient should not be referred to a peer. The surgeon should allow an unrealistic patient to find her own way from his practice so that the surgeon does not waste time, endure heartache, and engage malpractice attorneys. Declination of the opportunity to serve an unrealistic patient should be carefully documented.

I Don't Know

These are three of the most powerful, yet underused, words in a surgeon's vocabulary, but they can sometimes provide a simple solution to an unsolvable conundrum. Early in their careers, surgeons abhor these words, because they might represent a failure on the part of the doctor to study and learn. When a surgeon is presented with a difficult case such as vesiculobullous disease, early implant failure, atypical facial pain, or denied insurance coverage, the most truthful response is, "I don't know." Do not mislead the patient into believing that you know an answer to the problem when in fact you are guessing. It truly is OK not to know, and the patient will respect you for your honesty. There are many disorders of the human body that are understood poorly or not at all, and to admit that truth is not a defeat.

Errors

Don't be afraid to fail. Don't waste energy trying to cover up failure. Learn from your failures and go on to the next challenge. It's OK to fail. If you are not failing, you are not growing.

—STANLEY JUDD

All humans make errors. In the OMS profession those errors range from calling the patient by the incorrect name to removing the wrong tooth. Rather than being true surgical complications, these are basic errors that require admission and sincere apology by the surgeon. This act of being human and admitting it goes a long way toward maintaining healthy relationships with patients in the face of difficult circumstances.

Relationships between the Surgeon and Peers

Professional Organizations

All organizations need leadership. Good leadership comes from those who are inclined to help advance the members of their profession at the local, state, and national level. Join not for the limelight, but for the opportunity to serve and share.

Professional Jealousy

The worst part of success is trying to find someone that is happy for you.

—BETTE MIDLER

It is a rude awakening for a surgeon to learn that some of his colleagues are not interested in his successes. There will even be instances where professionals have propagated unflattering remarks to discredit a peer. One must learn to celebrate success within the self and turn a deaf ear to unflattering remarks. Only true friends will celebrate one another's accomplishments.

The Experienced Mentor

A mentor is an extension of education in the postgraduate world. Having such an experienced helping person is a blessing. If you don't ask, you will not know.

Visiting Peers

One of the most fruitful sources of help, information, and advice is a peer who is located just far enough away to avoid being a competitor. The entire staff can visit a peer and learn in all aspects of practice.

The Relationship between the Owners and the Community

We were born to unite with our fellow men, and to join in community with the human race.

—CICERO

Participation in community politics and organizations is more than being a good neighbor. It is an opportunity to market the practice. The encounters will build friendships in the community that will directly affect patient demand.

Membership, serving on committees and boards, and mentoring are valuable exposures in the local hospital, service organizations, churches, and educational institutions. OMS doctors who participate in community organizations are stating to the people of the community that they care about them, their businesses, and their families.

The Relationships between the Owners and their Advisors and Vendors

No man is an island.

—JOHN DONNE

Key relationships must be developed with legal, accounting, real estate, and financial advisors, and word of mouth is the best search engine. A surgeon spends many years learning to make an incision, but may be ignorant of the ways of the business world. In some instances, multiple advisors might be needed to find a consensus in a critical field.

Experienced vendor representatives have a broad knowledge of what works and what fails in practices because they have the opportunity to observe marketing and profitability from a distance. Treat them with respect and take advantage of their knowledge.

The Relationships between Owners and Third-Party Payers

No man can serve two masters: either he will hate the one and love the other, or else he will hold to the one and despise the other.

—MATTHEW 6:24 (KJV)

Surgeons owe their fidelity to their patients and not to their payments. If that premise is accepted, then in a dispute between a surgeon and the entity that pays for the treatment, a surgeon will defend the appropriateness of treatment rather than argue over the amount paid.

The Relationship between Surgeons and their Families

This above all: to thine own self be true.

—WILLIAM SHAKESPEARE THROUGH POLONIUS

There must be a logical division of time and energy among a surgeon's practice, his family, and himself. There are only 24 hours in a day, and it cannot be expanded. If too many of those precious hours are devoted to a surgical practice, there is insufficient time for family and personal health. If too few hours are allocated to personal fitness, then the surgeon's health will not support the quality time needed for family and loved ones. Time for fitness, for friends, and for family deserves scheduling just like consultations and surgeries. Do not leave this important part of life to chance.

Summation

The difference between a successful person and others is not a lack of strength, not a lack of knowledge, but rather a lack of will.

—VINCE LOMBARDI

Oral and maxillofacial surgery is a wonderful profession that affords OMS doctors the opportunity to bring relief to the suffering, to reap satisfaction from practicing a complex art, and to build dignity forged by hard work. It can be a deeply satisfying vocation enjoyed over a long career while allowing the surgeon to have meaningful interactions with other people.

It is not enough to be a good surgeon with adept fingers and a sharp eye. To be a success in our own eyes, we must study our souls for resonant goals and seek a compatible business model. We must search for like-minded partners, gifted employees, and faithful referring doctors. We must treat patients gently and honestly while we make peace with our peers. We must support our community and frequently seek the counsel of mentors and advisors. We must work as hard for ourselves and our families as we do for our practice. Work diligently toward excellence every day and recall that

When everything seems to be going against you, remember that airplanes take off against the wind, not with it.

—HENRY FORD

Oral and Maxillofacial Surgery Career Alternatives to Private Practice

DAVID A. BITONTI, KAREN M. KEITH, JESSE W. LEE, JOHN W. HULTQUIST, N. WHITNEY JAMES, PAUL M. LAMBERT, STANLEY W. SMITH, TIMOTHY O. WARD, GEORGE M. KUSHNER, JANICE S. LEE, MARTHA J. SOMERMAN, ANDREA B. BURKE, MARTIN E. EICHNER

Blue Angels and the *USS George H. W. Bush* (CVN 77).

Introduction

David A. Bitonti

The traditional career track for the largest percentage of oral and maxillofacial surgeons has been to transition from residency to a private practice opportunity. The purpose of this chapter is to provide information on potential career tracks that offer alternatives to this traditional practice model and that are academically, financially, and personally rewarding. These alternative career opportunities include public service, federal government employment, state government employment, academic and research employment, and a multispecialty dental services organization employment. It is important that practicing oral and maxillofacial surgeons be aware of these opportunities and understand some of what is involved in that particular type of practice, as well as the often unknown or misunderstood portions of these alternative practice opportunities. Whether a decision needs to be made early, following residency completion, or the decision is part of a career transition, these career alternatives to the

The views expressed are those of the authors and do not necessarily represent the views of the Department of Defense, Department of Health and Human Services, Department of Veterans Affairs, and Department of Justice; the United States Army, Navy, Air Force, Public Health Service, Indian Health Service, and Veterans Administration; or the Army, Navy, Air Force, Public Health Service, and Veterans Administration Medical Departments.

traditional private practice model warrant consideration by every oral and maxillofacial surgeon.

United States Army Oral and Maxillofacial Surgery Careers

Karen M. Keith

On March 3, 1911, President William Howard Taft signed legislation establishing the United States Army Dental Corps as a permanent corps of the Army Medical Department (AMEDD). Prior to this date, dental care within the Army was provided by hospital stewards or enlisted members with an interest or training as civilians. Assigned as a hospital steward at West Point in 1858, William Saunders was placed on orders as the first U.S. Army dentist in 1872. Graduate dental education was established in 1921, and the first dentist was sent for oral and maxillofacial surgery training in 1931.[1] The history of oral and maxillofacial surgeons (OMSs) within the Army is replete with significant clinical and command roles throughout the 104-year history of the U.S. Army Dental Corps. They continue to contribute immensely to leadership, research, academics, and surgical techniques, even when their time in service is complete.

During World War I, American Expeditionary Force maxillofacial teams that included a surgeon, a dental surgeon, and dental technicians were established with the vision of the plastic surgeon Major Vilray P. Blair. He recognized that dental expertise was required to properly care for the severity of gunshot wounds, complex jaw fractures, and avulsive soft tissue wounds. Protocols for wound management were developed that recognized the unique aspects of facial injuries. This included principles such as mechanical cleansing, minimal debridement, retention of bony fragments with soft tissue attachments, immediate fixation of jaw fractures, adequate drainage, and expeditious evacuation to base hospitals. With less than adequate logistical support, creative splinting techniques were employed.

During this era, wire fixation was used to temporize as well as to permanently stabilize bony fragments, rather than waiting for permanent dental splinting techniques. Oral and plastic surgeon Robert H. Ivy, who trained under Blair, is erroneously credited with the "Ivy loop" technique, but has stated that it originated with Colonel Robert T. Oliver. Oliver was a well-known oral surgeon who became the third chief of the Army Dental Corps from 1919 through 1924. Ivy should be better known for his soft tissue flap to reconstruct through-and-through facial wounds.[2] The early and consistent care touted by these pioneers continues with Army OMS as members of head and neck teams and as members of Combat Support Hospitals.

Another pioneer and exceptional leader, Major General Robert B. Shira, taught himself oral surgery in the Panama Canal Zone during World War II. Involved in World War II, Korea, and Vietnam, he made significant contributions during his 33-year career. His changes to dental delivery resulted in a 50% reduction in the number of Soldiers lost to battle in Vietnam because of dental disease. As Chief of the Army Dental Corps from 1967 to 1971, he helped establish the Army Dental Intern Program and an oral surgery residency program. At Walter Reed Army Medical Center, he pioneered closed-circuit color television demonstrations of surgical procedures for postgraduate courses. In 1966, he invited Professor Hugo Obwegeser from Zurich, Switzerland, to discuss new techniques in orthognathic surgery.[3]

This trajectory of illustrious careers and significant contributions of Army oral and maxillofacial surgeons continues throughout our history. Dr. Joe Hall Morris, best known for his Bi-Phase External Fixation Splint and the Orthognathic Surgery Simulating Instrument (OSSI), served 2 years at Fort Benning, GA, from 1951 to 1953. He played a significant role in the biomechanical aspects of the specialty. Ervin E. Hunsuck attained the rank of colonel and had a prolific research and academic career. Most noted for his bilateral sagittal split osteotomy modification, he also invested much research in trauma and fixation techniques. Colonel (Retired) Jan Faulk-Eggleston made her mark as the first female OMS to complete an Army OMS residency program and developed a niche in temporomandibular joint (TMJ) reconstruction. Numerous other OMS have contributed their expertise to the field of cosmetics, cleft lip/palate, and reconstructive techniques within the Army Dental Care System.

Currently, the Army OMS inventory is in the range of 113 officers, including residents. Eleven residents train at one of seven programs, with the number trained based on needs of the Army. In the summer of 2016, two Army residents will attend a civilian institution with the opportunity to earn the medical degree as well as the certificate of OMS completion. Efforts are underway to reinstitute the integration of medical school as part of the Army programs. It was offered from 1994 to 2001, and 86% of these surgeons stayed on active duty until retirement or still currently serve in excess of 20 years. One serves as the OMS Consultant to the Surgeon General (TSG), and four have served as OMS Residency Program Directors.

Two training programs are joint programs with our sister services. The National Capital Consortium (NCC) in Bethesda trains two Army residents annually at sites that include the Bethesda Naval Hospital, Fort Meade, and Fort Belvoir. San Antonio Military Medical Center (SAMMC) at Joint Base San Antonio, Texas, trains two Army OMSs annually with Air Force residents at Brooke Army Medical Center and at Wilford Hall Ambulatory Surgical Center.

Collocated with SAMMC is the prestigious Center for the Intrepid and the Dental Trauma and Research Detachment, part of the Triservice Battlefield Health and Trauma Research Institute. The other Army training sites are Eisenhower Army Medical Center at Fort Gordon, GA; Womack Army Medical Center, Fort Bragg, NC; William Beaumont Army Medical Center, Fort Bliss, TX; Madigan Army Medical Center, Joint Base Lewis McChord, WA; and Tripler Army Medical Center, Honolulu, HI.

Applicants to Army OMS residencies can be Health Professions Scholarship Program (HPSP) dental students as well as active duty dentists. Applications include a photograph, dental school transcripts, National Board Dental Examinations (NBDE) results, and results of the National Board of Medical Examiners (NBME). Applicants also complete a telephone interview with a panel of Army OMSs and submit letters of recommendation to attest to their integrity and potential. Potential applicants are strongly advised to spend at least 1 week at an Army training program to shadow residents and discern their commitment to the rigorous lifestyle. The Army Dental Corps conducts a specialty selection board once a year. Packets are independently assessed and rated, and an order of merit list determined. The best-qualified residents are selected for each program based on available positions. Board recommendations are forwarded to the Chief of the Army Dental Corps for approval. Human Resources Command (HRC), in consultation with the OMS Consultant to TSG, will assign residents to training locations based on the order of merit list, the residents' desires, and the OMS Program Directors' assessment.

The OMS residency is a 48-month certificate program accredited by the American Dental Association's Committee on Graduate Dental Education with an experience that rivals any civilian training program. Education is provided via experiences on the OMS service and rotations within the medical center. Trauma rotations are completed at the facility or with affiliated institutions known for high-volume encounters. The 5-month anesthesia rotation includes 1 month dedicated to pediatric anesthesia. Intubated general anesthesia is part of every Army OMS outpatient clinic training experience. A foundational skill, orthognathic surgery is an additional continual strength of all Army residencies.

Successful completion allows the graduate to apply for privileges in the full scope of the specialty. Attainment of board certification is advised as soon as practical. The new graduate should expect to serve a utilization tour for 3 to 4 years at a post where he or she might be the sole surgeon. Surgeons might serve at dental treatment facilities or within hospitals with inpatient and same-day surgery capabilities. Army OMSs also have the opportunity to compete for fellowship training. Craniofacial, cosmetic, temporomandibular joint, and trauma and reconstruction are among the potential fellowships current Army OMSs have completed.

Annual pay for Army oral and maxillofacial surgeons is based on rank, years of service, board certification, and several specialty specific pay incentives or bonuses. Other benefits of being a surgeon in the Army, available to all Army dentists, include the option of the Active Duty Health Professions Loan Repayment; 30 days of paid vacation earned annually; noncontributory retirement benefits with 20 years of qualifying service; and no-cost or low-cost medical and dental care for the Soldiers and their family. Dental Corps officers also have commissary (grocery store) and post exchange shopping privileges.

The Army Medical Department (AMEDD) has been undergoing a transformation over the past several years. As the health care system transforms, ensuring that the right people are at the right places will become critical. Preservation of surgical skills is vital while contributing to the readiness and wellness of Soldiers. OMS combat support roles have always been impressive. Oral and maxillofacial surgeons supported efforts in the Balkans. In February 2001, at the peak of the Persian Gulf War, 25 OMSs were deployed to support an Army force of 300,000.

Most recently, we have been a nation at war for the greater part of a decade. From 2003 to 2014, more than 30 OMSs deployed in support of Operation Iraqi Freedom or Operation Enduring Freedom, the vast majority of these volunteering. A completely updated oral and maxillofacial surgery instrument and equipment kit was fielded, and an assistant exclusively dedicated to the surgeon assigned. Panfacial trauma protocols were redeveloped in conjunction with our sister services to account for new injury patterns and concerns encountered with the implementation of improvised explosive devices (IEDs) over the past decade. Reconstructive challenges with tissue loss and burns exceeded even those seen during the trench warfare of WWI.[4] Technologies such as three-dimensional imaging, stereolithography, cone-beam scanners, and even virtual surgical planning have enhanced capabilities to render exceptional care to service members. Incredible advances in regenerative medicine offer promising therapies in the very near future. Collaboration with civilian research institutions has intensified our research strategies. Telemedicine has also proven a valuable asset, offering consultation services to front-line medics, dentists, and even NATO forces treating U.S. service members or handling complex humanitarian cases.

Career paths for Army OMS include education, research and command opportunities: Department of the Army Pamphlet 600-4, Army Medical Department Officer Development and Career Management, discusses the expectations, training, and utilization of Dental Corps Officers. The lifecycle model for surgeons includes: Oral and Maxillofacial Surgeon; Training Officer, Program Director, Assistant Program Director, Advanced Specialty Education Program in Oral and Maxillofacial Surgery; Chief, Surgery Branch, Dental Research Unit; Oral and Maxillofacial Surgery Consultant; OTSG; Chief, Department of Dentistry; Clinic Chief; and Researcher, U.S. Army Dental and Trauma Research Detachment (USADTRD). Oral and maxillofacial surgeons can even be part of Recruiting Command.

Surgeons are expected to continue their military education requirements as well as maintain their dental licensure educational requirements. Professional development includes clinical and military milestones depicted through various assignments requiring military education and professional training. Leaders are groomed through continuous professional study, self-development, and operational assignments. All officers are encouraged to attend the Combat Casualty Care Course (C4). Some might receive additional training at Airborne or Air Assault School if opportunities are available. Officers are encouraged to compete for and obtain the Expert Field Medical Badge (EFMB).

The AMEDD Captain's Career Course (CCC) should be completed between the third and sixth year of service. Intermediate Level Education (ILE) establishes a common Army operational war fighting culture to prepare field-grade officers for service at higher levels of responsibility and in conjunction with other services (joint assignments). Completion of ILE enhances competiveness for promotion to the rank of colonel and is required for Senior Service College (SSC) consideration and attendance. These courses prepare officers for higher-level command and staff duties. Surgeons are encouraged to accomplish the career milestones that make them eligible for the Surgeon General's "A" Proficiency Designator.

In addition to excelling in surgical skills and in surgical mentoring, Army OMSs continue to serve in leadership capacities outside of clinical practice. All Dental Corps officers have the opportunity to broaden their experiences as an Executive Dentist with diverse positions that include DENTAC Commander; Director of Dental Services; TOE Dental Unit Commander; Branch Chief, Dental Research Unit; Dental Staff Officer; OTSG; U.S. Army Medical Department Center and School Health Readiness Center of Excellence (Chief, Department of Dental Sciences); Combat Developments, AMEDD Personnel Proponent Directorate (APPD); Chief, Graduate Dental Education; Dental Surgeon, ACOM; USARC Dental Surgeon; FORSCOM Dental Surgeon; STARC; Regional Dental Command Commander; DENCOM Staff Officer; HRC Branch Chief; Career Development Officer, HRC; Corps Specific Branch Proponent Officer (CSBPO); and Forensic Dentist; U.S. Army Dental Command Commander. With the recent transformation of the Army Dental Corps within the AMEDD regiment, additional opportunities exist regarding the roles surgeons might have. OMSs and Army dentists in general will have the opportunity to command medical treatment facilities, and even strive for the role of Surgeon General.[5]

In the past decade, three Army OMSs have been Regional Dental Commanders. After his role as an OMS Residency Program Director and Regional Dental Commander, Colonel (Retired) Larry Hanson served as the eighth Dental Corps Commander from 2003 to 2006 and is the only oral and maxillofacial surgeon to have held that position. Oral and maxillofacial surgeons have commanded the USADTRD and have been involved with numerous research endeavors. Colonel (Retired) Robert Hale was instrumental in significantly accelerating research in regenerative medicine. Currently, several surgeons hold command positions, from a field dental unit to a Regional Dental Command. One OMS is serving at the Office of the Surgeon General. The 212th Combat Support Hospital in Germany has an OMS integral to that unit, heavily involved in training and preparation of assets to support European missions.[6]

Several Army OMSs have provided lectures at national or regional conferences, including the American Association of Oral and Maxillofacial Surgeons, the American Dental Society of Anesthesiology, and the annual Denver Board Review Course. Several former and current Army OMS serve as examiners for the American Board of Oral and Maxillofacial Surgery. Numerous former Army OMS have left military careers and become presidents of local professional societies, deans of universities, and presidents of national professional associations. They are highly desired candidates for competitive private-sector jobs upon leaving the service.

The contributions of all Army oral and maxillofacial surgeons continue to be appreciated. They provide subject matter expertise when updating field equipment, determining ancillary staff training, eliminating coding variance, and setting standards across the profession. As the Army continues to transform and reengineer its relevancy within our world, Army OMS will continue to ensure the highest level of training and professional development to provide the absolute best surgical services to Soldiers and to lead the Dental Corps into the next century.

United States Navy Oral and Maxillofacial Surgery Careers

Jesse W. Lee

The United States Navy (USN) Dental Corps has a long and storied tradition in which oral and maxillofacial surgeons have played an important role. The Dental Corps, established on August 22, 1912, recently celebrated its 103rd year of supporting America's Navy and Marines. The original authorization authorized 30 acting assistant dental surgeons to part of the Medical Department. The Dental Corps has since grown to more than 1000 officers.

When the United States entered World War I on April 6, 1917, 35 dental officers were on active duty. That number grew to more than 500 by the war's end. Most of these officers were assigned to ships or overseas activities. Two dental

officers were awarded the Medal of Honor during this conflict. World War 1 established the general recognition of the value of dentistry to the Naval Service. Early in 1922, the Bureau of Medicine and Surgery adopted a dental division and the U.S. Navy Dental School was established. By 1941, 759 dental officers were on active duty at 347 dental facilities. Two Dental Corps officers were among those killed in the attack on Pearl Harbor. Less than a month later, the Surgeon General directed that all dental officers become proficient in the treatment of casualties so they might assist in sick bays and operating rooms and assist in the delivery of anesthesia. This became the basis for the role oral and maxillofacial surgeons would play in the Navy in the future. Dental officers, assisted by dental technicians, performed such duties under duress and in some instances at the cost of their lives.

Dental personnel continued their support of our medical colleagues through the Korean conflict and Vietnam. The start of formal oral surgery residency training in the Navy had its roots in the Vietnam conflict. Oral surgeons provided front-line treatment for many injured service members and were an integral part of the forward-deployed medical units. The utility of forward-deployed dentists with medical training was demonstrated in the tragic bombing of the Marine Corps barracks in Beirut, Lebanon, in 1983. This attack left 241 American servicemen dead with 65 seriously wounded. All of the medical staff was killed in the attack. Two Navy dentists with their dental technicians coordinated and delivered emergency care and evacuations of the wounded. They both were awarded the Bronze Star for gallantry under fire.

In July 1984, the Navy began conversion of two supertankers to hospital ships. *USNS Mercy* (T-AH19) and *USNS Comfort* (T-AH20) were placed in service in December 1986 and August 1987, respectively. These platforms, with 1000 beds and 12 operating rooms, allow comprehensive oral surgery services worldwide, regardless of the situation, whether war or natural disaster. These, in addition to the forward-deployed fleet hospitals and surgical units allow oral and maxillofacial surgeons to treat patients in need anyplace, anytime.

Throughout the history of the United States Navy Dental Corps, oral and maxillofacial surgeons have played a vital role in the delivery of care. Oral and maxillofacial surgeons fill a wide array of positions across the globe. As with all dental and medical specialties, residency training is the foundation on which the specialty is built. As the specialty of Oral Surgery developed and grew, so did the Navy's programs. At first interested officers were sent to civilian institutions for training. The Navy also aggressively trained officers for 1 year in exodontia to alleviate the great numbers of servicemen requiring treatment. The Navy then instituted in-service training programs for oral and maxillofacial surgeons in the 1970s. Starting with 2 years of training, the programs grew as the specialty grew. Today, the three in-service programs offered by the Navy favorably compare with any in the civilian sector. The Navy trains six in-service residents a year in a 4-year certificate program and will usually send one or two officers to civilian programs as well. The Navy also sends on average one officer for subspecialty fellowship training a year for reconstruction, cosmetics, or craniofacial surgery. The selection process begins early, 16 months before the initiation of training. From scholarship students in their third year of dental school to senior dental officers, applications come from a wide variety of candidates. Unlike civilian residencies, the selections for the Navy programs are made by a selection board with close consultation from the OMS training community and specialty leader. Applications are evaluated on several criteria including undergraduate and graduate grades, class ranks, board scores, and scores on the Combined Basic Science Exanimation. Letters of recommendation, military potential, and professionalism are also evaluated. This rigorous approach ensures highly qualified, diverse candidates, many of whom have extensive clinical and leadership experience. Our 4-year certificate programs at the Naval Medical Center, Portsmouth, VA, and the Naval Medical Center, San Diego, have long been recognized for their excellence. The joint program with the Army at Walter Reed National Military Medical Center boasts state-of-the-art facilities with the heritages of both previously separated programs.

Each of the Navy's residency programs brings an educational opportunity comparable to any civilian program. A full, broad scope of practice gives residents outstanding hands-on experience in orthognathic surgery, cosmetic surgery, implant reconstruction, pathology including head and neck cancer with reconstruction, trauma, temporomandibular joint treatments, and dentoalveolar surgery. Each program is staffed with at least four full-time, board-certified oral and maxillofacial surgeons, a maxillofacial prosthodontist, pediatric dentist, orthodontist, endodontist, and orofacial pain specialist. Also, there are general dentists who assist in the General Practice Residencies that each of the training programs support. The Navy sponsors residents to participate in fellowship training in cosmetic surgery, palliative and reconstruction surgery, and craniofacial surgery. We support our residents in their pursuit of board certification with review courses and scheduled "mock board" sessions. The Navy Dental Corps candidates have a stellar 97% pass rate over the past 20 years on the ABOMS certification exam.

Oral and maxillofacial surgeons can join the Navy via direct accession and are eligible for the same benefits as surgeons who are trained while in the Navy. The financial assistance program is another avenue for non–active duty oral and maxillofacial surgeons who are interested in a career in the Naval Service while in residency. This program provides a stipend while in school as well as money toward fees, equipment, and housing and a bonus on graduation.

After completion of training, a world of opportunity is available to the OMS. From large training hospital to clinics, from sea to shore, the OMS selects his or her career path. Working closely with the Oral Surgery Specialty Advisor to the Surgeon General, each billet (job position) is carefully filled. With more than 80 spots from aircraft carriers,

hospital overseas, and clinics and hospitals stateside, the opportunities to find a spot that meets your personal and professional goals are many. Navy oral and maxillofacial surgeons practice in state-of-the-art facilities with the opportunity to use the latest technology in support of their practice. Digital radiology using cone beam CT imaging is now the standard of care at the majority of our facilities. Virtual treatment planning and remote splint fabrication are now standard at our training programs for orthognathic surgery, TMJ surgery, and implants. We use lasers and piezoelectric equipment in most of our hospitals and clinics. Our facilities at Walter Reed are on the cutting edge of facial reconstruction using transplant technology for our war trauma patients and patients with severe craniofacial anomalies.

The OMS who is looking for challenges beyond clinical care will find the Navy full of opportunity. Currently oral and maxillofacial surgeons have leadership roles throughout Navy Medicine. Positions include Residency Directors, Clinic Directors, Director of Surgical and Dental services, Executive Officers (civilian equivalent to Vice President of a hospital), and Commanding Officer of a clinic, dental battalion, or hospital (the civilian equivalent to CEO of a hospital). Oral and maxillofacial surgeons have served as the chief and deputy chief of the Navy Dental Corps, as Assistant to the Surgeon General of the Navy, and as commanding officers of large support commands. As rank and experience increase, the opportunities in executive medicine become more available. The interested OMS can tailor his or her career to any area of interest. This includes clinical, executive, research, education, or a combination of each. The group practice setting is unique and allows for multiple interests to be satisfied while providing the best in care for our patients. The ability to work closely with other oral and maxillofacial surgeons is one of the most appreciated benefits of military practice. Be it on a nuclear-powered aircraft carrier or overseas in one of our hospitals in Europe, Japan, or the Pacific, you always have the support of your colleagues and comfort in the knowledge that if you have a question or concern, there is another surgeon you can contact who will be able to help (Figures 3-1 and 3-2).

The experiences gained by the military OMS are valuable and readily transferred to the civilian practice of OMS. Former Navy oral and maxillofacial surgeons can be found in all aspects of the OMS community, from Program Directors of large university-based training programs to officers of the American Board of Oral and Maxillofacial Surgery. Most military oral and maxillofacial surgeons leave the military service to practice in the civilian community after their time in the Navy. Many take advantage of the liberal moonlighting policy the Navy has in place at most of its facilities. The Navy OMS truly can chart their own career course, wherever their interests might take them (Figures 3-3 and 3-4).

Oral and maxillofacial surgeons interested in a Navy career may receive additional information by contacting a local Navy Medical recruiter; by writing to the Navy Dental Corps, Career Planner, Bureau of Medicine and Surgery, 5113 Leesburg PK, Falls Church, VA 20598; or by calling

703-681-8919. Additional information about practicing as a Navy dentist can be found at www.navy.com.

United States Air Force Oral and Maxillofacial Surgery Careers

John W. Hultquist

The United States Air Force (USAF) Dental Corps was established in 1949 along with the creation of the Air Force Medical Service. The OMS residency program at Wilford Hall USAF Medical Center on Lackland Air Force Base (AFB) in San Antonio, TX, was the first dental residency in the USAF Dental Corps. It was started in 1957 and graduated its first residents in 1959. Ten years later, an additional OMS training program was started at David Grant USAF Medical Center on Travis AFB in Fairfield, CA, and graduated its first residents in 1971. In 2013, the Air Force and Army programs in the San Antonio area combined to form the San Antonio Military Oral & Maxillofacial Surgery (SAMOMS) residency. SAMOMS functions out of two military facilities in San Antonio—Wilford Hall Ambulatory Surgical Center and San Antonio Military Medical Center. SAMOMS graduated its first residents in 2014.

Opportunities exist to become an OMS in the USAF Dental Corps other than through in-service training. Individuals can be selected for Air Force sponsored training through the Air Force Institute of Technology (AFIT) or by direct accession into the Air Force as an OMS. The Financial Assistance Program (FAP) is also available through the USAF Recruiting Service for OMS residents currently in training who are interested in joining the USAF Dental Corps upon graduation.

A wide range of career opportunities exist for the OMS in the Air Force Dental Corps and Medical Service. Career vectors include clinical, educational, and leadership roles. Each year, a Dental Corps Developmental Team meets and vectors AF officers into one of these tracks. A large majority of oral and maxillofacial surgeons in the Air Force will, at some point in their career, be vectored into all three areas depending on level of experience and interests. The size and mission of a particular base or assignment will determine what role an OMS will play.

Early in the career of an Air Force OMS (captains and majors), there is an increased emphasis on their role as a clinician. Most young Air Force OMSs become involved in the academic arena as a junior faculty member in one of the Air Force's multiple Advanced Education in General Dentistry (AEGD) programs. As their career progresses, opportunities arise for a larger role in postgraduate dental education and administration of clinical operations.

As an Air Force oral and maxillofacial surgeon's career progresses and they become a senior-grade officer (lieutenant colonels and colonels), more opportunities arise to become involved in graduate dental education, whether in the AEGD programs or in the Oral and Maxillofacial Surgery residency programs, and in the leadership realm in various administrative and command roles. Senior oral and maxillofacial surgeons function as Department Chiefs, Flight Commanders, or Element Leaders. Their responsibilities include overseeing daily operations and administration of the OMS department and the assigned personnel, officer and enlisted.

Other leadership opportunities exist in the Air Force including Squadron Commander and Group Commander. Squadron commanders oversee the operations and administration of an entire department of dentistry, which includes all specialties of dentistry. These positions require more administrative time, and thus clinical time is somewhat reduced. Group commanders manage much larger organizations beyond that of just dental personnel and operations. These organizations are usually larger outpatient medical facilities or can be complete inpatient facilities with full surgical capabilities.

As previously stated, Air Force OMSs can be involved in education throughout all aspects of their careers. Thirteen of 14 stateside locations maintain AEGD programs (1-year or 2-year). In addition, 12 full-time faculty positions are available at the Air Force OMS residency programs in San Antonio and at David Grant Medical Center in northern California. Included at these two sites are program chairmen positions and program director positions. These individuals function similarly to their civilian counterparts and are responsible for daily operations, educational curriculum, and accreditation.

Currently, there are a total of 19 locations worldwide that have at least one OMS assigned. Excluding Lackland AFB and Travis AFB, 13 locations have two assigned oral and maxillofacial surgeons and the remaining 4 have one OMS assigned. Of the 12 stateside locations being manned

by Air Force oral and maxillofacial surgeons, all but 1 of those maintains an AEGD program. Most of these programs are located in or near large metropolitan areas such as Washington, DC, San Francisco, Las Vegas, San Antonio, and St. Louis. Locations outside the lower 48 states include Anchorage, Japan, the United Kingdom, and Germany.

Another great opportunity in the Air Force is to be able to practice full-scope oral and maxillofacial surgery. OMS clinics are either located in large medical centers or large outpatient surgical facilities, or collocated within dental clinics. All locations have access to operating rooms and inpatient facilities, whether within the Air Force medical facility itself or at a civilian hospital that has an agreement with the military treatment facility.

Most bases provide a wide range of services to meet dental and medical needs from not only the active duty military population but also their dependents and military retirees and their dependents. Certainly dentoalveolar and implant surgical services are a large portion of the workload, but pathology and reconstructive services are also offered if available. Orthognathic surgery is available at all Air Force locations with OMSs; most locations have an in-house orthodontist for a treatment team to manage functional dentofacial abnormalities and malocclusions. Facial cosmetic surgery can also be provided on a fee-for-service basis.

The management of maxillofacial trauma is paramount to the mission of all military oral and maxillofacial surgeons. Craniofacial and neck injuries are managed via a team approach working side-by-side with otolaryngology, plastic surgery, and oculoplastic and neurosurgery colleagues, ensuring a well-orchestrated collaborative effort. Air Force OMSs also manage maxillofacial trauma locally as needed and as the facility capability allows. Typical injuries involve sports-related or recreational activities but can also encompass motor vehicle collisions or assaults.

All Air Force facilities with OMSs are outfitted with state-of-the-art equipment and technology. Digital radiography and cone-beam CT imaging is available at all locations with an OMS clinic. Full stereolithographic modeling capabilities are readily available and are used to enhance treatment of trauma, craniofacial anomalies, and pathologic conditions. Laser, piezoelectric surgery, and hyperbaric oxygen chambers are available at a select number of medical centers with OMS capabilities.

An Air Force OMS also enjoys the opportunity for professional collaboration with other Air Force OMSs or other dental and medical specialists. All oral and maxillofacial surgery practices in the Air Force exist within a large group practice setting with orthodontists, prosthodontists, periodontists, endodontists, and general dentists. Collaborative treatment planning conferences are standard practice in the Air Force. These include dentofacial deformities boards and implant boards, as well as collaboration with their medical colleagues on craniofacial anomalies, sleep medicine, and head and neck tumor boards. Opportunities also exist to collaborate with civilian colleagues. Local continuing education symposia, journal clubs, and professional societies are available in which to participate.

Board certification is emphasized in the Air Force Dental Corps, especially oral and maxillofacial surgery. The Air Force has an outstanding record in oral and maxillofacial surgery, with more than 97% or all eligible surgeons achieving diplomate status with the American Board of Oral and Maxillofacial Surgery while on active duty. Also, every opportunity is extended to Air Force OMSs for funding the costs of board certification and attendance at board review courses. Competency and currency are also a major emphasis of the Air Force Medical Service, so, whenever possible, attendance at national meetings and continuing education courses is granted and funded.

Each year, the Air Force Dental Education Committee convenes to consider applications for various postgraduate dental programs. Air Force OMSs can be selected for fellowship training, which includes facial cosmetics, temporomandibular joint, tumor and reconstructive surgery, and craniofacial and cleft surgery. The fellowships are sponsored through the Air Force Institute of Technology and are completed at accredited civilian locations.

There are multiple benefits of being active duty military. These include professional liability coverage, medical and dental health care, and access to commissary and base exchange shopping. Additionally, each base offers various recreational activities in the local area and reduced rates on tickets for sporting events, amusement parks, and other venues. There are also multiple bonuses offered to the Air Force OMS including a monthly dental bonus, yearly dental bonus, yearly incentive pay specifically for the OMS, and board certification pay. Housing is also available on base, or the OMS can receive a basic allowance for quarters to rent or purchase a home off-base. Active duty members and their families are moved to their locations at the government's expense.

United States Public Health Service Oral and Maxillofacial Surgery Careers

N. Whitney James

The United States Public Health Service (USPHS) is directly under the Health and Human Services and is one of the seven uniformed services. It is composed of branch services

that include the Indian Health Service, National Institute of Health, Center for Disease Control and Prevention, National Health Service Corp, Federal Bureau of Prisons, and the National Oceanic and Atmospheric Administration. It also provides substantial health care services to the United States Coast Guard and backup services for the Department of Defense. The scope of practice and career opportunities for the oral and maxillofacial surgeon (OMS) are varied with a broad scope of services in the USPHS in-patient and out-patient hospital based programs. These programs extend from urban community hospitals to isolated rural clinics as well as provide consultation to outlying satellite clinics as an OMS Area Regional Consultant to National policies as an OMS National Consultant. OMS providers also participated in providing continuing education to the medical and dental communities on local and national levels to elevate the knowledge and clinical skills of other health care providers in the Public Health Service environment. Supervisory, administrative, and research positions are also available.

The Indian Health Service is the largest of the branch services within the USPHS with the greatest number of hospitals and OMS providers. These providers come into the USPHS under three scenarios:

- An OMS provider may receive a Congressional Commission and function as a Commissioned Officer of the USPHS. As a Commissioned Officer of the USPHS, the OMS Dental Officer is assigned to a hospital-based program to provide in-patient and out-patient services for that program. The Commissioned Officer also, in coordination with other USPHS Service Branches, has opportunities to participate in deployments in the event of national emergencies or natural disasters, or to assist and support the Department of Defense in its various programs as needed. Some overseas opportunities are also available as needs arise. A commissioned officer may also be assigned to other positions of supervision, administration, or research in any of the various branches of service within the USPHS. Temporary duty station assignments and mobility are also an option to the commissioned officer
- An OMS provider may be hired as a federal employee functioning as a Civil Servant. The Civil Servant is directly hired by a Federal hospital program that is under the direction of the Indian Health Service. A Civil Servant does not participate in deployment activities. Mobility is an option for the Civil Servant.
- As a direct contracted hire to a Tribal Program. A Direct Tribal Hire is directly hired by a tribally governed program and is an employee of that tribe or group of tribes. These programs are directed and administered by a Native American Tribe or a group of Tribes known as a "638 or Self Determination Program." As a direct contract hire, temporary duty assignments or mobility is not an option.

Pay, retirement programs, and benefits vary with each working option within the U.S. Public Health Service.

Veterans Affairs Oral and Maxillofacial Surgery Careers

Paul M. Lambert, Stanley W. Smith, Timothy O. Ward

The Department of Veterans Affairs (VA) comprises three components: veteran health care (VHA), veteran benefits (VBA), and national military cemeteries (NCA). VHA provides health care through the VA Medical Centers (VAMC), Outpatient Clinics (OPC), Community-Based Outpatient Clinics (CBOC), and VA Community Living Centers (VA Nursing Home) programs. VHA evolved from the first federal soldiers' facility established for Civil War veterans of the Union Army in 1865.

In 1918, Congress tasked two Treasury agencies with operating hospitals specifically for returning World War I veterans. They leased hundreds of private hospitals and hotels for the rush of returning injured war veterans and began a program of building new hospitals. Today's VHA continues to meet veterans' changing and challenging medical, surgical, and quality-of-life needs. New programs provide treatment for traumatic brain injuries, post-traumatic stress, suicide prevention, women veterans, and more. VA has opened outpatient clinics and established telemedicine and other services to accommodate a diverse veteran population, and it continues to cultivate ongoing medical research and innovation to improve the lives of America's patriots.

VHA operates one of the largest integrated health care systems in the world and the largest in the United States with 150 medical centers, nearly 1400 community-based outpatient clinics, community living centers, Vet Centers, and Domiciliaries. Together these health care facilities and the more than 53,000 independent licensed health care practitioners who work within them provide comprehensive care to more than 8.3 million veterans each year.

VA oral and maxillofacial surgeons (OMSs) enjoy extremely fulfilling careers caring for those who have served in defense of our nation—the most appreciative patient population that you will ever be privileged to serve. Currently, personnel returning from Iraq and Afghanistan have challenged VA OMSs with the responsibility for reconstructing and rehabilitating patients suffering from major facial, head, and neck injuries. The magnitude of their oral and maxillofacial injuries provides a challenging scope of surgical practice.

A career as an OMS with VA offers a future that is dynamic, innovative, and collaborative. As valued members

of an interdisciplinary health care team, VA OMSs enjoy the flexibility to move within the VA structure and the freedom to practice wherever an opening exists. In return for their commitment to quality health care for our nation's veterans, the VA offers its dentists competitive salaries, first-rate employment benefits, educational support, and tuition reimbursement programs while still retaining the ability to practice privately.

The hospital-based practice of oral and maxillofacial surgery offers opportunities and challenges that typically are not found in other environments. VA dentists and other dental professionals use the full scope of their skills and knowledge in their daily practice and are regularly challenged by patients who can be medically, physically, or emotionally compromised. Many VA medical centers offer the opportunity to work in a rewarding and collaborative fashion with other specialists providing comprehensive cutting-edge care, including head and neck surgery. Appropriately trained OMSs also independently manage head and neck pathology. All patient care is performed in an environment that adheres to the strictest protocols for infection control and assurances for quality patient treatment.

The VA is committed to a philosophy of technology-driven care that enhances staff performance and improves patient results. VA dentists work with today's state-of-the-art technology that directly pertains to patient treatment. Digital imaging, clinical operating microscopes, dental implantology, cone beam radiographic imaging, stereolithographic modeling, and computer-assisted design/computer-assisted manufacturing (CAD/CAM) are but a few of the advances that are in use by VA dentists, on a daily basis in some centers.

After years of development, the VA now has the most comprehensive electronic health record system in the nation. The health record puts each veteran's medical records, laboratory results, consults, radiographs, ECGs, and much more at the fingertips of dentists and the entire patient care team as they work together to design treatment interventions. The dental record component of the electronic health record is a sophisticated program that allows the clinician to view treatment plans, write notes, and monitor progress while seamlessly recording production data and other administrative tasks. Because the system is linked to every VA facility across the country, the care team can instantaneously pull up a traveling veteran's records to examine critical components (e.g., medications, medical problem list, or imaging reports) while making informed patient care decisions.

The VA also uses technology to enhance professional development. Computer-based networking (mail groups), regular teleconferences, and monthly ADA CERP approved webinar programs and other online training enable VA dentists across the country to obtain new information, share research, and exchange best practices.

OMSs with a special interest in clinical research or training find a rich environment at the VA. Many VA OMSs help guide students' fieldwork experiences. Others conduct ongoing research in such wide-ranging areas as laser-guided imaging, chairside point-of-care diagnosis or disease management using proteomics, and dental implantology. Historically, VA OMSs have been well published in nationally recognized professional journals. These education and research missions are further strengthened by the VA's affiliations with all schools of dentistry and 107 of the 125 schools of medicine. The VA provides training for a majority of America's medical, nursing, and allied health professionals. Roughly 60% of all medical residents obtain a portion of their training at VA hospitals, and VA medical research programs benefit society at large. The VA supports 380 dental residency training programs, providing a rich educational opportunity that welcomes OMSs as part of the faculty. Faculty appointments are encouraged, and time is available for active participation.

The VA Office of Dentistry has established a dental practice-based research network known as VA Dentists Engaged in Research (VADER). This network is composed of VA dentists who conduct research in their practices to address the issues and challenges that clinicians face daily in treating their patients. All VA dentists are invited to participate. Study areas of particular interest to OMSs are currently being developed, including medication-related osteonecrosis of the jaw (MRONJ), hyperbaric oxygen therapy, and earlier diagnosis of oral cancer. The MRONJ problem is the type of issue suited for investigation by VA dentists and the VADER dental practice-based research network. Although case series manuscripts and treatment guidelines have been published, additional well-designed clinical studies are required. VA dentists also participate in the ADA Professional Products Review.

Those surgeons interested in leadership positions within VA may apply for several excellent leadership development programs offered locally, regionally, and nationally. These include the Leadership Development Institute, Executive Career Field Candidate Development Program, and Leadership VA. OMSs may follow in the footsteps of those who have gone before them and assume positions at the medical-center level, including but not limited to chief of dental service; chief of staff; associate chief of staff for education; and chief of primary care.

At the system-wide level, OMSs have served on work groups dealing with developing clinical pathways for acute and chronic pain management, and diabetes. They have occupied positions at the highest policy-making level, including Assistant Under Secretary of Health for Dentistry. In that capacity, they have directed the entire scope of dental service delivery, including recommendations for manpower, resource allocation, standards of care, performance measurement, technology, quality improvement, education, postdoctoral training, and a host of other related issues.

VA OMSs may participate in organized dentistry at the local, state, regional, and national level. OMSs may serve on and chair committees and may serve as delegates and officers. Many OMSs have been elected to leadership positions in regional and national health care organizations, including president of the American Association of Oral and Maxillofacial Surgeons.

OMSs interested in a VA career may receive additional information by contacting a medical center in their area directly; by writing to the Department of Veterans Affairs, Placement Service, 1555 Poydras Street, Suite 1971, New

Orleans, LA 70112; or by calling 1-800-949-0002. Employment information can also be found on the Internet at www.vacareers.va.gov. Additional information about practicing as a VA dentist can be found at www.va.gov/dental or https://www.usajobs.gov, keyword VA DENTIST.

Academic Oral and Maxillofacial Surgery Careers

George M. Kushner

University of Louisville Oral and Maxillofacial Surgery Team 2014-2015.

Academic surgeons play a critical role in the ongoing advancement of the specialty of oral and maxillofacial surgery. Residents are the lifeblood of any specialty, infusing new energy and ideas that advance our field. Training these residents is one of our most important roles as academic oral and maxillofacial surgeons. Ensuring that residents are properly trained is a time-intensive and lengthy process that occurs over 4 to 6 years. The academic oral and maxillofacial surgery faculty is an important component of the overall workforce of the specialty, as this is a major focus of our day-to-day activities. The academic faculty is charged with training the next generation of oral and maxillofacial surgeons.

One of the main reasons for choosing an academic career is being in a stimulating environment. Interacting with residents and students on a daily basis provides a constant source of motivation. Faculty are constantly pushed to explain "why" to our mentees. It is commonly said that you cannot adequately perform a procedure until you can teach it to someone else. Oral and maxillofacial training programs are often located within academic health sciences centers. These centers are tertiary care referral centers that receive the most challenging clinical patients. Trauma, pathology, infections, and reconstruction dilemmas are dealt with on a weekly basis. This affords faculty to have a wide scope of practice within our specialty. One of the factors that attracts potential faculty is the ability to have major surgery as a significant portion of their practice.[7] Academic oral and maxillofacial surgery faculty are part of a team and thus gain fulfillment from the collegial interaction with our colleagues. Cases can include a multidisciplinary dental rehabilitation patient with our orthodontic and prosthodontic colleagues; a trauma patient treated with our general surgeons, neurosurgeons, and orthopedic surgeons; or a complex medical patient undergoing organ transplant that requires extraction of teeth before the transplant procedure. Providing clinical care for these extremely complex patients demands teamwork from the treating doctors but is very rewarding.

Many of the oral and maxillofacial training programs are based in dental schools. The presence of strong oral and maxillofacial surgery faculty provides the unique opportunity to future practicing dentists as to the scope of our specialty. The current dental students are our future referral base.

How oral and maxillofacial surgery faculty interacts with dental students and other graduate dental residents can have a profound impact on future relationships. Another important charge to academic oral and maxillofacial surgery faculty is to foster and nurture good relationships within the dental schools.

Many oral and maxillofacial surgery training programs are hospital based. OMS faculty has the unique opportunity to interact with our medical colleagues in providing quality patient care. OMS training programs at academic health care centers frequently treat patients at a level 1 trauma center. Providing care of the injured patient is one of the basic provisions of surgical care. Oral and maxillofacial surgeons have a long history of providing excellent care of maxillofacial injuries at our trauma centers. OMS faculty lead the team of residents in providing care for some of the most critically injured patients the region. Providing care to the traumatized patient is a huge benefit the people of your community or region. The American College of Surgeons, the main organization involved in trauma center verification, has recognized oral and maxillofacial surgeons for their contribution in care of the injured patient.

All OMS training programs, whether dental school based, hospital based, or free-standing facilities, have the opportunity to interact with our medical colleagues on a very close basis. This interaction allows OMS faculty to educate our medical colleagues about our dental specialty. Many aspects of oral and maxillofacial surgery can be considered medical, such as trauma, pathology, reconstruction, cleft lip and palate, obstructive sleep apnea, and TMJ surgery.

Educating our medical colleagues as to the scope of our specialty can provide a source for additional patient referrals and strengthen the position of OMS within the health care system.

For example, the University of Louisville offers a 6-year double degree OMS training program. OMS residents spend 2 years in medical school and interact with medical students. The medical students and faculty know and understand what the specialty of oral and maxillofacial surgery entails. During the general surgery year, OMS residents rotate on other medical/surgical subspecialties and further advance the knowledge about our specialty. Just as important during OMS training is the resident interaction with our other dental specialties. This relationship solidifies future referral patterns and educates our dental colleagues

as to the scope of oral and maxillofacial surgery. The OMS faculty is the driving force behind this complex interaction of activities that forges the relationship of oral and maxillofacial surgery with both dental and medical colleagues.

Research is another important task that is largely delegated to the academic OMS faculty. Research is vital to advance any profession and is essential in the field of health care.[8] Much of the clinical care delivered today is based on research and named evidence-based care. The surgeon's practice in the future will surely change in ways based on the best available research.

Research simply asks "Why?" or "Is there a better way?" All accredited OMS training programs must engage in scholarly activities. Scholarly activity can range from having a fully funded research laboratory with PhD investigators to poster presentations at the local dental meeting showcasing OMS departmental activities. Either way, OMS training programs are advancing the science of the specialty of oral and maxillofacial surgery. The OMS faculty is again the driving force behind the research activities. In reviewing journals covering the specialty of oral and maxillofacial surgery, the majority of published articles come from academic institutions. OMS faculty also attempt to nurture the inquisitive quality within each resident in the hope that this will continue in the future. OMS faculty constantly motivates the residents to be the best surgeons that they can be. This is one way we can grow the next generation of academic OMS faculty.

According to the American Association of Oral and Maxillofacial Surgeons (AAOMS) website, the following statistics were obtained for 2014-2015:

Oral and Maxillofacial Surgery Training Program Statistics

Accredited OMS training programs 101
Single-degree programs 55
Double-degree programs 46
Programs offering both single- and double-degree training 19

Oral and Maxillofacial Surgery Training Program Locations

Hospital-based training programs 43
Dental school based training programs 38
Medical school based training programs 10
Federal services training programs 10

There are approximately 250 oral and maxillofacial surgery residents starting an accredited program each year.

One can easily ascertain that the diversity of academic OMS faculty must be significant to fulfill all of the needs of the OMS residents. There are common aspects of all OMS training that must be covered in every accredited OMS training program. However, many sites offer training expertise in expanded-scope oral and maxillofacial surgery. Head and neck oncology, pediatric craniofacial and cleft lip/palate, and cosmetic surgery are being advanced by OMS academic faculty at their respective institutions. Dental implantology is a rapidly growing field that is predicted to grow steadily in future years. Dental implants have given our patients options that were not available in the past. The acceptance of dental implants by patients is constantly increasing as the benefits of implant treatment are realized. Fellowships in these advanced areas are available to OMS residents who want to further pursue these areas of interest.

Despite the advantages of an academic OMS career, there is a constant shortage of OMS academic faculty. Inadequate faculty numbers is a common infraction at OMS site visits, which occur every 5 years. Many academic programs have vacant faculty positions and are currently looking for qualified OMS faculty members. Only a small number of graduating residents pursue an academic career. Academic OMS faculty, once on board at an institution, often leave for an alternative career pathway, which often is the private practice sector. Recruitment and retention are the major problems for qualified academic OMS faculty.[9]

There are many potential reasons for this disparity. Financial disparity is at the top of the list. Academic positions generally pay less than private practice opportunities. Graduating OMS residents often have a debt load in the hundreds of thousands of dollars.[5] This debt load may be increased if a double-degree program was completed where medical school tuition was required.

Graduating OMS residents may not be able to meet their loan payments and living expenses based on an academic salary. The salary disparity in conjunction with increasing student/resident debt has profound implications for all aspects of dentistry, both academic and the private sector.

Another disadvantage of the academic OMS is the loss of control of the practice. Many OMSs are fiercely independent and choose a career where they have greater control of the practice. The surgeons have devoted a significant portion of their lives and considerable expense to gain the goal of being an oral and maxillofacial surgeon. In return, the surgeon wants to "call the shots."

Private practice surgeons have the option of controlling practice hours, days of the week, participation in insurance plans, hiring and firing of staff, and employee compensation, along with other practice variables. In the academic realm, many of the decisions are made by the institution with little or no input from the surgeon.

Additionally, there appear to be declining resources for academic institutions. State-supported institutions have felt a continuous decrease in financial support to the sponsoring institutions, which trickles down to the dental school or medical school program. Federally funded research is declining and more difficult to obtain. The patient care workload increases along with the pressure to generate more clinical income to offset the losses from decreasing institutional support. The net effect is less time for research and scholarly activities. Many academic OMS faculty are feeling the squeeze and are disappointed and frustrated.

The future still remains very bright for academic oral and maxillofacial surgery. There is a dedicated core of OMS faculty. The faculty meets yearly at the AAOMS annual meeting to discuss problems and continually search for solutions. The OMS Faculty Section has a governing body and bylaws to function adequately in the complex milieu of academic health care. The OMS faculty section is a forum

• BOX 3-1 Advantages and Disadvantages of a Career in Academic Oral and Maxillofacial Surgery

Advantages

Stimulating environment (constant learning and education)
Wide scope of practice (major and minor surgery)
Opportunity to train the next generation of oral and maxillofacial surgeons
Part of a team with dental and medical colleagues
Opportunity for research and scholarly activities

Disadvantages

Generally lower pay than private sector
Giving up control of the clinical practice
Increasing financial pressures to generate clinical income to offset declining institutional support

for all academic educators, both graduate and undergraduate. The OMS Faculty Section communicates well with AAOMS and other stakeholders to help all involved understand OMS faculty challenges. There has been tangible change for the better. Academic OMS faculty salaries have been increasing and the gap with private practice salaries is closing.

Faculty Educators Development Awards (FEDAs) have been established to entice younger faculty to academic careers by decreasing the financial constraints. Financial incentives are paid to promising young OMS faculty who stay in academics. The Faculty Section has pooled resources to create a National Curriculum Database (NCD). Faculty were asked to contribute lectures in an area of their interest or expertise to a national databank. Accredited OMS training programs have access to this lecture bank to facilitate adequate training of their residents in areas where the faculty may not have expertise. Academic OMS faculty are sharing the resources for the betterment of all, rather than acting as lone entities. The specialty of oral and maxillofacial surgery has placed a tremendous responsibility on the academic OMS faculty, the charge of educating the next generation of oral and maxillofacial surgeons. As in the past, the academic OMS faculty have always risen to the challenge and performed. This dedication to the profession will continue into the future (Box 3-1).

Surgeon-Scientist Oral and Maxillofacial Surgery Careers

Janice S. Lee, Martha J. Somerman, Andrea B. Burke

Progress in medicine and dentistry relies completely on research to advance knowledge on health and disease and to improve methods of prevention, diagnosis, and treatment of diseases. Oral and maxillofacial surgery (OMS) is no exception. A research career in OMS can be extremely rewarding; it is a career path in which one can truly delve into questions and problems with widespread impact that can change the course of treatment and improve patient outcomes.

Most surgeon-scientists are in academia and affiliated with a university. However, there are career opportunities for surgeon-scientists in government institutes, such as the National Institutes of Health (NIH), U.S. Food and Drug Administration (FDA), and Centers for Disease Control and Prevention (CDC). The Department of Veterans Affairs (VA), along with the United States Army, Navy, and Air Force, also provide opportunities for research careers for oral and maxillofacial surgeons.[10] National organizations that also have research careers include the ADA Foundation Dr. Anthony Volpe Research Center (located on the campus of the National Institute of Standards and Technology). Other opportunities may be found in industry, where private-sector pharmaceutical, biotechnology, and medical device companies provide approximately 58% of U.S. biomedical research and development (R&D) funding.[11-13]

Research in OMS can include clinical, translational/applied, and basic science. Clinical research typically includes studies on patient outcomes and clinical trials, new methods and technologies, retrospective reviews, phenotype to genotype, and population-based or epidemiologic studies. Evidence-based medicine, particularly randomized clinical trials, remains the most valued method of research.[14] Translational research includes clinical, preclinical, or animal studies that provide an iterative loop from bench (laboratory/basic research) to bedside (clinical application) and back. The intent is to accelerate the transition from basic research to human application. On the other hand, knowledge gained from clinical research may highlight the need to address fundamental unknowns through basic research in order to improve clinical outcomes or address unexpected outcomes. Basic research focuses primarily on understanding the mechanisms at the cellular and molecular level that control cells, tissues, and organs in states of health and disease. Other categories may include educational research, health policy research, and biomedical informatics (big data) research. Each of these forms of research can provide substantial knowledge and progress in OMS.

The foundation for a successful career in research involves strong training in research and good mentoring. Ideally, the earlier the exposure to research and the earlier determination that research is a true interest for an individual, the more time and guidance a person may have to delineate specific areas of research interest. Students in high school and college now have biomedical programs that introduce them to careers in biomedical research and medicine/dentistry. Additional training programs that are offered by OMS departments and dental/medical schools should be explored to solidify an interest in research. The NIH and National Institute of Dental and Craniofacial Research (NIDCR) have several levels of training programs on campus (Bethesda, MD) through the Division of Intramural Research. This includes the Medical Research Scholars Program (a 1-year program for medical or dental students),

the Dental Summer Research Internship, the NIDCR Clinical Research Fellowship (for those who have obtained a DDS/DMD and have demonstrated a research background), and the standard research postdoctoral fellowships (www.nidcr.nih.gov/careersandtraining/Fellowships/). A surgeon-scientist fellowship at the NIDCR (for those who have been accepted into an OMS program or completed an OMS program with evidence of a research background) is being explored.

Previous studies have shown that resident research experience is correlated with a greater likelihood of pursuing an academic medical career.[15] Currently, there are few OMS programs that provide the full span of research; thus it requires a proactive effort, resourcefulness, multiple contacts, and networking to identify an OMS program that may foster future surgeon-scientists. Research is not done in isolation, and going beyond OMS departments may be necessary. Team science and collaborations with multiple researchers have made great strides in bridging the gap from basic science to application. Examples include (1) craniofacial tissue engineering that involves material scientists, cell biologists, bioengineers, and surgeons; (2) head and neck cancer therapies that involve immunologists, hematologist-oncologists, cell biologists, and surgeons; (3) craniofacial anomaly therapies that involve developmental biologists, biochemists, geneticists, bioinformaticians, and surgeons; and (4) TMJ therapies that involve pain specialists, neuroscientists, bioengineers, pharmacologists, cell biologists, immunologists, and surgeons.

A common question is the necessity of an additional degree, such as a master's or PhD. The NIH R01 funding data suggests that PhDs and MD-PhDs receive greater funding than MD or DDS/DMD awardees.[16] However, the type of research and the level of necessary funding should dictate a person's pursuit of additional degrees. Because of the time that these degrees add to an OMS residency, it behooves candidates to discuss these career options with mentors, associate deans for research, and OMS program directors. The length of time required to pursue these degrees, however, is not significantly different from other surgical specialties that train surgeon-scientists.

A distinguishing feature of surgeon-scientists, compared to their clinical colleagues, is the pursuit of research funding. In a climate where biomedical funding has not increased, as in the doubling period of the NIH, obtaining a grant of any kind has become extremely competitive. Grant-writing workshops, grant management teams, and solid research mentoring remain critical to the success of the surgeon-scientist.

The NIH and NIDCR have various grant mechanisms that may assist a surgeon-scientist at different levels of his or her career: pre- or postdoctoral fellow, career-development, new-investigator, and established scientist awards. Predoctoral fellow awards (F) provide support for those interested in a dual degree (DDS/DMD-PhD). Postdoctoral fellow awards (F) provide support for trainees at academic institutions to broaden their scientific background. Mentored or career development awards (K) provide clinician-scientists with the opportunity to continue training while pursuing independent research. Research project grants (R) are for investigator-initiated research studies, available for new investigators and established surgeon-scientists. The NIH also provides a Loan Repayment Program (www.lrp.nih.gov) to clinical investigators engaged in research.

The OMS Foundation provides research support grants and student research training awards (http://omsfoundation.org). And in an effort to support young academic surgeons, the American Association of Oral and Maxillofacial Surgeons (AAOMS) created the Faculty Educator Development Award (FEDA) to promote academic recruitment and retention. We have included a list of additional funding agencies to be considered.

The maintenance of integrity and professional conduct in research is of utmost importance. The surgeon-scientist must be prepared to understand conflict of interest in research, particularly in funding and funding sources. Conflict of interest has been defined as "a set of conditions in which professional judgment concerning a primary interest (such as a patient's welfare or the validity of research) tends to be unduly influenced by a secondary interest (such as financial gain)."[17] Additionally, the surgeon-scientist must have a thorough understanding of their institutional review board (IRB) in order to conduct research on human subjects, whether it is a survey, chart review, or interventional study. The function of the IRB is to protect human subjects throughout the course of a research project. These boards were formed in response to the research abuse of humans such as the Tuskegee Syphilis Study. The aftermath of such egregious violation of human protection includes informed consent, the 1979 Belmont Report, and the Office of Human Research Protections.[15]

Research in OMS can change the way we practice by determining the etiology of diseases, developing novel treatments, enhancing standards of care, and creating new health policies. The opportunities for a research career in oral and maxillofacial surgery are vast and can provide a career filled with variety, flexibility, and satisfaction.

Key points:

1. Research is critical to OMS clinical practice.
2. Start early in exploring your research interest and cast a broad net, even beyond OMS.
3. Mentors are important.
4. Research integrity includes understanding conflict of interest and human subject protections.

Funding Opportunities

- NIH/NIDCR (F-awards, K-awards, R-awards—www.nidcr.nih.gov/grantsandfunding/Types_of_Grants_Awarded_by_NIDCR/FundingMechanisms/Funding%20Mechanisms.htm)

- Patient-advocacy foundations (e.g., March of Dimes, www.marchofdimes.org)

Dental Support Organizations

Martin E. Eichner

Many recent oral and maxillofacial surgery residents graduate from their training programs with a tremendous debt load. Student loan balances from undergraduate, dental school, and in some cases medical school tuitions are commonly in the hundreds of thousands of dollars. This makes it very difficult to open a new practice, buy an existing practice, or buy in as a partner/shareholder to an existing practice. Paying off debt may add stress to the challenge of practicing oral and maxillofacial surgery after residency. Many new OMS practitioners would like to start a family and purchase a house, but are worried about cash flow immediately out of residency or fellowship. Dental Support Organizations (DSOs) give the new OMS an alternative to private practice oral and maxillofacial surgery.[18]

The traditional model of OMS has the doctor responsible not only for the clinical aspect of taking care of patients in the office and hospital, but the business aspect of running the practice. The doctor must set fees, collect fees, hire staff, fire staff, manage payroll, keep an eye on the overhead, be up to date with state and federal laws and regulations, buy supplies, maintain equipment, pay rent, sign insurance contracts, file insurance claims, market the practice, and run study groups.

Many new practitioners are overwhelmed by the business aspect of private practice, and want to concentrate on patient care and becoming proficient in all aspects of OMS.

DSOs exist in many forms. The ADSO, or Association of Dental Support Organizations, is a national organization that enables DSOs to collaborate and improve the model. When an OMS joins a DSO, he or she is able to concentrate on patient care. The DSO conducts the business aspect of the practice. The doctor receives a salary and the DSO employs all members of the office team. The DSO also manages all the aspects of private practice noted earlier. A DSO may claim that the OMS will be more productive because he or she is freed from running the business aspect of the practice. There are claims that more oral and maxillofacial surgery will be performed, which will address issues of access to care. The DSO may negotiate with retailers for discounted rates on supplies because they are able to buy larger quantities and in bulk for multiple locations. The DSO is able to market to member dentists on a larger scale as opposed to what individual doctors may be able to do on their own. DSOs also run continuing education programs for the doctors, and are able to monitor outcomes and care delivered to patients.

The ADSO member DSOs agree that they should not interfere with clinical judgment and treatment planning. All oral and maxillofacial surgery treatment planning is based on the doctor's clinical judgment, and all surgery is performed based on his or her own decision making.

This model of practice of OMS is rapidly changing, evolving, and growing. Where it will be in 10 to 20 years is unknown. The DSO is an alternative to private practice for OMS practitioners who want to free themselves from running the business side of an OMS practice. There may be more time for clinical growth and less time spent on other tasks.

Conclusion

David A. Bitonti

The traditional private practice of oral and maxillofacial surgery is the more often chosen career path following residency training. The goal of this chapter was to provide background information for the OMS completing residency training, as well as OMSs seeking a career change or transition. All of the mentioned career opportunities and paths provide an avenue for a rewarding practice in oral and maxillofacial surgery, regardless of the career stage. In certain career paths, there may be specific age restrictions and physical requirements; however, points of contact and clarifying information are easily readily available to the interested OMS. There are varying ways to give back and to contribute to the specialty that is our calling. Take advantage of researching and becoming informed about all career opportunities before making a final decision on a career path, and know that other, equally rewarding opportunities exist should a career path change be a part of the future.

OMS Practice Transition: Decisions for the New Surgeon and the Established Surgeon

R. LYNN WHITE

Introduction

Probably the two most important decisions in the private practice life of an oral and maxillofacial surgeon (OMS) concerns how, when, and where a new surgeon enters into practice, then conversely, how and when a senior surgeon exits an established practice. These are also two of the decisions with the most important effect on personal finance and lifestyle issues. Both decisions should be the result of proactive preparation and careful planning.

As a backdrop for this discussion, we should look at some of the basic demographics of our specialty. The "baby boomer" generation is an expanding cohort within the OMS ranks. This generation represents the largest portion of established practitioners and the generation that might now be contemplating retirement and/or a significant reduction in practice hours. This subset group will be looking toward bringing a new surgeon into these respective practices. Roughly one half of the members of American Association of Oral and Maxillofacial Surgeons (AAOMS) are in solo practice, with another ~20% in a two-surgeon practice. The balance is spread over increasingly larger groups, although groups with more than six surgeons represent only ~5% of the total.[1]

The scenario of an expanding number of older-generation surgeons compared to the relatively small and static number of graduating OMS residents sets up an increasingly disproportionate supply-and-demand situation. Simply stated, the supply of graduating residents may not be able to meet the demand of established surgeons to bring in a new surgeon and bolster the needs of their existing practices. Ultimately, this will result in increased competition among existing practices to attract new surgeons and induce them to come on board.

The bottom line to consider is how best to plan for a practice transition that is fair, equitable, and transparent in its negotiations, structure, and ultimate agreed-upon settlement. The expectations and perspectives of all parties, regardless of the arrangement (associateship, partnership/buy in, buy out), need to be identified and understood.

What follows are guidelines for both the graduating resident and the established practitioner. They are written in the first and second person, so as to directly and personally address the issues of entrance planning considerations for the new surgeon(s) and exit planning strategies for the senior surgeon(s).

Entrance Planning: Considerations for the New Graduate Surgeon

Now What?

As some of you approach the last 2 years of your OMS residency, you should begin to assess how and where you want to begin your career in what I truly consider to be the best specialty in all of health care. Some of you will contemplate and hopefully pursue an academic faculty appointment. As I did when I was on the AAOMS Board of Trustees, I would heartily encourage you to do so. A small portion of you might consider a career in a branch of the federal services. Most of you, however, will pursue a career as a private practitioner. In doing so, you will have the following basic options:

1. Starting your own (solo) practice
2. Joining an existing solo practitioner
3. Joining an existing two surgeon practice

4. Joining an existing (larger) group practice
5. Signing on with a Dental Maintenance Service Organization (DMSO)
6. No commitment, only associate status with an existing practice

In your consideration of these choices, there are many questions (factors) that should go into your decision, many of which are obvious, and some of which may not be. I feel the most pertinent of these to be:

1. In what part of the country would you prefer to locate?
2. If you are married (or are about to be), where would your spouse want to live?
3. If you have children, where are the areas that are more "kid friendly" and have the best educational support systems?
4. What is your debt load, and what is the best situation to retire that debt?
5. Do you want to have solo responsibility for your practice?
6. Would you prefer to have a mentor and senior surgeon who can help you and support the practice while you transition into a more responsible role?
7. Do you only want to be an associate with no equity in a practice?
8. Do you want to practice the full scope of oral and maxillofacial surgery?

My commentary about the listed questions (and admittedly, there are more that could be posed) is that most are distinctly personal. I do, however, have a definitive comment about the last one. Given the horizon for health care delivery and health care economics, it is incumbent on the young oral and maxillofacial surgeon to establish a practice that embraces all aspects of our contemporary specialty. Granted, there are varied degrees of compensation for different procedures, especially given the expenditure of time and effort by the surgeon. Going forward, however, there will be significant competition for the "teeth and titanium" dollar as well as a drop off in the level of compensation for these procedures by third-party insurers. It is vital, therefore, that you remain a comprehensive and flexible practitioner as you begin your professional career.

Planting the Seeds

To have optimal success in private practice, you should plant positive seeds at the beginning—seeds that will germinate and grow into something of which you can be proud and which will go on to support you and your family well. Let's go back to the basic options that were mentioned earlier and examine each one with appropriate overview. They are as follows:

1. **Starting your own practice:** To borrow from Dickens, this can be "the best of times, and the worst of times." On the positive side, you will be your own boss and will have complete control of your staff. This gives you the opportunity to create a practice that reflects your personal and professional ideals. There can be significant upside if you have low debt, and if you can get your practice facility built out (before you arrive to practice), your staff selected, and your financing arranged to be reasonably loaded to allow for sequential payback. If, however, you enter practice with a significant debt load, you could very well find the stress of servicing past, present, and future debt to be quite burdensome. It is especially problematic to generate practice revenue flow while at the same time marketing your practice through face-to-face visitation with your referring doctors and their staffs. Add to this the responsibility of taking hospital call at various hours, and the need to "juggle all the balls in the air" becomes quite a task.
2. **Joining an existing solo practitioner:** This will probably be the most common scenario for someone entering into the private practice market of 2015–2018. The demographics of all regions of the country suggest that most of the baby boomer generation OMSs are in solo practice. Logic dictates that this demographic group will be the one that will present the greatest opportunity for flexibility and simplicity when you evaluate and negotiate becoming part of an existing practice. To me, the benefits of associating with an established practitioner far outweigh any downside possibilities, provided you are diligent in your selection process. The senior surgeon has already developed a referral base, has established a relationship and track record with a financing institution, and has a staff in place. This established practice will allow you the time to focus on developing your own referral base (which will probably include some of the existing referring doctors) and developing a relationship with your staff members (at least some of whom you might share with the senior surgeon). With the practice having an established banking relationship, you will get more favorable rates for your existing debt repayment, and for your anticipated buy-in to or buy-out of the practice. I will go into options and associated details for buying into, or buying out, a practice in a subsequent section.
3. **Joining an existing two-surgeon practice:** The characteristics of this choice will be similar to joining a solo practice, with the difference that you will be dealing with two individuals, with potentially different perspectives and personalities. Most probably, especially if the practice has been together for several years, there will be coherence and a shared practice philosophy between the partners. Typically, but not always, there is an age differential, with the senior surgeon considering retirement. Again, I will go into buy-in and buy-out options in a following section.
4. **Joining an existing (larger) group practice:** The dynamics and logistics of this scenario are more complex; however, many of these large groups have an established protocol for bringing a new surgeon into the group. Typically, these groups are in larger cities and have more than one practice location, often multiple locations.

5. **Joining a DMSO:** This primarily benefits you if you are unsure of where and how you want to practice and if you are willing to follow the dictates and practice philosophy of a large corporation.
6. **Practicing as an associate only:** Somewhat similar to the DMSO situation, this allows for some freedom and flexibility if you are not sure of where and how you want to practice. The upside is, if you feel this practice is probably in the geographic area where you want to locate, you can have the experience of living there without any financial commitments. There could also be an evolution of status, whereby you might be given an opportunity to buy into the practice at a later time. The downside is that the owner(s) of the practice may not want to offer you equity participation and would have no obligation to do so.

Closely Examining the Options

The previous sections gave you an overview of the various options you would have in the private practice arena. Most of you will not start up your own practice, but will instead be looking to become part of an existing practice, or buying one out. As mentioned before, there are quite a few benefits of joining an established practitioner or practitioners. I feel that it is important during this process to enlist the services of a practice transition specialist, especially one who is versed in the Objectives Based Practice Transition process. At some point, you probably want to get input from an attorney and accountant for review of documents. So, let's look more closely at the practice options and their ramifications.

1. **Associateship only (no equity):** There are a variety of compensation models:
   - straight salary
   - hybrid model with a (lower) base salary and a percentage of collections
   - only a percentage of collections or production

   Caveat: You should not enter into an associateship without a written employment agreement, which should at least stipulate the method of compensation along with the length of employment.
2. **Associateship leading to partnership via buy-in:** Even though this might be the most common approach to entering and eventually taking part in a practice, there are a variety of models through which this can be accomplished. To begin with, there is the "sweat equity" approach with a minimal salary for the associate, and a deferred partial buy-in (the percentage of which may be defined by how long the senior surgeon plans to continue practicing). It is important for both parties to discuss the method of compensation for the new associate—or, stated another way, the division of practice income for both the associating surgeon and the established surgeon(s). There are two remaining options, both of which have to do with the buy-out sale of the practice of a senior surgeon who has determined a timeline for exiting the practice, through either partial or complete retirement. These two options are discussed next.
3. **Pre-sale buy-out (with the senior surgeon staying in the practice):** This is an option where the established surgeon, moving toward retirement, sells the practice at the time the buyer/young surgeon begins his career. The financing of the practice buy-out is usually arranged through a banking institution, although the seller/established surgeon may elect, or be asked, to provide some degree of the financing. The ideal time to have the retiring surgeon stay in the practice is 1 to 4 years, most often on a part-time basis. This arrangement allows for an established cash flow from day 1, established staff support, and an established referral base. This also establishes a structured transition for eventual control of the practice by the younger surgeon. The essential components of a practice sale of this type are:
   - a completely transparent purchase agreement
   - independent advice from an attorney and accountant
   - guidance by a practice transition specialist
   - a detailed practice valuation/appraisal
   - a definitive non-compete/restrictive covenant agreement
   - a policy for division of income
4. **Deferred or incremental sale (established surgeon in practice with defined timeline):** This model for buying out the practice from the established surgeon structures the sale in deferred, or incremental, fashion over a defined period of time. There are several options for doing this. However, because the majority of established practices are incorporated, let's use the following example:
   - Dr. Buyer (young surgeon) creates a corporate entity (PC or Subchapter S), as does Dr. Seller (established surgeon) if he/she does not have one
   - In turn, an LLC is created; each corporation is a "member" of the LLC
   - All income goes into the LLC and all expenses are paid by the LLC
   - Compensation goes to each corporation based on the policy established by the purchase agreement (production/collections, equal distribution, etc.)
   - Dr. Buyer purchases 33.33% of the practice assets (tangible and intangible) at the sales closing (beginning of contract)
   - Dr. Buyer purchases another 33.33% after 2 years
   - Dr. Buyer then purchases the remaining 33.34% after 4 years of his practice life, which completes his contractual obligation. Dr. Seller can at this time completely retire from practice, or stay on if agreed to by Dr. Buyer, who at that time is the sole "Dr. Owner."

   The foregoing is only one example of several ways in which both the practice, and control of the practice, can transition from the established surgeon to the young surgeon/buyer. Although I think it is important that you consider having a practice transition specialist advise you with any practice arrangement you are considering, it is especially essential to do so with a

deferred or incremental sale. Again, as in the previous model, it is extremely important that you have:
- a completely transparent purchase agreement
- a definitive non-compete/restrictive covenant
- independent legal and accounting advice
- a detailed practice appraisal
- a clearly defined policy for division of income

5. **Walk-away sale (established surgeon retires upon sale of practice):** This is a total buy-out with the seller giving you total control of the practice from day 1. Having said this, I feel it is important to have him or her stay around long enough to acquaint you with whichever staff members elect to stay on, and whomever you wish to keep. It is also important for the seller to introduce you to his/her referring doctors, either individually or with a welcoming reception for those doctors, wives, and perhaps staffs. In the case of a walk-away sale, it is imperative to have a totally transparent purchase agreement. It is similarly imperative to engage an attorney and accountant, and advisable to have a practice transition specialist. Two other things are essential:
   - a detailed and comprehensive practice appraisal
   - a restrictive/non-compete agreement

With any of the listed buy-out or sales models, you should have a pro forma whereby you can see how, over a prescribed period of time (usually 6-8 years), you can retire the debt of the practice purchase while also producing a profit for income during this period. While the purchase of a practice may seem daunting, it is my belief that it is ultimately a very good economic decision for you to make.

Considering the Details of a Good Outcome

Regardless of the model chosen—associateship, partial buy-in of a partnership, or a buy-out of a practice—it is important to know the details and have a good understanding of the practice valuation and the employment, buy-in, or purchase, agreements to achieve a good outcome that is fair and equitable to all parties. I feel that these arrangements are all well facilitated by a practice transition specialist who is versed in Objectives Based Practice Transitions (OBT). So, what is that? OBT is a process that aligns the objectives and goals of both the young and established surgeons to achieve the best possible professional, personal, and financial outcomes. Success is accomplished when *both* surgeons win to a degree that could not have been accomplished without this practice transition process. Furthermore, I feel that although there is a clear fiduciary responsibility toward the established surgeon who is paying for the practice transition, it is also very important to be cognizant of, and responsive to, the needs of the young surgeon.

First, and this applies most to a practice buy-out and also to a buy-in, close attention must be given to the practice valuation and the methods by which it is achieved. There are standard procedures for appraisal of a practice, although there can be some variance of emphasis on certain aspects of any given practice and thus slight differences in the bottom-line valuation. The standard appraisal methods are as follows:

1. **The asset approach:** This needs to be detailed, consider depreciation, and be performed by an objective, experienced appraiser. Both tangible assets (real estate, building, equipment, supplies, furniture) and intangible assets (goodwill, restrictive covenant, practice culture) need to be considered.
2. **The income approach:** This should be a clear, reproducible, and reasonably precise valuation. It is derived by reviewing the practice accountant's provision of profit and loss statements along with tax returns of the present year and preceding 2 or 3 years. The present value of practice earnings can be computed by using currently available loan terms and interest rates.
3. **The market approach:** This will consider several factors such as demographics, traffic volume, and population trends. The practice history and patient volume should also be considered, as well as what management systems are in place, and finally, staff qualifications and their tenure in the practice.

After an objective review of the practice valuation, there needs to be subjective evaluation of the relationship issues between you and the individual(s) with whom you are associating or buying into, or buying out, their practice. There should be a philosophy of abundance over that of a zero-sum game; it is in everyone's best interest that each surgeon be successful. There should be excellent communication between both parties to prevent a lack of clarity, lack of unified focus, and any misinterpretation of intentions. There should also be clearly defined expectations so as to avoid any frustrations or any seeds of distrust during the negotiations of the practice transition. I feel these relationship issues are best facilitated by comprehensive needs analyses for both surgeons, performed and evaluated by the practice transition consultant. Further subjective evaluation should involve the practice culture. Was it created by, and is it characterized by, design or default? What is the practice culture's core ideology, its values, and its purpose? Are these consistent with your values, and will you have the ability to modify or change the culture, should you choose to do so?

In summary, let me present some brief comments to facilitate your focus as you contemplate your career choices:

1. Begin the process with the end goals in mind.
2. Use whatever legitimate resources are available to you.
3. Be respectful and understanding regarding the established surgeon's perspective.
4. Be reasonable and realistic with your own expectations.
5. Establish a core ideology early to support your decisions.
6. Identify and make use of your individual strengths as you integrate into your evolving practice.

I wish you well as you transition your life from residency to the practice of oral and maxillofacial surgery and join the ranks of the fine membership of the AAOMS.

Exit Planning: Strategic Considerations for the Established Senior Surgeon

Now What (and When)?

In speaking with a number of my peers who have been in the private practice of oral and maxillofacial surgery for many years, I hear common themes. Anecdotally expressed, they are:

- "I am getting more fatigued, physically and psychologically, with my practice."
- "I am working as hard as I feel I want to work."
- "I used to practice the full scope of oral and maxillofacial surgery procedures, but now have mainly an office procedure based practice."
- "I have made good money from my practice and I feel I am comfortable financially."
- "I would probably like to practice part time for another 1 to 3 years, but if someone buys my practice and wants complete autonomy, I would sure consider walking away."

I have received other input, but the above anecdotes represent more than 80% of the mindset of our baby boomer colleagues, and all of them are understandable. For those of you who have been in practice multiple years: what you do (and I have done) is hard work! Standing around an operating table or a dental chair for 6 to 10 hours/day is taxing, as is the demand that you do your best to attain an excellent surgical outcome. Add to that the stress of administering parenteral sedation and/or general anesthesia in the office, and you have the elements of a practice that can take its toll over a number of years, potentially leading to professional burnout.

The aforementioned scenarios can be mitigated by a proactive mindset to consider the possibilities for exiting clinical practice and doing so before burnout even becomes an issue. A well-developed exit strategy, with adequate time for implementation, is the best measure to ensure that you have the appropriate perspective for dealing with all the potentialities of practice transition. It will also help to ensure that you receive the optimal valuation for the practice that you have worked so hard to establish. It is essential to begin the exit planning process early enough that a strategic plan can be implemented with adequate time to be effective. I recommend a 2- or 3-year window as the optimum time frame for this process.

Planting the Seeds

Taking a proactive approach, the established surgeon(s) will have choices and options to consider. Moving forward toward practice transition, these considerations have to do with the logistics of the practice:

- solo practitioner versus small group versus large group
- single office site versus multiple office sites
- demographics of the patient population
- physical condition of the office
- quality and stability of the staff
- status of the equipment; is it state of the art (surgical, anesthetic/monitoring, radiographic, IT hardware/software)
- production, revenue stream, third-party penetration (including Medicaid), practice expense overhead, and miscellaneous other financial issues

As I stated in one of the introductory paragraphs, most OMSs are in a solo or a two-surgeon practice. Although there is a different dynamic involving these subsets, the inherent decisions for taking in a new surgeon are similar. These decisions are considerably different for a larger group, which most likely will have already established a protocol for bringing in a new surgeon.

Through this proactive approach you, as the established surgeon, have the discretion to best choose the timeline for reducing your hours of clinical practice and, more or less, when the actual retirement will take place. Obviously, your health can factor into this significantly and affect even the best-laid plans.

Once you have decided to transition the practice, there are several things to consider in preparation for this major event in your professional life. Foremost is to enlist a practice transition advisor to perform an objective and comprehensive appraisal of your practice. Regardless of the route chosen to transition the practice, you as an established OMS should be aware of the value of the practice as you seek to have someone share and participate in it with you. The best way for you to have confidence in that value is through a multiple-approach practice valuation by a certified appraiser. In the previous topic, I recommended a 2- to 3-year time frame for an exit strategy, because the practice appraisal is significantly factored on a 3-year performance as indicated in the financial statements of the practice.

Although I have gone into a more detailed description of the standard appraisal methods in the Entrance Planning section of this chapter, let me outline them again:

1. **The asset approach:** tangible (e.g., equipment) and intangible (e.g., goodwill) assets
2. **The income approach:** practice revenue and practice expenses
3. **The market approach:** demographics, practice history, patient volume, staff considerations

The practice valuation is generally based on a combination of these three methods, and perhaps another one or two considerations. It is very important for you and your accountant to provide the practice appraiser with accurate and complete financial information so that your practice can be appropriately judged and you can obtain the maximal fair market value. In my experience, the biggest delay in getting a practice placed on the market is due to some degree of inertia and communication issues between the doctor's office and the accountant doing the necessary balance sheets, profit and loss (P&L) statements, and practice tax returns.

Closely Examining the Options

In considering the options of taking in an associate, offering a partnership position, and entertaining a buy-in or buy-out, the central issue is determining the realistic timeline

for you to exit your practice. The longer I am in the business of practice transition, the more I have come to realize that most senior established surgeons have revised that timeline horizon downward, that is, toward exiting the practice sooner than they first anticipated.

As with the different methods of practice appraisal, I have gone into a little more detail on options for entering into an OMS practice in the section for the new surgeon. I will list these options again here, in somewhat less detail; however, I will address the considerations from an established practitioner's perspective. So let's look at your options:

1. **Offering an associate position only:** This is a way for you to take in someone who you are not certain will be the "right one" for a partnership offer. This may or may not be attractive for the new surgeon. If you are looking to retire from your practice in a year or two, having an associateship (only) without a prescribed partnership/buy-in or buy-out would probably not be advisable. It is imperative to have an employment contract that can be reviewed before the associate begins practice with you, and to have the terms of compensation and duration of employment spelled out.
2. **Offering a partnership and buy-in:** This is the advisable option if you feel good about the new surgeon and if you (and/or your existing partners) are planning to stay in the practice a few years (or more) going forward. Most graduating residents are looking for some assurance and continuity as they enter and plan for their practice life. It is essential to have the specifics of the partnership agreement laid out before the buy-in term begins. It is likewise essential to have your attorney, accountant, and practice transition specialist involved for the appropriate support and guidance throughout the process.
3. **Pre-sale buy-out:** This would probably be the simplest method by which you could sell your practice. It requires that the young surgeon/buyer be able to get familiar and comfortable with you, the office, and (most probably) your staff. The lending institution involved will require documentation regarding practice revenue, including balance sheets, P&L statements, and practice/corporate tax returns; probably all of these should go back 3 years. Although going with a bank/lending institution is the cleanest way of financing the purchase, you might elect to finance a portion of the sale yourself. I would advise you to be flexible as to how long you would stay in the practice part time (as an employee) and determine in your mind what would be required to truly facilitate and support the transition to the new doctor. Once again, your team of practice transition specialist, attorney, and accountant can guide both you and the surgeon buying the practice to achieve a fair and transparently negotiated asset purchase agreement (APA).
4. **Deferred or incremental sale:** Although this is somewhat more complex, if the valuation of your practice is in a higher range (>$1 million/established surgeon), the incremental sale approach may be the only feasible way for a new surgeon to purchase the practice. The agreed-upon purchase price is specified in the APA contract, as is the timeline for scheduled payments, beginning with the down payment (usually 25% to 33%), done at the closing of the sale and the beginning of the new surgeon's practice. The scheduled payout is typically done over a period of 2, 3, or 4 years, rendered in equal payments. An example of this type of sale is given in the Entrance Planning portion of this chapter, which in that case involved corporate entities. There are several ways in which this type of purchase can be structured. It is again advisable for you to be flexible regarding the length of time for you to continue in the practice on a part-time basis. It might be better for you to stay on for the same length of time as the payout, but that is not entirely necessary. Also, again, it is imperative that you engage your transition specialist, accountant, and attorney as you structure and negotiate all agreements inherent in this type of sale.
5. **Walk-away sale:** In this option, you would sell out completely to the new surgeon, who would then have total control of the practice upon the closing of the sale. Again it is important for you to be flexible and willing to be an employee of the practice for a few months to facilitate the transition with the office staff and to help the new surgeon become acquainted with, and accepted by, the referring doctors and their staffs. It is very important for you once again to have the guidance and support of your practice transition team as they work to make this transfer of assets and practice control most effective and efficient.

To finish this section, I should mention that with any buy-in or practice sale, you have to be willing to sign a Restrictive Covenant (Non-Compete Agreement) which will define a geographic radius and length of time within which you must not establish another practice. This is an integral part of the practice valuation and APA and is an important basis for a fair and transparent agreement in securing the transition of your practice.

Considering the Details of a Good Outcome

In this section, although I want to avoid repeating what was stated in the Entrance Planning portion of this chapter, I do want to re-emphasize the characteristics of a successful outcome in practice transition. Regardless of the model chosen (associateship, partnership/buy-in, buy-out/practice sale), it is very important to have a good understanding of your own perspective and that of the new surgeon. It is furthermore very important for you to have a good understanding of the details of the issues presented so that negotiations can begin and proceed effectively and eventuate in a fair, equitable, and transparent agreement.

This negotiated agreement should establish a structure that will provide for the success and satisfaction of both (or all) parties. As said before, when structuring a new venture in practice transition, there should be a philosophy of abundance over that of a zero-sum game in achieving this

successful agreement. Going further, a satisfactory and successful outcome is best obtained by open and honest communication between both/all parties involved. Also, your sincere consideration for, and appreciation of, the needs and expectations of the new surgeon is truly important as you prepare to either share, or turn over, the control of your practice.

Always remember that you have done more than just develop a practice that has become professionally and economically successful. You have truly established a legacy, and that legacy's survival is best accomplished by transitioning your practice to someone who will continue to make it viable and relevant. You owe this to your patients, your staff, your dental and medical community, and most of all, you owe it to yourself.

Let me conclude this Exit Planning portion of the chapter by saying that we have all, like you, been fortunate to have chosen oral and maxillofacial surgery as our professional life's field of endeavor. I hope this chapter has given you some degree of insight as to the best path to choose as you seek to move on with your life after practicing the best specialty in all of health care.

Performing Oral Surgery from the Sitting Position

TRAVIS A. WITHERINGTON

Introduction

Engaging in oral surgery from the sitting position makes professional life easier and more enjoyable for both the surgeon and the staff. The successful adaptation of this style is not a simple matter of buying a couple of operator stools. The surgeon must study the technique, comprehend the ergonomics, educate his staff on their roles and duties, and use dedicated equipment.

Background

Early surgical residency experiences encountered in the hospital operating room produce bias toward working in the standing position. There is little equipment available in the operating room for sitting, and what is supplied forces the surgeon to assume a humped-over, arm-high posture. Consequently, for the remainder of our careers, we discard the notion of sitting for our profession (Figure 5-1).

Because of the Law of Primacy,[1] we extrapolate the habit of standing for surgery into the office environment even when a comfortable sitting arrangement is readily available. Once acclimated to standing, surgeons become reluctant to change. They may sporadically try sitting, but if the proper equipment or education is missing, they usually find the experience to be unacceptable. By contrast, surgeons who embrace, study, and learn sitting surgery will never abandon it.

Rationale

The occupation of surgery is stressful on the mind and the body, and if we can find ways to reduce the harmful effects of that stress, we can make the job much more pleasurable and productive. Our goal in private practice should be to finish our day of well-executed surgeries with minimal fatigue and to finish our career with no occupationally related injury.

To be able to sit down in a comfortable posture during completion of a procedure reduces strain on the body that is induced by having to hold oneself in an unusual position. Sitting during a busy day filled with multiple surgeries allows banking of energy to be allocated for completing the task rather than for enduring strain and discomfort (Figure 5-2).

Numerous studies have been undertaken to examine the incidence of work-related injury in dentists, physicians, veterinarians, and other health professionals. Of these groups, the dental group had the highest incidence of work injuries and disabilities.[2-7] Modern dentistry understands the benefits of the sitting posture, and the technique is well researched and developed.[8-13]

Administering General Anesthesia

The adaptation of sitting to the dental specialty of oral and maxillofacial surgery presents difficulties because of these issues:

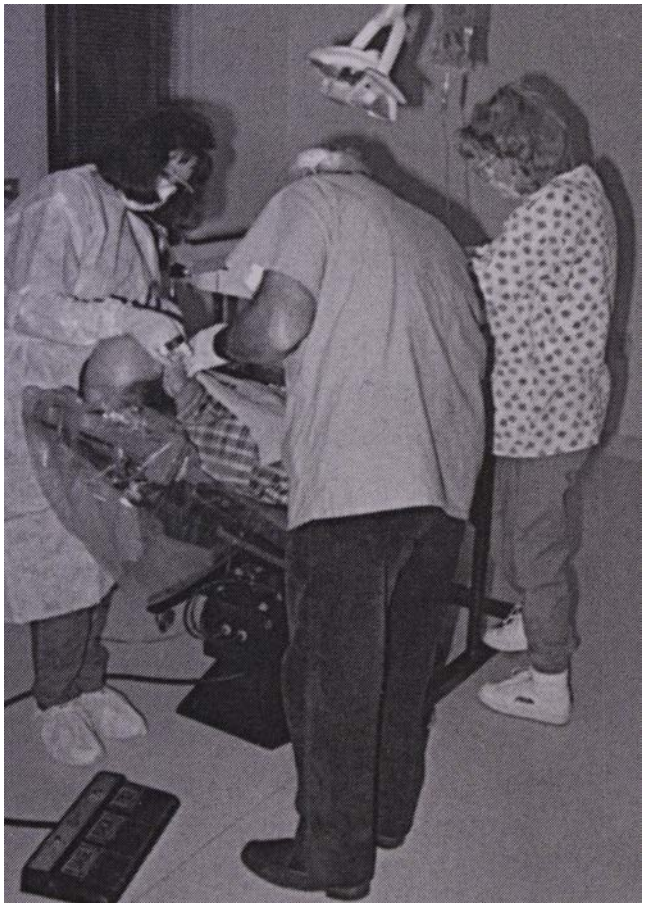
- Delivery of general anesthetic agents requires IV lines, electrical leads, gas tubing, and patient restraints.
- Bulky anesthetic equipment, monitors, and other devices are required.
- The surgical team enlarges to three members with the addition of the anesthesia nurse.

Space must be allocated and positions determined for the equipment and the three team members. The interaction between the members must be designed and rehearsed to treat the anesthetized patient in an array of positions and circumstances.

Equipment Selection and Location

Surgical Chair

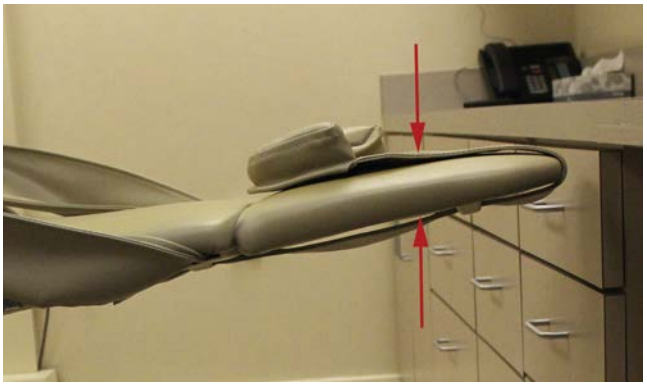
The operating chair should be a dental-type chair rather than a surgical table. A dental chair has a narrow and thin headrest that allows the operator to assume a position close to and under



• **Figure 5-1** Oral surgery performed by a standing surgeon and team.

• **Figure 5-2** Oral surgery performed by a seated surgeon and team.

• **Figure 5-3** Narrow headrest on a dental chair.



• **Figure 5-4** Thin headrest on a dental chair.

the patient's reclined head (Figures 5-3 and 5-4). This narrow headrest allows the patient to be brought within the view of the correctly positioned surgeon rather than forcing the surgeon to assume an awkward position to observe the reclined head.

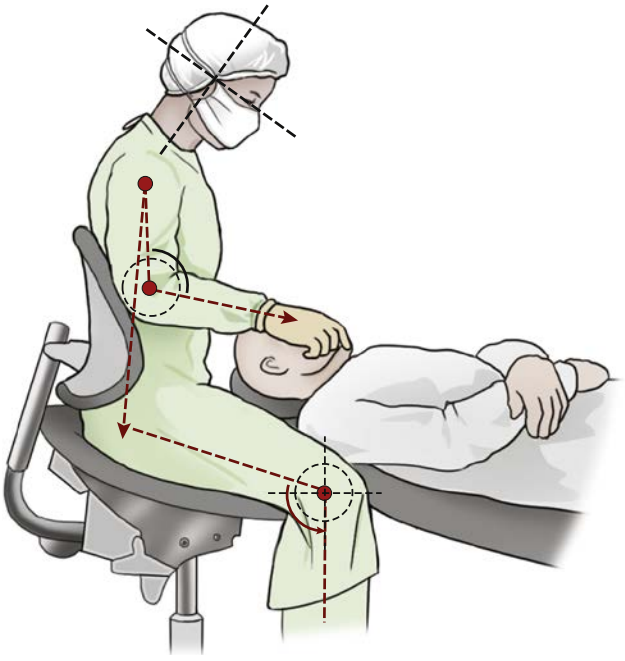
The arms of the patient are supported and restrained by slings that adjust to the reclining chair. The chair should be remotely adjustable by foot controls, because operating different areas of the mouth will require a frequent change of the patient's position. The physical size of the foot controls deserves mention. Some controls are large and bulky and can take up valuable foot space below the operator and the assistant (Figure 5-5).

Durability to corrosion is an important feature, because metal parts of the surgical chair will be subject to IV saline and corrosive surface cleaning agents.

Doctor's Stool

The doctor's stool allows the operator to assume a forward tilt proclination in modern dentistry.[14-16] A dental operator does not assume a position that is equivalent to the typical clerical office worker. Dentists are universally subjected to a

• **Figure 5-5** Foot controls for the dental chair and equipment.



• **Figure 5-6** The operator assumes a forward tilt proclination.

forward tilt from the hip, and the seat support must reflect this special circumstance to allow the operator's lower back to maintain its natural curve. Most dental stools are variants of the basic office seating and do not allow this positive forward support (Figure 5-6).

Assistant's Stool

The surgical assistant uses an elevated dental assistant's stool with a foot ring and arm brace that allows leaning over the surgical field (Figure 5-7).

Overhead Light

Some surgeons prefer a headlight for their operations, but if an overhead track light is selected, there are some

• **Figure 5-7** The surgical assistant uses an elevated stool with a foot ring and arm brace.

features that are important for good function in sitting surgery. The lingual aspect of the anterior mandible is the most difficult area to illuminate in the fully reclined patient. If the horizontal position of the track mounting on the ceiling is incorrect, the light source will not be able to extend to a position to light this area. Consultation with an equipment representative is needed before mounting the track to the ceiling and locating the surgical chair (Figure 5-8).

The length of the vertical support column running from the track car to the light source is determined by the height of the ceiling and the surgical chair height in the operating position. A column length appropriate for sitting surgery will not work well for standing. During standing surgery the light source will then bump the surgeon's head. Consider using a headlight in this circumstance.

• **Figure 5-8** Overhead lighting should be carefully located and mounted.

• **Figure 5-9** Access to computers and digital radiography in the surgery suite.

• **Figure 5-10** Anesthesia, suction, irrigation, and handpiece equipment.

Computer

Because it displays digital radiographic images and electronic medical records, the computer monitor must be viewable by the team. The data entry keyboard is to be positioned so that the both the surgeon and anesthesia nurse can manipulate it. The best location for the monitor is adjacent to the keyboard, but the surgeon must turn to view the screen. A second monitor could be mounted on the wall at the patient's head so that the surgeon and surgical assistant have an easy view (Figure 5-9).

Anesthesia Monitor, Suction, Irrigation, and Handpiece Delivery

With the reclined patient's head at the 12 o'clock location, the anesthesia monitoring equipment is located at the 4 o'clock position so that both the surgeon (right handed) and the anesthesia nurse will have an unobstructed view. The monitor could be placed on a mobile platform so that its position can be adjusted as needed. Distant locations have the disadvantage of making it difficult to read the waveform.

Most dental manufacturers offer a chair-mounted delivery arm or mobile cart for high-speed handpieces, suction tubing, and three-way syringe. The routine dental equipment works well here. The sterile water supply is mounted on an adjacent wall (Figure 5-10).

The surgical drill should be within reach of the surgical assistant or anesthesia nurse so that it can be passed to the surgeon. A good position is at 4 o'clock and atop a mobile stand within the nurse's reach (Figure 5-11).

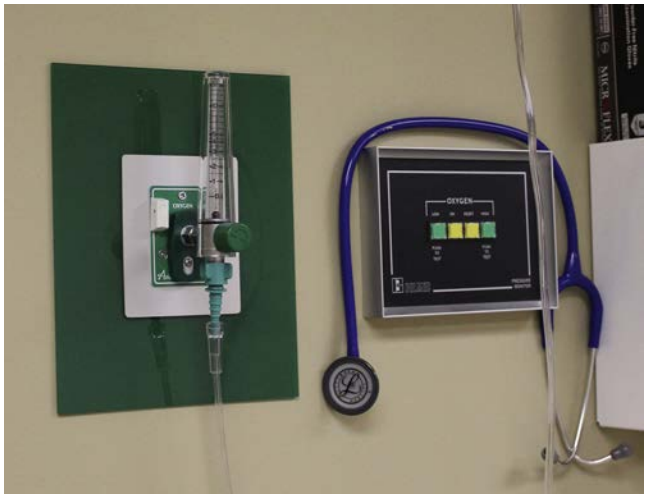
Anesthetic Gas Source

Wall delivery of anesthetic gases is common at either 12 o'clock or 9 o'clock. No matter which wall is used as the source, tubing snaked across the floor will present a tripping danger for personnel. Suspending the tubing with an extension overhead eliminates this issue (Figure 5-12).

Mayo Stand

This stand should be on rollers so that it can be readily moved to accommodate changing positions of the surgical assistant (Figure 5-13).

• **Figure 5-11** A good position for the surgical drill is 4 o'clock, on the mobile platform.



• **Figure 5-12** Anesthetic gases are wall delivered with suspended overhead tubing.

IV Delivery

Rather than a freestanding IV pole, a chain is hung from the ceiling to hold the bag near the nurse (Figure 5-14).

Counters and Cabinets

Cabinetry, countertops, and shelves are available on walls at 3 o'clock and 9 o'clock. The walls at 12 o'clock and 6 o'clock are best left blank to facilitate team movement. The countertop on the assistant's side is at standing height (36 inches) and has a sink. The countertop on the surgeon's side is at sitting height (30 inches) and runs the length of the room. There is no such thing as too much counter space (Figures 5-15 and 5-16).

Team Member Locations

The location of the team members starts with the surgeon, who is assumed to be right-handed. The surgeon assumes a comfortable sitting position that allows an unobstructed view of the surgical field. The other team members and equipment are then arranged into an efficient *pas de trois* with the reclined patient's face at 12 o'clock (Figure 5-17).

• **Figure 5-13** The Mayo stand is on rollers to accommodate shifts in position by the surgical assistant.

Surgeon

The surgeon moves to different positions that afford the best view of the operative field. This varies from 12 o'clock for the anterior mandible to 8 o'clock to work in the depth of the palate (Figures 5-18 through 5-20).

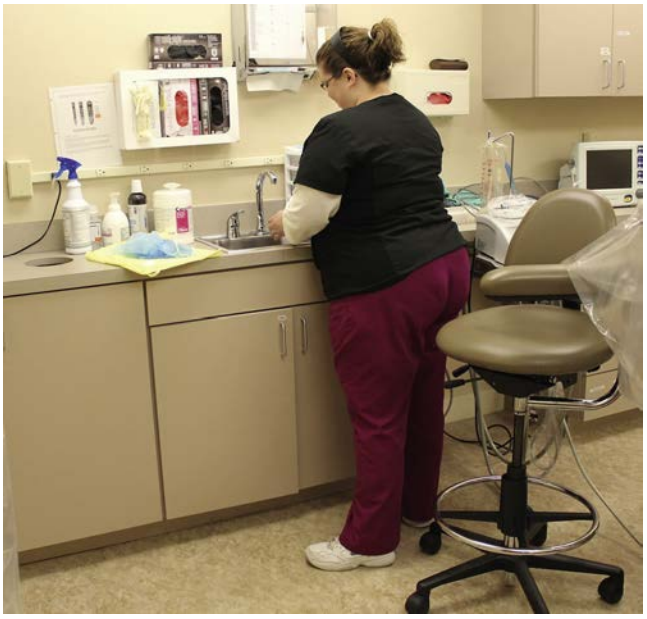
Surgical Assistant

The assistant positions herself opposite the surgeon and modifies her location to accommodate his changes. She is vertically positioned about 3 inches higher than the surgeon to prevent occluding his view or obstructing the light source (Figure 5-21).

Anesthesia Nurse

The anesthesia nurse will stand often and change positions frequently. Her location at 7 o'clock gives freedom of movement and access to the IV, anesthetic monitor and gases, computer, camera, cabinets, and countertops (Figure 5-22).

• **Figure 5-14** IV fluids are delivered from a bag hanging from a chain from the ceiling to eliminate clutter and make movement easier.



• **Figure 5-15** The countertop on the surgical assistant's side should be standing height and should have a sink.

• **Figure 5-16** The countertop on the surgeon's side should be sitting height.

Team Member Roles and Duties

The Surgeon

It is understood that the surgeon is the captain of the ship and assumes the responsibility of safely and accurately completing the surgery. The surgeon plans and directs the operation, so his distractions are minimized to allow him to visualize "the next two steps" of the surgical progression.

He calls for team members to hand instruments, obtain supplies, and initiate procedures as he observes the surgical site and immediate surroundings. Within his visual field, he can perceive oxygenation, bleeding, airway protection, and anesthesia effectiveness.

• **Figure 5-17** Overhead view of the surgical team and patient.

• **Figure 5-18** The surgeon's default position.

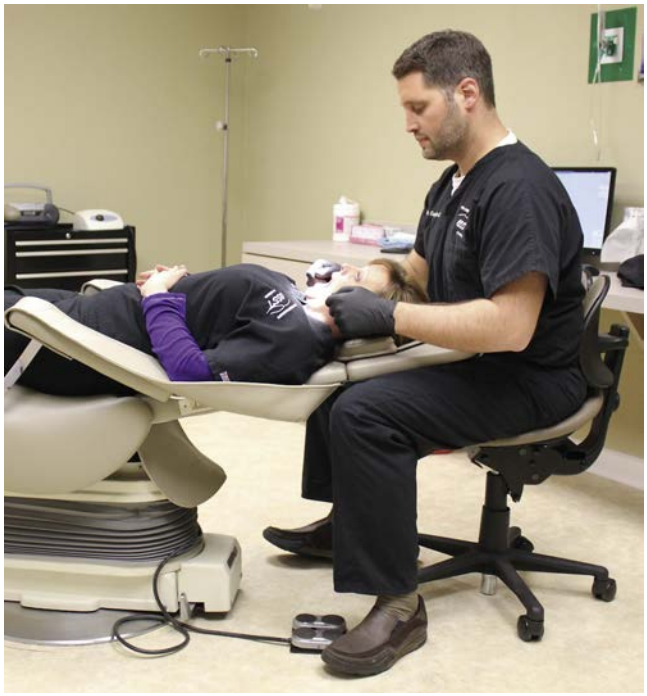
• **Figure 5-19** The surgeon moves his stool to gain a better view of the palate.

The surgeon responds to issues noted by the team members and decides on a course of action. With experience, the well-rehearsed team will develop silent signals to convey information during the surgery. That development will help build a strong sense of satisfaction within the team.

The Surgical Assistant

Although the surgical assistant's duties obviously include suctioning and retracting, she also functions as the guardian of the airway. She observes that the pharyngeal drape is appropriately positioned and is dry enough to absorb the fluids of surgery. The patient's head is tilted up by pressure on the underside of the mandible or to the anterior hard palate and premaxilla (Figure 5-23).

Manipulations by the surgeon deflect the head of the anesthetized patient, so the assistant counteracts these pressures by keeping the head stabilized within the surgeon's view. The head must be rigidly held during the use of sharps (Figure 5-24).



• **Figure 5-20** The surgeon moves to view the anterior mandible.

• **Figure 5-21** The surgical assistant should be seated about 3 inches higher than the surgeon to avoid interfering with the surgeon's view of the patient's mouth.

To avoid distracting the surgeon's attention from the field, the assistant is responsible for handing instruments to the surgeon as he calls for them (Figure 5-25).

During appropriate moments, the assistant rearranges the Mayo so that instruments are returned to their normal positions and easily found. This prevents searching for an instrument on a crowded, messy tray (Figure 5-26).

• **Figure 5-22** The anesthesia nurse's location at 7:00 o'clock gives her freedom of movement and access to the patient's IV, the anesthetic monitor, gases, the computer, camera, cabinets, and countertops.

• **Figure 5-23** The surgical assistant uses finger pressure under the chin for head tilt and airway control.

The surgical assistant intertwines the suction tip into the fingers of her left hand that is holding the patient's chin and tissues. This will free her right hand for picking and handing instruments from the Mayo (Figure 5-27).

The Anesthesia Nurse

The nurse's primary duty is ensuring patient safety by monitoring signs and patient movements. She administers medications at the direction of the surgeon and restrains the patient's limbs during the use of sharps by the surgeon (Figure 5-28).

Because the anesthesia nurse is not scrubbed, she functions as a circulator who deploys supplies, communicates

• **Figure 5-24** The patient's head must be rigidly held during the use of sharps.

• **Figure 5-25** The surgical assistant is responsible for handing instruments from the Mayo to the surgeon as he calls.

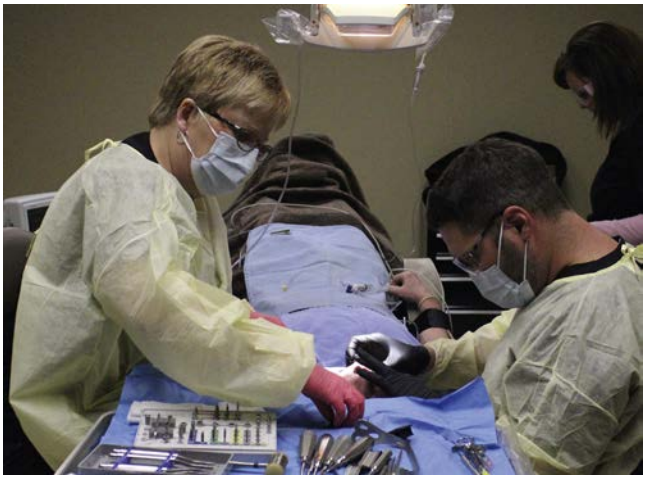
with outside personnel, and positions equipment for use (Figure 5-29).

The anesthesia nurse takes photographs while the surgeon and assistant retract (Figure 5-30).

Additional Suggestions

Patient Positioning

The anesthetized patient has a tendency to slide down to the foot of the chair as it is reclined. After sedation is administered and the patient is reclined, reposition the patient so that the head is in the top and center of the headrest (Figure 5-31).



• **Figure 5-26** During appropriate moments, the surgical assistant reorganizes the Mayo stand.

• **Figure 5-27** The surgical assistant holds the suction tip in the fingers of her left hand while picking instruments from the Mayo with her right.

Lumbar Support

Lengthy procedures may produce back discomfort in the patient. Anesthetized patients may show this by attempting to roll onto their sides and flex their knees. Place a memory foam pad in the lumbar area as well as one under the knees before the start of a long procedure (Figure 5-32).

Pharyngeal Drape and Nasal Trumpet

A 4 × 4 sponge is opened and folded into a 2 × 8 shape to protect the pharynx. With dry fingers, the surgeon pulls the tongue forward, then gently tucks the sponge behind the tongue. This holds the tongue forward and helps maintain the airway. The tail of the sponge is brought outside the lips (Figure 5-33).

• **Figure 5-28** The anesthesia nurse restrains the patient's limbs during the use of sharps.

In more recalcitrant airway obstruction from a large tongue, a nasal trumpet can be lubricated and inserted (Figure 5-34).

Agitated Patient

The anesthesia nurse is in a good position to restrain the arms and legs while protecting the IV site. Restraining the head, controlling bleeding, and maintaining the airway falls to the surgeon and the surgical assistant.

Each of the team members is in a unique position to observe agitation in the anesthetized patient and should be polled as to their opinion of the cause. The causes include:

1. Inadequate local anesthesia
2. Hypoxia
3. Anxiety
4. Full bladder
5. Back pain

When the patient moves with an avoidance gesture, apprehension is always suspected, but inadequate local anesthesia is the most common cause if movement is observed during the use of sharps. Accurately administer additional local anesthesia and consider using a different agent.

Movement during luxation or elevation could be from apprehension and should be treated with more general anesthetic agent. Do not attempt to reposition the patient's head and continue surgery until the general anesthetic is effective.

When a patient is combative, it may be more beneficial to raise the level of consciousness by withholding the anesthetic and surfacing the patient. Verbal reasoning after the patient surfaces usually brings cooperation and less movement.

• **Figure 5-29** The anesthesia nurse deploys supplies, communicates with outside personnel, and positions equipment for use.

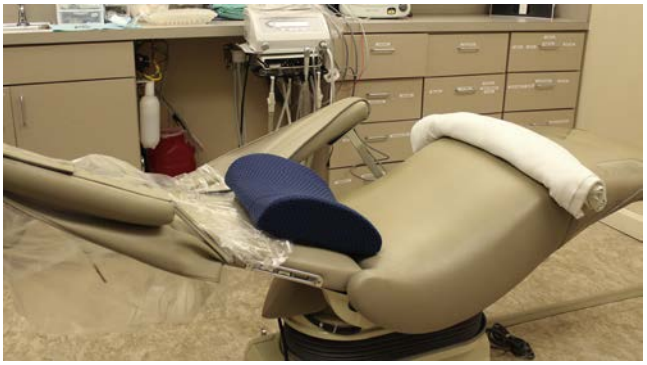
Unforeseen Circumstances and Running the Code

The simplest procedure can turn into chaos for the surgical team. Accessory equipment and supplies must be arrayed so that when things turn more complex, the anesthesia nurse can deploy the needed devices and call for help. A panic button is made available to the anesthesia nurse for calling a code in the office (Figure 5-35).

The surgical team must practice emergency protocols in the surgical suite in order to determine timing, sequence, and roles. Tasks must be assigned to each team member. Who calls for help, when and how? Who maintains the airway while the ambu is being deployed? Who does chest compressions, and who switches for relief? Who administers the emergency drugs? Who keeps the written record of the code? Where is the crash cart kept, and who fetches it?

• **Figure 5-30** The anesthesia nurse photographs procedures.

• **Figure 5-31** After reclining, reposition the patient to the top and center of the headrest.



• **Figure 5-32** To prevent back pain in the patient during a long procedure, place pads in the patient's lumbar area and under the knees.

• **Figure 5-33** A carefully placed sponge protects the airway.

• **Figure 5-34** A lubricated nasal trumpet may be used to enhance the airway.

• **Figure 5-35** The operating room should have a panic button.

Summary

The rational use of the sitting position to accomplish oral and maxillofacial surgery provides greater comfort to the operating team while helping to protect them from occupational injury.

Business Management of the Oral and Maxillofacial Surgery Practice

DANNY KETOLA, SCOTT E. GRAHAM, MICHAEL KURTZ

Introduction

Most people don't separate the business of oral and maxillofacial surgery from the clinical practice. In fact, they are very distinct from one another. Clinical oral and maxillofacial surgery focuses on delivering quality patient care to the patients, whereas the business focuses on the financial and related nonclinical aspects of the practice.

Oral and maxillofacial surgeons in training focus their time and energy on learning surgical skills and have very little exposure, didactic or otherwise, to the business side of dentistry and medicine. It is critical in today's medical and dental environment that practitioners gain knowledge of how to run a business. Otherwise, they are setting themselves up for a career that is less rewarding and will result in goals, financial or otherwise, not being met. This chapter focuses on the business side of oral and maxillofacial surgery from an operational, human resource, and financial perspective.

Operational Issues

The legal and compliance environment in dental and medical practices has changed drastically over the past several decades and will continue to evolve and change. With the recent passing of the Affordable Care Act,[1] changes occur at an exponential rate and predicting what health care will be like in the coming years is impossible. Consider the trend of corporate dentistry. A recent statistic shows the percentage of general dentists practicing in a group increased from 27% in 2003 to 38% in 2011.[2] Corporate dentistry continues to grow in scope of services and will continue to have an impact on specialists.

Keeping up-to-date and constantly assessing the business climate and adjusting will be the only way that private practices can survive. The "scope" of knowledge a clinician needed from a business perspective has broadened considerably over the last decade. This includes legal and compliance issues, Stark laws, banking and loans, insurance contracting, information technology, electronic billing, fraud, and embezzlement.

A surgeon fully engaged on the business side will need to have more than a basic knowledge of these subjects to be successful. These include but are not limited to governance, engaging advisors, assessing and evaluating operations, organizational issues, human resources, financial management, legal matters including managing risk, and information technology.

Legal Entities

Practices may take the form of several legal entities. Each of these present various advantages and disadvantages. Tax implications and personal liability are two of the most important differences. Possible practice structures include sole proprietorship (SP), general partnership (GP), limited partnership (LP), limited liability company (LLC), C corporations, or S corporations.

Unincorporated entities include SP, GP, limited liability partnership (LLP), and LLCs. For the oral and maxillofacial surgeon who does not plan to work in a group practice, the SP is a very convenient way to organize a practice. The surgeon-owner signs all contracts and collects revenues in his or her name. The surgeon-owner is also liable for all obligations of the practice, and personal assets could be attached if there is a settlement against the practice.

Each of the unincorporated partnerships generally have the following characteristics: There are two or more persons or entities in a business for profit, and any income or loss flows through to the partners for income tax purposes. The partnerships are therefore not taxable entities.

The GP is also a convenient entity to establish when there are a limited number of surgeons in the group. Typically, partners share equally in the profit and loss of the partnership, or, by proxy, alternative methods for revenue and expense sharing can be established. The personal assets of all partners are at potential legal risk, and all can be responsible for obligations incurred by other partners.

An LLP typically consists of at least one general partner and one limited partner. The general partner(s) can be liable for all obligations of the partnership, whereas the limited partner receives some shielding from debts and obligations of the partnership.

An LLC has characteristics of both a partnership and a corporation, and ownership may consist of multiple persons. Members of an LLC are not responsible for the debts and obligations of the LLC. Earnings pass through to the owners for tax purposes.

C and S corporations provide shielding from debt and other obligations for the shareholders. A C corporation is managed through a board of directors selected by the shareholders. The board of directors elects officers who are responsible for executing the policies. The C corporation is subject to double taxation because taxable income is subject to corporate income tax earnings, and funds distributed to the shareholders are individually taxed. S-corporation earnings, on the other hand, flow through to the shareholders for federal and state income purposes. A comparison of legal entities is shown in Table 6-1. Because of the complexity and potential tax implications of the legal structure, it is highly advisable to seek a knowledgeable accountant to guide your legal structure. Once the entity is formed and operational, it can be expensive to change entity structure down the road. Initial setup is important and should be designed for the long term.

Legal Documents

Basic legal document requirements of an OMS practice include articles of incorporation and/or operating agreement, employment agreements, buy-sell agreements, lease agreements, and third-party payer contracts. The number and complexity will vary greatly depending on the legal structure of the practice, local and state requirements, and advice from attorneys and other professionals.

Articles of Incorporation/Operating Agreement

The operating agreement specifies and formalizes how the entity shall run, whether a C or S corporation, LLC, or GP, and includes formation, election of officers, ownership, how reporting should take place, meetings, and dissolution.

TABLE 6-1 Comparison of Legal Entities

Entity	Corporation (C Corp and S Corp)	Partnership	Limited Liability Company (LLC)
Definition	Corporation for profit organized under the state corporations act S corporation designation under federal Internal Revenue Code	An association of two or more persons to carry on, as co-owners, a business for profit	Hybrid. An LLC formed under state LLC statute.
Designation of owners	Shareholders	Partners	Members
Liability of owners in organization	Shareholders generally not personally liable for debts of corporation, but liable for own acts	Partners are jointly liable for the obligations of the partnership	Members and managers are not liable for any debt, obligation, or liability of the LLC.
Management	Directors and officers	Partners	Members or managers
Persons in position to bind organization	Officers	Partners	Members or managers
Governing documents	Articles of incorporation, bylaws, and shareholders agreement	Partnership agreement	Articles of organization, operating agreement
Type and number of owners	No limits on type or number in C corp. S corp. limited to 75 persons.	No limit on type. Must have at least two partners.	No limits, although individual managers and members must be 18. Can have as few as one member in many states.
Ownership classes	Different stock classes allowed in C corp. S corp. is limited to one class of stock.	Any financial arrangement between partners allowed	Any financial arrangement allowed. In absence of agreement, interests are proportional based upon level of contribution/ capital account balance.
Tax treatment	As a C corp. unless S corp. is elected for tax purposes	Almost always as a partnership for federal tax purposes	Generally, as a partnership for federal tax purposes

Employment Agreement

Employment agreements describe the terms of employment for shareholders in the practice, associate physicians, and other key employees. These agreements should define the capacity in which the employee serves, compensation, benefits, termination, covenant not to compete, and future ownership. Box 6-1 is an example of a surgeon employment agreement, but it should not be construed as all-inclusive.[3] Variations will depend on the will and intent of the shareholders (given legal constraints) to provide an equitable work environment for those employed under these agreements.

Buy-Sell Agreements

Buy-sell agreements are the legal documents that cover a change in practice ownership and include provisions for surgeons entering and leaving the practice. Ownership should be considered a mutually agreeable arrangement between the surgeons and not a right or obligation.

Whether being bought out of or buying into a practice, the method of valuing the practice must be clearly spelled out. Practice valuation is typically based on several factors: gross production, collection percentage, hard assets, accounts receivable, and goodwill. Hard assets include equipment, such as computers, radiology equipment, surgical chairs, and other office furnishings. Accounts receivable includes monies owed the practice from patients and payers and should be discounted to the net collection rate of the practice. If the accounts receivable is $600,000 and the net collection rate is 95%, then the valuation of accounts receivable would be $570,000. Goodwill is often the most difficult asset to determine and will vary considerably in different geographic and socioeconomic situations.

• BOX 6-1 Surgeon Employment Agreement Outline

I. Duration of the Contract
  A. Length of the contract
    1. Option: annual with automatic renewal
  B. Effective date of the contract
II. Conditions Under Which Contract Can Be Terminated
  A. Voluntary termination by employee or employer with thirty (30) days' written notice
  B. Death of employee
  C. Suspension, revocation, or cancellation of employee's right to practice medicine or dentistry in the state of (state)
  D. Employee loses privileges to any hospital at which the practice regularly maintains admission privileges
  E. Employee fails or refuses to follow reasonable policies or directives established by the practice
  F. Employee commits acts amounting to gross negligence or willful misconduct to the detriment of the practice or its patients
  G. Employee is convicted of a crime involving moral turpitude, including fraud, theft, or embezzlement
  H. Employee breaches terms of the employment contract
  I. Employee becomes and remains disabled in excess of three (3) consecutive months
III. Compensation
  A. Amount of annual salary
  B. Incentive bonus, calculated as follows: (formula)
  C. Determine amount and duration surgeon will be paid during a period of disability
IV. Benefits
  A. Health insurance
  B. Retirement plan contribution
  C. Malpractice insurance and tail-end premium
  D. Dues, books, and periodicals
  E. Licenses
  F. CME expenses
    1. Annual allowance of $ (dollar amount)
  G. Entertainment
  H. Automobile
  I. Relocation
  J. Vacation leave
  K. Sick leave
  L. Life and disability insurance
  M. Cellular phone
  N. Pager
  O. Other
V. Outside Income
  A. Decide on the type of outside income the surgeon can retain and the type of outside income earned by the surgeon that the practice will be entitled to retain.
  B. At the same time as (A), discuss the surgeon's restrictions on outside employment.
VI. Surgeon's Duties
  A. Required work hours
  B. Required on-call schedule
  C. Discuss any restrictions on the acceptance of new patients by the surgeon.
  D. Discuss any provision if the surgeon is called to jury duty or other duty, such as military reserves.
VII. Termination Compensation
  A. Determine how much the surgeon will be paid if employment is terminated.
VIII. Opportunity to Buy into Practice Ownership
  A. How long after joining the practice?
  B. What exactly will the physician be allowed to buy into?
    1. Accounts receivable
    2. Hard assets of the practice
    3. Goodwill
  C. How will the assets be valued?
    1. By independent appraiser
    2. By fixed formula
  D. If applicable, how will accounts receivable be valued?
  E. How will fixed assets be valued?
  F. How will the buy-in price be paid for?
IX. Reasonableness of Covenant Not to Compete
  A. What is the duration of noncompete?
  B. What is the geographic area of noncompetition?
  C. What are the prospective penalties and/or compensatory damages?
  D. Is there a buyout clause?
  E. Is the covenant too restrictive?

From: Tinsley R: *Medical practice management handbook,* ed 8, 2002. Reprinted with permission from Reed Tinsley, CPA.

A professional firm experienced in practice valuation can be a valuable resource.

Practice valuation of a five-shareholder OMS practice:
Hard assets $450,000
Accounts receivable $570,000
Goodwill $620,000
Total practice value $1,640,000/5 shareholders
Per share value $328,000

In a multiple-physician practice, the ideal scenario would be equal valuation of a buy in and a buyout. Variables in this formula revolve around the length of payment in or out and interest or other fees. In the previous example, a surgeon buying into the practice would pay a total of $328,000 over 5 years ($65,600 annually or $5666 monthly). In the case of a surgeon being bought out, the practice could reimburse the partner over an extended time period so that the cash flow is not adversely affected. Box 6-2 is an outline of a sample buy-sell agreement. Because tax laws are constantly changing, the ramifications of the practice's buy-sell agreements should be regularly reviewed by the accountant, attorney, and shareholders.[3]

If a solo practitioner is selling his or her practice, the process of purchasing shares may be different from that in a group situation. The selling surgeon must agree on a price with the prospective buying surgeon. The buyer can work in the seller's practice for a specified period of time, which generates revenues, an agreed-upon portion of which can be used toward the purchase. During this time, the purchasing surgeon also has an opportunity to gain vast knowledge regarding the overall operation and administration of the business.

Another commonly used method is the capitalization of excess earnings. In this method the income statement is normalized to subtract items that personally accrue to the doctor. Then the normalized expenses are subtracted from the revenue to give the excess earnings. The past 3 years are then weighted, with the current year being weighted more heavily than the second, which is weighted more heavily than the third. This average excess earnings is then divided by the capitalization rate, which is based on more subjective factors. A typical capitalization rate is 0.25.

Other overly simplified valuation methods commonly used to determine the value of a practice are the W-2 method and Percentage of Gross Production. The W-2 method is a simplified version of the Capitalization of Excess Earning method discussed earlier. It essentially takes an average W-2 amount over a 5-year period and can be adjusted for factors such as increasing or decreasing volume trend, increase or decrease in local competition, changing market, or debt. The percentage of gross production method values a practice by taking the gross revenue and applying a percentage, usually between 60% and 70%, and adjusting for factors listed earlier.

Lease Agreements

The practice and/or shareholders may own or lease the office space they occupy. There are a multitude of possible ownership entities, including a sole ownership, LLC ownership, leasing from outside sources, or shared arrangements with other professional organizations. The decision is based on tax implications, geographic limitations, and other legal obligations. A contract is required, which has parameters including liability, duration of the agreement, shared responsibilities, and the financial obligations between the parties. Lease documents include rental rate per square foot, liability, duration of lease, leasehold improvements, and responsible party for utilities, repairs, property taxes, and maintenance. When the building is owned by the doctor, the practice leases the facility from the doctor. A retiring doctor who is selling the practice may choose to keep the building, using his lease payments to help maintain his lifestyle after retirement.

Risk Management

Risk management encompasses both the clinical and administrative aspects of the practice. Federal laws and guidelines will dictate many of the practices' protocols, whereas shareholder prerogatives guide others. Risk management in an OMS practice includes the following areas: informed consent, quality assurance, treatment protocols, collection protocols, OSHA and HIPAA compliance, and insurance laws, including private contracts, Medicaid, Medicare, and workers' compensation. Knowing these laws and what you can and can't do is necessary to avoid inadvertently committing insurance fraud.

• BOX 6-2 Buy-Sell Agreement Checklist

- Buyout events:
  Death
  Disability
  Retirement
  Voluntary and involuntary termination
- Agreement specifies details of buyout in the event of a disability.
- Agreement specifies any age restrictions for retirement (withdrawal before age 62 is voluntary and carries tax implications).
- Specify notification requirements for voluntary withdrawal.
- In the case of a voluntary withdrawal, agreement specifies whether there will be penalties to the buyout price if the owner forms a competing practice, joins a competing practice, or violates the employment contract.
- Vote requirements to admit a new surgeon into the practice.
- Periodic review of buyout calculations and methodology of payments.
- Qualifications of firm used for any appraisals.
- Routine review of tax consequences for the practice and surgeons for buy in and buyout.
- The buyout amount has been calculated for each owner using the current formula in the agreement.
- Periodic shareholders review of all contracts.

The AAOMS provides information and continuing education opportunities on the topic of risk management. OMS National Insurance Company (OMSNIC) is OMS surgeon owned and provides professional liability insurance for OMS providers, and they have regular seminars and online formats for their clients.

Informed Consent

The informed consent process begins with the first contact that the surgeon makes with the patient. All discussions and decisions must be documented in writing in the clinic note and then ultimately on a consent form specifically designed for the process. Some procedures will require a lengthier and more detailed educational process before obtaining a signed consent form. This process can take the form of printed materials or brochures, audiovisual presentations, or one-on-one discussion with the surgeon and/or designated staff members. It is important that the patient or legal guardian be given adequate opportunity to ask questions regarding their treatment plan, and that all alternatives be presented. The age at which a patient can legally give consent is generally 18 years. Exceptions may exist when a patient is emancipated from parental control or if they are married before 18 years of age. It is advisable that every practice verify with their attorney what their state laws are. In the event that the patient is incapacitated, it is necessary to carry out the entire presurgical discussion with the power of attorney and get their signature. Obtaining a signed consent form does not eliminate the possibility of legal action, but having good patient rapport, adequate discussion, and a well-documented patient record prevents many possible future problems.

Quality Assurance

Much as a hospital or surgical center requires certification and documentation of quality assurance, it is incumbent on every OMS practice to be vigilant regarding every aspect of patient care provided in their facility. Unsigned consents or missing documentation forms should be monitored and addressed. Periodic chart reviews can identify deficiencies that would otherwise go unnoticed. Patient complaints should be assessed, and an action plan established to prevent repeating a problem. If there have been any staff injuries or complaints, they need to be documented, along with any remedial action taken. Treatment protocols are helpful when complex procedures are expected. This protocol, which may be as simple as the route and type of drug used for subacute bacterial endocarditis prophylaxis or as complex as the work-up for an orthognathic or implant surgery, provides a road map for the treating team to follow.

Managed Care Contracting

In many areas of the country, some companies have employees enrolled in capitation insurance plans. Because of the large potential patient pool, it becomes a financial necessity for the OMS practice to consider participating in these plans. The ability for the practice to competently negotiate with third-party payers is a key factor in their financial success. The terms of reimbursement and the contractual language must be scrutinized carefully. If the surgeon is not familiar with these negotiations, then a consultant should be involved. Third-party payer contracts may also spell out terms for patient scheduling, emergency call, professional liability, and assignment of court costs in case of a lawsuit, all factors that may weigh heavily on the overall operations of the practice.

Practice Advisors

No individual can possess all of the comprehensive knowledge base that is necessary to establish and maintain a successful practice. A surgeon should surround himself or herself with a team of professional advisors, which include accountants, attorneys, bankers, insurance brokers, retirement plan administrators, other practitioners, an office manager, and, in larger practices, a practice administrator.

Selecting an Advisor

Selecting an advisor can be a daunting task and can have huge financial and quality-of-life implications. Consider selecting a financial advisor who brings a 3% higher return over the course of one's career, or an attorney who gives bad legal advice when it comes to an HR issue and a lawsuit is filed against you. How much could a good accountant save you in taxes during your career? As you can see, the right selection is extremely important, and the choice should be made systematically and after much research, thought, and consideration. If the selection is done correctly, it will only need to be done once, unless the advisor retires.

A good system to follow is to gather all the references you can via your network and relationships and then research them. After you have completed your research, set a meeting up and interview them. Be careful not to commit to the first one you interview. Many of them are trained at getting people to say "yes" and will tell you what you want to hear. Tell them up front you will be interviewing several candidates and a selection will not be made until all the interviews have been completed. You will find that you will gain a much better understanding after each interview, and at the end of the process you'll understand the purpose and need for such an advisor much better than when you started.

Many advisors overlap each other, and you will need to decide which advisors you will use in each area. An example is your accountant; many accountants also do financial advising. Do you want to use your accountant, banker, insurance agent, or stand-alone financial advisor? You may also seek advice from all of them and then make your decision. After the interview process, you will have a better understanding of the skills they possess and when and

how to use them. This is similar to how a dental patient can choose to use their dentist or an oral surgeon for an extraction. They both offer the services, but one choice may be better than the other.

Accountant

An accountant who has achieved the licensure of a certified public accountant (CPA) generally has a college degree or has completed significant course work in accounting, has successfully completed a comprehensive examination, and has practiced with an accounting firm for 2 years. Individual states may have specific licensure requirements. Typically a CPA can provide services including bookkeeping, creating a financial statement with analysis, tax return preparation and a good understanding of business entities. A person or firm that has health care experience and specializes in health care can give invaluable advice regarding every financial decision. The CPA should be proactive communicating to the management team with advice regarding decreasing overhead, improving cash flow, and increasing revenue. It is also important that they be aware of changes in the tax codes germane to the practice.

Attorney

The attorney or firm selected by the practice should have a comprehensive working knowledge of health care law, including malpractice, contract and corporate law, and tax and estate planning.

The attorney drafts legal documents pertaining to practice entity formation and other ownership entities, such as real estate or life insurance policies. Employment and buy-sell agreements are of particular importance to a group OMS practice to facilitate a smooth transition from the associate position to ownership and eventually to retirement. The quality of these agreements becomes particularly important should a dispute arise between partners, associates, or heirs. A surgeon contemplating joining an existing practice should hire his or her own attorney to review and make recommendations regarding any contracts. It is important to consult with an attorney before joining or starting a practice and working out the agreements. Once a disagreement arises, it is difficult if not impossible to work out the details.

Banker

A lender is selected before the inception of the OMS practice to establish guidelines for the financing of capital equipment, computers, or the purchase of office space. Discussion should include the possibility of a cash flow shortfall. Many banks offer special service lines that are tailored to health care organizations and surgical practices. A solid banking relationship is important over the life of a practice, and an effort should be made to find the right banking relationship and maintaining that relationship.

Insurance Broker or Representative

The insurance professional is an integral part of the professional organization's advisor team. This person can assist with decisions on how to protect business and property. They can also assist with buy-sell agreements and help get coverage in place. Other important areas include key person insurance, retirement planning, group insurance, and personal insurance for the surgeon-owner. You will need to decide how to use your agent and which services you will want him to provide.

Selection of an insurance representative is based on education, health care experience, and their access to a variety of insurance options. Various professional designations include chartered life underwriter, chartered financial consultant, certified financial planner, Master of Business Administration, and others.

Retirement Plan Advisor and Administrator

The professional life of an OMS surgeon can easily extend to 30 years or more, which enables the individual to potentially accumulate substantial retirement assets. A retirement plan administrator is usually partnered with a financial adviser to make up the team to provide plan administration and investment advice. Plan administration includes drafting documents, accounting for participants' account balances, and filing annual tax returns. As firms are interviewed, factors such as fees for administering the plan, timely reporting, and investment selection should be taken into consideration. Options for calculating service fees include a percentage of the total assets, a per-participant fee, and/or charges to carry out the testing of the plan. The team should provide cost projections and be prepared to discuss each facet. Once an investment team is selected, a 3- to 5-year timeline is established to achieve the investment objectives of the practice. There are multiple plan options, including but not limited to 401(k)s, self-employed pension plans (SEPs), Individual Retirement Accounts (IRAs), pension plans, and defined benefit plans. The type of investments selected for the retirement plan(s) will be driven by the risk tolerance and investment goals of the practice and its shareholders.

Practice Administrator

The practice administrator is an integral part of the management team and is responsible for ensuring that the practice functions in a seamless manner. If the employee charged with the direct oversight of the practice business and nonclinical areas does not have the core competencies, education, or experience required to manage a practice, ultimately a myriad of difficulties can develop. There are several organizations where candidates can be found: American College of Health Care Executives (ACHE), American College of Medical Practice Executives (ACMPE), and the Medical Group Management Association (MGMA).

Competent administrators will be well versed in finance, accounting, human resources, compliance/risk management, governance, information systems, and strategic planning. Many offices promote from within, so that someone who started at the front desk eventually becomes the office administrator. Practice owners should be careful in doing this and should make sure the staff member they have in this position has the skills necessary to perform all the functions you will require of them. Some practices elect for the surgeon to also fill the role of a practice manager. This can be time consuming and should be considered carefully. A surgeon filling this role must be aware that the time he spends on this may affect his bottom line and quality of life. This should only be done if the surgeon has a desire to run all business aspects and is dedicated to gaining the knowledge needed to do so.

Marketing and Public Relations

An OMS surgical practice is mostly referral driven; therefore, the importance of marketing and public relations cannot be overstated. Communication on multiple levels with the referral base is the cornerstone of a marketing strategy, but this is changing with the proliferation of corporate dentistry, and oral surgeons need to consider and learn how to market to the general public as well. Websites, social media, educational events, and so on all market to the public, and the person you put in charge of this should market the message you want given. Because each practice is unique, it is impossible to list or diagram a marketing scheme that fits all situations. More information on this subject can be found in Volume 1, Chapter 10 on marketing.

Benchmarking

Custom-designed surveys that are completed by patients and referrals are of great value to evaluate the health of a practice, although the need to survey patients is diminishing with the proliferation of electronic media. To find out how patients feel about your services, just go onto the Internet, and you can usually find some type of patient review. You will need to focus on getting positive reviews, as most people only give reviews if they have a negative experience. A digital marketing manager is a good person to have as an advisor, as he or she knows the landscape and can help build practice feedback via electronic means.

To effectively evaluate your practice from the referral standpoint, you should engage in effective relationship building. If you have a good relationship with your referrals, they are more likely to call if any issues arise. The sooner you are aware of an issue, the sooner it can be addressed and any negative impact can be limited.

If a practice chooses to solicit feedback from traditional surveys, it is best to limit them to around 5 questions. Surveys that are much longer are often ignored, as most people are not willing to spend their time on a survey that cannot be completed very quickly.

Organizational Structures

Solo Practice

The primary advantage that a solo practitioner possesses is the ability to set his or her own schedule and make all decisions. A solo practitioner normally has an independent personality, has a high energy level, and is not hesitant to simultaneously tackle the administrative and clinical challenges.

Overhead and staffing issues are far less complex in an SP situation. Unless the surgeon hires outside expertise, it will be necessary to manage multiple tasks that in group practice may be shared, such as computer repair, insurance coding, human resources, or accounts payable management.

Group Practice

Three possible advantages inherent in a group practice include sharing after-hours call coverage, potential leverage during managed care contracting and purchasing, and having colleagues to discuss various clinical issues, such as diagnosis and treatment planning.

As a group practice grows, it is possible to have a division of labor among the surgeons. Surgeons tend to gravitate toward a specific area of interest in the management arenas, such as marketing, staff education, or the financial aspects of practice management. Regardless of personal preferences, each member of a group practice must have an overall knowledge of the clinical and administrative aspects of the practice.

A managing partner is the initial liaison with the practice administrator or office manager. A managing partner should be a shareholder, should be elected by the other shareholders, and can be compensated for his or her additional responsibilities. A senior partner with practice experience is ideal for this position. As a group grows, it becomes increasingly difficult for a managing partner to provide the comprehensive supervision necessary. Larger groups can form committees with one or more of the surgeons as chairperson.

- *Finance*—retirement plan administration, review of financial statements, and decisions regarding capital investments and buy-sell arrangements.
- *Human resources*—continuing education, compensation, and benefits.
- *Quality assurance and risk management*—review of morbidity and mortality, infection rates, chart review, and site accreditation.
- *Compliance*—radiology regulatory issues, Occupational Safety and Health Administration (OSHA), and Health Insurance Portability and Accountability Act (HIPAA).
- *Information systems*—hardware and software, imaging, and electronic health records (EHR).

Associate or Salaried Position

At the end of the long process through undergraduate education, dental school, and residency, the individual is often

faced with a significant debt. For this reason, becoming a salaried associate without any additional financial responsibilities may be attractive. An existing practice can offer a potential associate a trial period of 1 to 2 years. The time period selected allows both the associate and the owners an opportunity to evaluate each other's working style, personality, and personal goals. Near the end of a surgeon's career, an associate position may enable them to step away from some of the responsibilities typically tied to practice and partnership.

Advantages of an associate position include a guaranteed salary and benefits with few administrative responsibilities and limited debt exposure. Disadvantages include limited involvement in practice decisions, no incentive for increased income with increased production, and no control of the benefits received.

Human Resources

Most dental practices are small businesses with sizeable gross revenue, multiple employees, sizeable real assets, and a large expense budget, yet dental schools or residency programs do little in the way of preparing a health care provider to manage such an enterprise. Irrespective of the finance and accounting operational functions, the human resource function can be the most daunting. Consider that labor costs can be 60% of a providers expense budget, probably the single most important task that contributes to practice success is getting the employment process right.

French philosopher and political commentator Jean Baudrillard used the term postmodernism, defined as a reaction to or rejection of the dogma, principles, or practices of established modernism, to reflect the dramatic changes and turmoil we see in life today.[4] Employees in this environment are much more likely to question authority. They will move to another job for a higher salary or at the first sign of conflict or dissatisfaction with working conditions. Arguably, turnover can be quite expensive and can create chaos that results in a negative impact on the bottom line.

Consider this; a recent Gallup survey found that 50% of American workers are not engaged in their work, and 20% of those workers are actively disengaged.[5] Martha Irvine, writing for the Associated Press, refers to Generation Xers in today's workforce as gloomy slackers who have the reputation of expecting a high salary and flexibility, yet have little willingness to take on grunt work or remain loyal. Simply put, yesterday's rules—where ability plus motivation plus environment equaled performance—do not apply.[6]

In fact, many management gurus now believe it's a myth that people are the greatest asset of an organization. According to Jim Collins, the *right* people are the greatest asset of an organization.[7] So the challenge is to get the wrong people off the bus and the right people on it. This section is a primer for hiring and retaining good employees, complying with labor laws and regulations, and engaging alternatives for managing the human resource function.

Assessment

Begin by taking a T-inventory of your current staff. Divide them into the three T's: termites, transmitters of the status quo, and transformers.

Termites are easy to identify. They are the negative types who consistently perform poorly and drag down the rest of the staff. They convey a simple message to patients: go somewhere else! And as with termites, by the time you realize it, they have already done considerable damage.

Transmitters of the status quo are the ultimate average employees. More often than not, transmitters do what they are told and nothing more. These employees show up for work every day and make few mistakes. However, alongside a termite they can be easily swayed to the dark side. Most employees fall into this category.

Transformers are those rare employees who are always positive and go out of their way to exceed patient expectations. They see themselves as stakeholders in your practice. Transformers exhibit what Daniel Goleman calls emotional intelligence (EQ).[8] Emotionally intelligent employees recognize feelings, are better at mood management, and are self-motivated and able to direct themselves toward a goal. They recognize feelings in others and are good at tuning in to verbal and nonverbal cues. Cooperation is their hallmark. People with high EQs understand the importance of managing relationships, handling interpersonal interaction, resolving conflict, and negotiating. Most hiring managers today agree that a high EQ supersedes a high IQ.

Hiring

The T-inventory process forces the practice to begin working toward improvement of all aspects of the practice. It is absolutely essential to develop *accurate* job descriptions. This includes a brief list of principal job responsibilities, a list of the knowledge skills and abilities required, education or licensure required, pay range for the position, and a summary of the working conditions. Most practices use job descriptions as a prequel to hiring.

The next step is to develop a job application form. Many practices simply ask for curriculum vitae or resume. However, it's important to remember this is the candidate's marketing material. The goal of the job application is to find out things the candidate is unwilling to tell up front but that you need to know to decide whether or not to bring him or her in for an interview. It also avoids wasting time interviewing candidates who have no chance of getting hired.

Appropriate items for a job application include a work history, salary history, reason for leaving previous employment, and at least three professional references. Include a check box to allow the candidate to consent to a criminal record check and drug screening along with permission to check references. A search on the Internet will provide several templates for you to choose from when looking for an application to use. In today's social media environment a search of Facebook may reveal applicant traits both desirable and undesirable that could affect the hiring decision. Be sure to become familiar with your state laws to make

sure you don't discriminate when making your hiring decision.

With the job descriptions and applications developed, it's time to get down and dirty with recruitment. Advertising on Internet venues or dental society publications is often very effective. Depending on the position offered and the job market in your community, it may be necessary to engage the services of a recruitment firm. Having a larger pool of applicants improves your chances of finding the one who will transform your practice. An important but often-violated rule is that no one should be hired out of desperation to put a warm body chairside. The cost of using a temporary agency pales in comparison to the damage that can result from hiring the wrong person.

Candidates who make the cut should have a personal interview. Always have more than one person interview candidates, because they can often pinpoint strengths and weaknesses you may miss. Preselect questions for the interview, and ask the same questions of all applicants to avoid bias. Questions might include: Why are you applying for this position? What made you choose this field of employment? How might you calm a nervous or angry patient? Why are you leaving your current position? Why do you feel you are the best candidate for this position?

After you have narrowed your candidates to one or two finalists, conduct a second interview. This often gives you a clearer definition of the candidate. It does not matter if you think you've found the diamond in the rough or may lose the candidate to competing job offers. Always take the extra time to check references and perform a criminal record check and a substance abuse screening. There are a number of companies that provide these services to small businesses for a nominal fee with a short turnaround time.

Retention

Even though we said that the most important thing practice managers do is hire, in no way is this the end of the staffing process. A well-designed orientation program can make a new employee productive from the first day. This first day should be a celebration, with either a breakfast or lunch period where the new employee can be introduced to everyone in the practice.

Assign a preceptor to the new employee. This is a staff member who is responsible for making sure the newbie is welcomed and who will serve as both trainer and mentor throughout the orientation period.

To ensure that the orientation is complete, create a new employee orientation checklist and start a personnel file that includes the job application, interview records, reference check information, and verifications of any credentials or certifications. Complete any necessary paperwork such as INS Form I-9, employment eligibility verification, employment agreement, receipt of your employee handbook, W-4 form for payroll withholding, personal data sheet for emergency contacts, home address and telephone number, social security number, benefit coverage election, and beneficiary designation forms.

In the first few days, the preceptor should explain the following practices and procedures of your organization, which should also be carefully addressed in your employee handbook: work hours and attendance/tardiness policy, payroll periods, when paychecks are delivered and when first check will arrive, rates of pay, overtime rules, parking arrangements, dress code, and training or introductory employment periods. The handbook should also contain all employee benefits for which the new employee is or may become eligible, including medical insurance, sick leave, vacation, personal leave, jury duty, holidays, pension programs, savings programs and/or stock plans, and life, disability, and accident insurance.

Also provide the new employee with copies of the following documents: employee handbook, safety plan, letter explaining COBRA (Consolidated Omnibus Budget Reconciliation Act of 1988) governing continuation of benefits following payroll separation, and an employee benefit booklet explaining each offered benefit. Show the employee any marketing or informational materials used with your patients. Play any videos or audio recordings you have prepared for employees or patients that explain your practice's offerings. Explain your practice's mission and philosophy.

Orientation should continue with in-depth training of technical and clinical aspects related to the employee's specific job. The preceptor and new staff member are accountable for the training's success. The orientation period ends with a formal evaluation of performance during this time. The OMSNIC and AAOMS websites are great sources for training material.

Before you can accurately evaluate an employee's performance, you must establish a system to measure that performance. This entails developing performance standards and goals appropriate to each position. Performance standards describe what workers in a particular job should accomplish and how you want the job done. These standards apply to every employee who holds the same position.

For example, a standard for a practice manager might be to maintain accounts receivable at no more than 45 days' unadjusted production. Make sure your standards are achievable and directly related to the employee's job.

Unlike performance standards, goals should be tailored to each employee, keeping in mind the individual's strengths and weaknesses. For example, a goal for a dental assistant might be to become certified with expanded function. Your staff can help you figure out what reasonable goals should be.

The first performance review should take place immediately after 90 days. This period is designed to make sure that the employee is a good fit for the practice. If for any reason you believe the person is not a good fit, then both parties can engage in a "no-fault divorce," and the employee can be released. This is not an orientation or probationary period. This is a result of employment at will. It serves as a fail-safe for mistakes or misperceptions during the hiring process. Schedule other performance reviews at 6 months and 1 year. Subsequent reviews are done annually unless performance lags.

Check with your attorney or advisor regarding employment-at-will in your state.

Deal with poor performance issues immediately, and follow up with a performance improvement plan that documents the areas of performance that need improvement, what the employee needs to do to correct the poor performance, and the consequences of not making the improvements, up to and including termination. Termination of a poor performer should never come as a surprise to an employee. A record of poor performance should be well documented. If this is done correctly, litigation will never be an issue. On the other hand, a practice should never keep a poorly performing employee because of fear or threat of litigation.

To retain emotionally intelligent employees who expect more from their employers, another step is necessary. Job enrichment motivates employees by giving them a career track that includes higher pay, increased responsibility, and variety. As the job becomes more interesting, employees become more energized. This has a positive impact on attitude and productivity and allows employees to have more control over planning their work and deciding how it should be accomplished.

This taps into the natural desire most employees have to do a good job, to be appreciated for their contributions, and to become stakeholders. Consequently, it may be beneficial to review your job descriptions to ensure that your practice is maximizing all of the available energy. An example of this would be to have different job descriptions for a specific category—such as surgical tech I, surgical tech II, or surgical tech III—with tiered responsibilities and tasks.

By using these steps, you will be able to concentrate on practicing dental medicine and not be bogged down in patient satisfaction issues related to staff problems. This creates a competitive edge that will result in higher profit and better performance.

Compliance

Navigating the federal and state employment regulatory minefields can be difficult, but the results of noncompliance can be expensive. Labor laws governing hiring practices, discrimination in the work place, health and safety, wage and hour laws, benefit and leave issues, termination, and privacy make it necessary to become and stay informed, as regulations change frequently. Make sure your employee handbook contains all necessary tools informing employees of their rights. The practice safety annual or OSHA handbook should be distinct from the employee handbook. Annually, have a training session on health and safety, sexual harassment, and privacy issues. Do not make any exceptions for policies or procedures that are dictated by federal regulations. Make sure the all labor law posters and notifications are posted in a place that all employees have access to. Remember, there are whistleblower laws and disgruntled and released employees are great sources of a practice's dirty laundry. Do not hesitate to seek the advice of your attorney.

HR Alternatives

An alternative to internally managing the HR function can be to contract with a professional employment organization (PEO). This can enable a practice to cost-effectively outsource the management of human resources, employee benefits, payroll, and workers' compensation. This allows a practice to focus on their core competencies to maintain and grow their bottom line without worrying about managing these increasingly complex human resource issues. Practices can contract with a PEO to assume these responsibilities and provide the necessary expertise. These services are integrated seamlessly into everyday practice operations and can be accomplished completely online. Advantages include improved employee practices; reduction of practice liability by improved risk management; access to comprehensive benefits that would only be available to a large employee pool, thus helping the practice to be competitive in the labor market; and improved productivity and profitability.

Managing an oral surgery practice's human resource function is a complex task. However, done properly, it can result in a workplace where staff and doctors can reach their full potential and where patient-centered care is delivered competently and efficiently. Successful HR management leads to high employee engagement and patient satisfaction, which translates into a bigger bottom line.

Financial Management

Unfortunately, dental school and OMS residency training curriculum has little to no financial management content. This places the new practitioner in a position where they must rely on other professionals to provide advice and guidance in the early stages. Your CPA and/or administrator will help a great deal in this area, but the practice owner must be involved to make the final decisions. Following are the areas that you will need to be familiar with to properly manage a practice from a business perspective.

Budgeting

Depending on the size of the organization, a budget may or may not be used for financial management. It is a good idea to use a budget or alternative method regardless of size as a benchmark to see where there are areas of improvement.

A budget is an essential part of the planning process for the practice and can include 1-, 3-, and 5-year projections. In today's practice environment, however, it is getting more difficult to plan out 5 years, and a 5-year budget is used mostly for large expenditures or for expansion. By comparing projected production, net revenue, and expenses against actual numbers, a variance can be derived. At any point in time over the fiscal year, it is possible to make decisions and adjustments based on performance compared with projections. Figure 6-1 is an example of a monthly budget variance report. Budget variances should be reviewed monthly

	Jan - Dec 14		Budget	$ Over Budget	% of Budget
Ordinary Income/Expense					
Income					
Gross Production	5,935,148		5,663,581	271,567	104.8%
Total Net Collected Fees	4,096,818		4,051,169	0	1.01
Gross Profit	4,096,818		4,051,169	45,648	101.13%
Expense					
Salaries/Wages	788,329	19.24%	805,000	(16,671)	97.93%
Payroll Taxes	90,658	2.21%	92,575	(1,917)	97.93%
Contract salary/expense	58,047	1.42%	79,350	(21,303)	73.15%
Employee related exp	350,380	8.55%	390,443	(40,063)	89.74%
Auto Related Exp	30,924	0.75%	32,054	(1,130)	96.48%

to determine reasons for revenue and cost differences from the projected amounts.

Alternatives to using a budget can be equally effective in managing the practice, and the method selected should be what you feel fits your practice best. Other alternatives include comparing current data to the previous year. This method is especially helpful for monitoring trends in production or expenses and can help determine if certain decisions or changes had the expected impact in any one area. Another method is to use national or regional percentage data and track expenses as a percentage of production.

Accounting

There are many software programs that can be used for accounting, and your accountant or administrator will help you select the correct program.

An important concept in accounting for an oral surgeon to know is accrual accounting versus cash accounting. For tax purposes, your accountant will need to keep financial statements using the accrual method. As an owner, you will most likely want to see only financial statements on a cash basis and have the accountant discuss the accrual statements with you for planning purposes.

Revenue Cycle

There are nine steps in the revenue cycle as the patient enters the practice and continues through to the completion of treatment: scheduling, registration, financial counseling, charge capture, coding, claims processing, denial management, account resolution, and payment posting.

Revenue cycle performance is one of the most critical elements in the practice's financial status and must be monitored regularly. In many instances, it may be 60 to 90 days until all of the fees are collected. Each step in the revenue cycle is dependent on the next for timely reimbursement. Practices typically fall into two categories: fee for service and those that participate with managed care plans. Practices that are fee for service are able to set their own financial policy. This should include the collection of a portion or all of the surgical fees at the time of service, leaving any unpaid portion to be billed to the patient. A fee-for-service practice is able to generate considerable cash flow on the front end of the revenue cycle. A practice that participates in a managed care plan will typically collect the appropriate co-payment at the time of service, file the insurance claim, and wait for reimbursements. If the claim is not filed accurately and needs to be refiled,

there are added days until the funds are collected. Whether to operate as a fee-for-service practice or to participate in managed care is a big decision, and many factors will need to be considered, as they can operate much differently from one another.

Financial Policy

The practice's financial policy describes expectations for patient and third-party payment and includes fees, a timeline for expected payment, interest charges for delay of payment, collection costs, allowable discounts, and any relationship with third-party payers. When a patient is initially scheduled, fees are quoted for the consultation, data gathering, diagnostic records, and treatment planning aspects. After the consultation is completed, fees and the financial obligations for the treatment are discussed with the patient. The patient signs an agreement acknowledging their understanding, which then forms the basis of a contractual relationship. The structure of the policy, along with the manner in which it is presented, forms one of the most important impressions that patients and families form of any practice.

The financial arrangements may vary if the treatment is provided on the same day as the surgery. The overall goal in all policy objectives is to minimize the time that accounts are unpaid and to maximize the practice's cash flow.

The following examples illustrate the financial effect with two different practice philosophies. In both scenarios, the fee for service is $1200. In practice A, the patient is required to pay one third of the fee at the time of treatment. This is followed by a second one third payment within 30 days and the balance within 60 days. Practice B requires half of the payment at the time of surgery and the balance within 60 days.

By collecting $400 at the time of treatment, practice A has $800 of its fee at risk, whereas Practice B has only $600 at risk. Practice A therefore has 16.6% more money at risk for non-collection. The risks for non-collection decrease with a higher percentage of insurance coverage. Local trends within the medical and dental community regarding payment for services and any contracts you have in place may need to be taken into account when forming your financial policy.

Financial Statements

Financial statements represent a formal record of the financial activities of an entity. These are written reports that quantify the financial strength, performance, and liquidity of a company. Financial statements reflect the financial effects of business transactions and events on the entity. These statements can be difficult for most people to interpret and are not necessarily needed for the surgeon or administrator to effectively manage the business, although they are necessary for your accountant to keep. The four main financial statements typically used are:

1. Balance sheet—this statement provides the financial statements on a given date and lists assets, liabilities, and owners' equity.
2. Income statement—this statement is also known as the profit & loss statement or P&L. It gives the financial performance in terms of profit or loss over a given period.
3. Cash flow statement—this statement outlines how cash flowed in the organization over a certain period.
4. Statement of changes in equity—this shows the movement in owners' equity over a period.

As stated earlier, your accountant will keep formal financial statements, and you will want to look at them when they are issued, but for most purposes it is best to use a modified financial summary that is easy to understand and gives the information that is relevant to your business. A good financial summary should contain information that is timely, relevant, and helpful in guiding the financial decisions of your practice (Figure 6-2).

Financial Trend Analysis

A useful financial tool is a trend analysis, which can be easily accomplished by comparing current-year data to previous-year data.

Through trend analysis, a practice is able to identify changes in costs over time and can make adjustments accordingly from month to month and year to year. A positive variance indicates a lowering of costs or higher revenues. Although costs typically rise over time, it is the rate of change that is most relevant. If revenues do not keep pace with costs, then profitability decreases.

Ratio analysis of the financial statements provides an ongoing assessment of the financial health of a practice. Commonly used ratios include gross collection ratio, net collection ratio, overhead ratio, and accounts receivable turnover.

Gross Collection Ratio

Gross collection ratio = cash collections/gross charges

The gross collection ratio is a measure of payment for services rendered over a specific time. It is affected by the practice's fee schedule, the patient financial policy, the prevalence of managed care plans and payer mix, and the manner in which the revenues are collected. If gross charges for a month are $600,000 and the cash collections are $480,000, then the gross collection ratio is 80%. The 20% not collected typically would result in contractual adjustments required by the managed care contracts in force with the practice. For example, if a practice has a contract with a payer that states that the payer will reimburse 80% of the usual and customary charges, then there will be a 20% contractual adjustment.

Net Collection Ratio

Net collection ratio = cash collections/net charges

Statistical Summary June 30, 2014

	MTD			YTD		
	2013	2014	Change	2013	2014	Change
Gross Production	$145,852	$161,251	110.56%	$752,000	$845,675	112.46%
			Percent of Production			Percent of Production
Courtesy W/O's	$4,506	$5,200	3.22%	$25,360	$27,850	3.29%

We started accepting XYZ Insurance in May of 2014

• **Figure 6-2** A sample of a financial summary.

The net collection ratio measures collections after allowing for managed care contractual write-offs. It reflects the effectiveness of the collection process in place. For example, if a practice has gross charges of $100,000 for the month and their contractual write-offs are 20%, then their net charges are $80,000. If they collected $75,000, then their net collection ratio would be 93.75% (75,000/80,000). The percentage not collected would typically be due to bad debt or a delay in insurance processing. If the practice is heavily involved with managed care, changes can be seasonal, and it's a good idea to use a rolling average or compare to the same period as the previous year.

Overhead Ratio

Overhead ratio = overhead expense/cash collections

The overhead ratio demonstrates the percentage of income that currently is used to operate the practice. Physician's compensation and benefits are normally not included in the overhead costs. For example, if practice collects $100,000 for the month and their expenses are $50,000, then their overhead expense would be 50%. Overhead can vary greatly among practices due to geographical demographics and/or expense and management philosophy. Some practices choose to run more expenses through a practice, and it will be up to the owner and accountant to decide which expenses are allowable under IRS guidelines.

Accounts Receivable Turnover

Accounts receivable turnover =
annual net production / average monthly A / R

The accounts receivable turnover ratio indicates how long monthly production typically spends in accounts receivable and will vary depending on payer mix, structure of managed care contracts, patient financial policy, and effectiveness of the collection process. Accounts receivable turnover also varies throughout the year, and a rolling average is recommended as well as comparison to the same period for the previous year. Financial reporting is normally done monthly.

Compensation Plans

Compensation plans assume a variety of forms and complexity. In a solo practice, a surgeon is compensated the net of revenues minus all expenses. In a multiple-surgeon

TABLE 6-2 Equal Share and Production–Based Compensation Model

	Dr. X	Dr. Y	Dr. Z	Total
Gross charges	$745,000	$600,000	$540,000	$1,885,000
Collection percentage	×0.80	×0.80	×0.80	×0.80
Cash collections	$596,000	$480,000	$432,000	$1,508,000
Percent of total	40	32	28	100
Equal Share Distribution Compensation Formula				
Collections allocated	$502,667	$502,667	$502,667	$1,508,001
(–) Overhead costs (50%)	$251,333	$251,333	$251,333	$754,000
Compensation	$251,333	$251,333	$251,333	$754,000
Compensation as % of collections	42%	52%	58%	
Production-Based Compensation Formula				
Collections by surgeon	$596,000	$480,000	$432,000	$1,508,000
(–) Overhead costs (50%)	$298,000	$240,000	$216,000	$754,000
Compensation	$297,000	$240,000	$216,000	$754,000
Compensation as % of collections	50%	50%	50%	50%

practice, the calculation of compensation may take the form of equal shares, a production-based formula, or a hybrid of both. Designing a fair compensation plan takes into account differences in practice style, production, and possibly other duties beyond treating patients. As the size of a group increases, the possibility of disproportionate production and income also increases.

The basic formula for physician compensation, whether in solo or group practice, is:

Net revenue – overhead costs (fixed, variable, and direct) = surgeon compensation

Equal Share Model

In an equal share model, the surgeon compensation is split equally among the shareholders. Table 6-2 illustrates how each surgeon receives identical compensation, despite different production levels. An equal share compensation model works well when providers have a similar range of production and do similar surgical procedures.

Production-Based Model

In a production-based model, compensation is based on the individual surgeon's collections and is useful if there are varied production levels. A potential disadvantage exists if there is competition for patient referrals within the same group.

Hybrid or Base-Plus Bonus Model

A base plus bonus model achieves a middle ground between the equal shares and production model(s). A base salary is established, which is not affected by production. It may be necessary to adjust the base from time to time to ensure that it is below the break-even point (B/E). In Table 6-3, the calculated B/E point is $50,000 in total monthly gross charges, and the amount by which each surgeon exceeds the base is bonus collections. A 50% overhead is illustrated in this example, which is allocated equally, and the predetermined base salary is $20,000 per month. The collection percentage for the practice month is 90% of gross charges. The overhead costs and the base salary are subtracted from the collected amount, which leaves $20,000 for bonuses. Distribution of the bonus is based on his or her production percentage of gross charges.

Compensation plans are not a governance tool, but a mechanism to equitably distribute the net revenue of the practice to the surgeons. Annual or semiannual reviews allow for adjustments. Modifiers to compensation can be added if there are additional duties that the individual surgeon carries out or lifestyle choices by some of the partners—for example, if they want to take more time off for family.

Collection Protocol

Patient financial policy and the associated counseling is the initial component of the collection protocol. As discussed in the revenue cycle section of this chapter, the practice's decision regarding what to collect at the initial visit (in a fee-for-service practice) is important in determining what will be "at risk." In practices that primarily participate with third-party payers, the decision is far less critical. The contract will determine the co-payment and subsequent reimbursement. The office policy needs to include a plan to manage delinquent payments. There are vendors that can externally act as collection agencies for the practice. There are state and federal guidelines pursuant to the collection of delinquent accounts.

TABLE 6-3 Hybrid or Base Plus Bonus Model

	Dr. X	Dr. Y	Dr. Z	Total
Gross charges	$62,500	$58,400	$56,100	$177,000
Amount exceeding B/E	$12,500	$8400	$6100	$27,000
Collection ratio	0.90	0.90	0.90	0.90
Cash collections	$56,250	$52,560	$50,490	$159,300
Percent of total gross charges	35%	33%	32%	100%
Overhead (50%)	$26,550	$26,550	$26,550	$79,300
Base salary	$20,000	$20,000	$20,000	$60,000
Amount available for bonus				$20,000
Bonus	$7000	$6600	$6400	$20,000

Summary

Management of an OMS practice can be challenging regardless of the number of surgeons, employees, or offices. It is improbable that one person can carry out all the aspects of business that are required each day. Surrounding oneself with an experienced team is the first step to success, but maintaining a daily active role will solidify the future. Taking CE opportunities to learn more about running a business and keeping up with the changes in the specialty will help the surgeon achieve a career that is rewarding both financially and in quality of life.

Risk Management in Oral and Maxillofacial Surgery

JAMES Q. SWIFT, OLOLADE I. MITCHELL

The purpose of this chapter is to provide the reader a general understanding of the concept of risk management as it relates to oral and maxillofacial surgery. Each reader should be able to identify some of the basic, more prominent, nonclinical risks associated with oral and maxillofacial surgery, and understand how proactive and reactive risk management can promote patient safety, minimize a surgeon's risk for legal prosecution and aid with his or her defense.

Clinical practice affects clinical outcomes. From the decision tree used to develop differential diagnoses to the development and execution of a treatment plan, the clinical decisions, surgical techniques, and treatment an oral and maxillofacial surgeon employs can greatly affect patient safety and determine if the surgeon can be defended in a court of law. The same is true for nonclinical practice decisions. Communication and documentation, two core risk management principles, have a significant impact on patient safety and can be the factor(s) that decide the disposition of a legal case, in some situations, regardless of the treatment outcome. Because of their importance, these two core principles are a focus of this chapter.

What Is Risk Management?

Performing oral and maxillofacial surgery, or any type of medical procedure, has inherent risk. According to Rattan and Tiernan, a risk is "the probability that a given hazardous event" such as a jaw fracture, nerve injury, or anesthesia complication "will occur, and that this event will have consequences" such as the need for further treatment, loss of normal daily function and sensation, or even, in rare cases, death.[1] Rattan and Tiernan describe consequences as those occurrences that "are deemed to be negative by some or all of those who are exposed to it" (i.e., the patient).[1] After first considering the pros and cons, namely the risks, benefits, and alternatives of treatment, each patient presents with personal fears, considerations, or concerns when they agree to proceed with oral and maxillofacial surgical care and/or sedation or general anesthesia. Consider the simple extraction of an erupted third molar with periodontal impact on an adjacent second molar as an example. Even in the best of hands, a patient can be exposed to a number of dreadful postoperative side effects that are not life-threatening and usually temporary (e.g., pain and swelling). The manner by which each patient reacts to these expected risks will be largely dependent on his or her own perception, past experiences, and understanding of the risk.

The spectrum of oral and maxillofacial surgery extends from simpler procedures, such as less invasive dentoalveolar surgical procedures, to very complex procedures such as invasive orthognathic and facial cosmetic surgery. This wide range of surgical procedures introduces varying degrees of risk. The fact of the matter is, adverse events are inevitable with oral and maxillofacial surgery. In the Institute of Medicine (IOM) publication *To Err Is Human: Building a Safer Health System*, the Quality of Healthcare Committee of the Institute of Medicine reported that although a vast majority of medical errors that occur are preventable, most medical errors are not the fault of brash (negligent) individuals or groups. Instead, the IOM found that most errors are the result of a broken system(s) and conditions that cultivate mistakes or fail to keep them from occurring. The report did not imply that health care providers and systems would not be held liable for irresponsible actions, nor did it suggest that providers should be negligent. The IOM finding was projected to create a foundation for the development of better health care systems—"systematically design safety into processes of care."[2]

Although risks are an inherent part of a surgical practice, some, because of their nature and extent, can and should be averted. Risk management is a process of risk mitigation that

has been defined over the years in many ways. According to Douglas Hubbard, "Risk management is the identification, assessment, and prioritization of risks followed by coordinated and economical application of resources to minimize, monitor, and control the probability and/or impact of unfortunate events."[3] In the world of finance, "Risk management refers to the practice of identifying potential risks in advance, analyzing them and taking precautionary steps to reduce/curb the risk."[4] In health care, risk management is a process of making and carrying out decisions that will assist in prevention of adverse consequences and minimize the adverse effects of accidental losses on an organization. Simply put, it is "the evaluation and monitoring of clinical practice to recognize and prevent patient injury."[5] The premise of risk management is patient safety, and the process of risk avoidance or mitigation is a key component in proactive risk management (claim prevention and claim mitigation) and reactive risk management (claim management).

Why Risk Management: Preventing and Mitigating Risk

The next two cases illustrate proactive risk management practices.

Case Example #1

In preparation for dentures, a 52-year-old man was referred to an oral and maxillofacial surgeon for removal of all of his remaining teeth. When he presented for evaluation and consultation, he reported no health problems, no previous surgeries, and no medication history. Informed consent was obtained for extraction of teeth #6, 11, 17-25, 27 and 30-32 under general anesthesia. That same day, in the surgeon's office, the extractions were performed without apparent complication. Recovery from general anesthesia was uneventful. Hemostasis and discharge criteria were achieved. The patient was discharged home with his wife. He was instructed to use gauze with pressure to control expected bleeding, call with any questions, and return to the office or go to a local emergency room if any problems arose. When the patient got home, he reportedly experienced "significant bleeding" and vomited "coffee ground" emesis. Subsequently, the patient's wife called the surgeon's office. She was informed by the office assistant that the patient's symptoms were normal and advised to elevate the patient's head. The next day, the emergency medical services (EMS) were activated and the patient was transported to a local emergency department (ED). The EMS providers recorded that the patient had "profuse bleeding from his gums" and "black emesis was noted on the wall next to his bed." In the ED, attempts were made to attain hemodynamic stability and hemorrhage control, but they were unsuccessful. The patient died the following morning, 2 days after the surgical extractions. The cause of death was identified as "hemorrhagic shock from tooth extractions." Chronic alcohol abuse was identified as a contributing factor.

A lawsuit was filed by the deceased's estate. The claims included an allegation of wrongful death against the oral and maxillofacial surgeon. Expert opinion was obtained by both the defense and the plaintiff. According to the expert for the oral and maxillofacial surgeon, the patient had preexisting liver disease that was not reported on the health history form. He opined that the decedent likely developed aggressive bleeding and eventual disseminating intravascular coagulopathy (DIC).

Although the defense had a plausible argument, significant challenges existed in the case, unrelated to the anesthetic and surgical care rendered. Review of the decedent's chart exposed illegible, scant, and incomplete chart notes that lacked thorough detail of the care and treatment rendered to the decedent. Preoperative radiographs identified that the majority of the teeth requiring extraction were periodontally compromised, but not bony impacted or likely to have required surgical removal. However, billing records for the procedure indicated coding for surgical extractions.

In the absence of the allegation of fraudulent billing and poor documentation, this claim would have been medically defensible. The billing issue, coupled with advice from the surgeon's private counsel, resulted in the case being settled at mediation.

Case Example #2

A 50-year-old man was referred for evaluation of a "nonrestorable" tooth #19 with extensive prior treatment. After a comprehensive oral exam, extraction and placement of an immediate implant at #19 was recommended. The risks, benefits, and alternatives were discussed with the patient, and a written informed consent delineating the procedure was obtained. A few days later, the patient returned and the procedure was completed. A postoperative radiograph of the surgical site revealed that the apical tip of the implant was positioned near the superior margin of the inferior alveolar nerve canal. On the basis of the radiographic finding, the surgeon elected to immediately withdraw the implant and reposition it coronally. The complication and treatment alternatives, addressing the complication, were well documented. A post-repositioning radiograph indicated successful coronal implant repositioning.

The patient called the office a few days later and reported that he was experiencing numbness in his lower lip and cheek. He was asked to return to the office. When the patient returned, neurosensory testing was conducted and documented. The test showed he had diminished sensation to the left lower lip (paresthesia). The patient was followed over the next several weeks and continued to have residual paresthesia with reported slight improvement. One month following the procedure, a referral to a micro-neurosurgeon for nerve repair evaluation was discussed, but the patient declined the referral. He continued to report improvement. All interactions with the patient were documented

thoroughly. Several months later, the patient went to another oral and maxillofacial surgeon with new complaints of dysesthesia in the left lower lip.

Shortly thereafter, the patient retained an attorney and brought suit against the initial oral and maxillofacial surgeon. He was seeking to recover economic damages for the costs of treatment, both past and future, as well as compensation for alleged pain and suffering. The patient suggested the initial implant was the wrong size, was not backed out far enough, and that additional diagnostic imaging should have been obtained before the procedure.

In this case, the oral and maxillofacial surgeon's documentation was excellent. Chart notes were timely, readable, and complete. A strong, supportive defense was obtained and a motion for early dismissal of the plaintiff's claim was requested. The motion was granted, despite rigorous opposition from the plaintiff.

Although the outcome for these two cases is different, each illustrates that preventative measures executed prior to an event (prevention) or before a patient's pursuit of legal action (mitigation) can greatly alter the disposition of the case. In Case Example #1, by no fault of his own, the oral and maxillofacial surgeon was not privy to the patient's significant comorbidity at the time of the surgical procedure. Hence, his decision to proceed with the operation was justifiable. According to the defense expert, the oral and maxillofacial surgeon performed a fairly routine procedure, and there was no reason why it should not have been done. The oral and maxillofacial surgeon evaluated the patient before proceeding with the case and he obtained informed consent, all of which are very important in practice. However, the oral and maxillofacial surgeon failed to maintain detailed records, and because of that, he essentially made the case difficult to defend.

In Case Example #2, along with maintaining excellent records, the oral and maxillofacial surgeon immediately responded to findings on the postoperative radiograph, performed a nerve function assessment, and monitored the patient's nerve function. He even offered and executed timely referral to a specialist for follow-up care. This surgeon's ability to request a motion for dismissal was directly correlated to his nonclinical practice and less to the adverse event.

Documentation

It cannot be overemphasized that a clear-cut pathway to proactively mitigate a potential claim is to maintain superlative records. Everyone is familiar with the adage "If it is not documented, it was not done." In a court of law, poor and incomplete documentation is considered the plaintiff attorney's best piece of artillery. Comprehensive clinical records are frequently the single largest deterrent to a claim.

An accurate and complete record serves many purposes. It contributes to the continuity of care, establishes whether or not the standard of care was met, improves the quality of care, and is the key to the defense of regulatory claim or a lawsuit. In Case Example #1, the lack of good records contributed to a settlement for an otherwise defensible case. There was limited documentation of the patient's medical and dental history, and inclusion of billing records in the clinical charting opened the defendant to a subsequent review of billing charges that were found to be questionable. In Case Example #2, record keeping was contemporaneous and complete. The patient's complaints, all reported symptoms, and testing were well memorialized within the chart. In this case, the record was the leverage used for the motion for dismissal.

Information about the patient's condition, the treatment rendered, and the rationale behind the treatment are the basic elements of a good record. A record should be organized as follows:

- **History & Physical:** The history of present illness, past medical/dental history, and the findings from the physical examination
- **Treatment Plan:** The determination of a need to treat with inclusion of treatment options and the associated risk and alternatives (including no treatment)
  - Clinical Examination & Differential Diagnosis
  - Informed Consent
- **The Procedure:** The details associated with the surgical procedure as well as the surgical outcome, including the determination that the discharge criteria have been satisfied
  - Time-Out
  - Anesthesia Record
  - Operative & Discharge Note
- **The Follow-up:** Subjective and objective postoperative findings with an explanation of any future surgical plans as applicable
  - Progress Note

Using this outline, the next section will explore the various components of the health record and identify some nonclinical practice considerations.

The History and Physical

All oral and maxillofacial surgeons should obtain and review a health history for every patient. In an office, oral and maxillofacial surgeons should use a health history form/questionnaire that is completed by the patient, before evaluation and treatment. When delivering acute care in a hospital setting, a patient's medical history is usually obtained during the initial history and physical (H&P) examination. Oral and maxillofacial surgeons treating patients in an operating room or surgical suite in a health care facility should use the health history form/questionnaire contained in or referenced to in the admission H&P.

Irrespective of the approach used to obtain a patient's health history, the elements, including the history of present illness and past medical/dental history, should be comprehensive. An oral and maxillofacial surgeon should use the health history form/questionnaire, for example, in addition to having an in-depth conversation with the patient. A patient's current health condition and health

history has the potential to affect the decisions made in an operating room during a surgical procedure. Envision the patient who has massive cardiopulmonary issues but omits checking the questionnaire box related to lung disease. A discussion or review of a patient's respiratory effort and cardiovascular reserve, triggered by the health history form/questionnaire and confirmed by the review, for example, can assist with assessing the patient's fitness to undergo surgery. If a patient or family member fills out the office health history form/questionnaire, it should be reviewed for completeness. Before treatment, the surgeon and/or his or her clinical staff should sign the form/questionnaire to confirm it was reviewed. Alternatively, if an H&P is used and it is obtained from a medical colleague or other qualified health care provider, the H&P should be based on both subjective and objective findings and reviewed by the treating oral and maxillofacial surgeon. Having a complete health history will ultimately increase patient safety.

The health history form/questionnaire should include all major medical conditions and medications pertinent to treatment, including herbals, vitamins, birth control medications, medical marijuana, daily aspirin and other anticoagulants, as well as bisphosphonates and other antiresorptive/antiangiogenic medications. When classifying temporomandibular joint (TMJ) disorders, be sure to include descriptors of TMJ symptoms (painful clicking/popping of the jaw joint) on the form. TMJ-related diseases and symptoms, although rare, can be quite costly if the patient suffers from them. It is not unheard of for an oral and maxillofacial surgeon to be accused of causing TMJ symptoms only to later find out this was a preexisting condition. Documenting this preexisting problem can save an oral and maxillofacial surgeon from a potential malpractice claim. In addition to the medical conditions and medications, consider including a comment section for items that may not be on the form, but may be relevant. This will provide the patient an area to describe any additional items directly on the form. In general, the health history form/questionnaire should be reviewed for relevancy annually, and any patient being seen for repeated visits should have his or her health history form/questionnaire updated at each visit.

Treatment Plan: Clinical Examination and Differential Diagnosis

During claim-related reviews of a health record, it is often noted that the oral and maxillofacial surgeon's thought process to a final diagnosis or "differential diagnosis" is omitted. A differential diagnosis, characterization of a particular condition from other conditions that present with similar symptomology, can often be the only manner in which an oral and maxillofacial surgeon can diagnose a specific disease or at least eliminate more life-threatening ones. Documentation of this speculation (i.e., infectious lesion vs. cancerous lesion) to support the course of action taken (i.e., prescribe antibiotics vs. biopsy) may be the difference in successfully defending a failure-to-diagnose claim.

All oral and maxillofacial surgical procedures should be performed in accordance with or in response to a provisional diagnosis made by the surgeon. This diagnosis should be a designation of the pathologic entity that is to be managed. For example, a description of the potential pathologic site (i.e., impacted third molar) is not a diagnosis but rather a clinical observation. Non-restorable carious lesion or periodontal disease on the distal aspect of a second molar adjacent to a partially erupted third molar is a diagnosis of pathology for which surgery may be recommended or necessary.

Let's look at another example. A patient presents to an office with a nonpainful swelling on the roof of his mouth, adjacent to a fractured tooth. The oral and maxillofacial surgeon quickly identifies that the swelling could be an infection or a neoplasm. The oral and maxillofacial surgeon realizes the seriousness of the possible diagnoses and the anatomic location, and documents exactly how he plans to treat the swelling (i.e., antibiotics and continued observation) and how he will manage follow-up (i.e., regularly scheduled visits). He also adds the alternative courses of treatment he plans to offer the patient (i.e., biopsy), if the treatment fails to resolve the swelling. When the patient returns for follow-up, if the lesion is larger, more painful, or both, the oral and maxillofacial surgeon may decide to biopsy versus continued structured and regular observation. Alternatively, he may refer the patient to a colleague or health care provider who has expertise in the management of oral and maxillofacial pathology. Documenting the differential diagnosis makes the process clean and concise, allowing the surgeon to update the status of the patient at future visits and determine any need or indication for an alternate course of therapy.

A differential diagnosis is a well-thought-out guide. It may be information that, when provided to a subsequent doctor, can hasten the process of determining the accurate diagnosis—but only if it is well documented. Think of it as documentation that any other oral and maxillofacial surgeon can pick up and read and fully understand what was done and why it was done. Adding diagrams and photographs may be helpful to demonstrate the differential diagnoses and validate the thought process that led to the ultimate diagnosis and treatment.

Treatment Plan: Informed Consent

Many oral and maxillofacial surgeons are aware of the need for an informed consent form, but they do not always recognize that the consent process does not begin and end with a signature on a paper or electronic device. True informed consent is initiated with a discussion between the oral and maxillofacial surgeon performing the surgical procedure and the patient. This discussion gives the oral and maxillofacial surgeon an opportunity to explain the pros and cons of surgical treatment to the patient so he or she can consider the options and make an informed decision. Think about the last time you saw a prescription drug commercial on TV. At the very end, the pharmaceutical company rattles off all the risks and potential complications

associated with the specific drug. So in addition to the words that appear on the TV screen, the pharmaceutical company supplies its consumers with verbal information they believe to be necessary to make a choice. Could a patient make an informed decision with only information flying across the TV screen? Prescription drug commercials are only part of the patient education process. In addition to this, patients are instructed to use their local pharmacists and receive careful instructions from the providers who prescribed the medication, but imagine the potential consequence if they were not.

Following the conversation, consider noting the discussion in the patient's record. Documentation of the informed consent discussion in the record serves to verify that the conversation took place. This chart entry bolsters the strength of the informed consent form and serves as a "second" documentation that connects the form to the patient and the office visit. If an adverse event results in litigation, patients will sometimes claim they did not read or understand the consent form, and therefore did not know about the possible complications of the procedure. Documenting the discussion in the record gives great credence to the oral and maxillofacial surgeon, who may not recall the specific conversation but can testify that the conversation took place. Consider using a phrase like this:

> *Confirmed procedure with [patient]. [Patient] identified [Tooth # or Teeth #] need to be extracted. Discussed with the above named patient the risks, intended benefits, and alternatives of this procedure (including no treatment), obtained verbal consent and signature. [Patient] had a chance to ask questions in my presence. [Patient] voices an understanding of and accepts treatment.*

This note may also prevent plaintiff's attorneys from separating the informed consent form from the remainder of the patient's record. In a number of states (i.e., Florida, Oregon, and Virginia), the courts have barred the presentation of the written informed consent form to the jury if the plaintiff has not alleged a lack of informed consent in the complaint. In these and other types of cases, the court will rule the informed consent document is not relevant, therefore allowing a plaintiff's attorney to prevent the jury from learning that the patient was advised about the risks or known complications. This is an even stronger reason for memorializing the informed consent discussion in addition to having the patient sign the informed consent form. It will ensure there is additional evidence that the patient was aware of the possibility of known complications.

In addition, some courts may not allow the written informed consent form to be introduced into a case if it was signed before the consent discussion. To ensure that the consent process is executed correctly, the discussion must take place before the patient or legal guardian signs the written consent form. The entire informed consent process must be executed before the surgical procedure is initiated, which includes induction of anesthesia and/or administration of a relaxant or sedative medication. The written informed consent form is not valid if it was signed when the patient was not of sound mind and judgment as a result of receiving a sedative. Consider those patients who are asked to come to the office the day of surgery after self-administering a prescribed opioid. The consent process should precede the diminution of mental function associated with opioid analgesics.

The performance of oral and maxillofacial surgery has some basic, less severe risks, such as those associated with any surgical procedure (i.e., pain, swelling, infection), but it also has some unique and more severe risks (i.e., paresthesia, anesthesia, osteomyelitis, or death). Let's look at a third molar extraction as an example. According to Brauer and colleagues, the frequency of complications from third molar extractions range from 2.6% to 30.9%.[6] The removal of teeth #1, 16, 17, and 32 can result in temporary or permanent inferior alveolar (0.3%) or lingual (<0.4%) nerve injury, immediate or late fracture of the mandible, unusual inflammatory processes and abscess formation, and displacement of the third molar or an instrument.[6] The informed consent discussion and associated form for a third molar extraction should identify these known material risks and should attempt to spell out the risks in layperson's terms (i.e., loss of feeling to the tongue). Informing a patient of all possible risks is impossible. An oral and maxillofacial surgeon is required to inform his or her patients of all those complications that another reasonably sound oral and maxillofacial surgeon would consider essential to making an educated decision to proceed with a procedure.

Not identifying a well-known potential complication on a written informed consent form or during the discussion could compromise the defensibility of a claim. Here's an example of this: An oral and maxillofacial surgeon obtains written consent from a patient and explains the possible risk of nerve injury. The patient, who signed the consent, later claims he was aware that the surgery could result in nerve injury, but alleges that he was not aware that the nerve injury may result in a permanent loss of taste (a very rare complication that can accompany a lingual nerve injury). In this example, loss of taste was not discussed or delineated on the consent form as a risk. A plaintiff's attorney would be able to prove that a reasonable person would have refused to undergo surgery if they knew that there was a potential for loss of taste. In addition to specifying well-known potential risks, both the consent discussion and form should describe the benefits of and alternatives to treatment. Remember, a valid treatment alternative is no treatment at all.

Two additional relevant aspects of informed consent are consent in an emergency situation and consent for patient refusal. When an oral and maxillofacial surgeon is faced with an urgent situation, where a patient presents (most likely in a hospital setting) and he or she is unable to consent and there is no power of attorney available, the oral and maxillofacial surgeon is required to use

his or her best professional judgment to proceed or not proceed with potential life-sustaining treatment without "consent." On the other hand, a patient who presents in an urgent situation, but is of sound mind, has the right to consent to or refuse recommended treatment. If a patient chooses to refuse treatment, it is extremely important that he or she be fully aware of the risks associated with this refusal.

Patients who are not lucid cannot refuse to receive *emergency care* and treatment, but the effort to support the clinical decision of "bad judgment" on the patient's part requires evaluation by a licensed psychiatrist, a process that is onerous at best. Treating contrary to a patient's wish should not be managed in an office setting, but may be necessary in a hospital setting where a patient might present with facial trauma and refuse emergency care. To support the informed refusal discussion, an oral and maxillofacial surgeon may choose to request the patient sign an informed refusal form. Patients may or may not agree to sign the informed refusal form, so there should be corresponding documentation to support the discussion in the patient's health record.

The Procedure: Time-Out

Many oral and maxillofacial surgeons perform a surgical time-out before proceeding with surgical procedures. This practice, if performed accurately, has the potential to prevent errors such as wrong-site tooth extractions or anesthetizing a patient who failed to remain NPO (refrain from eating and drinking) overnight. The time-out procedure requires the surgeon and his/her staff to address the basic preoperative necessities, preventing the surgical team from cutting corners. Just as important as it is to perform a time-out, it is equally as important to document that the surgical time-out was done. Document the process by using a Time-Out Checklist. This communication tool will employ a system of checks and balances and will ensure patient safety before any procedure, holding the entire surgical team accountable for every patient's individualized care.

The Procedure: Anesthesia Record

If a claim arises and there is an anesthesia component, the oral and maxillofacial surgeon's office records will be compared to a hospital anesthesia record. Brief and insufficient notes about the anesthesia or sedation used during a procedure are difficult to defend. An anesthesia record with a timed log that incorporates the patient's vital signs (including capnography and pulse oximetry), the type, amount, and time of medication administered, and the patient safety measures employed clearly demonstrates how the procedure progressed. In addition, an anesthesia record should include verification that a signed consent form is on file, the patient's pre-sedation ASA classification (I-V), body mass index (BMI), Mallampati Assessment score, cervical mobility, any limitation of mobility of the mandible that may complicate direct laryngoscopy, denial of pregnancy, and the patient's NPO status. In the midst of a busy day, having another documented trigger (in addition to the time-out) that evaluates the appropriateness for anesthesia or sedation promotes patient safety. This information will be important to have if the care comes into question in the case of an adverse outcome.

The Procedure: Operative and Discharge Notes

For a surgeon, the need to document the surgical details (i.e., type of instruments used, incision, surgical access, ostectomy employed, number of teeth removed, the condition of the teeth, etc.) of an operation is eminent. Less eminent, though, may be the need to accurately reflect what was done in the operatory as well as the patient's disposition. If a procedure was complicated or an unusual finding was identified and a change in the original treatment plan occurred, the operative note should explain that. Likewise, the condition in which the patient left the operatory and the office should also be detailed in a discharge note. It is important to document that the discharge criterion were met. Postoperative instructions are regularly given, but are not always followed by patients (i.e., the need for an escort and 24-hour postop care). The oral and maxillofacial surgeon cannot control what occurs when the patient leaves the office, but he or she can document what postoperative instructions were given and the name of the patient's escort. Whether and when the patient is scheduled for a return appointment should also be documented.

When documenting postoperative findings and discharge instructions, be wary of doing so in advance. Employees with good intentions, in an effort to save time, may complete the discharge note before the patient's actual discharge. If an emergency or a complication arose and the patient's record was out of sequence, it would appear careless when presented in the courtroom and would be hard to defend.

The Follow-Up: Progress Note

The SOAP (*S*ubjective *O*bjective *A*ssessment *P*lan) format is one documentation style well-known to oral and maxillofacial surgeons. When this format is used as an outline for the progress note, it is easy for any reviewer or other treating provider to assess the patient's condition, diagnosis, and plan for future care. The SOAP format allows a quick overview of the patient's clinical course to determine what has been and what still needs to be done. Outlining the progress note in the SOAP format will also help to ensure that the note contains only clinical information. All administrative information, including insurance and billing, should be maintained in the nonclinical part of the chart. The only exception is if the information will directly affect care. For instance, if a patient refuses or wishes to delay recommended care and treatment because of a lack of funds or insurance, noting this in the progress notes is pertinent to the care of the patient. If a claim for failure to treat were to occur, this documentation could explain why the treatment was not performed or was performed later.

Document a patient's status update at each and every visit. Most patients come to the oral and maxillofacial surgeon's office with a problem or concern, and documentation in the

chart usually reflects that primary complaint. However, when the condition or pain resolves, the subsequent resolution is often times omitted. For example, if a patient presented with pain to the lower right mandible and that pain resolved, but a new onset of pain to the left upper maxillary is reported, both should be documented. The patient may have selective memory and forget that the original issue was resolved. If that same patient claims that the oral and maxillofacial surgeon never did anything about his/her condition, a note such as, "I don't have pain anymore" will clearly refute the patient's claim. Similarly, if a referring specialist is treating the patient, he or she would be able to discern if the patient's issue is resolving or getting worse.

When composing a progress note, remember that patients and subsequent treating providers can access these records. If records are requested for legal purposes, an additional host of other people (i.e., attorneys) will also be able to access them. Imagine your record magnified on a courtroom screen. What is the jury going to see? What about the judge? All documentation in the health record should be composed in an objective manner. In most cases, this is not a difficult task, but documentation of disgruntled or difficult patients can make documenting objectively more challenging. For example, composing effective objective notes that demonstrate the patient's anger by using the patient's quote (i.e., patient screamed "expletive" and hung up) is a useful tool. This can reflect the situation without having to describe it with opinion and without personalization.

With the development of templates, in both paper and electronic form, new documentation issues have arisen. It is easier to enter or select incorrect information or omit pertinent information. Distinct from the paper templates, electronic templates are often pre-populated with the most common answers, clinical findings, etc. Using templates saves time and adds efficiency to charting, but if the oral and maxillofacial surgeon is not diligent in ensuring that the preselected information is accurate for the patient of record, documentation errors can occur. Errors in documentation can lead to serious patient safety issues, especially if follow-up care is needed. When creating a template, be sure it can be tailored to an individual patient. When completing it, pay careful attention to the selected responses.

The copy and paste function and the use of charting by exception are additional charting nuances that have added to the complexity of record keeping.[7] Here is an example that resulted in a pre-trial settlement: An oral and maxillofacial surgeon with a busy practice found himself reliant on the copy and paste functionality of a patient's operative record. After receiving a Summons and Complaint with a request for health records of two unhappy patients, he quickly copied and pasted the surgical procedure from one patient's chart to another. He failed to customize the notes and was later found to have unreliable documentation in both patients' records as a result of identical notes. Charting by exception, an additional charting nuance, or identifying conditions as "within normal limits" has the potential to omit necessary patient-specific conditions as well.[7] Be extra cautious when using these features in clinical charting.

The health record has evolved over time. In the past, all notes were maintained in a manila folder or colored binder and formulated on paper. With a desire to achieve contemporaneous documentation, templates and eventually the electronic medical record were developed as tools to make charting more efficient. Time constraints remain a huge factor in achieving contemporaneous documentation. For most surgeons, keyboarding takes more time than dictating, writing, or transcribing notes. Because we tend to forget a large portion of information we receive almost instantly, it is good practice to document concurrently. Document the progress note immediately after the treatment is rendered to ensure that nothing is inadvertently left out. If necessary, revisit the note to add any additional thoughts in an addendum. Adhering to this practice standard can be beneficial, especially in cases where a patient might be operated on by one oral and maxillofacial surgeon, but followed up by another. This is also an important practice to adhere to when documenting electronically, because of the significance of "metadata." Metadata "allows no ambiguity with a chart."[7] It is "the data on data entry and no computer is exempt from it," nor is it exempt from discovery.[7] In general, all entries are time stamped, but if there is concern of "fictitious, self-serving" entries in the record, metadata can be subpoenaed. However, unlike the paper record, there is no uncertainty as to the findings. Here's an example: A nurse states that she took a patient's blood pressure at 8 PM, but by way of metadata she was found to be in another part of the hospital at that time.

Noncompliance

Noncompliance is another important element of documentation that should be included in the health record. Even though it may not apply to all patients, the issue is important enough to warrant some discussion. The scenario presented earlier in Case Example #2 demonstrated how a lack of patient compliance can cause problems. The patient developed paresthesia and was referred for follow-up with a micro-neurosurgeon, but refused to be evaluated. A general thought may be that when a patient chooses to be noncompliant with recommendations, he or she should be responsible for any problems that might arise from his or her noncompliance. However, this is not always the case. Often, patients and their attorneys try to shift the responsibility to the doctor. As explained in the informed consent/refusal section, it is imperative that an informed discussion with the patient of the consequences of noncompliance be demonstrated in the record. If the issue related to noncompliance is more of a refusal to stop an activity such as smoking, it is also important to address it and document all steps taken at each visit ("patient states still smoking, warned to stop and suggested a nicotine patch"). An oral and maxillofacial surgeon should use his or her judgment to determine when the discussions and recommendations become futile and consider sending a notice of noncompliance letter.

A notice of noncompliance letter is a letter addressed to the patient that spells out the recommended care or treatment along with the frank consequences of noncompliant behavior. An oral and maxillofacial surgeon's genuine concern about the patient's care should also be mentioned in the letter. If the patient fails to follow the advice, the oral and maxillofacial surgeon may choose to dismiss the patient from the practice. It is important to apply focused professional judgment when considering when to stop treating a noncompliant patient. To prevent claims alleging patient abandonment, patient dismissal should be initiated at a good stopping point in a treatment plan, and a letter of dismissal should be sent. This letter should include the reason for dismissal, a notice of intent to provide emergency treatment for a minimum of 30 days, a referral source to find another oral and maxillofacial surgeon, an offer to transfer records to another provider and/or the patient, and an Authorization for Release of Medical Records form. Both the notice of noncompliance letter and the dismissal letter should be sent via certified and regular mail with a return receipt request. Consider state regulations to determine state-specific requirements and consult with local dental societies for guidelines.

Record Altering

A health record entry should *never be altered*. Altered records make a claim indefensible and can shatter an oral and maxillofacial surgeon's credibility, leading to a claim of spoliation, a criminal offense. In addition, juries can award amounts above the various limits set by state laws for personal injury cases, if a record is found to be altered. If there is a need to edit a paper record entry that is written in error, make use of the single-line strikethrough and date and initial the change. Perform the authorized technique used by the specific electronic health record program for editing errors in the electronic record. Some electronic health records save all versions of a note after an edit is done, ensuring that the original entry can still be retrieved even if it is "deleted." Contact the IT specialist or program developer used at your office for specific instructions.

Communication

Poor communication is one of the main reasons patients file lawsuits. Studies show that roughly 80% of all malpractice claims contain some component of failure to communicate, including a lack of interpersonal skills from the doctor.[8] Communication, both verbal and nonverbal, has the power to affect the disposition of a claim. When communicating with a patient, a surgeon must consider the tone, the posture, the facial expression, and the body language that is shown. Is the patient upset? What are his or her nonverbal cues? Statistically speaking, only 8% of our day-to-day communication is accomplished verbally. The other 92% is expressed through facial and other nonverbal cues.[9] Remember the saying, "You attract more bees with honey than you do with vinegar"? The same can be said for patients. Treating patients with empathy should be a foregone conclusion, but frequently this is not the case. "Treat[ing] others [your patients] as you would want to be treated" can make for a rewarding practice and a rewarding life. Patients who like their surgeon(s) are less likely to take them to court. Consider the use of empathetic gestures and remarks during conversations even in the midst of a good outcome. Dr. Jerome Groopman, author of the *New York Times* bestseller *How Doctors Think* (2007), said that patients are interrupted by their doctors within the first 18 seconds of a conversation.[10] Although there are probably time constraints within an office setting that makes being fully engaged and participating in a two-way conversation difficult, the use of active listening skills can save time on the back end. That time pales in comparison to the time it takes to get through a lawsuit that drags on for 3 or 4 years.

Employing good communication skills is most helpful when the communicator knows his audience. After an initial meeting with a patient, gauge his or her level of interest, educational capacity, and what they already know about the treatment. Explain and educate patients about their procedures in a way they understand, breaking it down as appropriate. Consider that "one in five American adults read at a fifth grade level or below and that the average American reads at an eighth and ninth grade level."[11] Poor understanding of the planned procedure can easily result in lack of compliance and dissatisfaction with the results. Be clear about expectations. Remember that technology has greatly affected the delivery of care. The patient may have accessed a wealth of information on the Internet before arriving at your office, but may not have a thorough understanding of the procedure, anticipated outcome and associated risks.

Technological advances to obtain medical information are growing at or faster than the pace that medicine is evolving. A new generation of patients is arising. "Today's patients are less likely to take what a physician tells them at face value, and often come to appointments armed with a self-diagnosis backed up by information they obtain from WebMD and Google."[12] According to Bendix and colleagues, "nearly 60% of patients are considered online diagnosers."[12] Although the idea of having knowledgeable patients is intriguing, the notion does pose its own potential problems. Treating these new-age patients requires a new mindset as it relates to the hierarchical nature of medicine, with the physician at the top and the patient at the bottom. Bendix suggested that although "Dr. Google" is widely consulted, an astounding percentage of patients are now informing their treating doctors about what they have read before they consider their options.[12]

Communication guidelines within a practice setting can also be beneficial. Consider an example where a developing infection went undetected because of a lack of communication between an office assistant and the oral and maxillofacial surgeon. In this example, the defense was complicated because the evidence showed that the patient

made several phone calls to the office after third molar extractions, but was never asked to come in to be evaluated. During the discovery phase of the claim, the depositions turned into a "he said–she said" blame game, which resulted in questions regarding the oral and maxillofacial surgeon's credibility. Questionable credibility in the midst of a claim can make the case difficult to defend. The person who answers the phone in the office has a great deal of responsibility. Does he or she have the qualifications to manage the office calls? Is there a protocol for calls received postoperatively? Is there a chain of command established? Staff training and office-based policies and protocols that establish communication guidelines are critical to delivering consistent and timely care, supporting patient safety. The time to train is before an untoward event occurs.

Another important issue that involves communication is patient referral. In the nerve injury case discussed earlier, the patient was appropriately referred to a micro-neurosurgeon a month after the oral and maxillofacial surgeon noted that the paresthesia was not fully resolved. Determining the best time to refer a patient to a specialist can be dependent on the reason for referral, the mechanism of the injury, patient-specific factors, and the comfort level of the oral and maxillofacial surgeon. Recommendations for the proper referral process have been published in the literature. According to Alhassani and AlGhamdi, referral to a micro-neurosurgeon is indicated within 2 months of failed improvement.[13] Alhassani and AlGhamdi added, "early referral will allow for early management before distant degeneration of the nerve takes place."[13] On average, degeneration of the nerve was found to occur about 4 to 6 months after the nerve injury. Renton suggests immediate referral for endodontic, implant, and third molar–related nerve injuries to ensure that lingual nerve exploration occurs before 12 weeks.[14] It is important that an oral and maxillofacial surgeon be aware of the research related to referrals to ensure compliance with the standard of care. Knowledge of the practices employed by other reputable oral and maxillofacial surgeons and decisions based on theory can be supported in a lawsuit.

Anesthesia/Emergency Preparedness

Proactive risk management is not a task that can be executed alone. Oral and maxillofacial surgeons practice in many different arenas (office, hospital, group practice, solo practice) with an array of clinical and nonclinical staff. Practicing in an environment with additional personnel only adds to the complexity of the profession. The precautions necessary to ensure that everyone is prepared to act or react in a given situation are the responsibility of the oral and maxillofacial surgeon.

Consider this example: A 21-year-old patient presents for third molar extractions following a previous consult visit. The patient develops respiratory distress after receiving anesthetic medications (midazolam, fentanyl, ketamine, lidocaine, and propofol). The respiratory distress develops into an airway obstruction, and attempts to maintain the airway are futile. The patient becomes bradycardic. He eventually goes into cardiopulmonary arrest and dies shortly after being transferred to a local emergency room. Review of the in-office emergency care revealed that the resuscitative efforts performed were substandard. The bag valve mask was nonfunctional, so positive pressure oxygen could not be provided. It was opined that the administered emergency medication, two sub-intubating doses of succinylcholine, contributed to the bradycardia. According to the EMS providers, the office staff was not prepared to manage the emergency. It was alleged that the emergency response failed to prevent the cardiopulmonary arrest and the eventual demise of the patient. The patient's family pursued legal action. Discovery (disclosure of facts and documents) in this case resulted in findings that demonstrated negligence (failure to exercise proper care resulting in injury) on behalf of the oral and maxillofacial surgeon and his staff. In addition to the staff being ill prepared, the equipment was damaged and nonfunctional. The case was deemed indefensible and was settled before trial.

Anesthesia complications in-office can be difficult to manage, but the fact is, the surgeon is ultimately responsible for the patient's well-being. In 2014, the American Association of Oral and Maxillofacial Surgeons (AAOMS) mandated that all surgeons begin using capnography as one more failsafe to promote a "culture of safety" in anesthesia delivery whenever possible. For complicated cases, CRNAs and dental anesthesiologists may be a useful asset for in-office anesthesia as well. Patients in need of oral and maxillofacial surgery may also be referred to treatment in a hospital setting, where an anesthesiologist will be responsible for the anesthetic management of the patient.

Regardless, it is essential to establish emergency preparedness before attempting to sedate or anesthetize any patient. The oral and maxillofacial surgeon and anesthesia team must understand the risks every patient presents with and deliver the appropriate anesthesia. Some surgeons believe moderate to deep sedation should not be performed in the office if the surgeon does not think he/she can get the patient intubated in the office. All in all, as an oral and maxillofacial surgeon, you must be honest with yourself and your patients, especially when their lives are at stake.

As for emergency equipment, check the equipment for functionality and ensure that backup equipment is available. If you are treating and anesthetizing pediatric patients in your practice, be sure to have the proper and necessary equipment to resuscitate a pediatric patient. Create a schedule of emergency training for the office staff, and challenge them to be accomplished at all tasks. Practice makes perfect. Because emergencies do not happen often, regular training is essential. If and when an emergency does occur, have a designated staff member document all treatments given and the time of delivery.

This will help the EMS and emergency department staff, who may be subsequent treating clinicians, understand the treatment already provided, and show the surgeon's expertise in treating emergencies.

Failure to Diagnose

Just as important, OMS National Insurance Company, RRG (OMSNIC) claims that experience indicates that failure-to-diagnose cases commonly involve a delay in the diagnosis of cancer, infection and/or osteomyelitis, and jaw fractures. Although only a small percentage of all claims, failure to diagnose accounts for over $30 million in indemnity and expense payments combined, since the inception of the company. Failure to diagnose is another area where interoffice collaboration is essential to reducing the number of claims.

Some failure-to-diagnose claims are the direct result of a lost or undelivered pathology specimen. This can happen for a number of reasons, one of which is that the pathology specimen was lost in the mail. A lost biopsy specimen can be disastrous. Therefore, it is a good idea to send every pathology specimen by a mail service where the package can be tracked (e.g., UPS, Fed Ex, USPS Express Mail). Be sure that all packages are securely wrapped and protected so that the specimen itself cannot fall out and be lost.

Lost or ignored pathology reports have also been the source of claims related to failure to diagnose. There are incidents where the pathology report was lost in the mail, sent to another doctor with the same name, or just not sent out at all. Consider using a laboratory log to track biopsy specimens and perhaps combining it with tracking of other items such as surgical guides. Having one place to look for items sent out will make it easier to keep track of them. Once a biopsy report comes in, the oral and maxillofacial surgeon should review it before it is filed. This will help ensure that a patient is not left waiting for a report that never comes. If the patient was referred for treatment, send a copy of the report with your assessment to the referring dentist or other practitioner.

Why Risk Management: Managing Risk

Now let's switch gears. Imagine you just finished seeing your last patient of the day. The office is quiet, and you can faintly hear some of your staff saying "goodbye" and "goodnight" as you slowly close your office door. You take a seat behind your office desk and pick up a handful of mail. You have seasoned and responsible staff. Your primary administrative staff places all your mail in your office inbox and tags them green, yellow, and red for "routine," "important," and "urgent." For the first time in weeks, you have an "urgent" document. You assume it's an urgent lab result, but you notice the letterhead reads "The Law Office of Johnson & Johnson." You realize you're reading your first legal claim letter. The attorney who authored the letter is informing you that all communications regarding your patient, who you thought was simply lost to follow-up, must now go through him. What do you do?

Professional Liability Insurance

Medical professional liability insurance or malpractice insurance provides coverage that protects health care providers from bearing the full cost of a defense related to a demand for compensation or claim of negligence or intentional harmful treatment decisions. This type of insurance coverage helps transfer some or all of the associated risks, which can be significant. Malpractice insurance does not cover criminal charges or punitive damages, but any reputable professional liability carrier typically provides (1) a robust defense for claims, grievances, and/or requests for compensation that are not yet lawsuits; (2) the associated costs of defense and monetary damages; (3) a competent defense against complaints filed with the department of professional regulation or board of dentistry/medicine; and (4) risk management education. Nearly all states require that physicians have liability insurance.[15] Most, if not all hospitals require proof of coverage in order to maintain hospital privileges. Although some physicians decide to take the risk and practice without coverage ("go bare"), they are the exceptions.[15] In a litigious society, where nearly 1 in 10 oral and maxillofacial surgeons may face a claim each year, why risk it?

When purchasing insurance, often the primary focus is cost. Although important, price should not be the only consideration. Imagine selecting a dental school or residency program simply because it is the cheapest. Other factors, such as the program's reputation, the quality of faculty, your "fit" with other students and residents, should also be considered. The same process should be considered when choosing a malpractice insurance carrier. How much does the carrier know about the oral and maxillofacial specialty?

Claims Data

According to data collected by OMSNIC, over the past decade, the frequency of claims filed against oral and maxillofacial surgeons has remained stable, but the amount of indemnity payments has risen substantially. The number of significant indemnity payments has increased, and a jury no longer considers $1 million to be a large award. With attorney fees consistently rising, defense expenses have also increased at a steady rate. By the end of 2013, OMSNIC researched and closed over 11,000 claims. Of these closed claims, approximately 71% were related to dentoalveolar surgery, 10% were related to dental implants, and 6% or less were related to orthognathic surgical procedures, TMJ surgery, maxillofacial trauma, and facial cosmetic surgery. It's no surprise that dentoalveolar surgery, the procedures that are performed most often by an oral and maxillofacial surgeon, accounted for the majority of the claims and

indemnity payments. TMJ-related procedures accounted for the second largest number of claims and indemnity payments. Dental implants and orthognathic surgery claims closely followed TMJ surgery, leaving maxillofacial trauma and facial cosmetic procedures with the fewest number of claims.

Of all the indemnity and defense costs paid out since the inception of the company, many were related to nerve injury. Malpractice claims ranked by percentage of indemnity and defense expense are nerve injury, improper performance of surgery, wrong tooth extraction, failure to diagnose, infection, and office or hospital death. It should be noted that wrong tooth extraction continues to be a common claim. However, our research tells us that most cases could have been avoided since they may be caused by both diagnostic and communication failures, specifically those between the referring dentist and the oral and maxillofacial surgeon. Even if a referral is incorrect, the oral and maxillofacial surgeon may be held responsible for extracting the wrong tooth. The cost to resolve lawsuits is significant, and it is certainly more expensive than any sum associated with taking the steps to avoid them in the first place.

The Tripartite

To better understand how reactive risk management can help improve care and benefit the bottom line, let's first outline the relationship between risk managers, claims professionals, and defense attorneys, a modern-day tripartite affiliation. This (tripartite) collaboration promotes risk mitigation, reduces litigation costs, and, essentially, improves the delivery of oral and maxillofacial surgery. When a lawsuit is filed against an oral and maxillofacial surgeon, the defense attorney is the lawyer who defends the allegations made against the surgeon. The claims professional is the professional liability insurance company representative who works alongside the defense attorney overseeing the claims file, producing reports, and performing additional litigation-related duties. The risk manager is the company professional behind the scene who dissects the case to identify its risks and uses the case-specific strengths and weaknesses to deliver oral and maxillofacial surgeon focused education.[16] In the hospital setting, the roles of a risk manager and a claims professional might overlap. The claims professional handles pre-litigation suits, but the risk manager is the first responder for all reported incidents. Often, in a hospital setting, the risk manager initiates the contact with the provider and interviews all of the parties involved in the case, prepares the report, manages the file, and hands it over to the claims professional if or when an actual claim is filed.

Regardless of the setting, failure to report the incident or claim to the appropriate party within a reasonable time frame could jeopardize the possible resolution of the claim and lead to the plaintiff (the patient) filing a lawsuit. As a general rule of thumb, one should contact their professional liability insurance carrier or hospital legal department immediately when there is:

- Death of a patient during or after treatment under any circumstances,
- Request(s) for release of medical records,
- Legal action against a colleague involving a patient you have treated,
- Receipt of a subpoena or suit papers,
- Contact by an attorney, peer reviewer, licensing agency or state dental board,
- Request for compensation or refund from a patient, or
- Any incident, adverse event or patient complaint that may later turn into a claim or suit.

Doing so can only benefit the results of a case.

The Incident versus the Claim

An incident is considered an adverse event or bodily injury that is believed to have the potential to result in a demand for money or services as compensation. A claim is a demand for money or services as compensation or reimbursement for a loss or bodily injury alleged to be the result of alleged negligence. Claims are typically initiated with a demand (i.e., request for compensation) made directly to the provider (the surgeon). The demand often alleges that an injury (i.e., nerve damage or death of a patient) was caused by an act or omission that fell below the standard of care (medical malpractice). Standard of care is generally defined as the level and type of care that a reasonably competent and skilled health care professional with a similar background would provide. As a medical specialist, the oral and maxillofacial surgeon's standard of care is defined by the care and treatment delivered by other oral and maxillofacial surgeons across the country who serve as expert witnesses. After the demand is made by the claimant, the oral and maxillofacial surgeon immediately reports it to his or her medical professional liability insurance carrier or hospital legal department, and a claim file is opened. The claims professional will then contact the claimant's attorney and commence an investigation.

During the claim phase, a monetary demand for damages and other appropriate compensation is typically made by the claimant. A claim may be resolved by means of a negotiated settlement or a denial. In some instances, an unresolved claim will lead to litigation. Litigation is not always preceded by notice of a claim. Sometimes it commences without prior notice in the form of a Summons and Complaint to the oral and maxillofacial surgeon.

The Lawsuit

The litigation process is initiated by the patient (the plaintiff) or the patient's attorney filing a legal complaint (Summons and Complaint) that is served upon the oral and maxillofacial surgeon (the defendant) by a sheriff or other law enforcement official. The Summons and Complaint must be followed by an official response from the defendant, typically within 30 days of receipt.

As mentioned before, it is essential that at this juncture, the oral and maxillofacial surgeon's professional liability insurance company or hospital legal department be contacted immediately so as to initiate the tripartite process. All communications by the oral and maxillofacial surgeon concerning the case and the patient should be limited to the claims professional and the defense attorney assigned to the case. The claims professional will obtain the relevant information, hire a defense attorney, and provide the oral and maxillofacial surgeon guidance on how to proceed. The defense attorney will follow up with a detailed conversation with the oral and maxillofacial surgeon and will prepare a Response to the Complaint. The defense attorney and the surgeon share an attorney-client privilege that prohibits third parties from gaining access to the communications shared between them. Disclosure of the confidential conversations to a third party generally waives this privilege. In other words, be sure to not discuss the case with anyone except your attorney or claims professional.

Depending on the complexity, the length of a case from start to finish can be as little as a few months or as long as several years. Imagine being on a roller coaster ride with a never-ending lift hill (upward-sloping section of the roller coaster track). There is a steep climb upward, but the point at which the train hits the peak in the track is unknown. With over 25 years of experience, OMSNIC has managed small claims as short as 3 months as well as more tenuous interminable claims that went on for 10 to 14 years. "On average, it takes 4 to 5 years to resolve a claim from the date of the incident."[15] Within this time, information is exchanged between parties to assist with the investigation (discovery). During the discovery period, the involved parties and appointed expert witnesses undergo a formal question-and-answer session called a deposition, which is conducted by counsel and recorded by a court reporter. The defense attorney preps the oral and maxillofacial surgeon and seeks his or her advice regarding the retention of an appropriate consulting expert. Throughout this process, the claims professional evaluates the case and reports to an internal committee or hospital board that oversees and reviews all of the cases, including those that are in the claim phase. For example, at OMSNIC, a committee of oral and maxillofacial surgeons reviews and evaluates the care, treatment, and expert findings. An informed and reasonable decision to resolve the lawsuit is then made.

The Resolution: Dismissal and Settlement

A lawsuit will be resolved in one of three ways. The case can be dismissed by a motion (a formal request to the court to take a particular action) either by the defense or by the plaintiff if he or she believes the chances of winning the case are nonexistent. The case can also be settled. Sometimes, a determination to settle is made when a case is perhaps medically defensible, but compromised because of poor documentation, weak support from the expert witness, or lack of informed consent. In other instances, a case is not deemed medically defensible and may need to be settled. If necessary, a form of alternative dispute resolution (i.e., mediation, arbitration, professional review panel) can be used to achieve settlement.

The Resolution: Trial

The final and most well-known type of lawsuit resolution is a trial. A trial is an arduous, foreign journey for most surgeons, and the outcome is never guaranteed. Jurisdiction, as it relates to geographic location, may have the same steering potential in the court of law as it does with politics. Some states are considered more litigious than others and are known to have more verdicts in favor of the plaintiff. Others are more known to favor the defendant. The time it takes to get to trial, the pool of jurors, the judge, the laws, the need for a unanimous or majority verdict, and the monetary damages allocated for a case are all matters that are affected by jurisdiction. The trial process begins with jury selection and concludes with jury deliberation. Although jurors are cautiously selected, their lack of knowledge and experience can greatly affect their ability to be impartial. Consider the pool of jurors that is convened to render a verdict for a pediatric oral and maxillofacial surgeon who resides in the same state where the top local story is about two children who died after receiving anesthesia in a dental office. Disclosure of the case to the public along with a great deal of media attention has the potential to limit the impartiality of the jurors.

After jury selection, the plaintiff and defense attorney deliver their opening statements, present the evidence to the jury by way of testimony, and conclude the trial with closing remarks. Once the final verdict is presented, the judge either agrees or disagrees and the final judgment is entered. If there is a defense verdict, it means no negligence was found and the plaintiff is not awarded any money. If there is a plaintiff verdict, it means negligence was determined and monetary damages (indemnity) are awarded to the plaintiff. If by chance, neither a defense nor plaintiff verdict is reached, the jury is considered "hung," and a new trial may take place at a later date.

Some basic but not fail-proof tips to help minimize the chances of participating in a claim or lawsuit include:

- Be aware of your patients' level of satisfaction. Intervene early. Be cognizant of a patient's complaint and take the time to resolve the complaint at the patient–provider level.
- Be an integral part of the review process before sending a patient to collections. Know if a patient who has failed to complete payment for treatment suffered from an adverse event or was dissatisfied with the care received.
- Once served with legal documents, never attempt to respond on your own or contact the patient or the attorney who is representing the patient; notify your insurance company and let your claims professional do that.

- When there is a known adverse event or unwarranted surgical outcome, notify your professional liability insurance company or hospital legal department before a claim is filed.
- If you don't have professional liability insurance and you are not covered by the hospital, you will be responsible.

Emotional Rollercoaster

According to Williams (as cited in Tang[17]), roughly 50 years ago, doctors were sued far less than they were 20 years ago. As a specialty, nearly 1 in 10 oral and maxillofacial surgeons has a claim per year, suggesting that there is a strong likelihood that an oral and maxillofacial surgeon will have to defend a lawsuit at least once over the course of his or her career. "For many physicians, the prospect of being sued for medical malpractice is a singularly disturbing aspect of modern clinical practice."[18] Even with state-enacted tort reforms, the medical-legal climate remains tenacious. Jury verdicts are becoming more and more difficult to predict and claim resolution payments are steadily increasing.

Being involved in litigation can be stressful, especially when the involvement is coupled with uncertainty and unpredictability of the litigation process and injured self-esteem. The stress encountered in litigation is not the same type of stress a surgeon learns to cope with in school or in practice. This stress can manifest itself physically (fatigue, anxiety, loss of sleep), economically, and in relationships (peers, family, etc.). The truth is, much of what goes on in the litigation process is beyond the surgeon's control. The timing of the trial, the length of discovery, and the retention of experts subpoenaed by plaintiffs are all matters that are dealt with as they occur. The best way to deal with the stress and anxieties that come with the words "You've just been served" is to learn as much as possible about the case and malpractice litigation in general, and engage in activities outside the practice to keep from dwelling on the litigation issues. The more knowledge one has about the process, the more confidence and comfort he/she can have about the case. As exasperating of a time as this could be, understand that participating actively in the defense will help restore your sense of balance.

Regulatory Awareness

While practice trends are advancing, health laws are adapting. Staying current with the most recent industry trends, laws, and regulations, both state and federal, can feel like an impossible task. However, the cost of not doing so could result in an untoward action against an oral and maxillofacial surgeon's dental, medical, or DEA license. For example, some oral and maxillofacial surgeons dispense pharmaceuticals in their offices. In some states, dispensing medication is not permitted by law, and not knowing is not an acceptable excuse.

We are constantly bombarded with information from various resources each and every day, making it a real challenge to stay organized. Consider setting aside a block of time, maybe 10 to 20 minutes each day, to peruse various industry sites and publications. Maintaining a folder of new information is a great way to keep track of and monitor current issues affecting your practice. There are several sites specific to oral and maxillofacial surgeons that can be helpful as well. The AAOMS website contains an Advocacy E-Newsletter and Government Affairs section, where information on legislation and regulatory activity on both state and federal levels is stored. The ADA Advocacy page is another great resource that provides links to current government and regulatory issues. When time permits, review the various oral and maxillofacial trade journals and the local dental society publications. Taking the extra step to stay informed will only serve to promote a successful practice and avoid unnecessary pitfalls.

A long-standing and well-known health law is the Health Insurance Portability and Accountability Act (HIPAA), which has been in place since 1996. HIPAA privacy and security requirements apply to all health care providers. All individuals involved in the health care delivery system should have HIPAA Privacy plans in place and be compliant with them. Here is an abbreviated overview of compliance practices to consider.

- Ensure that patient sign-in sheets include only limited information;
- Do not leave paper charts around the office or in clear plastic chart holders on exam room doors;
- Ensure that computer screens with electronic health records are not visible to patients or visitors;
- Do not post patient schedules in plain view;
- Do not hold confidential conversations where they can be overheard;
- Regularly change passwords and safeguard access to work areas;
- Give only authorized staff accessibility to medical records, lab reports, and faxes;
- Document safeguards for transfer of paper/electronic patient records and lab specimens;
- Document policies for termination of employment, including return of all keys, cards, and code and lock changes;
- Document procedures to protect confidential information if office equipment or files are taken from the premises;
- Inventory computer systems and software, and do a regular virus check;
- Develop a disaster recovery plan in the event of systems failure; and
- Protect email communications containing confidential information.

Concluding Thoughts

Applying good risk management practices before a complaint, claim, or lawsuit is filed is pivotal to the effectiveness of proactive risk management, but sometimes, despite excellent clinical care and good reactive risk management practices, lawsuits

are filed. The legal process is much different from rendering clinical care and guaranteed to not be as enjoyable. Why wait until a patient is in the chair with a serious concern to realize the value of proactive and reactive risk management? Being armed with tools to help prevent an incident, mitigate a claim, or manage a lawsuit is like knowing how to defend a claim before one arises. Risk management's proven techniques for communication and documentation have reduced the incidence of lawsuits, and if one does face litigation, the techniques have bolstered their defense.

By now, you might be asking yourself, "How am I supposed to do *all* of that or remember any of the information I just read?" Understanding risk management and more importantly, managing risk and promoting patient safety is not a job or task to be memorized or accomplished in a day. It takes time to change behavior, incorporate new practices, and obtain buy-in from your staff. Implementing good risk management practices requires time and commitment. Consider risk management practices like lifting weights for the first time. You may not be able to lift the 50-pound weight 10 times, but you may be able to lift the 10-pound weight 50 times. Eventually, the reps or sets will increase and before you know it, you're at your goal—but not without practice. Mastering good risk management skills takes consistent (daily) practice.

Coding, Insurance, and Third-Party Payers

TERRI BRADLEY

General Overview

As an oral surgeon, you will be billing to both medical and dental carriers. Your participation status notwithstanding, every service you do in your office is going to be billable to an insurance carrier whether you're contracted or not. (The only caveat to this rule would be if you were performing a cosmetic procedure; however, the patient may still request a claim to be submitted on their behalf.) Thus, you will need to become familiar with several different code sets. Dental insurance requires the use of Current Dental Terminology (CDT) codes on the ADA claim form. Except in limited cases, diagnosis codes are not required for the dental claim form. Medical carriers use Current Procedural Terminology (CPT) as their primary code set for the reporting of procedure codes. Medical carriers will also allow the use of Healthcare Common Procedure Coding System (HCPCS) codes (oral and maxillofacial surgeons would use it most often to report for medications, supplies, and dental procedures). In 2011, because of copyright agreements, the ADA codes or CDT codes were no longer available in the downloadable HCPCS files on the Center for Medicare and Medicaid Services (CMS) website. However, the ADA dental procedure codes are still a part of the HCPCS code set and can be reported on the CMS 1500 form to report for services provided not adequately described by a CPT code.[1] Unlike dental carriers, medical carriers do require providers to report diagnosis codes with every procedure.

Although some procedures are billed to both a medical carrier and a dental carrier, there are many instances when you will only be dealing with one carrier for a procedure. Medical carriers are billed for orthognathic cases, temporomandibular joint (TMJ) surgery, and oral pathology, whereas dentoalveolar procedures are submitted to dental carriers. The majority of dental implants and grafting are considered dental unless the procedure is being done to replace teeth lost by trauma and/or to reconstruct an arch that was damaged due to neoplastic diseases. Unfortunately, not everything is covered by insurance, and just because there is a code and the procedure needs to be done does not mean it will always be covered by the insurance carrier. I recommend determining whether or not a procedure is a covered benefit before performing the service. The majority of medical carriers have a list of their medical coverage determination guidelines on their website. From these guidelines, it is possible to research a particular carrier's policy on the majority of OMS procedures, such as sleep apnea, orthognathic surgery, or TMJ. Having access to this information ensures that you are not wasting time and resources submitting a claim for services that may not be covered.

An important caveat is that everything submitted on a claim form (medical or dental) must be substantiated by the documentation in the patient's medical record. The adage "If it is not recorded in the chart, it did not happen" holds true for billing. You as the doctor are ultimately responsible for the information and codes submitted on a claim form. The basic principles of documentation were established several years ago by the American Health Association, American Managed Care and Review Association, American Medical Association, American Peer Review Association, Blue Cross Blue Shield, and the Health Insurance Association of America. These include the following: The medical record should be complete and legible; the documentation of each patient encounter should include or provide reference to the reason for the encounter and any relevant history and examination findings, any prior diagnostic test results as appropriate, assessment clinical impression or diagnosis, the plan for care, and the legible identity of the observer. If not specifically documented, the rationale for ordering diagnostic and other ancillary services should be easily inferred. The past and present diagnoses should be accessible to the treating and/or consulting physician. The appropriate health risk

factors should be identified. The patient's progress, response to, and changes in treatment and revision of the diagnosis should be documented. And, last, the CPT and ICD CM (International Classification of Diseases, Clinical Modification) codes reported on a health insurance form or billing statement should be supported by the documentation in the medical record.[2]

Billing to medical insurance carriers is done on the CMS 1500 form. When reporting on a CMS 1500 form, CPT is the primary medical procedure code, if a specific code exists. If there is not a specific CPT code but an appropriate CDT exists, use of the CDT code is allowable. For example, there is no specific CPT code for removal of an impacted third molar. The only option is CPT code 41899, which is "unlisted procedure dentoalveolar structure." This code could represent many things; it could be a crown, a filling, an extraction, or a full bony impaction. Because the code is so vague, CDT code D7240, "removal of impacted tooth—completely bony" is reported. The most specific code available must be reported, whether it be a CPT, HCPCS, or CDT code. Any CPT codes ending in 89 or 99, such as 41899, require a narrative to describe the services being reported. This narrative can be reported in the shaded area of box 24 on the CMS 1500 form or in free-form text in box 19. Detailed instructions on how to complete the form can be found at www.nucc.org, the website for the National Uniform Claims Committee. The first thing the carriers check is whether or not the claim was submitted correctly with the most current codes. CPT, CDT, and ICD codes are updated annually. Carriers also want to be sure that the ICD code listed is at the highest level of specificity and that signs and symptoms are not listed as a primary, definitive diagnosis.

Medicare, as well as many commercial carriers, utilizes the National Correct Coding Initiative or CCI edits when processing claims. The Correct Coding Initiative was implemented to promote correct coding methodologies and to control improper coding leading to inappropriate payments (i.e., unbundling).[3] The CCI edits have basically matched procedure codes that are not billable separately except under specific circumstances. The edits are broken down into columns, Column 1 (comprehensive codes) and Column 2 (component codes), which, when billed together on the same day of service, are not both reimbursable.[3] This is often referred to as unbundling. In some circumstances it may be appropriate to report an additional modifier to override the CCI edit; however, this would be case specific. For example, the codes for debridement and repair of wounds are now bundled into a CCI edit. Now, in order to bill debridement of a wound prior to repair, it is necessary to report using a modifier that would explain the extenuating circumstances (has to be gross debridement) as to why you are billing separately for a service that the CCI edits consider part of the repair (i.e., cleaning the wound before you repair the wound). In addition to the Column 1 and Column 2 edits, there are also the Medically Unlikely Edits. MEUs are edits based on maximum number of units of services being reported and link between procedure and anatomy, as well as codes that are not usually performed at the same session.[3] These CCI edits are updated quarterly, and the updates are listed on the CMS website. Because the edits change so often, it is not uncommon for a provider to have claims for services they have been billing for quite some time suddenly begin to be denied as bundled by carriers. Keeping updated on the changes that affect the specialty of OMS and the procedure codes you bill frequently will help keep you informed.

Currently, all CPT codes are assigned a relative value unit, and these values are used to determine fee schedules based on RBRVS (Resource-Based Relative Value Scale). Carriers multiply the relative value unit by a conversion factor and thus develop their fee schedule for providers. Medicare's conversion factor is public information and is updated annually; however, the majority of the private carriers do not publish this information, and it is difficult to determine exactly what their conversion factor is.

The RBRVS is broken down into four categories for each code: the work relative value unit, which is the physician's skill and effort; the practice expense relative value unit (RVU), which is the office overhead—rent, supplies or staff; the malpractice expense, which is the cost of the liability insurance; and finally, the geographic practice cost index. The GPCI is the only category in that it will differ from practice to practice, factoring in the increased costs in operating in large urban settings versus suburban or rural settings. The RBRVS is considered budget neutral. Thus, if an RVU is increased for one code, it has to decrease for another code. I recommend reviewing the RVUs for the procedures you are performing within your practice when developing your own balanced fee schedule. There should be a relationship between your office fees and RVUs. You may want to develop your own internal conversion factor to help you determine your fees for CPT procedures.

Relative value units play a significant role when billing for multiple procedures at the same operative session. Medical insurance carriers apply the multiple procedure discount if you are performing more than one operative procedure on the same day. They will reimburse 100% of their allowable fee schedule for the first procedure (the first reported line) and 50% for each additional operative item. Many software programs will list procedures based on the highest fee, not necessarily by the highest RVU. Given that, it is easy for practices to lose money if their fee schedule has no correlation between their fee and the RBRVS used by insurance carriers. A great example of that is for sequencing for bone grafts of the mandible and the maxilla. Code 21210, bone graft of the maxilla, has a relative value unit of approximately 65.81. CPT code 21215, bone graft of the mandible, has a relative value unit of 117.75. Therefore, if you were doing both of these procedures at the same time and happened to charge the same for both, it would behoove you to list the code with the highest RVU (CPT 21215) first. The difference in reimbursement from a carrier could be thousands of dollars.

It should be noted that while RBRVS is the current standard for fee schedules, carriers are beginning to move toward a value-based payment modifier. Section 1848 (p) of the Social Security Act requires that Medicare establish a value-based payment modifier (Value Modifier) that providers for differential payment under the Medicare Fee Schedule (PFS) based on the quality of care furnished compared to the cost during a performance period. Section 1848 (p) required that the Value Modifier be applied to specific physicians and groups of physicians the Secretary determines to be appropriate starting January 1, 2015, and to all physician and groups of physicians by 2017. The statute requires the Value Modifier to be budget neutral. Budget neutrality means that, in aggregate, the increased payments to high-performing physician and groups of physicians equal the reduced payments to low-performing physicians and groups of physicians. Beginning in calendar year (CY) 2015, the Value Modifier will be applied to all groups of physicians with 100 or more eligible professionals. Proposals are anticipated in future rule-making on how to apply the Value Modifier to groups with fewer than 100 eligible professionals and to solo practitioners.[4] Although Medicare is at the forefront of this shift, what Medicare does, other carriers will follow in their guidelines. This is yet another topic that will have to be watched carefully as it unfolds, and the impact on payments to your practice as well as the additional administrative burden of reporting these values will have to be considered.

Insurance Contracts

Becoming a participating provider requires a great deal of consideration. You need to evaluate it not only from a patient care standpoint, but also from a business standpoint. When considering a contract, be sure to review the entire document, not just the fee schedule. Make sure you review the language in the contract such as the claims submission guidelines, non-covered services, termination clause, hold harmless clauses, and pre-authorization requirements. I always recommend to my clients that when evaluating a fee schedule, it's helpful to start by examining your top 25 procedures and comparing the allowable reimbursement rates for those procedures among all contracted or potential carriers. This will allow you to compare "apples to apples" before making any decisions. Many fee schedules can be negotiated, usually either annually or biannually.

When signing a contract, especially through dental carriers, it is important to consider which other carriers will now be able to use the fee schedule, such as with umbrella PPO plans or third-party administrators. Some companies such as Connection Dental and Dentemax are not insurance companies, but rather third-party administrators that create a network of providers and insurance carriers that essentially rent their network and their network fees. In essence, when you sign on with one of these companies such as Connection Dental, you are becoming an in-network provider for several carriers; sometimes the list can be up to 30 carriers with networks of patients that can now access your practice as an in-network provider. The same relationships exist on the medical side as well; companies such as Multi Plan are third-party administrators that rent out their networks to providers and carriers all across the country. In addition to these third-party administrators, more and more medical carriers are sharing networks. As a way to provide more coverage to their patients, smaller local insurance carriers are joining forces with the larger commercial plans so they can create a network across the country that will service their patients. New relationships between carriers are constantly being formed, and it is up to providers to keep up with these changes and the overall impact on their practice. The constant changes in the industry and keeping up to date can be burdensome for the administrative staff; however, it is necessary from a business standpoint to have a clear understanding of which carriers you are an in-network provider with, and what other networks can access you based on the initial contract that was signed. In some cases these third-party administrative contracts can be a good thing for a practice; in other cases it may be more beneficial to contract directly with a carrier. Be sure to do your due diligence in reviewing the fee schedule options and contract between the third-party administrator and the individual carrier to see which fits best with your business model. The American Dental Association and the American Association of Oral and Maxillofacial Surgeons can do a review of insurance contracts for you before sign up with a carrier.[5]

Code Sets

As mentioned at the beginning of this chapter, oral surgery is unique in that it is one of the few specialties that can and does bill both medical and dental insurances. Thus, it is important that oral surgeons be conversant with multiple different code sets in order to run a successful business.

The two main procedural code sets are CPT and CDT. CPT is the primary code set for billing to medical insurance carriers. It is copyrighted by the American Medical Association and updated annually.[2] The updated books are published in December, and the new codes take effect in January. CDT is the primary code set for dental billing; it is copyrighted and owned by the ADA and, like the CPT codes, it is updated annually. HCPCS is another HIPAA-approved procedural code set. There are several sections of codes within this HCPCS set that you would use—for example, pharmaceuticals (medications used in the office, such as Zofran) and durable medical equipment codes (oral appliance codes) are found in this code set. You can also find CDT codes or "D" codes. CDT codes, although copyrighted by the ADA, are also considered a HCPCS Level II code set, which allows providers to use dental codes on medical claim forms when appropriate. Although CPT and CDT are, by in large, stable code sets with annual updates and modifications, the diagnosis code set is currently undergoing an immense change.

The United States recently transitioned from the ICD-9 CM (diagnosis) code system to the ICD-10 CM code

system. The ICD-10 CM code set became effective on October 1, 2015. This was a big leap for the health care system. Robert Tennant, senior policy adviser in MGMA's government affairs department called switching to ICD-10 codes "probably the biggest change in healthcare since Lyndon Johnson signed Medicare into law in the 1960s."[6]

The ICD-9 CM code set contains approximately 14,000 codes. The ICD-10 code set has approximately 69,000 codes. Much of the world has already transitioned to ICD-10; health care worldwide has outgrown ICD-9, which simply did not have enough codes to accurately describe diseases and conditions. Thus, it was overhauled to ICD-10, which was adapted by the World Health Organization (WHO) in 1993 and here in the United States in 2015.

Medical insurance carriers require the submission of a diagnosis code with every procedure code reported on a CMS 1500 form. The diagnosis code that is reported should be that which best supports the medical necessity of the procedure performed based on the documentation in the patient's medical record. Diagnosis and procedure codes must be properly linked for the claim to be paid, and one should always code to the highest degree of specificity and certainty. The primary code should support the medical necessity of the service rendered. When determining the priority of the diagnosis codes, the primary consideration should be the cause of the immediate problem or, why the patient is in the chair. Any further symptoms or conditions can be reported as secondary codes.

Currently, diagnosis codes are not always required on dental claim forms; however, there is a section on the newest claim form that does allow for providers to report diagnosis codes. Within the industry, the expectation is that diagnosis codes will be required in the future (Table 8-1).

Medicare

There are a myriad of options regarding Medicare enrollment. You can enroll as a participating provider, as a non-participating provider, as an ordering and referring provider only, or as a DMEPOS (Durable Medical Equipment Prosthetics, Orthotics and Supplies) provider; or you can choose to formally opt out of Medicare. Should you choose to opt out, a formal affidavit prohibiting providers and participants from billing Medicare for 2 years must be signed. If you sign the opt-out affidavit, you must enter into a private contract with each Medicare patient before performing a Medicare-covered service. (For more information on this, contact CMS.) A formal choice regarding Medicare enrollment must be made and declared by each provider; the lack of a choice is not an option if services are being provided to Medicare patients. According to Medicare, "Dentists, including oral surgeons, must enroll in the Medicare program to receive reimbursement for services furnished to Medicare beneficiaries or to order covered items or services for Medicare beneficiaries. Oral surgeons would complete the same paper forms, or on-line application, as any other practitioner enrolling in PECOS" (the Provider Enrollment Chain and Ownership System).[7]

As an ordering or referring provider, you are enrolling as a provider that can order or refer services (laboratory, radiology, etc.) for Medicare beneficiaries, and will not submit claims for services furnished to Medicare patients. Medicare requires providers that order or refer services for Medicare patients to be enrolled in the Medicare system. Therefore, if you are not enrolled in the Medicare system (with any option listed earlier) and you refer a patient to a laboratory for testing, the lab fees would not be covered. DMEPOS is a separate enrollment process from traditional Medicare. If you are planning on providing oral sleep apnea appliances to Medicare patients, enrollment in this process is required.[7] Providers that have opted out of Medicare are not allowed to enroll as DMEPOS providers only. Enrolling in any of these options can be done through the online program PECOS.[7] Once the enrollment is completed, this same system can be used for re-validation and also for changing of status.

Whether you are enrolled as a participating provider or a non-participating provider, by federal law there is a mandatory claims submission for all services covered by Medicare.[7] For services that may not be covered by Medicare, if the patient requests that you submit a claim to Medicare, you are required to do so. Participating providers are required to accept assignment on all Medicare claims and to accept the approved amount as payment in full. Medicare will pay 80% of the Medicare-allowable fees, and the patient (or the supplemental Medigap plan) will pay the other 20%.

As a non-participating provider, you can accept assignment on a case-by-case basis. The approved fee for non-participating providers is 5% less than it is for providers that are participating providers. Non-participating providers can

TABLE 8-1 Diagnosis Codes

ICD-9	ICD-10
3-5 characters in length	3-7 characters in length
Approximately 14,000 codes	Approximately 69,000 codes
First character may be alpha or numeric Characters 2-5 are numeric	First character is alpha Characters 2-7 are alpha or numeric
Limited space for new codes	Flexibility for adding new codes
Lacks laterality	Has laterality
Difficult to analyze because of nonspecific codes	Specificity improves coding accuracy and depth of data for analysis
Codes do not adequately define diagnoses needed for medical research	Details improve the accuracy of data used in medical research
Does not support interoperability because it is not used in other countries	Supports interoperability and the exchange of health care data between other countries and the United States

charge Medicare patients more than the non-participating approved amount; however, charges are limited to 115% of the Medicare approved amount for non-participating providers.

Here's an example: If the Medicare allowable is $100, a participating provider would receive $80 from Medicare and $20 from either the patient or the Medigap plan. Using the same example for a non-participating provider: If the Medicare allowable is $100, the allowable becomes $95. Medicare would pay $76, the patient or supplemental insurance would pay $19, and the provider would thus receive 95% of the Medicare fee schedule for covered services. If the claim is unassigned, then the limiting charge is set at 115% of the allowable. For example, a fee schedule is $100 allowable; a 5% adjustment as a non-par status brings it down to $95. Limited charge is $95 × 115% or $109.25, the maximum amount you could bill a patient as a non-participating unassigned claim.

Participating and non-participating providers are required to inform patients if a service potentially may not be covered by Medicare (usually due to lack of medical necessity). This is done by the completion of an Advanced Beneficiary Notice, or ABN, form. The form must be completed for the individual patient with the specific reason why you expect Medicare to deny the services, along with the service being provided, the expected reason for the denial, and the estimated cost recorded on the form and reviewed with the patient before the services are rendered. If this process is not completed before the patient receives the service, and the claim is denied by Medicare, the patient cannot be billed.[7] ABNs are reported to Medicare on the claim form using modifiers. The GA modifier is used to let the carrier know that you have a completed ABN on file. The GY modifier attached to the procedure code would let the carrier know that this particular procedure is statutorily excluded; however, the patient wants the provider to submit the claim form. The GX modifier indicates that there is a notice of liability issues and it is voluntary under the payer policy. The GZ modifier indicates that the service is expected to be denied, and the GJ modifier is letting the carrier know that you have opted out, but the services you just provided for this Medicare patient were emergency based.[7] You cannot, of course, have every single patient that comes in your office over the age of 65 sign an ABN. There needs to be an open conversation between the doctor and the patient about services being provided and the potential that Medicare may not pay for them. Although Medicare generally does not cover many dental services, medical services such as excision of lesions are generally covered.

Section 1862-A-12 of the Social Security Act delineates the statutory dental exclusion

> *Where such expenses are for services in connection with the care, treatment, filling, removal or replacement of teeth or structures directly supporting the teeth except that payment may be made under Part A (hospital charges) in case of inpatient services in the connection with the provision of such dental services if the individual, because of his underlying medical condition and because of the severity of the dental procedure, requires hospitalization.*[7]

The dental services Medicare does cover are limited. Medicare will pay for those dental services that are an integral part of either a covered procedure such as reconstruction of the jaw following an accidental injury or for extractions done in preparation for radiation treatment of neoplastic diseases involving the jaw.[7] It will also pay for oral examinations, but not treatment preceding kidney transplantation or heart valve replacement under certain circumstances.[7]

Trauma

It is important to understand that the descriptions for repair of fractures in CPT are per *fracture*. Therefore, if a patient has multiple fractures being repaired, there needs to be separate CPT and diagnosis codes for each one. For example, a right angle fracture and left symphysis fracture would have separate diagnosis codes, each one linking to the proper CPT code describing the fracture repair. One common error I often find in client offices is the use of the multiple approaches code (CPT 21470). The description of this code is "open treatment of complicated mandibular fracture by multiple surgical approaches including internal fixation, interdental fixation, and/or wiring of the denture or splints."[8] Note that the description is mandibular *fracture,* not *fractures;* this code is often misused when reporting multiple mandibular fractures, which is incorrect. Also of note, multiple approaches does not mean separate incisions. Each fracture repair should have its own CPT code. Another common misconception involves billing for arch-bar placement and removal as their own procedures. The placement of arch bars is common in fracture repair and is included in some of the descriptions for the repair of fractures. If it is included in the description for the repair, arch-bar placement cannot be billed separately. However, the removal of arch bars during the postoperative period can be billed. The removal was not included as part of the RVU determination for the fracture codes and can therefore be billed separately. Although this is billable, it does fall within the 90-day global surgical package (GSP). In order to bill properly, the 58 modifier for stage procedure should be used.[8] While the procedural coding for fractures will remain the same with the transition to ICD-10, the diagnosis codes for trauma will now require much more detailed and in-depth reporting.

There are very significant changes in ICD-10 when reporting diagnosis codes for trauma cases. These codes are found in Chapter 19 of the ICD-10 code book. Within this section in the code set, you will be required to also report codes for the external causes of the trauma.[9] These codes capture how the injury happened (cause), the intent (unintentional or accidental; or intentional, such as suicide or assault), the place where the event occurred, the activity of the patient at the time of the event, and the person's status (e.g., civilian, military).[9] Another change in ICD-10 is the use of the seventh character in the code. In the S02 section

(fractures of the skull and facial bones), a seventh character (an alpha character) is needed to properly report the code: A, initial encounter for closed fracture; B, initial encounter for open fracture; D, subsequent encounter for fracture with routine healing; G, subsequent encounter for fracture with delayed healing; K, subsequent encounter for fracture with nonunion; and S, sequela.[9] This seventh character must be in the seventh space of the code; for any codes that are less than six characters, the letter "X" is used as a placeholder. For example, in ICD-10 to report a closed fracture of the angle of the mandible, the following code would be used: S02.65XA (fracture of the angle of the mandible, closed fracture, initial encounter). As the patient's treatment progresses, the seventh character will change. If you were to see the patient for postoperative x-rays and the healing was routine, the diagnosis code would be S02.65XD (fracture of the angle of the mandible, subsequent encounter for routine healing).[9]

Pathology

When coding for oral pathology, it is the recommendation of the American Medical Association as well as the CPT Board that you always wait for the final pathology report before you assign a diagnosis code.[10] This is done for several reasons, the most important being that coding is done based on specificity and certainty, and until the pathology report comes back, the final diagnosis is technically uncertain. It is incorrect to submit a diagnosis based on "rule out" or "suspected"; those are signs and symptoms only, and the words following rule out (such as "rule out malignancy") should not be used unless the diagnosis has been confirmed by a pathology report. There are diagnosis codes for uncertain behavior; those codes are to be used when the pathologist is uncertain about the behavior of the lesion, not when the surgeon submits the specimen to pathology.

It is also important to wait for the final pathology, as there may be specific procedure codes for removal of benign lesions versus removal of malignant lesions. In the areas where there are specific procedure codes to report for removal of malignant lesions, the RVUs are higher due to the additional coordination of care that will have to occur postoperatively. Specificity is not limited to benign versus malignant. It may also involve specific areas within the oral cavity. One of the more common areas of confusion is related to the lips. Procedures performed on the lipstick area should be coded as the skin of the lip; for areas inside the mouth, code using the vestibule; for the lip (non-lipstick area), code as the lip. Within each of these codes you will find codes for biopsy, excision without repair, with simple repair, complex repair, and so on. A suture is considered a repair and should be coded as such; to do otherwise is to undercode for the services performed. When determining whether to report for a biopsy or excision of lesion, you must consider the intent. If the intent is to remove a small portion for further pathologic review, then you would choose a biopsy code. If the intent is to remove the entire lesion, then choose the excision lesion code.[11]

With the advent of ICD-10, there is another shift in the reporting of diagnosis codes for oral pathology. In many sections you will have to report additional codes for contributing factors, such as tobacco and alcohol use. There are notations to report whether or not the patient has any alcohol abuse or dependence, whether there has been exposure to environmental tobacco smoke, and whether there is a history of tobacco use or tobacco dependence or current tobacco use. All of that information is currently not required under ICD-9 but will have to be reported in ICD-10.

E&M Codes

Although there are very few dental codes to choose from when coding for evaluation and management (E&M) services, there are more than 15 codes in CPT for billing to medical insurance for these services. Additionally, there is no clear cross code between the dental and medical codes. Therefore, it is important to become familiar with the descriptors and understand the various differences among the code levels.

Choosing the correct code for office visits and consultations (evaluation and management codes) depends on where you saw the patient: inpatient, outpatient, or emergency room. Coding for outpatient visits is determined by the status of the patient: a new patient visit (by CPT definition, a new patient is someone who has not been seen or treated by you or someone within your group for 3 years), an established patient (someone seen or treated within the past 3 years), or a consultation.[8] The outpatient visit codes start with a 992; the fourth character is based on type of the encounter (new patient, established patient, or consultation). New patient visits are in the 99201-99205 series of codes, established patients are 99211-99215 series, and consultations are the 99241-99245 series of codes.[8] The last character of the code is based on the level of the visit. Choose the correct level from a level 1 to a level 5 visit based on the documentation in the medical record. Specific criteria exist for the different levels based on the extent of the medical history, the physical examination, and medical decision making. The higher the level of the code, the higher reimbursement you will receive from the carriers. However, not all visits can be a level 4 or 5 visit. Documentation requirements for those levels are quite extensive. The details of documenting for the different levels are beyond the scope of this chapter, but they can be found in 1995 and the 1997 E&M guidelines through CPT.[8]

Several years ago, Medicare stopped accepting the consultation codes from providers for services rendered to patient. Their reason for no longer allowing the codes was based on the definition of "consultation" and the blurred lines between asking for another provider's opinion versus transferring care.[12] Since that time, other carriers have also adopted the same policy when it comes to billing for E&M services, and you will find several carriers that do not accept consultation codes.

When reporting for E&M visits for patients seen in the hospital, it is important to remember that once you operate on a patient, the global surgical package countdown begins, and this will include all routine postoperative visits. Thus, daily hospital visits and discharge services for patients who have been operated on cannot be billed so long as the global surgical package is still in effect.[8] Global surgical packages typically last for 90 days for major surgeries and 10 days for minor surgeries.[8] However, if you have not operated on a patient, then you can bill for daily hospital visits, admission, and discharge so long as you have provided the services. For example, if you admit a patient to the hospital for IV antibiotics for an infection, you can bill for admission and daily hospital visits (one visit per day) and discharge if no surgery occurs. If the patient is operated on, the billing of daily hospital visits would be appropriate until the surgery. The criteria change a bit for choosing the correct level of the code for inpatient versus outpatient E&M services. Where the outpatient E&M codes are based on three key components, the inpatient codes are often chosen by the amount of time the provider spends on the floor. It does not have to be face to face with a patient (as it does on the outpatient codes).

Modifiers

Modifiers are a way to communicate additional information to the carrier. They may help to improve the efficiency of claims processing if used appropriately and may also result in increased reimbursement when used appropriately. A complete list of modifiers can be found in Appendix A of the CPT book; the following is a review of the modifiers that are less straightforward and may require an explanation of their proper use.[11]

Some of the more common modifiers that you may report for the E&M visits are:

- 24: "Unrelated evaluation and management service by the same physician or other qualified health care professional during a post-operative period." Use of this modifier will require a different, separate diagnosis code than the one reported for the original procedure.[11]
- 25: "Significant, Separately Identifiable evaluation and management service by the same physician or other qualified health care professional on the same day of the procedure or other service."[11] This has to be above and beyond the usual E&M done on the same day as a procedure. It is most often reported with minor procedures (those with a GSP of 10 days). The reporting of this modifier on E&M codes has been heavily audited by carriers and has resulted in some carriers no longer allowing for this if the E&M is reported on the same day as a minor procedure. According to a recent Medicare bulletin, "both the medically necessary E&M service and the procedure must be appropriately and sufficiently documented to support the claim for the services."[13] Medically necessary E&M are the key words here—just because it is the first time you are seeing a patient, that does not mean that you can necessarily bill for an E&M service on the same day as a minor procedure.
- 57: "Decision for Surgery." Use this to report an E&M visit that results in the decision to perform surgery.[11] For example, if you see a patient in the emergency room for a fracture and then elect to treat the fracture that day, you would report the E&M with the 57 modifier.

Some of the more common surgery modifiers:

- 22: "Increased Procedure Services." To report this modifier, the work required to perform the service must be substantially greater than typically required.[11] Additional documentation to the carrier will be required.
- 51: "Multiple Procedures." This modifier is used to report multiple procedures on the same day of service.[11] This modifier is not usually required or even considered by the majority of insurance carriers. By reporting multiple lines on a claim form, the carrier is aware you performed multiple procedures.
- 52: "Reduced Services." In some circumstances a procedure or service may be reduced or eliminated.[11] For example, when reporting a maxillary bone graft CPT 21210, the description in the code specifically states it includes harvesting the bone; there is not a CPT code that describes the graft without the harvesting of the bone. So if the surgeon did not harvest the patient's bone and instead used bank bone to perform the graft, the procedure would be reported with the 52 modifier to reflect the reduced services. Another example would be if a surgeon not otherwise involved in the surgery harvested the bone.
- 53: "Discontinued Procedure." If the provider determines that it is unsafe for a patient to continue a procedure that has already been started, modifier 53 can be reported.[11] This modifier should not be used to report elective cancellation of a procedure. Also note that the procedure has to have been started by the surgeon.
- 58: "Staged or related procedure or service by the same physician or other qualified health care professional during the post-operative period." This modifier can be used when the procedure was planned or anticipated, when it was more extensive than the original procedure, or for therapy following a surgical procedure.[11] For example, modifier 58 could be reported when removing arch bars during the postoperative period for treatment of a fracture patient. In oral pathology cases, if you perform a biopsy and within the postoperative period remove the lesion, modifier 58 would be added to the excision of the lesion; otherwise the claim would be denied.
- 59: "Distinct Procedural Service." Use this modifier to report a procedure that was distinct or independent from other services on the same day. Documentation must support a different session, different procedure of surgery, different site or organ system, separate incision/excision, separate lesion, or separate injury not ordinarily encountered or performed on the same day by the same individual.[11] This modifier should only be used if there is not a better more descriptive modifier to report.

- 62: "Two Surgeons." Use this to report when two surgeons are working as primary surgeons performing distinct parts of the procedure.[11] This should *not* be used if you are acting as an assistant surgeon.
- 76: "Repeat Procedure or Service by the same physician or other qualified health care professional." If you are reporting the same CPT code within the postoperative period, report using this modifier.[11] For example, if you removed a lesion on the tongue and, when the pathology report was returned, it required you to re-excise the lesion to get a wider margin, and you are reporting the same CPT code, add the 76 modifier to the re-excision code.
- 77: "Repeat procedure or service by another physician or other health care professional." Use this modifier when reporting repeat procedures by a different provider.[11]
- 78: "Unplanned return to the operating room/procedure room by the same physician or other qualified health care professional following initial procedure for a related procedure during the post-operative period."[11] Do not use this modifier if the procedure was planned, such as removal of arch bars. The procedure has to be related to the original procedure.
- 79: "Unrelated procedure or service by the same physician or qualified health care professional during the postoperative period." The use of this modifier would require a different diagnosis than that reported with the original procedure.[11]

Radiology Codes

All radiology codes inherently have two components: one to take the film (technical component) and one to read the film (professional component). If you report a radiology code without any modifiers attached, you are letting the carrier know that you took the film and also read the film. For example, a panoramic x-ray 70355 submitted without modifiers tells the carrier that you took the film in your office and you also interpreted the film. If you did not do both components, then you should report using the appropriate modifier.

TC Technical component
26 Professional component

Coding and Billing for Patients with Systemic Diseases, Cancer, Diabetes, and Other Comorbidities

For patients with systemic diseases such as diabetes or Sjögren's, or patients with cancer and other comorbidities, coverage under their medical carrier for dental services varies from carrier to carrier and, in some cases, from plan to plan. You can do a great service for your patients if you can maximize the benefits available to them under their medical plans. This may take a little bit of work from the outset, but the level of customer service provided to the patient outweighs the additional work.

When trying to determine if a procedure is covered for a particular patient, the best way to start the research is online. The majority of the major insurance carriers have medical and clinical policy guidelines available online that detail their clinical criteria and coverage guidelines. I always recommend to clients to do the research before treating the patient and submitting claims so that everyone is aware up front what the coverage may be. You do not have to be a contracted provider to access this information; it is easily attainable through an Internet search. Some carriers even go so far as to list the covered CPT and ICD codes under the plan. The policies will give you detailed information on what specific conditions the patient must have in order to have coverage. For example, Medicare does not cover extractions for patients who are having extractions done prior to cardiac surgery.[14] Other plans will cover for patients in this circumstance, and some will cover for extractions for patients who are immunocompromised. Some plans will cover for dental implants when related to a trauma; other plans will not only cover the implants but the restorative treatment fees as well. I had one client who was able to have fees covered for both surgical and restorative fees for a patient with a cancer diagnosis. When a patient does have coverage for the services, it is always recommended that a letter of medical necessity describing the patient's condition, the services to be rendered, and the supporting medical documentation on their condition be submitted before the services are performed. This, along with reporting the most accurate and specific diagnosis codes, will maximize a patient's available benefits.

Over the past few years there has been a major shift in coverage by carriers, some of these related to the Affordable Care Act, and others related to the connection between dental care and overall health of a patient. More carriers now allow for additional dental benefits for patients with specific conditions such as diabetes or pregnancy. Although coverage has increased under dental carriers, the total dollar amount of benefits available has not; so although a diabetic patient may now be allowed to have more hygiene visits per year, the dollar amount available to that patient has remained the same. The same holds true for dental implants: More and more carriers are now "allowing" coverage for dental implants, yet very few have increased their benefits. This leaves the provider trying to explain to the patient how dental benefits work, regardless of whether or not there is coverage available. There are very few policies with a maximum benefit high enough to pay in full for an extraction, grafting, dental implant, and restoration, yet patients with implant coverage will and do expect the insurance to pay for the procedure. Understanding dental benefits and being able to explain this to your patients in a customer-friendly way is extremely important for any dental provider. I like to use the analogy of dental benefits being the equivalent of a gift card. Your "gift card" gets loaded at the beginning of the year with the maximum dollar amount of your benefits, and once the benefits are depleted, there is no more money available on that gift card.

Medical plans work very differently; it is less common to see a maximum dollar amount on medical plans for services provided in oral surgery. Thus, whenever services can be covered under a patient's medical plan, it may benefit the patient and the practice (depending on your contract status with the carrier) to bill the medical carrier. Over the past few years, there has been an increase in the number of plans with high deductibles that must be met before the carrier reimburses for any services. It is important that your staff be aware of these plans and how they work so your patients can be educated prior to receiving services.

Affordable Care Act

The Affordable Care Act is just unrolling as I am writing this chapter. Many parts of the ACA were supposed to be effective as of January this year and have been pushed out further and further. It is a topic that is under constant discussion and scrutiny from both Democrats and Republicans. There have been many changes made since the initial ACA, and I am sure there will be more changes as it unfolds. My best advice to you is to do your best to keep up with the changes, get information from multiple credible sources (AAOMS, AMA, ADA, CMS, and your local and state societies). Be proactive when it comes to the insurance contracts you have signed and are considering signing; read the fine print, and educate yourself and your staff on the changes as related to coding and billing for the practice. Use and rely on outside sources if necessary so you can continue to do what you do best, surgery. We are in the middle of a significant paradigm shift, with more and more involvement of third parties, to fee for service, to value-based fee reimbursement. It is going to be quite a ride over the next few years. Stay focused, stay aware, and prepare yourself to be able to make the necessary changes when the time comes.

9

Accreditation of Outpatient Surgery Facilities

MARK DAVID ZAJKOWSKI

The history of oral and maxillofacial surgery is richly intertwined with advances in outpatient surgery and anesthesia. On October 16, 1846, William Morton successfully demonstrated the use of ether as an anesthetic for removal of a neck mass. Like Crawford Long and Horace Wells before him, Morton helped usher in a new era of medicine. Never before could patients imagine surgery without pain or recollection of the events surrounding it. Naturally, anesthetic techniques and agents continued to evolve, as did their applications and the settings in which they could be offered. Today, mounting pressure from third-party payers for cost containment and patient demands for convenience and affordability have created a surge in demand for outpatient surgery and anesthesia.

In 2010, an estimated 57 million outpatient surgeries took place among dozens of provider types in a vast array of patient settings.[1] This increase in outpatient surgery and anesthesia has subsequently raised public awareness of complications in these settings, often with sensational headlines.[2] As a consequence to well-publicized mishaps, hurdles for providers who offer outpatient anesthesia have arisen in several states via legislation, regulation, or third-party payer policies. These regulations include limitation on the types of providers and types of facilities, or they mandate certification by a private agency. In 1988, New Jersey became the first state to regulate OBS offices, followed by California, Pennsylvania, and Rhode Island.

These states approached regulation in a varied format, with differing levels of scrutiny including some endorsing adoption of the American Society of Anesthesiologists guidelines and reporting of adverse events.[3] The closest challenges to date to mandate certification of OMS offices came in New York State in 2007 and Nevada in 2009. Both potential mandates aimed to require OMSs with a medical degree to have their facilities certified by a national accrediting agency. This was rebuffed with intense lobbying in New York, but OMS practices in Nevada were not so fortunate, as practitioners with an active medical license must submit to unannounced inspections and annual reporting of all anesthetics, with harsh penalties for noncompliance. In the Nevada case, the legislation was spurred not by an anesthetic mishap, but by an alleged breach in infection control protocol in an outpatient endoscopy center. Clearly, any type of outpatient setting that falls under public scrutiny reopens the debate on safety on a nationwide level for all specialties practicing in an ambulatory setting. For information regarding current state-by-state regulations for ambulatory facilities, online references are available.[4]

The push for transparency and safety in health care settings is not new. This movement can be traced to Boston in 1910, when Dr. Ernest Codman championed the concept of recording patient outcomes in a process that he referred to as an "end result system of standardization."[5] Codman also pioneered the first morbidity and mortality conferences and eventually founded his own hospital, aptly named the "End Result Hospital." Based on Codman's system, the American College of Surgeons (ACS) formed the first "Hospital Standardization Committee" to ensure quality of care, which then led to the *Manual of Hospital Standardization,* a guide to improve process and outcomes for patient care. By 1946, the federal government joined the movement, allowing funding only for hospitals that applied these standards of care.[6]

As the certification movement gained acceptance, the ACS worked with the American Medical Association, the American Hospital Association, and the American College of Physicians to form the Joint Commission on Accreditation of Hospitals (JCAH) in 1951.[7] By 1965, the JCAH gained recognition in the Social Security Amendments to further broaden the influence and scope of the accreditation process. The JCAH (now known as

The Joint Commission) now accredits nearly every major hospital in the United States as well as more than 2000 non-hospital facilities. These settings include ambulatory and office-based surgery centers, medical group practices, urgent care centers, imaging centers, sleep centers, laboratories, and more. Unlike hospital accreditation, however, many of these nontraditional sites are accredited voluntarily.

As certification of hospitals took root and gained widespread acceptance, oral surgeons understood the need to demonstrate safe practice in their outpatient setting, particularly with their anesthetic techniques. With the development of the office-based anesthesia evaluation by the Southern California Society of Oral Surgeons in 1968, the specialty had a template for oral surgeons to demonstrate their preparation for emergencies and ensure proper equipping of offices that provided anesthesia, naming it the office anesthesia evaluation (OAE). In some ways, these paralleled the standards development in hospitals and have served to quantify outcomes in this surgical setting, albeit to a less thorough degree. Many states still accept some form of this evaluation in allowing OMS facilities to provide outpatient anesthesia, particularly with the operator-anesthetist model. Indeed, Perrott et al. demonstrated a complication rate of only 1.3 per 100 patients in these settings, with the vast majority of complications deemed minor and a patient satisfaction rate of 94%.[8]

Discussion of voluntary certification (accreditation) in oral and maxillofacial surgery offices requires consideration of the role of the specialty in the greater health care picture, particularly with regard to patient safety. The 1999 Institute of Medicine (IOM) report *To Err is Human*[9] proved to be a seminal moment in the quality movement in patient care. Based on its reporting that tens of thousands of patients die annually from medical errors and hundreds of thousands more suffer nonfatal injuries, the inevitable conclusion that a high-quality care system would prevent these was formed. In the follow-up report, *Crossing the Quality Chasm: A New Health System for the 21st Century,* the IOM found "a health care system that frequently falls short in its ability to translate knowledge into practice, and to apply new technology safely and appropriately." In other words, medicine is using outdated systems to deliver care, and a *redesign of our care delivery systems is necessary,* including the use of information technology to support clinical and administrative processes.[10] With regard to errors, medicine traditionally has focused on the personal failings of the individual, leading to a culture of repetitive errors and the "culture of blame." Some argue that this has led to medical excess, with the practice of defensive medicine (which deviates from sound medical practice) and a subsequent increase in costs with unnecessary diagnostic tests and procedures, prescriptions, and patient referrals.[11] James Reason, a British psychology professor, described this recognition of human errors as either via the *person* approach (focusing on the individual's role in errors) or the *system* approach (assigns errors to failure of work systems).[12] Most, if not all, high-functioning organizations understand the need to focus on the *system* approach to minimize errors, create a culture of success and reliability, and engage and retain employees. This belief and practice in the system approach is the central principle in accredited offices and facilities.

In describing how major errors occur from a broad perspective, Reason developed the *Swiss cheese model*.[12] Reason's model vividly describes how a series of weaknesses in a system's defense must "align" to result in an untoward event. Simply put, one large error is often caused by a sequence of smaller errors that propagate, causing a catastrophe. Think of a particular clinical process as a block of Swiss cheese. Each step in the process represents one slice of cheese, including the holes. Each hole represents a weakness or hazard in the system. As we go through each successive step, the hole either continues (error propagated) or is blocked by the next slice (the hazard or error is corrected or no longer propagated). Each successive slice could be seen as safeguards in a process. In a catastrophic event, one error (hole) is continuous throughout the entire process and is propagated, culminating in the loss or adverse event.

Taking Reason's Swiss cheese model further, we can identify medical as well as nonmedical fields to understand the concept of the system approach to process improvement by studying *high-reliability organizations (HROs)*. These organizations are institutions where individuals work together in high-acuity situations facing great potential for error and disastrous consequences yet consistently deliver positive results.[13] HROs all share the goals of constant improvement through the use of measurement tools to eliminate unnecessary variation and to document the continuous improvement via outcomes.[14] The two major themes of HROs are *anticipation* (constant vigilance for potential error sources as a cultural baseline) and *containment* (immediate actions taken to reduce further damage when an error is identified). Five key principles are shared by HROs[15]:

1. **Preoccupation with failure:** Every error or near miss is reviewed to address system failures.
2. **Reluctance to simplify:** Does not allow a process to rely on a single person without redundancy.
3. **Sensitivity to operations:** Encourages situational awareness and information sharing.
4. **Committed to resilience:** Ability to recover from a system failure and limits its effects.
5. **Deference to expertise:** Those with the most relevant skill set are empowered to fix problems.

Office-based OMS practices that provide anesthesia are immersed in a high-risk environment that would be well served if it operated much like an HRO. These offices share several common errors with hospitals. These include (but are certainly not limited to) medication errors, wrong site/wrong patient/wrong implant errors, needlestick injures, and flow disruptions (issues surrounding team

communication, equipment failures, etc.).[16] Organizations that follow the HRO model treat "near misses" (close call, but no poor or unexpected outcome) as a gift, because they occur 3 to 300 times more frequently than adverse events and can act as powerful reminders of system hazards. Much like six-sigma manufacturing processes that stress constant improvement, outpatient surgery centers that follow accreditation standards enjoy a culture of systems reviews and safety that is unmatched in non-certified offices. Rather than focus blame on an individual who participated in one of a series of errors, the HRO-focused office understands that the system has vulnerabilities and works constantly to reduce and redesign processes to minimize hazards for patients.

Hupp contrasts the HRO-like performance of the aviation industry (with its corresponding decrease in deaths, injuries, and costs) with the current state in most dental (and OMS) offices.[17] He opines that adoption of such a culture will reap similar rewards in a health care setting, and outlines the mechanism for a dental or OMS practice to develop a culture of safety as six relatively straightforward steps:

1. Embrace the value of having a safety culture in the practice
2. Adopt a culture of safety as a practice core value
3. Work with the dental team to identify dangers to patients and team members
4. Determine if and how such dangers can be minimized
5. Implement protocols and practices to limit risks
6. Review and refine culture of safety practices regularly

What Does It Mean to "Be Accredited"?

Accreditation is an external, independent review of a health care delivery organization against nationally recognized standards and its own policies, procedures, processes, and outcomes.[18] In other words, accreditation is a tool to transform a practice into a high-reliability organization. In the United States, the three main agencies that accredit OMS offices are *The Joint Commission (TJC),* the *Accreditation Association for Ambulatory Health Care (AAAHC),* and the *American Association for Accreditation of Ambulatory Surgery Facilities (AAAASF)*. Each agency creates manuals specific to different types of office settings that govern the accredited office. For example, The Joint Commission typically accredits OMS practices under the ambulatory surgery center (ASC) or office-based surgery (OBS) programs, dependent largely on the number of OMS providers in the office. AAAHC offers similar programs, also based on the number of providers and/or number of operating or procedure rooms, but offers specific standards more tailored for OMS practices. AAAASF is unique in creating a specific certification program designed for OMS offices. It classifies offices based on the types of anesthesia delivered and defines the type of provider who is allowed to administer the anesthesia. Each agency also offers the ability of a facility to gain "deemed" status as a Medicare facility.

Each agency bases the review of accredited practices on global areas that are given chapters in their respective accreditation standards manuals. Table 9-1 compares the

TABLE 9-1 Comparison of Focus Areas among Accrediting Agencies

Joint Commission	AAAHC	AAAASF
Environment of Care	Facilities and Environment	General Environment
Emergency Management		General Safety
Human Resources	Administration	Personnel
Infection Prevention and Control	Infection Prevention and Control	
Information Management	Quality Management and Improvement	
Leadership	Governance	
Life Safety		Post Anesthetic Procedure Recovery Area
Medication Management		IV Fluids and Medication
National Patient Safety Goals	Quality of Care Provided	
Performance Improvement	Professional Improvement	Quality Assessment, Quality Improvement
Provision of Care, Treatment and Services	Surgical and Related Services	Procedure Room Policy, Environment and Procedures
Record of Care, Treatment and Services	Clinical Records and Health Information	Medical Records
Rights and Responsibilities of the Individual	Patient Rights	
Transplant Safety		
Waived Testing	Anesthesia Services	Anesthesia

areas of review for each agency; a brief description of these focus areas is found in Table 9-2.

Benefits of Accreditation

Becoming an accredited OMS facility can offer a number of advantages. These may include:

- Demonstration of the practice's commitment to the highest level of safety and patient care
- Certification by independent third party recognized by key stakeholders (boards, licensing agencies, regulators, payers)
- Increased reimbursement with preferred contracting by third-party payers
- Competitive advantage in the practice community
- Creation of a culture of "doing things right" that persists even with turnover of leadership
- Enhanced ability to recruit and retain staff and alignment with practice culture
- Ability to benchmark performance with similar practices nationwide

The decision to become accredited is a major one and requires an expenditure of time, staff resources, and money. Todd and colleagues[19] compared accreditation experiences with each of the three major agencies in a recent review. The authors all felt that some aspects of the accreditation process improved their practices and offered suggestions to tailor the process as more of a specialty-specific process.

Although each agency follows a different process and standards to initially certify and subsequently recertify offices, there are some commonalities among them. Any office seeking accredited status should review each of the agencies and choose one that fits their individual organization best. Once this is completed, the applicable standards must be reviewed and integrated into the practice. Some practices choose to hire consultants to shepherd them through the process and help build group engagement during the pre-survey readiness phase. Consultants can offer customizable templates and forms for key documents such as policy and procedure manuals, audits, studies, monitoring logs, in-services, and inspections that document compliance with accreditation standards. In many instances, existing forms that the office uses to document critical areas such as spore testing are adequate or need just minor modifications.

At the initial survey, the focus of the site visit is not only to assess compliance with the standards, but also on educating the practice on methods to improve patient care and safety. This session also allows the practice to demonstrate to the surveyor methods or techniques that it successfully

TABLE 9-2 Description of Accreditation Manual Chapters for Joint Commission Accredited Facilities

Chapter Title	Contents
Environment of Care	Reviews the space where care is provided, the equipment involved and all people in the facility involved in minimizing risk
Emergency Management	Assesses ability of facility to manage disruptions in care due to emergencies such as natural disasters, power loss, or community events
Human Resources	Reviews skills, knowledge and motivation of staff involved in patient care
Infection Prevention and Control	Assesses practice infection control plan, monitoring of sterilization equipment and practice efforts in minimizing infection risk
Information Management	Ensures security, privacy and integrity of health information
Leadership	Reviews role of leaders in maintaining culture of safety, provision of adequate resources, and ongoing performance improvement
Life Safety	Assesses ability of practice to manage patients incapacitated from anesthesia in event of fire or evacuation
Medication Management	Assesses storage, dispensing, delivery and monitoring of medications used in facility
National Patient Safety Goals	Updated annually. Core safety initiatives integrated into practice
Performance Improvement	Ensures measurement of processes used to deliver care, and data used for improvement
Provision of Care, Treatment and Services	Reviews entire episode of patient care from appointment to post-discharge
Record of Care, Treatment and Services	Assesses adequacy of medical records and documentation
Rights and Responsibilities of the Individual	Ensures patients notified of their rights and responsibilities to participate in their care
Transplant Safety	Ensures adherence to proper protocol, documentation and safety with transplanted tissues
Waived Testing	Applies to laboratory testing performed in facility to meet accuracy standards

uses to meet certification standards. After the site survey and findings are reviewed, the practice has a finite amount of time to address standards that were not fully met, if any. This can usually be completed with documentation of compliance over a defined period and submitted electronically, and the practice then gains full accredited status. Depending on the agency, provisional accredited status may be granted while the practice brings the identified areas into compliance.

Once accredited, compliance with the standards must remain continuous. The entire exercise of becoming an accredited office means that a commitment exists to constantly measure processes, review data, and develop action plans to improve on the results to optimize patient care. Agencies generally resurvey a facility every 3 years but may do so sooner in circumstances that may call the quality of care or services into question. As mentioned previously, consultants may be used to assist with compliance by updating the practice on new standards, as well as assisting with in-house peer review and quality improvement studies and the development of monthly or weekly checklists that staff can use to monitor critical processes. Table 9-3 is a brief summary of the differences among the three agencies in the accreditation process.

In an era of ever-increasing transparency in health care, accreditation of OMS practices offers many benefits for both the OMS and the patient. From the patient perspective, accreditation makes sense. Much as the public expects airline travel to be safe and reliable because of systems implemented in the aviation field, so too should they expect the system approach to patient safety in an office setting. The ability of oral and maxillofacial surgery to offer safe and cost-effective care is rooted in the safe provision of anesthesia in outpatient settings. The 20th-century surgeon created the standard for outpatient care, but the 21st-century OMS would be wise to elevate that standard, particularly with the current national focus on quality, safety, and value. Accreditation offers a unique opportunity to demonstrate a specialty's dedication to safety and quality of care for OMS patients, and it can transform the specialty for generations that follow.

Marketing the Oral and Maxillofacial Surgery Practice

JOSEPH NIAMTU, III

Well over a decade ago, I had the honor to author a chapter on marketing the oral and maxillofacial surgery (OMS) practice in Dr. Fonseca's text series. I consider it a further honor to once again be asked to update this marketing chapter. No one can dispute that a lot has changed since the original writing of this chapter. Huge paradigm shifts have occurred in our profession. In the original chapter, I described OMS marketing as it existed 15 years ago. At the time of the original writing:

- Most oral and maxillofacial surgeons were slaves to referring dentists; now many referrals are a virtue of participation (or lack thereof) in insurance plans, HMOs, PPOs, and so on.
- Most oral and maxillofacial surgeons were involved in the considerable practice of orthognathic and temporomandibular joint (TMJ) surgery, and now (for various reasons) many shun these procedures.
- Most oral and maxillofacial surgeons took on-call duties at local hospitals, and now (unfortunately) many oral and maxillofacial surgeons have abandoned this responsibility and privilege.
- Dental implants were popular, but now they represent a virtual "new age" in our profession.
- I practiced full-scope OMS, and now my practice is limited to cosmetic facial surgery.
- Having a website was a cute means of having some identity. Today it is not only the main way that society communicates and seeks information, it is essential for marketing, patient education, and registration and is expected by the public.
- The Yellow Pages were the mainstay of marketing; today the Internet has displaced telephone book advertising. We have gone from "Let your *fingers* do the walking" to "Let your *finger* do the walking."
- Mailing panoramic radiographs to and from referring sources was the standard; today digital imaging and electronic transfer of images is replacing hard copy transfer.
- Cellular telephones were a luxury; today one must post "turn off your cell phone" signs in the office so as not to be continually interrupted.
- This chapter discussed mailing newsletters to referring sources, and today an email blast is a more popular option.

Considering all of these changes, there is a new spin on some parts of marketing our wonderful profession. This chapter will repeat a lot from the past chapter because some of this material is timeless. Other information has been updated, changed, or refuted to reflect the contemporary changes of oral and maxillofacial surgeons.

To devote a chapter to marketing in such a comprehensive oral and maxillofacial textbook is indicative of progress. This progression has been made on many fronts. First and foremost is the progress made within our profession.

Whether in the military or in sports, the first rule of competitive strategy is to know your adversary. In the consideration of marketing the OMS practice, we too must realize the adversarial barriers.

OMS occupies a realm in the public perception interposed somewhere between that of dentistry and medicine. This fact has shrouded our identity and services with an air of ambiguity from the onset of the recognition of OMS as a specialty. This ambiguity of services rendered and the public's lack of awareness of our training and education presents a further marketing barrier. Finally, the voracious and aggressive increase in our scope of practice and procedures has sped up exponentially, leaving the consumer confused about what exactly we do or used to do.

The aforementioned situations cumulatively have held us back in the marketing and public awareness arena. Ask the man on the street what a plastic surgeon does, and he will likely give you an accurate description. That same question

posed to the same person about OMS will more than likely not be representative of the scope of services we perform. In my opinion, this public appreciation of scope has not increased proportionately, even though our national organization has made great strides in publicly conveying our training.

Entering this discussion with these principles in mind facilitates and obviates the barriers we face and the direction we, as a specialty, must pursue.

Social Media: The Game Changer

I have had the honor of writing and rewriting this chapter for three editions of this textbook. The first time was more than 10 years ago when I was performing full-scope oral and maxillofacial surgery, and practice management and marketing were topics of personal interest. At the second edition, my practice was (as it is now) limited to cosmetic facial surgery, and I added enhancements relative to this topic. It is amazing how things have changed over the past 5 or 6 years. Although social media existed then, it was in its infancy and really had little impact on the goings-on of the average oral and maxillofacial surgery practice. Today, this is simply not true, as social media can enhance or detract from any health care practice.

In the "old days" when a new doc finished residency, he or she had to go into a community as the low person on the totem pole, and often struggled with the long road of developing a practice. In short, surgeons who had been established for years had the upper hand in controlling referrals. That was always the way it was. Traditional marketing consisting of print, TV, and radio is extremely expensive and generally out of reach for new graduates. Because of all this, the road from opening a new office to getting busy often took decades.

Today, you can see situations where a new graduate enters a community and hits the street with a great website and mobile website, an intuitive Facebook page, an active Twitter account, numerous YouTube videos, a progressive Constant Contact marketing campaign, a great Instagram and Pinterest app, and this list could continue. He or she can develop an overnight patient following, and in some cases out produce the entrenched competition. I have seen it happen, and have done it myself with cosmetic facial surgery.

Many older patients follow traditional marketing lines and still use the Yellow Pages, but the majority of patients today are very tech savvy. They don't limit themselves to traditional information sources such as a phone book, local word of mouth, or even general practitioner referrals. They make their own way to a given surgeon through social media.

Your name is your reputation. In this digital age, no marketing option is as powerful as the surgeon's own name. The first thing anyone reading this article needs to do is to try to grab a "dotcom" with their name. If it is Niamtu, it is easy; if it is Johnson, then you may be out of luck. Always keep in mind the power of your own name and start early to capitalize and own any domain you can get with your name in it. "Your name" is what people will search for when looking for information and reviews.

Website

The mother of all contemporary marketing is an exceptional website. Patients don't want to see a "storefront" website with a picture of the doc and office hours. Today's sophisticated patients expect the "whole nine yards" in a website. They want print information, animations, videos, before and after pictures, and interaction. They expect a link to ask the doctor a question and to schedule an appointment. They expect online registration and online access to all patient forms.

The topic of website is so complex that it should have its own chapter. Some doctors hire firms to do all of the website work, while others (like me) have total control of content. I have a company to host my site and update templates, but I have personally written every word and posted all of the 8000 pictures on my site.

Those doctors that are personally involved with their sites most frequently have much more advanced and up-to-date content.

I can't stress the importance of dynamic site content that changes regularly. Patients who see the same unchanging website will migrate to your competition that stays contemporary.

Contemporary websites should also have a blog, and the blog needs regular updates. There should also be an "Ask the Doctor" section where patients can ask questions that are answered in a timely manner by the doctor.

Look at any top leader in any field, and you will see what it takes to have a successful website. It must blend with all the social media that will be discussed here.

Doctor Rating Sites and Reviews

Physician reviews are second only to restaurants in terms of the importance of online reputation for choosing a business. Your online reputation has never been more important, and you must take steps to protect it.

Surgeons must learn how to acquire positive patient feedback on a daily basis so that service and satisfaction can be monitored, and put to work to market the practice. When negative reviews occur (and they will), it is much easier to bury them underneath scores of positive reviews. If the surgeon does not have positive reviews, then he or she will scramble to try to obtain them, which is unethical and obvious to the reader. Remember, today's patients look for reviews and take them to heart when choosing doctors. Contemporary marketing shows money is being spent on fostering patient *loyalty* more than ever before. Keeping current customers happy and engaged is the best route to practice success in the coming years, especially when you take into account patients' social connections and raised expectation levels.

One of my friends always says, "When practices spend good money after bad on marketing, it's like diagnosing and treating the wrong ailment and expecting a healthy outcome." Some surgeons spend hundreds of thousands of dollars on marketing but provide mediocre patient care. They will be outshined by surgeons who hardly spend any money on traditional marketing, but offer superior patient experiences and receive positive rating feedback. Something as simple as the way the phone is answered or the speed of an email response can have a significant impact on revenue. It does not take many mishandled patients to detract from your practice, and many practices drive business to their competitors without realizing it. Patient service does not occur by happenstance. It takes concentrated effort with regular practice, studying, and discussion to truly develop an experienced team for exceptional customer service. It is never coincidence!

Whether you like them or not, or believe in them or not, doctor rating sites are important and here to stay. In some respects this is a positive aspect, as in the past a doctor could be rude, arrogant, and dismissive of customer service, and still fly under the radar. Today it is a different game, and no surgeon who cares about his or her business wants a negative review.

Is it fair? No. My sister can go online and give me a glowing review, while my jealous competitor's staff can pose as an unhappy patient. Given this unreliability, a few bad reviews are not usually overly damaging. If you have 100 positive reviews and 3 negative ones, they are offset, but if you have 5 reviews with 3 bad ones, it is damaging. Again, the key is to find a way to let patients know that their opinion is important. I have a review section on my website, and we have cards we give to patients letting them know how to rate us if they desire. It is awkward for a surgeon to ask a patient for a positive review, but when a patient tells a staff member how happy they are with the treatment and service, it is simple for the staff to tell the patient that an online rating will enhance our practice and ability to continue this service. Don't wait for negative reviews to get positive reviews; that is like waiting for an emergency to get emergency drugs. Be proactive.

What can you do about negative reviews? First, take a breath and look in the mirror. Is it true? If it is, vow to change things and respond to the review (most sites allow a response) with a humble and contrite tone. "We are truly sorry that Mrs. Smith had to wait so long at her appointment. Her time is as valuable as ours, and we take that seriously. Most often we run on time, but occasionally we have to see an emergency patient, and that has to take precedent. If it were Mrs. Smith or her family with the emergency, we would do the same thing. We apologize and hope Mrs. Smith will give us another chance."

Never, never be defensive or argumentative. The online community does not like arrogance, and it will work against you. If you are truly getting abused, you may say something like, "Due to patient confidentiality, we cannot discuss this case, but if all the facts were known, the reader might have a better understanding."

Finally, if the review is untrue, abusive, or slanderous, you can petition the review site to censor or remove it, and frequently they will.

What is the best way to get positive reviews? This is a multifaceted question, and there are numerous answers. Personally, I think the easiest way is for your staff to guide the patient. So, commonly, a patient will compliment the surgeon, staff, or office. This is a perfect time for the staff to say, "If you want to make the doctor's day and help us, a positive online review will be greatly appreciated." I will say this myself when a patient is complimentary. The problem is that you can't just leave the conversation at that point. You have to provide the patient some information on how to leave an online review and what site(s) to leave it on. I have printed glossy postcards that we leave out in the reception room and hand to patients who offer a review (Figure 10-1). It provides the exact site and instructions to leave the review.

It's All about That Blog

Blog is short for "web log" and is a means of writing about anything you wish. Obviously most of your blogging would involve your profession, but it is not uncommon to blog about anything else in the world that may be of interest

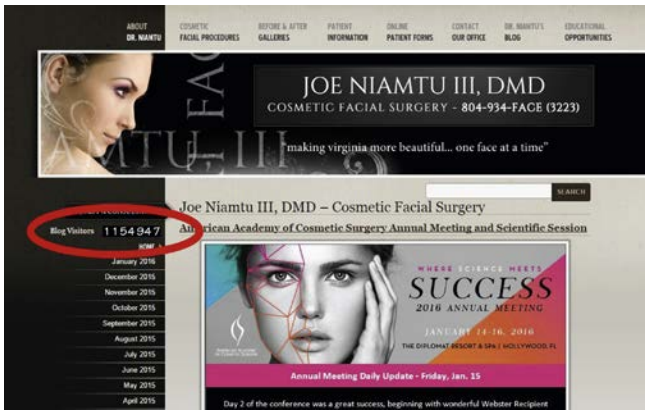
• **Figure 10-1** An example of the online review card that the office provides for patients interested in leaving an online review.

for someone to read. Having said this, when I first started blogging, I thought, "Who the heck cares about what I write?" Well, I was sorely wrong, and my blog has surpassed 1 million views (Figure 10-2). The point is that the World Wide Web truly is worldwide. It is simply amazing that somebody, somewhere cares to read what you write. I write almost exclusively about cosmetic facial surgery, but also do personal topics or other health topics of interest. One must be careful to keep the practice blog neutral and not get into topics such as politics or religion, as you can also offend or drive patients away. Blog entries should be short, concise, and informative. Also, readers love pictures and videos, and a plain print blog is boring. Sites such as WordPress (www.wordpress.com) make blogging easy and free.

One very important point about blogging is that it must be regular. You frequently see a doc bust out with five blog entries in a month, then drop the ball. If you want a following, you must post regularly. Even if you only do it once a month, do it regularly. The topic can be unlimited, so if you get writer's block, just write about some trendy topic or health topic or a charity you support. The material is endless. Lazy docs can get ghost writing services to do your blog, but to me, this takes the true personality out of writing. Your blog should obviously be linked to your webpage and simultaneously publish to your practice Facebook and Twitter pages.

YouTube Videos

One thing that has really changed in my 15-year tenure in cosmetic surgery is the information that patients want to see before choosing a surgeon. A decade ago I would never have considered showing a patient an intraoperative video of their proposed surgical procedure. It just was not something that was done. Today, with social media exposure, many patients are not only eager to see their actual procedures, they frequently choose a surgeon in this manner. I have treated patients from all over the country and world because they had viewed my YouTube videos on cosmetic surgery procedures. Such videos should not only show surgery, but should be informative like a lay lecture. They should discuss the diagnosis, procedure, and postoperative care. By "speaking" to the viewer, the surgeon also has a chance to introduce his or her personality to prospective viewers.



• **Figure 10-2** I thought my blog would go unnoticed and at the time of this writing have over 1 million visits.

At the time of this writing I have 4670 subscribers and more than 3.5 million views. I am amazed by this, as my thoughts about doing my first video were, "Who will watch it"?

It is not time consuming or difficult to produce relatively professional videos. YouTube has free editing software, but I prefer the video editor from AVS4you.com. This company has extremely powerful, simple, and intuitive video, photo, and audio programs, and it is unbelievably affordable.

Flickr Photo Sharing

I have always said "the best doctors take the most pictures," and I still feel that way. Pictures are mainstream, especially for cosmetic surgery procedures, and I have almost 100,000 jpg photos on my laptop and 8000 pictures on my website. These pictures not only serve as patient record but also work for me in many ways to promote my services and practice.

With thousands of images, keeping them organized can be difficult. Flickr has revolutionized my life, as all of my images (with patient consent) are stored online and I can easily create before-and-after galleries on my webpage where the images can be displayed from thumbnail size to full size. This service is free, but if you exceed a certain data amount, a very nominal fee is charged.

Facebook

Facebook has become the king of them all. More than 1 billion people communicate 24/7 on this site, which can serve as both a personal and business page. As much as I like and use social media, I am not a fan of receiving and answering messages all day and night—especially information like "on my way to the gym, just had a yummy muffin." I do spend about 30 minutes a day answering patient questions from my website and various social media outlets, but it is business focused. I don't do much with my personal Facebook page, but when I post on my blog, it goes to both my personal and business Facebook pages. This is a little redundant, but at the same time reaches different audiences. I do have colleagues who spend a lot of time on Facebook speaking with patients, doing contests and giveaways, and when I am with them, they are always typing on their phone. Not my cup of marketing tea, but nonetheless effective for some docs.

Regardless of your use or intent, to remain competitive, you must have a Facebook presence, even if it is basic info about your life and office. Remember that many young people use social media as their main source for searching and researching. This includes OMS and cosmetic surgery.

Pinterest, Instagram, and Twitter

As much as I enjoy and participate in social media, I have to admit that I don't have much presence on these sites.

I am not a "tweeter" and barely have enough time to do the things I have to do in life. All of my blog posts do go to Twitter, and that is the extent of my use. I have cosmetic facial pictures on Pinterest but don't feel it has spawned any direct patient encounters. At the time of this writing I do not participate in Instagram, but I have friends who are all over these three sites, and if they are not the prime movers, they have staff who do all the legwork.

RealSelf

RealSelf (realself.com) is a phenomenal site that links cosmetic surgery patients with prospective surgeons. It is an interactive site where doctors can advance through higher levels of visibility (higher levels cost money) and the users of this site treat it like gospel. I know of many plastic and facial plastic surgeons who obtain the vast majority of their cosmetic patients from this site. The big problem is that they will not allow single- or dual-degree OMSs to interact with most common cosmetic facial procedures. The list of "allowable" participation for OMSs (regardless of degree, training, and fellowship) include "teeth whitening, Invisalign, chin implant surgery, facial liposuction, and orthognathic surgery." Even though I do almost 100 facelifts a year, far more than their average plastic surgeon, I am prevented from soliciting or discussing this surgery with patients. This is an obvious slight controlled by competing specialties for patients and dollars. For this reason, I have discontinued participation with this site. It is powerful, but discriminatory.

Seeing Out-of-Town Patients

One caveat about using social media is the fact that it can propel your talents on a national and international level. I went from seeing patients from all over the city, to all over the state, to all over the country, to all over the world. This did not happen overnight and involves 30 years of practicing and marketing, but it was social media that made the biggest impact. In the past several months (as hard as it is to believe) I have seen patients from Europe and other continents for mole removal, cheek implants, facelift, otoplasty, and other common procedures I perform. Although this is a distinct honor for me, it is not without extra work for me and my staff. Out-of-town patients want to come in and out, and you must have stringent requirements for when they arrive and when they can leave post op. They also want to do online consults and Skype, and they expect exact diagnoses without a hands-on examination, which is difficult and illegal. These patients are, by definition, needy, as they are not local and need extensive information about travel, meals, housing, and caregivers. When you are set up for it, it becomes routine, but it is more time intensive than treating local patients. Also, the Web can be a magnet for younger patients with body dysmorphic disorder. There are many recognizable red flags, but most commonly young patients present with extreme image dissatisfaction, requesting surgeries uncommonly performed in that age group, or they want to look like a given movie star or celebrity. Avoid these patients at all costs.

The Bottom Line

One thing to keep in mind is that a surgeon must be competent to succeed. You can market extensively, but to keep the cycle going, you must have happy patients. Social media is a game changer, and this will not only progress in the current tangent, but will be exponential. The best docs will need to be on top of it in order to remain viable and contemporary with younger competing docs of the same and different specialties. This stuff is happening fast, and each time I update this chapter, there is new material. It will be exciting to see what the next version will reveal.

What's in a Name?

The majority of dentists graduating today receive a DDS degree, which implies surgical expertise to the public. The more descriptive DMD degree is of progressive thinking and public understanding. The specialty of OMS was in line for a name change for a long time. As a result of the politics of teaching institutions, many reputable OMS residency-training programs were forced to pursue nondentoalveolar procedures in a surreptitious manner. As a result of our excellent training in general anesthesia, many programs were able to perform some of the advanced procedures within their own clinic because of fear that other competing surgical specialties might protest. This proved, and in some programs still proves, to be a double-edged sword. On one hand, we were being trained in trauma, cosmetics, and so on, but on the other hand, this secretive approach breeds the mindset that propagates anonymity. For years we would not mention the word *cosmetic* because of fear of noncoverage by third-party carriers or criticism from other surgical specialties.

Some very progressive leaders in our national organization foresaw the need to change these preconceived limitations and levied for a name change within our specialty. Unbelievably, they met with resistance; however, history led us into the new profession of OMS.

The good news of the name change was that it was certainly more descriptive of our scope and gave us pride in pursuing procedures and techniques that were sometimes done in the after-hours clinic. The bad news is that the term *maxillofacial* is not understood by the general public and, in my opinion, has further masked what exactly it is that we do. I predict that the name of our specialty will be changed to "oral and facial surgery" within the next decade.

On top of this, our public perception is further hampered by the fact that much of what we do is painful, inconvenient, expensive, and without a tangible physical appreciation for the patient. Third molar surgery would be a perfect example of this concept.

Academic Marketing

Marketing is a popular major for many college students, and in the first-year courses, they learn the basics of the profession. Because many health care providers seem confused about the differences among marketing, selling, and advertising, it is appropriate to review the textbook definitions in Marketing 101.

Selling is concerned with the plans and tactics of trying to get the customer to exchange what they have (money) for what you have (goods and services).

Marketing is primarily concerned with the much more sophisticated strategy of trying to have what the customer or patients want.

By these definitions, one can clearly see that selling focuses on the needs of the seller, whereas marketing focuses on the needs of the buyer. Selling is concerned with the seller's need to convert their product or service to cash, whereas marketing is satisfying the needs of the customer.

A marketing-oriented office provides value-satisfying service that patients want. It provides the generic product (in our case, surgery), but also important is how the service is made available. Extended hours, payment plans, patient insurance assistance, a modern facility, state-of-the-art procedures, and painless treatment are just a few of the ways this service is made better.

Learning from Big Business

In the nineteenth century, the United States became a production-oriented economy and, over the past century, has shifted to a consumption economy. The energy and thoughts of the business community were once devoted to developing and improving ways of manufacturing. We now take our ability to manufacture for granted; the emphasis has shifted to a marketing orientation, and the energy and thought start with the customer (or in our case, the patient).

After the end of World War II, the General Electric Company pioneered the marketing concept in industry. The marketing concept is described as "a way of life in which all resources of an organization are mobilized to create, stimulate, and satisfy the customer and profit for the owner." If one truly understands this definition, they can begin to understand what marketing is really all about.

Corporations speak of the four Ps of marketing: product, price, promotion, and place. *Product* refers to making sure that the product is the right one and of superior quality. *Price* refers to establishing a price that makes the product as attractive as possible and still maintains a profit. *Promotion* is simply communicating with one's clients or potential clients. *Place* refers to putting the product where it can be most effectively used.

The correct analysis and mix of the four Ps are important, and marketing experts further maintain that a marketing leader must:

1. Determine the nature of changes in the market.
2. Identify and cultivate customers for the company's existing or potential services.
3. Meet the needs and wants of customers or potential customers.
4. Maintain a profitable position.

All of these factors are applicable to our profession. One merely needs to substitute the word *patient* for customer or client.

The second item in the list just given is very often overlooked. Historically, there have been many changes in the fee-for-service practice in medicine and dentistry. Before insurance coverage, patients understood their obligation to be responsible for health care costs. With the advent of health insurance plans, the burden of responsibility, at least in the mind of the patient, passed to the doctor. With the advent of exponentially increasing medical technology, the price of health care soared and became beyond the reach of most self-pay patients. Physicians' and hospitals' fees became obtrusive, and cost-cutting measures were instituted with shifts toward less hospital time and generalized cost containment. Managed care then entered the scene and has caused profound changes in our profession. There is now a shift to having primary care physicians triage patients, and surgeons are looking for ways to provide their services without the time and monetary expense of hospitals.

Physicians who had the ability to see these trend shifts were able to adjust their marketing and business strategies to meet the current need. Those who do not adapt may fail to thrive in this managed market.

Anyone who has read about corporate marketing is familiar with the concept of paradigm shifts. A paradigm is a model, and the paradigm for marketing OMS practices has been the same for years. Be a good physician, PR your referring sources, and you will prosper. We are now in the midst of a paradigm shift. With managed care, larger practices with multiple locations have positioned themselves to be attractive to the managed care plans of large companies. Now many patients are referred to a given surgeon, not because the general dentist wanted to send the patient, but rather because they had to use a participating specialist. Surgeons who refuse to explore managed care options may be driven out of business because they have not anticipated this paradigm shift.

A commonly used example of the loss of business domination from paradigm shifts is the Swiss watch-making industry. For hundreds of years, the Swiss dominated the making of watches and timepieces throughout the world. The paradigm for success was a mechanical product that was made from complex mechanical manufacturing and assembly of labor-intense intricacy. The Rolex chronometer wristwatch is an example of the fine product produced under this paradigm. The Swiss prospered and literally controlled the world production of wristwatches. In 1968 the Swiss controlled 65% of the world market in timepieces. They reaped 80% of the profit in the timepiece industry and employed 65,000 workers.

Around 1968 a Swiss company invented the liquid crystal watch and set up a booth at the 1968 World Watch Congress in Switzerland and introduced their new technology.

This concept was staggering. The watch had no moving parts, did not require movement or winding to function, and delivered accuracy 1000 times that of the finest Swiss timepieces. Although this timepiece technology was astounding, the major Swiss watchmakers were indifferent and did not even patent their own invention. Why? Because it did not fit their paradigm for what a wristwatch should be. Two companies, Seiko and Texas Instruments, did take notice, however, and saw the old paradigm for timepieces go out the door. They realized the potential of this new product and were able to move with this new paradigm. The rest is, of course, history. The Swiss workforce lost 50,000 employees and dropped from 80% of the market share to 10%. Today the Japanese dominate the world timepiece market; they had virtually no market share in 1968.

The point is that what works in marketing today may not be effective in the future, and the ability to predict and adapt is critical. Marketing is dynamic, not static.

Staying abreast of current technology is also important in the paradigm model. The bread and butter of our profession was once the extraction of carious teeth. It was only several decades ago that multiple full-mouth extractions were common on the office schedule of most oral and maxillofacial surgeons. Today because of fluoridation and education, full-mouth extractions have diminished rapidly to the point that some dental schools have trouble finding denture patients. Having four difficult impacted third molars removed simultaneously was not common 40 or 50 years ago. With the advent of high-speed drills, effective ambulatory anesthesia, and antibiotics, this procedure has become the mainstay of most OMS practices. Anytime a single procedure dominates the well-being of any business, its obsolescence could doom the business. The insurance coverage of third molars may fall into disfavor or be otherwise manipulated by insurance companies. We must, as a profession, be aware of this possible paradigm shift for what constitutes OMS.

Fortunately, our leaders have seen these caveats, and many of our ranks are entering the arenas of implant surgery, cosmetic surgery, and other nontraditional OMS procedures.

It is not uncommon to find physicians who are very averse to marketing in the form of advertising. These physicians say that they do not market. This is such a fallacy; we all present an image, and this is marketing. Some physicians are actually doing negative marketing by having poor staff and lack of policy while condemning an office committed to excellence.

Marketing Your Practice

I am fortunate enough to enjoy a mix of private practice and academic environments. The phrase "Always be a teacher and always be a student" drives many of our ranks to excel in both venues. I have written and lectured extensively on the subject of marketing the OMS practice and have found that, regardless of the community, state, or country, many physicians are in search of the "secrets of marketing." The delusion of these individuals confounds me time and time again. Practitioners want to know "what to do to get referrals." Sometimes, after a well-prepared and well-presented course on marketing, participants will confront me at the end of the lecture and say, "All of that is fine and well, but what is it that you really do to get patients? Do you give holiday presents? Do you do lunches? Do you need fancy imaging?" These physicians have missed the entire point. The correct answer is all of these and none of these.

Marketing is not the act of giving something to receive a patient on a one-to-one basis. Marketing is more of a mindset and a practice lifestyle. There are many successful practices that spend tens of thousands of dollars on marketing events and gifts, and there are just as many practices that thrive without spending a dime on those things. The latter type of practice focuses on two things: superlative patient care and simply knowing how to say thank you.

In addition to these examples, there are physicians who do all the correct marketing, even employing professional firms, yet have stagnant practices. These practices go through the motions, but have poor leadership principles and staffs that negate their marketing investment.

Successful marketing, as stated earlier, is a grass-roots level of excellence that starts before the patient ever gets a foot in the door. The bane of existence of any specialist in any discipline is the reliance on others for referrals. It is rare for a patient to see a sign for an OMS and drop in, whereas a "Family and Cosmetic Dentistry" sign may cause people to walk in and begin a relationship. In a thriving practice, one will see a constant trend of patients referred from sources other than general dentists. If an OMS office provides a warm, loving, and caring environment, patients of record and reputation will bring in as many or more patients than do primary referral sources. It is usually at this point that a physician really begins to feel and enjoy independence.

Getting to this point usually takes a number of years, but can be greatly accelerated by attention to basic communication skills and common sense.

The grass-roots level, of which we spoke, must literally permeate every aspect of one's practice, and it must be stressed that the staff is far more important in the spectrum of marketing than the physician. Most offices that are stressful and unprofitable suffer from poor leadership. Most physicians have no experience at human resource management and have accumulated what knowledge they have from hard knocks. It is shocking but correct to say that most employee problems are the fault of the employer and not the employee. Leadership is essential to make any team of individuals with a common goal cohesive and effective. In my opinion, 98% of the problems that make practitioners dislike their jobs stem from poor hiring and firing practices and the lack of leadership. There can be only one leader in an office, and that must be the physician. Leadership cannot be confused with management. One can delegate management and hire managers, but again there can only be one leader, and leadership cannot be delegated.

For the sake of comparison, let us envision two separate practices. One practice is a thriving, progressive, profitable practice that continues to grow. This office always seems to be on the forefront of the profession, and when you walk in, you are overcome with the energy of the staff. The environment is modern, clean, bright, and friendly and employs the latest technology. The physician and staff are aesthetically presentable, and smiles and warmth abound. When you have been in the office for awhile, it becomes evident that the office represents the leader. It is if she is "working at home." It is also evident that the physician has a passion for her profession, and practice is a joy and a privilege. The staff is cohesive; their careers seem enjoyable, and they work as if it is fun. This office presents an image, and that image is impressed on the patients who are exposed to this environment. It seems to rub off on them, and they leave with an enthusiasm for this staff. They sense the energy and the warm, friendly treatment and are impressed enough to comment to their friends and neighbors. Although they do not look forward to surgery, they do not mind and may even enjoy visiting the office. They enjoy being part of the energy and enjoy the special attention that seems so rare in this fast-moving technological era. The referring physicians and their staffs have the same feelings about this office and are confident that when they refer a patient, he will thank them for sending him to such a compassionate office. If a patient goes back to a referring dentist and says that the OMS was expensive, the surgery made them sore, and the recovery was extended, but thanks for sending them to such a warm, caring, and compassionate specialist, megamarketing has been accomplished. This is never a coincidence; it is the result of great effort and attention to detail. It is a result of the pursuit of excellence, based on the principles of leadership and policy.

Let us now contrast this office with one of mediocrity. This office may be right next door to our previous example, but always seems to be "chasing its tail." The office does not glow and is unkempt. The staff is stressed and bickering. The physician and the staff do not convey an aesthetic image and seem to have a goal of reaching 5:00 PM. Confusion and happenstance seem to rule, and there is an obvious lack of organization. The general atmosphere seems tense and rushed, and fun seems to be the last thing that anyone is having. The entire experience is reminiscent of old-fashioned dentistry. The staff turnover is high, and the future of health care seems bleak to these folks.

Although these contrasting examples are fictitious, we all can probably relate to a real-life example of each scenario. We must ask ourselves what exactly it is that makes such a difference. Knowing the answer to this question illuminates the principles of successful marketing. These are again leadership and human resource skills.

What Is Your Vision?

The first principle to discuss is vision. There are very few successful people in any walk of life who achieved their success by chance. Virtually everyone who has succeeded and reached professional contentment is a visionary. Such a person must have a clear idea of their goals and a plan for approaching them. Without this, chaos will rule. If asked, any oral and maxillofacial surgeon should be able to state their vision or guiding principles and their end point. This should also be second nature to the staff; after all, if you as a leader do not have a vision, then how can you expect your staff to know where you are going as an office? Your vision must be communicated with the staff and constantly reinforced. If you do not do this, you cannot build a cohesive team. It sounds trivial, but it is the single most important factor in beginning a journey to excellence. It is said that excellence is a journey, not a destination. In other words, there is no finish line; improvement and superlative patient care and the love of what you do are the dividends. If while reading this text you cannot immediately stop and write down your particular vision, then you should stop reading and start writing it—because it is the first rung of the ladder to excellence. By the same token, if you and your staff are not pursuing excellence, then you should send your patients elsewhere so that they will receive the best care available. Obviously, this sounds drastic, but it underscores the point.

A vision must be practical, ethical, and attainable; have a time frame; and be modifiable to bend with the curves of life. My own vision has been to: (1) build a large group practice that is enjoyable to both owners and staff and to serve patients with a warm, loving, and compassionate environment; (2) pursue technical excellence and to stay abreast of the forefront of our specialty; (3) become financially independent and serve those less fortunate with the ability to obtain our services through community work; (4) become a well-known entity for going out of the way to better provide for patients and referring offices; and (5) to have fun in the pursuit of excellence in OMS.

After you have developed a clear vision, the next critical step is to assemble a team of individuals capable of carrying out this vision. In any major team sport, tryouts are given, and the leaders search for certain critical attributes to best serve the effort. The vision is clear; it is to win. Can you imagine a team that merely selected its players without tryouts? They would never win because finding the right person for the right position would be all too random. With this in mind, it becomes obvious why some practices fail to win: The selection process is random.

Selecting the proper employees is a skill and can evade even the largest of businesses. There are scientific statistical methods for selecting the proper person for a job; however, the real answers are simple when applied to real life. For the sake of comparison, we will call a perfect employee a 10 on a 1 to 10 scale. In most progressive practices, a 7 or less is unacceptable. If a physician can surround themselves with 9s and 10s, marketing can be as easy as showing up for work. Because the caliber of employee is paramount and usually directly proportional to the success and stress level of any practice, the importance is obvious.

Hiring and Firing

Anyone who thinks that this topic is inappropriate in a marketing chapter already has serious misconceptions. Inevitably, when one closely examines the details of a successful OMS practice, exemplary hiring and firing practices exist. The converse is true for poorly run or unsuccessful stress-ridden practices. For the sake of comparison, I will continually compare the details of two practices. One practice is profitable, user friendly, energetic, and sets new standards for the community, and it has a physician and staff who enjoy their careers.

The other practice withers on profit, has a frustrated staff and physician, does not experience sufficient growth, has high staff turnover, and just is not fun to work for.

By contrasting the factors that differentiate these two practices, we can gain tremendous insight to some of the most common marketing problems. It is not going out on a limb to make two important statements. First, most problems a practice may have concerning marketing and communication can in some way be directly attributable to the hiring and termination policies of the practice. Second, the extent of the leadership of the physician will directly affect the policies or lack thereof in the office and will contribute to the employee relations problems. Most such problems are the fault of the employer, not the employee.

One of the inherent problems that have, for a long time, affected professionals in all branches of health care is the dearth of business courses offered to the physician in his or her preprofessional training. A thrust of today's medical and dental school curricula is the inclusion of business and practice management courses. Even in the most progressive didactic environments, this topic is usually too little, too late.

A compounding modifier to all this is the fact that medical and dental practices have traditionally evolved as small, independent, closed-circuit, business models that have been resistant to outside consultation or changes in the structural and managerial paradigm. This has created a very inbred system of strong independence, but little thrust toward interdependence. Although there certainly are positive points associated with this structure, it fails to adapt to changing paradigms, and because of this, physicians' offices tend to be trapped in a whirlpool of poor management, communications, and lack of adaptability. Inflexibility in this arena, to my mind, has led to our inability to predict the current managed care crisis. Cost containment and efficiency issues should have been predicted and dealt with a decade ago, instead of now. The ability to foresee and adapt to change is essential to succeed in any facet of business, including medicine.

The other component that has crippled the business of private practice surgery, in my opinion, is the failure to pay attention to changes in corporate America. We have been so steeped in autonomy that we have ignored the current trends in big business. Corporate America approaches management strategies with the same statistical scientific scrutiny that we afford our surgical literature. There exists a wealth of knowledge on human resources and marketing that has basically been ignored by health care providers. It is usually only through consultants that we gain exposure to this information. Because of this, we are constantly reinventing the wheel, which increases stress levels and decreases efficiency. It is a safe bet that the successful practices that we contrast already have an understanding of all of this.

Professional Consultation

The term consultant has been mentioned several times already, and now is an appropriate time to expound on this. We all seek advice from outside sources, especially in situations where the source knows more than we do about what we want to accomplish. Most oral and maxillofacial surgeons would not take apart their own engines if their car stops running, nor would they consider taking the transistors out of their TV if it falls into disrepair. Our everyday lives revolve around professional advice. Therefore, it is difficult to believe that so many physicians resist obtaining outside consultation. Our autonomy sometimes gets in the way. Anyone who runs a practice has very strong emotions and opinions about the way that practice runs. When you add partners to the scheme, these emotions and opinions increase logarithmically. It is very difficult to make prudent decisions in the face of emotional issues. Anyone who has made decisions to institutionalize a parent, euthanize a pet, terminate a marital relationship, or deal with similar issues will testify that it is very hard to make such decisions because emotions cloud the clarity of the issue. In these instances, we usually turn to those we trust to separate the issue from the emotions.

This emotional attachment to our practices often causes warped perceptions of the way the practice runs. To make rational decisions, one must have the big picture. A good metaphor for this situation would be a person enjoying a scenic boat ride along a beautiful river. The person in the boat is overcome with the beauty of the trees, water, and wildlife. The boat ride is absolutely wonderful—except that something ominous is happening. A person in an airplane that is flying over this boat can see more of the picture: 10 miles downriver is a huge waterfall that will kill everyone currently enjoying the boat ride. The person in the boat is disadvantaged by not seeing the entire picture, and the person in the airplane can avert disaster by alerting the captain of the boat to the impending danger. This metaphor illustrates the role that a consultant can play in your practice. Given the level of quality that we all seek in everyday life, it is unfathomable that so many physicians resist these ideas. In numerous practices, I have seen the entire office awakened by qualified consultants. Adapting an old adage, a physician who refuses to seek business advice has a fool for an advisor.

Another pitfall that I experience is "pseudoconsultation." This involves taking advice from the wrong people. Frequently, surgeons turn to their accountants or attorneys

for this type of advice because these individuals are familiar with the practice. However, most of these professionals have little practice management experience and often prove to be poor advisors. A frequent excuse for not seeking outside assistance is cost. Some physicians say that they quite simply cannot afford it. I am on record as saying that you quite simply can afford it.

Successful general dental practices have multiple hygienists doing recall visits. The dentist may pay these hygienists $200 per day. This can be a significant expense. These physicians may make a clear profit of $1000 per day after paying the hygienist. Many dentists never hire a hygienist because they "can't afford one." Again, how can they afford not to? A qualified practice management consultant and team may cost up to $10,000 for several days of work. If these people can institute changes that increase your accounts receivable, billing, coding, and staff relations by several percentage points, the payoff in profit and stress reduction may be tenfold. Why are so many physicians resistant to this concept? If a physician is truly interested in excellence, he or she must take the first step. Yet many cannot ever commit to take that step. As stated earlier, if someone is not about excellence, then they should send their patients to another oral and maxillofacial surgeon so they can have the best care.

Employee Relations

Because many new practitioners will be reading this chapter, I will begin at an elementary level and progress. The basis of the chapter is important for all employers, regardless of their time in practice.

There are universal situations that enhance or detract from any business, regardless of type, and choosing the correct employees is paramount. This applies especially to all service-oriented businesses, of which health care happens to be one. Unfortunately, many physicians never grasp the concept that their business is based around service and therefore struggle and endure unnecessary stress, whereas their colleagues who do understand the concept have fulfilling and profitable practices.

In any service-related industry, it is usually the level of service that sets businesses apart. For instance, if you had to ship one of your most prized possessions somewhere overnight and were ultimately concerned about its safe and timely arrival, would you choose Federal Express or the U.S. Postal Service? Most people would choose Federal Express because of their perceived high level of customer service and the lackadaisical attitude often attributed to government employees. Serving your customer or patient base is the key to success. A physician may be a genius and the best surgeon in a given area, but if the staff is abusing patients, the practice will not prosper. On the other hand, a mediocre physician can be elevated to hero status by a staff that nurtures their patients. Most physicians are clueless on correct hiring and firing concepts, and the ones with experience have often earned their knowledge through hard knocks. When I lecture to large groups of physicians in any locality, I always name employee relations as one of the top three factors in practice stress.

In the past, poor hiring and termination practices may have only meant increased employee turnover and physician stress. In today's litigious environment, improper human resource skills frequently lead to lawsuits. Wrongful discharge, sexual harassment, discrimination, and other employment-related litigation is on the rise. For a suit-prone employee, the ability to win a hugely unreasonable settlement holds much better odds than a lottery ticket. Sexual harassment suits have been settled for millions of dollars for innocently intended gestures or actions. This is a frank reality of modern employment law and circumstances. And it's the wrong arena in which to learn by mistake. Suits for sexual harassment are not covered by malpractice or umbrella insurance and are the responsibility of the defendant. Guilty or not, subsequent publicity can be very damaging to the morale, reputation, and pocketbook of the physician. Because most OMS offices involve a male physician with a female staff, I strongly advise all new practitioners to make a thorough study of local employment laws.

Initially, a new oral and maxillofacial surgeon will probably require a staff of at least three employees. The American Association of Oral and Maxillofacial Surgeons (AAOMS) recommends that two employees assist at surgery, and someone needs to tend to the front desk and clerical duties. Some new physicians may economize by using two employees and placing the telephones on a recorder during surgery; however, this compromises your availability to your referring physicians. There is no doubt that as soon as you can afford adequate staff, you will enjoy a safer and more efficient practice.

The easiest positions to fill are surgical assistants. There is a strong pool of dental assistants, nurses, surgical techs, and so on. As with any business, previous experience is preferable. A seasoned assistant can actually teach many things to a new physician. It is also preferable to hire an assistant who can also obtain hospital assisting privileges. As with all positions, a friendly, compassionate, presentable, mature assistant is optimal. One potential problem of hiring new employees is the age and experience levels of the applicant pool. This pay and experience level is filled with young, inexperienced women. Many have little experience, and their reliability and maturity levels may not suit the demands of the job. In addition, this segment of potential employees is often transient as a result of schooling, relationships, and childbearing. I have taken pride in hiring this type of employee and watching her grow into an excellent staff member. This, however, has been in the presence of superlative staff members who had the opportunity to mold her into a polished employee. Hiring this type of person without nurturing can lead to many employee-employer difficulties.

The job of practice receptionist is much more challenging. This employee is literally the ambassador of the practice and, more than any other employee, can add or detract from it. She is usually the first person to give an impression of the

spirit of your practice. In many cases, prospective patients call the office and are confronted by many barriers. Pain, expense, inconvenience, apprehension, third parties, and lack of appreciation of services are just some of the common barriers between physicians and their patients. Many of these patients are "shopping around" to find a caring and reassuring environment or the ability to tailor finances. An exceptional receptionist will attract these patients, whereas a rude or noncompassionate person may drive them away. This position calls for multitasking, especially for a new physician with a small staff. In addition to her duties as a receptionist, this employee must assist in coding, billing, insurance, accounts receivable, and collections. All of these functions are as vital to the success of the practice as the skill of the physician. This position begs for a mature, experienced individual and will command a higher salary. It is money well spent, because this person can literally help shape the future of the practice.

Where to Find Good Employees

This is a question posed by all businesspeople. Experience is very important, and the optimal situation is to hire someone who has worked in an OMS practice. I strongly advise against hiring an employee from a colleague's office, unless you discuss it up front with the other physician. A new physician can count on intimidating existing practitioners, and there is no need to start off in a deeper hole.

Local dental societies usually have newsletters with employment sections that can prove useful. The want ads in the local area are a traditional means of finding help. I would warn you not to place anyone's home telephone number in the ad for applicants. It is not unusual to have many, many calls at all hours of the day and night. Instead, I suggest a neutral address or P.O. box to which applicants can send résumés. If the new physician does not have hiring experience, it is best if a qualified party assists in the interview process. It is important to hire someone with the correct "fit," who will augment the personality of the physician. Many employment situations are a roll of the dice, but I caution against hiring someone who makes you feel suspicious. This is also no place for a demure introvert. Hire someone with good eye contact, a good smile, and an enthusiastic attitude. An employee who "glows" is a keeper and will infect the other employees and patients with that glow.

As the practice prospers, additional employees will be needed. It is not unusual for an OMS practice to have three to six employees per physician. As discussed later in this section, many offices believe that they are understaffed, when in reality, they are actually overstaffed.

New physicians are frequently in a quandary about starting salaries. By surveying colleagues in the general dental community, you can establish a scale for given positions in a given community. Additionally, many of the "throwaway" dental periodicals offer yearly regional staff salaries and regional fees.

For many people, one of the major incentives to work is to obtain insurance benefits. In health care professions, it is pretty much a given to offer health insurance as a benefit. Although there are many means of doing this, some of the most common are as follows.

Many companies offer group health plans at a substantial savings, whereas other employers give their staff a monetary sum for the employee to use for the plan of their choice. Because many employees may have coverage from spouses, they may not need all the benefits that another employee would. So-called cafeteria plans are a popular option, presenting a menu of options that employees can choose from. Other benefits include sick leave, holidays, uniform allowance, and retirement benefits. Most physicians have pension and profit-sharing plans and therefore are required to match funds for employees. This is a tremendous benefit and is often overlooked. An employee with longevity can save thousands of dollars in 401(k) plans or similar vehicles. This benefit must be fully explained to be appreciated and extends the gift of ownership to one's staff.

Let us now direct our attention to the actual art and science of hiring and firing. If there is one element of running a business for which most physicians are unprepared, it is finding, keeping, and terminating employees. Almost every seasoned practitioner bears some emotional scar from improper handling of employee issues. Many in our ranks have been parties to lawsuits for violating the most basic tenets of employment procedures. In discussing several commandments of hiring, it is important to include some absolute basics. Many of these principles probably existed in the marketplaces of ancient Rome, yet millions of bosses make these mistakes 2000 years later.

I strongly believe that it is an absolute mistake to hire spouses or family members as employees. Nepotism will at some time cause employee problems. I have lectured all over the country on this subject and am often met with resentment for stating this opinion. It never fails that at the end of a lecture a physician or spouse will confront me in stern disagreement. My response is that there are always exceptions to the rule, but I know of countless problems involving family. This is especially difficult for partners or other employees because they may perceive preferential treatment. In addition, the spouse may have the "coach's son syndrome" and apply stresses that are unnecessary. There is no doubt that it is difficult for a partner or manager to reprimand his or her spouse, and if there is a dispute, it is rarely the other person who must leave the practice. I have observed many state-of-the-art practices over the past 20 years, and it is rare to find an exceptional practice with family members as employees. Two exceptions are having family help at the very beginning of the practice as a cost-saving step, or casual summer employment for odd jobs.

On the subject of nepotism, it is also an unwise practice to hire relatives of current staff. The same pitfalls apply, and many embezzlement schemes have involved this type of situation.

Although it appears painfully obvious, professional physician-employee relationships should stay just that. In this era of sexual harassment, even the most benign of gestures can be grounds for a successful suit. I know of multiple cases throughout the country, involving very expensive and embarrassing outcomes for a surgeon—suits brought for telling off-color jokes, inappropriate body contact that was a "back rub," and commenting on an employee's attire or physical traits.

Another common violation is the temptation to manipulate money. Some physicians may pocket cash that comes across the front desk and believe that it is untraceable. Always remember that if a staff member witnesses a physician evading taxes or doing anything illegal, he now has a partner. If the physician can steal cash and no one knows, then why shouldn't the employee also steal?

Physicians spend as much or more time with staff than they do with their own family, and there exists a temptation to bare one's soul. I cannot stress enough the need to always keep some distance between your private life and what the employee knows or hears. I know several exceptional surgeons who were dragged through the mud by a terminated and disgruntled employee. Never underestimate the diabolic nature of a scorned employee. As in a nasty divorce, they will use any weapon of destruction, so don't give them ammunition.

Let us get back to hiring and discuss the interview process. There is a true art to being a good interviewer—the art of listening. Not only listening to what the employee says, but being able to read between the lines to know what he or she means. I will elaborate on this later.

First of all, the dress and demeanor of an interviewee is important. Given the fact that most people are at their best in dress and behavior at an interview, it is usually safe to assume that what you see is the best you will ever see. If dress or demeanor is inappropriate at an interview, it will only go downhill.

I believe strongly in hiring bubbly, enthusiastic employees, and an applicant who does not smile and show strong eye contact is usually a poor choice.

An additional caveat is an applicant who speaks negatively of previous employers. This should be a severe warning, especially if the applicant claims to be a "victim." There is little doubt that you will be the next bad guy in line.

As stated earlier, experience should be high on the list of employment attributes. Training someone to do a job is okay, but for a new physician, it merely adds further stress. For the new physician, it is better to hire a "teacher" than a "student." Interviews need not be exhaustive and should be standardized. In short, you have two people sizing each other up. Do not forget that the applicant is also interviewing you as a boss, and when an employee resigns, they are effectively firing you as a boss. It is a two-way street. One good question to ask is what the applicant liked or disliked about their previous job. This can extract key information about how they may fit in in your office. It is important to know if they can meet your standards in terms of overtime, Saturdays, and so on.

The next most important thing is to be able to relate your vision and the goals of your practice. You must actually present written documentation of who you are, where you are going, and how you plan to have this applicant assist your journey. Many physicians do not have these guiding principles in writing. How can an employee relate to goals that don't exist? Again, you should provide the applicant with his or her job description and discuss it in detail. If you want an exceptional practice, you need to employ exceptional people. If you do not have written job descriptions, you must settle for mediocrity. I suggest making an audiotape or videotape containing the guiding principles and visions of the practice. This will standardize the interview process and simplify this task.

If you have properly defined your goals and visions, you can effectively ask the applicant if he or she wants to play on your team and follow your rules. If you haven't defined the rules of the game, then how can you possibly expect the employee to play? I have sometimes done this with applicants who then stated that they could not comply with our expectations. They did both of us a tremendous service, because months of frustration might have passed before the employee quit or was terminated. The point is that if we did not have the job description and rules of the game defined, then we could not have gained this information.

Employee references can be perfunctory or very significant. Unfortunately, legal precedents have been set, and references can be grounds for a suit. Many employers are delighted to get rid of a problematic employee and want no backlash from a bad reference, so their word may not be accurate. On the other hand, an employer may be afraid to give an accurate reference because of concern about legal recourse. You will probably need to speak to several individuals to actually obtain an accurate impression. To simplify this process, it is important to ask the previous employer if he or she would hire that employee again. It is also prudent to ask them if the applicant possessed the attributes or lack thereof that we are about to discuss. This gives some standardization to the referral process and allows the new employer to find out more about the applicant's ability to fit into their office.

Any employer must be extremely careful about providing a negative reference. If an applicant can prove that you have prevented them from getting a job, you may be liable. Million-dollar damage awards have been won by employees who were able to prove defamation. I strongly caution any employer against giving a verbal or written negative reference, especially to a stranger. Many large companies will only verify employment history, the date an employee was hired, and the period of time that the employee worked. These companies refuse to comment on subjective questions. If an employer wants to provide a negative reference without jeopardizing himself, the statement "I cannot comment on this employee under advice from my attorney" should make the point without creating liability.

There is no doubt that hiring the incorrect employee can cost thousands of dollars. The cost of training, the loss of efficiency, and the negative impact are immeasurable.

I believe that there are eight attributes that make a perfect employee. For the sake of measurement, we will refer to a perfect employee as a "10." What we desire is to be able to screen for employees who are a "7" or above. The attributes listed in Box 10-1 will greatly assist this evaluation process. (I am grateful to Howard Rochesti of the Mercer Corp. in Santa Barbara, CA, for his ability to distill this valuable information into simple categories.)

Competency and Presentation

Competency is the foremost attribute required in the consideration. Again, in any service-oriented business, customers or patients expect and seek a certain level of care and service. When a person goes to a fine restaurant, they know in advance that it will be expensive. For that expense, they expect a high level of service (e.g., prompt seating, polite treatment, accurate ordering, fast service, and attention to detail). A waiter who cannot meet those expectations is incompetent. If you order a rare steak and salad with dressing on the side and get a well-done steak and a salad drenched in dressing, that is incompetence. This incompetence will, across the board, cause unhappy customers and invariably harm the reputation of the owner. What is frustrating here is that the restaurant owner may really have paid attention to detail. He may have a beautiful facility with ample parking. He may purchase only the finest ingredients, and he may have hired the best chef in the area. Despite all the attention to detail, a single incompetent employee can shatter his dream of having a fine restaurant by negating his attention to detail. There is a difference between inexperience and incompetence. If our waiter had a badge that said "waiter in training," we might expect a lesser level of service. This employee may become an excellent waiter, but should not be turned loose on the public without someone supervising. Presentation is also a very important factor to consider in our business. The discipline of OMS involves cosmetics, aesthetics, and health. One of your most powerful marketing principles is the appearance of the physician and staff. Slovenly, out-of-shape staff with yellow teeth or fingers from smoking or excessive body piercings or tattoos is not the image that we are trying to convey. An obese employee who is bubbly and neat may be an asset, but someone with cellulite bulging from dingy polyester white scrubs does not help with your marketing efforts.

• BOX 10-1 Key Interview Points to Consider When Interviewing Potential Employees

1. Competency and presentation
2. Unconditionally committed
3. Givers or takers
4. Offensive or defensive
5. Superstar or team player
6. Joyous
7. Self-managing
8. Learner

Unconditional Commitment

Unconditional commitment is defined as commitment without conditions. The closest example that I can find is a resident in a training program. As residents, we could not allow anything to take precedence over our work. None of us would have dreamed of telling our respective program chairman that we could not meet a deadline because we ate lunch and did not have time. We were in an environment where lunch was not a priority, and our work took precedence. Now, when we are called to the ER in the middle of the night, we cannot say, "It's late—call me in the morning." These are examples of unconditional commitment.

Owners of businesses have much more impetus to be unconditionally committed because they reap more of the benefits or failures than the employees. For this reason, it is rare to find this level of commitment in an employee. One thing about any society is that people identify and bond with cohesive organizational units that work toward a common goal. Fraternities, sororities, social clubs, sports fans, bowling leagues, scouting, and church groups are examples of situations where people unite and develop sometimes extreme loyalties. There is usually little monetary incentive in these groups; the point is that we are social animals and will expend great effort for "the cause." This same social nature extends into office settings, and when employees bond and identify, they will put forth great effort for the good of the practice. When you have a good leader, clear-cut goals, and the right employees, the business is a beautiful machine. Physicians who have exceptional and profitable practices probably are good leaders and have exceptional employees with a well-defined common goal.

An unconditionally committed employee will perform within reason to accomplish the task at hand. An applicant who will not work overtime or on Saturdays or follow your rules of the game is only conditionally committed and does not meet our criteria.

Finally, an employee may be unconditionally committed to you and not your vision. If an employee is only committed to you and you come into work with a poor attitude, then they will take on your attitude. However, if an employee is committed to your vision, then she will pull you aside and remind you of your commitment to excellence and point out that your attitude that particular day is not what our goals define.

Givers versus Takers

Everyone is either a giver or a taker. A giver is a loving, compassionate person who truly enjoys giving of themselves. These people understand the win-win concept and fully realize that the more they give, the more they will receive in return. They exude a generosity that is not measured in physical gifts, but more importantly, in the subjective sense. These people give gifts of advice, time, compassion,

empathy, and service. You should, by now, be getting a picture of what it is that we want in an employee.

A taker, on the other hand, operates in the win-lose environment: For them to win, someone else must look bad or lose. This was the student who reminded the teacher that she did not collect the homework assignments in school. The student's purpose was not to serve as a reminder, but rather to look good at the expense of others. This is a malignant personality trait and is manifested in all sections of culture. An oral and maxillofacial surgeon who refers to other ORL and maxillofacial surgeons as competitors instead of colleagues is another example of a taker. Any person who speaks negatively about anything to enhance their own identity is a taker. A giver would compliment the other person on their efforts and then focus on their own. Although it is impossible to screen for this attribute in an interview, this behavior must be identified and these people removed from your staff. One bad apple can spoil the whole bunch. If, as an employer, you ever come across the "What's in it for me?" attitude, you must take action. If an employee must have someone lose for them to win, guess who will be losing? The losers are the boss, the other staff, and the patients.

Offensive and Defensive Employees

In this categorization, we are referring to one's ability to accept change. Change is the basis for all molecular structure and all of life. Everything from the subcellular level on up involves motion, change, and energy. If you examine successful people and successful practices, you will see that they thrive on change. Change should breed excitement, but for many people, it causes fear and insecurity. If physicians are truly interested in approaching excellence, they must continually change all aspects of their practice to increase efficiency and service. I challenge and reward my staff for changing. We look at our forms, our policies, our furnishings, and so on and brainstorm, as a group, on how to improve. Accepted employee suggestions are validated by monetary rewards.

Some employees are intimated by change and take the "If it ain't broke, don't fix it" attitude. This is poison in a motivated practice. Employees who encourage and accept change are termed *offensive,* whereas those who fear and resist change are termed *defensive*.

I recently made significant changes to the charting system in my office. These changes meant altering the status quo of everyone's interaction with the structure and handling of the office charts. It was truly enlightening as an employer to witness the offensive staff immediately recognize the potential for increased efficiency and service, whereas the defensive staff members could only see problems. For these defensive staff, this meant doing things differently, and even though it was actually less work on their part, they resisted as a result of their personality trait.

It is appropriate for staff to challenge change. When I first proposed the charting system changes, I did not consider some shortcomings and was enlightened by challenge from the offensive staff. It was interesting that the pitfalls put forth by the defensive staff were less amenable to improving anything.

We all like change because it counters boredom. If we all wore the same clothes every day and ate the same food at every meal, life would not be as interesting. The same holds true in the workplace. A valid leader understands that not all change may be effective and must concede to their staff if a plan is not working. It is all right to make mistakes, but don't dwell on them. Better to move forward and, by trial and error, enhance the service to your patients. Successful practices have offensive players.

Superstars versus Team Players

The term *superstar* is not a positive adjective in the sense we are using it. A superstar is the type of employee who can do it all. Although this might be appropriate or even desirable for your first employee, you will have problems when you begin adding staff. The superstar manipulates situations so that all the attention swirls around them. It is not about winning the game; it is about how many points they scored. The superstar believes that because of their previous experience or superior intellect, they can "do better." They feel superior and are often overprotective of the physician and the practice. Their attitude is that they must "save" the practice from the incompetent hands of the other employees. These employees may take some time to recognize because they seem so dedicated on the surface. If you examine the attitudes of their co-workers, it will become evident if they are respected leaders and role models or self-servingly critical.

There are tricks to ferret out this personality type. They frequently place themselves in situations that "no one else can do." For instance, they are the only ones who can back up the computer or the only ones who do the payroll. They thrive on being needed for important functions. They frequently do this to become indispensable. They may cause many employee problems and know that the other employee will be fired, because the practice cannot run without the efforts of the superstar.

You cannot fire these employees because no one else can perform the vital functions, such as backup or payroll. The key to neutralizing superstar status is cross-training. Give several staff responsibility for critical functions. This is good business sense and lessens the chance of fraud and embezzlement. Cross-training prevents superstardom.

The examples I just gave do not mean that one person should not have responsibility. The difference is in the person. The superstar wanted other staff kept in the dark, but a team player would have communicated the important responsibilities to the other staff so that the office would function in his or her absence. Look for, hire, and reward team players; they will make your life and practice less stressful.

Although OMS is not physically challenging, many physicians go home at night exhausted and stressed. They are not exhausted from doing surgery; they are exhausted from having to constantly manipulate staff members to keep peace. Superstars embezzle from the practice—not

money, but energy. They are like sponges, and they steal the energy and excitement from the other staff or even patients. To counter this type of behavior in these "indispensable" staff, the physician must constantly be manipulating situations and environment. This is what becomes stressful and exhausting. Surround yourself with team players and you will be energized. Synergy occurs when the total is greater than the sum of the parts. Team players, offensive staff, and givers blend harmoniously to create synergy.

Enthusiasm, Joy, and Energy

Knowing that we spend a significant part of our time with our staff, it makes sense to seek enthusiastic, joyous, and energetic people. Happiness and enthusiasm are contagious and are self-perpetuating. Friendly people with high energy levels are a welcome addition to any group. If you truly believe that there are no dress rehearsals in life, then you should make the most out of every waking second. For movers and shakers, there is no room for pessimism. The form of OMS is not particularly exciting for the patient, but an enthusiastic, joyous, energetic staff member can greatly enhance the service and happiness level of patients through attitude. Surround yourself with enthusiastic, joyous, energetic employees, with the other previously mentioned attributes, and your practice will prosper.

Self-managing

Once you have found staff with these positive attributes, you need to make sure that they are self-managing. Some employees know just what to do, but will not perform unless directly supervised. This is a drain because you need two people to do the job of one. There is nothing wrong with the concept of a manager, but if you must literally stand over someone to ensure progress, you have an employee who is not self-managing. Self-managing employees are a pleasure to work with and take all the effort out of management.

Termination

If I could point to a single entity that holds back progress and perpetuates turmoil, it would be the ignorance and hesitancy of physicians to terminate an employee. You must make a decision whether to run a practice or an employee repair service. There is no doubt that terminating an employee is a decision that is fraught with emotional and legal ramifications. Firing someone or being fired can provoke so many emotions in both parties that many physicians procrastinate or endure years of unnecessary stress because they cannot bring themselves to "pull the trigger."

In this situation, we again ignore the tenets of big business. In the corporate world, termination and the factors leading to it are clearly defined, and it is not uncommon for an employee to be terminated in the presence of co-workers while a company security guard hands them a box in which to place their belongings, then escorts them to the door. It is very traumatic for an employee to be terminated, because it signifies failure and humiliation. It is even worse when the employee believes that they were unfairly terminated. If an employee is terminated for being tardy and has the retort that "Mary Ann is always late," your credibility is lost, and you may open yourself up for a wrongful termination suit. The best way to prevent termination is to use correct hiring principles. This sounds trite, but in most offices hiring is such a haphazard event that it becomes a roll of the dice. I am constantly amazed in my travels at the lack of attention to basic human resources policy. Time after time, well-established offices do not have written job descriptions, policy manuals, employee documentation files, or other basic information. Every office should have a written policy on exactly what it takes to be an excellent employee and what it takes to be terminated. In addition to this, employers must be consistent with these policies with every employee. If an employee does not know the goals of the practice, the day-to-day policies, and what is expected of them, how can they be expected to perform? Without structure, one has chaos. Unfortunately, many practices function in a chaotic state.

For all of these reasons, every practice needs a map and a compass. The map is the policy manual, and the compass is the leader of the practice, the physician. No one can get from point A to point B in unfamiliar territory or inclement weather without navigational aids. Can you imagine an NFL team with no one designated as the quarterback? If there was no leader and anyone could call any play at any time, chaos would rule, and the team would never advance. Similarly, if the team had a quarterback who knew all the plays but there was no playbook for the rest of the team, the same chaos would rule. Any successful team must have a leader and a playbook, and any pilot must have a map and a compass. Similarly, every office must have a leader and rules of the game, which we will enumerate later.

When the performance of an employee begins to falter, the leader must conscientiously ask himself or herself if it is an employee or employer problem. Often, as we have pointed out, the perceived employee problem is actually a leadership problem. If it is truly an employee problem and the employee can be salvaged, then a written warning and a second chance may be extended for a probationary period. If the employer believes that the employee is not catching on or is unsalvageable, then it is better to face the inevitable as quickly as possible. It is also important to document employee shortcomings and proof of counseling of the employee. This is critical in terms of defending a wrongful discharge suit or an unemployment claim.

If the proper pre-termination steps have been carried out, the actual task of termination need not be complicated. The single most important point is to have the entire script well prepared and clear in your mind. This is no time to ad lib or fumble around; absolute clarity is essential. It is also important to realize that if you are unhappy with the performance of a staff member, they are probably aware of this; they are also probably unhappy, and sometimes the termination of employment is actually a relief to both parties. I always terminate an employment relationship on a Friday afternoon, unless a significant infraction, such as theft

or substance abuse, has occurred. It is important to have a private environment away from other employees, and it is mandatory to have an employee, preferably of the opposite sex, present to document and witness. I very simply tell the employee that the employment relationship is not working. I further tell the employee that I believe that they are a fine person, but they are just not a good fit for the practice. I tell them that I have a certain vision and direction for the practice; the employee is not moving toward the goals of the practice, and again, it is not a good fit. I always prefer not to delve into specifics, because it opens the door for argument or comparison with other employees. If the employee pushes in that direction, I take control of the situation, reiterate that the topic is not open for discussion, and move on. It is imperative not to insult the employee and leave them with low self-esteem. If the situation is applicable, I offer the employee the ability to resign with severance benefits or be terminated with no benefits. I enter the interview with two predrafted letters, one for resignation and one for termination, and give the employee a choice. If I believe that there may be legal implications or retribution, I have the practice attorney present.

It is acceptable to have a manager or attorney do the actual firing, as long as the proper channels are followed. In fact, it may be wise for the physician to distance himself or herself from these proceedings. I have 8 partners and more than 50 employees. As a result of this size, we have an administrator with medical group management experience and a trained and experienced human resources manager. Hiring and firing is an ongoing occurrence and is beyond the scope and training of the physicians.

Although it may seem cold, it is an absolute necessity to obtain any keys, credit cards, or other practice possessions immediately. There are many cases of documented sabotage where this was not done. An even greater temptation for sabotage is to terminate an employee with 2 weeks' notice. This is a perfect invitation for this person to be unproductive or harmful within your office. A prudent employer will already have a replacement lined up to step right into the position. I said earlier that some physicians commit serious errors in judgment by taking money from the front desk, having affairs with staff, or allowing staff to know personal or family information. It is after firing an employee that they become disgruntled and expose any deceit or retribution. This is a real and all too common situation; do not fall victim.

Initiating a Marketing Plan

Although until now I have downplayed the specifics of a marketing plan, they are very important. But they are only relevant after the physician and staff are committed to understanding the theory and mindset of excellence and patient-centered care.

We, as physicians, have a dual commitment that is nonexistent in most other businesses. We have taken an oath and are expected to sacrifice for the well-being of our fellow man. Going to the ER in the middle of the night to treat a patient without funds is a good example of some of the problems that set us aside from other profitable businesses. In addition, what we do is expensive, and traditionally, people have a low priority for paying physician's bills. No one would go to a restaurant, order and enjoy a meal, and then be shocked to receive a bill and have to pay on the spot. This mentality has, in the past, not carried over to physicians because the general public considers health care a right and not a privilege. Things are quite simply different today, and we must again adapt to be profitable. Most physicians are compassionate and realize that their profession assists many people who may not have the ability to pay. On the other hand, without sufficient profit, the business will not thrive to a point to provide that service. We walk a tightrope, with patient care and medical ethics on one side and the need for aggressively structured business on the other side. An improper mix can detract from our humanity or force us out of business.

This is an opportune time to discuss profit. When I lecture on the subject, some physicians find the mere mention of profit objectionable or unprofessional. Yet this is a capitalistic society, and our economic thrust is profit. Profit is not a four-letter word, but loss is. There are few businesspeople who do not desire the amenities that society offers. Having a profitable business allows them to pursue their careers more contentedly, in addition to offsetting the mix of indigent treatment. Many of the frustrated practitioners in OMS are frustrated because of their lack of profit. Their poor hiring and firing practices and lack of formal policy and leadership are impeding their profitability and enjoyment, and this is all tied together in the marketing equation.

I have stressed the leadership concept and the importance of the staff to the success of the office. Let us now examine the role of the physician in the image of the office, because, after all, image and marketing are inseparable.

Most successful practitioners have a passion for their profession. In this day and age it is difficult to find time, but a marketing plan starts with clinical excellence. A physician needs to be well read and attend continuing education, concerning what is current and contemporary. By doing this, he or she is satisfying the public thirst for what is new. People are constantly intrigued by newer and better ways to accomplish mundane tasks. The mere incorporation of lasers, advanced implant technology, advanced imaging, minor cosmetic procedures, and advanced practice management systems will enhance the image of the practice. But this advancement will only occur if your patients and referral base know about the advances. Failure of communication is a pitfall for many physicians. You may be the most advanced surgeon in the area, but if your referral base and patients are not aware of it, you have sacrificed valuable marketing opportunities.

Communication is the essential measure of a successful practice and, in this age of computers, has never been easier. I believe that a physician should view his or her practice as a team, a family, and a center. This center is the nucleus

• **Figure 10-3** Personalized stationery and related communications convey a professional and team image. Some OMS have stationery for their OMS practice and separate stationery for Implants or Cosmetic Surgery which they use selectively depending upon the communication.

for what is current and best serves the patient. Generalists will rank the lack of communication with specialists high on their list of complaints. In the generalist relationship, they see a given patient and their family several times each year for many years and develop a special communication with these patients. The specialist may see most patients for two or three visits and be faced with the barriers of pain, expense, and fear. It is definitely more difficult to develop the level of communication experienced by the general dentist in just a few visits. We therefore must work harder and make a stronger impression. When a general dentist refers a patient to a specialist, he or she may not see that patient for months. If the oral and maxillofacial surgeon fails to send a referral letter detailing the surgery, it is very embarrassing for the dentist, who is ultimately responsible for the global care of his or her patients. Smart specialists realize that anytime they can communicate with their referring physician, it is free marketing. Each time your letterhead crosses the desk of a referring source, it makes a subliminal marketing impression. Communicate in writing with personalized stationery and, when possible, handwritten personalized notes (Figure 10-3). An astute surgeon will continually search for ways to communicate.

The previous areas of discussion are primarily philosophical, but, nonetheless, vital to understanding the global nature of marketing. We will now focus on some basics that can actually be applied to your individual practice. It is important to mention that the ideas expressed here are by no means exhaustive. They only scratch the surface as to important guidelines. I once participated in an AAOMS seminar in which five practitioners presented a slide show of a patient's journey through their office. This lecture focused on each physician's image, physical plant, referral and marketing strategies, patient care, and so on. Many simple but thought-provoking ideas were presented. The point is that satisfying a patient is an inexhaustible process, and there are endless means, some big, some little, of improving service and thanking referral sources.

When you consider the basics of your marketing plan, try to imagine your favorite restaurant. What is it that you like about it? They probably have a clean environment, with friendly and accommodating staff. Their service is probably excellent, and their food is unparalleled in presentation and taste. The restaurant probably has reasonable prices and has amenities such as staff who remember the patrons, easy parking, and a way of always making you feel that you are their only customer, even on their busiest nights. Try to apply this thought process to all the details of your practice. No matter how busy, we should try to make each patient feel that they are the only patient in our practice. Concierge care is all the rage in medical practices, but astute physicians have been providing concierge care free of charge all along.

Image and Logo

The most basic of basics in marketing is identity. The first thing that you need to do is to be remembered. Can you imagine if one of the major soft drink companies did not stress their logo? All people would remember is "that" company with the good taste. The cola wars are a Madison Avenue example of how essential image is. These companies spend billions of dollars making sure that society remembers their name. Some image marketing is so effective that a product name becomes the moniker for all products of that type. When you hear someone ask for Scotch tape or a Xerox, they probably are speaking in a generic sense. This psychology applies to health care marketing, and without a logo, it is much more difficult to gain an identity.

There are many ways to create a logo. You can consult with a graphic artist or marketing firm, or make it a project with your staff to do it internally. The logo should represent you and your practice. If sailing is your passion, a tasteful logo centered around a sailboat makes a point and is fun. Once decided, you should obtain a service mark for the logo to protect its unlawful usage. The logo should be distinctive and colorful and should be used whenever possible. I use my logo on prescription forms, all stationery, newsletters, invitations, and virtually anything that represents the practice, including scrubs (Figure 10-4).

When people see this logo, they think of our practice. If the logo is not distinctive, it is not as effective. I believe that the commonly used logo of a retrognathic and prognathic profile and a normal profile has been overused in our profession. It is also effective to have a slogan to complement your logo. It should say it all in a nutshell.

• **Figure 10-4** The author and his team. All teams have uniforms, and ours is no exception.

Uniformity

In my opinion, one of the beneficial aspects of the stringent Occupational Safety and Health Administration (OSHA) requirements was the widespread acceptance of surgical scrubs in the office. Having freshly laundered scrubs with the practice logo and the name of the employee embroidered on the scrub top is a functional and professional look and also designates the players on the team to the patients. The office is one place that you should be able to tell the players without a program. Going back to the sports metaphor, all teams have uniforms. The issue of name tags for employees is also important. When a patient is placed in the unfamiliar environment of an OMS office, he or she can feel intimidated. The unusual sights, sounds, and smells coupled with the fear of surgery and pain does not exactly present a relaxing environment. The patient, in this situation, looks for any vestige of warmth, friendliness, or compassion and will bond with these people, thus mitigating these fears. When you call a patient by name, this automatically puts him or her one step closer to a bond. If you examine the habits of very successful people, they inevitably are quick to remember a new name and use it frequently in a conversation. People like to hear their names. Many physicians write the first name of a patient on the chart in very large letters that can be seen across the room so that the entire staff can refer to the patient by name. Some offices use a chalkboard with "Welcome, Bill Smith" inside the treatment rooms. In any event, it is helpful and should be mandatory for all employees to have some sort of name tag. If for no other reason, it will allow a patient to be specific when they compliment or criticize an employee's performance.

The Art of the Evaluation: Breaking the Ice

The anxiety associated with visiting a physician is sometimes palpable. Some people become diaphoretic and obviously stressed. There are many subtle tricks that most seasoned practitioners employ to place patients at ease and make it a positive experience. First and foremost is to avoid isolation. In busy practices, the patient is often whisked into the

• **Figure 10-5** Many patients are nervous while waiting for the surgeon. A bubbly and caring staff member is a great icebreaker and can gather important information and educate the patient before the doctor enters the room.

treatment room and left alone while the team is seeing other patients. Leaving a patient alone in a room is negative marketing. A staff member should always accompany a waiting patient and engage them in relaxing conversation and discussion about their current visit. This is a great time for the employee to gather important information, bond with the patient, and engage in patient education (Figure 10-5). I have made an investment in large-screen television sets in all patient rooms (Figures 10-6 and 10-7). It is okay to leave a patient unattended if he or she has something to do, and handing them a remote for the big-screen TV will help them pass the time and reduce the feeling of waiting.

Nothing is more important than a smile. As a result of the stress associated with our career, we must sometimes force a smile, but no physician or employee should ever enter a treatment room without a smile. No other body language is as reassuring. In addition to smiling, patients like to be touched. Classic medicine from thousands of years ago talks of "the laying of the hands." There is something about appropriate compassionate touching that helps the physician-patient relationship. A hand shake or a pat on the shoulder is sometimes all that is necessary. Unhappy patients who feel rushed through one's office will frequently say, "The doctor didn't even touch me." There is an art to making people wait for your services without feeling that they waited too long. If you can keep them engaged and occupied, they will not realize the length of the wait.

Posture is also important when speaking to apprehensive patients, or any patient. Again, no matter how rushed a physician is, they should always sit down at some point during the patient conversation. It is better to be eye level with the patient; this shows that you are "into the patient."

• **Figure 10-6** Wide-screen TVs can serve to occupy or educate the patient. **A,** They can watch television while waiting for the doctor. I personally use my website on the wide-screen to assist in consultation, as all my pictures, animations, and videos are available **(B).**

• **Figure 10-7** In addition to recreation and education, the wide-screens can also be used as anesthesia monitors during surgery.

Masters of communication will always begin a professional visit by making small talk with the patient. People are impressed by the fact that a busy physician would ask about their hobbies, families, vocation, etc. Again, taking 30 seconds to informally chat with a patient can lessen the appearance of being too busy. A patient is really impressed when you remember a personal fact months later, and astute communicators will make a notation on the chart "Patient likes riding horses," etc. When the patient returns months later and you ask about their horses, it truly makes the patient feel appreciated and impressed with the surgeon.

Some patients are difficult to warm up, and complimenting them is a nice way to begin a conversation. The color of a dress, the smell of perfume, a piece of jewelry, or the patient's children are all easy compliments. Complimenting the great work of the patient's dentist serves to reinforce the patient's faith in their dentist, and they frequently repeat this fact the next time they visit the dentist, which has a positive marketing appeal for you.

There are many times that we are truly rushed in trying to accommodate overbooking, emergencies, and all the other problems with a busy schedule, but paying attention to the details just discussed can change the patient's perception. If a staff member precedes the physician and communicates in the same manner, a cumulative effect results. Every physician and staff member should always ask if there are any questions before discharging the patient. With positive communications, one can accomplish in 5 minutes what may take others 25 minutes. Providing a variety of high-quality and informative material on the physician, the staff, and the office will also help pass the time in a constructive manner and assist your marketing.

The Art of Waiting

Waiting is one thing that patients hate. This is one reason we refer to the lobby as a reception room and not a waiting room. Industries such as fast-food companies, banks, and retail stores have done many studies on waiting. Fast-food chains have found that people do not mind waiting as much if their order is taken immediately, even if there is a significant wait afterward. In addition, people who cannot wait are served first. Drive-through windows take precedence over counter customers. Retail businesses have found that customers pay less attention to time if they have something free. This may be a bowl of candy or a self-serve coffee station. We, as physicians, can take advantage of this type of psychology. In addition, if a patient is going to experience a long wait, they will do much better if they are informed of this. A progressive office will update the patients on the status of the wait and offer anyone the opportunity to use the telephone to adjust their other business, or reschedule the appointment. People become quite agitated when held in limbo. Again, if you are truly interested in marketing, make these patients comfortable, provide them with useful information about your office and services, and give them something to do.

I always apologize to patients for an unreasonable wait and tell them that their time is just as valuable as my own. In addition, I will often adjust the fee in the interest of patient relations. We further explain to the angry patient that we had to care for a patient with an emergency—if it

were the angry patient who needed our services, we would be there for them, and others would have to wait. Our office also sends an apology letter to patients who have experienced substantial waits.

Running behind on a schedule is a fact of life in many offices, but some common sense and special attention can mitigate this factor in patient dissatisfaction. This is marketing in its purest form.

Physical Plant

In the institution of a marketing plan, few things are as important as the home base. Although the first impression of your office usually begins before the patient arrives, the first 5 minutes in the reception room probably defines much of the patient's attitude. It is important to remember that our profession is about well-being and aesthetics, and our offices must represent this. From time to time, I will sit in my reception room during business hours and just observe. It is interesting to see how people interact with your office and to make observations yourself. Many intimidating and offensive things occur in our offices. When we walk through our own office, we are sometimes oblivious to these factors because of our accommodation. When we walk through the fragrance department of a large department store, we are usually impressed by the mix of fragrances; however, the employees behind the perfume counter do not notice the smell. In this case the smell is a positive factor—but the smell of burning flesh from a cautery, strong disinfectants or medications, burning dentin, and so on, is certainly not pleasant to your patients, even if you and your staff do not notice it. The same thing can be said about noise. There are few things more worrisome to anyone than the sound of a drill or the shriek of a patient in pain. Couple this with the sound of a patient with airway problems or anesthetic gagging, and you are subjecting your patients in the reception area to a cacophony of scary and unwelcome sounds. How are they supposed to feel if they are next to be treated, or if it is their family member in surgery?

Not all noxious sounds come from patients. In a professional environment, we must be very careful about staff and physician conversations being audible to patients. In the Capitol building in Washington, DC, there is a popular attraction that illustrates the peculiarities of acoustics. If you stand in a certain spot in one of the large rooms adjacent to the rotunda and whisper, the words can be heard with clarity in another area some 60 feet away. It is astounding that the acoustics carry a whisper that far.

This same acoustical situation can and does exist in offices. Patients often overhear remarks from the staff or physician, personal telephone calls, or employee bickering. Also, they may misinterpret what they hear. In many offices, receptionists make collection calls or speak with patients about sensitive financial or health information. The wrong conversations can provoke ill will or even legal problems.

I always recommend sound attenuation techniques for the reception room, the surgical suite, and the physician's private office. In addition, it is important to keep professional decorum at all times in the company of patients.

An office need not be elegant to make a good impression. Practice management experts will attest that cleanliness is one of the biggest factors that patients notice. In this day and age of potentially fatal communicable diseases, sterility and cleanliness are paramount. Many practitioners have signs posted throughout their office extolling their extra attention to sterilization and the like. This is pure marketing.

This is a good point to bring attention to another important point of marketing. If you go out of your way to improve service for someone, it is imperative to let them know. When we send cleaning to a dry cleaner and we get a shirt or blouse back with a tag attached to a button informing us that the cleaners saw that the button was missing and replaced it, we recognize extra service. Just think how frustrated you would be if you packed that shirt or blouse for an important out-of-town meeting and found, getting dressed before the meeting, that the button was missing. In this case the dry cleaner was providing exemplary service, and you only realized it because they pointed out their extra effort. Had you unpacked the clothing for the meeting and there was no tag on the button, you would have never realized the extra effort. When you go above and beyond the call of duty to extend service, let your patients know of your efforts or they may go unappreciated. As consumers, sometimes we pay extra for a superior product. We have all purchased something that was more expensive than usual, because it was explained to us that only the best parts were used and the guarantee is exceptional. People will pay more money for goods or services that they deem to be exceptional. If your office is exceptional, you need to point it out in every respect to your staff and patients.

It is great promotion to have the staff compliment the physician and vice versa. Patients often make telephone rounds with multiple offices to find the one that "feels" best. If a receptionist says to a patient, "Oh, you will love our doctor—she's so gentle and friendly; you'll just love her," the patient will believe that she really goes out of her way to make sure you have as pleasant an experience as possible. As a practitioner, I am absolutely positive that many patients who were on the fence or telephone shopping came to the office because of the complimentary nature of the staff. In return it also says a lot about a physician if he or she compliments the staff in front of a patient. Most of us are probably very appreciative of our staff, but fall far short in expressing thanks. Complimenting a staff person in the presence of a patient raises the morale of the employee and reinforces the cohesive nature of the team to your patient. If there is one fault that we all are guilty of as employers, it is having an employee that does 99% of things correctly and we jump on them for the 1% they do wrong. The world needs more compliments.

It pays to take a weekly stroll through your entire office when there are no patients present to visually inspect the state of your facility. Some subtle details will jump out that may not be noticeable in "the heat of battle." Outdated or

wrinkled periodicals, dirty carpeting, unhealthy plants or flowers, messy aquariums, outdated or worn furniture, dirty windows, and crooked pictures are just a few things that should be inspected by the staff and physician on a regular basis. The clinical areas must be clear of difficult-to-notice objects, such as wire, impression material, bits of suture, etc.

I strongly recommend redecorating the entire office every 5 years, whether you think it needs it or not. First of all, it probably does need renovation, and second, it is amazing how little things, such as paint, wallpaper, and furniture, can increase morale. Many of us spend as much or more time in the office than at home. For this reason alone, it should be nice and represent you and your interests. Although unfinished or pine furniture was once popular, it now portrays a yard sale image.

Identifying a Target Market

Again, image and marketing are inseparable. Every businessperson struggles for a way to identify their target market and spread the word of their goods or services. There is no disputing that word of mouth is a very effective means of marketing, but it is also the slowest. There are many means by which to mass market, and we will discuss them later.

Identifying the target market for any business is very challenging. It may cost several hundred thousand dollars to find out that Pepsi drinkers are 23-year-old Republican college graduates. Fortunately, for our profession, our target market is obvious. For the vast majority of us, general dentists or dental specialists are the funnel for our business. When I speak to new practitioners, I make the point that 10 general dentists could support an oral and maxillofacial surgeon if they were prudent practitioners and properly screened their patients. The problem for most of us is that we are not the only show in town. There are usually many choices for a dentist, so why choose our particular practice?

An entire text could be devoted to this question alone. Initially, many established referral relationships begin when a practitioner enters practice, and, if the service is appropriate, continue as habit. Why did this dentist originally begin referring to a new surgeon in the first place? Age distribution has an influence, in that many dentists refer to specialists of comparable age. They may know each other or at least relate. Established physicians may refer to a new physician because they have empathy for the new practice, or simply because the physician is just new and different. Perhaps they believe that the new physician has skill in the latest techniques. There are many reasons why an established general dentist might stop sending patients to an established practice and begin sending them to a newer or different practice. The biggest problem, however, is that it often has to do with a change in service.

When a practitioner first enters the practice, he or she is usually enthusiastic and hungry for business. As a result of this, new practitioners do all the right things. They see any patient at any time, they work until the job is done, they are quick to express gratitude for referrals, they are very friendly to patients and referring dentists, and they will bend over backward to get new business. They are humble but confident and are usually excited if not supercharged about OMS.

With this willingness and attitude in mind, it is easy to deduce not only why new physicians get patients, but also why experienced physicians might lose them. Obviously, most of us lose some vigor as we age, but too many physicians fall into a false sense of security as a specialist and assume that a decade-old referral relationship will continue out of habit. This could not be further from the truth. If physicians continually decrease their level of service, they are literally inviting competition into their referral area. When considering a marketing plan, remember to try and do as many of the things that made you successful as you can, and never, never let your guard down out of overconfidence. It requires much less energy to maintain a favorable referral relationship than to try to reenter one.

Pre-entry Materials

The best time to market is always. Many physicians are under the impression that they need not concentrate on marketing patients until the patient contacts the office. This is not true. First, many physicians mount tasteful and effective media marketing campaigns, and we will discuss these specifics later. More important is the ability to obtain a favorable position with the gatekeepers of your target market (e.g., the general dentist, dental specialists, local physicians, ERs, and pharmacies). A busy general dentist is very similar to a busy ER physician in that both need to get problem patients out of their facilities to stay on schedule. They will take the path of least resistance to get the patient to another caregiver, usually a specialist. If your office is easy to get a patient into, you are in the most favorable position; if your line is busy or your receptionist makes the general dentist's staff jump through hoops, then you are in an unfavorable position. A prudent specialist will constantly adapt their office to make it easy to make an appointment. If you are unsure of how hard or easy it is to make an appointment at your own office, have a friend call monthly to make sham appointments with different scenarios. Example scenarios would include an emergency appointment, a pushy patient, a handicapped patient, and so on. It is quite a learning experience to do this. It is also helpful to use the "secret shopper" scenario. This involves having an anonymous patient (one not even the physician knows) make an appointment with the practice for an evaluation. The secret shopper should document all aspects of care, conversations, office observations, waiting times, staff and physician demeanor, and so forth. This is then filed as a report and shared with the staff. I have done this many times, and it always serves to point out deficiencies.

There are many techniques to facilitate a favorable referral position. Many physicians supply the referral base with referral pamphlets with pictures of the physician and staff and pertinent information about the surgical experience.

These brochures often have a map to the specialist's office and important telephone numbers. Some practitioners include promotional gifts with the brochure, such as refrigerator magnets, fast-food coupons, discounts for surgical evaluation, adolescent-oriented coupons, etc.

A presurgical packet makes a nice presentation for a patient to receive and helps the patient identify with the specialty office before they ever walk through the door. I have found this to be an efficient and timesaving method that allows the office to schedule more patients, who will experience less waiting. In addition, we have found the patients to be more accurate when they can fill out forms at their leisure.

Any marketing, business, and promotion should involve the Internet. Many offices now employ online patient registration and appointment ability. Contemporary practices have a professional website that details all aspects of the practice and offers advance registration. Not having a website in this day and age is an obvious deficiency that makes a practice stand out in a negative way. Just having it is not enough—it must be attractive and informative. Contemporary patients seek information.

Making It Easy

Because most general dental offices have panoramic radiographs on their patients, they usually send them to the oral and maxillofacial surgeon for the patient's appointment. Sending the referring office a self-addressed stamped Panorex envelope greatly facilitates this process and puts that office in a more favorable position. Electronic transfer of digital radiographs is even better, assuming one's referral sources are as advanced. There are hundreds of ideas being used by successful offices. The challenge for us all is to constantly think of service-oriented ideas to better serve our referral bases and patients. It is fun and rewarding to challenge your staff to dissect everything that constitutes your office and try to reassemble it for better patient service.

Synergy in Marketing

Synergy occurs when the whole is greater than the sum of its parts. This can be applied to marketing only when the physician involves his or her staff. A physician can have the best marketing mind in the world, but be tremendously reduced in effectiveness if the staff is not involved. McDonald's fast-food chain has a policy of training their managers and franchise owners. They require these executives to literally begin at the bottom. Managerial trainees must flip burgers on the grill, run the French fryer, and make milkshakes for several weeks before putting on their white-collar clothes. Many businesses take this grass-roots approach because it brings home an enormous point. A manager is more effective if he or she understands everyone else's job. In addition, this experience will stimulate the innovative mind to find a more efficient and profitable way to get the job done. It is shameful that, as physicians, we do not spend one day of the year as a receptionist or surgical assistant. We would gain much insight into our practices. Our staff hears, sees, and feels things that elude the physician.

If a physician has the right staff (if you do not, you are negative marketing), they will exponentially complement the marketing experience. It is essential to communicate and formally launch a marketing campaign. It is very effective to refer to this as a patient-service enhancement campaign. I recommend canceling patients and having a half-day meeting. The purpose of this meeting is to point out to the staff the importance of patient-centered care and to explain the benefit of superlative service. Each staff position should have a specific job description, and it is imperative to challenge the staff to be innovative and try to improve each detail of the patient's experience. The physician must be prepared to reward the staff with some type of incentive for their contribution. This is a win-win situation because when the staff wins, the physician wins more. Once you have challenged the staff and they respond to the challenge, the increase in energy level is almost palpable. The ensuing enthusiasm serves to further fuel the synergy engine and draws the entire team to a common goal: superior patient service. I am continually amazed at the endless ideas submitted by the staff and frequently ask, "Why didn't I think of that?"

I require each employee to submit at least two ideas and reward them with a monetary bonus. An employee who does not submit two ideas cannot be reviewed until this is completed, and no review means no raise. An employee without an idea on how to improve patient service has no place in an office in pursuit of excellence.

Failing to enlist your staff in the marketing of your practice will deprive you of your most effective and most economical asset.

In 1995, the American Society for Quality conducted a survey on the reasons for customers switching service providers. Following are the interesting results:

- Death: 1%
- Moved away: 3%
- Influenced by friends: 5%
- Lured away by competition: 9%
- Dissatisfied with work: 14%
- Attitude of indifference on the part of an employee: 68%

This survey probably applies to every type of business on the planet. Most of us can relate to a restaurant that has great food but mediocre service; one rude waiter or waitress can ruin the best of products.

Patient Surveys

The quintessential marketing question is "What is it that I can do to better serve my patients, staff, and referral base?" This also translates into "How can I be more profitable?" Individuals spend thousands of dollars to find this answer when it is actually right under their noses. Ask your patients, staff, and referring physicians what they want and how you can better serve them, and they will tell you for free. Place a

two-dollar bill in the return envelope with the survey as an extra incentive for return of information.

The survey need not be exhaustive, and the more to the point it is, the more participation you will probably have. There are several schools of thought on how to execute this type of polling process. Many physicians believe that anonymity is important to obtain true and unbiased input. Some physicians will use a professional marketing firm to do this, although I believe that this is unnecessary. If you believe that bias is a possibility, a neutral return address and P.O. box can be used. I know of practitioners who rent a P.O. box and have envelopes and stationery printed with a fictitious company, such as "Martin Market Research." The survey contains a cover letter that states that they are a market research company conducting a survey for Dr. X's practice. Proponents of this type of approach believe that referring offices may be more candid with a third-party firm than they would be with the office itself.

I have experience with multiple methods of referral surveys, and I still prefer performing surveys from my own office on my own letterhead. Referrals have been very candid and specific and frequently sign the survey. I give the responder the option to sign or remain anonymous.

In this day and age and with the state of junk mail, it is difficult to get people to fill out a long form. The survey should be 10 to 15 yes-or-no questions followed by an open-ended area asking for any specific input on how we can improve our office.

Some of the basic questions asked are as follows:

- Is it easy to refer patients to our office?
- Are our hours of operation convenient?
- Is it easy to reach us for emergency patients?
- Is our after-hours answering service polite and effective?
- Do your patients generally relate a positive experience when returning from our office?
- Do our insurance and billing personnel serve your patients well?
- Is our office efficient in communicating about your referrals and prompt in returning your referral records?
- Does your office enjoy our educational and social functions?
- Do you have any suggestions for future social or educational functions?
- Please list any positive comments you have about our office.
- Please list any negative comments you have about our office.
- Please list any additional comments that may assist our office in serving your staff and patients.

These are merely examples of meat-and-potatoes survey questions. It is less important what you ask than the fact you care about asking. An office that does not take advantage of this powerful tool on a regular basis has surely missed the marketing boat.

If a given referral source makes a negative or interrogatory comment and signs the survey, it is important to respond in writing as soon as possible. Failure to do this may be ignoring a truthful critique of the physician and may be taken as offensive.

It is possible to oversurvey a referral base. This task should be done only every 2 years. I also use what I refer to as precision surveys. This is a very specific survey, concentrating on a single subject or procedure. An additional precision survey I use is one that is mailed only to referral staff and not intended as a physician survey. These can be even more accurate because it is often the staff that actually makes a referral. The general dentist may simply tell the assistant or hygienist to "send this patient to the oral surgeon for their wisdom teeth." From that point on, it is the staff of the dentist who deals with the patient and the specialist. In the consideration of a marketing plan, never, never overlook referring staff, because they may be your greatest allies.

Although a referral survey is an integral instrument for an office interested in excellence and patient-centered care, it only tells half of the story. To really discover how to better serve your patients, ask them, too.

I have gained tremendous insight into the perception of patients from random patient surveys. The operative word here is random. There are obviously multiple phases of the surgical experience, and, depending in what phase you catch a given patient, the survey may or may not be accurate. For instance, a patient who has been to the office for an evaluation may be very pleased, whereas a patient with a dry socket and a postoperative nerve dysesthesia may be disgruntled just then. By the same token, a patient may have had an excellent experience all the way through the office; however, 3 months later they become unhappy about their lack of insurance coverage and resultant balance owed to the office.

As a result of the temporal differences, you will not gain a representative sampling of the true global office experience unless all sectors are queried. I recommend a suggestion box in the reception area and a monthly random sampling of patients in various phases of their surgical experience. It is also significant to reinforce the need for statistically significant responses. Sending out 10 surveys may be futile, although any input is better than wondering, and this is especially important for negative criticisms.

The next link in the survey triad is your own staff. As I have said time and time again, the staff is your most powerful marketing tool. They work closely with patients in ways that we as physicians never see. Your staff has input that is vital to achieving excellence and a patient-centered office. Ask them, listen to them, and reward them for making things better. Once you have input from the survey and begin to institute changes, you will begin to notice a difference. It is also at this point that your patients will notice a difference. When this whole process gains momentum, a beautiful thing happens—it is called marketing. You can actually see and feel it. It is no coincidence, and it can and will work for anyone willing to take some time and follow some basic steps.

Lunches and Marketing

If there were a time-honored PR entity, it surely would be the business lunch. Many big deals have been negotiated

over a restaurant table, and many referring physicians have been courted over the same table.

This is one area that I believe is minimally effective as a PR tool, with notable exceptions. Our lives have continued to become more and more hectic, and people have accommodated in a variety of ways. Many people who sat around the breakfast table with the family as a child are now gulping down breakfast in the car on the way to work. Lunch for many businesspeople is a time to return telephone calls or catch up on the morning's work. It is safe to assume that most medical and dental offices run behind schedule. Trying to force a harried luncheon date of a social nature into a tight schedule can make a usually pleasant experience undesirable. By the time two people drive to a destination and order food, it is already time to leave. Instead of enlightening a referring physician, a rushed lunch may actually be an imposition. Exceptions to this are extended lunch hours that would allow both parties time to relax or if the referring physician is a good friend. In the case of a strong existing friendship, there is much less social strain to court the other physician. Another problem with lunches is that many specialists pursue referring physicians, and they sometimes are "lunched to death." A referring physician may actually be put off by the thought of a long lunch, but be embarrassed to turn you down. It is perhaps best to schedule a dinner or a weekend event that is not so bound by time constraints. Obviously, these matters are personal and do not apply to every situation; nonetheless, the subject warrants consideration.

It is sometimes wise to leave a referral relationship strictly the way it is. It is human nature to try to become close to someone who is sending you business. The referring office is probably sending you patients because you and your staff treat their patients well. Sometimes the best thing to do is to concentrate on the treatment and not the social value. A referring physician need not become your best friend, but you do need to find a means of saying "thank you." Really successful offices are those that know how to say it. Once you figure out how to do this by different means on a consistent basis, you have figured out marketing.

Obtaining Outside Consultation

I touched on the importance of this strategy in the beginning of this chapter, and additional discussion is warranted because it relates to the topics at hand.

Oral and maxillofacial surgeons are leaders by virtue of what they have achieved. Their ranks hold a most impressive array of talented men and women. I am always impressed when attending our annual meeting by the caliber of our membership. Many have entered this specialty to be independent, and it is sometimes difficult to look to others for assistance. One of the most beneficial things that I have done to benefit my practice is the use of outside consultants. Again, for many OMS practices, it would be unthinkable to consider a consultant because they believe that they know their practices or cannot justify the expense. With the proper consultant, this is so very far from the truth. We all believe that we know our practices, but we are blinded by a subjective factor—emotion. All practitioners truly want their practice to prosper, but unnecessary stress and inefficiency burden many physicians. These physicians assume that the practice must entail this drudgery and are destined to tolerate it for the sake of their careers. They have cheated themselves and given in to the cop-out that OMS "is not what it used to be" and cannot be enjoyed. They believe that they have an intimate knowledge of their practice and community, but they cannot see the burden that their emotion has created.

This same situation exists in our practice because a trained professional can see and appreciate things that we cannot. "A fish cannot see water because he is in it all the time" sums up the need for outside consultation. I have found this to be a constant breath of fresh air and change. It has been especially effective for partner relations, managerial selection, associate buy-in, employee relations, and plotting the course for the future. To spend $10,000 or $12,000 to make 5 to 10 times that in profitability seems a no-brainer. And the monetary gains are probably overridden by increased efficiency and decreased stress.

It is not only problematic or inefficient practices that require professional consultation. Thriving, prosperous practices also need preventive maintenance. It is always wise to change the oil before the engine blows up.

Often the product of a consultation visit leads to gross changes. Closing or opening satellites, terminating senior staff or associates, changing fee structures, and altering buy-in and buy-out policies are a few of the changes that I have experienced, but these have all been retrospectively beneficial for the entire practice.

Where does one find a qualified consultant? Professional associations often maintain lists of consultants recommended by the membership. One caveat is that just because a consultant calls himself or herself qualified does not mean that he or she can carry the load. The field of health care is replete with "consultants," and a former dental hygienist may not have the professional background to make hard business and accounting decisions. Another beneficial source is the Medical Group Management Association (MGMA). This professional organization is a nationwide entity with valuable health care resources. Any practice with a manager should require membership with this group. They have publications, multispecialty practice figures and forecasts, employment opportunities, and a vast network of printed material available. This organization can recommend a list of qualified consultants.

When considering a given consultant, always ask for references and check them thoroughly. Good people come highly recommended. Maintain a reasonable expectation of any consultant. Most mature practices have problems that took years to occur and cannot be fixed overnight. A good consultant will be able to focus on the main areas of weakness and initiate short- and long-term goals for the practice.

I would no more consider practicing without a consultant than without malpractice insurance.

Community Service

It has been said that what you give to your community, you will get back tenfold. I truly believe that this applies to OMS. There are many positives about being an active participant in community service programs. First of all, it gives a local physician a means of paying back and thanking the community. In any community, there are people who cannot afford our services, but are in great need. This type of charity work really brings a good feeling to the caregiver, and inevitably the community will notice. A caring physician donating his or her services to those in need is an impression that sticks in the mind of the citizenry and frequently generates publicity that further reinforces the giving role. My partners and I have had much experience with a multitude of community service projects, and everyone involved becomes a winner. It is a powerful means of assisting the less fortunate and building a reputation for compassion.

Procedure-Specific Marketing

There are procedures we perform as physicians that provide more clinical and economic satisfaction than the removal of carious teeth. It is these rewarding operations that most physicians wish to proliferate in their practices. It probably can be safely stated that the best means of marketing dentoalveolar procedures is to market to the general dental offices. Although this certainly holds true with such expanded procedures as implants, temporomandibular disorders (TMD), surgical orthodontics, and cosmetics, the general dental office in itself may not be the optimal marketing target. For one thing, certain referring dentists may not do or believe in such areas of surgery as TMD or implants. There are practitioners who have a captive audience of possible implant or TMD patients, but because of previous bad experiences or because the dentist has failed to stay current, their patients may be told on a daily basis that "implants don't work" or "TMJ surgery is ineffective" or "cosmetic surgery can only be provided by plastic surgeons." Obviously, this caliber of referring dentist is beyond the casual "go see the oral surgeon" mentality that more frequently exists. It is for reasons like this and the broader markets available that procedure-specific marketing can greatly enhance one's patient base.

The first and foremost factor in subspecialty marketing is clinical excellence. To profess this excellence, a physician must be on the cutting edge of education in a given area. Being on top of continuing education gives you information that you can disseminate to referring colleagues. It sets you apart as an expert and opens the door for preferred referral and confidence. Equally important is the need for OMS to achieve good treatment results. Nothing succeeds like success, and this certainly applies to specialty marketing. Once this type of relationship is established, it is not uncommon for a given referral source to continue to send patients to another oral and maxillofacial surgeon but send the procedure-specific cases to you because of your efforts and results. In many cases, this allows you to "get a foot in the door" to obtain all the patients referred from a given office. Without technical excellence, it is much more difficult to market to referring physicians or the public because they may be more informed than the treating physician. A specialist preaching antiquated techniques will soon lose the confidence of referrals.

Another reason that general dentists may not be an adequate target for procedure-specific marketing is that cosmetic surgery is beyond their training or interest, or they are simply uninformed. This brings us to the second important point in procedure-specific marketing: educating your target market. It is absolutely imperative that your primary marketing target, the referring dentists, is knowledgeable and aware of your services. The key is to educate this group to be aware of indications for the techniques that you offer. Given the emphasis on aesthetic dentistry, there is a fertile market and opportunity to present literature and discuss your given level of interest.

The specialist with these goals in mind needs to prepare information packets for referring dentists to give to patients and an educational experience to inform the dentist and staff.

The second half of the equation for successful procedure-specific marketing is the dissemination of information to the secondary target market, which is the public. We will discuss this specifically at a later point.

As the oral and maxillofacial surgeon matures in practice, he or she will find areas of the specialty that are more personally and financially rewarding, and most will desire to "subspecialize" or, in some cases, limit their practice to these specific techniques. I began the pursuit of cosmetic facial surgery over a decade ago and progressively began doing more and more such surgery each year. This became a passion and eventually led to limiting my practice solely to cosmetic facial surgery. At first this was met with some skepticism from the local dental community, but after I published more than 150 articles and lectured internationally on the subject, the naysayers warmed up and are quite supportive.

Internal Marketing

This is the most overlooked marketing tool in our profession. We are in somewhat of a unique situation in that our reception rooms hold a captive audience. We, on a daily basis, have patients escorted to our offices by individuals of varying ages. These people sometimes must wait for a long time and are frequently bored. Many people bring books or trust that physician's offices have magazines. The latest issue of *People* magazine will do little to promote your procedure-specific marketing efforts.

If a surgeon is truly interested in cultivating given areas of practice, then every person who walks in and out of that office becomes a prospective patient or referral source. It is

shameful that many of our colleagues are doing truly dramatic expanded OMS procedures on the other side of the door, yet the majority of potential patients a few yards away remain unaware.

With multiple advances in personal computers, it is now easy to make excellent display and educational materials that only 5 years ago would have required expensive professional assistance. Now anyone with a PC, desktop publishing software, and a color inkjet printer can make high-grade, quality pictures, pamphlets, newsletters, and a multitude of other promotional material. It is quite simple to make a Microsoft PowerPoint presentation of one's given clinical passion and display this in the reception room and other treatment rooms. Creative Memories or SnapFish are online companies that allow the user to send in pictures and text, and in several days an extremely professional glossy-cover photo book is ready to proclaim your talent to your patients at a very affordable price.

The choice is yours—a patient can wallow in boredom or pass time by looking at before-and-after photos, case presentations, educational videos, and interactive CD-ROMs (see Figure 10-6, *B*). People thrive on information and, especially in that environment, will read or look at anything put before them. I have not only found this to be an effective marketing tool, but have also created a broad area of interest for staff members to develop and become involved. This enhances the team concept because it makes the staff believe that they are truly contributing more directly.

Your reception room can have Norman Rockwell pictures or posters of functional and cosmetic patients in the preoperative and postoperative stages. If you are a contributor to the professional or media literature, it is very effective to display these articles in the reception room. Anything that shows the public your expertise or interest in specific expanded procedures is of great marketing advantage (Figure 10-8).

Although the patient can gain much information from a well-displayed reception room, it is imperative to give them information to take home. Brochure racks with informational and educational procedure-specific pamphlets are very popular with patients. Physicians who pursue the powerful potential of internal marketing will attest that many patients comment, "I didn't realize that oral surgeons did that." If a surgeon believes that it is too aggressive to place pictures and posters on the wall, then tasteful coffee table photo albums can serve the same purpose. If you have a clinical passion, brag about it, and the patients will become interested.

In all considerations of marketing, you must constantly ask the question, "How can I spread the word about these procedures that I enjoy doing?" The answer is to take everything to the next step. If you are making promotional media for your own office, how about distributing it to the offices of your known referral sources? A tastefully prepared album demonstrating the given procedure or procedures may well be a welcome addition to the reception rooms of your referring dentists.

• **Figure 10-8** Patients love to go to recognized doctors, and any awards and publications that are posted in the office breed pride and confidence in your patients.

Finally, and it may sound trite, I strongly recommend actually telling patients that you have expertise in or enjoy particular procedures. It is amazing how much people talk, and word of mouth is and always will be the ultimate marketing tool.

Offering wireless Internet service in your reception room or having a PC that is always online is also a welcome convenience for patients.

Newsletters and Media Packs

The following is dated, as virtually all newsletters are now electronic, but the styling is still relevant.

As is true of all marketing, informing a target referral or a target patient market of your services is key. We assume that most general dentists and patients are well acquainted with our professional capabilities. It has always amazed me that even newly graduating dental students are frequently misinformed about our capabilities.

Newsletters have become very trendy, but many of them are probably discarded without being read. The key to effective use of this powerful marketing tool is presentation and content. A Xerox copy of a newsletter on a folded white 8.5 × 11 piece of paper just does not get attention. In addition, a recipe for summer punch is not relevant. One can literally spend thousands of dollars in the development of a professional newsletter, but it can be done for almost nothing with a PC and a copy center.

First, people like reading news. It does not even have to be news that relates directly to your specific procedure. Almost everyone will listen to health-related news. Articles from the *New England Journal of Medicine* or the vast array of health news and studies available on the World Wide Web serve as good filler. If one is truly pursuing excellence in a specific

procedure, chances are that they are well acquainted with the current literature. Great articles can be built around scientific journal literature. Anything new, controversial, or of interest is likely to draw attention.

In most referral circles, referring offices are well acquainted with the specialty office, and some personal information may be of interest. Interoffice news, such as courses attended by the physicians, articles published, awards of physicians and staff, and other "gossip," may hold interest. There are many things that can be disseminated through newsletters. Office hours, new staff, seminars, insurance and coding information, and the like are very relevant. Pictures, graphs, tables, and color all enhance such a publication.

I should, however, warn of several pitfalls in using newsletters. To be effective, the newsletter must be consistent. Many offices begin with a very energetic newsletter and a commitment to continue, only to fizzle out after one or two issues. A well-constructed newsletter is work intensive, and setting realistic goals is paramount. It is far more effective to have a quality quarterly newsletter than a mediocre monthly publication. I suggest finishing the future issue before the present issue is released. This forces the office to have issues "in the can" for future uses. The other important point is to involve everyone in the practice. If each employee and physician is responsible for a given duty, the workload is dispersed and organized.

If you are serious about producing a newsletter that a referring office will appreciate, the quality and quantity cannot be overlooked. If you are truly providing useful information, chances are that your referring offices will wish to keep the publications. A personalized three-ring notebook with your office name and logo will give the physicians somewhere to store your newsletter and enhance the perceived value of your medium. Obviously, also offering the newsletter via email is advantageous.

A media pack is the equivalent of a fragmented newsletter intended for one's referring offices. An example may include brochures about your office, scientific article reprints, promotional freebies for the referring physician, actual case presentations of aesthetic or functional results, medical emergency tips, personalized pens, magnets, Post-it notes, and so on. This marketing tool is intended as a promotional "care package," and its contents can be innovatively constructed with the efforts of your staff (Figure 10-9).

Also on the subject of marketing for referrals, many offices miss a vital link—the referring staff. As I pointed out earlier, it is frequently the general dentist's assistant, hygienist, or receptionist who actually makes the referrals. Yet these individuals rarely receive a direct thank-you from referring offices. When this is done, it leaves a serious impression. Never underestimate the power of ancillary referring staff. Our practice has numerous CME activities, specifically for referring physicians and staff. This is typically done on a Friday (a bad time for an oral and maxillofacial surgeon to miss work, but a common day for the general dentist and specialist). These seminars discuss common OMS procedures and those that may be especially relevant to the dental practice. ACLS, office emergencies, cosmetic facial surgery, advances in dental implants, and antibiotic and medication updates are popular subjects. Our practice makes this a fun day and raffles some gifts, such as an iPod, Botox injection coupons, and other goodies. In addition, the staff and physicians receive continuing education credit for these meetings. Ladies' night out events are done once or twice a year, and a cosmetic surgery presentation to 250 women in elegant surroundings is a great referral source (Figure 10-10).

• **Figure 10-9** A ready stock of "goodie bags" is a great icebreaker for referral visits or new patients.

• **Figure 10-10** Public information seminars can be a truly effective technique to educate patients and introduce them to an exceptional doctor and staff.

Media Networking

Our nation and the world now seem smaller because of the ability to report news events as they unfold. In 1864, it took weeks for some rural people to find out about the assassination of President Lincoln. Most of the country, on the other hand, observed the events of Operation Desert Storm live. There are many sources of news and informational services, including satellite, cable TV, network TV, local TV stations, magazines, newspapers, and other printed material on national and local levels. With all these sources of news, these companies have a constant need to report anything of interest. Editors scramble to find anything that might provide interest to sell their respective media.

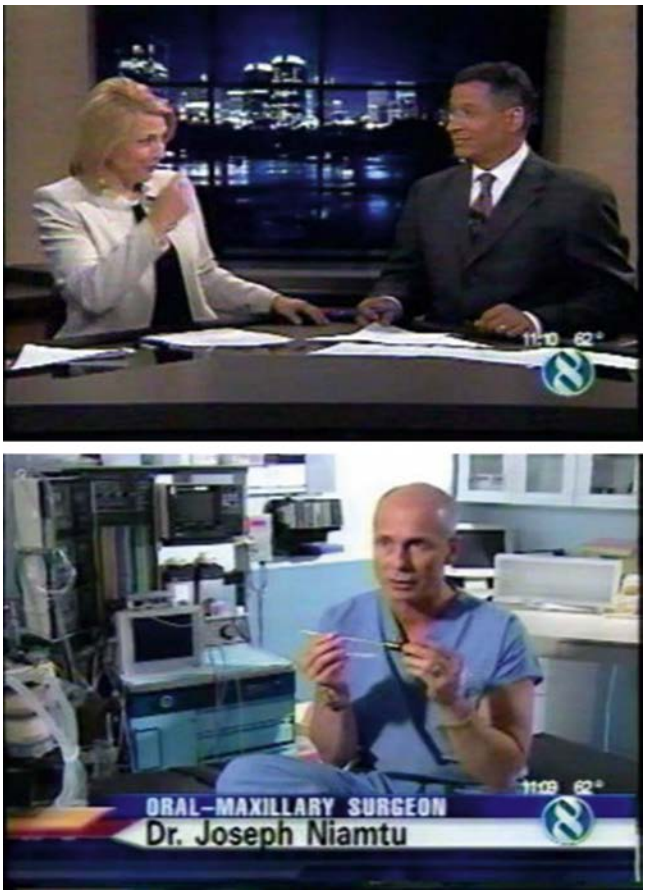
This need for news coupled with the rapid advances in our specialty provide a fertile situation for newsworthy material. The baby boomers are now into their 50s, and we have as health conscious a society as ever. People want to know and understand their health and disease. It is not unusual to turn on the television and see an actual surgical operation. Virtually every form of media has a health news section, and as oral and maxillofacial surgeons, we need to take advantage of this.

Many of the procedures we perform produce dramatic results and are therefore newsworthy. In addition, we are doing many new procedures that are even more interesting to the general public. Even such simple operations as dentoalveolar surgery hold interest for the public because they and their families will undergo many of these experiences.

There are many ways to gain this type of exposure. In some cases, editors will call local physicians to inquire about specific procedures. This is a hit-and-miss situation. Some physicians employ professional marketing firms to initiate a media campaign and usually obtain adequate results at a significant expense. The methods used by professional agencies are basically to saturate all media sources. This requires compiling press releases and distributing them to the usual sources. It is basically a simple procedure and requires little more than the ability to write and some mailings.

Instead of spending serious money on professional services, the average practitioner can do this in-house. A press release is no more than a short story with an interesting headline. "Teeth in One Day" or "Weekend Face-Lift" would be typical headlines followed by a several-paragraph description. It is important to keep these releases informational and not promotional and to focus on the operation and not the physician. Generally, the practitioner will be quoted, and the marketing is in associating his or her name with the technique. Sometimes, depending on the topic, the editor may do an in-depth article, and a subliminal promotion is usually appreciated by the public. It is important to remain accurate and quote average success rates and so forth. Sensationalism or fictitious information can severely reflect on the credibility of the editor and the company.

It is important for anyone who begins this type of media promotion to understand that the return may be one hit in 50 releases and not become discouraged with the ratio. It is persistence that frequently wins out. In addition, many health editors file away this type of information, only to use it months later when a related topic or article surfaces. It definitely helps to have a working relationship with local newspapers, television, and radio news or health editors (Figure 10-11).



• **Figure 10-11** Establishing a media relationship can take years, but if a surgeon can become the community expert, it is worth thousands in free marketing.

Finances

Many practitioners fail to see payment options as a significant marketing tool. This can be a true practice builder. Our country has been built by making it possible for people to purchase goods and services without paying for them at the time of purchase. Department stores established this concept years ago and issued charge cards. This has existed in our society for many years from the corner store to the biggest of businesses.

The thrust of insurance coverage will shift to significant patient responsibility, whereas many patients may be left without any coverage. All of this accentuates the need for a financial program. For most patients, what we do is a middle-class luxury, and we are a low priority for payment. It is not uncommon for a patient not to realize that they have impacted third molars until their dentist points them out. They are then referred for removal and undergo inconvenience, discomfort, and expense without any easily perceived benefit. People do not mind paying for something they see as important, but are quicker to default on items or services without obvious value.

If you extend payment plan options, you must inform the target market to turn this into a marketing tool. Obviously, a sensible ratio exists for each practice, and you do not want to set up too many payment plans. Keep in mind that when you extend someone credit, you are actually giving them an interest-free loan. Most physicians do not want to be in the banking business, but those with true business sense realize that a vast potential exists.

Although there are many honest individuals who will be compliant, payment options must be set up with the

noncompliant patient in mind. Payment options must be stringent and have signed contracts stating what happens in the event of default. Most of us are used to paying home or auto loans, and if we were to default, we would face consequences. The same must be instituted when formulating a payment plan. First, you must determine the patient's credit risk. My practice, like many others, maintains a modem connection with the credit bureau and can check on the record of a patient. It is interesting to see a credit history, because it is not uncommon for people to have good credit with banks, but multiple infractions with health care providers. Needless to say, a patient in this category is a poor risk. If a patient defaults on a payment plan, the balance is due immediately and will go to collections with the signed patient agreement. The agreement also states that it is the patient who is responsible for the attorney's fees. If default consequences are not explained up front, the plan is ineffective. In my office, there are certain requirements to qualify for credit, and a credit report is filed. Some patients remain ineligible, but the majority of applicants do qualify. A down payment is required at the time of surgery, and experience has shown that patients who are unable to pay this or resist doing so will have a high default rate. If a surgical procedure has a $1000 fee, we require one-third of the amount on the day of service and extend the remaining balance for three to six equal payments. The patient is issued a computer-generated coupon book similar to car loan coupons and an expected payment schedule. As stated earlier, if payments are tardy or missed, the account may be turned over to collections.

Many offices charge a reasonable interest rate on their loans, and this can be a profitable situation. It also takes some of the sting out of lending money.

There are corporations, such as Care Credit (www.carecredit.com), that greatly automate and simplify credit operations, and many offices have shifted most credit situations to this type of service.

Yellow Pages Advertising

In the previous edition of this text and chapter, I dedicated much space to this subject. Since the first printing, the Internet has overtaken the telephone book as a primary information source. Many practices have significantly backed down their emphasis on Yellow Pages advertising. It may still be important to have a presence here, but a generic ad that lists services and locations will probably suffice, and the money saved is better spent on Web services.

Cosmetic Surgery Marketing

In the past 30 years, we have witnessed an explosion in the scope of our profession. We have advanced from dentoalveolar and trauma specialists into orthognathic surgery, which increased our aesthetic awareness and opened the door for progress into the facial cosmetic arena. This says a lot about the aggressiveness and ability of our ranks.

Although at present, full-blown cosmetic practices constitute a mere fraction of our membership, this area promises great excitement and growth potential. Aesthetic surgery is especially attractive to the oral and maxillofacial surgeon for a variety of reasons. First of all, we have been doing cosmetic and nasal surgery with our osteotomies for some time. We have an excellent understanding of the face and are enthusiastic about providing surgical techniques that someone actually wants or looks forward to. Our ability to perform outpatient ambulatory surgery allows us a cost-effective forum, and, finally, with the current state of managed care, all specialties are looking for noninsurance reimbursement. This underscores the point I have made several times: that people will spend money on something that they perceive to be adding value to their lives. With the aging baby boomers, there is a more fertile market than ever before. The door is wide open for our specialty, providing we make cosmetic surgery part of our grass-roots training. Most residency programs teach cosmetic facial surgery procedures; it is part of the OMS board exam and is covered by OMS malpractice insurance. It represents part of the evolving contemporary scope of our profession.

For those of us already in practice, the challenge to keep up exists along with the ability to expand our practices. Someday in the future, people may well wander into an OMS office and ask for a face-lift. For now, however, we must raise the public's awareness of what it is that we do.

We are very lucky because we have a captive audience in our reception rooms on a daily basis. All of us who have done osteotomies and genioplasties should have enough before-and-after pictures to construct an interesting display in the reception and evaluation areas. As stated so many times earlier, to successfully market a technique, you must possess expert status and have significant experience with the technique and its complications. For this reason, you should tread lightly and not overmarket commensurate to experience. I believe that skin care, genioplasty, facial liposuction, facial mole and lesion removal, repair of split earlobes from pierced ears, chemical facial peels, lip and wrinkle enhancement with injectable fillers, and Botox injections are procedures that can be performed in the office and are easily within the capabilities of most oral and maxillofacial surgeons. With a basis of these procedures, it is possible to build a cosmetic surgery base with little expense. Some physicians may be satisfied with only these procedures, whereas others will progress to laser resurfacing, eyelid, nasal, and face-lift procedures. These obviously will take a significant commitment on the part of the physician and on our specialty as a whole. Fortunately, there are many worthwhile courses to enhance our education. A potential drawback may be the dental practice acts in some states. Most of us practice under the auspices of the dental laws, and they need to be constantly updated to remain current with our progression and advancement. It is imperative that our political ranks pursue this in all states.

A much simpler means of expanding one's practice into the cosmetic arena is to hire an associate with the expanded

training. This associate can kick off the introduction of the procedures and teach the other partners how to perform them.

Most cosmetic surgery practices cater to an affluent patient base. For most patients, aesthetic surgery is a luxury, and these patients are used to luxurious environments. An office dedicated to cosmetic surgical procedures cannot project the proper image with unfinished pine furniture and NASCAR magazines. These offices must look as nice as the living room of the clients seeking your consultation. Formal furniture with a professional decoration scheme is of utmost importance, in my view. Most patients seeking facial cosmetic procedures are female, and this is an important point to keep in mind and tailor the office to.

Confidentiality in cosmetic surgery is an entirely different ballgame, and neighbors or acquaintances do not necessarily want to be seen in this environment. In addition, the reception room is not the place for a prospective laser patient to see a 48-hour postoperative laser patient. Private entrances and cubicles can assist this situation immensely.

Cosmetic surgeons are keyed into informational sources and have a vast array of informational and skin care products available for their patients (Figure 10-12).

A cosmetic-oriented practice should be well stocked with literature explaining various procedures and techniques because these frequently open the door for various procedures. When performing chemical peels or laser resurfacing, there are many products that may be sold through the office that will assist the patient and income stream of the practice. In addition, there is an added convenience for the patient to be able to purchase their required products without going somewhere else. Many plastic surgery practices have ancillary staff who generate significant income from consultation and sales of pretreatment, posttreatment, and maintenance products. This should not be overlooked, but the staff must be well trained.

There are many avenues available to market the cosmetic practice. This is easy lecturing because of the level of public interest associated with this topic. As stated earlier, many social clubs and organizations exist that actively seek patients. This is grass roots marketing and will interest male and female members. To truly tap the prospective market, you must gain exposure to female clientele. There are many women's clubs, and speaking to a group like this can be a tremendous marketing experience. If one thinks about the habits of cosmetically inclined individuals, then beauty shops, makeup counters, and clothing stores are good marketing sources when tastefully done. Ear piercing kiosks at malls, tanning salons, and health clubs are also excellent sources of prospective patients. Providing referring dentists and OB-GYN offices with personalized informational brochures on cosmetic procedures can also be effective, although many physicians may not choose to display such material. Some practitioners publicize the fact that they offer significant discounts to staff of medical or dental offices. The strong testimonial from a satisfied medical staff person can provide powerful marketing.

• **Figure 10-12** For a cosmetic facial surgery practice, skin care products are a great way to instill interest and introduce patients into the mix.

Internal marketing is a good way to inform prospective patients and stay under the radar screen of competing specialists, who may go to unbelievable lengths to limit one's scope of practice. External marketing is effective, but will more likely bring on the wrath of the competition. Professional marketing firms are established in all cities and can initiate personalized marketing plans commensurate with given budgets. I spend a significant amount of time and money on cosmetic surgery marketing. It is more of a lifestyle than a task. Being extremely involved in publishing and lecturing says a lot about any surgeon and is a great asset when the public is informed. The dissemination of advertising in our practice includes television, radio, newspapers, local "throwaway" papers, websites, seminars, sponsoring of local events and charities, donating goods or services to local events, and performing pro bono cosmetic surgery on needy patients. I believe that it is important to segregate the cosmetic side of the practice from the dentoalveolar side because the competition has done its best to confuse the public about having cosmetic surgery from a "dentist." I am proud of my profession, but the difference between cosmetic surgery and dentoalveolar surgery is less confusing than segregating the two. Some practitioners physically segregate the facility, and others see cosmetic patients only at certain times or on particular days.

The cosmetic patient must be marketed from the first visit and continually thereafter. A welcome gift is provided for each patient and contains various marketing and informational materials, cosmetic sample product brochures, bottled water, magnets, pens, and sometimes discount or promotional coupons. In addition, each patient is sent a personal letter after their evaluation appointment thanking them for choosing our office. I do not charge for cosmetic evaluations and believe that charging is a barrier that can deter even wealthy patients. Often patients have been seen for a free cosmetic evaluation who have also been seen by competing specialists and end up choosing our office because they saw how special we are. In addition, offering same-day

procedures (same day as the evaluation), such as Botox or mole or spider vein removal, can build patient loyalty. I have performed many face-lifts on patients who wandered into the office for a Botox injection. Discount coupons are sometimes used that provide a free Botox injection; after nine injections, the tenth treatment is free. Alternatively, if a patient brings a friend for Botox or filler injection, they each receive a discount. Some physicians do not feel comfortable with this type of marketing, but all patients love it.

If the physician or a staff member is an interesting public speaker, many venues lie waiting for cosmetic presentations. Salons, spas, health clubs, and women's groups are excellent marketing opportunities.

Considering all possible marketing strategies, nothing can replace compassion and availability. I give my cell phone number and email to all cosmetic patients, and this level of availability is priceless for marketing. Calling postoperative patients (not only cosmetic surgery patients, but all postoperative patients) is also an unexpected and appreciated service.

Most of the marketing techniques applicable to procedure-specific marketing, as discussed in an earlier part of this chapter, are effective in the cosmetic arena. The use of a professional and educational website is invaluable. I have treated many patients from out of town and even out of the country solely as a result of Internet exposure. Most of our patients truly study the Web pages before making an appointment and by the time of the evaluation are already well educated.

Any physician who is serious about marketing needs to have a good camera and use it constantly. If one physician performs 100 procedures with no documentation, whereas another physician performs 10 procedures with great follow-up images and statistics, the second physician can market more effectively because of these valuable tools. Often the one who better tells the story better wins the prize. Digital imaging has changed the paradigm for taking and archiving images and has made this a much simpler task. Preoperative and postoperative images of cosmetic surgery (or any procedure) are invaluable for marketing, medicolegal considerations, and the patient record.

Call-on-Hold

You can promote your practice with call-on-hold devices. In a well-run office, patients on hold will be rare. Few things put patients off more than a long hold, especially when calling for an initial appointment. The receptionist should take a number and return the call within 5 minutes, rather than put the patient off. A long hold on the telephone is basically telling the patient that they are not a priority.

All offices, however, will experience holding telephone patients, and recorded promotional messages can be helpful. One caution I would offer is to have a script that stands out from others, because these devices are very popular, and many seem to use similar words. These devices may be purchased inexpensively from communication companies or telephone stores, or for a larger price, a professional company will take care of the hardware and scripting. We live in the information age, and patients want information.

Calling Postoperative Patients

In my opinion, this is the single most important PR technique that a physician can do. No other type of marketing can do so much for so little investment.

Many oral and maxillofacial surgeons call their patients in the evening to check on their status. These "phone rounds" are quite rare in the medical world, and many patients are taken aback by the fact that their surgeon took the time to personally call. Many times, patients have told me that the reason that they returned to the office or sent another patient was the exemplary fact that I called them after surgery.

If the physician cannot call the patient, then the surgical assistant should call, or the receptionist can dial up the patient the following day to have the physician say hello. The impact, however, is much more significant when the physician personally calls the patient the night of the surgery. If a surgeon did no other PR, he or she would get a lot of mileage out of this technique.

Activity Sponsorship

Marketing is recognition, and community sponsorship directly relates to recognition and helping individuals. My partners and I are active in many community groups, including Big Brothers Big Sisters, area mentally disabled citizens groups, scouting, Rotary Club, YMCA, minority groups, athletic teams, and charity groups. Some of this activity includes direct participation or speaking, whereas other involvement includes team sponsorship, buying uniforms with our name and logo, or placing ads in athletic programs or posters. Most aggressive marketing offices follow the tenet "every little bit helps."

Managed Care and Marketing

The fee-for-service environment along with the laws of supply and demand have set the stage for referral favoritism for a century. We are now in the midst of a managed care revolution, and many rules are rapidly changing. Although no one likes the fact that we are doing more and being paid less, we must learn to adapt to a thin environment. With all the negative talk, one positive is that managed care has made many of us better businessmen and businesswomen. Physicians have been notorious for being remiss in many business functions, but as a result of the previous profitability, they could afford to be sloppy with their business practices. The ensuing changes have forced many physicians to take a hard look at their coding, billing, collection, purchasing, and other business line items to control costs and raise profitability. Some physicians have actually found that attention to business detail will make them more profitable than before.

Because managed care companies recruit closed groups of participating physicians and specialists, there may be no choice as to specialists. In other words, we may have a captive audience of general dentists who have no choice but to refer patients to our office because of contractual participation. This negates many of the previous referral tactics that have been traditionally used to gain preference. There is still no substitute for superlative patient care, but depending how long managed care stays popular, traditional specialist marketing may become much less of an issue.

Do You Know What Is Happening at Your Front Desk?

As we have stated so many times previously, your staff is your greatest or worst marketing asset. Because the physician is usually far away from the front desk, many of us are unaware of what is truly going on. As stated earlier, I have sent "sham" patients to make appointments and progress, unknown to all staff and physicians, through the office. The office administrator or consultant are the only individuals who know the identity. At the next staff meeting, the "mystery patient" comes and presents his or her input and observations. This has been quite informative, in addition to keeping everyone on his or her toes. I also have individuals call to make appointments to check on the courtesy and consistency of the staff. And, it can be interesting to drop a $20 bill in your petty cash to see what happens with the monthly reconciliation.

An exceptional receptionist is the keystone of a successful office. This person can bond with prospective patients or drive them away in hordes. The key to being busy is to make it easy to make an appointment at your office. As stated earlier, there are many barriers to OMS. It hurts; it is expensive; insurance is complicated; it adds inconvenience; it causes apprehension; and patients perceive little value in many of the procedures performed. A great receptionist will work on these barriers with the prospective patient and turn an inquiry telephone call into an appointment. When a patient calls and is obviously afraid, a good receptionist will tell them how good the physician is and how gentle and painless the surgery is. If a patient calls and is concerned about finances, an astute receptionist will bring the patient in for a complimentary consult and explain to them that the practice has payment options. If the patient's concern is insurance hassles, the proficient receptionist will tell them the name of their personal insurance person in the practice who will process their insurance. If the concern is about inconvenience, a good receptionist will work the patient into the schedule to suit them. Many patients call various offices to shop for price or just a general feel of office demeanor. A smiling, energetic, enthusiastic receptionist will "attack" these patients with kindness and service and win them over. We use the word *smile;* although you cannot see a smile on the telephone, you can certainly sense it. All of our offices have signs at the front desk that say, "Always answer the phone with a smile." This is truly the first rule of service. We all have bad days from time to time, but they must stop when the telephone rings. It is absolutely imperative to treat every telephone call as if it was your best friend. Remember that the patient is our boss. I have some very trusted and competent employees who are not allowed to answer the telephone because of their rough edges when dealing with the public.

There are many simple tricks that an excellent receptionist can use. When a new patient comes to the front desk, and the receptionist asks, "Have you ever been a patient here before?" this can be very negative. This patient may have a purged chart, been a patient several years, and had a $15,000 osteotomy, and we are asking her if she has ever been here. This is an insult; the appropriate greeting is "When is the last time you have been to our office?" At worst, they will say "Never." When a patient of record calls, the staff should act obviously excited and engage in a minor conversation. People adore being remembered or being recognized. In this harsh world of automated answering, a smiling, friendly voice is a rare find. This is paramount when any referring physician calls. If your front desk people do not know something personal about your referring physicians, then you have the wrong staff. "Dr. Niamtu, it is so good to hear your voice, how have you been, are you still making people beautiful?" is much better than "How do you spell that name?" Making contributions to someone's office and not being recognized is a real turnoff. Even new employees must act like referring physicians, and patients are old friends.

One thing that occurs in all offices is cancellations. Most offices have patients who make appointments, but fall through the cracks for various reasons, usually finances, time, or fear. An excellent receptionist will reschedule a broken appointment before the patient hangs up. If the appointment is cancelled, this patient should be placed on a list and be called multiple times to reappoint. Staying busy involves working broken, missed, or cancelled appointments.

These same characteristics need to carry over to the clinical staff as well. These clinical and clerical positions are usually distinctly different, and if communication is lacking between "the front" and "the back," the office cannot be efficient. If you examine successful, happy, profitable offices, they invariably find a harmony between clerical and clinical employees. The key to this communication is cross-training. It is impossible for someone to truly appreciate someone's job unless they have done it themselves. We earlier alluded to the policy of fast-food chains, requiring their managers to spend time on the grill and French fryer as part of their training. During a citywide blizzard, I once assisted in answering the telephones, and from that day on I had ultimate respect for the ability to manage multiple telephone lines and maintain a smile. If an office stresses cross-training, then every employee will know the rigors of each other's job. If your receptionist cannot take a Panorex or assist in surgery, or if your assistant cannot make appointments, then you are shortchanging your patients, your staff, and yourself.

The clinical staff also has very special requirements involving patient service. A good assistant is a buffer between a

busy physician and apprehensive patients. On the evaluation, these employees can assist in filling in the blanks that the physician has not expressed. They can assist in patient treatment decisions and can quite often sway a patient toward a given treatment plan. Compassion is essential for these staff members. The ability to calm apprehensive patients and hold the hand of a preanesthetic patient can truly mold the entire surgical experience. This is no place for a gruff employee.

Putting It All Together through Communication

I have outlined many theories and techniques related to marketing and patient service. I have used the term "content, happy, and profitable practice" many times throughout this chapter. Anyone who has built this type of office will testify that it is a significant task, and the pursuit of excellence is never-ending. It is said that excellence is a journey, not a destination, because there is no finish line. If you are truly dedicated to their profession and practicing with enjoyment and profitability, then study the following tenets:

- Hire and maintain the correct staff.
- Provide leadership and enthusiasm.
- Make clear what is expected through a policy manual.
- Train the staff to be patient-centered service providers.
- Reward them for their efforts.
- Pursue excellence in all facets of your practice.
- Know when to terminate an employee.
- Constantly improve the level of training and communication.
- Always be a teacher and a student.

These tenets are key to set the stage for organized marketing. Without these, there is no marketing, unless it is negative marketing. A common misconception is that marketing merely involves the physical techniques mentioned earlier. A surgeon cannot market alone, and an uninformed or undertrained staff cannot market at all. Constant communication and consultation are vital to keeping the team sharp. No football team would ever reach the Super Bowl without practice. For the oral and maxillofacial surgeon, this practice involves staff communication. Any progressive practice has regular meetings with the physicians and managers and the staff. Even though your staff may know what to do and what to say, it has to be continually stressed to stay aware and sharp. Enthusiasm is contagious, and the same may be said of its lack. This team spirit must be perpetuated. I have monthly staff meetings with the partners and manager, quarterly staff meetings with everyone included, and an annual retreat for staff focused on communication, patient service, and continuing education. In addition to this, the manager has regular meetings with various locations. You do not need to have a group to do this; it is actually much easier with a smaller office. Regardless of size, everything in this chapter applies to all offices.

To enhance optimal communication, one must have policy and consistency in all positions. My partners and I have used a set of communication principles that is referred to as "the rules of the game." This is an excellent list from which to build and a valuable tool to show a prospective employee you are contemplating hiring.

As stated so many times earlier, every game has rules, and to win, you must be acutely aware of all of them to prevent a disqualification. The winners in OMS are happy, profitable practices, and the losers are those who go home exhausted and frustrated and dislike what they do for a living.

The following principles are referred to as the "rules of the game," and in my office they take precedence over all other forms of communication. All partners, managers, and employees are aware of the rules, and they are posted throughout the office in bright Day-Glo laminated frames. I believe that it is essential for every person in the practice to have intimate knowledge of the rules, and like referees in sports, the owners and managers must have even greater understanding. We will examine each rule and its implication as it relates to OMS.

- **Rule 1: Be willing to support our missions, values, and guiding principles.** This rule, although obvious, is the most often overlooked. I am amazed and confounded by how many OMS practices do not have a written policy manual with distinct job descriptions and a clear outline of the vision or goals of the practice. If you do not communicate these with an employee, how can you possibly expect them to support them?
- **Rule 2: Speak with good purpose.** Gossip among physicians and employees is one of the most destructive forces in an office. This involves speaking about someone outside his or her presence. This is done by idle, unchallenged employees and can undermine your entire staff and effort. It should be grounds for termination and strictly prohibited. This also applies to those who say one thing and do another. A leader must truly practice what they preach. As your mom said, "If you can't say anything nice, don't say anything!" This especially holds true for pessimists.
- **Rule 3: Be open and honest in your communication with each other.** Actually expressing true feelings is sometimes very difficult. We are often afraid to hurt someone's feelings, rock the boat, or cause friction, so it may seem easier to agree with someone or support their improper behavior than to express the truth. This is one of the most difficult things for some people to do, but if this rule is not followed, the others are meaningless. You must be able to look partners, managers, and employees in the eye and tell them exactly how you feel. If you do this consistently, you will be respected. For this to work, all individuals must take a pledge to be open and honest. This breaks the ice and paves the way for open communication. Failure to do this will perpetuate the problems of communication that plague many practices.
- **Rule 4: Complete agreements and be responsible to others and yourself.** When people sit down to iron out problems, it is human nature for everyone to want to jump on the bandwagon and to volunteer to take

responsibility to make a change. This frequently involves a task, a behavior change, or a sacrifice. All too often, those who are enthusiastic at the start lose their vigor or neglect to follow through on the task or the behavior that they promised. This is common and is one huge reason why some practices never get out of the hole. When someone says that they will do something, they must take the responsibility to follow through, and the leader of the practice must take the responsibility to coach them through their stated work and insist on its timely completion. Everyone must realize that when they fail to follow through on a task, they let down themselves and the practice.

a. Make only agreements that you are willing and intend to keep.
b. Clear up any broken or potentially broken agreements at the first appropriate time with the appropriate person. This is especially important. If you see that they are missing their promise or timeline, then it is important to discuss this with the correct person at the correct time. The immediate leader for this staff position must be made aware of the possible lack of follow-through, and it should be expressed immediately. Complaining to the incorrect person may be gossip, and failing to notify the leader immediately will compound the problem by procrastination.
c. Do not commit to others unless there is agreement. If a given individual believes that he or she has the correct idea or action, that does not make it correct. This must be clearly communicated to the group, and a positive response must ensue, which requires rule 3.

- **Rule 5: If a problem arises, look first at the system, not the people, then make the correction.** If there is one thing that many employers are guilty of it, is this. As I said earlier, most employee problems are the result of the employer, not the employee. This is usually true. Employees often take the brunt of criticism when the employer is guilty of being a poor leader. If there is no policy manual, no job descriptions, no vision or goals, then whatever occurs is happenstance or coincidence. Your chances of having an enjoyable, profitable practice become the chances of winning the lottery. Virtually any employee problem can be traced to improper leadership. Next time you are disappointed with an employee, stop and look in the mirror and ask yourself as a leader, "Did I do everything possible to make the rules and goals known and set clear standards to be followed in this case?" It takes a big person, but so often a leader cannot answer this in the affirmative. A true leader will admit the shortcoming and do better; a poor leader will continue to be a blamer.
- **Rule 6: Do not be a blamer.** No one likes taking criticism or being wrong, but blaming others for your own failure or shortcomings will only perpetuate mediocrity. The three hardest words to say are "I was wrong." Once you can speak with honesty and admit this, you will be respected and open the door to other individuals to exhibit this honesty. For this environment to exist, the other staff must be supportive and accept an apology and honesty and not persecute the individual or dwell on the admission.
- **Rule 7: Commit to add value by making more out of less.** For any business to thrive, each person must add value. It is when staff or physicians decrease value that stress and waste occur. The key to operating a successful business in this day of managed care and business is to be lean, economical, innovative, and value conscious, not only in physical spending, but also in decisions and the entire aura of the practice. Waste in policy or expenditures will severely affect the ability for some physicians to enjoy their work and make a profit. Staff members should constantly challenge each other and the practice to do more with less, and when an employee's suggestion is valid, he or she should be rewarded.
- **Rule 8: Have the willingness to win and allow others to win.** In a win-win situation, the attitude is, if I allow others to win, then I win also. With an employer, the win is even bigger. This is a competitive world, and many people are used to winning—to being promoted or advancing. Unfortunately, many of these people believe that they can only win if someone else loses. This creates a backstabbing environment, and for the person to win, someone must lose. If this person is your employee, then the practice will ultimately lose. These people are very goal oriented and are difficult to control. A win-win person, on the other hand, progresses and advances just as fast, but with less trouble, because they realize that by allowing others to win, they will win and may win bigger. It is this type of employee who portrays altruism and is a valuable asset to any practice. The world needs more winners.
- **Rule 9: Focus on what works, retreat on what does not.** Many times the best intentions are put forth with ideas or policies, only to have them fail or fall short of the intended benefit. A progressive leader will realize that some ideas, no matter how good they seem, are not possible. These leaders will admit the shortcoming, regroup, and attack the problem from another angle. A poor or resistant leader will not admit to the shortcoming and beat a dead horse, even though it is not in the best interest of the practice. Some leaders remain hardheaded and will propagate poor policy just because they cannot admit to being incorrect. No matter how good it sounded, if it does not work, move on. What is also important here is not to focus too much on the past. If you are surrounded by individuals who will not forget a mistake and continually reflect on what did not work, you are not fostering the proper environment to admit a mistake. Don't dwell on the past; learn from mistakes and move on.
- **Rule 10: Encourage the risk of innovation.** You must focus on the very best communication for the staff and the best service and care for the patients. To do this often requires going outside of the usual parameters for practice and service. If you follow the usual

procedures for running a practice, then you will have a usual practice. To have an exceptional practice, you must constantly challenge the leaders and the staff to think of innovative means to better the communication and patient service and care. Sometimes staffs are shy or hesitant to provide input. Sometimes those who provide input are ridiculed or ignored, or worse yet, go unrewarded. Big business learned decades ago that it pays to have good ideas, and one should pay for good ideas. If someone makes a suggestion that makes a difference, they deserve reward. They win, you win bigger, and your patients win biggest.

An example is how our practice decreased after-hour calls by 90%. No one loves being on call, and we all get nuisance calls. Many or most of the after-hours calls involve medications. Some are warranted, and many are drug seeking. Our practice simply put a message on our after-hours recorder that "No prescriptions are filled after hours or on weekends." We also posted these signs throughout the office. We initially feared that we might offend legitimate patients in pain, but we were wrong. Legitimate patients called during office hours, and drug seekers called someone else. We literally decreased our emergency calls by 90%.

- **Rule 11: Do not shoot the messenger.** Upon hearing bad news, the king would kill the messenger, or so the story goes. None of us want to hear bad things about our practice, but to ignore them only makes things worse. "Ignorance is bliss" is only for someone that wants to work in a stressful and nonprofitable environment. A good leader must demand to know what is good and what is bad and must liberate the staff, patients, and referring physicians to have unencumbered input. If you make it hard for someone to tell you negative things, you will never hear them. This is not reality. Sometimes it requires a negative to make a positive. True leaders have an open-door policy for constructive criticism and will act accordingly. Before criticizing someone, first try to understand the principles of the policy and always offer criticism in a positive and constructive manner, as stated in rule 3. Encourage critique.
- **Rule 12: Raise the "red flag" when overloaded.** Leadership requires energy, and sometimes, with the best of intentions, we put too much responsibility and burden on ourselves. Even though we think we can handle it, we become overloaded and begin to break rule 4. This, although with good intentions, actually encumbers the practice and skews all the other rules. We all have limits on the responsibility that we can handle and must maintain a good mix of relaxation and outside activities. If you become overloaded trying to make something better, you may actually make it worse. We all tend to multitask, and sometimes, instead of advancing a few prime goals, we wallow in stagnation. This leads to inefficiency and burnout. In addition, if our managers "raise the flag," we can appreciate their honesty, instead of admonishing them months later when we see that the projects are not done. It is far more advantageous to admit overload and ask for help to keep the practice on track. Never be afraid to ask for assistance, and never create an environment where this is frowned on.
- **Rule 13: Always maintain a sense of humor.** Life is a short ride, and we all have only so many heartbeats to enjoy it. Sometimes we take things far too seriously. There is a time for seriousness and a time for levity. Most influential and successful people I have had the pleasure of being associated with always find humor in life and make the best out of all situations. As oral and maxillofacial surgeons, we live in a high-stress environment and face sometimes grave decisions on a daily basis. No matter how bad things seem in a given crisis, history tells us that the crisis will pass. Optimism is a virtue and is contagious. Try to smile every second, and try to find humor in things. There are no dress rehearsals in life. How would you treat people tomorrow if you knew it was your last day on earth? The button that fell off your shirt or the flat tire would carry much less aggravation.

Summary

I have attempted to illustrate that marketing is not a specific task, but rather a lifestyle. If you examine very successful practices, you will invariably find an excited, energetic leader with an enthusiastic and caring staff that enjoys what they do for a living. Marketing, as I have illustrated, goes far beyond the bounds of a gift or party and is a total commitment to excellence and the desire to share this with patients, referring physicians, and the public. Marketing, like underwear, is very personal, and the same techniques will not work for every physician or locale. Each one of us needs to find his or her own comfort level and do as much as they can with what they have. Marketing need not be advertising or yelling and screaming. Target patients can be subtly informed of your services. Oral and maxillofacial surgeons are innovative individuals, and I could not possibly cover all the various strategies of marketing. I have tried to dissect the theoretical aspects of marketing and to present various options as I see them. "The customer is always right," "Do unto others as you would have done unto you," "Offer an excellent product at an affordable price," and "Always be a teacher and always be a student" are admonitions that may be centuries old. Certain common-sense factors in how you present your product or service will have an enormous impact on the success of your business and your happiness in their profession. Whether an office consists of multiple physicians and locations or a one-physician, five-employee single office, the theories and techniques presented here apply across the board.

Challenges of Retirement

R. DEAN WHITE

Introduction

For some, retirement will come earlier than for others; some will be forced to retire, while others will do so voluntarily, but we all will have to hang up the spurs sometime. This chapter is written to help prepare you for this major life change mentally, psychologically, physically, and emotionally. Preparing for retirement is not about getting your finances and investments in order; it is more about learning to invest in your life after a busy career as an oral and maxillofacial surgeon.

Richard Rovit, MD, probably said it best: "Each segment of the journey of life should be embraced fully and actively, ever mindful, however, that is a continuous passage with new challenges (opportunities). It is fair to reminisce about what has gone before, but it is neither helpful nor realistic to fight the ongoing stream, attempting to remain fixed in one area beyond one's allotted time."[1]

Change and Its Challenges

Some think that planning for retirement beyond financials is silly; why not move to south Florida and play golf and gin rummy and enjoy the golden years? The truth is that many of us will have a difficult time going from a healing profession where the focus is on the patient to just thinking about ourselves. Golf and gin rummy are fun for a while, but what will you do when you wake up one day feeling bored and unfulfilled?

Throughout our lives, we change cognitively, spiritually, and physically, regardless of our efforts otherwise. As we transition from our professional roles to retirement, many fear becoming irrelevant or meaningless. Many medical professionals have spent a lifetime in training and practicing a profession at the expense of other interests or endeavors. Retirement is the time to consider what you would have done had you not become an oral and maxillofacial surgeon. Think of it as a retrograde "bucket list." Have you fantasized about teaching high school biology? Coaching tennis? Being a fishing guide? Writing a novel? Going to seminary? Earning an MBA? The list of possibilities is endless.

The Importance of Balance

To avoid boredom during retirement, it is wise to start practicing a balanced life now. Euripides (480-406 BC) emphasized balance when he said, "The best and the safest thing is to keep balance in your life, acknowledge the great powers around us and in us. If you can do that, and live that way, you are really a wise man."

Many of us have not maintained balance in our working lives, but as we age, balance becomes critical for a healthy and meaningful retirement.

The four elements we all need to keep in balance are the following:

- Work
- Family and friends
- Recreation
- Spirituality

Many Type A, highly functioning personalities seem to neglect all but work, and the consequences are evident in their personal lives and relationships (e.g., anxiety, stress, strained relationships). Even if you previously lacked insight and commitment to balance, it becomes a necessity to your physical and mental health as your retire.

Work

The work part of balance will mean different things to different people. All of us will need to continue some form of "work." It may be volunteering at a local school, helping build homes for Habitat for Humanity, or other professional pursuits. You may elect to go on medical missionary trips, either faith-based or secular. Health Volunteers Overseas, Heal the Children, or countless other organizations are always looking for qualified professionals. It is critical to continue to serve as you have done your entire career. Don't stop helping others because you don't get paid. In fact, when there is no paycheck involved, the reward is greater.

Family and Friends

Family and friends are the second part of the balance equation. When you retire you will find yourself at home more often. Your spouse, who has gotten used to your long hours at the office and hospital, may look at you and say, "You can't stay home all the time." You can't go home and give your spouse a list of duties or rearrange the kitchen or the garage. You and your spouse need to learn how to live together again. Sure, you may have slept in the same bed for the past 30 years, but your sudden constant presence changes the balance of the home.

The next aspect of the balance equation is to have an in-depth conversation with your spouse or significant other, ideally before your final day at work. Talk together (key word) about finances, the possibility of moving to a new location, and goals and objectives as you go forward together. Retirement can be a tough time and needs to be dealt with prospectively. Single folks need to consider how they can best connect or reconnect with their friends, family, and the community.

Enjoy your children if you have any, but really enjoy your grandchildren. You can always give them back to their parents! They grow up fast.

Take time for your friends, new and old. Take time for visits, trips, meals, and just visiting together. Don't isolate yourself. Connecting with family and friends is one of the keys to health and happiness when you give up your day job. All of this takes time and effort, so take the initiative to include family and friends in your daily life.

Recreation

The third piece of the balance equation is recreation. Recreation should include physical and mental exercise because both are important for long-term health. Read, write, play word games, learn a new language, join a bridge club, or do whatever else makes you think. Learn square dancing or to play the piano. Mix social games with solitary games. Both are healthy.

Physical exercise is probably the most important factor that leads to physical and cognitive health as we age. My dad once said he was going to take up jogging when he saw just one jogger smiling. He died at 95 and never did jog, but he did stay healthy doing activities that engaged him. The type of physical activity is up to you, but pick a few different activities to keep your mind and body engaged. Variety will also keep you motivated.

Spirituality

The fourth element of the balance equation is spirituality. Spirituality is different for everyone, but it is crucial for maintaining a happy and healthy existence when you retire. Spirituality does not necessarily require a religious affiliation. It is simply the practice of recognizing you are part of something larger than yourself. Spirituality can be walking in the woods, attending religious services, yoga, prayer, meditation, fasting, or reading and contemplating religious or spiritual texts.

Mitchell Krucoff, MD, a professor of medicine and cardiology at Duke Medical Center, states that "prayer is the most ancient widely practiced therapy on the face of the earth." Father James Martin, a Jesuit priest, summed up his view of religion when he wrote, "False religion is the idea that if you believe, all will go well, and there is nothing to worry about. Real religion is the idea that if you believe, all may not go well, but, in the end there is nothing to worry about."[2]

Retirement will not always go well. One of my favorite books is written by a Harvard-trained neurosurgeon, Alan Hamilton, MD. He wrote *The Scalpel and the Soul: Encounters with Surgery and the Supernatural and the Healing Power of Hope*. He concludes this book by stating, "We cannot be ordered to love God, as powerful as God may be, no authentic love could exist between a human being and God without the freedom to choose. God's love may be everlasting, but each one of us alone must decide whether to declare it mutual."[3]

As you enter the fourth quarter of life, consider balance as a great strategy. None of us get out of this alive, so make the "back nine" meaningful and relevant.

Leaving a Legacy

Pericles (495-429 BC) said over 2000 years ago, "What you leave behind is not what is engraved in stone on a monument, but what is woven into the lives of others." What would you like your legacy to be?

Most of us don't like to think about leaving a legacy, as it sounds self-serving. But we all leave a legacy; it might be a good one, it might not. I suspect most of you will leave a pre-retirement legacy, one that involves an illustrious career with lots of happy patients and a staff that appreciated you and your work. Most of you reading this chapter will have accomplished a great deal in life outside of oral and maxillofacial surgery. I challenge you to use your personal and professional experiences and leadership skills to help others. For example, you could mentor a struggling clinician or someone with addiction or behavioral problems. Volunteer opportunities are endless. Big Brother/Big Sister, Habitat for Humanity, the local food bank, homeless shelters, and countless others all can use empathetic, service-oriented volunteers. Try it—you might like it. I assure you that you will receive a greater benefit than those you help.

Leaving a legacy doesn't have to be structured. Simply spend time with friends, some older and some younger. Your values may be contagious. It you were proficient with your personal and professional finances, help someone who is struggling to get back on track. Being a mentor or volunteering your time means you have to get out of your comfort zone, but you will be surprised at the results.

Behavioral Health

Leaving a busy practice where your patients and staff think you are the greatest can be a real challenge to your psyche. Most of us, during our education, training, and practice, probably did not have a lot of spare time or time for ourselves, which can be considered good and bad. There will be times after you retire that you just simply don't have enough to do. Solitude can be a blessing and a curse. Blaise Pascal, a French philosopher in the 15th century, wrote, "All unhappiness of men arises from one single fact, that they cannot stay quietly in their room . . . we require things to distract us from ourselves. Hence it comes people so much love noise and stir. It comes that the pleasure of solitude is a thing incomprehensible."

Use your newfound solitude to your advantage. It can be part of the balance equation. For example, some forms of recreation and spirituality require solitude. Use your time to write, read, paint, create, walk, run, cycle. Use it to contemplate. Go fishing. Henry David Thoreau said, "Many men go fishing all their lives without knowing that it is not fish they are after."

Unwanted solitude can lead to boredom, which can lead to situational depression, which is only one reason why it is crucial to plan your retirement. *Bored* may just be another word for *lazy*, or it can be a form of worry. Remember that staying engaged and productive is your responsibility and yours alone. The distinction between boredom and depression is that boredom is a lack of interesting things to do, as opposed to depression, which is not having any interest in doing things. Boredom is temporary, but depression may not be.

Gratitude

Another element of behavioral health as we retire and enter the "winter" of our lives is thankfulness and gratefulness. There is a fair amount of science demonstrating that thankful, appreciative people are healthier and happier than those who go through life glum and complaining. Cicero (106-43 BC) wrote, "Gratitude is not only the greatest of virtues, but the parent of all others."

P. Murali Doraiswamy, MD, head of behavioral psychology at Duke University, makes a strong case for working on your thankfulness skills. He states, "If thankfulness were a drug, it would be the world's best-selling product with a healthy benefit to every major organ system." His research has shown that a thankful attitude has measurable effects on chemical mood transmitters (serotonin and norepinephrine), reproductive hormones (testosterone), social bonding hormones (oxytocin), cognitive and pleasure related hormones (dopamine), inflammatory and immune system hormones (cytokines), and stress hormones (cortisol), as well as cardiac and ECG rhythms, blood pressure, and blood glucose. How is that for a list of benefits without side effects?

One way to exercise gratitude is to make a point of thanking those who have helped you in the past (they will not be here forever). Call or write that coach, teacher, professor, pastor, mentor, residency director, or attending and just say thanks for helping you along the way. You will be surprised at how good it makes you feel, even if you never receive a response.

Along the same line as thankfulness is apology. Consider apologizing to anyone you may have hurt or offended. This is a tough exercise. Many of us go through the majority of our lives without being able to admit when we were wrong, rash, or just plain stupid. Some of us are not very good at admitting when we fall outside of the rigid boundaries that we set for ourselves. Apologizing will save relationships, mend past hurts, and help you start this next chapter of your life with a clean slate.

The Agony and Ecstasy of Aging

Aging is inevitable, unless, of course, you die young. The average life expectancy in the United States in 2011 was 78.4 years, and it increases every year. The quality of life is infinitely more important than the quantity of life, but if we can have both, so much the better. The two goals of achieving a long, full life are the dreaded words "diet" and "exercise." I used to hate both—now I just dislike them.

We all know what we should eat and drink for the most part, but for the sake of argument, a paragraph on proper diet is in order. A proper diet should include daily intake of fresh fruits and vegetables. If possible, a vegetarian diet is healthiest. Lower your sugar and carbohydrate intake and minimize the amount of fried food you consume. In other words, cut back on the Twinkies and pimento loaf. Lower your cholesterol by diet, exercise, or medications, or a combination of all of them. It will save your heart and your head. Lower your intake of saturated fats, which for the most part are animal-based, and increase your unsaturated fats, which are derived from plants. Eat more fish. Throw away the salt shaker.

Most people decrease their alcohol consumption as they age, but one study showed that physicians, as they get older, not only drink more, but also drink more often than the rest of the aging population. The U.S. Department of Agriculture Center for Nutrition Policy and Promotion recommends that women should have no more than one glass of wine a day, and men should not have more than two. Moderate alcohol intake is probably beneficial, but excessive alcohol has many deleterious effects. Use alcohol as a drink, not a coping mechanism.

Exercise is just as important as proper diet. For a long time, I subscribed to the theory that we are only given a finite number of heartbeats, and you could use them up quickly or slowly, but my mind has changed over the years.

The key is to make exercise a habit. It can be vigorous cycling or brisk walking—choose an activity that feels good and keeps you motivated. Exercise makes you feel better; usually you will benefit from a mood boost within minutes of moderate exercise.[4] Physical activity can help alleviate short-term depression, and it can prevent long-term

depression.[5] Exercise may also help to slow mild to moderate dementia. A *Journal of the American Geriatric Society* study found that an exercise regimen of 1 hour twice a week resulted in significantly lower cognitive decline for patients in retirement centers.[6]

Dr. William Buchan, an eighteenth-century Scottish physician, wrote, "Of all the causes which conspire to render the life of man short and miserable, none has a greater influence than the want of proper exercise." The best recipe is cardiovascular training, strength training, and flexibility and balance exercises. The bottom line is that if you don't use it, you will lose it.

Cognitive health and the prevention of dementia are at the forefront of medical research today. Most of this research is driven by compassion for the patients and families who have or will have to deal with this devastating process, but much of the effort is to diminish the sheer overwhelming cost to society to take care of these patients. The one constant is that exercise slows down mental decline. Medications have not been developed that actively prevent or slow down the progression of the disease. The latest research has identified spinal fluid markers that may predict who will have Alzheimer's, and scientists are hopeful that this discovery will lead to strategies and pharmaceuticals that will cure the disease. Most patients develop Alzheimer's disease over a 30- to 40-year period. The key is for all of us to implement a lifestyle and diet and exercise program and a medication regimen that can "treat" the disease early. (See Chapter 12, on boundaries and impairments, for a more complete discussion of Alzheimer's disease.)

Piddling, Potholes, and Pearls

Most of us who have practiced or are practicing oral and maxillofacial surgery are constantly busy, with little time for other thoughts or activities. I practiced with the ever-present thought that Monday is coming. In other words, it was difficult for me to relax, think about nothing, or to not be planning cases 2 weeks in advance. I suffered from the tyranny of the urgent. As you enter this stage of your life, I encourage each of you to find the time to be unproductive and to truly enjoy your freedom. Napoleon once said that nothing is more difficult and therefore more precious than to be able to decide. Decision making can be difficult, and sometimes we don't get it right—but at least we have the freedom to do our own thinking. Retirement is your chance to decide how to spend your time.

Piddling

One benefit of retirement is the ability to piddle. I always had a difficult time piddling. Piddling is spending time in a wasteful, trifling, or ineffectual way. Piddling is relaxing. You don't get paid for it, or at least you shouldn't. You don't piddle with a time constraint, and you don't enjoy the fruits of your piddling. Piddling is mentally healthy. You could wax your car, even if it does not need it. Whittling something out of wood without a template or plan could be piddling. You don't need an education to piddle; in fact the more education you have, the more difficult it is to piddle. Piddling is personal. It clears the mind and helps purge our Type A personalities. It helps us live longer.

Potholes

I consider potholes to be unseen and unanticipated events or occurrences, such as the death of a spouse, the sudden loss of income, or a diagnosis of cancer. You are bound to hit a few potholes as you enter retirement. Some you don't see coming until it's too late, but lack of planning can also lead to potholes. For example, poor financial planning, not enough insurance, or a lack of balance are pretty deep potholes, and it is expensive and time consuming to repair the damage.

Self-pity can turn into a pothole. Don't focus on what you used to do, but on what you are going to do. I asked my mother on her 93rd birthday what she was doing with her time. She had had a stroke a year earlier and was living in an assisted living facility. She replied, "Nothing, and I don't start that until noon." Then she laughed. We should all have that perspective as we age. She stayed optimistic, understanding that we are all dealt a short hand every once in a while, instead of sinking into self-pity.

Another pothole is worrying about the state of affairs and the affairs of state. You can ruin a perfectly good day by reading too many newspapers. Agonizing about things over which you have very little control is not worth the energy. If the cause or issue is important to you, vote, volunteer, contribute, blog, but don't just sit there and tell everyone the world is going to hell. No one likes to sit next to that person at the Thanksgiving table.

As stated earlier, avoid the pothole of regret and unhappiness. Settle past conflicts and disagreements. Apologize and move on. A hateful heart is not a healthy heart. The deepest pothole is inactivity. Physical, mental, and spiritual inactivity will age you faster than time.

Pearls

Pearls are simple thoughts that personify what makes retirement meaningful and relevant. They can make each day a gift and help us work on thankfulness. They can help us grow and continue to learn, which in turn will make our lives longer and more meaningful. Pearls are different for everyone. What I consider a pearl, you may think is a lump of coal. The following is a list of pearls I have collected over the years; some are mine and some are borrowed.[7]

- Be kind to everyone.
- Journal daily, not what you did but what you thought.
- Remember we are all struggling, so treat everyone with empathy and respect.
- Try not to judge; be tolerant, but do not forsake your values.
- Make your spouse your partner.

- Share.
- Don't let someone else determine your happiness.
- Write something.
- Read something.
- Teach.
- Build something or create something for someone else.
- Challenge yourself, not others.
- Get outside your comfort zone by learning a language, how to fly a plane, or to dance.
- If you are fortunate enough to have a long-time spouse, thank him or her for putting up with you.
- Cultivate friendships.
- Pay it forward.
- Perform a random act of kindness.
- Give things away.
- Try not to worry about things you have no control over.
- Enjoy the birds and the flowers.
- Listen to others.
- Remember that your legacy may be unintended.
- Practice being alone; solitude is good for the soul.
- Get a dog or a cat.
- You will not be happy if you lose your options, so stay healthy.
- Thank people who helped you along the way.
- Be truly thankful for every day.
- Laugh, especially at yourself.
- Exercise your body, mind, and soul.
- Love.

The key to all this advice is to stay in the present. You can't go back, and you don't have any control over the future. Enjoy each and every day that you are given.

Boundary Violations and Physical and Mental Impairments

R. DEAN WHITE

Introduction

Anyone in a high-pressure career will, at some point, be faced with non-technical decisions that may have grave consequences that could affect his or her ability to practice. Some of the consequences of boundary violations, addiction, or aging are avoidable; some are based on an individual's genetics and background; and some are inevitable. This chapter is dedicated to helping the reader understand how personal boundaries can affect one's medical practice and when boundary violations constitute impairment.

Maintaining Proper Boundaries

We, as humans, are social beings, and that is a good thing. Based on my own experience, oral and maxillofacial surgeons, in general, have some of the best physician-patient relationships in all of medicine and dentistry. Oral and maxillofacial surgeons tend to have better communication skills than other types of practitioners and an empathetic approach to patients that is commendable.

However, at the risk of ignoring common sense for the sake of political correctness, medical professionals are all susceptible to boundary crossings and violations, as well as episodes of disruptive behavior that can compromise our patient care and, ultimately, our ability to practice.

Most of us are not aware of the boundary crossings and violations that we engage in on a daily basis. Most are not harmful; in fact, some are helpful at times. Patting a colleague on the shoulder, hugging a distressed patient in the office, and complimenting someone's attire can all be helpful acts of caring, but they can be misinterpreted by others as offensive or awkward. These examples are boundary crossings for the most part, depending on the intent. They can lead to a breakdown in the patient, employee, or hospital staff relationship as well.

Unfortunately, medical professionals don't get to decide what is or is not a boundary violation. By the nature of their education and degrees, medical professionals are the responsible ones in the room. They enjoy the power of the profession; therefore, they must be aware of this responsibility and use it wisely.

Most boundary violations are not a problem until an outside party perceives it as a problem. For example, dating an employee where you practice might not seem like a problem. Everyone may live happily ever after, or it can lead to ethical and legal problems that could affect the practitioner's licensure.

The inappropriate use of electronic media also puts medical professionals at risk of crossing boundaries. Emails, Facebook postings, tweets, and other online communications can all be positive, but if they are inappropriate, they can serve as a permanent record of inappropriate and unprofessional comments or behavior that can haunt you for your entire career. Pictures and comments spread on the Internet like a virus, so think twice before telling the off-color joke, forwarding the inappropriate email, or commingling personal postings with those of the practice.

Avoiding Disruptive Behavior

All of us want the best outcomes for our patients. Unfortunately, if a medical professional lacks empathy or appropriate social skills or had a mentor who thought condescending and argumentative behavior was effective, then he or she may be prone to disruptive behavior.

Most of us don't wake up in the morning with the intent of "losing it" when things don't go as planned. Physicians and surgeons who exhibit disruptive behavior are not bad practitioners; in their opinion, they are using the most effective tactics to get the outcomes they want. However, extensive literature suggests that disruptive behavior, such as

raising your voice or using sarcasm to call out a nurse's error, does not beget better patient outcomes.

Alan Rosenstein, MD, MBA, documented in the *American Journal of Nursing* in 2002 that 93% of his respondents had witnessed disruptive behavior in the hospital setting. Disruptive behavior isn't just throwing surgical instruments across the room or yelling at a nurse. It can take a more subtle form that eats away at professional and patient relationships.[1] One respondent to an American College of Physicians Executives survey in 2009 stated, "The worst behavior is not the most egregious; it is the everyday lack of respect and communication that affects patient care and staff morale."[2]

Continued disruptive behaviors can lead to a total breakdown of communication among the health care team, which can lead to untoward patient complications and medical errors that would not ordinarily be a problem and are totally preventable. Good communication is critical to good outcomes when you are working as part of a team. Any erosion of good communication puts patient safety at risk.

Lack of empathy (for example, an arrogant attitude or not fully listening to others) can be considered disruptive behavior. Thus, the goal is for all medical professionals to treat everyone (e.g., patients, patients' families, hospital staff, and employees) with empathy and respect. Empathy is not just understanding the other person's point of view, but also feeling it. Empathy in the clinical setting is not just about being nice to the patient or other members of the health care team. It is about recognizing the significance of illness in the patient's life and understanding why the surgical nurse may have handed you the wrong tool (did you communicate well?). A surgeon who cannot empathize with patients or understand his or her own role in any problems that might arise within the health care team cannot be an effective surgeon. It is sometimes difficult for physicians and surgeons to connect the disease to the patient. As surgeons, we were trained to find the problem and fix it, but the awesome privilege of taking care of another human being requires much more than technical skills.

Emotional Intelligence

If you are prone to disruptive or inappropriate behavior, consider the principles of emotional intelligence first published by Daniel Goleman in 1995.[3] Emotional intelligence is the ability to identify, use, understand, and manage your own emotions in positive and helpful ways, and understanding the four aspects of emotional intelligence may help alter disruptive or inappropriate behavior. There are four aspects of emotional intelligence:

1. Self-awareness
   - The ability to recognize your own emotions and the affect they have on others
2. Self-regulation
   - The ability to control impulses and manage your own emotional states by using positive self-talk
   - Taking the initiative and maintaining motivation
   - Following through with commitments
   - Having the ability to deal with change
3. Social awareness
   - Having empathy for others
   - Picking up on social cues
   - Interacting socially
   - Recognizing the power of a group or organization
4. Social and relationship skills
   - Recognizing the effect your emotions have on others
   - Communicating clearly
   - Inspiring and influencing others
   - Working well within a team
   - Managing conflict

We cannot alter our personalities or our intelligence quotients, but we can improve our emotional intelligence and thus reduce the incidence of disruptive behavior.

Addictions

When someone has an addiction, it is the elephant in the room, which no one wants to acknowledge, discuss, or confront. Demographically speaking, as with any disease, individuals suffering from addiction are distributed throughout the population regardless of education, training, or background. In other words, medical professionals are not exempt. In fact, they may be more prone to addiction given the pressure of their profession, the belief that they can effectively self-medicate, and the ready access to narcotics and other addicting drugs.

The American Society of Addiction Medicine defines addiction as a primary, chronic, neurobiological disease with associated psychosocial, environmental, and genetic factors. It is characterized by one or more of the following behaviors:

- Using drugs inappropriately or in the wrong dosages to obtain a certain result (e.g., an emergency department physician who uses stimulants to stay awake and alert during overnight shifts)
- Compulsive drug use
- Continued abuse of drugs despite consequences
- Craving

The neurobiological foundations of any addiction are dopamine and glutamate, which are released by the brain in response to a drug or other behavior. They, in turn, act as excitatory neurotransmitters that create a feeling of pleasure and satisfaction. That feeling becomes the center of the addict's life.

Substance Abuse

Ten percent to 14% of physicians and surgeons will become drug or alcohol addicts at some point in their careers. If alcohol is excluded, then the percentage becomes 2% to 3%. Because they have easy access to them, physicians misuse opioids and benzodiazepines more than the general population, and fentanyl is the intravenous narcotic of choice. Males tend to abuse more than females.[4]

The etiologies of substance abuse for medical professionals do not differ from those for the general population, except that medical professionals have easier access to narcotics. Of physicians with a substance abuse problem, 75% report a family history of addiction. The family of origin is often dysfunctional and disruptive, and the individual's history typically includes physical and/or sexual abuse. Physicians and surgeons are less likely as a group to seek help and are more likely to self-medicate.[5] Fifty-two percent to 98% of physicians and surgeons begin to self-medicate early in their careers. Unfortunately, they do not medicate themselves appropriately. Toxicology reports on physicians who committed suicide revealed that the physicians medicated themselves but did not prescribe antidepressants. They were using the wrong drugs to treat the depression because they were either in denial about having depression or did not know how to treat it effectively.[6]

Not all medical professionals who self-prescribe abuse medications, but 40% to 75% of those who do abuse medications, started by self-medicating.[7]

Sexual Addiction

The concept of sexual addiction is controversial. Many people consider it a moral failing and a weakness, not a disease. However, if you think of addiction as compulsive behavior, it can involve everything from substance abuse to gambling to sexual activity. Inappropriate sexual behavior that continues despite adverse consequences is an addiction.

Some addictions come in pairs. For example, individuals who exhibit sexual addiction also have a 38% chance of having a chemical dependence.[8] Cybersex is as addictive as crack cocaine, as documented by Deborah Corley, PhD. The prevalence of this addiction is 6% to 8% of the general population, and 20% of those affected are women. It is as difficult to treat as any other addiction and carries the same origins as other addictions.[9]

Individuals who have sexual addictions are likely to act out their addictions in the workplace, which can lead to allegations of sexual misconduct and harassment. Any allegation, no matter how minor, may severely jeopardize one's ability to practice medicine.

Treating Addictions

The good news is that addictions are treatable. Addiction is a chronic disease; there is no cure, but with proper treatment, support, counseling, advocacy, and follow-up, good outcomes are achievable.

Physician health programs have an excellent track record in the management of all types of addiction. These programs are present in most hospital staff organizations or are part of the state medical or dental association structures. They are manned by volunteers, are confidential, and practice both accountability and advocacy for the individual medical professional. Such programs are based on the three principles of support, advocacy, and consequences. The programs include frequent random urinary drug screens, 12-step programs, acute management of relapses, continued care for at least 5 years, a focus on lifelong recovery, and the management of coexisting psychiatric disease.[10] The success rate of these programs range from 70% to 90%; almost 80% of the physicians who have gone through a physician health program remain in recovery and still practice medicine.[11]

Impairment

An individual can become impaired through alcohol or substance abuse, sexual addictions, depression, physical or mental illness, or aging. Many of these issues are preventable or treatable (such as some forms of depression), but some are not (such as aging). It is therefore critical for hospitals and health care organizations to have strategies in place that can identify, confront, and treat medical professionals when they become impaired.

The signs of impairment are just as varied as the reasons for impairment and have to be taken in context. What that means is that some behaviors may not necessarily indicate addiction, but taken in the context of an individual's performance, they raise a red flag. A combination of the following behaviors might indicate an impairment:

- Mood swings
- Sudden personality or behavior changes
- Deficient personal hygiene or appearance
- Multiple physical complaints
- Unexplained tremulousness or sweating
- Watery eyes or runny nose
- Thick or slurred speech
- Missed appointments and unexplained absences

Practice patterns that might indicate impairment could include the following:

- Writing inappropriate orders
- Sloppy handwriting or charting
- Clinical misadventures that are unexplained
- Unavailability at night or during the day
- Behavioral problems with the staff and practice partners

If these signs or symptoms arise, then some investigation is in order. A spouse, good friend, another colleague, a golfing buddy, or another person close to the individual in question can help confirm a suspected problem. If there is a strong possibility that the individual has an addiction, then an intervention is in order. An intervention can be arranged by the physician health committee or a state medical or dental association.

Short-Term Illness

Most of us, at some point in our careers, will have to take a medical leave of absence. Most are short term. The number one goal of every medical professional should be patient safety ("First do no harm"). We all think we are bullet-proof and can work no matter what comes our way, but of course, that is foolhardy. Take a short-term illness or disability in stride, follow your physician's advice, and don't return to providing patient care too quickly.

Most hospital medical staffs will require a "return to work" authorization by your physician if you are away from your practice for longer than 45 days. If your leave is longer than that, the medical staff may require a test for current competence. Don't be insulted; remember that the hospital's primary purpose is to ensure patient safety. Your cases may be monitored, proctored, or reviewed. Depending on your illness or disability, you may want to start slowly. In other words, do not schedule a 4-hour double jaw surgery your first day back. Use your partners and empower them to help you by giving them permission to question your judgment or skill if they think you are not acting or performing in the best interests of patient safety.

Progressive Disease or Illness

Progressive disease or illness may include multiple sclerosis, heart disease, cancer, or any other significant diagnosis. Work as long as you are able, but recognize your limitations. Again, employ your partners to help you and empower your physicians and your partners to tell you when it is time to hang up the spurs. Your surgical privileges may need to be limited or altered as the disease progresses, but finish as a professional with patient welfare as your primary goal. All of us want to finish our careers on a high note, not with a train wreck.

Aging Impairments

If we are fortunate enough to practice over many decades, old age will eventually affect all of us. The effects may be cognitive and/or physical, but in either case, it is critical to recognize this eventuality. Make plans for the transition. (This transition is discussed in more detail in Chapter 11.)

In the *Annals of Internal Medicine,* Choudry and co-workers reviewed all existing literature concerning clinical experience and age and concluded that the majority of studies showed an inverse relationship between performance and years in practice.[12] The deficits were attributed to memory loss, deterioration of cognitive skills, decrease in reaction time, hearing or visual impairments, and a decrease in concentration during highly stressful situations.

Further, Waljee and colleagues reported in the *Annals of Surgery* that surgeons over 60 years of age had higher mortality rates, particularly in complex surgeries, than their younger counterparts.[13] Interestingly, the lower the surgical case volume, the higher the mortality rate. Wilson and co-workers reported in 1999 that "cognitive impairment in physicians is responsible for 63% of all cases of medical adverse events and that most were preventable."[14]

Dementia and Alzheimer's disease are two major risk factors for aging physicians. Betsy Williams, a neuropsychologist who has written extensively on dyscompetence in physicians, states that "age related dementias have been shown to affect not only memory, but executive function, the same capacity required for complex medical reasoning."[15] She adds, "There is currently no mechanism other than peer review and wellness committees to cause a physician with possible dementia to undergo assessment for mental and clinical decline" (Box 12-1).

• BOX 12-1 Executive Function

Executive function is the ability to plan and make decisions, troubleshoot and correct errors, succeed in situations that are not well learned or contain novel sequences or actions, successfully handle dangerous or technically difficult decisions, and overcome strong habitual responses in certain circumstances.

The prevalence of Alzheimer's disease is 0.6% for ages 65 to 69, 1.0% for ages 70 to 74, 2.0% for ages 75 to 79, 3.3% for ages 80 to 84, and 8.4% for ages over 85. Alzheimer's disease is usually diagnosed by MRI, PET scans, spinal markers, and neuropsychological testing.

Neuropsychological tests are a battery of tests performed by a neuropsychologist that assess cognitive abilities, as well as visual and spatial relations, and, to some degree, hand-eye coordination. The tests generally take 4 to 6 hours to administer and have been standardized and validated over many years. One of the batteries frequently used is the Halstead-Reitland Battery, but the neuropsychologist may use other individual tests, as well as groups of tests, depending on the suspected impairment. Neuropsychological tests typically measure progression of a stroke, special disability, and other areas of cognitive function, but they are probably most valuable in determining cognitive decline and whether it is progressive. Most neuropsychologists adjust for IQ and education, and many adjust for the age of the patient.

Many physicians and surgeons practice safely into their later years because of what is referred to as "crystallized intelligence," which is a component of long-term memory. A surgeon's crystallized intelligence compensates for his or her loss of "fluid intelligence," a component of short-term memory, but it does not compensate indefinitely.

Neuropsychological tests can determine if the surgeon has memory loss due to aging, mild cognitive impairment, or the loss of executive function. Memory loss due to aging or mild cognitive impairment is not reason to retire, but if a medical professional loses executive function, there is reason for concern. Given the definition of executive function, losing it equals losing the ability to practice safely.

The bottom line is that every practitioner and every practice must have a policy in effect that addresses possible impairment and provides a means to deal with it in a fair, compassionate, and safe manner. Regardless of age, if a medical professional exhibits signs of dementia or clinical or behavioral aberrations that are difficult to explain, has a significant head injury, has evidence of substance or alcohol abuse, or has a diagnosis of Parkinson's disease or other neurologic disease, then the individual should be evaluated using appropriate physical and mental status examinations. Many times, a practice can be altered to remain safe with the help of partners and employees, but this is a difficult situation at best. Remember—the patient is more important than the surgeon.

Conclusion

In an ideal world, no one would need to deal with these issues and impairments, but the odds are that you or a practice partner will encounter some of these "potholes." The key is to be objective and fair and have a policy in place that addresses all types of addiction and impairment before problems arise. Most of these issues are solvable and will not end a career, but if not confronted early and completely, they could end in disaster for everyone involved. We have been given an enormous privilege and responsibility by society. It is incumbent on us to not violate that trust.

13 Preoperative Evaluation

BRIAN KINARD, SHELLY ABRAMOWICZ

Introduction

Preoperative evaluation and risk stratification guides perioperative management, venue of surgical intervention, and anesthetic for each patient. This evaluation consists of a complete history and physical, possible laboratory tests, imaging, specialist consultations, and/or diagnostic/therapeutic interventions. Only preoperative testing indicated by information gained during the history and physical should be obtained.[1] A thorough review of this information allows the surgeon to stratify a patient's risk during the operation and to provide a personalized surgical plan.

The goals of this chapter are to provide a framework in a systems based approach for the preoperative evaluation of the oral and maxillofacial surgery (OMS) patient.

History and Physical Examination

A complete history and physical examination is the practitioner's opportunity to identify abnormalities that require further evaluation or planning before an elective operation. The history consists of medical, surgical, and anesthetic history. A patient's medications should be reviewed. Screening for exposure to antiresorptive and antiangiogenic medications that predispose to medication-related osteonecrosis of the jaws (MRONJ) should be part of the medication review process.[2] Certain medications are indicated for perioperative adjustment or discontinuation; however, most medications should be continued[3] (Table 13-1). Allergies and adverse reactions to medications or medical supplies (latex, tape, etc.) and specific allergic reactions should be recorded.

Surgical and anesthetic history should be reviewed. Previous complications, airway difficulties, and effective pain control should be recorded. Patients should be screened for previous anesthetic exposure, as well as a family history of anesthetic exposure to screen for malignant hyperthermia or pseudocholinesterase abnormalities.[3] A social history should be reviewed, including previous or current tobacco, alcohol, or illegal drug abuse with screening for pertinent sequelae. Women should be considered for pregnancy testing if of child-bearing age.[4]

The review of systems is a series of questions organized by body system that provides details regarding the severity of known medical conditions and potential undiagnosed new medical conditions. Positive responses should be further explored and, if not consistent with known medical comorbidities, may require further workup. Information gained from the history and review of systems can be further detailed by asking pertinent follow-up questions. For example, if a patient reports a history of shortness of breath, the practitioner should then ask additional questions to gain insight to their level of pulmonary dysfunction (for example, functional capacity, exacerbating or alleviating factors, or need for supplemental oxygen).

The physical exam should be organized, thorough and tailored for each patient. The physical exam includes vital signs, examination of head and neck, airway, cardiac, pulmonary, and gastrointestinal, with expansion to other systems if relevant from history. Information gained from the history and physical should be used to generate a perioperative, surgical, and anesthetic plan for the patient. Accordingly, the surgeon determines if further preoperative testing or consultations are indicated. The most-used risk stratification system is the American Society of Anesthesiologists (ASA) physical status classification system (Box 13-1).

Conducting the Preoperative Evaluation

Cardiovascular

Cardiovascular complications contribute significantly to perioperative morbidity and mortality. The risk of a major cardiac complication (cardiac death, nonfatal myocardial infarction, nonfatal cardiac arrest, and cardiogenic pulmonary edema) in a non-selected population is reported as 0.8% to 1.5%.[5] Many prediction models exist to assess and stratify perioperative risk of a cardiac complication for noncardiac surgery. The revised Goldman cardiac risk index

TABLE 13-1 Medications, Anesthetic Implications, and Recommendations for Preoperative Management

Medications	Anesthetic Implications	Recommended Management
Aminoglycosides	Can potentiate nondepolarizing relaxants	Monitor neuromuscular relaxants carefully
Aspirin	Platelet dysfunction, bleeding potential	Consider preoperative discontinuation for at least 10-14 days; discuss with prescribing physician regarding risk of stroke, myocardial infarction (MI), or thrombosis with discontinuation
Clonidine	Acute withdrawal can cause hypertensive crisis; decrease anesthetic requirements	Continue therapy the day of surgery; can use dermal delivery perioperatively; decrease anesthetic requirements intraoperatively
Lithium	Potentiate neuromuscular blockers, induce hypothyroidism in some patients; lithium concentrations increase with decreased serum sodium	Monitor neuromuscular blockade carefully, obtain thyroid function tests preoperatively if indicated; monitor serum sodium and avoid sodium-wasting diuretics
Monoamine oxidase inhibitors (isocarboxazid, pargyline, phenelzine, tranylcypromine)	Increased catecholamine stores; hepatotoxicity; rare but potentially fatal reactions with opioids, especially meperidine	Avoid indirect-acting sympathomimetics and use reduced doses of direct-acting agents; serum liver function tests if not done; avoid opioids, especially meperidine; for elective surgery, request psychiatrist to discontinue for 14-21 days unless suicide risk; less time needed for pargyline and tranylcypromine because reversibly bound
Warfarin	Excessive intraoperative bleeding	Manage with prescribing physician; withdrawal in advance; substitute with heparin; heparin may be stopped immediately preoperatively and restarted postoperatively

From Longnecker DE, Murphy FL: *Dripps/Eckenhoff/Vandam: Introduction to anesthesia*, vol 1, ed 9, Philadelphia, 1997, WB Saunders, p 13.

• BOX 13-1 ASA Physical Status Classification

I. Healthy patient
II. Mild systemic disease—no functional limitation
III. Severe systemic disease—definite functional limitation
IV. Severe systemic disease that is a constant threat to life
V. Moribund patient not expected to survive without the operation

(RCRI) was published in 1999 and has been externally validated by multiple studies.[5] The RCRI model allows for identification of patients at increased risk for a major cardiac complication. Six independent risk factors for cardiac complications were identified (Table 13-2). Patients undergoing head and neck surgery with no risk factors are estimated to have a 0.5% risk of a major cardiac complication, whereas those with three or more risk factors are estimated to have an 11% risk.[5]

The American College of Cardiology and the American Heart Association (ACC/AHA) guidelines, last updated in 2014, are another resource for risk assessment and cardiac evaluation for patients undergoing non-cardiac surgery. The ACC/AHA guidelines use the patients' functional capacity and planned surgery to estimate risk and provide perioperative recommendations (Figure 13-1).[6] The ACC/AHA guidelines measure functional capacity in total metabolic equivalents (METs). One MET is defined as 3.5 mL O_2 uptake/kg per min, which is the resting oxygen uptake in a sitting position. Perioperative cardiac and long-term risks are increased in patients unable to meet a 4-MET demand during most normal daily activities (Table 13-3).[6]

Coronary revascularization and other preoperative interventions are not indicated for the sole purpose of reducing perioperative risk. If they are indicated on their own merit, they should be performed prior to elective surgery. Following percutaneous intervention, it is recommended that an elective operation be delayed 7 days after balloon angioplasty, 30 days after bare metal stent, and 365 days after drug-eluting stent. Any decision to modify antiplatelet therapy should include all treating physicians as well as the patient.[6]

The optimal timing for an elective operation after a myocardial infarction (MI) is greater than 60 days. Morbidity and mortality decrease linearly after an MI, with the largest decrease in risk occurring in the first 60 days.[6] Age greater than 65 years and previous cerebrovascular incident are both independent risk factors for major adverse cardiac event in the perioperative setting.[6] Patients with heart failure undergoing a major non-cardiac operation have an increased risk of perioperative major cardiac event. The risk of perioperative mortality was shown to increase if left ventricular ejection fraction (LVEF) is less than 40% and the risk of death was further elevated for patients with LVEF <29%.[6]

TABLE 13-2 Revised Cardiac Risk Index

Risk Factor	Points
Cerebrovascular disease	1
Congestive heart failure	1
Creatinine level > 2.0 mg per dL (176.80 μmol per L)	1
Diabetes mellitus requiring insulin	1
Ischemic cardiac disease	1
Suprainguinal vascular surgery, intrathoracic surgery, or intro-abdominal surgery	1

Risk of Major Cardiac Event	
Points	**Risk % (95% confidence interval)**
0	0.4 (0.05 to 1.5)
1	0.9 (0.3 to 2.1)
2	6.6 (3.9 to 10.3)
≥3	≥11 (5.8 to 18.4)

TABLE 13-3 Total Metabolic Equivalents

Less Than 4 METs	Greater Than 4 METs
• Walk a block or two on level ground • Light to moderate work around the house like dusting, washing dishes, carrying groceries • Golfing with a cart • Walking at approximately 2 mph to 3 mph	• Climbing a flight of stairs • Walking up a hill • Walking on level ground at 4 mph • Performing heavy work around the house like scrubbing floors or lifting or moving heavy furniture

From Fleisher LA, Fleischmann KE, Auerbach AD, et al: 2014 ACC/AHA guideline on perioperative cardiovascular evaluation and management of patients undergoing noncardiac surgery: a report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines, *J Am Coll Cardiol* 64(22):e77-137, 2014.

Previously, the addition of a beta-blocker was recommended in the perioperative period to reduce cardiac morbidity and mortality. However, a recent ACC/AHA systematic review found that the risks may outweigh the benefits.[7] The systematic review reports beta-blockade started 1 day or less before non-cardiac surgery decreases the risk of nonfatal myocardial infarctions; however, it increases risks of stroke, death, hypotension, and bradycardia. Patients who chronically take beta-blockers should maintain use of beta-blockers through the perioperative period.[7] The AHA recommendations for antibiotic prophylaxis to reduce the risk of infective endocarditis were last published in 2007 (Tables 13-4, 13-5, and 13-6).[8]

Pulmonary

Postoperative pulmonary complications are as prevalent as cardiac complications and contribute to similar morbidity and mortality. The incidence of postoperative pulmonary complications is reported as 5% for general surgical patients, but as high as 20% for high-risk patients and procedures.[9] The most morbid of these complications are atelectasis, pneumonia, respiratory failure, and exacerbation of underlying chronic disease.[10] A thorough history and physical may be able to detect the most prevalent pulmonary diseases.

The severity of pulmonary disease should be documented, including onset of symptoms, diagnosis, current therapy, and functional limitations. Common tests available to characterize pulmonary disease include oxygen saturation, chest radiography, arterial blood gas analysis, and pulmonary function tests.

Patient related risk factors for perioperative pulmonary complications include chronic obstructive pulmonary disease, age greater than 60 years, ASA score of 2 or greater, functional dependence, hypoalbuminemia, and/or congestive heart failure.[1] Procedure-related risk factors for perioperative pulmonary complications are prolonged surgery, head and neck surgery, emergency surgery, and the use of general anesthetics.[11]

TABLE 13-4 Cardiac Conditions Associated with the Highest Risk of Adverse Outcome from Endocarditis for Which Prophylaxis with Dental Procedures Is Recommended

Prosthetic cardiac value
Previous infective endocarditis (IE)
Congenital heart disease (CHD)*
- Unrepaired cyanotic CHD, including palliative shunts and conduits
- Completely repaired congenital heart defect with prosthetic material or device, whether placed by surgery or by catheter intervention, during the first 6 mo after the procedure†
- Repaired CHD with residual defects at the site or adjacent to the site of a prosthetic patch or prosthetic device (which inhibit endothelialization). Cardiac transplantation recipients who develop cardiac valvulopathy

*Except for the conditions listed above, antibiotic prophylaxis is no longer recommended for any other form of CHD.
†Prophylaxis is recommended because endothelialization of prosthetic material occurs within 6 mo after procedure.

TABLE 13-5 Dental Procedures for Which Endocarditis Prophylaxis Is Recommended for Patients in Table 13-4

All dental procedures that involve manipulation of gingival tissue or the periapical region of teeth or perforation of the oral mucosa*

*The following procedures and events do not need prophylaxis: routine anesthetic injections through noninfected tissue, taking dental radiographs, placement of removable prosthodontic or orthodontic appliances, adjustment of orthodontic appliances, placement of orthodontic brackets, shedding of deciduous teeth, and bleeding from trauma to the lips or oral mucosa.

From Wilson W, Taubert KA, Gewitz M, et al: Prevention of infective endocarditis: guidelines from the American Heart Association: a guideline from the American Heart Association Rheumatic Fever, Endocarditis, and Kawasaki Disease Committee, Council on Cardiovascular Disease in the Young, and the Council on Clinical Cardiology, Council on Cardiovascular Surgery and Anesthesia, and the Quality of Care and Outcomes Research Interdisciplinary Working Group, *Circulation* 116(15):1736-1754, 2007.

There is no high-quality evidence for the routine use of chest radiography as a screening tool, and chest radiography rarely alters perioperative management.[1] Chest radiography should be considered in patients who have history of smoking, recent upper respiratory infection, chronic obstructive pulmonary disease, or cardiac disease.[4]

Chronic Obstructive Pulmonary Disease

Chronic obstructive pulmonary disease (COPD) is characterized by airflow limitation that is usually progressive

TABLE 13-6 Regimens for a Dental Procedure

Situation	Agent	Adults	Children
Oral	Amoxicillin	2 g	50 mg/kg
Unable to take oral medication	Ampicillin *or* Cefazolin or ceftriaxone	2 g IM or IV 1 g IM or IV	50 mg/kg IM or IV 50 mg/kg IM or IV
Allergic to penicillins or ampicillin—oral	Cephalexin *or* Clindamycin *or* Azithromycin or clarithromycin	2 g 600 mg 500 mg	50 mg/kg 20 mg/kg 15 mg/kg
Allergic to penicillins or ampicillins and unable to take oral medication	Cefazolin or ceftriaxone *or* Clindamycin	1 g IM or IV 600 mg IM or IV	50 mg/kg IM or IV 20 mg/kg IM or IV

Regimen: single dose 30 to 60 min before procedure.

From Wilson W, Taubert KA, Gewitz M, et al: Prevention of infective endocarditis: guidelines from the American Heart Association: a guideline from the American Heart Association Rheumatic Fever, Endocarditis, and Kawasaki Disease Committee, Council on Cardiovascular Disease in the Young, and the Council on Clinical Cardiology, Council on Cardiovascular Surgery and Anesthesia, and the Quality of Care and Outcomes Research Interdisciplinary Working Group, *Circulation* 116(15):1736-1754, 2007.

and associated with an enhanced chronic inflammatory response in the airways and lung to noxious particles or gases.[12] The relative risk of pulmonary complication in this disease group ranges from 1.8% to as high as 18%.[9,10] The relative risk of complications correlates with disease severity. Elective procedures should be delayed for patients with acute exacerbations. Bronchodilator therapy should be used throughout the perioperative period, and medications that may induce bronchospasm should be avoided.[9]

Smoking

Tobacco smoking is an independent risk factor for perioperative pulmonary complications.[13] For non-cardiac surgery, smoking increases the risk of postoperative pulmonary complications up to fourfold.[9] Smoking impairs ciliary clearance and thickens mucus, increasing the risk for re-intubation, pneumonia, aspiration, bronchospasm, and hypoxemia.[9] Smoking cessation results in a transient increase in sputum production, and the relative risk of perioperative pulmonary complications increases for 8 weeks after smoking cessation and then decreases to below that of a smoker.[11] Early smoking cessation for elective procedures should be emphasized, and smoking cessation resources should be used.

Asthma

Asthma can be classified by symptoms, treatment, and pulmonary function tests (PFTs) (Table 13-7). Patients with well-controlled symptoms and normal PFTs are not at an increased risk for postoperative pulmonary complications. Patients with pulmonary symptoms and abnormal PFTs have been shown to be at an increased risk.[9,14] Preoperative review should include current medications, stimuli, and severity and frequency of exacerbations. A patient with well-controlled asthma should continue to use routine inhalers. Patients with poorly controlled asthma require aggressive treatment before an elective operation.

Renal

Acute Kidney Injury

Acute kidney injury (AKI) is diagnosed and classified through a change in serum creatinine concentration, a change in urine output, or both (Table 13-8).[15] The perioperative incidence of AKI is reported to between 0.8% and 10%.[16] The majority of AKI in the perioperative period is associated with relative hypoperfusion of the kidneys and/or exposure of the kidneys to nephrotoxins such as intravenous contrast, angiotensin-converting enzyme inhibitors, and antibiotics (i.e., aminoglycosides and fluoroquinolones).[15] A recent multivariate analysis identified four independent risk factors for perioperative AKI: age, diabetes, increased revised cardiac risk index, and increased ASA physical status.[16] Patients with AKI had more cardiovascular complications and up to 3 times higher in-hospital mortality rate.[16,17]

Chronic Kidney Disease

Approximately 1 of every 10 adults in the United States has chronic kidney disease (CKD) with the greatest prevalence in patients greater than 65 years of age.[18] In the United States, diabetes mellitus, hypertension, and glomerulonephritis are responsible for approximately 75% of all CKD.[18] CKD is defined as glomerular filtration rate (GFR) <60 mL/min/1.73 m^2 or evidence of kidney damage (proteinuria, glomerular hematuria, abnormal imaging, or abnormal renal biopsy) for 3 months and is staged by GFR (Table 13-9).[19]

CKD is an independent risk factor for postoperative death and cardiovascular events.[19] Surgical optimization and management of CKD sequelae (Table 13-10) through

TABLE 13-7 Classifying Asthma Severity and Initiating Treatment for Patients 12 Years and Older

Classification of Asthma Severity ≥ 12 Years of Age*				
Components of Severity	**Intermittent**	**Persistent-Mild**	**Persistent-Moderate**	**Persistent-Severe**
Impairment				
Symptoms	≤2 days per week	>2 days per week, but not daily	Daily	Throughout the day
Nighttime awakenings	≤2 times per month	3 to 4 times per month	>Once per week, but not nightly	Often 7 times per week
Short-acting beta agonist use for symptom control (not for prevention of exercise-induced bronchospasm)	≤2 days per week	>2 days per week, but not more than once per day	Daily	Several times per day
Interference with normal activity	None	Minor limitation	Some limitation	Extremely limited
Lung function	Normal FEV, between exacerbations; FEV, >80% of predicted; FEV/FVC normal	FEV, ≥80% of predicted; FEV/FVC normal	FEV, >60% but <80% of predicted; FEV/FVC reduced 5%	FEV, <60% of predicted; FEV,/FVC reduced >%
Risk				
Exacerbations requiring oral systemic corticosteroids	0 to 1 per year†	≥2 per year†	≥2 per year†	≥2 per year†
	Consider severity and interval since last exacerbation; frequency and severity may fluctuate over time for patients in any severity category; relative annual risk of exacerbations may be related to FEV			

FEV, forced expiratory volume in one second; FVC, forced vital capacity.
Note: Normal FEV,/FVC by age is 85% for 8 to 19 years; 80% for 20 to 39 years; 75% for 40-59 years; and 70% for 60 to 80 years.
*Level of severity is determined by assessment of impairment and risk; assess impairment domain by patient's or caregivers recall of previous two or four weeks and spirometry; assign severity to the most severe category in which any feature occurs.
†At present, there are inadequate data to correspond frequencies of exacerbations with different levels of asthma severity. In general, more frequent and intense exacerbations (e.g., requiring urgent, unscheduled care; hospitalization; admission to intensive care) indicate greater underlying disease severity. For treatment purposes, patients who had two or more exacerbations requiring oral systemic corticosteroids in the past year be considered the same as patients who have persistent asthma, even in the absence of impairment levels consistent with persistent asthma.

Adapted from National Heart, Lung, and Blood Institute, National Asthma Education and Prevention Program: Expert Panel Report 3: guidelines for the diagnosis and management of asthma. *Summary Report* 2007:344. http://www.nhlbi.nih.gov/guidelines/asthma/asthgdln.htm. Accessed January 8, 2009.

TABLE 13-8 Rifle Criteria for Acute Kidney Injury

Stage	Glomerular Filtration Rate (GFR) Criteria	Urine Output Criteria
Risk	Increased serum creatinine ×1.5 or GFR decrease >25%	Urine output <0.5 mL/kg/h ×6 hours
Injury	Increased serum creatinine ×2 or GFR decrease >50%	Urine output <0.5 mL/kg/h ×12 hours
Failure	Increased serum creatinine ×3 of GFR decrease >75% or serum creatinine ≥4 mg/dL* (acute rise ≥0.5 mg/dL†)	Urine output <0.3 mL/kg/h ×24 hours or anuria ×12 hours
Loss	Persistent acute kidney injury = complete loss of kidney function >weeks (i.e., dialysis dependence for 4 weeks)	
End stage kidney disease	End stage kidney disease (i.e., dialysis dependence for >3 months)	

*≥353.6 μmol/L.
†≥44.2 μmol/L.
Source: Borthwick E, Ferguson A: Perioperative acute kidney injury: risk factors, recognition, management, and outcomes, *BMJ* 341:c3365, 2010.

TABLE 13-9 Chronic Kidney Disease Stages

Stage	Description	Glomerular Filtration Rate (eGFR) (mL/min/1.73m^2)*
1	Chronic kidney disease with normal glomerular rate but other kidney damage (e.g., hematuria and proteinuria)	≥90
2	Mild chronic kidney disease and other kidney damage	60 to 89
3a	Mild to moderate chronic kidney disease	45 to 59
3b	Moderate to severe chronic kidney disease	30 to 44
4	Severe chronic kidney disease	15 to 29
5	Established end stage renal disease	<15 or on dialysis

*eGFR is an estimate of kidney function, based on serum creatinine but taking into account age, race, and sex. In the UK, whenever a creatinine test is requested, laboratories will report a corresponding eGFR and the eGFR can be thought of as an approximate percentage of normal kidney function that the individual has. For some individuals, a preoperative assessment might be the first time they have had a creatinine check and therefore may be the first opportunity for chronic kidney disease to be diagnosed.

Source Borthwick E, Ferguson A: Perioperative acute kidney injury: risk factors, recognition, management, and outcomes, *BMJ* 341:c3365, 2010.

TABLE 13-10 Physiologic Disorders of Renal Failure That Affect Preoperative Management

Disorder	Consequence
Cardiovascular	
Increased renin secretion	Hypertension
Increased cardiac output, as a result of anemia	High-output failure
Left ventricular hypertrophy	Myocardial Infarction
AV shunt for dialysis	High-output renal failure
Volume overload or deficiencies following dialysis	CHF or hypovolemic hypotension
Associated diabetes > accelerated atherosclerosis	Myocardial infarction, stroke
Renal	
Failure to excrete potassium	Progressive hyperkalemia 7 mEq/L: Tall peaked T waves 8 mEq/L: Prolonged RR interval, QRS widening 9 mEq/L: P wave disappears, QRS widens further
Failure to excrete fixed acid	Progressive acidemia
Water excretion: Failure to excrete water (oliguria or anuria) Failure to concentrate urine	Volume overload, pulmonary edema Fasting dehydration, hypotension, salt wasting
Pulmonary	
Pulmonary calcification	Decreased diffusing capacity
Diaphragmatic elevation with peritoneal dialysis	Decreased functional residual capacity, restriction
Nervous System	
Uremic toxemia	Mental slowing, fatigue, seizures, myoclonus, coma
Sensory peripheral neuropathy	Lower extremity numbness
Dysautonomia	Orthostatic hypotension, gastroparesis
Gastrointestinal	
Increased volume and acidity of gastric contents	Increased risk of aspiration pneumonia
Ulcers	Gastrointestinal bleeding
Anorexia, nausea, vomiting	
Hematologic	
Erythropoietin secretion decreased	Anemia
Decreased red cell life span	Anemia
Dialyzable toxins impair platelet aggregation	Platelet dysfunction

TABLE 13-10 Physiologic Disorders of Renal Failure That Affect Preoperative Management—cont'd

Disorder	Consequence
Immune System	
Uremia impairs leukocyte chemotaxis Steroid treatment Loss of immunoglobulin	Infection, sepsis
Pharmacokinetics	
Diminished excretion of water-soluble drugs and metabolites	Accumulation of active metabolites of morphine, Demerol, benzodiazepines
Hypoalbuminemia	Increased free fraction of drugs bound to albumin
Acidosis	Drugs with acid pK_a are less ionized, have greater volumes of distribution and longer half-lives
Impaired function of blood-brain barrier	Accentuated effects of drugs with central nervous system effects

From Longnecker DE, Murphy FL: *Dripps/Eckenhoff/Vandam: Introduction to anesthesia*, vol 1, ed 9, Philadelphia, 1997, Saunders, p 316.

medications, treatments (Table 13-11), and consults should be considered. Nephrotoxic drugs such as nonsteroidal anti-inflammatory drugs (NSAIDs), morphine, and aminoglycoside antibiotics should be used with caution or avoided in patients with CKD.

Gastrointestinal

Gastrointestinal and hepatic disease can predispose to many generalized complications such as: poor wound healing, excessive bleeding (thrombocytopenia, decreased production of procoagulant proteins), cardiovascular demise secondary to decreased peripheral vascular resistance, fluid and electrolyte imbalance, severe anemia, and medication toxicity.[15] Identification of certain signs and symptoms during a thorough history and physical examination may raise concern for diagnosed or suspected gastrointestinal (GI) disease. Some of many possible signs and symptoms concerning for GI disease are dyspepsia, abdominal pain, nausea, vomiting, diarrhea, hematochezia, steatorrhea, pruritus, fatigue, and melena. Potential signs or risk factors of hepatic disease, such as history of hepatotoxic treatment, jaundice, history of blood transfusion, hepatomegaly, splenomegaly, ascites, asterixis, encephalopathy, icterus, spider angioma, and delirium, should raise suspicion and be further explored.

Gastroesophageal Reflux Disease

Gastroesophageal reflux disease (GERD) is a common disease process affecting up to one third of the U.S. population at least once a month.[20] GERD is characterized by decreased lower esophageal sphincter tone resulting in reflux of gastric contents into the esophagus. Symptoms of GERD include retrosternal chest pain that occurs after meals and while lying flat. It is possible for gastric contents to reach the larynx, resulting in cough, hoarseness, sensation of food on the back of the tongue, or burning mouth syndrome. Mild

TABLE 13-11 Preoperative Management of Renal Failure

Considerations	Management
Anemia	
Hgb ≥8 g/dL chronic	No treatment
Hgb <8 g/dL (physiologic changes)	Further evaluation and possible transfusion
Coagulopathy	
Uremic platelet dysfunction	Dialysis 24 hr before and possibly 24 hr postoperatively Desmopressin or cryoprecipitate can be considered
Hyperkalemia	
>5.5-6.0 mEq/L	Dialysis Gastrointestinal reduction (Kayexalate) Intracellular shift (insulin/glucose) Cardiac membrane stability (bicarbonate)
Infection	
Malnutrition Functional abnormality of neutrophils, monocytes, and macrophages	Antibiotic prophylaxis Aseptic technique
Symptomatic hypocalcemia	Replace calcium
Hyperphosphatemia	Phosphate binding antacids
Anesthetic and medication clearance	Adjust doses based on renal creatinine clearance
Hypervolemia or hypovolemia	Dialysis, consider invasive monitoring if congestive heart failure
Avoid nephrotic agents	Nonsteroidal anti-inflammatory, aminoglycosides, contrast dye, chemotherapeutic agents

GERD can be managed by diet and behavior modification as well as over-the-counter antacids. Chronic GERD is managed with proton pump inhibitors and H_2 blockers. These medications should be continued preoperatively as rebound can occur. Patients with well-controlled GERD who continue their medications are managed similarly to healthy patients, although anesthetic induction may be modified. An elective operation should be delayed in patients with poorly controlled GERD until their disease is better managed. If an emergent procedure is indicated, H_2 blockers, rapid sequence induction, and nasogastric suctioning may reduce risk of aspiration.

Peptic Ulcer Disease

Peptic ulcer disease (PUD) is an ulceration in the lining of the stomach or first part of the duodenum. PUD often presents with periodic exacerbation and remission, a result of an imbalance between the digestive (acids, pepsin) and protective factors.[21] Long-term use of NSAIDs or infection with *Helicobacter pylori* predisposes patients to developing PUD. Patients with PUD have variable symptoms ranging from painlessness to severe epigastric pain that can be alleviated or aggravated by eating.

Patients with symptoms of PUD are often treated empirically with medications such as proton pump inhibitors or H_2 blockers to allow healing. These patients should cease use of NSAIDs and be tested for and treated if *H. pylori* is present. A definitive diagnosis is obtained through upper gastrointestinal endoscopy, which allows for visualization and biopsy of the ulcer.

TABLE 13-12 Child-Pugh Scoring System

	Points		
	1	2	3
Encephalopathy	None	Stage I or II	Stage III or IV
Ascites	Absent	Slight (controlled with diuretics)	Moderate despite diuretic treatment
Bilirubin (mg/dL)	<2	2-3	>3
Albumin (g/L)	>3.5	2.8-3.5	<2.8
PT (prolonged seconds)	<4	4-6	>6
INR	<1.7	1.7-2.3	>2.3

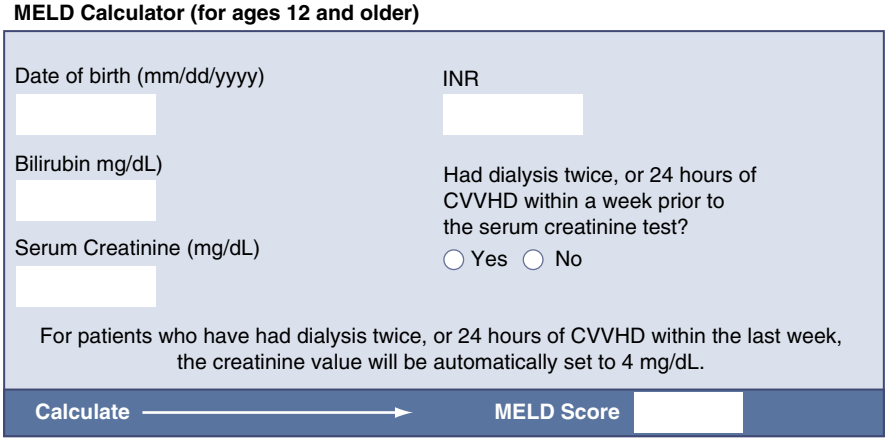
Class A = 5-6 points; Class B = 7-9 points; Class C = 10-15 points.
INR, International normalized ratio; PT, prothrombin time.
Child CG, Turcotte JG: Surgery and portal hypertension. In Child CG, editor: *The liver and portal hypertension,* Philadelphia, 1964, Saunders, pp 50-64.

Hepatic Disease

Patients with hepatic disease are at increased perioperative risk for morbidity and mortality.[22] This risk is a factor of the type and extent of hepatic disease, type of anesthesia, and the surgical procedure.

Screening for hepatic disease includes a review of risk factors for hepatic disease such as tattoos, history of intravenous drug use, chronic alcohol intake, blood transfusions, and family history of jaundice or hepatic disease. Signs and symptoms concerning for hepatic disease include spider angiomas, telangiectasia, gynecomastia, ascites, pruritus, fatigue, and testicular atrophy in males. Patients with liver disease should be assessed for the presence of jaundice, coagulopathy, electrolyte disturbances, renal dysfunction, thrombocytopenia, ascites, and encephalopathy. Some of these sequelae may require treatment prior to surgery, and all should be considered in perioperative management.

Surgical risk can be estimated through the Child-Turcotte-Pugh classification or the Model for End Stage Liver Disease (MELD) score. Historically, the Child-Pugh score (Table 13-12) was the standard for estimating perioperative risk. However, recently the MELD score (Figure 13-2) has been shown to be a more accurate predictor of perioperative risk.[23] For major surgery, patients with a



• **Figure 13-2** MELD Score. (From http://optn.transplant.hrsa.gov.)

Child-Pugh score less than 8 were found to have risk equal to patients without cirrhosis.[24] It is recommended that patients with a MELD score less than 10 be able to undergo elective surgery, patients with a MELD score of 10 to 15 undergo elective surgery with caution and surgical optimization, and those with a MELD score greater than 15 not be considered for elective surgery.[23]

Endocrine

Diabetes Mellitus

Approximately 8.3% of the U.S. population is reported to have diabetes. An additional 35% of the U.S. population has an above normal HgA1c level.[25] The American Association of Endocrinologists define diabetes at a fasting blood glucose (BG) >126 mg/dL or HgA1c >5.7%.[26] Diabetes is classified as type 1 (insulin dependent) or type 2 (non-insulin dependent). Type 1 diabetes is an autoimmune process that leads to destruction of pancreatic insulin-producing beta cells. Type 2 diabetes begins as an insulin resistant state with compensatory increase in insulin production by the beta cells. Severe type 2 diabetics can progress to a state where beta cells decompensate, requiring exogenous insulin. Infections, illnesses, and surgical procedures can alter carbohydrate metabolism and present a risk for the diabetic patient.

As many as 40% of non-cardiac surgical patients have a BG above 140 mg/dL and 25% above 180 mg/dL. Hyperglycemia in the perioperative period is associated with increased morbidity, mortality, and an increased use of health care resources.[27] Hyperglycemia causes dehydration and electrolyte disturbances, impairs immune function and vascular permeability, and increases pathogen growth. In the intensive care setting, relaxed perioperative BG goals of 140 to 180 mg/dL were found to have equally beneficial outcomes as intense management with BG of 80 to 110 mg/dL with 4 times less adverse events such as hypoglycemia.[27] Diabetes is the leading cause of kidney failure in the United States.[25] Diabetic patients are at an increased risk for cardiovascular disease, which is the major cause of perioperative mortality in the diabetic patient.[28] Presence of gastroparesis increases the risk of aspiration.

Chronic hyperglycemia has long-term sequelae such as microvascular complications (nephropathy, autonomic and peripheral neuropathy) and macrovascular complications (cardiovascular and peripheral vascular diseases).[29] These sequelae should be factored into the perioperative plan as they can alter management.

Most inpatients are transitioned from their home oral regimen and switched to an insulin-based regimen, which allows for more predictable and controllable BG. In 2011, the Society for Ambulatory Anesthesia released a consensus statement for perioperative management of antidiabetic oral medications and insulin (Table 13-13).[30] Operations for diabetic patients should be scheduled as early in the morning as possible. The surgeon, anesthesiologist, and internist or endocrinologist should collaborate to control the blood glucose levels throughout the perioperative period.

Thyroid

Thyroid hormone regulates multiple body systems. Thyroid hormone abnormalities are a result of an excess of thyroid hormone (hyperthyroidism) or a deficit of thyroid hormone (hypothyroidism) (Table 13-14).

TABLE 13-13 Instructions to Patient Regarding Preoperative Insulin and Noninsulin Injectable Administration

Insulin Regimen	Day Before Surgery	Day of Surgery	Comments
Insulin pump	No change	No change	Use "sick day" or "sleep" basal rates.
Long-acting, peakless insulins	No change	75-100% of morning dose	Reduce nighttime dose if history of nocturnal or morning hypoglycemia On the day of surgery, the morning dose of basal insulin may be administrated on arrival to the ambulatory surgery facility.
Intermediate-acting insulins	No change in the daytime dose 75% of dose if taken in the evening	50-75% of morning dose	See the comments for long-acting insulins
	No change		
Fixed combination insulins	No change	50-75% of morning dose of intermediate-acting component	Lispro-protamine only available in combination; therefore use NPH instead, on day of surgery. See the comments for long-acting insulin
Short and rapid-acting insulin	No change	Hold the dose	
Noninsulin injectables	No change	Hold the dose	

From Joshi GP, Chung F, Vann MA, et al: Society for Ambulatory Anesthesia consensus statement on perioperative blood glucose management in diabetic patients undergoing ambulatory surgery, *Anesth Analg* 111(6):1378-1387, 2010.

TABLE 13-14 Distinguishing Factors of Hyperthyroidism and Hypothyroidism

System	Hypothyroidism	Hyperthyroidism
General	Fatigue, cold intolerance, coarse/dry skin	Weight loss, heat intolerance, warm/moist skin, increased appetite, proptosis
Neurologic	Myxedema coma, cognitive impairment	Tremor, nervousness, hyperactive reflexes
Cardiovascular	Bradycardia, decreased cardiac output, decreased stroke volume, atrioventricular conduction defects, pericardial effusion, orthostatic hypotension, prolonged QRS, arrhythmia	Tachycardia, atrial fibrillation, congestive heart failure, increased stroke volume, widened pulse pressure, mitral valve prolapse insufficiency
Pulmonary	Decreased alveolar ventilation (blunt response to anoxia and hypercarbia), pleural effusion	Dyspnea, increased carbon dioxide production, decreased vital capacity, increased oxygen consumption
Renal	Decreased glomerular filtration rate, decreased plasma volume, decreased creatine clearance, peripheral edema, hyponatremia	Polyuria, hypomagnesemia, hypercalcemia and hypercalciuria
Gastrointestinal	Delayed gastric emptying, gastrointestinal bleeding, constipation	Hypermotility, diarrhea
Hematology	Anemia, platelet hyperaggregability, factor VIII and IX deficiency	
Musculoskeletal	Myopathies, increase of creatinine	Myopathies, protein wasting, bone resorption
Etiology	Idiopathic atrophy, Hashimoto thyroiditis, subtotal thyroidectomy	Graves disease, toxic multinodular goiter
Confirmatory laboratory tests	Decreased T_3 (triiodothyronine) Decreased T_3 resin uptake Increased thyroid-stimulating hormone (TSH) (unless cause from hypothalamic or pituitary dysfunction) Increased thyroxine-binding globulin (TBG)	Increased T_4 (levothyroxine) Increased T_3 resin uptake (RU) Increased T_3 RU/T_4 Decreased TSH Decreased TBG

Longnecker DE, Murphy FL: *Introduction to anesthesia,* vol 1, ed 9, Philadelphia, 1997, WB Saunders.

Hyperthyroidism

Hyperthyroidism is reported to involve 0.05% to 1.3% of the U.S. population, with the majority of individuals subclinical in presentation. Hyperthyroidism is commonly a result of Graves disease, multinodular goiter, or exogenous thyroid hormone.[29]

Hyperthyroidism is associated with fever, tremor, hyperdynamic cardiac functioning with hypertension, tachycardia, and increased cardiac output. Patients are at risk for arrhythmias such as sinus tachycardias and atrial fibrillation. A perioperative complication of hyperthyroidism is thyroid storm, which can be fatal in 10% to 75% of patients.[21,31] Thyroid storm has been associated with both the anesthetic and post-anesthetic period and can be incited by infection or surgical stress. Thyroid storm is a clinical diagnosis with nonspecific symptoms such as hyperpyrexia, tachycardia, and delirium. It is necessary to begin treatment empirically with beta-blockers, antipyretics, and thionamides.[31]

For an elective operation, a patient should be made euthyroid. This can be achieved with propylthiouracil, methimazole, or iodide treatment. Clinical response may take up to 8 weeks. In case of an emergent procedure, beta-blockers, such as propranolol, are the mainstay of treatment.[32]

Hypothyroidism

Hypothyroidism affects approximately 1% of the U.S. population, is more common in women, and most commonly a result of primary hypothyroidism or autoimmune hypothyroidism (Hashimoto thyroiditis). Hypothyroidism manifests as lethargy, fatigue, anorexia, depression, weight gain, and cold intolerance.[31] Studies do not provide clear evidence that patients with mild to moderate hypothyroidism are at a higher risk of anesthetic complication during an operation. However, physiologic changes that occur in hypothyroidism should be considered.[32] Hypothyroidism is associated with decreased cardiac output secondary to decreased stroke volume and heart rate, decreased ventilation response to hypercarbia and hypoxia, and impaired baroreceptor function. In severe cases, these patients can progress to myxedema coma.[29] These physiologic changes can alter sensitivity to medications and anesthetics. Consistent thyroid hormone replacement therapy, such as levothyroxine, can reverse these physiologic changes over time.

Adrenal Insufficiency

Patients undergoing surgery rely on adrenal glucocorticoid reserve to tolerate the physiologic stress response associated with the procedure. Cortisol, as the primary glucocorticoid in humans, plays the role of potentiating the effects of other hormones especially catecholamines. The hypothalamic-pituitary-adrenal (HPA) axis, which is regulated through a negative feedback loop, regulates the amount of cortisol secreted. Adrenal insufficiency (AI) is classified based on the site of dysfunction in the hypothalamic-pituitary-adrenal axis.

TABLE 13-15 Causes of Glucocorticoid Deficiency

- Withdrawal of glucocorticoid medications
- Idiopathic (presumably autoimmune)
- Tuberculosis
- AIDS
- Lymphoma
- Enzyme inhibitors
- Inborn errors of metabolism
- Fungal infections
- Metastatic cancer
- Pituitary disease
- Cytotoxic agents

Autoimmune adrenalitis (primary AI) and the withdrawal of chronic steroid use (secondary AI) are the most common reasons for glucocorticoid deficiency (Table 13-15).[21]

Patients who report recent corticosteroid use or have a review of systems positive for symptoms of AI should be considered for possible adrenal axis suppression or failure. Patients on chronic steroid therapy, such as transplant patients, are at low risk for AI. However, they may require stress-dose steroids should volume refractory hypotension occur.[33] Patients receiving physiologic corticosteroid replacement therapy are at increased risk, and patients who have taken >20 mg of prednisone (or equivalent) per day for more than 5 days are at risk, for axis suppression. Longer duration of 20 mg prednisone (or equivalent) therapy may suppress the HPA axis for 6 to 12 months.[31,33] Clinically, AI manifests as hypotension and decreased cardiac output despite fluid therapy and is treated with IV corticosteroids. [32] There are specific perioperative corticosteroid replacement recommendations for patients believed to have axis suppression or other forms of AI (Table 13-16).[34]

TABLE 13-16 Recommendations for Perioperative Glucocorticoid Supplements in Patients Believed to Have Adrenocorticoid Deficiency[34]

Level of Stress	Recommendation (Hydrocortisone Equivalent/Day)
Minor surgical stress (third molar extraction, genioplasty, etc.)	25 mg × 1 day
Moderate surgical stress (double jaw surgery, panfacial fractures, etc.)	50-75 mg × 2 days
Major surgical stress (large head and neck resection and reconstruction, etc.)	100-150 mg × 2-3 days

Hematology

Initial hematologic assessment relies on the history and physical examination. Bleeding diatheses may be detected through a history of easy bruising or excessive bleeding. Anemia may be detected through a history of dyspnea on exertion and pallor on physical exam. The severity of known or suspected hematologic abnormalities is obtained through laboratory tests including complete blood count (CBC), prothrombin time (PT), partial thromboplastin time (PTT), bleeding time, and fibrin split products.

Anemia

Anemia is defined as a hemoglobin concentration of less than 14 g/dL in males and 12.3 g/dL in females.[21] The history and physical exam may reveal symptoms such as malaise, dyspnea, palpitation, pallor, and cyanosis. If anemia is detected, an iron study and reticulocyte count may give insight into the etiology (Figure 13-3). Correctable causes of anemia, such as iron deficiency, may be addressed if time allows. Transfusion may be considered for time-sensitive procedures or the postoperative phase.

The American Association of Blood Banks recommends, with high quality of evidence, that transfusion should be considered at Hgb concentrations of 7 mg/dL or lower in hemodynamically stable patients and at concentrations of 8 mg/dL or lower in symptomatic patients (chest pain, orthostatic hypotension, or tachycardia unresponsive to fluid resuscitation) or congestive heart failure.[35]

Emergent operations with expected blood loss may require transfusions if the patient is likely to fall below the thresholds just given.

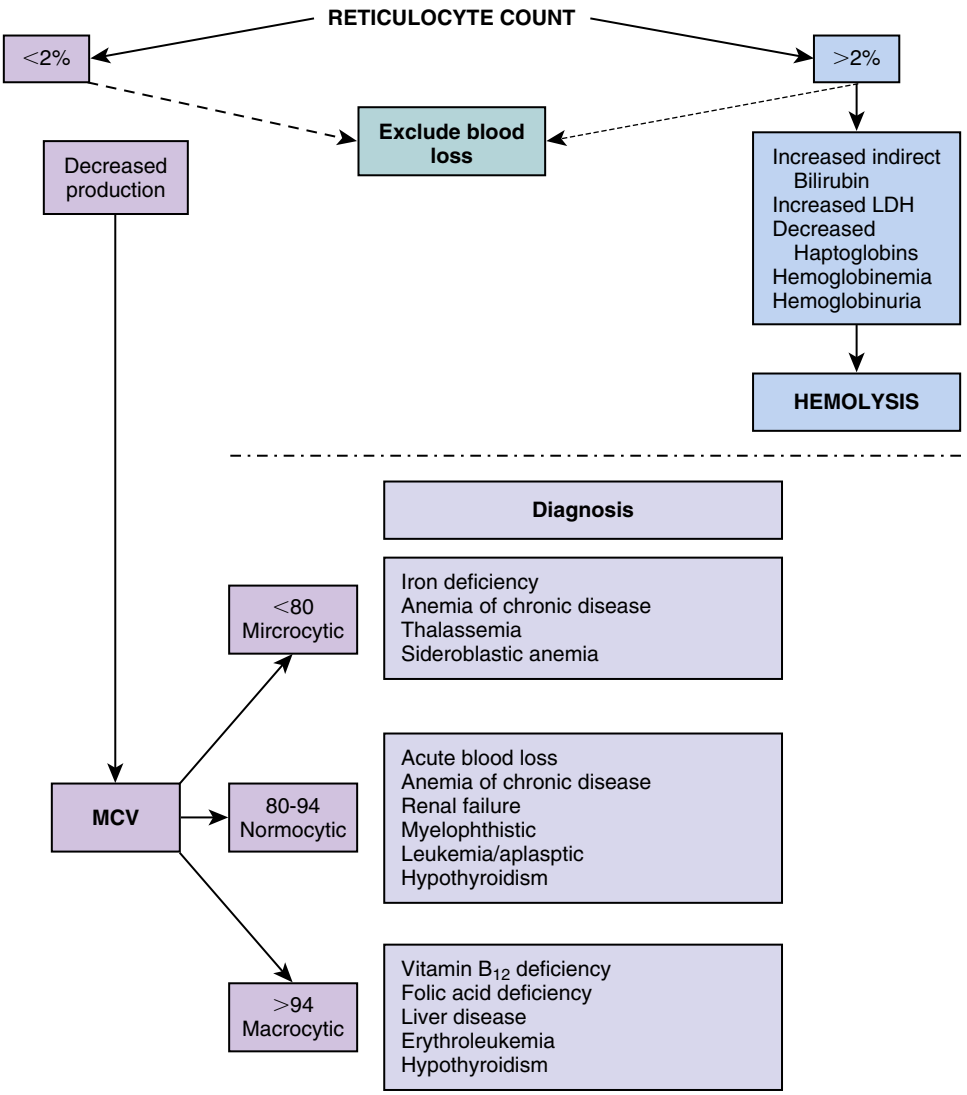
Sickle Cell Disease

Sickle cell anemia is the most common hemoglobinopathy. Approximately 1 of every 500 African Americans have sickle cell disease, and more than 2 million African Americans have the sickle cell trait. Hemoglobin S (HbS) occurs as a result of a genetic mutation substituting a valine for glutamic acid in the sixth position of the beta chain of the hemoglobin molecule.[21] Individuals who are heterozygous for HbS are described as having sickle cell trait and mostly have benign disease. Individuals who are homozygous for HbS manifest sickle cell disease.[36] The resulting alteration in the shape of the erythrocyte when the hemoglobin is deoxygenated can lead to anemia, chronic hemolysis, and vascular occlusion.[21] Multiple end-organ damage can result from these vaso-occlusive events.

History should include the time of last crisis, interval between crises, inciting events for crises, and need for previous blood transfusion. Perioperative management is focused on managing possible inciting events through oxygenation, adequate hydration, maintaining warm temperature, prophylactic antibiotics, maintaining patient comfort, and managing anxiety. A hematology consult is recommended to assess hemoglobin S and hemoglobin A levels to determine if transfusions or other treatments are indicated.

Bleeding Diatheses

A bleeding diathesis is a state in which an individual is predisposed to abnormal bleeding. The bleeding diathesis can be a result of numerous disease states. Commonly, it is a result of



• **Figure 13-3** Evaluation of anemia.

low or abnormal platelet function or abnormalities in the coagulation cascade. A history of easy bruising; excessive bleeding with previous surgery or trauma; history of hematuria, hematochezia, melena, or hemarthroses; and physical exam findings of petechiae, purpura, ecchymoses, and mucosal bleeding are suggestive of a bleeding diathesis and require further evaluation.

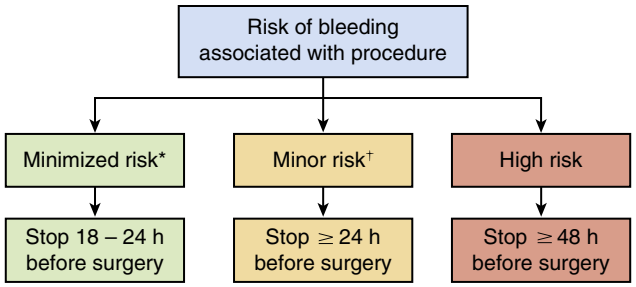
Thrombocytopenia

Thrombocytopenia is a quantitative platelet disorder, where there is increased platelet destruction, decreased platelet production, or abnormal distribution and/or increased sequestration. A common cause of thrombocytopenia is immunologic, where autoantibodies destroy existing platelets. This disorder could present with other autoimmune disorders (lupus or autoimmune hemolytic anemia), human immune deficiency virus, or chronic lymphocytic leukemia. This patient subset may be treated preoperatively with corticosteroids, immunoglobulin, or platelet transfusions.[21]

Other causes of decreased platelet levels include a decrease in production as a result of insufficient megakaryocytes[21] (Table 13-17) or an increase in splenic sequestration. In a normal state, up to one third of all the circulatory platelets are sequestered by the spleen. In patients with splenomegaly, up to 80% to 90% of the circulatory platelets may be sequestered by the spleen.[37]

TABLE 13-17 Etiology of Megakaryocyte Suppression[21]

Medications	Chloramphenicol, phenylbutazone, parenteral gold, alcohol, thiazide diuretics, sulfa drugs
Cytotoxic chemotherapy and radiation	
Infection	Hepatitis
Bone marrow infiltration	Leukemic or lymphomatous infiltrates, fibrosis, granulomas, metastatic cancer
Nutritional	Vitamin B_{12} or folate deficiency



• **Figure 13-4** Management of New Age Anticoagulants. (From Lai A, Davidson N, Galloway SW, Thachil J: Perioperative management of patients on new oral anticoagulants, *Br J Surg* 101(7):742-749, 2014.)

Platelet transfusion should be considered when platelet count is less than 50,000 /μL or higher if significant blood loss is expected. A single platelet concentrate usually yields an incremental rise in platelet levels of 10,000/μL/m^2.[21] A platelet count should be obtained approximately 1 hour after the appropriate transfusion amount is administered to confirm the platelet count.[21] In general, a patient with a platelet count of 60,000 to 100,000/μL or greater can tolerate most routine operations.

Coagulation Disorders

Hemophilia

The most commonly inherited clotting factor defect is hemophilia A (factor VIII deficiency). Hemophilia B (factor IX deficiency) is less frequent; however, it shares in the X-linked pattern of inheritance with hemophilia A.[37] Hemophilia A and B patients typically have an increased activated partial thromboplastin time (aPTT) and a normal PT. The severity of hemophilia A corresponds to the levels of factor VIII. Those with mild hemophilia A can at times be successfully treated with deamino-D-arginine vasopressin (DDAVP), which increases the level of circulating factor VIII. Those with more severe disease require supplementation with factor VIII.[35]

Von Willebrand Disease

Von Willebrand disease is the most commonly inherited abnormality affecting platelet function and is caused by a deficiency or dysfunction of von Willebrand factor (vWF).[35] Von Willebrand factor is the carrier protein for factor VIII and, when activated, binds platelets to exposed collagen. The most common type and mildest form of von Willebrand disease, type 1, is a partial quantitative deficit of vWF. Type 2 and 3 are less common, generally more severe where vWf is either deficient qualitatively or quantity, respectively.[21,35] Symptoms are typically recurrent mucosal bleeding (e.g., epistaxis, bruising, and GI bleeding). Prothrombin time may be elevated, as vWF carries factor VIII. Preoperative management of von Willebrand includes DDAVP or vWF/factor VIII concentrate.[35]

Anticoagulant and Antiplatelet Therapy

Preoperative management often includes the management of anticoagulant therapy (warfarin, heparin, factor Xa inhibitors, direct thrombin inhibitor) or antiplatelet therapy (clopidogrel, aspirin). A medication history should include the indication for anticoagulant or antiplatelet therapy, duration of therapy, and previous adverse events associated with medication changes. Anticoagulation therapy with warfarin can be measured with the international normalized ratio (INR), through an aPTT for heparin or factor Xa inhibitors or direct thrombin time for direct thrombin inhibitors. Antiplatelet therapy levels can be measured through a bleeding time study. Elective procedures should include discussion with the patient and prescribing physician to formulate a perioperative medication plan. Emergent procedures may require anticoagulant reversal or supportive care for factor Xa inhibitors and direct thrombin inhibitors, as no reversal agent currently exists (Figure 13-4).[38]

Neurology

Seizures

Approximately 1% of the U.S. population has been diagnosed with epilepsy, and a much larger number of individuals with a seizure history.[39] A history should include the inciting event, if provoked; type, duration, and frequency of seizure; and current antiepileptic medication.

Perioperative management includes minimal changes in antiepileptic drug therapy, minimizing physical and psychological stress, and avoidance of pro-convulsive medications. The risk of perioperative seizures is proportionately related to the baseline frequency of seizures. A history of seizures has not been shown to increase the risk of postoperative complications.[39]

Cerebrovascular Accident

Cerebrovascular accident (CVA), or stroke, is the fourth most common cause of death in the United States. Each year, approximately 800,000 U.S. citizens experience a stroke. Approximately 90% of CVAs are ischemic, and the remaining 10% are hemorrhagic.[40] Patients who have endured a CVA and present for preoperative evaluation should be evaluated for their current anticoagulant regimen and current deficits, as well as receiving a focused vascular exam that includes assessment of distal pulses and auscultation for bruits.

The risk of a major cardiovascular event, including a new ischemic stroke, acute myocardial infarction, or cardiovascular mortality is most increased in the first 9 months following an ischemic stroke. After 9 months, the risk plateaus at a stable yet still elevated level.[41]

Conclusions

Preoperative evaluation and risk stratification guides perioperative management, venue of surgical intervention, and anesthetic for each patient. This information allows the surgeon to stratify a patient's risk during the operation and to provide a personalized surgical plan.

Acknowledgment

Monitoring for the Oral and Maxillofacial Surgery Patient

STUART LIEBLICH, LUKE L'HEUREUX

Introduction

The available literature continues to demonstrate that appropriate use of monitoring during the provision of anesthesia strongly correlates with a decrease in morbidity and mortality. The term *monitor* is a derivative of the Greek word *monere*, "to warn, advise." In the following discussion, monitoring refers to the investigative methods and instruments used to generate meaningful information in the evaluation of a patient.

Because of the time-sensitive nature of most abnormalities discovered on routine monitoring, significant efforts have been put forth in developing diagnostic instruments that quickly and accurately detect changes in vital signs. The ideal monitor is one that is accurate, noninvasive, reliable, inexpensive, easy to read, and can be used continuously. In addition to recognizing the indications for each of the monitors to follow, it is crucial to understand how they work so that the operator is aware of their limitations and can appropriately interpret the results.

According to the standards put forth by the ADA, monitoring and documentation will vary based on the levels of sedation and anesthesia administered to the patient. However, certain patients with potentially unstable medical conditions may still benefit from more extensive monitoring than indicated by the planned level of anesthesia. These may include assessments of level of consciousness, oxygenation (color and oxygen saturation), ventilation (chest rise, auscultation, end-tidal CO_2, or verbal communication), and circulation (blood pressure [BP], heart rate, continuous electrocardiogram [ECG]). The following definitions are those approved by the House of Delegates at the 2012 Annual Meeting of the American Dental Association and reflect the practice guidelines for sedation and analgesia by non-anesthesiologists.[1] These definitions provide the basis for understanding the goals of anesthesia delivery in the oral and maxillofacial surgery practice (Table 14-1).

Definitions

- **Minimal sedation:** a minimally depressed level of consciousness, produced by a pharmacologic method, that retains the patient's ability to independently and continuously maintain an airway and respond normally to tactile stimulation and verbal command. Although cognitive function and coordination may be modestly impaired, ventilator and cardiovascular functions are unaffected.[2] Under this definition it is understood that the medications and techniques used to provide this level of consciousness should carry a margin of safety that does not allow rendering of an unintended loss of consciousness.
- **Moderate sedation:** more recently referred to as moderate sedation, conscious sedation is a drug-induced depression of consciousness during which patients respond purposefully to verbal commands, either alone or accompanied by light tactile stimulation. No interventions are required to maintain a patent airway, and spontaneous ventilation is adequate. Cardiovascular function is usually maintained.[2]
- **Deep sedation:** a drug-induced depression of consciousness during which patients cannot be easily aroused but respond purposefully following repeated or painful stimulation. The ability to independently maintain ventilatory function may be impaired. Patients may require assistance in maintaining a patent airway, and spontaneous ventilation may be inadequate. Cardiovascular function is usually maintained.[2]
- **General anesthesia:** a drug-induced loss of consciousness during which patients are not arousable, even by painful stimulation. The ability to independently maintain ventilator function is often impaired. Patients often

TABLE 14-1 Levels of Sedation and Anesthesia

	Minimal Sedation Anxiolysis	Moderate Sedation (Conscious Sedation)	Deep Sedation	General Anesthesia
Responsiveness	Normal response to voice	Purposeful response to tactile stimulation	Purposeful after repeated or painful stimulation	Unarouseable
Airway	Unaffected	No intervention needed	Intervention may be required	Intervention is required
Spontaneous ventilation	Unaffected	Adequate	May be inadequate	Frequently inadequate
Cardiovascular function	Unaffected	Usually maintained	Usually maintained	May be impaired
Examples in dental anesthesia	Oral benzodiazepine (low dose) and/or nitrous oxide	Low-dose intravenous benzodiazepine	Intravenous benzodiazepine + opioid + low-dose intravenous agent (e.g., propofol)	Higher dose intravenous agents, multiple drug technique. Potent inhalational agents (e.g., sevoflurane)

require assistance in maintaining a patent airway, and positive pressure ventilation may be required because of depressed spontaneous ventilation or drug-induced depression of neuromuscular function. Cardiovascular function may be impaired.[2]

- **Continual:** repeated regularly and frequently in steady succession.[2]
- **Continuous:** prolonged without any interruption at any time.[2]
- **Time-oriented anesthesia record:** documentation at appropriate time intervals of drugs, doses, and physiologic data obtained during patient monitoring.[2]

History and Evolution of Monitoring Guidelines

"Practice guidelines" are a collection of recommendations provided by authorities in a specialty that are founded on sound evidence. They are often periodically updated and meant to help providers practice at a common level; however, they are not considered requirements. "Standards of care" relate to recognized recommendations to which providers in a given region will be held. These are often brought up in legal settings as a means of comparing what happened to what should have happened. Even as such, they still are not requirements. "Requirements" are acknowledged proceedings that are considered mandatory by a governing body and often supported by irrefutable evidence.

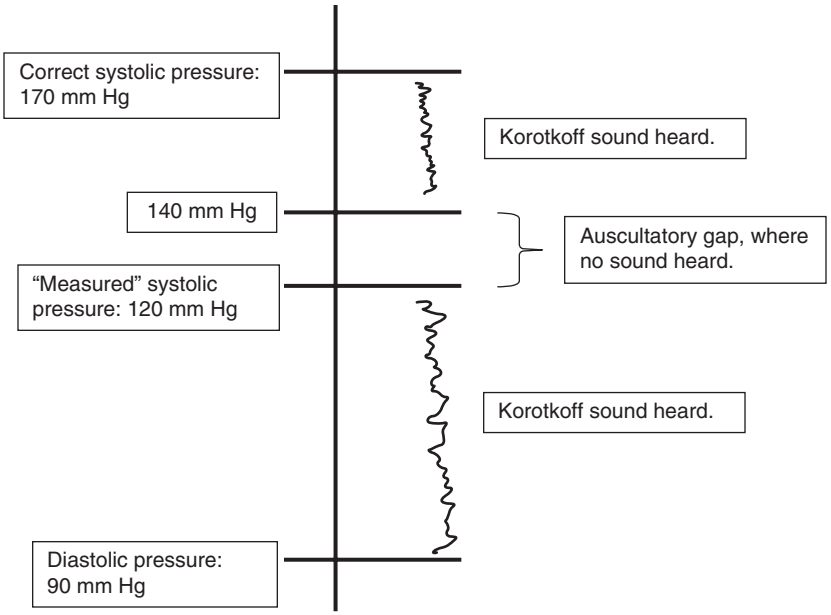
Circulatory System Monitoring

Intraoperative monitoring of the circulatory system is done using electrocardiography, pulse oximetry, blood pressure assessment, and physical diagnosis. Capnography, as noted later, also provides information regarding cardiac output and general metabolism. These modalities allow for evaluation of cardiac conduction, heart rate, blood pressure, and oxygen saturation.

Blood Pressure Monitor

Blood pressure is one of the fundamental parameters for the assessment of cardiovascular health and a critical tool for monitoring the anesthetized patient. The use of an occlusive cuff for measurement of blood pressure (BP) during surgery was first described in 1903 by Harvey Cushing. Large and abrupt changes in BP are often seen in the intraoperative and perioperative periods. These large swings, if not managed appropriately, can lead to significant morbidity. Of particular importance is rapid-onset hypotension, which during the intraoperative period may herald cardiovascular collapse. Less severe, although far more common, is the mild hypotension that results from bolus infusion of vasoactive medications. This hypotension is often offset by surgical stimulation; however, if the hypotension is prolonged, there may be significant end organ damage. Hypertension can similarly be very detrimental to the overall well-being of the patient. Severe hypertension can lead to decreased coronary artery perfusion and increased stress on the myocardium. Therefore, regardless of the direction of the abnormality, substantial alterations in BP can lead to myocardial ischemia and eventual infarction. It is for these reasons that frequent BP assessment is important for safe and effective anesthesia.

Previously, the most common method used to assess blood pressure was the auscultatory technique. During this technique a provider listens for the appearance and disappearance of Korotkoff's sounds as the pressure is relieved from a blood pressure cuff that is occluding an artery (conventionally the brachial artery). The pressure at which the first sound appears as the cuff is deflated is recorded as the systolic blood pressure, and the pressure at



• **Figure 14-1** Representation of an auscultatory gap. If the cuff pressure was not pumped up greater than 140 mm Hg in this example, then the true systolic pressure would be under the true value.

which the sounds cease is recorded as the diastolic blood pressure. As with many of the instruments in the discussions to follow, there are several factors that affect the accuracy of any given measurement. One of the most common errors in BP determination is choosing an improperly sized blood pressure cuff. In fact, in the outpatient setting, the most common error in BP assessment is miscuffing (84% of errors).[3] The proper cuff should have a bladder length that is 80% of the arm circumference, and bladder width that is at least 40% of the arm circumference.[4] When a small cuff is used inappropriately, one can expect a falsely elevated BP, and conversely when a larger than recommended cuff is used, one can expect a falsely reduced BP. The presence of an auscultatory gap (Figure 14-1) can lead to underestimating the true systolic pressure in a patient. This presents as a loss and reappearance of the Korotkoff sounds during deflation of the cuff. If a radial pulse is still palpable even though there are no sounds heard as the cuff is inflated, then there is an underestimation of the true systolic pressure. By inflating the cuff above the point that the radial artery pulsations are not palpable, a more accurate recording of the systolic pressure will be identified. Auscultatory gaps are more prevalent in patients with systemic sclerosis. Using electronic oscillometric devices avoids this issue (see later discussion).

Other factors of great importance in the measurement of blood pressure are the location of the cuff during a measurement and the position of the extremity. As one moves distally along an extremity, the systolic blood pressure increases and the diastolic blood pressure decreases. In patients with significant atherosclerotic disease, calcifications within the distal arteries may prevent complete occlusion even at suprasystolic blood pressures. In this instance, an overestimation of the systolic blood pressure results. When measuring BP, the location of the cuff should be level with the patient's heart. If the cuff is above the patient's heart, a falsely low BP will result. On the other hand, if the cuff is below the level of the patient's heart a falsely elevated BP will result.

Although the auscultatory method can be used, its use is not practical when frequent recordings are necessary. Most automated systems today use the oscillometric method for BP determination. This method depends on oscillations of a manometer needle due to arterial pulsations as the cuff is deflated from a suprasystolic pressure. Systolic, mean, and diastolic pressures are believed to correspond with the time of rapid increase in oscillation, maximum oscillation, and disappearance of oscillation, respectively.[5]

Automated systems are easy to use and allow for objective and consistent readings. As they do not depend on an operator's ability to detect auditory pulsations, they also work well in the noisy environment of an operatory or operating room. Although automated BP assessment techniques are noninvasive and convenient, they are not without risk. Compartment syndrome and nerve palsies have been documented.[6,7] Thus it is important to avoid excessively repeated cycles of pressure measurement, and to also avoid placement of the cuff across a joint where nerves may be traumatically compressed. Caution should also be observed when using automated blood pressure cuffs in patients with preexisting neuropathies and arterial or venous insufficiency, as they are at increased risk of complication.

Electrocardiogram

The coordinated electrical activity across the heart as individual cells depolarize can be read by electrodes placed on the skin surface. Willem Eintoven first recorded the ECG in a clinically relevant scenario at the beginning of the twentieth century using a string galvanometer.[8] Since

that time, several of his successors have made improvements in lead configuration and have demonstrated its use in diagnosing cardiac dysrhythmias and acute disease. The standard ECG tracing contains repeated complexes made up of upward and downward deflections from an isoelectric baseline. These deflections have an amplitude and duration that become helpful in diagnosing pathologic conditions.

Today the ECG is still an essential tool in the monitoring of the sedated patient. In fact, the standards for basic anesthetic monitoring put forth by the American Society of Anesthesiologists (ASA) require that every patient receiving moderate sedation or deeper levels of anesthesia have an ECG continuously displayed.[9] With the standard three-lead ECG, as used by Einthoven in the early 20th century, one may detect changes in heart rate, rhythm or conduction abnormalities, electrolyte disturbances, and even ischemia. It is common practice to use bipolar lead II during intraprocedure sedation because of its ability to detect inferior wall ischemia, the clarity of the P wave, and its tremendous potential in picking up dysrhythmias.[10] Lead II however, should be supplemented with a precordial lead in patients with significant risk factors for cardiac events. For instance, lead II and V_5 together have been found to detect a significant proportion of ischemic episodes. Blackburn and Katigbak, in an exercise lab, found that the combination of leads II and V_5 detected 96% of ischemic events.[11] In a more common clinical setting, London and colleagues found that V_5 and II were able to detect 80% of ischemic episodes.[12] In their study, patients were either known or suspected of having significant coronary artery disease (CAD) and were undergoing noncardiac surgery.

As mentioned earlier, the ECG is an extremely valuable tool for detecting myocardial ischemia. One established ECG change that may signify ischemia is ST segment elevation or depression of greater than 1 mm from the baseline. Another such change is T wave inversion, although this is also seen in ventricular hypertrophy, some bundle branch blocks, and digoxin therapy. When present in multiple leads, ST elevation and depression can represent an area of ischemia localized to a certain vessel or region of the heart. Though criteria for detecting ischemia are known, putting them into useful practice has its limitations. Mangano and co-workers demonstrated that on visual inspection, ST segment changes are only detected 50% of the time or less.[13,14] Leung and colleagues, however, demonstrated that the ST segment trend analysis used in many current monitors has a potential for 78% sensitivity and 90% specificity in detecting ischemia.[15]

Respiratory System Monitoring

Much of the focus of monitoring during an anesthetic procedure is directed toward securing and maintaining an appropriate airway (Figure 14-2). Monitoring the respiratory system is a truly multimodal undertaking. On visual inspection, one can appreciate the chest rise or color changes of the mucous membranes. Breath sounds can be heard with the use of a precordial stethoscope. Even the tactile sense is used in practice to monitor for the presence or absence of respirations. Despite the many physical methods available to monitor respirations, they are not enough to ensure a patent and secure airway. Additional tools at our disposal and required by many national and international specialty groups are pulse oximetry and capnography. These additional instruments are able to detect early respiratory compromise, which is often found to precede significant untoward events during sedation and anesthesia.

• **Figure 14-2** The oral surgery anesthesia team is depicted. One assistant is the surgical assistant while a second assistant maintains the airway and is observing the monitors. During a deep sedation, a patient's airway reflexes are obtunded, so a throat pack (gauze behind surgical site) and protection of the upper airway are provided.

Precordial/Pretracheal Stethoscope

The precordial/pretracheal stethoscope is a simple tool for the continuous assessment of the circulatory and respiratory systems. It consists of a weighted stethoscope head, conduction tubing, and custom monaural earpiece. For best assessment of the respiratory system it is placed over the trachea on the anterior neck. In this *pretracheal* position, it allows for clear, unobstructed auscultation of breath sounds. In the oral and maxillofacial surgery office setting, this may be the ideal position for the stethoscope head, as respiratory depression and apnea are more common than cardiovascular compromise from the sedative agents used there. In the *precordial* position, one is able to listen to both breath sounds and heart sounds. The ideal location for the stethoscope head is placed on the skin of the chest wall on a line between the sternal notch and the left nipple. Despite the low cost and minimal maintenance needed for this device, its routine use has fallen out of favor. The lack of quantitative information, automation, and alarm system have made other systems used in evaluation of the respiratory and cardiovascular systems more desirable. Some clinicians avoid its use due to a feeling of being tethered to the patient. The use of a Bluetooth device can avoid this connection

and even be sent to an external speaker to allow the entire anesthesia team to hear the breath sounds during a procedure.

Pulse Oximeter

The pulse oximeter is a widely used and indispensable tool in anesthesia monitoring. As the name implies, it provides the user with information on both the heart rate and percent oxygen saturation of the hemoglobin molecules in a patient's blood. In the oral and maxillofacial surgery setting, these measures are critical, and it has been estimated that a desaturation of 10% occurs in as many as 53% of anesthetized patients.[16]

Before oximetry, detection of hypoxemia was reliant on either arterial blood gas measurement or the observer's ability to recognize the clinical manifestations of cyanosis. As hypoxemia can have severe and long-lasting adverse effects on all tissues, early detection and reversal is paramount. Detection of cyanosis by even the most seasoned health professionals is notoriously unreliable. Regardless of the total hemoglobin, approximately 5 g of reduced hemoglobin per 100 mL of capillary blood is necessary to yield visually detectable cyanosis.[17] The earliest time at which some clinicians are able to detect cyanosis is when oxygen saturations drop to approximately 80%, with 25% of clinicians unable to detect cyanosis at oxygen saturations of 71% to 75%.[18] Even with the ability to detect cyanosis, it is a relatively late finding and requires a significant reduction in concentration of oxygenated hemoglobin.

Reduced hemoglobin and oxygenated hemoglobin differ in many regards, one of which is the ability to absorb light. Pulse oximeters emit and detect two wavelengths of light, 660 nm, which is in the red spectrum, and 940 nm, which is in the infrared spectrum. This light passes through a capillary bed, most often that of a finger, and is picked up by an opposing photodetector. At 660 nm, oxygenated hemoglobin allows passage of more light than deoxygenated hemoglobin, and at 940 nm, the converse is true. This differentiation allows for the determination of the arterial oxygen saturation in a capillary bed using a predefined algorithm. Another important feature of the pulse oximeter is the ability to differentiate between arterial and venous blood. It is able to detect the arterial flow by noting the changing volume of the vascular bed with each pulsation. Multiple reviews have been conducted to assess the accuracy of monitoring. Manufacturing standards are able to produce less than 3% error at oxygen saturations of greater than 70%, which has been verified by multiple studies.[19] At these levels, pulse oximetry has even been shown to be as accurate as arterial blood gas sampling.[19,20] Below 70% oxygen saturation, pulse oximetry remains relatively accurate, although there appears to be a trend toward overestimation of the determined oxygen saturation by as much as 4%.[21] However, those inaccuracies are not clinically significant, as rapid intervention is still necessary.

Despite its ubiquitous use and incredible value, there are several limitations to the use of pulse oximetry. Most errors are due either to inappropriate quantity of signal (improper placement, low-flow state) or to a secondary influence on the signal (ambient light, electrocautery, movement). Both prospective and retrospective studies have confirmed comparable pulse oximeter failure rates. In one large prospective study of 11,046 patients, a failure rate of 1.12% was discovered.[22] In this particular study, a documented failure had occurred only after all conventional sites had been tried and all mechanical errors had been ruled out.

One source of error in pulse oximetry that deserves special attention is the mechanism in which the oxygen saturation is interpreted. When presented with carboxyhemoglobin and oxyhemoglobin, the pulse oximeter is unable to tell the difference.[23] In one laboratory study assessing a patient with carbon monoxide poisoning, the saturation level detected by the pulse oximeter was found to be the sum of the carboxyhemoglobin saturation level and the oxyhemoglobin saturation level.[24] Thus, in the setting of carbon monoxide poisoning or tobacco smoke inhalation, a normal oxygen saturation as determined by pulse oximetry may not reflect the actual percent of oxygenated hemoglobin. Another form of hemoglobin that may contribute to an inaccurate measurement on pulse oximetry is methemoglobin. Methemoglobin, like oxyhemoglobin, absorbs light at 660 nm and 940 nm. The effect of methemoglobin on pulse oximetry readings is that readings decrease by about half of the methemoglobin percent concentration (up to methemoglobin concentrations of 20%).[25] At higher methemoglobin concentrations, there is a trend toward a fixed pulse oximetry reading of 85%. When interpreting pulse oximetry readings, it is essential to note that in normal, nonsmoking individuals, carboxyhemoglobin concentrations are less than 2%,[26] and methemoglobin concentrations are less than 1%.[27] This becomes important when clinical findings do not correlate with an apparently normal pulse oximetry reading. Some substances that may contribute to this scenario are cigarette smoke and carbon monoxide, which significantly increase carboxyhemoglobin concentrations. Local anesthetics, including prilocaine and benzocaine sprays, sulfonamide antibiotics, and nitrites, can increase methemoglobin concentrations in susceptible patients.[28]

Pulse oximetry overall has significantly reduced the morbidity of sedation, and it appears to be best used as a monitor for desaturation. Although there are several known sources of error related to pulse oximetry, it is important to be mindful of abnormal readings and treat them as representing a low arterial oxygen content until disproven by other methods.

Capnography

Probably the most recent change to anesthesia monitoring, especially in the outpatient setting, is the attention to end-tidal CO_2 monitoring. Although, as noted earlier, pulse oximetry does provide an accurate measurement of oxygen saturation, decreases are often delayed in presentation because the patient is receiving supplemental oxygenation. Capnography provides a more rapid appreciation of the ventilation status of the patient.

According to the most recent AAOMS Parameters of Care, end-tidal CO_2 monitoring should be a consideration in any moderate sedation, and is indicated for any

deep sedation or general anesthesia unless precluded by the nature of the procedure or patient specific issues.[29] Although capnometry, or the measuring of the partial pressure of CO_2 during the respiratory cycle, was initially introduced to the clinical setting in the 1940s, it was only mandated by the ASA for their use in endotracheal general anesthesia in 1996.[30]

The device used in measuring the inhaled or exhaled CO_2 concentration is referred to as the capnometer, and it outputs the capnograph, or the graphic record of the measured CO_2 concentrations. Most capnometers use infrared absorbance or mass spectrometry passed across a sample of gas to determine a partial pressure of carbon dioxide in the sample. Ideally the sample of gas is obtained from a sampling line that directly attaches to a closed circuit. More commonly, however, the sample is obtained from a modified nasal cannula or a sampling line passed through or under a nasal hood (Figure 14-3). Although not ideal, several studies have corroborated that end-tidal CO_2 measurements obtained in this manner correlate well with measured arterial partial pressures of carbon dioxide.[31,32]

Circulation

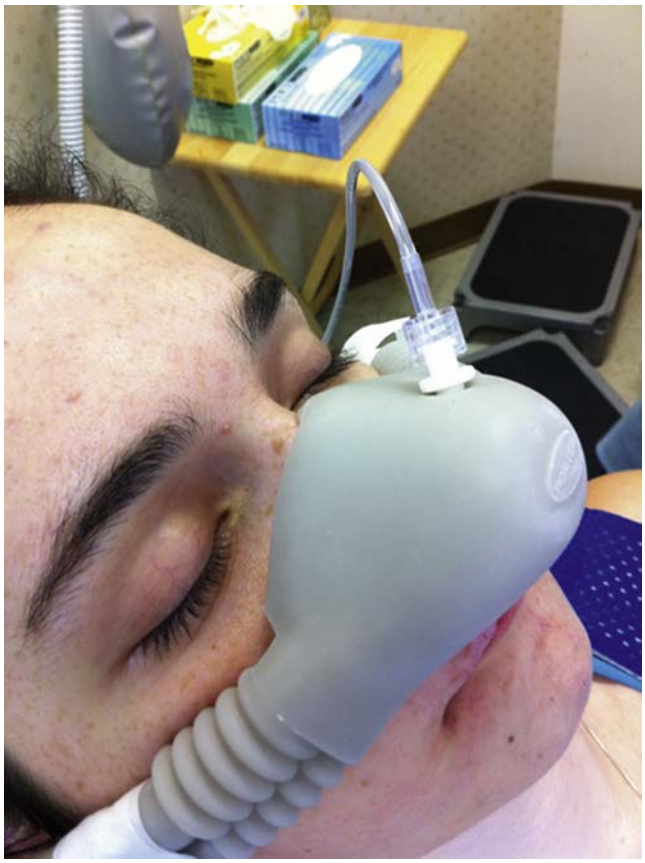
End-tidal CO_2 measurements can also be used to indirectly assess a patient's circulatory status. In a normal, healthy individual, the end-tidal CO_2 ($EtCO_2$) measurement is lower than the arterial partial pressure of CO_2 ($PaCO_2$) by 2 to 5 mm Hg [(aEt)CO_2 gradient].[33] As a patient's cardiac output increases, there is a corresponding increase in alveolar perfusion and delivery of CO_2 for elimination. In this circumstance the (aEt)CO_2 gradient is minimized and remains in the normal range. Conversely, as a patient's cardiac output decreases, there is a decrease in alveolar perfusion and delivery of CO_2 for elimination. When this occurs, the (aEt)CO_2 gradient increases; therefore, a sharp decrease in end-tidal CO_2 or increase in the (aEt)CO_2 gradient in an unwell patient can herald circulatory collapse.

Metabolism

Carbon dioxide and H_2O are normal byproducts of cellular metabolism, and hence increases in their production can signify a hypermetabolic state, altered circulation, or change in ventilation. In a continuously and mechanically ventilated patient, increases in $EtCO_2$ most likely represent hypermetabolism. Other conditions that increase metabolic activity of tissues and thus increase $EtCO_2$ include hyperpyrexia, metabolic acidosis, pain, and muscle activity. One notable condition in which $EtCO_2$ increases before any measurable temperature increase is malignant hyperthermia. In this condition, elevated $EtCO_2$ can be the first abnormality to present.

Respiration

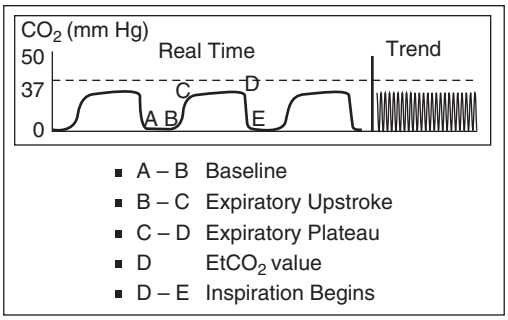
One of the primary uses for $EtCO_2$ monitoring is for the evaluation of a patient's respiratory status. The normal



• **Figure 14-3** Example of side stream sampling of end-tidal CO_2. The barb perforates both layers of the nitrous oxide scavenging hood. As long as the patient is breathing through their nose, good measurements of $EtCO_2$ are obtained.

expected range for $EtCO_2$ is approximately 40 to 48 mm Hg, with the capnogram exhibiting four distinct phases (ascending phase, alveolar plateau, inspiratory limb, and deadspace ventilation).[34] In phase I the airway deadspace is exhaled and the partial pressure of CO_2 is essentially zero. As exhalation progresses and alveolar gas is expelled (phase II) there is a sharp increase in CO_2. For the rest of the exhalation, the partial pressure of CO_2 remains relatively stable (often has a gentle upward slope) and there is a plateau phase (phase III) that reflects the partial pressure of CO_2 that exists in the alveoli. The maximum level of CO_2 during phase III represents the $EtCO_2$ value. Finally, with inhalation, the partial pressure of CO_2 rapidly returns to zero and the cycle repeats itself.

The normal capnogram is not age exclusive and has the following traits: the four main phases are discernable, the CO_2 concentration starts at zero and returns to this baseline with each cycle, there is a maximum CO_2 concentration that is reached with each breath, the amplitude depends on the $EtCO_2$, the width depends on the expiratory time, and there is a characteristic rectangular or trapezoidal shape to the capnogram (Figure 14-4).[34] Any variation from the normal capnogram signifies a clinically relevant condition, and actions should promptly be taken to correct the abnormality.



• **Figure 14-4** Normal morphology of the capnogram exhibiting the five distinct phases.

In the clinical setting, capnography has gained significant popularity for procedural sedation because it promptly identifies respiratory abnormalities. Multiple studies in pediatric[35,36] and adult[37] populations have demonstrated that capnography is able to identify respiratory depression in cases where pulse oximetry and clinical examination could not. Additionally, in cases of acute respiratory compromise identifiable by both pulse oximetry and capnography, capnography was able to identify an abnormality as much as 4 minutes earlier than pulse oximetry.[38]

Temperature Monitor

The AAOMS Parameters of Care mandate that a means for assessing a patient's temperature be immediately available.[29] Indeed, not all sedated patients require continuous temperature monitoring; however, in instances where fluctuations in temperature are expected, core temperature should be documented as frequently as every 5 minutes. Normally, neurohumeral mechanisms allow for tight regulation of body temperature within a well-tolerated range. This steady state is achieved via a combination of thermoregulatory effectors that upregulate metabolic heat production, reduce heat loss, and/or increase dissipation of heat to the environment.

In the setting of general anesthesia, the normal range of acceptable temperatures for homeostasis is broadened, and the mechanisms used to prevent heat loss are recruited at a lower temperature.[39,40] Thus, the vast majority of patients undergoing general anesthesia become hypothermic by 1° to 3° C.[41] Studies demonstrate that the changes in core temperature during general anesthesia follow a distinctive pattern. Characteristically, there is a rapid 1° to 1.5° C drop in temperature in the first hour, followed by a slow linear decrease over the next 2 to 3 hours.[42] Typically a plateau in temperature is finally achieved as compensatory mechanisms allow for a match between heat production and heat loss to the environment.[43] The most important factor in combating the cutaneous heat loss during general anesthesia is sympathetically mediated vasoconstriction.[44] In fact, in a quantitative study of corporeal heat distribution during anesthesia, it was discovered 65% of the decrease in core temperature over the initial 3 hours was due to redistribution of blood flow.[45]

Several adverse effects of perioperative hypothermia have been well documented. Those complications that have a causal relationship include increased blood loss,[46] morbid myocardial outcomes,[47] prolonged post-anesthetic recovery[48] and hospitalization,[49] negative nitrogen balance,[50] and surgical site infection.[49]

Temperature monitors vary greatly in their makeup and their site of use. The most ubiquitous transducers are thermistors and thermocouples, which use differences in electric potential to determine temperature. Most temperature probes used in anesthesia are thermistors.[51] A thermistor is composed of a semiconductor, the resistance of which varies indirectly with temperature. This predictable correlation allows conversion of the voltage output into a temperature value. Since thermistors are solid-state devices, they can be made into small sizes and accommodate many different environments. A thermocouple, also commonly used, differs in that it is composed of two different metals that generate an electromotive force when a temperature difference exists between them.[52] The advantages of the thermistor and thermocouple probes are that they are disposable, sensitive to small temperature changes, accurate, and relatively low cost. Alternatives to thermocouples and thermistors are liquid crystal thermometers and infrared thermometers. Liquid crystal thermometers depend on the thermal properties of a series of organic compounds. These thermometers are also inexpensive, disposable, and noninvasive; however, they are less accurate and may be adversely influenced by external heat sources and humidity. Infrared thermometers have become popular for spot temperature monitoring and are commonly used in the ear canal. These thermometers are generally accurate and determine temperature by recording the amount of infrared radiation emitted by an object.

As important as the device used in thermometry is the site of temperature measurement. Because the core temperature dictates the body's thermoregulatory response and is directly related to complications in the setting of hypothermia, it is crucial to choose a site that directly reflects core temperature. The gold standard for core temperature measurement remains the transducer on the end of the pulmonary artery catheter. Today, the most common sites for temperature measurement include the nasopharynx, esophagus, tympanic membrane, oral cavity, bladder, rectum, trachea, and skin of the axilla and forehead. Because of the nature of oral surgical procedures, probes placed in the nasopharynx and oral cavity may be obstructive and provide inaccurate readings. Similarly, the sedated patient will generally not tolerate tracheal, bladder, rectal, or esophageal temperature assessments. As a result, common and acceptable sites for temperature measurement during oral surgical procedures include the tympanic membrane and skin.

Neuromuscular Monitor

Neuromuscular blockade (NMB) is generally used to facilitate endotracheal intubation, abolish patient movement, and to allow for total control of respiratory variation.

Depending on the indication, differing degrees of relaxation may be desired. Given that there are numerous available neuromuscular blocking agents and that individuals may respond differently to the same agent, it is of vital importance to be able to monitor the depth of NMB in a sedated patient. The most common method employed to monitor NMB is through artificial stimulation of a peripheral nerve, commonly the ulnar nerve. During the assessment, 20 to 60 mA of current is applied between two electrodes placed on the skin surface over the nerve. The measured effect is the presence and degree of thumb adduction by the adductor pollicis.[27] When conducting this assessment, it is important to remember that different muscles return to function at different times. It is due to this fact that the facial nerve rather than the ulnar nerve is often chosen as the site of monitoring because it closely reflects the response of airway musculature.

Neuromuscular transmission monitoring has different purposes depending on the stage of the anesthetic procedure. During induction, NMB is directed at relaxing the laryngeal muscles enough to accommodate the endotracheal tube. Throughout the maintenance phase of anesthesia, the goal of NMB is to prevent patient movement, but to allow return of spontaneous respiration. Finally, assessment of NMB at the conclusion of the procedure is directed at determining both if the blockade is reversible and if the patient is suitable for extubation. Neuromuscular monitors themselves have several different methods of stimulation, each with differing interpretation. Single-twitch stimulus can be used to determine readiness for intubation, and the response to this stimulus is the same regardless of the class of neuromuscular blocking agent (depolarizing or nondepolarizing).

The train-of-four (TOF) pattern of stimulation, in which four repeated impulses are given, can be used to determine the type of neuromuscular blocking agent used and is also commonly used in determining readiness for extubation. However, it is not the most sensitive test for the latter purpose. Another commonly used test to determine extubation readiness is the ability to maintain a head lift for 5 seconds. Again, this usually indicates that a patient has sufficient tone to protect their airway. The most sensitive and objective test, however, is the ability to clamp the jaws closed and prevent removal of a wooden spatula. This test correlates with a TOF of greater than 0.86, compared to the 5-second head lift, which is associated with a TOF of 0.6.[53]

The last pattern of stimulus afforded by neuromuscular monitors is tetanic stimulation. Tetanic stimulation refers to repeated single-twitch stimuli that are on the order of 30 to 100 stimuli per second. When NMB is absent, there is a sustained contraction of the target muscle. In the setting of residual NMB from depolarizing muscle relaxants, the tetanic contractions are sustained but weakened uniformly. In contrast, with nondepolarizing muscle relaxants, the resulting tetanus is depressed but also not sustained. The advantage of tetanus over the other methods of stimulus is that it can be used in deeper levels of NMB when the single twitch or TOF are unsuccessful in generating a useful response.

Depth of Sedation

A reliable method for assessing depth of sedation is exceedingly desirable and would aid in providing patients with their expected experience while maintaining their safety. Under ideal circumstances, one would be able to preserve amnesia, analgesia, and anxiolysis all while preventing respiratory depression, hypotension, laryngospasm, and dysrhythmias.

In the past, measures such as heart rate, blood pressure, respiratory rate, and patient movement were used to assess anesthetic depth. Today, scales that use subjective criteria to score clinical findings are often used to assess a patient's level of sedation. These sedation scales are easy to use, and documentation of their use is a mandated part of the anesthesia record. Additionally, depending on the depth of sedation, a separate individual is required to focus solely on continuous assessment of the patient's level of consciousness.

Of all the scales commonly used for this assessment, one of the most widely used is the Ramsay Sedation Scale,[54] which scores level of consciousness into six categories based on the patient's ability to respond to a stimulus. As this scale requires a response by the patient, it cannot be used in the setting of NMB. Other available scales not widely used in the Oral and Maxillofacial Surgery setting include the Observer's Assessment of Alertness/Sedation Scale, the Riker Sedation-Agitation Scale, and the Motor Activity Assessment Scale. As with all subjective measures, accuracy may be compromised by differences in interobserver, and even intraobserver, interpretation of clinical findings.

Bispectral Index (BIS) Monitor

Because of the unreliable nature of the sedation scales in assessing level of consciousness, other methods of monitoring have been developed. The electroencephalogram (EEG) was an obvious target for further development as it is able to continuously monitor brain activity in a noninvasive manner. The cortical EEG of an awake patient is typically characterized by high-frequency and low-amplitude waveforms. In the initial stages of anesthesia, the frequency of activity decreases and the amplitude of the waves increases. As the sedation progresses and larger doses of medications are used, the waves further decrease in frequency and increase in regularity. Finally, at deep levels of sedation and general anesthesia, periods of isoelectric activity appear separated by bursts of undulation.[55]

One of the first products available for monitoring anesthetic depth that used intraoperative EEG recording was bispectral analysis (BIS). The BIS monitor was first approved for use in 1996 and has become the most widely used method for monitoring depth of anesthesia. The BIS

monitoring systems use a sensor applied to the forehead, which generates an EEG recording. The proprietary BIS algorithm is then applied to the EEG, and a BIS Index is generated. The BIS index is a number from 0 to 100 generated from statistical analysis of a series of EEGs in normal patients, where 0 represents an isoelectric EEG. Bispectral analysis incorporates several variables including EEG power and frequency, burst suppression, bicoherence, and β activation. The main hypothesis that underlies BIS monitoring is that specific EEG features can be correlated with depressed consciousness and that these are seen regardless of the method by which the depressed consciousness is achieved.

Since its introduction, several studies have been performed to validate the BIS index as an indicator of depth of anesthesia. From the results of these studies, several guidelines for sedation have been established. Awake patients will generally have a BIS index of 90 to 100. An index of 70 to 90 represents light to moderate sedation. Below a BIS index of 70, the likelihood of explicit recollection drops off rapidly, with an index of 60 to 70 representing deep sedation, and one between 40 and 60 representing general anesthesia.[55]

Use of BIS monitoring during sedation has several well-documented beneficial effects. In a meta-analysis looking at BIS monitoring in ambulatory anesthesia, it was shown to allow for decreased anesthetic drug requirement (19% reduction in consumption), decreased incidence of postoperative nausea and vomiting (PONV) (6% decreased incidence), and decreased length of recovery room stay (decreased by 4 minutes).[56] Although these findings are indeed significant, the overall reduction in each of the measured outcomes was marginal in most cases. For instance, the authors of the aforementioned study documented a number needed to treat (NNT) of 17 to prevent one instance of PONV. This was directly compared to the NNT for several common antiemetic agents (ondansetron, dexamethasone, and droperidol) when used for the same purpose (NNT 4 to 7).[56,57]

One potential factor that may preclude BIS monitoring use is that not all anesthetic agents produce the same predictable changes to an EEG of a sedated patient. One anesthetic agent in particular, ketamine, actually has an activating influence on the EEG. Ketamine, by increasing the high-frequency activity in the EEG, may lead to elevated BIS index values that will not correspond correctly to the apparent level of consciousness.[58] Other medications that contribute to error in BIS index monitoring include narcotics and nitrous oxide. These medications, in low doses, often contribute to a seemingly deeper level of anesthesia without a significant change in EEG.

Overall, the BIS monitor may provide a reliable objective measure of sedation in most instances; however, there are significant limitations for use in the typical oral surgery practice. These limitations stem directly from the unreliability of the BIS index when certain ubiquitous medications are used. Use of BIS monitoring has also demonstrated only a marginal cost savings, and therefore it has not been adopted by most oral and maxillofacial surgery practices.

The Anesthesia Record

The anesthesia record is a critical component of the patient chart. It should be a contemporaneous record of the care provided during a sedation visit. Included in this record must be the names and doses of all medications administered during the visit, as well as measurements of temperature and $EtCO_2$ when indicated, pulse oximetry, heart rate, blood pressure, and respiratory rate.[29] Also included in the record should be a documented interpretation of the ECG recording and level of sedation.

Although much of the anesthesia record is focused on the intraoperative period, the ASA's standards require that it be a comprehensive log of the perioperative period including the preoperative, intraoperative, and postoperative phases of care.[59] For moderate and deep sedation, the physiologic parameters monitored during the intraoperative period should continue to be recorded during the other stages of the visit.

As a permanent part of a patient's chart, the anesthesia record has multiple purposes. It may serve as a data log for medication use and baseline physiologic measurements, a patient management tool, and also as a medicolegal document. As a medicolegal document, it is extremely important for the content of the anesthesia record to be precisely and legibly recorded. Anesthesia information systems (AIS) are now available and in widespread use to simplify the gathering and recording of data. Anesthesia information systems, by nature of their digital format, are more legible, complete, and accurate sources of information relating to the office encounter. Though they are becoming more popular in the hospital setting, there has yet to be direct evidence for improved outcomes with daily use in the typical oral and maxillofacial surgery practice.

Monitoring During Recovery

Most hospitals and outpatient surgery centers have predefined discharge criteria and guidelines for monitoring patients as they return to their preoperative physiologic state. Recovery is often divided into stages which include: early recovery (Phase 1), which commences after the last anesthetic agent is discontinued and continues until recovery of protective reflexes; intermediate recovery (Phase 2), which is marked by readiness for transfer home; and late recovery (Phase 3), when the patient has finally returned to his or her preoperative physiologic state.[60] Although the same phases are observed following oral and maxillofacial procedural sedation, physical separation of the phases via transfer to a different unit is not practical.

Safe and timely progression through the stages of recovery is critical in the success of office-based anesthesia. One commonly employed scoring method to determine readiness for discharge is the Aldrete scoring system.[61] Using this system a patient receives a score from 0 to 10, with 0, 1, and 2 points given for each of five categories (motor activity,

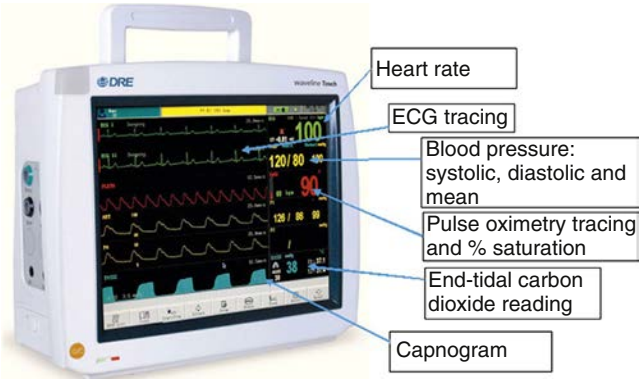
TABLE 14-2 Modified Aldrete Scoring System

Parameter	Description of Patient	Score
Activity level	Moves all extremities voluntarily/ on command	2
	Moves two extremities	1
	Cannot move extremities	0
Respirations	Breathes deeply and coughs freely	2
	Is dyspneic, with shallow, limited breathing	1
	Is apneic	0
Circulation	Is 20 mm Hg ≤ preanesthetic level	2
	Is 20 to 50 mm Hg > preanesthetic level	1
	Is 50 mm Hg > preanesthetic level	0
Consciousness	Is fully awake	2
	Is arouseable on calling	1
	Is not responding	0
Oxygen saturation (by pulse oximetry)	Has level >90% when breathing room air	2
	Requires supplemental oxygen to maintain level >90%	1
	Has level <90% with oxygen supplementation	0
Maximum total score = 10		

Data from Aldrete JA: The postanesthesia recovery score revisited, *J Clin Anesth* 1:88-91, 1995.

respiration, circulation, consciousness, and color). With the addition of pulse oximetry, a modified Aldrete scoring system was devised (Table 14-2).[62] Under the modified system, a score of 9 corresponds to readiness for transition from phase 1 to phase 2 of recovery. In the oral and maxillofacial surgery practice, this often equates to readiness for discharge home[62] under the supervision of a responsible adult. Another similar scoring system devised by Chung[63] is the Postanesthesia Discharge Scoring System (PADSS). Similar to the modified Aldrete scoring system, patients are again given a 0, 1, or 2 for criteria in each of five categories (vital signs, ambulation, pain, PONV, and surgical bleeding). Once again, a score of 9 or higher signifies suitability for discharge home. Using the PADSS system, Chung was able to demonstrate that the majority of patients were suitable for discharge within 1 to 2 hours of surgery.[64] Today, there is still no universally accepted discharge scoring system. Regardless of the system used, it is important to be consistent with your evaluation and to document that an assessment of readiness for discharge was indeed performed.

Monitoring systems will continue to evolve and practice guidelines will continue to change as evidence for improved safety becomes available (Figure 14-5). Although some monitors are often able to perform many of the tasks once left to the anesthesia provider, they are unable to adjust



• **Figure 14-5** Example of multimodal monitor useful for outpatient anesthetic procedures. (Courtesy of DRE Medical, used with permission.)

appropriately to each individual patient and correlate their data with the overall clinical picture. Until that time, we as clinicians must remain contemporary in our understanding of the current equipment and be able to recognize situations in which there is conflicting data or adjust appropriately in the setting of equipment failure.

Local Anesthetics

JEREMY R. GIES, MICHAEL T. MOONEY, ROBERT M. LAUGHLIN

History of Local Anesthetics

Local anesthesia forms the backbone of pain control techniques in oral surgery. Local anesthetic use can be traced as far back as the highlands of ancient Peru, where the Incas used the leaves of the coca plant as a local anesthetic to relieve fatigue and hunger and to produce a feeling of exhilaration.[1-3] Cocaine was isolated in 1860 and first used as a local anesthetic in 1884. In that year, at Roosevelt Hospital in New York, Richard John Hall and William Stewart Halsted were the first to describe regional block or "perineuronal" anesthesia.[1-3] Using cocaine, they performed what today is referred to as infraorbital and inferior alveolar nerve blocks for dental operations and later perfected many other regional anesthetic techniques.[2] The search for a less toxic and less addictive substitute led to the development of the amino ester local anesthetic stovaine in 1903 and procaine (Novocaine) in 1904. Since then, several synthetic local anesthetic drugs have been developed and put into clinical use, notably lidocaine synthesized by Nils Lofgren in 1943, bupivacaine in 1957, and prilocaine in 1959. Lidocaine has become the drug of choice in most clinical settings because of its potency, rapid onset, and lesser allergenicity.

Chemistry of Local Anesthetics

Nerve conduction involves the propagation of an electrical signal generated by the rapid movement of sodium (Na^+) and potassium (K^+) across a nerve cell membrane. Action potentials are generated by a sudden increase in the permeability of the nerve membrane to Na^+ ions and a resultant rapid influx of positively charged Na^+ ions, changing the electrochemical gradient of the membrane potential. This causes a depolarization, thus activating the nerve and sending a wave of sequential polarization down the nerve membrane. Repolarization takes place when sodium permeability decreases and K^+ permeability increases, resulting in an efflux of K^+ from within the cell and restoration of the electrical gradient. The Na^+-K^+-adenosine triphosphate pump restores both ions to their initial intracellular and extracellular concentrations. Na^+ channels in the nerve are characterized as voltage gated.

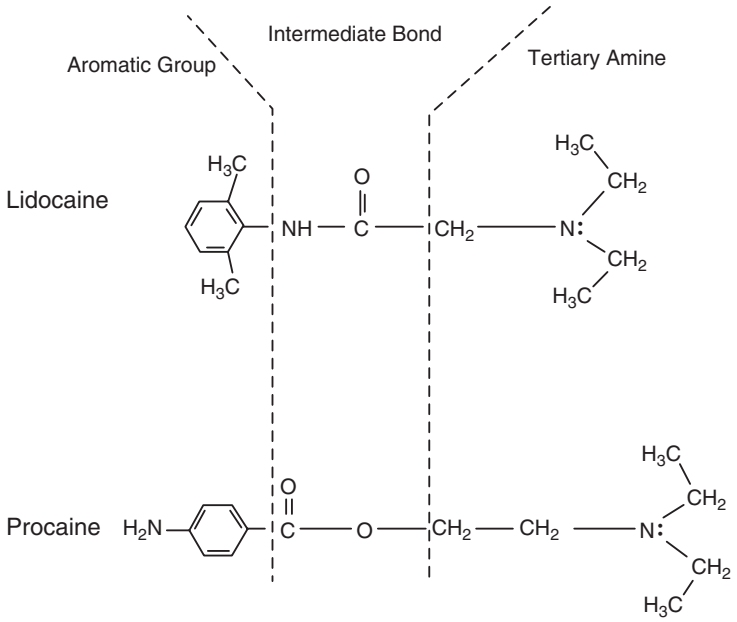
Local anesthetics prevent the generation and conduction of nerve impulses by binding to the α subunit of the Na^+ channel and preventing the influx of Na^+ into the cell, halting the transmission of the advancing wave of depolarization down the length of the nerve. The electrical gradient generated across the nerve membrane is initiated at the outermost surface of the nerve (mantle) and continues toward the center of the nerve (core). The outer surface is responsible for innervating the proximal structures, whereas the core is responsible for innervating distal structures. Consequently, the more proximal anatomic structures are blocked first, and blockage evolves from proximal to distal structures.

Structure and General Properties of Local Anesthetics

The local anesthetic molecule consists of three structural domains: a lipophilic aromatic ring, intermediate ester or amide chain, and terminal amine (Figure 15-1). The nature of the domains determines the pharmacologic properties of local anesthetic agents. The physicochemical properties of these agents largely influence their potency and duration of action.

The aromatic ring improves the lipid solubility of the compound, thus enhancing diffusion through nerve sheaths and nerve membranes. This property correlates with *potency* because a greater portion of an administered dose can enter neurons. Potency is a comparative term that estimates the effective amount of one drug relative to another (Table 15-1). Because bupivacaine is more lipid soluble than lidocaine, it is more potent and only a 0.5% solution (5mg/mL) is required to obtain a comparable local anesthesia to a 2% solution (20mg/mL). Unfortunately, greater lipid solubility increases toxicity, decreasing the therapeutic index.

The intermediate portion of the molecule affords the necessary spatial separation between the lipophilic and



• **Figure 15-1** Lidocaine is the prototypical aminoamide. Procaine is the prototypical aminoester. (From Giovannitti JA, Rosenberg MB: Pharmacology of local anesthetics used in oral surgery, *Oral Maxillofacial Surg Clin N Am* 25:453-465, 2013.)

TABLE 15-1 Relationship between Lipid Solubility and Local Anesthetic Concentration

Drug	Lipid Solubility	Concentration
Articaine	40	4%
Mepivacaine	42	2%-4%
Prilocaine	55	4%
Lidocaine	110	2%
Bupivacaine	560	0.5%

Source: Jastak JT, et al: *Local anesthesia of the oral cavity*, Philadelphia, 1995, Saunders.

hydrophilic portions and divides local anesthetics into two distinct chemical classes: the esters (-COO^-) and the amides (-$NHCO^-$). Esters are primarily metabolized in the plasma by pseudocholinesterases. *para*-Aminobenzoic acid (PABA) is a by-product of this metabolic process and has been implicated in allergic responses by a small portion of the population. Amides are metabolized primarily in the liver and possess a lower risk of allergic reactions. Methylparaben, a chemical preservative structurally related to PABA, has been removed from dental cartridges after it was discovered to produce allergic reactions in some patients. Methylparaben can still be found in multidose vials.

The terminal amine exists in a tertiary form that is lipid soluble or as a quaternary form that is positively charged and renders the molecule water soluble. The terminal amine acts to allow the anesthetic to exist in either lipid-soluble or water-soluble conformations, which plays a pivotal role in the initiation of a conduction block. Once injected into tissue, the local anesthetics exist in both an ionized and a nonionized form. The coexistence of the two forms of the drug is important because drug penetration of the nerve membrane by the local anesthetic requires the base (unionized) form to pass through the nerve lipid membrane; once in the axoplasm of the nerve, the base form can accept a hydrogen ion and equilibrate into the ionized form. While in the nerve axon, the ionized form is predominant and produces a blockade of the Na^+ channel.

The pK_a generally correlates with the *speed of onset* of action of most amide local anesthetic drugs; the closer the pK_a of a local anesthetic to the pH of tissue (7.4), the faster the onset. The pK_a (the pH at which 50% of the drug is ionized and 50% is unionized) of the local anesthetic is related to pH and the concentrations of the cationic and base forms by the Henderson-Hasselbalch equation: $pH = pK_a + \log([\text{base}]/[\text{cation}])$. Local anesthetics are weak bases with a pK_a range of 7.7 to 8.9 (Table 15-2). When the local anesthetic is injected into an inflamed or acidic environment, the more hydrophilic portion of the drug will be preponderant, resulting in decreased neuronal penetration and potency. At physiologic pH of 7.4 or higher, local anesthetics with a lower pK_a, such as mepivacaine, lidocaine, and prilocaine, will have a higher percentage of their free base available for neuronal diffusion. Local anesthetics are typically manufactured as an acidic hydrochloride salt, with a pH ranging from 3.5 to 6.0. This improves the water solubility of the local anesthetic and stabilizes the vasoconstrictor. Because of the low pH, approximately 99% of local anesthetic will carry a positive charge. As a result of the buffering capacity of the soft tissue, it is only after injection that local anesthetic is converted into the free base form, capable of penetrating the nerve sheaths.

TABLE 15-2 Relationship between pK_a, Ionization, and Local Anesthetic Onset at a pH of 7

Drug	pK_a	% Cationic	% Free Base	Onset Time (min)
Mepivacaine	7.7	67	33	2-4
Lidocaine	7.8	71	29	2-4
Prilocaine	7.8	71	29	2-4
Articaine	7.8	71	29	2-4

Efficacy and Duration of Action of Local Anesthetics

Various factors influence the efficacy and duration of local anesthetic action. Of paramount importance is accurate anatomic placement of the local anesthetic in the vicinity of the desired nerve. This is especially true of the mandibular nerve, which has been shown to possess many accessory branches.[4,5] The second factor has to do with the actual chemical makeup of the local anesthetic. Properties such as the solubility of the local anesthetic into the nerve sheath or the presence or absence of a vasoconstrictor, along with the intrinsic activity of the local anesthetic, can make a difference in the efficacy and duration of action.

Local anesthetics can be used in three modes: topical application, local infiltration, and nerve blockade. A mixed peripheral nerve or nerve trunk consists of individual nerves surrounded by an investing epineurium. When a local anesthetic is deposited in proximity to a peripheral nerve, it diffuses from the outer surface toward the core along a concentration gradient. Nerves located in the outer mantle of the mixed nerve are blocked first, and the local anesthetic eventually diffuses inward to block the more centrally located fibers. In this way, the block evolves from proximal structures to distal structures.

The differential rate of blockade exhibited by fibers of varying sizes and firing rates is of considerable practical importance. The sensation of pain is usually the first modality to disappear; it is followed by the loss of sensations of cold, warmth, touch, deep pressure, and, finally, loss of motor function, although variation exists among patients and different nerves (Table 15-3).

Duration of Blockade/Protein Binding

The duration of nerve block anesthesia depends on the physical characteristics of the local anesthetics and the presence or absence of vasoconstrictors. Local anesthetics are in large part bound to plasma and tissue proteins. The most important binding proteins for local anesthetics in plasma are albumin and alpha1-acid glycoprotein (AAG), with local anesthetics binding to AAG preferentially compared with albumin. This property of protein binding correlated with their affinity for protein within sodium channels predicts how long they will sustain neural blockade.

Note that the fraction of drugs bound to protein in plasma correlates with the duration of local anesthetic activity: bupivacaine > etidocaine > mepivacaine > lidocaine > procaine. However, no direct relationship exists between local anesthetics plasma protein binding and binding to specific membrane-bound Na^+ channels. Rather, there is a direct correlation between protein binding and lipid solubility, as there is for all drugs. The more lipid soluble the drug, the more likely it will remain in the lipid-rich environment of the axonal membrane where the Na^+ channel resides.

In general, local anesthetics can be divided into three categories: short acting, intermediate duration, and long acting. The degree of block prolongation with the addition of a vasoconstrictor appears to be related to the intrinsic vasodilatory properties of the local anesthetic. As a general rule, the duration of anesthesia in soft tissues lasts longer than pulpal anesthesia by a factor of 2 to 3.7.[6-8] Table 15-4 displays the more commonly used dental anesthetic cartridges. For the listed local anesthetics, there is a range of maximum dosage recommendations, with the number in parenthesis based on Malamed's more conservative guidelines. The higher numbers are based on the package inserts and Jastak and colleagues.

Long-acting local anesthetics, such as bupivacaine, are highly lipid soluble and bind more tightly to protein and lipid structures within the nerve membrane than other local anesthetics.[6,9,10] When administered via mandibular block, these long-acting anesthetics with 1:200,000 epinephrine possess a longer duration of pulpal anesthesia than other marketed anesthetic solutions.[11,12] However, several studies of infiltrative or PDL injections of bupivacaine with 1:200,000 epinephrine show that in the maxilla, the pulpal anesthesia duration is not longer, and in some cases is even shorter, than the duration of 2% lidocaine with 1:100,000 epinephrine.[13,14] With a variety of local anesthetics to choose from, the local anesthetic should be tailored to the duration of the surgical procedure, need for hemostasis, and anticipated degree of pain.

Use of Vasoconstrictors

Vasopressors are combined with local anesthetics to provide local hemostasis in the operative field and to delay their absorption. Delayed absorption of local anesthetics not only reduces the risk for systemic toxicity, but also prolongs the duration of anesthesia.

Today the two most common vasoconstrictors used in dental anesthetic solutions in the United States are epinephrine and levonordefrin. Local anesthetics containing

TABLE 15-3 Nerve Fiber Types and Nerve Blocking

Neuron Type	Function	Myelination	Diameter (μm)	Order of Blockage—Signs
A alpha	Motor, proprioception	Myelinated	12-20	5th—Loss of motor function
A beta	Sensory—touch, pressure	Myelinated	5-12	4th—Loss of sensation to touch and pressure
A gamma	Motor—muscle spindles	Myelinated	3-6	3rd—Loss of proprioception
A delta	Fast pain, temperature	Myelinated	2-5	2nd—Pain relief, loss of temperature sensation
B	Autonomic, preganglionic sympathetic	Myelinated	<3	1st—Increased skin temperature

norepinephrine (NE) are no longer manufactured in the United States, but continue to be used elsewhere in the world.[15] In general vasoconstrictors are classified as adrenergic or sympathomimetic because they are, or closely resemble, the natural mediators of the sympathetic nervous system and are classified as catecholamines.[2,8,16]

The adrenergic system is composed of both α and β receptors. Each receptor type is further subdivided into α_1 or α_2 and β_1 or β_2. For the most part, the β-adrenergic system is mostly systemic, whereas the ? -adrenergic system is mainly peripheral with less systemic action.[17] The main action of the β_1 receptor is at the heart, where its activation increases heart rate and automaticity of the heart via the sinoatrial node, along with increasing contractility and conduction of the heart. β_2 receptors are located in the vascular beds of skeletal muscles and pulmonary vasculature. Their activation leads to vasodilation or relaxation of the trachea and bronchioles. On the other hand, α_1 receptors are found in the peripheral vasculature and cause severe vasoconstriction of the peripheral arterioles and veins on stimulation. Last, the stimulation of α_2 receptors, which are mostly found in the central nervous system (CNS), leads to decreased sympathetic outflow from the brain and a decrease in the release of NE from the presynaptic neurons.

The physiologic result of β_1 stimulation is an increase in blood pressure, whereas the stimulation of β_2 receptors tends to decrease blood pressure.[2,8,18] The α receptors mainly cause vasoconstriction at the peripheral circulation, skin, and mucous membranes, with a nominal increase in the blood pressure.[17,18]

When examining the actions of catecholamines, subtle differences are noted. Table 15-5 shows that epinephrine is the most potent with respect to α receptor stimulation, as compared with NE, levonordefrin, and phenylephrine. NE

stimulates the β_1 receptor preferentially over β_2, therefore causing an increase in blood pressure when used as a vasoconstrictor in local anesthetic. On the other hand, epinephrine has an equal affinity for both α and β receptors, causing no dramatic increases in blood pressure as a result of β2 vasodilation.[17] The vasodilatory β_2 receptors are believed to be more sensitive to low blood levels of epinephrine than are the vasoconstrictive α_1 receptors. This explains why small doses of epinephrine often increase heart rate and systolic blood pressure yet actually reduce diastolic blood pressure, with the mean arterial pressure (MAP) remaining unchanged.[2,8,19]

As a result of systemic side effects, NE was removed from most local anesthetic formulations in the United States.[20,21] Levonordefrin, which is the least potent of the catecholamines, is most similar to NE, possessing less α_1 but slightly more β_2 action. It is still available in a 1:20,000 solution (0.05 mg/mL). At low blood levels, its pressor effects closely resemble those of NE.[2,8,16,22] Even though NE and levonordefrin have less α_1 activity, one might think that they would be preferred over epinephrine in patients with heart disease. On the contrary—with the preservation of the patient's ability to increase their peripheral vascular resistance, more stress can be placed on the heart when NE or levonordefrin is given.[18] Hence patients with documented hypertension should not receive NE or levonordefrin because both will exert unrestricted activation of α_1 receptors, which could lead to uncontrolled increases in blood pressure. This is especially true in patients with severe, uncontrolled hypertension; refractory arrhythmia, myocardial infarction, or stroke within 6 months; uncontrolled congestive heart failure; and uncontrolled hyperthyroidism.[23]

Potential Benefits of Vasoconstrictors

The use of vasoconstrictors decreases the clearance of the local anesthetic, reduces the total required amount, increases the duration and depth of anesthesia, and aids in hemostasis of the surgical wound. Studies show that with the presence of a vasoconstrictor there is a delay and a reduction in the peak blood levels of the local anesthetic.[6,16,18,22,24,25] This is of importance because excessive blood levels of local anesthetics are known to cause systemic toxicity, especially in the pediatric dental population.[6,8,26,27]

In addition, local anesthetics, especially lidocaine, inherently cause vasodilation, further strengthening the need for vasoconstrictors. Experiments show that with the addition of vasoconstrictors, the duration of action of all local anesthetics is prolonged. This is especially true with lidocaine compared to mepivacaine or prilocaine. As shown in Table 15-4, 2% plain lidocaine possesses a pulpal anesthesia of about 5 to 10 minutes. With the addition of 1:100,000 epinephrine, the duration is increased tenfold to approximately 60 minutes. This increase in the duration of action is less dramatic with bupivacaine, possibly as a result of its higher lipophilic properties.[8,18,28]

TABLE 15-5 Vasoconstrictor Selectivity and Potency

Vasoconstrictor	β_1 Selectivity	β_2 Selectivity	Relative α Potency
Epinephrine	50%	50%	100%
Norepinephrine	85%	15%	25%
Levonordefrin	75%	25%	15%
Phenylephrine	95%	5%	5%

Source: Henslee TM et al: Vasoconstrictive agents commonly used in combination with local anesthetics: a literature review, *J Foot Surg* 26(6):504-510, 1987.

The presence of vasoconstrictor also seems to be beneficial in patients with cardiovascular disease because it reduces the release of reactionary endogenous NE.[29,30] Dental anxiety, fear, anesthesia, and surgery are all accompanied by physiologic, psychological, and biochemical changes. Physiologically, this translates into changes in the heart rate and blood pressure, cardiac arrhythmias, and release of endogenous catecholamines. Multiple studies show that in dental treatment, even with adequate anesthesia, there are increased levels of endogenous catecholamines. In turn, significant increases in blood pressure can be seen, leading to adverse reactions.[31,32,33]

It is generally agreed that the concentration of vasoconstrictors needs to be somewhere between 1:100,000 and 1:200,000 to improve duration of action.[16,22] Higher concentrations do not provide better onset or duration for inferior alveolar nerve block[34,35] or reduce local anesthetic serum concentrations.[36] However, greater concentrations may provide better hemostasis at the surgical site when this influence is desired. In one third molar study, there was a 50% reduction in blood loss with the use of 2% lidocaine plus 1:100,000 epinephrine versus 3% plain mepivacaine.[37] Hemostasis also lends itself to a more visible surgical field and decrease in the risk of aspiration of blood, especially during intraoral procedures. It is important to note that the optimum concentration of local anesthetic needed for adequate hemostasis is specific to each local anesthetic. Studies clearly indicated lidocaine with a concentration of 1:50,000 epinephrine is more effective than the less concentrated solutions of 1:200,000.[18,38] Along the same lines, 1:200,000 mixture of epinephrine seems to impart adequate hemostasis when used with prilocaine and bupivacaine.[8,18]

Potential Systemic Side Effects of Vasoconstrictors

Even though vasoconstrictors reduce systemic absorption of the local anesthetic, there is still systemic absorption of the vasoconstrictor itself, especially if there is an inadvertent intravascular injection.[19,39-44] There is continued debate regarding deleterious influences of vasopressors on patients with cardiovascular disease. Clinical trials have confirmed

unequivocally that even small doses of epinephrine in local anesthetic solutions have an influence on cardiovascular function. Dionne and colleagues[45] studied the influence of three cartridges of 2% lidocaine with 1:100,000 epinephrine. Submucosal injection of this dose increased cardiac output, heart rate, and stroke volume. Peripheral resistance was reduced, and mean arterial pressure remained essentially unchanged. The issue we must address is whether these influences pose a significant risk to patients with cardiovascular diseases. Putative standards and guidelines continue to be presented but in fact are all anecdotal. Ultimately, the decision requires the surgeon to exercise sound clinical judgment based on a thorough analysis of each patient under consideration.

In the event that vasoconstrictors cannot be used, 2% to 3% mepivacaine or 4% prilocaine are the two dental local anesthetics that can provide acceptable pulpal anesthesia without the use of vasoconstrictors.

Potential Drug-Drug Interaction with Vasoconstrictors

Drug-drug interaction with vasoconstrictors is one area that continues to evolve. Misconceptions regarding adverse interactions between vasoconstrictors and antidepressants persist despite literature that dispels this concern.[46] The concerns are related to pharmacokinetic interactions predicated on clearance of catecholamines. Although neuronal uptake is the principal method for termination of endogenous adrenergic neurotransmitters, hepatic biotransformation is the principal pathway for termination of exogenously administered adrenergic drugs.[47] Most noncatecholamines are metabolized in liver by monoamine oxidase, but those having a catecholamine structure are primarily inactivated by catechol-*O*-methyltransferase. Epinephrine and levonordefrin are catecholamines and are metabolized primarily by catechol-*O*-methyltransferase, not monoamine oxidase or neuronaluptake.[47,48] Patients treated with monoamine oxidase inhibitors are not hindered in clearing either of these vasopressors.[49] Newer antidepressants (e.g., fluoxetine [Prozac]) selectively inhibit serotonin reuptake and likewise are not a concern.

With regard to tricyclic antidepressants, this particular class of antidepressants has an ability to produce cardiac arrhythmias, which could be potentiated by a similar tendency shared by all sympathomimetic agents. For these patients, vital signs should be monitored continually if more than one or two cartridges containing any vasopressor are used.

The contaminant use of antihypertensive medications with vasoconstrictors has always been a critical question on the minds of many dentists. For this reason, in 1955 the American Heart Association addressed this topic by issuing a statement that recommended a maximum of 200 µg of epinephrine be used during one dental appointment in patients with heart disease. That equals 11 cartridges of 1:100,000 epinephrine, which is slightly below the 13.9 cartridge limitation for local anesthetic toxicity.[50] Then, in a joint statement in 1964, the American Heart Association and the American Dental Association concluded, "Concentrations of vasoconstrictors normally used in dental local anesthetic solutions are not contraindicated in patients with cardiovascular disease when administered carefully and with preliminary aspiration."[51] Subsequently, recommendations were made to use 23- to 30-gauge needles for intraoral injections because of their ease in aspiration. Any needle smaller than a 30-gauge makes aspiration very difficult and unreliable.[30]

β-Blocking agents have been used for years to treat hypertension and other medical conditions, such as angina and cardiac arrhythmias. β-Blockers are typically classified as either "nonselective," with both β_1 and β_2 activity, or "selective," meaning that they preferentially block β_1 receptors in the heart. If a nonselective β-blocker is used, the β_2 vasodilatory effects of epinephrine will be blocked, allowing only α_1 vasoconstrictive effect. This may lead to a serious increase in blood pressure, with a concomitant reflex bradycardia.[2,6,8,52,53] For this reason, some advocate complete avoidance of vasoconstrictor-containing local anesthetic solutions in patients receiving nonselective β-blockers, especially if hemostasis is not required.[52,53] Others recommend checking for any significant change in blood pressure before the initiation of the procedure. This can be accomplished by initially injecting a 1-mL test dose of vasoconstrictor-containing solutions and monitoring blood pressure for 5 to 10 minutes to identify any adverse reaction.[6,8,52]

Finally, it appears that the administration of lidocaine in combination with a vasoconstrictor has a cardioprotective effect, thus justifying its limited use in patients with cardiovascular disease. Previous concerns about the safety and efficacy of vasoconstrictors have been reduced based on more recent prospective, blinded, randomized, human clinical trials. They speak to the safety of epinephrine as a local anesthetic vasoconstrictor.[17,21,29,30,39,42]

Patient Considerations and Maximum Dosages for Vasoconstrictors

Certain patient populations may have difficulty tolerating additional increases in systemic epinephrine levels. Most patients with cardiovascular disease would be expected to be prone to adverse effects from catecholamine administration. Yet conflicting data fail to consistently show the deleterious effects of local anesthetics with vasoconstrictors in patients with hypertension or cardiovascular disease. Recommendations from various authorities range from absolute avoidance of vasoconstrictors to a maximum dose of 200 µg set by the American Heart Association in 1955.[54] The dosages shown in Table 15-6 are recommended for healthy American Society of Anesthesiologists (ASA) class I patients, keeping in mind that the 1:50,000 concentration should be used only for local hemostasis and not routinely.[6,8] Yet even with these recommendations, one must realize the great variability that exists in this patient population, for there are no absolutes when it comes to patient stratification. Last but not least are the ASA class III and IV patients with unstable angina and poorly controlled ventricular arrhythmias who

require emergency treatment under local anesthesia.[18] In this patient population, elective surgery should be delayed until the underlying medical condition is brought under control. Box 15-1 lists a number of conditions in which it would be prudent to completely avoid the use of vasoconstrictors.[6,55,56] In 1986, a joint statement by the American Heart Association and the American Dental Association concluded that "vasoconstrictor agents should be used in local anesthesia solutions during dental practice only when it is clear the procedure will be shortened or the analgesia rendered more profound. Extreme care should be taken to avoid intravascular injection and the minimum possible amount of vasoconstrictor used."[57]

Complications of Local Anesthetics

Allergy to Local Anesthesia

It is common for patients to claim they are allergic to local anesthetics. However, with further questioning their experience was a syncopal episode associated with the injection or cardiac palpitations attributed to epinephrine either contained in the solution or released endogenously. Although rare, reports of allergic reactions to local anesthetics have appeared in scientific literature, but none of these have confirmed an IgE-mediated hypersensitivity reaction.[46] Reported cases in the literature are attributed to preservatives (methylparaben) or antioxidants (bisulfites) contained in the solution.[58] Methylparaben is included in multidose vials to prevent microbial growth and is no longer found in single-dose vials or dental cartridges. Metabisulfites prevent the oxidation of vasopressors and are included only in dental cartridges containing epinephrine or levonordefrin.

As described by Adkinson,[59] for drugs to be immunogenic, they must be of high molecular weight and possess multiple valences to be recognized by the immune cells. Molecules that are too small must combine with other molecules that act as carriers, in which case the drug is described as a hapten, and this can elicit an allergic reaction. Frequently a metabolite of the drug is the actual molecule that functions as the hapten. This moiety is common to other derivatives of PABA such as methylparaben and some, but not all, ester local anesthetics. In these cases there may be the potential for cross allergenicity among similar compounds because of a common moiety. Articaine is classified as an amide local anesthetic because of the linkage between its lipid-soluble ring and terminal amine. Its thiophene ring contains a sulfur atom, which has no immunogenic property, and an ester side chain that renders the compound inactive after hydrolysis. However, articaine does not liberate a metabolite resembling PABA and does not introduce concern regarding immunogenicity. In contrast, procaine is representative of esters derived from PABA, and hydrolysis liberates a moiety that is potentially immunogenic.

If a patient describes a reaction that is clinically consistent with allergy, avoid using the offending agent until the patient

• BOX 15-1 Conditions in Which the Use of Vasoconstriction Should Be Avoided or Minimized

Heart Diseases

is evaluated by an allergist. In the event an anesthetic is required before medical clearance can be obtained, the wisest choice would be either mepivacaine or prilocaine without vasopressors.[46] Conventional wisdom holds that, if local anesthetics do indeed produce allergies, esters of PABA would be capable of cross-reacting, but this would not be likely among amide local anesthetics. Furthermore, by avoiding those solutions containing vasopressors, one avoids bisulfites that are included as antioxidants. Sensitivity to bisulfites is possible, especially among asthmatic or atopic patients.

Prolonged Sensory Alteration

In 1989 the Ontario (Canada) high court ruled that prolonged sensory alteration did not need to be an essential part of informed consent because the risk was so "infinitesimal, minimal, extremely small, or in order of magnitude 1:800,000."[60] Based on Dower's data analysis, the frequency of paresthesia is most common with articaine at 1:219,949 and least frequent with lidocaine at 1:4,405,130.[61] Even though the chance of prolonged sensory alteration is quite small, every clinician should try to prevent this outcome because each case can become a nuisance, not just for the patient but also for the clinician. Persistent sensory alteration is reportedly the most common reasons for lawsuits against oral and maxillofacial surgeons.[62]

Prolonged sensory alteration is defined as persistent anesthesia or altered sensation, such as itching or tingling, that persists well beyond the expected duration of anesthesia. It can also mean dysesthesia, painful sensation, or hyperesthesia. The most common complaints as a result of paresthesias are speech changes, loss of taste, and drooling, with the lingual nerve being the most common cause. Most of these are transient sensory alterations that resolve within 8 weeks, but they may also become irreversible.[60] If the damage to the nerve is more severe, the risk of permanent paresthesia is increased, most commonly involving the tongue, then the lower lip.[60] If the patient's neurodeficit persists beyond 2 months, he or she should be referred to an oral surgeon or a neurologist for consultation. In a study by Hillerup, third molar extractions accounted for the majority of injuries to the lingual, inferior alveolar, and buccal nerves. The injection of local anesthetics was the second most frequent cause. In the same study, the female gender was overrepresented in incidence of injured nerves, although no gender difference was found in the severity of paresthesias.[63,64]

Although it is known that the most frequent cause of prolonged sensory alteration is direct surgical trauma,[65-67] studies show that the local anesthetic itself can be a source of nerve trauma. In a 21-year retrospective study in Ontario, Canada, Haas and Lennon demonstrated in nonsurgical extractions cases that 4% articaine and 4% prilocaine were significantly more likely to cause prolonged neurologic deficits than were other local anesthetic solutions.[60] It should be noted that both articaine and prilocaine are marketed as 4% solutions, the highest concentrations available in dentistry. All reported cases involved anesthesia of the mandibular arch, with symptomatic tongue or the lip. Articaine was the offending anesthetic in 49% of cases, prilocaine in 42.2%, lidocaine in 4.9%, and mepivacaine in 3.9%. Table 15-7 indicates that 4% articaine is 20 times more likely to cause prolonged sensory alteration than is 2% lidocaine.[60] This claim has been further strengthened by another study in Denmark where 54% of nerve injuries were associated with 4% articaine, a substantial increase in the number of injuries after its introduction in the Danish market.[64]

Based on all the reported data, nerve damage seems to be concentration dependent, which would explain the increase in paresthesia cases. Yet contradictory results were obtained by Hoffmeister, who studied direct nerve injury caused by toxicity. He noted no histologic changes with intrafascicular administration of articaine, claiming that "when used in normal concentrations, local anesthesia does not have a toxic effect."[68] The jury is still out on this issue, requiring further investigation into this matter before making any definitive conclusions. For this reason, some recommend 4% articaine and 4% prilocaine only be used for infiltrative anesthesia and not for inferior alveolar nerve blocks.[69] The package insert from the articaine manufacturers puts the overall rate below 1%, based on clinical trials in the United States and United Kingdom.[70]

In terms of direct injury to the lingual or inferior alveolar nerve, the neurovascular bundle can be traumatized by the sharp needle tip.[60,65-67] Using the "traditional" inferior alveolar block, otherwise known as the Halstead approach, local anesthetic is deposited near the mandibular foramen. Coincidentally, the lingual nerve is directly in the path of needle insertion. Furthermore, with the mouth wide open during the injection, the lingual nerve becomes more taut, reducing its chance of being deflected by the searing needle. This will lead to a greater likelihood that the needle will penetrate the nerve potentially (1) severing nerve fiber; (2) damaging small blood vessels located within the epineurium

TABLE 15-7 Distribution of Analgesic Solution and Nerve Affected Including 54 Nerve Injuries in 52 Patients

Local Anesthetic	Inferior Alveolar Nerve	Lingual Nerve	Sum N (%)
Articaine 4%	5	24	29 (54%)
Prilocaine 3%	4	6	10 (19%)
Lidocaine 2%	3	7	10 (19%)
Mepivacaine 3%	0	4	4 (7%)
Mepivacaine 3% + Articaine 4%	0	1	1 (2%)
Number of nerve injuries	12	42	54 (100%)

From Hillerup S, Jensen R: Nerve injury caused by mandibular block analgesia, *Int J Oral Maxillofac Surg* 35(5):437-443, 2006.

and leading to intraneural hemorrhage; or (3) damaging connective tissues within the nerve via edema. All three events can lead to prolonged sensory alteration, which may be transient or permanent.

Trismus

Trismus is a relatively uncommon complication after local anesthetic injection. It may be due to injury, spasm, or infection within the medial pterygoid muscle, which is typically violated during an inferior alveolar nerve block. This can be prevented by following the basics of atraumatic injection technique.[6] With application of hot, moist towels to the affected side, in conjunction with range-of-motion exercises, improvement should be noted in about 2 to 3 days.

Hematoma

This is typically seen right after the injection as a localized mass of extravasated blood that follows inadvertent injury to the underlying blood vessels. Vessels most commonly involved are the pterygoid plexus of veins, the posterior superior vessels, and the mental vessels.[71] Prevention is the best measure, by reducing the number of times the mucosa is penetrated. If a visible hematoma develops, apply direct pressure. Ice can be applied immediately to the area to minimize pain and potentially reduce the size of the hematoma by vasoconstriction. Heat can be applied the following day to vasodilate the area and carry blood products away. Analgesics may be indicated. Inform the patient that the hematoma should slowly resolve over 1 to 2 weeks. The patient should expect discoloration in the area during this time, and should return for evaluation with any concerns for increasing size. Document hematoma occurrence and follow-up findings in the patient's record.

Pain on Injection

This is most often due to the speed of local anesthetic delivery. If the solution is injected too quickly, it distends the tissue rapidly, causing a painful stimulus. Furthermore, if the temperature of the anesthetic is too high or too low, more pain will be sensed. According to Malamed, each cartridge should be injected over a 1-minute period, and the anesthetics should be stored at room temperature.[30]

Needle Breakage

Although uncommon, a sudden unexpected movement from the patient or a bent needle can lead to needle breakage, which most commonly occurs at the hub. As expected, smaller-diameter needles, such as 30-gauge needles, tend to break more often than larger-bore needles of 25 gauge or higher. To prevent this complication, the following are recommended: The needle should not be bent more than once, never insert the needle up to its hub, and do not apply excessive force or redirect the needle once within the soft tissue. If breakage occurs, inform the patient and document the event. Refer the patient to an oral and maxillofacial surgeon with all the pertinent radiographic images and documentation for prompt retrieval of the foreign object.[71]

Facial Nerve Paralysis

Because the facial nerve (CN VII) traverses the parotid capsule, it is not surprising that transient paralysis can occur if the local anesthetic is deposited within the parotid capsule. Again prevention is the best medicine, paying attention to the direction and depth of the needle. If facial paralysis occurs, reassure the patient, create an eye patch to protect the cornea, and have the patient remove contact lenses if indicated. Eye drops may also be indicated. Return of function will occur within a few hours, depending on the type of local anesthetic used.

Systemic Complications from Local Anesthesia

As the injected local anesthetic diffuses away from the site of injection, it is systemically distributed and absorbed by the internal organs for metabolism and excretion. The typical doses of local anesthetic used in dentistry are minimal, and therefore systemic effects tend to be uncommon. However, in susceptible patients with repeated injections over the recommended limits, systemic overdoses and even death have occurred. The initial sign of a systemic overdose may be muscle twitching, tremors, shivering, or even tonic-clonic seizures.[72] This excitatory reaction is thought to be due to the disinhibition of select inhibitory neurons within the limbic system of the CNS. As the toxic blood concentrations continue to rise, drowsiness, lethargy, sedation, and respiratory depression will follow. Eventually, with extremely toxic levels, cardiovascular conductivity will be disrupted, leading to cardiac arrhythmia and bradycardia.

Long-acting local anesthetics, bupivacaine and etidocaine, are known to possess a greater risk of cardiotoxic events than do other local anesthetics.[8,27,73] Bupivacaine's cardiotoxic property is related to its ability to produce a dose-dependent or high-frequency blockade at normal heart rates. The treatment of these types of toxic events is largely supportive, making prevention the first and foremost strategy in avoiding systemic toxicities. The local anesthetic dosing guidelines are typically based on body weight, and because of this, children tend to be at greater risk for toxic reactions. True dose-dependent toxicities to local anesthetics are reported in the pediatric population.[74] Because local anesthetics have a relatively narrow therapeutic index, most overdoses in children are seen with formulations greater than the 2% concentrations without epinephrine.[30,75] This is commonly seen in children receiving plain 3% mepivacaine or 2% lidocaine with 1:100,000 epinephrine, without any regard for maximum dosing guidelines.[75-79a]

Methemoglobinemia is another unique reaction that can be seen with the use of local anesthetics. It typically occurs 1 to 3 hours after the administration of the local anesthetic. Other medications, such as nitrates and sulfonamide antibiotics, can also act as the initiating factor. In terms of local anesthetics, prilocaine is thought to cause oxidation of the iron atom in hemoglobin from the reduced Fe^{2+} state to the oxidized Fe^{3+} state, leading to a deficient oxygen transport phenomenon characterized by a cyanotic-appearing patient.[8] The clinical signs of cyanosis are initially noted as the level of methemoglobin reaches 10% to 20%. With an increase in the level nearing 35% to 40%, dyspnea and tachycardia will ensue. Fortunately, in patients without significant cardiovascular or pulmonary disease, this reaction is well tolerated. However, in pediatric patients and patients with hereditary methemoglobinemia who already have a portion of their hemoglobin in the Fe^{3+} state, small quantities of prilocaine can cause a serious reaction. Other risk factors for this reaction include patients with glucose-6-phosphate dehydrogenase and methemoglobin reductase deficiency. In these patient populations, an alternative local anesthetic solution should be used. If a patient becomes cyanotic, treat appropriately with intravenous methylene blue (1 to 2 mg/kg).

Table 15-4 lists the maximum recommended dosages of various local anesthetic solutions. Because these dosages are based on a patient's body weight, a 14-kg pediatric patient can theoretically tolerate only one fifth of the local anesthetic given to a 70-kg or greater adult patient. It is important to realize the local anesthetic agent being used, percentage, and presence or absence of a vasoconstrictor to avoid toxic dosing. Studies have failed to show that 3% mepivacaine produces a shorter duration of lip and tongue anesthesia than an equal volume of 2% lidocaine plus 1:100,000 epinephrine. For this reason, the use of 3% mepivacaine and 4% prilocaine should be avoided in young children. Note that in very obese children, the maximum dose should be calculated using the ideal body weight and not the true body weight.

Local Anesthetic Comparisons

As previously mentioned, local anesthetic drugs are classified as esters or amides (see Figure 15-1). Esters are no longer packaged in dental cartridges and are used infrequently in comparison to amide local anesthetics.

Ester-Linked Local Anesthetics

Ester-linked local anesthetics are hydrolyzed at the ester linkage in plasma by pseudocholinesterase. The rate of hydrolysis of ester-linked local anesthetics depends on the type and location of the substitution in the aromatic ring. However, the rate of hydrolysis of all ester-linked local anesthetics is markedly decreased in patients with atypical plasma pseudocholinesterase. Another hallmark of metabolism of ester-linked local anesthetics is that their hydrolysis leads to the formation of PABA. PABA and its derivatives carry a small risk potential for allergic reactions as discussed earlier.

Cocaine

Cocaine occurs naturally in the leaves of the coca shrub and is an ester of benzoic acid. The clinically desired actions of cocaine are blockade of nerve impulses and local vasoconstriction secondary to inhibition of local norepinephrine reuptake. However, its toxicity and the potential for abuse have precluded wider clinical use of cocaine in modern practice. Its euphoric properties are due primarily to inhibition of catecholamine uptake, particularly dopamine, at CNS synapses. Cocaine is unique in that it is the only local anesthetic to cause vasoconstriction. Currently, cocaine is used primarily to provide topical anesthesia of the upper respiratory tract, where its combined vasoconstrictor and local anesthetic properties provide anesthesia and shrinking of the mucosa with a single agent.

Procaine

Procaine, an amino ester, was the first synthetic local anesthetic. Procaine is characterized by low potency, slow onset, and short duration of action. Consequently, although it was once widely used, its popularity declined after the introduction of lidocaine, and it is no longer used in dentistry.

Benzocaine

Benzocaine is commonly used for topical pain relief. Benzocaine is poorly water soluble, making it the drug of choice for anesthetizing mucosal surfaces because it is not absorbed systemically. In spite of this, benzocaine is not totally innocuous, as evidenced by case reports of methemoglobinemia in children who received large doses.[80] Methemoglobinemia is more likely to occur with benzocaine in patients with predisposing conditions, such as glucose-6-phosphate dehydrogenase deficiency or concurrent use of medications that cause methemoglobin. As mentioned earlier, if a patient becomes cyanotic, treat appropriately with intravenous methylene blue (1 to 2 mg/kg), if medically indicated. A 20% ointment is typically sufficient at the mucosal surface and will reduce needlestick pain. Its onset and duration characteristics are similar to those of 5% lidocaine ointment, with the onset typically between 2 to 3 minutes and a duration of 15 minutes.

Tetracaine

Tetracaine is an ester local anesthetic that is highly lipid soluble and rapidly absorbed when placed on mucous membranes. It is the most potent topical anesthetic and thus the most toxic. It is typically sold in a spray form, composed of 14% benzocaine, 2% butyl aminobenzoate, and 2% tetracaine and sold under the name Cetacaine. It is indicated for the production of anesthesia and control of pain at all accessible mucous membranes except the eyes.

It has been used to control gagging during endoscopy and other surgical procedures of the ear, nose, mouth, pharynx, larynx, trachea, bronchi, and esophagus.[30] Because of its rapid absorption and toxic potential, the maximum recommended dose for an adult is only 20 mg. Care should be taken not to exceed the "2-second spray" rule. Average expulsion rate of residue from spray, at normal temperatures, has been calculated at 200 mg/sec. On rare occasions, methemoglobinemia has been reported in connection with Cetacaine as a result of the presence of benzocaine. Injudicious administration, especially in the form of unmetered sprays for widespread surface anesthesia or to reduce the gagging reflex, can lead to serious toxicity; fatalities have been reported.[8] Remember that the onset of action is rapid, approximately 30 seconds, and the duration of anesthesia is typically 30 to 60 minutes.

Amide-Linked Local Anesthetics

As opposed to ester-linked drugs, amide-linked local anesthetics are metabolized in the liver by a dealkalization reaction in which an ethyl group is cleaved from the tertiary amine. The hepatic blood flow and liver function determine the hepatic clearance of these anesthetics. Consequently, factors that decrease hepatic blood flow or hepatic drug extraction both result in an increased elimination half-life. Renal clearance of unchanged local anesthetics is a minor route of elimination, accounting for only 3% to 5% of the total drug administered.

Lidocaine

Lidocaine was introduced in 1948 by the Swedish drug manufacturer Astra, and it remains the most versatile and widely used local anesthetic. Lidocaine can be used in almost any peripheral nerve block in which a local anesthetic of intermediate duration is needed. A concentration of 1% or 2% with or without the addition of epinephrine is most commonly used for surgical anesthesia. Two percent lidocaine with 1:100,000 epinephrine is the most commonly used dental anesthetic.

Mepivacaine

Mepivacaine, introduced in 1957, is an intermediate-duration amino amide local anesthetic. Pharmacologic properties are similar to those of lidocaine. Mepivacaine, as well as prilocaine, has less vasodilatory activity than lidocaine.[6] Solutions of 3% mepivacaine in the absence of a vasoconstrictor can produce pulpal anesthetic durations in the 20- to 55-minute range, which makes mepivacaine ideal in a patient who cannot tolerate epinephrine.

Prilocaine

Prilocaine is an intermediate-duration amino amide local anesthetic with a pharmacologic profile similar to that of lidocaine. The primary differences are a lack of vasodilatation and an increased volume of distribution, which reduces its CNS toxicity. However, it is unique among amide local anesthetics for its propensity to cause methemoglobinemia, an effect of metabolism of the aromatic ring to *o*-toluidine. The development of methemoglobinemia depends on the total dose administered (usually requiring 8 mg/kg) and does not have significant consequences in healthy patients. If necessary, it is treated by intravenous administration of methylene blue (1 to 2 mg/kg).

Articaine

Articaine (Septocaine) is an intermediate-acting amide local anesthetic approved by the U.S. Food and Drug Administration (FDA) in 2000. Although articaine is classified as an amide because of linkage of its intermediate chain, the thiophene ring also contains an ester side chain. This chain is hydrolyzed by plasma esterases, rendering the molecule inactive. The result is that articaine has a half-life of only 20 minutes, compared with about 90 minutes for lidocaine and other amides that require hepatic clearance. It should be clarified that articaine is classified molecularly as an amide, not an ester. It does not produce a metabolite resembling PABA, reducing chance for allergic reactions. Despite anecdotal claims regarding the superiority of articaine, double-blind studies have confirmed that its efficacy is comparable with that of lidocaine.[81,82]

Bupivacaine

Bupivacaine was introduced in 1963 and has been one of the most commonly used local anesthetics in regional and infiltration anesthesia. Its structure is similar to that of lidocaine, except that the amine-containing group is a butylpiperidine. Bupivacaine is a long-acting agent capable of producing prolonged anesthesia and analgesia that can be prolonged even further by the addition of epinephrine. It is substantially more cardiotoxic than lidocaine. Bupivacaine is implicated as one of the more painful agents during injection.[83-85]

Special Considerations

Pregnancy

Most local anesthetics have not been shown to be teratogenic in humans and are considered relatively safe for use during pregnancy. The recommendation for caution (category C) label placed on mepivacaine and bupivacaine is related to limited data collected in animal teratogenicity studies. Therefore, adverse drug effects to humans cannot be ruled out for these agents. Because all local anesthetics can cross the placenta and cause fetal depression, limiting the dose to the minimum required for effective pain control is obviously advisable. Epinephrine, a naturally occurring hormone, is generally considered to have no teratogenic effects when administered with dental anesthetics.[86] Because epinephrine is known to stimulate cardiovascular function, administration demands careful technique to prevent intravascular injection and proper dosing.

New Developments and the Future of Local Anesthetics

There is a continual search to improve anesthetic products, create techniques, and provide alternative methods in an effort to alleviate patient anxiety and pain associated with receiving local anesthesia. This effort must also include the goal of providing a safe, reliable anesthetic in a predictable manner. Although some of these alternative methods have been on the market for some time, some still require further perfecting before it will be widely accepted by the provider. Following is a brief synopsis of these products and techniques and what to expect in the near future; it is not meant to be comprehensive.

Extended Release Formulations

Postsurgical pain relief with extended duration of action local anesthetics is a desirable goal. Exparel (bupivacaine liposome injectable suspension; Pacira Pharmaceuticals, Parsippany, NJ) was approved by the FDA in October 2011 as a single-use injectable agent providing long-acting pain relief in the postsurgical period. Multivesicular liposomes—microscopic spherical structures with an aqueous, bupivacaine-containing core encapsulated by a phospholipid bilayer—allow extended release of the drug over time through progressive breakdown of the lipid bilayer.[87,88] The efficacy of Exparel compared to placebo was evaluated in two multicenter, randomized, double-blinded clinical trials. Soft tissue (hemorrhoidectomy) and orthopedic (bunionectomy) studies were used as trials.[87,89,90] Both trials demonstrated a significant reduction in pain intensity compared to placebo up to 24 hours postoperatively.[89,90]

Intraosseous Anesthesia

Intraosseous anesthesia is useful for anesthetizing a single tooth by providing local anesthesia directly into the cancellous bone surrounding the root of the indicated tooth. Two such systems create a hole in the cortical bone, allowing for a smaller-circumference needle to penetrate the cancellous bone and provide local anesthetic to the indicated teeth. Each system offers both advantages and disadvantages. Stabident (Fairfax Dental, Miami, FL) was the first such system developed, with the X t.i.p. (X t.i.p Technologies, Lakewood, NJ) introduced in 1999.

Computer-Controlled Injections

There are currently a number of computer-controlled injection devices. They also offer a number of advantages and disadvantages. As compared with traditional syringes, these devices are larger, require more space, and are more expensive. Because of a more aesthetically pleasing needle and handle, they are generally better received by patients with needle phobias. The computer is able to control the rate and the pressure of the injection, allowing for titration of the anesthetic for patient comfort. In 1997 Milestone Scientific launched a Computer Controlled Local Anesthetic Delivery System (CCLADS), known as the "wand," which has subsequently been renamed "CompuMed—Featuring the Wand Hand-Piece." The CCLAD was designed to deliver a potentially painless injection of local anesthetic. Since the availability of the CCLAD, numerous studies have been conducted to compare pain associated with the CCLAD and a hypodermic needle and syringe. In a study of 40 patients undergoing either Mohs microscopic surgery for treatment of skin cancer removal or a skin biopsy procedure to determine a positive skin cancer for Mohs surgery, the CCLAD was reported in patients with a normal to low tolerance to cause less pain than what was experienced with prior injections or the control group using hypodermic syringes.[91a] In a study of 101 patients undergoing hair transplant, True and colleagues reported that anesthesia with the CCLAD was less painful than the conventional syringe technique.[91] In contrast, Whalen and co-workers reported in their study that 11 of 15 patients experienced less pain with the traditional injection than with CCLAD-administered local anesthetic.[92] The contradictory results reported by these two groups could perhaps be due to the experience of the person administering the local anesthetic.

Needleless Injections

The administration of medication without the use of a needle has always been highly desirable. Initial reports of this novel approach were first reported in 1947 by Hingson and Hughes.[92a] Refinement of this technique took place over the next few decades; in the 1970s, multiple reports showed promising reduction of pain in patients with cancer. These systems can be divided into three types. The first group is the disposable, single-use tips, such as J-Tip and Biojector 2000. The second type has multiple-use nozzles, such as Ped-O-Jet, Med-E-Jet, and Syrijet. Syrijet Mark II (Keystone Industries, Cherry Hill, NJ) has the benefit of accepting standard dental cartridges.[93] The third type of device is designed for single-patient use: Medi-Jector, which is used for self-administration of variable doses of insulin. Generally speaking they all employ a technology based on a piston-pressure expulsion system that forces local anesthetic into the desired area. In 2000, Cooper and colleagues compared the efficacy of needle-free injections versus injections using 25-gauge needles before venous cannulation and found that patients reported less pain on injection with the needle-free system.[93a]

Electronic Dental Anesthesia (EDA)

Electronic dental anesthesia (EDA) is one of the latest developments in pain control. Based on the same principles as transcutaneous electronic nerve stimulation (TENS), it uses electrical wave forms and voltage/amperage parameters to facilitate the disruption of the neuronal pathways transporting the pain stimuli to the brain. Although this technology

has been used successfully in the field of medicine for back pain and sports injuries, its impact in the dental field still remains to be seen.

A local anesthetic reversal agent has been introduced that claims to effectively reverse the influence of vasopressors on submucosal vessels. Phentolamine (OraVerse) is an alpha receptor blocker formulated in dental cartridges. When it is injected into the identical site where anesthetic was administered, vessels dilate, leading to enhanced absorption of local anesthetic, which shortens the duration of anesthesia.[94] It will likely receive limited use because of its expense and the fact that sustained anesthesia is generally a benefit during the postoperative period for pain management. However, it may be useful in the management of small children or patients with special needs who may be prone to self-inflected injury while tissues remain numb. A consideration may also be given to the fragile diabetic or elderly patient for whom adequate nutritional intake maybe hindered by prolonged numbness. Reversal may also be offered to the busy patient who must return to work and communicate effectively.

Pharmacology of Drugs in Ambulatory Anesthesia

CRYSTAL PIRAS, SARAH RINGDAHL, JEFFREY DEMBO, MICHAEL POWERS

Introduction

The use of ambulatory anesthesia has increased throughout the practice of dentistry. Less invasive procedures and safer anesthesia have allowed patients to undergo procedures in the office with anesthesia provided by the practicing dentist. Different drugs are useful with each subset of patients and offer unique, beneficial side effects that allow procedures to occur with fewer complications. In this chapter, we outline the history, mechanism of action, and clinical side effects of benzodiazepines, opiates and opioids, intravenous sedating hypnotics, ketamine, and inhalation anesthetics.

Benzodiazepines

Discovery and Development

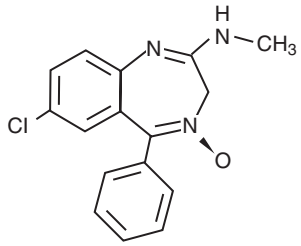
During the summer of 1949, neurochemistry researcher Eugene Roberts was working in a laboratory in Bar Harbor, Maine, studying the amino acid content of neuroblastomas in mice. Using paper chromatography, Roberts analyzed brain extracts of mice with neuroblastoma to compare them with mice that were tumor free. He discovered a chemical that was present in the tumor-free mice and was absent when neuroblastoma was present. This chemical was soon afterwards identified as γ-amino butyric acid (GABA), but its role was unclear at the time. It was not until 1957 that GABA was identified as an important inhibitory neurotransmitter of the central nervous system (CNS).[1]

The 1950s also represented an earnest search for sedative-hypnotics that could work as effectively as the barbiturates and phenothiazines but with fewer side effects and lower abuse potential. Dr. Leo Sternbach, a scientist at Hoffman-LaRoche, was working with a class of compounds that held promise as barbiturate replacements, but found only one compound in this group that had any chemical activity. The compound was shelved and forgotten for several years, and, while cleaning his laboratory, Sternbach came across the compound and decided to test it further. This compound was chlordiazepoxide, a benzodiazepine (BZD)—it was found to have sedative and muscle relaxant properties and later to also possess anticonvulsant and amnestic effects (Figure 16-1).[2] It was approved by the FDA in 1960 and marketed by Hoffman-LaRoche as Librium, the prototype of a drug group that would dramatically change the landscape of anesthesia practice.

The connection between the BZDs and GABA was not fully elucidated until the 1970s, when GABA receptors were identified in mammalian CNS.[3] This led to the development of additional BZD agonists and the search for antagonists. The first true antagonist, flumazenil, was synthesized in 1979.

Structure and Activity of Benzodiazepines

All BZDs are characterized by having one benzene ring fused to a seven-membered diazepine ring. They act in two locations: at central receptors on neuronal membrane and peripherally on receptors on mitochondria. The



Chlordiazepoxide

• **Figure 16-1** Chlordiazepoxide. (Modified from López-Muñoz, Francisco: The discovery of chlordiazepoxide and the clinical introduction of benzodiazepines: half a century of anxiolytic drugs, *Journal of Anxiety Disorders*, 25:4, 554-562, 2011.)

pharmacologic actions of the BZD are closely related to the inhibitory neurotransmitter GABA. GABA exerts its inhibitory effect by opening the chloride ion channel on neuronal membranes, thus hyperpolarizing the cell membrane and making it less likely to depolarize (Figure 16-2). BZDs bind to benzodiazepine receptors presynaptically and postsynaptically, which facilitates the binding of GABA and potentiates its activity, causing CNS inhibition. In the absence of GABA, the BZDs have no innate pharmacologic effects.

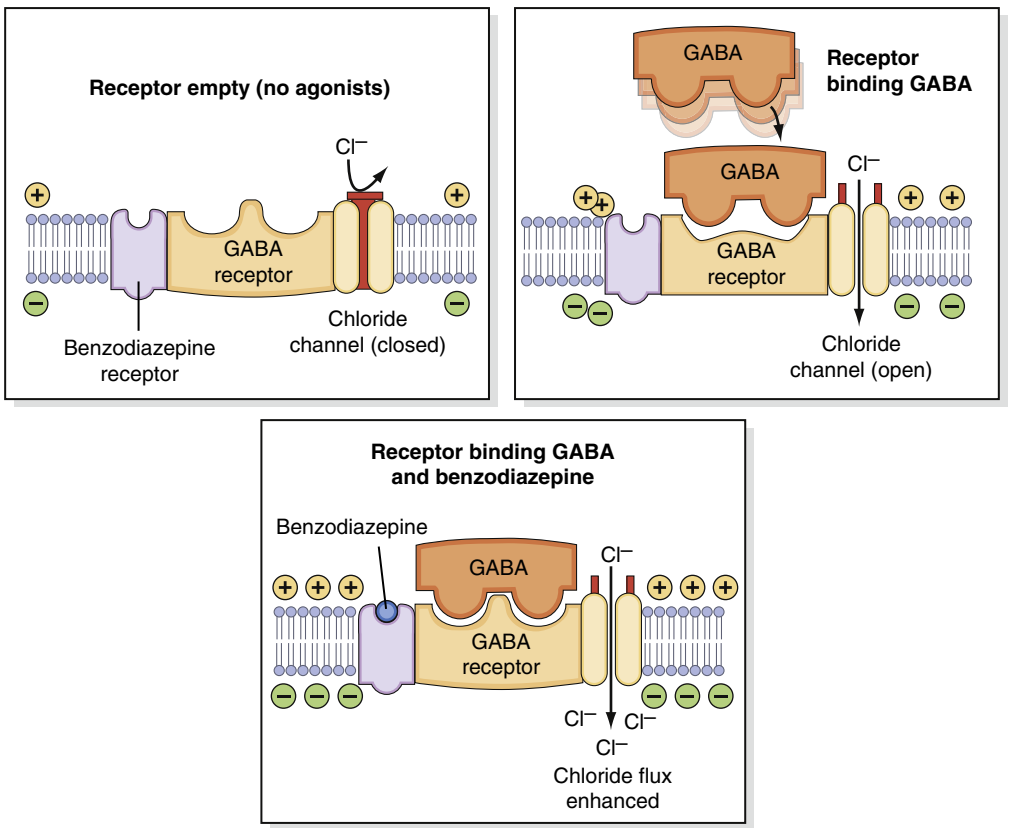
The GABA-BZD receptor complex has been studied extensively and, although the precise three-dimensional configuration has not been mapped, there is general agreement that it is a macromolecular complex containing at least 16 different types of subunits.[4] These subunits include $GABA_A$ receptors, a BZD receptor, a barbiturate receptor, and a chloride channel. A BZD receptor must be linked to $GABA_A$ receptors, but not all $GABA_A$ receptors are paired with BZD receptors.[5] It is still unknown why a BZD receptor exists, because to date no endogenous BZD-like chemicals have been identified. All BZDs, both agonists and antagonists, bind to the receptors reversibly and competitively.

Other drugs have been found to bind to the GABA-BZD receptor complex, although their relationships to GABA activity do not appear to be as specific as the BZD. These include barbiturates, propofol, steroids, etomidate, and inhalation anesthetic agents (Figure 16-3). Other anesthetics, such as ketamine and nitrous oxide, appear to have no activity at the GABA-BZD receptor complex.

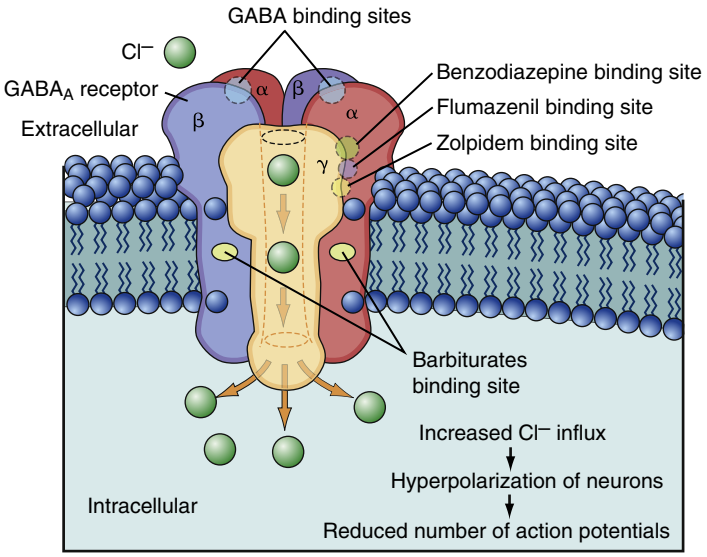
Clinical Effects

The pharmacodynamic effects of BZDs have been well characterized and include anxiolysis, sedation-hypnosis, muscle relaxation, amnesia, and anticonvulsant activity (Figure 16-4, *A*). Each BZD has a differing affinity for the receptor, causing differences in potency and pharmacokinetics between drugs. Nevertheless, regardless of the BZD administered, the clinical effects are similar between drugs and are closely related to receptor saturation.[6] At present the clinical effects are linked, and one cannot administer a BZD to achieve one therapeutic effect (e.g., anxiolysis) without risking amnesia or sedation. However, there are ongoing research efforts to identify and isolate compounds that can selectively create anxiolysis alone without creating amnesia, sedation, or muscle relaxation. As more is learned about the BZD receptor subunits, it may provide future clinicians with classes of drugs that can selectively provide anxiolysis with no other effects.[7]

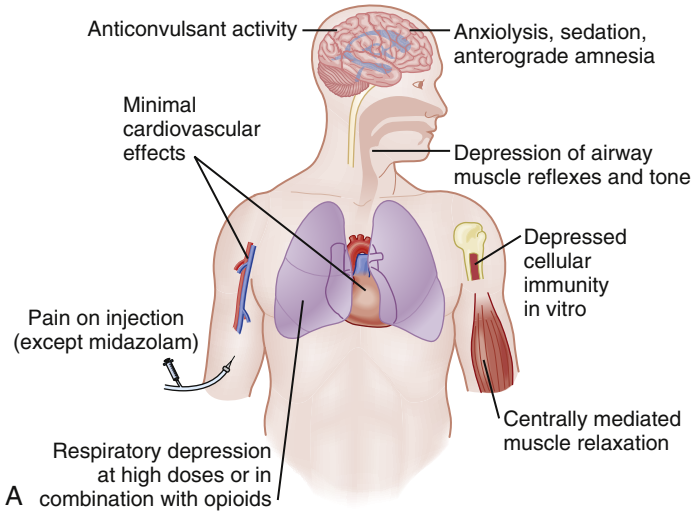
Anxiolysis is the first therapeutic effect achieved when titrating a BZD. There are few studies that support any particular BZD as being most effective in creating anxiolysis.



• **Figure 16-2** Benzodiazepine–γ-aminobutyric acid (GABA)–chloride ionophore complex. Benzodiazepines increase the frequency of channel opening. Barbiturates increase the length of time that the channels remain open. Both of these increase the function of the GABA receptor. (Modified from Pazdernik TL, Kerecsen L: CNS *Rapid review pharmacology,* ed 3, St Louis, 2010, Elsevier.)



• **Figure 16-3** Structure and function of GABA receptor and drug interactions. GABA binds to its receptor in a different location than benzodiazepines, flumazenil, zolpidem, and barbiturates. Binding of all of these molecules results in an increase in chloride transport which hyperpolarizes neurons and reduces the number of action potentials. (Modified from Raffa RB: Drugs used in disorders of the central nervous system and treatment of pain. In *Netter's illustrated pharmacology updated edition*, vol 3, St Louis, 2014, Saunders, pp 57-91.)



• **Figure 16-4** Side effect profile of benzodiazepines. **A,** Side effects of benzodiazepines and their associated organ system. **B,** Verrill sign, a common sign of the induction of sedation, is relaxation causing ptosis of the eyelids to the point that the lower border of the eyelid bisects the pupil. (**A,** Modified from Garcia P: Intravenous anesthetics. In Hemmings HC, Egan TD, editors: *Pharmacology and physiology for anesthesia*, St Louis, 2013, Saunders, pp 137-158. **B,** From Malamed SF: *Sedation: a guide to patient management*, St Louis, 2009, Mosby, pp 316-354.)

The level of anxiolysis is dose related. Older textbooks instructed clinicians to titrate a BZD until Verrill sign was noted (i.e., relaxation causing ptosis of the eyelids to the point that the lower border of eyelid bisected the pupil; see Figure 16-4, *B*). However, Verrill sign is a sedative—not an anxiolytic—end point, and it is possible that some patients will have benefited sufficiently from anxiolytic doses of the BZD that there would be no need to administer additional drug toward a sedative end point. The inherent benefit of titrating to an anxiolytic end point would be to minimize the total drug dose and therefore decrease the time for recovery. The liability of this practice, however, is that amnesia to the surgery would occur less predictably.

The sedative-hypnotic effects of the BZDs are linearly related to dose and receptor saturation. Anxiolysis is produced when less than 20% of receptors are occupied; sedation occurs when there is 30% to 50% occupancy; and unconsciousness when more than 60% of receptors are occupied.[8]

Anterograde amnesia is a well-documented effect of the BZD and is dependent on dose and route of administration. For example, diazepam 10 mg given orally can provide anxiolysis and sedation, but only 40% of patients will have some degree of amnesia.

For more than 70% of patients to be amnestic, oral doses of 20 mg or more would have to be administered. Intravenously, doses of 5 mg and 10 mg of diazepam can produce amnesia in 50% and 90% of patients, respectively.[9] The incidence is similar with midazolam, with complete amnesia in 67% of patients who received 5 mg midazolam intravenously.

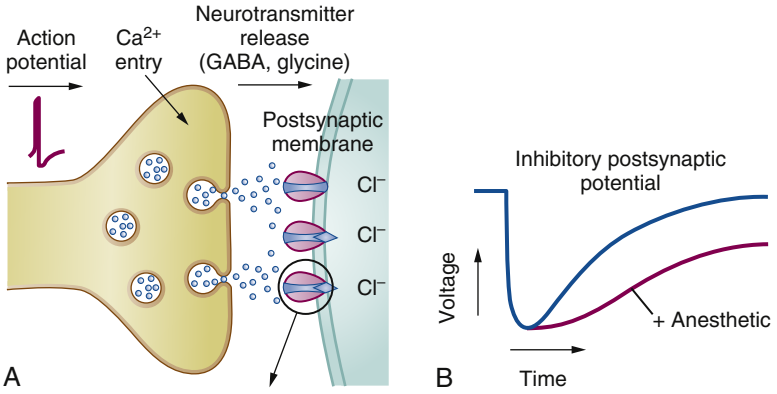
Patients often appreciate being amnestic to an oral surgical procedure, and the degree of amnesia roughly follows in a linear fashion the depth of sedation. However, despite an adequate depth of sedation, it is possible there still may be recall, and there are no reliable predictors to tell us which patients may remember portions of the surgery. Therefore, unless absolute general anesthesia is planned throughout the entire surgery, it would be wise to inform patients that awareness during the anesthetic may occur and the patient may retain some memory of the surgery.

The muscle relaxant effect of the BZD occurs both centrally and at the spinal cord. Glycine is the major inhibitory neurotransmitter in the brainstem and spinal cord, and BZDs mimic glycine, thus causing decreased muscle tone (Figure 16-5).[10] The actions of the BZDs are not related to the motor end plate or neuromuscular transmission.

The BZD depress the central respiratory drive and CO_2 response curve. When BZDs are used alone and in typical doses to achieve conscious sedation, the respiratory depressant effects rarely cause clinically significant hypoventilation or apnea. However, when used with other agents (e.g., opioids) or when used in elderly or medically compromised patients, the respiratory depressant effects can be significant and long lasting. It was in elderly patients undergoing endoscopic procedures that the respiratory depressant effects of midazolam were first noted to be potentially dangerous, primarily because of respiratory arrest. For diazepam there may be a 50% to 65% decrease in minute ventilation, and for midazolam it can be anywhere from a 25% to 65% decrease that can last for hours.

When used alone in healthy patients, BZDs cause very slight changes in heart rate, blood pressure, left ventricular end diastolic pressure, and systemic vascular resistance (see Figure 16-4, *A*). This cardiovascular stability is thought to result from the maintenance of normal baroreceptor function. Diazepam has a beneficial effect on coronary blood flow, increasing it 22% in healthy patients and 73% in patients with coronary disease.[11] Midazolam neither increases nor decreases coronary blood flow.

Whereas the effects of BZDs in younger patients may not become clinically significant, the elderly are much more sensitive to these effects and may, in fact, show significant cardiovascular changes. Even with modest doses and with minor surgical procedures, a significant number of patients can experience hypotension after administration of midazolam.[12]



• **Figure 16-5** The effect of anesthetics on inhibitory synaptic transmission of the GABA receptor. **A,** When bound to its receptor, GABA increases the release of chloride into the postsynaptic neurons. **B,** Anesthetics cause a greater increase in the release of chloride, which causes a larger inhibitory effect than GABA, as shown with the decrease in voltage over time. (Modified from Hudson AE: Pharmacology of inhaled anesthetics. In Hemmings HC, Egan TD, editors: *Pharmacology and physiology for anesthesia*, St Louis, 2013, Saunders, pp 159-179.)

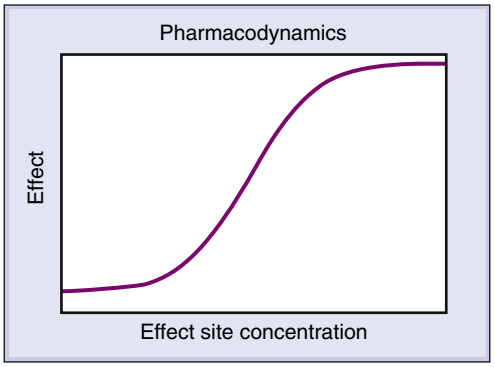
When the BZDs are combined with other drugs (e.g., opioids), there may be significant changes in mean arterial pressure, systemic vascular resistance, cardiac index, and stroke volume.

Pharmacokinetics and Metabolism

Plasma concentrations of BZDs follow a linear to slightly sigmoid dose-response curve (Figure 16-6). All are highly bound to plasma proteins, with slight differences between drugs (Table 16-1). Metabolism occurs in the liver through glucuronide conjugation and hepatic microsomal enzymes (Table 16-2). Because liver function can diminish with age and with disease, metabolism can be expected to occur more slowly in the elderly and in patients with cirrhosis or hepatitis. Concomitant administration of certain drugs can also increase elimination time; this includes erythromycin, oral contraceptives, and calcium channel blockers. All BZDs are eliminated through the kidneys.

The BZDs have among the widest toxic-therapeutic ratios of any agent used for sedation and anesthesia, making them a safe drug class. There have been reported cases of ingestion of 2000 mg diazepam orally by an adult and 300 mg by a 2-year-old, with complete recovery in both cases.[13]

The only true contraindications to the use of any BZD are allergy to the drug and acute narrow-angle glaucoma.



• **Figure 16-6** Basic sigmoidal drug plasma concentration graph. Benzodiazepines exhibit a similar graph. (Modified from Obara S: Pharmacokinetic and pharmacodynamic principles for intravenous anesthetics. In Hemmings HC, Egan TD, editors: *Pharmacology and physiology for anesthesia*, St Louis, 2013, Saunders, pp 20-42.)

TABLE 16-1 Benzodiazepine Half-Lives and Protein Binding

	Elimination Half-Life (hr)	% Protein Bound
Midazolam	1-5	95
Diazepam	20-40	97
Lorazepam	10-20	88-92
Triazolam	1-5	85-90
Alprazolam	9-15	70
Flumazenil	0.7-1.3	54-64

Modified from Smith RB, Corey SE, Kroboth PD: Pharmacokinetics of benzodiazepines. In Bowdle TA, Horita A, Kharasch ED, editors: *The pharmacologic basis of anesthesiology*, New York, 1994, Churchill Livingstone, p 263.)

Diazepam

In 1965 the introduction of diazepam to dental practice greatly improved the dentist's ability to provide conscious sedation (Figure 16-7). In contrast to the multidrug regimens that were commonly used, diazepam could be very effective as the sole sedative and anxiolytic agent.

The pH of diazepam ranges from 6.2 to 6.9, and it has an elimination half-life of more than 40 hours.

Because it is not water soluble, a number of different solvents have been used over the years to create a preparation for parenteral use. The preparation approved by the FDA included the solvent propylene glycol, whose irritating properties cause the risk of phlebitis and venous thrombosis. To minimize this risk, the manufacturer's package insert cautions that the drug must be administered slowly—no more than 1 mL (5 mg) per minute—and it should not be injected into small veins, such as the dorsum of the hand or the wrist.[14] The injectable solution also contains 10% ethanol, 5% sodium benzoate (a buffer), and 1.5% benzyl alcohol (a preservative). For several years, a preparation of diazepam was available that used a solvent containing the same lipid emulsion as propofol (Dizac), but this product was discontinued in 2000.

Diazepam is metabolized into several other BZDs, some of which have sedative properties (see Figure 16-7). The long half-life of the drug and the presence of active metabolites make this drug less than ideal for use in elderly patients or those who are medically compromised.

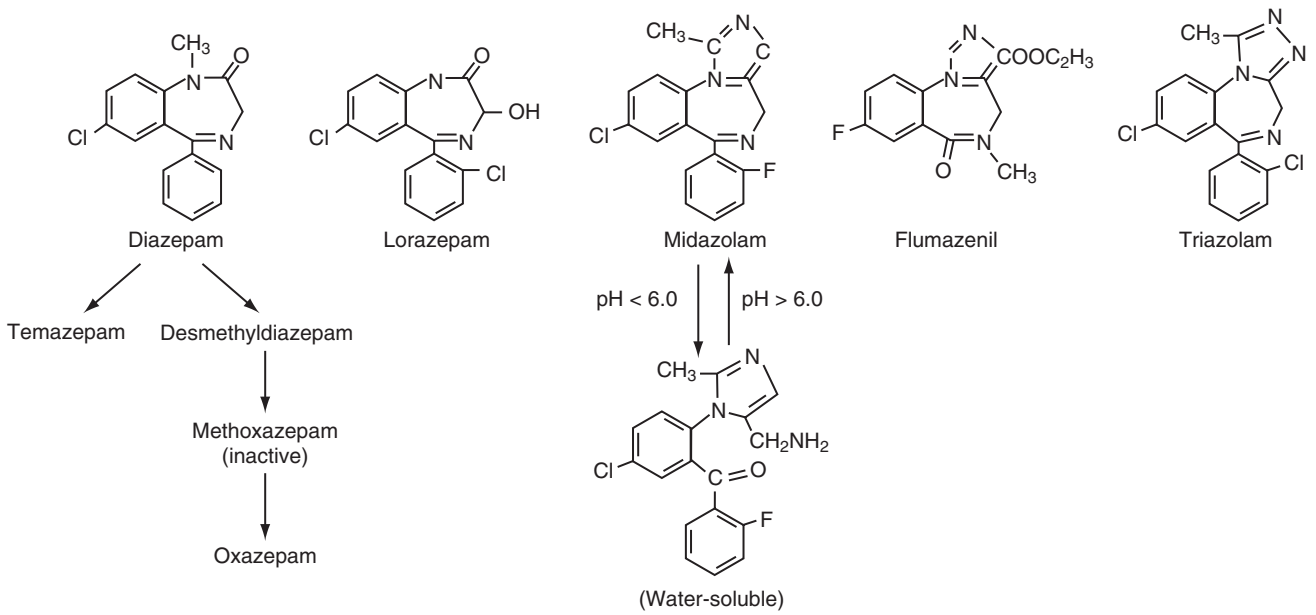
Midazolam

Midazolam was synthesized in 1975 and introduced for clinical use in 1986, offering several notable advantages over diazepam: It had a much shorter half-life, did not have active metabolites, and was water soluble (see Figure 16-7). This provided shorter recovery time for patients and avoided the injection of solvents that were irritating to veins. Midazolam's water solubility derives from an imidazole ring that can selectively open and close, depending on ambient pH. At an acidic pH of less than 4.0, the ring is open, making the molecule hydrophilic and thus water soluble. Hence midazolam is packaged in vials that have an adjusted pH of 2.9 to 3.7. Once the solution is injected and is exposed to plasma pH of 7.4, the ring closes, and the molecule becomes lipophilic and is able to bond to receptors on the neural membrane. The ring closure is not instantaneous, and complete closure may not occur for 5 to 10 minutes after injection.[15] Because the clinical effects cannot occur until the ring has closed, peak drug effects may not be seen immediately after injection.

Its water solubility has permitted midazolam liquid to be administered intramuscularly, nasally, rectally, and orally, routes that were not available for use with diazepam. Oral

TABLE 16-2 Metabolic Reactions of Drugs in the Liver

Conjugation Reaction	Endogenous Conjugant	Intracellular Sites	Common Substrates	Drug Examples
Acetylation	Acetyl-CoA	Cytosol	—OH, —COOH, —NH_2, —NR_2, —SH	Clonazepam, dapsone, isoniazid, sulfonamides, valproate
Glutathione conjugation	Reduced form of γ-Glu-Cys-Gly (the most common intracellular thiol)	Cytosol and microsomes	Electrophilic benzyl halides, aliphatic nitrate esters, epoxides, and quinines	Acetaminophen, ethacrynic acid
Gly (amino acid) conjugation	Gly, Glu, others	Mitochondria	—COOH	Benzoic and salicylic acid
Glucuronidation	UDPGA (uridine-5′-diphospho-α-D-glucuronic acid)	Microsomes	Hydroxyl, amino, or sulfhydryl groups	Acetaminophen, codeine, diazepam, disulfiram, ethinyl estradiol, fentanyl, galantamine, lorazepam, modafinil, morphine, propranolol, paroxetine, sulfonamides
Methylation (*N*-, *O*-, and *S*-)	CH, from *S*-adenosylmethionine (SAM)	Cytosol (e.g., COMT)	—OH, —NH_2, —SH	Oxprenolol (*N*-), clomethiazole and isoproterenol (*O*-), captopril (*S*-)
Sulfate conjugation	3′-Phosphoadenosine-5′-phosphosulfate (PAPS)	Cytosol	—OH, —NH_2	Acetaminophen, ethinyl estradiol, methyldopa, paroxetine, steroids, triamterene



• **Figure 16-7** Structures of commonly used anesthetics in dental anesthesia, some of which are also active anesthetics. (Modified from Reves JG: Intravenous anesthetics. In Miller RD et al., editors: *Miller's anesthesia.* Philadelphia, 2010, Churchill Livingstone, pp. 719-768.)

administration of midazolam was first investigated in 1988, and a number of clinical studies confirmed its effectiveness in children. In 1997 the FDA approved the use of midazolam in children, and it became available in an oral syrup form in 1998.

Triazolam (Halcion)

This BZD was originally marketed in the Netherlands in 1977 as a hypnotic and suspended from use after allegedly causing "raving madness" in some patients, but a thorough investigation failed to provide sufficient evidence to keep

the drug off the market. A similar concern was raised in the United States, but it was never removed from the market, although the manufacturer discontinued manufacturing the highest dose (0.5 mg) tablet.

It has a rapid onset of action (1 hour) and a short elimination half-life, and it is eight times more effective than diazepam as a hypnotic. Because of its favorable pharmacokinetics, it has remained popular as an oral premedicant before outpatient surgical procedures. Most recently there has been increased attention focused on sublingual administration of triazolam (see Figure 16-7). Because the first-pass effect through the liver is eliminated compared with traditional oral administration, there is a 28% increase in bioavailability of the drug when given sublingually compared with orally, causing greater anxiolysis and amnesia.[16]

Lorazepam

Lorazepam (Ativan; see Figure 16-7), frequently used in intensive care units for prolonged sedation, does not have a favorable profile for ambulatory anesthesia. It has a short distribution half-life and a long elimination half-life. As a result of its lower lipid solubility, its effects do not reach a peak until 30 to 60 minutes after the initial IV dose. It is more effective at producing amnesia than diazepam, and the amnestic effects may last many hours after administration.

Flumazenil

At the time the most popular BZDs, diazepam and midazolam, were introduced for clinical use, there were no specific antagonists available. Nonspecific antagonists, physostigmine or aminophylline, were used to reverse the effects of BZDs. The "reversal" effects were actually generalized CNS excitation that frequently would overshadow some of the sedative effects of the BZD. However, this was not true reversal, because no specific action occurred at the BZD receptor. Flumazenil, the first true antagonist, was synthesized in 1981 and introduced into clinical practice in 1992 (see Figure 16-7). Flumazenil is an imidazobenzodiazepine that interacts with the GABA-BZD complex and competitively displaces the BZD (see Figure 16-3). It is not protein bound, and its half-life is roughly 1 hour, making resedation a risk when a longer-acting BZD or high doses have been administered. Flumazenil reverses all BZD effects, but does not antagonize the effects of other drugs that affect the GABA receptors, such as ethanol, barbiturates, opioids, or ketamine.

Flumazenil is a very safe drug, with extremely high doses reported to be given with generally no adverse effects. The few adverse effects that have been reported, including anxiety, crying, tachycardia, and nausea and vomiting, are likely related to the sudden reversal of the therapeutic effects of the BZD.

Opiates and Opioids

Discovery and Development

Archaeologic evidence and written records confirm that the pharmacologic effects of the juice from the opium poppy, *Papaver somniferum,* were known to prehistoric man and early ancient civilizations (Figure 16-8). Over centuries of time, opium was used as an analgesic, antidepressant, antidiarrheal, and cough suppressant. The drug was ingested orally as a tea or mixed with alcoholic beverages, and it was smoked.

• **Figure 16-8** *Papaver somniferum*. Opioids including morphine and codeine are alkaloids of opium obtained from the seed capsules of this plant. (Modified from Larson, MD: History of anesthetic practice. In Miller RD, et al, editors: *Miller's anesthesia.* Philadelphia, 2010, Churchill Livingstone, pp. 1-41.)

In 1805 morphine was isolated from opium in Germany. It and its methylated derivative codeine are still produced today directly from commercially grown opium. In the mid-1800s, when the syringe and needle became available, morphine was the first drug injected using the newly designed syringe. Hence by the time of the Civil War, it was possible to treat soldiers injured in combat by injecting morphine.

The first semisynthetic opioids were heroin and hydromorphone (Dilaudid), produced by making simple chemical changes to morphine's piperidine ring, the portion that confers its pharmacologic activity (Figure 16-9). The next breakthrough was the synthesis of meperidine, discovered during the search for an atropine-like drug. It was serendipitously learned that meperidine, in addition to antimuscarinic effects, also possessed opiate-like effects even though its chemical structure was different. Later, the phenylpiperidine structure of meperidine was used as the basis for creating a whole series of synthetic opioids beginning with fentanyl, and later alfentanil, sufentanil, and remifentanil (Figure 16-10). The only ones in the fentanyl series that have not been used for humans are carfentanil and

lofentanil. Their potency is so great that they are generally considered to be useful only for veterinary management of large animals.

A class of agonist-antagonists was also developed, beginning with pentazocine (Talwin), which was introduced in 1967. The major goal of developing this class of drugs was to provide dose-dependent analgesia while limiting the adverse effects (e.g., respiratory depression). Later, other agonist-antagonists were developed, including butorphanol (Stadol), nalbuphine (Nubain), buprenorphine (Buprenex), and dezocine (Dalgan).

Structure and Activity

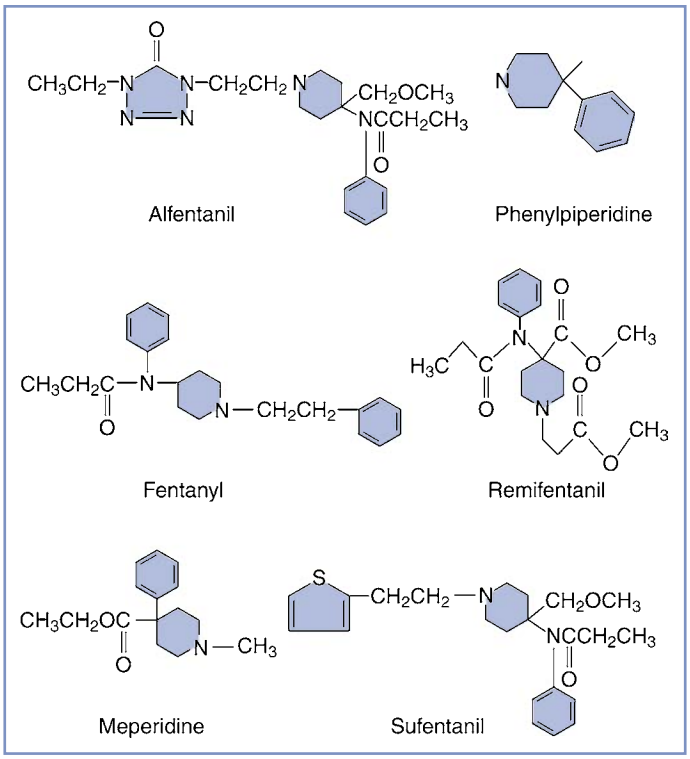
From the 1950s until the early 1970s, the idea of an opioid receptor had been postulated but remained unproven. In 1973 the first articles appeared demonstrating the presence of opiate receptors, followed by studies that demonstrated the presence of endogenous opiates.[17,18] Later a number of different opiate receptor subtypes were characterized. There are three major receptors (mu, delta, kappa) with as many as eight subtypes.

The agonist-antagonists possess partial agonist activity at μ and other receptors in addition to competitive antagonist activity. This has been shown to create a ceiling effect that limits respiratory depression regardless of dose administered. It also limits the possibility of physical dependence.

The antagonists competitively bind at opioid receptors, displacing any agonists present and thus reversing the effects of the agonist.

Clinical Effects

The primary desirable effect of opioids is analgesia. Analgesia can be created at the spinal level through activation of presynaptic opioid receptors. This leads to decreased levels of neurotransmitters and thus decreased transmission of pain-induced action potentials. Supraspinal analgesia occurs by activation of postsynaptic opioid receptors in the brainstem and midbrain, leading to hyperpolarization and thus



• **Figure 16-10** Fentanyl and its analogs that have been synthesized and used throughout the history of anesthesia. (From Bucklin BA: Local anesthetics and opioids. In Chestnut DH et al, editors: *Chestnut's obstetric anesthesia: principles and practice*, ed 9, St Louis, 2014, Saunders, pp 261-299.)

neuronal inhibition. Analgesia may also be created through peripheral mechanisms, as evidenced by reduction of pain when morphine is injected directly into joints postoperatively (Figure 16-11).[19]

When used as an adjuvant drug for ambulatory anesthesia, the desired effects of opioids and opiates are not necessarily analgesia but rather sedation and euphoria, both of which supplement and augment the actions of other sedative agents.

The respiratory depressant effects of the opioids are caused by a dose-dependent depression of the brainstem response to increased CO_2 and decreased O_2. The respiratory pattern changes as well, characterized by a low respiratory rate with a large tidal volume. Respiratory depression is accentuated by a variety of factors, including increasing age, concomitant administration of other CNS depressants, circadian rhythms, and sleep deprivation (Figure 16-12).

Opioids are known to cause histamine release. There is also a central decrease in sympathetic tone, leading to a tendency toward vagal-dominated bradycardia. As a result of these two effects, direct and indirect vasodilation occurs (Box 16-1).

Opioids can rapidly cross the placental barrier and are found at significant concentrations in the breast milk of nursing mothers. After opioid administration has ceased, it can take up to 96 hours for these concentrations to clear, making it necessary for nursing mothers to feed their infants using stored milk and to express and discard breast milk produced during this period of time.[20]

Opioids have been associated with chest wall rigidity that usually occurs only after loss of consciousness and is associated with high doses and rapid administration. That said, cases have been reported where it occurred in an awake patient who received a small dose. The mechanism is still not completely understood. Some have concluded that it results solely from glottic closure.[21] Others have opined that it relates to the effects of opioids on specific sites in the CNS, such as the nucleus raphe pontis in the reticular formation of the brainstem.[22] It is not caused by direct stimulation of skeletal muscle, because it can be prevented by pretreatment with muscle relaxants. Of all the opioids, fentanyl is the one most prominently implicated in causing chest wall rigidity.

Meperidine

Meperidine, the first totally synthetic opioid, is also known by its non-U.S. name "pethidine" (see Figure 16-10). Its duration of action is anywhere from 3 to 5 hours.

The atropine-like effects of meperidine differ from those of other opioids: tachycardia, decreased myocardial contractility, and mydriasis. One of the metabolites, normeperidine, is long acting and pharmacologically active and can cause toxic effects in the CNS that can result in increased EEG activity, myoclonus, and seizures. These effects are not reversible by naloxone.

Of all the opioids, meperidine is the one most likely to cause histamine release. In one study, patients showed as high as a 200-fold increase in serum histamine levels several minutes after its administration, a far greater amount than either morphine, fentanyl, or sufentanil.[23] In addition to the potential to create symptoms similar to anaphylaxis, this

histamine release may also be responsible for vasodilation that can lead to clinically significant hypotension.

Fentanyl

Fentanyl is 60 to 80 times more potent than morphine, and there is a 2 to 3 times greater affinity for fentanyl at the opiate receptor compared with morphine (see Figure 16-10).[24] After injection, fentanyl is characterized by a rapid onset of action owing to its ease of crossing the blood-brain barrier. It is rapidly eliminated, with 99% of a single dose cleared from the plasma within 60 minutes.[25]

Remifentanil

Remifentanil, the most recently introduced opioid, possesses unique properties by being μ-selective (see Figure 16-10). It also has an ester linkage and is thus metabolized by tissue and plasma esterases. This imparts an extremely short half-life and limits the accumulation of the drug in the tissues. This pharmacokinetic profile makes it ideal for continuous infusion because a steady-state level can be reached very rapidly, and after discontinuing the infusion, the level of detectable drug in the serum drops very quickly (see Figure 16-12).

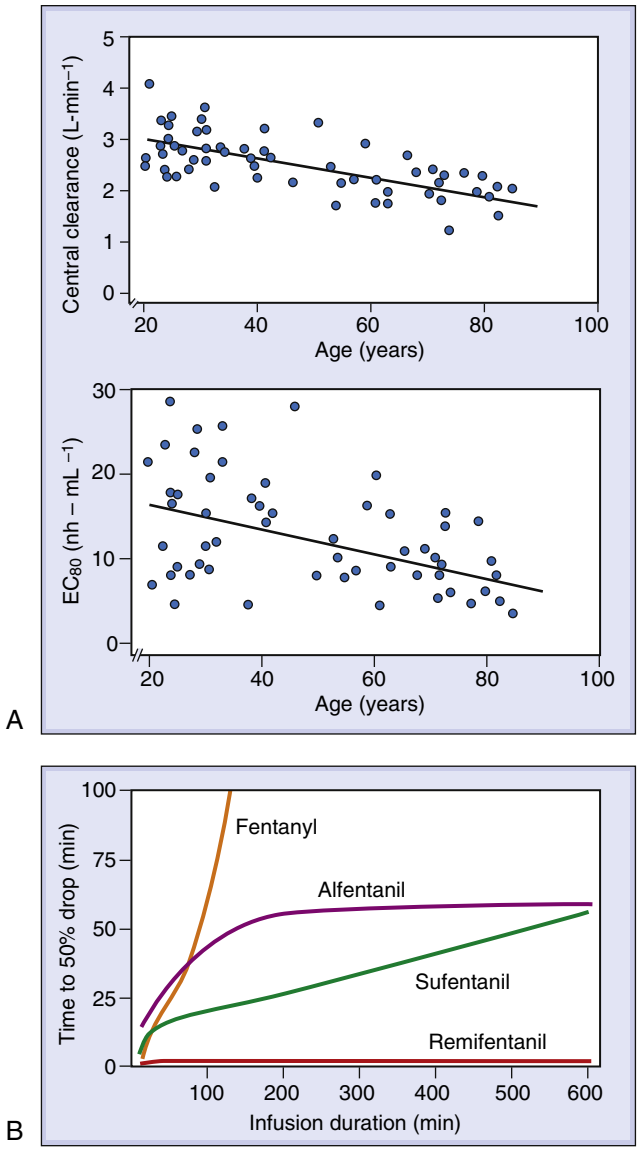
Naloxone

This short-acting antagonist can be used to quickly reverse the effects of opioids (see Figure 16-9). Its short duration of action, however, implies there could be recurrence of the agonist effects when a long-acting opioid was used. Naloxone is associated with nausea and vomiting, the incidence of which increases with dose and rapidity of administration. Sudden reversal of an opioid with naloxone has also been associated with rebound sympathetic stimulation that can cause dysrhythmias, hypertension, myocardial infarction, stroke, and pulmonary edema.

Intravenous Sedative-Hypnotics

Discovery and Development

The barbiturates were the mainstay of intravenous anesthetic agents for more than 80 years. Their use began in 1864 with von Baeyer's discovery of barbituric acid, produced by mixing malonic acid with urea (Figure 16-13). Although it had no discernable pharmacologic properties, chemists substituted and added side chains to the molecule until, in 1903, the first pharmacologically active barbiturate, diethylbarbituric acid (Veronal), was identified. Shortly afterwards, in 1912, phenobarbital (Luminal) was synthesized, a drug that became popular as an anticonvulsant, sedative, and anxiolytic. Thiopental (Penthothal), a thiobarbiturate, was synthesized during this same time period and introduced into clinical



• **Figure 16-12** Infusion duration and clearance of remifentanil. **A,** Among many other factors, age decreases the central clearance of remifentanil, giving it a higher potency measured by EC50 or the effective concentration for 50% of maximal effect. **B,** The half-life concentration of remifentanil is very short compared to other opioids and is not influenced by the duration of the infusion. (**A,** modified from Ogura T: Opioid agonists and antagonists. In Hemmings HC, Egan TD, editors: *Pharmacology and physiology for anesthesia*, St Louis, 2013, Saunders, pp 253-271. **B,** modified from Butterworth JF, IV, Mackey DC, Wasnick JD: In *Morgan & Mikhail's clinical anesthesiology,* ed 5, New York, 2013, McGraw-Hill.)

practice in 1929. It became the prototype of an anesthesia induction agent owing to its rapid onset of action and short duration of action.

Methohexital, an oxybarbiturate, was adopted into clinical practice in the 1960s and was found to offer some advantages over thiopental, in particular a shorter duration of action. For this reason, it became among the most widely used parenteral anesthetics in dentistry. It is uncertain whether methohexital will remain a part of our anesthetic armamentarium because there have been intermittent shortages in the United States over the past decade, and its use in the United Kingdom has been discontinued since 1999.

In an effort to identify new intravenous nonbarbiturate anesthetics, propofol (2,6-diisopropyl phenol) was developed during the early 1970s (see Figure 16-13). Clinical trials began in 1977, resulting in availability for clinical use in the United Kingdom in 1986. Stuart Pharmaceuticals received FDA approval in 1989 for sale of propofol in the United States under the brand name Diprivan. Because propofol is not water soluble, it is formulated in a lipid emulsion containing soybean oil, egg phosphatide (lecithin), and glycerol. After its introduction, case reports of septicemia began to surface, with the subsequent discovery that the lipid emulsion was an excellent culture medium for bacteria. The manufacturer responded by adding a preservative, EDTA, to the preparation and by including a warning in the package insert stating that "strict aseptic technique must always be maintained during handling."[26] Over the past several years, two generic products have since been formulated with the only difference being the use of either sodium bisulfite or benzyl alcohol as preservatives instead of the EDTA that was used in the original patented product.

There is ongoing research using fospropofol, a prodrug that is converted by alkaline phosphatase to propofol once injected (Figure 16-14).[27] The putative advantage is that fospropofol is water soluble, avoiding the need for a lipid solvent. This eliminates the risk of bacterial growth in the solvent and diminishes pain on injection. However, owing to the fact that it takes time for the prodrug to be converted to active drug, there would be a potential delay in onset of action once injected.

• BOX 16-1 Undesirable Clinical Side Effects of Opioids

The significant side effects and precautions of opioids include:

- **Histamine release:** May lead to hypotension, bronchospasm, flushing, and urticarial (especially with morphine; use with caution in patients with compromised hemodynamics or reactive airway disease)
- **Respiratory acidosis and respiratory failure** due to blunting of hypoxic respiratory drive
- **Worsening hypotension** in hemodynamically compromised patients
- **Reduced gut transit or ileus**
- **Urinary retention**
- **Opioid withdrawal:** For patients exposed to high-dose narcotics for more than 1 week, opioid infusions should be decreased no more than 25% per day to avoid withdrawal symptoms

Structure and Activity

Methohexital and propofol are thought to exert their action by interacting with GABA receptors (see Figure 16-3). Although it is unclear whether they both have common sites of action, it is certain those sites are different from the sites associated with the BZD.

Clinical Effects

Methohexital

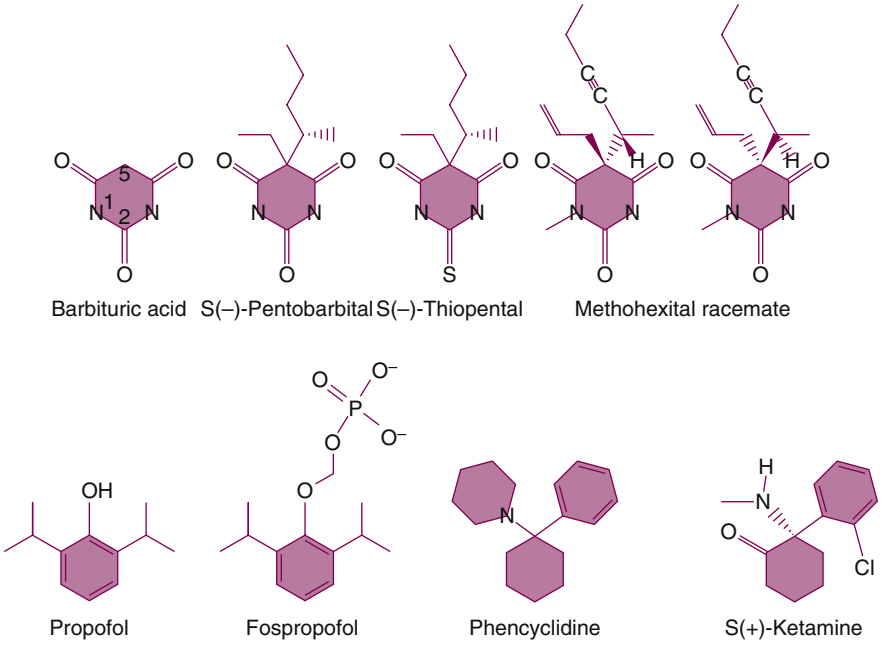
Excitatory effects, such as hiccups and myoclonic movement, have classically been associated with methohexital, occurring as frequently as 90% of the time in patients who receive it (Figure 16-15).[28] Methohexital causes tachycardia and hypertension because there is cardiac compensation for peripheral vasodilation. It also tends to cause increased EEG activity and has potential as an epileptogenic.[29] Methohexital and other barbiturates appear to lower the pain threshold and have been credited with antianalgesic properties, but there is still debate whether this is a real phenomenon.[30]

Propofol

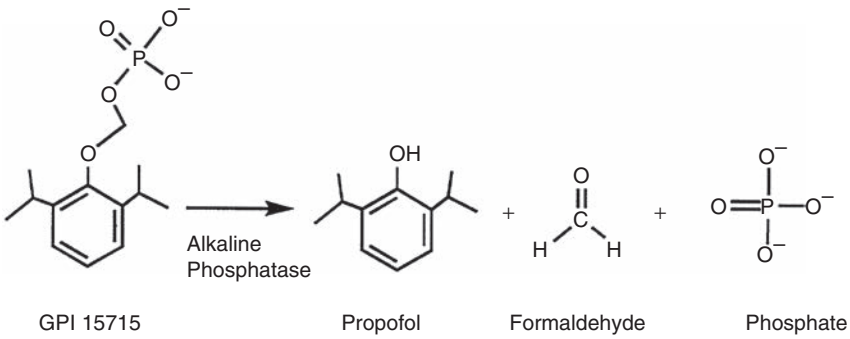
Propofol tends to provide cardiovascular stability by exerting a central sympatholytic effect that maintains a stable heart rate (Figure 16-16). There is also an accompanying decrease in systemic vascular resistance, but in the healthy patient and in the doses typically used in oral and maxillofacial surgery, there might be a slight—but clinically insignificant—decrease in blood pressure.[31] However, in the patient with significant cardiac disease, in the hypovolemic patient, or when very large boluses are given, there may be hypotension on induction. Propofol appears to cause few changes in electrical activity of the heart and is not typically associated with dysrhythmias. Both propofol and methohexital can cause apnea following large induction doses.

Because sensitivity to propofol increases with age and clearance of the drug decreases, a 30% to 50% reduction in drug dose may be required to prevent oversedation.[32]

Propofol has relatively few side effects. It does not cause nausea and vomiting; to the contrary, it possesses antiemetic properties and has been administered in subhypnotic doses for the treatment of nausea and vomiting.[33] The mechanism for its antiemetic effect has not yet been elucidated.



• **Figure 16-13** Chemical structures of intravenous anesthetics, including propofol and new agents such as fospropofol. (Modified from Garcia P: Intravenous anesthetics. In Hemmings HC, Egan TD, editors: *Pharmacology and physiology for anesthesia*, St Louis, 2013, Saunders, pp 137-158.)



• **Figure 16-14** Activation of fospropofol. Fospropofol, here GPI 15715, is metabolized by the enzyme alkaline phosphatase into its active form, propofol. (From Melton MS: New medications and techniques in ambulatory anesthesia, *Anesthesiol Clin* 32(2):463-485, 2014.)

Propofol causes little or no histamine release and has not been associated with allergic reactions.[34] It has bronchodilating properties that may be due to direct effects on smooth muscle.[35] The literature also suggests that propofol may have analgesic effects, as evidenced by decreased need for postoperative analgesics by patients who received propofol compared with another anesthetic agent.[36]

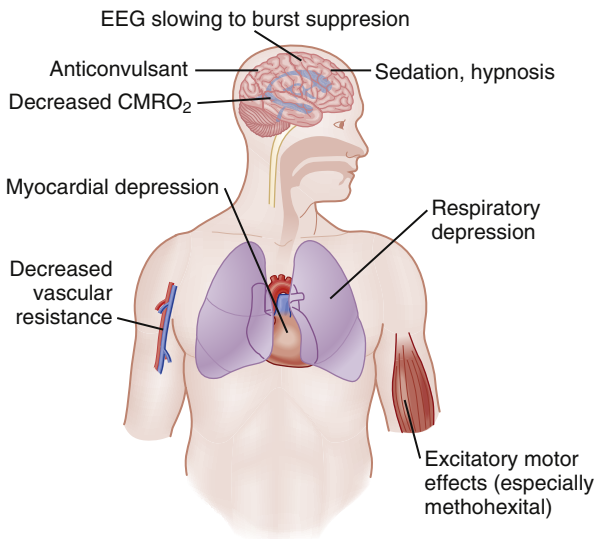
Propofol does not cause tissue damage when given intraarterially or when accidentally infiltrated into tissues.[37] However, it is associated with pain on injection, particularly when small veins are used. Some clinicians have recommended injecting 1% lidocaine into the intravenous catheter before beginning injection of propofol, and others have admixed lidocaine into the vial or syringe containing propofol.[38]

A recently identified adverse effect associated with the drug has been labeled "propofol infusion syndrome." It tends to occur with propofol infusions longer than 48 hours, but has also been reported after short-term infusions using large doses. The syndrome is characterized by the combination of metabolic acidosis, acute bradycardia and/or asystole, and rhabdomyolysis, and it can be fatal (see Figure 16-16). Although the mechanism is not entirely understood, it is thought to result from direct effects on mitochondria.[39]

Pharmacokinetics and Metabolism

Methohexital

The short clinical effects of methohexital are due largely to redistribution of drug, first to vessel-rich tissues, then to muscle, and finally to fat. The elimination phase, however, is long, with slow metabolism of the active drug given up by extravascular tissues (Table 16-3). Although it would be possible to keep a surgical patient asleep for many hours using incremental boluses or a continuous infusion of methohexital, the patient would remain obtunded for a lengthy period of time postoperatively owing to significant pooling of nonmetabolized drug in muscle and fat (Figure 16-17).



• **Figure 16-15** Clinical side effects of barbiturates. (Modified from: Garcia P: Intravenous anesthetics. In Hemmings HC, Egan TD, editors: *Pharmacology and physiology for anesthesia*, St Louis, 2013, Saunders, pp 137-158.)

Barbiturates, including methohexital, remain contraindicated in patients with inducible porphyria. Because methohexital induces the enzyme δ-aminolevulinic acid, porphyrin synthesis is increased, leading to increased production of heme and its precursors. In those with porphyria, this could lead to excessive accumulation of porphyrins and thus would exacerbate the disease.

Propofol

Propofol has a favorable pharmacokinetic profile because recovery from the drug is based on drug clearance and redistribution, not redistribution alone (see Table 16-2). There is a large volume of distribution and very rapid clearance as a result of rapid and efficient hepatic metabolism. At 30 minutes following a bolus dose of propofol, less than 20% of unchanged drug can be recovered from the serum.[40] Because propofol is metabolized so rapidly, there continues to be speculation that there are sites outside the liver where metabolism also occurs.[41] This rapid metabolism makes propofol an ideal drug for continuous-infusion anesthesia. When a propofol infusion is discontinued at the end of a 2-hour procedure, eye opening will occur within 5 minutes.[42]

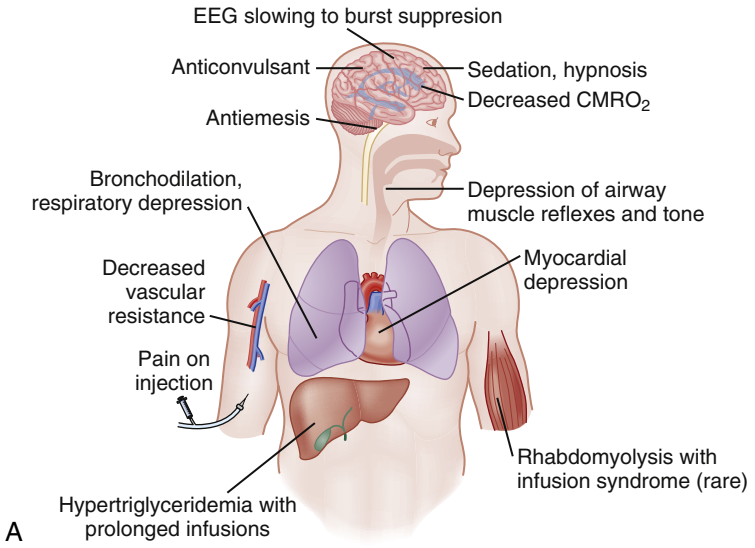
The quality of recovery also appears to benefit from this rapid metabolism. Patients who received propofol typically appear to be alert and clearheaded, often within 20 minutes of discontinuing the agent.[43] This subjectively favorable recovery may also be due to the euphorigenic properties of propofol, promoting positive mood changes and thus a better quality of recovery.[44]

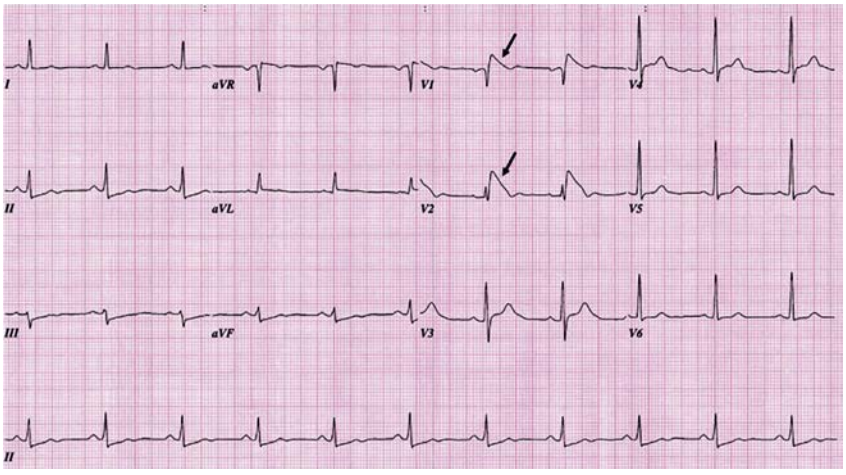
There is still concern regarding whether or not propofol can be used for patients with allergies to eggs or soy. Allergic reactions to food stems from an immune response to proteins or glycoproteins contained within that food. Until recently the propofol package insert only stated that a contraindication to the use of propofol was a "known hypersensitivity to propofol or its components." However, the FDA issued a labeling revision in February 2007 by adding a new caution regarding propofol infusion syndrome. The caution also became more explicit by stating that propofol is "contraindicated in patients with allergies to eggs, egg products, soybeans or soy products."[45] However, because the organic components (egg lecithin and soybean oil) are highly purified and protein free, it appears unlikely that propofol would trigger an allergic response even in a patient with an undiagnosed allergy to soy or eggs. The very low incidence of allergic reactions to all propofol preparations seems to bear this out, and the few reported cases of acute immune responses were usually characterized by co-administration of or sensitivity to other agents (e.g., muscle relaxants) that are more strongly associated with allergic reactions.[46]

Ketamine

Discovery and Development

Phencyclidine (PCP) was originally developed in the late 1950s for an analgesic screening program and was found to





• **Figure 16-16** **A,** Propofol produces many clinical side effects including myocardial depression. **B,** The electrocardiogram (ECG) shows sudden nodal bradyarrhythmia seen in propofol infusion syndrome. produce anesthetic effects in monkeys (see Figure 16-13). It was introduced as the intravenous anesthetic Sernyl for human clinical trials in 1957. Its effectiveness was hampered by a high incidence of postanesthetic emergence reactions. Agitation, excitement, delirium, and hallucinations were seen in a significant number of patients, and these unpleasant side effects led the investigators to abandon further clinical investigation. PCP (also known as "angel dust") is now solely a drug of abuse and is used specifically for its hallucinogenic effects.

Following the negative experiences with PCP, a search began for a PCP analog that would retain the anesthetic effects but with a reduced incidence of emergence phenomena. This led to the discovery of ketamine in 1963. Clinical trials of ketamine began in 1966, and the drug was

TABLE 16-3 Pharmacokinetics of Intravenous Agents

	Distribution Half-Life (min)	Elimination Half-Life (hr)	Clearance (mL/min)
Midazolam	7-15	2-4	300-550
Diazepam	3-10	20-40	15-35

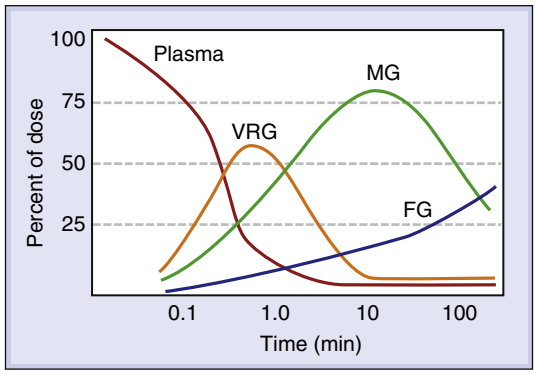
Propofol	2-4	1-3	1400-2800
Ketamine	11-17	2-3	1250-1400

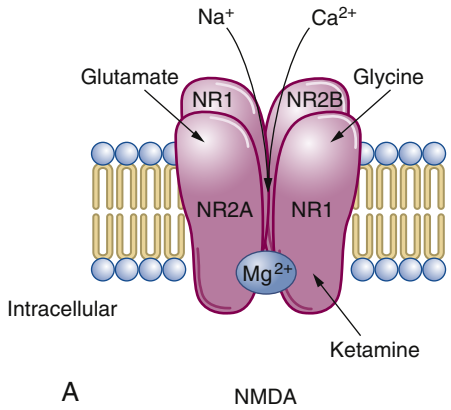


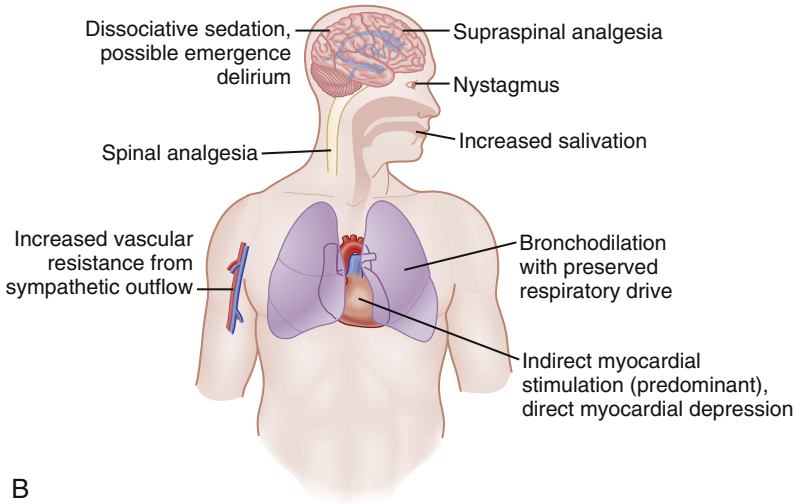
• **Figure 16-17** Distribution of methohexital occurs similarly to thiopental throughout the body over time. Body distribution includes plasma to the vessel-rich group (VRG; brain, heart, liver, kidney, endocrine glands), to the muscle group (MG), and finally to the fat group (FG). (Butterworth JF, IV, Mackey DC, Wasnick JD: Intravenous Anesthetics. In *Morgan & Mikhail's Clinical Anesthesiology,* ed 5, New York, 2013, McGraw-Hill, Chapter 9.)

introduced for clinical use as Ketalar in 1970. Although it has remained a cornerstone of veterinary anesthesia, there have been cycles of enthusiasm for its use in human anesthesia. Over the past decade, it has enjoyed a resurgence of popularity, particularly when used in lower doses and in combination with other intravenous anesthetics.

Structure and Activity

Glutamate is an excitatory neurotransmitter in the brain and is important for many higher CNS functions, including learning and memory. Glutamate receptors have multiple subtypes, of which the *N*-methyl-D-aspartate (NMDA) receptor is a cationic subtype (Figure 16-18, *A*). These receptors are found ubiquitously throughout the brain and spinal cord, but are concentrated more heavily at higher levels of the cerebral cortex. Glutamate, particularly in the presence of glycine, binds to the NMDA receptor and causes increased flow of sodium, potassium, and calcium, resulting in neural excitation.





C

Absolute Contraindications	Relative Contraindications	Relative Contraindications continued
Hypersensitivity to ketamine	Moderate to severe hypertension	Intracerebral mass or hemorrhage, Increased ICP
Open eye procedures	Ischemic heart disease	Eye injury, increased intraocular pressure, glaucoma
Acute porphyria	Congestive heart disease	Psychiatric disorders: schizophrenia, acute psychoses
Liver failure	Pre-eclampsia	Non-controlled hyperthyroidism
	History of CVA	Patients taking thyroxin
	Acute or Chronic Alcohol Intoxication	Cerebral trauma

• **Figure 16-18** Phencyclidine and ketamine. **A,** NMDA receptor is the binding site of ketamine. Once ketamine is bound, glutamate activity is inhibited and sodium, magnesium, and calcium cannot cross the cell membrane into the cell. **B,** Clinical side effects of ketamine. **C,** Absolute and relative contraindications to the use of ketamine. (Modified from Garcia P: Intravenous anesthetics. In Hemmings HC, Egan TD, editors: *Pharmacology and physiology for anesthesia*, St Louis, 2013, Saunders, PP 137-158.)

Ketamine is a noncompetitive antagonist of NMDA, thus inhibiting glutamate activity and causing CNS depression. There are other drugs that cause NMDA antagonism as well, including certain opioids (e.g., methadone) and the over-the-counter antitussive dextromethorphan. Ketamine is also thought to selectively bind to opioid receptors, possibly providing an explanation for the analgesic effects of the drug.[47]

Ketamine is a water-soluble racemic mixture of S(+) and R(–) isomers. Its antagonism of the NMDA receptor is stereospecific, with the S(+) enantiomer possessing a three- to fourfold greater affinity for the NMDA receptor and has greater dissociative potency than the R(–) form, thus making it more potent than the racemic mixture.[48] The R(–) form, in addition to being less effective, is also associated with a greater incidence of emergence phenomena. Hence there is increasing interest in the clinical use of S(+) ketamine for anesthesia, postoperative analgesia, and sedation. In 2004 a U.S. patent was granted for a process to isolate S(+) ketamine and, although it is not yet commercially available, S(+) ketamine offers promise for use in ambulatory anesthesia in oral and maxillofacial surgery.

Ketamine has partial affinity for opioid receptors and thus can cause analgesia by inhibition of excitatory transmission at spinal and supraspinal sites. Despite the implication of involvement of opioid receptors, it does not appear that ketamine analgesia can be predictably reversed by naloxone.

Clinical Effects

Ketamine is described as causing a functional dissociation of EEG activity between the hippocampus and the thalamoneocortical system. Other sedative-hypnotics act more specifically on discrete locations within the midbrain and brainstem.

Ketamine causes a profound dose-dependent analgesia. Because the analgesia occurs at subanesthetic doses and outlasts the anesthetic effects, ketamine becomes a useful adjunct for patients where it is not possible to achieve absolute local anesthesia (e.g., when maxillofacial infections require incision and drainage). The analgesic effect of ketamine is equal to that of opioids along with the benefit of less respiratory depression.

Ketamine is sympathomimetic through direct CNS stimulation, thus causing an increase in heart rate, cardiac contractility, and rate pressure product (see Figure 16-18, *B*). This can result in increased coronary and cerebral blood flow and increased intracranial pressure (see Box 16-1). Regarding electrical activity in the heart, ketamine has been variably described as causing arrhythmias and preventing them.

Ketamine causes a mild respiratory depression that is not usually of clinical significance except when very large doses are given rapidly. The brainstem response to hypercarbia is maintained, as is the functional residual capacity. Ketamine is a bronchodilator by relaxing smooth muscle as a result of its sympathomimetic effects. There is increased secretion from respiratory mucous glands and salivary glands.

Pharmacokinetics and Metabolism

Ketamine is metabolized in the liver by the cytochrome P450 system, and the metabolites are excreted in the kidney. The principle metabolite is norketamine, an active drug that has been described as being anywhere from one-third to one-tenth the potency of ketamine. There are three other minor metabolites, all of which are inactive.

Contraindications and Adverse Effects

Over the decades that ketamine has been available, the adverse effects receiving the greatest amount of attention are the psychoactive effects. These can range from mild confusion and distorted perceptions to paranoia, delusions, and hallucinations. These psychoactive effects occur more frequently in adults than children and more often in females than in males. They are also more common with large doses (>2 mg/kg IV) and rapid administration (>40 mg/min). Patients with preexisting personality disorders or psychiatric disease are at greater risk for these psychoactive effects.

A number of studies have addressed the incidence and prevention of these psychoactive effects. Some benefit has been found from informing the patient about possible vivid imagery and playing music during the anesthetic, and nitrous oxide may also diminish the severity. However, coadministration of BZDs is the single most effective method of suppressing or eliminating psychoactive effects.

Contraindications to ketamine include patient situations where the sympathomimetic effects could be dangerous: uncontrolled hypertension, unstable angina, recent myocardial infarction, open globe injury, poorly controlled congestive heart failure, and uncontrolled hyperthyroidism (see Table 16-3). Ketamine would also be contraindicated in the presence of intracranial trauma or an open globe injury. Ketamine should be avoided for patients with psychiatric disorders with a history of recreational drug use.

Inhalation Anesthetics

Discovery and Development

The story of the discovery of nitrous oxide has been published extensively in many texts and articles. In the late 1700s, Joseph Priestley had discovered a number of gases, among them oxygen and nitrous oxide. At the end of the 18th century, Sir Humphry Davy reported on the pharmacologic effects of nitrous oxide, describing its analgesic and mood-altering properties, yet over the 40 years that followed, nitrous oxide was not used therapeutically, but was mainly a source of amusement at demonstrations. It was not until Horace Wells, a dentist in Hartford, Connecticut, attended a nitrous oxide demonstration that the therapeutic effects of nitrous oxide were explored. Wells had witnessed a young man who, under the influence of nitrous oxide at a town demonstration, injured his leg and appeared unaware of the injury. This caused Wells to

wonder if exodontia could be performed painlessly using nitrous oxide. The following day Wells self-medicated with nitrous oxide and had a fellow dentist remove one of his wisdom teeth. Afterwards Wells reported there was no pain with the extraction. Wells was permitted to demonstrate a tooth extraction on a patient under the effects at Harvard in front of a group of students and faculty; however, because the patient cried out during the extraction, Wells was booed off the stage.

Around the same period of time there was development of and experimentation with other gaseous agents, including diethyl ether and chloroform. Over the next 80 years, these agents, along with nitrous oxide, were the only inhaled anesthetics available to support the growing practice of surgery under anesthesia.

In the 1920s, there began a new effort to design drugs based on structure–activity relationships. It was during this time that divinyl ether (Vinethene), a flammable agent, was synthesized. A decade later cyclopropane, another flammable agent, was introduced for use in anesthesia. However, the dangerous risks of fire and explosion made these agents less than ideal, and research continued. In 1951 a new, nonflammable compound called halothane was synthesized and introduced as Fluothane for clinical use in 1956. Shortly after, methoxyflurane (Penthrane) was introduced, followed by enflurane (Ethrane) in 1966 and its isomer isoflurane (Forane) in 1971. These agents became the mainstay of inhalation general anesthesia for the next two decades. Two newer agents have all but replaced these because of their superior pharmacologic properties: desflurane (Suprane) and sevoflurane (Ultane), introduced in 1993 and 1995, respectively.

Structure and Activity

The activity of all inhalation agents is based on diffusion of the gas from the alveoli into the bloodstream. The amount and speed of diffusion is determined by the partial pressure of the gas in the alveoli compared with that in the bloodstream. Once in the bloodstream, the amount of gas available to exert its pharmacologic effect is determined by the blood-gas solubility coefficient (i.e., the amount of gas that can be dissolved in blood). The more soluble the gas, the less active gas is present to exert its effect. This property also influences the rapidity of onset of an agent and the recovery from its effects. Of all the gases, nitrous oxide is the least soluble, providing a very rapid onset of action and recovery (Table 16-4).

At least two locations have been identified at which inhalation agents exert their analgesic effect: supraspinal opiate receptors in the brainstem and adrenergic receptors in the spinal cord.[49] The precise location at which inhalation agents produce unconsciousness and amnesia has not been identified, although proposed sites of action include the hippocampus and the thalamus.[50] There is sufficient evidence, however, to indicate that the potent inhalation agents (not including nitrous oxide) increase inhibitory transmissions via the GABA pathway by interaction with the GABA receptor. Nitrous oxide, it appears, interacts with and blocks NMDA receptors and does not have any activity at the GABA receptor.[51]

The potency of anesthetic agents is described by the minimum alveolar concentration (MAC), the alveolar concentration of anesthetic at which 50% of patients are unresponsive to a standard surgical stimulus (see Table 16-4). However, there is a lower concentration at which most patients will be asleep—this has been termed the MAC_{awake}, or the alveolar concentration at which 50% of patients are asleep. MAC can be affected by many factors, most notably co-administration of other anesthetics or sedative drugs.

Clinical Effects

Nitrous Oxide

Nitrous oxide is a weak general anesthetic but a powerful analgesic. It has been estimated that a 20% concentration of nitrous oxide affords the same degree of analgesia as a dose of 15 mg of morphine.[52] Nitrous oxide is also a euphorigenic agent and a sedative.

Nitrous oxide is poorly soluble in blood and tissues, thus making induction and recovery rapid. Within 5 minutes

TABLE 16-4 Physical and Chemical Characteristics of Inhaled Anesthetics

	Nitrous Oxide	Halothane	Isoflurane	Desflurane	Sevoflurane
Boiling pt (°C)	50.2	48.5	22.8	58.5

after induction, tissue saturation is 90% of inspired concentration. Upon discontinuation of the agent, 95% will be eliminated after 10 minutes.

This rapid diffusion of N_2O from blood to lungs can result in a decreased CO_2 arterial tension, thus causing decreased stimulus for respiration (Figure 16-19). This rapid diffusion dilutes alveolar O_2 as well with a resultant hypoxic gas mixture in the alveoli. This leads to a potential effect called diffusion hypoxia, a phenomenon that is more theoretical than clinically significant. However, it is recommended in many texts that patients should receive 100% oxygen (and not room air) for 5 minutes after nitrous oxide is discontinued.

Nitrous oxide causes a decrease in myocardial contractility, peripheral vascular resistance, cardiac output, and blood pressure. It causes a decrease in respiratory rate but an increase in minute ventilation because of increased tidal volume. There is no change in the CO_2 response curve.

At higher doses, nitrous oxide can cause nausea and vomiting through a central effect.

The toxic effects of nitrous oxide continue to receive attention, particularly because of the prevalent use of nitrous oxide in dental operatories. Chronic exposure can lead to peripheral neuropathies and bone marrow suppression through inactivation of the methionine synthetase pathway. Surveys have suggested an increased incidence of spontaneous abortion and decreased fertility in health care providers exposed to nitrous oxide on a regular basis.

Nitrous oxide diffuses into empty body cavities because it displaces nitrogen. This can create morbidity in the presence of emphysema, pneumothorax, an open globe, or following middle ear surgery.

Isoflurane

Isoflurane is an ether that is nonexplosive. Its blood-gas partition coefficient is 1.4, making it the most soluble of the current gases in widespread use. Its MAC with oxygen is 1.15%, and when used with 70% nitrous oxide, it is 0.5%. Compared with the older gases, such as halothane, it has greater respiratory depression but less myocardial depression and does not sensitize the myocardium to catecholamines. There is no kidney or liver toxicity, and only 0.4% is metabolized. Its pungency does not make it a good choice for an inhalation induction.

Desflurane

Because of its low boiling point, desflurane requires a special heated vaporizer. Its blood-gas coefficient is 0.42, providing a rapid onset and recovery from the anesthetic. It is also less soluble in tissues compared with the other inhalation agents. The MAC of desflurane is 6% when used with oxygen and 3% when used with 70% nitrous oxide. The usual maintenance concentration is 6% to 8%. The pungent odor of desflurane precludes its use for inhalation induction. Desflurane causes little change in heart rate and a mild decrease in systemic arterial pressure. It is metabolized significantly less than other inhalation agents and does not cause any organ-specific toxicity.

Sevoflurane

This agent is nonflammable and has an MAC of about 2% alone and 0.66% when used with nitrous oxide. The usual maintenance concentration is 2% to 3%. Sevoflurane is a good agent to use for inhalation induction and does not cause the coughing and breath holding associated with isoflurane or desflurane.

Sevoflurane depresses respiration at high concentrations and relaxes bronchial smooth muscle. It decreases systemic arterial pressure and cardiac output while causing little change in heart rate. Sevoflurane has been associated with increased EEG activity and seizure-like activity. Some metabolism (2%) occurs in the liver, and two of its metabolites include formaldehyde and fluoride, the latter of which has the potential to cause renal toxicity.

Sevoflurane is known to react with certain carbon dioxide absorbents used in breathing circuits (soda lime and Baralyme) causing formation of several breakdown products. The one most studied has been termed Compound A. During a lengthy anesthetic with sevoflurane, there may be enough accumulation of Compound A to cause nephrotoxicity. Ongoing research is aimed at identifying absorbents that do not interact with sevoflurane.

Conclusion

Several different types of anesthetics are used in the ambulatory setting for dental procedures. Each class, including benzodiazepines, opiates, ketamine, intravenous, and inhalation anesthetics, has a specific known binding site and mechanism of action. Most of these drugs have similar clinical side effects, but the unique side effects offer benefits during procedures with different subsets of patients with comorbid conditions. It is important to understand the known contraindications and be able to recognize the clinical side effects when administering these medications.

Anesthetic Concepts and Techniques

JEFFREY D. BENNETT, KEVIN BUTTERFIELD

Introduction

Providing office-based sedation, anxiolysis, and analgesia to the oral and maxillofacial surgery patient has been standard practice for decades. The goal has always been to establish an environment in which the patient is comfortable, cooperative, and hemodynamically stable. The focus has also been on rapid patient recovery with efficient use of time. Numerous advancements in pharmacology, equipment, and techniques over the years provide the surgeon with various alternatives. There may be several different adequate choices in regard to anesthetic agent or technique for a particular situation. Many surgeons have a standard technique, which works well for them for most situations. However, the standard anesthetic regimen may be inappropriate for a particular patient or situation, and the surgeon must avoid a reflexive thought process of using the same drug or technique for all patients or all surgical procedures.

Levels of Sedation

Anesthesia is a continuum from consciousness to general anesthesia. The recognized levels of sedation are minimal sedation (formerly referred to as anxiolysis), moderate sedation/analgesia (formerly referred to as conscious sedation), deep sedation/analgesia, and general anesthesia. The patient's responsiveness, airway maintenance, spontaneous ventilations, and cardiovascular function categorize these different levels or depths of sedation.

Minimal sedation is defined as a "drug induced state during which patients respond normally to verbal commands. Although cognitive function and coordination may be impaired, ventilatory and cardiovascular functions are unaffected."[1,2]

Moderate sedation/analgesia (which we refer to as moderate sedation) is defined as a "drug induced depression of consciousness during which patients respond purposefully to verbal commands, either alone or accompanied by light tactile stimulation. No interventions are required to maintain a patent airway, and spontaneous ventilation is adequate. Cardiovascular function is usually maintained."[1,2]

Deep sedation/analgesia (which we refer to as deep sedation) is defined as a "drug induced depression of consciousness during which patients cannot be easily aroused but respond purposefully following repeated or painful stimulation. The ability to independently maintain ventilatory function may be impaired. Patients may require assistance in maintaining a patent airway, and spontaneous ventilation may be inadequate. Cardiovascular function is usually maintained."[1,2]

General anesthesia is defined as a "drug induced loss of consciousness during which patients are not arousable, even by painful stimulation. The ability to independently maintain ventilatory function is often impaired. Patients often require assistance in maintaining a patent airway, and positive pressure ventilation may be required because of depressed spontaneous ventilation or drug induced depression of neuromuscular function. Cardiovascular function may be impaired."[1,2]

These levels of sedation are not dependent on the route of drug administration nor the specific anesthetic agent or combination of agents administered. For example, given a large enough dose or a more typical dose in a medically compromised patient, an oral benzodiazepine could induce a level of moderate to deep sedation/analgesia. Various oral agents (e.g., benzodiazepines or chloral hydrate) when coadministered with nitrous oxide have produced more profound levels of sedation, inducing deep sedation/analgesia or general anesthesia.[3,4] Alternatively, propofol and methohexital, which are commonly associated with deep sedation/analgesia and general anesthesia, can be administered so as to produce levels of sedation that range from minimal sedation to moderate sedation/analgesia.

Goals of Sedation

The goals of sedation are to: (1) provide an optimal environment for completion of the surgical procedure, (2) minimize patient anxiety and optimize patient comfort, (3) control

the patient's behavior and movement and optimize patient cooperation, (4) optimize analgesia and minimize patient discomfort and pain, (5) maximize the potential for amnesia, and (6) optimize patient safety and maintain hemodynamic stability. Each situation (involving the patient and the specific surgical procedure) is independently evaluated to determine the depth or level of sedation required to achieve these goals.

The sedation of a child is different from that of an adult. For the young child, who lacks coping capability and social adaptability, the primary goal is to control the child's behavior and movement and to optimize patient cooperation. This differs from that of an adult patient, where the primary goal is to minimize patient anxiety and optimize patient comfort. Because of the different goals, the child frequently will require a greater depth of anesthesia. Alternatively, if moderate or deep sedation is used instead of a general anesthetic for the management of the pediatric patient, the practitioner will need to have a different level of tolerability. For example, the practitioner must be willing to accept some crying and possible movement that may require minimal restraint if moderate sedation (or possibly deep sedation) is planned for a pediatric patient.

The practitioner must also select which medications will be used to achieve the anesthetic plan. Although specific medications, such as propofol, may more commonly be used to achieve an anesthetic depth of deep sedation or general anesthesia, all of the anesthetic drugs that are used for "lighter" levels of anesthesia, such as minimal sedation, can result in effects associated with deep sedation or general anesthesia. Alternatively, in appropriate doses, propofol can be titrated to achieve a level of moderate sedation. The dissociative state resulting from ketamine provides a favorable surgical environment in which the patient becomes relatively immobile while maintaining an intact and stable airway. The desire to incorporate the drug into every technique needs to be weighed against an understanding of the drug's sympathetic effect. For example, injudicious use of the drug in a cardiovascularly compromised patient or a patient on a tricyclic antidepressant can have unfavorable consequences. In the former, the increased sympathetic stimulation can negatively affect the myocardial imbalance of oxygen supply and demand, and in the latter the patient may have prolonged sympathetic effects because of the interaction of the two drugs.

Concept of Rescue

There is a prevailing thought in medicine that human errors are inevitable and that these errors are not necessarily due to incompetence. An American Society of Anesthesiologists (ASA) closed claims analysis reported that up to 80% of anesthetic mishaps could have been prevented and were attributable to human error.[5] The concept of rescue therefore is essential to safe sedation. The office-based environment cannot be dependent on emergency medical services (EMS) as the primary intervention for adverse events. The office must be equipped and the staff able to manage the most serious of adverse events. The first line in preventing an adverse event is prevention. This has two components: (1) preoperative assessment and (2) ensuring that the practitioner who is administering the anesthetic is trained and capable of rescuing the patient from a deeper level of sedation than was initially planned.

Preanesthetic assessment is the focus of a separate chapter. However, there are a few points that I would like to emphasize here. The preanesthetic or preoperative assessment is the process in which the practitioner ensures that the patient is fit for anesthesia and surgery. The aim of the assessment is to obtain a good medical history and complete a focused physical examination. The medical history alone reveals up to 90% of the needed information. Two distinct types of office-based surgery practices exist among our oral and maxillofacial surgery colleagues: those who perform this preanesthetic assessment solely on the day of surgery; and those who perform this on a separate appointment before the scheduled surgery date. There are a few advantages to the latter methodology: (1) the ability to assess the patient's level of anxiety and provide psychological intervention either behaviorally or pharmacologically and (2) the ability to modify and direct treatment based on the patient's medical history (e.g., management of long-term medication, such as what medications should be taken and what should not be taken on the day of surgery).

Rescue therapies require continuous and repeated training to ensure a level of skill and knowledge. This is particularly important in an environment, such as the oral and maxillofacial surgery office, in which significant adverse events rarely occur. Several measures can be taken by the practitioner to prevent the occurrence of an adverse event or minimize its undesirable consequences. The practice of ambulatory office-based anesthesia in the oral and maxillofacial surgeon's office emphasizes team management. The concept of team management has been shown to optimize performance and minimize errors in medicine.[6,7] In addition, the practitioner and the anesthetic team should prepare for anesthetic care like a flight crew. Using this comparison, the anesthetic team must be comfortable and familiar with the anesthetic equipment. If the equipment is new to their office, this may entail a more detailed review to ensure familiarization. If the equipment is older, although the office may be familiar and fairly comfortable with it, its inspection must focus on potential effects resulting from age and ensure that it remains optimally functional. This requires a protocol in which the equipment (whether used for routine care or emergency intervention) is regularly inspected and the anesthetic team has the opportunity to practice with it. The latter point emphasizes the other concept in training and performance testing among pilots. Pilots use simulators to artificially create a scenario that is analogous to real life. Simulators can provide scenarios that represent normal anesthetic management and emergency situations. The ability to represent emergency situations is of particular interest because many individuals may never encounter a particular

emergency until they must deal with it during actual clinical patient care.

There are four different types of simulators: screen-based text simulators, screen-based graphical simulators, mannequin-based simulators, and virtual reality simulators. The mannequin-based simulator includes an anatomically correct physical model of a patient. The mannequins vary in complexity. The level of mannequin sophistication may allow the trainee to ventilate and/or intubate the mannequin, auscultate heart and lung sounds using anatomically placed speakers, assess respiratory efficacy by measuring end-tidal CO_2 and pulse oximetry, palpate carotid and radial pulses, and establish intravenous (IV) access. These simulators have been shown to enhance skills without endangering the health of patients.[8] They facilitate acquisition of knowledge and skills that are transferable back to clinical care. However, the mannequin simulators are expensive and lack easy portability. The screen-based graphical simulators attempt to visually recreate the clinical environment. The simulation programs provide physiologic data (such as heart rate, blood pressure [BP], electrocardiogram [ECG], oxygen saturation, and end-tidal CO_2), provide patient interaction (such as patient responses to preset questions), allow responses to physical examination (such as breath or heart sounds or level of responsiveness), and provide realistic responses to drug administration based on the pharmacokinetic and pharmacodynamic properties of the medications. Two studies completed at the University of Washington demonstrated that those trained using the screen-based graphical simulator demonstrated better retention and better application of skills and knowledge than those who used a text solely.[9,10]

Airway Assessment

Assessment of the airway is one of the most critical components of the preoperative assessment. This is exemplified by two separate ASA closed claims analysis publications that reported respiratory adverse events as the most common mechanism of injury to the patient. Forty-one percent of these claims were for death or permanent brain damage. The incidence of respiratory adverse events, most of which were inadequate oxygenation/ventilation, was comparable between monitored anesthesia care and general anesthesia.[11,12] The first step in preventing these adverse respiratory events is to identify a potential difficult airway.

Airway assessment consists of both history and examination. The history obtained from the patient should inquire about prior surgeries on the airway or difficulties with airway management during prior surgeries. The examination component of the assessment focuses on several anatomic components to the airway that can predict difficult airway management: (1) modified Mallampati test, (2) thyromental distance, (3) mandibular retrognathia, (4) interincisal opening less than 3 cm, (5) short neck, (6) thick neck (increased neck circumference of 17 inches for males and 16 inches for females), and (7) diminished range of motion of head and neck with the inability to extend or flex the neck (such that the tip of the chin can touch the chest). The modified Mallampati test assesses the airway based on the ability to visualize the uvula and faucial pillars when the mouth is wide open, the tongue is maximally protruded, the neck is extended forward into the sniffing position, and the patient phonates. The modified Mallampati classification has five categories that are defined in Table 17-1, with the higher class supposed to predict greater difficulty in intubation.

TABLE 17-1 Mallampati Classification

Class 0	Ability to see any part of the epiglottis on mouth opening and tongue protrusion
Class 1	Soft palate, fauces, uvula, anterior and posterior pillars seen
Class 2	Soft palate, fauces, and uvula seen
Class 3	Soft palate and base of uvula seen
Class 4	Soft palate only seen

The thyromental distance is a measurement from the mandibular menton to the prominence of the thyroid cartilage with the neck in full extension. The distance should be at least 6 cm or approximately three ordinary fingerbreadths. These tests were initially proposed, and most studies to date have investigated their ability to predict difficult intubations. Used independently, none of these tests was sufficient to consistently predict the difficulty of airway intubation.[13] Combining several different tests (such as the Mallampati test and the thyromental distance) to assess a patient's ease of intubation did result in a higher sensitivity, higher positive predictive value, and fewer false-negative results.[14] Because most office-based anesthesia for oral and maxillofacial surgery is done on the nonintubated patient, we are actually more interested in the ability to ventilate and to maintain airway patency than we are in the ability to intubate a patient. There are fewer studies assessing the ability to ventilate a patient or maintenance of airway patency. The incidence of being unable to ventilate a patient is approximately 5% of the general adult population. The Mallampati test was found to be no better in predicting difficult mask ventilation than difficult airway intubation. One publication did show a correlation in difficulty in mask ventilation among patients who were difficult to intubate[15] (Box 17-1).

Maintaining airway patency in the nonintubated patient is always potentially a risk because operating in the oral cavity can result in airway obstruction secondary to such factors as the positioning of the mandible, head-neck flexion-extension, or posterior displacement of the tongue. The above criteria provide some guidance as to the level of sedation, which would be appropriate or inappropriate for a particular patient in regard to the potential for airway difficulty. The surgeon may decide to manage the patient with significant findings with a minimal sedation in the office

• BOX 17-1 Difficult Mask Ventilation Predictors

Edentulousness
Lingual tonsil hypertrophy
Macroglossia
Skeletal abnormalities (e.g., retrognathia)
Poor atlanto-occipital extension
Facial hair
History of snoring
History of obstructive sleep apnea
BMI >26 kg/m^2

or may plan on using advanced airway techniques (either a laryngeal mask airway [LMA] or intubation) either in the office or in a hospital or surgery center. If the potential for a difficult airway is recognized, then appropriate preparations can be made to increase the likelihood of a good outcome. The complexity with the ability to predict a difficult airway lies not with the extremes of the assessment criteria but with those patients who fall in the middle. Other factors, such as obesity, history of snoring, abnormal oropharyngeal or neck masses, prior airway surgeries, or congenital, developmental, or acquired facial deformities (e.g., craniofacial syndromes, burns to the head and neck) may provide further guidance.

Obesity warrants further comment because its incidence is rapidly increasing in the United States, with a 2012 incidence in children and adolescents that is approximately 15% and in adults that approaches 40%. Physical findings previously discussed that are found in the obese patient include a decrease in cervical and mandibular range of motion, a decrease in thyromental distance, and a less favorable Mallampati class. The patient's airway is more likely to collapse during anesthesia, and the distribution of tissue in the patient's neck and chest will complicate airway management. This is compounded by the fact that the patient is more susceptible to developing hypoxemia or hypercapnia because of restrictive lung disease (an increased chest wall mass decreases chest wall compliance and diaphragmatic excursion), increased closing volume, and ventilation-perfusion mismatch. There is also a higher incidence of obstructive sleep apnea (OSA) in the obese patient. It is estimated that OSA is undiagnosed in 80% of patients who have the condition (Table 17-2). This extends the concern with airway and respiratory management beyond the intraoperative period into the postoperative period. The literature is insufficient to evaluate the effects of various analgesic medications on OSA. These patients will benefit from multimodal analgesic techniques (e.g., preemptive nonsteroidal anti-inflammatory) and minimization of opioids, and their respiratory depressant effects will most likely reduce the potential for adverse events.[16] The ASA guidelines suggest that the "OSA patient be monitored for a median of 3 hours longer than their non-OSA counterparts before discharge from the facility."[17]

TABLE 17-2 STOP BANG Questionnaire

Read the following questions and check Yes or No.	Yes	No
1. *S*noring: Do you *s*nore loudly (louder than talking or loud enough to be heard through closed doors)?		
2. *T*ired: Do you often feel *t*ired, fatigued, or sleepy during daytime?		
3. *O*bserved: Has anyone *o*bserved you stop breathing during your sleep?		
4. Blood *P*ressure: Do you have or are you being treated for high blood *p*ressure?		
5. *B*MI: *B*MI more than 35 kg/m^2?		
6. *A*ge: *A*ge over 50 yr old?		
7. *N*eck circumference: *N*eck circumference greater than 40 cm?*		
8. *G*ender: *G*ender male?		

High risk of obstructive sleep apnea (OSA): answering yes to three or more items
Low risk of OSA: answering yes to less than three items
*Neck circumference is measured by staff.

Laryngeal Mask Airway

Traditional anesthetic management for intraoral surgery is unique in that the surgical site is contiguous with the unprotected nonintubated airway. The patient is susceptible to airway obstruction, airway irritation, and hypoventilation or apnea. This can necessitate surgical interruption to manipulate the airway to eliminate the obstruction and establish airway patency. This may be as easy as readjusting the pharyngeal curtain or performing a head-tilt maneuver. Various interventions may also be required to remove airway irritation. These could likewise include repositioning the pharyngeal curtain, which could be an irritant to the pharynx, or suctioning the pharynx of some irrigating solution that may have passed beyond the pharyngeal curtain. Rarely, the patient may require positive pressure ventilation.

The LMA forms an intermediate form of airway management between the face mask and the endotracheal tube. For intraoral surgery, it provides the ability to obtain, maintain, and secure a patent airway. The advantage of the LMA is that it is passed beyond the tongue, forming a seal with the laryngeal inlet and eliminating the most common cause of upper airway obstruction in the nonintubated patient. Because there is not a direct conduit into the trachea as achieved with endotracheal intubation, there is a potential for airway obstruction, which has been reported as high as 30%. This obstruction generally responds to head repositioning with no need to reposition the LMA or interrupt surgery. Breathing may be spontaneous, assisted, or

controlled with the LMA, avoiding the need to interrupt surgery to provide positive pressure ventilations. The LMA is also an excellent barrier against aspiration of irrigating solution, surgical debris, and blood. A pharyngeal curtain, however, is recommended to keep any surgical debris contained within the oral cavity and minimize the potential for aspiration of surgical debris when the LMA is removed.

General anesthesia is indicated when using the LMA. Using the standard technique, the LMA is inserted blindly after induction of general anesthesia. The blind insertion technique, which requires less airway manipulation compared with intubation, is associated with less sympathetic stimulation and potential hemodynamic fluctuations. Campbell and colleagues recommend laryngoscopy and direct visualization of LMA insertion as an alternative to optimize anatomic placement and minimize the epiglottis from impinging on the glottic opening.[18] Theoretically, this should improve airflow dynamics. These authors reported that the brief laryngoscopy for LMA placement did not adversely result in sympathetic stimulation and hemodynamic changes. Neither the blind nor the laryngoscopic insertion technique require neuromuscular blockade. The LMA is also advantageous compared with endotracheal intubation in that its anesthetic requirements during both maintenance and emergence are less.

Smoking

Approximately one quarter of the U.S. adult population smoke cigarettes.[19] Cigarette smoking is a cause of increased perioperative morbidity. This may be secondary to the chronic diseases associated with smoking, such as ischemic heart disease and chronic obstructive pulmonary disease. The constituents of cigarette smoke, such as nicotine and carbon monoxide, also have acute effects on both the cardiovascular and respiratory systems.

From a cardiovascular perspective, nicotine activates the sympathoadrenergic system. This increases heart rate, blood pressure, peripheral resistance, and oxygen demand. Expired carbon monoxide levels have also been shown to correlate with ST depression under general anesthesia.[20] Cigarette smoking also promotes a hypercoagulable state, contributing to arterial thromboembolism and coronary vasospasm.

Effects on the respiratory system include impaired mucociliary clearance and mucous hypersecretion, which results in increased airway irritability. This may be manifested clinically by a higher incidence of laryngospasm and airway obstruction. Small airway narrowing contributes to increased closing capacity, which results in ventilation-perfusion mismatch. Cigarette smoking also increases the blood carbon monoxide level and a leftward shift in the oxygen-hemoglobin dissociation curve. The increase in the carboxyhemoglobin level (8% to 10%) results in less oxygen being carried by hemoglobin. The leftward shift in the oxygen-hemoglobin dissociation curve results in less oxygen being released to the peripheral tissues. The net effect is a decrease in tissue oxygenation. Passive smoke exposure has also been shown to be a risk factor in children contributing to airway complications (laryngospasm ~5 times greater and airway obstruction ~3 times greater) during the intraoperative and postoperative period.[21]

Smoking can also have a detrimental effect on wound healing, including wound dehiscence, infection, and impaired bone healing.[22] This may be secondary to effects on the immune system or changes in tissue oxygenation.

Patients are usually counseled to stop smoking during the perioperative period. To achieve the greatest benefit from this counseling, the period of smoking cessation should be at least 6 to 8 weeks. The benefit from abrupt cessation before surgery is related to the half-life of nicotine and carboxyhemoglobin, which are 2 hours and 4 hours, respectively. The elimination of nicotine and carboxyhemoglobin decreases adrenergic stimulation, minimizing adverse cardiovascular effects, and increases both the oxygen-carrying ability of the blood and the amount of oxygen released to the peripheral tissues, resulting in increased tissue oxygenation. Overnight abstinence from smoking is beneficial, however, as the half-life of both nicotine and carboxyhemoglobin can be prolonged during sleep; a 24-hour "cigarette smoke-free" period is preferable.[23]

There has been controversy over smoking cessation beyond the initial 24 hours and a 6- to 8-week period. This controversy focuses on a paradoxic effect in which there is a transient increase in airway secretions and airway irritability associated with smoking cessation. This concept is best understood by recognizing that many smokers complain of increased airway secretions and airway irritability during the first several weeks after smoking cessation. Anesthetically, it is best to appreciate that it takes several weeks for the reduction in pulmonary complications to be apparent. During this time there may be a slight but not significant increase in pulmonary complications seen in anesthetized patients.[24,25]

The polycyclic hydrocarbons present in cigarette smoke are potent inducers of liver enzymes. Smoking cessation decreases these metabolic enzymes, potentially increasing blood levels of drugs that interact with the cytochrome P450 pathway. Coumadin is one drug that is metabolized by the affected enzymes, which may result in increased postoperative bleeding. Interestingly, postoperative nausea and vomiting are less in smokers. This may be attributed to the induction of liver enzymes. These enzymes may be responsible for the metabolization and excretion of various chemicals that may affect postoperative nausea and vomiting.[26]

Preoperative Fasting

The concept behind preoperative fasting is to minimize the risk of pulmonary aspiration, which may result in laryngospasm, chemical pneumonitis, or partial or complete airway obstruction as a result of particulate matter. The concept dates back to the mid-1940s, when Mendelson (who was an obstetrician) described a series of patients undergoing general anesthesia for vaginal delivery in which he documented respiratory complications secondary to

aspiration. He noted two distinct situations: (1) aspiration of particulate matter resulting in obstruction and (2) aspiration of liquid gastric contents resulting in dyspnea and cyanosis consistent with what is now referred to as aspiration pneumonitis.[27] Since this report, subsequent studies have sought to determine the minimum pH and volume of the aspirate. A pH less than 2.5 is associated with pathologic changes. The actual residual gastric volume associated with aspiration is more difficult to determine because not all regurgitated fluid is aspirated. A classic study suggested that a volume of 0.8 mL/kg with a pH of less than 2.5 when directly instilled into the trachea produces aspiration pneumonitis.[28] Other authors have suggested that this equates to a residual gastric volume of greater than 200 mL for passive regurgitation and pulmonary aspiration to occur during anesthesia. Gastric volumes of this magnitude may be found, but they are not normal. The typical residual gastric fluid volume in a patient fasted more than 8 hours for solids and 2 hours for clear liquids should be less than 30 mL.[29]

The basic premise of preoperative fasting is to minimize the volume and the acidity of the residual gastric fluid. The ASA adopted new fasting guidelines in 1999. A basic knowledge of gastric emptying times facilitates an understanding of these modifications. Gastric emptying for solid food is variable. A surgeon should be aware that approximately 50% of the contents of an ingested solid meal will remain in the stomach after 2 hours. Alternatively, gastric emptying for liquids is rapid, with a mean half-time of 10 minutes. Approximately 80% of ingested clear liquid will have passed into the duodenum after the first hour.

The current ASA recommendation allows the consumption of clear liquids up to 2 hours before the anesthetic. It is recommended that an individual fast for a minimum of 6 hours after the consumption of a "light meal" (e.g., toast, and avoidance of fat-containing solids and liquids) and up to 8 hours after the consumption of "fatty" solids.[30] The advantage of allowing clear liquid consumption up to 2 hours before the anesthetic is that it minimizes the risk of dehydration and hypoglycemia. It also decreases the potential for noncompliance and patient irritability (especially among children).

A preoperative evaluation assessing for comorbidities may result in a modification of the general guidelines of 2 hours with nothing by mouth (NPO) for clear liquids and 6 hours NPO for a "light meal." There are numerous situations that may delay gastric emptying: high sympathetic tone as a result of pain and anxiety, opioid use, cigarette smoking, cannabinoids, and functional dyspepsia. Several clinical conditions are associated with gastroparesis: diabetes mellitus, systemic lupus erythematosus, lack of coordination of swallowing or respiration, functional or mechanical obstruction to digestion, gastroesophageal dysfunction, Parkinson disease, and anorexia or bulimia. Of these, diabetes is the most commonly associated with gastroparesis. In the diabetic patient, the delay in gastric emptying is more significant for solids than for liquids. Obese patients do not present an increased risk for aspiration as a result of acidity and gastric volume, but have a higher incidence of difficulty in airway management with the potential for resultant gastric distention that may translate into an aspiration risk.

The use of gastrointestinal stimulants (e.g., metoclopramide), histamine-2 receptor antagonists (e.g., cimetidine), nonparticulate antacids (e.g., sodium citrate), and antiemetics to reduce the risk of aspiration is not routinely recommended in patients who have no increased risk of aspiration.

Fluid Administration

Total body water is approximately 60% of total body weight. It exists in two major compartments: intracellular and extracellular. Two thirds of the total body water is compartmentalized into the intracellular space, and the remaining one third is compartmentalized into the extracellular space. The extracellular compartment is further subdivided into intravascular and extravascular compartments. The intravascular compartment consists of one fourth of the extracellular body water or one twelfth of the total body water.

Sodium and chloride are primary extracellular electrolytes. These electrolytes are not diffusible between compartments. The distribution of free water is dependent on ionic and osmotic pressures.

Understanding fluid compartmentalization is critical to understanding intraoperative fluid administration. The administration of a hypotonic solution, such as D_5W, will result in a rapid redistribution of free water with only one twelfth of the water remaining in the intravascular space. Alternatively, the administration of an isotonic solution, such as 0.9% normal saline, will result in a preferential distribution of the fluid within the extracellular space. The fluid will remain within the intravascular compartment for 15 to 30 minutes before equilibration within the extracellular compartment. This provides the advantage of countering the vasodilatation secondary to the anesthetic agents.

The use of D_5W or the inclusion of dextrose in the intraoperative IV fluid is controversial for other reasons as well. The perioperative period is usually associated with a transitory hyperglycemia secondary to the release of the hormones: epinephrine, cortisol, and glucagon. The infusion of a dextrose solution may intensify the hyperglycemia. In the event of hypoxemia and anaerobic metabolism, the hyperglycemia will result in increased carbon dioxide production and intracellular lactic acidosis, potentially worsening neurologic injury associated with the hypoxemia.[31,32] The foregoing is relevant in regard to resuscitation of the trauma patient and fluid management for major surgery. It also has relevance in the event of resuscitation of a patient in the office. However, for dentoalveolar surgery, a minor risk surgical procedure as defined by the AHA/ACC, the stress induced hyperglycemia is transitory and can be followed by a period of hypoglycemia.[33] The postoperative hypoglycemia may be compounded by limited caloric intake during

this period because of local wound discomfort and soft tissue swelling that compromise the patient's ability and desire to take postoperative fluids.

Perioperative fluid administration for office-based surgery consists of the administration of crystalloid solutions (e.g., 0.45% saline, 0.9% saline, D_5/0.45% normal saline, D_5/0.9% saline). In minor surgery, there is no concern about fluid loss or fluid shift; however, fluid administration provides the ability to correct the preexisting fluid deficit secondary to preoperative fasting guidelines. Rehydration of the patient's fluid deficit during the perioperative period has been shown to improve the "quality" of recovery.[34] The fluid deficit can be calculated using the formula for maintenance requirements, which is 4 mL/kg/hr for the first 10 kg, 2 mL/kg/hr for the second 10 kg, and 1 mL/kg/hr for each additional kilogram. For a 70-kg lean individual who has fasted 8 hours (between midnight and 8 AM), the fluid deficit approximates 1 L. Whereas the current fasting guidelines allow unrestricted clear fluid consumption up to 2 to 3 hours before surgery, there are many patients who for various reasons have a 1- to 2-L fluid deficit. For office-based anesthesia in the healthy patient, it would be reasonable to administer 500 to 1000 mL of a crystalloid solution instead of using the IV access solely as a route of drug administration. Considering the patient's potential limited ability to take sustenance postoperatively, the administration of a 1-L dextrose-supplemented 0.45% or 0.9% saline solution could provide approximately 250 kcal of carbohydrate energy.

Whereas the preceding paragraph focuses on the recommendation to adequately rehydrate a patient, the practitioner must also be cognizant of excessive fluid administration. Most practitioners will be attentive to a patient who has a history of a systemic disease that requires fluid restriction, such as congestive heart disease. Special consideration must be given to the young pediatric patient. Overhydration can occur with any solution; however, with a hypotonic solution (such as D_5W), overhydration can rapidly result in cerebral edema and significant morbidity or patient mortality. This is merely another reason to consider administering either maintenance or replacement fluids (e.g., 0.45% or 0.9% normal saline). Prevention of overhydration can also be minimized by using a microdrip infusion set in the pediatric patient.

Anesthetic Techniques in Office-Based Anesthesia

The guiding principle of ambulatory anesthesia for office-based oral and maxillofacial surgery is to achieve adequate anxiolysis, sedation, amnesia, analgesia, and hemodynamic stability, so as to provide for a safe surgical environment resulting in rapid recovery and discharge of the patient home. There are several controversial aspects to anesthetic technique management. In this section, we focus on depth of anesthesia monitoring, anesthetic delivery techniques (bolus vs. continuous infusion), and choice of anesthetic agents or combinations.

Depth of Anesthetic Monitoring

When anesthetizing a patient in the office, the desired depth of anesthesia is most commonly assessed by subjectively assessing the patient's movements and facial expressions or lack thereof and objectively assessing the patient's respiratory (respiratory rate and oxygen saturation) and cardiovascular (blood pressure, pulse, and rhythm) function and stability. The anesthetic plan may be driven simply to achieve patient comfort and cooperation. Alternatively, the anesthetic plan may be dictated by the intent to maintain a specific anesthetic depth. Several factors influence the selection of the anesthetic plan: the patient's desired depth of anesthesia or lack of awareness; the surgeon's desired depth of sedation or amnesia; the surgical procedure; and/or the patient's systemic health.

Awareness with intraoperative recall is a major concern for all surgeons and anesthesiologists. Without minimizing the problem of intraoperative awareness, the situation is different in the intubated patient compared with the nonintubated patient. Awareness is frightening in the intubated patient because of a lack of ability to communicate both their awareness and inadequate anesthetic depth. For the nonintubated patient who always maintains the ability to communicate, there are different potential problems. For a planned general anesthetic, how does the surgeon optimally assess the anesthetic depth of a patient who appears relaxed, comfortable, eyes closed, and hemodynamically stable without unnecessarily administering an excess of anesthetic agent, which can be associated with adverse effects and delay recovery, or administer inadequate anesthetic agent such that the patient comments that they were awake despite appearing very comfortable and asleep?

The bispectral index (BIS) is a monitor that focuses on changes in the electroencephalogram (EEG) and uses an algorithm to assign a linear dimensionless number that correlates with anesthetic depth (Table 17-3). For the agents frequently used in oral and maxillofacial surgery (propofol, midazolam), BIS is relatively agent independent. However,

TABLE 17-3 Correlation of Bispectral Index (BIS) Value with Sedation Level

BIS Value	Sedation Level
100	Awake
70	Light hypnotic effect Low probability of recall
60	Moderate hypnotic effect Unconscious
40	Deep hypnotic effect

BIS is not entirely agent independent and does not reflect the clinical effects of ketamine or nitrous oxide in addition to the low dose of opioids generally used for office-based oral and maxillofacial surgery.[35] As many surgeons use nitrous oxide in combination with IV agents, and ketamine is making a resurgence as a component of the anesthetic cocktail in oral and maxillofacial surgery practices, BIS monitoring has clear limitations. In addition, there is individual variation in BIS's correlation with clinical indices of sedation, which may make it less accurate for any particular patient.[36] Sandler and colleagues have demonstrated the use of BIS in oral and maxillofacial surgery.[37] Although these studies demonstrated a strong positive relationship between BIS and the Observer's Assessment of Alertness and Sedation Scale (OAA/S) and a trend toward earlier return of motor function, they also showed a lack of correlation between BIS and the OAA/S at deeper levels of sedation consistent with deep sedation and only a trend toward earlier recovery. Periods of more intense stimulation balanced by less stimulating periods and relatively brief surgical procedures, which are not atypical for dentoalveolar surgery, may further limit BIS effectiveness in this environment.

Even if BIS is demonstrated to reliably define depth of sedation, what impact would this have on anesthetic management in the oral and maxillofacial surgery office? To use less drug and to expedite recovery, would the goal be to maintain a level of general anesthesia that is close to the transition between general anesthesia and deep sedation? Would titration of anesthesia to this specific zone increase the risk of the patient transitioning to a level of anesthetic excitability with its inherent risks? Alternatively, for the nonintubated patient who appears to be at an appropriate anesthetic depth and is dependent on spontaneous ventilation, would it be more appropriate to monitor ventilations and oxygen saturation in conjunction with clinical assessment of anesthetic depth or titrate the anesthetic agents based on BIS monitoring? Could administering anesthetic medications based on BIS readings potentially result in a patient who no longer maintains adequate ventilations or a patent airway? The literature is inadequate in regard to BIS analysis demonstrating that it optimizes anesthetic management and that it decreases anesthetic morbidity and mortality when incorporated into anesthetic care for the typical office dentoalveolar surgical procedure.

The preceding discussion focuses on the use of BIS in monitoring a deep sedation/general anesthetic. BIS may have more benefit in monitoring a patient with moderate to deep sedation for a prolonged procedure. The goal would be to maintain a BIS value between 70 and 80, which would correlate with eyelid ptosis and patient response only to loud or repeated calling of their name or mild prodding or shaking. A deviation outside these values would suggest a level of anesthesia either too light or too deep, warranting additional administration of the bolus agent, an increase or decrease in the continuous infusion, and/or more attentive monitoring to ensure airway patency and spontaneous ventilations.

Additional controversy focuses on BIS cost effectiveness. There is a cost for each unit and the disposable electrodes that may not be countered by the reduced anesthetic agent and ability to discharge the patient more rapidly. Obviously the questions raised cannot be taken individually, and a multitude of factors need be used in optimizing anesthetic management.

Anesthetic Delivery Technique and Choice of Anesthetic Agents or Combinations

Rapid recovery and early return to preoperative function are fundamental principles in ambulatory anesthesia. Pharmacokinetic and pharmacodynamic properties of many of the current IV and inhalational anesthetic agents facilitate these objectives. This section focuses on techniques of administration and choice of agent(s). A separate chapter discusses the pharmacology of the drugs.

IV anesthesia is the principal anesthetic technique used by oral and maxillofacial surgeons. It can be achieved with single or multiple IV drug combinations, with or without nitrous oxide. The anesthetic drug(s) can be administered solely at the beginning of the surgery or titrated throughout the surgery. The anesthetic drugs can be administered by intermittent bolus, by continuous infusion, or a combination of both. The goal for all forms of administration is to achieve and maintain an appropriate concentration of anesthetic drug at the effector site within the central nervous system to achieve a desired anesthetic depth.

The choice to administer anesthetic drugs solely at the beginning of the surgery is commonly for the following reasons: (1) this achieves a sedative depth to facilitate the local anesthetic administration; (2) the pharmacologic profile of the selected agents is such that they will provide a satisfactory depth of sedation of appropriate duration for the planned surgery; and/or (3) the surgical time is of such short duration that additional drug administration is not required.

The benzodiazepine-opioid combination of midazolam and fentanyl is commonly titrated to a selected anesthetic depth before the administration of the local anesthetic agent. The pharmacologic profile of these agents is such that they provide a satisfactory depth of sedation of appropriate duration for many surgeons to perform dentoalveolar surgery without additional drug administration. There is a benefit to this drug combination in that it provides anxiolysis, amnesia, sedation, and analgesia. Of additional benefit is the availability of a reversal agent for each class of drug. There is a limitation to the anesthetic combination in that the onset and recovery of each agent is relatively slow. An induction agent, such as propofol, may be administered as a bolus before the local anesthetic agent to provide a more profound anesthetic depth of brief duration.

The pharmacokinetics and pharmacodynamics of propofol are ideal for office-based anesthesia because they provide rapid onset and rapid recovery and return to "street readiness." An intermittent bolus technique remains the

most commonly used technique for administration of these agents in oral and maxillofacial surgery. The disadvantage to this technique is the potential for high peak plasma concentrations of anesthetic drug with resultant unwanted effects (primarily hypoventilation or apnea or airway obstruction). An alternative to the intermittent bolus technique is a continuous infusion technique with or without intermittent boluses.[38] The infusion pump is used in an attempt to parallel the simplicity of administering an inhalational agent with a vaporizer. The infusion can be titrated up or down in response to clinical signs and/or BIS monitoring. The intermittent bolus can be administered to adjust the sedative depth before an anticipated increased surgical insult. The sustained baseline plasma level achieved from the continuous infusion should result in a more rapid response to the intermittent bolus administration. Ideal application of this technique requires the use of an infusion pump in which the practitioner can set a dose per weight per time infusion. Newer target-controlled infusion delivery systems use pharmacokinetic models to achieve effect-site concentrations. Mathematical calculations alter the infusion based on interindividual variability and surgery. Advocates of a continuous infusion anesthetic technique claim that the technique will result in a more stable plasma level of anesthetic drug, which will provide a safer and more optimal anesthetic.[39]

Combined Infusions

The components of an anesthetic consist of anxiolysis, amnesia, sedation, analgesia, and hypnosis. Propofol produces anxiolysis, sedation, and amnesia and is frequently administered to produce hypnosis. Peripheral vasodilation and a central sympatholytic effect associated with the administration of propofol can result in a decrease in both blood pressure and heart rate. Ketamine establishes a dissociative state that creates a degree of "immobilization" in addition to analgesia. Its administration is frequently associated with an increase in both blood pressure and heart rate. Opioids produce analgesia. The goal of combining medications is to maximize the optimal effects of a medication and to minimize the agent's adverse effects. (For example, propofol and ketamine counter the detrimental effects of each agent: propofol—bradycardia with ketamine—tachycardia; propofol—hypotension with ketamine—hypertension; propofol—antiemetic with ketamine—emetic.)

Traditionally, each drug is administered as an individual bolus. The advantage of a continuous infusion is that it provides a stable plasma level with the goal of establishing a stable minimally fluctuating anesthetic depth. With an understanding of the pharmacokinetics of each agent, different combinations of agents have been combined into the same syringe and administered as a co-infusion. Propofol-remifentanil and propofol-ketamine combinations have been described in the literature (Table 17-4). Although these drug combinations are physically and chemically compatible such that they may be combined in the same syringe, they should be prepared just prior to the procedure and discarded immediately after the anesthetic.[40]

An alternative and nontraditional method of sedation is patient-controlled sedation. The concept of patient-controlled sedation is that it enables the patient to vary the degree of sedation. A patient has the ability to administer a predefined bolus of IV anesthetic agent. Various parameters can be set into the devices that limit the total amount of

TABLE 17-4 Propofol-Remifentanil and Propofol-Ketamine Combinations

Propofol-Remifentanil Mixture	
Mix 100 μg of remifentanil in 20 mL of propofol to create a 5 μg/mL remifentanil/,10 mg/mL propofol mixture	
For deep sedation, infuse mixture at a rate of propofol 75-100 μg/kg/min	For a 70-kg patient, this results in an infusion of 2.5 μg/min remifentanil. The sedation infusion rate for remifentanil is 0.4-0.1 μg/kg/min. If propofol were infused at a rate of 75 μg/kg/min, a remifentanil infusion rate of 0.4 μg/kg/min for a 70-kg patient would be 2.8 μg/min.
For general anesthesia, infuse mixture at rate of propofol 100-140 μg/kg/min	For a 70-kg patient this results in an infusion of 5 μg/min remifentanil. The general anesthesia infusion rate for remifentanil is 0.1-1 μg/kg/min. If propofol were infused at a rate of 140 μg/kg/min, a remifentanil infusion rate of 0.1 μg/kg/min for a 70-kg patient would be 7 μg/min.
Propofol-Ketamine Mixture	
Mix 1 mg of ketamine in 20 mL of propofol to create a 1 mg/mL ketamine to 10 mg/mL propofol mixture	
Initial bolus: 500 μg/kg propofol	For a 70-kg patient this results in: Propofol dose of 35 mg Ketamine dose of 3.5 mg
Maintenance infusion: 100 μg/kg/min propofol	For a 70-kg patient this results in: Propofol infusion of 7 mg/min Ketamine infusion of 0.7 mg/min

drug, the intervals at which a patient can self-administer the anesthetic agent, and the rate at which a drug is administered. Although various agents have been used, the pharmacokinetic properties of propofol make it the most appropriate agent for patient-controlled sedation.[41-43]

Inhalation Induction

Inhalation induction by mask is the technique most commonly used for pediatric patients by our anesthesiology colleagues because it can be achieved relatively easily and rapidly in most children and is less objectionable than the insertion of an intravenous catheter.

The average child is usually cooperative but may be frightened by the unusual environment. The most reassuring approach initially involves gentle banter, in a smooth nonthreatening tone, allowing for a constant conversation and communication between the child and the treating clinician. It is usually best if the treating clinician alone does the talking, and if it is continual. This should continue throughout the application of monitoring instrumentation (pulse oximetry, precordial stethoscope, ECG, and BP). If there is any concern that the application of monitoring will increase anxiety and compromise a smooth induction, minimal monitoring should include a pulse oximeter and precordial stethoscope (positioned over the left sternal border at the second to fourth intercostal space with a double-stick adhesive so that both the breath and heart sounds will be heard clearly). A full face mask is then gently introduced. The child needs repeated reassurance that he or she is doing well. Typically, 100% oxygen is introduced with the anesthesia mask being gently held close to the face without touching the skin at first. Apprehensive children can hold the mask to their face themselves. This instills a sense of self-control, thus reducing anxiety. Pleasing scents placed in the facemask will often improve child acceptance of the mask. Following a few minutes to allow for appropriate pre-oxygenation, 70% nitrous oxide is introduced, and the mask is held gently touching the skin of the face. Two to 3 minutes of nitrous oxide sedation will usually allow the introduction of sevoflurane. A gradual increase of sevoflurane, increasing 1% every 2 to 3 breaths, up to 2 MAC (minimum anesthetic concentration) will allow for appropriate induction. The concentration of sevoflurane can be increased rapidly to 6% to 8% in otherwise healthy patients without causing significant hypotension or bradycardia. A well-done study compared three techniques of sevoflurane induction: traditional incremental increases in sevoflurane, versus 8% sevoflurane, versus 8% sevoflurane and 1:1 mixture of N_2O and O_2.[44] Minimal differences were seen among the three techniques, with the addition of nitrous oxide reducing the time to eyelash reflex and incidence of excitement during induction.

Once eye closure is achieved, the child may not move, but may lose consciousness slowly and continue to hear very accurately. Apprehension may increase as the child becomes disoriented, requiring the clinician to continue to maintain reassuring contact with the child. Care is taken to not stimulate the child as induction is achieved, but adequate monitoring (ECG, pulse oximetry, capnography, noninvasive BP) must be established as soon as the patient is sufficiently asleep to tolerate this without causing excitement phase reflexes. The first sign of anesthetic induction is the presence of nystagmus; the eyes then close; respirations become slower, regular, and deeper, then shallower and more rapid, until the child settles into a more regular breathing pattern. Throughout this transition, the child should not receive any significant stimulation. Once the child does not respond to a voice and the eyelash reflex is absent, the IV can be placed. An assistant should be ready to help position the child and perform venipuncture as the treating clinician maintains the airway. Joshi found that the time for effective IV cannulation in 95% of patients is approximately 3.5 minutes (range 2.68 to 6.77 min) following the introduction of sevoflurane.[45] Once an IV is established, the sevoflurane can be continued at a reduced concentration, or intravenous agents can be introduced for a standard outpatient anesthetic technique. Knowledge of the signs of early induction is mandatory (see Table 17-1), in order to avoid stimulating the child during stage 2 of anesthesia.

Choice of Anesthetic Agent

Nitrous oxide is the most commonly used inhalational agent among oral and maxillofacial surgeons. Use of nitrous oxide in conjunction with either IV agents (e.g., propofol) or potent inhalational agents (e.g., sevoflurane) potentiates the effect of the other anesthetic agent. This can reduce the amount of required anesthetic agent and result in a shorter wake-up time. However, many surgeons feel that the excellent pharmacokinetic properties of the current IV agents minimize these benefits potentially achieved with nitrous oxide. It has also been suggested that nitrous oxide contributes to a higher incidence of nausea and vomiting, although this has been challenged.[43]

IV sedation is most commonly achieved with a combination of benzodiazepine (e.g., midazolam), opioid (e.g., fentanyl, remifentanil), and propofol. Ketamine is also popular and can be incorporated into a standard anesthetic regimen or used as a drug to scavenge an anesthetic. Ketamine provides two effects that are advantageous in optimizing the anesthetic. First, the cataleptic state establishes a degree of immobility, and as the patient recovers from the effect of ketamine, there is a slow "robotic" type of return to purposeful patient movement compared with the rapid and "violent" type of movement that may be seen with propofol. Second, when ketamine is administered as a slow bolus in doses of 0.25 to 1 mg/kg (which are customary for office-based ambulatory oral and maxillofacial surgery), airway patency, spontaneous ventilations, and functional residual capacity (FRC) are maintained.

Remifentanil is an ultrashort-acting opioid. It has advantages over other opioids because of its rapid onset (~90 seconds, compared with fentanyl ~5 minutes) and rapid offset (context-sensitive half-life of 3 to 6 minutes). Because of its

pharmacokinetic profile, it is frequently administered as an infusion. Remifentanil can be combined with midazolam (for amnesia and anxiolysis) instead of propofol.[47,48] The use of remifentanil provides a degree of intense analgesia in which the patient has excellent pain control. When combined with midazolam, the patient is frequently awake and less amnestic of the procedure than if propofol were administered. However, the use of remifentanil establishes a surgical environment in which the patient, although less sedated and clinically more awake, does not move and does not transition from lighter to deeper anesthetic depths with the associated patient movement and potential airway irritability. Attentive respiratory monitoring is required with remifentanil, with different authors reporting varying degrees of hypoxia and ventilator depression.

Dexmedetomidine

Dexmedetomidine is an α_2-adrenoreceptor selective agonist that produces hypnosis and analgesia without respiratory depression. Respirations are comparable to those of a patient during "natural" sleep. The drug can be used as a premedicant (administered intranasally to the pediatric patient) or as an induction or maintenance drug as a component of the anesthetic cocktail. Intravenously, the drug is typically administered as a slow bolus supplemented with a continuous infusion.

Dexmedetomidine may be advantageous in selected situations. The ability to provide sedation, anxiolysis, and analgesia without respiratory depression establishes an environment for awake intubation in the patient with a compromised airway. The same properties are ideal for a patient who is to remain intubated after surgery or to supplement postoperative analgesia and attenuate hemodynamic parameters. However, as an adjunct to ambulatory outpatient anesthesia, the data are controversial as to its benefit. as it may produce bradycardia and orthostatic hypotension and prolong recovery. Given the agent's cost, the authors do not feel that dexmedetomidine is an ideal anesthetic agent for ambulatory office-based oral and maxillofacial surgery.

Patient Positioning

Patient positioning for office-based oral and maxillofacial surgery is usually dependent on the surgeon's preference and the specific surgical procedure. The typical positioning varies from supine to a head-up position of approximately 60 degrees, with most surgeons using some variation of head-up positioning. Head-up positioning has some physiologic advantages.

In the erect individual, the rib cage, the diaphragm, and the abdomen expand with inspiration. In the supine individual, thoracic expansion is more dependent on rib cage expansion, abdominal expansion is lessened, and the contents of the abdomen displace the diaphragm cephalad. The cephalad displacement of the diaphragm in the supine patient can cause a decrease in the FRC of approximately 0.5 L.[49]

FRC is the lung volume at the end of normal expiration. In the normal adult patient, the FRC is approximately 2 L with the total lung capacity being approximately 5 L. In the anesthetized patient, the FRC can further decrease by another 0.5 L in the supine patient. The importance of the FRC is that it provides an oxygen reserve in the event of impaired ventilations. Several studies have demonstrated the benefit of head-up positioning of varying degrees on minimizing oxygen desaturation after preoxygenation and induction of anesthesia.[50,51]

In addition to nonerect patient positioning, several other factors decrease FRC, including obesity, pregnancy, restrictive pulmonary disease, and short stature.

Patient positioning is also important in regard to prevention of neurologic injuries. In an ASA closed claims analysis, nerve injuries were the second most common type of complaint. Ulnar neuropathies were preponderant in these case reports.[52] These injuries may occur secondary to stretching or compression. Diabetes, alcohol, or smoking may contribute to an increased incidence of postoperative neuropathies.[53] The patient seated in a dental surgical chair is most susceptible to ulnar or radial nerve injuries, as opposed to lower extremity nerve injuries. Whereas patient positioning may contribute to neural deficit, the present observation of ulnar or radial nerve injuries suggests that these neuropathies are not secondary to patient positioning.[54,55]

Postoperative Recovery and Discharge

Office-based surgery typically is of short duration with a focus on rapid recovery. Anesthetic recovery is a continuum from the end of surgery when the last sedative/anesthetic agent has been administered and the patient emerges from sedation/anesthesia (early recovery), to a time in which the patient has satisfactorily achieved "selected" criteria that indicate that the patient is stable to be discharged (intermediate recovery), to a time in which the patient returns to the preoperative physiologic state (late recovery). Clinically, early recovery is categorized by the patient awakening, having intact airway reflexes, maintaining a patent airway, ventilating, oxygenating, and being hemodynamically stable. Most patients who have been sedated without advanced airway devices for office-based oral surgery progress almost immediately through early recovery to the intermediary recovery phase. Until patients progress into the intermediary recovery phase, they need to be intensively observed, generally by the oral and maxillofacial surgeon or recovery nurse. Pediatric patients have less reserve and warrant diligent care.

During intermediary recovery, continued observation by an individual trained to recognize complications should persist until the patient is discharged. During intermediary recovery, the observation need not be as intensive, requiring one-on-one observation. Monitoring as described later, with set audible alarms and diligent periodic observation,

is acceptable. To avoid having the patient unattended, the patient's escort can be allowed to remain with the patient at this time.

Respiratory and cardiovascular monitoring should be continued throughout the early and intermediary phases of recovery. Respiratory monitoring should assess oxygenation (pulse oximetry) and ventilation (respiratory rate and airway patency). Oxygen administration is generally discontinued during the intermediary recovery period. This assesses the patient's ability to maintain oxygenation on room air. Cardiovascular monitoring should minimally assess blood pressure and pulse. Electrocardiographic monitoring is not absolutely mandated but should be immediately available. For selected patients with significant cardiovascular disease, continual ECG monitoring should be considered. Vital signs consisting of blood pressure, pulse, respiratory rate, and oxygen saturation should be recorded at regular intervals. IV fluid hydration is not routinely indicated at this time, and continued administration may mask hemodynamic stability or lack thereof. Maintaining IV access, however, provides the ability to manage adverse events if necessary and is recommended to be removed just before discharge.

Intermediary discharge criteria determining home readiness are a continuum from the several parameters mentioned above. Vital signs (blood pressure, pulse, respiratory rate, and oxygen saturation) must be stable and consistent with preoperative values within acceptable parameters. In general, blood pressure and pulse should be within 20% of preoperative values, and a deviation of 40% warrants investigation. Oxygen saturation should be maintained above 90% on room air or consistent with preoperative value in the undisturbed patient. The patient should be alert and oriented unless the mental status was initially abnormal, in which case the patient's mental status should have returned to baseline. The patient must be able to ambulate at preoperative levels. Nausea and vomiting should be minimal and responsive to treatment. Routine antiemetic prophylaxis is only indicated in selected patients with a high incidence of postoperative nausea and vomiting. There should be minimal to no pain. Good local anesthesia is beneficial in reducing the anesthetic requirements and providing prolonged patient comfort, minimizing sympathetic stimulation, which can adversely affect hemodynamic stability and nausea and vomiting (because sympathetic stimulation increases incidence of nausea and vomiting). Last, surgical bleeding should be minimal and consistent with that expected for the surgical procedure.[56] Gauze pressure dressing applied to the intraoral wound for hemostasis should consist minimally of 4 × 4 gauze sheets that partially protrude from the mouth until the patient has fulfilled discharge criteria. Smaller gauze sheets or gauze packed solely intraorally increases the potential risk for aspiration and airway obstruction.

For select patients, fluid intake (diabetic patient) and urinary voiding may be indicated. Routinely mandating fluid intake, however, is unnecessary and can contribute to nausea and vomiting, prolonging discharge.[57] There is a higher incidence of nausea and vomiting in ambulatory patients who have received opioids. This is secondary to the interaction between the labyrinthine vestibular system, opioids, and the chemoreceptor trigger zone. Because the potential for hypoglycemia and the associated morbidity as a result of a lack of glucose intake is high in the diabetic patient, both mandating fluid intake in the office before discharge and providing home instructions to ensure fluid intake and glucose monitoring upon discharge are critical. Urinary voiding is also not routinely recommended. Perioperative medications that could contribute to urine retention include the opioids and anticholinergic agents. For patients at low risk for urine retention, most have voided within 3 hours of surgery.[58] There are also several reasons as to why there may be a lack of urinary urgency in the ambulatory oral surgical patient. Many patients are asked to void before surgery. This has the benefit of minimizing perioperative bladder distention, which could contribute to patient discomfort, sympathetic stimulation (associated with hypertension and tachycardia), subsequent urine retention, and/or inadvertent urinary incontinence. In addition, unless the patient's fluid deficit is replaced during surgery, the patient may not have a volume of urine to void. Patients should be instructed to seek medical assistance if they are unable to void within 6 to 8 hours of discharge.

The final determination and responsibility to discharge the patient is the responsibility of the anesthetist-surgeon. This task should not be delegated to office staff. Patients should be discharged to a responsible adult who will accompany them home and provide postoperative care.

Know When to Stop

Sedation is a wonderful modality that optimizes the quality of care within our offices. Office-based anesthesia in oral and maxillofacial surgery is mostly accomplished in the nonintubated patient. The technique of providing such anesthesia is both art and science. The "art" in anesthesia as administered by the oral and maxillofacial surgeon involves the ability to establish a good surgical environment in a patient who maintains spontaneous ventilations. However, there are times in which the balance of having a good surgical environment in which the patient is "asleep, immobile, cooperative, and comfortable" and maintains a patent airway with spontaneous ventilations is not accomplished.

When such a situation arises, the anesthetic team is confronted with a decision. The question that most frequently is on individuals' minds is how to achieve the anesthesia and complete the planned surgery. It may be appropriate to consider alternative pharmacologic agents or techniques. Ketamine is one such alternative agent that many practitioners may consider. It can establish a dissociative state and "scavenge" many such anesthetics. Some practitioners may convert a failed anesthetic in the nonintubated patient to a technique in which the airway is secured with either an endotracheal tube or an LMA. However, ketamine may not "smooth" out the anesthetic, and the patient may have a difficult airway that cannot be secured with various airway devices.

When deviating from the planned anesthetic treatment, there must be limits as to what is acceptable. Not all patients can be anesthetized "as planned" in the office. For example, a patient who was planned for general anesthetic may only be able to be minimally or moderately sedated. If a patient requires a general anesthetic, it may be more appropriate to seek the assistance of an anesthesiologist. Although there is a natural desire not to want to admit defeat, optimal patient care is the goal, and the practitioner needs to "know when to stop."

Concepts in the Management of Acute Postoperative Pain

JAMES M. ROGÉR, JOSEPH J. FANTUZZO

"It would be a great thing to understand pain in all its meanings."

Peter Mere Latham

Introduction

The practice of oral and maxillofacial surgery requires that the practitioner be able to manage patients who have pain. Latham's quote is a lofty goal indeed, and although there is vast knowledge regarding neurogenic pathways and processing nociceptive stimuli, the surgeon must be able to clinically understand a patient's acute postoperative pain and provide appropriate therapy aimed at reducing and managing this pain following surgery. Pain management following oral and maxillofacial procedures can affect the immediate postsurgical patient experience as well as many quality-of-life outcomes.[1-6]

The association of pain with third molar extraction is so intertwined that it is a major clinical research model in which to evaluate postoperative pain therapy.[7] Pain is the result not only of tissue damage and peripheral neuron messaging but also of processing in the central nervous system. An individual's response to pain is difficult to quantify; this is summarized by Sessle's definition of pain as "a complex, multidimensional experience encompassing sensory-discriminatory, cognitive, affective, and motivational aspects."[8]

Pain serves as a diagnostic tool and a clinical alarm. The clinician must not assume that the patient's perception of postoperative pain is merely due to the controlled trauma that is part of surgery. Pain perception may in fact relate to further underlying neuropathic, pathogenic, and psychosocial processes. Management of a patient's expectations regarding pain associated with a given procedure begins long before the day of surgery. A discussion about the expected timeline of discomfort during the healing process, held during preoperative consultation appointment, will ultimately set the stage for the success of postoperative pain management. Additionally, the patient's anxiety about a procedure can be affected preoperatively by interactions with the surgeon's front office and clinical staff; pain management is everyone's job.

This chapter describes the use of pharmacotherapies in acute postoperative pain management. There have been substantial discussions regarding nonpharmacologic methods of pain management; they are not discussed here.[9] A brief review of relevant neuroanatomy and pathophysiology of pain is followed by a detailed discussion of the use of common pharmacologic agents, and concludes with a summary treatment strategy algorithm.

Review of Neuroanatomy and Pathophysiology of Pain

Tissue damage that occurs during oral and maxillofacial surgery is ultimately perceived by the higher brain centers via nociceptive pathways from the site of injury.[10] Extracranial tissue damage and pain nociception follows a slightly different pathway than pain sensation from the oral and craniomaxillofacial region. In the periphery, free nerve endings stimulated by mechanical, chemical, and thermal sensation act as afferent pain receptors synapsing in the dorsal horn. The impulse then crosses to the contralateral ascending spinothalamic tract and travels to the thalamus. In the dorsal horn, ascending impulses can be modulated by descending pain-modifying pathways from the cerebral cortex, midbrain, and brainstem.[11]

There are two main afferent nerve fibers associated with pain transmission: A-delta and C fibers. A-delta fibers are lightly myelinated, large diameter, and fast conducting. They are primarily activated by mechanical stimulation and are perceived as a sharp or shooting sensation. C fibers are activated by thermal, chemical, and mechanical stimuli. They are unmyelinated, small diameter, and slow conducting and are most associated with a dull or aching sensation.

Pain sensation from the oral and maxillofacial region occurs as just outlined, but with different specific nerves transmitted to higher brain centers. The main sensory nerve of the orofacial region is cranial nerve V (the trigeminal nerve). Cranial nerves VII, IX, X, and XII and branches of cervical spinal nerves C1, C2, and C3 also contribute sensory innervation from the orofacial region. Painful stimuli in tissue innervated by the trigeminal nerve is transmitted to the central nervous system (CNS) via the Gasserian (trigeminal) ganglion and then through a portion of the brainstem known as the trigeminal brainstem sensory nuclear complex (VBSNC). This bilateral, multinucleated structure resides in the dorsolateral brainstem extending from the pons to the upper cervical spinal cord.[8,12] After synapsing in the VSBNC, the impulses travel to the thalamus and are relayed to higher brain centers, including the somatosensory cortex and the limbic system. As in the peripheral pathway, descending pathways are present and can affect transmission and perception of pain (Figure 18-1).

Opioid Analgesics

The naturally occurring products of the opium poppy are opium, morphine, and codeine; they are referred to as opiates. Compounds that are manufactured to mimic the chemical structure of these products and are targets for the same receptors are termed opioids.

Regardless of their origin, opioids all target the opioid receptors: mu, kappa, and delta. The specific interaction of the molecule with the receptor further classifies opioids as agonists, partial agonists, or antagonists. Agonists bind their receptors and elicit their analgesic effect—for example, morphine and codeine are agonists at mu and kappa receptors. Antagonists bind opioid receptors but do not elicit a response—for example, naloxone will bind and displace other opioids but produces no analgesic effect. Naloxone is used to reverse the binding of other opioids. Finally, partial agonists, also known as agonists-antagonists, will elicit their effect at one type of receptor and bind as an antagonist at another—for example, pentazocine binds as an agonist at kappa and an antagonist at mu.

The effects of opioid compounds are dependent on the type and location of their receptor target. The analgesic effects are mostly due to inhibition of nociceptive impulses in the CNS. These receptors are found in the ascending pain pathways: the dorsal horn of the spinal cord, the brainstem, the thalamus, and the somatosensory cortex.[13] Receptors are also found in the midbrain and medulla and activate descending inhibitory pathways. Peripheral receptors can also modulate opioid analgesia but are most implicated in the negative effects of opioid use (Box 18-1).[14,15] Subsequent or concomitant administration of the peripheral-specific opioid antagonist methylnaltrexone has been shown to help reduce the extracerebral side effects of opioids.[16]

Binding of the opioid receptor leads to:

1. Decrease in calcium influx at afferent nerve terminals, leading to decreased presynaptic release of neurotransmitter
2. Increased potassium efflux, resulting in hyperpolarization of postsynaptic neurons
3. Inhibition of GABAergic transmission, leading to the excitation of descending inhibitory pathways.

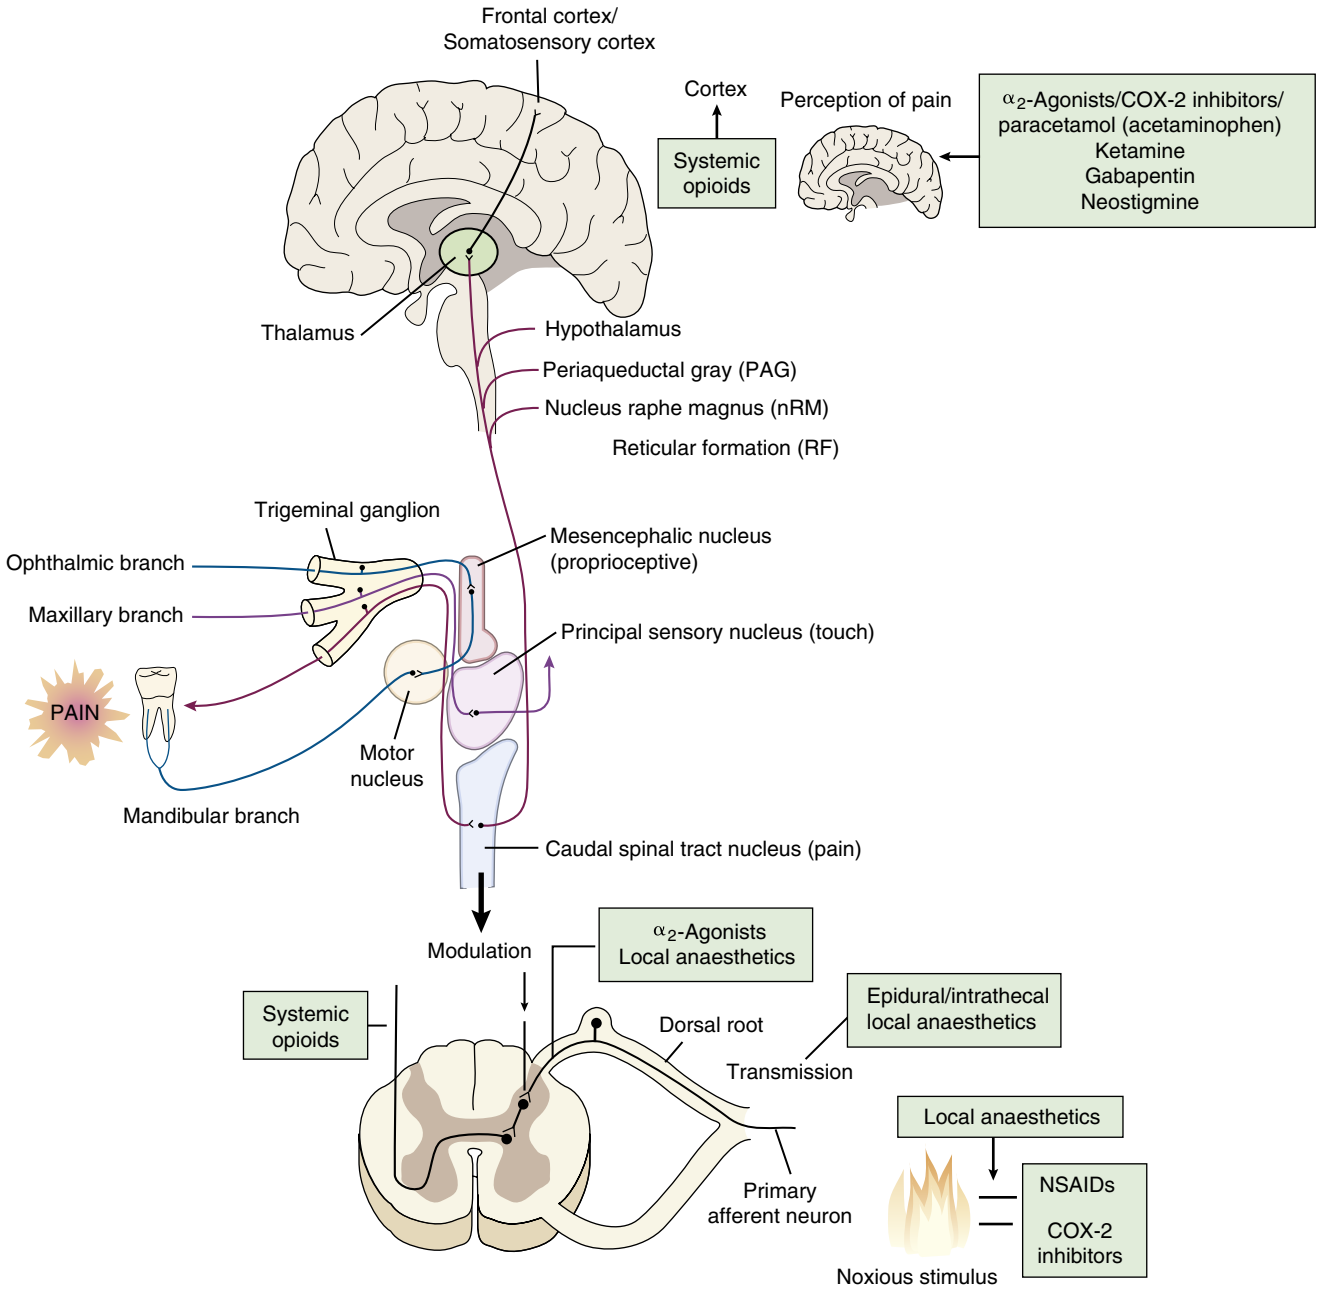
The desired clinical effect of opioids is their analgesic property, but opioids and the activation of mu receptors are associated with many adverse side effects (see Box 18-1). Critically, the central activation of mu receptors will reduce the respiratory drive and rate, which is the leading risk in opioid-associated overdose and the most frequent cause of opioid-associated death. Other CNS effects include sedation and euphoria; all patients prescribed opioids should be counseled to avoid operating motor vehicles or heavy machinery and refrain from making important decisions while taking the opioid medication. Nausea, vomiting, and constipation are very common complaints. Recent evidence is promising that blocking peripheral opioid receptors concomitant with opioid therapy can reduce these effects.[17-19]

Opioid cardiovascular effects include vasodilation, which can result in hypotension. Along with pain control, vasodilation may benefit the patient having a myocardial infarction. Morphine is included in the common mnemonic "MONA greets all MIs," which suggests that all patients presenting with acute cardiogenic pain receive morphine, oxygen, nitroglycerine, and aspirin.

Opioids also cause an increase in smooth muscle tone, which may result in urinary retention and chest wall rigidity. Pruritus (itching) is common because of the release of histamine from mast cells and the disinhibition of itch-specific neurons.[20]

The subjects of addiction, dependence, abuse, and tolerance are central to the discussion of prescribing opioid medication. Tolerance in drug administration lowers the effect and raises the required effective dose/concentration required to obtain the same effect. Drug dependence, which can result in significant physical withdrawal symptoms when the drug is discontinued, is another concern. Physical and psychological symptoms that patients may experience from taking opioids can lead to abuse or even addiction. Abuse is defined as the use of a drug outside of clinical recommendations or for goals beyond the prescribed clinical endpoints. Abuse can lead to addiction, in which the behavior patterns of obtaining and consuming the drug dominate patient efforts.[21]

Oral and maxillofacial surgeons must consider these factors for each patient regardless of the duration (often short) of postoperative analgesia therapy. Many patients will present with unrelated chronic pain in addition to their potential acute oral pain/problem. Prescribers may consider "pain contracts," agreeing to manage the pain associated with the procedure only for a specified period of time with referral back to a patient's primary care provider for other complicating or lingering pain without obvious etiology.



• **Figure 18-1** Sensory innervation of the orofacial region is predominately carried out by the trigeminal nerve. The first-order neurons have their cell bodies in the trigeminal ganglion. The peripheral processes of these cells innervate the orofacial structures, whereas the central processes enter the brainstem and synapse with the second-order neurons at various levels of the trigeminal brainstem sensory nuclear complex. This complex may be subdivided into the caudal spinal tract nucleus, which transmits pain, and the rostral principal sensory nucleus, which transmits afferent inputs such as touch. Proprioceptive impulses end in the mesencephalic nucleus, which is connected to the motor nucleus. The subnucleus caudalis extends into the cervical spinal cord and merges with the dorsal horn and peripheral sensory innervation. It possesses gating mechanisms capable of modulating painful stimuli. Specific locations of pharmacodynamic effects are indicated. *COX-2,* cyclooxygenase-2; *NSAID,* nonsteroidal anti-inflammatory drug. (From Ong CK, Seymour RA: Pathogenesis of postoperative oral surgical pain, *Anesth Prog* 50(1):5-17, 2003.)

This "acute on chronic pain" presents unique challenges in management. Therapy for these patients will include non-opioid analgesia and, when appropriate, likely higher doses of opioid analgesia.[22-24] The primary consideration should be to maximize the patient's analgesia while minimizing the adverse side effects.

Commonly Prescribed Opioids

Oral and maxillofacial surgeons most often prescribe oral formulations of the opioids listed in Table 18-1. It is important to remember that oral medications are subject to first-pass hepatic metabolism. In the office and hospital, opioids

• BOX 18-1 Adverse Effects of Opioid Administration

Abuse potential
Constipation
Respiratory depression
Nausea and vomiting
Sedation
Euphoria
Urinary retention
Impaired decision making

are also administered via intramuscular, intravascular, transdermal, transmucosal, subcutaneous, and rectal routes.

Regardless of the route of administration, the pharmacodynamics and pharmacokinetics of the agent must be considered. Table 18-2 provides summary data of the drug effective onset time and duration of action.

Although there are many different options available to the clinician, opioid potency can vary by route of administration as summarized in (Table 18-3).

Administration of IV opioid analgesics for severe acute pain should be done only in a monitored setting with initially low doses titrated to effect. Although opioids have a ceiling effect for analgesia, the clinical dose is a balance between the undesired effects and the analgesic properties. Of note: Meperidine is no longer commonly prescribed because of the neurotoxicity of one of its active metabolites, normeperidine. Meperidine also interacts with monoamine oxidase inhibitors, causing potential hypertensive crisis, hyperpyrexia, and cardiovascular collapse. Meperidine is included here because it is often used to reduce shivering in an inpatient anesthesia setting.[20]

When prescribing codeine, a weak mu agonist, doses greater than 60 mg are to be avoided because the adverse side effects will dominate the analgesic effects. Hydrocodone and oxycodone are available in the oral form and are commonly prescribed between 5 and 10 mg every 6 hours. These drugs are typically formulated with acetaminophen.

Tramadol is a synthetic opioid compound, which is chemically unrelated to the other synthetic agents. It has two mechanisms of action: (1) it is a weak mu agonist, and (2) it inhibits serotonin and norepinephrine reuptake. Because of the distinct chemical structure of tramadol, respiratory inhibition and abuse potential are lower. The equipotency of tramadol compares with that of codeine, and tramadol is commonly prescribed in 50- to 100-mg doses.[25,26]

In the acute postoperative setting, opioids, and opioid/acetaminophen combinations are often prescribed with nonsteroidal anti-inflammatory drugs (NSAIDs).

History, Legislation, and Clinicians' Attitudes about Narcotics Prescribing

Over the past two decades, a national epidemic of opioid use and abuse with associated consequences has escalated. Initial efforts were focused on increasing opioid use, citing the undertreatment of pain, which led to the liberalization of laws governing the prescribing of opioids for the treatment of chronic pain by individual state medical boards. Many arguments about the prescribing of opioids are based solely on history, tradition, and anecdotal observations.

Results of the 2010 National Survey on Drug Use and Health showed that of an estimated 22.6 million people aged 12 or older who were current or past month illicit drug users, 5.1 million had abused pain medication (second behind marijuana). It has also been shown that only one in six users of nontherapeutic opioids indicated that they received the drugs through a prescription from a single provider. In 2011, hydrocodone was the top prescribed drug with 136.7 million prescriptions, and total narcotic analgesics exceeded 238 million prescriptions.[27]

Individual laws, policies, and prescriber tools regarding the standard medical practice for opioid prescribing are being constantly revised. In some instances, state-run prescription drug monitoring programs are available to physicians. The level of participation in these programs varies by state. Effectiveness of and funding for continuation of these programs is an ongoing concern. With federal and state laws in flux, clinicians must remain abreast of these changes and the issues driving them, which will affect safe and appropriate care of patients in pain.[28]

A recent survey of oral and maxillofacial surgeons indicated that whereas most clinicians prescribe an average postoperative opioid course of 20 tablets and/or 5 days, many still (as many as 20%) routinely prescribe more tablets than are believed necessary to control pain after the removal of impacted third molars—up to and exceeding 40 tablets. These pills could become a source of drug diversion, and the provider must be mindful of patient comfort in balance with appropriate use of controlled substances.[29]

Joint Commission Standards and Pain Assessment and Pain Control

The Joint Commission on the Accreditation of Healthcare Organizations (JCAHO) introduced new pain management standards in 2000.[30] Since then, an increased awareness of the right to pain relief, growth of organizations supporting the use of opioids, and aggressive marketing by the pharmaceutical industry have contributed to the increase in opioid prescriptions (Box 18-2).

Non-opioid Analgesia

Nonsteroidal anti-inflammatory drugs (NSAIDs) are nearly the ideal postoperative analgesic, possessing both anti-inflammatory and antipyretic properties. They are a non-narcotic way to reduce pain, fever, and inflammation. The primary mechanism of action is the inhibition of cyclooxygenase (COX), thereby inhibiting the conversion of arachidonic acid to prostaglandin. There are two different isoforms of COX: COX-1 and COX-2. COX-1

TABLE 18-1 Common Opioid Analgesics

Name	Equianalgesic IM dose*	IM/PO Potency	Starting Oral Dose Range (mg)	Comments	Precautions
Morphinelike agonists					
Morphine	10	6	30-60†	Standard of comparison for opioid analgesics; sustained-release preparations (MS Contin, Oramorph SR, and Kadian)	Lower doses for aged patients; impaired ventilation; bronchial asthma; increased intracranial pressure; liver failure
Hydromorphone (Dilaudid)	1.5	5	4-8	Slightly shorter acting; HP IM dosage form for tolerant patients Good oral potency; long plasma half-life	Like morphine Like morphine; may accumulate with repetitive dosing, causing excessive sedation
Methadone (Dolophine)	10	2	10-20	Like methadone	Like methadone
Levorphanol (Levo-Dromoran)	2	2	2-4	Not available orally; available as a rectal suppository	Like IM morphine
Oxymorphone (Numorphan)	1	See comments	See comments	Immediate-release (Roxicodone and Oxy IR) and sustained-release (Oxycontin) forms; also lower doses in combination with nonopioids for less severe pain	Like morphine
Oxycodone	20	_	15-30	Slightly shorter acting; used orally for less severe pain	Normependine (toxic metabolite) accumulates with repetitive dosing causing CNS excitation; not for patients with impaired renal function or receiving monoamine oxidase inhibitors‡
Meperidine (Demerol)	75	4	Not recommended	Used orally for less severe pain	Like morphine
Codeine	130	1.5	See comments	Transdermal fentanyl (Duragesic); also oral transmucosal fentanyl citrate for breakthrough pain	Transdermal creates skin reservoir of drug; 12-hour delay in onset and offset; fever increases absorption
Fentanyl	0.1	_	_	Used orally for less severe pain; mixed agonist-antagonist	May cause psychotomimetic effects; may precipitate withdrawal in opioid dependent patients; not for myocardial infarction
Mixed agonist-antagonists					
Pentazocine (Talwin)	60	3	See comments	Not available orally; like IM pentazocine but not "scheduled" Not available orally like IM nalbuphine	Incidence of psychotomimetic effects lower than with pentazocine Like nalbuphine
Nalbuphine (Nubain)	10	See comments	See comments	Not available orally; sublingual preparation not yet in U.S.; does not produce psychotomimetic effects	May precipitate withdrawal in opioid-dependent patients; not readily reversed by naloxone; avoid in labor
Butorphanol (Stadol)	2	See comments	See comments

TABLE 18-1 Common Opioid Analgesics—cont'd

Name	Equianalgesic IM dose*	IM/PO Potency	Starting Oral Dose Range (mg)	Comments	Precautions
Partial agonists					
Buprenorphine (Buprenex)	0.4	See comments	See comments		

For these equianalgesic IM doses (also see comments), the time of peak analgesia in nontolerant patients ranges from 30 minutes to 1 hour and the duration from 4 to 6 hours. The peak analgesic effect is delayed and the duration prolonged after oral administration. Oramorph SR and Roxicodone are manufactured by Roxane Laboratories (Columbus, OH); Kadian, by Faulding USA (Elizabeth, NJ); Oxycontin, by Purdue Pharma PL (Norwalk, CT): Dilaudid, by Knoll Pharmaceuticals (Mt. Olive, (New York, NY); Duragesic, by Janssen Pharmaceuticals (Titusville, NJ); Nubain, by Du Pont Merck Pharmaceuticals (Wilmington, DE); Stadol, by Bristol-Meyers Squibb (Princeton, NJ); and Buprenix, by Reckitt & Colman (Richmond, VA).
*These doses are recommended starting IM doses, from which the optimal dose for each patient is determined by duration and the maximal dose limited by adverse effects. For single intravenous bolus doses, use half the IM dose.
†A value of 3 is used when calculating an oral dosage regimen of every 4 hours around-the-clock.
‡Irritating to tissues on repeated administration.

Oxycodone (immediate release)	20-45	1.5-2	3-4	80
Oxycodone (controlled release)	30-60	4-6	10-12	80

is constitutively produced by many different cells in the body contributing to homeostasis in the gastrointestinal (GI) tract, kidney, heart, brain, and vasculature. COX action and prostaglandin production protects GI mucosal integrity via mucus and bicarbonate production. In the kidney, prostaglandins regulate blood flow, renin release, and salt and water absorption. Prostaglandins in the vasculature regulate platelet function. Production and action of COX-2 is specific to the inflammatory state caused by tissue insult. Prostaglandins produced via the action of COX-2 activate secondary inflammatory mediators such as histamine, leukotrienes, bradykinin, and substance P. The inflammatory modulators result in increased vasodilation and increased vascular permeability, edema, erythema, hyperalgesia, and pain—the classic signs of local inflammation.

NSAIDs decrease surgically induced inflammation by inhibiting COX-2 and prostaglandin production; this decreases sensation at the nociceptive nerve terminal and reduces afferent activity of nociceptive neurons. NSAIDs are the first-line choice for management of postoperative pain resulting from tissue injury and inflammation.

Many of the adverse effects of opioids are not seen with NSAID administration. NSAIDs do not have a sedative or respiratory depressant effect and do not directly interfere with bowel or bladder function. They have a high therapeutic index and a low dependence rate. When prescribed for acute postoperative pain, the course is usually short

(5 days), resulting in fewer side effects. Contraindications to administration of NSAIDs include patients with known GI disease (peptic ulcer, known alcohol abuse). Patients with chronic hepatic and/or renal disease may have effective plasma concentrations higher than those without because of altered NSAID-plasma protein binding. Consideration of patient-specific and NSAID-specific pharmacokinetic principles is critical.[31]

Numerous clinical trials have investigated the effectiveness of initiating NSAID therapy prior to surgery. Most often 400 mg oral (PO) ibuprofen was administered 30 minutes before surgery; it has been shown consistently that postoperative discomfort is improved.[32-34] Ibuprofen is the most tolerated cost-effective NSAID with the fewest side effects.[35] A maximum recommended "preemptive analgesic" dose of 400 mg of ibuprofen given preoperatively has been shown to delay onset and decrease severity of postoperative pain, as well as to reduce the immediate postoperative need for narcotic pain use.[36,37]

Additionally, patients treated with preoperative 30 mg of intravenous (IV) ketorolac reported significantly lower pain intensity scores when compared with those receiving ketorolac postoperatively. The pretreated patients also reported a significantly longer time to rescue analgesic and less postoperative analgesic consumption.[38] When comparing pretreatment with ketorolac with that with tramadol, the ketorolac patients reported less postoperative discomfort.[39]

• BOX 18-2 1999-2000 Comprehensive Accreditation Manual for Hospitals (CAMH) Assessment of Patients Chapter

Standard PE.1.4 Pain is assessed in all patients.

Examples of implementation for PE.1.4:

All patients at admission are asked the following screening or general questions about the presence of pain: Do you have pain now? Have you had pain in the last several weeks or months? If the patient responds "yes" to either question, additional assessment data are obtained about the following elements:

- Pain intensity (use a pain intensity rating scale appropriate for the patient population; pain intensity is obtained for pain now, at worst, and at best or least; if at all possible, the pain rating scale is consistently used in the organization and between disciplines);
- Location (ask the patient to mark on a diagram or point to the site of pain);
- Quality, patterns of radiation, if any, character (elicit and record the patient's own words whenever possible);
- Onset, duration, variation, and patterns;
- Alleviating and aggravating factors;
- Present pain management regimen and effectiveness;
- Pain management history (including a medication history, presence of common barriers to reporting pain and using analgesics, past interventions and response, manner of expressing pain);
- Effects of pain (impact on daily life, function, sleep appetite, relationships with others, emotions, concentration, and so forth);
- The patient's pain goal (including pain intensity and goals related to function, activities, quality of life); and
- Physical examination observation of the painful site.

Patients often have more than one site of pain. An assessment system or tools with space to record data on each site is provided on the assessment sheet.

A hospital may need to use more than one pain intensity measure. For example, a hospital serving both children and adults selects a scale to be used with each of those patient populations. Assessment of cognitively impaired patients may also require assessment of behavioral factors signaling pain or discomfort.

Staff are educated about pain assessment and treatment including the barriers to reporting pain and using analgesics. Staff encourage the reporting of pain when a patient and/or family member shows reluctance to discuss pain, denies pain when pain is likely to be present (e.g., postoperative, trauma, burns, cardiac emergencies), or does not follow through with recommended treatments.

Pain intensity scales are enlarged and displayed in all areas where assessments are conducted. For organizations using clinical pathways, pain assessment is incorporated in some way into every appropriate clinical pathway.

An organization selects pain intensity measures to ensure consistency across departments, for example, the 0-10 scale, the Wong-Baker FACES pain rating scale (smile-frown), and the verbal descriptor scale. Adult patients are encouraged to use the 0-10 scale. If they cannot understand or are unwilling to use it, the smile-frown or the verbal scale is used.

A unit caring for persons with Alzheimer's disease developed a pain scale for each resident based on the long-standing knowledge of their residents and their knowledge of common pain syndromes in elderly people.

A pediatric hospital includes in its orientation materials for parents information about pain and pain assessment, including the parent's role in interpreting behavioral changes of the child that may indicate pain or discomfort.

Commonly Prescribed Non-opioid Analgesics

Although aspirin has proven consistently to provide effective analgesia, anti-inflammatory, and antipyretic activity, it has a low therapeutic index, and it can cause gastric ulcerations, bleeding (due to irreversible platelet inhibition), and possible development of Reye syndrome in children with viral infections. For this reason, the derivative diflunisal may offer safer application in the salicylic acid derivative class of drug (Table 18-4).

Acetaminophen, although not technically an NSAID, has tremendous therapeutic application in the postoperative period. It is often taken alone for mild pain or formulated with opioid medications (codeine, hydrocodone, and oxycodone) commonly prescribed by the oral and maxillofacial surgeon. Concerns for hepatic damage (contraindicated in alcohol abusers or patients with hepatic disease) and its low therapeutic ceiling require the clinician to assess the use of acetaminophen therapy alone or in combination based on the individual patient condition.

Diclofenac is an NSAID that is available in a potassium salt (immediate release) and a sodium salt (delayed-release and extended-release). In animal studies, diclofenac has shown superior action in acute inflammation models.[40] Modifications in the delivery formulations of diclofenac have made this NSAID a powerful tool for postextraction acute management.[41] Phase 3 trials to determine the effectiveness have elucidated that oral diclofenac/potassium salt is effective in providing patients a greater reduction in pain and a quicker time to pain reduction, and it required less rescue medication (re-dosing) versus placebo. Further studies confirmed that even a single postoperative dose was effective for pain relief following third molar extractions.[42]

As discussed earlier, the inhibition of COX-2 is the primary mechanism of action for NSAIDs. Inhibition of COX-1 is responsible for some of the adverse effects in the GI tract and vasculature. COX-2 specific inhibitors were first brought to market in 2004, and soon thereafter all but one agent was withdrawn.[10] Celecoxib is currently the only commercial COX-2 inhibitor available. In theory, by inhibiting only COX-2 prostaglandin production, celecoxib should be a superior postoperative agent, but little evidence has shown the analgesia of celecoxib to be superior to ibuprofen despite being substantially more expensive[43] (Box 18-3).

Local Anesthetics

Local anesthesia allows for painless manipulation of hard and soft tissue during surgery. By blocking sodium channels and inhibiting nerve ending excitation and nerve impulse propagation, surgeons are able to perform many different procedures in the office setting. Although local anesthesia plays its dominant role in the perioperative period, it should also be considered a powerful tool for postoperative acute pain management.

The pharmacology and modes of action of local anesthetics are addressed in another chapter. Lidocaine,

NSAID, Nonsteroidal anti-inflammatory drug.

mepivacaine, and articaine are commonly used during surgery and are of relatively short effective duration; when formulated with epinephrine, soft tissue may be anesthetized for 3 to 5 hours. Long-acting amide local anesthetics such as bupivacaine and etidocaine can block nociceptive input and nerve conduction for 8 to 12 hours (commonly formulated 0.5% bupivacaine with 1:200,000 epinephrine, and 1.5% etidocaine with 1:200,000 epinephrine).[44] The use of bupivacaine either as the primary agent or as an adjunct in third molar surgery has been shown to improve postoperative pain experience compared to lidocaine alone.[45] It has been suggested that the long-term blockade of nociceptive input combined with an overall decrease in hyperexcitability in the CNS can reduce the dose of required analgesia.[46]

When using local anesthesia, adherence to the principle of *aspiration before injection* and staying below the maximum doses of all the agents is critical. Initial signs of local anesthetic overdose begin with a period of excitation possibly followed by generalized tonic-clonic seizures. As levels of systemic local anesthetic increase, heart rate, blood pressure, and cardiac contractility decrease; respiratory rate declines, and ultimately circulatory collapse is possible.[44]

Adjunctive Medications

Steroids

Corticosteroids have long been used in oral and maxillofacial surgery to suppress acute edema following major procedures. Steroids act earlier in the inflammatory cascade, inhibiting arachidonic acid production with subsequent decrease in leukotriene and prostaglandin production.[10] Steroids also have central nociceptive suppression at the spinal cord level and antinausea effects.[47]

For procedures expected to cause a high degree of inflammation, such as orthognathic surgery or third-molar extraction, methylprednisolone or other oral steroids have been routinely prescribed. It has been shown that perioperative steroid therapy leads to greater opioid sparing and antiemetic effects compared with ketorolac.[48]

Considerations for the patient's postoperative condition, other pharmacologic agents, and comorbidities must be considered with steroid administration. Concomitant steroid and NSAID therapy can increase the risk of GI bleeding. Prolonged steroid therapy can suppress the immune response and is contraindicated in patients with acute infection.

Neuropathic Targeted Medications

Patients may experience different types of pain at the same time—for example, both visceral and somatic pain following third molar extraction. In the case where the inferior alveolar nerve has been stretched, bruised, or damaged, the patient may also have neuropathic pain. Neuropathic pain does not often respond well to standard NSAID and opioid postoperative therapy. Agents such as antidepressants (tricyclic) and anticonvulsants (gabapentin, pregabalin) have been shown to reduce continuous and episodic pain.[49]

Recent investigation into the usefulness of gabapentinoids has shown some reduction in total opioid use in the perioperative period and up to 24 hours following surgery for knee arthroplasty; this positive effect did not extend beyond postoperative day 4 or at longer-term follow up appointments.[50] In patients undergoing hemorrhoid surgery, pain was significantly reduced in the perioperative gabapentin group versus opioid only on postoperative days 1, 7, and 14; the gabapentin group also required less opioid, but this difference was not significant.[51]

Additional receptors and pathways have been elucidated as contributory to peripheral neuropathic pain. Interestingly, within the angiotensin-renin system, the binding of angiotensin II type 2 receptors has been shown to be effective in management of chronic neuralgia; these pipeline therapeutics may eventually assist in the management of acute and chronic neuralgia following oral surgery and/or nerve insult.[52]

Cannabinoids

Cannabinoid analgesia is based on the suppression of both spinal and thalamic nociceptive neurons and at peripheral sites of action. Pain that occasionally follows peripheral tissue or nerve injury often does not respond to traditional inflammatory pain management therapy. Recently, progress has been made in understanding the role of the endocannabinoid system in the modulation of postoperative and chronic pain.

Endocannabinoids have been shown to behave as analgesics in models of both acute nociception and clinical pain such as inflammation and painful neuropathy. The framework for such analgesic effects exists in the cannabinoid receptors, which are found in areas of the nervous system important for pain processing as well as those cells in the immune system that regulate the interactions that mediate inflammatory hyperalgesia. In vitro and in vivo studies have shown that cannabinoids can act on neuronal cells to inhibit the release of pro-inflammatory cytokines.

Cannabinoid administration has been found to suppress behavioral and neurophysiologic responses to all types of

nociceptive stimuli tested. In human clinical trials, administration of cannabinoid receptor agonists has been shown to be effective in treating neuropathic pain conditions and, in some instances, to rival the analgesic efficacy of morphine. It has been shown that low doses of smoked cannabis (D9-THC) can reduce the pain induced by intradermal capsaicin, whereas at higher doses the pain is increased.[53] In addition to smoked cannabis, other cannabinoids that have been approved in the United States or Europe include dronabinol, nabilone, and GW-100. All of these drugs contain D9-THC or an analogue and are nonselective with respect to cannabinoid 1 and cannabinoid 2 receptors.[54]

Muscle Relaxants

Generally, somatic and visceral pain following oral surgical procedures is well managed with NSAID and opioid therapy. These agents address the specific surgical trauma and subsequent inflammatory reactions, which are the primary mediators of postoperative pain. It is worth discussing the consequences of the logistics of the operation, including patient positioning, duration of surgery, and surgical access (usually defined by minimum incisal opening). In the case where a patient's postoperative discomfort is spasmodic or musculoskeletal in the neck or back or at the temporomandibular joint and/or musculature, consideration can be given to administration of a short course of muscle relaxants. There is evidence that cyclobenzaprine, carisoprodol, orphenadrine, and tizanidine are effective compared to placebo in patients with acute postoperative muscle spasm or suspected musculoskeletal pain (primarily back or neck pain).[55]

Anxiety Management

Preoperative and postoperative consideration of the patient's anxiety is paramount to any pain management plan. Oral diazepam has been shown to be a very good adjunct to the overall pain modulation strategy. Preoperatively and postoperatively, diazepam has the benefit of lowering the patient's anxiety level and potentiating the effects of opioid therapy, respectively. At low doses diazepam is shown to be a good muscle relaxant without causing profound muscle impairment. The clinician should not overlook the patient's attitude and anxiety level at the preoperative appointment and prescribe appropriate anxiolytic agents preoperatively.[56,57]

Acute Pain Management Strategies

Management of acute pain begins long before the day of surgery. The overall goal is to understand the individual patient's requirements regarding not just analgesia, but also perioperative anxiety, stress, nausea, and additional patient-specific concerns. Patient education before a painful and often emotionally demanding surgery can determine postoperative analgesic success.

The patient must also understand the appropriate timing and use of medications (opioid and non-opioid medications alike) for pain management following surgery. Often patients believe that the medications work best after the pain has started or by augmenting their medications at the peak of the pain, when in fact preemptive analgesia has been shown to be far more effective.

For the clinician: When a minimum interval and dosage are specified and the patient is allowed to receive the remainder of the expected analgesic requirement as a rescue dose, time and again, patients report much improved pain control[24] (Figure 18-2).

"Pain as the 5th Vital Sign"

To improve pain management, the Veterans Health Administration (VHA) launched the "Pain as the 5th Vital Sign" initiative in 1999, requiring a pain intensity rating (0 to 10) at all clinical encounters. This initiative was subsequently included in the JCAHO standards for pain assessment (presented earlier). Initially, it had four primary goals for performance improvement: a reduction in the percent of patients reporting moderate to severe pain, increased documentation of pain assessments, implementation of pain plans of care, and patient pain education.

Recognizing the rising use of opioid prescriptions, in 2008, the VHA launched a comprehensive patient safety initiative, including an Opioid—High Alert Medication Initiative, which served to provide policy guidance and specific recommendations to promote safe and effective use of opioid therapy for the management of acute and chronic pain in inpatient and outpatient settings.[58]

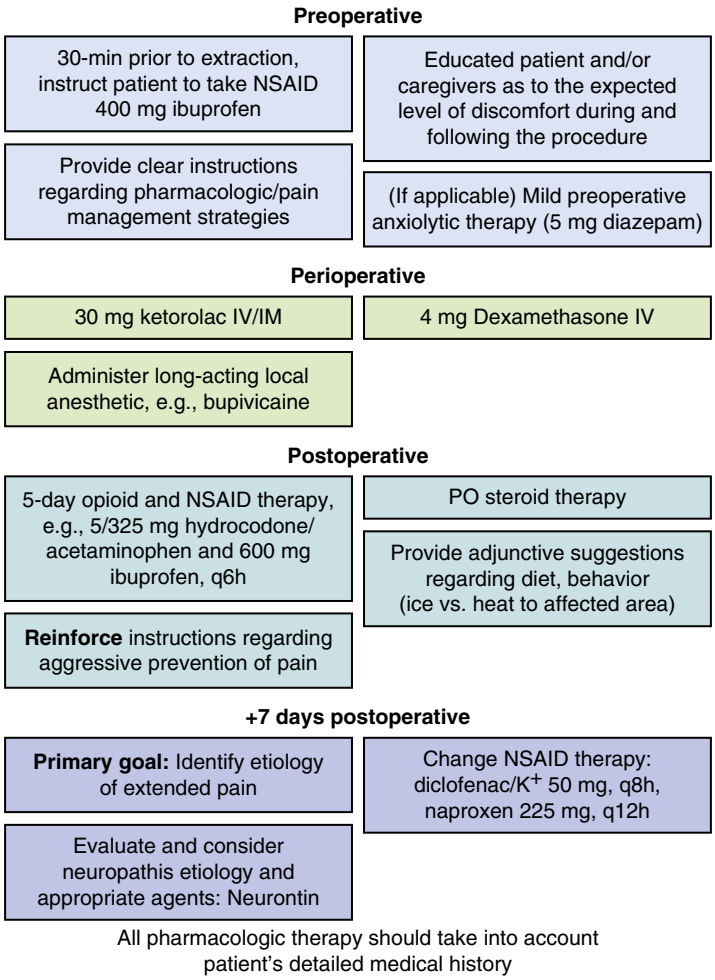
Patient Assessment and Reassessment

The most reliable source for determining both the existence and intensity of any pain is the patient. The most common type of pain relevant to oral and maxillofacial surgery is somatic pain (described as pinprick or sharp). Visceral pain (generalized aches or pressure) and neuropathic pain (described as burning or tingling) are also often experienced and present further challenges to management.[59]

One of the greatest challenges for the oral maxillofacial surgeon is the patient who presents more than 1 week postoperatively reporting lingering or consistent pain since the day of surgery. It is at this appointment that reassessment is critical, and any new pathology must be elucidated and treated. In the case where there is no new or different source of pain, the clinician must remember that according to published studies, half of our patients do not experience adequate analgesia with conventional pain management strategies.[60] The type of pain, reevaluation of the analgesic therapy/agents, and consideration of referrals to specialists, such as neurology for suspected neurogenic pain, should be considered.[59]

Inpatient Analgesia

Patient-controlled analgesia (PCA) is an option for the hospital patient. This self-directed analgesia allows the



• **Figure 18-2** An example strategy for complete perioperative pain management. *IM,* Intramuscular; *IV,* intravenous; *NSAID,* nonsteroidal anti-inflammatory drug; *PO,* oral.

patient a minimum of control inside of the provider's broad pain management plan. A programmable infusion pump delivers narcotic medication at a specified rate in addition to a patient-controlled bolus function. Bolus frequency versus safety is managed via a lock-out interval specified by the prescriber. The primary advantages are preemptive pain management with a component of patient-centered control. In a review of more than 30 clinical trials comparing the efficacy of PCA with conventional opioid treatment, improved analgesia and decreased risk of pulmonary complications were observed using the PCA.

The idea of PCA is appealing. Theoretically, there is improved analgesia and satisfaction, because patients may independently titrate the analgesic to their individual level of pain. Trials have consistently come down in favor of PCA, and the authors have consistently noted that in almost all cases, patients prefer this option.[61]

Conclusion

Oral and maxillofacial surgeons must understand that pain is both a primary motivation for our patients to seek treatment and a natural but manageable sequela of the procedures that we perform. The provider must work to educate and directly help manage the patient's acute postoperative pain using combinations of non-opioid and opioid medications.

Consideration must be given to the patient's current level (if present) of chronic pain medications, and the surgeon should be prepared to augment these therapies in the acute setting in consultation with other providers. Recognizing that postoperative pain management can begin by administering preoperative NSAIDs is crucial to a broad effective strategy. The administration of appropriate combinations of *scheduled* medications rather than as-needed (PRN) directions is also important to preempt the pain.

Beyond the pharmacologic management of a patient's acute pain, the clinician must consider the overall experience for the patient. This begins at the front desk of the office even before the patient arrives. Preparing the patient for expected postoperative discomfort should begin at the consultation appointment so that the patient's expectations are well established long before the day of surgery and the acute postoperative period.

Pediatric Pharmacosedation and General Anesthesia

LARRY P. PARWORTH, TRENT W. LISTELLO, GREGORY S. BELL

Introduction

Since the inception of the specialty of oral and maxillofacial surgery, the delivery of anesthesia has been the cornerstone of our practice. The control of pain and anxiety is a valuable service to the public, especially for the pediatric population. The majority of pediatric patients exhibit fear and anxiety when coming in for surgical treatment, and providing care for the pediatric patient can be a challenging but rewarding experience. When behavioral management techniques fail or when they are not practical, pharmacologic intervention will be necessary. The goals of pediatric anesthesia are to provide efficient, safe, reversible, and profound anesthesia, sedation, or analgesia to allow safe and effective completion of the surgical procedure.[1]

Children are not simply small adults. Children have unique anatomic and physiologic differences that provide special challenges during anesthetic management. Maintaining a patent airway can be problematic as a result of large tonsils, a pliable funnel-shaped trachea, and other things. Airway loss with subsequent hypoxia and resultant cardiovascular compromise account for the majority of poor outcomes during pediatric anesthesia.[1]

Preanesthetic assessment for children should have areas of focus different from that of adults. A complete review of systems must include screening for endocrine disorders, congenital cardiac defects, hematologic disorders, and any familial history of malignant hyperthermia. Children tend to have more frequent upper respiratory tract infections and a higher incidence of asthma, and thorough investigation is critical.

Safety in the practice of state-of-the-art anesthesia is of the utmost importance to all oral and maxillofacial surgeons. Conditions contributing to major morbidity from office anesthetic procedures include unfamiliarity with pediatric anesthesia.[2] One study concluded that the judgment and skill of the provider was one of the prime determinants related to anesthetic mortality.[3] Constant review of the literature, having a thorough knowledge of current advances in technology and techniques, and ensuring maintenance of pediatric anesthesia skills are essential to providing the highest quality of care for our young patients.

This chapter discusses pediatric anatomy and physiology, preanesthetic workup, and equipment and monitoring for the safe and effective delivery of anesthesia. Current anesthetic drugs and techniques are reviewed along with the more common complications and their prevention and management.

Pediatric Anatomic, Physiologic, and Pharmacologic Differences

The successful management of pediatric patients undergoing anesthesia requires a thorough understanding of the anatomic and physiologic differences between pediatric patients and adults. These differences lead to many modifications in the delivery of anesthesia from the preanesthetic evaluation to the actual delivery of pharmacologic agents.

Cardiovascular System

The cardiovascular system undergoes significant changes at birth and continues to change throughout childhood. Transitional circulation describes the changes that take place as the fetus adjusts to the circulatory changes after birth. The end product of these changes includes the closure of the foramen ovale, closure of the ductus arteriosus, and closure of the ductus venosus, the combination of which causes the fetal circulation to become an adult-type circulation. These shunts do not close definitively immediately after birth; as a result, certain clinical conditions may contribute to the persistence of fetal circulation or to the reappearance of fetal shunts under stress. Factors such as hypoxia, hypercarbia,

acidosis, infection, hypothermia, and anesthesia-induced changes in peripheral vascular tone, act as a stimulus for maintaining high pulmonary vascular resistance and a return to fetal circulation. Blood may be shunted past the lungs through the patent foramen ovale, and a rapid downhill spiral may occur and result in severe hypoxemia.[4,5] Furthermore, after the neonatal period, it is estimated that 50% of children younger than 5 years of age and 28% of adults will demonstrate probe patency of the foramen ovale,[6] indicating the need for careful elimination of all air bubbles from an intravenous (IV) line in a pediatric patient.

Cardiac Output and Blood Pressure

Cardiac output in pediatric patients is higher than in adults and is necessary to meet the higher demands for metabolic oxygen consumption.[7] Cardiac output is defined as stroke volume multiplied by heart rate. The myocardial structure of the pediatric heart is significantly less developed than in adults. In particular the volume of cellular mass devoted to contractility is less in the pediatric heart, resulting in a noncompliant and poorly developed left ventricle that has minimal ability to alter stroke volume.[4,8] Therefore without the ability to alter stroke volume, cardiac output in a pediatric heart is dependent on heart rate.

Mean arterial blood pressure is proportionate to cardiac output multiplied by systemic vascular resistance. The pediatric cardiovascular system has little ability to alter systemic vascular resistance; it is less able to respond to hypovolemia with vasoconstriction[4] and also is very sensitive to volume overloading, with little ability to compensate. Therefore blood pressure in the pediatric patient is largely dependent on cardiac output. Bradycardia is the most lethal arrhythmia in pediatric patients[7] leading to large decreases in cardiac output and a resultant decrease in blood pressure. Perhaps the most frequent cause of bradycardia in pediatric patients is hypoxemia. Other frequent causes include anesthetic overdose or activation of the parasympathetic nervous system (Table 19-1).

Neural Innervation

In pediatric patients, the sympathetic nervous system is not fully developed, giving the parasympathetic nervous system greater control and increased tone. A severe and sudden bradycardia can often be the result of this parasympathetic hypertonia or "increased vagal tone."[10] The clinician should always be prepared to treat a vagal induced bradycardia because it can happen in people of all ages; however, it is important to note that the incidence is inversely proportional to age with a sharp decline in incidence for children over the age of 3 years[11] (Table 19-2).

TABLE 19-1 Typical Vital Signs by Age

Age in Years	1	3	6	12	Adult
Respiration rate/min	25-35	20-30	18-25	15-22	8-15
Heart rate/min	100-140	80-125	80-120	75-110	60-80
Blood pressure mm Hg	90/60	100/60	110/60	110/65	125/80

Modified from Dembo JB: Pediatric outpatient anesthesia, *Selected Readings Oral Maxillofac Surg* 5(4):1-19, 1997.

Respiratory System

During the first years of life, the respiratory system undergoes significant changes. Immaturity of the respiratory system in young children (under age 2) makes anesthesia particularly dangerous and should only be attempted by providers adept in pediatric anesthesia. This section will discuss the changes that occur in the development of the respiratory system, which will be divided into the upper airways, the chest wall, and the lungs.

Upper Airways

Differences in airway anatomy between pediatric and adult airways make airway management and intubation difficult in pediatric patients. The upper airway of infants differs in a number of ways, making pediatric patients more prone to obstruction than adults.[4,12,13] First, the infant's tongue is large in relation to the oral cavity. Second, the laryngeal cartilage is located higher in the neck. Third, the epiglottis is large and can cover the soft palate, which makes the airway more prone to obstruction and encourages nasal breathing, often referred to as "obligatory" nasal breathing. Most infants can convert to oral breathing if the obstruction lasts more than 15 seconds,[14] and almost all infants can easily convert to oral breathing by 5 months of age.[15] Young children also have proportionately larger tonsils than adults, with tonsils and adenoids reaching their largest size between ages 4 to 10 years.[9]

Endotracheal intubation is also influenced by the upper airway anatomy of the pediatric patient. The pediatric larynx is funnel shaped and is narrowest at the cricoid cartilage, whereas the narrowest part of the adult airway is the glottic opening (Figure 19-1).

For this reason, endotracheal tubes that pass through the vocal cords of an adult will sit passively in the trachea. However, in pediatric patients, an endotracheal tube that passes through the vocal cords may be tight just below the cords

TABLE 19-2 Frequency of Bradycardia During Anesthesia in Children, by Age

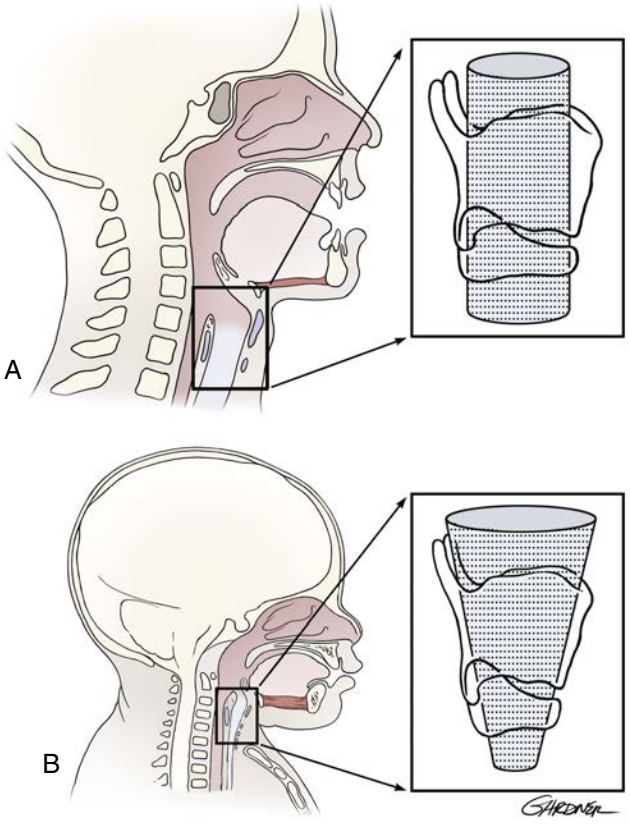
	0-1 Yr	1-2 Yr	2-3 Yr	3-4 Yr
Total anesthetics	4645	1932	774	628
With bradycardia	59	19	5	1
% Bradycardia	1.27	0.98	0.65	0.16

Modified from Keenan RL, et al: Bradycardia during anesthesia in infants: an epidemiologic study, *Anesthesiol* 80:976, 1994.

in the area of the cricoid cartilage. Any endotracheal tube, cuffed or uncuffed, that is placed in a pediatric patient must be checked to ensure air will "leak" around the tube at no more than 25 cm H_2O. At pressures greater than 25 cm of H_2O the mucosal capillaries may become damaged leading to subglottic inflammation, a dangerous phenomenon leading to further narrowing of an already narrow airway. The small diameter of the airways and further narrowing profoundly increases resistance to airflow because resistance is inversely proportional to the radius raised to the fourth power.

Over the first 2 years of life, the epiglottis, larynx, and hyoid bone move downward. The facial skeleton grows vertically, and the mandible lengthens from front to back. This growth continues until the age of 10 to 12 years when the pediatric airway fully develops into an adult airway.

Another difference between the pediatric and adult upper airway is that the pediatric trachea is more compliant. The negative pressures generated during inspiration tend to collapse the trachea. The most compliant region of the upper airway is the pharynx, which makes this region most susceptible to collapse. The pharynx is usually protected from collapsing by the tone of the upper airway muscles, which also contract during inspiration. However, small upper airways have a higher resistance to flow and may necessitate greater negative pressures to produce sufficient inspiratory flow. This results in a greater tendency for the pediatric upper airway to collapse.[16,17]



• **Figure 19-1** Sagittal section of the adult **(A)** and infant **(B)** airway. Notice that the adult larynx is cylindrical shaped with the narrowest part occurring at the glottic opening. The infant larynx is funnel shaped with the narrowest part occurring at the level of the cricoid cartilage.

Chest Wall

There are several properties of the chest wall and associated muscles of respiration that diminish the efficacy of ventilation in the pediatric population.

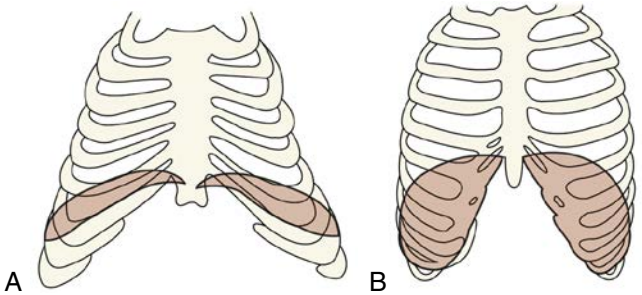
Pediatric ribs are very pliable because they are composed mainly of cartilage. As a result, the chest wall of an infant is very compliant and cannot easily maintain negative intrathoracic pressure, resulting in a decreased mechanical efficiency and less ventilatory reserve. In the infant, the compliance of the chest wall is almost three times that of the lung. By the age of 3 years, the ribs mineralize and become stiffer, making the chest wall and lung compliance similar.[16] The efficacy of ventilation in the pediatric patient is further diminished by the anatomy and composition of the respiratory muscles, which bear the load of respiration. In an infant, the diaphragm inserts in an almost horizontal fashion, compared with the oblique insertion in an adult[18] (Figure 19-2).

As a result, there is decreased contraction efficiency in infants; the flat diaphragm has a shorter downward course with less rib cage expansion. In addition to having a decreased inspiratory capacity, the composition of the intercostal muscles and the diaphragm allow little room to increase ventilation in the face of increased work of breathing. The diaphragm is made up of a mixture of fatigue-resistant and fatigue-susceptible muscle fibers. The number of fatigue-resistant fibers in the diaphragm at birth is approximately one half of the adult level. By 2 years of age, the diaphragm has matured to have approximately the same number of fatigue-resistant fibers as an adult.[16,19] This decreased inspiratory capacity coupled with less fatigue-resistant fibers places the pediatric patient at a higher risk to develop ventilatory fatigue quickly after small changes in respiratory load.

Lungs

There are several properties of the lungs that influence anesthesia delivery to the pediatric patient. Many anatomic differences exist between the pediatric and adult lung.

Respiration is not possible until both the pulmonary airways and vascular system have matured enough to allow gas



• **Figure 19-2** **A,** Newborn and **B,** adult rib cage. The shaded areas represent the anterior projection of the diaphragm.[16,18]

exchange. Marginal gas exchange capability is possible by approximately the 24th week of gestation, which is a critical step in allowing postnatal survival.[16] Alveoli form both before and after birth, and initial studies suggested that postnatal alveolar multiplication was slow after the age of 4 and ended by the age of 8.[20,21] However, more recent studies with larger groups of cases have shown that the great bulk of alveoli are present by the age of 2, and limited or no alveolar multiplication occurs thereafter.[22-25] Following the end of alveolar multiplication, lung development is considered complete, and the lung enters a period of normal growth until adulthood.[23,24]

In the newborn, the partial pressure of oxygen in arterial blood (PaO_2) is approximately 70 mm Hg, versus 97 mm Hg in the adult.[26-28] In theory, the low PaO_2 values may be due to ventilation-perfusion mismatch and a short capillary transit time that does not allow proper diffusion between the alveolar-capillary interface. The PaO_2 rises rapidly during the first 3 years of life with children aged 1 to 3 having an average PaO_2 of 83 mm Hg. The PaO_2 then slowly increases up to the age of 8 years.[27,28] Thereafter, PaO_2 values remain stable and similar to those seen in adults.[29] The fairly low PaO_2 values in infants and young children are close to the steep part of the oxygen-hemoglobin dissociation curve. Any further decrease in PaO_2 can induce severe oxygen desaturation.

The physiology of the pediatric lung is affected by the limited number of alveoli and compliant rib cage. Functional residual capacity (FRC) is the volume of gas remaining in the lung at the end of a normal tidal expiration. It represents the balance point between the inward elastic recoil of the lungs and the outward elastic recoil of the chest wall. In infants the chest wall is very compliant, making the outward elastic recoil very small.[30] Conversely the lung is stiff, making inward elastic recoil high, possibly as a result of the small and limited number of alveoli. As a result of this balance, the FRC of a pediatric patient is lower than that of an adult, promoting low residual lung volumes at expiration. During anesthesia FRC represents oxygen stores during periods of apnea. The closing capacity is the volume of air that is needed to keep the airways open. If FRC falls below the closing capacity, airway closure occurs leading to a shunt. The closing capacity is greater in the pediatric patient. A decreased FRC coupled with an increased closing capacity predisposes the pediatric patient to shunting, or perfusing areas of the lung that are receiving no ventilation. This requires more energy on top of an already higher metabolic demand and oxygen consumption rate. Clinically, this correlates to rapid oxygen desaturation during periods of apnea (e.g., during intubation or airway obstruction). In one model describing the rate of oxyhemoglobin desaturation during apnea, a child took 41 seconds to desaturate to 85%, whereas an adult took 84 seconds to desaturate to 85%[31] (Table 19-3).

Kidneys

Pediatric patients have decreased renal function under the age of 2. Multiple renal differences are seen early in life including decreased glomerular filtration rate, impaired sodium retention, and impaired glucose excretion. At birth glomerular filtration rate is approximately 15% to 30% of normal adult values. As a result, renal clearance of drugs is diminished. In addition, neonates are "obligate sodium losers" because their kidneys resorb less sodium in response to aldosterone than adult kidneys.[7] Finally, glucose excretion is impaired in neonates. This is intended to offset the impaired glycogen stores present in neonates and tendency toward hypoglycemia. Meticulous drug, fluid, and glucose regulation is important in early life before renal function maturation. Functional maturation may be delayed in premature infants; however, by the age of 2, functional maturation should be complete.[4,32]

Liver

At birth the liver is functionally immature, with minimal glycogen stores that may lead to hypoglycemia.[7] This is counterbalanced by decreased renal excretion of glucose as previously discussed. An immature liver is also reflected in immature liver enzyme systems. The cytochrome P-450 system, responsible for phase 1 drug metabolism of many lipophilic compounds, reaches approximately 50% of adult values at birth, suggesting decreased capacity for drugs metabolized by this system. Phase II reactions involving drug conjugation, which facilitates renal excretion, is also impaired. These immature reactions alter drug metabolism and lead to long drug half-lives. By age 1, these reactions achieve adult activity.[7,33]

Thermoregulation

Pediatric patients have a greater surface area to body weight ratio, or a larger surface area per kilogram than adults. They also have less muscle mass and less fat content than adults; as a result, pediatric patients quickly lose body heat to the environment. This makes pediatric patients more prone to hypothermia, which is associated with cardiac instability, respiratory depression, increased pulmonary vascular resistance, altered drug responses, and slower awakening from anesthesia. With a limited ability to shiver, infants respond to the stresses of a cold environment by increasing release of norepinephrine that enhances brown fat metabolism, a process called nonshivering

TABLE 19-3 Respiratory Variables

	Newborn	3 Yr	5 Yr	12 Yr	Adult
Tidal volume	21	112	270	480	575
Minimum ventilation	1.05	2.46	5.5	6.2	6.4
Vital capacity	120	870	1160	3100	4000
FRC	80	490	680	1970	3000

Modified from Dembo JB: Pediatric outpatient anesthesia, *Selected Readings Oral Maxillofac Surg* 5(4):1-19, 1997.

thermogenesis.[8,34] Environmental temperature is closely linked to the metabolic rates of infants, providing important sensory input.[35] Under resting conditions, ambient temperature is the most important determinant of metabolic rate.[16] An infant's metabolic rate is the lowest when environmental temperatures are within a neutral range. Cold stress will lead to increased metabolic rate of brown fat via nonshivering thermogenesis, increased oxygen consumption, hypoxemia, and metabolic acidosis.[4]

Developmental Pharmacology

Pediatric patients have a dramatically different response than adults to medications. Their response is altered by body composition, distribution of cardiac output, protein binding, and functional maturity of the liver and kidneys. As a result, drugs that have a very predictable response in adults may have a very unpredictable response in children.

The body composition of a person changes with age. The total body water in a term infant accounts for approximately 73% of body weight versus 60% for an adult. As the child grows, total body water decreases as fat and muscle content increase.[36] The implications of a drastically different body composition are twofold. First, drugs that are water soluble have a larger volume of water in which to distribute, which leads to initially larger doses to achieve the desired effect. Second, with less fat and muscle content, drugs that depend on redistribution into fat or muscle will remain intravascularly longer, leading to a longer clinical effect.

Distribution of cardiac output is different in pediatric patients, which results in unpredictable drug behavior. Pediatric patients have a higher cardiac output to vessel-rich groups (brain), which leads to a rapid onset of drugs. Pediatric patients also have decreased plasma levels of albumin leading to less protein binding and subsequently greater levels of free/active drug in the serum. Lastly, immature hepatic and renal function lead to long drug half-lives and decreased excretion.

As children grow, their body composition, distribution of cardiac output, protein binding, and functional maturity of the liver and kidneys all change to further affect drug behavior. The body composition of a child over the age of 2 is similar to that of an adult; they have normal adult values for protein, and the liver and kidney have functional maturity. Of particular importance is that a greater proportion of cardiac output is directed toward the already matured liver and kidneys, giving many medications a shorter half-life. As the child approaches adulthood, the half-life of many drugs lengthens to adult values. Overall most medications will have a prolonged elimination half-life in infants, a shortened half-life in children aged 2 to the early teen years, and a lengthening of half-life in those approaching adulthood.[4,37]

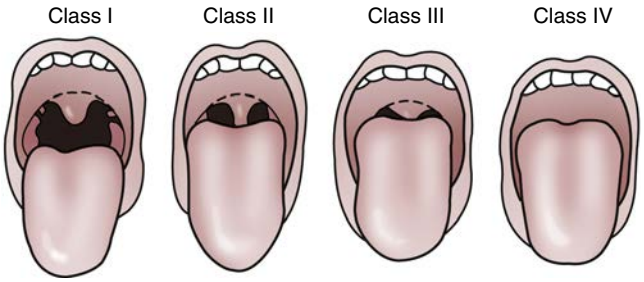
Preanesthetic Assessment

The ultimate goal of any preanesthetic assessment is to establish a treatment plan for the patient. Many medical problems discovered on the preanesthetic visit will prompt a change in patient management. One study found that the preanesthetic evaluation leads to changes in the treatment plan for more than 15% of American Society of Anesthesiologists (ASA) class I and II patients.[38] Although a similar study has not been conducted in pediatric patients alone, the significance of the study is understood. A focused history and physical examination with special attention to those medical conditions that will prompt a change in treatment is necessary. Whereas some medical conditions that require a change in patient management will be obvious and would not escape the attention of most parents (i.e., insulin-dependent diabetes mellitus, congenital cardiac defects), others are quite obscure and may only be brought to light with focused questions. Specific questions to ask should focus around gestational age, recent upper respiratory infection (URI), asthma, gastroesophageal reflux, and history of bleeding problems or hematologic disorders. Premature infants can have multiple medical problems usually caused by immaturity of major organ systems or intrauterine asphyxia.[8] Pulmonary complications of prematurity, including bronchopulmonary dysplasia, are particularly important to ask about because normal respiratory function may be delayed for many years, even up until age 6.[9,39] It is also important to ask about history of previous anesthesia and family history of musculoskeletal diseases or malignant hyperthermia.

The physical examination should include the child's general appearance, alertness, color, and activity level. Motor and verbal skills are also noted. Vital signs including height and weight are recorded. The physical exam should also focus on the cardiovascular, pulmonary, airway, and any other systems as indicated from the patient history. The presence of a heart murmur in a healthy, asymptomatic child is unlikely to indicate any significant cardiac pathologic condition.[8] Innocent murmurs are usually soft systolic ejection murmurs that are best heard along the upper left or lower left sternal border without significant radiation and may occur in more than 30% of normal children. Endocarditis prophylaxis is required for children with congenital heart defects. If any question exists in regard to the significance of a heart murmur, consultation with a pediatrician or pediatric cardiologist is recommended.

According to the American Association of Oral and Maxillofacial Surgeons clinical practice guidelines for anesthesia in outpatient facilities, most poor outcomes in pediatric anesthesia are related to loss of the airway.[1] The airway exam is extremely important in the physical examination of any patient undergoing anesthesia and especially in the pediatric patient with little respiratory reserve.

The airway exam should focus around three main characteristics that will help to detect a difficult airway. The first characteristic assesses the size of the tongue in relation to the oral cavity. The patient opens the mouth as widely as possible and protrudes the tongue as far as possible. The



• **Figure 19-3** Classification of the upper airway in terms of the size of the tongue and pharyngeal structures visible upon mouth opening. In class I patients, the soft palate, fauces, uvula, and anterior and posterior tonsillar pillars can be seen; in class II patients, all of the above can be seen except the tonsillar pillars, which are hidden by the tongue; in class III patients, just the base of the uvula can be seen; and in class IV patients, not even the uvula can be visualized.[40,41]

airway can then be classified according to what pharyngeal structures can be seen, also known as the "Mallampati" classification (Figure 19-3).

This classification is important because the ability to see vocal cords on direct laryngoscopy is almost always good in class I patients and almost always poor in class IV patients.[40] Additional factors that can complicate airway management include large tonsils and loose teeth. The second characteristic assesses the atlanto-occipital joint extension. If the neck can be flexed to approximately 25 degrees to 35 degrees, the atlanto-occipital joint is extended, and the oral, pharyngeal, and laryngeal structures are nearly aligned, allowing for easier laryngoscopy. It should be noted that children with Down syndrome may have atlanto-occipital joint instability, and extension of the neck during intubation may lead to cervical dislocation and spinal cord trauma. Appropriate clinical assessment including extension and flexion lateral neck films may be necessary to detect instability before anesthesia for these patients.[41] The third characteristic in evaluation of the airway is measuring the mandibular space, also known as the thyromental distance. This is the space anterior to the larynx and is an indication for how easily the laryngeal axis will align with the pharyngeal axis during direct laryngoscopy. This value is expressed by the number of "fingerbreadths," with more "fingerbreadths" being indicative of easier laryngoscopy. Neonates should have at least one "fingerbreadth" and adolescents at least three to ease in direct laryngoscopy.[40,42-44]

Preoperative Fasting

Pediatric patients are more prone to dehydration than adults, and as a result their preoperative fasting guidelines have been less strict. Additionally, asking a pediatric patient to fast for an extended period of time will lead to increased irritability of the patient. Conversely, the incidence of aspiration is three times higher in pediatric patients than in adults (9 per 10,000 vs. 3 per 10,000), indicating the need for careful attention to the matter.[45] Fortunately, if aspiration does occur, serious respiratory morbidity is rare in the immediate postoperative period in pediatric patients.[45,46] In 1999 the ASA appointed a task force to establish practice guidelines for preoperative fasting and the use of pharmacologic agents to reduce the risk of pulmonary aspiration in healthy patients undergoing elective procedures (Table 19-4).

TABLE 19-4 Summary of Fasting Recommendations to Reduce the Risk of Pulmonary Aspiration

Ingested Material	Minimum Fasting Period (Hr)
Clear liquids	2
Breast milk	4
Infant formula	6
Nonhuman milk	6
Light meal	6

Modified from American Society of Anesthesiologists: American Society of Anesthesiologists task force on preoperative fasting and the use of pharmacologic agents to reduce the risk of pulmonary aspiration practice guidelines for preoperative fasting and the use of pharmacologic agents to reduce the risk of pulmonary aspiration: application to healthy patients undergoing elective procedures, *Anesthesiol* 90:896, 1999.

The ASA points out that with clear liquids there is no difference in the gastric volume of children who fasted 2 to 4 hours versus more than 4 hours. Examples of clear liquids include water, fruit juices without pulp, and carbonated beverages. The ASA also points out that nonhuman milk is similar to solids in gastric emptying time, and therefore the amount ingested must be considered when determining an appropriate fasting time. Finally, ASA notes that a "light meal" typically consists of toast and clear liquids. Meals that include fried, fatty foods, or meat may prolong gastric emptying leading to a fasting recommendation of 8 or more hours before elective procedures.[47] Whereas some published evidence supports the routine use of pharmacologic agents to reduce the risk of pulmonary aspiration, the ASA states that routine use of pharmacologic agents to reduce the risk of pulmonary aspiration in patients who have no apparent increased risk for aspiration is not recommended.[47]

Upper Respiratory Infection

During the preanesthetic evaluation, it is important to ask if the child has had any recent colds that may indicate a recent upper respiratory infection (URI). If the child has in fact had a recent cold, it is important to differentiate between a URI and simple rhinitis. Clear rhinorrhea is usually not a concern, and anesthesia is not contraindicated. A URI is usually associated with fever, mucopurulent green or yellow discharge, and a productive cough. Children with URIs have irritable airways and are at an increased risk for laryngospasm, breath holding, postintubation croup, atelectasis, pneumonia, and episodes of desaturation.[48-51] Furthermore, airway hyperreactivity may last for up to 6 weeks after a URI, and the incidence of

complications in children recovering from a URI is almost the same as in children who have active URIs.[51] The presence of URI in a child is particularly important because increased airway edema and inflammation in an already narrow airway will cause profound increases in resistance to airflow. Traditional guidelines for treatment of patients with URIs suggest that the procedure be delayed for 4 to 6 weeks after cessation of the URI to decrease the risk to the patient.

Asthma

Asthma is one of the most common chronic conditions in the United States, with the prevalence being highest for people under the age of 18.[52] Moreover, the prevalence among children aged 5 to 14 has increased 74% from 1980 to 1994 and 160% among children under the age of 4 from 1980 to 1994.[52] Given the degree of prevalence among the pediatric population it is likely that oral and maxillofacial surgeons will treat pediatric patients with asthma. Treating pediatric patients with moderate to severe asthma can be particularly dangerous because the overall mortality rates of asthma are highest between the ages of 5 to 14.[53] Moreover, acute and fatal bronchospasm can occur during anesthesia and endotracheal intubation in children with asthma. Whenever possible, endotracheal intubation should be avoided in these patients.[54]

In patients with asthma, elective cases should not be undertaken unless their asthma is well controlled. During preoperative assessment of the asthmatic patient, it is important that the disease is assessed by the cause, frequency and severity of attacks, hospital and intensive care admissions, and by drug history. A thorough examination is required, which may reveal expiratory wheezes, use of accessory muscles, or an overdistended chest. If a child is actively wheezing, elective surgery should be canceled. A child should be free of wheezing for at least 1 week before surgery. Attempts to control wheezing with an increase in β-agonists or the addition of steroids are indicated preoperatively. Preoperative steroids may be needed for children with asthma who continue to wheeze despite an increase in β-agonists or as a stress dose for children who have received steroids over the last year to control their asthma.[42,54] The addition of prednisone, 1 mg/kg given 24 and 12 hours before surgery, will considerably decrease airway reactivity.[42] If preoperative wheezing cannot be controlled with conservative therapy as an outpatient, admission for more aggressive therapy and consultation with a pediatrician is indicated.

Monitors

The ASA has set the standards for basic anesthetic monitoring for all anesthesia care.[55] The goal of these standards is to encourage quality patient care while noting that it is but one component of care and that the monitors alone do not offer patient safety guarantees. Two basic standards rely on both provider vigilance and basic monitoring. Although the various monitors and alarms are a very important component of anesthesia care, they do not replace the anesthesia provider.

The first standard states that a qualified anesthesia provider must be present in the room through all stages of anesthesia care. The objective of this standard is based on the need for a qualified anesthesia provider to monitor and address any of the possible rapid changes in patient status and to be present continuously. Although it is not currently necessary, it is highly recommended that providers administering anesthesia to children have current certification in Pediatric Advanced Life Support (PALS). The observation of levels of consciousness during anesthesia will reduce risks and most likely prevent many complications if adverse drug responses are detected in a timely manner.[56]

The second standard states how oxygenation, ventilation, circulation, and temperature are to be continually monitored. *Continually* is further defined as "repeated regularly and frequently in steady rapid succession."

Oxygen concentration is assessed in inspired gas and blood with pulse oximetry during any form of anesthesia delivery. Pulse oximetry will be accompanied by pitch pulse tone with audible, low threshold tone alarms. Adequate lighting will help with visual assessment of physical appearance to ascertain appropriate oxygenation of tissues. This is especially important in small children because of the rapid rate of desaturation and avoidance of hypoxic episodes.

Adequate ventilation should be evaluated by continual observance of qualitative clinical signs, such as chest expansion, reservoir breathing bag movements, and chest auscultation. Carbon dioxide detection is necessary during use of general anesthesia including verification of placement of an endotracheal tube or laryngeal mask airways (LMAs) and will be monitored continually unless undetectable as a result of nature of patient, procedure, or equipment. This will be done from initial placement of the airway device until removal. This measurement will be done with capnography, capnometry, or mass spectroscopy. Mechanical ventilation units must include an audible disconnect alarm. All other forms of anesthesia care should also be evaluated by continual observation of clinical signs and/or detection of exhaled carbon dioxide, although it would be expected to be lower if using a nonclosed breathing circuit, such as a nasal cannula, where the presence of exhaled carbon dioxide is the means of detection.

Circulation will be monitored by continuous electrocardiogram and heart rate display and arterial blood pressure display at a minimum of 5-minute intervals. Additional measures, such as pulse palpation or heart sound auscultation and intra-arterial pressure tracings, could also be used for general anesthesia patients. Blood pressure cuffs should be appropriately fitted for each child to ensure correct measurements because a cuff that is too large will underestimate readings. Each patient should be sized with a blood pressure

cuff that has a width 20% to 50% greater than the diameter of the patient's extremity.[57]

Every child receiving anesthesia shall have temperature monitoring when a clinically significant change in body temperature is intended, anticipated, or suspected.

Alternative Monitors

Adjuncts to standard monitors evaluate other clinical and physiologic processes. The use of a precordial stethoscope adds the ability to hear heart sounds and airway status easily. Bispectral analysis (BIS) is a noninvasive method to evaluate levels of anesthesia, and it is based on the principle that electroencephalogram (EEG) waveforms change with the level of alertness. The manufacturer has developed numeric value, known as the BIS index, based on an algorithm of EEG digital signals. The numeric value corresponds to level of sedation: 90 to 100 awake, 70 to 90 light to moderate sedation, 60 to 70 deep sedation, 40 to 60 general anesthesia, and less than 40 a deep hypnotic state. The BIS index has been shown to be closely associated to sedation scales, which would prevent possible oversedation.[58]

Transcutaneous capnometry is being studied as an alternative method of detecting ventilatory malfunction and prevention of hypoxemia in patients in addition to pulse oximetry. Pulse oximetry is always accompanied with a delay, and a combination of the two provides the advantage of monitoring both alveolar ventilation (capnometry) and oxygen transport to the periphery (pulse oximetry) noninvasively. Stein et al. investigated two transcutaneous capnometers for clinical use, but do not currently recommend their use in clinical conditions in the current form because they provide only an approximate estimation of $PaCO_2$.[59]

Alarms

Monitors and associated alarms may only alert the provider if they are activated. Block et al. reported that a majority of anesthesiologists routinely disable or mute audible alarms because of a number of false alarms.[60] False alarms are a common source of disruption and distraction in the operating suite because they alert the anesthesia provider of known information that is already being controlled or monitored by the anesthesia provider. The Joint Commission on Accreditation of Healthcare Organizations and the Anesthesia Patient Safety Foundation (APSF) both recommend the use of audible alarms.[61,62] Alarms have proven their importance by preventing and reducing the severity of anesthetic incidents, but sole reliance on monitors without clinical support may also lead to inappropriate interventions.[63] Providers should become familiar with their equipment and determine the proper alarm settings based on ASA guidance and clinical judgment.

Equipment and Room Preparations

The treatment of pediatric patients requires some adjustments to the setup in preparation for the procedure and presence of additional and often helpful elements in the operating arena. Some of these address emergency medications, equipment, fluid delivery access, and delivery. Initial preparations should be to change monitoring and anesthesia equipment to pediatric settings.

All pediatric operatories should have emergency equipment that is located in a well-known, easily accessible area. This equipment should be well maintained and inspected on a periodic basis. Appropriate algorithms and medicines to treat perioperative emergencies should be included in that location as well. A defibrillator with pediatric paddles along with emergency suction, auxiliary oxygen supplies, and alternative source of light should be available in case of loss of power. The oxygen source should be able to deliver under pressure for a minimum of 1 hour. At our institution, each pediatric patient has his or her information included in a worksheet that takes patient vital statistics and converts that information into appropriate equipment sizes, fluid replacement amounts, and doses of common perioperative medications. This form is then placed in the operative setting to be reviewed as needed (Figure 19-4).

Broselow Emergency Pediatric Tape provides a reference at each color bar on the tape to select equipment sizes to perform emergency resuscitation based on weight zone. The tape also shows precalculated medication dosages and infusion rates based upon each colored weight zone. Other commercial and institutional items are available to provide similar information.

An average setup of pediatric patient treatment begins with setup of room and equipment. Because infants and children have a greater surface area to body weight ratio causing greater body heat losses, temperature of the operating suite should be adjusted to between 80° F to 90° F.[64] Most oral surgery procedures completed as outpatient procedures are relatively short, so clinical judgment should determine suitability of additional measures, such as warm fluid and heating blankets.

Airway

Items needed to access and control the airway should be readily available; these include appropriately sized nasal cannulas, nasopharyngeal airways, oropharyngeal airway, endotracheal tubes, and LMAs (Table 19-5).

Pocket masks and bag-mask-valve devices with positive pressure ventilation ability should be included. Inclusion of a system of emergent airway access, such as a cricothyrotomy kit, should be available in case situations arise where other methods have failed to establish a patent airway. Transtracheal catheter jet ventilation may be considered for support of oxygenation when a surgical airway is required for pediatric patients, but only in situations where oxygenation and ventilation cannot be provided any other way.[65] Ravussin et al. used transtracheal jet ventilation during pediatric endoscopic laser treatment of laryngeal and subglottic stenosis.[66] Adequate control of the airway and satisfactory gas exchange were obtained in all cases; however, they reported

a severe life-threatening complication rate of 10.7% including pneumomediastinum and bilateral pneumothoraces (see Figure 19-4).

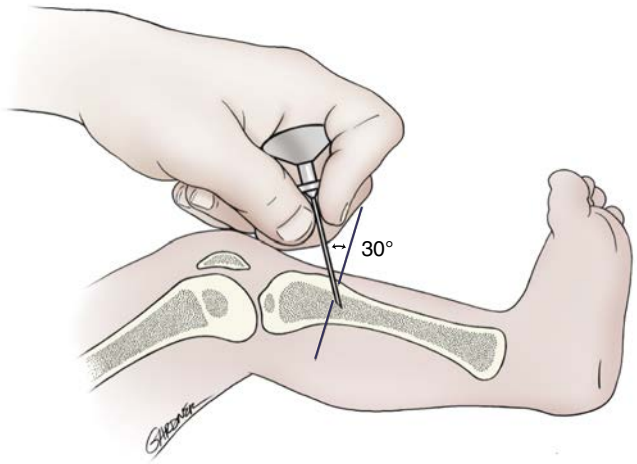
A simple method to size an oropharyngeal airway is by placing the anterior portion at the commissure and the posterior portion to the angle of the mandible. Endotracheal tubes should also be available and sized appropriately. A common method for sizing an endotracheal tube for children over 2 years old is found in the formula:

$$4 + (\text{age}/4) = \text{tube diameter (in mm)}$$

For example, an 8-year-old patient would likely require a 6-mm tube. An alternative method involves selecting an endotracheal tube size equivalent to the diameter of the child's fifth finger. Verification of the correct size is based on ease of passage into the larynx and the development of air leak at 15 to 20 cm H_20 pressure. Absence of air passage at that pressure is an indication that the selected tube is too large. If the leak is present at less than 10 cm H_20, the tube should be changed to the next larger size. If the patient is planned for intubation, two endotracheal tubes of selected size and one each of a size above and below should be available to allow rapid access if the size is incorrect. Length of the tube placed at the lips can also be figured with the following formula:

$$12 + (\text{age}/2) = \text{length of tube (in cm)}$$

These formulas are approximate and sizing should always be confirmed clinically by auscultating bilateral breath sounds, epigastric auscultation, chest expansion, and presence of exhaled carbon dioxide. A standard cutoff for use of a cuffed endotracheal tube has been 8 years or older, but with advent of low-pressure cuffs the use of cuffed tubes is becoming more common.[67,68] If desired nasal intubation can be performed with an RAE design nasal tube, appropriate-size laryngoscopes should also be available, and lights and attachments verified before each case. A narrow handle and straight blade aid intubation in children younger than 5 years old. A pediatric circuit should be used with appropriate face mask for mask induction or general anesthesia. Tidal volume (8 to 10 mL/kg) and respiratory rates (increased to 18 to 30) should be adjusted for each patient. A small dental suction should be nearby and functioning appropriately for evacuation of secretions. Reservoir bags should be 1 L for small children and 2 L for larger children. If the child is 8 years or older, an adult circuit may be used.



• **Figure 19-5** Emergent situations may call for placement of IO cannulation 1 to 3 cm below the tuberosity in the middle of the anteromedial surface of the tibia. Care is taken to avoid the epiphyseal plate while gently twisting the needle. Loss of resistance, aspiration of marrow, and upright needle when unsupported indicate proper placement. Resuscitation drugs, fluids, and blood products may be delivered through this route.

Intravenous Access

IV access may be accomplished in several ways. At the preoperative appointment, one can employ the "tell-show-do" method by showing how the procedure will proceed and also to see how the child reacts. Parents may also inform the providers how they think their child will handle the attempts. A popular choice for cutaneous anesthesia is the use of EMLA cream (lidocaine 2.5% and prilocaine 2.5%) under an occlusive dressing and intact skin. By applying a thick layer to the skin at two to three sites 90 minutes before the procedure, adequate skin anesthesia should be achieved for IV access.[69] Older children may benefit from subcutaneous injection of 2% lidocaine at the site of venipuncture. Younger children may be unable to cope with the process, and alternative methods may be used, such as mask induction before IV placement. Emergent situations may require the use of intraosseous (IO) placement of a catheter for delivery of resuscitation drugs, fluids, and blood products. An IO infusion needle kit with stylet is available from Cook Critical Care Co (Bloomington, IN). If an IO needle is not available, a butterfly or standard hypodermic needle can also be used. The location for IO cannulation is often the tibia, the site being approximately 1 to 3 cm below the tuberosity in the middle of the anteromedial surface of the tibia (Figure 19-5).

In this location, the tibia is close to the skin, and it is easy to palpate the flat, smooth surface to be cannulated. Other locations include distal femur, medial malleolus, and anterior iliac spine. The IO needle is inserted through the skin into the flat anteromedial surface of the tibia with a gentle twisting motion; it is directed perpendicular to the surface of the tibia or slightly toward the toes to avoid entering into the epiphyseal plate. If using another location, it is preferred to place away from the nearest joint space. When a loss of resistance is felt, stop the needle advancement and attempt marrow aspiration. If marrow is aspirated, irrigate to prevent obstruction of the needle. Other indications of proper placement include an upright needle when unsupported and a fluid delivery without subcutaneous edema.[70] IO placement has been shown to be performed easily after diverse training with minimal complications. Complications of IO access include osteomyelitis, subcutaneous access, compartment syndrome, extravasation, fracture, growth plate injuries, and fat emboli.[71] Fractured bones should not be accessed.

Intraoperative Fluids

Once IV access has been gained, fluid may be delivered. It has become common to use an IV delivery device, such as a buretrol or volutrol, with a microdrip chamber (60 drops/mL) attached between the IV fluid bag and the IV catheter; it is used to deliver IV fluids in a controlled manner with 100 mL placed at a time in the chamber. Lactated Ringer's (LR) or another balanced salt solution is usually adequate because of the fact that most outpatient oral surgery procedures are short, and hypoglycemia or electrolyte imbalances are not of concern. For longer outpatient cases in the operating room where hypoglycemia becomes a concern, 5% dextrose in LR may be added or used as the maintenance fluid itself.[72]

Fluid management is based on fluid maintenance, replacement, and deficit. Fluid maintenance is based on the 4:2:1 rule: 4 mL/kg for the first 10 kg, and then 2 mL/kg for the second 10 kg and 1 mL/kg/hr for each remaining kg. In a child weighing 30 kg, the calculations for maintenance regimen would be:

$$10 \text{ kg} \times 4 \text{ mL} = 40 \text{ mL}$$

$$10 \text{ kg} \times 2 \text{ mL} = 20 \text{ mL}$$

$$10 \text{ kg} \times 1 \text{ mL} = 10 \text{ mL}$$

$$30 \text{ kg} = 70 \text{ mL/hr}$$

Fluid replacement takes into consideration the amount of time in hours the patient was *nil per os* (NPO) multiplied by the fluid maintenance amount plus hourly maintenance, surgical blood loss, urine output, and insensible losses (1 to 3 mL/kg/hr for most oral surgery procedures). The fluid deficit is given back incrementally; half is given over the first hour and then the remaining half given over the next 2 hours. If a patient was NPO for 8 hours with a maintenance rate of 100 mL/hr, 400 mL would be given the first hour, then 200 mL given each of the next 2 hours. Surgical blood loss would be replaced with either crystalloid solution (LR) in a 3:1 ratio or 1:1 ratio for colloid (5% albumin) or actual blood replacement.

Pharmacosedation and General Anesthesia

Oral surgery on pediatric patients can be a very pleasant operative experience if the patients are reasonably calm and cooperative. Cooperation is important to provide for patient, provider, and staff safety; it also allows for proper monitoring and physical cooperation during the procedure. The primary goals of pediatric sedation are to reduce typical fear and anxiety, increase cooperation, and ensure patient comfort by providing adequate forms of amnesia and analgesia. Pharmacosedation or general anesthesia may be needed to meet these goals by providing the adequate level of anesthesia.

Premedication for Fear and Anxiety

Premedication is used to reduce presurgical anxiety. Children may be unable to communicate their fears and may express them in undesirable ways: scared looks, agitation, trembling, crying, and, most important, noncompliance. Most fear comes from anticipated pain and separation from parents. Fear of separation from parents is to be expected from children between the ages of 6 months and 6 years.[73] These fears may be addressed at the initial preoperative appointment when the routines of the day of surgery may be reviewed with the child and their parents, to include a visit to the surgery suite and a trial run of the placement of the IV access. Parents should be counseled to take part in allaying the fear and anxiety of patients by remaining calm themselves and providing gentle encouragement. At our institution, the health and physical exam is completed 2 days before the day of surgery, allowing for the child to become familiar with the surgical environment. The parents are given details of the patient's preoperative fasting, postoperative expectations, postsurgical care instructions, and use of analgesics at this appointment. This is also the time to determine the need for premedication and the extent the parents will play in the perioperative period and if their presence is needed at the time of induction of anesthesia. Although parental presence decreases their anxiety and increases satisfaction, parental presence has no effect on the child's anxiety.[73] Premedication not only allows for greater patient cooperation, it may also reduce the amount of anesthesia provided at induction and intraoperatively.[75]

Midazolam

Midazolam is a benzodiazepine with a rapid onset of action, short duration of action, has no active metabolites,

and provides retrograde amnestic properties. These qualities make midazolam ideal for both premedication and sedation. Midazolam is available for delivery in many forms, and its dose is determined by delivery choice. Oral midazolam is available in a cherry-flavored syrup; this method of delivery is the most popular and is delivered at 0.5 to 1.0 mg/kg with a maximum of 15 to 20 mg.[8,76,77] Orally delivered midazolam is effective in approximately 30 minutes and does not result in significant changes in heart rate, respirations, or blood pressure with doses of 0.5 to 0.75 mg/kg.[77] However, the disadvantages of orally administered drugs include inability to titrate, unreliable absorption as a result of hepatic first-pass metabolism, and moderate failure rates. At doses greater than 0.75 mg/kg, midazolam may not provide additional sedation at 30 minutes after premedication and in some instances may be associated with a greater incidence of side effects including dysphoria and blurred vision.[77] Midazolam may also be delivered nasally or rectally, both offering adequate sedation if the child is unwilling to swallow the syrup. Intranasal administration had been used often in the past, but is not well accepted by children because of irritation to nasal mucosa and taste of medication when swallowed, which also subjects the medication to absorption in the digestive tract. Roelofse et al. administered rectal midazolam (1 mg/kg) to 100 children 30 minutes before dental treatment.[78] The rectal delivery was well accepted by 70% of the patients with reliably good anxiolysis and sedation without loss of respiratory drive or protective airway reflexes. If patients have IV access, sedation can be accomplished with 0.1 to 0.15 mg/kg and titrated to effect. Because midazolam has no analgesic properties, it is necessary to achieve adequate local anesthesia with possible addition of other analgesic medications based on the amount time and expected stimulation of the procedure. Golparvar et al. reported an incidence of 3.4% of pediatric patients with paradoxical reactions with the use of IV midazolam.[79] Signs and symptoms included restlessness, violent behavior, physical assault, self-injury, restraint, panic, anger, dysphoria, and disorientation. The time of onset varied between 3 to 6 minutes and was unlikely to spontaneously resolve. Patients were treated successfully by the administration of the rescue tranquilizer ketamine.

Fentanyl

Fentanyl is an opioid agent that is most commonly used after IV access during surgery; it has a rapid onset of action and duration of action usually under an hour. It may be used for sedation often in concert with midazolam. Although it is available in lollipop form, it must be absorbed through the oral mucosa; if swallowed, effectiveness decreases as a result of liver first-pass metabolism.[80] Similar to other opioid agents, the most common side effects with fentanyl use are respiratory depression, pruritus, and postoperative nausea and vomiting.[81] Because of the potential respiratory depression and effects of synergism with additional medications such as midazolam, fentanyl should only be delivered with ASA monitors in place.

Ketamine

Ketamine is a dissociative anesthetic agent that produces an anesthetic state consisting of catalepsy, analgesia, amnesia, and different degrees of consciousness.[82] Ketamine produces a dissociative state that is created by the generation of dissociation between the cortical and limbic systems, which disrupts interpretation of visual, auditory, and painful stimuli from the brain.[83] At subanesthetic doses, ketamine has the advantage of providing analgesia without respiratory depression associated with opioids, and it also reduces the amount of additional opioids necessary in the postoperative period.[84] Ketamine directly stimulates smooth muscle dilatation, which decreases risk of bronchospasm. Ketamine is also beneficial because it usually maintains upper airway musculature tone and spontaneous respirations.[17] Ketamine increases saliva production, heart rate, blood pressure, and intracranial pressure (ICP). If a closed head injury is suspected, ketamine should not be used because of increases in ICP. Additional fluids produced by excess salivation may cause laryngospasm if secretions contact the vocal cords, so anticholinergics (atropine or glycopyrrolate) are often given before use of ketamine.[85] Emergence delirium is often cited as one of the possible side effects from use and can include hallucinations that are pleasant, bizarre, or terrifying. Risk factors for emergence delirium are age over 10 years, female gender, underlying psychiatric disorder, IV route, high doses, and excessive noise or stimulation on emergence.[86] The addition of Versed before ketamine use reduces the incidence of emergence delirium.

Ketamine is usually given parenterally, but it can also be given through oral, rectal, and intramuscular (IM) routes.[78] Oral ketamine has been investigated for use in sedating anxious pediatric dental patients.[87] Ketamine 6 mg/kg was given orally, with an onset of approximately 20 minutes and a mean duration of sedation of 36 minutes. Nitrous oxide 30% to 50% was also administered during treatment. The quality of sedation was rated as good for 65% of the patients, with a mean recovery time of 56 minutes. IM is also popular because patient cooperation is not required, and it has been shown to be an ideal medication for short procedures in the ER. This can be accomplished by using ketamine (4 mg/kg) combined with atropine or glycopyrrolate in a single injection to provide desired dissociation.[88] Alternative combinations described used ketamine 3 mg/kg, midazolam 0.05 mg/kg, and glycopyrrolate 0.005 mg/kg injected into the lateral thigh to provide sedation for children with minor facial injuries seen in the emergency department.[89] Satisfactory sedation was achieved in 32 of 37 patients, with 5 others requiring a second ketamine injection of 1 mg/kg. Onset of sedation was within 6 minutes, and adequate working time of 30 minutes was evident in those children receiving one injection. Emergence delirium and hallucinations were

not observed, and protective airway tone and respiratory drive were preserved.

Propofol

Propofol is an alkylphenol in an oil at room temperature and only slightly soluble in water with soybean oil, glycerol, and purified egg phosphatide. It is the only IV anesthetic that can be used for total IV anesthesia because the recovery period for others, such as ketamine and midazolam alone, would be too long. Propofol is chemically unrelated to benzodiazepines, steroids, opioids, and barbiturates.[90] Propofol can be used in infants and young children because it offers a safe and smooth induction with a low incidence of side effects.[91] Respiratory depression and apnea are common when used and may require some form of intervention in settings of sedation, including the simple but effective chin-lift procedures to open the airway or more aggressive intervention during deep sedation or general anesthesia. The length of apnea is slightly longer when compared with barbiturates.[92,93] The major advantage of using propofol is the lower incidence of laryngospasm, postoperative nausea and vomiting, and a rapid emergence.[91,94-96]

The major disadvantage for propofol use is pain at the injection site, which can be reduced by placing IV access in larger veins or the use of lidocaine 0.2 mg/kg either directly before or mixed in with propofol.[97] Other disadvantages of propofol are increased periods of hypotension and bradycardia at higher doses, both of which occur more often in children.[17]

Induction dosages vary with size of the child and whether it will be used for induction, sedation, or general anesthesia at higher levels. Propofol maintenance is ideal because of the rapid and short-acting mechanism of propofol. Infusion pumps may be used to titrate the drug to the desired level of sedation. Controlled boluses of propofol may also be used for short procedures (Table 19-6).

Inhalation Anesthesia

Nitrous oxide was the first anesthetic introduced by Horace Wells in 1844 and is currently known for having a wide margin of safety and few side effects, which supports its use in pediatric patients.[98] Advantages of nitrous oxide include rapid induction and emergence, insignificant cardiovascular and respiratory changes, and ability to produce analgesia. Nitrous oxide can be combined with other anesthetic agents producing sedation and analgesia during pediatric procedures. Litman et al. premedicated 34 children with 0.7 mg/kg of oral midazolam 15 to 20 minutes before administering 40% nitrous oxide during pediatric oral procedures.[99] This technique did not result in any clinically significant respiratory depression, but in three children resulted in a level of deep sedation and a level approaching general anesthesia in one child. Nitrous oxide can also be combined with volatile anesthetics, creating the "second gas effect," where uptake of the blood by the "first" gas (nitrous oxide) increases both the alveolar concentration of the "second" gas (e.g., sevoflurane) and the input of additional second gas into the alveoli via augmentation of the inspired volume.[100]

Inhalational anesthetics have two main uses in pediatric anesthesia, and both are amenable to same day procedures. Sevoflurane is an inhalation agent with a favorable profile, making it useful for mask induction and maintenance.

Sevoflurane is halogenated ether, which has rapid onset and recovery attributes. It has gained favor in oral surgery procedures in children as a result of decreased potential for side effects possible with other inhalation anesthetics, including sensitization of myocardium when local anesthetics with epinephrine are used, possible development of ventricular arrhythmias, cardiac depression, and hepatic necrosis. Sevoflurane produces a dose-dependent increase

TABLE 19-6 Pediatric Drug Doses

Drug	Comment	Dosage
Midazolam	Premedication (PO)	0.5 mg/kg
	Maximum dose (PO)	20 mg
	Premedication (intranasal)*	0.2-0.6 mg/kg
	Sedation (IM)	0.1-0.15 mg/kg
	Maximum dose (IM)	7.5 mg
	Sedation (IV)	0.05 mg/kg
Fentanyl	Pain relief (IV)	1-2 µg/kg
	Pain relief (intranasal)	2 µg/kg
	Premedication (Oralet)	10-15 µg/kg
	Anesthetic adjunct (IV)	1-5 µg/kg
	Maintenance infusion	2-4 µg kg/hr
	Main anesthetic (IV)	50-100 µg/kg
Ketamine	Initial dose (IM)	4 mg/kg
	Supplemental dose (IM)	1-2 mg/kg
	With adjunctive agent (N2O) (IM)	2 mg
	Low dose (PR)	5 mg/kg
	Dissociative dose (PR)	10 mg/kg
	Induction (IV)	1-2 mg/kg
	Sedation (IV)	0.5-1.0 mg/kg
	Maintenance infusion	25-75 µg/kg/min
	Premedication (PO)	6-10 mg/kg
Propofol	Induction (IV)	2-3 mg/kg
	Maintenance infusion	60-250 µg/kg/min

From Morgan GE, Mikhail MS, Murray MJ: Pediatric anesthesia. In *Clinical anesthesiology*, ed 4, New York, 2006, McGraw-Hill, pp 922-950; Gonty AA: Ketamine-a new look at an old drug, *Oral Maxillofac Surg Clin North Am* 4:815-823, 1992

*From Shankar V: Procedural sedation in the pediatric patient, *Anesthesiol Clin North Am* 23:635-654, 2005.

in respiratory rate and a decrease in tidal volume, as do most volatile anesthetics. The advantages of sevoflurane over halothane are decreases in incidence of breath holding and laryngospasm, faster onset of action and recovery, and improved patient acceptance.[101]

Mask induction with sevoflurane is successful because of patient acceptance and tolerance of large minimum alveolar concentrations (MAC). Sevoflurane demonstrates the least airway irritation of all the currently available inhalation agents. Morgan et al. describe two methods of mask induction.[8] Mask induction can be accomplished using a single-breath technique with 8% sevoflurane and 50% nitrous oxide and oxygen or with 100% oxygen. If the child is cooperative, then 0.5% incremental doses every 3 to 5 breaths of sevoflurane can be added as the child is breathing 70% nitrous oxide and oxygen 30%. Once the lid reflex is lost, IV access can be accomplished and appropriate methods of anesthesia can be delivered and maintained. The improved acceptance of mask induction is possible with the use of scented lip balm or sprays placed inside the mask. The MAC of sevoflurane is 2.5% for patients 6 months to 12 years and 3.2% to 3.3% for infants less than 6 months old if general inhalation anesthesia is used.[102]

Techniques of Deep Sedation/General Anesthesia

At our main office in Asheville, the majority of scheduled outpatient pediatric procedures are dentoalveolar surgeries lasting from 10 to 30 minutes under deep sedation or nonintubated general anesthesia for apprehensive children. Because of the previously mentioned anatomic and physiologic characteristics evident during early childhood, we limit our pediatric outpatient deep sedations and general anesthetics to include ASA 1 or 2 patients age 8 and older. Children under the age of 8 are scheduled in the main operating room and managed by an anesthesiologist.

Obtaining IV access preoperatively cannot always be accomplished in pediatric patients, but we have experienced good success with the application of EMLA cream 60 to 90 minutes before the appointment in the 8- to 12-year-old age group. Children in this age group may prefer an IV start to the pungent odor of volatile anesthetics during mask induction. Our preferred method of pediatric outpatient anesthesia for children able to cooperate for IV access consists of initial doses of 0.05 mg/kg of midazolam, and 0.50 mcg/kg of fentanyl. For procedures lasting less than 10 minutes, intermittent boluses of 0.25 to 0.50 mg of propofol are then administered until the desired plane of anesthesia is achieved. For cases anticipated to last longer than 10 to 15 minutes, we have found a modification of the technique described by Blankenstein[103] to be effective for pediatric patients. Boluses of midazolam and fentanyl are administered as described previously, followed by ketamine 0.2 to 0.3 mg/kg, injected slowly to reduce the incidence of apnea. Glycopyrrolate 0.01 mg/kg has been given as an antisialagogue to control secretions. After this an infusion of propofol at 75 to 125 mcg/kg/min is started and adjusted as necessary to maintain a plane of deep sedation/general anesthesia. If required, additional boluses of 0.25 mg/kg of propofol are added to deepen anesthesia and prevent undesirable patient movement. The use of ketamine and propofol together complement each other, and we find less airway obstruction than when using propofol alone. Also the cardiostimulant effects of ketamine and glycopyrrolate are reduced by the cardiodepressant effects of propofol. Another advantage of this technique is that the low dose of ketamine and the antiemetic properties of propofol together result in a low incidence of postoperative nausea and vomiting. Prolonged recovery and nausea have been shown to be insignificant when the total dose of ketamine is less than 0.4 mg/kg.[104]

Although other techniques of anesthesia are available for treating pediatric patients, we find that the preceding techniques provide excellent working time, maintenance of cardiovascular and respiratory function, smooth emergence, and quick recovery. However, we are always prepared to assist with ventilation as necessary, have emergency drugs drawn into syringes placed on the bracket tray, and have all equipment required for intubation immediately available if required.

Perioperative Complications

Regardless of the type of anesthesia delivered, there are several important complications that could occur. These may deal with surgical environment, medications given, and physical responses of each patient. Complications of the procedure and type of anesthesia to be delivered should be discussed during the preoperative appointments and at the time of consent. The parent's and child's questions should be answered and their understanding reviewed. Each practitioner providing anesthesia services should be well versed in the signs and symptoms of each complication to include rapid and appropriate identification and treatment.

Laryngospasm

A common and frightening anesthetic complication is the occurrence of laryngospasm, which is a forceful involuntary spasm of the laryngeal musculature, causing a partial or complete airway obstruction. It is caused by the stimulation of the superior laryngeal nerve by secretions or foreign bodies, such as an endotracheal tube passing through the larynx during extubation.[8] Signs of laryngospasm are the absence of sound in a complete obstruction or squeaks, grunts, or whistles in incomplete obstructions.[17] Methods of preventing laryngospasm would include controlling excess secretions, protecting against foreign body aspiration, avoiding stimulating the patient during "light" anesthesia, and deepening the level of anesthesia or extubating the spontaneously breathing patient while they are still deeply anesthetized.

Treatment of suspected laryngospasm would include an initial airway assessment with simple head-lift, jaw-thrust maneuver, elevation of the tongue, suction of oropharynx, and if confirmed, application of gentle positive pressure ventilation with anesthesia bag and mask using 100% oxygen. If this does not break the laryngospasm and hypoxia occurs, succinylcholine or rocuronium should be given to paralyze the laryngeal muscles, and atropine 0.02 mg/kg should be administered first when succinylcholine is used in children to prevent bradycardia. If laryngospasm occurs in patients where IV access is not available and in whom more conservative measures have failed, IM succinylcholine can be administered at a dose of 4 to 6 mg/kg.[8] The application of muscle relaxants should be followed by controlled ventilation until the patient regains adequate respiratory mechanics. Succinylcholine is for emergency use only in children because children with undiagnosed myopathies are more susceptible than adults to hyperkalemic cardiac arrest, malignant hyperthermia, and masseter muscle spasm.[8] If it is used in an emergency situation, the provider must be vigilant to the signs and symptoms of evolving malignant hyperthermia (MH) or hyperkalemia.

A severe complication that could occur from prolonged airway obstruction accompanied with respiratory efforts is negative pulmonary pressure edema, which is caused most commonly by larygnospasm.[106] Other causes include obstruction of the endotracheal tube or a misplaced LMA resulting in the folding of the epiglottis over the opening of the trachea. Although exact incidence is unknown, it is most likely caused by the generation of markedly negative intrathoracic pressure as a result of forced inspirations caused by the laryngospasm, resulting in transudation of fluid from pulmonary capillaries to the interstitium following relief of the upper airway obstruction. Upon relief of the obstruction, developing dyspnea with pink frothy sputum caused by pulmonary hemorrhage and frank hemoptysis could be seen. A chest radiograph would demonstrate bilateral pulmonary infiltrates. Supportive treatment would include observation for several hours in the hospital setting with maintenance of adequate oxygenation and airway patency. Most cases resolve without lasting consequences, but some patients may require diuretics (furosemide), intubation, and mechanical ventilation.[107]

Anaphylaxis

Anaphylaxis is generally an unanticipated severe allergic reaction that can occur suddenly. Anaphylaxis is a Gell and Coombs classification Type I immunoglobulin IgE-mediated hypersensitivity reaction causing direct activation of mast cells and basophils.[108] In the clinical setting, this can be caused by agents that are used commonly in the operative setting (Table 19-7).

During many same-day oral surgery procedures, the initial signs and symptoms could be easily recognized as a result of exposure of some or most of the skin, such as pruritus, flushing, urticaria, angioedema, and conjunctivitis. Severe hypotension, greater than 40% of baseline, after a slow infusion or small increments of drugs may indicate an allergic reaction.[109] Wheezing and dyspnea may be followed by abdominal pain, nausea, vomiting, diarrhea, and cardiovascular collapse and death.[108] Initial treatment would be immediate removal or discontinuation of the offending object or medication followed by immediate administration of epinephrine to treat hypotension, cardiovascular collapse, and provide smooth muscle relaxation. Diphenhydramine should be administered if urticaria and angioedema are present, and the addition of steroids and bronchodilators may also be considered.[110]

Bronchospasm

Bronchospasm is a constriction of bronchial smooth muscles and is common in the postoperative period. It can be caused by aspiration, histamine release secondary to medications, allergic response, or existing pulmonary conditions—especially asthma in the pediatric population. Bronchospasm may be caused by secretions, deep pharyngeal suctioning, aspiration, or intubation. Treatment consists of removing any possible irritants or drugs and administering inhaled β_2-sympathomimetic agents, such as albuterol. For uncooperative or obtunded patients, a subcutaneous injection of epinephrine is appropriate for most intraoperative occurrences. If the patient is intubated, approximately 5 to 10 puffs of albuterol can be administered through the endotracheal tube followed by positive pressure ventilation with 100% oxygen. Nebulized atropine or glycopyrrolate can be used to control excess secretions. IV epinephrine should not

TABLE 19-7 Drugs Involved in Perioperative Anaphylaxis

Substance	Incidence of Perioperative Anaphylaxis (%)	Most Commonly Associated With Perioperative Anaphylaxis
Muscle relaxants	69.2	Succinylcholine, rocuronium, atracurium
Natural rubber latex	12.1	Latex gloves, tourniquets, Foley catheters
Antibiotics	8	Penicillin and other β-lactams
Hypnotics	3.7	Propofol, thiopental
Colloids	2.7	Dextran, gelatin
Opioids	1.4	Morphine, meperidine
Other substances	2.9	Propacetamol, aprotinin, chymopapain, protamine, bupivacaine

From Hepner DL, Castells, MC: Anaphylaxis during the perioperative period, *Anesth Analg* 97:1381-1395, 2003.

be used unless hypotension is present and concurrent anaphylaxis is suspected. Intubation may be necessary if the patient continues to be hypoxic.[111]

Aspiration

Aspiration has been shown to be a cause of laryngospasm and bronchospasm and pneumonitis. Aspiration of gastric contents aspirated in greater than 0.3 to 0.5 mL/kg may cause the most serious consequences of aspiration, but the aspiration of food, pus, or dental materials is also serious and may need to be treated with antibiotic coverage, bronchoscopy, and removal of foreign objects. Of all aspirated contents, blood is the least worrisome. Pneumonitis had previously been treated with antibiotics and steroids, but the current standard of care is application of continuous positive airway pressure (CPAP) ventilation. Antibiotics are useful only in cases of purulent discharge aspiration.[112] Control of airway and secretions are necessary to prevent this type of injury, and the pediatric patient should have received appropriate perioperative medications and verification of NPO status before anesthesia is initiated. Proper surgical techniques, such as consistent use of throat packs, control of secretions, and securing small instruments continue to be the best preventative measures for preventing aspiration and its potential consequences.

Malignant Hyperthermia

Malignant hyperthermia (MH) is a hypermetabolic syndrome occurring in genetically susceptible patients after exposure to either a volatile anesthetic or succinylcholine. Muscle contraction is sustained as a result of a reduction in the reuptake of calcium from the sarcoplasmic reticulum, resulting in a hypermetabolic state, tachycardia, hypercarbia, hypoxemia, and increased heat production. The first signs of MH usually occur in the operating room, but may be delayed for more than 1 hour after termination of anesthesia. MH is rare, with a higher incidence in pediatric patients (1:15,000) than in adult patients (1:40,000).[8]

MH follows an autosomal pattern of dominance in about 50% of susceptible families, and an autosomal recessive form has also been associated with King-Denborough syndrome. Diagnosis can be established by exposing a fresh skeletal muscle biopsy to a contracture test with caffeine, halothane, or a combination of both. The earliest signs of MH are masseter muscle rigidity (MMR), tachycardia, and hypercarbia, with two or more of these signs greatly increasing the likelihood of MH. MMR occurs in only 15% to 30% of true MH episodes, but can also be present following administration of succinylcholine. The safest course is to assume that masseter spasm is due to MH and postpone elective surgery; however, some anesthesiologists may proceed if no other signs of MH are evident and then change over to nontriggering anesthetic agents.[8]

Treatment involves first discontinuing all triggering agents, changing breathing tubes, breathing bags, and soda lime. Hyperventilation is initiated with 100% oxygen, and dantrolene sodium is mixed with sterile water and administered 2.5 mg/kg as soon as possible. If a significant rise in body temperature is evident, cooling measures including ice packs applied to the body, cold IV fluids, and cold solution lavage of the stomach and body cavities should be initiated. Acidosis is treated with sodium bicarbonate, 1 to 2 mg/kg IV, and hyperkalemia is treated with IV insulin and glucose. Calcium channel blockers should not be used with dantrolene because hyperkalemia can result. Additional doses of dantrolene can be administered if needed, and the patient should be transferred to intensive care for at least 24 hours until vital signs have returned to normal.

Recovery and Discharge

All pediatric patients should be closely monitored while recovering from anesthesia until ready for discharge. Pediatric patients are vulnerable to postanesthetic laryngospasm that can occur in the recovery room as the patient wakes up and chokes on pharyngeal secretions.[8] For this reason, all pediatric patients should be recovered in the lateral position to allow oral secretions to drain away from the vocal chords.

Discharge criteria for children are different than those for adults. Each pediatric patient must appear fully awake and back to his or her baseline behavior with no clinical signs of complications from anesthesia or surgery. Pediatric discharge criteria should address each of the following: state of consciousness, vital signs, respiratory efforts, age-appropriate ambulation, return of normal airway reflexes, clear liquid tolerance, adequate pain control, and absence of postoperative nausea and vomiting.[113] Patel et al. reported that the most common cause of unplanned admissions after attempted same-day procedures in children was protracted vomiting.[112] Ondansetron, a serotonin receptor agonist, has been shown to reduce postoperative nausea and vomiting in pediatric patients when given at a dose of 0.05 to 0.15 mg/kg IV.[114] Dexamethasone has also been shown to decrease the incidence of postoperative nausea and vomiting in children following tonsillectomy at a dose of 1 mg/kg not to exceed a total dose of 25 mg.[115] Although postoperative vomiting was also the most common postoperative complication reported by parents after ambulatory surgery, the cost-effectiveness of routine prophylaxis is controversial.[112] Other common reported complications postoperatively are sore throat, headache, sore muscles, and surgical pain.[116] These issues are usually easily resolved by use of appropriate analgesia medications.

FDA Warning Against Codeine Use in Children[117]

The U.S. Food and Drug Administration (FDA) is reviewing reports of children who developed serious side effects or died after using codeine for postoperative pain management after tonsillectomy and/or adenoidectomy for obstructive sleep apnea syndrome. Recently three children aged two to

five died and one child suffered a nonfatal but life-threatening case of respiratory depression. These children all had evidence of an inherited ability to convert codeine into life-threatening or fatal amounts of morphine in the body. All children received codeine doses that were within the normal dose range.

The FDA issued a safety announcement dated February 2, 2013 by adding a new boxed warning to the drug label of codeine-containing products about the risk of codeine in postoperative pain management in children following tonsillectomy and/or adenoidectomy. The FDA is recommending health care professionals prescribe an alternative analgesic for postoperative pain control in children who are undergoing tonsillectomy and/or adenoidectomy. Codeine should not be used for pain in children following these procedures. For management of other types of pain in children, codeine should only be used if the benefits are anticipated to outweigh the risks.

Parents or caregivers who observe unusual sleepiness, confusion or difficult or noisy breathing in their child should discontinue the codeine and seek medical attention immediately because these are signs of an overdose.

Summary

The performance of oral surgery in children frequently requires pharmacosedation or general anesthesia to reduce fear and anxiety, increase cooperation, and ensure adequate forms of amnesia and analgesia to safely and effectively complete the surgical procedure. Selection of anesthetic technique is based on the patient's needs, the nature of the procedure, the facility, and the surgeon's training, experience, and level of comfort.

20 Pediatric Dentoalveolar Surgery

JOHN H. CAMPBELL, MICHAEL Y. NAGAI

Introduction

Children are not simply small adults. Every surgeon is familiar with this concept, and from a physiologic standpoint, for children up to the age of 12 it is largely true. The major impact of pediatric physiologic differences, however, relates to administration of anesthesia rather than surgical intervention itself. In essence, hard and soft tissue dentoalveolar surgery may be somewhat more difficult because of a smaller operative site, but the techniques of surgery are largely similar to those provided for adult patients. Smaller instrumentation can help to alleviate access problems resulting from a "miniature" operative field, but with adequate care the pediatric patient should not experience an increase in surgical complications as a result of reduced surgical access.

Even adult patients may not relish surgical procedures; the child is still less likely to approach a planned oral surgery intervention in a completely cooperative fashion. For this reason, it is important to consider a consultation visit for even minor procedures in a child. The child's response to the office visit, ability to cooperate in performance of an oral examination, and general demeanor will assist greatly in planning a successful intervention. These factors will largely determine whether the patient is a candidate for local anesthesia, nitrous oxide inhalation analgesia, or more involved inhalation and/or intravenous anesthetic management.

A consultation visit should include the parent or guardian most familiar with the child's medical history, allergies, and medications. Other relatives or caregivers are often unfamiliar with conditions that may affect the surgeon's ability to safely perform a procedure, and they are unable to legally consent to a procedure for the patient. A parent cannot simply "assign" the responsibility for consent to another individual without appropriate legal documentation. In addition, it is important for the surgeon and staff to ascertain the interactions between parent and child that could indicate overprotective or negligent parental behavior which might predict a difficult surgery or recovery period.

This chapter is written to aid the reader in the assessment of conditions that may indicate the need for dentoalveolar surgery in the pediatric patient, and to suggest techniques that will lead to safe and effective surgical management when necessary. Anesthetic management is addressed elsewhere, and genetic, developmental, and pathologic conditions are not discussed except as they relate to management of dentoalveolar surgery in the pediatric population.

The Pediatric Demographic

The U.S. Food and Drug Administration defines the pediatric population as persons age 21 years or younger at the time of their diagnosis and/or treatment. Within this range are a number of subpopulations.[1]

- Neonates: Birth through the first 28 days of life
- Infants: 29 days of age to less than 2 years of age
- Children: 2 years of age to less than 12 years of age
- Adolescents: 12 years of age through 21 years of age

This creates a large and complex patient demographic that presents treating clinicians with unique challenges in physiology, anatomy, pathology, and patient management. Each subpopulation presents its own distinct treatment challenges, but for the purposes of this chapter, the "pediatric population" will be referred to as a single entity. It is important for surgeons to understand the nature and course of disease that is unique to the pediatric population, and that these patients, as previously indicated, are not "small adults" in a physiologic sense. Treatment decisions and timing of surgical intervention can have a profound impact on clinical outcomes and lifelong development. Nowhere is collaboration between subspecialists as important as in treating this demographic. A team approach among general dentists, pediatric dentists, orthodontists, oral surgeons, and pediatricians certainly provides the most comprehensive and thorough care for these young patients.

It should be the goal of the treating surgeon to address both patient and parental concerns regarding the nature of the office or hospital visit. Many times, it is difficult to identify a clear chief complaint in the pediatric population, as patients are often withdrawn, in pain, afraid, and unable to communicate clearly and effectively. Adding to the challenge is the sometimes superfluous information parents offer for what they believe is causing distress to their child.

Filtering out critical and pertinent information is an essential skill that can make the difference in a successful course of therapy. Acting within acceptable moral and ethical clinical standards, the general therapeutic goals for dentoalveolar surgery should include:[2]

- Elimination of acute and or chronic infection
- Reduction or elimination of pain
- Restoration of anatomic form
- Restoration of masticatory function
- Preservation of vital structures
- Limited period of disability
- Elimination of existing pathology
- Appropriate understanding by the patient and family of treatment options and acceptance of the treatment plan
- Appropriate understanding by the patient and family of the risks, benefits, and alternative treatments
- Prevention of future problems.

Pediatric Dental Development

Odontogenesis is a complex process with numerous mechanical and chemical interactions between mesenchymal and epithelial tissues. Teeth begin to develop within generally well-defined areas of the stomodeum, and, by maturational extension, are guided to the oral cavity and alveolar processes of the jaws. Confounding elements include the embryologic nature of Rathke's pouch, which can cause a number of associated developmental anomalies, including cysts and tumors, within the developing dental arches.[3] It is important to remember that during development, the oral and maxillofacial region contains remnants of salivary glands, seromucous glands, sinonasal epithelium, nasopalatine duct epithelium, and dermatologic epithelium, all of which can create pathologic entities. This complex synergism gives rise not only to the normal anatomic structures of the head and neck, but also to their associated diseases.

The formation of primary teeth typically begins between 6 and 8 weeks in utero with the development of the dental lamina. By the end of the eighth week, all 20 tooth buds have typically been formed. From this point, all subsequent development of both deciduous and permanent teeth will take place in a somewhat predictable pattern when growth proceeds normally.[4] Throughout this prolonged span of development, the teeth are subject to both genetic and environmental influences, and a deviation from this normal growth pattern may help a practitioner to recognize an underlying disease process that may require further investigation. This is highlighted by recommendations from the American Academy of Pediatric Dentistry (AAPD), the American Dental Association (ADA), and the American Academy of Pediatrics (AAP); all suggest a childhood dental visit by the age of 1 year.[5] It is certainly beneficial to approach pediatric dentoalveolar surgery from a preventive standpoint. Emergency visits create an unpleasant treatment experience and increase overall health care costs. Exposing pediatric patients to regular preventive care will allow them to develop good dental habits from an early age and build positive rapport with their providers, setting the stage for a lifetime of improved oral and systemic health.

There are a number of odontogenic epithelial stages that ultimately give rise to the functional dentition and surrounding structures. It is therefore important for oral and maxillofacial surgeons to understand and respect the intricate nature of development in order to best recognize and treat dilemmas in dentoalveolar surgery. Familiarity with normal eruption patterns is critical so that early recognition of eruption failure can be investigated and appropriate intervention instituted. Teeth not present in the oral cavity by the normal time frame can indicate failure of tooth development, genetic developmental anomalies, pathologic conditions, or tooth malposition, among others. Early recognition may reduce the likelihood of untoward permanent sequelae. Table 20-1 indicates normal eruption sequences for the human dentition.

Pediatric Anatomy

The many physical differences between children and adults can have a significant impact on treatment of pediatric patients. A characteristic example is the administration of local anesthetic in a young person. Often, accessory innervations of the mandible lead to difficulty in achieving profound anesthesia during inferior alveolar nerve block (IANB). The mandibular foramen is also situated at a level further below the occlusal plane and more proximal than in an adult. Thus, the injection must be made slightly lower and more posterior than in an adult (Figure 20-1).

It has recently been suggested that developing tooth buds have the potential for damage during routine administration of local anesthesia in children,[6] as the location of the third molar follicle is close to needle penetration during IANB. A statistically greater incidence of missing third molars was found in quadrants that had a definitive history of receiving IANB compared with quadrants that had no history of injection, but further research is needed to quantify clinical significance. In either case, it is important that clinicians understand and appreciate anatomic considerations when providing even basic care.

Pediatric patients also have smaller, more delicate structures in their mouths. This creates difficulties in access and visualization during treatment. When performing extractions, the teeth themselves may actually be easier to remove then their adult counterparts due to the more forgiving bone and widened periodontal ligament space present in children, but when combined with previously mentioned limitations, extraction of even routine teeth may become problematic. Of course, procedures can be made exponentially more difficult when the patient is precooperative or uncooperative. Other relevant anatomy that must be considered in dentoalveolar surgery includes the proximity of teeth to the developing permanent dentition, neurovascular structures, and airway dimension.

The anatomy of the pediatric airway differs significantly from that of adults, and although the majority of differences may be more pertinent during intubation for general

TABLE 20-1 Eruption Sequences of Primary and Permanent Dentition

Deciduous Dentition			Permanent Dentition		
Tooth	Eruption (mo)	Root Completion (yr)	Tooth	Eruption (yr)	Root Completion (yr)
Maxillary			**Maxillary**

This table uses the Zsigmondy system of classification.

• **Figure 20-1** **A,** Inferior alveolar nerve enters pediatric mandible slightly more posterior and inferior than in the adult. **B,** Adult mandible.

anesthesia, the major differences should be known in the event that emergency maneuvers must be undertaken. The classic works by Fink, Demarest, Eckenhoff, and Negus form the foundation of our knowledge about the structure and function of the pediatric and adult airway.[7-9] They suggest that there are five major anatomic differences between the pediatric and adult airways: tongue, larynx, epiglottis, vocal folds, and subglottis. In the past, it was believed that a disproportionately larger tongue compared to the rest of the oral cavity was a major contributing factor

in airway obstruction. It is now felt that the tongue grows in relation to the bony structures of the oral cavity, and it is more likely that nasopharyngeal and epiglottic collapse contribute more to the obstructive potential.[10] The angles and dimensions of the smaller airway (inversely proportional to the radius of the lumen to the fourth power) also create a much higher resistance to air flow and, when coupled with even slight edema, can contribute to airway compromise. Proper airway management is always of paramount importance when performing any procedure, and an understanding of pediatric anatomy is critical to delivering safe and effective treatment.

Physiology

Children are physiologically distinct from adults. Body temperature, blood pressure, heart rate, and the ability of body systems to compensate in situations of stress differ tremendously from those in the healthy adult. A pediatric patient who presents to the office with an odontogenic infection may be severely ill without showing obvious signs of distress. To complicate matters, pediatric patients can often deteriorate rapidly, turning an urgent situation into an emergency. It is important that practitioners know the clinical signs of impending cardiopulmonary collapse and be prepared to handle an emergency if one should arise.

Often, it is difficult for the pediatric patient to convey what is wrong or if they are in pain. A thorough investigation of the medical, dental, and family histories, which includes input from parents and other family members, along with a focused physical exam, should be undertaken in each patient. The decision to treat a patient who may currently have an upper respiratory infection—or who underwent tonsillectomy a week earlier—will face each clinician, and all factors should be taken into consideration when treatment plans are developed. A thorough understanding of the Pediatric Advanced Life Support (PALS) and Basic Life Support (BLS) algorithms will help both doctor and office staff to approach the pediatric patient with the skills necessary to manage problematic circumstances. Waiting until a patient recovers from a respiratory infection before an elective extraction, or referring a patient back to his or her pediatrician or the emergency department, can be potentially lifesaving.

Hard Tissue Surgery

Dental Extraction

Size and anatomic differences of primary teeth may preclude use of adult extraction forceps for tooth removal. Deciduous teeth, in addition to their small size, have bulbous crowns, and molars have widely separated roots that predispose to root fracture unless there is resorption associated with underlying erupting bicuspids. The likelihood of root fracture is exacerbated in the event of ankylosis, which may be indicated by submersion of the crown in relation to the surrounding dentition and by altered percussion sounds.

Many adult instruments can, however, be used in treatment of the primary dentition. With the exception of forceps, the extraction armamentarium remains essentially the same as for the permanent dentition. It is important to be judicious with the use of dental elevators and forceps to avoid mobilization of adjacent partially resorbed deciduous teeth or permanent teeth with incompletely formed roots. Thin or resorbed roots of primary teeth may fracture during removal, and removal of residual fragments should be attempted. Consideration should be given to leaving the retained root in place if damage to an erupting permanent tooth or adjacent primary tooth is likely. These fragments will rarely cause problems and can be removed at a later date if clinically necessary.

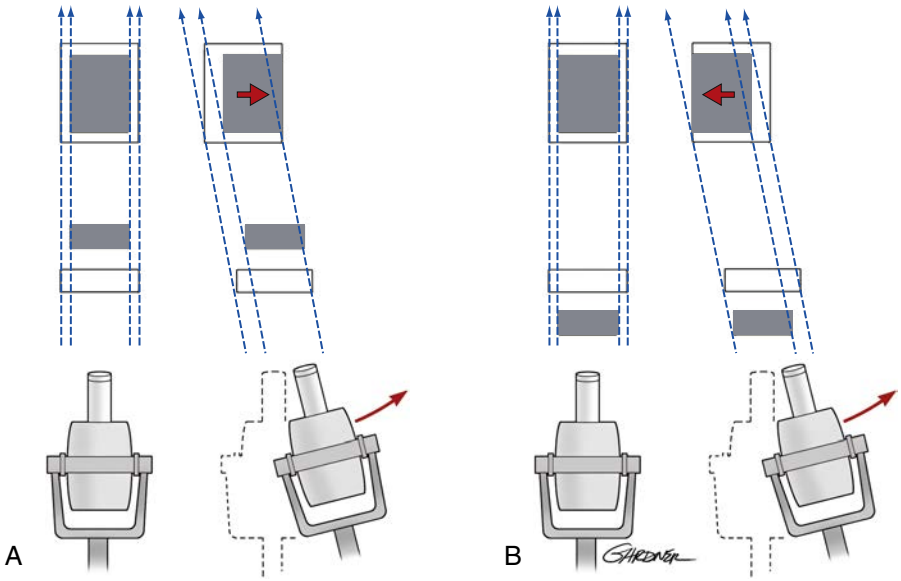
Impacted Teeth

Impacted teeth are commonly encountered in an oral and maxillofacial surgery office, and it can often be difficult to coordinate treatment among referring providers, surgeons, and orthodontists.

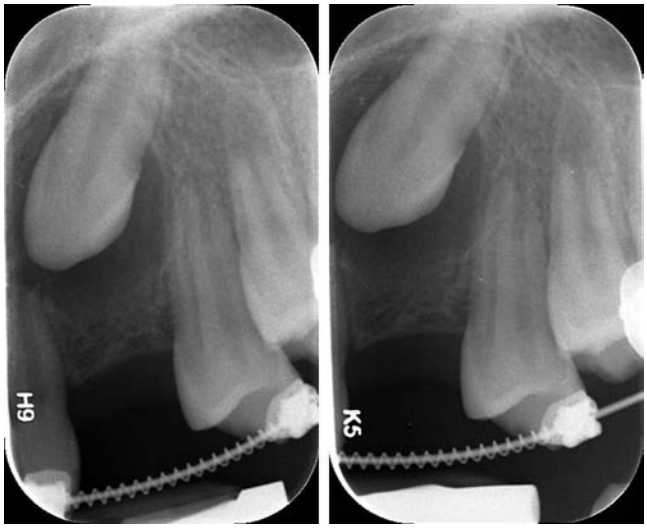
When a tooth's eruption is delayed beyond the normal age-appropriate time frame, it is said to be impacted, and any tooth may become impacted. The literature suggests a broad prevalence of impaction, ranging from 1% to 18% in some populations.[11] Tooth positions may range from vertical to mesioangular, horizontal, distoangular, and even inverted, and teeth can appear in almost any region of the maxillofacial skeleton. If third molars are excluded, the maxillary canine is the most likely tooth to be impacted. Mandibular second premolars, mandibular and maxillary second premolars, and maxillary central incisors follow, in that order.[12] Primary teeth rarely become impacted, but when a primary tooth does fail to erupt, it is most likely to be a mandibular molar.[13] Etiologies of impacted teeth include both systemic and local disturbances. Illness and its treatment (radiation, for example), congenital syndromes, deficiencies in eruption space, ankylosed primary teeth, cysts, and tumors may all be associated with impacted teeth, and even dietary changes in modern civilization have been implicated.[14] In some cases, no specific etiology can be determined.[15]

Once a disturbance in eruption pattern has been identified clinically, it is important to obtain appropriate imaging studies to help evaluate the position of impacted teeth and rule out other pathology within the facial skeleton. The radiographic examination may include a panoramic film plus additional imaging modalities, when clinically indicated, to provide a three-dimensional (3D) picture.

Periapical films can aid in determining buccal or palatal position of impacted teeth. A periapical radiograph is first exposed according to conventional techniques. A second film is positioned in the same location as the first, but the x-ray source is moved either mesially or distally (Figure 20-2). The impacted tooth will seem to move in either the same or opposite direction as the beam source. If it moves in the same direction, it is palatal or lingual to the adjacent teeth (Figure 20-3). Movement in the opposite direction



• **Figure 20-2** **A,** Tube-shift technique demonstrating a palatally impacted object. **B,** Depiction of a buccally impacted object.



• **Figure 20-3** Periapical radiographs are helpful in localizing an impacted tooth. In the image on the right, the crown of the impacted cuspid is located in the edentulous space. As the x-ray source is moved forward (mesially), the cuspid crown also moves mesially and appears to approach the root of the lateral incisor *(left image)*. The cuspid is thus located on the palatal surface of the maxilla.

will indicate that the tooth is buccal or labial to the adjacent teeth. This is Clark's rule, commonly remembered by use of the acronym "S.L.O.B." (same = lingual; opposite = buccal). Minimal or no movement of the impacted tooth may indicate a mid-alveolar location.[16]

Occlusal films also provide an excellent diagnostic view if the patient can tolerate the larger film, and may be combined with panoramic radiography to determine the position of impacted teeth at or near the midline. In this case, the source beam is adjusted superiorly or inferiorly in a fashion similar to that used for Clark's rule. The x-ray source is typically positioned at 60 degrees superior or inferior to the horizontal plane to create enough separation to determine tooth position. This technique has the added advantage of visualizing the entire impacted tooth in many cases, and it necessitates only one, rather than two, additional films.[17,18]

With increasing frequency, intraoffice cone-beam computed tomography (CBCT) is used for surgical planning and assessment of adjacent structures. Determining the position of the impacted canine, for example, is crucial to determining the feasibility of surgery and planning a suitable approach to expose the tooth and predict the best vector for potential orthodontic force. Walker showed the benefits of 3D volumetric imaging of impacted canines, which can demonstrate the presence or absence of the canine, size of the follicle, inclination of the long axis of the tooth, relative buccal and palatal positions, amount of bone covering the tooth, 3D proximity and resorption of adjacent tooth roots, condition of adjacent teeth, local anatomic considerations, and overall stage of dental development.[19] The increased cost, time, radiation exposure, medicolegal issues, and lack of universal availability associated with CBCT have, however, limited its routine use.[20]

The Impacted Canine

Canine teeth are considered the "cornerstones" of the dental arches, essential to the normal and harmonious function of the dentition, optimization of the facial profile, and maintenance of esthetics. Failure of the maxillary canines to erupt into a proper position can result in compromised oral health including periodontal disease, loss of arch length, formation of cysts, and recurrent infection.[21] It has been suggested that maxillary canine impaction occurs in approximately 2% of the population and is twice as common in females as in males.[22] The prevalence of canine impaction in the maxilla is more than twice that in the mandible.[23] Historically, it was believed that approximately one third of impacted maxillary canines were located labially, and two thirds were

located palatally.[24,25] Some literature suggests a 6:1 ratio of palatal to labially impacted cuspids.[26] These data were based on plain film evaluation. Recent assessment of the canine position by use of CBCT scanning to definitively determine the position of the impacted maxillary canine showed a different distribution: 45.2% impacted buccally, 40.5% impacted palatally, and 14.5% impacted midalveolus.[27] This finding, however, may reflect only the population reported in the study and is not indicative of the experience of most surgeons.

The exact cause of canine impaction is unknown. It is likely multifactorial and due to a combination of local and systemic factors. The results of Jacoby's study showed that 85% of palatally impacted canines had sufficient space for eruption, whereas only 17% of labially impacted canines had sufficient space.[25] Therefore, arch length discrepancy is thought to be a primary etiologic factor for labially impacted canines. Two major theories associated with palatally displaced maxillary canines have been proposed: genetic and guidance. Proponents of the genetic theory believe that canine impaction is under genetic influences and cite increased occurrence of other dental anomalies, bilateral occurrence of impaction, familial occurrence, and population differences as support for this premise.[28] The guidance theory is based more on local factors influencing the proper eruption of the canine. It proposes that the canine erupts along the root of the lateral incisor, which serves as a guide, and if the root of the lateral incisor is absent or malformed, the canine will not erupt.[29] At present, no definitive answer explains why the maxillary canine is so variable in its pattern of eruption, and dental professionals need to be vigilant for signs of potential maxillary canine impaction. These include delayed eruption of the permanent canine, retention of the primary canine, absence of a labial bulge, presence of a palatal bulge, and crown tipping of the lateral incisor.[30] Once this problem is recognized, appropriate definitive care can be initiated.

Treatment

The simplest form of treatment is observation. Retention of the impacted canine in its impacted position, with serial imaging, is a viable option in certain circumstances. This, of course, would be determined by factors that include age, medical and dental comorbidities, patient preference, and local considerations.

In the pediatric population, most orthodontists and surgeons agree that some form of intervention is indicated, and that preventing maxillary canine impaction provides the best long-term results. Other treatment options are available and include:[31]

- Extraction of the impacted tooth and retention of the primary, which can be esthetically recontoured
- Extraction of the impacted tooth and primary canine followed by orthodontic space closure, substituting the first bicuspid for the extracted canine ("bicuspid substitution")
- Extraction of the impacted tooth and primary canine with replacement using an implant-supported crown
- Surgical exposure of the impacted canine with orthodontic alignment of the ectopic tooth after its surgical exposure
- Autotransplantation of the impacted tooth into its anatomic position in the arch after orthodontic pretreatment for space opening.

Extraction of deciduous canines can occur as early as 8 or 9 years of age. Interceptive treatment is influenced by the degree of impaction, the canine's position in relation to the lateral incisor, and the patient's age at diagnosis. Using panoramic techniques, Ericson and Kurol found that early extraction of primary maxillary canines could result in normal eruption of ectopically displaced permanent maxillary canines.[32] They proposed that extracting the primary canine before the patient is 11 years of age can allow eruption of the permanent canine in over 90% of cases if the crown of the canine is distal to the midline of the lateral incisor root. Eruption drops precipitously, however, (to about 64%) if the permanent canine crown is mesial to the midline of the lateral incisor root. Early intervention by practitioners may lead to a normal positioning of the canines and alleviate the need for future complex orthodontic and surgical treatment.

In the absence of preventive treatment, surgeons have several options to assist the movement of permanent canine teeth into their correct position within the dental arch. Orthodontic movement to create adequate space is the first line of treatment, followed by surgical exposure and/or assisted eruption. There is an obvious need for clear and unambiguous communication between specialists so as to approach the planning and surgical phases of treatment with a common goal. The conventional methods used to bring a palatally impacted canine into occlusion include surgically exposing the tooth and allowing it to erupt naturally during early or late mixed dentition,[33,34] or surgically exposing the tooth and placing a bonded attachment to the crown for application of orthodontic force.

Surgical options include "open eruption techniques," such as excisional uncovering and apically positioned flaps, or "closed eruption techniques." In the open technique, the surgical access created is left open to the oral environment. Exposure alone may allow eruption, but more commonly an orthodontic device is applied at the time of surgery or left for later placement at the discretion of the orthodontist. In the closed technique, the orthodontic device must be placed at the time of surgery, as the site is closed with mucosal tissue and only the orthodontic chain is visible for activation. Tooth position and the amount of attached gingiva in the area (in the case of labially positioned canines) help determine which method will be used.

Excisional uncovering may be employed to expose either labially or palatally impacted teeth. For labially located teeth, however, the position of the impaction is of significance. The majority of the crown must be located occlusal to the mucogingival line such that several millimeters of attached gingiva remain to withstand occlusal and chewing

forces. Lack of attached gingiva may lead to recession and root exposure.

Excisional uncovering is most often used to expose palatally impacted canines. It is relatively straightforward if the crown can be palpated, but more difficult if there is no observable palatal bulge. For palpable teeth, local anesthesia is administered routinely, with additional anesthetic infiltrated into the area adjacent to the tooth. This aids hemostasis and assists in separating soft tissue from the underlying tooth. A window is made in the soft tissue to expose the crown, and associated follicular tissue is removed with hand instruments. Exposure of the crown to approximate the cementoenamel junction is then accomplished with hand or rotary instrumentation. Some practitioners will use a dental elevator to assess for ankylosis, but even if the tooth can be mobilized, eruption is not assured. If attempting to allow spontaneous eruption, a dressing may be placed for comfort, although it can be difficult to stabilize at this site. Often an orthodontic appliance is placed for later application of traction. It can be difficult to maintain a dry field to adequately etch and apply an orthodontic bracket, but the newer cements can often adequately secure the device even in a moist field. If unsuccessful, it may be necessary to delay application of an appliance until some healing has taken place, usually in a week to 10 days. It is important to excise adequate soft tissue to prevent regrowth that can cover most, or in some cases all, of the crown.

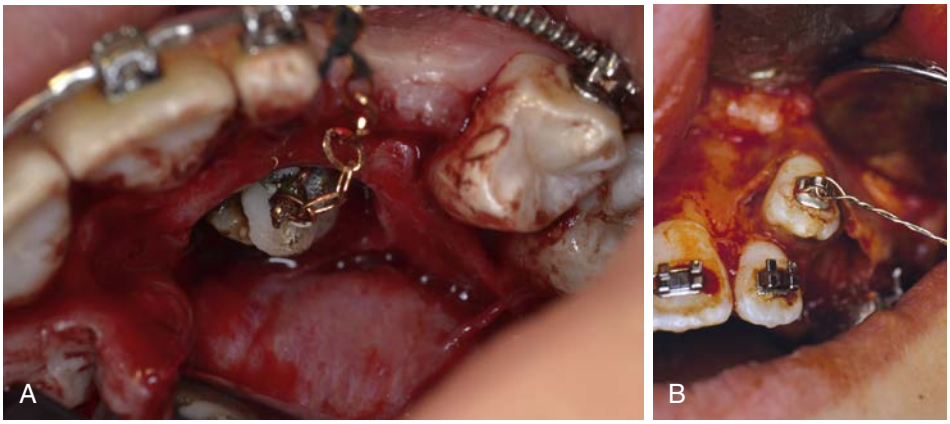
If there is no palpable palatal bulge, excisional uncovering becomes more difficult. This may require a full-thickness palatal flap and a search for the tooth crown. Adequate preoperative imaging is particularly important in this scenario, as it is easy to become disoriented. Based on the radiographs, bone is judiciously removed at the site of the presumed tooth location. A color difference is usually noted when the crown is encountered, with the crown appearing whiter than the surrounding bone. Absence of bleeding is also an indicator that the crown has been encountered. Once adequate crown has been exposed, a needle penetrating the soft tissue flap can be used to mark the area of soft tissue that is to be removed. The flap is then returned to its anatomic position and sutured in place. A dressing or orthodontic appliance can then be placed.

Closed eruption is perhaps more routinely employed for palatally impacted cuspids because there is no annoying palatal opening present as the tooth erupts. A full-thickness flap is developed to expose the tooth (or teeth in the case of bilateral impactions), and bone is removed as for the excisional technique. An orthodontic appliance with attached chain is cemented to the crown, and the chain is brought out through the flap in the area of the crestal incision and secured to the arch wire or adjacent bracket (Figure 20-4).

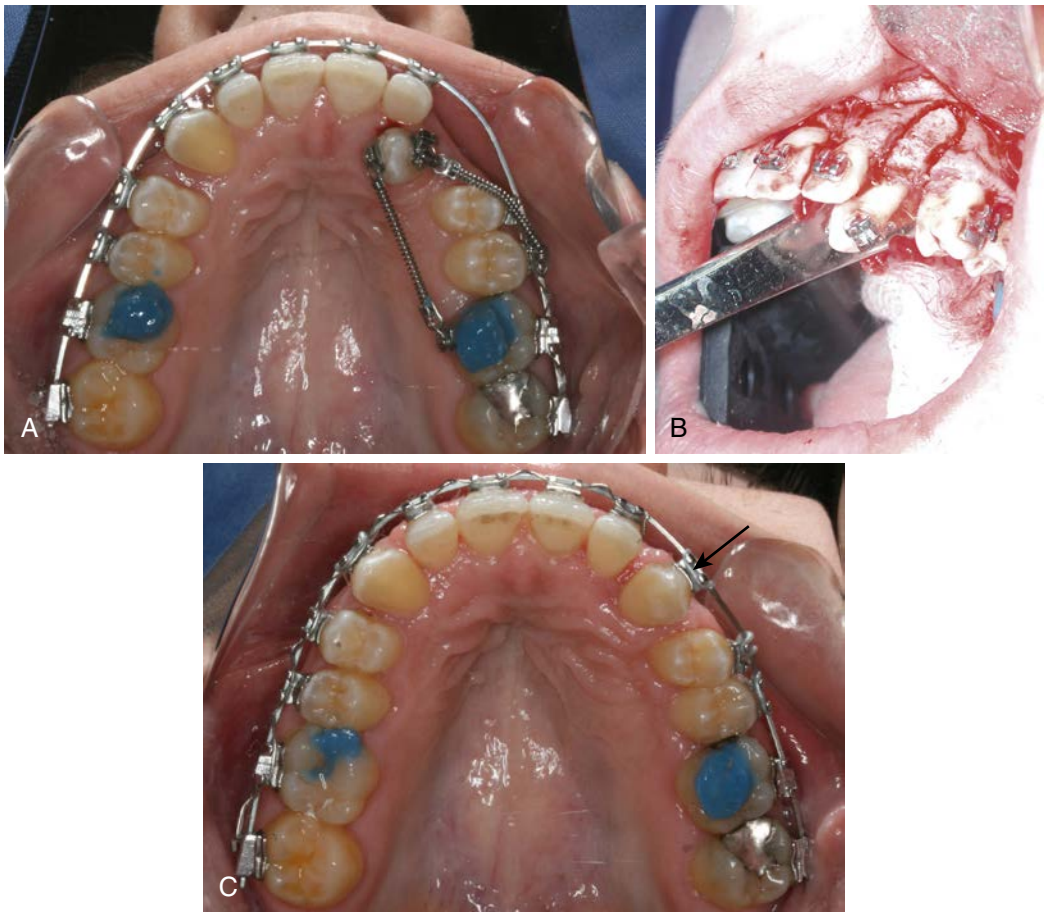
The position of labially impacted cuspids determines the appropriate exposure technique. Unlike palatally impacted teeth where inadequate attached gingiva is unlikely, the lack of keratinized tissue can be problematic for labially positioned cuspids. Excisional uncovering can be accomplished if the crown is near the alveolar crest and 2 mm or more of keratinized tissue will remain for periodontal support after excision of the soft tissue.

More commonly, however, the crown will reside higher apically, and an alternative technique may be necessary. If the tooth is no higher than mid-alveolus, consideration may be given to an apically positioned flap. A crestal incision incorporating attached gingiva and both mesial and distal releasing incisions are made, before elevating a full-thickness flap to expose the crown. Beveling the vertical legs of the flap away from the anterior aspect of the mouth may aid esthetics after healing by altering light reflection from the resultant scars. Often there is minimal bone covering the crown of the impacted tooth, and follicular tissue is readily removed. The flap is positioned near the cementoenamel junction and sutured in place. A bracket may be placed if desired for later orthodontic traction. This technique should not be used for very high impactions because it has been associated with late reintrusion of the cuspid. In addition, moving the flap too far apically makes adequate closure difficult.

Labially positioned teeth above the mucogingival line are often better treated with the closed eruption



• **Figure 20-4** **A,** Closed eruption of a palatally impacted cuspid before flap closure. An orthodontic attachment has been bonded to the tooth and the chain secured to the arch wire. **B,** Closed eruption of a labially impacted cuspid before flap closure. An apically positioned flap here would compromise the periodontium of the lateral incisor.



• **Figure 20-5** **A,** Palatally located cuspid that could not be moved orthodontically into the arch. **B,** Corticotomy performed to aid in orthodontic traction. **C,** Two months post-corticotomy, tooth is positioned within the dental arch *(arrow)*.

technique. This may require a generous flap, particularly if very superiorly located. A distal release is recommended if necessary because of esthetic concerns. Once the tooth is exposed, an appliance is cemented and a chain sutured to the arch wire for later activation. Bleeding is generally less of a problem compared with palatal impactions, and secondary re-bonding of a bracket is almost never necessary.

Occasionally, orthodontic traction alone will not be able to adequately position the tooth into the dental arch. In such cases, corticotomy may allow tooth movement. The cortical bone is removed with a small round bur to outline the tooth root, taking care to avoid exposing the root surface. This will often enable relatively rapid tooth positioning (Figure 20-5).

Unfortunately, orthodontic brackets occasionally become detached at some time during tooth movement. In this case, repeat exposure may become necessary. In the past, other traction methods were employed, including wire ligatures placed at the cementoenamel junction or pins incorporating an eye for wire placement that were screwed or cemented into the crown. With improved cements, however, these methods are not often necessary. Because they may damage teeth and directing forces can be more difficult, they should be avoided if possible.

The position of an eruptive device may have a significant impact on the ability to achieve appropriate orthodontic traction forces, and it is advisable to consult the orthodontist about bracket placement. An intraoperative photograph may be invaluable in providing the orthodontist with information about position of the impaction, location of the bracket, and preexisting damage to incisor roots from canine position.

A decision tree to aid clinicians in choosing the proper surgical technique based on imaging findings and tooth location is illustrated in Figure 20-6.

Intraoperative photographic documentation can be used as a means of communication with the orthodontist so that he or she will have a better understanding of the impacted tooth's position and a more precise idea of force vectors for activation of orthodontic traction. Rapid electronic transmission of such information can be achieved even during the surgical procedure in the event of questions regarding the placement of attachments or unanticipated findings such as root exposure or resorption. Feedback from the orthodontist may, in some circumstances, allow modification of the planned surgical procedure.

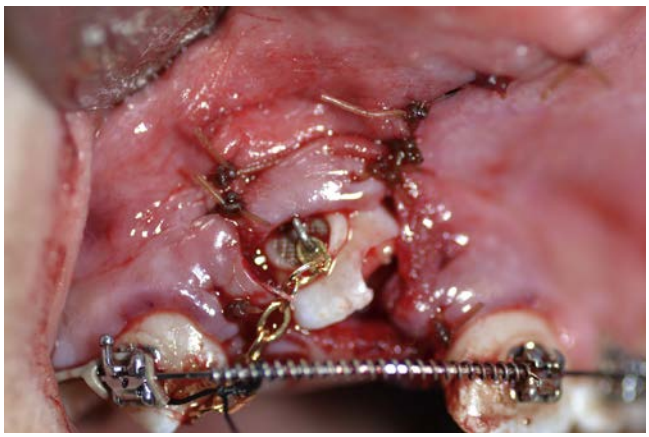
Impacted Premolars

Mandibular second premolars rank third, after third permanent molars and maxillary permanent canines, in the frequency of impaction.[35] There is a relative paucity of literature relating to impacted premolars despite the fact that mandibular second premolars account for approximately 24% of all non–third molar dental impactions.[36] The overall prevalence of impacted premolars has been reported at 0.5%[37] and is under the influence of many physiologic, environmental, and local factors. Extractions are performed in a manner commensurate with the degree of impaction and overall treatment needs. It is often the case, however, that access is difficult because the tooth is in close approximation to the mental nerve, lingually positioned, or locked under the adjacent bicuspid and molar. Extreme care must be used in elevating flaps, and in some cases both buccal and lingual flaps must be raised for adequate tooth access. After judicious crown exposure, a small straight elevator may be helpful in assessing the malposed tooth for ankylosis. There is often an inadequate path for extraction of the tooth, and sequential sectioning of crown and root may be necessary for its removal.

Impacted Incisors

Impacted incisors are an infrequent occurrence in the oral and maxillofacial surgery office, but they can pose significant challenges. Incisors are a critical element in facial esthetics, especially in the maxillary arch. If a central incisor is lost, practitioners are left to deal with the unfortunate sequelae, including alveolar bone loss leading to a thin and deficient ridge, adjacent tooth movement, and gingival distortion that make an esthetic restoration extremely difficult. It is therefore advantageous if the natural tooth can be maintained and manipulated into position with the assistance of orthodontic or surgical means. Maxillary incisors may become impacted after early loss of the primary incisors, from local causes (such as odontoma, supernumerary teeth, or follicular cysts), or as a result of traumatic injury.[38] Open or closed eruption techniques, as described for the impacted cuspid, may also be performed for these teeth (Figure 20-7).

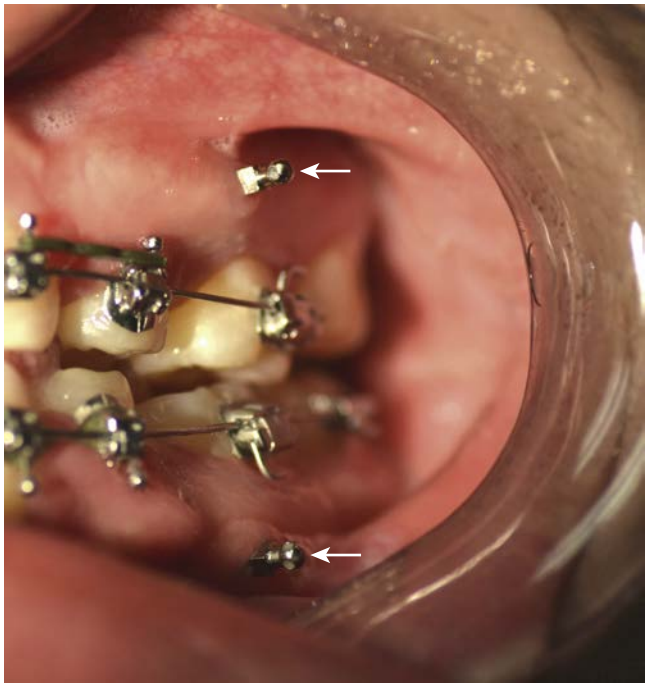


• **Figure 20-7** Apically positioned flap for exposure of an impacted central incisor. The mesial incisal edge has been disrupted by the associated compound odontoma.

Impacted Molars

The prevalence of impacted second molars is thought to be approximately 3 in every 1000 patients.[39] Most literature cites deficiencies in arch length as the primary reason for molar impaction. However, even with adequate space, mandibular second molars can be seen to become impacted in a mesial inclination under the distal of the first molar. Alling and colleagues[40] suggested that eruption of the second molar requires guidance by the distal root of the first molar, paralleling the "guidance" theory of maxillary canine eruption, described earlier. Of course, all of the previously

• **Figure 20-8** Impacted second and third molars. Late detection and associated pathology preclude orthodontic intervention.



• **Figure 20-9** Temporary orthodontic anchorage devices (TADs) see *arrows*.).

discussed potential causes of tooth impaction apply to the molar teeth, and no definitive etiology has been accepted for its occurrence.

Failure of timely eruption of permanent molars warrants radiographic evaluation to determine the etiology, as there is little probability that a first molar will spontaneously erupt after age 7 years.[41] Agenesis or pathology must be considered (Figure 20-8); in many instances, however, the reason for eruption failure cannot be determined. Assisted eruption by orthodontic or combined surgical and orthodontic means has been reported by several authors,[42-45] but it is more difficult at this location because of limited options for orthodontic anchorage. Surgical access to molar teeth may be even more difficult than for impacted cuspids. Bone-anchored devices are available from several manufacturers, and these can provide significant assistance in appropriate anchorage and force vectors (Figure 20-9).

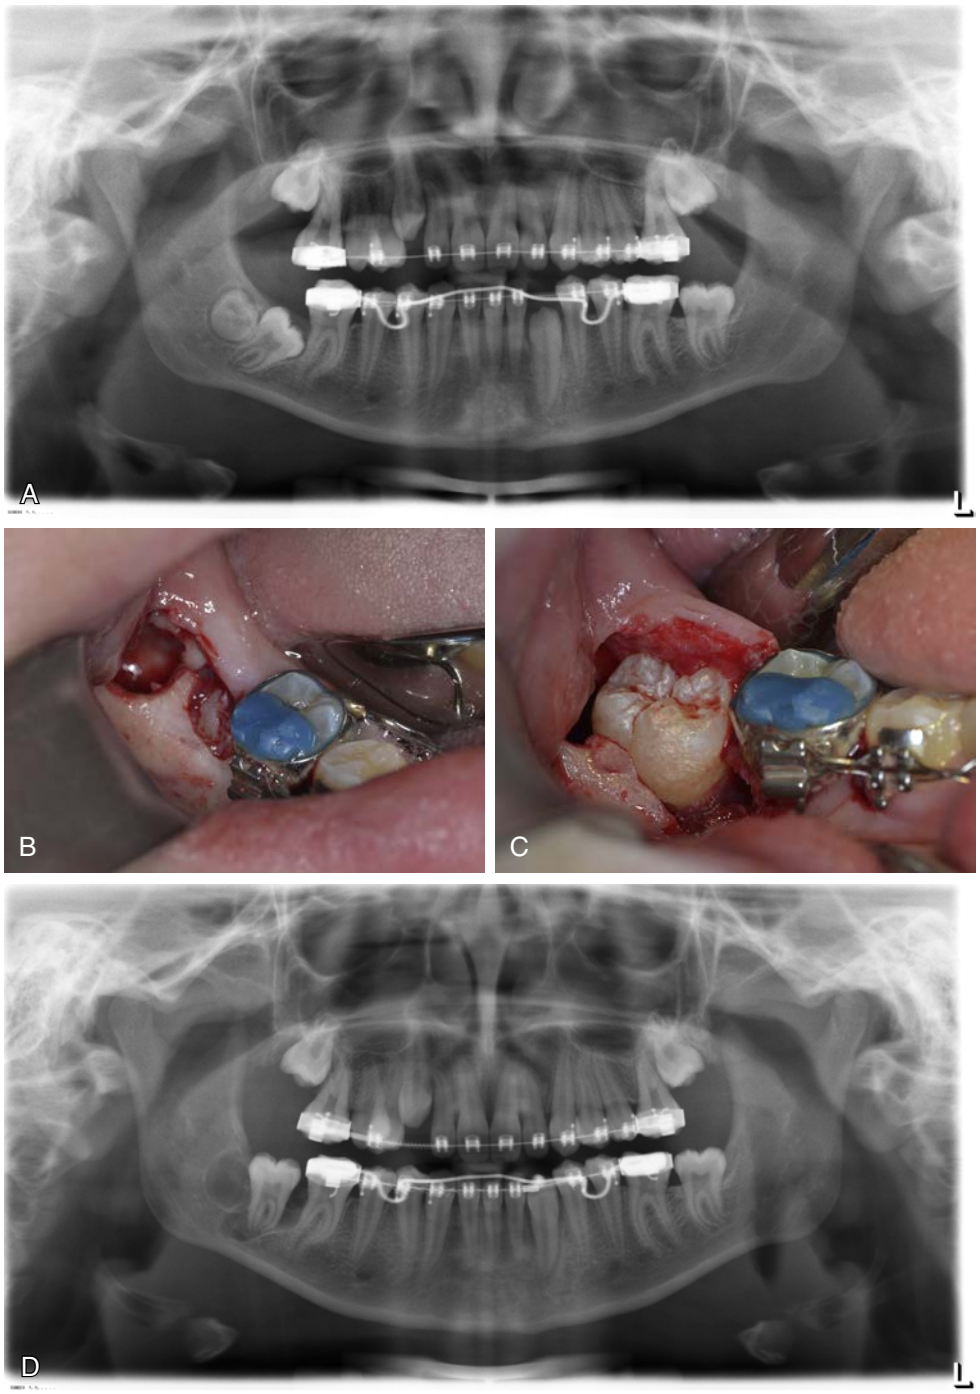
Surgical uprighting of a mesially inclined second molar provides a quick and predictable answer to these problems if performed at the proper time, and the technique has been described by multiple authors.[46-49] Some authors recommend consideration of criteria that include root length and form, available space within the dental arch, arc of rotation, occlusion, periodontal status, and jaw development.[50] The optimal root length should be one third to one half of the eventual length of the fully formed root to enhance the chance of revascularization after tipping and bodily movement. Before that, stabilization of the second molar in its new position can be compromised. If performed after root development is completed, a restricted blood supply from the constricted apical foramen can result in pulpal necrosis. To provide adequate space and access for the procedure, extraction of the third molar may also be necessary (Figure 20-10).

The management of impacted second molars is relatively straightforward. Often positioned mesioangularly and trapped below the height of contour of the adjacent first molar, these teeth may be surgically uprighted when about two thirds of the root has formed. To achieve this, a standard third molar incision is made from the external oblique ridge across the ridge crest to include the papilla of the first molar. No vertical release is made. The full-thickness flap will expose the area of the adjacent third molar, and the third molar should be removed after judicious bone excision. It is important to leave adequate bone at the mesial aspect of the third molar, for this will aid in stabilizing the second molar after uprighting. Bone covering the occlusal aspect of the second molar is then removed, and an elevator is wedged at the mesiobuccal line angle to upright the second molar to the level of the occlusal plane of the first molar. Hyperocclusion is not usually a problem, but the occlusal surface of the uprighted tooth can be slightly reduced if necessary. The mesial bone from the third molar socket will usually provide enough stability that the tooth will not require additional fixation to maintain its position. If there is excessive mobility, however, the tooth can be further stabilized with an orthodontic bracket and arch wire or other similar technique.

In most cases, the tooth will remain vital and can be positioned orthodontically into the dental arch. Mesial bone fill will occur in the majority of cases without further intervention.[45,47,48] On rare occasions, however, root fracture or devitalization may occur. Endodontic treatment may rarely be indicated. The angle of rotation for uprighting the second molar should not exceed 90 degrees according to Pogrel, who postulates that exceeding this limit would cause the tooth to behave like a transplant, thus diminishing the chance of future vitality.[47]

Supernumerary Teeth

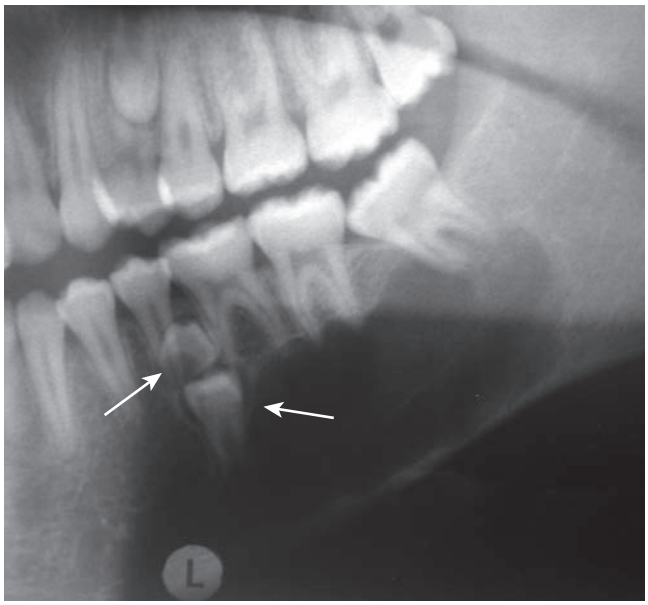
Any tooth in addition to the normal 20 deciduous teeth and 32 permanent teeth is deemed "supernumerary" (Figure 20-11). The prevalence of supernumerary teeth



• **Figure 20-10** **A,** Radiograph illustrating impacted permanent second molar tooth prior to uprighting. **B,** Impacted third molar removed in preparation for uprighting second molar. **C,** Second molar uprighted; no stabilization was necessary. **D,** Postoperative radiograph illustrating adequate second molar position.

ranges from less than 1% to greater than 6% in various literature studies.[51] The etiology of supernumerary teeth has not been definitively determined, but genetic syndromes and familial influences have been associated with their occurrence.[52-55] Ethnicity also affects prevalence, with African Americans demonstrating a higher prevalence.[56] These anomalies are reported to occur with greater frequency in permanent teeth, and supernumerary teeth often have abnormal forms. (See reference 53 for review.)

Supernumerary teeth may, in some circumstances, impede eruption of deciduous or permanent teeth. As with any impacted tooth, they may be associated with pathologic conditions such as formation of dentigerous cysts. Because they can occur anywhere in the jaws, in some cases they may impede orthodontic tooth movement or surgical procedures such as dental implant placement. In the absence of a specific indication for their removal, and in the case of high surgical risk to other anatomic structures, supernumerary



• **Figure 20-11** Supernumerary bicuspid teeth with associated lytic lesion in the left mandible. Note also the additional supernumerary tooth between the maxillary bicuspids.

teeth may be left in place. The patient and parent should, however, be informed that regular surveillance is necessary to identify pathology that may develop over time. It is not clear, however, if the risks of repeated radiographic surveys and probability of failure to follow up outweigh the risk of surgical removal for most patients.

The removal of supernumerary teeth is approached in a fashion similar to other dental impactions. The specifics of removal depend on tooth location, and adequate imaging is critical to determine the safest surgical approach. The imaging techniques described earlier in this chapter will aid in determining the relationship of the supernumerary tooth to adjacent roots and neurovascular structures. In some cases where an individual has lost a permanent tooth to disease or trauma, consideration may be given to transplant of an appropriately sized supernumerary tooth to an edentulous site.

Odontomas

Odontomas are hamartomas rather than true neoplasms.[57] They may resemble a collection of tooth-like calcifications called denticles in the compound type, or a more amorphous mass of calcified material in the complex type. They may impede eruption of teeth, and failure of eruption should elicit radiographic assessment of the cause. These lesions are generally surrounded by a radiolucent border that aids their excision. Removal should be performed as for supernumerary teeth. They do not recur (Figure 20-12).

Tooth Transplantation

Tooth transplantation may provide an attractive alternative to dental implants in the growing child. This procedure was first performed more than 50 years ago, but it has not gained general acceptance in many places despite high reported success rates. Unlike implants, transplanted teeth can behave just like other natural teeth, maintaining alveolar bone and occlusion as the child develops. Even if the transplant later fails and must undergo extraction, it has provided function and aided development of the alveolus so that dental implants can often be placed later without extensive site preparation.

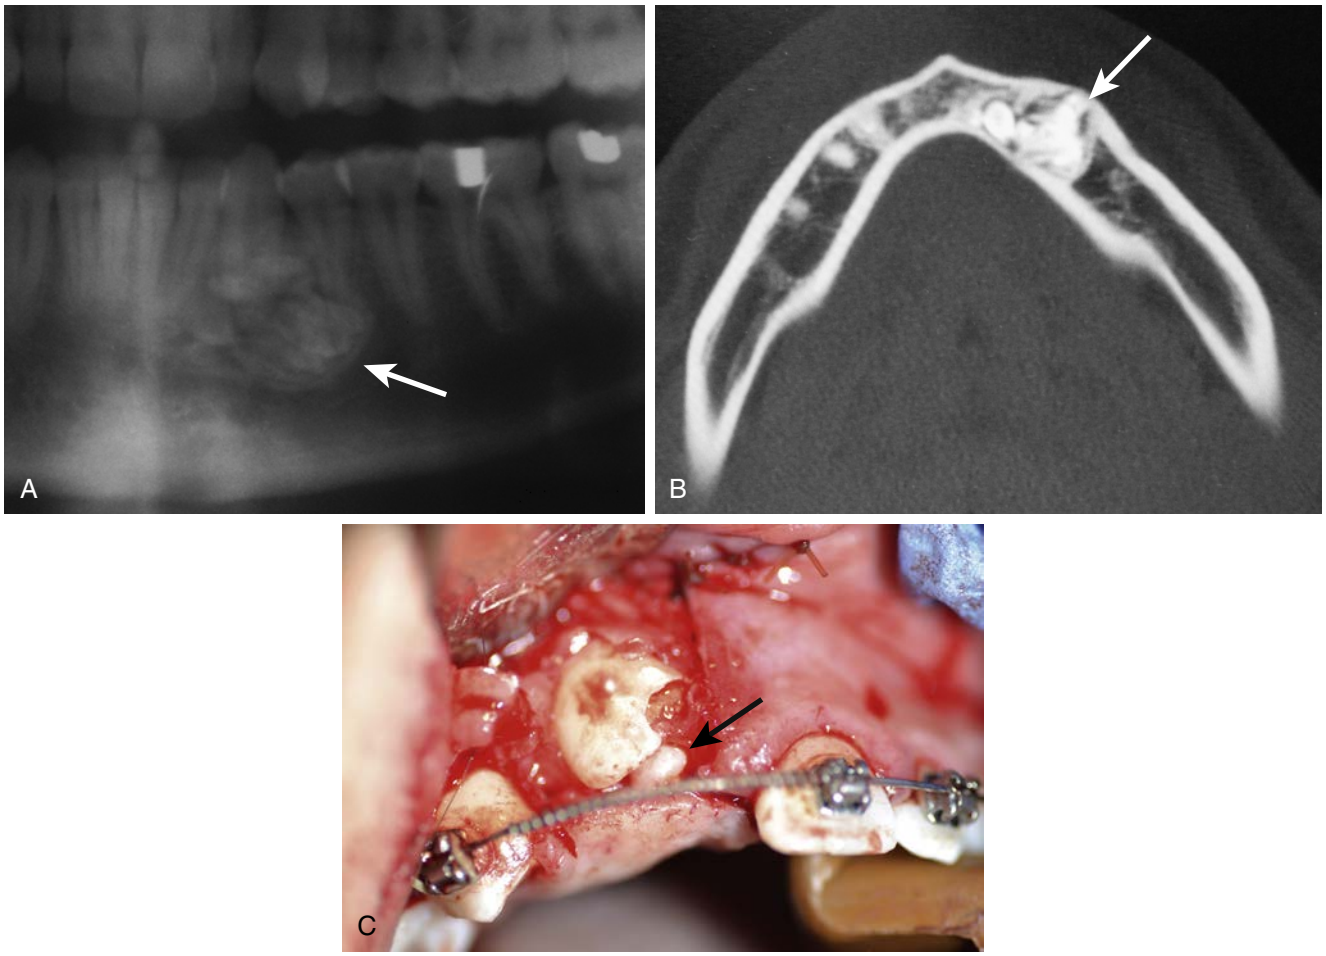
Indications for transplant may include tooth loss due to trauma or pathology, failure of teeth to develop or erupt, and ankylosis resulting in nonfunctional teeth.[58] Donor candidates for autotransplantation include teeth planned for extraction due to dental crowding (especially bicuspids), grossly malpositioned impacted cuspids, third molars, and even supernumerary teeth. Although some authors suggest that the ideal time for tooth transplantation is when roots are between 50% and 75% formed, high survival rates are also reported with transplant after complete root formation.[59,60] When roots are only partially formed, endodontic therapy can often be avoided, and teeth may remain vital as root development continues. Survival rates for transplanted teeth are reported to be greater than 90% in some studies.[61,62]

Impacted cuspid teeth may sometimes be located in such an unfavorable position that exposure and orthodontic traction cannot adequately orient the tooth in the dental arch. If surgically accessible, these teeth can be extracted and placed in a socket freshly prepared in the alveolus. This may, however, require presurgical orthodontic space development.

Transplants can be very effective for replacement of missing central or lateral incisors. Maxillary second bicuspids are a good transplant choice when rotated 90 degrees about the vertical axis to expose the broadest surface of the tooth. This makes camouflage with tooth-colored materials relatively straightforward. Although lower bicuspid teeth may also serve as transplants in these sites, they are more difficult to contour to mimic a maxillary incisor. Endodontic treatment may sometimes be necessary because of the extent of tooth modification necessary to provide a good esthetic result.

Molar transplantation is more difficult because of greater root complexity and concomitant greater risk of root damage or fracture during extraction. Site preparation is also somewhat more difficult, but success rates are still within acceptable ranges.

Transplant technique varies based on location of donor and recipient sites, stage of root development, and size of tooth to be transplanted. Teeth with less than 50% or more than 75% root development have been shown to have higher root resorption rates rate than teeth with 50% to 75% formed root structures.[63] Teeth with open apices may not require root canal therapy, but those with fully formed roots are less likely to revascularize.[64] Site preparation requires a full-thickness mucoperiosteal flap and creation of a recipient "socket" with drills or trephines. Multirooted teeth make this process more complicated. Because maintenance of periodontal ligament cell vitality



• **Figure 20-12** **A,** Compound odontoma of left mandible *(arrow)*. **B,** Computed tomographic image of odontoma in **A** *(arrow)*. **C,** One of several denticles associated with a compound odontoma preventing eruption of the permanent incisor *(arrow)*.

is thought to be critical to transplant success, the time between extraction of the transplant and its placement in the new location should be minimized. Some authors suggest completion of root canal therapy if possible before removal of the transplant from its socket to reduce explant time.[63] With increased availability of cone-beam imaging and rapid prototyping, it is now possible to fabricate a transplant analogue to aid in recipient site preparation before extraction of the donor tooth.[64] Both these techniques presume that the donor tooth will be extracted without significant damage or root fracture. Although some authors report no need for stabilization of the transplanted tooth or stabilization only with sutures, we recommend stabilization in slight infraocclusion with a resin and wire splint for 10 days to 2 weeks.

Despite the high success rate of tooth transplantation, complications may occur. These include infection, internal and/or external root resorption, poor periodontal healing, ankylosis, tooth fracture during extraction, and failure of the transplant to stabilize in its new location. Patients should be advised that additional procedures may be necessary to manage such complications, and that loss of the transplant could occur.

Dental Implants in Children

Although the permanent dentition, with the exception of third molars, is present in the oral cavity by the early teenage years, continued facial growth and tooth eruption continue well past puberty.[65,66] Because dental implants integrate with bone and lack a periodontal ligament, once placed they do not move occlusally as normal teeth do in the eruption process. They are, in effect, ankylosed. This may result in submersion of the implant as the other teeth assume their final place in the dental arches.[67,68] Correction of this problem may result in esthetic and mechanical compromise to the implant as longer abutments and crowns become necessary to reestablish the occlusion. For these reasons, dental implants are best avoided in most instances in growing children until the dentition is fully erupted.[69]

There are some circumstances, however, where implants should be considered before jaw growth and tooth eruption are complete. Syndromic (as in ectodermal dysplasia) and non-syndromic hypodontia, oligodontia, or anodontia can create significant esthetic and functional hurdles for afflicted individuals. Both conventional and mini dental implant reconstruction has been of benefit to many patients, and

fixed or removable prostheses can greatly aid both function and esthetics.[70-72] Implants do not seem to restrict jaw growth (with the exception of implant submersion in a height-restricted alveolus), and in the case of some congenital conditions the benefits may outweigh the risks associated with early implant placement.[73] Most of the literature regarding implants in growing children, however, is not of sufficient scientific rigor to provide strong evidence for the routine placement of dental implants in this population.

Soft Tissue Procedures

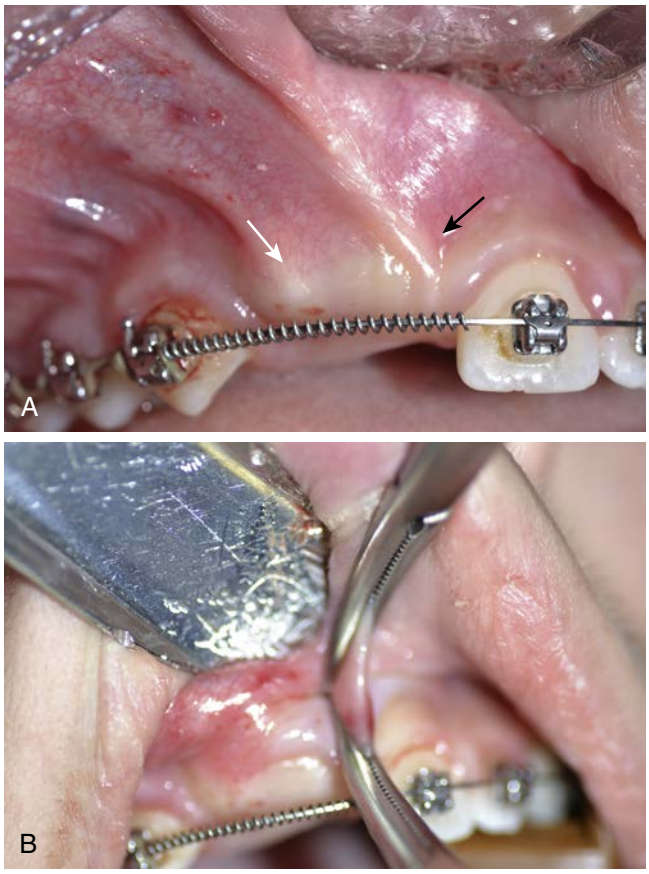
A frenum is a band of soft tissue that connects the lips, cheeks, or tongue to the maxilla or mandible. In the oral cavity, prominent frena are found in the midlines of the upper and lower lips connecting the mucosal surfaces of the lips to the corresponding alveolus, and in the floor of the mouth connecting the undersurface of the tongue to the lingual aspect of the mandible. Smaller attachments occur on the facial aspects of both the upper and lower arches and are sometimes termed frenulae, although these terms are generally used interchangeably. Frena are composed of mucosa and connective tissue and may contain skeletal muscle.[74]

Frena may be more prominent or absent in certain disease states and may thus serve as important indicators of underlying pathologic conditions. Prominent frenal attachments may also have a familial tendency, in some cases showing an autosomal dominant inheritance pattern.[75] In most cases, however, excessive frenal attachments are not associated with other disease states.

Both labial and lingual frena commonly attach near the alveolar crest at birth and in most cases recede as the alveolus grows and teeth erupt. A prominent maxillary labial frenum has been associated with difficulty in breastfeeding and persistence of a midline diastema.[76] In the lower jaw, buccal and lingual plaque and bleeding scores have been shown to increase when the frenum connects in the attached ginviga.[77] Excessive lingual frena may cause ankyloglossia and associated difficulty in breastfeeding and possible speech abnormalities, among other difficulties.[78,79] These potential problems have traditionally been treated by frenal release (frenotomy) or complete excision of the frenum (frenectomy). It should be noted, however, that the literature evidence for performance of these procedures is not compelling.[80-82] Neither is there significant evidence *against* surgical release of the prominent frenum. In light of the low risk of surgical complications, frenoplasty or frenectomy may be performed for treatment or prophylactic indications.

Surgery for the Labial Frenum

The maxillary midline frenal attachment may be so prominent as to cross the ridge crest and insert into the incisive papilla. Once the decision for frenal release is made, any of several techniques may be employed. Local anesthesia is generally adequate for these procedures. Use of a nitrous oxide nasal hood may impede adequate upper lip retraction and result in inadequate frenal release.

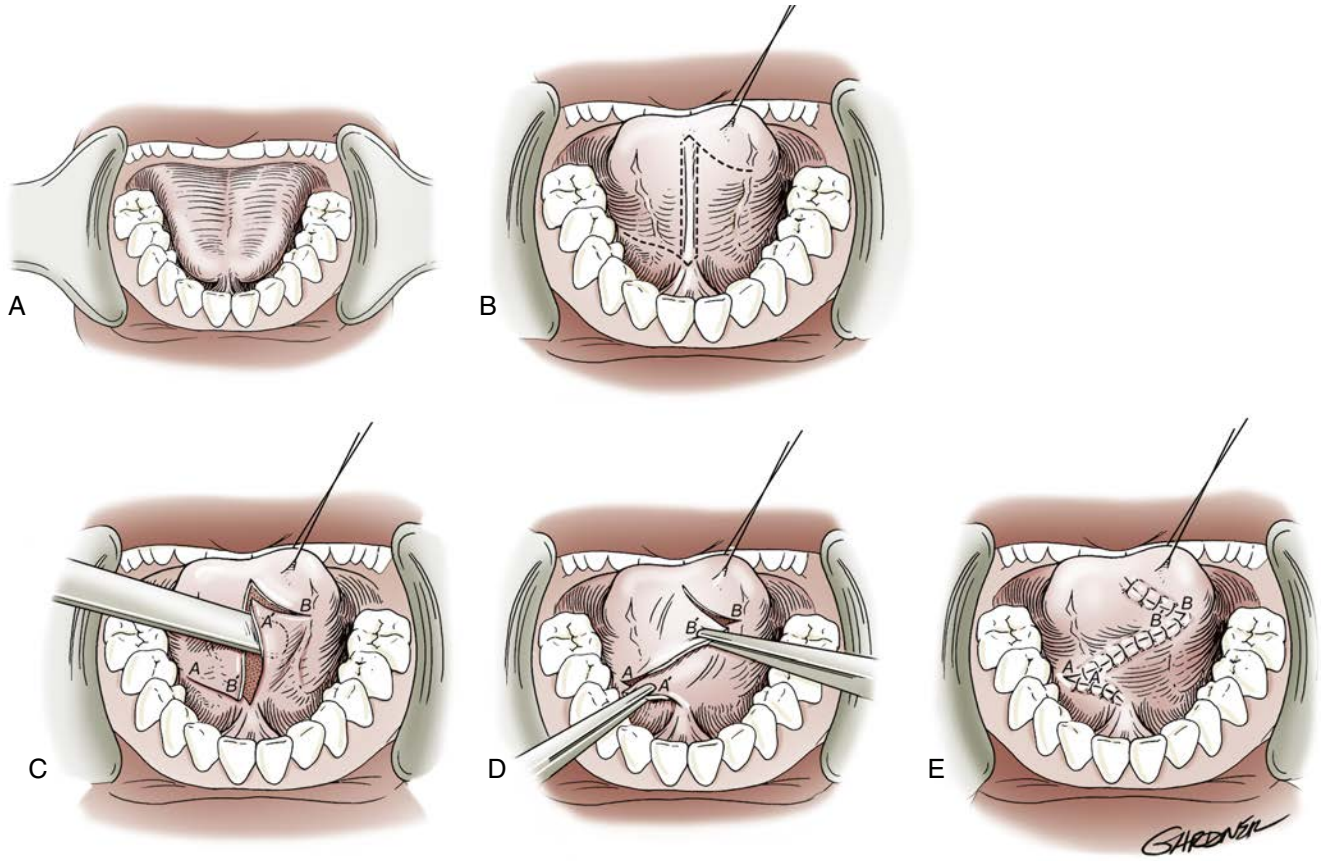


• **Figure 20-13** **A,** Maxillary labial frenum inserts into alveolar crest *(black arrow)*. Bulge representing permanent central incisor is visible submucosally *(white arrow)*. **B,** "Two-clamp" technique; frenum is isolated from labial and alveolar tissues by curved hemostats. After release of clamps, incision is made through crushed tissue to aid hemostasis. Labial mucosa is closed primarily, while keratinized gingival tissue is allowed to granulate.

Treatment of the prominent frenum is typically performed by one of three techniques: frenotomy (or vestibular extension), excision, or Z-plasty. Any of these techniques will adequately manage the frenum; maximum effect has been reported to be seen with Z-plasty, but frenectomy seems to have fewer postsurgical symptoms.[83]

Frenotomy releases the soft tissue attachment and repositions it at the depth of the vestibule. The lip is retracted superiorly (or inferiorly in the case of the lower labial frenum) and the alveolar portion of the frenum is incised with a scalpel, electrosurgery device, laser, or scissors. Minimal undermining toward the lip will allow repositioning of the frenum to the depth of the vestibule, where it is sutured to periosteum. The resultant V-shaped defect overlying the alveolus is left to heal by secondary intention. Pressure applied to the denuded area is generally adequate to obtain hemostasis.

Frenectomy is commonly performed with the "two-clamp" technique (Figure 20-13). Two small curved hemostats are placed, one on each arm of the frenum, after retraction of the lip. These are left in place for 30 to 60 seconds. After removal, the clamped tissue is excised, leaving a diamond-shaped defect. The labial mucosa is undermined and closed primarily, and the



• **Figure 20-14** **A,** Preoperative depiction of a prominent lingual frenum. **B,** Proposed incisions for a lingual frenectomy with Z-plasty closure. **C,** Undermining wound margins. **D,** Transposition of Z-plasty flaps. **E,** Final closure.

alveolar portion is allowed to heal secondarily. Z-plasty or V-Y closure techniques are employed by some practitioners, but these are not necessary to achieve a successful result.

Complications are generally minimal for these procedures. Light bleeding, mild swelling, and infection are possible. For maxillary midline frena that reach the alveolar crest or insert into the incisive papilla, it is important to excise the full extent of the frenum if diastema closure is to be anticipated. Temporary altered sensation of the surgical area may occur, but this can be expected to resolve in most cases within weeks to a few months.

Surgery of the Lingual Frenum

A prominent lingual frenum may limit tongue movement, resulting in ankyloglossia (tongue tie). As breastfeeding has become more common, attention has again been focused on the lingual frenum and its role in effective infant nutrition. There is ample literature delineating adverse effects of limited tongue mobility in relation to breastfeeding and documenting improvement with release by lingual frenotomy.[84-86] There is limited evidence that ankyloglossia is associated with altered speech or that surgery will benefit periodontal status.

As with labial frenal surgery, there are several techniques proposed for ankyloglossia release. Frenotomy is straightforward and is reported in many instances without anesthesia,[86,87] although local anesthesia with vasoconstrictor may aid hemostasis. The infant is stabilized by an assistant (who may be the parent), and the surgeon is positioned cephalad to the child. The tongue is manually elevated, and a blunt-tipped scissor is used to cut the inferior aspect of the lingual frenum to free the tongue. Minimal undermining may be performed with an instrument or cotton-tipped applicators, and hemostasis is achieved with direct pressure without suturing. This technique has been reported to result in immediate or near-immediate improvement in feeding and maternal comfort during feeding, and it has the advantage of avoiding general anesthesia.[83,84]

Frenectomy techniques are more involved and are more likely to require advanced sedation or general anesthesia techniques, although local anesthesia may be adequate for a cooperative child. As for labial frenectomy, the two-clamp technique may be used, and the frenum can be incised with cutting instruments or laser.[87] After excision, the resulting diamond-shaped defect is undermined and closed primarily on the ventral surface of the tongue and floor of the mouth. Care must be exercised to avoid damage to the submandibular ducts during excision and closure.

Lingual frenectomy and closure with Z-plasty is illustrated in Figure 20-14. Either single or double Z-plasty may be used, and genioglossus myotomy may be performed; these

techniques have been suggested to provide additional tongue mobility when necessary.[88-90]

Potential complications of frenotomy and frenectomy include bleeding and hematoma formation, damage to the submandibular ducts or lingual nerves, infection, and recurrence. Complications are generally minor and self-limiting.

Pediatric Challenges

As discussed throughout this chapter, the pediatric population poses some great challenges in terms of physiology, anatomy, and treatment planning. One significant dynamic that must be considered whenever treating pediatric patients is their unpredictable and often uninhibited behavior. The simplest procedure can become impossible when a patient is unable or unwilling to be cooperative in the chair. Oral and maxillofacial surgeons have a variety of tools at their disposal to help alleviate some of the behavioral turbulence that often accompanies treatment. Both nonpharmacologic and pharmacologic techniques can be tailored to the individual patient and practitioner to allow for safe and effective care. "Behavior guidance" is a term developed by the American Academy of Pediatric Dentistry and is a continuum of interaction involving the dentist, the dental team, the patient, and the parent directed toward communication and education. Its goal is to ease fear and anxiety while promoting an understanding of the need for oral health and the process by which that is achieved.[91] Oral surgeons can use behavior guidance, various sedation techniques, or a combination thereof with many of the surgical procedures discussed in this chapter. Occasionally, however, a pediatric patient is unable to tolerate the proposed care, and alternative options must be explored. General anesthesia, either in-office or in a controlled operating room environment, can be offered in a situation where patient or provider safety is at risk or where quality of care could be compromised. Oral surgeons are in a unique position among dental providers, as they often have admitting privileges to hospitals and the medical background to handle complex pathologic processes. It is important that the specialty of oral and maxillofacial surgery accept and welcome these challenges to continue leadership in the delivery of safe and proficient care to the pediatric population.

Basic and Complex Exodontia and Surgical Management of Impacted Teeth

GREGORY M. NESS, KATHARINE C. POWERS

Introduction

Despite advances in dental restorative techniques, simple extractions remain common, and the need to remove impacted teeth has remained a fixture in the repertoire of oral and maxillofacial surgeons. Extensive training, skill, and experience are necessary to perform extraction of an impacted tooth with minimal trauma. Inexperience of the surgeon leads to a significant rise in complications. Furthermore, tooth replacement is the gold standard of restorative dentistry, requiring the surgeon to manage and to maintain the site of extraction for use, rather than abandonment, in future treatment. Determining whether a tooth is non-restorable can be particularly problematic, as certain scenarios are determined by available scientific data and parameters, while others call on the surgeon's clinical experience and professional judgment. Even so, contemporary medical and dental practices demand evidence-based decision making, where the surgeon is called on more and more frequently to justify surgical procedures, including the removal of third molars.

Removal of Erupted Teeth

Indications for Exodontia

Caries

Dental decay is one of the most common diagnoses leading to dental extraction. Clinical and radiographic detection of caries is fundamental to dentistry, but decision making regarding restoration or extraction of a tooth is often challenging and may be influenced by a variety of factors extrinsic to the tooth itself. These include the location and position of the tooth, the health and number of adjacent teeth, the systemic health of the patient, other local or regional diseases or planned operations, and the relative financial and social costs of treatment alternatives. Clear communication among patient, surgeon, and restorative dentist is vitally important to forming a mutually satisfying treatment plan.

Periodontal Disease

Adult periodontitis remains a highly prevalent dental disease despite its almost completely preventable nature. Like dental caries, the presence of periodontitis is sometimes more easily and objectively determined than the prognosis of the tooth. However, extraction is indicated for teeth with a poor survival prognosis, those that have failed appropriate periodontal therapy, or where the other extrinsic factors noted earlier for caries become significant.

Orthodontic Purposes

Although orthodontists strive to attain ideal arch coordination without sacrificing adult teeth, in some cases of severe crowding or jaw size discrepancy it is useful to remove overcrowded teeth to allow alignment of the dentition within the available arch length. Typically first or second premolars are removed, but other teeth may also be considered according to individual circumstances and the orthodontic, and perhaps prosthodontic, treatment plan.

Other Indications

Teeth that are otherwise individually healthy or restorable may be removed for a variety of less common purposes. These include non-carious dental fracture, association with an adjacent pathologic or traumatic condition, interference with planned prosthodontic care, or risk of harm to the patient from future pathology. The last indication may be

particularly important in a patient who will undergo head and neck radiation, high-dose chemotherapy, or high-dose antiresorptive or antiangiogenic therapy.

Diagnosis and Treatment Planning

Global medical assessment and selection of appropriate anesthetic techniques are addressed in detail elsewhere in this text, and this knowledge and skill is essential to proper planning and execution of all dentoalveolar surgery. A thorough clinical examination of the head, neck, and oral cavity, as well as appropriate radiographs, is also essential to the surgical planning for dental extractions.

Clinical examination must include assessing access to the surgical area, which may be hampered by limited mouth opening, a small oral aperture, or soft tissue interferences from large or hyperactive cheeks or tongues. The overall dental and periodontal health should be evaluated, with special attention to any conditions adjacent to the surgical site that might add complexity or increase the risk of complications. These include large or overhanging adjacent restorations, interproximal decay in neighboring crowns, preexisting periodontal conditions, or other findings that would predispose adjacent teeth to damage during extraction. The periodontal status of nearby teeth should also be determined, as removing the most diseased tooth in the area may "unmask" a previously asymptomatic or unrecognized problem, even if it was preexisting. Patients must be informed of these risks before, not after, treatment. The presence of unusually dense bone, tori, or exostoses should be noted, as these all increase the difficulty of the planned extraction.

Radiographs must be of acceptable diagnostic quality and include the entire tooth to be removed as well as the immediate vicinity, especially any structures such as adjacent roots, the sinus floor or mandibular neurovascular canal, and so on. Periapical radiographs are often adequate, although a panoramic radiograph will allow better examination of a wider zone around the teeth. Although there is not yet a broadly accepted standard of care regarding the use of cone-beam imaging, the expanding availability of this very useful in-office imaging technique will only increase its role in diagnosing unusual or complex clinical situations, such as complex impactions, multiple superimposed teeth and roots, or a tooth's suspected proximity to vital structures. Teeth to be removed should be assessed for indicators of difficulty, such as absence of a defined periodontal ligament space or unusual bony density, missing or severely decayed crown to the level of supporting bone, large or dilacerated roots, ankylosis or external root resorption, or other complicating findings.

Principles of Simple Extraction

Simple extraction is accomplished by applying a controlled and focused force to the tooth. The steps of tooth removal are based on simple principles of mechanics and are easily understood, but the keen tactile sense that defines an excellent surgeon is developed only with time and experience. Successful extractions also depend on the surgeon's thorough and detailed understanding of the anatomy of the teeth involved, including the root form and angulation, their attachment to the periodontal apparatus, and the associated bone morphology and characteristics.

The extraction process begins with loosening the supracrestal soft tissue attachments as necessary, followed by minor alveolar bone expansion with elevator and/or forceps, separation of the periodontal ligament, and finally coronal delivery of the tooth.

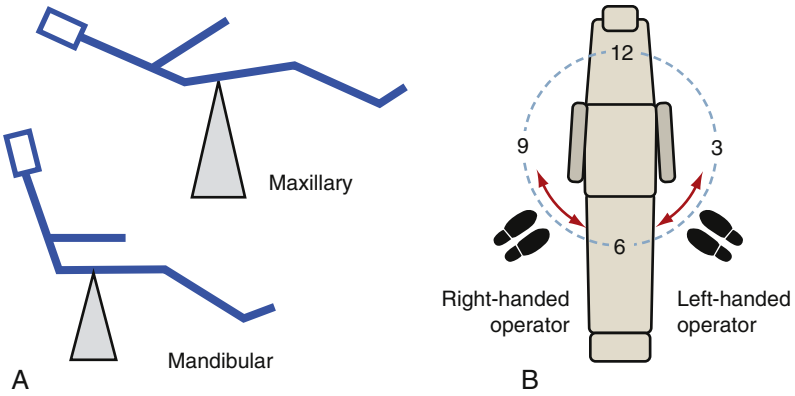
Patient Positioning

In most cases, the patient position will be determined by the arch from which the tooth or teeth will be removed. When extractions are being performed in the lower arch, the patient is positioned so the mandible is parallel to the floor. When extracting a maxillary tooth, the patient should be reclined so the maxillary occlusal plane is 45 to 60 degrees to the plane of the floor. In both cases, the height of the chair should be adjusted so the surgeon's elbows remain comfortably relaxed, without tensing the shoulders to reach into the mouth with extraction instruments. The surgeon's position relative to the patient also varies, depending on which tooth is being extracted and on the surgeon's dominant hand (Figure 21-1).

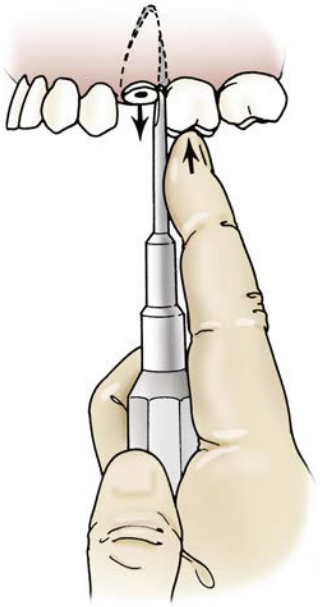
During extraction, the surgeon's free hand may, if possible, hold the alveolar process in a "pinch grasp" with the thumb on one side and the forefinger on the other side. This allows direct palpation of any movement or bony expansion within the alveolus, helps to retract adjacent soft tissues, and provides a gauge of the degree and direction of force being applied to the tooth and the alveolar process.

Initial Elevation

In most cases, the extraction begins with separation of the soft tissue attachment around the neck of the tooth, usually with a No. 9 Moldt periosteal elevator or a No. 1 Woodson elevator. This maneuver also serves to verify soft tissue anesthesia at the site. Next, a narrow straight dental elevator is used to begin moving the tooth. This instrument may be inserted into the mesial interproximal space, perpendicular to the tooth being removed, and then rotated so the more coronal edge of its concave surface pushes the tooth distally, levering against the interproximal crestal bone, not the adjacent tooth. Alternatively, the instrument may be inserted vertically along the mesiobuccal line angle of the root and used as a wedge to disrupt the periodontal ligament and expand the tooth socket (Figure 21-2). In some periodontally diseased and mobile teeth, or in areas with thin or low-density alveolar bone, this technique is sufficient to elevate the tooth from its socket and deliver it into the mouth for retrieval. In other cases, the narrow elevator may be followed with a broad elevator to further mobilize the tooth and expand the alveolar bone.



• **Figure 21-1** **A,** Controlled force is delivered most effectively when a low, upright chair position is used for the extraction of mandibular teeth. A higher, more reclined chair position is used for the extraction of maxillary teeth. **B,** Most extraction instruments are designed to be used from the right (or left) front chair location with the surgeon standing. (From Pedersen GW: Uncomplicated extraction. In Pedersen, GW: *Oral surgery*, Philadelphia, 1988, WB Saunders.)



• **Figure 21-2** The elevator is forcing the root upward and outward as its blade is being forced apically into the periodontal ligament space. As the surgeon's experience increases, such forces can be used to direct the tooth's delivery. Note that the index finger is extended and can be used to control the forces required to remove the root. (Modified from Peterson LJ, editor: *Contemporary oral and maxillofacial surgery*, ed 3, St Louis, 1998, Mosby.)

Forceps Luxation

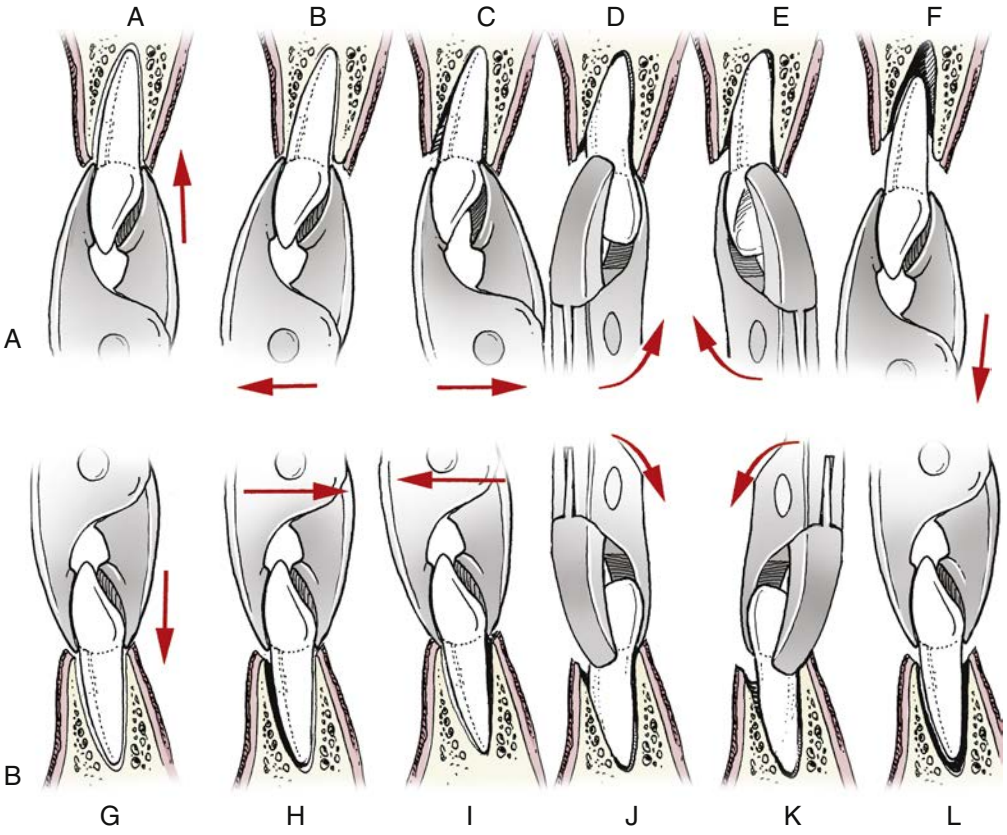
Dental extraction forceps are designed to engage the root surface of a tooth just below the cementoenamel junction and apply highly concentrated but controlled force to a very small area, with minimal movement. A wide variety of forceps are manufactured, with beaks shaped to fit well on specific teeth. However, most extractions may be accomplished with use of "universal" upper and lower forceps (No. 150 and No. 151, respectively), or with one of a limited selection of more specialized instruments. Choosing the right forceps is important to securely grasping the cervical portion of the tooth and eliminating movement of the forceps against the tooth. It is useful to think of seating the forceps as its own separate step in the process, as engaging the tooth effectively is necessary to transmit the luxating force directly to the tooth. The beaks should be pushed as far apically as possible, which shifts the tooth's axis of rotation apically as well. This allows the most effective alveolar bone expansion and reduces the risk of fracture at the root apex. Sharp elevators and forceps are desirable because they engage the tooth in a more firm and predictable manner and reduce slippage.

When extracting maxillary anterior lateral and central incisors and/or mandibular anterior teeth, the predominant extraction force is mainly rotational (Figure 21-3). For the maxilla, a universal No. 150 forceps or a straight-handled No. 1 forceps work well. In the mandible, a universal No. 151 or an Ash forceps, whose beaks are hinged 90 degrees compared to other American-style forceps, may be used.

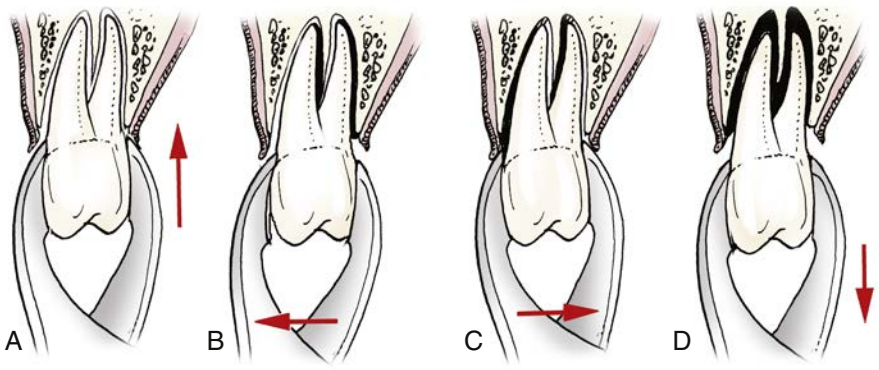
The roots of maxillary canines and the lower anterior teeth, however, have oval cross-sections and are thinner in the mesiodistal dimension, and they require more buccal-palatal or labial-lingual luxation. The maxillary premolars often have root tips that are thin and easily fractured if early luxation is too vigorous. A maxillary universal forceps is typically used for these teeth to be extracted. Careful buccal-palatal movement, allowing time for the bone to expand under firm pressure, is repeated until the alveolar bone is expanded, the tooth is mobile, and the periodontal attachment loosened (Figure 21-4).

A similar technique is used for the maxillary molars, taking care to avoid excessive force which could fracture the buccal plate. A variety of specialized maxillary forceps have been designed with beaks that engage the buccal furcation and fit the larger palatal root securely (Figure 21-5).

Lower molar extraction is made difficult by the thick, dense alveolar bone anchoring the teeth, which often strongly resists efforts to expand it. A lower universal forceps (No. 151) is often used, but a No. 23 cowhorn forceps is frequently a useful choice as well. Unlike other forceps, the No. 23 has pointed beaks curving toward one another that are designed to seat in the buccal and lingual furcations of a lower molar. Once the beaks are seated, squeezing the forceps handles wedges the beaks into the



• **Figure 21-3** **A,** Rotation is performed with a No. 1 forceps or a No. 150 (maxillary universal) forceps. The forceps is seated against the tooth (*A*) and then forced apically. Continued apical pressure is applied, and buccal luxation begins (*B*), followed by palatal luxation. Once some mobility is noted, the conical root of the anterior maxillary teeth allows rotational forces to be used. The tooth is rotated distally (*C*) and then mesially (*D*). The process is repeated until the tooth can be delivered from its socket (*E* and *F*). This technique can be used for the maxillary lateral incisor and the canine. However, the canine often requires greater force and effort to remove it from its socket. **B,** The ideal forceps for the removal of the mandibular premolar is the English/Ash forceps or the No. 151 (mandibular universal) forceps. All anterior mandibular teeth can be extracted similarly with this technique. The forceps are placed and seated apically (*G*), and then light luxation is used to push the tooth lingually *(H)*, followed closely by buccal movements (*I*). Rotational movements *(J,K)* can be used because the roots are frequently single and conical in nature. Traction *(L)* should be minimal.

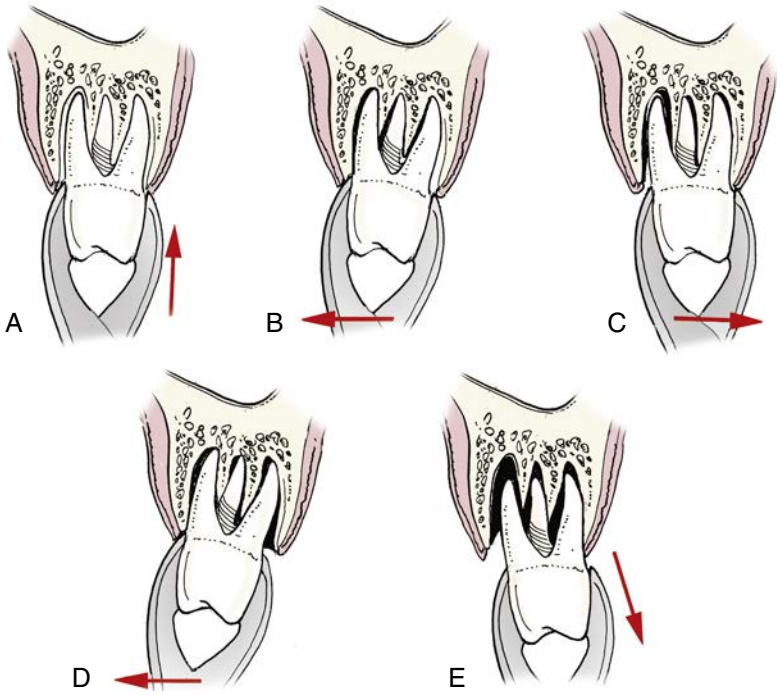


• **Figure 21-4** The maxillary premolar has two thin and slender roots of variable length. These can be easily fractured if careful technique is not used. Initially, the forceps is seated and pushed apically **(A).** Then the tooth is luxated buccally **(B),** and palatally **(C).** This is repeated in a careful and deliberate fashion. Occasionally, cautious figure-eight movements can be used until the tooth is removed from its socket **(D)** with minimal, gentle traction.

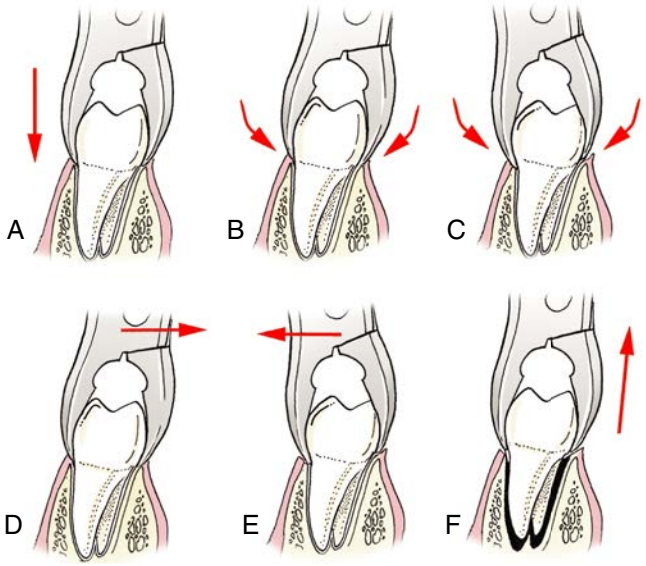
furcation and displaces the tooth coronally (Figure 21-6). Often the tooth elevates intact, but the cowhorn forceps may also divide the tooth into mesial and distal halves, which are usually mobile and less difficult to engage and remove separately.

Tooth Delivery and Socket Care

Once a tooth has been luxated to the point of separating the periodontal ligament attachment, it is generally delivered from the socket by gentle traction or luxation toward the



• **Figure 21-5** The maxillary molars are commonly removed with a No. 150 (maxillary universal), No. 210s, No. 53, or No. 88 L/R forceps. Their three-rooted nature can complicate a relatively simple-looking extraction with divergent or curved roots. The initial step is to seat the forceps and apply apical forces **(A)** and then to apply slow and deliberate forces in the buccal and palatal directions, allowing for initial expansion of the alveolus (**B** and **C**). Because the maxillary bone is less compact, large initial forces can result in buccal plate fractures and occasionally tuberosity fractures. Increasing forces and movements follow **(D),** until the tooth is then carefully delivered out of the mouth buccally **(E).** If the gingiva begins to tear, stop the extraction so that the likely buccal plate fracture causing it can be dissected free of the gingiva.



• **Figure 21-6** Mandibular molars are commonly removed with No. 151 (universal) or No. 23 (cowhorn) forceps. Once the forceps is seated **(A),** heavy apical pressure is applied. If a cowhorn forceps is being used, the tips of the beaks should be firmly seated into the furca of the tooth by squeezing the handles of the instrument and gently rocking the beaks into position (**B** and **C**). Once the beaks are tightly seated around the crown, heavy luxation of the tooth occurs in a buccal and lingual direction (**D** and **E**). When the tooth is adequately mobile, a rotating or figure-eight motion can be used to extract it from its socket **(F).**

path of least resistance at the thinner cortical plate of alveolar bone. In most cases this is toward the buccal, but lower second and third molars may be delivered lingually.

Older descriptions of dental extraction emphasize the need to compress the alveolar socket, but this step is actually counterproductive in the era of dental implants where preservation of maximal alveolar width is often essential. It is important, however, to carefully palpate the bony margins of the socket and ensure that no loose bone fragments or sharp, splayed bone margins are present. These must be removed or smoothed to prevent lingering pain and impaired healing. The socket should be curetted free of granulation tissue or periapical pathology, if present, and irrigated free of any debris or calculus. As soon as this is done, coagulation within the socket should be encouraged, as this is the first step toward uncomplicated healing.

Principles of Surgical Extraction

Not all erupted teeth will be removable by simple technique. Often, indicators of potential difficulty are present and detected on examination before the procedure, and surgical removal can be planned. Common indications for surgical extractions are listed in Box 21-1. However, even experienced exodontists are sometimes surprised by a seemingly easy extraction that turns complicated. In other cases, a tooth might be removable with forceps luxation and delivery, but at the cost of losing alveolar

• BOX 21-1 Indications for Surgical Extraction

- Retained roots with minimal radiographic periodontal ligament space
- Severely carious teeth that will fracture with forceps extraction
- Endodontically treated teeth
- Teeth with internal or external resorption
- Teeth with multiple, widely divergent roots
- Teeth with dilacerated or greatly curved roots
- Ectopic or severely crowded teeth in positions where forceps cannot be used
- Teeth that are positioned close to vital anatomic structures
- Unerupted teeth other than third molars
- Hypercementosis
- Ankylosed teeth
- Multi-rooted teeth located in areas of the jaw where bone preservation is critical for implant placement
- Tooth that will be used for autotransplant

cortical bone essential for future implant support or ideal esthetics. In such cases, the prudent surgeon will electively use surgical extraction technique to minimize the bone loss required. Finally, surgical extraction may be indicated when several adjacent teeth will be removed simultaneously, increasing the likelihood that alveoloplasty will be required. Thus, familiarity with surgical technique is essential for the provider who wishes to perform any but the simplest of extractions. A proper diagnostic workup and careful surgical planning before starting an extraction procedure will usually save time, reduce complications, and improve outcomes for patient and surgeon.

Basic Concepts

Surgical extraction, like all other oral and maxillofacial surgery procedures, demands careful planning, adequate surgical access and visibility, hemorrhage control, meticulous handling of hard and soft tissues, maintenance of good blood supply to flaps, proper instrument mechanics, cleanliness, and painstaking repair of the surgical wound. By definition, surgical exodontia requires one or more of the following steps:

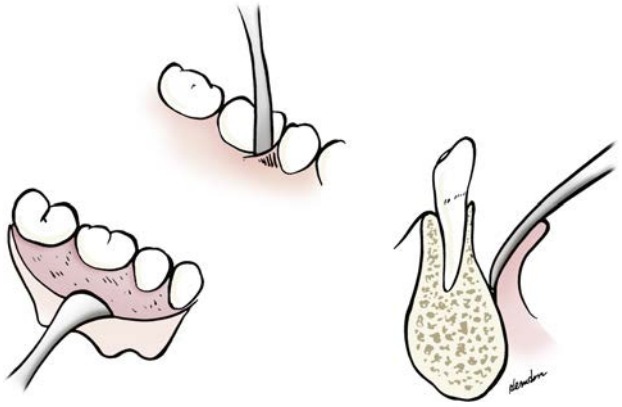
1. Elevation of a mucoperiosteal flap
2. Bone removal
3. Sectioning of the tooth

These steps are followed by debriding the wound, smoothing any rough or sharp bony margins, thorough irrigation, and soft tissue closure with sutures as needed.

Flap Design

In surgical exodontia, a full-thickness mucoperiosteal flap is used to expose the underlying tooth or root fragment and its surrounding alveolar bone. Careful consideration must be given to the position of the incisions and to the type and shape of the flap. The following are principles for flap design for surgical extractions:

- Incisions should be placed over bone not planned for removal
- The incision should allow for a flap that will give sufficient exposure and permit retraction without tension or risk of tearing



• **Figure 21-7** The envelope flap made with a periosteal elevator. (From Costich ER, White RP: *Fundamentals of oral surgery*, Philadelphia, 1971, WB Saunders.)

- The base of the flap should be wider than the reflected free margin
- Incisions must avoid vital structures such as the mental foramen or lingual nerve

Three basic designs are commonly used: the envelope flap, the triangle flap, and the trapezoidal flap.

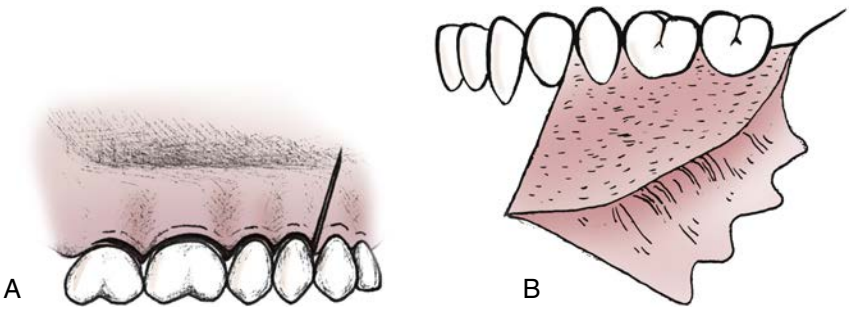
Most surgical extraction can be accomplished well using an envelope flap. A sulcular incision is made with a No. 15 blade around the necks of the teeth, including the interdental papillae. Typically, the incision extends to include one tooth mesial to the extraction site to two teeth distal. The flap is elevated from the sulcular incision deep to the periosteum, which is reflected away to expose the alveolar bone buccal to the extraction site (Figure 21-7). If the exposure is not adequate or the flap is under excessive tension, a releasing incision may be added at the mesial end of the flap, converting it to a triangle flap (Figure 21-8, *A* and *B*). The release should be angled mesially away from the alveolar crest, making the flap's base wider than the free margin. Care must be taken to avoid the mental nerve when working in the mandible.

When additional working access is necessary, particularly in the molar area, a second vertical incision angled distally may be added, converting the triangular flap into a trapezoidal flap (Figure 21-9).

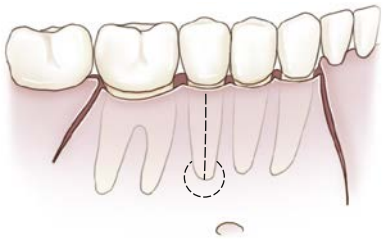
Bone Removal

In some cases, surgically exposing the crestal bone and the remaining tooth structure provides all the access needed to elevate the tooth without further bone removal. More often, some amount of alveolar bone must be removed to expose the underlying tooth and provide purchase for its removal. This is usually done with a dental burr in a surgical drill under constant irrigation (Figure 21-10, *A*). If the cortical bone is thin, a rongeur may be used.

As little bone as is necessary should be removed. In general, buccal bone removal should be done to expose roughly a third of the remaining root length. In most cases this amount of exposure will allow adequate purchase of an instrument on the exposed root structure (see Figure 21-10, *B*). In cases with unusually dense surrounding bone



• **Figure 21-8** **A,** A sulcular incision with a vertical release. The release is angled to provide a wide base for the flap and meets the sulcular incision without including the interdental papilla. **B,** A mucoperiosteal flap with an anteriorly based releasing incision. (**A** adapted from Dym H, Ogle OE: *Atlas of minor oral surgery*, Philadelphia, 2001, WB Saunders. **B** adapted from Costich ER, White RP: *Fundamentals of oral surgery*, Philadelphia, 1971, WB Saunders.)



• **Figure 21-9** A sulcular incision in the posterior mandible with vertical releases anteriorly and posteriorly. The vertical release in the anterior should be at the canine or lateral incisor area to prevent injury to the mental nerve.

or heavily decayed, soft root structure, additional bone removal is often necessary. If adjacent teeth will not be threatened, bone can also be removed within the alveolus along the interproximal periodontal ligament space to allow the introduction of a narrow elevator.

Sectioning and Removal of Multi-Rooted Teeth

When removing multi-rooted teeth, the surgeon may gain considerable advantage by dividing the tooth so that each root may be removed separately. While unnecessary as a routine step, this is commonly necessary in cases with unusually dense alveolar bone, divergent or curved dental roots, when care must be taken to preserve the maximum alveolar bone, or where excessive force applied to remove the tooth intact would risk damage to adjacent teeth or structures.

Lower molars may be divided into mesial and distal halves (Figure 21-11) which are then removed with straight or Cryer elevators (Figure 21-12) or, if the crown is largely intact, with extraction forceps (Figure 21-13, *A* and *B*). Similarly, maxillary molars may be divided with a handpiece so the buccal and palatal roots are separated (Figure 21-14). The buccal roots are usually removed first (Figure 21-15), improving access to the larger buccal root, which is frequently angled palatally and delivered into the space vacated by the buccal roots.

Once the roots have been delivered, the socket is managed as described earlier for simple extraction. The socket and the space beneath the soft tissue flap must both be thoroughly irrigated to remove any debris, and the soft tissue is repositioned and sutured into place. Unless necessary for unusual circumstances such as impending radiation or chemotherapy, it is not necessary to achieve primary closure over the extraction socket, which would otherwise require additional alveoloplasty.

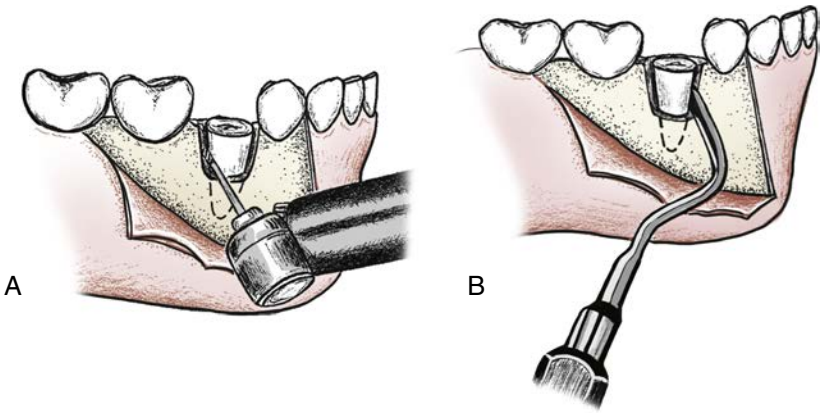
Complications of Erupted Tooth Removal

Bleeding

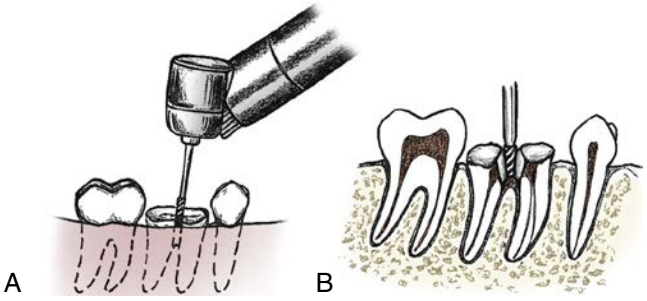
A minimal amount of postsurgical bleeding is normal and expected following dental extractions. Initial management with pressure using moist gauze should stop bleeding within several minutes. Patients should be instructed in how to properly replace the gauze and apply firm biting pressure as needed for any early recurrent bleeding. However, bleeding that persists, is not stopped by properly applied simple pressure, or recurs beyond the first 24 to 48 hours is not normal. Management of this complication requires clinical examination to determine if an identifiable and treatable local source exists, treatment with local hemostatic measures, and investigation for any contributing systemic coagulopathy.

Pain

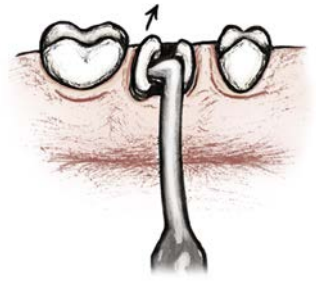
Simple extractions generally result in mild pain for 1 or 2 days, which is well managed by over-the-counter pain medications and gentle but complete oral hygiene. Multiple extractions or surgical extractions involving soft tissue reflection, bone removal, or prolonged effort to retrieve roots may result in moderate pain lasting several days. Nonsteroidal anti-inflammatory drugs, elevation, ice, and rest are all useful means of controlling pain in the proper setting. Combination narcotic analgesics remain important and useful pain control adjuncts even in the current climate of concern over diversion and abuse of prescribed controlled substances. Pain control should never be a rote regimen but must be individualized for each patient, considering the patient's medical history, lifestyle and activity demands, and past responses to analgesics, in addition to the expected consequence of the surgery. Pain lasting more than a few days often indicates a healing complication, so a new assessment of the patient is necessary before re-prescribing medications.



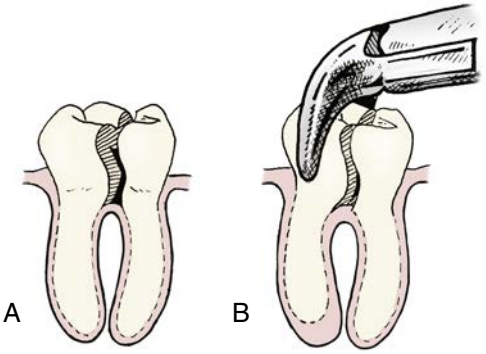
• **Figure 21-10** **A,** Teeth often fracture during extraction, leaving root fragments in alveolar bone. Adequate access must first be established by either an envelope or three-cornered triangle flap. Buccal plate is removed with a burr to expose root fragment. Space should be made to allow introduction of narrow elevator. **B,** Root is removed with elevator wedged between root and alveolar bone. Controlled luxation is performed to prevent root displacement and soft tissue injury. (From Dym H, Ogle OE: *Atlas of minor oral surgery*, Philadelphia, 2001, WB Saunders.)



• **Figure 21-11** Division of a mandibular molar **(A),** resulting in two single-rooted segments **(B).** (From Dym H, Ogle OE: *Atlas of minor oral surgery*, Philadelphia, 2001, WB Saunders.)



• **Figure 21-12** After one root of molar roots has been removed, the Cryer elevator is placed into the empty socket and turned with sharp point engaging interseptal bone and root to elevate remaining root. (From Dym H, Ogle OE: *Atlas of minor oral surgery*, Philadelphia, 2001, WB Saunders.)



• **Figure 21-13** A mandibular molar with intact crown is sectioned into mesial and distal halves **(A),** allowing forceps removal of the segments **(B).** (From Archer WH, editor: *Oral and maxillofacial* surgery, vol 1, ed 5, Philadelphia, 1975, WB Saunders.)

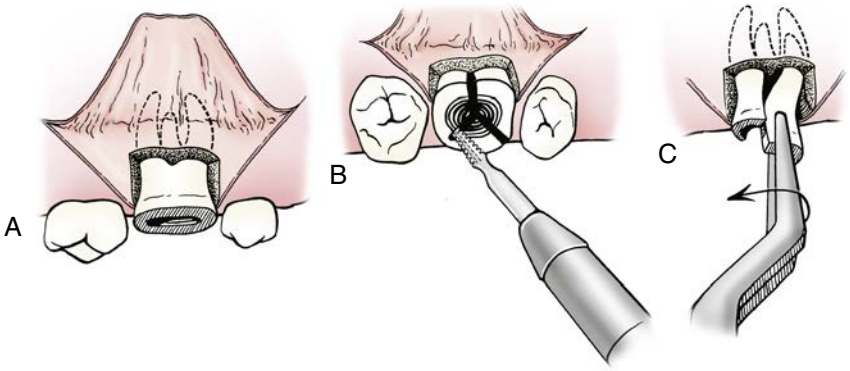
Swelling

Removal of erupted teeth usually causes little or no extraoral swelling. When soft tissue flaps are elevated, swelling is generally localized to the adjacent gingiva and alveolus, mild, and self-limited. Removal of multiple or impacted teeth is more commonly associated with moderate extraoral swelling, which is minimized by head elevation, ice for the first 24 hours, administration of glucocorticoids perioperatively, and minimizing soft tissue dissection and trauma. When patients report this symptom in other settings, they should be reexamined for other complications such as infection.

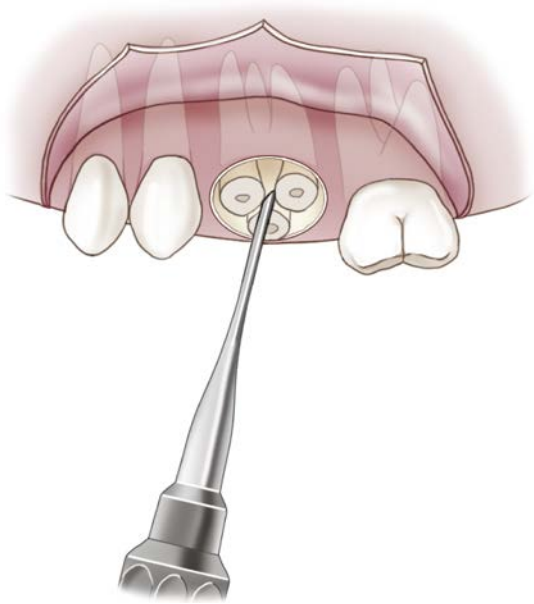
Damage to Other Structures

It is an inescapable reality that removing a tooth leaves behind a defect, and that the defect may extend into adjacent alveolar bone and expose or damage adjacent tooth roots, the maxillary sinus, or the inferior alveolar nerve. The physical access required to deliver a tooth may jeopardize adjacent teeth, especially when they have large or overhanging restorations or fragile tooth structure undermined by caries.

These risks are almost always predictable, and the surgeon is wise to discuss them with the patient, as well as their potential short- and long-term consequences, before they might occur. Finally, tooth removal requires force, but if that force is not well controlled, instruments may collide with and damage teeth or soft tissues away from the extraction site. Care must be taken to minimize the risk of such an injury, which is usually the result of improper technique or instrument misuse.



• **Figure 21-14** The maxillary molar is sectioned in a "Y" fashion to allow for removal of each root individually (**A-C**). (From Archer WH, editor: *Oral and maxillofacial surgery*, vol 1, ed 5, 1975, Philadelphia, WB Saunders.)



• **Figure 21-15** Buccal roots are separated and delivered with a straight elevator.

Dry Socket

Dry socket, or alveolar osteitis, results from premature loss of the blood clot within the socket, leaving a painful, malodorous, slow-healing defect with exposed alveolar bone within. The phenomenon is described more fully in the following section on impacted teeth, but it may occur with any extraction. Typically arising on the third or fourth day after surgery, it is best managed with one of many available dressing ointments to keep the area clean and less painful while awaiting initial healing, which may take 2 weeks or more. Smoking is a strong risk factor. Avoiding nicotine and providing good, gentle postoperative care to the extraction site are important steps the patient can take to minimize occurrence of this complication.

Infection

Postsurgical infection is exceedingly rare following routine dental extractions, even in the setting of periapical periodontitis or acute bacterial pulpitis. Patients should be advised to return if they are not experiencing resolution of pain or worsening of swelling in the area within a few days. Management of serious odontogenic infections is covered elsewhere in this text.

Impacted Teeth

Not all unerupted teeth are impacted. Impaction occurs when the expected development and timetable for eruption have passed and no reasonable expectation for eventual eruption can be achieved. Beyond radiographic interpretation and clinical experience, the surgeon must have intimate knowledge pertaining to development and eruption patterns of teeth in order to correctly diagnose impaction.

Any tooth in the mouth may be impacted, but third molars are the most commonly impacted teeth, followed by maxillary canines and mandibular premolars. This reflects the normal eruption sequence, with those teeth erupting last the most likely to have insufficient arch space available for eruption.

Indications for Impaction Removal

Just as not all unerupted teeth are impacted, not all impacted teeth require surgical intervention. The National Institutes of Health (NIH) last addressed guidelines for removal of third molars in 1979, noting that patients with impacted teeth who wait until symptoms occur before seeking removal have greater morbidity associated with their surgery. The least morbidity was also associated with third molar removal removed between the ages of 15 and 25 or when the roots are only two thirds formed, based on the roots being straight and not curved, bone being softer and more pliant, the inferior alveolar nerve being further away from the root apices, and more rapid potential healing. Clearly, early intervention in the surgical removal of impacted third molars will benefit most patients. More recently, the Third Molar Clinical Trials conducted a large scale, multicenter study supported by the American Association of Oral and Maxillofacial Surgery (AAOMS) and the Oral and Maxillofacial Surgery Foundation. A plethora of papers derived from this and related studies has been summarized in an AAOMS White Paper

updating recommendations regarding removal of third molars.[1] The following indications must be considered by the dentist and surgeon to determine the need for removal of impacted teeth.

Caries

Non-restorable decay is the leading cause of tooth extraction in general, and it remains an important indication for impacted third molars exposed to the oral cavity. In the mandibular third molar, the most common location of dental caries is at the cervical line, due to its inaccessibility to both the patient and the dentist in terms of adequately cleaning and restoring the decay. Approximately 15% of impacted mandibular third molars are extracted as a direct result of the presence of caries.[2]

Periodontal Disease

Periodontal disease in the third molar region is also directly related to the difficulty in keeping that area clean and free of plaque and bacteria, leading to attachment loss, pocket formation, pathogen formation, and inflammatory response at the distal of the second and third molars.[3-5] This accounts for 5% of impacted third molar removal.[6-10] In addition, the connection between third molars and periodontal disease has been well documented.[11]

Pericoronitis

Pericoronitis occurs when a third molar partially erupts through the oral mucosa, becoming a potential bacterial trap causing a mild to moderate, and in some rare cases severe, inflammatory response. This most commonly occurs in mandibular third molars, especially those with soft or hard tissue overlying the posterior aspect of the crown.[12] The inflammation can be caused by food debris that is often trapped under the soft tissue flap overlying the impacted wisdom tooth and cannot be effectively cleansed. As a result, bacteria, most commonly *Peptostreptococcus*, *Fusobacterium*, and *Bacteroides (Porphyromonas)*, can invade the site and initiate the infectious process.[13-15] Occlusal trauma from the opposing maxillary third molar can also damage the overlying soft tissue of the mandibular third molar, resulting in operculitis. Left untreated, pericoronitis can lead to mild infection or a severe fulminating infection that requires hospitalization and an aggressive surgical course of treatment.

Treatment of pericoronitis involves extraction of the offending tooth or opposing maxillary third molar, debridement of the periodontal pocket, and disinfection with an irrigation solution such as chlorhexidine or hydrogen peroxide. Only in severe cases is antibiotic therapy warranted. The primary prevention of pericoronitis is extraction of third molars that are at high risk of developing inflammation. Operculectomy has previously been recommended as a prevention tool; however, soft tissue regrowth is a frequent occurrence due to the available space between the anterior border of the ramus and the space and angulation of the erupting crown, making this an incomplete prevention technique.

Extraction of mandibular third molars due to pericoronitis accounts for 25% to 30% of overall extractions of impacted teeth.[6-10] One study found the incidence of pericoronitis in third molars to be as high as 43% in 1 year.[16] The incidence of pericoronitis increases with age, becoming a more prominent indication for removal of the offending tooth. Most significantly, pericoronitis is the main cause of impacted third molar extraction after the age of 20 years.

Cysts or Tumors

The most significant pathology that is related to impacted third molars is the dentigerous cyst. These occur when the follicular sac that is responsible for formation of the developing crown undergoes cystic degeneration within the mandibular bone. In rare cases, odontogenic tumors arise at the impacted tooth, very rarely with malignant transformation potential.[17] The general incidence of neoplastic change in impacted third molars has been reported to be around 3%.[18,19] However, other large retrospective studies have found that only 1% to 2% of all third molar extractions are due to the presence of odontogenic cysts or tumors.[6-10] It has also been postulated that the risk of neoplastic change around third molars decreases with age, as most associated pathologies are found in patients younger than 40 years of age.

Orthodontic Needs

For impacted teeth other than third molars, orthodontic considerations strongly influence whether the tooth might be extracted or exposed so that it can be moved into a functional position within the dental arch. Orthodontic consultation and collaborative treatment are essential in such cases. The decision to expose or remove a tooth is usually jointly made by the surgeon, orthodontist, and restoring dentist. Available or anticipated space, angulation, and age of the patient are all considerations.

Regarding impacted third molars, longitudinal reviews with large subject populations have provided solid evidence that they are not a significant cause of post-orthodontic anterior crowding.[20,21] However, an impacted third molar may obstruct orthodontic treatment, especially when the orthodontist attempts to move molars distally. If orthognathic surgery is planned, the mandibular third molar may interfere with the surgery. When the third molars are not removed before a mandibular osteotomy or advancement, the thickness and quality of the lingual bone at the proximal aspect of the distal segment, where internal fixation is applied, is reduced in quality. The surgeon must plan well in advance of these procedures, as it is best to remove the third molar and allow sufficient time for the extraction site to heal with mature bone before proceeding.

Other Indications

Resorption of Adjacent Roots

Just as permanent teeth resorb the roots of primary teeth during their normal eruption patterns, misaligned teeth and third molars have the ability to resorb the roots of adjacent teeth as well. Research has suggested that the occurrence of

significant root resorption affiliated with third molar causation is as high as 7%.[22] If root resorption is noted, the surgeon should remove the offending tooth as soon as possible; reparation of the resorbed root may occur with the deposition of a layer of cementum over the damaged area and the formation of secondary dentin. If the degree of root resorption is severe, however, removal of both the third molar and the affected tooth may be warranted.

Prosthetic Preparation

Retained impacted teeth may interfere with denture design, or they may become exposed as the overlying bone is resorbed, particularly if they have little or no overlying bone. The need to remove such impacted teeth must be carefully weighed against the expected morbidity of the procedure. Deeply impacted teeth without adjacent pathology and which are unlikely to become exposed may be safely retained and observed.

Pre-Radiation for Head and Neck Cancer

Radiotherapy has been linked to significant increases in xerostomia and soreness, which leads to increased incidence of decay and inflammation. The epithelium of the cells lining the mouth becomes prone to ulceration. It is important to adequately manage sites of decay or inflammation before beginning radiation treatment, most especially when the focus of the radiation will be on the head and neck. Impacted teeth are potential problems and, if there are no contraindications, are best removed before head and neck cancer treatments.[23]

Prevention of Jaw Fracture

An impacted third molar that is present along a fracture line presents an area of weakened resistance to fracture of the mandible.[24-26] It may be advisable that patients who play contact sports have their impacted third molars removed to prevent jaw fracture during competition. In addition, the presence of an impacted tooth invites a number of complications in the treatment of jaw fracture.

Pain of Unknown Origin

On rare occasions, patients may present complaining of pain whose origin cannot be confirmed on clinical or radiographic examination. Resolution of this pain can often be achieved by removal of the impacted tooth in question. Currently, no research provides an explanation as to the cause of this pain, but approximately 1% to 2% of mandibular third molars are extracted for this reason.[6-10] It is important that the surgeon ensure that all other potential sources of the unknown pain are ruled out before proceeding with extraction. It is also prudent to explain to the patient that removal of the tooth may not provide the sought-for relief.

Contraindications to Extraction of Impacted Teeth

Elective removal of impacted teeth, like all surgical procedures, should not be performed if the risks outweigh the expected benefits. Clearly, patients with significantly compromised and unstable medical conditions are not candidates for elective removal of impacted teeth showing no evidence of active pathology.

Age

It is the consensus of most surgeons that asymptomatic third molars in the adult population over the age of 50 years should not be removed routinely, especially if no inflammation or periodontal disease exists. As patients age, there is a decreased healing response,[27] which may result in greater bony defects postoperatively, as well as less toleration for the surgical procedure and longer recuperation periods. Bone also becomes more calcified with age, making the extraction more difficult and more likely to cause fracture. As a general rule, if a patient has a fully impacted third molar that is completely covered with bone, has no obvious potential source of communication with the oral cavity, and has no signs of pathology such as an enlarged follicular sac, and if the patient is over age 40, the tooth probably should not be removed. Long-term follow-up by the patient's dentist should be performed periodically, with radiographs performed every several years to ensure that no adverse sequelae are occurring. If signs of pathology develop, the tooth should be removed. If the overlying bone is very thin and a removable denture is to be placed over that tooth, the tooth should probably be removed before the final prosthesis is constructed.

It is also recommended that impacted teeth not be removed in the very young either. There have been reports of extraction of the tooth bud of third molars in patients as young as 8 or 9 years old,[28] but this may be imprudent, largely because of the inaccuracy of predictions as to whether a developing tooth will become impacted or erupt.

General Health

Another general contraindication to extraction of impacted teeth is a compromised medical status. As age increases, so does the incidence of cardiovascular disease, pulmonary disease, and a myriad of other complicating health problems. On the contrary, in younger patients with congenital coagulopathies, asthma, or epilepsy, it may be advisable to remove the tooth before the incipient diseases progress. The presence of compromising systemic disease requires close communication between the surgeon and the physician to determine the best course of action for the patient's overall health.

Risk to Adjacent Structures

The potential for surgical damage to adjacent structures, including nerves, teeth, and sinuses, sometimes makes it necessary to leave the impacted tooth in situ. This concern is commonly evident for the inferior alveolar nerve. If the impacted tooth is in close proximity to this nerve, leaving the tooth in place may be considered, if it is not symptomatic and is judged to present a low risk of future pathology. Similarly, surgical extractions that will result in significant bony defects, especially in older patients, may be

contraindicated if they pose a high risk of further deterioration of periodontal health or loss of adjacent teeth.

Impacted Third Molars

Third molars are the most frequently impacted teeth, followed by maxillary canines and mandibular premolars. Factors cited as causing this phenomenon include inadequate space in the dental arch for eruption, obstruction of the tooth eruption because of pathology (cyst, supernumerary tooth, or other tumors), or the angulation of the erupting tooth. In one study of 5000 army recruits, 10,979 impacted teeth were found, but only 212 were not third molars.[29]

Assessing Eruption Potential

The average age for third molar eruption is 20 years; however, the range of eruption age extends as late as 24 years. Although positioning of the third molar does not substantially change past the age of 25 years,[30] large studies suggest that movement is not completed until as late as the fourth decade of life.[31] It is important to remember that the position of the third molar in an 18-year-old will change; these impactions have as much as a 30% to 50% chance of fully erupting by the age of 25.[32-34]

The most important prognostic indicators for eruption are the angulation of the teeth and the space available within the dental arch.[35-38] Figure 21-16 illustrates the various angulations assumed by maxillary and mandibular third molars. Evaluated at age 18 to 20 years, mandibular third molars that are horizontal or significantly mesioangular are less likely to successfully erupt than those that are vertically oriented. Distoangular oriented teeth have a variable eruption success rate. Fortunately, the most common angulation, mesioangular, is also the least difficult to access and remove.

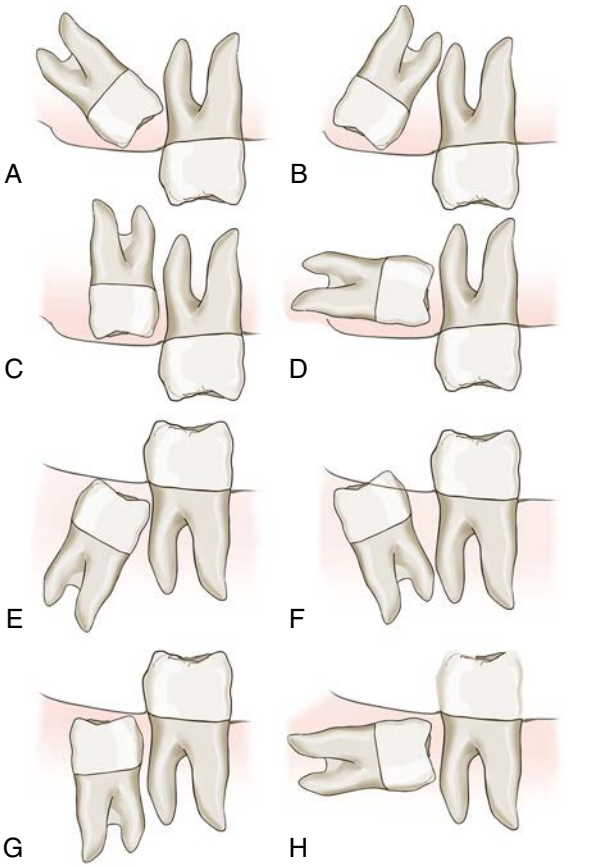
In terms of available space within the dental arch, a lower third molar is more likely to erupt if its crown is narrower than the horizontal radiographic space between the anterior mandibular ramus and the distal surface of the second molar. If this space is smaller than the third molar's crown, or if the molar is rotated away from the vertical, successful eruption of the third molar is unlikely.

Finally, delayed maturation of the third molar, with associated lagging of the dentition behind skeletal and mandible growth, has been shown to increase the incidence of impactions. Clinically, this manifests as third molars having a higher likelihood of impaction when the roots are partially developed, compared to a third molar with fully developed roots in a similar position at the same age.

Surgical Technique

Instrumentation

Box 21-2 lists the hand instruments necessary for third molar removal. In addition, a high-torque surgical handpiece with either a straight fissure burr or a round burr is used for bone removal and tooth sectioning. Irrigation with sterile saline and suction complete the armamentarium.



• **Figure 21-16** Angulation classification of impacted teeth. Maxillary third molar impactions: mesioangular (*A*), distoangular (*B*) vertical (*C*), and horizontal (*D*). Mandibular third molar impactions: mesioangular (*E*), distoangular (*F*), vertical (*G*), and horizontal (*H*).

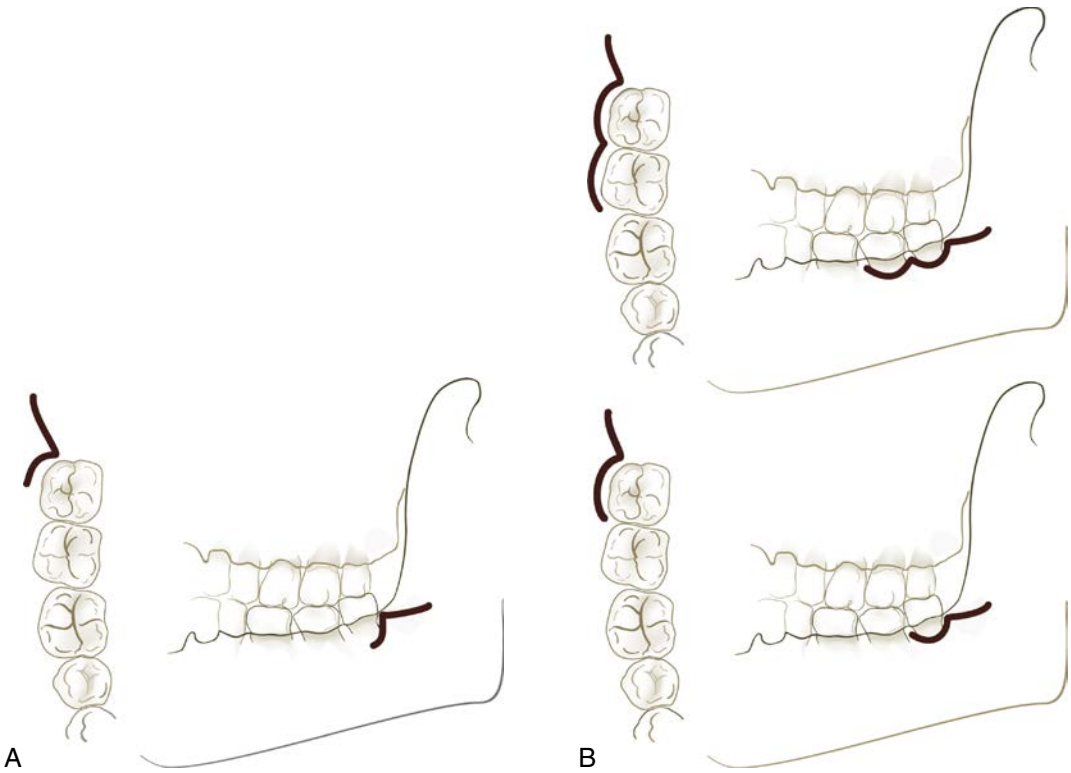
Flap Design

Mandibular impacted third molars are exposed by reflecting an envelope flap. The common description is a "hockey stick" incision with an arm extending distally from the distobuccal of the second molar posteriorly and laterally along the palpable ascending ramus. Care is taken to keep the incision on the retromolar pad angled buccally in order to avoid the lingual nerve, which may in some cases travel near the crest of the retromolar area. From the distobuccal of the second molar, the incision either drops inferiorly into the buccal vestibule as a mesial release (Figure 21-17, *A*) or runs anteriorly in the buccal sulcus of the second or first and second molars (see Figure 21-17, *B*).



• **Figure 21-17** A well-designed, adequate mucoperiosteal flap allows appropriate access to the tooth. The distal release must follow the ascending ramus laterally **(A),** not aim lingually where it would jeopardize the lingual nerve. Some surgeons prefer an anterior release at the distal of the second molar as shown here. A common alternate flap design is an envelope flap carried anteriorly to the mesial of the second or first molar **(B).**

• **Figure 21-18** A high maxillary impaction is exposed more easily when a mesial vertical release is added to the incision. (From Dym H, Ogle OE: *Atlas of minor oral surgery*, Philadelphia, 2001, WB Saunders.)

Maxillary impacted third molars are exposed via similar incisions. When the occlusal surface of the third molar is at about one third or higher of the height of the second molar root, a mesial releasing incision is often useful (Figure 21-18).

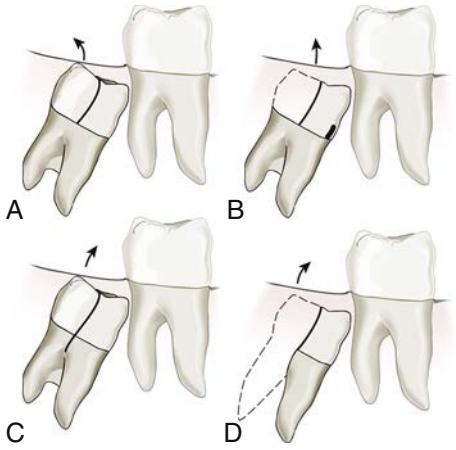
Bone Removal

In the mandible, bone is removed with a burr under copious saline irrigation until most of the occlusal surface and the buccal surface are exposed to the level of the cervical height of contour or the cemento-enamel junction, depending on the expected difficulty of the procedure. Care is taken to avoid injury to the lingual aspect of the occlusal surface, where the lingual nerve may be injured. Bone is removed distally to fully expose the distobuccal line angle of the third molar crown, but excessive bone removal from the distal surface risks perforation lingually and often results in increased bony bleeding from the loose cancellous bone in the ramus just posterior to the third molar crown. Mesially, the mesiobuccal line angle must also be exposed to allow insertion of an elevator as a wedge from the mesial.

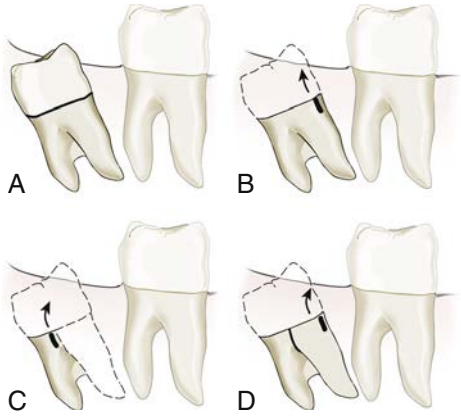
Buccal bone overlying the impacted maxillary third molar is often very thin and can be removed with a periosteal or dental elevator. It is rare that a handpiece is necessary to remove bone around maxillary third molars.

Tooth Sectioning

Using the surgical handpiece, the tooth is sectioned according to its angulation, unless it can be elevated intact easily, without undue force. Figure 21-19 illustrates the approaches used when sectioning a mesioangular third molar, and Figure 21-20 shows tooth sectioning for a distoangular lower third molar. Generally, mesioangular teeth are split into a mesial and distal half, directing the burr toward the root furcation. Distoangular and horizontally impacted teeth are often divided by cutting the crown free from the roots at the neck of the tooth, sometimes in two steps. If necessary, the roots are then divided. In all cases, care is taken not to cut too deeply either toward the lingual or inferiorly,



• **Figure 21-19** Mesioangular impaction: After bone removal is accomplished, the distal portion of the crown or the complete crown should be sectioned **(A),** fractured with an elevator, and removed **(B).** If possible, it is helpful to keep part of the mesial aspect of the crown attached to the mesial root to act as a handle and fulcrum for removal of the mesial root. Frequently the mesial and distal roots need to be sectioned from each other at the bifurcation **(C)** and removed independently **(D).**



• **Figure 21-20** Distoangular impaction: The crown may be sectioned at the neck and removed completely **(A),** allowing elevation of the roots with a mesial purchase point if necessary **(B).** Alternatively, the roots may be divided once the crown is removed and then elevated separately **(C-D).**

where the lingual or inferior alveolar nerves may be at risk of injury. Generally, the tooth is not intentionally cut completely through to the lingual or inferior surface (when lying horizontally—see Figure 21-21) but is cut most of the way through and then split by insertion of an elevator and wedging the tooth segments apart.

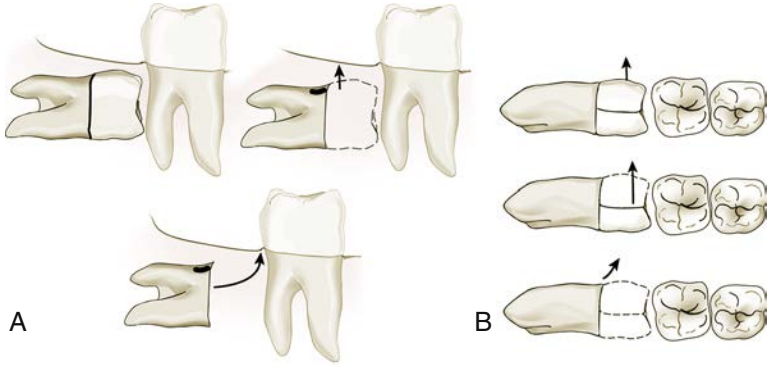
Maxillary third molars rarely require division and are usually elevated intact (Figure 21-22). The overlying bone is thin and relatively elastic, and even when the bone is thicker, extraction can be achieved by removing relatively more bone rather than resorting to sectioning the tooth. Occasionally, a widely divergent buccal root or extreme root dilacerations will require sectioning the tooth into two or more pieces to remove the roots individually. Most surgeons find such cases among the most challenging of all impaction operations.

Tooth Delivery

The intact tooth or the sectioned portions of the tooth are elevated from the socket using a narrow dental, Cogswell B, or Crane elevator. More complicated impactions may require a series of sometimes delicate divisions, followed by careful separation and elevation of small segments.

Socket Care and Closure

Once the tooth is removed, any remaining follicle or granulation tissue is removed, particularly from the distal surface of the second molar. Care must be taken to avoid injuring the lingual soft tissue in the mandibular third molar socket out of caution for the lingual nerve. Any rough or very thin bony margins around the socket are smoothed with a file, and in the maxilla the posterior vestibule is palpated for any sharp margins under the flap that might create postoperative healing problems. The socket and flap are irrigated with large quantities of saline, and the flap closed. Most surgeons prefer a resorbable suture for this purpose. Paradoxically, a tight wound closure has been shown to increase the incidence of postoperative complications. In the maxilla, a vertical release must be closed if it was made, but often the reflected soft tissue will lie passively in place and a suture is not always necessary across the tuberosity area.



• **Figure 21-21** Horizontal impaction: The crown must be sectioned and removed completely before the roots can be displaced into the vacated space **(A).** Care must be taken to not cut too deeply the lingual or inferior directions when sectioning the crown. A useful alternative is removing the crown in several segments **(B),** allowing vision of the bony walls of the socket.

Impacted Maxillary Canines

Maxillary canines are the second most commonly impacted teeth, occurring in 1% to 2% of the general population and more commonly in females than males. Eighty-five percent of impacted maxillary permanent canines are palatal impactions, and 15% are labial.[39,40] The impaction of this tooth has considerable clinical implications, as the maxillary canine is the foundation of functional occlusion and an esthetic smile. Because of its importance, the impacted maxillary canine should be preserved when possible, and all necessary precautions should be taken to avoid a bone defect or root resorption when exposing and moving it.

Preoperative Planning

Because canine teeth are frequently retained and not removed, preoperative planning includes coordination with the treating orthodontist and general dentist to sequence the necessary care. In general, exposure and bonding of an impacted tooth is preceded by placing orthodontic appliances and beginning to create space into which the tooth can be guided orthodontically. The timing of extraction of any remaining deciduous teeth must also be determined.

The majority of impacted maxillary canines are located in the palate, although some are impacted buccally. Clinical examination may reveal their location through a visible or palpable bulge, but more often the location and angulation of the impacted tooth is determined radiographically. Multiple radiographs exposed at different angles are interpreted according to the "same lingual, opposite buccal" (SLOB) rule examining apparent movement of the impacted tooth versus those in the dental arch. When available, cone-beam imaging provides excellent localization of the impacted tooth as well as additional useful information on the proximity of adjacent roots and any resorption that may be already present.

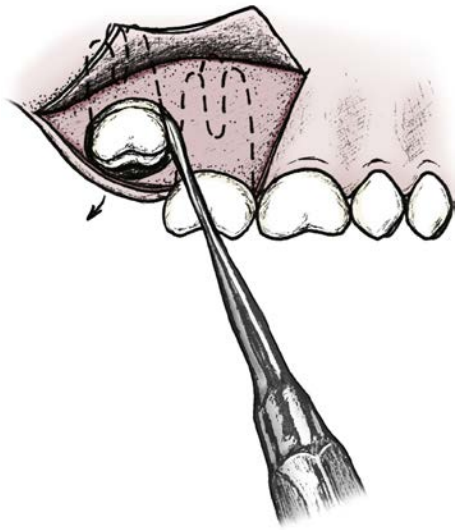
Surgical Technique

Exposure

The principles of soft tissue exposure are very different between palatal and buccal impacted canines. On the palate, the thick, fully keratinized palatal soft tissue forms a robust flap that heals well with little or no consequence to the periodontal health of the canine or other adjacent teeth. In contrast, care must be taken on the buccal side to preserve the available keratinized gingival tissue in the canine site and ensure that the tooth erupts with that tissue on its facial surface.

The palatally impacted canine is approached through a posteriorly based palatal flap. A full-thickness mucoperiosteal flap is developed from a sulcular incision extending from the premolar or molar on the affected side to the midline or beyond, if necessary, for adequate tension-free exposure (Figure 21-23). If necessary, the incisive neurovascular bundle can be cut through without significant consequence. If both canines are to be exposed, the incision extends to the contralateral molar area, creating a single flap. A drill under irrigation is used to expose the most superficial surface of the impacted crown without damaging its enamel. The cementoenamel junction is not exposed unless the tooth will be removed.

On the labial side, the tooth may be exposed and bonded using a closed or open technique, depending on the vertical height of the impaction. In general, if the cusp tip of the canine is within several millimeters of the adjacent crowns, a trapezoidal flap with relatively parallel releases is reflected superiorly and repositioned apically above the facial surface of the exposed canine crown. Thin overlying bone is removed to expose enough enamel to bond a bracket or button, and the flap is sutured into its new position (Figure 21-24). If the tooth is more lateral or farther superior, a closed technique is used instead. An envelope incision with any needed release is developed, the



• **Figure 21-22** Using a straight elevator, the tooth is then elevated out of its bony crypt in a distobuccal direction. (From Dym H, Ogle OE: *Atlas of minor oral surgery*, Philadelphia, 2001, WB Saunders.)

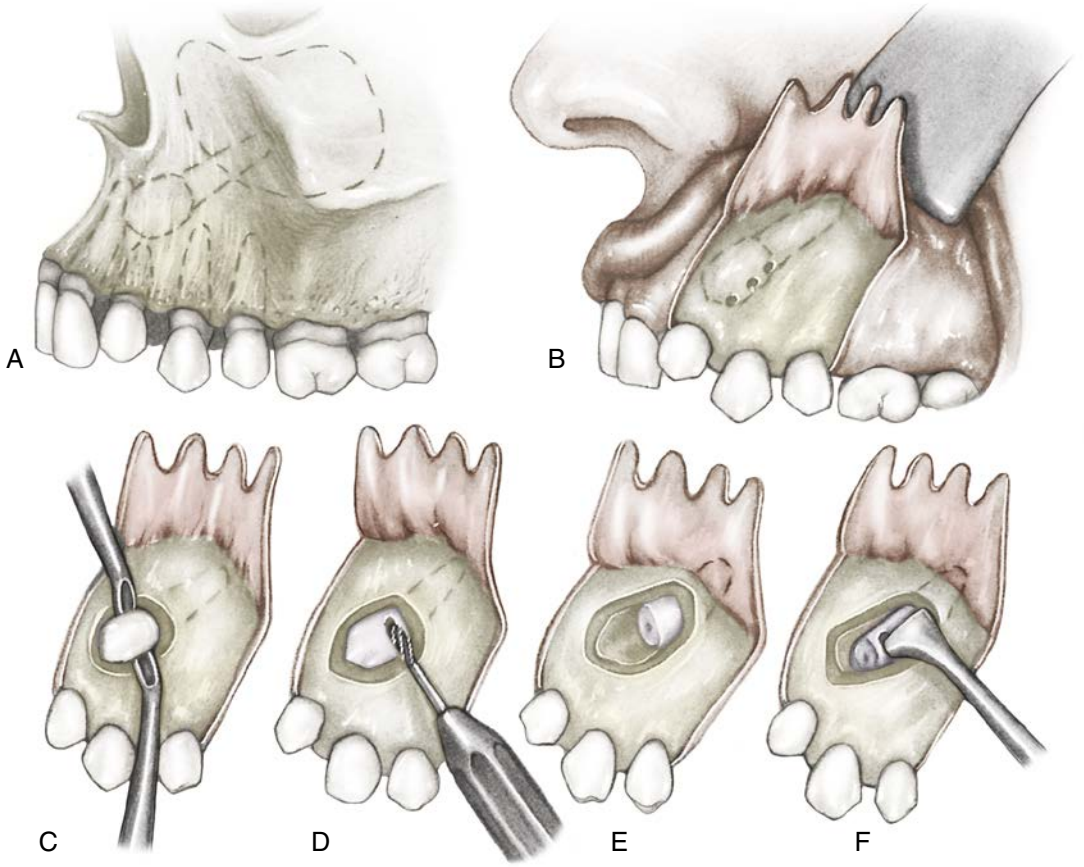
• **Figure 21-24** A trapezoidal incision to expose underlying buccal impacted canine **(A).** The flap is apically repositioned to expose canine crown **(B),** keeping the attached gingiva at the crown's neck, which is critical for periodontal long-term health of tooth. (From Dym H, Ogle OE: *Atlas of minor oral surgery*, Philadelphia, 2001, WB Saunders.)



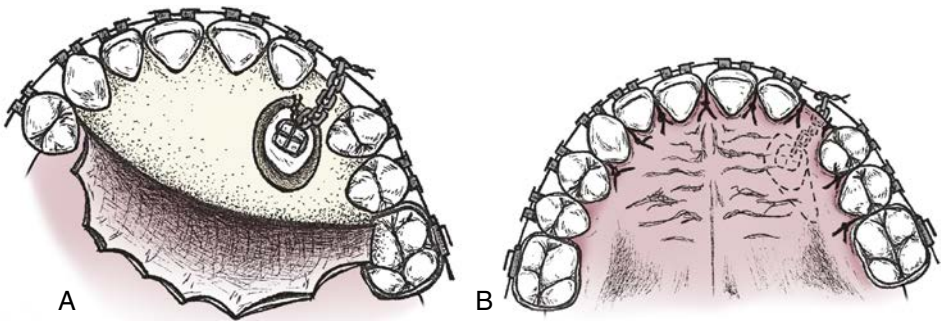
• **Figure 21-25** A labially impacted tooth **(A)** is exposed via a mucoperiosteal flap with limited bone removal around the crown **(B,C).** A similar approach may be used to bond a bracket to the tooth using the closed flap technique. In this case, the crown is sectioned **(D),** a purchase point is placed **(E),** and the root is elevated and removed **(F).** Great care is exercised to avoid adjacent tooth roots, the nasal floor, and the maxillary sinus during these procedures in the lateral and anterior maxilla. (From Archer WH, editor: *Oral and maxillofacial surgery*, vol 1, ed 5, 1975, Philadelphia, WB Saunders.)

crown exposed, and the flap replaced in its original position, not unlike the process used for palatal impactions (Figure 21-25).

Bonding or Extraction

If a palatally impacted canine will be extracted, the crown is sectioned and removed first, then the root displaced into the space vacated by the crown and removed as well. If fully developed, the root may be removed in sections to avoid making a larger intrabony defect and risking injury to adjacent roots.

If the tooth will be repositioned orthodontically, a bracket or a button and chain are bonded to the exposed enamel surface. This is accomplished using any of multiple



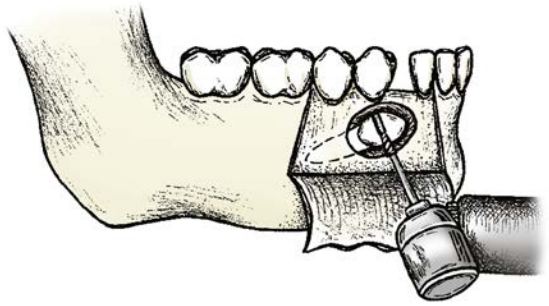
• **Figure 21-26** **A,** Palatal flap retracted with bracket applied to canine crown and chain attached to orthodontic arch wire. **B,** Palatal flap closed with the chain emerging at the crest of the alveolus in the edentulous space. (From Dym H, Ogle OE: *Atlas of minor oral surgery*, Philadelphia, 2001, WB Saunders.)

commercially available bonding agents, according to the manufacturer's instructions. Care must be taken to make the field as dry as possible, which means careful attention to hemostasis and removal of any follicular tissue with a curette. Local anesthetic with epinephrine can be injected into bleeding tissue to help achieve the necessary dry field. Once the bond is tested and found to be secure, the loose end of the chain is attached to the orthodontic appliances so that it will emerge from the soft tissue on the crest of the ridge in the tooth's proper site, and the flap is sutured back into place (Figure 21-26).

Other Impacted Teeth

The next most common impacted teeth after third molars and maxillary canines are mandibular premolars, mandibular canines, and maxillary premolars. These teeth are managed much like maxillary canines. When feasible, they are bonded and erupted into occlusion with orthodontic assistance; otherwise, they are generally removed. In the case of mandibular impactions, cone-beam imaging is particularly useful because these impacted teeth may be located buccally, lingually, or centered in the alveolus. Cone beam imaging also allows examination of the health of adjacent roots and aids in determining which of the several teeth present are the best candidates for long-term retention. Proximity of adjacent teeth and the mental nerve must be considered in deciding the best surgical approach: Sometimes it is necessary to approach impacted mandibular canines and premolars from both sides of the alveolus to minimize bone removal and gain access to bond, or section and remove, the impacted teeth. Figure 21-27 provides a schematic illustration of the principles of removing an impacted mandibular canine.

Maxillary premolars, other more rare impactions, and supernumerary teeth are managed in a similar fashion. Most impacted maxillary premolars are positioned with their crowns tipped toward the palate, and sometimes they can be removed by simple elevation with a small straight elevator. It is usually not possible to place extraction forceps, as the adjacent teeth are crowded against the impaction, and caution must be used to not mobilize these other teeth (Figure 21-28).



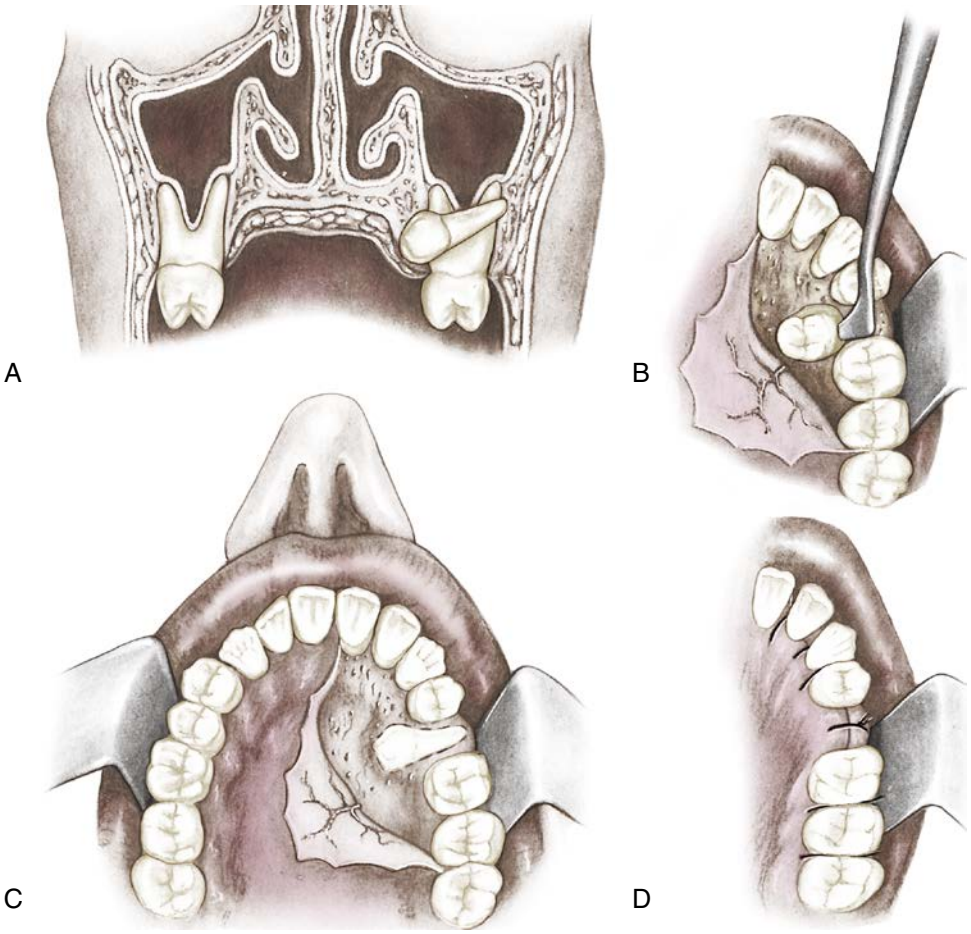
• **Figure 21-27** The mandibular impacted canine is most frequently located buccally, and the surgeon must be cognizant of the mental foramen in or near the surgical field. The underlying bone and canine are exposed through a vertical releasing incision and a posterior release if access is found to be restricted with only the one anterior release. The overlying bone is carefully removed and the crown sectioned. (From Dym H, Ogle OE: *Atlas of minor oral surgery*, Philadelphia, 2001, WB Saunders.)

Perioperative Management

Unlike removal of erupted teeth, surgery for impacted teeth has a significant impact on quality of life for several days after surgery. Third molar removal is by far the best studied impaction surgery, and even without complications patients should expect to curtail their usual activities significantly. However, impaction surgery for non-third molars should also be expected to result in many of the consequences described later.

Multiple studies have looked at the short-term impact of third molar removal on quality of life.[41-43] As expected, third molar removal has a profoundly negative impact for the first 4 to 7 days. Longer follow-up indicates that this rapidly improves, most likely due to elimination of chronic pain and inflammation, most often in the form of pericoronitis. This information is of particular importance to the surgeon and patient during the preoperative consult, not to mention when dealing with a patient experiencing complications following third molar extraction.

True complications occur with a 10% incidence following surgical removal of the third molars.[44] These complications range from the more common, mild, and transient, to severe and permanent. Predictable outcomes include swelling, pain, stiffness, and mild bleeding. Severe outcomes



• **Figure 21-28** A maxillary impacted premolar **(A)** is exposed via a posteriorly based palatal flap extending from the second molar to the midline. The tooth may be elevated with a Cryer **(B)** when space permits, preserving the adjacent teeth and their alveolar bony support **(C).** The flap is reapproximated using interdental and interrupted sutures **(D).** (From Archer WH, editor: *Oral and maxillofacial surgery*, vol 1, ed 5, Philadelphia, 1975, WB Saunders.)

include inferior alveolar nerve anesthesia and fracture of the mandible. The depth of the impaction, presence of a complete bony impaction, and the age of the patient influence overall incidence and severity of the complications.[45] The experience and competence of the surgeon also play a role in the incidence. Less experienced surgeons will experience a higher incidence of complications compared to more experienced counterparts.[46,47]

Managing Bleeding

Postsurgical bleeding can be minimized by using a good surgical technique and by avoiding the tearing of flaps or excessive trauma to the overlying soft tissue. When a vessel is cut, the bleeding should be stopped to prevent secondary hemorrhage following surgery. The most effective way to achieve hemostasis following surgery is to apply pressure with moist gauze directly over the site of the surgery. In some patients, immediate postoperative hemostasis is difficult, either because of limited ability to cooperate or a surgical site (e.g., hard palate) where biting down is not useful. In such situations, a variety of techniques can be employed to help secure local hemostasis, including oversuturing and the application of topical thrombin on a small piece of absorbable gelatin sponge into the bony defect. The defect can also be packed with oxidized cellulose. Unlike the gelatin sponge, oxidized cellulose can be packed into the socket under pressure. In some situations, microfibrillar collagen can be used to promote platelet plug formation. Patients who have known acquired or congenital coagulopathies require extensive preparation and preoperative planning (e.g., determination of international normalized ratio, factor replacement, or hematology consultation) before third molars are removed surgically.

Postoperative Antibiotics

The exact incidence of infection following surgery of impacted third molars is unknown; it is generally a rare occurrence, meaning it is unusual to see pain, swelling, and purulence that require incision and drainage and antibiotic therapy. That being said, a competent and experienced surgeon would have an expected infection rate of 1% to 3% for all third molar procedures, which are considered clean-contaminated surgery.[48] It is difficult to reduce the incidence of infection below 3% by using prophylactic antibiotics; thus, many authorities believe

it is unnecessary to prescribe them routinely for a normal, healthy patient undergoing impaction surgery. Although the literature remains divided, there is good evidence that prophylactic antibiotics do not reduce postoperative infections in third molar cases.[49,50]

A more common occurrence following third molar extraction is the dry socket, or, more accurately, alveolar osteitis, described more completely later. Prophylactic antibiotic use has been shown to reduce the incidence of dry sockets postoperatively. Similar risk reduction has been found with copious irrigation, preoperative rinses with chlorhexidine, and placement of antibiotics directly into the extraction site.[47,51-56] Thus, although antibiotics are helpful, they may be no more effective than other local measures, some of which do not require active patient participation. On the other hand, broad increases in antibiotic-related complications such as antibiotic allergy, growth of resistant bacteria, gastrointestinal side effects, and secondary infections must be considered before routinely prescribing antibiotics. Consequently, many authorities do not recommend that postoperative systemic antibiotics be used routinely following the extraction of impacted molars.

Controlling Pain and Swelling

Corticosteroids are widely used to reduce postoperative swelling, trismus, and pain, as well as postoperative nausea and vomiting. The best-studied and most widely used steroids are methylprednisolone and dexamethasone, both pure glucocorticoids with little mineralocorticoid effect. Both these steroids also have limited depressing effect on leukocyte chemotaxis. Methylprednisone is most commonly given intravenously at 125 mg at the time of surgery, followed by lower doses at 40 mg orally, three or four times a day, for 2 days postoperatively. Dexamethasone is given in a 4- to 12-mg dose intravenously at the time of surgery, followed by 4 to 8 mg twice a day for 2 days postoperatively. Although high-dose, short-term steroid use is associated with minimal side effects, its method of use is highly variable, and it is hoped that further research will establish a most effective therapeutic regimen. Perioperative and postoperative steroid use is contraindicated in patients with gastric ulcer disease, active infections, and certain types of psychosis.[57-61]

Postoperative Instructions

Before patients are discharged, close inspection of the surgical site should be performed to check for hemostasis. The patient should be given both verbal and written postoperative instructions with a contact number to access the treating surgeon in case of emergency. Additional gauze pads should also be provided, along with any appropriate prescriptions.

Most postoperative instructions are based on clinical experience over decades, although there is little, if any, strong scientific evidence for many common recommendations. Even so, most authorities agree on the instructions described here. Patients should be advised to keep moist gauze directly on the surgical site with firm biting pressure for 20 to 60 minutes postsurgery, to avoid smoking and hard spitting or sucking on straws, to apply ice to the surgical area for the first 24 hours, and to eat soft foods, avoiding hot food or drink for the first 24 hours. Patients should be told to brush their teeth gently in the surgical site, avoiding scrubbing on the gums, and to rinse very gently during the immediate postoperative period. Patients are also advised to limit vigorous exercise activity for the first 24 hours following surgery for difficult impactions. The patient should be told to expect some swelling and discoloration and to take all prescriptions as directed. If persistent bleeding is a concern, aspirin should be avoided.

Complications

Infection

An uncommon postsurgical complication related to the removal of impacted third molars is infection. The incidence of infection following the removal of third molars is very low, ranging from 1.7% to 2.7%.[62] Infection after removal of mandibular third molars is almost always a minor complication. About 50% of infections are localized subperiosteal abscess-type infections, which occur 2 to 4 weeks after a previously uneventful postoperative course. These are usually attributed to debris that is left under the mucoperiosteal flap and are easily treated by surgical debridement and drainage. Of the remaining 50%, few postoperative infections are significant enough to warrant surgery, antibiotics, and hospitalization. Infections occur in the first postoperative week after third molar surgery approximately 0.5% to 1% of the time. This is an acceptable infection rate and would not be decreased with the administration of prophylactic antibiotics.

Tooth Fracture

One of the most frequent problems encountered in removing third molars is the fracture of a portion of the root, which may be difficult to retrieve. In these situations, the root fragment may be displaced into the submandibular space, the inferior alveolar canal, or the maxillary sinus. Uninfected roots left within the alveolar bone have been shown to remain in place without postoperative complications.[63] The pulpal tissues undergo fibrosis, and the root becomes totally incorporated within the alveolar bone. Aggressive and destructive attempts to remove portions of roots that are in precarious positions seem to be unwarranted and may cause more damage than benefit. Radiographic follow-up may be all that is required.

Alveolar Osteitis

The incidence of alveolar osteitis or dry socket following the removal of impacted mandibular third molars varies between 3% and 25%. Most of the variation is likely a result of the definition of the syndrome. When "dry socket" is defined in terms of pain that requires the patient to return to the surgeon's office, the incidence is probably in the range of 20% to 25%.[47,64-71]

The pathogenesis of alveolar osteitis has not been clearly defined, but the condition is most likely the result of lysis of a fully formed blood clot before the clot is replaced with granulation tissue. This fibrinolysis occurs during the third and fourth days and results in symptoms of pain and malodor after the third day or so following extraction. The source of the fibrinolytic agents may be tissue, saliva, or bacteria.[67] The role of bacteria in this process can be confirmed empirically based on the fact that systemic and topical antibiotic prophylaxis reduces the incidence of dry socket by approximately 50% to 75%. The periodontal ligament may also play a role in the development of alveolar osteitis.

The incidence of dry socket seems to be higher in patients who smoke and in female patients who take oral contraceptives.[68,69] Its occurrence can be reduced by several techniques, most of which are aimed at reducing the bacterial contamination of the surgical site. Presurgical irrigation with antimicrobial agents such as chlorhexidine reduces the incidence of dry socket by up to 50%.[47] Copious irrigation of the surgical site with large volumes of saline is also effective in reducing dry socket.[71] Topical placement of small amounts of antibiotics such as tetracycline or lincomycin may also decrease the incidence of alveolar osteitis.[64-66,70]

The goal of treatment of dry socket is to relieve the patient's pain during the delayed healing process. This is usually accomplished by irrigation of the involved socket, gentle mechanical debridement, and placement of an obtundent dressing, which usually contains eugenol. The dressing may need to be changed daily for several days and then less frequently after that. The pain syndrome usually resolves within 3 to 5 days, although it may take as long as 10 to 14 days in some patients. There is some evidence that topical antibiotics such as metronidazole may hasten resolution of the dry socket.[72]

In summary, alveolar osteitis is a disturbance in healing that occurs after the formation of a mature blood clot but before the blood clot is replaced with granulation tissue. The primary etiology appears to be one of excess fibrinolysis, with bacteria playing an important yet ill-defined role. Antimicrobial agents delivered by perioperative mouth rinses, topically placed in the socket, or administered systemically all help to reduce the incidence of dry socket. Mechanical debridement and copious saline irrigation of the surgical wound also are effective in reducing the incidence of dry socket. Combining multiple approaches would include preoperative chlorhexidine rinses for approximately 1 week before surgery, irrigating the wound thoroughly with normal saline at the conclusion of surgery, placing a small square of gelatin sponge saturated with tetracycline in the socket, and continuing chlorhexidine rinses for 1 additional week.

Nerve Disturbances

Surgical removal of mandibular third molars places both the lingual and inferior alveolar branches of the third division of the trigeminal nerve at risk for injury. The lingual nerve is most often injured during soft tissue flap reflection, whereas the inferior alveolar nerve is injured when the roots of the teeth are manipulated and elevated from the socket. The generally accepted incidence of injury to the inferior alveolar and lingual nerves following third molar surgery is about 3%.[73-75] Only a small proportion of these anesthesia and paresthesia problems become permanent. However, there is a significant incidence of some minor alterations of sensation after injury caused by third molar surgery. As many as 45% of nerve compression injuries, which are typical in third molar surgery, result in a permanent neurosensory abnormality.[75]

Inferior alveolar nerve injury is most likely to occur in specific situations. The first and most commonly reported predisposing factor is complete bony impaction of mandibular third molars. The angulation classifications most commonly involved are usually mesioangular and vertical impaction. In some cases, nerve proximity to the root is indicated by an apparent narrowing of the inferior alveolar canal as it crosses the root or severe root dilaceration adjacent to the canal. Other well-documented radiographic signs are diversion of the path of the canal by the tooth, darkening of the apical end of the root indicating that it is included within the canal, and interruption of the radiopaque white line of the canal.[76] In surgically verified inferior alveolar nerve injuries, the presence of more than one of these signs was highly sensitive but not highly specific for the risk of injury, whereas the absence of all of these signs had a strong negative predictive value.[77] When they are noted on a preoperative evaluation of the radiograph, the surgeon should take extraordinary precautions to avoid injury to the nerve, such as additional bone removal or sectioning of the tooth into extra pieces, and the patient should be counseled in advance regarding his or her increased risk of nerve injury.

When an injury to the lingual or inferior alveolar nerve is diagnosed in the postoperative period, the surgeon should begin long-term planning for its management, including consideration of referral to a neurologist and/or microneurosurgeon. These issues are dealt with elsewhere in this textbook.

Rare Complications

The complications already discussed are the more common occurrences, accounting for the great majority of complications in surgery to remove impacted third molars. Several additional complications occur only rarely and are mentioned briefly.

Maxillary third molars that are deeply impacted may have only thin layers of bone posteriorly separating them from the infratemporal fossa, or anteriorly separating them from the maxillary sinus. Small amounts of pressure in an errant direction can result in displacement of the maxillary third molar into these adjacent spaces. When a maxillary third molar is displaced posteriorly into the infratemporal fossa, the surgeon should try to manipulate the tooth back into the socket with finger pressure placed high in the buccal vestibule near the pterygoid plates. If this is unsuccessful, the surgeon can attempt to recover the tooth by placing the suction tip into the socket and aiming it posteriorly. If

both of these maneuvers are unsuccessful in recovering the tooth, the most effective technique is to allow the tooth to undergo fibrosis and to operate 2 to 4 weeks later to remove it. If the tooth is asymptomatic, is not causing any restriction in jaw movement, and is not causing pain, the surgeon should consider leaving the tooth in place. If the decision is made to remove the tooth, three-dimensional localization of the tooth should be made before surgery is initiated.

If the tooth is displaced into the maxillary sinus, retrieval is usually done by a Caldwell-Luc procedure at the same appointment. The surgeon should localize the tooth with at least a one-dimensional radiographic view and preferably a three-dimensional study before performing the retrieval surgery.[78]

Fracture of the mandible during the removal of impacted mandibular third molars is a rare occurrence. The typical situation is a deeply impacted third molar, most commonly in an older individual with dense bone. The surgeon places excessive pressure on the tooth with an elevator in an attempt to deliver the tooth or tooth section into the mouth; the fracture occurs, and the remaining portion of the tooth is easily retrieved. The surgeon should then perform an immediate reduction and fixation of the fracture. If the surgeon has the experience and the armamentarium available, rigid internal fixation with miniplates is an excellent choice in this unfortunate situation. Wire fixation and application of intermaxillary fixation is an acceptable alternative. Late mandible fractures usually occur 4 to 6 weeks following extraction in patients over age 40 years.

Periodontal Healing

Two of the important reasons for removing impacted third molars are to preserve periodontal health or to treat a periodontitis that already exists.[79,80] In contrast, removal of completely bony impacted teeth in older patients with good periodontal health is contraindicated, because it may actually create a persistent postsurgical defect.

Periodontal healing following third molar removal is best when the impacted tooth is removed before it becomes exposed in the mouth, before it resorbs bone on the distal aspect of the second molar, and when the patient is as young as possible.[81-83] If a third molar is partially exposed in the mouth, it should be removed as soon as possible. In such cases, there is by definition a deep and potentially destructive periodontal lesion under the operculum partially covering the third molar, which is difficult for the patient to maintain. Even if the patient is asymptomatic, removing the impacted tooth allows the best possible periodontal healing after surgery.

Acknowledgement

The authors would like to acknowledge the important influence of Drs. Manaf Saker, Orrett E. Ogle, and Harry Dym who wrote the previous edition of this chapter. We are grateful most especially for their illustrations, which are retained in this edition.

Complications of Dentoalveolar Surgery

JOSHUA CAMPBELL, ANDREW CHEUNG, LINDSEY NAGY

See the positive side, the potential, and make an effort.

Dalai Lama

Introduction

The age-old saying is, "If you practice long enough, you are bound to have complications." This is just as true in oral surgery as in other medical fields. The key is understanding how to approach and manage complications when they arise.

Exodontia is the most common procedure performed by oral maxillofacial surgeons. The Public Health Service reports that "more than three-quarters of the total cost of payments for oral surgery procedures were allocated to removal of third molars."[1] It stands to reason that most of the complications we see are related to exodontia. These can be common or rare and can occur during or after treatment. Nevertheless, with careful treatment planning and adhering to good surgical techniques and principles, surgeons can minimize the frequency of complications. In addition, early recognition and proper management can help to improve the outcome of procedures. Considering the fact that complications are a risk and potential sequela of any surgery, it is imperative that surgeons notify patients of them while obtaining informed consent. Complications can occur even when the surgeon adheres to good surgical principles. Variations in anatomy and the patient's response to healing can result in complications even when the surgeon executes the surgical procedure within the standard of care.

Complications during exodontia include the following:

1. Removal of the wrong tooth
2. Injuries to teeth and adjacent structures
3. Residual root remnants
4. Displacement of teeth or root tips
5. Soft tissue injuries
6. Oroantral communications
7. Swallowing or aspiration of teeth, fragments of teeth, or restorations and crowns
8. Tissue emphysema
9. Sensory nerve injuries

Complications after exodontia:

1. Alveolar osteitis (dry socket)
2. Infection
3. Trismus, swelling, and pain
4. Temporomandibular joint problems
5. Bone spicules

Complications that can occur during or after exodontia:

1. Hemorrhage
2. Injuries to osseous structures

Complications during Exodontia

Removal of the Wrong Tooth

Extraction of the wrong tooth is one of the most dreaded complications in oral surgery. It can happen for a number of reasons: miscommunication between the referring doctor and the specialist, incorrectly labeled radiographs or referral slips, and disagreement between the dentist and the patient. The best way to prevent this complication is to take a careful history with a review of recent radiographs, and to make a thorough clinical examination.

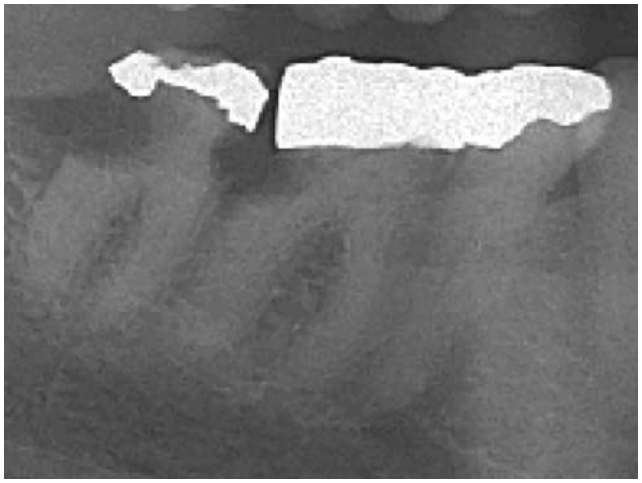
If the inadvertent removal of the wrong tooth is discovered at the time of surgery, and the tooth is healthy and salvageable, it should be reimplanted immediately and stabilized. The patient should be informed that the tooth not scheduled to be removed was removed and should be placed on antibiotics, and a follow-up appointment should be scheduled. The patient must not be abandoned, and appropriated follow-up care is essential.

If the patient has a referring dentist, they should also be made aware of what occurred. Document the event carefully in the patient's chart.

Injury to Adjacent Structures

Damage to Adjacent Tooth or Crown of Tooth

Fractures and loosening of adjacent teeth and dislodging of large restorations or crowns can accidentally occur during



• **Figure 22-1** Radiograph of roots with a crown in close proximity.

• **Figure 22-2** Additional radiograph of roots with a crown in close proximity.

exodontia. Careful evaluation of the surrounding dentition and radiographs should be done before instituting treatment (Figures 22-1 and 22-2). Often this complication is unavoidable because of loose crowns or large restorations with recurrent decay under the restoration. The patient should be made aware of the potential for these events occurring. If teeth are partially avulsed during removal of adjacent teeth, they should be repositioned and stabilized. Any dislodged crowns from teeth that do not show signs of decay can be permanently re-cemented. Teeth under crowns with decay should be reinserted with temporary cement, and the general dentist should be informed of the event. Adjacent teeth that are fractured or that have large restorations dislodged should be temporized. The patient should be referred back to their general dentist for definitive treatment. The incident should be well documented in the patient's chart, and the patient should be made aware of the problem.

Fracture of the Root of an Adjacent Tooth

Unintentional excessive pressure and/or accidental introduction of the drill into adjacent tooth or root structures can pose a challenge for both the patient and the oral surgeon.

Depending on the severity (fracture of the root versus drilling into enamel, dentin, or pulp), it is recommended that an image be taken to determine the extent of damage. Oftentimes, observation with regular follow-up is recommended for a fractured root. If the root is fractured such that its removal is required, apply mineral trioxide aggregate (MTA) to the end of the root and close the area.

Similarly, if pulpal tissues are exposed, apply agents that are similar to MTA topically to assist with the recovery.

Residual Root Remnants

During exodontia, roots can often fracture in spite of good surgical technique. Usually this occurs because the root is dilacerated or divergent. If the remnant is a couple of millimeters in diameter and in close proximity to a vital structure, such as a nerve or the sinus, risks versus benefits should be considered. Usually a root remnant this size will be of no consequence if not grossly infected. If a decision is made to leave it, the patient should be informed, postoperative radiographs should be taken, documentation should be entered in the patient's chart, and the patient should be evaluated periodically both clinically and radiographically to ensure uneventful healing.

Displacement of Teeth and Root Tips

Displacement of teeth and root tips is a rare occurrence.[2-5] Some causative factors that have been implicated are inexperience of the surgeon, uncontrolled force, improper use of instrumentation, and difficult access with poor visualization and inadequate exposure.[2,6] Variations in anatomy, such as a thin lingual plate of bone in the mandibular molar area of the maxillary sinus wall extending between the roots of the maxillary molars, can increase the potential for the displacement of teeth or root tips into the floor of the mouth or maxillary sinus, respectively.

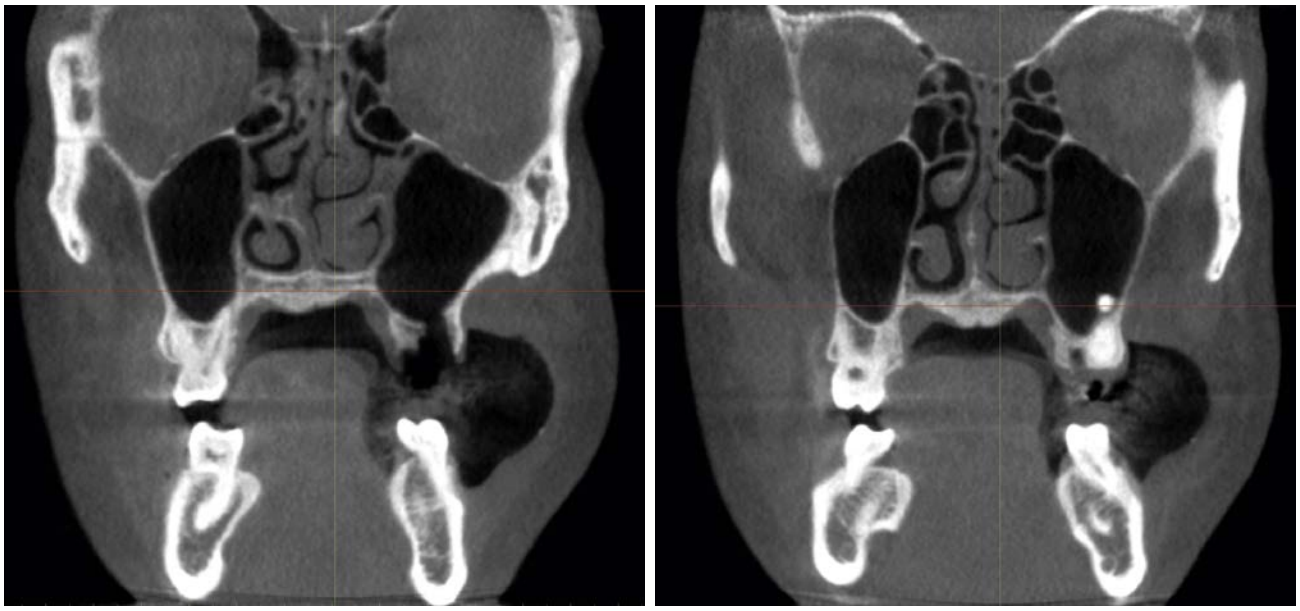
The sites most frequently involved are the maxillary sinus, the submandibular space, and the infratemporal fossa.[2-12] Some reports describe accidental displacement of a third molar into the lateral pharyngeal space.[2,10]

Displacement into the Maxillary Sinus

Displacement of root tips or impacted teeth into the maxillary sinus or infratemporal fossa usually occurs because of the close proximity and thinness of the sinus floor or wall. In removing a superiorly distally impacted third molar, adequate bone removal, good visibility with careful elevation, and a distal stop is a must. If inadvertently a tooth or root tip is dislodged into the sinus, an attempt should be made to retrieve it through the extraction site with a suction tip. If the attempt is unsuccessful, radiographs should be taken to localize the tooth and a Caldwell-Luc approach should be used to remove it (Figure 22-3).

Displacement into the Infratemporal Fossa

If a third molar is displaced into the infratemporal fossa, begin to solve the problem by taking radiographs to



• **Figure 22-3** Cone-beam computed tomography of maxillary molar with root dislodged into maxillary sinus.

determine its position. There are two possible approaches when a tooth enters into the infratemporal fossa: immediate retrieval or a delayed approach.

The immediate approach almost always involves using a three-dimensional image to help locate the tooth. After determining fixed reference points/landmarks, extend an incision posteriorly to the tonsillar fauces, and with careful blunt dissection, attempt to identify and remove the molar with direct visualization.[6]

A C-arm can also be used intraoperatively to retrieve the tooth. Once the patient is asleep in the operating room, an initial image is presented to the surgeon. Another object such as a spinal needle can be advanced using serial imaging to pinpoint the location of the dislodged tooth. Once the spinal needle has located the tooth, make an incision with dissection to the tooth following the path of the spinal needle.

Another alternative for the immediate retrieval of the tooth at the hospital involves merging data from a three-dimensional image and a "real-time tracking" optical or electromagnetic surgical navigation unit. Not all medical centers provide this technology, and where it is available, it is only FDA approved for use in the maxilla.

An in-office unit (XNAV, Lansdale, PA) is available for oral and maxillofacial use to track and locate tooth and root fragments. Merging the three-dimensional image with a patient tracker with fiducial markers paired with the patient's anatomy can aid in guiding the surgeon to the remaining fragments.

Regardless of the approach, care must be taken to prevent injury to the pterygoid plexus of veins, which can result in brisk bleeding. If this happens, the procedure should be aborted and fibrosis should be allowed to develop around the tooth, from several days[13] to several weeks.[14] An attempt can be made to remove it by a hemicoronal or an intraoral approach after computed tomographic (CT) analysis to determine its location. Some authors recommend careful follow-up if the patient is asymptomatic.[14] One report indicated no adverse affects after 15 months.[14,15]

Displacement into the Submandibular Space

Care should be taken in attempting to remove the distal roots of third molars because the lingual cortex of the mandible curves laterally and is often thinner in the submandibular space. If a root tip is displaced into the sublingual space, first try to palpate it digitally and push it back into the socket (Figure 22-4). If this is unsuccessful, a full flap is raised on the lingual and the mylohyoid muscle is dissected free from its attachment, trying to keep the tip in position to prevent further displacement and thus facilitate its removal. Root tips rarely become displaced deep into the submandibular space, but if this should occur, let fibrosis take place. If removal is necessary, an extraoral approach can be used to retrieve it.

Infrequently, roots are punched through thin cortical plates in the maxillary bicuspid and molar regions. Usually, they can be palpated subperiosteally and pushed back through the socket, or an incision can be made below the socket to remove the root.

Some reports describe accidental displacement of third molars into the lateral pharyngeal space. Care must be taken with the use of surgical instruments to avoid such untoward effects during exodontia.

Infrequently, roots are pushed through thin cortical plates in the maxillary bicuspid and molar areas. Usually, they can be palpated subperiosteally and can be pushed back through the socket, or an incision can be made below it to remove it.

• **Figure 22-4** Cone-beam computed tomography of root tip of mandibular third molar dislodged into submandibular space.

Some reports describe accidental displacement of third molars into the lateral pharyngeal space.[2,10] Care must be taken with the use of surgical instruments to avoid such untoward effects during exodontia.

Soft Tissue Injuries

Soft tissue injuries can occur when performing exodontia. Soft tissue injuries include lacerations of the flap, burn injuries and abrasions from drills, puncture wounds, and tissue emphysema.

Lacerations of the Flap

Lacerations of the flap can be caused by inadequate reflection of the flap, by creating a flap that is too small (coupled with excessive pressure to reflect the flap), and by overretraction. These tears can increase the chance of wound dehiscence and can delay healing. If a tear does occur, reapproximate the margins and suture the wound carefully. Excise the edges before closing if the tear is jagged. Designing larger flaps with releasing incisions and using less retraction can prevent this complication.

Burns and Abrasions

Burns and abrasions are caused by rotary drills. Careful attention is necessary when using drills. Avoid catching the soft tissue with the shank of the burr and creating a laceration or shred injury. This injury usually occurs with the buccal mucosa and the corner of the mouth. Using a burr guard will help prevent this problem. These burns and/or abrasions are quite painful and are slow to heal. Antiinfective ointment or silver sulfadiazine can be used to treat these burns and/or abrasions. This complication can be prevented by careful attention of the assistant to the location of the shank of the burr when the surgeon is cutting. Maintenance of the burr guard is important to prevent overheating, which can cause severe burns to the lip.

Puncture Wounds

Puncture wounds to the soft tissue can be the result of uncontrolled forces with sharp instruments such as a No. 9 periosteal or a straight elevator. These injuries can often be prevented by using finger rest support from the opposite hand to protect the area from potential slippage with an instrument. But if a puncture wound occurs, small wounds should be left open and not sutured once hemostasis is achieved. If hemostasis cannot be achieved, sutures may be necessary. Because the instrument that punctured the soft tissue could contain debris and bacteria, place the patient on antibiotics.

Tissue Emphysema

Tissue emphysema is a complication that has been seen less frequently since the introduction of reverse turbine rotary instruments such as the Hall drill and electric hand pieces. It is caused by the introduction of air under pressure into the subcutaneous soft tissue. During the removal of bone or the sectioning of teeth with an air-driven dental handpiece, air can be forced under the skin and cause rapid swelling. Other causes are the use of an air syringe and a patient coughing or sneezing when a large flap is elevated.

When tissue with air in it is palpated, there is a feeling of crepitus; occasionally, the patient will acknowledge some tenderness associated with the site. Radiographs can show air in the soft tissue adjacent to the surgical site. Extensive subcutaneous emphysema can be life threatening or result in an infection leading to meningitis or mediastinitis.

Treatment consists of applying ice to the affected site, treating with systemic antibiotics, and monitoring. The condition usually resolves in several days; however, in severe cases, patients may require hospitalization and intravenous antibiotics.

Oroantral Communication

The roots of the maxillary premolars and molars are adjacent to the maxillary sinus. Occasionally a perforation can develop in the sinus when these teeth are extracted. It is important to discuss this possibility with the patient during the informed consent discussion.

If the maxillary sinus is exposed during the extraction, determine the course of treatment by the size of the communication. Do not probe the communication, as that could further tear the membrane.

For communications less than 2 mm, consider packing the site with a collagen plug. This will help maintain a good blood clot. Place the patient on special postoperative sinus instructions; advise him or her not to sneeze, smoke, rinse, spit, suck on a straw, or blow the nose for 1 month. If the

patient has obstructive sleep apnea and uses a continuous positive airway pressure (CPAP) machine, make sure to consult the patient's sleep specialist to help modify the pressure/cessation of the machine to assist with healing.

For moderate-sized communications (2 to 6 mm), place a collagen sponge with figure-of-eight sutures to prevent dislodgment. Place the patient on postoperative sinus instructions and prescribe a 1-week course of antibiotics, antihistamines, and nasal decongestants. Usually, amoxicillin/clavulanate (Augmentin), clindamycin, or cephalosporin can be prescribed to decrease the possibility of maxillary sinusitis.

For large communications (greater than 6 mm), the sinus communication must be primarily closed with a flap procedure. An advancement rotation flap can be used to assist with primary closure. Another option could involve use of the buccal fat pad as an interpositional pedicle flap under mucosa.

Swallowing or Aspiration of Teeth, Fragments of Teeth, or Restorations and Crowns

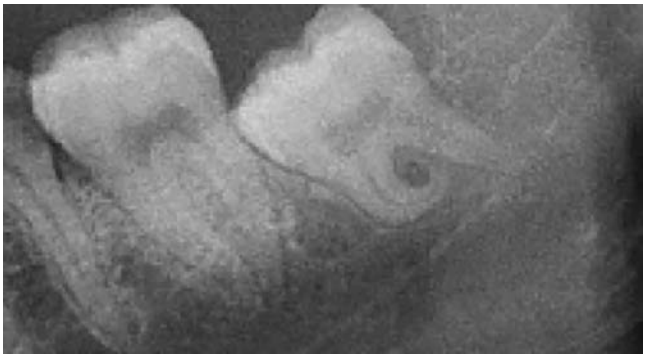
During exodontia, it is advisable to place an oral drape to prevent swallowing or aspiration of loose teeth, dislodged crowns or fragments of teeth, root tips, or dental restorations. In the event of a foreign body being swallowed, the patient should be sent to the hospital for radiographs to localize it. Usually posteroanterior (PA) and lateral chest radiographs and kidney, ureter, bladder (KUB) radiographs will identify the foreign body. If there is any doubt after these images have been taken, a spiral CT will further assist with identification of the dislodged foreign body.

If a tooth, root tip, or other foreign body is aspirated during surgery and it becomes lodged in the trachea, methods used in Advanced Cardiac Life Support, such as abdominal thrusts, back slaps, or the Heimlich maneuver, should be used in an attempt to remove it.[14] If the patient becomes unconscious, an attempt should be made to remove the object with a laryngoscope and a McGill forceps, or an emergency cricothyrotomy should be attempted. In the event the object passes the vocal cords, it will most likely enter the right mainstem bronchus or the right lung. The patient should be transported to the hospital where an emergency bronchoscopy can be performed to remove the object.

If the object has been swallowed, it will usually pass through the gastrointestinal tract uneventfully. A detailed description of the event should be recorded in the patient's chart.

Sensory Nerve Injuries

Sensory nerve injuries can occur with the removal of teeth whose roots are close to the inferior alveolar nerve, lingual nerve, or mental nerve. Temporary or permanent sensory nerve disturbances can occur anywhere from 0.4% to 2% of the time.[16] It is important for the surgeon to obtain a detailed informed consent from their patients concerning these complications. The incidence of sensory nerve injuries from third molar surgery is related to many factors. Tooth proximity to the inferior alveolar nerve canal and variation in the anatomic relation of the lingual nerve to the crown of the mandibular third molar are major factors that contribute to nerve injuries.[17]



• **Figure 22-5** Radiograph of a mesioangular impacted third molar close to the canal.

A higher incidence of nerve injuries occurs with the removal of horizontally impacted teeth compared with mesioangular or distoangular impacted third molars[17] (Figure 22-5). The depth of the impaction, presence of completely developed roots, the use of rotary instruments, and sectioning of teeth can all contribute to nerve injuries. Division of the inferior alveolar nerve is infrequent, but pressure and compression of the nerve can take place during the removal of the third molar. Neurosensory alteration of the inferior alveolar nerve can occur when normal intraoperative and postoperative hemorrhage occurs and extends into the mandibular canal. Because this is a rigid osseous structure and the nerve is confined within this canal, the accumulation of blood within the canal can cause a compressing nerve injury. Usually the neurosensory alteration will be temporary, but it can be permanent. Injury to the lingual nerve occurs during the reflection of the flap, fracture of the lingual cortical plate, or perforation of the lingual cortical plate during sectioning of the tooth. The path of the lingual nerve as it passes on the lingual surface of the mandible near the mandibular third molar is variable. In approximately 17% of cases, the nerve lies above the crest of lingual bone and can be adherent to the follicle of the third molar. Therefore in these cases, a stretch injury or even a transection of the nerve can occur when the surgeon has performed the extraction technique within the standard of care.

The mental nerve can be injured during the removal of a premolar or during flap development or retraction. In the event of a high risk for nerve injury, the use of partial odontectomy may be indicated (see Figure 22-5). Seddon and Sunderland developed classifications for nerve injuries.[18,19] The Seddon classification is based on time from injury and degree of recovery. It includes neuropraxia, axonotmesis, and neurotmesis. Sunderland expands his classification to include first degree (neuropraxia), second degree (axonotmesis), third degree, fourth degree, and fifth degree (neurotmesis).

Neuropraxia results from minor nerve compression or traction injury. Since there is no loss of axonal continuity, usually there is complete recovery within 2 months. Microsurgery is not indicated. Axonotmesis is produced by blunt trauma, crushing, or a severe traction injury. Continuity of the axon is disrupted but not the epineurial sheath. Thus sensory recovery can take 2 to 6 months, though some cases have taken 1 year. Microsurgery is not indicated unless a foreign body is associated with it.

Sunderland's third- and fourth-degree nerve injury is the result of a compression, crush, or chemical injury. There can be some spontaneous recovery, but not completely, with a possible poor outcome. Microsurgery may be indicated if there is no improvement after 3 to 6 months. It should be emphasized that as long as the patient is exhibiting signs of improvement, microsurgery should be delayed.

Neurotmesis is the result of a complete transection of the nerve. The prognosis for spontaneous recovery is poor. Microsurgery is indicated for these injuries. Neurosensory testing should include two-point discrimination, light touch, brush strokes, vibrational sense, pain stimuli, and thermal discrimination. This will help determine the injury classification and recommended treatment. For the best results, nerve repairs should be performed by surgeons proficient in microsurgery.

Complications after Exodontia

Alveolar Osteitis (Dry Socket)

Dry socket, or alveolar osteitis, is one of the more commonly reported postoperative surgical complications. Some studies have shown the incidence to be as low as 3% with all extractions.[20-23] Other studies in the literature place the incidence of dry socket in the removal of mandibular third molars as high as 30%.[22-25] Dry sockets rarely occur in the maxilla. Although the cause is not known, data suggests that saliva with a high bacterial count may be the etiologic factor in causing destruction or malformation of the blood clot after extractions.[24] Other theories suggest fibrinolytic action as a possible cause because the use of antifibrinolytic agents demonstrated a decreased incidence of occurrence.[24,26,27] Additional factors that may be responsible for dry sockets occurring are smoking,[28] oral contraceptives,[25] experience of the surgeon,[29] complexity of the extraction,[30] and poor oral hygiene.[23]

The symptoms of a dull throbbing pain usually present themselves around the third to fifth day after surgery and are often confused with an earache, headache, or pain from another tooth with no evidence of pathologic condition. Neither narcotic analgesics nor nonsteroidal anti-inflammatory drugs give relief. Clinically, the classic signs of infection are not present, but there is a fetid odor, and the extraction site is devoid of a clot or shows evidence of poor healing and food debris. After irrigation and insertion of a medicated dressing, relief is experienced within minutes. Commercially prepared radiograph-detectable dressings containing 20% eugenol are available for use. Dry socket pastes containing eugenol, guaiacol, chlorobutanol, and balsam of Peru are also available and can be impregnated onto radiograph-detectable filament gauze for use as a dressing. The dressings are usually replaced every day or two after irrigation with normal saline. The symptoms dissipate after several days; however, on occasion they may persist longer. Beyond 3 weeks, radiographs should be taken and reviewed, and the patient should be examined clinically to rule out a different cause for the discomfort.

Infection

Postoperative infections can be minimized by following good surgical techniques, using copious irrigation, and adhering to principles of asepsis. Infections following extractions can occur even when the surgeon uses proper surgical techniques. The patient's local and systemic response to the surgery, the virulence of the bacteria on the area of the surgery, and the postoperative compliance or noncompliance of the patient can increase risk of infection.

Infections can occur postoperatively 3 to 4 days to several weeks after surgery. Most of these develop in third molar extraction sites, and the incidence has been reported to be anywhere from 3% to 5%.[30,31] Signs and symptoms include increased swelling, trismus, and tenderness along with redness, an elevated temperature, general malaise, and often a purulent exudate. Infection after dental extractions usually occurs in surgical cases requiring flap elevation and bone removal.[14] Patients who have poor oral hygiene or periodontal disease and are immunocompromised are more susceptible to postoperative dental infections.

Streptococcal species of bacteria appear to be the largest group causing postoperative oral infections, and studies have shown that these infections have an average of four different bacteria with anaerobic outnumbering aerobic species.[32] The most effective treatment continues to be penicillin. However, because of the increased recognition of anaerobic organisms in these infections, metronidazole or clindamycin can be substituted for penicillin.[22,32,33] When given prophylactically to patients with debilitating medical conditions or periodontal disease, antibiotics are thought to be of some value. Use of preoperative and postoperative antibiotics is still a controversial topic.[34-40] This practice may make treatment of subsequent infections more difficult because of resistant strains of bacteria.[36-40] There are some reports of a bacteremia being associated with the extraction of teeth.[41,42] This is a rare occurrence. In addition to antibiotic therapy, an incision and drainage should be performed and cultures obtained for sensitivity testing. In severe cases, consultation with an infectious disease specialist should be sought.

Infection can progress to osteomyelitis, even in a young, healthy patient. It is imperative to see and treat patients in a timely fashion to address this complication. The definition and treatment are outlined in a separate section of this textbook.

Medication-Related Osteonecrosis (MRON)

Oral bisphosphonates, such as Fosamax, Actonel, Boniva, Didronel, and Skelid, are being used to treat osteoporosis, osteopenia, Paget disease of bone, and osteogenesis imperfecta of childhood.[43-46] The intravenous bisphosphonates pamidronate disodium (Aredia) and zoledronic acid (Zometa) are being used in the treatment and management of cancer-related conditions.[46] In 2003 and 2004, oral surgeons published reports of nonhealing exposed bone in the maxillofacial region in patients on intravenous bisphosphonates (Figure 22-6). Subsequent to these reports, additional case series were published.[47-57] In 2004, health care professionals were notified by the manufacturer of the complications with intravenous (IV) bisphosphonates, and in 2005 a broader class warning was released that included the oral bisphosphonates.[57-59] The American Association of Oral and Maxillofacial Surgeons (AAOMS) considers a patient to have MRON if they have all three of the following characteristics:

1. Current or previous treatment with a bisphosphonate
2. Exposed bone in the maxillofacial region that has persisted for more than 8 weeks
3. No history of radiation therapy to the jaws

Currently the estimated cumulative incidence of MRON in patients on IV bisphosphonates, which is based on retrospective studies with limited sample sizes, is from 0.8% to 0.12%.[46,60-68] Patients on oral bisphosphonate therapy are at a much lower risk than those on IV therapy, with the estimated risk following extractions to be 0.09% to 0.34%; however, the risk appears to increase if the duration of therapy exceeds 4 years.[46]

In patients with a diagnosis of MRON, the goals of treatment should be to eliminate pain, control infection, and prevent the occurrence or progression of osteonecrosis.[46] Hyperbaric oxygen (HBO) therapy has not been proven to be effective in treatment of these patients,[46,69] and they do not respond as predictably to surgical treatments that are used for osteomyelitis and osteoradionecrosis.[48-50,55] The AAOMS has proposed the staging and treatment strategies listed in Table 22-1 for the treatment of patients with MRON.[46]

Any unsalvageable teeth should be extracted before IV bisphosphonate therapy begins. It has been proposed that if systemic conditions permit, oral bisphosphonates should be discontinued for 2 months before and should not be restarted until osseous healing has occurred. No alteration or delay of treatment is required for patients who are on oral bisphosphonates for less than 3 years and have no clinical risk factors. If these patients have also been taking steroids, because this may increase the risk of MRON, it is recommended that they take a drug holiday for 3 months until osseous healing has occurred. It is recommended that prescribing physicians be consulted about discontinuing oral bisphosphonates in patients for 3 months before treatment if they have been taking them with or without steroids. Therapy should not be restarted until osseous healing is complete.[46]

• **Figure 22-6** Medication-related osteonecrosis of the jaw after extractions.

Osteoradionecrosis

Osteoradionecrosis (ORN) is an avascular necrosis of bone caused by the three H (hypocellular, hypovascular, hypoxic) tissue effects of radiotherapy (Figure 22-7). It can develop when teeth are removed before radiotherapy but treatment is begun shortly thereafter (early trauma-induced ORN) or when a tooth is removed more than 3 years after therapy without HBO (late trauma-induced ORN).[71] Management of osteoradionecrosis is discussed in another chapter.

Trismus, Pain, and Swelling

Pain and swelling are a usual consequence of any surgical insult to the body. Swelling and pain are the result of the production of inflammatory mediators, such as leukotrienes, prostaglandins, and thromboxane A_2.[14] Most swelling reaches a peak in 24 to 48 hours, then gradually plateaus and begins to dissipate over the next 48 to 72 hours. Some factors that can contribute to increased swelling are the complexity of the extraction, excessive retraction, and the length of the operating time. The trismus that results is due to inflammation of the muscles of mastication and is probably a protective mechanism to limit function and further trauma. Either the surgical procedure or the administration of local anesthetic can cause trismus. Pain usually peaks several hours after surgery. Fisher and his colleagues placed peak pain at 3 to 5 hours after surgery.[72] Many studies have suggested the use of steroids and nonsteroidal anti-inflammatories to decrease swelling and pain. Preoperative intravenous steroids, such as dexamethasone and betamethasone, have also been shown to reduce postoperative swelling and pain that is associated with third molar surgery.[2,23,73] Narcotic combinations are used most frequently to control postoperative pain, but long-acting local anesthetics have also been shown to be effective in reducing postoperative discomfort. The reason for the effectiveness of local anesthetics is believed to be that anesthetic lasts longer than the peak pain period. Analgesics should be given before the local anesthetic wears off. Ice, which is advocated as a method to limit postoperative swelling by many practitioners, was not considered to be a considerable factor by Forsgren and his colleagues.[74] Paying close attention to good surgical techniques and using copious irrigation is also believed to be effective in reducing postoperative pain.[75-77]

TABLE 22-1 Staging and Treatment Strategies

MRONJ* Staging	Treatment Strategies†
At risk category: No apparent necrotic bone in patients who have been treated with either oral or IV bisphosphonates	• No treatment indicated • Patient education
Stage 0: No clinical evidence of narcotic bone, but non-specific clinical findings, radiographic changes and symptoms	• Systemic management, including the use of pain medication and antibiotics
Stage 1: Exposed and necrotic bone, or fistulae that probes to bone, in patients who are asymptomatic and have no evidence of infection	• Antibacterial mouth rinse • Clinical follow-up on a quarterly basis • Patient education and review of indications for continued bisphosphonate therapy
Stage 2: Exposed and necrotic bone, or fistulae that probes to bone, associated with infection as evidenced by pain and erythema in the region of the exposed bone with or without purulent drainage	• Symptomatic treatment with oral antibiotics • Oral antibacterial mouth rinse • Pain control • Débridements to relieve soft tissue irritation and infection control
Stage 3: Exposed and necrotic bone, or a fistula that probes to bone, in patients with pain, infection, and one or more of the following: exposed and necrotic bone extending beyond the region of aveolar bone (i.e., inferior border and ramus in the mandible, maxillary sinus and zygoma in the maxilla) resulting in pathologic fracture, extra-oral fistula, oral antral/oral nasal communication, or osteolysis extending to the inferior border of the mandible of sinus floor	• Antibacterial mouth rinse • Antibiotic therapy and pain control • Surgical débridement/resection for longer term palliation of infection and pain

Discontinuation of the IV bisphosphonates shows no short-term benefit. However, *if systemic conditions permit*, long-term discontinuation may be beneficial in stabilizing established sites of MRONJ, reducing the risk of new site development and reducing clinical symptoms. The risks and benefits of continuing bisphosphonate therapy should be made only by treating oncologist in consultation with the OMS and the patient.
Discontinuation of the oral bisphosphonate therapy in patients with MRONJ has been associated with gradual improvement in clinical disease. Based on the experience of two task force members managing 50 MRONJ patients who were treated with oral bisphosphonates, discontinuation of oral bisphosphonates for 6-12 mo may result in either spontaneous sequestration or resolution following débridement surgery. *If systemic conditions permit*, modification or cessation of oral bisphosphonate therapy should be done in consultation with the treating physician and the patient.
MRONJ, Medication-related osteonecrosis of the jaw.
*Exposed or probable bone in the maxillofacial region without resolution for greater than 8 weeks in patients treated with an antiresorptive and/or an antiangiogenic agent who have not received radiation therapy to the jaws.
†Regardless of the disease stage, mobile segments of bony sequestra should be removed without exposing uninvolved bone. The extraction of symptomatic teeth within exposed, necrotic bone should be considered since it is unlikely that the extraction will exacerbate the established necrotic process.

• **Figure 22-7** Osteoradionecrosis after extractions.

Bone Spicules

Occasionally, as the bone heals after an extraction, small fragments of bone will necrose and work their way through the soft tissue to be exfoliated (Figure 22-8). This process can be extremely painful for the patient. The soft tissue ulcerates and becomes inflamed. During this period, it can be helpful to reflect the overlying soft tissues and smooth the roughened bone. This can greatly reduce the length of the patient's discomfort.

Temporomandibular Joint Problems

Trauma to the temporomandibular joint during mandibular extractions is usually due to lack of support against lateral forces during exodontia. These lateral forces can be counteracted by providing support to the mandible with the other hand or by using a bite block. Patients will usually complain if too much force is being used during extractions.

It is very important to perform a thorough history and physical exam to document any previous temporomandibular

• **Figure 22-8** Bone spicule after extractions.

joint problem. Certain studies have shown that 60% of the population may suffer from some form of temporomandibular joint dysfunction, with the problem distributed equally between men and women.[75,78] Patients without a history of internal derangement of the temporomandibular joint may develop symptoms from extraction forces. Any history or signs of temporomandibular joint problems should be documented in the patient's chart before treatment. During the consultation, the patient should be made aware of this potential complication.

Surgical extractions may be indicated if the patient has a previous temporomandibular joint dysfunction or if too much force will need to be exerted during the procedure. Patients who develop symptoms after exodontia should be placed on a liquid or soft diet, instructed to limit their opening, apply moist heat to the affected side several times a day, and be prescribed nonsteroidal anti-inflammatories and muscle relaxants for 2 weeks. Rarely will splint therapy be necessary in these cases because the discomfort usually dissipates within a week or two. Most often if a patient requires splint therapy because of persistent discomfort, it is probably because they have a previous history of temporomandibular joint dysfunction. In extremely rare situations, magnetic resonance imaging (MRI) may be indicated to rule out a disc displacement.

Dislocation of the condyle is a more acute problem if it occurs during mandibular extractions. This complication can be prevented by applying appropriate support during extraction. If this complication occurs, it should be immediately corrected. Some surgeons stand behind the patient and place downward pressure on the external oblique ridge of the mandible with their thumbs to reduce the dislocation, whereas others stand in front with the patient lower and use similar maneuvers. The patient should then be placed on analgesics and a soft diet.

Complications that Can Occur during or after Exodontia

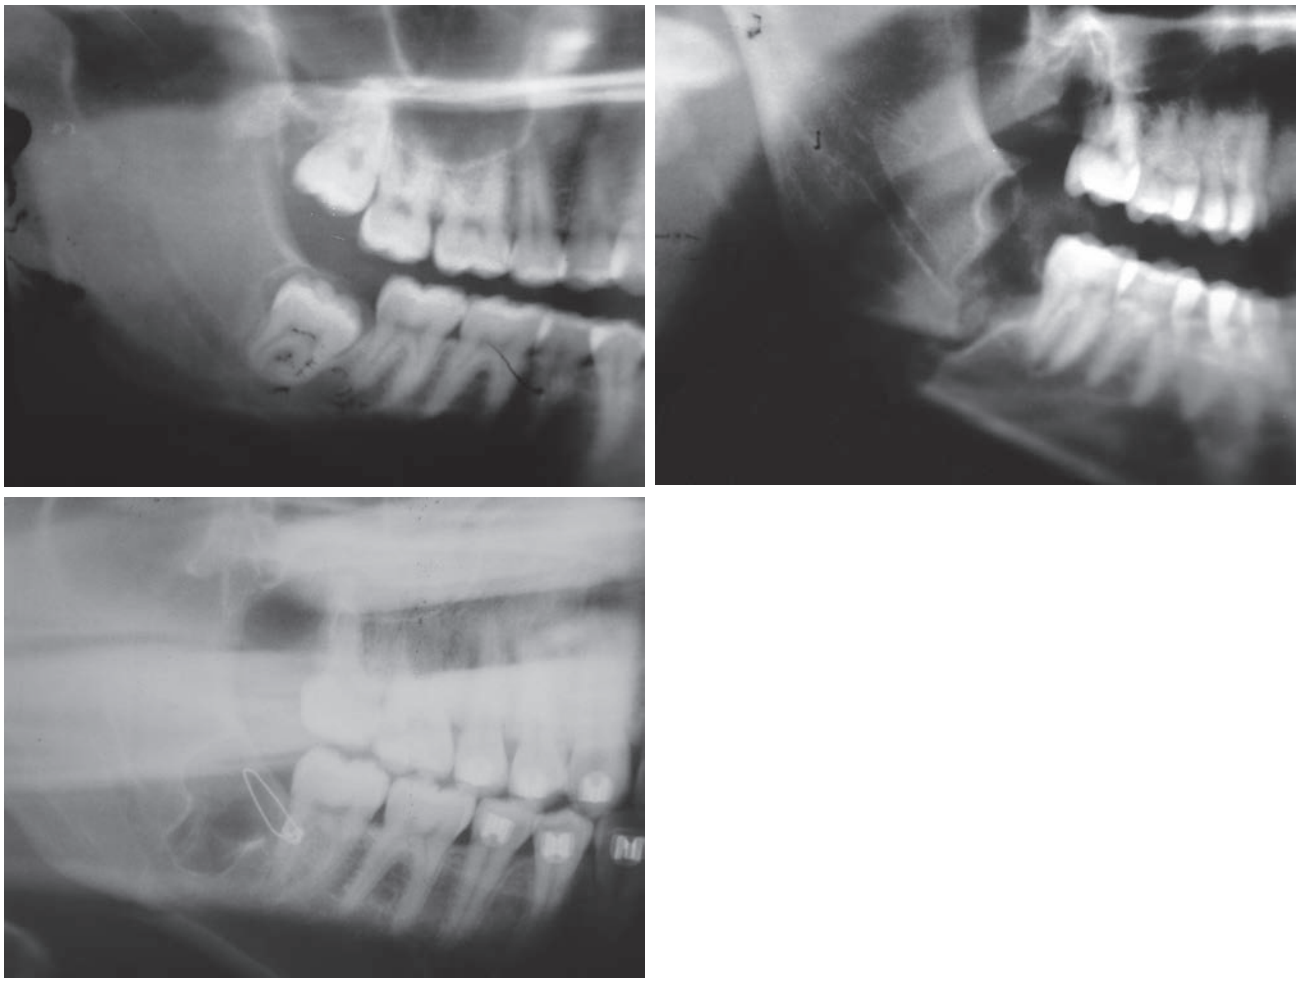
Hemorrhage

The majority of intraoperative or postoperative bleeding problems are not from coagulopathies but from local factors

• **Figure 22-9** Ecchymosis after extractions.

(Figure 22-9). Oral fibrinolysis has been suggested as a possible cause of hemorrhage from extraction sites in patients who have a normal bleeding profile and do not bleed after extraoral trauma.[75,80,81] For the most part, if there is history of previous extractions with no persistent hemorrhage, a local source should be identified and treated. It is wise to call patients to determine their status the evening after surgery. If there is a complaint of persistent bleeding, the patient should be instructed to remove any excessive exophytic clot from the area and rinse with a mixture of hydrogen peroxide and water, then salt water, followed by pressure with a moistened tea bag or a moistened gauze pad. If bleeding continues for 30 to 60 minutes, the patient should be seen. After the patient is anesthetized, any clots should be removed by curetting the socket, and an attempt should be made to identify the source. Remove any remaining granulation tissue. Bleeding from bone within the socket can be controlled by crushing or burnishing of the source with an instrument, placing bone wax, or cauterizing the site with a bovie/pocket cautery/laser/electrosurgery unit. If an arterial bleeder is identified, it should be ligated or cauterized. The surgical site should be resutured, and any persistent local oozing from the surgical site can be treated with the application of hemostatic agents, such as absorbable gelatin sponges (Gelfoam), oxidized regenerated cellulose (Surgicel), microfibrillar collagen (Avitene), absorbable collagen dressings (Collatape, CollaPlug), or topical thrombin applied to some of these agents.

Occasionally, when administering a posterior superior alveolar nerve block, swelling can develop rapidly in the



• **Figure 22-10** Fracture after extraction of mandibular third molar.

area of the cheek. This is a hematoma that is usually caused by perforating the posterior superior alveolar artery or vessels in the pterygoid plexus of veins. Treatment consists of immediate application of topical pressure and ice packs. In patients who are kept on anticoagulant therapy because of the potential for a thromboembolic event, local measures have been used to control postoperative bleeding. These include Surgicel and suturing. Other measures that have been used are a fibrin adhesive (Beriplast P, Centeon LTD, West Sussex, UK), tranexamic acid rinses, and an argon beam coagulator.[82-98]

Injuries to Osseous Structures

Bony fractures can occur in many areas. Some common sites are the labial and buccal plate in the areas of the maxillary and mandibular canine, bicuspid, and molar teeth.[99] Infrequently (0.00049% of cases), a bony fracture can occur in the mandible during the removal of third molars (Figure 22-10).[22,100] On occasion with removal of maxillary third molars, inadvertently the maxillary tuberosity fractures and the palatal mucosa will tear. It has been suggested that if the tooth is not carious, an attempt should be made to stabilize the tooth and segment with arch bars.[14] We have not had much success with this. Another alternative to stabilization with arch bars would be orthodontic brackets and heavy wire or wire ligatures. If a decision is made to remove the tooth with its bony tuberosity, it must be carefully dissected free from the soft tissue and the tissue tear closed. The site of the tear can be quite uncomfortable, and in spite of a careful repair, sloughing of the area can occur. The area usually heals and epithelializes by secondary intention. The bony segment can be used to graft the area.[14] A primary closure should be used to close the site, especially if the sinus was violated. When solitary teeth with a pronounced canine or buccal eminence are to be removed, it is advisable to reflect the mucosa and remove the tooth surgically to prevent a traumatic fracture and tissue tear. In the event of this happening, an alveoloplasty should be performed, and the tissue should be closed as judiciously as possible.

During the removal of third molars, if a nondisplaced fracture occurs, the fractured mandible should be treated immediately with a closed reduction using either arch bars or orthodontic brackets. If a fracture is severely displaced, arch bars or orthodontic brackets and a transoral open reduction can be attempted to reduce it. If this is

unsuccessful, the patient should be hospitalized, and an extraoral open reduction should be performed with internal rigid fixation using a Risdon or a percutaneous approach.

Skeletally Based Implant Assisted Orthodontics

KEITH H. SHERWOOD

Introduction

In the past 15 years, implanted orthodontic anchor devices and techniques have evolved and become an important component of patient care. This chapter is designed to help the oral and maxillofacial surgeon understand this rapidly expanding and interesting field of surgical/orthodontic cooperation. It will include a comprehensive review of the literature, a description of the contemporary orthodontic implant options available, the evidence-based application, and enough of the orthodontic planning and treatment to allow cross specialty cooperation. Sharing this chapter with an orthodontic colleague will foster dialogue on the subject and improve communication and patient care.

History and Literature Review

Bone implants designed to provide anchors for orthodontic tooth movement have been proposed, studied, or used for nearly 40 years.[1,2] Most of the early fixture prototypes were abandoned because of problems with infection, difficulty with placement or removal, and premature mobility. However, in the 1980s, the success of endosseous dental implants led to a resurgence of academic interest in skeletal anchorage for orthodontics. Most of the early articles on implant-anchored orthodontic treatment were case reports describing dental implants recruited for dual use to assist with orthodontic treatment and dental restoration. Later studies were published on the temporary insertion of cylindrical implants in the retromolar area to be used for nonconventional orthodontic anchorage.[3] A short, cylindrical implant system designed specifically to be placed in the palate and connected to a transpalatal orthodontic appliance was briefly popular.[4]

Interest in miniplate-assisted orthodontics has been especially high as an alternative to certain types of orthognathic surgery. Jenner and Fitzpatrick published an early case report on the use of miniplates as anchors in the mandible to correct a skeletal Class III malocclusion.[5] In 1999, Umemori and colleagues reported on several extraordinary cases where miniplates were placed in the mandible to assist in orthodontically correcting major skeletal open bite.[6] Sherwood and co-workers later reported on the use of miniplates in the posterior maxilla as orthodontic anchors to intrude maxillary molars where skeletal open bite usually originates.[7]

Miniscrew implants (MSIs) or temporary anchorage devices (TADs) designed specifically for orthodontic anchorage were FDA approved in the United States in 2004 but have been researched and reported extensively in the literature for more than 15 years.[8,9] These implants have largely replaced the "onplant"[10] and the palatal endosseous implant for more straightforward anchorage use. The MSI is the easiest anchor to place, but success, especially long term, demands more rigorous control of the many technical variables involved than is necessary with other systems.

Most of the orthodontic implants mentioned are still widely used for skeletal anchorage, and each fixture has unique advantages and disadvantages. However, in contemporary practice, MSIs and miniplates are far more commonly studied and utilized by orthodontists, and will be discussed in depth. Although implant-anchored orthodontics is a relatively new field, research and experience is helping surgeons and orthodontists make informed decisions on choosing a suitable implant for a particular treatment objective.

Orthodontic Concepts for Surgeons

An in-depth discussion of orthodontic biomechanics is beyond the scope of this chapter. However, some general concepts will help the surgeon understand important factors in pretreatment communication with the referring orthodontist. Although the orthodontist may take the lead with treatment planning, much of the specifics of materials and methods associated with skeletal anchorage will be

left to the discretion of the surgeon. Clinical research and experience with orthodontic bone anchors suggests that implant type and specifications ideally should be matched to treatment goals. Attention to engineering details such as location, size, surface properties, and three-dimensional orientation can maximize predictability. Without understanding what the orthodontist is trying to do, the surgeon may place an implant that cannot be used optimally or will fail.

Moving teeth orthodontically in the direction needed to effectively correct a malocclusion, while preserving dental/periodontal health and improving cosmetics, is the complex challenge of orthodontics. An understanding of the fundamentals of orthodontics requires some knowledge of the biomechanics involved, which in turn are based on Newton's laws of physics. The important third law states in essence that each action has an equal and opposite reaction. Appreciating the clinical application of this law is critical to successful orthodontics. For example, if you attach an elastic chain to the bracketed teeth on either side of an edentulous area, each tooth will respond to the equal and opposite force moving it into the space, thus honoring Newton's law. However, orthodontics is never so simple. Retracting a canine into a first bicuspid extraction socket, for example, usually requires keeping the molars and second bicuspid teeth immobile while the canine moves posteriorly. To accomplish this, the posterior teeth may be ligated together to create an "anchorage block" or "anchor unit." In this tug of war, the molars and bicuspid act together as the anchor and will move mesially much less than the lone canine moves distally. Orthodontic anchorage is defined most simply as resistance to unwanted tooth movement. If anchorage is not controlled ("anchorage loss"), tooth movement is chaotic, may worsen malocclusion, and can cause irreparable root and bone damage.

There are two traditional types of orthodontic anchorage, dental and skeletal. The example just given, where several posterior teeth are used as an anchor unit to allow primarily the distal movement of a canine into an extraction socket, is an example of dental anchorage. In contrast, headgear is a type of skeletal or orthopedic anchorage. The skull and neck act as an anchor to retract the first molars or restrain maxillary anterior growth.

Implants are a type of skeletal anchorage. Some, such as endosseous implants and miniplates, may provide nearly "absolute" anchorage, whereas others such as miniscrews (TADs) often move slightly under orthodontic force. Implants can help the orthodontist avoid the anchorage loss often seen with dentally based anchorage. They may also allow orthodontic treatment of severe skeletally based malocclusions, such as open bite, that may be difficult or impossible to treat without orthognathic surgery.

Implant anchorage can be further subdivided into two categories, direct and indirect, based on how the implant is used. Direct anchorage is defined as placing orthodontic force directly from the implant to the tooth or teeth that need to be moved. Direct anchorage is demonstrated in Figure 23-1, where upper molars are being intruded with an elastic thread connected to an exposed inferior loop of a miniplate anchor that has been fixed superiorly to the cortical plate of the maxilla.

• **Figure 23-1** Miniplate tied to molars with an elastic thread for direct anchorage to intrude teeth.

• **Figure 23-2** Miniscrew implant ligated with wire to a first molar to provide indirect anchorage.

Indirect anchorage usually involves connecting the implant with a ligature wire to a tooth or teeth to create an anchorage unit. This is called "reinforced anchorage," because the implant is supporting the anchor teeth. Standard orthodontic forces can then be placed on the anchored teeth in the unit without the risk of significant anchorage loss. An example of indirect anchorage is shown in Figure 23-2, where a miniscrew implant inserted into the interproximal bone between the roots of a bicuspid and canine is attached with a wire ligature to the lateral incisor. The lateral incisor and miniscrew are now an anchor unit. Elastic chain has been stretched from the lateral incisor to the central incisors to close space and correct the midline to the left. With anchorage support from the miniscrew, the lateral incisor will remain in place while the midline is corrected.

Direct anchorage may require a more stable implant system to avoid fixture displacement, or a combination of shorter treatment time, more implants, or lighter orthodontic force. In contrast, indirect anchorage incorporates teeth into the anchor unit support, which reduces force on the implant. Understanding how the implant will be used affects the decision on the type of implant, its size, and where it should be placed.

Types of Orthodontic Implant Anchors

There are three major orthodontic implants types in contemporary use; miniplates, miniscrews, and endosseous cylinders. Most of these titanium implants are alloyed with other metals that affect properties like strength and ductility. Some even have surface treatment, such as standard dental implants meant to encourage healing. It is important to remember, however, that the orthodontic implant is usually temporary and will need to be removed within 6 to 24 months of placement. Whereas expedited healing and biocompatibility are essential, integration into bone is generally not desirable. Ease of placement and removal are important considerations for patient and clinician.

Most fixtures are designed to allow the orthodontist to attach springs, wires, or elastic chain and thread. Some implants have greater stability over time, so the duration and level of force the implant will be expected to support is important to determine preoperatively. When the patient is referred to the surgeon for treatment, the orthodontist may already have a strong opinion about what is preferable for an implant anchor type and anatomic positioning in the jaw. Others with less experience or understanding with implants may ask the surgeon to make recommendations.

This evidence-based, heavily referenced section is structured to help the surgeon and the orthodontist in choosing an implant type, placement location, and orientation that suits the goals of treatment, increases predictability, and satisfies the clinical needs of the orthodontist. Multiple references are provided where there is still significant disagreement on a topic. Familiarity with the commonly used implants will facilitate an understanding of the treatment planning process and clinical application reviewed in the next section.

Miniplate

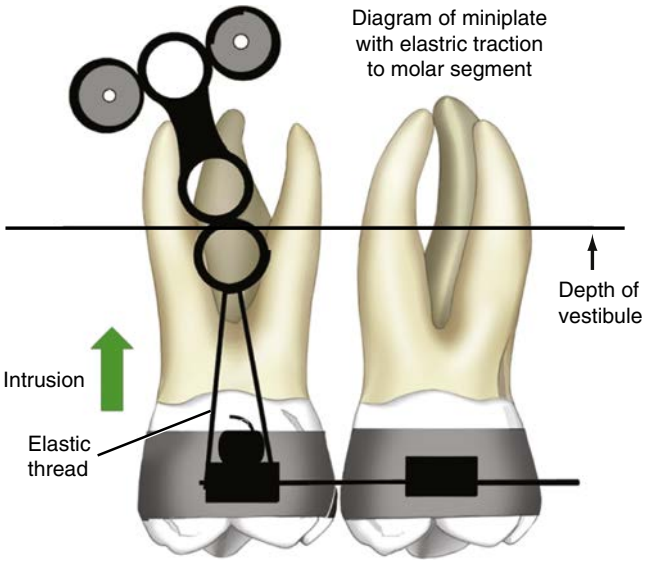
Miniplate-assisted orthodontics has been reported for more than 30 years.[5] However, recently there has there been intense interest in the use of skeletal fixation devices as bone anchors in the management of complex malocclusions. A maxillary orthognathic surgery plate is often used with a loop or "working end" emerging transmucosally through the buccal vestibule or gingiva, and the other subperiosteal end secured to the buccal cortical bone with two or more short screws (Figure 23-3). They are particularly desirable where superior stability in the face of heavy orthodontic force over time is required. The multiple miniplate screws that secure the plate to cortical bone gives this orthodontic anchor the three-dimensional stability that is lacking with the popular miniscrew implant discussed later. Severe skeletal malocclusions such as open bite,[11] class III,[12] and class II[13,14] have been successfully treated orthodontically with the aid of miniplates, avoiding the need for orthognathics. Miniplates have also been attached to orthopedic appliances for distraction osteogenesis[15] and functional appliances that are used instead of headgear.[16]

• **Figure 23-3** Miniplate secured to the maxilla with two fixation screws. The working end is the terminal loop emerging through the wound.

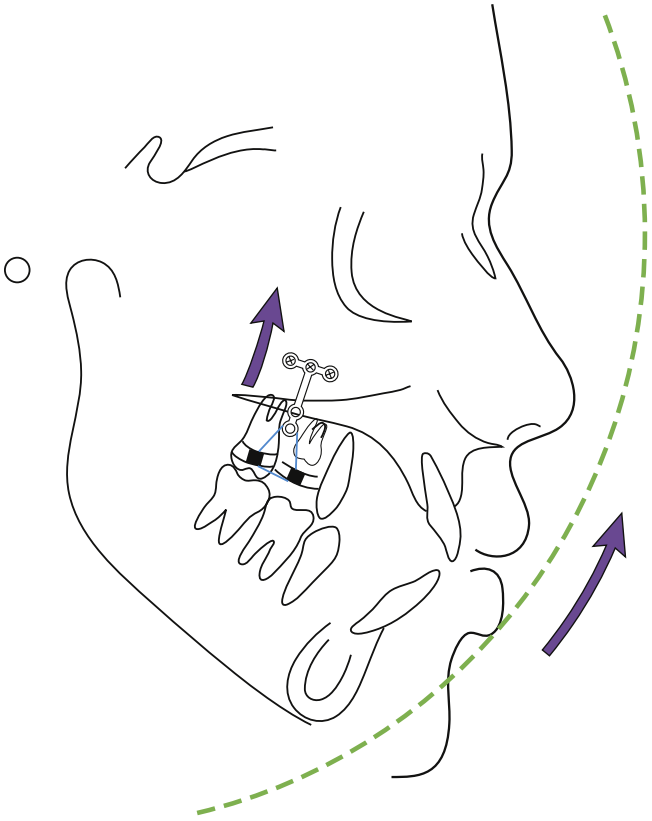
One of the strongest indications for using miniplate anchors is to treat skeletal anterior open bite. Treatment of skeletal open bite with orthodontia only in teen and adult dentition is likely to relapse and risks resorption of delicate incisor roots due to elastic use.[17,18] Traditionally these patients have undergone orthognathic surgery in an effort to predictably treat this disabling malocclusion. Miniplate-assisted orthodontic closure of open bite has been reported extensively since the early studies confirming the efficacy and safety of the procedure.[19,20] The miniplate in this technique is used as skeletal anchorage to support intrusion of molars and bicuspids. This increases the interocclusal (freeway) space, thus allowing the mandible to autorotate superiorly and close the anterior open bite (Figures 23-4 and 23-5). There is no reported risk of sinus or inferior alveolar nerve damage from intruding roots.[21,22] Root resorption is minimal and in keeping with what is normally observed with orthodontic treatment.[23] Relapse, when seen, is comparable to that for patients having orthognathic surgery.[24] The technique is described in depth in the next section on Clinical Application.

Recently, several interesting studies by De Clerk have shown success with miniplates anchors placed in growing patients to correct class III malocclusion by growth modification in maxilla-deficient patients.[25-27] The plates have hooks to attach intraoral class III elastics or reverse pull headgear, to assist with stimulating orthopedic maxillary anterior growth and restraint of anterior mandibular growth (Figure 23-6).[28,29] Miniplate anchors keep the orthodontic forces in the basilar bone of the maxilla and mandible, thus avoiding tooth-borne orthodontic appliances that often cause unwanted tooth movement.[30] They can also reduce the need for patient compliance, which is a major issue with extraoral orthodontic appliances.

Studies have shown the miniplate to be one of the most stable and predictable implant anchors.[31-33] Where miniscrew implants have failed, miniplate anchors offer an excellent alternative. Miniplates also have the virtue of needing only small screws placed well away from roots. They are less likely to injure roots and generally do not create potential obstacles for tooth movement as other implants do.

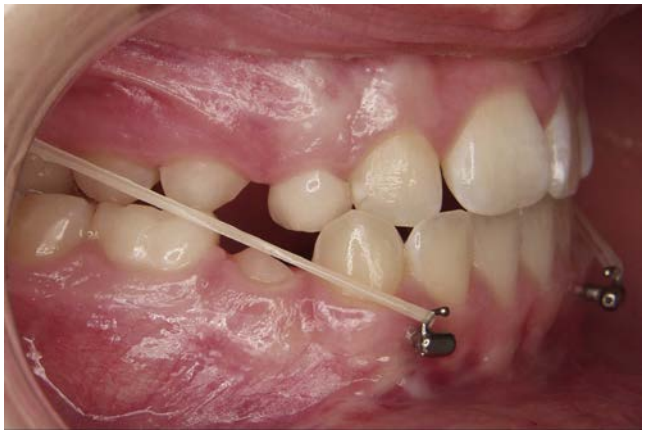


• **Figure 23-4** Miniplate anchorage setup for intruding molars with elastic thread to correct anterior open bite.



• **Figure 23-5** Arc of rotation of the mandible allowing closure of anterior open bite by intruding maxillary molars with miniplate anchors.

This allows for safe placement of the miniplate in the jaws almost anywhere the orthodontist needs an anchor to support orthodontic force. They are also the only implant that can be adjusted with bending to improve positioning. Many plating companies with ortho-implant systems have miniplates with orthodontic attachments welded to the exposed portion of the plate designed to accept ligatures and even



• **Figure 23-6** Bollard style miniplates used to attach elastics to correct preadolescent skeletal class III. (Courtesy Dr. Hugo De Clerk.)

arch wires. However, the exposed loop on a standard plate used for maxillary osteotomies is usually sufficient for open bite treatment.

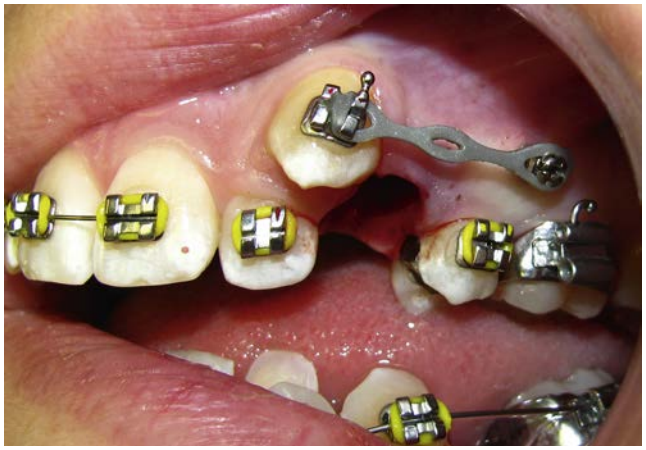
Miniplates require significantly more surgery and expertise to place and remove than do miniscrew implants. Furthermore, they are usually less practical on the palate and the lingual of the mandible, where other implants are easier to insert. However, miniplates are well accepted by patients and providers and are an effective and predictable adjunct to orthodontic treatment of complex malocclusions.[32]

Miniscrew Implant

The popular miniscrew implant (MSI) or TAD (temporary anchor device), developed specifically for orthodontic anchorage, has been intensely studied and improved over the past decade. MSIs are designed to be threaded into the interproximal bone between teeth. All have some type of hole, hook, or grooved design in the external, exposed portion that allows the orthodontist to connect elastic chains or wire ligatures (Figures 23-7 and 23-8). They are relatively simple to place, although avoiding tooth roots can be a challenge.

Orthodontists, especially recent trainees, may place their own miniscrew implants because of the limited surgery involved. However, predictability varies tremendously between practitioners depending in part on experience. Studies looking at percent success (which often is creatively defined) give ranges from 50% to 95%.[33-35] The commonly used monocortical miniscrew anchors have less stability with orthodontic loading then bicortical screws and other types of implants.[36] Thus, most studies in the past 10 years have focused on MSI design and insertion protocols that increase predictability. Miniscrew characteristics, bone density, gingiva type and health, insertion technique, patient issues, and orthodontic forces are all factors that affect success rates. This evidence-based section summarizes the relevant literature on miniscrew implants and assists the surgeon with selecting an anchor system and surgical approaches that improve stability.

• **Figure 23-7** Miniscrews with button attachment or hole to attach elastic chain, ligature wires, or springs. (From Suzuki EY, Suzuki B: Placement and removal torque values of orthodontic miniscrew implants. *Am J Orthod Dentofacial Orthop* 139(5):669-678, 2011.)



• **Figure 23-8** Miniscrew inserted between second bicuspid and molar used for direct anchorage to retract canine.

Miniscrew Design Factors

Ideal screw dimensions have been heavily investigated. The threaded portion of the screw should be at least 1.3 to 1.5 mm in diameter to prevent breakage during insertion or removal.[37] Wider-diameter and bicortical screws are more stable, although placement is more difficult and carries greater risk of tooth-root injury.[36,38] Realistically, 2-mm diameter threads are the maximum that should be used between tooth roots, because it is critical to avoid the periodontal ligament.[39] Insertion at least 5 mm into bone helps with stability, so the threaded portion should be at least 5 to 6 mm long.[40]

Several other design characteristics may affect MSI success at least initially. Increased pitch (frequency) of the threads[41-43] has benefit but also increases torque insertion forces (discussed later). A tapered threaded portion provides greater early stability as compared to the cylindrical shape, though there is not a significant long-term difference.[44] However, early stability may be important if the MSI is loaded immediately. Finally, a lower profile of the exposed portion of the MSI, which will be attached to a spring or elastic, may also lend greater stability by reducing biomechanical stress on the fixture and bone.[45]

Bone Considerations

After MSI design, bone factors that may affect clinical success have been studied most extensively. Despite this, there is still disagreement on ideal bone characteristics to support MSIs. The assumption that greater bone density and cortical bone thickness is beneficial has been confirmed in some studies,[42,46-49] but disputed in others.[50-52] The discrepancy may in part be caused by study design. Primary or immediate stability is clearly related to bone density and cortical bone thickness, whereas long-term stability over the course of months of orthodontic force application is affected by many other factors. Insertion torque, which is higher in denser, thicker bone, has been shown to be a good measure of primary stability with MSIs.[42,46,47,53] However, the presence of dense bone may lead to excessive torque pressure with MSI insertion. Some clinical studies have suggested that this leads to reduced stability over time, possibly secondary to necrosis.[54,55] Although optimum torque levels for clinical purposes have not been established, medium torque levels between 10 and 15 Ncm may be more predictable.[54,55] With higher torque, a small pilot hole should probably be drilled. Furthermore, wider-diameter, tapered-shape, self-drilling, and/or bicortical screws, which increase torque, may improve outcomes.[48,46,55] If torque is impractical to measure, anatomic knowledge of bone density and cortical thickness is important. In general, bone density is less in the alveolus than in the basilar bone, is greater in the mandible than the maxilla, and in the buccal alveolus increases progressively from anterior to posterior in both jaws.[56] There seems to be agreement in the literature that the alveolus from the second bicuspid to the first molar is, in general, optimum in terms of bone quality and other factors.[57-59] However, as discussed next, many other considerations are involved with selecting an ideal anatomic location for MSI insertion.

Technique Factors

Success with MSIs has been linked more closely with operator experience than other types of implants.[34] This likely speaks to the underlying instability of the monocortical miniscrew and the preponderance of factors that need to be controlled to allow predictability. However, attention to good technique can mitigate problems that contribute to screw failure even in the hands of the inexperienced clinician.

Root Proximity

Root proximity, especially when the periodontal ligament is invaded, is a major risk factor for early loss of the miniscrew fixture.[39,50] Minor root damage seems to be a manageable risk of MSI insertion. Studies have demonstrated repair without serious consequence when the injury is limited to abrasion of the cementum.[60] However, more serious injuries are possible, and ankyloses, root resorption, and pulpal necrosis have been reported.[61,62] If the periodontal ligament is contacted by the MSI, the patient will feel pain unless local anesthetic has been injected. Immediate radiographs are recommended. If there is tooth contact, the implant should be removed immediately. Surgical guides,[63] cone beam computed tomography, and stents[64-66] may help the inexperienced operator with safe MSI placement.

Drill versus Self-drill

Most MSIs are available with self-tapping (drilling required) and/or self-drilling (drill-free) options. In the maxilla, there does not appear to be a significant difference in clinical success between self-drilling and predrilled self-tapping screws long term.[67-70] However, for screw placement in the dense bone of the mandible or midline of the palate, drilling a small pilot hole is recommended to reduce high insertion torque.[67,71] It is also important to not heat the bone while drilling, which would lead to bone necrosis and fixture loss.[72]

Self-drilling screws are easier and quicker to place in the medium to soft bone of the maxilla. They usually require only topical anesthetic so patient comfort is improved. Furthermore, if injectable local anesthetic is avoided, the operator is alerted to root contact by patient discomfort. Self-drilling screws have higher insertion torque values, which could translate into better primary stability.[42,46,47,53]

Angle of Placement

The more closely an MSI long axis approximates the line of applied orthodontic force, the more stable and resistant to failure it will be.[73] For example, if the treatment plan requires vertical intrusion force on a tooth, the screw should be angled with the threaded portion aimed apically. Angulation along the long axis of the force vector may not be possible with mesio-distal forces and screw placement in the narrow bone between roots. Alternatively, placement of the screw at 90 degrees to the bone was found to be advantageous biomechanically for most applications.[74] Ideal angulation obviously requires communication with the orthodontist regarding treatment goals.

Orthodontic Loading

As explained in the section on biomechanics, direct or indirect orthodontic loading forces may be placed on the MSI by the orthodontist. With direct loading, the elastic chain or spring is tied from the exposed portion of the fixture to the tooth or teeth that are being moved. In contrast, with indirect loading, the fixture is tied passively with a wire ligature to stabilize a group of teeth, and orthodontic forces are then applied to the teeth instead of the implant. Indirect loading reduces forces on the implant and probably reduces the risk of MSI failure.[75]

Most studies and clinical experience with direct loading of MSIs suggest that immediate orthodontic forces of 100 to 200 g are safe, at least for the short term.[76-78] However, the amount of force the screw can tolerate is probably limited by screw length, bone density, and the other variables listed earlier. The monocortical MSI is not immobile, and excessive direct force may be detrimental. The phenomenon of drift, where an otherwise healthy functioning fixture tips slowly toward the origin of the force, may cause root or even nerve damage.[68,69,79]

It is the responsibility of the orthodontist to load the fixture judiciously. Whatever information the surgeon can communicate regarding bone density and screw properties will help the orthodontist decide how best to make use of the implant anchor.

Gingival Factors

It is debatable to what extent the nature of the gingiva through which a miniscrew is placed affects stability. Many studies suggest that failure rates are reduced when MSIs are placed through thin attached gingiva.[80-83] Other studies maintain that MSIs can be safely placed in sites that lack keratinized gingiva.[84] Gingiva type probably has little effect on short-term (primary) stability, because mechanical interlock in bone is paramount the first month postoperatively.[53] Long term, it seems logical that gingival issues could cause MSI instability from inflammation.[80,81,85] Along with good oral hygiene, locating the miniscrew in attached gingiva when possible will reduce inflammation and likely improves longevity.

Controlling the variables just discussed with miniscrew implant placement will reduce the risk of fixture failure and the resulting interruption of orthodontic treatment that is frustrating for patient and clinician.

Clinical Application and Case Presentation

This section on the clinical application of implant anchorage is organized to help the surgical-orthodontic team with treatment planning and to facilitate safe and effective implant placement. Although miniscrew implants or miniplates can often be used for similar malocclusions, the quality of bone, the duration and level of force with which the implant is to be loaded, and patient comfort should dictate the type of implant that is selected. Once an implant system is chosen, the orthodontist should determine the ideal location for the implant to meet the biomechanical goals of treatment. The cases reviewed reflect common application of implant-anchored orthodontics. In general, miniplates are used when the treatment time is expected to be long (up to a year or more), bone quality is questionable, or skeletal malocclusions are being treated. When miniscrews are used, treatment time is relatively short, bone quality good, and multiple fixtures or indirect anchorage employed to limit the force on individual implants.

Miniplates

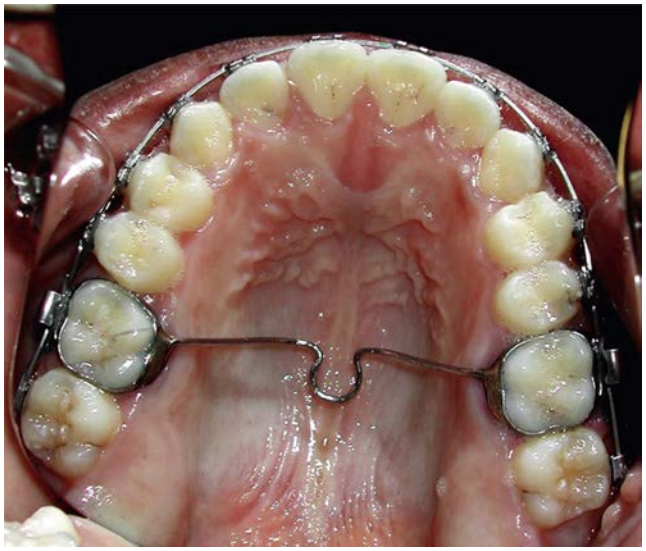
Skeletal Anterior Open Bite Treatment

Growth-related (skeletal) anterior open bite is one of the most difficult malocclusions for the orthodontist to manage. Severe relapse is common, especially when orthodontic-only treatment is attempted on teen and adult patients and anterior teeth are intentionally or inadvertently extruded.[86] Studies have shown that skeletal anterior open bite often derives from excessive posterior vertical growth, especially in the molar alveolus.[87] Historically, this has been managed with orthognathic surgery. Advances in implant anchorage have enabled true orthodontic intrusion of molars, a treatment once thought to be biomechanically impossible. As shown by the diagram in Figure 23-5, intrusion of posterior

teeth increases freeway space, which permits autorotation of the mandible, leading to closure of anterior open bite. The ratio of molar intrusion to incisor open bite closure is 1:2 to 1:3. As will be seen, it is important for the orthodontist to determine preoperatively approximately how much intrusion will be needed.

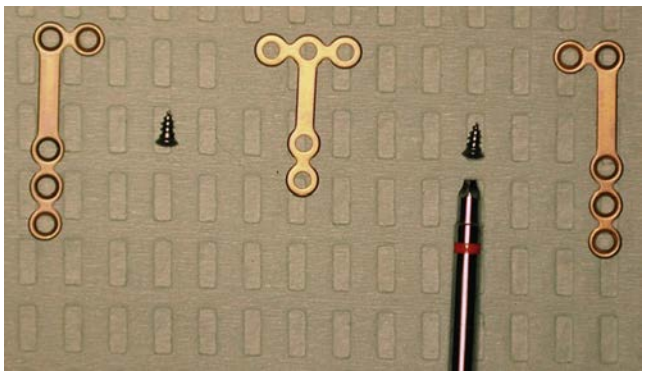
Treatment begins with banding of the molars and bracketing of all the teeth including the second molars. Because of the accentuated curve of Spee usually seen with anterior open bite, sectional archwires often must be used to prevent undesirable extrusion of incisors that would occur with a continuous wire. The three wire sections usually include the canines and incisors together anteriorly and the bicuspids and molars in two separate posterior segments (Figure 23-9). To prevent buccal tipping of the molar segments during intrusion mechanics, a TPA (transpalatal arch) must be placed preoperatively by the orthodontist that is offset from the palate the distance the molars are expected to intrude (Figure 23-10).

• **Figure 23-9** Orthodontic setup for open bite closure with miniplate anchored intrusion of molars. Due to the curve of Spee, the maxillary archwire is in sections, canine to canine and bicuspids to molars.



• **Figure 23-10** Transpalatal appliance (TPA) pre-surgery relieved from the palate the expected distance for orthodontic molar intrusion.

The miniplate insertion can be done using light sedation or even local anesthesia in tolerant patients. Plates from a maxillary orthognathic plating system (Figure 23-11) or orthodontic anchor kit (Figure 23-12) can be used. Standard plates should be positioned so that the last loop (working end) of the plate emerges from the mucosa far enough apically from the first molar band so that after intrusion is complete, the loop will not contact the most gingival tube on the band. This distance is determined by the number of millimeters of expected intrusion. For example, a 10-mm incisor open bite requires 5 mm of molar intrusion and a corresponding 5 mm or more of vertical space from the headgear tube to the miniplate loop (see Figure 23-9). Anteriorly-posteriorly, the loop should emerge between the first and second molars and should be bent buccally well clear of the tissue to allow easy access for the orthodontist and to prevent compression of the gingiva by the elastic thread or coil (Figures 23-1 and 23-13). The other end is fixed with two to three 3- to 5-mm-long screws (depending on bone thickness), placed far enough apical to the roots to guarantee that they will not contact the intruding root tips during treatment (Figure 23-14). The plate should be oriented so that its long axis is approximately in line with that of the teeth to be intruded (Figure 23-15).

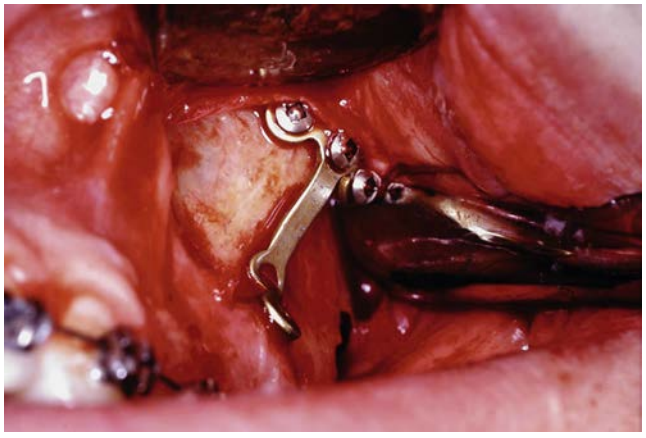


• **Figure 23-11** Standard maxillary osteotomy plates and screws that can be used as skeletal anchors for molar intrusion. (Courtesy Stryker Corporation.)

• **Figure 23-12** Orthodontic only miniplates with hooks on working end. (Courtesy KLS Martin.)

The orthodontist will use an elastic thread or coil from the molar bands to the miniplate loop to intrude the posterior teeth (see Figures 23-1 and 23-13). The thread is changed every 4 weeks. Intrusion usually proceeds at approximately 1 mm per month but can advance faster in young patients and more gradually in older adults.

• **Figure 23-13** Working end of miniplate loop emerging through the mucosa between first and second molars and bent buccally to prevent compression of gingiva by attached coil spring.



• **Figure 23-14** Surgical placement of miniplate anchor and fixation with three screws well above molar roots. Note contouring of plate to maxillary strut, emergence of plate through wound margin, and buccal bending of working loop off the gingiva.

It is recommended that third molars be removed in a jaw receiving miniplates.

The case presentation for this technique shows a 17-year-old patient with a severe, disabling skeletal anterior open bitethat in the past could only be treated with an osteotomy (Figure 23-16, *A*). The archwire was sectionalized distal to the canines, and miniplate anchored molar intrusion was initiated. Figure 23-16, *B* through *D*, shows the progression of bite closure exclusively by molar intrusion. After debracketing, the orthodontist elected to use standard retainers, and there has been good stability after 3 years. However, retainers with posterior bite blocks are recommended.

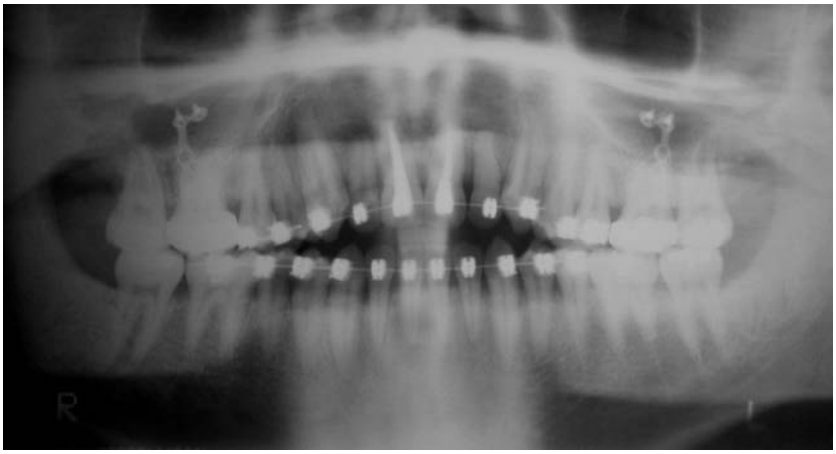
Molar Intrusion, Space Closure, Correction of Class III

This 28-year-old man had supererupted lower left molars due to missing maxillary posterior teeth, a class III dental relation on the left, an anterior crossbite, and a mandibular midline discrepancy (Figure 23-17, *A*). The patient refused maxillary appliances, so treatment goals were limited to creating vertical space for maxillary left implants and correcting the class III, anterior crossbite and lower incisor midline discrepancy.

After intrusion, the miniplate was ligated to the molars, creating an anchorage block. Extraction of the second premolar and elastic chain use from the intruded first molar to the anterior teeth allowed en masse (simultaneous multiple tooth) retraction and space closure, and correction of the anterior crossbite and midline discrepancy (see Figure 23-17, *B*). Maxillary posterior implants were placed during active orthodontic treatment. After completion of orthodontics (see Figure 23-17, *C*), they will be uncovered and restored before debracketing to prevent re-eruption of the orthodontically intruded lower molars.

Miniscrew Implants

The miniscrew implant anchorage case presentation section has been divided into direct and indirect anchorage applications. It demonstrates how monocortical MSIs are



• **Figure 23-15** Panographic radiograph of orientation of miniplate to long axis of molars requiring intrusion.

commonly used as orthodontic anchors and can be safely loaded to avoid loosening or migration (drift).

Direct Anchorage

Direct Anchorage to Intrude Molars/Premolars and Retract Anterior Teeth

The adult patient shown in Figure 23-18, *A*, had hypererupted maxillary molars and bicuspids due to the lack of opposing dentition, posterior bite collapse, proclination of incisors, and a class II canine relationship. A bridge connected the lateral incisor and canine with a cantilevered first bicuspid pontic. The pontic was removed to create space, and miniscrew implants were placed mesial and distal to the first molar. An elastic thread was tied below the headgear tube on the band to create the vertical force to help intrude the molar. The miniscrews and molar/bicuspid teeth created an anchorage block that was then used to help retract and upright the anterior teeth en masse by using a coil spring stretched from the anterior miniscrew to a welded hook on the archwire (see Figure 23-18, *B*). After retraction of the incisors, they were stabilized with a ligature wire attached from the anterior miniscrew to the archwire hook, and the posterior space was closed with elastic chain (see Figure 23-18, *C*).

Direct Anchorage to Upright Impacted Second Molar

Impacted second molars are a common problem in orthodontic treatment. Orthodontic uprighting is the safest and most predictable method to treat this condition. If there is enough space and bone behind the second molar, a miniscrew implant can be placed in the retromolar area or ascending ramus and used to upright the molar. Ideally the third molar should be removed, the second molar exposed, and the miniscrew placed simultaneously.

Figure 23-19 demonstrates uprighting of a horizontally impacted mandibular left second molar in a 16-year-old patient who was missing the third molar. After exposure of the second molar, a button bracket was cemented to the disto-occlusal surface of the molar. A miniscrew was inserted into the bone well distal to the impacted tooth, at a 45-degree angle to the occlusal plane, and inferior enough to avoid the opposing maxillary second molar in centric occlusion. An elastic chain was connected from the bracket to the miniscrew to distally rotate and upright the molar.

Indirect Anchorage

Indirect Anchorage to Correct a Class II

This adult patient had a class II molar/canine malocclusion. A miniscrew was inserted buccally between the second bicuspid and first molar roots. A wire ligature was tied from the miniscrew to the bracket on the canine to create an anchor unit supporting the canine. A compressed expansion coil was threaded onto the archwire between the canine and first molar (Figure 23-20, *A*). The canine, which otherwise would be pushed mesially from the coil, was immobile because of its ligation to the miniscrew anchor. The force of the expansion spring opening distalized the molars into a class I relation (see Figure 23-20, *B*). The space created mesial to the premolar is caused by transseptal periodontal fiber pull from the distalized molar to the bicuspid. This space will allow the orthodontist to eventually retract the canine and premolar into a full class I relation.

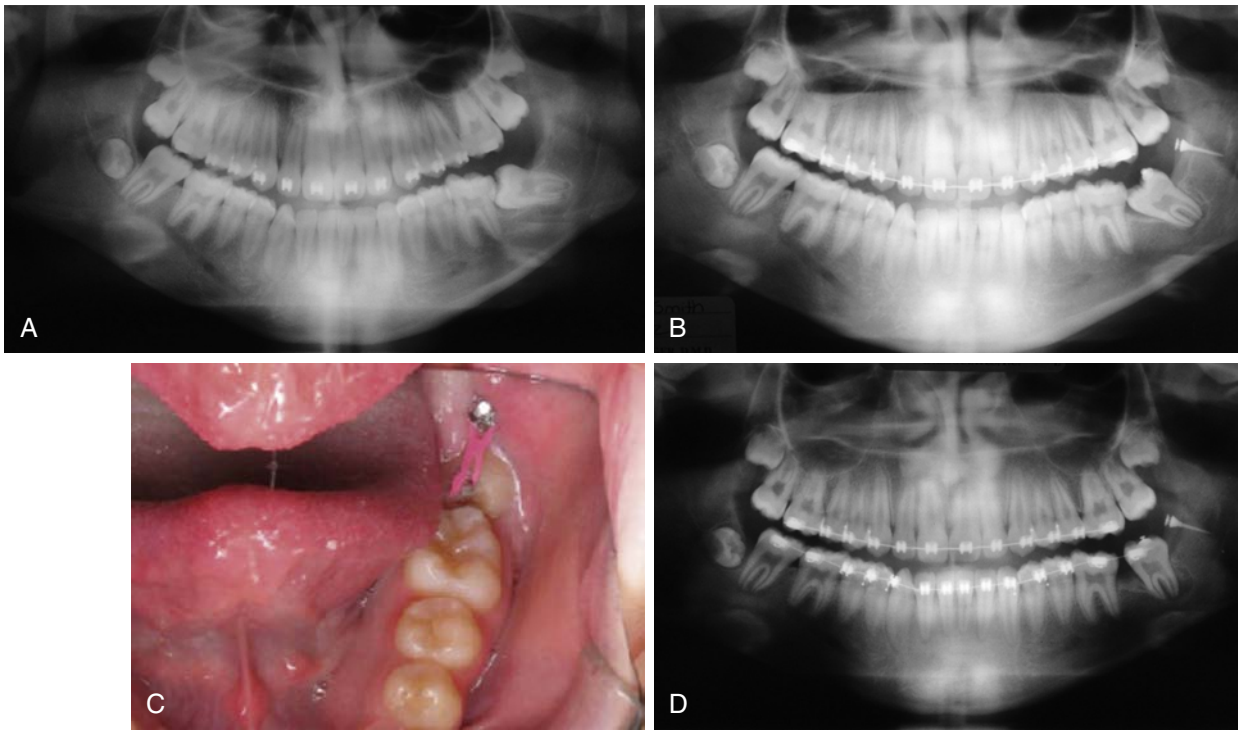
Surgical Techniques and Materials

Miniplate Implant Placement

Miniplates from a standard bone plating kit for maxillary orthognathic surgery are usually adequate and less costly for most orthodontic anchorage applications. The exposed end is the terminal plate loop to which elastic threads or coil springs can be attached. This plate can be trimmed to size if necessary. Alternatively, plates with orthodontic attachments on the working end may be needed if the orthodontist intends to have the patient wear elastics to the plate, for growth modification. The orthodontic attachment plates have an orthodontic tube or hook that can accommodate elastics, ligatures, and archwires (Figure 23-21). Short, 4- to 5-mm miniscrews are usually adequate to support the plate. Longer screws do not significantly add to stability and may interfere with tooth movement or cause injury if they contact a root or other structure. However, it is important



• **Figure 23-19** **A**, Pretreatment panographic radiograph showing impacted mandibular left second molar. **B**, Radiograph 2 weeks after exposure and disto-occlusal bracketing of second molar, insertion of miniscrew, and elastic chain uprighting. **C**, Clinical appearance at 2 weeks with elastic chain from occlusal button bracket to miniscrew implant. **D**, Radiograph 6 months after molar uprighting complete. (Images courtesy Dr. Gabriella Marquez.)

that the screw engage cortical bone and not be stripped or loose. Self-cutting/tapping screws work well in the maxilla. In the mandible, it may be necessary to predrill a screw hole because of bone density. At least two and ideally three miniscrews suffice for most applications, depending on cortical bone thickness.

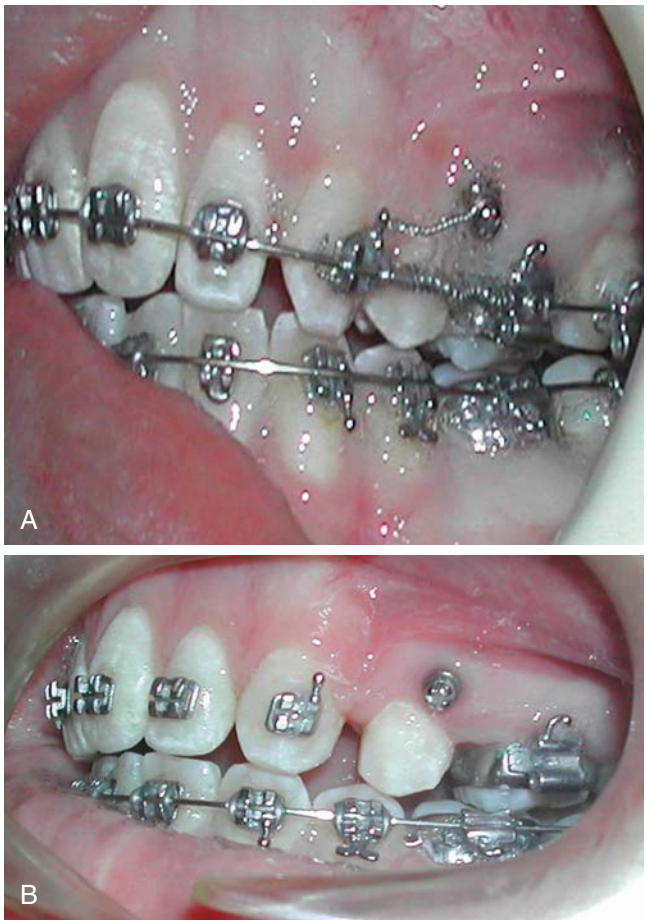
Similar to trauma and orthognathic applications, miniplates placed in the maxilla are best supported in the thicker cortical bone of the zygomatic buttress and piriform rim. In the mandible, where bone density and cortical thickness is high, it is important to avoid overheating the bone when holes are drilled.

Miniplates can be placed with local anesthesia only, but because of the stretching and pressure associated with screw insertion, many patients prefer light sedation. A horizontal incision is made at the junction of the attached and unattached gingiva. Either a full-thickness envelope flap is raised or, for better visibility and access, a releasing incision is carried to the mucobuccal fold (Figure 23-22). The miniplate should be contoured to lie as passively as possible against the underlying bone to avoid dead space and reduce stress on the screws (see Figure 23-14). The plate will need to be positioned so that the screws avoid roots both at the time of placement and during the predicted orthodontic tooth movement. Ideally, the working (exposed) end should emerge through attached gingiva to avoid inflammation. However, because this is not always possible, the priority with positioning the plate is to make sure that it will function optimally for the anticipated tooth movement and orthodontic loading. Location and orientation was discussed in depth in the application section.

Miniscrew Implant Placement

Miniscrew implant insertion is less involved than surgery for miniplate implants. However, because of the risk of root contact and the latent instability of monocortical MSIs, careful pretreatment planning, skilled fixture placement, and control of the other variables discussed in the miniscrew section on anchor types are critical to success. Good preoperative films to evaluate root position are essential. At a minimum, a good quality panographic radiograph and one or more periapical films should be available.

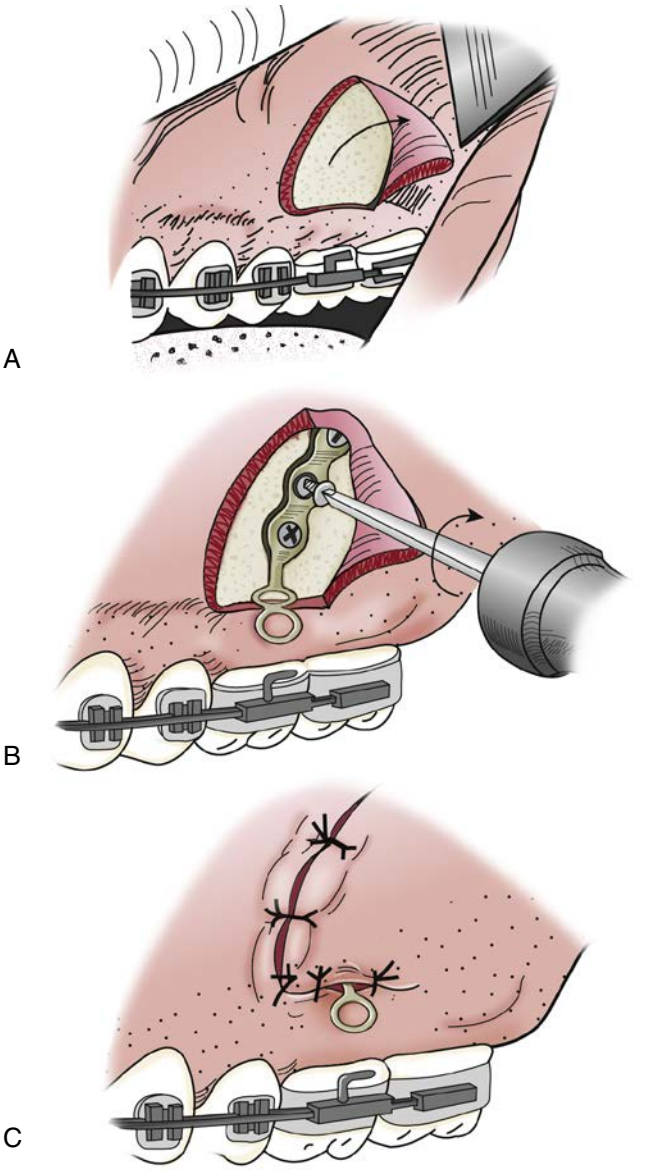
Self-drilling MSIs can be used for most applications. In the maxilla the screw is directly threaded into the bone transmucosally. In the mandible, where bone density is high, drilling of a pilot hole without heating the bone is advisable. With drilling, a small incision or tissue punch may be appropriate to expose the underlying bone. The depth of the pilot hole depends on the expected thickness of the cortical plate of bone and is usually between 1.5 and 3 mm in the mandible.[88] The self-drilling screw is then introduced and threaded into the bone until its threads are covered. Heavy torque insertion forces that might lead to screw fracture or poor healing are discouraged.



• **Figure 23-20** **A**, Adult patient with a class II molar/canine relation. A miniscrew was inserted between the maxillary first molar and bicuspid and ligature tied to the canine. An expansion coil spring was placed on the archwire between the molar and canine. **B**, Distalization of the molar into a strong class I in 6 weeks.

• **Figure 23-21** Orthodontic miniplates that can act as hooks or accept an archwire. (Courtesy Stryker Corporation.)

The miniscrew implant should be inserted perpendicular to the bone in attached gingiva (Figure 23-23) unless space allows orientation in the same direction as the orthodontic force. For example, with a planned bicuspid intrusion, the screw can be inserted slightly apically (i.e., the cutting tip is more apical than the exposed head) so that the long axis of the screw is more in line with the orthodontic force vector (Figure 23-24). Miniscrews always resist pullout forces better than tipping forces.



• **Figure 23-22** Placement of a maxillary anchor plate. **A**, Incision over maxillary buttress is horizontal along mucogingival junction then vertical release to depth of vestibule. **B**, Fixation of straight plate with three screws, and transmucosal inferior loop bent buccally. **C**, Primary closure leaving working end of plate exposed intraorally and well above band on first molar.

Adjunctive Care

Intraoperative or postoperative radiographs are recommended to evaluate screw positioning. As with most dental implants, a 7-day postoperative course of antibiotics may be beneficial.[89] Bacterial biofilms can attach to implant and gingival surfaces, leading to inflammation. Although good oral hygiene is the most important method to reduce oral bacterial levels, pre- and postoperative rinsing with chlorhexidine may be appropriate. Patients should be encouraged to look at the fixtures and keep them clean with a cotton tipped applicator soaked in peroxide or chlorhexidine. Smoking should be discouraged. MSI failure rate, in particular, has been shown to be higher in smokers.[90]

• **Figure 23-23** Perpendicular insertion angle of miniscrew implant mesial to first molar in attached gingiva.

• **Figure 23-24** Miniscrews inserted (angled) apically for intrusion of maxillary bicuspids. Elastic thread is tied as a sling over the occlusal wings of premolar brackets then to both miniscrews.

Prevention of Complications

Placement of orthodontic implant anchors is a relatively benign procedure with few serious risks. Complications of surgery both operatively and long term mirror those associated with dental implants. As discussed in previous sections, common problems relate primarily to premature loss of the fixture and poor orientation. More significant problems such as root or nerve damage and serious infections are possible but preventable and usually treatable. The purpose of this section is to summarize what the surgeon can do to avoid complications.

Planning orthodontic implant placement can be as detailed as planning dental implant therapy and even orthognathics. Interspecialty communication regarding treatment goals, fixture type, location, and orientation is essential. Referrals are usually initiated by the orthodontist, who should inform the surgeon about the biomechanical plan and preferences for implant type and location. At the preoperative visit, the surgeon must evaluate the patient and radiographs to determine bone availability and inter-root space, and to decide on an appropriate fixture.

Miniplates are more stable and are recommended where orthodontic treatment time is expected to be prolonged or heavy forces used. Treatment of open bite, growth modification, poor bone density, and a desire to keep screws away from roots for orthodontic reasons are good indications for using miniplates. Monocortical miniscrew implants are inherently unstable when loaded but require less surgery and are particularly useful when indirect anchorage is employed by the orthodontist or direct loading time is expected to be less than 6 months. Multiple mutually supported miniscrews or the use of bicortical screws lessens the concern with instability, but the surgical time, expense, and risks could potentially exceed those for a single miniplate.

Root contact is a major cause of miniscrew anchor failure. However, if root injury occurs, it is usually physiologically repairable as long as the damage is limited to the cementum and the screw is removed. Root contact will also interfere with orthodontic tooth movement and, if severe, could cause fracture or ankyloses.

Inadequate bone support may lead to fixture mobility, especially with MSIs. This may be caused by poor bone quality, technique problems, or fixture issues. Bone density is patient specific, but the surgeon should have a working knowledge of cortical bone thickness as previously described. Tapered self-drilling screws tend to have higher immediate stability but may be more difficult to place in dense bone. If the bone is too dense and excessive torque is needed to insert a screw, a hole should be drilled. Care must be taken to prevent excess torque and bone heating, both of which can cause bone necrosis and early fixture loss. The fixture should have at least 5 mm of thread embedded in bone. Miniscrew implants with 1.5- to 2-mm-diameter threads are less likely to fracture or contact tooth roots. If fracture occurs, retrieval of the segment may be difficult. Consultation with the orthodontist is recommended to determine if the embedded screw will interfere with tooth movement.

Inflammation and periodontal pathogens may lead to fixture failure or infection. Hygiene is easier to maintain in attached gingiva, and if possible the working end of the implant should emerge in keratinized tissue. However, locating the implant where it is most functional and accessible for the orthodontic treatment objectives always takes priority. Prophylactic use of antibiotics and chlorhexidine rinse is advocated by many, but good oral hygiene, as discussed in the last section, is more important in the long term. Patients with active, poorly controlled periodontal disease are poor candidates for implant anchors. If an implant anchor becomes infected but is stable, a trial course of antibiotics is appropriate. If the implant has loosened, however, it should be removed. A new fixture can be placed in a different site as soon as the infection is resolved.

Finally, orthodontic variables such as loading are largely beyond the purview and control of the surgeon. If the orthodontist overloads a miniscrew, it will drift or loosen. However, it is the responsibility of the surgeon to relay

concerns about bone or gingival quality and hygiene to the orthodontist. By making an effort to understand how the orthodontic forces will be loaded on an implant anchor, the surgeon can select, locate, and angle the fixture in a way that maximizes its stability and long-term functionality.

Conclusions

Implant-supported skeletal anchorage for orthodontics is a relatively new and exciting clinical field that has a burgeoning and evolving evidence base. Its application continues to expand, along with its acceptance by orthodontists as a vital component of contemporary clinical practice. In conjunction with other surgical techniques that facilitate correction of malocclusion, it will serve as yet another platform for collaboration between oral and maxillofacial surgeons and orthodontists.

Lasers in Oral Surgery

ROBERT A. STRAUSS, NICHOLAS J. KAIN

Laser Physics

Because of their many advantages for certain procedures, lasers have become a ubiquitous tool in the armamentarium of the oral and maxillofacial surgeon. However, in order to choose the correct laser, and to use that laser correctly for any specific procedure, it is imperative to thoroughly understand the physics of light and its laser application. Unlike scalpel and electrocautery surgery, which rely primarily on one mechanism of depth control (pressure and power, respectively), lasers have a multitude of variables that can and should be employed to control their depth of penetration and effect. As lasers have a definite degree of risk when used improperly, it is incumbent on the surgeon to understand and apply the appropriate physics to any clinical situation in order to ensure the best and safest possible results.

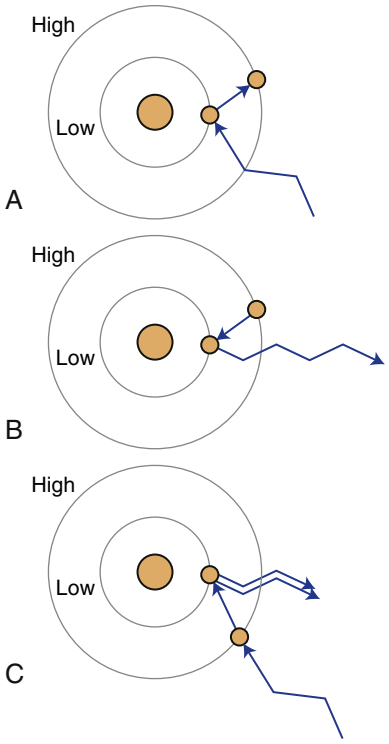
Generation of Laser Light

Light amplification by stimulated emission of radiation (LASER) is based on the theoretical hypothesis of quantum theory developed by Albert Einstein and first reported in 1917.[1] Amazingly, it took another 40 years before Theodore Maiman, a physicist at the Bell Laboratories, introduced the first functional laser using a ruby diode. Since that time, many different types and wavelengths of laser have been produced; however, all are based on the same principles of physics. [2]

To understand stimulated emission one must first understand simple emission of energy from an atomic body. In the hypothetical and vastly simplified simulation of an atomic body, one thinks of a nucleus surrounded by electron shells. The electron shells closest to the nucleus represents the lower energy shells while the outer shells signify higher energy levels (Figure 24-1). Electrons, by nature, stay in the lower energy shell unless acted upon. When external energy is added to the system, typically by direct current electricity or a photo strobe light, the system becomes excited and electrons are pushed into the higher energy shells (see Figure 24-1, *A*). This is termed *absorption*. As this is not a stable state, the excited electrons will eventually fall back into the lower energy shells. The system will then emit a packet of energy as that electron goes from the higher to the lower energy shell. That packet of energy, or photon, is emitted in a specific wavelength that is related to the specific molecular body involved. This is termed *spontaneous emission* (see Figure 24-1, *B*). A good example of this is the process by which a neon sign works. The neon gas inside the tube is electrically excited, undergoes spontaneous emission, and gives off a photon of energy, which, based on the neon gas, is in the wavelength of the color red. Other colors of "neon" lights actually use alternative materials that emit different specific wavelengths (e.g., argon gas emits a green color).

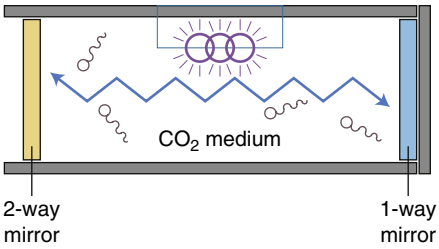
When an atomic body already in the excited stage (i.e., with electrons in the unstable higher energy shell) is excited further, before it has the chance to undergo spontaneous emission, it can actually "force" the electron down into the lower energy shell. When this occurs, the atomic body will emit not one, but rather, two photons of energy. Thus we have *stimulated emission*. More importantly, these two emitted photons will be of the exact same wavelength and will be both parallel and in phase with one another, with all the peaks and troughs of the waves aligned with each other (see Figure 24-1, *C*). These two emitted photons can then be the exciting energy for two more atomic bodies, which undergo stimulated emission and can then provide the energy for four atomic bodies, and so on. In order for this system to sustain itself, more than 50% of the atomic bodies must be in the excited stage at any one time to allow the continued and increasing production of photons. This is termed *population inversion*, when there are more excited atomic bodies than normal ones, and explains why some materials can be used as laser mediums (e.g., carbon dioxide, argon) and others cannot. Only those materials capable of maintaining population inversion can be used as laser mediums.[3]

A laser tube is deceptively simple. It is merely a glass or metal tube that has the lasing medium inside (the lasing

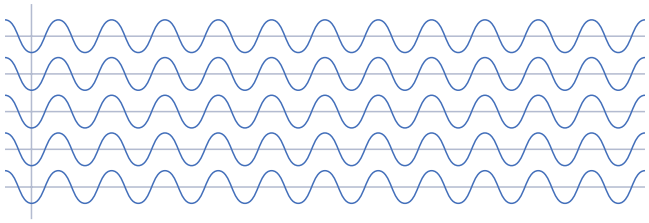


• **Figure 24-1** **A**, Absorption of energy. **B**, Spontaneous emission. One photon of energy is released. **C**, Stimulated emission. Note that two photons are released, and they are in phase and collimated.

medium being the material that will undergo stimulated emission), an energy source or *pumping mechanism* (again, typically an electric source or a photo strobe light) to impart energy for absorption, and two mirrors placed exactly parallel to each other at either end of the tube (Figure 24-2). One mirror is a standard one-way fully reflective mirror, and the other is a partially reflective–partially transmissive mirror (a so-called two-way mirror that at low light levels reflects light like any mirror but at high light levels allows some or all of the light to transmit or pass through the mirror). As the stimulated emission of light occurs inside the tube, the majority of the stimulated photons will pass harmlessly into the sides of the tube and are emitted as simple light or heat. When a photon happens to hit exactly perpendicular to one of the mirrors, it will bounce through the tube, hit the opposite mirror, and begin a period of oscillation between the mirrors. Of course, while this is happening many other photons are being given off, most of which are lost as light or heat into the container, but some will also oscillate between the mirrors. This process of recruitment continues until enough of the photons are oscillating between the mirrors that the energy they contain overwhelms the two-way mirror and a packet of light is emitted out of the end of the laser tube. Importantly, they will all be one wavelength based on the laser medium (monochromatic), parallel to each other (collimated), and synched in phase with one another (Figure 24-3). This defines laser, or *coherent light*, and because of the additive properties of these photon's energy, as a result of their coherency and uniformity of phase (unlike regular light,



• **Figure 24-2** Components of a laser tube.

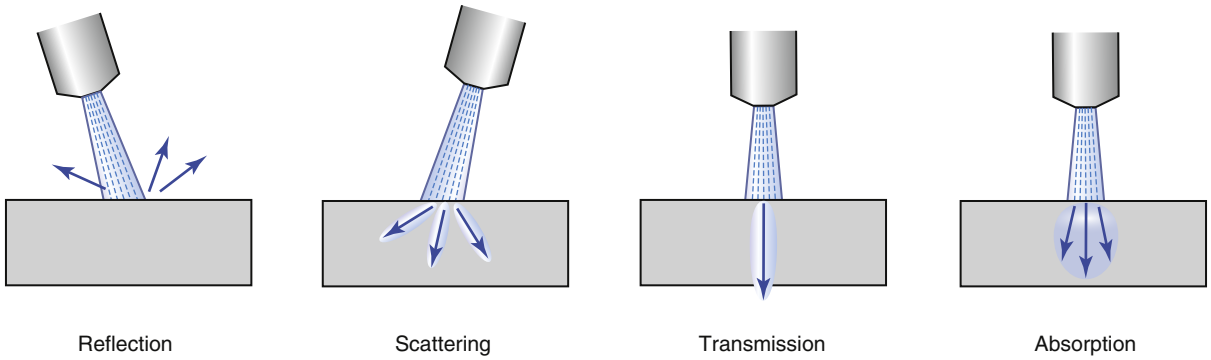


• **Figure 24-3** Coherent light showing a single wavelength, uniformity of phase, and collimation.

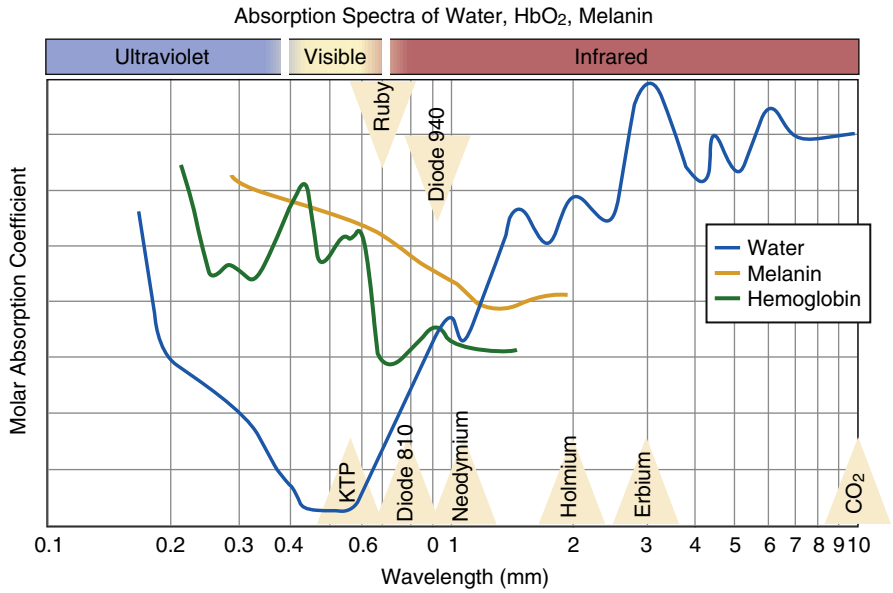
which spreads out in all directions from its source and loses its power quickly), the light is hugely concentrated and powerful.

Once produced, and depending on the wavelength, the light can be transmitted to the tissue by a series of articulated arms (hollow tubes with mirrored knuckles), hollow wave guides (flexible metal fibers whose entire internal surface is mirrored), or fiberoptic cables. Each of these has advantages and disadvantages related to ease of use, focusing abilities, and their ability to be used with microscopes and micromanipulators. [4]

Once laser light hits human tissue, one of several interactions may occur (Figure 24-4). The light can be transmitted through the tissue (imagine a laser being shined through glass, except that some lasers can travel right through solid tissues in a similar fashion), be reflected off the tissue, scatter inside the tissue, or be absorbed into the tissue (much as a black shirt absorbs sunlight and gets hot in the summer). There are many wavelengths of clinical lasers, ranging from the far infrared to the ultraviolet range (and likely the military has some in the x-ray and perhaps gamma ray range). Although the ability of a laser to transmit through tissue, and subsequently act on a deeper structure, has some allure and use in specific cases (e.g., for a port wine stain), choosing the correct laser in oral and maxillofacial surgery is usually (but not always) related to the ability of a particular laser to be absorbed into the intended target tissue. The material within the tissue that actually absorbs the energy (e.g., water, hemoglobin, or collagen) is termed a *chromophore* for that particular wavelength (Figure 24-5).[5] The major component of human soft tissue, water, is the primary chromophore for lasers in the mid and far infrared range, such as the carbon dioxide (CO_2) laser; the erbium:yttrium-aluminum-garnet (Er:YAG) laser, which uses a YAG crystal doped with the rare earth element erbium; and the similar erbium: chromium:YSGG laser. Thus, these lasers have excellent



• **Figure 24-4** Tissue interactions.



• **Figure 24-5** Laser absorption chart.

and useful effects on tissues that contain water. Another laser popular with non-surgeons is the diode laser. These small, inexpensive, and easily transported lasers use a small diode as the lasing medium and can be transmitted via fiberoptics. As they have little absorption for water, their primary tissue chromophore is pigment. In tissue that contains primarily water and no pigment, the laser will travel deep within the tissue before having an effect, leading to potentially uncontrolled tissue damage. In non-pigmented tissue, therefore, the only way for this laser to work safely and as expected on the surface tissue is to "initialize" the tip of the fiber with some pigmented material (e.g., carbon paper), which then picks up the laser and generates heat in the tip. Thus, much of this laser's effectiveness is based, not on direct tissue absorption by the laser, but rather on tip absorption and using the heat generated in the tip to affect the tissue. This hot tip cuts and cauterizes the surface using only the heat generated, not the laser wavelength itself, unless uninitiated and used for deeper pigmented tissue. Because of this, the diode laser is far less effective for surgical procedures, but is very popular with non-surgeons, who prefer this over the much more powerful and more efficient (but inherently more dangerous and difficult to control) lasers that directly use water as the chromophore.[6]

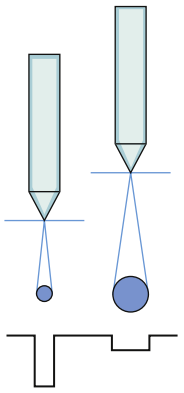
Lasers that have hemoglobin as their primary chromophore for absorption are often used when managing deep vascular lesions. Examples of these would include the copper or gold vapor lasers and the flashlamp-pumped tunable dye laser. Having a wavelength specificity for hemoglobin, and little for water in the surface cells, allows the laser to ablate vascular lesions with little to no effect on the overlying mucosa or skin.

Although the use of lasers in hard tissue has been more problematic, recent advances have made hard tissue laser surgery a possibility. Whereas intracellular water in soft tissue can be vaporized very quickly using a CO_2 or erbium laser, effectively vaporizing the rest of the cell, vaporizing hydroxyapatite in hard tissue with these lasers would require massive amounts of energy, and the resultant heat would damage adjacent structures. Newer erbium and CO_2 lasers, in the 9300-nm wavelength range rather than the typical 10,600-nm wavelength range, target the minute amount of water between the crystals of hydroxyapatite, causing them to explode and create a shock wave that removes hard tissue

somewhat effectively and with little heat generated. The new 9300 nm-CO_2 laser in particular has some allure for surgeons because it can be used for both hard and soft tissue.[7] However, few articles in the literature support these theoretical concepts as yet.

Regardless of the wavelength, all lasers in surgery use one of three operative techniques: incision, vaporization/ablation, and hemostasis/coagulation.[8] It is imperative that the surgeon understand when and how to apply these techniques, along with understanding their related physics, to obtain the best and safest surgical results. Incision is essentially using the laser as you would a scalpel to make a thin, deep cut in the tissue. This requires that the laser beam be focused down to a small point (with most lasers this is 0.1-0.4 mm), which concentrates the energy into a small volume, thus increasing the amount of energy per unit of area. This is termed power density (Figure 24-6). With a high power density and a small spot size of the laser, the result will be that the laser will cut deeply and thinly into tissue. This is the technique that would most commonly be used for incisions, excisions, biopsies, and so on. Vaporization/ablation is a technique that involves spreading out the laser energy into a larger spot size (generally 0.8-3 mm), resulting in a lower power density. This will produce very shallow removal of tissue, but over a larger area. Typically, this would be used to remove the surface tissues for leukoplakias, dysplasias, cosmetic skin resurfacing, and so forth. The final technique, hemostasis/coagulation, is used to control bleeding in tissue or to remove a vascular lesion. Lasers are inherently hemostatic when used for incision or vaporization, resulting from vascular contraction of adjacent vessels from the heat generated in lasered tissue. However, this will work only on vessels whose diameter is smaller than the zone of thermal spread from the laser wound. With regular (or continuous wave) CO_2 lasers, the zone of lateral thermal spread is approximately 300 to 500 μm. If a laser that is primarily absorbed by hemoglobin is used, deeper hemangiomas and vascular lesions can be ablated as well.

Accomplishing the techniques just described requires adjusting the spot size of the laser to change the power density. With fiberoptic lasers, which are mostly used in contact with the tissue, this is adjusted by choosing the width of the fiber (typically 300-800 μm). With non-contact lasers, such as the CO_2, this is most commonly done by moving the laser closer to or farther from the target, allowing expansion and contraction of the beam, much as one does with a magnifying lens. Putting the beam at the focal point, or smallest spot size, allows for high power density and incision. Moving the laser handpiece farther from the target allows for larger spot sizes, lower power density, and surface ablation.



• **Figures 24-6** Focusing and defocusing the beam to decrease or increase the size of the beam, and thus power density. Focusing causes a thin but deep cut, whereas defocusing causes a wider but shallower ablation.

Power density is based on the amount of power per unit of spot size. It determines the depth of laser effect per unit of time. A specific power density, of any laser, will cut or vaporize tissue to a specific and repeatable depth for each unit of time applied. However, the total depth of effect is dependent on how long the laser is used in total. A simple hypothetical example would be that a laser at 5 W of power and a 1-mm spot size might cut 1 mm deep into tissue for every second of use (of course this will depend on the specific laser and how much of its chromophores are in that specific tissue). In 1 s it will, indeed, cut 1 mm deep, but if used for 2 s, it will cut 2 mm deep, and so on. Thus, the complete extent of the cut is based on both the power density and the total amount of time that the laser is applied to the tissue. This is termed *energy density* or *fluence*.

One of the most important factors to be aware of with the use of lasers is the lateral spread of heat away from the intended target. Lasers generally work by creating heat within the tissues. Enough heat with a CO_2 or erbium laser can vaporize intracellular water or the water trapped in enamel and cut or ablate soft tissue, bone, and tooth structure. However, given enough time, some of that heat will leak away in concentric circles from the target and can damage normal adjacent tissues. A 10,600-nm CO_2 laser applied to the enamel of a tooth would take so long to have an effect on the hard tissue that the heat generated would be devastating to adjacent tissues and dental pulp. The way to prevent this from happening, unless you purposely want some lateral heat to contract adjacent blood vessels, is to apply large amounts of energy density in a very short period of time (microseconds to nanoseconds). This limits the time for lateral thermal spread and allows for precise laser effect in the target tissue with little lateral thermal leakage. For example, a 9300-μm CO_2 laser applied in ultrashort and very powerful bursts of energy can remove hard tissue with little time for adjacent tissue damage.[7] Manufacturers have applied many names and used different mechanisms to obtain this concept, such as Superpulsing, Ultrapulsing, Q-Switching, and Flashlamp Pumping. All are various ways to increase energy density while decreasing the duration of laser pulses in order to limit the lateral spread of heat.

When considering or performing laser surgery, the surgeon must always consider the correct choice of laser wavelength, the mechanism of delivery, the appropriate base technique (incision, vaporization, or coagulation), the parameters of power–time–spot size that will be used, and

the distance from that target that will provide the correct spot size. As you read through the various procedures in this chapter, try to keep these concepts in mind.

Common Laser Wavelengths

Since the first laser was used in live surgery in 1970 (the CO_2 laser), many wavelengths of lasers have been used in oral and maxillofacial surgery.[8,9] Some have persisted and are still used today (e.g., CO_2), while others have seen their commercial availability diminish or disappear due to improved specificity of newer laser wavelengths (e.g., argon). Choosing the correct wavelength laser for any particular surgical indication is a function of many variables, such as the type of effect desired (incision, vaporization, or coagulation), the intended target tissue and the chromophores it contains, the need for a micromanipulator, the preferred delivery system, and laser cost and availability. Outlined next are several commonly used lasers in oral and maxillofacial surgery.

Carbon Dioxide Lasers (10,600 nm)

Carbon dioxide lasers were the first lasers used in clinical practice and today remain the most commonly used laser in oral and maxillofacial surgery. These are highly efficient lasers that can be used for cutting, ablation, and to some degree, coagulation (although there are better lasers for this). Its main chromophore is water, and because water is the primary component of all soft tissues, it is generally considered the gold standard laser for all soft tissue surgery.

As with all lasers, the CO_2 laser emits a single monochromatic wavelength; however, this laser now has three different monochromatic wavelengths that can be produced. These wavelengths are the mid-infrared 10,600 nm (the traditional wavelength used since the 1960s), 9,600 nm, and 9,300 nm. The latter are newer wavelength CO_2 lasers, which allow for some uses not traditionally associated with this laser. These include cutting hard tissues, including tooth structure and bone. One such 9,300-nm CO_2 laser, the unique wavelength created by replacing normal $C^{16}O_2$ with isotopic $C^{18}O_2$ as the lasing medium, has recently been FDA approved for both hard and soft tissue use because of its high absorption for both water and hydroxyapatite. Preliminary studies indicate that this wavelength has effects in soft tissue similar to those of the standard 10,600-nm CO_2 laser.[10] The FDA approval for hard tissue is for enamel and dentin, but cutting bone is equally possible. Because the incredibly short laser pulse can be too fast for the brain to recognize any pain in many, but not all, patients it is also possible to perform the cutting of tissues without the need for local anesthesia.

Certainly, this is an important factor for patient comfort, but an equally important variable is the speed with which the surgeon can cut hard tissue with a laser versus other methods. Although this new laser wavelength represents an improvement in this regard, its time efficiency and practicality in oral and maxillofacial surgery remain in question. Although as yet there are few data in the literature to support its widespread use in oral and maxillofacial surgery, the development of combined hard and soft tissue lasers is a promising sign of the future of lasers in our specialty.

The traditional 10,600-nm wavelength CO_2 laser is available from many manufacturers. The basic difference between them is primarily based on the temporal delivery of the beam. Although all can be emitted as continuous wave (i.e., continually delivered from the laser tube and controlled only by a foot pedal or optical or electronic shutter), some are capable of being electronically pseudo-pulsed within the tube itself. Because they are not able to be pumped by a flashlamp, traditional optical "pulsing" is not possible. Pseudo-pulsing involves electronically over pumping the laser tube to increase the peak power while simultaneously decreasing the pulse width. By limiting the time the laser is applied to the tissue, the time for lateral spread is reduced and there is minimal lateral thermal damage. This is particularly useful for skin surgery where even small zones of lateral thermal damage result in significant scarring. However, the reduced zone of lateral thermal effect also decreases the ability of the laser to seal adjacent blood vessels.

CO_2 lasers can be delivered to the tissues in several ways. Regardless of the delivery system, the CO_2 laser, unlike most fiberoptic lasers, is always used in a non-contact fashion. This has some advantages in terms of ablational ability, but as there is no tactile sensation, it requires some additional time to feel comfortable with its use and control. While current glass fiberoptic cables cannot transmit the infrared wavelength of carbon dioxide, other types of fiberoptic cables (e.g., silver halide) are being investigated to transmit this wavelength. It is only a matter of time until these fibers become common in the clinical environment.[11] In the meantime, CO_2 lasers must be transmitted via articulated arms, hollow metal tubes with prisms at the articulations, or via waveguides, hollow flexible fibers that are mirrored on the internal surface. Hollow waveguide technology has improved over the past decade, and they almost mimic fiberoptics in their ease of use (Figure 24-7). The hollow waveguides remain non-contact, however, and are not easily used via endoscopy. Articulated arm technology is more cumbersome, but it does allow for microscopic attachment and the use of a micromanipulator.

Diode Laser (805-1064 nm)

Many manufacturers produce diode lasers, delivering wavelengths in the range of 805 to 1064 nm. They are compact and portable in design, and are relatively inexpensive surgical units with fairly efficient and reliable benefits for use in some soft tissue *oral surg*ical procedures (Figure 24-8). Although not as efficient as the CO_2 laser for soft tissue procedures, their relative safety, incredibly low cost (many are commercially available for less than $2000, compared to $12,000-$60,000 for CO_2), ease of use, and versatility have made them a common choice for minor office-based surgery, primarily by non-surgeons. However, most oral and

• **Figures 24-7** A current office based CO_2 laser. Note the hollow wave guide that allows flexibility similar to a fiberoptic guide. (Courtesy LightScalpel, LightScalpel LLC, Woodinville, WA.)

• **Figures 24-8** Portable diode laser. Most such diode lasers are small, inexpensive, and use fiberoptics, but are less efficient than CO_2 lasers.

maxillofacial surgeons find them too slow for the majority of surgical procedures when compared to the CO_2 laser.

Diode lasers can be used in continuous-wave or gated-pulse modes, and in contact or out of contact with tissue. The primary chromophore for most diode lasers is tissue pigments, with relatively little absorption by water. Thus, they are relatively poorly absorbed by most non-pigmented tissues and rely on the use of an external pigment applied to the end of the optical fiber (e.g., articulating paper melted onto the end of the fiber). This leads to wavelength absorption not by the tissue itself, but by the pigment on the fiber. This results in the tip becoming essentially red hot, causing the fiber to have a cautery-like thermal effect on the tissue. It is this thermal effect, not an optical effect, that results in the tissue effects. The 980-nm diode laser, however, with an optical penetration of less than 300 μm, has significantly higher absorption in water making and cuts somewhat more optically than thermally. Romanos and Nentwig found that the 980-nm diode laser produced a more precise incision margin compared with other diode laser wavelengths.[12] In addition to various other soft tissue oral surgical procedures, the 980-nm diode lasers have become as popular as CO_2 lasers in the treatment of peri-implantitis because they offer a bactericidal effect without causing implant surface alterations.[13]

Neodymium:YAG Laser (1064 nm)

The neodymium:yttrium-aluminum-garnet (Nd:YAG) laser's active medium is a crystal of yttrium, aluminum, and garnet doped with neodymium ions.[14] By functioning in the near-infrared part of the spectrum at 1064 nm, the Nd:YAG laser exhibits minimal surface tissue absorption and maximal penetration. This allows for coagulation of tissue in depth, but relatively inefficient surface cutting.[15] The optical delivery is free-running but must be used in a "pulsed" mode because of the Nd:YAG laser's ability to penetrate deeply into soft tissues. Romanos reported that most procedures could be performed without local anesthesia because the pulse duration is shorter than the time required to initiate a nerve action potential.[16]

Comparing Nd:YAG laser surgery to conventional scalpel surgery, White and colleagues concluded that the laser could be used successfully for intraoral soft tissue applications without anesthesia and with minimal bleeding.[17] When the procedure involves significant ablation or resection of tissue, however, local anesthesia is necessary for patient comfort.[15]

As with the diode lasers, the Nd:YAG laser can be used in contact (excision) or in non-contact (coagulation) mode. These properties have led to its use in a variety of maxillofacial procedures, including coagulation of angiomatous lesions, hemostasis in bleeding disorders, arthroscopic surgery of the temporomandibular joint (TMJ), resections in vascular tissues (in combination with CO_2 wavelength), and palliation of advanced neoplasms.[18] The Nd:YAG laser has demonstrated some benefit with minimally invasive

periodontal therapies, including sulcular debridement and bacterial decontamination, resulting in potential new attachment of gingival tissues, regeneration of supporting bone, and regrowth of periodontal ligament.[19] This procedure, termed the Laser Assisted New Attachment Procedure (LANAP), despite having FDA approval, has limited data to support it and is considered quite controversial.

Erbium Lasers (2780-2940 nm)

The erbium family of lasers, including two similar wavelengths, the Er:YAG and the Er:Cr:YSGG, have gained recent popularity in general dentistry and in dental implant surgery because of properties that they share. The erbium lasers are free-running, pulsed lasers with thermal effects that interact solely with the surface layers of soft and hard tissue due to their exceptionally high degree of absorption by water.[20] The beams are reflected by polished metal surfaces such as titanium, so they have no direct adverse effects on dental implants.[21] Application of the erbium lasers in dental implant surgery has been advocated for the preparation of hard tissue, second-stage surgery, revision of soft tissue, and treatment of peri-implantitis.[21-23]

Although the erbium lasers are capable of osseous surgery, such as crown lengthening, harvesting autogenous bone grafts, and sectioning teeth, these procedures require significantly more time than traditional methods.[24] For this reason, oral and maxillofacial surgeons, who spend much of their time treating osseous tissue, have generally not embraced erbium laser technology.

Because they are so well absorbed by water, the erbium wavelengths are rapidly extinguished by superficial layers of tissue, and this prevents significant penetration into the tissue. Although this limits their usefulness for deeper cutting or ablational procedures, it also allows for very superficial vaporization of tissue, which is ideal in some ways for skin ablation as used in cosmetic skin resurfacing. Recovery from skin resurfacing is very rapid due to the superficial effect, but also results in less long-term effectiveness when compared to CO_2 skin resurfacing.[25]

Benefits of Laser Surgery

The benefits of using lasers in surgical procedures are significant, for both the oral and maxillofacial surgeon and the patient. Laser light is monochromatic, coherent, and collimated; therefore, it delivers a precise burst of energy to the targeted area. Laser energy incises tissue more efficiently than the scalpel, generates complete vaporization, and coagulates blood vessels. For contouring procedures, the laser is perhaps the surgical instrument of choice because of its ability to sculpt soft tissues by selective ablation.

The hemostatic effect created when the laser's energy thermally interacts with collagen in vascular walls minimizes or eliminates excessive bleeding, a factor that has traditionally hindered surgeons, and creates a clean surgical field. This allows for increased precision and greatly improves visualization of the surgical site, making laser surgery easier and more accurate. Certainly, those lasers with absorption by hemoglobin are best for this purpose, although any laser that creates enough heat in the tissue to contract collagen in blood vessel walls will seal the vessels, leading to near-bloodless surgery as well.

Examined histologically, laser wounds have been found to contain a significantly lower number of myofibroblasts.[26] This results in less wound contracture or scarring and, ultimately, improved healing.[27,28] Mobility to the dynamic tissues (lips, tongue, floor of mouth, soft palate) is attained more readily postsurgically. As a result of improved healing and hemostasis, intraoral laser wounds can often be left without sutures, healing by secondary intention, except when cosmesis is a concern.

With laser technology, the patient typically experiences less postoperative swelling and pain.[29-31] A compromised airway during oral surgery is less of a concern, mainly due to the decreased swelling. Although not always predictable, the decreased postoperative pain can be managed with over-the-counter, non-narcotic oral analgesics for most laser procedures. The physiology of this effect is still unknown but most likely correlates with decreased tissue trauma and an alteration of neural transmission.[15]

Because the patient typically has a painless surgical experience with minimal postoperative complications, many procedures are performed on an outpatient basis. Patients can often return to work within 1 day or even immediately after surgery.

Disadvantages of Laser Surgery

Despite the laser's many advantages, when determining the appropriate treatment for a patient, the clinician also must consider its drawbacks. Although the healing process following laser surgery is generally marked by considerably decreased scarring and increased function, some have found that the speed of healing is slightly prolonged compared with other types of wounds.[25] This delay in healing is undoubtedly caused by the sealing of blood vessels and lymphatic channels and the subsequent need for neovascularization during healing. Typical intraoral healing after laser surgery may take as long as 2 weeks for wounds that would otherwise take 7 to 10 days to completely heal. If sutures are indicated, delayed healing times must be taken into account when considering suture removal, to prevent premature dehiscence of the wound.[9]

Unsutured CO_2 laser wounds heal by forming a fibrinous coagulum that functions as a biological dressing. Because of the slow epithelialization of CO_2 laser wounds, the fibrinous coagulum may be present beyond 2 weeks.[29] A clinician new to lasers should not confuse this healing process for infection and unnecessarily perform a wound debridement or prescribe antibiotics when there is no indication. Unlike postsurgical healing after conventional techniques, an increase in pain 4 to 7 days postoperatively may occur as nerve tissue regenerates, which can normally be controlled

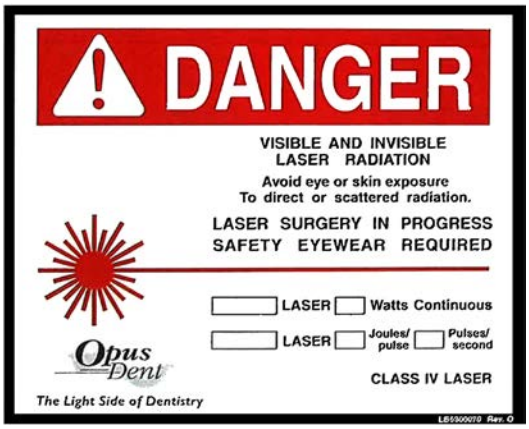
with minimal oral analgesics. The clinical appearance and anticipated discomfort after laser surgery should be discussed with patients to avoid confusion and prevent the perception of surgical complications.

Laser Safety

Lasers are incredibly useful tools in the armamentarium of the oral and maxillofacial surgeon. However, because of their optical properties—including non-contact surgery by many wavelengths and intrinsic collimated and coherent beams, which if not altered or focused, allow the beam to travel long distances with unrestrained effect—they also have inherent dangers. Therefore, laser safety is paramount to the use of lasers for oral and maxillofacial surgical procedures. All laser equipment should be thoroughly inspected and tested on an inert object, such as a moistened tongue blade, before patient use to confirm proper energy levels and safe operation of the laser. Adequate precautions must be taken to prevent inadvertent exposure of operating room personnel and the patient to unintentional laser energy not directed toward the therapeutic target tissue. Upon completion of the energy delivery to the operative site, the machine should be inactivated before moving the laser to prevent inadvertent laser burns to the patient or operatory personnel. The operatory room door must be closed during the procedure, and warning signs indicating the use of the laser and requiring additional eyewear must be placed on the operatory doors while the laser is in use (Figure 24-9). Generally, when performing laser surgery in an operating room, there will be a nurse designated as the "safety officer" to oversee laser use and ensure that proper safety measures are followed.

Problems of inadvertent laser exposure can include corneal or scleral scarring by direct exposure and retinal damage with some wavelengths not absorbed by water, making the use of wavelength-specific safety glasses with side shields mandatory (Figure 24-10). If the patient is receiving periorbital laser therapy, metal corneal shields with topical anesthetic and lubrication must be used (Figures 24-11 and 24-12). Otherwise, the patient's eyes should be completely covered with laser glasses or moistened towels.[32] The resultant laser plume should be properly evacuated via high-power vacuum with high-efficiency particulate arrestance (HEPA) filters held near the operative field, along with the use of viral filtering face masks to prevent possible contamination of operating room personnel with bacteria or viruses during laser procedures (Figure 24-13).[33]

The use of nonflammable surgical skin preparations containing no alcohol, such as povidone-iodine (Betadine) or hexachlorophene, should be followed by wiping with sterile water to prevent skin color changes. The use of isopropyl alcohol or chlorhexidine preparations containing alcohol should be avoided because of potential flammability with pooling in facial crevices or potential flammability with vaporization of the alcohol after the facial application.[33,34] Nonflammable patient drapes for use with lasers or moistened towels should also be used. The teeth must also be protected with moistened gauze or commercial silicone teeth protectors when using the laser around the mouth or intraorally because enamel can be damaged by absorbed laser energy along with possible thermal damage to pulpal tissue from heat conduction.[17] Protection of adjacent oral tissue from damage is also required, such as the use of wet sponges, moistened tongue blades, and nonreflective ebonized instruments, to prevent unintentional tissue damage.



• **Figures 24-9** Warning signs indicating the use of the laser and requiring additional eyewear must be posted on the operatory doors while the laser is being used. (From Convissar RA: Principles and practice of laser dentistry, ed 2, St. Louis, 2016, Elsevier.)

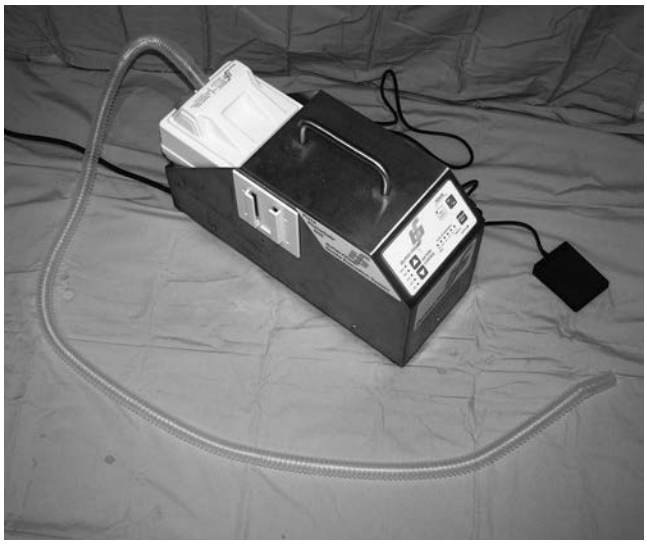
• **Figure 24-12** Corneal shield. These are easily placed with topical anesthesia. When using a laser, the shield should be metal and not plastic to prevent perforation.



• **Figure 24-13** Typical laser HEPA evacuator.

The use of lasers in the presence of supplemental oxygen requires the use of precautions to prevent inadvertent fires. Patients under general anesthesia should be intubated with a commercially available reflective or absorptive material-covered endotracheal tube specific for laser use or have the tube wrapped with non-reflective foil to prevent a possible fire in the endotracheal tube, which with pressurized oxygen can create a torch-like effect. The cuff should be inflated with normal saline versus air, and the tube should additionally be protected with wet sponges if exposed intraorally. If the patient is being sedated and supplemental oxygen is used via a nasal cannula or face mask, care must be used to prevent ignition of items within the airway, and the oxygen delivery cannula or the mask should be wrapped in foil to prevent an airway fire. There are also commercially available reinforced endotracheal tubes wrapped with foil or silicone material.[34] Oxygen can be delivered through a nasopharyngeal airway under low flow while packing off the posterior pharynx with moistened gauze. Supplemental oxygen should be used at a low flow or can be turned off while the laser is being used. Many anesthesia machines are now fitted with compressed air tanks to limit the concentration of oxygen. The use of facial drapes that can cause a high oxygen concentration to accumulate under the drapes, possibly leading to a fire, should be avoided. Saline or sterile water should also be readily available to extinguish an airway fire if needed.

Intraoral Laser Soft Tissue Surgery

The use of lasers in oral and maxillofacial surgery has continued to evolve since its introduction in 1960 by Theodore Maiman.[2] Lasers have commonly been used to treat a variety of pathologic conditions, and the use of lasers for other modalities has continued to grow. The laser has proven to be a useful tool within the practice of oral and maxillofacial surgery for procedures, such as implant uncovering, gingival recontouring, surgical exposure of teeth, frenectomy, treatment of maxillofacial vascular and pathologic conditions, cosmetic skin resurfacing, laser-assisted arthroscopic TMJ surgery, and many other applications. The use of the laser within oral and maxillofacial surgery continues to progress with new radiant-energy wavelengths and lasing mediums, decreased cost of laser units, and new clinical indications and applications.

Polanyi initiated the use of lasers for oral and maxillofacial surgery with the use of a CO_2 laser to incise living tissue with the development of a handheld laser delivery system.[9] The CO_2 laser remains the most commonly used laser for oral and maxillofacial surgery as a result of the excellent absorption of the 10,600-nm infrared laser wavelengths by tissues with high water content. A multitude of other lasers (i.e., argon, holmium:YAG, erbium:YAG, neodymium:YAG, diode, copper vapor, low-level, KTP, dye, ruby, and alexandrite) are used for selected applications in oral and maxillofacial surgery.[8]

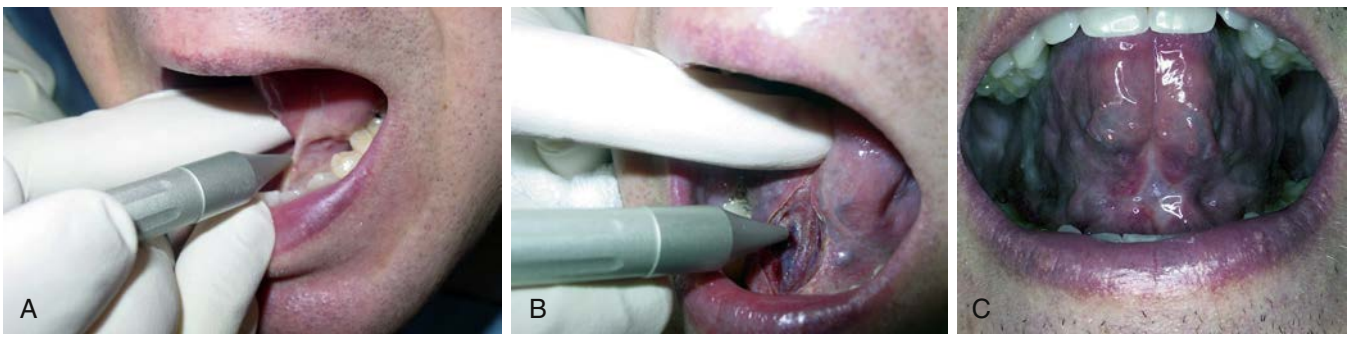
Oral mucosa has a 90% water composition, making it ideal for absorption of infrared CO_2 laser energy. CO_2 laser energy is absorbed by intracellular water, resulting in a photothermal effect. The laser energy–associated photothermal effect results in cellular disruption and vaporization of the mucosal tissue. A zone of lateral thermal damage (500 μm or less) is created in adjacent tissue via heat generation and conduction. This allows for coagulation of vessels of the same or less diameter.[8,32] CO_2 lasers provide excellent coagulation and hemostasis with an associated decrease in wound contracture and scarring, as a result of decreased fibrosis with wound healing.[26] Other benefits of laser surgery include decreased postoperative pain and edema. The laser can also be used in areas of limited exposure within the oral cavity where surgical access with conventional techniques can be difficult. Lasers do have the disadvantage of delayed wound healing (2 to 3 weeks) when compared to conventional surgical techniques (7 to 10 days) because laser wounds are slower to epithelialize. Mucosal laser wounds heal by secondary intention as a fibrous coagulum initially covers the wound and is slowly replaced by epithelial migration from the wound margins.[30]

Laser soft tissue surgery allows for minimal adjacent tissue damage, provides excellent wound hemostasis, decreases surgical and postoperative pain, and decreases surgical site infection via bactericidal effects.[30,33] Postsurgical bacteremia is also reduced via sealing of adjacent vascular and lymphatic vessels.[33] The CO_2 laser is set on a continuous wave in a range of 2 to 10 W with a spot size of 0.1 to 0.5 mm for most incisional and excisional procedures. In a focused mode the power per unit area is maximized, and at the focal point, the smallest spot size, the laser is used to produce an incision of a controlled depth and thinnest width. The laser can also be defocused to permit coagulation of blood vessels (up to 500 μm in diameter) to aid in hemostasis.[8]

During laser excision of a labial or lingual frenum, the mucosa and underlying muscles are easily excised (Figure 24-14). Following the administration of local anesthesia, the frenum attachments are separated and the surrounding tissue is preserved. The wound demonstrates complete hemostasis, and suturing is rarely required. Following laser frenectomy, the wound heals more slowly than those done with sharp dissection, although the patient will usually experience less postoperative pain.

The laser can be used to excise mucosal lesions, which is frequently performed in an elliptical manner (Figure 24-15). Including an additional soft tissue margin, usually extending 0.5 mm beyond the normal surgical margin, allows for a laser-induced zone of lateral necrosis within the specimen. This allows for more accurate histopathologic interpretation, as the zone of lateral necrosis can be difficult to interpret histologically.[8] The subsequent wound can be closed with sutures or left to granulate. Ranulas and mucoceles can be is treated with the laser by excising the covering layer of mucosa at the periphery for marsupialization or by undermining the lesion followed by complete excision (Figures 24-16 and 24-17). The laser will provide excellent hemostasis of the surgical site. The need for counter-traction is negated with the use of the laser in the floor of the mouth and other areas of freely movable mucosa. The surface of the ranula can be vaporized instead of marsupialized with no difference in recurrence.[35] Laser-assisted sialolith excision in the floor of the mouth is performed by incision through the mucosa and salivary duct in the area of the stone. A flash of light is noted once the stone is encountered with the laser, and then the sialolith can then be removed. The wound is left to granulate, without suturing, to prevent stricture or obstruction of the underlying salivary duct.[8]

Laser treatment has been advocated for benign and premalignant oral lesions, such as leukoplakia, erythroplakia, epithelial dysplasia, hyperkeratosis, lichen planus, nicotine stomatitis, actinic keratosis, and others. Laser treatment of mucosal lesions also permits the ablation or vaporization of tissue at controlled depths of less than 1 mm while simultaneously preserving the submucosal tissue (Figure 24-18). This is performed with the use of high power density at short application times or, more commonly, in a defocused mode to maximize the spot size and minimize the depth to the surface epithelium only. Mucosal lesions and premalignant lesions can be adequately managed with laser vaporization or ablation, as there is no significant increase in the number of recurrences when compared to traditional



• **Figure 24-14** Frenectomy. **A**, Incising the frenum in focus. **B**, The frenum has been excised. Note the lack of bleeding. **C**, Healing after 2 weeks.

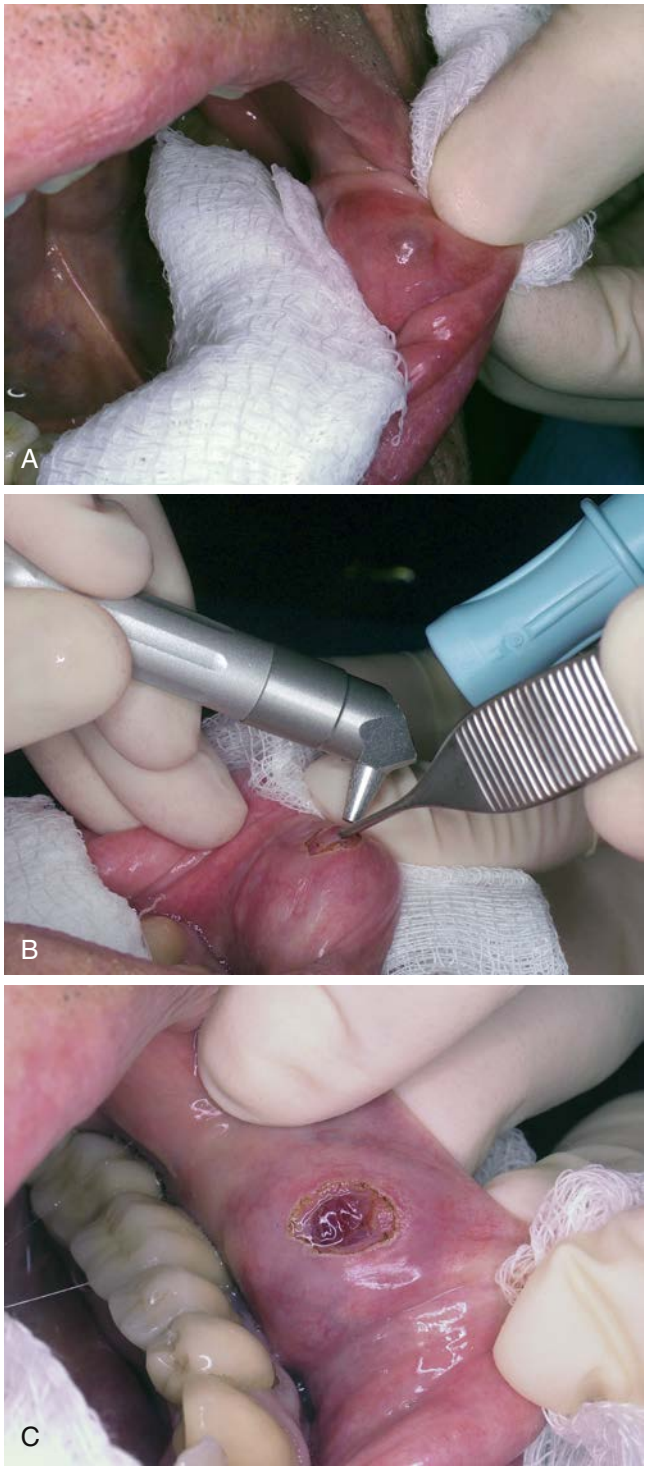
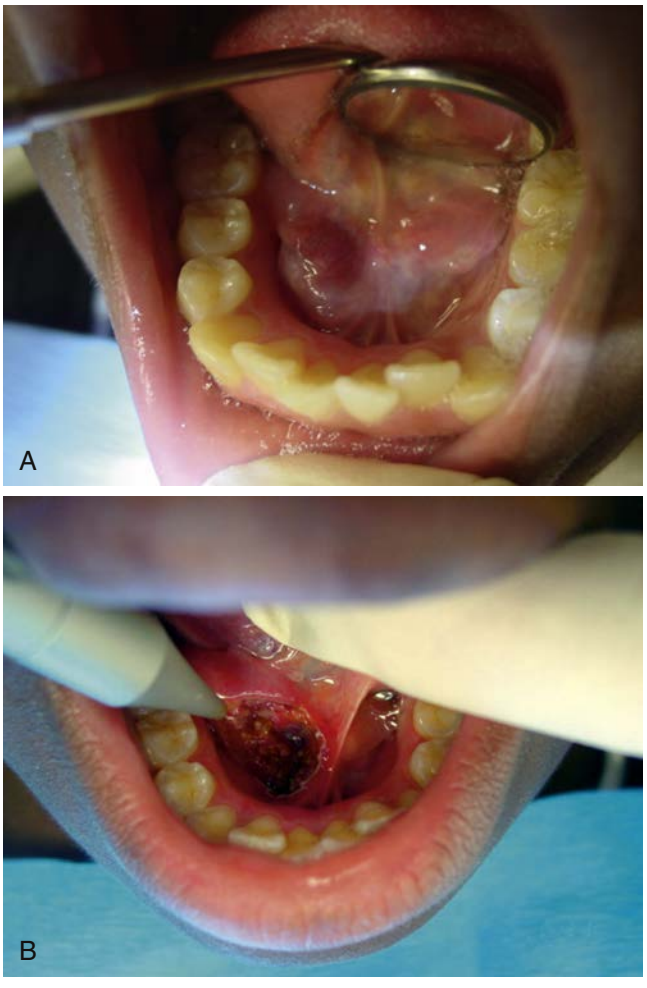
methods of treatment.[8] All lesions should have a definitive diagnosis before laser therapy because laser vaporization or ablation does not provide a tissue sample for histopathologic review. Defocusing the laser beam produces a rapid bubbling of the epithelium and crackling noise as the epithelium turns opalescent, leaving a light-colored base after char removal.[33] The mucosal lesion is first outlined, and then treated by complete coverage of the entire lesion surface with the use of a vertical or horizontal paralleling "U" pattern to evenly treat the entire lesion. A second pass in a direction perpendicular to the first pass using a similar "U" pattern can be performed if an inadequate depth was obtained initially (Figure 24-19). This ensures complete and even treatment of the lesion.[8] In continuous mode, vaporization removes approximately 200 to 400 μm of epithelium per pass. Ablation to the level of the basement membrane preserves submucosal structures and prevents wound hemorrhage. Mucosal ablation allows re-epithelialization from the wound margins as well as from the epithelial adnexal structures. Ablated areas of 1 cm^2 or less generally re-epithelialize in 2 to 3 weeks.[36] Benefits of laser treatment versus standard excision include decreased scarring, less potential to damage associated vital structures, preservation of tissue elasticity, and decreased need for reconstructive surgery, which can alter the detection of recurrent lesions.[33] Laser treatment is advocated for the treatment of multifocal or diffuse mucosal lesions where



• **Figure 24-16** Mucocele removal. **A**, Outline and incising around the mucocele in focus. If the mucosa is intact, the overlying mucosa can be linearly incised rather than excised. **B**, Undermining and removing the lesion in focus. **C**, Lesion removed and left open to heal.



• **Figure 24-17** Ranula marsupialization. **A**, Ranula in anterior floor of mouth. **B**, Using the laser in focus to excise the top of the ranula, exposing the bottom of the ranula, which then becomes the floor of the mouth.

sharp excision is impossible due to the large surface area involved by the lesion. Laser treatment of diffuse or multifocal mucosal lesions avoids excision and produces minimal underlying or adjacent tissue damage while simultaneously minimizing pain, edema, and scarring.[37] The neomucosa formed by the lased wound behaves like normal mucosa

• **Figure 24-19** Ablation technique. The laser is defocused and used in a series of U-patterns to ensure even coverage of the lesion.

and permits additional laser treatment of recurrent lesions. As with any other surgical treatment of mucosal lesions, long-term reevaluation must be performed.

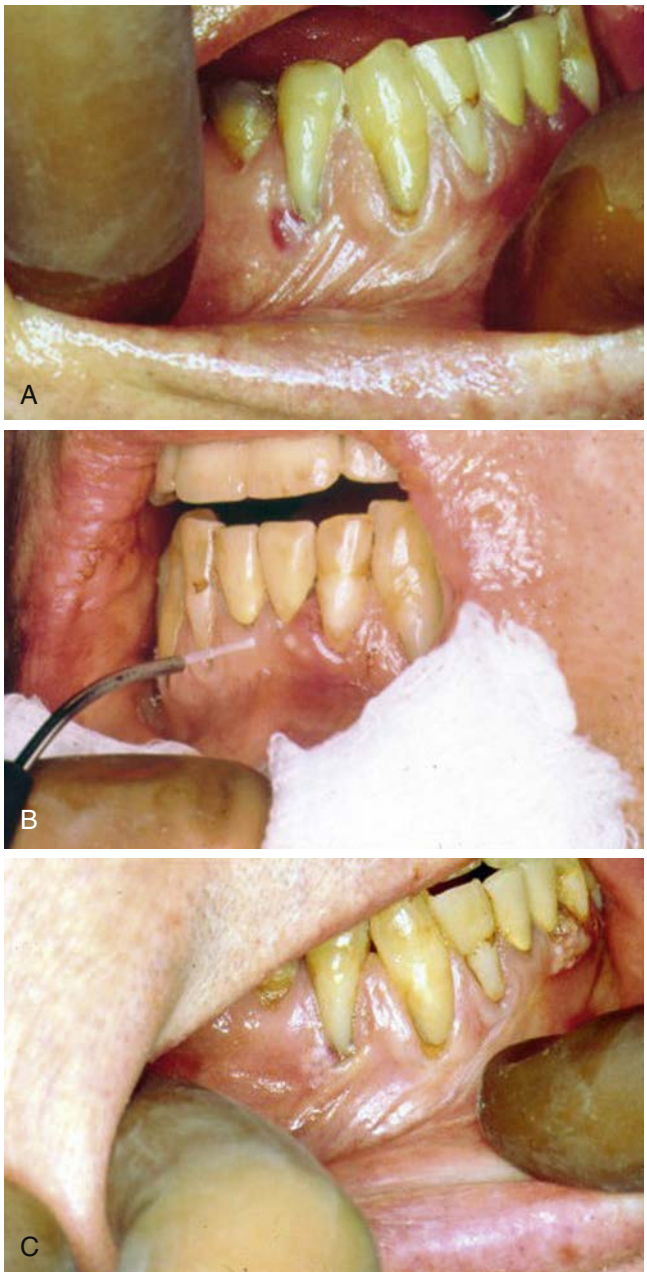
Histologic studies of wound healing following laser treatment have shown some carbonization, coagulation necrosis, intercellular voids, and areas of cellular vaporization.[38] The lasered wound exhibits fewer myofibroblasts in the wound with resultant minimal wound contracture and scarring.[37] The spread of malignant or premalignant cells is also limited by the laser-induced coagulation of adjacent blood and lymphatic vessels.[39]

Lasers can be used to treat intraoral vascular lesions (i.e., hemangiomas, telangiectasias, vascular lakes, and varicosities) because certain laser wavelengths are highly absorbed by hemoglobin and the lesion itself can be ablated (Figure 24-20). With lasers that are not absorbed well by hemoglobin, they can be used on adjacent normal margin tissue and the associated lateral thermal heat produced causes vascular constriction by contraction of collagen in the vessel walls (Figure 24-21). Thus, the vascular lesion can be excised in toto in the normal adjacent tissue without actually cutting into the vascular lesion and with little bleeding. The CO_2 laser, for example, can be used to contract vessels up to 500 μm in diameter. A variety of lasers can be used for the treatment of intraoral vascular lesions, including the CO_2, argon, copper vapor, tunable dye, and neodymium:YAG lasers using one of these techniques.[40]

Laser therapy has also been used as an adjunctive tool in oral medicine to treat ulcerations associated with aphthous and herpetic stomatitis. Aphthous stomatitis has responded well to diode laser therapy with an overall reduction in pain and duration of the lesions.[41]

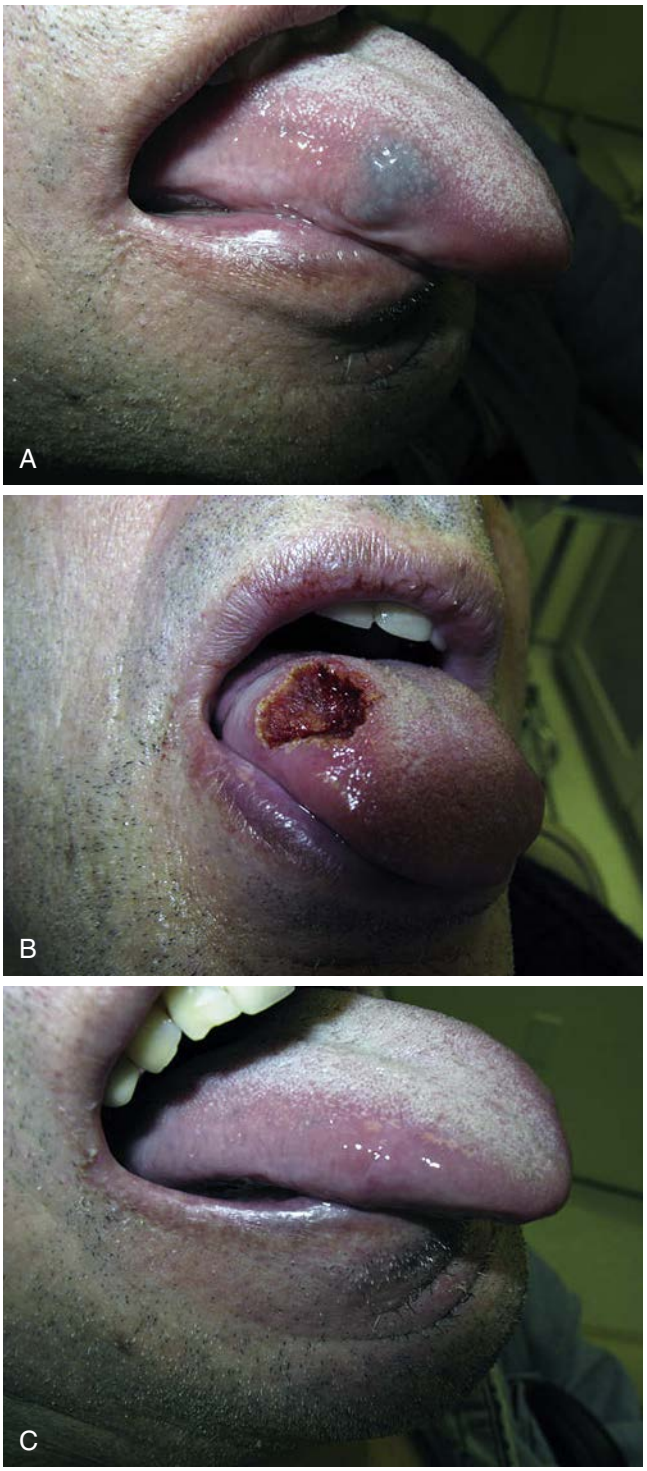
Low-Level Laser Therapy

Traditional lasers that have physical effects, primarily the formation of heat, in tissue are termed *therapeutic* lasers. Some lasers are used at such lower powers that they have no heat-producing abilities within tissue and are termed *athermal* or *low-level lasers*. Low-level laser therapy (LLLT) uses



• **Figure 24-20** Vascular lesion removal using a KTP:YAG vascular specific laser. **A**, Hereditary hemorrhagic telangiectasia lesion of the right mandibular gingiva. **B**, The KTP:YAG laser used in non-contact fashion to ablate the lesion. **C**, The lesion is ablated after approximately 10 pulses.

a phototherapeutic process with wavelengths in the visible and near-infrared, invisible range of 400 to 980 nm and a low power of 1 to 75 mW.[42] Most of these devices are diode lasers and, when in the visible spectrum, essentially resemble large lecture-type laser pointers. Low-level lasers can be used for phototherapy to deliver a small amount of energy to exposed living cells with minimal to no appreciable heat production and beneficial cellular effects labeled as *biomodulation* or *biostimulation*. The effects of LLLT were not recognized in the United States as FDA-accepted therapy until recently, and there are still limited numbers of indications that have been proven to be objectively improved



• **Figure 24-21** Vascular lesion of tongue. **A**, Hemangioma of right tongue. **B**, After laser excision using a CO_2 laser in focused mode. Note the lack of bleeding. **C**, Tongue healed after 6 weeks.

with LLLT. This has resulted in "off-label" use by health care practitioners and others for a wide variety of questionable indications. However, more recent data indicate that LLLT can indeed be of value in some cases, including TMJ disease, postoperative surgical management, and chronic mucositis.[43,44] Because they are of such low power, low-level lasers are classified by the FDA as having no significant associated

medical risks and require no specific precautions other than eye protection and avoidance of use on cancerous tissues, the thyroid, reproductive organs, infected wounds, with pregnant patients, and patients with cardiac pacemakers.

The effects of LLLT are not completely understood, but benefits on living tissues have been proposed as a result of multiple mechanisms that include changes in microcirculation, cell membrane potential, increased cellular metabolism, activation of cellular enzymes, increased wound healing, decreased inflammation, increased oxygen consumption, and other changes. There is recent evidence that many of the effects are related to the increase in adenosine triphosphate (ATP) production within the mitochondria of the cells involved.[45] The changes produced by LLLT result in a photochemical effect on biologic molecules within tissues to affect the cell by altering the cellular reactions, membranes, energy use, and metabolism to produce a therapeutic effect on the tissues in the area of the therapy. LLLT may also stimulate production of substances such as prostaglandins, endorphins, enkephalins, and other vasoactive or pain-modulating chemicals, resulting in decreased pain, decreased inflammation, and increased healing.[46]

Lasers and Wound Healing

There have been many studies undertaken to associate the use of LLLT with wound healing. The possible association of LLLT with increased wound healing has been postulated because of alteration of the fibroblast response and collagen production to result in more efficient and faster wound healing.[46] The effects have been documented in animal studies, and current beneficial applications include the possible use with diabetic wounds, infections, and tissue grafting.

Effects of Lasers on Postoperative Pain and Swelling

The use of LLLT to modulate the pain response has also been investigated and proven to be beneficial. LLLT has been shown to modulate the pain response by producing an analgesic-like effect, possibly by increasing the pain threshold and modulating the pain response of nerves. The inflammatory response to prostaglandins may also be altered to decrease the amount of overall inflammation, edema, and pain associated with surgical procedures postoperatively. Overall, results have been somewhat inconsistent regarding the pain response with LLLT following extraction or surgical removal of teeth, but meta-analysis does indicate some positive effects of LLLT.[47] The use of LLLT with nerve paresthesias has also been evaluated, with patients reporting improved sensation and comfort following the use of LLLT. Multiple studies have shown LLLT to be beneficial in the treatment of paresthesias, resulting in a reduction in the severity and a decrease in the overall distribution of the sensory changes. To date, however, most of the evidence regarding LLLT and nerve injury is not well proven.[48] The ability of LLLT to modulate healing and postsurgical pain needs additional investigation with controlled studies to determine the overall benefits of LLLT with surgical pain and edema because optimal laser energy levels, exposure times, and number of optimal treatments should be evaluated.

Laser Use in Dental Implant Surgery

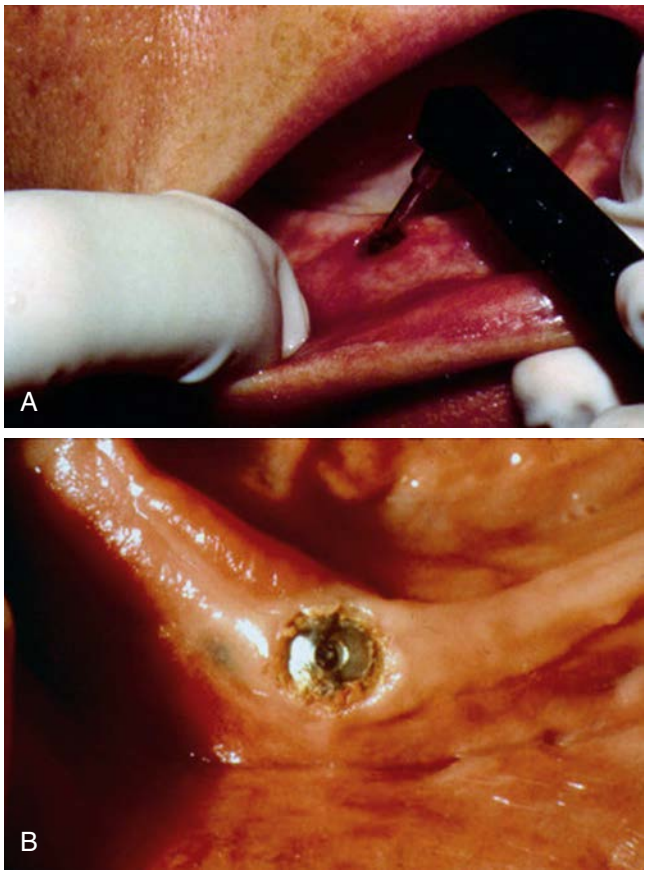
Lasers can be used in dental implant surgery with the advantage of potentially soft tissue and bone cutting combined with hemostasis. Both types of laser use decrease pain and edema related to the surgical procedure as a result of decreased mechanical and thermal trauma to the adjacent tissue. The CO_2 laser is an excellent laser for peri-implant soft tissue surgery because the laser energy is not absorbed but reflected by titanium.[8]

The soft tissue flap for implant surgery can be incised with the laser through cellular water vaporization with thermal rupture producing tissue ablation. The thermal-mechanical tissue ablation results in minimal adjacent tissue damage of the extracellular collage matrix to 5 μm or approximately two cell widths. Minimal tissue shrinkage of 0.5 mm is encountered when compared with the 3 mm of shrinkage associated with incision of soft tissue with a blade.[49]

Laser therapy has proven beneficial in some adjunctive implant-associated procedures. Lasers can be used to osteotomize the lateral sinus wall with a decreased incidence of perforation of the sinus membrane during maxillary sinus augmentation. The use of the yttrium-scandium-gallium-garnet (YSGG) laser with a 2780-nm wavelength has been used to prevent iatrogenic perforation of the sinus membrane with the osteotomy and initial flap elevation.[49] The intact sinus membrane eliminates the need for placement of a covering membrane to prevent loss of grafted bone associated with sinus membrane dehiscence. The use of the YSGG laser for osteotomy of ramal bone or symphyseal bone has been described. Laser use for autogenous bone graft harvest decreases the amount of donor site bone necrosis, decreases the osteotomy diameter when compared to rotary instruments, and results in a quicker and less painful postoperative healing period.[50]

The laser can also be used for second stage implant uncovering (Figure 24-22). The laser results in less overall tissue trauma, allowing for preservation of the attached gingival tissue adjacent to the implants. The technique of laser exposure of implants can be beneficial for optimal soft tissue preservation and maintenance in the aesthetic zone.

Laser treatment of peri-implantitis is another area that has been investigated. Peri-implantitis can be a difficult-to-manage implant-related complication, resulting in progressive loss of peri-implant bone secondary to bacterial contamination and penetration of the tissues. Common treatment regimens have centered on antimicrobial therapy (chlorhexidine, citric acid, tetracyclines) in combination with surgical treatment to facilitate chemical or mechanical debridement of the contaminated implant surface. The therapeutic goal is to decontaminate the implant surface and surrounding tissues to promote



• **Figure 24-22** Implant uncovering. **A**, Using a CO_2 laser to remove the tissue overlying the implant. This can be done using a combination of focused and defocused mode. **B**, The implant exposed.

regeneration of the peri-implant bone and periodontium. Problems with traditional therapy include limited effectiveness of antimicrobials and potential damage to the implant surface with mechanical debridement.

Diode lasers have been proven to be beneficial for antimicrobial decontamination of the implant and peri-implant tissues. Treatment of peri-implantitis with the diode laser at 905 nm for 1 minute following application of toluidine blue to sensitize the bacterial cell membrane to the laser light has been reported.[13] The CO_2 laser has also been used for the treatment of peri-implantitis with no alteration of the implant surface, which has been encountered with the use of the Nd:YAG laser.[13] Laser treatment of peri-implantitis has been beneficial before bone grafting of peri-implant defects following removal of the surrounding tissue and implant surface contamination. Care should be taken when the laser energy is directed to the implant surface to prevent elevation in temperature of the implant-bone interface above the 47° C threshold of potential thermally related bone necrosis.[8]

Laser-Assisted Temporomandibular Joint Surgery

The use of lasers for treatment of pathologic conditions of the TMJ has developed over the past few decades as both laser and arthroscopic technology have progressed. The use of both lasers and arthroscopic access to the TMJ represent a major development for TMJ surgery by providing a less invasive form of treatment than traditional open joint surgery.

Ohnishi initiated arthroscopic surgery of the TMJ in 1975 with the first reported diagnostic arthroscopy.[51] McCain and Sanders advanced the use of diagnostic and therapeutic arthroscopic TMJ surgery within the United States in the 1980s.[52] Indresano and Koslin then initiated the use of laser-assisted arthroscopic TMJ surgery to provide visualization of the joint and simultaneously allow surgical manipulation of intra-articular tissues.[53,54]

Early difficulties in laser-assisted arthroscopic TMJ surgery included the inability to use a CO_2 laser as a result of the inflexible optical system and inability to transmit laser waves through a liquid medium.[54] The Nd:YAG laser presented difficulty in controlling the beam depth and adjacent tissue damage. The use in 1990 by Koslin of the holmium:YAG laser for arthroscopic use in small joints was a major achievement in arthroscopic TMJ surgery.[54] The holmium:YAG laser is able to transmit energy through a fluid medium with good absorption by tissue within the TMJ and minimal lateral thermal damage. The holmium:YAG laser has good adaptability for use with arthroscopic cannulae. Holmium:YAG laser assisted TMJ surgery can be used for synovectomy, disc repositioning procedures, intrajoint hemostasis, treatment of hypermobility, and recontouring of perforated discs.

Techniques of arthroscopic-assisted laser therapy of the TMJ are fairly standard. The joint is accessed by traditional arthroscopic techniques with the introduction of a second cannula for laser insertion. Correct portal placement through McCain's techniques using anatomic measurements and palpation allows adequate joint access while minimizing the potential complications of arthroscopic surgery.[55] Triangulation is used to position the laser for treatment of intraarticular pathologic conditions. Ohnishi developed a double cannula, which permits simultaneous and parallel positioning of the arthroscope and laser within the joint.[14]

The holmium:YAG laser can be used arthroscopically for the treatment of a variety of derangements of the TMJ as expertly described and documented through the excellent works of Koslin. Patients with painful anterior disc displacement and no improvement following conservative splint or nonsurgical arthroscopic manipulation are candidates for arthroscopic laser surgery. Nonsurgical treatment can rarely decrease the popping, clicking, or other loud noises with joint function.[55] Painful anterior disc displacement with or without close locking is commonly treated with laser-assisted arthroscopic surgery.

The laser-assisted surgery is performed by dividing the adhesions causing anterior release and freeing of the disc. The anterior synovial tissue and disc attachment are divided to the level of the lateral pterygoid muscle from a medial to lateral position. The laser is used by lightly contacting the synovial tissue at a power of 1 J and a setting of 8 pulses/s,

providing simultaneous resection of the synovium and hemostasis.[54] The thickened anterior disc tissue acts as a ridge limiting condylar movement and produces loud popping or clicking as the condyle passes onto the disc. The thickened disc tissue is thinned using the laser at 0.5 J and 14 pulses/s.[56] The disc is mobilized from the anterior attachments with the laser and then repositioned posteriorly with a blunt probe. A suture is placed through the posterior disc and synovial attachment and retrieved through the accessory portal. The disc is repositioned posteriorly with the aid of the suture, and the retrodisc synovial tissue is thinned using the laser. Care is taken to prevent lasing the tissue at the oblique protuberance to prevent tethering and limited mobility of the disc.[56] The disc is repositioned in a more posterior position and stabilized by the shrinkage of the posterior synovial tissue and the stay suture. Postoperatively the patient is placed into physical therapy with a goal maximum vertical opening of 35 mm.[56] The patient is maintained on a soft diet, and a splint can be maintained over a 3-month postsurgical recovery period to diminish postoperative pain and residual joint noise.[56]

Joint adhesions at one time were thought to be a significant contributor to TMJ dysfunction. Present literature and experience by Koslin has indicated that joint adhesions are not as common as once thought and only result from severe inflammatory joint disease or trauma-induced intraarticular joint bleeding.[56] Adhesions are most commonly seen in the anterior joint recess and can limit joint mobility and function. Arthroscopically aided lysis and lavage can be performed to break the adhesions with a combination of irrigation to distend the joint and arthroscope or blunt probe manipulation to sweep the joint. The holmium:YAG laser can also be used to break the synovial adhesions by ablation. The laser ablates the adhesions at the point of attachment to the fossae by using a 0.5-J setting at 14 pulses/s.[56]

Hypermobility of the TMJ is exhibited by patients who displace the condylar head anterior to the articular eminence, which results in the inability to reduce the joint or severe pain with reduction. TMJ hypermobility has been previously treated with eminectomy, translation-blocking osteotomies, bone grafts, plating, and lateral pterygoid myotomy. Laser therapy can treat TMJ hypermobility through coagulation and fibrosis of the retrodiscal tissue to produce a contractile force and stabilize the disc in its new position. Other treatment options include arthroscopic laser scarification of the oblique protuberance combined with suturing of the posterior disc attachment for disc stabilization. The holmium:YAG laser is used to coagulate the tissue at 20 W power for 0.5 seconds in conjunction with triangulation and positioning through the helium-neon aiming beam.[56] Joint hypermobility can also be treated with the use of a holmium:YAG laser on redundant tissue of the medial capsule to cause fibrosis and stabilization. The holmium:YAG laser provides less tissue penetration than the Nd:YAG laser. The KTP laser provides benefits similar to those of the holmium:YAG laser. All of the laser-assisted joint procedures reduce the anterior joint space and overall mobility of the condyle within the glenoid fossa. Postoperative physical therapy limits joint movement to prevent immediate subluxation of the joint. Ideally the joint opening should be restricted to 30 mm for a period of approximately 3 months to allow the joint tissue to normalize. The use of postoperative occlusal splint therapy is not necessary.[56]

Arthroscopic laser treatment of hyperplastic and hyperemic synovium can be performed as an alternative to motorized shavers or electrocautery devices.[56] Inflammatory joint disease is commonly a result of mobility or dysfunctional problems associated with the TMJ. Patients can also exhibit pain with no identifiable internal derangement on imaging, possibly related to parafunctional habits, excessive loading of the joint, or arthritides. These inflammatory conditions of the joint can be diagnosed by arthroscopy and treated with the use of lasers. Laser-assisted synovial surgery can target areas of synovial abnormality better than rotary shavers or electrocautery and spare healthy adjacent tissue from thermal or direct mechanical damage.[56] The use of the laser is much more precise and controlled than mechanical treatment of the synovial pathologic condition. The technique uses a holmium:YAG laser at a distance of approximately 3 mm from the synovium directed by a helium-neon guide beam at 0.5 J and approximately 10 pulses/s.[56] The synovium will slightly blanch from an erythematous state and constrict, with no burning or scar production, as the areas of pathologic synovium are treated with the laser. Selected steroid injections of the inflamed synovium can be performed before exiting the joint. Physical therapy, with a graduated goal of obtaining 40 mm of opening, is initiated along with the use of a soft diet and occlusal splint therapy.[56]

TMJ disc perforations can also be treated with the use of the arthroscope and laser. Traditional articular disc perforation surgery involved open-joint techniques of disc repair or meniscectomy, with or without replacement. Ideally, the condition of the bony condylar head should be evaluated radiographically before any laser treatment of a disc tear or perforation is performed. Bony changes of the condylar head on the articulating surface are a contraindication to any attempt at an articular disc repair. Arthroscopic laser-assisted treatment of disc perforations or tears is performed to attempt disc preservation and prevent the need for disc replacement procedures with grafting. Torn fragments of disc can be smoothed, and the disc can be recontoured with the laser. The Nd:YAG laser on 0.5 to 1 J of energy and 14 pulses/s can be used to remove and recontour fragmented discal tissue through triangulation techniques.[56] The reduction of any disc tears or fragments should permit the free function of the condyle. Disc recontouring can be combined with disc repositioning procedures through an anterior release to relocate the area of the perforation away from the area of condylar function.[56] Physical therapy, soft diet, and use of a splint are recommended postoperatively to prevent the development of disc adhesions immediately after surgery. Meniscectomies can also be performed by laser-assisted arthroscopy with the use of a holmium:YAG

laser to remove the disc followed by rotary contouring of the condylar head and glenoid fossa.[57]

Laser-assisted arthroscopic TMJ surgery can be associated with certain risks. The risks are similar to those for diagnostic and surgical arthroscopy of the TMJ and include facial nerve injury, otic injuries, including perforation of the tympanic membrane and external auditory canal, intracranial perforation, significant hemorrhage, extravasation of fluid, and instrument breakage.[58] The laser can actually be beneficial in relation to some complications of standard TMJ arthroscopy, such as intraoperative bleeding. The holmium:YAG laser can be used for hemostasis of small vessels during the arthroscopic procedures, although its effectiveness with profuse bleeding from larger vessels is limited.[56]

Low-level laser therapy (LLLT) has been advocated for the treatment of temporomandibular joint dysfunction and disorder (TMD). Commonly, TMD can have a variety of clinical conditions involving pathologic conditions of the masticatory musculature, TMJ, or both. LLLT has been used as another modality in the treatment of the muscular component of TMD in conjunction with nonsurgical therapies such as the use of anti-inflammatory medications, soft diet occlusal splints, and physical therapy.[59]

Phototherapy LLLT devices for the treatment of TMD have been used since the mid-1960s.[60] Recent studies have shown the effective use of LLLT for the treatment of musculoskeletal and neurogenic pain pathologic conditions associated with TMD. LLLT has been proven to be beneficial for pain fibers with applications, such as TMD and postherpetic neuralgia. Recent studies by Cetiner and colleagues have demonstrated that LLLT is an appropriate treatment for TMD and should be considered an alternative noninvasive therapy. The study revealed that patients treated with LLLT for TMD, including myogenic pain, limited mandibular mobility, chewing difficulty, and joint tenderness, had statistically significant improvement versus patients treated with a placebo laser therapy. The study used a gallium-aluminum-arsenide diode laser with a wavelength of 830 nm and duration of 162 seconds and a dosage of 7 J/cm^2 with application to the overlying skin of the most tender areas for 10 sessions daily for 10 weeks. The LLLT improved TMJ mobility by approximately 20% by comparison of maximal mouth opening measurements for the patient test group.[59]

The effects of LLLT in TMD may be beneficial as a result of both analgesic and anti-inflammatory effects by increasing the pain threshold, muscle stimulating effects, and alteration of neural sensation. The immediate effects of LLLT with pain reduction are possibly due to a direct effect on nerve cell membranes producing a local anesthetic-like effect limiting nerve conduction. The effects can last from days to weeks. Prior studies have also shown the benefit of the use of LLLT in patients with arthritides of the TMJ.[60] The optional application of LLLT in TMD needs further refinement regarding duration, dosages, and wavelengths for significant effects. Studies by Nunez and associates have also shown that LLLT is more effective for treatment of TMD than transcutaneous electrical nerve stimulation (TENS) on mouth opening.[61] Earlier studies by Gray have also shown that LLLT, ultrasound, and short-term diathermy are all beneficial for TMD treatment.[62] Therefore, LLLT can be an appropriate and alternative treatment of TMD as a result of its noninvasive nature and ease of use for myogenic pain and other TMD-related complaints.

Laser-Assisted Facial Skin and Cosmetic Surgery

Many oral and maxillofacial surgeons are involved in cosmetic procedures for facial rejuvenation and revision. Laser treatment of the face is a common modality for treatment of aging, sun-related skin damage, and traumatic and pathologic conditions of the face. Skin aging can be from intrinsic chronologic skin changes or from extrinsic sun-related photoaging.

Extrinsic photoaging from environmental ultraviolet light (UV) exposure results in cosmetic defects, including drying, coarseness, and roughened skin along with pigmentation, wrinkling, telangiectasias, and actinic keratosis.[63] Intrinsic skin aging results in thin, fragile, finely wrinkled, inelastic skin.[63]

Skin cancer is associated with both aging and photoaging with exposure to UVB radiation. Basal cell carcinomas, squamous cell carcinomas, premalignant actinic keratosis, and melanomas are all related to sun exposure. Treatment of premalignant and malignant skin lesions is necessary for overall health measures, unlike elective cosmetic-related skin procedures. Skin damage can be quantitated by the use of scales proposed by Griffiths and Glogau.[64,65] The Glogau skin classification provides specific criteria with five skin types based on the degree of skin wrinkling, photoaging, and acne scarring.[65] Another recently developed skin classification was developed by Obagi, which includes skin color, oiliness, thickness, laxity, and fragility along with suitable skin rejuvenation procedures, including preoperative and postoperative skin care recommendations.[66]

A multitude of treatments are available for photoaging including both topical treatments, such as retinoid vitamin A derivatives, alpha-hydroxy acids derived from fruit and dairy products, and antioxidants, such as vitamin C and E related compounds.[63] Rejuvenation procedures can include the use of botulinum toxin injection, augmentation of soft tissues with collagen or hyaluronic acid fillers, and resurfacing with peeling, dermabrasion, or laser resurfacing.

Skin resurfacing is used for the treatment of photodamaged skin by generalized controlled wounding, which stimulates new skin growth. The new skin replaces the photodamaged epidermal layers and tightens the dermal layers by shortening existing collagen along with the production of new collagen, improving the overall facial appearance.[67] Resurfacing can be accomplished through the use of chemical peels, mechanical dermabrasion, and laser skin resurfacing. All methods can be divided into superficial depth into

the stratum corneum and papillary dermis, mid-depth of the upper reticular dermis, and deep wounding of the mid-reticular dermis.[63]

Thorough evaluation of the patient, especially in regard to skin condition, is needed to determine the most effective skin resurfacing modality. Commonly, the depth of skin surface irregularities correlates to the depth of injury required by the resurfacing procedure. Consideration of scar formation must be discussed along with other important aspects of overall facial health, including any history of facial trauma, facial surgery, prior rejuvenation or resurfacing procedures, radiation therapy, and recurrent herpes viral infections.

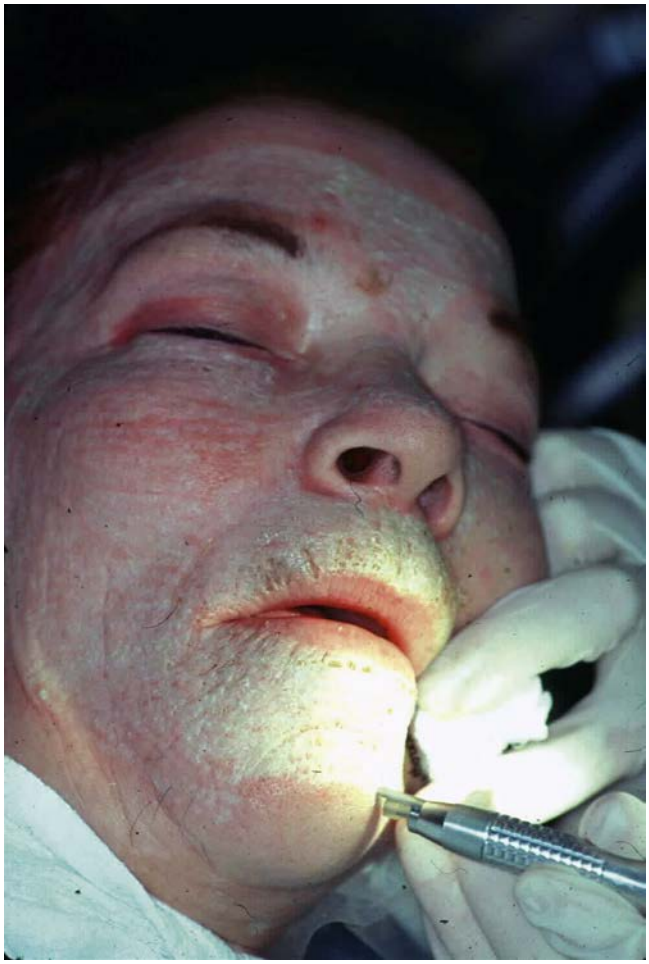
An active herpes infection of the face is a contraindication for resurfacing, and the procedure should be postponed until complete resolution of the infection. Obagi suggest the patient should be started on prophylactic acyclovir at 400 mg twice a day starting 2 days before the procedure and maintained until 5 days after the procedure or, alternatively, valacyclovir (Valtrex) 500 mg twice a day with the same regimen.[68] Many other antiviral regimens exist and grossly depend on practitioner preference and bias. Additional attention should be paid to the use of medications that affect facial healing and possible hyperpigmentation, including isotretinoin, corticosteroids, and hormone replacement therapy. The Fitzpatrick skin classification system, which is based on skin color and ability to tan or burn, should also be used to screen potential candidates for laser skin resurfacing.[69] Patients with darker skin types (Fitzpatrick IV through VI) are at a greater risk of hypopigmentation with resurfacing procedures extending into the reticular dermis.

Anti-infective use with laser skin resurfacing for bacterial and fungal prophylaxis is controversial, with no conclusive literature supporting the use of anti-infectives. Again, anti-infective regimes depend on practitioner preferences. Generally, anti-infectives should be considered if occlusive skin dressings are used for more than 48 hours after laser skin resurfacing. Extended use of occlusive dressings can place the patient at risk for bacterial and fungal infections.[68]

The development of laser skin resurfacing has grossly replaced the use of dermabrasion procedures to correct superficial skin imperfections. Laser resurfacing most commonly uses pulsed CO_2 lasers to produce controlled photothermal skin damage of layers of the epidermis and outer dermis. Outer epidermal layers are vaporized, and additional heat transfer produces collagen shrinkage resulting in contraction of the dermis, which eliminates superficial skin imperfections along with an overall tightening of the facial skin.

The use of the CO_2 laser under various laser modalities, such as limited dwell time, pulsation, and delivery time, can limit overall thermal damage and provide superior results. Pulse duration can range from 600 µs to 1 ms.[70] Laser-delivered energy provides better depth control of wounding to the skin than the use of chemical peels. CO_2 lasers provide optimal treatment of cutaneous photoaging, especially for lighter skin types (Figure 24-23).

Laser skin resurfacing is well known to be useful for treatment of irregular pigmentation, acne scars, lentigines, fine wrinkles, shallow rhytids, actinic keratosis, and other effects of photodamage to skin. The treatment of deep rhytids with the CO_2 laser can lead to suboptimal results, scarring, and cutaneous depigmentation. Care must be demonstrated with full-face resurfacing because of possible hypopigmentation and erythema, although the use of hydration under the topical anesthetic EMLA (eutectic mixture of local anesthetic) can limit the incidence of thermal damage and injury, producing suboptimal results.[71]



• **Figure 24-23** Full face laser cosmetic skin resurfacing (CSR). This is most easily accomplished using a mechanical scanner to uniformly distribute the laser over a large area.

The erbium:yttrium-aluminum-garnet laser (Er:YAG) can be used for patients with dark skin color or pigmentation to limit thermal injury because the Er:YAG laser energy is better absorbed by water than CO_2 laser energy, resulting in a shallower depth of penetration and less thermal damage.[63] The use of newer techniques, such as nonablative laser resurfacing, has limited epidermal damage via selective cooling while applying selective energy to the dermis. The overall benefit is improved healing as a result of limited epidermal damage, with less need for anesthesia of the skin and simplified wound care.[71] These nonablative laser skin resurfacing procedures fall under numerous names depending on the technique and individual laser unit used. These techniques can be used for all skin types and are useful to treat fine skin lines and shallow

rhytids not associated with muscular movement. It should be noted that the nonablative laser treatments are less effective than ablative laser skin resurfacing.

The use of skin conditioners can improve overall laser skin resurfacing results. The skin conditioners should be used both pre- and postoperatively. The preoperative benefits of skin conditioning include enhanced wound healing and limiting pigmentation changes associated with the resurfacing procedure. Regimens include the use of tretinoin to normalize keratinization, regulate skin depigmentation, and increase collagen production for faster wound healing. Hydroquinone, a skin lightener, is used to decrease melanocyte activity, which in turn minimizes hyperpigmentation during healing. In general, the epidermal cell cycle time is 6 weeks to allow maturation of keratinocytes from the basal layer to the stratum corneum. The skin-conditioning program should be started approximately 6 weeks before laser skin resurfacing.[68] The program should then be reinitiated after reepithelialization and healing, along with use of sunblocks when exposed to outdoor sun.

Generally, most surgeons prefer to avoid occlusive dressings and use topical creams such as Eucerin or Aquaphor. This allows easier cleaning and visibility. Wound healing after laser resurfacing can be improved, according to some authors, with the use of occlusive dressings and tretinoin. The overall healing period lasts from 5 to 14 days depending on the depth of resurfacing. Occlusive dressing, such as non-adhesive pads, silicone sheeting, and hydrogels, can promote faster reepithelialization and decrease pain.[68] The occlusive facial dressings are generally used for the first 48-hour period following laser treatment.[68] It should be noted that the use of occlusive dressings is practitioner dependent and there is wide variation in the preferred dressing technique. In any case, the patient is instructed to gently cleanse the face twice daily and to apply emollients.[63] Compresses with water and mild acetic acid are used every 4 to 6 hours to decrease bacterial skin counts. The compresses are followed by reapplication of the emollients. Sun exposure should be avoided for 3 to 6 months after the facial laser resurfacing treatment, and then a routine sun exposure regimen should be initiated.[63]

Contraindications to laser skin resurfacing include a multitude of conditions. Seasoned practitioners frequently combine cosmetic facial surgery procedures with facial laser skin resurfacing, but procedures, such as face-lifts, brow-lifts, and rhinoplasty, can interrupt lymphatic drainage and result in extensive edema after surgery.[68] Use of some medications, including steroids, retinoids, penicillamine, and phenytoin, is contraindicated with laser resurfacing.[68] Psychiatric disorders such as body dysmorphic syndrome, prior head and neck radiation therapy resulting in loss of adnexal structures, and any history of keloid or hypertrophic scar formation are all contraindications to laser skin resurfacing. Active skin disorders, such as rosacea, acne, psoriasis, or verruca infections, are also contraindications to laser skin resurfacing. Smoking can cause delayed healing following laser resurfacing.[68]

Common complications of laser skin resurfacing often result from overaggressive treatment (Figure 24-24). The complications can include persistent erythema, beyond 2 to 3 months, and hyperpigmentation, especially in patients with darker skin types, such as Asians, Hispanics, and African Americans.[72] Postoperative hyperpigmentation will usually resolve with time, sun exposure protection, and treatment with topical steroids, tretinoin, and hydroquinone as necessary. Hypopigmentation, as a result of overaggressive laser resurfacing, can be more serious because it can be permanent as a result of

• **Figure 24-24** Complications of laser skin resurfacing. **A**, Postoperative hyperpigmentation. **B**, Postoperative infection.

violation of melanocytes and will manifest as a late complication, months after treatment. Extreme care should also be taken in patients with vitiligo because the Koebner phenomenon can result in unmasking more areas of vitiligo.[72] There are no specific treatments for hypopigmentation, making it very problematic. Sun exposure will not fade or blend areas of hypopigmentation. Hypertrophic scarring is another complication of laser skin resurfacing and results from overaggressive treatment into the underlying deep dermal layers of the skin, especially in the perioral region of the face.[73] Hypertrophic scarring can be difficult to predict, although patients of dark skin types, such as African Americans or Asians, are more prone to this complication. Prevention by limiting the laser energy and only treating the skin to chamois or champagne color to prevent overtreatment into the dermis is advised.[72] Treatment of hypertrophic scars can include traditional methods, such as steroid scar injections, topical steroids, silicon sheeting, or customized elastomeric compression dressings, such as those used for burns.

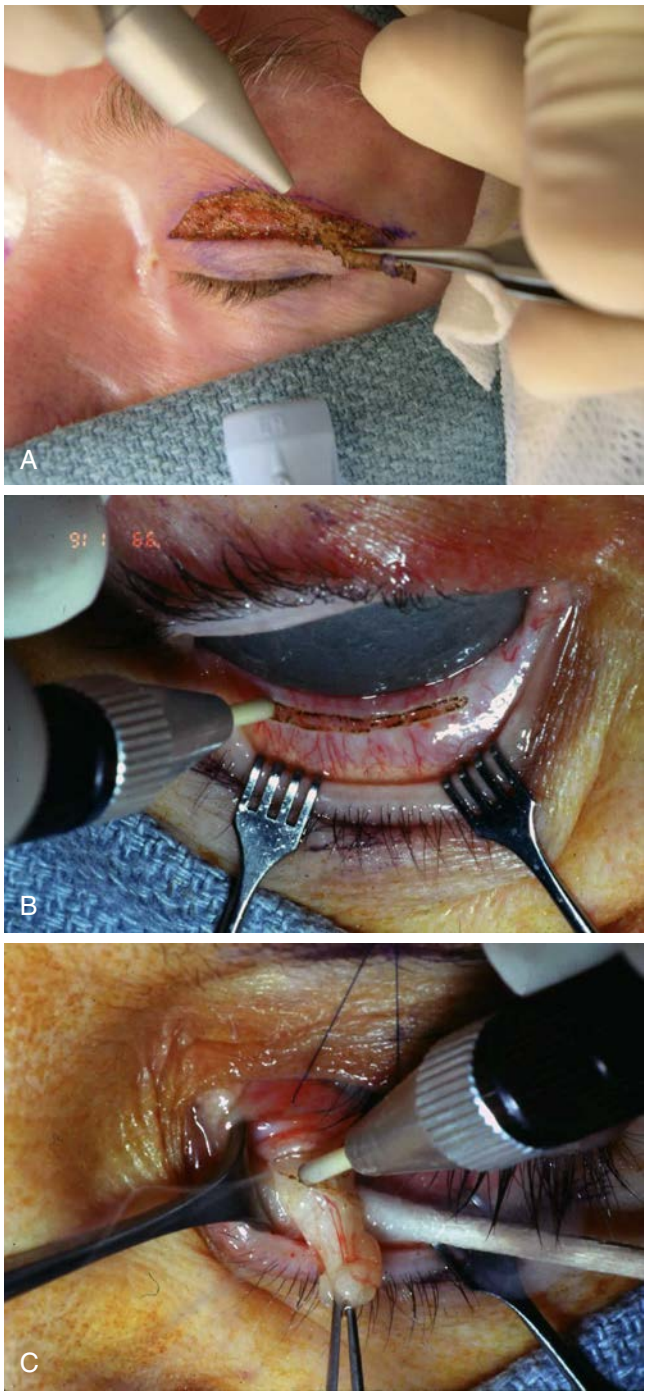
Scar revision for both traumatic and surgical scars is another excellent indication for laser surgery (Figure 24-25). The ability to revise scars through the use of a pulsed dye laser, with a wavelength of 585 nm, has provided beneficial results with decreased erythema and hypertrophy. Pulsed dye lasers act on the chromophore oxyhemoglobin and specifically target blood vessels within the scar tissue, leaving the overlying epidermis intact. The laser stimulates collagen remodeling and production of new collagen along with minimizing the fibroblast scar response. Pulsed dye lasers reduce scar erythema and produce a less erythematous and softer, flatter scar. Multiple laser scar treatments may be needed to achieve optimal clinical results, and the laser scar revision therapy can be combined with other treatments, such as steroid injections.[74,75] Atrophic scars are best treated by ablation with the CO_2 or Er:YAG lasers. The laser-induced de-epithelialization helps soften scar depressions and stimulate neocollagenesis to fill the depressed scar defect. Slightly elevated scars are also treated easily and quickly with the CO_2 laser by standard skin resurfacing techniques. Spot laser ablative scar revision is indicated for small or localized scars, but for larger or multiple scars entire facial cosmetic units should be treated to prevent noticeable postoperative skin pigmentation and texture changes. Most scars require two to three passes with the ablative laser for optimal treatment. The procedure has the same risks and complications as laser skin resurfacing. Postoperative care is the same for the two ablative laser procedures.[74]

Blepharoplasty procedures have also be performed with a variety of lasers, including the CO_2, Nd:YAG, and KTP lasers (Figure 24-26). The goal of blepharoplasty surgery is to create aesthetic and functional eyelids with the removal of prolapsed fat and redundant eyelid skin and muscle.[76] The laser aids in providing excellent hemostasis and allows a clean dissection to minimize postoperative ecchymosis and edema. Preparation includes the use of metal corneal

• **Figure 24-25** Laser scar revision. **A**, Preoperative view showing elevated scar. **B**, After laser resurfacing of scar to the level of adjacent tissue

shielding. Incision through skin can be made with a scalpel or laser, and the dissection is then continued with the laser in a cutting, focused mode to continue the dissection to remove the excess skin and redundant orbicularis muscle. The removal of the herniated fat pads is also performed with the laser. The overall procedure results in better hemostasis with the use of the laser than surgery with the use of blades and electrocautery.[76] The option of laser skin laser resurfacing is also provided if any skin redundancy exists when a transconjunctival access is used for lower lid blepharoplasty. Laser skin resurfacing modalities can be used to treat skin wrinkles of the lower lid alone, in combination with a transconjunctival blepharoplasty procedure, or combined with a delayed blepharoplasty procedure using cutaneous incisions. The laser skin resurfacing of the lower lid is performed with a CO_2 laser as a single pass to treat fine skin wrinkles.[76]

Complications of laser-assisted blepharoplasty procedures include potential damage to the globe, the associated periorbital skin and appendages, and the lacrimal apparatus. Complications associated with traditional and laser-assisted blepharoplasty procedures include ectropion, entropion, excessive scleral show, and wound infection or breakdown. Laser-assisted blepharoplasty or laser skin resurfacing of the eyelids should be performed with extreme caution in patients who have had previous blepharoplasty procedures



• **Figure 24-26** Laser blepharoplasty. **A**, Upper blepharoplasty. **B**, Lower lid transconjunctival laser incision. Note the metal eye shield for protection. **C**, Laser excision of the lower lid fat pad.

because these patients are very prone to ectropion with additional procedures.[72]

Laser Treatment of Vascular Lesions

Laser-assisted treatment of vascular lesions of the face prevents the excision of tissue, reducing scar and cosmetic defects. The use of the pulsed dye laser at 585 nm and short pulses of 450 μs is the preferred treatment for vascular lesions, including hemangiomas, vascular malformations, and ectasias.[77] The chromophore for the pulsed dye laser is oxyhemoglobin. The thermal relaxation time of small- to medium-sized blood vessels is approximately 1 to 5 ms. The short pulse permits selective energy transfer to the targeted blood vessels and hemoglobin while minimizing heat conduction and damage to the overlying epithelium and adjacent tissue. Melanin and hemoglobin are both chromophores that compete for yellow light, leading to potential nonselective absorption of laser light in the 500- to 600-nm wavelengths. Increased melanin absorption of the laser light is more pronounced in patients with pigmented skin or suntan. Melanin in the epidermis and dermis may overlie the vascular lesion, decreasing the effectiveness of the laser treatment. It is best to spot test the laser in an inconspicuous area prior to treatment of vascular lesions to prevent gross pigmentation alterations secondary to melanin destruction.[77] Selecting a laser type for use in treating vascular lesions depends on surgeon preference, lesion type, lesion depth, and availability of the laser apparatus.

Hemangiomas are a common benign vascular lesion present at birth or shortly thereafter, with approximately 80% appearing in the head and neck region. Hemangiomas can be superficial or deep and exhibit a growth phase of approximately 18 months followed by an involution phase of 3 to 10 years. Even though most hemangiomas involute, the lesion may be cosmetically and socially unacceptable while present.[77] Vascular malformations are always present at birth, vary in color, do not demonstrate a proliferation or involution phases, and grow slowly in conjunction with the patient's overall growth. Ectasias are permanently dilated vessels in the skin that are visible to the naked eye and do not exceed 1 mm in diameter. Telangiectasias are acquired and grow with age and can be associated with intrinsic factors such as cutaneous disorders, including rosacea, and systemic diseases, including carcinomas, collagen vascular diseases, or pregnancy. Telangiectasias can also be associated with extrinsic factors, such as alcohol ingestion, estrogen use, and facial trauma.[77]

The pulsed dye laser has been used to treat cutaneous vascular lesions of the face, such as ectasias and port-wine stains, with the laser energy focusing on the oxyhemoglobin chromophore within the vasculature of the lesion while sparing the adjacent normal tissue. Ectasias can often be treated with a single session, whereas larger port-wine stains require multiple sessions. A major drawback of using the pulsed dye laser is the resultant purpura of the treated skin secondary to vessel rupture due to the rapid energy absorption of the lasing energy. This purpura can last for 10 or more days postoperatively.[77]

Deeply seated vascular lesions are difficult to consistently treat with the pulsed dye laser due to its limited depth of penetration. Oxyhemoglobin has separate broad peak absorption of energy of 800- to 1,200-nm wavelengths. The 1064-nm Nd:YAG laser can be used for deep vascular

lesions as it is excellently absorbed by oxyhemoglobin and has coagulative effects at approaching 6 mm depth of penetration.

Laser Treatment of Pigmented Lesions and Tattoos

Treatment of cutaneous pigmented lesions is another common use for lasers with either ablation or resurfacing techniques (Figure 24-27). The pigmented melanocytes allow effective laser treatment, and the type of laser used and wavelength will depend on the depth of the lesion. The depth of the melanocyte can be determined with the use of a Wood's lamp. Epidermal melanin will light up under the Wood's lamp, indicating a superficial lesion, whereas dermal melanin is not visible.[77] The need for accurate diagnosis of cutaneous pigmented lesions is absolute, and a biopsy should be performed before any laser treatment with the patient being well informed about the possible need for additional treatment depending on the final histopathologic diagnosis.

Ablative lasers, such as the CO_2 (10,600 nm) and Er:YAG (2940 nm), can be used, but do not target any specific chromophore; therefore, careful removal of the lesion must be demonstrated to prevent scarring.[77] Conservative treatment with ablative lasers is encouraged, as it is easier to re-treat or touch up pigmented lesions than to treat scar. Lesions should be treated until the base is a chamois-leather color. Smaller, superficial pigmented lesions such as lentigines, keratosis, ephelides, dermatosis, and dermatosis papulosa nigra can be successfully treated with the 532-nm diode laser. The need to establish the depth of the melanocytes either into epidermis or deeper into dermis must be diagnosed because the deeper lesions cannot be superficially ablated. The use of non-contact Nd:YAG or the Q-switched ruby laser has been useful to treat deeper pigmented lesions, including melanotic nevi, nevi of Ota, blue nevi, and solar lentigines. These lasers generate longer wavelengths of high peak energy at rapid pulses, allowing deeper tissue penetration without excess scarring or overlying and adjacent tissue destruction.[78] Q-switched ruby lasers have the benefit of targeting melanin as a chromophore, but have absorption by oxyhemoglobin, leaving vessels undamaged.[77]

The use of the laser for removal of intentional or traumatic tattoos is another commonly performed cosmetic procedure. Removal of tattoos is often desired because the patient will often perceive the tattoo as unaesthetic for a variety of reasons, including fading of the ink, nonprofessionally produced tattoos, or wanting to remove a symbol or letter after a period of time. Tattoos were previously treated with CO_2 laser in the 1990s, although the use of the CO_2 laser for this purpose has been replaced by other types of lasing wavelengths specific for certain tattoo color chromophores.[79] The removal of tattoos has been successful through the use of the Q-switched ruby laser.[77] Tattoo pigment within the dermis selectively absorbs the laser waves and is fragmented into small particles, which are phagocytized by macrophages within the body to produce a gradual fading of the tattoo over time without affecting the overlying epithelium. Multiple laser removal sessions can be required for some tattoos. Results are better than previously attempted methods, such

• **Figure 24-27** Removal of benign pigmented nevus. **A**, Preoperative view; **B**, postoperative view.

as dermabrasion or excision, because of a lower incidence of pigmentation alteration and decreased scarring.

Laser Hair Reduction/Removal

Laser removal of unwanted hair or laser hair reduction is one of the most commonly performed cosmetic procedures. Excessive hair growth represented by either hirsutism, hair in unusual places, or hypertrichosis, representing excessive non-androgenic hair growth in men and women, can be localized or generalized throughout the body.[75] Laser hair reduction is regulated by U.S. Food and Drug Administration guidelines, which require a 30% reduction of hair growth at 3 months following a single laser hair reduction treatment. The need for an additional three to five treatments is not uncommon.[75] Laser hair reduction is based on the affinity of exogenous chromophores or melanin within the hair shaft to laser waves, with the heat production killing the hair follicle. Ruby (694 nm), alexandrite (755 nm), Nd:YAG (1064 nm), and diode (810 nm) lasers can be used for laser hair reduction with wavelengths of approximately 500 to 1000 nm at pulsations greater than 100 μs to destroy hair follicles while preserving the epidermis.[80] Intense pulsed light (IPL) with a wavelength of 515 to 695 nm can also be used for hair reduction. Laser hair reduction can only occur in the telogen phase, when the follicle is preparing to grow new hair and the chromophores are most sensitive to the laser energy. Laser hair reduction may therefore require multiple intermittently spaced laser treatments to increase the success of overall hair reduction. Thermal relaxation time of hair follicles depends on diameter and is estimated to be 10 to 100 ms. Laser pulses longer than 100 ms have been found to be more conducive to long-term hair reduction.[80]

Laser Use in General Dentistry

The application of lasers for general dental use continues to grow, with routine use for restorative dentistry, periodontal care, orthodontics, and dental hygiene. The use of soft tissue lasers is becoming increasingly popular for preprosthetic gingival procedures. The benefit of hemostatic control with the excision of gingival tissue can produce optimal restorative and prosthetic results.[81] Restorative and prosthetic treatment often requires the removal of gingival tissue to gain access and moisture control for the treatment of tooth structure below the gingiva.

Gingival tissue can be removed by the use of a scalpel, electrosurgery, or laser. The scalpel has the disadvantage of eliciting bleeding, which is a major problem for subsequent restorative dental treatment. Electrosurgery can also be used to remove gingival tissue with good hemostasis. However, excess heat can be generated, which can cause irreversible recession of the soft tissue at the gingival margins and possibly damage the underlying alveolar bone.[81] The recession can lead to exposure of restorative margins, resulting in suboptimal aesthetics in the anterior portion of the mouth. Lasers can offer a greater degree of control for the removal of gingival tissue with minimal damage to the adjacent soft tissue. Diode lasers offer the advantage of operating at wavelengths that are absorbed by gingival tissue and not by adjacent tooth structure.[81]

Aesthetic crown lengthening can be performed with the use of a diode laser with 810-nm wavelengths.[81] The use of the diode laser provides greater operator control for the creation of more precise gingival margins. Before the use of the diode laser for gingival recontouring or crown lengthening, a thorough periodontal evaluation should be performed with attention to the biologic width, indicating the amount of attached gingival tissue and the location of crestal bone. The possible need for osseous contouring via flap surgery versus soft tissue contouring alone can be determined. The use of the diode laser also facilitates the placement of final direct bonded or provisional prosthetic restorations as hemostasis is achieved.

Diode lasers at a wavelength of 810 nm exhibit little or no affinity for hard tooth structure, metal alloys, composites, or porcelain.[81] This benefit allows the laser to be used for soft tissue recontouring procedures around tooth structures or dental implants. The laser has little to no effect on cementum or enamel and does not conduct or produce heat through existing metal tooth-related structures. This prevents thermal pulpal injury.

The diode laser is used with the tip contacting, with aiming facilitated by a guide beam. The removal or contouring of gingival tissue is performed along the tip of the laser. Shallow tissue penetration produces slower and more controlled soft tissue cutting than an electrosurgical unit. The diode laser is usually used in a pulsed mode to minimize thermal conduction to adjacent tissue, carbonization, and char formation. The development of an external bevel to provide optimal gingival contour can be done with hemostasis, providing increased patient comfort.[81]

The use of the laser to aid in taking accurate impressions can produce optimal prosthetic results. Exposure of subgingival finish lines combined with good moisture control through hemostasis can be obtained with the use of the diode laser. This technique eliminates the need for retraction cord and produces minimal adjacent tissue necrosis. This allows preservation and complete regeneration of adjacent soft tissue with little to no gingival recession.[81]

Lasers are increasingly being used for minor soft tissue procedures related to orthodontic treatment.[82] Lasers can be used to treat gingival hyperplasia secondary to orthodontic treatment as a result of poor oral hygiene measures. Aesthetic tissue contouring with altered tooth eruption and soft tissue exposure of unerupted teeth can be performed to provide optimal orthodontic results.

The diode laser is an excellent tool for soft tissue recontouring procedures, with no effect on the teeth or related hard tissue components. The laser energy results in production of some heat, which vaporizes cells through a photothermal effect called ablation. The resultant soft tissue

wound heals faster and with minimal pain because the wound is sealed, sanitized, and protected by a biodressing.[82]

The creation of optimal aesthetics following orthodontic treatment can be planned because the orthodontist can achieve ideal embrasures and gingival contours. Delayed passive eruption limiting crown exposure can be treated with the diode laser to facilitate proper orthodontic bracket placement. Proper bracket placement allows proper orientation and alignment of the tooth with the use of preformed wires. The diode laser can also be used to expose unerupted teeth with excellent hemostasis for orthodontic bonding.

The diode laser can also be used to debride hyperplastic tissue associated with inflammation as a result of poor oral hygiene with orthodontic treatment.[82] The diode laser removes hyperplastic inflamed papillae and pseudopocketing to improve overall gingival health. The diode laser has also been used to performed crestal fiberotomies to aid in prevention of orthodontic relapse and to assist in the rotation of teeth as a quick and bloodless procedure.[82]

The diode laser has been recently used as an adjunct treatment of periodontal disease in combination with scaling and root planing (SRP). The adjunctive effects of the diode laser with conventional SRP have been proven to be beneficial.[83] The use of the diode laser for the treatment of periodontal disease is based on the model that periodontal disease is an inflammatory response of the periodontal tissue to bacterial infection and the presence of a biofilm in the periodontal pocket. The diode laser has offered the dental professional an advantage in the treatment for periodontal disease as a result of the bactericidal effect of the laser in combination with SRP.[84] The use of the diode laser with SRP was noted to decrease postoperative pain. The microbiology of the periodontal pocket revealed a decrease in the number of microbial colony-forming units in laser-treated sites following SRP, including decreased levels of *Actinobacillus actinomycetemcomitans*, which is associated with aggressive periodontal disease.[83] The use of the diode laser provided an alternative means of treatment of *A. actinomycetemcomitans* with periodontal disease versus traditional treatment with antibiotic therapy.

The reduction in bacterial colony forming units and the overall reduction in *A. actinomycetemcomitans* bacteria has been postulated to be a result of the bacteria responding to the diode laser energy at 810 nm at 0.8 W, although this has not been confirmed.[83] The diode laser has also been used to alter soft tissue in furcations to allow access to the furcation for periodontal maintenance. The diode laser also results in faster wound healing with SRP, resulting in increased comfort of the patient following the periodontal therapy.

Overall the diode laser at a wavelength of 810 nm and power of 0.8 W was equivalent to the treatment of chronic periodontitis with SCP in regard to reduction of subgingival bacterial counts and pocket depth. The use of the diode laser did not result in a statistically significant increase in periodontal attachment levels.[83]

The technique involves placement of the tip of the diode laser in the periodontal pocket, and the laser is moved in a sweeping motion from anterior to posterior to the base of the pocket. The optical fiber system to deliver the laser energy is only end-lasing, with the energy exiting at the end of the fibers and not from the side wall. The laser is directly on the root surface. The laser produces a stimulatory effect on the gingival soft tissue while reducing pocket depth and resulting in faster and less painful healing. The laser energy is not used to remove tissue. It is only focused on the tissue within the pocket to produce a nonablative thermal event, which decontaminates the periodontal pocket by reducing the number of bacteria within it, along with a decrease in the exotoxins, such as hyaluronidase and collagenase, that are responsible for periodontal tissue destruction.[84] The laser-assisted SRP procedure provides the benefit of hemostasis with a less invasive procedure than flap surgery.

The latest application of the diode laser for periodontal therapy involves its use with initial pathologic pocket formation as indicated by loss of clinical attachment, bleeding on probing, the presence of inflammation, and loss of alveolar bone height. The diode laser is used as a preventive measure in combination with SRP before pocket formation. The diode laser has been used to control periodontal disease through tissue debridement and bacterial reduction. Studies have assessed the effect of the laser to decrease bleeding on probing when used in combination with SRP versus SRP alone. The laser can also be used to palliate pericoronitis through the excision of the operculum in patients unable to have the third molar removed at the initial appointment. The patient is informed of the need for third molar removal at a later date.[84]

General dental treatments where the laser has been beneficial include the use of lasers for power bleaching of teeth. A diode laser raises the temperature of hydrogen peroxide to accelerate the chemical bleaching process.[85]

The use of lasers with operative dentistry includes their use for tooth preparation. The Er:YAG laser has been used for removal of enamel, dentin, and nonmetallic restorations.[85] The treatment is based on the expansion of hydroxyapatite by laser energy heating the water within the hydroxyapatite structure and ablating the crystal. The laser can be used to remove decay or sound tooth structure and decreases the need for local anesthetic use because the friction and heat production with drilling is eliminated.

In endodontic treatment, the use of the laser has been established for debridement of infected tissue and associated bacteria. The laser has been shown to be an excellent tool to clean and sterilize the root canal system. Studies have shown the laser energy to be superior for removal of microorganisms within the canal and smear layer of the surrounding dentin of the canal versus chelating agents or chemical irrigants, such as hypochlorite.[86] The lasers also have a bacterial effect to sterilize the canal before obturation. The use of lasers for endodontic treatment is becoming more common and has known benefits over traditional rotary instrumentation of canals, such as ease of use, decrease in the separation of instruments, and decrease in the number of endodontic failures.[85]

Laser Use in Craniofacial Surgery

Laser scan–based registration can be used for the treatment of patients with tumors, bone malformations, and foreign bodies of the craniofacial complex.[87] The laser scan uses the registration of complete areas and surfaces instead of single-point registration markers, producing a more accurate surgical navigation system. The laser scanner registers approximately 200,000 measuring points on a patient's face within a 2-second period, allowing for function as a surgical system navigator. The laser scan–based system was more accurate than marker-based registration systems. The radiation associated with some scanning systems, such as computed tomography, and the need for placement of artificial markers such as titanium pins or screws are both avoided.[87,88]

Laser scanners are also currently being used clinically to identify and quantify the severity of craniofacial asymmetries and defects. This aids in both patient understanding and education regarding his/her specific abnormalities. This quantitative understanding also facilitates ideal and achievable surgical treatment planning by the craniomaxillofacial surgeon.[89]

Trigeminal Nerve Injuries

JOHN M. GREGG, JAMES A. GIGLIO

During their careers, most oral and maxillofacial surgeons practicing full-spectrum treatments will have patients who have sustained trigeminal nerve injury.[1,2] These patients will present with a wide range of disturbing symptoms and impaired functions (Table 25-1). Although acute neurosensory symptoms in lingual and inferior alveolar nerve (IAN) regions are frequently present 1 week after routine surgeries such as third molar removal, most symptoms will resolve spontaneously by 3 weeks.[3] An unfortunate patient subset of 15% to 25%, however, will retain abnormal sensations and impaired orofacial functions for 3 months or more, and accumulating studies indicate that more than half of nerve-injured patients will experience some level of long-term disturbing paresthesias and neuropathic pain.[4,5] Neuropathies persisting more than 1 year are considered permanent and may not be surgically reversible.

Some trigeminal nerve injuries may be unavoidable because of disease conditions that require treatment. At especially high risk for injury to trigeminal nerves are patients treated for orofacial trauma, developmental deformities, reconstructive surgeries with endosseous implants, and, most commonly, pathology associated with third molar surgery. And, unfortunately, nerve injury complications are still presumed by uninformed patients to be evidence of surgical negligence.

There have been significant advances, however, in understanding the mechanisms of traumatic neuropathies and improvements in surgical and nonsurgical treatments. Most notably, more than 3 decades' experience with nerve injury surgeries have demonstrated marked functional improvements for more than half of treated patients.[6-8] Microsurgical repairs of lingual nerves have proven to be more effective than inferior alveolar repairs. And, because early medical treatments and timely surgeries of acute nerve injuries may prevent the transition to chronic refractory neuropathies and intractable dysesthesias, it is recommended that patients be treated within 3 to 6 months of injury, if possible.[9,10] Results also have shown that microsurgical repairs are likely to improve on lost sensory functions but less likely to eliminate preexisting chronic neuropathic pain.[11] Internal neurolysis procedures and traditional autologous nerve grafting procedures have yielded disappointing outcomes and secondary morbidities, whereas microsurgical decompressions with neuroma resection and direct reanastomoses have yielded the most favorable results.[12-14] Most significantly, this past decade has seen the development and clinical application of a promising cadaver-processed allograft for patients with extensive nerve tissue loss injuries.[15,16]

Causes, Classification, and Injury Responses

Maxillofacial trauma is likely the most common source of orofacial dysfunction, trigeminal sensory loss, and neuropathic pain.[17] They are most often associated with maxillomandibular lacerations and fractures, where the inferior alveolar and infraorbital nerves are almost always affected and chronic impairment persists in up to 35% to 50% of patients.[18] Injuries to inferior alveolar and lingual nerves occur in 0.1% to 10% of cases during third molar surgery, are the overwhelming iatrogenic cause of neuropathy, and result in the full spectrum of mechanical damages from transient mild compressions to complete nerve lacerations and gap avulsions.[2,5,19,20] Endosseous implant surgery accounts for an increasing number of cases of injury to mandibular nerves, especially in patients with more severe bony atrophy and in those who have undergone nerve repositioning surgeries.[21,22] Chronic post-traumatic neuropathies from local anesthetic injuries, although rare as mechanical injuries in comparison to the number of injections carried out, appear to be increasing in incidence caused by chemical neurotoxities.[23,24] Nerves acutely injured by caustic root canal or surgical medicaments are associated with extreme pain and require immediate clinical treatments.[25,26] Orthognathic surgery, particularly sagittal mandibular osteotomy, has a high incidence of

TABLE 25-1 Nerve Injury Clinical Terms

Term	Description
Paresthesia	Abnormal sensation(s), whether spontaneous or-evoked
Dysesthesia	Unpleasant or painful abnormal sensations, spontaneous or evoked
Anesthesia	Absence of responsiveness to any level of tissue stimulation; may be due to traumatic nerve injury or pharmacologically induced by local or centrally acting agents
Hypoesthesia	Decreased responsiveness to stimulation in neural distribution(s)
Hyperesthesia	Increased responsiveness to stimulation in neural distributions(s)
Allodynia	Pain due to natural or applied tissue stimuli that do not normally provoke pain; may lead to painful response(s)
Hyperpathia	Burning or shocking pain due to blunt, non-noxious repetitive stimuli applied over abnormal nerve or its distribution
Hyperalgesia	Increased pain response(s) to noxious stimuli; includes excess responses to mechanical, thermal or environmental stimuli
Sensitization	A state of increased nociceptor irritability and drop in thresholds; may display spontaneous discharges and spread of affected fields; includes peripheral and central sensitization
Trigeminal Neuralgia	Pain caused by lesions of the peripheral trigeminal structures; includes classic trigeminal neuralgia (idiopathic vs. neuralgia); includes syndromes caused by mechanical injuries (traumatic trigeminal neuralgia), infections (herpes zoster), chemical neurotoxicities (local anesthetics, endodontic, surgical agents); differentiated from central malignant or degenerative disorders
Ageusia	Loss of taste as revealed by subjective patient reports and objective testing; may be "partial taste loss" isolated to specific chorda-lingual nerve distribution(s) or more generalized, reflecting possible systemic causation

Adapted from definitions of the International Association for the Study of Pain (www.iasp-pain.org).

intraoperative nerve injuries, good levels of early spontaneous recovery, but some degree of long-term altered sensation in up to 50% of patients.[27,28]

A Mechanistic Classification of Nerve Injuries

Sir Herbert Seddon and Sir Sydney Sunderland developed nerve injury classifications that still provide a useful framework for characterizing nerve injuries.[29,30] Seddon's hypothesis was that increasing nerve damage results in greater permanent loss of sensation. Sunderland's scheme emphasized a progressive destruction of nerve structures with wallerian axon degeneration, and disruption of endoneurial, perineurial, and finally epineurial tissues. The value of combining these two classification schemes has been shown by quantitative sensory testing (QST), which has verified that the depth of trigeminal sensory loss correlates generally with increasing physical nerve destruction.[31,32] The Seddon-Sunderland linear injury scales also correlate well with decreasing potential for spontaneous nerve recovery, with increasing likelihood of dysfunctional neuroma formation, and with increasing need for surgical repair interventions. More recently, Mackinnon modified the Seddon-Sunderland classification scheme by adding a sixth injury type to account for "mixed injuries"[33] (Table 25-2).

Sunderland type 1 (Seddon "neuropraxia") injuries result from ischemic effects of minor nerve trunk traction, mild compression from edema, hematoma, or temporary increases in local inflammation. Paraneural heat in the 48° to 54° C range, generated by rotating surgical instruments, may produce type 1 damage. The neurologic effects are primarily conduction block resulting in slowed stimulus responses. Although isolated sites of neural demyelination may occur, wallerian axon degeneration is not expected and there are no grossly visible effects on the epineurium. Rapid spontaneous recovery toward normal sensation and sensory functions is expected within days to a few weeks. Microsurgery is not indicated except for the removal of compressive paraneural foreign bodies.

Sunderland type 2 (Seddon "axonotmesis") injuries result from more forceful crush or abrupt nerve traction greater than 25 g.[34] Partial compression from implants or displaced bone may induce this level of injury. QST reveals deeper loss of sensory responses, particularly for fine touch discrimination. Some degree of axon degeneration may occur, but the endoneurium, perineurium, and epineurium remain intact. Therefore, axonal regeneration and sensory recovery is expected within 2 to 4 months. Extraneural hematoma and secondary scarification may be associated with this level of injury and perpetuate mild neuropathy. In such cases surgical decompression may enhance recovery.

TABLE 25-2 Nerve Injury Classifications, Injury Responses, Surgical Indications

Injury Classification	Causes	Responses	Recovery	Microsurgery
Neuropraxia (Seddon) First-degree injury (Sunderland)	Minor nerve compression, stretch, thermal, acute infection	Neuritis, paresthesias, conduction block, no structural damage	Spontaneous recovery, less than 2 months	Not indicated unless foreign body preventing nerve recovery
Axonotmesis (Seddon) Second-degree injury (Sunderland)	Partial crush, traction, thermal, chemical injury, hematoma, chronic infection	Intact epineurium, isolated axon loss, episodic dysesthesia	Spontaneous recovery in 2-4 months	Repair not indicated except decompression if foreign body or perineural fibrosis
Third-degree injury (Sunderland)	Traction, crush, puncture, thermal, chemical injury	Wallerian axon loss, some internal fibrosis, peripheral sensitization	Recovery crude senses, >1 year neuropathy	Decompression and repair if poor function, sustained pain at 3 months
Fourth-degree injury (Sunderland)	Full crush, extreme stretch, high thermal, direct chemical injury	Neuroma-in-continuity, hypoesthesia, triggered hyperpathia	Permanent injury, minimal spontaneous recovery	Repair, neuroma resection if intolerable dysfunction, pain after 3 months
Neurotmesis (Seddon) Fifth-degree injury (Sunderland)	Transection, tear, laceration, avulsion of nerve trunk	Amputation neuroma, anesthetic, evolving deafferentation pain	Permanent injury, no spontaneous recovery	Neuroma resection with neurorrhaphy or graft if intolerable dysfunction and intractable neuropathic pain
Sixth-degree injury (Mackinnon)	Mixed partial mechanical, chemical, anesthetic, compression, ischemia	Neuroma-in-continuity, endo-to-epineural damage	Partial spontaneous recovery	Surgical decompression, micro repair if intolerable dysfunction, dysesthesia

Type 3 Sunderland injuries are caused by more severe mechanical crush, puncture, high-concentration local anesthetics, and chemical and thermal traumas and result in wallerian degeneration at the injury site and some degree of cell loss in the trigeminal ganglion.[35,36] The endoneurium is also damaged, and some intraneural bleeding and scarification may potentially interfere with complete axon recovery. For this reason, this injury level may be associated with permanent neurosensory disturbances. Painful burning paresthesias and hyperphenomena may be seen within hours of type 2 and type 3 injuries and may prompt surgical exploration and repair if sensory test responses fail to show satisfactory recovery within 3 months.

Type 4 Sunderland injuries result from extreme nerve crush, thermal effects above 55° C, instrument punctures, intraneural local anesthetic injections, high-concentration local anesthetics, and caustic medicaments in contact with the nerve. The epineurium is grossly intact, although contused, and may be devascularized; internal nerve structures are damaged, however, and are replaced by disorganized scar. Trigeminal ganglion cell necrosis occurs, and central deafferentation effects can be measured as high as thalamic levels, resulting in centralized and spontaneous pain syndromes along with severe peripheral sensory loss.[37,38] QST reveals deep hypoesthesia to all stimuli, and percussion of the injury site may elicit a hyperpathic aching pain and paresthesia. Neuroma-in-continuity has formed in such cases, and microsurgical resection and repair will be required if functional sensory reflexes are to be restored.

Sunderland type 5 (Seddon "neurotmesis") is the most extreme injury type where there has been complete transection of the nerve trunk, loss of significant trigeminal cells with centralized effects, and amputation neuromas forming at the injury site. Patients who have sustained full transection injuries of intrabony inferior alveolar nerves, yet have retained good nerve-end apposition and support within the mandibular canal, may undergo satisfactory levels of spontaneous recovery. Many type 5 injured patients, however, will experience poor oral-facial functions and intractable pain and may benefit from repair. In almost all type 5 injuries to lingual and infraorbital nerves, satisfactory spontaneous recovery will not occur, and such an injury should be microsurgically repaired as soon as its nature is confirmed by sensory testing demonstrating anesthesia, with or without dysesthesia (see Table 25-2).

Type 6 (Mackinnon) mixed nerve injuries may be caused by direct mechanical instrument trauma, puncture or crush injuries, or chemical, anesthetic, or ischemic damage. Because of their mixed nature, type 6 injuries may involve pathologic changes in all portions of the nerve from endoneurium through epineurium and result in highly varied clinical combinations of sensory losses, paresthesias, and dysesthesias.

Determinants of Nerve Injury Responses

A number of factors, both local and host-related, will determine the neurologic responses to injury.[39] The *type of injury* is a primary determinant of the neurologic responses.

Clean-incision lacerations are less problematic than irregular or avulsive lacerations.[40] Injuries are clinically more disruptive when they involve mixed nerve receptor types, such as combinations of somatosensory mechanoreceptors and taste receptors, and somatosensory-autonomic fiber combinations, such as maxillary nerve branches that contain post-ganglionic parasympathetic fibers. Injuries that occur at proximal positions on the peripheral nerve are more significant than those that occur at more distal sites, as they are more likely to result in loss of trigeminal ganglion cells and initiate retrograde deafferentation effects into the central nervous system. Multiple nerve injuries are also more significant than isolated injuries because of accumulative central deafferentation effects.[41]

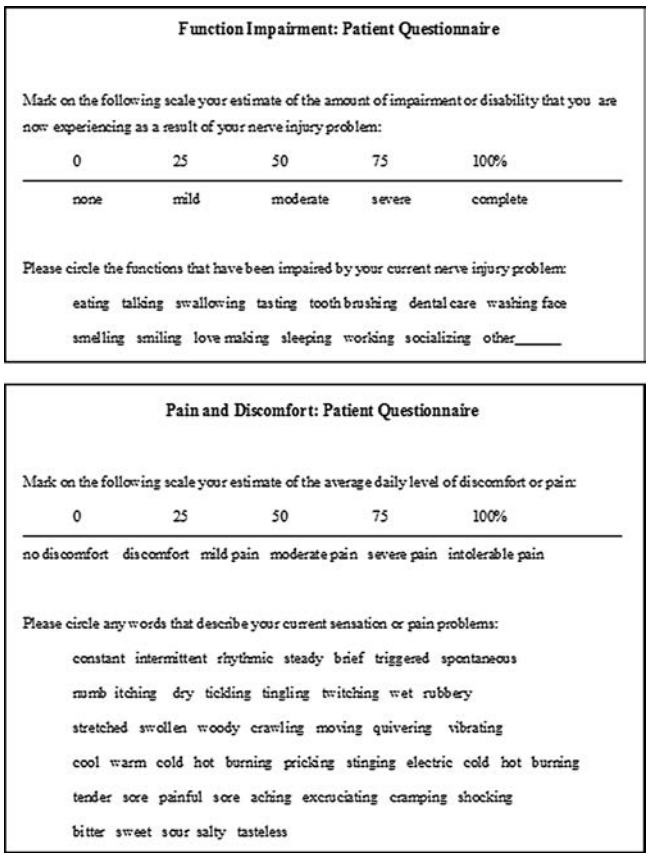
Complete nerve lacerations or avulsions produce markedly different responses than partial or incomplete nerve injuries. Paradoxically, lesser neurotrauma, as seen with Sunderland types 2 and 3 injuries and partial or puncture injuries, is more likely to be associated with early hyperesthesias such as triggered pain, hyperalgesia, allodynia, and immediate post-injury dysesthesias. Severe type 4 internal nerve damage and type 5 complete laceration or avulsion injuries, by contrast, are often not immediately painful but eventually lead to the formation of dysfunctional chronic neuroma-in-continuity and amputation neuromas. These initially anesthetic lesions are with time often associated with poor oral-facial functions, referred and radiating forms of unpleasant paresthesias, and spontaneous pain.[32,42]

Host factors are also significant determinants of the responses to nerve injury. Female gender and greater age are associated with higher incidences of nerve injuries and poorer recoveries from injury.[43-46] Genetic factors, although inadequately understood at this time, may be important determinants through effects such as increased intraneural collagenization, extraneural scar, and autonomic derangements.[47,48] The presence of chronic inflammation, secondary bacterial infections, or herpes simplex or zoster viral outbreaks in the nerve injury distributions can also interfere with the injury response and the recovery process.[49,50] Even low-grade repetitive irritations of the injured nerve trunk or neuroma may induce a retrograde process of central sensitization known as "wind-up."[37]

Systemic influences also may influence nerve injury responses; they include neurovascular diseases such as chronic arthritis, systemic lupus, and diabetic neuropathy. Exposure to environmental neurotoxins, therapeutic medicaments, nicotinic acid, and nitrosamine components of tobacco may all influence nerve injury responses by impairing Schwann cell regenerative functions.[51]

Clinical Measurement and Diagnoses

Arriving at distinct diagnosis and establishing a sound basis for nerve injury treatments requires an assessment of both subjective and objective injury effects. Evaluation begins with a review of injury sources, the recent clinical course, and a recording of patient reports of impaired functions, discomfort, and pain. This may be facilitated by the use of patient input questionnaires. Evaluation then proceeds to objective neurosensory testing and pictorial mapping of measured sensory losses and painful responses to test stimuli. When dysesthesia is present, patient responses to nerve block testing also may be useful. Finally, when these baseline clinical assessments are complete, a diagnostic impression statement can be recorded, and the patient's current level of neural functional recovery can be rated.



Function Impairment: Patient Questionnaire

Mark on the following scale your estimate of the amount of impairment or disability that you are now experiencing as a result of your nerve injury problem:

0	25	50	75	100%
none	mild	moderate	severe	complete

Please circle the functions that have been impaired by your current nerve injury problem:

eating talking swallowing tasting tooth brushing dental care washing face

smelling smiling love making sleeping working socializing other_____

Pain and Discomfort: Patient Questionnaire

Mark on the following scale your estimate of the average daily level of discomfort or pain:

0	25	50	75	100%
no discomfort	discomfort	mild pain	moderate pain	severe pain	intolerable pain

Please circle any words that describe your current sensation or pain problems:

constant intermittent rhythmic steady brief triggered spontaneous

numb itching dry tickling tingling twitching wet rubbery

stretched swollen woody crawling moving quivering vibrating

cool warm cold hot burning pricking stinging electric cold hot burning

tender sore painful sore aching excruciating cramping shocking

bitter sweet sour salty tasteless

• **Figure 25-1** Patient questionnaire for entering complaints of function impairments and/or unpleasant/painful sensations after trigeminal nerve injury. (Pain descriptors adapted from McGill pain questionnaire; Melzack R, Terrance C, Fromm G, et al: Trigeminal neuralgia and atypical facial pain: use of the McGill Pain Questionnaire for discrimination and diagnosis, *Pain* 27:297-302, 1986.)

Patient-Reported Impaired Functions

Trigeminal nerve injuries disrupt both orofacial and general life functions. Questionnaires that assist patients in communicating and quantifying the severity of their stated impaired functions are useful (Figure 25-1). Assessments are made of global life functions (sleeping, eating, working, socializing) as well as function levels specific to the oral-facial region (eating, speaking, kissing, oral hygiene). These same function impairment assessments are to be used at follow-up patient visits to monitor progress over time and after treatments.

Patient-Reported Discomfort and Pain (Dysesthesia)

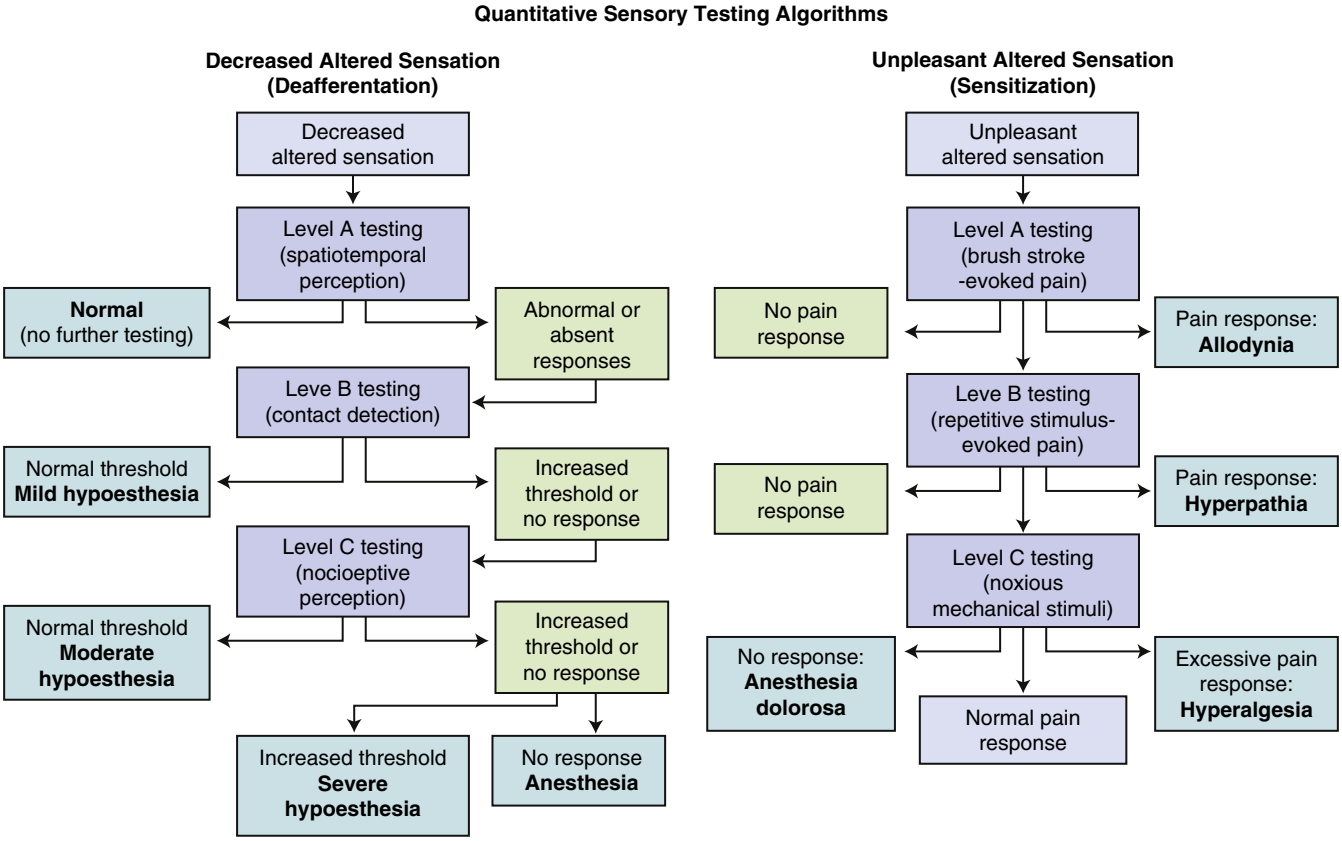
Patient questionnaires modified from the extensively verified McGill Pain Inventory are useful for eliciting patient-perceived levels of neurosensory discomfort and pain.[52] These include visual analogue scaling on which patients are instructed to focus on their region of nerve injury and rate their disturbed sensations (paresthesias) and current pain (dysesthesia) levels on global scales ranging from zero through 100%.

A list of McGill verbal neurologic descriptors is presented to patients to elicit qualitative information about their neuropathy (see Figure 25-1). These can be helpful in revealing underlying mechanisms of sensory abnormality, pain, and dysfunction. Particular patterns of verbal descriptors may help the clinician discriminate between different categories of pain and paresthesias.[53] Certain forms of traumatic neuropathies have been linked by the McGill descriptors, including hypoesthesia ("numb, rubbery, swollen"), paresthesia ("tingling, tickling, itching"), and dysesthesia ("tender, pricking, burning").[54]

A note of caution for clinicians interpreting verbal symptom complaints after nerve injury: Most English-speaking patients, when asked about altered sensation in their affected nerve distributions, use the term "numbness." However, quantitative sensory testing reveals that there is a wide range of objective sensory loss among patients who use the term "numbness;" some patients test severely hypoesthetic and even anesthetic, whereas other "numb patients" display near-normal stimulus responses with objective testing.[55] It is also important to recognize this communication factor when final assessments of the success of spontaneous recovery or surgical treatments are made. Even in cases where there have been significant improvements in objective neurosensory functions, some patients may interpret their recovery as "unsuccessful" or "incomplete" because they still retain "numbness."

Clinical Neurosensory Testing

Clinical neurosensory testing is done to determine the degree of sensory loss, detect unpleasant or painful neuropathic states, monitor recovery, and help determine whether trigeminal nerve repair is indicated. Although a wide range of protocols for experimental and clinical quantitative sensory testing are currently in use, no single system is universally accepted.[56-58] Neurosensory testing of patients with altered sensation measure two signs of neuropathy: *loss* of sensory stimulus detection (deafferentation) and *excess* unpleasant responses (sensitization) to sensory stimuli (Figure 25-2). In QST protocols, a range of stimuli from light mechanical (Level A) through repetitive crude touches (Level B) to noxious stimuli (Level C)



• **Figure 25-2** Algorithms for neurosensory testing of nerve-injured patients who complain of decreased altered sensation (deafferentation) and/or unpleasant/painful altered sensation (sensitization). Diagnoses are in bold print. (Adapted from Zuniga JR, Essick GK: A contemporary approach to the clinical evaluation of trigeminal nerve injuries, *Oral Maxillofac Surg Clin N Am* 4:353-367, 1992; Meyer RA, Bagheri SC: Clinical evaluation of nerve injuries. In Miloro M, editor: *Trigeminal nerve injuries*, Berlin, 2013, Springer, pp 167-198.)

are presented to the patient's region of nerve injury, and patients' responses are compared to "control" responses from their own (contralateral) uninjured tissues.

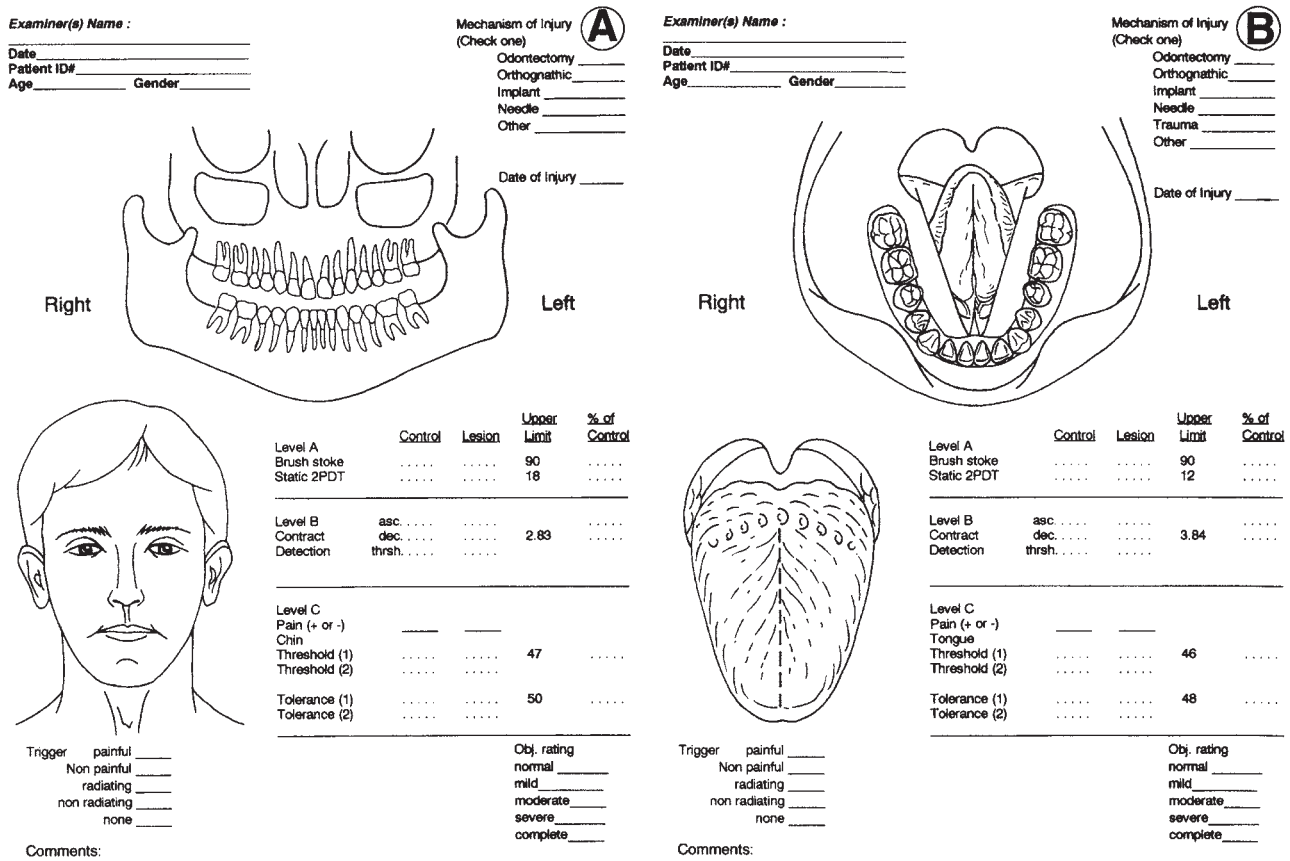
Quantitative sensory testing begins with *Level A testing,* the stimulation of large, myelinated A-beta nerve fibers associated with fine touch spatiotemporal discrimination (see Figure 25-2, *A*). A-beta fibers are the most susceptible to mechanical nerve injuries and the least likely to regenerate fully ("first to degenerate, last to recover").[59] This is in contrast to "Level C" testing of small nociceptor C fibers, which are the least susceptible to compressive injury but tend to regenerate excessively within traumatic neuromas.[60,61]

Level A stimulus techniques include choices such as two-point touch discrimination, static touch stimuli with light von Frey (Semmes-Weinstein) monofilaments, or directional detection of dynamic brushing or cotton wisp stroking.[58] The patient's level of correct detection in nerve-injured zones is compared to uninjured "control" tissues, and the quantified results are recorded numerically or on a response scale and then mapped on an oral-facial picture (Figure 25-3). Level A testing may result in normal control levels of patient stimulus detection, or complete loss of fine-touch discrimination.

Level A fine touch stimuli are also used to expose signs of abnormal "excess" sensory responses that indicate neurologic sensitization (see Figure 25-2, *B*).[57] In this test phase, patients may report that fine touch stimulations such as brush stroking increase their unpleasant altered sensations (paresthesias) or trigger varied levels of pain (dysesthesias). Fine touch-elicited pain is known as *allodynia,* defined as "pain due to a stimulus which does not normally provoke pain."[62] If allodynia has been elicited, patients are then asked to rank these excess responses as mild, moderate, or severe (+1 to +3). The neural mechanisms of allodynia found with Level A testing may be due to entrapment of sensitized A-beta fibers within neuroma-in-continuity as well as peripherally initiated central sensitization.[59,63-65]

If Level A tests indicate measured sensory loss, neurosensory testing next proceeds to *Level B testing* of the patient's crude touch contact detection, mediated by the smaller A-beta and the small myelinated A-delta nerve fibers. More intense, blunt, and repetitive punctate forms of mechanical stimuli are used, such as thick von Frey monofilaments, non-noxious light pin touching, or Q-tip wood pressures. The stimulus intensities required for patients to detect these Level B stimuli are recorded and mapped as with Level A. Patients who display deficits for (Level A) fine discriminative stimuli, yet have good detection levels for crude touch Level B stimuli without pain, are not usually candidates for microsurgery, as this is considered a functionally useful sensory recovery level that is not reliably surpassed by surgical repairs.

Level B crude touch stimuli, however, may also elicit excess patient responses, including uncomfortable paresthesias and pain responses. Applying Level B stimuli and



• **Figure 25-3** Quantitative Sensory Test Recording and Neuropathic Mapping Form.

supplemental digital pressures or tapping over the injured nerve trunk distribution may elicit the excess response known as Tinel *hyperpathia,* defined as "a painful syndrome characterized by an abnormal painful reaction to a stimulus, especially a repetitive (mechanical) stimulus, as well as increased threshold."[62] Radiating and shocking hyperpathic trigger responses are likely due to presence of sensitized A-beta or A-delta fibers entrapped in neuromas and may localize injury target sites for nerve repair.[59,65]

Level C testing presents noxious stimuli to the injured nerve distribution, testing for the level of C fiber protective abilities. Useful Level C clinical stimuli include deep pin pressures, calibrated hemostat pinches, or instruments heated to 48° to 50° C. Non-radiating hyperpathic shocking responses to digital percussion may signify a site of amputation neuroma, excess C fiber regeneration, and Class V injury type.[60] Patients who respond to noxious stimulation by reporting pain well above that experienced from stimulation of their control tissues are hyperalgesic. *Hyperalgesia* is defined as "an increased response to a stimulus which is normally painful."[62] It represents another form of neural sensitization due to both peripheral and central sensitization.[63,64,66]

Patients who fail testing at levels A and B but have retained or regained basic detection of noxious stimuli can usually protect themselves from secondary autotraumas such as lip or tongue biting. However, they often have difficulties with orofacial functions such as mastication and speech, and they are candidates for microsurgery to improve on these functions. Patients who are anesthetic to Level C noxious stimuli are obvious candidates for surgical repair.

Recording Neurosensory Responses and Neural Recovery Scales

When completed, neurosensory test results are recorded and pictorially mapped as baselines for monitoring future patient progress (see Figure 25-3).

A final task is to grade the patient's current nerve injury recovery level. A four-level Nerve Injury Recovery Scale (NIRS) is suggested (Table 25-3). This scale has been modified from the Medical Research Council Scale (MRCS), which places emphasis on measured sensory losses, and also the German Research Network on Neuropathic Pain (DFSN), which focuses on measures of excess stimulus responses.[57,58,67] In the NIRS recovery scale, zero grading represents no measurable neurosensory recovery (anesthetic), zero to 1 the recovery range of Level C noxious detection functions, 1 to 2 the recovery range of Level B crude touch functions, 2 to 3 the recovery range of Level A fine tactile functions, and 4 full normal (control level) functions with no excess stimulated pain or unpleasant paresthesias.

A word of caution to clinicians regarding the limitations of neurosensory recovery scaling based solely on objective neurosensory testing: It should be recognized that patients' primary concerns are their impaired daily functions and the levels of unpleasantness and pain associated with altered sensations. These patient concerns are not fully addressed by any existing recovery scale.

Evaluating Patients with Traumatic Neuropathic Pain

Sustained, unpleasant altered sensation and varied forms of neuropathic pain occur in more than 50% to 70% of trigeminal nerve-injured patients presenting for treatment.[68,69] Their pain syndromes reflect mechanisms of deafferentation, peripheral and central sensitization, and dysautonomia.

Patients commonly cluster in two differing dysesthesia profiles: hypoesthetic pain and hyperesthetic pain.[41,42,55] Those with predominantly hypoesthetic patterns complain immediately after injury of "numbness" and often report minimal neuropathic pain at this stage. When examined with quantitative sensory testing, these patients are markedly

TABLE 25-3 Nerve Injury Recovery Scale

Recovery Grade*	Stimulus Detection Levels	Excess Stimulus Responses
4 (normal)	Full control level detection, all stimuli	No excess stimulus responses present
3	Full control level detection, all stimuli	Allodynia, hyperpathia, hyperalgesia may be present
2.5	Intermediate detection, fine touch stimuli	Allodynia, hyperpathia, hyperalgesia may be present
2.0	Full detection, crude touch stimuli Some, minimal detection, fine touch stimuli	Allodynia, hyperpathia, hyperalgesia may be present
1.5	Intermediate detection, crude touch stimuli	Hyperpathia, hyperalgesia may be present
1	Full detection, light noxious stimuli Some, minimal detection, crude touch stimuli	Hyperpathia, hyperalgesia may be present
0.5	Some detection, deep noxious stimuli	Hyperalgesia may be present
0 (anesthetic)	No responses to any stimuli	

Modified from Medical Research Council Scale (MRCS) and German Research Network on Neuropathic Pain (DFSN).
*Grades 2, 3, 4 indicate useful functional sensory recovery (FSR) on MRCS scale.

deficient in neurosensory responses for all types and levels of neurosensory testing. Days to weeks after injury, however, hypoesthetic patients gradually report intensifying paresthesias and pain perceived diffusely in the injured nerve region and complain of "constant, dull, deep, crawling, and especially burning" discomfort.[68,69]

When presented with Level B crude touch stimuli, patients with hypoesthetic patterns often experience intensified "phantom" paresthesias, afterimaging, and radiating, burning hyperpathias. Studies have shown that many of these patients have formed traumatic neuroma-in-continuity from Sunderland type 4 injuries or amputation neuromas from type 5 or type 6 injuries.[41,61] If identified within a few weeks after nerve injury, these patients may respond favorably to early surgical exploration and repair.

Unfortunately, with longer post-injury time, many patients with hypoesthetic neuralgias will experience further increases in constant, spontaneous, and spreading pain that does not respond well to local anesthetic blocks applied to the injured nerve trunks, suggesting that central sensitization has developed.[50,63] This pattern is central deafferentation syndrome, or "anesthesia dolorosa," and is associated with severe nerve lesions, permanent loss of trigeminal ganglion cells, and distorted afferent input to the brainstem.[38,64] It has been postulated that major deafferentation leads to "irritable foci" that develop through glial activation in the spinal cord and extend to thalamic and even cortical levels.[37,70,71] Deafferentation pain syndromes, if sustained for weeks or months after nerve injury, may become refractory to both medical therapies and delayed surgical repairs.[55,72]

Patients with predominantly hyperesthetic pain patterns, in contrast to those with hypoesthetic neuralgias, often have more severe pain within hours to days of nerve injury. Their primary verbal descriptors are "shocking, tingling, burning, electric, and episodic."[50,54] Early, intense responses more likely follow partial nerve injuries, such as traction, compression, puncture, local anesthetic, chemical, and burns.[55,73]

A prime clinical feature of hyperesthetic post-traumatic neuralgias is the presence of triggered paresthesias, allodynia, and hyperalgesia, phenomena that may be expressions of both peripheral and central sensitization.[65,71,74] Local anesthetic nerve blocks produce a transient but complete pain remission from these excess stimulus responses. Patients with hyperesthetic patterns are candidates for surgical decompression and repair if their triggered pain and dysfunctions are intolerable or refractory to medical treatments.

It is also important that hyperesthetic neuralgia patients be closely monitored through serial neurosensory examinations after injury to detect signs of emerging central sensitization, seen as a spread of the neuropathic symptoms to adjacent nerve distributions (referred pain, surround hyperalgesia) as well as possible symptoms contralateral to the injured nerve distribution (mirror pain).[75-77]

Rare patients with both hypo- and hyperesthetic nerve injury patterns will also display signs of complex regional pain syndrome type II (CRPS II), formerly known as causalgia (Box 25-1).[62] Although CRPS most commonly follows appendage and spinal nerve injuries, head and neck CRPS cases have also been well documented.[78,79] Patients typically describe their CRPS pain as long-standing, with both sustained spontaneous burning and episodic shocking elicited by oral-facial movements, touching the face, and exposure to cold. Triggered pain is also experienced well beyond the anatomic limits of the original nerve trauma. In addition, many patients also display diffuse swelling throughout their hemifacial regions. Examination of patients with CRPS-II most commonly reveal signs of elicited hyperesthesias, specifically allodynia and hyperalgesia. Less frequently, episodes of facial edema and skin discolorations (reddening) are seen (Figure 25-4). CRPS II has been linked to both peripheral and central nervous sensitization. In addition, post-traumatic autonomic derangements, specifically sympathetic components, have long been implicated as a primary pathophysiologic mechanism; hence the term *sympathetic mediated pain* (SMP).[80,81] Stellate ganglion diagnostic blocks may confirm the presence of head and neck SMP.[82] Unfortunately, CRPS in all body regions is refractory to most medical and reparative surgical therapies. Serial sympathetic blocks may achieve transient remissions, and intravenous ketamine and topical blocking by the alpha-2 adrenergic agent clonidine have been used with limited success.[78,83,84] Recently, trigeminal neurectomy has been revisited as a potential therapy for refractory CRPS.[85]

For all patients with post-traumatic dysesthesias, anesthetic trigeminal nerve block testing may help define the specific neuropathic mechanisms and predict the likelihood of success or failure of nerve repairs. Small amounts of lidocaine 1% are first administered adjacent to the distal portions of injured nerves, and patients are asked after a few minutes to quantify the level of pain reduction experienced compared to their baseline. Subsequent small anesthetic blocks are then instilled at more proximal nerve sites, noting responses in the patient's dysesthetic nerve region. Pain reductions of less than 50% after any blockade are

• BOX 25-1 Complex Regional Pain Syndrome, Type II Following Trigeminal Nerve Injury

Diagnostic factors:

1. Injury to trigeminal nerve, documented by history and/or measured sensory loss
2. Neuropathic pain greater than 3 months' duration, spontaneous and/or elicited, and disproportionate to any inciting event
3. Spread of pain beyond the originally injured nerve territory
4. Clinical features of regional autonomic derangement

Modified from Harden RN, Bruel S, Stanton-Hicks M, Wilson PR: Proposed new diagnostic criteria for complex regional pain syndrome, *Pain Med* 8:327-331, 2007.

• **Figure 25-4** **A**, Complex regional pain syndrome type II, 2 years after local anesthetic injections; allodynia treated with stellate ganglion blocks and ketamine infusions. **B**, Complex regional pain syndrome type II, 12 months after apical escape of sodium hypocholorite during maxillary endodontic treatment, treated acutely with incision and drainage. **C**, Complex regional pain syndrome type II, 14 months after third molar removal, unresponsive to medical and neurolytic treatments.

considered placebo-level "negative" responses and inaccurate identifiers of neuroma site or reliable predictors of therapeutic value with surgical repairs. Nerve block testing may also help the clinician differentiate neuropathic from non-neuropathic peripheral sources of pain.

Nonsurgical Treatments

Acute Nerve Injuries: Prevention and Early Care

The primary goals of immediate and early nerve injury treatments are to remove sources of ongoing or secondary nerve injuries, create a tissue environment for optimal nerve recovery, and prevent the development of chronic neuropathic sensitizations.

Minimizing chronic neuropathic sensitization is important for all surgical patients, but especially those at high risk for intraoperative nerve injury and those with preexisting regional pain. Evidence has shown that use of multimodal analgesics in the perioperative period may block the transfer of acute surgical pain to chronic neuropathic pain.[86] Presurgically applied analgesics, including gabapentinoids, COX-2 inhibitors, and an alpha-2 adrenergic agonist (clonidine), have been shown to prevent centralization.[87,88] Intraoperatively, NMDA (ketamine) infusions are recommended as well as regional nerve blocks with long-acting agents such as bupivacaine.[89,90] These multimodal therapies should extend

into the immediate postsurgical period among patients at risk for nerve injury.

When acute nerve injury has occurred, immediate supportive interventions are indicated. Soft diet is advised, hypermobile fractures stabilized, and cryotherapy applied to the region. Injured nerves, if visualized, should be freed of compressing foreign bodies, bone or tooth fragments, toxic materials, or implants. Infection and inflammation control, both topically and systemically, should be maximized. Exposed nerves should be cleansed with isotonic solution, gently coapted, and stabilized with temporary 6-0 or 7-0 epineural sutures if possible. Toxic socket dressings such as eugenol should be avoided.

Anti-inflammatory, opiate analgesic and psychosedative agents for anxiety control and sleep promotion are used to minimize acute CNS excitation in the first week after nerve injury. This would also include local anesthetic nerve blocks with long-acting agents.[90] A course of systemic corticosteroids such as dexamethasone 8 to 12 mg per day may minimize perineural inflammation during the first post-injury week.[91,92] A time-based nonsteroidal anti-inflammatory such as ibuprofen 200 to 400 mg every 6 hours is also advised during the first weeks after injury and may prevent development of chronic neuropathic pain.[93] Rapid-acting anticonvulsant agents such as clonazepam, given preventively in divided doses at 2 to 10 mg daily, are useful at this stage; in cases where more severely painful neuropathic shocking and triggering are present and unresponsive to opioid analgesics, the anticonvulsant pregabalin is useful, titrated from 75 mg three times daily to pain relief.[94,95] Sub-anesthetic doses of ketamine as well as 12-hour-release analgesic 5% lidocaine dermal patches applied over the surgical nerve distributions may further prevent early development of dysesthesias.[89,96]

Baseline clinical examination with quantitative sensory testing should be done at this acute stage and the affected nerve distributions mapped. Patients should be openly counseled regarding the nature of the nerve injury, the optional need for secondary consultations, and the possibility of a protracted course of nerve recovery.

Chronic Nerve Injuries: Nonsurgical Patient Care

Because many trigeminal nerve injury cases are not conducive to immediate or early repairs, or surgery is delayed, supportive and palliative treatments are needed. It is especially important when clinical exam exposes spontaneous dysesthesias, triggered allodynias, and incapacitating spread of symptoms over time, a possible indication of emerging central sensitization in spinal trigeminal subnucleus, thalamus, and the large area of third-order trigeminal neurons projecting to the cerebral cortex. And clinical depression, whether previously present or of recent onset, is a common comorbidity of chronic neuropathy and neuralgia.[97] Those patients for whom surgical treatments are not indicated should also understand that complete resolution of their pain and paresthesias may not be possible with nonsurgical treatments. The goals for those patients are improved oral-facial functions and reduced pain. Their nonsurgical treatments will rely on the use of topical and systemic analgesic agents, chemical nerve blockade, sensory reeducation, and behavioral therapies.

Topical Analgesics

Topical analgesics are useful and safe adjuncts for dysesthesia management, avoiding the significant central side effects of directly administered systemic drugs, particularly somnolence and cognitive impairment. The primary topical agents are local anesthetics, capsaicin patches, and compounded drug combinations with proven analgesic effects on neuropathic pain.

Lidocaine

A lidocaine dermal patch or mucosal gel can help provide localized relief of pain symptoms. Twelve-hour lidocaine release patches are self-adhesive and can be cut to fit over the affected areas on the skin.[96] Patients should be monitored for signs of adhesive contact dermatitis.

Capsaicin

Capsaicin, available as 5% and recently marketed as 8% patches, has demonstrated sustained neuropathic pain relief for post-herpetic neuralgias following single patch treatments.[98] There are no reports yet available, however, that indicate efficacy for traumatic trigeminal neuralgias, and patients with hypersensitive neuropathic symptoms have difficulty applying the irritating capsaicin chemicals to their skin.

Compounded Analgesics

Analgesic agents compounded in a lipuronic acid cream carrier are widely used in rehabilitation medicine and have also proven useful in the treatment of neuropathic trigeminal injury pain.[99,100] Combinations of agents with known neuropathic analgesic actions include ketamine 10%, 0.2% clonidine, 8% gabapentin, and 10% and 5% lidocaine. These are prescribed and formulated in 60-g creams at a compounding pharmacy. Topical ketamine has shown particular efficacy for controlling refractory allodynias after nerve injury through both peripheral and central action.[101] Other useful topical compounds for neuropathic pain include co-medication with lidocaine and amitriptyline as well as anti-inflammatory formularies applied to regions of neuroma formation.[102,103]

The compounded creams are applied directly to areas of facial skin innervated by the injured branches of the trigeminal nerve, typically three to five times daily as needed. Care must be taken if the patient is taking clonidine or comparable antihypertensive agents, as there may be an additive effect leading to hypotension.

Intraoral neural lesions may be treated with oral troches compounded as gabapentin 80 mg, ketamine 50 mg, and lidocaine 2 mg. The troches dissolve slowly when placed directly over the posterior lingual mucosa at the base of

the tongue for treatment of lingual neuralgias and over the mental foramen for inferior alveolar neuralgias. Clonidine is not included in the troche preparations because the more rapid absorption through the vascular mucosa compared to skin may cause marked hypotension.

Systemic Analgesics

Current systemic analgesics used for management of traumatic neuropathic pain consist of "first-line" analgesics (anticonvulsant and antidepressant agents), and "second line" analgesics (opiates and novel developing agents).[104]

Anticonvulsants

Titrated anticonvulsant (antiepileptic) agents have a long history of effective treatment for trigeminal neuralgias, most prominently with carbamazepine and the chemically related oxcarbazepine. Their effects on trigeminal nerve-injured pain models appear to be on the suppression of ectopic activity in damaged axons.[105] Because of undesirable side-effect profiles, however, including bone marrow suppression and co-sensitivity with tricyclic antidepressants, these agents have been largely displaced by the less toxic gabapentinoid class of anticonvulsants.[95,104]

Gabapentin, a GABA analogue, is used to treat partial seizure disorders and has also demonstrated potential for reversal of nerve injury sensory deficits, paresthesias, and mechanical allodynia.[106] Patients also report improved spontaneous pain relief, sleep, and quality of life.[87] Depending on symptoms and patient side effect tolerance, initial dosage is 100 to 300 mg per day in divided doses and titrated to pain relief in therapeutic ranges of 1800 to 2400 mg daily.

Pregabalin, another anticonvulsant medication, is a more potent and rapidly acting alternative to gabapentin, useful either for treatment of early post-injury pain or in cases where gabapentin is not effective.[107] Initial dosing is at 75 mg twice a day and can be titrated to 600 mg per day as needed. Pregabalin may be better tolerated than gabapentin.

Side effects of the gabapentinoids are dizziness, memory loss, somnolence, weight gain, dry mouth, and, according to recent warnings, increased suicidality.[108] Before prescribing gabapentin, the indications and contraindications, side effects, and drug interactions should be reviewed and patients advised accordingly.

Antidepressants

Three classes of antidepressant drugs with known analgesic efficacy for neuropathic pain are the tricyclics, the SNRI (serotonin–norepinephrine reuptake inhibitor) and NMDA (*N*-methyl-D-aspartate) antagonists. Analgesic effects of the antidepressants precede and are independent of their antidepressant actions, and these agents are increasingly being used as co-medicants with anticonvulsant agents.[109]

Amitriptyline, the most fully evaluated tricyclic antidepressant, has long been proven as an effective analgesic in the management of neuropathic pain.[110] Suggested dosing begins with 25 mg at bedtime and can be increased to 100 mg daily. Side effects of the tricyclics are similar to those of gabapentin and pre-gabalin but also involve fluid retention, weight gain, and allergy development.

The more recently developed SNRI class of antidepressants has shown positive analgesic action for neuropathic pain without some of the side effects of the tricyclics.[111] The most extensively tested SNRI has been duloxetine (Cymbalta) in dose ranges of 60 to 120 mg per day. Side effects include nausea, hypersomnolence, and xerostomia, and the SNRIs are contraindicated for patients with severe hepatic dysfunction or unstable arterial hypertension.[112]

The NMDA antagonist ketamine, a clinically potent analgesic with antidepressant actions, has a well-established role in the treatment of acute and chronic pain.[113,114] Outpatient protocols using intravenous infusions of both subanesthetic and anesthetic doses of ketamine have resulted in sustained relief of refractory deafferentation pain and spreading centralized pain with phantom, allodynia, and hyperalgesia features.[84] Unfortunately, the full use of NMDA antagonist agents for neuropathic analgesia is limited by their psychotomimetic side effects.

Opiates

It has been documented over a 30-year time frame that traditional morphine-equivalent opiate analgesics are not as effective for sustained neuropathic pain as for acute nociceptive and surgical pain.[115] Classically cited reports have found reliable opiate pain relief in only one of three patients and their estimated pain reductions at 30%.[116,117] And, rapidly developing drug tolerance is known to stimulate increasing opiate dosing requirements, leading to potential abuse.[115] For these reasons, opiate analgesics are now considered second-line agents for management of nonmalignant neuropathic pain. They remain useful, however, for specific subpopulations of well-selected patients who have failed first-line medical or surgical therapies.[118]

Tramadol, a centrally acting synthetic opioid analgesic combined with the NSAID agent acetaminophen, has also been recommended as a short-term neuropathic pain management formulation. If used for chronic episodes of "breakthrough" pain, however, there are risks of drug interaction with serotonin reuptake agents and especially among elderly patients for renal or hepatotoxicity due to overuse of acetaminophen.[115]

Cannabinoids

Definitive laboratory investigations have shown that delta-9-tetrahydrocannabinol, the primary psychoactive component of marijuana, is a potent analgesic for nerve injury pain, including trigeminal dysesthesias, acting on both peripheral neural and central endocannabinoid receptors.[119,120] Centuries of anecdotal testimonies and early clinical reports indicate considerable promise for the development of useful novel cannabinoid analgesics.[121,122] With the current legal

and societal attitude changes regarding medical uses of marijuana, the near future may see full clinical trials reporting on the safety, efficacy, and guidelines for prescribing cannabinoid agonists for treatment of traumatic neuralgias.[123]

Chemical Nerve Blockade

Local Anesthetics

Peripheral nerve blocks, applied at nerve terminals, trunks, and ganglia, with long-acting local anesthetics such as bupivacaine 0.5%, often combined with corticosteroids, are a mainstay of pain management for a wide range of chronic pain conditions.[124] This is based on the long-standing demonstration that blocking chronic pain cycles by injecting muscle tender points or neuropathic trigger sites often induces pain remissions that far outlast the expected duration of drug action.[125] Although employed empirically by many therapists for pain palliation, anesthetic block therapy has scant literature support from controlled studies.

Botulinum Neurotoxin Type A (BoNT-A)

Injections of Botox into painful regions of previous trigeminal nerve injuries may induce transient remissions for weeks to months.[126,127] Peripherally deposited BoNT-A has no effect on acute pain thresholds. However, chronic pain relief from BoNT is attributed to reduced sensitization of nociceptors by antagonizing the effects of local-released afferent peptides SP and CGRP.[128,129] In those clinical cases where traumatized trigeminal nerves are adjacent to masticatory or facial muscles, Botox injections may also relieve pain because of their known mechanism of action on acetylcholinesterase-mediated neuromuscular endplates.

In Botox therapy, approximately one half carpule of long-acting local anesthetic is administered first. This has the benefit of opening the tissue planes and allowing nerve access for the Botox. Ten to 50 units for a total of less than 100 units is injected into neural trigger sites or administered similar to IAN, lingual, or infraorbital anesthetic blockade.[130] Care must be taken to confine the Botox solutions to areas in direct proximity to the injured nerve, and injections should not be made into infected tissues.

Sensory Reeducation

As a simple but effective stimulus to sensory normalization, sensory reeducation is a psychophysical intervention that promotes "perceptual relearning" of functional connections at somatosensory and associative hippocampal cortical levels.[131]

Recovery of sensory functions depends on the inherent "plasticity" of the CNS, and there is strong evidence that recovery may be hastened and final results enhanced by applying psychophysical exercise protocols that assist the brain in interpreting newly configured sensory input.[132] Research has shown that recovery of more "normal" sensations perceived in lips, chin, oral mucosa, tongue, and face can be enhanced by having patients regularly perform tactile, visual, and imagery "reeducation" exercises during active stages of neural regeneration.[54,133] Patients are instructed in the purposes and applications of sensory reeducation and are given a written protocol (Figure 25-5).

Behavioral Pain Management

For patients with long-term trigeminal painful neuropathies, referral to consultants in pain management, neurology, psychiatry, and clinical psychology may be essential resources for a multidisciplinary team approach to recovery. Pain management and neurology specialists, however, are often more familiar with managing body regions other than the oral-facial complex and may lack full appreciation of trigeminal injury patients' specific problems and needs. Therefore it is incumbent on the oral and maxillofacial surgeon to contact and speak directly with a pain specialist to carefully outline the nature of the injury and treatments thus far rendered. Periodic communications between the surgeon and pain management specialist are essential for effective patient management.

Because depression is a near-universal comorbidity with chronic neuropathies and chronic pain, active psychiatric care and use of psychopharmacology may be indispensable for comprehensive treatment.[97,134] Clinical psychologists consulted should be well versed in behavioral techniques such as acceptance and commitment therapy (ACT) and especially cognitive-behavioral therapy (CBT), which has been shown to have potential to reduce nerve injury—induced central sensitization hyperalgesias.[135,136]

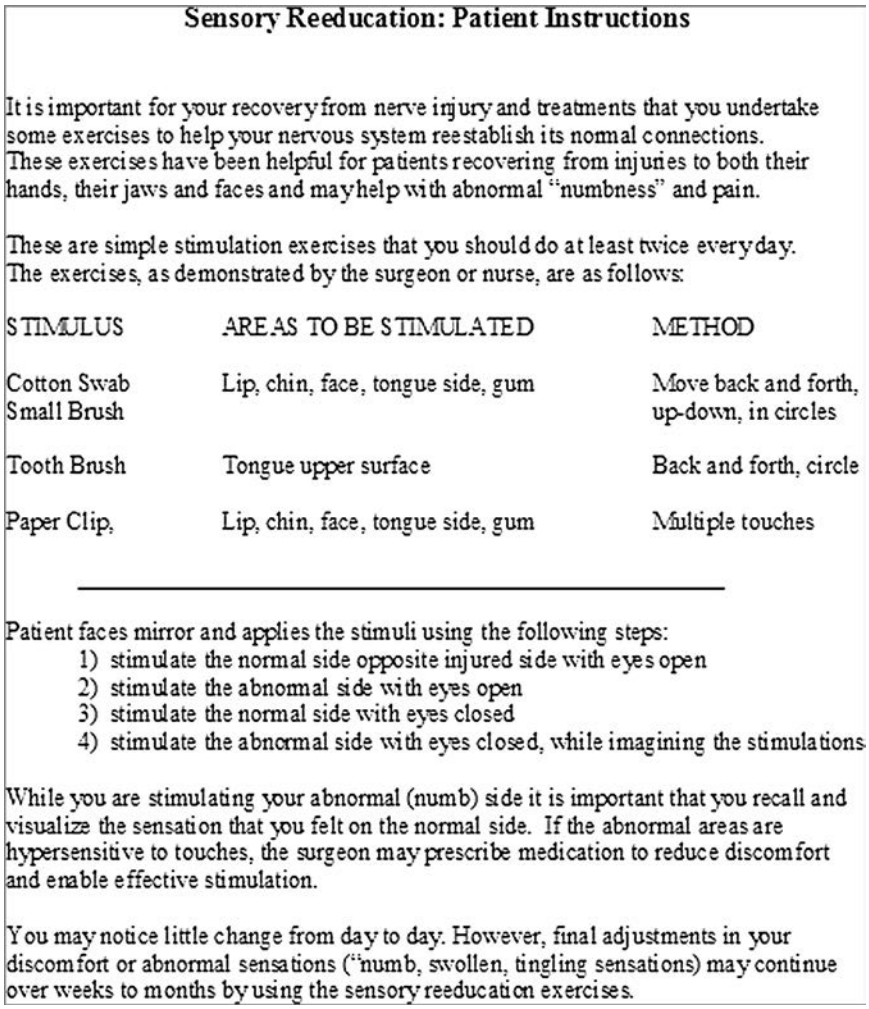
Surgical Management of Nerve Injuries

Surgical Management: Purposes and Patient Selection

Neurosurgical interventions for patients who have sustained trigeminal injuries have two main purposes: to restore oral-facial sensory functions and to manage pain and discomfort. Repairs are done on sensory trigeminal branches only, the motor root being inaccessible except for major cranial-base procedures. The sensory trigeminal nerves most commonly amenable to repair are the inferior alveolar-mental, lingual, and infraorbital nerves, and less frequently the supraorbital and supratrochlear branches. The long buccal nerves are often damaged during routine oral surgeries; however, symptom complaints of posterior gingival and buccal mucosa triggered pain are infrequently reported.[137] The auriculotemporal nerves are also susceptible to injury during facial trauma and surgeries for parotidectomy and temporomandibular joint reconstruction. Although pain and dysfunction are also encountered following auriculotemporal injuries, there are no definitive reports of microneurosurgical treatments for these conditions.

Indications

Indications for surgical exploration and repair of trigeminal nerves are: (1) observed mechanical nerve injuries with immediate post-traumatic symptoms, (2) presence



Sensory Reeducation: Patient Instructions

It is important for your recovery from nerve injury and treatments that you undertake some exercises to help your nervous system reestablish its normal connections. These exercises have been helpful for patients recovering from injuries to both their hands, their jaws and faces and may help with abnormal "numbness" and pain.

These are simple stimulation exercises that you should do at least twice every day. The exercises, as demonstrated by the surgeon or nurse, are as follows:

STIMULUS	AREAS TO BE STIMULATED	METHOD
Cotton Swab Small Brush	Lip, chin, face, tongue side, gum	Move back and forth, up-down, in circles
Tooth Brush	Tongue upper surface	Back and forth, circle
Paper Clip,	Lip, chin, face, tongue side, gum	Multiple touches

Patient faces mirror and applies the stimuli using the following steps:

1) stimulate the normal side opposite injured side with eyes open
2) stimulate the abnormal side with eyes open
3) stimulate the normal side with eyes closed
4) stimulate the abnormal side with eyes closed, while imagining the stimulations

While you are stimulating your abnormal (numb) side it is important that you recall and visualize the sensation that you felt on the normal side. If the abnormal areas are hypersensitive to touches, the surgeon may prescribe medication to reduce discomfort and enable effective stimulation.

You may notice little change from day to day. However, final adjustments in your discomfort or abnormal sensations ("numb, swollen, tingling sensations) may continue over weeks to months by using the sensory reeducation exercises.

• **Figure 25-5** Sensory reeducation patient instructions.

of paraneural neurotoxic chemicals or impinging foreign bodies such as tooth or bone fragments or endosseous implants, (3) unchanging anesthesia or dysfunctional hypoesthesia more than 3 months after injury, and (4) medically intractable neuropathic pain. Additional clinical indicators that are predictive of surgical success include presence of specific dysesthetic (hyperpathic) trigger points indicating possible underlying traumatic neuroma, and significant relief of pain after local anesthetic test nerve blockade.

Contraindications

Contraindications for trigeminal surgical exploration and repair, although not absolute, are: (1) objective signs of improving neurosensory functions based on serial quantitative sensory testing, (2) patient acceptance of existing levels of impaired functions, discomfort, or pain, (3) deafferentation pain not relieved by local anesthetic nerve blocks, (4) signs of central sensitization including spreading regional dysesthesia, secondary hyperalgesia, and referred pain, (5) clinical signs of autonomic derangement (burning sensations, erythema, or facial swelling), (6) extremes of age or systemic or neurologic disease, (7) excessive time since original nerve injury, and (8) unrealistic patient expectations (restoration of full normal, pain-free neurosensory functions).

Timing of Surgery

Surgeries are categorized according to their time of repair relative to their injury dates. They are primary (immediate), delayed primary, and secondary. Primary repairs are done in those instances when the nerve has been exposed and the injury was observed, as is common during surgeries for trauma, dentoalveolar pathology, and orthognathic, implant-reconstruction, and some third molar surgeries. Immediate (primary) nerve surgeries, if technically possible, are the preferred time of repair from a biologic perspective. Axonal regeneration is known to be optimal at earlier time frames, within the first 3 weeks after injury, and before neuroma formation and restrictive secondary scarring can occur. Limited acute primary nerve repairs may be possible even in office or operating room settings. Surgical loupes can enable nerve decompression, passive nerve apposition, limited epineurial suturing, and placement of alloplastic barriers around the exposed nerve. Observed nerve injuries

may also be treated by "delayed primary" repairs if needed, done within a few weeks of injury when regional tissues have recovered from acute trauma effects and plans can be made for definitive nerve microsurgical repair.

Unobserved trigeminal nerve injuries are the more common circumstance and require secondary surgical repairs under controlled conditions and after patients have adequately met the surgical indication criteria. The question of optimal timing for secondary surgeries remains controversial and the subject of ongoing research.[9,138,139] There is much evidence that earlier surgical repairs, within one to a few weeks following injury, are preferred over longer delays for three basic reasons: (1) optimal regenerative capacity occurs within the first few weeks after injury, (2) early intervention may prevent the development of traumatic neuromas and both peripheral and central sensitization, and (3) tissue quality is superior compared to chronic injury status. With longer delays, microsurgical repairs become more difficult because of retraction and progressive atrophy of nerve segments, increased extraneural and intraneural collagen deposition, and Schwann cell scarring. Outcome analyses have shown that lingual nerve and inferior alveolar repairs done within 90 days of injury can result in functional sensory recovery levels as high as 66% to 93% at the 1-year mark.[8,10] These same reports have shown, however, that useful sensory recovery levels as high as 63% can be gained for selected cases operated after 90 days. Other studies support the conclusion that there is no association between delayed repairs and sensory outcomes.[12,140]

The timeline for successfully repairing soft tissue nerve injuries such as lingual, infraorbital, and mental nerves is much shorter than for intrabony nerve injuries such as inferior alveolar. This is due to the very limited capacity for spontaneous regeneration of transected soft tissue nerves as compared to intrabony branches where the mandibular canal can act as a natural conduit for nerve recovery, given enough time.[141]

Surgical Principles and Techniques

The surgical principles for effective trigeminal microsurgery emphasize gentle tissue management, avoidance of secondary damage to epineurium, and minimizing ischemic injuries to surface microvasculature. Hemostasis should be optimized to enhance repairs and attention given to removal of paraneural foreign bodies and adhesive scar. Careful identification and excision of dysfunctional neuroma segments are required, and transected nerve segments should be aligned and rejoined under minimal tension. In those less optimal circumstances when direct neurorrhaphy is not possible, the surgical goal is to create a microenvironment that permits effective axonal downgrowth to nerve receptors, through either interpositional nerve grafting or entubulation.

Trigeminal nerve repairs require a quiet and controlled operating room environment. Surgical assistants familiar with the goals and procedures of the microrepair are essential. The microsurgical environment is more demanding of surgical assistants because of the limited surgical field access and the extra requirements of stable retraction, hemorrhage control, and delicate tissue management. Endotracheal intubation with selective muscle relaxation is needed to prevent inadvertent patient movements. Hemostasis can be enhanced with reverse Trendelenburg positioning and local anesthesia with vasoconstrictor field blocking. Hypotensive general anesthesia may be required to assist in hemorrhage control, along with bipolar electrocautery used to avoid collateral injuries to the nerve under repair. Although nerve access, nerve release, and decompression can be accomplished with minimal magnification such as 3× to 4× surgical loupes, many experienced surgeons prefer an operating microscope with greater than 250-mm focal length and multiple heads for assistant views of the operating field. Primary microsurgical instruments for intraoral repairs also require extra-length micro instruments and also include a selection of small retractors, vein and nerve hooks, varied-length microforceps, straight and curved needle holders, and microscissors. Self-retaining flat vascular spreaders and vascular clamps can be used in some circumstances. Preferred sutures are nonreactive nylon or Prolene, 7-0 through 9-0. Nonreflective background materials such as opaque foils or rubber matting are helpful for visibility and tissue control and to assist in atraumatic microsuctioning. A selection of nerve wrap cylinders should be available for protecting the microrepair sites. Their purposes are to eliminate dead space, minimize compression ischemia, prevent paraneural hematoma and scarification, and prevent secondary collagen ingrowth at the repair sites.

Nerve Access

Lingual Nerve

Lingual nerve injuries are approached through incisions placed either in the paralingual floor of mouth or via a modified lateral vestibular incision similar to third molar or bilateral sagittal split osteotomy (BSSO) incisions. The paralingual approach is effective if minimal dissection or distal floor of mouth locations are required. It may be inadequate if there is need for wider nerve release, for injuries higher in the medial ramus, and for full neuroma resection and repair. The paralingual incision may also be inadequate if the nerve has been fully transected and has retracted proximally into the pterygomandibular space.

The more common lateral vestibular incision leads to mucoperiosteal flap elevation over the external oblique ridge for approximately 2 cm. A second full-thickness lingual mucoperiosteal flap is also developed by incising the lingual gingival papillae and elevating a flap from the retromolar pad anteriorly to the first molar. The lingual flap elevation should be done carefully, as the damaged lingual nerve may have been positioned at a "high" alveolar crest level when injured or has retracted and become entrapped superficially within the lingual flap. Once the lingual nerve is identified, it may be released distally into the floor of the mouth if needed, avoiding exposure beyond its crossing by the submandibular duct.

Infraorbital Nerve

Infraorbital nerve injuries that have occurred distal to the orbital rim are easily approached through transoral vestibular

incisions. More proximal injuries that include trauma to the orbital floor are best approached through a subconjunctival blepharoplasty incision. Proximal infraorbital nerve injuries in the orbital floor may require decortication of the canal roof within the orbital floor as well as osseous relief at the infraorbital rim before repair can be done.

Inferior and Mental Alveolar Nerves

The surgical access for damaged mental and inferior alveolar nerves is dictated by the anatomic site and nature of the nerve injury as determined by history and clinical exam. For inferior alveolar injuries in the mandibular mid-body, superficial third molar region, and distal IAN injuries including those near mental foramen, a transoral buccal plate osteotomy exposure is recommended.[14] Lateral bone cuts are made vertically from alveolar crest to the inferior border 1.5 cm proximal and distal to the targeted nerve injury site using a tapered fissure diamond bur or piezotome blades. A parasagittal superior alveolar bone burr cut then joins the two vertical cuts. A final lateral scoring can be made at the inferior border using the angled semilunar or piezotome saw. The rectangular buccal osteotomy is then released using small curved osteotomes.

For more inferior and medially positioned mandibular nerve injuries where longer nerve lesions are suspected, as with angle fractures, endodontic paste injuries, and in chronic cases related to previous sagittal osteotomy orthognathic nerve injuries, an exposure through sagittal osteotomy may be required. Injuries to the IAN in the posterior third molar or lateral angle region may require submandibular Risdon incision approach and lateral cortical block osteotomy for nerve exposure.

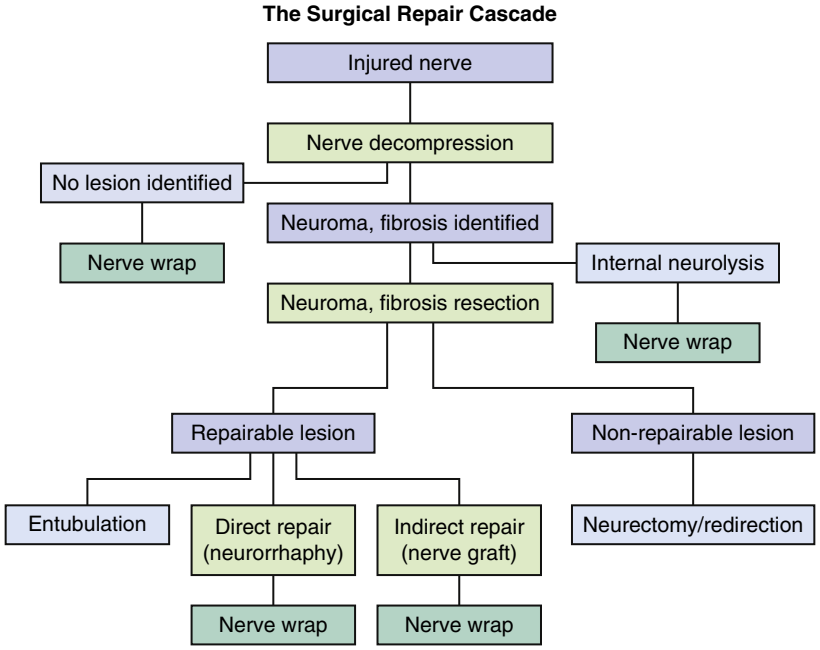
Damaged mental nerves are approached through free gingival margin incisions, with careful subperiosteal flap exposure of the usual three branches and the bone overlying the IAN proximal to the mental foramen. The nerve trunk and mental branches are further exposed through "donut hole" osteotomy widening of the foramen and gentle lateralization of the distal portions of IAN.

The "Surgical Repair Cascade"

Once access to the injured nerve has been accomplished, a "surgical cascade" of nerve repair options is undertaken (Figure 25-6). The cascade includes (1) soft or hard tissue *decompression* of entrapped injured nerves with removal of foreign bodies and release of paraneural compressing tissues or scars, (2) inspection and resection of traumatic neuromas and internal *nerve fibrosis and traumatic neuroma,* (3) microsurgical repair with *neurorrhaphy* (direct reanastomosis), and (4) *nerve graft repair* if direct neurorrhaphy cannot be accomplished, (5) placement of *protective "nerve wrap" cylinders*. Second-line nerve repair techniques may be considered for special circumstances, and include (6) *entubulation,* (7) *internal neurolysis,* and, when nerve repair is not technically possible or effective, (8) *neurectomy* and *nerve redirection*.

Decompression

Also known as "external neurolysis," nerve exposure and microsurgical decompression is the first phase of all nerve repair procedures. Soft tissue injured nerves are approached through flap incisions placed adjacent to the nerve injury site. Once identified, the nerve is released from paraneural scar using 3× to 6× magnification. The freed nerve is fully mobilized and controlled by placing umbilical tapes proximal and distal to the gross nerve injury site. Access to intrabony nerve lesions is gained by careful osteoplasty of



• **Figure 25-6** "Surgical repair cascade" algorithm for treating trigeminal nerve injuries.

lateral bone plates or opening of constrictive bony foramina, done ideally by using piezotome burrs. Impinging foreign bodies, bone or tooth fragments, and constricting scar tissues are then removed while preserving the epineurium and its microvasculature. The nerve injury site is then inspected, observing for nerve discontinuity and presence of amputation neuroma, one of the varied neuroma-in-continuity types, or signs of internal neural fibrosis.

In cases of Sunderland type 1 or 2 injuries, when high-magnification nerve inspection and palpation have failed to reveal signs of nerve fibrosis or neuroma, decompression may be the only surgery required. Nerve decompressions, especially when applied in cases of compressive intrabony nerve lesions from dentoalveolar or implant trauma, have a convincing history of favorable outcomes, improving sensation and reducing dysesthesia.[12,142-144] As a final step, the decompressed nerves are wrapped with barrier protection tubules.

Resection of Neuromas and Nerve Fibrosis

After decompression, nerves are inspected using magnification and transillumination, searching for signs of neuroma and internal fibrosis. Trigeminal neuromas present as varied physical types (Figure 25-7).[41,145] The most easily recognized type is the discontinuity *amputation neuroma*, the result of Class V and Class VI injures with complete internal fibrosis. These neuromas will require excision, nerve-end trimming and microrepair with neurorrhaphy, entubulation or interpositional nerve grafting. *Neuroma-in-continuity* presents as four subtypes: the fusiform *expanded, atrophic narrowed, lateral exophytic,* and *lateral adhesive* variants (Figures 25-7, 25-8, *A*, and 25-9, *A*).

The extent of nerve internal fibrosis of neuroma lesions is determined by transillumination at high magnification, noting signs of nerve opacity or loss of surface vasculature, and testing for internal fibrosis by gently compressing the nerve with microforceps. Fibrotic and neuroma lesions are resected sharply with a Beaver blade 2 to 3 mm proximal and distal to the damaged tissue and submitted for histologic analysis. Satisfactory excision produces a normal herniation of axoplasm from intact fascicles within the proximal nerve stump. Adequacy of neuroma resection can also be determined by submitting 1-mm cross-sectional biopsies for frozen-section histologic finding of normal nerve fascicles. The tissue stumps are finally trimmed in preparation for microsurgical nerve repair.

Neurorrhaphy

In those cases where neuroma or severe nerve fibrosis have been found and these lesions fully resected, the residual proximal and distal segments are trimmed and then gently coapted using microforceps to determine the feasibility of direct reanastomosis, known as neurorrhaphy. Direct epineural microsurgical neurorrhaphy is best done using 6× to 12× magnification, placing 7-0 to 9-0 nonreactive sutures at three to five circumferential locations (see Figure 25-8, *B*). Completed neurorrhaphies should display no bulging or wrinkling between sutures, and the nerve should lie passively when released. Minimal repair line tension is significant as it has been shown that tension greater than 25 g across nerve microrepair sites may inhibit axon downgrowth to the distal nerve.[146] When neurorrhaphy is complete, the repair site is further protected from hematoma, fibrous tissue in-growth, and secondary neuroma formation by entubulating the nerve with an alloplastic protective nerve wrap. In cases of proximal infraorbital neurorrhaphies, an alloplastic graft barrier is secured in the floor of the orbit.[147]

Nerve Graft Repairs

In cases of more severe nerve injuries, direct neurorrhaphy repair may not be feasible. Clinical experience has shown that nerves gap-injured within intrabony sites such as the mandibular or orbital canals cannot be easily mobilized to permit direct neurorrhaphy. Even soft tissue injuries such as lingual nerve gaps greater than 15 mm cannot be routinely bridged by direct neurorrhaphy without requiring excessive nerve dissection release that risks ischemia and excessive tension at the repair site. Therefore, a range of interpositional nerve graft procedures have been developed to repair more extreme avulsive injuries or neuroma resection gaps. They include autologous nerve grafts, the recently developed allogeneic processed cadaver grafts, and interpositional entubulation.

Autologous Grafting

The "gold standard" for trigeminal nerve gap repairs over the past few decades has been autologous donor nerves from the sural, greater auricular, and antebrachial cutaneous nerves.[148,149] Advantages of autografting are their immunocompatibility and the very adequate donor tissue lengths of 6 cm or more that can be obtained. Grafts are attached with minimal epineural microsuturing using the fewest possible sutures because of the friability of donor nerves. The entire graft complex is finally wrapped using protective nerve cuffs.

Comorbidities with autologous grafts are significant, however, and include complaints of disturbing paresthesias, dysesthesias, and occasional neuroma formation at the donor sites.[150] In the case of sural nerve donors, the lateral and posterior foot may display deficits and difficulties with hyperesthesia from shoe contact and ankle movements. Patients whose greater auricular nerves have been harvested may complain of paresthesias over the lateral neck and jaw angle, a problem for those patients with adjacent trigeminal injury neuropathies.

An added technical problem with autologous nerve grafts is the poor match in shape, size, and fascicle numbers between grafted nerves and trigeminal nerves. The lingual nerve averages 3.2 mm in diameter and the IAN 2.4 to 3.1 mm, with both nerves being generally cylindrical in shape. This contrasts with the sural nerve at approximately 2.1 mm in diameter and greater auricular 1.5 mm, both being

generally flat in shape and with far fewer fascicles than the trigeminal branches.[151] Direct fascicular alignment between graft and trigeminal nerve in the grafting procedure is therefore inexact and encourages disorganized axonal regeneration across the repair sites. Given the potential problems with autologous donor site morbidities, the search for alternative grafting procedures continues.

Processed Allogeneic Cadaver Grafting

A potential major advance in the surgical management of trigeminal injuries is the recent introduction of allogeneic (human cadaver) processed nerve grafts. The "Avance" allografts (AxoGen, Alachua, FL) became available in 2007 and were tested in experimental and mixed nerve injury models.[15,152,153] Successful trigeminal clinical grafts were then reported in a case series of eight patients with a 50% success rate followed by confirmation at other treatment centers.[16,154] A recent series of 23 lingual and IAN discontinuities treated with the allogeneic graft has demonstrated an impressive 87% improvement in neurosensory scores without adverse clinical effect.[16] In addition, 2-year patient outcomes after 29 allogeneic lingual nerve graft repairs were found to be objectively and subjectively superior to outcomes after 18 direct neurorrhaphy repairs.[155]

The Avance grafts are processed by exposing cadaver nerves to chondroitinase enzymatic decellularization and DNA removal detergents, secondary gamma irradiation, and freeze-thaw cycles.[156] The final products are then sent to operating room storage units, maintained at –80° C, and are readied for clinical use through thaw and hydration.

The clear advantage of the processed grafts is the elimination of need for donor site surgery and systemic immunosuppression; these grafts retain the basal lamina and endoneurial scaffolding that serve as conduits for nerve fiber regeneration. Primary applications of the decellularized grafts have been for large gap injuries of lingual nerve and especially IAN gap injuries where the mobilization of nerves for direct neurorrhaphy is limited (Figure 25-10, *B*).

Nerve Wrapping

The placement of protective nerve wraps has been shown to improve recovery outcomes from nerve decompressions and all types of nerve repairs by minimizing perineural hematomas, reducing recurrent scarring, stabilizing suture repairs, and enhancing sensory improvement.[13,157,158] There is also evidence that nerve wraps may reduce recurrent traumatic neuralgias.[159,160] Both alloplastic and autologous wraps are in use.

Alloplastic Wraps

Two nerve wrap alloplastic products have been used the biodegradable collagen type I NeuraGen sleeve (Integra LifeSciences, Plainsboro, NJ) and the more recently developed porcine nerve cuff AxoGuard (AxoGen) (Figure 25-11). Wrap stability may be improved by placing tacking microsutures through the wrap before final site closure.

Autologous Wraps

Inside-out vein cuffs used to wrap lingual repair sites have recently resulted in superior functional recoveries compared to non-wrapped nerves.[161]

Entubulation

Successful alternatives to neurorrhaphy and graft repairs of nerve gap injuries have been sought for decades and include both biologic autologous and alloplastic conduits.[149]

Autograft Entubulation

Arterial and venous autograft tubules are attractive potential donors because their harvesting is minimally invasive and

these tissues are readily available. Vascular entubulation grafts to date, however, have not resulted in acceptable sensory recovery levels, perhaps because of collapse of the grafted vessels and consequent interference with axonal downgrowth.[162,163]

Alloplast Entubulation

The search for a successful *alloplast* that would promote bridging of nerve gaps has a lengthy history. Alloplastic grafts have the obvious advantages of availability and avoidance of the morbidities found at nerve graft donor sites. The nonbiodegradable conduits silicone and Gore-Tex (polytetrafluoroethylene) have been used successfully for digital and limited inferior alveolar repairs, but have yielded poor outcomes for lingual repair gaps greater than 6 mm, a level of discontinuity that is usually manageable with direct neurorrhaphy.[164,165]

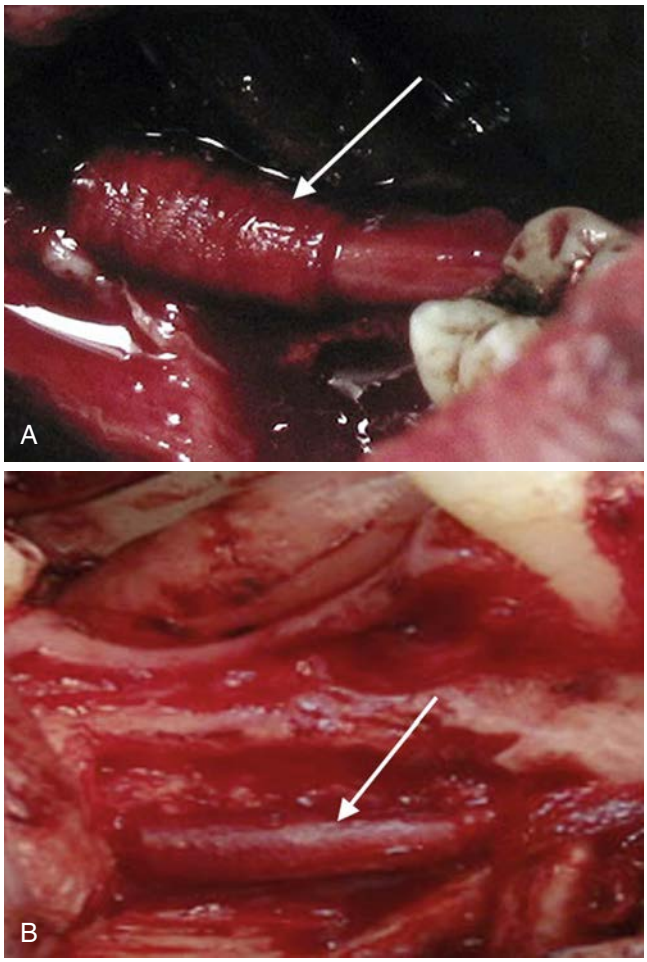
Biodegradable synthetic conduits, however, have been used more successfully for both digital and trigeminal case repairs beginning with a polyglycolic acid product Neurotube (Synovis Life Technologies, St Paul, MN).[166,167] The most thoroughly tested tubules in current clinical use have been the bovine collagen type I nerve guide products NeuraGen (Integra LifeSciences) and Neuroflex (Collagen Matrix, Franklin Lakes, NJ). More recently, the porcine-based product AxoGuard (AxoGen) has become available as a potential tubulation. The porcine tubes are not fully resorbed as are the collagen tubules, but become incorporated and vascularized as an extraneural biologic layer.

Stem Cell Entubulation

A recent innovation for improving nerve injury sensory outcomes and reducing dysesthesia has been the seeding of repair tubules with progenitor neuronal stem cells.[168,169] Cultured Schwann cells, bone marrow, and adipose-derived stem cells with tubules have all shown promise for experimental nerve injury models.[170,171] Definitive reports of successful clinical trigeminal applications of stem cell entubulation, however, are not yet available.

Internal Neurolysis

A procedure used successfully in the treatment of in-continuity injuries of large spinal nerves is known as internal



• **Figure 25-11** **A**, Lingual nerve repair wrap using "NeuraGen" collagen-based product; **B**, Inferior alveolar repair wrap using "AxoGen" porcine-based product.

neurolysis and has also been used for trigeminal nerve injuries.[13,172,173] In this procedure, saline is injected beneath the epineurium in the nerve-injured zone. The fluid-ballooned region is then incised longitudinally, exposing the internal nerve microstructure. When effective, this permits release of internal nerve scar constrictions and frees the nerve fascicles. The most urgent indication for internal neurolysis is the removal of intraneural neurotoxic foreign materials such as endodontic sealants, which must be done within the first 24 to 72 hours after intraneural contamination. Internal neurolysis has also been used for milder cases of chronic internal fibrosis from Sunderland types 2 and 3 mechanical injuries. If no fascicular release occurs, however, and internal nerve fibrosis remains after microdissection, the affected zone must be excised and followed by neurorrhaphy. Internal neurolysis has a long history of successful use for treatment of spinal or digital nerves where there are large fascicles and thick perineuria. Similar techniques are less feasible for trigeminal nerves, however, where fascicles are smaller and perineuria are thinner. Unfortunately, there are no convincing published reports of internal neurolyses being used effectively for trigeminal nerve repairs, and patients treated by this chapter's authors with internal neurolysis alone have had disappointing outcomes.

Neurectomy and Nerve Redirection

For those unfortunate circumstances in which inspection reveals that trigeminal nerve repair is not possible, and after all other options for conservative treatment have been exhausted, neurectomy and nerve redirection may be used. Their primary indications would be cases of nerve inaccessibility, absence or severe atrophy of the transected proximal or distal nerve trunks, failed surgical repairs, and medically intractable dysesthesias.

Neurectomy

Surgical ablations of peripheral nerves for relief of neuralgias were a mainstay of neuralgia management well into the twentieth century.[174] These procedures fell out of favor, however, and were largely considered obsolete because of complications of stump neuroma reformation, neuralgia recurrence, and centralized "anesthesia dolorosa" dysesthesias.[175] There has been renewed interest in the use of ablative trigeminal neurectomies; however, recognizing that they may reverse sympathetic mediated pain syndromes, may induce immediate pain relief for months and are relatively simple procedures that can be repeated if needed.[176,177]

Nerve Redirection

A logical extension of neurectomy is the use of nerve redirection. In this procedure, originally developed for orthopedic applications and now with applications for trigeminal injuries, the residual proximal nerve trunk is engaged and sutured into adjacent viable static skeletal muscle such as the mylohyoid or masseter muscles.[14,178-180] Nerve redirection is believed to decrease the likelihood of reformation of active traumatic neuroma at the proximal nerve stump interface, but will result in permanent deafferentation, with or without pain.

Post–Nerve Repair Management

Following surgical nerve repairs at any stage, patient counseling reinforces information about their anticipated course of recovery. An expected period of minimal pain and subjective "numbness" of 6 weeks or more is explained to patients, and a limited soft diet is recommended to avoid secondary accidental tissue trauma. A restricted range of mandibular motion is also anticipated, especially where lingual nerve repairs have been carried out; this may require temporomandibular physical therapies for restoration of full joint functions and mandibular range of motion.

Early postoperative medical support uses a 5-day tapering course of corticosteroid such as dexamethasone or methylprednisolone.[91,92] A short-acting anticonvulsant-psychosedative agent such as clonazepam (Klonopin) 0.5 mg twice daily, combined with titrated opiate analgesics, is used to prevent central sensitization.[94]

During intermediate and later stages of neurosensory recovery after surgery, transient episodes of hyperesthesia often occur. Supportive medical therapy at these stages stresses use of anticonvulsant, antidepressant, and topical analgesic lidocaine therapies (see "Nonsurgical Treatments").[95,96,106,107,109] Patients are instructed to begin active sensory reeducation exercises within the first month after surgical repairs (see Figure 25-5). Counseling after nerve repair stresses the expected gradual recovery of functions over a minimum 1-year time frame. Patients are recalled regularly to monitor their recovery of orofacial and neurosensory functions, and adjust their palliative therapies as needed.

Clinical Applications

Postsurgical Pain

Postsurgical pain is expected following most oral and maxillofacial surgery. It usually lasts 1 to 4 weeks depending on the procedure and is the primary focus of patients' quality-of-life concerns.[181] Although full recovery from the painful state occurs spontaneously for most patients after many types of surgery, others experience persistent postsurgical pain (PPSP) of 2 or more month's duration, and for some patients postsurgical pain becomes permanent.[182]

The prevalence of PPSP for oral and maxillofacial procedures varies greatly by procedure but may approach 25%.[5,65] The underlying etiology of transitions from postsurgical acute to chronic pain is unclear. Systematic reviews of PPSP from wide-ranging types and locations of surgeries has concluded that PPSP is primarily a neuropathic condition.[86,183] Nerve injury is considered a frequent source of acute inflammation that activates a pathway leading to a high incidence of chronic central sensitization.[184] In the case of maxillofacial PPSP, acute trigeminal neuritis often stems from combinations of nerve trauma and chronic inflammatory conditions such as osteomyelitis and unresolved temporomandibular dysfunction.[27,185] The overall goals of postsurgical pain management, therefore, are to maximize the management of the acute stage of postsurgical pain, to recognize key clinical signs of neuropathic transition, and to take steps to prevent the establishment of chronic central sensitization (Table 25-4).

Acute-Phase PPSP

Acute-phase PPSP maxillofacial postsurgical pain lasts a few days to weeks, depending on the operation, and is characterized by classic neurogenic inflammatory responses to musculoskeletal and trigeminal trauma. Clinical signs of peripheral sensitization include sustained swelling, discoloration, reduced range of motion, dull pain aggravated by percussion, and complaints of "tingling and numbness."

Perioperative treatments of acute-phase postsurgical pain are primarily pharmacologic, using intraoperative and postoperative ketamine, trigeminal nerve blocks, and oral and parenteral corticosteroids.[89,90,92] Postoperatively, oral or transdermal opioids are prescribed on a time-based schedule with supplements added for breakthrough pain. Sedative and antispasmodic agents are also used at the acute stage to manage anxiety and muscle spasms.

Transition-Phase PPSP

Transition-phase PPSP, typically spanning 2 to 6 weeks, is characterized by nonresolving peripheral sensitization and emerging clinical signs of central and autonomic sensitization. These present as (1) both constant and elicited ("triggered") pain, (2) allodynia, hyperpathia, and hyperalgesia, (3) pain phantoms and afterimaging, (4) anatomic spread of neuropathic symptoms beyond damaged territory, and, less frequently, (5) neurovascular episodes of edema and discolorations.[186,187] In cases of known direct damage to trigeminal nerves, painful traumatic neuromas that have formed in the few weeks after surgery may be an added peripheral source of transitional pain. Treatments for the transition phase shift from reliance on short-acting agents to antiepileptic and antidepressant combinations titrated to pain relief and side effect tolerance (see "Nonsurgical Treatments").[87,106] Topical compounds of multimodal analgesics are helpful at this stage, as are periodic trigeminal nerve blocks. Time-based and limited NSAID blood levels are maintained, and opioids become second-line agents except for closely monitored pain breakthroughs.[93,104]

Chronic PPSP

Chronic PPSP is characterized by established neuropathic peripheral, central, and autonomic sensitizations. Cognitive-behavioral problems develop, with sustained anxiety and depression, social dysfunctions, and sleep impairments. Pain becomes refractory to conventional physical, medical, and surgical therapies. Functional brain imaging has shown that cortical degenerative and demyelinative changes are present in response to nerve injuries and may be a common mechanism of chronic postsurgical pain.[188,189] If firmly established and refractory 2 or more months after surgery, PPSP often requires multidisciplinary pain management (see Table 25-4).[134-136]

Maxillofacial Trauma Nerve Injuries

Maxillofacial traumas, especially those involving fractures, are associated with high levels of trigeminal neuropathy that often go undiagnosed, untreated, and underreported. This may be attributed in part to patient factors; traumatized patients tend to not complain or even be aware of sensory problems in the acute stages of their injuries and often are not available for long-term follow-up neurosensory assessments and treatments.

In addition, surgeons treating patients with maxillofacial fractures in the past have understandably focused their attention on stabilizing the multisystem-injured patient, reestablishing normal facial contours, achieving anatomic reduction and fixation of fractures to promote union, and regaining functional dental occlusions. Often these goals

TABLE 25-4 Management of Persistent Postsurgical Pain

Clinical Signs		Treatments

NSAIDs, Nonsteroidal anti-inflammatory drugs.

have been achieved to the exclusion of assessment and treatment of associated sensory neuropathies.[190,191] In recent years, however, protocols from level-1 trauma centers and the American Association of Oral and Maxillofacial Surgeons have increasingly recognized the importance of restoring neurologic functions for patients with maxillofacial trauma.[192-194]

Neuropathy Prevalence

Cumulative studies estimate that post-traumatic neurosensory disorder of inferior alveolar-mental nerve injuries occurs in 46% to 58% of patients with mandibular angle and body fractures. Immediately following treatment of these fractures, neuropathy may rise transiently to as high as 91% of patients, and permanent (1 year) neurosensory disorders average 38.8%.[17,18,34]

Acute infraorbital nerve neuropathies assessed by quantitative sensory testing are found in 76% of patients with zygomatic-maxillary fractures and rise to 100% among patients with orbital floor involvement.[195] Permanent infraorbital neuropathy has an QST-determined patient average of 60% 1 year after treatment.[196] Unfortunately, there is little published information on chronic levels of dysesthesia after facial trauma.

Neuropathy Determinants

Increases in permanent neurosensory deficits are found among female and older patients.[17,34] Deficits are greater when fracture displacements are greater than 5 mm, occurring in 73.5% of patients as compared to 25% of those with nondisplaced fractures, and when time intervals are greater than 1 week between injury and repair; rigid fixation produces more neuropathies than non-rigid; and mandibular open reduction treatments result in more sensory neuropathies than closed reductions, with neuropathy levels actually increasing after open reductions compared to the pre-repair levels.[197,198] Interestingly, the reverse recurs with open reductions of zygomatic-maxillary fractures where neuropathies decrease after open reductions as compared to preoperative levels.[199]

Acute Injury Nerve Repair

Acute injury nerve repair is ideally done at the time of fracture repair. Nerve management is indicated when the fractures are displaced greater than 3 to 5 mm, when the nerves are seen to be transected, gapped, or significantly displaced. Nerves must be accessible for repair, and the surgeon must have the necessary skills, instrumentation, and operative environment. Immediate epineurial neurorrhaphy repair is done placing 2 to 4 nylon sutures of 6-0 to 8-0 gauge. The osseous mandibular canal or mental or infraorbital foramen is enlarged to prevent secondary compression during osseous recovery. Finally, the injury-repair site is enturbulated with a protective nerve wrap. Postoperatively, acutely nerve-injured trauma patients should begin sensory reeducation

psychophysical exercises within the first 2 weeks after treatment.

If primary nerve repair is not feasible, however, the damaged nerve should be tagged with 6-0 or 7-0 nylon suture in anticipation of secondary microsurgical repair that may be done after fracture union is assured.

Secondary (Delayed) Microsurgical Repair

Secondary (delayed) microsurgical repair treatments are indicated for maxillofacial trauma patients who (1) test anesthetic after 3 to 6 months, (2) have disabling orofacial sensory dysfunctions, or (3) have developed intolerable chronic neuropathic pain. The full protocol of the nerve injury "surgical repair cascade" may be needed, and treatment outcomes for nerve repaired maxillofacial trauma patients have compared favorably with outcomes from repairs done for other nerve injury causes, achieving overall useful sensory recovery levels as high as 86%.[17,34]

Local Anesthetic Injection Nerve Injuries

Acute Trigeminal Nerve Injuries

Acute trigeminal nerve injury symptoms after local anesthetic injections are common; the exact incidences are unknown and probably underreported, with estimates that 1 in every 200 mandibular blocks will be associated with a "traumatic episode" of pain or paresthesia.[200,201] Over 80% of acutely symptomatic patients fortunately will experience resolution within 1 week. However, approximately 10% to 17% will have some level of sustained or permanent neuropathy resulting in function impairment and burning dysesthesias (see Figure 25-4, *A*).[202,203]

Chronic Nerve Injuries

Permanent nerve injuries have been reported in both lingual and inferior alveolar nerves once in every 26,000 to 800,000 mandibular blocks.[23] Lingual neuropathies occur most frequently, are more incapacitating, and have higher incidence of burning dysesthesias as compared to injured IANs. If lingual neurosensory recovery has not been near completion by the fourth week after injection, 86% will not recover further and are considered permanent.[23] These data alone suggest that any full-time dental clinician will have at least one patient during his or her career who has permanent nerve involvement resulting from mandibular nerve blocks. Clinicians have also noted less frequent but increasing cases of cranial nerve injuries following anesthetic blocks involving long buccal, infraorbital, nasopalatine, and superior alveolar branches.[34,204,205]

Mechanisms of Local Anesthetic Injuries

Three potential mechanisms have been considered causes of anesthetic neuropathies: (1) vascular damage, (2) mechanical nerve injuries, and (3) indirect chemical neurotoxicities.

Vascular-based injuries include punctures or tears of extraneural vessels resulting in hematomas that may become organized and chronically compress the nerve.[206] Tears of extrinsic plexuses of epineural microvasculature may also cause segmental nerve ischemia. Trauma to intrinsic plexuses (vasa nervorum) may result in intraneural hematoma, causing axon irritability and intraneural fibrosis.

Another vascular basis for local anesthetic neuropathies is inadvertent intravascular injection, producing rapid-onset regional trigeminal pain, swelling, mucocutaneous ischemia due to vasoconstriction, and distant spread along the valveless facial vessels. Extreme cases of spreading intravascular local anesthetics may result in cranial motor nerve effects in facial musculature and extraocular muscles, as well as visual-field optic effects.[205,207]

Mechanical injuries may theoretically result from direct intrafascicular penetrations or indirect needle trauma from a barbed needle tip.[208] There is much evidence, however, that needle contact with nerve during injection, producing "electric shock" for the patient, is not likely a prime cause of nerve injury. Multiple clinical series show no correlation between the frequency of "shocking" during injection and subsequent sustained neuropathies.[202,203] The same conclusions come from experimental studies with human cadavers and experimental animals showing that needles penetrating the much larger peripheral nerves will pass harmlessly through without damaging the nerve fascicles.[209] Direct local anesthetic mechanical needle injuries, therefore, appear to be of minor importance as a cause of sustained sensory neuropathies following local anesthetic injections.[210]

Chemical neurotoxicity appears to be the most significant factor causing post-anesthetic neuropathies. Several experimental studies have proven that all local anesthetic agents are potentially neurotoxic, and there are direct correlations between the concentration of the anesthetic and degrees of axonal degeneration, necrosis of cultured ganglion cells, and nerve conduction deficits.[210-212]

Convincing clinical evidence also points to chemical neurotoxicity as the primary cause of trigeminal anesthetic injuries. Early clinical reports showed markedly higher rates of nerve injuries in relation to market shares of higher-concentration anesthetics, specifically 4% articaine and prilocaine, after their introduction in Europe in the 1970s.[213] Similar findings were reported after 4% articaine became available in 2000 in the United States.[203,214] A landmark epidemiologic report then appeared in the 2010 U.S. dental literature, showing a threefold to sevenfold greater incidence of neuropathy than expected by market penetration following use of articaine 4% compared to 2% lidocaine.[215] These findings have been confirmed and supplemented by studies that indicate no advantage in surgical anesthesia for articaine compared to lidocaine.[216,217]

Neuropathies attributed to articaine most commonly affect the lingual nerves, found in 70% to 80% of reported cases after mandibular blocks.[215] Less frequently, patients with neuropathies have been encountered following 4% anesthetic nerve blocks of infraorbital and superior alveolar nerves.[34,204] The weight of evidence regarding the increased risks of trigeminal neuropathy and neuralgias with use of 4%

articaine has convinced faculty of many oral and maxillofacial training centers and schools of dentistry in the United States and Canada to discontinue routine use of this agent.[201]

Anesthetic Injury Prevention

There are no current anesthetic techniques or protocols that absolutely prevent anesthetic nerve injuries, in part because of the "blind" nature of all injections. There are preventive guidelines, however, that may minimize their severity: (1) Avoid purposeful stimulation of paresthesias during injection to assist in localizing the nerve, (2) minimize multiple injections into similar anatomic zones, (3) avoid bone contact with needle tips, and replace the needle if a barb is detected at the tip, and (4) if there are intraoperative signs of shocking-burning pain, indicating that nerve contact may have been made, the needle should be retracted a few millimeters prior to release of anesthetic solution.

Anesthetic Injury Treatments

Sensory reeducation psychophysical treatments should be prescribed for patients with sustained post-anesthetic paresthesias. Those with chronic dysesthesias may receive modest benefits from palliative medical therapies consisting of titrated combinations of anticonvulsants such as pregabalin or gabapentin and antidepressant agents—tricyclics or SRNIs. (See the "Nonsurgical Treatments" section earlier in this chapter.)

Surgical interventions for patients with long-standing post-anesthetic lingual burning pain, taste loss, and lip-chin allodynia have thus far failed to significantly improve patient symptoms.[218] This may be due in part to physical differences between chemically injured and mechanically traumatized nerves. An isolated report based on a postal survey of U.S. microneurosurgeons who had exposed lingual nerves injured by local anesthetic injections revealed few objective signs of mechanical injury.[203] The typical appearance of the exposed nerves was of minimal perineural fibrosis, visible perineural microvasculature, slightly reduced nerve transparency upon transillumination, and intact nerve fascicles. The nerves displayed remarkably normal microanatomy, even in those cases where patients had reported dysesthesia. These experiences and lack of objective clinical trials have led to a general consensus among maxillofacial microneurosurgeons that surgical repair attempts of trigeminal nerves traumatized by local anesthetic blocks are not indicated.

Surgical Medicament and Endodontic Injuries

Oral and maxillofacial surgeons may encounter neuropathic complications when using topical medicaments for treatment of dentoalveolar infections, controlling intrabony hemorrhage, relieving post-extraction osteitis, or treating cysts or malignant pathologies. Surgeons may also be called upon to assist in the management of patients with acute endodontic nerve injuries whose injuries may be severe and require immediate attention to avoid permanent neuropathies.[34,219,220]

Surgical Medicament Injuries

Historically, tetracycline powders were placed in third molar extraction sockets for prevention of osteitis. However, studies have questioned the effectiveness of this treatment and also found signs of chronic paraneural inflammatory responses when tetracycline has been placed near IANs.[221] Rare cases have also been cited of persistent neuropathies among patients with post-extraction alveolar osteitis treated with topical applications of eugenol pastes on exposed IANs.[221]

Inferior alveolar nerves are at particular risk during socket and alveolar hemorrhage control using direct packing with low-pH agents such as oxidized regenerated cellulose (Surgicel) and gelatin sponges.[222] The overuse of these acidic agents in contact with human peripheral nerves is therefore discouraged. Control of intrabony hemorrhage with bovine collagen and bone wax, however, appears to be well tolerated by peripheral nerves, as is intra-alveolar liquid nitrogen used to prevent recurrences of enucleated keratocysts.[223,224]

Endodontic Injuries

Trigeminal injuries from endodontic treatments appear to have decreased in frequency and severity over the past 3 decades; this may be due to development of the specialty of endodontics with improved techniques, greater awareness of the toxicities of medicaments, and the implementation of operating microscopes. However, endodontic neural injuries are among the most severely debilitating events, potentially involving multiple cranial nerves and representing true surgical emergencies. The exact incidence of trigeminal nerve injuries resulting from endodontic treatments is not known, as the available literature consists mainly of case series of 10 or fewer patients. There are three proposed mechanisms of nerve injuries resulting from endodontic treatments: (1) direct nerve trauma, (2) compression trauma ischemia, and (3) chemical burn neurotoxicities.[34,219,220]

Direct Nerve Trauma

Especially if the posterior mandibular root apex is close to the underlying inferior alveolar canal, endodontic broaches and files may pass beyond the apex, penetrate the canal, and puncture the IAN. This may result in immediate pain, intraneural bleeding, and nerve disruption with partial or complete severance.[225]

Compression Injuries

Overfilling of root canals, even with usually inert filling materials such as gutta percha and zinc oxide eugenol, may lead to compression of the IAN, either outside the mandibular canal or directly on the nerve itself (see Figure 25-10, *A*). In such cases the compressing materials and associated hematoma are acting in a closed compartment and their presence perpetuates the resulting neuropathy; their prompt removal, therefore, is imperative.[226]

Chemical Burns

The endodontic medicaments most associated with chemical paresthesias are sodium hypochlorite irrigant, phenols, aldehydes and halides, and paraformaldehyde found in the formerly used Sargenti (N2) pastes. Milder chemical effects also are also seen with the use of calcium hydroxide, gutta percha, steroids, and antibiotics.[219] The primary determinants of chemical burn nerve injury appear to be the amount and concentration of foreign agents in contact with the nerve, the duration of contact, the agent's pH, and associated epineural mechanical injury.[225]

Calcium hydroxide and gutta percha, although widely used and safe in small intra-alveolar quantities, are high in alkalinity. If placed under pressure at high temperatures, these agents may migrate periapically and enter into the mandibular canal, where they migrate further proximally and distally. In such cases there may be widespread wallerian degeneration, neural necrosis, minimal regenerative capacity, and intractable burning neuropathic pain.[226]

Sodium hypochlorite (bleach solution) is the most common irrigating solution in current use because of its excellent proteolytic and antibacterial actions. Unfortunately, sodium hypochlorite is also extremely neurotoxic with pH levels of 10 to 12. This markedly increases vascular permeability, allowing the agent to spread rapidly into periapical, periodontal, and adjacent anatomic spaces. The risk of these events occurring is increased by the presence of accessory canals, root perforations, apex overinstrumentation, or irrigation done under excessive pressure.[220,227]

Most cases of endodontic neuropathies have been associated with inferior alveolar injuries. However, profound maxillary endodontic injuries have also been reported, with the primary offending toxic agent having been sodium hypochlorite.[228] Sodium hypochlorite may escape into loose maxillary spaces such as the canine fossa, maxillary sinus, orbit, or infratemporal fossa, often with dramatic clinical effects. There is sudden onset of severe burning pain, rapid mid-facial swelling, dentoalveolar bleeding and ecchymosis, facial muscle paresis, and hemifacial loss of sensation (see Figure 25-4, *B*).

Surgical Treatments

Acutely injured endodontic patients require early and aggressive treatment as soon as the complications are recognized. Imaging is done with plain films or cone-beam computed tomography (CBCT) to help define injury limits. Systemic corticosteroids, palliative analgesics, and preventive antibiotics are prescribed, and cold packs are applied. Patients should be scheduled for surgery, ideally in an operating room setting, using general anesthesia and within 48 to 72 hours if possible. The primary goals are to remove foreign body materials, decompress effected nerves, and irrigate and drain the regional tissues.

Acutely injured nerves are exposed by lateral decortication decompression of the mandibular canal, followed by removal of chemical foreign bodies, irrigation of the nerves with isotonic solution, and placement of nerve barrier protections.[229] In cases where sealant materials appear to have penetrated the epineurium, internal neurolysis through longitudinal nerve incision will be required to remove the toxic foreign materials and allow placement of protective nerve wraps.[13,173]

Surgical treatment of patients with chronic sensory loss and dysesthesia after endodontic injuries will usually require wider exposure through decortication or sagittal osteotomy.[229] This is dictated by imaging signs of extensive spread of neurotoxic materials in the mandibular canal. If surgical exposure reveals extensive nerve necrosis, fibrosis, or gapping of the IAN, liberal resection of damaged nerve segments is carried out and repairs done with nerve grafting and entubulation in order to promote secondary regeneration.

Orthognathic Nerve Injuries

Neurosensory disorder is a known potential complication of orthognathic surgery, involving inferior alveolar, lingual, and infraorbital nerves and occasionally the maxillary trunk.[230] Although neuropathy is present for many patients following orthognathic surgery, most appear to tolerate even long-term mild neurosensory disorder in order to correct their dentoskeletal discrepancies and improve orofacial functions and esthetics.[28]

Injuries may result from direct instrument lacerations, stretches during osteotomy mobilizations, or punctures or nerve compression during placement of transosseous pins or plate fixation. After injury, orthognathic patients may display the full range of hypoesthesias, hyperesthesias, nonpainful paresthesias, and dysesthesias. The greatest functional difficulties and dissatisfactions, however, are cases where there are frequent long-term triggered paresthesias and dysesthesias.[54,65]

Neuropathy Prevalence

Neuropathic symptoms in the first week after BSSO are nearly universal. Subjective analyses and objective quantitative sensory testing have found IAN disorder in as many as 97% of BSSO patients 1 week after surgery.[54,231,232] Acute lingual neuropathy has been reported at between 9% and 18%.[233,234] Six months after orthognathic surgery, 63% of a large patient series reported abnormal spontaneous sensations and 84% had abnormality in response to tissue stimulations.[235] One year or more after sagittal osteotomy surgery, inferior alveolar neurosensory disorders range from 9% to 35%.[28,230,235] The 1-year postoperative neuropathies, presumed to be permanent, were rated as "mild" by 32% and "disturbing" by 3%.[231] Other surveys have shown that even permanent sensory complications do not serve as the most significant determinant of patient satisfaction after orthognathic surgery. Patients report that functional gains and esthetic improvements outweigh residual neurosensory disorder when asked about "quality of life" satisfaction after surgery.[235,236]

Neurosensory complications to lingual and maxillary nerves after BSSO are much less common than IAN injuries

and are attributed to retractor compression and improper transosseous plate placements.[233,237]

Sustained neuropathic pain after orthognathic surgery is also rare. Studies of sagittal osteotomy patient cohorts showed prevalence of chronic pain and disturbing paresthesias to be 0.5% to 5%.[59,65,238]

Neuropathy Determinants

The highest rates of neurosensory deficits occur among patients older than 35, as high as 50% after age 40.[235,239] Long-term disorder is higher among women than men, and patients with history of depression and obstructive sleep apnea.[238] Neuropathies are more common when monocortical plate fixation is used rather than rigid bicortical pin fixation, and for longer advancements of retrognathic mandibles.[28] Other factors increasing the risk of IAN injuries include mandibular canals located less than 0.8 mm of the lateral mandibular cortex surface, if impacted third molars have been retained, and when the rate of advancement in distraction osteotomies is greater than 1 mm per day.[239-241] Manipulation of soft tissues of the pterygomandibular space immediately medial to the mandibular lingula has also been associated with higher levels of sensory disorder.[28] Combining BSSO with genioplasty slightly raises neuropathy incidence, whereas combining BSSO with maxillary osteotomy has not proven to increase risk of neuropathy.[236] Nor have biodegradable screws and plates for osseous fixation been associated with higher levels of sensory disturbances.[242]

Lingual nerves are at higher risk for injury if not protected from horizontal drilling during bicortical pin fixation in the retromolar mandible and if pins are overextended through the medial cortex into the sublingual space.[233] Lingual nerves injured at the level of the mandibular lingula prior to or during the medial osteotomy cut may not be repairable because of their inaccessibility.

The most important determinants of chronic sensory neuropathies among BSSO patients are nerve entrapment in the proximal ramus segment and compression of nerves during fixation of the osteotomy segments.[28,230]

Acute Surgical Nerve Repairs

There are limited published reports that address surgical treatments of intraoperative orthognathic trigeminal injuries. It is recommended, nevertheless, that direct neurorrhaphy be carried out immediately if possible when nerve separation is observed during orthognathic surgery.[243] The specific technique will be dictated by the site and nature of injury. When the IAN is injured proximally at the point of entrapment in the medial aspect of the distal osteotomy segment, it is necessary to complete the osteotomy split in order to access the nerve for repair. In the event of IAN injury during the vertical cutting of lateral cortex, the nerve may need to be freed by lateral corticotomy and released peripherally to the mental foramen. This is especially important for mandibular advancement cases in order that the nerve may be repaired without tension. If the nerve has been transected or significantly disrupted, immediate microsurgical repair is ideal treatment using epineurial neurorrhaphy or, if available, interpositional allogeneic cadaver graft repair. All nerves traumatized during BSSO, whether suture repaired or not, will benefit from internal widening of the exposed mandibular canal and from placement of protective nerve wrap entubulation.

Secondary (Delayed) Surgical Nerve Repairs

For those patients with long-term unacceptable sensory loss, secondary trigeminal nerve repairs are typically delayed for 12 weeks after orthognathic surgery to allow for bone healing. The surgical approach will be dictated by the likely site and dimensions of nerve injury; these are determined by operative history and objective clinical signs such as narrowed compressing bony nerve canals as revealed by CBCT, and the presence of percussion-triggered hyperpathias (Tinel sign) indicating traumatic neuroma formation. Because nerves traumatized during BSSO may have lengthy neuroma-in-continuity, microsurgical repair with grafting may require wide exposure through secondary sagittal osteotomy.

Outcomes of secondary repairs of a series of 54 patients with chronic orthognathic neuropathies have shown that 85% regained acceptable sensory functions.[243]

Implant Nerve Injuries

Since their introduction in the 1980s, there have been dramatic increases in the number of dental implants placed as more dental practitioners carry out these surgeries. The most significant frequent complications result from implants placed in the posterior mandible, damaging the IANs, and less frequently the lingual nerves.[244] Implant nerve injuries result in a spectrum of symptoms from mild transient paresthesias to permanent anesthesias and neuropathic pain as well as impaired orofacial functions for speech, eating, touching the face, shaving, and kissing.[21,245]

Incidence of acute nerve injuries after implants have been reported as high as 40% with permanent neuropathies reaching 19%.[21,245,246] Early studies of patient outcomes where nerve repositioning (transposition and lateralization) was done to facilitate implantation resulted in 100% acute paresthesias and permanent loss of crude touch abilities in 10% to 40% of patients.[247] More recent outcomes have fortunately improved as repositioning techniques have evolved.[22] The current prevalence of both acute and chronic neuropathies following implant placements are not fully known and are probably underreported because of inconsistent reporting and lack of an international registry.

Nerve Injury Causes

Implant nerve injuries are caused by: (1) inaccurate and incomplete presurgical planning, (2) direct nerve trauma during drilling, (3) indirect compression injuries during implant placement, and (4) secondary factors such as flap nerve injuries and peri-implant factors such as infection and hematoma.[248]

Incomplete pre-implant planning includes failure to calculate root lengths such that implants are placed closer than 2 mm from the inferior alveolar canal. This may be due to inaccurate measurements resulting from the known 10% to 40% distortions inherent in some panoramic radiographs. Surgeons may also inadequately prepare drill "guides" and "stops" calculated from computed tomography (CT)-based navigation systems.[249] Nerve injury risks may also be increased by incomplete preoperative assessments of bone quality and atrophy and failure to compensate for patient factors of increased age, being female, having chronic systemic disease, and using tobacco.[250]

Direct nerve injuries during the pilot twist drilling are probably the main cause of implant neuropathies.[14] Overly deep drilling may be due to "slippage" in less dense spongy bone found in the posterior mandible, leading to mandibular canal penetrations.[250] In such cases nerve injury has occurred even though the postoperative imaging may indicate proper implant positioning. Drill penetration nerve injuries may be partial or complete, but tend to be qualitatively "ragged" compared to incision injuries.[40] For this reason IAN injuries from twist drill injuries will often require nerve grafting for successful repair. Nerve injuries may also result from drill-generated bone heat exceeding 47° C, potentially causing both IAN damage and peri-implant bone necrosis.[251]

Implant placement nerve injuries may result from both compression collapse of the mandibular canal bone as well as direct nerve crushes within the canal from the implant.[245] Concurrent bleeding and hematoma formations in or around the mandibular canal further exacerbate the nerve injury in this "closed box" compartment.[248]

Treatment of Implant Nerve Injuries

When acute nerve injury symptoms have occurred, patients should return ideally within 24 to 36 hours of surgery so that the nature of their altered sensation and discomforts in the surgical region can be documented, baseline maxillofacial examination and sensory testing carried out, and postoperative imaging assessment obtained to determine the anatomic relation of the implant to the mandibular canal. Corticosteroid medical therapy and titrated sedative-analgesics are begun at this time.

If there are no imaging signs of implant encroachment on the mandibular canal, supportive treatments and serial QST should be done. However, when there are signs of possible canal encroachment, imaging should advance to CT or CBCT analyses. If implant encroachment on IAN and patient sensory loss are confirmed, immediate implant position changes are urgently needed: either partial "backing out" or complete removal of the implant and possible replacement with a shorter and wider implant.[248]

For those patients with measurable, unresolving sensory losses, disturbing paresthesias or intractable neuropathic pain continuing 4 to 6 weeks beyond implant placement, microsurgical referrals for possible surgery should be considered. This timing is selected before neuroma has formed, before centralized symptoms have developed, and before implant osseointegration has occurred. Definitive nerve repairs may require decompression through lateral mandibular corticotomy, direct or graft-assisted repair, and nerve wrap protection (see Figure 25-10, *C* and *D*). Nerve repositioning lateralization may also be considered at this operative stage to retain healthy and integrated implants.[22]

Mandibular Third Molar Nerve Injuries

Injury to trigeminal nerves is the most significant and potentially long-term complication associated with the removal of impacted mandibular third molars.[19] Classic works by Alling and Kipp pointed to potential problems with impairments in speech, mastication, swallowing, social functions, and sustained paresthesias and dysesthesias.[4,5,252] Inferior alveolar nerves are injured more often than lingual nerves. However, lingual nerve injuries are functionally more disabling and have lower spontaneous recovery rates.[13,14] The long buccal nerve frequently may also be injured during mucosal incision and flap reflection, but symptomatic long buccal neuropathies are rarely reported and have few functional consequences.[34]

Nerve Injury Prevalence

The overall reported acute incidence of IAN injuries ranges from 0.3% to 8.4% and lingual nerve injuries from 1% to 22%.[2,5,46] Approximately 15% to 25% of patients who sustain acute exodontic nerve injury will have residual and probably permanent effects 1 year after injury.[4,19,20,252]

A recent survey of 535 oral and maxillofacial surgeons reported that 94.5% had patients with acute symptomatic IAN injuries over a 12-month period, and 53% reported lingual nerve injuries; permanent career injuries to IAN occurred in 76% of OMS practices and permanent career lingual nerve injuries in 46%.[2]

Nerve Injury Risks: Patient Factors

Increasing age is a primary risk factor for third molar injuries to IAN, but interestingly, older age is not a factor for lingual nerve injury.[39,45,46,253] This may be attributed to progressive root formation with aging and its related pathology as well as the known negative effects of age on recovery from all types of nerve injuries and after repairs. Being female is also an increased risk factor, particularly for lingual injuries, possibly a consequence of smaller mandibles.[34,45]

The depth and type of impaction is significant for inferior alveolar injuries; mesioangular and deeper horizontal impactions are associated with the highest paresthesia rates and dysesthesias.[254] Depth of impaction does not influence lingual nerve injuries, but increased risks are found with distoangular impactions.[255]

Preexisting pathology also increases risk of lingual nerve injuries. These include lingually positioned ankylosed teeth, root penetrations of the lingual cortex, and erosion of the lingual plate by chronic infection, cyst, or malignancy.[253,255] These factors increase the likelihood of injury to the exposed

nerve during extraction or during socket curettage of residual follicles or cysts containing entrapped nerves.

The strongest patient-based predictor of IAN damage is the anatomic relationship between nerve canal and dental roots as seen on imaging.[256] The key imaging risk signs are: (1) diversion and narrowing of the mandibular canal, (2) darkening and deflection of the roots, and (3) interruption of the white line of the canal. Studies have demonstrated that when one of these radiographic predictors are present, there is a 16% occurrence of nerve damage, and when two or more predictors are present, the incidence is 30%.[256] Properly executed periapical radiography and panoramic methods are sufficient for identification of these key indicators of root-nerve superimpositions.[257] With the advent and increasing availability of low-dose CBCT technology, more accurate three-dimensional imaging may better clarify the anatomic relationship between the IAN and the lower third molar.

Nerve Injury Risks: Surgical Factors

The primary surgical determinants of third molar trigeminal nerve injuries are; (1) incision and flap techniques, (2) nerve exposures, and (3) alveolar ostectomies.

Incisions and Flap Techniques

The *lingual nerve* is at increased risk for injury when opening incisions are placed on the lingual aspect of the retromolar ridge instead of over the external oblique ridge in the lateral vestibule.[5] Retromolar incisions that follow the line of the posterior dental occlusion risk dropping the blade directly into the pterygomandibular space because of the lateral flare of the mandibular ascending ramus. There is strong evidence-based consensus, therefore, that mandibular third molar incisions and flap elevations should be confined to the lateral buccal vestibule.[5] Incisions in the lingual and mid-retromolar pads are within the known anatomic "danger zone" for direct lingual nerve trauma. Several cadaver and MR imaging studies have revealed the high variability of normal lingual nerve locations, showing that between 10% and 25% of lingual nerves lie superficially and unprotected by bone within 1.2 mm of the lingual alveolar crest and in contact with the cortical bone plate.[258-261] In rare cases the nerve is found within the retromolar mucosal pad itself. These anatomic risk factors may help explain the occasional reports of bilateral lingual nerve injuries and the common reports by operating surgeons of lingual nerve injury "surprises" following simple removal of superficially impacted third molars.

Intraoperative Nerve Exposures

In the majority of cases of third molar lingual nerve injuries, the cause of injury is reported by surgeons as unknown, that is, the nerve injury was not observed.[2] The IAN, however, is frequently exposed and visualized in extraction sockets. When exposed, there is a 20% risk of acute sensory alteration and 30% of those exposed will retain altered sensation at 1 year, for an overall 1-year sensory alteration incidence of 6%.[262] From a clinical standpoint, therefore, the finding of an exposed, intact IAN bundle during third molar surgery suggests there is a 1 in 5 chance of developing paresthesia and those patients with postoperative paresthesia have a 1 in 4 chance of neuropathy persisting 1 or more years.

Alveolar Ostectomies

The greatest iatrogenic causes of lingual nerve injury appear to be perforations, fractures, or ostectomies of the lingual cortical plate, causing direct lacerations or nerve punctures.[39] This is most likely to occur from overdrilling during crown sectioning or bone "trenching" done blindly under the flap posterior to the impacted third molar.[5,255] The highest levels of inferior alveolar paresthesia and dysesthesia have been shown to result from ostectomy inferior and mesial to horizontally impacted teeth.[34,39]

Two controversial surgical techniques have been advocated for prevention of third molar surgery-related trigeminal injuries: planned exposure and retraction protection of the lingual nerve, and coronectomy for avoidance of root damage to IAN.

Lingual Nerve Retraction

The purposeful reflection of a lingual flap, identification of lingual nerve, and placement of subperiosteal protective separators is a technique that has been traditionally taught in some parts of the world.[12,263] This approach does allow greater access for special cases of lingually positioned third molars and may prevent crown or root displacement into the paralingual space. Although markedly higher rates of paresthesias occur 1 week after lingual nerve retractions, permanent neuropathy rates after lingual retractions done by surgeons specifically trained in this technique have resulted in outcomes comparable to buccal-only flap elevations.[255,264] However, the weight of evidence from retrospective and prospective studies has led to the conclusion that lingual flap elevations significantly increase the risks of permanent lingual neuropathies and should be avoided as a routine practice.[5,46,265]

Coronectomy

Also called partial odontectomy or deliberate root retention, coronectomy may be considered for patients at extreme risk for IAN injury during conventional one-stage removal of impacted roots.[266,267] This technique is indicated if preoperative imaging reveals an intimate relationship between the root of the tooth and the IAN, including nerve encirclement by roots.[268] The technique is not indicated for teeth or roots that are mobile, where there is active root or apical infection, or with horizontally impacted teeth in direct contact with the nerve.[266]

The goals of coronectomy are to leave the parts of roots in direct contact with the nerves undisturbed, and to not mobilize the retained roots. The crowns are transected with a narrow fissure burr and enough root is removed to permit bone to form superiorly, usually at least 3 mm inferior to the bony crest. Coronectomy has an overall failure rate of

5%.[269] It also has known risks that include root migrations, pulp necrosis, apical infections and osteomyelitis, increased antibiotic and radiography needs, and possible risk to lingual nerves from bone perforations.[270]

Since its introduction 25 years ago, however, there has been accumulating international evidence that coronectomy reduces IAN damage without significant complications when compared to similar high risk patients treated with conventional complete odontectomies.[5,271]

Acute Third Molar Nerve Injury Surgical Treatments

Lingual Nerves

Lingual nerves are infrequently exposed in third molar surgical fields, but if they appear to be intact, they will likely recovery satisfactorily without microsurgical repair. Placing a perineurial protective wrap around the exposed lingual nerve may minimize secondary scarring and enhance regeneration. Completely separated (Class 5) lingual nerve injuries observed during third molar surgery, however, have almost no potential for spontaneous recovery and microsurgical repair is indicated as soon as possible.[13] Immediate placement of 6-0 or 7-0 epineurial sutures is ideal treatment. Because that may not be feasible at the time of third molar surgery, the cut nerve ends should be tagged with nylon suture in preparation for delayed microsurgical repair (see "The 'Surgical Repair Cascade'").

Inferior Alveolar Nerves

Inferior alveolar nerves are more frequently exposed during third molar surgery and also require immediate attention. Osseous hemorrhage should be controlled with bleeding point pressure and bone wax as needed, avoiding pressure directly on the nerve or collapsing bone into the adjacent mandibular canal. If the nerve appears intact and is supported by the mandibular canal bone floor and at least one wall, simple supportive care is carried out using mild irrigation with isotonic saline to clean the nerve of foreign bodies and excess blood. If a protective nerve wrap tubule is available, it may be possible to place it around the exposed nerve.

For IANs found to be completely transected, satisfactory spontaneous recovery may occur if the cut nerve ends can be placed passively in direct apposition and are supported by intact surrounding bone. Ideally, and if access permits, 7-0 or 8-0 epineural suture and nerve wrap may be placed at this time. However, IA nerves observed to be transected, gapped, lacking bone support, and with nerve ends that cannot be passively aligned may require secondary microsurgical repairs if unsatisfactory spontaneous recovery does not occur (see "The 'Surgical Repair Cascade'"). In preparation for possible secondary repair, the cut nerve ends should be tagged by nylon microsuture to assist in localizing the injury site.

If early post-extraction infectious or inflammatory complications such as alveolar osteitis occur, no topical medicaments should be placed over the nerve exposed in the third molar socket. In all cases of acutely injured trigeminal nerves, supportive physical therapy and medical care with analgesic, anticonvulsant, and anti-inflammatory agents should be initiated.

Chronic Nerve Injury Surgical Treatments

Delayed secondary repairs of inferior alveolar and lingual nerves are preferably carried out within 6 months of injury and as soon as patients meet the primary criteria for nerve repairs: sustained dysfunctional sensory loss and intractable dysesthesia. Secondary surgeries for third molar nerve injury patients may require the full spectrum of decompression, neuroma resection, direct neurorrhaphy or graft-assisted nerve repair (see "The 'Surgical Repair Cascade'").

Outcomes and Conclusions

The majority of acutely injured patients experience acceptable spontaneous recoveries within weeks of injury. For a minority, however, symptoms and function impairments become sustained; if they are not treated, spontaneous recovery after 6 months is rare and after 1 year, zero.[6,12] By comparison, accumulating outcome reports indicate generally positive improvements among nerve injury patients who have been actively treated.[7,8] However, these improvements must be weighed against the potential for treatment failures and complications after surgical repairs.[272]

The efficacy of nerve injury treatments are based on two general criteria: patient "subjective" ratings and clinician "objective" measures of neurosensory functions. Patients subjectively relate their levels of (1) *orofacial functions* (speech, eating, hygiene, facial washing, kissing), (2) impressions of *normalcy of sensation* (lack of "numbness" or paresthesias of any degree, and (3) levels of *discomfort and pain*, either spontaneous or elicited ("triggered"). Clinician outcome assessments are mainly based on "objective" neurosensory test responses.

Clinician (Objective) Outcome Ratings

Current microsurgical options result in improved objective stimulus-response measures (QST) in more than half of operated patients, with overall reports of useful sensory recovery functions ranging from 51% to 90%.[8,10] Best improvements are reported for young male patients with non-painful type 4 or 5 Sunderland injuries. Primary gains are reported for C-fiber and A-delta fiber functions that afford protection against secondary injuries such as lip or tongue biting and improve on patient perceptions of crude pressures.

Early post-injury lingual nerve repairs with direct neurorrhaphy have the most favorable outcomes for measurable neurosensory functions and regaining modest levels of touch discrimination.[7,13] This may reflect in part the improved awareness among oral and maxillofacial surgeons of the value of timely patient referrals and early surgical

treatments of lingual nerve injuries. IAN-injured patients, by comparison, experience better spontaneous recoveries given enough time.

IANs treated by surgical decompressions result in the best overall improvements.[142,144] However, full IAN microsurgical repairs result in poorer overall outcomes compared to lingual nerves; they are technically more difficult, resist repair without nerve grafting, and are associated with more complications.[14,272]

No single nerve repair procedure has been identified that compensates for all types of nerve injury. The most appropriate procedures must be selected and applied from the "surgical repair cascade" options, dictated by the physical and physiologic characteristics of the damaged nerve.

Patient Outcome Ratings

For an unfortunate subset of nerve-injured and surgically repaired patients, the good successes in restoring clinician-measured useful sensory functions are not mirrored by improvements in patient ratings of functional "normalcy" and pain relief. Patients report that annoying abnormal sensations (paresthesias) have rarely been eliminated by surgical or nonsurgical treatments, and complain of varying degrees of sustained "numbness," tingling-shocking, "crawling" phantom sensations, "after-imaging," and exacerbations during cold, hot, or inclement weather.

There are no nonsurgical therapies available that have significant influences on regeneration of damaged trigeminal nerves. Modern nonsurgical multimodal pain management therapies combine behavioral, peripheral topical and neurolytic blockade, and systemic combinations of anticonvulsant and antidepressant agents. These treatments often improve tolerance of impaired orofacial functions and dysesthesias, and cognitive-behavioral therapies with sensory reeducation may hasten recovery of more normal central nervous system perceptual functions.[236]

There is a notable knowledge gap regarding the effectiveness of neurosurgical repairs for patients with traumatic dysesthesias. Microsurgical repairs rarely induce new or additional forms of pain among patients who were pain-free before repair.[11,12] The best outcomes for relief of neuropathic pain after repair surgeries are those patients who had short-term hyperesthetic post-traumatic pain, responded favorably to local anesthetic test blocks in the distribution of nerve injury, had sustained recent Sunderland type 4 or 5 injury, and displayed amputation or severe in-continuity neuromas at the time of surgical repairs.[145]

Although more than half of repaired patients report satisfaction with regard to pain reduction, more than 35% report that long-term pain was not improved by surgery, suggesting that patient selection may be a prime determinant of responses to surgery.[8,11] The poorest pain relief outcomes following nerve repairs have been reported for older female patients operated at longer time intervals after their original injuries and those patients with pre-repair pain of three types: deafferentation pain ("anesthesia dolorosa"), centrally sensitized pain (spreading hyperalgesias), and those showing signs of dysautonomia (sympathetic mediated pain, swelling, erythema episodes).[41,42,69] Outcomes for these patients tend to match the poor levels of relief seen with nonsurgical treatments. The clinician's burden is to correctly identify the patients who are most at risk.

Complete Recovery after Nerve Repair

The consensus of many experienced surgical clinicians who treat trigeminal nerve-injured patients is that recovery of 100% normal sensation, absence of all unpleasant paresthesias, and complete pain relief is "uncommon," "unlikely," and "rarely if ever" complete.[8,11,12,272] "Successful treatment of unpleasant paresthesias and dysesthesias after trigeminal nerve injuries, therefore, remains one of the most difficult (and unsolved) clinical management problems."[12]

Esthetic Implant Dentistry: Diagnosis and Treatment Planning

SAJ JIVRAJ, MAMALY RESHAD

Introduction

Achieving esthetics with implant restorations is significantly more challenging than with conventional restorations. Diagnosis and appropriate treatment planning are critical in obtaining a successful outcome. Implant concepts have undergone a significant evolution,[1,2] not only in terms of designs, materials, and surfaces but also in clinical and technical management. Clearer understanding of the soft tissue and bone responses to implants enables the clinician to better plan the esthetic outcomes of implant treatment.

Providing an esthetic outcome requires understanding of the objective and subjective criteria related to hard and soft tissue esthetics.[3,4] Ceramists can often produce restorations to match adjacent teeth in terms of color, but if the surrounding tissues are not reconstructed, an esthetic outcome is not likely (Figures 26-1 and 26-2). The ultimate aim is for the implant restoration to harmonize into the frame of the smile, face and, more importantly, the individual.

The predictability of the esthetic outcome of an implant restoration is dependent on many variables including, but not limited to:

1. Patient selection and smile line
2. Tooth position
3. Root position of the adjacent teeth
4. Biotype of the periodontium and tooth shape
5. The bony anatomy of the implant site
6. The position of the implant

Patient Selection and Smile Line

Patients' esthetic expectations must be evaluated together with their lip activity and lip length.[5] A high smile line poses considerable challenges when planning for implant supported restorations in the esthetic zone because the restoration and gingival tissues are completely displayed. In these types of clinical situations maximal effort toward maintaining peri-implant tissue support throughout the planning, provisional, surgical, and restorative phases will be required.

The low smile line is a less critical situation because the implant restoration interface will be hidden behind the upper lip. However, this cannot be assumed, and the patient's input must be sought to confirm this.

Tooth Position

The tooth needs to be evaluated in three planes of space: apicocoronal, faciolingual, and mesiodistal. The existing tooth position will significantly influence the presenting gingival architecture. In many instances, teeth with a poor prognosis are thoughtlessly extracted. These teeth can significantly influence both the hard and soft tissue configuration.

Apicocoronal

Assessment of the apicocoronal position of the tooth may show it to be more apical, more coronal, or ideal and mimicking the level of the adjacent gingival margin. Numerous authors have shown that following extraction and insertion of an ovate pontic there is likely to be up to 2 mm of gingival recession,[6] and on extraction and placement of an implant immediately the migration of the gingival margin is likely to approximate 0.2 mm.[7]

Thus, if there is a hopeless tooth positioned ideally or apically that is extracted, the gingival margin is likely to migrate apically. Restoratively, long clinical crowns, pink porcelain, or visible metal margins will compromise the esthetic outcome. These teeth can benefit from orthodontic extrusion (Figures 26-3, 26-4, and 26-5) prior to extraction, which will serve to position the gingival level at a more harmonious level.[8,9]

• **Figure 26-1** Implant restoration utilizing pink ceramics. Although the patient was satisfied, this could only be achieved in a patient with a low smile line.

• **Figure 26-2** Patient's smile; transition line is hidden. (Lab work by Jungo Endo, CDT).

• **Figure 26-3** Orthodontic extrusion is utilized to overcompensate and bring tissue level more coronally.

It is the author's opinion that a cone beam scan should be taken of the area of concern. There must be sufficient bone labial to the tooth for orthodontic extrusion to be effective.

• **Figure 26-4** Implant is placed in adequate bone volume.

• **Figure 26-5** Provisional restoration is used to sculpt tissue levels. Patient is left in a provisional restoration for 3 to 6 months.

Faciolingual

In this dimension the tooth position may present with different concerns. The tooth may be positioned too far facially, which often results in very thin or nonexistent labial bone. These teeth are not good candidates for orthodontic extrusion because of inadequate underlying bone. Extraction of these teeth results in significant vertical bone loss and collapse of the gingival architecture. This type of situation benefits from bone and soft tissue augmentation procedures prior to implant placement. A tooth positioned more lingually benefits from the presence of an increased amount of facial bone. This situation is more favorable prior to extraction because the resultant discrepancy in the facial free gingival margin may be minimal.[8,10]

Mesiodistal

The proximity of the adjacent teeth necessary to provide proximal support and volume of interdental papillae should be evaluated. Ideally, the mesiodistal tooth width should be equal to that of the contralateral tooth so that an esthetic outcome can be achieved (Figures 26-6 and 26-7). Excesses or deficiencies in this dimension should be addressed through

• **Figure 26-6** The space of the tooth being replaced should be equal to the contralateral tooth.

• **Figure 26-7** Esthetic integration can be achieved with symmetry. Implant restoration in upper right central incisor.

the use of orthodontics, enameloplasty, or restorations. For patients with diastemas, it is imperative that the decision to maintain or close the space be made prior to implant placement. If the patient refuses these presented options to close the space and insists on closing the space with the implant restoration, there is a likelihood that a black triangle may ensue. This results from inadequate support from the adjacent tooth to maintain the papilla. It is important that the clinician discusses this with the patient ahead of time to avoid disappointment with the final outcome (Figures 26-8, 26-9, and 26-10).

Root Position of the Adjacent Teeth

Part of the diagnostic work for patients who need implants is a periapical radiograph, because root position often will preclude placing of implants. Many of these patients can benefit from orthodontics to reposition malposed teeth.

Teeth with root proximity also possess very little interproximal bone. This thin bone creates a greater risk of lateral resorption, which will decrease the vertical bone height after extraction or implant placement. When teeth are present,

• **Figure 26-8** Patient was going to lose central incisors but also wanted diastema between anterior teeth closed.

• **Figure 26-9** Implants placed in central incisor region.

• **Figure 26-10** Bonded porcelain restorations used to close diastema.

the use of orthodontics serves as a valuable adjunct to create space. This can be advantageous for support of proximal gingival architecture.[11,12]

Biotype of Periodontium and Tooth Shape

The position of the gingival tissue around a tooth is determined by the connective tissue attachment and the bone level. Two periodontal biotypes have been described in

• **Figure 26-11** Patient showing thin biotype.

• **Figure 26-12** Patient showing thick biotype.

relation to the morphology of the interdental papilla and osseous architecture: the thin, scalloped periodontium and the thick, flat periodontium.[13]

The thin, scalloped periodontium, found in less than 15% of cases, is characterized by a delicate soft tissue curtain, a scalloped underlying osseous form, and often has dehiscence and fenestrations present and a reduced quantity and quality of keratinized mucosa. Generally, interproximal tissue does not completely fill the space between adjacent teeth. This form of gingiva reacts to insults by receding facially and interproximally. As recession occurs and the inter-root bone resorbs, the subsequent soft tissue loss compromises the overall esthetic result (Figure 26-11).

The tooth form in this type exhibits a contact point toward the incisal third, essentially triangular anatomic crowns, and contact areas of teeth that are small faciolingually and apicocoronally. Due to extreme taper of the roots, the interproximal bone tends to be thicker.

Characteristics of the soft tissue biotype will play a prominent role in final planning for the shoulder position of the implant. A thin biotype with highly scalloped tissue requires the implant body and shoulder to be placed more palatal to mask any titanium show-through. When implants are placed toward the palate, a slightly deeper placement is required to allow for proper emergence profile.

The combination of factors in a patient with a high lip line and a thin biotype is extremely difficult to treat. Patients who fit into these treatment categories should be made aware of the challenges involved in obtaining an esthetic result before treatment begins.

The thick, flat periodontal biotype is characterized by a denser, more fibrotic soft tissue curtain; a flat, thicker underlying osseous form; and an increased quantity and quality of attached keratinized gingiva. This tissue often reacts to insults by pocket formation. Flat gingiva is associated with a tooth form that is more bulbous, with contact areas located more toward the middle third of the tooth, primarily square anatomic crowns, and contact areas that are wide faciolingually and apicocoronally (Figure 26-12).

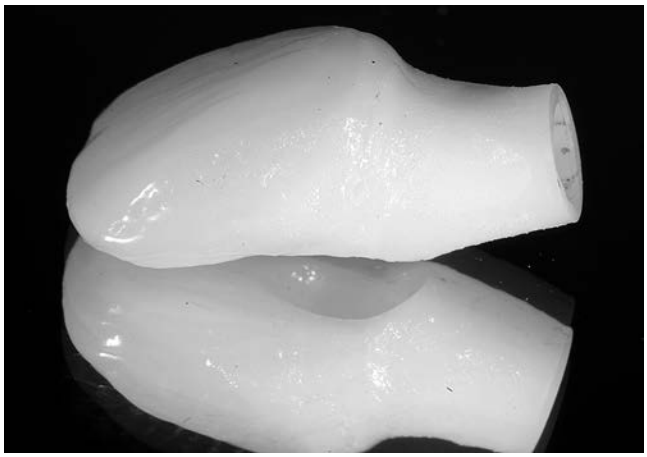
Tooth morphology appears to be correlated with the soft tissue quality. The triangular tooth shape is associated with the scalloped and thin periodontium. The contact area is located in the coronal third of the crown, underlining a long and thin papilla. The square anatomic crown shape combines with a thick and flat periodontium. The contact area is located at the middle third, supporting a short and wide papilla.

Loss of interproximal tissue in the presence of a triangular tooth form will display a wider black triangle than in a situation where a square tooth is present. In some cases when the adjacent teeth are to be restored, the crown form can be modified prosthetically to compensate for partial interproximal tooth loss. The contact area of the prosthetic tooth is positioned more cervically, reducing the volume of the interdental space.

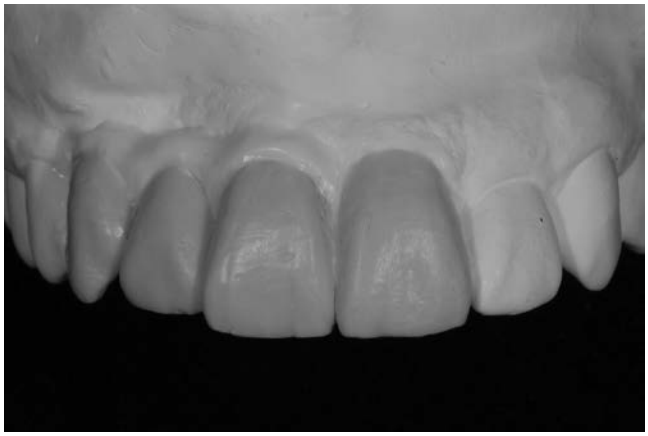
The presenting tooth shape will also influence the implant restoration shape. The implant restoration should mimic its contralateral natural tooth coronal to the free gingival margin. However, apical to the free gingival margin the implant restoration will not be an anatomic replica. A delicate balance must be developed that provides adequate support of the gingival architecture yet does not provide excessive pressure. The subgingival contour of the restoration must take into account the existing height of the free gingival margin and its comparison with the contralateral tooth. If the existing free gingival margin is apical, a concave subgingival contour is encouraged to allow the soft tissue to drape more coronally (Figure 26-13). If the existing free gingival margin is more coronal, a fuller subgingival contour is required to push the soft tissue more apically.

Bony Anatomy of the Implant Site

For successful esthetic restoration of implants, the bony housing must have a three-dimensional configuration that permits placement of an implant in a restoratively ideal position.[14] If the bony anatomy is inadequate, a bone grafting procedure may be required to enhance the site. When these situations are encountered the patient must be made to understand that a successful outcome will involve more than just replacing a "missing tooth." The patient must understand that the missing hard and soft tissue architecture also will need to be rebuilt so that optimum esthetics can be achieved.



• **Figure 26-13** A concave subgingival contour allows tissue to drape more coronally.



• **Figure 26-14** A diagnostic wax-up should replace missing tooth and tissue so the treating clinician can anticipate the esthetic challenge.

The definitive implant restoration needs to be surrounded by a hard and soft tissue environment that is in harmony with the surrounding dentition. It is not only the amount of bone and soft tissue present prior to implant surgery, but also the precision of surgical execution that leads to an overall favorable outcome. Several key analyses must be performed prior to commencing with implant placement. A diagnostic wax-up, which highlights tissue deficiencies and final tooth positioning, can assist in the planning process (Figure 26-14).

Faciolingual ridge anatomy should be evaluated to determine if there is sufficient crest width to house the implant. Deficient alveolar crest width will require a bone augmentation procedure to allow the implant to be placed in the ideal position. A cone beam scan can assist in diagnosing deficiencies in this dimension.

Mesiodistal space should be equal to that of the contralateral tooth; excess or deficiency in this dimension need to be addressed through orthodontics, enameloplasty, or restoration either prior to or after implant placement.

The most critical dimension remains the apicocoronal dimension. Deficiencies in this dimension can result from periodontal disease, trauma, atrophy, and infection. Vertical

• **Figure 26-15** Sounding to the bone gives the clinician an indication of how much tissue recession will occur after extraction.

grafting is complex and the site may require several surgeries to achieve an optimal configuration.

Two anatomic structures are important in determining predictability of soft tissues after implant placement. The first is the height and thickness of the facial bony wall and the second is the bone height of the alveolar crest in the interproximal areas.

Height and Thickness of Facial Bony Wall

The position of the osseous crest is an important predictor for gingival levels. A survey of 100 patients[15] classified patients as having high, normal, or low crests based on the vertical distance of the osseous crest to the free gingival margin. The greater the distance from the osseous crest to the free gingival margin, the greater the risk of tissue loss after an invasive procedure. Kois proposed that if the total vertical distance of the total dentogingival complex on the midfacial aspect is 3 mm, a slight apical loss of tissue up to 1 mm is anticipated after extraction and immediate implant placement. Greater or lesser than 3 mm indicates the change will be relatively negligible to more than 1 mm. Measuring the distance from the free gingival margin to the osseous crest prior to extraction is an important diagnostic predictor of the anticipated final position of the free gingival margin (Figures 26-15 and 26-16).

Height of Bony Crest in the Interproximal Area

The interproximal bony crest plays a critical role in the presence or absence of peri-implant papillae. A clinical study measured the distance from the interproximal contact to the vertical height of bone and observed how frequently the interproximal space was filled completely by soft tissue.[11] When the contact point to the bone was 3 to 5 mm, papilla always filled the space. When the distance was 6 mm, papilla was absent 45% of the time and with a distance of 7 mm, papilla did not fill the space 75% of the time.

A difference of 1 to 2 mm is significant in obtaining soft tissue esthetics. This has been confirmed with implant supported restorations,[16] and multiple authors have also shown that the height of peri-implant papillae in single tooth gaps is

• **Figure 26-16** Radiograph of patient in Figure 26-15, showing bone loss. The clinician cannot anticipate that papilla will be maintained in this situation and must consider utilizing a long contact area to disguise the loss of tissue.

independent of the proximal bone level next to the implant but is dependent on the interproximal bone height of the adjacent teeth. From a diagnostic perspective, sounding from the tip of the papilla to the interproximal bone crest of the adjacent tooth is an important predictor. If this distance is 5 mm or less there is an increased likelihood that the interproximal tissues will be predictably maintained following implant placement and restoration. If the distance is greater than 5 mm the papilla cannot be predictably maintained after surgical intervention.

Implant Position

Esthetic implant placement is driven by both a restorative and biological philosophy. Esthetically, the implant should be placed to satisfy the parameters of contour so that the restoration is pleasing. Biologically, it should be placed to allow maintenance of both hard and soft tissue architecture. If the tooth to be replaced has not yet been removed, several determinations should be made prior to the extraction.

Placing the implant immediately after extraction helps to shorten the treatment time and may reduce the amount of ridge width reduction that accompanies tooth extraction. In addition, if bone deficiencies are present, orthodontic eruption of the tooth prior to extraction can help to increase the amount of hard and soft tissue in the future implant site.[17]

In most situations involving a single anterior implant restoration, esthetic considerations are more important than functional considerations. As such, axial loading is not as critical as it is with posterior implant restorations. Implant position is critical to the final esthetic outcome and should be considered in all three dimensions and in relation to the adjacent teeth. Misalignment of the implant in the prosthetic space can have adverse esthetic consequences.

Apicocoronal Placement

Apicocoronal positioning appears to be the most critical aspect. Deficient tissue in this dimension can result from several factors, and this type of tissue must be addressed during treatment planning. Because of the complexity of vertical hard and soft tissue grafting, these patients are placed in a high-risk group.

Most often tooth loss is followed by bone loss of minor or major importance. It is necessary to evaluate the discrepancy between the bone level at the proposed implant site and the level at the adjacent teeth. Too large a difference represents a risk to both periodontal and peri-implant tissue health. In this case, the surgeon should consider reconstructing the ridge prior to implant placement.

The apicocoronal positioning of the implant is the vertical discrepancy between the occlusal surface of the implant and the peaks of the bony septa proximal to the adjacent teeth; the most pleasing esthetic result occurs when this discrepancy is minimal.

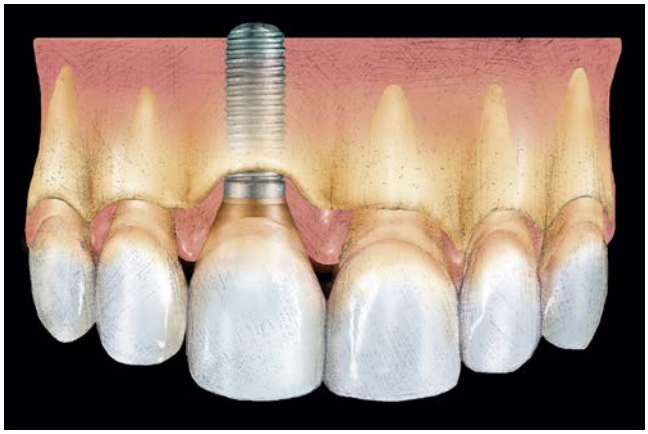
To obtain appropriate apicocoronal positioning of the implant a diagnostic wax-up should be completed and from this a surgical guide is made. The emergence profile and the shape of the restoration are reproduced on the guide to verify the implant positioning on placement.

A maxillary central incisor measures on average 7 to 8 mm mesiodistally and 6 mm faciolingually at the emergence from the soft tissue. A 4.0-mm implant needs to be placed 3 to 4 mm apical to the gingival margin of the contralateral tooth to allow the restoration to emerge with a natural profile. A vertical distance of 3 to 4 mm is needed for gradual transition from the 4-mm diameter of the implant platform to the 7 to 8 mm dimension at the gingival margin. If a lateral incisor were being replaced, the implant would not have to be placed so apically because the average diameter of the crown at the gingival margin is 5 mm and less room is required for transition (Figure 26-17).

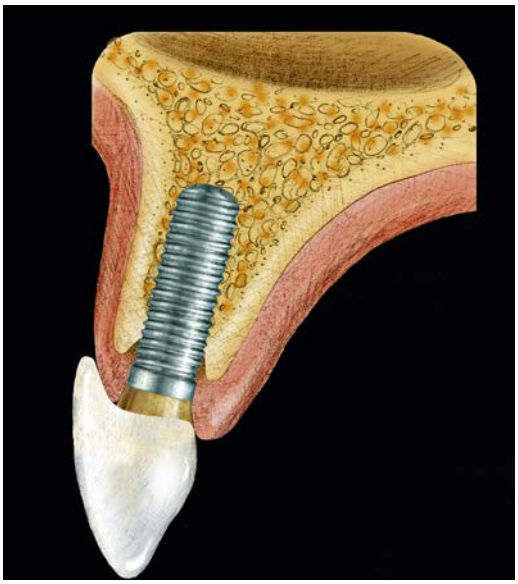
Situations in which there is excess tissue height also require attention. In these types of patients a bone scalloping procedure is required to allow placement of the implant shoulder in a subgingival position; once again, the most efficient way to examine this is through a surgical guide highlighting the proposed gingival margin.

Errors in apicocoronal implant placement can have serious esthetic and biomechanical implications. An implant placed too coronally will not allow adequate transition from the head of the implant to the point where the restoration exits from the free gingival margin. The restoration will look short in comparison to the contralateral tooth. The only prosthetic "bailout," for this type of situation is to provide a ridge-lapped restoration with contours that are pleasing to the observer's eye but may have long-term repercussions on the health of the soft tissue (Figure 26-18).

Problems can also result when implants are placed too apically. Clinically, if an implant is placed too apically



• **Figure 26-17** Ideal placement of the implant should be 3 to 4 mm apical to the free gingival margin.

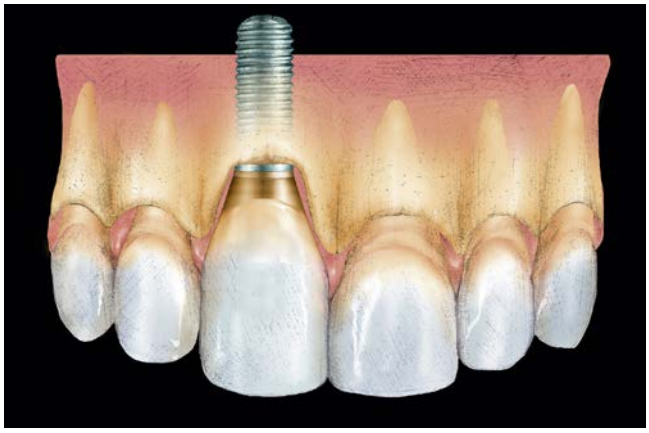


• **Figure 26-18** If the implant is placed too shallowly, a ridge lap may be required on the facial, which may compromise soft tissue health.

with excessive countersinking procedures, an unnecessary amount of bone loss will occur (Figure 26-19). Because this bone loss takes place circumferentially it will affect not only the proximal bone structure but also the height of the facial bone wall, and can lead to undesirable soft tissue contours.

A practical problem in placing an implant too deeply is access for instrumentation. Making an impression of a deeply placed implant can be a difficult experience (Figure 26-20); the soft tissue tends to collapse, there is tissue impingement when trying to locate the head of the implant, and seating is difficult to evaluate. This is specific to external hex systems.

If an implant is placed too deep, a screw-retained restoration is the treatment of choice. The literature shows that removing all the cement when an implant is placed so deeply can prove to be a difficult endeavor. Agar et al.[18] found that when six experienced investigators were asked to remove cement there was a surprising amount of cement left behind; this can lead to serious soft tissue complications.



• **Figure 26-19** Too deep an implant placement can cause instrumentation problems for the treating clinician.

• **Figure 26-20** Too deep an implant placement can also jeopardize the health of the adjacent teeth.

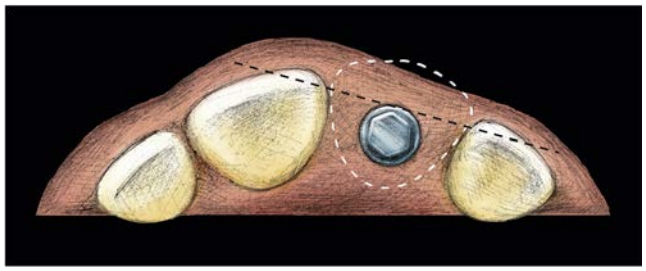
Mesiodistal Placement

Improper mesiodistal positioning of implants can have a substantial effect on the generation of interproximal papillary support as well as on the osseous crest of the adjacent tooth. An implant should be placed 1.5 mm to 2 mm from an adjacent tooth. Placement too close to the adjacent tooth can cause resorption of the interproximal alveolar crest to the level of that on the implant.[19] With this resorption comes a reduction in papillary height. Restorative problems exist as well. Poor embrasure form and emergence profile will result in a restoration with a long contact zone and compromised clinical outcomes.

The loss of crest height on adjacent teeth is caused by circumferential bone loss routinely found around the implant shoulder in implants. This has two dimensions, horizontal and vertical. Radiographs only demonstrate the horizontal aspect of the bone loss; the proximal bone loss measures 1 to 1.5 mm from the implant surface. This distance must be respected on implant placement to prevent vertical bone loss on adjacent teeth.[20]

Faciolingual Placement

The crest width must be examined to determine the presence or absence of bone atrophy. Placement will vary



• **Figure 26-21** Ideal faciolingual placement of the implant.

• **Figure 26-22** Implants placed too palatally will result in biomechanical compromise.

depending on the mechanism of retention of the final restoration (screw retained versus cement retained). Deficient alveolar crest width may require augmentation so that the implant can be positioned in the correct faciolingual position.

Computerized tomographic scan techniques are useful in assisting to determine width. The amount of bone available should be at least 1 mm greater than the implant diameter on each side. Hence a 4-mm diameter implant would require 6 mm of bone. The single implant placed in the maxillary anterior region should be situated palatal to an imaginary line that outlines the curve of the arch formed by the facial surfaces of the adjacent teeth (Figure 26-21). Implants placed too palatally complicate development of hygienic contours (Figures 26-22 and 26-23). Implants are often mistakenly placed too facially. This error can result in excessive resorption of the supporting osseous structure, resulting in a restoration that will appear long in comparison to the contralateral tooth. From a prosthetic perspective, this clinical scenario requires use of custom abutments in the provisional and definitive phases of the restorations (Figures 26-24 through 26-28).

Strategies to Reduce Bone Loss Around Implants

Clinicians have often questioned the reasons for small changes in crestal bone height following implant restoration.

• **Figure 26-23** Contours of the restoration must be designed so they are cleansable. Note the facial cantilever.

• **Figure 26-24** Implant placed too deep and too facially.

• **Figure 26-25** A customized acrylic abutment is fabricated for provisional restoration.

• **Figure 26-26** Provisional restoration fabricated.

• **Figure 26-27** The cement margin should follow the contour of the tissue.

• **Figure 26-28** Provisional restoration in place.

Several theories exist as to the observed changes in crestal bone height. Among them are:

1. Surgical trauma
2. Stress concentration at the coronal region of the implant when implants are placed into function[21]
3. Bacterial leakage due to configuration and position of the implant-abutment microgap[22]
4. Localized inflammation at the implant-abutment interface[23]
5. Biological width theory whereby the soft tissue attempts to establish a mucosal barrier around the coronal aspect of the implant[24]
6. Micromovement of the prosthetic components
7. Repeated screwing and unscrewing of the abutment[25]
8. Implant neck geometry
9. Presence of infection

Implant companies have attempted to address the causes of bone loss and have incorporated design features to attempt to minimize it. Clinicians have also varied implant placement techniques to maximize bone preservation. Features to minimize bone loss include:

1. Altering the implant neck design
2. Microthreads at the coronal aspect of the implant
3. Altering implant surface characteristics
4. Altering the diameter of implant used
5. Use of one-piece implants
6. Placing implants in relation to the alveolar crest[7]
7. Platform switching

Altering Implant Neck Design

There is no evidence to show that marginal bone preservation is improved by altering the marginal neck geometry. Bateli et al.[26] performed a systematic review that included changes in implant neck length and design, implant surface characteristics, implant diameter, and/or insertion depth; the addition of microthreads; the use of one-piece implants; and the concept of platform switching. After subsequent filtering, 20 studies were finally selected and involved the following methods: the use of microthreads (1 study); modifications in implant surface characteristics (11 studies), implant diameter (4 studies), or insertion depth (2 studies); the use of one-piece implants (3 studies); and platform switching (1 study). Because of the heterogeneity of the studies, it was not possible to analyze the data statistically. No evidence was found regarding the effectiveness of any specific modification in the implant neck area in preserving marginal bone or preventing marginal bone loss. They concluded that current literature provides insufficient evidence about the effectiveness of different implant neck configurations in the preservation of marginal bone. Long-term randomized controlled clinical trials are needed to elucidate the effects of such modifications.

Microthreads at the Coronal Aspect of the Implant

Microthreads have been added in the implant neck area by manufacturers, their purpose being to distribute the forces around an implant when an implant is under functional load and also to increase the bone-to-implant contact. Commercially available implant systems employing this modification present a pitch distance of 0.185 mm between threads. A five-year prospective study by Palmer et al.[27] looked at Astra-tech implants with microthreads. The mean marginal bone loss in the study was 0.39 mm after 5 years, which is much lower than the original

machined surface external hex implants. However, the research did not specifically isolate this design feature, so the conclusion cannot be made that the microthreads were responsible for the bone preservation.

Implant Surface Characteristics

There have been many modifications of the implant surface in an attempt to increase bone-to-implant contact. Techniques such as oxidizing, sandblasting, and acid etching have been employed to accelerate the process of osseointegration. The rough surface implants do have a better osteoconductive capacity than the machined implants and have improved bone-to-implant contact.[28]

Surfaces have been compared to determine if a rougher surface resulted in better bone maintenance of bone around dental implants. Wennstrom et al.[29] compared implant groups with the same implant design that differed only in their surface characteristics. Their conclusion was that no significant difference was attributable to the enhanced surface. There is no evidence to support marginal bone preservation for any specific surface modification.

Implant Diameter

Wide diameter implants were designed to be placed in compromised situations where available bone height and quality were limited. Manufacturers suggested that wide diameter implants may exhibit less horizontal bone resorption than regular diameter implants. It was claimed that increasing the diameter of the implant would decrease the stress and strain on the alveolar crest and lead to less bone loss. Ivanoff[30] showed that 5-mm diameter implants demonstrated the highest failure rates in comparison to 3.75-mm and 4.00-mm implants. Long-term randomized controlled trails with split-mouth designs are needed to substantiate the claim that wide diameter implants are effective in preservation of marginal bone levels.

One-piece Implants

A one-piece implant is defined as an implant in which the bone anchoring portion, the soft tissue traversing portion, and the prosthetic abutment are all in one piece.[31] The theory behind one-piece implants is that they are placed in a one-stage surgery and therefore bypass the two-stage procedure, avoiding further manipulation of the soft and the hard tissues, and are supposed to eliminate the implant abutment microgap. It was claimed that the elimination of the microgap through the use of one-piece implants resulted in less bone loss.[32] Other studies have shown no difference in bone loss when a two-piece implant system was compared to a one-piece implant system.[33] Currently the evidence is not clear if one-piece implants serve an advantage over two-piece implants in terms of bone maintenance.

Insertion Depths

Clinicians have altered the placement of two-piece implants at varying locations with respect to the gingival margin and marginal bone levels to determine if this has an influence on bone loss. Callan et al.[34] suggested that more bone loss was associated with implants where the implant abutment interface is placed below the gingival margin. Hartman and Cochran[35] found a relationship between the amount of bone remodeling and the location of the rough-smooth border placed at or near the alveolar crest. Although these studies provide us with some information, the possible interference of surface modifications in the studies referring to insertion depth makes it difficult to draw any reliable conclusions about the outcome of the varying locations of the implant abutment interface in two-piece implants with respect to the gingival margin or alveolar crest.

Platform Switching

This concept refers to the inward horizontal repositioning of the implant abutment junction so that it is positioned away from the outer edge of the implant and adjacent bone. Lazzara and Porter[36] introduced the concept by using standard diameter components on wide platform implants. They found a reduction of the expected postrestoration crestal bone remodeling in comparison to the "standard" implants. There are multiple theories as to why the platform-switching concept works.

The Biomechanical Theory

Connecting the implant to a smaller diameter abutment may limit bone resorption by shifting the stress concentration zone away from the crestal bone–implant interface and directing the forces of occlusal loading along the axis of the implant.

The Biologic Width Theory

Shifting the implant-abutment connection may medialize the location of the biologic width and minimize the marginal bone resorption. Placing the IAJ at or below the crestal bone level may cause vertical bone resorption to reestablish the biologic width.

The Inflammation at IAJ Theory

This theory postulates that bone resorption is caused by an inflammatory infiltrate at the IAJ. The presence of periimplant microbiota was suggested to influence the crestal bone resorption by maintaining the inflammatory cell infiltrate at the IAJ. The physical repositioning of the IAJ away from the outer external edge of the implant and neighboring bone may limit bone resorption by containing the inflammatory cell infiltrate within the angle formed at the interface away from the adjacent crestal bone.

The question becomes, does platform switching influence bone remodeling? Canullo et al.[37] placed 22 implants of 5.5-mm diameter immediately in extraction sockets in the maxilla. They were randomly divided where 11 implants were connected with 3.8-mm diameter abutments and 11 implants had 5.5-mm diameter abutments. The follow-up was 25 months. What they found was lower crestal bone loss in the platform-switched group compared to the non-platform-switched. They also found a wider and more resistant zone of connective tissue in the platform-switched group compared to the platform-matched group.

Hurzeler et al., Atieh et al., and Rodriguez-Ciurana et al.[38,39,40] found similar results supporting the platform-switching concept. The conclusions from these studies were that the biologic width around platform-switched implants is located more coronally and there is a reduction in the vertical and horizontal components of bone loss.

Just as there are many studies supporting the concept there are many studies refuting the claim that platform switching actually works. Studies by Baffone et al., Batelli et al., Enkling et al., Van Steenbergh et al., and Jacobs et al. question the platform-switching concept.[41-44] Conclusions from their studies included:

1. Geometry of the implant abutment connection was of limited importance in preservation of hard and soft tissues.
2. No evidence in a meta-analysis showed that the implant neck configuration contributed to preservation of marginal bone level, and marginal bone loss occurred regardless of all the efforts to eliminate it.
3. Bacterial colonization can occur as a consequence of leakage at the IAJ or as a result of contamination during implant placement.
4. A split-mouth design comparing Astra Tech and Branemark implants showed that there was no significant difference in probing depths, presence of plaque, or change in marginal bone level.
5. Mean radiographic bone loss after the first year was small and was less than 0.5 mm for both implant systems up to 15 years after prosthetic loading.

There are many causes of bone loss around dental implants and many clinicians have studied various aspects of implant design in an attempt to reduce the bone loss that is seen. Manufacturers have attempted to incorporate all the features within their individual systems to aid clinicians in achieving the ultimate in esthetics and biomechanics. The clinician's goal is to produce a restoration that mimics nature. As our quest for perfect restorations continues, we must realize there still is much that is unknown and despite our best efforts to maintain bone, the bone loss is multifactorial and cannot be isolated to one aspect of implant design. Operator variables and systemic health of the patient will also influence the bone loss that is seen. As clinicians we can only utilize all the tools that are available to us in the hope that the bone will be maintained and this will ultimately result in a life-like restoration.

Considerations for Multiple Implants

Patients with extended edentulous spaces present greater anatomic and esthetic challenges, making it even more difficult to obtain an esthetic result with certainty. Following extraction and wound healing of two adjacent teeth, the ensuing apical and faciolingual resorption results in an edentulous segment that is flattened. The same diagnostic considerations need to be addressed as when looking at single-tooth edentulous sites.

The aim prior to implant placement is to have a three-dimensional configuration of hard and soft tissue, which will allow placement of implants in an ideal position. The placement of two missing central incisors poses an additional challenge. Following surgical placement, additional peri-implant bone remodeling takes place. In the frontal plane, two processes occur: one between the implant and the adjacent natural tooth and one between the two adjacent implants.

On the tooth implant side, the predictability of the interdental papilla is governed by the height of the interproximal bone crest of the tooth. If this height is favorable there is a good certainty that the interdental papilla will be maintained following implant placement. The bone crest between the two implants is likely to undergo further resorption in an apical direction. This is accompanied by a loss of inter-implant soft tissue that, in the case of multiple edentulous sites, will result in black triangles between the adjacent restorations.

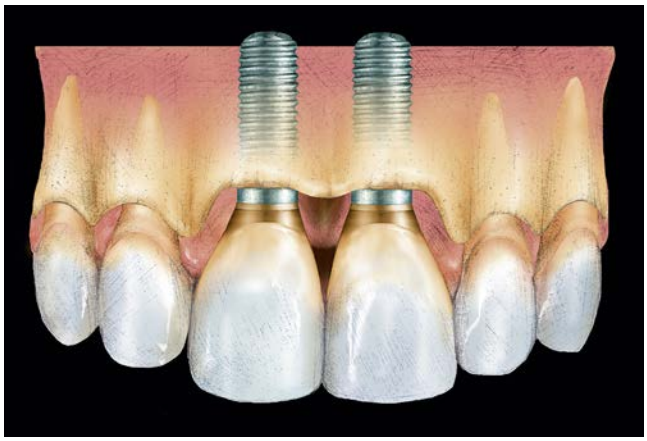
Many clinicians have sought after the ideal implant distance required to maintain the interdental papilla. Tarnow et al.[45] performed a radiographic study to address this clinical problem. Radiographic measurements were taken at a minimum of 1 and 3 years after implant exposure. All radiographs were taken with a paralleling technique. Radiographs were computer scanned and magnified for measurement. The following measurements were taken:

1. Lateral distance from the crest of the inter-implant bone to the implants
2. Vertical crestal bone loss
3. Distance between the implants at the implant/abutment interface

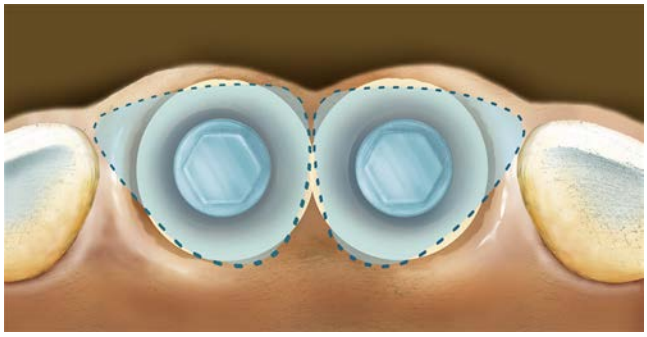
When implants were placed too close together, the bone remodeling overlapped to a great degree and consequently resulted in loss of vertical bone height and this subsequently had soft tissue implications. When implants were separated by 3 mm and greater, lateral bone loss from the adjacent implants did not overlap, with minimal resultant crestal bone loss.

They concluded that it is more difficult to create or maintain papilla between two adjacent implants than it is between an implant and a natural tooth. Their recommendation was that when two implants are placed adjacent to each other in the esthetic zone a minimum of 3 mm of bone should be retained between them at the implant-abutment level. If implants are placed too close together this can compromise the contours of the restoration (Figures 26-29 through 26-32).

This particular study addressed bone loss between the implants. It should be remembered that the bone loss has two dimensions, horizontal and vertical. Radiographs only demonstrate the horizontal aspect of bone loss. Bone loss occurs circumferentially around the implant and, when two implants are placed adjacent to each other, facial bone loss also occurs (Figure 26-33). This has implications in terms of stability of the facial gingival margin. If the implants are placed too far facially there will be less facial bone and this will ultimately result in apical migration of the free gingival margin (Figure 26-34).



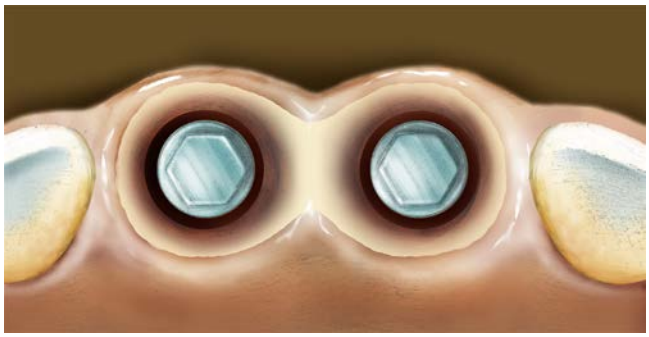
• **Figure 26-29** Implants placed too close together can compromise the contours of the restoration.



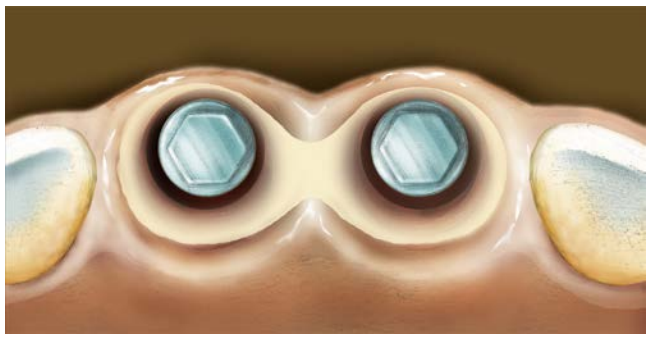
• **Figure 26-30** Contours compromised mesial to both planned restorations.

• **Figure 26-31** Implants placed too close together. Note loss of papilla and flattening of tissue.

• **Figure 26-32** Restorations fabricated with long contact area to disguise loss of tissue.



• **Figure 26-33** Implants ideally should be placed at least 3 mm apart; however, this must take into account the size of the anticipated teeth.



• **Figure 26-34** Implants placed too facially will result in thinning of bone. Consequences can be tissue recession and loss of interproximal papilla.

Tarnow et al.[45] also performed a study to determine the height of the soft tissue to the crest of the bone between two adjacent implants. This was done independent of the location of the contact point. They looked at 136 interimplant papillary heights in 33 patients by eight examiners. A standardized periodontal probe was used and placed from the height of the papilla to the crest of the bone. They found that the mean height of papilla between two adjacent implants was 3.4 mm, with a range of 1 to 7 mm.

Although this was a retrospective study and there were many variables such as operator, implant type, placement, and so forth, it did give us information that soft tissue between two adjacent implants in the esthetic zone is not entirely predictable. The patient must be aware of this when treatment planning or alterations must be made in the treatment plan to provide an esthetic result.

Recreating interdental papilla between two adjacent implants is a formidable task. Restoratively, clinicians alter the position of the contact point to give the illusion of

• **Figure 26-35** Patient presented with two central incisors failing.

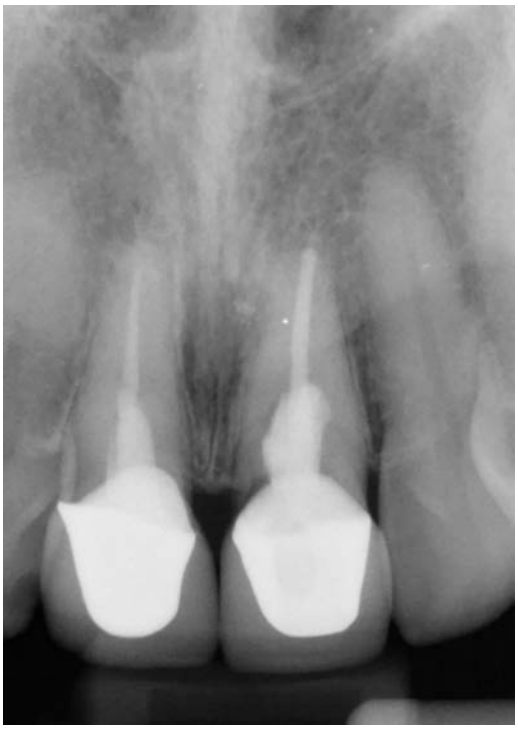
papilla. The thin spicule of bone remaining between the implants may be sufficient to maintain the papilla during the first few years of the restorations service but may resorb over time, resulting in loss of soft tissue.

To achieve a result that is as close to ideal as possible, two adjacent implants should be placed in a correct three-dimensional position. If primary stability permits, provisional restorations should be fabricated and the implants loaded the same day. The provisional restorations act as a scaffold around which the soft tissue heals. Particular attention should be paid to the subgingival contours of the restoration so as to not compress the tissue. Interproximal and occlusal contacts should also be relieved in the provisional phase. The patient should be given instructions to maintain a soft diet. Following healing, the soft tissue contours can be transferred to the laboratory technician at which time the definitive restorations can be fabricated (Figures 26-35 through 26-43).

Another clinically challenging situation is replacement of a maxillary canine and adjacent lateral incisor. This becomes more challenging because the edentulous space is smaller and the inter-implant soft tissue tends to be less voluminous. Consideration in this instance should be given to placement of a single implant in the canine region and cantilevering a lateral incisor from it. Placement of the implant should follow all the principles discussed previously.

Replacement of several missing teeth with implants allows for the use of fixed partial dentures and the opportunity to utilize pontic form to help support the soft tissue and give an illusion of papillae.

The authors have encountered many situations where a "one implant per tooth" philosophy has been utilized. This can be particularly detrimental in the esthetic zone. The literature is quite clear that maintaining papillae between implants is not predictable. Even with the advent of more sophisticated implant designs there are no long-term studies showing papilla maintenance. For an esthetic outcome, it is more predictable to place implants away from each other so that the intervening soft tissue can be sculpted to give the illusion of papilla. If the patient is missing maxillary lateral incisor to lateral incisor, there are many combinations of



• **Figure 26-36** Radiograph of patient in Figure 26-35.

• **Figure 26-37** Teeth extracted and implants placed immediately into extraction sockets. (Surgery by Dr. Hooman Zarrinkelk.)

• **Figure 26-38** Accurate pilot hole preparation is critical to correct three-dimensional placement of the implants.

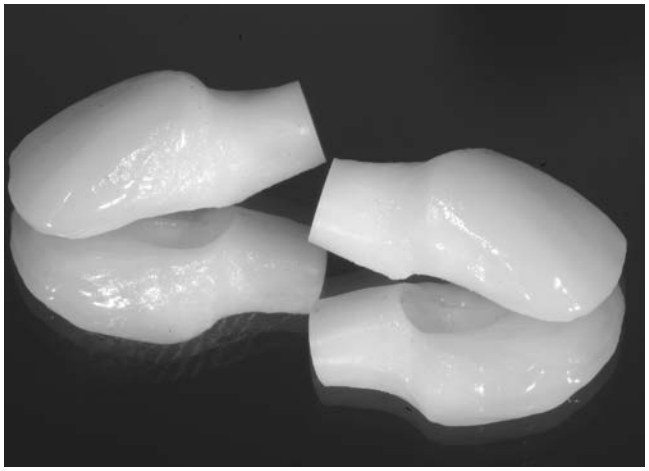
• **Figure 26-39** Screw-retained acrylic provisional restorations are fabricated and delivered on the day of surgery. All occlusal and interproximal contacts are relieved.

• **Figure 26-40** Healing at one month.

• **Figure 26-41** Sculpting of the interproximal tissue by the provisional restorations.

implant placement which can be considered. The clinician must look at the variables that will influence the esthetic outcome, which include but are not limited to the following:

- Ridge width
- Soft tissue volume
- Smile line



• **Figure 26-42** Subgingival contour of definitive restorations is concave to allow tissue to drape more coronally.

• **Figure 26-43** Screw-retained single unit definitive restorations.

If there is an adequate volume of bone, placement of two implants in both lateral incisor regions and fabrication of a fixed partial denture, sculpting the intervening tissue with ovate pontics is likely to produce an illusion of papilla, which will be more pleasing to the observer's eye.[46] The diameter of implant selected will be relative to the bone width, with the clinician's objective being to have a maximal amount of bone facial to the implant. This placement philosophy can also be reserved for extended edentulous spans where esthetics is of paramount importance (Figures 26-43 through 26-47).

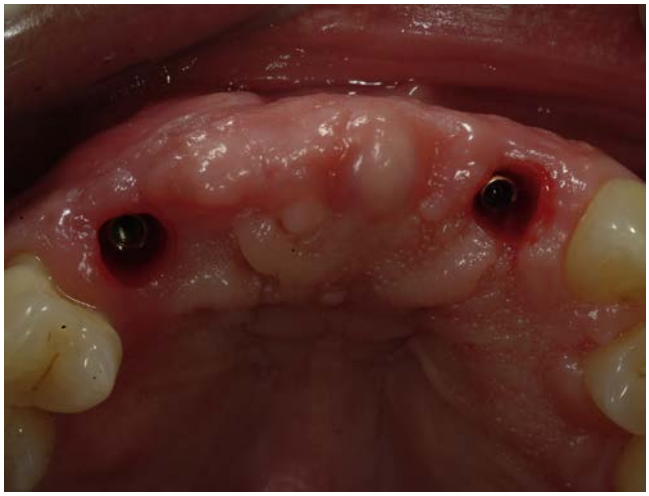
Unfortunately, patients often present with existing edentulous spaces where thickness of soft tissue is not optimal for ovate pontic development. In these situations alternative pontic designs have to be considered. Cascione et al.[47] introduced a novel design in which pontic site development is facilitated by scoring of the master casts in the pontic area. This allows compression of tissue and the topography of these sites is changed gradually with pressure. Provisional restorations are fabricated to test the soft tissue response, with the ultimate goal being optimum soft tissue health and pleasing esthetics. Once this has been satisfied, the definitive restoration is fabricated (Figures 26-48 through 26-61).

• **Figure 26-44** If bone dimensions allow, implants should be placed in the lateral incisor position.

• **Figure 26-45** Note sculpting of pontic area. Abutments are designed so that margins follow contour of tissue to allow easier clean-up of cement.

• **Figure 26-46** Definitive four unit restoration; note excellent tissue response.

• **Figure 26-47** Restoration must have ideal emergence profile.



• **Figure 26-48** Patient presentation; two implants have been placed for an extended edentulous span.

• **Figure 26-49** The edentulous span will require correct three-dimensional positioning of the teeth.

Placement of implants in multiple edentulous spaces must follow the same principles as for single-tooth situations; placement must follow appropriate diagnosis and treatment planning, which includes a diagnostic wax-up and fabrication of a surgical guide to facilitate implant placement. If these techniques are not followed, it is all too easy to find implants in the wrong position, requiring utilization of prosthetic strategies to satisfy the patient's demand for esthetics. In situations like these, patient expectations are unlikely to be met.

Summary

Esthetic restoration of anterior teeth with implant-supported restorations is one of the most difficult procedures to execute. Bone resorption following anterior tooth extraction often compromises gingival tissue levels for the implant restoration. In the last 10 years the focus has shifted from osseointegration to creation of an implant-borne restoration that is in harmony with the surrounding hard and soft tissue. Complete reconstruction of tooth and gingival esthetics remains the primary objective and in some instances can be very difficult to achieve. The predictability of esthetic success depends on the tissue loss present at the initiation of treatment. The greater the amount of bone and soft tissue loss, the more difficult it becomes to produce an ideal esthetic result. Improvements in implant design, surfaces, and materials have assisted us in obtaining esthetic results. However, the ultimate esthetic result can be obtained only through a correct diagnosis and appropriate treatment planning.

Acknowledgment

The authors would like to thank Domenico Cascione for assistance with the laboratory work.

Immediate Implants

HOWARD H. PARK, DANIEL R. CULLUM

Introduction

Schulte[1] is credited with being the first clinician to attempt immediate implant placement into fresh extraction sockets, his work having been published in German in 1978. Lazzara[2] in 1989 revisited the concept with respect to restorative advantages. The concept of placing implants into fresh extraction sockets has recently regained the interest of clinicians and scientists to reduce treatment time. Minimizing the number of surgical procedures required to restore a missing tooth has obvious advantages for patients who are in need of implant therapy. Immediate implant survival rate has been studied under various factors: presence of infection, vertical fracture, failing endodontic treatment, and antibiotic therapy. The only statistically significant factor seen to increase the survival rate was postoperative antibiotic therapy.[3] Immediate placement of dental implants into fresh extraction sockets with an immediate delivery of a provisional restoration in the esthetic zone is a concept first reported by Wöhrle[4] in 1998. In a randomized prospective study with 2-year follow-up, Crespi and colleagues[5] reported a 100% survival rate with no statistically significant radiographic differences when immediate implants with immediate provisionalization (IIIP) was compared with delayed implants with immediate provisionalization in single maxillary anterior tooth replacement. Cornelini and co-workers[6] reported 22 cases with 12 months of follow-up utilizing IIIP (within 24 hours) in 2005. The authors reported a 100% survival rate with Jemt's papilla index[7] of 2 (at least half of the height of papilla present) on 27 papillae and 3 (the papilla is present in the entire interproximal space) on 17 papillae. Valentini and colleagues[8] also reported a 95.3% survival rate, with 78% of the subjects scoring papilla index of 3 in 1 year follow-up in a similar study. De Rouck and associates[9] reviewed 11 studies on maxillary anterior single IIIP (within 24 hours) and reported survival rates between 93.5% and 100% (6 to 52 months of follow-up), but cautioned against this technique, as midfacial gingival recession was identified as a common esthetic complication. Kan and co-workers[10] reported a 100% survival rate in 35 IIIPs. The authors reported increased marginal bone level and spontaneous papilla regeneration with a mean follow-up time of 4 years, but also reported continuing recession of the facial gingival tissue. With the high survivals reported with immediate implant therapy, discussions in this chapter will primarily focus on factors that affect the esthetic outcome of this treatment modality.

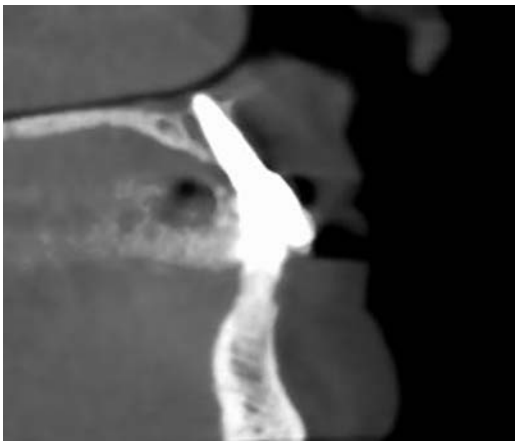
Esthetic Complications

Relative contraindication for immediate implant placement in the maxillary esthetic zone include smoking, periodontally involved teeth, infection, and compromised buccal bone plates. All of these risk factors can lead to esthetic failure of restored implants. The most common complications reported when implants are placed in the esthetic zone include apical recession of the facial gingival margin and the loss of papilla height[5,8-12] (Figures 27-1 and 27-2). Investigators have identified key components related to these complications. Currently recognized major factors include, but are not limited to, buccal plate integrity,[18-22] gingival phenotype,[18] implant positioning,[23] flap elevation,[24] abutment design,[25] and smoking.[26,27] Controversies exist in the literature regarding the proper management of compromised extraction sockets with respect to the integrity of the buccal plate. Historically, much of the literature has recommended avoiding immediate implants in the esthetic zone when the buccal plate is compromised.[28,21,22] Most studies evaluating the effect of compromised buccal plates on facial gingival margin involved raising a full-thickness flap to visually confirm the buccal defect and to perform subsequent hard and soft tissue grafting.[28-33] However, elevation of a full-thickness flap compromises blood supply to the residual alveolar bone and increases subsequent resorption.[24] In 2007, Kan and colleagues[30] treated 23 consecutive patients with immediate implants and immediate provisionalization restoration and found that in 15 of the 23 patients it was necessary to raise full-thickness flaps for guided bone regenerations due to compromised buccal plates. These results showed marked facial gingival recession greater than 1.5 mm 1 year after restorations in patients with

• **Figure 27-1** Apical migration of mid-facial marginal gingiva on tooth #8.

• **Figure 27-2** Shortened distal papilla of restored implant #9 with exposed restorative margin of #10.

• **Figure 27-3** Five years post restoration #7.



• **Figure 27-4** Cone-beam computed tomography showing little or no facial bone on #7 implant.

large buccal plate defects. This occurred despite guided bone regenerations and subepithelial connective tissue grafts. Based on these findings, they concluded that compromised buccal plates led to more gingival recession, confirming the notion that immediate implant placement should not be attempted in sockets with compromised buccal plates. However, recent studies suggest that a positive esthetic result can be achieved even in sites with a compromised buccal plate. Valentini and colleagues[8] reported in 2010 on treatment of 40 patients with compromised buccal plates (confirmed by visual inspection with flap elevation) by placing immediate implants with immediate or early (7 days postoperative) provisionalization restoration. Follow-up after 12 months showed minimal marginal bone loss with average papilla index of 2.81, but the level of midfacial gingival margin was not studied. More recently, using flapless technique, Rosa and co-workers[34] treated 18 patients with compromised buccal plates by placing autogenous bone into the buccal defect followed by IIIP. During the average of 58 months of follow-up, they reported no facial gingival recessions on any of these patients. Valentini's study required flap elevation to confirm the buccal plate defect, whereas Rosa's used periodontal probes to "map out" the defect through the extraction socket without raising flaps. Both studies emphasized the importance of placing the implants in a more palatal position to create enough labial space for augmentation.

When cone-beam computed tomography (CBCT) is used to evaluate the presence of facial bone on restored implants, it is sometimes surprising to see no visible bone despite adequate esthetic results (Figures 27-3 and 27-4). Quantifying the amount of facial bone in restored implants with CBCT has its limitations. Because of the beam-hardening effect of CBCT technologies, bone thickness of less than 1.0 mm next to the implant body is difficult to visualize, making buccal plate evaluation a challenge.[35] Benic and colleagues[36] followed 14 patients for 7 years and noted that 5 patients did not show any detectable buccal bone facial to the implant on CBCT and yet only showed 1 mm recession on facial-free gingival margin. It is probable that there was indeed bone present in the amount not detectable by the CBCT in their study.

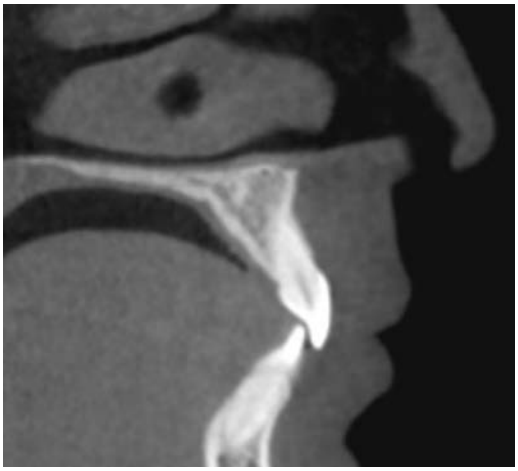
Thin gingival phenotype has been associated with post-restoration midfacial recession.[18] Commonly accepted methods to identify the thin phenotype are using a probe in the sulcus and by visual inspection. Kan and associates[37] studied the gingival phenotype of 48 patients who were scheduled to have maxillary anterior teeth removed for immediate implant

placements. Two calibrated clinicians were asked to evaluate patients before extraction to determine their gingival phenotype by either using a probe in the sulcus or by visual inspection. Following extraction, the soft tissue thickness was measured with calipers at 2 mm apical to the free gingival margin. When these direct measurements were correlated with pre-extraction findings, 15 of 39 patients who were visually assessed as thick had less than 1.0 mm of soft tissue thickness, while 9 of 30 patients who were probed and probe-assessed as thick, had less than 1.0 mm soft tissue thickness. Based on these findings, Kan and colleagues recommended treating every esthetic case as if the patient had a thin gingival phenotype.

Smoking has been associated with a higher failure rate of implants and compromised esthetics.[26] Raes and co-workers[27] reported a prospective study involving 39 smokers and 46 nonsmokers who received a single dental implant in a healed ridge of the maxillary anterior area with immediate provisionalization. After 2 years in function, they noted more midfacial gingival recession and shortened papilla among smokers.

Preoperative Workup

Risk of esthetic complications and any limitations should be thoroughly discussed with the patients during the preoperative record collection. Periapical radiographs are required to identify proximal bone levels on adjacent teeth. Adjacent teeth with compromised proximal bone levels may have shortened papilla heights. An adequate amount of palatal bone must be available in order to engage the implant (Figure 27-5). Lau and colleagues,[38] in a retrospective review of 500 CBCTs, reported 98% of maxillary central incisors have enough palatal bone for implant placement. Kan and coworkers[39] also retrospectively studied CBCTs of 100 patients and concluded that 87.6% of the patients had adequate palatal bone to engage the implants. With the broad application of CBCT technologies, three-dimensional imaging is now cost effective with minimal radiation exposure. CBCT is a powerful tool to allow formulation of a comprehensive diagnosis and treatment plan and should be incorporated as a routine part of preoperative record collection. Chronically infected teeth with fistula tracts do not necessarily preclude the option of immediate implant placement.[40] The height of interdental papilla around the implant restoration is determined by the interproximal bone height of the adjacent teeth.[11,41,42] Patients with high smile lines, class II div II deep bites, or thin gingival phenotypes with "high scalloped" papillae should be avoided until the clinician becomes very comfortable with this technique. Patients with restorations on adjacent teeth such as full-coverage crowns, veneers, or cervical or interproximal composite restorations can have risk of restorative margin exposure due to soft tissue recession after immediate implant placement (Figures 27-6 and 27-8).



• **Figure 27-5** Typical findings on maxillary central incisor with available palatal bone.

Surgical and Restorative Principles for Immediate Implant Placement

Peri-implant Biological Width

Biological width refers to the vertical dimension of "seal" around the dentogingival junction.[43] It is made up of the

• **Figure 27-6** Preoperative view of fractured #8 crown to be removed.

• **Figure 27-7** Four weeks after immediate implant with immediate provisionalization via flapless procedure on the right maxillary central showing exposed restorative margins on adjacent teeth.

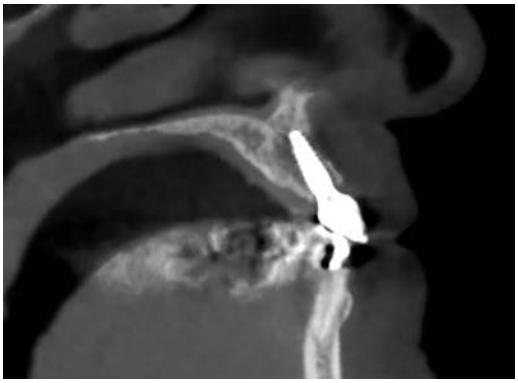
sulcus depth, junctional epithelium, and connective tissue attachment and averages about 3 mm in healthy periodontium.[44] Around dental implants, a similar soft tissue structure exists with similar dimensions.[45] This corresponds to about 2 mm of vertical bone loss[45] as originally defined by Albrektsson and colleagues,[46] with less than 0.2 mm of vertical bone loss per year thereafter. In a healthy peri-implant environment, consistent inflammatory cell infiltrates can be found around the micro-gap, and yet the amount of bone loss is limited to about 1.5 mm in the vertical dimension.[47] Such findings suggest that this type of self-limiting bone loss is an adaptive response to the local condition, supporting the theory that a new peri-implant biological width is being established.[45] This is in contrast to conditions leading to "peri-implantitis," which is defined by chronic inflammation of peri-implant mucosa accompanied by a progressive crestal bone loss beyond the dimension of biological width requiring therapeutic interventions.[48]

A significant change in macro-design of implant/abutment interface described as "platform switching"[49] has led to minimizing this marginal bone loss. Platform switching refers to an "act of changing an implant abutment to one with a smaller diameter, so as to place the implant-abutment interface medial to the edge of the implant platform,"[50] and its effect on marginal bone loss was discovered when a mismatched abutment was inadvertently used in a wide platform implant.[49] The net effect of platform switching is to reduce the inflammatory response at the implant-abutment junction, thereby minimizing bone loss.[51] A split-mouth animal study by Makigusa and colleagues[51] showed that the "bone was maintained vertically and new bone formed horizontally around the platform-switched implants," whereas non–platform switched implants showed both vertical and horizontal bone loss. A meta-analysis of 13 randomized controlled trials revealed significantly less vertical marginal bone loss at implants with the platform-switched configurations.[52] The biological seal around the implant, however, has two more dimensions to be elucidated. The horizontal dimension that extends mesiodistally is reported to be about 1.4 mm[53] and has a direct correlation with the papilla height, especially when two implants are placed next to each other in the esthetic zone.[53] A similar distance exists in the bucco-palatal dimension, and violating this dimension by placing the implants too close to the facial plate has led to facial gingival recession[23,54] CBCT has allowed clinicians to visualize and measure the bucco-palatal dimension[55,56] (Figure 27-9). This dimension is a critical factor in determining the proper bucco-palatal positioning of the implant in the maxillary esthetic zone. In fresh extraction sockets, there is typically a "gap" separating the implant from the buccal plate, and the ideal gap size is debatable, but most agree it should be at least 2 mm.[9,57]

Buccal Plate Remodeling Following Immediate Implant Placement

A recent systematic review by Lang and colleagues[3] showed that within 6 months of extraction, the alveolar ridge will result in 3.8 mm of horizontal reduction and 1.24 mm of vertical reduction. Although studies have shown that the horizontal dimension of the ridge is still reduced regardless of the techniques and types of material used for grafting, most clinicians now accept that socket preservation technique should be used to minimize bone volume loss, especially in the maxillary esthetic zone.[58] CBCT has allowed visualization of bone volume not previously possible with conventional radiographs. Several CBCT studies have shown that the thickness of buccal plate near the crest is less than 1.0 mm in the majority of patients.[59,60] This thickness has been independently verified by others who took direct measurements following extractions.[32] Most of the crestal buccal bone consists of bundle bone (lamina dura) providing the attachment surface for Sharpey fibers of the periodontal ligament. The thickness of this bone layer varies from anterior to posterior teeth ranging from 0.22 mm to 0.54 mm.[61] Bundle bone receives 100% of its blood supply from the periodontal ligament (PDL) and thus is resorbed completely when the tooth is removed. When one considers that the blood supply only comes from three sources (PDL, periosteum, and marrow space), raising a full-thickness flap to remove teeth can greatly compromise the blood supply to this area.[62] As most studies looking at the buccal plate remodeling process included flap elevation

• **Figure 27-8** Teeth #7, #8, and #9 were restored with new restorations.



• **Figure 27-9** Palatofacial dimension can be measured on cone-beam computed tomography.

for direct measurements, the question remained whether flapless procedures would make a difference in the amount of buccal plate resorption. Studies comparing an open flap versus flapless procedures on the effect on labial tissue volume loss showed clear advantage of flapless procedures.[63,64] Using CBCT to evaluate the buccal plate, Lee and associates[65] were able to show minimal amount of remodeling when IIIP technique was combined with flapless procedure. Roe and colleagues[56] noted a mean horizontal facial bone reduction of 1.23 mm at the level of implant platform 12 months after the immediate implant placement using flapless technique combined with IIIP.

Implant Positioning
