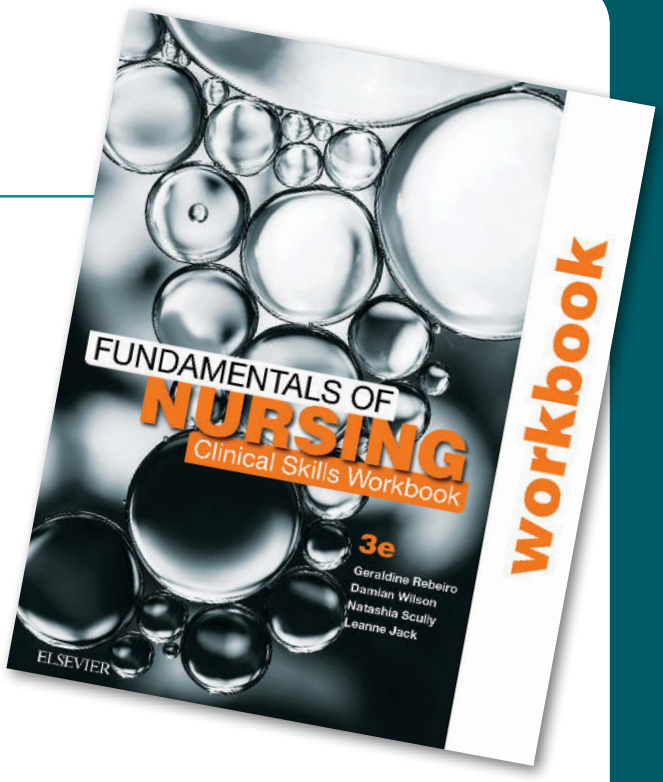
Fundamentals of Nursing Clinical Skills Workbook 3e

By Geraldine Rebeiro, Damian Wilson, Natashia Josephine Scully and Leanne Jack

Fundamentals of Nursing Clinical Skills Workbook 3e is an indispensable tool that will assist you in mastering the clinical skills that are essential to becoming a confident, effective and agile nurse.

Each skill has been fully revised to align to the updated skills in *Potter and Perry's Fundamentals of Nursing 5e*, including a total of 14 new skills to reflect contemporary nursing practice.



KEY FEATURES:

- Directly aligned to *Potter and Perry's Fundamentals of Nursing 5e*
- Aligned to the *Registered Nurse Standards for Practice*, 2016 (AUS) and *Competencies for Registered Nurses*, 2007 (NZ)
- 78 *Clinical Skills* linking applied nursing skills to effective clinical practice, each featuring:
  - an overview of each skill, containing rationales to help understand how and why the skill is performed
  - a focus on therapeutic relationships and patient considerations, reminding students that the patient is central to care provision
  - equipment checklist
  - a step-by-step approach, clearly explaining how to perform each skill
  - *Critical decision points*, alerting students to critical steps that ensure quality and safety in patient care
  - *Competency checklist*, providing a valuable tool for assessment, including the five-point Bondy Rating Scale
  - reflection opportunity at the end of each Competency checklist to encourage learning
- 11 new skills, including patient handover, making a post-operative bed, assessment of fluid status, and assessment and management of the deteriorating patient
- 3 additional skills (not featured in the main text):
  - Pouching a urostomy
  - Regulating CVC intravenous flow rate
  - CVC dressing change and flush

PART 1

Evolving nursing: nursing and the healthcare environment 1

1 Creating a proactive and dynamic nursing profession 2

Frances Hughes, David Stewart and Amanda Davies

Introduction 3
Nursing's contribution to quality patient outcomes 3
Nursing defined 4
Person-centred care 5
Challenges facing the Australian and New Zealand health systems 5
Australia's and New Zealand's health 6
The growing cost of health care 7
The future of the workforce 7
Addressing challenges through health reform 7
Nursing leadership and healthcare reform 8
Regulation of the nursing profession 8
Decision-making framework 9
Scope of practice 9
Continuing education and professional development 10
Pathway to optimised practice 11
The future of nursing: leading change 12
Conclusion 12

2 Building nursing practice: the Fundamentals of Care Framework 15

Tiffany Conroy, Rebecca Feo, Jan Alderman and Alison Kitson

Introduction 16
The Fundamentals of Care Practice Process: concepts, working hypotheses, frameworks and theories 16
Concepts 16
Working hypothesis 16
Conceptual frameworks 16
Theories 17
Concepts and working hypothesis 18
The Fundamentals of Care Framework 19
Relationship between theories, practice and patients: using the Fundamentals of Care Practice Process 23
Why do I need to know about theories? 25
Types of theories 26
Linking theories to nursing knowledge, research and education 26
Biomedical model 26
Biopsychosocial model 27
Positives and negatives of using theories 27
Conclusion 28

3 Engaging patients and keeping them safe 30

Rebecca Feo, Tiffany Conroy, Jan Alderman and Alison Kitson

Introduction 31
Developing a relationship 31
Safety as one of the fundamentals of care 33
Patients' physical safety 34
Patients' psychosocial safety 35
Patients' environmental safety 38
Personal safety of the nurse 40
Summary 43

PART 2

Framing nursing: critical processes in nursing practice 45

4 Developing clinical reasoning for nursing practice 46

Clint Douglas and Jackie Crisp

Introduction 47
The importance of the clinical reasoning process for effective nursing practice 49
The process of clinical reasoning 50
Developing your nursing knowledge and skills through the clinical reasoning process 52
Critical thinking – knowledge, skills and attitudes for sound clinical reasoning 55
Conclusion 57

5 Gathering relevant information and making decisions 60

Clint Douglas and Jackie Crisp

Introduction 61
Taking a critical thinking approach 61
Gathering data and information 62
Forms of data and information 63
Sources of data and information 64
Methods of data and information collection 65
Interview 65
Data documentation 69
Making nursing judgements and decisions 69
Clinical judgements are more influenced by what the nurse brings to the situation than the objective data about the situation at hand 69
Sound clinical judgement rests to some degree on knowing the patient and his or her typical pattern of responses, as well as engagement with the patient and his or her concerns 71
Clinical judgements are influenced by the context in which the situation occurs and the culture of the nursing unit 71
Nurses use a variety of reasoning patterns alone or in combination 72

Reflection on practice is often triggered by breakdown in clinical judgement and is critical for the development of clinical knowledge and improvement in clinical reasoning 74
Conclusion 80

6 Setting priorities, taking action and evaluating outcomes 81

Clint Douglas and Jackie Crisp

Introduction 82
Setting priorities 82
Critical thinking in establishing goals and expected outcomes 82
Goals of care 82
Expected outcomes 83
Formulating goals and expected outcomes 84
Specific evaluation criteria 86
Planning nursing care 87
Purpose of care plans 87
Care plans in various settings 87
Writing the nursing care plan 88
Critical (or clinical) pathways 88
Protocols and standing orders 89
Critical thinking in designing nursing interventions 93
Types of interventions 93
Critical thinking and the implementation process 94
Updating the nursing care plan 94
Organising resources and care delivery 94
Implementing nursing interventions 96
Achieving a patient's goals of care 96
Communicating nursing interventions 97
Critical thinking skills and evaluation of care 97
Evaluation of goal achievement 97
Unmet goals 99
Conclusion 100

7 Developing and using nursing knowledge 101

Jackie Crisp

Introduction 102
Three levels of nursing inquiry 103
Inquiry involving critical engagement in everyday practice 104
Inquiry involving collaborative and ongoing evaluation of local practice 105
Inquiry involving nursing research for advancement of nursing knowledge 106
Practice development 111
Facilitation of practice development 112
Person-centredness and person-centred practice 113
Taking a PEEP 114
Taking a PEEP at people 115
Taking a PEEP at practice effects 115
Taking a PEEP at impact of environment on nursing practice 116
Taking a PEEP at engagement through praxis 116
The complexity of nursing inquiry 117

PART 3

Positioning nursing: professional responsibility and accountability for safe and effective care 119

8 Coordinating care and teamwork 120

Patricia Mary Davidson and Louise D Hickman

Using evidence to inform teamwork and nursing practice 121
Building a nursing team and coordinating care teams 122
Approaches to delivering nursing care 124
Models of nursing care 125
Models of nursing care promoting wellness, autonomy and self-care 125
Approaches to coordination of care and teamwork 126
Communication, collaboration and coordination among teams 128
Leadership skills for nursing students 129
Measuring outcomes of nursing care 129
Quality improvement processes for nurses 129
Nursing-sensitive indicators 131
Developing skills for complex and dynamic healthcare systems 131
Increasing burden of ageing and chronic care 131
Positive practice environments 132
The role of the registered nurse 133
Skill-mix for the student nurse 134

9 Examining the ethical practice of nursing 138

Megan-Jane Johnstone

Terms and concepts 140
Ethics and morality 140
Bioethics 141
Nursing ethics 141
Moral principles 141
Moral rules 142
Rights 142
Moral duties 142
The importance of ethics 143
Moral conduct in nursing 143
Moral accountability and responsibility 144
Guides to ethical professional conduct 145
Moral theories 146
Deontological ethics 146
Teleological ethics 147
Ethical principlism 147
Moral rights theory 148
Virtue ethics 148
Cross-cultural ethics 149
Nursing codes of ethics 150
Moral problems in nursing 151
Nursing point of view 151
Distinguishing moral problems from other kinds of problems 152
Identifying and responding effectively to moral problems in nursing 152
Processes of ethical reasoning and decision-making 153
Bioethical issues in nursing 158
Conclusion 161

10 Practising nursing within Australian regulatory frameworks 165

Mary Chiarella and Amanda Adrian

Regulation of nursing in Australia 166
The safety and quality framework 167
The application of the safety and quality framework to clinical practice 168
Complaint and disciplinary procedures 168
Sources of law 170
Legal liability in nursing 171
Torts 172
Dying with dignity 180
Legal relationships in nursing practice 183
The law of contract 183
Relationships between nurses and other health professionals 184
Do not resuscitate orders 185
Workload problems 186
Legal issues in nursing specialties 187
Primary healthcare/community health nursing 187
Nursing in emergency departments 187
Nursing children 187
Medical/surgical nursing and gerontological nursing 188
Critical care nursing 189
Perioperative nursing 189
Mental health nursing 189
Hospital in the home and outreach services 190
Remote area nursing 190
Professional involvement of nurses 190

11 Acting in accordance with New Zealand regulatory frameworks 194

Elaine Papps

Regulation of nursing in New Zealand 195
Continuing competence and annual practising certificates 195
Registration of nurses from Australia or other countries 197
Competence notifications and reviews 197
Health notifications 198
Health and Disability Commissioner 198
Health Practitioners Disciplinary Tribunal 199
Sources of law 200
Legal liability in nursing 200
Treatment injury 200
Exemplary damages 200
Torts 200
Negligence 201
Standards of care 201
The need for careful documentation 201
Confidentiality and privacy 201
Obtaining consent 203
Use of human tissue and organ donation 204
Legal relationships in relation to employment 204
The law of contract 204
Legal issues in nursing specialties 205
Professional responsibility of nurses 206
Disclaimer 206

12 Placing communication at the centre of person-centred care 209

Jane Stein-Parbury

Communication and person-centred nursing practice 210
The context of nursing practice 210
Why nurses need to communicate 211
Dynamics of interpersonal communication 211
Knowing the patient 212
Patient-centred communication 213
Healthcare environments and communication 213
Communication and interpersonal relationships 213
Nurse–client relationships 214
Nurse–family relationships 216
Healthcare team relationships 217
Skill 12-1 Patient handover 218
Levels of communication 221
Intrapersonal communication 221
Interpersonal communication 221
Small-group communication 221
Forms of communication 221
Verbal communication 221
Non-verbal communication 222
Developing communication skills 223
The need to 'unlearn' previous communication patterns 224
Elements of professional communication 224
Courtesy and use of names 224
Privacy and confidentiality 225
Trustworthiness 225
Respect 225
Therapeutic communication techniques 225
Facilitative communication interventions 226
Authoritative communication interventions 230
Putting therapeutic communication techniques into action 231
Emotional intelligence 232
Conclusion 232

13 Documenting, retrieving and using information to inform practice 235

Elizabeth Cummings and Bryan Macdonald

eHealth 236
Individual professional record-keeping 237
Multidisciplinary communication within the healthcare team 237
Documentation 238
Purposes of records 238
Guidelines for high-quality documentation and reporting 241
Quality reporting in clinical information systems 243
Standards 244
Types of documentation 244
Charting by exception 247
Case management and clinical pathways 247
Common record-keeping forms 248
Home healthcare documentation 251
Long-term healthcare documentation 252
Reporting 252
Change-of-shift (handover) report 252
Telephone report 254
Transfer report 255
Incident reports 256

PART 4

Adapting nursing: people, context and culture 259

14 Understanding and applying cultural safety: philosophy and practice of a social determinants approach 260

Leonie Cox and Chris Taua

The context of health and nursing in Australia and Aotearoa New Zealand 261
Indigenous peoples of Australia 262
Indigenous peoples of Aotearoa New Zealand 264
Cultural diversity 265
Cultural safety 266
Cultural safety and holism 268
What is culture? 268
Worldviews and lifeworlds 269
Whiteness, race, ethnicity, class 270
Race 272
Ethnicity 272
Social class 273
Ethnocentrism, stereotyping, racism and discrimination 273
Ethnocentrism and othering 273
Stereotyping 273
Racism and prejudice 274
Discrimination 274
Power 275
What is health? 276
Professional nursing regulation and cultural safety 276
Applying cultural safety in professional practice 277
Reflecting on self; reflecting on practice 277
Nursing practice and social determinants 279
Communication skills 280
Developing trust 281
Negotiating knowledge 282
Negotiating outcomes 283
Summing up 283

15 Engaging in family-centred care 288

Nicola Brown

What is a family? 289
Trends in family structure and function 289
Migration 290
Diversity 290
Social change 290
Family theory and models 291
Family systems theory 292
Family developmental theory 292
Bioecological systems theory 292
The International Family Strengths Model 293
Linking family theory and models to nursing 294
Family-centred care 294
Family nursing 296
Family as context 296
Family as client 296
Family as system 297
Family nursing care 297
Family assessment 297
Facilitating family involvement in care 298
Self-care when working with families 300

16 Considering the developmental context from conception to adolescence 302

Jane Davey, Robyn Galway and Shaun Thompson

Growth versus development 303
Developmental theorists 303
Stages of growth and development 303
Critical periods 304
Conception 305
First trimester 308
Second trimester 308
Third trimester 310
Transition from intrauterine to extrauterine life 310
Physical changes 311
Psychosocial changes 311
The newborn 312
Physical changes 312
Cognitive changes 313
Psychosocial changes 315
Other health considerations for newborns 316
The infant 317
Physical changes 317
Cognitive changes 319
Psychosocial changes 319
Other health considerations during infancy 321
Immunisation 324
Child abuse and neglect 324
Nutrition and feeding practices 324
Dentition 327
The toddler 327
Physical changes 327
Cognitive changes 328
Psychosocial changes 328
Other health considerations during toddlerhood 329
The preschooler 331
Physical changes 331
Cognitive changes 332
Psychosocial changes 332
Moral development 334
Other preschooler health considerations 334
School-age children and adolescents 334
Middle childhood 336
Preadolescence 343
Adolescence 343

17 Considering the developmental context of youth and adults 356

Robyn Rosina

Human development theory 357
Growth versus development 357
Growth and development theories 357
Ecological systems theory 359
Biophysical development theories 359
Gesell's theory of biophysical development 360
Genetic and cellular theories of ageing 360
Physiological theories of ageing 361
Psychosocial theories 361

Freud's psychoanalytical model of psychosexual development theory 362
Erikson's development across the lifespan theory 363
Havighurst's developmental tasks theory 367
Cognitive development theories 368
Piaget's theory of cognitive development 368
Moral developmental theories 369
Piaget's moral development theory 369
Kohlberg's moral development theory 369
The developing adult 372
Socio-cultural change in adult roles 372
Young adulthood 373
Physical changes 373
Psychosocial changes 373
Cognitive changes 374
Health and wellbeing of young adults 374
Health and health risk in young adulthood 377
Pregnancy and parenting 381
Middle adulthood 384
Physical changes 385
Cognitive changes 386
Psychosocial changes 386

18 Working with older people 393

Susan Hunt

Older adults as part of our population 395
Life expectancy 395
Immigration 395
Gerontology as a nursing specialty 396
Healthy ageing 396
Ageism 397
Abuse of the elderly 399
Towards an understanding of how we age 400
Understanding normal ageing 400
Physiological changes 401
Cognitive changes 405
Psychosocial changes 405
Assessment of the older adult 405
Risks to healthy ageing 406
Risk factors 407
Health issues experienced by older people 407
Impaired cognition 407
Urinary incontinence 411
Constipation and faecal incontinence 411
Pain 412
Adverse drug events 413
Successful ageing 414
Services for older people 416
Home (community) care 416
Retirement villages or communities 416
Adult daycare 416
Respite care 417
Subacute care/rehabilitation care 417
Residential aged care 418
Maintaining psychosocial health 418
Therapeutic communication 418
Body image 419
Conclusion 420

19 Considering the person with disability 422

Julie Pryor and Murray Fisher

Who is the person with disability? 423
Definitions of disability 424
The extent of disability in Australia and New Zealand 425
Mechanisms of disability 425
Physiological mechanisms of disability 425
Psychological mechanisms of disability 426
Social mechanisms of disability 427
Biopsychosocial mechanisms of disability 428
Person-centred care for the person with disability 429
Communication 430
Context 430
Normal and abnormal body functioning 430
The lived experience of disability 435
Assistive technologies 436
Key skills for person-centred care for persons with disability 438
Autonomy-supportive interventions 439
Conservation and restoration of function 439
Enriched environments 439

PART 5

Relating nursing: human basis of nursing practice 443

20 Self-identity: life as a journey of self-discovery 444

Anthony Welch

Dimensions of the self 445
Identity 445
Body image 445
Self-esteem 446
Role performance 446
Spirituality 447
Development of self-concept 449
Stages of development 449
Stressors affecting self-concept 452
The family and self-concept development 455
The role of the nurse 455
Altered self-concept 456
Stressors and spirituality 456
Chronic illness and spiritual healing 458
Clinical reasoning process 458
Gathering relevant information and data 459
Making appropriate judgements and decisions 460
Setting priorities and establishing goals 462
Preparing for and taking action 464
Evaluating impacts and outcomes 467

21 Understanding sexuality and sexual health 472

Donna Tilley and Joanne Perks

Introduction 473
Sexuality 473
Definitions of terms 473
The sexual trichotomy model 473
The sexual response model 474
Communication and sexual health history-taking 475
Safe sex 476
The sexual health history 477

Impact of health conditions on sexuality and sexual health 478
Chronic diseases 478
Mental health and wellbeing 479
Cancer 480
Sexual health 481
Sexually transmitted infections and blood-borne viruses 481
Female reproductive health 484
Pregnancy 485
Termination of pregnancy 485
Menopause 485
Female genital mutilation 486
Female contraception 486
Emergency contraception 486
Reproductive cancer screening and prevention 489
Breast cancer 489
Cervical cancer 489
Ovarian cancer 490
Prostate cancer 490
Testicular cancer 490

22 Working with dying, death and grief 494

John P Rosenberg

The physiological, psychological, existential and social aspects of dying 495
Key approaches to care and support for the dying person 496
Palliative care 496
Palliative approach 497
What does 'quality of life' mean? 497
Settings of care 497
Advance care directives 499
Nursing priorities and goals for care 499
Assessment 499
Care of the body following death 510
Loss, grief, bereavement and mourning 512
Categories of loss 514
Normal grief patterns for adults 515
Normal grief patterns for children 518
Personality 519
Social roles 519
Personal values 519
Perception of the deceased person's importance 519
Complicated or high-risk grief 519
Sudden and unnatural death 520
Nursing practice and grief 522
Supporting the grieving person 522
Clinical reasoning process 523
Making appropriate judgements and decisions 523
Self-care for nurses providing end-of-life care 526
Coping strategies 526
Reflective practice 526

PART 6

Practising nursing: scientific basis of nursing practice 531

23 Monitoring vital signs: using a primary survey approach for patient assessment 532

Anthony Schoenwald and Clint Douglas

Introduction 533
The importance of nursing assessment for patient safety 533
Airway 535
Breathing 535
Skill 23-1 Assessing respirations 539
Skill 23-2 Measuring oxygen saturation (SpO_2) 543
Circulation 547
Skill 23-3 Assessing the radial and apical pulses 548
Skill 23-4 Measuring blood pressure (BP) 558
Disability 565
Exposure 565
Skill 23-5 Measuring body temperature 569
Conclusion 576

24 Undertaking a focused assessment: physical assessment of body systems 578

Anthony Schoenwald and Clint Douglas

Introduction 579
Building on the primary survey approach to patient assessment 579
Fundamental physical assessment skills 580
Skill 24-1 Nursing physical assessment using a body systems framework 581
Preparing for patient assessment 586
Neurological system 587
Skill 24-2 Focused neurological assessment 587
Cardiovascular system 593
Skill 24-3 Focused cardiovascular assessment 594
Respiratory system 603
Skill 24-4 Focused respiratory assessment 604
Gastrointestinal system 605
Skill 24-5 Focused gastrointestinal assessment 608
Renal system 611
Skill 24-6 Focused renal assessment 612
Musculoskeletal system 613
Skill 24-7 Focused musculoskeletal assessment 614
Integumentary system 616
Skill 24-8 Focused skin or integumentary assessment 617
Documentation and communication of assessment findings 620
Conclusion 620

25 Understanding infection control 622

Sonya Osborne

Nature of infection 623
Chain of infection 623
Infectious agents 623
Reservoir 625
Portal of exit 625
Modes of transmission 626
Portal of entry 627
Susceptible host 627
The infectious process 628
Healthcare-associated infections 629
Multi-resistant organisms 630
Defences against infection 631
Normal flora 631
Body system defences 632
Inflammatory response 633
Immune response 634
Clinical reasoning process 635
Gathering relevant information and data 635

Making appropriate judgements and decisions 638
Setting priorities and establishing goals 639
Preparing for and taking action 639
Skill 25-1 Handwashing 644
Skill 25-2 Preparing an aseptic field 663
Skill 25-3 Surgical hand antisepsis ('scrubbing'): preparing for gowning and gloving 666
Skill 25-4 Open gloving 670
Skill 25-5 Donning a sterile gown and performing closed gloving 672
Evaluating impacts and outcomes 677

26 Maintaining skin integrity and undertaking wound care 681

Damian Wilson and Michelle Gibb

Normal integument 682
Skin changes associated with ageing 683
Principles of skin assessment 685
Wound classification 687
Phases of wound healing 691
Haemostasis 691
Inflammation (0–3 days) 691
Proliferation (2–24 days) 692
Maturation (24 days to 1 year) 692
Modes of wound healing 693
Complications of wound healing 693
Hypergranulation 693
Hypertrophic scars 693
Keloid scars 693
Contractures 694
Haemorrhage 694
Haematoma 694
Evisceration 694
Fistula 694
Wound infection 694
Skill 26-1 Performing a bacterial wound swab 696
Factors affecting wound healing 698
Wound assessment 698
Wound history 698
Cause of the wound 699
Wound size 699
Wound photography 699
Wound edge 699
Wound location 699
Clinical appearance 700
Wound exudate 702
Surrounding skin 702
Wound infection 702
Pain 703
Psychosocial impact of wounds 703
Wound documentation 703
Principles of wound management 703
Assess and correct cause of tissue damage 703
Assess wound history and characteristics 704
Ensure adequate tissue perfusion 704
Wound-bed preparation 704
Skill 26-2 Performing a wound dressing 710
Assessment, management and prevention strategies for common wound types 712
Acute wounds 712
Skill 26-3 Assessment, management and prevention of skin tears 717
Chronic wounds 721
Skill 26-4 Assessment for risk of pressure injury 730
Acknowledgements 746

27 Administering medications 748

Vanessa Brotto

Quality use of medications 749
The medication team 750
Application of pharmacology in nursing practice 751
Pharmacokinetics as the basis of medication actions 755
Types of medication action 757
Routes of administration 760
System of medication measurement 763
Medication administration 766
Distribution systems 769
Clinical reasoning in administering medications 770
Accountability and responsibility 770
Safe medication administration 771
Clinical reasoning process 773
Gathering relevant information and data 773
Making appropriate judgements and decisions 774
Setting priorities and establishing goals 774
Preparing for and taking action 775
Evaluating impacts and outcomes 780
Methods of administration 780
Skill 27-1 Administering oral medications 781
Skill 27-2 Administering nasal instillations 788
Skill 27-3 Administering ophthalmic medications 791
Skill 27-4 Administering vaginal medications 797
Skill 27-5 Administering rectal suppositories 800
Skill 27-6 Using metered-dose inhalers (MDIs) 802
Mixing medications 809
Skill 27-7 Preparing injections 810
Administering injections 815
Skill 27-8 Administering injections 816
Safety in administering medications by injection 826
Skill 27-9 Adding medications to intravenous fluid containers 827
Skill 27-10 Administering medications by intravenous bolus 832
Skill 27-11 Administering intravenous medications by piggyback/tandem set-up, intermittent intravenous infusion sets and mini-infusion pumps 836

PART 7

Focusing nursing: basic human needs 843

28 Promoting mobility 844

Georgina Willetts

Promoting mobility and preventing immobility 845
Overview of body mechanics, exercise and activity 845
Regulation of movement 847
Pathological influences on mobility 848
Complications of immobility 849
Systemic effects of immobility 850
Psychosocial effects 854
Developmental changes 854

Clinical reasoning process 857
Gathering relevant information and data 857
Making appropriate judgements and decisions 866
Setting priorities and establishing goals 867
Preparing for and taking action 868
Skill 28-1 Applying sequential compression devices (SCDs) 872
Skill 28-2 Applying elastic stockings 875
Skill 28-3 Positioning patients in bed 881
Skill 28-4 Transfer techniques 891
Evaluating impacts and outcomes 903

29 Ongoing hygiene 907

Mary Huynh

Introduction 908
The skin 908
The feet, hands and nails 908
The oral cavity 909
The hair 910
The eyes, ears and nose 910
The perineal area 911
Social practices 911
Personal preferences 911
Body image 911
Socioeconomic status 912
Health beliefs and motivation 912
Cultural variables 912
Physical condition 912
Clinical reasoning process 912
Gathering relevant information and data 913
Making appropriate judgements and decisions 923
Setting priorities and establishing goals 924
Preparing for and taking action 927
Skill 29-1 Bathing a person 928
Skill 29-2 Perineal care 936
Skill 29-3 Menstrual hygiene 941
Skill 29-4 Administering a back rub 945
Skill 29-5 Performing nail and foot care 948
Skill 29-6 Providing oral hygiene 954
Skill 29-7 Performing mouth care for an unconscious or debilitated person 957
Skill 29-8 Caring for the person with contact lenses 964
Skill 29-9 Making an occupied bed 975
Skill 29-10 Making a postoperative bed 983
Evaluating impacts and outcomes 985

30 Fostering sleep 988

Christopher J Gordon

Physiology of sleep 989
Sleep–wake cycle 989
Circadian rhythms 990
Sleep state 990
Sleep stages 991
Functions of sleep 992
Dreams 993
Effects of illness on sleep 993
Sleep disorders 993
Insomnia 994
Sleep apnoea 994
Narcolepsy 995
Parasomnias 996
Normal sleep requirements and patterns 996
Neonates 996
Infants 996
Toddlers 996
Preschoolers 996
School-age children 997
Adolescents 997
Young adults 997
Middle-aged adults 997
Older adults 998
Factors affecting sleep 998
Sleep deprivation 998
Drugs and other substances 998
Lifestyle 998
Usual sleep patterns and excessive daytime sleepiness 999
Emotional stress 999
Environment 999
Exercise and fatigue 1000
Food and kilojoule intake 1000
Clinical reasoning process 1000
Gathering relevant information and data 1000
Making appropriate judgements and decisions 1005
Setting priorities and establishing goals 1006
Preparing for and taking action 1006
Evaluating impacts and outcomes 1012

31 Sustaining nutrition 1016

Andrea Marshall and Shelley Roberts

Nutrition: the basics 1017
Units of nutrition 1017
Energy 1017
Macronutrients 1018
Anatomy and physiology of the digestive system 1023
Digestion 1023
Absorption 1024
Metabolism and storage of nutrients 1025
Dietary guidelines 1026
Nutrient reference values 1026
Australian Dietary Guidelines 1027
Food labels 1031
Nutrition during the life cycle 1032
Infants 1032
Toddlers and preschoolers 1033
School-age children and adolescents 1034
Young and middle-aged adults 1034
Older adults 1035
Alternative food patterns 1035
Alcohol 1037
Clinical reasoning process 1037
Gathering relevant information and data 1037
Making appropriate judgements and decisions 1039
Setting priorities and establishing goals 1039
Skill 31-1 Inserting a small-bore nasoenteric tube for enteral feedings 1045
Skill 31-2 Administering enteral feeding via nasoenteric tube 1049
Skill 31-3 Administering enteral feeding via gastrostomy or jejunostomy tube 1053
Preparing for and taking action 1059

Evaluating impacts and outcomes: ensuring continuity of care 1059
The nurse's role in nutrition care 1059

32 Maintaining bowel elimination 1064

Elizabeth Watt

Mouth 1065
Oesophagus 1065
Stomach 1066
Small intestine 1066
Large intestine 1066
Caecum 1066
Colon 1066
Rectum 1067
Factors affecting bowel elimination 1067
Age 1068
Diet 1068
Fluid intake 1068
Physical activity 1068
Personal habits 1068
Position during defecation 1069
Psychological factors 1069
Pain 1070
Pregnancy 1070
Surgery and anaesthesia 1070
Infection 1070
Medications 1070
Diagnostic tests 1071
Common bowel elimination problems 1071
Constipation 1071
Impaction 1072
Diarrhoea 1072
Incontinence 1072
Flatulence 1073
Haemorrhoids 1073
Bowel diversions 1074
Clinical reasoning process 1075
Gathering relevant information and data 1075
Making appropriate judgements and decisions 1080
Setting priorities and establishing goals 1081
Preparing for and taking action 1082
Skill 32-1 Administering a prepared enema 1088
Skill 32-2 Pouching an ostomy 1092
Skill 32-3 Inserting and maintaining a nasogastric tube (for decompression) 1097
Evaluating impacts and outcomes 1104

33 Maintaining urinary elimination 1107

Elizabeth Watt

Urinary system 1108
Kidneys 1108
Ureters 1109
Bladder 1110
Urethra 1110
Pelvic floor muscles 1110
Micturition 1110
Factors affecting urinary elimination 1111
Growth and development 1111
Fluid balance 1112
Changes to renal function 1112
Changes to bladder function 1113
Illness and frailty 1113
Psychological and environmental factors 1113
Surgical procedures 1113
Medications 1113
Common urinary elimination problems 1113
Lower urinary tract infections 1114
Urinary incontinence 1114
Prostatic hypertrophy and prostate cancer 1114
Urinary retention 1116
Chronic kidney disease 1116
Renal calculi (nephrolithiasis) 1117
Clinical reasoning process 1117
Gathering relevant information and data 1117
Skill 33-1 Collecting a midstream (clean-voided) urine specimen 1122
Making appropriate judgements and decisions 1128
Setting priorities and establishing goals 1129
Preparing for and taking action 1130
Skill 33-2 Inserting a straight or indwelling catheter 1135
Skill 33-3 Applying a sheath/condom drainage device 1144
Evaluating impacts and outcomes 1148

34 Balancing fluid, electrolyte and acid–base status 1151

Karen Wotton

Distribution of body fluids 1152
Composition of body fluids 1154
Movement of body fluids 1158
Osmosis 1158
Diffusion 1159
Filtration 1161
Active transport 1161
Regulation of body fluids 1161
Fluid intake 1161
Fluid output 1163
Regulation of electrolytes 1163
Cations 1163
Anions 1163
Regulation of acid–base balance 1167
Chemical buffer systems 1167
Physiological buffer systems 1168
Disturbances in electrolyte, fluid and acid–base balances 1168
Electrolyte imbalances 1169
Fluid disturbances 1170
Acid–base balance disturbances 1170
Types of acid–base imbalances 1172
Application of knowledge of fluid and electrolyte balance to practice 1175
Clinical reasoning process 1176
Gathering relevant information and data 1177
Making appropriate judgements and decisions 1189
Setting priorities and establishing goals 1189
Skill 34-1 Assessment of fluid status 1189
Preparing for and taking action 1194
Skill 34-2 Subcutaneous infusion (hypodermoclysis) 1197
Skill 34-3 Initiating a peripheral intravenous (IV) infusion 1204
Skill 34-4 Regulating intravenous flow rate 1214

Skill 34-5 Changing intravenous solution and infusion tubing 1218
Skill 34-6 Changing a peripheral intravenous dressing 1224
Skill 34-7 Care of the patient requiring a blood transfusion 1228
Evaluating impacts and outcomes 1238

35 Preserving oxygenation 1241
Natashia Scully
Introduction 1242
Cardiovascular physiology 1242
Structure and function 1242
Respiratory physiology 1248
Structure and function 1248
Ventilation and work of breathing 1248
Factors affecting oxygenation 1252
Alterations in cardiac functioning 1255
Developmental factors 1262
Lifestyle factors 1264
Environmental factors 1265
Clinical reasoning process 1265
Gathering relevant information and data 1266
Skill 35-1 Continuous cardiac monitoring ECG 1271
Skill 35-2 Conducting a 12-lead ECG 1274
Making appropriate judgements and decisions 1281
Setting priorities and establishing goals 1282
Preparing for and taking action 1283
Skill 35-3 Suctioning 1290
Skill 35-4 Care of patients with chest tubes 1298
Skill 35-5 Applying a nasal cannula or oxygen mask 1304
Skill 35-6 Using home liquid oxygen equipment 1308
Skill 35-7 Cardiopulmonary resuscitation – basic life support 1310
Evaluating impacts and outcomes 1316

36 Managing pain 1319
Anthony Schoenwald and Clint Douglas
Introduction 1320
Defining pain 1320
Acute pain 1321
Chronic pain 1322
Nociceptive pain 1322
Neuropathic pain 1322
Evolution of pain theories 1322
Early pain theories 1322
Gate control theory of pain 1323
Post-gate control theories 1324
Person-centred care: working from a biopsychosocial perspective 1324
Biopsychosocial model of pain 1324
Physiology of pain 1325
Psychosocial factors influencing pain 1327
Clinical reasoning process 1331
Gathering relevant information and data 1332
Making appropriate judgements and decisions 1340
Setting priorities and establishing goals 1340
Preparing for and taking action 1340
Skill 36-1 Focused pain assessment 1341
Acute pain management 1344
Multimodal analgesia 1344
Pharmacology of analgesics 1344
Non-drug pain management interventions 1358
Evaluating impacts and outcomes 1361

37 Managing stress and adaptation 1364
Patricia Barkway
Stress and stressors 1365
Physiological adaptation 1365
Mechanisms of physiological adaptation 1365
Limitations of physiological mechanisms of adaptation 1366
Models of stress 1366
Response-based model 1366
Adaptation model 1367
Stimulus-based model 1367
Transaction-based model 1367
Factors influencing response to stressors 1368
Adaptation to stressors 1368
Response to stress 1368
Physiological response 1369
Local adaptation syndrome 1369
General adaptation syndrome 1370
Psychological response 1372
Psychological/emotional reactions 1372
Developmental factors 1372
Intellectual factors 1373
Social determinants 1373
Spiritual considerations 1373
Clinical reasoning process 1373
Gathering relevant information and data 1374
Making appropriate judgements and decisions 1378
Setting priorities and establishing goals 1379
Preparing for and taking action 1379
Evaluating impacts and outcomes 1385
Conclusion 1385

PART 8

Situating nursing: contexts of care 1389

38 Focusing on community-based care: the older person 1390
Lynn Chenoweth and Ann McKillop
Health support for older people in Australia and New Zealand 1391
Ageing population profile 1391
Policy contexts 1393
Health care for populations as well as individuals 1395
Primary healthcare 1396
Community and people-focused health care 1397
Integrated community health services 1398
The older person with chronic illness 1402
Impact of chronic illness 1403
Evidence-based chronic illness models 1405
The changing scope of community nursing practice 1406
Advanced community nursing 1406
Competencies for community nursing 1408
Nursing competencies for integrated care 1411
Quality community nursing services for older people 1413
Challenges for community nurses 1413
Overcoming community nursing challenges 1414
Summary 1414

39 Working in acute care environments 1420

Nicole M Phillips and Debbie Massey

Introduction 1421
Defining acute care 1421
Promoting patient safety in the acute care setting 1422
Recognising and responding to patient deterioration 1422
Skill 39-1 Assessment and management of the deteriorating patient (ABCDE) 1424
Patient identification and procedure matching 1429
The essentials of safe and quality care for patients undergoing a procedure or surgery 1429
Clinical reasoning process: the preoperative phase 1430
Gathering relevant information and data 1430
Making appropriate judgements and decisions 1434
Setting priorities and establishing goals 1435
Preparing for and taking action 1435
Skill 39-2 Demonstrating postoperative exercises 1440
Evaluating impacts and outcomes 1452
The essentials of safe and quality care post-procedure/surgery 1452
Immediate postoperative recovery 1452
Discharge from the PACU 1453
Recovery in same-day surgery 1453
Clinical reasoning process: the postoperative phase 1454
Gathering relevant information and data 1454
Making appropriate judgements and decisions 1457
Setting priorities and establishing goals 1458
Preparing for and taking action 1460
Evaluating impacts and outcomes 1464

40 Meeting the mental health needs of individuals and their carers 1467

Anthony O'Brien

Mental health issues within acute nursing contexts 1468
The mental health service system 1468
Mental health scope of practice 1468
History of mental health nursing 1469
Hildegard Peplau and interpersonal care 1469
Recovery and mental health 1470
Mental illness 1470
Mental illness and personality disorders 1471
Substance use 1472
Intellectual disability 1474
Self-harm and suicide 1474
Psychiatric diagnosis 1474
Mental health assessment in nursing 1475
Skill 40-1 Mental state assessment 1476
Practice contexts 1480
Treatment modalities 1481
Individual psychotherapy 1481
Cognitive therapy 1481
Dialectical behaviour therapy 1481
Acceptance and commitment therapy 1482
Group therapy 1482
Electroconvulsive therapy 1483
Culture and mental illness 1483
Stigma 1484
Hearing voices 1484
Mental health legislation 1485
Clinical supervision in mental health nursing 1485
Mental health promotion 1486
Professional organisations in mental health nursing 1486
Summary 1486
Note 1488

41 Caring for the cancer survivor 1490

Patsy Yates

Introduction 1491
The effects of cancer on quality of life 1492
Physical wellbeing and symptoms 1493
Psychological wellbeing 1494
Social wellbeing 1496
Spiritual wellbeing 1497
Cancer and families 1497
Family distress 1497
Implications for nursing 1498
Survivor assessment 1498
Client education 1499
Providing resources 1500
Components of survivorship care 1501
Survivorship care plan 1501
Implications for people with active and advanced disease 1502
Summary 1503

Picture credits 1505
Index 1506

Preface

To the student

Welcome to the fifth edition of the most successful fundamentals text ever to be published for students of nursing across Australia and New Zealand. In this new edition we have maintained the core format of a fundamentals text that you have told us you enjoy and find easy to navigate, while taking a more active and overt approach to partnership with people and families in decisions about the delivery of nursing care.

In this edition, we welcome a number of academics and clinicians to the experienced writing team, and acknowledge their expert contemporary knowledge and contribution to perspectives on health and health care. We retain an emphasis on the very important basics – the fundamentals of care that are the building blocks on which professional nursing practice is built. The clinical skills sections have been updated to reflect current best practice and are designed to support your preparation for practical learning within the ever-changing and increasingly technological world in which health care is delivered. We also re-emphasise the importance of self-reflection and awareness as important personal fundamentals for delivering quality care to the increasingly diverse populations we work with.

There is a large body of international evidence supporting the position that the quality of nursing care not only influences the way people experience illness, but also impacts on initial and long-term outcomes, quality of life and morbidity. Nurse staffing, education, workload, skill-mix and the context of care are also important determinants of quality in nursing and contribute substantially to the cost of health care. As we move into a time where the cost of hospital-based acute services is becoming unsustainable for many countries, it is the intelligent, agile and creatively competent nurse working across all sectors – including in community and primary healthcare – who will make a difference to keeping people well and cared for, more often in their own homes in the future.

Accepting the invitation to join the editorial team for the fifth edition was an easy decision for me. Not only was I excited to join an experienced and clearly successful group of editors, writers and educators, the concept of emphasising the importance and at the same time, the complexity, of fundamental nursing care, is one that resonates with me. It has been my experience that those things which may seem simple and trivial to others can have the most profound impact on people's experience of illness and health – cleaning teeth, washing hair, a kind word, a smile, a gentle touch. It has also been personally rewarding to think about, talk about and essentially reconnect with the fundamentals of nursing by working with authors, reviewers and editors on this edition. A seriously impressive bunch!

The editorial team sincerely want you to discover why seemingly routine activities, such as feeding, bathing, toileting, walking or turning patients, are so critically important to your nursing and nursing care. The moments during which you perform these tasks are crucial to forming respectful relationships and partnerships with your patients and their families, and can give powerful insights into the aspects of care, recovery and rehabilitation that are the most valued. As in previous editions, the *Clinical examples* and *Critical reflection points* throughout the text underscore how nursing knowledge and skill implemented in practice can mean the difference between effective uncomplicated recovery and independence and costly, life-threatening complications, functional decline and disability.

The fifth edition is presented to you in eight parts. First, we situate nursing within the environments of Australia and New Zealand. Concepts around partnership in care and keeping people safe are important inclusions to this section.

We introduce a new framing for clinical reasoning in Part 2, offering a scaffold for systematic and critically reflective approaches to your practice. What is your first step? Knowing how to gather appropriate information and data is critically important as this will likely be different for every patient and family. What do you do next? What does the research tell you? How does best practice apply within this context and how is it relevant to the needs of your patient and their family? Making appropriate judgements and decisions for the application of relevant, high-quality information to shared decisions about priorities and actions, and the evaluation of outcomes (from the patient's perspective) are introduced as effective ways of thinking about and embracing the value and meaning of partnerships in care.

The theme of safe and effective partnership in care continues in the third part of the text, but this time it is viewed through the lens of professional responsibility and accountability. Regulation, communication and documentation are key elements of professional and ethical practice.

Parts 4 and 5 discuss human development across the lifespan. In addition to reviewing the theoretical and practical aspects of growth and development, disability, ageing, dying and death, nursing of the developing human is situated within the complex contextual environments that we all live in and share. Here, you are invited to reflect on your own culture and values as a means of discovering personal insight into how these might affect therapeutic relationships throughout your nursing career.

The next section moves into the scientific bases of nursing practice and how these relate to basic human needs – the fundamentals of nursing. Part 6 explores the science behind physical assessment, infection control, therapeutic medication and medication management, including their practical applications. Part 7 emphasises what is at the core of this text – basic human needs, such as breathing, fluid and electrolyte balance, eating and sleeping, and how nursing practice and shared nursing knowledge aims to support people who are temporarily or permanently unable to meet specific needs by themselves.

Finally, Part 8 examines nursing in different contexts. Partly because large sectors of the Australian and New Zealand populations have access to safe food, water, shelter and a stable society; partly because contemporary Western medicine has been successful in developing and delivering treatments for disease; and partly because our world is increasingly complex and pressured – there are growing numbers of people requiring maintenance health care because of chronic conditions, people surviving previously fatal diseases, children with complex congenital and genetic birth defects who will live long and productive lives, and an ever larger group experiencing the normal degenerative conditions of ageing. While the majority of nursing graduates remain likely to commence work in acute care settings, the work of nurses in the future will be very much in demand in other locations.

Ongoing change in health care is the norm. Nursing of the future will be situated in many contexts and we believe it is crucial for you to understand the dynamic and evolving nature of your practice. To remain competent, engaged, agile and effective, having an intelligent, inquiring approach to your own learning and sharing of knowledge with others is vital.

Everyone who has contributed to this text has done so because they want you to be the best nurse you can possibly be. On behalf of the editorial team, I wish you every success in your career in health.

Donna Waters
on behalf of the Editorial Team

Acknowledgements

We would like to acknowledge a debt of gratitude to the following people who made the publication of this new edition possible:

- Catherine Taylor, for her tireless work on the first three editions
- The Elsevier publishing team: Libby Houston, Natalie Hunt, Elizabeth Coady and Karthikeyan Murthy
- Margaret Trudgeon (copy editor) and Sarah Thomas (permissions editor).

The publisher and editors would like to also thank all past and present contributors and reviewer\s. The book as it stands is the accumulated effort of many dedicated writers and nursing educators, and their invaluable work in all editions of this book is acknowledged with thanks.

The editors and publisher would like to pay tribute to Natashia Scully (author of Chapter 35 Preserving oxygenation), who passed away during the development of this text. We are so fortunate to have worked with Natashia and to have benefited from her dedication, passion and the invaluable contribution she has made to nurse education in Australia and New Zealand.

Special acknowledgements

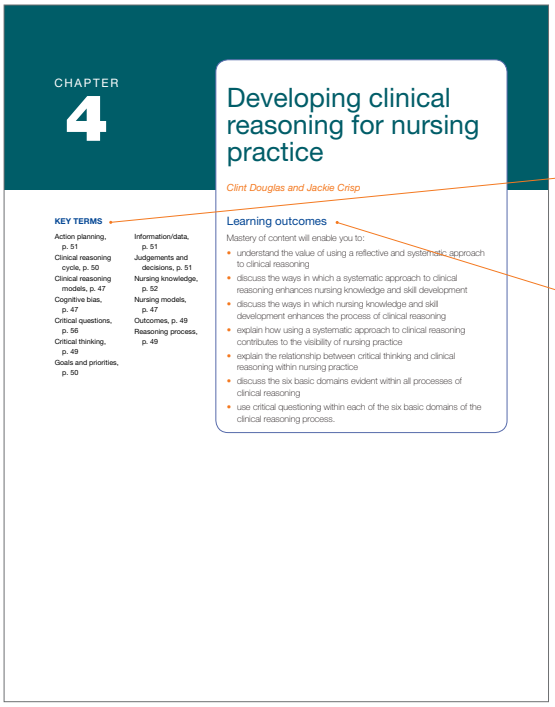
To all who have worked on this, and past, editions of this book, for their commitment and expertise
– Jackie Crisp

To Natalie
– Clint Douglas

My thanks to Damian, whom I am so privileged to have as a critical friend
– Geraldine Rebeiro

To those who have a role in preparing nurses for the future
– Donna Waters

Text features



CHAPTER
4

Developing clinical reasoning for nursing practice

Clint Douglas and Jackie Crisp

KEY TERMS

Action planning, p. 51
Clinical reasoning cycle, p. 50
Clinical reasoning models, p. 47
Cognitive bias, p. 47
Critical questions, p. 56
Critical thinking, p. 49
Goals and priorities, p. 50
Information/data, p. 51
Judgements and decisions, p. 51
Nursing knowledge, p. 52
Nursing models, p. 47
Outcomes, p. 49
Reasoning process, p. 49

Learning outcomes

Mastery of content will enable you to:

- understand the value of using a reflective and systematic approach to clinical reasoning
- discuss the ways in which a systematic approach to clinical reasoning enhances nursing knowledge and skill development
- discuss the ways in which nursing knowledge and skill development enhances the process of clinical reasoning
- explain how using a systematic approach to clinical reasoning contributes to the visibility of nursing practice
- explain the relationship between critical thinking and clinical reasoning within nursing practice
- discuss the six basic domains evident within all processes of clinical reasoning
- use critical questioning within each of the six basic domains of the clinical reasoning process.

Key terms are listed at the beginning of each chapter and defined within the text.

Learning outcomes identify the major content and foci of each chapter.

Clinical reasoning process offers a systematic and critically reflective approach as the foundation of safe and effective nursing care.

the griever. A list of local psychologists or counsellors who are skilled in bereavement support can be an invaluable resource, as can an after-hours telephone support number or liaison persons in the griever's community.

CLINICAL REASONING PROCESS

Grieving is a natural response to a loss and is considered to be a beneficial coping process. It is also a reactive process and has therapeutic value. Grieving is healthy and enables the bereaved to reflect on and accept the reality of the loss. The nurse must feel confident to assess the situation critically and make an initial needs analysis. The overall goal of nursing assessment is to gather relevant information and data in order to gain a total view of the client's health and psychosocial status. By carefully exploring information gained from interaction and collating the data in a precise and methodical way, appropriate judgements and decisions can be made to work with the client in their grieving process. Assessment provides an opportunity for the nurse to explore with the client information relating to perceived and actual priority problems (mental and physical).

MAKING APPROPRIATE JUDGEMENTS AND DECISIONS

Verbal and non-verbal communication techniques can encourage free flow of information and provide meaningful data for evaluation (see Chapter 12). These include listening, reflecting, clarifying, using non-verbal cues, appropriate use of silence, sharing perceptions, confronting contradictions and reviewing the discussions.

Culture and developmental considerations are two factors that influence communication. Culture has a profound effect on the way people communicate and behave. It is therefore important to keep in mind that cultural differences may influence how verbal and non-verbal messages are interpreted. For example, in many South-East Asian cultures – of which there are significant immigrant populations in both Australia and New Zealand – many women avoid eye contact with men. Conversely, many Western women look directly at the person to whom they are talking. *Age or developmental level* can also affect the way the assessment is handled, especially if the client is very young or very old. In the young, communication depends on the child's cognitive maturity, as noted above. In the elderly, consideration must be given to the extent to which the memory and sensory function may be affected by the ageing process. There are times when both the young and the elderly, in particular, are hesitant to share personal information, and developing communication skills that maximise the possibility of open communication is a priority for student nurses.

During periods of loss or anticipated loss, a client's emotions and behaviours may be in a state of flux. This makes assessment all the more challenging. Nurses should not assume they know how a client or family members will react. Continual assessment is essential if support and/or interventions are to be compatible with their current needs. Assessment of the client and family begins by exploring the meaning of the loss to the people involved. Examples of topics to be explored include the survivor's model of the world, personal characteristics such as personality, values, the nature of family relationships, support systems, nature of loss, cultural and spiritual beliefs, loss of personal life goals, hope, phase of grief, risks and nursing role perceptions.

When interviewing the client and family, it is important that an honest and empathetic approach is taken. Be mindful of setting the tone and direction of the interview, and of establishing a mutual understanding of the purpose of the exchange. In the initial phase it is important to establish rapport, ensure a comfortable and non-threatening setting and clarify the expectations or goals of the interview.

Establishing rapport

Establishing trust and rapport is a challenging process, particularly given the cultural diversity of Australian and New Zealand populations. A clear demonstration of respect for the client and an acceptance of the client's uniqueness as a person facilitate rapport. Greet the client by name and introduce yourself. It is usual practice not to use the client's first name unless invited to do so. In Australasian society, offering to shake hands is one way to demonstrate sincerity and acceptance.

Non-verbal behaviours

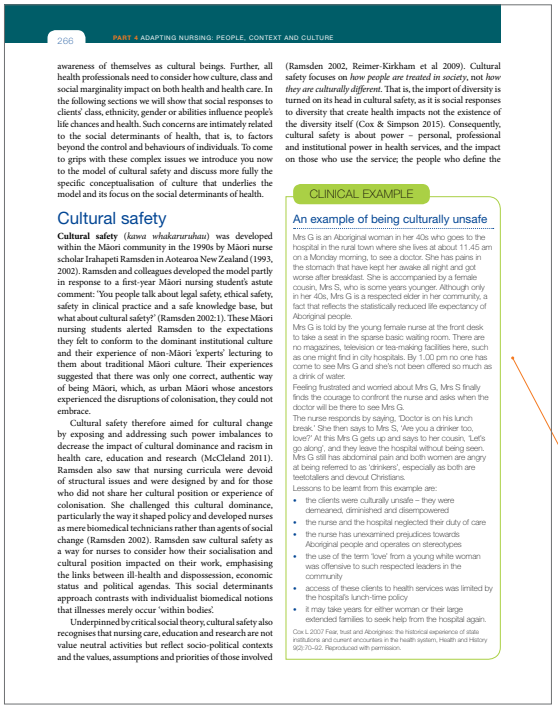
Non-verbal behaviours should match the verbal messages. Appropriate and sensitive eye contact and non-intimidating positioning should be used. Sincere and open eye contact (except in certain cultures/circumstances) is often vital with a vulnerable person, as normal contact with others may be disrupted by the emotions generated from circumstances surrounding the death. Position yourself so that you are facing the client. If the client is seated, sit at a slight angle opposite but facing, with an appropriate distance between. Avoid non-verbal behaviours such as frowning or yawning, or expressions of impatience or boredom, which imply a lack of interest. When beginning the interview, it may be appropriate to start with a brief but casual conversation that helps the client relax. Client-focused casual conversation may help alleviate any awkwardness the client may feel in talking to a stranger in the healthcare setting. Casual conversation can also be a source of valuable information.

Ensuring comfort

Ensure that the exchange of information takes place in a private setting free from interruptions and distractions. It is important to clarify that the client is feeling up to the interview before starting. Verbal therapeutic communication techniques involve open-ended questions that give the client a sense of control over the process – for example, 'Tell me about your family', 'How are you feeling now?' or 'What can you tell me about your relationship with X?'

Defining expectations

At the beginning of any interaction it is important to clarify what both the nurse and the client expect from the exchange. Make it clear that any information exchanged will be treated with sensitivity and respect. This is especially important in Australian Indigenous culture where the abuses of the past continue to have impacts on establishing trust in services (see Chapter 14). During the assessment phase, it is important to focus on how the client is reacting, not on how you believe they should be reacting. Give special attention to grief-related behaviours displayed by the client, and pay careful attention to the client's experience and the tasks of grief that may be left incomplete, which may threaten the client's psychological or physical



awareness of themselves as cultural beings. Further, all health professionals need to consider how culture, class and social marginality impact on both health and health care. In the following sections we will show that social responses to clients' class, ethnicity, gender or abilities influence people's life chances and health. Such concerns are intimately related to the social determinants of health, that is, to factors beyond the control and behaviours of individuals. To come to grips with these complex issues we introduce you now to the model of cultural safety and discuss more fully the specific conceptualisation of culture that underlies the model and its focus on the social determinants of health.

Cultural safety

Cultural safety (*kawa whakaruruhau*) was developed within the Māori community in the 1990s by Māori nurse scholar Irahapeti Ramsden in Aotearoa New Zealand (1993, 2002). Ramsden and colleagues developed the model partly in response to a first-year Māori nursing student's astute comment: 'You people talk about legal safety, ethical safety, safety in clinical practice and a safe knowledge base, but what about cultural safety?' (Ramsden 2002:1). These Māori nursing students alerted Ramsden to the expectations they felt to conform to the dominant institutional culture and their experience of non-Māori 'experts' lecturing to them about traditional Māori culture. Their experiences suggested that there was only one correct, authentic way of being Māori, which, as urban Māori whose ancestors experienced the disruptions of colonisation, they could not embrace.

Cultural safety therefore aimed for cultural change by exposing and addressing such power imbalances to decrease the impact of cultural dominance and racism in health care, education and research (McCleland 2011). Ramsden also saw that nursing curricula were devoid of structural issues and were designed by and for those who did not share her cultural position or experience of colonisation. She challenged this cultural dominance, particularly the way it shaped policy and developed nurses as mere biomedical technicians rather than agents of social change (Ramsden 2002). Ramsden saw cultural safety as a way for nurses to consider how their socialisation and cultural position impacted on their work, emphasising the links between ill-health and dispossession, economic status and political agendas. This social determinants approach contrasts with individualist biomedical notions that illnesses merely occur 'within bodies'.

Underpinned by critical social theory, cultural safety also recognises that nursing care, education and research are not value neutral activities but reflect socio-political contexts and the values, assumptions and priorities of those involved (Ramsden 2002, Reimer-Kirkham et al 2009). Cultural safety focuses on *how people are treated in society*, not *how they are culturally different*. That is, the import of diversity is turned on its head in cultural safety, as it is social responses to diversity that create health impacts not the existence of the diversity itself (Cox & Simpson 2015). Consequently, cultural safety is about power – personal, professional and institutional power in health services, and the impact on those who use the service; the people who define the

CLINICAL EXAMPLE

An example of being culturally unsafe

Mrs G is an Aboriginal woman in her 40s who goes to the hospital in the rural town where she lives at about 11.45 am on a Monday morning, to see a doctor. She has pains in the stomach that have kept her awake all night and got worse after breakfast. She is accompanied by a female cousin, Mrs S, who is some years younger. Although only in her 40s, Mrs G is a respected elder in her community, a fact that reflects the statistically reduced life expectancy of Aboriginal people.

Mrs G is told by the young female nurse at the front desk to take a seat in the sparse basic waiting room. There are no magazines, television or tea-making facilities here, such as one might find in city hospitals. By 1.00 pm no one has come to see Mrs G and she's not been offered so much as a drink of water.

Feeling frustrated and worried about Mrs G, Mrs S finally finds the courage to confront the nurse and asks when the doctor will be there to see Mrs G.

The nurse responds by saying, 'Doctor is on his lunch break.' She then says to Mrs S, 'Are you a drinker too, love?' At this Mrs G gets up and says to her cousin, 'Let's go along', and they leave the hospital without being seen. Mrs G still has abdominal pain and both women are angry at being referred to as 'drinkers', especially as both are teetotallers and devout Christians.

Lessons to be learnt from this example are:

- the clients were culturally unsafe – they were demeaned, diminished and disempowered
- the nurse and the hospital neglected their duty of care
- the nurse has unexamined prejudices towards Aboriginal people and operates on stereotypes
- the use of the term 'love' from a young white woman was offensive to such respected leaders in the community
- access of these clients to health services was limited by the hospital's lunch-time policy
- it may take years for either woman or their large extended families to seek help from the hospital again.

Cox L 2017 Fear, trust and Aborigines: the historical experience of state institutions and current encounters in the health system, Health and History 19(2):70–92. Reproduced with permission.

Clinical examples bring concepts to life and assist students to apply theory to practice with realistic case studies and clinical scenarios.

Research highlights provide examples of the most up-to-date knowledge, evidence and practice.

CHAPTER 3 ENGAGING PATIENTS AND KEEPING THEM SAFE 33

RESEARCH HIGHLIGHT

Research focus
Developing a positive relationship with patients is known to be important for the delivery of high-quality care. This paper sought to identify the factors that contribute to the development of a caring relationship between the nurse and patient.

Research abstract
The study involved conducting an umbrella review. Umbrella reviews bring together evidence from existing systematic reviews in order to synthesise the available evidence on a particular topic. This umbrella review looked at studies examining patients' and nurses' perspectives on what is important in the nurse–patient relationship. The umbrella review identified six key areas that are associated with developing and maintaining caring, positive nurse–patient relationships. They are:
- nurses' and patients' expectations of the relationship
- nurses' values and beliefs (e.g. their thoughts, perceptions, attitudes and associated behaviours)
- nurses' knowledge and skills (both clinical skills and support behaviours)
- nurses' ability to communicate effectively in a variety of ways
- how the physical and social contexts in which care is taking place affect the nurse–patient relationship
- the impact of the relationship on patients/families, nurses and nursing students.

Evidence-based practice
- The nurse–patient relationship should be based on nursing's inbuilt values such as trust, sympathy, support and responsibility, and these values should be reflected in the attitudes and behaviours of nurses.
- Compassionate care and technical skill are equally important in developing and maintaining the nurse–patient relationship.
- Nurses need to consider the context in which they are providing care and how this might impact the nurse–patient relationship.
- The nurse–patient relationship not only has an impact on patients and families/carers, but on nurses as well. Nurses find great reward in a positive relationship with their patients but can also experience guilt and frustration when a good quality nurse–patient relationship is not achieved.

in decision-making about the care they receive. A meaningful relationship with the patient enables you as the nurse to make sound clinical decisions that are based on the patient's best interests.

Safety as one of the fundamentals of care

Patient safety was of central concern to Florence Nightingale as reflected in her quote, 'the very first requirement in a hospital is that it should do the sick no harm' (Nightingale 1859). Safety continues to be a concern for many modern healthcare systems, with evidence suggesting that Nightingale's doctrine of 'doing no harm' is not being completely followed. The Institute of Medicine's (IOM) landmark publication *Crossing the Quality Chasm* (2001), for example, argued that the US healthcare system was failing to deliver consistent, high-quality medical care, with such care instead frequently harming or injuring patients. The IOM called for fundamental changes to 21st-century healthcare systems to ensure the safety of all patients.

In this part of the chapter, we consider how the Fundamentals of Care Framework helps you to address patient safety concerns when providing care. As can be seen from Figure 3-1, safety is conceptualised as a fundamental of care, along with other fundamentals such as nutrition, hydration and elimination. The nurse–patient relationship is central to ensuring this fundamental need is appropriately met. While policy and organisational structures focusing on safety undoubtedly have an impact on the ability of nurses to deliver safe and effective care, our focus in this chapter is on equipping you as a student and beginning nurse with the skills to operate in a safe manner. That is, to ensure patient safety becomes part of your personal and professional responsibility as a nurse.

Patient safety encompasses three interrelated elements: physical, psychosocial and environmental safety. At the intersection of these different types of safety lies the patient's **personal safety** (see Figure 3-2). It is only when each of these types of safety are appropriately met that patients can be considered safe. Ensuring patients' personal safety requires nurses to embed patients' needs in their thinking, reflection and assessment processes (Kitson et al 2014). Careful assessment and planning prior to any intervention or interaction with a patient will ensure that injury and harm do not occur and that any safety **risks** are reduced.

Working with diversity encourages students to consider culture, lifestyle, gender and age-related issues and choices in the broadest possible way.

CHAPTER 9 EXAMINING THE ETHICAL PRACTICE OF NURSING 149

of 'characterological excellence' in determining ethical conduct (Oakley 2006, Van Hooft 2014). This is made manifest by the expression of such moral virtues as care, compassion, kindness, empathy, sympathy, altruism, generosity, respectfulness, trustworthiness, personal integrity, wisdom, courage and fairness. Virtue theorists claim that without the characterological excellence of virtue, 'a person could, robot-like, obey every moral rule and lead the perfectly moral life', but in doing so would be acting more like 'a perfectly programmed computer' than a morally responsible human being (Pence 1991). There is a sense in which being moral involves much more than merely following rules; the missing link, claim virtue theorists, is character. On this point, Pence (1991) writes:

> we need to know much more about the outer shell of behaviour to make such judgments, that is, we need to know what kind of person is involved, how the person thinks of other people, how he or she thinks of his or her own character, how the person feels about past actions, and also how the person feels about the actions not done.

Virtue ethics is particularly relevant to nursing and to nursing ethics since virtuous conduct is intricately linked to therapeutic healing behaviours and the promotion of human health and wellbeing.

The nursing profession's well-articulated ethic of care (regarded by many influential nurse theorists as the moral foundation, essence, ideal and imperative of nursing) is consistent with a virtue theory of ethics (see the classic works of the following nurse theorists: Benner & Wrubel 1989, Gaut 1991, Gaut & Leininger 1991, Leininger 1988, 1990, Roach 1987, Watson 1985a, 1985b). Significantly, virtue ethics is enjoying a renaissance in the nursing ethics literature – particularly in regard to the issue of caring for vulnerable and marginalised groups of people at risk of being treated as 'different' by healthcare providers (Armstrong 2006, 2007).

Cross-cultural ethics

As highlighted by the 'Mr G' case discussed on p. 139, another perspective on ethics and bioethics that warrants consideration by nurses is cross-cultural ethics. The basic assumptions of **cross-cultural ethics** reflect the views that:
- ethics is very much a product of the culture, society and history from which it has emerged
- all cultures have a moral system, but what this system is and how it is applied will vary across, and sometimes even within, different cultures
- there is no such thing as a universal ethic; that is, one ultimate standard of moral conduct which applies to all people equally regardless of their individual circumstances, context and culture – in other words, a 'one size fits all' approach to ethics (Johnstone 2012, 2016).

In any culturally diverse society it is imperative that a culturally informed, knowledgeable and sensitive approach to health care is taken (Johnstone 2012, Johnstone & Kanitsaki 2008). One reason for this is that a failure to adopt such an approach can result in otherwise serious moral harm being caused to people. Cross-cultural ethics, therefore, goes far beyond merely considering and critiquing the nature and content of mainstream ethical theories; it also involves a systematic examination of the moral implications of cultural and linguistic diversity in healthcare domains; for example, the extent to which patients of non-English-speaking and diverse cultural backgrounds suffer unnecessarily on account of the cultural and language differences between them and their professional carers (see de Bruijne et al 2013, Divi et al 2007, Johnstone & Kanitsaki 2006, 2009a, Suurmond et al 2010).

Nurses and other healthcare workers have a stringent moral responsibility to avoid and/or prevent the otherwise avoidable moral harms that can result from a failure to take into account the language and cultural needs of their patients (Johnstone & Kanitsaki 2006, 2008, 2009a). The harmful aftermath of racism in health care is a particular example of this. Racism in nursing and health care is a problem that has not been formally recognised as an important ethical professional issue (Johnstone & Kanitsaki 2009b, 2010). A cross-cultural approach to ethics would not only help identify the existence of racism in nursing and healthcare contexts, but also guide an effective response for dealing with it and, if not successful in eradicating it, at least minimise its harmful consequences to patient health.

WORKING WITH DIVERSITY

Truth-telling around cancer and other life-limiting diagnoses stands as one of the most controversial issues in cross-cultural health care. Research has shown that truth-telling is not just an issue for people from Greek backgrounds, but also for people from other traditional cultural backgrounds (e.g. Iranian, Pakistani, Japanese, Italian, Korean, Chinese). In these cases, truth-telling about a diagnosis of serious life-limiting illnesses (especially cancer-related illnesses) is regarded as harmful, 'undesirable' and hence to be avoided – most notably on the grounds that it could undermine the ill loved one's hope and the will to live (Johnstone 2012, 2016). Problems most commonly arise in situations where the healthcare provider (e.g. doctor, nurse) does not share the same cultural background as the patient and family, whose cultural world views are unfamiliar and even confronting to them and which they do not understand.

Critical reflection points are placed at intervals throughout each chapter as a way of inviting students to reflect on what they are reading.

8 PART 1 EVOLVING NURSING: NURSING AND THE HEALTHCARE ENVIRONMENT

Nursing's contribution to these three elements is greater than any other health profession. The nursing workforce is the single largest clinical workforce with the most direct clinical care time. Nurses continue to provide care with resilience and versatility, while often with minimal resources and organisational support. Nursing can be, as the International Council of Nurses (ICN 2015) states, 'a force for change'.

Unfortunately, reform may have short-term goals, including immediate funding reductions. As the largest workforce and, therefore, the highest cost burden, the nursing workforce is often cut, leaving fewer people to do more work. Research shows that RN staffing levels have direct implications for patient care. It demonstrates that hospitals with a higher ratio of degree-prepared RNs-to-patients have lower mortality rates (Aiken et al 2014). Hospitals with lower RN staffing numbers are linked to an increased number of adverse events including falls and medication errors (Duffield et al 2014). As a result, the aims of healthcare reform are not realised.

The escalating costs of health care require that measures be taken to contain costs to levels that countries can afford and sustain. These pressures highlight the need for how resources in health care, particularly nursing, can be used to their optimal level. When the nursing profession is optimised, evidence demonstrates that the quality of health service provision improves. When the quality of services improve, resources are often used more efficiently. For example, an optimised and appropriately resourced nursing workforce is linked to reduced adverse events (as mentioned above), improved health literacy of patients, reduced length of stay, decreased readmission rates, improved hospital avoidance and better patient outcomes (Aitken 2014). As such, the three aims of health reform can be achieved.

• CRITICAL REFLECTION POINT

Why would supporting RNs to work to their full scope of practice create a more efficient health system? How important is health literacy to the future of healthcare provision and how can nursing contribute to improving health literacy?

Nursing leadership and healthcare reform

The nursing profession is uniquely placed to lead **healthcare reform**. Nurses have close interaction with patients and their families in all health settings across the health continuum. They can help interpret and understand people's needs and expectations for health care. They are actively involved in decision-making within the clinical team and in management. They do this with a foundation of care informed by research and evidence. This understanding, experience and proximity to the patients' needs are critical components of what nursing can bring to the table and how it can enable reform.

As such, nurses have an important contribution to make in health service planning, management and policy setting. Nurses must contribute to public policy development through management and leadership roles at all levels and with direct engagement with their professional organisations. To achieve this level of responsibility, it cannot be assumed that it will automatically be provided to the profession. Historically, in many instances, nurses have been left out of the decision-making process and have been left with implementing an initiative or policy that has not been well informed. The role of the profession therefore must be proactive to maintain this level of influence and involvement.

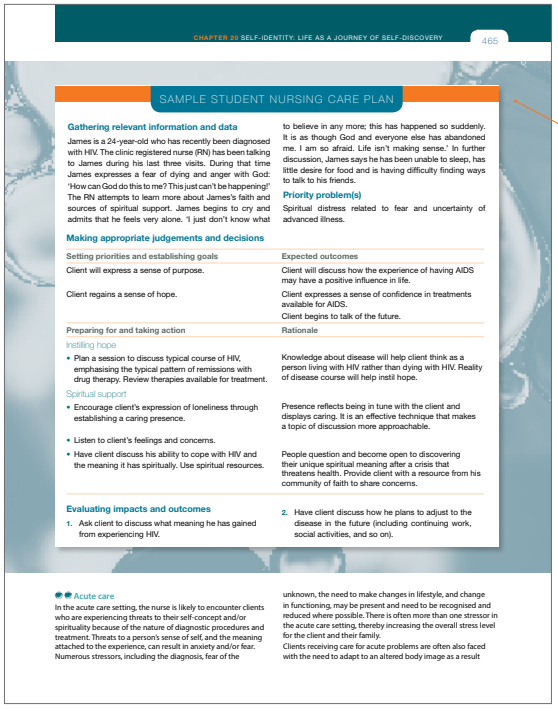
Just as important as the planning and policy setting, nurses need to be leaders in healthcare management. The International Council of Nurses (2015) asserts that nursing services must be directly managed by nurses. The reason for this is that the profession must be responsible for the professional practice of nursing. No profession outside of nursing is well positioned enough to be held to account and to lead the scope of practice and the standards for practice of the RN.

• CRITICAL REFLECTION POINT

Think about a recent health issue discussed in the news. Did nursing have a voice? How do you think nurses can promote their stories, insights, research and expert opinions via social media?

Regulation of the nursing profession

The Nursing and Midwifery Board of Australia (NMBA) and Nursing Council of New Zealand are responsible for **professional regulation** and setting standards, codes and guidelines for the nursing and midwifery professions (Box 1-2). The role of professional colleges and associations in developing specific standards of practice and credentialling individual nurses is increasing. RNs are individually accountable for their own practice and have a personal responsibility to maintain their competency and meet professional standards in order to maintain their licence to practise. The role of the RN has evolved along with changes in advancing technology, newly defined patient needs and changes to the way health care is delivered. In this way, it is not unreasonable to expect that the role of the RN will continue to evolve and change. It is



CHAPTER 20 SELF-IDENTITY: LIFE AS A JOURNEY OF SELF-DISCOVERY 465

SAMPLE STUDENT NURSING CARE PLAN

Gathering relevant information and data

James is a 24-year-old who has recently been diagnosed with HIV. The clinic registered nurse (RN) has been talking to James during his last three visits. During that time James expresses a fear of dying and anger with God: 'How can God do this to me? This just can't be happening!' The RN attempts to learn more about James's faith and sources of spiritual support. James begins to cry and admits that he feels very alone. 'I just don't know what to believe in any more; this has happened so suddenly. It is as though God and everyone else has abandoned me. I am so afraid. Life isn't making sense.' In further discussion, James says he has been unable to sleep, has little desire for food and is having difficulty finding ways to talk to his friends.

Priority problem(s)

Spiritual distress related to fear and uncertainty of advanced illness.

Making appropriate judgements and decisions

Setting priorities and establishing goals	Expected outcomes
Client will express a sense of purpose.	Client will discuss how the experience of having AIDS may have a positive influence in life.
Client regains a sense of hope.	Client expresses a sense of confidence in treatments available for AIDS. Client begins to talk of the future.
Preparing for and taking action	**Rationale**
Instilling hope	
• Plan a session to discuss typical course of HIV, emphasising the typical pattern of remissions with drug therapy. Review therapies available for treatment.	Knowledge about disease will help client think as a person living with HIV rather than dying with HIV. Reality of disease course will help instil hope.
Spiritual support	
• Encourage client's expression of loneliness through establishing a caring presence.	Presence reflects being in tune with the client and displays caring. It is an effective technique that makes a topic of discussion more approachable.
• Listen to client's feelings and concerns.	
• Have client discuss his ability to cope with HIV and the meaning it has spiritually. Use spiritual resources.	People question and become open to discovering their unique spiritual meaning after a crisis that threatens health. Provide client with a resource from his community of faith to share concerns.

Evaluating impacts and outcomes

1. Ask client to discuss what meaning he has gained from experiencing HIV.
2. Have client discuss how he plans to adjust to the disease in the future (including continuing work, social activities, and so on).

Acute care

In the acute care setting, the nurse is likely to encounter clients who are experiencing threats to their self-concept and/or spirituality because of the nature of diagnostic procedures and treatment. Threats to a person's sense of self, and the meaning attached to the experience, can result in anxiety and/or fear. Numerous stressors, including the diagnosis, fear of the unknown, the need to make changes in lifestyle, and change in functioning, may be present and need to be recognised and reduced where possible. There is often more than one stressor in the acute care setting, thereby increasing the overall stress level for the client and their family.

Clients receiving care for acute problems are often also faced with the need to adapt to an altered body image as a result

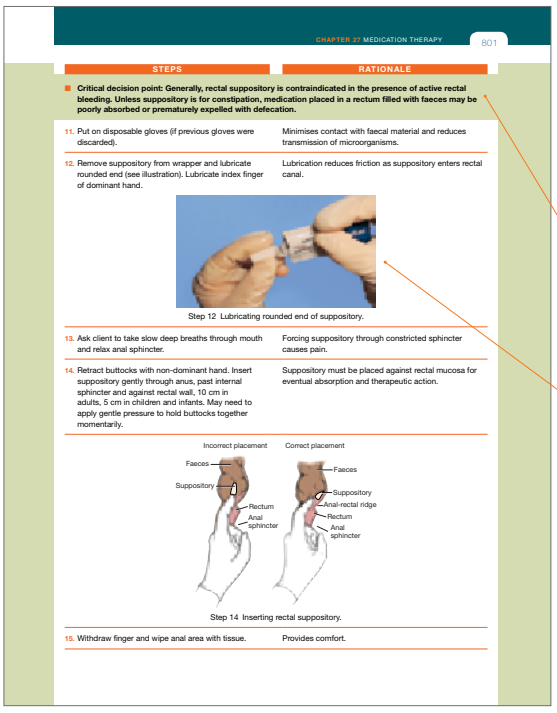
Sample student nursing care plans provide worked examples of how nursing care planning is individualised, based on scientific rationales and research evidence.

Therapeutic relationship and patient considerations

Reminds students that the person is central to care provision in the therapeutic relationship for each skill.

Steps and rationale

Each skill features the trusted step-by-step approach with rationales to help students understand how and why a skill is performed.



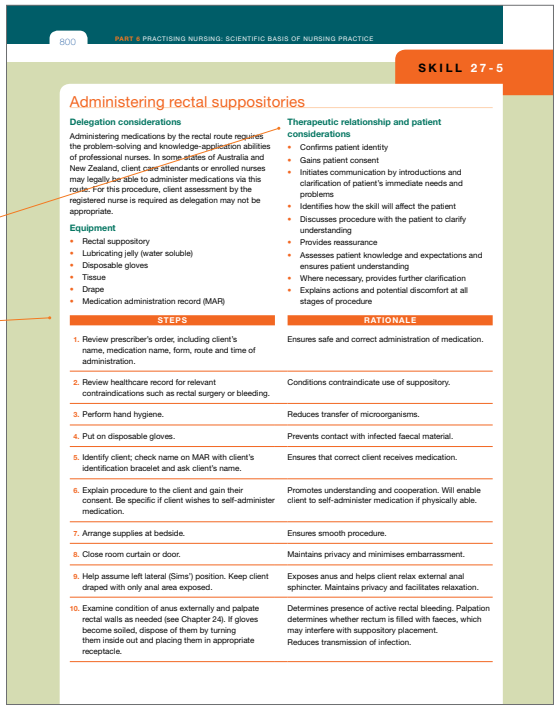
CHAPTER 27 MEDICATION THERAPY 801

STEPS	RATIONALE
■ **Critical decision point: Generally, rectal suppository is contraindicated in the presence of active rectal bleeding. Unless suppository is for constipation, medication placed in a rectum filled with faeces may be poorly absorbed or prematurely expelled with defecation.**	
11. Put on disposable gloves (if previous gloves were discarded).	Minimises contact with faecal material and reduces transmission of microorganisms.
12. Remove suppository from wrapper and lubricate rounded end (see illustration). Lubricate index finger of dominant hand.	Lubrication reduces friction as suppository enters rectal canal.
Step 12 Lubricating rounded end of suppository.	
13. Ask client to take slow deep breaths through mouth and relax anal sphincter.	Forcing suppository through constricted sphincter causes pain.
14. Retract buttocks with non-dominant hand. Insert suppository gently through anus, past internal sphincter and against rectal wall, 10 cm in adults, 5 cm in children and infants. May need to apply gentle pressure to hold buttocks together momentarily.	Suppository must be placed against rectal mucosa for eventual absorption and therapeutic action.
Step 14 Inserting rectal suppository.	
15. Withdraw finger and wipe anal area with tissue.	Provides comfort.

Critical decision points alert students to critical steps within a skill to ensure quality and safety in client care.

Images support learning and demonstrate how to perform techniques.

Skills featuring the step-by-step approach and rationales:



800 PART 6 PRACTISING NURSING: SCIENTIFIC BASIS OF NURSING PRACTICE

SKILL 27-5

Administering rectal suppositories

Delegation considerations

Administering medications by the rectal route requires the problem-solving and knowledge-application abilities of professional nurses. In some states of Australia and New Zealand, client care attendants or enrolled nurses may legally be able to administer medications via this route. For this procedure, client assessment by the registered nurse is required as delegation may not be appropriate.

Equipment

- Rectal suppository
- Lubricating jelly (water soluble)
- Disposable gloves
- Tissue
- Drape
- Medication administration record (MAR)

Therapeutic relationship and patient considerations

- Confirms patient identity
- Gains patient consent
- Initiates communication by introductions and clarification of patient's immediate needs and problems
- Identifies how the skill will affect the patient
- Discusses procedure with the patient to clarify understanding
- Provides reassurance
- Assesses patient knowledge and expectations and ensures patient understanding
- Where necessary, provides further clarification
- Explains actions and potential discomfort at all stages of procedure

STEPS	RATIONALE
1. Review prescriber's order, including client's name, medication name, form, route and time of administration.	Ensures safe and correct administration of medication.
2. Review healthcare record for relevant contraindications such as rectal surgery or bleeding.	Conditions contraindicate use of suppository.
3. Perform hand hygiene.	Reduces transfer of microorganisms.
4. Put on disposable gloves.	Prevents contact with infected faecal material.
5. Identify client; check name on MAR with client's identification bracelet and ask client's name.	Ensures that correct client receives medication.
6. Explain procedure to the client and gain their consent. Be specific if client wishes to self-administer medication.	Promotes understanding and cooperation. Will enable client to self-administer medication if physically able.
7. Arrange supplies at bedside.	Ensures smooth procedure.
8. Close room curtain or door.	Maintains privacy and minimises embarrassment.
9. Help assume left lateral (Sims') position. Keep client draped with only anal area exposed.	Exposes anus and helps client relax external anal sphincter. Maintains privacy and facilitates relaxation.
10. Examine condition of anus externally and palpate rectal walls as needed (see Chapter 24). If gloves become soiled, dispose of them by turning them inside out and placing them in appropriate receptacle.	Determines presence of active rectal bleeding. Palpation determines whether rectum is filled with faeces, which may interfere with suppository placement. Reduces transmission of infection.

Key concepts provide a summary of each chapter's key points to reinforce learning outcomes.

12 PART 1 EVOLVING NURSING: NURSING AND THE HEALTHCARE ENVIRONMENT

greater competency, so eventually the novice becomes the advanced beginner, who in turn moves through being competent to proficient and finally to expert. At the expert level, the RN is able to provide care to patients with complex health needs and requires only indirect governance and support.

Throughout the journey across the practice pathway, the RN is protected by significant safety and quality frameworks, which are themselves underpinned by evolving legislation, registration standards, professional practice standards and policies that align with best practice and evidence.

The future of nursing: leading change

Through the effective use of the professional and regulatory frameworks, informed through postgraduate education and relevant experience, RNs can lead service transformation. Possible examples of new ways of working and new models of care may include:

- nurse proceduralists undertaking new diagnostic functions, such as endoscopy
- nurse-led clinics delivering integrated care to palliative care patients
- nurse triage models to streamline referral pathways into outpatient and specialist services
- public–private partnerships for nurse practitioners, including admission privileges, that enhance consumer choice
- RNs working in sustainable and economically viable self-employment models focused on community chronic disease management
- brokerage and community case management for disability clients through the National Disability Insurance Scheme (NDIS)
- nurses delivering care and ongoing management to rural and remote patients through outreach services delivered through use of technology and Telehealth
- expanded access to diagnostics and medicines to improve the patient journey and deliver services closer to a patient's home.

CRITICAL REFLECTION POINT

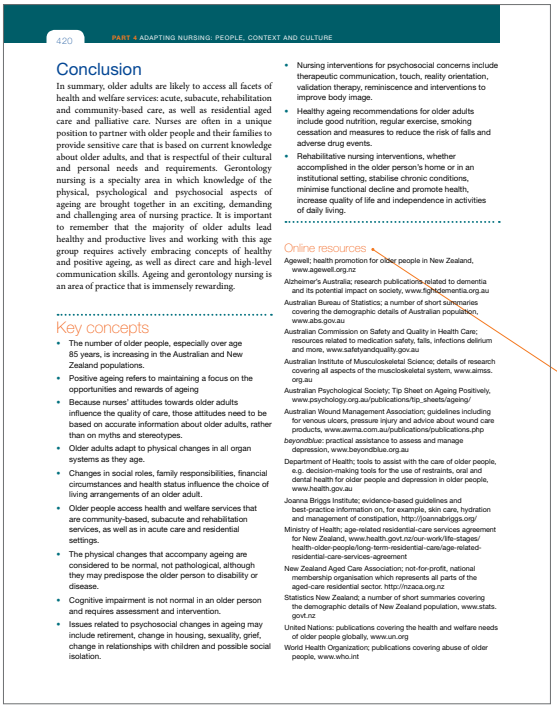
In thinking about the future directions of nursing practice, what are the capabilities you will need for success in new work environments that are constantly evolving?

Conclusion

We live in a dynamic and exciting time in the history of nursing and health care. We have an insatiable appetite for safe, accessible, affordable and quality healthcare services. The demand for professional care provided by nurses has never been greater. RNs across Australia and New Zealand are stepping up and meeting the challenges their environments are providing. They are delivering person-centred care in diverse models and settings across the continuum from primary to tertiary care. We have the safety and regulatory mechanisms that surround us to ensure we practise to our scope and can be responsive. The challenge is to maintain our ability to be responsive to our communities and be confident and resilient in an ever-changing environment. Ensuring we work to our full scope, underpinned by ongoing postgraduate education, is not only the answer to new models of care, but also to the professional and personal satisfaction of us as nurses. Nursing leadership at all levels of the healthcare system is essential to secure better health and wellbeing for our nations.

Key concepts

- Nursing practice is evolving in response to social, economic and political factors and changing population health needs. These drivers help to shape the context in which the RN practises and delivers care.
- Healthcare costs are growing at an unsustainable rate. An efficient and effective healthcare system that reduces wastage is critical to ensuring population health and wellbeing.
- Health reform is continuous and will create more opportunities for nurses to work in new models of healthcare delivery that provide quality health services to individuals, families and communities.
- Nurses are the largest group of health professionals in the health system. A proactive and dynamic nursing profession is pivotal to future healthcare provision.
- It is important that nurses are educationally prepared for an evolving context of practice across a range of healthcare environments, including those that have never been available before as a result of innovation and technology.
- Registered nurses must be supported to work to their full regulated scope of practice in order to maximise the efficiency and effectiveness of the nursing workforce.
- Nurses working to their full potential will result in personal, professional and career satisfaction, as well as ensuring the delivery of safe, quality patient outcomes.
- It is important to recognise and reinforce the important contribution of the nursing profession at all levels of the healthcare system, including direct clinical care, coordinating complex patient care, driving safety and quality, policy and systems management, research, education and executive leadership.



420 PART 4 ADAPTING NURSING: PEOPLE, CONTEXT AND CULTURE

Conclusion

In summary, older adults are likely to access all facets of health and welfare services: acute, subacute, rehabilitation and community-based care, as well as residential aged care and palliative care. Nurses are often in a unique position to partner with older people and their families to provide sensitive care that is based on current knowledge about older adults, and that is respectful of their cultural and personal needs and requirements. Gerontology nursing is a specialty area in which knowledge of the physical, psychological and psychosocial aspects of ageing are brought together in an exciting, demanding and challenging area of nursing practice. It is important to remember that the majority of older adults lead healthy and productive lives and working with this age group requires actively embracing concepts of healthy and positive ageing, as well as direct care and high-level communication skills. Ageing and gerontology nursing is an area of practice that is immensely rewarding.

Key concepts

- The number of older people, especially over age 85 years, is increasing in the Australian and New Zealand populations.
- Positive ageing refers to maintaining a focus on the opportunities and rewards of ageing
- Because nurses' attitudes towards older adults influence the quality of care, those attitudes need to be based on accurate information about older adults, rather than on myths and stereotypes.
- Older adults adapt to physical changes in all organ systems as they age.
- Changes in social roles, family responsibilities, financial circumstances and health status influence the choice of living arrangements of an older adult.
- Older people access health and welfare services that are community-based, subacute and rehabilitation services, as well as in acute care and residential settings.
- The physical changes that accompany ageing are considered to be normal, not pathological, although they may predispose the older person to disability or disease.
- Cognitive impairment is not normal in an older person and requires assessment and intervention.
- Issues related to psychosocial changes in ageing may include retirement, change in housing, sexuality, grief, change in relationships with children and possible social isolation.
- Nursing interventions for psychosocial concerns include therapeutic communication, touch, reality orientation, validation therapy, reminiscence and interventions to improve body image.
- Healthy ageing recommendations for older adults include good nutrition, regular exercise, smoking cessation and measures to reduce the risk of falls and adverse drug events.
- Rehabilitative nursing interventions, whether accomplished in the older person's home or in an institutional setting, stabilise chronic conditions, minimise functional decline and promote health, increase quality of life and independence in activities of daily living.

CHAPTER 33 URINARY ELIMINATION 1149

nursing interventions through comparisons with baseline data. The nurse evaluates for change in the patient's voiding pattern, presence of urinary tract alteration, and physical condition. Outcomes are compared with expectations to determine the person's health status. Continuous evaluation allows the nurse to determine whether new or revised therapies are required or if any new nursing diagnoses have developed.

Patient expectations

If the nurse has developed a relationship of trust with the person, indications of the person's degree of satisfaction with the care will be evident. Keep in mind that it may take several months before any measurable improvement in urinary incontinence can be determined. These people need ongoing support so that their treatment goals can be realised. The nurse can also assist the person in redefining unrealistic goals when impairment in function is not likely to be altered as completely as the person might like.

CRITICAL REFLECTION POINT

Mrs Joseph is an 82-year-old woman with mild cognitive changes associated with Alzheimer's disease. Her daughter, with whom she lives, has brought her to the general practitioner's clinic for assessment and advice. You are the practice nurse in the clinic. As you assess Mrs Joseph, you ask her daughter how she is coping with caring for her mother. The daughter replies that her mother does not seem to remember how to go to the toilet. Mrs Joseph will go into the bathroom but forget to pull down her underwear before going to the toilet. After such an incident she becomes upset and blames her daughter for her wetness. The daughter asks you for suggestions on how to manage, as she has noticed that her mother's perineal skin is reddened and sore.
What assessments would you need to complete before planning interventions for Mrs Joseph's care?

Key concepts

- The act of micturition or voiding is influenced by voluntary control from higher brain centres and involuntary control from the spinal cord.
- Symptoms common to urinary disturbances include urgency, frequency, dysuria, incontinence, nocturia, polyuria, oliguria and difficulty in starting the urinary stream.
- Methods of promoting the micturition reflex help patients sense the urge to urinate and control urethral sphincter relaxation.
- An increased fluid intake results in increased urine formation that flushes particles and solutes from the urinary system.
- An indwelling urinary catheter remains in the bladder for an extended period, making the risk of infection greater than with intermittent catheterisation.
- One of the main functions of the elimination process is fluid and electrolyte balance.
- A catheter drainage system should remain a closed system and the drainage bag should be positioned to allow free drainage of urine by gravity.
- Incontinence is a significant health issue. An accurate assessment must be undertaken to determine the type of continence problem before a treatment program can be developed.
- Alterations in the urinary system can cause alterations in other organ systems.

Learning outcomes

Mastery of content will enable you to:

- reflect on personal capabilities needed for a successful nursing career, in a future healthcare system characterised by rapid change
- discuss the broad aims and factors that are driving health reform in Australia and New Zealand
- understand the key elements of the nursing profession's regulatory framework in Australia and New Zealand
- discuss factors influencing nursing scope of practice
- appreciate the importance of nursing leadership at all levels for a proactive and dynamic profession.

Scope of practice, p. 9

Introduction

Nursing as a profession continues to evolve in Australia and New Zealand, with nurses tackling a wider range of healthcare responsibilities, triggered by crucial health reforms. These government reforms are designed to make the health system more efficient, while relieving some of the pressures associated with growing healthcare costs (Productivity Commission 2015). The growing burden on governments to fund healthcare services is being driven by population ageing, costly medical technologies, increasing community expectations and the rising incidence of chronic diseases. While research is providing better drugs, devices and interventions to keep people healthier and living longer, subsidising these is increasingly expensive (Biggs 2014). There is renewed focus on the role and scope of practice of nurses in the context of mounting pressures on the health system, and the potential of the profession to respond to increasingly complex care needs across the life span, particularly those associated with an ageing population and the growing number of people with chronic health conditions.

Nursing education and research is crucial for a proactive and dynamic profession. With the right knowledge and skills, nurses are prepared for leading widespread change in health care and responding to demands by consumers, governments and health service providers with evidence-based models for practice that are efficient and effective at improving access to health care across a range of settings. Nurses, working as clinicians, managers, leaders, teachers, researchers, scholars and policy-makers all influence the delivery of safe, high-quality care and improve the health and wellbeing of individuals, families, communities and populations through advancing nursing practice (Nelson et al 2014).

It is imperative for nurses to be intelligent, critical thinkers, committed to lifelong learning, great caregivers but also great innovators, who are able to collaborate with other healthcare providers to lead new approaches in how health care is delivered, while actively engaging consumers as key decision-makers in shaping the future of healthcare provision. Opportunities to realise long-term health reform options cannot be achieved without nurses and without our proactive contributions and participation at all levels of the healthcare system.

Nursing's contribution to quality patient outcomes

As the largest clinical workforce, nurses have a significant impact on the overall productivity and efficiency of the healthcare system. Nursing labour costs make up one of the largest components of overall health service budgets, which often makes nursing human resources the target of fiscal constraint and workforce reforms. A large body of research demonstrates the strong relationship between a registered nurse (RN) workforce and improved patient outcomes. RNs are a critical part of the healthcare team, and the number of RNs in the team is directly linked to patient safety (Twigg et al 2010).

Traditionally, hospitals have focused on productivity (hours per unit of service, such as hours per patient day) to determine staffing levels. This approach creates unintended incentives to reduce the number of nurses on the floor, which then limits the time spent on quality

RESEARCH HIGHLIGHT

Research focus

This article provides a comprehensive review of the research linking nurse staffing to patient outcomes at a time of growing shortages, highlighting that a policy response based on substituting RNs with lower skilled workers may have adverse effects on patient outcomes.

Research abstract

An electronic search of articles published in English using the Cumulative Index to Nursing and Allied Health Literature (CINAHL), Journals @ OVID and Medline was undertaken.

Evidence-based practice

Robust evidence exists nationally and internationally linking nurse staffing to patient outcomes. Recent meta-analyses have found that there was a 3–12% reduction in adverse outcomes and a 16% reduction in the risk of mortality in surgical patients with higher RN staffing. Evidence confirms that improvements in nurse staffing is a cost-effective investment for the health system, but this is not fully appreciated by health policy advisers.

Conclusion

An appropriate policy response demands that the evidence that patient safety is linked to nurse staffing be recognised. Policy-makers must ensure there are sufficient registered nurses to guarantee patient safety.

Reference

Twigg D et al 2010 The impact of nurses on patient morbidity and mortality – the need for a policy change in response to the nursing shortage. Aust Health Rev 34(3):312–16, with permission from CSIRO Publishing.

patient care. An evolved approach to RN staffing is focused on optimising nursing skill mix, leading to lower costs, improved RN satisfaction and improved patient outcomes (Berlin et al 2014). Job satisfaction is important to nurses, and is critical for retention across career paths, as well as attracting individuals into the profession in order to halt an imminent nursing shortage. Change is needed to improve the transition from education to the workplace, keeping nurses in their jobs, particularly in the early and later part of their careers, and in the way nurses are deployed in order to make the most of their valuable clinical skills (Health Workforce Australia 2014a, 2014b).

The nursing profession must also provide ongoing career development opportunities that capitalise on the profession's skills and expertise. Nursing roles with enhanced autonomy and decision-making have developed in response to increasingly complex healthcare needs. This has established a more flexible **nursing workforce**, with wide-ranging capabilities underpinned by robust regulatory frameworks, required to meet changing service requirements, new models of care and, more importantly, consumer expectations (Duffield et al 2011). The rapid uptake of the nurse practitioner role across Australia and New Zealand attests to identification by those at the front line of health service delivery that this nursing role is dynamic and improves the quality, timeliness and access to health care for under-served population groups, including minority groups and indigenous peoples (Middleton et al 2011).

In the current healthcare landscape, RNs need to be able to articulate their roles, describe the complexity of the care they provide and demonstrate how contemporary nursing practice contributes to quality patient outcomes. There is potential for serious quality and safety risks if there is an ongoing failure to recognise the overall value of nursing's contribution to health care.

• CRITICAL REFLECTION POINT

Why is it important for nurses to articulate their scope of practice?

Nursing defined

Registered nurses have acquired greater responsibility as autonomous and collaborative practitioners leading health and wellness programs, managing their own services and running their own nurse-led clinics. Many are at the forefront of developing innovative roles and services, acquiring new skills, conducting clinical research and finding new ways to improve health and wellbeing across Australia and New Zealand.

The International Council of Nurses (ICN 2014), which represents more than 16 million nurses worldwide, defines the role of the nurse from an international context as:

> **Encompassing autonomous and collaborative care of individuals of all ages, families, groups and communities, sick or well and in all settings. Nursing includes the promotion of health, prevention of illness, and the care of ill, disabled and dying people. Advocacy, promotion of a safe environment, research, participation in shaping health policy and in patient and health systems management, and education are also key nursing roles.**

At all stages of life, in situations of health, illness, injury and disability, RNs deliver direct healthcare services, coordinate care and support consumers in managing their own health (Nelson et al 2014). This highlights the unique position of the nursing profession to contribute to changes in the healthcare system by virtue of their combined professional and executive leadership, across a wide range of practice settings, including clinical practice, management, education and research (Talbert 2012).

While hospitals remain the major employers of nurses, increasingly there will be a shift from nursing at the hospital bedside to nursing at the patient's side, working in settings across the healthcare continuum. It is important that the nursing workforce is educationally prepared for an evolving context of practice across a range of healthcare environments, including those that have never been available before, including the adoption of technology-enabled care. There is also an expectation that RNs will continually develop their knowledge and professional practice in accordance with the health needs of the population.

The community trusts that nurses will act in the best interests of those in their care and that nurses will base that care on an assessment of the individual's specific needs (NMBA 2016).

Nurses have an evidence-based education that enables them to meet changing healthcare needs, working both on their own and in teams with other professionals along the entire continuum of health and illness. In addition, it is essential to increase the research capability of the RN, and to systematically evaluate nursing efficiency and effectiveness. Nurses must be involved in leadership and decision-making for health policy, for which preparation should begin on initial undergraduate education and continue throughout their career (Commission on the Future of Nursing and Midwifery 2010).

Nursing as a profession offers a diverse, fulfilling career pathway with high levels of responsibility and autonomy, and opportunities for personal and professional development. New stories of nursing need to be told, framed by a clear understanding of the profession told through the lived experience of the consumer.

Person-centred care

The healthcare system continually challenges nursing practice to adapt to the broader determinants of health, including social, physical, psychological, economic and political influences on society. The philosophies of the profession will never change, with the heart of the profession remaining committed to meeting basic human needs and advocating for the most vulnerable in society. Nurses are the healthcare professionals closest to people in all settings of society, and can have an enormous impact in terms of reducing healthcare costs, while improving health outcomes (ICN 2015). As a profession, we reach people that other practitioners never see, both in urban and rural and remote communities.

In the past, people were expected to fit in with the routines and practices that health services felt were most appropriate. But in order to offer more **person-centred care**, services must change to be more flexible to meet consumer needs in a manner that is best for them. This involves working with people and their families to find the best way to provide for their care needs through a partnership that allows them to make choices (Australian College of Nursing 2014).

Making sure that people are involved in and are central to their care is now recognised as a key component of developing high-quality healthcare and is central to providing holistic nursing care (Australian Commission on Safety and Quality in Health Care 2011).

• CRITICAL REFLECTION POINT

Think about an experience you have had as a patient accessing health care. Did the clinician listen to you, consider your needs and understand what was important to you?

Challenges facing the Australian and New Zealand health systems

The challenges that the health system is facing today and into the future are well known (Box 1-1). One particular focus has been on population ageing as a key driver of **health expenditure** (Productivity Commission 2015). One of the reasons for this is that healthcare expenditure is generally higher in the older age groups. The highest expenditure is generally spent in the last 6 months of life. In 2008–09, expenditure on adults aged over 85 was almost 20 times higher per person (AIHW 2014).

On the surface it could be assumed that if the number of people in this age group continues to grow, the demand for health expenditure will increase. However, ageing cannot be considered the sole contributor to expenditure growth (Figure 1-1). Over the past 25 years, health expenditure has risen at a faster rate than either population growth or ageing (AIHW 2014). Other components attributed to the increased health expenditure can be linked to non-demographic factors such as the development of new treatments including technologies, pharmaceuticals and improved techniques. These elements have enabled treatments that can be used for a wider range of health conditions. This in turn has led to greater community awareness and expectation. Growing consumer demand and healthcare utilisation are driving up health expenditure faster than demographic factors have predicted (AIHW 2014). Figure 1-1 shows that increases in health expenditures are not primarily driven by an ageing population, but by people of all ages using healthcare services more often (volume per case).

There is some concern about the extent to which the predicated growth in health expenditure is underestimated. It is likely that over time an **ageing population**, with higher levels of chronic disease, increased expectations and access to new technologies and services, will increase

BOX 1-1 Challenges facing the health system

- Decreasing available revenue and increased health expenditure
- Increased burden of disease
- Ageing population
- Increased demand for health services across all demographics
- Innovations in treatments and techniques
- Insufficient workforce.

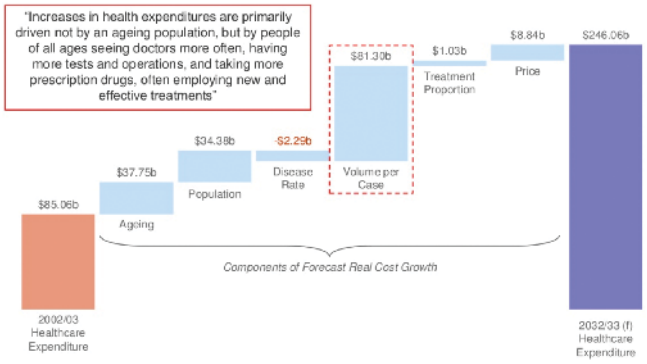

Figure 1-1 Contributors to growth in healthcare expenditure.

John Goss, AIHW.

and compound the independent effect of population ageing on the health system costs (AIHW 2014).

It is hard to deny the challenge that is set before the health system. But it is even harder to acknowledge and act on future challenges. The complex environment in which we live and work actively prevents us from dealing with the situation appropriately. For example, governments have previously identified various ways to improve the efficiency and effectiveness of the health system. However, this has often been stymied due to factors such as fractured political and funding responsibilities, poor design and implementation, inadequate resourcing or lack of political will.

Yet the challenges cannot be dismissed or ignored. In addition, we cannot expect that how we do things now will be effective in addressing them. As Albert Einstein stated: 'We cannot solve our problems with the same thinking we used when we created them'. The nursing workforce is pivotal in leading the health system to meet these challenges. Nursing needs to have a voice at the table in shaping the future of good health and healthcare provision. To achieve this, the nursing workforce must have a comprehensive understanding of the context of the health environment.

• CRITICAL REFLECTION POINT

Why is it important for nurses to understand the challenges facing the health system?

Australia's and New Zealand's health

Good health is at the core of human wellbeing, a prosperous society and good economic progress. The healthcare system is a critical component in ensuring and maintaining the health and wellbeing of populations. Health is seen as a precondition and an indicator for sustainable development. Countries that have good health have significantly higher economic development because the populations are generally more productive. In contrast, countries with poor health outcomes can find that this erodes economic growth (ICN 2015).

Australia and New Zealand spend a lot of money on the provision of health care. This money comes from numerous sources, such as taxes, insurance premiums and direct payments. This expenditure is rapidly growing. While the health system produces good outcomes in comparison to other countries around the world, there are still elements within it that are not performing as efficiently as they could be. This can be seen in areas such as wasteful spending, reduced access and substandard quality and safety outcomes (Productivity Commission 2015).

Australians and New Zealanders are among those with the highest life expectancies in the world. However, does this mean that we are healthy? Data demonstrates that mortality rates continue to decrease, meaning that people are living longer. But just as importantly, it demonstrates that people have been living with more years free from disability (AIHW 2014, Ministry of Health New Zealand 2016).

The highest causes of death are **chronic disease** rather than acute illness. This has completely changed from 100 years ago when acute illness was the predominant cause of death (Table 1-1). Chronic diseases, such as cardiovascular disease, diabetes and some cancers, are increasing as a result of changes to our lifestyles. Chronic disease has a profound effect not only on the individual and community, but also on the health system that seeks to resource and manage the illnesses (Table 1-2).

It is important to note that while we are living longer than previous generations, we are also living more years free of disability. A baby born in 2012 is expected to live 62.4 years free of disability and 17.5 years with some form of disability. Compare this with a child born in 1998 where they could expect to live 58 years free of disability and 17.9 years with some form of disability (Commonwealth Fund 2015). These changes have occurred as a result of improved sanitation and housing and the availability of vaccines to help our fight against infectious disease. We also enjoy one of the best health systems in the world with access to increasingly innovative and sophisticated health care, including improved detection, diagnosis and treatments that were not available to previous generations.

While it is clear that we are not as healthy as we could be, Australians and New Zealanders still have some of the highest life expectancies in the world. But

TABLE 1-1 Top five causes of death, 1907 and 2000

1907		2000	
Organic heart disease	8.3%	Ischaemic heart disease	21%
Tuberculosis	8.2%	Cerebrovascular disease	7.4%
Diarrhoea	7.1%	Lung cancer	6.9%
Senility	6.6%	Other heart disease	4.9%
Congenital	6.1%	Chronic obstructive pulmonary disease	4.7%

Australian Institute of Health and Welfare (AIHW) 2006 Mortality over the twentieth century in Australia: trends and patterns in major causes of death. AIHW. Canberra.

TABLE 1-2 Chronic disease in Australia and New Zealand

Condition	Australia	New Zealand
Diabetes mellitus	1 in 19	1 in 16
Cardiovascular disease	1 in 5	1 in 5
Cancer – risk of being diagnosed before the age of 85	1 in 2 (male) 1 in 3 (female)	not reported
Chronic kidney disease	1 in 10	1 in 10
Mental illness – adult	1 in 5	1 in 6
Musculoskeletal conditions	1 in 4	1 in 4
Untreated oral health conditions (adult)	3 in 10	1 in 3
Respiratory disease	1 in 10	1 in 7

ABS 2013 Australian Health Survey: Updated Results 2011–2012. Cat no. 4364.0.55.003; Ministry of Health 2015 Health of New Zealanders data and stats.

this life expectancy is not enjoyed by all population groups within these two countries. There continue to be inequalities in health among Indigenous communities where there are significant health disparities, particularly life expectancy (OECD 2014). In addition, people living in lower socioeconomic areas tend to experience increased health risk factors compared with others with the same nationality (OECD 2014).

Access to health services is a growing problem in Australia and New Zealand. Over the past decade an increased demand for elective surgery has been observed. The capacity of the health system to respond to this is limited by funding and workforce availability. It is essential that those with the greatest need will receive quality care in a timely and effective manner.

• CRITICAL REFLECTION POINT

What does it mean to measure the health of a nation? How can nursing influence the health of a nation? How might the burden of chronic disease influence the role of nursing into the future?

The growing cost of health care

A vast amount of funding is spent on health care. In New Zealand, 9.5% of Gross Domestic Product (GDP) is spent on health, while Australia spends 8.8% of its GDP on health (OECD 2015). What is concerning is that healthcare costs continue to grow faster than the broader economy. The Australian Government (Commonwealth of Australia 2010), for example, estimate that GDP will need to more than double within the next 40 years *in order to meet healthcare costs*. This has significant impact on funding for other services such as transport, education and defence. Governments all over the world are realising that the way health care is provided now is unsustainable. Something has to change. There is greater emphasis on the need to become both more productive and more efficient with the resources available.

The future of the workforce

One of the biggest areas of health expenditure is labour costs. This comes at a time when the workforce required to support future health needs is becoming smaller and smaller. The *Australia to 2050* report (Commonwealth of Australia 2010) states that in 2010 for every retiree there were five people working. By 2031, it is expected there will be three people working for every retiree. These projected workforce changes will have a dramatic effect on how health services deliver care to patients. The workforce will simply not be there to provide care in the way it does today.

Addressing challenges through health reform

Internationally there is a rapidly growing focus on providing more effective and efficient health care leading to greater value for money to meet future challenges such as the growing burden of chronic disease and rising costs. As the population of today is living longer and making lifestyle choices that contribute to the growing burden of chronic disease, this results in increased ongoing care and management. In Australia, for example, it is estimated that chronic disease accounts for 83% of all premature deaths and causes 80% of hospitalisations and allocated expenditure (AIHW 2014).

There is a growing emphasis on health reform as the way to improve productivity and efficiency. Previously, health reform was seen as intermittent and gradual. Reform is now considered a constant and continual experience. It should no longer be considered as a surprise but rather expected. According to the Institute for Healthcare Improvement (2015), the aim of any health reform should be based on these three elements:

- Reduce costs – reducing the per capita cost of health care.
- Enhance patient experience – improving the patient experience of care (including quality and satisfaction).
- Improved health outcomes – improving the health of populations.

Nursing's contribution to these three elements is greater than any other health profession. The nursing workforce is the single largest clinical workforce with the most direct clinical care time. Nurses continue to provide care with resilience and versatility, while often with minimal resources and organisational support. Nursing can be, as the International Council of Nurses (ICN 2015) states, 'a force for change'.

Unfortunately, reform may have short-term goals, including immediate funding reductions. As the largest workforce and, therefore, the highest cost burden, the nursing workforce is often cut, leaving fewer people to do more work. Research shows that RN staffing levels have direct implications for patient care. It demonstrates that hospitals with a higher ratio of degree-prepared RNs-to-patients have lower mortality rates (Aiken et al 2014). Hospitals with lower RN staffing numbers are linked to an increased number of adverse events including falls and medication errors (Duffield et al 2014). As a result, the aims of healthcare reform are not realised.

The escalating costs of health care require that measures be taken to contain costs to levels that countries can afford and sustain. These pressures highlight the need for how resources in health care, particularly nursing, can be used to their optimal level. When the nursing profession is optimised, evidence demonstrates that the quality of health service provision improves. When the quality of services improve, resources are often used more efficiently. For example, an optimised and appropriately resourced nursing workforce is linked to reduced adverse events (as mentioned above), improved health literacy of patients, reduced length of stay, decreased readmission rates, improved hospital avoidance and better patient outcomes (Aitken 2014). As such, the three aims of health reform can be achieved.

• CRITICAL REFLECTION POINT

Why would supporting RNs to work to their full scope of practice create a more efficient health system? How important is health literacy to the future of healthcare provision and how can nursing contribute to improving health literacy?

Nursing leadership and healthcare reform

The nursing profession is uniquely placed to lead **healthcare reform**. Nurses have close interaction with patients and their families in all health settings across the health continuum. They can help interpret and understand people's needs and expectations for health care. They are actively involved in decision-making within the clinical team and in management. They do this with a foundation of care informed by research and evidence. This understanding, experience and proximity to the patients' needs are critical components of what nursing can bring to the table and how it can enable reform.

As such, nurses have an important contribution to make in health service planning, management and policy setting. Nurses must contribute to public policy development through management and leadership roles at all levels and with direct engagement with their professional organisations. To achieve this level of responsibility, it cannot be assumed that it will automatically be provided to the profession. Historically, in many instances, nurses have been left out of the decision-making process and have been left with implementing an initiative or policy that has not been well informed. The role of the profession therefore must be proactive to maintain this level of influence and involvement.

Just as important as the planning and policy setting, nurses need to be leaders in healthcare management. The International Council of Nurses (2015) asserts that nursing services must be directly managed by nurses. The reason for this is that the profession must be responsible for the professional practice of nursing. No profession outside of nursing is well positioned enough to be held to account and to lead the scope of practice and the standards for practice of the RN.

• CRITICAL REFLECTION POINT

Think about a recent health issue discussed in the news. Did nursing have a voice? How do you think nurses can promote their stories, insights, research and expert opinions via social media?

Regulation of the nursing profession

The Nursing and Midwifery Board of Australia (NMBA) and Nursing Council of New Zealand are responsible for **professional regulation** and setting standards, codes and guidelines for the nursing and midwifery professions (Box 1-2). The role of professional colleges and associations in developing specific standards for practice and credentialling individual nurses is increasing. RNs are individually accountable for their own practice and have a personal responsibility to maintain their competency and meet professional standards in order to maintain their licence to practise. The role of the RN has evolved along with changes in advancing technology, newly defined patient needs and changes to the way health care is delivered. In this way, it is not unreasonable to expect that the role of the RN will continue to evolve and change. It is

BOX 1-2 Regulation of the nursing profession

The Nursing and Midwifery Board of Australia

The Nursing and Midwifery Board of Australia regulates the practice of nurses and midwives in Australia. One of its key roles is to protect the public by making sure that only nurses and/or midwives who are suitably qualified to practise in a competent and ethical manner are registered. The National Board sets registration standards as well as professional codes, standards and guidelines that underpin safe and competent practice. All applicants for nursing and/or midwifery registration must meet a range of requirements to become eligible for registration. Registration standards define the requirements that applicants for registration or renewal of registration need to meet to be registered.

The Nursing Council of New Zealand

The Nursing Council of New Zealand is the regulatory authority responsible for the registration of nurses. Its primary function is to protect the health and safety of members of the public by ensuring that nurses are competent and fit to practise.

The Nursing Council sets standards for nursing in New Zealand. These standards are applied to:

- all education programs in New Zealand
- nurses working in New Zealand
- overseas trained nurses who wish to work in New Zealand.

Any person who wishes to nurse in New Zealand must first meet these standards in order to become a nurse and then continue to maintain requirements to demonstrate they are competent and fit to practise nursing.

Nursing and Midwifery Board of Australia (NMBA) 2016 Registered Nurse standards for practice. NMBA, Melbourne. Online. Available: www.nursingmidwiferyboard.gov.au/Codes-Guidelines-Statements/Professional-standards.aspx; Nursing Council of New Zealand 2007 Competencies for registered nurses: regulating nursing practice to protect public safety.

important that RNs, consumers and employers understand that nursing practice has a rigorous safety and quality framework that is regulated, endorsed and monitored by professional bodies. This regulatory framework ensures high standards of care.

Decision-making framework

Decision-making within a sound risk management, professional, regulatory and legislative framework is a considered and rational process that enables nurses to work to their full potential and scope of practice (NMBA 2007). The *National decision-making framework* (NMBA 2007) provides guidance and support to the nursing profession. Use of the framework enables RNs' scope of practice to be extended and expanded safely. Broadly, the RN is responsible for assessing, planning, implementing, directing, supervising and evaluating direct and indirect nursing care. This includes providing actual nursing care, supervising enrolled nurses and unregulated carers, and taking ownership of their own delegation decisions.

Scope of practice

A profession's **scope of practice** is the full spectrum of roles, functions, responsibilities, activities and decision-making capacity that individuals within that profession are educated, competent and authorised to perform, and is determined by the profession itself (NMBA 2007). Registered nurses practising to their full potential have the ability to transform services and care delivery and enable clients to meet their health and wellness needs. It is important that RNs understand the role they have in the delivery of health services – this is fundamental to quality health care.

Individual nurses may have specific capabilities that are influenced by factors (ANMC 2009), such as:

- practice context
- wider environment
- legislation
- health service policy
- education level
- standards
- health needs of the population.

These are not defined in the scope of practice of their profession, but rather by the level of education and experience of the individual nurse. Decisions about both the individual's and the profession's practice can be guided by the use of the *National decision-making framework* (NMBA 2007).

While legislation, standards and other regulatory controls determine the overall scope of practice and the boundaries for registered nurses, other factors, such as organisational arrangements, influence the practice of the individual RN, including:

- health needs of the client
- context of practice, including clinical governance arrangements
- capability – based on education level of the individual
- clinical knowledge, research and evidence-based practice.

Optimising the RN contribution to health is not solely related to the incorporation of a particular skill or activity, but to the complex interplay of professional attributes, experience, learning, scientific knowledge and critical

thinking. It is also affected by elements across the context of practice and the degree to which those elements are supportive of the nursing scope of practice.

Certain factors on the **practice pathway** can enable or restrict the RN in performing to their full scope of practice. In order to maximise the efficiency and effectiveness of health service, enablers need to be strengthened and barriers challenged or removed. Highlighting how these factors can shape an RN's contribution to health provides opportunities to optimise their contribution. A range of these factors are detailed in Figure 1-2.

Continuing education and professional development

Continuing education and **professional development** are the keys to the RN's contribution to health and development of their professional pathway throughout their career. Experience in the absence of ongoing education, professional development, governance and support will not develop reflective practice that increases the individual's capability. Each step in the RN practice pathway builds on previous education, experience and the development of practice knowledge, competence and confidence in practice. The RN is expected to undertake postgraduate university programs as part of advancement and development of their practice. The initial education program for entry to practice that an RN must complete is designed to develop assessment and problem-solving skills and enable the graduate nurse to manage resources to deliver complex physical, psychological and behavioural care in a lawful and ethical manner. RNs are required to contribute to education and research, practise nursing that is underpinned by theory and continually develop practice through translation of evidence into clinical practice. One theory that has been widely adopted is Benner's practice pathway. Benner (1984) proposed that nursing knowledge develops through research and integration into clinical practice and experience. Importantly, experience is not a time-based activity, but can only develop in the context of education and knowledge acquisition. Characteristics acquired throughout the RN professional career contribute towards a sustainable profession through:

- role modelling
- clinical leadership
- mentoring and coaching
- supervision
- teaching
- research.

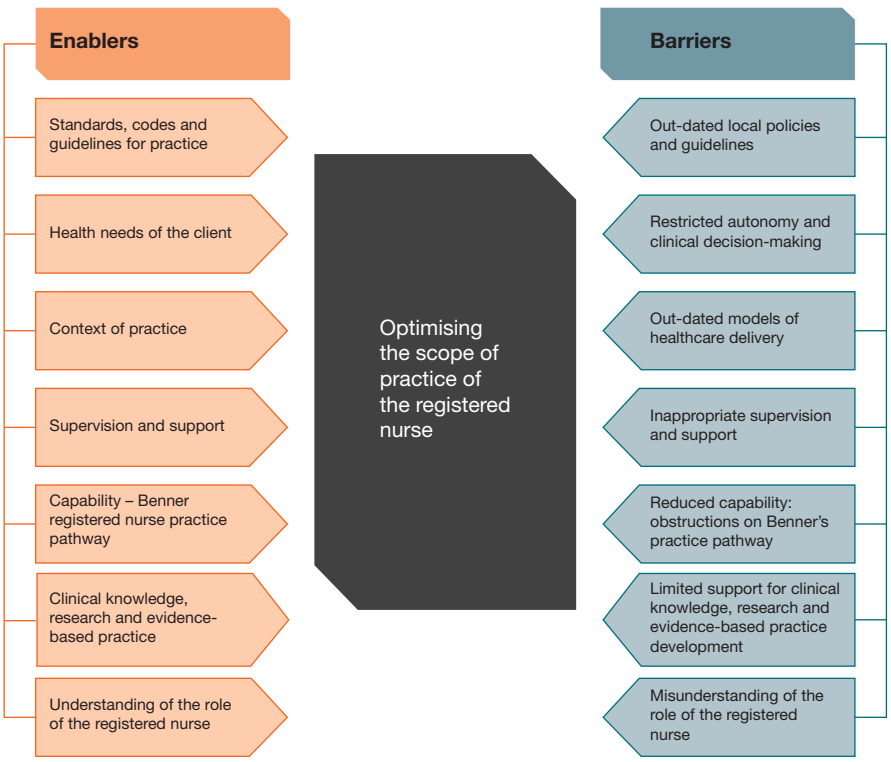

Figure 1-2 Barriers and enablers to nursing practice.

Queensland Health 2013 Registered nurse professional practice in Queensland: Guidance for practitioners, employers and consumers. Brisbane.

For the purpose of this chapter, increasing capability of the RN will be aligned to Benner's novice to expert model. Benner's model describes five levels of nursing capability and capacity and states that nursing skills increase and develop over time, depending on experience and education (Box 1-3).

BOX 1-3 Benner's novice to expert model

Novice – a beginner with no experience, behaviour is rule-governed, limited and inflexible.

Advanced beginner – has gained prior experience in actual situations and is able to recognise recurring meaningful components. Principles based on experiences begin to be formulated to guide actions.

Competent – plans own actions based on analytic thinking, achieves efficiency and organisation.

Proficient – holistic decision-making, able to modify plans based on learning from experience.

Expert – intuitive knowing in clinical situations with flexible, highly proficient performance.

Pathway to optimised practice

Drawing on the Australian qualification framework (Australian Qualification Framework Council 2013), Benner's model and contextual enablers and barriers to practice, Figure 1-3 represents an idealised pathway through which the optimisation of nursing will be achieved. Optimised practice can be achieved at each progression point through Benner's practice pathway. The novice, advanced beginner, competent, proficient and expert RN are able to optimise their practice, regardless of whether they intend to continue along the practice pathway, or if they are professionally and personally content with their current role.

Figure 1-3 details that the role the RN assumes will depend on their initial nursing qualification for initial registration (for clarity Figure 1-3 does not reflect entry to practise Masters level qualifications), specialised postgraduate education qualifications, informal training and clinical experiences. Following initial registration, the novice is able to focus on continued professional development and postgraduate qualifications relevant to identified areas of specialisation and/or contexts of practice. Additional education and experience builds

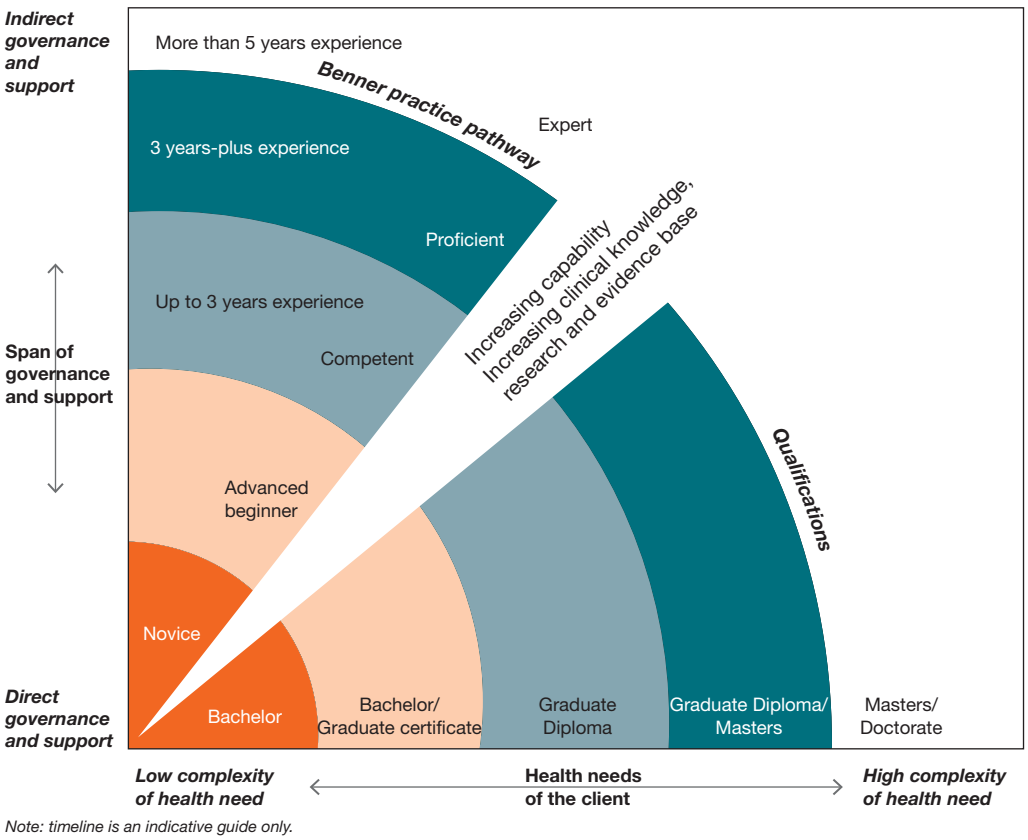

Figure 1-3 Pathway to optimised practice.

Queensland Health 2013 Registered nurse professional practice in Queensland: Guidance for practitioners, employers and consumers. Brisbane.

greater competency, so eventually the novice becomes the advanced beginner, who in turn moves through being competent to proficient and finally to expert. At the expert level, the RN is able to provide care to patients with complex health needs and requires only indirect governance and support.

Throughout the journey across the practice pathway, the RN is protected by significant safety and quality frameworks, which are themselves underpinned by evolving legislation, registration standards, professional practice standards and policies that align with best practice and evidence.

The future of nursing: leading change

Through the effective use of the professional and regulatory frameworks, informed through postgraduate education and relevant experience, RNs can lead service transformation. Possible examples of new ways of working and new models of care may include:

- nurse proceduralists undertaking new diagnostic functions, such as endoscopy
- nurse-led clinics delivering integrated care to palliative care patients
- nurse triage models to streamline referral pathways into outpatient and specialist services
- public–private partnerships for nurse practitioners, including admission privileges, that enhance consumer choice
- RNs working in sustainable and economically viable self-employment models focused on community chronic disease management
- brokerage and community case management for disability clients through the National Disability Insurance Scheme (NDIS)
- nurses delivering care and ongoing management to rural and remote patients through outreach services delivered through use of technology and Telehealth
- expanded access to diagnostics and medicines to improve the patient journey and deliver services closer to a patient's home.

• CRITICAL REFLECTION POINT

In thinking about the future directions of nursing practice, what are the capabilities you will need for success in new work environments that are constantly evolving?

Conclusion

We live in a dynamic and exciting time in the history of nursing and health care. We have an insatiable appetite for safe, accessible, affordable and quality healthcare services. The demand for professional care provided by nurses has never been greater. RNs across Australia and New Zealand are stepping up and meeting the challenges their environments are providing. They are delivering person-centred care in diverse models and settings across the continuum from primary to tertiary care. We have the safety and regulatory mechanisms that surround us to ensure we practise to our scope and can be responsive. The challenge is to maintain our ability to be responsive to our communities and be confident and resilient in an ever-changing environment. Ensuring we work to our full scope, underpinned by ongoing postgraduate education, is not only the answer to new models of care, but also to the professional and personal satisfaction of us as nurses. Nursing leadership at all levels of the healthcare system is essential to secure better health and wellbeing for our nations.

Key concepts

- Nursing practice is evolving in response to social, economic and political factors and changing population health needs. These drivers help to shape the context in which the RN practises and delivers care.
- Healthcare costs are growing at an unsustainable rate. An efficient and effective healthcare system that reduces wastage is critical to ensuring population health and wellbeing.
- Health reform is continuous and will create more opportunities for nurses to work in new models of healthcare delivery that provide quality health services to individuals, families and communities.
- Nurses are the largest group of health professionals in the health system. A proactive and dynamic nursing profession is pivotal to future healthcare provision.
- It is important that nurses are educationally prepared for an evolving context of practice across a range of healthcare environments, including those that have never been available before as a result of innovation and technology.
- Registered nurses must be supported to work to their full regulated scope of practice in order to maximise the efficiency and effectiveness of the nursing workforce.
- Nurses working to their full potential will result in personal, professional and career satisfaction, as well as ensuring the delivery of safe, quality patient outcomes.
- It is important to recognise and reinforce the important contribution of the nursing profession at all levels of the healthcare system, including direct clinical care, coordinating complex patient care, driving safety and quality, policy and systems management, research, education and executive leadership.

Online resources

Australian College of Nursing 2015 White Paper: Nurse Leadership, www.acn.edu.au/sites/default/files/leadership/ACN_Nurse_Leadership_White_Paper_FINAL.pdf

This White Paper outlines the relevance of nurse leadership within the healthcare system and highlights the connection between nurse leadership, workplace environment, staff retention and patient outcomes. It describes the challenges that exist when driving the necessary change within healthcare systems and organisations and the need to recognise the contribution that nurse leaders can make.

Nelson et al 2014 Optimising Scopes of Practice, New models of care for a new health system. Canadian Academy of Health Sciences, Ontario, cahs-acss.ca/optimizing-scopes-of-practice-new-models-of-care-for-a-new-health-care-system/

This international publication highlights that a healthcare system must be built upon collaborative care models, where the right professional provides the highest quality of care in the right setting and at the right time based upon the needs of the individual patient. Optimal scopes of practice are described as an essential element in leading healthcare transformation for the future.

CHAPTER

2

Building nursing practice: the Fundamentals of Care Framework

Tiffany Conroy, Rebecca Feo, Jan Alderman and Alison Kitson

Learning outcomes

Mastery of the content will enable you to:

- use the Fundamentals of Care Practice Process to deliver person-centred nursing care
- recognise and understand perceptions of nursing held by you and others
- identify and use concepts, working hypotheses, frameworks and theories to inform the delivery of your nursing care
- think creatively about nursing and providing person-centred care
- access a range of theories.

KEY TERMS

Biomedical model, p. 26
Biopsychosocial model, p. 27
Concepts, p. 16
Conceptual framework, p. 16
Context of care, p. 20
Fundamentals of Care Framework, p. 17
Fundamentals of Care Practice Process, p. 17
Relationship, p. 19
Tacit knowledge, p. 16
Theories, p. 17
Working hypothesis, p. 17

Introduction

Each individual's understanding of nursing comes from personal experiences; from the way they reflect on, make sense of and learn from those experiences; from how nursing is perceived by society; and from how it is viewed politically. The way we respond to and organise all of this information helps us to generate theories or ways of thinking about nursing. The purpose of this chapter is to help beginning nurses through each step of this process – recognising and understanding their perceptions of nursing and then using concepts, working hypotheses, frameworks and theories to inform the delivery of nursing care. This chapter will help you understand how to use your everyday clinical experiences, how to access the range of theories you need to draw from, and explain why you need to think creatively about nursing and providing person-centred care. The Fundamentals of Care Framework (described in more detail on p. 19) is the intersection of concepts, working hypotheses and theories and enables you to deliver care in a holistic manner.

The Fundamentals of Care Practice Process: concepts, working hypotheses, frameworks and theories

When you decided to become a nurse you might have assumed that you would need to develop a range of intellectual and practical clinical skills to provide care. However, you may not have given much consideration to the basis for those skills: how we decide what is needed for our patients, how we choose the correct care interventions for them, and how we use our skills to deliver these interventions. Applying these skills in practice relies on identifying our concepts about a patient's needs and understanding how these concepts can be used to develop our working hypothesis about what is needed for the patient. It relies on the framework we employ to ensure all of the patient's needs are addressed, and on the theories we use to inform the delivery of care. Each of these elements is discussed in detail below.

Concepts

Concepts are general ideas or things we use to help us organise and make sense of the world. Concepts can be linked to real things in the world (e.g. our concept of a dog), or they can reflect abstract ideas (e.g. the concept of free-will or empowerment). A fact is a concept whose truth can be proved. Values and beliefs are the things that shape how we judge the world and how we judge the merits and demerits of concepts. We use our experiences of the world to refine our notions of the concepts around us. Our experiences can generate new knowledge. Formal knowledge is what we learn in a structured way (e.g. knowing how to read or do mathematics). Other knowledge is more hidden. This is called informal or **tacit knowledge**. It comes from our ability to experience and observe the world around us and to reflect on whether it is making sense to us (Kothari et al 2012).

There are three different ways that our use of concepts influences the approach that we might consider when we are presented with a patient requiring care: ideas/opinions, facts and tacit knowledge. First, based on our initial contact with the patient, we might form some ideas or opinions about what is wrong with them. These beliefs are determined by our own personal assumptions and, at this point, have not been tested or proven; they are still ideas. Second, we can determine if there is some factual information or evidence based on what we can see or what we already know about the patient. These facts are not open to interpretation but are based on evidence. Third, we might have had previous experience with a similar issue. This experience might have been in our personal or professional capacity. For example, if you have had previous experience of a condition, either personally or with a close family member, you might have a different understanding of a patient's needs than someone who has not had such an experience. This type of concept is called tacit knowledge and it covers emotional, experiential, intuitive and observational ways of knowing. We may not have all three types of concepts for every patient presentation. However, when we combine the concepts that are available to us to inform our understanding of the situation, we begin to develop a working hypothesis about what is needed for our patient.

Working hypothesis

Our working hypothesis is our determination or informed guess about the patient's problem(s), which we will use to establish the priority of care for the patient. Our working hypothesis is derived from the meaningful integration of the information obtained from our different concepts. For each patient presentation you are likely to develop multiple working hypotheses. It is your job to determine the most important or pressing priority and address that first before addressing the other problems you have identified. Your working hypothesis may evolve as your interaction with the patient progresses.

Conceptual frameworks

When providing care to a patient, a **conceptual framework** provides an integrated way of looking at the

patient's problem (your **working hypothesis**) and helps to ensure that care is provided in a holistic and person-centred manner. A conceptual framework brings together a range of related concepts (e.g. ideas/opinions, facts and tacit knowledge) to provide a broad understanding of a particular phenomenon or to guide research (Green 2014). Its aim is to synthesise concepts drawn from many sources and to demonstrate the relationships between them.

Unlike theories, conceptual frameworks do not provide causal explanations or make predictions about events or phenomena (Jarabeen 2009). Instead, they help us to map the main concepts around a particular phenomenon and to understand how those concepts relate to one another. In this way, a conceptual framework helps to provide some meaning to our many different concepts.

The **Fundamentals of Care Framework** (Kitson et al 2013a) is an example of a conceptual framework. It illustrates the need to establish a trusting relationship with the patient and to integrate and address a patient's physical, psychosocial and relational needs that are associated with any nursing care provision. The framework is also the intersection point for the application of theories to your working hypothesis.

Theories

Theories offer explanations for why things happen in a particular way. The purpose of theory is to provide nurses with a perspective for viewing patient situations in ways that help them work out what to do and why. We therefore use theories to understand, to innovate, to solve problems, and to aid our critical thinking. Theories find their way into practice through the use of frameworks such as the Fundamentals of Care Framework. They provide meaningful information that helps us to apply frameworks in practice. Multiple theories can inform a single framework. For example, when we are providing fundamental care to a child, we might be influenced by Piaget's developmental theory as well as Bowlby's attachment theory (Pallini & Barcaccia 2014).

A conceptual framework provides the intersection for these different theories; it is where the theories come together and inform how we use the concepts in our framework. We might also find in our nursing practice the need to 'pick and mix' from various theories, depending on our patient population and care environment. In addition to nursing-specific theories, nursing also uses theories from a range of disciplines. Some disciplines we borrow from include psychology, microbiology, medicine and public health. In using theories we incorporate relevant theoretical knowledge as an explanation for what is happening to our patient and why.

• CRITICAL REFLECTION POINT

Which nursing theories are you aware of? The Nursing Theory website provides a useful resource (see *Online resources* at the end of this chapter). Here you can find an overview of many nursing theories and which theories are linked to which areas of nursing practice. You will notice that some theories apply in many areas of practice. Choose two of these and explain why this is the case.

So how do we move from concepts, working hypotheses, conceptual frameworks and theories to delivering care in practice? The Fundamentals of Care Practice Process (described in detail on p. 23) illustrates this process. We begin by identifying our concepts (ideas, facts and tacit knowledge) and integrating them to create our working hypotheses. Once these hypotheses have been created, we can then begin thinking about how we might address the problems we have identified. In doing so, we consider the Fundamentals of Care Framework and what this tells us about how we should best deliver care. We also need to identify what theories are relevant to help us address our working hypotheses in a person-centred manner. That is, we must identify which theories inform the delivery of the fundamentals of care specific to our patient's problem. Once we have considered our working hypotheses in the context of the Fundamentals of Care Framework and relevant theories, we can continue with the clinical reasoning process.

It is important to note that moving from concepts to theories and then to practice is not a once-only activity for each patient. The process is dynamic and recurring; you will likely identify multiple working hypotheses for patients and will need to evaluate the outcome of your care interventions to determine whether your working hypotheses were correct. New concepts will also arise while caring for a patient, which you will need to address by going through the **Fundamentals of Care Practice Process**. Importantly, in using the Fundamentals of Care Practice Process you will develop the skills of critical reflection and evaluation of the impact your actions have had on your patient – both intended and unintended consequences. We explain each part of the process in more detail using an example.

The *Clinical example* below illustrates how nurses are faced with seemingly straightforward tasks, but hidden behind these are multiple levels of complexity. In this scenario the student will have to draw on their previous experience and knowledge.

CLINICAL EXAMPLE

You are a first-year student nurse and your first academic assignment is to conduct a psychosocial health assessment on a patient. Your instructions are to gain permission from the patient or resident and use a range of interviewing skills to gain the information required to complete the assignment. You choose a male patient, 'Barry', who has recently been admitted to the Spinal Unit of your hospital. The patient is 59 years of age and sustained a spinal injury when he was 21 years old, which resulted in paraplegia. His current admission is for traction and pain management of his cervical spine.

You approach the registered nurse (RN) in charge of the ward and tell them about your assignment. The RN reads the assignment instructions and decides that you do not have sufficient experience to deal with the potentially traumatic nature of this encounter. The RN is especially concerned about the questions relating to the patient's mental health, stating that most of the patients on the ward are depressed and that an interview of this nature will just upset them.

Following a discussion between the RN and your clinical tutor/supervisor, it is agreed that you can stay in the unit and engage in conversation with the patient; however, you are not able to specifically administer the assessment. You are given permission to care for Barry.

• CRITICAL REFLECTION POINT

1. **You decide to initiate a conversation with Barry while helping him with his breakfast because you are interested in building a picture of what Barry's life is like outside the hospital environment. What questions would you ask to elicit this information?**
2. **How would you know that you have established rapport with Barry?**
3. **Consider how you might interpret and validate the information that Barry has supplied.**
4. **Why do you think it is important for you as Barry's nurse to know about his psychosocial wellbeing?**

While assisting Barry to eat his breakfast you are able to build a rapport, which provides you with the information required to describe his general characteristics. You discover he was born in regional South Australia (Whyalla) to Australian-born parents. He finished high school but has been on a disability pension since his motor vehicle accident (MVA), which happened when he was 21 years old. He has never had paid work. You validate this data by reading his case notes. You also notice that he does not eat much or show much interest in watching TV or reading books/magazines. He also seems to sleep a lot.

• CRITICAL REFLECTION POINT

1. **Think about the different concepts you might have available to you.**
   - **Ideas and opinions (What do I think?): What assumptions could you make about Barry's psychosocial health status?**
   - **Facts (What do I know and what can I see?): Consider the information you have obtained by talking to Barry.**
   - **Tacit knowledge (Is this scenario familiar to me?): How will your personal experiences or beliefs help you to develop working hypotheses about Barry's current health status?**

Let's review Barry's case and use the Fundamentals of Care Practice Process to help link theories to practice and determine his fundamental care needs.

Concepts and working hypothesis

Concepts: First, what are our ideas about this patient? We might assume he is feeling sad and helpless in his situation. What are the facts? We know he is injured with lifelong consequences, and he seems reluctant

WORKING WITH DIVERSITY

When working with people with a spinal cord injury you may find yourself thinking about how they view their quality of life (QoL). The notion that living with a disability equals a lower QoL is a common assumption. However, many people with serious disabilities report that they experience good QoL. It is important to remember that QoL is a subjective experience and one that is strongly influenced by economic, social and cultural differences. It is influenced by personal choices, and also by the cultural environment in which people are raised and live. Employment opportunities, participation and economic circumstances all play an important role in the QoL for patients with spinal cord injuries.

Implications for practice:

- Recognise that your view of QoL will not necessarily be the same as your patient's.
- Reflect on the three types of concepts in Figure 2-1. Your working hypothesis, that is, your ideas/opinions, tacit knowledge and the facts you have about living with a spinal cord injury, need to be explored when you are establishing the relationship with your patient.
- QoL is subjective and the patient's perspective must be considered the true measure of their QoL.
- Providing meaningful opportunities for employment and participation will assist patients with a spinal cord injury to maintain their QoL.

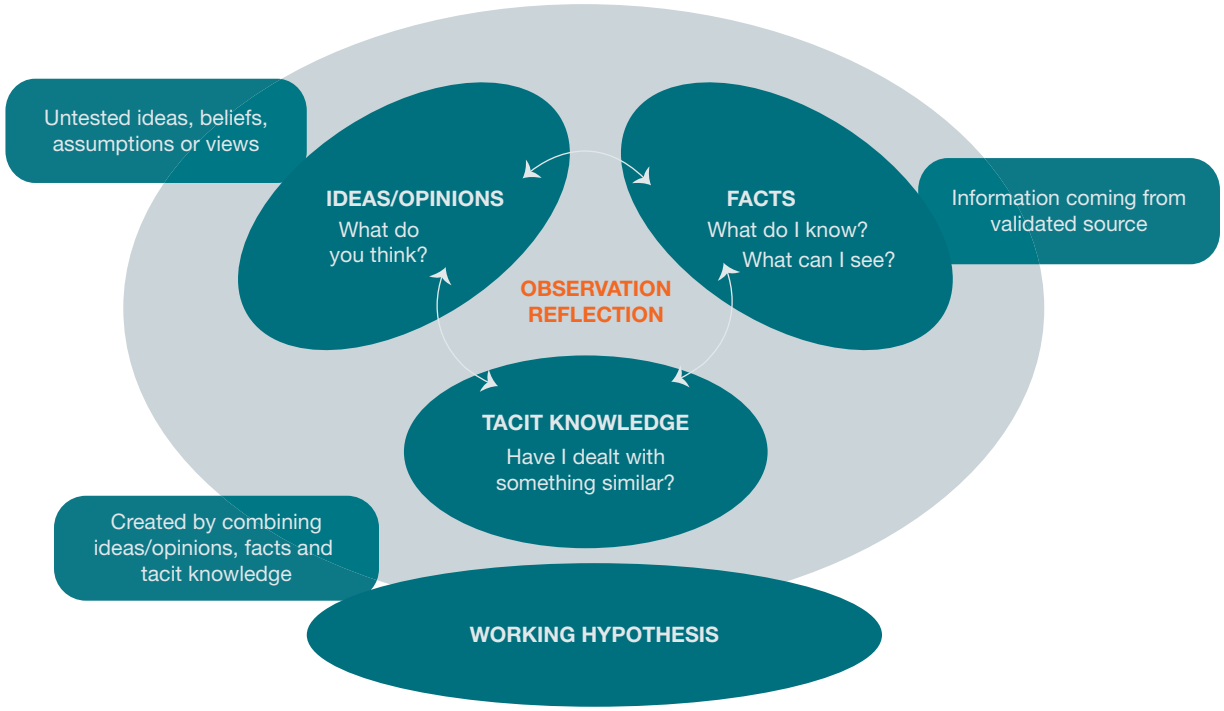

Figure 2-1 **Concepts and working hypothesis.**

to engage with staff and visitors. What is our tacit knowledge? Do we have any experience in this area? We might have known other people who have had similar experiences and have shared their feelings and thoughts with us (Figure 2-1).

Working hypothesis: Putting together our concepts, what could be our guess about what the patient's problem is? For Barry there could be many working hypotheses, from unresolved pain to depression, to lack of motivation.

These hypotheses are a vital part of the Fundamentals of Care Practice Process. Another important part of the process is the Fundamentals of Care Framework.

The Fundamentals of Care Framework

The Fundamentals of Care Framework assists the nurse to connect with the patient and help them meet their fundamental care needs. It focuses on enabling the patient and the nurse to confidently and competently assess, plan, implement and evaluate care around the fundamental care needs. As can be seen in Figure 2-2, the framework consists of three dimensions: 1) establishing the **relationship** with the patient; 2) being able to integrate and address the patient's fundamental care needs; and 3) a commitment from the wider health system to be responsive to these core tasks. Effective nursing care is achieved by aligning these

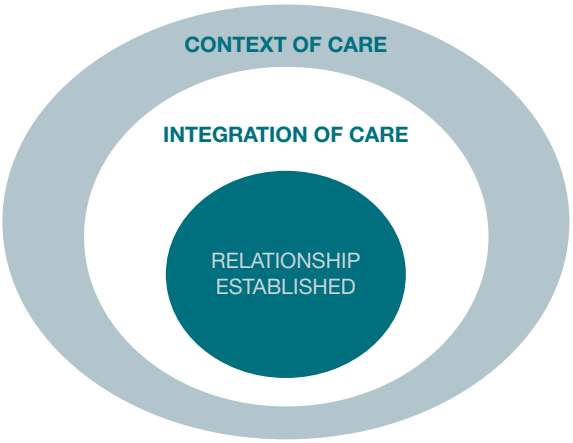

Figure 2-2 **The three dimensions of the Fundamentals of Care Framework.**

three elements. The dimensions of the Fundamentals of Care Framework revolve around the nurse, the patient, the family and the health system or context. The fundamentals of care are multidimensional and are determined by the relationship between the care provider (the nurse) and the recipient of that care (the patient) as conducted within each care encounter.

As you can see in Figure 2-2, the relationship is the central or core component of the framework. This must be successfully established before any of the other elements in the framework can be addressed. Establishing a positive

relationship with a patient is based on a commitment by you as the nurse to care for the patient (Kitson et al 2013a). There are five elements that help you establish a positive relationship with a patient: 1) developing a *trusting* relationship with the patient; 2) *focusing* on them and giving them your undivided attention; 3) *anticipating* their needs or concerns; 4) *knowing* enough about them to act appropriately; and 5) *evaluating* the quality of the relationship (Kitson et al 2013a). These five elements are involved in a process: the relationship begins when trust is established – as the nurse you need to be trustworthy and trusting. This trusting relationship then guides your actions and interactions with the patient (Figure 2-3).

Once you have established trust, you need to actively focus on the patient (and their family), and anticipate their needs so that they feel safe and free from anxiety and distress. Only when a patient is feeling calm and secure can you get to know them and their unique issues, and use this information to act appropriately and set patient goals. The final step in the process is evaluating the actions and experiences that have occurred within the relationship to determine its quality. Much like the Fundamentals of Care Practice Process, establishing a relationship with a patient is not a once-and-for-all process; it is dynamic and constantly changing. Once trust is established it will not be maintained unless you keep engaging in interactions that continually build and reinforce that trust. Likewise, you need to keep focusing on the patient and anticipating their needs at different times throughout the care encounter and continually evaluate the quality and outcome of the relationship.

The next dimension of the framework after establishing the relationship (and demonstrated by the second circle in Figure 2-4) focuses on the way the nurse addresses the patient's fundamental care needs, such as nutrition, hydration and elimination. An activity that has been routinely and independently undertaken by a person in their lifetime (e.g. bathing or going to the toilet) may, in an instant, become something that is both challenging and embarrassing. This needs to be acknowledged by the nurse and the organisation where care is being provided. Therefore, each time you address a person's fundamental care needs, there is a range of physical, psychosocial and relational needs that must be addressed for a positive patient experience to occur (Kitson & Muntlin Athlin 2013). Delivering fundamental care around hygiene, for example, involves not only keeping the patient clean, but also keeping them calm, involved, dignified and respected. This dimension of the framework incorporates the patient's journey from potentially being totally dependent upon the nurse to help them with all of their fundamental care needs to the patient being fully independent and autonomous in their self-care. It also recognises that some patients will stay dependent or become more dependent during the care encounter and these possibilities also have to be managed in respectful, dignified ways. The fundamentals of care identified in the framework are described in Table 2-1.

Figure 2-3 **Establishing the relationship in the Fundamentals of Care Framework.**

The final dimension of the Fundamentals of Care Framework (the outer circle in Figure 2-4) refers to the **context of care**, and outlines the system and policy requirements that are needed to support the nurse–patient relationship and the delivery of fundamental care. It is important that the nurse has the right resources to help them fulfil their commitment to the patient. The quality of the relationship the nurse develops with the patient is as dependent upon the wider contextual factors within the healthcare system as it is upon the skill, commitment and abilities of the individual nurse.

Systems requirements include:

- resources – physical resources in terms of environment, equipment, infrastructure and human resources, including skill-mix and staffing
- culture – organisational culture, that is, the values and norms of the system and statements about the goals of the organisation, how staff are respected and valued; and the organisation's commitment to innovation and learning
- leadership – explicit and implicit styles of leadership that are promoted in the organisation; how roles are defined and supported and how staff are mentored and coached
- evaluation and feedback – processes at individual, team and organisational levels that provide feedback in a supportive, constructive way.

Policy requirements refer to a broader set of factors that influence the health system. These might seem to be

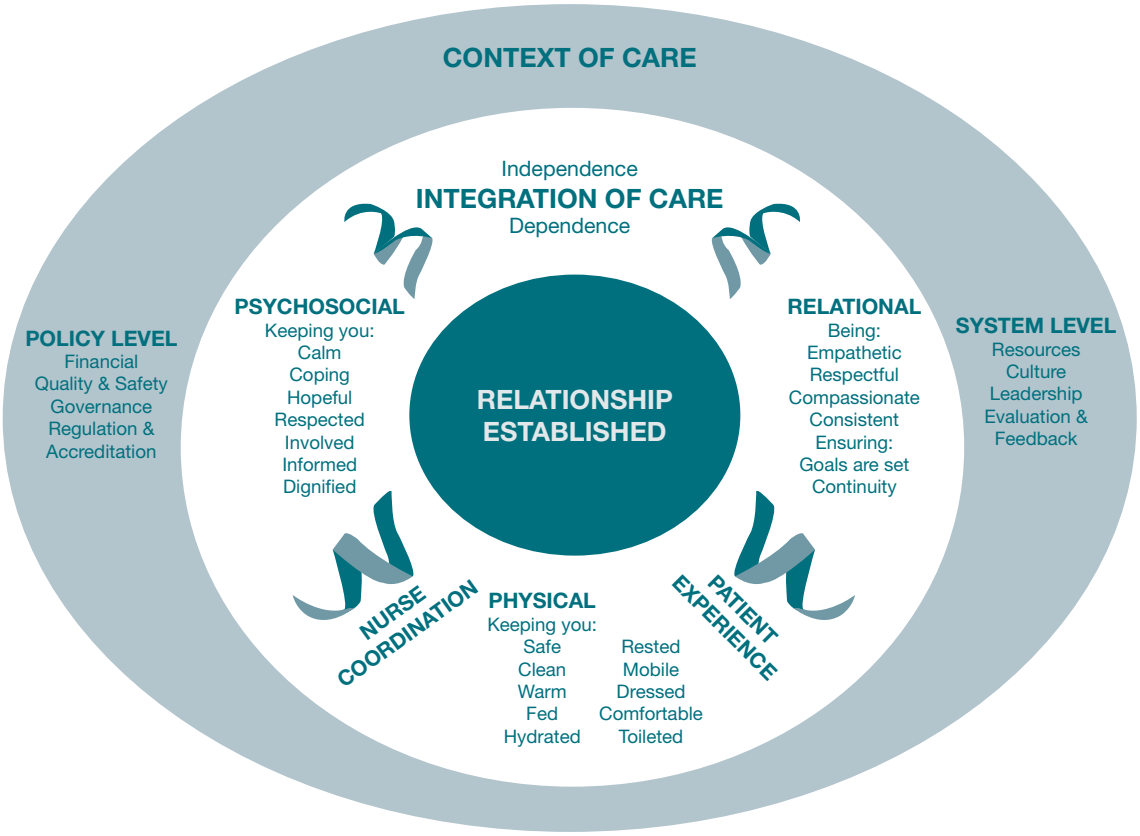

Figure 2-4 **The Fundamentals of Care Framework.**

RESEARCH HIGHLIGHT

Research focus

This research aimed to explore the Fundamentals of Care from the patient's perspective.

Abstract

The study involved examining three patients who had survived a stroke and self-reported experiences of the treatment they received throughout their hospitalisation. Patients' narratives, or stories, were reviewed to explore if, how, when and in what circumstances they discussed their experiences of fundamental care. Understanding how patients experience the fundamentals of care may help to explain the complex processes involved in providing high-quality, comprehensive nursing care. This study illustrates the multiple dimensions – physical, psychosocial and relational – identified in the Fundamentals of Care Framework.

Evidence-based practice

- The experiences of the patients highlighted the entwined nature of delivering the Fundamentals of Care. Physical needs can only be addressed when psychosocial and relational needs are also met. This reinforces that nursing is not a series of tasks but requires a highly skilled practitioner who is continually critically reflecting on and modifying their care to meet patients' needs.
- The study could not conclusively determine directions for practice, as the stories of three stroke survivors may not be representative of a wider patient experience.
- Further systematic investigation of patients' experience is required with a wider healthcare user group.
- The Fundamentals of Care Framework has the potential to be used as a predictive, evaluative and explanatory tool.

TABLE 2-1 Fundamentals of care descriptions

Physical Fundamentals of Care ***Keeping you:***	
Safe	The patient is safe from any physical, psychosocial and environmental harm.
Comfortable	The patient is comfortable and receives adequate relief from nausea and/or pain. Also consider a patient's physical and emotional comfort and wellbeing.
Warm	The patient is not too hot or too cold.
Fed Hydrated	The patient has adequate food and drink (i.e. they receive their allocated meals and are provided adequate fluids). The patient is able to reach their food and drink, open any food packets or containers, and use their utensils. Assist patients to eat and drink when mobility or cognitive impairment is an issue. Assess and attend to patients' dietary requirements and choices (including allergies, intolerances and preferences).
Rested	The patient receives adequate rest and sleep. Consider the person's sleeping habits and preferences (e.g. their usual sleeping and waking times) and how these can best be accommodated. Assess any difficulties with sleeping, and help to minimise these difficulties as much as possible (i.e. identify ways to promote good quality sleep or to assist patients to settle during the night). Assist patients (where necessary) with any equipment they require during sleep (e.g. CPAP machine for sleep apnoea).
Mobile	Assess a patient's mobility and need for mobility aids. Help patients with tasks that require them to be mobile (e.g. toileting). Help and encourage patients to remain mobile (as much as they can) to promote recovery and prevent pressure sores. Assist patients to turn or change position regularly or teach them different ways of relieving pressure. Assist patients with the use of mobility aids and attend to their mobility preferences.
Clean Dressed	The patient's preferences with regard to hygiene, grooming and their physical appearance are respected. Respect a patient's right to privacy when cleaning and dressing.
Toileted	The patient's toileting needs are met. Assist the patient to the toilet and help them to toilet if necessary (such as when mobility is an issue), or provide alternative means for toileting (such as a bed pan) for patients whose mobility is restricted. Assess whether patients are experiencing any discomfort that might indicate issues with elimination, and ensure that patients' privacy and choices/preferences with regard to toileting are respected. Attend to toileting needs as soon as possible to prevent patient anxiety and distress that might arise due to fear of incontinence.
Psychosocial Fundamentals of Care ***Keeping you:***	
Calm	Acknowledge and address any frustrations the patient may have, minimise noise and distractions; keep patients informed about their care, check their understanding of their condition and care plan, listen to the patient's concerns.
Coping	Listen and encourage patients to talk about their feelings and needs. Validate their emotional reactions. Use plain language. Communicate person-to-person rather than healthcare professional-to-patient.
Hopeful	It is important to view hope within the context of people's lived experience and what is important to them (Tutton et al 2009). Setting goals for care can help patients to feel hopeful about their situation and the quality of care they will receive regardless of their clinical condition or chance of recovery.
Respected	Respect a patient's choices relating to their care (e.g. not wanting assistance with toileting). This includes respecting any religious or cultural practices that might be affected by (or affect) hospitalisation and care. Respect a patient's choices with regard to independence (or their move towards independence, including discharge planning), and support patients in their desire to achieve independence.
Involved	Patients are consulted and given the opportunity to contribute to decisions about all aspects of their care.
Informed	The patient is continually kept abreast of all aspects of their proposed and ongoing care.
Dignified	Treat patients with dignity regardless of their age, ethnicity, gender, sexual orientation, religion, linguistic or cultural background or the presence of a mental health issue, disability, illness or injury.
Relational Fundamentals of Care ***Being:***	
Empathetic	Identify and set aside any biases in order to work with the patient effectively. Seek to understand the patient's perspective. Be sincere and genuinely care about what happens to patients.
Respectful	Ensure that the relationship is positive and does no harm. Be courteous and considerate when interacting with the patient.

continued

TABLE 2-1 ***continued***

Compassionate	Be conscious of others' distress, suffering and misfortune, with a desire to alleviate it. Demonstrate characteristics such as empathy, sensitivity, kindness and warmth (Farenden 2014).
Consistent	Ensure coordinated and uninterrupted healthcare services. Make sure the care you deliver is consistent with that of your colleagues, so patients do not receive fragmented or contradictory care.
	Ensuring:
Goals are set	Set mutually agreed, realistic targets for recovery. Patients are free to renegotiate these goals at any point during their care.
Continuity	Ensure continuity across the delivery, facilitation and coordination of care.

beyond the direct influence of the individual but still need to be recognised. They include financial and funding issues, international, national and local quality and safety agendas, governance processes and accountability, and regulation and accreditation.

As can be seen from the process in Figure 2-5, the Fundamentals of Care Framework is the intersection of your working hypothesis, relevant theories and the clinical reasoning process. The framework indicates it is important that we do not address care activities in isolation. Returning to our *Clinical example* with Barry, if we try to address the possible presence of depression without establishing a trusting relationship, the intervention is likely to fail. Equally, in chatting with Barry while helping him with his breakfast, we would be able to assess his interest in food and his appetite, check his oral hygiene and note his upper body mobility and hand–eye coordination.

When we are delivering nursing care we are also guided by how the theories we are using describe the patient's needs, the context (or environment we are working in), and the relationship we need to have with our patient. The theories that might help inform our care for Barry include those related to grief and loss (Kübler-Ross, Parkes) and self-care deficits (Roper, Logan and Tierney), as well as Neuman's systems model, a framework for thinking about the nurse–client interaction; and Roy's adaptation model, which focuses on psychosocial, psychological, sociological and dependent–interdependent processes. We could even draw on a sociological theory around the way people take on the 'sick role' and become more dependent than they really need to (Parsons). By being open and receptive to the various ways we could interpret what is happening in front of us, we reduce the possibility of jumping to a conclusion too early and labelling people. Once we have applied the Fundamentals of Care Framework and relevant theories to our working hypothesis we can then move to the clinical reasoning process.

Relationship between theories, practice and patients: using the Fundamentals of Care Practice Process

Let us apply the Fundamentals of Care Practice Process to the following situation. Our patient is an 18-month-old child presenting with vomiting, diarrhoea and a fever. First, consider the different concepts related to this scenario. The child is accompanied by his mother who seems anxious (this is our idea/opinion). You also know that the mother is crying, trembling, and having difficulty concentrating on what you are saying to her. The child also has poor skin elasticity, no wet nappies, dry mucous membranes, and a high temperature (38.7°C). The mother's behaviour and the child's symptoms form our facts. Our working hypotheses are that: (1) the child is possibly dehydrated due to his high temperature; and (2) the child might be uncomfortable and in pain.

Now that we have developed our working hypotheses we need to address them. We could move straight from our hypotheses to the clinical reasoning process. That is, we could take the child from the mother and start intravenous fluid therapy to rehydrate the child if this was prescribed. But what would be missed if this was our initial reaction? Without using a framework and relevant theories, the consequences could be that the child becomes distressed because he is in an unfamiliar environment and separated from his mother. The mother might also become anxious at seeing her child distressed and being unsure of what is happening to her child.

To deliver holistic and person-centred care we need to understand the Fundamentals of Care Framework and the relevant nursing (and other disciplinary) theories that inform our practice. Without considering frameworks and theories and instead moving straight to the clinical reasoning process, we might miss important information

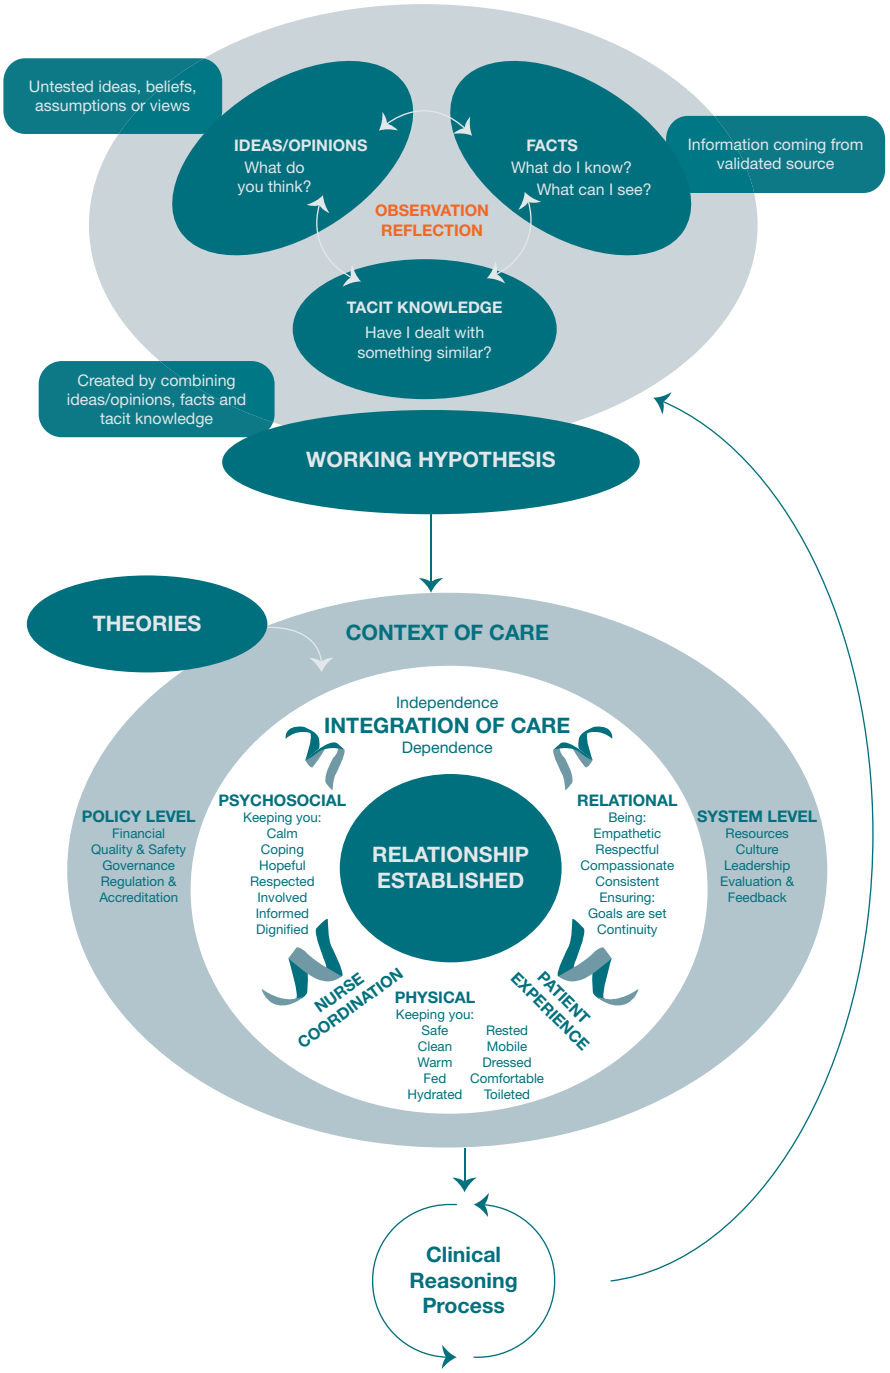

Figure 2-5 **The Fundamentals of Care Practice Process.**

that can help to deliver safe and effective care. In this paediatrics example, we might refer to attachment theory, and Piaget's theory of cognitive development to better understand how the child might react if separated from his mother.

From the Fundamentals of Care Framework we also know that it is crucially important to develop a trusting relationship with the mother and child. This can be established using theories of family-centred care. There are also many other nurse–patient relationship theories that might be relevant in a given scenario, including Peplau's interpersonal relations theory, which sets out four developmental stages of the nurse–patient relationship, and Orlando's dynamic nurse–patient relationship theory (Peden et al 2015). We also need to recognise the child's ability to understand and communicate with us, based on his developmental age and incorporate this into the way we care for him. Due to the child's age, we cannot

rely on him to self-report his symptoms. As such, closer monitoring and observation might be required.

The information that we have gathered through our framework and relevant theories then feeds into our clinical reasoning process. Without thinking about relevant theories and conceptual frameworks, the care we provide will become task-based. Focusing on the physical fundamentals (e.g. hydration) only would be inadequate and might lead to a negative care experience in which the child and parent become increasingly distressed. When providing care, we also need to consider people's relational and psychosocial needs and those of their family/carers.

You can see how nursing is complicated and needs to integrate many theories. The Fundamentals of Care Framework helps us to incorporate these and provide high-quality, holistic, person-centred care to our patients.

• CRITICAL REFLECTION POINT

Review the following scenario. Identify your concepts (ideas/opinions, facts and tacit knowledge). Develop a working hypothesis. Identify the possible theoretical influences and apply these within the Fundamentals of Care Framework.

Scenario:

An elderly person is found on the floor of their nursing home in a pool of liquid. They are unable to communicate. There is visible bruising on the person's arms and face.

What are your concepts?

- **Ideas/opinions**
- **Facts**
- **Tacit knowledge**

What is your working hypothesis?

What fundamentals of care might you need to consider and why? For example, the Fundamental of Care regarding communication needs to be considered because establishing a relationship is crucial to assessing cognition and determining the person's needs.

What theories inform the Fundamentals of Care Framework in this situation? For example, what are the underlying theories relating to communication with older people?

Why do I need to know about theories?

The example of germ theory provides a useful way to explain the importance of a theory and its application to practice. Germ theory was used to explain the role that microorganisms play in causing disease. These small organisms, too small to see without magnification, were thought to invade humans, animals and other living hosts. Using this theory, Louis Pasteur, a French chemist and microbiologist, showed that microorganisms in the air cause fermentation and putrefaction. He discovered that the growth of microorganisms could cause food and drinks to spoil, and, extrapolating from this, hypothesised that microorganisms were likely to affect humans and animals in a similar way, causing disease. He proposed preventing the entry of microorganisms into the body in order to promote health. His experimental work and discoveries provided direct support for germ theory (Pasteur et al 1878).

Through applying germ theory to practice, Louis Pasteur was instrumental in contributing to many practical applications in microbiology and medicine, including:

- instituting changes in hospital/medical practices to minimise the spread of disease by microbes or germs
- discovering that weak forms of a disease could be used to develop immunity against stronger forms
- introducing the medical world to the concept of viruses.

In 1865, a Scottish surgeon called Joseph Lister applied the concept of germ theory to practice, believing that the cause of infection in many of his postoperative patients was airborne microorganisms. Lister had heard that carbolic acid had been used to eliminate a cattle parasite and to treat sewage. He decided to see if this liquid could also stop wounds from becoming infected. He began by cleaning the wounds of his patients with the carbolic acid; he also soaked the dressings in antiseptic liquid. Between 1864–1866, the death rate for his patients was 45.7%. However, between 1867 and 1870, after he introduced his new antiseptic treatment, the death rate fell to 15%. He tested his theory in practice and provided support for the belief that airborne microorganisms were causing the disease in wounds. Once these aseptic techniques were accepted, surgery was revolutionised and saved millions of lives.

Germ theory was also utilised by Robert Koch, a German doctor. In the 1880s, he further refined the experimental processes used to demonstrate that a disease is caused by a particular organism. In doing so, Koch identified the organisms that cause tuberculosis and cholera, providing further support for germ theory. The application of germ theory to nursing practice is obvious: from the 'Five moments for hand hygiene' (World Health Organization 2006) to a myriad of policies and procedures to prevent cross-infection and contamination.

As a nurse, theories are critical to informing your practice, contributing to an evidence base relating to nursing and the delivery of care, and generating new knowledge. Professional nurses use theories from nursing and the behavioural sciences (e.g. psychology, sociology, counselling) to analyse and interpret people's health

situations and to solve problems. By practising theory-based nursing, combined with critical thinking skills, nurses are able not only to deliver high-quality, efficient and cost-effective care but also to describe a rationale for what they do.

Nursing theory is a notion or an idea that interprets observation, describes relationships, and projects outcomes for nursing (Parker & Smith 2010). Nursing theories differentiate nursing from other disciplines and activities by describing, explaining, predicting and controlling desired outcomes of nursing practices. Through informing practice and the development of new knowledge, theories also help us to distinguish the complementary roles of the healthcare team (e.g. nursing and social work). Nursing theory helps us to identify our role as being different but complementary to other healthcare professionals. Nursing theory defines what it is that nurses do and how this contributes to the delivery of health care. By working together with other members of the healthcare team who have complementary expertise and responsibilities, we can ensure we deliver integrated, holistic, person-centred care. Nursing theory can be used to guide knowledge development and can direct education, research and practice. The contribution of nursing researchers ensures that nursing work remains relevant, current and useful and has a positive impact on health outcomes. Nursing theory makes nursing unique as it not only explains what nurses do, it is also a means of testing knowledge through research and by expanding nursing's knowledge base to meet the healthcare needs of a complex, multicultural society (Fitzpatrick & Whall 1996).

There are many theories of nursing, some of which have been developed with a specific focus. For example, Florence Nightingale's theory focuses on the environmental aspects of care, Orem's theory is linked to the self-care deficits of the patient and Virginia Henderson's theory is based on identifying patient needs. There are some theories that can appear more relevant to specific clinical circumstances, such as the Tidal Model of Mental Health Nursing, used to promote mental health recovery (Barker & Buchanan-Barker 2005). As mentioned above, in our nursing practice we might also find the need to 'pick and mix' from various theories, depending on our patient population and care environment.

Types of theories

There are many different types of theories that might inform the Fundamentals of Care Framework and help to address our working hypotheses as part of the Fundamentals of Care Practice Process. Some of the theories we might consider include grand theories, mid-range theories and practice-level theories. Each type of theory differs in terms of its scope, what it describes, its level of abstraction, how easily it can be tested, and the implications it has for nursing practice (Masters 2015). Grand theories are abstract and broad in scope. They involve large unifying ideas that are not intended to guide specific nursing interventions, but to explain phenomena and provide the structural framework for broad, abstract ideas. Mid-range theories are less abstract and narrower in scope than grand theories (Masters 2015, Smith & Parker 2015). Mid-range theories cover specific phenomena or concepts, such as uncertainty, social support or incontinence. Practice-level theories are the most limited and narrow in scope. They are developed for a specific range of nursing situations and interventions and have a more direct effect on nursing practice than grand or mid-range theories (Smith & Parker 2015).

• CRITICAL REFLECTION POINT

- **What theories do we use in our everyday life? What are some of the things we might 'take for granted' that have a theoretical explanation (e.g. gravity, friction)?**
- **Think about the mobility of patients. Nurses used to keep people in bed for five days post-surgery, but now they get them moving as soon as possible. Why? What theories contributed to this change of practice?**

Linking theories to nursing knowledge, research and education

So far in this chapter we have shown how theories help impact your practice through their ability to inform conceptual frameworks. We have shown that, in nursing, theories guide your nursing practice by helping you to: organise, understand and analyse patient data; make decisions related to nursing interventions; plan patient care; predict outcomes of care; evaluate patient outcomes; and think critically as you plan and provide nursing care (Masters 2015). We will now consider how certain ways of looking at health have influenced nursing knowledge, research and education. These perspectives are not theories but they are ways of structuring the world around us. There have been two major models that have profoundly influenced the way we think about health care – the biomedical model and the biopsychosocial model.

Biomedical model

The **biomedical model** assumes that all disease results from a single physical cause, such as cellular abnormalities or imbalances in homeostasis (Wade & Halligan 2004).

The model therefore prioritises activities that will lead to diagnosis and cure of physical anomalies and places primary value on objective knowledge (e.g. doctor expertise) rather than subjective knowledge (e.g. patient expertise) (Russell 2014). It views the mind and body as separate entities and likens the body to a machine that can be reduced to its component parts (Russell 2014, Treiber & Jones 2015). Each part of the body is then examined and treated separately for its underlying physical abnormality.

The biomedical model's focus on underlying pathophysiology provided important answers to the serious medical problems of the 19th and early 20th centuries. At the time, challenges to health and health care primarily centred on acute, life-threatening diseases, including infectious diseases such as small-pox and childhood diseases such as polio (Weiner 2007). By focusing on physical anomalies, the biomedical model provided a useful framework for research that led to the treatment and cure of these life-threatening illnesses, and to the subsequent development of such modern healthcare staples as antibiotics and vaccinations. Naturally, the model would have drawn upon all the key theories relating to germ theory, sepsis and immunisation.

However, the model has also had other impacts on health care. Its focus on purely the physical aspects of disease typically means that any aspect of illness or treatment that is not easily explained by cellular and molecular processes occurring within the body is excluded. As such, social and psychological determinants of health and illness and non-physical and non-curative aspects of care, such as compassion and empathy, are often overlooked in research, education and practice (Borrel-Carrió et al 2004, Russell 2014). It would also be correct to assume that the theories underpinning these dimensions would not be valued within the biomedical model. The model might also be less fitting for today's current healthcare challenges, characterised by the increasing complexity of disease and higher incidence of chronic, incurable conditions. As a response to these new health problems, we have seen the emergence of biopsychosocial approaches to health care.

Biopsychosocial model

Unlike the biomedical model, the **biopsychosocial model** argues that illness cannot be reduced to biology alone. Rather, the causes and consequences of illness are seen to exist at multiple levels – biological, psychological and social (Borell-Carió et al 2004, Engel 1978, Weiner 2007). The model therefore provides a more integrated, holistic explanation for the development and treatment of disease than the biomedical model. In this way, the biopsychosocial model is better able to explain the acquisition of many modern illnesses, particularly those related to lifestyle factors (e.g. diabetes and cardiovascular disease).

The model is also better able to deal with the complexity of chronic, incurable disease. The increased burden that such disease places on patients, families and healthcare systems means that, in addition to physical diagnosis and cure, these systems must also focus on long-term care and management, particularly around the fundamentals of care. Meeting another person's fundamental care needs involves more than the simple act of attending to a biological need (i.e. providing food to stop hunger); it also requires that a number of psychosocial needs are met (i.e. being treated with dignity and respect, feeling safe). Unsurprisingly, the theoretical basis for the biopsychosocial model is embedded in the psychological and social sciences, thus attempting to align the biological with the psychological and social.

In contrast to the biomedical model, the biopsychosocial model also argues that subjective experiences – the ways in which people conceive of and are affected by their illness – are essential to accurate diagnosis and positive outcomes (Borell-Carrió et al 2004). The model therefore advocates that people receiving care are not seen merely as objects/patients with a disease but as persons with unique and varied circumstances that impact their experience of illness and their recovery. The model encapsulates the contemporary person-centred care paradigm that focuses on actively engaging and involving people in the care they receive (Kitson & Muntlin Athlin 2013, Kitson et al 2013b).

Research using the biopsychosocial model investigates the interactions of biological factors with behavioural and/or social issues. Behavioural issues can include cognition, attitudes, emotions, motivation, perception and communication, as well as eating, drinking, sexual and parenting behaviours. One example of a biopsychosocial approach to research is examining the effects of interactions between genetic and environmental factors on health outcomes.

Positives and negatives of using theories

Many nurses believe theory is essential to guide our practice; however, there are some who devalue, misunderstand or dismiss the need for theories. The reasons we might or might not use theories are discussed below.

We can use theories to inform our practice. The Fundamentals of Care Practice Process (Figure 2-5) illustrates when and how we use theories to deliver our

patients' fundamental care needs. In using theories we can create or add to the existing body of nursing knowledge. Nursing research can generate new theories or test existing theories for their relevance and applicability in specific situations. The scenarios we have visited in this chapter have explored how using theories can prevent nursing care from being task-driven and delivered without reflection. Exploring the relevant theories and how they contribute to delivering the fundamentals of care encourages us to critically reflect on our practice. We can ask ourselves questions about how the care was received by the patient and their family. Did we achieve the outcomes we were seeking and how might we do things differently when presented with a similar situation in the future? We can take from the many different theories what we need for the patient and their situation. A 'pick and mix' approach allows us to apply relevant theories in part or in full.

We need to ensure that when we use theories we don't assume that one-size-fits-all. Theories can be criticised for being too rigid and inflexible for nursing practice in the 'real world'. There can also be difficulties when we are faced with theories that conflict with other theories; how can we determine which is correct and applicable for our circumstances? Not all theories have been 'tested'; they remain an idea rather than a proven method. Can we justify basing our care delivery on a specific theory if there is no proof it works? Also, it can take us some experimentation to find the best theory or combination of theories that work for our patient group and us. This is made even more difficult when theories are complex and difficult to understand and apply in practice. If theories are considered in isolation, without a conceptual framework to help operationalise them, they might seem too abstract for practice. Using the Fundamentals of Care Framework to operationalise the theories can help us to overcome this issue.

The most important thing to remember about theories is that they should provide us with explanations that help us understand what to do with and for our patients. If we just follow checklists and sets of tasks, we are not operating as thinking, reflective professionals. So the sooner we learn to enjoy using theories to shape our practice and to help us test and refine how we care for our patients the better it will be for us and our patients.

CLINICAL EXAMPLE REVISITED

You are assisting Barry with his morning wash and you initiate a conversation relating to how he manages this at home. You discover that Barry lives with his mother who is his main carer. His father has passed away and he has a brother who lives close by. He tells you that his mother does all his shopping and cooking for him. He can attend to most of his hygiene needs by himself and when at home uses a wheelchair to get around. You are now establishing a trusting relationship with Barry and this additional information leads you to further identify his needs and how you might meet them.

• CRITICAL REFLECTION POINT

- **What is the theoretical model for your nursing curriculum? Is it a biomedical model or a biopsychosocial model? What are the pros and cons of these models?**
- **Would one model work better in some nursing specialties than others? Why?**
- **What sorts of theories would underpin a person-centred care model of nursing practice?**

• CRITICAL REFLECTION POINT

1. **How would you apply nursing theory to the identified problems for Barry? Which theories might apply?**
2. **How would these theories contribute to the delivery of the Fundamentals of Care for Barry?**

Conclusion

Although nursing is viewed as a practice discipline, it is underpinned by concepts, frameworks and theories and we need to approach every patient interaction as an opportunity to determine these and apply them to the care we deliver. The Fundamentals of Care Practice Process demonstrates how they fit together and enables us to practise nursing in a holistic and integrated manner. Establishing a relationship with those we care for is essential, as this becomes the basis for delivering person-centred fundamental care. Even tasks that may be initially considered simple require us to be reflective practitioners and integrate all the sources of information we have to support our practice and ensure person-centred care.

Key concepts

- Nursing practice relies on identifying concepts about a patient's needs and understanding how these can be used to develop a working hypothesis about the care they require.
- The Fundamentals of Care Framework shows the need to establish a trusting relationship with the patient and to incorporate and address a patient's physical, psychosocial and relational needs.
- The Fundamentals of Care Framework consists of three dimensions: establishing the relationship with the patient; being able to integrate and address the patient's fundamental care needs; and a commitment from the

wider health system to be responsive to these core tasks.

- The Fundamentals of Care Practice Process demonstrates how the Fundamentals of Care Framework is the intersection of your working hypothesis, relevant theories and the clinical reasoning process.

CHAPTER

3

Engaging patients and keeping them safe

Rebecca Feo, Tiffany Conroy, Jan Alderman and Alison Kitson

Learning outcomes

Mastery of the content will enable you to:

- address patient safety using the Fundamentals of Care Framework
- identify potential negative consequences of your actions and how to minimise these
- engage with patients and their families to establish a therapeutic relationship
- assess all elements of a patient's personal safety, including physical, psychosocial and environmental safety
- identify and address possible risks to your personal safety as a nurse
- assess when your relationship with a patient has moved from therapeutic to non-therapeutic
- be aware of appropriate work health safety and occupational health and safety regulations and codes of practice.

Introduction

This chapter will demonstrate how you can address patient safety using the Fundamentals of Care Framework, introduced in Chapter 2. The framework emphasises the importance of establishing a positive relationship with the patient. As nurses, our first objective should be to do no harm. Therefore, we need to know the potential negative consequences of our actions and attempt to minimise these. Using the Fundamentals of Care Framework enables us to provide safe, holistic and continuous care.

The World Health Organization (2011) considers engaging with patients and their families an essential element of patient safety. It is crucial that nurses understand the ways in which patients can be involved as partners in their health care. The requirements for **engagement** are: actively encouraging patients to share information; effective communication; and showing empathy, honesty and respect. These are all reflected in the Fundamentals of Care Framework. Importantly, all these requirements rely on the development of a positive relationship between the nurse and the patient.

• CRITICAL REFLECTION POINT

1. **How do you engage with a patient? What does engaging mean?**
2. **What does keeping a patient safe mean for nurses?**
3. **What does safety mean to patients and their families?**
4. **How do the views of the healthcare provider and the patient differ? How might this impact on a patient's experience of care?**

Developing a relationship

Establishing a relationship with the patient is the basis for engagement. The relationship you develop with a patient (the nurse–patient relationship) is part of a wider network of interprofessional and family/carer relationships. You as a nurse will be working as part of an interdisciplinary team of health professionals. In turn, patients will be receiving care from, and building relationships with, this team of professionals. It is vital that you work effectively with colleagues to ensure patients receive holistic, integrated care. Patients also have relationships with family and carers that are important to them. When building a relationship with a patient you will also generally be building relationships with their family and carers as well. As indicated in the **Fundamentals of Care Framework** (see Figure 3-1), developing a positive nurse–patient relationship within this wider network has five requirements: trust, focus, anticipate, know and evaluate (Kitson et al 2013, 2014).

Trust is crucial to patient **safety**. Patients need to *feel* safe; it is not sufficient that they might be safe. To feel and be safe, patients need to trust the person looking after them (Wassenaar et al 2015). It is the nurse's responsibility to develop and nurture this trust, which encourages the sharing of relevant information that can help you to keep the patient safe. To focus on the patient means to give them your undivided attention. While time might be limited, it is important that the patient feels you have listened to them and have responded to their emotional and physical needs. Focusing on the patient is therefore vital to ensuring the patient feels well cared for as well as for detecting changes in the patient's physical and emotional state. Knowing the patient involves an understanding of their individuality, including knowledge of why they are receiving care and knowledge of their concerns and preferences with regard to their care. This need to know must be balanced with the patient's wishes regarding privacy. Anticipating a patient's needs enables the nurse to plan and discuss a proposed course of action with the patient. Finally, both the patient and the nurse should evaluate the quality of their relationship by reviewing its progress and providing feedback to each other.

The **therapeutic relationship** you develop with the patient is central to the care that you provide and can either be strengthened or weakened through your care delivery. The second circle of the Fundamentals of Care Framework demonstrates how a positive and trusting nurse–patient relationship is integral to the delivery of care around patients' fundamental needs. As can be seen from the diagram, patients' fundamental care needs can be physical (e.g. nutrition, elimination and hygiene), psychosocial (e.g. feeling calm, able to cope, respected and involved) and relational (e.g. the nurse is empathic, respectful and compassionate) (Kitson et al 2013, 2014). A positive relationship helps you attend to each of these needs to ensure patients are not only safe, fed, comfortable and hydrated, but that they are dignified and calm and receive care that is respectful, compassionate, consistent and empathic. It helps you to set mutual goals around the delivery of care, ensure patients' preferences are respected, and that patients and their families are kept involved and informed. The Fundamentals of Care Framework therefore helps you to build a relationship with a patient in order to deliver safe and effective care.

Nurses need to have the necessary skills to develop a safe therapeutic relationship with a patient. Some of the skills required include:

- active listening
- collaborative decision-making

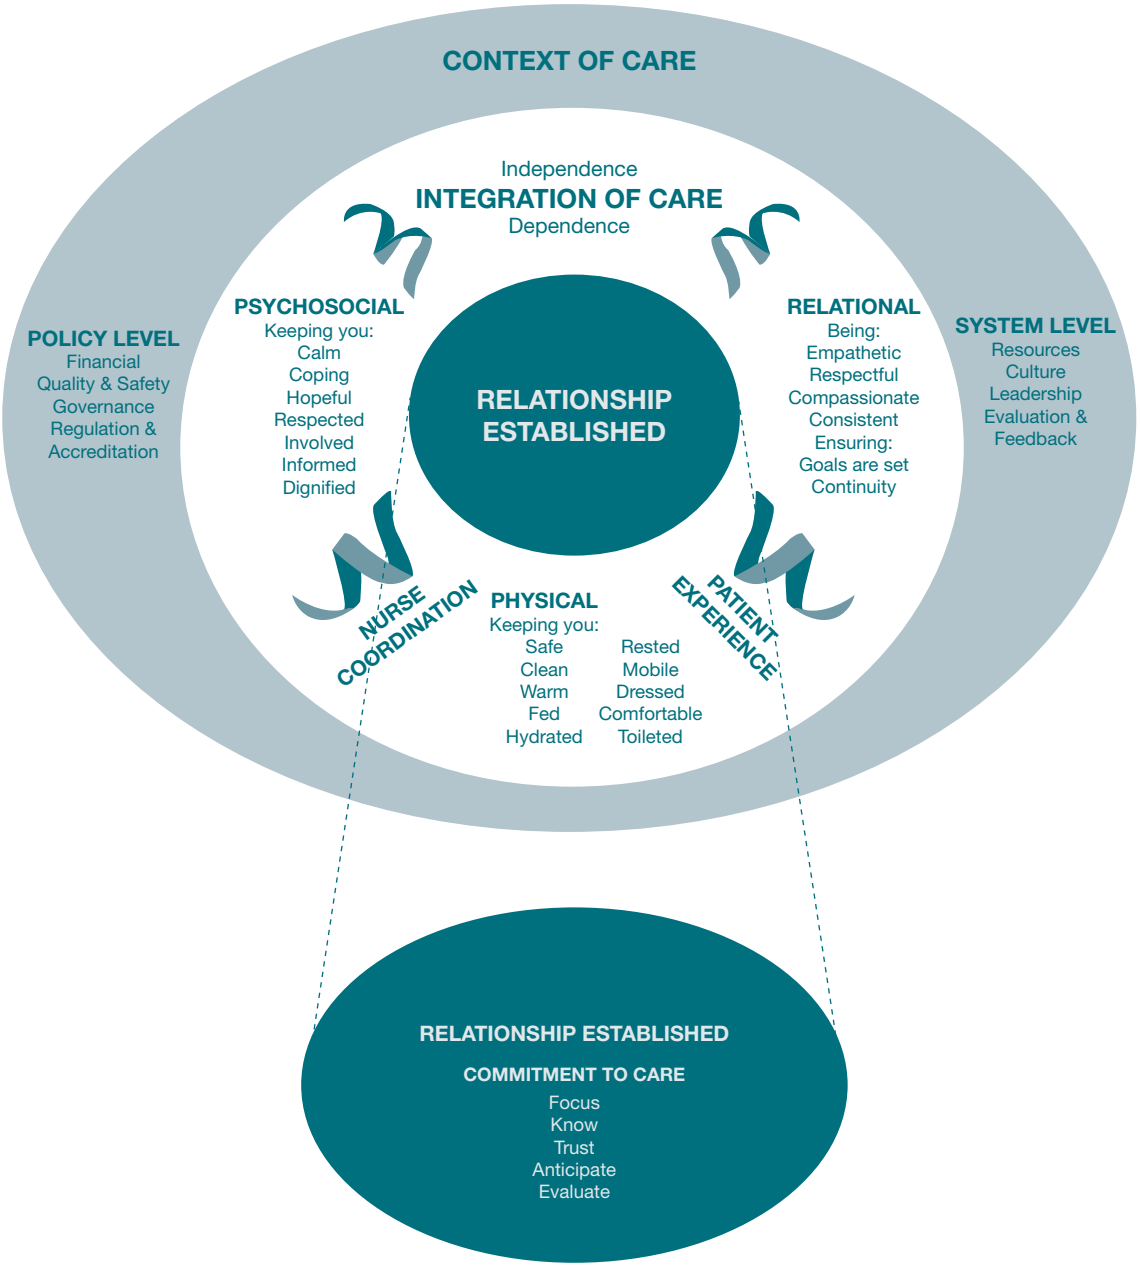

Figure 3-1 **The Fundamentals of Care Framework.**

- acknowledging the patient as the expert on his/her experience
- treating the development of trust and rapport as an ongoing and dynamic process
- communicating in a language that is appropriate for the person being cared for
- taking responsibility for actions and/or mistakes
- regularly talking to and observing patients in order to get a feel for how things are going for them (Wiechula et al 2015).

Being receptive and responsive to both verbal and non-verbal communication will assist the nurse to establish what aspects of care are most important to the patient and to tailor care around these needs and preferences.

When building a relationship with patients and their families/carers, engagement must occur at a meaningful level. Tokenistic engagement, where patients are told what has been decided or what has already happened with regard to their care, is not sufficient. The patient and any nominated family/carers should be full participants

RESEARCH HIGHLIGHT

Research focus

Developing a positive relationship with patients is known to be important for the delivery of high-quality care. This paper sought to identify the factors that contribute to the development of a caring relationship between the nurse and patient.

Research abstract

The study involved conducting an umbrella review. Umbrella reviews bring together evidence from existing systematic reviews in order to synthesise the available evidence on a particular topic. This umbrella review looked at studies examining patients' and nurses' perspectives on what is important in the nurse–patient relationship. The umbrella review identified six key areas that are associated with developing and maintaining caring, positive nurse–patient relationships. They are:

- nurses' and patients' expectations of the relationship
- nurses' values and beliefs (e.g. their thoughts, perceptions, attitudes and associated behaviours)
- nurses' knowledge and skills (both clinical skills and support behaviours)
- nurses' ability to communicate effectively in a variety of ways
- how the physical and social contexts in which care is taking place affect the nurse–patient relationship
- the impact of the relationship on patients/families, nurses and nursing students.

Evidence-based practice

- The nurse–patient relationship should be based on nursing's inbuilt values such as trust, sympathy, support and responsibility, and these values should be reflected in the attitudes and behaviours of nurses.
- Compassionate care and technical skill are equally important in developing and maintaining the nurse–patient relationship.
- Nurses need to consider the context in which they are providing care and how this might impact the nurse–patient relationship.
- The nurse–patient relationship not only has an impact on patients and families/carers, but on nurses as well. Nurses find great reward in a positive relationship with their patients but can also experience guilt and frustration when a good quality nurse–patient relationship is not achieved.

in decision-making about the care they receive. A meaningful relationship with the patient enables you as the nurse to make sound clinical decisions that are based on the patient's best interests.

Safety as one of the fundamentals of care

Patient safety was of central concern to Florence Nightingale as reflected in her quote, 'the very first requirement in a hospital is that it should do the sick no harm' (Nightingale 1859). Safety continues to be a concern for many modern healthcare systems, with evidence suggesting that Nightingale's doctrine of 'doing no harm' is not being completely followed. The Institute of Medicine's (IOM) landmark publication *Crossing the Quality Chasm* (2001), for example, argued that the US healthcare system was failing to deliver consistent, high-quality medical care, with such care instead frequently harming or injuring patients. The IOM called for fundamental changes to 21st-century healthcare systems to ensure the safety of all patients.

In this part of the chapter, we consider how the Fundamentals of Care Framework helps you to address patient safety concerns when providing care. As can be seen from Figure 3-1, safety is conceptualised as a fundamental of care, along with other fundamentals such as nutrition, hydration and elimination. The nurse–patient relationship is central to ensuring this fundamental need is appropriately met. While policy and organisational structures focusing on safety undoubtedly have an impact on the ability of nurses to deliver safe and effective care, our focus in this chapter is on equipping you as a student and beginning nurse with the skills to operate in a safe manner. That is, to ensure patient safety becomes part of your personal and professional responsibility as a nurse.

Patient safety encompasses three interrelated elements: physical, psychosocial and environmental safety. At the intersection of these different types of safety lies the patient's **personal safety** (see Figure 3-2). It is only when each of these types of safety are appropriately met that patients can be considered safe. Ensuring patients' personal safety requires nurses to embed patients' needs in their thinking, reflection and assessment processes (Kitson et al 2014). Careful assessment and planning prior to any intervention or interaction with a patient will ensure that injury and harm do not occur and that any safety **risks** are reduced.

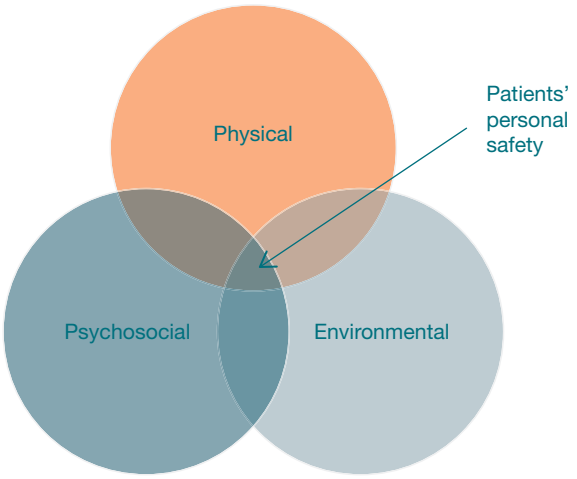

Figure 3-2 **Patients' personal safety.**

Figure 3-3 **Involving patients in their care decisions and management leads to better outcomes.**

Patients' physical safety

Keeping patients safe from physical harm promotes recovery, healing and quality of life, and helps to reduce hospital stay, prevent hospital-acquired infections and deconditioning, and lower the risk of re-admission (see Barker et al 2011, Gorecki et al 2009, Morris et al 2011, Reddy et al 2006, Schweickert et al 2009, Vollman 2006). Ensuring the **physical safety** of a patient includes attending to the following: skin integrity (e.g. the prevention of pressure injury); patient assessment (e.g. vital signs); falls; personal safety (i.e. threat of harm to self or from others, such as family members or carers); discharge planning; appropriate use of restraints; and fundamentals of care such as nutrition and hydration, comfort (e.g. pain management and rest and sleep), elimination and continence, hygiene and mobility.

Nurses engage in a continual process of critical thinking, observation, assessment, planning, evaluation and documentation to identify, address and minimise risks to patients' physical safety. As outlined above, and as reflected in the Fundamentals of Care Framework, a trusting and positive nurse–patient relationship is essential for ensuring patients' physical safety, and can be developed through the elements of trust, focus, anticipate, know and evaluate. Developing this relationship requires that you regularly consult with the patient, keep them involved and informed, and genuinely consider their preferences and wishes regarding care. The relationship you develop helps you to understand the patient's specific physical safety needs and to set mutual goals around those needs. The needs, goals and safety risks that you identify with the patient can then inform the development of an individualised care plan. You and other health professionals caring for the patient can use this care plan to guide the actions you take in addressing the patient's physical safety risks.

It is important to remember that physical safety needs may change over a person's life span. The types of physical safety risks that are relevant for an infant are generally not going to be the same as those for an adult, pregnant woman or an elderly person. Understanding these life span and developmental differences is an important part of *anticipating* patients' needs. Keeping in mind, of course, that while developmental needs might generally change over the life span, not all people in a particular age group will have the exact same needs. It is still important to get to *know* each patient individually and *focus* on their unique needs.

• CRITICAL REFLECTION POINT

Consider the types of risks that might be relevant for an infant as opposed to an older adult. For example, small children are typically susceptible to choking, whereas older adults might be at higher risk of falls and could be more susceptible to deconditioning while in hospital. What other risks can you identify for these different age groups?

A key element of attending to physical safety risks is to document your observations and risk analysis to ensure patients' needs are met and that care is continuous, consistent and effective. It is vital to continuously evaluate the effectiveness of care and your attempts to ensure the patient's physical safety. Ask yourself: Is the patient warm, fed, clean, hydrated, mobile, rested, dressed, toileted and comfortable? Does the patient *feel* safe and as though their care is being well managed? If not, you might have to modify your actions, taking into consideration input

from other healthcare professionals, the patient and their family. Some of the elements of the framework to consider when determining whether patients feel safe include: Is the patient being involved in and informed about their care? Are their wishes and beliefs being considered and is communication occurring in a respectful way? Is a trusting relationship in place in which the nurse follows through on requests and delivers care as they have promised? Is the patient calm and able to cope?

Let us consider in more detail how the Fundamentals of Care Framework helps you to think critically, observe, understand and assess a patient's physical safety needs in the following *Clinical example*.

CLINICAL EXAMPLE

You are a newly graduated registered nurse (RN) working in a hospital. A senior RN asks you to deliver medication to a patient. You are unsure what the medication is and have not had any previous interaction with the patient. When you deliver the medication, the patient asks you what the medication is for. She informs you that she is having a procedure tomorrow and is unable to have her normal daily aspirin. She asks you whether the medication is aspirin or another form of 'blood thinner'. You do not know the answer.

What are some of the potential safety risks that can be identified in this situation? For example, the patient might receive inappropriate medication that delays her upcoming procedure. In turn, the extra stay in hospital might contribute to emotional and/or financial distress. There might also be an issue as to whether you are giving the medication to the right patient, considering you have not met the patient before. How might these risks be minimised before entering the patient's room? First, determine what the medication is for and double check the patient's case notes to ensure you are administering the correct medication. In this way, you are *anticipating* the patient's needs and pre-emptively minimising safety risks.

Consider how you can use the Fundamentals of Care Framework to engage with the patient in order to minimise safety risks and address their concerns. First, when delivering the medication, address the patient by name to ensure you are delivering the medication to the right person. This is an important part of getting to *know* the patient. Second, genuinely listen to the patient's concerns. This is part of *focusing* on a patient and giving them your undivided attention. It also lets them know that they (and their views) are being *respected*. You could let the patient know that you will check what the medication is and come back and tell them. Following through in this way (i.e. returning when you say you will with the appropriate information) helps to develop a *trusting* relationship with the patient. Without this follow-up, patients are unlikely to trust that you will follow through with other aspects of their care. Such follow-up is also important for helping patients to feel *informed* and *involved* in the care they are receiving.

• CRITICAL REFLECTION POINT

You are on clinical placement in an operating theatre. A patient is being prepared for major cardiac surgery. The patient is elderly, diagnosed with dementia and was being cared for by his family at home. Once sedated for his operation, prior to intubation, the anaesthetist opens the patient's mouth. The patient's mouth is not clean and has a foul odour. The patient also has partial dentures in place. The anaesthetist decides that the patient is not fit for surgery and wants to know why the patient was sent to the operating theatre in this condition.

- **Using the Fundamentals of Care Framework, what safety issues can you identify for this patient (i.e. why were they considered unfit for surgery)? See Chapter 39 on preoperative care to help.**
- **How would you approach a conversation with the RN who accompanied the patient from the ward to the operating theatre to find out why the patient was considered fit for surgery?**
- **What should have been done to determine the patient's preparedness for surgery?**

As the *Clinical example* demonstrates, attending to patients' physical safety needs is complex and requires continual critical thinking, assessment and evaluation on the part of the nurse, using elements of the Fundamentals of Care Framework to help guide your actions. However, physical safety needs are not the only ones that patients can experience. When providing care to a patient, they will also experience a range of psychosocial needs, including emotional, cultural and psychological needs. It is equally important that these needs are identified and addressed.

Patients' psychosocial safety

A patient's **psychosocial safety** includes their cultural safety and their emotional and psychological wellbeing. As outlined by the Nursing Council of New Zealand (2011), culture includes, but is not limited to, a person's age or generation, gender, sexual orientation, occupation, socioeconomic status, ethnicity, migrant experience, spiritual or religious beliefs, and disability. Cultural safety involves understanding a person in the context of their culture, respecting their beliefs and values, identifying how their beliefs might differ to your own, and recognising how the patient's beliefs might impact health and healthcare delivery. All patients, regardless of their age, gender, sexual orientation, socioeconomic status, religion, ethnicity, or the presence of a disability or mental health issue, should feel safe to express their cultural, religious and sexual identities and to expect care that is free from discrimination. Crucially, cultural safety is defined by the person receiving care, not by the person providing care (Nursing Council of New Zealand 2011). It is the role of the nurse to deliver care in a way that the patient deems culturally safe.

Cultural safety also involves more than simply being aware of and sensitive to a patient's cultural differences. It requires that nurses examine their own personal values, understandings and actions and how these might impact the care they provide (Nursing Council of New Zealand 2011). When there are differences in values between patients, the nurse and the healthcare team or facility, this can have an adverse impact on patient care. For example, if the patient believes that humans can do little to overcome the forces of nature, that illness and death are inevitable, or that their condition is 'God's will', this might be in conflict with a mainstream biomedical approach that values 'mastery over nature' and believes that health outcomes are generally within our control. As a nurse, it is your responsibility to determine the patient's values, identify any differences in these values to your own values or those of the healthcare team/facility, and respond respectfully and appropriately to these differences in your care delivery. Through self-reflection on your own cultural values and beliefs, the aim is to avoid engaging in culturally determined behaviours that might lead to discriminative practice and poor quality care.

Ensuring a patient's emotional wellbeing is just as important as ensuring their physical safety. Receiving care outside the home, being away from family, and being sick or injured can all create significant stress and anxiety. Patients might have concerns about particular aspects of their illness or treatment and require reassurance and information to help them feel calm and able to cope. For people from minority groups, such as Aboriginal and Torres Strait Islander people, Māori and LGBTIQ (lesbian, gay, bisexual, transgender, intersex and queer), accessing mainstream health services can be stressful, frightening and alienating, and they can often experience stigma and discrimination (Kendall & Barnett 2015, Koh et al 2014, Moolchaem et al 2015, Riggs et al 2014, Shahid et al 2009, Shields et al 2012, Ware 2013). Attending to patients' emotional wellbeing can help them feel safe, reassured and less isolated and overwhelmed. Respecting a patient's wish to carry out religious practices during care, such as praying or visiting with a priest, might minimise stress and help them feel less alienated in an unfamiliar environment. Also consider and accommodate any preparations that might be involved in a patient's prayer ritual – for example, some patients might need to wash themselves beforehand. Ensuring patients have access to an interpreter can also help them acclimatise to their surroundings and better understand and participate in the care they are receiving.

BOX 3-1 Reflecting on your values

This exercise is based on the Value Orientation Profile developed in 1961 by Kluckhohn and Strodbeck (Meleis & Lipson 2004).

- Reflect on your values. What do you feel is the relationship of humans to nature? Your choices are: mastery over nature, subjugation to nature and harmony with nature.
- How do you conceptualise the nature of time? The choices are: past orientation, present orientation and future orientation.
- What is human activity for? The choices are: doing, being, and being and becoming.
- How should people relate to each other? The choices are: individualism and family/community focus (collateral relationships).
- How might a conflict in values for each of these areas impact on patient care? For example, if you are describing the possible impact of poor blood glucose control to a patient who is newly diagnosed with diabetes, it is easier if they have a future orientation to time and understand the longer term impact of their condition. How could you motivate them if they were oriented to the present? Think about the concept of individualism and how it might differ from a concept of community. How might these two approaches differ in terms of the value placed on patient autonomy? What might you do if you were caring for a patient whose family did not value such autonomy and was therefore keeping the patient uninformed about their life-threatening condition?

Meleis A, Lipson J 2004 Cross-cultural health and strategies to lead development of nursing practice. In: Daly J, Speedy S, Jackson D (eds) Nursing leadership. Elsevier Australia, Marrickville, NSW.

• CRITICAL REFLECTION POINT

Jenny Price is an Aboriginal woman admitted to your ward for an aortic valve replacement. She suffered with rheumatic fever as a child, which has slowly weakened the valve in her heart. Jenny is from an Indigenous community outside of Tennant Creek in the Northern Territory. She has never been to a hospital before. Her daughter, who is a community worker in Tennant Creek, accompanies her. Jenny is very shy and anxious and will not look at you when you address her. You need to explain the surgery to Jenny and what she can expect during her recovery.

- **How can you use the Fundamentals of Care Framework to engage with Jenny and better understand why she is feeling anxious?**
- **How can you engage with Jenny to understand her cultural beliefs and how they might influence her approach to the impending surgery?**
- **What practical things could you do for Jenny that would help her feel safe?**

As with any form of patient safety, ensuring patients' psychosocial safety involves developing a positive relationship with, and getting to know, the patient and their families/carers. Engaging in discussions with patients about any cultural practices that they would like accommodated during their care ensures patients are provided opportunities to express their unique cultural identities. Such conversations also help to identify situations where a patient's preferences might contradict or compromise the care they are being given. For example, a Moslem woman might not want to be cared for by a male healthcare worker, which can be difficult if only males are available. In some cultures it is customary to drink warm water rather than cold. A patient therefore might not take their medication if it is provided with cold water. In these situations it is important to understand your patient's preferences and how their needs can be met in the context of delivering safe and effective care. Developing a trusting relationship with the patient helps you to negotiate a situation in which both their physical and cultural safety needs are addressed. There are many resources on cultural safety that can help you as a student or beginning nurse to provide culturally safe care, some of which are provided in the resources section at the end of the chapter.

Getting to know how patients communicate and how they might signal distress, such as through body language and other non-verbal cues, will help you to identify and address their emotional safety risks. Genuinely listening to patients' worries, concerns and fears with regard to their illness and/or treatment, as well as those of their family and loved ones, is a crucial part of delivering person-centred care. Patients and their family members should feel as though they are integral members of the healthcare team, that they are engaged, involved and informed, and that their preferences and expertise are considered rather than dismissed.

• CRITICAL REFLECTION POINT

Consider how psychosocial needs might change over the life span. For example, providing care to a young child without their parent or caregiver could be traumatic and lead to unnecessary emotional distress. However, this might not be the case when providing care to adults. How else might psychosocial needs change over the life span?

Once you have a good understanding of the patient's cultural preferences, psychosocial needs and developmental or life span needs, document these and discuss them with your healthcare team (with the permission of the patient) so that the patient receives care that is consistent and holistic rather than contradictory and fragmented. Continually observe and assess how patients appear to be coping and check in with them to determine whether their psychosocial needs are being met.

CLINICAL EXAMPLE

Your patient is an 80-year-old man whose first language is Mandarin and who has limited English. He has bowel cancer with metastases and you are providing him with palliative care. His family does not want him to know his diagnosis and have kept him uninformed. You are unsure if this is consistent with what the patient wants. When the patient is alone he cries and looks distressed.

First, consider how you can build a trusting relationship with the patient, given the language barrier. You could have a conversation with his family to discuss whether they would prefer all communication to occur through them or if they would be happy for you to arrange an interpreter. Given that the family is involved in the patient's care and are a key way in which you can communicate with the patient, developing a positive relationship with the family is also crucially important.

Next, consider the psychosocial needs the patient might have. You might surmise that the patient is distressed or anxious and requires emotional support that will help him to feel calm and able to cope. You could consult the patient's family about the type of support that will be most appropriate, such as from a family member, a friend, or a cultural or religious leader. A conversation with the patient's family or with the patient through an interpreter will also help you to get to know the patient and better understand why he appears to be distressed.

It is also important to engage respectfully with the patient's family to better understand why they are choosing not to inform the patient about his diagnosis. This information can help you to respect the family's wishes when providing direct care to the patient. Such a conversation is best held in the context of a trusting relationship. Respecting and following through with the family's wishes will also help to reinforce that relationship. An important scenario to consider is how you might respond if the patient asks about his condition and why he is in hospital. Having a conversation with the patient's family can help to anticipate this need on the part of the patient and negotiate a way to respectfully address the patient's concerns while also adhering to the wishes of the family.

As outlined at the beginning of this chapter, the nurse–patient relationship is part of a wider network of interprofessional and family/carer relationships. Such relationships are crucial in this example. We have already highlighted how we need to build a strong and respectful relationship with the patient's family in order to deliver high-quality care. Equally, an integrated, multidisciplinary team approach is important to ensure that the family's wishes are understood by all who are providing direct care to the patient and to ensure that care is not only culturally safe but also consistent.

Let us consider how we might use the Fundamentals of Care Framework to attend to a patient's psychosocial needs in the following example.

• CRITICAL REFLECTION POINT

A medical registrar arrives to tell a patient his diagnosis and, realising that he does not speak English, asks if a translator can be found. The nurses point out that there is a student nurse currently on the ward who is from Afghanistan, which is the same country of origin as the patient. The student agrees to translate the diagnosis for the patient. The registrar then explains that the man has a tumour, that the prognosis is terminal, and that there is no treatment they can offer him. The student is very uncomfortable about translating this information because in his culture patients are not told that they are going to die.

The student translates the information to the patient. The patient sits quietly and listens. He does not ask any questions. Later the student nurse returns to the patient to talk to him about his understanding of the diagnosis and what supports he might have at home.

- **What different values can you identify in this situation? (Refer to the exercise based on the Value Orientation Profile in Box 3-1 on p. 36)**
- **What conflicting loyalties and obligations does the nurse face in this situation?**
- **How could this situation have been managed differently?**

As outlined at the beginning of the chapter, patients' safety risks are interrelated. Where there are physical safety risks to a patient there are likely to also be psychosocial safety risks, both of which need to be addressed. Consider the following *Clinical example*:

CLINICAL EXAMPLE

A Muslim female patient has just returned to a hospital ward from theatre. The patient's daughter had previously informed the nursing staff that, as a Muslim, her mother does not eat pork. When the patient returns to the ward she has missed the scheduled meal-time. Nursing staff have not organised an alternative meal for the patient. Upon request from the patient's daughter, a member of the nursing staff attempts to find the patient a meal. A nurse returns with a ham sandwich and gives it to the patient.

In this scenario, there are risks both to the patient's physical safety and psychosocial safety. First, the staff had not made sure that the patient had something to eat after returning to the ward, meaning the fundamental of care of nutrition was not appropriately met. Second, the patient's cultural needs and preferences were not respected. Despite being informed of the patient's cultural and religious needs with regard to nutrition, these were not considered in the care provided to the patient.

In addition to physical and psychosocial safety risks, there are also a number of environmental safety risks that need to be considered when providing care to patients. We will consider these environmental risks next.

Patients' environmental safety

A patient's physical environment is crucial to their recovery (Huisman et al 2012, Reiling et al 2008). Attending to a patient's **environmental safety** involves ensuring a clean, safe and secure physical environment for the patient (and their family/carers). This can include infection prevention as well as interventions to optimise the therapeutic environment, such as appropriate lighting, minimal noise, privacy, appropriate bed location and height, orientation aids, and the presence of familiar objects. These environmental safety risks were of paramount importance to Florence Nightingale, and were encapsulated in her Environmental Theory (Nightingale 1860, Selanders 2010). In this theory, Nightingale argued that the design of a hospital, in allowing for fresh air and water, light, warmth, cleanliness and quiet, is crucial to patient safety and recovery. Nursing, according to Nightingale, is the act of using these elements of a patient's environment to assist in their recovery. In modern healthcare environments, appropriate staffing numbers and skill-mix on nursing shifts are also important elements of a patient's environment that ensure safe and effective care.

While environmental safety risks relating to infections, sharps management, falls, pressure injuries and medication are more readily acknowledged and documented within healthcare systems, all of the fundamentals of care are important to consider when assessing a patient's environmental safety risks. If an environment is too hot or cold it is not only uncomfortable for patients but can lead to adverse patient outcomes. Environmental noise, particularly during night shifts, can interrupt patients' sleep, which is vital for their recovery. Patient privacy not only involves a patient's right to have their personal information maintained in a confidential manner. Nurses also ensure a private environment for the patient, particularly during physical examinations and when attending to personal hygiene and dressing.

Although you may encounter some situations where you are limited as to how much you as an indvidual nurse can alter your work environment, there are still things you can do to ensure environmental safety for patients. For example, ensuring the workplace is not cluttered and that both patients and staff have a safe thoroughfare is important for minimising physical safety risks. You can also ensure proper lighting in medication dispensing areas to avoid medication errors, and ensure availability of hand

sanitiser for handwashing to prevent infection. If possible, let natural light into patients' rooms by opening blinds or shades. You can also make sure that blinds are kept closed and lights are turned off when patients are trying to sleep. Reducing levels of noise, such as by turning the volume down on the television in patient and staff rooms, particularly during night shifts, and minimising talk between staff during rounds, can help patients to sleep. Providing access to music might also help to eliminate extraneous noise. Closing curtains or doors during examinations, washing and dressing, is also important to ensure privacy in the patient's environment.

• CRITICAL REFLECTION POINT

The critical care unit presents nurses with one of the most challenging environments in which to work. These environments were created to closely monitor very ill patients. As such, patients are in close proximity to nurses and to each other. The effects of this environment mean that patients are continually exposed to noise, light and interruptions. Critically ill patients sleep poorly and the nature of their illness, the effects of medication and the physical discomfort they experience can predispose them to cognitive impairment and poor memory, leading to confusion. Poor sleep can also cause cardiovascular stress and impaired immune system. Patients being cared for in critical care units often experience stress and anxiety (Urden et al 2016).

Imagine you are an intensive care unit (ICU) nurse rostered for night shift in a busy city hospital. You arrive to a well-lit ICU department to receive handover of your allocated patient. The number of nursing and medical staff has doubled at this time and noise is at a maximum. Handover begins.

- **What environmental safety risks to the patient can you identify in this setting? How might you mitigate these risks?**
- **Given that ICU patients are often sedated and ventilated, what data could you collect to assist you in assessing the level of stress your patient is experiencing in this environment? Who might be able to assist you with gathering this information?**
- **How can you use the Fundamentals of Care Framework to engage with critically ill patients and their families to reduce their anxiety and ensure they feel secure in your care?**
- **How might the multidisciplinary team assist the family to cope in this stressful environment, and reduce environmental safety risks?**

It is also important to consider how patients' specific developmental and life span needs are affected by their environment. For example, children are susceptible to choking. You can ensure the work environment is free from choking hazards in order to help minimise this risk. Likewise, elderly patients are susceptible to falls. Consider the aspects of the environment that might increase this susceptibility, such as wet or slippery floors or patient beds that are too high, and how you might address these safety risks.

• CRITICAL REFLECTION POINT

You are a newly graduated RN and you are working on a busy surgical ward in a large hospital. You arrive for an afternoon shift and discover that you are the team leader. The ward has a capacity of 18 beds and all beds are occupied with pre- and postoperative patients. You are allocated one enrolled nurse (EN) to assist you and one third-year student nurse. You know that this level of staffing is inadequate for this number of patients, so you request more staff from the nurse manager. Your request is unable to be met because many staff are on sick leave.

- **What would the risks to patient safety be in this understaffed environment?**
- **Can you identify any strategies to modify these risks, knowing that you are not able to change the current staffing level? For example, who might you allocate to care for the preoperative patients compared to the postoperative patients?**

As highlighted previously, the different types of patient safety – physical, psychosocial and environmental – do not occur in isolation. It is much more common for all three types of safety risks to be present at the same time when you are caring for a patient.

Throughout this chapter we have focused on how patient safety risks can change over the course of their life span. Consider the following:

- What are the different safety issues (physical, psychosocial and environmental) you might consider for an infant, a toddler, a young adult and an elderly person?
- How would you use the Fundamentals of Care Framework to identify and address these issues? (Refer to the *Clinical example* on p. 37.)
- What communication and cognitive issues might be relevant for an infant, a toddler, a young adult and an elderly person?
- How can you use the Fundamentals of Care Framework to build a trusting relationship with a patient whose communication or cognition is impaired or not yet developed?

WORKING WITH DIVERSITY

An important part of developing a positive, trusting nurse–patient relationship is avoiding making assumptions about a patient's life and needs. One common assumption is that patients are heterosexual and/or in a heterosexual

continued

relationship. It is important to respect the diversity of sexual orientation and family relationships and to respect the person identified by a patient as their significant other. Assumptions around a patient's cultural identity and preferences should also be avoided. A 'one-size-fits-all' approach to care where all patients from the same cultural or religious background are viewed as having the same needs is insufficient – it is important to get to know each patient individually and understand their unique needs and preferences. Likewise, rather than assuming that all patients in a particular age group will have the same needs, or have a limited capacity for recovery, it is important to have conversations with patients to better understand their distinctive needs and abilities. Such conversations will help you to develop trust, anticipate and address patients' concerns, and assist them in their recovery.

Implications for practice

It is important to continually check whether assumptions are making their way into your care. Consider your answers to the *Critical Reflection Point* on p. 34. Did you make any assumptions about the needs of patients in different age groups? How can you tell? How might you use the Fundamentals of Care Framework to engage with patients and their families to understand whether certain age-related risks are relevant to a particular patient?

Consulting and revisiting the Value Orientation Profile introduced in Box 3-1 on p. 36 can help you to determine whether assumptions are finding their way into your care delivery.

You can also refer to Chapter 2 and use the Fundamentals of Care Practice Process to double check your assumptions about a patient and how they might impact the care you provide.

Personal safety of the nurse

When considering safety practices in the healthcare environment it is not only the patient who needs to be protected; nursing staff are also at risk of injury and other harm on a daily basis. The management of risk is an integral component of nurses' practice, irrespective of the context in which care is being delivered (e.g. hospital or community setting).

Risks to nurses' safety can be physical, psychosocial and environmental. Physical risks include lifting and mobilising patients, needle stick injuries, being assaulted, and infectious diseases. Many healthcare organisations have implemented 'no lifting' policies, where the manual lifting of patients is eliminated or minimised and replaced with mechanical lifting devices to aid in the safe mobilisation, transport and transfer of patients. It is important to know how such policies operate in your healthcare organisation and how best to adhere to them. It is also important to ensure that you stay out of arm's reach of potentially violent patients or patients you do not know well in addition to having an exit from the room.

At all times when assessing an interaction with a patient, such as administering an injection or taking a patient to the shower, you must assess the possible risks to yourself and be aware of appropriate Work Health Safety and Occupational Health and Safety regulations and codes of practice. These regulations and codes cover staff health, safety and welfare in the workplace and are put in place to guide your work and help keep you and your patients safe. Awareness of safe work practices, such as in relation to manual handling, is part of nurses' ongoing professional development. As a nurse, you will be required to undertake mandatory training around lifting, handling waste and sharps management. It is also important that any work-related injuries are reported and investigated.

CRITICAL REFLECTION POINT

You are a student nurse and you answer a call bell of a patient you do not know. When you get to his room he is sitting in his chair and points to his bed. You assume he wants to move from the chair to the bed. You know from handover that he has had a stroke. You observed him being moved the previous day by another nurse, so thought this would be an easy task to attempt yourself. You position yourself in front of the patient and ask him to lean on you and stand up. As you do this you realise the patient has no strength in his legs and he has weakness down one side of his body. You think he might fall, so you sit him back down again.

- **What are the potential safety risks that you can identify in this situation (both to yourself and to the patient)?**
- **Using the Fundamentals of Care Framework, how would you engage with the patient to identify and address these safety issues?**
- **What assessments could you have performed before moving the patient?**
- **What did you already know that would have led you to investigate how mobile this patient was?**

Psychosocial safety risks to nurses can include being threatened by aggressive patients and relatives, sexual harassment, intimidation, and bullying from colleagues, other staff, patients or their families. The key to minimising these risks is managing stress and maintaining wellness, such as through work–life balance and appropriate nutrition, exercise and sleep. It is important to report incidences of intimidation, threats, bullying, harassment and assault from patients or staff, being sure to adhere to any relevant workplace guidelines and policies. Seeking appropriate support, both within and outside your organisation, can also help following these events.

It is also important to consider how and to what extent you engage with patients and what you can do to keep yourself safe when building therapeutic relationships with patients and their families. Setting professional boundaries around patient relationships will help you to minimise emotional burnout and other safety risks. **Professional boundaries** are the limits placed around the nurse–patient relationship that allow for a safe, therapeutic connection between you and the patient (and their family and friends) (Nursing and Midwifery Board of Australia 2010). Such boundaries mark the edges between a professional, therapeutic relationship that exists for the purpose of meeting the needs of the patient and a non-professional, personal relationship. Figure 3-5 below, taken from the Nursing and Midwifery Board of Australia's (2010) guide to professional boundaries, demonstrates how every nurse–patient relationship can be plotted on a continuum of nurses' professional behaviour (see also National Council of State Boards of Nursing 2007, from which the diagram was adapted). This continuum shows the difference between therapeutic and non-therapeutic nurse–patient relationships. You can use this diagram to evaluate your behaviour and consider if you are acting within the confines of a therapeutic relationship (National Council of State Boards of Nursing 2007).

CRITICAL REFLECTION POINT

When building a relationship with patients and their families, consider what constitutes your duty of care and what level of engagement is appropriate. While you might provide reassurance to patients and their families in the care setting, is it appropriate or necessary to maintain contact with patients outside of this setting to provide continued support? While you might help patients reconcile disagreements with their family regarding the delivery of their care, what level of engagement is appropriate? What do you do if the conflict involves more than just a disagreement about the care being provided?

Examples of boundaries that can be set around the therapeutic nurse–patient relationship include avoiding excessive self-disclosure. Carefully consider the need to disclose personal information, such as personal problems, to a patient. Excessive personal disclosure can move the nurse–patient relationship from professional to personal. Self-disclosure should be limited to revealing information that is of therapeutic value. The same applies for the information you obtain from the patient – you only need to know information that will help you in caring for

Figure 3-5 The continuum of the nurse–patient relationship.

Nursing and Midwifery Board of Australia, 2010 A nurse's guide to professional boundaries. Nursing and Midwifery Board of Australia, Melbourne.

the patient and meeting their needs. You can also set boundaries around how much time you spend with a particular patient. Notice whether you are singling out a patient for care, spending large amounts of time with them, visiting them on your day off or swapping shifts to care for them or to spend time with their family and loved ones (Nursing and Midwifery Board of Australia 2010).

Maintaining patient confidentiality is also important. For example, it is unlikely that you will need to look at the notes of a patient for whom you are not providing direct care. You can also set boundaries by avoiding developing friendships or romantic relationships with patients and socialising with them both in and outside of the care setting. In some cases it might be appropriate to socialise with former patients, such as when the patient is vulnerable, requires ongoing care or has difficulties with decision-making (College of Registered Nurses of British Columbia 2006). Also consider your conduct on social media. Making a comment via social media regarding an incident, your employer or a particular patient may be a breach of patient confidentiality or privacy and an example of a boundary violation (National Council of State Boards of Nursing 2007). This can be the case even if the comment is made during your own time and in your own home.

To determine whether a particular behaviour might go outside the limits of a professional relationship, and where your relationship with a patient sits on the nurse–patient relationship continuum, ask yourself: Does the behaviour meet a clearly identified therapeutic need for the person receiving care? Is it part of their care plan? Is it in the person's best interests? Is the behaviour within my scope of practice as a nurse and in keeping with standards for practice (National Council of State Boards of Nursing 2007, Nursing and Midwifery Board of Australia 2010)? Policies and codes will help guide your actions and determine what constitutes your duty of care to patients and their families within and outside the care setting. Relevant policies and codes include:

- *Code of Professional Conduct for Nurses in Australia* (Nursing and Midwifery Board of Australia 2008b) and *Code of Conduct for Nurses in New Zealand* (Nursing Council of New Zealand 2012a)
- *Professional boundaries guidelines* from the Nursing and Midwifery Board of Australia (2010) and the Nursing Council of New Zealand (2012b)
- *Code of ethics* from the New Zealand Nurses Organisation (2010) and the Nursing and Midwifery Board of Australia (2008a)
- *Social media policy* from the Australian Health Practitioner Regulation Agency (2014).

If you have concerns relating to boundaries in therapeutic relationships with patients and families you can also seek support and guidance from supervisors and more experienced nursing colleagues.

CRITICAL REFLECTION POINT

- **What are some of the boundaries that you might establish in order to keep yourself safe when engaging with patients and their families?**
- **Consider how you might respond in the following scenarios:**
  - **You have recently cared for a patient with whom you established good rapport and a positive relationship. The patient is now being discharged and has asked to connect with you on social media.**
  - **A patient you have been caring for is being discharged from hospital. She is not steady on her feet and so you and a colleague assist her to the taxi rank outside the hospital. You notice that the patient has some difficulties with communication and seems confused. You are concerned for her safety. Your colleague suggests that you both get into the taxi with the patient to ensure that she arrives home safely.**
  - **You notice that a colleague has been behaving towards a patient in a way that you consider to be violating the therapeutic nurse–patient relationship.**

Environmental risks for nurses can include infectious diseases, equipment malfunction, handling of medications, exposure to radiation, and latex allergies. To minimise risks around medication it is vital to ensure proper handling, management and disposal of medications (such as chemotherapy drugs), as well as correct and consistent use of personal protective equipment (e.g. coverall or gown, head covering, closed footwear, protective gloves, protective eyewear and respiratory protective devices where inhalation risk exists) (Worksafe Victoria 2013). In the event of spills of certain medications, a spill kit should be used. Also ensure that emergency skin and eye decontamination kits are readily available. To prevent the acquisition of infectious diseases, nurses must receive the required immunisations for their work activities and role (e.g. hepatitis A and B and measles), in addition to undergoing tuberculosis screening. As a student you probably would have had these tests before being permitted to work in a healthcare setting. Healthy workplace policies and procedures on Occupational Health and Safety are also important in mitigating nurses' environmental risks.

CRITICAL REFLECTION POINT

As mentioned earlier in the chapter, the different types of patient safety – physical, psychosocial and environmental – do not occur in isolation. Likewise, when there are risks to a patient's safety there are probably risks to your safety

as well. And these risks are just as important to address. Consider the following example.

A 20-year-old male presents to the emergency department. He is combative and his behaviour is erratic. He is yelling at staff and other patients. He will not lie on the bed and so has to be restrained. You assume he has been engaging in drinking and drug use, which is confirmed through testing.

- **What are the physical, psychosocial and environmental safety risks to:**
  - **the patient**
  - **yourself**
  - **other staff**
  - **other patients?**
- **How can you establish a relationship and engage with the patient, considering he is combative and under the influence of drugs and alcohol?**
- **How would you ensure the safety of the patient when he is not able to communicate with you properly? How do you ensure your safety in this situation?**
- **How might you de-escalate the situation?**

Summary

Ensuring patient safety is an important element of providing high-quality, person-centred care. The Fundamentals of Care Framework helps you to understand why a positive and trusting nurse–patient relationship is integral to maintaining patients' physical, psychosocial and environmental safety. Through building a positive therapeutic relationship and engaging respectfully with patients you are able to identify patients' unique safety risks and address these risks in a way that is suited to patients' (and their families'/carers') preferences and wishes. When assessing each care situation for the potential safety risks to patients it is also important to consider your safety as the nurse and to identify the strategies you can put in place to minimise these risks.

Key concepts

- Ensuring patient safety is an important element of providing high-quality, person-centred care.
- The Fundamentals of Care Framework illustrates how a positive and trusting nurse–patient relationship is integral to maintaining patients' physical, psychosocial and environmental safety.
- A positive therapeutic relationship and engaging respectfully with patients enables the nurse to identify patients' unique safety risks and address these risks in a way that is best suited to patients' preferences and wishes.
- When delivering nursing care, it is always important to consider your own safety as the nurse and consider how any risks can be mitigated.

Developing clinical reasoning for nursing practice

Clint Douglas and Jackie Crisp

Learning outcomes

Mastery of content will enable you to:

- understand the value of using a reflective and systematic approach to clinical reasoning
- discuss the ways in which a systematic approach to clinical reasoning enhances nursing knowledge and skill development
- discuss the ways in which nursing knowledge and skill development enhances the process of clinical reasoning
- explain how using a systematic approach to clinical reasoning contributes to the visibility of nursing practice
- explain the relationship between critical thinking and clinical reasoning within nursing practice
- discuss the six basic domains evident within all processes of clinical reasoning
- use critical questioning within each of the six basic domains of the clinical reasoning process.

KEY TERMS

Action planning, p. 51
Clinical reasoning cycle, p. 50
Clinical reasoning models, p. 47
Cognitive bias, p. 47
Critical questions, p. 56
Critical thinking, p. 49
Goals and priorities, p. 50
Information/data, p. 51
Judgements and decisions, p. 51
Nursing knowledge, p. 52
Nursing models, p. 47
Outcomes, p. 49
Reasoning process, p. 49

Introduction

This chapter will introduce you to the process of clinical reasoning, which will support your development as a nurse and make the critical thinking that guides nursing practice more visible to yourself and to others. A major goal in introducing you to a systematic process of clinical reasoning from the beginning of your nursing career is to enable its conscious and automatic use – no matter where you are practising or your level of experience as a registered nurse. We believe that those who establish such a systematic approach to their learning and practice are significantly more likely to have access to their own thinking and be more able to share their thinking and practices with others (Huang et al 2014), therefore making the complex clinical decisions that form the basis of nursing practice evident to ourselves, our colleagues and to those we care for. Put quite simply, the extent to which we engage in the process of clinical reasoning determines our ability to learn, to share that learning and to use what we have learnt in our day-to-day practice. It also helps us practise competently and confidently. Engaging in a reflective process in practice helps us to avoid the traps of **cognitive bias**, associated with self-fulfilling prophecy, prejudices, avoidance, group think and other challenges to safe and effective nursing care (Lieberman et al 2014).

Sound clinical reasoning does not happen by accident, nor does it occur by simply observing expert RNs practise (Levett-Jones et al 2010). Learning to think like a nurse requires deliberate practice and a structured approach to working through clinical problems. There is no surprise, then, that the process of clinical reasoning we outline below has several key domains that capture a systematic approach to: (1) gathering relevant information and data; (2) making appropriate judgements and decisions; (3) setting priorities and establishing goals; (4) preparing for and taking action; (5) evaluating impacts and outcomes; and (6) learning from the process to inform future practice. This process forms the first level of inquiry discussed in Chapter 7, and sets the foundation for all other levels of inquiry associated with the production and utilisation of nursing knowledge.

Previous editions of this book have used one specific framework (i.e. the Nursing Process, see Figure 4-1) to illustrate the clinical reasoning process (American Nurses Association 2010). From this edition onwards, however, we have decided to take a more inclusive and descriptive approach for ease of understanding and application. In addition, while the clinical reasoning process is depicted most commonly as a cycle (e.g. Levett-Jones 2013, Figure 4-2; Tanner 2006, Figure 4-3), we have decided to foreground the domains evident within those models, and background the notion of a cycle-like process. Within this chapter we take a generic, descriptive and inclusive approach, so that novices, such as yourselves, can understand how the range of available **nursing models** seek to achieve the same end, irrespective of specific language or depictions (Box 4-1). While there is indeed a logical process in the ordering of the domains that is cycle-like, we also know that everyday practice is inevitably more complex than starting at the beginning of the cycle, working through the domains of the cycle in a predetermined order and then closing the loop before moving on to the 'next reasoning process'. Often, nurses need to focus simultaneously on several domains in relation to overlapping issues related to one patient. This chapter seeks to provide fundamental learning in relation to each domain that can be utilised across the range of clinical reasoning models.

So it does not matter which of the many **clinical reasoning models** you may be asked to use, or you decide you like best, as long as you understand that the basic domains remain constant. And, no matter which models you encounter, the fundamental knowledge, skills and attitudes associated with sound critical thinking will always lie at the heart of clinical reasoning (problem-solving, clinical judgement or diagnostic reasoning).

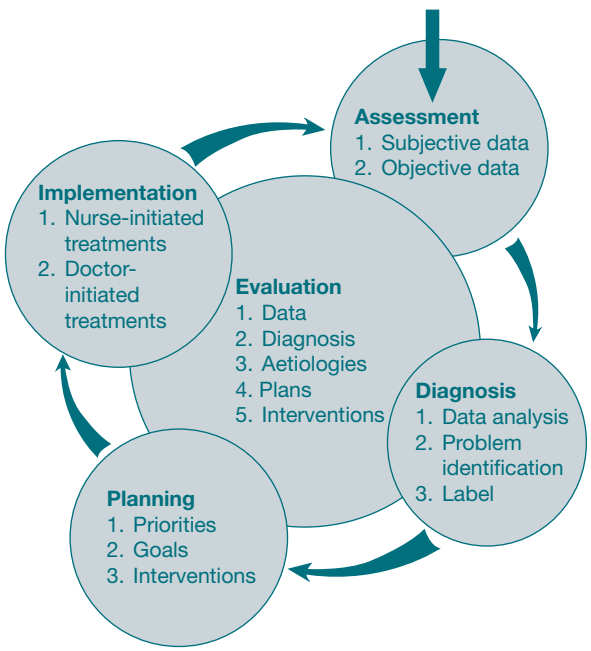

Figure 4-1 **The nursing process.**

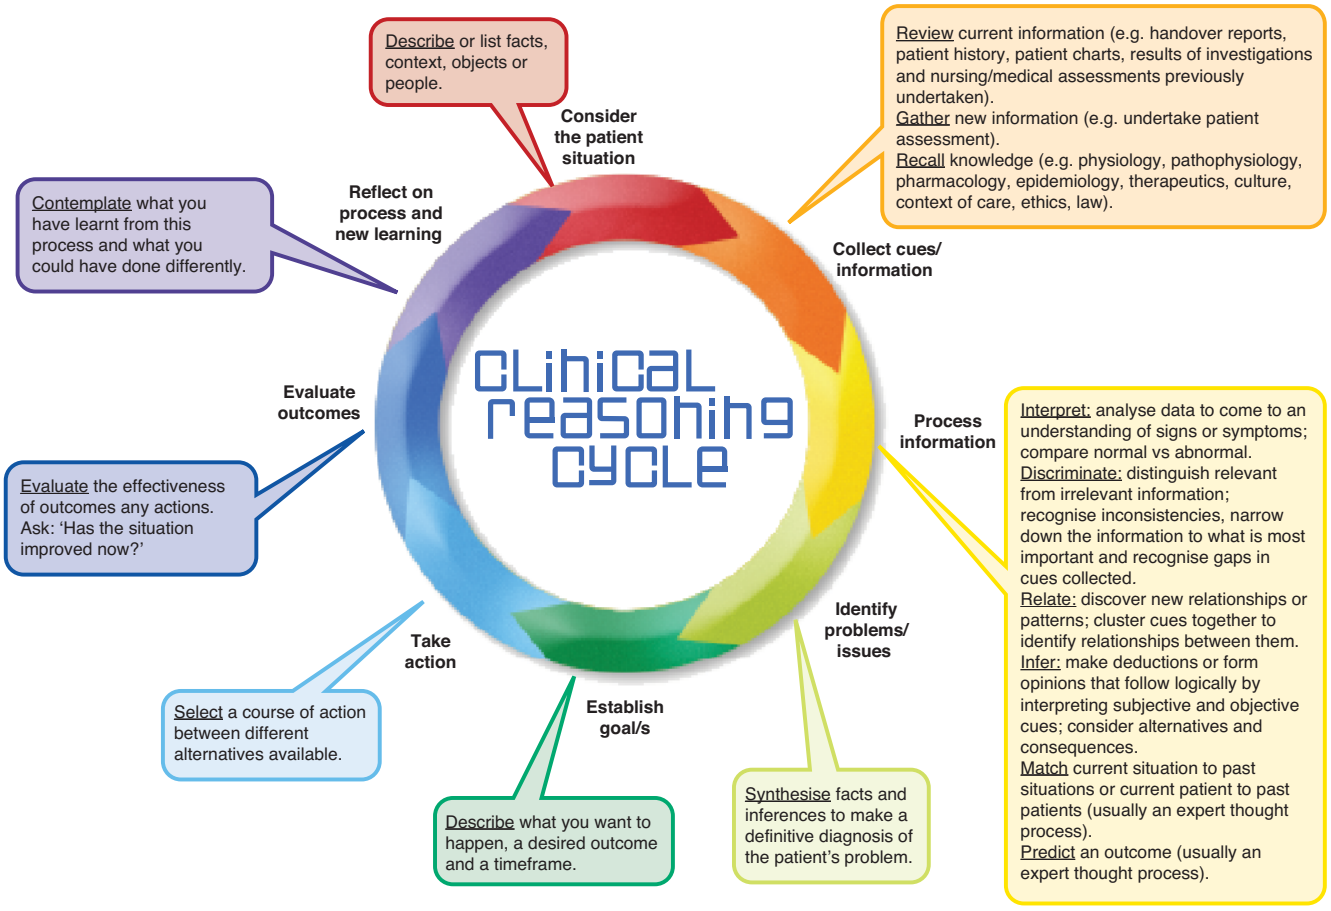

Figure 4-2 Clinical reasoning cycle.

BOX 4-1 Six domains evident within all depictions of the clinical reasoning process

a Gathering relevant information and data
b Making appropriate judgements and decisions
c Setting priorities and establishing goals
d Preparing for and taking action
e Evaluating impacts and outcomes
f Learning from the process to inform future practice

The importance of the clinical reasoning process for effective nursing practice

Our intention across this book overall is to help you build the fundamental knowledge and skills required for your development as a nurse. To do that, you need to engage effectively with the thinking/actions and learning associated with all six of the domains outlined and described across Chapters 4–7.

As you move through your nursing program you will come to realise that all of the chapters making up this book enhance your capacity to take a reflective and critical approach to the process of clinical reasoning. For example, several chapters focus on the accountabilities and responsibilities that need to be considered throughout the clinical **reasoning process**; these include those that are professional, ethical and legal in nature (e.g. Chapters 9–11). Other chapters provide you with an understanding of healthcare systems: the ways in which nurses, along with other healthcare professionals, work within these systems in general to achieve the best possible experiences and **outcomes** for patients and their families (e.g. Chapters 1–3, Chapter 8); and the roles and realities of working as nurses within specific healthcare contexts (Chapters 38–41). The knowledge and skills that will enhance your ability to take a person-centred approach in the care you provide to patients and families are outlined in Chapter 12 and across Chapters 14–22. The remaining chapters support your development in relation to specific clinical knowledge and skills. It is, however, the clinical reasoning process that focuses all of the above knowledge and skills, and sits at the heart of effective nursing practice.

There is a great deal of ongoing confusion around the definition, overlap among, and usage of the terms clinical thinking, clinical reasoning, clinical decision-making and clinical judgement (as well as other similar terms). For a thorough description of these constructs, see Alfaro-Lefevre (2013). In this fifth edition we have decided to take a slightly different approach to that of the first four editions. In an attempt to highlight critical thinking within the clinical context – that is, nursing care provided to patients – where the process of reasoning and action are intimately linked, we are using the term **critical thinking** in relation to the knowledge, skills and attitudes required for sound thinking, and we are using the term clinical reasoning to capture the systematic process demanded in the application of that thinking in the delivery of nursing care.

To begin, let us consider the process of reasoning in relation to one common area of our everyday lives: our dental health. You might, for example, go months without even consciously considering your teeth, how they feel and how they look. One day you may notice a slight pain in a molar and then find yourself actually looking more closely and thinking about what is going on in your mouth. You may see some discolouration and feel a build-up of plaque behind your teeth. You start to worry that your mouth looks unappealing and that you might have some real problems brewing. Then you go into your exam period and forget about your mouth and it might take six months to get back to even thinking about it – unless your toothache worsens to a point where you cannot avoid it. Maybe you get back to thinking about it and even decide that you need to go to the dentist; you make the appointment and then cancel it – no money! Your mother might comment on your dental hygiene, but she is just trying to have a go at you and she doesn't know what you are going through or understand … It may take several months for you to seek out the advice of a dentist; and then several more months to act on that advice … Or you may never do anything. If you do take some of the advice, such as flossing every day, it may only last a couple of weeks because your teeth don't look any different, so why bother?

Replace this dental example with 'eating habits', 'exercise', 'hygiene', 'stress management', or any of a myriad of areas related to your day-to-day decisions and actions and you will recognise the stop/start, approach/withdraw, cost/benefit type dynamics we all experience at times. You can see from the above example that the critical points in the process of reasoning relate to:

- what we pay attention to or 'see', and the extent to which we trust what we 'see'
- how we make sense of what we 'see' (the story we tell ourselves)
- what we decide to do and why
- when we do it
- how we do it
- if we do it
- determining if it worked for us.

The chaotic and hit-or-miss nature of the approach most of us take in relation to some aspects of our personal lives is, however, simply not acceptable within the context of our nursing practice, where clinical reasoning determines patients' experiences of care as well as minor and major health outcomes. For example, failure to recognise and rescue hospitalised patients at risk of clinical deterioration is related to poor clinical reasoning skills (Levett-Jones et al 2010). We are responsible for providing safe, effective and appropriate nursing care to those we work with, and we have an obligation to ensure we do that to the best of our ability. Decisions concerning what we do and do not notice, and the actions we take (even the action of doing nothing) in response to that will determine both the experiences of care and outcomes achieved for patients. This is as true in relation to relatively 'mundane or common' aspects of nursing care (such as administering medications, oral hygiene or patient comfort) as it is for those that are viewed as more dramatic and associated with survival (such as cardiopulmonary resuscitation). One of the challenges nurses face is finding ways of providing care that covers the range of patient needs: from day-to-day care and support to care that is unequivocally life changing (or sustaining). The extensive work on patient safety and focus on patient satisfaction reflects the extent to which these distinctions are far more subjective, complex and interrelated than many think; and providing effective fundamental care can, and does, have a profound impact on patient experiences and outcomes (see Chapters 2 and 3).

Take, for example, a process triggered by an observation that a woman in your care on an acute unit is visibly upset after a visit by her husband. You could tell yourself that she is obviously missing her family and she will get over it, so decide to ignore her distress and stay away from her for an hour so she can calm down. You could tell yourself that she is lonely and work to cheer her up and spend as much time as you can with her, telling jokes and engaging her in superficial chatting. You could just choose to not think about it because it is probably something personal and none of your business. The truth is that you are making assumptions based on nothing you have verified beyond your own perspective/insight. An appropriate response to the observed distress involves a process of seeking additional information concerning the observed distress from the patient, seeking to understand the basis of the distress and the consequences of that distress for the patient, determining what you might do as a nurse in response to the distress, generating some strategies to support the patient and taking related actions, and keeping in touch with the patient to ensure that the actions you took have been helpful. The development of effective nursing practice, then, requires the use of a systematic process of clinical reasoning that maximises the use of all relevant information, leads to sound judgements and decisions, identifies appropriate **goals and priorities**, and leads to assessable outcome-based actions and learning.

• CRITICAL REFLECTION POINT

Now that you have a better understanding of the domains of clinical reasoning, reflect on the following:

1. **What existing knowledge bases, skills and experiences can you draw upon to enhance the development of clinical reasoning within your practice?**
2. **Identify three strategies that you will use to support your development in this area.**

The process of clinical reasoning

As discussed in the introduction to this chapter, there are a myriad of conceptual models seeking to explicate the process of clinical reasoning; and you will undoubtedly encounter several of these in your studies and across various clinical settings. One thing that everyone does agree on, however, is that clinical reasoning (by any name) is crucial for effective nursing practice (Box 4-2). Australian and New Zealand students are commonly exposed to the nursing process as a problem-solving approach to practice (see Figure 4-1), the **clinical reasoning cycle** (see Figure 4-2) or Tanner's clinical judgement model (see Figure 4-3). There is no surprise in this; however, the similarities and differences among such models/cycles can

BOX 4-2 Developing clinical reasoning skills

Developing clinical judgement – clinical reasoning skills – is one of the most important and challenging aspects of becoming a nurse. It's important because people's lives depend on it. It's challenging because thinking in the clinical setting is often fraught with more anxiety and risks than any other situation … It entails things like knowing what to look for, how to recognise when a patient's status is changing, and what to do about it. For beginners, this is particularly taxing because it requires an ability to recall facts, put them together into a meaningful whole, and apply the information to a current clinical situation (a situation which is often fluid and changing).

Alfaro-LeFevre R 2009 Critical thinking and clinical judgement: A practical approach to outcome-focused thinking, 4th edn. Saunders Elsevier, St Louis, p. 99.

be confusing. Just remember that they are all underpinned by a logical structure for working through a thinking process and associated actions: 'see something', 'make some interpretations or judgements concerning what is going on and what might be done about it', 'do something' and 'look to see if what was done achieved what it was intended to achieve' (see Box 4-1). And finally: learn from the experience.

• CRITICAL REFLECTION POINT

Go to your favourite search engine and insert 'define clinical reasoning'. What will appear – along with the URLs for a myriad of relevant sites – are some images of clinical reasoning models, cycles, stages, etc. Open up some of these and examine the ways in which the particular person, professional group or organisation describes their particular approach.

1. **What similarities and differences do you see among the models you examine?**
2. **Do one or more of these resonate with you and the way you think about nursing?**
3. **Why do you think so many different approaches have evolved across time, professions and contexts?**
4. **What do you think is behind our decision to take a more generic and inclusive approach to discussing the process of clinical reasoning?**

The starting point of clinical reasoning involves the identification and bringing together of **information/data** triggered by an observation or insight. For example, the observation that a patient has a high blood pressure reading triggers the gathering of information relevant to that observation: history, previous readings, diagnosis, other assessments of the patient and so forth. This information can be in existence already, or may need to be generated. The goal within this domain is to have all of the information/data required to move into making **judgements and decisions** concerning the appropriate response or actions. This process is dependent on your ability to obtain clear information from the patient and/or family members, the knowledge you were given at handover or through reading the patient's notes, and your existing knowledge of the area (e.g. normal range of blood pressure readings, factors that influence readings, etc), local policies and practice guidelines. You will also need to undertake a focused physical assessment of the patient (Chapters 23 and 24).

As the relevant information or data are obtained, the process moves on to making appropriate judgements and decisions concerning what these mean, and what actions may need to be taken. One possible, and very common, outcome at this point is the recognition of the need for more information, or different forms of information/data. There are of course other possible next steps, including the need to involve additional people in the process or the need to act quickly in response to one vital piece of information (e.g. the blood pressure falls well outside the normal range and the patient requires immediate assessment by the appropriate medical team). As a novice, one of the most common steps to be taken at this stage is identifying the best person to assist you in making sense of what is going on and what needs to happen next. Your ability to share your observations/data or information in a clear and concise manner will determine both the quality and quantity of support you receive from more experienced colleagues, as well as the timeliness of that support.

The decisions that are made concerning appropriate action then need to be prioritised and specific goals established. This involves considering options and determining what is likely to be most effective: for example, evidence from previous experience, local guidelines/data or research evidence (Chapter 7), what is possible and what is acceptable. Priorities and goals are of course linked to the impacts or outcomes that are sought through the actions to be taken. And, of course, **action planning** can uncover the need for either additional information/data or for input from others to gain additional judgements and potentially lead to different decisions.

Remember, the decision not to act is in itself an action. All actions should be preceded by appropriate preparation: this may include getting physical resources together and developing specific skills, or locating someone with those skills. And even if the patient and the family have been closely involved in the decision-making process, it always involves ensuring their input, understanding and agreement.

In order to ensure the effectiveness of nursing practice we need to avoid assumptions that those actions we take will always achieve the intended goal or outcomes. Indeed, you may find that some actions have unexpected or detrimental effects. Nursing practice is complex; human beings are complex; and healthcare environments are complex. A particular practice might work well for one patient but not for another; and the reasons for this may be unclear. Some patients experience straightforward recovery from the same procedure that causes distress in others. 'Closing the loop' or assessing the outcomes of your actions or practice is fundamental to both the ongoing development of nursing practice and to your learning.

In summary, the process of clinical reasoning works equally well across contexts and throughout all stages of your development as a nurse. That is, the process remains constant, although in different contexts the focus of each

domain (e.g. what data are available, what actions are possible or acceptable) may vary dramatically. In addition, as you develop your knowledge and expertise, the nature of your engagement in the process will evolve: as a student nurse you will need to access the support of others as you work through the cycles; as a more experienced and knowledgeable nurse your judgements and decisions will become more autonomous.

Developing your nursing knowledge and skills through the clinical reasoning process

What both drives and emerges from the clinical reasoning process is **nursing knowledge**. As your nursing knowledge base develops, the meaning you give to situations changes and learning occurs. You then take this learning with you to the next situation and create new meanings and experiential knowledge. Conway and McMillan (2014) explain this concept well in Figure 4-4 and demonstrate this continual process of learning as an outcome of nursing experience.

However, experience is 'cheap', and, as Conway and McMillan (2014) argue, experiential knowledge is not merely accumulated as a result of working as a nurse or nursing student. Experiential knowledge is generated through ongoing learning that comes from critical and reflective approaches to making sense of, and building on, our existing knowledge. Learning, rather than merely experiencing, occurs when we apply concepts to practice, manage complex patient-care situations that trigger uncertainty, and are accountable for our clinical reasoning in practice. Becoming comfortable with questioning and justifying our clinical decisions based on evidence is crucial to developing as a professional (see Box 4-3).

BOX 4-3 Learning from practice

- Was the clinical management of this patient supported by scientific rationales, research evidence and the patient's responses to treatment?
- Were there plausible alternatives to the chosen interventions?
- To what extent were my clinical decisions influenced by personal assumptions and beliefs?
- What were the most important personal learning outcomes – including awareness of my personal strengths and weaknesses?
- What actions would I take if presented with a similar situation in the future, and why?

The depth and extent of your nursing knowledge will influence your ability to think critically about and act effectively in different clinical situations. Consider the following *Clinical example*.

CLINICAL EXAMPLE

Postoperative fever

You are working on a surgical ward during a clinical placement and are asked by your buddy RN to take routine postoperative observations on a patient who is

continued

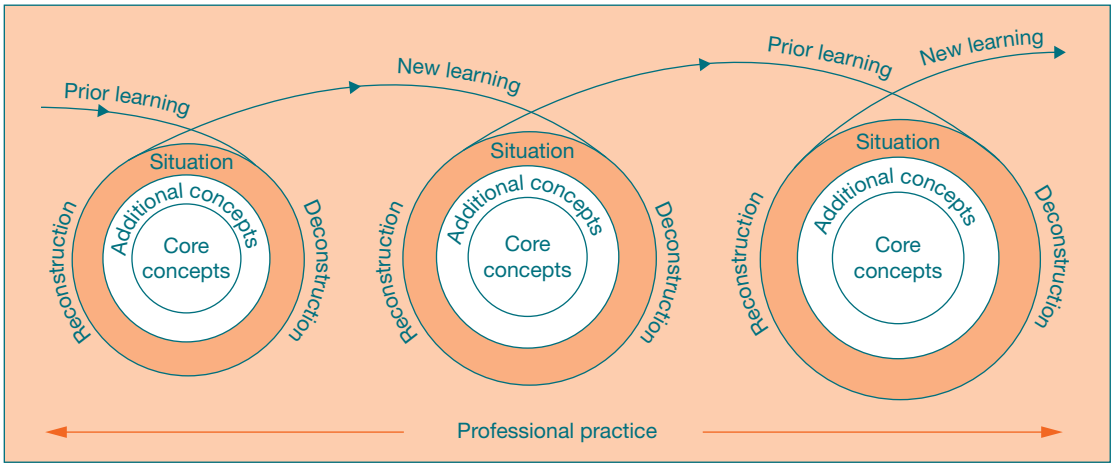

Figure 4-4 The relationship between situation analysis, learning and professional practice.

Conway J, McMillan M 2014 Connecting clinical and theoretical knowledge for practice. Fig 22.2; In Daly J, Speedy S, Jackson D (eds) Contexts of nursing, 4th edn. Elsevier, Chatswood NSW.

24-hours post-laparoscopic appendicectomy, and is to be discharged later in your shift. When you take his body temperature you find it is 38°C. You wonder whether this is significant and whether you need to do anything about it.

You discuss the finding with your buddy RN, who explains that a low-grade fever appearing soon after surgery (24–48 hours) is often part of the body's inflammatory response. Other common causes of postoperative fever include atelectasis, pneumonia, wound infection, urinary tract infections or infected IV sites. Also, because your patient has had an appendicectomy, he should be observed for evidence of peritonitis. With this information in mind, you return to the patient to complete a focused body systems assessment in order to confirm or rule out these potential causes (see Chapter 24).

On assessment you find:

- Primary survey and vital signs: The patient looks well and appears to be in no acute discomfort or distress. Other vital signs are within normal limits: Respiratory rate 14/min, SpO2 98% on room air, pulse rate 70/min, blood pressure 120/70 mmHg. On the observation chart, the temperature pattern shows a low-grade fever since admission.
- Chest: The patient's breathing is relaxed. Lungs are clear to auscultation.
- Abdomen: Soft, slight tenderness at wound sites. Bowel sounds present. No guarding.
- Wounds: Port sites are dry and intact.
- Extremities: IV in right hand without redness, oedema or tenderness.

Based on the focused assessment data, you rule out any of the possible complications identified earlier. While the patient's temperature is elevated, there is no data to suggest a problem at this time. In collaboration with your buddy RN, you decide the appropriate course of action is to monitor the patient's temperature more frequently before discharge. You explain your findings to the patient, and discuss how and why you will be monitoring his body temperature over this shift.

Later you and your buddy RN determine that there has been no change in temperature, that the patient and his family understand how to monitor for postoperative fever, and are aware of the potential complications. In reflecting on this experience and how it will influence the way you respond to similar situations in the future, you identify the new knowledge you have gained about how to analyse and respond to a patient with postoperative fever, as well as further learning needs such as gaps in your knowledge about the possible complication of peritonitis. Finally, the experience of discussing your thinking 'out loud' and hearing the way the RN could explain her decision-making and actions helped you develop confidence in discussing nursing practice. You realise that increasing your ability to make your clinical reasoning visible is a critical component of effective nursing practice.

Reference

Adapted from Lewis P, Douglas C 2014 Analysing data using critical thinking skills. In Lewis P, Foley D (eds) Health assessment in nursing, 2nd edn. Lippincott Williams & Wilkins, North Ryde, pp 56–62.

The *Clinical example* above makes clear that safely and effectively moving through each domain of clinical reasoning depends on the nurse's knowledge and critical thinking ability. Determining the most relevant data/information to collect and making appropriate judgements and decisions are difficult skills for beginning nurses, until they have developed enough knowledge and clinical experience to draw upon. Put simply, your ability to recognise abnormal data will be directly related to how much you already know about the problem. In the *Clinical example*, the RN with postoperative care experience was immediately able to consider the most likely causes of this patient's elevated temperature: respiratory complication (atelectasis), surgical complication (peritonitis), or a normal variation in response to appendicitis and surgery. In order to confirm or refute these possible explanations, the experienced RN is able to quickly focus assessment and gather additional data. While you might be tempted to jump to a conclusion based on one piece of data (i.e. body temperature 38°C), you can begin to see how this could lead to errors in clinical reasoning. An elevated body temperature in a postoperative patient could have many causes, and without further assessment, a sound clinical judgement cannot be made.

Alfaro-LeFevre (2009:99) states that: 'using sound clinical judgement means drawing valid conclusions and acting appropriately based on those conclusions (e.g. monitor more closely, begin independent treatment, or contact a more experienced professional to activate the chain of command)'. We can see in the example how, together with the RN, the decision was made to monitor the patient's temperature more closely before discharge. However, had you clustered further abnormal data along with the patient's temperature of 38°C, such as increasing abdominal tenderness with 'guarding', nausea and absent bowel sounds, this would have suggested the potential complication of peritonitis. In this situation the priorities would have been to notify the medical team and initiate fundamental nursing care and collaborative interventions to manage the complication.

Of course, taking action and determining outcomes in this relatively simple clinical example also required nursing knowledge and skill in a range of areas such as health assessment, medical–surgical nursing and patient teaching. In reality, clinical reasoning is rarely a straightforward or linear process and experienced nurses

will move backwards and forwards between domains. However, they will always be able to balance priorities and focus on nursing care that achieves the best experiences and outcomes for the patient. Consider a more complex *Clinical example* below to see this process in action: where the RN draws on her nursing expertise to work through the same process of clinical reasoning we have been discussing, albeit at a more complex level, to save the patient's life.

CLINICAL EXAMPLE

The overlooked symptom

I came to work that morning and had two patients in our transplant intensive care unit. One was a 22-year-old man who had received a liver transplant about 48 hours earlier. When I was doing my morning head-to-toe check, I found that he was very sleepy, his eyes were closed, he was jaundiced and he wouldn't respond when I talked to him. When he did try to talk to me, he mumbled incomprehensibly.

I knew these symptoms were a problem. As an experienced transplant nurse, I knew that when you give somebody a liver and it works, they're not jaundiced and they're alert. They're perky, eating, talking and even walking the halls.

This young man was doing none of that. So I checked all his vital signs, his blood pressure, pulse, temperature. Everything was where it should have been at that point in time, two days post transplant. Although his urine output was okay, the urine was a dark amber colour – which was a concern. I did his morning lab work, and everything was fine. But I was still worried. As the shift progressed, he became more lethargic and sleepy. I did another set of blood work on him, and it started to document that life in his liver was deteriorating. His urine output was now a very thick sludge that was brown-coloured and basically unmeasurable as a liquid.

I paged the resident, who blew me off with some comment like, 'I'm the doctor,' and so I shouldn't worry. I told him bluntly that I was worried and that I was going to talk to the chief resident, and he said, 'No, don't call the chief resident. I think it's all right, but I'm going to keep an eye on him.' To which I replied, 'I am, too.'

A few hours later, when I became more concerned because the patient was even more unresponsive, I paged the resident again and got the same response.

'Look,' I told him, 'I'm sorry, I'm going to call the chief or the surgeon because this is not good; we're wasting time,' and I hung up.

Just as I got off the phone with the resident, the surgeon walked in. 'Lou,' I said, 'look, this young guy's in liver failure. His liver has failed.'

I presented all the data supporting this conclusion. I explained that he was going into a hepatic coma, becoming encephalopathic. He was filling up with poisons that his new transplanted liver was not able to detoxify. Because I had been a transplant nurse for over eight years, I determined this even without doing any neurological testing.

I was right. Indeed, his new blood work reflected a failed liver. The other critical liver lab values also reflected that fact. So did his urine. The dark brown sludge in his urine was bile that the liver was not utilising properly (usually you excrete your bile in your stool, which is why your stool is brown). The fact that his labs were normal in the morning was meaningless because they had rapidly changed over the course of the shift.

'We have to put him back on the list to get a new liver,' I told the surgeon. 'We're wasting time by not being proactive.'

The surgeon gave the patient a once-over and agreed that I was spot-on. We immediately relisted the young man. He got a transplant, not that night but the next. Forty-eight hours later, he was sitting up in bed, eating and chatting. Six days later, he went home with his parents and younger brother.

The bottom line is that the process of clinical reasoning is the basis for your practice as a registered nurse. One of the most important goals of nursing education is to develop your clinical reasoning skills so that you can make the transition from student to graduate RN capable of taking action based on sound clinical judgements. As Table 4-1 makes clear, as a beginner encountering new clinical situations, you need to be active in learning and

TABLE 4-1 The difference between cue collection in experienced and novice nurses

Experienced nurses	Novice nurses
Select relevant and specific cues	Less focused in their selection; tend to 'over-select cues'
Select cues that are context dependent	Follow rules when collecting cues, ignoring context
Collect information on a range of factors in addition to the patient's presenting symptoms	Concentrate on presenting symptoms only
Have a way of 'being with a patient' and instantly knowing the patient after scanning him/her; they know what to pay attention to and what questions to ask	Focus on task and technology rather than the patient, and often miss important cues

Levett-Jones T et al 2010 The 'five rights' of clinical reasoning: an educational model to enhance nursing students' ability to identify and manage clinically 'at risk' patients. Nurse Education Today 30(6):515–20.

seeking support through this transition. Fundamental to your success in becoming an effective clinical nurse is a commitment to lifelong learning and critical self-awareness. Learning to take a critical approach to your nursing practice will at times challenge your personal assumptions and beliefs. It involves making honest appraisals of your personal strengths and weaknesses. And it means knowing when and where you need to seek support to meet patient needs.

Critical thinking – knowledge, skills and attitudes for sound clinical reasoning

Contemporary neuroscience is providing a range of lenses through which to view the challenges we all face in engaging in sound critical thinking: that is, challenges associated with being a human being, working as, and with, other human beings, being human! Work within one area, *cognitive bias*, is particularly relevant to our ability to think critically and engage in the process of sound clinical reasoning. Put quite simply, our 'beliefs, decisions, and actions can be influenced by the unconscious drivers of cognitive bias' (Lieberman et al 2014, p 4). It appears that as human beings we need to accept this fact, understand the potential implications for our thinking and decision-making and find ways to minimise these in our day-to-day practice.

Recent work in the area of cognitive bias identified above generated four categories into which the 150-odd biases evident within the literature on cognitive bias may be organised and a range of strategies for mitigating these (Box 4-4). It is a mistake to believe that those of us who have experienced the benefits of higher education and those of us who have accrued a lot of expertise are immune to bias; as it is to believe that the more 'intelligent' we are the less likely we are to be biased (Lieberman et al 2014). However, the more we work in teams, where information is shared and multiple perspectives are taken into consideration as a matter of course, the more 'bias-proof' we make our decisions. So teamwork is not simply about different members of the team having different knowledge and skill-sets associated with different aspects of the work of the team; it is also about having multiple sets of eyes and perspectives in play across all of the team's work (Chapter 8).

Critical thinking is, then, a skill that demands a good deal of self-insight and willingness to challenge our own thinking, as well as that of others. Although critical thinking has many definitions (Huang et al 2014), there are common factors identified in the literature on critical thinking processes, all of which result in a change in belief or course of action (Riddell 2007):

- reflection
- identification and appraisal of assumptions
- inquiry, interpretation and analysis, and reasoning and judgement
- consideration of context.

BOX 4-4 Ways to reduce the impact of bias on critical thinking and clinical reasoning

As you develop your understanding of cognitive bias and the forms it takes, you will be able to identify a range of strategies to help you minimise the impact of these unconscious biases on your thinking and actions. Here are some that are a useful starting point:

- Seek out the opinions of independent others before making decisions
- Engage with colleagues who you know have different ideas or perspectives in order to challenge your own thinking
- Ask yourself, 'What would I do if this patient was my grandmother/sister/brother etc?' in situations where you are making decisions
- Get to know your colleagues and discuss your shared goals and values to maximise your sense of inter-connectedness around practice
- After making complex decisions, take some time out and revisit your decision before taking action
- Develop a reflective approach to your practice in order to evaluate critically your actions and the associated outcomes
- Find a clinical supervisor or other more experienced colleagues who can help you think through your practice decisions
- Contribute to a culture where identifying own errors or performance challenges is accepted practice and the level of defensiveness surrounding these processes is low
- Practise becoming more of an objective observer of your own practice and that of your colleagues
- Seek out as much information or data as possible to inform decisions and actions
- Develop the high-level knowledge and skills required to ensure the above, including: critical thinking, critical reflection, high challenge/high support conversations.

Lieberman M, Rock D, Cox C 2014 Breaking bias. NeuroLeadership Journal 5. Online. Available:www.scn.ucla.edu/pdf/Lieberman(2014)NLJ.pdf; accessed 29 April 2016.

Taken together, critical thinking is essentially the activity of questioning what is usually taken for granted (Parker 2014). A critical thinker identifies and challenges assumptions, considers what is important in a situation, imagines and explores alternatives, applies reason and logic, and thus makes informed decisions (Alfaro-LeFevre 2013). Critical thinking involves the application of nursing knowledge and experience to identify patient problems and to direct clinical judgements and actions that result in positive patient outcomes (Benner et al 2008).

As a nursing student, critical thinking begins when you start to seriously question what it is you do as a nurse, why you do what you do and how you might do it differently. Critical thinking presupposes a certain basic level of intellectual humility (i.e. acknowledging one's own ignorance); an understanding of one's values and possible biases; a commitment to think clearly, precisely and accurately; and the confidence to act on the basis of a well-argued position. When an RN directs critical thinking towards understanding and helping patients to find solutions to their health problems, the process is purposeful and goal oriented. Evaluation of the impact and outcomes achieved allows us to examine the extent to which our critical thinking achieved those goals.

As outlined above, the process of clinical reasoning is systematic and consistent across context and level of development of the nurse using it; however, context and level of expertise does affect the focus of each domain and the nature of the nurse's engagement within each domain. A student nurse, for example, will require input from a range of people and external resources when seeking to work within each domain; and an experienced RN will inevitably move through the process more quickly than a student nurse (see Box 4-5). And as you saw above, the complexity of the situation at hand will determine whether the process is relatively straightforward – with a logical beginning and end point – or whether it is complex and dynamic.

The contemporary nursing practice environment is characterised by rapid change (Chapter 1). Even new graduates are involved with increasingly complex decisions because of greater acuity and complexity of patient care. Undergraduate nursing programs are designed to develop students' core critical thinking skills such as those identified by the American Philosophical Association (Table 4-2). Huang and colleagues (2014) suggest potential milestones for the development of critical thinking (Table 4-3). It is clear that sound clinical thinking skills and knowledge, and a positive attitude to the development of these, will determine the effectiveness of clinical reasoning, and the minimisation of error and mismanagement of patient care. The development of such skills demands ongoing commitment and engagement in lifelong learning.

The crucial issue, whatever the context or knowledge base of the nurse involved, is the commitment of that nurse to actively engage in critical thinking throughout the clinical reasoning process. To arrive at more accurate conclusions, you will need to address **critical questions** as you work through each domain rather than make assumptions about patient problems and initiate interventions that have not been adequately considered. Box 4-6 provides some broad critical questions that provide a good starting place when working through the basic domains of a clinical reasoning process.

BOX 4-5 Novices and experts – bridging the gap

Clinical decision-making is a skill that is acquired with experience. The expert has learnt to deal with complexity, be receptive to nuance, to recognise urgency, to predict outcomes, to make decisions based on incomplete information, and to accept that an action may prove to be incorrect but was the 'most right' one to make at the time. They also have insight into their own thinking processes and personality, are better able to contain negative emotions and weigh up the opinions of others, and know how to get the team to work effectively.

Novices often feel compelled to make the right decision and want to gather all the information according to 'the rules' they have been taught before making the decision. They have a limited knowledge base and are uncomfortable with uncertainty and the negative emotion it may impart. They may have little experience in performing the task that is consequent to their decision, so rationalise against the decision. They are more likely to be influenced by the opinion of others, and to defer to others' 'expertise', even if they suspect it is wrong.

Bridging the gap requires both the experts and novices to be aware of these differences. Novices need to recognise their limitations, and understand that they are in training and are not expected to perform like an expert.

Experts need to be aware that the thinking processes of novices are not equivalent to their own and that the information being conveyed by telephone is not the same as being there.

Karen Dunn, Paediatric Emergency Physician, Royal Children's Hospital, Melbourne, Australia. In: Victorian Institute of Forensic Medicine 2015. Clinical Communiqué 2(1):6.

TABLE 4-2 Critical thinking skills proposed by the American Philosophical Association

Consensus list of CT cognitive skills and sub-skills

Skill	Sub-skills
1. Interpretation	Categorisation Decoding significance Clarifying meaning
2. Analysis	Examining ideas Identifying arguments Analysing arguments
3. Evaluation	Assessing claims Assessing arguments
4. Inference	Querying evidence Conjecturing alternatives Drawing conclusions
5. Explanation	Stating results Justifying procedures Presenting arguments
6. Self-regulation	Self-examination Self-correction

Facione PA (project director) 1990 Executive summary of critical thinking: a statement of expert consensus for purposes of educational assessment and instruction (the APA Delphi report). Newark, DE, American Philosophical Association. ERIC Doc No. ED 315–423, Table 3, p 6.

• CRITICAL REFLECTION POINT

Now that you have been introduced to some basic ideas concerning brain-based imperatives and their potential impact on thinking and behaviour, re-read and reflect on Table 4-3. How does a neuroscience lens help us make sense of the knowledge, skills and attitudes of a 'novice' versus a 'master'?

Conclusion

Sound clinical reasoning processes are the foundation of effective nursing care. Even if it is not at the level of conscious awareness, each clinical action we take as a nurse is the result of a reasoning process. Unless this is made visible and supported during your development as a registered nurse, faulty thinking and decision-making have obvious implications for patient safety and outcomes. We have argued that while there are several frameworks, models or cycles that use slightly different language or descriptions of clinical reasoning, they all seek to capture the same processes: gathering information, making decisions, setting goals, taking action and evaluating the outcomes achieved. Critical thinking is a skill that sits at the heart of sound clinical reasoning processes – and, like all skills, it can be

TABLE 4-3 Potential milestones for development of critical thinking knowledge, skills and attitudes

Stage	Knowledge	Skills	Attitudes
Novice	Emphasises content over process. Lacks knowledge of critical thinking skills.	Has rudimentary ability to compare and contrast information. Is dependent on prompting from others. Uses memorisation to solve problems.	Is not self-reflective. Believes that the more facts the better. Places priority on memorisation.
Intermediate	Has basic/emerging knowledge of critical thinking skills. Senses limits of knowledge.	Has emerging skills – slows down, sees limits of knowledge, asks for help. Begins to discriminate facts. Sees linkages between domains. Begins to prioritise.	Self-reflection is emerging. Recognises need for more information. Awareness of personal role in error is evolving. Accepts second-order decision-making.*
Master	Modulates content, process and context well. Has intricate knowledge of critical thinking skills. Knows the critical thinking skills related to error.	Flexibly integrates and applies critical thinking to patient care. Uses adaptive expertise (toggles between Systems 1 & 2 thinking).# Uses metacognition routinely. Is able to teach and articulate own thinking process.	Considers arguments on both sides as well as 'grey areas'. Appreciates need to develop critical thinking skills to improve patient outcomes. Embodies intellectual humility. Accepts uncertainty. Sees self as lifelong learner.

* Rules we make up in our lives either to avoid making complex trade-offs or to remove the need to continuously reassess everyday choices.

'System 1' is fast, instinctive and emotional; 'System 2' is slower, more deliberative and more logical.

Modified from Huang GC, Newman LR, Schwartzstein RM 2014 Critical thinking in health professions education: summary and consensus statements of the millennium conference 2011. Table 3. Teach Learn Med 26(1):95–102.

BOX 4-6 Broad questions associated with each of the basic domains within the clinical reasoning process

Gathering relevant information and data

- What information/data exist and can be accessed?
- What additional information/data are needed?
- How reliable are the information/data?
- How confident am I in obtaining relevant information and do I need input from others?

Making appropriate judgements and decisions

- What do the information/data mean?
- What actions are indicated?
- Are the required actions acceptable or possible?
- How confident am I in making these judgements and decisions and do I need input from others?

Setting priorities and establishing goals

- What needs to happen and when?
- How are these goals to be achieved?
- What are the expected outcomes and timeframes?
- How confident am I in setting priorities and establishing goals and do I need input from others?

Preparing for and taking action

- What knowledge/skills do the actions demand?
- What resources are required?
- How will appropriate people become involved?
- How confident am I in my ability to take these actions and do I need input from others?

Evaluating impacts and outcomes

- What has been achieved?
- What is still to be achieved?
- Where do we go from here?
- How confident am I in evaluating the impacts and outcomes and do I need input from others?

Learning from the process to inform future practice

- How might input from others assist me or enhance my learning?
- What have we learnt that can inform future practice – related to the current patient/situation or in general?

RESEARCH HIGHLIGHT

Research focus

The complexity and challenges of contemporary health care mean that critical thinking skills are more important than ever for all healthcare professionals. The centrality of critical thinking is clearly reflected in competency frameworks across the health professions; although many clinicians achieve critical thinking through experience and observation rather than explicit instruction, others never master this skill.

Research abstract

The purpose of the work described here was to bring together experts from across medicine and nursing in order to develop a range of strategies that would support the explicit teaching of clinical thinking across medical and nursing curricula. Participants were selected from North American Medical Schools and met the criteria of a) demonstrated commitment to curricular innovation; b) consideration of the cognitive sciences in curriculum development; and c) quality of the team members. The authors state that the decision to include nursing colleagues in this process was based on the significant contribution of nursing to the literature on critical thinking. Data were derived for this summary from small-group discussion notes, videotape review of large group conference events, and preliminary consensus documents circulated among the participants.

Evidence-based practice

Overall strategies to support the development of critical thinking skills:

- Slowing down the pace of the learning process to enable students to digest and apply knowledge.
- Actively engaging the learner in tasks that require problems to be solved.
- Compelling students to justify how they arrive at decisions.
- Making thinking explicit.
- Requiring self-reflection on the part of the learner.

enhanced over time through focus and practice. Critical thinking, and therefore clinical reasoning, is susceptible to cognitive bias, and individuals and organisations need to develop appropriate strategies to minimise its impact. Chapters 5 and 6 provide in-depth discussion of a range of factors and issues associated with each domain of the clinical reasoning process; and, Chapter 7 explores the utilisation of the knowledge gained through the reasoning process.

Key concepts

- Each of us engages in a reasoning process in our everyday lives. In a nursing practice context, this is called clinical reasoning and demands a critical approach to ensure patient safety.
- Although you will no doubt encounter many different frameworks or models to explain clinical reasoning, the process involves six basic domains: 1) gathering relevant information and data; 2) making appropriate judgements and decisions; 3) setting priorities and establishing goals; 4) preparing for and taking action; 5) evaluating impacts and outcomes; and 6) learning from the process to inform future practice.
- Asking critical questions at each domain of clinical reasoning helps us to become more aware of our assumptions and cognitive biases, leading to better clinical decisions.
- A commitment to developing as a reflective practitioner – being critical and learning from practice – is the essence of good nursing.

CHAPTER

5

Gathering relevant information and making decisions

Clint Douglas and Jackie Crisp

Learning outcomes

Mastery of content will enable you to:

- discuss the domains of clinical reasoning that involve gathering relevant information and making decisions
- understand the interrelationships among data collection, analysis and critical thinking
- explain the difference between a comprehensive and a focused health assessment
- seek patient and family perspectives and expectations during assessment
- differentiate between subjective and objective data
- use a range of different sources and methods of data collection for nursing assessment
- explain the purpose of a health history and physical examination
- perform and document a nursing health assessment
- understand the process of data analysis to make nursing judgements and decisions.

KEY TERMS

Assessment framework, p. 61
Clinical judgement, p. 69
Closed-ended questions, p. 62
Decision-making, p. 72
Interview, p. 65
Nursing health history, p. 66
Objective data, p. 64
Open-ended questions, p. 62
Patient-centred problems, p. 62
Person-centred care, p. 61
Physical examination, p. 62
Subjective data, p. 63

Introduction

Nurses make lots of clinical decisions. Estimates from observational studies suggest acute care nurses face a decision or judgement every 10 minutes and critical care nurses every 30 seconds (Thompson et al 2013). Unlike many other health professionals in acute care settings, who tend to 'treat' and then 'retreat,' registered nurses (RNs) are primarily responsible for ongoing surveillance to recognise patients at risk of clinical deterioration and to prevent medical errors and serious adverse events (Levett-Jones 2013). Developing your ability to collect, interpret and act on relevant data, therefore, is critical for the quality and safety of patient care.

In Chapter 4 we introduced you to the process of clinical reasoning that lies at the heart of effective nursing care, including the role of critical thinking, its role in the evolution of nursing practice (see Chapter 7) and the ongoing learning that is crucial for the development of nursing knowledge and associated skills; and their application in our day-to-day practice. In addition, we outlined six domains of thinking/action/learning that are part of the clinical reasoning process, no matter how it is depicted in specific models (Box 5-1). This current chapter focuses on the first two of these: a) gathering relevant information and data; and b) making appropriate clinical judgements and decisions.

• CRITICAL REFLECTION POINT

To what extent do you believe registered nurses are responsible and accountable for their clinical decisions? What kind of judgements and decisions do you believe you will have to make as a nurse? Some beginning nursing students hold the belief that nurses follow 'doctors' orders' – the clinical reality is that you will have to make judgements and decisions for every action you take and be prepared to intervene based on your clinical reasoning skills as the patient's condition changes over time.

BOX 5-1 Description of the six domains evident within all depictions of the clinical reasoning process

Domain	Focus
a	Gathering relevant information and data
b	Making appropriate judgements and decisions
c	Setting priorities and establishing goals
d	Preparing for and taking action
e	Evaluating impacts and outcomes
f	Learning from the process to inform future practice

Taking a critical thinking approach

Professional practice standards require that nurses solve problems accurately, thoroughly and quickly. In order to do that, nurses review information or data from a variety of sources and make judgements concerning the relevance or meaning of the information/data; and, what, if anything needs to be done in relation to those judgements. Nurses systematically collect, verify, analyse and communicate information and data about a patient by:

- collecting and verifying data and information from primary (patients) and secondary sources (family, healthcare professionals)
- judging the needs of patients and making decisions as nurses seeking to provide effective care.

The purpose here is to establish and document a comprehensive picture of the patient's health problems and responses to those problems.

Nurses also seek to understand the patient's subjective experience of health and illness – engaging with the patient's stories and personal experiences of health care to gain a shared understanding of perceived needs, health practices, goals, values, lifestyle and expectations of care. The information contained in the resulting 'assessment database' is the foundation for making appropriate judgements, which enable nurses to make decisions and plan individualised, or **person-centred care**. Bringing the perspectives of patients and families directly into the planning, delivery and evaluation of health care, and thereby improving its quality and safety, is at the heart of patient- and family-centred care.

Gordon (2010) describes two approaches to collecting data. One is a structured, comprehensive assessment framework and the other is a problem-oriented approach focusing on the patient's presenting situation.

The comprehensive approach moves from general to specific and utilises a holistic framework such as functional health patterns (see Table 5-1). When you work within this **assessment framework** you collect data across all 11 functional health patterns and then review these to uncover existing patterns of problems. For each of the 11 patterns, nurses assess patients by organising behaviour and physiological responses that pertain to a functional health category. The data are then compared to the patient's baseline (e.g. usual blood pressure, weight and nutritional intake) and established norms based on age, gender, cultural, social or other norms, such as religious practices, ethnic dietary guidelines and healthcare practices. Description and evaluation of health patterns

TABLE 5-1 Gordon's functional health patterns and associated data/information required from the patient or family members

Area of assessment	Focus of data/information collection
Health perception–health management pattern	Patient's perceived level of health and wellbeing, and on practices for maintaining health
Nutritional–metabolic pattern	Patient's food and fluid consumption relative to metabolic need
Elimination pattern	Patient's excretory patterns: bowel, bladder and skin
Activity–exercise pattern	Patient's activities of daily living requiring energy expenditure, including self-care activities, exercise and leisure activities
Cognitive–perceptual pattern	Patient's ability to comprehend and use information and sensory functions and experiences including pain
Sleep–rest pattern	Patient's sleep, rest and relaxation practices
Self-perception–self-concept pattern	Patient's attitudes towards self, including identity, body image and sense of self-worth.
Role–relationship pattern	Patient's roles in the world and relationships with others
Sexuality–reproductive pattern	Patient's satisfaction or dissatisfaction with sexuality patterns and reproductive functions
Coping–stress–tolerance pattern	Patient's perception of stress and on his or her coping strategies
Value–belief pattern	Patient's values and beliefs, including spiritual beliefs, and/or the goals that guide choices or decisions

Gordon M 2010 Manual of nursing diagnosis, 12th edn. Jones and Bartlett Publishing, Sudbury, Mass.

help you identify patient strengths and areas of need, both of which allow planning of appropriate care.

The second, and more common approach to gathering information is the problem-focused approach. This process begins with specific **patient-centred problems** (such as shortness of breath) and broadens to relevant areas of the patient's life. For example, your assessment might begin with a focused respiratory assessment and then broaden to categories such as how this health problem influences the patient's lifestyle, family relationships and work habits. Once you have completed that part of the assessment, the presenting problem of shortness of breath will be thoroughly analysed so that a comprehensive approach can be used to plan interventions directed towards relief.

Whatever approach is used, nurses analyse data to identify emerging patterns and potential problems. Once a question has been asked of a patient or an observation has been made, the information often branches to an additional series of questions or observations (see, for example, Figure 5-1). Knowing how to frame questions is a skill refined over time (see Chapter 12). For example, simply asking a patient if they have pain may elicit a yes or no answer, but not enough information to effectively plan interventions. If you framed the question differently, for example, 'How would you describe the pain in your chest?' the patient may give a fuller description of the onset, severity and type of pain experienced. These examples describe the difference between **open-ended** and **closed-ended questions**. The nurse decides which questions are relevant to the situation while at the same time making sure the assessment is complete: proceeding from something given, a cue or datum, to a conclusion.

Gathering data and information

Identifying and assessing important cues requires the use of all of your senses. For example, when assessing a patient with shortness of breath, you will need to explore the patient's subjective experience of dyspnoea – which is a symptom – as well as draw on a range of objective data to determine the patient's level of respiratory distress – which is a sign. The skills of **physical examination** enable you to examine the patient's work of breathing, such as observing the patient's respiratory rate and listening to the patient's lung sounds (see Chapter 24). When making clinical judgements, nurses connect patterns of data with their knowledge and experience.

Assessment does not include inferences or interpretative statements that are unsupported by data. It is important to encourage patients to tell their story from their perspective. For example, a patient may describe their pain as a 'deep, throbbing pain in the stomach'. A nurse's observation may be 'the patient lies on the right side holding the abdomen; legs drawn up'. The nurse conducts a focused examination and records only

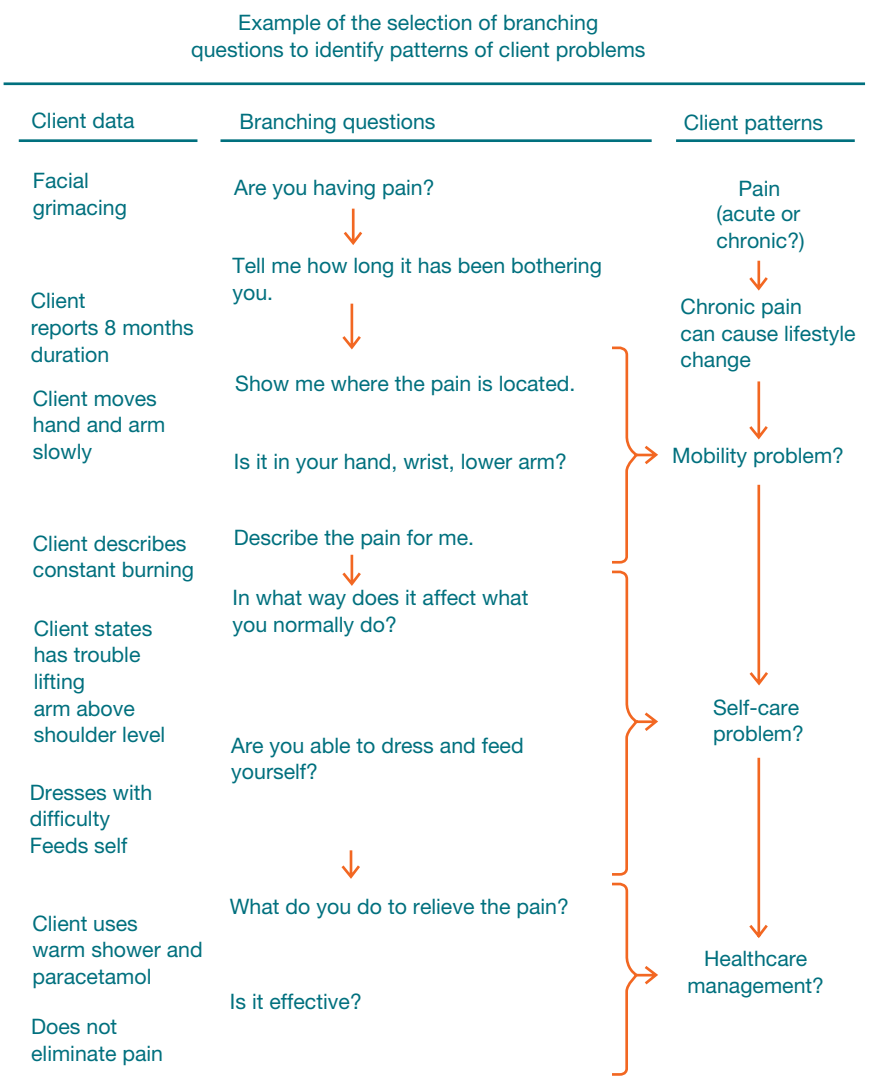

Figure 5-1 **Example of branching logic for selecting assessment questions.**

observations, avoiding prejudicial and discriminatory statements (e.g. 'the patient tolerates pain poorly').

As the information and data are collected, they are summarised using appropriate clinical language and terminology (see Chapter 13). For example: 'Patient describes a "deep, throbbing pain" in the right upper quadrant of the abdomen. Pain began 48 hours before hospitalisation 2 hours after a high-fat meal. Not relieved by antacids.' Complete data collection results from obtaining all information relevant to the actual or potential health problems.

The collection of inaccurate, incomplete or inappropriate data may lead to incorrect identification of the patient's healthcare needs, and subsequent inaccurate judgements and incomplete or inappropriate nursing decisions. Inaccurate data result if we fail to collect information relevant to a patient's problems, if we are disorganised or if we are unskilled in assessment techniques. Data may be incomplete if we jump to conclusions about a potential problem, stop asking questions prematurely or make assumptions without validation.

Forms of data and information

Data and information that form the basis of nursing judgements or decisions can be either subjective or objective. **Subjective data** are patients' perceptions about their health problems. Only patients can provide information about a symptom's frequency, duration, location and intensity. Subjective data may include feelings of anxiety, physical discomfort or mental stress. Although only patients can provide subjective data relevant to these feelings, you need to remain aware that these problems can result in physiological and behavioural changes, which are identified through objective data collection.

Objective data are observations or measurements made by nurses. Assessment of a patient's wound and identification of the size of a localised body rash are examples of observed objective data. The measurement of objective data is based on an accepted standard, such as the Celsius measure on a thermometer or centimetres on a measuring tape. Bodyweight and height are examples of measured objective data.

Sources of data and information

Nurses need to gather and process information from multiple sources. Subjective data are obtained from the patient, family and significant others, healthcare team members and health records. Objective data are obtained through physical examination, results of diagnostic and laboratory tests and pertinent nursing and health literature. A nurse's own past experience with similar types of patients is an additional source of data. Each source provides information about the patient's level of wellness, anticipated prognosis, risk factors, health practices and goals and patterns of health and illness, as well as information relevant to the patient's healthcare needs. The patient who is oriented and answers questions appropriately can provide the most accurate information about his or her healthcare needs, lifestyle patterns, present and past illnesses, perception of symptoms and changes in activities of daily living.

Family and significant others

Families and significant others can be interviewed as primary sources of information about infants or children and critically ill, cognitively impaired, disoriented or unconscious patients. In emergency situations, paramedics, police officers and other emergency workers may be the primary source of information about the nature of a patient's problem. In severe illness, families may be the only available sources of data about a patient's health–illness patterns, current medications, allergies, onset of illness and other vital information.

Figure 5-2 Nurse palpates temperature of skin to assess quality of circulation.

The family and significant others are also important secondary sources of information. Often partners or close friends will sit in during an assessment and provide their view of the patient's health problems or needs. Not only can they supply information about the patient's current health status, but they may also be able to indicate when changes in the patient's status occurred and how the patient's functioning was affected. For example, the partner of an elderly woman with symptoms of memory loss may be able to recall the onset of the symptom and any related factors.

Healthcare team members

The healthcare team consists of nursing, medical, allied health professionals and other employees working in a healthcare setting (see Chapter 8). Because assessment is an ongoing process, nurses communicate with other healthcare team members whenever possible to gather information about the way the patient interacts within the healthcare environment, the patient's reaction to information about diagnostic tests and, in acute and restorative care settings, how the patient responds to visitors. Patients will frequently discuss their feelings and perceptions with other staff on the unit who can be a valuable source of feedback to nurses.

You may also seek validation of your findings by an expert colleague such as a nurse practitioner; not just during your time as a student, but also as you encounter patients with needs that are beyond your level of expertise throughout your career. For example, a patient who is being cared for in an orthopaedic unit following the application of traction for lower leg trauma may also present a history of type 1 diabetes, which requires careful management due to a change in diet and immobilisation. The expertise of a diabetes nurse educator may assist nurses with less expertise plan to care for the patient's hospital stay as well as prepare the patient for eventual discharge home.

• CRITICAL REFLECTION POINT

Think about your role as a nurse in sharing information with a range of professionals, with differing perspectives, roles and goals. What can you do to maximise the likelihood that others will have confidence in your observations and judgements? How will you maximise the likelihood that you will be able to take on board the range of differing observations and judgements you may encounter as the team works to integrate care?

Healthcare records

The present and past healthcare records of the patient can verify information about past health patterns and treatments or can provide new information. By reviewing these records, nurses can identify patterns of illness, previous responses to treatment and past methods of coping. Other records such as educational, military and employment records may contain pertinent healthcare information (e.g. immunisations, previous illnesses). Any information obtained is confidential and is treated as part of the patient's legal healthcare record (see Chapters 10 and 11). Reviewing evidence-based literature may also help the nurse to complete the database. A review increases the nurse's currency of knowledge about the symptoms and related aetiology.

Methods of data and information collection

Patient interviewing, health history, physical examination and results of laboratory and diagnostic tests establish the nursing assessment database. Each method contributes information about the patient's past and present level of wellness.

Interview

The **interview** is a pattern of communication initiated for a specific purpose and focused on a specific content area. In nursing, the major purposes of the interview are to obtain from the patient a health history, identify health needs and risk factors and determine specific changes in level of wellness and patterns of living. Most importantly, the interview should help patients relate their own interpretation and understanding of their condition. This means the nurse and patient must be partners during the interview rather than the nurse controlling the interview. Unless an interview allows a patient to express needs from their perspective, the interaction will be unsuccessful.

An interview may be focused, as in the case of a patient admitted to the emergency department, or it can be comprehensive, as in the case of a new patient for whom a complete health history is required. The interviewer obtains information about the patient's health, lifestyle, support systems, patterns of illness, patterns of adaptation, strengths and limitations, and resources. As the nurse listens to and considers the information given, the patient may be directed to give more detail or discuss a topic that seems to reveal a possible problem. The nurse later uses objective methods to validate and build on subjective data from the interview. For example, if the patient reports difficulty in walking, the patient's gait and muscle strength will be examined.

When conducting the interview, use specific communication skills to focus attention on the patient's level of wellness. Nurses also help patients understand the change that is occurring or will occur once health care begins. This chapter briefly describes communication skills and the interview, whereas Chapter 12 discusses communication for nursing practice in more depth.

First, a nurse–patient relationship is initiated which encourages the sharing of information, ideas and emotions, and enables nurses to express a level of caring for patients. The *Clinical example* below shows how one nurse establishes a beginning rapport with a newly admitted patient.

CLINICAL EXAMPLE

The RN is preparing an admission history on Mr Brown, a 60-year-old man hospitalised for the first time.

Nurse: Good afternoon, Mr Brown. I'm Wendy Thomas, the registered nurse who will be managing your care during your hospital stay and through discharge to your home.

Mr Brown: Hello, Wendy. Please call me Bill. What do you mean by managing my care?

Nurse: That means I'm responsible for coordinating your nursing care with the rest of the nurses while you're hospitalised. I will work with them to plan for your discharge back to your home. Although other nurses will sometimes take care of you when I'm off, I'm the nurse who plans your care. Once you're discharged, I'll call you at home to see how you are doing and if you have any questions.

Mr Brown: I guess that's a lot like being a coach. You may not play the game, but you're responsible for winning or losing.

Nurse: I suppose that's one way of looking at it. To better plan your care I will be asking some questions about your health. We call this a health interview. Any information you give me is confidential. The total interview should take about 20 to 30 minutes. Is it okay if I begin the interview in a few minutes?

Mr Brown: Can you give me half an hour? My wife is about to leave. She needs to pick up the grandchildren at daycare. That way we can have some time together. I'll be ready after that.

Nurse: That's fine. Since you're in a private room, I will do the health interview here. (Mr Brown nods.)

Thirty minutes later, Wendy returns to the room.

Nurse: Okay. Before I get started, do you have any questions for me?

Mr Brown: Yes. Why is there an outlet for oxygen on the wall above my bed? Does that mean that I'm really sick? Did they put me in a special room?

Nurse: No, that's not it. Every bed in this hospital has an oxygen outlet located on the wall above the head of the

continued

bed. The reason is that this hospital has a central oxygen delivery system, and when a patient needs oxygen, we're able to supply it quickly, easily and safely.

Mr Brown: Okay. I wasn't actually worried. I was basically just curious. That was the only piece of equipment I couldn't explain.

Nurse: (pause) Bill, you mentioned that you and your wife have grandchildren in daycare. Tell me a bit about your family.

An interview seeks information about patients' physical, developmental and psychosocial dimensions. Physical and developmental information reflects normal functioning and the pathological changes in a person's pattern of living induced by illness, trauma or developmental crisis. Emotional information includes the behavioural responses to changes in health and pattern of living. Relevant emotional information includes mood, perceptions, body image, self-concept and attitudes about sexuality. Intellectual information includes intellectual performance, problem-solving ability, educational level, communication patterns and attention span. Social information involves environmental, cultural, ethnic or social patterns that can affect the present or future level of wellness. Nurses also collect information about values, beliefs and religious practices, which are part of the spiritual dimension.

Interviews also provide the opportunity to observe patients. Nurses observe interactions between the patient and family and between the patient and the healthcare environment: relevant observations may include use of eye contact, non-verbal communication and other body language. Nurses compare their observations with the verbal information that they are obtaining from the patients throughout the interview process. Inconsistencies between what the patient is saying and what the nurse is observing are often important sources of information. For example, if the patient does not disclose concern about an upcoming diagnostic test but appears anxious and irritable, the data are in conflict. Observations during an interview lead nurses to gather additional objective information to form accurate conclusions.

If a positive nurse–patient relationship has been established, the patient will feel comfortable asking the nurse questions about the healthcare environment, treatments, diagnostic testing and available resources. The patient needs this information to participate in decision-making regarding goals and the plan of care. It is important to ask patients about their expectations of healthcare providers. In addition, the interview is a first step towards establishing a therapeutic relationship between the nurse and patient so that health interventions such as education or counselling can occur.

• CRITICAL REFLECTION POINT

'When you talk, you are only repeating what you already know. But if you listen, you may learn something new' – Dalai Lama

Nursing health history

The **nursing health history** is information collected at interview about the patient's level of wellness (present and past), family history, changes in life patterns, sociocultural history and psychosocial responses to illness. The objective is to identify patterns of health and illness, risk factors for physical and behavioural health problems, deviations from normal, and available resources for adaptation. Although many health history forms are structured, nurses learn to use the questions as starting points.

Biographical information

Biographical information is factual demographic data about the patient. The patient's age, address, occupation and working status, and marital status should be included.

Reason for seeking health care

Nurses ask why the patient sought health care, because the information contained on the initial admission form may differ greatly from the patient's subjective reason. Clarification of the patient's perception identifies potential areas for education, counselling or community resources required throughout all phases of diagnosis and recovery. When recorded, the statement is enclosed in quotation marks to indicate that these words came directly from the patient.

Patient expectations

The assessment of patient expectations is not the same as the reason for seeking health care, although they are often related. It is becoming more important for nurses to acknowledge what is important to the patient who is seeking health care. Failure to identify a patient's expectations of healthcare providers and a healthcare institution can result in poor patient satisfaction. Patient satisfaction is becoming a standard measure of quality for almost every major healthcare institution throughout the country. Patients typically have expectations in the following areas:

- Information needed to care for their health problems independently.
- Caring and compassion expressed by care providers.
- Timeliness of caregivers' response to patient requests.
- Relief of pain and symptoms.
- Involvement in decision-making.

This information helps establish the goals of nursing care, as well as determines whether patients' expectations of themselves and the healthcare providers are realistic. In addition, such expectations provide information on patient perceptions about patterns of illness or changes in lifestyle.

• CRITICAL REFLECTION POINT

Think about the expectations you would have as a patient seeking care in an emergency department. Next time you are at a hospital, spend several minutes sitting in the waiting room and observing. How do you think you would react if you were in pain and waiting to be seen? What impact do you think that might have on how you interact with staff, what information you provide and your ability to focus on the questions they ask?

Present illness

If an illness is present, nurses gather essential and relevant data about the onset of symptoms: when the symptoms began, whether they began suddenly or gradually, and whether they are always present or come and go. Nurses ask about the duration of symptoms. In the section on the history of present illness, the nurse records specific information such as location, intensity and quality of a symptom. The development and use of a symptom assessment mnemonic such as PQRST is cited in the literature (Gaunt 2014) as a useful tool to assist nurses to evaluate each symptom by describing provoking or palliating factors (P), quality or quantity (Q), severity or intensity of the system (S), region (R) and timing (T) (see Box 5-2). Examples of in-depth symptom assessment can be found in the clinical chapters of this text.

BOX 5-2 PQRST mnemonic for symptom analysis

Factors	The client is asked to describe:
P – Provoking or palliative	What brings on the symptom? What makes it worse or better?
Q – Quality or quantity	How does the symptom feel, look, sound or smell?
R – Region and radiation	Where does the symptom occur? Does it spread to other areas?
S – Severity	How severe is the symptom? (Use a rating scale) Does the severity change? How does the severity affect your normal activity?
T – Timing	When did the symptoms begin? Was the onset sudden or gradual? If intermittent, how often does it occur? How long does the symptom persist?

Past health history

The information collected about past health history provides data on the patient's healthcare experiences and includes many dimensions (Figure 5-3). Nurses assess whether the patient has experienced a serious illness, been hospitalised or undergone surgery. Also essential in planning nursing care are descriptions of allergies, including allergic reactions to food, latex, drugs or pollutants. If an allergy is present, the specific reaction and treatment are noted on the assessment form.

Nurses also identify habits and lifestyle patterns. Use of alcohol, tobacco, caffeine, over-the-counter drugs, illicit drugs or routinely taken medications can place the patient at risk of diseases involving the liver, lungs, heart, nervous system or thought processes. Noting the type of dependence, as well as the frequency and duration of use, provides essential data.

Assessing patterns of sleep, exercise and nutrition is important when planning nursing care. The plan of care within a healthcare setting should match a patient's lifestyle patterns as much as possible. Often, variations in sleep, activity and nutritional patterns can be accommodated.

Family history

The purpose of the family history is to obtain data about immediate and blood relatives. The objectives are to determine whether the patient is at risk of illnesses of a genetic or familial nature and to identify areas of health promotion and illness prevention. The family history also provides information about family structure, interaction and function that may be useful in planning care. For example, a cohesive, supportive family can be a resource in helping a patient adjust to an illness or disability and should be incorporated into the plan of care. If the patient's family is not supportive, it may be better not to involve them in care.

Environmental history

The environmental history provides data about the patient's home environments and any support systems that they or family members might need. Information pertaining to the home environment may include function of utilities, layout of rooms in the house and the presence of any barriers or risks to patient safety. In addition, the environmental history identifies exposure to pollutants that can affect health, existence of high crime that prevents patients from walking around their neighbourhoods and available resources that can help patients return to the community.

Psychosocial history

A complete psychosocial history will reveal the patient's support system, which may include spouse/partner,

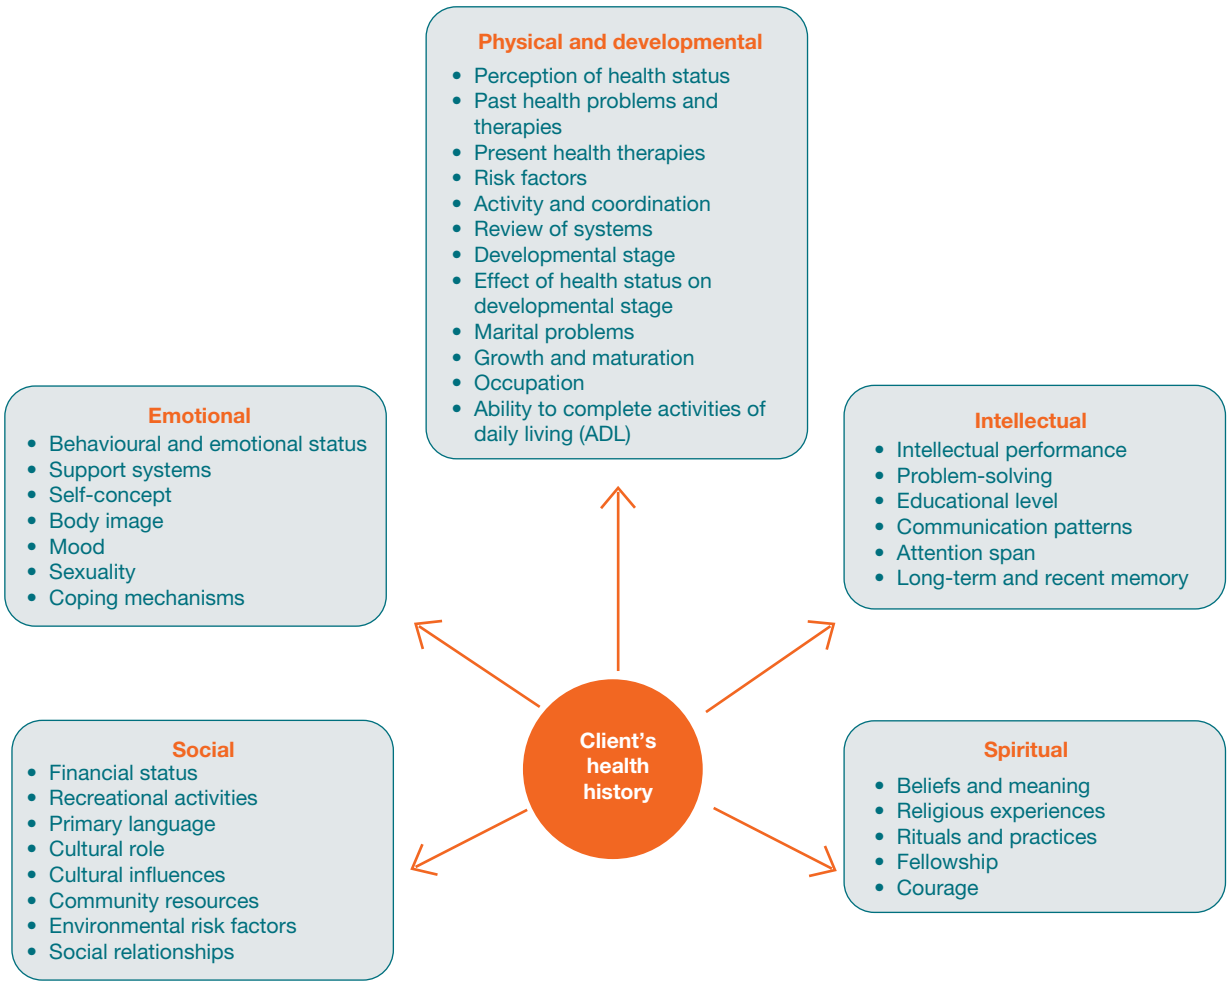

Figure 5-3 **Dimensions for gathering data for a health history.**

children, other family members and close friends. The psychosocial history includes information about ways the patient and family typically cope with stress (see Chapter 42). The same behaviour, such as taking a walk, reading or talking with a friend, can be used as a nursing intervention if the patient experiences stress while receiving health care. Nurses also learn whether patients have experienced any recent losses that create a sense of grief.

Physical examination

The physical examination and collection of diagnostic and laboratory data involve the gathering of objective data (see Chapter 23). The physical examination is the taking of vital signs and other measurements and the examination of all body parts using the techniques of inspection, palpation, percussion, and auscultation. Nurses observe for abnormalities that may yield information about past, present and future health problems. Throughout the examination, data are measured against a standard, which is an established rule or basis of comparison in measuring or judging capacity, quantity, content and value of objects in the same category. Selected standards are reliable and relevant for the category being compared. For example, there are established standards for ideal height and weight that are used to determine whether an individual is overweight or underweight; there are standards for blood pressure ranges for patients of particular age groups. Example standards for nursing physical examination of body systems provided by Rothman and colleagues (2012) are presented in Box 5-3.

Investigations

The final source of assessment data is the results of diagnostic and laboratory tests. The tests are usually ordered by medical or nurse practitioners. It is important to review the results to verify alterations identified in the nursing health history and physical examination. Laboratory data are compared with the established norms for a particular test, age group and sex. In addition, laboratory data can be used to evaluate the success or

BOX 5-3 Example standards for nursing physical assessment of body systems

Neurological: Alert, oriented to person, place, time and situation. Speech is coherent.

Cardiac: Pulse regular, rate 60–100 bpm, skin warm and dry. Blood pressure less than 140/90 and no symptoms of hypotension.

Peripheral/vascular: Extremities are normal or pink and warm. Peripheral pulses palpable. Capillary refill < 3 sec. No oedema, numbness or tingling.

Respiratory: Respiration 12–24/min at rest quiet and regular. Bilateral breath sounds clear. Nail beds and mucous membranes pink. Sputum clear if present.

Food/nutrition: No difficulty with chewing, swallowing or manual dexterity. Patient consuming > 50% of daily diet ordered as observed or stated.

Gastrointestinal: Abdomen soft and non-tender. Bowel sounds present. No nausea or vomiting. Continent. Bowel pattern normal as observed or stated.

Genitourinary: Voids without difficulty. Continent. Urine clear, yellow to amber as observed or stated. Urinary catheter patent if present.

Musculoskeletal: Independently able to move all extremities and perform functional activities as observed or stated (includes assistive devices).

Pain: Without pain or visual analogue scale < 4 or experiencing chronic pain that is managed effectively.

Psychosocial: Behaviour appropriate to situation. Expressed concerns and fears being addressed. Adequate support system.

Safety/fall risk: Safety/fall risk factors not present. Patient is not a risk to self or others.

Skin/tissue: Skin clean, dry and intact with no reddened areas. Patient is alert, cooperative and able to reposition self independently. Braden scale > 15.

Rothman MJ et al 2012 Clinical implications and validity of nursing assessments: a longitudinal measure of patient condition from analysis of the Electronic Medical Record. BMJ open 2(4):6.

failure of interventions. Specific laboratory tests and the nursing responsibilities associated with them are detailed in Parts 6 and 7 of the text.

Data documentation

Data documentation is the last part of a complete assessment (see Chapter 13). Thoroughness in data documentation is essential for two reasons. First, all data pertinent to a patient's status are included. Second, observation and recording of patient status is a legal and professional responsibility. A range of nursing Acts and Regulations, under which nurses practise, regulates the completeness and accuracy of data collection and recording required. There are also legal requirements surrounding the storage of and access to any information recorded (see Chapters 10 and 11).

When recording data, pay attention to facts and make an effort to be as descriptive as possible. Anything heard, seen, felt or smelt should be reported exactly. Because assessment includes the collection and documentation of subjective and objective data, nurses should make certain that the database is complete and factual before data clustering (putting together cues which illuminate emerging problems). Premature clustering can lead to false judgements and poor nursing decision-making. Focused clustering data for Mr Brown can be found in Box 5-4.

In situations where the patient has just been admitted or when the patient's status is changing rapidly, it is better to continually update data records.

• CRITICAL REFLECTION POINT

Following uncomplicated surgery for the emergency removal of a ruptured ovarian cyst, Mrs A's postoperative recovery is uneventful. However, while undertaking a postoperative assessment you have noticed that she is withdrawn and weepy. On initial questioning she expresses concern about being able to have a baby in the future. What information or data would you seek in this situation? As a student nurse, who would you take your observations to for discussion? What would you do if the person you took your observations to responded: 'Don't worry, she will be okay when we give her something for pain.'

Making nursing judgements and decisions

Tanner's (2006) and Cappelletti and colleagues' (2014) systematic reviews of **clinical judgement** and reasoning among RNs are valuable in bringing together the current research evidence, as well as pointing to the importance of human factors which influence the quality and safety of clinical decision-making. Based on these reviews, six key evidence-based conclusions can be drawn which are considered here in terms of your development as a nursing student.

Clinical judgements are more influenced by what the nurse brings to the situation than the objective data about the situation at hand

It is important to remember that the extent of a nurse's ability to notice clinically significant changes in a

BOX 5-4 Focused information and data for Mr Brown using different assessment frameworks

Body systems framework

Integumentary system
- Intact, flushed skin that is hot and dry to the touch
- Dry oral mucosa, coated tongue and cracked lips

Gastrointestinal system
- Distended, firm abdomen that is tender to palpation in lower quadrants
- Hyperactive bowel sounds in all quadrants
- History of diarrhoea and cramping for 3 weeks
- Poor nutritional intake over last week

Investigations
- Laboratory tests indicating elevated white blood cell (WBC) count and haematocrit level; hypernatraemia
- Abdominal X-ray examination showing gas-filled loops of bowel
- Admitting diagnosis of gastroenteritis

Functional health pattern framework

Activity and exercise pattern
- Statement of increased fatigue when walking
- Demonstration of ability to perform activities of daily living (ADLs)
- Fatigued, dyspnoeic and diaphoretic appearance when performing ADLs
- Increased pulse from 90 to 126 beats per minute during ADLs
- Previous history of decreased activity tolerance and poor sleeping 2 weeks before hospital admission for congestive heart failure
- Chest X-ray film showing pulmonary congestion

Sleep and rest pattern
- Report of difficulty in falling and remaining asleep
- Denial of use of sleeping aids

Coping–stress–tolerance pattern
- Anxiety about illness
- Pain

patient's condition and grasp the meaning of the data being collected and analysed is based on the nurse's knowledge, experience and personal values. What experienced nurses notice depends on their expectations of the situation based on caring for similar patients in the past. For example, nurses experienced in postoperative care for patients after cardiac surgery will know the typical responses and will understand the physiological and pathophysiological changes for this population, such as targets for adequate perfusion and ventilation, body temperature and need for re-warming, output from chest drains, the need for sedation and analgesia, fluid and electrolyte disturbances, emotional responses and need for family support; all of which shape the nurse's expectations for patient care and whether those expectations are met (Tanner 2006).

Developing nursing knowledge will improve your ability to ask relevant questions and collect physical assessment data related to the patient's expectation of care or underlying healthcare needs. As a student nurse, validation of your assessment and any abnormal clinical findings by experienced nurses will also assist you to gain competence and confidence in the assessment process.

What is most important is for you to learn to think critically about what to assess, as the clinical implications and validity of nursing assessments are crucial for patient safety (Rothman et al 2012). Gathering the most relevant information or data, and making appropriate judgements and decisions, requires the ability to remain open-minded and avoid the inevitable cognitive bias that is an ongoing challenge to critical thinking and clinical reasoning (Lieberman et al 2014).

A nurse who applies the stereotype of 'young children cope best when they don't have to worry about what is going to be happening' will never 'hear' the child asking for information; a nurse who believes that all elderly patients love to feel included and called by their first name, will never see the distress this may cause for some of those in her or his care; and a nurse who 'knows' that people from some cultures are prone to exaggerating pain, will run the ongoing risk of providing substandard nursing care. Busy wards and units, the pressure to 'fit in' with the culture of the team in which you work, your own uncertainty around your knowledge and skill base and many other factors can influence your observations and the judgements you make in relation to those. And all nurses need to develop strategies that enable the reflective and critical approach to thinking that effective nursing demands.

• CRITICAL REFLECTION POINT

Take some time to reflect on some of the beliefs you have about pain and the ways in which people vary in coping with acute and/or chronic pain. What forms of coping do you think are 'best'? Do you think that individuals from certain age groups, socioeconomic backgrounds or ethnic groups are easier to nurse because they cope better? What impact do you think those beliefs will have on your observations and judgements concerning appropriate nursing care?

Sound clinical judgement rests to some degree on knowing the patient and his or her typical pattern of responses, as well as engagement with the patient and his or her concerns

A person-centred philosophy brings to the foreground the importance of the nurse–patient relationship for safe and effective care (see Chapters 2 and 3). Knowing how a patient typically responds and knowing the patient as an individual affects nurses' judgement of what is important to and for the patient. It also allows for individualising nursing responses and actions.

Time pressures are an important constraint to patient engagement and recognising individual trends in assessment data over time, such as subtle trends over a number of days (Cappelletti et al 2014). If data are incomplete, omitted or inaccurate, errors may be made. If data collection is disorganised, the diagnostic process is scattered (Box 5-5). As a beginner the student needs a great deal of practice to develop the confidence and skills required, and should consider the following strategies:

- What is my level of skill? The beginner should approach assessment in steps. For example, the first experience may be completing an interview of a family member or collecting physical assessment data on one body system.
- Am I hearing correctly? Nurses must determine the accuracy of data collected. For example, a nurse who auscultates abnormal lung sounds for the first time may be unsure of what is being heard through the stethoscope. To minimise the risk of inaccuracy, the nurse must have a more experienced colleague validate findings or explain why they are incorrect.
- Is my assessment complete? Reviewing patient assessments in clinical or classroom settings provides nurses with a constructive learning opportunity to determine when assessments are complete or when further revisions are needed.
- What other sources can I call on to assist my judgements and decision-making?
- How organised am I? Before assessment, nurses should have the appropriate forms and examination equipment. Nurses can achieve an organised assessment if the environment is private, quiet and comfortable for the patient.

BOX 5-5 Sources of error

Collecting

Lack of knowledge or skill
Inaccurate data
Missing data
Haphazard or poorly organised approach
Premature or early closure

Judging

Inaccurate interpretation of cues
Failure to consider conflicting cues
Using an insufficient number of cues
Using unreliable or invalid data
Failure to consider cultural influences or developmental stage

Deciding

Failure to validate nursing judgements with patient
Overlooking perspectives of other healthcare professionals
Not seeking appropriate guidance

Clinical judgements are influenced by the context in which the situation occurs and the culture of the nursing unit

Nursing students quickly encounter the importance of the work environment and workplace culture in shaping nurses' decision-making and responses to patient problems: 'This is the way we do it here.' Cappelletti and colleagues (2014) found that the context of a unit, which includes how information is gathered and shared, as well as the broader culture in which nursing is situated, influences the types and depth of clinical judgements that nurses make.

An interesting example is nurses' decision to call for help when a ward patient deteriorates. Most Australian and New Zealand hospitals have a rapid response system (RRS) designed as a safety net for deteriorating ward patients. Hospitals typically have standardised medical emergency team (MET) call criteria and escalation protocols based on vital sign monitoring. When MET call criteria are triggered by staff at the bedside, a rapid response team with critical care expertise arrives to assess and stabilise the deteriorating ward patient.

However, staff frequently do not activate the RRS despite MET call criteria being met and there is a growing nursing literature exploring factors that influence how acute care staff use RRSs. Overall, findings suggest that nurses view the outcomes of a RRS positively because it legitimises their concerns and is a way of working

around ward and systems barriers to escalate care (Kitto et al 2015). Yet, there are major obstacles and professional tensions between nursing and medical staff (Douglas et al 2015, Kitto et al 2015). A recent Australian study found that instead of being used as an early intervention strategy, RNs spoke about managing deteriorating patients in ways that conflated MET and cardiac arrest calls, with a MET being perceived as a last resort (Massey et al 2014). Fears of being reprimanded or appearing incompetent to others were powerful reasons for delaying activation.

• CRITICAL REFLECTION POINT

What kind of hospital culture is needed for patient safety? What strategies will be helpful to you as a beginning practitioner to advocate for patient needs?

Nurses use a variety of reasoning patterns alone or in combination

Nursing judgement and **decision-making** involves the recognition of patterns or trends, comparison of these to normal standards and coming to a reasoned conclusion about the patient's needs, concerns or health problems. Thompson and colleagues (2013) provide examples of the types of clinical judgements and decisions nurses regularly make in Table 5-2. As an example, consider the following excerpt from an interview with an experienced heart failure nurse discussing a patient, where Thompson and Dowding (2009:4) have highlighted the different kinds of clinical judgements made:

> **Although he's generally unwell (*descriptive judgement*), he wasn't dramatically worse than he had been (*evaluative***

TABLE 5-2 Types of clinical judgements and decisions made by nurses

Judgement	Definition	Exemplar
Causal judgement (diagnosis)	A statement expressing a state or condition based on the presence of attributes that are used to explain a problem	Nurse diagnoses the cause of a patient's incontinence (based on information collected during a full assessment)
Descriptive judgement	A statement expressing a state or condition based on the presence of attributes that have been observed directly or obtained from another source	Nurse judges that the patient is 'stable' (based on information collected during a full assessment)
Evaluative judgement	A statement expressing a quantitative difference in a state or condition based on the presence of attributes that been observed directly or obtained from another source	Nurse judges that the patient's condition has 'deteriorated' (based on information collected about the patient at this point in time, compared with a previous occasion)
Predictive judgement	A statement expressing a belief in the likely course of a patient's state or condition, based on the presence of attributes that been observed directly or obtained from another source	Nurse judges that the patient will have problems postoperatively (based on information collected about the patient preoperatively)

Decision (Uncertainty)	Exemplar
Intervention: choosing between interventions (intervention)	Choosing a mattress for a frail elderly man who has been admitted with an acute bowel obstruction
Targeting: choosing which patient will benefit most from the intervention (intervention)	Deciding which patients should get anti-embolic stockings
Timing: choosing the best time to employ an intervention (intervention)	Choosing a time to commence asthma education with newly diagnosed asthmatics
Communication: choices in delivering and receiving information to and from patients, families or colleagues (intervention and prognostic)	Choosing how to approach cardiac rehabilitation following acute myocardial infarction in an elderly patient who lives alone, although his family is nearby
Service organisation, delivery and management: the configuration or process of service delivery (intervention)	Choosing how to organise handover, so that communication is most effective
Experiential, understanding or hermeneutic: the interpretation of cues in the process of care (diagnostic but unlikely to be resolved using quantitative research knowledge)	Choosing how to reassure a patient who is worrying about cardiac arrest after witnessing another patient arresting

Thompson C, Aitken L, Doran D, Dowding D 2013 An agenda for clinical decision making and judgment in nursing research and education. Int J Nursing Studies 50(12):1720–6.

***judgement*) … we started to go through things like blood pressure, blood pressure OK (*descriptive judgement*), did his heart rate and it was 30, so it was 'Oops' and obviously you're stopped in your tracks because there's something not quite right here (*descriptive judgement*) and went back over things, what's happened, what drugs was he on and we actually hadn't altered any of his medication. So we had to try to work it back and there wasn't anything obvious but obviously there had been some kind of acute event or some acute change (*causal judgement*), so we had to organise an ECG. No – in fact we didn't – we discussed it with the consultant and because of his age and he was so slow we actually admitted him (*decision*) and it turned out that he was in complete heart block, possibly related to his beta-blockers or an ischaemic event because he was diabetic (*causal judgement/diagnosis*).**

When looking for a pattern or trend, nurses examine all available data. Clusters of signs or symptoms may be grouped together in a logical order to allow the emergence of patterns and themes within the data. Alone, these signs or symptoms tell nurses little and no clear judgement or decisions can be made. However, when these signs are placed or brought together as a group, nurses see a relationship among the assessment findings. For example, Box 5-6 includes a summary of relevant data from Mr Brown's nursing assessment. By looking at these data in combination nurses are able to think about functional health patterns and the potential effect that Mr Brown's illness may have on his independence. When nurses recognise relevant patterns and identify the relationships among them, patient-centred nursing emerges (Manley et al 2011).

The identified pattern is then compared with data that are consistent with normal, healthy patterns. Nurses use widely accepted norms, such as normal laboratory and diagnostic test values, and professional knowledge as the basis for comparison and judgement. When comparing patterns, nurses judge whether the grouped signs and symptoms are normal for the individual patient and whether they are within the range of healthy responses. Box 5-7 and Table 5-3 provide examples of this process in relation to Mr Brown.

It is important to continually review assessment data to identify patient needs, and not to focus solely on the patient's health problems. For example, a patient experiencing social isolation due to their relocation into a retirement village has a need to gain friends, social supports and familiarity with new surroundings. Working with the patient to meet these needs may ultimately result in improving the patient's independence and level of wellness and can help the patient avoid future health problems. When patient needs/problems are identified, it is important for nurses to remember that the challenges experienced by patients may not be solely the result of illness or physiological alterations.

BOX 5-6 Summary of relevant information and data from Mr Brown's nursing assessment

Physical and developmental

- Diarrhoea for 3 weeks
- Productive cough on rising each morning
- Scattered crackles in lung bases
- 7 kg weight loss 3 weeks before hospitalisation
- Haemoglobin 100 g/L
- Slight change of emphysema shown on chest X-ray
- Distended abdomen
- Squamous cell cancer
- Biopsy obtained during outpatient colonoscopy
- Smoked for 20 years 2 packs a day (40 pack-years)
- Family history of stomach cancer
- Family history of heart attack
- Married 40 years
- Self-employed for 20 years
- One adult son, 35 years old
- Two sisters, 50 and 48, with no major health problems

Intellectual

- Talkative
- Frequently asks nurses if he has cancer and 'can it be treated?'
- Good attention span

Emotional

- Anxious
- Withdrawn after biopsy report of squamous cell cancer
- Awaiting colon resection and temporary colostomy

Social

- Walks with neighbour
- Active in his neighbourhood
- Married with children

BOX 5-7 Information and pattern recognition for Mr Brown

Recognise pattern

- Diarrhoea for 3 weeks
- Ribbon-shaped or watery stools
- Distended abdomen
- Cramping before and during each bowel movement

Compare with normal standards

- Soft, formed stool daily
- Abdomen soft, non-distended
- Defecation non-painful

Make a reasoned conclusion

- Bowel elimination problem

TABLE 5-3 Foundation of nursing judgements and decisions for Mr Brown

Clustering data	Identification of patient need	Nursing judgements/Decisions
Diarrhoea for 3 weeks	Stabilise elimination patterns	Diarrhoea related to irritation
Distended abdomen		
Family history of stomach cancer		
Weight loss: 7 kilograms	Increase bodyweight	Not meeting nutritional requirements due to poor absorption of nutrients because of chronic diarrhoea over past 3 weeks
Anaemia, haemoglobin level of 100 g/L		
40 pack-year history of smoking	Avoid postoperative respiratory complications	Ineffective airway clearance after surgery related to incisional pain
Slight change of emphysema shown on chest X-ray film		
Crackles auscultated in lung fields		
Productive cough on rising each morning		
Temporary colostomy	Adapt to changes in body image	Challenges to self-esteem due to changes in body image
Abdominal incision		
Patient resistance to viewing of abdomen		
Patient verbalisation of fear of stomach cancer	Develop strategies to cope with fear	Challenged in dealing with unknown prognosis associated with cancer
Patient withdrawal after biopsy report		
Anxiety		

Consider the following *Clinical example*, which provides an 'unfolding story' of an acutely ill patient requiring RNs to gather relevant assessment data, interpret data and make clinical decisions, and act on and communicate those decisions in order to keep the patient safe.

Reflection on practice is often triggered by breakdown in clinical judgement and is critical for the development of clinical knowledge and improvement in clinical reasoning

Nursing judgements that are clinically astute and those that lead to patient harm both offer the opportunity for reflection and clinical learning (Tanner 2006). Whereas beginning nurses face the challenge of applying theoretical concepts to practice, experienced nurses must avoid being dominated by task-based routines that may not produce clinical judgements in the individual's best interests (Cappelletti et al 2014). The research literature suggests reflection enhances nurses' clinical judgement, often in response to an actual or perceived breakdown in practice (Tanner 2006, Cappelletti et al 2014). In Chapter 4 we introduced a critical questioning approach for each domain of clinical reasoning (Box 4-5), as well as examples of common cognitive errors and biases that can lead to errors in judgement. These provide a basic framework to identify where you may have, for example, made assumptions or reached premature conclusions without sufficient data or to what extent your thinking was influenced by common cognitive biases.

Cappelletti and colleagues (2014) found that education strategies, such as high fidelity simulation and concept-based learning, may improve nursing students' clinical reasoning and judgement. Reflective journaling and structured debriefing sessions after real or simulated clinical experiences can be effective strategies to examine students' clinical judgements and ways in which they can improve (see *Research highlight*).

CLINICAL EXAMPLE

PRESENTING COMPLAINT
Abdominal pain

Time: 1000 (Emergency Triage)

Patient states
Female, 24 yrs old
Generalised abdominal pain for 18/24
Lethargy
Mild nausea (Nil vomiting)
Bowels normal
Reduced appetite
Feels 'off'
Mother with patient and states she 'looks unwell'

Triage Nurse documents
Primary survey:
Airway: Patent
Breathing: Work of breathing effortless. Patient talking in sentences
Circulation: Slightly pale, skin warm and dry

Patient does not appear distressed. States generalised abdominal pain. Pain rated 3/10. Nil nausea or vomiting at triage. No difficulty passing urine
Past history: Endometriosis, tonsillectomy, asthma.
Triaged category 4 and sent to waiting room

Time 1130 (Emergency Waiting Room)

Patient in Waiting Room for 1.5 hours
Patient presents back to triage
States pain worse – now 6/10
Nausea increasing and states she had 1 vomit
Feels slightly dizzy

Assessment in Waiting Room by Triage Nurse (Time 1135)
Airway: Patient alert. Airway patent
Breathing: Effortless
Circulation: Skin pale, warm to touch, dry
Nil diaphoresis
Pain more prominent right side of abdomen
BP = 110/70, HR = 80, RR = 15, SpO_2 = 100% RA and
Temp = 37.2°C
Taken to cubicle

Patient arrives in cubicle 1145
Handover given to cubicle nurse from triage nurse
'Hi, Sally, this is Emily. Emily is 24 years old. She presents with generalised abdominal pain for the past 18 hours. At triage her pain was 3/10 and she had no nausea or vomiting. When she was in the waiting room she stated the pain increased to 6/10, and became more prominent on her right side. She also had one vomit. She has a past history of endometriosis, tonsillectomy and asthma. She states the pain is different from the pain she gets with endometriosis. I brought her through now because she looks worse to me than when she arrived.'

continued

Nursing assessment
Nurse documents:
1200
Airway: Airway patent. Nil obvious obstruction
Breathing: Slight increased work of breathing (talking in phrases associated with intermittent increases in pain)
Circulation: Skin, pale, warm, slightly sweaty on palpation
Patient appears slightly distressed from pain
Rates pain 6–7/10. More severe to right side of abdomen. Patient asks for analgesia
Mild nausea – no further vomiting since patient arrived in cubicle. Bowels open yesterday – diarrhoea. Bowels opened 0800 and described as normal by the patient. Patient's mother in attendance and states patient looks very pale to her and 'not right'

Medications: Oral contraceptive pill
Past history: Endometriosis, tonsillectomy, asthma
Allergies: None known

Vital signs
BP = 102/55
HR = 92
RR = 17
SpO_2 = 100% RA
Temp = 37.6°C

IV cannula size 18 inserted. Blood taken and sent to the lab. Await medical review and results

1225 hrs
Nurse gets called away to help with another patient

1245: Nurse returns to cubicle

Vitals signs re-taken
BP = 95/55
HR = 102
RR = 18
SpO_2= 100% RA
Temp = 37.8°C
Pain 8/10

Nurse documents: 'Pt groaning with pain. States pain increased to 8/10. Describes pain as 'stabbing' pain to right side of abdomen. Reporting worsening nausea. Patient guarding stomach. Patient's mother expresses concern stating 'she is used to pain with her endometriosis but this looks a lot worse'. Doctor notified of pt condition and order for morphine 2.5 mg IV and Maxolon 10 mg given.'

Nurse goes to get analgesia and antiemetic – returns to cubicle

Nurse documents: 'Patient pale. Skin hot to touch. Patient is sweaty. Patient holding her abdomen. States pain remains 8/10. Patient had one further vomit. Nil blood or mucous in vomit. Patient given 2.5 mg IV morphine and 10 mg IV Maxolon. Doctor in charge notified of patient condition. Awaits review. Patient's mother becoming anxious and wanting to know how long until a doctor will review patient. Patient's mother notified patient is next to be seen.'

continued

1310: Nurse goes back to room to check on patient

Doctor is in the room assessing the patient. He states he will review the blood test results and has ordered an ultrasound. He leaves the room.

Nurse documents: 'Patient appears slightly more comfortable after analgesia. Vitals signs re-checked. Patient states pain reduced to 6/10 and requests more morphine for the pain. Nil vomiting. Nausea settled. Patient states pain localised to the right lower quadrant. Patient not voided since arrived to Emergency Department. Pt mother states she 'looks so pale'. Further morphine 2.5 mg given to patient.

Vital signs
BP = 95/45
HR = 115
RR = 20
SpO_2 = 98% RA
Temp = 38.1

1320: Nurse documents: 'Patient taken for ultrasound. Doctor notified that patient requests more analgesia and that further 2.5 mg IV morphine was given. Doctor stated he has notified the surgeon of her admission, and request for her to be admitted to the ward. Possible surgery tonight for ? appendicitis. The surgeon will review pt on the ward when he arrives at the hospital at 1500 hrs. If the ultrasound is normal she will remain in hospital for monitoring overnight.'

Nurse in Charge states: Ward bed ready in 2 South. Pt to be transferred to ward on her return from ultrasound.

1345: Patient returns to cubicle

Nurse documents: 'Patient returns to cubicle following ultrasound. Instructed by doctor and nurse in charge to transfer patient to the ward. Pt pale, skin hot to touch. Slightly sweating. Pt lying in the bed. Currently asleep. Seems comfortable. All belongings taken to ward.'

1400: Arrives to Ward 2, handover given to ward nurse at nurses' station

Nurse states: 'Hi, Kate, this is Emily. Emily is 24 years old. She has come into hospital today with abdominal pain. She has a past history of endometriosis, tonsillectomy and asthma. She states this pain is different from the pain she gets with endometriosis. The pain started about 18 hours before she came into ED. She had one vomit in the waiting room but I gave her Maxolon when she came into the cubicle and has not vomited any more. Just before we transferred her to the ward she went to ultrasound. She was given 2.5 mg of IV morphine for her pain prior to the ultrasound. On return she looked a lot more settled. Before going for the ultrasound she was holding her stomach and groaning. She said the pain was generalised but more severe on her right side. Her mother has been here the whole time, and said to me she was concerned at how much pain she was in and how pale she was. Her last observations before ultrasound were: BP = 95/45, HR = 115, RR = 20, SpO_2 = 98% and Temp = 38.1°C. The plan is for a surgical review this afternoon and most likely theatre tonight for an appendicectomy. Blood tests were taken but I have not seen the results yet. The surgeon will review the ultrasound when he arrives. Her only regular medication is the oral contraceptive pill and she is not allergic to anything.'

1410: Ward nurse goes in to introduce herself to patient and do an assessment

On arrival to room patient appears to be asleep. RN Kate says hello and gently rubs on her shoulder. Pt groans and opens her eyes. RN Kate notices her skin is very hot to touch and she feels sweaty. RN Kate immediately takes patient's vital signs.

Vital signs
BP = 85/40
HR = 135
RR = 24
SpO_2 = 96% RA
Temp = 38.9°C

1420: RN calls a MET call for hypotension, tachycardia and fever

continued

1425: MET arrive and conduct a patient assessment

Primary survey
Airway: Patent. Nil obvious obstruction to airway
Breathing: Spontaneously breathing. Noted increased work of breathing. Use of accessory muscles. Respiratory rate is 22. Pt able to speak in phrases to sentences depending on pain levels
Circulation: Skin pale, diaphoretic. Capillary refill is 3 seconds. Pulse strong, fast and regular
Disability: GCS is fluctuating between 14 and 15. Pt drowsy but rouses to voice and touch. States pain 9/10 to right side of abdomen
Exposure: Nil rash noted to limb or torso. Nil obvious abdominal mass. Nil lesions. Nil dilated veins

Secondary survey (Focused assessment)
Nurse conducts assessment of patient

When did it start?
'I have had this pain now for nearly 24 hours.' Patient describes constant dull pain across entire abdomen. But now it is much more severe. It is sharp pain to right lower quadrant. She states 'It is so severe I feel like I can't breathe properly.'

Have you ever had this pain before?
'No. I have endometriosis but the pain is very different. That pain is lower down and is crampy – this feels so much worse.' Patient's mother adds: 'I have had to take my daughter to the GP before when she was in pain caused by her endometriosis, but it was nothing like this. I have never seen her in so much pain.'

What is the quality of the pain (sharp, dull, tender, cramping, burning)?
'It's sharp pain. My entire stomach is aching, it's very sharp and more prominent on the right side.'

Is it intermittent or continuous?
'The aching pain is continuous, and the sharp pain is intermittent.'

Does the pain travel anywhere (radiate) or is it localised?
'As I said my entire abdomen is sore. I can't tell anymore, it's just so painful. It hurts around into my back on the right side.' Patient indicates that pain is most severe in the lower right quadrant.

On a scale of 0 to 10 with 0 being no pain and 10 being the worst pain ever felt, what is your pain level right now?
'Right now, the pain is a 9. But when the severe pain comes it is 10/10.'

Does anything make the pain better or worse?
'No, it just hurts all the time. Well, the morphine took the edge off for a little while, but that only lasted about 45 minutes. I took Panadeine Forte at home. I usually take that when I get pain from my endometriosis and it works well. But this time, it did nothing. I have never felt this pain before. It didn't even touch the sides.'

Is the pain associated with eating? Has the pain affected your food intake and appetite?
'I'm not sure, I have not eaten since lunch time yesterday. I just have not wanted to eat, I've had no appetite.'

Have you had any recent weight loss? If so, was it planned weight loss or not planned?
'No, I have not lost any weight.'

Have you had any abdominal surgeries? If so, what was the procedure and what was the outcome of the procedure?
'I had a laparoscopy 2 years ago. That is when I found out I had endometriosis. As I said, I just take Panadeine Forte when the pain is bad, but it has been okay now for around 6 months.'

Have you had any menstrual irregularities recently? When was your last period?
'I have not had a period for 2 months. But that is normal for me. The last period was normal.'

Do you have any pain when having intercourse? Any vaginal discharge?
'No'.

Is there any chance you could be pregnant?
'No.'

Are there associated symptoms, such as nausea and vomiting and/or diarrhoea?
'I felt nauseated all night. I had one vomit in emergency. I felt better after I was given Maxolon, but now I feel really nauseated, like I will vomit anytime soon.'

Have you noticed any black stools or blood in your stool? Have your stools been white or chalky?
'No. Yesterday I had one episode of diarrhoea at 2 pm. I did not notice any blood in my stool. This morning I had a normal bowel action.'

Have you noticed blood in your urine? Do you have frequency?
'No, I haven't had any blood. But last time I went to the toilet was around 2 am. It was quite dark at that time. I have not been since then. I don't even feel like I need to go.'

continued

Do you feel as though you have had a fever?
'I don't know. The nurse said I did. I know I have been sweating a lot. But I feel really cold. When I was having the ultrasound I was shaking. I couldn't stop it. I was so freezing.'

Physical examination
Nurse palpates patient's abdomen
Palpation: Involuntary rigidity noted suggestive of peritoneal inflammation. Abdomen is very firm and distended. Pain is reported to be greater with the withdrawal of the hands as compared to palpation itself, thus positive for rebound tenderness. Rebound tenderness could indicate peritoneal inflammation

Listens to patient's bowel sounds
Hypoactive bowel sounds

Listens to patient's chest
Chest clear. Equal air entry to bases. Nil wheeze. Nil crackles. Nil reported cough

The following information is combined:
Subjective data from patient
Discussion with patient's mother
Physical assessment data including patient's visual appearance, assessment of circulation, skin, chest, abdomen and vital signs
Blood test results
Ultrasound report

Medical diagnosis: Peritonitis caused by perforated appendix

Problem statements
Pain related to perforated appendix
Risk for deficient fluid volume related to vomiting and inadequate fluid intake
Fever related to infection

Immediate plan
- Immediate surgery – to remove appendix and wash out blood and pus from the abdominal cavity
- IV antibiotics – sensitive to the specific bacteria to treat the infection
- Intravenous fluids – to rehydrate the body and replace lost electrolytes
- Vital signs every 15 minutes until taken to the operating theatre
- Nil by mouth

Bucknall T, Hewitt N, Guinane J 2016 Focused assessment. In Forbes H, Watt E (eds), Jarvis's physical examination and health assessment 2nd edn. Elsevier, Chatswood, NSW.

RESEARCH HIGHLIGHT

Research focus
Clinical judgement is an essential skill needed by registered nurses and as such nursing programs seek to support the development of requisite knowledge and skills prior to graduation.

Research abstract
The author undertook a qualitative, interpretive description study in which she reviewed the reflective journals of 30 nursing students who participated in four progressive high-fidelity simulation (HFS) scenarios during a medical-surgical nursing course. Eight themes were identified in the reflective journals:

1. Expectations about the patient
2. Recognition of a focused assessment
3. Interpretation of medications, laboratory data, and diagnostics
4. Communication with the patient
5. Collaboration and interprofessionalism
6. Prioritising interventions
7. Skilfulness with interventions
8. Incorporation of skills and information into real patient situations.

Evidence-based practice
This study indicated that reflective journaling following progressive HFS scenarios might be an effective teaching–learning strategy to assist nursing students in the development of clinical judgement.

Conclusion

This chapter has presented a broad introduction to the nurse's role in gathering relevant assessment data and making appropriate clinical judgements and decisions. We hope that it has highlighted the importance of being systematic as you work through these first two domains, and to personalise your approach to meet individual patient and family needs. In many places it has emphasised the role of nursing knowledge, experience and context in shaping patient assessment and decision-making. As a new nurse, taking the time to reflect on complex patient care situations that triggered uncertainty and seeking to connect concepts you are learning to practice, will promote the development of safe and effective clinical reasoning skills.

Key concepts

- Assessment requires the application of knowledge and experience in making the necessary observations and measurements for gathering data about patients.
- The nature and amount of data in assessment are always changing, requiring a nurse to anticipate and ask questions to be sure assessment is accurate and complete.
- Gordon's 11 functional health patterns is an example of a comprehensive assessment framework that moves inquiry from the general to the specific so that patterns of problems can be identified.
- The nursing health history involves data about level of wellness, past medical history, family history, environmental history, psychosocial and cultural history and a review of the body systems.
- Physical assessment skills are used to collect objective data.
- Making appropriate judgements and decisions involves critical analysis and interpretation of data, identification of all relevant factors and formulation of potential relationships among those factors.
- Errors can occur at any point in the reasoning process: in data collection, in the interpretation and analysis of data, in judgements related to the data or in the decisions about what needs to happen in response to those judgements.

CHAPTER

6

Setting priorities, taking action and evaluating outcomes

Clint Douglas and Jackie Crisp

Learning outcomes

Mastery of content will enable you to:

- apply a framework to determine clinical priorities and specific patient goals
- create nursing care plans which demonstrate a person-centred approach to care
- select appropriate nursing interventions, understanding the difference between independent and collaborative interventions
- determine evaluation criteria to measure a patient's progress towards goals
- explain the crucial place of critical thinking within the processes of goal-setting, taking action and evaluating outcomes.

KEY TERMS

Activities of daily living (ADLs), p. 83
Clinical pathways, p. 87
Clinical priorities, p. 82
Collaborative interventions, p. 93
Evaluation, p. 97
Expected outcomes, p. 82
Nursing care plan, p. 87
Nursing intervention, p. 93
Patient outcomes, p. 83
SMART goals, p. 84

BOX 6-1 Description of the six domains evident within all depictions of the clinical reasoning process

Domain	Focus
a	Gathering relevant information and data
b	Making appropriate judgements and decisions
c	Setting priorities and establishing goals
d	Preparing for and taking action
e	Evaluating impacts and outcomes
f	Learning from the process to inform future practice

Introduction

This chapter discusses the next three domains within the clinical reasoning process which form a sound foundation for planning effective nursing care (Box 6-1). Such planning involves creating patient-centred goals and identifying expected outcomes; and nursing actions or interventions are selected to achieve these goals and outcomes. The learning associated with systematically engaging in planned interventions and explicitly seeking evidence that these have been successful provides the foundational knowledge that allows you to build your skills and expertise; and generates evidence required for ongoing improvement of nursing practice.

Setting priorities

Nursing work is complex and requires critical thinking to prioritise patient problems and interventions. **Clinical priorities** are the most important or pressing patient problems or issues based on the assessment data collected. The primary survey (ABCDE) provides a structured and practical framework of assessment and prioritisation in acute care situations, breaking down a complex clinical situation into more manageable parts (Considine & Currey 2015). Life-threatening problems are treated when encountered, before moving on to the next part of the assessment (Box 6-2).

BOX 6-2 The ABCDE of initial assessment and treatment in acute situations

A = airway – is the airway patent?
B = breathing – is breathing sufficient?
C = circulation – is circulation sufficient?
D = disability – what is the level of consciousness?
E = exposure – what might explain the patient's condition?

Patients entering the healthcare system generally have unmet needs. For example, a person brought to an emergency department experiencing acute pneumonia has an unmet need for oxygenation, the most basic physiological need. An older woman living alone may be concerned about the safety of her home while she is hospitalised, and may have a need for psychological security from fear that her home will be burgled. You were introduced to Mr Brown and the assessment of his needs in Chapter 5, and it may be useful to review this scenario and consider the clinical priorities at this point.

Patient problems which, if untreated, could result in harm to the patient or others, have the highest priority. For example, impaired gas exchange, decreased cardiac output and the risk of violence or self-harm are high priority needs. High priorities can occur in both the psychological and the physiological dimensions, so avoid classifying only physiological problems as high priority. Lower priority problems involve the non-urgent, non-life-threatening needs of the patient. This includes problems and patient needs that may not be directly related to a specific illness or prognosis.

Whenever possible, seek patient involvement in setting priorities. In some situations, the patient and staff may assign different rankings to the same situation or problem. If they place different values on healthcare needs and treatments they can resolve these differences through open communication. However, when the patient's physiological and emotional needs are at stake, decisions concerning priority-setting become more complex. At such times you need to maintain principles of person-centred care and find ways of working with the patient and their family towards a shared goal (McCance et al 2013). When determining care priorities, the needs of the patient, the resources of the healthcare system and the limitations of time need to be considered.

Critical thinking in establishing goals and expected outcomes

There are two main purposes for writing goals and **expected outcomes**: (1) to provide direction for individualised nursing interventions; and (2) to set standards for determining the effectiveness of the interventions. There is also strong evidence that patient involvement in setting goals enhances patient outcomes (Revello & Fields 2015).

Goals of care

Goals are defined as guideposts to the selection of nursing interventions and as criteria in the evaluation of those

interventions. To create a plan of care, first develop goals relevant to the patient's clinical priorities as evidenced by your assessment. Development of nursing knowledge enables the planning of goals. For example, a patient with pneumonia may have impaired gas exchange. Knowledge of the pathophysiology of pneumonia coupled with knowledge of respiratory care principles informs the goals of care. Similarly, indications of improved gas exchange will be effected in outcomes such as 'return of oxygen saturation to > 95% on room air, absence of pulmonary secretions'. Finally, interventions that are likely to be successful are selected drawing on a combination of research evidence, patient preferences and clinical experience with other patients with respiratory problems.

A patient-centred goal is a specific, measurable objective designed to reflect the patient's highest possible level of wellness and independence in function. Patient-centred goals require active involvement by the patient. Goals should be realistic and based on patient needs and resources.

For patients to participate in goal-setting, they should be alert and have some degree of independence in completing **activities of daily living (ADLs)**, problem-solving and decision-making. This is important, as nurses and patients are partners in care. If a patient's cognitive and physical impairments are so severe that they cannot actively participate in goal-setting, the nursing team works with family or significant others and acts on the patient's behalf to develop patient-centred goals. When developing goals, act as an advocate for patients by developing nursing interventions to promote their return to health or to prevent further deterioration in their level of wellness.

• CRITICAL REFLECTION POINT

Can you think of other examples where the patient may be unable or unwilling to participate in their care? What strategies could you use to overcome this?

Goals should not only meet the immediate needs of the patient, but should also strive towards prevention and rehabilitation. Two types of goals, short and long term, are developed with the patient depending on the nature of the patient's need or problems and the nature of the nursing services provided.

Short-term goals

A short-term goal is one that is expected to be achieved in a short time, such as within a 24-hour period (Carpenito-Moyet 2008). With the present healthcare system and shorter hospital stays, short-term goals are the direction for the immediate care plan. A short-term goal for a patient with ineffective airway clearance, for example, may be 'patient's lungs will remain clear postoperatively'.

Long-term goals

A long-term goal is an objective that is expected to be achieved over a longer period of time, usually over weeks or months. Long-term goals may be more appropriate for problem resolution after discharge, especially from acute care settings (Carpenito-Moyet 2008). Long-term goals are appropriate for patients in home care settings and those adapting to chronic illnesses who live in extended-care facilities, and for some patients in rehabilitation, mental health, ambulatory care and community nursing settings. For example, a long-term goal for a patient with an ineffective airway clearance might be to remain free of upper respiratory infection for 6 months. These goals often focus on prevention, rehabilitation and health education.

Goal-setting establishes the framework of the nursing care plan. Mr Brown was introduced in Chapter 5. Imagine it is now one day after Mr Brown had surgery for a bowel resection. Table 6-1 shows example nursing judgements that are linked to goals and expected outcomes for Mr Brown. By setting specific goals you are able to provide continuity of care and promote the best use of time and resources.

Expected outcomes

An expected outcome is the specific, step-by-step objective that leads to attainment of the goal and resolution of the underlying problems. An outcome is a measurable change of the patient's status in response to nursing care (Carpenito-Moyet 2008). **Patient outcomes** have been referred to as the ultimate definition of effectiveness and efficiency, and there is an increased emphasis on identifying and measuring the results of nursing interventions and practice. Outcomes are the desired responses of a patient's condition in the physiological, social, emotional, developmental or spiritual dimensions. This change in condition is documented through observable or measurable patient responses (Ignatavicius & Workman 2016).

The expected outcomes determine when a specific, patient-centred goal has been met and later help in the evaluation of the response to nursing care and resolution of the problem (Table 6-2). Expected outcomes provide a direction for nursing activities because they are projected before nursing actions are selected. They provide a projected timespan for goal attainment and an opportunity to state any additional resources that may be required to achieve the goal, including additional equipment, personnel or knowledge. Nurses use expected outcomes as criteria to evaluate the effectiveness of nursing activities.

TABLE 6-1 Examples of goal-setting with expected outcomes for Mr Brown

Nursing judgements and decisions	Goals	Expected outcomes (all within 24 hours)
Challenges to coping related to fear of negative prognosis	Patient will openly discuss diagnosis	Asks pertinent questions about diagnosis Expresses fears Identifies at least two strategies for dealing with fears
Ineffective airway clearance related to incisional pain	Patient's lungs will remain clear throughout postoperative period	Continues deep-breathing and coughing exercises every hour Raises three balls in the tri-flow incentive spirometer Pain level remains < 3 on a pain scale of 0–10
Needs support in order to manage postoperative care at home	Patient will understand the major postoperative risks before discharge	Tolerates sips of clear liquids Names three signs of wound infection States home activity restrictions
Risk of postoperative venous thromboembolism	Patient will maintain adequate tissue perfusion by discharge	Performs active range of motion exercises every 2 hours while resting in bed Toes remain warm, dry with capillary refill of < 2 seconds Sits in a chair for 30 minutes (or more) at least three times Assisted walk at least three times

When writing expected outcomes, nurses should ensure the outcome statement is written in measurable behavioural terms. A useful mnemonic here is **SMART goals** (Figure 6-1). This allows nurses to reframe vague patient responses about goals of care as specific expected outcomes.

In the current healthcare environment, more attention needs to be given to measuring outcomes of nursing interventions for both everyday practices (see first *Research highlight*) and more complex practices (see second *Research highlight*); and generating robust evidence concerning their implementation and effectiveness.

Developing a plan of care must also incorporate the role of other healthcare disciplines, the family and community resources. In the planning of care, nurses display attitudes such as creativity and perseverance to develop a plan of care that is tailored to the patient/family needs and has measurable outcomes.

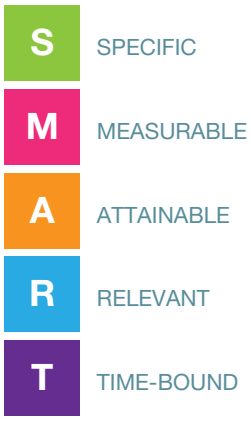

Figure 6-1 SMART goals.

CLINICAL EXAMPLE

Revello and Fields (2015) give the example of a nurse converting the original vague patient goal of 'I want to go home' to the SMART goal of 'tomorrow I will increase my water intake to four glasses':

Patient: 'I want to go home.'

Nurse: 'Why are you in the hospital?'

Patient: 'I haven't been taking in enough fluids and the doctor said I am dehydrated.'

Nurse: 'It sounds like you need to increase your fluid intake.'

Patient: 'I drank two cups of water today.'

Nurse: 'That's good; however, what if we make it a goal that you will drink four glasses of water tomorrow? Can you do that?'

Patient: 'I will try.'

Nurse: 'When you can increase your oral intake to eight glasses of fluid per day we can get the IV out, which is an important step towards getting you home. I will write your goal on your whiteboard.'

Revello K, Fields W 2015 An educational intervention to increase nurse adherence in eliciting patient daily goals. Rehabilitation Nursing 40:320–6. doi: 10.1002/rnj.201.

Formulating goals and expected outcomes

Patient-centred approach

Statements of goals and expected outcomes of care focus are derived through comprehensive assessment of the

RESEARCH HIGHLIGHT

Research focus

The use of Normal saline flushes in place of heparin to maintain the patency of peripheral intravenous locks (IVLs).

Research abstract

While there is a recent move to use Normal saline rather than heparin, the frequency with which cannulas require flushing varies due to the lack of clear evidence. This study was an open, non-inferiority, randomised controlled trial. Children, aged 1–17 years, were randomly assigned to receive saline flushing every 12 hours (Group A) or every 24 hours (Group B). The outcomes measured included the maintenance of catheter patency and a range of catheter-related complications. Group A included 198 children; Group B included 199. Occlusion of the catheter occurred in 15 children (7.6%) in Group A and 9 children in Group B (4.5%) ($p = 0.21$). Catheter patency was more frequent (+3.1%) in Group B (95% CI –1.6% to 7.7%). There was no difference between the two groups in relation to catheter-related complications (12.1% in Group A vs 9.5% in Group B; $p = 0.42$).

Evidence-based practice

One flush per day of Normal saline allows maintenance of catheter patency without an increase in catheter-related complications. This approach reduces costs (materials use and nursing time), labour and unnecessary accessing of catheters, potentially reducing distress in younger children and their parents.

RESEARCH HIGHLIGHT

Research focus

Ward-based interventions for patients with hemispatial neglect in stroke rehabilitation.

Research abstract

The *JBI Reviewers' Manual* was used to guide the overall procedure of the review. A preliminary literature search was undertaken in the Cochrane Controlled Trials Register; as well as searches of PubMed, CINAHL and PsychINFO databases for relevant articles published between January 2006 and June 2014. Additional literature was identified through manual searches of relevant journals and reference lists and tracking citations of the selected articles. Two reviewers evaluated the risk of methodological bias independently by using quantitative appraisal forms from the Joanna Briggs Institute (JBI) and disagreements were resolved by consensus. The selected studies were graded according to the strength of their evidence (Levels 1–5); the proposed interventions were given recommendation grades (Grades A–D).

Eleven forms of intervention were identified: 1) contralesional neck vibration (Grade C); 2) emotionally salient stimuli and reward (Grade D); 3) family participation and intensity of training (Grade C); 4) limb activation training (Grade C); 5) mental imagery training (Grade D); 6) mirror therapy (Grade C); 7) music therapy (Grade D); 8) right half-field eye patching (Grade D); 9) smooth pursuit eye-movement training (Grade B); 10) virtual reality and computer-based training (Grade C); and 11) visual scanning training (Grade D).

Evidence-based practice

- Smooth pursuit eye-movement training showed promise as a ward-based intervention. However, the low level of evidence found, and the diversity of interventions investigated, means that no clear recommendations concerning interventions, or combinations of interventions, can be made.
- Interventions should be based on careful evaluation of each patient's unique capacities and problems.
- In this area, as well as many areas of nursing interventions, there is a need for sound research evidence to guide their use.

Reference

Klinke ME et al 2015 Ward-based interventions for patients with hemispatial neglect in stroke rehabilitation: A systematic literature review. International Journal of Nursing Studies 52(8):1375–403.

patient: gathering information and data related to the patient, and making judgements and decisions that flow from this assessment. These statements reflect expected patient behaviour and responses as a result of nursing interventions.

Mutual setting of goals and expected outcomes ensures that the patient and nurse agree on the direction and time limits of care. Mutual goal-setting can increase the patient's motivation and cooperation. However, you may need to direct some of the goals and expected outcomes to keep

the patient physically and emotionally stable and safe. For example, a patient may be refusing pain medication because of fear of addiction. Yet the pain is preventing mobilisation and exercise, which can lead to complications.

Specific

Each goal and expected outcome statement should refer to only one behavioural response. This singularity provides a precise method of evaluating patient response to the nursing action. For example, an incorrect outcome statement might read 'patient's lungs will be clear on auscultation, and respiratory rate will be < 24 per minute'. If the lungs are clear but the respiratory rate is 28 per minute after nursing actions, it is difficult to determine whether the expected outcome has been achieved. By splitting the statement into two parts – 'lungs will be clear on auscultation' and 'respiratory rate will be < 24 per minute' – it can be determined if each outcome has been achieved.

Measurable

We need to objectively demonstrate the effectiveness of nursing interventions on the patient's level of health. Observable changes can occur in physiological findings and in the patient's level of knowledge and behaviour. The results can be obtained by directly asking the patient about the condition or by using assessment skills. Examples of outcomes involving assessment skills are 'lungs will be clear on auscultation' and 'purulent wound drainage will cease'.

Goals and expected outcomes are written as a standard against which to measure the patient's response to nursing care. Examples are 'body temperature will be < 37.5°C' and 'apical pulse will remain between 80 and 100 beats per minute'. A goal or an outcome stated in measurable terms allows the team to objectively quantify changes in the patient's status.

Common mistakes are made when vague qualifiers such as 'normal', 'stable', 'acceptable' or 'sufficient' are used as evaluation criteria. Terms specifically describing quality, quantity, frequency and weight allow evaluation of whether the expected outcome was achieved.

Attainable

Short-term, realistic goals and expected outcomes can quickly provide the patient with a sense of accomplishment. In turn, this sense of accomplishment can increase motivation and cooperation. When establishing realistic goals consider the:

- resources of the healthcare facility, family and patient
- patient's physiological, emotional, cognitive and sociocultural potential, and
- economic cost and resources available to reach expected outcomes in a timely manner.

Establishing goals and expected outcomes without a thorough assessment of patient, environment or resources is problematic because the plan then contains unrealistic goals.

Relevant

You need to apply critical thinking to determine the most relevant evaluation criteria to decide on the effectiveness of an intervention or improvement in the patient's condition. For example, if a diuretic is administered to reduce pulmonary congestion in a patient with heart failure, the most relevant data would include improvement in respiratory rate, oxygen saturation and lung sounds. Noting an increase in urine output from the diuretic is not the most relevant data.

Time-limited

The timeframe for each goal and expected outcome indicates when the expected response should occur (e.g. a 24-hour patient goal). Timeframes help determine that progress is being made at a reasonable rate. When the date of evaluation arrives, assess the patient to determine whether that particular expected outcome has been reached. If the outcome is not achieved, but it is still appropriate for the patient's care, another appropriate time is set.

Specific evaluation criteria

Expected outcomes are the expected results of a goal-oriented process. They are statements of progressive, step-by-step responses or behaviours that the patient needs to accomplish to achieve the goals of care provided. When outcomes are achieved, assessment data indicating patient problems no longer exist. For example, for a nursing judgement that physical immobilisation has caused the development of a pressure ulcer, the patient goal is attaining intact skin in the area of injury. This will be accomplished by meeting the outcomes of 'the skin lesion will be clean without drainage' and showing evidence of healing through 'reduction in size and inflammation'. If the outcomes are met, nurses have successfully eliminated pressure over the skin and used therapies that have healed the skin lesion. Expected outcomes have short timeframes (depending on the healthcare setting) and include as few as one or two intervention sessions.

After a specified interval or when all interventions in the plan of care have been completed, evaluate the patient's ability to demonstrate the behaviour or response stated in the outcomes. Achievement of clinically useful

and measurable patient outcomes sensitive to nursing interventions is needed to determine the effectiveness of planned interventions, and can improve the patient's level of health. If the patient achieves the expected outcomes, either continue the care plan or discontinue interventions because the goal of care is met. If evaluation determines that the expected outcomes were not met or only partially met, begin reassessment and revision of the care plan. As a nursing student, evaluation criteria can be developed and justified by searching the evidence-based literature for your patient's condition and the chosen interventions.

Planning nursing care

There are many ways to communicate a patient's nursing care. One is the **nursing care plan**, which includes the judgements or decisions concerning problems, goals, expected outcomes and specific nursing activities and strategies. In many settings, nursing care plans are integrated into multidisciplinary plans of care. The nursing component of a multidisciplinary plan is easily recognisable. A second way is critical pathways, often known as **clinical pathways**. Critical or clinical pathways are multidisciplinary treatment plans that prescribe interventions and the timeframe for achieving expected outcomes for selected patients over a projected length of stay. Many health institutions also utilise protocols and standing orders, which are integrated into an individualised plan of care.

Purpose of care plans

The nursing care plan is a written guideline for patient care. Written care plans document the patient's healthcare needs. In addition, the written care plan communicates to other nurses and healthcare professionals the patient's pertinent assessment data, a list of problems and therapies. A written care plan is designed to decrease the risk of incomplete, incorrect or inaccurate care.

The care plan is organised so that any nurse can quickly identify the actions to be delivered. In hospitals, outpatient clinics and community-based settings, the patient often receives care from more than one nurse, medical officer or allied health professional. The written nursing care plan makes possible the coordination of nursing care, subspecialty consultations and scheduling of diagnostic tests.

The care plan can also identify and coordinate resources – human, physical and financial – required to deliver nursing care. The nursing care plan enhances the continuity of care by documenting specific nursing actions necessary to achieve the goals of care. Written nursing care plans organise information exchanged by nurses in change-of-shift reports. Nurses focus these reports on nursing care and treatments delineated in care plans. At the end of shifts, nurses discuss care plans with the next caregivers. Thus all nurses are able to discuss current and pertinent information about the patient's care plan.

The written care plan also includes the long-term needs of the patient. Incorporating the goals of the care plan into discharge planning is particularly important for a patient who will be undergoing long-term rehabilitation in the community. A complete care plan enhances the continuity of nursing care between nurses in the hospital and in the community. When developing an individualised care plan, involve the patient and family. The family can help the patient meet health goals. In addition, meeting some of the family's needs may improve the patient's level of wellness.

Care plans in various settings

The format of the nursing care plan varies from one healthcare setting to another. For example, in a hospital, a care plan may consist of columns for assessment, goals, interventions and expected outcomes. The nursing care plan developed for the patient returning home is usually based solely on long-term health needs. In addition, the patient, family and significant others are more involved and assume more responsibility for care because the patient is receiving nursing care in the home.

In a community health setting, the care plan may be in a narrative form. Despite variations, the overall purpose of the care plan is to provide written guidelines so that the healthcare needs of the patient and subsequent therapies are communicated to all healthcare team members. Sample care plans are included in the clinical chapters of this text. It is also a good learning resource to collect, with permission, sample care plans from clinical placement experiences.

Nursing students also frequently learn to write and use a nursing care plan to develop clinical reasoning, written communication and organisational skills needed for nursing care. The student care plan is often more detailed than a care plan in a hospital or community healthcare agency because its purpose is to teach the process of planning care. Student care plans vary from one educational program to another, and between beginning and more advanced students. Some educational institutions model the student care plan on the care plan used in an affiliated healthcare agency. The only modification might be that the educator requires the beginning student to include the scientific rationales for the nursing interventions selected (see Table 6-2).

TABLE 6-2 Rationale for the student care plan

PRIORITY PROBLEM: Risk of breakdown of skin integrity related to immobility resulting from stroke.

DEFINITION: Risk of impaired skin integrity is the state in which an individual's skin is at risk of being adversely altered.

Assessment	Goals	Implementation	Rationale	Expected outcomes
Fever: higher than 39°C for 72 hours Diaphoresis Incontinence of urine	Skin remains intact Muscle mass is retained over bony prominences	Turn patient every 2 hours in following sequence: 8 am – supine 10 am – left side Noon – prone Repeat, beginning with supine position Administer antipyretics as ordered	Critical time for skin tissue breakdown is between 1 and 2 hours of constant pressure	No skin breakdown is noted. Skin warm, pink, capillary refill < 2 seconds. Patient is afebrile within 24 hours
Decreased skin turgor No skin breakdown noted		Keep patient's skin dry at all times	Moisture increases maceration of skin and promotes bacterial growth	Skin remains dry and intact Skin turgor is improved within 24 hours

Planning care for patients in community-based settings, such as clinics, community centres or patients' homes, involves the same principles of nursing practice. However, in these settings a more comprehensive community, home and family assessment is needed. Ultimately, the patient/family must be able to independently provide the majority of health care. Nurses design a plan to:

- educate the patient/family about the necessary care
- teach the patient/family how to integrate care with family activities, and
- allow the patient/family to assume a greater percentage of care in graduated increments.

Writing the nursing care plan

The highest clinical priority is the starting point for the nursing care plan, and is followed by others in order of assigned priority. The example in Table 6-2 shows how to write a care plan in a five-column format. The assessment column (column 1) includes all information and data relevant to the priority problem. The previously developed goals are written in the next column (column 2). At this point, the short- and long-term goals are developed into action plans that anticipate the needs of the patient, coordinate nursing care and select appropriate nursing interventions.

Write the action plan in the implementation column (column 3). Each nursing action is written to include information necessary to implement nursing care. It may help to ask whether the stated interventions answer the following questions:

- What is the intervention?
- When should each intervention be implemented?
- How should each intervention be performed?
- What resources may be needed for the intervention?
- Who should be involved in each aspect of intervention?

In addition, you should be able to articulate the rationale (column 4) for chosen interventions; and, although you will not find this column used in practice, throughout this book the rationale has been included as a means of supporting your learning (i.e. within clinical chapters). Non-specific nursing interventions result in incomplete or inaccurate nursing care, lack of continuity among caregivers and poor use of resources.

Common omissions in writing nursing interventions include action, frequency, quantity, method or person to perform the action. Table 6-3 illustrates these types of errors by showing incorrect and correct statements of nursing interventions.

Column 5 of the care plan contains the evaluation criteria previously identified. Listing all outcomes on the care plan provides a written estimation of when the goal of care is to be achieved. When outcomes are met the plan can be revised, thus indicating when a particular nursing intervention is no longer relevant to the patient's care.

Critical (or clinical) pathways

Critical pathways allow staff from all disciplines, such as nursing, medicine, pharmacy and social work, to develop integrated care plans for a projected length of stay or

TABLE 6-3 Common errors in writing nursing interventions

Type of error	Incorrectly stated nursing intervention	Correctly stated nursing intervention
Failure to precisely or completely indicate nursing actions	Nurse assistant will turn patient every 2 hours	Nurse assistant will turn patient every 2 hours, using the following schedule: 8 am – supine 10 am – left side Noon – prone 2 pm – right side Repeat sequence at 4 pm and at midnight
Failure to indicate frequency	Nurse assistant will observe patient cough and deep-breathe	Nurse assistant will observe patient cough and deep-breathe at 10 am–2 pm–6 pm–10 pm
Failure to indicate quantity	Primary nurse will provide hydrogen peroxide (H_2O_2) mouthwash to patient every 2 hours while awake: 8–10–12–2–4–6–8–10	Primary nurse will provide 50 mL of H_2O_2 mouthwash to patient every 2 hours while awake: 8–10–12–2–4–6–8–10
Failure to indicate method	Primary nurse will change patient's dressing once a shift: 6 am–2 pm–10 pm	Primary nurse will replace patient's dressing, with Neosporin ointment to wound and two dry 10 cm × 10 cm dressings secured with hypoallergenic tape, once a shift: 2 pm–10 pm–6 am
Failure to indicate person to perform the action	Irrigate nasogastric (NG) tube every 2 hours (even) round the clock with 30 mL of Normal saline (NS)	Primary nurse will irrigate NG tube every 2 hours around the clock with 30 mL NS

number of visits for patients with a specific case type (see example in Figure 6-2). For example, a pathway for a trans-urethral resection of the prostate (TURP) may recommend on a day-by-day basis the patient's activities, consults, procedures and discharge planning activities, and educational topics expected for the patient's progression through the process (for example, see Chapter 37). Nurses and other healthcare team members use the pathway to monitor a patient's progress and as a documentation tool.

Once developed, critical pathways become a case management tool that indicates desired interventions and patient outcomes within specific timeframes. However, you need to apply critical thinking and clinical judgement to determine whether the components of the pathway apply to your patient. Nursing care should be individualised to meet the patient's clinical priorities based on your assessment.

Protocols and standing orders

A protocol is a written plan specifying the procedures to be followed during care of a patient with a selected clinical condition or situation, such as care of a postoperative patient. Nurses providing primary care for patients in an outpatient setting may follow treatment and diagnostic protocol. In such a setting, nurses assess the patient and identify abnormalities. The protocol delineates the conditions that nurses are permitted to treat, such as controlled hypertension, and the types of treatment they are permitted to administer, such as immunisations.

A protocol can also be strictly within the framework of nursing, such as a protocol for admission and discharge, pain management, or initiating cardiopulmonary resuscitation. Protocols are also used in interdisciplinary settings for diagnostic testing and physical, occupational and speech therapies.

A standing order is a document containing prescriptions for the conduct of routine therapies, monitoring guidelines and/or diagnostic procedures for specific patients with identified clinical problems. The orders direct the conduct of patient care in various clinical settings. They are commonly found in critical care settings, where patients' needs can change rapidly and require immediate attention. Such a standing order might specify a certain drug, such as morphine for pain. For example, after assessing a patient in acute pain, an emergency nurse independently decides to administer morphine based on a standing order in the department. Standing orders are also common in the community and remote health settings, in which nurses encounter situations that do not permit immediate contact with a doctor.

Thus, standing orders and protocols give nurses legal protection to intervene appropriately in the patient's best

Care Plan ▲

The aim of the Care Plan is to achieve the following outcomes prior to discharge:

- Observations are within acceptable parameters for the patient.
- No fresh bleeding or excess swelling to operative area.
- Patient has tolerated diet and fluids as ordered.
- Patient able to ambulate and peform self cares as expected.
- Patient and carer understands post procedure care instructions.

interest. Before implementing any therapy, including those in protocols and standing orders, sound judgement and clinical competency is needed to determine whether the intervention is correct and appropriate (e.g. medication standing orders – see *Online resources*).

Critical thinking in designing nursing interventions

Nursing interventions, strategies or actions are selected after priorities and goals are established. Nursing interventions are those actions designed to help the patient move from the present level of health to that which is described in the goal and measured with the expected outcomes. A **nursing intervention** is defined as any treatment based on clinical judgement and knowledge that a nurse performs to enhance patient outcomes.

The patient may require intervention in the form of a wound dressing, treatment for the current condition, patient–family education, treatment to prevent future health problems, or social, emotional or physical support. Interventions that promote culturally safe care increase the chances of attaining the goals and expected outcomes of nursing care. When choosing suitable nursing interventions, nurses:

- know the scientific rationale for the intervention (see, for example, Table 6-2)
- possess the necessary psychomotor and interpersonal skills, and
- are able to function within a particular setting to use the available healthcare resources effectively.

Many examples of specific clinical interventions and their scientific rationale are given throughout the clinical chapters of this text.

Types of interventions

Nurse-initiated interventions

Nurse-initiated interventions are the independent response of nurses to the patient's healthcare needs. This type of intervention is an autonomous action based on scientific rationale that is executed to benefit the patient and meet patient-centred goals (Carpenito-Moyet 2008). Nurse-initiated interventions involve aspects of professional nursing practice covered by licence and law. These interventions require no supervision or direction from others. For example, interventions for increasing a patient's knowledge about adequate nutrition or ADLs related to hygiene are independent nursing actions. According to the various state Acts and Regulations governing the conduct of nursing, actions pertaining to ADLs, health education, health promotion and counselling are within the domain of nursing practice. These Acts and Regulations delineate the legal scope of the practice of nursing within the boundaries of their jurisdiction (see Chapters 10 and 11).

Several factors make decision-making more difficult when choosing among independent nursing interventions. Evidence-based literature on the effectiveness of nursing interventions is increasingly available through online databases such as the Joanna Briggs Institute (see *Online resources* at end of this chapter), but much work remains to be done. A second factor is that nurse-initiated interventions are often not mutually exclusive. For example, you may need to include relaxation, massage and guided imagery techniques with prescribed analgesics for pain management. Before implementing a plan of care, it may be necessary to consult the agency's standards. It is important to know what the guidelines are for procedures and to whom the procedures may be delegated.

Collaborative interventions

Collaborative interventions are therapies that require the knowledge, skill and expertise of multiple healthcare professionals. Nurses collaborate with other members of the healthcare team when they have identified a patient problem that cannot be solved by the RN alone. For example, nurses administer treatments prescribed by advanced practitioners, such as medication, implementing an invasive procedure or changing a dressing. It is not always within the legal practice of nursing for a nurse to prescribe and order these treatments, but nurses have ethical and legal obligations to assess all planned care. Nurses are not relieved of malpractice liability simply because they were administering treatment as prescribed. For example, when administering medications, nurses are responsible for knowing the classification of the drug, its physiological action, normal dosage, side effects and nursing interventions related to its action or side effects. With an invasive procedure or dressing change, nurses are responsible for knowing when the procedure is necessary, the clinical skills necessary to complete it, and its expected outcome and possible side effects. Nurses are also responsible for adequate preparation of the patient and proper communication of the results.

When a specific diagnostic or laboratory test is prescribed, nurses are responsible for knowing when the test is scheduled, preparing the patient, and knowing the normal findings and nursing implications associated with it. When encountering collaborative interventions, nurses do not automatically implement the therapy but must determine whether it is appropriate for the patient.

Every nurse encounters an inappropriate or incorrect order at some time. The ability to recognise and query incorrect therapies protects the patient and members of the healthcare team. Nurses carrying out an incorrect or inappropriate intervention are as much in error as the person who wrote or transcribed the original order, and are liable for any complications resulting from the error.

Consider an older woman who is a hemiplegic (paralysed on one side) from a recent stroke, which has also severely affected her speech. She is unable to make herself understood, and is anxious and frustrated by her futile efforts. She is also at risk of problems related to impaired mobility, and she is unable to independently complete ADLs. In order to maintain her present level of health she requires multiple interventions, including nursing interventions to prevent pressure ulcer development, physiotherapy interventions to prevent musculoskeletal changes from immobility, speech therapy interventions for communication difficulties and occupational therapy interventions for eating and hygiene needs. Caring for this patient requires the coordination of collaborative interventions from multiple healthcare professionals, all directed towards the long-term goal of maintaining her present level of health.

Consultation is a process in which the expertise of a specialist is sought to identify ways to handle problems in patient management or the planning and implementation of programs. In clinical nursing, consultation is used to solve problems in the delivery of nursing care or the use of resources. Nurse consultants are most often approached for advice about difficult clinical problems. Nurses are often consulted for their clinical expertise, patient education skills or staff education skills. For example, a team caring for a patient with a recent colostomy might request a consultation from an enterostomal therapist to determine the materials needed to clean the colostomy site and the specific techniques to use during the procedure.

Critical thinking and the implementation process

Updating the nursing care plan

Before beginning care, review the care plan and compare it with assessment data to validate the priorities of care and determine whether the nursing interventions are the most appropriate for the clinical situation. If the patient's status has changed and the existing nursing interventions are no longer appropriate, the nursing care plan needs to be modified.

Modification of the existing written care plan includes several steps. First, data in the assessment column are revised to reflect the patient's current status. New data entered in the care plan should be dated to inform other members of the healthcare team of the time that the change occurred.

Second, the patient's problem statements are revised. Those that are no longer relevant are deleted, and new ones are added and dated. Because the patient's status and healthcare needs have changed, the priorities, goals and expected outcomes must also be revised. The revisions are also dated on the care plan.

Third, specific implementation methods are revised to correspond to the new problem statements and patient goals. This revision reflects the patient's present status. In addition, revised implementation can include the patient's specific needs for healthcare resources, such as a specific form of dressing.

Finally, determine what methods of evaluation will be used. For example, a preoperative care plan was developed for Mr Brown. As he progressed through the postoperative period his nursing needs changed. The nurse made modifications in the care plan in one area: breathing patterns post-surgery related to abdominal incisional pain. On the second postoperative day the nurse assessed the patient and noted decreased oxygen saturation, crackles that were auscultated in the right base and an elevated temperature (39°C). On further assessment the nurse determined that his breathing was impaired due to uncontrolled postoperative pain. Mr Brown had a chest X-ray, which revealed a right lower lobe collapse. The plan was revised to read ineffective airway clearance related to abdominal incisional pain (Table 6-4). The goal of maintaining patent airways was still appropriate. Specific new nursing interventions were developed to help resolve the breathing problem. Finally, new evaluation criteria were set.

Organising resources and care delivery

Equipment

All necessary supplies should be gathered and put in a convenient location, usually where they will be used, before implementing the care plan. Extra supplies should be available in case of mishaps. By having extra sterile gloves, for example, a nurse anticipates the possibility of a break in aseptic non-touch technique. The nurse also arranges the supplies in the order in which they will be used.

Personnel

Before intervention, consider the competencies of personnel available and the model of care delivery being used.

TABLE 6-4 Modified nursing care plan for Mr Brown

PRIORITY PROBLEM: Ineffective airway clearance related to abdominal incisional pain.

DEFINITION: Ineffective airway clearance is the state in which an individual is unable to clear secretions or obstructions from the respiratory tract to maintain airway patency.

Assessment	Goals	Implementation	Evaluation
Smoked two packs/day for 20 years; chest X-ray film showing slight change of emphysema; crackles auscultated in lung field; scheduled for abdominal surgery	Maintains clear airways postoperatively	Demonstrate turn, cough and deep-breathing exercises to patient Have patient perform exercises every 2 hours while awake	Breathing effortless SpO_2 > 95% on room air Chest clear to auscultation
Modified 24 hours after surgery			
Decreased oxygen saturation (< 92%); coarse crackles in right base that do not clear with coughing; abdominal pain (6/10) on coughing and deep breathing	Practises coughing and deep-breathing exercises every hour	Encourage use of patient-controlled analgesia Splint incision with pillow before and during coughing Use tri-flow every hour	Pain score < 4 on coughing and deep breathing SpO_2 > 95% on room air Lung fields are clear on auscultation

Agency policies also help to clarify what interventions various levels of staff can perform. Nursing care delivery systems vary among facilities and must be considered when allocating resources. The system by which nursing is organised determines the way in which personnel are designated for patient care delivery. The most common types of nursing delivery systems are functional, team, total patient care, primary nursing and case management; review of these systems can be found in later chapters.

Depending on the system of healthcare delivery, the nurse who develops the care plan may not perform all of the nursing interventions. Some activities may be delegated to other members of the healthcare team and coordinated by the nurse. When delegating aspects of a patient's care to another staff member, the nurse assigning the tasks must ensure that each task is appropriately assigned and completed according to the standard of care.

Environment

Environmental factors influence the delivery and reception of care. The surroundings in which nursing activities occur should be safe and conducive to the implementation of the therapy. If the patient has sensory deficits, physical disability or an alteration in level of consciousness, the environment must be arranged to prevent injury. Having special rooms, rearranging furniture and equipment, keeping rooms free of clutter and providing for additional personnel are examples of creating safe surroundings.

Privacy promotes relaxation when body parts are exposed. Reducing distractions enhances a patient's learning opportunities. Adequate space and lighting promotes efficiency when procedures are performed.

Patient

Making sure the patient is comfortable before initiating interventions enables the patient to participate more fully. For example, if patient alertness is needed, the dose of pain medication should be enough to relieve discomfort but not cause sedation. Also consider the patient's level of endurance and plan only the amount of activity that the patient can comfortably tolerate.

Awareness of the patient's psychosocial needs helps create a favourable emotional climate. Some patients feel reassured by having a significant other present to lend encouragement and moral support. Other strategies include planning sufficient time or multiple opportunities for the patient to work through and ventilate feelings and anxieties.

Anticipating and preventing complications

Risks to the patient arise from both illness and treatment. Take the time to identify these risks, evaluate the relative benefit of the treatment versus the risk and initiate risk-prevention measures. Many patient conditions place the patient at risk of additional complications. For example, the patient with pre-existing left-sided paralysis following a stroke 2 years earlier is at risk of developing a pressure ulcer following surgery that limits mobility. Some nursing procedures also pose risks for the patient. For example, the patient receiving enteric feeding through a nasogastric tube is at risk of aspiration. Elevate the head of the bed and have pharyngeal suction equipment at the bedside before initiating the feedings.

Identifying areas of assistance

Some nursing situations require help from additional personnel, knowledge and/or nursing skills. For example, a nurse assigned to care for an overweight, immobilised patient may need additional personnel to help turn, transfer and position the patient. Nurses need to determine the number of additional personnel and when they are needed.

Some nursing situations require additional knowledge and skills, as well as additional personnel. A nurse needs additional knowledge when administering a new medication or implementing a new procedure. Such information can be obtained from a hospital's procedure or policy manual. If still uncertain about the new procedure, other members of the healthcare team can be consulted. Asking for help occurs often in all types of nursing practice, and is a learning process that continues throughout educational experiences and into professional development.

Implementing nursing interventions

Select from the following nursing intervention methods to achieve the patient-care goals:

- Performing, assisting or directing the performance of ADLs, activities usually performed in the course of a normal day; they include walking, eating, dressing, bathing, teeth brushing and grooming.
- Counselling and teaching the patient and family. Counselling is an implementation method that helps the patient use a problem-solving process to recognise and manage stress and to facilitate interpersonal relationships among the patient, family and healthcare team. Teaching presents correct principles, procedures and techniques of health care to patients and informs patients about their health status.
- Providing direct care to achieve patient-centred goals; nurses initiate interventions to compensate for adverse reactions, use preventive measures in providing care, apply correct techniques in administering care and prepare the patient for special procedures and initiate life-saving measures in emergency situations. The specific knowledge and skills needed to carry out these nursing procedures are detailed in subsequent chapters.
- Delegating, supervising and evaluating the work of other staff members and recording and exchanging information relevant to the patient's continued care.

Nursing practice includes cognitive, interpersonal and psychomotor (technical) skills. Each type of skill is needed to implement interventions. Nurses are responsible for knowing when one of these methods is preferred over another, and for having the necessary theoretical knowledge and psychomotor skills to implement each.

Achieving a patient's goals of care

The patient's healthcare goals can be achieved by:

- providing an environment conducive to meeting such goals
- adjusting care in accordance with the patient's expressed or implied needs
- stimulating and motivating patients, thereby enabling them to achieve self-care and independence
- encouraging patients to accept care or adhere to the treatment regimen.

For each nursing intervention, the nurse and patient work together to meet the mutually developed goals. The nurse assumes a more active or more passive role depending on the intervention.

Whether patients are in a hospital, outpatient clinic or community setting, take measures to provide privacy. In an environment of privacy, patients may feel free to share concerns, ask questions about their diagnosis and treatment and resolve personal problems.

Nursing care and other therapeutic measures are designed to meet the patient's needs. As a further help in attaining healthcare goals, the nursing care plan should be flexible so that the patient is not placed in a fixed routine. The degree of flexibility, however, depends on the nature of the need, the severity of the patient's disability or illness and the patient's dependence on nursing care. Patients with severe and chronic diseases are encouraged to increase their levels of self-care and independence. To avoid discouraging patients, it is best to progress gradually. The care plan is implemented so that patients successfully achieve one level of independence before attempting the next.

Patients with chronic diseases may need to adhere to many treatment regimens. Patient adherence means that patients and families invest time in carrying out the required home treatments. For example, a patient with chronic obstructive pulmonary disease (COPD) may need to spend several hours a day performing respiratory therapies designed to keep the airways open and maintain an acceptable level of wellness. Investments of time, money and personal resources for a long period can be discouraging. Nurses are able to intervene and help the patient adhere to the treatment plan. Adequate discharge planning and education of the patient and family help promote a smooth transition from one healthcare setting to another or to the home.

Communicating nursing interventions

Nursing interventions are incorporated into the nursing care plan and patient's healthcare record. The care plan usually reflects proposed nursing interventions. After the interventions are completed, the patient's response to the treatment is recorded on the appropriate record. Documenting a brief description of pertinent assessment findings and the patient's response in the patient's healthcare record validates the need for a specific nursing intervention. Recording the time and the details of the intervention documents that the procedure was completed.

Unless communication is timely and accurate, caregivers may be uninformed, interventions may be needlessly duplicated, procedures may be delayed or tasks may be left undone. Patients can tell when members of the healthcare team communicate inconsistent messages, indicating that no one is in charge. Nurses commonly communicate orally when conferring with colleagues, changing shifts, transferring a patient to another unit or discharging a patient to another healthcare agency. Whether the nursing intervention is written or communicated orally, the language should be clear, concise and to the point.

Critical thinking skills and evaluation of care

Evaluation of care requires you to think about patient responses to nursing interventions and to determine their effectiveness in promoting the patient's wellbeing. Evaluation requires knowledge of the characteristics of improved care in all patient domains, expected and unexpected outcomes of interventions from nursing and other disciplines, characteristics of improved family and group dynamics, and community resources. For example, when evaluating a patient for a change in vital signs, the nurse applies knowledge of disease processes and physiological responses to interpret whether a change has indeed occurred and whether the change is desirable. For example, a patient in acute pain may present with an increased heart rate and increased muscular tension. The nurse knows that this is a sympathetic nervous system response to painful stimuli. After administering a pain medication and repositioning the patient, the nurse will return to evaluate whether vital signs have returned to either a more acceptable level or the patient's pre-pain baseline. Positive evaluations occur when established outcomes are achieved, leading the nurse to conclude that the medication dosage and nursing intervention effectively met the patient's goal of improved comfort. Negative evaluations or undesired results indicate that the intervention was not effective in minimising or resolving the problem or in avoiding a potential problem. As a result, the nurse must change the care plan and try different therapies or a different approach to administering existing therapies.

This sequence of evaluating and revising therapies continues until problems are appropriately resolved. Evaluation is dynamic and ever-changing, depending on the patient's condition; as problems change, so too may expected outcomes. A patient whose health status continuously changes requires more frequent evaluation. In addition, priority problems are often evaluated first; for example, evaluating a patient's acute pain before evaluating the status of a knowledge deficit.

Evaluation of goal achievement

The purpose of nursing care is to help the patient resolve actual health problems, prevent the occurrence of potential problems and maintain a healthy state. Evaluation of the goals of care determines whether this was accomplished (Table 6-5). For example, during an initial assessment a postoperative patient may report acute abdominal pain, rate the pain as 8 on a scale of 0–10 and grimace or hold the abdomen during attempts to move in bed. This baseline is used by the nurse to identify the presence of acute pain and establish the comfort–function goal of < 3/10 pain. Evaluation determines whether the outcomes that reflect goal accomplishment were met. Did the interventions of positioning, proper and timely administration of analgesics and use of relaxation successfully reduce the patient's pain? To objectively evaluate the degree of success in achieving a goal, use the following steps:

1. Examine the goal statement to identify the exact desired patient behaviour or response.
2. Assess the patient for the presence of that behaviour or response.
3. Compare the outcome criteria with the behaviour or response.
4. Judge the degree of agreement between outcome criteria and the behaviour or response.
5. If there is no agreement (or only partial agreement) between the outcome criteria and the behaviour or response, what are the barriers? Why did they not agree?

There are different degrees of goal attainment. If the patient's response matches or exceeds the outcome criteria, the goal is met. If the patient's behaviour begins to show changes but does not yet meet the criteria set, the goal is

TABLE 6-5 Evaluation measures to determine the success of goals and expected outcomes

Goals	Evaluative measures	Expected outcomes
Patient's pressure ulcer will heal within 7 days	Inspect colour, condition and location of pressure ulcer	Erythema will be reduced in 2 days
	Measure diameter of ulcer daily	Diameter of ulcer will decrease in 5 days
	Note odour and colour of drainage from ulcer	Ulcer will have no drainage in 2 days Skin overlying ulcer will be closed in 7 days
Patient will tolerate ambulation to end of hall by 20/11	Palpate patient's radial pulse before exercise	Pulse will remain below 110 beats per minute during exercise
	Palpate patient's radial pulse 10 minutes after exercise	Pulse rate will return to resting baseline within 10 minutes of exercise
	Assess respiratory rate during exercise	Respiratory rate will remain within 2 breaths of patient's baseline rate
	Observe patient for dyspnoea or breathlessness during exercise	Patient will deny feeling of breathlessness
Patient will have improved grief resolution by 15/1	Ask patient about frequency of periods of crying, sadness	Patient reports decreased frequency of crying, sadness in 2 months
	Review patient's sleeping log	Patient has periods of 6–7 hours of sleep without interruption within 10 days
	Review patient's dietary intake	Patient has no weight loss in 1 month

partially met. If there is no progress, the goal is not met (Table 6-6). A clearly defined goal with specific outcomes is easily measured.

As goals are evaluated, adjustments to the care plan are made as indicated. If a goal was successfully met, that portion of the care plan is discontinued. Unmet and partially met goals require nurses to continue intervention. This is an important step in critical thinking – knowing how the patient is progressing and how problems either resolve or worsen. The nurse's careful monitoring and early detection of problems are a patient's first line of defence. Groves and colleagues (2014) describe the importance of nurses learning how to anticipate at-risk patients. Clinical judgements are based on the nurse's observations of what is occurring with a specific patient, and not merely on what may happen to patients in general. Changes are often very subtle. Evaluation must be patient-specific, based on a close familiarity with each patient's behaviour,

TABLE 6-6 Examples of objective evaluation of goal achievement

Goals	Outcome criteria	Patient response	Evaluation findings
Patient will self-administer insulin	Patient prepares insulin dosage in syringe Patient demonstrates self-injection	Patient prepared accurate dosage in syringe Patient administered morning insulin dosage; self-injection was correctly performed	Patient has progressed and achieved desired behaviour
Patient's lungs will be free of secretions	Coughing will be non-productive	Patient coughed frequently and productively	Patient will require continued therapy
	Lungs will be clear to auscultation	Lungs were clear to auscultation	Condition is improving
	Respirations will be < 20 per minute	Respirations were 18 per minute	
Patient will be able to perform self-care measures without discomfort	Patient will rate pain as < 3 on a scale of 0–10 Patient will initiate bathing	Patient reports right-sided abdominal pain as 5/10 while attempting bathing	Patient's condition still indicates a problem Continued therapy with possibly new care measures is required

physical status and reaction to caregivers. Critical thinking skills promote accurate evaluation, which leads to the appropriate revision of ineffective care plans and discontinuation of any therapy that has been successful (see Table 6-7 and Figure 6-3).

Unmet goals

As hospital stays become shorter, many patients are discharged before all goals are met and all clinical problems are resolved. When preparing a patient for discharge, evaluate the status of each nursing intervention and write an evaluative statement identifying the patient's progress towards goal achievement and problem resolution. Appropriate revisions to the care plan are made for home or follow-up care (e.g. an extended-care facility). Clearly distinguish between goals that have been met and goals that require continued intervention.

When goals are not met, identify the variables or factors that have interfered with goal achievement. Usually a change in the patient's condition, needs or abilities makes alteration of the care plan necessary. For example, when teaching self-administration of insulin a nurse discovers that the patient has a literacy problem or a visual impairment that prevents the reading of insulin dosages on the syringe. As a result, original outcomes cannot be met. Thus new interventions are needed and revised outcomes to meet the goal of care.

The evaluation of interventions examines two factors: the appropriateness of the interventions selected, and the correct application of the implementation process.

Figure 6-3 Nurse evaluates circulation following application of elastic wrap bandage.

Potter PA, Perry AG 2004 Fundamentals of nursing, 6th edn. Mosby, St Louis.

TABLE 6-7 Modification of nursing care plan for Mr Brown

Reassessment	Nursing judgement or decision	Goals and expected outcomes	Interventions
40 pack-year history of smoking Infiltrates present on chest X-ray film Crackles present over right lung fields Achieves only 60–70% of incentive spirometry goal because of incisional pain Reluctant to turn, cough and deep-breathe because of incisional pain Does not splint abdominal incision Oral temperature of 39.8°C	Ineffective airway clearance related to poor control of incisional pain	Goal: Patient's acute pain will be well controlled	
		Expected outcomes: Improved respiratory function	
		Patient will use PCA more frequently	Demonstrate proper use of PCA and rationale for regular use of medication
		Patient will splint incision before each cough and deep-breathing exercise	Demonstrate correct splinting procedure. Allow for return demonstration by patient
		Patient's level of pain decreases to < 3 on a scale of 0–10	
		Patient's lungs will become clear	
Infrequent, irregular use of patient controlled analgesia (PCA) Reports 7/10 pain on a 0–10 scale	Patient's lungs will become clear to auscultation	Assist patient with splinting procedure	
		Patient will achieve 90% of incentive spirometry goal	Demonstrate and assist patient with incentive spirometry
		Patient's oral temperature will return to normal	
		Patient will turn, cough and deep-breathe	Encourage patient to turn, cough and deep-breathe every hour

The appropriateness of an intervention may be based on the standard of care for a patient's health problem. A standard of care is the minimum level of care accepted to ensure a high quality of care to patients. Standards of care define the types of therapies typically administered to patients with defined problems or needs.

During implementation, evaluate the patient's response during and immediately after intervention. Evaluation must be integrated with ongoing nursing care. If the response is favourable, implementation continues. Re-evaluation occurs when the intervention proves to be unsuccessful. Changes in implementation should be guided by the nature of the patient's unfavourable response. Consulting with other nurses may yield suggestions for improving the approach to care delivery. Senior nurses are often excellent resources because of their clinical experience. Regular evaluation ensures that a patient's care plan is current and appropriate.

Conclusion

This chapter has unpacked some key concepts as we move through the next three domains of the process of clinical reasoning. Clinical priorities are set in collaboration with the patient, family and other members of the healthcare team. The process of planning nursing care involves identifying health problems and setting goals specific to the patient and the agreed outcomes of care. Only then can appropriate nursing actions or interventions be identified and implemented. The appropriate selection of patient outcomes will provide a base for evaluation of the care, given the patient's progress towards goals and the standard of care received. As you move into Chapter 7, which provides an overview of the quality improvement and research processes, you will undoubtedly notice strong parallels between these and the clinical reasoning process outlined within the last three chapters.

Key concepts

- Clinical priorities are the most important or pressing patient problems or issues based on the assessment data collected.
- Partner with the patient and family to develop goals for each priority problem that are SMART (specific, measurable, achievable, relevant and timely).
- The care plan is a written guideline for care, documenting the individualised nursing actions for each goal.
- Independent nursing interventions are within the RN's scope of practice and are initiated autonomously to address patient problems, whereas collaborative interventions require a prescription from an advanced practitioner, but always require nursing judgement or decision-making.
- Taking action also requires planning of resources and determining when help is needed.
- Evaluation determines a patient's response to nursing actions and the extent to which goals of care have been met.
- The nursing care plan is then modified based on evaluation data.

Learning outcomes

Mastery of content will enable you to:

- recognise the place of ongoing inquiry in nursing practice
- appreciate the three levels of nursing inquiry:
  1. Inquiry into own practice through ongoing critical reflection on experiences and learning associated with the clinical reasoning process
  2. Inquiry into local practices through ongoing collaborative evaluation and development of practice
  3. Inquiry into nursing practice through ongoing utilisation of research evidence produced through the ongoing development of nursing knowledge through research
- recognise the role that workplace culture plays in the effectiveness of all levels of inquiry and the place of practice development in creating the collaborative and person-centred cultures associated with positive patient experiences and health outcomes
- understand how a PEEP framework – People, Effects, Environment, Praxis – forms a useful organising structure when thinking about different broad domains of nursing inquiry and the utilisation and production of nursing knowledge and practice
- discuss the characteristics of systematic practice: reflection, evaluation and research processes
- understand how different levels of inquiry are crucial in generating different kinds of knowledge for practice
- begin to build a picture of the complexity of nursing practice, and the need for ongoing participation at all levels of inquiry.

For those who believe, no proof is necessary. For those who don't believe, no proof is possible.
Stuart Chase

Introduction

Being effective as a nurse is a constant state of 'becoming'; that is, being an effective clinical nurse entails continuous development of the self and of practice through ongoing **processes** of inquiry, which maximise the likelihood that we take a curious and open-minded approach to building our knowledge and expertise. This development of self as a nurse, and of our nursing practice, is influenced by the extent to which we understand ourselves, take care of ourselves and find ways to engage actively in our own development through ongoing inquiry. To do this we need to understand and avoid the human tendency for 'seeing' only what we 'believe' and 'believing' only what we 'see' (see above quote).

Our development as clinical nurses is also influenced by the cultures within the contexts in which we gain our experience as nurses, and the nursing team's shared beliefs about the forms of inquiry that are practised and those that are not. Some workplace cultures perpetuate established practices through a 'don't rock the boat' or 'we have always done it like this' attitude; others challenge and support critical and systematic examination of established practices (or rituals) in order to find ways to continuously improve the care they provide. Many vacillate between these two positions practice-by-practice and day-by-day.

Lastly, our development, and that of our practice, is dependent upon the generation of meaningful nursing knowledge through systematic research, and the appropriate integration of this knowledge into our understandings and practices. The appropriate utilisation of research evidence is highly dependent on a sound understanding of the people to whom the evidence may relate, of the **environment** to which the evidence may apply, and of the nature and strength of the evidence itself. Understanding the complexity surrounding evidence utilisation helps us make sense of the fact that practice change based on research evidence is extraordinarily difficult to achieve, and the range of publications and initiatives seeking to support clinicians in achieving the translation of research-based knowledge into practice attest to this fact (see *Online resources* on p. 117).

This constant state of becoming an effective clinical nurse then, is supported by our engagement in three interrelated areas or levels of inquiry (Box 7-1). The first is engagement in ongoing inquiry into, and development of, our own knowledge and expertise. The links between this form of inquiry and the content of Chapters 4, 5 and 6 will become obvious, and we suggest you become familiar with the notion of clinical reasoning (Chapter 4) and think about that process as the basis of this first level of inquiry. That is, the way in which the ongoing learning (the sixth domain of clinical reasoning) provides the foundation upon which evidence-based practice and nursing research are built.

The second area involves engagement in ongoing collaborative inquiry through evaluation, and development of local practices. It is not difficult to see that this second level of inquiry is more likely to occur when individual nurses are actively engaging at the first level. Some writers label this second level of inquiry as 'continuous quality improvement', 'total quality management' or similar, and highlight a project-based approach to examining improvements in specific practices – for example, pressure area care or fall prevention – for addressing identified clinical problems (e.g. Sollecito & Johnson 2013). An alternative to this project-based approach involves a broader concern for the creation of person-centred workplace cultures (Dewing et al 2014), which are known to lead to more positive patient experiences and better health outcomes (Manley et al 2011a). While this broader approach also involves the identification and improvement of specific areas of practice, the intention is always to address the underpinning social processes and systems in order to reduce the likelihood of similar problems occurring in the future (Manley et al 2011b; see Evolve site: Essentials of Care Program). It also increases the likelihood that when the team identifies the need for improvement, the required changes or refinements to current practice are implemented. This chapter takes this second approach, and discusses one methodology – practice development – for enhancing the workplace culture in order to generate sustainable improvements and positive practice change at the second level of inquiry (Dewing et al 2014).

The third area addressed within this chapter is the ongoing development of nursing practice produced through the integration of new knowledge and understandings generated through healthcare or nursing research. And, just as the quality of inquiry at the second level (or indeed the likelihood that nurses even engage at that level of inquiry) is related to engagement in level one inquiry, level two inquiry is a crucial foundation for level three inquiry. It is important to understand that the majority of nurses will never lead their own research projects, although many may be involved as collaborators or participants in research undertaken by others. All nurses will, however, need to access and assess the findings of research undertaken by others if they are to provide

BOX 7-1 Three levels of nursing inquiry

1. Inquiry into own practice through ongoing critical reflection on experiences and learning associated with the clinical reasoning process.
2. Inquiry into local practices through ongoing collaborative evaluation and development of practice.
3. Inquiry into nursing practice through ongoing utilisation of research evidence produced through the ongoing development of nursing knowledge through research.

BOX 7-2 The PEEP framework

- **P** the People involved, their experiences and their preferences
- **E** relevant evidence of the Effects of nursing practice
- **E** the local Environment or contextual realities of practice
- **P** Praxis as a means of learning and evolving practice actively

best practice (see Box 7-1). Accessing and determining the relevance of specific research findings requires a good deal of knowledge: of research methods and the extent to which findings derived through specific research approaches are relevant to local practice decisions. The focus over the last two decades on providing clinicians with useful summaries or guidelines for integrating research evidence into practice has helped deal with the reality that many nurses are novices when it comes to judging and applying research findings in their practice. This chapter provides a beginning point for a journey that will extend across the remainder of your career in nursing.

The process of developing the knowledge and skills required for **critical inquiry** may feel overwhelming at times. If that happens to you, we urge you to stay engaged in the learning process and to work with others, provide each other with challenges and support, and strive to continue to develop your knowledge and skills. To assist you in the early stages of this journey, this chapter provides material that will help organise some of the complexity and provide some foundational understandings of the nature of nursing inquiry and its role in the development of effective nursing practice.

This chapter explores processes for engaging in critical inquiry as a nurse, which requires an understanding of different forms of knowledge, and an understanding of how nurses must work with knowledge critically and translate that knowing into practical action. To achieve that goal we have divided the chapter into three major sections.

The first section draws out the main features of the three **levels of nursing inquiry** and argues for ongoing engagement of all nurses in the processes associated with each level. The integration among these levels of inquiry will become more obvious as your knowledge and confidence builds. That is, your practice will draw upon the knowledge you have developed through your own experiences, from the insights you have gained through engaging in local practice development and from your understanding of relevant research findings. The knowledge/evidence generated through each of these levels of inquiry impacts on, and is impacted on, by the knowledge/evidence created across all three levels.

The second section outlines contemporary ideas relating to practice development and its place in creating person-centred cultures that enable nursing inquiry and continuous integration of new knowledge into nursing practice.

The third section is organised according to the **PEEP framework – People, Effects, Environment and Praxis**. This framework provides a means of thinking about broad domains of nursing inquiry (People, Effects and Environment), and the integration of new knowledge into nursing practice (**Praxis**) (see Box 7-2). Within the first three of these four domains (PEE*), we discuss the methods used for both evaluating local nursing practices and undertaking nursing research. Discussion of the fourth domain (***P) focuses on the integration of knowledge through praxis.

Three levels of nursing inquiry

This section provides material that we hope will convince you that nursing inquiry is a part of everyday practice; not, as some would argue, simply the domain of academics or senior clinicians/managers who bear the major responsibility for nursing research. The view that the ideas of nursing inquiry and evidence for practice are limited to nursing research and the evidence produced through a limited range of methods denies a world of learning and development that is crucial for the provision of effective nursing care.

• CRITICAL REFLECTION POINT

Think about the kind of information that you feel confident to hold as 'factual' and the kind of information that you are less confident about. How easy is it to track the origin of the things that you believe to be true?

Inquiry involving critical engagement in everyday practice

Every experience of working with colleagues and patients is an opportunity to engage with an inquiring mind in order to learn and develop your nursing expertise. The cornerstone of this process is clinical reasoning, which is discussed at length in Chapter 4. This day-to-day practice inquiry and learning is enhanced through critical reflection and experiential learning. You will encounter the ideas behind critical reflection and experiential learning across many of the subjects you undertake within your undergraduate and postgraduate courses – in nursing and beyond. Different lecturers or clinicians may cite different theorists and have slightly different ways of discussing the processes involved and the underpinning theoretical frameworks. Broadly speaking, however, critical reflection can be undertaken by those seeking to become more self-aware (learn) and take action (act) in relation to improving the clinical knowledge, skills or attitudes they require to provide the best possible nursing care.

Reflection

The link between **reflection** and learning has been around for a long time. Dewey (1933) believed that the function of reflective thought is to:

> **transform a situation in which there is experienced obscurity, doubt, conflict, disturbance of some sort, into a situation that is clear, coherent, settled and harmonious.**

The work of Donald Schön (1983, 1991) has been highly influential in the development of reflective practice. Schön believed that clinicians needed to develop ways of understanding the unpredictable, complex, everyday world of practice in order to learn from it. Schön also emphasised the need for a safe environment in which reflective conversation can be held. We will pick up on this point in our discussion of effective workplace cultures (Manley et al 2011b).

Jack Mezirow's (1991) work in reflective practice is significant because it addressed one of the most important aspects of learning for adults: that of *perspective transformation*. Transforming perspective about practice and about the self is a central objective of guided reflection (McCormack & Johns 1998). This involves a process of becoming critically aware of how and why our assumptions about the world in which we operate have come to constrain the way we see ourselves, our relationships with patients and our practice.

Mezirow argued that there are two ways of achieving perspective transformation. First, one can develop a sudden insight. This sort of *mirror imaging* often occurs when one is faced with a situation that is so challenging that it creates doubt about previously held assumptions. An example of this would be realising in a conversation with a patient that we hold a particular belief or value system that influences the way we respond to the patient's particular circumstances.

The second way perspective transformation can be achieved is by proceeding through a series of transitions whereby one revises previously held assumptions, about oneself and others, until these assumptions are transformed. Mezirow described six levels of *critical reflectivity* that assist in this process (see Box 7-3). While their hierarchical nature may be criticised, the levels are useful within the reflective process, if they are seen as *reflective foci* rather than a hierarchy. In this way they can be used as a means of reflecting on one's development as a reflective clinician. The literature on reflection within nursing practice is extensive and used within all nursing programs. Somerville and Keeling (2004) provide a straightforward overview that you may find useful.

Experiential learning and action

Revans (1983) and McGill and Beaty (1995) argue that experiential learning is a more viable alternative than traditional education methods for adults in a constantly changing environment. Inextricably linked to experiential learning is the resultant action. Revans (1983) describes action learning as 'learning by doing' and a social process: 'those who try it learn with and from each other.' He believes this learning occurs more effectively in small groups (with structure and discipline) than in simple pairs. Revans believes that action learning is not about teaching. He differentiates between what he calls 'programmed

BOX 7-3 The levels that Mezirow describes

Reflectivity – having a level of awareness and being able to observe and describe.

Affective reflectivity – awareness of how we feel about ourselves and how we think and act.

Discriminant reflectivity – awareness of the process of decision-making and the effectiveness of our perceptions.

Judgemental reflectivity – awareness of value judgements and assumptions made in our practice.

Conceptual reflectivity – awareness and understanding of the concepts involved in decision-making and the identification of the need for further learning.

Theoretical reflectivity – using experience to generate theories. Awareness of how practice is influenced by theory. Recognition of the various forces that influence our perceptions, thoughts and actions.

knowledge' found in books or passed on by experts and 'questioning insight' which engages experience. Like Revans, Pedler and colleagues (1991) emphasise the importance of the action element of action learning: 'there is no learning without action and no sober and deliberate action without learning'. Action learning enables the art and the science of nursing to be articulated and made real for the practitioner through the facilitation of reflection on their practice. This reflection enables the practitioner to embody (internalise and make real from one's own perspective) complex knowledge and theory that would otherwise feel alien and disconnected to the realities of practice.

Professional nursing practice is an art form in itself – one that is created and re-created with every interaction. However, like all artists, professional nurses have core elements that transcend all relationships, interventions and activities. These are largely hidden to the gaze of the novice clinician; and like any work of art, the first viewing reflects the finished product. It is only through repeated inquiry into the product (and multiple products) that the hidden dimensions of the finished product are revealed. Collaborative learning facilitates the process of uncovering the hidden dimensions. Several collaborative approaches have been identified as effective in assisting in this process: critical companionship (Hardiman & Dewing 2014), clinical supervision (Brunero & Stein-Parbury 2008), **active learning** groups (Shin et al 2015) and action learning sets (Haith & Whittingham 2012), to name but a few. These approaches are collaborative in nature.

In collaborative learning experiences, there is no distinction between knowledge generators and knowledge users. Instead, the process of deconstructing and reconstructing practice experience results in a shared learning that enables individual learning, the development of effective practice and cultural change to occur in parallel.

The second level of inquiry (see Box 7-1) is also about collaborative learning and action; however, the difference is that the learning and action flow from a broader and systematic inquiry into the experiences and outcomes resulting from current practice.

Inquiry involving collaborative and ongoing evaluation of local practice

As is the case for all professionals working within health care, nurses should work with others to evaluate the effectiveness of their practice; this may involve you in any of the stages outlined in Box 7-4. The aims of all healthcare services should include continuous improvement in the quality of care provided to service users (Gawande 2008). *Quality of care* is a broad concept that is inclusive of aspects such as accessibility, efficiency, effectiveness, safety, and responsiveness to consumer needs. Evaluation of the ongoing improvements in the quality of nursing practice will, therefore, involve comparison of current practice with past performance, and evaluation of current practice against established standards or best practice.

Clinical audit involves ongoing cycles of continuous improvement, each of which includes stages that follow a systematic process of:

- establishing best practice
- measuring current practice against the established criteria
- taking action to improve care
- monitoring to sustain improvement.

BOX 7-4 Stages in clinical audit cycle

Stage 1: identify the focus, practice, problem or issue

This stage involves the selection of a focus for the audit. This selection may be influenced by:

- stakeholder (patient feedback)
- areas where problems have been encountered in practice
- where there is a clear potential for improving practice
- areas of high volume, high risk or high cost, in which improvements may be made.

Stage 2: define criteria and standards

The overall purpose of the audit should be determined and the specific questions that require answers should be written; these form the audit criteria. The criteria define what is to be measured and what can be measured objectively. A standard is the threshold of the expected compliance for each criterion, usually expressed as a percentage.

Stage 3: collect data

Data to be collected may already exist in a clinical information system, or a new data collection system may need to be developed.

Ethical issues must be considered; the data collected must relate only to the objectives of the audit, and staff and patient confidentiality must be respected.

Stage 4: compare performance with criteria and standards

This is the analysis stage in which data are compared with criteria and standards and conclusions drawn in relation to how well the standards have been met.

Stage 5: implement change

The results of the audit are published and discussed and an action plan developed to record recommendations.

Re-audit: sustain improvements

After an agreed period, the audit should be repeated.

Adverse occurrence screening and critical incident monitoring are crucial components of continuous quality improvement. Peer review of cases that have caused concern or from which there was an unexpected outcome is undertaken by a team of clinicians. The goal of this critical analysis is to identify what went wrong and to find ways of preventing similar events occurring in the future. This is sometimes called a *significant event audit*.

Peer review involves assessment of the quality of care provided by a clinical team with a view to improving clinical care. Peers discuss individual cases to determine whether the best care was given. This is similar to the method used for critical incidents, but is not restricted to problematic cases.

Patient surveys and focus groups are methods used to obtain users' views about the quality of care they have received. In addition, patient stories of their experiences of care can be obtained and reviewed by clinicians seeking to develop deeper understanding of the experiences of patients in their unit or ward.

Evaluating local nursing practices requires the use of approaches that engage practitioners in assessing the processes and outcomes of their practice. Many of these approaches are synonymous with reflection and collaborative inquiry. Ongoing practice evaluation contributes to both the development of local practice and the development of workplace cultures where research is valued. Through practice-based evaluation, new avenues for engaging differently in practice can be explored and compared with established external research evidence. For example, while there may be strong international evidence about a particular nursing practice, the way this evidence translates into practice may vary across contexts (Estabrooks et al 2008, Masso et al 2014, Øvretveit 2011). Evaluation of models of care, communication, assessment practices, record keeping and multidisciplinary relationships will all help to inform the best use of the evidence. Therefore, we need to use systematic and rigorous approaches to exploring, making sense of and evaluating our everyday practices. Research methods have much to offer us in this respect.

• CRITICAL REFLECTION POINT

What do you think would be the major barriers to clinicians exploring the experiences of the patients receiving care on their ward? How do you think regular clinical audits might overcome some of those barriers?

Inquiry involving nursing research for advancement of nursing knowledge

Approaches used in nursing research

Nursing researchers use a wide range of **research** approaches (methodologies and methods), many with their origins in disciplines such as sociology, psychology, epidemiology, anthropology and history. Selection of the appropriate research approach is based both on the intention that the researcher has in mind in undertaking the research and on the specific question to be addressed within the research (Table 7-1). Some research approaches, for example, focus on providing a deeper understanding of the experiences of people and their interpretations of those experiences (see Box 7-5); others focus on measuring the extent to which a particular nursing intervention achieves a desired outcome in order to establish the effects of nursing practice (see Table 7-2). Other research approaches are more concerned with bringing about and researching sustainable practice change in particular environments (see Box 7-6).

No matter which approach is used, however, nursing research is a systematic examination of phenomena important to nursing: in the delivery of services to patients and their families; in the advancement of teaching and learning approaches; in the development of leadership and management strategies; and in the advancement of nursing as a professional discipline. Research is needed in order to ensure the effectiveness of nursing interventions, for providing the knowledge necessary for practice and its development, and for helping nurses to be accountable by demonstrating to society the safety, effectiveness and efficiency of services provided.

Approaches used in data collection

A variety of data collection methods are used in nursing research. Broadly speaking, however, data are often categorised as *qualitative* – most commonly words or text derived from interviews, diaries or discussions; or *quantitative* – information collected either in the form of numbers or converted into numbers for the purposes of analysis (Table 7-3).

Data collection and analysis need to be undertaken in a manner that maximises the *rigour* of the study – the extent to which the findings can be believed. Some researchers use terms such as *validity* and *reliability* in relation to their research processes; others use broader terms such as *accuracy*, *trustworthiness* and *transparency*. The appropriate term is a function of the approach taken and

TABLE 7-1 Intention of the research and types of research questions associated with quantitative and qualitative data analysis

Purpose of research	Questions for quantitative data and analysis	Questions for qualitative data and analysis
Identification		What are the phenomena?
Description	How frequent are the phenomena? What are the characteristics of the phenomena?	What are the dimensions of the phenomena? What is important about the phenomena?
Exploration	What factors relate to the phenomena? What are the antecedents of the phenomena?	What is occurring with the phenomena? What is the process by which the phenomena are experienced?
Explanation	What are the measurable associations among the phenomena? What causes the phenomena? Does the theory explain the phenomena?	How do the phenomena work? Why do the phenomena exist? How did the phenomena occur?
Prediction	What will happen if an intervention is used? If phenomenon X occurs will Y follow? How can we make the phenomena happen? Can the phenomena be controlled?	

BOX 7-5 Approaches used for PEEPing at people

Narrative research

This approach is concerned with the interpretation of stories told by individuals in normal conversational situations and involves the in-depth study of personal stories, of those receiving care or those involved in providing that care. These stories provide insights into the meanings attached to experiences of nursing and health care, and are often a rich source of data for identifying improvements needed in care processes, service delivery models and organisational structures and processes.

Phenomenology

The focus of phenomenology is what people experience in regard to daily practices or experiences and how they interpret those experiences. The goal of this type of research is a full description of the experience of patients, their perceptions of how these events happened, how they and others made decisions, the meaning of those decisions to them and, finally, how these events have shaped their lives from their perspective.

Hermeneutics

Hermeneutics is another form of research that seeks to understand the meanings that people attach to experiences, events and practices. Unlike phenomenology with its focus on describing the meanings people attach to experience, hermeneutic research attempts to interpret these meanings by breaking down each experience into parts and exploring these in the context of the whole experience. Originally used by the Greeks as a method of interpreting texts, hermeneutics is concerned with bringing to understanding the nature of the social world from both the subjective interpretation of the individual and the more general meanings abstracted from individual interpretations.

Grounded theory

Grounded theory is an approach to collecting and analysing data which has the aim of developing theories and theoretical propositions that are grounded in real-world observations. That is, the goal is development of a theoretical explanation for behaviour observed in qualitative investigations.

TABLE 7-2 Designs used in research for PEEPing at effects

Goal of research	Design labels used traditionally in nursing research	Contemporary clinical epidemiological design labels
Describe – what is going on?	Descriptive: qualitative or quantitative data	Prevalence
Identify relationships – are factors related?	Correlational	Incidence Case series Before-and-after studies
Test causation – do interventions work?	Quasi-experimental Experimental Integrative review	Cohort Case-control Randomised controlled trials Multi-site randomised controlled trials

BOX 7-6 Approaches used for PEEPing at environment

Ethnography

The focus of researchers using an ethnographic approach is deep understanding of the social perspective and cultural values of a particular group by participating with or getting to know their activities in depth and in detail. Ethnography is founded on the idea that a system's properties cannot be understood in isolation.

Critical ethnography

The focus of critical ethnographers goes beyond describing 'what is' to asking 'what could be?' There is no one accepted definition, but in general the approach has a political purpose: of seeking the empowerment of their 'subjects' through raising awareness of the structures and processes that maintain inequalities and oppression.

Ethnonursing

The focus of researchers using an ethnonursing approach is the shifting of nurses' views from the emphasis on medical disease and a perception of reliance on research methods associated with medicine. This approach was developed to help form holistic pictures of cultures through examination of shared cultural care values, meanings and modes of action, leading eventually to the identification of transcultural care concepts. The major goal of ethnonursing is to understand the diversity and universality of care.

Critical inquiry

Critical inquiry involves using various modes of inquiry and perspectives or methodologies to conceptualise, investigate, derive meaning, challenge taken-for-granted assumptions and generate actions for changing the status quo and the power imbalances reflected within social structures and systems.

Action research

Action research is participatory research that focuses on enabling practitioners to gain the power needed to bring about change in their and/or others' practice. Through processes of critical reflection on experience and methods of research that are practitioner focused, new knowledge is generated. Thus, action research has three purposes: the development of practice, the facilitation of practitioners to learn and become empowered, and the facilitation of practitioners to contribute to or refine theory.

Evaluation

Evaluation is the systematic determination of the merit, worth and significance of specific nursing practices to relevant stakeholders through testing of context/mechanism/outcome/configurations (CMOCs). Experimental methods are used to test CMOCs and to inform theory, policy and practice. Realistic evaluation is similar but focuses on testing more-realistic theories; that is, theories that take into account multiple perspectives and interpretations.

TABLE 7-3 Forms of data and approach to data analysis

Forms of data	Forms of analysis
Unstructured interviews, discussions or conversations	Thematic analysis: inductive coding for themes
Written text, such as diaries and stories	Template analysis: predetermined themes based on conceptual model or similar
	Narrative analysis: used in relation to stories
Semi-structured interviews, observations or surveys	Content analysis: for descriptive categories
	Coding of responses: with allocation of numbers
Structured interviews, observations, surveys or measures	Statistical analysis seeking to describe, identify relationships or establish cause and effect

associated assumptions about subjectivity/objectivity and the nature of reality. Meaningful discussion of these issues is beyond the scope of this text. As you develop your interest in nursing research, you will need to access materials and people with the knowledge and expertise to assist you with your learning. Understanding the assumptions and beliefs associated with particular approaches to research is a vital part of making sound decisions about the relevance of any findings to your practice.

The major push over the past decade for the use of research evidence in clinical decision-making has led researchers to convey their findings in a form more easily understood by clinicians. Within research employing quantitative analysis this has meant a move away from focusing on *statistical significance* – the probability of obtaining a particular result by chance, with probabilities of less than 5 times in 100 deemed by convention to be significant. (You may have seen this expressed as $p < 0.05$.)

Researchers are now more likely to report their findings using more intuitively meaningful measures of clinical significance (Box 7-7). Research and professional journals have also moved to publish a broader range of research and encourage researchers to present their findings in a manner that makes their knowledge claims or relevance to nursing practice more explicit (Greenhalgh 2014).

Approaches to bringing research evidence together

The findings of nursing research, and the research of other health disciplines relevant to nursing, are published in a vast array of research and specialist journals. One of the greatest challenges in using research evidence is the overwhelming number of articles that need to be accessed and considered. An alternative challenge is the complete absence of relevant work to be found in relation to areas of nursing practice. In the latter case, you will need to rely on your own clinical expertise, the expertise of others you work with, and locally produced knowledge as a basis for your practice. You can see, then, that the more actively you engage in levels one and two of inquiry the more able you will be at making good decisions concerning level three knowledge and evidence.

Whether there is an abundance of research evidence or not, there is a need for both clinical and research expertise to determine the 'so what?' of the research in relation to clinical practice. In recent years there has been exponential growth in the production of materials/publications that summarise the relevant research and/or make recommendations for practice. Some of the most common of these are included in Box 7-8.

The growth in systematic summaries of research and practice guidelines based on the best available research evidence has been driven by the evidence-based practice movement and both positive and negative (and often strong) responses to it (Greenhalgh 2014). Many clinicians have defined **evidence-based practice** across

BOX 7-7 Measures of clinical significance

Numbers needed to treat (NNT): the number of patients who would need to be treated in order for one patient to gain the desired outcome.

Relative risk (RR): the risk of a negative outcome for one group compared with the risk of that outcome in the comparison (control) group.

Odds ratio (OR): the odds of a patient benefiting from a treatment over the odds of benefiting from the alternative.

Coefficient of determination (R^2): the percentage of the variance in an outcome accounted for by a particular factor (or group of factors).

Mean difference: the difference between the extent of achievement of an outcome of one group compared with the extent of achievement of an outcome determined through comparison of group averages.

Confidence interval (CI): a range established around any point estimate (mean difference, RR, %, etc), within which there is 95% confidence that the population 'difference', 'risk', 'percentage' actually falls.

BOX 7-8 Common approaches to bringing together the findings of multiple research studies

Systematic review

Involves the application of a precise method to accessing, assessing and combining the results of all valid and reliable research undertaken in relation to a specific clinical question – normally comparisons of two or more interventions or treatments – in order to make as definitive a statement as possible concerning best practice (e.g. the approach to administering bronchodilators that has the largest effect on length of stay in hospital). Systematic reviews may or may not include a meta-analysis, which is the use of statistical procedures to combine the findings of several studies. The data from individual studies can be combined into a larger data set as long as the studies used similar interventions (e.g. nebulisers versus spacers in emergency departments) and similar outcomes (e.g. admission to hospital, number of hours spent in emergency department, spirometry).

Meta-narrative review

Is an approach that is broader than systematic reviewing; it covers a wide range of issues within a given topic. In addition, a narrative review bases the decision to include or exclude studies on descriptive grading of forms of evidence, rather than the narrow hierarchy of evidence used in systematic reviews. The outcome is, therefore, a comprehensive overview of the topic or area of interest.

Realistic review or synthesis

Similar to a narrative review, but more heterogeneous and iterative in terms of the sources of evidence and their contribution to the findings. The processes used in accessing evidence from a full range of sources, making decisions about the inclusion of material, sifting and assessing the material and bringing together synthesised findings and recommendations are rigorous and systematic.

Research-based guidelines

Systematically developed statements, based on the best available research evidence, generated to assist healthcare professionals and patients make decisions about screening, prevention, treatment or care for specific illnesses or conditions.

the spectrum of healthcare disciplines (Box 7-9) and there are ongoing debates concerning the hierarchies of evidence and the ways in which particular approaches to research (e.g. randomised controlled trials – RCTs) are valued over others. However, the major issue is finding and assessing the usefulness of research that addresses the question at hand. For example, if the question is about the effectiveness of a particular approach to treating pressure ulcers, an RCT provides the 'best' evidence. However, if the question is about the feasibility and acceptability of that approach to treatment in particular contexts, research designs employing qualitative analysis would potentially provide more useful insights.

Given the expertise and time needed to integrate research evidence into clinical decision-making, adequate resources and support are crucial (see *Research highlight*).

Accessing relevant research literature demands the development of some fundamental skills in database searching. You need to take advantage of library teaching sessions so you can become familiar with the systems in place within your library and online. Locating the forms of publications outlined in Box 7-8 will be useful, particularly in sourcing research evidence in relation to best practice. For example, the Joanna Briggs Institute (http://joannabriggs.org/) supports the development of a range of reviews and guidelines relevant to nursing; the Cochrane Collaboration (www.cochrane.org) provides systematic reviews which cover topics relevant to nursing practice, although predominantly relating to medical diagnosis, prognosis, therapies and harm/risk. Both of these organisations have broadened the focus of their reviews to be more inclusive of the full range of research approaches associated with meaningful integration of research into practice.

BOX 7-9 A common definition of evidence-based nursing practice

The practice of nursing in which the nurse makes clinical decisions based on the best available current research evidence, his or her own clinical experience and the needs and preferences of the patient.

Harris et al 2010 Mosby's dictionary of medicine, nursing and health professions – Australian and New Zealand edition, 2nd edn. Elsevier, Sydney.

RESEARCH HIGHLIGHT

Research focus

A good deal of research is being undertaken to identify strategies to improve the utilisation of research evidence in everyday nursing practice. Barriers to the use of research evidence can be clustered into factors associated with individual clinicians, those related to the nature of the evidence itself or aspects of organisational structure and/or culture.

Research abstract

The purpose of this research was to determine whether individual or organisational qualities could be identified that were related to registered nurses' readiness for evidence-based practice (EBP) as measured by their reported EBP barriers, ability, desire, and frequency of behaviour.

The researchers used a descriptive cross-sectional survey in collecting data from 2441 nurses working within the healthcare system in the United States. The American Nurses Credentialing Center (ANCC 2014) had designated some of the organisations in which the nurses worked as 'Magnet' or 'Pathway to Excellence' facilities; some facilities in which the nurses worked had neither designation. Participants completed a modified version of the Information Literacy for Evidence-Based Nursing Questionnaire. Data were analysed using a range of appropriate descriptive and inferential statistical tests.

The researchers found that education, research, and certification standards promoted by the Magnet program may provide a nursing workforce that is better prepared for EBP. Organisations should continue structural supports that increase professional development and research opportunities so nurses are empowered to practice at their full capacity (Wilson et al 2015:12).

Evidence-based practice

1. Nurses with degree-level education appear more likely to desire and engage in EBP.
2. Nurses who participate in research and ongoing professional development appear more likely to report readiness to engage in EBP.
3. Organisations that are successful in meeting the standards set by the ANCC for Magnet status appear more likely to support nurses in the use of research evidence within their day-to-day practice.

In summary, nurses must use the knowledge generated within each of the three levels of inquiry to improve both processes and outcomes of care for patients. One means of overcoming some of the major challenges to ongoing practice improvement is what has become known as *practice development* (PD). The next section outlines some of the most important aspects of PD.

• CRITICAL REFLECTION POINT

You are concerned about the likelihood that an older, immobilised patient will develop pressure ulcers. What are the best sources of evidence related to preventing ulcers? Where would you find that evidence? How would you determine if the evidence is a good basis for your practice?

Practice development

Contemporary nursing practice requires nurses to develop their practice continuously, through ongoing inquiry into practice and taking action to improve practice wherever change is needed (see Evolve, Essentials of Care). This is not easy to do in a systematic way, and nurses require support and resources to maintain learning and practice improvements. The following overview establishes the crucial role that practice development can play in stimulating and sustaining nursing inquiry and the integration of new knowledge into practice.

Practice development has been described as meaning many things to different people. However, the definition developed by Manley and colleagues (2008) forms the basis of our discussion here (Box 7-10). As you seek deeper understanding of practice development you will need to access a number of the theoretical and research papers that are becoming increasingly available.

Garbett and McCormack (2004) identify five elements of practice development. These are:

1. an emphasis on improving patient care
2. transforming the contexts and cultures in which nursing care takes place
3. the importance of employing a systematic approach to effect changes in practice
4. the continuous nature of practice development activity
5. the nature of the facilitation required for change to take place.

BOX 7-10 Definition of practice development

Practice development is a continuous process of developing person-centred cultures. It is enabled by facilitators who authentically engage with individuals and teams to blend personal qualities and creative imagination with practice skills and practice wisdom. The learning that occurs brings about transformation of individual and team practices. This is sustained by embedding both processes and outcomes in corporate strategy.

Manley et al 2008 International practice development in nursing and health care. Blackwell, Oxford, p. 9.

Manley and McCormack (2004) outline what they call technical practice development. Technical practice development focuses on the development of technical knowledge to improve technical skills and emphasises the changing of specific aspects of practice. Best practice is universally defined (i.e. what is considered best practice in one part of the world will apply everywhere else in the world), therefore, and there is a central assumption that if clinicians know the evidence, then their practice will be effective. In many respects this form of practice development resembles more traditional, passive approaches to research utilisation, whereby it is assumed that practice change flows naturally from awareness of deficiencies in clinical practice and education concerning best practice. However, contemporary research suggests otherwise, and critiques of technical approaches to helping people use knowledge in practice have highlighted the naivety of assuming that acquired knowledge will automatically lead to a change in practice (Stetler et al 2011).

Manley and McCormack (2004) contrast the technical approach with emancipatory and transformational practice development. *Emancipatory practice development* is an approach that emphasises sustained development of practice through helping practitioners to free themselves from the taken-for-granted assumptions they make about practice. Through facilitated approaches, practitioners are helped as individuals and teams to make changes that bring about more-empowered practice cultures. Facilitating these processes involves cycles of reflective learning and action, so that clinicians develop awareness of the need for change by identifying contradictions between what is espoused about practice and the realities of practice. The process therefore involves action to change practice and refines action through reflection. *Transformational practice development* focuses on both getting the products of inquiry (knowledge and research evidence) into practice and creating a culture of innovation and clinical effectiveness (Manley et al 2011a). It focuses on helping practitioners to transform their practice and to achieve person-centred cultures of practice through their engagement with multiple intelligences and both the art and the science of practice.

These facilitated processes help clinicians remove barriers to action and enable cultures of effectiveness to be

developed (Titchen et al 2013). While research evidence is important to transformational practice development, best practice is locally defined and contextually bound. So for evidence to be understood and used it has to be placed in a local context that makes sense to the immediacy of practice experience. Thus, evidence in this context comes from a variety of sources – clinician experience, user preferences, local data and research evidence – and is understood through reflective engagement with collective practice experience (see Stetler et al 2011).

In terms of evaluating effectiveness, therefore, the emphasis is on both the outcomes achieved from the development of practice and the processes used to achieve those outcomes. Thorough understanding of the processes used to achieve particular outcomes makes these processes more likely to be transferred appropriately to other contexts, thus creating cultures of continuous improvement that are committed to increasing effectiveness in person-centred care.

The key processes of emancipator or transformational practice development include:

1. identifying a particular practice requiring consideration
2. clarifying values and beliefs among team members about the particular practice
3. identifying the existence of these values and beliefs in day-to-day practice
4. identifying the gap that exists between the espoused and the real values through processes of inquiry and evaluation
5. negotiating systematic approaches to developing practice and creating action plans to develop practice
6. using collaborative, inclusive and participatory approaches (McCormack et al 2007) to increase the likelihood that key stakeholders (i.e. those affected by potential developments) have a sustainable commitment to learning from the processes, via reflective learning strategies such as action learning (McGill & Brockbank 2004) and supported reflective practice (Johns 1998).

The example presented in Box 7-11 highlights the central role that facilitation plays in enabling the processes involved in practice development to evolve fully and the goals to be achieved.

Facilitation of practice development

Facilitation is fundamental to practice development (Crisp & Wilson 2011). *Facilitation* has long been used as a process for enabling individuals and groups to understand what they have to go through to change aspects of their behaviour or attitudes in relation to themselves, their work or other individuals (Marshall & McLean 1988). A similar interpretation is apparent in some approaches to practice-based learning in health care, the aim being to challenge existing practice and support the development of new ways of working (Figure 7-1).

Just as there are at least two types of practice development (technical and emancipatory/transformational) (Manley & McCormack 2004), facilitation styles can be similarly characterised. *Task-orientated facilitation* may increase the use of theoretical or empirical knowledge in practice, but it requires the facilitator to have a lot of expertise in facilitation as well as technical knowledge associated with the practice in question. Knowledge expertise alone is inadequate because it is still the facilitator

BOX 7-11 Examples of the implementation of EPD processes

Scenario: A medical-surgical nurse providing care for older adults with mobility problems starts to observe an increase in the number of patients with pressure injuries. The nurse would collaborate with others in the ward to:

1. Gather any data that exists in relation to the incidence of pressure injuries in the ward to confirm or disconfirm the observation. If there is a cause for concern, they would then move on to the second step in the process.
2. Clarify values and beliefs held by others in the ward about pressure-area care practices.
3. Seek evidence that these values and beliefs influence day-to-day practice through auditing pressure-area care or structured observations of care.
   - These structured observations enable the identification of any gaps between what nurses value and identify as important and the values evident in practice.
   - Using a systematic approach, such as claims, concerns and issues, all stakeholders would be invited to create action plans to develop best practice around pressure-area care.
   - Reflective learning strategies, such as action learning and supported reflective practice, would be used to support ongoing engagement with the practice of pressure-area care within the ward.

who is ultimately responsible for the success or failure of the initiative and the development of practice (Box 7-12).

In contrast to the task or technical approach, the overall aim of the emancipatory or *transformational facilitator* is to enable individuals and teams to become empowered to develop a transformational culture in their individual and collective service that can nurture and sustain the development of a particular goal or task (Titchen et al 2013). Although the overall approach may encompass elements of technical facilitation, it is essential to recognise that technical facilitation must be integrated into holistic approaches if the different needs of stakeholders are to be met. Crisp and Wilson (2011) provide a framework that helps make sense of the development of expertise required for the transformation of individuals and practice.

Within a holistic facilitation approach, the focus is on the social system as well as the practice of individuals or groups. Facilitators help participants become aware of, and freed from, taken-for-granted aspects of their practice and the organisational systems constraining them. They foster a climate of critical inquiry through reflective discussion; incorporating the various ideas of group members enables individuals and groups to act. Responsibility for action rests with the individual or group (Kemmis 2006). By considering the external climate and broader social system in which nurses work, collective insight, understanding and ownership develop through clinicians' own actions, rather than the actions of others (Box 7-13).

Practice development, then, has a central focus on developing person-centred cultures that facilitate human flourishing, clinical effectiveness and the development and integration of knowledge through ongoing inquiry.

BOX 7-12 Skills used in technical facilitation

The skills used in technical facilitation are narrow and focus on:

- sourcing information
- assessing the relevance and adequacy of that information
- translating the information into differing formats (e.g. protocols, guidelines, information sheets)
- developing training programs
- training
- information giving
- audit and monitoring.

BOX 7-13 Skills of the holistic facilitator

The skills of the holistic facilitator are broad and responsive:

- Working with values, beliefs and assumptions.
- Challenging contradictions.
- Developing moral awareness about the most appropriate way to act.
- Focusing on the impact of the context on practice, as well as practice itself.
- Using self-reflection and fostering reflection in others.
- Enabling others to 'see the possibilities'.
- Fostering widening participation and collaboration by all involved.

• CRITICAL REFLECTION POINT

Before reading the next section, think about what person-centred workplaces might look like. What do you think such workplaces would feel like to those working there?

Person-centredness and person-centred practice

The word *person* aims to capture those attributes of people that represent our humanness and the factors we regard as the most important and the most challenging in our lives. A person should always be treated as an end in his or herself and not as a means to another's end – a principle that guides many ethical, legal and moral frameworks in Western society (see Chapter 9). What this means is that we should never do things to people that are not going to benefit them as a person. Thus Tom Kitwood (1997:8) defined personhood as:

> **a standing or status that is bestowed upon one human being, by others, in the context of relationship and social being. It implies recognition, respect and trust.**

BOX 7-14 Core concepts at the heart of person-centred nursing

- Being in relation
- Being in a social context
- Being in place
- Being with self

If we accept this well-respected and widely used definition of personhood, then four core concepts can be identified as lying at the heart of person-centred nursing (Box 7-14).

Being in relation

Relationships are central to **person-centredness**. Indeed, models of nursing, irrespective of their philosophical underpinnings, have emphasised the importance of relationships (e.g. Boykin & Schoenhofer 1993, Johns 1994, Peplau 1952, Rogers 1986, Watson 1985). In person-centred nursing, the relationship between the nurse, the patient and others important to the patient is paramount. Sustaining a relationship that is nurturing to both nurse and patient requires valuing of self, moral integrity, reflective ability, knowing of self and others, and flexibility derived from reflection on values and their place in the relationship.

Being in a social context

This concept recognises that patients have a social context and that this context contributes to shaping who they are as people, how they respond to stimuli and how they might make sense of things they experience. Listening to, collecting and analysing patients' stories help us to understand who the person is in a social context. Stories afford us the opportunity to understand the local spheres of meaning that bear on and enter into the nurse–patient relationship and to understand the person's context.

Being in place

The context in which care is provided has the greatest potential to enhance or limit the facilitation of person-centred practice (McCormack et al 2010). Indeed, Andrews (2003) argues that the concept of *place* and its impact on care experiences is poorly understood in nursing. Paying attention to place in care relationships is increasingly recognised as important.

When facilitating person-centredness, nurses find they not only balance competing care values, but often they find it necessary to consider organisational values too. Nurses are not free to fulfil a moral obligation to the patient without considering organisational and professional implications. While the freedom of the nurse is a significant issue in the facilitation of person-centredness, other characteristics of context have been found to be of equal significance; these include systems of decision-making, staff relationships, organisational systems, power differentials and the potential of the organisation to tolerate innovative practices and risk-taking.

Being with self

Respect for values is central to person-centred practice (McCormack & McCance 2006). It is important to develop a clear picture of what patients value about their life and how they make sense of what is happening to them. This provides a standard against which the nurse can compare current decisions and behaviours of the patient with those values and preferences made in life in general and which form the basis of a care plan. Assisting the patient to find meaning in care may help them to tolerate the incongruity of their situation in order to create a future. This can only be achieved when we have a clear picture of what is important to the patient and others, what they really value about their life and how they make sense of the things happening to them. For this reason, nursing care decision-making ought to adopt a negotiated approach between nurse and patient.

To work effectively as a person-centred nurse and to create care environments that are person-centred requires the integration and blending of different kinds of knowledge: knowledge about people, knowledge about what it means to be clinically effective and knowledge about the care environment. Nurses need to know the person in their patients; know their colleagues as people; understand what it means to be clinically effective; and understand the culture of the place in which they work. To do that, they need to take a PEEP.

• CRITICAL REFLECTION POINT

You have found what you believe to be best evidence related to preventing pressure ulcers. How would you ensure that your use of that evidence is person-centred?

Taking a PEEP

Within the PEEP framework (see Box 7-2), the people domain is about variation in individuals' needs and preferences for care, as well as the ways in which different stakeholders experience receiving or giving care and use different kinds of knowledge. The **effects** domain refers to the kinds of evidence used in determining best practice. Research evidence is one kind of evidence, and this informs and is informed by the evaluation of **outcomes** and the cost–benefit of these outcomes. However, it is

increasingly recognised that the environment in which care is provided has an impact on effectiveness. The environment of care is often referred to as the context, and how much that context supports a culture of learning and change through supportive challenge is an essential consideration in the use of knowledge in practice. It is increasingly acknowledged, however, that an environment which takes account of people's perspective, choices and preferences, which uses a variety of sources of evidence to inform the evaluation of effectiveness, and which provides a culture of learning through supportive challenge, is an effective workplace. Clinicians and leaders in such workplaces demonstrate praxis; that is, they engage in critical practice development as part of everyday practice.

Taking a PEEP at people

When reading research studies, nurses should avoid automatically generalising the findings to individuals or groups for whom they care. While the researchers may have identified best practice in relation to a specific nursing intervention – for example, a particular approach to healing venous leg ulcers – the decision to use that practice in relation to a specific patient requires both an understanding of the evidence and an understanding of the patient's circumstances and preferences.

Effective nursing care needs to work with variation in individual needs and preferences for care, as well as the ways in which different stakeholders experience receiving or giving care. It also needs to use different kinds of knowledge. Patients, for example, may express preferences that are not consistent with what is known to be the best evidence; or nurses may find particular care practices personally distressing. In such situations, decision-making will be influenced by the balance between expressed preferences, the priorities of the nurse and the personal and professional beliefs and values of all those involved in the decision. Thus, thinking about how people engage in decision-making and the factors that influence decision-making is important to being clinically effective as a nurse.

Working effectively requires forming therapeutic relationships between nurses and patients (and others significant to them in their lives), between nurses as colleagues and between nurses and the wider healthcare team. These relationships are built on mutual trust, understanding and a sharing of collective knowledge (see Chapter 12, Nolan et al 2004). Nursing literature on therapeutic caring where the concept of person is central, for example, Watson's theory of human caring (1985), support this view.

To be person-centred in a relationship with a patient and others significant to them, nurses need to be able to work with the beliefs and values of a patient and their family; have an engaged relationship with the patient and family; demonstrate understanding of the patient's feelings; share decision-making; and provide for physical needs. Liaschenko and Fisher (1999) delineate three types of knowledge that may assist you in working effectively with patients. These are *case knowledge*, which is generalised and objective knowledge, such as anatomy and physiology and pharmacology; *patient knowledge*, which is knowledge of how individual patients are experiencing and responding to their illness situation; and *person knowledge*, which is knowledge of the unique individuality of the patient (Stein-Parbury 2005).

Working with patients' beliefs and values reinforces one of the fundamental principles of person-centred nursing, which places importance on developing a clear picture of what the patient values about their life and how they make sense of what is happening to them. This is closely linked to shared decision-making, and focuses on nurses facilitating patient and family participation through providing information and integrating newly formed perspectives into established practices. This must involve a process of negotiation that takes account of individual values to form a legitimate basis for decision-making, the success of which rests on successful processes of communication (Chapter 12).

The extent to which you are successful in achieving the forms of relationships and ways of working with patients that lead to effective care can be evaluated through ongoing reflections and critical discussions with colleagues, a mentor or a critical companion (Hardiman & Dewing 2014). Evaluation of the extent to which local practices meet the needs of patients in a person-centred way involves systematic data collection, such as patient stories and collection of patient satisfaction surveys. Nursing researchers seeking to generate new knowledge in relation to the experiences of people cared for by nurses will commonly use one of the approaches outlined in Box 7-5. This material may be brought together within narrative or realistic reviews or syntheses that can be used to inform your thinking about your work with patients and their families (Box 7-8).

Taking a PEEP at practice effects

As you develop expertise in nursing you will accumulate expertise related to specific nursing practices and the outcomes that you achieve. The area in which you work will undertake clinical audits and other forms of quality enhancement projects that identify the outcomes being

achieved in relation to current practice. Both of these forms of inquiry are vital to understanding the extent to which specific practices achieve their desired outcomes or, conversely, to identifying factors that are having negative impacts on achieving the desired outcomes.

If an intervention appears to work for most patients, the nurse may be satisfied with this success without questioning whether there might be a better way. If the intervention is not successful, the nurse might use an approach practised by a colleague or try a different sequence of accepted measures. Even if an intervention discovered with this approach is effective for one or more patients, it may not be appropriate for those in other settings. Practices must be tested to determine the measures that work best with specific patients; that is, those that determine best practice.

Research approaches associated with testing the effectiveness of nursing practices include those listed in Table 7-2. This form of research is most easily drawn together in systematic review with meta-analysis; and as long as the studies that have been undertaken are rigorous and able to be combined, some clear pointers to the most effective approach may be available.

• CRITICAL REFLECTION POINT

An RN decides to investigate the effectiveness of pressure-area care within the ward. What level of inquiry is needed? How would the nurse go about this investigation?

Taking a PEEP at impact of environment on nursing practice

As discussed previously, the environment of care is often referred to as the context, and how much that context supports a culture of inquiry, learning and change through supportive challenge is an essential consideration in the use of knowledge in practice. The competence of nurses, particularly in relation to interpersonal and communication skills, was drawn out in a study undertaken by McCabe (2004). McCabe concluded that nurses can communicate well with patients when they use a person-centred approach, but that the ability to do so is heavily influenced by the work and culture of the organisation; that is, the care environment. The care environment focuses on the context in which care is delivered and includes the following: appropriate skill-mix, systems that facilitate shared decision-making, effective staff relationships, organisational systems that are supportive, the sharing of power, and the potential for innovation and risk taking. Key characteristics of context include the culture of the workplace, the quality of nursing leadership and the commitment of the organisation to the use of multiple sources of evidence to evaluate the quality of care delivery.

Research approaches associated with the environments or context in which nursing takes place are outlined in Box 7-6. These approaches fall into two categories: describing the context and culture in order to provide a deeper understanding of the social relationships and systems that influence the way that things are done, or working with people within particular contexts to identify and bring about change in the way things are done.

Taking a PEEP at engagement through praxis

As discussed previously, effective workplace cultures demand that all nurses demonstrate praxis; that is, they engage in critical inquiry and practice development as part of everyday practice. An enormous amount of effort has gone into research and thinking about ways of achieving practice change based on the local knowledge generated through the quality-improvement processes, or getting the products of research into practice since the mid-1990s (e.g. Greenhalgh et al 2004, Kitson et al 1998). However, continuous practice improvement is complex and requires critical reflection, systematic evaluation, behaviour change and facilitation. The **PARiHS model (Promoting Action on Research Implementation in Health Services)** is a framework that recognises and accommodates this complexity (Rycroft-Malone et al 2004, Stetler et al 2011). This framework suggests that if we are to translate evidence/knowledge into practice successfully, we have to consider the quality of the evidence, the context in which it is to be implemented and the approach used to facilitate the implementation process – all issues discussed earlier in this chapter. This integration is consistent with the meaning of praxis and involves practising with the moral intent of person-centredness.

Aristotle distinguished between two kinds of action – poiesis and praxis (Welldon 1987). Poiesis means 'making action' and praxis means 'doing action'. *Poiesis* involves action that is focused on achieving a predetermined end; that is, the construction of a product or an object is its endpoint (e.g. a successfully completed surgical intervention). According to Carr (1987:169), poiesis is 'a species of rule-following action'. The worth of practice in this way is judged on the quality of the end-product. Worth is decided on by the way the practice is judged to conform to recognised and predetermined standards and current understanding of what counts as good quality in the particular practice area. We see this evidenced in the way that quality of practice is judged solely on diversions

from care pathways, adverse events rates, throughput, complaints or levels of satisfaction.

Praxis, on the other hand, is not only concerned with the end-product, but also with morally worthwhile action that cannot be predetermined in advance as it is dependent on the context in which the action is undertaken. The achievement of an end-product and the process of getting there are not separate entities, because the quality of the end-product is inseparable from the means of getting there.

Good practice, understood as praxis, involves more than the application of theory and research evidence or the exercise of a skill. Determining the right thing to do at the right time and in the right way (often seen as the essence of clinical effectiveness) involves a particular kind of knowledge – *practical knowledge* (Eraut et al 2000). Titchen and colleagues (Titchen & Higgs 2001) use the terms *professional craft knowledge* or *practical know-how*. This knowledge is expressed and embedded in practice, is often tacit (i.e. it is embedded in our thinking and taken for granted) and intuitive, and it combines perception, reasoning and virtue. Good-quality practice from this view is concerned with technical outcomes (such as the effectiveness of a particular intervention), but it is equally concerned about the experience of achieving the outcome from the perspective of patients and staff and the learning derived from engaging in the process itself.

The complexity of nursing inquiry

In summary, providing the most effective care for a given person or group of people, in a specific context, involves complex decision-making. The most productive way of dealing with this complexity is to work systematically with the knowledge and practical skills that you have developed and to gather additional knowledge in the form of local practices and research evidence. Essentially, engaging with these different forms of inquiry will enable the artistry of practice to shine through. We know from research that when we blend our personal qualities, practice skills and our creativity we develop what has been referred to as practice wisdom. Being wise as a practitioner comes from many years of systematic reflection on practice and, in particular, the artistry of practice. Professional artistry blends the science and art of practice and enables complex scientific and objective facts to be translated into the particular requirements of professional practice. Thus to be an effective practitioner, nurses need to be able to reflect on practice, put into practice new understandings gained through reflection, generate questions for further inquiry and use external research processes and outcomes to generate and verify new knowledge.

Key concepts

- Nurses develop their knowledge-base and expertise through processes of ongoing inquiry into nursing practice.
- There are three levels of nursing inquiry that are crucial to the development of nursing knowledge and expertise: active engagement in everyday practice, ongoing evaluation of local nursing practices, and production and refinement of nursing knowledge through research.
- Practice development plays a crucial role in stimulating and supporting all levels of inquiry.
- The PEEP framework – People, Effects, Environment, Praxis – forms a useful organising structure when thinking about different broad domains of nursing inquiry and the integration of the products of inquiry into effective nursing practice.
- Nursing practice should be subjected to systematic evaluation and underpinned by the best evidence available at the time.
- A range of research methodologies and methods are required for the spectrum of research questions that arise from nursing practice.
- Nurses need to utilise evidence for practice in a person-centred manner.

Online resources

The range of online resources available to nurses and others working in health care who are seeking to extend their understanding of knowledge generation or utilisation is extensive, and we encourage you to seek assistance from academic and library staff in locating those relevant to your specific focus. Here are four of the major sites for Australian and New Zealand health research and for practice development internationally.

www.nhmrc.gov.au is the website of the Australian National Health and Medical Research Council, where you will find a range of material related to the production and utilisation of research findings.

www.hrc.govt.nz is the website of the New Zealand Health Research Council, where you will find a range of material related to the production and utilisation of research findings.

www.fons.org is the Foundation of Nursing Studies' Centre for Nursing Innovation, where you will find a range of materials – including free access to the International Practice Development Journal – relating to practice development.

www.health.nsw.gov.au/nursing/projects/eoc.asp gives access to the Essentials of Care Program of the Nursing and Midwifery Office of the NSW Ministry of Health, an example of a health-sector-wide program using a practice development approach.

Learning outcomes

Mastery of content will enable you to:

- describe the importance of teamwork in providing high-quality care
- identify factors that support coordination of care and teamwork
- describe the importance of an evidence-based approach to managing care
- explain and review the unique role of nurses in multidisciplinary and interdisciplinary teams
- describe approaches to delivering nursing care, including person-centred care, interdisciplinary, multidisciplinary and primary care
- identify the nurse's role in managing and coordinating care with the patient and family/carer as team members
- describe the importance of leadership in the clinical setting
- describe the scope of nursing practice and the levels of competency required to manage nursing care
- describe and appreciate the legal, policy and regulatory frameworks that influence the context of nursing practice
- discuss ways to apply strategies to promote client autonomy and promote self-management
- understand and demonstrate how nursing care contributes to clinical and organisational outcomes in the healthcare setting
- illustrate how the quality improvement process can promote optimal client outcomes and model of care development
- appreciate the importance of developing and monitoring nursing-sensitive patient outcome measures.

Nurses comprise almost 80% of the healthcare workforce, and in these times of increasing patient complexities, ensuring appropriate coordination of care contributes significantly to improving outcomes of patient care. Nurses work in both independent and dependent practice settings but invariably in a healthcare team. Globally, healthcare systems are challenged by a range of factors, including workforce shortages, ageing populations, increasing rates of chronic conditions and escalating health inequities (Crisp et al 2014). Yet, in spite of these challenges nurses have never before been equipped with such a robust body of research and scholarship to inform their practice. Although there is an increasing diversity of professionals in the healthcare setting, nurses are responsible for the greatest proportion of client care and are often responsible for coordination. As a consequence, nurses are driving a range of healthcare reforms through innovative care delivery models, such as using link nurses in palliative care settings to improve cross-sector collaboration between primary, secondary and tertiary care (Ellerbe et al 2012). Internationally, healthcare systems are looking at a range of reforms to address the increasing demands for health care and the need to decrease health disparities. Nurses in contemporary healthcare systems are at the forefront of planning and managing care, directing the agenda of healthcare delivery in the policy setting, as well as managing and delivering care in the preventive, acute, community and residential care settings (Davidson et al 2013, Jackson et al 2014).

Principles informing a nursing approach to care delivery include ensuring that models of care:

- are fiscally responsible, using resources such as people, facilities, equipment and time, appropriately and efficiently
- are informed by the best available evidence derived from high-quality patient-centred research and clinical guidelines endorsed by peak bodies
- promote a wellness model focusing on the health and wellbeing of the wider community
- promote autonomy of the individual and engage in activities to promote self-care
- tailor processes and desired outcomes to meet the unique needs of clients and their families
- are mindful of the unique role nursing plays in the interdisciplinary team
- are culturally safe and appropriate and tailor care for culturally and linguistically diverse populations
- foster both independent and collaborative nursing practice, where nurses both initiate and evaluate nursing therapies and interventions and also work with other healthcare providers to achieve optimal outcomes
- are directed at promoting optimal client and organisational outcomes (Davidson et al 2006).

In the United States, collaboration between the Institute of Medicine and the Robert Wood Johnson Foundation, *The future of nursing: leading change, advancing health*, lays an important framework for developing nursing into the future (Committee on the Robert Wood Johnson Foundation Initiative on the Future of Nursing 2011). This report recommends that nurses should be enabled to practise to the full extent of their education and training; achieve higher levels of education and training through an improved education system; be full partners, with doctors and other healthcare professionals, in healthcare reform; and engage in workforce planning and policy development based upon high-quality data. These recommendations are salient for managing client care internationally and have cast the spotlight on advanced practice nursing roles (Shamian & Ellen 2014).

Using evidence to inform teamwork and nursing practice

Evidence-based practice is essential for optimising patients' health outcomes and strategically allocating finite health resources. Adopting an evidence-based practice approach to care ensures that optimal clinical decisions are made, based on the best available research evidence, clinician expertise and patient/community preferences (Sackett et al 1996). Nurses are in a unique position to make a significant difference to health outcomes for a broad range of individuals and communities by providing care in accordance with the best available evidence.

Contemporary approaches to coordinating and providing team-based care should be driven by evidence-based practice and a strong foundation of nursing scholarship. Innovative nursing research is driving clinical practice and defining the importance of nursing in both independent and collaborative practice settings. The *Research highlight* describes that implementation of **multidisciplinary**, supported, evidence-based protocols, initiated by nurses in the acute phase of stroke, for the management of fever, hyperglycaemia and swallowing dysfunction, delivers better patient outcomes after discharge from stroke units (Middleton et al 2011). This study has important implications for identifying nurses' integral role in improving health outcomes and their role in the multidisciplinary team.

RESEARCH HIGHLIGHT

Research focus

Optimising health outcomes following stroke is dependent on the monitoring of blood sugar, swallow reflex and temperature. This is a critical role for nurses.

Research abstract

Patient outcomes 90 days after hospital admission for stroke were assessed following a multidisciplinary intervention targeting evidence-based management of fever, hyperglycaemia, and swallowing dysfunction in acute stroke units.

Evidence-based practice

Implementation of multidisciplinary, supported, evidence-based protocols initiated by nurses for the management of fever, hyperglycaemia, and swallowing dysfunction delivers better patient outcomes after discharge from stroke units.

Reference

Middleton et al 2011 Implementation of evidence-based treatment protocols to manage fever, hyperglycaemia, and swallowing dysfunction in acute stroke (QASC): a cluster randomised controlled trial. The Lancet. 378(9804):1699–706.

The pressures facing healthcare systems also require nurses to respond effectively and appropriately to challenges such as skill-mix diversification and increasing financial pressures (Davidson et al 2015). Effective models of nursing care, a strong research base for practice and **positive practice environments** promoting quality, safety and clinical leadership are important drivers in promoting optimal client care and improving the working life of nurses.

For example, the increased importance of the nursing role in primary care and an emphasis on universal health care (Henderson et al 2014) has led to an exponential rise in research internationally. Increasingly, nursing is provided in ambulatory, community and also tele-healthcare settings. As you progress in your career you are likely to see a decreased emphasis on hospital-based care and a greater focus on the needs of the individual and their family. The increased focus on person-centred care is an important influence on healthcare policy (Cloninger et al 2015).

It is, however, also important to be mindful of consumers' views in developing innovative approaches and role substitution (Halcomb et al 2014). For example, it may take consumers time to access nursing providers when they are accustomed to medical clinicians. In order to achieve role clarity for both healthcare consumers and other healthcare professionals, we need to work towards an increased standardisation of titles (Parker et al 2014).

• CRITICAL REFLECTION POINT

Take time to reflect on your own communication style and how easy or challenging you find asserting your ideas or opinions:

1. **How will you build confidence in communicating and questioning those in authority respectfully and collegially?**
2. **How will you communicate change supported by the evidence so it can be translated into practice?**

Many of us enter nursing because we are passionate about improving patient care and are adamant about being patient advocates. However, an argument positioned by evidence and a strong rationale and data is much more likely to be effective than an emotive outburst. Think about your personal communication style and seek critical feedback from mentors and colleagues. Reflect on strategies that will assist on improving person-centred care and interdisciplinary team communication, as communicating with team members who you do not know, who may be external to your organisation, can be difficult.

Building a nursing team and coordinating care teams

A range of descriptors have been applied to nursing care models. Regardless of the term used to describe the approach to nursing care, nurses work in a multidisciplinary milieu and the nursing role cannot be considered in isolation from the roles of other healthcare professionals and overarching drivers affecting the healthcare system, such as financial constraints. As nurses are the largest group of healthcare providers, they have an invaluable role in supporting and building a coordinated team approach to the complex care required by the older person. A multidisciplinary approach, focusing on interdisciplinary models, is essential given the need to provide patient-centred care. The increasing complexities of patient conditions and psychosocial support needs and information requirements demand a collaborative multidisciplinary or interdisciplinary team approach (Hickman et al 2015). Often you will be involved in either multidisciplinary teams or interdisciplinary teams. A multidisciplinary team may be composed of a range of healthcare professionals functioning under

one organisational umbrella or by professionals from a range of organisations, including private practice, who function as a virtual team to meet each patient's unique needs (Mitchell et al 2008). On the other hand, in an ideal setting an **interdisciplinary** team approach to care can be composed of healthcare providers (e.g. public health nurses, general nurses and practice nurses) who are required to interact, collaborate and negotiate in the provision of care (O'Neill et al 2008).

Teamwork is seen when a group of people contribute their knowledge and skills and work together to achieve a common goal/task. The **complexity** of contemporary health care demands effective teamwork, and it is important that healthcare professionals contribute to the work of their teams (Pearce et al 2011). A team can be described as a group of people with a range of experiences and skills who have come together with a common purpose. It is the common purpose or goal that defines this group as a team (Hartgerink et al 2014). More importantly, people have to work together to achieve this goal; there is an assumption that the contribution and input of a group of individuals is more beneficial than the contribution of the individuals alone. It's important to include patients, their families and volunteers where appropriate in the team. In addition, the more tangible and measurable the team goal, the more effective the team is likely to be. Increasingly, there is an emphasis on inter-professional education to enable health professionals to work in teams (Reeves et al 2008).

Defining measurable goals has led to a range of clinical improvements through the use of collaborative methodology. Collaborative methodology is a method of driving improvements in clinical care by closing the gap between what is known and what is practised. Collaborative methodology uses a continuous improvement cycle to bring about small, rapid changes that create a larger change within the system over a finite period, by using change management principles and evidence-based goals and targets. This method is being used increasingly in Australia and internationally to drive quality improvement. For example, 16 acute adult mental health inpatient services across Queensland have worked together to develop clinical indicators related to the inpatient treatment of schizophrenia (Plever et al 2010).

Goals of practice that do not provide effective and tangible goals for planning, delivering and evaluating care are likely to be inadequate. In the instance where constructs are poorly defined, they can have a range of meanings for different people. A more appropriate way of negotiating a goal is to make it measurable. For example, a goal of care could be to deliver it in accordance with best-practice guidelines with assessable outcomes, such as the proportion of people admitted to hospital with a stroke who are assessed for their ability to swallow, or the proportion of women who have a vaginal delivery compared to those who have a caesarean section. These examples show that client outcomes are often dependent on the role of nurses in the broader healthcare system.

For the most part, nurses deliver care in complex and dynamic circumstances, in collaboration with health and social service providers, as well as with family members and caregivers (Hickman et al 2015). Teams do not occur spontaneously, but grow and are developed and nurtured by positive practice environments and effective managers and leaders. A range of factors contribute to developing an effective team, and many of these factors are dependent on the aptitudes and capabilities of clinical leaders. Some of the characteristics of effective teams and leaders include:

- negotiating goals and intended outcomes of nursing interventions
- leading by inspiring, enabling and motivating rather than dominating
- effectively communicating strategies and processes for sharing information
- clarifying the roles, responsibilities and accountability of team members
- collaborating and seeking external opinion and expertise
- regularly reflecting on team progress and how this relates to the team goals
- taking the time to celebrate successes and to support each other when things are not going well
- leadership and support at all levels along the healthcare spectrum
- effective formal and informal communication processes that are transparent
- participation in decision-making regarding clients and organisational decision-making in respect of clinical care delivery models
- promotion of a safe work environment that provides adequate education and opportunity for personal and professional development and recognition of achievements
- implementation and monitoring of equitable and manageable workloads.

Regardless of the approach to nursing care, nurses work within an interdisciplinary context and are subject to a range of internal and external factors. Examples of internal factors include the organisation's approach to

management, while external factors can include funding and staff-mix models prescribed by government bodies.

Approaches to delivering nursing care

A range of nursing models has been used to describe the organisation of nursing care. Yet it is important to recognise that many models implemented in the clinical setting are actually hybrid approaches; that is, they incorporate a range of elements from different models. Increasingly, in clinical environments nurses are required to be flexible and responsive to policy demands and changes as well as increased heterogeneity and diversity in the health workforce (Davidson et al 2015). Dynamic staff-mix and acuity of case-mix mean that various models can be used interchangeably, depending on the needs of the clinical setting, patient-mix and staffing arrangements in place. The key approaches to providing nursing care are described below. Table 8-1 summarises the strengths and limitations of each of these approaches. As you review each of these nursing models, consider which clinical environments these approaches will be most applicable to in the care settings that you have been exposed to. Take the time to reflect on your clinical experiences to date and categorise the approaches to client care in these settings. Consider whether the approach used was optimal for the clinical setting and client's needs.

Team nursing

The team nursing approach is based on using nurses with a range of skill-mix and scopes of practice. For example, assistants in nursing (AINs), enrolled nurses (ENs) and **registered nurses** (RNs) work under the leadership and coordination of the RN. Ideally, in this model nurses are assigned client-based tasks, in response to the needs of the individual and the clinical area. This approach is commonly used in acute care hospitals and residential aged care.

Total patient care

In a total patient care approach, the RN retains overall responsibility for the client, working collaboratively with other team members to coordinate clinical care. The RN may delegate elements of clinical care to other members of the healthcare team, but retains overall responsibility and accountability of care. Adequate staffing models of RNs are necessary for this approach.

TABLE 8-1 Strengths and limitations of approaches to care delivery

Model of nursing care delivery	Strengths	Limitations
Functional nursing	Nurses become proficient in a designated task Potential for efficiencies in time management	Lack of an integrated approach to care management Client needs subsumed in organisational demands
Team nursing	Accommodates a range of skill-mix and scopes of practice Allows for a collaborative approach and uses a range of expertise	Less RN involvement may impact adversely on client outcomes Dependent on high-level organisational, delegation and coordination skills of the RN
Total patient care	High level of coordination of care Access to high-level clinical skills and decision-making	Increased costs associated with high numbers of RNs Decreased capacity for skill development in more junior members of the nursing team
Primary nursing	Strongly client-centred model of care promoting autonomous decision-making Promotes continuity of care and interdisciplinary communication	Efficacy of the model dependent on the quality of the care plan and communication within the healthcare team Greater dependence on RN models of care Potential for role burden for the RN
Case management	Promotes continuity of care Optimal for clients with chronic and complex care needs Creates a point of contact for clients and the healthcare team	Need for communication structures such as regular team meetings which can be time-consuming Dependent on coordinating and communication skills of case manager
Telehealth	Promotes access to individuals living in rural and remote areas Creates a point of contact for clients and the healthcare team	Requires standardised protocols and processes Requires access to information technology

Functional nursing

In a functional nursing model, nursing workload is based upon task allocation where nurses exclusively perform a designated task, such as medication administration, for a range of patients. These tasks are traditionally assigned by the nurse coordinating the shift. The appropriateness and relevance of functional nursing models is dependent on the nursing skill-mix, patient acuity and complexity and scope of practice of nursing tasks.

Primary care nursing

The primary care nursing model designates an RN's responsibility for a set of clients over a designated period, such as an episode of care. Based on a comprehensive and holistic assessment, the RN develops a care plan (see Chapter 7). When the primary care RN is off-duty, the plans are continued by associate nurses. There is scope to negotiate care plans within the broader healthcare team. A primary care nursing model is often applicable to the community nursing sector.

Case management

Relying on a comprehensive assessment and expert knowledge of the clinical situation, the RN liaises with health and social service professionals and agencies and advocates on behalf of clients. The case management model is an iterative, responsive approach to care where goals are constantly re-evaluated and care modified according to the client's conditions and changing social circumstances. In some settings, such as mental health, terms such as 'care management' are used as it is considered to be a more client-centred terminology. Case management approaches are often used in the mental health setting.

Telehealth

Telehealth is the use of electronic information and tele-communications technologies to support long-distance patient care. This mode of nursing intervention is commonly used for individuals living in rural and remote areas, as well as a support for chronic disease management.

Models of nursing care

Nursing care is provided in a range of settings and contexts. The way in which care is planned, delivered and evaluated should be based upon a prospective plan or template appropriate to the care setting, which can also be known as a model of nursing care.

Models are tools that are a standard for comparison, describing the relationship of concepts (Davidson et al 2006). In nursing, models should be dependent on the needs of the client group, the scope and skills of the nursing workforce and anticipated health outcomes. In parallel with international trends, the Australian healthcare system faces workforce shortages with increasing pressure on the acute care sector. These factors are compelling nurses to explore innovative approaches to care delivery. Nursing and nursing models should be flexible and responsive to the needs of clients and the healthcare system. Nurses can work independently, such as in the nurse practitioner role; dependently based on delegation, such as in the general practice setting; interchangeably, as in the doctor assistant role; and collaboratively, such as in nurse-coordinated models of care. These approaches challenge traditional hierarchical approaches and functional models of care, and have provoked discussion and debate surrounding the benefits and disadvantages of approaches to models of nursing care.

Describing a model of care provides a structure for nurses to systematically plan, deliver and evaluate client care (Davidson et al 2006). This structure should become the blueprint to scope and plan care delivery. It is therefore important for nurses to appreciate the conceptual underpinnings and goals of a nursing model of care. For example, what does *person-centred care* mean, and how can nurses measure and evaluate these goals? As the diversification of the workforce increases, along with acknowledgement of the importance of interdisciplinary care, the importance of teamwork is underscored (Hobgood et al 2010).

Models of nursing care promoting wellness, autonomy and self-care

Contemporary **models of nursing care** should be culturally sensitive and flexible, focusing on collaborating with clients and meeting their needs. This is in contrast with traditional nursing models of care, such as functional nursing, which can be inflexible and prescriptive. Key goals of nursing models of care should be to promote independence and wellness. Pivotal to promoting client independence and autonomy is engagement in activities that promote self-care. **Self-care** refers to the activities that an individual undertakes to manage their condition. This can include taking medication, performing activities of daily living (ADLs) and having strategies for monitoring their condition. **Self-management** embraces the concepts of self-care, but also refers to a broader set of knowledge, skills, attitudes and beliefs that prepare the individual to interact collaboratively with healthcare professionals, including nurses, to achieve negotiated goals (Riegel et al 2009). As a consequence, it may be advisable to work with clients to develop and assess their competency in

undertaking self-management tasks, such as daily weights, rather than doing these tasks for patients.

Nurses need the necessary skills to be culturally sensitive to the needs of individuals and their families, and they need to engage in strategies for supporting belief in the individual's ability to learn self-management skills. In the clinical setting, nurses need to empower clients to be independent and undertake monitoring of their own condition. For example, a client with diabetes should undertake the monitoring of their blood sugar levels and be encouraged to discuss appropriate strategies in response to these readings.

Migration and globalisation are defining characteristics of the contemporary world, and countries such as Australia and New Zealand have a rich and diverse cultural mix. As health and illness behaviours are embedded in culture and ethnicity, it is important that nurses approach client care within a context of cultural competence. The terms 'culture' and 'ethnicity' both refer to combinations of socioeconomic, religious and political qualities of human groups, including language, diet, dress, customs, kinship systems and historical or territorial identity, whereas 'competence' implies having the capacity to function effectively (Davidson et al 2010). A failure to respect and address these factors can result in marginalisation and potentially adverse health outcomes for clients. It is also important to consider that sometimes adverse behaviours can actually be labelled racist (Durey 2010).

As part of becoming culturally competent practitioners, nurses need to be aware of their own beliefs and attitudes about ethnic minorities in order not to impose them on clients. In addition, nurses need to understand the worldview of the client and their family without judging them, and to use culturally competent skills when interacting with ethnically diverse clients and groups. Key factors in developing culturally competent models of care include administration and leadership; policy-making and governing boards; clinical standards and guidelines; and an effective vision and mission to drive organisational priorities. As discussed above, positive policy environments that prime the practice setting for respect and reciprocity are pivotal in achieving optimal health-related outcomes.

Although particular settings drive characteristics of models of nursing care, generic principles that underpin the shaping of care delivery need to incorporate interventions and strategies for:

- promoting clients' understanding of their clinical condition, treatment plan and the anticipated trajectory of their condition
- developing clients' skills and opportunities necessary for negotiating and following a care plan in partnership with their healthcare professionals
- providing resources and knowledge for clients monitoring and managing the signs and symptoms of their condition
- encouraging clients to adopt lifestyles that promote risk-factor modification and focus on prevention and early intervention to promote health and wellbeing
- increasing client access to support services, including social and financial support.

Within Australia and New Zealand, addressing the health disparities of the Indigenous peoples is an important consideration in developing and evaluating nursing and midwifery models of care (Thompson et al 2011).

Approaches to coordination of care and teamwork

The approaches outlined above describe the relationship between the individual client and the nurse. A range of roles also exist for coordinating client care at an organisational level. At a macro level, where there is a focus on the development of policy and strategic directions at a government level, roles such as chief nursing officer (CNO) are pivotal in shaping workforce issues. At a meso level, directors of nursing function to develop professional nursing issues and strategic directions on an organisational basis, while at a micro level, the nursing unit manager (NUM) is responsible for directing and monitoring implementation of organisational policy and operational matters. Many organisations are focusing on decentralising decision-making and responsibility to an operational level. This has increased the nurse manager's responsibility for the unit or ward's budget, workforce performance and welfare of nursing staff, as well as monitoring the quality of patient care. The nurse manager has a multifaceted role of being an expert nurse, clinical leader and manager (Duffield et al 2009).

As you can see, the NUM position is a demanding and challenging role, incorporating a range of responsibilities. To function effectively in this role, the RN requires more than expert clinical and technical knowledge; they also need to be an effective communicator, demonstrate clinical leadership and have knowledge of financial and management principles. Box 8-1 describes the roles and responsibilities of the NUM. Because of the demands of this position, roles such as clinical coordinator, team leader, liaison nurse and team educator have been introduced into the clinical setting. In these roles, senior and expert nurses, many of whom are clinical nurse

BOX 8-1 Roles and responsibilities of the nursing unit manager

- Determine the vision and model of care for the clinical setting in consultation with the organisational goals and mission
- Identify best-practice standards and guidelines for the clinical discipline
- Develop a mechanism for monitoring professional standards and practice
- Continually evaluate nursing standards and practice and amend care plans accordingly
- Determine appropriate staff and skill-mix and engage in recruitment and retention issues
- Ensure that scheduling and rostering of staff is appropriate and consistent with the acuity and complexity of the client-mix
- Engage in negotiating professional goals with staff and actively monitoring these in regular appraisals
- Encourage and reinforce the use of clinical portfolios in appraisal and evaluation systems
- Establish and monitor mechanisms for communicating information internally within the nursing team and externally with other health and service providers
- Represent the clinical specialty and nursing role in interdisciplinary and organisational committees
- Provide clinical leadership in the clinical setting
- Communicate with clients and consumer representatives
- Promote a culture of evidence-based practice and reflective practice
- Manage the clinical setting within fiscal requirements
- Promote a culture of transparent and accountable practice
- Develop and monitor a business case for the clinical setting in consultation with the nursing team, consumer representatives and other health professionals
- Encourage and promote professional development and a culture of lifelong learning
- Promote a culture of collegiality and mutual respect among all team members
- Promote clinical care that is culturally competent and appropriate to client needs

BOX 8-2 Responsibilities of RNs in clinical settings

- Seek clarification of the vision for nursing and model of care in the clinical setting
- Identify the reporting and monitoring structure within the clinical setting
- Report and monitor actual and potential adverse events
- Document appropriately and accurately all clinical care and other relevant information
- Actively contribute to clinical evaluation and engage in quality improvement initiatives
- Engage in professional development activities
- Maintain a clinical portfolio and have a personal professional development plan
- Communicate effectively and accurately and promote a culture of accountability and transparency
- Function as an effective role model engaging in accountable, clinical practice models
- Identify preceptors and mentors to support your professional growth
- Provide clinical care that is culturally competent and appropriate to client needs
- Engage in ongoing professional development and lifelong learning

specialists, are responsible for coordinating and directing clinical care, usually on a shift basis. Often, in these roles the RN does not have a client-mix assigned to their direct care; as nursing skill-mix diversifies, the proportions of ENs and assistants in nursing are increasing in number in the workforce. Therefore, the RN may monitor and support clinical care on a ward or unit basis. In these models, delegation and monitoring skills are particularly important. It is also important to consider that nursing care is delivered on a 24-hour basis, so there is a need to ensure that there are adequate expert nursing knowledge and managerial skills available around the clock.

Nurses have a range of responsibilities associated with optimal client outcomes (Box 8-2). As you can see, every nurse has a responsibility to contribute collaboratively to the care team. Effective **teamwork** leads to improved staff job satisfaction, improved patient safety and improved **quality of care** (Rafferty et al 2001). Your capacity to be successful and enjoy your work environment will depend on your capacity to work in a team. Taking the time to evaluate your own working style is important in relation to how you will function in a team in the healthcare environment (Eng et al 2015).

Tools to support coordination of care and team work

A range of tools are available to support managing client care, and the Internet provides a rich and informative source. There are many websites that will provide useful resources to help in planning your care (see *Online resources*). For example, the Cochrane Collaboration and the Joanna Briggs Institute provide evidence-

based resources and best-practice information sheets that have been developed following a critical appraisal of the evidence using the systematic review process. Peak bodies nationally and internationally, such as the Royal College of Nursing Australia and Sigma Theta Tau International, provide rich and reliable information as well as the capacity for networking and information sharing.

Accessing accurate and timely information is important for making effective clinical decisions and monitoring clinical conditions. Communication of information across care settings, particularly from the acute care sector to the community, is also critical in coordinating care. Consequently, significant resources and focus are being placed on developing effective technological solutions for promoting high-quality client care (Hannan 2011). As a student nurse you need to develop and consolidate technological skills that allow you to work effectively with information technology solutions in addressing management of information. It is likely that in the future much of the work of the nurse will be undertaken in a technological milieu (Gray et al 2010).

Clinical practice guidelines and clinical care should be based upon the best available evidence in accordance with the client's values and clinical expertise. Accessing the vast amount of information is beyond the scope of the individual clinician, so a number of expert bodies have developed **clinical practice guidelines** to assist in providing evidence-based care. These are readily accessible through the National Health and Medical Research Council, the Joanna Briggs Institute and the Australian Resource Centre for Healthcare Innovations, as well as a range of peak bodies such as the National Heart Foundation and Cancer Australia. In New Zealand, peak bodies include the Health Research Council of New Zealand and the Cancer Society of New Zealand.

Clinical pathways are tools used to organise, sequence and integrate health care from a range of health and social service providers. These are derived through a process of negotiation, consensus and appraisal of best-practice guidelines. These tools describe the sequence of events necessary to identify anticipated client outcomes and achieve desired outcomes with optimal efficiency, along with also measuring variances that occur in the anticipated course of clinical care. Clinical pathways are sometimes referred to as critical pathways. Clinical pathways are used in both the acute and community-based settings to guide clinical care. They can be a valuable resource in achieving an integrated and coordinated approach to care.

A range of risk assessment tools is available to assist in planning and managing care. These can be used for predicting conditions such as delirium, risk of falls and pressure ulcers (Kennedy et al 2014). Remember that astute clinical assessment and anticipation of risk are key aspects of the RN's role (see Chapter 6). Valid and reliable assessment tools can assist you in clinical decision-making, particularly in your early years working as an RN. Learn to use these risk assessment tools to monitor your client's clinical condition and avoid adverse health outcomes.

• CRITICAL REFLECTION POINT

You have just received the morning shift handover report on your clients. You have been assigned the following clients:

- **Frederica, a 74-year-old woman, who is day 3 following a total hip replacement. She has an intravenous cannula and a patient-controlled analgesia infusion.**
- **Frank, a 72-year-old man admitted to hospital for a fractured femur, has new-onset shortness of breath and is becoming agitated.**
- **Rachel, a 64-year-old woman, was admitted to hospital with a stress spinal fracture as a consequence of bony metastases. She has a morphine infusion running and you note in handover that she has scored 7 on a 0–10 pain rating scale.**

In what priority order do you need to attend to these clients? Justify your answer.

Communication, collaboration and coordination among teams

Communicating with nursing colleagues and other members of the healthcare team is critical in delivering effective coordinated care. Increasingly, the quality of communication has been identified as a predictor of patient outcome. The handover process, team meetings, communication books and noticeboards are ways of communicating not only clinical but also organisational and operational information (Abraham et al 2014). As an RN, it is your responsibility to actively engage in communicating with the healthcare team to promote optimal client care. Ineffective communication is a root cause for adverse events (Lee et al 2014). Effective communication networks, clearly delineated staff roles and responsibility are important strategies in promoting the quality and safety of patient care. Implicit in creating effective communication networks is providing a vision and direction for the healthcare team through effective leadership, teamwork and a positive policy environment.

Leadership skills for nursing students

Contemporary clinical environments are placing increasing pressure on the RN to focus on clinical care and team coordination, rather than being solely responsible for a small number of patients, as in the total patient care models evident in previous decades. This is particularly the case in non-critical-care settings. In order to do this, the RN requires not only expert skills in clinical care, but also, equally importantly, needs to appraise the clinical situation, delegate appropriately and promote effective communication with clients, their families and healthcare professionals. Volunteers are also starting to play a larger role in healthcare delivery and often work within the organisation/community for long periods of time. Where appropriate, they also need to be included in team coordination (Phillips et al 2014). As a student you can develop your clinical leadership skills by using critical thinking strategies for making effective clinical decisions through astute clinical assessment, appraisal of the evidence and assessment of client needs (see Chapter 4); learning from your mistakes and those of others and actively seeking guidance and mentorship; and collaborating closely with professional nurses and striving to improve your performance during each client interaction. This can be as simple as taking the time to look up any terms or diagnostic tests you do not know about, or talking to clients about the aspects of clinical care that they find most satisfying. There are certain leadership skills that the nursing student can learn to use, including clinical care coordination, team communication, delegation and knowledge building. Seeking feedback from your preceptors, facilitators and fellow students can be useful in developing your communication and coordination skills. It is never too early to develop and refine your leadership skills, and often this is a process just as much of personal as of professional growth (Hinds et al 2015).

Measuring outcomes of nursing care

Nurses play a critical role in the quality and safety of clinical care. Adverse events in the clinical setting are the leading cause of death and injury, and are responsible for high healthcare costs as well as distress to families and clinicians. The reasons for the high rates of adverse events in the healthcare setting are multifactorial and can be attributed to system, clinician and client factors. Nursing models of care and systems for promoting information flow between healthcare providers are important strategies in preventing adverse events and promoting **patient/client safety** and quality of care. Impaired access to accurate, reliable and valid information to inform decision-making, as well as ineffective communication among the healthcare team, have been shown to cause adverse events, such as delays in diagnosis, inappropriate treatments and adverse health outcomes.

Measuring the impact of nursing interventions on client outcomes is becoming increasingly important, as there is a growing emphasis on evidence-based practice and monitoring client outcomes (see Chapter 7). It is often difficult to separate nursing from the inputs of other professional groups and incorporate patients' perspectives. As a consequence, there is an increasing focus on nurse-sensitive patient outcome indicators and on how these factors contribute to the quality of clinical care. Measurements, assessing both process and outcome measures of nursing care, are important for developing and evaluating approaches to nursing care delivery (Burston et al 2014).

For example, in a patient suffering from an acute myocardial infarction, the process measure can be the time to a definitive revascularisation strategy, such as thrombolysis or percutaneous coronary intervention; while an outcome measure can be in-hospital mortality. The impact of nursing can be evaluated in terms of costs, length of stay and **clinical outcomes**, as well as client and carer satisfaction. For evaluation of nursing outcomes to occur, there needs to be a culture that supports evaluation, as well as adequate infrastructure and resources.

Quality improvement processes for nurses

Nurses should strive to provide care which is evidence-based, culturally appropriate, client-centred and designed to achieve optimal clinical outcomes and organisational efficiencies. The primary goal of quality-improvement programs should be the ongoing improvement of the delivery, quality, efficiency and outcome of patient care and services. This is accomplished through a systematic examination of information generated through ongoing monitoring, evaluation and quality-improvement activities. Organisations should strive to promote a culture that enables critical review of practice and a no-blame culture promoting review and development of nursing practice. All quality activities should be benchmarked in accordance with core nursing competencies, scope of practice and regulatory, ethical and legal frameworks.

BOX 8-3 Examples of goals for improvement in clinical care

- Increase the rate of smoking cessation programs to clients identified as smokers
- Improve identification of patients at risk for falls
- Reduce use of restraints
- Initiate appropriate isolation precautions upon identification of established criteria
- Decrease medication errors
- Decrease delay in transfer to the clinical area from the emergency department
- Decrease the incidence of pressure ulcers

Box 8-3 provides examples of quality-improvement initiatives. Figure 8-1 provides a conceptual model for an iterative and reflective process for engaging in processes to improve nursing care delivery.

The Australian Council on Healthcare Standards (ACHS) is an independent, not-for-profit organisation dedicated to improving the quality of health care in Australia. It is the principal independent authority for measuring and implementing quality-improvement systems in Australian health care. The ACHS Evaluation and Quality Improvement Program (EQuIP) provides healthcare organisations with a continually updated framework to deliver a person-centred service focusing on the continuum of care. In addition to organisational quality indicators, there is an increasing emphasis on the unique role that nurses play in achieving optimal health-related outcomes. The EQuIP Quality Program uses a cycle (over 3 or 4 years, depending on the program) to assist members undertake self-assessment, an organisation-wide survey and ultimately a peer-reviewed survey to ensure they are working towards quality improvement.

• CRITICAL REFLECTION POINT

John is an RN working in a community nursing centre. He notices that the referrals from the acute aged care ward are not providing sufficient information to effectively prioritise and deliver care. He finds that he is wasting time chasing up discharge summaries and is concerned that the medication lists are not always appropriate. John raises this at the team meeting, and the NUM suggests that he liaise with the acute care ward to coordinate a quality project to improve the quality of the discharge summary.

1. **How would you advise John to approach this topic?**
2. **Who should John choose to be on the project team?**
3. **Can you suggest some data items that might reflect that the quality of the discharge summaries has improved?**

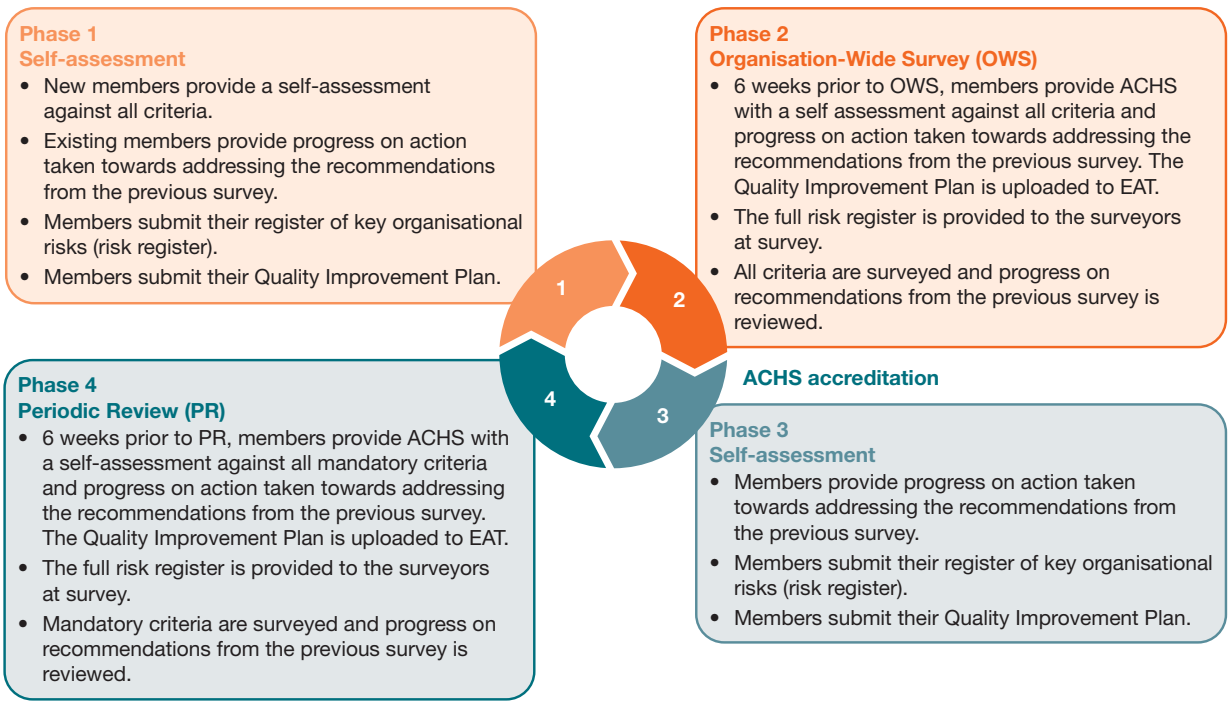

Figure 8-1 EQuIP6 quality cycle.

The Australian Council on Healthcare Standards (ACHS) 2016 The EQuIP guide, 6th edn. ACHS, Sydney.

Nursing-sensitive indicators

Increasing the emphasis on guaranteeing the quality of care, ensuring financial efficiencies and evaluating the diversity of skill-mix in the healthcare setting have led to the development of outcome indicators that are sensitive to nursing interventions and staffing levels. Nursing-sensitive outcomes are defined as changes in health status upon which nursing care has had a direct influence (Lindberg et al 2012). Variables affecting patient outcomes include diagnosis, socioeconomic factors, family support, age and gender, and the quality of care provided by other professionals and support workers.

Examples of **nursing-sensitive indicators** include:

- adverse events such as urinary tract infections, pressure ulcers, hospital-acquired pneumonia and deep vein thrombosis/pulmonary embolism
- wound infection and respiratory failure in surgical patients, and
- failure to respond to deterioration in clinical conditions such as shock, cardiac arrest and deep vein thrombosis, also known as failure to rescue.

The use of nursing-sensitive outcome indicators helps to focus attention on the safety and quality of patient care, and is important in demonstrating the critical difference that nurses make in providing safe and effective clinical care. Studies comparing staffing levels and patient outcomes show that when there is a greater proportion of RNs in the skill-mix, there are fewer adverse events, fewer complications, shorter lengths of stay, decreased mortality rates and even lower overall costs (Griffiths et al 2014). Higher levels of nursing personnel are associated with fewer adverse effects such as urinary tract infections, pneumonia and upper gastrointestinal bleeding.

Developing skills for complex and dynamic healthcare systems

The student nurse needs to develop and consolidate skills to develop, plan, implement and evaluate nursing care within complex and dynamic healthcare delivery systems. Importantly, this involves the capacity to access credible population data and evidence of effective clinical interventions. It is also important to recognise that nursing practice is undertaken in complex social, political and economic environments. For example, regulatory frameworks and policies determine the amount of resources allocated to healthcare services and also the level of nursing skill-mix (Casey et al 2015). For example, issues such as nurse prescribing are strongly linked to regulatory frameworks. As a consequence of regulatory frameworks and models of funding and reimbursement, these are critical factors in planning, managing and evaluating approaches to care. Being aware of factors external to nursing practice and developing skills for addressing these issues as a student nurse will lay a strong foundation for developing as an effective nurse clinician, administrator, educator and researcher. When planning a new nursing initiative, there are a number of factors that need to be considered. These include:

- developing a business case which includes costing factors such as staffing and equipment. A business case also involves examining the strengths, weaknesses, opportunities and threats of a planned approach to coordinating care. For example, a nurse undertaking a home visit in the community needs to be mindful of safety risks; introducing innovative strategies for pressure ulcer management may require additional expenditure for pressure-relieving devices
- demonstrating that nursing activities are conducted within professional, legal, regulatory and ethical frameworks. For example, nurses can only work within their scope of practice. When developing a model of care, nurses need to be mindful that they work within frameworks approved by regulatory and professional bodies
- considering how nursing initiatives affect other healthcare professionals. For example, an accelerated discharge plan may need the cooperation and collaboration of an interdisciplinary team of pharmacists, resident medical officers, administrative staff, general practitioners and community health teams
- undertaking coordination of care within a context of acceptable community standards and within a framework of cultural competence. For example, some cultural groups may not find it acceptable to have both men and women in the same ward or exercising together in cardiac rehabilitation settings.

Increasing burden of ageing and chronic care

Population ageing requires that healthcare services be configured to meet the needs of older persons within the acute care hospital environment. This is particularly relevant given that increased longevity is likely to increase mortality rates attributable to non-communicable diseases to 52 million by 2030 (WHO 2014). The Chronic Care Model (CCM), developed by Wagner, has been used by the World Health Organization (WHO) for the development of the Innovative Care for Chronic Conditions (ICCC)

framework (Nuño et al 2012). The WHO has promulgated the CCM as an organising conceptual framework for the development and delivery of integrated **chronic care** for community healthcare organisations and other healthcare organisations. This aims to strengthen partnerships, policy, advocacy, consistent financing, and allocation of resources across sectors (Hickman et al 2010). Through using a person-centred care approach, nurses can empower people and communities to be active in their healthcare journey, engage them in self-management strategies and promote adherence. This approach also requires nurses to be active in communicating across healthcare providers and services. Increasingly, there is a focus on the social determinants of health and how this impacts on health outcomes (Marmot et al 2005). The social determinants of health are the conditions in which people are born, grow, work, live and age. This means that economic policies and systems, development agendas, social norms, social policies and political systems can have an influence on the accessibility and type of health care. It is important to consider nursing within this context. In the United States, a striking example is the impact of the Affordable Care Act, not just on access to care but on models of nursing care (Koh et al 2010).

Positive practice environments

The environment in which nurses work is increasingly associated with favourable patient outcomes. Positive practice environments are endorsed by the International Council of Nurses (2011). Positive practice environments are characterised by supporting excellence, striving to ensure the health, safety and personal wellbeing of staff, supporting high-quality client care as well as enhancing motivation, productivity and performance of individuals (Adams et al 2006). These factors underscore the importance of policy, regulatory, legal and ethical frameworks that provide a strong foundation for healthcare delivery. They also emphasise the importance of quality improvement and reflective practice. In Australia, universal healthcare coverage is an important driver for ensuring optimal health outcomes, as it promotes models of care that are accessible and equitable. This allows the development of models of nursing care that promote continuity and coordination of care delivery.

The diversity and skill-mix of the healthcare team, including nursing roles, is rapidly changing (Davidson et al 2015). This makes it important to consider the attributes, scope of practice and key competencies of nursing roles. The work undertaken by nursing assistants is vastly different to that of the RN. Allocated responsibilities and activities are commensurate with level of education and level of responsibility for client care. Increasingly, the role of the RN is to engage in clinical decision-making, planning and coordination of care. This set of skills goes beyond advanced clinical knowledge; it includes communicating, delegating and coordinating, as well as promoting cohesion and collaboration between an increasing number of healthcare and social services. This requires that the nurse commit not only to acquiring clinical knowledge and skills, but also to engaging in personal development strategies to enable effective and active participation in the healthcare team. This entails using strategies such as appreciative inquiry, which promotes a manner of reflective review, to encourage positive relationships and build on the organisation's capacity for collaboration and change through critically evaluating activities and building upon strengths and capacities (Kavanagh et al 2010). As you move through your nursing career, it will be important to find positive practice environments and also recognise your individual contribution to making these supportive and enabling environments.

Nurses are expected to engage in client interactions in a manner that, both personally and professionally, will

BOX 8-4 Elements of positive practice environments

- Occupational health, safety and wellness policies that address workplace hazards, discrimination, physical and psychological violence and issues pertaining to personal security
- Fair and manageable workloads and job demands/stress
- Organisational climate reflective of effective management and leadership practices, good peer support, worker participation in decision-making, shared values
- Healthy work–life balance
- Equal opportunity and treatment
- Opportunities for professional development and career advancement
- Professional identity, autonomy and control over practice
- Job security
- Decent pay and benefits
- Safe staffing levels, recruitment and retention
- Support, supervision and a safe working environment
- Open communication and transparency
- Recognition programs
- Access to adequate equipment, supplies and support staff

International Council of Nurses. Online. Available: www.icn.ch/images/stories/documents/publications/fact_sheets/9d_FS-Positive_Practice_Environments.pdf; accessed 7 August 2015.

maintain public trust and confidence in the profession. Nurses have a responsibility to the individual, society and the profession to provide safe and competent nursing care. Professional behaviour is based upon principles of **accountability** (ultimate responsibility), autonomy, promoting trust among clients, monitoring of professional standards and scope of practice, observing ethical principles, taking personal responsibility for professional competence and adhering to accepted codes of practice (see Box 8-5).

The Australian Nursing and Midwifery Accreditation Council (ANMAC) is the independent accrediting authority for nursing and midwifery under the National Registration and Accreditation Scheme; it determines standards for accreditation, and accredits nursing and midwifery courses and providers. Nurses are also required to work within an ethical framework that reflects the prevailing social mores and legal context of Australian society (Chapter 9). A breach of this code may constitute professional misconduct or unprofessional conduct. It is useful to reflect upon the premises of professional practice and what distinguishes the RN's role from other providers of nursing care. Exploring the boundaries of professional practice of nursing roles will allow you to identify the skills and attributes of RNs and the factors that contribute to professional status and the associated accountabilities.

BOX 8-5 Code of professional conduct for nurses in Australia

1. Nurses practise in a safe and competent manner.
2. Nurses practise in accordance with the standards of the profession and broader health system.
3. Nurses practise and conduct themselves in accordance with laws relevant to the profession and practice of nursing.
4. Nurses respect the dignity, culture, ethnicity, values and beliefs of people receiving care and treatment, and of their colleagues.
5. Nurses treat personal information obtained in a professional capacity as private and confidential.
6. Nurses provide impartial, honest and accurate information in relation to nursing care and healthcare products.
7. Nurses support the health, wellbeing and informed decision-making of people requiring or receiving care.
8. Nurses promote and preserve the trust and privilege inherent in the relationship between nurses and people receiving care.
9. Nurses maintain and build on the community's trust and confidence in the nursing profession.
10. Nurses practise nursing effectively and ethically.

Nursing and Midwifery Board of Australia 2008 Code of professional conduct for nurses in Australia. Online. Available: www.nursingmidwiferyboard.gov.au/Codes-Guidelines-Statements/Codes-Guidelines.aspx; accessed 28 July 2015.

The role of the registered nurse

As you develop as a nursing professional, you need a clear understanding of how the role and responsibilities of the RN contribute to professional status. For example, key elements distinguishing the RN role from the enrolled nurse (EN) role are the capacity for the RN to be responsible for independent practice and the potential to plan and scope clinical care. All tiers of nursing are critical in developing clinical care; it is important that you obtain a clear understanding of the role and scope of each designation of nurse in the contemporary healthcare system.

The Nursing Council of New Zealand is the accrediting authority for New Zealand while the Nursing and Midwifery Board of Australia (NMBA) is the peak national nursing and midwifery organisation within Australia. This board sits within the Australian Health Practitioner Regulation Agency (AHPRA) (established in July 2010). In consultation with state and territory nursing and midwifery regulatory authorities, the NMBA strives to develop a national approach to nursing and midwifery professional standards. As part of this process, Registered Nurse Standards for Practice have been developed to ensure safe and effective care (NMBA 2016). RNs provide care in a wide range of settings, such as acute care, community, residential and extended-care settings, homes, educational institutions or other work settings. Care provided across these settings needs to be tailored and modified according to the practice setting and model of care delivery. Importantly, the regulatory body advocates that professional practice should be planned and evaluated within a context that considers societal and epidemiological trends in health and illness (Smith et al 2012).

The RN should:

- demonstrate competence in providing nursing care, as specified by the registering authority's licence to practise, educational preparation, relevant legislation, standards and codes and context of care
- practise independently and interdependently, assuming accountability and responsibility for their own actions
- delegate aspects of client care to ENs and health workers, considering their educational preparation and the context of care
- monitor and evaluate aspects of client care delegated to other nurses and healthcare professionals

- provide evidence-based nursing care to people of all ages and cultural groups, including individuals, families and communities
- promote and maintain health and prevention of illness for individuals with physical or mental illness, disabilities and/or rehabilitation needs
- provide effective, appropriate, ethical and acceptable palliative care at the end of life
- assess, plan, implement and evaluate nursing care in collaboration with the client and the multidisciplinary healthcare team so as to achieve goals and health outcomes
- recognise that ethnicity, culture, gender, spiritual values, sexuality, age, disability and economic and social factors affect an individual's responses and beliefs about health and illness, and plan and modify nursing care appropriately
- assume a leadership role in the coordination of nursing and health care within and across different care contexts to facilitate optimal health outcomes
- contribute to high-quality health care through promoting a culture of lifelong learning and professional commitment to nursing research, clinical supervision and development of policy and clinical practice guidelines.

• CRITICAL REFLECTION POINT

Tamara, a newly registered nurse, is working in a small regional hospital in the coronary care unit. A client she is caring for is suffering central chest pain and is diaphoretic. Tamara administers glyceryl trinitrate and performs a 12-lead electrocardiogram which shows ST-segment elevation across the anterior leads. She suspects that the client is suffering from an acute myocardial infarction and calls the medical officer on duty. After Tamara has related the information, the medical officer asks her to administer a bolus dose of thrombolytic therapy. She is certain this is beyond her scope of practice and tells the medical officer so. He becomes irate and argumentative.

1. **What would you do in Tamara's case?**
2. **Who would you contact to seek support and clarification?**
3. **How would you communicate with the medical officer in a collegial and professional manner?**

Box 8-6 lists the Australian Registered Nurse Standards for Practice (see Chapter 10 for further details of these (NMBA 2016) and Chapter 11 for details of New Zealand Competencies for Registered Nurses (NCNZ 2007b)).

You need to familiarise yourself with the standards and competencies relevant to the country in which you are studying/practising. As a student nurse, these standards and competencies will shape your professional goals and crystallise what the expectations will be of you when you enter the workplace. Although the list may be daunting, remember that nursing is a collegial profession where there is a strong emphasis on an integrated and collaborative approach to delivering nursing services. As a consequence, there are many people to help you in your professional journey, including clinical nurse educators, clinical nurse consultants, nursing practitioners and medical and allied health colleagues.

In New Zealand, the Nursing Council of New Zealand is the statutory body governing the practice of nurses that also monitors the standards of practice (NCNZ 2007a). As the heterogeneity of the healthcare workforce increases, along with acknowledgement of the importance of interdisciplinary care, teamwork is increasingly important (Davidson et al 2010, 2015, Riegel et al 2009).

BOX 8-6 Standards and competencies for registered nurses

a. Australian Registered Nurse Standards for Practice

Standard 1: Thinks critically and analyses nursing practice

Standard 2: Engages in therapeutic and professional relationships

Standard 3: Maintains capacity for practice

Standard 4: Comprehensively conducts assessments

Standard 5: Develops a plan for nursing practice

Standard 6: Provides safe, appropriate and responsive quality nursing practice

Standard 7: Evaluates outcomes to inform nursing practice

b. New Zealand Competencies for Registered Nurses

Domain 1: Professional responsibility

Domain 2: Management of nursing care

Domain 3: Interpersonal relationships

Domain 4: Interprofessional health care & quality improvement

Nursing and Midwifery Board of Australia (NMBA) 2016 Registered Nurse Standards For Practice. Online. Available: www.nursingmidwiferyboard.gov.au/Codes-Guidelines-Statements/Professional-standards.aspx; accessed 14 June 2016. Nursing Council of New Zealand (NCNZ) 2007 Competencies for Registered Nurses. Online. Available: www.nursingcouncil.org.nz/Nurses/Scopes-of-practice/Registered-nurse; accessed 2 Feb 2016.

Skill-mix for the student nurse

The student nurse is defined as an undergraduate or graduate (pre-registration) student undertaking an approved program

of study to obtain a bachelor of nursing degree, whose clinical practice is under direct supervision by university faculty and facility-based clinical educators. Often during the undergraduate course there is a preoccupation with gaining competencies in technical skills, such as blood pressure assessment and inserting a nasogastric tube. However, it is just as important to develop a suite of skills that will prepare nurses to be effective and efficient members of the healthcare team and lifelong learners. Key skills that you need to develop are your capacity for effective communication (written, oral and non-verbal), for critical, reflective practice and for consciously engaging colleagues and mentors to stimulate and monitor your professional development.

BOX 8-7 Time management considerations in managing care

The more organised and focused your activities are, the more efficient you will be – this means taking time to plan, evaluate, reflect and seek advice.

Goal-setting

Review the goals of care for the day for your allocated clients and accommodate the processes required, for example, communication goals with different team members, internal and external, to enhance patient safety, providing handover and writing reports.

Time allocation

Anticipate how long it will take you to attend to planned activities, such as administration of medications, and contacting and communicating with team members.

Setting priorities

Using the process of prioritising the acuity of client needs, plan the activities for the day; for example, it is important to assess intravenous therapy and invasive treatments such as chest tubes at the beginning of your shift. A to-do list can be useful.

Allow for interruptions

Anticipate interruptions; these will occur. Try not to become annoyed or frustrated when they do occur. Also take the time for your meal breaks and attending to your professional development, such as attending in-service education; this will assist in improving your efficiency.

Evaluation

At the end of each day, take time to think about how effectively time was used. If you are having difficulties in managing your time, ask for help sooner rather than later. Also remember that handing over care to your nurse colleagues and different team members is an expected part of care delivery. Do not feel inadequate; develop skills for participating in a care delivery team and accept tasks graciously when they are given to you. Using an activity log can be a useful reflective practice strategy.

Managing your workload and time management can be challenging, particularly in the early period following registration. Being able to determine priorities based upon clinical assessment is an important skill to develop. Often you will need to be adaptive and flexible. It is important to determine the priorities at the beginning of each shift, to provide a baseline of the patients' clinical progress. Taking time to plan for your shift and seeking advice from other clinicians can increase your efficiency. Develop your own system to prioritise your work plan, such as a notebook with a checklist. As discussed in the section above, to be an effective practitioner it is imperative that you spend some time identifying and evaluating your work style. Box 8-7 will provide you with some additional strategies in planning care delivery.

Many new graduates take on existing practices in clinical areas because of power relationships and socialisation. It is important to evaluate all practices critically and strive to ensure that your nursing care is optimal in meeting the needs of clients, rather than a prevailing culture based upon historical care models.

It is also important to take care of your own physical and mental health to sustain your stamina in demanding clinical settings. Taking time to exercise and engage in stress management are important strategies in promoting your own health and being an effective role model to other staff members and clients.

Also take the time in your early career to critically evaluate the management and clinical styles of your peers. It is often through this reflective process that we develop and cultivate our own working style. Look for favourable role models and adopt their practices. If possible, it is also optimal to identify a mentor, an individual who can assist and support you in your career development.

Key concepts

- A positive practice environment is required to develop and sustain an effective and efficient nursing workforce.
- Evidence-based practice should be the platform for effective nursing care.
- Nurses work in a range of settings in independent, dependent and collaborative nursing roles.
- Acknowledging key competencies is an important step in becoming an RN.
- The nursing unit manager plays an important role in establishing a philosophy of nursing practice and monitoring nursing standards.
- Key competencies for the RN relate to professional practice, recognising their professional, legal, regulatory and ethical responsibilities.
- Coordination, organisation and provision of nursing care include the assessment of individuals/groups, planning, implementation and evaluation of care.

- Nurses make an important contribution to the interdisciplinary healthcare team to improve client outcomes.
- Nurses are required to develop and consolidate professional relationships with individuals and groups to optimise clinical care.
- Models of nursing care should be tailored to the needs of individuals and their families.
- Approaches to nursing care should be developed and evaluated within the context of the clinical setting, client needs, available nursing skill-mix and considering the strengths and weaknesses to approaching care delivery.
- Nursing management models are dependent on the organisational structure and vision, although key concepts relating to vision, leadership, reflective practice, commitment to evidence-based practice and supporting lifelong learning should be integral to all management models.
- Effective communication is critical in ensuring optimal patient care.
- Integrated quality-improvement initiatives are important in driving improvements in clinical care.

CHAPTER

9

Examining the ethical practice of nursing

Megan-Jane Johnstone

KEY TERMS

Bioethics, p. 141
Codes of ethics, p. 150
Cross-cultural ethics, p. 149
Deontological ethics, p. 146
Ethical issues, p. 152
Ethical principles/ principlism, p. 147
Ethics, p. 140
Moral accountability, p. 145
Moral conduct, p. 144
Moral decision-making, p. 146
Moral duty, p. 142
Moral principles, p. 142
Moral problem, p. 143
Moral rules, p. 150
Moral theories, p. 146
Morality, p. 140
Nursing ethics, p. 141
Responsibility, p. 145
Rights, p. 142
Sound (moral) justifications, p. 146
Teleological theory of ethics, p. 147
Utilitarianism, p. 147
Virtue ethics, p. 149

Learning outcomes

Mastery of content will enable you to:

- discuss the key terms listed and their relevance to guiding ethical professional conduct in nursing domains
- discuss the importance of ethics to, and in, the profession and practice of nursing
- examine critically what constitutes ethical professional practice
- discuss the notions of moral accountability and responsibility
- identify moral theories, which may be used to guide professional practice
- examine the nature and authority of nursing codes of ethics
- outline 10 moral problems that may arise in nursing and healthcare contexts
- discuss how moral problems can be distinguished from non-moral problems
- discuss five steps that may be taken to identify and deal with moral problems using processes of ethical reasoning
- apply one systematic model of moral decision-making to a clinical situation
- discuss critically at least six ethical issues of importance to the nursing profession.

When people enter the nursing profession they are required to make a commitment to upholding exemplary standards of ethical conduct – that is, standards that are above what would normally be expected of the 'ordinary person in the street'. The ethical standards that nurses are expected to uphold are prescribed in various codes of ethics, codes of conduct, standards for practice, and position statements which have been developed and published by recognised professional nursing organisations. Some examples can be found in the codes of ethics and codes of conduct published respectively by the International Council of Nurses (ICN 2012), the Nursing and Midwifery Board of Australia (NMBA) (NMBA 2008a, 2008b), the New Zealand Nurses Organisation (NZNO 2010), the Nursing Council of New Zealand (NCNZ 2012a) and other similar bodies (Box 9-1). A search of the home pages of the peak nursing organisations, which have developed and ratified these codes, reveals a range of associated guidance documents and position statements on issues with which nurses and student nurses ought to be familiar. Some examples include, but are not limited to, position statements on such issues as: the responsible use of social media in both personal and professional contexts, maintaining professional boundaries when entering into therapeutic relationships with patients, workplace bullying, professional and legal requirements for making voluntary and mandatory notifications of nurses whose conduct or practice places the safety of the public at risk, conscientious objection, and advertising regulated health services (including giving false or misleading information, testimonials, gifts, and encouraging indiscriminate or unnecessary use of services).

In addition to being expected to uphold exemplary standards of ethical professional conduct, nurses are required to also be able to identify and respond effectively to a wide range of ethical issues that may, and do, arise in nursing care and related healthcare contexts. How well nurses are able to respond to these requirements, however, will depend on their knowledge and understanding of what ethics is and how it can best be practised in a culturally, socially and geographically diverse world. Consider the case scenario in the *Clinical example* below.

Both the *Code of ethics for nurses in Australia* (NMBA 2008a) and the NZNO (2010) *Code of ethics* explicitly require nurses to respect the needs, values, culture and vulnerability of people in the provision of nursing care and to ensure that the care provided to patients is culturally informed, safe and appropriate. However, the Codes also require nurses to 'accept the rights of individuals to make

NZNO (2010) Code of ethics

CLINICAL EXAMPLE

The case of 'Mr G'

'Mr G', a 69-year-old Greek-born man who had migrated to Australia from rural Greece and who spoke little English, was admitted to a major metropolitan hospital for follow-up assessment and treatment of a cancer-related illness. Unfortunately, test results revealed that his condition had unexpectedly worsened, that his prognosis was poor and that palliative care was his best option. Upon learning of this bad news, Mr G's family pleaded with the attending doctor not to tell their father that his medical condition had worsened and that his prognosis was poor. Mr G's eldest daughter explained to the doctor that were he to tell Mr G that his cancer had spread, 'this would destroy his hope and affect his quality of life'. She further explained that, in their Greek culture, 'it was wrong to tell someone they had terminal cancer'. The doctor objected to the daughter's request, however, arguing that the matter was 'not about culture, but about ethics' and that her father 'had a right to know' (Johnstone 2012, 2016).

Johnstone M 2016 Bioethics: a nursing perspective, 6th edn. Churchill Livingstone, Sydney; Johnstone M 2012 Bioethics, cultural differences and the problem of moral disagreements in end-of-life care: a terror management theory. Journal of Medicine and Philosophy 37(4):181–200.

informed choices in relation to their care'. In the *Clinical example* on the previous page, relating to Mr G's case, it seems that these two requirements clash, raising the important question of the right thing to do in this and similar scenarios (see also Johnstone 2012). When, if ever, should a family's pleas be taken into consideration in determining when (if at all), where, how and by whom a cancer diagnosis and poor prognosis should be disclosed to a patient? How are nurses and other members of the healthcare team to decide these things? Moreover, do they have the cultural competence necessary to enable them to engage in moral decision-making processes in a culturally meaningful, appropriate and morally safe way? In the case of the NZNO *Code of ethics*, another ethical dimension is added, since this Code also prescribes that nurses must recognise that many sociocultural groups 'place the importance of the collective on a par with the needs and rights of the individual' and that the rights of 'both the individual and the collective must be respected' (NZNO 2010:12).

Being able to respond to this and other kinds of case scenarios in a morally just, responsible and competent way requires nurses to have at least a working knowledge and understanding of:

- key terms and concepts commonly used in discussions on ethical issues in nursing practice
- the importance of ethics to the profession and practice of nursing
- what constitutes ethical professional practice
- notions of moral accountability and responsibility
- reliable guides to ethical professional conduct
- key moral theories that are commonly used to guide ethical decision-making and practice in nursing (including cross-cultural ethics)
- the nature and authority of nursing codes of ethics
- the kinds of moral problems that can and do arise in nursing and healthcare domains
- how moral problems can be distinguished from other kinds of problems (e.g. legal problems)
- processes for identifying and dealing with moral problems arising in practice contexts
- moral decision-making in practice contexts
- bioethical issues of importance to the nursing profession.

Without the requisite knowledge and understanding of these things, it would be very easy for nurses to 'rush to judgement' when engaged in moral decision-making and, as a consequence, make moral mistakes (i.e. do the wrong thing). If moral mistakes are made, this can result in morally significant harm to patients, their loved ones and also to healthcare providers. It is for this reason that nurses must make every effort, individually and collectively, to ensure that they are well informed about and adequately prepared to deal with the moral complexities and quandaries that are likely to arise in their practice and places of work.

Terms and concepts

To be able to discuss ethical issues in nursing in a meaningful way, it is important to have an understanding of such key terms and concepts as ethics, morality, bioethics, nursing ethics, moral principles, moral rules, moral rights and moral duties.

Ethics and morality

Ethics (which may be used interchangeably with the term 'moral') is a general term used for referring to various ways of understanding and examining the 'moral life' (Beauchamp & Childress 2013). More specifically, ethics involves thinking critically about and engaging in a systematic examination of what constitutes right and wrong/good and bad behaviour, and the bases upon which we might justify our judgements that an action or decision is 'morally right or wrong', all things considered. For example, a nurse may make the moral judgement that abortion is wrong and conscientiously object to assisting with an abortion procedure. Whether conscientious objection ought to be permitted, however, requires a critical examination of the bases on which the nurse has made that judgement, and the provision of sound (moral) justifications (reasons) for the action taken. Ethics, then, is concerned not just with giving values to certain things (e.g. abortion is right/wrong, good/bad), but also with *justifying* the bases on which judgements about these things might be made (Johnstone 2016, Kerridge et al 2013, LaFollette 2014).

It is important to clarify the use of the term '**morality**' in discussions on ethics. In some nursing texts, the terms 'ethics' and 'morality' are treated as though they refer to different things. This use, however, is incorrect and misleading. There is, in fact, no philosophically significant difference between the terms 'ethics' and 'morality', and hence they may be used interchangeably. The only distinction that may be drawn with validity between these two terms is that the word 'ethics' comes from the Greek *ethikos* (originally meaning custom or habit), and 'morality' from the Latin *moralitas* (also originally meaning custom or habit) (Johnstone 2016). Of course, today these terms refer to something much more sophisticated than merely custom or habit, as this chapter will show.

Bioethics

The term **bioethics** (from the Greek *bios* meaning life, and *ethikos*, *ithiki* meaning ethics) – literally, ethics in the realm of life – is a relatively new term that first found its way into public use in the early 1970s in the United States (Reich 1994). Although the term was originally defined to include environmental concerns, as it is used today its main focus is on (Reich 1995):

- the rights and duties of patients and healthcare professionals
- the rights and duties of research participants and researchers
- the formulation of public policy guidelines for clinical care and biomedical research.

Although originating in the United States, bioethics has developed and been institutionalised as a discipline in its own right in countries around the world (Düwell 2013); it has also developed as a major international movement of popular interest to professionals and laypersons alike. Today, issues most commonly the subject of bioethics debate in professional journals, as well as in the mass circulation media, include:

- abortion
- euthanasia and medically assisted suicide
- organ transplantation
- reproductive technology (including genetic engineering, surrogacy, ectogenesis, and embryonic and stem cell research)
- patients' rights to privacy and confidentiality
- informed consent
- the economic rationalisation of health care
- research ethics.

Nursing ethics

Contemporary nursing ethics has been profoundly influenced by the modern bioethics movement to the extent that some regard nursing ethics as being merely a subcategory of bioethics; that is, nursing bioethics. Despite the influence of bioethics on nursing ethics, it is important to acknowledge that the nursing profession has its own rich and distinctive history of identifying and responding effectively to ethical issues in nursing and health care. In addition to having its own distinctive history of professional ethics, nursing can be said to have developed its own distinctive (nursing) ethics as a discipline and field of inquiry (see Johnstone 2015a, 2015b, 2015c). Not only has this development been necessary, it was also inevitable. It has been necessary because 'a profession without its own distinctive moral convictions has nothing to profess' and will be left vulnerable to the corrupting influences of whatever forces are more powerful (be they social, political, legal or other in nature) (Churchill 1989). Furthermore, as Churchill (1989) has asserted in his classic article on the subject, 'Professionals without an ethic are merely technicians who know how to perform work, but who have no capacity to say why their work has any larger meaning.' Without meaning, there is little or no motivation to perform well.

What, then, is nursing ethics? **Nursing ethics** can be broadly defined as the examination of all kinds of ethical and bioethical issues from the perspective of nursing theory and practice, which in turn rest on the agreed core concepts of nursing, namely person, culture, care, health, healing, environment and nursing itself (or, more to the point, its end good), all of which have been comprehensively articulated in the nursing literature. In this regard, then, nursing ethics is not synonymous with, and indeed is greater than, an ethic of care, although an ethic of care has an important place in the general scheme of things, encompassing nursing and nursing ethics (Johnstone 2016).

Unlike other approaches to professional and healthcare ethics, nursing ethics recognises the 'distinctive voices' of nurses, and emphasises the importance of collecting and recording nursing 'stories from the field'. Like other approaches to ethics, however, nursing ethics also recognises the importance of providing practical guidance on how to decide and act morally. Drawing on a variety of ethical traditions, nursing ethics, at its most basic, could thus also be described as a nursing practice discipline that aims to provide guidance to nurses on how to decide and act morally in the contexts within which they work.

Moral principles

General standards of conduct that make up an ethical system are known as moral principles. To say that a principle is moral is merely to assert that it is a behaviour guide that entails particular imperatives or obligations; that is, to do or to refrain from something that may have a morally significant outcome. It is generally accepted that moral principles function by specifying that some type of action or conduct is prohibited, required or permitted in certain circumstances (Beauchamp & Childress 2013, Johnstone 2016). By this view, an action or behaviour is generally considered morally right or good if it accords with a given moral principle, and morally bad or wrong when it does not.

Moral principles commonly referred to in healthcare ethics include those of autonomy, non-maleficence, beneficence and justice (see Moral theories on p. 146).

To illustrate how moral principles work, consider the principle of autonomy. The principle of autonomy demands respect for individuals as self-determining choosers and is widely accepted as a general standard of moral conduct. Given this principle, conduct that respects an individual's self-determining choices (e.g. a patient's competent decision not to accept a recommended medical treatment) could be appraised as having accorded with the principle of autonomy and therefore as being morally 'right' and justified. Conversely, conduct that is disrespectful of an individual's choices (e.g. a competent patient's decision to refuse medical treatment is rejected and overridden by a professional caregiver) could be appraised as having violated the principle of autonomy and therefore as being morally 'wrong'. **Moral principles** thus not only guide conduct, they can also be appealed to for justifying the conduct in question.

Moral rules

Like moral principles, moral rules also have a place in making up a system or scheme for guiding moral action. And like moral principles, moral rules also function by specifying that some type of conduct is prohibited, required or permitted (Beauchamp & Childress 2013, Johnstone 2016). What distinguishes a moral rule from a moral principle, however, is its nature and force. Moral principles, for example, tend to be general in nature (e.g. do no harm; promote good). Moral rules, in contrast, are both derivative of, and justified by, parent principles and are very specific in their focus (e.g. do not kill others; do not tell a lie). It can be seen, then, that moral rules have a different force, sanctioning power, condition of existence, scope of application and level of concreteness from moral principles. In application, they are generally regarded as having less force than principles.

Rights

Common to discussions on nursing ethics is the notion of **rights** – including moral rights, human rights and patient or health consumer rights. An understanding of these key terms is, therefore, warranted.

Moral rights

These are to be distinguished here from other kinds of rights, such as civil rights, legal rights, institutional rights and the like. Moral rights generally entail a claim about some special entitlement or interest which ought, for moral reasons, to be protected. For example, people commonly claim rights to such special interests as life, freedom, fair treatment, bodily integrity, health and so on. The language used in asserting rights typically involves expressions like 'I have a right to …', 'You have a right to …', 'They have a right to …', and 'We have a right to …'.

Human rights

In contrast, human rights refer to a set of special interests that human beings (as opposed to non-human beings, such as animals) are entitled to claim by virtue of being human. Human rights can include moral rights, legal rights, civil rights and so on. A good example of human rights statements can be found in the United Nations (1948) Declaration of Human Rights. This declaration has influenced the development of nursing codes of ethics, not least the ICN's (2012) revised *Code of ethics for nurses*, the NMBA's *Code of ethics for nurses in Australia* (Nursing and Midwifery Board of Australia 2008a) and, to some extent, the NZNO's (2010) *Code of ethics*, which although not overtly informed by a human rights framework, nonetheless contain statements that prescribe the protection of rights (see Box 9-1).

Patient rights

Patient rights can be described as a subcategory of human rights, the global movement for which dates back to the late 1960s and early 1970s in the United States (d'Oronzio 2001). Statements of patient rights tend to entail statements about particular moral interests that a person might have in healthcare contexts and that require special protection when that person assumes the role of a patient. Patient rights that might be commonly claimed include the right to health care, the right to make informed decisions, the right to privacy and confidentiality, the right to dignity and the right to be treated with respect.

Moral duties

A **moral duty** (as distinguished from a legal duty, a civic duty and so on) is an action which a person is bound, for moral reasons, to perform. Language used in identifying duties typically involves expressions such as 'I have a duty …', 'You have a duty …', 'They have a duty …' and 'We have a duty …'. In a rights view of ethics, someone claiming a valid right supplies a moral reason for why another must act morally towards them. Because of this, moral duties are sometimes described as being correlative; that is, in relation to another's rights claims. To put this another way, if one person claims a right this may entail another having a correlative duty to respect and respond to that right. For example, if a patient claims the right to make an informed decision regarding nursing care, then an attending nurse could be said to have a correlative duty to respect and uphold that right. Moral reasons can also be supplied by an appeal to ethical principles. For example,

adoption of the principle of autonomy would impose on decision-makers a duty to uphold its prescriptions; namely, to respect people as self-determining choosers.

A critical task for decision-makers is deciding just what their duties are in given situations. Making the correct decision depends on determining what counts as an overriding moral reason for doing something (bearing in mind that moral reasons are generally regarded as being stronger or more pressing than other kinds of reasons, such as personal preferences, civic duty and group membership). For example, in the case of a rights claim being made, whether or not another has a corresponding duty will depend on whether the right being claimed is genuine, whether the entity has moral rights at all and whether an agent does in fact have a duty correlative to the rights claim being made.

Sometimes people confuse rights with duties, and vice versa. A useful way to guide an understanding of the distinction between rights and duties is to consider that when people claim a right they are making a claim with respect to their own interests; in contrast, when people claim a duty they are making a claim with respect to the interests of another or others.

The importance of ethics

Nursing has a profound ethical dimension. Its practice never occurs in a moral vacuum and is never free of moral risk (Johnstone 2016). Even the smallest of nursing actions (e.g. giving an aspirin tablet) could, potentially, result in significant moral consequences – bad as well as good. Moreover, as long as nurses work with and care for other people, they will never be able to avoid the moral problems and issues that will invariably arise during the course of their practice.

During their everyday practice, nurses will often be confronted by such questions as: 'What should I do in this situation?', 'How do I know I'm doing the right thing?', 'What are my moral obligations in this case?' The case of 'Ms Winnow', a competent patient with a health history of diabetes, obesity and large areas of skin breakdown who refused nursing care, helps to illustrate this point (Dudzinski & Shannon 2006). The care which Ms Winnow initially refused included being turned, having wound care for her decubitus ulcers and undergoing incontinence management. Ms Winnow's refusals left attending nurses confronted with the dilemma of, on the one hand, wanting to respect her wishes and yet, on the other, knowing that respecting her wishes would place her at further risk of harm and suffering – including further breakdown of her ulcerated skin. In this case, provocative questions arise: What should her attending nurses do? What are their moral obligations to Ms Winnow? And how are they to know that, whatever they decide to do, they have done the right thing, all things considered?

When encountering an ethical problem in the workplace, nurses often worry about whether the moral decisions they make are 'correct'; nurses are also known to experience feeling perplexed, stressed and even distressed when – for various reasons – they did not 'get it right' or were unable to carry out what they had carefully and conscientiously thought was the right thing to do. It is for these kinds of reasons that ethics has assumed paramount importance in nursing.

Moral conduct in nursing

Nurses face many complex and varied **moral problems** during the course of their practice, which cannot be ignored. Accordingly, there are stated expectations in nursing standards of conduct that nurses must be able to identify and respond appropriately to a range of ethical problems and issues in nursing and healthcare contexts. There is the additional expectation that nurses also must be able to demonstrate moral competence and capabilities in regard to these things.

'Competence' in nursing is generally taken as referring to a combination of essential skills, knowledge, attitudes and values expected of registered nurses. In the case of moral/ethical competence, nurses need to be able to demonstrate that they: have knowledge and understanding of the different ethical concepts and theories that are pertinent to ethical decision-making and conduct in nursing and healthcare contexts; have the capacity to engage in sound moral reasoning and decision-making; are well informed about common ethical issues arising in and affecting nursing and healthcare practice; have a working knowledge of codes of ethics, guidelines and standards of practice relevant to the profession and practice of nursing; and have a sound knowledge and understanding of the power dynamics of the social, cultural, political, legal and institutional environment in which ethical issues arise in nursing and their possible influence on the way in which ethical issues are perceived and addressed (Johnstone 2015d). Nurses need also to develop a set of moral skills, including assessment skills (e.g. being able to identify moral problems, correctly 'diagnose' the nature of the moral problems at hand, and access relevant resources to assist in addressing the problems identified); implementation skills (e.g. be able to apply their moral knowledge effectively to address the problems at hand and evaluate the success or otherwise of the outcomes of their interventions); and interpersonal skills (e.g. 'good' communication skills, ability to listen to

others, and the capacity to guide effective problem-solving with patients and other members of the healthcare team) (Johnstone 2015d).

In Australia, the specific standards pertaining to **moral conduct** expected of registered nurses are outlined in the NMBA's *Registered nurse standards for practice* (NMBA 2016). It is intended that these standards are read, interpreted and applied in conjunction with the NMBA's companion documents, including the *Code of ethics for nurses in Australia* (2008a) and the *Code of professional conduct for nurses in Australia* (NMBA 2008b). Taken together, the NMBA *Standards* and companion documents make it clear that registered nurses in all areas and levels of practice 'are accountable for their decisions, actions, behaviours and the responsibilities that are inherent in their nursing roles', and that, in fulfilling their roles, nurses must use ethical frameworks when making decisions. While all of the stated registered nurse standards have an ethical dimension, the particular standards that encompass the requirement for nurses to conduct themselves ethically are listed in Box 9.2.

In New Zealand, the specific moral competencies expected of registered nurses are outlined in the NCNZ's (2012b) *Competencies for registered nurses*. These standards require registered nurses to be able to demonstrate knowledge and judgement and be 'accountable for own actions and decisions, while promoting an environment that maximises patient safety, independence, quality of life and health'. The particular moral competencies (and related indicators) expected of a registered nurse are variously listed under *Domain 1: Professional responsibility* and *Domain 2: Management of nursing care*, and include the following:

- Accepts responsibility for ensuring that his/her nursing practice and conduct meet the standards of the professional, ethical and relevant legislated requirements.
- Maintains clear, concise, timely, accurate and current health consumer records within a legal and ethical framework.
- Discusses ethical issues related to healthcare/nursing practice (for example, informed consent, privacy, refusal of treatment and rights of formal and informal health consumers).
- Promotes a quality practice environment that supports nurses' abilities to provide safe, effective and ethical nursing practice.

BOX 9-2 Registered nurse standards for practice pertaining to ethical conduct

Standard 1: Thinks critically and analyses nursing practice

1.5 uses ethical frameworks when making decisions

Standard 2: Engages in therapeutic and professional relationships

2.1 communicates effectively, and is respectful of a person's dignity, culture, values, beliefs and rights

2.2 advocates on behalf of people in a manner that respects the person's autonomy and legal capacity

Standard 3: Maintains the capability for practice

3.4 accepts accountability for decisions, actions, behaviours and responsibilities inherent in their role, and for the actions of others to whom they have delegated responsibilities

Standard 6: Provides safe, appropriate and responsive quality nursing practice

6.1 practises in accordance with relevant policies, guidelines, standards, regulations and legislation.

Nursing and Midwifery Board of Australia (NMBA) 2016 Registered nurse standards for practice. Online. Available: www.nursingmidwiferyboard.gov.au/Codes-Guidelines-Statements/Professional-standards.aspx; accessed 8 April 2016.

• CRITICAL REFLECTION POINT

Even when well informed about the ethical dimensions of nursing practice standards, nurses may still appeal more to their own values, beliefs and convictions rather than to a systematic application of ethics (concepts and theories) when making moral decisions. Take the time to think carefully about what the implications of this might be for patients and families who do not share the values, beliefs and convictions that attending nurses might be appealing to when making moral decisions about the patient's care and treatment.

Moral accountability and responsibility

In identifying and responding effectively to moral problems in the workplace and, indeed, when practising in a professional capacity generally, nurses are morally accountable and responsible for their actions (Johnstone 2016). Thus, when a nurse breaches the agreed ethical standards of the nursing profession, there is an expectation that they will be made to account for and, ultimately, be held responsible for their conduct. Moral accountability and responsibility, however, do not reside only in individual nurses. The nursing profession as a whole, and those charged with the responsibility of regulating it, are also morally accountable and responsible for their actions. This is an important point, since it has a significant bearing on the kinds of strategies that might otherwise be used to respond effectively to situations in which the agreed

RESEARCH HIGHLIGHT

Research focus

This systematic review of the literature synthesises the evidence obtained by empirical studies investigating how nurses' ethical competence and their capacity to fulfil their moral responsibilities as nurses are supported in practice contexts.

Research abstract

A key finding of the review was that, although ethical competence is an essential element of nursing practice, there is little evidence of support being provided to nurses enabling them to gain and develop this element of practice and to fulfil their moral responsibilities as nurses. Although nurses' ethical competence in terms of ethical decision-making, ethical sensitivity, ethical knowledge and engagement in ethical reflection have been studied, how to support these things has been the subject of recommendations only. Recommendations have typically included: ethics education, ethics rounds, ethics committees and ethics consultations.

Implications for ethics-based practice

- Processes for enabling nurses to develop their ethical competence and fulfil their moral responsibilities as nurses are under-investigated.
- To enable meaningful comparative research to be conducted, the conceptual, theoretical and practical perspectives of ethical competence require further scholarly inquiry.
- Further research is also required on the kinds of support that nurses need in order to maintain their ethical competence and fulfil their moral responsibilities in difficult work environments.

ethical standards of the profession are at risk of being or have already been breached.

Understanding the nature and moral implications of professional accountability and responsibility in nursing requires a commensurate understanding of moral theories of accountability and responsibility. For example, in the philosophical literature, accountability has classically been taken to mean:

> **[being] obliged to give satisfactory reasons for one's actions, to be capable of giving an explanation for one's actions, to be responsible for one's conduct, to be made to pay for one's conduct, or to reckon with the consequences of one's actions (Fry-Revere 1992).**

In turn, the notion of **responsibility** (of which accountability is a form) has been taken broadly to include not only one's 'intentional conduct' (i.e. a person's deliberate acts and omissions), but also:

> **anything with which one is seen to have a causal relationship (whether this perception is justified or not), including moral character, physical and psychological characteristics, salvation, and even unintentional effects on one's own life or the lives of others (Fry-Revere 1992).**

Drawing on both of the above accounts, moral theories of accountability hold that:

> **a person X, is accountable for his or her actions if X acted freely or intentionally and X's action or inaction is causally related to the outcome for which X is being held accountable (Fry-Revere 1992).**

Theories of **moral accountability** tend to emphasise accountability to oneself or to a superior entity. Either way, claims of moral accountability tend to assume that:

> **Human beings are free to act and cause events for which they are directly responsible and that some form of internal mechanism of accountability, whether based on conscience or belief, is essential to human interaction (Fry-Revere 1992).**

It can be seen, then, that the issues of moral accountability and responsibility have important implications for nurses. For example, an ongoing problem facing the nursing profession is that although nurses have enormous responsibilities as healthcare providers, they often lack the lawful authority they need in order to be able to fulfil these responsibilities in a safe and effective way (Johnstone 1994, 2016).

Guides to ethical professional conduct

As has previously been considered, when making moral judgements and decisions in nursing care domains, nurses are often faced with such perplexing questions as 'What should I do and what is the right thing to do in such-and-such situation?', 'Are my judgements and decisions morally correct, all things considered?', 'How should I decide?' and 'Have I done (am I doing) the right thing?'. These and similar questions become even more pressing when considered against the backdrop of stringent moral accountabilities and responsibilities otherwise expected of registered nurses.

Possible answers to these and related questions can be sought by appealing to moral theories and/or nursing codes of conduct, noting, however, that neither of these

is without some difficulties with respect to their moral authority and capacity to guide and justify particular actions in specific contexts. One of the ongoing challenges facing nurses and others is that even if a general ethical theory or 'perfect' code of conduct were available, it may still not be possible to find satisfactory answers to the questions and quandaries encountered during the course of one's everyday practice (Beauchamp & Childress 2013, Düwell 2013).

Moral theories

It is generally accepted that moral theory is crucial, not just for the purposes of guiding moral decision-makers in their thoughts and actions, but also for providing **sound justifications** for the decisions made and actions taken.

Moral problems frequently arise in healthcare contexts. This is not surprising given the culturally diverse range and complexity of the moral values that are operating and expressed in healthcare domains. Indeed, healthcare practice is profoundly value-laden in a morally significant sense, and hence it is inevitable that moral conflicts and disagreements will arise. Further, given the complexity of the values that operate in healthcare domains, it is inevitable that sometimes the choices made (by nurses as well as others) will be problematic, insofar as they may express moral values, beliefs and evaluations that are not shared by others or with which others do not agree.

When experiencing situations involving moral problems and disagreement, it is tempting for decision-makers to rely on their own ways of thinking and personal preferences to sustain the points of view they are advocating. Sometimes, however, a person's ways of thinking and personal preferences may not be reliable or worthy action guides because these can result from prejudice, self-interest or ignorance. Thus, decision-makers need to look elsewhere to justify their moral choices and actions. Ethical/moral theory is commonly regarded as a reliable source from which such justifications can be sought.

There are a number of different **moral theories** that can be appealed to for guiding and justifying **moral decision-making** and conduct, all of which, to varying degrees, have both formed the basis of and influenced the development and practice of nursing ethics. Notable among these are deontological ethics, teleological or consequentialist ethics, ethical principlism, moral rights theory, virtue ethics and cross-cultural ethics. A brief summary of each of these theories is outlined below.

Deontological ethics

According to **deontological ethics**, duty is the basis of all moral action. Taken at its most basic, deontology asserts that some acts are obligatory (duty-bound) regardless of their consequences. For example, a deontologist might assert that one has a duty to always tell the truth. By this view, the deontologist is duty-bound to always tell the truth, even when doing so might have horrible consequences. An important question to ask here is: How do we know what our duty is?

One possible answer to this question can be found in classical deontological theory that derives from religious ethics and is otherwise known as 'divine command theory'. According to this view, it is God's command that determines our moral duties. If, for example, God commands 'Thou shalt not kill', 'Thou shalt not steal' and the like, then conduct that accords with (obeys) these commands is morally praiseworthy (right and justified). Conduct that contradicts God's commands, in contrast, warrants condemnation (as wrong and unjustified). This is because and only because it is God's command (Morriston 2009, Wainwright 2005).

There are many examples of deontological ethics influencing decision-making in healthcare domains. For example, Jehovah's Witnesses refuse life-saving blood transfusions on the grounds that to accept such treatment would be tantamount to violating God's command that prohibits taking blood. Another example can be found in a deontological adherence by some doctors and surgeons to the preservation of 'medically hopeless' human life whatever the costs (read 'consequences'), resulting in the administration of 'futile' medical treatment to patients, sometimes even against their will (Schneiderman & Jecker 2011).

Another answer can be found in what is otherwise known as ethical rationalism. This view dates back to the work of the 18th-century German philosopher Immanuel Kant, who held that the supreme principle of morality was reason, the ultimate end of which is goodwill. According to a 1972 translation, Kant stated that reason is free (autonomous) to formulate moral law and to determine just what is to count as being an overriding moral duty. Kant held duty to be that which is done for its own sake, and 'not for the results it attains or seeks to attain' (Kant 1972). Kant further believed that moral considerations (duties) were always overriding in nature – in other words, should take precedence over other considerations.

In terms of determining what one's actual duty is, Kant suggested that this can be done by appealing to some formal (reasoned) principle or maxim. In choosing such a maxim, however, Kant warned that we must take care not to choose something that would privilege our interests over the interests of others. Kant's solution to this problem was to establish a universally valid law

called the 'categorical imperative'. This law states: 'Act only on that maxim through which you can at the same time will that it should become universal law' (Kant 1972). In other words, we should act only on maxims that we are prepared to accept as holding for everybody (including ourselves) throughout space and time. A variation of Kant's law can be found in what is popularly known as the Golden Rule: 'Do unto others as you would have them do unto you.'

Teleological ethics

According to teleological theory (also known as consequentialism), actions can be judged right and/or good only on the basis of the consequences they produce. In this respect, teleology denies everything that deontology asserts.

The most popularly known **teleological theory of ethics** is utilitarianism, which has as its central concern the general welfare of people as a whole, rather than of individuals. In short, **utilitarianism** views the world not in terms of certain individual rights which people may or may not claim, but in terms of the collective and overall welfare and interests of people generally (a consequentially 'good outcome'). The perspective of utilitarianism is persuasive in that it promotes a universal point of view; namely, that one person's interests cannot count as being superior to the interests of another just because they are personal interests. To put this in another way, I cannot claim that my interests are more deserving than your interests are, just because they are my interests.

Classical utilitarianism, first advanced by the English philosopher Jeremy Bentham (1748–1832) and later modified by the work of the British philosopher John Stuart Mill (1806–73), holds roughly that moral agents have a duty to 'maximise the greatest happiness/good for the greatest number' (Bentham 1962, Mill 1962). This view has resulted in classical utilitarianism being dubbed the 'greatest happiness principle'. Because of difficulties associated with calculating both individual and collective happiness and unhappiness, and the problem of individual interests being sacrificed for the collective whole, classical utilitarianism theory has been largely abandoned in favour of recent utilitarian theory. Of particular note is 'preference utilitarianism', which views the maximisation of individual preferences as being of intrinsic value rather than the maximisation of happiness per se. This is because, as Beauchamp and Childress (1989) have classically explained, 'what is intrinsically valuable is what individuals prefer to obtain, and utility is thus translated into the satisfaction of those needs and desires that individuals choose to satisfy.'

Preference utilitarianism is also considered more plausible because it is relatively easy to calculate what people's preferences are – all we have to do is to ask people what it is they prefer. And where their preferences are at odds with ethical conduct we have no obligation to respect them. This position, however, rests on assumptions about the 'use' of utility and its supposed intrinsic value, which some contend it does not have.

Ethical principlism

One of the most popular ethical theories used today when considering ethical issues in nursing and health care is the theory of ethical principlism. **Ethical principlism** is the view that ethical decision-making and problem-solving are best undertaken by appealing to sound moral principles (Beauchamp & Childress 2013). The principles most commonly used are those of autonomy, non-maleficence, beneficence and justice.

Autonomy

As a concept, autonomy refers to a person's self-contained and independent ability to decide. As a principle, autonomy prescribes that people ought to be respected as self-determining choosers and that it is wrong to violate a person's considered and autonomous choices. This is so even if we do not agree with another's choices and regard them as foolish, provided they do not interfere significantly with the moral interests of others. Applied in nursing and healthcare contexts, the principle of autonomy imposes on healthcare professionals a moral obligation to respect patients' choices regarding recommended medical treatment and associated care. Further, this obligation holds even if attending healthcare professionals do not agree with the choices that patients make.

Non-maleficence

Maleficence refers to harm or hurt, so non-maleficence means to avoid harm or hurt. Simply stated, the principle of non-maleficence prescribes 'do no harm'. Applied in nursing and healthcare contexts, the principle of non-maleficence would provide justification for condemning any act that unjustly injures a person or causes a person to suffer an otherwise avoidable harm. Harm, in this instance, may be broadly taken as involving the invasion, violation, thwarting or 'setting back' of a person's significant welfare interests to the detriment of that person's wellbeing.

Beneficence

The principle of beneficence, similar in meaning to the word 'benefit', entails a positive obligation to 'act for the benefit of others'; that is, to promote their welfare and wellbeing

(Beauchamp & Childress 2013). Thus, it prescribes 'do good'. Beneficent acts can include such virtuous actions as care, compassion, empathy, sympathy, altruism, kindness, mercy, love, friendship and charity (Johnstone 2016), all of which stand to find ready application in nursing and healthcare contexts.

Justice

The principle of justice can be conceptualised in a variety of ways. For example, justice can be interpreted as involving retribution (retributive justice, e.g. 'an eye for an eye'), an equal distribution of benefits and burdens (distributive justice), justice as mercy, justice as harmony, justice as equality ('equals must be treated equally, and unequals unequally'), justice as fairness, justice as what is deserved ('just deserts'), and justice as inclusiveness, fellowship, compassion and respect (Beauchamp & Childress 2013, Nussbaum 2006, Sen 2009). Justice has also been conceptualised controversially as a basic human need (Johnstone 2011a, Taylor 2006). The conceptualisations of justice most commonly used in health care are those of justice as fairness (an intuitive sense of justice) and as an equal distribution of benefits and burdens (a rationalistic sense of justice). For example, on the basis of both an intuitive and a rational appeal to the principle of justice, it might be concluded that it is manifestly unfair and disproportionately burdensome to withhold life-saving treatment (e.g. cardiac surgery) from those who cannot afford to pay for such treatment. Such an action stands as being burdensome since it places the poor in a disadvantaged position in relation to the rich – the poor stand to suffer a burden of compromised life expectancy (which the rich do not) on account of their inability to pay. At an intuitive level, such a situation does not feel right in that it feels 'unfair'.

Although vulnerable to criticism on a variety of accounts, ethical principlism has increasingly come to replace more classical theoretical approaches to identifying and resolving moral problems in healthcare contexts. Since ethical principlism is widely appealed to in the healthcare and related ethics literature, it is important that nurses have at least a working knowledge and understanding of this approach. It is necessary for nurses to be aware, however, that principlism is not without its limitations. As the cases of 'Mr G' and 'Ms Winnow', considered earlier, have demonstrated, applying these principles in practice can be difficult and may not result in the moral outcomes either desired or intended.

Moral rights theory

Another popular and commonly used moral theory is that of moral rights theory, a form of deontological ethics. Moral rights have been particularly influential in the development of discourses on patients' rights and the development of various codes and charters outlining patients' rights in health care. As discussed earlier, a moral right is a special interest that a person may have and which ought to be protected and upheld for moral reasons. Moral rights are generally distinguished from legal rights (sometimes also called civil rights or statutory rights), which refer to certain entitlements that a person or legal entity has under law and which are recognised and protected by laws sanctioned by the state. The right to vote is an example. Although moral and legal rights sometimes overlap, they can also conflict, which is one of the reasons why care must be taken to distinguish between them when making and justifying moral decisions (Johnstone 2016).

There is no simple thesis of moral rights (Campbell 2006, Dyck 2005). Indeed, there are a number of bases on which an entity could validly claim moral rights, including natural law, common humanity, rationality and interests.

Natural law

By this view, rights are the product of the laws of nature and apply equally to everybody; thus everybody is subject to them, just as they are to the laws of nature (e.g. gravity).

Common humanity

All human beings have rights equally, just by virtue of being human. This is because being human is not something over which human beings have control.

Rationality

Only people who are capable of rational, autonomous thought are entitled to claim rights. This means, controversially, that entities such as babies, unconscious people, people with severe brain injuries and the like are excluded from having rights.

Interests

In order to have rights an entity must have interests, and in order to have interests an entity must have the capacity to be benefited or harmed; this, in turn, presupposes sentience (the capacity to experience pleasure and/or pain) (Feinberg 1979). This classic view is commonly seen as being among the most tenable theses of moral rights, since it is more inclusive than the other theories; for example, it includes both the rational and the non-rational, and other species besides human beings.

Virtue ethics

In recent times there has been a resurgence of virtue theory in ethics and a re-examination of the importance

of 'characterological excellence' in determining ethical conduct (Oakley 2006, Van Hooft 2014). This is made manifest by the expression of such moral virtues as care, compassion, kindness, empathy, sympathy, altruism, generosity, respectfulness, trustworthiness, personal integrity, wisdom, courage and fairness. Virtue theorists claim that without the characterological excellence of virtue, 'a person could, robot-like, obey every moral rule and lead the perfectly moral life', but in doing so would be acting more like 'a perfectly programmed computer' than a morally responsible human being (Pence 1991). There is a sense in which being moral involves much more than merely following rules; the missing link, claim virtue theorists, is character. On this point, Pence (1991) writes:

> we need to know much more about the outer shell of behaviour to make such judgments, that is, we need to know what kind of person is involved, how the person thinks of other people, how he or she thinks of his or her own character, how the person feels about past actions, and also how the person feels about the actions not done.

Virtue ethics is particularly relevant to nursing and to nursing ethics since virtuous conduct is intricately linked to therapeutic healing behaviours and the promotion of human health and wellbeing.

The nursing profession's well-articulated ethic of care (regarded by many influential nurse theorists as the moral foundation, essence, ideal and imperative of nursing) is consistent with a virtue theory of ethics (see the classic works of the following nurse theorists: Benner & Wrubel 1989, Gaut 1991, Gaut & Leininger 1991, Leininger 1988, 1990, Roach 1987, Watson 1985a, 1985b). Significantly, virtue ethics is enjoying a renaissance in the nursing ethics literature – particularly in regard to the issue of caring for vulnerable and marginalised groups of people at risk of being treated as 'different' by healthcare providers (Armstrong 2006, 2007).

Cross-cultural ethics

As highlighted by the 'Mr G' case discussed on p. 139, another perspective on ethics and bioethics that warrants consideration by nurses is cross-cultural ethics. The basic assumptions of **cross-cultural ethics** reflect the views that:

- ethics is very much a product of the culture, society and history from which it has emerged
- all cultures have a moral system, but what this system is and how it is applied will vary across, and sometimes even within, different cultures
- there is no such thing as a universal ethic; that is, one ultimate standard of moral conduct which applies to all people equally regardless of their individual circumstances, context and culture – in other words, a 'one size fits all' approach to ethics (Johnstone 2012, 2016).

In any culturally diverse society it is imperative that a culturally informed, knowledgeable and sensitive approach to health care is taken (Johnstone 2012, Johnstone & Kanitsaki 2008). One reason for this is that a failure to adopt such an approach can result in otherwise serious moral harm being caused to people. Cross-cultural ethics, therefore, goes far beyond merely considering and critiquing the nature and content of mainstream ethical theories; it also involves a systematic examination of the moral implications of cultural and linguistic diversity in healthcare domains; for example, the extent to which patients of non-English-speaking and diverse cultural backgrounds suffer unnecessarily on account of the cultural and language differences between them and their professional carers (see de Bruijne et al 2013, Divi et al 2007, Johnstone & Kanitsaki 2006, 2009a, Suurmond et al 2010).

Nurses and other healthcare workers have a stringent moral responsibility to avoid and/or prevent the otherwise avoidable moral harms that can result from a failure to take into account the language and cultural needs of their patients (Johnstone & Kanitsaki 2006, 2008, 2009a). The harmful aftermath of racism in health care is a particular example of this. Racism in nursing and health care is a problem that has not been formally recognised as an important ethical professional issue (Johnstone & Kanitsaki 2009b, 2010). A cross-cultural approach to ethics would not only help identify the existence of racism in nursing and healthcare contexts, but also guide an effective response for dealing with it and, if not successful in eradicating it, at least minimise its harmful consequences to patient health.

WORKING WITH DIVERSITY

Truth-telling around cancer and other life-limiting diagnoses stands as one of the most controversial issues in cross-cultural health care. Research has shown that truth-telling is not just an issue for people from Greek backgrounds, but also for people from other traditional cultural backgrounds (e.g. Iranian, Pakistani, Japanese, Italian, Korean, Chinese). In these cases, truth-telling about a diagnosis of serious life-limiting illnesses (especially cancer-related illnesses) is regarded as harmful, 'undesirable' and hence to be avoided – most notably on the grounds that it could undermine the ill loved one's hope and the will to live (Johnstone 2012, 2016). Problems most commonly arise in situations where the healthcare provider (e.g. doctor, nurse) does not share the same cultural background as the patient and family, whose cultural world views are unfamiliar and even confronting to them and which they do not understand.

Implications for practice

There are a number of questions that nurses can ask when participating in moral decisions about the care and treatment of people from diverse cultural backgrounds, and which will assist them to check that they are 'on the right track'. These questions are:

- Is my understanding of this person's values and value systems such that it entitles me to override her or his family's requests or instructions?
- Can I by way of a third party (such as an interpreter) really ensure that the interventions or communications being proposed will result in benefits not harms to that person?
- Are my values and frame of reference the only ones that warrant overriding consideration in this relationship?
- How do I know my judgements in this relationship are morally and culturally appropriate? In short, how do I know I am right? (Johnstone 2016 – with reference to Kanitsaki 1989).

• CRITICAL REFLECTION POINT

Think of a situation in which you either observed or directly experienced behaviour that was prejudicial and/or discriminatory towards either yourself or another person. Reflect on how this experience or observation affected you – what thoughts and emotions did you have? How did you feel about it? How did you respond? If you did not respond, reflect on why you did not respond. Then consider how you would respond if placed in a similar situation again. Would your response be the same, or would it be different? Reflect on the rationale for your answers.

Nursing codes of ethics

Nursing codes of ethics have long featured as guides to ethical professional conduct in nursing. Just what they are, however, and how they function have not always been clearly understood.

As discussed extensively elsewhere (Johnstone 2016), a code may be defined as a conventional set of rules or expectations devised for a select purpose. By this view, a code of professional ethics could be described as a document laying out a set of **moral rules** and/or expectations devised for the purposes of guiding ethical professional conduct. Although **codes of ethics** are not fully developed systematic theories of ethics, they nevertheless tend to reflect a rich set of moral values that have been expressed and explained through a process of extensive consultation, debate, refinement, evaluation and review by practitioners over time.

Codes can be either prescriptive or aspirational in nature. In the case of prescriptive codes, provisions are 'duty-directed, stating specific duties of members' (Skene 1996). In contrast, aspirational codes are 'virtue-directed, stating desirable aims while acknowledging that in some circumstances conduct short of the ideal may be justified' (Skene 1996). Either way, codes of ethics have as their main concern directing 'what professionals ought and ought not to do, how they ought to comport themselves, what they, or the profession as a whole, ought to aim at' (Lichtenberg 1996).

In Australia, for example, the NMBA's *Code of ethics for nurses in Australia* (NMBA 2008a) and *Code of professional conduct for nurses in Australia* (NMBA 2008b) make explicit the ethical standards that Australian nurses are expected to uphold in the interests of promoting and protecting the moral interests and welfare of consumers, and the actions that must be taken against nurses if these agreed standards are breached; similarly, the NZNO's (2010) *Code of ethics* and the NCNZ's (2012a) *Code of conduct for nurses* (see Box 9-1).

Historically, the professional–patient relationship has been a special one in which certain privileges have been accorded to the attending professionals in return for the special (read 'expert and often essential') services they provide to their patients in the community at large. The professional–patient relationship has also tended to be an unequal relationship, with the professional usually holding the balance of power. This imbalance of power has been implicated in both potential and actual vulnerability of patients when seeking and receiving professional services. Although the nature of the professional–patient relationship has changed dramatically in recent decades, it nevertheless remains characterised by an imbalance of power involving, among other things, an imbalance of knowledge and legitimated authority to use knowledge.

This imbalance of power has helped to create a demand and given rise to an expectation among members of the community that professionals ought to, and will, submit to a system of rules imposing a greater constraint on their professional conduct than would otherwise be imposed on the conduct of ordinary (lay) people. All in all, there has emerged a general expectation that professionals will act in a supremely ethical manner when rendering services to patients.

Over the past several decades, recognition of the responsibility of professionals to act in an ethically exemplary manner has seen considerable attention being given to devising and agreeing to a system of rules to govern both personal and professional conduct (Coady & Bloch 1996, Kerridge et al 2013). A code of ethics serves this purpose by providing a clear and singular guide to conduct.

Codes of ethics serve a variety of functions. Key among them are to maintain ethical standards of conduct and to help the regulation of ethical professional conduct. These outcomes are thought to be achieved by the direct and the indirect value of codes in fostering and maintaining the standards of ethical professional conduct by cultivating moral character, by articulating certain characteristics and ideals of a profession, by facilitating the internalisation of these values and ideals by members of the professional group in question, and by prescribing and proscribing conduct that is otherwise not amenable to legislation, by specifying rules of conduct; for example, 'Nurses will keep in confidence information gained in the professional–patient relationship'.

A characteristic feature of codes of ethics is their voluntariness. What this means is that persons subscribing to or upholding the terms of a given code of ethics do so free from any coercive or manipulative influences. In other words, compliance is and ought to be both autonomous and voluntary.

Like other moral action guides, however, codes are not without their limits. Problems include their having limited moral authority (being mostly a statement of rules, codes cannot override the demands of a more systematic and reflective system of moral principles and standards) and limited practical application (e.g. codes may offer very little practical guidance on how to make sound moral decisions when dealing with complex ethical issues and/or particular situations). The case of Mr G (p. 139), underscores this point.

Despite these limits, codes of ethics and, of relevance to this discussion, nursing codes of ethics have an important role to play in regard to:

- advising the public of the values and ideals it can expect of nurses when delivering care to patients
- informing nurses of the values and ideals they are expected to uphold upon becoming members of the broader nursing profession
- providing standards against which nurses' conduct can be measured and, if found to be in breach of these standards, censured via the lawful processes of disciplinary action.

Moral problems in nursing

When delivering nursing care to patients, nurses will encounter moral problems. These problems range from the relatively simple to the extraordinarily complex, and can cause varying degrees of perplexity and distress in those who encounter them. Nurses, like other healthcare professionals, have a fundamental and unavoidable moral responsibility to be able to identify and respond effectively to the moral problems they encounter – which includes self-care (Johnstone 2016).

The ability of nurses to deal effectively with the problems they encounter will depend on:

- their ability to correctly identify a given moral problem
- the level to which they are prepared educationally, psychologically and emotionally to be able to respond to various moral problems as they arise and are identified
- the extent to which institutional norms and practices are supportive of the moral authority and experience of nurses to deal with moral problems in the workplace
- the extent to which other legal processes recognise and are responsive to the moral authority of nurses and the ethical standards of the nursing profession generally.

Nursing point of view

When moral problems arise in healthcare contexts, the nurse's observations and considered judgements (the 'nursing point of view') can play a vital role in the correct identification and mitigation of the problems at hand. Since nurses may be involved in very intimate physical acts with patients, such as bathing, feeding and special procedures, information that is not generally solicited by other attending healthcare workers, including doctors and social workers, is often revealed to nurses by patients and their families. Details about family life at home, information about coping styles or personal preferences, and details about fears and insecurities may come out during nursing interventions. Such information can be vital to ensuring sound moral decision-making concerning patient care.

On the other hand, it is important for nurses to remember that care of any one patient has become multidisciplinary and fragmented. The nursing point of view is part of a larger picture that is best built by all members of the healthcare team, including the patient and family. Managers and administrators from different professional backgrounds may also contribute to 'moral conversations', as they are able to bring knowledge of systems, allocation of resources, financial possibilities or constraints to the decision-making process.

Wherever moral problems arise, the nursing point of view is valuable and often essential. It is both an obligation and a privilege for the professional nurse to accumulate information on the issues, examine personally held moral values and beliefs, and share knowledge with patients and with colleagues in an effort to overcome the difficult issues that often underlie and/or constitute moral problems.

Distinguishing moral problems from other kinds of problems

Being able to identify and respond effectively to moral problems in professional practice requires an understanding of what a moral problem is and how it might be distinguished from other kinds of problems, such as a legal problem or a clinical problem.

It is generally accepted that a moral problem has as its central concerns:

- the promotion and protection of people's genuine wellbeing and welfare, including their interests in not suffering unnecessarily
- responding justly to the genuine needs and significant moral interests of different people
- determining and justifying what constitutes right and wrong conduct in a given situation (Johnstone 2016).

Nurses are fundamentally involved with promoting and protecting people's genuine wellbeing and welfare and, in achieving these ends, responding justly to the genuine needs and interests of different people. And so long as nurses work and interact with people in a professional capacity, they will continue to be involved in the promotion and achievement of these moral ends.

Moral problems (also called **ethical issues**) fall roughly into three categories:

1. those that involve procedural difficulties associated with the actual identification and satisfactory resolution of moral problems in nursing and healthcare contexts, such as unethical conduct, moral impairment, moral incompetence, moral disagreement and ethical dilemmas
2. those that involve everyday ethical issues that arise in face-to-face 'hands-on' encounters with patients and co-workers
3. the more 'exotic' issues of applied ethics involving bioethical issues, such as patients' rights to informed consent, confidentiality or euthanasia/assisted suicide.

Identifying and responding effectively to moral problems in nursing

All nurses are expected to be able to correctly identify and effectively respond to moral problems in the workplace. The kinds of problems that may be encountered are summarised below.

Moral unpreparedness

A person is not adequately prepared educationally, psychologically or emotionally to deal with a presenting moral problem. When faced with a moral problem a morally unprepared nurse may not take appropriate action to remedy a troubling situation on the grounds of 'I did not know what to do'.

Moral blindness

A nurse (or other member of the healthcare team) is blind to the ethical dimensions of a presenting problem; for example, they may wrongly regard the problem at hand as a clinical or technical problem requiring only a clinical solution, not a moral one. By analogy, like a colour-blind person who cannot see certain colours, a morally blind person cannot see the moral dimensions of a given situation or problem. Take, for example, a medical decision not to resuscitate a patient. This may be construed as simply 'good medical practice' and, as such, outside the concerns of ethics, regardless of the fact that such a decision may have been based firmly on quality-of-life considerations and made without the patient's knowledge or consent.

Moral indifference

A nurse (or other member of the healthcare team) is largely unconcerned about the demands of ethical professional conduct. A nurse who is morally indifferent may, for example, demonstrate a lack of interest in or concern about a patient's wellbeing and/or welfare. The morally indifferent nurse might refrain from engaging in any discussions or activities aimed at patient advocacy, or disregard a patient's pain and discomfort.

Amorality

A nurse or other member of the healthcare team literally has no morality. As the word itself suggests, there is an absence of morality in these people.

Immorality/unethical conduct

A nurse or other member of the healthcare team accepts ethical standards of conduct, but nevertheless deliberately violates them. An example is the case of a nurse who steals money from an elderly patient or fraudulently uses her credit card.

Moral complacency

A nurse or other member of the healthcare team is unwilling to accept that their moral beliefs and viewpoints may be mistaken. Such a nurse is reluctant to accept that their point of view is often just one among many that deserves to be considered, compared and contrasted. For example, a morally complacent nurse may hold firmly to the view that it is morally wrong to perform resuscitation

on people over the age of 75 (regardless of the person's wishes to the contrary), since they are already old, at the end of their lives and should not be troubled by having to decide such burdensome issues.

Moral fanaticism

A nurse or other member of the healthcare team uncritically holds extreme moral views. For example, a nurse might uncritically and fanatically uphold the view that, irrespective of their stated cultural values and beliefs and expressed wishes, people diagnosed with cancer should be told their cancer diagnosis by an attending doctor. Moreover, such information should be communicated 'directly' and 'frankly' to the person by the doctor, regardless of the person's or the family's wishes in regard to what information should be given, when, where, how and by whom. Such a nurse might further hold the view that 'even if this information may result in causing the patient otherwise preventable distress, they should still be told directly whether they wish it or not, whether the family is there or not, because "they have a right to know". And this is just the way it should be.'

Moral disagreement

Nurses or other members of the healthcare team may disagree about the morally correct course of action to take in a given case. Disputing parties may share and subscribe to common moral standards, but disagree as to:

- when one set of standards should override another set, for example, whether the principle of autonomy is stronger than the principle of non-maleficence in a situation involving the disclosure of a poor diagnosis to a patient
- what should count as acceptable exceptions and limitations to applying the standards in question; for example, a nurse might be willing to act as a patient's advocate but only so long as their own significant moral interests are not compromised; another nurse might not subscribe to this limitation
- whether a given set of standards should be chosen at all; for example, two nurses might disagree that the moral principle of autonomy ought to be given consideration in the euthanasia debate.

Moral disagreement may also arise when disputing parties do not agree on any ethical standards at all.

Moral dilemmas

Nurses or other members of the healthcare team may find themselves between what is colloquially referred to as 'a rock and a hard place'. Broadly speaking, a moral dilemma may be described as a situation involving a choice between what seem to be two equally undesirable alternatives. Moral dilemmas commonly take one of three forms:

1. Where there exists a logical incompatibility between two or more moral principles; for example, in the context of informed decision-making, where the information being disclosed is potentially harmful it may not be possible to uphold both the principle of autonomy (i.e. respect a patient as a self-determining chooser) and the principle of non-maleficence (i.e. protect the patient from otherwise avoidable harm) (refer to the case of Ms Winnow, discussed earlier).
2. When competing moral duties exist and a nurse cannot fulfil both, they must choose which duty to fulfil; for example, in a life-and-death situation a nurse might feel duty-bound to protect both a patient and the chosen carers from the harm of suffering associated with the crisis at issue. That might not be possible and no matter what strategies the nurse uses, someone is going to suffer. Here the nurse might ask: 'Which duty ought I to fulfil?'
3. When competing and conflicting interests exist; for example, two patients may have equally deserving rights claims and a nurse may be in a position to respond to only one of these claims at a time. Abortion is a good example here, especially in cases where the rights of the mother might compete with the rights of a fetus and/or the father. Here the nurse might ask: 'Whose interests ought I to uphold?'

Moral stress, distress and perplexity

A nurse or other member of the healthcare team may experience stress, distress and perplexity on account of having identified a given moral problem but been largely unsuccessful in resolving it. These states can manifest as emotional turbulence, indignation, incredulity, rage and outrage, anger, despair and an overwhelming and paralysing sense of hopelessness. Some scholars have labelled these states controversially as 'moral distress'. Whether this labelling is correct, however, remains a point of contention (see *Nursing ethics* 2015 'Special issue: Moral distress').

Processes of ethical reasoning and decision-making

Moral problems, like other kinds of problems, can be approached using a systematic and critically reflective decision-making process. Like the clinical reasoning process that is used in nursing, identifying and resolving moral problems in healthcare contexts involves at least five steps captured in Figure 9-1 and outlined in Box 9-3.

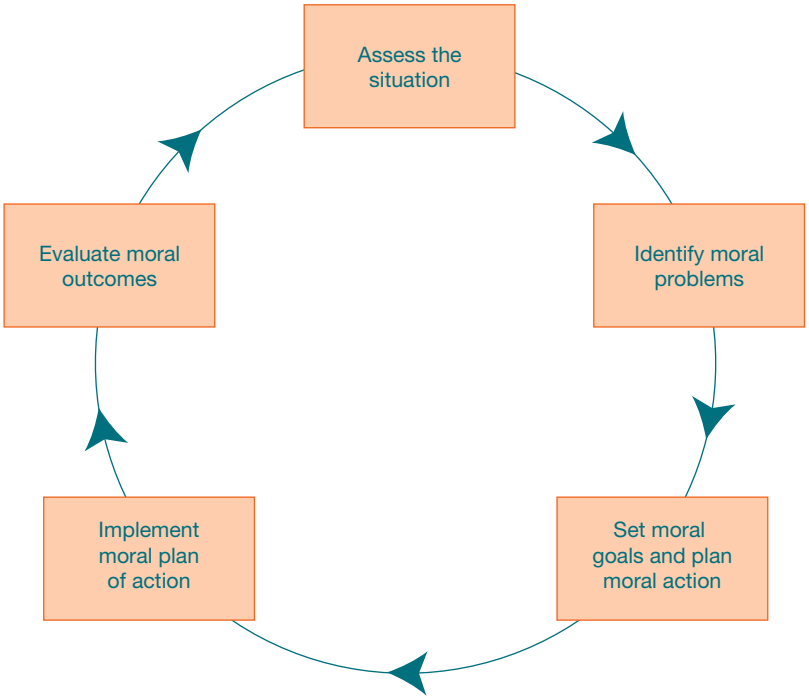

Figure 9-1 Moral decision-making.

Johnstone M-J 2016 Bioethics: a nursing perspective, 6th edn. Churchill Livingstone, Sydney.

BOX 9-3 Ethical reasoning process

1. Assessing the situation

Every effort is made to obtain all the relevant information pertaining to the case to enable a proper assessment of the nature of the problem that is presenting and whether, indeed, it is a moral problem at all. Sometimes what seems like a moral problem may, in fact, be a legal problem or a clinical problem or a problem of some other practical non-moral nature.

2. Identifying and analysing the moral problem

The information collected is appraised and a careful judgement made on the nature of the problem at hand. It might be concluded on the basis of the information that has been collected and appraised that the moral problem at hand involves a case of, for example, unethical conduct or a full-blown ethical dilemma; conversely, the problem at hand may be shown to involve little more than a breakdown in communication, hence not requiring a moral remedy per se.

3. Setting moral goals and planning an appropriate course of action

A specific plan of action is devised to resolve the moral problem(s) identified. If the problem involves a moral dilemma or a moral disagreement, then the plan of action will have as its focus, for example, an attempt to resolve the impasse that has arisen and to find a satisfactory solution; that is, achieve 'good' outcomes that can be justified on moral grounds.

4. Implementing the plan of action

The decision-maker engages in the implementation of the plan of action; that is, 'sets the wheels in motion', Depending on the problem(s) identified, this could involve a range of actions, including reporting the matter to a supervisor or manager, and even seeking the involvement of an institutional ethics committee for advice.

5. Review and evaluation of moral outcomes of the actions taken

A review is undertaken and an assessment is made with respect to whether the desired moral outcomes of the actions taken were achieved. If the evaluation proves negative, then the whole situation needs to be re-appraised using the same systematic process. Critical questions need to be asked about 'What went wrong'? What can be done to improve the situation? What are the lessons to be learnt from this scenario to prevent reoccurrences of similar situations?

Johnstone M 2016 Bioethics: a nursing perspective, 6th edn. Churchill Livingstone, Sydney.

This approach to ethical reasoning and decision-making is by no means the only one that might be used to deal with moral problems. Nevertheless, it is a useful approach and one that is relatively easy to use. It does, however, presuppose that decision-makers have at least a working knowledge and understanding of ethics and the ability to think critically when applying ethics to and in professional practice. What follows is an outline of the application of this process to a clinical example (review Box 9-3 before studying the application of the process in the following *Clinical example*).

CLINICAL EXAMPLE

The case of 'Mrs B'

On your ward, a 35-year-old woman ('Mrs B') has been hospitalised in the final stages of a struggle with brain cancer. She is a single mother, with two young children at home. Despite treatment, the tumour continues to grow and the medical team has agreed that further treatment would be futile. You have cared for 'Mrs B' during past admissions, and during one especially open discussion, she expressed wishes to explore 'do not resuscitate' (DNR) directives. During the current admission, her medical consultant is out of town. The attending on-call doctor does not know the patient personally, but he has spent some time with her. He has reviewed the clinical data and agrees that 'Mrs B' is entering advanced stages of her disease. In his opinion, however, 'Mrs B' is not ready to discuss end-of-life issues. In fact, he states that on being offered the option to discuss DNR, 'Mrs B' declined. You have asked him to convene a family conference to discuss DNR directives but he refuses to do so.

Applying the ethical reasoning process to the *Clinical example*

Step 1 Assess the situation and ask: what are the relevant facts of this case?

What may at first appear to be a question of ethics may not be such at all, and may be resolved by clarifying one's knowledge base about clinical facts and reviewing policy and procedure, standards of care and other relevant information. When it can be shown, however, that perplexing questions remain about the patient's genuine wellbeing and welfare (including her interests in not suffering unnecessarily), that the genuine needs and significant moral interests of different people are at stake and in need of protection, and that assistance is required in determining and justifying what constitutes right and wrong conduct in the situation at hand, then it is evident that a moral problem exists. The next step is to ascertain what kind of moral problem exists. This is crucial to the moral decision-making process, since unless the type of moral problem is correctly identified, any plan of action risks failing to achieve a satisfactory moral outcome.

Further review of the available information will probably not contribute to a resolution of the problem, but it is important to review the information carefully to make this determination. It is evident that there is disagreement, but this does not revolve around whether the patient is in a seriously ill state, so further clinical information will not change the basic question: Should the patient have an opportunity to discuss the 'do not resuscitate' (DNR) directive at this time? The question is perplexing. Basically, two professional team members disagree on an assessment of a patient's readiness to confront the very difficult issues around dying. The answer to the question concerning the patient's readiness has important implications for her wellbeing and welfare. If she is not ready, then raising the issues may cause anguish and fear in the patient and her family. If she is ready, and the team avoids discussion, she may suffer unnecessarily in silence. If she is very close to death, then the lack of a DNR directive will necessitate the application of cardiopulmonary resuscitation (CPR), which could also result in harmful moral consequences. Knowing that CPR can cause pain and is not without risks, its application in a situation where further life is unlikely could prolong suffering and reduce dignity.

In assessing the situation at hand, it is necessary for the nurse to gather as much relevant information as possible. Since resolution of moral problems may arise from unlikely sources, it is helpful to incorporate as much knowledge as possible at every step of the process. At this point, the information could include looking at laboratory and test results, the clinical state of the patient in question and perhaps current literature about the diagnosis or condition of the patient. It may include careful investigation of the psychosocial concerns of the patient and of the patient's significant others. A patient's cultural, religious and family orientation is part of the nurse's assessment.

In this scenario, all the clinical information pertinent to the case would be obtained. It might be helpful to determine if the patient retains most cognitive functions, even though her brain tumour is aggressive. A review with the attending medical consultant might result in agreement that she is fully competent, but definitely afraid and overwhelmed by the prognosis. Since the problem seems to exist because two professionals do not agree on a patient's state of mind, it may be helpful to reassess the patient, or even to request that an independent person assesses the patient's readiness to discuss end-of-life issues. Sometimes, family members or significant other people in

the patient's life will hold important clues to a patient's state of mind and also how best to approach a given situation in a culturally informed and appropriate manner. In addition to this, the moral standards that are guiding the decision-making should be clarified. What might be at issue in this case is a moral disagreement about the appropriateness of appealing to and applying the respective moral principles of autonomy and non-maleficence. Thus, what might initially look like a disagreement in professional opinion may in fact be much more than that – it may also involve a fundamental disagreement in moral viewpoint, or moral disagreement.

Step 2 Indentify and analyse (diagnose) the moral problem

Once the nurse is satisfied that the problem is a moral problem rather than some other kind of problem, for example, a disagreement about the patient's health status which could be clarified by appeal to the clinical facts of the case, then it becomes necessary to make a more definitive moral diagnosis. The possibilities, as have been shown above, can include one or more of the following:

- moral unpreparedness
- moral blindness
- moral indifference
- amorality
- moral complacency
- moral fanaticism
- moral disagreement
- moral dilemmas
- 'moral' stress, distress and perplexity.

The *Clinical example* meets the criteria for a moral problem. However, a more definitive moral diagnosis is needed. One possibility is that this case exemplifies a moral disagreement, since both doctor and nurse share a common moral commitment to preventing harm to the patient, but disagree on how this harm prevention might be achieved – the doctor believes that imposing unwanted information (though crucial to informed decision-making) on the patient could result in her being caused unnecessary harm, whereas the nurse believes that withholding the information could likewise result in her being caused unnecessary harm. This situation could also be said to pose an ethical dilemma, since both doctor and nurse are situated between 'a rock and a hard place' and confronted by the question, 'What ought I to do?' Further information about the case might result in still other moral diagnoses being made.

Step 3 Setting moral goals and planning action

Once all the relevant information has been gathered and a correct moral diagnosis made, attention can then shift to more specific questions such as: Should this patient discuss the DNR directive at this time? What are the benefits and what constitute the risks of a DNR order at this time? An important question also seems to involve the patient's current state of mind: Is she afraid to speak? Is she feeling cut off from her normal network, including her medical consultant? Are these feelings contributing to confusion about DNR decisions? Has she been approached in a culturally informed and appropriate (culturally competent) manner?

Once these and similar questions are raised, it becomes easier to consider possible courses of action. What action is, in fact, planned will depend on still further questions being asked.

Other questions and possible courses of action could include: Should you initiate a discussion with the patient independently of the doctor? Would you be outside your professional domain if you facilitated a DNR directive? What if your assessment was incorrect: would you contribute not to the dignity but to the distress of the patient? The answers to these questions may be elusive, since they depend on an understanding of the patient's views and wishes that are not necessarily obvious. Even if legally the nurse cannot actually write a DNR directive, this fact does not relieve the nurse of moral questions since the ability to influence an attending doctor's or a patient's decision regarding DNR remains. On considering these and similar questions, you might set the following goal and strategies:

- Goal: to achieve an outcome that genuinely maximises the patient's best interests (wellbeing and welfare) and otherwise avoidable harmful moral consequences.
- Strategies: seek a meeting of the healthcare team to discuss the case and to work collaboratively to achieve a 'best outcome'. This step represents the most important and delicate part of the process. Team members could be approached informally on a one-to-one basis within the ward setting and invited to attend. Team members might also be requested by a manager to attend a meeting. Whatever meeting takes place, the nurse has an obligation to articulate and justify the moral stance he/she is taking.

Alternatively, if efforts at the ward level fail to achieve a resolution, it may be necessary to refer the case to a unit or institutional ethics committee for guidance on how best to deal with the problem. If an ethics committee meeting is convened, the discussion will usually be multidisciplinary in focus. A facilitator or chairperson will ensure that all points of view are examined, and that all pertinent issues are identified. A decision or recommendation is the usual outcome of discussion. In the best of circumstances,

participants discover a course of action that meets criteria for acceptance by all. Occasionally, however, participants may leave the discussion disappointed or even opposed to the decision. But in a successful discussion, all members will have agreed on an action or decision that can be implemented.

Step 4 Implement plan of action

Once the nurse has formulated a plan of action, it is then possible to implement it. In this case, the nurse may embark on discussions with members of the healthcare team. In other words, the nurse engages in the moral actions that have been planned.

The discussion focuses on the disagreement between the nurse's assessment and the doctor's regarding the patient's readiness to discuss end-of-life issues. The approach to moral decision-making might include a discussion of the principles of autonomy, beneficence and non-maleficence: Does the patient want something different from what she is expressing? Is the team approaching the patient in a culturally appropriate manner? Which plan would provide the most good for this patient, a DNR directive or no directive? Would a direct discussion with the patient promote wellbeing or anguish? Should the discussion be held with her family first?

With several members of the healthcare team present, the discussion proceeds. In the end, the team proposes a formal meeting with the patient, where you, the nurse, the attending doctor and a supportive family member are all present. This proposed course of action will maximise the support of the patient's existing network. In a trusting environment, the patient is most likely to express her fears, insecurities and wishes most accurately. Team members agree to keep the discussion open-ended and exploratory. Rather than asking if the patient wants a DNR directive written, perhaps the team could wait for her to bring up the issue. In this way, the team could be assured of her consent and willingness to participate in the discussion.

Step 5 Evaluate the moral outcomes of the action taken

After implementing the planned moral course of action, the nurse should evaluate whether the projected moral goals and the desired moral outcomes were achieved.

At the meeting, the patient in fact opens up. She expresses relief at the chance to explore her options and feelings. Pain management issues are clarified. She wants to discuss a DNR directive, but requests a visit from her priest before making a final decision. The goal of maximising the patient's best interests has been achieved. The possibility of harmful moral consequences to the patient has, it seems, been averted.

If the moral goals of action have not been achieved, then the process will need to begin again with questions asked as to why a desired moral outcome was not achieved. For example, it may transpire that not all the relevant facts of the matter were obtained and consequently the problem was misdiagnosed.

RESEARCH HIGHLIGHT

Research focus

This literature review provides a comprehensive analysis of the literature on nurses' ethical reasoning and decision-making and the processes they use to implement their decisions in practice.

Research abstract

A key finding of this review was that nurses engage in a complex process of reasoning, decision-making and implementation in their practice. However, their process of decision-making was more strongly influenced by personal and contextual factors, rather than cognitive reasoning. That is, nurses in the studies reviewed tended to decide and justify their moral decisions by appealing to their own personal values, convictions and beliefs, rather than selecting ethical theories. Nurses' ethical practice was also found to be influenced by their work environment. When nurses encountered difficult working environments they often capitulated to the decisions made by others, which in turn led nurses to behave in a conformist rather than an individually accountable and critically reflective way.

Implications for ethics-based practice

The review has yielded important insights into nurses' ethical practice and the way nurses decide and act when working in difficult environments.

To improve understanding of nurses' ethical practice, further research is required on the link between how nurses reason and how they ultimately behave in practice.

• CRITICAL REFLECTION POINT

There will be times when you will have to make an ethical decision about patient care. Take the time to think carefully about the ethical decision-making process that has been presented in this chapter and then reflect on how, if at all, you would use it to guide your ethical decision-making in practice. Consider also what other approaches you might take. In either case, reflect on how you would determine whether or not – using the decision-making process selected – you have made the 'right decision'.

Bioethical issues in nursing

Since the inception of bioethics as a discipline in the early 1970s, a number of bioethical issues have emerged that are of particular relevance to nurses. Key among these are the issues of informed consent, confidentiality, quality of life, DNR directives, euthanasia/assisted suicide and resource allocation in health care. New and emerging ethical issues include the problems of equity and social justice associated with the health impacts of climate change, peak oil, pandemic influenza, and anti-microbial resistance (AMR) (see Johnstone 2016 for further discussion on these issues).

Informed consent

The main aims of informed consent processes are to promote and protect the patient's right to self-determination and to remind healthcare practitioners of their duty to provide patients with the information necessary to make intelligent choices about whether to accept recommended care and treatment (Düwell 2013). The main way of meeting these goals has been to share knowledge about clinical findings and management plans as they are implemented. In certain well-defined situations, the patient must provide written evidence of consent, such as consent to a surgical procedure or consent to participate in an experimental regimen.

Obtaining informed consent prior to a medical procedure is standard practice in Australian and New Zealand jurisdictions. Moreover, healthcare providers go to great lengths to share information that promotes informed decision-making. Institutional policies and civil law protect the patient's right to informed consent. Its practice represents a clear effort to respect the autonomy of patients, and in this way also represents a fundamental paradigm shift from medical paternalism ('doctor knows best') that was once characteristic of healthcare practice (Düwell 2013), to patient and carer participation ('patients are "expert" in their own conditions' and can/should actively participate in decision-making and negotiate their health care) (Bellows et al 2015, Hernan et al 2014, WHO 2013).

A commitment to the concept of informed consent does not ensure a lack of controversy. The concept depends on a certain level of competence on the part of the provider to communicate well, and also depends on a level of competence on the part of the patient to understand. It is not always easy to secure these competencies. Furthermore, studies on communication skills demonstrate that healthcare providers are more likely to share information with patients who have similar cultural backgrounds to the provider. Providers may be more likely to give directives or advice than truly share knowledge with patients who they perceive to be less educated or less intelligent and, in the case of patients who do not speak English or do not speak it proficiently, may even fail to communicate relevant information at all (Johnstone & Kanitsaki 2006, 2009b).

For consent to be properly informed it must satisfy the criteria in Box 9-4.

Confidentiality

It is generally accepted that nurses, like other members of the healthcare team, have a stringent moral duty to keep secret any private information gained in the professional–patient relationship. Nursing codes of ethics make explicit the nurse's duty in this regard, and make it clear that nurses must exercise critical judgement if and when disclosing otherwise confidential information to a third party. The main aim of the rule of confidentiality is to protect patients against the morally harmful consequences that can occur when unconsented disclosures are made.

BOX 9-4 Criteria for informed consent

- The patient was given relevant information to enable an intelligent choice to be made. Relevant information may be taken as referring to any information that would make a material difference to the choices being made.
- The patient understood the information disclosed.
- The patient's consent was given voluntarily; that is, it was provided in a context that was free of coercive and/or manipulative influences.
- The patient was competent to exercise the choices made.
- The patient gave consent and understood the implications of doing so; that is, in consenting, the patient was consenting to something (e.g. a medical procedure) being done to them

Beauchamp T, Childress J 2013 Principles of biomedical ethics, 7th edn. New York, Oxford University Press; and, Kerridge I et al 2013 Ethics and law for the health professions, 4th edn. Federation Press, Sydney.

An unconsented disclosure of, for example, a patient's newly diagnosed HIV-positive status could result in the patient being rejected by family and friends and hence left without social support at a time when it is most needed. It might also result in the patient losing his/her job, which although illegal still happens, compounding their loss of social support.

Confidentiality is not, however, an absolute principle. What this means is that although, as a general rule, we ought to keep information gained in the professional–patient relationship secret, there may be times when disclosing such information is morally warranted. Indeed, it is generally recognised and accepted that sometimes there may be overriding moral reasons for disclosures. For example, where such disclosures could otherwise help prevent harm to innocent others. If a patient disclosed that, for example, he intended to act out a revenge fantasy and kill someone he disliked, then the duty to keep this information confidential could be overridden by a stronger duty to warn the intended victim. In cases involving known or suspected cases of child abuse or elder abuse, disclosures might not only be morally warranted but legally mandated as well.

Quality of life

It is difficult to imagine a concept with a more personal, or more elusive, definition than quality of life. For each individual, quality of life is something that is intensely personal and particular. Yet society uses quality-of-life measures to help determine the benefits of medical intervention and, as a result, discussions about quality of life abound (Jecker et al 2011, Kerridge et al 2013). Some social scientists have proposed formulas or other objective measuring devices that can be applied to individual and group situations, and to whole populations. These formulas might take into account the age of the patient, ability to live independently and ability to contribute to society in a gainful way. Such a formula might help a committee determine, for example, the relative merits of giving an organ to one recipient over another. Or, a quality-of-life measure could help a patient and family decide on the merits of a certain risky intervention, such as organ transplant or experimental drug management. The question of quality of life is paramount to discussions about so-called medically futile treatment, euthanasia/medically assisted suicide, and DNR directives.

Given the diverse ways in which the notion of quality of life can be defined, it is important that nurses are clear about what they mean by this concept and that they ensure they do not inadvertently impose their views about what quality of life is on the patient (Johnstone 2016).

Do not resuscitate (DNR) directives

At some stage during their practice, nurses will encounter patients who have been made the subject of a 'do not resuscitate' or DNR directive. A DNR directive (also sometimes written as a 'do not attempt resuscitation' (DNAR) or 'not for resuscitation' (NFR) directive) is made by an attending medical officer, and typically prescribes that in the event of a cardiac or respiratory arrest, no emergency resuscitation or life-supporting measures will be initiated. In other words, were the patient to suffer a cardiac or respiratory arrest, CPR would not be performed. The issue of DNR has long been a controversial bioethical issue for nurses, as discussed elsewhere (Johnstone 2016). One reason for this has been that, at least in the past, it was not uncommon for DNR directives to be given without the patient's knowledge or consent. This was often justified on the questionable grounds that such knowledge would only cause the patient unnecessary distress. Other problems related to DNR directives are listed in Box 9-5.

Today, the issue of DNR is discussed more openly with patients and their families as well as with members of the healthcare team. Nevertheless, the issue remains problematic and continues to invite debate in both the bioethics and the nursing ethics literature. Even though there have been notable improvements in the development and operationalisation of DNR policies and practices in local healthcare institutions, research has shown that wide variations continue to exist (Brown et al 2014, Hayes 2012, Sidhu et al 2007).

BOX 9-5 Other problems related to DNR directives

- Lack of institutional policies and guidelines for prescribing DNR.
- The use of vague criteria for deciding whether a patient ought to be made the subject of a DNR directive.
- Poor communication of medical decisions surrounding DNR practices.
- Poor documentation processes; for example, in the past, a DNR directive was commonly communicated via the use of coloured dots (usually black ones) being placed on the patient's chart or against their names on the ward admission board.
- Nurses being left to carry a disproportionate burden of responsibility with respect to the execution of such directives.

Johnstone M 2016 Bioethics: a nursing perspective, 6th edn. Churchill Livingstone, Sydney.

Euthanasia/medically assisted suicide

Euthanasia/medically assisted suicide involves the deliberate administration of a lethal substance to end a patient's life, usually in a clinical context (Johnstone 2016). Some people request euthanasia in instances where they have come to view their life or suffering as 'unbearable'. Over the past decade supporters of euthanasia have advocated 'advance euthanasia directives' (also called 'pre-emptive euthanasia') whereby requests for euthanasia are made in advance of an anticipated state of suffering (mental or physical) being experienced (Hertogh 2009). Nurses, like others in the community, hold diverse values, opinions and beliefs about the moral permissibility of euthanasia/medically assisted suicide and whether it should be legalised. Of particular concern to nurses in Australia and New Zealand (where euthanasia is illegal) is the confronting question of whether the nursing profession should formally and publicly support calls for the legalisation of euthanasia/medically assisted suicide and whether nursing organisations should adopt a formal policy position to this effect (Johnstone 2016). Also confronting is the question of whether nurses should themselves assist with performing euthanasia in the event of it being made legal. Nurses and professional nursing organisations have an obvious stake in the outcome of the euthanasia/medically assisted suicide debate. Accordingly, nurses have a moral and professional responsibility to ensure that they are kept well informed about the issues in question and keep abreast of developments discussed critically in the legal and bioethics literature. This includes questioning public opinion, which indicates nothing more than a certain percentage of the population holding a particular opinion on the matter. Whether public opinion (which currently favours the legalisation of euthanasia) has the authority to prescribe a society's moral values is another matter entirely (Johnstone 2016).

Access and equity in health care

Access and equity in health care are poised to become the most pressing ethical issues in the 21st century. This is because over the next 40 years, population ageing, the increasing burden of chronic disease, the possible health consequences of climate change and the depletion of the world's non-renewable resources (e.g. petroleum) will all place unprecedented and overwhelming demands on the healthcare system and the individuals comprising it. In the case of population ageing, people over the age of 65 years are expected to become frequent users of the public health system and 'real health spending' during the period 2010 to 2050 will increase exponentially for this population group (Johnstone 2010, 2016, Johnstone & Kanitsaki 2009c). Critics contend that the costs associated with an ageing population and the associated burden of chronic disease will be so high that the level of health care currently being provided will not be sustainable. The future will therefore be one in which 'tough moral choices' will have to be made.

Adding to the problem of future access to and equity in health care is the potential negative impact of climate change. Experts predict that climate change will see a significant increase in illness and deaths from frequent and severe heat-waves, vector-borne diseases, and other extreme weather events (McMichael et al 2006). Peak petroleum (the point at which the world's oil reserves begin to decline, which some say may already have been reached) will also affect healthcare delivery in deleterious ways (Frumkin et al 2007, 2009, Hess et al 2011, Schwartz et al 2011). This is because healthcare services are utterly dependent on petroleum products (e.g. medical supplies and equipment, pharmaceuticals, transportation and service delivery, and energy) without which they will come to a halt (Johnstone 2011b).

In order to mitigate the negative impact of these developments, authorities have increasingly emphasised the need for healthcare reform and a more responsive and better coordinated healthcare system. Healthcare reform, in this instance, has been clarified to include making adjustments to healthcare spending in order to obtain 'better value for money'. Some argue, however, that healthcare reform is not just a matter of making the system 'work better'. Callahan suggests, for example, that if the common good is to be achieved we need to rethink some of our fundamental values about health and health care. This, he suggests, is going to require a 'cultural revolution' in our thinking about medical technology, progress, dying, death and ageing, because the brutal reality is that 'there are no reliable or seriously envisioned practical and politically accepted means of managing costs anywhere near the extent that is necessary' (Callahan 2009). He further argues that when the costs of the benefits of medical technology begin to exceed what a community or nation can afford, then questions need to be raised about when 'enough is enough' and how the point of 'enough' might be determined (Callahan 2009).

The complexities associated with an ageing population, the increasing burden of chronic disease, climate change and the depletion of the world's non-renewable resources raise critical questions about how prepared the nursing profession is to respond to what have been termed the 'three Rs' (Wynia 2007) when faced with 'extreme events', that is: *rationing* (e.g. of medications, mechanical life support), *restrictions* (e.g. on people's access to and from

healthcare services) and *responsibilities* (of healthcare professionals to continue providing care and treatment when resources are scarce or depleted).

The ethical consequences of these evolving scenarios are likely to be incremental, rather than sudden. Even so, without forward planning encompassing a comprehensive vulnerability analysis, nurses will not be well placed to prepare for or mitigate the tough ethical challenges and choices that lie ahead.

Being ethical in extreme situations can be particularly challenging because it may not be clear what is the right thing to do. Considering ethical quandaries in advance will help mitigate this difficulty. In the meantime, it is timely for attention to be given to the following questions:

- What steps need to be taken now to ensure the development of a viable and sustainable healthcare system that is responsive and well coordinated to meet the needs of future generations?
- Will the solutions proposed be effective and just?
- What processes do the nursing profession need to engage in if it is to contribute meaningfully to public policy debate and agenda setting for achieving a sustainable and just healthcare system for all people across the life span?

• CRITICAL REFLECTION POINT

Review the six commonly identified ethical issues in nursing. Then reflect on how important you believe these issues really are to the profession and practice of nursing and what other issues ought also to be placed on the nursing ethics agenda for consideration and debate by nurses. Then compare these to the 'everyday ethical issues in nursing' which have been presented in this chapter. Reflect on whether you agree or disagree with this list and the rationale for your response.

'Everyday' ethical issues in nursing

As well as having to deal with the procedural issues of ethics – that is, identifying ethical issues and responding to them effectively – and the 'life and death' issues commonly associated with the discipline of bioethics, nurses have to grapple with 'everyday' ethics. Everyday ethics in nursing derives from the experiences of nurses (and their patients) in day-to-day 'hands-on' practice. Unlike the more 'exotic' issues of bioethics (discussed above), everyday ethics in nursing concern such things as:

- moral boundaries of nursing
- catalysts to moral action (e.g. the look of suffering in a patient's eyes)
- operating moral values (e.g. sympathy, empathy, compassion)
- ethical decision-making processes in nursing and healthcare contexts
- barriers to ethical practice
- need for cathartic moral talking
- self-care.

When nurses talk about everyday ethical issues, their conversations are not about the so-called paramount or exotic issues of bioethics (such as abortion and euthanasia), but about the more fundamental issues of (Johnstone 2016):

- how to help a patient in distress in the 'here and now'
- how to stop 'things going bad for a patient'
- how to best support a relative or chosen carer during times of distress and when the 'system' appears to be against them
- how to make things 'less traumatic' for someone who is suffering
- how to reduce the anxiety and vulnerability of the people being cared for
- where nurses can get help for their own distress
- how to make a difference in contexts where indifference to the moral interests of others is manifest.

The moral responsibility of nurses to engage in 'self-care' (see Value statement 4 of the *Code of ethics for nurses in Australia* (NMBA 2008a)) is another 'everyday' issue that is finding its way into the conversation of nurses.

The above concerns are just as worthy of attention by nurses and others as are the more 'exotic' issues of bioethics. The everyday ethical issues identified constitute an important component of nursing ethics and warrant in-depth consideration in the interests of promoting ethical practice in nursing and related care contexts.

Conclusion

The courage, moral wisdom and intelligence to act, both as an advocate for patients and as a professional member of the healthcare team, come only after a committed effort to learn and to understand ethical issues in nursing and health care. The professional nurse has an important point of view regarding patients, the healthcare system that supports patients and the institutions that constitute the healthcare system. The nurse both owes a duty and enjoys a privilege to articulate that point of view. Learning the language and practice of ethics is a part of the skill necessary to exercise this duty and privilege. In addition, review and contemplation of various ethical constructions of different issues assist nurses in the formulation of considered ethical professional points of view, a necessary ingredient in the negotiation of difficult ethical situations.

Key concepts

- Ethics involves thinking critically about and engaging in a systematic examination of what constitutes right and wrong/good and bad conduct, and the bases upon which we might justify our judgements about the ideals of right and wrong conduct.
- Bioethics refers specifically to ethical issues that arise in the context of biomedical research and healthcare service delivery.
- Nursing ethics involves the examination of all sorts of ethical issues from the perspective of nursing theory and practice.
- A code of ethics is a conventionalised set of rules or expectations devised for the purposes of guiding ethical professional conduct.
- The study of ethics, bioethics and nursing ethics is of fundamental importance for members of the nursing profession.
- Nurses are morally accountable and morally responsible for their actions.
- Nurses maintain ethical competence in practice and assume responsibility for nursing judgements.
- Nurses have a professional ethical responsibility to patients, the profession and society to provide safe, high-quality healthcare and to maximise patient wellbeing and welfare.
- Common ethical principles used to guide decision-making and conduct in health care are autonomy, beneficence, non-maleficence and justice; they are not, however, the only guides to moral conduct and may even be inappropriate for guiding decision-making in some cultural contexts.
- Rights and duties are also important considerations in guiding moral decision-making and conduct in healthcare settings.
- Ethics is the product of the culture and times from which it has arisen and is fundamentally concerned with the promotion of human wellbeing and welfare.
- Moral problems can arise when practitioners lack educational preparation for dealing with ethical issues in the workplace. These include differences in moral values, beliefs and attitudes, and commitment with respect to performing one's moral duty. Professional role change, technological advances and social issues also challenge unthinking perspectives about what constitutes the moral life.
- Moral problems can be resolved by using a systematic process for moral decision-making and action. Critical thinking, moral intuition and emotion are all-important to the decision-making process.
- Moral problems may occur in any segment of the healthcare delivery system.
- Moral mistakes can be made when nurses and allied health workers 'rush to judgement' and rely on personal opinion, values and beliefs rather than evidence and sound moral theory to guide their moral decision-making and actions.
- The nurse's observations and considered judgements (the 'nursing point of view') can play a vital role in the correct identification and resolution of moral problems.

Online resources

Global Alliance for the Rights of Older People (GAROP) – information and resources on the rights of older people to be free of discrimination and to have their human rights respected; co-participant in global campaign calling for the development of a Convention on the Rights of Older People, www.rightsofolderpeople.org/

HelpAge International – information and resources concerning the global campaign calling for the development of a Convention on the Rights of Older People together with the creation of a new special rapporteur on older people's rights who would report to the Human Rights Council, www.helpage.org/what-we-do/rights/towards-a-convention-on-the-rights-of-older-people/

People's Health Movement – resources and information including Charters and Declarations (including the People's Charter for Health), position statements, newsletters, videos, photographs and other publications on people's right to health, www.phmovement.org/en

The Virtues Project – resources and information including publications, posters, audiovisual material, and a list of 52 virtues which are presented as core ingredients that people may use to 'create a culture of character'. Some examples of the better known moral virtues include: altruism, caring, compassion, cooperation, courage, diligence, empathy, excellence, fairness (justice), forgiveness, friendship, generosity, kindness, love, loyalty, personal integrity, reliability, respectfulness, sympathy, trustworthiness and wisdom, www.virtuesproject.com/

World Health Organization (WHO) Quality Rights Project – resources and information on the Quality Rights Project, which aims to 'improve the quality and human rights conditions in mental health and social care facilities and empower organizations to advocate for the rights of people with mental and psychosocial disabilities'. It is envisaged that the Project will leave a lasting legacy of respect for the human rights of people with mental illnesses and psychosocial disabilities, www.who.int/mental_health/policy/quality_rights/en/

CHAPTER

10

Practising nursing within Australian regulatory frameworks

Mary Chiarella and Amanda Adrian

Learning outcomes

Mastery of content will enable you to:

- recognise and define key terms and principles
- explain the legal concepts that apply to nurses
- describe the legal responsibilities and obligations of nurses
- identify sources for standards of care for nurses
- define the legal aspects of nurse–patient, nurse–doctor, nurse–nurse and nurse–employer relationships
- give examples of legal issues that arise in nursing practice.

KEY TERMS

Assault and battery, p. 178
Brain death and organ donation, p. 182
Caring for persons who are dying, p. 182
Community health nurses, p. 187
Confidentiality and privacy, p. 177
Consent, p. 178
Continuing professional development, p. 167
Critical care nursing, p. 189
Documentation, p. 176
Do not resuscitate (DNR), p. 186
Dying with dignity, p. 181
Emergency departments, p. 187
Floating, p. 187
Giving information, p. 179
Guiding principles for safe, professional practice, p. 168
Hospital in the home, p. 190
Law of contract, p. 184
Legal and professional boundaries (of nursing), p. 168
Legal issues, p. 187
Legal liability in nursing, p. 171

Safe nursing practice requires an understanding of the legal framework within which nurses must function. As with all aspects of nursing today, an understanding of the implications of the law supports and informs critical thinking on the nurse's part. Nurses need not fear the law, but instead view the information that follows as the framework for understanding what can reasonably be expected by society from professional nurses. It is important to be aware that the laws in our society are constantly changing to meet the needs of the people they are intended to protect. This is particularly so in the area of health, where rapid developments in healthcare technology pose unforeseen ethical dilemmas for clinicians and the community, many of which have to be resolved by legal determinations, either through the courts or through the passing of new legislation. In 1970, Justice Windeyer made the observation that the 'law march[es] with medicine but in the rear and limping a little' (*Mount Isa Mines Limited v Pusey* (1970)). In addition, the community is becoming better informed about their rights to health care. Although federal laws apply to all states and territories, there are variations in state and territory laws across the country that will have implications for nursing practice. It is therefore important that nurses familiarise themselves with the laws in the jurisdiction(s) where they work and also those that might relate to their profession and particular specialist area of practice.

As midwifery is now regulated as a separate profession, unless there is a matter that overlaps both nursing and midwifery, this chapter will only discuss matters relating to nursing.

Regulation of nursing in Australia

The **regulation of the nursing profession** in Australia is now part of a national registration and accreditation scheme (NRAS) under the Health Practitioner Regulation National Law (the National Law) as in force in each state and territory. The nursing and midwifery professions have separate registers but are governed by a single national board – the Nursing and Midwifery Board of Australia (NMBA). The Australian Health Practitioners Registration Authority (AHPRA) administers the NRAS on behalf of the 14 national boards, one of which is the NMBA.

The primary purpose of the Australian (and most other) regulatory schemes is to protect the community from people not 'suitably trained and qualified to practise in a competent and ethical manner' (s. 3(2)(a) National Law). The area of law that governs the regulation of their conduct and practice is known as a **protective jurisdiction** and the agencies, boards and other instruments created by it, all exist to protect the community from the risk of harm. This form of occupational regulation provides:

- a barrier to entry to the professions by untrained persons
- the establishment of codes and standards for professional education, conduct, ethics and practice
- mechanisms for these codes and standards to be enforced
- an avenue for consumers to have complaints against nurses and midwives addressed (N3ET 2006).

There are two entry portals into the nursing profession: as a registered nurse (RN); and as an enrolled nurse (EN). In addition, it is also possible for an RN to later become endorsed as a nurse practitioner (NP).

Once students have successfully completed their education program they apply for registration as an RN or EN. This process requires the student to provide evidence in two areas: the first is evidence that they have the requisite academic qualifications and have demonstrated all the relevant standards for practice and/or competencies to practise as a new graduate and beginning practitioner (NMBA 2016); the second is evidence that they meet the registration standards related to English language (NMBA 2015a), professional indemnity insurance standard (NMBA 2012) and criminal history (NMBA 2015b).

Students enrolled in nursing programs are also required to be registered from first year. However, the obligation to register students is on education providers, who are responsible to ensure they have provided the AHPRA, on behalf of the NMBA, with the details of all students enrolled in an approved program of study or who are undertaking clinical training. An 'approved' program of study is one that is accredited by the Australian Nursing and Midwifery Accreditation Council (ANMAC) and approved by the NMBA. Students are registered in the interests of community safety. Student registration allows the NMBA to act on matters relating to students with health impairments or when convictions of a serious nature may affect community safety. Unlike the register for registered nurses, the student register is not published on the NMBA or AHPRA websites and is not publicly available, nor is it accessible to education providers, health services or students. Under the National Law, information on the student register must remain confidential (NMBA 2015c). For registered nurses, renewing registration each year requires nurses to attest they are continuing to practise competently and ethically, meeting the initial standards for registration and, in addition, maintaining and developing their professional knowledge, skills and expertise by also meeting the recency of practice standard (NMBA 2010a)

and the **continuing professional development** standard (NMBA 2010b).

The safety and quality framework

The NMBA also provides guidance for practising safely and ethically to meet the expectations of the community and the nursing profession. This guidance in Australia is set out in a safety and quality framework and includes a number of key documents that contain strong statements about the standards expected of the nurse. Students enrolled in nursing programs are also expected to conduct themselves according to these codes and standards and their continuing enrolment and student registration is contingent on behaving in a professional manner, even as students.

Professional conduct

Professional conduct is the manner in which a person behaves while acting in a professional capacity as a nurse. It is generally accepted that, when performing their duties and conducting their affairs, professionals will uphold exemplary standards of conduct, commonly taken to mean standards not generally expected of lay people or the 'ordinary person in the street'. The *Code of professional conduct for nurses in Australia* (NMBA 2013a) forms one of the key elements of the safety and quality framework for the nursing profession in this country. The purposes of the Code are to:

- outline a set of minimum national standards of conduct that members of the nursing profession are expected to uphold
- inform the community of the standards of professional conduct it can expect nurses in Australia to uphold
- provide consumer, regulatory, employing and professional bodies with a basis for evaluating the professional conduct of nurses.

The conduct statements contained in the *Code of professional conduct for nurses in Australia* are set out in Box 10-1.

Each of the conduct statements is accompanied by a series of explanations to further clarify their meaning.

Ethical behaviour

Ethical behaviour is the necessity to 'respect, promote, protect and uphold the fundamental rights of people who are both the recipients and providers of health care'. The *Code of ethics for nurses in Australia* (NMBA 2013b) forms another of the key elements of the safety and quality framework for nurses in Australia. Like the *Code of professional conduct*, *the Code of ethics* addresses the ethical challenges that confront nurses in their professional and personal lives as an RN. The purposes of the *Code of ethics for nurses in Australia* are to:

- identify the fundamental ethical standards and values to which the nursing profession is committed, and that are incorporated in other endorsed professional nursing guidelines and standards of conduct
- provide nurses with a reference point from which to reflect on the conduct of themselves and others
- guide ethical decision-making and practice, and
- indicate to the community the human rights standards and ethical values it can expect nurses to uphold.

The *Code of ethics for nurses in Australia* contains a number of value statements, each with explanatory notes.

Standards for practice

These are the core standards or competencies by which performance is assessed to obtain and retain registration as an RN, EN or NP, and outline the standards expected for the application of knowledge, skill, judgement and care in the practice of nursing. In Australia, these have traditionally been titled 'national competency standards'.

BOX 10-1 Professional Conduct Statements

- Nurses practise in a safe and competent manner.
- Nurses practise in accordance with the standards of the profession and broader health system.
- Nurses practise and conduct themselves in accordance with laws relevant to the profession and practice of nursing.
- Nurses respect the dignity, culture, ethnicity, values and beliefs of people receiving care and treatment, and of their colleagues.
- Nurses treat personal information obtained in a professional capacity as private and confidential.
- Nurses provide impartial, honest and accurate information in relation to nursing care and healthcare products.
- Nurses support the health, wellbeing and informed decision-making of people requiring or receiving care.
- Nurses promote and preserve the trust and privilege inherent in the relationship between nurses and people receiving care.
- Nurses maintain and build on the community's trust and confidence in the nursing profession.
- Nurses practise nursing reflectively and ethically.

Nursing and Midwifery Board of Australia (NMBA), Australian College of Nursing and Australian Nursing Federation 2013b Code of Professional Conduct for Nurses in Australia (rebranded).

However, they are now known as 'standards for practice' (RN – NMBA 2016, EN – NMBA 2011, NP – NMBA 2014). The purpose of these standards is to provide an evidence base to describe the core standards for practice for each professional group within nursing. The standards are regularly updated and reviewed and can be used by educators, governments, nursing professionals, employers and regulators to prepare and assess the performance of a nursing professional.

Decision-making framework (DMF)

Nurses, particularly RNs, often lead a team of health professionals and other workers. This team may include other RNs, ENs and assistants in nursing (AINs), as well as other staff such as porters and care assistants. In addition, nurses work closely with other health professionals such as medical practitioners, physiotherapists, pharmacists and other allied health staff. Work sometimes flows seamlessly between these groups based on issues such as the context of practice and patient needs. However, it is sometimes difficult for nurses to make decisions as to when to make and accept delegations of care and the purpose of the DMF is to provide advice and guidance in relation to making and accepting delegations (NMBA 2013c).

Boundaries of professional practice

Professional boundary violations have been a recurrent source of notifications to nursing regulatory bodies in Australia. Professional nurses must understand the **legal and professional boundaries** of their daily nursing practice. Such an understanding, combined with a sound ethical compass, good judgement and clinical skills, supports safe and appropriate nursing practice.

Nurses have previously identified four categories of concern in relation to setting **professional boundaries** and the risks of boundary violations (ANMC 2007). These were: therapeutic relationships, access to or disclosure of information, gifts or services and financial relationships, and dual relationships. One frame of reference that can be used to illustrate the range of professional behaviour is the 'continuum of professional behaviour' contained in the document *A nurse's guide to professional boundaries* on the NMBA website (NMBA 2013d). The concept is that professional behaviour exists on a continuum from under-involvement to over-involvement. In the centre of that continuum is the 'zone of helpfulness', which is delimited by flexible boundaries. The **guiding principles for safe, professional practice** have been derived from the categorisation of reported behaviours and are used in conjunction with a framework for boundary decision-making, which was also developed as part of the study. The 16 principles of safe practice provide a set of guidelines based on the collective wisdom of experienced nurses to help other nurses in establishing and maintaining professional boundaries (NMBA 2010b).

The application of the safety and quality framework to clinical practice

These documents have been developed to assist nurses in their daily practice. They are not prescriptive but principle based, and their intent is to enable nurses to reflect on the complex and sometimes difficult professional and ethical issues they encounter in clinical practice. Should a nurse be called to account for their practice in a court, tribunal or other regulatory body, these are the documents that will inform the standards against which they would be judged.

Complaint and disciplinary procedures

The National Law also establishes complaint and disciplinary procedures to ensure the protection of the community from nurses who, for whatever reason, may be unsuitable or unable to safely, competently or ethically practise. The registering authority has wide-ranging powers to ensure the protection of the community, from requiring nurses to undertake additional education to the ultimate sanction of removal of a nurse's name from the register. By far the most common form of sanction or legal involvement for a nurse in Australia is to be involved in professional disciplinary proceedings, a far more common occurrence than civil proceedings. It is important for nurses to appreciate that the registering authorities regard their duty to protect the public very seriously through the hearing of legitimate complaints. Complaints may be about a range of matters and, while not all complaints proceed to disciplinary hearings, all complaints will be the subject of a preliminary investigation and consideration by the regulatory authority. A range of processes is available to the NMBA on receipt of a complaint, ranging from a determination to do nothing about the complaint to a decision to have the complaint heard before a disciplinary hearing. The outcome of a disciplinary hearing may result in sanctions to protect the public, ranging from conditions being placed on the nurse's ability to practise at one end of the spectrum to removal of their name from the register or roll at the more serious end.

Under the legislation, practitioners, employers and education providers are all mandated by law to report *notifiable conduct* relating to a practitioner or, in the case

of a student, an impairment that may place the public at substantial risk of harm.

Notifiable conduct, in relation to a registered healthcare practitioner, means the practitioner has:

a. practised the practitioner's profession while intoxicated by alcohol or drugs; or

b. engaged in sexual misconduct in connection with the practice of the practitioner's profession; or

c. placed the public at risk of substantial harm in the practitioner's practice of the profession because the practitioner has an impairment; or

d. placed the public at risk of harm because the practitioner has practised the profession in a way that constitutes a significant departure from accepted professional standards (s. 140 National Law) (AHPRA 2014a).

It should also be noted that notifications and complaints are managed differently in New South Wales and Queensland, with state legislation working alongside the National Law in a co-regulatory way. In NSW, the Nursing and Midwifery Council (NMC) carries out its regulatory functions in conjunction with the Health Care Complaints Commission established under the Health Care Complaints Act 1993 (NSW) (AHPRA 2014b).

In Queensland, complaints are received by the Office of the Health Ombudsman (OHO) under the Health Ombudsman Act 2013 (Qld). The OHO assesses the severity and determines which complaints go to the NMBA, and those to be managed by the OHO. When complaints are referred to the relevant national boards (which AHPRA will manage on their behalf), the process that is followed is the same as in other states and territories (AHPRA 2014a).

Notifications or complaints about nurses generally fall into the three categories of performance:

1. **Performance** – where it is alleged the standard of a nurse's performance has fallen significantly below the standard reasonably expected, given the individual nurse's level of training or experience. As a result of a performance assessment, the NMBA can take a number of actions including referring the matter to a performance and professional standards panel, imposing conditions on/accepting an undertaking from the practitioner, cautioning the practitioner, requiring the practitioner to undergo a health assessment or referring the matter to a tribunal (AHPRA 2013).
2. **Professional conduct –**
   a. ***Unprofessional conduct*** of a nurse means professional conduct that is of a lesser standard than that which might reasonably be expected of the health practitioner by the public or the practitioner's professional peers (s. 5 National Law).
   b. ***Professional misconduct*** of a registered health practitioner is the more serious of the two categories and relates to unprofessional conduct by the practitioner that amounts to conduct that is *substantially* below the standard reasonably expected of a registered health practitioner of an equivalent level of training or experience. Complaints that are substantiated can result in the suspension or cancellation of the practitioner's registration (s. 5 National Law).

   Conduct issues are generally related to behavioural acts or omissions. Following investigation of a complaint, disciplinary action may be taken by a professional standards committee or tribunal, depending on the seriousness of the complaint (AHPRA 2014b).
3. **Health –** Complaints about health matters concerning nurses relate to physical or cognitive impairment, substance abuse and/or mental illness. A non-disciplinary Impaired Registrants Panel (IRP) may be established to assess the physical or mental impairment of the nurse and determine a course of action. This may result in assisting impaired nurses to manage their condition while they remain employed or there may be a recommendation to make their registration conditional, for example, suspension (AHPRA 2013).

The NMBA and the Nursing Council have the power to take immediate action to suspend or place conditions upon the practice of a nurse if they are provided with information that the conduct, health or performance of a nurse is likely to pose a serious risk to the community. The NMBA can also accept an undertaking from a nurse and the surrender of their registration (s. 155 National Law).

This is only an interim step, while a complete investigation can take place and other action can occur after a formal hearing by a committee, panel or tribunal. Table 10-1 lists situations where the NMBA and the Nursing Council may take immediate action.

This is a serious step and not taken lightly by the NMBA or Council. The threshold to take immediate action is necessarily high and to do so the NMBA must reasonably believe that:

- because of their conduct, performance or health, the nurse poses a 'serious risk to persons' and that it is necessary to take immediate action to protect public health or safety, or
- the nurse's registration was improperly obtained, or
- the nurse's registration was cancelled or suspended in another jurisdiction (s. 156 National Law).

TABLE 10-1 Matters the NMBA may consider require immediate action

CATEGORY	EXAMPLE
Police charges	Particularly offences relating to a health practitioner's work or professional practice, for example, assaulting a patient.
Patient outcome	A patient has died unexpectedly or a routine operation has had severe adverse outcomes.
Drugs	Notified by a practitioner, or an independent body. Includes accusations of self-administering, and inappropriate prescribing of illicit or prescription drugs.
Alcohol	Allegations of presenting to work under the influence of alcohol.
Sexual behaviour	Inappropriate touching or professional/sexual boundary violation.
Theft	Stealing drugs from the workplace.
Health	Impairments – serious (e.g. involuntary admission to hospital under the Mental Health Act) or concerns about memory/behaviour.
Breach of conditions	A practitioner has conditions on their registration and the conduct/incident described may breach registration conditions.

Australian Health Practitioner Regulatory Agency (AHPRA) 2013 Fact Sheet: Immediate action, June. Melbourne. Online. Available www.ahpra.gov.au/Notifications/Fact-sheets/Immediate-action.aspx; accessed 16 July 2015.

Comprehensive information about the notifications process, investigation, panels and tribunals is available through the NMBA and AHPRA websites.

In relation to registered students, the NMBA's focus is mainly on managing notifications. This applies to those students who have a health impairment to such a degree that there may be substantial risk of harm to the community; have been found guilty of an offence punishable by 12 months imprisonment or more; have a conviction of, or are the subject of, a finding of guilt for an offence punishable by imprisonment; or contravened an existing condition or undertaking (NMBA 2015c).

Sources of law

If nurses are to understand and comply with the law, they must be able to find it. The two major **sources of law** are legislation and case law. *Legislation* includes both primary legislation, such as statutes or Acts of Parliament, and secondary legislation, such as regulations and by-laws. The government makes primary legislation, either at federal level or at state and territory level. The federal government makes legislation governing, for example, the operation of Medicare (Human Services (Medicare) Act 1973 (Cth)), whereas the state or territory governments make legislation governing, for example, the management of the hospitals and health services (Health Administration Act 1982 (NSW)), as well as the legislation previously mentioned regulating the nursing and midwifery practitioners (Health Practitioner Regulation National Law 2009 as in force in each state and territory).

Case law as a source is usually referred to as common law. It consists of the individual decisions made by judicial decision-makers, such as judges in courts of law and other legal hearings. It is sometimes called 'interstitial law' because, like interstitial fluid, it fills the gaps left by the legislative sources of law. Examples of common law include famous cases like the Australian High Court decision in *Rogers v Whitaker* (1992) in which the High Court determined the extent of the medical practitioner's duty to advise a patient before performing surgery. At state level, case law includes both tribunal decisions and appeals against the decisions of disciplinary tribunals, such as *Nursing and Midwifery Board of Australia v Buckby* [2015] WASAT 19 (9 March 2015).

Figure 10-1 provides a useful schema for understanding common law.

The regulation of nurses and midwives through the National Law is in the areas of administrative law and protective law. However, at the third level, the common law is classified into the two main areas of criminal and civil law. *Criminal law* can be defined as 'essentially rules of behaviour, backed up by the sanction of punishment, which govern our conduct in the community, having regard to other people and their property' (Staunton & Chiarella 2013). There are laws relating to misuse of controlled substances, such as drugs of addiction, which provide examples of criminal law that impinge on nursing practice, for example, the Drugs Misuse Act 1986 (Qld). It is usually the role of the police to enforce criminal law and they have extensive powers to be able to do so.

In contrast, *civil law* deals with the resolution of private disputes between individual persons and/or organisations. Civil law has many divisions within it, such as family law, industrial law, land and environment law, and workers' compensation. There is also what is known in civil law

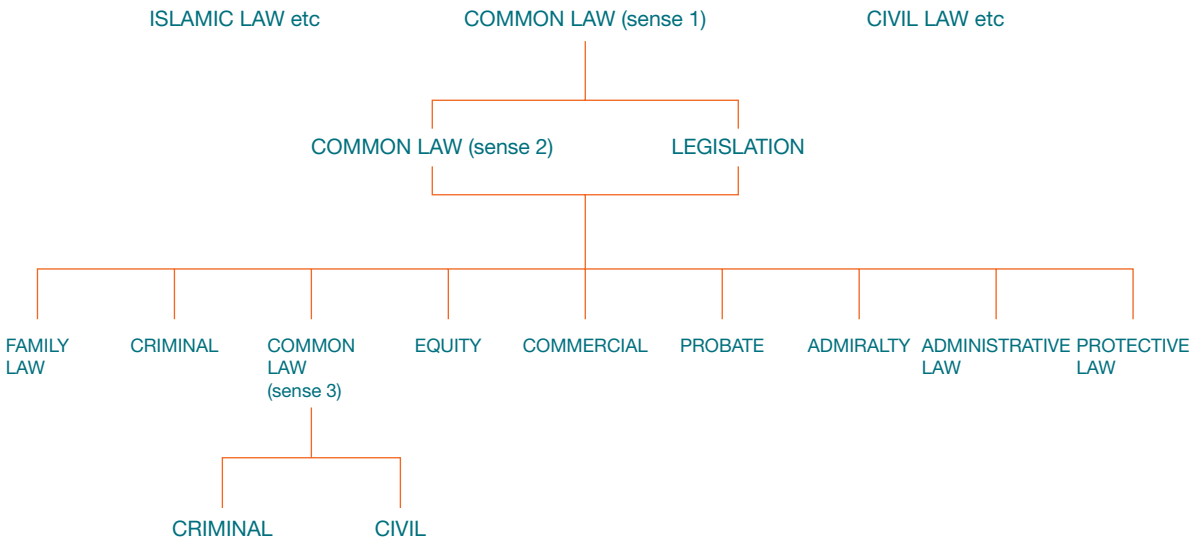

Figure 10-1 Common law and sources of law.

Chisholm R, Nettheim G 2012 Understanding law, 8th edn. LexisNexis Butterworths, Chatswood.

as a common-law division which deals with the most recognised common-law principles, such as contract law, negligence, defamation or nuisance (Staunton & Chiarella 2013). Generally, violations of civil law cause harm or damage to people or property. Civil law remedies often involve payment of compensation, but other remedies may involve reinstatement in a job, as in the industrial courts.

Legal liability in nursing

Legal liability in nursing means that an individual is subject to a legal obligation. One of the important distinguishing features of the breach of a legal obligation is that there is usually some form of legal action for its breach. There are four potential legal actions available to patients who might suffer an adverse event as a result of their healthcare experience:

- punish offenders and deter potential offenders (criminal law)
- compensate injured victims (civil law)
- protect the public against incompetent or grossly deficient moral qualities or technical proficiency (protective law – professional misconduct)
- provide information and review decision-making procedures (administrative law).

The first three remedies or legal actions are divided into the divisions of criminal law, civil law and protective law, and have already been discussed in this chapter. Administrative law remedies only occasionally affect the individual nurse and will not be discussed further here.

The way in which liability is apportioned always depends on the facts of the case and the extent of culpability of each person involved. In criminal and professional misconduct cases, the nurse is personally liable for their wrongs if found to be the culpable party, and is the person who has to undergo the punishment in a finding of criminal liability. In professional misconduct cases, it is the nurse who personally has to answer to the disciplinary tribunal; and who could be subject to conditions being imposed on their registration, or could even lose registration in a finding of professional misconduct. It is clear that such outcomes will affect the nurse directly, and so these two remedies (criminal and professional misconduct) are categorised as ones for which the nurse is personally liable.

In civil cases, in which compensation of the injured party is the remedy, unless the nurse is self-employed or practising outside the scope of their employment conditions, it is most likely that the employer would be held to be what is known as 'vicariously liable' for the wrongs of the nurse. **Vicarious liability** is based on the principle that you are responsible for the actions of those you engage to do your work for you and has its roots in the existence of the special relationship between employer and employee, where the employer is liable for the wrongful acts of the employee provided that they were performed in the course of the employee's employment (Adams 2003). The underlying purpose of the doctrine is to ensure that people who have a legal right to receive compensation are able to receive it, as it is likely to be difficult to obtain compensation payments

from the average employee (Staunton & Chiarella 2013). In Australia, most nurses are employees and are therefore subject to the doctrine of vicarious liability for civil wrongs, such as the tort (wrongful act) of negligence. This does not absolve a nurse from responsibility for their acts, even though they would not have to provide the compensation personally, as they would still have to appear in court and give evidence about their conduct. They might also be subject to criticism from the judges and suffer industrial consequences, such as losing their jobs, depending on the seriousness of the problem. If the matter raises an issue of the professional conduct of the nurse, they may also have a complaint made against them, which is dealt with in the protective jurisdiction of the disciplinary tribunal.

It is possible that an employer might seek to recover some or all of the compensation paid out to the injured party on behalf of the employee nurse, and the employer has the right to do so at common law (*Lister v Romford Ice and Cold Storage Co.* (1957)). In practice, this is rarely done, since there is very little point in seeking money from people who are unable to pay. Some states have even passed legislation to prevent an employer from doing so; in NSW, for example, the Employees Liability Act 1991 states that if the employee commits a tort in circumstances where the employer would be vicariously liable, the employee does not have to indemnify or pay any contribution to the employer in respect of the liability incurred (s. 3). The only exceptions to this are if the conduct of the employee was serious and wilful misconduct or did not occur in the course of, and did not arise out of, the employment of the employee (s. 5); or if the employee was already independently insured or indemnified (s. 6). If no such provision exists, personal professional indemnity insurance would be required. The national registration scheme requires all healthcare professionals to ensure and confirm they have professional indemnity insurance (PII), either through their employer or personally, before they practise (s. 109 National Law). The only exception is in the case of midwives providing homebirth care, as no insurance is available. However, they are required to have insurance for ante-partum and post-partum care, and are also expected to comply with the NMBA's safety and quality framework (s. 284 National Law). Similarly, nurses who are self-employed are personally liable for their own actions and require their own insurance. All states and territories have now developed a statutory basis for civil negligence which provides for similar, although not identical, civil liability arrangements in each jurisdiction (Australian Government Treasury 2004).

Torts

A **tort** is a civil wrong committed against a person or property. The most important torts involving nurses are negligence and trespass to the person. Defamation is also of limited concern for nurses, although the need for confidentiality ought normally to override any risk of defamation. In relation to the purposes of the law of torts, it has been argued that 'the first of these purposes is the pursuit of corrective justice. This entails the normative proposition that innocent people should not bear the financial burden of harm caused by the negligent actions of another. The second purpose relates to tort law's role in setting standards of conduct' (Grey 2006:557). Whichever purpose is relevant, the actual outcome of a compensation claim is to shift the financial burden of injury from the one who suffered it to the one who was responsible for its cause.

Negligence

The tort of **negligence** relates to incidents where a person has suffered an injury to themselves or their property as a result of another person's act or omission that fell below an expected standard of care. For an action in negligence to succeed, the person complaining of the injury must prove, to a requisite standard of proof, that:

1. the person or organisation causing the injury owed them a duty to take reasonable care (known as a duty of care)
2. there was a breach of that duty, and
3. the damage that the injured person suffered occurred as a reasonably direct result of the breach of duty (Staunton & Chiarella 2013).

In negligence, it does not matter that the person who caused the injury did not mean to do so, because the purpose of the action is to recover damages for the injury.

For Australian nurses, although there are very few negligence cases involving nurses, the sorts of acts or omissions that might give rise to an action in negligence have included such diverse matters as:

- failure to question further a wrong medical order for ear drops, causing the recipient to go deaf – *Henson v Board of Management of Perth Hospital* (1939)
- failure to adequately sterilise a container for eye drops, leading to the child suffering from defective eyesight – *Smith v Browne & ors* (1974)
- failure to give an immunisation injection in the proper place, leading to severe scarring – *Stepanovic v ACT* (1995)
- failure to account for the swabs accurately during an operation, leading to a swab being left in a patient's

abdomen – *Langley & anor v Glandore Pty Ltd (in Liq) & anor* (1997); *Elliott v Bickerstaff* [1999].

It is important to realise that it is not the severity of the injury that determines the question of negligence (although it will be critical to the extent of the compensation), but rather the question of whether there was a departure from the proper standard of care that caused the patient's injury. Even with the best care in the world, sometimes in health care there are tragic outcomes that are not foreseeable.

The best way for nurses to avoid being involved in actions related to negligence is by maintaining contemporary and professional standards of care; providing care that is safe and within the limits of their own competence; communicating carefully and coherently with other healthcare providers; documenting assessments, interventions and evaluations fully; and developing and maintaining respectful and positive relationships with patients. Good communication and relationships are critical in this regard. Failure in doctor–patient communications has been stated not only to lead to generalised patient dissatisfaction, but also to increase the risk of litigation should the patient suffer an injury or other adverse event while in hospital (Australian Commission for Safety and Quality in Health Care 2008). Overall, the Australia community thinks very highly of nurses – in ethics and honesty polls, nurses regularly come high on the list of people Australians trust (Roy Morgan 2015). Nurses must justify this faith in them by ensuring that they deliver safe and appropriate nursing care.

Students' participation in the delivery of nursing care

As noted above, students enrolled in nursing programs in Australia are required to be registered to be able to participate in the essential workplace experience components of their education. Nursing students are expected to uphold professional standards when practising in the clinical areas, should be carefully supervised when learning new skills and should otherwise practise within the limits of their competence.

Patients are entitled to receive a safe standard of care, regardless of whether the care is delivered by a registered or a student nurse. However, if students were not allowed to touch patients, they would never properly learn nursing skills or the nuances of clinical decision-making in a 'real' environment. Similarly, experienced nurses have a professional obligation to share their knowledge and expertise to assist less-experienced nurses to give optimal patient care. Both experienced nurses and nursing students are jointly responsible for ensuring that students are properly supervised and are never placed in a situation where the patient's wellbeing might be at risk in any way. When students are learning a new clinical skill the supervising clinician must ascertain whether or not the student is adequately prepared to undertake the procedure. They should have had previous practice in the nursing laboratories, and should be carefully supervised by an experienced and competent nurse, either from the faculty or from the clinical environment where the student is working. If students feel uncertain for any reason, it is their responsibility to advise the supervising nurse of their concerns. Faculties of nursing need to make specific arrangements with facilities where students are placed regarding supervision and liability for any adverse events that may occur. All supervising staff, be they faculty or clinical, need to be very clear about their responsibilities towards the students and the patients in their care.

Many nursing students find work as assistants in nursing or as nurses' aides when not attending classes. However, it is important to recognise that, although such employment will undoubtedly provide valuable experience in interpersonal skills and basic nursing care, the student is employed as an unqualified member of staff and must not take on responsibilities outside the scope of that employment, just because it is possible to do so by virtue of their educational program. In such a situation, the employing authority whose staff assigns such work to students may be liable for any adverse events that occur because of the delegation, as may the students themselves if they practise outside the scope of their employment. Valuable advice on the delegation and acceptance of authority for registered nurses, midwives and students can be found in the decision-making frameworks for nurses and midwives endorsed by the NMBA (NMBA 2013c).

Standards of care

Section 39 of the National Law provides that the Board may develop and approve codes and guidelines and section 41 of the National Law provides:

> **An approved registration standard for a health profession, or a code or guideline approved by a National Board, is admissible in proceedings under this Law or a law of a co-regulatory jurisdiction against a health practitioner registered by the Board as evidence of what constitutes appropriate professional conduct or practice for the health profession.**

The most important sets, standards, codes and guidelines approved by the NMBA for nurses to be aware of are the registration standards and those identified as part of the safety and quality framework discussed above:

- The *Code of professional conduct for nurses in Australia* (NMBA 2013a).
- The *Code of ethics for nurses in Australia* (NMBA 2013b).

- *Decision Making Frameworks* (DMF) (NMBA 2013c).
- *A nurse's guide to professional boundaries* (NMBA 2013d).
- The standards for practice/competency standards for RNs, ENs and NPs identified earlier (RN – NMBA 2016, EN – NMBA 2011, NP – NMBA 2014).

The national standards for practice/nursing competencies have been accepted by the NMBA for registration as the minimum competencies to be demonstrated by nurses for entry to the practice of nursing. It is expected that all nurses, registered and enrolled, will be able to demonstrate these competencies, with experienced nurses achieving higher standards than beginning practitioners. All education providers must demonstrate that nursing education programs leading to registration or enrolment enable students to meet these standards for practice/competencies, and all graduating nurses have to be able to meet these criteria to be eligible for entry to the registers. These standards have been used in courts of law to determine appropriate standards of practice, for example, *HCCC v Kocsis* [2011]. Box 10-2 below outlines the current national standards for RNs.

In a recent decision of the Western Australian State Administrative Tribunal (WASAT) *Nursing and Midwifery Board of Australia v Buckby* [2015] WASAT 19, the Tribunal relied on the *Code of professional conduct for nurses in Australia* (NMBA 2013a), the *Code of ethics for nurses in Australia* (NMBA 2013b) and *A Nurse's guide to professional boundaries* (NMBA 2013d) to find the conduct of the nurse in that case was in breach of the standards outlined in these codes and guidelines to such an extent that:

> **The practitioner's conduct would reasonably be regarded by his professional brethren of good repute and competency as dishonourable. The practitioner's conduct would incur strong criticism from them. His conduct was an egregious departure from the elementary and generally acceptable standards of nurse practitioners[1] [*sic*]. His conduct and comments portray indifference to Patient A [and B] and to … [their] vulnerable state and were an abuse of the privileges which accompany registration as a nurse practitioner [*sic*].**
>
> **The Tribunal finds the practitioner guilty of professional misconduct.**

1. The nurse was a registered nurse, **not** a nurse practitioner in this case.

BOX 10-2 Registered nurse standards for practice

Standard 1: Thinks critically and analyses nursing practice

RNs use a variety of thinking strategies and the best available evidence in making decisions and providing safe, quality nursing practice within person-centred and evidence-based frameworks.

The registered nurse:

1.1 accesses, analyses, and uses the best available evidence, that includes research findings, for safe, quality practice

1.2 develops practice through reflection on experiences, knowledge, actions, feelings and beliefs to identify how these shape practice

1.3 respects all cultures and experiences, which includes responding to the role of family and community that underpin the health of Aboriginal and Torres Strait Islander peoples and people of other cultures

1.4 complies with legislation, regulations, policies, guidelines and other standards or requirements relevant to the context of practice when making decisions

1.5 uses ethical frameworks when making decisions

1.6 maintains accurate, comprehensive and timely documentation of assessments, planning, decision-making, actions and evaluations, and

1.7 contributes to quality improvement and relevant research.

Standard 2: Engages in therapeutic and professional relationships

RN practice is based on purposefully engaging in effective therapeutic and professional relationships. This includes collegial generosity in the context of mutual trust and respect in professional relationships.

The registered nurse:

2.1 establishes, sustains and concludes relationships in a way that differentiates the boundaries between professional and personal relationships

2.2 communicates effectively, and is respectful of a person's dignity, culture, values, beliefs and rights

2.3 recognises that people are the experts in the experience of their life

2.4 provides support and directs people to resources to optimise health-related decisions

2.5 advocates on behalf of people in a manner that respects the person's autonomy and legal capacity

2.6 uses delegation, supervision, coordination, consultation and referrals in professional relationships to achieve improved health outcomes

2.7 actively fosters a culture of safety and learning that includes engaging with health professionals and others, to share knowledge and practice that supports person-centred care

2.8 participates in and/or leads collaborative practice, and

continued

2.9 reports notifiable conduct of health professionals, health workers and others.

Standard 3: Maintains the capability for practice

RNs, as regulated health professionals, are responsible and accountable for ensuring they are safe, and have the capability for practice. This includes ongoing self-management and responding when there is concern about other health professionals' capability for practice. RNs are responsible for their professional development and contribute to the development of others. They are also responsible for providing information and education to enable people to make decisions and take action in relation to their health.

The registered nurse:

3.1 considers and responds in a timely manner to the health and wellbeing of self and others in relation to the capability for practice

3.2 provides the information and education required to enhance people's control over health

3.3 uses a lifelong learning approach for continuing professional development of self and others

3.4 accepts accountability for decisions, actions, behaviours and responsibilities inherent in their role, and for the actions of others to whom they have delegated responsibilities

3.5 seeks and responds to practice review and feedback

3.6 actively engages with the profession, and

3.7 identifies and promotes the integral role of nursing practice and the profession in influencing better health outcomes for people.

Standard 4: Comprehensively conducts assessments

RNs accurately conduct comprehensive and systematic assessments. They analyse information and data and communicate outcomes as the basis for practice.

The registered nurse:

4.1 conducts assessments that are holistic as well as culturally appropriate

4.2 uses a range of assessment techniques to systematically collect relevant and accurate information and data to inform practice

4.3 works in partnership to determine factors that affect, or potentially affect, the health and wellbeing of people and populations to determine priorities for action and/ or for referral, and

4.4 assesses the resources available to inform planning.

Standard 5: Develops a plan for nursing practice

RNs are responsible for the planning and communication of nursing practice. Agreed plans are developed in partnership. They are based on the RNs appraisal of comprehensive, relevant information, and evidence that is documented and communicated.

The registered nurse:

5.1 uses assessment data and best available evidence to develop a plan

5.2 collaboratively constructs nursing practice plans until contingencies, options priorities, goals, actions, outcomes and timeframes are agreed with the relevant persons

5.3 documents, evaluates and modifies plans accordingly to facilitate the agreed outcomes

5.4 plans and negotiates how practice will be evaluated and the time frame of engagement, and

5.5 coordinates resources effectively and efficiently for planned actions.

Standard 6: Provides safe, appropriate and responsive quality nursing practice

RNs provide and may delegate, quality and ethical goal-directed actions. These are based on comprehensive and systematic assessment, and the best available evidence to achieve planned and agreed outcomes.

The registered nurse:

6.1 provides comprehensive safe, quality practice to achieve agreed goals and outcomes that are responsive to the nursing needs of people

6.2 practises within their scope of practice

6.3 appropriately delegates aspects of practice to enrolled nurses and others, according to enrolled nurse's scope of practice or others' clinical or non-clinical roles

6.4 provides effective timely direction and supervision to ensure that delegated practice is safe and correct

6.5 practises in accordance with relevant policies, guidelines, standards, regulations and legislation, and

6.6 uses the appropriate processes to identify and report potential and actual risk related system issues and where practice may be below the expected standards.

Standard 7: Evaluates outcomes to inform nursing practice

RNs take responsibility for the evaluation of practice based on agreed priorities, goals, plans and outcomes and revises practice accordingly.

The registered nurse:

7.1 evaluates and monitors progress towards the expected goals and outcomes

7.2 revises the plan based on the evaluation, and

7.3 determines, documents and communicates further priorities, goals and outcomes with the relevant persons.

Nursing and Midwifery Board of Australia (NMBA) 2016 Registered nurse standards for practice. Online. Available: www.nursingmidwiferyboard.gov.au/Codes-Guidelines-Statements/Professional-standards.aspx; accessed 14 June 2016.

In addition, as nurses begin to specialise and become more advanced in their practice, there are specialist standards developed by the specialist nursing organisations that advise nurses as to the level of care they are expected to provide. These, too, can be used to assess appropriate standards for practice in a court of law. Other sources of information regarding **standards of care** are policy and procedure manuals, government policy documents and circulars and other guidance that may be added from time to time by the NMBA and can be found on the NMBA website at: www.nursingmidwiferyboard.gov.au.

The best way for nurses to keep up to date with the standards required of them for professional practice is to keep abreast of the current literature, both professionally and in their field of practice; to access online learning opportunities; and attend seminars and conferences relevant to their area of practice. As noted above, there is a requirement for nurses to meet the continuing professional development registration standard for them to renew their registration each year (NMBA 2010b). This is particularly important today with the increasing emphasis on evidence-based practice, and the means of this supporting quality and safety improvement (ACSQHC 2011).

Nurses also need to know and comply with the policies and procedures of their workplace and jurisdiction. They must be aware of the common sources of adverse events, such as medication errors, falls and pressure-area injuries, and must be particularly vigilant regarding the potential for such adverse events to occur. The Australian Commission on Safety and Quality in Health Care (ACSQHC) is an important source of national standards in health care in Australia and has been very active in developing evidence-based standards in important areas including infection control, medication safety, clinical handover, falls prevention and pressure injuries (ACSQHC 2008, 2014).

Document, document, document

If a nurse does become involved in any form of judicial hearing, there is no doubt that good-quality **documentation** will help the nurse defend their conduct in the case. There have been cases in which the nursing records were so complete that the nurse's account of the facts in dispute were accepted in preference to anyone else's account (e.g. *Briffet v Gander and District Hospital Board and ors* (1992); *Spasovic v Sydney Adventist Hospital* [2003]). When the nursing records have been poor, however, the nurse's accounts of any facts in dispute have often been discredited, to the detriment of the nurse (e.g. *Laidlaw v Lion's Gate Hospital* (1969)).

Most states and territories have policies regarding the writing, storage and access to healthcare records and there are many texts that provide useful advice on documentation. Staunton and Chiarella (2013) provide sound guidance for any nurse when writing records. These points are summarised in Box 10-3. There is no doubt that careful, well-written records significantly assist in good patient care, as they provide an accurate account of the care the patients have received, the patients' condition and progress, and care they need to receive in the future. Such information helps clinicians assess patients accurately, evaluate the success or appropriateness of the care given to date, and plan and implement relevant future care. When patients receive well-documented, high-quality care, the likelihood of any complaints or litigation is significantly reduced.

BOX 10-3 Guidelines for documentation and report writing

- Reports are accurate, brief and complete.
- Handwritten records are legible.
- Reports are objective – record only what you saw, heard or did.
- Reports are made at the time of an assessment, treatment, care or incident.
- Avoid making notes and transcribing these onto a patient's healthcare record at a later time.
- Abbreviations are only used if they are universally accepted or authorised by the health service.
- If healthcare terminology is used you are sure of the exact meaning.
- Any errors are corrected by drawing/striking a line through the incorrect component and noting who made and when the correction was made whether in handwritten or electronic records – the corrected component should remain readable.
- Electronic records are checked for errors generated by predictive text or auto-correct.
- Always check the patient's name, healthcare record number and other identifying data on the record before entering any information and ensure that information is on every page of any record you create.
- No entry should be made concerning a patient's assessment, treatment, care or incident on behalf of another nurse or health professional except in circumstances where authorised, for example, observing and recording active management during a cardiac arrest.

Adapted from Staunton P, Chiarella M 2013 Law for nurses and midwives, 7th edn. Elsevier, Sydney.

Confidentiality and privacy

The legal obligations of **confidentiality and privacy** necessarily arise when creating, managing or using healthcare records. However, these two areas deal with matters that are broader than healthcare records, as they go to relationships, trust and having adequate information to provide safe, competent care to patients while ensuring their dignity and integrity is maintained. Although these two concepts are often used interchangeably, they have in fact quite distinct meanings and should be distinguished. 'Confidentiality refers specifically to restrictions upon private information revealed in confidence where there is an explicit or implicit assumption that the information shared will not be disclosed to others' (Kerridge et al 2013: 298), whereas 'Privacy refers to one's ownership of one's body or information about one's self' (Kerridge et al 2013: 298). The expectations of both privacy and confidentiality give rise to legal obligations in Australia.

With regard to privacy, the Privacy Act 1988 (Cth) regulates the handling of personal information by Australian Government agencies and some private sector organisations, requiring agencies to conform to a set of 13 National Privacy Principles (NPPs) when dealing with personal information. These NPPs cover issues including collection, use, disclosure, quality and security of data, as well as issues such as access and openness. State and territory legislation also places similar obligations on agencies and organisations, including private hospitals and health services. This applies to any sensitive information and certainly applies to patient healthcare records and health information.

In relation to confidentiality, there is a range of different common law and statutory mechanisms for imposing confidentiality obligations on nurses. At common law, there are expectations in *contract* (often the nurse's employment contract will contain a confidentiality clause) and *tort* (the standard of care expected of a nurse would include a duty of confidentiality). Under statute, there are several statutory provisions at state and territory level that impose a duty of confidentiality. To illustrate, 'human tissue and public health' statutes (e.g. the Transplantation and Anatomy Act 1978 (ACT)) in all states and territories impose a duty of confidentiality regarding particular pieces of sensitive information. Such a requirement seems quite obvious; after all, patients would not feel able to tell healthcare professionals their most intimate and private details if they could not expect that they would be treated in the strictest confidence. When nurses need to share information that patients have disclosed to them in confidence, such as with other healthcare professionals, they have to seek the patient's permission to do so. Likewise, when another healthcare professional reveals information about a person to the nurse, the nurse must always treat the information as confidential unless advised otherwise.

For nurses there are also the legal and professional obligations imposed on them as the principles of privacy and confidentiality are distilled in the codes of professional conduct and ethics for nurses in Australia and the national standards for practice/competency standards. For example, the *Code of professional conduct for nurses in Australia* notes that nurses have ethical and legal obligations to protect the privacy of patients receiving treatment and care. Information obtained in the course of the relationship between nurses and patients must be kept confidential and restricted to use for professional purposes only (NMBA 2013a, 2013b). Gossiping in the work tearoom about 'interesting patients' or 'amusing moments', or sharing these on social media may seem reasonable, but they are explicit breaches of privacy. They could lead to nurses having a complaint made about their conduct under the National Law (such as in the case of *HCCC v Burggraaff* [2012]), or being dealt with in the court system for a breach of confidentiality or privacy.

There are some exceptional circumstances when healthcare professionals are required by law to disclose highly sensitive information, such as in cases of child abuse or notifiable diseases. The important thing to remember about these exceptions to the duty of confidentiality is that they are not general exceptions. The duty to notify confidential information is always limited to the specific people or authorities that need to know the information, and the extent of the information to be notified is also always limited to the very specific information that is required. The protection of authorised persons who make disclosures under such legislation is usually dealt with as protection from prosecution under the general common law and legislation, for example, under the Public Health and Wellbeing Act 2008 (Vic).

• CRITICAL REFLECTION POINT

Think about the complexity surrounding confidentiality and privacy in nursing practice, where nurses become aware of a great deal of information relating to their patients. What do you think the challenges of maintaining confidentiality and privacy might be in situations where:

1. **You are asked by a relative about something to do with a patient for whom you are caring.**
2. **You overhear colleagues discussing confidential information in a public area.**
3. **A patient reveals information concerning their behaviour that has a potentially detrimental effect on the treatment, but asks you not to tell anyone.**

4. **You are present in the operating theatre when you are asked to take photos on your mobile phone of a patient with a large anatomical deformation and email them to the registrar who has never seen such a thing before. Subsequently, you see them posted on a social media site.**
5. **A famous person is admitted to the unit you are working in and you continue to receive calls from people asking how they are.**

Assault and battery

The terms **assault and battery** might evoke concepts of incredibly violent acts, but they have rather different meanings in civil law, and form part of a group of torts known as 'trespass to the person'. These tort laws exist mainly to protect an individual's personal space, and to deliver compensation when that personal space is violated. Professor Fleming (1998:24) explains that the tort of battery is committed 'by intentionally bringing about a harmful or offensive contact with the person of another. The action serves the dual purpose of affording protection to the individual, not only against bodily harm, but also against any interference with his person which is offensive to a reasonable sense of honour and dignity'. An assault occurs when an individual experiences the threat of such a battery occurring. Ian Kennedy (1984) made the observation that 'the tort of battery exists to keep us free from unconsented-to touchings'.

It is quite clear that nurses may be involved in many procedures that could, in some circumstances, be an interference with the person and offensive to a reasonable sense of honour and dignity. But, of course, the important thing about the personal care nurses provide and the procedures they perform for patients is that these are normally carried out with the patient's **consent**. This is the critical factor in relation to trespass to the person. If the patient consents to the touching or the contact, then there is no battery. Of course, it is important that the patient understands what that touching entails. For example, if a nurse asked to take a patient's pulse and the patient agreed, expecting that the nurse was going to take the radial pulse, but the nurse had in mind the femoral pulse and proceeded to place their hand in the patient's groin, the patient would be rightfully aggrieved that they had not been informed that such a personal intrusion was to occur. In the Australian High Court decision in *Rogers v Whitaker* (1992) at 633, it was held that 'the patient's consent to the treatment may be valid once he or she is informed in broad terms of the nature of the procedure which is intended'.

Obtaining consent

When any healthcare professional wishes to touch a patient, normally there is a requirement for **consent** to be obtained.

On most occasions the patient is able to give consent and it is important to know the requirements for valid consent:

1. Consent must be freely and voluntarily given.
2. Any consent given is given when the person has been provided with adequate information about the procedure, its benefits, side effects, complications and alternate treatments, and has had their questions answered.
3. The person giving consent must: have the legal capacity to give it, that is, be of age, and this varies from state to state/territory; have the mental capacity to understand the intended procedure (Staunton & Chiarella 2013).

In addition, it is important to know how consent may be given, so that nurses know when they have obtained it.

The requirements for a valid consent are exactly the same, regardless of how the consent is given, whether implied, verbal or in writing. An *implied consent* may be given if, for example, a patient rolls up their sleeve and holds out their arm to receive an injection. However, as previously stated, the nurse must be sure that the information which has been given to elicit the implied consent is adequate for the patient to understand exactly how the 'touching' is to occur. A *verbal consent* is the most common type of consent given in nurse–patient interactions. Normally the nurse explains to the patient what is about to happen and the patient agrees verbally to the nurse proceeding. Sometimes the patient may ask questions; for example, if the nurse intends to change a dressing on the patient's wound, the patient might ask whether the procedure will hurt, how long it will take or what the wound might look like. It is important that the nurse takes the time to answer these questions carefully and honestly, otherwise the patient's consent to proceed could be invalid. It is also important to ensure that patients understand what is being explained to them. Patients may be hearing-impaired, or may have difficulty with the language or terminology the nurse is using. Telling a person that sutures are about to be removed or that a cannula will be inserted may be as unhelpful as saying nothing at all.

Written consent is the form of consent used for all major procedures, for any procedure carrying a level of risk and for any experimental procedures. Organisations usually have specific consent forms that try to ensure that all the requirements for valid consent are covered,

and also that the requirements for information-giving are met. The critical factor regarding written consent is that the consent form is only as good as the consent it represents. If the consent itself is invalid for any of the reasons discussed above, having a completed form will be of little benefit. Notwithstanding this fact, the purpose of having written consent forms is to provide evidence of a valid consent. It is anticipated that the requirement to fill out the consent form will act as a trigger to healthcare professionals to obtain a valid consent. This will require them to ensure that the appropriate level of information is provided and an adequate level of understanding is achieved, and will provide evidence that such was the case in the event of any future dispute. Many state and territory health departments have developed stringent and complex policies regarding the obtaining of written consent for procedures, and have designed their own consent forms to ensure some degree of uniformity in the documentation of consent. Usually, medical practitioners obtain written consent for procedures, as they perform most of the major invasive procedures. In some instances, nurses may be called to witness signatures on consent forms, but it should be clear from the discussion above that this is not the same as obtaining consent from the patient.

It is also important to be sensitive to the cultural issues of consent. For example, although in Australia there is a strong Western emphasis on individuality and the right of individuals to make decisions concerning their own health care, in other cultures decisions about such important matters might be made on a far more collective basis. However, the decision to involve others still rests with the patient.

The major exception where the valid consent of the person concerned is not required is in an urgent or emergency situation, when there are both common-law and statutory exceptions to that requirement. For example, under section 174(1) of the Children and Young Persons (Care and Protection) Act 1998 (NSW), a medical practitioner may carry out medical treatment on children or young people without their or their parents' consent if the medical practitioner is of the opinion that it is necessary, as a matter of urgency, to treat them in order to save their life or to prevent serious damage to their health. Also, if the patient is a child, or is unable to give consent due either to intellectual impairment or to some other form of mental incapacity, respective state and territory legislation enables others to give consent on behalf of that person. Sometimes the authority to give consent may be delegated to a parent or spouse, but on other occasions, where the procedure to be carried out may have significant consequences for the individual (such as sterilisation of a person with an intellectual disability), the state or territory legislation may assign the giving of consent to a court or statutory authority. It is important for nurses to know the relevant provisions relating to obtaining consent when the patient lacks capacity to consent.

CRITICAL REFLECTION POINT

- **Reflect on what you now consider consent to be within the context of nursing practice.**
- **What is the nurse's scope of responsibility when giving information to a patient about forthcoming surgery?**
- **What should you do if you come to the conclusion the patient does not have a clear understanding about the procedure for which they have signed a consent form?**

The right of the patient to receive information

Although the discussion about a patient's right to receive information is situated with consent in this chapter, it is not related to the tort of battery. Instead, it is part of the tort of negligence. However, because obtaining consent and **giving information** often go together, it seems most appropriate to discuss it at this point. In the previously mentioned case of *Rogers v Whitaker* (1992), the High Court, after determining the requirements for consent, went on to say that in addition to receiving sufficient information to give consent, the patient also had the right to be warned of any material risks involved in a procedure. Failure to warn a patient of a material risk, which led to the patient suffering damages unexpectedly as a result of undergoing the procedure, would constitute negligent advice. The High Court defines material risk in two ways: 'a risk is material if, in the circumstances of the particular case, a reasonable patient in the patient's position, if warned of the risk, would be likely to attach significance to it or if the medical practitioner is or should reasonably be aware that the particular patient, if warned of the risk, would be likely to attach significance to it' (*Rogers v Whitaker* (1992), at 632, 634). Because these requirements seemed so broad (the risk that the 'particular patient' was not warned about in the *Rogers v Whitaker* case was a 1 in 14,000 risk), the National Health and Medical Research Council (NHMRC 2004) developed guidelines for medical practitioners on giving information to patients. Section D of these guidelines sets out general principles about the information that doctors should normally discuss with patients. The guidelines also provide useful advice on how to communicate and how to identify a material risk (Box 10.4).

Although these guidelines are directed at medical practitioners, they apply equally to a nurse or midwife who is going to perform a significant procedure on a patient.

BOX 10-4 General guidelines for medical practitioners on giving information to patients

Information to be given

Doctors should normally discuss the following information with their patients:

- the possible or likely nature of the illness or disease
- the proposed approach to investigation, diagnosis and treatment:
  - what the proposed approach entails
  - the expected benefits
  - common side effects and material risks of any intervention
  - whether the intervention is conventional or experimental
  - who will undertake the intervention
- other options for investigation, diagnosis and treatment
- the degree of uncertainty of any diagnosis arrived at
- the degree of uncertainty about the therapeutic outcome
- the likely consequences of not choosing the proposed diagnostic procedure or treatment, or of not having any procedure or treatment at all
- any significant long-term physical, emotional, mental, social, sexual or other outcome which may be associated with a proposed intervention
- the time involved
- the costs involved, including out-of-pocket costs.

Informing patients of risks

Doctors should give information about the risks of any intervention, especially those that are likely to influence the patient's decisions.

Known risks should be disclosed when an adverse outcome is common even though the detriment is slight, or when an adverse outcome is severe even though its occurrence is rare. A doctor's judgement about how to convey risks will be influenced by:

- the seriousness of the patient's condition; for example, the manner of giving information might need to be modified if the patient were too ill or badly injured to digest a detailed explanation
- the nature of the intervention; for example, whether it is complex or straightforward, or whether it is necessary or purely discretionary. Complex interventions require more information, as do interventions where the patient has no illness
- the likelihood of harm and the degree of possible harm; more information is required the greater the risk of harm and the more serious it is likely to be
- the questions the patient asks; when giving information, doctors should encourage the patient to ask questions and should answer them as fully as possible. Such questions will help the doctor to find out what is important to the patient
- the patient's temperament, attitude and level of understanding; every patient is entitled to information, but these characteristics may provide guidance to the form it takes
- current accepted medical practice.

National Health and Medical Research Council (NHMRC) 2004 General guidelines for medical practitioners on providing information to patients. © Commonwealth of Australia, 2015. http://www.nhrmc.gov.au/guidelines-publications/e57

Indeed, they set the standard of care for information-giving. It is important to remember that nurses are often significant secondary information-givers. Therefore, they also need to take reasonable care to ensure that the information they give conforms to the standard established by the courts and the NHMRC. A number of health services and other organisations have now developed helpful information in electronic form or printed booklets for patients who are undergoing particular procedures or treatments. Although these are no substitute for direct communication, they are often a useful complement.

The patient's right to refuse treatment

Because touching a patient without consent constitutes a battery, it follows that if a patient does not consent to be touched, treatment cannot proceed. In addition, patients who are being treated can revoke their consent at any time (refuse treatment) and, provided that they are competent to do so, that is, they are of legal age and sound mind, they are perfectly entitled to do so. There are, however, certain statutory provisions, such as section 21 of the Human Tissue Act 1985 (Tas), that make it possible for a medical practitioner to override a parent's wishes based on religious beliefs, if the medical practitioner believes that the child's life may be in danger. This is a complex area of law and requires further reading that cannot be provided in this chapter (e.g. Kerridge et al 2013, Staunton & Chiarella 2013).

Dying with dignity

The consequences of patients refusing treatment can vary from simply seeking an alternative form of treatment, such as medical management rather than surgery, to choosing palliative care until death. As long as patients understand the nature and consequences of their decisions, they are legally able to make such decisions, regardless of the consequences. Although at present in Australia there is no legal right to die per se, it seems obvious that this

right to refuse treatment, whether situated in common law or expressly provided in legislation, may lead to a person's death. Problems arise because many people who find themselves in life-threatening situations have never contemplated the need to refuse treatment; for example, a young person in a car accident. Other people may no longer be mentally competent when the time comes and there may be different views on whether or not to continue treatment; and there may be others still who would not have wished to continue with treatment had they been given the choice, but there is no way of asking them, and their relatives are often reluctant to let go.

In the past, if a person was dying, the major concerns were often how long the process would take and what it would be like. The prospect that death could be postponed by artificial life-support measures such as ventilators, inotropes, tube/parenteral feeding was undreamed of, as was the notion of cardiopulmonary resuscitation (CPR). Determining when a person ought to be 'allowed' to die was not an issue, as there came a stage (generally earlier rather than later) where medical and nursing measures to save life were exhausted and the person simply died. The medical and nursing staff did all they could, and death took its natural course. This is, of course, still the case in many developing countries where there are simply neither the financial resources nor the equipment to prolong life or extend the dying process as we can in developed countries.

However, given our ability to maintain life-support measures for long periods of time, the dilemma for nurses and doctors is more pronounced, and questions such as 'How far should we go in resuscitation?', 'When ought we to maintain life?' and 'If we can do it, should we do it?' dominate the debate. In earlier times when CPR first became popular, it seemed that clinicians felt they ought to resuscitate almost everyone, regardless of age and diagnosis, and often irrespective of their wishes. If they were in an acute unit in the health service (and, indeed, sometimes even if they were not), to save lives was considered the main responsibility of the clinical team. Death was almost an admission of failure rather than a part of life, because the technology was available to at least try to do something about it.

On the whole at that time, resuscitation was carried out automatically and rarely discussed with patients or their families beforehand. If any discussion did ensue, it was more likely to occur with the family than with the patient, whose wishes were often not taken into consideration. The feeling was that, because it was possible to prolong life, there was an obligation to try to do so.

The other problem, going hand in hand with whether one ought to withhold life-sustaining treatment, was the question of whether to withdraw life-sustaining treatment after it had been instituted. One of the ways of managing this problem was the development of the legal concept of *brain death*, which was incorporated into human tissue transplantation legislation. Obviously, if someone were legally dead while on a life-support system, taking them off the life-support system did not kill them. Difficulties arose with people who were not brain dead, but in a persistent vegetative state. If life support were withdrawn, these people may well die, and if so would that mean that they had been killed and, further, that the nursing staff or the medical staff had killed them?

It is not necessary to go into the intricacies of murder and manslaughter here, but there is no doubt that both acts and omissions that cause death have been held to be ways of committing murder. Thus, if one intentionally committed an act that caused a person's death or omitted to do something and a person died because of this omission, arguably one could be charged with murder under the criminal law. There are, of course, many counter-arguments relating to issues of causation in cases of people who are terminally ill, but it has been a concern for healthcare professionals, and continues to be so (O'Neill & Peisah 2011). When the emphasis was placed solely on the responsibility of the healthcare professionals to save life, the situation was at risk of becoming ridiculous. At best, it placed unrealistic expectations on health care, and at worst, it denied the reality of death as a normal part of the life cycle.

Two events occurred that brought a degree of sanity to the situation and restored the balance in practice somewhat. The first was the publication of the work of Elizabeth Kübler-Ross in relation to death and dying (Kübler-Ross 1993). She enabled death to be viewed as a meaningful experience – **dying with dignity** – rather than as a medical failure. This approach enabled palliative care to become a more respectable area of practice. The second was the increasing recognition by the courts of patients' rights and patient autonomy in the United States, Canada, England and Australia during the 1970s and 1980s. After all, as previously noted, if patients do not wish to be touched, they have a legal right not to be, and this is protected by the tort of trespass to the person, specifically in civil actions in battery. At common law, however, the requirement for a patient's consent to be touched can be overridden in an emergency. Also, the person has to be mentally competent in order to give or withhold that consent.

Because some terminally ill patients are no longer mentally able to withhold their consent at the time when they might wish to do so, statutory mechanisms have been developed in most states and territories to give legal effect

to their wishes after they have ceased to be competent. South Australia pioneered this legislation with the Natural Death Act 1983. Basically, this statute enabled people who were terminally ill to give advance notice in writing of their intent to refuse extraordinary life-sustaining treatment. The statute gave definitions for both terminal illness and life-sustaining treatment, and there was some criticism of the legislation because of the narrowness of these definitions. The Northern Territory has enacted a similar model in its Natural Death Act 1988. The South Australian legislation has since been repealed in favour of the Consent to Medical Treatment and Palliative Care Act 1995.

In 1988 the Victorian parliament passed a revolutionary piece of legislation, the Medical Treatment Act 1988. The Act was much wider in its scope than was the original South Australian legislation and established the right of a patient to register, by certificate, a refusal to accept medical treatment. It also enacted a new offence of 'medical trespass' and provided protection for doctors and other healthcare professionals who act in reliance on a certificate. Although the term 'medical treatment' is defined within the legislation, the right to refuse treatment is unqualified to the extent that a person may refuse treatment generally or specifically but cannot refuse palliative care. The Act was amended in 1990 to enable a person to appoint an agent to carry out the wishes should the patient become incompetent, and has continued to have minor amendments since. In Western Australia the Guardianship and Administration Act 1990 (WA) and the Civil Liability Act 2002 (WA) enable people to develop advance health directives under Part 9B.

Not all states have passed legislation, enabling patients to make decisions in advance about their treatment. New South Wales has guidelines in place, meaning patients have no statutory right to refuse treatment, decide issues or provide advance directives concerning their care when they are terminally ill; however, the common-law right to refuse treatment still exists. The NSW Health guidelines are: *Using advance care directives (NSW)* (2005a) and *Guidelines for end-of-life care and decision-making* (2005b). Both provide valuable advice to clinicians, patients and families on the law and practice surrounding end-of-life decision-making. In addition there is now the opportunity for people in NSW to engage in advance care planning, providing the opportunity for patients, families and clinical staff to engage in regular conversations about their wishes for end-of-life care at key milestones in their life.

Euthanasia, which was briefly legalised under the Northern Territory Rights of the Terminally Ill Act (1995), is no longer legal in any state or territory, although continues to be discussed in a number of jurisdictions. Nurses who may wish to actively help a person die need to understand that they would currently be in breach of the criminal law. Although there continue to be compelling moral debates on this matter in the medical and nursing press, the legal situation is unambiguous.

Caring for the dying

In **caring for persons who are dying**, the nurse's responsibilities are to treat each patient's wishes and concerns with respect and to ensure that they are able to discuss their wishes with the senior medical and nursing staff responsible for their care. Careful documentation of such discussions and their outcomes is critical. Good palliative care is essential in terms of pain and symptom relief. Nurses need to concentrate on the quality of life for each dying person and on helping them to resolve their own issues and concerns to enable them to die peacefully. Providing adequate and appropriate pain relief is considered to be a legitimate act, even if the drugs may be seen to have the double effect of shortening the patient's life (Reid et al 2008). It is a privilege to nurse a person who is dying, and nurses should treat this time as a very important one for patients and their loved ones. When a patient dies, there may be special religious or cultural rituals relating to the care of the body, and nurses should take great care to acquaint themselves with the particular requirements for each patient.

Brain death and organ donation

Each state and territory has developed identical requirements for the management of **brain death and organ donation** to enable organ donors and organ recipients to be matched across state and territory boundaries. Each state and territory has a transplant coordinator, who has a record of all those waiting for organ transplants. When donor organs become available, it is the role of the transplant coordinator to ensure that the best available tissue match is made, which may require transporting the donor organs to very distant parts of Australia.

The criteria for the identification and pronouncement of brain death are very strict and the process is highly technical, and only senior medical practitioners with the requisite qualifications are able to make such a pronouncement. After the pronouncement of brain death, raising the question of organ donation must be handled with great sensitivity, and all involved must learn to manage the situation with great tact and compassion. Accuracy of information is critical, as is the need for confidentiality. There are courses for healthcare practitioners and others involved in health care to help them manage the care of donors and their families appropriately.

These days, some people have already made the decision to donate some or all of their organs, and this information may be recorded on their driver's licences. However, even when this is the case, the donor family may have difficulty coming to terms with the fact that their loved one is dead, and may wish to revoke the wishes of their loved one. Consideration of their needs is paramount at such a time.

The coroner and coroner's court

The coroner, and the coroner's court in most states and territories, is a specialist agency and court established to investigate certain types of deaths and in some jurisdictions, fires and explosions. The purpose of these investigations is to consider ways that similar deaths and fires may be prevented in the future.

Special categories of death must be reported to the court and the coroner must investigate and review a number of these.

In NSW the following deaths are reportable to the coroner and a certificate as to the cause of death should not be issued:

- the death was unexpected
- the death was violent or unnatural (e.g. homicide; suicide; drug, alcohol and poison related deaths)
- the death resulted, directly or indirectly, from an accident or injury, even if there is a prolonged interval between the incident and death (e.g. drownings; deaths caused by a traumatic event such as a motor vehicle accident)
- the death occurred during or following a health-related procedure where the death is or may be causally related to the procedure and a registered medical practitioner would not, immediately before the procedure was undertaken, have reasonably expected the death
- a Medical Certificate of Cause of Death has not been signed and is not likely to be signed (e.g. where an opinion about the probable cause of death cannot be formed)
- the person had not been attended by a doctor in the last six months
- the identity of the person is unknown
- the death occurred in custody
- the person was in, temporarily absent from or residing at a declared mental health facility within the meaning of the Mental Health Act 2007 (NSW) for the purpose of receiving care, treatment or assistance (Coroners Act 2009 (NSW)).

When a death is reported, the coroner investigating a death must find, if possible:

- the identity of the deceased person
- how the death occurred
- the date, place and cause of death
- the details needed to register the death with the Registry of Births, Deaths and Marriages (Coroners Court of Victoria 2015).

It is important that nurses understand the coronial jurisdiction as a nurse may become involved in coronial inquiries by the very nature of nursing work. Many situations merely require a nurse to give evidence as a witness to what occurred and will have no professional consequences for the nurse. However, matters where the investigation reveals evidence such as poor documentation of clinical assessments, adverse events involving nurses leading to a patient's death and breakdown in communication between members of a clinical team are just a few examples where nurses may find themselves subject to criticism of their care. The findings from a coronial inquest may have serious implications for a nurse and lead to a complaint being made about a nurse's conduct; civil proceedings being commenced against a nurse; and/or a criminal charge being laid against a nurse where the conduct or omission has been serious enough to be deemed as criminal.

Nurses should be aware of situations where the death of a patient may give rise to a coroner's inquest as legal advice may be necessary and a draft statement prepared at the time of the patient's death rather than having to rely on their memories a long time after the event, sometimes many years. Health service policy should also provide guidance (Staunton & Chiarella 2013). Other guidance may be obtained from nursing professional associations.

Legal relationships in nursing practice

The law of contract

Nursing practice has **legal responsibilities**. 'A contract is an agreement that gives rise to rights and obligations between the parties to the agreement, and such rights and obligations will be protected and enforced by law' (Staunton & Chiarella 2013). Most people enter into numerous contracts every week of their lives, from buying goods at the supermarket to buying a new car or taking on a new job. Patients enter into a contract when they go into hospital or visit their medical practitioner, although this is not usually spelt out in the case of public patients. Private patients are often far more aware of their

contractual relationships with the health service, as they have to sign forms agreeing to pay for the services they receive, albeit usually through their private healthcare funds. Nevertheless, in both public and private healthcare encounters, such contracts exist and bring with them express and implied terms and conditions with which the parties to the contract are expected to comply. A good example of such a term or condition is that a person is entitled to safe and appropriate care while in hospital. There are many rules relating to the **law of contract** that have been developed through common law, but there are an increasing number of statutory provisions governing the law of contract.

A very important form of contract for nurses is their contract of employment. This is covered by an area of law known as industrial law, governing the relationships between employer and employee. Although this area of law goes well beyond the scope of this textbook, there are a range of common-law and statutory obligations that are imposed on the employee and employer that are worthy of documenting here (see Box 10-5).

In Australia, an industrial award, which is negotiated between the nurses' trade union and the relevant employer, covers almost all nurses' working conditions, whether they work for public or private hospital authorities. The award can cover any aspect of employer–employee relations, from overtime to education. These awards are ratified by industrial commissions and are binding on the employers.

Relationships between nurses and other health professionals

The **nurse–doctor relationship** has a great deal in common with the roles these professionals play. Whether it is termed comfort or counselling, good nurses and doctors do it. Whether it is termed preliminary patient assessment or provisional diagnosis, good nurses and doctors do it. But at some point in clinical management the two can and do diverge, with the doctors focusing on the treatment and the nurses focusing on the patient's existence, and it is important to recognise that each has specific responsibilities and authority in their areas. Most of the time, the best interest of the patient (to be cured of whatever condition led them into the doctor's care in the first place) unites nurses and doctors in their work. The doctors plan and order various forms of treatment, much of which is carried out by the nursing staff, who also monitor and optimise the quality of the patient's existence

BOX 10-5 Employee and employer obligations under common law and/or statute

Employee's obligations

1. The employee has a duty to obey all lawful and reasonable directions of the employer. The significant words are 'lawful' and 'reasonable'. In most workplaces many of the employer's lawful and reasonable commands are conveyed to the employee via written policies, procedures and protocols and the employee is required to comply with them. What would be reasonable depends on the facts and circumstances of the situation under consideration.
2. The employee has a duty to display due care and diligence in the performance of his or her work and to perform it competently.
3. The employee has a duty to account to the employer for all moneys and property received in the course of employment.
4. The employee has a duty to make available to the employer any process or product invented by the employee in the course of employment.
5. The employee has a duty to disclose to the employer information received by the employee relevant to the employer's business.
6. The employee has a duty to be faithful and loyal to the employer's interests.
7. The employee has a duty to indemnify the employer for financial liability incurred by the employer on his or her behalf under the doctrine of vicarious liability. This common-law duty is generally not enforced by the employer and, in New South Wales, South Australia, the Northern Territory and the Commonwealth, specific statutory provisions have been introduced to prohibit the employer from enforcing the employee's duty to indemnify.

Employer's obligations

Generally speaking, an employer's obligations have been almost totally reinforced by the creation of industrial agreements and by statute. The employer's obligations may be generally expressed as:

- The duty to pay salary or wages and provide any other conditions of employment agreed upon or expressly provided for by statute or otherwise.
- The duty to provide a safe system of work.
- The duty not to discriminate against people in employment on various grounds such as sex, religion, race or disability.

Adapted from Staunton P & Chiarella M 2013 Law for nurses and midwives, 7th edn. Sydney, Elsevier. pp. 183–4.

while this therapy is going on. Usually, if the treatment is unsuccessful, both doctors and nurses are able to agree when 'enough is enough'; aggressive treatment is discontinued and palliative care is implemented. At this stage, the patient's existence becomes the critical focus, and it is fair to say that doctors are often advised by nurses in such situations on what is the best course of treatment. Indeed, a key role for nurses is to report information about a patient's progress to the medical staff, and nurses have often been severely criticised for failing to do so (Chiarella 2002).

Issues that nurses highlight as being particularly problematic are related to feelings that the patient's existence is being made so intolerable by the treatment and cure that it should stop, or that the treatment is not effecting a cure and is not likely to do so. This difficulty is compounded if in the nurse's view the patient would have a better remaining existence if they were palliated, but the doctors wish to persist with the treatment. These are very difficult issues for nurses, as patients and their relatives quite understandably are hopeful of treatment and cure. But one of the characteristics of the nursing role is intimacy (Chiarella 1990), and one of the conditions with which nurses are profoundly intimate is human suffering. When nurses have to witness the suffering of patients and relatives at an acutely intimate level, they often come to experience the suffering vicariously. This is both a disadvantage and an advantage. It is a disadvantage because sometimes they know how much the patient is suffering despite their best efforts and, because they cannot relieve the patient's suffering, they do not wish them to have to go on. The patient's suffering becomes the nurse's suffering, and it is difficult for the nurse to bear. It is also difficult because so often the patients cannot give them any indication of their views; the nurses rely on the wishes of relatives and loved ones or the people responsible for their care. But it is also an advantage, because often nurses are so 'in tune' with their patients that they are able to bring the unique knowledge related to the extent of their experience to the situation. They know exactly how well skin integrity is maintained, how bruised they are from repeated injections, what happens to their blood pressure and pulse when they are moved, whether or not their pain is being managed effectively and how they tolerate suctioning. Such insights can be critical to patient management and nurses are entitled to insist that they be brought into the planning equation. It is important to be aware that if nurses feel strongly about a matter relating to patient care, they are entitled to speak strongly about it. In addition, if nurses cannot tolerate the patient's suffering, they are entitled to ask for relief both for themselves and for the patient. It becomes extremely difficult, however, if the relatives and the doctors still have treatment and cure as the priority while only the nurses have quality of existence as the priority. In such a situation it may be necessary to accept that what is occurring is a difference of priority, rather than a case of right and wrong. But if the relatives are ambivalent and the nurses believe firmly that the doctor is wrong (this would be the exception rather than the rule), they should take their views as high as is necessary to have their concerns heard.

Nurses are under no obligation to obey any order that they believe, on reasonable grounds, might cause harm to the patient. Indeed, they are under an obligation to do no harm to the patient and should take any such concerns to their nursing supervisor.

It is also important that nurses take great care when receiving verbal orders from doctors regarding treatment, such as telephone orders or emergency orders. The proper course of action with all medical orders is that they be recorded in the notes or on the prescription sheet by the medical practitioner. When this is not possible, the nurse should carefully repeat the order to the doctor, preferably in the presence of a second person, and then record the order in the nursing record. The doctor should then verify that order within 24 hours.

The same principles apply for relationships between nurses and other health professionals. Increasingly, nurses are working closely with other health professionals in acute, primary healthcare, aged care and other areas of the health system. While there is a greater emphasis on inter-professional learning and practice, it is important that nurses maintain the integrity of their professional judgement and care for patients in these settings and that good communication is maintained with patients and all members of the clinical team.

Do not resuscitate orders

Particular care is needed with respect to CPR. CPR is an emergency procedure and as such is provided without requiring a patient's consent. The purpose of CPR is to recommence cardiac output or respiration by artificial means until such time that the cause of the cardiac or respiratory arrest can be treated. It is important to recognise that it is not always successful, and for people with terminal illnesses it may not be the treatment of choice.

To institute CPR routinely for all patients begs the question of whether or not there are worse injuries than death; whether the indignity of resuscitation itself might be worse than allowing a person to die. The duty of care to the patient need not always involve prolonging

life. Sometimes, to prolong life unnecessarily might of itself constitute an injury and, when the decision is not a balance of positive outcomes but rather a balance of negative outcomes, a dignified and peaceful death may be the better choice.

The NSW Health *Guidelines for end-of-life care and decision-making* (2005) are particularly helpful in advising how decisions to palliate, rather than to resuscitate, ought to be written. It recommends that the term '**No cardiopulmonary resuscitation** (**No CPR**)' should be used, as it is less ambiguous than the orders of '**Do not resuscitate (DNR)**' or 'Not for resuscitation (NFR)'.

The document explains that a 'No CPR' order may still mean that the patient receives maximum therapeutic care, short of CPR. The treating clinician and treating team should reassure the patient, or their family, that all comfort and other appropriate care will be provided. The use of the old term (DNR) was a negative concept, implying that there was really only one form of action, that of resuscitation. The term implied that staff members were doing nothing. But as all palliative care clinicians know, even after the oncologists or the surgeons announce that there is nothing more to be done, this is manifestly not so – there is much to be done. At this stage patients require palliative care, reconciliation, preparation and much loving and even laughing. The *Guidelines for end-of-life care and decision-making* take cognisance of that fact. They offer advice on both the content and the wording of documentation. It is critical that decisions not to resuscitate are clearly and unambiguously documented. The advice is extremely pragmatic and valuable, and acknowledges the valuable role that healthcare professionals take in caring for the dying (Box 10-6).

BOX 10-6 Guidelines for No Cardiopulmonary Resuscitation (No CPR)

The term *No Cardiopulmonary Resuscitation (No CPR)* order is preferred as less ambiguous than Do Not Resuscitate (DNR) or Not For Resuscitation (NFR) orders and the interventions to which they apply.

The principles for withholding CPR are consistent with those for withdrawing life-sustaining treatment as outlined in these guidelines. Decisions relating to withholding CPR should be made on an individual basis, not involving blanket decisions or policies, for example, related to age or disability.

A No CPR order may be compatible with providing the patient with maximum therapeutic care, short of CPR. The treating clinician and treating team should reassure the patient, or their family, that all comfort and other appropriate care will be provided. No CPR orders should be clearly written in the patient's medical notes as with other treatment decisions. Use of covert symbols on charts, medical notes or wristbands is not appropriate. Where the decision to apply a No CPR order has not been discussed with the patient because they lack decision-making capacity, that fact should be documented.

Where no explicit decision has been made about the appropriateness, or otherwise, of attempting resuscitation of the hospitalised patient, then resuscitation should be commenced until a senior doctor is available who should determine, based on the likely prognosis, whether CPR should continue and then direct the team accordingly. Where paramedics have been called to a patient whose condition has deteriorated and cardiac arrest occurs, there is a presumption that emergency medical care is appropriate.

NSW Health 2005a Using advance care directives (NSW). Sydney, NSW Health.

• CRITICAL REFLECTION POINT

- **What is your personal reaction to the idea of No CPR or NFR orders?**
- **How do your personal reactions fit with your duty of care to patients with No CPR orders?**

Workload problems

Workload problems, such as **staff shortages** or a nursing skill-mix inadequate for patient care, are worrying for nurses, as these situations cause nurses to be concerned that they will not be able to deliver optimal-quality care, or worse, that something might go wrong, leading to an adverse event concerning a patient. However, financial pressures on the health services continue to mean that, on occasion, nurses may face unavoidable shortages. As a result of pressure through the various industrial awards and industrial action, each state and territory has developed strategies to address workload difficulties. Pressure to introduce nurse-to-patient ratios is increasing with some states and territories introducing the requirements into the regulation of public health services, for example, the Safe Patient Care (Nurse to Patient and Midwife to Patient Ratios) Act 2015 (Vic).

When nurses are concerned that patient care might be at risk from staff shortages or incorrect skill-mix, it is their legal responsibility to bring the matter to the attention of the nursing supervisor. If an adverse event were to occur as a direct consequence of, say, a shortage of staff, and the nurse had foreseen that this might be the case but had not advised the supervisor, the nurse might be found to be negligent, particularly if the supervisor could have assigned staff from another ward to assist the nurse had the shortage been reported. Nursing management needs to know about staff shortages. It is possible that they will

be able to reassign staff or organise agency staff; but if they are unaware of the situation, they can do nothing. If management is unable to find extra staff for the unit, the concerned nurse should keep a written record of the expression of concern, as it is evidence of the fact that the authorities were alerted to the problem, which is the expected behaviour of a reasonable nurse. If the nurse is faced with the situation where staffing is short and no further staff can be found, the responsibility is to prioritise those aspects of the patient's care that are required for safety, and to ensure that such care is delivered over and above the other care that nurses would normally provide for the patient's wellbeing and general hygiene. However difficult the situation may be, it is important for the nurse to remember not to allow frustration to affect the relationship with the patient.

Floating or relieving

Nurses are sometimes moved from the specialty in which they work to another area to alleviate staffing difficulties (sometimes called **floating** or relieving). Although management might be required to do this to provide safe staffing levels, it is important for all nurses to recognise the limitations of their competence and to advise management and other staff on the unit to which they are moved of their inexperience or lack of current knowledge about the specialty area. If management decides to move them despite this limitation, the nurse should make a personal file note of any objections and concerns. If nurses are regularly moved in a particular place of employment, management has a responsibility to educate staff about the specialties to which they are likely to be moved.

Legal issues in nursing specialties

Within every specialty area there are legal issues that affect nursing practice. Some of the more common **legal issues** follow.

Primary healthcare/community health nursing

Nurses work in various healthcare settings other than hospitals. Included in **primary healthcare** or community health settings are occupational and industrial sites where nurses provide preventive and ongoing primary healthcare to workers. Nurses also work in public or community health when preventive services such as immunisation and child screening are provided in homes, schools and clinics. In such situations nurses often work as autonomous practitioners. As always, they are accountable for the judgements they make and their treatment and care in whatever community setting they work, and must work collaboratively with other healthcare team members to ensure that the care they provide is timely and appropriate.

A wide range of laws apply to the practice of nurses working in primary healthcare settings. In addition to all the laws that have been discussed to date, they may be subject more directly to a range of public health legislation, such as reporting of suspected child abuse, notification of infectious diseases and intervention in relation to workplace safety. **Community health nurses** working with families and young children are also expected to play a role in encouraging immunisation. Public health legislation is enacted at state, territory and federal level, with the Commonwealth alone having responsibility for 30 statutes that affect the health of the community (Bidmeade & Reynolds 1997).

Nursing in emergency departments

Nurses working in **emergency departments** are at the front line of hospital care. Triage nurses in particular have significant responsibilities for ensuring patients who present to emergency are prioritised as to when and how quickly they see a medical practitioner or a nurse practitioner. Emergency departments are one of the areas where NPs are beginning to take on significant complementary roles to tackle waiting times and blocks to accessing hospital facilities (e.g. lack of beds, equipment or nursing staff).

The threat of violence can also be a problem for emergency nurses, as patients and relatives who present to emergency may be under the influence of alcohol or other drugs. Nurses working in emergency departments need to be aware of hospital protocols for dealing with aggressive and/or intoxicated patients. Another difficulty that emergency nurses can encounter is when patients wish to leave the emergency department without being fully screened or treated. Patients of sound mind who wish to leave are, of course, perfectly entitled to do so. However, if possible the nursing and/or medical staff should try to explain the possible consequences of leaving before their assessment or treatment is complete. Such premature departures need to be carefully documented by the staff involved. Incident reports must also be used for such purposes.

Nursing children

There are several significant legal matters concerned with **nursing children**. When children are admitted to hospital, great care must be taken to ensure that they do not come to any harm. Treatment rooms and medications must be kept securely fastened, and wards must be secure

to prevent children wandering off. In addition, visitors to children's units must be carefully screened to avoid potential abductions.

The most obvious legal issue is that the child does not possess legal capacity to consent to treatment, and each state and territory therefore has legislation governing the ability of a parent or guardian to consent on behalf of the child. As far as the law is concerned, a child is a person under the age of 18 years. However, most legislation provides for a child over the age of 16 years to give consent (e.g. see the South Australian Consent to Medical Treatment and Palliative Care Act 1995). In addition, there is a common-law acceptance that children under the age of 18 years can give consent providing they understand the nature and consequences of the treatment and it is in the best interests and wellbeing of the child to have the proposed treatment (*Gillick v West Norfolk and Wisbech AHA* (1985); *Department of Health and Community Services (NT) v JWB (Marion's case)* (1992)).

There have also been instances where the wishes of the parent or guardian in relation to the treatment of a child have been overturned. The question of blood transfusions has already been discussed. A NSW case in 1982 overturned the decision of the guardian of a 15-year-old girl to refuse her a termination of pregnancy. The guardian was the then Minister for Youth and Community Services, the girl being a ward of the state; but a judge overturned his decision, finding that the termination was in the girl's best interests (*K v Minister for Youth and Community Services* (1982)). As with all other emergency situations, there is no requirement for consent to treat a child in an emergency.

Another major issue when nursing children is the requirement to report suspected child abuse under the various state and territory child protection legislation. Child abuse invariably includes psychological as well as physical abuse, and neglect. Healthcare professionals are often under a mandatory statutory duty to report reasonable suspicion; but even where the statutory duty is discretionary, there are often government policies that impose a mandatory duty to report. As long as the report is made in good faith, the notification and any accompanying report are protected from civil action, such as defamation (Staunton & Chiarella 2013). If child abuse is suspected, there are provisions to remove a child from the parents and to detain a child without parental consent for examination and treatment.

Medical/surgical nursing and gerontological nursing

Many people in acute **medical and surgical units** are likely to be older persons. In addition, as a result of the decreased length of hospital stay and the high dependency levels of patients, many residential aged care facilities resemble medical/surgical units, as residents leave hospital earlier and may still be unwell at this stage. Over the past 25 years, the quality of care available for older persons in aged care facilities has been a matter of concern. The Australian Government has now taken over as the sole regulator for aged care in Australia and the Aged Care Act 1997 (Cth) is the principal piece of legislation governing the care of older persons living in residential aged care facilities or receiving aged care services funded by government. Section 54(1)(b) provides that the responsibilities of an approved provider in relation to the quality of the aged care that the approved provider provides is to maintain an adequate number of appropriately skilled staff to ensure that the care needs of care recipients are met. This legislation has replaced the significantly more prescriptive state and territory legislation that required the involvement of qualified nurses in the delivery of nursing care in these facilities. For example, nursing care was defined as 'nursing care given by or under the supervision of a registered nurse' under section 3 of the now repealed Nursing Homes Assistance Act 1974 (Cth). Likewise, under the Private Health Facilities Act 2008 (NSW), there are provisions to ensure that the director of nursing of an establishment is a suitably qualified registered nurse (s. 37).

The Quality Care Principles 2014 (Cth) are subordinate legislative instruments made under the Aged Care Act 1997 (Cth) and set out the responsibilities of approved providers in providing care and services for residential and home care. The principles: specify the care and services that an approved provider of residential care is to provide; set out the accreditation standards that must be met by a residential care service to achieve accreditation; specify the care and services that an approved provider of home care is to provide; set out the home care standards that a home care provider is expected to meet as a part of quality review.

While arguably this legislation has substantially contributed to moving towards improving the provision of quality of aged care services at a national level, what has been controversial about the introduction of this federal legislation, designed to provide a homelike environment for residents, is that more and more unskilled workers are being employed to meet the increasingly very high care needs of the residents. These care needs are those that have been generally recognised as nursing care. However, fewer and fewer registered nurses are being employed in these services and there is increasing concern about the diminution in the quality of care provided. These are often frail aged people with chronic and complex care needs

and multiple medications, needing the coordination and care that has traditionally been the role of the qualified nurse. Clinical management of dementia, palliation and dying, depression, poor skin integrity, incontinence, poor nutrition and compromised mobility, to name only some, are all aspects of expert nursing care. The registered nurses who do work in these facilities have increased supervisory and decision-making responsibilities that command their attention in relation to meeting their legal and professional responsibilities to the persons in their care.

Another controversial issue when caring for the elderly is the question of restraint. Many now believe that the use of restraint for managing confused older persons is inappropriate and that with proper nursing care and adequately designed facilities it is much safer not to restrain people in any way. Although the national aged care regulatory system has come some way towards addressing this problem, not all older people are cared for in appropriately designed facilities and there are still occasions when the decision is made to restrain an older, confused patient or resident. Such decisions must be made with extreme care, as restraint is a significant infringement of one's personal space and liberty and could constitute trespass to the person. The only valid reasons for restraining a person are either to protect them from harm or to protect others from harm, including the staff. Restraint must never be used as a matter of convenience. NSW Health has produced an excellent guideline entitled *Working with people with challenging behaviours in residential aged care facilities – using appropriate interventions and minimising restraint* (2006).

Critical care nursing

Critical care nursing requires highly specialised skills in the use of advanced patient monitoring and the care of patients and relatives when the patient is critically ill. Staffing ratios in an intensive care unit need to be significantly higher than in a general ward, often one nurse to one patient. One of the important issues for the intensive-care nurse is to remember not to become completely reliant on the technology to assess and make judgements about the patient's condition. There have been significant incidents when the patient was not progressing well and the equipment was faulty and did not record the patient's deterioration – a careful examination of the patient rather than the machine would have revealed that there was a problem. Another important issue for nurses assigned to work in critical care is that they acknowledge the limitations of their competence, particularly if they are asked to relieve there due to a shortage of staff.

Perioperative nursing

The term **perioperative nursing** encompasses anaesthetic and recovery room care, as well as operating room nursing (*peri* means 'around' or 'beyond', so refers to all nursing associated with a surgical operation). For anaesthetic and recovery room nurses, the comments are very similar to those for intensive-care nurses, since there are many similarities in the type of work that these nurses do. There is no doubt that perioperative nurses carry significant legal liability for the smooth running of the operative procedure, particularly in relation to the swab and instrument count. In a Queensland Supreme Court decision, it was held that the scrub nurse (i.e. the nurse scrubbed and gowned to assist the surgeon) was the 'primarily responsible accounting party' (*Langley & anor v Glandore Pty Ltd (in Liq) & anor* (1997)). Similarly, in *Elliott v Bickerstaff* [1999], the Court held that the surgeon was entitled to rely on the nurse's sponge count. The Australian Confederation of Operating Room Nurses (ACORN) has developed standards for many of the procedures for which nurses are responsible in the operating rooms, and the swab and instrument count standards were those used to assess the requisite standard of care in *Langley & anor v Glandore Pty Ltd (in Liq) & anor* (1997).

Mental health nursing

Following the report of the inquiry into the tragedy of Chelmsford in the 1970s (Slattery 1990), where psychiatric patients were given experimental treatments in unsafe conditions, leading to many deaths over a long period, most states and territories have enacted **mental health legislation** that pays careful regard to the rights of people with mental illness. Some legislation contains specific provisions that express the intent of parliament in relation to the care of mentally ill persons. For example, the Mental Health Act 2000 (Qld), dealing with the care of mentally ill people, specifically states in section 4 that:

> **The purpose of this Act is to provide for the involuntary assessment and treatment, and the protection, of persons (whether adults or minors) who have mental illnesses while at the same time:**
>
> **a. safeguarding their rights and freedoms; and**
>
> **b. balancing their rights and freedoms with the rights and freedoms of other persons.**

All the state and territory legislation makes provision for voluntary and involuntary patients to be treated for mental illnesses, and pay careful attention to their ability to consent to treatment. Although there are situations identified within the legislation where patients may be restrained and/or treated without their consent, these provisions usually relate only to situations in

which patients pose an imminent and serious threat to themselves or others. There are also special provisions in the legislation regarding some of the more controversial forms of therapy, such as electroconvulsive therapy and psychosurgery. Nurses who are working in mental health must be aware of the relevant legislation (see Staunton & Chiarella 2013).

Hospital in the home and outreach services

One of the more recent developments in Australia is the concept of acutely ill patients being cared for at home (**hospital in the home**) by a combination of visiting specialist nurses, other health professionals and family or carers. Sometimes the nurses who visit the patients at home are hospital-based clinical specialists or nurse practitioners who have a dual role of specialist nursing care and family and patient education. In other situations, community or primary healthcare nurse specialists or nurse practitioners who have formed a rapport with the patient and family while in hospital deliver the care. Still other services provide a combination of the two. Although many patients prefer to be cared for in this way and tremendous advances have occurred in the management of patients undergoing renal dialysis and even of ventilated patients at home, such arrangements place considerable strain on the family and carers, who must also be the focus of the outreach nurse's attention during visits. Careful documentation and prompt referral in such situations are vital.

Remote area nursing

Because of the size of Australia, many nurses work in remote outposts or in communities where there are no medical practitioners, or indeed other health professionals living in the community. In such situations, the **remote area nurse** may be the only healthcare professional available to care for all health emergencies. These nurses usually have access to medical advice via telephone (e.g. from the Royal Flying Doctor Service) and are able to evacuate patients by aeroplane in serious emergencies. However, most of the time these nurses are sole practitioners and have to be able to manage a wide range of conditions across the spectrum of health conditions, injuries and events, including childbirth. Until recently, nurses in such situations often acted perilously close to the edge of the law, using clinical protocols and guidelines to enable them to prescribe, order diagnostic tests and make referrals when necessary. However, today most states and territories have either introduced or are working towards legislation to enable expert clinicians to become authorised as nurse practitioners. This will mean that they are legally able to prescribe a relevant range of medications, order pathology and radiology and make referrals necessary to their specialty area of practice and appropriate for the local conditions where the clinician practises. The first legislation to enable these changes to occur was the Nurses Amendment (Nurse Practitioners) Act 1998 (NSW). Changes to the Poisons and Therapeutic Goods Act 1966 (NSW) now enable the director-general to authorise a nurse practitioner, or class of nurse practitioners, to possess, use, supply or prescribe any poison or restricted substance for the purposes of the practice of a nurse practitioner's profession (s. 17A). All other jurisdictions have now legislated to provide for the regulation of nurse practitioners. In addition, since November 2010, privately practising nurse practitioners and eligible midwives now have access to items under the Medical Benefits Schedule (MBS) and can also write prescriptions for which their patients will receive subsidised medications under the Pharmaceutical Benefits Scheme (PBS).

Professional involvement of nurses

In all of the above specialties, it can be seen that nurses are expected to have specialist as well as good general nursing knowledge. Such knowledge is not gained unless nurses have **professional involvement** in ongoing education and debate. It is also critical for nurses to be involved in their professional and industrial organisations. These organisations influence the development of policy and law relating to nursing practice. If clinical nurses do not get involved, the law and policy that is developed will not reflect reality, or may advantage other professional groups to the detriment of nurses. Nurses must be willing to represent nursing and the patient's perspective when appropriate on boards and committees. As a professional group, nurses spend more time directly with patients than any other group, and thus have an important perspective to offer on all aspects of health care.

For nurses to renew their registration each year they must continue to meet the NMBA requirements to continuing professional development (NMBA 2010b).

Key concepts

- Nurses today understand their legal obligations and responsibilities to patients to ensure high-quality patient care.
- The civil law is concerned with the protection of people's private rights, whereas the criminal law system deals with the rights of individuals and society; the

protective jurisdiction is to protect the rights of the community more generally.

- Practising nurses practise according to the requisite standards of care, usually available online through the Nursing and Midwifery Board of Australia (NMBA) standards for practice/competencies, codes of conduct and ethics, the standards developed by professional organisations and the policies and procedures of jurisdictions and employing institutions.
- Registered and enrolled nurses are licensed to practise by the NMBA; the regulatory authorities determine the criteria for accreditation of education programs leading to entry, but all beginning practitioners must be able to demonstrate that they meet the relevant NMBA standards for practice/competencies.
- Nursing students are expected to uphold professional standards when practising in the clinical areas, should be carefully supervised when learning new skills and should otherwise practise within the limits of their competence.
- Nurses are responsible for performing all nursing care correctly and exercising professional judgement as they carry out medical orders. Nurses are not expected to carry out a medical order that they believe on reasonable grounds might harm the patient.
- All patients are entitled to confidential health care and freedom from unauthorised release of information. Unless there is a requirement by law to release confidential information, such information should be disclosed only with the patient's consent.
- Patients may not be touched without their consent, except in an emergency. Obtaining a patient's valid consent to be touched is a defence to an action in battery.
- Patients are entitled to be advised of all material risks inherent in a proposed procedure. Failure to advise a patient of a material risk may result in an action for negligent advice.
- Patients have a right to be treated with reasonable care. Nurses must avoid any act or omission that might reasonably be foreseen to cause damage or injury to the patient. Failure to do so would result in an action for negligence.
- If nurses are found to be criminally or professionally liable for their wrongful acts, they will personally bear the penalty for their behaviour; however, because most nurses are employees, their employing authority is usually vicariously liable for any wrongful acts that might incur civil liability. If a nurse is self-employed, the nurse bears personal liability for any civil wrongs. This may also be the case if the nurse is independently insured or if the act or omission constitutes gross or wilful misconduct.
- Legal issues surrounding the death of a patient require careful documentation of the events leading to death, and respectful and compassionate care of the patient and family before and after death.
- Competent adults may consent to donate any or all of their organs, as may relatives after death has been declared. Situations involving organ donation require sensitive and compassionate management.
- If nurses are concerned about staffing levels or skill-mix, they advise their nursing management formally of their concern. If nothing can be done to alleviate the situation, they keep a personal record of their expression of concern.
- All nurses know the laws that apply to their area of practice and know how to remain up to date with changes in the law and attendant policy.

11

Acting in accordance with New Zealand regulatory frameworks

Elaine Papps

Learning outcomes

Mastery of content will enable you to:

- recognise and define key terms and concepts
- explain the legal concepts that apply to nurses
- describe the legal responsibilities and obligations of nurses
- identify standards of care relevant for nurses
- define the legal aspects of nurse–patient and nurse–employer relationships
- provide examples of legal issues that arise in nursing practice.

KEY TERMS

Competence, p. 195
Confidentiality and privacy, p. 201
Consent, p. 203
Discipline, p. 198
Documentation, p. 201
Law of contract, p. 204
Legal issues, p. 205
Mental health (nursing), p. 206
Negligence, p. 199
Nursing care of children, p. 205
Professional boundaries (of nursing), p. 204
Professional misconduct, p. 199
Regulation of the nursing profession, p. 195
Right to refuse treatment, p. 203
Standards, p. 199
Tort, p. 200

The healthcare system in New Zealand is governed by many laws and legal frameworks. Nurses, like all other healthcare professionals, must practise safely and within the boundaries of the law. Nurses are held accountable for their practice by healthcare consumers, employers and the Nursing Council of New Zealand (NCNZ), as well as other agencies, such as the Health and Disability Commissioner and the Health Practitioners Disciplinary Tribunal.

This chapter provides a synopsis of laws that nurses in New Zealand encounter in everyday nursing practice. While this list is not exhaustive, the areas that are outlined and discussed should assist with identifying how the law in health care provides protection for the public and for healthcare professionals. Statutes and codes that form part of legal frameworks are written in rather formal language, and in some places legal language is used to discuss various laws and codes. Critical thinking exercises at various points in the chapter should assist you to reflect on the meaning of laws and codes, and how they affect nursing practice. All cases and legislation (Acts) referred to are listed in the references, along with web addresses. In addition, endnotes (indicated by a superscripted letter in the text) give additional information on particular points.

Regulation of nursing in New Zealand

Regulation of the nursing profession in New Zealand is governed by the Health Practitioners Competence Assurance Act 2003 (HPCAA). The enactment of the HPCAA repealed previous legislation governing healthcare professions. For nursing and midwifery this was the Nurses Act 1977 and its amendments and regulations, which had its origins in the Nurses Registration Act 1901. The principal purpose of the HPCAA is to 'protect the health and safety of the public by providing mechanisms to ensure that health practitioners are competent and fit to practise their professions'. It does this by establishing regulatory authorities which register and regulate healthcare practitioners. Under the HPCAA, there are now separate authorities for nursing and midwifery. The NCNZ continues to be the authority for nurses, and the Midwifery Council regulates midwives. This chapter focuses on nursing.

The HPCAA requires regulatory authorities to prescribe scopes of practice, and outlines that a regulatory authority may describe a scope of practice in any way it thinks fit, in one or more of the following ways:

a. by reference to a name or form of words that is commonly understood by persons who work in the health sector

b. by reference to an area of science or learning

c. by reference to tasks commonly performed

d. by reference to illnesses or conditions to be diagnosed, treated, or managed (HPCAA 2003, s. 11(2)).

The NCNZ has three scopes of practice with the following titles:

- registered nurse (RN)
- enrolled nurse (EN)
- nurse practitioner (NP).

Each of these scopes of practice has associated competencies – *Competencies for registered nurses* (2007), *Competencies for enrolled nurses* (2012a) and *Competencies for the nurse practitioner scope of practice* (2012b). The scope of practice and competencies for RNs are outlined in Box 11-1. All of these competencies may be revised from time to time and are always available from the New Zealand Nursing Council website (see the list of *Online resources* at the end of this chapter).

Continuing competence and annual practising certificates

The HPCAA requires regulatory authorities to 'set standards of clinical competence, cultural competence, and ethical conduct to be observed by health practitioners of the profession' (HPCAA 2003, s. 118(i)). However, the HPCAA does not provide a definition of competence, as this is the responsibility of regulatory authorities (Vernon et al 2012). The NCNZ defines **competence** as 'the combination of skills, knowledge, attitudes, values and abilities that underpin effective performance as a nurse' (NCNZ n.d.). As nurses work in a variety of roles, in order to determine whether a nurse requires a practising certificate the NCNZ has defined nursing practice as when a nurse is:

> [u]sing nursing knowledge in a direct relationship with clients or working in nursing management, nursing administration, nursing education, nursing research, nursing professional advice or nursing policy development roles, which impact on public safety (NCNZ n.d.).

The NCNZ has developed and implemented a Continuing Competence Framework, which has been in place since 2004. This framework requires nurses to demonstrate annually that they remain competent and fit to practise. The three current requirements of the Continuing Competence Framework are:

- evidence of ongoing professional practice. This refers to nursing practice according to the definition of practising – a minimum of 60 days or 450 hours within the preceding 3 years

BOX 11-1 Nursing Council of New Zealand scope of practice and competencies for registered nurses

Registered nurse scope of practice

Registered nurses utilise nursing knowledge and complex nursing judgement to assess health needs and provide care, and to advise and support people to manage their health. They practise independently and in collaboration with other health professionals, perform general nursing functions and delegate to and direct enrolled nurses, healthcare assistants and others. They provide comprehensive assessments to develop, implement and evaluate an integrated plan of health care, and provide interventions that require substantial scientific and professional knowledge, skills and clinical decision-making. This occurs in a range of settings in partnership with individuals, families, whanau and communities. Registered nurses may practise in a variety of clinical contexts, depending on their education preparation and practice experience. Registered nurses may also use this expertise to manage, teach, evaluate and research nursing practice. Registered nurses are accountable for ensuring all health services they provide are consistent with their education and assessed competence, meet legislative requirements and are supported by appropriate standards. There will be conditions placed on the scope of practice of some registered nurses according to their qualifications or experience limiting them to a specific area of practice.

Competencies for registered nurses

Domains of competence

There are four domains of competence for the registered nurse scope of practice. Evidence of safety to practise as a registered nurse is demonstrated when the applicant meets the competencies within the following domains:

Domain one: Professional responsibility

This domain contains competencies that relate to professional, legal and ethical responsibilities and cultural safety. These include being able to demonstrate knowledge and judgement and being accountable for own actions and decisions, while promoting an environment that maximises client safety, independence, quality of life and health.

Domain two: Management of nursing care

This domain contains competencies related to client assessment and managing client care, which is responsive to the consumers' needs, and which is supported by nursing knowledge and evidence-based research.

Domain three: Interpersonal relationships

This domain contains competencies related to interpersonal and therapeutic communication with health consumers, other nursing staff and interprofessional communication and documentation.

Domain four: Interprofessional health care and quality improvement

This domain contains competencies to demonstrate that, as a member of the healthcare team, the nurse evaluates the effectiveness of care and promotes a nursing perspective within the interprofessional activities of the team.

Each of the domains of competence has associated indicators. Further information is available on the Nursing Council of New Zealand website. Available: www.nursingcouncil.org.nz/Nurses/Scopes-of-practice/Registered-nurse; see also Nurses Scopes of Practice. Online. Available: www.nursingcouncil.org.nz/Nurses/Scopes-of-practice; accessed 2 Nov 2015.

© Nursing Council of New Zealand, www.nursingcouncil.org.nz/Nurses.

- evidence of ongoing professional development. This refers to ongoing education – a minimum of 60 hours in the last 3 years
- evidence of meeting the Council's competencies for the nurse scope of practice. This involves a self-declaration that states the nurse meets the Council's competencies for their scope of practice (Vernon et al 2011).

Each year the NCNZ requires 5% of nurses applying for practising certificates to complete an audit. Nurses who are enrolled in employer Professional Development and Recognition Programme (PDRP) recertification programs approved by the NCNZ are not selected for audit. Nurses who have not been practising for more than 3 years or have not completed the required amount of professional development will be assessed individually and may be

RESEARCH HIGHLIGHT

Research focus

Continuing competence of registered nurses, enrolled nurses and nurse assistants in New Zealand.

Research abstract

The aim of this study was to explore nurses' perceptions, understanding of, and satisfaction with, the Nursing Council of New Zealand (NCNZ) Continuing Competence Framework (CCF); and the effectiveness of associated processes. A response rate of 43% was obtained (n = 1157) when a random sample of New Zealand nurses was sent a web-based survey designed to determine their satisfaction with the NCNZ CCF. The majority of participants believed that the CCF contains appropriate indicators for ascertaining continuing competence, and there were no suggested changes to the three indicators of competence (self-declaration, evidence of practice hours, and evidence of ongoing professional development).

Conclusion

The authors found that although CCF indicators cannot guarantee that a nurse is safe to practise on any given day, nurses who participated in this research believed they demonstrated continuing competence.

Reference

issued with an interim practising certificate until all requirements are met.

Under the HPCAA, regulatory authorities may decline to issue an annual practising certificate if it is believed that an applicant:

- **has failed to maintain the required standard of competence**
- **has failed to comply with a condition included in the scope of practice**
- **has failed to satisfactorily complete a competence program ordered by the authority**
- **has not held a practising certificate or practised lawfully for the preceding 3 years, or**
- **is unable to perform the functions required for the applicant's profession because of some mental or physical condition (HPCAA 2003, s. 12(4)).**

The required standard of competence is defined as 'the standard of competence reasonably to be expected of a health practitioner practising within that health practitioner's scope of practice' (HPCAA 2003, s. 5(1)).

Registration of nurses from Australia or other countries

The Trans-Tasman Mutual Recognition Act 1997 (TTMRA), which came into force on 1 May 1998, allows the reciprocal regulation of nurses and midwives in New Zealand and Australian states. Under the TTMRA, Australian nurses who wish to register in New Zealand must give written notice to the NCNZ that they wish to be registered in New Zealand. Once the relevant registration authority has received an application, it has 1 month to confirm registration and decide whether to impose conditions. Conditions may be imposed for the purpose of:

- achieving equivalence of occupation
- imposing on the applicant's NZ registration a condition that applies to the applicant's registration in Australia, or
- any other purpose relating to the implementation of the TTMRA principles in respect of occupations.

If the registration of an Australian nurse is cancelled or suspended, or is subject to a condition on disciplinary grounds or because of pending or completed criminal, civil or disciplinary proceedings, their New Zealand registration is affected in the same way. The New Zealand authority may reinstate registration or waive conditions if it is satisfied that it is appropriate to do so in the circumstances.

For any nurses other than those registered under the TTMRA, the standards applied as entry criteria for New Zealand registration are qualifications equivalent to New Zealand qualifications. The NCNZ must be satisfied that applicants have the required New Zealand competencies for their scope of practice. Information about internationally qualified nurses and their regulation in New Zealand is available on the NCNZ website (see *Online resources*).

Competence notifications and reviews

A healthcare practitioner may voluntarily notify the relevant authority if they consider that another healthcare practitioner (not necessarily of the same profession) poses a risk of harm to the public by practising below the

required standard of competence (HPCAA 2003, s. 34). The Health and Disability Commissioner (see below) is required to notify the relevant authority if they have reason to believe that the practitioner may pose a risk to the public. Employers are required to make a notification if the practitioner has resigned or has been dismissed for reasons relating to competence. There is no mandatory requirement on other practitioners, but the HPCAA provides authority to make a notification and protection from liability as long as the notification is made in good faith.

Once a competence notification has been received, the registration authority must make inquiries into the notification to determine whether or not a competence review should take place. The NCNZ generally asks for further information from the nurse and the employer to enable it to make this assessment. If there are reasonable grounds for believing that the practitioner poses a risk of serious harm to the public, the Act allows the relevant authority to suspend the practitioner pending a review (HPCAA 2003, s. 39). Information about the NCNZ's review process is available on its website (see *Online resources*).

Health notifications

Section 48 of the HPCAA requires any healthcare practitioner with reason to believe that another healthcare practitioner (whether of the same profession or not) is unable to practise because of a mental or physical condition to notify the relevant authority. A mental or physical condition includes a condition or impairment caused by alcohol or drug abuse.

Practitioners who have a health condition are required to undergo an examination by a medical practitioner, who provides a report for the regulatory authority. The authority then meets with the practitioner to discuss that report. The authority's role is to determine whether the practitioner has a mental or physical condition that means they are unable to perform the functions of nursing or midwifery. The authority may suspend the practitioner, include conditions in their scope of practice or take no further action on the notification. Any suspension or conditions may be revoked or reviewed once the authority is satisfied that it is appropriate and in the public interest to do so. Information about the NZNZ's health process is available on its website (see *Online resources*).

Complaints about nurses

Complaints about nurses may result in disciplinary action. Nurses are disciplined under the HPCAA in the same way as all other healthcare practitioners. If the Registrar of the NCNZ receives a complaint about a nurse and the conduct of that nurse has affected a healthcare consumer, the complaint must be referred to the Health and Disability Commissioner under the Health and Disability Commissioner Act 1994 (HDCA). The Commissioner may decide to investigate the conduct or refer the matter to the relevant authority if the appropriateness of the conduct, fitness to practise (health) or competence of the practitioner is in doubt.

If a complaint has been referred to the Registrar of the NCNZ by the Health and Disability Commissioner, or the conduct does not affect a healthcare consumer, it may be referred to a Professional Conduct Committee (PCC). PCCs also consider court convictions and other grounds of **discipline** (see below). Court convictions that are considered by PCCs are those where the penalty for the offence is 3 months imprisonment or an offence against the legislation listed in the HPCAA (HPCAA, s. 67). A PCC will investigate the complaint and provide the practitioner with an opportunity to respond in person and/or in writing to the information gathered during that investigation. The PCC will then decide whether or not there is sufficient evidence of an offence and whether the conduct is sufficiently serious to lay a charge. Charges are heard before the Health Practitioners Disciplinary Tribunal (HPDT). A PCC may also make recommendations to refer a practitioner for competence review, or to be considered under the health process, or that conditions be included in the practitioner's scope of practice. It may also recommend that the complaint is referred to the police or for conciliation or that the practitioner is counselled (receives a letter of education). Information about the NCNZ's disciplinary processes is available in the publication *Complaints and discipline process* on its website (see *Online resources*).

• CRITICAL REFLECTION POINT

The Health Practitioners Competence Assurance Act 2003 allows some conduct that falls below a standard expected of a registered nurse to be managed through the remedial competence review process rather than by a disciplinary process. Think about the following questions:

1. **Whose interests are being addressed in such situations?**
2. **How does this provide protection to the public?**
3. **Why is competence for nurses and other healthcare practitioners enshrined in legislation?**

Health and Disability Commissioner

Reference has been made above to the Health and Disability Commissioner. This role was established in

BOX 11-2 Code of Health and Disability Consumers' Rights

There are 10 rights in the Code of Health and Disability Consumers' Rights:

Right 1	Right to be treated with respect.
Right 2	Right to freedom from discrimination, coercion, harassment and exploitation.
Right 3	Right to dignity and independence.
Right 4	Right to services of an appropriate standard.
Right 5	Right to effective communication.
Right 6	Right to be fully informed.
Right 7	Right to make an informed choice and give informed consent.
Right 8	Right to support.
Right 9	Rights in respect of teaching or research.
Right 10	Right to complain.

Full details about the Code of Rights is located on the Health and Disability Commissioner website. Online. Available: www.hdc.org.nz/media/24833/leaflet%20code%20of%20rights.pdf; accessed 2 Nov 2015.

Health and Disability Commissioner website, www.hdc.org.nz/media/24833/leaflet%20code%20of%20rights.pdf.

1994 with the enactment of the HDCA (see Burgess 2008), and provided for the 1996 Code of Health and Disability Services Consumers' Rights (the Code of Rights). All healthcare practitioners are called 'providers' under the HDCA and have a duty to give effect to the rights of patients (consumers). These rights are codified in the Code of Rights, which is a regulation made under the HDCA (Box 11-2). This Code may be revised from time to time. The Commissioner publishes an annual report, which explains the Commissioner's role and discusses complaints and their resolution from the previous year (see *Online resources*).

When, after investigation, the Commissioner is of the opinion that the nurse is in breach of the Code of Rights, recommendations may be made by the Commissioner to the provider or the matter may be referred to the Director of Proceedings (DP). The DP has discretion as to whether to lay a charge of professional misconduct before the HPDT and/or to bring proceedings against a healthcare practitioner in the Human Rights Review Tribunal. The Human Rights Review Tribunal has the power to award up to NZ$200,000 compensation to a patient/consumer whose rights under the Code of Rights have been breached. If the injury is covered under the Injury Prevention, Rehabilitation and Compensation Act 2001, this compensation may be barred unless there was flagrant disregard of a consumer's rights.

Health Practitioners Disciplinary Tribunal

The HPCAA established a single multidisciplinary tribunal (HPDT), which is separate to the registration authorities. When a disciplinary charge is being considered, the Tribunal will consist of a legal chair, a layperson and three registered members of the relevant healthcare profession. Disciplinary charges relate to professional misconduct, which is defined in the HPCAA as:

- any act or omission that amounts to malpractice or negligence in the scope of practice the practitioner is registered in at the time the conduct occurred
- any act or omission that has brought or was likely to bring discredit to the profession that the health practitioner practised at the time that the conduct occurred (HPCAA 2003, s. 100(1)).[a]

Negligence and *malpractice* have been interpreted as conduct in the performance of a practitioner's professional role, and arise when a practitioner has breached a professional duty. The test is an objective one and the guide is the **standards** applied by competent, ethical and responsible practitioners. For a finding of **professional misconduct** to be made, the behaviour must fall well short of conduct that is considered acceptable and must not be inadvertent error, oversight or carelessness.

In order to satisfy a charge of *bringing discredit on the profession*, there has to be a professional aspect to the conduct complained of. The complaint must refer to conduct which affects professional or public confidence, and may include behaviours related to the practitioner's work or professional standing. The HPDT's role in considering professional misconduct charges is to determine whether the conduct that is the subject of the charge is proved and that it amounts to professional misconduct. The onus of proof is on the PCC or the DP who prosecutes the charge, and the standard of proof is the civil standard – the balance of probabilities.

Other grounds on which a nurse may be disciplined are if they have been convicted of an offence that reflects adversely on fitness to practise, have practised without holding a current practising certificate, have performed a healthcare service outside their scope of practice, have failed to observe any conditions included in their scope of practice or have breached an order of the HPDT.

The purpose of disciplinary proceedings is to:

- enforce high standards of propriety and professional conduct
- ensure that no person who is unfit because of their conduct is permitted to practise

- protect the public and the profession against practitioners who are unfit to practise
- enable the profession to ensure that the conduct of members conforms to the standards generally expected of them.

The HPDT has a number of penalties available to it:

- Cancellation of registration.
- Suspension of registration (3 years).
- Inclusion of conditions in a practitioner's scope of practice (for 3 years after commencing practice after the order is made).
- Censure.
- Fine (up to NZ$30,000).
- Awarding costs and expenses of investigation, prosecution and hearing.

Decisions made by the HPDT are available on its website (see *Online resources*).

Sources of law

Most law affecting healthcare practitioners in New Zealand is found in legislation (Box 11-3).

BOX 11-3 Sources of law

Most laws affecting healthcare practitioners in New Zealand are found in legislation, namely:

- Health and Disability Commissioner Act 1994
- Health and Disability Commissioner (Code of Health and Disability Services Consumers' Rights) Regulation 1996
- Health Information Privacy Code 1994
- Health Practitioners Competence Assurance Act 2003
- Human Rights Act 1993
- Injury Prevention, Rehabilitation and Compensation Act 2001
- Intellectual Disability (Compulsory Care and Rehabilitation) Act 2003
- Medicines Act 1981 and its Regulations
- Mental Health (Compulsory Assessment and Treatment) Act 1992
- New Zealand Bill of Rights Act 1990
- New Zealand Public Health and Disability Act 2000
- Privacy Act 1993.

New Zealand laws relating to the misuse of controlled substances and drugs include the Misuse of Drugs Act 1975 and the Medicines Act 1981 and Regulations.

Legal liability in nursing

In Australia, parties may seek to recover compensation for personal injury through civil actions in tort, usually in negligence. However, New Zealand law generally prohibits claimants from seeking compensation for personal injury through a civil action in the courts. This is because it has a no-fault compensation scheme administered by the Accident Compensation Corporation (ACC). If claimants are covered for their personal injury by the ACC legislation, currently found in the Injury Prevention, Rehabilitation and Compensation Act 2001 (IPRCA). They are then barred from seeking compensation through any other means.

Treatment injury

Under changes made to the IPRCA, which came into force on 1 July 2005, *treatment injury* is personal injury suffered by a person caused by treatment (previously referred to as 'medical misadventure'). Personal injury caused 'wholly or substantially by a gradual process, disease or infection' is excluded from the definitions of personal injury. However, if the injury is a treatment injury, the development or progression of a disease or infection may amount to 'physical injury' where it is caused by treatment or by the failure to diagnose or treat a physical condition. There is now no requirement to find fault by a registered healthcare professional for cover to be provided, which brings medical misadventure in line with other accidents under the scheme. However, if the ACC believes that there is a risk of harm to the public by a registered or unregulated healthcare practitioner as a result of information gathered in the course of assessing claims, it must report that risk to the relevant authorities, which includes regulatory authorities. The ACC gains assistance in determining whether or not it should report events from the New Zealand Ministry of Health's sentinel/serious events threshold (Ministry of Health 2001).

Exemplary damages

ACC legislation does not bar claims for exemplary (punitive) damages. Exemplary damages may be awarded where the conduct that led to the injury was 'outrageous' and calls for punishment. This has been interpreted to include conduct that was intentional wrongdoing or conscious recklessness, or where the practitioner has departed so far and so flagrantly from professional standards or standards of care that the conduct calls for punishment.

Torts

A **tort** deals with a wrong committed by one person against another. In health care, issues of negligence, defamation,

and assault and battery are important for nurses to be aware of. While these may seem to be alarming terms in relation to nursing practice, they are managed through mechanisms and processes, such as standards of care, confidentiality and privacy, and informed-consent processes.

Negligence

The test for negligence at common law is that a duty to take reasonable care is owed; that the duty was breached; that some loss or harm occurred; and that the loss or harm was caused by the breach. In *Staite v Psychologists Board*,[b] Young J stated that he did not believe professional negligence, in the sense of simple carelessness, could be invoked to support a disciplinary charge in circumstances where an action for 'professional negligence' could not have been brought because the law would not have recognised a duty to take reasonable care. This duty of care, to the standard of the reasonable practitioner, is a requisite element of a negligence action.

Standards of care

As mentioned earlier, under the HPCAA 2003, the NCNZ is required to set standards of 'clinical competence, cultural competence and ethical conduct' (HPCAA 2003, s. 118(i)). Guidelines as to what is reasonable and the minimum standards of practice and/or care for nurses can be found in the publications listed in Box 11-4. These standards and guidelines may be revised from time to time.

It is important for nurses to understand that any or all of these guidelines may be referred to by the Health and Disability Commissioner or in proceedings in respect of complaints against nurses before the HPDT (refer to the HPDT website in *Online resources* for further examples).

The need for careful documentation

The Health Information Privacy Code 1994 issued under the Privacy Act 1993 regulates health information.[c] In particular, Rule 8 of the Health Information Privacy Code provides that a health agency holding health information must not use that information 'without taking such steps as are in the circumstances reasonable to ensure that, having regard to the purpose for which the information is proposed to be used, the information is up-to-date, accurate, complete, relevant and not misleading'.[d]

Documentation is a significant component of nursing practice. It is important to be aware that health records may be used in investigations of complaints by a number of authorities, including the Health and Disability Commissioner, the Privacy Commissioner, regulatory authorities and the police. Health records may also be obtained through the Official Information Act 1982, and through subpoena (Burgess 2008).

The New Zealand Nurses Organisation (2003) has produced some useful guidelines on the need for careful documentation (see *Online resources*).

Confidentiality and privacy

The principles pertaining to **confidentiality and privacy** are found in common law and statute, and both apply in New Zealand. The law relating to disclosure of health information and a patient's right to protection against interference with their privacy is contained in the Health Information Privacy Code 1994 and later commentary. That Code is subject to all other legislation and there are numerous statutory provisions which require that health information must be made available and/or disclosed (ss. 22C, 22D, 22F and 22G of the Health Act 1956, among others).[e] Other statutes also require practitioners to disclose health information when child abuse is suspected; see sections 49, 52, 53 and 56 of the Children, Young Persons and Their Families Act 1989.

Health Information Privacy Code

In general, this Code requires health information to be collected for lawful and necessary purposes from the individual concerned. At the time when it is collected, the individual must be made aware that the information is being collected, the purpose of the collection and who will receive the information.

Health information must be collected without unreasonable intrusion on the individual's personal affairs,

and must be collected lawfully and fairly in a situation in which that person feels comfortable. The information must be protected by reasonable safeguards against loss, unauthorised access, modification, disclosure and other misuse, and disposed of in a manner that preserves the individual's privacy. Where information can be readily retrieved, the individual may be entitled to have access to that information, and may request correction of that information. Information must not be kept longer than is necessary for the purposes for which it is lawfully used and, if collected for one purpose, should not be used for another unless authorised or it is necessary because of a threat to public or individual health and safety. Unique identifiers (numbers) may only be assigned where necessary to enable a health agency to carry out its functions more efficiently. All health information is subject to the limits on disclosure imposed by the Code for a 20-year period from the date of death.

Complaints about breaches of the Health Information Privacy Code may be made to the Privacy Commissioner. The Commissioner may investigate the complaint if it falls within their jurisdiction and form a provisional opinion as to whether an interference with privacy has occurred. Any practitioner who has a complaint made against them is provided with the opportunity to provide a response to the complaint before the Commissioner reaches a provisional opinion. The parties are also invited to respond to the provisional opinion and to reach a settlement about the alleged breach. The Commissioner may then make a final opinion, which is advisory only, and may make recommendations. The Privacy Commissioner may refer the matter to the Proceedings Commissioner who may issue proceedings in the Human Rights Review Tribunal if a settlement cannot be reached. If the Tribunal is satisfied on the civil standard that a breach of privacy has occurred, it may make orders, declarations or award damages and costs. It has the power to award damages up to NZ$200,000. More information on the Privacy Commissioner and the Health Information Privacy Code is available on the Privacy Commissioner's website (see *Online resources*).

The Health (Retention of Health Information) Regulations 1996 impose obligations on practitioners to retain health records/information for a minimum period of 10 years from the last date of treatment or care. The Public Records Act 2005 may require some health records to be transferred to Archives New Zealand for future reference.

Privileged communications

Communications made by a patient to a healthcare practitioner for the purposes of treatment or examination or where that person is caring for the patient are legally protected by confidentiality and privacy law only to a certain extent, and there are numerous exceptions to the general confidentiality rule. However, in the case of communications made to a medical practitioner or clinical psychologist, there are some instances where the confidentiality of such communications is totally protected and the medical practitioner or clinical psychologist cannot disclose them even in court (Evidence Act 2006, s. 59).

Figure 11-2 Nurses need a sound understanding of informed consent in relation to their practice.

iStockphoto/fotostorm.

• CRITICAL REFLECTION POINT

Confidentiality can be complex in nursing practice, and there are numerous challenges that arise when nurses need to maintain confidentiality. Reflect on what you think the challenges of maintaining confidentiality might be in situations where:

1. **You are in the staff cafeteria and overhear colleagues discussing confidential information about a well-known local identity.**

2. **You are asked by a colleague from another area of the hospital you are working at for information about a patient you are caring for.**
3. **A relative asks you for information about the prognosis of a patient you are caring for.**

Discuss your reflections with fellow students, clinicians and your lecturers and generate strategies for dealing with these and similar situations you may encounter.

Obtaining consent

Nurses provide a range of care and treatment in nurse–patient interactions. Usually, verbal **consent** is given when a nurse explains an intended action or procedure. If the nurse does not explain and/or provide the opportunity for a patient to ask questions about what the nurse is going to do and if, for example, this might be painful, informed consent could arguably be invalid. In New Zealand, the requirements for obtaining consent are found in Rights 5, 6 and 7 of the Code of Rights. In particular, Right 7(1) provides that consumers have a right to make an informed choice and give informed consent except where any enactment, common law or provision in the Code of Rights provides otherwise. A consumer is presumed to be competent to make an informed choice and give informed consent unless there are reasonable grounds to believe that they are not competent. Where a consumer has diminished competence, they have the right to make an informed choice and give consent to the extent appropriate to their level of competence.

If a consumer is not competent, and there is no other person entitled to consent on their behalf, services can be provided where they are in the best interest of the consumer and reasonable steps have been taken to ascertain the consumer's views, and where the provider believes the services to be consistent with any choice the consumer would have made or are views of other suitable people interested in the consumer's welfare (Right 7(4)). Where a consumer is not capable of consenting on their own behalf, there is no common-law rule that enables a spouse or next-of-kin to give effective consent on their behalf. Under the Protection of Personal and Property Rights Act 1988 (the PPPRA), a Family Court may appoint a welfare guardian for an incapacitated adult if the consumer wholly lacks the capacity to make or communicate decisions and if the appointment is the only satisfactory way to ensure appropriate decisions are made. The PPPRA also provides for the appointment of an enduring power of attorney, where a competent person is able to confer powers to an 'attorney' which continue in the event that the person becomes incapacitated. This power in relation to personal care and welfare only comes into force when the consumer becomes incapacitated.

The right of the patient/consumer to receive information

Right 6(1) of the Code of Rights entitles the consumer to receive information that a reasonable person in the circumstances would expect to receive. That information must include:

- an explanation of their condition
- an explanation of the options available; namely, assessment of expected risks, side effects, benefits and costs of each option
- advice of the estimated time within which actual services will be provided
- notification of any proposed research or teaching
- any other information required by legal, professional, ethical and other relevant standards
- the results of tests and procedures.

Right 6(3) entitles the consumer to receive information on the provider's identity and qualifications and recommendations as to how to obtain another opinion and test results. Consumers are entitled to receive a written summary of the information upon request.

The right to refuse treatment

In New Zealand, a patient's 'right to refuse any medical treatment' is enshrined in section 11 of the New Zealand Bill of Rights Act 1990. Right 7(7) of the Code of Rights provides consumers with 'the right to refuse services and withdraw consent to services'. In addition, the Code of Rights provides that consumers have a right to have services provided in a manner that respects the dignity and independence of the individual (Right 3). Consumers can also use an advance directive in accordance with the common law if they so wish (Right 7(5)). The **right to refuse treatment** should be an informed choice, so full information about the likely outcome of not receiving the treatment should be provided.

The law relating to refusal of services on behalf of someone who is not competent to make a choice, however, is not as straightforward. In most cases, the courts will override parents who refuse life-prolonging treatment for their children. For example, in the case of *Healthcare Otago v Williams-Holloway*,[f] parents refused treatment for their three-year-old son to receive his third cycle of chemotherapy to treat a neuroblastoma of the jaw. The High Court intervened, and by order placed the child in the custody of the Director-General of Social Welfare and issued a warrant authorising police or social welfare authorities to locate and apprehend the child for the purpose of treatment (the boy had been taken into hiding by his parents). In a recent decision by the High Court of

New Zealand (*Auckland District Health Board v James Dee* [2015] NZHC 304 (27 February 2015), the High Court of New Zealand assumed legal guardianship of a nine-year-old boy in order to ensure that he received recommended medical treatment. The boy had been diagnosed with HIV when an infant; however, the parent and guardian of the child did not accept the diagnosis, and subsequently the boy did not receive prescribed antiretroviral medication.

Use of human tissue and organ donation

The legislation regulating the removal, use and transplantation of body parts in New Zealand can be found in the Human Tissue Act 2008, the Code of Rights and common law. This law is complex and includes addressing sensitive cultural and spiritual needs, values and beliefs. It is suggested that interested readers refer to the link given in *Online resources*. Keenan (2010) also discusses the issues surrounding the use of human tissue and organ donation.

Legal relationships in relation to employment

The law of contract

Contract between a healthcare practitioner and the patient

The **law of contract** between provider and patient/consumer is set out in Right 4 of the Code of Rights, which provides consumers with a legal right to services of an appropriate standard. This includes the right to have services provided with reasonable skill and care that comply with legal, professional, ethical and relevant standards, which are consistent with the consumer's needs and which are provided in a manner that minimises the potential harm to, and optimises the quality of life of, the consumer (Rights 4(1), 4(2), 4(3) and 4(4)). Consumers also have the right to cooperation among providers to ensure quality and continuity of services (Right 4(5)).

Additional obligations placed on healthcare professionals, including nurses, in respect of the care of consumers are:

- the right to be treated with respect (Right 1)
- the right to freedom from discrimination, coercion, harassment and exploitation (Right 2)
- the right to effective communication (Right 5).

Nurses also have an obligation to maintain clear **professional boundaries**. In 2012, the NCNZ published a guideline for this, *Guidelines: professional boundaries* in association with a revised *Code of conduct for nurses*.

Employment contracts and related matters

Employed nurses in New Zealand have employment agreements with their employers that are governed by the Employment Relations Act 2000 (ERA), the Holidays Act 2003, the Parental Leave and Employment Protection Act 1987, the Minimum Wages Act 1983 and the Wages Protection Act 1983. The ERA provides for two types of employment agreement – an individual employment agreement and a collective employment agreement. Collective employment agreements can be negotiated only through a registered trade union.

A number of multi-employer collective agreements (MECAs) are in place in New Zealand, negotiated by the New Zealand Nurses Organisation (NZNO), a union and professional organisation that represents both nurses and midwives. Membership details of NZNO can be viewed on its website. Other unions include the New Zealand Public Service Association (PSA), which covers healthcare practitioners working in the public sector. Nurses may also apply for membership of the College of Nurses Aotearoa (NZ) Inc., a professional organisation that provides indemnity insurance but is not a union. Nurses who are employed in mental health may belong to Te Ao Maramatanga (New Zealand College of Mental Health Nurses).

An employee who believes there is 'serious wrongdoing' in or by an organisation may disclose information to an appropriate person and be protected from prosecution, civil liability or professional disciplinary action for doing so. The Protected Disclosures Act 2000 applies to both public and private sector organisations.[g] The employee must take these concerns through an established internal procedure or may take their concerns directly to the head of the organisation. If the concerns of the employee are not resolved using these methods, the employee may disclose those concerns to others, including the Ombudsman or a cabinet minister. The purpose of this whistle-blowing legislation is to facilitate disclosure and investigation of matters of serious wrongdoing in or by an organisation and to provide protection for employees who may – provided they make the disclosure in accordance with the Act – disclose such matters, including matters constituting a serious risk to public health or safety. The legislation resulted from a case where a nurse reported his concerns about the release of a dangerous psychiatric patient from hospital to the Opposition Spokesperson for Justice (*Pugmire v Good Health Wanganui Ltd (No 2)* [1994] 1 ERNZ 174). The nurse was suspended by his employer and then dismissed for his actions.

The Safety in Employment Act 1992 requires that employers ensure the safety of employees, but also places an obligation on employees. Section 19 of this Act notes that:

> **Every employee shall take all practicable steps to ensure**
>
> **a. The employee's safety while at work (including by using suitable protective clothing and protective equipment provided by the employer) ... and**
>
> **b. That no action or inaction of the employee while at work causes harm to any other person.**

Further information about issues in employment law in New Zealand is discussed in Keenan (2010).

Legal issues in nursing specialties

In New Zealand, nurses working in community or specialty health settings must also be aware of the wide range of legislation affecting their practice, particularly public health laws, which place mandatory obligations on healthcare professionals in some circumstances.[h] The ageing population means that there is an increasing number of older people in residential and continuing care facilities, and although there is no specific legislation in New Zealand relating to aged care, the Health and Disability Services (Safety) Act 2001certifies and monitors the provision of care in the aged residential care sector (see *Online resources*).

Nursing children

Several **legal issues** relate to the **nursing care of children**. Of particular note is that there is no age of consent under the Code of Rights. A child is presumed competent until otherwise assessed, and a competent child has the right to make an informed choice and give or refuse consent (Right 7(2)). The test is whether a child or young person is competent to make an informed choice and give informed consent. This provision is for the purpose of Code of Rights liability. The informed consent provisions of the Code of Rights have effect unless any other legislation or the common law provides otherwise; there are numerous statutes relating to the provision of services for children and young people that do provide otherwise.

At common law, the capacity to consent to treatment is not dependent on someone being above a certain age. However, the younger the child and the more important the decision, the less likely that the child will be considered competent to give consent. Under section 36 of the Care of Children Act 2004, young people over 16 years of age can consent or refuse to consent to healthcare procedures. As with any adult, a healthcare practitioner can overturn this right if there are reasonable grounds for believing that a person is not competent. A young person who is married, living in a civil union or living with a de facto partner is also able to give or refuse consent to healthcare procedures. A female child of any age can give consent to the termination of her pregnancy or a refusal to a termination (Care of Children Act 2004, s. 38).

Under section 37 of the Care of Children Act 2004, no civil, criminal or disciplinary proceedings may be brought against a person for the administration of a blood transfusion to a person under the age of 18 years by reason of the lack of consent of a person whose consent is required by law. No consent is required for the examination of children (on a court order) on suspicion of child abuse or neglect (Children, Young Persons and Their Families Act 1989, s. 49); the child is entitled to have an adult present during the examination (s. 54).

• CRITICAL REFLECTION POINT

In the paragraph above, there is reference to consent in relation to the administration of a blood transfusion in relation to individuals under the age of 18 years. Discuss with a colleague the reasons this might be the case.

Reference is also made about consent not being required for the examination of children where abuse or neglect is suspected. What reasons behind the rationale for this are apparent to you?

Where the Chief Executive of Social Welfare has been appointed sole guardian of the child, consent can only be given by the Chief Executive (Children, Young Persons and Their Families Act 1989, s. 110(2)(a)); a child aged 14 years or over can apply to the court to overturn a refusal of consent by the Chief Executive in respect of any important matter which affects the child (s. 116).

Under section 125 of the Health Act 1956, authorised persons, including some nurses, may examine children attending a school or early-childhood education centre, and may notify the child's parent or guardian of any condition that is affecting the health or normal development of the child or of any disease or defect from which the child may be suffering.

Section 4 of the Contraception, Sterilisation and Abortion Act 1977 permits a parent or guardian, medical practitioner or carer of any mentally subnormal female to administer any contraceptive to that female if it is considered in the best interests of the female to do so. A female is mentally subnormal if she is suffering from subnormality of intelligence as a result of arrested or incomplete development of mind to the extent that she is incapable of living an independent life or of guarding herself against serious exploitation or common physical dangers, or to the extent that she is incapable of

understanding the effective use of contraceptives or the desirability or need for their use.

It is not possible for any person to consent to the sterilisation of another person if that other person lacks the capacity to consent on their own behalf by reason only of their age (Contraception, Sterilisation and Abortion Act 1977, s. 7). Where a patient lacks the capacity to consent to an abortion because of mental incapacity, the certifying consultants must consult with a medical practitioner or another qualified and experienced person in the field who is able to make an assessment of the patient's condition and the likely effect on it of the continuance of the pregnancy or an abortion (Contraception, Sterilisation and Abortion Act 1977, s. 34).

Useful information about consent issues in child and youth health is available on the Ministry of Health's website and from the Office of the Children's Commissioner (see *Online resources*).

The Vulnerable Children Act (2014) has recently been introduced into New Zealand legislation. The focus of this Act is better protection for children from neglect and abuse (see *Online resources*).

Mental health nursing

In New Zealand, rights for the mentally ill are provided for in the Code of Rights in the same way as for any other consumer of healthcare services. Where a person has such a severe mental illness that it amounts to a mental disorder within the meaning of the Mental Health (Compulsory Assessment and Treatment) Act 1992 to the extent that the person requires compulsory assessment or treatment, then that person has additional rights under that Act (Part VI, ss. 64–75).

Standards and guidelines are important documents for nurses and other healthcare practitioners working in the **mental health** area, and are available through simple web searches or via the Ministry of Health website (see *Online resources*). These standards and guidelines may be revised from time to time.

Professional responsibility of nurses

All nurses, irrespective of where they practise nursing, have a professional responsibility to be acquainted with the law that relates to health care and nursing practice and are accountable under that law. While employers may provide education and training for nurses in this regard, it is important for nurses to be aware that it is their individual responsibility to maintain competence in and currency with legal and professional issues.

Disclaimer

This chapter is intended to provide a first point of reference for matters in respect of legal implications in nursing practice. It should not be acted or relied upon as a substitute for professional legal advice. Specialist legal advice should always be sought in relation to any particular circumstances.

Notes

a. For examples of cases that have been found to amount to professional misconduct and upheld by the High Court on appeal, see *Collie v Nursing Council of New Zealand* [2001] NZAR 74 (registered nurse working as a practice nurse found guilty of professional misconduct for accepting gifts from an elderly couple totalling NZ$25,000); *Harangi Biddle v Nursing Council of New Zealand*, HC Wellington, France J, 4 March 2003, AP 90/02 (registered midwife found guilty of professional misconduct for failing to assess and investigate a mother's concerns about postpartum symptoms). Findings of professional misconduct are reported in the *New Zealand Gazette* and in *Kai Tiaki: Nursing New Zealand*, the journal of the New Zealand Nurses Organisation.

b. *Staite v Psychologists Board*, HC Christchurch, Young J, 18 December 1998, P 52/98 22p.

c. Health Information Privacy Code 1994 issued by the Privacy Commissioner under the Privacy Act 1993 contains 12 rules that apply to health information about identifiable individuals.

d. Deciding what are reasonable steps will depend on the proposed use to be made of the information and its impact on the patient: for example, the case of *P v J* 27/10/98, High Court Auckland 117/98, where the High Court held that there was no interference with the privacy of the complainant who was concerned that her mental health background – and in particular a referral letter from a GP to a psychiatrist that the complainant said was not accurate – would affect her ability to get a job.

e. For example, section 22C of the Health Act 1956 provides that health information can be disclosed to specified persons including a medical officer of a penal institution, a probation officer, a social worker, the police, a Ministry of Health employee, the Ministry of Agriculture and Fisheries, the Land Transport Safety Authority; section 22D provides for disclosure to the Minister of Health by District Health Boards; section 22F provides for disclosure to other providers of health services on request for diagnostic and other treatment purposes.

f. *Healthcare Otago Ltd v Williams-Holloway* [1999] NZFLR 804, 812; and for other cases where the Court has ordered treatment against parents' wishes, see, for example, *Re J* [1996] 2 NZLR 134(CA), 3-year-old had life-threatening nosebleed; *Re P* [1992] NZFLR 95, twins born at 26/40 gestation needed blood transfusions; *Re CL* [1992] NZFLR 352, 4-year-old needed blood during congenital heart defect correction; *THJL v SL & LL* 4/11/97 Salmon J, High Court Auckland, M708/97, testicular biopsy ordered on 2-year-old and orchidectomy if malignant; *Re Norma* [1992] NZFLR445, chemotherapy ordered for 19-month-old Samoan girl with likely Ewing's sarcoma; *Auckland Healthcare Services v Lui* 11/7/96, High Court Auckland, M812/96, repair of partially detached retina ordered for 12-year-old boy. The High Court assumed legal guardianship of a 9-year-old boy in order to ensure that he received antiretroviral medication; *Keane, J, Auckland District Health Board v James Dee* [2015] NZHC 304 (27 February 2015). www.nzlii.org/cgi-bin/download.cgi/cgi-bin/download.cgi/download/nz/cases/NZHC/2015/304.pdf. For full discussion of the New Zealand legal position when parents refuse treatment for their children, see Manning (2001); the issues are also discussed in Chapter 7 in Keenan (2010).

g. The Protected Disclosures Act 2000 applies to both public and private sector organisations and the term 'serious wrongdoing' encompasses the following:

   a. an unlawful, corrupt or irregular use of public funds or public resources

   b. an act, omission or course of conduct that constitutes a serious risk to public health or public safety or the environment

   c. an act, omission or course of conduct that constitutes a serious risk to the maintenance of law, including the prevention, investigation and detection of offences and the right to a fair trial

   d. an act, omission or course of conduct that constitutes an offence

   e. an act, omission or course of conduct by a public official that is oppressive, improperly discriminatory or grossly negligent, or that constitutes gross mismanagement.

h. Section 77 of the Health Act 1956 empowers a Medical Officer of Health to enter any premises and examine any person believed to be suffering from, or recently exposed to, an infectious disease. Section 79 empowers a Medical Officer of Health to isolate a person to a hospital or other suitable place to prevent the spread of an infectious disease. This was used in May 1999 in Christchurch to prevent two intellectually disabled men from spreading AIDS. See also section 59 of the Tuberculosis Act 1948, which permits detention of patients in hospital; section 125 of the Health Act 1956, which permits examinations of children in public or private schools; and the Mental Health (Compulsory Assessment and Treatment) Act 1992 and the Alcoholism and Drug Addiction Act 1996, which permit detention for treatment.

CHAPTER

12

Placing communication at the centre of person-centred care

Jane Stein-Parbury

Learning outcomes

Mastery of content will enable you to:

- understand professional obligations to become skilled at communication
- recognise the process and content aspects of interpersonal communication
- explain how conflict styles affect collaboration with healthcare colleagues
- understand different types of nursing knowledge
- appreciate the importance of communication in the development of therapeutic relationships with clients and their families
- identify significant features and therapeutic outcomes of nurse–client helping relationships
- list nursing focus areas within the four phases of a nurse–client helping relationship
- differentiate authoritative and facilitative therapeutic communication techniques
- describe qualities, behaviours and communication techniques that affect professional communication
- relate emotional intelligence to communication competence
- understand how reflective practice promotes communication competence.

KEY TERMS

Active listening, p. 226
Authoritative interventions, p. 226
Collaboration with colleagues, p. 217
Communication, p. 210
Emotional intelligence, p. 232
Empathy, p. 228
Facilitative interventions, p. 226
Healthcare environments, p. 213
Interpersonal communication, p. 221
Intrapersonal communication, p. 221
Knowing the patient, p. 212
Mental models, p. 218
Non-verbal communication, p. 222
Paraphrasing, p. 229
Patient-centred communication, p. 213
Presence, p. 227
Self-disclosure, p. 231
Sympathy, p. 228
Team collaboration, p. 217
Therapeutic communication techniques, p. 225
Verbal communication, p. 221

Communication and person-centred nursing practice

Interpersonal communication involves the capacity to convey thoughts, feelings and attitudes through spoken, written and non-verbal means in order to exchange ideas and construct human meaning. Most professional people are required to be effective communicators in the conduct of their work, and the nursing profession is no different. However, the content and process of communication varies across professions according to the particulars of context. For example, professional engineers are often required to communicate effectively through technical report writing; computer programmers are required to communicate through symbolic languages unique to the computing world; and salespeople must acquire skills of persuasion in order to be successful.

While the skills of effective communication may be similar to those in other professions, the knowledge and attitudes required for therapeutic intentions are particular to the nursing context. For example, a nurse encouraging a depressed client to engage in physical exercise may use persuasive communication techniques that are similar to those of a salesperson. However, the intention of encouraging a depressed client to be active is based on knowledge that physical movement affects mood; that is, persuasion is used for the purpose of helping the client. Person-centred care means that communication is always 'for' the client; the nurse is morally positioned to communicate in a manner that serves the client's best interest. Clients perceive that good communication with nurses is centred on their needs and concerns (McCabe 2004). Therefore, effective communication is a core element in person-centred care (Kitson et al 2013).

This chapter presents the basic aspects of effective and therapeutic communication within the context of person-centred nursing practice. The qualities, behaviours and communication techniques described characterise professionalism in therapeutic relationships with clients and collaborative relationships with colleagues. Although the terms 'client' and 'patient' are often used interchangeably, the same principles can be applied when communicating with any person in any nursing context.

The context of nursing practice

Some aspects of **communication** stand out as more relevant than others; it is therefore important to consider the particular aspects of effective professional communication within the context of nursing practice. In the particular context of nursing, effective interpersonal communication

RESEARCH HIGHLIGHT

Research focus

In order for nurses to communicate effectively with patients they need a clear understanding of what constitutes 'effective' communication from a variety of perspectives. Previous studies have examined patients' perspectives, but it is also important to understand nurses' perceptions of effective communication. Participants in this study, clinicians and educators, identified what they considered to be effective communication.

Research abstract

Participants viewed videos of simulated interactions between nurses and patients. They recorded their observations of the interactions in relation to what they considered effective and less effective communication, and how they would provide feedback to the nurse in the video. They then participated in focus group interviews which were audio-recorded and analysed thematically. The findings were reported as four main themes: approach, manner, technique and communication. Approach included the degree of person-centredness evident and was considered the overarching theme; manner included engagement, being friendly and tone of voice; techniques included types of questions, explaining and checking understanding; and communication included non-verbal and verbal behaviour.

Evidence-based practice

- The extent to which nurses engage the patient during interactions is central to effective communication.
- Focusing on the patient's concerns and needs is not only evidence of effective communication but also of the degree of patient-centredness in interactions.
- Nurses understand that effective communication includes both techniques/skills and general demeanour.
- Nurses should neither devalue nor diminish the importance of how they approach patients during interpersonal encounters.

Reference

O'Hagan et al 2014 What counts as effective communication in nursing? Evidence from nurse educators' and clinicians' feedback on nurse interactions with simulated patients. J Adv Nurs 70(6):1344–56.

is required for the exchange of health-related information, the promotion of therapeutic relationships with clients and the development of collaborative relationships with other healthcare professionals. Nurses must be competent in the use of effective interpersonal communication skills and knowledgeable about healthcare matters, while simultaneously assuming an attitude of being 'for' the client. Focusing attention on the client is central to communication in nursing practice (O'Hagan et al 2014).

The competent nurse is able to therapeutically adjust and accommodate the use of effective communication skills in response to specific clinical contexts. Context helps to shape client needs. For example, a client who is undergoing diagnostic tests for possible cancer does not need detailed information about managing the possible side effects of radiotherapy (as might a client about to undergo radiotherapy). Such information might increase client anxiety during the diagnostic phase of an illness.

In addition to influencing the content of communication, context also affects the processes of communication. For example, intensive-care nurses rely on non-verbal communication from their patients when interacting with patients who are rendered speechless by mechanical ventilation, and community nurses spend much time enabling client self-care through health education communication. Consideration of context requires critical thinking about what is of benefit in meeting client needs, and such thinking is based on the nurse's understanding of the therapeutic value of communication.

Why nurses need to communicate

A public expectation that nurses are effective communicators is embedded into standards for practice for nurses (Nursing and Midwifery Board of Australia (NMBA) 2006, Nursing Council of New Zealand (NCNZ) 2007, see also Chapters 10 and 11), and professional codes of ethics and conduct (Australian Nursing and Midwifery Council (ANMC) 2008a, 2008b, Nursing Council of New Zealand 2009, see also Chapter 9). Standards for practice include the nurse's ability to collect relevant information from clients about their functional health status, and effective communication is required to elicit such data during client interactions. Standards for practice also require a professional nurse to provide relevant healthcare information to clients and their families in an effort to facilitate their understanding of health events and encourage their active participation in healthcare decisions. Effective communication is essential to the provision of such information. Enabling therapeutic relationships with clients through communication is one way that nurses demonstrate expected public standards of professional competency and conduct. The reason that communication is built into standards for practice and codes of conduct in nursing is that effective communication promotes client health and wellbeing (Fleischer et al 2009).

Dynamics of interpersonal communication

Interpersonal communication operates at two levels: *content* and *process*. The content level encompasses what is being discussed; that is, the subject matter. For example, when interviewing a client for the first time the content will most likely involve a history of the client's health status and immediate care needs. The content level of communication is easily identified. The second level, that of process, is more subtle. This level involves *how* something is communicated rather than *what* is being communicated. For example, if the nurse conducting an initial interview with a client does so in a cold, clinical manner by simply asking a series of questions that follow a pre-set format, the client may not perceive the nurse to be genuinely concerned and caring. In this way the process level reveals the nature of the relationship between nurse and client. Content and process go hand in hand. For example, if the nurse is warm and open, demonstrating genuine interest in the client (process level), then clients are likely to be willingly forthcoming with information about their health status and concerns (content level).

Interpersonal communication is effective when meanings are shared between people. Messages that are sent are received with understanding when the person receiving the message understands the intent of the sender. However, interpersonal communication is not quite this straightforward. The intention of the sender of a message may not be easily understood by the receiver; and the receiver also has intentions that might not be clear to the sender. There are numerous aspects to consider in being an effective communicator.

Effective communicators are those people who can assert their own ideas while being able to respond with understanding to other people's ideas. That is, skilled communicators are able to blend and balance two basic types of communication techniques: *responsive* and *assertive*. Responsive techniques facilitate mutual understanding between people; that is, from the same point of view. For example, a nurse who expresses empathy towards the suffering of a client is being responsive. Responsive techniques operate from an empathic understanding of a health event from the client's perspective. In contrast, assertive techniques offer new insights and information from the nurse's knowledge and professional perspective, for example, health teaching and

education. Assertive techniques promote understanding of differing points of view.

Skills in being both responsive and assertive are what constitute effective communication in nursing practice (Figure 12-1). Nurses who are skilled at being assertive yet are not responsive are at risk of being too domineering, and may not take into consideration the feelings and personal perspectives of clients. Such nurses may expect clients to simply 'do as they are told'. Nurses who are skilled at being responsive yet are not assertive are at risk of becoming overly accommodating, and may not challenge a client's faulty thinking or misinformation. Moreover, assertive skills are required when collaborating with other healthcare professionals, as nurses present their views of client care from a nursing perspective. Nurses who are skilled in assertive communication techniques are more likely to advocate for clients and peers who are vulnerable, afraid or experiencing a threat to their human rights (MacDonald 2007).

Generally speaking, assertive skills are often used when advocating for clients while responsive skills are employed for the purpose of building relationships with patients and their families, which are based on the nurse's understanding of their needs, concerns and desires. Developing such understanding is the heart of person-centred care. In recent reviews of the concept of patient-centred care, communication is consistently identified as a key element (Constand et al 2014, Kitson et al 2013, Sidani & Fox 2014). This is because person-centred care is based on collaboration between clients and healthcare professionals in which clients are active participants in their care. Therefore, nurses must use communication and relationship-building skills in order to understand what clients desire in order to respond to their needs 'as they perceive them to be'.

Knowing the patient

Through communication the nurse comes to know the patient/client, not only as a patient or client, but also as a person with a unique perspective and life history. Termed '**knowing the patient**', this concept entails understanding what the health situation means to the client (Zolnierek 2014). By understanding the situation from the client's point of view, nurses are able to not only individualise care but also create a relationship based on empathic understanding (Bundgaard et al 2012, Mantzorou & Mastrogiannis 2011). Knowing the patient as a person is a critical aspect of safety and quality in nursing practice; more importantly, it is the essence of person-centred care.

Liaschenko and Fisher (1999) offer a useful schema to understand the meaning of knowing the patient. They describe three types of knowledge that nurses use in the conduct of their work. The first is termed *case knowledge*, and encompasses objective facts such as anatomy and physiology, disease processes and pharmacokinetics. The next is *patient knowledge*, which includes understanding how a client is responding to a particular health event, for example, side effects of medications and the experience of pain. The third type is *person knowledge*, which includes an intimate understanding of the person's life history, their values and belief systems and their familial connections. Patient knowledge includes both physiological as well as emotional responses, which can be observed; however, person knowledge requires communication with the client. Figure 12.2 illustrates that the three types of knowledge intersect; it is in the intersecting spaces that nurses work. They use all three types of knowledge in a holistic manner.

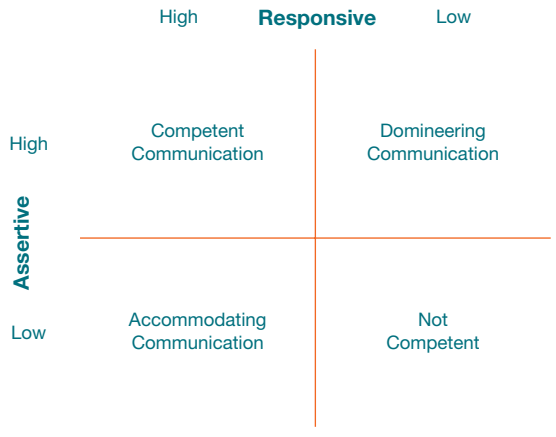

Figure 12-1 **Communication competence.**

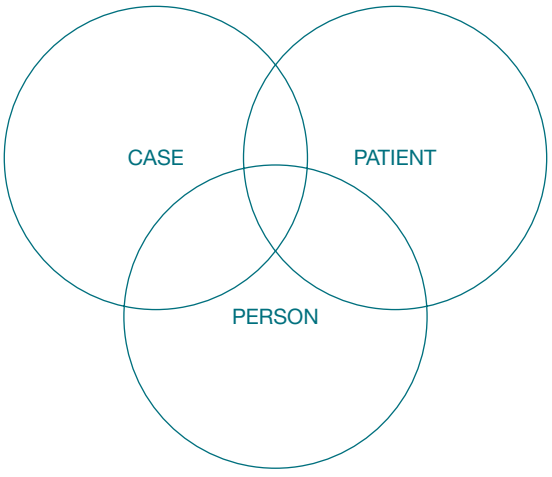

Figure 12-2 **Types of nursing knowledge.**

According to this schema, the concept of 'knowing the patient' is encapsulated in patient and person knowledge. The degree to which a nurse comes to 'know the patient' varies with context. For example, in a study conducted in an outpatient endoscopy clinic, the nurse identified 'knowing the patient' in a practical sense, for example, their immediate concerns about the procedure they were about to undergo (Bundgaard et al 2012). In an emergency situation, it is unlikely that person knowledge will be of critical relevance (unless making a decision to cease treatment).

Patient-centred communication

Current efforts in healthcare systems reform are aimed at making communication, and care itself, more patient-centred (Newell & Jordan 2015, van Dulmen 2011). Being patient-centred means that the needs and expectations of patients are placed at the heart of communication and, more importantly, their voice in decision-making about their care is heard and heeded. **Patient-centred communication** contrasts with what has been a more traditional style focused on biomedical matters such as signs and symptoms. In nursing practice, being patient-centred contrasts with being task-focused. There is evidence to suggest that patient-centred communication increases not only patient satisfaction but also adherence to treatment and general improved health (Charlton et al 2008, Newell & Jordan 2015); the reason is that patients become more active participants in their own care.

While it may seem obvious that patient-focused communication should be standard, studies have demonstrated that communication often does not take into account what patients want and how they feel (Bolster & Manias 2010, Nordehn et al 2006). What is important to realise is that patients have varying desires to participate in care; some want to follow orders and 'toe the line', while others want to make decisions for themselves (Tobiano et al 2015). Patient-focused communication establishes the degree to which the patient desires to participate and their preferences for treatment.

Using a patient-focused approach to communication not only results in understanding how patients want to participate in care, but also includes understanding their nursing care needs, such as sleep problems, anxiety and pain. Unfortunately, such understandings are not always evident, as nurses often misperceive, underestimate or overestimate patient needs (Florin et al 2005, Sobo 2004). For this reason it is important that nurses share their perceptions with patients, clarify their understanding and paraphrase what the patient seems to be communicating. All of these skills are reviewed later in the chapter.

Healthcare environments and communication

Current **healthcare environments** can work against effective communication, especially when there is an emphasis on task completion and a sense of little time to do so. There are often competing demands in actual nursing practice that limit nurses' capacity to spend time interacting and developing therapeutic relationships with clients. Most of the time nurses only interact with patients in hospital when performing a task or function (McCabe 2004, Newell & Jordan 2015). Lack of time is a factor that is often espoused by nurses as they perceive that communication that is focused on relationship-building takes more time than that focused on tasks (Chan et al 2012). The espoused professional value of the importance of therapeutic relationships is often at odds with the values of tasks needed to be completed in set timeframes, especially in organisational settings such as hospitals. In current healthcare systems, which are focused on efficiency, there is little value given to the importance of communication, and relating to and coming to know the patient is often not viewed as nursing 'work' (DeFrino 2009). Professional nurses must learn to reduce this variance by remaining true to the value placed on communicating with and relating to clients, in the knowledge that this is central to therapeutic practice. More importantly, they should be active in healthcare reform to redress the devaluing of communication with clients.

Communication and interpersonal relationships

At the core of nursing are caring relationships formed between nurses and clients, and communication is the means of establishing these relationships and coming to know the client. The knowledge gained about the client through relational work is at the heart of nursing practice, and the communication skills required are not simply a matter of 'being nice' to patients but rather are a professional duty (DeFrino 2009). The nurse's ability to relate to others rests on effective interpersonal communication, which includes being able to take the initiative in establishing and maintaining communication, to be authentic (one's self), and to respond appropriately to the other person.

Professional relationships are created through the nurse's application of knowledge, understanding of human behaviour and communication, and commitment to the moral stance of being 'for the client'. Having a philosophy based on caring and respect for others will help the nurse

be more successful in establishing relationships of this nature with clients. Being responsive to client needs is basic to therapeutic communication. Nurses also communicate in the context of other professional relationships that may require an emphasis on being assertive. For example, when collaborating with a multidisciplinary healthcare team, nurses must be able to assert their views from the perspective of nursing knowledge.

Nurse–client relationships

Helping relationships with clients are central to therapeutic nursing practice. In such relationships, the nurse assumes the role of professional helper and comes to know the client as an individual who has unique health needs, human responses and patterns of living. Knowing the client is a central caring behaviour that also functions as an aid to clinical problem-solving and decision-making and is also central to client participation in care (Zolnierek 2014). Through knowing the client, nurses are able to understand health events from the experience of the client, adapt their care to the unique needs of the individual and judge how a person is responding to healthcare events. This type of knowing requires effective communication between nurse and client so that mutual understanding can be achieved.

Therapeutic and social relationships

Communication involves complex social activity more than other aspects of nursing practice, such as technical proficiency and skills. Through communication, nurses relate to a variety of people during direct client care and within healthcare organisations. However, the social activity in nursing is different from other forms of social activity, such as friendships. Communication in nursing is professional and therapeutic, and is thus different from communication in friendships.

In therapeutic nurse–client relationships there is an explicit timeframe, a goal-directed approach and a high expectation of confidentiality. The nurse establishes, directs and takes responsibility for the interaction, and the client's needs take priority over the nurse's needs. In acting in the client's best interest, the nurse maintains professional boundaries.

There are clear legal boundaries, as nurses must practise within the scope of their professional knowledge and skill, while codes of conduct (ANMC 2008a, NCNZ 2009) specify ethical boundaries. However, professional boundaries are not always as clearly laid out as geographical ones, for example those between countries. Nurses cross professional boundaries when they do not act in the best interest of the patient (Hartlage 2012), but rather act in a manner that meets their own needs, such as the need to be liked. Having a sexual relationship with a client is a clear boundary violation, as it is focused on the nurse's needs. More subtly, nurses can cross boundaries when they burden clients with their own problems, such as being short-staffed and under pressure. The relationship is always 'for the patient' and this is the best principle to follow in maintaining professional boundaries.

The relationship is also characterised by the nurse's non-judgemental acceptance of the client. Acceptance conveys a willingness to hear a message or to acknowledge feelings. It does not mean the nurse must always agree with the other person or approve of the client's decisions or actions.

A therapeutic relationship between nurse and client does not just happen – it is created with care and skill and is built on the client's trust in the nurse. In her seminal work, Patricia Benner (1984) prefers not to use the term 'therapeutic' because of its association with psychotherapy, yet describes a helping role of the nurse in a similar fashion. She states that 'helping encompasses transformative changes in meanings, and sometimes simply the courage to be with the client, offering whatever comfort the situation allows' (Benner 1984:48). A helping relationship between nurse and client is one in which the nurse comes to understand the patient as a person with a unique point of view. Forming such relationships enables nurses to provide care that is individualised to that person and their family, therefore providing person-centred nursing care.

The nurse–client relationship is characterised by a natural progression of four goal-directed phases that often begin before the nurse meets the client, and continue until the caregiving relationship ends (Box 12-1). Even a brief interaction uses an abbreviated version of the same *pre-interaction*, *orientation*, *working* and *termination* phases. For example, the nursing student may gather client information to prepare in advance for caregiving, meet the client and establish trust, accomplish health-related goals through use of the nursing process and say goodbye at the end of the day.

Socialising is often an important initial component of interpersonal communication. It helps people get to know one another and relax. It is easy, superficial and not deeply personal, whereas therapeutic interactions are often more intense, difficult and uncomfortable. A nurse often uses social conversation to help the client feel comfortable and lay a foundation for a closer relationship. Clients value nurses being 'friendly and chatty' (Henderson et al 2007, McCabe 2004). An informal and warm communication style helps establish trust, but nurses must get beyond social conversation to talk about issues or concerns

BOX 12-1 Phases of the helping relationship

Pre-interaction phase

Before meeting the client, the nurse:

- reviews available data, including the medical and nursing history
- talks to other caregivers, who may have information about the client
- anticipates health concerns or issues that may arise
- identifies a location and setting that will foster comfortable, private interaction
- plans enough time for the initial interaction.

Orientation phase

When the nurse and client meet and get to know one another, the nurse:

- sets the tone for the relationship by adopting a warm, empathetic, caring manner
- recognises that the initial relationship may be superficial, uncertain and tentative
- expects the client to test the nurse's competence and commitment
- closely observes the client and expects to be closely observed by the client
- begins to make inferences about client messages and behaviours
- assesses the client's health status
- prioritises the client's problems and identifies the client's goals
- clarifies the client's and nurse's roles
- forms contracts with the client that specify who will do what
- lets the client know when to expect the relationship to be terminated.

Working phase

When the nurse and client work together to solve problems and accomplish goals, the nurse:

- encourages and helps the client to express feelings about their health
- encourages and helps the client with self-exploration
- provides information needed to understand and change behaviour
- encourages and helps the client to set goals
- takes actions to meet the goals set with the client
- uses therapeutic communication skills to facilitate successful interactions
- uses appropriate self-disclosure and confrontation.

Termination phase

During the ending of the relationship, the nurse:

- reminds the client that termination is near
- evaluates goal achievement with the client
- reminisces about the relationship with the client
- separates from the client by relinquishing responsibility for their care
- achieves a smooth transition for the client to other caregivers as needed.

affecting the client's health. During social conversation, clients may ask personal questions about the nurse's family, place of residence and so on. Students often wonder if it is appropriate to reveal such information; that is, to self-disclose. In an attempt to 'be professional' they sometimes assume it is inappropriate to share anything of themselves. Although a high degree of self-disclosure is characteristic of intimate friendships, it does not fit the context of a therapeutic relationship; however, nurses can use self-disclosure to benefit the relationship with the client, provided they remain professional and do not overstep their professional boundaries (Stein-Parbury 2014).

Nurses often encourage clients to share personal stories; in doing so, nurses come to understand the context of other people's lives and learn what is meaningful for them from their perspective. For example, a nurse asked a client to tell about a time in his life when he had to make a hard decision. He related the following story:

> **When I was a young man, I worked on the family farm. An uncle died and left me some money. All of a sudden I could afford to go to the city for a university education, but Dad didn't want me to go because he needed me there. I had to decide whether to stay or go, and it was hard, because at first I just wanted to get away. I talked to our priest, and he said it was up to me, to pray about it and then do what my heart told me to. So I stayed. Oh, I've thought from time to time what might have been, but I never regretted it. I've had a good life on the land.**

From this brief story, the nurse understood that it was important to the client to put his family's needs above his personal desires, and that seeking spiritual guidance was an important component of his decision-making.

Nurses also provide information and use strategies that help clients understand and change behaviour. The nurse also acts as an advocate to keep the client informed of healthcare alternatives and give support in decision-making. For example, the nurse can ask clients and family members for input and suggestions about goals, interventions and evaluation of the plan of care. This type of mutuality (give-and-take, creative mutual exchanges) has been shown to balance power and respect, and to promote productive provider–client communication (Tejero 2012). It gives the other person a greater sense of purpose and

direction, encourages personal responsibility for health, helps establish priorities for care, gives the opportunity for self-expression and strengthens the client's problem-solving ability. This depends on the vulnerability of the client; that is, the degree to which personal resources are available, adequate and appropriate to the situation at hand. Information is one such possible resource.

Nurse–family relationships

Providing person-centred health care is not only focused on individual clients, but also includes involving families, which is being family-centred (see also Chapter 15). The same principles that guide one-to-one helping relationships apply when the client is a family unit, although communication within families requires additional understanding of the complexities of family dynamics, needs and relationships. For example, when communicating with families there is often a 'spokesperson' who may be the primary carer, but could also be the family member who is most knowledgeable about health matters or who knows the client most intimately.

Family members have needs for collaboration and involvement in care when their loved ones are in need of health care (Bauer & Nay 2011, Tallon et al 2015, Wong et al 2015). This is especially true when their loved one is in a highly vulnerable state, such as being a patient in an intensive care unit, being a child in hospital or experiencing cognitive impairment in dementia. The communication needs that are most relevant to family members are the need for information about their family member's situation. Nurses are well placed to provide such information, especially as families have the most contact with nursing staff in the majority of healthcare settings.

In addition to their need for information, families require emotional support from nurses. Such support is perceived when nurses listen to their concerns (Tallon et al 2015). It is important for nurses to explore these concerns through clarifying and asking relevant questions. Often, their concerns are related to the need for information and assurance as to their loved one's comfort and wellbeing.

While it is important that nurses recognise and meet the needs of families, it is equally important that they understand that families are an important source of

RESEARCH HIGHLIGHT

Research focus

Patients admitted to an intensive care unit (ICU) are critically ill and often unable to speak because they are mechanically ventilated (with a tube in their airway). The involvement of family members is paramount, not only because they are distressed but also because they are in a position to provide comfort to their family member. For this reason they rely on nurses to keep them informed of their family member's situation, and nurses can turn to them for information about their family member. It is important that nurses understand the communication needs of families whose loved one is in ICU. This study is an exploration of families' experiences of interpersonal interactions with ICU staff.

Research abstract

This study was an exploration of the experiences of family members of critically ill patients who were admitted to an ICU in a major metropolitan Australian hospital. In-depth interviews that focused on the participants' experiences when interacting with ICU staff were conducted with 12 participants. Data were analysed based thematically on the principles of grounded theory, with three major themes identified. The first was 'obtaining information', which included strategies used to obtain information and using nurses as communication channels. The second theme related to the type of language used, such as using lay terms and being open and honest. The final theme was 'supportive communication', which was reassuring to the participants.

Evidence-based practice

- Obtaining information is very important to families and they usually turn to nurses to gain such information.
- Families want honest communication and do not want information 'sugar-coated' by nurses in an effort to avoid distressing them.
- The language used in conveying information to families needs to be provided in a way that they understand so nurses need to be mindful about using 'medical jargon'.
- Families found it reassuring when the provided information was consistent.
- Families felt support when nurses responded to their non-verbal cues that indicated they were distressed, anxious or confused.
- Although this study involved critically ill patients, the findings are not confined to ICU. They are relevant to any area of nursing.

information about clients. They are in a position to provide relevant health information and insights into the person who is the client. In addition, they are often in a position to act as advocates and speak on behalf of the client (Stein-Parbury et al 2015).

Healthcare team relationships

Nurses are members of a larger healthcare community and often function in roles that require interaction with multiple healthcare team members. The basic elements of effective communication that apply to the nurse–client relationship are also relevant in relationships with colleagues. That is, nurses must be responsive in understanding the views of their professional colleagues, and they must also be assertive in stating their views about client care. Communication in relationships with colleagues may be geared towards team-building, facilitating group process, collaboration, consultation, delegation, supervision, leadership and management. Various communication skills are needed, including presentational speaking, persuasion, group problem-solving, providing performance reviews and writing business reports.

Both social and therapeutic interactions are needed between the nurse and other healthcare team members to build morale and strengthen relationships within the work setting. Nurses need friendship, support, guidance and encouragement from one another to cope with the many stressors imposed by the nursing role, and must extend the same caring communication used with clients to build positive relationships with colleagues and co-workers.

Collaboration in healthcare team communication

In the contemporary healthcare climate there is a focus on enhancing teamwork and interprofessional collaboration that is focused on improved quality and safety. In part this is due to reports that demonstrate that poor and inadequate interprofessional communication is a major factor in events that result in patient harm (Brock et al 2013). Pannick et al (2014) identified that staff communication and **collaboration with colleagues** was a major theme in a review of evidence related to quality and safety of general medical units, rather than specialised units that have more stable teams such as intensive care or operating theatre units. Therefore, improving collaborative teamwork as a way to enhance positive patient outcomes is receiving attention because this is believed to have a greater effect than other strategies (Barrow et al 2015).

Team collaboration works best when members of the team are able to communicate effectively and

RESEARCH HIGHLIGHT

Research focus

While teamwork in health care is considered important, relying on traditional concepts about 'teams' (such as sports teams) does not take into account that healthcare professionals have different professional backgrounds, perspectives and identities. In addition, traditional notions of 'teams' do not address the social structures and culture of healthcare organisations, for example, the hierarchical nature of most hospital systems. More importantly, healthcare teams are often assembled 'ad hoc' with fluid and changing membership.

Research abstract

In this New Zealand study, 14 senior medical registrars and consultants and 17 nursing managers, clinical nurse consultants and nurse practitioners were interviewed. The interviews were focused on how the participants viewed interprofessional, collaborative practice and their ways of working as team members. The findings revealed that nurses and doctors used different parameters in evaluating each other's ability to contribute to care decisions. While they both recognised that biomedical discourse was dominant, the doctors recognised that it is the nurses who have intimate knowledge of the patient, as a person not as a disease. In addition, doctors perceived that nurses had a holistic view while theirs was more focused on the illness and treatment. While doctors were more individualistic and autonomous in their approach to care, nurses were viewed as collectivist and protocol-driven.

Evidence-based practice

- Simply having a shared goal, such as the delivery of quality patient care and good communication, is not sufficient for creating a functioning interprofessional team.
- Nurses and doctors operate from different professional perspectives, with nurses having knowledge of the person who is the patient.
- Nurses should value their knowledge of the patient as important information to contribute when collaborating with other healthcare professionals.

develop an understanding of each other's perspective. In doing so they develop what is termed a 'shared mental model' (McComb & Simpson 2013). Effective collaboration in the form of interdisciplinary rounds has proven to be an effective way to decrease errors and improve patient safety; these rounds work best when there are structured systems for the communication of patient information. Such systems are 'shared **mental models**', which have been shown to improve quality and safety. One of the most widely used formats is the ISBAR tool, which is used for patient handover, as described in Skill 12-1.

SKILL 12-1

Patient handover

Delegation and other considerations

Patient handover can be conducted by any healthcare professional providing care for the patient. Where possible, the registered or enrolled nurse who is providing direct care for the patient should be the one to provide the handover. If this is not the case, the nurse in charge or a senior nurse familiar with the patient should provide handover.

Equipment

- Patient handover sheet
- Patient bedside folder or charts
- ISBAR checklist

Therapeutic relationship and patient considerations

- Confirms patient identity
- Gains patient consent
- Initiates communication by introductions and clarification of patient's immediate needs and problems
- Identifies how the skill will affect the patient
- Discusses procedure with the patient to clarify understanding
- Provides reassurance
- Assesses patient knowledge and expectations and ensures patient understanding
- Where necessary, provides further clarification
- Explains actions and potential discomfort at all stages of procedure

STEPS	RATIONALE
Critical decision point: Prior to handover, review all your patients and charts to ensure the information that you are going to give is accurate and up to date.	
1. Inform the patient prior to starting handover that during the change of shift you will be informing the oncoming nurse about their progress and any updates to their care plan.	An increasing number of healthcare facilities conduct handover at the bedside. To a patient who is new to the ward or unfamiliar with the handover procedure, this may be confronting or confusing. Remember to ensure patient confidentiality when conducting a bedside handover – all confidential information should be discussed later and in a private area (Higgs et al 2012).
2. Assess patient comfort, offer toileting and provide analgesia where appropriate.	It is important that you make sure your patient is comfortable and pain-free prior to handover. Although standardised handovers are designed to shorten handover, delays are possible (Street et al 2011).
3. Gather all appropriate documentation including patient handover sheet, patient folders or notes and ISBAR checklist.	Ensuring that all required information is available will prevent interruptions and ensure smooth delivery of patient information.
Critical decision point: Prior to commencing handover, it is important to identify that both healthcare professionals know and are familiar with the ISBAR checklist.	

STEPS	RATIONALE
4. Commence handover of your patient following each key characteristic of the ISBAR mnemonic.	
a. Identify – identify yourself, your role, your ward or location – identify the name, role of the receiver – identify the patient: include name, patient ID number, date of birth, age, gender.	Introducing yourself professionally improves collegiality and ongoing or future working relationships. To prevent errors, use a minimum of three (3) identifiers for each patient, when handing over (South Australia Health 2012).
b. Situation – inform the receiver of the reason for the patient's admission (or for your call if handover is external) – provide any additional patient information, including health status.	Explain to the receiver what is happening to the patient and why you are providing handover. Depending on the location and mode of communication, the situation may be obvious.
c. Background – provide relevant details such as presenting complaint, past history, assessment, investigations and any interventions.	Explain the story of the patient and identify the current problem, relevant information and any interventions (medication, IV fluids, CT scans) that have been completed (LeMone et al 2014, Marshall et al 2009).
d. Assessment – provide an outline of what you believe is wrong with the patient. Give your assessment of the patient's current health status.	It is important to utilise critical thinking based on the assessment of the patient, and not an opinion. Make sure this information is clear and not confusing to the receiver.
e. Request – state what you want from the receiver. Make sure the receiver understands what is being asked of them.	Be specific about what you want from the receiver – patient transfer, patient review, medication or patient handover.

■ **Critical decision point: Depending on the health profession (medical officer, registered nurse, physiotherapist), the purpose of the handover and the information received may vary; however, the overall structure of the information received should be standardised.**

RECORDING AND REPORTING

- Record assessment findings in patient's healthcare record following local hospital policy and protocols.
- Report any abnormal data following comprehensive assessment to the senior nurse, acute pain service or another appropriate medical officer.

HOME CARE CONSIDERATIONS

- Has a discharge plan been created?
- Has the client received information about the ongoing plan and follow-up arrangements?
- Do the family or significant others have concerns or need information to help with the plan?

Nursing knowledge and healthcare team collaboration

When nurses collaborate with other healthcare professionals they bring knowledge that is specific to the practice of nursing. While nurses can communicate their knowledge of the patient's clinical condition (case knowledge), their focus is related more to the patient and person knowledge. Their focus on patient knowledge means that they will bring an understanding of how the patient/client is responding to their clinical condition and its treatment, for example, the degree of distress experienced or a side effect of medication. In addition, they are likely to know the private, idiosyncratic world of the patient (person knowledge), including their values and belief systems. It is for this reason that interprofessional communication can break down because different professionals operate from a different, albeit potentially compatible, knowledge base (Barrow et al 2015, Stein-Parbury & Liaschenko 2007); they do not share the same 'mental model'.

The potential breakdown in communication may result in conflict between professionals because they simply do not fully understand the perspective of the other and do not make the communicative effort to build mutual understanding. Conflict in communication is not necessarily negative; in workplace situations it can be positive as multiple perspectives are brought to bear in solving problems.

Collaboration and conflict

When conflict does arise, there are a number of ways that a healthcare professional can respond. They can become:

- **aggressive and competitive – not attending to others' concerns and running rough shod over others;**
- **passive and avoidant – not engaging and evading the conflict;**
- **accommodating and submissive – neglecting own concerns and acquiescing to others;**
- **compromising and finding the middle ground – partially satisfying both concerns; or**
- **collaborative and understanding – fully satisfying both concerns (Thomas & Killman 1977).**

These ways of responding in a conflict situation directly relate to communication competence as depicted in Figure 12-3. An aggressive response is domineering communication; a submissive response is accommodation communication. Avoiding or evading conflict is considered to be ineffecitive at resolving conflicts. The competent communicator will approach conflict in a collaborative way. A compromising response relates to all aspects of communication competence. Finding a middle ground through compromise, negotiating a 'give-and-take' solution, may work in some contexts, such as conflict over workload; but a compromise in the healthcare setting may jeopardise patient safety and wellbeing. Collaboration, where all voices are heard and understood, including the patient's viewpoint and wishes, has been shown to result in quality and safety in the healthcare arena (Pannick et al 2014).

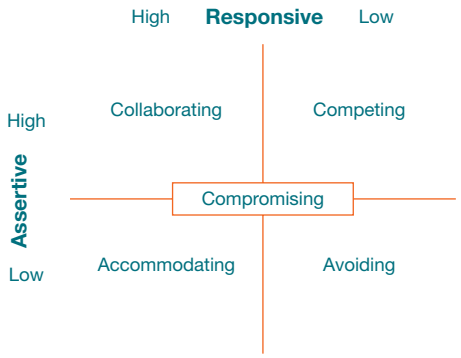

Figure 12-3 Styles of conflict responses.

Adapted from Thomas KW, Kilmann H 1977 Developing a forced-choice measure of conflict-handling behavior: the 'mode' instrument. Educ Psychol Meas 37(2): 309–25.

Evidence shows that nurses who work in a clinical setting tend to be accommodating and submissive when dealing with interprofessional conflict (Iglesias & de Bengoa Vallerjo 2012, Kaitelidou et al 2012, Mahon & Nicotera 2011). They are likely to meet conflict in the workplace in a passive manner, rather than with active and assertive attempts to collaborate. While this tactic may keep the peace, failing to express a viewpoint that is different from others' can result in poor quality health care. People who use passive strategies are seen as more likeable and this may be one reason nurses behave this way. Another reason is that nurses are trained to communicate therapeutically; they focus on feelings, rather than finding solutions to conflict (Northam 2009). Because they are caring and compassionate towards patients, nurses may suffer under what Street (1992) has termed the 'tyranny of niceness'. That is, they may think that active assertion, which is required for successful negotiation, is not compatible with being a caring person (McCartan & Hargie 2004).

• CRITICAL REFLECTION POINT

View the video clip titled 'Just a Routine Operation' which can be found at https://www.youtube.com/watch?v=JzlvgtPIof4

After viewing, consider the following questions:

1. **How did the nurses respond to this critical situation? What did they do? What did they say? Note especially**

when they brought the tracheostomy trolley into the room.

2. **How did the doctors respond to the nurses in this situation, especially when they brought in the tracheostomy trolley and discussed the intensive care unit (ICU) bed? What evidence was there that they heard and registered what the nurses said?**
3. **Why did the nurse cancel the ICU bed after she had booked it for the patient? What made her think that she was overreacting to the situation?**
4. **What could the nurses have done differently in this situation?**

Not only are passive strategies, such as avoiding and giving in, not always successful in resolving the conflict, but they are also associated with increased stress and decreased mental wellbeing in nurses (Chang et al 2007). Therefore, it is important that nurses learn how to deal with workplace conflict through the use of assertive skills. When used deliberately, compromising and acquiescing can be assertive in their own right; however, more active assertion is often required when dealing with workplace conflict. Successful resolution of conflicts can bring people closer and adds to satisfaction and creativity in the workplace; when handled poorly, conflicts can create extra strain and tension. More importantly, workplace conflict affects patient outcomes and leads to errors (Northam 2009).

Levels of communication

Nurses use different levels of communication in their professional role. The nurse's communication skills need to include techniques that reflect competence at each level.

Intrapersonal communication

Intrapersonal communication is a powerful form of communication that occurs within an individual. This level of communication is also called self-talk, self-verbalisation, self-instruction, inner thought and inner dialogue. People's thoughts strongly influence perceptions, feelings, behaviour and self-concept. Intrapersonal communication creates a set of conditions through which life is experienced. Nurses should be aware of the nature and content of their thinking and try to replace negative, self-defeating thoughts with positive assertions. Positive self-talk can be used as a tool to improve the nurse's or client's health and self-esteem. Self-instruction can provide a mental rehearsal for difficult tasks or situations so individuals can deal with them more effectively. Nurses and clients can use intrapersonal communication to develop self-awareness and a positive self-concept that will enhance appropriate self-expression.

Interpersonal communication

Interpersonal communication is one-to-one interaction between the nurse and another person that often occurs face to face. It is the level most often used in nursing situations and lies at the heart of nursing practice. It takes place within a social context and includes all the symbols and cues used to give and receive meaning. Since meaning resides in persons and not in words, messages received may be different from messages intended. Nurses work with people who have different opinions, experiences, values and belief systems, so meaning must be validated or mutually negotiated between participants.

Small-group communication

Small-group communication is interaction that occurs when a small number of people meet together. This type of communication is usually goal-directed, and requires an understanding of group dynamics. When nurses work on taskforces or committees, lead client support groups, form research teams or participate in client care conferences, a small-group communication process is used. Small groups are more effective when they are a workable size, have an appropriate meeting place, suitable seating arrangements, and cohesiveness and commitment among group members (Hybels & Weaver 2008). Small-group communication is effective when the group achieves its objectives in a manner that is inclusive of all members and results in satisfaction with decision-making processes.

Forms of communication

Messages are conveyed verbally and non-verbally, concretely and symbolically. As people communicate, they express themselves through words, movements, voice inflection, facial expressions and use of space. These elements can work in harmony to enhance a message, or conflict with one another to contradict and confuse it.

Verbal communication

Verbal communication uses spoken or written words. Verbal language is a code that conveys specific meaning as words are combined. The most important aspects of verbal communication are discussed below.

Vocabulary

Communication is unsuccessful if people cannot translate each other's words and phrases. When a nurse cares for a client who speaks another language, an interpreter may be necessary. Even those who speak the same language use variations of certain words: dinner may mean a noon meal to one person and the last meal of the day to another.

Medical jargon (technical terminology used by healthcare providers) may sound like a foreign language to clients unfamiliar with the healthcare setting, and should be used only with other healthcare team members. Children have a more limited vocabulary than adults. They may use special words to describe bodily functions or a favourite blanket or toy. Teenagers often use words in unique ways that are unfamiliar to adults.

Meanings of words and phrases

A single word can have several meanings. The *denotative meaning* is shared by individuals who use a common language: 'tennis' has the same meaning for everyone who speaks English, but the word 'drug' may have different meanings to a healthcare professional and to a layperson. The *connotative meaning* is the shade or interpretation of a word's meaning influenced by the thoughts, feelings or ideas people have about the word. Families who are told a loved one is in a serious condition may believe that death is near, but to nurses 'serious' may simply describe the nature of the illness. Nurses should carefully select words that cannot be misinterpreted, especially when explaining a client's medical condition or therapy. Even a much-used phrase such as 'I'm going to take your observations', can be unfamiliar to an adult or frightening to a child.

Clarity and brevity

Effective communication is simple, brief and direct. Fewer words result in less confusion. Speaking slowly and using examples to make explanations easier to understand achieves clarity. Repeating important parts of a message also clarifies communication. Phrases such as 'you know' or 'okay?' at the end of every sentence detract from clarity. Brevity is achieved by using short sentences and words that express an idea simply and directly. 'Where is your pain?' is much better than 'I would like you to describe for me the location of your discomfort'.

Timing and relevance

Timing is critical in communication. Even though a message is clear, poor timing can prevent it from being effective. For example, the nurse should not begin routine teaching when a client is in severe pain or emotional distress. Often the best time for interaction is when a client expresses an interest in communicating. If messages are relevant or important to the situation at hand, they are more effective. When a client is facing emergency surgery, discussing the risks of smoking is less relevant than explaining how to keep the lungs clear postoperatively.

Non-verbal communication

Non-verbal communication is message transmission through body language, without using words. Non-verbal communication often reveals true feelings because it is hard to control: a colleague who says nothing is wrong but has tears in her eyes is probably in distress. Non-verbal cues add depth to verbal messages and help the nurse judge their reliability. Becoming an astute observer of non-verbal behaviour takes practice, concentration and sensitivity to others. Nurses should avoid sending 'mixed messages' through non-verbal communication.

Intonation

Tone of voice dramatically affects a message's meaning. Depending on intonation, even a simple question or statement can express enthusiasm, anger, concern or indifference. The nurse must be aware of voice tone to avoid sending unintended messages. For example, clients may interpret a nurse's patronising tone of voice as condescending, and further communication may be inhibited. A client's voice tone often provides information about their emotional state or energy level.

Posture and gait

The ways people sit, stand and move reflect attitudes, emotions, self-concept and health status. For example, an erect posture and a quick, purposeful gait communicate a sense of wellbeing and confidence. Leaning forwards conveys attention. A slumped posture and slow, shuffling gait may indicate depression, illness or fatigue.

Facial expression

The face is the most expressive part of the body. Facial expressions convey emotions such as surprise, fear, anger, disgust, happiness and sadness. Some people have an expressionless face, or flat affect, which reveals little about what they are thinking or feeling. An inappropriate affect is a facial expression that does not match the content of a verbal message, such as smiling when describing a sad situation. People can be unaware of the messages their expressions convey. For example, a nurse may frown in concentration while doing a procedure and the client may interpret this as anger or disapproval. Clients often closely observe nurses. Although it is hard to control all facial expression, the nurse should develop awareness of meanings that are conveyed through facial expression.

Eye contact

People signal readiness to communicate through eye contact. Maintaining eye contact during conversation

shows respect and willingness to listen. Eye contact also allows people to closely observe one another. Lack of eye contact may indicate anxiety, defensiveness, discomfort, or lack of confidence in communicating. However, in some cultures, eye contact with a person who is considered superior can be interpreted as offensive and disrespectful (see Chapter 14).

Gestures

Gestures emphasise, punctuate and clarify the spoken word. Gestures alone carry specific meanings, or they may create messages with other communication cues. A finger pointed towards a person may communicate several meanings, but when accompanied by a frown and a stern voice, the gesture becomes an accusation or threat. Pointing to an area of pain may be more accurate than describing the pain's location.

Territoriality and personal space

Territoriality is the need to gain, maintain and defend one's right to space. Territory is important because it provides people with a sense of identity, security and control. *Territory* can be separated and made visible to others, such as a fence around a yard or a bed in a hospital room. *Personal space* is invisible, individual and travels with the person. During interpersonal interaction, people maintain varying distances between one another depending on their culture, the nature of their relationship, and the situation (Chapter 14). When personal space is threatened, people respond defensively and communicate less effectively. This is especially important when interacting with a client who is in bed, as 'standing over' them is often intimidating. Situations dictate whether the interpersonal distance between nurse and client is appropriate. Examples of nursing actions within zones of personal space are listed in Box 12-2, along with zones of touch. Nurses often move into clients' territory and personal space due to the nature of caregiving. The nurse must convey confidence, gentleness and respect for privacy, especially when actions require intimate contact or involve a client's vulnerable zone.

BOX 12-2 Zones of personal space and touch

Zones of personal space

Intimate zone (0–45 cm)
Holding a crying infant
Performing physical assessment
Bathing, grooming, dressing, feeding and toileting a client
Changing a client's dressing

Personal zone (45 cm–1.2 m)
Sitting at a client's bedside
Taking the client's nursing history
Teaching an individual client
Exchanging information at change of shift

Social zone (1.2–3.6 m)
Making rounds with a doctor
Sitting at the head of a conference table
Teaching a class for clients with diabetes
Conducting a family support group

Public zone (3.6 m and greater)
Speaking at a community forum
Testifying at a legislative hearing
Lecturing to a class of students

Zones of touch

Social zone (permission not needed)
Hands, arms, shoulders, back

Consent zone (permission needed)
Mouth, wrists, feet

Vulnerable zone (special care needed)
Face, neck, front of body

Intimate zone (great sensitivity needed)
Genitalia

Developing communication skills

The complex array of communication skills that nurses are required to develop and maintain is detailed later in this chapter and categorised according to therapeutic intention. Beginning practitioners of nursing will notice that they are inclined to use some skills more than others and that some skills come more naturally than others. Developing professional communication competence means paying close attention to these personal habits and predilections through critical reflective practice. The deliberate use of skills that do not come naturally requires conscious effort and consideration of therapeutic intention.

Self-awareness is critical to the development of effective communication skills because the way that they are used will be personal and unique to each nurse. Awareness of personal values and beliefs is especially important, as these may interfere with being open with and accepting of clients. For example, a belief that people who engage in behaviours that are harmful to their health, such as smoking and overeating, are weak-willed may hinder a nurse's effort to be helpful.

• CRITICAL REFLECTION POINT

1. **What are your personal beliefs about religion?**
2. **What types of people do you like? What types do you dislike?**
3. **What do you value in life?**
4. **How might any of these values and beliefs affect your communication with clients?**

The need to 'unlearn' previous communication patterns

When interacting with clients in a professional role, beginning nurses will often rely on their usual communication patterns, some of which are neither helpful to the client nor to the development of a therapeutic relationship. These include expressing approval or disapproval, stereotypical responses and false reassurance.

Approval and disapproval

In everyday conversations people often express approval or disapproval, yet in a professional role it is not helpful to clients when nurses impose their own attitudes, values, beliefs and moral standards. Other people have the right to be themselves and make their own decisions. Judgemental responses by the nurse often contain terms such as 'should', 'ought', 'good', 'bad', 'right' or 'wrong'. Agreeing or disagreeing sends the subtle message that nurses have the right to make value judgements about client decisions. Approving implies that the behaviour being praised is the only acceptable one. Often, the client shares a decision with the nurse, not in an effort to seek approval but to provide a means for discussing feelings. On the other hand, disapproving implies that the client must meet the nurse's expectations or standards; for example, commenting that 'It is silly for you to feel like that'. Instead, the nurse should help clients explore their own feelings, beliefs and decisions. The nursing response 'I'm surprised you say that you feel that way. Tell me more about it' gives the client a chance to express ideas or feelings without fear of being judged.

Stereotypical responses

A cliché is a stereotypical comment, such as 'You can't win them all' or 'Every cloud has a silver lining' that tends to belittle the other person's feelings and minimise the importance of their message. These automatic phrases communicate that the nurse is not taking concerns seriously or responding thoughtfully. Most often they are said with a good intention, to reassure a client; however, they are a form of false reassurance and are often not helpful.

False reassurance

Saying 'Don't worry, everything will be all right' may make the nurse feel better, but it does not have the same effect on the client. When a client is seriously ill or distressed, the nurse may be tempted to offer hope to the client with statements such as 'You'll be fine' or 'There's nothing to worry about'. When a client is reaching for understanding, false reassurance from the nurse may discourage open communication. Offering reassurance not supported by facts or not based in reality can do more harm than good. Although it might be intended kindly and have the secondary effect of helping the nurse avoid the other person's distress, it tends to block conversation and discourage further expression.

• CRITICAL REFLECTION POINT

You have been caring for Beth Mitchelton, aged 40, for 3 days, following her radical mastectomy. You have really 'hit it off' together and you find it easy to communicate with her. Like you, she is outgoing, enthusiastic and optimistic. In fact, you cannot quite believe how well she is coping with the loss of her breast. You think to yourself, 'I wonder how I would cope, being so young', as you find her fortitude amazing. Today is the day of her discharge from hospital; everything is in order and she is waiting for her husband. You enter her room to say goodbye and find her crying. You realise that saying something like 'You will be fine, don't worry' may not be helpful. What should you say?

Elements of professional communication

Professional appearance, demeanour and behaviour are important in establishing the nurse's trustworthiness and competence. They communicate that the nurse has assumed the professional helping role, is clinically skilled and is focused on the client. An individual nurse's inappropriate appearance or behaviour can harm nursing's professional image.

At work a healthcare professional is expected to be clean, neat, well groomed, conservatively dressed and free of strong scent and other odours. Professional behaviour should reflect warmth, friendliness, confidence and competence. Professionals speak in a clear, well-modulated voice, use good grammar, listen to others, help and support team-mates and communicate effectively. Being on time, organised, well prepared and equipped for the responsibilities of the nursing role also communicate one's professionalism.

Courtesy and use of names

Common courtesy is part of professional communication. To practise courtesy, nurses need to remain friendly, ask

permission to enter the client's space, address clients by name and always introduce themselves to clients by stating their name and explaining their role and purpose for interacting. This last point is particularly important when students are caring for clients in the clinical setting, as it is important that the student role of learner is understood by clients. The nurse's failure to give a name, indicate status (e.g. student, registered nurse or enrolled nurse) or acknowledge the client by name can convey an impersonal lack of commitment or caring. More importantly, clients have the right to know who is talking to them and in what professional capacity.

Addressing others by name conveys respect for human dignity and uniqueness. Using surnames is respectful in most cultures, but may seem too formal in others (Chapter 14). Therefore, in the initial interaction with clients the nurse should always ask them how they would prefer to be addressed and let others know their personal preference. Using first names is appropriate for infants, young children, confused or unconscious clients and close team members. Terms of endearment such as 'luv', 'dolls', 'Grandma' or 'darling' are inappropriate in a professional interaction. Avoid referring to clients by diagnosis, room number or other attribute, as it is demeaning and sends the message that the nurse does not care enough to know the person as an individual.

Privacy and confidentiality

Maintaining confidentiality is a sign of respect and a hallmark of professional behaviour. It is essential that the nurse safeguard the client's right to privacy by carefully protecting information of a sensitive nature. Sharing personal information or gossiping about others violates nursing ethical codes and practice standards. It sends the message that the nurse cannot be trusted and damages interpersonal relationships. Team members directly involved in the client's care should be given only relevant information about the client's status.

Trustworthiness

Trust is relying on someone without doubt or question. Being trustworthy means helping others without hesitation when help is needed. To foster trust, the nurse communicates warmth and demonstrates consistency, reliability, honesty and competence. Sometimes it is not easy for a client to ask for help. Trusting another person involves risk and vulnerability, but it also fosters open, therapeutic communication and enhances the expression of feelings, thoughts and needs. Without trust, a nurse–client relationship rarely progresses beyond superficial interaction and care. Avoid dishonesty at all costs. Knowingly withholding key information, lying or distorting the truth violates both legal and ethical standards of practice.

Respect

Respect is based on the belief that every human has inherent worth and dignity (Stein-Parbury 2014). Demonstrating respect is one of the central keys to effective interpersonal communication in nursing because respect means accepting the client's perspective and assuming their goodwill. Respect generates from a belief that the client is capable and resourceful. This involves being open and not imposing the nurse's value system on the client; that is, not judging the client because they hold views and beliefs that are different and possibly foreign to the nurse. Respect is especially relevant when communicating with clients who are of a different cultural background to the nurse.

For example, maintaining eye contact is a sign of trustworthiness in most Western cultures; that is, 'looking people in the eye' demonstrates honesty. In other cultures it is disrespectful to make eye contact with a person who is perceived as superior. Clients who avoid eye contact with nurses could be demonstrating respect, not dishonesty. Sensitivity to the culture of other people is needed in respectful communication (Chapter 14).

More importantly, nurses should not base their judgements about client behaviour on the basis of their own culture alone; this is disrespectful. Similarly, it is important to avoid cultural stereotypes that assume all people of a certain background will behave in the same way. Such thinking can lead to misunderstanding and a failure to communicate. An even greater danger of stereotyping is the risk that clients will be rejected or negatively judged because a nurse does not understand and respect their cultural value and belief systems.

Therapeutic communication techniques

The most basic nursing interventions used in communication are therapeutic communication techniques. **Therapeutic communication techniques** are specific responses that encourage the expression of feelings and ideas and convey the nurse's acceptance and respect. Learning these techniques helps the student develop awareness of the variety of nursing responses available for use in different situations. Although some of the techniques may seem artificial at first, skill and comfort will increase with practice. Tremendous satisfaction will result as therapeutic relationships and outcomes are achieved.

Heron (2001) offers a useful schema for understanding therapeutic intention through a classification system of two types of communication interventions: *authoritative* and *facilitative*. **Authoritative interventions** take responsibility on behalf of the client; **facilitative interventions** promote client autonomy and self-responsibility. When a nurse offers a client new knowledge, makes suggestions or directs the client, authoritative intentions are at play. When a nurse encourages a client to solve problems and express emotions, then facilitative interventions are at play.

The basis for Heron's intervention analysis is similar to the responsive and assertive dimensions of effective communication (presented earlier in this chapter). Authoritative interventions are assertive in nature and focus on new understandings, such as instructing a client newly diagnosed with diabetes on dietary management. Facilitative interventions are responsive and focus on existing understandings, such as how the client is experiencing a health event. Both types of interventions are potentially therapeutic, depending on context.

Facilitative communication techniques form the backbone of therapeutic communication because they help to build a relationship based on mutual understanding, and this type of mutuality is the basis of therapeutic relationships in nursing practice. In order to be of help, nurses must understand the meaning of a health event from the perspective of the client and their experience of that event.

At times, facilitative communication is therapeutically sufficient. For example, clients often find comfort in another person's human understanding of their situation; they might gain relief through finding humour in their situation. At other times, authoritative communication techniques are necessary to therapeutic endeavours, such as encouraging and persuading a recently disabled adult client to participate in everyday activities like dressing himself.

• CRITICAL REFLECTION POINT

Jack Stone is a 78-year-man who has been fit and healthy for most of his life. He was admitted to hospital 3 days ago with a suspected stroke. So far, all of the diagnostic tests have been inconclusive. You find that it is difficult for you to communicate with Jack as he complains a lot and gets angry at times. You enter his hospital room in order to conduct a neurological assessment. After asking him 'What day is it today?', he snaps at you and says, 'You people just keep asking me the same questions over and over again; what's wrong with you? I'm not stupid.'

1. **Should you use an authoritative or a facilitative approach when responding to Jack?**
2. **What is your intention in selecting the type of response that you think you should use?**

BOX 12-3 Classification of communication techniques according to therapeutic intention

Facilitative communication interventions

Active listening
Sharing observations
Expressing empathy
Offering hope
Sharing humour
Sharing feelings
Using touch
Using silence
Asking relevant questions
Paraphrasing
Clarifying

Authoritative communication interventions

Providing information
Focusing
Summarising
Self-disclosing
Confronting
Suggesting
Advising
Instructing
Persuading
Encouraging
Offering direct assistance

The choice between the two techniques depends on the vulnerability of the client. Determining the vulnerability of the client requires assessment of the resources available to meet the demands of a health event. The therapeutic communication techniques that follow are categorised according to therapeutic intention, as listed in Box 12-3.

Facilitative communication interventions

Facilitative techniques encourage clients to think for themselves and facilitate mutual understanding between them and the nurse. They are considered the backbone of therapeutic communication and are based on a philosophy of patient-centred care. When using facilitative techniques, the nurse follows the client's lead.

Active listening

Active listening means listening attentively with one's whole being – mind, body and spirit. It includes listening for conversational themes, acknowledging and responding,

giving appropriate feedback and paying attention to the other person's total communication, including the content, the intent and the feelings expressed (Stein-Parbury 2014). Active listening allows the nurse to better understand the entire message being communicated, and is an excellent way to build trust. In many nursing situations the other person simply needs someone to listen.

To listen attentively, the nurse faces the client at a distance of about 90 cm, removes any physical barriers if possible, maintains eye contact (if culturally appropriate), assumes a relaxed posture and sits quietly, leans forward slightly and nods in acknowledgment when the client talks about important points or looks for feedback. Fidgeting, breaking eye contact, daydreaming during conversation or only pretending to listen conveys the message that what the other person has to say is not important. These inhibit conversation and undermine trust.

Being available means offering oneself and expressing a willingness to listen, talk or be physically present with another person when the client needs it. By expressing availability, even though the client may not make their needs known, the nurse shows a caring attitude. When clients feel that the nurse is listening they sense a connection that enables the relationship to develop; they value nurses who take the time to listen to them (Kagan 2008, Marshall et al 2012). Therefore, listening is essential to the process element of therapeutic communication.

Availability and active listening are often described as nursing presence, an inter-subjective encounter between a nurse and a client in which the nurse encounters the client as a unique human being in a unique situation and chooses to 'spend' themself on the client's behalf (Zyblock 2010). **Presence** is the nursing quality of 'being there' for the client – not just physically present, but also listening attentively from a caring perspective: 'I'll stay with you a while. If you want to talk, I'll be glad to listen.' However, the ability to be fully present does not lie simply within the nurse; it requires a healthcare environment that is conducive to the formation of relationships between nurses and clients (Fingeld-Connett 2008, McMahon & Christopher 2011).

Challenges and potential pitfalls when listening

One of the key factors in being able to actively listen to clients is an ability to 'tune out' other thoughts in order to fully attend. Often when nurses are attempting to listen they are preoccupied with other matters; for example, they may be thinking about an onerous workload or worrying about a personal matter. More subtle is the tendency to make judgements about what a client is saying; for example, by thinking that the client is being silly or complaining too much. When emotions are being expressed, especially when clients are angry, it is often difficult to hear what they are expressing.

Changing the subject is an indication that the nurse is not listening; for example, saying, 'Let's not talk about your problems with the insurance company. It's time for your walk.' Changing the subject when another person is trying to communicate something important is rude and shows a lack of empathy. It tends to block further communication, and the client may then withhold important messages or fail to openly express feelings.

Using silence

It takes time and experience to become comfortable with silence. Most people have a natural tendency to fill empty spaces with words, but sometimes those spaces give time for the nurse and client to collect their thoughts and consider what has been communicated. Silence also allows the nurse to pay particular attention to non-verbal messages, such as worried expressions or loss of eye contact. Remaining silent demonstrates the nurse's patience and willingness to wait for a response when the other person is unable to reply quickly. Silence may be especially therapeutic during times of profound sadness or grief.

Sharing observations

Nurses make observations by commenting on how the other person looks, sounds or acts. Stating observations often helps the client communicate without the need for extensive questioning, focusing or clarification. For example, the nurse observes a young client holding his body rigidly erect and his voice being sharp as he says, 'Going to surgery is no big deal'. The nurse replies, 'You say having surgery doesn't bother you, but you look a little worried. It is natural to worry about surgery.' This approach may result in encouraging the client to further express current concerns.

Sharing feelings

Emotions are subjective feelings that result from one's thoughts and perceptions. Feelings are not right, wrong, good or bad, although they may be pleasant or unpleasant. If feelings are not expressed, stress and illness can worsen. Nurses can help clients express emotions by making observations, acknowledging feelings, encouraging communication, giving permission to express 'negative' feelings and modelling healthy emotional self-expression. At times, clients may direct anger or frustration prompted by their illness towards the nurse, who should not take such expressions personally. Acknowledging clients' feelings communicates that the nurse listened to and understood the emotional aspects of their illness.

When nurses care for clients they must be aware of their own emotions, because feelings are difficult to hide. Students may wonder whether it is helpful for the nurse to share feelings with clients. Sharing emotion makes nurses seem more human and can bring people closer. It is appropriate to share feelings of caring, or even cry with others, as long as the nurse is in control of how those feelings are expressed and does so in a way that does not burden the client. Feelings are shared with clients in an effort to assist them, not the nurse.

Expressing empathy

Empathy is the ability to understand and accept another person's reality and to accurately perceive feelings. Empathic communication conveys that the nurse not only has heard what the client has expressed, but also understands what the client means. In expressing empathy, the nurse communicates this understanding to the client. Such empathic understanding requires the nurse to be both sensitive and imaginative, especially if the nurse has not had similar experiences. Statements reflecting empathy are highly effective because they tell the person that the nurse heard the feeling content, as well as the factual content, of the communication. This results in clients feeling accepted and valued, thereby facilitating the therapeutic relationship.

Challenges and pitfalls in expressing empathy

There is a difference between empathy and sympathy. An example of a sympathetic expression is 'I feel so sorry about your amputation; it would be terrible to lose a leg.' **Sympathy** is concern, sorrow or pity felt for the client generated by the nurse's personal identification with the client's needs. Empathy is imagining what *it would be like* to be in the circumstances of the client; sympathy is assuming that the nurse knows *what it is like* (Stein-Parbury 2014). Sympathy is a subjective look at another person's world that prevents a clear perspective of the issues confronting that person. Although sympathy is a compassionate response to another's situation, it is not as therapeutic as empathy. A more empathic approach would be: 'Losing your leg has been a major change. How has it affected your life?' While it may seem that such a response might increase client distress, evidence shows that an empathic response such as this actually decreases their distress and enables them to cope (Lelorain et al 2012).

• CRITICAL REFLECTION POINT

Helen Simpson has had a resection of her bowel for cancer and now has a colostomy. You have been asked to begin assisting her with learning how to care for her colostomy when she is discharged. You read about how to instruct patients and feel confident that you know how to explain colostomy care. When you enter Helen's hospital room she is quiet and withdrawn, and tells you 'There's no need to bother with all of that. I'll be fine'. What should you say to Helen that would express empathy for her situation?

Offering hope

Hope is productive to healing, and offering hope communicates a 'sense of possibility' to clients (Fitzgerald Miller 2007). Appropriate encouragement and belief that the client can cope, along with concrete feedback about how the client is progressing, are important in fostering hope by boosting self-confidence and helping clients achieve their potential. Sharing a vision of the future and reminding others of their resources and strengths can also strengthen hope. Clients can be reassured that there are many kinds of hope and that meaning and personal growth can come from illness experiences (Fitzgerald Miller 2007).

Sharing humour

Humour is an important therapeutic resource in nursing interactions. It serves to build relationships by conveying respect for the personhood of the patient and creates a sense of cohesiveness between nurses and their clients. It helps decrease client anxiety, depression and embarrassment. Laughter can be good medicine when nurses use humour to help clients adjust to stress imposed by illness. Humour can increase the nurse's effectiveness in providing emotional support to clients and can humanise the illness experience. Laughter provides both a psychological and a physical release for both nurse and client. Humour can help others to interact more openly and comfortably and can make nurses' own humanity more apparent.

Using touch

Touch is one of the nurse's most potent forms of communication. Nurses are privileged to experience more of this intimate form of personal contact than almost any other professional. Many messages, such as affection, emotional support, encouragement, tenderness and personal attention, are conveyed through touch. Comfort touch, such as holding a hand, is especially important for vulnerable clients who are experiencing severe illness with its accompanying physical and emotional losses.

Since much of what nurses do involves touching, nurses must learn to be sensitive to others' reactions to touch and use it wisely. There are times when touch should be withheld; highly suspicious or angry people may respond negatively or even violently to the nurse's touch.

Asking relevant questions

Asking questions allows nurses to seek information that is vital to client care. Nurses should ask only one question at a time, and fully explore one topic before moving to another area. During client assessment, questions follow a logical sequence and usually proceed from the general to the more specific. Open-ended questions allow the client to take the conversational lead and introduce pertinent information about a topic: 'What happens when you and your husband argue?' Focused questions are used when more-specific information is needed in an area: 'What do you argue about most often?' The nurse should allow clients to fully respond to an open-ended question before asking more-focused questions. Closed-ended questions elicit a yes, no or single-word response: 'How many arguments did you have last week?' They are generally less useful during therapeutic exchanges, although they are often essential to client assessment.

Challenges and potential pitfalls in questioning

Asking too many questions can be dehumanising, because clients can feel as though they are being treated like an object. A useful exercise is to try conversing without asking the other person a single question. By giving general leads ('Tell me about it …'), making observations, paraphrasing, focusing, providing information and so on, nurses can discover much of importance that would have remained hidden if questions alone had been used during the communication process.

A nurse may be tempted to ask clients to explain why they believe, feel or have acted in a certain way. Asking for explanations, for example, 'Why are you so anxious?', is not helpful to clients; people often do not know why they feel the way they do, and a question such as this can put them on the defensive. Moreover, clients frequently interpret 'why' questions as accusations and this can cause resentment, insecurity and mistrust (Stein-Parbury 2014). They are best avoided and replaced with open-ended questions that explore the situation further.

Asking personal questions that are not relevant to the situation simply to satisfy the nurse's curiosity, for example 'Why don't you and John get married?', is not appropriate professional communication. Such questions are intrusive and unnecessary. If clients wish to share private information they will. If the nurse needs to know more about the client's interpersonal roles and relationships, a question such as 'How would you describe your relationship with John?' can be asked.

Paraphrasing

Paraphrasing is re-stating another's message briefly, using one's own words. Through paraphrasing, the nurse sends feedback that lets others know whether their messages were understood. If the meaning of a message is changed or distorted through paraphrasing, communication may become ineffective. For example, a client may say 'I've been overweight all my life and never had any problems. I can't understand why I need to be on a diet'. Paraphrasing this statement by saying 'You don't care if you're overweight or not' is incorrect. It would be more accurate to say 'You're not convinced you need a diet because you've stayed healthy'.

Paraphrasing is an effective way to clarify what a client is communicating. By putting their words into the nurse's own words, clients can not only correct any misunderstandings, for example, 'That's not exactly what I meant', but can also expand and elaborate on what they are meaning. A paraphrase is a useful way to encourage further interaction by demonstrating that the nurse is trying to understand the client's experience.

• CRITICAL REFLECTION POINT

The next time you are talking to one of your friends who is experiencing some difficulty in their life and telling you about it, try to simply rephrase what they are expressing. This is not an easy way to respond, so you will have to concentrate. Notice what effect paraphrasing has on the conversation. How is this conversation different to ones you normally have?

Challenges and pitfalls in paraphrasing

Paraphrasing is not the same as parroting – repeating what the other person has said word for word. Parroting is easily overused and is not as effective as paraphrasing. A simple 'Oh?' can give the nurse time to think if the other person says something that takes the nurse by surprise.

Nurses are sometimes reluctant to paraphrase what clients say out of fear of appearing incompetent; that is, they think that they should just know what the client means without having to say what they think. Another reason for a reluctance to use a paraphrase is the fear of 'reinforcing' distressing negative emotions, when that is what the client is conveying. The paraphrase is comforting to clients when they are distressed because it demonstrates that the nurse is listening and trying to understand (Stein-Parbury 2014).

Clarifying

To check whether understanding is accurate, the nurse can re-state an unclear or ambiguous message to clarify the meaning. Instead of paraphrasing the message, the nurse can also ask the other person to rephrase it, explain further or give an example of what the person means. Without clarification, the nurse may make invalid assumptions and

miss valuable information. Despite efforts at paraphrasing, the nurse may not understand the client's message and should let the client know if this is the case: 'I'm not sure I understand what you mean by "sicker than usual". What is different now?'

Authoritative communication interventions

Authoritative communication operates from the philosophy that the nurse needs to take charge and lead the client, instead of following the client, as is the case with facilitative techniques. While authoritative techniques can be used to promote client autonomy, for example, through health teaching, often they are not as patient-centred as facilitative techniques. More importantly, they are often overused in healthcare situations.

Providing information

Providing relevant information tells other people what they need or want to know so that they can make decisions, experience less anxiety and feel safe and secure. It is also an integral aspect of health teaching. It is usually not helpful to hide information from clients, particularly when they seek it. Clients have a right to know about their health status and what is happening in their environment.

Research has shown that the provision of information is highly individual in the sense that some clients require more information than others (Tobiano et al 2015). Identification of the amount and type of information needed by an individual client is essential in the use of this intervention.

• CRITICAL REFLECTION POINT

Some clients want to know every detail about their health status and care, while others want only minimal information. How might you assess how much information a client desires?

Instructing

This technique is similar to providing information, but is a more direct way of communicating. For example, a nurse might need to provide instructions to a postoperative client about how to splint the incision when attempting to cough.

Suggesting

Nurses often help clients by offering suggestions about what might be of benefit. For example, a nurse might suggest distraction as a useful way to cope with worry about pending diagnostic results. Suggestions should be posed tentatively and operate from an understanding of the client situation and knowledge of health. They are not based on the nurse's personal opinions or values.

Advising

Nurses are often in a position to offer sound advice about health matters. Like suggestions, advice is not based on personal opinions of the nurse, but rather on an understanding of the health event.

Challenges and pitfalls in advising

Giving personal opinions, for example, 'If I were you, I'd put your mother in a nursing home', must be avoided. When the nurse gives a personal opinion, it takes decision-making away from the client. It inhibits spontaneity, stalls problem-solving and creates doubt. Personal opinions differ from professional advice. At times, clients need suggestions and help to make choices. Suggestions are presented to clients as options because the final decision rests with the client. Remember, the problem and its solution belong to the other person and not the nurse. A much better response would be: 'Let's talk about what options are available for your mother's care.'

Persuading

When advising and suggesting do not seem to be helpful to the client, a nurse often has to become persuasive in pursuing a therapeutic aim. For example, emergency-room nurses may need to persuade family members of a client who has died suddenly not to drive themselves home from the hospital while still in a state of shock at the death.

Focusing

Focusing is used to centre on key elements or concepts of a message. If conversation is vague or rambling or clients begin to repeat themselves, focusing is a useful technique. The nurse does not use focusing if it interrupts clients while discussing an important issue. Rather, the nurse uses focusing to guide the direction of conversation to important areas: 'We've talked a lot about your medications, but let's look more closely at the trouble you're having in taking your tablets on time.'

Summarising

Summarising is a concise review of key aspects of an interaction. Summarising brings a sense of satisfaction and closure to an individual conversation and is especially helpful during the termination phase of a nurse–client relationship. By reviewing a conversation, participants focus on key issues and can add relevant information as needed. Beginning a new interaction by summarising a previous one helps the client recall topics discussed

and shows the client that the nurse has analysed communication. Summarising also clarifies expectations, as in this example of a nurse manager who had been working with a dissatisfied employee: 'You've told me a lot of things about why you don't like this job and how unhappy you've been. We've also come up with some possible ways to make things better, and you've agreed to try some and let me know if any of them help.'

Self-disclosing

To use **self-disclosure**, the nurse reveals personal experiences, thoughts, ideas, values or feelings in the context of the relationship with the intent of helping the other person. This is not therapy for the nurse; rather, it shows clients that their experiences can be understood and are not unique. Self-disclosures should be relevant and appropriate and made to benefit the client rather than the nurse. They are used sparingly so that the client is the focus of the interaction: 'That happened to me once, too. It was devastating, and I had to face some things about myself that I didn't like. I went for counselling, and it really helped … What are your thoughts about seeing a counsellor?'

Confronting

To confront someone in a therapeutic way, the nurse helps the client to become aware of inconsistencies in his or her feelings, attitudes, beliefs and behaviours. This technique improves client self-awareness and helps the client recognise growth and deal with important issues. Confrontation should be used only after trust has been established, and it should be done gently, with sensitivity: 'You say you've already decided what to do, yet you're still talking a lot about your options.'

Encouraging

Like offering hope, nurses are often in a position to encourage clients, especially when discouragement is evident. Encouragement is best offered in concrete terms, such as 'I can see that you are able to walk much better today. It only took you a few minutes to get to the toilet today. A few days ago it took nearly 20 minutes.'

Offering direct assistance

It may seem obvious that nurses assist clients. However, a direct offer of assistance can help when clients are overwhelmed with unpleasant feelings. 'Here, let me help you with putting on your shoes' is an example of direct assistance. In doing so, it is important that the nurse does not take over for clients and make them feel useless and more vulnerable.

Putting therapeutic communication techniques into action

The most critical aspect in determining which type of communication intervention to use is the intention of the nurse. For example, sharing observations such as 'you look a bit worried to me', is used with the intention of gaining more information about a particular aspect of the client's wellbeing, while an open-ended question such as 'how was your day yesterday?' is employed to gain general information. The former leads clients to discuss something in particular while the latter allows clients to bring up whatever is most relevant to them about the topic. Therefore, choice of technique is dependent on the purpose and intention of the communication. Becoming skilled at using the technique that is appropriate to each situation requires a great deal of self-awareness and reflective practice.

Being reflective is the key to developing effective communication skills in nursing practice. This reflection occurs prior to communicating, for example, to consider the intention of the interaction with a client, and after interacting with a client to determine the degree to which that intention was met. Reflection after communicating enables nurses to consider whether they have been of assistance in helping the client, thus enabling them to develop insight into a situation, and to challenge themselves and change their perspectives (Asselin et al 2013, Bulman et al 2012). More than any other skill in nursing, the ability to communicate effectively is one that requires lifelong learning. And that learning will not be productive without reflection and self-awareness. This is especially true for those situations that are emotionally challenging (Rees 2013).

• CRITICAL REFLECTION POINT

When Mark entered Mrs Simpson's hospital room he noticed that she looked uncomfortable and was holding an emesis bag. She stated that she thought she was 'going to vomit'. Mark replied by saying, 'Well, you have the bag in your hand'. She responded by telling him in no uncertain terms that she considered him a 'smart alec' and did not want him looking after her. At first, Mark went to his nursing manager and told her what had happened. She agreed to have his assignment to her changed. Upon reflection, Mark was not really satisfied with this outcome, and he considered how he might have come across to Mrs Simpson. He decided to go back to her room to try to sort out the situation. He began by saying, 'I think we got off on the wrong foot this morning. I can see how you became upset with me and I am sorry that I came across

the wrong way'. Mrs Simpson accepted the apology and agreed to have Mark care for her that day.

1. **What role did reflection play in Mark's response to this situation?**
2. **What did he learn from the situation?**

Emotional intelligence

In nursing, **emotional intelligence** is required for interpersonal competence (Powell et al 2015). This is because nursing care is delivered through interpersonal relationships which include making an emotional connection with clients (Stein-Parbury 2014). In providing nursing care, emotional responses are inherent, especially in relation to interacting with and building meaningful relationships with clients. Because of the nature of nursing work, these interactions and relationships can be filled with emotions (Dwyer & Hunter Revell 2015). It is for this reason that nurses need to be skilled in managing their emotions as well as understanding others' emotions. This ability is termed 'emotional intelligence', which has been shown not only to improve the quality of nursing care (Adams & Iseler 2014) but also is associated with decreased stress in nurses (Görgens-Ekermans & Brand 2012). In addition, nurses who have a high degree of emotional intelligence are more likely to use collaboration in resolving conflict, while nurses with a low degree are more likely to use an accommodating response when faced with conflict (Morrison 2008).

According to Goleman (1998), who popularised the concept, there are five dimensions of emotional intelligence, which are both interdependent and hierarchical. The first is *self-awareness*, the basis of emotional intelligence, which involves the accurate assessment and knowledge of self in relation to others. Self awareness enables the regulation of emotions. *Self-regulation* does not mean that nurses do not experience emotions, but that these emotions do not become so intense as to render the nurse unable to function. With awareness and emotional regulation nurses are able to move to the third dimension – *motivation* – and engage meaningfully with others. *Empathy*, the fourth dimension, allows the nurse to understand others. Finally, emotional intelligence involves managing situations that require *social skills*, especially when dealing with conflict.

Conclusion

Nurses need to be skilled in the art of interpersonal communication in order to provide care that is truly person-centred. The purpose of communication in nursing is to understand the meanings that are conveyed by clients, their families and other healthcare colleagues. It is through understanding such meanings that effective relationships are formed. Effective means that they are helpful to clients and families, and collaborative with colleagues. Communicating with and relating to clients, their families and healthcare colleagues can be some of the most challenging aspects of nursing practice. Nonetheless, forming meaningful relationships with others has the potential to be one of the most rewarding aspects of being a nurse.

Key concepts

- Communication is the means by which nurses meet their professional obligation to form therapeutic relationships with clients.
- Communication is a powerful therapeutic tool and an essential nursing skill used to influence others and achieve positive health outcomes.
- The dynamics of communication include both process and content.
- Effective communication involves being both responsive and assertive.
- Nurses consider many contexts and factors influencing communication when making decisions about what, when, where, how, why and with whom to communicate.
- Nurses must be able to communicate effectively with other members of the healthcare team in order to promote collaborative practice.
- Effective verbal communication requires appropriate intonation, clear and concise phrasing, proper pacing of statements and proper timing and relevance of a message.
- Effective non-verbal communication complements and strengthens the message conveyed by verbal communication so that the receiver is less likely to misinterpret the message.
- Nurses use intrapersonal, interpersonal and small-group interaction to achieve positive change and health goals.
- Helping relationships are strengthened when the nurse demonstrates caring by establishing trust, empathy, autonomy, confidentiality and professional competence.
- Effective therapeutic communication techniques are both facilitative, in which the nurse follows the client's lead, and authoritative, in which the nurse takes the lead.
- Ineffective communication techniques are inhibiting and tend to block the other person's willingness to openly express ideas, feelings or concerns.
- The nurse must blend social and informational interactions with therapeutic communication techniques so that others can explore feelings and manage health issues.
- Nurses need to engage in reflective practice in order to continuously develop their communication competence.

- Emotional intelligence is required for effective and skilled communication in the healthcare setting.

Online resources

Australian Institute for Patient and Family Centred Care is an organisation of patients, family members and healthcare professionals that promotes partnerships between patients, families and healthcare professionals. There are two videos of highlights of two healthplays 'Hear Me' and 'Do you know me?'. They depict the importance of involving family and knowing the patient, http://www.aipfcc.org.au/

Communication for Health in Emergency Contexts (CHEC); an interactive learning resource that focuses on communication with patients in an emergency department, www.chec.meu.medicine.unimelb.edu.au

TeamStepps is a teamwork system designed to improve quality and safety in health care. An overall description of the program is found at http://teamstepps.ahrq.gov/about-2cl_3.htm. A pilot of the program conducted in South Australia can be found at www.safetyandquality.gov.au/wp-content/uploads/2012/03/TeamSTEPPS-Implementation-of-a-teamwork-programme-into-an-Australian-Setting-Public-Report-on-Pilot-Study.pdf

CHAPTER

13

Documenting, retrieving and using information to inform practice

Elizabeth Cummings and Bryan Macdonald

Learning outcomes

Mastery of content will enable you to:

- discuss the importance of documentation and reporting to patients and nurses
- discuss the difference between paper-based records and electronic records
- describe the relationship between documentation and healthcare financial reimbursement
- identify the purposes of a healthcare record
- describe and apply guidelines for effective documentation and reporting
- discuss legal guidelines for recording client care
- describe different methods of record-keeping
- discuss the advantages of standardised documentation forms
- identify critical elements of a client's discharge plan
- describe the role of critical pathways in multidisciplinary documentation
- identify the important aspects of long-term care documentation
- discuss issues related to computerisation in documentation
- describe the purpose and content of a change-of-shift report (handover) and other forms of reporting
- describe handover reporting tools
- explain the process of verifying telephone orders.

KEY TERMS

Acuity charting, p. 249
Case management, p. 247
Change-of-shift report, p. 252
Charting by exception, p. 247
Clinical information systems, p. 236
Critical pathways, p. 247
DAR, p. 245
Diagnosis-related group (DRG), p. 236
Documentation, p. 238
Electronic health records, p. 238
Flow sheets, p. 249
Focus charting, p. 245
Incident reports, p. 256
myHealth Record, p. 238
Nursing informatics, p. 237
PCEHR (personally controlled electronic health record), p. 238
PIE, p. 245

Record, p. 238
Report, p. 252
Resident, p. 252
SOAPIE, p. 245
Source record, p. 246
Standardised care plans, p. 249
Transfer report, p. 255
Variances, p. 247

A core nursing competency is the ability to document and effectively communicate information about care, the client's response to illness, interventions and changes in their condition or circumstances (Wilkinson 2007). Nursing documentation must be accurate, concise, comprehensive, reflective, accessible and honest in conveying a timely account of nursing care. Nursing documentation is fundamental to providing client care, ensuring effective communication, and practising effectively and safely. Clients come into contact with many healthcare professionals and those points of contact must be linked by effective communication, with documentation being a permanent record of care across the many disciplines involved. High-quality, accurate information recorded by nurses is accessed and used by other members of the multidisciplinary care team in order to provide a comprehensive team approach to the client's plan of care. If documentation is not available, delays or omissions in treatments, referrals, discharge planning and recovery may occur, resulting in poorer client outcomes.

An optimal standard of nursing documentation describes all care administered throughout the course of the shift. Much of what nurses do for the client, however, may be lost through lack of appropriate acknowledgment in the record of care. Subsequently, if documentation is poor, the level and quality of continuing care can be reduced and the client may not receive the required care (Calleja et al 2011). This is particularly important under the current diagnosis-related group/case-mix system used in Australia whereby hospitals are reimbursed a set amount for each **diagnosis-related group (DRG)** treated (Box 13-1). Inaccuracy in documentation can have a direct effect upon the funding of the hospital and the staffing levels. Therefore the Australian Council on Healthcare Standards (ACHS 2010) specifies guidelines for the documentation of clinical data for classification purposes. Universal nursing terminology should form the basis of documentation and ensure that what is recorded and the care provided are consistent (Saranto & Kinnunen 2009). According to Paans et al (2010), there is a lack of consensus relating to the exact nature of an accurate record. However, in addition to poorer client outcomes, poor documentation can result in professional, ethical and legal consequences.

This chapter focuses on the documentation required within an acute care facility, but the principles of good documentation and use of data remain the same irrespective of the care situation. All organisations have documentation guidelines and the nurse is responsible for accessing and adhering to these guidelines. The provision of guidelines is consistent with the National Safety and Quality Health Service (NSQHS) Standard 1 (ACSQHC 2011).

eHealth

Globally, eHealth systems such as electronic medical records (EMR), electronic health records (EHR), and **clinical information systems** have been identified as major drivers for stimulating the changes necessary to enable coordination of care and sharing of information within health systems. eHealth innovations have huge potential to support an integrated health system and the realisation of a more efficient, safer, knowledge-based, patient-centred health system that provides universal, accessible and affordable care. Digital systems are significantly changing the way nursing documentation occurs in relation to the type of information recorded, the structure of the data and the input methods.

Increasingly, healthcare professionals are collecting and recording data using a wide range of devices. These vary from setting to setting, but the use of standard desktop computing is rarely sufficient for current healthcare needs. Tablet and other handheld devices are being introduced for recording observations and medication administration at the bedside; various electronic devices, including smart phones, are being used for client education (Ventola 2014). Pen-based, automated speech-recognition (ASR) or voice-recognition technology may eventually become extremely effective for nursing documentation now that palm-top technology is being used in the healthcare setting. Advances in information technology can provide the foundations for important improvements in healthcare delivery, such as cost efficiencies, targeting client education, screening and early treatment.

mHealth is the term used for health care supported by mobile devices, most frequently devices such as mobile phones, and tablet or laptop computers. These mobile devices are used to access health services and information. mHealth is a sub-discipline of eHealth, and can be implemented to collect clinical health data in the community, for access to healthcare information and for real-time monitoring of patients.

The Quantified Self is the term given to the recent trend of using technology to monitor regular aspects of daily life. This can include monitoring activity, diet, mood and vital signs, and usually combines wearable sensors and mobile computing. Many patients are becoming more aware of the benefits of self-managing their health and in time nurses will see more patients entering data into their electronic health records for healthcare practitioners to access.

Nursing documentation in the digital environment is integral to improving client care. As defined by the International Medical Informatics Association (IMIA), 'Nursing Informatics science and practice integrates nursing, its information and knowledge and their management with information and communication technologies to promote the health of people, families and communities world wide' (IMIA NI 2009). The ultimate goal of practising **nursing informatics** is to maximise people's health by managing information efficiently and effectively (Kennedy & Hussey 2015). So while the healthcare environment creates many challenges for accurately documenting and reporting the care delivered to clients, accurate documentation opens up many opportunities to improve care delivery.

BOX 13-1 Diagnosis-related groups

A diagnosis-related group (DRG) is a series of decision trees designed to cluster groups of clients together by diagnosis, surgical procedures, complications, comorbidities (pre-existing illness) and age.

The statistical weight of a DRG is multiplied by a hospital's specific rate of reimbursement.

The hospital is reimbursed a fixed amount for every client grouped into the DRG regardless of length of stay or cost of treatment.

An assigned DRG may change on the basis of documentation.

CLINICAL EXAMPLE

Mrs Staples is an 89-year-old woman who presents to the Emergency Department (ED) at 0730 hours with a fractured neck of femur after a fall at home. Mrs Staples lives alone with her dog and cat. Her daughter Debbie assists with shopping and taking her to appointments. Debbie tells the ED nurse that her mother has become quite forgetful, so may need frequent reminding that her neighbour will care for her animals, otherwise she will probably become agitated. The ED nurse advises the doctor of Mrs Staples's poor memory, but does not document Debbie's request, instead reporting it to the ward nurse when Mrs Staples is admitted at 1000 hours to the surgical ward.

At handover at 2300 hours, the night-shift ward nurse is told that Mrs Staples has been increasingly upset about her animals, but her daughter has not been contactable. At 0200 hours, Mrs Staples falls trying to get out of bed, and the nurse finds her crying, agitated to get home to her animals as she says no one is there to care for them. The nurse tries to reassure Mrs Staples and gives analgesia, but Mrs Staples remains upset and agitated. The nurse reviews the progress notes but cannot find any information about social arrangements for this patient. Mrs Staples has sustained a left-sided Colles' fracture as a result of her fall.

• CRITICAL REFLECTION POINT

Consider all the aspects of the *Clinical example* above.

1. **What are the main issues you can identify about documenting care?**
2. **What impact did or could this have on the people involved in the situation?**
3. **What are some alternative courses of action you would take in regard to documentation?**
4. **How could this situation have been different if Mrs Staples had a myHealth Record and she entered details there?**

Individual professional record-keeping

As independent practitioners, nurses are expected to maintain their own individual professional records. The development and updating of a professional portfolio is a good way of presenting skills, qualifications and continuing professional development, and is important for all nurses. An ePortfolio is a collection of digital artefacts that documents your learning, career, achievements and reflections over time. It is assembled and managed by the user and can be provided to support job applications, demonstrate educational progression, or simply as a repository for work-related information. This can be an important record for nurses as it can be used to document events that may have a legal impact at a later date.

Multidisciplinary communication within the healthcare team

Increasingly, nurses are working in a wide range of settings as members of multidisciplinary teams. Multidisciplinary collaboration demands effective communication between members of the healthcare team to achieve and maintain a high standard of care for clients. Reporting requires exchanges of both oral and written information between caregivers. At the end of a work shift, nurses give a verbal or taped report to nurses on the next shift. A doctor may call a ward to receive a verbal report on a client's condition and progress, or a nurse may call the doctor and report immediate care issues and request a review, along with, in the short term, care orders appropriate to the client's condition. The laboratory submits a report providing the results of diagnostic tests, or the physiotherapist undertakes a physical assessment and reports this to the team. All these communications require documenting and sharing.

It is always important to remember that a client's record or chart is a permanent legal document of information

relevant to the client's healthcare management. After each occasion of care, information about the client's health care is recorded. With each successive occasion the record is available to the doctor and other members of the healthcare team, and is a continuing account of the client's healthcare status and needs. Increasingly, these records are being documented and shared electronically.

• CRITICAL REFLECTION POINT

Consider the information you need as a clinician to be able to give safe, effective care to your patients. What would be the information you would look for every time you access patient documentation? Do you use this list as a checklist for things to include when you undertake documentation? This may include safety aspects (e.g. patient name and identifiers), care documentation (specific details versus broad comments), time of recorded entry, identified changes in patient status with cues/patient data supporting this determination, future management plans for the patient, patient preferences, etc.

Write a list of things to look for or include in your documentation every time. Consider this for patient progress notes, documenting health assessment and physical examination, clinical pathways, observations and other measurements recorded during patient care.

Continuity of care, discussed in detail in Chapter 8, is a concept that is at the basis of many quality-improvement movements across the healthcare industry. Continuity of care as a quality focus has arisen from concerns of care fragmentation for patients who often see many healthcare providers in various settings (Haggerty et al 2003). There are two core elements to the concept of continuity of care: *care of the individual patient* and *care delivered over time*. Haggerty et al (2003) describe three types of continuity of care: informational continuity, management continuity and relational continuity (Box 13-2). Effective documentation complemented by oral or written reporting is essential to maintain informational continuity and management continuity. Without an applied understanding of the nurse's role in maintaining continuity of care, the nurse may struggle to provide the patient with the appropriate level of care and safety.

The role of **electronic health records** in assisting with maintenance of continuity of care is evident through the simple and timely sharing of information. In Australia, the government has committed to the introduction of a personally controlled electronic health record, the **PCEHR**, or more recently renamed **myHealth Record**. This record places the client at the centre of their health care and allows them to access their own health information when and where it is needed. Clients have access to summary information about their medical history, medications, test results, immunisations and allergies, which can assist them and their healthcare providers in decision-making. Clients can give permission for health professionals anywhere in the country to access their relevant history. They can also record information about their health and wellbeing in their own section that can be shared with healthcare providers as required.

BOX 13-2 Continuity of care

Informational continuity – the use of information on past events and personal circumstances to make current care appropriate for each individual.

Management continuity – a consistent and coherent approach to the management of a health condition that is responsive to a patient's changing needs.

Relational continuity – an ongoing therapeutic relationship between a patient and one or more providers.

Haggerty JL et al 2003 Continuity of care: a multidisciplinary review. Br Med J 327:1219. Reproduced with permission of BMJ Publishing Group Ltd.

Documentation

Documentation is defined as 'any written or electronically generated information about a client that describes the care or service provided to that client' (Professional Development Committee of the Nursing Council of Hong Kong 2010). Effective documentation reflects the quality of care and provides evidence of each healthcare team member's accountability in the delivery of that care. Nursing documentation should be a record created by nurses to document care given or to communicate information relevant to the care of the particular client (NMBA 2016, see Box 13-3).

Purposes of records

Records serve multiple purposes in health care. In addition to demonstrating compliance with professional standards or competencies, records are used for: communication, assessment, financial reimbursement, education, research, auditing and legal documentation. These purposes are discussed in detail below.

Communication

The **record** is a means by which healthcare team members communicate their actions in relation to the client's care, including individual therapies, client education and use of referrals for discharge planning. The plan of care should be clear to anyone reading the chart. When a staff member is caring for a client and refers to a client's notes, the record should communicate the measures needed to maintain continuity and consistency of care.

BOX 13-3 Fundamental elements of records

- Client identification and demographic data
- Record of informed consent for treatment and procedures
- Admission nursing history
- Nursing diagnoses or problems
- Nursing or multidisciplinary care plan
- Clinical pathways and any variance from the norm
- Record of nursing care, treatment and evaluation
- Medical history
- Medical diagnosis
- Therapeutic orders
- Medical and healthcare professionals' progress notes
- Reports of physical examinations
- Reports of diagnostic studies
- Summary of operative procedures
- Discharge plan and summary

Assessment

A client history and baseline nursing assessment is completed when a client is admitted to a nursing care unit. This usually contains biographical data (e.g. age, marital status), method of admission, reason for admission, a brief medical–surgical history (e.g. previous surgeries or illnesses), allergies, current medication (prescribed, over-the-counter and illicit substances), the client's perceptions about illness or hospitalisation, and a review of health risk factors. A physical assessment of all body systems is either incorporated into the nursing history or included on a separate form.

The record provides data that nurses use to assess, identify, plan and evaluate appropriate interventions for nursing care. Information previously provided by the client should be verified by the nurse to confirm its accuracy. In an electronic system you may find that much of the data is prefilled, although the admitting nurse retains the responsibility for verifying the prefilled data.

Before caring for any client, the nurse should refer to the client's record for information regarding the reason for admission and general health status. The nurse is then able to conduct an individualised assessment of the client, which includes a comprehensive physical assessment, and psychosocial and environmental overview. It is important to note that in some settings the initial client assessment will be undertaken by the nurse; for example, in accident and emergency, in community care and in rural and remote area clinics.

Accurate assessment data generated by each member of the healthcare team provide an overview of the client's health status. For example, after inspection of a wound, the nurse may conclude that healing is delayed. Assuming due diligence and accurate recording of findings has occurred, the record will provide additional information, including the client's appetite, descriptions of the wound's previous appearance, an image of the wound, and laboratory results indicating the presence or absence of infection. Such information can help explain the reasons for and implications of changes in client condition, and should prompt direction and focus of care given by the healthcare team.

Financial reimbursement

As previously noted, the client care record is a document that shows the extent to which healthcare agencies should be reimbursed for services. DRGs form the basis for establishing reimbursement for client care. Detailed recording helps in establishing codable diagnoses that are used to determine a DRG. The nurse's contribution to documentation can assist the coding team to clarify the type of treatment a client receives. When client charges exceed the length of stay allowed for a particular DRG, appropriate documentation is essential to justify the additional time and cost.

Education

Students of nursing and other healthcare-related disciplines use these records as educational resources. A client's record contains a variety of information, including diagnoses, signs and symptoms (clinical features) of disease, successful and unsuccessful therapies, diagnostic findings and client behaviours. An effective way to learn the nature of an illness and the individual client's response to it is to read the client care record. While clients' records will not be identical, patterns of information can be identified in records of clients with similar health problems. This information can assist students in learning what patterns to look for in relation to various health problems and increase their ability to anticipate the type of care required by a client.

Research

Statistical data relating to the frequency of clinical disorders, and complications, the use of specific medical and nursing therapies, recovery from illness and deaths can be gathered from client records. Records are a valuable resource for describing characteristics of the client populations in a healthcare agency. A nurse may use clients' records during a research study to collect information on certain factors. For example, if a nurse

uses a new method of pain control for a group of clients, the records provide data on the clients' responses to the therapy. Recording entries that describe the type and dose of analgesic medications used and clients' subjective reports of pain relief could be used to evaluate pain-control measures. Nurses may also research records of previously discharged clients to identify nursing care problems. For example, a study to determine the incidence of infection in clients with specific types of intravenous catheters might be performed by means of a chart review. Chart reviews may also be used to research decisions made by health workers or as a measure of their written communication effectiveness. With the advent of electronic health records and standardised data entry it has become easier to gather and analyse large data sets in relation to all aspects of health care. It is important for the nurse to first acknowledge the legal and ethical considerations that apply before using or reproducing any material gathered from client care records in their setting, such as obtaining approval from recognised and appropriate ethics committees and from clients prior to access.

Auditing

The Australian Council on Healthcare Standards (ACHS) requires hospitals in Australia to establish quality-improvement programs for conducting objective, ongoing reviews of client care. The ACHS imposes standards for information to be included in the client's record, such as indications that a plan of care is developed with the client as a participant and that discharge planning and client education have occurred. The ACHS requires institutions to establish standards for quality of care, and regular review of information in client records provides the basis for evaluation of the quality and appropriateness of care provided in an institution. Nurses monitor or review records throughout the year to determine the degree to which quality-improvement standards are met. Deficiencies identified during monitoring are shared with all members of the nursing staff so that corrections in policy or practice can be made. Quality-improvement programs keep nurses informed of standards of nursing practice to maintain excellence in nursing care.

Medical records are also audited to review charges for the client's care. Auditors from the federal and state governments review records to determine the reimbursement that a client or a healthcare agency receives. Accurate documentation of supplies and equipment that have been used ensures that costs are recovered and that clients receive the care they require.

Electronic health records can assist in auditing processes as they enable the rapid accessing and collating of data in relation to standard data sets.

Legal documentation

Accurate documentation is one of the best defences against legal claims associated with nursing care. The record serves as a description of exactly what happened to a client and who was involved in providing care. This is particularly important because a lawsuit may not be filed for years after an incident and so documentation may be the crucial evidence protecting the nurse and the facility (Austin 2010). Nurses should also record a reflection of such incidents in their portfolio to ensure they have evidence if there is legal action at a later date. In contrast, documentation not completed to professional standards places nurses in jeopardy of a negligence claim from the clients in their care. Key areas of documentation that pose a risk of legal action for the nurses are (Forrester & Griffiths 2010):

- not charting the correct time events occurred
- failing to ensure that information is clear, concise and accurate
- charting actions in advance to save time, and
- documenting incorrect data.

Some of these issues are mitigated in the electronic health records; however, with increasing use of the EHRs, new unanticipated issues can arise. This is particularly concerning if a password is shared or an individual does not log out of a record, providing others with the means to accidentally enter data under another's name. Research into the effect of the introduction of EHRs in clinical settings has identified this can result in unintended consequences such as the introduction of technology-induced errors, workarounds, and workflow disruptions (Ash et al 2007). On the other hand, electronic records and health information systems bring with them a myriad of benefits. Kuziemsky et al (2012), for example, discuss a range of unintended benefits of health information systems (HIS) for patients, service delivery and administration (Kuziemsky et al 2012).

The law protects information about clients that is gathered by examination, observation, conversation or treatment. Nurses may not discuss a client's status with other clients or staff uninvolved in the client's care. Nurses are legally and ethically obligated to keep information about clients' illnesses and treatments confidential. Only those members of the healthcare team directly involved in care have legitimate access to the records. Clients often request copies of their medical records, and they have the right to read those records. Each institution has policies for controlling the manner in which records are shared. In most situations, clients are required to give written permission for release of medical information. Nurses are responsible for protecting records from all unauthorised readers. This includes handover notes, or informal,

identifiable notes that nurses make during the day and carry with them to assist in caring for patients.

When nurses and other healthcare professionals have a legitimate reason to use records for data gathering, research or continuing education, appropriate authorisation must be obtained according to agency policy. Nursing students and university teaching staff may be required to present identification indicating that access to the record is authorised. The nurse should know the location of the record at all times. The record is stored by the healthcare agency after treatment ends, and ownership of the record usually resides with the agency.

• CRITICAL REFLECTION POINT

How do you rate your ability to document patient care? What are the learning strategies that you use to improve this skill? Documentation truly is a skill that improves with practice. Some suggestions for improving your documentation can include:

- **practising in your university/college setting for the simulated case studies within the course**
- **having a colleague/fellow student read your documentation and ask you questions about the patient care you have documented**
- **practising documentation on scrap paper, and having a registered nurse check it before entering it into a patient's chart**
- **every time you provide care, while you are undertaking care or immediately after providing care, consider what information needs to be documented. If you are unable to document the information immediately, jot it down on scrap paper so you can recall it when you document (but always be vigilant about destroying/disposing of your scrap notes appropriately)**
- **reading through patient charts when you have access to them, noting the entries that give you a clear picture of the patient status/care given and comparing these with unclear entries. What is the difference between them? What lessons can you learn and apply from doing this? This is a form of auditing, and is a great way to learn what to do and what not to do.**

Guidelines for high-quality documentation and reporting

High-quality documentation and reporting are necessary to enhance efficient, individualised client care. Documentation must have meaning today, tomorrow and in the unforeseen future. One of the difficulties with documentation is that we never know when the document may be required, or under what circumstances (Austin 2010). Irrespective of the record type or data entry method, high-quality documentation and reporting follow five important guidelines: *fact*, *accuracy*, *completeness*, *currency* and *organisation*.

Fact

A record contains descriptive, objective information about what a nurse sees, hears, feels and smells. An objective description is the result of direct observation and measurement. The use of inferences without supporting factual data is not acceptable because they can be misunderstood. The use of words such as 'appears', 'seems' or 'apparently' is not acceptable because they suggest that the nurse did not know the facts. For example, the description 'The client seems anxious' does not accurately communicate facts and does not inform another caregiver of the details regarding the behaviours exhibited by the client that led to the use of the word 'anxious'. The phrase 'seems anxious' is a conclusion without supported facts. Documentation needs to clearly explain the nurse's observations of the client's behaviours. When recording subjective data, document the client's exact words within quotation marks. For example, 'Client states "I feel very nervous and out of control."' Any objective findings that are related to the client's anxiety, such as an increased blood pressure and pulse rate, can also be added.

Accuracy

The use of exact measurements ensures that a record is accurate. The nurse makes descriptions such as 'Intake, 360 mL of water' rather than 'Client drank an adequate amount of fluid'. Measurements are later used as a means to determine whether a client's condition has changed. Charting that an abdominal wound is '5 cm in length without redness, drainage or oedema' is more accurate than 'large wound is healing well'. Adhering to an institution's accepted abbreviations, symbols and system of measures (e.g. metric) ensures that all staff members will use the same language in their reports and records. Use abbreviations carefully to avoid misinterpretation. To avoid any chance of error, write words out in their entirety the first time before abbreviating them to avoid confusing terminology; otherwise, terminology can be confusing. When using electronic dropdown text menus ensure that you select the correct option as frequently there are a number of similar choices available.

Correct spelling is important and demonstrates a level of competency and attention to detail – misspelling can contribute to serious adverse treatments. Many terms can be easily confused or misinterpreted (e.g. dysphagia or dysphasia), so the nurse needs to understand the impact the documentation can have on client outcomes.

The ACHS EQuIP5 Guideline 1.1.8 (ACHS 2010) provides an overview of the details care providers must document in the client's clinical record, including that all entries must be legible, dated and signed with designation.

Records need to reflect accountability during the timeframe of the entry. This is best accomplished when nurses chart their own observations and actions. Each entry in a client's record is identified with the caregiver's initials or full name and status, such as 'Julie Smith, RN'. Each time initials are used, the full name and status must also appear on the same page. Nursing students enter their full name and educational institution, such as 'David Jones, SN, UTAS' (SN: student nurse), followed by the university affiliation. The signature holds that the nurse is accountable for information recorded. If information was inadvertently omitted from the record, it is acceptable for nurses to ask colleagues to chart information after they leave work. The entry needs to clearly show what was done and by whom: for example, 'At 1630 hours Sam Turner, RN, called and reported that at 1530 hours the client Joseph Podwera was administered the oral contrast solution required for his medical imaging procedure at 1700 hours.'

Should an incorrect entry be made in a client record, the nurse who made the entry must write a subsequent note in the record identifying the error and correcting it. Incorrect information should never be deleted or made illegible; rather, it must be identified as inaccurate and corrected with a subsequent note which is signed and dated.

Completeness

The information within a recorded entry or a report needs to be complete, containing concise, appropriate and thorough information about a client's care. Concise data are easy to understand. Clear, succinct recording and reporting give essential information, avoiding unnecessary words and irrelevant detail.

Criteria for thorough communication exist for certain health problems or nursing activities (Table 13-1). The nurse makes written entries in the client's medical record, describing nursing care that is administered and the client's response. An example of a nurse's thorough note follows:

> **2000 hours. Client verbalised sharp throbbing pain localised along medial side of right ankle, beginning at approximately 1900 hours after twisting his foot on the stairs. Pain increased with movement 7/10, slightly relieved with elevation 5/10. Pedal pulses equal bilaterally. Right ankle circumference 1 cm larger than left. Ice pack applied. Dr Walker notified at 1920 hours, nil further actions requested. Paracetamol 1 g given for pain at 1920 hours. Client states that pain has reduced to 3/10 at 1955 hours. L Turner, RN.**

Currency

Timely entries are essential in the client's concurrent care (ACHS 2010). In order to increase accuracy and decrease unnecessary duplication, many healthcare

TABLE 13-1 Examples of criteria for reporting and recording

Topic	Criteria to report or record
Assessment	
Subjective data	Description of episode in quotation marks Location, severity, onset, precipitating factors, frequency and duration, aggravating and relieving factors
Client behaviour (e.g. anxiety, confusion, hostility)	Onset, behaviours exhibited, precipitating factors
Objective data (e.g. rash, swelling, breath sounds)	Onset, location, description or quality of findings, aggravating or relieving factors
Nursing interventions and evaluation	
Treatments (e.g. enema, bath, dressing change)	Time administered, equipment used (if appropriate), client's response (objective and subjective changes) compared with previous treatment; for example, 'client denied pain during dressing change' or 'client reported severe abdominal cramping during enema'
Medication administration	Time administered, preliminary assessment (e.g. pain level, vital signs), client response or effect of medication; for example, 'client reports pain level 2 (scale 0–10) 30 minutes after paracetamol was given', or 'pruritus and hives developed over lower abdomen 1 hour after penicillin was given'
Client teaching	Information presented, method of instruction (e.g. discussion, demonstration, DVD, booklet), client response, including questions and evidence of understanding such as return demonstration or change in behaviour
Discharge planning	Client goals or expected outcomes, progress towards goals, need for referrals

agencies use bedside records, which facilitate immediate documentation of information as it is collected from a client. Activities or findings to communicate at the time of occurrence include:

- vital signs
- monitoring of interventions (chest tube observations)
- administration of medications and treatments
- preparation for diagnostic tests or surgery
- change in status
- admission, transfer, discharge or death of a client
- treatment for a sudden change in status.

This information is often included in flow sheets kept at the bedside. Nurses often also keep a worksheet when caring for several clients, making notes as the care occurs to ensure that entries recorded later in the record are accurate, as mentioned when discussing legal requirements affecting client information. Most healthcare agencies use the 24-hour system, avoiding misinterpretation of a.m. and p.m. times (Figure 13-1).

Organisation

The nurse communicates information in a logical order. For example, an organised note describes the client's pain, the nurse's assessment and interventions and the client's response. To write notes in an organised fashion, the nurse needs to think about the situation and sometimes make notes of what is to be included before beginning to write in the permanent clinical record.

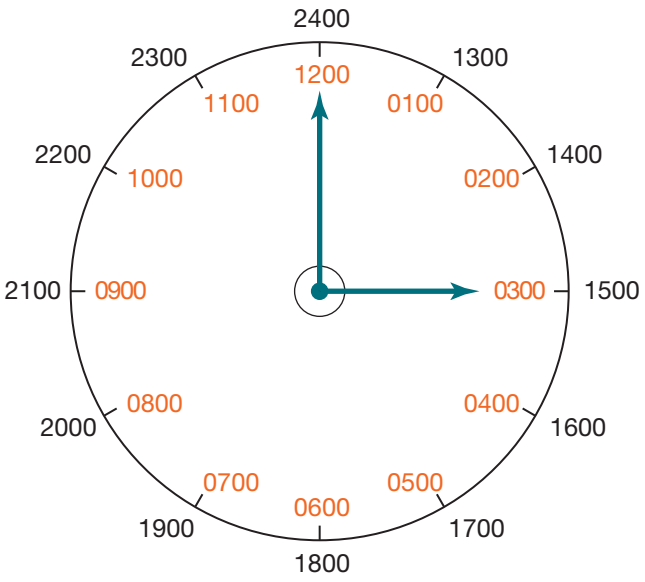

Figure 13-1 **24-hour time clock.**

Quality reporting in clinical information systems

While generally the same principles apply, whether using paper-based or electronic systems, there are some differences when using a clinical information system that nurses need to be aware of. These are described below.

Correcting documentation errors or making 'late entries'

Clinical information systems are designed to facilitate the easy entry of documentation. When a clinician documents a progress note, they are unable to edit this unless the note is in draft form. Draft documentation is not viewable to other users until the clinician determines it complete. Once it is complete and saved (i.e. not as a draft) it is viewable for any other clinician to review. Should the clinician then determine that it is incorrect or requires amendment, they must 'Cancel' the progress note entry. This automatically 'strikes out' the note and flags it as cancelled, while remaining viewable to other clinicians as cancelled.

Most clinical information systems do not generally support backdating of documentation (i.e. progress notes). As information is saved in the application, it is date- and time-stamped as to when it was created. Generally, the clinicians will denote that the situation occurred at a previous time when they provide the documentation, similar to the current practice in the paper-based medical record. Clinical information systems will always display the latest update made to any documentation to the user.

Preventing the deletion of information

Clinical information systems will always adhere to the medical documentation standards applicable at state and federal level. As a result, information is never deleted from the clinical information system. Where information is deemed not correct or appropriate (i.e. the information was recorded against the wrong client), the system will enable the user to remove the information; however, the system will only flag it as deleted. In most cases it will still be visible to the users so they are aware it has been deleted.

In some cases (i.e. in assessments where responses are removed or updated), the clinical information system will display the latest information to the user. However, it will still record for auditing purposes the historical changes to the information in the database tables.

In other cases, the information may be removed (i.e. cancelled as in progress notes); however, this is only enabled for the same clinician that wrote the information. Clinicians other than the original documenter are able

to delete another clinician's documentation in some circumstances where appropriate.

Identifying the changes and updates to the record

All changes in the clinical record within a clinical information system are recorded and saved against the individual logged in user. This is required to ensure that appropriate auditing can be undertaken (i.e. in the case of a coroner's inquest).

The clinical information system will always display the latest information to the clinician so that they can make clear, informed clinical decisions at the time. In most circumstances where information is updated, it will clearly show the clinician when and who made the updates to the record.

Note: Many clinical information systems are able to provide reports to the system administrators of changes to the record in audit reports.

Standards

The ACHS lists the following two criteria as mandatory in their EQuIP5 standards criteria and elements for healthcare standards (ACHS 2010):

> **1.1.5 Processes for clinical handover, transfer of care and discharge address the needs of the consumer/patient for ongoing care.**
>
> **1.1.8 The health record ensures comprehensive and accurate information is collaboratively gathered, recorded and used in care delivery.**

National standards or competencies, codes of ethics and professional conduct form practice guidelines and underpin responsibilities for nurses in Australia and New Zealand. All these documents outline broad roles and responsibilities for documentation and reporting (refer to your country's appropriate standards), and underpin registration and enrolment requirements for nurses. Some organisations also have further detail on how these roles and responsibilities will be enacted by nurses in their organisation.

In Australia, documentation needs to follow ACHS standards and guidelines in order to maintain institutional accreditation and lessen liability. Current standards require that all clients who are admitted to a healthcare institution have an assessment of physical, psychosocial, environmental, self-care, client education and discharge planning needs. In addition, the ACHS stresses the importance of evaluating client outcomes, including the client's response to treatments, teaching or preventive care. The nursing service department of each healthcare agency selects the method that is used to document client care. The method reflects the philosophy of the nursing department and incorporates the standards of care. Assessment data are recorded to offer to all healthcare team members a database from which to draw conclusions about the client's problems. Information describing the client's problems or diagnoses then directs caregivers to choose an appropriate plan of care with nursing therapies. Evaluation of care communicates the client's status, degree of progress and success in meeting expected outcomes of care.

Types of documentation

Narrative documentation

Narrative documentation is the traditional method for recording nursing care. It is simply the use of a story-like format to document information specific to client conditions and nursing care. Narrative charting, however, has many disadvantages, including the tendency to have repetitious information, be time-consuming and require the reader to sort through a lot of information to locate desired data (Blair & Smith 2012).

Problem-oriented medical records

The **problem-oriented medical record (POMR)** is a method of documentation that places emphasis on the client's problems. Data are organised by problem or diagnosis. Ideally, each member of the healthcare team contributes to a single list of identified client problems. This assists in coordinating a common plan of care. The POMR has the following major sections: database, problem list, nursing care plan and progress notes.

Database

The database section contains all available assessment information pertaining to the client: for example, history and physical examination, the nurse's admission history and ongoing assessment, the dietitian's assessment, laboratory reports and radiological test results. The database is the foundation for identifying client problems and planning care. The database is revised as new data become available, and accompanies clients through successive hospitalisations or clinic visits.

Problem list

After data are analysed, problems are identified and a single list is made. The problems include the client's physiological, psychological, social, cultural, spiritual, developmental and environmental needs. The problems are listed in chronological order and filed in the front of the client's record to serve as an organising guide for the client's care. New problems are added as they are identified. When a problem has been resolved, the date is

recorded and it is highlighted or a line is drawn through the problem and its number.

Nursing care plan

A nursing care plan is developed for each problem by the disciplines involved in the client's care. Nurses document the plan of care in a variety of formats. Generally, these plans of care include nursing diagnoses/client problems, expected outcomes and interventions.

Progress notes

Healthcare team members monitor and record the client's problems in the progress notes (Box 13-4). The information can be expressed in various formats of structured notes. One method is **SOAPIE**:

S Subjective data (verbalisations of the client)
O Objective data (that which the nurse can measure and observe)
A Assessment (problems identified based on the data)
P Plan (what the caregiver plans to do)
I Intervention
E Evaluation.

• CRITICAL REFLECTION POINT

Joseph Page is an 80-year-old admitted with a diagnosis of pneumonia. He complains of general malaise and a frequent productive cough, worse at night. Vital signs are: blood pressure 150/90 mmHg; pulse rate 92 beats per minute; respirations 22 breaths per minute; and temperature 38°C. During your initial assessment he coughs violently for 40–45 seconds without expectorating. His lungs have wheezes and crackles in both bases and are otherwise clear.

Differentiate between which of these data are objective and which are subjective.

In the **PIE** format, the assessment information is documented on special flow sheets. The narrative note includes:

P Problem
I Intervention
E Evaluation.

The PIE notes are numbered or labelled according to the client's problems. Resolved problems are dropped from daily documentation after the nurse's review. Continuing problems are documented daily.

Focus charting, or **DAR** notes, include:

D Data, both subjective and objective
A Action or nursing intervention
R Response of the client; that is, evaluation of effectiveness of the intervention.

One distinction of focus charting is its movement away from only charting problems, which has a negative connotation. Instead, the notes are structured according to client concerns: a sign or symptom, a condition, a nursing diagnosis, behaviour, a significant event or a change in a client's condition. Documentation is written in accordance with the nursing process; nurses are encouraged to

BOX 13-4 Progress notes – examples of different formats

SOAPIE

19/1/2008 Knowledge deficit related to uncertainty regarding surgery
1630 hours
S 'I'm worried about what it will be like after surgery.'
O Client asking frequent questions about surgery. Has had no previous experience with surgery. Wife present, acts as a support person.
A Knowledge deficit regarding surgery related to inexperience. Client also expressing anxiety.
P Explain routine preoperative preparation, including the purpose of deep-breathing and coughing (DBC) exercises.
I Provided explanation and teaching booklet on general postoperative care. Demonstrated and explained rationale for DBC exercises.
E Patient discusses rationale for DBC exercises and general care provided, and demonstrates the exercises correctly.
S Lazarus, RN

PIE

P Knowledge deficit regarding surgery related to inexperience.
I Explained to client normal preoperative preparations for surgery. Demonstrated DBC exercises. Provided booklet to client on postoperative nursing care.
E Client demonstrates DBC exercises correctly. Needs review of postoperative nursing care.
S Lazarus, RN

Focus charting

D BP in left arm 90/60, client's skin diaphoretic, client responds to name.
A Placed client in Trendelenburg's position, increased IV fluid rate to 100 mL/h per protocol, called Dr Arkin.
R Client remains responsive, BP in left arm 94/68, 3 min after increasing fluids.
S Wilson, RN
D Twisting in bed, grimacing with movement, states has sharp lower back pain (8/10).
A Administered morphine sulfate 10 mg IM.
R Verbalised relief within 15 minutes, lying quietly, pain level now 4/10.
T Newson, RN

broaden their thinking to include any client concerns, not just problem areas, and critical thinking is encouraged. Focus charting is easily understood by caregivers and adaptable to most healthcare settings.

Source records

In a **source record** the client's chart is organised so that each discipline (e.g. nursing, medicine, social work or physiotherapy) has a separate section in which to record data. One advantage of a source record is that caregivers can easily locate the proper section of the record in which to make entries. Table 13-2 lists the components of a source record. A disadvantage of the source record is that information is not organised by client problems, so that details about a specific problem may be distributed throughout the record. For example, the nurse describes the character of abdominal pain and use of relaxation therapy and analgesic medication in the nurses' notes. The doctor's notes describe the progress of the client's bowel obstruction and the plan for surgery in a separate section of the record. The results of X-ray examinations that show the location of the bowel obstruction are in the test results section of the record. The method by which source records are organised does not show how information from the disciplines is related or how care is coordinated to meet all of the client's needs.

The nurses' notes section is where nurses enter a narrative description of nursing care and the client's response (Box 13-5).

BOX 13-5 Sample narrative note

8/6 1100 hours

Client states, 'I'm having a hard time catching my breath.' Respirations, laboured at 28/min; P, 96; BP, 112/70. Client using intercostal muscles during inhalation. Breath sounds auscultated, crackles over both lower lobes. Chest excursion equal bilaterally. Elevated head of bed to Fowler's position. Obtained arterial blood gas analysis at 1045 order. Results are pH, 7.34; PCO2, 44 mmHg; PO2, 80 mmHg. Dr Stein called. Applied O2 at 4 L/min per mask as ordered. Remained at bedside to calm client.

P Haske, RN

In a clinical information system, the record is more integrated, but separate areas for writing and displaying information are also available (Figure 13-2).

• CRITICAL REFLECTION POINT

The nurse positions Mr Page in a semi-Fowler's position and encourages increased fluid intake for fever. One hour later the client is resting in bed. Vital signs are: blood pressure 130/86 mmHg, pulse 86 beats per minute, respiration 22 breaths per minute and temperature 37.8°C. The client states he has been able to sleep. His fluid intake has been 200 mL of water.

Use the given information to write a nursing progress note using each of the SOAPIE, PIE and DAR formats.

TABLE 13-2 Example of organisation of a traditional source record

Sections	Contents
Admission sheet	Specific demographic data about client: legal name, identification number, sex, age, birth date, marital status, occupation and employer, health insurance, nearest relative to notify in an emergency, religious preference, name of attending doctor, date and time of admission
Doctor's order sheet	Record of doctor's orders for treatment and medications, with date, time and doctor's signature
Nurse's admission assessment	Summary of nursing history and physical examination
Graphic sheet and flow sheet	Record of repeated observations and measurements such as vital signs, daily weights and intake and output
Medical history and examination	Results of initial examination performed by doctor, including findings, family history, confirmed diagnoses and medical plan of care
Nurses' notes	Narrative record of nursing process: assessment, nursing diagnosis, planning, implementation and evaluation of care
Medication records	Accurate documentation of all medications administered to client: date, time, dose, route and nurse's signature
Doctor's progress notes	Ongoing record of client's progress and response to medical therapy and review of disease process
Healthcare discipline's records	Entries made into record by all health-related disciplines: radiology, social work and laboratories
Discharge summary	Summary of client's condition, progress, prognosis, rehabilitation and teaching needs at time of dismissal from hospital or healthcare agency

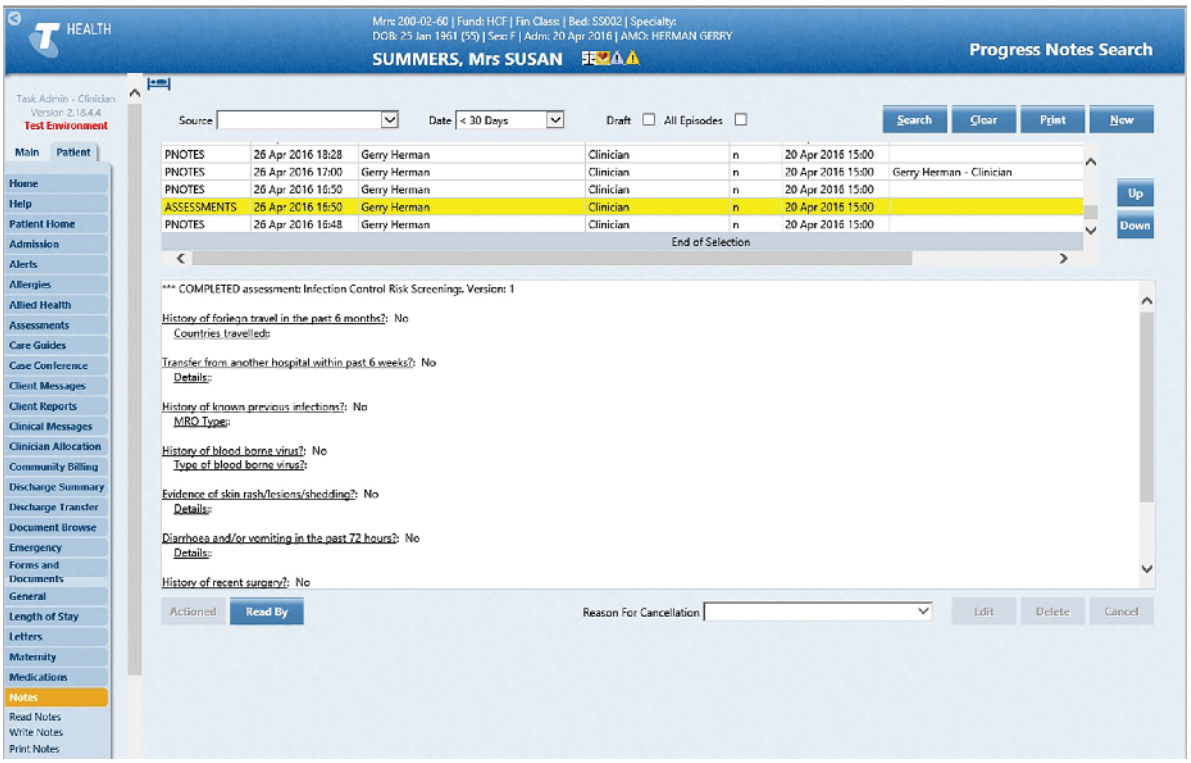

Figure 13-2 Viewing nursing notes in clinical information system.

Charting by exception

Charting by exception is an approach used to streamline documentation. It reduces repetition and time spent in charting. It is a shorthand method for documenting normal findings and routine care based on clearly defined standards of practice and predetermined criteria for nursing assessments and interventions. Clearly defined standards of practice that specify nurses' responsibilities to clients provide the framework for routine care of all clients. With standards integrated into documentation forms, such as predefined normal assessment findings or predetermined interventions, a nurse need document only significant findings or exceptions to the predefined norms. In other words, the nurse writes a progress note only when the standardised statement on the form is not met. Assessments are standardised on forms so that all caregivers evaluate and document findings consistently.

Because the standard assessments are located in the chart, client data are already present on the permanent record and caregivers have easy access to current data. The assumption with charting by exception is that all standards are met unless otherwise documented. When nurses see entries in the chart, they know that something out of the ordinary has been observed or has occurred. For that reason, when changes in a client's condition have developed, it is easy to track them.

Case management and clinical pathways

The **case management** model of delivering care incorporates a multidisciplinary approach to documenting client care. The standardised plan of care is summarised into **critical pathways**, for a specific disease or condition. Clinical pathways – or critical pathways, care paths, integrated care pathways or care maps – are multidisciplinary care plans that offer many benefits by focusing on key interventions and expected outcomes within established timeframes. The nurse and other team members, such as dietitians, social workers and physiotherapists, use the same clinical pathway to monitor the client's progress during each shift.

The aim of clinical pathways is to improve the quality of care, client satisfaction and efficiency in the use of resources and to reduce risks (De Bleser et al 2006). In general, the clinical pathway identifies the expected outcomes for each day of care (Figure 13-3). Any divergence from the stated pathway of care, whether clinical or procedural, is regarded as a variance. Recognition of **variances** is

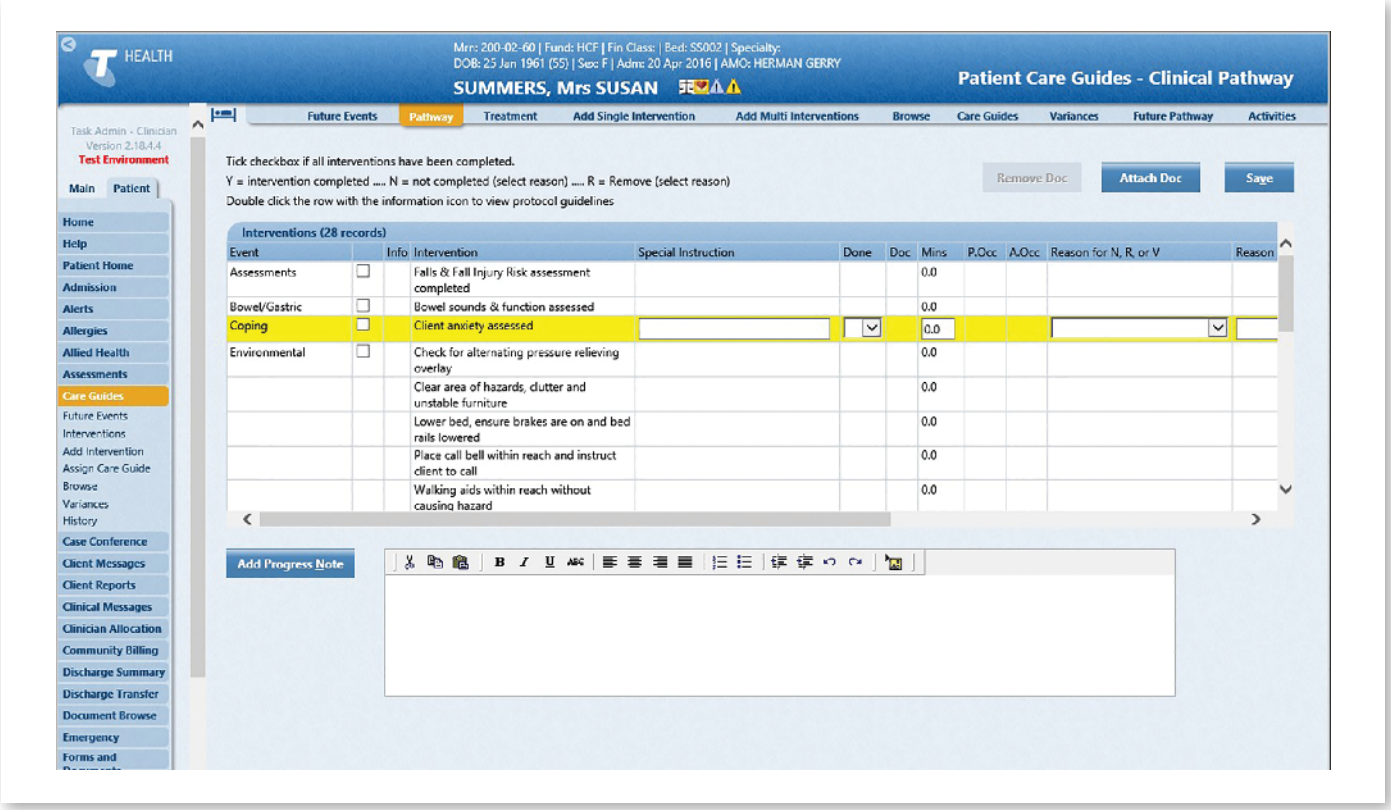

Figure 13-3 Clinical pathway in clinical information system.

© Emerging Systems, a Telstra Health business.

vital to client outcomes and should be documented in a timely fashion (Sheehan 2002). A negative variance occurs when the activities on the clinical pathway are not completed as predicted or the client does not meet the expected outcomes. An example of a negative variance is when a client develops pulmonary complications postoperatively, requiring oxygen therapy and monitoring pulse oximetry. A positive variance occurs when a client progresses more rapidly than expected; for example, use of an indwelling urinary catheter may be discontinued a day early. A variance analysis is necessary to review the data for trends and for developing and implementing an action plan to respond to the identified client problems (Box 13-6).

It must also be acknowledged that variance from the clinical pathway may be related to a client's comorbidities. These results are unexpected and not accounted for within the normal procedural outcomes, so there will be a reassessment of the use of the pathway as a clinical tool.

BOX 13-6 Variance documentation example

A 56-year-old client is on a surgical unit one day after cholecystectomy. He is beginning to have an elevated temperature, his breath sounds are decreased bilaterally in the bases of both lobes of the lungs and he is slightly confused. Ordinarily, one day after surgery the client should be afebrile with lungs clear. The following is an example of the variance documentation for this client.

23/9/08 1000 hours

Breath sounds diminished bilaterally at the bases. T, 38.2; P, 92; R 24/min; oxygen sat, 84. Daughter states he is 'confused' and did not recognise her when she arrived a few minutes ago. Oxygen started at 2 L per standing orders. Will monitor pulse oximetry and vital signs every 15 minutes.

Doctor notified of change in status.

Daughter at bedside.

Common record-keeping forms

Various forms are available which are specially designed for the type of information nurses generate during their client assessment. The categories within a form are usually derived from institutional standards of practice or guidelines established by accrediting bodies.

Nursing history

A client history form (often referred to as a nursing history) is completed when a client is admitted to a ward. The history form guides the nurse through an assessment of the client's social and health-related issues. These data then provide the framework for the nurse to develop a comprehensive, holistic approach to planning client care. All care delivered during an admission relies on an accurate initial assessment as the baseline for changes in client progress. Each institution designs a nursing history form differently, based on the standards of practice, philosophy of nursing care and the nursing care delivery system. The data gathered in any initial nursing assessment, however, become the foundation for planning clients' ongoing management up to and following their discharge.

Graphic sheets and flow sheets

Flow sheets are forms that allow nurses to assess the client and to document, quickly and effectively, using a coding system, vital signs and routine care, such as bathing, walking, meals and safety and restraint checks (Figure 13-4). If something on the flow sheet is unusual or changes significantly, a focus note is needed. For example, if a client's blood pressure becomes dangerously high, the nurse completes a focus assessment and records this, as well as action taken in the progress notes. Flow sheets provide a quick, easy reference for the healthcare team members in assessing a client's status. Critical care and acute care units commonly use flow sheets for all types of physiological data (Box 13-7).

Acuity charting systems or client dependency systems

Staffing patterns can be determined by examining the acuity levels of the clients on a particular nursing unit. The client-to-staff ratios depend on a composite gathering of data in relation to the 24-hour interventions that are necessary for implementing care. **Acuity charting** requires that staff assign a number scale to interventions, thereby obtaining a numerical level of acuity for each client. For example, an acuity system might rate bathing clients from 1 to 5 (1 is totally dependent, 5 is fully independent). A client returning from surgery requiring frequent monitoring and extensive care may be listed with an acuity level of 1. On the same continuum, another client awaiting discharge after a successful recovery from surgery has an acuity level of 5.

Standardised care plans

Many institutions have attempted to make documentation easier for nurses with **standardised care plans**. The plans, based on the institution's standards of nursing practice, are preprinted, established guidelines which are used to care for clients who have similar health problems. After a nursing assessment is completed, the nurse identifies the standard care plans that are appropriate for the client. The care plans are placed in the client's medical record. Modifications can be made in ink to the standardised plans to individualise the therapies. Most standardised care plans also allow the nurse to write in specific goals or desired outcomes of care, as well as the dates by which these outcomes should be achieved.

One advantage of standardised care plans is the establishment of clinically sound standards of care for similar groups of clients. These standards can be useful when quality-improvement audits are conducted. Another advantage is education; nurses learn to recognise the accepted requirements of care for clients. The standardised care plans can also improve continuity of care among professional nurses.

The use of standardised care plans is controversial. The major disadvantage is the risk that the standardised plans inhibit nurses' identification of unique, individualised therapies for clients. When standardised care plans are used in a healthcare facility, the nurse remains responsible for an individualised approach to care. Standardised care plans cannot replace the nurse's professional judgement and decision-making. In addition, care plans need to be updated on a regular basis to ensure that content is current and appropriate.

There is the trend in many hospitals to computerise care plans. With such a system, daily computer-generated care plans are printed and incorporate several nursing diagnoses or problems in a single care plan. Such a system facilitates the process of revision and individualisation of plans. Care facilities using this system will all use slightly different approaches.

Discharge summary forms

Significant emphasis is placed on preparing a client for an efficient, timely discharge from a healthcare institution. A prospective payment system based on DRGs encourages healthcare institutions to be more efficient and to discharge the client as soon as possible. However, it is important to ensure that a client's discharge results in desirable outcomes.

Ideally, discharge planning begins at admission. Nurses revise the plan as the client's condition changes. There needs to be evidence of the involvement of the client and family members in the discharge planning process so that the client and family have the necessary information and resources to return home. The planning for discharge

BOX 13-7 Benefits of using a flow sheet

Information is accessible to all members of the healthcare team
Time spent on writing a narrative note is decreased
Information is current
Errors resulting from transfer of information are decreased
Team members can quickly see trends over time

may also require the nurse to assess the client's need of ancillary assistance if the client does not have significant others or an established support system at home. Clients and their significant others also need to be made aware of potential post-discharge complications and any ongoing management they may require, such as follow-up appointments, medication management and emergency numbers.

When a client is discharged from institutional care, a discharge summary is prepared by the various members of the healthcare team and given to the client or family, general practitioner, home healthcare, rehabilitation or long-term care agency. Discharge summary forms (Figure 13-5) make the summary concise and instructive and should be a tool to assist in the ongoing management of the client following discharge.

• CRITICAL REFLECTION POINT

Several days later, following treatment with intravenous antibiotics, Mr Page is feeling much better and preparations are being made for discharge. He is to take Cephalexin 500 mg every 6 hours for the next 10 days, continue to drink extra fluids and get extra rest. Mr Page lives alone. Although he is generally cooperative, he does not like drinking water or taking pills. He is to make an appointment with his doctor for 1 week from today and should call the doctor if he develops symptoms of recurrence.

Write a discharge summary for the nursing care, including any patient education required, and discharge instructions for the patient which are concise and instructive.

Home healthcare documentation

Home health care continues to grow, with shorter hospitalisations and larger numbers of older adults requiring home healthcare services. Many state governments have specific guidelines for establishing eligibility for home healthcare reimbursement. According to these guidelines, nurse input into the documentation must reflect an accurate

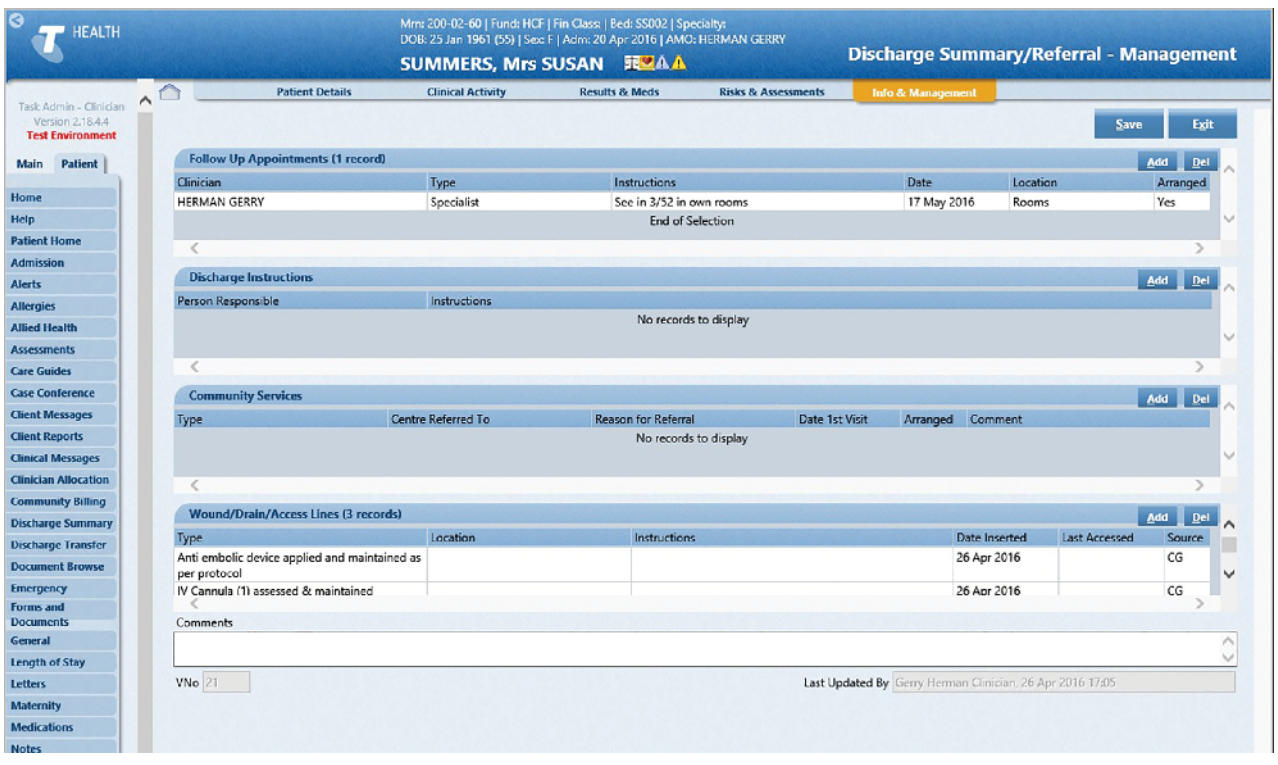

Figure 13-5 Discharge summary view clinical information system.

© Emerging Systems, a Telstra Health business.

assessment and the nurse's accountability to the client and the taxpayer.

Documentation in the home healthcare system has different implications from that in other areas of nursing. Nurses in this context must have astute assessment skills in order to gather the required information about changes in the client's healthcare status, as they often work independently and do not have others nearby to validate the client's condition or issues that may arise. In addition, documentation systems need to provide the entire healthcare team with the necessary information to be able to work together effectively (Box 13-8).

Some parts of the record are needed in the home with the client; other information is needed in an office setting. This means that duplication of documentation is necessary, or agency policies are needed regarding what forms nurses need to leave at their office versus what forms need to be taken into the homes. Computerised client records are a way of handling these different needs. With the use of tablet and laptop computers, it is becoming possible for the records to be available in multiple locations, which allows greater access to the multidisciplinary needs often present in home health care (Figure 13-6). This includes the ability to share documents and images, and conduct telehealth consultations with specialist team members from the client's home.

Long-term healthcare documentation

An increasing number of elderly people require care in long-term healthcare facilities. Since many individuals will live in this setting for the rest of their lives, they are referred to as **residents** rather than clients. The information provided within nursing documentation has a direct influence on the level of care a resident will receive.

Long-term client care in Australia has particular aspects that make documentation practices somewhat unique (Voyer et al 2014). In extended care, government agencies are instrumental in determining the standards and policies for documentation. In addition, the health department in each state or territory governs the frequency of written nursing records of the residents in long-term care facilities. Since residents are often stable, daily documentation may be completed using flow sheets. Assessments done several times a day in the acute-care setting may be required only at weekly or monthly intervals in the extended-care setting.

Extended-care agencies are also developing skilled-care units for residents requiring increased levels of care, in response to the demands for shorter hospital stays. Extended-care documentation supports a multi-disciplinary approach in the assessment and planning process. Communication among healthcare providers, such as nurses, social workers, occupational therapists and dietitians, is essential in the regulated documentation process.

BOX 13-8 Home healthcare forms for documentation

The usual forms used to document home care include:

- Client assessment
- Referral source information/intake form
- Discipline-specific care plans
- Doctor's plan of treatment
- Medication sheet
- Clinical progress notes
- Miscellaneous (conference notes, verbal order forms, telephone calls)
- Discharge summary
- Reports to third-party payers

Modified from Iyer PW, Camp NH 1999 Nursing documentation: a nursing process approach. Mosby, St Louis.

Reporting

Nurses communicate information about clients so that all team members can make appropriate decisions about their care. Four types of **report** made by nurses are the change-of-shift report, telephone report, transfer report and incident report.

Change-of-shift (handover) report

Towards the end of each shift, nurses report information about their assigned clients to the nurses working on the next shift. The purpose of the report is to provide continuity of care among nurses who are caring for a client. If one nurse finds a certain pain-relief measure effective for a client, it is important that the information be relayed to the next nurse caring for the client so that pain-control interventions can be continued.

The **change-of-shift report** (handover) may be given orally in person or via a recorded medium. Oral reports may be given in staff rooms, with staff members from both shifts participating or at the patient's bedside. An advantage of an oral report is that it allows staff members to ask questions or clarify explanations. When nurses make rounds, the client and family members also have the opportunity to participate in any decisions. The nurses can see the client together to perform needed assessments, evaluate progress and discuss the interventions best suited

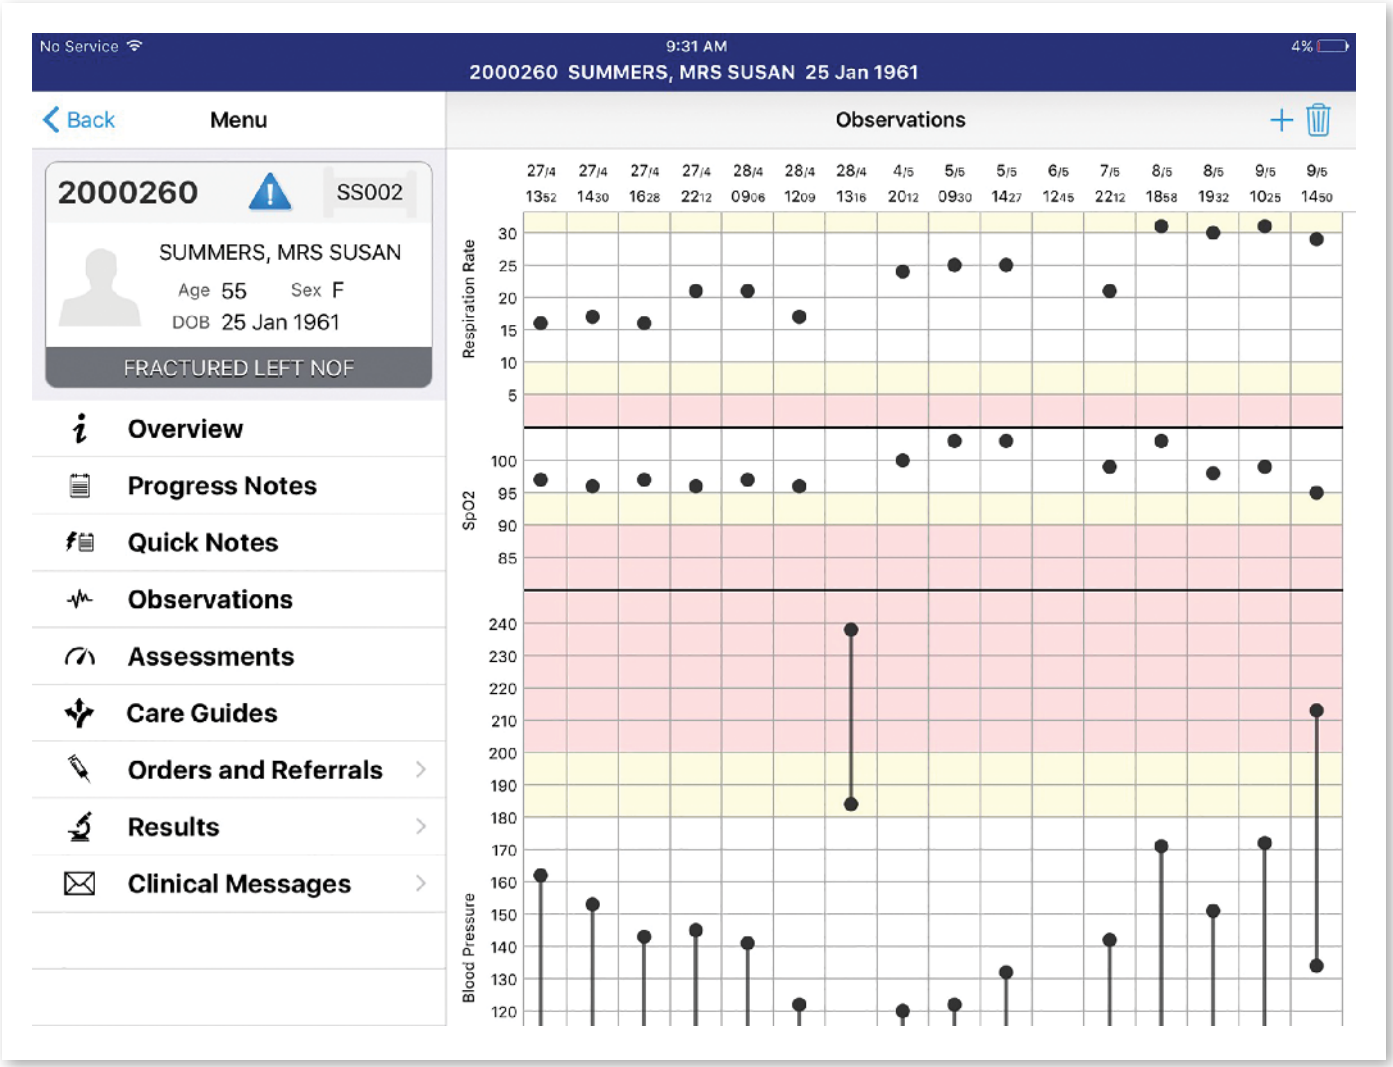

Figure 13-6 **Tablet-based observation recording.**

© Emerging Systems, a Telstra Health business.

to the client's needs. An audiotape report is given by the nurse who has completed care for the client and it is left in a secured area to ensure confidentiality for the nurse on the next shift to review. Taped reports can improve efficiency by allowing staff to report when time is available.

Because of a nurse's many responsibilities, it is important that a change-of-shift report be conducted quickly and efficiently (Table 13-3). A good report describes clients' health status and lets staff on the next shift know exactly what kind of care the clients require. Significant facts about clients are reviewed (e.g. the condition of wounds or episodes of chest pain) to provide a baseline for comparison during the next shift. Data about clients need to be objective and concise. An organised report follows a logical sequence. To prepare for the report, the nurse gathers information from worksheets and the client's care plan.

Reporting and handover has been a focus of quality improvement in Australia and New Zealand since 2007–08, with international importance placed on quality of handover as paramount to patient safety. See NSQHS Standard 6 for details on clinical handover (ACSQHC 2011). Handovers that are not structured or comprehensive can interrupt continuity of care, lead to poor practice and may cause harm (Calleja et al 2011). Structures and frameworks for reporting (Box 13-9) have been the focus of recent research as a means to improve quality. See Skill 12-1 in Chapter 12.

When giving a report, the nurse provides crucial information concerning clients and family members and discusses relevant issues in a professional manner. It is important that the nurse refers to the Nursing and Midwifery Board of Australia's *Registered nurse standards for practice* (NMBA 2016) or the Nursing Council of

TABLE 13-3 Comparison of do's and don'ts for change-of-shift reports

Do's	Don'ts
Do provide only essential background information about client (i.e. name, sex, age, doctor's diagnosis and medical history)	Don't review all routine care procedures or tasks (e.g. bathing, scheduled changes)
Do identify client's nursing diagnosis or healthcare problems and their related causes	Don't review all biographical information already available on file
Do describe objective measurements or observations about client's condition and response to health problem; emphasise recent changes	Don't use critical comments about client's behaviour, such as 'Mrs Wills is so demanding'
Do share significant information about family members as it relates to client's problems	Don't make assumptions about relationships between family members
Do continuously review ongoing discharge plan (e.g. need for resources, client's level of preparation to go home)	Don't engage in idle gossip
Do relay to staff significant changes in the way therapies are given (e.g. different position for pain relief, new medication)	Don't describe basic steps of a procedure
Do describe instructions given in teaching plan and client's response	Don't explain detailed content unless staff members ask for clarification
Do evaluate results of nursing or medical care measures (e.g. effect of back rub or analgesic administration)	Don't simply describe results as 'good' or 'poor'; be specific
Do be clear about priorities to which oncoming staff must attend	Don't force oncoming staff to guess what to do first

New Zealand (2007) *Competencies for registered nurses* to ensure compliance with the recognised professional standards pertaining to reports and the information contained within them. It is often necessary to describe the interactions among clients, nurse and family members in behavioural terms. The nurse needs to avoid using judgemental language such as 'uncooperative', 'difficult' or 'bad' when describing such behaviours.

• CRITICAL REFLECTION POINT

At the end of your shift 6 hours later, you have identified fluid volume deficit as a problem for Mr Page. Since his admission he has had fluid intake of about 600 mL and his urine output was 300 mL of dark, concentrated urine. His temperature is back up to 38.3°C, his mucous membranes are dry and he states that he feels very weak. Using a handover framework, list the information that should be included in the change-of-shift report.

Telephone report

Nurses inform doctors of changes in a client's condition and communicate information to nurses on other units about client transfers; laboratory staff or radiologists may report results of diagnostic tests. Those involved with a telephone report need to provide clear, accurate and concise information.

Information in a telephone report is documented when significant events or changes in a client's condition have occurred. To document a phone call, the nurse includes when the call was made, who made it (if other than the writer of the information), who was called, to whom information was given, what information was given and what information was received, and if any additional or change in orders were received. For example, 'At 1022 hours called Dr M's rooms to inform her that Ms Demos's STAT potassium level taken at 0800 hours was 3.2 mEq/L. Dr M to review patient on ward this afternoon. Carole Towns, RN'.

Telephone orders

Telephone orders involve a doctor stating a prescribed therapy over the phone to a registered nurse. Clarifying messages is important when a nurse accepts a doctor's orders over the telephone. The order needs to be verified by repeating it clearly and precisely. Many institutions require that the doctor repeat the telephone order to a second RN to reduce the possibility of a transcription error occurring. Then the nurse writes the order on the appropriate chart, such as the medication chart, and signs it. For example, '14–2–2012: 19.20 hours – Telephone order from Dr Reis for Mr Rogers UR 92762344 morphine 5 mg IM stat. Carol Towns, RN, and Mary Walters, RN'. The doctor later legally verifies the telephone order by signing it within a set time period (e.g. 24 hours).

Telephone orders are frequently given at night or during an emergency, and should be used only when

BOX 13-9 Reporting structures/tools

HAND ME AN ISOBAR

Step 1 – Preparing for handover	H Hey, it's handover time – reminding everyone about importance of handover A Allocate staff to care for patients during the handover (continuity of care) N Nominate participants, time and venue D Documentation should be updated before handover
Step 2 – Organise handover	M Make sure all participants have arrived E Elect a leader (usually shift coordinator/supervisor)
Step 3 – Environmental awareness	A Alerts, attention and safety N Notice about potential patient movements, staffing or other potential environmental issues
Step 4 – Minimum data set for individual patient handover	I Identification of patient S Situation and status O Observations B Background and history A Assessment and actions R Responsibility and risk management

SBAR

S Situation – chief complaint, current status

A Assessment – What are the problems? (results of assessment, vital signs and symptoms)
R Request/recommendation – What do I recommend/request be done? (suggested and anticipated changes, critical monitoring)

SHARED

S Situation – reason for admission/phone call; change in condition; diagnosis-specific information
H History – medical, surgical, family, etc; recent treatments, response and events
A Assessment – results of any testing, severity of condition
R Risk – allergies, infection control, literacy/cultural, drugs, skin integrity, mobility/falls
E Expectation – expected outcomes, plan for care with timeframes, discharge planning, who to call with specific concerns/treating team
D Documentation – progress notes, referral, anything relevant for patient

Adapted from Australian Commission on Safety and Quality in Health Care (ACSQHC) 2010. The OSSIE guide to clinical handover improvement. ACSQHC, Sydney. Online. Available: www.safetyandquality.gov.au/wp-content/uploads/2012/01/ossie.pdf; accessed 19 July 2016.

absolutely necessary. Certain guidelines can be used to prevent errors in receiving telephone orders (Box 13-10).

With the increasing adoption of electronic health records it is becoming possible for doctors to securely access patient records remotely. This should result in a decrease in telephone orders as the doctor can add orders into the EHR directly.

Transfer report

Clients may be transferred from one unit to another to receive different levels of care. For example, clients are transferred from an intensive care unit or the recovery room to general nursing units when the client no longer requires such intense monitoring. In order to promote continuity of care, transfer reports may be given by phone or in person. When giving a **transfer report**, nurses include the following information:

- client's name, age, primary doctor and medical diagnosis
- summary of progress up to the time of transfer
- current health status (physical and psychosocial)
- current plan of care
- any critical assessments or interventions to be completed shortly after transfer (helps receiving nurse to establish priorities of care)

BOX 13-10 Telephone order guidelines

- If the doctor sounds hurried over the phone, use clarification questions to avoid misunderstandings
- Clearly determine the client's name, room number and diagnosis
- Repeat any prescribed orders back to the doctor
- Write a telephone order to include date and time given; name of client, nurse and doctor; and the complete order
- Follow agency policies; some institutions require telephone (and verbal) orders to be reviewed and signed by two nurses
- Have the doctor co-sign the order within the timeframe required by the institution (usually 24 hours)

- any special considerations, such as isolation status or resuscitation status
- need for any special equipment.

After completion of the transfer report, the receiving nurse needs an opportunity to ask questions about the client's status. In some cases, written documentation must include a record of information reported.

• CRITICAL REFLECTION POINT

Reconsider the *Clinical example* at the beginning of this chapter.

Mrs Staples was the elderly woman admitted with a fractured neck of femur who later fell and sustained further injuries. We cannot know for sure, but perhaps if Mrs Staples had been reassured continually about who was looking after her pets, her outcome might have been different. What is relevant here is that unless information is written down, it is likely to be lost (Calleja et al 2011).

Research into handover and verbal reports has found that accuracy and retention of correct information is difficult when relying on verbal reports alone to carry information forward (Calleja et al 2011). One study that simulated clinical handover studied types of handover and data lost during handover (these were: purely verbal; note-taking style; and a typed sheet with verbal handover) over a period of five cycles of patient handovers (Pothier et al 2005). Findings included degradation of data in all three groups; however, the verbal-only style experienced the most data loss, until no original or correct data was handed over for any of the simulated patients. This substitution was not present in the other handover styles. The note-taking group showed steady data loss; at the end of five cycles, only 31% of data was accurate. Finally, the group with typed page accompanying verbal handover had very little data loss over the five cycles. This is of interest as nursing in particular is often seen as a discipline that has a 'verbal' culture (often information is passed on via verbal means with less detail given in documented notes).

Incident reports

An incident is any event that is not consistent with the routine operation of a healthcare unit or with the routine care of a client. Incidents may involve clients, staff or visitors. Examples of incidents include client falls, needle-stick injuries to staff, a visitor having symptoms of illness, medication administration errors, accidental omission of ordered therapies, and circumstances that led to injury or risk of injury. Analysis of **incident reports** helps with the identification of trends in systems and unit operations that provide justification for changes in policies and procedures, or in-service seminars. Incident reports are an important part of the quality-improvement programs of healthcare facilities.

When an incident occurs, the nurse involved or the witness(es) to an injury complete an incident report. A report is completed even if an injury does not occur or is not apparent. Most institutions have incident report forms, which are sent to the risk-management office for review and follow-up action. For example, the employees' health department might review all incidents involving employee needle-stick injuries, and the legal department might review incidents for which the potential for legal action against the hospital exists.

When a client or a visitor is involved in an incident, the nurse who observes the incident or who receives the report deals with the situation and then completes a detailed report. In many cases, a doctor is notified and decides on actions to be taken to determine whether any injury has been suffered. If a client is affected, the doctor documents the examination and findings in the client's medical record. The nurse documents only an objective description of what was actually observed and any follow-up care that occurred, and does not specify in the medical record that an incident report was prepared. Examples of an accurate and an inaccurate note are:

> **Accurate note: 2200 hours. Heard a thump in ward. Patient Margaret Baldwin found on floor, complained of aching pain in left hip, 8 (scale 0–10). Noted external rotation and shortening of left leg. Lifted into bed using Hoyer lift. Vital signs: blood pressure 142/88 mmHg; pulse 90 beats per minute; respiration 22 breaths per minute. Bed rails up, call bell within reach, patient reassured and instructed to remain in bed. Dr Smith notified at 2210 hours, portable X-ray ordered.**

> **Inaccurate note: Patient fell out of bed, complained of pain in left hip. Noted external rotation and shortening of left leg. Dr Smith notified.**

One of the more common types of incident is a medication error (Chapter 35). An incident report for a medication

error needs to include an accurate, concise description of the event, all important related information, such as the medical officer notified, and a record of any adverse reactions suffered by the client.

Nurses become involved in client-related incidents at some point in their career. The following list provides guidelines for correctly completing an incident report.

- The nurse who witnessed the incident or who found the client at the time of the incident files the report.
- Describe specifically what happened in concise, objective terms.
- Describe objectively the client's condition when the incident was discovered.
- Any measures taken by the nurse, other nurses or doctors at the time of the incident are reported, along with the outcomes of such interventions.
- Do not interpret or attempt to explain the cause of the incident or blame anyone.
- The report is submitted as soon as possible to the appropriate administrator.
- Keep a written account of the incident report for personal files.

Most jurisdictions have introduced electronic incident reporting systems allowing incident data collection and analysis at local (unit or organisation), state and national levels. This ensures that data can be used to gain a comprehensive understanding of the type, frequency and severity of clinical incidents. These analyses can provide important information on contributing and preventative factors and lead to targeted quality-improvement initiatives. It is important that the nurse also keeps a record of the event, usually in their professional portfolio, to assist with recalling the incident accurately if legal action ensues.

Key concepts

- The medical record is a legal document, and requires information describing the care that is delivered to a client.
- All information pertaining to a client's healthcare management that is gathered by examination, observation, conversation or treatment is confidential.
- Multidisciplinary communication is essential within the healthcare team.
- Accurate record-keeping requires an objective interpretation of data with precise measurements, correct spelling and proper use of abbreviations.
- A nurse's signature on an entry in a record designates accountability for the contents of that entry.
- Any change in a client's condition warrants immediate documentation, to keep a record accurate.
- Problem-oriented medical records are organised by the client's healthcare problems.
- The intent of SOAPIE, PIE or DAR charting is to organise entries in the progress notes by the nursing process.
- Critical pathways are instrumental in documenting methods that will produce a better quality of client outcomes.
- Long-term care documentation is multidisciplinary.
- Computerised information systems provide information about clients in an organised, accessible fashion.
- The major purpose of the change-of-shift report is to maintain continuity of care. Use of tools and frameworks can help improve the quality of handovers and reports.
- Rounds allow nurses to perform needed assessments, evaluate clients' progress and determine the best interventions for clients' needs.
- When information pertinent to care is communicated by telephone, the information needs to be verified.
- Incident reports objectively describe any event that is not consistent with the routine care of a client.

Understanding and applying cultural safety: philosophy and practice of a social determinants approach

Leonie Cox and Chris Taua

Learning outcomes

Mastery of content will enable you to:

- understand how the history of Australia and Aotearoa New Zealand impacts on the current health status of Indigenous persons in both countries
- understand what is meant by social constructionism and a critical approach and their relevance for nursing care
- describe the context of nursing in Australia and Aotearoa New Zealand and issues of culture in professional regulation
- develop awareness of, describe and discuss the theoretical principles underlying cultural safety and how it produces person-centred care
- explore your own culture (including your gender and gender identity/ies, age, ethnicity, class, attitudes, beliefs, behaviours, ability) and discuss the potential of these to affect your nursing practice
- consider the role of power and power imbalances in health care and how these relate to social stratification, systemic racism and biases, and structural violence
- practise culturally safe nursing care
- recognise the social determinants of health and discuss how cultural safety can help nurses to address health inequalities.

This chapter introduces a number of concepts and perspectives that you will need in your professional nursing practice to effectively address the interaction between culture/s and nursing care. The approach we advocate for is called cultural safety (Ramsden 2002),[1] and is defined as:

> **… the effective nursing of a person/family from another culture, and is determined by that person or family … The nurse delivering the service will have undertaken a process of reflection on [their] own cultural identity and will recognise the impact that [their] personal culture has on [their] professional practice. Unsafe cultural practice is any action which diminishes, demeans or disempowers the cultural identity and well-being of an individual (Nursing Council of New Zealand 2011:7).**

Underpinning this chapter and cultural safety is a philosophical commitment to social constructionism and a **critical approach** to understanding the influence of social processes on health and on nursing care. **Social constructionism**, a sociological theory, recognises that humans create society, its structures, institutions, knowledges and technologies and that all are shaped by the interests, priorities and '… values of the more powerful and influential members of society' (Willis & Elmer 2011:71). Social constructionism also recognises that people are shaped by society as it imposes limits on our actions and free will through rules, structures and dominant forms of knowledge. However, professional nurses are critical thinkers; we do not just passively accept things, but take a questioning approach to life, to knowledge and to our practice. We shape society by our actions as we negotiate life through communication and power relationships (Willis & Elmer 2011).

Such a position is in sharp contrast to that underlying a biomedically dominated healthcare system, which sees 'reality' as an unproblematic 'given' and, in caring for clients, disregards pertinent issues, such as social position, social experience, meaning and power. To help readers come to grips with these complex issues, this chapter discusses concepts that mainstream health cultures assume have a universal meaning, but which are in fact socially constructed. Examples include the concept of 'health' itself and those of 'race', 'ethnicity' and 'culture', which experience shows are constructed in numerous ways by clients and professionals in healthcare systems.

Because one-to-one relationships are the basis of all nursing care it is easy to see that care can be compromised when clients and nurses are working from different assumptions about identity; the nature of reality; health priorities; what it means to be healthy; what causes and what might cure illnesses; and what illness and wellness mean. It is these complex circumstances that provoke us to ask you to consider a number of perspectives in nursing that may be different to those you currently hold and to explore a number of influences that you may have not considered relevant to nursing.

We know that recent nursing graduates thinking about diversity and the delivery of nursing care seek a simple solution to help them cater for the holistic needs of clients; but there are no magic formulas. However, the model of cultural safety, and its practice and application, does develop a range of strategies that will enhance best practice. In this chapter we give you an overview of the societal context of nursing in Australia and Aotearoa New Zealand, considering the historical and contemporary state of the relationship between colonisers and the Indigenous people in both countries and the ongoing impacts on their health. We introduce you to the concept of the social determinants of health, which does not focus on individual behaviours, but looks at how health and the conditions necessary to attain and maintain wellness are intimately related to society and the dynamics between government, policies, institutions, media, public opinion and systems.

Accordingly, we explore the potential influence of various social and historical processes on nursing care and on health, not only for Indigenous peoples, but also more broadly. We have a closer look at cultural safety, exploring various socially constructed concepts such as culture, worldviews, lifeworld, whiteness, race, ethnicity and class. We consider power and health and the related issues of ethnocentrism and discrimination. These factors are all important in practising in a culturally safe way. We conclude with an overview of the regulation of the nursing profession in Australia and Aotearoa New Zealand and the practical application of cultural safety, taking into account the social determinants of health we will have discussed.

The context of health and nursing in Australia and Aotearoa New Zealand

The Australian mainland was a culturally diverse society long before Europeans set foot on the shores of Botany Bay, having already been occupied by its Traditional Owners for upwards of 40,000 years. Up to 700 different Indigenous[2] language groups occupied the continent (Australian Museum 2013) and lived in well-defined socioeconomic, political, land-owning units (Elkin 1964). In addition, the Torres Strait Islands constituted further diversity (Nakata 2004). These islands were gathered under Queensland ownership in 1872 when this state annexed all islands within a 60-mile radius of the mainland.

Aotearoa New Zealand had a somewhat different beginning. The first settlers to arrive in Aotearoa New Zealand between 250 and 1150 CE were Polynesian people (Belich 1996). By the 12th century there were numerous settlements, mainly along the coastline. These Polynesian settlers became known as Māori, and although dialectal differences developed, these peoples shared many common cultural traditions (Rice 1992). When Europeans decided to not only visit but to stay, both Australia and Aotearoa New Zealand were colonised by the British. However, significant differences marked this process in the two countries.

Indigenous peoples of Australia

Australia was colonised in the late 18th century with the British Crown claiming that the land was *terra nullius* (unoccupied) and therefore open to annexation without treaty (see Lippmann 1999, McGraw 1995, Reynolds 1987, 1989). This claim was justified on social Darwinist notions that the Traditional Owners were not humans, and ignored the fact that Macassan traders had been visiting the shores of the continent for several hundred years, while Europeans had first visited in the 1600s. As Nakata (2004:155) observes: 'As inhabitants of a seaway, Islanders in the Torres Strait had long been used to welcoming or defending themselves against visitors and were themselves travellers of considerable distances, both north to Papua New Guinea and south to Cape York Peninsula'. On mainland Australia the initial impact of a permanent European presence was far from peaceful. Land was taken by force and the period was characterised by massacres and punitive expeditions against Indigenous groups who fought to defend their land, its resources and their right to ceremonial practices and lore/law (Evans et al 1975). For the original owners, all of these sociocultural aspects are inseparable from Country.

The population was further decimated by infectious diseases that arrived with the colonisers. This period was followed by over 200 years of dispossession and dislocation, made possible by laws and policies applicable only to Indigenous Australians. These laws, and the policies and practices they enabled, were intrinsically racist and aimed to segregate, assimilate and control the Traditional Owners. This history is generally discussed with reference to the policy eras of dispersion, segregation, protection, integration and assimilation (see the work of Broome 2001, Cox 2007, Eckermann et al 2010, Kidd 1997, Reynolds 1987). Essentially, Indigenous Australians were treated by the state as inferior and every aspect of their lives, including language, family organisation, food and shelter, employment, education, recreation and religion, was strictly controlled by some government instrumentality.

Indigenous peoples and their supporters were never passive in the face of these genocidal processes, but actively resisted them in numerous ways such as dismantling bridges to prevent further incursions (Evans et al 1975) and the establishment in 1958 of the Federal Council for the Advancement of Aborigines and Torres Strait Islanders (FCAATSI) (National Museum of Australia 2014). A national referendum in 1967 ushered in policies for self-management and self-determination, although true self-determination is still not realised nearly 50 years later. The 1967 referendum determined that the First Australians would finally be recognised as citizens in the national census and that the Commonwealth Government could legislate for the benefit of Indigenous people. These events saw the gradual dismantling of some repressive state-based legislation, permitting the first Aboriginal-community-controlled medical and legal services to be established in the 1970s (Willis & Elmer 2011:184). The Aboriginal and Torres Strait Islander Commission (ATSIC) was established in 1990. Although subject to much critique and controversy, the formation of ATSIC was the closest Australia has come to having a truly representative Indigenous body. As Sanders (2004) argues, ATSIC improved political participation and enhanced regional representation and social reform among Australia's Indigenous peoples. However, ATSIC was abolished after 14 years of operation, having had its health responsibilities removed in 1995 (HREOC 2004).

Under the new policy eras of self-management and self-determination there has been major and extensive effort in relation to both Land Rights and Native Title. The Aboriginal Land Rights (Northern Territory) Act (1976), the Mabo decision in 1992 and the Wik decision in 1996 are just some of the major developments in this area, which space does not permit us to cover here (see Northern Land Council in *Online resources*). Smith and Morphy (2007) give an extensive overview of these developments in their edited volume on the social effects of Native Title. Although favourable Native Title judgements are valued acknowledgements of Traditional Owners, the authors conclude that Native Title does not constitute Land Rights and that the impact of Native Title judgements on improving the social position of Indigenous Australians is patchy at best.

In an attempt to address the seemingly intractable nature of Indigenous disadvantage, the Close the Gap (CTG) campaign was launched in 2007. This campaign

is a collaboration between government, Indigenous and non-Indigenous health organisations, the Human Rights and Equal Opportunity Commission (since 2008 known as the Australian Human Rights Commission (AHRC)) and community leaders. The aim of CTG is to close the health and life-expectancy gap between Indigenous and other Australians within a generation. A recent progress report on CTG shows that from 2005–07 to 2010–12 Indigenous life expectancy '… is estimated to have increased by 1.6 years for males and by 0.6 of a year for females. But a life expectancy gap of around ten years remains for Aboriginal and Torres Strait Islander people when compared with non-Indigenous people' (Close the Gap Steering Committee 2015:1). The Prime Minister's CTG Report stated: '… the disparity in outcomes remains … It is profoundly disappointing that most Closing the Gap targets are not on track to be met' (Commonwealth of Australia 2015:1).

Other recent notable events include the Royal Commission into Aboriginal Deaths in Custody (RCIADIC) following agitation by Black Deaths in Custody groups concerned about the over-representation of Indigenous people in jails and watch-houses and their preventable deaths while in custody (Johnston 1991). Marchetti (2006:453) comments that it was hoped the RCIADIC would 'transform race relations', but concludes that its 339 recommendations have had limited impact on the social and economic position of Indigenous Australians. Further, the report was noted to be deeply colonising in that it failed to 'understand or incorporate Indigenous worldviews and values' (Marchetti 2006:454). Deaths in custody continue and the incarceration rates of Aboriginal people remain disproportionately high (ABS 2014b). Nonetheless, RCIADIC Recommendation 247 states that all healthcare professionals need education on the impacts of forced child removal on Aboriginal people (Johnston 1991), an effort that continues to the present time and is evident in the context of this chapter.

It is noteworthy that this RCIADIC recommendation focused on what is perhaps the most enduring blight on Australian history: the genocidal policy and practice of forced child removal. Governments deemed Indigenous people incapable of raising their children with any white ancestry and removed them to be raised by white families, or in orphanages and dormitories on missions and reserves. The report of the Royal Commission also informed a national inquiry into the removal of Aboriginal and Torres Strait Islander children from their families (Human Rights and Equal Opportunities Commission 1997). The report of that inquiry, commonly called *Bringing Them Home*, articulated government child removal practices in detail and led to thousands of non-Indigenous Australians saying sorry to Indigenous Australians for the wounds of the past by signing 'Sorry Books' during a campaign launched in 1998 (National Sorry Day Committee Inc., n.d.). Eventually these processes led to a national apology to Indigenous Australians from then Prime Minister Kevin Rudd in February 2008 (Celermejer & Moses 2010:35).

The national apology was welcomed by Indigenous Australians and seemed to mark a new era in Australian history. However, as McAuley (2011:1) states:

> **Not only did the Apology make no provision for compensation for the wrongs suffered by those who were taken from their families, but the Rudd and Gillard governments have substantially maintained the controversial Northern Territory National Emergency Response (NTNER), or 'Intervention', introduced in the dying days of the Howard government.**

The Intervention followed the release of the Northern Territory Government's Board of Inquiry report into the protection of Aboriginal children from sexual abuse (Northern Territory Government 2007). Its implementation required the suspension of the Racial Discrimination Act 1975 and implied that Aboriginal people were child-abusers, incapable of looking after their money or taking their children to school or for health checks.

The NT Board of Inquiry report had been used by the Howard government to justify a political discourse about a 'crisis', defending the highly intrusive actions of the Intervention despite the fact that the report states that 'the problems [of sexual assault] do not just relate to Aboriginal communities. The number of perpetrators is small and there are some communities, it must be thought, where there are no problems at all' (Northern Territory Government 2007:6). Aspects of the NT Intervention have continued to evolve and have gained bipartisan support. Many processes are now legislated for by the 2012 Stronger Futures in the Northern Territory Act which focuses on alcohol abuse, income management and school attendance. The NT Intervention further marginalised and infuriated Indigenous people, and Indigenous-led movements such as 'Roll Back' (Box 14-1) are still trying to have the Intervention dismantled. These arrangements have been extended until 2022 under the Stronger Futures legislation (see *Online resources*).

In summary, it is crucial that nurses and all healthcare professionals grasp the fact that history has left its mark on Australian identity and attitudes towards the country's Traditional Owners, as well as on the life chances of today's Indigenous Australians whose ancestors (the old people) are revered in social memory (see Cox 2007, 2009, Saggers & Gray 1991). Structural inequality was created and firmly entrenched by historical circumstances, and is reinforced by contemporary policies and practices that

BOX 14-1 Roll back the Intervention

… Our voices are not being heard since 2007 … The Intervention has made it so hard for us to live on land and in our communities … Many communities were forced to sign 40-year leases and hand over control of their land to the government. Now they want to destroy our traditional ownership of the land by dismantling the historic NT Land Rights Act 1976.

The Intervention also forced the Basics Card on us, which quarantines half of the Centrelink payment. We are treated like children and told how to spend our money. We are humiliated on a daily basis when we go shopping. Reports show that the Basics Card is not working; it is not having healthy outcomes for Aboriginal people. But now the government wants to put us on a 'Healthy Welfare Card' where 100% of our money will be quarantined …

The Intervention has not produced jobs for our people – it has taken them away. They took away work from communities when they stopped the CDEP [Community Development Employment Projects] and left people with nothing to do and no way to make a living. This forced people off their homelands and into towns to look for work. But there is little work for Aboriginal people in the big towns and many end up on the street being harassed by police or in jails … We need real jobs with real wages in our communities.

… more Aboriginal children are being taken from families and put with foster parents, usually non-Aboriginal people. This child removal has to stop …

Our kids are turning to crime out of boredom or despair with many of their family members being locked up, often for minor offences such as not paying fines. More and more young people have no hope and are turning to harming themselves.

Rollback the Intervention 2015, Invasion Day Alice Springs 2015 blog. Available: https://rollbacktheintervention.wordpress.com/; accessed 2 Feb 2016.

continue to discriminate against Indigenous people (such as the 'Intervention' mentioned above) and hinder the right of Aboriginal and Torres Strait Islander peoples to self-determination (see Brown & Brown 2007). As we will see later in the chapter, such processes contribute to the social determinants of health which the model of cultural safety seeks to address.

Indigenous peoples of Aotearoa New Zealand

The colonisation process for Māori, the Indigenous people of Aotearoa New Zealand, presented many parallel impacts to those discussed for the Traditional Owners of Australia; however, there were some differences. One of these differences was the British acknowledgement of Māori as Indigenous *tangata whenua* (people of the land). However, despite this acknowledgement, the devastatingly negative biological and social effects of colonisation were not lessened. Dishonest purchasing of land, land wars and the introduction of diseases for which Māori had little or no immunity had significant impacts on the Māori population. Other consequences were impoverishment and the breakdown of Māori social structure, culture, language, life chances and health (Kearns et al 2009). In an attempt to recognise the legal rights of Māori and enable the British to colonise Aotearoa New Zealand in 1840, representatives of the British Crown and representatives of many of the multiple *iwi* (tribes) and *hapū* (sub-tribes) of Aotearoa New Zealand signed a treaty called the *Te Tiriti O Waitangi*/The Treaty of Waitangi (hereinafter referred to as Te Tiriti). Although Te Tiriti conferred the right on British settlers to settle in Aotearoa New Zealand, it also created a corresponding duty on the Crown to ensure Māori retained their existing property and citizenship rights (Human Rights Commission 2013).

Unfortunately, there were discrepancies between the Māori and British translations of Te Tiriti that were not initially recognised. Kingi (2007:5) states that 'while the objectives of Te Tiriti were in part designed as a platform for Māori health development, based on the continued population decline, it proved to be less than successful. In fact, the 1800s was a century characterised by significant and sustained Māori de-population'. This outcome was perhaps related to the fact that the intent and provisions of Te Tiriti were largely ignored until the 1970s, when a tribunal was eventually formed to ensure that the government and statutory bodies upheld their responsibilities as stated by Te Tiriti. The introduction of the Waitangi Tribunal Act in 1975 ensured a refocus on reparations to Māori, compelling the government to acknowledge the importance of the Crown's relationship with Māori (see *Online resources*).

Currently, Te Tiriti offers a mechanism for rectifying some of the consequences of colonisation, and provides a set of three principles for all persons living in Aotearoa New Zealand to follow. These principles are outlined in the *New Zealand Royal Commission on Social Policy Report* (RCSP 1988) as partnership, participation and protection (Ministry of Health 2004). Thus, *partnership* means working together with iwi, hapū, whānau and Māori communities to develop strategies for Māori health gain and appropriate health and disability services; *participation* at all levels means involving Māori at all levels of the sector in decision-making, planning, development and delivery of health and disability services; and *protection* and improvement of Māori health status means working to ensure Māori have at least the same level of health as non-Māori, and safeguarding Māori cultural concepts, values and practices.

Cultural diversity

While Aotearoa New Zealand had a colonial experience somewhat different from that of Australia, the process of colonisation still resulted in the loss of economic resources, the creation of structural inequality and widespread institutional **racism** – just as the equivalent processes in Australia did for the Traditional Owners. Although Australian and Aotearoa New Zealand societies are culturally diverse, it is important to acknowledge the status of Indigenous people in both societies as the original owners, and not diminish their status as just another ethnicity among many. In Australia, Indigenous peoples constitute 3% of the total population (ABS 2014a). Current census data shows that 24.6% of Australia's population was born overseas and 43.1% of people have at least one overseas-born parent (ABS 2012). The 2013 New Zealand Population Census found that Māori constitute 14.9% of the total population, while 11.8% of the population is of Asian descent and 74% identified with one or more European ethnicities (Statistics New Zealand 2014).

Despite the cultural diversity in both Australia and Aotearoa New Zealand, it should be remembered that cultural diversity does not mean that either country is marked by structural diversity. The dominant language and the underlying philosophies and practices within the mainstream legal, political, educational, agricultural and health institutions in both countries are monocultural in that they derive from one source (Britain) and are often referred to by the broad and generic term 'Western'. It is within this context that nursing education and practice occurs. In caring for people you will encounter beliefs and **values** that appear, or indeed are, inconsistent with the practices of 'Western' medicine, nursing philosophies and nurses' personal cultures. How nurses respond to clients' beliefs and behaviours is strongly related to their own beliefs and values, and will determine how effective they are in caring for and promoting clients' wellness and creating client- or person-centred care (see Figure 14-1).

To provide the best possible health care it is imperative that nurses understand concepts such as *culture*, *class*, *whiteness/race/racism* and *ethnicity* and have a strong

Figure 14-1 The diversity of which we are all a part makes health care challenging and rewarding.

(clockwise from top left): Dreamstime/Rsusanto, iStockphoto/andersen_oystein, Shutterstock/Tatiana Morozova, iStockphoto/Juanmonino, Shutterstock/Petro Feketa, Shutterstock/zhuda, Shutterstock/Tomasz Markowski, iStockphoto/Ian McDonnell.

awareness of themselves as cultural beings. Further, all health professionals need to consider how culture, class and social marginality impact on both health and health care. In the following sections we will show that social responses to clients' class, ethnicity, gender or abilities influence people's life chances and health. Such concerns are intimately related to the social determinants of health, that is, to factors beyond the control and behaviours of individuals. To come to grips with these complex issues we introduce you now to the model of cultural safety and discuss more fully the specific conceptualisation of culture that underlies the model and its focus on the social determinants of health.

Cultural safety

Cultural safety (*kawa whakaruruhau*) was developed within the Māori community in the 1990s by Māori nurse scholar Irahapeti Ramsden in Aotearoa New Zealand (1993, 2002). Ramsden and colleagues developed the model partly in response to a first-year Māori nursing student's astute comment: 'You people talk about legal safety, ethical safety, safety in clinical practice and a safe knowledge base, but what about cultural safety?' (Ramsden 2002:1). These Māori nursing students alerted Ramsden to the expectations they felt to conform to the dominant institutional culture and their experience of non-Māori 'experts' lecturing to them about traditional Māori culture. Their experiences suggested that there was only one correct, authentic way of being Māori, which, as urban Māori whose ancestors experienced the disruptions of colonisation, they could not embrace.

Cultural safety therefore aimed for cultural change by exposing and addressing such power imbalances to decrease the impact of cultural dominance and racism in health care, education and research (McCleland 2011). Ramsden also saw that nursing curricula were devoid of structural issues and were designed by and for those who did not share her cultural position or experience of colonisation. She challenged this cultural dominance, particularly the way it shaped policy and developed nurses as mere biomedical technicians rather than agents of social change (Ramsden 2002). Ramsden saw cultural safety as a way for nurses to consider how their socialisation and cultural position impacted on their work, emphasising the links between ill-health and dispossession, economic status and political agendas. This social determinants approach contrasts with individualist biomedical notions that illnesses merely occur 'within bodies'.

Underpinned by critical social theory, cultural safety also recognises that nursing care, education and research are not value neutral activities but reflect socio-political contexts and the values, assumptions and priorities of those involved (Ramsden 2002, Reimer-Kirkham et al 2009). Cultural safety focuses on *how people are treated in society*, not *how they are culturally different*. That is, the import of diversity is turned on its head in cultural safety, as it is social responses to diversity that create health impacts not the existence of the diversity itself (Cox & Simpson 2015). Consequently, cultural safety is about power – personal, professional and institutional power in health services, and the impact on those who use the service; the people who define the

CLINICAL EXAMPLE

An example of being culturally unsafe

Mrs G is an Aboriginal woman in her 40s who goes to the hospital in the rural town where she lives at about 11.45 am on a Monday morning, to see a doctor. She has pains in the stomach that have kept her awake all night and got worse after breakfast. She is accompanied by a female cousin, Mrs S, who is some years younger. Although only in her 40s, Mrs G is a respected elder in her community, a fact that reflects the statistically reduced life expectancy of Aboriginal people.

Mrs G is told by the young female nurse at the front desk to take a seat in the sparse basic waiting room. There are no magazines, television or tea-making facilities here, such as one might find in city hospitals. By 1.00 pm no one has come to see Mrs G and she's not been offered so much as a drink of water.

Feeling frustrated and worried about Mrs G, Mrs S finally finds the courage to confront the nurse and asks when the doctor will be there to see Mrs G.

The nurse responds by saying, 'Doctor is on his lunch break.' She then says to Mrs S, 'Are you a drinker too, love?' At this Mrs G gets up and says to her cousin, 'Let's go along', and they leave the hospital without being seen. Mrs G still has abdominal pain and both women are angry at being referred to as 'drinkers', especially as both are teetotallers and devout Christians.

Lessons to be learnt from this example are:

- the clients were culturally unsafe – they were demeaned, diminished and disempowered
- the nurse and the hospital neglected their duty of care
- the nurse has unexamined prejudices towards Aboriginal people and operates on stereotypes
- the use of the term 'love' from a young white woman was offensive to such respected leaders in the community
- access of these clients to health services was limited by the hospital's lunch-time policy
- it may take years for either woman or their large extended families to seek help from the hospital again.

Cox L 2007 Fear, trust and Aborigines: the historical experience of state institutions and current encounters in the health system, Health and History 9(2):70–92. Reproduced with permission.

worth of nurses' practice (Richardson 2004). Cultural safety is also about **trust**, being trustworthy and the way trust is constructed personally, culturally and institutionally; it requires the dominant culture to be accountable for the access and delivery of appropriate health care to all cultures (see *Clinical example*).

There is no doubt that there has been a growth in awareness of diversity issues in the nursing and midwifery professions. Although cultural safety was conceptualised by Māori nurses and colleagues and originated in a post-colonial context, it is *applicable to any encounter whatsoever*, because the interaction between a nurse and a client is always a bicultural relationship, whether differences between individuals are expressed by gender, sexuality, social class, occupational group, generation, ethnicity or other variables. The underpinning tenet of cultural safety is that each person should receive care that takes account of their unique identities and experiences. A plethora of **cultural awareness** orientation programs have recently been implemented, aiming to increase **cultural sensitivity** and understanding between people from different cultures, but these have been shown to have very little impact on changing behaviour and attitudes (NACCHO 2011). Such approaches often espouse providing culturally sensitive care *regardless of differences* and many still have not realised that a key point of difference in cultural safety is that it respects a person's cultural values and preserves their wellbeing *regardful of differences* (Ramsden 2002). Further, Ramsden (2002) illustrated that the impacts of cultural safety reached beyond cultural awareness and sensitivity (see Figure 14-2). This progression clearly highlights that the terms 'cultural awareness' and 'cultural sensitivity' are not interchangeable with 'cultural safety'; they are separate concepts (Ramsden 2002). All need to be achieved for nurses to be in a position to negotiate culturally safe care with clients.

Another key difference in approaches is that 'cultural safety does not ask nurses to discover the dimensions of any culture apart from their own. It does not believe that nurses should, or even could, gain an insider's understanding of any culture other than their own; instead the focus of care is on the client's experience as the determinant of effective nursing care' (Eckermann et al 2010:185). Self-awareness through personal self-reflection is therefore critical and requires nurses to bring to consciousness their own historical, cultural, social and personal context; their own beliefs, attitudes and values; and their own personal biases and cultural assumptions about others. Nurses then need to consider how all of these dimensions may affect the nursing care they provide to those assumed to be either different or the same as themselves. We will return to these important processes presently.

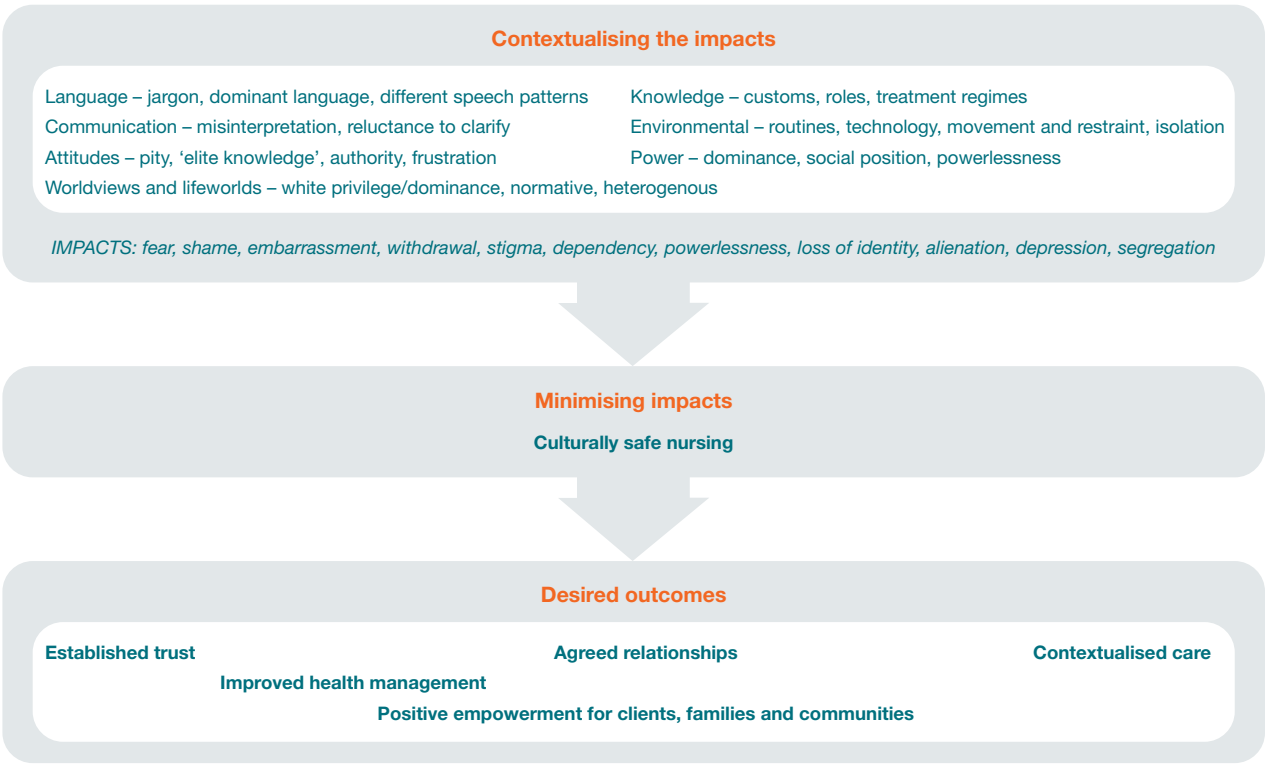

Figure 14-2 **Contexualising the impacts of culture.**

• CRITICAL REFLECTION POINT

To help you to start on your own journey of self-reflection:

1. **Write down at least three cultures that you identify with – these may be your religious or spiritual culture, one or more of your personal ethnicities, your professional culture, your generation, your gender, and so on.**
2. **Write down as many norms or rules you can think of that are part of the cultures you identified.**
3. **In your work as a nurse, consider some of the norms or rules that relate to the hygiene needs, mobility needs and nutrition needs of the people you serve. Are these the norms or rules of your job, or are they the norms or rules of the people you serve?**
4. **Think about some of the rewards and punishments that have helped you learn the norms or rules of one or other of your cultures.**
5. **Identify at least four of the beliefs and values of at least one of your own cultures and discuss them with other members of the culture you identify with. How important are they to you?**

A common misunderstanding in discussions on the impact of nurses' individual culture and values on nursing care, and the need for cultural safety, is the notion of 'treating everyone the same'. The authors have often heard nursing students exclaim 'But I treat everyone the same', or 'Why should they get different treatment to anyone else?' While nurses should treat everyone with the same level of positive regard and respect, these remarks reveal that the students have confused notions of equity and equality by suggesting that these terms mean 'sameness'. In fact, everyone is not the same: each person is unique and has unique needs. A deeper problem with such ways of thinking is that they also suggest everyone has the same advantages, opportunities and privileges, so they deny inequality.

Cultural safety and holism

Cultural safety is a **holistic** concept that is dedicated to **person-centred care**. Therefore, all aspects of that person must be considered in order to achieve such care (Ramsden 2002). Giving culturally safe care means that each person receives care and treatment according to their individual needs. Importantly, through Ramsden's work, the emphasis has changed from nurses' assessment of practice in terms of clients' needs – to clients' assessment of the type of service and care they would value. That is, the client, not the nurse, determines what culturally safe care is. Further, cultural safety is concerned with the transfer of power between healthcare providers and those receiving the service. As Ramsden (2002) points out, nurses need to become aware of the level of distrust that will mark their interactions with Indigenous and other clients from minority groups due to their previous experiences of oppression with healthcare systems, as previously discussed (see also Cox 2007, Forsyth 2007). As we have seen, the process of colonisation is typically associated with structural and cultural violence against Indigenous peoples. As the Nursing Council of New Zealand states: 'Any nurse who can understand their own culture, the theory of power relations and their impact in practice, can be culturally safe in any context' (cited in Ramsden 2002:199). Therefore, actions that reinforce respect, responsibility and the legitimacy of difference are likely to support cultural safety (Ramsden 2002).

The keys to holistic care are developing trust, negotiating knowledge, negotiating outcomes and understanding the socio-historical factors that influence health and nursing care. Strategies to achieve such outcomes include **self-reflection** and awareness; reflection on one's own culture, **attitudes**, beliefs and profession; understanding the influence of power imbalances; enhancing communication skills; and drawing on the skills of interpreters. Before considering these issues we will take a close look at the definition of culture used in cultural safety, because without grasping this concept, culturally safe practice will be elusive.

What is culture?

In coming to grips with the theory and practice of cultural safety it is essential to grasp the definition of culture underlying the model. There have been many definitions of culture over the past 150 years, a fascinating discussion of which can be found in Rapport and Overing (2007). Many people assume incorrectly that culture only relates to a person's ethnicity. Clearly, from our introductory comments on social constructionism, our understanding of culture is that it does not just exist as an unproblematic, observable entity – culture is constructed by humans in attempts to influence their social world, understand their experience and give it meaning. **Culture** is constructed socially in the interactions between people who live in networks of relationships characterised by power relationships. Cultures are contextual, dynamic, strategic and messy, not static systems practised to an equal degree by everyone who identifies as belonging to a particular culture. Many definitions emphasise notions of culture as learned, shared and complex. Rapport and Overing (2007:113) cite Wagner's critique of the 'idea of shared, stable systems of collective representations' within which 'instead lives a constant flux of continual re-creation'.

In contrast to functionalist views that see cultures as fixed and bounded wholes with members who equally share systematised **beliefs** that are the same, our everyday

lived experience is different. Our experience shows that while some aspects of culture may be shared, other aspects are highly contested and heterogeneous. We need only to think of the terms 'Aussie' or 'Kiwi'[3] as cultural identifiers to realise how diverse Australians or New Zealanders are in terms of attitudes, beliefs, values, practices, religions, languages and so on. Further, individuals can belong to many different cultures simultaneously and therefore have unique cultural needs that will not be met by seeking to learn normative ideals (worldviews) and practices of only one of the cultures that a client might embrace. The person may alter their behaviour, language, conversational topics and body language depending upon the group they are identifying with at any given time. An example might be a person who identifies as a European, Jewish, female, heterosexual nurse from a privileged economic background. Can you see how this person might behave differently depending on which cultural group/s she is interacting with at any particular time?

• CRITICAL REFLECTION POINT

1. **What cultural aspect of the person we have described above would you focus on? How would you provide care according to this person's needs? Figure 14-3 shows some of the many influences that shape cultures and an individual's cultural identity.**
2. **Define what culture means to you. Explore more clearly the society to which you belong and the subgroup(s) influencing your actions, beliefs and values. What internal and external environments helped to shape the subgroup(s) with which you identify? Analyse how you prefer to learn, use language and interact, what motivates you, how you make decisions, how you express yourself and how and with whom you prefer to interact.**

To help you reflect on this exercise and deepen your understanding of culture as it is used in cultural safety we turn now to a closer look at the concepts of the worldview and the lifeworld.

Worldviews and lifeworlds

Some definitions of culture restrict themselves to a consideration of **worldviews** and these emphasise idealised cultures (*normative culture*) rather than the lived experience of everyday life (*descriptive culture*). We argue that understanding human social experience in the **lifeworld** and interactions with the worldview is much more relevant for the interaction between culture and health care. All of us have a worldview. It is the framework we use to interpret and act in the world; the lens through which we view our experiences, think about the meaning and purpose of our lives and ponder how we got here, how the world came about, what happens

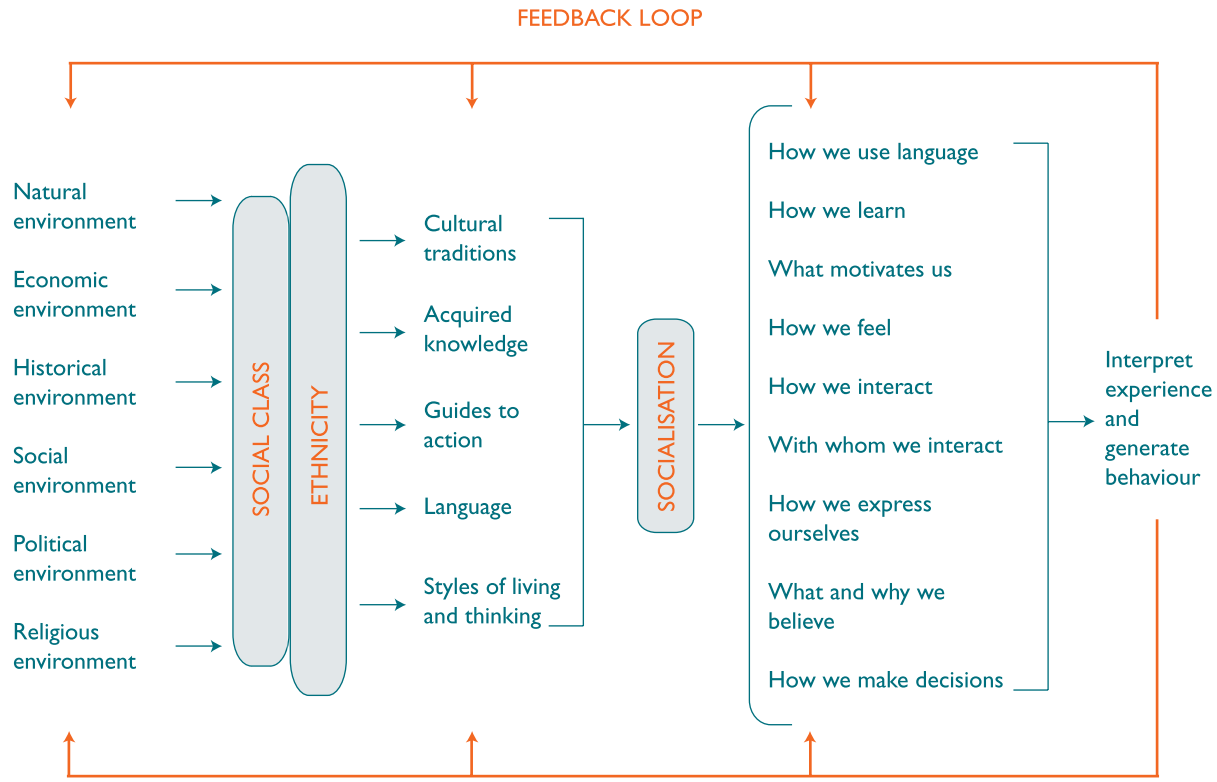

Figure 14-3 **The interrelationship of culture and environment.**

after our bodily passing, whether humans are alone in the universe and many other metaphysical and existential matters. Rapport and Overing (2007) note that the term worldview is the English translation of the German concept *Weltanschauung*, meaning our overall outlook, philosophy or conception of the world or, as Geertz would have it, 'a way of thinking about the world and its workings' (Geertz 1973, cited in Rapport & Overing 2007:432). Our worldview may have aspects that are shared with others, but it will also have aspects that are unique to us alone. Nonetheless, our worldviews affect the way we think and act, our beliefs about right and wrong, our perceptions of people and things around us, and our emotional reactions to our own experiences and to others.

• CRITICAL REFLECTION POINT

1. **Talk to some of your peers about their worldviews. Are they different from yours?**
2. **What about your family members?**
3. **Think about how you have come to have similar or different worldviews.**
4. **Write down a few ways in which the worldviews of clients might affect their health care.**
5. **Write down a few ways your worldview might affect your nursing care.**

The challenge in culturally safe nursing is to become aware of how the personal cultural biases (values, beliefs, attitudes, assumptions) that we hold can influence the care we deliver. Nurses interact with people throughout various stages of their life cycle and deal with a whole range of life events and problems. This is where Husserl's phenomenological concept of the lifeworld comes into play, as the lifeworld is the everyday world in which we live our lives – it refers to the world as it is experienced (Dahlberg & Drew 1997). When we consider issues of social position and power, it is clear that even though people may live in the same society and even share a cultural identity, their lifeworlds might be quite different to one another, being comprised of events, problems, privileges, opportunities and other circumstances that are not necessarily experienced by members of the same society or culture.

• CRITICAL REFLECTION POINT

1. **Talk to some of your friends about their lifeworlds. How do they experience their everyday life?**
2. **Is their experience different to yours? Are there differences in privileges and opportunities?**
3. **What about your family members?**
4. **Think about how you have come to have similar or different lifeworlds.**
5. **Write down a few ways that the lifeworld of clients might affect their health care.**
6. **Write down a few ways your lifeworld might affect your nursing care.**
7. **Think about how your lifeworld might come into play if you are the one who needs nursing care.**

It follows, then, that how we interpret and explain adverse events and problems is influenced by both our particular worldviews that inform our experiences, and the lifeworlds in which those experiences take place. Nursing, therefore, requires us to at least achieve some empathy towards the worldviews and lifeworlds of our clients *within their social context*, since it is only from doing so that we can gain understanding of clients' illness and healthcare needs (see *Research highlight*). To examine this proposition further we will take a closer look at health as a social construct in a later section.

In summary, in cultural safety, culture is conceptualised as changeable, learned, strategic and socio-political and the term '… is used in its broadest sense to apply to any person or group of people who may differ from the nurse/midwife because of socio-economic status, age, gender, sexual orientation, ethnic origin, migrant/refugee status, religious belief or disability' (Ramsden 2002:114). Culture is socio-political since issues arising from social, political, historical and environmental contexts are factors influencing what motivates people to interact, with whom they prefer to interact, and in what way. These factors are important social determinants of health. The interaction between culture and health shows that not all members of a society have equal access to power and resources: depending on their identity, social experience or social class, individuals are afforded different opportunities in life. They have access to varying levels of power, are permitted varying levels of input into decision-making processes, and their power to change their life circumstances for the better varies greatly. Indeed, some have suggested that being white is the best protector of health there is. We explore these issues further below.

Whiteness, race, ethnicity, class

As discussed earlier, the British way of life with its laws, understandings and beliefs around health and illness became the prevailing ethos in both Australia and Aotearoa New Zealand, and resultant power and control became situated in the domains of 'white' people. Consequently, the dominant philosophies and practices of health care in both societies stem from biomedicine and

RESEARCH HIGHLIGHT

Research abstract

Cancer mortality is higher for Indigenous Australians when compared with non-Indigenous Australians. Key issues are poor access to screening, treatment and support services. Research in Western Australia explored experiences of services and the barriers faced. Thirty interviews were undertaken with people from urban (n = 11), rural (n = 9) and remote (n = 7) areas.

Thematic analysis revealed that the participants' main needs were for practical and emotional support throughout the treatment process. Specific issues included:

- financial aspects – tests, medication, transport, parking, food, accommodation
- problems with travel, such as discomfort in entering areas where they had no formal invitation
- displacement from family and dealing with family responsibilities
- the hospital environment
- lack of information to prepare people for what to expect (new environment, treatment, follow-up, costs)
- lack of appropriate support persons – strong need for more Aboriginal interpreters or Aboriginal Liaison Officers, especially for ongoing support following discharge.

The researchers found that since most of the urban Aboriginal population lives on the fringes of Perth, they faced similar socioeconomic barriers as rural and remote participants, which were more extreme for remote participants. For some, not knowing their way around the large cities was likened to 'landing on the moon' (Shahid et al 2011:237).

The study identified an important systemic issue where rules relating to access to health services was one of several issues that prevented family members accompanying relatives travelling from remote areas.

The hospital environment

Participants found the hospital alienating:

- lifts could be terrifying
- loss of independence and dignity was disempowering
- inflexibility of the system to cope with extended families
- invasion of privacy, shame and discomfort during ward rounds.

'One participant said her 84-year-old grandfather "hated being heavily dependent on strangers" in hospital as he was a proud, independent man who disliked having to ask for things when he needed them; he hated being restricted to bed and detested the food' (Shahid et al 2011:238).

Positive support experiences

Some participants reported positive outcomes. However, many of those who reported positive experiences already had contacts or knowledge of the systems. Many often knew nothing about the system (for health services and financial support) and didn't know who to ask.

Researcher's recommendations

- Effective communication
- Feelings of trust
- Ensuring culturally safe treatment and service response.

To achieve the above:

1. Better management of costs – people avoid treatment if they feel they can't afford it or bring family for needed support.
2. Improve hospital environments to minimise feelings of alienation and fear – more support persons and interpreters, artwork, places to sit and yarn, access to preferred foods.
3. Reduce the need to travel – have regionally-based coordinators to link people to and between services.

In conclusion, it is often not remoteness in itself that is the actual problem. The problem is the lack of treatment infrastructure to meet clients' needs to ensure they do not feel demeaned and demoralised.

the cultural dominance of the 'white' way of doing things. It is easy to see what an advantage these circumstances bring to the wellbeing of those already situated in white domains. As Puzan (2003) outlines, members of the white (or mainstream) culture are inheritors of unearned, unexamined and unacknowledged privileges. Further, **whiteness** is espoused as 'the norm' and everyone else is seen as outside of the norm. Those who are racially designated are therefore measured against the largely implicit standards of whiteness, regardless of whether they are able/unable, and willing/unwilling to meet 'white norms' and are often made to feel deficient or subordinate. Whiteness, then, does not simply refer to the colour of someone's skin but to a whole domain of power and privilege, which presents an alternative way to discuss systemic/institutional and personal racism that turns the gaze from continual scrutiny on 'the racialised other' to white purposes, practices and cultures.

Puzan (2003:193) describes whiteness as '… a socially constructed category of race, wherein non-white people are racially designated, while whites escape such designation and occupy positions which allow them to carry on as if what they say is neutral, rather than historically and ideologically situated'.

Just as cultural safety counters the invisibility of whites as cultural subjects, studies of whiteness counter the invisibility of whites as racial subjects, enforcing an acknowledgement from that domain of participation in diversity and therefore challenging the assumed right to define and police the diversity of others vis-a-vis white spheres of influence.

It is these dimensions of whiteness and of white power that cultural safety seeks to address. Practitioners undertake processes of critical cultural self-reflection and power sharing in order to facilitate the recognition of themselves as cultural beings who belong to a culture that has profound impacts on human health and wellbeing. Whiteness does not always control by force, but through the 'inequitable social distribution of punishments and rewards', through control of discourse and definitions, through control of what 'counts as knowledge' and of what action or treatments should be undertaken, through control of acceptable 'words and deeds' and through 'rules and laws', 'bureaucratic hierarchies', 'technologies of surveillance' and dominant ideologies (Puzan 2003:194–6).

It is likely that you can recall your own examples of unthinking expressions of white dominance. For example, the way 'Australians' comment on how many 'Asians' live here – ignoring the fact that many people of Asian descent have lived in Australia for the entire period since colonisation or for many generations. Of course, all these modes of dominance are experienced interpersonally and impact on individual consciousness. It is evident that the majority of nurses are white; that the rules, norms and conventions of nursing, and the knowledge passed down through nursing education, is white. It is also evident that white privilege, along with that of class, influences who can undertake nursing education and where that person may eventually be employed. Curriculum standards and pedagogies are informed by the knowledge of the dominant cultural group, that of the 'white' system, and anyone outside this group is in general required to learn the standardised white way (Solomon et al 2005).

Race

Historically, white privilege concerned the social construction of the notion that there were discrete and different evolutionary lines of humans that were called races. Although the term '**race**' first arose in Europe in the 15th century as a means to account for differences more generally, the theory of human races developed during the 19th and 20th century. Outlaw (1990:62) refers to '… the abundant knowledge that the deployment of race has almost always been to service political agendas' and in racial thinking, whites saw themselves as subordinate only to God and as the pinnacle of an evolutionary line of progressive human perfectibility from primitive to civilised.

From this lofty position, white people assumed the right to control racialised others and marshal them towards the perfection they saw themselves as having achieved. So, as Outlaw describes, race: '… continues to be a major fulcrum of struggles over the distribution and exercise of power' (1990:67). Although race is a social construction that has no biological or scientific basis (see Templeton 2002, 2003, Willis & Elmer 2011), the concept of race has destructively seeped into people's perceptions of others. Many problems arise from the situation where racial beliefs became the organising principle of the modern world, not the least of which is the various forms of racism that continue to influence the work of individuals and institutions such as healthcare services.

Ethnicity

Ethnicity is a related term that refers to the group or groups that people identify with or feel they belong to. Ethnicity can be based on religion, customs, or common ancestral or geographic origins. A person may identify with some or all of the shared characteristics of a group and may choose different ethnic affiliations at different times in their life. In some respects, however, the term ethnicity has come to have a commonsense meaning of 'minority' and is seen by some to be a less emotive term than 'racial minority'. It could be argued that those belonging to the dominant cultures in Australia and Aotearoa New Zealand do not generally see themselves as having ethnicity or as belonging to a 'race', more often reflecting on their cultural identity as simply 'Australian' or 'New Zealander'. However, using the above definition, everyone has 'ethnicity', and, notwithstanding experiences of removal and adoption, can trace the specific roots that form their ethnicity.

• CRITICAL REFLECTION POINT

Have you ever been in a situation where a way of understanding a health issue from the perspective of the dominant white culture is discussed, and the educator

turns to a student of different ethnicity and asks them to explain how this is understood in their ethnic group? What is happening when this occurs?

First of all, the educator has not only given privilege to the dominant way of understanding the issue, but has also assumed that the 'other' student is representative of all 'others'.

How would you respond if you were asked to speak for all people from the ethnic group you belong to? Could you do that?

Social class

Class is another marker of privilege and a social determinant of health. In countries such as Australia and Aotearoa New Zealand, people are categorised by educational, social and economic factors into different classes, which are accorded different social status. Just like the concepts of culture and race discussed above, 'class' is another social construction created by people in the attempt to order, understand and control their world. Such categorisation of people into classes is known as **social stratification** – the ordering of society into groups or classes which have differential access to power, privilege and status.

Membership of a social class often determines whether an individual will or will not complete intermediate or higher education or acquire sufficient meaningful work and income to satisfy their basic needs. Class is therefore another aspect of culture and an indicator of differential life chances that impact on health and wellbeing. *The Black Report* on health inequalities in Britain (Department of Health and Social Services 1980) clearly illustrated this by identifying a widening gap in health inequalities between rich and poor communities. Over the decades following *The Black Report*, other reports have reached similar conclusions, including *Fair Society, Healthy Lives* (*The Marmot Review*) (Marmot 2010). Little doubt remains that the relationship between health and social disadvantage is of major significance (Wilkinson & Pickett 2010), not only because of the economic cost to many, but also because of the social injustice caused by health inequalities.

Although it contradicts egalitarian Australian ideals, it is now well known that there are patterns of inequality in health and illness that can be better understood by focusing on the social dimensions of health; the impact of society's reactions to 'race', ethnicity and class stratification creates significant health impacts (Willis & Elmer 2011). To gain a better understanding of **social determinants of health** we now look at the impact of forms of discrimination and imbalanced relations of power.

Ethnocentrism, stereotyping, racism and discrimination

The preceding discussion about race/whiteness, ethnicity and class suggests that challenges may occur when one group assumes power over another and/or attempts to control them and enforce their beliefs, values and cultural practices. Such circumstances characterise the situation of Indigenous peoples and other minorities when the practices of mainstream cultures are related to beliefs such as ethnocentrism.

Ethnocentrism and othering

Ethnocentrism is the belief that our own cultural group (or those we identify with in a given context) is not only essentially different from, but is also superior to others (Eckermann et al 2010) and this results in what can be called 'othering'. **Othering** refers to a process where anyone perceived as different to the self (the other) is seen as inferior, suspicious, strange, exotic, unable to be understood, or considered not worth the effort of trying to understand. For example, residents may see strangers in a small town as 'other' (often referred to in Australia by the slang derogatory term 'blow-ins'). Australian or Aotearoa New Zealand-born citizens might see those born overseas as 'foreigners', or the privileged may see the poor as 'not one of us'. Otherness is a term that can be assigned to various cultural aspects such as class, sexual orientation, religious or spiritual beliefs, ethnic origin, migrant experience, gender, gender identity, age and disability.

Stereotyping

Although there is an educational emphasis on acknowledging individual differences between clients as consumers of health services and ourselves as nurses, it is equally important to emphasise that the healthcare workforce is itself extremely diverse. So, nurses may assign otherness to doctors (and vice versa), or to health professional colleagues, other nurses and clients, leading to further challenges to culturally safe workplaces. These 'othering' processes invoke **stereotypes** which arise from systematised models of culture we critiqued earlier, where everyone who shares a cultural identity is assumed to actually be the same (in terms of worldviews, lifeworlds and related behaviour). Ideas that cultures are static are problematic due to the variable ways in which individuals express and embrace their culture and to the different lifeworlds in which life's circumstances unfold.

Stereotypes can be both positive and negative. For example, a positive stereotype about nurses is that they

are always loving and caring, and a negative stereotype is that all female nurses are promiscuous. These over-generalisations always deprive the 'object' of individuality. As a result of applying stereotypes, we develop misguided mindsets and attitudes (whether these are positive or negative) towards people, which are dangerous in healthcare settings. A real-life example concerns a woman who is Aboriginal and has always lived in urban areas. She was horrified when it was suggested that her family might be interested in 'traditional birthing methods'. The stereotype assumed that all Aboriginal people are the same and that traditional Aboriginal birthing models, long struggled for by some Indigenous women in remote Central Australia, would also be welcomed by those living in urban South-East Queensland. Another example is a man who identified his ethnicity on an admission questionnaire as Māori and was then visited by the Māori health worker. He had not requested this visit and had never previously had any particular contact with Māori health services. He told the nurse that he would have preferred to have been asked first.

Racism and prejudice

Prejudices (literally prejudgements) are sometimes positive, but are more usually the negative attitudes people develop around stereotypes they have about others who they see as essentially different from themselves. *Personal racism* in the form of put-downs, 'jokes', violent acts and so on, is one form of prejudice and is one of three levels of racism: the others being *systemic/institutional* and *scientific* racism (discussed below). Personal prejudices are usually based on myths, rumours or over-generalisations from specific experiences. Just like other aspects of culture, prejudices and racism are learned during childhood socialisation, so that often the prejudices of parents or societies are passed on to successive generations. It is not uncommon for people to defend their prejudices and justify them by linking them to their values and beliefs. For example, following a process of reflection on a role-play where one of the authors (Cox) played the part of a beggar, a student admitted that they 'had no time for' (held deep prejudices against) people on the streets who tried to beg from them and that they perceived as homeless. The student went on to defend the prejudice by explaining that they were brought up to work hard and to take care of themselves – no one had given them any hand-outs, and besides they 'reckoned that people' become homeless because they are drug addicts or lazy or both.

This example of prejudice shows a lack of empathy or openness towards the myriad of other possible circumstances that might lead a person to beg on the street; instead there were several entrenched stereotypes about homeless people and beggars that informed their prejudice. Because prejudices are part of a person's worldview and reflect their values, people invest a good deal of their emotions in them and are quite resistant to change. However, adults develop **agency** and are able to challenge prejudices that their families, professions or society may have tried to socialise into them as part of their developmental pathway. Developing awareness of values and prejudices is crucial for nursing practice, as prejudices lead to discrimination.

Discrimination

Discrimination is the acting-out of prejudice: the act of speaking or acting against those who are perceived as different from 'us'. The progression from ethnocentrism to stereotyping, to prejudice, to discrimination, originates in our tendencies and encouragement to be proud of our culture, of who we belong to and who we are. Pride in one's cultural identity and group is not necessarily harmful. However, when prejudice and ethnocentrism become an outcome of cultural pride, the development of an insidious cycle of prejudice can ensue (Figure 14-4). Discrimination has important implications for communication between people from diverse cultures. It is easy to get caught in a cycle of prejudice, especially in a diverse society with a colonial history. If people are unfamiliar with the varied cultural backgrounds of others, it is easy to make faulty assumptions and to treat people according to entrenched social stereotypes based on people's religion, sexuality or geographical origin. This effect is perpetuated if those around us (family, friends and colleagues) and the media convey specific images of another group.

Racial discrimination is a problem of long standing for all Indigenous peoples across the globe, with positive images and stories of Indigenous individuals and their communities only rarely appearing in the media internationally. Although there is some evidence of change in Australia with the release of films such as *Bran Nue Dae* (2010), a dedicated Indigenous channel (NITV), and greater exposure of popular musicians, successful athletes, academics and so on, there is still the struggle against a negative focus that constantly invokes and embraces stereotypes. The racist targeting of the 2015 Australian of the Year (Adam Goodes) demonstrates the profound racism that underpins our society. One only has to think of policies and processes such as the Northern Territory Emergency Response discussed earlier to appreciate how deeply-entrenched stereotypes continue to justify the application of punitive practices to highly diverse people that are again universally rendered guilty and irresponsible (Brown & Brown 2007).

Power

Within the complex interaction of racism, ethnocentrism, stereotypes, prejudice and discrimination, power becomes extremely important. In anthropological theory, power is a particularly complex concept with an interesting genealogy. One way of understanding power comes from the work of the sociologist Max Weber (Bendix 1996), who identified three kinds of power evident within society: political, economic and social power (Box 14-2).

An essential feature of power is that those who dominate in imbalanced power relations work hard to maintain their position. We can see this dynamic in relation to whiteness, as discussed earlier, where those who have limited access to power and self-determination are subjected to systemic bias. The system itself, controlled by those who already hold dominant positions in power relationships, maintains the powerful because those not 'in the know' may not understand the rules, regulations, norms and values or do not possess the resources that provide access to the system.

If we take the example of the health system, one must first understand the system to be able to have influence within it; to understand it one must have some knowledge of it and have been successful in it; to be successful in it one must generally have come from a part of society that has traditionally been influential in developing and controlling the system. As Taylor and Guerin (2010) demonstrate, *systemic racism* or *institutional racism* are terms used to describe the disadvantage of minorities in their attempts to engage and access systems of institutions, and the ways in which the dominant system fails to extend the same advantage to them. Taylor and Guerin (2010) give the example of anti-smoking programs that were designed by dominant groups. The example reveals the operation of power, as the program is designed *by* the dominant group it operates *for* the dominant group, leading to the decrease of smoking rates among dominant groups, but not among various other populations in Australia.

BOX 14-2 Three types of power

- *Political power* is evident in formal government policy, informal control and influence in the political process and influence over public opinion.
- *Economic power* rests on income, wealth, access to credit, control of employment and control of wages and prices.
- *Social power* or social status is evident in access to political/economic power and how the community evaluates these.

Bendix R 1996 Max Weber: an intellectual portrait. Methuen, London.

This type of systemic bias effectively excludes some sections of society from accessing and participating in decision-making. These dynamics not only lead to entrenched patterns of domination and dependence, but also result in forms of **structural violence**, evident in the continuing differences in health between Indigenous peoples and other Australians, for example. Overall, the combined power effects of whiteness, class and ethnocentrism, and of racism, discrimination and poverty, show that for some, violence is inherent in the social system, which limits life chances. It is therefore important, in the pursuit of culturally safe nursing care, to understand the pressures that these dynamics exert on the health of individuals and their families/communities.

What is health?

Similar to other concepts discussed above, health is socially constructed and is not a universally agreed condition. Definitions of health often differ between cultures, but also within any one culture. The conditions thought to be necessary to maintain or regain health, and healthcare practices (be they lay or professional), reflect the lifeworld and particular values and beliefs of people regarding health and the causes of illness. Holistic definitions of health, such as that of the World Health Organization (WHO), are echoed in the documents of organisations such as the National Aboriginal Community Controlled Health Organisation (NACCHO) (see *Online resources*). In 1982, the precursor to NACCHO, the National Aboriginal and Islander Health Organisation (NAIHO), defined health as 'not just the physical wellbeing of the individual but the social, emotional and cultural wellbeing of the whole community' (cited in Eckermann et al 2010:64). This viewpoint is also supported in Aotearoa New Zealand, where the focus is on the interaction between people and the wider social, cultural, economic, political and physical environment (Durie 2003).

Another aspect of how each individual expresses their cultural being is their agency. As described previously, humans are not cultural carbon-copies of one another and are not automatons; each of us acts on and in the world with a degree of free will. It is these dynamics that account for the fact that cultures, including professional cultures such as nursing, can be described in both normative and descriptive terms; in terms of ideal professional values, beliefs and practices; and in terms of what the particular group actually values and believes; and how that culture behaves and practises in the real world. The implications of these circumstances for nursing practice are that the way we meet clients' needs is influenced by both our worldviews and our lifeworlds.

Despite the awareness that cultural beliefs and life experiences influence how people understand sickness and health, some explanations of health and illness are more powerful than others. In Aotearoa New Zealand and Australia, the **biomedical model** remains the dominant paradigm and has the most legitimacy, both socially and politically. Within the biomedical model, health is defined merely as the absence of disease. The causes (aetiology) of illnesses are based on a decontextualised and mechanistic view of individual humans, rendering their unique worldviews and lifeworlds irrelevant to the medical enterprise. This dominant paradigm is so entrenched and pervasive that it is difficult to provide any comparative analysis or critique (Willis & Elmer 2011).

Nurses' comprehension of the construction of health and illness is shaped by their socialisation within the profession and will, consequently, reflect the dominant biomedical ideology. Remember, culture represents a way of perceiving, behaving in and evaluating one's world. It is learned, grounded in life's circumstances and environment, and is dynamic, forever changing. Just as we are socialised through our family and wider social environment into particular ways of being, perceiving and acting in the world (culture), so are we socialised into our profession through education and the idealised values and behaviours we accept as appropriate to our profession. In relation to health and care, the professional culture of nursing provides the blueprint or guide for determining a definition of health and associated values, beliefs and practices. Crucially these might not always be of benefit to consumers. We turn now to consider the regulation of nursing and the application of cultural safety in professional practice.

• CRITICAL REFLECTION POINT

Think back now to our discussion on 'whiteness'. Can you see any aspects of the dominant culture in your way of thinking or in your nursing practice? How might these aspects affect a person who is not considered part of that dominant culture?

Professional nursing regulation and cultural safety

From the outset it is important to remember that nursing care is about a relationship between a nurse and a person/family/community being cared for. Culturally safe nursing care centres on the experience of that person/family/community. The various models and terms used in discussions of culture and nursing can be confusing for the beginning nurse. While

the Nursing and Midwifery Board of Australia (NMBA 2006:2) states: 'A graduate midwife has a commitment to cultural safety within all aspects of her practice and acts in ways that enhance the dignity and integrity of others', the NMBA Code of Ethics uses the term '**cultural competence**' (Australian Nursing and Midwifery Council 2008a). The term 'cultural competence' is often criticised due to the challenges involved in assuming that a practitioner can reach an endpoint and 'be' competent in someone else's culture (Taylor & Guerin 2010). Taylor and Guerin (2010:17) describe how notions of cultural competence have been expanded within Australian social sciences to include many elements of cultural safety, especially those concerning the implications of colonial history, notions of power (and disempowerment and empowerment), and the consideration of how one's own culture affects the provision of care. We advocate avoiding the notion of 'cultural competency' and encourage you to focus instead on the application and practice of cultural safety.

Applying cultural safety in professional practice

The Nursing Council of New Zealand (NCNZ) regulates nursing practice in Aotearoa New Zealand, specifying four domains of competence for registered and enrolled nurses: professional responsibility, management of nursing care, interpersonal relationships, and interprofessional health care and quality improvement (NCNZ 2012). Within each of these four domains are sets of indicators against which competency is determined, with requirements for culturally safe and competent practice encompassed within all the domains and their associated indicators. More specifically, Competency 1.5 (NCNZ 2007:13) states that the nurse 'Practises nursing in a manner that the client determines as being culturally safe', with the following indicators:

- Applies the principles of cultural safety in own nursing practice.
- Recognises the impact of the culture of nursing on client care and endeavours to protect the client's wellbeing within this culture.
- Practises in a way that respects each client's identity and right to hold personal beliefs, values and goals.
- Assists the client to gain appropriate support and representation from those who understand the client's culture, needs and preferences.
- Consults with members of cultural and other groups as requested and approved by the client.
- Reflects on his/her own practice and values that impact on nursing care in relation to the client's age, ethnicity, culture, beliefs, gender, sexual orientation and/or disability.
- Avoids imposing prejudice on others and provides advocacy when prejudice is apparent.

In Australia, the requirements for professional registration are not nearly so clear-cut. Many elements of the definitions discussed above are reflected in the *Code of ethics for nurses in Australia* and the *Code of professional conduct for nurses in Australia* (ANMC 2008a, 2008b). Nurses are expected to respect individual needs, values, culture and vulnerability. Recently revised *Registered nurse standards for practice* (NMBA 2016) recognise the context of practice in Australia as a 'rich mixture of cultural and linguistic diversity' with the registered nurse recognising 'the importance of history and culture to health and wellbeing' (NMBA 2016). Specifically, standards relating to critical thinking (Standard 1) and engaging in therapeutic relationships (Standard 2) contain criteria for demonstrating cultural safety and respect and a more general criteria recognising that 'people are the experts in the experience of their life' (NMBA 2016). The current range of expectations for beginning nursing practice in Australia and Aotearoa New Zealand closely mirror those outlined in the definition of culture used in cultural safety. It is also of note that the standards refer to the individual, rather than homogenising people by suggesting that they can receive appropriate care based on a group identity.

Reflecting on self; reflecting on practice

Cultural safety is not about attempting to learn about cultures. This tends to lead to 'recipe' thinking and assumptions about particular cultural ways of being. Further, as we have noted above, nurses working in Australia and Aotearoa New Zealand will encounter many forms of diversity in their work; learning about all of these would pose an insurmountable task. Ramsden (2002) and many other writers agree that the first step towards culturally safe care is exploration of the nurses' own attitudes and beliefs; the social, cultural and professional structures into which we have been socialised; and the influences these have on the relationships formed with people when in the dominant position in the power relationship. Further, the worldviews of nurses and how we communicate these is partly influenced by professional socialisation and partly by the personal worldviews and lifeworlds that we bring to the profession.

During professional education, nurses acquire a range of symbols (medical jargon, linguistic shortcuts and specialist knowledge) that may not be readily understood

by others. Taylor and Guerin (2010:125–7) suggest that nurses, like other professionals, often assume that both colleagues and clients share these professional symbols, knowledge, assumptions and beliefs, and that all can speak and understand the same (nursing/medical) language. This assumption can lead to serious misunderstandings and, along with the other factors we have discussed, is why self-reflection is the very first step in applying cultural safety in practice.

Ramsden (2002:47) acknowledges that, as a member of a minority group operating in mainstream society, 'Unless I understood myself very well as the bearer of culturally derived attitudes such as internalised racism and social class, I could very well become the oppressor of Māori and others who were less powerful than myself.' There are particular challenges for members of the dominant white culture in Australia and Aotearoa New Zealand when writing about or researching the areas of culture and health. The process of unpicking our own culturally constructed attitudes to ensure that nursing work does not add to the oppression of others is not easy. The endeavour has to be based on sincere dialogue, consultation, negotiation, monitoring and evaluation by those most likely to be affected by the results of this work.

It is therefore crucial for nurses to reflect on:

- personal cultural identity
- assumptions about health and illness and people
- personal definitions of health
- the client's definition of health
- the systems' definition of health
- whose definitions are legitimised (by law and by society)
- implications for nursing practice
- consequences for clients' health care.

When nurses reflect on the points above, they can be clearer about the attitudes, values, beliefs, practices and traditions acquired through their own personal background and experiences, and those of the culture of nursing (Figure 14-5). We may find that the ideal of treating everyone with respect and dignity might be harder to extend to some clients and their families than to others. Contact between people with differing cultural assumptions and circumstances is sometimes marked by suspicion, fear and self-doubt. This can work both ways, with nurses, clients and their families experiencing such feelings when confronted with one another. However, being open to client stories of their illness, negotiating with them and, if appropriate, with others from their family, friends or cultural group can help to minimise these consequences. Nurses sometimes have to learn to cope with feeling uncomfortable. Your own ideas and values will be challenged in the pursuit of excellence in holistic care.

Many people enter healthcare environments with feelings of anxiety, isolation, loss, confusion and powerlessness – not to mention the immediate effects of the presenting complaint or illness. These feelings can be especially acute for those outside 'white' spheres of control. Others can be disadvantaged by the language, culture, rules and regulations of the health system – it is a complex system. This reality affects all who are hospitalised to some extent, but imagine what it means to someone who comes from a group that has been historically targeted by the very people who are now responsible for their care, or for a person who does not share the language or sociocultural conventions taken for granted by the majority. Those who do not belong to the dominant culture, or who are unfamiliar with healthcare/hospital environments, may experience significant stress. This situation is related to differences in communication, attitudes and beliefs as well as differences in everyday routines that staff may take for granted, but which are invisible to consumers. Such stress will invariably affect consumers' capacity and willingness to engage with the priorities and treatments of healthcare systems and therefore impacts on their ability to recover from illness.

• CRITICAL REFLECTION POINT

Describe your experience of caring for a client who has experienced discomfort in the healthcare system because they did not 'belong' to mainstream culture.

1. **What was it that alerted you to the client's discomfort?**
2. **What stressors were experienced?**
3. **Identify at least one culturally safe strategy you implemented or, on reflection, that could have been implemented to support the client.**
4. **Have you ever had similar experiences? Write down what happened and how it felt.**

When considering health definitions and constructions, healthcare professionals have a special language based on their discipline(s) and even cultivate a particular form of shorthand (medical or nursing abbreviations), as already observed. These spoken and written forms of communication facilitate efficient understanding between healthcare professionals, yet are mostly foreign to outsiders. Similarly, the routines, technology, customs and rituals of a hospital are largely developed to make the institution work as efficiently as possible, yet they may seriously stress and disempower patients and clients. When these stressors are coupled with illness, isolation, unfamiliar attitudes and beliefs, there is potential for serious disadvantage. We can appreciate the impact of these dynamics when we consider, for example, that Indigenous people in Australia are hospitalised at 2.5 to 5.7 times the rate of other Australians (AIHW 2013). In Aotearoa New Zealand, avoidable mortality rates are over two-and-a-half times higher for Māori than for non-Māori, and avoidable hospitalisation rates are more than one-and-a-half times higher than those for non-Māori (Ministry of Health 2014). The NZ Ministry suggests that these rates could be either avoided or decreased with a focus on the right interventions to meet the needs of the population.

Aboriginal liaison officers and health workers (ALOs/AHWs), and Māori health workers, are integral members of the healthcare team and can contribute valuable insights into health issues experienced by Indigenous populations and the delivery of health care. But this workforce is often very small and stretched within mainstream institutions. Further, in rural and regional areas particularly, ALOs and AHWs often find themselves in situations where they are expected to be experts on every issue related to their own cultural group(s), while having to cope with the constant pressure of operating in demanding cross-cultural environments characterised by various languages, health priorities and behaviours, social positions and cultural constructions. Working in partnership and sharing 'power' with staff in these positions is critical, as is including family members or other significant people in decisions and care.

Nursing practice and social determinants

Social determinants of health include the systems and circumstances that are beyond the control of individuals. Social determinants are those conditions of everyday life in which people are born, grow, live, work and age. Many are socially constructed, and all are interwoven. Social determinants include those factors already identified as important to understanding culture, such as age, gender, gender identity, ethnicity, class (income, education, housing, employment), access to health services and a sense of control over one's life situation and environment (WHO 2011). If nurses are to develop skills appropriate to working with the diversity within and between us, our clients and colleagues, we need to keep in mind the way differences within and between groups can be evaluated. This is achieved through recognising the concepts of culture, race, class, ethnicity and the associated issues of power, discrimination and racism that were introduced above. It is critical to understand the social forces that impact on people's health, as interventions will flounder if health professionals are unable to understand the social determinants of health and understand each person within their own personal context.

For Indigenous peoples in Australia and Māori in Aotearoa New Zealand, there are additional socio-historical factors that continue to have impacts on health. These include alienation from country and resources; disruptions to and/or loss of language, ceremony and customs; and kinship and family fragmentation due to oppressive government policy. There are other factors that compound these social determinants. For example, it is now well established that racism has profound impacts on mental health, cardiovascular health and the endocrine system (NACCHO 2014). We also know that harassment contributes to very high levels of Indigenous incarceration, with profound impacts on the health and wellbeing of individuals, families and communities (Krieg 2006).

Systemic racism is not just witnessed in encounters between staff and patients, but in the decisions staff make about care and in the decisions police and others make about Indigenous people. In the 2014 Australian census, the proportion of prisoners identifying as Aboriginal and Torres Strait Islander ranged from 8% in Victoria to 86% in the Northern Territory (ABS 2014b). Similar geographic differences are evident in Aotearoa New Zealand. Health delivery and healthcare decisions will be influenced by these demographics. Further, the social construction of gender has profound effects on men and women and those outside of the dominance of heteronormativity such as those who identify as lesbian, gay, bisexual, transsexual, intersex or queer – the LGBTIQ community (Willis & Elmer 2011). It is easy to see that there may be compounding health effects, for example, on someone who might be a transsexual male, Indigenous and from a socially or economically disadvantaged background.

Those from migrant and refugee backgrounds also have specific social determinants affecting their health – in addition to all levels of racism that may characterise their Australian experience and any of the other social determinants outlined. These specific determinants may include the impacts of war, trauma, civil unrest and the ordeal of getting to Australia, the destruction or fragmentation of families, and profound grief and loss. The latter is not only due to the death or injury of loved ones, but also due to complex losses that moving to another country brings in terms of alienation from one's language, community, land, and the loss of everything known and held dear. From outside these experiences, one can only dimly imagine the suffering and distress which, for many, is then compounded by being held in detention centres, for example.

Experiencing inequalities leads to disempowerment and loss of personal control. It is critical that nurses view and care for each person within their personal context and in light of the social determinants of health that arise from their environment, life experiences and social context. We have discussed how understanding the influence of privilege and power imbalances, and the need for reflecting on self, and one's own culture and profession, matters in regard to our own attitudes and beliefs about 'the other'. Finally we turn to a number of skills concerned with communication, trust and negotiating knowledge and outcomes that nurses can develop for culturally safe care.

Communication skills

Chapter 12 of this text explores the importance of placing communication at the centre of safe and effective care. Here we briefly overview some issues of relevance to cultural diversity. Sharing a common language is obviously a basic component of effective communication, but in health care this is far from given (see *Clinical example*). As this scenario demonstrates, language is a significant cultural issue as it conveys meaning. Consequently, communication is culturally defined, so both verbal and non-verbal communication can be primary causes of discomfort or stress in health care.

The use of 'plain' English in verbal and written communication means avoiding overly complex, technical language and medical jargon when communicating with clients. While it is easy for nurses to recognise that someone from a migrant or refugee background might struggle with English, something that is not widely appreciated is that many Indigenous Australians have Indigenous languages as their first language and many others use Aboriginal English, which may be heavily accented and is recognised as distinct (Taylor & Guerin 2010:125–7). When nurses become aware that clients are not able to understand what is being said, the help of professional interpreters or ALOs is critical. The *Clinical example* illustrates the importance of such a service. A major problem in the scenario was that no one bothered to resolve the language issues inherent in dealing with the client before a plan was made. It is, however, important to remember that the interview with the interpreter needs to be planned and structured in such a way that there is time to explore and translate each issue. Nurses should avoid using a relative, spouse or child to interpret as they may not have the language skills necessary to interpret information accurately. In addition, the use of spouses or relatives may introduce greater power or emotional imbalances, stimulate gender role conflict and present confidentiality issues.

A further concern in this *Clinical example* was that the medical notion of 'normality' was in direct conflict with this woman's experience of grief. This factor reinforces

CLINICAL EXAMPLE

Language and culture

The importance of interpreters is increasingly about more than mere language translation – there can also be elements of cultural brokerage in their work, as shown in the following example.

A Polish woman in her 80s was admitted to a mental health facility. She had a depressed mood on admission but was not suffering from clinical depression. The woman was not fluent in English; she could only answer simple questions. She did say that she was sad, and she cried a lot. Sometimes she raised her hands in the air and wailed. Being in hospital was also distressing for her, so this was making her more tearful.

A young worker from the community sector (she worked in an NGO, a non-government organisation) decided that the woman should not live by herself and that it was too much to make visits every couple of days to check on her welfare and do her shopping. The mental health staff did not use an interpreter to properly assess the woman, but proceeded on collateral information from the community worker only. Nobody clarified with the woman when her husband had actually passed away, and it was assumed from the discussion with the community worker that the husband had died years before. In fact, the woman's husband had passed away just two weeks earlier.

Due to the NGO making an application to the public trustee, all of the woman's finances were taken into the care of the public trustee, who also interviewed her without an interpreter. There was a decision taken by those concerned that she would have to go into care.

The woman's daughter, who had returned to Poland about 20 years earlier, came back to Australia when she heard that her mother was going to go into a home for care and would have her finances managed by others. Subsequent work with the daughter, mental health services and an interpreter established that the woman was not mentally incapacitated in any way and could manage her finances with no problem. They filed an application to get her finances back into her own care.

It took many months (which were very distressing to the client and her family) to get the decision reversed. A natural grieving process for her husband had led to this chain of events, but due to nurses' cultural assumptions and the failure of health professionals to use interpreters at every step, the capacity for this woman to remain independent in her own home was entirely misjudged and mismanaged.

Personal communication, Kerry Kennedy 12 December 2011, reproduced with permission.

earlier comments about the need to explore the influence of culture on a client's health beliefs and health behaviours, as well as power and powerlessness, when professional beliefs conflict with those of clients. As the work of Cox (2009, 2010) demonstrates, it is absolutely essential that expertise from someone knowledgeable about the cultural identity of an individual is sought when there is concern about their 'mental health status', to determine what is considered 'normal' for this individual within a cultural context. However, an even more fundamental issue is that the Western medical model categorises people and their symptoms in terms of 'body' and 'mind' or 'physical' and 'psychological' parts. This view of the world and the assumptions underlying it are far from universal.

This, and the following *Clinical example* highlight issues of miscommunication, stereotypes and fear. However, they also highlight systemic factors within health care, particularly those related to unbalanced power relations. Indeed, nurses need to explore how they personally define, think and feel about 'other' people. **Power imbalances** can have further impacts on communication, leading clients to feel uncomfortable because they expect to be discriminated against in a system which they experience as alien and unfriendly. As Eckermann and others (2010:82) point out, if people always react to us with suspicion or other negative patterns then 'we start to wonder about ourselves, our worth, our traditions, our background. This wondering adds to the stress and tension of trying to cope with the society we live in.'

These issues become particularly important in situations where the cultural identities of a nurse and a client have historically occupied differential power positions, such as in the case of Indigenous minorities in Australia and Māori in Aotearoa New Zealand, and the dominant 'white' majority working within health and social care systems. As a result, members of a minority group may find it difficult to cope with feelings of insecurity and inferiority when relating to the dominant majority. The consequences are apparent in the next *Clinical example*, but are even more apparent in the profile of health disparity experienced by colonised minorities worldwide. It would, of course, be wrong to believe that only members of minorities might find themselves in such situations; indeed, many older people from varying cultural identities express similar experiences in accessing health systems. Any person who feels – or is made to feel – incompetent in a particular situation will begin to question their abilities and knowledge. It is argued, however, that for individuals who are part of the dominant group and who belong to the middle class in terms of access to education, information and decision-making, such episodes are transient and generally linked to specific crises. For many minority group members, however, such episodes are continuous and a lifelong experience.

Developing trust

Ramsden (2002) and Eckermann and others (2010) believe that establishing trust is basic to creating a

CLINICAL EXAMPLE

The power of attitude

A young mother of three children, two of whom were at school, reported to the Review Team that she had decided to take the baby to the medical centre and inquire about immunisation. She escorted the older children to school and carried the baby on to the centre, without an appointment. Dressed casually, she entered the centre and approached the nurse at the reception area. At first the nurse ignored the mother until she had completed her current task, then before the young woman spoke, the nurse turned to her with an expression of impatience and distraction.

The mother said that she felt so uncomfortable that she shrank away, excused herself and left. There was no exchange of words, yet the interaction had been so powerful that it completely blocked further access to health service. The young woman said that she felt shy and ambivalent, and did not feel able to assert herself in the medical centre and in the presence of the nurse who was exhibiting behaviour which the mother felt was an unspoken commentary on her baby, her casual appearance, her social class and her being Māori. Whether the nurse had intended to convey a negative message was not the issue; her professionalism should not have permitted her to behave in a way that could have been interpreted as obstructive to contact by the mother seeking her assistance.

Lessons to be learnt from this example:

- It is possible to create active barriers to service without recourse to spoken words.
- There are other discourses which are unarticulated and unanalysed but shape the behaviour of patient and professional.
- The influence of attitude can be a powerful inhibitor or initiator of professional interaction.
- It is the responsibility of the nurse as the power-holder to create an environment that enables people to feel safe in the presence of the nurse.
- Unfavourable attitudes are easily recognised by those who have been exposed to their negative effects.
- Those who have experienced the power of attitude imposition are always vigilant to the possibility of its presence.

Ramsden IM 2002 Cultural safety and nursing education in Aotearoa and Te Waipounamu, unpublished PhD thesis. Victoria University of Wellington, Wellington, pp. 62–3.

culturally safe environment, a position that we strongly support. Likewise, Taylor and Guerin (2010) propose that trust is a cornerstone of good care and can easily be achieved by finding a point of commonality or interest with the client, rather than being overly business-like and focused on clinical issues from the first meeting. Trust will develop when people do what they promise to do in a way that does not place other people at risk, culturally, spiritually and physically. There is no checklist for developing trust – it will grow as relationships grow. However, trust may be initiated at first contact simply by the level of respect and concern demonstrated by the nurse (Ramsden 2002). Inevitably, the nurse's ability to establish and maintain trust with a client is an essential prerequisite to negotiating and maintaining culturally safe care.

Further, the context of health and nursing in Australia and Aotearoa New Zealand presents specific challenges related to the level of distrust that may impact nurses' interactions with clients from minority groups, arising from histories of oppression (Cox 2007, Forsyth 2007, Ramsden 2002). The capacity of health professionals to acknowledge and validate their clients' experiences and perspectives is central to the development and maintenance of trust. To overcome these circumstances, nurses must learn to acknowledge and be aware of their own position of power over others.

Negotiating knowledge

As professionals, nurses need to 'know' a lot of information about their clients, to be sure of facts, and to feel confident that all possible evidence is taken into consideration during assessment. This is part of our professional socialisation. Having become aware of the need to consider the interaction between culture and health, educators have been inclined to teach knowledge 'about' various cultures in order to provide appropriate educational intervention (see, for example, the 'community' profiles on the Queensland Health website in *Online resources*). However, we have argued throughout this chapter that ideas of health and culture are constructed. Therefore, knowledge is also constructed to serve the particular purposes and interests of knowledge producers. As Nakata explains (2006:266), 'Understanding the theoretical and methodological issues [of knowledge production] is critical to producing new and more effective approaches to negotiating the intersections of different knowledge systems as they converge, circumscribe and condition the possibilities for both understanding the past and its legacies, and improving Indigenous futures.' The healthcare environment in which nurses work presents just such a context of intersecting knowledge systems – those of nurses, doctors, clients and their families and communities.

Ramsden (2002) highlights the need to negotiate appropriate knowledge with people about their cultural needs and perspectives to prevent compounding the powerlessness of outsiders to healthcare systems. Negoti-

ating knowledge means that the nurse and the client become learners in a bicultural (two cultures – the nurse and the client) relationship. Each has something to contribute to the other's understanding of the factors influencing the reasons for seeking the interaction. One way to equalise power imbalances is to actively negotiate outcomes as well as appropriate knowledge. Remember that negotiation is a two-way process – it requires dialogue.

Negotiating outcomes

All healthcare providers have a duty of care to provide safe care leading to positive outcomes. The reality is that care and positive outcomes are more likely to be defined on the basis of professional socialisation and culture (nurses and health systems) and the institutional and political demands made upon them. Clients may not share nurses' definitions of positive outcomes, and health system policy and practice can create culturally unsafe situations. It can be difficult for individual nurses to overcome these systemic factors that affect their capacity to provide culturally safe care. In remote and even in rural Australia, for example, it is the practice to transfer pregnant women from their home to a hospital birthing unit at 38 weeks in order to ensure a safer birthing environment (Eckermann et al 2010). The result is that many Indigenous women abscond from hospital after transfer because, for them, it is more important to give birth in their community and on their Country. Some Indigenous women may avoid antenatal care and other health authorities to avoid being removed, placing them and their baby at greater risk.

For many Indigenous mothers, staying within their family and community is not only important in terms of having the family nearby for support and cultural reasons, but also where the baby is born has impacts on that baby's identity and their future rights and responsibilities in and for Country, family and law/lore. The far-distant hospital presents its own social and emotional dangers caused by separation from family and community, and expectations to function in unfamiliar and sometimes hostile cultural environments. While the decision to birth on Country may not always be sound from a medical perspective, from the cultural perspective of the mother and her family and the baby's paternal family, it may be the only safe decision. However, what is considered safe is the controversial point here in regard to what is being privileged. Are practices such as those described above for medical safety, or the mother's and the family's cultural safety, or are they to protect the system and health professionals? This example not only highlights the problem of making policy on the basis of a cultural identity rather than according to individual needs, it also shows how such practices result in systemic discrimination rather than person-centred care. Of course, some pregnant women may need to be evacuated for medical reasons; however, many do not need this level of intervention and power exercised against them and their birthing choices. Others may choose to give birth in a hospital environment. A respectful conversation needs to take place between health professionals, the mother and family about what is medically safe and what care is valued by them, and this can be negotiated to maintain cultural safety.

Summing up

All clinical practice implies a theoretical, social, economic and political stance on the part of those involved in decision-making; that is, those who dominate in relationships of power. Even in the most straightforward terms, nurses are clearly in a position of power when interacting with their clients. A person's illness frequently renders them physically, mentally and emotionally diminished or incapable. Clients are often reliant on nurses for the most basic yet intimate and complex of needs, up to and including the maintenance of life itself. At a more complex level, interactions between nurses and clients involve a process that brings a whole range of personal, linguistic, historical, social and economic factors to bear. When perceptions and expectations within and about these factors are not shared by both a nurse and client, conflict will inevitably occur. Within such conflict, nurses are most likely to be more powerful. Nurses are supported by a professional culture, language, traditions and customs, which are a shorthand way of ensuring efficiency and effectiveness for those 'in the know', but which effectively and efficiently exclude those who 'do not know'. Nurses' language, tone of voice and body language, rightly or wrongly, convey attitudes and prejudices, indicate concern or lack of it, and can generate frustration and anger as well as trust and cooperation. These situations can occur in any nursing encounter, even when the nurse and the client share a cultural identity. However, when the nurse and client do not share a similar language, a common frame of understanding, compatible expectations and perceptions, or in short, do not share a similar cultural background, the potential for frustration is amplified.

Although the influence of culture on nursing practice is generally raised in relation to the rapidly changing and diversified demography of nations, following Ramsden (1993, 2002), we argue that all healthcare professionals are required to be culturally safe because whenever we are interacting with a client we are entering a bicultural relationship. Even if you and your client share a cultural

identity, your values, health beliefs and practices will not necessarily be the same. Remember that from the perspective of cultural safety, nurses' care can only be effective, appropriate, positive and empowering if the recipients of care – the clients, their families and communities – assess it as such (Richardson 2004).

In summary, a number of processes enhance the ability of nurses to provide culturally safe care which recognises the impacts of the social determinants of health on individuals and then works to minimise these impacts (Figure 14.2).

These processes include:

- reflecting on self; on one's own culture, profession, power imbalances, attitudes, beliefs about and reaction to others
- enhancing communication skills and drawing on the skills of interpreters
- understanding the influence of history on health and that health is political and social
- developing trust
- negotiating knowledge and outcomes
- understanding the influence of power imbalances on 'care'.

Notions of health and wellness are far more complex than simply the absence of disease; both are inextricably linked to the circumstances of people's lives, their sense of self, their social and economic situations, and their ability to access health systems and comprehend health information. Nurses can engage in social transformation and be agents of change by engaging in critical self-reflection as cultural beings, by recognising their power, by negotiating outcomes in partnership with clients and families, and by being knowledgeable about the socio-political dimensions of health and nursing care. The practice of cultural safety in nursing enhances compassion, limits victim-blaming and increases the chances of people accessing appropriate services and being treated well when they do. Critically, the practice of cultural safety brings about client-centred care by balancing the needs of systems and professions to focus on the needs of clients and families.

Key concepts

History and health

- Australia and Aotearoa New Zealand both have Indigenous populations; both societies arose from colonisation; and their current institutions are still heavily reliant on the values and beliefs of the British, despite the fact that both nations are composed of many cultures.
- Colonisation dispossessed and disempowered the Traditional Owners of Australia and Māori people of Aotearoa New Zealand, seriously affecting their life chances.
- Mainstream institutions in both countries generally struggle to work effectively with the diverse environment of their healthcare systems.

Culture

- The definition of culture is contested. We use a definition that accepts that cultures are dynamic and changing and include the dimensions of gender, age, ethnicity, ability/disability and class.
- Culture influences our values, beliefs, traditions and patterns of decision-making.
- History, socioeconomic, religious, political and natural environments influence cultures and individuals.
- Our attitudes, values and beliefs are created during socialisation/education/enculturation, and through various mediums, including language.

Culture and health

- The influence of culture on health is well known; indeed, health beliefs and actions are basic to perceptions of self and our understanding of the world.
- In nursing, various approaches have been developed to recognise the influence of culture on nursing practice and to enhance nursing care in culturally diverse environments.
- We recommend cultural safety.

Cultural safety

- Cultural safety has a basis in social justice, meaning that how people are treated in society (including health systems) is more important than how they might be culturally different.
- Cultural safety maintains that all nurse–client interactions are bicultural since even persons sharing a cultural identity are not necessarily the same.
- Cultural safety maintains that all nurse–client interactions are based on differential power relationships. All nurses must therefore understand their own culture, the culture of the medical systems they work in and the culture of nursing, and incorporate an understanding of power and its impact on their practice.
- Culturally safe practice does not rely on an understanding of the values and beliefs of various cultural groups. Its focus is on nurses' awareness of their own cultural biases, attitudes, beliefs and values and then moves beyond cultural awareness and sensitivity to build trust, share power and provide opportunity for clients, their families and communities to safely negotiate the nurse's service. As such, those who receive the service define culturally safe practice.

Endnotes

1. This is the first of various references that may seem out of date to students. Older references have been retained for seminal and historical works.
2. The authors are aware that using the term 'Indigenous' is far from ideal, as it tends to homogenise many different people. Where possible we use the term Traditional Owners and register the original inhabitants as 'status' or First Nations Peoples. We also use the term Indigenous for brevity; however, it should be noted that Indigenous people of mainland Australia and the Torres Strait Islands comprise many different groups, with language group names and other terms that they use to refer to themselves. Indigenous people also use terms that are roughly based on state boundaries: New South Wales: Koori, Goorie, Koorie, Coorie, Murri; Victoria: Koorie; South Australia: Nunga, Nyungar, Nyoongah; Western Australia: Nyungar, Nyoongar; Northern Territory: Yolngu (top end), Anangu (central); Queensland: Murri; Tasmania: Palawa, Koori. The term 'Aboriginal and Torres Strait Islander(s)' tends to be used most often, but remember that both the Torres Strait Island context and the mainland context are informed by locally specific cultural and historical backgrounds and are extremely diverse.
3. Common terms used to refer to someone from Australia and Aotearoa New Zealand respectively.

CHAPTER

15

Engaging in family-centred care

Nicola Brown

Learning outcomes

Mastery of content will enable you to:

- discuss the diversity in family structure and characteristics in Australian and New Zealand society
- explore theories and models informing family nursing practice
- consider models of care that promote family engagement in care
- reflect on your own values and beliefs about families
- recognise the benefits and challenges in working with diverse families
- discuss strategies that you can use to manage your own responses to working with families.

KEY TERMS

Community strengths, p. 293
Cultural strengths, p. 293

Person-centred care, p. 294
Self-care, p. 300

Families are both universal and diverse. While we are all born into a family, the perceptions of 'family' vary greatly between people from different social and cultural backgrounds. Although Australian and New Zealand families have become smaller and more diverse in structure in recent decades, the family continues to fulfil important social roles and functions. In this chapter, you will explore the current situation of families in the Australian and New Zealand context in order to understand the importance of families in the delivery of health and health care.

What is a family?

Well, it depends on who you are asking, where you are, and even which time in history the question is being asked! Many people may initially respond to this question with a description of their own family. But as we think about families more deeply we soon start to see that there is more variation to family structure than that by which we define our own. There is significant diversity in terms of biological, legal and socially constructed relationships, marital status, relationships with extended family and social networks, and more. For some people, family may only include those people related to them by birth or marriage. For others, family may include long-term friends, household members and pets. While we may have a strong sense of family as individuals, organisations and legal statutes further propose different definitions to our own. These legally or organisationally constructed definitions can determine access to individual or family resources and data such as taxation, superannuation or social welfare benefits.

There is no single universal definition of a family, especially as families can vary so much in structure. One example of a definition is provided by the Australian Bureau of Statistics (ABS 2015):

> **Two or more persons, one of whom is aged 15 years or over, who are related by blood, marriage (registered or de facto), adoption, step or fostering; and who are usually resident in the same household.**

Note that the ABS definition includes residence in the same household as one of the criteria for defining family. But for many people, family includes people who may reside in another household. It is therefore important to bear in mind when reviewing census data that information on families is based on the household composition, rather than on who the individual person considers to be their family. In addition, more than one family may live together in the same household.

When considering the kind of structure a family might have, it is important to think about what it is that families do. Most families have some shared core functions including: maintaining wellbeing and sense of belonging for all individuals in the family group; raising children; establishing group values; sharing financial and material resources; and passing on knowledge of the culture and values of the group to the next generation (Families Commission 2013). Importantly for nurses, families often function as direct healthcare providers to other members. It is also worth considering that family members may have values and beliefs about lifestyle that could enhance or endanger the health of other members. Although shared functions may be common to many families, the extent to which these functions are seen as important varies according to the cultural background of the family and their shared values and beliefs. It is also important to consider that not all families will have the same expectations of what is considered successful family functioning.

Figure 15-1 Family celebrations and traditions strengthen the role of the family.

iStockphoto/Mark Bowden.

Trends in family structure and function

Now that we have clarified that families vary according to individual, organisational, social and legal contexts, it is useful to consider the patterns of family groups that are present in our society (see Box 15-1 and *Working with diversity*). The traditional **family structure** of the predominantly white Anglo-Saxon populations of Australia and New Zealand has been called the nuclear family – consisting of a heterosexual married couple with children. As the population has diversified, social values regarding relationships and marriage have changed and there is greater variation in family structure and household composition than ever before.

Migration

At an international level, migration has influenced the structure of families and has contributed to an increasingly diverse and multicultural society. This change has implications for both family structure and the social expectations of families. For example, in the most recent New Zealand census in 2013, the number of extended families had increased by almost 55% since 2001 (Statistics New Zealand 2014). These extended families were likely to include individuals from three or more generations. The range of family structures now includes couples living with or without children, single parents, separated parents who share care of their children across two households, blended families, same-sex couples with or without children, single people living alone or in groups, and extended families (Families Commission 2013, Qu & Weston 2013).

Diversity

As social values have become more inclusive in recent years, there has been increasing public and political momentum for marriage equality for same-sex couples. Legislation enabling same-sex marriage was passed in New Zealand in 2013. The Australian Government has proposed a plebiscite to inform a decision about marriage equality, but the debate continues without resolution.

Although homosexual couples are not permitted to marry by law in Australia, many couples form family households through cohabitation. Some homosexual families have children through adoption, fostering, assisted reproduction techniques or from previous relationships. An increasingly diverse and multicultural population also means that there is considerable variation in beliefs regarding parenting, expectations of child behaviour and childrearing practices (Wise and da Silva 2007).

BOX 15-1 Key concepts: diversity in family structures

Nuclear family

The nuclear family consists of father and mother (with one or more children).

Couple-only family

Couples without dependent children.

Extended family

The extended family includes relatives (aunts, uncles, grandparents and cousins) in addition to the nuclear family.

Single-parent family

The single-parent family is formed when one parent leaves the nuclear family because of death, divorce or desertion, or when a single person decides to have or adopt a child.

Blended family

The blended family is formed when parents bring unrelated children from prior or foster-parenting relationships into a new, joint-living situation.

Alternative patterns of relationships

These relationships include group households, 'skip-generation' families (grandparents caring for grandchildren), communal groups with children, 'non-families' (adults living alone), related individuals residing in the same household, but not in a couple or parent–child relationship, cohabitating partners, and same-sex couples.

Social change

The fastest-growing age group across the globe are those aged 65 years and older, and this ageing population is having a significant impact on family life (Chapter 18). The structure of New Zealand and Australian families has become more variable as the aged population increases and changes in relationship formations occur. These relationship changes are reflected in different types of living arrangements, reduced family size, less frequent marriages and more people living alone (particularly the elderly).

Many more middle-aged people are balancing the need to raise their own children while caring for ageing parents. Likewise, grandparents are more often involved in the care of grandchildren to enable both parents to return to the workforce. As both Australian and New Zealand Indigenous populations continue to have a shorter life span than the population average (ABS 2015, Statistics New Zealand 2013), Indigenous families may have less social support from their elders than other families. Further, migrant families are often separated from their extended family members and thus have diminished sources of social support.

Single households are the fastest growing household type. In Australia and New Zealand, the number of people living alone has increased to nearly 23% (Qu & Weston 2013, Statistics New Zealand 2014). This increase is a function of both an ageing population and a falling birth rate. Men and women are living longer, children are staying at home longer, couples are marrying later, and women are delaying childbirth or not having children at all.

The fertility rate has stabilised in recent years to approximately 1.93 babies per woman in Australia (ABS 2012), and 2.03 babies in New Zealand (Statistics New Zealand 2013). However, the median age of childbearing has increased to approximately 30 years of age and

WORKING WITH DIVERSITY

Focus on cultural care

New Zealand readers will be familiar with the word whānau, a Māori word often used to describe family, including immediate and extended family. However, the word whānau can have different meanings and interpretations. For example, whakapapa whānau refers to people related through shared ancestry, and therefore encompasses more than just immediate and extended family members. In recent times, whānau has also been used to describe a group of people joined together through a common bond or shared purpose (kaupapa whānau) (Cunningham et al 2005).

A recent New Zealand strategy to improve health care has been through whānau ora, a philosophy of care that recognises the importance of family in health and in contributing to enhancing the wellbeing of whānau through self-management of health, healthy lifestyles, te ao Māori, social participation and wealth creation. For example, some Māori healthcare providers have begun to employ whānau ora workers to support families with chronic physical or mental health illnesses (Boulton et al 2009, Kidd et al 2010). Whānau services have been established at some hospitals in New Zealand. These services provide social and practical support such as accommodation, and usually operate under Māori tikanga (protocol).

approximately one in five women will not have children (ABS 2012). In general, women from lower socioeconomic areas, and Indigenous women, are likely to have more children at a younger age than others (ABS 2012, Families Commission 2015). While the rate of adolescent pregnancy has declined, Australia and New Zealand continue to have relatively high rates of teen pregnancy compared with other developed countries (AIHW 2012).

Couple relationships have also changed as social and economic opportunities for women have expanded and social views of sexuality have broadened. Most women with dependent children have employment outside the home, and this has meant that more children require care outside the family (AIHW 2012, Families Commission 2013). As families with children have become increasingly dependent on two incomes, the role of fathers in Western developed nations has changed. More fathers now take leave when their child is born, and more are caring for their child(ren) while the mother is working (Featherstone 2009, Hosking et al 2010). Although fathers are increasingly involved in childcare, working and non-working women with children still carry a significantly higher burden of responsibility for household work than fathers (Craig & Mullan 2010).

As the rate of separation and divorce has increased over the last 40 years, the number of single-parent households has also increased. Approximately 11% of all families in Australia and 10% in New Zealand are single-parent families, with women more frequently positioned as head (Families Commission 2013, Qu & Weston 2013). Many single-parent families face economic challenges. In Australia, single parents are more likely to be reliant on government-funded pensions for income and are more likely to be unemployed. Even when single parents do work, they are more likely to have worse economic outcomes, primarily due to the lack of a second household income (AIHW 2012).

• CRITICAL REFLECTION POINT

1. **When you think of family, what do you imagine?**
2. **Do you have strong beliefs and values about families?**
3. **Could your beliefs and values affect your nursing practice?**
4. **If you think your beliefs and values could affect your practice, what strategies could help you in working with families?**

Family theory and models

Family theories have their origin in the social sciences, but have often been applied to family nursing practice and research. **Family theories and models** can give us a better understanding of different aspects, views or contexts of families in health and illness. There is no *single* theory, model or concept that has universal application for families and nursing. Rather, each offers a way of looking at families from a particular viewpoint (Kaakinen & Hanson 2015).

While drawing on a range of sources to explain family responses to health and illness provides a rich basis for research and practice, the myriad of different theories and models can make theoretical concepts of family very confusing. For clarity, the focus of this chapter will be limited to an introduction of the more common family theories or models that you might be asked to review as part of your studies, or which may be useful to your nursing practice. Among key theories and models listed in Table 15.1, family systems theory, family developmental theory, bioecological systems theory and family

TABLE 15-1 Key theories and models influencing family nursing

Theory	Focus
Family systems theory	Interactions among members of the family or between the family and their environment, which may result in either functional or dysfunctional outcomes
Developmental theory	The life cycle of families; stages of family development
Family cycle of health and illness	Cyclical model that describes common patterns of stress, reaction and adaptation to families when members become ill
Structural functional theory	Families as an institution; how they function to maintain family and social networks
Family stress theory	Analysis of how families experience and cope with stressful life events

Adapted from Kaakinen JR et al 2015 Family health care nursing. Theory, practice and research, 5th edn. F.A. Davis, Philadelphia.

partnership concepts and models are discussed below. As you review these, you will see many similarities in the concepts underpinning each theory or model.

Family systems theory

A systems theory approach means that we view the family as a whole system, or as individuals within a system who interact and are interdependent. An important premise of family systems theory is that the system (family) strives for balance and stability, either through adaptive or maladaptive methods. The systems theory approach allows healthcare professionals to visualise individual members of the family as participants of the broader family group; however, the emphasis when using family systems theory is still on achieving stability in the system, rather than on the needs of the individual. Systems theory has had a significant influence on the social sciences and in the development of family therapy.

Several key concepts underpin family systems theory (Kaakinen et al 2015). The first is that all parts of the system (family) are interconnected. So if one family member is unwell, this has implications for all family members. The second is that the family as a whole is composed of more than the sum of its parts. The third is that all families have some form of boundary between them and the environment. These boundaries may be open or closed to the environment (or community). Finally, systems can be subdivided into subsystems, Therefore, healthcare professionals may need to focus on subsystems within a family (such as mother-to-child or partner-to-partner relations).

Family developmental theory

Family developmental theory describes how the role and structure of families changes throughout the life span. Similar to life-span developmental theories, the theory proposes that families need to achieve certain 'milestones' before they can develop and move on to the next stage. The original family developmental theory was developed by Duvall (1977, 1985, cited by Kaakinen et al 2015). Subsequently, the model was expanded by Carter and McGoldrick (1999), in recognition of the social changes families were experiencing in moving from heterosexual marriage-based structures to greater diversity in the formation and legal recognition of couple relationships.

Key concepts underpinning family developmental theory are based on families experiencing change over time (see the family life cycle, Table 15.2). These changes are often related to changing social roles, are predictable to a large degree, and bring similar stresses, for example, the role changes that occur from being a couple to becoming parents. Families experience transitions from one stage to another and these transitions can result in stress while redefining relationships and understanding what the family is, or is becoming (Carter & McGoldrick 1999).

Bioecological systems theory

The bioecological systems theory (Brofenbrenner & Lerner 2004) combines aspects of both developmental and systems theory to explain individual or family growth. Essentially, this theory proposes that the characteristics of the individual or family system (physical, emotional, cognitive), and their unique environment systems (microsystem, mesosystem, exosystem and macrosystem) directly or indirectly interact over time (chronosystem), and that through these interactions the development of the individual or family is shaped (Figure 15.2).

The *microsystem* consists of the individual or family and their immediate environment, including family, school and neighbourhood. The *mesosystem* incorporates interactions between two or more microsystems in which the individual or family actively participates such as the interaction between the family and school, or the household and neighbourhood. *Exosystems* refer to external environments that may influence individuals and families indirectly such as parent work environments, family support networks or public policy. *Macrosystems* refer to the broader prevailing cultural and social mores or belief systems that influence the culture in which the individual or family lives, such as societal attitudes to family and parenting. Finally, the *chronosystem* refers to changes in environment and context that take place over time that affect the other four systems.

TABLE 15-2 The family life cycle

Family life-cycle stage	Emotional process of transition: key principles	Changes in family status required to proceed developmentally
Leaving home: single adults	Accepting responsibility for self and separation from parent(s)	Differentiation of self in relation to family of origin Development of intimate peer relationships Establishment of self in work and financial independence
Joining of families through marriage: the new couple	Commitment to new system	Formation of marital system Realignment of relationships with extended families and friends to include spouse
Family with young children	Accepting new generation of members into system	Adjusting marital system to make space for children Taking on parental roles Realignment of relationships with extended family to include parenting and grandparenting roles
Family with adolescents	Increasing flexibility of family boundaries to include children's independence	Shifting of parent–child relationships to permit adolescents to move into and out of system Refocus on midlife material and career issues Beginning shift towards joint care and concern for older generation
Launching children and moving on	Accepting multitude of exits from and entries into family system	Renegotiation of marital system as dyad Development of adult-to-adult relationships between grown children and their parents Realignment of relationships to include in-laws and grandchildren Dealing with disabilities and death of parents (grandparents)
Family in later life	Accepting shifting of generational roles	Maintaining own or couple functioning and interests in the face of physiological decline; exploration of new familial and social role options Support for more central role for middle generation Making room in system for wisdom and experience of older adults; supporting older generations without over-functioning for them Dealing with loss of spouse, siblings and other peers, and preparation for own death; life review and integration

Adapted from Carter EA, McGoldrick M 1999 The expanded family life cycle: individual, family and social perspectives. Allyn & Bacon, Boston.

The International Family Strengths Model

The **International Family Strengths Model** is an example of a family partnership model. Developed originally in the United States by Stinnett and DeFrain, the model was based on research that studied families to identify the characteristics, qualities and behaviours that made them successful. Over the past few decades, this work has been extended internationally to demonstrate key universal traits of strong families, and to consider the contribution that culture and community make to family strength.

- **Community strengths:** a supportive, safe and secure local environment that values family, demonstrates supportive community social behaviours, education, religious community relevant to the family, family support services.
- **Cultural strengths:** a rich cultural history that has developed over time, shared cultural meaning with the family, stability in the political structures, viable economic conditions and an understanding of the global society.

While recognising the diversity of families across cultures and countries, research has consistently demonstrated that there are international similarities in the way in which successful families work together (Table 15.3). Families do not acquire these characteristics overnight – essentially, family strengths develop over time, often in response to challenges or crises. In addition, all families have some strength, and strong families are not necessarily perfect. The purpose of the model is not necessarily to categorise families as 'strong' or not, but to focus on positive traits and build on these.

TABLE 15-3 International Family Strengths Model

Qualities of strong families	
Appreciation and affection	Individuals in strong families have deep emotional connections with each other and share their feelings of affection for each other.
Commitment	Family members have an enduring commitment to the family, which is held to be most important and above that of other commitments in their lives.
Positive communication	The appreciation and affection that family members have is reflected in their patterns of communication. Strong families are characterised by positive, open and honest communication.
Enjoyable time together	Strong families spend time together that is enjoyable and occurs frequently. Critically, the nature of the activity conducted is not as important as the sense of a positive connection that is achieved by spending time together.
Spiritual wellbeing	The sense of spiritual wellbeing reported by strong families encompasses more than the need to have a shared religious belief. Strong families share ethical values and beliefs about the world, their connection to their environment and a shared commitment to social values.
The ability to manage stress and crisis effectively	Strong families rally together in times of stress and crisis, attempt to ameliorate or reduce the impact on the family and may even see the crisis as an opportunity for the family and its participants to grow and develop.

Adapted from DeFrain J, Asay SM 2007 Strong families around the world: an introduction to the family strengths perspective. In DeFrain J, Asay SM (eds) 2007 Strong families around the world: strengths-based research and perspectives. The Haworth Press, Pennsylvania pp. 1–10.

Linking family theory and models to nursing

As you have read through this section you may have started to get some idea of how these concepts might be used as frameworks for nursing assessment and interventions with families; for research to explain family responses to illness; or for organising nursing practice. Family systems theory is often used to guide the organisation of care to include families, and in research that explores how the family interacts with other systems, such as a hospital. For example, family systems theory has been used as a framework for research into parental needs and expertise in caring for a child with autism (Cridland et al 2014). Developmental family theories are often used as frameworks for delivering health care to families at different life stages, such as transition to parenting and adjustment to illness across the life span. In a study of distress and perception of illness intrusion in parents of young people with juvenile rheumatic diseases, for example, family life cycle was used as a model to explain family adjustment to childhood chronic diseases as children reached different ages (Andrews et al 2009).

Family-centred care

Family are increasingly acknowledged as partners by all disciplines in their development of healthcare services and greater recognition of the role of family has led to the development of new models of care. *Person-centred care* and *family-centred care* are terms that have been used to encompass multidisciplinary models of care or service delivery that focus on the individual in the context of family, or the family unit as a whole. In the past, the patient- and family-centred care approach has predominantly related to child health care; however, more recently, the principles have been adapted and applied more widely. The more inclusive terminology of **person-centred care** is now more commonly used (Kitson et al 2013). As a result, there is some confusion around the terms and what they mean to people in different contexts. For purposes of clarity, the focus in this chapter will be on the principles of family-centred care.

There are a number of definitions of **family-centred care**. Many have been adapted to suit the context in which family-centred care operates. A broad definition that focuses on a system-wide approach to patient- and family-centred care is provided by the US-based Institute for Patient- and Family-Centered Care (2010):

> **an approach to the planning, delivery, and evaluation of health care that is grounded in mutually beneficial partnerships among health care providers, patients, and families … that shapes policies, programs, facility design, and staff day-to-day interactions.**

The interest in family-centred care first developed in relation to the care of children in hospitals. Changing social values in relation to children, and research into the effects of separation, led to increased involvement of families in the care of children in hospital. Over time, it has become widely accepted that the benefits of involving families in health care are relevant to people of all ages, not just children. Young people, adults and elderly people have greater autonomy in health care than children do, and therefore the term 'person-centred' is used to make the role of individuals more explicit while also ensuring that families are still included in the design and delivery of health care (IPFCC 2010).

Family-centred care recognises that the care of a patient's health occurs within the context of their family,

Figure 15-2 Observing family interactions between individuals within families assists in understanding family functioning.

iStockphoto/jarenwicklund.

and, therefore, the family is a key stakeholder in decisions about health care. In a healthcare service that is family-centred, the focus on families should extend through every facet of the work that the service undertakes – from the way in which healthcare professionals work in partnership with families, to the design of the building itself. While this may sound good in theory, it is potentially challenging to achieve in reality. As a result, the feasibility and outcomes of family-centred care remain controversial, and to date most research has been limited to developed Western countries (Foster et al 2010).

Additionally, there are situations where family circumstances may detract from the health and wellbeing of an individual. A common example is that of a child who has suffered parental abuse. In such circumstances, the focus on a person-centred approach to maintain the safety of the child, rather than family-centred care, may be more appropriate in the first instance.

RESEARCH HIGHLIGHT

Research focus

Working with clients and their families is a critical element of aged care nursing practice. This paper provides evidence of ways in which positive staff and family relationships can be achieved in aged care settings.

Research abstract

The purpose of this systematic review was to present the most recent and best evidence of factors related to staff–family relationships in institutional aged care. Studies were included in the review if their participants included residents or patients within acute, subacute, rehabilitation and residential settings who were aged over 65 years, their relatives, and staff members of the facility. Intervention studies were included if they used strategies and practices within the facility to promote constructive relationships and organisational characteristics. Outcome measures of interest for the review included perceptions of staff–family relationships, staff outcomes (e.g. stress, relationship and job satisfaction, retention), and family and resident satisfaction. Searches of relevant electronic databases using key search terms were performed. Studies that met the inclusion criteria were obtained and reviewed. Data were extracted using standardised tools. Quantitative data were not appropriate for meta-analysis; therefore, the studies were reported in narrative. Thematic analysis of the interpretive and critical papers was performed. Results were categorised and then aggregated to produce final results.

Research findings

A total of 50 studies were reviewed, including 35 from the earlier review and 15 from the updated review. The majority of studies that were included were qualitative. In-depth interviews were the most common method of data collection, and thematic or content analysis was most commonly used for analysis. The updated review supported findings from the first review. In addition, the updated review highlighted that factors important to effective relationships included monitoring of care, involving families in decision-making, upholding the uniqueness of the individual older person, promotion of trust, the multidisciplinary team and family dynamics.

Evidence-based practice

- There are a range of contextual, organisational and individual factors that influence staff–family relationships in aged care settings.
- Individual characteristics that are most important to the development of positive staff–family relationships are respect, trust, familiarity and empathy.
- Interventions that promote positive staff–family relationships are those that promote collaboration in care planning and decision-making; promote effective communication skills; have a clear process; and involve the multidisciplinary team.
- Organisational and management support for these interventions is essential for their success.

Reference

Haesler E et al 2010 Recent evidence on the development and maintenance of constructive staff–family relationships in the care of older people: a report on a systematic review update. Int J Evid Based Healthc 8:45–74.

There are four key principles that underpin a patient- and family-centred approach to care (IPFCC 2010):

1. *Respect and dignity*. Healthcare practitioners listen to and honour patient and family perspectives and choices. Patient and family knowledge, values, beliefs and cultural backgrounds are incorporated into the planning and delivery of care.
2. *Information sharing*. Healthcare practitioners communicate and share complete and unbiased information with patients and families in ways that are affirming and useful. Patients and families receive timely, complete and accurate information in order to effectively participate in care and decision-making.
3. *Participation*. Patients and families are encouraged and supported in participating in care and decision-making at the level they choose.
4. *Collaboration*. Patients and families are included on an institution-wide basis. Healthcare leaders collaborate with patients and families in policy and program development, implementation and evaluation; in healthcare facility design; and in professional education, as well as in the delivery of care.

The *Research highlight* above reports the results of a systematic review of positive relationships between aged-care residents, families and staff members. Systematic reviews offer a synthesis of high-quality evidence on a topic. It is notable that the findings from the study share similarities with the four key principles of family-centred care.

Family nursing

Family nursing is perhaps a little difficult to describe (Figure 15-3). Many nurses in acute care settings are comfortable with the notion of being a 'cardiac nurse', a 'paediatric nurse' or an 'emergency department nurse' because it is often easier to define what we do based on where our work is located. However, identifying family nursing as a branch or specialty within nursing is less easy. Regardless of what medical or other specialty we might define our work by, most people we care for are part of either their own or another family.

Figure 15-3 Nurse and family members.

iStockphoto/Christopher Futcher.

Family nursing therefore features across many areas of nursing practice and the approach to family nursing is more determined by the family we are working with, the nature of their health and the context in which nursing care takes place. Nurse academics studying the field of family nursing propose slightly different approaches depending on whom or what is the focus of care (Kaakinen et al 2015). In this chapter, approaches to family nursing have been categorised as *family as context*, *family as client* and *family as system*.

Family as context

When the focus of nursing care is on a particular individual within a family, the approach is to view, assess and care for the individual as the primary focus with recognition that the family context influences the health of that individual. In the family as context approach, nurses would plan and implement care for the individual, but would also consider the extent to which the family might support and influence the individual's health and wellbeing. For most nurses working in acute care settings, family as context is the most common approach to family nursing. The following *Clinical example* illustrates the family as context approach.

CLINICAL EXAMPLE

Stephen is a 30-year-old man who has insulin-dependent diabetes. Stephen is married to Jasmine, aged 29 years, and they are expecting their first child. You are the nurse working with Stephen to develop a plan for managing insulin administration and blood glucose monitoring. If your approach to nursing care viewed family as context, you would focus on Stephen as an individual. You would assess Stephen's knowledge of glucose monitoring, insulin storage and Stephen's skills in blood glucose monitoring and insulin administration. You might also consider Stephen's living circumstances, and discuss with him the need for his wife Jasmine to have information on emergency care in the event that Stephen becomes unwell.

Family as client

The family is viewed as the client when family functioning is the focus of care. In this situation, the nurse would plan and implement care for the family in one of their functions as a family, and assess the way the family operates as a whole (rather than the individuals). The following *Clinical example* provides an example of family as client.

CLINICAL EXAMPLE

Stephen and Jasmine are expecting their first child. Jasmine is from a Fijian Indian background while Stephen is English. Jasmine's parents (both retired) live some distance away. Stephen's parents are both deceased, and his siblings live overseas. Jasmine needs to return to work soon after the baby is born. The plan is that Jasmine's parents will live with Jasmine and Stephen during the week, so that they can care for the baby while his parents work. You are the early childhood nurse working with this family to provide guidance on child development and transition to parenting and to monitor the baby's growth and development. If your approach to nursing care viewed the family as client, you would focus on the way in which all members of the family approach the childrearing role, while assessing the baby's progress. You might meet with both parents and grandparents to provide education and support in child development and parenting.

Family as system

In considering the family as a system, the family is viewed as a system with parts that interact. The whole of the family system is greater than the sum of its individual parts. The focus of care is on interactions between the family members within the system. There are elements of family as context and family as client within this approach, as illustrated in the following *Clinical example*.

Dealing with complex family interactions can be challenging, and often interventions to assist the family require multidisciplinary input. It is important to recognise the boundaries of nursing practice, and to utilise the skills and knowledge of the multidisciplinary team to meet family needs.

CLINICAL EXAMPLE

After a healthy pregnancy, Jasmine gives birth to a well infant boy, Mathew. Jasmine and Stephen have been struggling financially, and Jasmine needs to return to work as soon as possible. However, following the birth Jasmine experiences great difficulty establishing breastfeeding, and is increasingly concerned that she won't be able to manage breastfeeding and work. This causes great stress to her relationships with Stephen and her mother, who both want her to give up trying to breastfeed and change to infant formula. You are the early childhood nurse working with this family. If your approach to nursing care viewed the family as system, you would assess the way in which the interactions between Jasmine, Stephen and Jasmine's mother were affecting the transition to parenting within the family. You might identify that some form of counselling or social support was needed to assist the family with their financial and social difficulties. This could require you to suggest a referral to other healthcare professionals, and you would continue to support the family with their transition to parenting and monitor Mathew's progress.

Family nursing care

Health professionals care for families in a variety of settings – in hospitals, in the community and in the home. The approach to gathering relevant information and data for assessment often depends on the particular healthcare problem; however, the purpose of assessment is the same, irrespective of where it is conducted. The aim is to ensure that family needs are met, that any gaps in the family intervention or action plan are identified, and that support and resources required by the family are provided.

You may have noticed similarities between approaches to the nursing care of individuals and the nursing care of families. Kaakinen and others (2015) propose a modified nursing process model for family nursing that also includes reflection. Nurses using the family nursing care model gather relevant information and data from the family, make priority judgements and decisions with the family, set priorities and establish goals in collaboration with the family, take action, and evaluate impacts and outcomes according to family values and priorities. For example:

- *Assessment of the family:* the nurse gathers information from a variety of sources to develop a family story.
- *Analysis of family story:* the nurse examines the assessment data to find information that explains the family management of the healthcare issue.
- *Develop family plan of care:* the nurse and the family collaborate to develop the best possible approach to managing the healthcare issue and the expected outcomes.
- *Family intervention:* the family and nurse implement the plan of care.
- *Family evaluation:* the family and the nurse determine whether the desired outcomes have been achieved, or what modification needs to occur.
- *Reflection:* the nurse uses self-reflection to explore their experience of working with the family.

Family assessment

Two tools that are commonly used by healthcare professionals in **family assessment** are the **genogram** and the **ecomap**. These tools are useful for mapping a visual representation of family structure and relationships within and beyond family boundaries. Both genograms and ecomaps should be developed in collaboration with the family. These are a really useful way of engaging families in an active discussion about their structure and can

appear a lot less threatening than pages of handwritten or computer notes.

The *genogram* is also a useful format for capturing the family tree over a period of three generations. Typically, the genogram is drawn in freehand during a family interview and is used to check that you, as the nurse, have understood the nature of relationships and family history within a household and have identified any family relationships outside the household that the family considers important. Figure 15-4 provides an example of a basic genogram that describes family relationships and generations both within and beyond a household setting. Note the conventions used to indicate gender, relationships and dates of significance. The dotted circular line, around Beth and her children, is used to identify those members of the family that are currently living in the household. The double circle around Beth indicates that she is the family member with the presenting healthcare issue.

An *ecomap* (Figure 15-5) is used to illustrate the contact between the family or household and systems outside of the family boundary that provide either support or stress to the family. Ecomaps place the family in the context of their current environment, whereas genograms tend to situate families within an historical context (Wright & Leahey 2009). Genograms do form part of an ecomap, as they represent the structure of the family at the centre of the diagram. In this example, the ecomap (Figure 15-5) is used to identify sources of support and areas of stress for Beth. The lines (dotted, scored or full) are used to indicate the quality of the family's relationship with others.

Facilitating family involvement in care

Considering the importance of families to the wellbeing of the people we care for, you might expect that there would be a wealth of evidence to guide nurses and other health-care professionals in their approach to involving families in care. However, there is still relatively little published evidence on exactly what is effective in family-centred care (Kitson et al 2013, Shields et al 2012). A recent literature review of studies on person-centred care across nursing, medicine and healthcare policy literature (Kitson et al 2013) proposed some approaches that may be useful to nurses working with patients and their families. In particular, the establishment of a genuine, positive and mutually respectful relationship between the healthcare professional, the patient and their family is a significant factor for family involvement in care. In addition, enabling participation and involvement in care that respects the autonomy of the individual and family, designing care that is tailored to their individual needs, and consideration

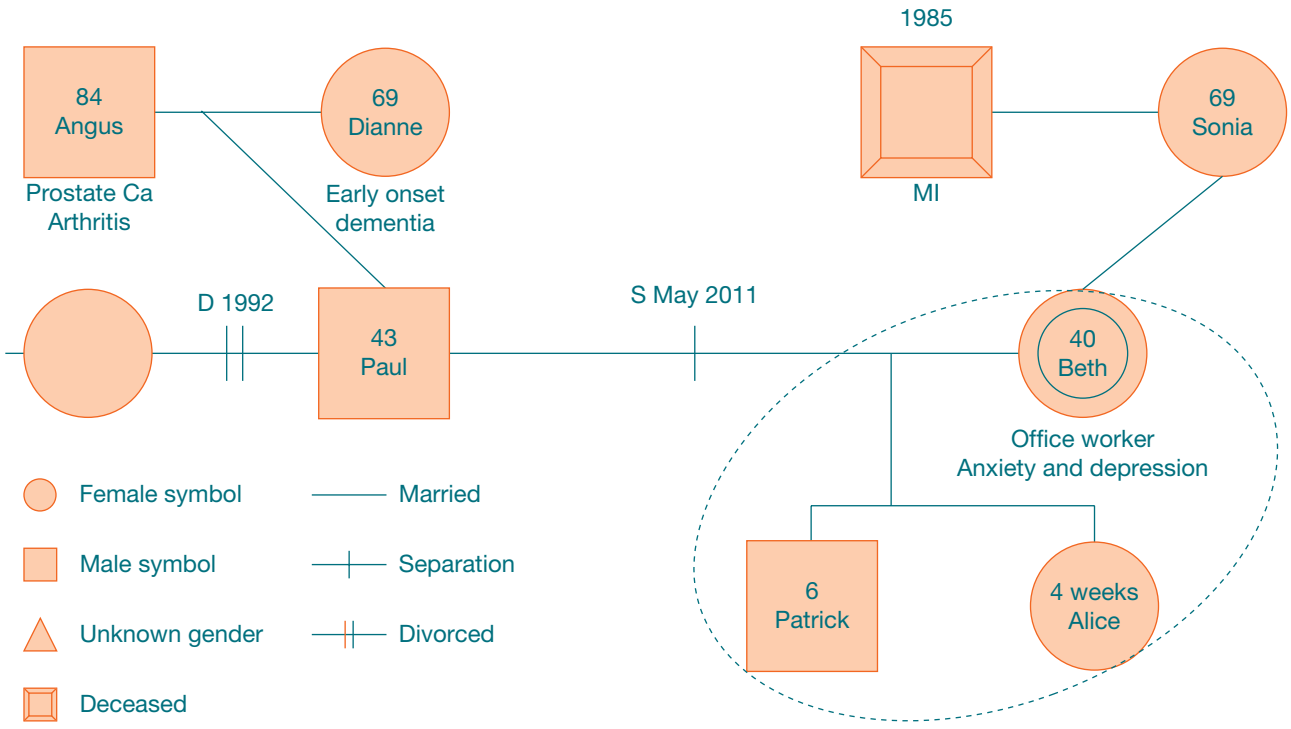

Figure 15-4 **Example of a genogram.**

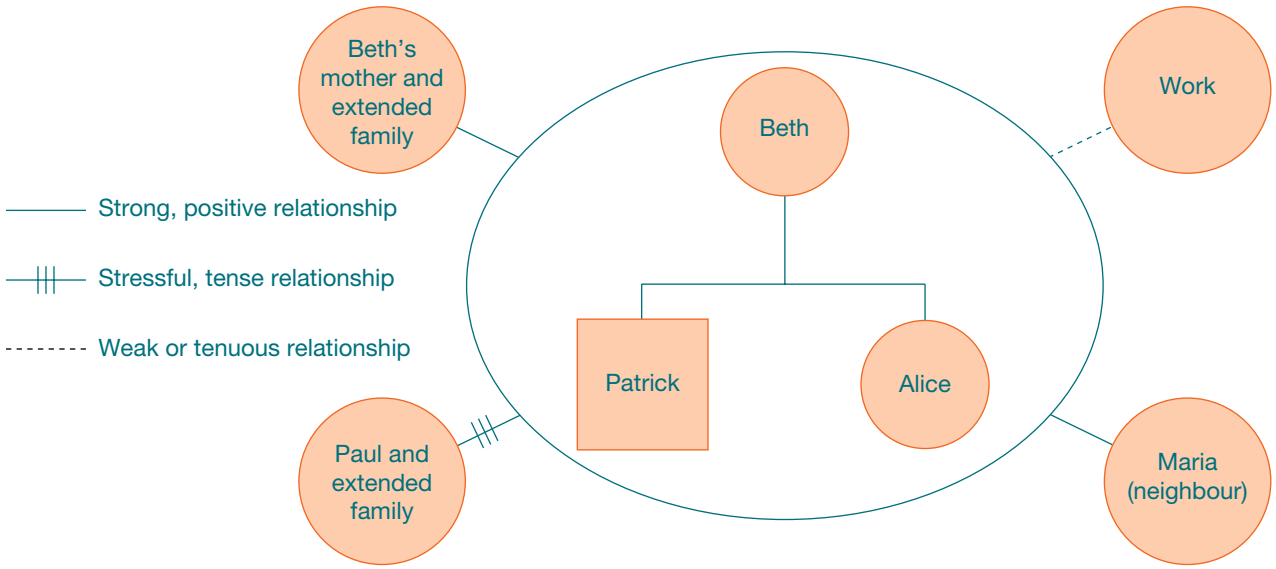

Figure 15-5 **Example of an ecomap.**

of the context in which care is delivered, seem to be the most common tenets of person- and family-centred care (Table 15.4).

While there are obviously universal themes in involving families in care, as Kitson and colleagues (2013) outline, the individual and unique differences in the settings where families are cared for will influence how we work with those families. The context of care is an important consideration in the delivery of care, so it is important that research is undertaken in a variety of settings to provide us with examples of a range of practices that support families.

TABLE 15-4 Core themes in patient-centred care

Themes	Sub-themes
Patient participation and involvement	Participating as a respected and autonomous individual
	Care plan based on individual needs
	Addressing individual physical and emotional needs
Relationship between the patient and the health professional	Genuine clinician–patient relationship
	Open communication of knowledge and expertise between clinician and patient
	Health professionals have appropriate skills and knowledge
	A cohesive and cooperative team of professionals
The context of care	System issues (environment, policy, access, organisational factors)

Adapted from Kitson A et al 2013 What are the core elements of patient-centred care? A narrative review and synthesis of the literature from health policy, medicine and nursing. J Adv Nurs 69(1):4–15.

Some insight into how to approach family-centred care within a particular context of care comes from an Australian study by Trajkovski and others (2012). In this small qualitative study, nurses caring for neonates and their families in a neonatal intensive care unit (NICU) were asked to explore their understanding of family-centred care, and explain their role in facilitating parent involvement in the care of their babies. Firstly, nurses believed it was important to 'get to know parents and their wishes' in order to deliver care that was individualised and specific to the needs of the family. The nurses also identified the importance of involving family in the day-to-day care of their baby through supportive involvement in the physical care. This included explaining aspects of care to all members of the family, not just the mother, and emphasising to parents that being present in the NICU was important for the nursing and general care of the baby. Neonatal nurse participants in the study were very aware that as the neonates were unwell, parental touch needed to be moderated by the nurse according to acuity, and that this was counter to the development of normal parent-to-infant relationships after birth. Nurses described needing to find a 'happy medium' between wanting parents to be involved, understanding that not all parents are equally able to participate at all times, expecting parents to be involved and still wanting to retain control. Finally, the nurses anticipated needing to prepare parents for taking on the care of their infants as their condition improved.

This is a small study based in only one unit, and caution must be taken in generalising these findings to other settings. However, some parallels can be observed between the neonatal nurses' descriptions of their

approach with family involvement in care and the themes identified by Kitson et al (2013) in Table 15.4 – especially the importance of a good relationship, mutual respect and an individualised approach to care. Considering the context of the study – a neonatal care unit – it can be appreciated that when patients are at their sickest families can and should be involved in their care.

• CRITICAL REFLECTION POINT

1. **Do you recollect a time where you or another family member was in hospital?**
2. **If you do, can you recall ways in which healthcare professionals involved you or your family in care? How did you feel about this?**
3. **In different contexts of practice, can you recall examples of ways in which you have seen nurses or other healthcare professionals involve families in the care of a patient or client? Do these differ depending on the time and place of care?**

Self-care when working with families

Working with families can be a rewarding aspect of the work that nurses do. In some situations, families can be a significant source of support to vulnerable family members, and this support can make the work of caring for others easier for all concerned, including healthcare professionals. However, a key part of working with families is to provide support to families, and in some circumstances this can be challenging. Sometimes the situations we face at work can raise issues or memories from our own experience that we find difficult to deal with. Sometimes there is a fine line between a caring, professional relationship and a relationship that is over- or under-involved.

• CRITICAL REFLECTION POINT

The following *Clinical examples* illustrate some of the types of situations that can develop when working with families. As you read the examples or think about situations you might have been involved in, ask yourself the following questions:

1. **Are you comfortable with the way in which the nurses in the examples are working with families?**
2. **What would you do in the same situation?**
3. **If you were confused or unsure of what to do, who could you discuss your concerns with?**
4. **What sort of things do you do to make sure that you are looking after yourself well, while caring for families?**

A good starting point for thinking about **self-care** when looking after families is the Australian and New Zealand guidelines on professional boundaries for nurses (Australian Nursing and Midwifery Council and Nursing Council of New Zealand 2010). These guidelines can assist nurses to identify when they are at risk of over-involvement or under-involvement in the care of families.

CLINICAL EXAMPLES

A. Karen is the mother of Conrad, aged 23 months. Karen is a 42-year-old single woman with a history of schizophrenia. Although Karen is well, she is unable to work and is dependent on a single-parent pension. Conrad is often unwell, with frequent upper respiratory tract infections, and Karen finds it difficult to care for him when he is unwell. Even if Conrad is mildly unwell, Karen brings him to the emergency department and requests that he be admitted to hospital. Each time, Karen refuses to stay in hospital with Conrad. Conrad becomes very distressed when his mother leaves, and cries for long periods of time. Other parents in the ward express their concern about the little boy, and the nurses feel frustrated that his mother won't stay and cannot care for him at home. The nurse unit manager raises their concerns about the emotional impact of admission on Conrad with his doctor.

B. Janine is a registered nurse working in an aged care setting in a small country town. She has a strong friendship bond with Eileen, an 86-year-old woman. Eileen's family is involved in her care and frequently visits her. They welcome the friendship that has formed between Janine and Eileen, and see Janine as a member of their extended family. Eileen's granddaughter is having a baby, and has asked Janine to be a godparent to her child.

C. Ward 2J is a large paediatric oncology unit, caring for children with oncological conditions from across the country. Simon is a 9-year-old boy receiving treatment for acute lymphoblastic leukaemia. His mother Yasmin is staying in hospital with him. Simon and Yasmin have little social support and no contact with Simon's biological father. Yasmin has struggled with depression for many years, is frequently tearful and emotional and needs lots of support from all the staff. Some of the nurses have befriended Yasmin, and have invited her on a night out to have a break from the ward.

Key concepts

- The family influences the lives of its members, and family members influence one another's health beliefs, practices and status.
- The concept of family is highly individual and requires a broad family-centred view in order to provide health care that is appropriate to the client and their family.

- The family's structure, functioning and relative position in society significantly influence the health of the family and the ability of members to respond to health problems.
- Values and beliefs about family structures and functioning vary. Nurses need to be aware of their own values and beliefs in order to become aware of their potential impact on the care provided.
- There is a range of theories that can be used to inform nursing practice in relation to children and families.
- The family unit can be viewed as (1) an important context for individual family members; (2) the client; or (3) a system (simultaneously viewing the family as both client and family in context).
- Measures of family health involve more than a simple summation of individual members' health.
- Social class, economic stability and racial and ethnic background influence the context of family approaches health.

Toddlerhood, p. 327

Learning outcomes

Mastery of content will enable you to:

- identify basic principles of growth and development
- discuss factors influencing growth and development
- outline the main premise of developmental theorists: Freud, Kohlberg, Erikson and Piaget
- discuss physiological and psychosocial health during transition from fetus to neonate
- describe characteristics of physical growth from conception to adolescence
- describe cognitive and psychosocial development from birth to adolescence
- describe the interactions that occur between parent and child
- describe variables influencing how children learn about and perceive their health status
- explain the role of play in the development of the child
- identify factors that contribute to self-esteem in young people
- describe the influence of the school environment on the development of the child
- plan culturally appropriate health-promoting activities for children of all backgrounds
- discuss ways that nurses can help parents meet their children's developmental needs.

Understanding children and their growth and development is essential to promoting, maintaining and restoring health. There are recognised patterns or stages of developmental change that occur throughout infancy, childhood and adolescence, but it is important to keep in mind that there is a wide variation in individual capability development. The ranges of development identified in this chapter are for guidance; they are not prescriptive. Having a clear understanding of patterns of developmental change helps the nurse to plan, deliver and support age-appropriate and individualised care.

Nursing practice based on principles of growth and development is organised and directed at helping children and their families respond to changing internal and external conditions. This chapter discusses concepts of growth and development from the perspective of recognised developmental theorists, together with their application to promoting health from conception to adolescence.

Growth versus development

It is important to be aware of the difference between growth and development. **Physical growth** is the quantitative aspect of an individual's progression in physical measurements. Measurable growth indicators include height, weight, teeth, skeletal structures and sexual characteristics. For example, children generally double their birthweight by 5 months of age and their birth height by 36 months; however, the pace and behaviour of this progression is highly individual.

Development implies a progressive and continuous process of change leading to a state of organised and specialised capacity occurring over time. The processes of development are cumulative, as a function of increasing age and mastery of skills. Development is reflected in behaviours that enable the individual to be self-regulating. For example, an observable change for preschoolers is participating in telephone conversations with their parents. Before achieving this capability, the child must develop a small vocabulary, learn to put words together in phrases and sentences and develop a cognitive understanding of object permanence (that a person or object that is out of sight still exists). The ability to progress successfully through each developmental phase influences the holistic health of the individual. Success or failure within any phase may affect the ability to complete subsequent phases. A child who has not learnt to walk by 18 or 20 months, for example, demonstrates delayed gross motor ability, which slows exploration and manipulation of the environment. A child who is walking by 10 months is able to explore and find stimulation in the environment, thereby enhancing learning.

There are two further terms often associated with growth and development: maturation and differentiation. **Maturation** is the process of ageing and can be described as a more qualitative type of change. Maturation involves an individual's biological ability, physiological condition, and desire to learn more mature behaviour. To mature, an individual may have to relinquish previous behaviours and learning, integrate new patterns into existing behaviour, or both. Maturation influences the sequence and timing of changes associated with growth and development. For example, an infant relinquishes crawling for walking because walking permits more extensive investigation of the environment. However, an infant cannot walk until the biological ability and structures to perform the action (i.e. increased muscle cells and tone) have developed.

Differentiation is the process by which cells and structures become modified to facilitate development from simple into complex activities, and the development of more refined individual characteristics. For example, embryonic cells begin as vague and undifferentiated and develop into complex, highly diversified cells, tissues and organs.

Developmental theorists

Theories of human growth and development have been acquired through systematic observations of people going about their daily lives. From these observations, a series of logically connected hypotheses have been proposed that enable us to explain and predict potential physical and behavioural outcomes throughout the life span. Table 16.1 introduces four well-known developmental theorists and their major hypotheses. Reference will be made to theorists throughout this chapter and in Chapter 17.

• CRITICAL REFLECTION POINT

Table 16-1, overleaf, is just the beginning of learning about developmental theorists and their hypotheses concerning human growth and development. We challenge you to explore the work of others such as: behavioural and social learning theorists (e.g. Bandura, Skinner, Watson), ecological systems (e.g. Bronfenbrenner) and information processing (e.g. Chomsky).

Stages of growth and development

Human growth and development are continuous, intricate and complex processes that are often divided into stages organised by age groups, such as from conception to adolescence (Box 16-1). Although this chronological division is arbitrary, it is based on the timing and sequence

TABLE 16-1 Comparison of major developmental theories

Developmental stage (approximate age)	Freud (psychosocial development)	Erikson (psychosocial development)	Piaget (cognitive development)	Kohlberg (moral development)
Infancy (birth to 18 months)	Oral stage: focus on mouth/sucking	Trust versus mistrust: Ability to trust others to meet needs and thus begins to trust self versus withdrawal	Sensory motor period (stage 1–3) – gains understanding of: object permanence and cause and effect.	
Toddler/Early childhood (18 months to 3 years)	Anal stage: focus on self-control of bowels	Autonomy versus shame and doubt: begins to act independently, developing self-control versus defiance	Sensory motor period (stage 4–6) – coordinates more than one action, can recall, and tries new ideas to see what occurs	
Preschool (3–5 years)	Phallic stage: self-centred	Initiative versus guilt: imitates roles and follows rules, developing sense of purpose versus self denial/ restriction	Preoperational period: begins to use symbols, gives life to inanimate objects, can only see from own point of view (egocentric), developing language and pretend play skills	Preconventional (stage 1): obeys rules to elude punishment
Childhood (6–12 years)	Latent stage: suppression of sexual urges with focus on achievement	Identity versus inferiority: develops ability to make friends and achieve tasks versus withdrawal from school and friends	Concrete operations period: can understand more than one piece of information, develops logical thinking on factors that are present; unable to think about the future	Preconventional (stage 2): conforms to gain reward or acknowledgment
Early adolescence (12–14 years)	Genital stage: deals with sexual urges, seeks partner	Identity versus role confusion: developing understanding of self and personal beliefs versus confusion, indecisiveness and antisocial behaviour	Formal operations period: can think in an abstract method and hypothetically. Develops scientific reasoning. Concerns about own needs and self-gratification. Developing moral sense of right and wrong	Conventional: seeks good relations and approval of family and friends. Developing sense of responsibility
Middle adolescence (14–16)	Genital	Identity versus role confusion: learns to know self	Formal operations: can order ideas	Conventional: obedience of law, respect for authority
Late adolescence (17–21)	Genital	Develops career goal and ability to share all aspects of life with others	Formal operations: able to test own hypotheses and think ahead. Often period of utopian thinking	Post conventional: develops sense of responsibility, concerned with individual's rights, developing conscience orientation

Adapted from: Haith M, Benson J 2008 Encyclopaedia of infant and early development, Elsevier, Waltham MA; Leifer G, Fleck E 2013 Growth and development across the lifespan, 2nd edn. Elsevier, St Louis.

of developmental tasks that the child must accomplish to progress to another stage.

Critical periods

Stages of growth and development involve the concept of **critical periods**. A critical period is a specific span of time during which the environment has its greatest impact on the individual. During these critical periods, some form of sensory stimulation is necessary for developmental progression. Without stimulation, developmental task completion may be difficult or unattainable. For example, the toddler who has not been encouraged to learn to walk during a critical period may have difficulty learning to walk at another time. Therefore, developmental progression depends on the timing and degree of stimulation as well as on readiness to be stimulated by the environment. A stimulus provided too early may not be useful. For example, an 18-month-old child cannot learn to write, regardless of the intensity of the stimuli. There are also a number of other internal and external environmental

BOX 16-1 Developmental age periods

Prenatal period: conception to birth

Germinal: Conception to approximately 2 weeks

Embryonic: 2–8 weeks

Fetal: 8–40 weeks (birth)

A rapid growth rate and total dependency make this one of the most crucial periods in the developmental process. The relationship between maternal health and certain manifestations in the newborn emphasises the importance of adequate prenatal care to the health and wellbeing of the infant.

Infancy period: birth to 12 or 18 months

Neonatal: Birth to 28 days

Infancy: 1 to approximately 12 months

The infancy period is one of rapid motor, cognitive and social development. Through mutuality with the caregiver (parent), the infant establishes a basic trust in the world and the foundation for future interpersonal relationships. The critical first month of life, although part of the infancy period, is often differentiated from the remainder because of the major physical adjustments to extrauterine existence and the psychological adjustment of the parent.

Early childhood: 1 to 6 years

Toddler: 1–3 years

Preschool: 3–6 years

This period, which extends from the time the children attain upright locomotion until they enter school, is characterised by intense activity and discovery. It is a time of marked physical and personality development. Motor development advances steadily. Children at this age acquire language and wider social relationships, learn role standards, gain self-control and mastery, develop increasing awareness of dependence and independence and begin to develop a self-concept.

Middle childhood: 6 to 11 or 12 years

Frequently referred to as the 'school age', this period of development is one in which the child is directed away from the family group and is centred around the wider world of peer relationships. There is steady advancement in physical, mental and social development with emphasis on developing skill competencies. Social cooperation and early moral development take on more importance, with relevance for later life stages. This is a critical period in the development of a self-concept.

Later childhood: 11 to 19 years

Prepubescence: 10–13 years

Adolescence: 13 to approximately 18 years

The period of rapid maturation and change known as adolescence is considered to be a transitional period which begins at the onset of puberty and extends to the point of entry into the adult world – usually at the end of secondary school. Biological and personality maturation are accompanied by physical and emotional turmoil, and there is redefining of the self-concept. In the late adolescent period the child begins to internalise all previously learnt values and to focus on an individual rather than a group identity.

Adapted from Hockenberry MJ, Wilson D 2015 Wong's nursing care of infants and children, 10th edn. Mosby, St Louis.

factors that may interact to affect individual development, as shown in Table 16-2.

Developmentally appropriate care is facilitated through theoretical approaches that encourage organised care directed at the child's current level of functioning to motivate self-directed healthy choices, as indicated in Table 16.1. For example, nurses might encourage toddlers to feed themselves to advance their developing independence and promote their sense of autonomy. Or, understanding an adolescent's need to be independent should prompt the nurse to establish a shared contract about the care plan and its implementation.

Conception

Human development proceeds at a predictable and rapid rate from the moment of conception. During the prenatal period, the **embryo** grows from a single cell to a complex, physiological being. All major organ systems develop in-utero, with some functioning before birth (Figure 16-1). Fertilisation of the ovum takes place in the outer third of the fallopian tube and occurs within 24 hours of the ovum's release. Only one sperm penetrates the ovum. Once fertilisation takes place, the material from both cell nuclei unites. The organism then has its full genetic complement in one pair of sex chromosomes and 22 pairs of autosomal chromosomes. The ovum and the sperm each contribute one chromosome to each pair. It is through this mechanism that genetically determined characteristics (such as eye colour) and genetically programmed diseases (such as Down syndrome) are transmitted from parent to child.

The fertilised ovum, or *zygote*, passes through the fallopian tube to the uterus within 3 to 4 days. During this time the zygote continues to divide. Within 3 days, a solid ball of cells, called the *morula*, has formed. The morula continues to develop and forms a central cavity, or *blastocyst*. Even at this early stage of development, cells begin to differentiate in structure and function. Cells at one end of the blastocyst develop into the embryo, and

TABLE 16-2 Major factors influencing growth and development

Factors	Relevant influences
Forces of nature	
Heredity	Genetic endowment determines sex, race, hair and eye colour, physical growth, stature, and to some extent psychological uniqueness
Temperament	Temperament is the characteristic psychological mood with which the child is born and includes behavioural styles of easy, slow-to-warm and difficult. It influences interactions between the individual and environment
External forces	
Family	Family purpose is to protect and nurture its members Family functions include means for survival, security, assistance with emotional and social development, assistance with maintenance of relationships, instruction about society and world and assistance in learning roles and behaviours Family influences through its values, beliefs, customs and specific patterns of interaction and communication Ordinal position and sex influence individual's interaction and communication in family
Peer group	Peer group provides new and different learning environment Peer group provides different patterns and structures of interaction and communication, necessitating different style of behaviour Functions of peer group include allowing individual to learn about success and failure; to validate and challenge thoughts, feelings and concepts; to receive acceptance, support and rejection as unique person apart from family; and to achieve group purposes by meeting demands, pressures and expectations
Life experiences	Life experiences and learning processes allow an individual to develop by applying what has been learnt to what needs to be learnt Learning process involves series of steps: recognition of need to know task; mastery of skills to perform task; mastery of task; expertise in performing task, which expands capabilities; integration into whole functioning; and use of accumulated skills and experiences to develop repertoire of effective behaviour
Health environment	Level of health affects individual's responsiveness to environment and responsiveness of others to the individual
– Prenatal health	Preconception (e.g. genetic and chromosomal factors, maternal age, health) and post conception (e.g. nutrition, weight gain, use of tobacco and alcohol, medical problems, use of prenatal services) factors affect fetal growth and development
– Nutrition	Growth is regulated by dietary factors. Adequacy of nutrients influences whether and how physiological needs, as well as subsequent growth and development needs, are met
– Rest, sleep and exercise	Balance between rest or sleep and exercise is essential to rejuvenating body. Disturbances diminish growth, whereas equilibrium reinforces physiological and psychological health
– State of health	Illness or injury potentially hampers growth and development. Nature and duration of health problem influence its impact. Prolonged injury or illness may cause inability to cope and respond to demands and tasks of developmental stages
Living environment	Factors affecting growth and development include season, climate, home life and socioeconomic status

Adapted from Hockenberry MJ, Wilson D 2015 Wong's Nursing care of infants and children, 10th edn. Mosby, St Louis.

those at the opposite end form the *placenta*. Between days 6 and 10, enzymes are secreted that allow the blastocyst to burrow into the endometrium and become completely covered. This part of the process is known as *implantation*. Finger-like projections called chorionic villi develop to obtain oxygen and nutrition from the maternal blood supply and dispose of carbon dioxide and waste products.

Before implantation, the embryo is relatively protected from the external environment, but with implantation it becomes more vulnerable to the larger maternal environment via exchange of materials through the placenta. The placenta produces essential hormones that help maintain the pregnancy. Because the placenta is extremely porous, noxious materials such as viruses and drugs can also pass from mother to child. The effect of noxious agents on the unborn child depends on the developmental stage in which exposure takes place, with the embryonic stage being the most crucial. The embryonic stage lasts from day 15 until approximately 8 weeks after conception; this is a crucial stage in the development of organ systems and main external features (Figure 16-1). Following the embryonic stage, the developing child is known as a **fetus**.

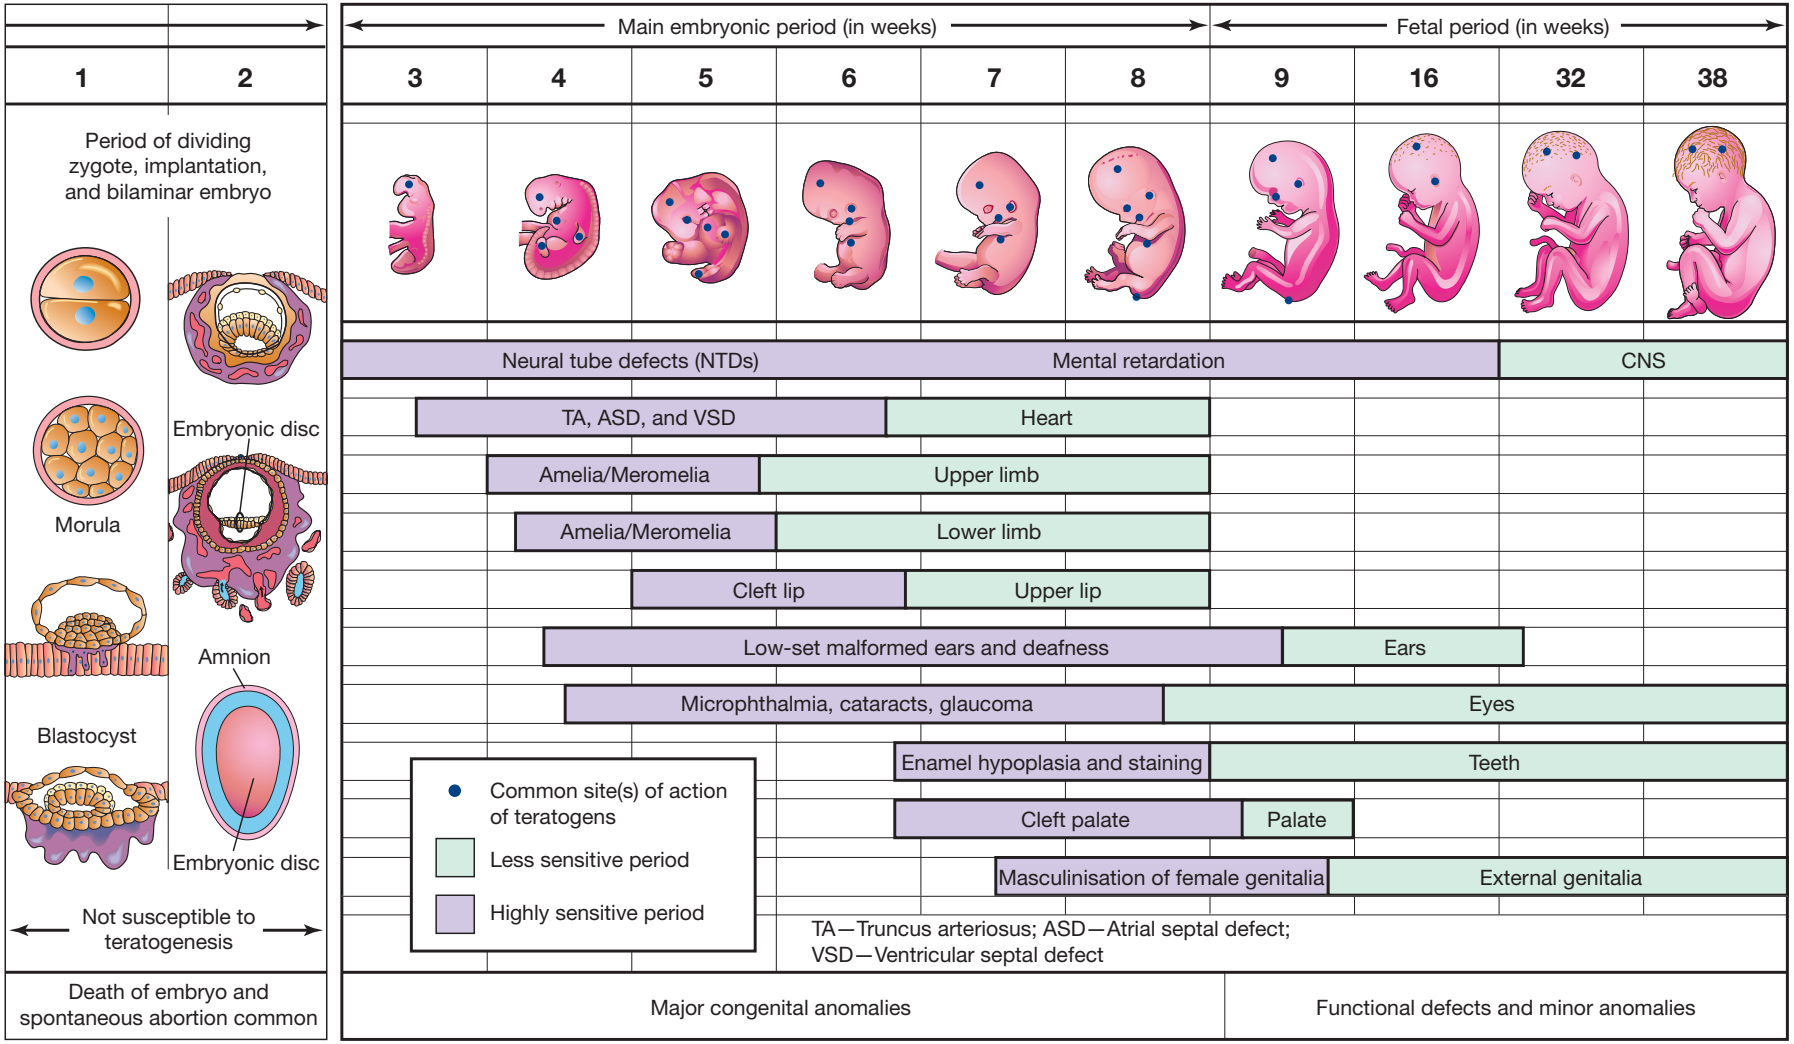

Figure 16-1 Critical periods in human development (mauve denotes highly sensitive periods when major birth defects may be produced).

Moore KL, Persaud TVN, Torchia, MG 2013 The developing human: clinically oriented embryology, 9th edn. Saunders Elsevier, Philadelphia, p. 489.

Women were calculating the date their baby would be born (based on the cycles of the moon), and successfully giving birth, for many thousands of years before modern medicine. Intrauterine life that reaches full term lasts 10 lunar or 9 calendar months, which equates to 40 weeks or 280 days. The length of pregnancy is calculated by determining the first day of the last menstrual period (LMP) to which 280 days is added. A second calculation method takes into account variation of individual menstrual cycles and is made by adding 280 days to the length of the menstrual cycle, then subtracting 28 days from the first day of the LMP (Grigg 2015). Gestation is often divided into three periods called *trimesters*.

First trimester

During the first trimester (the first three calendar months), implanted fetal cells continue to differentiate and develop into essential organ systems. These processes of cellular change (differentiation) and staged organ change (development) occur at different rates and times, with each organ being extremely vulnerable to environmental or other assault during this period. Interference with growth can cause the congenital absence of an organ system or extensive structural or functional alterations. Because several organ systems develop at the same time, disruption of one system may coincide with the disruption of others. Figure 16-1 shows the approximate times of critical differentiation for some of the major organ systems and their overlapping development.

Promoting first trimester health

There are many agents, referred to as *teratogens*, capable of producing adverse effects in the fetus during the first trimester. Some teratogens produce defects only if the fetus is exposed to the agent when the vulnerable organ is developing. One such teratogen is rubella or German measles virus, which can cause spontaneous abortion, stillbirth or defects of the eyes, ears and heart with exposure in the first trimester. It is important for the nurse or midwife to ensure the mother and family are aware of avoiding exposure to teratogenic agents.

Many drugs and medications are also teratogenic during rapid organ growth (**organogenesis**) in the first trimester. Past and present use of home remedies, herbs, and prescription or over-the-counter and illegal drugs must be carefully assessed. Barbiturates, anticoagulants, antimicrobials, alcohol, cancer chemotherapeutics and hydantoin anticonvulsants are only a few of the chemical agents associated with fetal abnormalities, and many other agents are still under investigation. The benefits of any medication needed to maintain the mother's health must be weighed against potential harm to the fetus. Abuse of drugs such as cocaine, LSD, heroin, ecstasy or amphetamines may result in significant fetal compromise (Thorogood & Crowther 2015). Smoking has been shown to reduce birthweight and increase the incidence of fetal and neonatal death (Thorogood & Crowther 2015). Infants exposed prenatally to alcohol can develop fetal alcohol syndrome (FAS), fetal alcohol effect (FAE) or an alcohol-related birth defect (ARBD) (Thorogood & Crowther 2015). Caffeine also crosses the placenta, and while a small intake has been found to have no ill effect in a well and healthy woman (Kuczkowski 2009), the pregnant mother should be encouraged to limit her intake and discuss the potential effects with her doctor, nurse or midwife.

Similarly, the diet of a woman both before and during pregnancy has a significant effect on the developing fetus in-utero. An adequate iron and folic acid intake is recommended for any woman contemplating pregnancy because of an association with iron deficiency anaemia and neural tube defects (see Box 16-2). It has been repeatedly demonstrated that mothers who maintain a healthy diet have fewer complications of pregnancy and childbirth and bear healthier babies than those with poor nutritional intake (Gibbons & Wratten 2015). Therefore, as there are consequences of maternal malnutrition for both maternal wellbeing and fetal development, attention to the assessment of women's nutritional status during pregnancy is important.

Second trimester

As the fetus grows in size, maternal physical changes during the second trimester (from the end of month 3 to the end of month 6) are concerned with the uterus becoming an abdominal organ. Measurement of the height of the uterus, above the symphysis pubis, is one indicator of fetal growth. The height of the uterus can also indicate approximate gestational age and alert health professionals to possible risk situations. The *fundus*, or top of the uterus, typically measures 1 cm for each week of gestation up to 36 weeks; a 16-week gestation should therefore measure 16 cm above the top of the symphysis pubis. Between 16 and 20 weeks, the mother begins to feel fetal movement. This feeling of life is referred to as *quickening*.

Fetal physical changes involve some organ systems continuing basic development, while the functional capabilities of others are refined. By the end of the sixth month, most organ systems are complete and can function. The fetus is usually considered *viable*, or capable of life outside the uterus if given intensive environmental support, at this time. At this point, the fetus weighs about

BOX 16-2 Ensuring adequate folic acid intake

Objectives

1. Women with no family history of neural tube defects will consume 0.5 mg of folic acid every day for 1 month prior to conception and for the first 3 months of pregnancy.
2. Women with a family history of neural tube defects will increase that dose to 5 mg.
3. Women taking anticonvulsants should take folic acid supplements only under the supervision and monitoring of a specialist doctor.

Teaching tips

- Ensure that females of childbearing age are aware of the benefits of folic acid to the developing fetus.
- Folic acid is a water-soluble vitamin and is readily excreted in the urine; therefore, encourage consumption of the appropriate amount of folic acid daily.
- Discuss the need for any woman contemplating pregnancy to have an adequate daily intake of folic acid because the moment of conception is not always known.
- Daily recommended folic acid intake may be consumed in food sources; however, adolescents are usually deficient. Deficiency is not related to socioeconomic status.
- Discuss foods that are rich in folic acid, such as green leafy vegetables, liver, kidney and asparagus. Limited amounts may be found in milk, poultry and eggs.
- Use sample menus to suggest ways of incorporating folic-acid-rich foods.

Evaluation

Review client's 3-day diet intake diary.

World Health Organization 2011 Periconceptional supplementation with folic acid to prevent neural tube defects; AIHW 2011 Neural tube defects in Australia. Canberra. Cat no. PER53.

0.7 kilograms (kg) and is approximately 30 centimetres (cm) long. Fingers and toes are differentiated, there is rudimentary kidney function and the sex of the fetus can be determined. The fetus is covered with *vernix caseosa*, a white cheese-like substance coating the skin. *Lanugo*, or fine hair, covers most of the body. These substances protect the thin, fragile skin of the fetus and decrease in amount as the pregnancy nears its completion; thus infants born before 38 weeks of gestation will typically have more obvious vernix and lanugo covering than full-term infants.

Any infant born before 37 weeks of gestation is identified as being premature. Causes for **prematurity** are poorly understood, and may be the result of maternal, fetal or placental problems. Maternal risk factors include physiological stresses such as renal and cardiovascular disease, diabetes mellitus, or uterine and cervical abnormalities. Mothers with mental health problems, poor socioeconomic circumstances, or who have received limited or no prenatal care, are also at risk of experiencing a preterm birth. Multiple pregnancies and fetal infections are also potential risk factors for prematurity. Placental factors include abruptio placentae and placenta praevia (Thorogood & Donaldson 2015a).

A preterm delivery is one that occurs between 20 and 37 weeks gestation. *Tocolysis*, using the calcium ion channel inhibitor nifedipine, may be implemented to temporarily inhibit preterm labour (Hunter & Gunn 2015). The highest risk of mortality and morbidity arises in deliveries prior to 34 weeks gestation (Thorogood & Donaldson 2015b). Advances in medical knowledge and treatments mean that it is now possible for 500 g babies of only 24–26 weeks of gestation to survive; however, there may be significant risk of long-term morbidity.

Promoting second trimester health

The promotion of healthy eating, activity and limiting exposure to teratogens continues into the second trimester, but there is a greater emphasis on how the fetus is growing. The fetal heartbeat becomes audible to stethoscope auscultation, and the mother becomes aware of fetal movement. Both events are highly significant to the parents because they provide tangible evidence of the pregnancy and reassure them that the fetus is alive.

During this period women often focus on planning for the birth, personal safety, health and appearance. Education about gestational events, employment, appropriate maternal rest, nutrition, dental care, physical activity and posture can be conducted during prenatal visits and in prenatal classes. This is also a good time to help the woman prepare for life at home with a new baby by discussing changes to family dynamics and infant care such as breastfeeding, settling and sleep. Because of dramatic changes occurring to the mother's body, including the renal system, asymptomatic urinary tract infections may occur. Urinary tract infections greatly increase the risk of preterm labour; therefore, voiding habits such as completely emptying the bladder with each void, ensure wiping from 'front-to-back' and post coital hygiene should also be discussed with the mother during this time.

Childbirth is always a significant and challenging event for women. It is important for women and their birth partners to understand how midwives and obstetricians will help their labour and birth, and to comprehend physical signs and symptoms that may indicate compli-

cations. Understanding the processes that are occurring both within themselves and for the developing fetus helps women to take appropriate action in response to any change they may detect in their health status.

Third trimester

Physical changes during the last 3 months of intrauterine life involve the fetus growing to approximately 50 cm in length. Subcutaneous fat is stored, and weight increases to between 3.2 and 3.4 kg. The skin thickens, lanugo begins to disappear and the fetal body becomes rounder and fuller. A tremendous spurt in brain growth begins during the third trimester and lasts well into the first few years of life. The central nervous system has established the total number and also the connections between neurons, and myelination of nerve fibres progresses at a rapid rate.

Relationships between prenatal events and cognitive development are difficult to establish. However, periods of diminished oxygen during fetal life are known to cause deficits in later cognitive functioning, and inadequate prenatal nutrition has been associated with lower brain weight. The large volume of research on developmental outcomes in low-birthweight (LBW) and very-low-birthweight (VLBW) infants indicates that these infants have an increased risk of learning disorders, school failures, temperament problems, neurological and motor impairment and developmental delays. Many additional factors affect an infant's temperament. Such factors include prenatal exposure to drugs, maternal analgesia during labour, and length of gestation. The Cochrane Library has a vast amount of information on developmental outcomes for LBW and VLBW infants (see *Online resources*).

By the end of the third trimester, the healthy fetus is physically able to make the transition from intrauterine to extrauterine life. The cardiac system is ready to change its circulation pattern to end bypassing of the lungs and the lungs are capable of maintaining the inflated state for gas exchange. The primitive temperature maintenance systems, reflexes and sensory organs are ready for use.

In the 10 years between 2001 and 2011 the number of registered Australian births increased by 22% (AIHW 2013). Caesarean section rates have also increased dramatically over recent years, yet there is little evidence to suggest that higher intervention rates in normal childbirth lead to lower perinatal morbidity and mortality. With anticipated exponential growth in caesarean section rates in subsequent pregnancies, there is growing concern about the implications of this trend for maternal and infant outcomes, and its impact on future services. In Australia, there is now a coordinated movement to increase the choices of childbearing women through the provision of midwifery-led models of care. Midwifery-led services have been in place in New Zealand for many years. For more information on the models of midwifery care in Australia you might like to consult the text *Midwifery: preparation for practice* (Pairman et al 2015).

Promoting third trimester health

Exposure to noxious agents and the absence of essential nutrients at this time can cause damage to the developing central nervous system and result in alteration of high-level cognitive functions. The nurse/midwife raises the mother's awareness of these specific threats through education and counselling, and continues to assist her to evaluate the quality of her nutritional intake.

Thoughts of delivering a healthy baby are foremost in the mother's mind as she focuses on preparing herself for the birth. Parents often seek information about the process of childbirth and breastfeeding from childbirth education groups, internet resources and blogs. Depending on the family's location and circumstances, different types of childbirth education are available. Some groups are for first-time parents or may focus on specific age groups, for example, the adolescent or the older (35 years or more) mother. Others may focus on refreshing baby care skills, preparing for an elective caesarean section or attempting a vaginal birth after a caesarean section (VBAC). Because some areas may have limited access to childbirth classes, parents should be encouraged to investigate local classes early or be recommended good quality online support.

The majority of Australian and New Zealand babies are born in hospitals and, in recent years, hospitals have attempted to become more family-centred, welcoming birth partners, helpers and family members and providing spaces with home-like furnishings. A very small percentage of mothers choose to deliver at home, often for reasons of greater choice over the birthing process. Another advantage of home birthing is that the entire family, or other people close to the family, can be part of the event. Most home births occur with low-risk pregnancies and are supported by a registered and experienced midwife. An open relationship with medical and hospital maternity services is necessary should hospitalisation and obstetric intervention become necessary.

Transition from intrauterine to extrauterine life

The transition from intrauterine to extrauterine life requires rapid changes in the newborn. Gestational age and development, exposure to depressant drugs before or

during labour, and the newborn's own behavioural style influence adjustment to the external environment. Initial assessment therefore encompasses a variety of physical and psychosocial elements to determine the newborn's ability to adjust to the external environment and to plan for any interventions that may be necessary, while also facilitating opportunities for the parents and child to develop a close physical and emotional attachment.

Physical changes

At birth, an immediate assessment of the newborn's condition is performed to determine the physiological functioning of the major organ systems. The most extreme physiological change occurs when the newborn leaves the in-utero circulation and develops independent respiratory functioning. Nursing/midwifery care is directed at maintaining an airway, stabilising and maintaining body temperature and protecting the newborn from infection.

The most widely used newborn assessment tool is the **Apgar score**. Heart rate, respiratory effort, muscle tone, reflex irritability and colour are rated to determine overall status. The Apgar assessment is generally conducted at 1 and 5 minutes after birth, and may be repeated until the newborn's condition stabilises. Table 16-3 outlines the scoring criteria related to physiological functioning. A total score of 0–3 signifies severe distress, a score of 4–6 represents moderate difficulty and a score of 7–10 indicates little difficulty in adjusting to extrauterine life. The nurse/midwife can use the Apgar score to determine areas requiring further assessment and careful observation. In addition, the nurse/midwife monitors the newborn's body temperature and other vital signs until these stabilise.

Airway patency and body temperature

Patency of the newborn airway is best ensured by removing nasopharyngeal and oropharyngeal secretions with suction or a bulb syringe. However, if the newborn has a lusty cry immediately after birth, they may have cleared these secretions themselves. Because hypothermia increases oxygen needs, the newborn's body temperature must be stabilised and maintained. The newborn may be placed directly on the mother's abdomen and covered in warm blankets; be dried and wrapped in warm blankets, being sure to keep the head well covered; or be placed unclothed in an infant warmer with a temperature probe in place for regular monitoring. For newborns unable to sustain adequate body temperature, isolettes and incubators, which supply radiant heat, are preferred.

Prevention of infection

As the newborn's immune system is immature, it is especially important that all standard infection control precautions are applied in childbirth and perinatal settings. Of these, good handwashing technique is the most important factor in protecting the newborn, mother and health professionals from infection. Cover gowns do not need to be worn while providing care for the healthy newborn once blood and amniotic fluid have been removed from the infant's skin.

Psychosocial changes

After immediate physical assessment and application of identification bracelets, the nurse/midwife promotes the parents' and newborn's need for close physical contact. Early parent–child interaction encourages parent–child attachment. Physical factors (e.g. fatigue, hunger, pain) and emotional factors (e.g. happiness and need for affection and touch) are assessed.

Most healthy newborns are awake and alert for the first half-hour after birth. This is an opportune time for parent–child interaction to commence. Close body contact, often including breastfeeding, is a satisfying way for most families to start their relationship. If immediate contact is not possible, the nurse/midwife incorporates this into the plan of care as early as possible. This may require bringing

TABLE 16-3 Apgar scoring

Sign	Score 0	Score 1	Score 2
Heart rate	Absent	Slow (below 100 bpm)	Over 100 bpm
Respiratory effort	Absent	Slow, irregular, hypoventilation	Good, crying lustily
Muscle tone	Flaccid	Some flexion of extremities	Active motion, well flexed
Reflex irritability	No response	Crying, some motion	Vigorous cry
Colour	Blue, pale	Pink body, blue hands and feet	Completely pink

Modified from Wheeler BJ 2015 Health promotion of the newborn and family. In Hockenberry MJ, Wilson D 2015 Wong's essentials of pediatric nursing, 10th edn. Mosby, St Louis.

the newborn to an ill parent, or bringing the parents to an ill or premature child.

Attachment is a complex and ongoing process of interaction that is important for an infant's sense of security. John Bowlby's (1969) original research on attachment is a cornerstone upon which others have continued to build. Attachment occurs when parents and newborn elicit reciprocal and complementary behaviours. Attachment behaviours include attentiveness and physical contact, requiring maintenance of newborn contact with the parent. Preterm, ill newborns and ill mothers have more difficulty with attachment if separation is prolonged. The attachment process is further complicated if parents are unable to care for the usual infant needs. You will find more information about attachment in the Cochrane Library (see *Online resources*). Facilitating attachment behaviours and interactions is a priority in postnatal care. Midwives and child health nurses need to plan carefully to optimise close contact, and pay particular attention where health issues of either infant or mother may impede this contact.

The newborn

The **neonatal period** is classified as the first 28 days of life. During this stage the newborn's physical functioning is mostly reflexive, with stabilisation of major organ systems being the body's main task. Behaviour greatly influences interaction between the newborn, the environment and caregivers. For example, the average 2-week-old smiles spontaneously and is able to note their mother's face. The impact of these reflexive behaviours is generally a surge of maternal feelings of love that prompt the mother to cuddle the baby. Nurses/midwives can apply their knowledge of this stage of growth and development to promote newborn and parental health. Understanding, for example, that the newborn's cry is generally a reflexive response to an unmet need (such as hunger) can help parents identify ways to meet those needs, such as feeding their baby on demand rather than adhering to a rigid schedule.

Physical changes

A comprehensive physical assessment is performed as soon as the newborn's physiological functioning is stable, generally within a few hours after birth. At this time the nurse/midwife measures height, weight, head circumference, temperature, pulse and respirations and observes general appearance, body functions, sensory capabilities, reflexes and responsiveness. The average newborn weighs around 3400 grams (g), is 50 cm in length and has a head circumference of 35 cm. Up to 10% of birthweight is lost in the first few days of life, mainly through fluid losses by respiration, urination, defecation and low fluid intake. Birthweight is usually regained by the second week of life, and a gradual pattern of increase in weight, height and head circumference is evident. During the first month, these increases average 115–230 g in weight per week, 0.6–2.5 cm in length and 2 cm in head circumference (Wheeler 2015).

The newborn's heart rate ranges from 120 to 160 beats per minute. The average blood pressure is 74/46 mmHg. The newborn's respiratory movements are mainly abdominal, and vary in rate and rhythm with an average rate of 30–50 breaths per minute. The axillary temperature ranges from 36°C to 37.5°C and generally stabilises within 24 hours of birth (Wheeler 2015).

Normal physical characteristics include the continued presence of lanugo on the skin of the back; cyanosis of the hands and feet for the first 24 hours; and a soft, protuberant abdomen. Skin colour varies according to racial and genetic heritage and gradually changes during infancy. **Moulding**, or overlapping of the soft skull bones, allows the fetal head to adjust to the various diameters of the maternal pelvis during vaginal birth. The skull bones readjust within a few days, producing a more rounded appearance of the head. The sutures and **fontanelles** are usually palpable at birth. The diamond shape of the anterior fontanelle and the triangular shape of the posterior fontanelle between the unfused bones of the skull are shown in Figure 16-2.

Neurological function is assessed by observing the newborn's level of activity, alertness, irritability, responsiveness to stimuli, and the presence and strength of reflexes. Normal reflexes include blinking in response to bright lights and jerking in response to sudden, loud noises. Table 16-4 describes other commonly evaluated reflexes. An absence of any of the reflexes may indicate prematurity, trauma, or central nervous system complications. Because the newborn depends largely on reflexes for response to environment, assessment of these characteristic responses is vital.

Normal behavioural characteristics of the newborn include periods of sucking, crying, sleeping and activity. Movements are generally sporadic, but they are symmetrical and involve all four extremities. The relatively flexed fetal position of intrauterine life continues as the newborn attempts to maintain an enclosed, secure feeling. Newborns normally watch the caregiver's face, reflexively smile, and respond to sensory stimuli – particularly the primary caregiver's face, voice and touch. Als's (1986) seminal work examining the complex relationships between growth and development and the behaviours of preterm infants has prompted a global shift in the practices

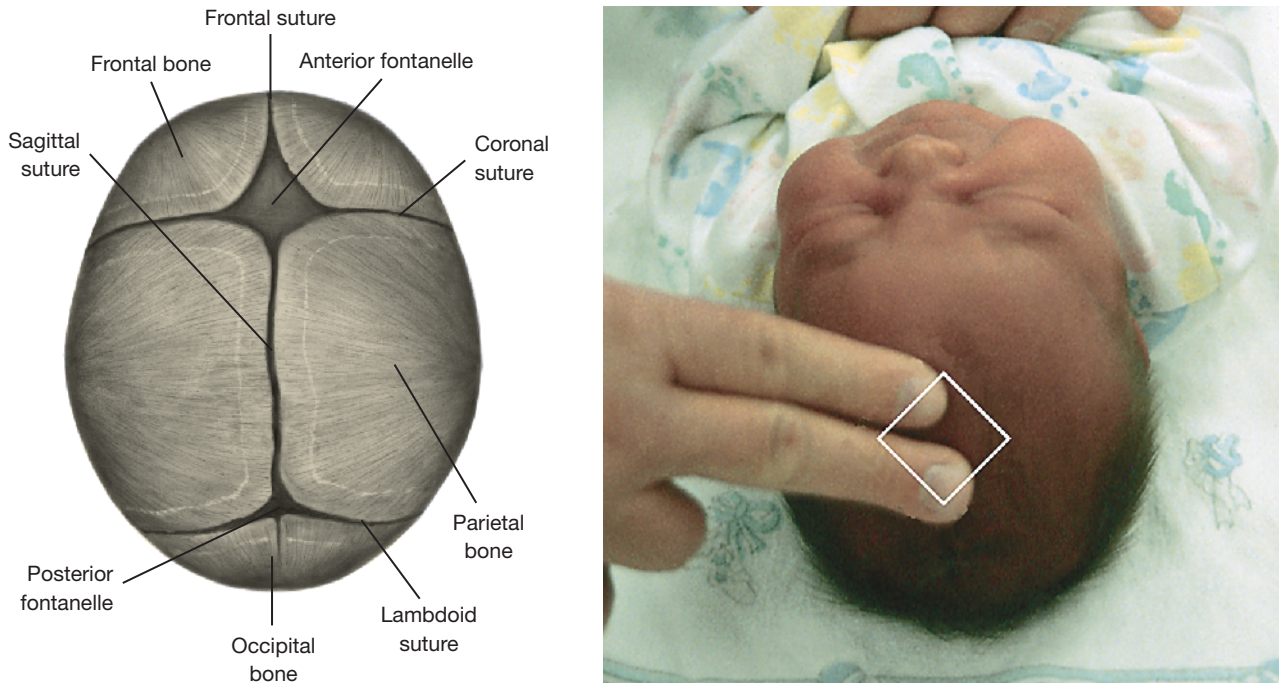

Figure 16-2 Fontanelles and suture lines.

Hockenberry MJ, Wilson D 2015 Wong's essentials of pediatric nursing, 10th edn. Mosby, St Louis, p. 261.

of neonatal intensive units that involve modifying the neonate's environment to promote optimum physical, cognitive and psychosocial development. This change in practice is referred to as 'developmental care' and you can find out more about it by looking up a recent meta-analysis in the Cochrane Library (see *Online resources*).

Sleep

The first hour of the unmedicated newborn's life is spent mainly in a quiet, alert state with wide-open eyes and vigorous sucking activity. Then neonates sleep almost continuously for the next 2–3 days to recover from the exhausting birth process. Thereafter, sleep periods vary from 20 minutes to 6 hours, with little day–night differentiation (Figure 16-3). Infant behaviour is characterised by five distinct states that are highly influenced by environmental stimuli. It is important for parents to understand these states (summarised in Table 16.5) and their implications for parental interaction.

The sleep environment and sleeping position of infants has been the subject of intense scrutiny over the past 20 years, motivated in part by the puzzle of Sudden Infant Death Syndrome (SIDS). Discussed later in this chapter, SIDS is defined as the unexpected and (after post-mortem examination) unexplained death of an infant. Sleep physiology develops throughout infancy and childhood. Sleep–arousal patterns occur within the child's social context but sleep patterns take considerable time to develop. Infants take time to distinguish between day and night and to develop consistent patterns of wakefulness and sleepiness, most taking the best part of 12 months (Stores 2001). The nursing assessment of infant sleep problems includes an investigation of the parents' expectations, as well as the settling and feeding practices that are used in individual households. It may first be necessary to support a change in adult expectations about infant sleeping habits and environments, rather than promote infant management strategies (See *Working with diversity* and Chapter 30).

Cognitive changes

Early cognitive development begins with innate behaviour, reflexes and sensory functions. Newborns initiate reflex activities and learn behaviours and desires. For example, newborns learn to turn to the nipple and that crying results in a parental response.

Sensory functions contribute to cognitive development in the newborn. At birth, children can focus on objects about 20–25 cm from their faces and can perceive forms. A preference for the human face is apparent. Auditory and vestibular systems function from birth. These sensory capabilities allow newborns to elicit stimuli rather than simply receive them. It is therefore important that parents understand the infant's need for sensory stimulation,

TABLE 16-4 Assessment of common localised reflexes in the newborn

Reflexes	Expected behavioural responses
Eyes	
Blinking or corneal reflex	Infant blinks at sudden appearance of bright light or at approach of object towards cornea. Reflex persists throughout life
Doll's eye	As head is moved slowly to right or left, eyes lag behind and do not immediately adjust to new position of head. Reflex disappears as fixation develops. Persistent occurrence indicates neurological damage
Nose	
Sneeze	Nasal passages respond spontaneously to irritation or obstruction. Reflex persists throughout life
Glabellar	Tapping briskly on glabella (bridge of nose) causes eyes to close tightly
Mouth and throat	
Sucking	Infant begins strong sucking movements of circumoral area in response to stimulation. Reflex persists throughout infancy, even without stimulation, such as during sleep
Gag	Stimulation of posterior pharynx by food, suction or passage of tube causes infant to gag. Reflex persists throughout life
Rooting	Touching or stroking cheek along side of mouth causes infant to turn head towards that side and begin to suck. Reflex should disappear at about 3–4 months but may persist up to 12 months
Extrusion	When tongue is touched or depressed, infant responds by forcing it outwards. Reflex disappears by 4 months
Cough	Irritation of mucous membranes of larynx or tracheobronchial tree causes coughing. Reflex persists throughout life and is usually present first day after birth
Swallowing	Appropriate swallowing of liquid introduced into mouth. Can also be elicited by directing a puff of air at infant's face
Extremities	
Grasp	Touching palms of hands or soles of feet near base of digits causes flexion of hands and toes. Palmar grasp lessens after 3 months and is replaced by voluntary movement. Plantar grasp lessens by 8 months
Babinski	Stroking outer sole of foot upwards from heel and across ball of foot causes toes to hyperextend and hallux to dorsiflexion. Reflex disappears after age 1 year (see the illustration below)
Mass	
Moro	Sudden jarring or change in equilibrium causes sudden extension and abduction of extremities and fanning of fingers, with index finger and thumb forming C shape, followed by flexion and adduction of extremities. Legs may weakly flex. Infant may cry. Reflex disappears after 3–4 months and is usually strongest during first 2 months
Startle	Sudden, loud noise causes abduction of arms with flexion of elbows. Hands remain clenched. Reflex disappears by 4 months
Dance or step	If infant is held so that sole of foot touches hard surface, there is reciprocal flexion and extension of leg, simulating walking. Reflex disappears after 3–4 weeks and is replaced by deliberate movement
Crawl	When placed on abdomen, infant makes crawling movements with arms and legs. Reflex disappears at about 6 weeks
Placing	When infant is held upright under arms and dorsal side of foot is briskly placed against hard object, such as table, leg lifts as if foot is stepping on table. Age of disappearance varies

Figure 16-3 Newborn sleep periods have little day–night differentiation.

Shutterstock/Dhoxax.

such as talking to their babies and holding them to see their faces. This allows infants to seek or take in stimuli, thereby enhancing learning and promoting cognitive development.

It is debatable whether infant crying is the precursor of refined language. However, because crying elicits a response, and caregivers can distinguish cry patterns, crying has significance to newborns and parents. For newborns, crying is a means of providing cues to parents. Some babies cry because their nappies are wet or they are hungry or want to be held. Others cry just to make noise or because they need a change in position or activity. Working with parents to recognise patterns of behaviour in their infant can reduce some of the frustration parents feel when they cannot see an apparent cause, or find a solution, for crying.

Psychosocial changes

During the first month of life, parents and newborns normally develop a strong bond that grows into a deep attachment. Interactions during routine care enhance or detract from the attachment process. Feeding, hygiene and comfort measures consume much of an infant's waking time. These interactive experiences provide a foundation for the formation of deep attachments and newborns are active participants in this process.

TABLE 16-5 States of sleep and activity of infants

State	Behaviour	Duration	Implications for parenting
Regular sleep	Closed eyes Regular breathing Occasional body jerks	4–5 hours/day 10- to 20-minute sleep cycles	Infant not aroused by external stimuli Usual house noises can continue Check frequently Pat but don't wake
Irregular sleep	Closed eyes Irregular breathing Slight muscle twitching of body	12–15 hours/day 20- to 45-minute sleep cycles	External stimuli may arouse infant Periodic groaning or crying is usual; not an indication of discomfort
Drowsiness	Eyes may be open Irregular breathing Active body movement	Variable	Most stimuli arouse infant Pick infant up during this time rather than leave in cot
Alert inactivity	Responds to environment by active body movement and staring at close range objects	2–3 hours/day	Satisfy infant's needs such as hunger Place infant in area of activity Place toys/objects within infant's view
Waking and crying	May begin with whimpering and slight body movements Progresses to strong, angry cry and uncoordinated thrashing of extremities	1–4 hours/day	Remove intense internal/external stimuli Repeat activities that were effective during alert inactivity Rock and swaddle to decrease crying

WORKING WITH DIVERSITY

Focus on sleep

Although the biophysical aspects of sleep architecture and function are universal, sleep patterns, habits and rituals are culturally constructed. For example, the tendency to encourage infants and young children to sleep alone, away from other family members, is a relatively new Western social practice, bringing with it its own problems and challenges for early childhood development, secure attachment and wellbeing. In contrast, in some Asian groups, close sleep for infants is believed to be essential as a protective mechanism from a range of physical and spiritual harms. In societies where extended family homes and smaller houses are the norm, closer sleeping arrangements for infants and children are the norm. This means that what are considered normal or problematic sleep habits in infants and young children may vary from family to family.

Implications for practice

- Assess expectations, beliefs and values and sleep routines with families.
- Assess child's sleep patterns including total hours of nocturnal sleep, patterns of wakefulness, alertness during the day, numbers of naps taken.
- Assess bedtime rituals and habits.
- Assess sleep issues and plan interventions from the perspective of what is normal for the specific family.

If parents or children experience health complications after birth, attachment may be compromised. An infant's behavioural cues may be weak or absent, and caregiving may be less mutually satisfying. Tired or ill parents may have difficulty interpreting and responding to their infants. Children with congenital anomalies may be unwell or non-responsive to parental cues, and require special supportive care. For example, infants born with heart defects may tire easily during feedings. They may need to rest frequently after several bursts of sucking and fall asleep after taking only small amounts (30–45 millilitres). Infants may wake up after only a few hours, crying because they are hungry again. Not understanding that crying is a physiologically dictated sequence of events, parents may think that their infant is being fussy or that they themselves are inadequate. If both mother and infant experience decreasing pleasure from feeding, attachment may be halted or reduced.

Other health considerations for newborns

Hyperbilirubinaemia

Hyperbilirubinaemia is an excessive amount of accumulated bilirubin in the blood and is characterised by a yellow colouring of the skin, or jaundice. This accumulation occurs when the infant's body is unable to balance the destruction of red blood cells (RBCs) and the use or excretion of by-products. This balance can be upset by prematurity, breastfeeding, excess production of bilirubin, certain disease states such as Rhesus iso-immunisation or a disturbance of liver function such as biliary atresia. Because bilirubin is highly toxic to neurons, an infant with levels greater than 18 mg/100 mL is at risk of brain damage. Phototherapy (Biliblanket/overhead UV light) is used to help break down the bilirubin for easier excretion. Special care must be given to properly shield the infant's eyes to protect from exposure to the UV light. Because excretion of the extra bilirubin can cause watery stools, fluid balance must be monitored and maintained (Royal Prince Alfred Hospital 2009).

Inborn errors of metabolism

Inborn errors of metabolism (IEMs) refer to genetic disorders caused by the absence or deficiency of a substance, usually an enzyme, essential to cellular metabolism that results in abnormal protein, carbohydrate or fat metabolism. Although IEMs are rare, they account for a significant proportion of health problems in children. Blood tests can be used to determine IEMs, and in many places a routine blood sample is obtained on filter paper (newborn screening test) between 48 and 72 hours after birth. Nurses and midwives coordinate newborn screening and other laboratory tests as indicated by the newborn's state of health. Neonatal screening can detect phenylketonuria (PKU), hypothyroidism, galactosaemia, amino acid disorders and cystic fibrosis, allowing early commencement of appropriate treatment that can either fully prevent or delay neurological and other organ damage.

Circumcision

Newborn male circumcision is no longer practised on a routine basis in Australia or New Zealand, except for specific religious and cultural reasons. Current rates of male circumcision are about 10–20%, compared with 90% in the 1950s (RACP 2010). Circumcision remains a controversial issue, one that is argued in terms of human rights as well as for potential risks and benefits. The most commonly recognised medical indications for circumcision include: reduction of urinary tract infections – particularly

TABLE 16-6 Normal physiological parameters in infants and children

Age	Weight (kilograms)	Blood pressure, systolic (mmHg)	Heart rate (beats per minute)	Respiratory rate (breaths per minute)
Term	3.5	50	100–170	40–60
3 months	6	50	100–170	30–50
6 months	8	60	100–170	30–50
1 year	10	70–90	100–170	30–40
2 years	13	80–95	100–160	20–30
3 years	15	80–100	80–130	20
4 years	20	80–100	70–115	16–20
6 years	25	90–110	70–110	16–20
8 years	30	90–100	60–105	16–20
10 years	40	100–120	60–100	16–20
14 years	50	100–120	60–100	16
17+ years	70	100–120	60–100	16

Adapted from Thomson K, Tey D, Marks M (eds) 2009 Paediatric handbook, 8th edn. Blackwell, London; Samuels M, Wietska S (eds) 2011 Advanced paediatric life support. The practical approach, 5th edn. Wiley-Blackwell, West Sussex.

in the first year of life; reduction in the risk of cancer of the penis in later life; and there is some evidence of a decreased risk of contracting sexually transmitted diseases. On the other side of the debate, arguments against circumcision include complications associated with the procedure which may include: bleeding; infection; damage to the head of the penis; pain associated with the procedure; and reduction in sexual pleasure later in life. Care should be taken to ensure that parents making the decision to circumcise their son (or not) are directed to the most up-to-date and unbiased information available, and are given the opportunity to discuss this with appropriate health professionals (RACP 2010).

The infant

Infancy is the period from 1 month to 1 year of age (Box 16-1). This period is characterised by rapid physical growth and psychosocial development during which the infant increasingly interacts with their environment and moves from an innate reflexive behavioural pattern to one that is more purposeful. Parents/carers know the infant best, and are therefore most aware of any changes. Their involvement is critical when undertaking any comprehensive assessment.

Physical changes

An infant's steady and proportional growth is more important than absolute growth values. There are many norm-referenced percentile charts for age, gender, feeding type and growth, which you will find in a variety of texts, journals and health websites. However, it is important that culturally and geographically appropriate norms are referenced. Measurements of weight, length and head circumference recorded over time are the best way to monitor growth. Deviations across any of the recorded measurements may be an indicator of a potential health problem that may require further consultation or medical intervention.

Overall, infant size increases rapidly during the first year of life, with birthweight doubling in approximately 5 months and trebling by 12 months (Glasper & Richardson 2010). Height increases by an average of 2.5 cm during each of the first 6 months and 1.25 cm during the next 6 months. This 50% increase in birth height occurs mainly in the trunk (Berk 2014). The fontanelles become smaller, with the posterior fontanelle closing at approximately 2 months of age and the anterior closing between 12 and 18 months of age.

Changes in size and physiological function (Table 16-6) lead to an increased capacity for bodily movements. In infancy, initial movements are reflexive and spontaneous. As the central nervous system matures there is a consequential development of voluntary movement. Gross motor skills develop in a cephalocaudal and proximodistal pattern; that is, head control develops before trunk control, which in turn is established before leg control (Rathus 2014). Table 16-7 identifies major milestones in infant

TABLE 16-7 Gross and fine motor development 0–12 months

Age	Gross motor skills	Fine motor skills
1 month	Can lift head fleetingly when prone	Hands predominantly closed
	Can turn head to side when prone	Strong grasp reflex
	No head control when placed in sitting position	
	Marked head lag when moved from lying to sitting position	
2 months	Able to hold head erect and steady when upright	Hands mainly open
	Able to lift head 45 degrees when prone	Follows moving person with eyes
3 months	Can lift head and shoulders and chest when prone	Looks at own hands
	Bears weight on forearms when prone	Grasps a toy/rattle when placed in hand
		Reaches for objects; however, unable to grasp
4 months	Balances head when placed in a sitting position	Holds objects with two hands
	Rolls from back to front/side	Hands begin to come together in the midline
		Plays with hands
5 months	Able to sit when supported	Reaches out for toys and successfully grasps them
	No head lag when moved from lying to sitting position	Places all objects to mouth
	Puts feet to mouth when supine	
	Rolls from front to back	
6 months	When prone can lift chest with weight supported by arms	Transfers objects from hand to hand
	Able to sit in high chair	Uses palmar grasp
	Able to support own weight when lifted to standing position	Holds own feeding bottle
7 months	Able to sit alone; will lean forward taking weight on arms	Bangs toys on table/floor
	Will bounce on legs when held in standing position	Tries to retrieve small objects
8 months	Sits unsupported	Beginning pincer grip
	Bears weight on legs when supported	Stretches for toys beyond reach
	May pull to stand when holding on to sturdy object	Plays with toys for purposeful outcome, e.g. presses buttons for sounds
	Adjusts posture in order to reach/attain object	
9 months	Starts to crawl	Compares toys in hands by bringing together
	Sits for longer period unsupported (10 minutes)	Dominant hand use prevalent
		Holds more than two objects concurrently
10 months	Moves self from prone to sitting positions	Interactively plays simple games
	Balance easily regained when sitting	Able to purposefully release objects
	Lifts foot off the ground to take step while standing	
11 months	Walks while holding on to furniture (cruising)	Good pincer grip
	Stands alone	Explores toys more thoroughly
	Able to reach backwards while sitting	Better able to manipulate objects
		Places objects into container
12 months	Walks alone or with one hand held	Repeatedly throws objects
	Can sit down from standing position	Can turn book pages
		No longer puts all objects to mouth

Adapted from Berk LE 2014 Development through the lifespan, 4th edn. Pearson, Boston; Wilson D 2015 Health promotion of the toddler and family. In Hockenberry MJ, Wilson D 2015 Wong's essentials of pediatric nursing, 10th edn. Mosby, St Louis.

gross motor and fine motor development. Understanding these physical changes and how they progress over time is fundamental to caring for infants and their family. Delays in the achievement of expected milestones may indicate delays in development that could be assisted or improved by appropriate interventions, or may have lifelong implications for the family.

Cognitive changes

An infant learns by experiencing and manipulating the environment around them. Developing motor skills and increasing mobility expand that environment and expose the infant to a greater number of sensory stimuli, which in turn enhance cognitive development. Jean **Piaget**, a Swiss psychologist (Table 16-1), created the **cognitive** (or 'how one thinks') **theory of development**. This theory describes how sensory and motor interactions with the environment allow information to be processed and an action to be formed in response. These information processes are thought to be the basis for ongoing problem-solving abilities (Leifer & Fleck 2013). In infancy, this early cognitive development is demonstrated with the repetition of actions (Rathus 2014). For example, an infant will perceive sucking as pleasurable and then will go on to generalise this feeling with the sucking of fingers, clothes and coverings. There is more about Jean Piaget's theory of development in Chapter 17.

A neonate has a well-developed sense of smell, and by 1 month of age has sufficient cognitive capacity and visual acuity to see, fix and follow the path of a moving object. Over the ensuing months, sensory development concerned with visual acuity, hearing and eye–hand coordination continue along their respective developmental pathways. Rudimentary colour vision is usually present by 2 months of age. At this age, the infant will also enjoy complex designs to look at, with a preference for the human face. By 6 months of age the infant can see many colours, localise and discriminate sounds as well as grasp objects in their path, which makes the environment around them a much more interesting place to explore (Rathus 2014, Wilson 2015).

Given the important role sensory stimulation plays in cognitive development, appropriate opportunities must be provided when an infant is not in their usual environment. For example, an unwell or hospitalised infant may experience a change in their usual temperament, or lack the energy to interact with their environment. This has the potential to slow their cognitive development. In this situation, simple verbal interaction, an interesting colourful environment, eye contact, and having an expressive face at frequent intervals are essential components of nursing care.

• CRITICAL REFLECTION POINT

You may find it helpful for your future clinical practice to develop your own list of age-appropriate strategies that would enhance the cognitive development of a hospitalised infant. Take a moment now to develop your list.

Another significant cognitive change during infancy is the development of speech. Infants proceed from crying, cooing and laughing to imitating sounds, comprehending the meaning of simple commands, and repeating words with knowledge of their meaning. Table 16-8 outlines major milestones in language development during the first two years of life.

Psychosocial changes

Psychosocial developmental theory is concerned with the development of personality and identity via the social environment and through social interactions. The German psychologist Erik Erikson (Table 16-1) was influenced by **Freud's pyscho-sexual development theory**; however, he placed more emphasis on the social and cultural aspect of personality development. Erikson described development as evolutionary, stating that individuals needed to successfully pass through each of eight stages in order to achieve a healthy personality and enable successful social

TABLE 16-8 Milestones of language development in first two years

Age	Language ability
1 month	Responds to voice and sounds
3–4 months	Coos (oo-oo), turns towards voice and sound
6–9 months	Babbles, sing song speech, copies waving goodbye, takes turn when playing games, responds to own name
9–12 months	Two parts babbling (e.g. da da), copies sounds (eg broom broom for car), uses sound patterns, waves and claps hands on request
12–18 months	Expresses wants through gesture and facial expression, points to objects when named, begins to use single words (naming people and objects,verbs and negatives), uses one word for many meanings, attempts to imitate new words and familiar songs
18 months to 2 years	Uses two words together, vocabulary approximately 25 words growing quickly to 100–200 words, listens to a short story, understands simple commands

Adapted from Boyd D, Bee H 2010 The growing child. Allyn & Bacon, Boston; Berk LE 2014 Development through the lifespan, 4th edn. Pearson, Boston.

interactions (Erikson & Erikson 1997, Leifer & Fleck 2013, Heffner 2001).

Erikson describes infancy as the period of 'trust versus mistrust'. During this period the major emphasis is on positive parental or carer contact and nurturing of the infant, particularly in terms of visual contact and touch. If an infant has their needs for warmth, love and security met, they will develop optimism, trust, confidence and security within the world around them as they progress through childhood. Conversely, if an infant does not experience trust, they may develop insecurity, worthlessness and a general mistrust of the world in their childhood years. Development of trust occurs when parental or carer contact is constant and reliable.

During their first year, infants begin to differentiate themselves from others as separate beings capable of acting on their own. Initially, infants are unaware of the boundaries of self, but through repeated interactive and social experiences within the environment, they learn where the self ends and the external world begins. As infants determine their physical boundaries, they begin to respond to others (Figure 16-4). Infants begin to smile responsively rather than reflexively by 2–3 months of age. Similarly, they can recognise differences in people when their sensory and cognitive capabilities develop. By 8 months of age most infants can differentiate a stranger from a familiar person and respond differently to the two. Close attachment to primary caregivers, in most cases the parents, is usually established by this age, and infants seek out these people for support and comfort during times of stress. When an infant is hospitalised, they may have difficulty establishing physical boundaries because of repeated bodily intrusions that may be associated with painful sensations. Therefore, an important nursing consideration is to limit negative experiences where possible and ensure that pleasurable interventions such as play are included in daily care activities to support early psychosocial development.

Figure 16-4 **Smiling at and talking to an infant encourages the infant to respond, which increases interaction with parent or caregiver.**

Shutterstock.

Infant play

Play is considered to be the occupation of childhood and is a vital component in promoting both cognitive and psychosocial development, as well as structure and chemistry within the brain (Erikson 1963). Lester and Russell (2008) propose that play is influential in a child's ability to thrive in both social and physical environments and is necessary to enhance the physical and emotional functioning of the child and adult. Play during infancy enables the child to engage with all that exists within their surroundings (Youell 2008). Play provides opportunities for the infant to develop many motor skills. Much of infant play is exploratory, using senses to observe and examine their own body and objects of interest in their surroundings. Activities such as placing their toes in their mouth provide infants with pleasure and information about their own body, also helping to shape their early self-concept. Tickling, singing and talking to young infants, games such as 'peek-a-boo', or songs using fingers and toes, are ideal for early play. Gurgling and smiling during this early play promotes the development of play language before the introduction of language and toys (Youell 2008).

As the infant develops motor control, play becomes more manipulative. Adults can facilitate infant learning by planning activities that promote the development of milestones and providing toys that are safe for infants to explore with the mouth and manipulate with the hands, such as rattles, wooden blocks, plastic stacking rings and squeezable stuffed animals. Infants most often engage in solitary (one-sided) play but do enjoy watching others, particularly the antics of their siblings. Infants thrive on being played with and stimulated through interaction with others.

CLINICAL EXAMPLE

You are caring for Toby, a four-month-old male infant who has been hospitalised since birth with a long-term gastrointestinal disorder. With your understanding of family theory from Chapter 15, and now play, how would you promote Toby's growth and development? An example might be encouraging mum to actively engage with Toby through storytelling and singing. What other activities would enhance Toby's normal growth and development?

Other health considerations during infancy

Accidental injury

Accidental injury is a major cause of hospitalisation and death in childhood. Box 16-3 lists the main types of injuries that can occur and possible preventive strategies based on major developmental accomplishments. It is important to remember that infants are not immune from accidental injury while in hospital and health professionals must also be mindful of injury prevention in this setting.

BOX 16-3 Injury prevention during infancy

Age: Birth to 4 months

Major developmental accomplishments

- Involuntary reflexes, such as the crawling reflex, may propel infant forwards or backwards, and the startle reflex may cause the body to jerk
- May roll over
- Increasing eye–hand coordination and voluntary grasp reflex

Injury prevention

Aspiration

- Not as great a danger to this age group, but should begin practising safeguarding early (see under Age: 4–7 months)
- Never shake baby powder directly on infant; place powder in hand and then on infant's skin; store container closed and out of infant's reach
- Hold infant for feeding; do not prop bottle
- Know emergency procedures for choking*
- Use dummy with one-piece construction and loop handle

Suffocation/drowning

- Keep all plastic bags stored out of infant's reach; discard large plastic garment bags after tying in a knot
- Do not cover mattress with plastic
- Use a firm mattress and loose blankets; no pillows
- Make sure cot design follows state regulations and mattress fits snugly – cot slats 6 cm apart
- Position cot away from other furniture and away from radiators
- Do not tie dummy on a string around infant's neck
- Remove bibs at bedtime
- Never leave infant alone in bath
- Do not leave infant under 12 months alone on adult or youth mattress

Falls

- Always raise cot rails
- When in doubt as to where to place child, use the floor
- Restrain child in infant seat and never leave child unattended while the seat is resting on a raised surface

Poisoning

- Not as great a danger to this age group, but should begin practising safeguards early (see under Age: 4–7 months)

Burns

- Install smoke detectors in home
- Use caution when warming formula in microwave oven; always check temperature of liquid before feeding
- Check bath water

continued

- Do not pour hot liquids when infant is close by, such as sitting on lap
- Beware of cigarette ash that may fall on infant
- Do not leave infant in the sun for more than a few minutes; keep exposed areas covered
- Wash flame-retardant clothes according to label directions
- Use cool-mist vaporisers

Motor vehicles

- Do not leave child in parked car
- Check surface heat of car restraint before placing child in seat
- Ensure that children travel in approved restraints suitable for the child's age and size
- Do not travel with infants on a seat or on your lap
- Do not place child in a pram or stroller behind a parked car
- Do not place infant or child in front passenger seat with an air bag

Bodily damage

- Avoid sharp, jagged objects
- Keep nappy pins closed and away from infant

Age: 4–7 months

Major developmental accomplishments

- Rolls over
- Sits momentarily
- Grasps and manipulates small objects
- Re-secures a dropped object
- Has well-developed eye–hand coordination
- Can focus on and locate very small objects
- Mouthing is very prominent
- Can push up on hands and knees and crawl backwards

Injury prevention

Aspiration

- Keep buttons, beads, syringe caps and other small objects out of infant's reach
- Keep floor free of any small objects
- Do not feed infant hard lollies, nuts, food with pits or seeds or whole or circular pieces of meat
- Exercise caution when giving teething biscuits, because large chunks may be broken off and aspirated
- Do not feed infant while child is lying down
- Inspect toys for removable parts
- Keep baby powder, if used, out of reach
- Avoid storing large quantities of cleaning fluid, paints, pesticides and other toxic substances
- Discard used containers of poisonous substances
- Do not store toxic substances in food containers
- Discard used button-sized batteries; store new batteries in safe area
- Know telephone number of Poisons Information Centre

Suffocation

- Keep all latex balloons out of reach
- Remove all cot toys that are strung across cot or playpen when child begins to push up on hands or knees or is 5 months old

Falls

- Restrain in a high chair
- Keep cot rails raised to full height

Poisoning

- Make sure that paint for furniture or toys does not contain lead
- Place toxic substances on a high shelf or in locked cabinet
- Hang plants or place on high surface rather than on floor

Burns

- Keep taps out of reach
- Place hot objects (cigarettes, candles, incense) on high surface
- Limit exposure to sun; apply sunscreen

continued

Motor vehicles
- See under Age: Birth to 4 months

Bodily damage
- Give toys that are smooth and rounded, preferably made of wood or plastic
- Avoid long, pointed objects as toys
- Avoid toys that are excessively loud
- Keep sharp objects out of infant's reach

Age: 8–12 months

Major developmental accomplishments
- Crawls/creeps
- Stands, holding onto furniture
- Stands alone
- Cruises around furniture
- Walks
- Climbs
- Pulls on objects
- Throws objects
- Is able to pick up small objects; has pincer grasp
- Explores by putting objects in mouth
- Dislikes being restrained
- Explores away from parent

Injury prevention

Aspiration
- Keep lint and small objects off floor and furniture, and out of reach of children
- Take care in feeding solid food to ensure that very small pieces are given
- Do not use beanbag toys or allow child to play with dried beans
- See also under Age: 4–7 months

Suffocation/drowning
- Keep doors of ovens, dishwashers, refrigerators, and front-loading washing machines and dryers closed at all times
- If storing an unused appliance, such as a refrigerator, remove the door
- Supervise contact with inflated balloons; immediately discard popped balloons and keep uninflated balloons out of reach
- Fence swimming pools
- Always supervise when near any source of water, such as cleaning buckets, drainage areas, toilets
- Keep bathroom doors closed
- Eliminate unnecessary pools of water
- Keep one hand on child at all times when in bath

Falls
- Fence stairways at top and bottom if child has access to either end
- Dress infant in safe shoes and clothing (soles that do not 'catch' on floor, tied shoelaces, pant legs that do not touch floor)
- Avoid walkers, especially near stairs
- Ensure that furniture is sturdy enough for child to pull self to standing position and cruise

Poisoning
- Administer medications as a drug, not as lollies
- Do not administer medications unless they are prescribed by a practitioner
- Replace medications and poisons immediately after use; replace caps properly if a child-protector cap is used

Burns
- Place guards in front of or around any heating appliance, fireplace or furnace
- Keep electrical wires hidden or out of reach
- Place plastic guards over electrical outlets; place furniture in front of outlets
- Keep hanging tablecloths out of reach (child may pull down hot liquids or heavy or sharp objects)

Modified from Wilson, D 2015 Health promotion of the toddler and family. In Hockenberry MJ, Wilson 2015 Wong's essentials of pediatric nursing, 10th edn. Mosby, St Louis.

• CRITICAL REFLECTION POINT

Take the time to reflect on your experiences of visiting a hospital ward and make a list of the dangers an infant might face, and then think of some strategies to prevent harm. One example could be ensuring that the infant is placed in a suitable sleeping environment – a cot which complies with Australian safety standards (Product Safety Australia 2013). See *Online resources* at the end of this chapter for more information.

Death in infancy

Death in infancy may occur from a variety of conditions such as congenital abnormalities, perinatal/maternal complications, and for reasons that are unclear such as Sudden Infant Death Syndrome (SIDS) (AIHW 2012). SIDS accounted for 50 infant deaths in Australia in 2012 (ABS 2014). There are factors known to increase the risk of SIDS, such as the infant sleeping on the abdomen and side, the use of soft sleeping surfaces and/or loose bedding, overheating through overdressing or wrapping, smoking and sharing of beds (Hunt & Hauck 2006). Nurses caring for infants must be cognisant of these SIDS risk factors and have a responsibility to share this knowledge with parents or primary caregivers (*Working with diversity* on p. 316). The SIDS and Kids Organisation Australia has a very informative website of frequently asked questions (FAQs) by parents and caregivers that would be worthwhile for you to visit (see *Online resources*).

Immunisation

Fortunately, infant deaths from vaccine-preventable diseases are relatively rare in Australia and New Zealand (Royal College of Pathologists 2012). As infants and children require a number of immunisations in the first few years of life to protect against serious infections of childhood, sharing information about the most up-to-date schedule is important. In addition to the schedule of immunisations, it is also important for health professionals to be able to communicate concepts related to the importance of an immunised community. The most up-to-date and accurate information on immunisation schedules is provided on government websites (see *Online resources* for Australia and New Zealand). Most parental concerns relate to the potential side effects and possible risks of vaccination. As with all medications, some contraindications exist and, in general, no vaccines should be given during a severe febrile illness. This precaution avoids adding possible side effects to an already ill child.

Child abuse and neglect

Child maltreatment includes intentional physical abuse or neglect, emotional abuse or neglect, and sexual abuse. Infancy is a high-risk period for child abuse, with emotional abuse and neglect being the most common (AIHW 2014). Neglect refers to failure to provide for a child's basic needs. This includes the provision of adequate care, food, shelter, clothing, supervision, hygiene, education or medical attention. Neglectful behaviours could be physical, emotional, educational or environmental (Child Family Community Australia 2012). It is mandatory for all healthcare workers, police and education professionals to report suspected cases of child abuse to the relevant child protection agency (Mathews & Scott 2014). As a nurse working with infants and children, it is your responsibility to be aware of signs that could be the result of maltreatment (see Box 16-4) or could be mistaken for maltreatment (see Box 16-5). As a nurse working with children, you may be involved with cases of suspected or confirmed maltreatment.

• CRITICAL REFLECTION POINT

Take some time to reflect on your legal and ethical responsibilities in cases of suspected maltreatment. Also be aware of any personal feelings you may have when you consider such situations. Make a note of what your responsibilities as a nurse are in relation to mandatory child protection reporting.

Nutrition and feeding practices

Nurses and other health professionals caring for infants and children appreciate that no one diet is effective for all children or for any particular age group. Further, the quality and quantity of nutrition combines with family culture, food preferences and food allergies in influencing the infant's growth and development.

For any infant, nutritional wellbeing is protected and nurtured through breastfeeding. The National Health and Medical Research Council of Australia Infant Feeding Guidelines (2012) recommend 'exclusive' breastfeeding (the consumption of breast milk only) for the first 6 months of age. From 6 to 12 months of age, the continuance of breastfeeding with appropriate complementary foods is recommended. In 2010, it was found that while 96% of Australian mothers initiated breastfeeding, only 39% of infants were exclusively breastfed at 3 months of age. At 5 months of age, 21% of infants continued to be breastfed; however, only 15% were exclusively breastfed. This indicates the introduction of non-breast milk fluids or solids for the remainder (AIHW 2011). From 6 months of age, breast milk can provide at least half the daily

BOX 16-4 Clinical manifestations of potential child maltreatment

Physical neglect

Suggestive physical findings

- Failure to thrive
- Signs of malnutrition, such as thin extremities, abdominal distension, lack of subcutaneous fat
- Poor personal hygiene, especially of teeth
- Unclean and/or inappropriate dress
- Evidence of poor health care, such as untreated infections, frequent colds
- Frequent injuries from lack of supervision

Suggestive behaviours

- Dull and inactive
- Self-stimulatory behaviours, such as finger-sucking or rocking
- Begging or stealing food*
- Absenteeism from school*
- Drug or alcohol addiction*
- Vandalism or shoplifting

* in older child

Emotional abuse and neglect

Suggestive physical findings

- Failure to thrive
- Feeding disorders, such as rumination
- Enuresis
- Sleep disorders

Suggestive behaviours

- Self-stimulatory behaviours such as biting, rocking, sucking
- During infancy, lack of social smile and stranger anxiety
- Withdrawal
- Unusual fearfulness
- Antisocial behaviour, such as destructiveness, stealing, cruelty
- Extremes of behaviour, such as overcompliant and passive or aggressive and demanding
- Lags in emotional and intellectual development, especially language
- Suicide attempts

Physical abuse

Suggestive physical findings

- Bruises and welts on face, lips, mouth, back, buttocks, thighs or areas of torso
- Regular patterns descriptive of object used, such as belt buckle, hand, wire hanger, chain, wooden spoon; squeeze or pinch marks
- Burns, injuries, fractures, lacerations or bruises in various stages of healing on soles of feet, palms of hands, back or buttocks
- Patterns descriptive of object used, such as round cigar or cigarette burns, 'glove-like' sharply demarcated areas from immersion in scalding water, rope burns on wrists or ankles from being bound, burns in the shape of an iron, radiator or electric stove burner
- Absence of 'splash' marks and presence of symmetric burns
- Whiplash from shaking the child
- Unusual symptoms, such as abdominal swelling, pain and vomiting from punching
- Descriptive marks such as from human bites or pulling out of hair
- Unexplained repeated poisoning or unexplained sudden illness

Suggestive behaviours

- Wariness of physical contact with adults
- Apparent fear of parents or of going home
- Lying very still while surveying environment
- Inappropriate reaction to injury, such as failure to cry from pain
- Lack of reaction to frightening events
- Apprehensiveness when hearing other children cry
- Indiscriminate friendliness and displays of affection
- Superficial relationships
- Acting-out behaviour, attention-seeking behaviours
- Withdrawn behaviour

continued

Sexual abuse

Suggestive physical findings

- Bruises, bleeding, lacerations or irritation of external genitalia, anus, mouth or throat
- Torn, stained or bloody underclothing
- Pain on urination or pain, swelling and itching of genital area
- Penile discharge
- Sexually transmitted disease, non-specific vaginitis or venereal warts
- Difficulty in walking or sitting
- Unusual odour in the genital area
- Recurrent urinary tract infections
- Presence of sperm
- Pregnancy in young adolescent

Suggestive behaviours

- Sudden emergence of sexually related problems, including excessive or public masturbation, age-inappropriate sexual play, promiscuity or overtly seductive behaviour
- Withdrawn behaviour, excessive daydreaming
- Preoccupation with fantasies, especially in play
- Poor relationships with peers
- Sudden changes, such as anxiety, loss or gain of weight, clinging behaviour
- In incestuous relationships, excessive anger at mother for not protecting daughter
- Regressive behaviour, such as bed-wetting or thumb-sucking
- Sudden onset of phobias or fears, particularly fears of the dark, men, strangers or particular settings or situations (e.g. undue fear of leaving the house or staying at the day-care centre or the babysitter's house)
- Running away from home
- Substance abuse, particularly of alcohol or mood-elevating drugs
- Profound and rapid personality changes, especially extreme depression, hostility and aggression (often accompanied by social withdrawal)
- Rapidly declining school performance
- Suicide attempts or ideation

McCarthy K, Health problems in early childhood, in Hockenberry, MJ, Wilson, D 2015 Wong's essentials of pediatric nursing,10th edn. Mosby, St Louis.

BOX 16-5 Conditions that can be mistaken for sexual abuse

- Accidental straddle injuries
- Accidental impaling injuries
- Non-specific vulvovaginitis and proctitis
- Group A beta-streptococcal vaginitis and proctitis
- Nappy rash
- Foreign bodies
- Lower extremity girdle paralysis as in myelomeningocele
- Defects that cause chronic constipation, Hirschsprung's disease, anteriorly displaced anus
- Chronic gastrointestinal disease, Crohn's disease
- Labial adhesions
- Anal fissures

American Academy of Pediatrics 2013 Supplemental information Appendix. Conditions that may be mistaken for child sexual abuse. Pediatrics 132(2):S11–S18.

nutrient requirements or more, depending on the amount of breastfeeding each day and complementary foods ingested. Children who continue to breastfeed into their second year may obtain up to a third of their daily nutrient requirements from breast milk.

In Australia and New Zealand, as in many other countries, the study of lactation and assisting mothers to breastfeed is a specialised area of nursing/midwifery practice. Nurses and midwives are therefore well placed to influence and support infant feeding practices, including the promotion of breastfeeding. In order to work with a mother to establish and maintain the best infant feeding practices, it is helpful to assess the mother's goals and knowledge, her lifestyle commitments, values and beliefs, as well as the influences on her thinking about breast-feeding, including family, friends and a wide range of lay and professional resources. Nurses and midwives can assess and advise on breastfeeding technique in order to ensure good attachment and drainage of the breast during

nutritive sucking and on expressing and breast-milk storage techniques. You can find out more about breastfeeding for healthcare workers at the websites of the World Health Organization or, within Australia, that of the Australian Breastfeeding Association (see *Online resources*).

Many infants will consume a combination of breast milk and breast-milk substitutes (formulas) during their first year of life. A clean and safe water supply is essential for the preparation of powdered infant formula and manufacturers' instructions for reconstitution must be followed. All types of cow's milk (whole, 2% and skim) and imitation milks are not recommended in the first year because of the infant's decreased ability to digest the contained fat. Cow's milk also contains more sodium and protein, which, when ingested, increases the renal solute load making it too heavy for immature infant kidneys to handle. Because cow's milk is low in iron and high in calcium and phosphorus, absorption of iron may be decreased, thereby resulting in anaemia (National Health and Medical Research Council 2012).

The addition of complementary foods is not recommended before 6 months of age because the gastrointestinal tract is not sufficiently mature to handle heavy, complex nutrients. The introduction of cereals, fruits, vegetables and meats during the second 6 months of life provides iron and additional sources of vitamins. These become especially important when children are weaned from breast milk or formula and begin drinking whole cow's milk after their first birthday. Well-cooked table foods are also tolerated by 1 year. While the amount and frequency of feeding will vary among infants, it is important to recognise that healthy lifetime eating patterns are established from this time.

Dentition

Tooth eruption varies with each infant and child. In general, the first tooth erupts between 6 and 9 months. Occasionally, an infant is born with a tooth, while others remain toothless at 1 year. The order of tooth eruption is fairly predictable, with the lower central incisors being first to appear, closely followed by the upper central incisors.

Teething may result in considerable discomfort for some infants and little or none for others. The inflammation of the gum as a tooth emerges may result in a low-grade fever and irritability. Some infants have increased drooling, biting or finger sucking. The Australian Dental Association (2011) recommends gentle rubbing of the infant's gum with a clean finger, or providing a dummy, teething ring or wet cloth to relieve discomfort. Discomfort should not be prolonged, and if the infant is unwell or has a prolonged or high fever, medical attention should be sought. Dental hygiene and dental habits should be encouraged through the use of a soft toothbrush and water in infancy, preferably twice a day.

The toddler

Toddlerhood ranges from the time children begin to walk independently until they walk and run with ease, usually from 12 to 36 months of age. Toddlerhood is the first part of the early childhood period (Box 16-1) and is characterised by increasing independence bolstered by greater physical mobility, language development and cognitive ability. Toddlers are increasingly aware of their abilities to control some aspects of the world around them and are pleased with successful efforts in this new skill. This success leads them to repeated attempts to control their environments. Unsuccessful attempts at control may result in negative behaviour and temper tantrums and sometimes physical injury. Toddlerhood is an exciting and frustrating time for parents and carers as brain development generally exceeds the physical growth and capabilities of the child.

Physical changes

The rapid development of motor skills allows the toddler to participate in self-care activities such as feeding, dressing and toileting. In the beginning, the toddler walks in an upright position with a broad-stance gait, protuberant abdomen and with arms out to the sides for balance. Soon the toddler begins to navigate stairs, using a rail or the wall

Figure 16-5 Toddlers must be correctly restrained in vehicles.

iStockphoto/BrianAJackson.

to maintain balance while progressing upwards, placing both feet on the same step before continuing. Success provides the courage to attempt the upright mode for descending the stairs in the same manner. Locomotion skills soon include running, jumping, standing on one foot for several seconds and kicking a ball. Most toddlers can ride tricycles, climb ladders and run well by their third birthday (Glasper & Richardson 2010).

Fine motor capabilities move from scribbling spontaneously to drawing circles and crosses accurately. By 3 years the toddler draws simple stick-people and can usually stack a tower of small blocks. If the toddler has developed the necessary cognitive abilities, increased locomotion skills, the ability to undress, and development of sphincter control allow toilet training. Parents often consult nurses for an assessment of readiness for toilet training. Reminding parents to look for cues that the toddler is ready or may be interested in toileting is a first step. Thereafter, patience, consistency and a non-judgemental attitude, in addition to the toddler's readiness, are essential to successful toilet training.

The cardiopulmonary system becomes stable in the toddler years. The heart and respiratory rates slow, and blood pressure varies slightly from infancy as shown in Table 16-6. The anterior fontanelle closes between 12 and 18 months of age, ending the period of most-rapid growth of the skull and brain. Routine measurement of head circumference is recommended until 3 years of age.

The rate of increase in weight and length slows. By 2½ years the toddler weighs approximately four times their birthweight and is approximately half of their adult height (Kleigman et al 2011). Height during toddlerhood increases by about 7.5 cm a year, mainly as a result of increases in leg length (Wilson 2015).

Cognitive changes

Piaget's development staging during toddlerhood is one of 'preoperational thought'. Advances in intellectual development enable toddlers to comprehend themselves as a separate identity from others. Toddlers are able to obey simple instructions, can increasingly use language to communicate and express ideas, and begin to solve simple problems themselves. Thinking during this stage is *concrete*; that is, the toddler is unable to reason, use logic or see things from another's point of view.

Toddlers use symbols to represent objects, places and persons. This function is demonstrated when toddlers imitate the behaviour of another, such as pretending to shave like Daddy or pretending their finger is a gun. Using play and make-believe are ways toddlers can express their experiences and help them to understand events. Along with the maturity of cognition comes the development of speech. The rate of speech development varies from toddler to toddler, with girls generally developing speech at a faster pace than boys (Berk 2014). It is important to understand that a toddler will *comprehend* vocabulary to a much greater degree than they are able to express vocabulary (Wilson 2015).With this in mind, it is important to include the toddler when discussing their health care or treatment. The 18-month-old uses approximately 10 words. By 24 months of age, the toddler has a vocabulary of up to 300 words and is generally able to speak in short sentences. 'Who's that?' and 'What's that?' typify questions asked during this period. Verbal expressions such as 'Me do it' and 'That's mine' demonstrate the 2-year-old toddler's use of pronouns and desire for independence and control, which again are important considerations when planning care for toddlers and their families.

Psychosocial changes

According to theorist Erikson, toddlers pass through the developmental stage of 'autonomy versus shame and doubt' (Table 16-1). If the child has successfully developed a sense of trust during infancy they are now ready to develop a sense of their own abilities. Through physical development, toddlers develop the ability to master control of bladder and bowel and with developing muscles are able to do more for themselves, and strive for independence. Their strong wills are frequently exhibited in negative behaviours when caregivers attempt to direct their actions. Temper tantrums may result when toddlers are frustrated by parental restrictions (you may have heard people refer to the 'terrible twos'), as this is a stage of development when the child is trying to assert their autonomy (Berk 2014). Toddlers thrive on graded independence, and allowing them to do small things that will not harm themselves or others, such as dressing, will support their development. Firm consistent limits, patience and support allow toddlers to develop socially acceptable behaviour, independence and self-control without a loss of self-esteem (Berk 2014). This is often a challenging time for parents and caregivers. Unrealistic adult expectations or strict discipline may impact on the development of self-esteem and result in a toddler feeling unable to act capably and thus develop a sense of doubt in his/her abilities to master self in the world (see Chapter 20).

The child continues to engage in solitary play during toddlerhood, but also begins to participate in parallel play, which is playing beside rather than with another child. Toddlers who are just learning what belongs to them are often possessive of their toys. They learn the joy of sharing when they offer parents toys to hold and the parents

express pleasure. Socially, toddlers remain strongly attached to their parents, feel safe in their presence, and fear separation from them.

Other health considerations during toddlerhood

Safety

The newly developed locomotion and insatiable curiosity of toddlers make them a danger to their own wellbeing. Toddlers need close supervision at all times, particularly when in environments that have not been modified with child safety in mind. Poisonings occur frequently because toddlers nearing 2 years of age are interested in placing any object or substance in their mouth. Removing or locking up all possible poisons, including plants, cleaning materials and medications, is a safety strategy that nurses can discuss with parents. Toddlers also lack awareness of the danger of water, and combined with newly developed walking skills, means that drowning is a major cause of accidental death in this age group. Limit-setting is extremely important for toddler safety. Toddlers completely depend on their parents and carers for physical safety and maintaining a safe environment for exploratory behaviour. Table 16-9 identifies developmental abilities related to the risk of injury during this age period, and accompanying injury prevention strategies.

Perceptions of wellness

A toddler's perception of their own health is limited by their cognitive capabilities. Toddlers are able to recognise internal body sensations but have difficulty pinpointing their location. Therefore, toddlers who deviate radically from their usual patterns of eating, sleeping or playing require assessment to determine whether these alterations have resulted from illness. Toddlers also associate generalised responses with illness; for example, emotional distress may be represented as a 'sore tummy'.

Nutrition

The nutritional requirements of toddlers are increasingly met by consumption of healthy solid foods, and less from breast milk or breast-milk substitutes. The healthy toddler requires a balanced daily intake of bread and grains, vegetables, fruit, dairy products and protein. It is common for toddlers' tastes to change, and they may develop aversions to some foods and strong desires for others. The child's developing independence may also cause mealtimes to be stressful as the desire to feed self

TABLE 16-9 Injury prevention during early childhood

Developmental abilities related to risk of injury	Injury prevention
Motor vehicles	
Walks, runs and climbs	Use government-approved car restraint; if restraint is not available, use lap belt
Able to open doors and gates	Supervise child while playing outside
Can ride tricycle	Do not allow child to play on kerb or behind a parked car
Can throw ball and other objects	Do not permit child to play in pile of leaves, snow or large cardboard container in trafficked area
	Supervise tricycle riding
	Lock fences and doors if not directly supervising children
	Teach child to obey pedestrian safety rules
	Obey traffic regulations; walk only at pedestrian crossings and when traffic signal indicates it is safe to cross
	Stand a step back from kerb until it is time to cross
	Look right, left and right again and check for turning cars before crossing street
	Use footpaths; when there is no footpath, walk on right, facing traffic
	Wear light colours at night, and attach fluorescent material to clothing
Drowning	
Able to explore if left unsupervised	Supervise closely when near any source of water, including buckets
Has great curiosity	Keep bathroom doors and lid on toilet closed
Helpless in water, unaware of its danger; depth of water has no significance	Have fence around swimming pool and lock gate
	Teach swimming and water safety (not a substitute for protection)

continued

TABLE 16-9 ***continued***

Developmental abilities related to risk of injury	Injury prevention
Burns	
Able to reach heights by climbing, stretching, standing on toes and using objects as a ladder Pulls objects Explores any holes or opening Can open drawers and cupboards Unaware of potential sources of heat or fire Plays with mechanical objects	Turn pot handles towards back of stove Place electric appliances, such as kettle and frying pan, towards back of counter Place guard rails in front of radiators, fireplaces or other heating elements Store matches and cigarette lighters in locked or inaccessible area; discard carefully Place burning candles, incense, hot foods, ashes, embers and cigarettes out of reach Do not let tablecloth hang within child's reach Do not let electric cord from iron or other appliance hang within child's reach Cover electrical outlets with protective devices Keep electrical wires hidden or out of reach Do not allow child to play with electrical appliances, wires or lighters Stress danger of open flames; teach what 'hot' means Always check bathwater temperature; adjust hot-water heater temperature to 50°C or lower; do not allow children to play with taps Apply a sunscreen with SPF 15 or higher when child is exposed to sunlight
Poisoning	
Explores by putting objects in mouth Can open drawers, cupboards and most containers Climbs Cannot read warning labels Does not know safe dose or amount	Place all potentially toxic agents (including plants) in a locked cabinet or out of reach Replace medications and poisons immediately; replace child-resistant caps properly Refer to medications as drugs, not as lollies Do not store large surplus of toxic agents Promptly discard empty poison containers; never use to store a food item or other poison Teach child not to play in garbage containers Never remove labels from containers of toxic substances DO NOT induce vomiting unless advised Keep the emergency number of the nearest Poisons Information Centre next to the telephone
Falls	
Able to open doors and some windows Goes up and down stairs Depth perception unrefined	Keep screen in window, nail securely and use guard rail Place gates at top and bottom of stairs Keep doors locked or use child-resistant doorknob covers at entry to stairs, high porch or other elevated area, such as laundry chute Remove unsecured or scatter rugs Put non-skid mat in bath or shower Keep cot rails fully raised and mattress at lowest level Place carpeting under cot and in bathroom Keep large toys and bumper pads out of cot or playpen (child can use these as 'stairs' to climb out), then move to youth bed when child is able to crawl out of cot Avoid using walkers, especially near stairs Dress in safe clothing (soles that do not 'catch' on floor, tied shoelaces, pant legs that do not hang on floor) Keep child restrained in vehicles; never leave unattended in shopping trolley or stroller Supervise at playgrounds; select play areas with soft ground cover and safe equipment
Choking and suffocation	
Puts things in mouth May swallow hard or inedible pieces of food	Avoid large, round chunks of meat, such as whole sausages (slice lengthwise then into short pieces) Avoid fruit with pips, fish with bones, dried beans, hard lollies, chewing gum, nuts, popcorn, grapes, marshmallows Choose large, sturdy toys without sharp edges or small removable parts Discard old refrigerators, ovens and so on; if storing old appliances, remove doors Keep automatic garage door transmitter in inaccessible place Select safe toy boxes or chests without heavy, hinged lids Keep venetian blind strings out of child's reach Remove drawstrings from clothing

continued

TABLE 16-9 ***continued***

Developmental abilities related to risk of injury	Injury prevention
Bodily damage	
Still clumsy in many skills Easily distracted from tasks Unaware of potential danger from strangers or other people	Avoid giving sharp or pointed objects – such as knives, scissors or toothpicks – especially when walking or running Do not allow lollies or similar objects in mouth when walking or running Teach safety precautions (e.g. to carry fork or scissors with pointed end away from face) Store all dangerous tools, garden equipment and firearms in locked cabinet Be alert to danger of animals, including household pets Use safety glass and stickers on large glassed areas, such as sliding glass doors Teach personal safety Teach name, address and phone number and to ask for help from appropriate people (cashier, security guard, policeman) if lost; have identification on child (sewn in clothes, inside shoe) Avoid personalised clothing in public places Teach child to never go with a stranger Teach child to tell parents if anyone makes child feel uncomfortable in any way Always listen to child's concerns regarding others' behaviour Teach child to say 'no' when confronted with uncomfortable situations

Child Accident Prevention Foundation of Australia 2012; Leifer G, Fleck E 2013 Growth and development across the lifespan, 2nd edn. Elsevier, St Louis.

can result in spillage or not finishing the meal, which may be frustrating for both caregiver and child.

It may be advisable that those following specific food practices, such as strict vegan diets, consult with a dietitian to ensure an adequate, balanced protein intake for toddler growth and development, as parents may assume adult eating patterns can be applied. Toddlers who are unwell, are undergoing surgery, have diseases or inborn errors of metabolism involving digestion or absorption, also benefit from consultation with a paediatric dietitian, as increased caloric requirements or alterations to the balance and types of foods may be necessary.

• CRITICAL REFLECTION POINT

Take the time to think of some developmentally appropriate strategies to promote healthy and safe nutrition for a toddler. To achieve a sense of autonomy, for example, serving a meal of appropriate size will allow the toddler to experience accomplishment of the task of finishing the meal. Now it's your turn to think of other examples.

The preschooler

The **preschool period** refers to those years between the ages of 3 and 6 and represents the latter part of the early childhood period (Box 16-1). Children of preschool age refine the mastery of their bodies and have increasing emotional, psychosocial and cognitive capacity to meet formal educational challenges. Many people consider these the most intriguing years of parenting, because children can now effectively interact and communicate with adults. Physical development continues to slow, while cognitive and psychosocial development remains rapid.

Physical changes

Several aspects of physical development continue to stabilise in the preschool years. See Table 16-6 for average heart rates, respiratory rates and blood pressure ranges. Preschoolers gain, on average, 2–3 kg a year and grow 6–7.5 cm a year, having doubled their birth length at about 4 years (Glasper & Richardson 2010). There is an elongation of the legs, which results in the preschooler appearing more slender. Little difference exists between the sexes, although boys are slightly larger with more muscle and less fatty tissue.

Large and fine muscle coordination improves, enabling preschoolers to run well, walk up and down steps with ease and learn to hop. By 5 years of age, preschoolers can usually skip on alternate feet, use a skipping rope and begin learning to swim. Improving fine motor skills allows intricate manipulations. Preschoolers learn to copy crosses and squares. Triangles and diamonds are usually mastered between 5 and 6 years of age. Scribbling and drawing help to further develop fine muscle skills and eye–hand coordination (Leifer & Fleck 2011).

Preschoolers need opportunities to learn and practise new physical skills. Although children of preschool

age with acute illnesses benefit from rest and exclusion from usual daily activities, those experiencing chronic conditions or who have been hospitalised for long periods need ongoing exposure to developmental opportunities. Parents and nurses can work together to weave these opportunities into the daily experiences of children who are hospitalised or who are being cared for at home. The scope of activities should correspond to their abilities, needs and energy levels.

Cognitive changes

Preschoolers continue to master Piaget's preoperational stage of cognition (Table 16-1). The first phase of this period, from 2 to 4 years of age, is known as 'preconceptual thought' and is characterised by perceptual-bound thinking in which children judge people, objects and events by their outward appearance, or *what seems to be*. That is, during preconception, preschoolers have difficulty reasoning, thinking logically or comprehending that some things stay the same even if their appearance has changed. For example, if a volume of fluid is poured from a wide container into a narrow container, the preschooler will still assert that the narrow vessel contains more fluid because it is at a higher level within the container (Glasper & Richardson 2010).

Around 4 years of age, the intuitive phase of 'preoperational thought' develops, and children's ability to think in a more complex way is demonstrated by their ability to classify objects according to size or colour and by questions such as 'Why do they call it the thirty-first day of the month instead of the thirty-last?' Egocentricity persists, but is slowly replaced with social interaction, as illustrated by the 5-year-old who offers a sticking plaster to a child with a cut finger. Children become aware of cause-and-effect relationships, as illustrated by the statement 'The sun sets because people want to go to bed'. Early causal thinking is also evident in preschoolers' transductive thoughts (reasoning occurs from one particular thought to another). If two events are related in time or space, children link them in a causal fashion. The hospitalised child, for example, may reason: 'I cried last night, and that's why the nurse gave me the injection.' As children near age 5, they begin to use (or can be taught to use) rules to understand causation. They then begin to reason from the general to the particular. This forms the basis for more formal logical thought. The child can now reason: 'I get an injection twice a day, and that's why I got one last night' (Wilson 2015).

Preschoolers' knowledge of the world remains closely linked to concrete (perceived by the senses) experiences. Even their rich fantasy life is grounded in the perception of reality. The mixing of these two aspects can lead to childhood fears, and may be misinterpreted by adults as lying when children are actually presenting reality from their perspective. The greatest fear of this age group appears to be that of bodily harm. This can be seen in children's fear of the dark, animals, thunderstorms and medical personnel. This fear often interferes with their willingness to allow nursing interventions such as measurement of vital signs. Allowing preschoolers to help measure the blood pressure of a parent, or hold and manipulate the nurse's equipment, may assist cooperation.

The preschoolers' vocabulary continues to increase rapidly so that by 5 years of age they are able to use more than 2000 words, can define familiar objects, identify colours and express desires as well as frustrations. Speech is more social, with questions expanding to 'Why?' and 'How?' in the quest for information. Phonetically similar words such as *die* and *dye* or *wood* and *would* may cause confusion in preschool children. These aspects of speech development are important to keep in mind when preparing children for procedures and assessing comprehension of explanations. Nurses also need an awareness of normal speech development expectations, as failure to develop speaking skills can be a sign of failure to develop both cognitively and emotionally (Leifer & Fleck 2011).

Psychosocial changes

The preschoolers' world expands beyond the family into the neighbourhood, where children meet other children and adults. Their curiosity and developing initiative lead to the active exploration of the environment, the development of new skills and the making of new friends. Preschoolers have a surplus of energy that permits them to plan and attempt many activities that may be beyond their capabilities, such as pouring milk from a two-litre container into their cereal bowls. Guilt arises within children when they overstep the limits of their abilities and feel they have not behaved correctly. Children of preschool age need help to understand that 'wishing' for something to happen does not make it occur. Children who may have wished their sibling were dead during an expression of anger, for example, experience guilt if that sibling becomes ill. Erikson (1963) recommends parents to help their children strike a healthy balance between initiative and guilt by allowing them to do things on their own, while setting firm limits and providing guidance.

During times of illness or stress, preschoolers may revert to bedwetting or thumb-sucking and want their parents to feed, dress and hold them. Box 16-6 lists behaviours related to stress in preschoolers. These

BOX 16-6 Stress and related behaviours in preschoolers

3-year-old

Infantile behaviour – reverts to babyish ways; can't completely let go of babyhood

Stubbornness – although is developing an interest in social relationships and a concept of 'we', may lapse into uncooperative behaviour

Possessiveness – guards belongings and may be bossy about them

Jealousy – particularly when it comes to parents' love

Separation anxiety

Stranger anxiety

Confusion – cannot always discriminate between fantasy and reality

White lies – may result from wishful thinking, fantasy and desire to please or impress

Imaginary playmate – often blamed for misdeeds

Fears – may be precipitated by imagination, may also fear dogs or other animals

Speech – may stutter or stumble over words

Activity level – seems to be in perpetual motion; may exhaust himself or herself

Eating – may forget to eat or lose interest in food

Nap or bedtime – may fear bad dreams, the dark or missing out on some fun while asleep

Destructiveness – may damage or destroy objects

Questions – continually asks 'why', and is upset if trusted adults do not respond or do not know the answer

4-year-old

Insecurity – may develop nervous habits such as nail biting, facial tics, thumb sucking, genital manipulation, blinking or nose picking; may insist on bringing a familiar item from house to preschool

Exaggerations – may attempt to boost self-image with boasts

Companionship – enjoys interacting with friends, although there may be many quarrels

Silliness – tends to engage in silly play; likes words and is fascinated by rhyming syllables or foul language; is disciplined for lack of control

Property rights – protects belongings; may become bossy

Sex – interested in the human body; may engage in exhibitionism

Activity level – enjoys running, jumping and slamming doors; may be punished for disruptive behaviour

Fears – picks up fears from adults; may fear dark room, snakes and lizards or anything perceived as 'creepy'

Attention – likes to talk and is frustrated if ignored or put off; whines to get own way

5-year-old

Approval – parents' love and acceptance are vital; seeks praise

School – may have difficulty adjusting to kindergarten

Separation anxiety – particularly fears loss of mother

Infantile behaviour – may occasionally lapse into babyish behaviour as a result of realising that babyhood has ended

Worrying – may develop irrational fears, take information out of context or fret over a misinterpreted, overheard conversation

Masturbation – is concerned about being 'bad'

Belongings – protects possessions

Showing off – performs in order to gain praise

Procrastination – may dillydally now and then

Name-calling – insults others to boost self-image but is upset when she or he is the victim of mockery

Kuczen B 1982 Childhood stress: don't let your child be a victim. Delacorte Press, New York.

dependent behaviours are often confusing or embarrassing to parents, who may benefit from reassurance that they are normal preschooler coping behaviours. Offering the preschooler experiences that they can master and perceive as successful, helps them return to their prior level of independent functioning. As language skills develop, children should be encouraged to talk about their feelings. Play is also an excellent way for preschoolers to vent frustration or anger and is a socially acceptable way to deal with stress.

Preschool play

The play of preschool children becomes more social after the third birthday as it shifts from parallel to associative play. In many play activities, preschoolers display awareness of social context. Sex-role identification is strengthening, and children most often assume roles of persons of their own sex (Rathus 2014). Children often mimic or repeat social experiences. This tendency is especially significant for the nurse working with hospitalised children. Through play, children may express questions, fears, anger and misunderstanding about their illnesses and care. The nurse should be alert to such clues and ensure that children can play within their physical possibilities and energy limits. Play can provide a healthy outlet for frustration when children have been subjected to painful or restrictive experiences against their will.

Pretend play involving imaginary situations depends on children's ability to retain images of things they have seen or heard. This sociodramatic play involving other children occupies about a third of 5-year-old children's playtime. Pretending allows children to learn to understand others' points of view, develop skills in solving social problems and become more creative. Some children have imaginary playmates. These playmates serve many purposes – they are friends when the child is lonely, they can accomplish what the child is still attempting, and they can experience what the child wants to forget or remember. Imaginary playmates allow the child to distinguish between reality and fantasy and are healthy inventions (Berk 2014). Children who watch a great deal of television engage less often in imaginative play, possibly because they develop the habit of passively absorbing images rather than generating their own (Wilson 2015).

• CRITICAL REFLECTION POINT

Play is considered to be the occupation of childhood. Through play, cognition, language and social skills all develop. Hospitalisation is a major stressor for the preschooler and may limit opportunities for play. If you were designing a paediatric inpatient service, take a moment to think about the environment and resources that would be helpful to create a space that would promote/allow play. You may find the following resource helpful: The Association for Wellbeing for Children in Healthcare Policy relating to the provision of play for children in hospital, www.awch.org.au/pdfs/AWCH_Play_Provision_Policy.pdf

Moral development

Lawrence **Kohlberg** is a recognised moral theorist who provides a developmental perspective aligned to the work of Piaget (Table 16-1). **Moral developmental theories** attempt to explain how the child constructs their schema of right and wrong. During toddlerhood, moral development is at beginning stages and is closely associated with cognitive abilities. It is theorised that toddlers do not understand concepts of right and wrong but do understand that some behaviours bring pleasant results (positive reinforcement) and others elicit unpleasant results (negative reinforcement). The moral development of the preschool child expands to include a beginning understanding of behaviours considered socially right or wrong. However, the child continues to be motivated by the wish to avoid punishment or the desire to obtain a reward. The main difference between this stage of moral development and that of a toddler is that a preschooler is better able to identify behaviours that elicit rewards or punishment, and begins to label these behaviours as right or wrong (Berk 2014, Leifer & Fleck 2013).

• CRITICAL REFLECTION POINT

Take time to reflect on the cognitive and moral development of the preschooler and think about how their understandings of the world and events within that world may affect the nursing care you give. For example, an unpleasant procedure may be perceived as punishment for wrongdoing; if so, how would you approach such a situation?

Other preschooler health considerations

Safety

Falls become much less of a problem as fine and gross motor skills develop and the child becomes more coordinated with better balance. Guidelines for injury prevention in the toddler also apply to the preschooler (Table 16-9) with particular awareness in this age group to the risks of poisoning and pedestrian motor vehicle accidents.

Nutrition

Nutrition requirements for the preschooler are similar to toddlerhood. The average recommended daily intake is 7500 kilojoules. Parents may still worry about the amount of food their child is consuming. The quality of the food is more important than quantity in most situations. Preschoolers consume about half of the average adult portion. Fussy eating habits are characteristic of the 4-year-old, but the 5-year-old is more interested in trying new foods (see *Online resources*).

Sleep

The average number of hours of nocturnal sleep for children reduces over time. Preschoolers average 12 hours of sleep a night and take infrequent naps. Although children of this age group tend to sleep soundly, sleep disturbances are not uncommon. Disturbances may range from trouble getting to sleep, nightmares, or prolonging bedtime with extensive rituals. Preschoolers frequently have an overabundance of activity and stimulation during the day, so helping them to slow down before bedtime and instigating pre-bedtime routines, such as reading/story-telling usually results in less resistance.

School-age children and adolescents

School-age children and adolescents lead demanding and challenging lives. The developmental changes between 6 and 18 years of age are diverse, with physical,

psychosocial, cognitive and moral skills being expanded and refined. The environment also expands and develops, incorporating family, friends, school, community and spiritual influences. When assessing school-age children and adolescents, it is important to keep developmental theories and their associated age expectations in mind. According to Erikson, children in this age group strive to achieve a sense of identity and industry within a given social and moral context. Working through this period of development, the younger child establishes their own peer group while the adolescent often starts to engage in risk-taking behaviour. There are many other behavioural considerations for this age group, as identified in Table 16-10.

TABLE 16-10 Developmental behaviours of school-age children and adolescents

School-age children	Adolescents
Relationships with parents	
Children gradually learn that parents are less than perfect; they can be disillusioned with them and wish that friends' parents were their own. Sometimes they believe that they must be adopted. They rely on parents for unconditional love, security, guidance and nurturing.	Adolescents' desires for increasing independence and autonomy and continuing need for some dependence and limit-setting by parents place strain on their relationship. Effective communication and democratic parenting are the best tools for meeting this challenge.
Relationships with siblings	
School-agers seem to be at odds with one another at home; yet they are each other's best defenders away from home. Younger children often idolise older siblings, and this frequently leads to competition. Older children may envy attention that younger siblings require and be quite bossy and somewhat abusive.	Younger siblings rarely understand their adolescent siblings' need for privacy to think, dream and talk with peers. Adolescents often enjoy interacting with and guiding younger brothers and sisters when timing is convenient for them and they can remain in control.
Relationships with peers	
During primary school (6–9 years), children of both sexes play together, depending on who is available and interested. Around age 8, social groupings of same-sex peers form. These 'gangs' allow children to declare their independence from parental rules and establish their own secret codes or languages and rules of membership and behaviour. This period is often referred to as the secret society of childhood. Preadolescent (10–12 years) friendships are characterised by having best friend of same sex. These relationships may be transient, but they are intense and allow discussion of all areas of life. Some interest in heterosexual relationships develops but they are usually not reciprocated.	Peer group is a factor of critical influence to adolescents, who have increasing need for recognition and acceptance. Companionship offered by peer groups provides a secure environment for individuals to try out new ideas and share similar feelings and attitudes. Adolescents often form cliques with peers from the same socioeconomic group with similar interests. Cliques, which are highly exclusive, help their members, who have strong emotional bonds, develop their identities. The crowd, which is more impersonal than the clique, offers opportunities for heterosexual interaction and social activities. The crowd also maintains rigid membership requirements; clique membership is usually a prerequisite for crowd membership.
Self-concept	
Children's feelings of competence regarding mastery of tasks are key elements in forming self-esteem. Children need to receive positive feedback from teachers and parents regarding their efforts. It is important for children to develop skills in at least one area such as reading, music or swimming. Pets that require children's care and attention reward them with unconditional love and promote feelings of self-worth.	Formal and informal peer groups are the primary force in shaping self-concept of group members. Popularity and recognition within peer group enhance self-esteem and reinforce self-concept. Total immersion in peer group may make it appear that adolescents have no original thoughts and are incapable of making decisions. Adolescents who withdraw from peers into isolation struggle with developing identity.
Fears	
There is a decline in fears related to body safety, such as storms, dogs, darkness, noises, scrapes and scratches. Fears of the supernatural, such as ghosts and witches, persist and decline slowly. New fears related to school and family occur. They fear ridicule from teachers and friends and disapproval and rejection of parents. They also become frightened about death and items that they hear on news such as war and destruction of environment.	Fears in this age group centre around peer group acceptance, body changes, loss of self-control and emerging sexual urges. Adolescents constantly examine their bodies for changes and signs of imperfection. Any defect, real or imagined, is a cause of endless worry. Adolescents' developing awareness of economic and political problems may result in fear of going to war with its resulting death and destruction.

continued

TABLE 16-10 ***continued***

School-age children	Adolescents
Coping patterns	
To deal with stress, school-agers use problem-solving and defence mechanisms including regression, denial, aggression and suppression. Several categories of coping behaviours of hospitalised school-agers include inactivity (total silence, lack of activity and apathy), orientation or precoping (looking and listening, walking around and exploring, and asking questions), cooperation (compliance with care), resistance (attempt to get away from the situation by turning away or making physical or verbal attacks) and controlling (assuming responsibility for self-care and suggesting how things could be done).	Repertoire of coping behaviours has expanded with experiences adolescents have gained from life and from developing cognitive maturity. By age 15, most use full range of defence mechanisms, including rationalisation and intellectualisation. Adolescents' problem-solving abilities have matured, and they can reason through philosophical discussions and complex situations that require abstract thinking and proposition of hypotheses. Some adolescents use avoidance coping strategies in which the problem is denied or repressed and an attempt is made to reduce tension by engaging in chemical abuse or avoiding people.
Morals	
Children learn rules from parents, but their understanding of rules or reasons for them is limited until about 10 years. Before that, they are concerned with their own needs first and may cheat to win. After 10, justice is based on 'eye for an eye', and punishment should correct situation (e.g. if children break something, they should pay to have it fixed).	According to Kohlberg (1964), as youths approach adolescence they reach the conventional level, where internalisation of expectations of their family and society begins. Initially there is considerable conformity to rules to win praise or approval from others and to avoid social disapproval or rejection; later, they seek to avoid criticism from persons of authority in institutions.
Diversional activity	
School-agers play cooperatively in group activities such as skipping, hopscotch, soccer and basketball. Play becomes competitive, and children often have difficulty learning to lose. Teasing, insults, dares, superstitions and increased sensitivity are characteristics of this age.	Many teenagers develop special interests in certain sports and concentrate on developing maximal skills therein. Recreational activities are often determined by what is popular with peers and what can provide independence from parents (e.g. computers, cars).
Nutrition	
Children have definite likes and dislikes. Few nutritional deficiencies occur in this age group. Children have voracious appetites after school and need quality snacks such as fruit and sandwiches to avoid empty-kilojoule food such as chips and lollies.	Total nutritional needs become greater during adolescence. Girls' energy needs decrease, and their need for protein increases slightly. Iron needed by adolescents is almost twice that of adult men, and growth spurt increases calcium demand.

Rodgers CC 2015 Health promotion of the school age child and family. In Hockenberry MJ, Wilson D 2015 Wong's essentials of pediatric nursing, 10th edn. Mosby, St Louis.

• CRITICAL REFLECTION POINT

This would be a good time to reflect on how the information provided in Table 16-10 might guide you in conducting a thorough clinical nursing assessment and ongoing plan of care. After you have done the thinking, make sure you take the time to write your hard work down and place it in your professional portfolio.

Middle childhood

Middle childhood is generally described as the period between 6 and 12 years of age (Box 16-1). This period coincides with entry to school, as well as greater exposure to adult roles in work, recreation and social interaction. As the child and young person is exposed to these various educational and social interactions, their world expands and they undergo a transition from a life of relatively free play to a life of structured play, learning and work, where certain rules, expectations and social norms become incorporated into their sense of who they are. As a consequence, the child or young person begins to make decisions, accept responsibility and learn from life's experiences.

Physical changes

The rate of growth during the early school years is slower than at any time since birth, but continues steadily. The early school-age child appears slimmer than the preschooler, as a result of changes in fat distribution and thickness. Children in the middle years also experience differences in rate of growth, with approximate averages for height and weight being 5 cm and 2–3 kg respectively per year (Glasper & Richardson 2010).

School provides children with an opportunity to compare themselves with large numbers of other children of varying ages. Boys are slightly taller and heavier than

girls during these early school years. Approximately 2 years before puberty, children experience a rapid acceleration in skeletal growth. Girls, who reach puberty first, often begin to surpass boys in height and weight. These changes may begin as early as 7.5 years in girls and 10.5 years in boys; the average, however, is generally 10 and 12 years respectively (Glasper & Richardson 2010).

All body functions are refined and stabilised during the early school-age years, leading to changes in heart rate, blood pressure, respiratory rate and lung function, as shown in Table 16-6. Large-muscle coordination, strength, and gross and fine motor skills also improve and strengthen during this period. Activities of childhood, such as running, jumping, balancing, throwing and catching, writing and colouring, and computer games, all contribute to refinement of neuromuscular function and skills. Table 16-11 describes the specific gross motor and fine motor skills of the school-aged child and how they may be used in managing self-care in this group.

In the middle years, illness and hospitalisation threaten children's control of how they care for themselves. It is therefore important to allow them to participate in their own care and to maintain as much independence as possible. This participation is still possible for children whose care demands restriction. One example might be a child who is fluid restricted. In this situation the child may be able to choose the type of fluid they consume and when they consume it.

Other physical changes take place during the middle school-age years, such as steady skeletal growth in the trunk and extremities, together with small- and long-bone ossification, which is generally complete by 12 years of age. With this pattern of skeletal growth, body appearance and posture change. Earlier posture, which

TABLE 16-11 Motor development in the school-age child

6–7 years	8–10 years	10–12 years
Fine motor skills		
Uses knife to butter bread and learns to cut tender meat	Uses knife and fork simultaneously	Learns to peel apples and potatoes
Cuts, folds and pastes paper	Learns to thread needle and tie knot	Sews simple garments on machine
Prints with pencil	Uses hammer, saw and screwdriver	Builds simple objects like bird-house
Draws man with 12–16 details	Becomes proficient at writing cursive	Enjoys using decorative script
Copies triangle at 6 years and diamond by 7 years	Uses symbols in drawing (e.g. bird, star)	Begins to use creative and artistic talents
Colours within lines of picture	Builds simple models of cars and planes and does simple handicrafts	Builds complex models of cars and planes and does complex handicrafts
Needs assistance to clean teeth thoroughly	Learns to play marbles	Learns to play musical instrument
	Can learn to floss teeth effectively and be independent in tooth care	Becomes proficient in caring for teeth with braces and other appliances
Gross motor skills		
Remains in constant motion	Can catch, throw and hit ball	Can do standing broad jump of 1.5 m
Moves more cautiously at 7 years than at 6 years	Engages in alternate rhythmic hopping in 2–2 2–3 or 3–3 pattern	Can do standing high jump of 90 cm
Hops and jumps into small squares	Engages in complex styles of skipping rope accompanied by verbal jingles	Plays games involving simultaneous use of two or more complex motor skills such as rollerskating
Learns to rollerskate, skip, ride bicycle and swim		
Self-care		
Takes bath without supervision	Learns to clean bathroom after bath	Dusts, vacuums and straightens own room
Often returns to finger feeding	Enjoys fixing own snacks and school lunch	Learns to cook simply prepared foods
Learns to brush and comb hair in acceptable fashion without help	Learns to part hair and tie hair ribbons	Washes, dries and fixes own hair in plaits, curls and ponytails
Puts on most clothes but may need assistance with shirt-tails, sashes and final adjustments	Dresses self completely and can help younger siblings with clothes	Learns to sort, wash, dry and iron own clothing
	Can make own bed	Learns to care for fingernails and toenails

Rodgers CC 2015 Health promotion of the school age child and family. In Hockenberry MJ, Wilson D 2015 Wong's essentials of pediatric nursing, 10th edn. Mosby, St Louis.

was characterised by a stoop-shouldered, slightly lordotic stance and prominent abdomen, changes to a more erect posture. Facial bones grow and remodel, which is reflected in an alteration of eye shape that results in improved visual acuity and the attainment of normal adult vision. Screening for vision and hearing problems is easier, and results are more reliable because middle school-age children can more fully understand and cooperate with the test directions. Dental growth is rapid during the middle school-age years with the first permanent teeth erupting at approximately 6 years of age. Figure 16-6 illustrates the pattern and timing of dental shedding and eruption.

Cognitive changes

Cognitive changes in the middle school-age child offer the ability to think in a logical manner about the here and now, but not about abstraction. The thoughts of middle school-age children are no longer dominated by their perceptions, and their ability to understand the world greatly expands. Piaget identifies this period of maturing cognitive ability as 'concrete operational'. In this developmental stage, the middle school-age child and young person are able to use symbols to carry out operations in thought, rather than in action. They begin to use logical thought processes or mental activities to deal with concrete materials (objects, people and events they can touch and see).

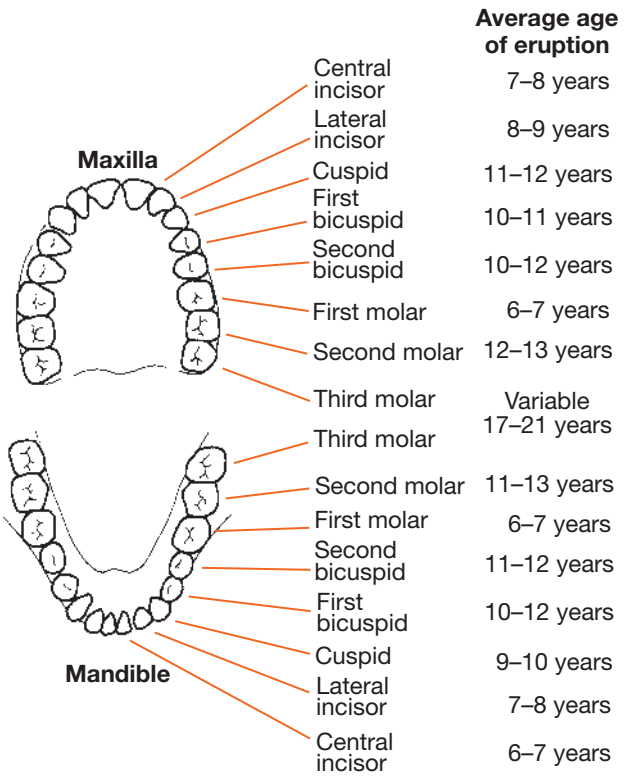

Figure 16-6 Sequence of eruption of secondary teeth.

Hockenberry MJ, Wilson D 2015, Wong's Nursing care of infants and children 10th edition, Mosby, St Louis.

Middle school-age children can use their newly developed cognitive skills to solve problems. Some children are better than others at problem-solving because of native intelligence, education and experience. Parents and health professionals can help middle school-age children improve their problem-solving abilities and assume responsibility for their general health by helping them to articulate problems and by actively planning care with them around their healthcare needs (Glasper & Richardson 2010). For example, when a child is newly diagnosed with type 1 diabetes, the nurse will play an integral part in assisting the child and their family to meet the new demands and challenges of this chronic illness.

• CRITICAL REFLECTION POINT

Can you think of strategies you might use in caring for the child and their family described above?

Language development is rapid during the middle school-age years, with the average 6-year-old child having a vocabulary of approximately 3000 words. This quickly expands with the introduction to formal reading, exposure to peers and contact with adults. With this exposure, children understand the use of language and realise that words have arbitrary, rather than absolute, meanings. Children within the middle years can use different words for the same object or concept, and understand that a single word may have many meanings. In the healthcare setting, middle school-age children are able to use their understanding of language to articulate their health problems and understand the consequences of that articulation. For example, a child complaining of pain might receive pain relief in the form of an injection; as a consequence of that experience, the child might not verbalise when they are next in pain due to the negativity experienced with that injection. Therefore, health professionals cannot always rely on the use of language for accurate clinical assessment when caring for middle school-age children.

Psychosocial changes

Erikson (Table 16-1) identified the developmental task for middle school-aged children as 'industry versus inferiority' (Leifer & Fleck 2013). During this time, children strive to acquire the competence and skills necessary for them to function as adults. School-age children in the middle years who are positively recognised for success feel a sense of worth. Those faced with failure

can feel a sense of mediocrity or unworthiness, which may result in withdrawal from school and peers. Refer back to Table 16-1 and consider the school-age child and young person's need for a moral code and social rules that are cognisant with their cognitive abilities.

As the child progresses into middle years, social and moral codes assume even greater importance to positive growth and development experiences as a young person. For example, 12-year-olds are able to consider what society would be like without rules because of their ability to reason logically and their experiences with group play. They view rules as necessary principles of life, not just dictates from authorities. In the early school years, children strictly interpret and adhere to rules. As they develop, they make more flexible judgements and evaluate rules for applicability to a given situation. Middle school-age children consider motivations and the actual behaviour when making judgements about the way their behaviours affect themselves and others. The ability to be flexible when applying rules and taking the perspective of others is essential in developing moral judgements. These abilities are present at times in earlier years, but are more consistently displayed in middle and later school years.

Group and personal achievements, and success in physical and cognitive activities, are important to the middle school-age child (Figure 16-7). Play involves peers and the pursuit of group goals. Although solitary activities are not eliminated, they are overshadowed by group pursuits. Learning to contribute, collaborate and work cooperatively towards a common goal becomes a measure of success. The middle school-age child prefers same-sex peers to opposite-sex peers and this close network of same-sex companions evidences strong gender identity. In general, girls and boys view the opposite sex negatively and peer influence becomes quite diverse. Conformity is evidenced in mannerisms, clothing styles and speech patterns, which are reinforced and influenced by contact with peers. During this time, clubs and peer groups become prominent. Group identity increases as the middle school-age child approaches adolescence.

Figure 16-7 **School-age children gain a sense of achievement when playing with peers.**

iStockphoto/Photo_Concepts.

The eminent psychologist Sigmund Freud was the first to provide a structured and complex theory of personality development. Freud's theory is grounded in the belief that two internal biological forces (aggressive and sexual forces) essentially drive psychological change in the child. Freud believed that the major motivation for behaviour is to achieve pleasure and avoid the pain created by these aggressive and sexual forces. Maturational changes occur as these forces come into conflict with the reality of the world. Table 16.1 provides a brief overview of Freud's five psychosexual developmental stages. Freud described middle childhood as a period of latency, where children have little interest in their sexuality. Yet in contemporary society, various forms of media emphasise the sexual curiosity of middle schoolers. While some children may experiment with sexuality through play, this is usually transitory. Emotional consequences can result from how parents deal with these behaviours or how the child believes the action would be interpreted from the parental point of view. Children's curiosity about adult magazines, or meanings of sexually explicit words, is another example of interest in sexuality during this period of development (The National Child Traumatic Stress Network 2009).

The middle school-age child goes through many adjustments. During this stage, the nurse's role is more likely to involve assisting parents and children to identify potential stressors and designing interventions to minimise the child's stress response to illness. Box 16-7 provides an overview of potential sources of stress encountered by middle school-age children.

• CRITICAL REFLECTION POINT

Take a moment to reflect on your own journey through school and the stressors you may have encountered. How did you manage them?

Other middle childhood health considerations

Major health problems

Injuries, poisonings and cancer (leukaemia and solid brain tumour) are the major health problems affecting Australian middle school-age children (ABS 2014). It is therefore crucial that those caring for children in

BOX 16-7 Potential sources of stress in middle childhood

Sources of stress for the 6-year-old

Expectations – parents, teachers and other adults begin to demand more

School – first year introduces the child to the more formal academic setting; it may be the child's first experience away from home all day

Activity level – may find it difficult to sit still for long periods of time; may have frequent accidents, such as spilling milk

Competition – the child wants to be 'first' or best

Shyness – may initially be shy in a new situation but usually recovers quickly

Aggression – may become hostile or aggressive; temper tantrums peak

Sensitivity – begins to read body language or facial expressions and becomes upset when disapproval is sensed

Teasing – engages in teasing, but becomes upset when on the receiving end

Decisions – has difficulty coping with increasing independence

Jealousy – sibling rivalry is common

Fears – usually centre around newly found independence and might include fear of getting lost or fear of making an embarrassing social blunder

Sources of stress for the 7-year-old

Moodiness – is often moody, unhappy or pensive

Approval – continues to need praise and approval from peer group and parents

Modesty – demands privacy when in the bathroom or dressing

Organisation – is comfortable with rules, regulations, routines and order; becomes upset when they are disrupted

Interruptions – hates to be disturbed when intensely involved in an activity

Idols – has a desire to be more like an admired idol

Friendship – becomes more selective about playmates

Sources of stress for the 8-year-old

Self-criticism – is very critical of personal ability and performance

Parental authority – is beginning to resent parental authority

Loneliness – likes frequent interaction with friends; may hate to miss school

Praise – continues to seek approval but can identify when praise is not genuine

Independence – many begin to stay alone for brief periods of time while parents run errands, with resulting feelings of uneasiness

Sources of stress for the 9-year-old

Rebelliousness – occasionally tests independence by rebelling

Opposite sex – engages in sex-segregated play, expresses an aversion to the opposite sex

Fair play – has a keen sense of what is fair and is vehement in demanding personal rights when a situation is perceived as unfair

Interruptions – continues to dislike interruptions but will usually resume an activity after an interruption

Propriety – has a sense of propriety and will often be upset if siblings or parents offend the child's notion of decorum or dignity

Sources of stress for the 10–12-year-old

Sexual maturation – girls, in particular, may become self-conscious regarding obvious signs of development

Social issues – a new level of awareness can generate concern regarding pressing societal problems

Size – both boys and girls may be upset by the fact that the girls are taller; the extremely small or extremely large child may be concerned about their size

Shyness – if the child already has a problem in this area, it will probably become more pronounced at this stage

Opposite sex – may become interested, yet shy, around members of the opposite sex

Confusion – too much freedom can cause the child to flounder

Health – it is not uncommon for a child to become a hypochondriac during this period of development

Money – child is anxious to earn and handle money, but often uses poor judgement

Competition – continues to be highly competitive and looks to peer group for prestige

Burnout – child may become vigorously involved in so many activities that he or she finally becomes exhausted

Self-concept – may engage in teasing, scapegoating or vicious attacks to temporarily boost their self-image; guilt often ensues; may be self-conscious about attempting a new skill

Parents – often becomes highly critical or intolerant of parents

Idols – continues hero worshipping

Fair play – continues to have a highly developed sense of fair play

Drugs and sex – may be tempted to experiment with drugs or sex because 'everyone' is doing it

Peer pressure – becomes a powerful motivating force

Self-criticism – child may be highly critical of personal performance

Kuczen B 1982 Childhood stress: don't let your child be a victim. Delacorte Press, New York.

the middle years understand the relationship between developmental abilities related to risk of injury and appropriate prevention strategies (see Table 16-12).

Long-term or chronic conditions also occur in the middle school-age years and are most commonly allergy-related conditions such as asthma, hay fever, sinusitis and eczema. Otitis media and eyesight problems are the next most common long-term conditions. This age group are also more likely to experience common health complaints such as colds, coughs, sore throats or influenza (ABS 2014).

Certain groups of middle school-age children are more prone to disease and disability, such as those with an intellectual disability, mental health disorder, learning disorder or sensory impairment. There is a well-known correlation between poverty and the prevalence of illness at any age. Children living in impoverished circumstances are often malnourished and have limited access to health care, health promotion or health prevention initiatives. A search of the relevant government's health website will identify some of the major health challenges experienced by disadvantaged families and specific cultural communities. Involvement with social reform, environmental change and person-centred methods of healthcare delivery is necessary to positively influence the future health of children and their families.

TABLE 16-12 Injury prevention during school-age years

Developmental abilities related to risk of injury	Injury prevention
Motor vehicles	
Is increasingly involved in activities away from home	Educate child regarding proper use of seatbelts when they are a passenger in a vehicle
Is excited by speed and motion	Maintain discipline while a passenger in a vehicle (e.g. keep arms inside, do not lean against doors or interfere with driver)
Is easily distracted by environment	Remind parents and children that no one should ride in the back of a ute or truck
Does not always perceive injury risk	Emphasise safe pedestrian behaviour
Can be reasoned with	Insist on wearing safety apparel (e.g. helmet) where applicable, such as when riding a bicycle or motorcycle
Drowning	
Is apt to overdo	Teach child to swim
May work hard to perfect a skill	Teach basic rules of water safety
Is cautious, but not fearful	Select safe and supervised places to swim
	Check sufficient water depth for diving
	Swim with a companion
	Use an approved flotation device in water or boat
	Adhere to legislation requiring fencing around pools
	Learn cardiopulmonary resuscitation (CPR)
Burns	
Has increasing independence	Make sure smoke detectors are in homes
Enjoys trying new things	Set hot-water temperatures to 50°C to avoid scald burns
	Instruct child in behaviour in areas involving contact with potential burn hazards (e.g. petrol, matches, bonfires or barbecues, lighter fluid, firecrackers, cigarette lighters, cooking utensils, chemistry sets); avoid climbing or flying kites around electricity wires
	Instruct child in proper behaviour in the event of fire (e.g. fire drills at home and school)
	Teach child safe cooking (use low heat, avoid frying, be careful of steam burns, scalds or exploding foods, especially from microwaving)
Substance abuse and poisoning	
May be easily influenced by peers	Educate child regarding hazards of taking non-prescription drugs and chemicals, including aspirin and alcohol
Has strong allegiance to friends	Teach child to say 'no' if offered illegal or dangerous drugs or alcohol
	Keep potentially dangerous products in properly labelled receptacles – preferably locked and out of reach

continued

TABLE 16-12 ***continued***

Bodily damage	
Has increased physical skills	Help provide facilities for supervised activities
Needs strenuous physical activity	Encourage playing in safe places
Is interested in acquiring new skills and perfecting attained skills	Keep firearms safely locked up except during adult supervision
	Teach proper care of, use of and respect for devices with potential danger (power tools)
Is daring and adventurous, especially with peers	Teach children not to tease or surprise dogs, invade their territory, take dogs' toys or interfere with dogs' feeding
Frequently plays in hazardous places	Stress eye, ear or mouth protection when using potentially hazardous objects or devices or when engaged in potentially hazardous sports (e.g. football)
Confidence often exceeds physical capacity	Teach safety regarding use of corrective devices (glasses); if child wears contact lenses, monitor duration of wear to prevent corneal damage
Desires group loyalty and has strong need for friends' approval	Stress careful selection, use and maintenance of sports and recreation equipment such as skateboards and inline skates
Attempts hazardous feats	Emphasise proper conditioning, safe practices and use of safety equipment for sports or recreational activities
Accompanies friends to potentially hazardous facilities	Caution against engaging in hazardous sports, such as those involving trampolines
Delights in physical activity	Use safety glass and stickers on large glassed areas, such as sliding glass doors
Is likely to overdo	Use window guards to prevent falls
Growth in height exceeds muscular growth and coordination	Teach name, address and phone number and to ask for help from appropriate people (cashier, security guard, policeman) if lost; have identification on child (sewn in clothes, inside shoe)
	Teach stranger safety: – avoid personalised clothing in public places – caution child to never go with a stranger – have child tell parents if anyone makes child feel uncomfortable in any way – always listen to child's concerns regarding others' behaviour – teach child to say 'no' when confronted with uncomfortable situations

Modified from Rodgers CC 2015, Health promotion of the school age child and family. In MJ Hockenberry & D Wilson (eds) 2015 Wong's Nursing care of infants and children, 10th edition, Mosby, St Louis.

Perceptions of wellness

During the middle school-age years, identity and self-concept become stronger and more individualised. Perceptions of wellness are based on readily observable facts, such as the presence or absence of illness and adequacy of eating or sleeping. Functional ability is the standard by which personal health and the health of others are judged. The middle school-age period is crucial for the acquisition of behaviours and practices for a healthy adult life. As cognition advances, possibilities for developmentally appropriate and effective health education increase. The promotion of good health practices is frequently organised and conducted within the school environment, with the support of school-based nurses working within a primary healthcare framework. Nurses support curriculum planning, teaching and learning about heath and self-care. They provide advice and information on health matters, conduct individual consultations and screening, immunisation and dental care, and are strong advocates for young people. Age-appropriate input on topics such as alcohol, drugs, tobacco, HIV, menstruation, sexual intercourse, sexually transmitted infections, reproduction, relationships and identity are all-important aspects of nursing work with middle school-age children.

Safety and nutrition

Since accidents are a leading cause of death and injury in the middle school-age period, safety is a priority health consideration. Children and young people should be encouraged to take responsibility for their own safety. Nurses working with middle school-aged children can contribute to meeting national policy goals by role-modelling healthy behaviours, promoting healthy lifestyle habits, including maintaining healthy weight and nutrition, and promoting safety measures to prevent accidents. Middle school-age children should participate in educational programs that enable them to plan, select and prepare healthy meals and snacks. Box 16-8 outlines several learning activities appropriate for this age group.

Although actual growth may slow during the middle school-age period, the body is preparing for a pubescent

BOX 16-8 School-based interventions to promote healthy nutrition

- Have young children collect pictures of healthy foods and make a poster for display in the school cafeteria.
- Make healthy foods (fruits, vegetables, whole grains, low-fat snacks) available in school vending machines and at school sporting events.
- Discourage the use of high-fat foods (lollies and chocolates) as part of school fund-raising projects.
- Avoid the use of food as rewards for behaviour; use verbal praise and token gifts to reinforce healthy eating and physical activity.
- Have teachers and school personnel model healthy eating habits.
- Ask children to select foods from a fast-food restaurant menu and to identify those foods high in fat, cholesterol and sodium.
- Ask each child to keep a diary of foods eaten in one day; using the food pyramid, evaluate these foods.
- Incorporate nutrition education into other classes (such as using a computer to analyse the nutritional content of foods).
- Have students keep a diary to identify cues for their eating behaviour (e.g. hunger, stress, other people, social situations).
- Teach students how to read and discuss the nutrition labels on foods.
- Ask students to examine television commercials, magazine advertisements and billboards to identify social influences on eating and physical activities.
- Use role-playing to help students learn to cope with social and peer pressures to eat specific foods.
- Have students identify environmental barriers to healthy eating.
- Have students prepare nutritious foods, plan menus and develop a recipe book of healthy foods.
- Involve parents in nutrition education through homework assignments or by inviting parents to attend student-led nutrition fairs.

St Ledger L, Young I, Blanchard C, Perry M 2010 Promoting health in schools. From evidence to action. Online. Available: www.dhhs.tas.gov.au/__data/assets/pdf_file/0007/117385/PHiSFromEvidenceToAction_WEB1.pdf; accessed 25 April 2015.

growth spurt, with a build-up of weight occurring at this time. Additional weight should not be a concern if the child has healthy eating habits in place. Children are invariably hungry after school and providing access to fresh fruit, raw vegetables, cheese and high-protein nutritious snacks is often the best way for a parent to ensure good nutritional intake. Children and young people can learn a great deal about a balanced diet by helping to prepare their own lunches and snacks.

Activity levels vary from day to day, and children's appetites and consumption of food varies accordingly. When children are overweight, they should be encouraged to increase their expenditure of kilojoules through exercise and vigorous play. Children who become overweight have lower self-esteem, have difficulty keeping up with other children in physical activities and may be rejected by their peer group (see *Online resources*).

• CRITICAL REFLECTION POINT

What do you know about current initiatives in the area of childhood obesity?

Preadolescence

Behavioural scientists often refer to the transitional period between middle childhood and adolescence as **preadolescence**. Others have referred to this period as late childhood, early adolescence and pubescence (Box 16-1). Physically, this developmental stage refers to the beginning of the second skeletal growth spurt, when physical changes such as the development of pubic hair and female breasts begin. These physical changes announce the approach of puberty and begin about two years earlier in girls than in boys. Children become much more social, and their behavioural patterns become much less predictable.

Development of close social networks of both same- and opposite-sex peers commences during the period of preadolescence. This expanded network may progress to new intimate relationships and is likely to influence the beliefs, perceptions and actions of this age group. These newly acquired social relations extend beyond immediate peers to other adults, providing the preadolescent with an opportunity to gain information regarding the attributes necessary for social and emotional maturity.

Adolescence

Adolescence is the period of development during which an individual makes the transition from childhood to adulthood, usually between 13 and 20 years (Box 16-1). The term adolescent usually refers to the psychological maturation of the individual, whereas **puberty** refers to the point at which reproduction becomes possible. The hormonal changes of puberty result in changes in the appearance of the young person, while mental development results in the ability to hypothesise and deal with abstractions. Adjustments and adaptations are needed to cope with these simultaneous changes and the attempt to establish a mature sense of identity. These adaptations

push the adolescent to develop coping mechanisms and styles of behaviour that will be used throughout life. Table 16-13 gives an overview of three sub-phases which are said to exist during the period of adolescence – early, middle and late adolescence.

A good understanding of development offers a unique perspective for helping teenagers and parents anticipate and cope with the stresses of adolescence. Nursing activities, particularly health education in a variety of settings inhabited by the young person, can promote healthy development.

• CRITICAL REFLECTION POINT

When caring for adolescent patients it is important to establish a partnership so that the adolescent has ownership of their care decisions and is able to maintain some independence. Thinking about Kohlberg's theory outlined in Table 16-1, adolescence is concerned with social responsibility and internalised standards; therefore, negotiation of care would provide an excellent opportunity for health education and promotion. With these thoughts in mind, what health promotion topics would you consider for the adolescent and how would you ensure information was adequately provided?

TABLE 16-13 Growth and development during adolescence

Early adolescence (11–14 years)	Middle adolescence (14–17 years)	Late adolescence (17–20 years)
Growth		
Rapidly accelerating growth reaches peak velocity Secondary sex characteristics appear	Growth decelerating in girls Stature reaches 95% of adult height Secondary sex characteristics well advanced	Physically mature Structure and reproductive growth almost complete
Cognition		
Explores newfound ability for limited abstract thought Clumsy groping for new values and energies Comparison of 'normality' with peers of same sex	Developing capacity for abstract thinking Enjoys intellectual powers, often in idealistic terms Concern with philosophical, political and social problems	Established abstract thought Can perceive and act on long-range operations Able to view problems comprehensively Intellectual and functional identity established
Identity		
Preoccupied with rapid body changes Trying-out of various roles Measurement of attractiveness by acceptance or rejection of peers Conformity to group norms	Modifies body image Very self-centred; increased narcissism Tendency towards inner experience and self-discovery Has a rich fantasy life Idealistic Able to perceive future implications of current behaviour and decisions; variable application	Body image and gender-role definition nearly secured Mature sexual identity Phase of consolidation of identity Stability of self-esteem Comfortable with physical growth Social roles defined and articulated
Relationships with parents		
Defining independence–dependence boundaries Strong desire to remain dependent on parents while trying to detach No major conflicts over parental control	Major conflicts over independence and control Low point in parent–child relationship Greatest push for emancipation; disengagement Final and irreversible emotional detachment from parents; mourning	Emotional and physical separation from parents completed Independence from family with less conflict Emancipation nearly secured
Relationships with peers		
Seeks peer affiliations to counter instability generated by rapid change Upsurge of close, idealised friendships with members of the same sex Struggle for mastery takes place within peer group	Strong need for identity to affirm self-image Behavioural standards set by peer group Acceptance by peers extremely important – fear of rejection Exploration of ability to attract the opposite sex	Peer group recedes in importance in favour of individual friendship Testing of male–female relationships against possibility of permanent alliance Relationships characterised by giving and sharing

Early adolescence (11–14 years)	Middle adolescence (14–17 years)	Late adolescence (17–20 years)
Sexuality		
Self-exploration and evaluation Limited dating, usually socialises with a group Limited intimacy	Multiple plural relationships Decisive turn towards heterosexuality (if homosexual, knows by this time) Exploration of 'self-appeal' Feeling of 'being in love' Tentative establishment of relationships	Forms stable relationships and attachment to another Growing capacity for mutuality and reciprocity Dating as a male–female pair Intimacy involves commitment rather than exploration and romanticism
Psychological health		
Wide mood swings Intense daydreaming Anger outwardly expressed with moodiness, temper outbursts and verbal insults and name-calling	Tendency towards inner experiences; more introspective Tendency to withdraw when upset or feelings are hurt Vacillation of emotions in time and range Feelings of inadequacy common; difficulty in asking for help	More constancy of emotion Anger more apt to be concealed

Modified from Ethington MD, Gallager MR & Wilson D, Health promotion of the adolescent and family. In MJ Hockenberry & D Wilson (eds) 2015, Wong's Nursing care of infants and children, 10th edition, Mosby, St Louis.

Physical changes

Physical changes occur rapidly in adolescence. Sexual maturation occurs with the development of primary and secondary sexual characteristics. *Primary characteristics* are physical and hormonal changes necessary for reproduction. *Secondary characteristics* externally differentiate males from females. The four main aspects of physical development are:

- increased growth rate of skeleton, muscle and viscera
- sex-specific changes, such as changes in shoulder and hip width
- alteration in distribution of muscle and fat
- development of the reproductive system and secondary sex characteristics.

Wide variation exists in the timing of physical changes associated with puberty between sexes, and within the same sex. In general, girls tend to begin their physical changes earlier than boys, with variations more pronounced in boys. The sequence of growth changes in puberty is the same in most individuals (see Table 16-14).

Physical changes during the period of adolescence occur when the hypothalamus begins to produce gonadotropin-releasing hormones. These signal the pituitary gland to secrete gonadotropic hormones. Gonadotropic hormones stimulate ovarian cells to produce oestrogen and testicular cells to produce testosterone. These hormones contribute to the development of secondary sex characteristics such as hair growth and voice changes, and play an essential role in reproduction. The changing concentrations of these hormones are also linked to acne and body odour.

As with increases in height and weight, the pattern of sexual change is more significant than their time of onset. However, being similar to peers is extremely important for adolescents. Any deviation in the timing of physical changes can be extremely difficult for the adolescent, and any large deviations require investigation. Emotional support is important for adolescents undergoing assessment of early or delayed puberty. Even adolescents whose physical changes are occurring within normal timeframes may seek confirmation and reassurance of their normalcy.

Height and weight increases usually occur during the prepubescent growth spurt. The growth spurt generally begins between 8 and 14 years of age for girls with height increases between 5–20 cm, and weight increases of 7–25 kg. The male growth spurt usually takes place between 10 and 16 years of age; height increases by 10–30 cm, and weight increases by 7–30 kg. The final 20–25% of adult height and final 50% of adult weight is gained during this time period (Ethington et al 2015). Girls attain 90–95% of their adult height by **menarche** (the onset of menstruation) and reach their full height by 16–17 years of age, whereas boys continue to grow taller until 18 to 20 years of age. Fat is redistributed into adult proportions as height and weight increase, and gradually the adolescent torso takes on an adult appearance.

TABLE 16-14 Average sequences of physiological changes in adolescence

Characteristics	Girls*	Boys*
Beginning of skeletal growth spurt	8–14½ (peak: 12)	10–16½ (peak: 14)
Beginning of breast development	8–13	
Enlargement of testes and scrotal sac		10–13½
Appearance of straight, pigmented pubic hair, which gradually becomes curly	8–14	10–15
Early voice changes (cracks)		11–14½
Enlargement of penis and prostate gland		11–14½
Menarche	10–18 (average: 12¼)	
Spermatogenesis (ejaculation of sperm)		11–17 (average: 13½)
Ovulation and completion of breast development	14–18 (average: 15½)	
Appearance of downy facial hair		12–17
Appearance of axillary (underarm) hair and increased output of oil and sweat-producing glands, which may lead to acne	10–16	12–17
Widening and deepening of female pelvis, with deposition of subcutaneous fat that gives rounded appearance to body	10–18	
Increase in shoulder width		11–21
Deepening of voice in males, with appearance of coarse and pigmented facial hair and appearance of chest hair		16–21

* Age ranges are in years.

Modified from Ethington MD, Gallager MR & Wilson D, Health promotion of the adolescent and family. In MJ Hockenberry & D Wilson (eds) 2015, Wong's Nursing care of infants and children, 10th edition, Mosby, St Louis.

Although there are many individual and gender differences, growth follows a similar pattern for both sexes. Growth in the length of extremities occurs earliest, making the hands and feet appear very large and the legs very long; the individual often appears awkward and clumsy. At the same time the lower jaw and nose become longer and the forehead higher and wider, as the baby face of childhood disappears. Next the thighs widen; then the shoulders broaden, and growth of the trunk proceeds. Widening of the female hips and broadening of the male shoulders continues throughout adolescence.

Recording individual growth during routine health assessments helps to assess physical development and evaluate any change in pattern. Sustained progression along a growth curve is more important than comparison against a norm. Adolescents are sensitive about physical changes that make them different from peers. For this reason they are generally interested in the normal pattern of growth and their personal growth curves. Sharing information and discussing normal patterns and variations reassures adolescents that their own patterns are normal.

Cognitive changes

The widening social environment of the adolescent continues to shape cognitive capacity, resulting in the highest level of intellectual development described by Piaget as 'formal operations' (Table 16-1). Without an appropriate educational environment, young people who possess sufficient neurological capacity to reach this stage may not attain it. Conversely, those who are guided towards education and rational thinking may reach this stage early. Swartz (2009) notes that adolescence is a time of behaviour change with this age group more likely to initiate 'multiple risk taking behaviours' possibly contributing to potentially preventable health problems associated with smoking, drug and alcohol use, unintended pregnancies, sexually transmitted disease and sedentary habits.

The adolescent develops the ability to solve problems through logical operations. The adolescent can think abstractly and deal effectively with hypothetical problems. When confronted with a problem, the adolescent can consider an infinite variety of causes and solutions. For the first time, the young person can move beyond the physical

or concrete properties of a situation and use reasoning powers to understand the abstract. Middle school-age children think about what is, whereas adolescents can imagine *what might be*. These newly developed abilities allow the adolescent to have more insight and skill in playing games (such as video, computer and board games) that require abstract thinking and deductive reasoning about many possible strategies. An adolescent can even solve problems requiring simultaneous manipulation of several abstract concepts.

Development of these higher-level abilities is clearly important for the pursuit of education and for establishing an identity. For example, newly acquired cognitive skills allow the adolescent to define appropriate, effective and comfortable sex-role behaviours and to consider their impact on peers, family and society. The ability to think logically about these behaviours and their outcomes encourages the adolescent to develop personal thoughts and means of expressing sexual identity. In addition, a higher level of cognitive functioning makes the adolescent receptive to more detailed and diverse information about people and their behaviours.

By mid-adolescence there is an introspective quality emerging with regard to cognition. At this time adolescents believe an 'imaginary audience' (Elkind 1998) provides them with an evaluative means and a sense of being unique. This concept may account for some typical adolescent behaviour, including self-consciousness and the desire for privacy. Elkind (1998) also describes another characteristic of cognitive function, the personal fable. This is a story created by the adolescent that is not true. This developmental milestone may account for undesirable risk-taking behaviours, since the adolescent believes they are immune from negative consequences.

This complex development of thought also leads adolescents to question society and its values. While adolescents have the ability to think equally as well as an adult, they do not have experiences on which to build their thoughts. It is common for adolescents to consider their parents narrow-minded or materialistic. Cognitive abilities and performance vary greatly and, in fact, an adolescent may perform at different levels in different situations based on their past experiences, formal education, motivation in the use of logic, and effective deductive reasoning.

Language development is mostly complete by adolescence, although vocabulary continues to expand. The main focus becomes communication skills that can be used effectively in various situations. Adolescents need to communicate thoughts, feelings and facts to peers, parents, teachers and other persons of authority. The skills used in these diverse communication situations are varied. Adolescents must select the person with whom to communicate, decide on the exact message and choose the way to transmit the message. For example, the way adolescents tell parents about failing a subject is not the same as the way that they tell friends on social media. The increasing influence of social media on the developing adolescent is significant and is a topic of considerable debate, particularly with reference to cyber bullying. Adolescents develop different skills and styles of communication and learn how and when to use them most effectively (Figure 16-8). These diverse communication skills are used and refined throughout life. Good communication skills are critical for adolescents to overcome peer pressure to participate in non-healthy or risky behaviours.

Figure 16-8 Interacting with peers helps to increase self-esteem during puberty.

Psychosocial changes

The search for personal identity is the major task of adolescent psychosocial development. Adolescents must establish close peer relationships or risk remaining socially isolated. Erikson sees identity (or role) confusion as a prime challenge of this stage (Table 16-1) and suggests that the cliquishness and intolerance of differences seen in adolescent behaviour are defences against this confusion (Simanowitz & Pearce 2003). Adolescents work at becoming emotionally independent from their parents, while retaining family ties. In addition, they need to develop their own ethical systems based on personal values. Choices about vocation, future education and lifestyle must be made. The various components of total identity evolve from these tasks and compose an adult personal identity that is unique to the individual. Behaviours indicating negative resolution of developmental tasks for this age are indecisiveness and the inability to make an occupational choice.

According to Erikson (1968), adolescence provides a time-out period when society allows the physically mature teenager to delay the assumption of adult responsibilities. This is a time for young people to try a variety of ideological and vocational roles before making a commitment. This psychosocial moratorium ends in the selection of values and a consolidation of identity.

Sexual identity

Achievement of sexual identity is enhanced by the physical changes of puberty (Figure 16-9). In Freud's view, these physiological changes reactivate the *libido*, the energy source that fuels the sex drive. This is evidenced by the adolescent's interest in developing intimate relationships with partners outside of the family, and the practice of masturbation. The physical evidence of maturity encourages the development of masculine and feminine behaviours. If these physical changes involve deviations from what is perceived normal, the young person has more difficulty developing a comfortable sexual identity. Adolescents depend on these physical clues because they seek assurance of maleness or femaleness, whereas others may seek non- or trans-gendered identities. Other influences are cultural attitudes and expectations of sex-role behaviour and available role models.

Group identity

Adolescents also seek a group identity because they desire esteem and acceptance; however, this need may conflict at times with the search for personal identity. Similarity in dress or speech is common in adolescent groups and popularity is a major concern. Trends in the desire for popularity have not changed significantly in recent years. Peer groups provide the adolescent with a sense of belonging and approval and the opportunity to learn acceptable behaviour. Popularity with both opposite-sex and same-sex peers is important.

Figure 16-9 Adolescents acquire sexual identity during social interaction.

© Petrenko Andriy.

Family identity

The movement towards stronger peer relationships is contrasted with the adolescent's movement away from parents. Although financial independence is not the norm for adolescents growing up in developed nations, many adolescents work part-time, using their income to bolster independence. When adolescents cannot have a part-time job because of studies, school-related activities or other factors, financial allowances for clothing and incidentals encourage adolescents to develop decision-making and budgeting skills.

Some families have more difficulty during the adolescent years than others. Adolescents need to make choices, act independently and experience the consequences of their actions. This is most safely tested within a firm, supportive family environment. This environment may involve curfews and participation in family chores. Emancipation from the immediate family is most successful when accomplished gradually. Families unable to provide this support complicate movement towards identity formation.

Vocational identity

The selection of an occupation or vocational direction in life provides a goal for adolescents and a path to possible further education. Because of society's changing needs, adolescents must be future-oriented when making these choices. However, adolescents do not know which jobs will be available or which jobs will be rewarding 10 or 20 years in the future. Selecting a career is a complicated task and the emotional support of family and friends helps adolescents to select courses of action that promote self-satisfaction, self-identity and continued opportunities for growth.

Moral identity

Not all adolescents attain the same level of moral development. There is, however, a general forward movement through the stages of moral development, with similar sequencing for all individuals, even when their time of achievement varies. Kohlberg (1964) explains moral development in terms of stages (Table 16-1), with the highest level derived from individual principles of conscience. Kohlberg's theory has a focus on justice, based on reciprocity and equal respect. Adolescents judge themselves by internalised ideals, which often lead

to conflict between personal and group values; however, group values become less significant in later adolescence.

The development of moral judgement depends heavily on cognitive ability, communication skills and peer interaction. Although moral development begins in early childhood, it is consolidated in adolescence because of the development of certain skills. Adolescents learn to understand that rules are cooperative agreements that can be modified to fit the situation, rather than absolutes. Adolescents learn to use their own judgement to avoid punishment rather than using the rules, as in earlier years.

Perceptions of wellness

Another component of personal identity is the perception of health and wellness. This component is of specific interest to healthcare providers. Healthy adolescents tend to evaluate their own health according to feelings of wellbeing, their ability to function normally and the absence of symptoms (Ethington et al 2015). The rapid changes during this period make health promotion programs especially crucial (see *Research highlight*). Adolescents try new roles, begin to stabilise their identity and acquire values and behaviours from which their adult lifestyle will evolve. Interventions to improve health might, therefore, concentrate on the adolescent period.

Other adolescent health considerations

There has been a significant amount of research by governments, health and welfare groups and others interested in reducing adolescent risk-taking behaviours and their consequences. Study results vary from place to place, and from time to time. You will be able to gather the most current statistics by accessing websites such as those of the Australian Bureau of Statistics, the Australian Institute of Health and Welfare, the Australian Department of Health and Ageing and the New Zealand Ministry of Health (see *Online resources*). The following section provides information about some of the most common areas of health risk for adolescents.

Accidents

Accidents remain the leading cause of death in Australian and New Zealand adolescents. Motor vehicle accidents, which are the most common cause of death, result in almost half of the fatalities from the mid-teen years. These accidents are often associated with alcohol or drug

RESEARCH HIGHLIGHT

Research focus

The physical, social and cognitive needs of adolescents requiring inpatient health services is an important health promoting strategy, and one overlooked in health-service infrastructure. Multiple negative risk-taking behaviours often adopted during the adolescent period frequently result in negative health outcomes. Adopting health strategies that focus on these clustered negative behaviours and their occurrence together is vital. Health education programming designed to address multiple risk behaviours concurrently in youth may be warranted.

Research abstract

The purpose of this study was to examine the co-occurrence of eight negative health behaviours among adolescents in order to inform educational interventions. The prevalence, co-occurrence and clustering of suicide attempt, lifetime history of sexual activity, tobacco use, mobile phone use while driving, risky weight loss, daily softdrink consumption, sedentary behaviour and extreme video game use were examined among 1354 high school students. The results showed that more than 80% of students engaged in one to three risk behaviours. Ever having sex was the most common co-occurring risk behaviour and four distinct clusters of risk behaviours emerged. The findings suggest that the adoption of multiple risk behaviours is extremely common among the adolescent population and therefore health education strategies should be designed to address multiple behaviours rather than focusing on the one, for example, smoking and sexual health.

Evidence-based practice

- Adequate and specialised education should be provided for nurses in psychosocial, physical developmental challenges and risk-taking behaviours of adolescents.
- There needs to be specific education and training for nurses in communication with the adolescent population in regard to sensitive subjects.
- Facilities need to be organised to promote age-appropriate physical, cognitive and social activity and behaviour for adolescents.
- Independence and autonomy need to be supported and guided by including adolescents in decision-making and scheduling of daily activities and treatments when they are inpatients.

use. Adolescents are more likely than other age groups to never or rarely use a seatbelt, ride a motorcycle or a bicycle without a helmet, ride with someone who has been drinking alcohol, become involved in fights and seriously consider suicide (AIHW 2010, Ministry of Health 2014). The other frequent cause of accidental death in teenagers is drowning.

Suicide

Suicide rates remain a focus of attention in Australian and New Zealand adolescents, especially males. Even though rates have been declining, suicide remains the leading cause of death for all Australians aged 15–34 years (ABS 2010). A review by Harrison and others (2009) showed that the rate of suicide in Australian males had declined from 29.8 per 100,000 in 1997 to 17.0 per 100,000 in 2006. Equivalent rates for females were 7.8 and 4.8 per 100,000, respectively. Similarly, data from the New Zealand Ministry of Health (2014) also shows that in 2011, the rate of suicide among youth (aged 15–24 years) decreased by 32.8% since the peak in 1995. The male-to-female youth suicide ratio is 2.8:1, and the combined suicide rate for New Zealand youth is 19.3 deaths per 100,000. Suicide in Indigenous young people accounts for 4.2% of all deaths compared to 1.6% for all Australians (ABS 2010). Youth suicide rates from both countries continue to remain almost double those of all ages, and males continue to have higher rates than females (Harrison et al 2009, Ministry of Health 2014).

Young males are more successful at suicide attempts than females, in part because of the methods they use. Depression and social isolation commonly precede a suicide attempt, but suicide probably results from a combination of several factors. Although suicide is a complex issue, there are warning signs which often occur for at least a month before suicide is attempted:

- decrease in school performance
- withdrawal
- loss of initiative
- loneliness, sadness and crying
- appetite and sleep disturbances
- talking about suicide.

Other associated suicide risk factors are listed in Box 16-9. Where nurses are working with youth, it is important they know the factors associated with adolescent suicide risk and how these interact with precipitating events. Immediate referrals to mental health professionals need to be made when assessment suggests that adolescents are depressed or may be considering suicide. Guidance can help adolescents focus on the positive aspects of life and strengthen their coping abilities. The need for

BOX 16-9 Suicide risk factors

Past history

- Previous suicide attempt
- Family member or friend has made a suicide attempt
- History of child abuse or neglect
- Past psychiatric hospitalisation
- Death of a parent when child was young

Individual factors

- Hopelessness
- Marked, persistent depression
- Alcohol or drug abuse
- Impulsiveness
- Difficulty tolerating frustration
- Feelings of self-hatred or excessive guilt, feelings of humiliation
- Thinking disorder (wishes to join a deceased person, hears voices telling to kill self)
- Physical/body image problems (delayed puberty, chronic illness, disability, attention deficit hyperactivity disorder, learning disorders)
- Gender identity concerns; gay or lesbian in an unsupportive environment
- Sees self as totally helpless – a victim of fate
- A need to do things perfectly

Family factors

- Difficult home situation – long, bitter parent–child conflict
- Hostile parents
- Overt rejection by one or both parents
- Divorce or separation of parents
- Recent or impending move
- Family break-up or parental loss
- Exposure to unrealistically high parental expectations
- Parental indifference with very low expectations

Social/environmental factors

- Firearms in the home
- Incarceration
- Lack of effective social support system
- Isolation
- Exposure to suicide of another
- Few social, vocational, educational opportunities

McLean J, Maxwell M, Platt S et al 2008 Risk and protective factors for suicide and suicidal behaviour: a literature review. Scottish Government Social Research, Edinburgh. Online. Available: www.gov.scot/Publications/2008/11/28141444/0; accessed 15 April 2015; World Health Organization 2014 Preventing suicide: A global imperative. Geneva. Online. Available: www.who.int/mental_health/suicide-prevention/world_report_2014/en/; accessed 10 April 2015.

suicide intervention has been recognised, including the need for training health professionals to screen for suicide ideation, intent and risk (Yearwood & DeLeon Siantz 2010).

Substance abuse

Many adolescents attempt experimental or recreational substance use, but those who have unconventional values or difficult family situations may be at greater risk of chronic use and physical dependency. Adolescents may believe that mood-altering substances create a sense of wellbeing or improve their level of performance. Some adolescents believe that substance use makes them more mature. The Australian Institute of Health and Welfare and the New Zealand Ministry of Health both publish current data concerning drug use in young people. The most recent reports are based on data collected during 2007–08, which you can access from the websites listed in *Online resources*.

Eating disorders

Adolescent girls or young women form the largest group suffering from eating disorders, but males of the same age groups are also represented. The number of young people with eating disorders continues to increase. Such disorders are associated with the developmental challenges of identity and autonomy, and the social constructions of body image (Chapter 20), rather than with diet. Eating patterns and extreme weight changes may offer clues to the presence of an eating disorder. Areas to include in health assessment are past and present diet history, food records, eating habits, attitudes, health beliefs and socioeconomic and psychosocial factors (Forman et al 2015).

Although anorexia nervosa and bulimia are classified as separate eating disorders, there is significant overlap between the two and up to 50% of patients with anorexia develop bulimic tendencies (Devlin et al 2010). *Anorexia nervosa* is considered a clinical syndrome with both physical and psychosocial components. The majority of sufferers are adolescents and young women. Attending a highly competitive school and being from a professional, upper-middle-class family increases the risk of this disorder. People with anorexia nervosa have an intense fear of gaining weight and use their bodyweight and image to control their environment and identity. *Bulimia nervosa* is most identified with binge-eating and behaviours to prevent weight gain. Behaviours include self-induced vomiting, misuse of laxatives and other medications, and excessive exercise. Because adolescents rarely volunteer information about behaviours to prevent weight gain, it is important to take a thorough dietary history. Bulimia is considered a biopsychosocial illness. Both anorexic and bulimic people have a strong awareness of society's emphasis on being thin.

Sexual experimentation

Sexual experimentation is common among adolescents. Peer pressure, physiological and emotional changes, and societal expectations, contribute to early heterosexual and homosexual relations. The proportion of young people who are sexually active in their mid-teenage years continues to increase (AIHW 2011). By about 14 years of age, 27% of Australian adolescents report being sexually active and that number increases to 56% by 18 years of age. New Zealand figures show that around 24% of adolescents report having had sexual intercourse while around 18% report being sexually active (Adolescent Health Research Group 2012). Young people from Indigenous groups report becoming sexually active at an earlier age (AIHW 2011, Ministry of Health 2001). The two most challenging consequences of adolescent sexual activity are sexually transmitted infections and unwanted pregnancies.

Sexually transmitted infection

Knowledge of the symptoms and types of **sexually transmitted infections (STIs)** is generally poor among this age group and many adolescents remain unaware of the short- and long-term consequences of contracting even the most common STIs (AIHW 2011). The high incidence of STIs makes it imperative that sexually active adolescents be screened, even when they have no symptoms. The annual physical examination of a sexually active adolescent should include a thorough sexual history and a careful examination of the genitalia. Recommended tests for young women include Papanicolaou (Pap) smears. The healthcare provider can take the initiative by using the interview process to identify risk factors in the adolescent and initiate prevention and targeted screening. For the most current information about STIs, visit the family planning websites listed in *Online resources*.

Infection with the human immuno-deficiency virus (HIV), which may progress to acquired immune deficiency syndrome (AIDS), is transmitted through unprotected sexual intercourse, the use of shared needles, and infected blood products. Education about HIV and other diseases associated with sexual intercourse has been only partially successful in reducing risk-taking behaviours. Therefore, the risks associated with adolescent sexual activity and drug-use make adolescents one of the most vulnerable groups for acquiring HIV. Again, the family planning websites listed in *Online resources* will give you the most up-to-date information.

Pregnancy

The rate of adolescent pregnancy has fallen in Australia as a result of effective education, the ready availability of contraception and, in most states, legal abortion. The birth rate in adolescents reached an all-time low in 1988 and has remained below 20 babies per 1000 female teenagers aged 15–19 years ever since. The most recent statistics from the Australian Bureau of Statistics show that the rate of teenage pregnancy for 2012 was 16.1 per 1000 in the 15–19-year age group (ABS 2013).

Adolescent pregnancies occur in young women from all socioeconomic classes, all ethnic and religious backgrounds, and in all parts of the country. Two factors believed to account for adolescent childbearing trends are adult childbearing levels and trends, and poverty. The Australian Bureau of Statistics, Australian Institute of Health and Welfare and family planning websites will give you more information related to these issues.

General health concerns

Adolescence is an important period for the formation of healthy habits of daily living. Emphasis on exercise, sleep, nutrition and stress-reduction are increasing general health concerns.

Health education

Community and school-based health programs for adolescents focus on health promotion and illness prevention. Nurses are involved in community health through screening and health education programs. The services provided to adolescents must be easily accessible and confidential. Not surprisingly, adolescents are more likely to reveal intimate information about their risk-taking behaviours when they feel comfortable and respected within the interaction.

Nurses can play an important role in preventing injuries and accidental deaths. Encouraging adolescents to openly discuss alternative plans to driving when under the influence of drugs or alcohol prepares them to consider other options when such an occasion arises. Identifying adolescents at risk provides an opportunity to prevent accidents related to substance abuse and to provide counselling to those in rehabilitation. Effective adolescent health care focuses on health promotion while also engaging with the adolescent to address issues of role conflict, identity, parental involvement, confidentiality, and the varied coping strategies that are common to this group (Swartz 2009). Sex education and relationship counselling are also important areas where nurses can support adolescents. Nurses are in a good position to help adolescent mothers access support services and continue their education, by helping to organise flexible teaching and learning arrangements, uniforms and alterations in attendance schedules, as well as integration of an infant into the school environment.

Rural adolescents

Declining rural populations, the global financial crises, long distances between population centres, together with the subsequent reduction of opportunities and services, can have negative influences on adolescents living in rural or remote areas. Areas of concern for these adolescents include all of the above health risks, as well as risk of farm accidents, limited access to health care, limited privacy inherent in small towns, and possible lack of transportation to health care due to poverty or circumstance (e.g. lack of public transport). Nurses have always played an important role in rural areas, particularly where other types of medical support are lacking. Decreasing barriers to care, facilitating health promotion education and self-care, developing coping strategies and assessment of health beliefs are important areas where nurses can contribute.

Indigenous adolescents

Indigenous youth have a special set of challenges. Indigenous adolescents may feel alienated both from mainstream society and from traditional culture. They may experience a higher incidence of health problems and greater barriers to health care than their non-Indigenous peers. Health issues confronting Indigenous adolescents living in both urban and isolated areas include learning or emotional difficulties, violence, death from suicide, accidental injuries, poverty and high rates of adolescent pregnancy and STIs. The rate of alcohol and drug abuse is especially high within Australian Indigenous youth, with petrol sniffing of particular concern (Australian Indigenous HealthInfoNet 2010).

Culturally safe practice includes identifying personal ethnocentrism, stereotypes and prejudices and learning about social group dynamics in order to understand the issues and identify effective culturally sensitive coping strategies that enable Indigenous adolescents to overcome stresses inherent in their environment. In addition to the political, economic, social, cultural, environmental, behavioural and biological factors that influence health and wellbeing, health practitioners should also be aware that for many Indigenous peoples, health also has important spiritual and cultural dimensions (Commissioner for Children and Young People 2014). Health-promoting initiatives must incorporate these factors and be based on topics of concern for Indigenous adolescents themselves. Further, the appropriate presentation of health-promoting materials, in terms of methods and language, is not only important for Indigenous youth, but for all young people.

Key concepts

- Growth and development are patterned, complex and interdependent processes that continue throughout life.
- Nurses care for children at various developmental stages and during various transitions. Developmental theory provides a basis for nurses to assess and understand behavioral and other responses to health issues and treatments.
- Developmental theory is a way to account for how and why children grow as they do. Theories provide a framework and a way to clarify and organise existing observations to explain and predict behaviour.
- A developmental perspective helps the nurse understand commonalities and variations in developmental tasks and challenges for infants, young children and adolescents and the impacts these have on the client's health.
- The interdependence of physical, cognitive and psychosocial development means that each can affect infant, child or adolescent achievement at any particular stage.
- Growth and development are internally influenced by heredity and temperament, and are externally influenced by family, peers, life experiences and environmental elements.
- Because the embryo and fetus grow and develop throughout the intrauterine period, genetic factors and environmental factors (teratogens) may affect body systems in-utero.
- Physiological, cognitive and psychosocial developmental challenges continue from conception to adolescence. Nurses and other health professionals must be familiar with normal parameters to identify potential problems and promote optimal growth and development.
- Physical growth during the school years is slow and steady until the skeletal growth spurt just before puberty.
- The major psychosocial developmental task of the school-age child is the development of a sense of industry, which is gained through personal achievements and results in positive self-esteem.
- Cognitively, the young school-age child develops conservation, the mental operation that allows thought processes to become more logical.
- The prepubescent growth spurt usually occurs two years earlier in girls than in boys; during this time, development of secondary sexual changes begins.
- Adolescence begins with puberty, when primary sexual characteristics begin to develop and secondary sexual characteristics complete development.
- The adolescent is able to solve complex mental problems, use deductive reasoning and hypothesise about the future.
- The adolescent's rapid change in physical appearance heightens self-consciousness and concerns regarding body image.
- Accidents are a major cause of death in childhood and adolescence.

CHAPTER

17

Considering the developmental context of youth and adults

Robyn Rosina

Learning outcomes

Mastery of content will enable you to:

- discuss developmental theories of young and middle-aged adults
- list and discuss major life events of young and middle-aged adults and the childbearing family
- describe developmental tasks of the young adult, the childbearing family and the middle-aged adult
- discuss the significance of family in the life of the adult
- describe normal physiological changes in young and middle adulthood and in pregnancy
- discuss cognitive and psychosocial changes that occur during the adult years
- describe health concerns of the young adult, the childbearing family and the middle-aged adult
- apply the nursing process to administer care to young and middle-aged adults.

KEY TERMS

Biophysical development, p. 360
Climacteric, p. 386
Cognitive development, p. 368
Developmental pathway, p. 357
Emotional health, p. 373
Epigenetics, p. 375

Maturity, p. 362
Menopause, p. 385
Middle age, p. 389
Moral development, p. 369
Personal lifestyle assessments, p. 373
Pregnancy, p. 381
Psychosocial development, p. 363
Psychosomatic illness, p. 389
Puerperium, p. 383
Routine health screening, p. 389
Vocational adjustment, p. 375
Young adulthood, p. 363

This chapter will discuss human life from age 25 to 64 years and will focus on life transition at the close of adolescence through young adulthood and the middle years of adult life. The focus will include theoretical and health-promoting perspectives.

A young person moving from adolescence to young adulthood and then on to the middle years is in a constant state of change. This change includes physical development (although settling into a normal rhythm for most at this point, apart from pregnancy, birth and lactation) and psychosocial development. The individual both experiences, and responds to, multiple interactions from the external world and as a consequence of life experiences, undertakes significant change and growth. In order to place youth and adulthood within a developmental context, this chapter presents a further explanation of human development theories introduced in Chapter 16, followed by a health risk and health promotion focus on young and middle adulthood of life.

The experience of good health optimises the unique response of the individual's interaction with the world. The presence of good health and the ability to contribute to responsive caregiving, further enhances physical growth and psychosocial progression. In contrast, the presence of poor health as a consequence of either acute (excluding short self-limiting illnesses) illness, injury, chronic illness, disability (congenital or acquired, including mental illness) or trauma can lead to suboptimal physical and psychosocial developmental outcomes. A positive or successful growth and developmental outcome in adult life is often regarded as a personal sense of happiness and wellbeing, or a feeling of life fulfilment, despite the experiences of adversity and challenge that are evident in every human life. Poor health or wellbeing, and insufficient access to health resources, challenges individuals and communities and can impede the rate of physical growth and the quality of psychosocial development at any given time in human life.

Each individual developmental outcome is mediated by a unique response to interactions between our internal and external worlds. The external environment is made up of people and resources that enable good health and safety and this environment constantly mediates the internal world, in multiple ways and in multiple settings. This interaction can be referred to as a person–environment context. As the person interacts with the environment, physical growth and psychosocial developmental progression can potentially be achieved. This process is often referred to as a **developmental pathway** and is the focus of development theories. In this chapter we will first examine and discuss the theoretical understandings of growth and development during young adulthood to the middle years of adult life. This will be followed by a discussion of some of the expected health experiences of individuals during the life course from young to middle adulthood.

Human development theory

We saw in Table 16-1 (p. 304) how the human development theories of four well-known theorists (Freud, Erikson, Piaget and Kohlberg) offer a framework for us to more easily understand, explain and predict the human developmental trajectory. This trajectory can be explained as a number of stages or milestones that are achieved throughout the course of human life, with development relying on successfully achieving the milestones of each stage. In this chapter we will return to these theorists, as well as introducing others related to human growth and development. These theoretical frameworks and developmental trajectories are particularly helpful when assessing normal and abnormal development alongside a health problem when individuals access healthcare services. Knowledge of the normal or usual trajectory offers a context for nurses and other health professionals to examine, assess, support and potentially optimise the physical and psychosocial developmental context for individuals receiving health care and to make recommendations for self-care. But first, let's review some of the basic terms introduced in Chapter 16.

Growth versus development

In the previous chapters we have described the difference between growth and development. *Growth* refers to the quantitative changes that can be measured and compared with norms, for example, taking the height and weight of a child and comparing the measurements with standardised growth charts. *Development* implies a progressive and continuous process of change leading to a state of organised and specialised functional capacity; for example, a child's progression from rolling over to crawling to walking. In the context of this chapter, another example of developmental progression is the adolescent achieving a sense of identity and role for life as they begin study and then work, or a young adult achieving intimacy with another, or an adult achieving a meaningful relationship with another.

Growth and development theories

Without necessarily being aware of doing so, we frequently use theories to guide behaviours in our daily lives. Theories are not just guesses – they are based on information from

our existing knowledge and previous experiences. For example, I have a theory that if I drive my car through a red light there can be three possible outcomes. First, I may have an accident, crashing into another car or pedestrian; second, I may be fined and lose demerit points on my licence; or third, I may be lucky and get away with it without having an accident or getting caught. This is a simple theory based on what normally happens in a specific circumstance and the logical possibilities. Such a theory can be used to guide the way we behave, taking into account the likelihood of each outcome so that a favourable one is more likely. In the example above, knowing the chances of each outcome of driving through a red light may guide us to make a sensible and informed decision. Of course, there are many other factors that will influence such decisions, such as if we are affected by alcohol, in a great hurry, talking on the mobile phone, bad weather and so on.

Theories are, therefore, a series of logically connected hypotheses based on evidence about particular situations which allow us to explain and predict potential outcomes. The example of the red light is not a very complex situation compared with a theory about the kind of conditions required for a child to develop into a physically, emotionally and socially healthy adult. Complex situations require more complicated theories with many propositions. When we try to understand what resources a person needs to develop into the best adult he or she can be and to maintain that state throughout adulthood, we have a very complex situation with multiple internal and external factors influencing the outcome.

In order to understand the continuation of growth and development into youth and middle adulthood, or the continuing formation of human personality, we require not just one but many theories. These theories explore aspects of personality development as well as the physical and cognitive abilities influencing a person's ability to make ethical decisions that affect the wellbeing of themselves and others. Understanding how people develop psychosocially, physically, cognitively and morally is tremendously important for nurses because we often meet people at vulnerable moments, when they are facing crisis points in their lives. The way we support people to manage these crises can have long-term ramifications and impact on their successful physical and psychosocial development. Sensitive and knowledgeable support from healthcare professionals can help people negotiate these crises more effectively.

Theories of human growth and development were established through systematic observations of people as they went about their daily lives. There are, however, several caveats that we should bear in mind when applying such theories to specific situations.

1. While theories are built upon layers of evidence, they may apply in many but not all circumstances.
2. It is very difficult to be certain of developmental predictions because it is often impossible to undertake systematic research to test them, partly because it is not possible to compare results with control groups.
3. It is important to keep in mind that it is not possible for any theorist to observe people from all cultures.

Therefore, theories are necessarily culturally based in most situations and as a result their propositions may not be universally applicable. Indeed, attempts to generalise across cultures inevitably gives rise to erroneous conclusions (see Chapter 14). Australia and New Zealand are both multicultural societies and as nurses we will care for people from many diverse backgrounds and cultures. While our personal experience may be limited in terms of understanding the extent of diversity, we know that people are more similar than they are different. Developmental theories can therefore offer a useful guide about what to expect at various stages of life, regardless of culture, but this is only possible if theories are not applied too rigidly.

It is also important to remember that growth and development is not a linear process, but possibly for ease of description, many developmental theories are presented in a linear way. The theories referred to in this chapter are meant to form the basis of a meaningful observation of an individual's multidimensional pattern of growth and development. All theories require validation through research and application to become fact. Developmental theories are, however, valuable guides for understanding important human processes that can allow nurses to begin to predict human behaviours and responses to specific stressful situations and recognise normal and abnormal health behaviours.

In this chapter we consider theories not only from the perspective of the individual theorist, but within the context of a broader world view (Ecological Systems Theory) and within the four major areas of human development: *biophysical*, *psychosocial*, *cognitive* and *moral*. Developmental theories help nurses to use critical-thinking skills to understand how and why people respond as they do to certain situations in health and illness. From the diverse set of theories included in this chapter, and the experiences of health and ill-health discussed, the complexity of human behaviour becomes easier to understand. However, when applying theories it is important to keep in mind that no one theory successfully describes human growth and development in all of its complexity, nor the uniqueness of human beings.

Theorists themselves demonstrate their own values and beliefs through the focus of their theoretical explanations, as well as in the subjects chosen for their work, and work within their own socio-cultural and historical context to understand the uniqueness of human experience.

Ecological systems theory

Urie Bronfenbrenner, a Russian psychologist, offers Ecological Systems Theory (EST) as a frame to understand the context for human development. Bronfenbrenner's clinical work began in the military during World War II and was concerned with the effects of social adversities such as war on the psychological development of individuals (Bukowski & Cillessen 1998). Bronfenbrenner strongly believed that human development is a result of the interactions between individuals and the environment they live within. His theory argues that human development is an outcome of interactions between the individual (internal world) and their environment (external world) (Figure 17-1).

The central tenet of EST is that the developmental outcome of individuals, particularly those facing adversity, can potentially be manipulated within the internal and external environments to enhance or impede developmental outcomes. For example, the developmental outcome for children living in low socioeconomic areas can be influenced by providing sufficient access to good health services. EST is widely referred to in the literature as a means of organising complex systems into a logical framework to understand human development and how it can be enhanced by improvements to the personal and environmental context. The environmental (external) context provides opportunities for nurses and others to bring about positive change or promote health to individuals as they access healthcare services.

Biophysical development theories

Biophysical development is concerned with the way our bodies change physically over time. In the following sections we look at theories about how children develop as they grow and how adults change as they age. As infants grow into adults, their physical changes can be measured. Such measurements can then be compared with those that normally occur, known as 'established norms'. The progress

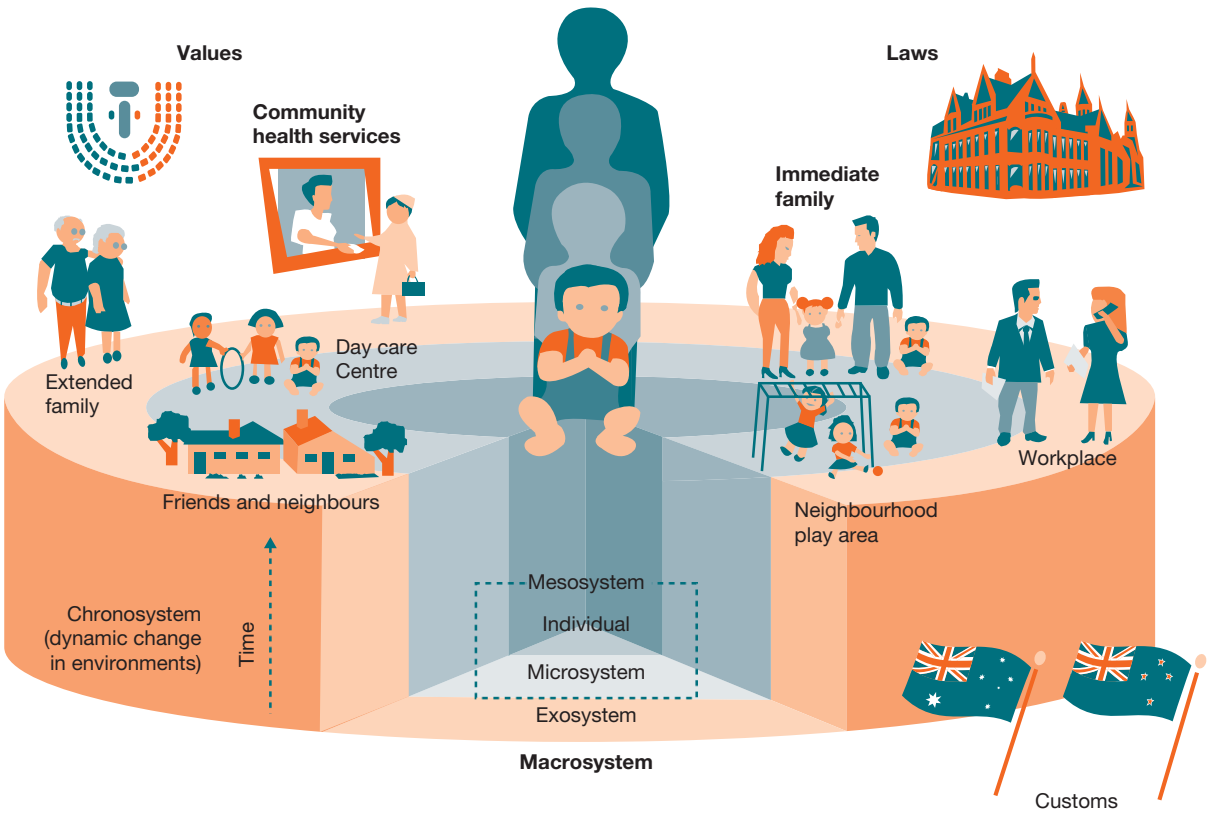

Figure 17-1 Ecological Systems Theory.

Adapted from Bronfenbrenner U 1995 The bio-ecological model from a life course perspective: reflections of a participant observer. In P Moen, GHJ Elder (eds), Examining lives in contexts: Perspectives on the ecology of human development. American Psychological Association, Washington.

of a child's maturation into adulthood can therefore be monitored against these normative standards.

Gesell's theory of biophysical development

Arnold Gesell (1880–1961) was a psychologist and doctor who initially studied development in children with an intellectual disability. He soon came to realise that to understand abnormal development, it is necessary to first understand the process of normal development. Gesell (1948) was one of the first theorists to describe **biophysical development** based on his observations of children and, as a consequence, he developed norms for the typical age at which children reach developmental milestones. Such milestones included motor development, personal hygiene tasks, expression of emotions, interpersonal relations and play. These norms are still used as primary sources of information for childhood development today.

Gesell's (1948) observations led him to believe that although each child's pattern of growth and development is unique, it remains genetically based. Environmental (including cultural) factors can support and modify the pattern, but do not generate it. Through his observations he learned that maturation has a fixed developmental sequence in all humans. For example, most children will learn how to crawl before they learn how to walk, but not every child develops those skills at exactly the same time. Gesell concluded that the environment does play a part in the development of a child, but it does not play any part in the *sequence* of development. Gesell believed that a child could not be pushed to develop faster than that child's unique timetable. However, it is worth noting that unhealthy development environments can impede the quality of development and the timing of developmental milestones for children, therefore potentially impacting on developmental progress. For example, children who spent their early years institutionalised are much slower in reaching the normal developmental milestones of sitting, standing, walking and play; however, the process can be restored with improved developmental environments such as being in good quality foster care (Kerkez 2011).

Gesell's norms have contributed much to our understanding of child development and provide a basis for both parents and professionals to know what to expect of children at various ages. However, it is important to keep in mind that he developed his norms based on observations of children in New Haven, United States. These children may not be typical of other cultures, such as Arabic, Australian Aboriginal or Māori children. There are many other theories of biophysical development, but each falls into one of three categories: the *genetic theories of ageing*, *non-genetic cellular theories* and the *physiological theories of ageing* (see Table 17-1).

TABLE 17-1 Biophysical theories of development

Theory category	Specific theories
Genetic theories – how DNA molecules transfer information that determines function and life span of cells	Programmed cell death
	Radiation influence on DNA molecule
	Error theory of ageing
Non-genetic cellular theories – how changes in the molecules and structural elements impair a cell's effectiveness	Wear-and-tear theory
	Cross-linking theory
	Free radical theory
Physiological theories of ageing – theories related to the performance of a single organ or impairment of the physiological control mechanisms	Kilojoule intake and effect on ageing
	Effect of stress on immune system
	Effect of stress alone on the body

Genetic and cellular theories of ageing

Genetic theories of ageing try to answer such questions as 'Why do people with long-lived parents and grandparents live longer than people whose parents die before the age of 50?' Such differences may be explained by genetic inheritance (such as a tendency towards the production of high cholesterol) or learned behaviours (such as lifestyle) or a combination of both. Genetic theories explain how deoxyribonucleic acid (DNA) molecules transfer information via the formation of proteins, which determines the function and life span of specific cells (Cavanaugh 1993, Eliopoulos 1999). This programmed cell death is a function of physiological processes that cause cells to trigger processes in other cells and self-destruct. How such processes are triggered is unknown. Considerable research is being conducted to explore the theory of ageing.

One DNA theory looks at how exposure to different types of radiation shortens the life span. Laboratory studies have shown that animals have a shortened life span when exposed to non-lethal doses of radiation. This process is thought to occur in humans, and is supported by the fact that ultraviolet light in sunlight causes wrinkling of the skin and is a known cause of melanoma (skin cancer).

The error theory of cellular ageing looks at how errors in the genetic code can occur during the process of transporting DNA information in the production of the protein and enzyme molecules required by the cell (Cavanaugh 1993, Eliopoulos 1999). When these errors

occur, the altered protein or enzyme synthesis leads to defective cellular structure and function.

Non-genetic cellular theories look at the cellular level (as opposed to that of DNA) and how changes that take place in the molecules and structural elements of cells impair their effectiveness (Cavanaugh 1993, Eliopoulos 1999).

The *wear-and-tear theory* works on the premise that our bodies just 'wear out'. This theory can explain some specific processes of ageing (such as osteoarthritis) that contribute to ageing, but it does not explain general ageing.

Cross-linking theory finds that certain proteins within human cells interact with molecules to form cross-links that alter the physical and chemical properties of the molecules involved. These molecules then no longer function in the same way they did before. Cross-links accumulate over time. These processes occur in arteries, muscles and skin tissues and account for age-related changes in the body.

The *free-radical theory* proposes that ageing is due to unstable molecules which are highly reactive chemicals causing cellular damage and thereby impairing the functioning of the organ. The rate of formation of these free-radicals is accelerated by radiation but inhibited by the presence of antioxidants, lathyrogens, prednisolone and penicillamine. This theory has spurred research in the inhibitory properties of antioxidants (especially vitamins A, C and E) and how these vitamins counteract the effects of free-radicals, thereby extending life. Research so far has shown insufficient evidence for the usefulness of antioxidants in the treatment of certain conditions such as dementia (Birks & Grimley 2009, Isaac et al 2008) and motor neurone disease (Orrell et al 2007).

Physiological theories of ageing

Physiological theories of ageing look at either breakdown in the performance of a single organ or the impairment of physiological control mechanisms (Cavanaugh 1993, Eliopoulos 1999). Under this category, various theories relate to single organs or the metabolic processes being tested. For example, how many kilojoules one consumes. Reducing kilojoules appears to lower the risk of premature death and slow down normative age-related changes (Edwards et al 2010). This is supported by facts we currently know about the problems caused by obesity, high cholesterol levels and vitamin deficiencies.

The effect of stress on the immune system, either alone or in combination, is the basis of two further theories of ageing. Some theorists suggest that alterations in the effectiveness of the immune system are responsible. The body may lose its ability to distinguish its own proteins from foreign ones, and will attack and destroy its own tissues. The second immunological theory proposes that as the body ages, it is less able to fight off infection. This is thought to be a factor in the development of chronic diseases such as cancer, diabetes and cardiovascular disease.

Biophysical theories all attempt to describe the processes of how and why our bodies mature and age. Gesell went as far as to propose that it is our biological body that determines our behavioural development, but remember, no one theory explains every aspect of ageing, but each can add to our understanding. Psychosocial theories look at the process of development from a very different perspective, and as such add even further to our understanding of ageing processes (Figure 17-2).

Psychosocial theories

As we have seen from the previous chapter, a number of psychologists have conducted systematic and careful observations of children and adults and have put together various psychosocial theories about the development of human behaviour. Many of these theorists have devoted their entire lifetime to the development of a consistent understanding of how we become successful human beings, or in contrast, to explain poor developmental outcomes and what changes might intervene to optimise human development.

Human behaviour is extremely complex and therefore difficult to capture within one theory. That is why different theorists have tended to focus on different aspects of human psychosocial behaviour such as the psychosexual, psychological, cognitive and moral aspects of development. Despite having a slightly different focus, the four psychosocial theorists compared in Table 16-1 (see p. 304) all believed that as we grow and develop, humans progress through a series of sequential stages. As each

stage is negotiated, the child's personality increases in **maturity** potentiating successful adult development.

Freud's psychoanalytical model of psychosexual development theory

The first person to provide a structured and complex theory of personality development was Sigmund Freud (1856–1939). Freud was a psychologist who practised in Europe. Freud developed his theory based on systematic observation of his patients. Despite much debate and criticism, Freud's theory is still very influential today. Terms such as 'denial' and 'repression' were introduced by Freud, whose work provided the basis for the development of the discipline of psychology.

Freud's theory is grounded in the belief that two internal biological forces (aggressive and sexual forces) essentially drive psychological change in the child. Freud believed that the major motivation for behaviour is to achieve pleasure and avoid pain, created by these aggressive and sexual forces. Maturational changes occur as these forces come into conflict with the reality of the world. He defined 'sexual' somewhat broadly as anything that produces bodily pleasure (Freud 1962). Sources of such pleasure develop at different ages. Infants, for example, find pleasure mainly in the oral area from sucking. Freud described five developmental stages, each of which he believed to be associated with the development of a sensual pleasurable zone.

Through these five stages, the components of personality develop. Freud believed that the functions of these components govern and explain adult behaviours. These components are the id, the ego and the superego. The *id* is the pleasure-seeking aspect of personality and is predominant in infancy. Infants are dominated by the desire to seek pleasure without the constraints of what is realistic or right. The *ego* represents the reality components, mediating conflicts with the world when the person is driven by the id. The ego develops during childhood and helps us to judge reality accurately, to regulate impulses and to make good decisions. The third component, *superego*, performs inhibiting, restraining and prohibiting actions. Often referred to as the conscience, the superego is initially derived from the standards of external social forces (such as parent, teacher, carer). The superego starts to develop in childhood and continues developing into adolescence. An adolescent, for example, may be motivated to seek pleasure (id) from spending vast amounts of time in leisure activities. His sense of reality (ego) may constrain him because he recognises that other activities such as learning and homework also need to be done. His developing conscience (superego) may also restrain him because he wishes to contribute to the good of society by volunteering, for example. In order to contextualise development into adulthood, we review Freud's five stages of psychosexual development in Box 17-1.

BOX 17-1 Freud's psychosexual developmental stages

Stage 1: Oral (birth to 12–18 months)

In this first stage, oral satisfaction through sucking is not only vital to life, but is also extremely pleasurable in its own right. The id – basic instinctual impulses to achieve pleasure – is the most primitive part of the personality and originates with the infant and forms the infant's drive to seek oral pleasure. Late in this stage, the infant begins to realise that the mother/parent is something separate from self. Disruption in the physical or emotional availability of the parent (e.g. mental disability, chronic illness, substance abuse) can therefore impact significantly on the infant's development.

Stage 2: Anal (12–18 months to 3 years)

The focus of pleasure changes to the anal zone. Children become increasingly aware of the pleasurable sensations of this body region with interest in the products of their effort. This is the stage when the child is first asked to withhold pleasure to meet parental/societal expectations through the toilet-training process. The ego starts to develop during this stage when the child begins to realise that reality (such as parental expectations) must moderate pleasure-seeking.

Stage 3: Phallic or oedipal (3–6 years)

During this stage, the sexual organ gains prominence. According to Freud, the boy becomes more interested in the penis and the girl becomes aware of the absence of the penis. These are times of exploration and imagination as the child fantasises about the parent as their first love interest. Freud believed that sexual wishes are temporarily driven underground through the action of the developing superego, or conscience, during this stage.

Stage 4: Latency (6–12 years)

This is the stage in which Freud believed that the aggressive and sexual urges are submerged in the unconscious at the end of the oedipal stage, and channelled into productive activities that are socially acceptable. Latency was thought to be a time of minimal sexual interest or activity. Within the educational and social worlds of the child, there is much to learn and accomplish and this is where the child places energy and effort.

Stage 5: Genital (puberty to adulthood)

This stage is Freud's final stage as he did not formally continue his theory into adulthood. This stage is described as a time of turbulence when sexual urges re-emerge. Freud believed that the task of moving from sexual attachment to the parent, to the separation and emotional independence of adulthood is difficult to achieve.

Freud did not formally continue his theory into adulthood. The final stage of Freud's psychosexual development theory describes the period from puberty to adulthood (Genital Stage). This stage is described by Freud as a time of turbulence, with the task of moving from sexual attachment to the parent, to the separation and emotional independence of adulthood being difficult to achieve.

The goal of development as seen by Freud was to achieve balance between the pleasures of the world and the domination of guilt and shame that comes from indulgence of these pleasures. The fully developed adult would have a strong sense of conscience that allowed the experience of pleasure within a clear appraisal of reality. Although Freud's theory has been soundly criticised for gender and cultural biases, he did give other theorists a firm basis on which to build their own observations of **psychosocial development**.

• CRITICAL REFLECTION POINT

How might Freud explain the impact of excessive violence and sexuality in today's films and computer games based on his theory of child development?

Erikson's development across the lifespan theory

As we saw in Chapter 16, Erik Erikson (1902–1994) refined Freud's theory and expanded it to include three stages of adult development, thus completing a psychosocial theory of development across the life span. Erikson was born in Germany of a Jewish mother. When the Nazis came to power, he left for the United States, where he spent most of his professional life. Erikson was largely influenced by the work of Freud, but placed more emphasis on the social–cultural aspect of personality development, rather than the psychosexual.

The primary tenet of Erikson's theory is that human development occurs across the life span in psychosocial developmental stages. This position is in contrast with earlier Freudian explanations that development occurred in psychosexual stages, with the basic personality completed at five years of age and development largely complete at the close of adolescence. In Erikson's theory, overcoming a crisis is described as a turning point of increased vulnerability. Each crisis also holds an opportunity for enhanced potential for developmental achievement and progression to the next stage (Erikson 1968). The experience of illness, trauma or insufficient access to resources for good health and a safe world increases the vulnerabilities for developmental achievement throughout childhood and adolescence. These vulnerabilities are associated with cumulative risks to psychosocial developmental achievement at each stage from birth to old age.

Erikson described eight stages of life, the first five coinciding with Freud's five stages (Box 17-1). Erikson believed that development is an evolutionary process based on the sequencing of biological, psychological, cultural and social events. Further, social and cultural expectations compel the individual to establish equilibrium related to a specific developmental task at each developmental stage (Erikson 1963, 1987). Each task is framed as opposing tendencies (the crisis), such as the adolescent's need to develop a sense of personal identity at a time when there are many confusing choices. A sense of identity is important for the adolescent to progress to adulthood and form satisfactory intimate relationships with others. Adolescents who are unable to develop a sense of identity tend to remain confused about who they are and how to relate to others. In such a way, each stage builds on the successful resolution of the previous developmental task and predisposes the person to be ready for the next task. Readiness for the task is necessary for success.

Erikson believed that it is not necessary for the conflict to be entirely resolved in the positive, but rather that the outcome be positive, on balance. The relative mastery of each development stage, building on the former stage, from infancy to adulthood, is required to master the tasks of adolescence, **young adulthood**, middle age and late adulthood. Given the importance of incremental and cumulative developmental outcomes for adulthood, we review Erikson's eight stages of life from infancy, continuing through the stages of childhood, young adulthood, middle age and late adulthood.

Erikson's eight stages of life

Trust versus mistrust (birth to 1 year)

Starting with oral satisfaction, the infant learns to trust the caregiver. The caregiver is representative of the greater world. Trust is achieved when the infant will let the caregiver out of sight without undue distress. The infant has learned to trust not only others but also self. When infants' needs are consistently met, they come to regard the world as a generally safe place. Neglect during infancy leads to the child becoming filled with mistrust – a negative feature. However, even the most cared-for infants experience occasional neglect when needs go unmet. The balanced outcome or relative mastery of this stage is the achievement of general trust with the ability to understand that all people are not equally trustworthy. In adult life, people need some scepticism to avoid being gullible or being cheated by dishonest people.

Autonomy versus shame and doubt (1–3 years)

Having developed a sense of trust in the adults in their lives, the growing child is now ready to develop a sense of their own abilities. The child now realises, in part through gaining bowel and bladder control, that there is a choice of holding on or letting go, and therefore begin to understand that they have a degree of control over their environment. In this way a sense of autonomy starts to develop. Understandably, toddlers may try to exert such control inappropriately over relationships, personal desires and manipulative objects such as toys. At this age children are sometimes willing to share toys, and cooperate some of the time, but not all of the time, and with some people but not others. Children also learn that parents and society have expectations about these choices. The manner in which autonomy is regulated, with empathetic guidance and support from caregivers, has an impact on the achievement of successful control without loss of self-esteem. Harsh discipline can lead the child to doubt their abilities and feel a sense of shame. Extremely permissive approaches leave the child unable to test the limits of their abilities with the safety of a watchful adult.

Initiative versus guilt (3–6 years)

As discussed in Chapter 16, the preschool period is a time of expanding physical and intellectual abilities. Having developed a realistic sense of their basic capabilities, the preschool-aged child can now build on these to make plans, set goals and reach achievements. In so doing, they begin to acquire a sense of initiative and learn new ways of using their recently acquired skills (Figure 17-3). This sense of initiative can be observed in the games children play.

Figure 17-3 Play is therapeutic at any age and provides a means for release of tension and stress in the environment.

Shutterstock/ZINQ Stock.

While playing, the child may come into conflict with another child, and this requires a response from an adult. This is the stage when the beginnings of a conscience (or superego) begin to emerge. If adults' responses are too punitive, the child may be left with a feeling of guilt and initiative may be thwarted. Teaching cooperative behaviours to children can enhance their ability to meet developmental tasks. Informing parents of the changes that the preschooler is facing can help the family support the child's growth and development (Box 17-2). It is also important for parents to understand that it is still necessary to place limits on children's initiative so that they can understand what is required of them to live safely within a society.

BOX 17-2 Threats to growth and development

Growth

Prenatal risk factors:
- Altered nutrition
- Substance use/abuse

Individual risk factors:
- Caregiver and/or individual maladaptive feeding behaviours
- Chronic illness
- Substance abuse

Environmental risk factors:
- Deprivation
- Poverty
- Violence

Caregiver risk factors:
- Abuse
- Mental illness
- Mental retardation
- Severe learning disability

Development

Prenatal risk factors:
- Substance abuse
- Lack of, late or poor prenatal care
- Poverty

Individual risk factors:
- Congenital or genetic disorders
- Brain damage (haemorrhage in postnatal period, shaken baby, abuse, accident)
- Chronic illness
- Failure to thrive
- Inadequate nutrition
- Behaviour disorders
- Substance abuse

Environmental risk factors:
- Poverty
- Violence

Caregiver risk factors:
- Abuse
- Mental illness
- Mental retardation
- Severe learning disability

Industry versus inferiority (6–11 years)

Erikson believed that the adult's attitudes towards work could be traced to successful achievement of this task (Erikson 1963). School-aged children are eager to apply themselves to learning socially productive skills. Children learn to work and play with their peers. Lack of achievement occurs in part because children lack adult capacities. This may create a sense of inadequacy and inferiority for children as they judge their performance against unrealistic standards. Children need to be helped to understand what is reasonable for them to achieve. Take the example of a disabled child struggling to learn to read. As a consequence of a biological difference and delayed achievement, this child may have difficulty avoiding a sense of inferiority. At this age, children need to be supported to understand where their talents lie and to achieve in those areas.

Identity versus role confusion (puberty 11–20 years)

Dramatic physiological changes mark this stage. There are also new social demands, opportunities and conflicts associated with sexual and aggressive drives that relate to the emergent identity and separation from family. This is the milieu in which identity development begins. Alternatives are tested with the goal of achieving some perspective or direction to answer questions such as 'Who am I?' and 'What kind of adult will I become?'

Acquiring a sense of identity is essential for making adult decisions such as choice of vocation or marriage partner. Each adolescent moves in their unique way into society as an interdependent member (Figure 17-4), and peers play a major role in the lives of adolescents (see *Research highlight*). Continuing the example of

Figure 17-4 Adolescents use being alone as a method of coping with stress. Healthcare professionals need to assess whether this method also indicates an attempt to cope with depression.

Dreamstime/Dmiskv.

RESEARCH HIGHLIGHT

Research focus

The health of young people is increasingly being researched and the results contribute methods of helping young people to successfully negotiate adolescence. One method that has become the focus of researchers is the development of helping skills in adolescent peers. These helping skills focus on supporting young people as they cope with their experiences of adolescence.

Research abstract

Peer support is used frequently in addressing the health of young people. The Helping Friends program builds on existing peer helping networks in schools to improve the availability, accessibility and appropriateness of social and personal support. It increases young people's knowledge of and access to referral options (in and out of school) and assists in the development of a safe and supportive school environment. Twenty-two schools in North Queensland, Australia, participated in the program with many participating on several occasions. An evaluation of the Helping Friends program using the Social Provision Scale was undertaken to determine whether there was an increase in perceived social support as hypothesised. Results revealed small yet significant increases along subscales of the Social Provision Scale. Pre- and post-measures of helping skills and knowledge of helping topics also revealed a significant increase following students' participation in training workshops. The results are discussed in terms of the efficacy of peer support programs for addressing the health needs of young people. The findings can be used to guide secondary schools in making decisions on the value of peer support programs and their application in school and out-of-school settings.

Evidence-based practice

- The Helping Friends program has been effective in increasing knowledge of helping behaviour.
- Peer influence is an important consideration in designing programs that target adolescent health.
- Identifying respected friends and enhancing existing skills can reinforce the level of social support within and across peer groups.

adolescence, a person who is ready to develop an intimate relationship will be reasonably comfortable with the sort of person he or she is, but is sufficiently malleable to be able to merge their identity with another and become a functioning couple.

Nurses can offer anticipatory guidance about changes and challenges for the adolescent. Nurses who understand the developing adolescent also recognise that adolescents need to be recruited as partners in their care. They are fully entitled to be consulted, along with their parents, about their progress and treatment.

• CRITICAL REFLECTION POINT

Imagine you are caring for a chronically ill adolescent. How might you ensure that the care provided is adolescent-focused? What key areas of development would be important to ensure that you deliver developmentally focused and person-centred care?

Intimacy versus isolation (young adult 20–40 years)

Having developed a sense of identity, young adults deepen their capacity to love others and care for them (Table 17-2). Successful intimate relations require the partners to develop a joint identity. Joint identity is difficult to achieve when the partners do not have a strong sense of who they are. If young people have not achieved a sense of personal identity, they may experience feelings of isolation from others and the inability to form attachments. Their willingness to share and mutually regulate their lives with another marks the completion of this task.

Young adulthood is the time to become fully participative in the community, enjoying adult freedom and the responsibility that goes with that freedom. Understanding the developmental needs of young adults will guide nurses in supporting clients' obligations towards their education, occupation, partners or offspring, particularly when unwell.

TABLE 17-2 Adult developmental theorists

Adult stages (approximate ages)	Erikson	Havighurst
Early early-adult (16–22 years)	Intimacy versus isolation: Ability to form intimate relationships	Early adulthood stage: Selecting a mate Learning to live with a marriage partner Starting a family Rearing children Getting started in an occupation
Late early-adult (22–34 years)		Early adulthood stage: Taking on civic responsibilities Finding a congenial social group
Middle adult (34–60 years)	Adulthood: Generativity versus stagnation, productivity and creativity	Middle age: Assisting teenage children to become responsible adults Achieving adult social and civic responsibility Reaching and maintaining satisfactory performance in one's occupation Developing adult leisure-time activities Relating to one's spouse as a person Accepting and adjusting to the physiological changes of middle age Adjusting to ageing of parents
Late adult/old age (60–85 years)	Integrity versus despair, disgust	Later maturity: Adjusting to decreasing physical strength and health Adjusting to retirement and reduced income Adjusting to death of a spouse Establishing an affiliation with one's age group Adopting and adapting social roles in a flexible way Establishing satisfactory physical living arrangements

• CRITICAL REFLECTION POINT

In current times, the high cost of living means many young people remain with their parents long into their 20s. How might this affect their development within Erikson's intimacy versus isolation stage?

Generativity versus stagnation (middle age 40–60 years)

Following the successful development of an intimate relationship, the middle-aged adult can focus on assisting the younger generation to develop useful and satisfying lives. This ability to sacrifice one's own needs to care for others is possible with or without the production of offspring. The emphasis on independent achievement, so prevalent in Western cultures, can create a situation in which adults become overly absorbed in their own success and neglect the needs of others. Adults at this stage are frequently at the peak of their careers (with the attendant demands), are often responsible for adolescent children, and may also be responsible for ageing parents. Such responsibilities may be a source of stress, but can also be a source of great satisfaction. Illness and/or disabilities that inhibit the discharge of these responsibilities may be a cause of considerable distress.

CLINICAL EXAMPLE

Greg is a 45-year-old male. He holds a senior executive position at a local corporation. Greg enters the emergency department with intense chest pain. Upon evaluation, it is determined that he has severe cardiovascular disease and requires emergency open-heart surgery.

His children, aged 13 and 17, and wife accompany him at the hospital. Greg is the sole wage earner for the family. Both children attend private schools and the whole family enjoys a comfortable and privileged lifestyle. After Greg settles into his private room at the hospital, he asks for computer access to complete some work before his surgery. What might you say to Greg and his family to convey your understanding of his developmental tasks while needing to balance stress?

Integrity versus despair (old age 60 years until death)

As the ageing process creates physical and social losses, the adult may also suffer loss of status and function, such as through retirement or illness. These external challenges are also met with internal struggles, such as the search for meaning in the life lived (Chapter 18). However, meeting these challenges also creates further potential for growth and wisdom. Many older people review their lives with a sense of satisfaction, even with knowledge of inevitable mistakes or poor choices made along the way. Others see themselves as failures, with marked contempt and the inevitable despair that comes from the realisation it is now too late to achieve hoped-for goals. Nurses are often in positions of influence within their communities and can contribute to the valuing of people at all ages and stages. Erikson (1963) stated, 'Healthy children will not fear life, if their parents have integrity enough not to fear death.' Erikson completed significant research during his academic career with varied cultural traditions and gender groups and believed his theory to be widely applicable.

Havighurst's developmental tasks theory

Basing his ideas on Erikson's work and his observation of mainly middle-class American families, Robert Havighurst (1900–1991) was an educator who identified a series of essential tasks that need to be achieved throughout the life span (see Table 17-2) (Ashburn 1978). We know from our own experiences, and from observing those of others, that we tend to achieve certain goals at a specific time of our lives. For example, we learn to walk and talk as babies, to read and write as children, to form sexual partnerships during adolescence and adulthood, and so on. When we accomplish these tasks we develop a sense of mastery and satisfaction and this sets us up to achieve subsequent developmental tasks. The psychosocial theories of both Havighurst and Erikson provide explanations and structure for our observations.

Havighurst believed that the pressures to achieve these tasks, as well as social pressures, develop from our increasing physical maturity and our personal goals and aspirations. Developmental tasks require the individual to reconcile increasing physical maturity with skills such as walking, talking or eating. Cultural pressure creates the conditions necessary to learn social behaviours and ethical norms. For example, although an adolescent girl may be physically able to accomplish the task of having a child, the preparation and timing for the onset of parenthood can also be considered from a perspective of cultural pressure from both the youth and the adult cultures. The desire to have a child might also grow out of the individual's personal aspiration to be a parent.

Similarly, Havighurst's theory proposes that there are critical periods when the individual is most receptive to the learning necessary to achieve success in performing

these tasks. In a similar way to Erikson, Havighurst believed that effective learning and achievement of tasks during one period leads to success with later tasks. Success may also lead to happiness and acceptance by society. Failure leads to unhappiness, disapproval by society, and difficulty with later tasks; for example, the struggle that an adolescent might experience in preparing for a work career after having failed to develop fundamental skills in reading.

As an educator, Havighurst believed that schools have considerable responsibility for helping a child attain the success necessary to lead to achievement of later adult development. His theory is a structure of both non-recurrent tasks specific to a stage of development (such as learning to walk), and recurrent tasks that re-emerge in new ways (such as learning to get along with age-mates). Critics of Havighurst's theory suggest that it is limited in its cultural application because it describes developmental milestones from the perspective of middle-class norms within the American culture. However, we already know that no one single theoretical framework is able to successfully describe the complexity and uniqueness of all human growth and development.

Cognitive development theories

Piaget's theory of cognitive development

Jean Piaget (1896–1980) was a Swiss biologist and philosopher whose interest was in the development of cognitive organisation – or how we think. Piaget created a theory of **cognitive development** which includes four periods, claiming that children move through these specific periods at different rates but in the same sequence or order (Crain 1992). His theory was built on years of observing children as they explored, manipulated and tried to make sense out of the world in which they lived, and ends with achieving the developmental stage of adulthood. In Piaget's cognitive development theory (Piaget 1954), external or internal forces did not shape thinking, although he acknowledged their presence in the process. Piaget's theory includes four general periods of development with a number of stages within each (Box 17-3) and is contrasted with those of Freud, Erikson and Kohlberg in Chapter 16 (Table 16-1, p. 304).

BOX 17-3 Piaget's cognitive development stages

Period I: Sensorimotor intelligence (birth to 2 years)

The infant develops the schema or action patterns for dealing with the environment. The schema basically consists of motor reactions to the environment as perceived through the infant's senses. These schemas may include hitting, looking, grasping or kicking. Schema gradually become self-initiated activities; for example, the infant learns that sucking achieves a pleasing result and generalises the action to suck fingers, blankets or clothing. Successful achievement of this stage leads to greater exploration, and exploration is essential for the child's subsequent development.

Period II: Preoperational thought (2–7 years)

The second period is a time when children learn to think with the use of symbols and images. This requires the child to reorganise their thinking, with play being the initial method of non-language use of symbols. Imitation and make-believe are ways to represent experience. As language develops, possibilities for thinking about the past or the future also develop. Children can now communicate about events with others.

Children are frequently egocentric in this period, in that they are unable to distinguish their perspective from that of another person. This egocentricity is illustrated by the way children of this age play, which is called 'parallel play'. Later in this stage, children learn to cooperate with each other to play a game such as 'mothers and fathers'. Such experiential learning complements the natural changes in thinking as children live with the responses of others to their actions.

Period III: Concrete operations (7–11 years)

Children achieve the ability to think systematically during the third cognitive period, but only when they can refer to concrete objects or activities; that is, experiences that can be seen, felt and tasted. They can now describe a process without actually performing it. At this time they are able to coordinate two concrete perspectives. In other words, they can appreciate the difference between their perspective and that of a friend. Children begin to cooperate and share new information about the act they perform. The potential develops for play and relationships to become more complex, as the child begins to comprehend the nature of rules and their usefulness in regulating activities.

Period IV: Formal operations (11 years to adulthood)

The individual's thinking moves to abstract and theoretical subjects in the formal operations period. Thinking can venture into such subjects as achieving world peace, finding justice and seeking meaning in life. Adolescents can organise their thoughts in their minds without needing concrete objects before them. They have the capacity to reason with respect to possibilities. New cognitive powers allow the adolescent to do more far-reaching problem-solving that includes their futures and those of others. This type of thinking continues to mature in the adult years as experience is accumulated.

In the fourth and final period of Piaget's cognitive development theory (known as Formal Operations) the individual's thinking continues to develop in complexity and moves towards more abstract and theoretical subjects than in the rule-driven and regulated 'Concrete Operations' period (Box 17-3). The adolescent continues to explore thinking across many dimensions, discovering interest in politics or the environment, for example. The expanded cognitive powers of adolescence permit better organisation of thought, greater ability to reason and respect differences of opinion, and skills in communicating and proposing solutions to perceived problems. This experience with theorising and abstract reasoning accumulates and continues into the adult years.

Piaget believed that the sequencing of the four stages of his theory (Box 17-3) occurred for all children, but that the rate of achievement could vary. He also theorised that this sequencing is true for all cultures. He acknowledged that biological maturation played a role in his developmental theory, but believed that rates of development depended on the amount of intellectual stimulation and challenge within the environment of the child.

• CRITICAL REFLECTION POINT

A 7-year-old boy has been diagnosed with immune-mediated (type 1) diabetes. A nurse initiates the educational process with him and his family. Which developmental tasks must the nurse determine are already accomplished by the child and his family in order to design an effective educational program and meet the needs of a family now faced with a chronic illness in one of its members? Based on this boy's cognitive development, how would the nurse work with him to achieve self-management of his diabetes?

Moral developmental theories

Moral developmental theories try to explain 'how individuals acquire moral values and how such values help guide the way those persons treat other people' (Thomas 1997). Although various psychosocial and cognitive theorists have discussed aspects of moral development within their respective theories, Piaget and Kohlberg are two who have proposed a specific theory of moral development.

Piaget's moral development theory

In his studies of 5–13-year-old boys from middle-class backgrounds, Piaget noted that the environment and stage of **cognitive development** are both factors that influence a child's moral development. Piaget noted that a natural shift in **moral development** occurs around the same time as the cognitive transition from preoperational to operational thought (Kurtines & Gewirtz 1984). In his theory of moral development, Piaget termed his two stages *heteronomous morality* and *autonomous morality*. In the stage of heteronomous morality (during the preschool period 3–5 years of age), children follow the rules set up by those in authority, such as parents, teachers, clergy or police. When a young person reaches the stage of autonomous morality (early adolescence 12–14 years of age), moral judgements are based on mutual respect for the rules and mutual regard for the person. The person at this stage starts to consider information related to the subjective intent in making moral judgements that involve others.

Piaget first saw the child as following, but not necessarily understanding rules. Children see rules as fixed and handed down by adults or by 'God', so they cannot change them. Young children base their moral decisions on the extent of the consequences of the action, not necessarily on the action itself. For example, a young child will not eat a biscuit before dinner not because the mother said not to, or because the child can see that it is not good practice nutritionally, but because the child is afraid of the punishment that would result from disobedience. Around 10 or 11 years of age, children's cognitive ability matures and the rules children follow are understood more within the context of community life and the interaction with those around them. Children understand that rules can be changed if everyone agrees to change the rules. Moral maturity is the internalisation of the principles, the desire to weigh all the relationships and circumstances before making a decision. Rules are the tools that humans use to grease the wheels of social interaction.

Kohlberg's moral development theory

Lawrence Kohlberg expanded on Piaget's moral development theory during his graduate work in psychology at the University of Chicago, initially interviewing boys at ages 10, 13 and 16 years. As outlined in Chapter 16, Kohlberg felt that Piaget did not go far enough in the development of his stages. His further development of Piaget's theory included presenting his research subjects with a series of moral dilemmas and analysing their responses. In this way, he identified six stages of moral development under three broad levels, extending into early adulthood (Kohlberg 1973, 1981). Kohlberg found that there was a link between moral development and Piaget's cognitive development: a child's moral development did not advance if the child's cognitive development did not also mature. Like Piaget, Kohlberg believed that we proceed in a sequential manner

through the stages of moral development, and do not skip any stages. He also believed that not all individuals progress to the higher stages of moral development, but may remain as adults in an earlier stage, particularly in Stage 4 as described below.

Level I: Preconventional level

At Level I the person reflects on moral reasoning based on personal gain. This kind of reasoning closely correlates with Piaget's first stage, in that the person's moral reason for acting relates to the consequences the person believes will occur. These consequences can come in the form of punishment or reward. It is at this level that children may view illness as a punishment; for example, for fighting with their siblings or not obeying their parents. The nurse must be aware of this thinking and reinforce to the child that they cannot become ill because of wrongdoing.

Stage 1: Punishment and obedience orientation

In this first stage, the child's response to a moral dilemma is unquestioning deference to authority (specifically their parents or caregivers) to avoid punishment. The child relies on authority to decide what is right, and in so doing avoids punishment. While children will test authority, they will ultimately follow their parents' instructions, such as refraining from hitting another child, to avoid being punished. If children are punished or if unpleasant things happen to them, they will tend to reason that they must have been guilty. Similarly, children at this age will believe that if other children are punished then they must have been naughty. The concept of justice has not begun to develop.

Stage 2: Instrumental relativist orientation

In the second stage, a child recognises there is more than one authority: a teacher may have a view different from that of the child's parent, or a mother may have different views from a father. The decision to do something morally right is based on satisfying one's own needs, and occasionally the needs of others. The child may play one authority off against another. Punishment is perceived not as proof of the child being wrong (as in Stage 1), but as something that one wants to avoid. Children at this stage will follow their parents' rule about being home in time for dinner because they do not want to be confined to their room for the rest of the evening if they do not get home on time.

Level II: Conventional level

At Level II, the person sees moral reasoning based on their own personal internalisation of societal and others' expectations. A person wants to fulfil the expectations of the family, group or nation and also develop a loyalty, actively maintain support and justify the order. Moral decision-making at this level moves from 'What's in it for me?' to 'How will it affect my relationships with others?' Nurses may observe this when family members make end-of-life decisions for their relatives; individual members may struggle with this moral dilemma. Grief support will involve an understanding of the level of moral decision-making of each family member.

Stage 3: Good boy–nice girl orientation

Stage 3 correlates with Piaget's second stage of moral development (see Table 16-1, p. 304). The individual wants to win approval and fulfil the expectations of the immediate group. 'Being good' means to have good motives, show concern for others, and keep mutual relationships through trust, loyalty, respect and gratitude. One earns approval by 'being nice'. A person in this stage may stay after school and do odd-jobs to win the teacher's approval.

Stage 4: Society-maintaining orientation

Individuals expand their focus from a relationship with others to societal concerns in Stage 4. Moral decisions take into account this societal perspective. 'Right' behaviour is doing one's duty, showing respect for authority and maintaining the social order. Adolescents may choose not to attend a party where they know alcohol will be served, not so much because they are afraid of getting caught, but rather because they know that it can lead to unsocial behaviour and create problems for others.

Level III: Postconventional level

The young person finds a balance between basic human rights and obligations, and societal rules and regulations at this level. Individuals move away from moral decisions based on authority or conformity to groups to define their own moral values and principles. Individuals at this stage start to look at what an ideal society would be like.

Stage 5: Social contract orientation

Having reached Stage 5, an individual may follow the societal law but recognises the possibility of changing the law to improve society. The individual also recognises that different social groups may have different values but believes that all rational people would agree on basic rights, such as liberty and life. Individuals at this stage make more of an independent effort to think out what society ought to value, rather than what is actually valued, as would occur in Stage 4. An individual at this stage recognises laws as social contracts that the citizens have agreed to uphold, but believes that there must be a mechanism to change unfair laws by democratic means (Crain 1992).

Stage 6: Universal ethical principle orientation

Stage 6 defines 'right' by the decision of conscience in accord with self-chosen ethical principles. These principles are abstract and appeal to logical comprehensiveness, universality and consistency (Kohlberg 1981). For example, the principles of justice require the individual to treat everyone in an impartial manner, respecting the basic dignity of all people, and guide the individual to base decisions on an equal respect for all (Figure 17-5). Stage 5 emphasises basic rights and the democratic process, whereas Stage 6 defines the principles by which agreements will be most just.

Later research by Kohlberg made him question his earlier conclusions regarding Stage 6, as he found that very few subjects consistently reasoned at this stage. He concluded that his research method of presenting people with moral dilemmas did not draw out the main differences between Stages 5 and 6. He later termed Stage 6 a 'theoretical stage' and tended to ignore this stage in preference for a combination of Stages 5 and 6 in his subsequent research.

• CRITICAL REFLECTION POINT

A 12-year-old girl is admitted to the emergency department after being involved in a motor vehicle accident. She has suffered a fractured pelvis, a fractured tibia and has internal bleeding. She will need immediate surgery. No other person was injured in the accident. Taking into account her psychosocial, cognitive and moral development stages, list as many strategies as you can that healthcare professionals and her parents might use to help her through her hospitalisation and rehabilitation.

Figure 17-5 **Adults must take responsibility for themselves.**

Shutterstock/wavebreakmedia ltd.

Nurses need to be aware of their own level of moral reasoning when caring for others as this becomes essential to helping clients clarify their own decisions about their care. The personal beliefs and values of health professionals cannot, and should not, dominate the client's decision-making process. Nurses may also find that their own level of moral decision-making can influence decisions made by the healthcare team. Consider the following scenario: A nurse is caring for a homeless person and believes that all clients deserve the same level of care. The case manager, being responsible for resource allocation, complains about the client's length of stay and the amount of resources being expended on this one client. The nurse and the case manager are in conflict because of their different levels of moral decision-making within their practices.

Critics of Kohlberg's theory

Kohlberg has been recognised as a leader in moral developmental theory, but many identified theoretical differences seem to have arisen from his choice of research subjects. His theory has been criticised for mainly basing observations on males within Western philosophical traditions, and for mainly using cross-sectional (rather than longitudinal) methods to observe development. In cross-sectional studies, different children are observed at each age, so it is difficult to conclude that as a whole they followed a specific sequence. A child may not progress through the stages in order or may skip a stage, and this would not be detected under this method. Research attempting to support Kohlberg's theory by studying individuals raised under Eastern philosophies has found that those study participants never progressed beyond Stages 3 or 4 of Kohlberg's theoretical model. This does not necessarily mean they did not reach higher levels of moral development, but rather that Kohlberg's choice of research subjects did not allow a way to measure those raised within a different culture. Kohlberg's theory has also been criticised for age and gender bias, with Kohlberg himself admitting in later studies that Stage 5 might not be reached until adulthood (Kohlberg 1981).

Carol Gilligan (1982), an associate and co-author of Kohlberg, has proposed that Kohlberg's theory is biased in favour of men. A psychologist and researcher, Gilligan started questioning the differences she observed in the way men and women approached and answered questions about moral dilemmas. Gilligan believes that men and women develop in parallel ways in relationships and issues of dependency, with neither being superior to the other (Gilligan 1982). For example, separation and

individuation are critically tied to male development, as separation from the mother is essential for the boy in his development of masculinity. Girls do not need to separate from their mothers to achieve feminine identity; it is through this attachment to their mother that their identity is formed. Further, male moral development may focus on logic, justice and social organisation, whereas female moral development focuses on interpersonal relationships. Interestingly, studies using Gilligan's critique as the research design have been inconclusive and, as a result, Gilligan's position remains controversial (Cavanaugh 1993). However, according to Gilligan, all developmental theories are subject to this gender bias and it is only relatively recently that our society has conducted research to recognise the differences between men and women in the ways they think and how they have been raised to make moral and other decisions.

The developing adult

Young adults constitute about a quarter of the populations of Australia and New Zealand and, as they pass through alternating periods of stability and change, will make choices and build structures around themselves, while also re-evaluating these choices and considering new alternatives (Erikson 1968, 1982).

Young adulthood is the period between late teens and mid- to late 30s. Young adults experience natural processes of maturation and socialisation and actively adapt to new experiences. Young adulthood is usually a time when young people decide to separate from their families of origin, establish career goals and decide whether to marry and begin families, or remain single. Young adults also make decisions about their sexuality, forming heterosexual or homosexual relationships, and/or managing a continuing or emerging gender identity.

Middle age occurs between the mid- to late 30s and the mid-60s. The transition into middle adulthood occurs when young people become aware that changes in reproductive and physical abilities signify the beginning of another stage in life. This is a time of continuing transition when individuals may reassess their goals in life and add new goals. Some may change relationships and make new families in middle adulthood, while others remain single.

Ideally, those in middle adulthood have reached a mature balance in physiological, psychosocial and cognitive growth. Individuals tend to feel comfortable with the abilities, knowledge and responses that they have developed over the years and look at the world with a broad view, based on a blend of insight, emotion and imagination. Individuals take on problems that can be solved but also recognise and learn to live with insoluble problems. Balanced adults tend to be open to suggestions and to accept constructive criticism without a major loss of self-esteem. They weigh other people's input and recommendations when making decisions, but are not overly influenced or intimidated by others. Above all, mature people develop by learning from their own and others' experiences. Other characteristics of maturity are related to interpersonal communication and behaviour. Mature people tend to acknowledge accomplishments and shortcomings in themselves and others. Mature adults are able to confront tasks openly, use decision-making techniques to solve problems and be accountable and responsible for their actions.

Socio-cultural change in adult roles

In many cultures familial authority has historically been associated with males, who have traditionally assumed major power positions. Boys learn how to be men by absorbing messages about manliness from parents, siblings, peers, teachers, and television and cinema action movies. These messages encourage boys to be competitive, focus on external success, rely on their intellect, withstand physical pain and repress their vulnerable emotions. Traditional masculine roles include providing and protecting.

As women have increasingly taken on the roles of providing and protecting, men's roles have tended to move into disequilibrium. Faced with a societal structure that differs from the norm experienced by their fathers, some men are challenged with determining what it means to be a man and how to feel good about being male in today's society (Brooks 2010). As a provider, for example, a man is traditionally viewed as the main supporter of the family, but with more women pursuing successful careers, the relative importance of the male breadwinner has declined. In the last two decades and the ensuing global financial crises, real family income has been maintained only by the increased participation of women in the workforce. The traditional roles of men and women in young and middle adulthood have changed to a more equal power and family responsibility base. However, this phenomenon is more of a Western social cultural change, with many areas of society maintaining the traditional realm of male and female societal roles.

We have discussed adult maturity and the associated socio-cultural changes for young and middle-aged people. Now we will discuss the health and wellbeing of young adults as they move through life transitions into middle age.

Young adulthood

Physical changes

We have seen in Chapter 16 that adolescence is a common period for the emergence of mental health problems, accidents and injuries. Identification of risk-taking behaviours, mental health problems and the promotion of healthy living through appropriate access to health services ideally begin during the school years. Given the tendency of young adults to avoid health care, it is important that when young people do access healthcare services that they receive a thorough bio-psychosocial assessment. This will provide a good understanding of their health status (physical and mental health) as they enter adulthood, and is a valuable opportunity for health promotion activities, wellness strategies, answering questions about safe sexual practices and advice on any risk-taking behaviours.

Young adults are mostly active and busy participating in vocational and social activities. This group is less likely to be affected by severe physical illness; however, they do tend to ignore physical symptoms, and often postpone seeking health care. Except for pregnant or lactating women, most young adults have completed physical growth by the age of 20 years. For many couples, young adulthood is a time for childbearing and childrearing, and holds a range of biological, physical, psychosocial and economic challenges. While the physical, cognitive and psychosocial health concerns of the pregnant woman and the childbearing family may be extensive, most young adults experience good physical health.

The physical characteristics of young adults begin to change at the approach of middle age. Unless the young adult has a chronic illness, the findings of a health assessment will generally be within normal limits. Young men may be especially reluctant to seek medical advice and such a view may also be inadvertently reinforced by healthcare professionals (Hale et al 2010). Nurses should take great care to encourage self-care and the appropriate use of health services for both young men and young women.

Young adults in this developmental stage may benefit from a **personal lifestyle assessment**. This may assist with the identification of habits that increase the risk of cardiac, malignant, pulmonary, renal or other chronic diseases. A personal lifestyle assessment of the young adult includes assessment of general life satisfaction; hobbies and interests; habits such as diet, sleeping, exercise, sexual health, and use of caffeine, alcohol and illicit drugs; home conditions, including housing, economic condition, pets and type of health insurance; and their occupational environment, including type of work, exposure to hazardous substances, and physical or mental strain.

Psychosocial changes

The **emotional health** of young adults is related to the individual's ability to resolve personal, vocational and social tasks. Young adults are often caught between wanting to prolong the sense of freedom and minimal responsibilities of adolescence, and wanting to assume adult commitments. We acknowledge here that this is not the experience of all young adults. Many young adults live in impoverished circumstances, developing economies, or in places with strict political and cultural regimes that result in different life experiences. This may lead to differences in the timing and accomplishment of psychosocial development outcomes relative to their contextual life experiences.

During the young adult years, considerable attention is given to occupational and social pursuits. In this period, individuals attempt to improve their socioeconomic status, and upward mobility is sought through career choices. Recent trends towards corporate downsizing and increasing casualisation of the workforce, however, are leading to fewer full-time high-level positions. Consequently, many young adults are facing the added stress of greater competition in the workplace for fewer positions and an ever-changing skills base demanded by an increasingly technology driven market. For many young adults, two incomes are needed to provide for their families and preferred lifestyles. Career and personal counselling can help individuals identify learning and career choices and to set realistic goals.

However, certain patterns or trends are predictable. Between the ages of 23 and 28 years the young person refines their self-perception and ability for intimacy. From 29 to 34 years the young person directs enormous energy towards achievement and mastery of the surrounding world. The years from 35 to 43 are a time of vigorous re-examination of life goals and relationships. Alterations are made in personal, social and occupational lives. Often the stresses of this re-examination result in what some call a 'midlife crisis'. For some, this heralds a change in marital partner, lifestyle or occupation.

Ethnic and gender factors have sociological and psychological influences in an adult's life. These factors sometimes pose a challenge for appropriate and effective nursing care. Each person holds culture-bound definitions of health and illness. We are just beginning to understand the experience of illness, ageing and trauma for some individuals and its impact on the future of health care.

Nurses and other healthcare professionals bring distinct practices and ideas for the prevention and treatment of illness, often shaped by their own cultural experience. Knowing too little about a client's self-perception or

beliefs regarding health and illness, or relevant history such as violence or trauma, may create conflict between the nurse and the client. Of critical importance here is that healthcare professionals are prepared to actively listen to clients to gain an understanding of the way the client understands health and illness, and something of their life experience. The skills required to listen effectively are described in Chapter 12.

Changes in the traditional role expectations of both men and women in young and middle adulthood have also led to greater challenges and creativity in nursing care. Women and men often continue to work during the childrearing years, and many struggle with balancing careers, partners, parenting, education, employment and possibly other carer responsibilities. This is a potential source of stress for young adults that continues into middle adulthood for many. Nurses can support access to culturally and socially appropriate information, and appropriate referral, to provide opportunities for the achievement of potential, despite health problems. Health is not merely the absence of disease but involves a self-perception of wellness in all human dimensions. Acknowledgement of the psychosocial needs of young adults and their possible needs in other dimensions is a significant aspect of nursing practice.

The young adult must make decisions concerning career, a partner, possible marriage or parenthood and lifestyle. Although each person makes these decisions based on individual factors, the nurse should understand the general principles involved in these aspects of psychosocial development. This is undertaken while assessing the young adult's psychosocial status and tailoring support in times of illness. A range of psychosocial assessment tools are utilised, often associated with the type of illness and/or age or development stage of the client. Two examples are the HEADSPACE psychosocial assessment tool for young people aged 12–25 years (National Youth Mental Health Foundation 2013) and the Palliative Care Psychosocial Assessment Tool (Department of Health and Human Services Tasmania 2007).

Cognitive changes

Rational thinking habits increase steadily through the young and middle adult years. By the mid-20s the prefrontal cortex of the brain is fully developed. The prefrontal cortex governs the person's ability to reason in a mature way and to control reckless impulses. In addition, formal and informal education, general life experiences and occupational opportunities dramatically increase the individual's conceptual, problem-solving and motor skills during this period of life. Adults enter learning situations with a background of unique life experiences. For some, this may include migration from other lands, different languages and cultures. For others, background experience may include illness (physical and mental), emotional or physical trauma or disability. Adults are individuals with their unique life story.

Identifying preferred occupations is a major task for young adults. When people are aware of their own skills, talents and personality characteristics, educational preparation and occupational choices are easier and more satisfying. Many young adults, however, lack either the resources or the support systems to facilitate further education or the development of skills necessary for many positions in the workplace. As a result, some young adults may have limited occupational choices.

For the young adult receiving health care, individual compliance with regimens such as medications, treatments or lifestyle changes (such as quitting smoking) involve complex decision-making processes. When determining the amount and type of information the individual needs to make informed decisions about the prescribed course of therapy, the nurse should consider the external evidence available (from research) and those factors that may affect the individual's contextual compliance with the regimen, including educational level, social and economic factors, cultural diversity, motivation and desire to learn. Young and middle-aged adults are continually evolving and adjusting to changes in their home, workplace and personal lives, so their decision-making processes need to remain flexible. The more secure adults are in their roles, the more flexible and open they are to change. Adults who feel insecure tend to be more rigid and less confident in making decisions.

Health and wellbeing of young adults

Lifestyle

The health and wellbeing of individuals and wider society is also dependent on lifestyle behaviours and responses to the external environment. Certain lifestyle behaviours such as smoking, the abuse or misuse of alcohol, illicit, prescribed and over-the-counter substances, insufficient exercise, poor diet, and poor dental and personal hygiene can all increase or contribute to a future risk of illness. Family history and, as is being revealed by research, our genetic codes, can increase our risk for cardiovascular, renal, endocrine or neoplastic disease.

The nurse's role in promoting health is to identify factors that may increase the young adult's risk of health problems and to provide education and support to reduce

unhealthy lifestyle behaviours. Those lifestyle habits that activate the stress response also increase the risk of illness. Prolonged stress increases wear and tear on the body's capacity to adapt, leading to the development of stress-related diseases such as emotional disorders and infections.

Smoking is a well-documented risk factor for pulmonary, cardiac and vascular diseases in both smokers and those who are exposed to environmental smoke. Inhaled pollutants from smoking increase the risk of lung cancer, emphysema and chronic bronchitis. The nicotine in tobacco is a vasoconstrictor that acts on the coronary arteries, increasing the risk of angina, myocardial infarction and coronary artery disease. Nicotine also causes peripheral vasoconstriction and may lead to vascular problems. Alcohol consumption and especially 'binge' drinking is an increasing problem among young people, with young males particularly at risk (Chartier et al 2011). Other health and risk-taking behaviours are discussed later in the chapter.

Epigenetics

Epigenetics is a new frontier of knowledge bringing new understandings to our personal lifetime risk of disease (Francis 2012). Current knowledge has allowed us to establish links between the biological or genetic, and extrinsic or environmental causes of disease. Epigenetic research explores the ways in which environmental (including lifestyle behaviours) or ecological (environmental context as discussed earlier in this chapter) factors alter the way in which genes express themselves. Specifically, **epigenetics** explores the mechanism by which genes are turned on, or turned off, expressed or not expressed, as a result of environmental influences (Francis 2012). This field offers an exciting new direction for governments, health services and health professionals to determine and promote health and preventative interventions to specific groups of individuals with high-risk genetic markers for disease.

• CRITICAL REFLECTION POINT

Mason is a 24-year-old man who smokes two packets of cigarettes per day. He began smoking when he was 14 years old. During a work-based health assessment, Mason complains, 'I just can't seem to kick the habit no matter how hard I try.'

1. **What does the nurse need to know about smoking cessation programs in order to negotiate with this client?**
2. **What questions would the nurse ask Mason in order to assess his motivation and opportunities to quit smoking?**
3. **What physical assessment would the nurse conduct, and for what reasons?**
4. **What follow-up plan might the nurse negotiate in order to provide support for Mason's efforts if he attempts a quit-smoking program?**

Careers and work

Young men and women aspire to careers that will enable them to realise their occupational dreams and financially support themselves. Young adults may formulate short- and long-term goals in traditional or non-traditional careers and successful **vocational adjustment** is important in the lives of most. Successful employment not only ensures economic security, but also leads to friendships, social activities, and support and respect from co-workers. Career-related stressors include changes in one's work demands, location or job security, or in those of a partner. The combined employment demands of the adult members of a household may place stress on their domestic needs. These stressors may be managed by dividing labour among family or extended family (e.g. grandparents), or by outsourcing some domestic activities such as house-cleaning, childminding and gardening, depending on the family income.

There is a current trend for young adults, with or without partners, to return or remain with their parents in the family home for longer periods of time. Parents are increasingly supporting young adults financially and emotionally during their early periods of study and work. Many young adults cannot maintain the costs of living as well as undertake post-school education, and therefore rely on subsidised accommodation at home for support. Some young adults are supported by parents or family to work or study in other countries to improve work opportunities and family prosperity back at home. Other more privileged young people may experience the opportunity to work and travel for fun. This situation has created a very multi-cultural context in higher education and in the workplace for many young people, expanding their life experiences and friendships.

Sexuality

The development of secondary sexual characteristics occurs during the adolescent years (see Chapter 16) and is accompanied by an increased interest in intimacy. The young adult has usually developed the emotional and cognitive maturity to complement their physical ability and is able to develop mature sexual relationships and have children. Young adults who have failed to achieve the developmental task of personal integration may, however, develop relationships that are superficial and unfulfilling, or even damaging (Haber et al 1997).

The psychodynamic aspect of sexual activity is as important to young adults as the type or frequency of sexual intercourse. Psychological beliefs and expectations give feelings of pleasure and satisfaction to adults. In order to maintain total wellness, adults should be encouraged to explore various aspects of their sexuality and be made aware that sexual needs and concerns will continue to evolve. As the age of initiation of sexual intercourse continues to decrease, young adults become more at risk of sexually transmitted infections (STIs). Consequently, they need early preventative and screening information regarding modes of transmission, prevention, symptom recognition and treatment of STIs.

Lifestyle and relationships

While there is a trend towards more young adults living with parents or extended family members, many are remaining single and living independently. Expanding career opportunities for women is one reason for the increase in the independent singles population. Women now enter the job market with greater career potential and therefore greater opportunities for financial independence. Further, more single people are choosing to live together outside of partnering (e.g. friends benefit financially from purchasing a house together), as well as becoming single parents, either biologically or through adoption. Those who establish long-term relationships or eventually choose to become partners experience several changes as they take on new responsibilities. For young adults who remain single and without children, parents and siblings may remain the nucleus of their family, although the young adult maintains independence from parental controls. Close friends and associates of the single and childless young adult may also be viewed as the individual's 'family' (see Chapter 15).

Relationships: partners and marriage

The social pressure to get married is not as great as it once was. In Australia (Australian Bureau of Statistics 2007a) and New Zealand (Baker 2001), the median age for women to marry was 25 years in 1988 and 29 years in 2007. The corresponding ages for men were 27 and 29. Many young adults will form long-term same gender or opposite gender relationships and many will choose not to marry at all. Married couples may choose to separate or divorce if they find their marital situation unsatisfactory and many more couples are leaving parenting decisions well into their 30s, and a few beyond into their 40s. The divorce rates for New Zealand and Australia are similar, at around 2.5–2.6 divorces per 1000 people (ABS 2007b). In the 1970s and 1980s the divorce rate rose quite sharply in both countries because of changes to family legislation.

Every couple's relationship is unique. Compatible beliefs and values are seen as important to building a happy relationship, as are motivations for commitment. When establishing a shared relationship, a couple agrees to work on the following tasks:

- establish a mutually respectful intimate relationship
- decide on and work towards mutual goals
- establish guidelines for power and decision-making issues particularly childraising and finances
- set standards for extra-family interactions
- find companionship with other people for a social life
- choose morals, values and ideologies acceptable to both.

These major tasks of adulthood require considerable psychosocial and cognitive maturity and self-esteem. When accomplished, however, they provide the foundation for a stable relationship. Growth in partnership or marriage extends over many years and a range of challenges present themselves. The couple learns patterns of sexual expression and ways to live intimately with each other. In order to live harmoniously the couple needs to learn styles of conflict resolution, decision-making and role patterns. In addition, each partner may experience a sense of loss of individuality and self in the transition from *me* to *we*. Success in solving the challenging problems that occur in any intimate and committed relationship offers partners significant insight into each other and significant personal development opportunities.

Family orientation

The family orientation stage is directed towards childbearing and childrearing activities and caring for older family members. Parenting roles must be defined, united and practised. The nurturing and socialisation needs of children can put pressure on the couple's intimate relationship. In addition, expectations for 'perfect parenting' may be unreasonable and conflict with reality. Other challenges emerge as family growth brings greater financial demand to meet housing, social and lifestyle expectations. Young adults often experience stress during this time and some families begin to be affected by violence, substance abuse and gambling during this period of life.

Some young women will experience depression and anxiety during pregnancy and following childbirth (the perinatal period). Undertaking a risk assessment as women access health services for antenatal and postnatal care offers an important opportunity to detect depression and/or anxiety in the perinatal period. The Edinburgh Post Natal Depression Scale (Cox et al 1987) is commonly used to assess for depression in pre- and postnatal women.

• CRITICAL REFLECTION POINT

Alisha is aged 32 and is 34 weeks pregnant. She attends the outpatient prenatal clinic at the local public hospital. During her interview with the midwife, Alisha describes feeling very tired and teary. She finds working full-time and caring for her two other children demanding. Her husband works in the mines and is away from home for long periods. The situation is distressing her and she feels down a lot.

Consider the presenting problem and priorities and goals for planning care with Alisha to respond to these issues.

Decisions about parenthood

The availability of contraception makes it possible for today's couples to decide when and if to start a family (see Figure 17-6). One factor influencing this decision is the reason for wanting a child. Social and, in some countries, political factors may also influence a couple to limit the number of children they have. In many developed countries, economic considerations frequently drive the decision-making process. For those living in low resource or developing nations, having children is a way of ensuring that someone will be available to care for the aged parent and family into the future. General health status and age are also considerations in decisions about parenthood as couples in many developed countries are getting married later and postponing pregnancies.

Figure 17-6 **Parent–child nurturing is important in adult transitions incorporating parenthood.**

iStockphoto/McInnch.

Unplanned pregnancy

Young adults sometimes have educational and career goals that take precedence over family development. Interference with these goals can affect future relationships and later parent–child relationships. An unplanned or even a planned pregnancy can act as a stressor and present emotional and physical health risks. Determination of situational factors that may affect the progress and outcome of an unplanned pregnancy is important. Exploration of problems such as finance, career, living accommodation, family support systems, potential parenting disorders, depression and coping mechanisms is important in assessing the health of a woman with an unplanned pregnancy.

Emotional health

Most young adults have sufficient physical and emotional resources and support systems to meet the many challenges, tasks and responsibilities of young adulthood. During the psychosocial assessment of young adults, assessing the 10 hallmarks of emotional health (Box 17-4) is one way to determine successful maturation in this developmental stage.

Health and health risk in young adulthood

Young adults are generally active and have minimal health problems. However, their lifestyles may put them at risk

BOX 17-4 10 hallmarks of emotional health

1. A sense of meaning and direction in life
2. Successful negotiation through transitions
3. Absence of feelings of being cheated or disappointed by life
4. Attainment of several long-term goals
5. Satisfaction with personal growth and development
6. When married, feelings of mutual love for partner; when single, satisfaction with social interactions
7. Satisfaction with friendships
8. Generally cheerful attitude
9. No sensitivity to criticism
10. No unrealistic fears

Modified from Stanhope M, Lancaster J 1996 Community health nursing: process and practice for promoting health, 4th edn. Mosby, St Louis.

of illness or disability during their middle or older adult years. Young adults may also be genetically susceptible to certain chronic diseases such as diabetes mellitus and familial hypercholesterolaemia (McCance & Huether 2012). Crohn's disease, a chronic inflammatory disease of the small intestine, most commonly occurs between 15 and 35 years of age.

Health risk and illness

Health risk factors for the young adult originate from their community, lifestyle and family history. For example, a young man whose father and paternal grandfather had myocardial infarctions (heart attacks) in their 50s has a higher risk for myocardial infarction. The presence of chronic illnesses in a family also increases the family member's risk of developing a disease. Risk may be a genetic factor and carried down through the family ancestry, or environmental; for example, the increased risk of lung cancer with the presence of secondary cigarette smoke in the home or heart disease as a result of poor family dietary habits over many years. It is also common for young adults to have misconceptions about the transmission and treatment of sexually transmitted infections (STIs) and they often need encouragement to discuss partner health status and risk.

Acute hospital care for young adults is frequently related to accidents, substance abuse, and exposure to environmental and occupational hazards, stress-related illnesses, respiratory infections, gastroenteritis, influenza, urinary tract infections and minor surgery. An acute minor illness can cause a disruption in the life activities of the young adult and increase stress in an already hectic lifestyle. Dependency and limitations posed by treatment regimens can also increase frustration for the young adult. To give young adults a sense of maintaining control of their healthcare choices, it is important to ensure they are well informed about their health status and that you, as the nurse, partner with them in healthcare decisions.

Chronic conditions are not common in young adulthood, but they can occur. Chronic illnesses such as hypertension, coronary artery disease and diabetes may have their onset in young adulthood without being diagnosed until later in life. Causes of chronic illness and disability in the young adult can include accidents, multiple sclerosis, rheumatoid arthritis, HIV/AIDS and cancer. Those born with genetic or congenital conditions of childhood, such as cystic fibrosis or congenital heart disease, now live well into their adult years and challenge health services to deliver appropriate care during adulthood. Chronic illness and disability can affect the accomplishment of important developmental tasks in young adulthood. The threat to the young adult's indpendence that is caused by chronic illness or disability can result in the need to change personal, family and career goals. Nursing interventions for the young adult faced with chronic illness or disability should acknowledge potential developmental problems related to sense of identity, the establishment of independence, reorganisation of intimate relationships and family structure and launching of a chosen career (Brown & Edwards 2007).

Health screening and assessment

Routine health screening has beneficial outcomes for the detection, management and prevention of a range of health disorders. Routine screening and assessment reduces the risk of preventable disease (see Chapter 24). In Australia, there are currently eight National Health Priority Areas: arthritis and musculoskeletal conditions, asthma, cancer control, cardiovascular health, diabetes mellitus, injury prevention and control, mental health and obesity (AIHW 2011). These priority areas have been associated with 91% of all deaths in this country. In New Zealand, the national health targets for 2011–12 are shorter stays in emergency departments, improved access to elective surgery, shorter waits for cancer treatment, increased immunisation, better help for smokers to quit, and better diabetes and cardiovascular services (Ministry of Health 2011a).

Breast screening (mammography) is included in current initiatives since breast cancer continues to be one of the most common causes of cancer deaths among women in Australia and New Zealand (Breast Cancer Australia 2011, Ministry of Health 2011b). Health screening not only involves professional activities, but relies on individuals conducting self-assessments, for example, regular examination of skin, breasts or genitalia. Nurses have a role in supporting young adults to understand the importance of integrating regular self-assessment into their daily lives and in promoting activities such as sun safety. It is vital that nurses have the skills to engage in effective educational processes to support young adults to adopt self-assessment and self-care practices for maintaining health and reducing risk (see Chapters 16 and 21).

Personal hygiene

As in all age groups, the personal hygiene habits of young adults are important and can impact on health. Regular bathing and healthy eating are important for maintaining healthy skin, hair and nails. Sharing eating utensils with a person who has a contagious disease increases the risk of illness. Poor dental hygiene increases the risk of periodontal disease and, as is now known, heart disease. Gingivitis (inflammation of the gums) and periodontitis (loss of tooth support) can be avoided through good oral hygiene (see Chapter 29).

Exercise

Exercise patterns can affect health status and this is a particularly important area of concern in countries where a sedentary lifestyle is common. For many young adults a lack of exercise is often related to work that requires sitting for long periods or long commutes to work. Insufficient physical activity and lack of exercise are associated with obesity, diabetes and cardiovascular diseases. Exercise that produces a sustained increase in the pulse rate for about 30 minutes every day improves cardiopulmonary function by lowering blood pressure and heart rate. In addition, exercise decreases fatigability, insomnia, tension and irritability. Related health assessment includes musculoskeletal assessment, joint mobility and muscle tone.

Psychosocial health

The psychosocial health concerns of the young adult are often related to work, study, relationship or family stress. As noted in Chapter 20, stress is not always bad. Stress can be valuable in motivating a person to change their situation. However, if the stress is prolonged and the young adult is unable to adapt to the stressor, health problems can develop. Mental health is an increasingly important issue for Australians and New Zealanders. In Australia, young adults are more likely to die from suicide than any other age group and the rate is higher for young men than women (ABS 2010b). Comparatively, the peak age for suicide among Aboriginal and Torres Strait Islander people (male and female) for 2012 was 25–29 years (ABS 2013a). This group suicide at a rate that is higher than non-Indigenous people. In 2014, suicide among Aboriginal and Torres Strait Islander peoples accounted for 5.2% of all Indigenous deaths compared to 1.8% for all deaths among non-Indigenous people (ABS 2016).

The second peak (the first is after age 85 years) in age for suicide in Australia is between the ages of 40 and 44 years for men and women (ABS 2013b). Similarly, in New Zealand, suicide continues to occur at significantly higher rates in Māori (16.1 per 100,000) than non-Māori (9.9 per 100,000) (Ministry of Health 2009).

Most young adults are able to handle day-to-day crises and variable levels of work stress. Situational job stress may occur when a new boss enters the workplace, a deadline is approaching or the worker is given new or greater responsibilities. A trend in today's business world and a risk factor for job stress is corporate downsizing, leading to increased responsibilities for individual employees and fewer vacant positions within corporate structures. Work stress also occurs when a person becomes dissatisfied with a job or their work responsibilities. Because individuals perceive jobs differently, the types of job stressor vary from person to person. Assessment of the young adult should include a description of the usual work performed and the present work functions, if different. Work assessment also includes conditions and hours, duration of employment, changes in sleep or eating habits, and evidence of increased irritability or nervousness.

Family stress can occur at any time during the peaks and troughs of normal family life (see Chapter 15). Situational stressors particularly occur during significant life events such as births, deaths, illnesses, marriages, divorce and job loss. Because of the multiplicity of changing relationships and structures in the emerging young adult family, stress is frequently high. The paid and unpaid work responsibilities of both partners may lead to temporary or permanent dysfunction in the young adult's family. For example, the highest divorce rate occurs during the first 3–5 years of marriage for young adults under the age of 30 years.

Families develop certain roles or jobs for their members. These roles enable the family to function as a unit and to contribute effectively to their broader society. An important role is that of the family 'leader'. In many families, one parent is the leader, or in others, both parents act as co-leaders. In single-parent families the parent or occasionally a member of the extended family is the family leader. When the role of leader is threatened (as a result of illness, for example), a situational crisis may occur. Indeed, any illness in the family has flow-on effects for all members, creating family strain. Assessment of environmental and familial factors, including the support systems and coping mechanisms commonly used by family members, is an important aspect of the health assessment. When any client presents with stress-related symptoms, it is useful to first explore significant family events.

Alcohol and substance use

Substance abuse directly or indirectly contributes to mortality and morbidity in young adults. Young adults under the influence of alcohol and/or other drugs may be severely injured in motor vehicle accidents, assaults or from self-harm. They are more likely to engage in other high-risk behaviours that may result in death or permanent disability to themselves or others. Increases in binge drinking and illicit drug use have led to alarming increases in emergency department presentations in recent years. One-third of Australian young people have been found to drink sufficient quantities of alcohol to put them at risk of short-term alcohol-related harm (AIHW 2007).

Dependence on stimulant or depressant drugs can result in long-term addiction, physical and mental health problems or death. Further, illegal possession and use of

illicit drugs is a criminal offence. Overdose of a stimulant drug ('upper') can stress the cardiovascular and nervous systems to the extent that death occurs. The use of depressants ('downers') can also lead to an accidental or intentional overdose and death.

Substance misuse is not always detectable. Non-judgemental questions about the use of legal drugs (prescribed drugs, tobacco and alcohol), use of soft drugs (marijuana) and use of illicit drugs (cocaine, heroin or 'ice') should be a routine part of any physical health assessment. Important information may be obtained by making specific inquiries about past medical problems, changes in food intake or sleep patterns, or emotional instability. Previous criminal convictions, such as for driving while intoxicated, domestic abuse or disorderly conduct may be relevant for alerting the healthcare professional to probe for the possibility of substance misuse or addiction.

Cannabis

For some, cannabis use commenced in adolescence continues through the young adult years. Also known as marijuana, this drug is developed from the flowers or extracted resin of the cannabis plant and is often smoked using unfiltered implements. The brain, specifically the hippocampus, amygdala, striatum and the cerebellum, have receptors that are impacted by cannabis. As a consequence, the user experiences a distorted sense of perception and a false sense of tranquillity sleepiness or restlessness, and can lead to feelings of depression.

Although correlations around the frequency and duration of use are unclear, cannabis use can result in impaired memory, increased anxiety, impaired psychomotor control, increased appetite, increased heart rate and alteration of sleep. Longer term use can (but is not limited to) increase the risk of mental illness, personality changes, hormonal problems, immune system suppression and injure blood vessels, as well as the structures of lungs and brain. Another more positive side effect of cannabis is pain reduction. Medical cannabis is increasingly being used to treat nausea associated with chemotherapy and other drug therapies and to reduce chronic pain and seizures.

Methamphetamines

The current worldwide trend of youth and young adults to consume methamphetamines is of significant concern for current and long-term health status. Methamphetamine is a synthetic (man-made) drug, often manufactured in non-regulated laboratories in residential suburbs or remote locations. The drug is made from the ingredients of a number of common cold and flu medications to increase its strength. These ingredients may be combined with other substances such as battery acid, lamp fuels, cleaning products and anti-freeze. Already high-risk, it is often the unknown contents of self-manufactured methamphetamines that significantly increase the risk of consuming this drug.

Crystal meth or 'ice', as it is often called, gives the person a false sense of themselves, often resulting in behaviours associated with personal violence and accidents. The 'down' or 'crash' as the drug wears off causes physical and emotional pain, leading to further drug seeking. Long-term health effects include increased heart rate and high blood pressure, damage to blood vessels in the brain and heart, leading to stroke or cardiac rhythm irregularities and possibly death. There is also risk for brain, liver, kidney and lung damage. Withdrawal from this drug and rehabilitation is long term and difficult.

Gambling

The 15–24-year age range is a high-risk period for engaging in gambling. Interestingly, higher rates of problem gambling have been linked to those with symptoms of self-reported Attention Deficit Hyperactivity Disorder (ADHD) persisting into young adulthood (Breyer et al 2009). Poor ability to cope with stress, anxiety, anger and other emotions have also been identified among young adult gamblers who go on to experience adult gambling addictions (Messerlian et al 2005). A recent study has reported that problem gambling among young adults is associated with higher rates of illicit substance use, alcohol and cigarette use, aggressive behaviours and unemployment, and lower rates of education (Hayatbakhsh et al 2012).

Young adults risk multiple health and social problems when they become involved in gambling, particularly when begun in adolescence. Problem gambling is a relatively under-researched area of health, but appears to be linked to a number of long-term health and social impacts.

Violence and injury

Violence is the greatest cause of mortality and morbidity in the young adult population. Death and injury can occur from physical assault, motor vehicle or other accidents and intentional self-harm or suicide. In Australia, 25% of male deaths and 17% of female deaths between the ages of 15 and 24 years are due to suicide (Harrison et al 2010). In Australia (AIHW 2006) and New Zealand (Ministry of Health 2014), young adults are much more likely to die from suicide or accidents (including road accidents or homicide) than disease. However, the number of deaths of children and young adults from motor vehicle

accidents has reduced considerably in the last two decades (AIHW 2010).

Media attention has focused on the increase in violent crime among youth, but adults still commit the majority of crimes. Factors that may predispose adults to violence, with subsequent injury or death, include poverty, family breakdown, domestic violence, child abuse and neglect, and repeated exposure to violence. Community and domestic violence are major causes of homelessness among women (AIHW 2005). Psychosocial assessment, including questioning about behaviour patterns, history of physical abuse, substance abuse, education, work history and social support systems, is an important part of the health assessment to detect personal and environmental risk factors.

Environmental or occupational factors

A common environmental or occupational risk factor is exposure to airborne particles that may cause lung diseases and cancer. Such lung diseases include silicosis from inhalation of talcum and silicon dust, and emphysema from inhalation of smoke. Cancers resulting from occupational exposures may involve the lung, liver, brain, blood or skin. Questions regarding occupational exposure to hazardous materials should be a routine part of the health assessment (Table 17-3).

TABLE 17-3 Occupational hazards associated with diseases

Occupational hazard	Work-related condition
Asbestos	Asbestosis, mesothelioma (pleural and peritoneal), lung cancer
Sunlight	Skin cancer
Wood dust	Nasopharyngeal cancer
Metal dust	Lung disease
Anaesthetic gases	Reproductive effects, cancer
Cement dust	Dermatitis, bronchitis
Solvents	Liver disease, dermatitis
Metal powders	Cataracts
Repetitive wrist motion on computers	Tendonitis, carpal tunnel syndrome, tenosynovitis
Petroleum distillates	Cancer of lung, larynx
Vinyl chloride (plastics)	Liver cancer (haemangiosarcoma)
Vibration (as in jackhammer use)	Raynaud's phenomenon
Dyestuffs	Bladder cancer, dermatitis
Pesticides	Pesticide poisoning
Cleansers, latex gloves	Allergies

Modified from Stanhope M, Lancaster J 2008 Community and public health nursing, 7th edn. Mosby, St Louis.

Sexually transmitted infections

Sexually transmitted diseases (STDs) or infections (STIs) continue to be a significant health problem for sexually active adolescents and adults. STDs include syphilis, chlamydia, gonorrhoea, genital herpes and HIV or acquired immune deficiency syndrome (AIDS). Some STIs have immediate and obvious symptoms such as discharge and discomfort. In others, symptoms are less obvious (particularly in women) and failure to treat may lead to significant consequences such as chronic infection from genital herpes; infertility from gonorrhoea; or disability and death from AIDS. Nurses should be alerted to the possibility of STIs when clients complain of urological or gynaecological problems (see Chapters 21 and 23). Health promotion for the prevention of STIs, safe sex and sexual safety is usually begun in early adolescence and is part of many school-based health and personal development learning activities.

Infertility

Infertility is the involuntary inability to conceive. In most sectors, infertility is defined as the inability to conceive after a year or more of regular sexual intercourse. While the fertility rate has increased in Australia and New Zealand (ABS 2007c, Statistics New Zealand 2011), an estimated 15–20% of otherwise healthy adults are infertile and many infertile clients are young adults. However, about 50% of the couples evaluated and treated in infertility clinics eventually become pregnant. In about 10–20% of couples, the cause of infertility is unknown and they remain infertile. In the remaining 30%, the cause of infertility is diagnosed but the couples remain infertile because of endometriosis, blocked fallopian tubes or decreased sperm motility. For some infertile couples, a nurse or health professional may be the first person they talk to about their inability to conceive. Assessment of the infertile couple should include a comprehensive health history of both the male and the female to determine factors that may have affected fertility, as well as relevant physical findings.

Pregnancy and parenting

A significant developmental task for many young adults is the decision to parent children (Figure 17-7). Physiological, cognitive, emotional and psychosocial transitions are part of a woman's **pregnancy** and childbearing experience

Figure 17-7 Ongoing prenatal care reduces complications of pregnancy.

iStockphoto/Gene Chutka.

(see Figure 17-8). The significant family of a woman, particularly a partner but also other family members such as parents, will also experience psychosocial transitions associated with the pregnancy and childbirth. Conception, fetal development and aspects of health during pregnancy and childbirth are discussed in Chapter 16.

Conception, pregnancy, birth and the puerperium are major phases of the childbearing cycle. Women experience significant complex changes in physiological condition, emotion and body image during pregnancy and early motherhood. Women who are anticipating pregnancy will benefit from good health practices before conception; these include maintaining a balanced diet, including an increased intake of folates (National Health and Medical Research Council 2003), a health check-up, avoidance of alcohol and cessation of smoking.

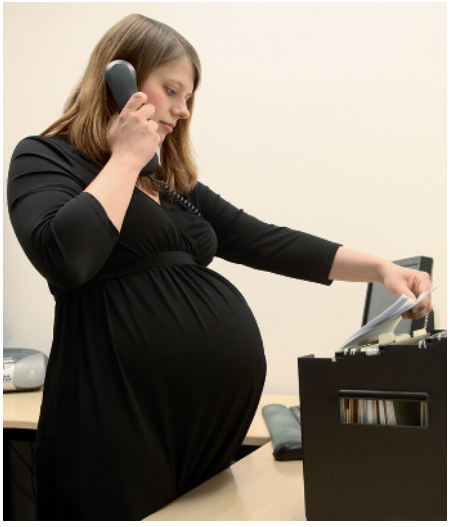

Figure 17-8 The ability to handle day-to-day challenges at work minimises stress.

Potter PA, Perry AG 2013 Fundamentals of nursing, 8th edn. Mosby, St Louis.

Physiological changes and needs

The major physiological changes and needs of the pregnant woman vary with each trimester (Table 17-4) and are also discussed in Chapter 16.

Prenatal care

Prenatal care, also known as antenatal care, is the routine examination of the pregnant woman by a midwife, obstetrician or general practitioner. Prenatal care includes physical assessment, for example, of the pregnant woman's weight, blood pressure, urine testing for glucose, acetone and protein, and measurement of the pregnant uterus (fundal height). Information is shared regarding sexually transmitted diseases, other vaginal infections and urinary infections that could adversely affect the health of the woman or fetus. The pregnant woman may be counselled about exercise, diet and childcare. Regular antenatal care monitors for conditions associated with pregnancy such as preeclampsia, eclampsia, gestational diabetes, excessive weight gain and the high-risk infant.

First trimester

All women experience some physiological changes in the first trimester of pregnancy, but not all will experience the physical effects of these changes, as outlined in Table 17-4. The midwife's role is to work with women to assess and monitor physical signs and symptoms, to monitor fetal health and growth, to suggest strategies to minimise discomfort from morning sickness or fatigue, as well as to refer the woman to medical services if any signs suggest a maternal or fetal problem.

Second trimester

During the second trimester women often report increased energy levels and, for most, nausea experienced during the first trimester reduces or disappears. Urinary frequency often experienced in the first trimester also ceases. Growth of the uterus and fetus results in a woman's shape visibly changing during this trimester. The pregnant woman often experiences changes in sensory perception. Temporary changes occur in visual and hearing acuity, taste and smell. Many pregnant women stroke their abdomen, possibly because of a change in the sensation of touch or other increased sensory need, or to initiate the attachment process with their child (Chapter 15).

Third trimester

During the third trimester some women feel increasingly fatigued and some will experience the return of uncomfortable symptoms such as urinary frequency and heartburn. Many, but not all, will experience Braxton Hicks contractions (irregular, short contractions) during this trimester. These are often mistaken for the beginning

TABLE 17-4 Major physiological changes during pregnancy

Signs and symptoms	Causes
First trimester	
Amenorrhoea	Fertilisation and implantation of egg
Morning sickness	Increased serum hormone levels
Breast changes Enlargement Tenderness Darkened and enlarged nipples	Increased oestrogen levels
Urinary frequency	Pressure of uterus on bladder
Fatigue	Increases in hormone levels Increased nutritional demands Decreased nutritional intake resulting from morning sickness
Second trimester	
Integumentary changes Pigmented nipple and breast Hyperpigmentation of abdominal line (linea nigra) Mottling of cheeks or forehead (chloasma or 'mask of pregnancy') Local or generalised pruritus	Increased levels of melanocyte-stimulating hormone
Hypertrophy of gums causing gingival swelling and bleeding	Proliferation of interdental papillary blood vessels resulting in local inflammation and hyperplasia
Increasing size of uterine fundus	Growth of fetus
Sensation of movement or gas-like movements (quickening)	Fetal movement
Braxton Hicks contractions	Expanding uterus and preparation of uterus for labour
Third trimester	
Increased colostrum	Hormonal influence; preparation of breasts for lactation
Increased urinary frequency	Pressure on bladder from enlarged fetus

Data from Dickason E et al 1998 Maternal–infant nursing care. Mosby, St Louis; Lowdermilk D, Perry S 1998 Maternity nursing, 6th edn. Mosby, St Louis.

of labour and this in itself can be frustrating and confusing. Women prepare for childbirth and parenting in a range of different ways and during this time their efforts can be supported through regular prenatal care.

Puerperium

The **puerperium** is the period approximately 6 weeks after childbirth. During this time the woman's body reverts to its pre-pregnant physical status. The nurse/midwife supports early parenting and the transition to motherhood in the first instance through systematic assessment of the woman's physical status and psychosocial wellbeing, as well as promoting attachment.

Education

The entire childbearing family may choose to be supported through educational processes about aspects of pregnancy, labour, birth, breastfeeding, sleep and settling practices, as well as the more general transitions to parenthood and integration of the newborn into the family. Traditionally, childbirth (antenatal or prenatal) classes help parents plan for the birth of the child and focus on the normal physiological changes of pregnancy, symptoms of impending labour, methods of pain control, the processes of labour and birth, and care of the newborn. Many healthcare centres also have sibling and grandparent preparation classes. Not all pregnant women will attend childbirth classes: childbirth education may not be accessible to women of all socioeconomic groups, and some may choose not to attend because of cultural beliefs about childbirth or lack of knowledge about the importance of childbirth education.

Prenatal classes can prepare pregnant women, their partners and other support people for participation in the birthing process. Social support has been associated with improved health practices in pregnant women (Cannella 2006) and with a lower incidence of postnatal depression

(Xie et al 2009). A current trend in some healthcare agencies is to provide a support person during labour to help women who have no other sources of support.

Psychosocial changes

Similar to the physiological changes of pregnancy, psychosocial changes occur at various times during the nine months of pregnancy and into the puerperium. Major psychosocial changes involve changing body image, role, sexuality, and coping mechanisms and stress during the puerperium. Table 17-5 summarises these psychosocial changes and their implications for nursing/midwifery intervention.

Health concerns

It is normal for the pregnant woman and her partner to have many questions. For example, they may wonder whether the pregnancy and baby will be normal. The majority of health needs related to pregnancy can be met during antenatal care, but this relies on parents having access and the opportunity to attend.

Middle adulthood

Middle adulthood is marked by the individual making lasting contributions through their involvement with others. Generally, the middle adult years begin around the early to mid-30s and last through to the late 60s. This period is one of happiness and stability for many as personal and career achievements are being realised. Although there is also reasonable socioeconomic stability for many middle-aged adults, there are also many pressures on domestic finances such as mortgages, lifestyle and family-related expenses. Changes in workplace organisation have significantly altered employment patterns in recent years. Although the overall unemployment rate is lower than during the late 20th century, many more adults work part-time, choosing to explore more balance in their lives, or with increased employment flexibility, organising their lives around more than one part-time job.

Many middle-aged adults find particular satisfaction in helping their children and other young people to become productive and responsible adults. This is also a time when many middle-aged adults help ageing parents. This is particularly true for women, daughters and daughters-in-law (Perrig-Chiello & Hutchison 2010). Using leisure time in satisfying and creative ways is a challenge for some and a necessity for others. If met satisfactorily, creativity in pursuing activities outside employment enables middle-aged adults to prepare for a productive and successful retirement (see Chapter 18).

Acute illnesses and conditions experienced in middle adulthood are similar to those of young adulthood. However, injuries and acute illness experienced in middle adulthood may take longer to recover from because of the slowing of recuperative processes with advancing age.

TABLE 17-5 Major psychosocial changes during pregnancy

Category	Implications for nursing
Body image	Morning sickness and fatigue may contribute to poor body image
	Client may feel big, awkward and unattractive during third trimester when fetus is growing more rapidly
	Increase in breast size may make the woman feel more feminine and sexually appealing
	May take extra time with hygiene and grooming, trying new hairstyles and makeup
	Begins to 'show' during the second trimester and starts to plan maternity wardrobe
	General feeling of wellbeing when woman can feel the baby move and hear the heartbeat
Role changes	Both partners think about and can have feelings of uncertainty about impending role changes
	May have feelings of ambivalence about becoming parents and concern about ability to be parents
Sexuality	Need reassurance that sexual activity will not harm fetus
	Desire for sexual activity may be influenced by body image
	May desire cuddling and holding rather than sexual intercourse
Coping mechanisms	Need reassurance that childbirth and childrearing are natural and positive experiences, but can also be stressful
	Often unable to cope with particular stressors such as finding new housing, preparing the nursery or participating in childbirth classes
Stresses during puerperium	May return home from hospital fatigued and unfamiliar with infant care
	May experience physical discomfort or feelings of anxiety or depression
	May be necessary for woman to return to work soon after delivery with subsequent feelings of guilt, anxiety or, possibly, sense of freedom or relief

Further, acute illnesses and injuries experienced in middle adulthood are more likely to become chronic conditions. Stress remains a significant confounder for middle-aged adults experiencing an injury or acute illness as they try to balance responsibilities related to their employment, finances, family life, care of children and care of ageing parents, especially while recovering.

Chronic illnesses such as type 2 diabetes, hypertension, rheumatoid arthritis, chronic obstructive pulmonary disease or multiple sclerosis may impact on the roles and responsibilities assumed by the middle-aged adult. Strained family relationships, modifications in family activities, increased healthcare tasks, increased financial stress, the need for housing adaptation, social isolation, medical concerns and grieving may also result from chronic illness. The degree of disability and the client's perception of both the illness and the disability determine the extent to which lifestyle changes and adaptation will occur. Some examples of the challenges experienced by clients who develop debilitating chronic illness during adulthood include role reversal, changes in sexual behaviour and alterations in self-image and self-identity (see Chapter 20).

Men and women in middle adulthood must also adjust to the inevitable biological changes of ageing. As in adolescence and youth, middle-aged adults use considerable emotional energy to adapt self-concept and body image to physiological realities, changes in physical appearance and societal pressures and values.

Physical changes

Major physiological changes occur between 40 and 65 years of age. Table 17-6 summarises normal developmental changes to consider when conducting a physical examination of the middle-aged adult. The most visible changes are the greying of the hair, wrinkling of the skin and thickening of the waist. Balding commonly begins during the middle years, but may also occur in young adult males. Decreases in hearing and visual acuity are often noted during this period. For many, the visibility of physiological changes of ageing have the most impact on self-concept and body image. Two of the most significant physiological changes during middle adulthood are menopause in women and the climacteric in men.

Menopause

Menstruation and ovulation occur in a cyclical rhythm in the woman from adolescence into middle adulthood. **Menopause** is the disruption of this cycle, mainly because of the inability of the neuro-hormonal system to maintain its periodic stimulation of the endocrine system. The ovaries

TABLE 17-6 Physical assessment in the middle-aged adult

Body system	Findings
Integument	Intact condition Appropriate distribution of pigmentation Slow, progressive decrease in skin turgor Greying and loss of hair (baldness patterns in males are established by age 55; hair loss after this time might have other causes)
Head and neck	Symmetry of scalp, skull and face Normal accessory organs of vision
Eyes	Visual acuity by Snellen chart that is less than 20/50 Pupillary reaction to light and accommodation Normal visual fields and extraocular movements Normal retinal structures
Ears	Normal auditory structures and acuity
Nose, sinuses and throat	Patent nares and intact sinuses, mouth and pharynx Location of trachea at midline Non-palpable lateral thyroid lobes
Thorax and lungs	Increased anteroposterior diameter Respiratory rate 16–20 breaths per minute and regular Ratio of respiratory rate to heart rate: 1 : 4 Normal tactile fremitus, resonance and breath sounds
Heart and vascular system	Normal heart sounds Systole: S1 less than S2 at base Diastole: S1 greater than S2 at apex Point of maximal impulse: at fifth intercostal space in midclavicular line and 2 cm or less in diameter Vital signs Temperature: 36.7°C to 37.6°C Pulse: 60–100 (conditioned athlete < 50) Blood pressure: 95–140/60–90 mmHg Respirations: 12–20 breaths per minute All pulses palpable
Breasts	Decreased size resulting from decreased muscle mass Normal nipples
Abdomen	No tenderness or organomegaly Decreased strength of abdominal muscles
Female reproductive system	Change in menstrual cycle and in duration and quality of menstrual flow 'Hot flushes' Change in cervical mucosa
Male reproductive system	Normal penis and scrotum Prostatic enlargement in some individuals
Musculoskeletal system	Decreased muscle mass Decreased range of joint motion
Neurological system	Appropriate affect, appearance and behaviour Lucidity and appropriate level of cognitive ability Intact cranial nerves Adequate motor responses Responsive sensory system

RESEARCH HIGHLIGHT

Research abstract

Menopause is a universal life experience. Historically, menopause has been conceived as a pathological condition and, therefore, medicalised by healthcare providers. The purpose of the study was to give voice to the menopausal experiences of women. The research question was: What has your experience been with perimenopause and/or menopause? Thirteen women, meeting inclusion criteria and obtained through snowball effect, were interviewed. Data were collected through semi-structured interviews and drawings. The women interviewed repeatedly had questions and concerns regarding perimenopause, and often reported receiving conflicting and confusing information. Transition theory was used to understand the thematic results. The major themes that emerged were My Body, Sharing with Others, Not My Mother and Going on with Life.

Evidence-based practice

- Menopause is a universal life event for women.
- Women lack information regarding menopause and are often confused and anxious about it.
- The information they receive is often inadequate and presents menopause as a deficit condition and a negative experience.
- Nurses and other healthcare practitioners should provide accurate and positive information to women well before they have symptoms and thus decrease some of the anxiety and misunderstanding associated with it.

Marnocha SK, Bergstrom M, Dempsy LF 2011 The lived experience of perimenopause and menopause. Contemp Nurse 37(2):229–30.

no longer produce oestrogen and progesterone, and the blood levels of these hormones drop markedly. Menopause typically occurs between 45 and 60 years of age. Menopause can be a particularly challenging transition in women's lives if it occurs before the age of 40 (see *Research highlight*). Approximately 10% of women have no symptoms of menopause other than cessation of menstruation, 70–80% are aware of other changes but have minimal disruption and approximately 10% experience changes severe enough to interfere with activities of daily living (Lowdermilk et al 2011). While a universal phenomenon, it is important to understand that menopause can be perceived and experienced very differently by individual women (see *Working with diversity*).

Climacteric

The **climacteric** occurs in men in their late 40s or early 50s (see Chapter 21) and is caused by decreased levels of androgens. Throughout this period and thereafter, a man is still capable of producing fertile sperm and fathering a child. However, penile erection is less firm, ejaculation is less frequent and the refractory period is longer.

Cognitive changes

Changes in the cognitive function of middle-aged adults are rare except with illness or trauma. The middle-aged adult can continue to learn new skills and information. For many, middle adulthood is a significant period for enrolling in educational or vocational programs to prepare for promotion or other employment opportunities.

Psychosocial changes

In the middle adult years, as children depart from the household, the family enters the post-parental family stage. Time and financial demands alter, and adults face the task of redefining their own relationships. As grandchildren arrive, grandparenting styles must be chosen. It is during this period that many middle-aged adults begin to take on a healthier lifestyle. Although it is not advisable to wait until this stage in life to think about health promotion, 'better late than never' does apply. The assessment of health-promoting activities for the middle-aged adult include ensuring adequate rest, encouraging leisure activities, regular exercise, good nutrition, reduction or cessation in the use of tobacco or alcohol, and regular health-screening examinations. Assessment of the middle-aged adult's social environment is also important, including relationship concerns; communication and relationships with children, grandchildren and ageing parents; and caregiver concerns with their own ageing or disabled parents.

According to Erikson's psychosocial developmental theory (see earlier), the main developmental task of the middle years is to achieve **generativity** (Erikson 1968, 1982). Middle-aged people who have successfully negotiated the task of young adulthood are well placed to contribute to the development of those younger than themselves. Generativity is the willingness to care for and guide others and can be a great source of satisfaction and fulfilment in middle adulthood. Middle-aged adults can achieve generativity through the guidance of their own children, their junior work colleagues, the children of

WORKING WITH DIVERSITY

Focus on cultural care

Understanding women's perceptions of menopause and its impacts on their lives, health and wellbeing is at the heart of engaging in illness prevention and health promotion strategies with perimenopausal women. In Western societies, perceptions of menopause have been dominated by biophysical changes and medical treatments that potentially minimise symptoms and reduce the risk of other disorders that may increase in likelihood following menopause. However, perceptions of menopause, its symptoms and challenges vary greatly between different cultures and ethnic groups. The cultural value placed on reproductive ability, social status in midlife and understandings of the links between menstruation and good health are just a few of the perceptions that form the basis for the way women understand and respond to menopause. Although there is high reporting of physical symptoms in Western countries, this is not the case in many societies, although there are differences between rural and urban groupings in some cultures. The way women respond to menopause issues also varies. They use traditional, complementary, Western and spiritual practices. Many women will use a combination of strategies; some are more focused on managing issues and some on preventing ill effects. Culturally competent nursing practice requires the provision of culturally appropriate care.

Implications for practice

- Understanding women's perceptions of their health, the transitions they face and the implications of menopause, on an individual basis, is critical.
- Listening to women's perceptions and issues without cultural bias and setting aside one's own imperatives is important in order to support women's needs.
- Accessible and appropriate health services with adequate language support are required.
- Peer support is valued and helps many women learn strategies that are appropriate for their socio-cultural context – nurses can facilitate community advocates.
- Information and explanation of symptoms and treatment options need to be provided in culturally appropriate forms.

close friends, or through social interactions with younger generations. There is satisfaction in knowing that they have helped those who will outlive them. Adults who have not been able to achieve successful development in their young adult years tend to remain socially isolated and are less likely to achieve generativity. This may lead to developmental stagnation – expressed as excessive concern with themselves at the expense of those younger, or destructive behaviours towards their children and the community.

Career transition

Career changes may occur by chance or by choice, or as a result of changes in the workplace or society. In contrast to the previous 'one job for life' generations, middle-aged adults are increasingly likely to change occupations to improve their upward mobility, to pursue employment security or to seek an occupation that is more challenging or exciting. In some cases, technological advances or economic downturns have driven middle-aged adults to seek new careers. Being made redundant or losing a job can be a major source of stress as the middle-aged person worries about their ability to compete and find another job (Gabriel et al 2010). The stress caused by such changes, particularly when unanticipated or undesired, can affect health, family relationships, self-concept and other dimensions.

Sexuality

Sexuality and sexual relationships undergo transition in the middle adult years. For some people, refocusing on an existing partnership leads to increasing sexual satisfaction. For others, new relationships and partnerships are formed. Sexual practices are affected not only by realignment of relationships but also by biophysical changes. The onset of menopause can affect the sexual health and libido of some women, and during middle age, a man may notice changes in the strength of his erection and a decrease in his ability to experience repeated orgasm. Other factors influencing sexuality during this period include work stress, diminished health of one or both partners, and the use of prescription medications such as antihypertensive agents with side effects that may influence sexual desire or functioning. Middle-aged adults may experience stresses related to sexual changes or a conflict between their sexual needs and self-perceptions and social attitudes or expectations (see Chapter 21).

Family orientation and relationships

Psychosocial factors involving the family may include the stresses of singlehood, marital changes, transition of the family as children leave home, and the care of ageing parents. The departure of the last child from the home may be particularly stressful. Many parents welcome freedom from childrearing responsibilities, whereas others feel lonely or without direction because of this change. Eventually, partners must reassess their relationships

and plan for their future. Changes in marriage and partnerships that may occur during middle age include death of a spouse, separation, divorce and the choice of remarrying or remaining single. A widowed, separated or divorced adult experiences a period of grief and loss in which it is necessary to adapt to the change. Grieving is complex and involves a series of phases taking time to resolve. How much time is difficult to assess, but it may take years for some people.

Care of ageing parents

The increasing life spans of people living in Australia and New Zealand has led to increased numbers of older adults in the population. As a result, greater numbers of middle-aged adults are attending to the personal and social needs of their ageing parents for a longer period of time. Many middle-aged adults, particularly women, find themselves in the 'sandwich generation', caught between the responsibilities of caring for dependent children and those of caring for ageing or ailing parents (see Chapter 18).

Housing, employment, health and economic realities have changed the traditional social expectations between generations in families. The middle-aged adult and the older adult parent may have conflicting priorities related to their relationship, while the older adult strives to remain independent. Negotiations and compromises help in defining and resolving problems. Nurses deal with middle-aged and older adults in the community, extended-care facilities and in hospitals. The nurse has a role in identifying the health needs of both groups and can help the multigenerational family determine the health and community resources available to them as they make healthcare decisions and plans. Assessing environmental resources (e.g. access to stairs, bathrooms, home safety) in relation to meeting the healthcare demands of the older adult can also be helpful to the family.

• CRITICAL REFLECTION POINT

Paulina is 48 years old. She is married and is the mother of two sons aged 13 and 16. Paulina has recently had to assume responsibility for caring for her 78-year-old mother after she suffered a stroke. Paulina presents to the local hospital emergency department with breathlessness and reports feeling highly stressed.

Describe the nurse's role in helping Paulina care for her mother.

Health challenges

Health challenges during middle adulthood include managing stress, maintaining a level of wellness, embracing positive ageing, self-care and the continuation of positive health habits, such as adequate exercise and healthy eating. In 2013, heart disease was identified as the leading cause of death among Australians, with dementia and Alzheimer's disease now recorded as the second leading causes (ABS 2015). For New Zealanders, the leading causes of death in 2011 were cancer, ischaemic heart disease (heart attacks) and cerebrovascular (stroke) disease, and for the Māori population specifically, cancer, ischaemic heart disease and chronic lower respiratory disease (Ministry of Health 2014).

Stress and stress reduction

Similar to all developmental stages, the perceptions of middle-aged adults are important to maintaining a sense of wellbeing during physiological change. Middle-aged people are often at the top of their career trajectory and, as already discussed, are likely to have responsibilities for teenage or young adult children, as well as ageing parents. Today's complex world makes individuals more prone to stress-related illnesses such as hypertension, migraine headaches, ulcers, inflammatory bowel disease, autoimmune diseases, backache, arthritis, cancer and heart attack. When middle-aged adults seek health care, a focus on the goals of wellness and balance can guide clients to evaluate their current health behaviours, lifestyle and environment. Attention to modifiable risk factors to improve health such as stress reduction, weight loss, reducing alcohol or tobacco consumption and improving nutrition and exercise can markedly increase the quality of life.

Throughout life, people are exposed to many stressors (see Chapter 37). Identifying these stressors is the first step towards intervening to modify the stress response. Specific interventions for stress reduction can fall into three categories.

1. Efforts to reduce the frequency of stress-producing situations are discussed with the client and coping strategies are offered. Together the nurse and client identify approaches to prevent stressful situations, such as habituation, change-avoidance, time blocking, time management and environmental modification.
2. Psycho-physiological preparation to increase stress resistance is commenced, such as increasing self-esteem, improving assertiveness, redirecting goal alternatives and reorienting cognitive appraisal.
3. The physiological response to stress is avoided. The nurse may suggest relaxation techniques, imagery and biofeedback to recondition the client's response to stress. These general interventions are explained in greater detail in Chapter 37. Advice can also be given about community services that provide stress reduction programs.

Forming positive health habits

A *habit* is a person's usual practice or manner of behaviour. This behaviour pattern is reinforced by frequent repetition until it becomes the individual's customary way of behaving. Some habits support health, such as healthy eating, exercise and brushing and flossing the teeth each day. Other habits involve risk factors to health, such as smoking or eating foods with little or no nutritional value. During assessment, the nurse often obtains data indicative of both positive and negative health behaviours. Examples of positive health behaviours include regular exercise, adherence to healthy dietary habits, avoidance of excess consumption of alcohol and recreational drugs, participation in **routine health screening** and diagnostic tests for disease prevention (e.g. blood testing for serum cholesterol, blood pressure monitoring, mammography), and lifestyle changes to reduce stress.

Health education and health counselling are directed at improving health habits (Box 17-5). In the planning, implementation and evaluation phases, nurses work with their clients to maintain habits that protect and promote health in daily life. The more fully the nurse understands the dynamics of behaviour and habits, the more likely it is that interventions will help the client to achieve or reinforce health-promoting behaviours.

BOX 17-5 Education for positive health habits

Objective

- Client will increase exercise patterns to include several walks per week to assist weight loss and improve cardiopulmonary function.

Education strategies

- Review with client the daily work schedule and identify potential times for exercise.
- Inform client about the effect of exercise on weight control and improved cardiac function.
- Demonstrate how to calculate target heart rate and assess pulse correctly.
- Provide warm-up and cool-down exercises and demonstrate how to do them.
- Instruct client about support shoes for walking exercises.

Evaluation

- Have client keep log of exercise periods.
- Have client demonstrate pulse measurement.
- Have client demonstrate warm-up and cool-down exercises.
- Inspect client's feet for blisters or sores.

The forming and sustaining of positive health habits is facilitated by listening to the client's interests, imperatives, likes and dislikes and negotiating activities and outcomes supported by accurate, evidence-based and useful information. While consciousness-raising is important, barriers to change do exist (Box 17-6). Some barriers are more amenable to change than others; some can be built into the nurse–client relationship, and others require community, health service and political action. Ultimately, it is the client who decides whether to change their health behaviours and which of these will become sustained habits of daily living.

Psychosocial health and positive ageing

The **middle-age** years are a time of great satisfaction for many adults. Children are becoming or are independent, life and work are settled and there is a sense of being able to regain one's sense of self. However, some adults experience anxiety in response to the physiological and psychosocial changes of middle age. In a positive way, anxiety can motivate the adult to rethink life goals and stimulate productivity. For others, however, this anxiety can precipitate **psychosomatic illness** or a preoccupation with the amount of time left to live. Anxiety is a critical maturational phenomenon related to change, conflict and perceived control of the environment (Erikson 1968). Clearly, a life-threatening illness, a relationship transition or job stressor can increase anxiety. Crisis intervention or stress management techniques may help the client more successfully adapt to the changes of the middle adult years (see Chapter 37).

Although depression most commonly begins in adolescence or young adulthood, it is increasingly present in middle age with the incidence in women twice that of men. Depression affects individuals differently and can

BOX 17-6 Barriers to changing health behaviours

External barriers

- Societal perceptions of healthy activities
- Workplace practices and values
- Community resources, including green spaces and safe environments
- Lack of social support
- Lack of material resources

Internal barriers

- Conflicting priorities and goals
- Motivation
- Insufficient skill or knowledge

manifest in a variety of ways. Adults in their mid- to late 50s may begin to notice mild cognitive impairment and memory loss, or an increase in somatic symptoms and insomnia. Possibly associated with the grief and loss of children leaving home or changes in adult relationships, for example, this may not be immediately recognised as depression (Wolitzky-Taylor et al 2010). The onset of depression, or increased depressive symptoms during middle age, is associated with an increased risk of dementia (Barnes et al 2012). People experiencing mild depression describe themselves as being stressed, as feeling sad, blue, downcast, down in the dumps and tearful. Other symptoms include alterations in sleep patterns such as difficulty in sleeping (insomnia) or sleeping too much (hypersomnia), irritability, feelings of social disinterest, and decreased alertness. Physical changes such as weight loss or gain, headaches or feelings of fatigue, regardless of the amount of rest, may also indicate depression. Depression occurring during the middle adult years is commonly characterised by moderate-to-high anxiety and physical complaints. Mood changes and depression are common during menopause. Depression may be worsened by alcohol abuse or other substances.

Focused data collection regarding individual and family history of depression, mood changes, cognitive changes, behavioural and social changes, and recent physical changes are essential elements in the assessment of the middle-aged adult. In determining whether a client may be depressed, assessment data should be collected from both the client and the client's family, since the family may be able to offer particular insights, depending on the level of depression being experienced.

Community health and primary healthcare

Community health programs are designed to prevent illness, promote health and detect the early stages of disease. Many young and middle-aged adults participate in regular community health screening (e.g. breast, bowel and prostate cancer, hypertension and diabetes) or exercise programs (yoga, pilates, gym classes) offered in private or community settings. Nurses can make valuable contributions to the health of the community by taking an active part in the planning of screening and education programs at local community centres, supporting community development initiatives and through their work in general practices or community nurse-led clinics. Liaison with other health, housing and social services, general practitioners, community organisations and businesses is integral to a community nursing role which is broad, complex and multidisciplinary.

CRITICAL REFLECTION POINT

Greg is a 49-year-old man. He is married with two young children and works in a plant nursery as a horticulturist. Apart from his work he gets little exercise, mainly because of the demands of his family. He is moderately overweight, reports experience of feeling stressed and his blood cholesterol and blood pressure are both on the high side of normal.

What strategies should be considered when devising a plan for Greg to develop a healthier lifestyle? Who might you consider should be involved in Greg's care?

Key concepts

- Human development does not end at adolescence. Human adults continue to grow and develop in response to life experiences to an optimal state of organised and specialised functional capacity.
- Nurses care for human beings at various developmental stages, and during health and life crises.
- Developmental theory provides a basis for nurses to assess and understand their clients' behaviour and vulnerability in response to illness or trauma.
- Biophysical development explores theories of why individuals grow and age from a biological standpoint.
- Psychosocial developmental theory is a way to predict, understand and explain how and why people become and behave as they do.
- Psychosocial theories attempt to describe the development of the human personality with varying degrees of influence from internal biological forces and external socio-cultural forces.
- Psychosocial developmental crisis refers to a person's difficulty in meeting and resolving tasks of the current developmental period. Relative success at each stage is built upon by each subsequent stage to bring about adult maturity.
- Cognitive development focuses on rational thinking processes, which include changes in how children and adolescents perform intellectual operations.
- Socialisation is the process whereby humans interact with each other to form families, communities and the broader society.
- Moral development attempts to define how moral reasoning matures for an individual.

Working with older people

Susan Hunt

Learning outcomes

Mastery of content will enable you to:

- describe healthy ageing and common myths and stereotypes about older adults
- discuss the significance of nurses' attitudes towards older adults
- describe the types of community-based healthcare services available to older adults
- describe some of the biological and psychosocial theories of ageing
- discuss common developmental tasks of older adults
- discuss common physiological changes of ageing
- discuss common health issues experienced by older adults
- differentiate between delirium, dementia and depression
- discuss issues related to psychosocial changes of ageing
- identify nursing interventions related to the physiological, cognitive and psychosocial changes of ageing.

Unlike other life stages, it is not clear when older adulthood begins. Many people find themselves described as 'older' from 50 years, and travel and shopping concessions generally begin at 55 years. In the past, retirement from work has been used as a marker of older adulthood – traditionally at 65 years. However, being retired is no longer a useful indicator of older adulthood. With the introduction of superannuation schemes, many people have been able to retire at 55 years or earlier, while others, because of their good health and continued interest in their work, have delayed retirement to work productively into their 70s and 80s. Others may choose a pre-retirement phase, negotiating shorter and more flexible work hours for a period of time. Recent changes in world economics have also contributed to adults working longer. A decrease in savings, as well as anxiety that savings will not fund a lengthy retirement period, have influenced many older adults to either stay within the workforce or to return to part- or full-time work.

Similar to many developed countries, Australian and New Zealand governments use the age of 65 years and over as a basis for planning health and welfare services for older adults. The population characteristics of both countries are changing, with more people living into older age. For some years there have been warnings that the growing numbers of older people and their need for services will challenge both countries, coupled with public debate about how these services should be funded.

While the number of older people is growing as a proportion of the population of both countries, it is important to remember that the majority of older people have active and productive lives which are generally healthier than in previous generations (Figure 18-1). There are many older people, such as those involved in running households, properties and farms who will never actually retire from work. Healthy ageing (or **positive ageing**) refers to maintaining a focus on the opportunities and rewards of ageing, rather than on the challenges. The Australian Psychological Society describes positive ageing as the 'process of maintaining a positive attitude, feeling good about yourself, keeping fit and healthy, and engaging fully in life as you age' (APA 2015). Increasing numbers of older adults across the world are experiencing better long-term physical and mental health due to the effects of maintaining a positive attitude and re-imagining the types of contribution they can make to community and society.

A challenge for healthcare professionals is the scope of older adulthood. Older adulthood can span 40-plus years and includes a range of older people who are active and healthy through to those who have low, medium or high levels of disability. The prevalence of disability generally

Figure 18-1 Enjoying life in older age improves both physical and mental health.

iStockphoto/Cathy Yeulet.

increases gradually throughout middle age and then, after the age of 50, disability prevalence rises from 20% in the 50–54 age groups to 81% among people aged 85 and over. Rates of severe activity limitations are even more strongly associated with age, with limited activity reported by almost one-third (31%) of people aged 75 and over (AIHW 2014). Consequently, the group of people known as 'older adults' in contemporary Australian and New Zealand societies must be considered a heterogeneous group, and it is therefore difficult to make generalisations about their needs. Family circumstances, physical abilities, economic circumstances and health and welfare service needs are likely to vary greatly among people of 65–90+ years.

Older adults are consumers of services in all health-delivery settings: community care, rehabilitation, acute care, specialised outpatient clinics, residential aged care and palliative care. It is important, therefore, for healthcare professionals to understand the diverse needs of older people and to work with them in two ways: firstly

to ensure that the services provided are appropriate to their needs; and secondly, to understand these needs from the perspective of the older person. Like people at all ages and stages of development, older people want to have greater control of the services they receive, and want to be considered as active partners in their care. All people increasingly expect health professionals to work 'with' them rather than 'on' them, and in most care settings for older people, the contemporary concepts of restorative care, reablement and enablement form the basis of care delivery (Lewin et al 2013). Given the increasing emphasis on quality and safety as part of service provision, it is also important that healthcare professionals are aware of the special quality and safety needs of older adults, as well as the increasing diversity of people within this group.

Older adults as part of our population

Those aged 60 years and over are the fastest growing global population (United Nations 2013). In New Zealand and Australia, populations are ageing *numerically* (in that the numbers of older people are increasing), and *structurally* (in that the proportion of people aged over 65 years is rising) (ABS 2013, Statistics New Zealand 2015). Consequently, the age composition of both countries is projected to change considerably as a result of population ageing. For example, it is projected that one in five New Zealanders will be aged 65+ years by 2031, compared with one in eight in 2009 (Statistics New Zealand website 2016). It is projected that between 2012 and 2032 the number of people of 65 years and over in the Australian population will increase by 82% (AIHW 2013) coupled with a lower proportion of people aged under 15 years in both Australia and New Zealand (ABS 2013, Statistics New Zealand website 2016).

There is a staggering 100% increase projected in the number of people aged 85 years and over in the Australian population between 2012 and 2032, with a similar pattern occuring in New Zealand (ABS 2013, Statistics New Zealand 2015). Growth in the population aged 85 years and over is particularly significant for aged care service planning, as this group is more likely to require health services, including residential care.

Life expectancy

The main factors affecting the ageing of Australia's and New Zealand's populations are the sustained low birth rates combined with low mortality rates, resulting in increasing life expectancy at birth. Improved living conditions and healthier lifestyles along with medical advances, particularly in the treatment of cancer and cardiovascular disease, have greatly increased life expectancy (AIHW 2014). However, overall, those who are economically or socially disadvantaged still experience lower health status and a reduced life expectancy.

Life expectancy is not uniform across populations within Australia and New Zealand. While life expectancy at birth for non-Māori New Zealand men and women in 2013 was 80.3 years and 83.9 years respectively, the life expectancy of Maori people at birth was 73.0 years and 77.1 years, respectively (Ministry of Health 2013, 2015). While the gap between Māori and non-Māori life expectancy at birth has continued to narrow, Māori people still remain overrepresented in most disease groups, with an estimated 26% of the excess burden of disease experienced by Māori people caused by vascular disorders (Ministry of Health 2013, 2015). Aboriginal and Torres Strait Islander peoples also have a much lower life expectancy than the general Australian population and an overall burden of disease two to three times greater than the general Australian population (AIHW 2014). The estimated life expectancy for Indigenous males is about 10.6 years less than that of non-Indigenous males; for Indigenous females the gap is approximately 9.4 years (AIHW 2014). In addition, the incidence of ill-health for many Aboriginal and Torres Strait Islander people is higher than that of non-Indigenous people, for example, higher levels of injury, diabetes, kidney disease and psychological distress (AIHW 2014).

Immigration

Both Australia and New Zealand have had active migration programs, and consequently the populations of both countries are culturally and ethnically diverse. Overseas-born people in both countries have a lower death rate for most of the major causes of death, and overall, their experience is as good as, if not better health than, that of native-born people. In general, immigrant populations have a lower rate of death and hospitalisation as well as lower rates of disability. Known as the 'healthy migrant effect', it has been hypothesised that the general good health and the resulting longer life span of overseas-born people is a result of the selection processes for migration, which generally favour healthy people (AIHW 2011). However, both Australia and New Zealand have also accepted vulnerable people as refugees. The life expectancy of these more recent migrants may prove not to be as high as other migrants. Further, accessing health care and navigating the health system (often described as a 'maze'), has been noted to be extremely difficult for those with low health literacy or with English as a second language (AIHW 2014).

Gerontology as a nursing specialty

While working with older adults is increasingly recognised as a specialty area of nursing, most nurses who work with older people identify themselves as working within a specific care context, for example, rehabilitation, community care or residential aged care. Some nurses identify themselves as specialising in specific conditions common to older adults, for example, dementia care or continence promotion. Knowledge of the most frequently used terms in caring for older adults, and their definitions, clarifies the differences and improves communication between families and health professionals.

Geriatrics is the branch of medicine dealing with the illness of old age. Geriatric care is concerned with the physiological and psychological aspects of ageing and with the diagnosis and treatment of diseases affecting older adults.

Gerontology is the study of all aspects of the ageing process and its consequences. **Gerontological nursing**, a term frequently used in Australia and New Zealand, is concerned with assessment of the health and functional status of older adults; diagnosis, planning and implementing of health care and services to meet identified needs; and evaluating the effectiveness of such care. Gerontology nursing can encompass personal care, restorative care and rehabilitation, as well as end-of-life care. By working in partnership with an older person and their family or carers, the overall aim is to increase the quality of life of an older person and assist in minimising their functional decline. Gerontic nursing is a term often used in the international literature and is used interchangeably with gerontology or gerontological nursing.

Figure 18-2 **Eating well is an important part of healthy ageing.**

iStockphoto/DavidsAdventures.

There is increasing acceptance that working with older adults is a challenging area that demands highly skilled and knowledgeable nurses. Given the age range and variability of needs that an older adult may have, a critically informed understanding of how older people contribute and relate to society, as well as knowledge of ageing and the common health issues experienced by older people, is necessary for appropriate clinical decision-making.

Healthy ageing

Maintaining a positive attitude towards ageing can significantly influence the choices older people make, and the degree to which they maintain control over important decisions in their life. Education, supportive personal and social environments, good medical care and superannuation entitlements all contribute to better life chances in old age and to the likelihood of maintaining good health into advanced age. Increasingly, there is an emphasis on older people continuing to be active members of their communities, with the health authorities of both New Zealand and Australia undertaking community campaigns to promote healthy eating, regular exercise and continued social and community involvement as beneficial to ageing productively and well.

Healthy ageing describes the ongoing activities and behaviours that each person undertakes to reduce the risk of illness and disease, with the result of an increase in physical, emotional and mental health. Healthy ageing activities assist in minimising functional decline and increasing the quality of life as people age. Healthy ageing also incorporates activities to combat illness and disease, resulting in a faster and more enduring recovery should illness occur. Activities contributing to healthy ageing include maintaining social connections; exercising the body and mind; eating and sleeping well; volunteering or maintaining part-time work; managing stress; and maintaining a positive attitude.

There is a common misperception that older people are all dependent in some way, and are destined to live in residential aged care. However, although the proportion of older people living in non-private dwellings increases with age, the reality is that the majority of older people live in private dwellings – either with a partner or as part of a family household, as a member of a group, or by themselves. Less than 6% of older people in Australia are estimated to live in non-private dwellings, including

private hostels or hotels, guest houses and residential aged care (AIHW 2013). There is a similar picture in New Zealand (Statistics New Zealand website 2016).

The likelihood of living alone increases with age, with 35% of those aged 85 years and over living in lone-person households (AIHW 2013). The policies of successive governments of both New Zealand and Australia have focused on community care, and increasingly older people with disability or impaired health are able to be supported at home or in the community. Consequently, those living in residential aged care tend to be older, with the majority being over 75 years, and with a greater level of disability and ill-health (AIHW 2013, Statistics New Zealand website 2016).

As noted earlier, being retired is no longer a useful indicator of when a person has entered older adulthood. Many older adults undertake a planned pre-retirement period as a test of their financial, social and accommodation needs. Those who are self-employed, such as farmers or small business owners, make decisions about work and succession planning with family and others. Workplaces offering pre-retirement contracts, for example, provide opportunities to reduce working hours over a number of years, or more flexible hours to ease out of full-time into part-time work, and eventually to full retirement. The majority of older people continue to make valuable contributions to their families and to society. People aged 65 years and over provide a substantial proportion of volunteer hours (AIHW 2013, Statistics New Zealand 2009), and therefore contribute to the economic, political, social and cultural life of society. In addition, older people provide the majority of the informal caring for friends and family, including children, people with disabilities, and other older people (AIHW 2013). A recent phenomenon is the increasing number of grandparents who are taking on caregiver roles for grandchildren. This may be due to current economic pressures on parents to maintain full-time employment or may be due to family-related events such as death, divorce, substance abuse, incarceration, abandonment, ill-health or child abuse. Many more grandparents are raising (or parenting) their grandchildren, in addition to contributing unpaid child-minding.

It is also relatively common for older New Zealanders and Australians to use their time following retirement for travelling (known colloquially as the 'Grey Nomads'), or to change their way of life and move to either the country or the coast to begin a new phase of their lives. Future ideas of old age and the role that older people play in society are changing as we see increasing numbers of 'Baby Boomers' – those born between 1946 and 1961 – reach retirement age. It has been suggested that this group have seen what has been offered by society to their own parents, and want something more for themselves in older age (Hunt 2007). The large cohort of Baby Boomers are said to have redefined a number of the 'age stages' as they have passed through them, and come with their own ideas as to what is acceptable in terms of lifestyle, choice and access to health services and health care. It is expected that this group will continue to change how older age is defined as they live within and beyond each stage.

• CRITICAL REFLECTION POINT

It is likely that there are older adults in your own family. Are the older adults in your family physically well? Would you consider them active members of your family, despite any disability? What role does the older person have in the family unit?

Perhaps you have worked in a healthcare setting with a client who was an older person. Do your expectations of older people affect how you talk and interact with them? Have you ever witnessed interactions that were demeaning to an older person?

Ageism

The term **ageism** is attributed to Robert Butler, who first used it in 1969 to describe the process of stereotyping and discriminating against people because they are old (Butler 1969). The United Nations has identified three types of security needed in late life: *human capital* (health, work skills and self-knowledge); *social capital* (family and community networks); and *economic capital* (savings and pension plans). Programs to eradicate poverty, unemployment and social exclusion are needed to help people balance these resources, as well as gain access to financial services and safeguards from physical, mental and financial abuse (United Nations 2010a). Ageism is seen as a barrier to these programs and, in the opinion of the United Nations, must be eradicated. Indicators of ageism in the broader community include myths, stereotyping and negative attitudes towards older people (Table 18-1). The United Nations has provided a number of examples of how ageism can be expressed: in compulsory retirement; consideration for employment; migration; travel insurance; access to mortgages and bank loans; and for health or life insurances.

Myths of ageing and stereotyping of older adults continues, despite ongoing research in the field of gerontology that continually shows the majority of older adults are not ill, disabled or dependent. For example, a common misconception is that older adults are not interested in sex and that any interest in sexual activities

TABLE 18-1 Myths about older adults

Misconception	Reality
All old people are senile	*Senility* is an outdated term and is definitely not part of normal ageing Memory problems are a feature of some disease processes, e.g. Alzheimer's disease
Older people are preoccupied with dying	Older people do think about mortality, as do people of all ages
Older people cannot learn new skills	This is a variation on 'you can't teach an old dog new tricks'. Many older people enjoy learning, as testified to by the numbers of older people who enrol in university courses and local adult education activities. Older people are also among the 'early adopters' of new technology, particularly the use of the internet and communication devices such as Skype
Most older people live in nursing homes	The majority of older people live in the community in private dwellings rather than in institutions
Older people are not interested in sex	Many older people remain very interested in sex and seek ways to express their sensuality and sexuality. This remains a challenge to younger people and healthcare professionals who often do not wish to explore this area of health care
Older people are a burden on society	The majority of older people lead productive, independent lives. They participate in all areas of society, including undertaking the bulk of volunteer work Over half of older people aged 85+ years live alone, maintaining their own day-to-day care needs

Nay R, Garratt S, Fetherstonehaugh, D 2013 Older people: issues and innovations in care, 4th edn. Churchill Livingstone, Sydney; AIHW 2013 Australia's welfare 2013, Cat. no. AUS 174. Canberra. Online. Available:www.aihw.gov.au.

is abnormal and should be discouraged. Yet older adults report continued enjoyment of sexual relationships and research shows a positive correlation between sexual expression and quality of life for older people (Flynn et al 2014) (Box 18-1). A study of sexuality and health among older adults illustrates that part of the problem for many older adults is their reluctance to discuss sexual issues with healthcare professionals, possibly because of a fear of disapproval (Connaughton et al 2015). It is the disapproval of others that has caused some older people who identify themselves as being lesbian, gay, bisexual, transgender or intersex (LGBTI) to hide their sexual orientation from service providers (Department of Health and Ageing 2012b). With policies of inclusiveness, governments are encouraging service providers to consider how their current practices may discriminate against older people in general, and against specific groups of older people in particular.

Although the process of continual learning may be affected by age-related changes in vision or hearing, or by reduced energy and endurance, older adults are lifelong learners. Importantly, the benefits for an older adult taking part in education and health-promoting activities are usually quite high. There is evidence that activities which promote smoking cessation and encourage healthy eating, increased physical activity and social engagement are very successful with older adults (Haber 2007), particularly when framed within the perspective of the older person. Recent research from New Zealand indicates that physical comfort, integration, contribution, security, autonomy

BOX 18-1 Sex and sexuality

- Research has consistently shown that sexual activity remains important for many older people.
- For many older people there is a link between sexual expression and their quality of life.
- Sexual expression can include touching/holding hands, embracing/hugging, kissing, mutual stroking, masturbating and intercourse.
- With reasonable health and a partner, sexual relations are possible into the ninth decade of life.
- Sexual drive varies with each person, and in each person, from time to time.
- Older people may be heterosexual or identify as being lesbian, gay, bisexual, transgender and intersex.
- Not all older people want to be sexually active and those that do may choose to express their sexuality in a range of ways.
- Denial of an individual's sexuality is an infringement of that individual's human rights.
- Sexual problems are frequent among older adults, but these problems are infrequently discussed with healthcare professionals.

Flynn T-J, Gow AJ 2015 Examining associations between sexual behaviours and quality of life in older adults. Age and Ageing; Connaughton C, McCabe M 2015 Sexuality and Aging. Encyclopaedia of Geropsychology; United Nations 1948 The Universal Declaration of Human Rights. United Nations, Geneva. Online. Available www.un.org

and enjoyment are concepts and activities that older people think are important for their health (Stephens et al 2015). Like people of all ages, it is important to provide health-promoting messages that correspond to the identified interests of the older adult, rather than to areas believed to be important by the healthcare professionals. Understanding the needs and interests of the older person also ensures that self-care education includes techniques that compensate for any sensory changes, provides additional time for remembering and responding, is appropriate to context and draws on the older adult's past experiences, culture and values.

• CRITICAL REFLECTION POINT

Take a moment to consider the health-promoting activities that are currently on offer to older adults in the community in which you live. You may not be aware of all of them – many activities are offered through places like the local bowling club, golf club or local art centre, as well as the local community centre and public library.

What activities do you recommend to your older clients as part of their ongoing health promotion? Do you advise a varied set of activities? Do you check out their interests before making your suggestions?

The general perception of the value and contribution of older adults to Australian and New Zealand societies is mixed. On the one hand, older people are considered to be sources of valuable life knowledge, experience and support. On the other hand, they are often invisible within the community and excluded from opportunities to contribute. Older people tend to regard age as a relative term. The main discriminators of ageing are more likely to be the state of mind of the individual, their quality of life and their state of health.

Older people have expressed concerns about the use of unrealistic and negative stereotyping in the media, with older people frequently depicted as frail, defenceless victims described in terms of their dependency rather than their contribution. These unhelpful images not only undermine older people's self-confidence, but also the confidence that other people have in them, particularly younger people. The United Nations has identified the media as a principal agent for eradicating ageism by showing older people as being capable, rich in experience and history, and independent in thought and action.

The attitudes of healthcare professionals can also be influenced by stereotypes, and this may have flow-on effects to the type and standard of care provided to older adults. At times, institutional settings such as hospitals and residential aged care facilities have treated older adults as patients or objects, rather than independent, dignified contributors to society. Because of the nature of their interactions with clients, nurses are in a unique position to encourage and reinforce the positive self-image of an older person and contribute to eradicating ageism.

Figure 18-3 Technology is accessible to all age groups and offers many opportunities for health and health care.

Abuse of the elderly

Abuse of the elderly is a significant social issue and can be described as the poor and often illegal behaviours of trusted people, such as family members or caregivers, towards an older person or their carers. Abuse of an older adult is often not recognised or acknowledged. Abuse may be directed towards an older person or the carer and can take different forms: physical, psychological, financial, sexual or neglect.

Abuse of an older person can include:

- physical and chemical restraint
- over-medication
- actions which show lack of respect
- hitting, slapping, pushing
- threats, humiliation, bullying
- swearing at the person
- treating the person like a child
- name-calling
- denying the right to money
- misappropriating money/valuables
- sexual teasing, innuendo or inappropriate/unwanted touching
- sexual assault
- failure to provide food/fluid/hygiene/personal care
- neglect/avoidance
- ignorance leading to mistreatment.

The abuse of older adults is thought to be under-reported. In 2008, the World Health Organization (WHO) recommended that screening for abuse should be included in all areas of care delivery, particularly primary care. However, in 2015, screening for abuse was still to be implemented as part of the routine assessment undertaken on the admission of older people to most services.

There may be many reasons for an older adult not to report abuse, including feelings of shame to admit that a person close to them mistreats them or blaming themselves for the behaviour. They may also be worried about what other people might think, or think that people might not believe them. They may also be frightened of the consequences of telling someone about their situation. For those living in rural and remote locations, options for family or other types of care are limited. It is important to note that there is legislation in both Australia and New Zealand to protect older people from elder abuse (see Chapters 10 and 11).

Care issues identified by the WHO (2015) that have been found to increase the risk of abuse occurring are:

- social and physical isolation of the older person or their carers
- language and cultural barriers
- a family member who is financially dependent on the older person
- a carer with addiction or mental illness
- a carer experiencing significant stress.

• CRITICAL REFLECTION POINT

The WHO considers that abuse of older people is a common problem. In the care setting where you work, what cues could indicate that an older client might be experiencing abuse? Would you be alert to the potential for abuse? Is screening for abuse part of the general assessment of the older person in the areas you have worked?

There is a fine line between abuse and poor-quality care. The language used by healthcare professionals when working with older people can be a subtle expression of underlying attitudes, such as their use of child-like or demeaning language. Abuse of the elderly rarely has a single cause. Ignorance about the ageing process and the needs of older people, and a lack of skill on behalf of caregivers are among the factors that contribute to an abusive situation.

Towards an understanding of how we age

Throughout history, people have been trying to understand the process of ageing – what causes it, what its purpose is. There is no single accepted theory of ageing; instead, a number of theories have been developed to explain the ageing process (Box 18-2). **Biological theories of ageing** seek to explain the anatomical and **physiological changes** that occur with ageing, and **psychological theories** attempt to explain the thought processes and behaviours of ageing people – the changes in behaviour, roles and relationships that occur as an individual ages. It is important to remember that theories of ageing are hypotheses and are attempts to seek explanation or meaning for what is observed or experienced.

Ageing can be defined in terms of biological age or chronological age. However, there is no agreement as to the definition of human ageing, nor are there any precise measures of ageing. One of the difficulties with the study of ageing is the lack of biomarkers of ageing. A question that is often posed in the research literature is how or against what we can measure the rate of ageing – since chronological age is the least useful method. **Chronological age** (age in years) and **physiological age** (functional capacity) do not always coincide. People can look younger or older than their chronological age: some people appear to age quickly, others slowly. The definitions of old age used for policy development, research or the planning of services are essentially socially constructed – they have a tenuous relationship to the biological 'ageing' of individuals. It is important to realise that 'old age' is generally defined in an arbitrary way.

What has puzzled researchers is why some older adults are active and vital at age 90 years while others are frail at age 60. Why is there so much variation in ageing? Biological theories have sought to answer these questions, and can be divided into two main groups: **stochastic theories**, which propose that ageing is the accumulated effect of cellular and molecular errors or damage over time; and **non-stochastic theories**, which propose that ageing is predetermined by the programmed mechanisms of the body (Box 18-2).

Understanding normal ageing

The nursing care of older adults poses special challenges because of the large variations in physiological, cognitive and psychosocial health status. Older adults also vary widely in their levels of functional ability. While rating themselves as having poorer health than younger people, older people tend to have a positive view of their health. Thirty five per cent of Australians aged 75–84 years currently rate their health as 'excellent' or 'very good' and 33% as 'good'. About 30% of those aged 85 and over also rated their health as 'excellent' or 'very good' and 32% as 'good' (AIHW 2014).

BOX 18-2 Theories of ageing

Biological theories of ageing

Stochastic theories

Free-radical structure theory Cellular structure is altered through parts breaking off, or from the loose electrons from these free parts attaching to other cells. Environmental pollutants are thought to promote free-radical activity. Foods that are thought to reduce free-radical activity are those rich in vitamins A, C and E.

Somatic mutation theory Defective cellular structure and function structure as a result of DNA alteration, RNA mutations and protein or enzyme synthesis.

Cross-linked collagen theory Collagen constitutes 25–30% of body protein and forms gelatine-like cell matrix. With age, collagen cross-links become more insoluble and rigid.

Wear and tear theory Damage from external as well as internal sources leads to the progressive failure of the body to repair itself.

Non-stochastic theories

Programmed cells theory Cells are thought to be programmed to 'age' at specific times.

Run-out-of-program theory This is an extension of the programmed cell theory – each organism is thought to have a specific number of cell divisions and specific life span.

Neuroendocrine theory Efficiency of signals between body's control mechanisms – pituitary and hypothalamus – is altered or lost.

Autoimmune reactions Immunological system loses capacity for self-regulation and begins perceiving normal or age-altered cells as foreign matter. System reacts by forming antibodies to destroy cell.

Psychological theories of ageing

Disengagement theory The foundation of this theory is that there is decreased interaction between the old and others within their environment, and that this is an inevitable and universal consequence of ageing. A significant argument is that the social withdrawal experienced by the elderly is due to their deprived situation rather than a consequence of ageing.

Activity theory This theory emerged in the 1950s and essentially links keeping active with happiness and 'successful' ageing. Studies have demonstrated the relationship between physical activity and wellbeing.

Continuity (development) theory This theory suggests that essential psychological patterns such as personality and basic patterns of behaviour are consistent throughout the life span. Concepts and patterns developed over a lifetime will determine whether individuals remain engaged and active or become disengaged and inactive.

Bengston VL 2009 Handbook of theories of aging. New York, Springer.

Physiological changes

Normal physiological changes are expected in older adults (Table 18-2). These physiological changes are not pathological processes, but may make older adults more vulnerable to some common clinical conditions and threaten self-identity. Some older adults experience all of these changes, and others experience only a few. The body changes continuously with age, but the effects depend on genetics, health, lifestyle, stressors and environmental conditions. Being aware of the normal effects of ageing assists nurses to provide appropriate care for older adults, and to work with older adults adapting to physiological change. Older adults are subject to more frequent questioning and testing of their physiological and cognitive abilities; for example, driving tests and health checks are required more frequently.

Integumentary system

The skin loses resilience and moisture in older adulthood. The epithelial layer thins, and elastic collagen fibres shrink and become rigid. Wrinkles of the face and neck reflect lifelong patterns of muscle activity and facial expressions, the pull of gravity on tissue, and diminished elasticity (Marieb 2014). Spots and lesions may also be present on the skin. Smooth, brown, irregularly shaped spots (age spots, or senile lentigo) initially appear on the backs of the hands and on forearms. Small, round, red or brown cherry angiomas may be found on the trunk (Marieb 2014). Seborrhoeic lesions or keratoses may appear as irregular, round or oval, brown, watery lesions. Years of sun exposure contribute to the ageing of the skin and may lead to premalignant and malignant lesions. Examination of skin lesions aims to rule out three different types of malignancies related to solar exposure: melanoma, basal cell carcinoma and squamous cell carcinoma. If any suspicious areas are noted, the client should be referred for medical assessment.

Pressure ulcers (**decubitus ulcers**) are areas of skin breakdown (usually over a bony prominence) that result from prolonged pressure on the skin by an external object, such as a bed or chair (Box 18-3). Most commonly occurring

TABLE 18-2 Normal physiological changes of ageing

System	Normal findings
Integument	
Skin colour	Spotty pigmentation in areas exposed to the sun; pallor even in absence of anaemia
Moisture	Dry, scaly condition
Temperature	Cooler extremities; decreased perspiration
Texture	Decreased elasticity; wrinkles; folding,
Fat distribution	Decreased amount on extremities; increased amount on abdomen
Hair	Thinning and greying on scalp; often, decreased amount of axillary and pubic hair and hair on extremities; decreased facial hair in men; possible chin and upper lip hair in women
Nails	Decreased growth rate
Head	Sharp and angular nasal and facial bones; loss of eyebrow hair in women; bushier eyebrows in men
Eyes	Decreased visual acuity; decreased accommodation; reduced adaptation to darkness; sensitivity to glare; diminished light reflex
Ears	Decreased pitch discrimination; diminished hearing acuity
Nose and sinuses	Increased nasal hair; decreased sense of smell
Mouth and pharynx	Use of bridges or dentures; decreased sense of taste; atrophy of papillae of lateral edges of tongue
Neck	Nodular thyroid gland; slight tracheal deviation resulting from muscle atrophy
Thorax and lungs	Increased anteroposterior diameter; increased chest rigidity; increased respiratory rate with decreased lung expansion; increased airway resistance
Heart and vascular system	Significant increase in systolic pressure with slight increase in diastolic pressure; usually insignificant changes in heart rate at rest; common diastolic murmurs; easily palpated peripheral pulses; weaker pedal pulses and colder lower extremities, especially at night
Breasts	Diminished breast tissue; pendulous
Gastrointestinal system	Decreased salivary secretions, which may make swallowing more difficult; decreased peristalsis; decreased production of digestive enzymes, including hydrochloric acid, pepsin and pancreatic enzymes; reduced motility leading to constipation
Reproductive system	
Female	Decreased oestrogen; decreased uterine size; decreased secretions; atrophy of epithelial lining of vagina
Male	Decreased levels of testosterone; decreased sperm count; decreased testicular size
Urinary system	Decreased renal filtration and renal efficiency; subsequent loss of protein from kidney; nocturia; decreased bladder capacity
Female	Decrease in perineal muscle tone
Male	Prostatic enlargement
Musculoskeletal system	Decreased muscle mass and strength; bone demineralisation; shortening of trunk as result of intervertebral space narrowing; decreased joint mobility; decreased range of joint motion; enhanced bony prominences
Neurological system	Decreased rate of voluntary or automatic reflexes; decreased ability to respond to multiple stimuli; insomnia; shorter sleeping periods

Marieb EN, Hoehn KN 2014 Human anatomy and physiology. 9th edn. Pearson New International, Harlow, Essex.

on the elbow or sacrum, there is international support to rename pressure ulcers 'pressure injuries' to reflect that the majority of such ulcers can be prevented (Australian Wound Management Association 2012). Pressure ulcers are not part of normal ageing; however, older adults who are bed- or chair-bound are at risk of developing a pressure injury. *The Pan Pacific clinical practice guidelines for the prevention and management of pressure injury* (2012) is a useful tool to inform the prevention and management of pressure injuries (see *Online resources*).

BOX 18-3 Risk factors for the development of a pressure injury

- Immobility
- Malnourishment
- Loss of subcutaneous fat over bony prominences
- Excessive moisture on skin surfaces or in skin folds
- Urinary and/or faecal incontinence
- Cardiovascular disease
- Poor arteriole pressure
- Cognitive impairment
- Diminished sensory perception

Head and neck

The facial features of the older adult become more pronounced from loss of subcutaneous fat and skin elasticity (Marieb 2014). Facial features may appear asymmetrical because of missing teeth or improperly fitting dentures. Common vocal changes include a rise in pitch and a loss of power and range in the voice.

The older adult's visual acuity declines. This may be the result of retinal damage, reduced pupil size, development of opacities in the lens or loss of lens elasticity. **Presbyopia**, a progressive decline in the ability of the eyes to accommodate for close, detailed work, is common. There is a reduced ability to see in darkness and to adapt to abrupt changes from dark areas to light areas (and the reverse). Older adults also have increased sensitivity to the effects of glare. Changes in colour vision and discolouration of the lens make it more difficult to distinguish between blues and greens, and among pastel colours (Marieb 2014).

Auditory changes are often subtle. The earliest losses of hearing acuity may be ignored until compensatory attempts such as turning up the volume on televisions and radios are commented on by friends and family members. A common age-related change in auditory acuity is called presbycusis. **Presbycusis** affects the ability to hear high-pitched sounds and sibilant consonants such as s, sh and ch (Marieb 2014). Before assuming presbycusis, inspect the external auditory canal for the presence of cerumen (ear wax). Impacted cerumen is an easily treated cause of diminished hearing acuity.

Taste buds atrophy and lose sensitivity. The older adult becomes less able to discern salty, sweet, sour and bitter tastes. The sense of smell is also decreased, further reducing taste. Salivary secretion is also reduced (Marieb 2014).

Thorax and lungs

Because of changes in the musculoskeletal system, the configuration of the thorax sometimes changes. Around 55 years of age, respiratory muscle strength begins to decrease. The anteroposterior diameter of the thorax increases. Vertebral changes due to **osteoporosis**, which involves the loss of minerals such as calcium more quickly than the body can replace them, lead to a loss of bone mass or density which in turn leads to **dorsal kyphosis**, the curvature of the thoracic spine sometimes called 'dowager's hump' because of the increased incidence in older women. Calcification of the costal cartilage can cause decreased mobility of the ribs. The chest wall gradually becomes stiffer. Lung expansion decreases. If kyphosis or chronic obstructive lung disease is present, breath sounds are distant (Marieb 2014).

Heart and vascular system

Decreased contractile strength of the myocardium results in a decreased cardiac output (Marieb 2014). The decrease is significant when the older adult is stressed by anxiety, excitement, illness or strenuous activity. The body tries to compensate for decreased cardiac output by increasing the heart rate during exercise. However, after exercise, it takes longer for the older adult's rate to return to baseline.

No significant rise in diastolic pressure occurs with ageing, but due to stiffening of the large arteries there is a gradual increase in systolic pressure (Marieb 2014). Although common, hypertension is not a normal ageing change, but predisposes an older adult to heart failure, stroke, renal failure, coronary heart disease and peripheral vascular disease. Peripheral pulses are often weaker, although still palpable in the older adult. Older adults may complain that their lower extremities are cold, particularly at night.

Breasts

Decreased muscle mass, tone and elasticity result in smaller breasts in older women (Marieb 2009). In addition, the breasts sag. Atrophy of glandular tissue, coupled with more fat deposits, results in a slightly smaller, less dense and less nodular breast. Gynaecomastia (enlarged breasts in men), may be due to medication side effects, hormonal changes or obesity. Both older men and older women remain at risk of breast cancer development (Marieb 2014).

Gastrointestinal system and abdomen

Ageing leads to an increase in the amount of fatty tissue in the trunk. As a result, the abdomen may increase in size. Because muscle tone and elasticity decrease, the abdomen may also appear more protuberant (Marieb 2014).

RESEARCH HIGHLIGHT

Translating research into practice

Although the prevalence of venous leg ulcers in the community is not known, they are a very common health problem in both Australia and New Zealand. Part of the problem for understanding exactly how common venous leg ulcers are is the lack of a consistent definition for a venous leg ulcer, including aetiology.

Venous leg ulcers affect the quality of life of the sufferer: they are painful, affect mobility and are difficult to heal. Venous leg ulcers are costly both to the individual – wound-care products are expensive and not covered entirely by the national health schemes of either Australia or New Zealand – and costly to the community. Community-dwelling older adults with a venous ulcer require a high level of domiciliary nursing services, and sufferers often require lengthy hospitalisations. The cost impact includes pathology, radiology investigations and pharmaceuticals as well as adjunct therapies.

Access to appropriate services for diagnosis and management of venous leg ulcers is not equal throughout New Zealand and Australia; rural areas in particular do not have sufficient resources.

The Australian Wound Management Association (AWMA) and the New Zealand Wound Care Society (NZWCS) sought to address the issue by developing a clinical practice guideline for the prevention and management of venous leg ulcers that would guide the practice of all healthcare professionals, with specific reference to the practice of nurses. A priority is to optimise the prevention, assessment and management of venous leg ulcers via the dissemination of best available evidence, and to simplify clinical decision-making processes for healthcare professionals.

The research

The development of a clinical practice guideline is an important step in the translation of research into practice. The development of the guideline required both organisations to work together, review the relevant literature and manage a consensus process with the experts of both countries. A rigorous approach must be taken which evaluates the available evidence. The guideline presents a comprehensive review of the assessment, diagnosis, management and prevention of venous leg ulcers within the Australian and New Zealand healthcare context, based on the best evidence available up to January 2011.

Australian Wound Management Association and New Zealand Wound Care Society 2011 Australian and New Zealand clinical practice guideline for prevention and management of venous leg ulcers. Online. Available: www.awma.com.au/publications/2011_awma_vlug.pdf; accessed 16 Jan 2016.

Changes in gastrointestinal function include a slowing of peristalsis and alterations in secretions. The older adult may experience these changes as the development of intolerance to certain foods, or discomfort due to delayed gastric emptying. Alterations in the lower gastrointestinal tract may lead to constipation, flatulence or diarrhoea.

Reproductive system

Changes in the structure and function of the reproductive system occur as the result of hormonal alterations. Female menopause is related to a reduced responsiveness of the ovaries to pituitary hormones and a resultant decrease in oestrogen and progesterone levels. In men, there is no definite cessation of fertility associated with ageing. Spermatogenesis begins to decline during the fourth decade but continues into the ninth (Marieb 2014). The changes in reproductive structure and function, however, do not affect libido. Many older people remain sexually active but less-frequent sexual activity can result from illness, death of a sexual partner, decreased socialisation or loss of sexual interest.

Urinary system

While urinary incontinence is not a normal part of ageing, there are some physiological changes that put older adults at risk of developing **incontinence**. The bladder capacity gradually declines so that it can hold less maximal volume, and it becomes more prone to unstable contractions known as **detrusor instability**. If these contractions are strong enough they may result in urge incontinence. Stress incontinence is also common, particularly in men who have undergone prostate surgery (Abrams et al 2012).

Hypertrophy of the prostate gland may develop in older men. This hypertrophy enlarges the gland, which may cause pressure on the neck of the bladder. As a result, urinary retention, frequency, incontinence and urinary tract infections can occur. In addition, **prostatic hypertrophy** can result in difficulty initiating voiding and maintaining a urinary stream (Abrams et al 2012).

Musculoskeletal system

With ageing, muscle fibres are reduced in size. Muscle strength diminishes in proportion to the decline in muscle

mass. Bone mass also declines. Older adults who exercise regularly do not lose as much bone and muscle mass or muscle tone as those who are inactive. Postmenopausal women have a greater rate of bone demineralisation than older men, although osteoporosis is also a problem for older men (Marieb 2014). Older men with poor nutrition and decreased mobility are at risk of bone demineralisation. Older adults who maintain calcium intake, coupled with vitamin D (either as a supplement or through sun exposure) throughout life, have less bone demineralisation than those who do not.

Neurological system

The number of neurons in the nervous system begins to decrease during the second decade of older age, leading to possible functional changes (Marieb 2014). These changes can affect the senses (smell, sight etc.), as described earlier. In addition, the older adult may experience a decreased sense of balance or uncoordinated motor responses.

Older adults often report alterations in the quality and quantity of their sleep. This may include difficulty falling asleep, difficulty staying asleep, difficulty falling asleep again after waking during the night, waking too early in the morning and excessive daytime napping. Age-related sleep changes are summarised in Box 18-4 and are also discussed in Chapter 30.

Cognitive changes

A common misconception about ageing is that cognitive impairment is an inevitable consequence. Because of this misconception, older adults may fear that they are, or soon will be, cognitively impaired. Similarly, younger adults may assume that all older adults are confused and no longer able to make decisions or handle their affairs. Disorientation, loss of language skills, loss of the ability to calculate, and poor judgement are not normal ageing changes. Structural and physiological changes within the brain, such as reduction in the number of cells, deposition of lipofuscin and amyloid in cells, and changes in neurotransmitter levels are seen in older adults with and without cognitive impairment (Marieb 2014).

Psychosocial changes

Psychosocial changes occurring with ageing mainly involve changes in roles and relationships as parents become grandparents, partners or adult children become caregivers, or partners die. Group membership roles and relationships also change as the older adult retires from work, moves away from a familiar neighbourhood or stops attending social activities because of the inability to drive, to hear social conversation in group situations or declining health. These changes are particularly isolating for those living in remote or rural communities where losing the ability to drive, for example, has significant consequences for work and daily living.

BOX 18-4 Age-related sleep changes

- Ageing does not increase sleep disorders; however, approximately 50% of older adults complain of difficulty in sleeping.
- Older adults report sleeping on average 7 hours per night – the same or more than that reported by younger adults.
- Awakenings are frequent, increasing after age 50 years.
- Sleep is subjectively and objectively lighter (more stage I, less stage IV, more disruptions).
- A side effect of many medicines prescribed to older adults is changes to sleep.
- Sleep disturbances are associated with indications of poor health.
- Restless leg syndrome is more common in older adults.
- Insomnia – difficulty in falling or staying asleep – is often comorbid with medical and psychiatric illness.
- Sleep-disordered breathing (SDB) – snoring through to sleep apnoea – is more prevalent in the older population. The main symptom of SDB is snoring.
- Continuous positive airway pressure (CPAP) is a useful treatment for SDB in older adults, with research showing that older adults are compliant with CPAP usage.
- Assessment of sleep problems should include a sleep history including unintentional napping, plus medical history, details of medication regimen, and food and alcohol consumption patterns.

Neikrug AB, Ancoli-Israel S 2010 Sleep disorders in the older adult – a mini-review. Gerontology 56(2):181–9.

Assessment of the older adult

Gerontological nursing offers creative approaches for maximising the potential of older adults. With a comprehensive assessment including the older adult's strengths, resources and limitations, the nurse and older adult together identify needs and problems and select interventions that maintain the older adult's physical abilities and create an environment for psychosocial and spiritual wellbeing. A thorough assessment requires the nurse to actively engage with the older adult and provide them with enough time to share important information about their health. Most health services have adopted or developed valid and reliable assessment tools relevant

to their service provision. However, some services do not utilise assessment tools to support clinical decision-making and may only collect limited demographic data.

Obtaining a comprehensive assessment of an older adult may take more time than the assessment of a younger adult because of the longer life and medical history and the potential complexity of that history. Planning extra time for the assessment ensures the nurse and older adult are less likely to feel rushed. During the assessment process the nurse may find it necessary to allow rest periods or to conduct the assessment in several sessions because of the reduced energy or limited endurance experienced by some frail older adults.

Sensory changes may also affect data gathering. The nurse's choices of communication techniques will be influenced by visual or hearing impairments in the older adult. If older adults are unable to understand the nurse's visual or auditory cues, assessment data may be inaccurate or misleading. For example, if older adults have difficulty hearing the nurse's questions, inappropriate responses may lead the nurse to believe that they are confused. Table 18-3 suggests techniques to use during the assessment of older adults with sensory problems.

Memory deficits may affect the accuracy and completeness of the data collected. Information contributed by a family member or other caregiver may be needed to supplement the older adult's recollection of past medical events and gain information about allergies and immunisations. Tact must be used when involving another person in the assessment interview with the older adult.

TABLE 18-3 Techniques for assessing older adults with sensory problems

Sensory alteration	Assessment technique
Visual disturbance	Position self in full view of client
	Provide diffuse, bright light; avoid glare
	Make sure client's glasses are worn and in good working order
	Face client when speaking; do not cover mouth
Hearing deficit	Speak directly to client in clear, low tones at a moderate rate; do not cover mouth
	Articulate consonants with special care
	Re-state if client does not understand question initially
	Speak towards 'good' ear
	Reduce background noises
	Make sure client's hearing aid is worn and is working properly

With the older adult's consent, an additional person can supplement answers to assessment questions, particularly if they are a carer of the older adult, but the older adult should remain the focus of the interview.

Perception of wellbeing can define quality of life. Understanding the older adult's perceptions about their health status is essential for accurate assessment and development of clinically and personally relevant interventions. Older adults' ideas of health generally depend on personal perceptions of functional ability and their expectations of older age. Older adults engaged in the normal activities of daily living (ADLs) usually consider themselves healthy, whereas those whose activities are limited by physical, emotional or social impairments may perceive themselves as unwell.

The nurse assesses the nature of the psychosocial changes facing an older adult and the adaptation of the older adult to those changes. Areas covered during the health assessment include understanding family and/or partner support, culture and values, intimate relationships, past and present occupations, finances, housing, social networks, activities and spirituality. Specific topics related to these areas may include questions about retirement, housing and environment, social isolation, sexuality and death.

Risks to healthy ageing

There are a number of contributors to loss of healthy-life years among older adults. Important risk factors to explore during the nursing assessment are physical inactivity, obesity, high blood cholesterol, inadequate intake of fruit and vegetables, smoking and excessive alcohol consumption (AIHW 2014). It is important to remember that risk factors are not necessarily causes of disease, but they may put an individual at risk of experiencing disease. Risk factors often co-exist, so it is not unusual for a nursing assessment to reveal a number of risk factors. There is, however, potential for health gain at all life stages through appropriate management of risk factors, in addition to early prevention. Making changes to lessen one risk factor generally lessens other risk factors.

Common conditions experienced by older adults include arthritis, cardiovascular disease, including hypertension, and sensory loss – particularly hearing disorders (AIHW 2014). Heart disease, stroke and cancer remain the highest causes of death in Australia and New Zealand but dementia is the greatest single contributor to the burden of disease due to disability, as well as the greatest single contributor to the cost of care in residential aged care.

Risk factors

Bodyweight

People who are overweight at any age have higher mortality and morbidity rates for non-insulin-dependent (type 2) diabetes, coronary heart disease, respiratory disease, some types of cancers, gallbladder disease and osteoporosis. Weight loss among those who are overweight reduces the incidence and severity of high blood pressure, high blood cholesterol, diabetes, osteoarthritis and some types of cancers. However, unintentional weight loss in an older person is a cause for concern and always needs to be investigated. Such weight loss may actually mean that the older person is losing muscle rather than adipose tissue. This can lead to a condition called **sarcopenia**, which results in loss of muscle bulk and tone giving rise to functional decline, poor wound healing, increased risk of falls and an overall loss of quality of life. Prevention of sarcopenia includes ensuring adequate calorie intake, ensuring the diet has sufficient protein – protein requirements for older people are similar to those of younger people – and weight-bearing exercise (Australian Institute of Musculoskeletal Science 2015).

Physical inactivity

Physical inactivity is an independent risk factor for cardiovascular disease, and is also associated with other risk factors such as high blood pressure, high blood cholesterol and excess bodyweight. Participation in physical activity by older people has benefits in relation to falls prevention and musculoskeletal health, the promotion of urinary continence, mental health and relief of pain from arthritis. Physical activity can also help in the prevention and treatment of type 2 diabetes especially among people already at risk. Physical exercise is an important factor in preventing sarcopenia. Greater understanding of the importance of exercise for older people is reflected in an increase in the number and type of programs that specialise in movement for older people, such as gyms, tai chi groups, aqua aerobics and dance groups. Residential aged care homes are increasingly introducing weight-bearing and other exercise programs for residents, including for those with advanced dementia.

Blood cholesterol

High blood cholesterol is a major risk factor for coronary heart disease. Saturated fat in the diet is a major factor in raising blood cholesterol levels for most people. Diet modification, increased exercise and, if necessary, medication, are the usual treatments.

Hypertension

High blood pressure is also a major risk factor for coronary heart disease as well as stroke, heart failure, peripheral vascular disease and renal failure. The risk of disease increases as the level of blood pressure rises. High blood pressure is more likely to develop among people who are overweight or physically inactive, or have high dietary salt intakes.

Impaired glucose tolerance

Impaired glucose tolerance (IGT) is common in people who are physically inactive and overweight, and is more common in older people. As well as being a risk factor for type 2 diabetes, IGT is linked to a greater risk of heart disease. With increasing age, the cells in the pancreas that produce insulin – the hormone that enables the body to convert glucose to energy – become less efficient. This, combined with decreased physical activity and increased bodyweight, contributes to the higher prevalence of IGT (and type 2 diabetes) among older people.

Tobacco smoking

Smoking increases the risk of lung cancer, chronic obstructive pulmonary disease, ischaemic heart disease and other diseases; there are benefits to stopping smoking at all ages.

Alcohol consumption

Excessive and long-term alcohol consumption is associated with liver disease, pancreatitis, diabetes, epilepsy and some cancers. The body's tolerance for alcohol decreases with age. Of particular relevance to older people are the risks associated with drinking and driving and the risk of alcohol interacting with medicines. However, there is some evidence to suggest that low to moderate levels of alcohol consumption may protect against hypertension, ischaemic heart disease and stroke.

Health issues experienced by older people

A number of health issues experienced by older people can have a profound effect on their functional ability, quality of life and ability to remain independent, and can precipitate admission into residential aged care.

Impaired cognition

Three common conditions affecting cognition are *delirium*, *dementia* and *depression*. Distinguishing between these three conditions is challenging, but essential (see Table 18-4, which compares the clinical features). Remember

TABLE 18-4 A comparison of the clinical features of delirium, dementia and depression

Clinical feature	Delirium	Dementia	Depression
Onset	Acute/subacute, depends on cause, often at twilight or in darkness	Chronic, generally insidious, depends on cause	Coincides with major life changes, often abrupt
Course	Short, diurnal fluctuations in symptoms, worse at night, in darkness and on awakening	Long, no diurnal effects, symptoms progressive yet relatively stable over time	Diurnal effects, typically worse in the morning, situational fluctuations, but less than with delirium
Progression	Abrupt	Slow but uneven	Variable, rapid or slow but even
Duration	Hours to less than 1 month, seldom longer	Months to years	At least 6 weeks, can be several months to years
Awareness	Reduced	Clear	Clear
Alertness	Fluctuates, lethargic or hypervigilant	Generally normal	Normal
Attention	Impaired, fluctuates	Generally normal	Minimal impairment, but is easily distracted
Orientation	Generally impaired, severity varies	Generally normal	Selective disorientation
Memory	Recent and immediate impaired	Recent and remote impaired	Selective or 'patchy' impairment, 'islands' of intact memory
Thinking	Disorganised, distorted, fragmented, incoherent speech, either slow or accelerated	Difficulty with abstraction, thoughts impoverished, judgement impaired, words difficult to find	Intact but with themes of hopelessness, helplessness or self-deprecation
Perception	Distorted, illusions, delusions and hallucinations, difficulty distinguishing between reality and misperceptions	Misperceptions usually absent	Intact, delusions and hallucinations absent except in severe cases
Psychomotor behaviour	Variable, hypokinetic, hyperkinetic, and mixed	Normal, may have apraxia	Variable, psychomotor retardation or agitation
Sleep–wake cycle	Disturbed, cycle reversed	Fragmented	Disturbed, usually early-morning awakening
Associated features	Variable affective changes, symptoms of autonomic hyperarousal, exaggeration of personality type, associated with acute physical illness	Affect tends to be superficial, inappropriate and labile, attempts to conceal deficits in intellect, personality changes, aphasia, agnosia may be present, lacks insight	Affect depressed, dysphoric mood, exaggerated and detailed complaints, preoccupied with personal thoughts, insight present, verbal elaboration
Assessment	Distracted from task, numerous errors	Failings highlighted by family, frequent 'near miss' answers, struggles with test, great effort to find an appropriate reply, frequent requests for feedback on performance	Failings highlighted by individual, frequently answers 'don't know', little effort, frequently gives up, indifferent towards test, does not care or attempt to find answer

Phillips J et al 2010. No time like the present. Online. www.dementia-assessment.com.au/resource/No_time_like_the_present.pdf; accessed 18 Jan 2016; Sansoni J et al 2008. Online. Available: http://ro.uow.edu.au/cgi/viewcontent.cgi?article=1348&context=ahsri; accessed 18 Jan 2016; Department of Health and Human Services 2006 Clinical practice guidelines for the management of delirium in older people © Commonwealth of Australia.

that these conditions are not mutually exclusive, and that individuals may have more than one condition at any one time. Appropriate nursing interventions are specific to the cause of the cognitive impairment.

Delirium

Delirium is a transient disorder characterised by impaired cognitive function and reduced ability to focus, sustain or shift attention. The disturbance develops over a short period of time. Some common causes include:

- pain
- medication – side effects, drug–drug interactions (prescribed, over-the-counter, complementary medicines)
- alcohol use
- infection, e.g. pneumonia, urinary tract infection

- malnourishment
- dehydration
- urinary retention
- hypoxia, hypotension, cardiopulmonary disorders leading to anoxia or transient ischaemia
- electrolyte imbalance
- constipation and faecal impaction.

Delirium may occur in any setting – the home or community, hospital or in residential care. The onset of delirium is typically sudden, and there are rapid fluctuations in symptoms and severity. The presence of delirium requires prompt assessment and intervention. In some emergency departments delirium is treated as a medical emergency, in the same way as a suspected heart attack. The cognitive impairment secondary to delirium is usually reversed once the cause is identified and treatment started. Being potentially reversible is one of the characteristics that differentiate delirium from dementia. If delirium in the older adult is not recognised and treated promptly, the sufferer can become very unwell. Delirium is often not recognised, and consequently treatment can be delayed; however, a number of guides for the management of delirium are available, including from the Australian Commission on Safety and Quality in Health Care (see *Online resources*).

• CRITICAL REFLECTION POINT

Reflect on the last time you worked with an older adult who had impaired cognition. What common causes of delirium were investigated during the assessment? An older adult may have dementia, with delirium occurring as an acute problem. The onset of delirium may be related to urinary retention, dehydration or pain.

Dementia

Dementia describes a collection of symptoms caused by disorders affecting the brain; therefore, dementia is not one specific disease. Dementia affects thinking, behaviour and the ability to perform everyday tasks. Brain function is affected enough to interfere with the person's normal social or working life. The deterioration of cognitive function leads to a decline in the person's ability to perform basic and instrumental ADLs such as managing personal hygiene and nutrition. There is memory loss, impaired visual spatial skills, and behavioural and personality changes, known as the behavioural and psychological symptoms of dementia or BPSD, as well as a decline in thinking ability. The progression of dementia in each individual is unique to that person. Clinical signs of depression may be present. The earliest symptoms of dementia may be very subtle and may be dismissed by the older adult's family as insignificant. The older adult may attempt to conceal the effects of memory loss, to compensate for or deny them.

Unlike delirium, dementia is characterised by a gradual, progressive, irreversible cerebral dysfunction. Because of the close resemblance between delirium and dementia, the presence of delirium must be ruled out whenever dementia is suspected.

The most common form of dementia is **Alzheimer's disease**, named after Dr Alois Alzheimer who published the first description of it. Alzheimer's disease, also called dementia of the Alzheimer type, is characterised by brain atrophy and the development of senile plaques and neurofibrillary tangles in the cerebral hemispheres. The cause of the disease is not known, and although several theories are being studied, none are definitive at this time.

Vascular dementia results from interruptions in blood flow to the brain, as in cerebrovascular disease, cardiovascular disease and haemorrhage. Formerly referred to as multi-infarct dementia, vascular dementia is also very common. Diagnosis may not be made until the cumulative effect of a series of small vascular events becomes clinically apparent. Although older adults with this form of dementia may display symptoms similar to dementia of the Alzheimer's type, vascular dementia is distinguished by periods of remission, preservation of personality, insight and unstable emotions.

Dementia with Lewy bodies (DLB) accounts for almost 10% of dementia diagnoses. It is a form of dementia associated with the growth in the brain of intracellular bodies (Lewy bodies). While the development of Lewy bodies is not completely understood, DLB is characterised by fluctuating cognition, visual and auditory hallucinations and motor features in common with those of Parkinson's disease. The older person may present with frequent falling, syncope, sensitivity to neuroleptic drugs, delusions and memory impairment.

Other forms of dementia include the dementias that occur in some individuals with Parkinson's disease, acquired immunodeficiency syndrome (AIDS) and Huntington's chorea (AIHW 2014). Dementia may also follow head injury, as with dementia pugilistica, in which the injuries are sustained from the sport of boxing.

The nursing management of older adults with any form of dementia can be complex. Interventions must reflect the needs of the older adult and their family. Pre-existing acute and chronic physical conditions, sensory impairments, depression and environmental stressors may also be present for the person living with dementia. Environmental stressors include unfamiliar environments, such as hospitals, and conditions within

any environment, such as glare, excessive noise, hurried activities and unfamiliar people. The accident and emergency department of a public hospital, for example, can be a frightening and confusing place for someone with dementia and/or delirium.

The older adult living with dementia often poorly understands environmental stressors, for example, noise. These misunderstandings lead to increased confusion and agitation. There is increasing emphasis on good environmental design within hospitals and aged care homes to facilitate people with impaired cognition to live with minimum anxiety.

Depression

Delirium and depression are both reversible disorders, but are often mistaken for irreversible dementia in the older adult. This is because cerebral dysfunction and cognitive impairment occur with delirium and depression, as well as with dementia. Consequently, older adults with such disorders may not be appropriately assessed and treated. When dementia and depression occur together, the distress of the older adult and the family is markedly increased.

Depression reduces happiness and wellbeing, contributes to physical and social limitations, complicates the treatment of concomitant medical conditions and increases the risk of suicide. There is chronic underreporting of depression in all populations, but older people are particularly vulnerable as they may be experiencing loss of health, vitality, independence and possibly relationships (beyondblue, see *Online resources*). It is thought that one cause is the failure of healthcare professionals to recognise the symptoms of depression, which can present or be described differently in older people. Another reason is the false belief that depression is normal in older people. Therefore, depression in older people is not always recognised or treated.

Other risk factors for depression in older adults include:

- being female
- recent bereavement
- living in a residential aged care home
- multiple physical comorbidities
- dementia
- medication regimen which includes antihypertensive, analgesics or hypoglycaemic agents
- social isolation
- prior history of depression.

Cognitive impairment related to alcohol abuse

Apart from those with a lifelong pattern of heavy drinking, alcohol abuse often arises in older age as a coping mechanism to deal with loss, anxiety, depression, boredom or to relieve pain. In addition to the physiological effects, alcohol abuse can affect cognitive functioning. As a result of normal physiological changes, older adults are more susceptible to the effects of alcohol. A greater proportion of alcohol is delivered to the brain because of changes in the distribution of body fluids and the proportion of body fat to muscle.

Abuse of alcohol may be under-identified in older adults as the clues to alcohol abuse are subtle, and assessment may be complicated by co-existing dementia or depression. Suspicion of alcohol abuse increases when there is a history of repeated falls and accidents, a change in behaviour or personality, social isolation, recurring episodes of memory loss and confusion, a history of skipping meals or non-compliance with a medication regimen and difficulty managing household tasks and finances. When abuse of alcohol is suspected, treatment includes age-specific approaches that acknowledge the stresses experienced by the older adult and encourage involvement in activities that match the older adult's interests and improve feelings of self-worth. The identification and treatment of co-existing depression is also important.

Falls

Falls in people aged 65 years and over are of particular concern because of their frequency, associated morbidity and mortality, and cost to the healthcare system and community. Falls are the leading cause of hospitalisation among people 65 years and over.

It is recognised that the cause of falls is multifactorial – a number of factors may be present simultaneously contributing to the risk of a fall. While the physical changes in an older adult can contribute to increased falls risk – stooped posture, bone and joint problems – so can the effects of medicines and environmental hazards such as rugs, electrical cords, slippery floors, poor lighting and unsafe shoes (see Box 18-5).

Many people experience a fall when they get up to use the toilet at night. Research evidence suggests that exercise, such as strength and balance training, tai chi or walking is effective in reducing the risk of falls in older people. High-dose vitamin D with calcium has been found to be effective in reducing fractures of older adults living in residential aged care and in the community. In addition, hip protectors have been shown to dramatically reduce hip fractures in people in residential aged care. Evidence-based guidelines for falls prevention in acute care, the community and in residential aged care can be found on the website of the Australian Commission on Quality and Safety in Health Care (see *Online resources*).

BOX 18-5 Risk factors for falls

Residential aged care facilities

Intrinsic factors

- Acute health status
- History of falls
- Wandering behaviour
- Cognitive impairment
- Maximal drop in postprandial systolic blood pressure
- Deterioration in performance of activities of daily living
- Reduced lower extremity strength or balance
- Unsteady gait/use of a mobility aid
- Use of antidepressants medication/polypharmacy
- Independent transfers/wheelchair mobility

Extrinsic factors

- Relocation between settings
- Environmental hazards

Acute care settings

Intrinsic factors

- Age (sharp rise over 60 years of age)
- Circulatory system disorders most likely, followed by nervous system, respiratory system, musculoskeletal and digestive system disorders
- Previous cerebrovascular accident
- History of falls
- Depression
- Cognitive impairment
- Incontinence of bowel or bladder
- Requiring assistance with walking/impaired balance
- Sensory deficits such as impaired vision and dizziness/vertigo
- Use of psychotropic medicines (with greatest risk for those taking more than two medicines)

Extrinsic factors

- Hospitalisation for 19 days or more
- Environmental factors

Department of Health and Ageing 2004 An analysis of research on preventing falls and falls injury in older people: Community, residential care and hospital settings. Australian Commission on Safety and Quality in Health Care (ACSQHC) 2009 Preventing falls and harm from falls in older people: best practice guidelines for community care.

Urinary incontinence

Urinary incontinence is a debilitating disorder, which can affect the sufferer physically, psychologically, socially and economically. Although urinary incontinence can affect all age groups, women, the elderly and the disabled are particularly vulnerable. Over the last 30 years there have been great advances in our understanding of how to promote healthy bladder function. The modern approach to this problem is one of the promotion of continence, rather than the management of incontinence.

It is recognised that seeking treatment for incontinence is difficult for some people, and many sufferers never seek treatment. Although it is not known how many sufferers could be cured, it is thought that a large percentage of those experiencing urinary incontinence could become dry. It would be easy to think that everyone living in a residential aged care facility is incontinent. However, with good assessment and help with maintaining good bladder habits, avoidance of constipation and the use of bladder re-education programs, many residents of aged-care facilities can be helped to become continent or have their incontinence minimised.

Although urinary incontinence is common in older people, ageing does not cause it – that is one of the myths about ageing. Damage and disease can cause incontinence, such as damage to the bladder, sphincters and pelvic floor, or diseases such as diabetes or trauma such as a cerebrovascular accident (stroke). In addition, one of the common problems that can aggravate urinary incontinence is constipation (Abrams et al 2013). Urinary incontinence has been defined by the International Continence Society expert review as the involuntary loss of urine that can be objectively demonstrated (Abrams et al 2013). The main types of incontinence in older people are described in Box 18-6.

Constipation and faecal incontinence

Faecal incontinence affects a relatively small number of people, although the numbers affected are not really known (see Chapter 32). Predisposing factors include damage to pelvic floor muscles through childbirth, side effects of some medicines, and diseases such as ulcerative colitis or Crohn's disease. The most common cause of faecal incontinence among older and disabled people is constipation and impaction of faeces. Factors that contribute to constipation in older people include poor diet, particularly a diet low in fibre, poor fluid intake,

BOX 18-6 Major types of incontinence

Functional incontinence – a condition that many older people living in an institution are described as having. It means that, because of functional decline, e.g. from immobility, impaired dexterity or impaired cognition, the person is unable to manage to use a toilet. It is also thought that there is no such condition as functional incontinence, merely a lack of appropriate help and support.

Nocturnal enuresis – the involuntary loss of urine occurring during sleep.

Post-micturition dribble – leakage of urine following voiding, common in older men.

Stress incontinence – the involuntary leakage of urine on effort or exertion, or on laughing, coughing or sneezing. Aggravated by pregnancy or obesity. Common in men post-prostate surgery.

Urge incontinence – the involuntary leakage of urine accompanied by or immediately preceded by urgency.

limited exercise, and the side effects of medicines. Like many clinical problems affecting older people, it is better to prevent the condition occurring than to treat an established condition. Aspects of assessment are outlined in Box 18-7.

Pain

Unrecognised and poorly managed pain results in an unnecessary and serious decline in the quality of life of an older person. Pain is not a normal part of ageing; however, the incidence of pain increases with age and illness. There is commentary within the research literature about the widespread lack of awareness of good pain management techniques for older people, particularly in residential aged care. Some of the possible reasons for the lack of awareness of pain experienced by older people include:

- a lack of understanding of the extent of pain among the older population
- a lack of understanding of the varied expression of pain in older people
- inconsistent pain identification assessment and treatment
- use of poor assessment tools which do not facilitate clinical decision-making
- a lack understanding how pain might be the cause of impaired cognition (delirium) or how pain might be expressed by someone with dementia or depression
- a culture which considers behaviours of an older person as 'challenging' or a 'problem to be controlled or managed' rather than the expression of an underlying issue
- a lack of understanding of the potential therapies available.

Pain management, whether for community-dwelling older people or within acute care or residential aged care, is an area where nurses can make an effective contribution. Nursing management requires being alert for the possibility of pain and, using good assessment techniques, being able to help the older person problem-solve the cause of the pain and develop effective management strategies.

Like many aspects of working with older people, assessing and managing pain can be a challenge, but if managed well it will greatly minimise functional decline and promote quality of life for the older person. See Table 18.5 for pain assessment and management strategies.

Adverse drug events

It has been well documented that the levels of total medicine use (prescribed and non-prescribed) are higher in older than in younger people (Hunt 2007). Although ageing itself is not a disease process, as people age they tend to develop pathologies for which medicines are used to reduce the effects. The elderly, however, have a reduced ability to cope with medication, due to altered drug kinetics and responses, altered sensitivity to drugs and impaired compensatory mechanisms. This creates clinical dilemmas for the prescriber, the carer, and for the older adult (the consumer of health care). Although medicine use can do much to contribute to the quality of life of an older person, a large number of older people experience negative health outcomes directly related to medicine usage. For example, immobility and instability, falls, urinary incontinence and intellectual impairment including delirium and sedation have all been identified in the literature. Each of these clinical issues has implications for the quality of life of the older person and the cost of providing care, whether the older person involved is community-dwelling or living in residential care.

An adverse drug event might result from a medication prescribing error, a dispensing error, medication administration error, interaction between medicines or between food and medicines or, as a result of polypharmacy. Box 18-8 lists the risk factors for an adverse drug event.

Many healthcare organisations have nominated a specific number (e.g. five or nine medicines) to indicate polypharmacy, however, there is little research to support an arbitrary number. Recognising that medicines help older people to maintain a healthy lifestyle, it is increasingly thought that 'inappropriate polypharmacy' may be a better term. Several medicines may be needed to promote the health of an older person with hypertension and/or diabetes and/or arthritis, but an older person can have an adverse drug event from any or only one of these. It is important that all healthcare professionals maintain a watchful stance related to medicines, older people and

TABLE 18-5 Pain assessment and management

Successful pain management needs:

- Alertness that an older person may be experiencing pain
- Clinicians to have genuine concern and a sympathetic approach
- Good observations skills
- The correct diagnosis of the cause

Good pain assessment includes:	Management strategies includes:
• Being alert for the presence of pain • Watching for non-verbal expressions of pain: frowning, sadness, anxiousness, sighing, moaning, calling out, impaired cognition or confusion, pacing, rigid body posture, guarding, restricted movement, mobility changes • Use of valid and reliable assessment tools to assist with clinical decision-making • Assessment data: – Pain history – when did pain begin, site, quality, severity, aggravating and relieving factors, radiation – General medical history – relevant diseases (arthritis, dementia, depression, vascular, neurological, gastrointestinal, renal) – Physical examination – sites of reported pain, signs of arthritis, inflammation, musculosketal and neurological systems – Impact of pain on ADLs, movement, comfort, activity – Psychosocial assessment – coping mechanisms, cognitive state, beliefs about pain, expectations about relief, effect on sleep – Social impact – impact on relationships and social activities – Review of medication and other treatments – what has been tried, effectiveness	• Understanding the meaning of the pain for the older person • Educate client as to reason for pain • Taking a multidisciplinary approach • Treat underlying cause • Analgesia – monitoring effectiveness carefully • Comfort measures – positioning, supportive chairs, heat/cold • Physical therapies – TENS, massage, passive exercises, strength training, stretch exercises • Consider use of psychological-educational approaches – cognitive-behaviour therapy, teaching new coping mechanisms, relaxation training, distraction and imagery techniques, stress reduction • Monitor effectiveness, change care plan as required

BOX 18-8 Risk factors known to predispose older people to medication-related problems

- Currently taking 5 or more regular medicines
- Taking more than 12 doses of medication per day
- Significant changes in medication treatment regimen during the last 3 months
- Medication with a narrow therapeutic index and/or requiring therapeutic monitoring (e.g. warfarin, digoxin)
- Symptoms suggestive of an adverse drug reaction
- Poor response to treatment with medicines
- Suspected non-compliance or inability to manage medication-related therapeutic devices
- Literacy or language difficulties
- Dexterity problems
- Impaired sight
- Confusion/dementia or other cognitive difficulties
- Attending a number of different doctors, both general practitioners and specialists
- Recent discharge from an acute care facility (in the last 4 weeks)

Department of Health and Ageing 2012a Guiding principles for medication management in residential aged care facilities. Australian Government; Therapeutic Goods Administration 2011. Adverse events. Australian statistics on medicine.

the potential for adverse health outcomes. The key is in monitoring for expected effects as well as unexpected side effects, and to minimise the number of medicines an older person is either prescribed or administered.

Medication review

Medication reviews undertaken by an accredited pharmacist are now an established part of the routine health monitoring of both community-dwelling older people and those living in residential aged care. Consumer medicines information provided by the supplying pharmacist on dispensing a medicine, or available through NPS MedicineWise (see *Online resources*), provide consumers and their carers with relevant information about their medicines. Packaging of medicines in dose-administration aids has been demonstrated to help community-dwelling older people to manage their medicine regimes. There is little research to demonstrate the usefulness of this practice within residential aged care settings, although packaging medicines into some form of aid has become a widespread practice. There is a distinct role for nurses to promote the quality and safe use of medicines in all clinical situations. Ensuring that older clients know and understand their medicines is the responsibility of all healthcare professionals.

Medication management

Reducing adverse drug events or drug errors and maximising the effect of a medicine regimen is the goal of care. This is a high priority for institutionalised elderly people who are at particular risk of experiencing ill-health related to their medications. A medication review enables a current relevant drug profile to be created for each person. Ongoing monitoring and evaluation of that drug profile is essential. Nurses tend to be responsible for the administration of medication, or have oversight of medication management with this vulnerable group. Therefore, nurses have an important role in monitoring desired effects and the possible side effects of medicines, for example, ensuring that adequate and appropriate pain, bowel or sleep assessment is undertaken to ensure that prescribed, *prn* (as needed) or nurse-initiated medicines or over-the-counter medicines remain effective.

As many non-pharmacological options are very effective, for example, changing diet to include more fibre to prevent constipation, the prescription of medicines is not always the first treatment option, particularly for the management of challenging or concerning behaviours. It is important that nurses take the opportunities to increase their understanding of clinical conditions and the various non-pharmacologic and pharmacologic therapies available, and their effects on older people. There are many resources available for nurses, other health professionals, and for consumers on the NPS MedicineWise website (see *Online resources*).

Successful ageing

Each stage of life brings challenges, needs and adjustments, known as developmental tasks (Box 18-9). These tasks are considered part of an adult's continual growth. Older adults face adjusting to the physical and emotional changes that accompany ageing. The extent and timing of these changes vary from individual to individual, but as body systems age, changes in appearance and functioning occur. These changes are inevitable but are not associated with a disease. The presence of disease may alter the timing of the changes or their impact on daily life.

Some older adults find it difficult to accept ageing. This is seen in benign behaviours, for example, understating one's actual age in years. But some older adults deny

BOX 18-9 Developmental tasks of the older adult

- Adjusting to decreasing health and physical strength
- Adjusting to retirement and reduced or fixed income
- Adjusting to death of a spouse
- Accepting self as an ageing person
- Maintaining satisfactory living arrangements
- Redefining relationships with adult children
- Finding ways to maintain quality of life

their own ageing in ways that are potentially problematic, such as denying functional decline and/or refusing to ask for assistance with tasks that place their safety at risk. Acceptance of personal ageing does not mean retirement into inactivity, but it does require a realistic review of strengths and limitations. The pre-retirement period can be used effectively to test and challenge significant changes to work and social life, and to work out what financial and practical planning is required and what replacement activities will be pursued. Papers related to successful ageing can be found on the United Nations website (see *Online resources*).

Although no two individuals age in the same way, either biologically or psychosocially, ageing occurs within the context of an individual's community. The United Nations suggest that the community challenges identified for successful ageing are:

- changes in work patterns to enable older people to remain active in the workforce
- pre-retirement planning and education
- the provision of appropriate housing for older people
- the provision of appropriate community services
- the provision of public transport that is convenient and easy to use
- protection of the legal position of older adults in society, including issues associated with euthanasia, abuse and violence.

Older adults retired from employment outside the home may be challenged to cope with the loss of their work role and identity (see Chapter 20). Older adults who have worked at home also face role changes as their relationship adapts to both partners being together each day in the home or in retirement activities. Many older adults welcome retirement as a time to pursue new interests and hobbies, to spend more time with grandchildren or contribute to family, to participate in volunteer activities, to continue their education, to start a new business career or to travel. Retirement plans for some older adults include changes of residence, such as moving to a different city or state or moving to a different type of housing within the same area.

Reasons other than retirement may also lead to changes of residence. For example, physical impairments may require relocation to a smaller, single-level home. Severe health problems may require the older adult to live with relatives or friends. A change in living arrangements for the older adult may require an extended period of adjustment, during which assistance and support from healthcare professionals, friends and family members are needed.

A large number of older people have to adjust to the death of a spouse, partner, friend or adult children and grandchildren. These deaths represent both losses and reminders of personal mortality. Coming to terms with these deaths can be difficult, and there is an important role for nurses and other health professionals in helping with the grieving process (Chapter 22). The redefining of relationships with children that occurs as those children grow up and leave home continues as older adults experience the challenges of ageing. A variety of issues may arise, including but not limited to, role reversal, control of decision-making, dependence, conflict, guilt and loss. How these issues surface and how they are resolved depends in part on the past relationship between the older adult and their adult children, other family members or friends. All parties bring past experiences and powerful emotions to the situation. When adult children help the older adults of their family, they must find ways to balance the demands of their own children and careers. As adult children and ageing parents go through these changing roles, nurses can help by listening, advising, and helping families to understand and differentiate between behaviours related to their parents' illness from those related to normal ageing, and to take account of their parents' lifelong preferences and patterns of behaviour in planning care.

As the ageing process brings both physical and social change, the adult may also suffer loss of status and social

CLINICAL EXAMPLE

Joyce is a 76-year-old woman who has just been diagnosed with breast cancer. She also has severe cardiovascular disease that limits her choices of treatment. Her oncologist has recommended a series of chemotherapy treatment that her cardiologist believes would be fatal. Her family is urging her to do all that is recommended to stay alive. Joyce is in good spirits despite her diagnosis and after discussing her options with her cardiologist and family, chooses palliative care. How can you help the family adjust to her choice?

function. External struggles are also met with internal struggles, such as the search for meaning in the life they have lived. Meeting these challenges creates the potential for developmental growth and wisdom. Many older people review their lives with a sense of satisfaction, even with the inevitable mistakes. Others may see themselves as failures with a despair that comes from the realisation that it is now too late to achieve hoped-for goals. Nurses are in positions of influence within their workplace and communities to contribute to the valuing of people of all ages and stages of their lives, and to discourage stereotypical views of ageing and ageism.

Ageing is an inevitable process, and despite claims made by the cosmetic industry, it is a process that cannot currently be eliminated or reversed. However, people can make the most of their potential and age positively and well by:

- being physically active, particularly by doing weight bearing exercises (such as walking and weight-training) and exercise that promotes flexibility (such as swimming and tai chi)
- remaining mentally active, for example, by talking with others, reading, listening to the radio, joining in club activities
- eating a fat- and kilojoule-controlled diet which is varied and includes all food groups with particular attention to intake of calcium and vitamin D
- managing stress effectively, for example, talking over concerns, using exercise to dispel stress
- avoiding physical insults to the body, for example, exposure to tobacco, drugs, excessive alcohol, excessive noise, ultraviolet light
- ensuring adequate rest and sleep
- preventing infections and diseases and seeking assistance early when these are identified.

Services for older people

The policies of successive Australian and New Zealand governments have resulted in the majority of older people being able to access support in the community. The type and mix of services offered in both countries is consistently under change, with forms of transition care for older people leaving hospital before returning home, and restorative or rehabilitation services increasing for community-dwelling older people. Consequently, reference to legislation that provides for service provision and how that might be funded or subsidised is not explored here. **Consumer-directed care**, where older people are either in direct control of the money they pay for services or have greater control as to who provides their services, is increasingly being considered as the basis of how governments will fund care delivery in the future. This may bring a shift in the *type* of services offered as well as *how* services are provided.

Home (community) care

Home care and home help services prevent or delay the need for older adults who need assistance with daily living to move into residential care. Professional nurses and therapists, or non-professional staff, such as personal care assistants, can all be involved with providing direct care in the home and in recommending safety improvements or procuring adaptive equipment, such as shower chairs. Technical care can also be offered within a home environment, ranging from the use of a syringe driver for medication administration, through to the equipment needed to support a person dependent on a ventilator. The installation of ramps and hand rails, for example, can make a huge difference to an older person being able to continue to cook or bathe themselves. The result of changes to home care has seen more frail older people being supported to remain within their community rather than moved into residential care. Services provided to older people at home vary according to funding sources.

Retirement villages or communities

Retirement villages offer an alternative to living in a single-family dwelling. Generally, retirement villages have apartment-style units with design features that support the independence of older adults and services to help with day-to-day living. Some retirement villages have been developed on a resort-style model with golf courses and swimming pools, and residents are encouraged to have an independent and active lifestyle inclusive of daily exercise and social activities. Others incorporate spare bedrooms to encourage and accommodate family members such as grandchildren to 'sleep-over'. Some are built adjacent to child care centres to permit older people to contribute and be visible to children in daycare. Residents in retirement communities may be offered a choice of services according to their needs, such as meals, housekeeping, transport, emergency response systems and planned social activities.

Adult daycare

Adult daycare offers health and rehabilitative services for the older adult and respite from caregiving activities for family caregivers. Clients of daycare centres are usually not seriously ill, although they may have chronic conditions, disabilities or cognitive impairments that limit independence. Activities offered by the day centre might focus on minimising functional decline.

Respite care

Respite care is temporary relief for the primary caregiver of a dependent older adult. Service is provided either in the home of the older person, or within an institution such as a residential aged care facility. Respite care enables the caregiver to be away from home for a few hours, several days or weeks.

Subacute care/rehabilitation care

There has been substantial growth in subacute and rehabilitative care services in both Australia and New Zealand. Subacute care provides assessment and rehabilitation services for people who might otherwise be admitted (or remain as inpatients) within acute care settings. Rehabilitation services specifically for older adults include transition and restorative services. Early development of rehabilitative care evolved from the need to manage disability resulting from wars, industry or road trauma. More recently, quality-of-life issues have driven the focus of rehabilitative care for older people, for example, for those who have suffered a cardiovascular accident, have musculoskeletal injuries such as hip fracture or suffer diseases such as severe osteoarthritis or Parkinson's disease. Fast becoming a specialty area within health care, the major goal of rehabilitation programs for older people is to help them manage personal ADLs through the use of adaptive techniques and equipment, with the goal to minimise the need for external assistance.

Subacute facilities admit clients from the community or from acute care settings, and provide multidisciplinary assessment and ongoing care planning. These facilities generally combine the services of a geriatrician, case coordinators, therapists who specialise in the health needs of older people, and specialist services such as a memory (dementia) clinic, wound clinic, continence services, pain management and/or falls clinics. Many subacute facilities offer day-time services for community-dwelling elderly people who visit the facility on an outpatient basis for treatment or social activity. Some of the larger subacute facilities also have specialist nurses and therapists who visit community-dwelling older people in their own homes and therefore forestall admission to care. In particular, modification of the home environment with rails or other equipment can do much to ensure a safe environment and therefore a longer stay within the person's own community.

Chronological age was often used as a basis for offering rehabilitation services in the past, but current thinking is that the major consideration regarding suitability for rehabilitation services should be the ability of the individual to benefit from it. For those admitted to a

WORKING WITH DIVERSITY

Focus on cultural care

The move to person-centred care

Older people from culturally and linguistically diverse backgrounds can face barriers to accessing appropriate aged care services. There is as yet very little provision for the necessary cultural and linguistic services to provide holistic, culturally appropriate care to all of the groups that make up Australia and New Zealand. Institutionalised care can compound cultural isolation of a client by the removal of a person from their language and from interactions with others from their cultures.

This alienation can cause both the older person and family members extreme distress, and can have a direct impact on care provided and accepted. For example, the move to residential aged care is a stressful time for all family members. This is highlighted when family members feel guilty that they can no longer care for their older relative at home. This guilt can lead to a situation where a family member's inability to discuss the care their relative needs makes it difficult for the staff of the facility to provide appropriate care.

Older adults may feel the need to hide their cultural values and preferences for fear of being considered abnormal.

There is increasing recognition in both Australia and New Zealand that aged care is a reflection of the diverse population that make up either country – people wish to be treated as unique individuals, consulted about their care and treated with respect. In both countries, person-centred care is becoming the foundation of care.

Implications for practice

Nurses can work towards providing person-centred care by:

- accepting that they are cultural beings
- critically examining their own values and attitudes
- dispelling simplistic assumptions about how people of culturally and linguistically diverse backgrounds might think, feel or behave about their harmony and collectivity, e.g. an assumption that the family will always look after an older person
- accepting that there are differences within cultural groups because of a variety of migration patterns, work opportunities and language abilities
- clarifying with the older person and family members the importance of culturally unfamiliar behaviours
- avoiding labelling
- being educated – attending workshops and seminars, reading about cultural differences and specific needs of people from culturally and linguistically diverse backgrounds; about sexual expression in the older adult; and how person-centred care can be promoted.

subacute facility, the future might mean being transferred home with community support, such as district or home nursing, moving to a location that offers greater access to health and community care, linen services or meals-on-wheels, or transfer to the appropriate level of residential aged care. The increasing emphasis is on minimising functional decline and increasing the quality of life of an older person.

Residential aged care

Declining health, decreased physical strength, cognitive impairment, increased dependence and limited caregiver resources may make it necessary for an older adult to move to a residential aged care facility. Licensed facilities range from assisted-living through to facilities that provide for a high level of frailty. Australia and New Zealand, like similar industrialised countries, face difficult decisions related to the amount of care that can be financially subsidised, and the amount of resources required to provide appropriate services. Currently, Australian and New Zealand governments both require an assessment of the need for care before admission, if the care is to be subsidised by public funds.

Those needing residential aged care tend to have high levels of self-care deficit, and are likely to suffer from impaired mobility and/or impaired cognition; heart disease, hypertension, musculoskeletal conditions and one of the various forms of dementia. Urinary incontinence, a history of falls and impaired cognition tend to be predictors of the need for admission to residential aged care facilities (AIHW 2014).

Residents requiring care may need a mix of personal care assistance, professional nursing services (aged care nursing), supervision of prescribed medical care, rehabilitation services and psychosocial services. In facilities that offer care to older adults with high dependency needs, residents tend to be older with multiple health problems, and may have greater cognitive deficits and functional impairments. It is important that care delivery in residential aged care is culturally sensitive in order to enable and support the health needs of diverse groups (see *Working with diversity*).

The decision to move into a residential facility is not easy, and should be made only after the older adult and their family have considered the full range of care choices. Although the decision is never final and, once admitted to a facility a resident may be discharged home or to another facility, many older adults view the residential aged care facility as their final residence. As a result of the general ill-health of those admitted into residential aged care, access to specialised palliative care services may be needed.

Maintaining psychosocial health

Interventions supporting the psychosocial health of older adults resemble those for other age and developmental groups. However, some interventions are more crucial for older adults experiencing social isolation, cognitive impairment or stresses related to retirement, relocation or approaching death. These interventions include therapeutic communication, touch, reality orientation, validation therapy, reminiscence and interventions to improve body image.

Therapeutic communication

Therapeutic communication respects the older adult's uniqueness. The nurse who communicates effectively will be accepted as one who shares a genuine concern for the older person's welfare. It is not possible for any health professional to simply enter an older adult's environment and immediately establish a therapeutic relationship. Nurses and other health professionals must first acknowledge their own and others perceptions and biases, and be knowledgeable and skilled in therapeutic communication techniques.

Touch

Throughout life, touch tells us about our environment and the people around us. Gentle touch conveys affection and friendliness. A firm handclasp may convey security or dominance. Older adults may be deprived of touching when separated from family or friends. An older adult who is isolated, dependent or ill, who fears death or who lacks self-esteem has a greater need for touch.

Touch is a therapeutic tool that nurses can use to help comfort the older adult. Touch can provide sensory stimulation, induce relaxation, provide physical and emotional comfort, orient the person to reality, convey warmth and communicate interest. Touch is therefore a powerful physical expression of a relationship.

Nurses frequently touch others during the course of offering assistance with hygiene or nutrition or delivering treatment. Therefore, nurses are usually the one healthcare professional who can recognise that older adults may be suffering from *touch deprivation*. Older adults may demonstrate this need for touch by reaching for the nurse's hand. Unfortunately, older men are sometimes wrongly accused of sexual advances when they reach out to touch others. Nurses' use of touch should never be condescending, such as patting an older adult on the head, but should always convey respect and sensitivity.

Reality orientation

Reality orientation is a communication technique used to help an older adult be more aware of time, place and person. The purposes of reality orientation include restoring a sense of reality, improving the level of awareness, promoting socialisation, elevating independent functioning and minimising confusion, disorientation and physical regression.

Although reality orientation techniques can be used in any healthcare setting, they may be especially useful in the acute care setting. The older adult experiencing a change in environment, surgery, illness or emotional stress is at risk of becoming disoriented. Environmental changes, such as bright lights, unfamiliar noises, sleep deprivation and lack of windows in specialised units of a hospital, often lead to disorientation and confusion. Absence of familiar caregivers is also disorienting. When anaesthesia, sedatives, tranquillisers, analgesics and physical restraints are used, disorientation is increased. It is important to monitor for disorientation and confusion as possible consequences of hospitalisation, relocation, surgery, loss or illness, and to incorporate interventions based on reality orientation into the care plan.

The key elements of reality orientation include frequent reminders of person, time and place; the use of environmental aids such as clocks, calendars and personal belongings; and stability of environment, routine and staff. Communication is always respectful, patient and calm. The nurse answers questions from the older adult simply and honestly with sensitivity and a caring attitude.

Validation therapy

Validation therapy is an alternative approach to communication with a confused older adult. Where reality orientation insists that the confused older adult should agree with the nurse's statements of time, place and person, validation therapy accepts the description of time and place as stated by the confused older adult. In validation therapy, statements and behaviours of the confused older adult are not confronted. They are believed to represent an inner need or feeling. By listening with sensitivity and validating what is expressed, the nurse conveys respect, reassurance and understanding. Validation does not involve reinforcing the confused older adult's misperceptions, but reflects sensitivity to hidden meanings in statements and behaviours. Validating or respecting the feelings of confused older adults in the time and place that is real to them is more important than insisting on the literally correct time and place.

Reminiscence

Reminiscence is recalling the past. Looking back at positive resolutions to problems reminds the older adult of coping strategies used successfully in the past. Reminiscing is also a way to express personal identity. Reflection on past achievements supports self-esteem. For some older adults, the process of looking back on past events uncovers new meanings for those events.

During the assessment process, the nurse may use reminiscence to assess self-esteem, cognitive function, emotional stability, unresolved conflicts, coping ability and expectations for the future. Reminiscence also occurs during direct care activities. Taking time to ask questions about past experiences and listening attentively conveys to an older adult the nurse's respect and concern for them.

Body image

The way older adults present themselves has a significant impact on body image and feelings of isolation. Some physical characteristics of older adulthood are socially desirable, such as distinguished-looking grey hair. Other features are also impressive, such as a lined face that displays character or wrinkled hands that convey a lifetime of hard work. Too often, however, society sees older people as incapacitated, deaf, confused, ugly or shrunken in stature. Consequences of illness and ageing that threaten the older adult's body image include invasive diagnostic procedures, pain, surgery, and loss of sensation in a body part, skin changes, loss of teeth and hair, and incontinence. Body image is also affected by the need to use replacement devices and aids such as dentures, hearing aids or artificial limbs, and by temporary or permanent solutions for chronic conditions such as indwelling catheters, ostomy devices and enteral feeding tubes.

The importance to the older adult of presenting a socially acceptable image must be considered. When older adults have acute or chronic illnesses, the related physical dependence makes it difficult for them to maintain body image. By helping with grooming and hygiene, nurses can have a direct influence on the older adult's appearance and therefore, their self-esteem. It takes little effort to help the older adult with combing hair, cleaning dentures, shaving or changing clothing. The older adult does not choose to have an objectionable appearance. In addition, it is important to be sensitive to odours in the environment caused by urine, faeces or specific illness presentations. Unpleasant odours may cause visitors to shortening their stay or not come at all.

Conclusion

In summary, older adults are likely to access all facets of health and welfare services: acute, subacute, rehabilitation and community-based care, as well as residential aged care and palliative care. Nurses are often in a unique position to partner with older people and their families to provide sensitive care that is based on current knowledge about older adults, and that is respectful of their cultural and personal needs and requirements. Gerontology nursing is a specialty area in which knowledge of the physical, psychological and psychosocial aspects of ageing are brought together in an exciting, demanding and challenging area of nursing practice. It is important to remember that the majority of older adults lead healthy and productive lives and working with this age group requires actively embracing concepts of healthy and positive ageing, as well as direct care and high-level communication skills. Ageing and gerontology nursing is an area of practice that is immensely rewarding.

Key concepts

- The number of older people, especially over age 85 years, is increasing in the Australian and New Zealand populations.
- Positive ageing refers to maintaining a focus on the opportunities and rewards of ageing
- Because nurses' attitudes towards older adults influence the quality of care, those attitudes need to be based on accurate information about older adults, rather than on myths and stereotypes.
- Older adults adapt to physical changes in all organ systems as they age.
- Changes in social roles, family responsibilities, financial circumstances and health status influence the choice of living arrangements of an older adult.
- Older people access health and welfare services that are community-based, subacute and rehabilitation services, as well as in acute care and residential settings.
- The physical changes that accompany ageing are considered to be normal, not pathological, although they may predispose the older person to disability or disease.
- Cognitive impairment is not normal in an older person and requires assessment and intervention.
- Issues related to psychosocial changes in ageing may include retirement, change in housing, sexuality, grief, change in relationships with children and possible social isolation.
- Nursing interventions for psychosocial concerns include therapeutic communication, touch, reality orientation, validation therapy, reminiscence and interventions to improve body image.
- Healthy ageing recommendations for older adults include good nutrition, regular exercise, smoking cessation and measures to reduce the risk of falls and adverse drug events.
- Rehabilitative nursing interventions, whether accomplished in the older person's home or in an institutional setting, stabilise chronic conditions, minimise functional decline and promote health, increase quality of life and independence in activities of daily living.

CHAPTER

19

Considering the person with disability

Julie Pryor and Murray Fisher

Learning outcomes

Mastery of the content will enable you to:

- identify your own attitudes towards persons with disability
- identify and discuss a range of definitions of disability
- discuss a variety of mechanisms of disability
- discuss the lived experience of disability
- identify environmental factors and how they influence a person's functional performance
- discuss how nurses and other healthcare workers can act as enablers or barriers to human functioning
- identify strategies for interacting authentically and respectfully with persons with disability
- plan nursing care to prevent or minimise sensory alterations
- plan nursing care to facilitate communication with persons experiencing impaired communication
- discuss a range of assistive technologies and identify sources of information about assistive technologies
- plan nursing care to prevent functional decline
- discuss strategies for enriching inpatient and institutional care environments.

KEY TERMS

Proprioception, p. 431
Reception, p. 431
Sensory deficit, p. 433
Sensory deprivation, p. 434
Sensory overload, p. 434
Stereognosis, p. 431

Disability is a commonly used word, and it is likely that each of us knows someone with a disability. Knowing someone with a disability can inform the way we think about people with disability. But the way we think about people with disability is also informed by a much wider range of influences.

It is most important to be aware that these influences (both positive and negative) can be subtle and resistant to change; some are cultural while others may be embedded in legislation and policies, and the structures and processes they inform. Some are literally set in stone in the way we design our public spaces and buildings. How accessible is your local cafe or park for a person using a walking frame?

Awareness of our personal understanding of what constitutes a disability and awareness of own attitudes and beliefs about people with disability is the starting point for nurse-effectiveness when working with people with disability.

• CRITICAL REFLECTION POINT

Write down your personal understanding of what constitutes a disability.

Reflect upon your attitudes and beliefs about people with disability, noting what you think they should and should not do. Also note how you feel about people with disability and how you think they should be treated. Do you feel sorry for people with disability? Do you feel uncomfortable in the presence of people with particular types of disability? If so, what type/s of disability?

In this chapter you will be introduced to the 'disabled person' as a person with disability and abilities. Mechanisms of disability will be explained and person-centred nursing care for the person with disability will be explored. Key terms listed at the beginning of the chapter will be explained throughout.

Who is the person with disability?

Disability can be seen as a defining characteristic of some people. As a word, disability denotes limitations and inability. When used as a comparative term, the comparison always determines the person with a disability as lacking something; lacking normality or even some degree of personhood. The undesirability of disability seems to be related to being different and, more specifically, different to an extent that falls outside the range of acceptable difference (Patston 2007).

In explaining **personhood** as a 'status that is bestowed upon a human being by others', Kitwood (1997:8) highlights the fragility and dependence of an individual's status. If a person with disability is regarded by someone else as a lesser person, their very personhood may be questioned.

Disability is more than a characteristic or static state. It is a **lived experience**, which, along with day-to-day challenges, is more generally often associated with disadvantage. For example, persons with disabilities 'experience worse educational and labour market outcomes and are more likely to be poor than persons without disabilities' (WHO 2011:39).

• CRITICAL REFLECTION POINT

The range of acceptable difference varies from one person to another. Do Angus, Diane or Molly, in the following stories, fall within or outside your range of acceptable difference? Do you consider one or more of them to be disabled?

- **Angus, a man in his early 50s with chest pain, is in your emergency department patient allocation. Angus is a footy fan and is keen not to miss Saturday's match as he has tickets to attend with his friend Daniel. Angus and Daniel work together, both have an intellectual disability, are deaf and use sign language. Angus is fretting about the upcoming football match and wants to go home, despite the pain in his chest.**
- **Diane has been teaching science at the local high school for the past 6 years. She is highly regarded by teaching colleagues and parents. The students like her best in the role of coach of the elite basketball team, a team that has been undefeated for the past 3 years. Her 10-year-old twins often attend matches along with their dad to cheer the team on. Diane has used an electric wheelchair for the past 8 years following a motor vehicle accident on the way to a basketball match; she has a spinal cord injury and as a result has no movement or sensation below her armpits. She has been admitted to your ward with sepsis and her priority is to organise today's after-school pick-up for her children because her partner is working interstate for the week.**
- **At 95, Molly has many stories to tell of her adventures travelling the world as a young woman, but does not recognise any of her grandchildren who visit her regularly. Interactions with her children are unpredictable and often stressful given her advancing dementia. A fall in the garden triggers much discussion about treatment options for her fractured neck of femur and Molly's wishes.**

Disability, especially profound disability, can trigger questions about the definition of personhood and whether there is ever a circumstance when a human body is no longer a person. The inability to respond to others in a recognisable manner is one such situation where these questions might arise. Profound brain injury can render someone minimally responsive, and at times, not responsive at all. An important point to note is that 'post-

coma unresponsiveness' and 'brain dead' are not the same thing; while the former is about living and the latter is not (National Health and Medical Research Council 2008), decisions in these situations are complex and often take protracted periods of time to make.

Knowing the wishes of a person in an unresponsive or minimally conscious state is far from straightforward. Personhood is not static; it can have experiential, temporal and perhaps spatial and situational variations. The decisions I make in today's context may differ from decisions I would make in a different context. Consider how well informed a person can be when, in a perfectly healthy state, they say they don't want lifesaving treatment if they have a major injury. Compare this to a situation in which the person may appear not to uphold the same view if they are conscious and in no discernible distress, despite severe cognitive impairment.

Imagine being fully aware of one's surroundings, but unable to communicate your wishes to anyone. You may have read *Ghost Boy* (Pistorius with Davies 2011), an autobiography of Martin Pistorius who has lived with locked-in syndrome since the age of 12 when he contracted an unexplained illness. While at the time of writing his book Martin was a participating member of society, this was not always the case. This story highlights the role that others play in defining personhood for individuals unable to communicate their preferences and priorities. The important point here is that unresponsive does not always mean the person is not aware of what is going on around them.

While understanding disability and the experience of living with disability are central to nurse-effectiveness, this responsibility is not limited to our professional lives. In 2007, Australia and New Zealand joined a long list of countries as signatories to the 2006 United Nations Convention on the Rights of Persons with Disabilities (see *Online resources*). This means that all Australians and New Zealanders have a responsibility to uphold the purpose of the Convention, namely, 'to promote, protect and ensure the full and equal enjoyment of all human rights and fundamental freedoms by all persons with disabilities, and to promote respect for their inherent dignity' (United Nations 2006, 2015).

Definitions of disability

On a conceptual level, our understanding of disability is informed by the World Health Organization (WHO), which defines key terms relevant to disability in the *International Classification of Functioning, Disability and Health* (WHO 2001). **Functioning** is 'an umbrella term for body functions, body structures, activities and participation' (WHO 2001:212–13). **Disability** is 'an umbrella term for impairments, activity limitation and participation restrictions' (WHO 2001:213, AIHW 2015b). Functioning and disability are ends of the one continuum in relation to each and every aspect of human life. An important point to note here is that this classification system 'is about all people' (WHO 2001:7).

While disability is a natural part of the human condition, tighter definitions of disability are needed for various purposes. For example, in Australia the definitions used to determine eligibility for disability-related support services or payments differ from those used in population-based surveys on disability. People responding to the 2012 Australian Bureau of Statistics (ABS) Disability, Ageing and Carers Survey were guided by a definition of disability which included their experiencing one of a list of 17 limitations, restrictions or impairments (see Box 19-1), which had lasted, or were likely to last, for at least 6 months, and restricted everyday activities (ABS 2015).

New Zealand used a slightly different definition in their *2006 Disability Survey* (Statistics New Zealand 2009). Disability is defined as 'any self-perceived limitation in activity resulting from a long-term condition or health

BOX 19-1 ABS survey definitions of disability

- loss of sight (not corrected by glasses or contact lenses)
- loss of hearing where communication is restricted, or an aid to assist with, or substitute for hearing is used
- speech difficulties
- shortness of breath or breathing difficulties causing restriction
- chronic or recurrent pain or discomfort causing restriction
- blackouts, fits, or loss of consciousness
- difficulty learning or understanding
- incomplete use of arms or fingers
- difficulty gripping or holding things
- incomplete use of feet or legs
- nervous or emotional condition causing restriction
- restriction in physical activities or in doing physical work
- disfigurement or deformity
- mental illness or condition requiring help or supervision
- long-term effects of a head injury, stroke or other brain damage causing restriction
- receiving treatment or medication for any other long-term conditions or ailments and still being restricted
- any other long-term conditions resulting in a restriction.

ABS 2015 Psychological disability, 2012. ABS Cat. No. 4433.0.55.004. Online. Available: http://www.abs.gov.au/ausstats/abs@.nsf/Lookup/3A5561E876CDAC73CA257C210011AB9B?opendocument; accessed 4 May 2016.

problem; lasting longer or expected to last longer than six months or more and not completely eliminated by an assistive device'. Inclusion of the role of an assistive device is an interesting one in the New Zealand definition as it suggests a person no longer has a disability if self-perceived activity limitations are eliminated by the device. However, this is only possible when the assistive device is fully accessible by the person. Recognition of the role of contextual factors in relation to disability, especially as enablers or barriers to functioning, highlights the possibility (and perhaps probability) of variations in accessibility of assistive devices between different situations. For example, when a person's walking aid is put out of reach, dependence and disability may result; this can happen when the person is in bed, in a café or at the cinema.
