ADULT-GERONTOLOGY PRACTICE GUIDELINES

ADULT-GERONTOLOGY PRACTICE GUIDELINES

EDITOR

Jill C. Cash, MSN, APRN, FNP-BC, a family nurse practitioner (NP) for over 27 years, currently practices at Vanderbilt University Medical Center for the Vanderbilt Medical Group at Westhaven Family Practice in Franklin, Tennessee. She is a faculty member for the School of Nursing at Vanderbilt University. She has been a clinical preceptor for NP students for a variety of programs over the past several years. Her previous experience includes high risk obstetrics as a clinical nurse specialist in maternal–fetal medicine, as well as practicing as an NP in women's health, family practice, and rheumatology. In 2017, Ms. Cash was awarded the 2017 American Association of Nurse Practitioners State Award for Excellence in Illinois. Ms. Cash has authored several chapters in a variety of nursing and NP textbooks. She is the coauthor of *Family Practice Guidelines* (first, second, third, fourth, and fifth editions) and *Adult-Gerontology Practice Guidelines* (first, second, and third editions). Ms. Cash is an active member of the American Association of Nurse Practitioners and Sigma Theta Tau International Honor Society.

ADULT-GERONTOLOGY CONSULTANTS

Ann McQueen Blair, DNP, FNP, WHNP, GNP, is board-certified as a nurse practitioner in both women's health and family nurse practitioner as well as gerontologic nurse practitioner. With over 30 years of NP experience, her clinical practice has included women's health and reproductive endocrinology, integrative family practice, and geriatric practice including geriatric assessment focused on dementia care. She currently practices at the University of Virginia Student Health and Wellness in Charlottesville, Virginia. She teaches at the School of Nursing at the University of Virginia. Geriatrics and family medicine are her areas of experience as a clinical professor and an expert lecturer. Her doctoral evidence-based practice initiative focused on celiac disease awareness for healthcare providers, and she aims to implement more educational programs on this topic into other healthcare settings. Dr. McQueen Blair is an active member of the American Association of Nurse Practitioners, Nurse Practitioners in Women's Health, and Gerontological Advanced Practice Nurses Association.

L. Douglas Smith Jr., DNP, APRN, ACNP-BC, CCRN, CNRN, SCRN, FCCM, is an acute care nurse practitioner at HCA TriStar Centennial Medical Center and a faculty member in the Adult-Gerontology Acute Care Nurse Practitioner program at Vanderbilt University School of Nursing. He has 15+ years of experience caring for aged adults in various inpatient settings. Doug is published in multiple journals and textbooks and regularly speaks at conferences. He is an active member of several national organizations, including the American Association of Critical-Care Nurses, the American Association of Nurse Practitioners, and the Society of Critical Care Medicine. Doug is a Fellow in the American College of Critical Care Medicine.

Medicine is an ever-changing science. Research and clinical experience are continually expanding our knowledge, in particular our understanding of proper treatment and drug therapy. The authors, editors, and publisher have made every effort to ensure that all information in this book is in accordance with the state of knowledge at the time of production of the book. Nevertheless, the authors, editors, and publisher are not responsible for any errors or omissions or for any consequence from application of the information in this book and make no warranty, expressed or implied, with respect to the content of this publication. Every reader should examine carefully the package inserts accompanying each drug and should carefully check whether the dosage schedules therein or the contraindications stated by the manufacturer differ from the statements made in this book. Such examination is particularly important with drugs that are either rarely used or have been newly released on the market.

Contributors *xv*
Acknowledgments *xvii*
Instructor Resource *xix*

SECTION I: GUIDELINES

1. NORMAL PHYSIOLOGIC CHANGES IN THE AGING ADULT 3
L. Douglas Smith Jr.

Introduction 3
Brain and Nervous System 3
Ears 4
Smell and Taste 4
Cardiovascular System 4
Respiratory System 4
Gastrointestinal System 5
Metabolism and Body Weight 5
Endocrine System 5
Musculoskeletal 5
Genitourinary System 5
Reproduction and Sexuality 5
Blood and Blood Components 5
Skin, Hair, and Nails 6

2. HEALTHY LIVING FOR THE ADULT-GERIATRIC CLIENT 7
Ann McQueen Blair and Kathleen Bradbury-Golas

Health Maintenance During the Life Span 7
Adult Risk Assessment Form 7
Adult Preventive Healthcare 8
Adult-Geriatric Screening Recommendations 8
Abdominal Aortic Aneurysm 8
Bone Mass Density Measurement for Osteoporosis 15
Cardiovascular Disease and Cardiac Screening (Cardiac Calcium Score) 16
Colorectal Screening 18
Dental Care 18
Depression Screening 19
Diabetes Screening 19
Hepatitis C Screening 20
HIV Screening 20
Immunizations 20
Mammography 22
Pap Smear/Pelvic Examination 24
Prostate Cancer Screening 24
Sexually Transmitted Infection Screening 25
Vision Screens 25
Pretravel Health Screenings 25

3. ADULT-GERIATRIC ASSESSMENTS 27
L. Douglas Smith Jr.

Comprehensive Assessment in Gerontology 27
Polypharmacy 28
Functional Ability 32
Psychological Well-Being 36
Socioenvironmental Status 40
Advanced Care Planning 45
Client Teaching Guides 47

4. CAREGIVER AND END-OF-LIFE ISSUES 53
Ann McQueen Blair

Caregiver Support Issues 53
Formal and Informal Caregivers 53
Informal Caregiver Demographics 53
Care Recipient Demographics 54
Informal Caregiver Concerns 54
Providers' Assistance With the Caregiver 55
Caregiver Resources 55
Advance Directives 56
Palliative Care 58
Special Considerations: Hospice Care 59
Key Factors of Care in the Elderly Client at the End of Life 59
Physical Aspects of Care 61
Symptom Management 63
Social Aspects of Care 70
Spiritual, Religious, Cultural, and Existential Aspects 71
Ethics 72

5. GERIATRIC SYNDROMES 77
Wesley Cook

Introduction 77
Frailty and Sarcopenia 79
Functional Dependence 79
Falls 79
Dementia, Depression, and Delirium 81
Poor Appetite and Unintentional Weight Loss 82
Pain 84
Incontinence 85
Conclusion 86

6. PAIN MANAGEMENT GUIDELINES 89
Kathleen Bradbury-Golas

Acute Pain 89
Chronic Pain 91
Pain Assessment and Management in the Aging Population 96
Low Back Pain 99
Client Teaching Guides 102

7. DERMATOLOGY GUIDELINES 105
Jill C. Cash and Amy C. Bruggemann

Acne Rosacea 105
Acne Vulgaris 106
Atopic Dermatitis 108
Benign Skin Lesions 110
Bites 111
Bullous Pemphigoid 114
Candidiasis 115
Cellulitis and Abscess 117
Contact Dermatitis 119
Erythema Multiforme 121
Folliculitis 122
Herpes Simplex Virus Type 1 123
Herpes Zoster (Shingles) 125
Lice (Pediculosis) 126
Lichen Planus 127
Pityriasis Rosea 129
Precancerous or Cancerous Skin Lesions 130
Psoriasis 131
Scabies 133
Seborrheic Dermatitis 134
Tinea 136
Tinea Versicolor 137
Warts 138
Wound Care: Lower Extremity Ulcer 139
Wound Care: Pressure Injuries/Ulcers 141
Wounds of The Skin 143
Wound Healing: High-Protein Nutrition 145
Xerosis (Winter Itch) 146
Client Teaching Guides 147

8. EYE GUIDELINES 173
Jill C. Cash and Nancy Pesta Walsh

Blepharitis 173
Cataracts 174
Chalazion 176
Conjunctivitis 177
Corneal Abrasion 179
Dacryocystitis 180
Dry Eyes 181
Excessive Tears 183
Eye Pain 184
Glaucoma, Acute Angle Closure 186
Hordeolum (Stye) 187
Macular Degeneration 189
Refractive Disorders 190
Retinopathy 191
Subconjunctival Hemorrhage 192
Uveitis 193
Client Teaching Guides 194

9. EAR GUIDELINES 199
Jill C. Cash and Emily Y. Brignola

Acute Otitis Media 199
Cerumen Impaction (Earwax) 200
Hearing Loss 201
Otitis Externa 203
Otitis Media With Effusion 205
Presbycusis 206
Tinnitus 208
Client Teaching Guides 210

10. NASAL GUIDELINES 215
Jill C. Cash and Sarah Hendershott Taylor

Allergic Rhinitis 215
Epistaxis 217
Nonallergic Rhinitis 219
Sinusitis 220
Client Teaching Guides 223

11. THROAT AND MOUTH GUIDELINES 229
Jill C. Cash and Kathleen Bradbury-Golas

Dental Abscess 229
Dysphagia 230
Epiglottitis 232
Oral Cancer, Leukoplakia 233
Pharyngitis 235
Stomatitis, Recurrent Aphthous Stomatitis 237
Thrush 239
Client Teaching Guides 240

12. RESPIRATORY GUIDELINES 245
Audra Malone Cave

Asthma 245
Bronchitis, Acute 251
Bronchitis, Chronic 252
Chronic Obstructive Pulmonary Disease 254
Common Cold/Upper Respiratory Infection 259
Cough 260
Dyspnea 262
Emphysema 264
Influenza (Flu) 268
Obstructive Sleep Apnea 272
Bacterial Community-Acquired Pneumonia 274
Pneumonia (Viral) 277
Tuberculosis 279
Client Teaching Guides 282

13. CARDIOVASCULAR GUIDELINES 301
Debbie A. Gunter and Laura A. Petty

Acute Myocardial Infarction 301
Arrhythmias 303
Atherosclerosis and Hyperlipidemia 306
Atrial Fibrillation 310
Carotid Artery Stenosis 314

Chest Pain 316
Chronic Venous Insufficiency and Varicose Veins 321
Deep Vein Thrombosis 324
Heart Failure 326
Hypertension 334
Lymphedema 338
Murmurs 340
Palpitations 343
Peripheral Arterial Disease 344
Superficial Thrombophlebitis 347
Syncope 350
Client Teaching Guides 352

14. GASTROINTESTINAL GUIDELINES 363
L. Douglas Smith Jr., Ann McQueen Blair, and Justin Calabrace

Abdominal Pain 363
Appendicitis 367
Bowel Obstruction 369
Celiac Disease 372
Cholecystitis 375
Cirrhosis of the Liver 377
Colorectal Cancer Screening 381
Constipation 383
Crohn's Disease 387
Cyclosporiasis 394
Diarrhea 395
Diverticulosis and Diverticulitis 398
Elevated Liver Enzymes 400
Fecal Incontinence 404
Gastroenteritis, Bacterial and Viral 407
Gastroesophageal Reflux Disease and Dyspepsia 410
Giardia Intestinalis 414
Hemorrhoids 416
Hepatitis A 418
Hepatitis B 422
Hepatitis C 427
Hernias, Abdominal 431
Hernias, Pelvic 433
Hiatal Hernia 436
Irritable Bowel Syndrome 438
Jaundice 441
Malabsorption 444
Nausea and Vomiting 447
Pancreatitis 450
Peptic Ulcer Disease 453
Postbariatric Surgery Long-Term Follow-Up 457
Ulcerative Colitis 463
Client Teaching Guides 467

15. GENITOURINARY GUIDELINES 487
Kristina A. Potts and Nancy Pesta Walsh

Benign Prostatic Hyperplasia 487
Chronic Kidney Disease 491
Epididymitis 495
Hematuria 498
Interstitial Cystitis 500
Nocturia 503
Prostatitis 506
Proteinuria 510
Pyelonephritis 513
Renal Calculi, or Kidney Stones (Nephrolithiasis) 516
Sexual Dysfunction, Male: Erectile Dysfunction 519
Sexual Dysfunction, Male: Premature Ejaculation 525
Sexual Health Issues in the Aging Population 527
Sexuality and Chronic Health Conditions 532
Sexuality and End of Life 533
Sexuality and Physical Disabilities 533
Testicular Torsion 535
Urinary Incontinence 536
Urinary Retention 541
Urinary Tract Infection (Acute Cystitis) 544
Varicocele 548
Client Teaching Guides 549

16. OBSTETRICS GUIDELINES 565
Penny Wortman

Prepregnancy Counseling: Identifying Clients at Risk 565
Prenatal Care: Initial Prenatal Visit 568
Prenatal Care: First Trimester Overview 568
Prenatal Care: Second Trimester Overview 569
Prenatal Care: Third Trimester Overview 570
Postpartum Overview 571
Anemia, Iron-Deficiency 573
Gestational Diabetes Mellitus 575
Hypertensive Disorders 578
Preterm Labor 582
Pyelonephritis in Pregnancy 585
Vaginal Bleeding: First Trimester 586
Vaginal Bleeding: Second and Third Trimesters 589
Postpartum Breast Engorgement 591
Endometritis 592
Mastitis 594
Postpartum Depression 595
Secondary Postpartum Hemorrhage 599
Wound Infection 601
Postpartum Exam 602
Client Teaching Guides 603

17. GYNECOLOGIC GUIDELINES 617
Rhonda Arthur and Jill C. Cash

Amenorrhea 617
Bacterial Vaginosis (*Gardnerella*) 619
Bartholin Cyst or Abscess 621
Breast Pain 622
Cervical Cancer Screening Guidelines and Interpretation 624
Cervicitis 626
Contraception 628
Dysmenorrhea 632
Emergency Contraception 634
Endometriosis 636
Female Sexual Dysfunction 639
Genito-Pelvic Pain/Penetration Disorder (Dyspareunia) 642

Genitourinary Syndrome of Menopause 644
Impaired Fertility 647
Menopause 651
Pelvic Inflammatory Disease 655
Pelvic Organ Prolapse 658
Premenstrual Syndrome and Premenstrual Dysphoric Disorder 663
Preventive Care for Adult Survivors of Sexual Violence 665
Vulvovaginal Candidiasis 667
Client Teaching Guides 669

18. SEXUALLY TRANSMITTED INFECTIONS GUIDELINES 689
Dana N. Hughes

Chlamydia 689
Gonorrhea 691
Herpes Simplex Virus: Genital Herpes 693
Human Papillomavirus 695
Syphilis 697
Trichomoniasis 700
Client Teaching Guides 701

19. INFECTIOUS DISEASE GUIDELINES 709
LaDawna R. Goering

Cytomegalovirus 709
Encephalitis 712
Lyme Disease 715
Meningitis 718
Mononucleosis (Epstein–Barr) 722
Rheumatic Fever 724
Rocky Mountain Spotted Fever 727
Toxoplasmosis 730
Varicella (Chickenpox) 733
West Nile Virus 735
Client Teaching Guides 738

20. SYSTEMIC DISORDERS GUIDELINES 745
Jill C. Cash, Kristin K. Ownby, and Dana N. Hughes

Cancer Management 745
Fevers of Unknown Origin 748
Human Immunodeficiency Virus 750
Immune Thrombocytopenia 754
Iron-Deficiency Anemia (Microcytic, Hypochromic) 756
Lymphadenopathy 758
Malnutrition 761
Megaloblastic Anemia 764
Myalgic Encephalomyelitis/Chronic Fatigue Syndrome 766
Client Teaching Guides 769

21. MUSCULOSKELETAL GUIDELINES 777
Carsen Cash and Jill C. Cash

Aging Knee/Knee Pain 777
Bunion 779
Degenerative Disc Disease (Neck/Lumbar) 780
Hammer Toe 782
Morton Neuroma 783
Neck and Upper Back Disorders 784
Plantar Fasciitis and Bone Spurs 786
Sciatica 788
Shoulder Pain 789
Spinal Stenosis 792
Sprains: Ankle and Knee 796
Client Teaching Guides 798

22. RHEUMATOLOGIC GUIDELINES 807
Jill C. Cash and Hsiao-Hui "Joyce" Ju

Ankylosing Spondylitis 807
Fibromyalgia 809
Gout 811
Osteoarthritis 812
Osteoporosis/Kyphosis/Fracture 814
Polymyalgia Rheumatica 818
Pseudogout 819
Psoriatic Arthritis 821
Raynaud Phenomenon 822
Rheumatoid Arthritis 825
Systemic Lupus Erythematosus 828
Temporal Arteritis/Giant Cell Arteritis 831
Vitamin D Deficiency 832
Client Teaching Guides 834

23. NEUROLOGIC GUIDELINES 843
Jill C. Cash, Justin Calabrace, and Lauren E. Kimbrell

Alzheimer Disease 843
Bell's Palsy 846
Carpal Tunnel Syndrome 848
Guillain–Barré Syndrome 849
Headache 852
Migraine Headache 855
Mild Traumatic Brain Injury 860
Multiple Sclerosis 863
Myasthenia Gravis 867
Neurocognitive Disorders (Dementia) 869
Normal Pressure Hydrocephalus 872
Parkinson Disease 874
Restless Legs Syndrome 876
Seizures 879
Stroke 884
Transient Global Amnesia 888
Transient Ischemic Attack 890
Trigeminal Neuralgia 893
Vertigo 895
Client Teaching Guides 899

24. ENDOCRINE GUIDELINES 913
Jill C. Cash and Hsiao-Hui "Joyce" Ju

Addison Disease 913
Cushing Syndrome 915
Diabetes Mellitus 917
Galactorrhea 925
Gynecomastia 926
Hypogonadism 927

Metabolic Syndrome/Insulin Resistance Syndrome 929
Obesity 931
Polycystic Ovarian Syndrome 934
Thyroid Disease 937
Thyrotoxicosis/Thyroid Storm 945
Client Teaching Guides 946

25. PSYCHIATRIC GUIDELINES 953
Kristina A. Potts and Doncy J. Eapen

Anxiety 953
Attention Deficit Hyperactivity Disorder 955
Bipolar Disorder 957
Depression 962
Failure to Thrive 966
Grief 968
Intimate Partner Violence 971
Sleep Disorders 975
Substance Use Disorders 978
Suicide 987
Violence Against the Older Adult 989
Client Teaching Guides 991

SECTION II: PROCEDURES

Bimanual Examination: Cervical Evaluation During Pregnancy 1003
Canalith Repositioning (Epley) Procedure for Vertigo 1005
Clock-Draw Test 1007
Cystometry 1009
Establishing the Estimated Date of Delivery 1011
Evaluation of Sprains 1013
Hernia Reduction (Inguinal/Groin) 1014
Insertingan Oral Airway 1015
Intrauterine Device Insertion 1016
Neurologic Examination 1018
Pessary Insertion and Management 1019
Prostatic Massage Technique: Two-Glass Test 1023
Rectal Prolapse Reduction 1024
Removal of a Foreign Body From the Nose 1025
Removal of a Tick 1026
Trichloroacetic Acid/Podophyllin Therapy 1027
Wet Mount/Cervical Cultures 1028

SECTION III: APPENDICES

A NORMAL LABORATORY VALUES 1035

B DIETARY RECOMMENDATIONS 1039
Bland Diet 1040
DASH Diet: Dietary Approaches to Stop Hypertension 1041
Foods to Avoid While Taking Warfarin (Coumadin, Jantoven) 1045
Fermentable Oligosaccharides, Disaccharides, Monosaccharides, and Polyols (FODMAP) Diet 1046
Gluten-Free Diet 1047
High-Fiber Diet 1048
Lactose-Intolerance Diet 1049
Low-Fat/Low-Cholesterol Diet 1050
Nausea and Vomiting Diet Suggestions 1051
Nutrition for Wound Healing 1052
Food Sources and Recommendations for Common Vitamin and Mineral Deficiencies 1053
Food Sources and Recommendations for Vitamin D and Calcium 1054

ACKNOWLEDGMENTS

It has been a pleasure to work with the editorial staff and production team at Springer Publishing Company.

To Joe Morita, Executive Acquisitions Editor: Thank you for being a steadfast proponent of this work.

To Taylor Ball, Director, Content Development: Thank you for your energy, enthusiasm, and support that you always shared on our Friday afternoon Zoom calls when planning the development of this textbook.

To Kris Parrish, Production Manager, and Joanne Jay, Vice President, Production: Thank you for your talent and support for finalizing the material and guiding this book toward publication.

To Dr. Anne McQueen Blair and Dr. Doug Smith: It has been a pleasure to work with you. Thank you for sharing your expertise in caring for our older adult clients.

—Jill

CHAPTER 1

NORMAL PHYSIOLOGIC CHANGES IN THE AGING ADULT

L. Douglas Smith Jr.

INTRODUCTION

A. As we age, our bodies progress through a continuum of predictable changes to basic biologic processes affecting our ability to interact with the environment. Aging is a complex process that begins at conception and progresses through death. Aging is a heterogeneous process; no person ages the same as another, and organs within the same individual experience age-related changes at different times due to the unique confluence of genetic makeup, lifestyle choices, and environmental exposure through the life span. No singular theory adequately explains the holistic nature of the aging process—aging is the result of the complex interplay of many factors (e.g., biologic, psychologic, sociologic).

B. Routine age-related change is not synonymous with pathology. Ongoing discoveries suggest that many chronic maladies historically associated with aging (e.g., joint pain) may result from long-lived lifestyle choices more than changes related to age. The concept of successful aging considers an aged individual with good physical and cognitive function free of chronic disease. Still, aging is an inevitable process that results in predictable changes in physiologic function; the following is a brief discussion of common changes with age.

BRAIN AND NERVOUS SYSTEM

A. Anatomic changes in the central and peripheral nervous systems result in functional alterations in the autonomic and somatic nervous systems. Cerebral blood flow decreases, and there is a loss of compensatory mechanisms for normal fluctuation in blood pressure. Neuronal shrinkage and loss (most notable in the cerebellum and cerebral cortex) decrease overall brain volume. Accumulation of neurofibrillary tangles and neuritic plaques occurs routinely—although less than in Alzheimer disease. Significant decreases in the ability to synthesize and degrade neurotransmitters and a loss of myelin sheath result in impaired electrical transmission.

B. Observable effects due to anatomic changes in the nervous system vary between individuals. Muscular atrophy and strength decreases are seen due to decreased innervation and resting neurologic tone. Fine motor coordination and agility decrease; tremors may develop, making it difficult to perform activities of daily living. Changes to autonomic sensory neurons result in impaired proprioception, balance, and coordination, leading to a higher risk of falls. As a result of decreased nerve conduction speed, autonomic and somatic reflexes slow and contribute to delayed reactions times to touch and pain.

COGNITION

A. Cognitive impairment has long been thought normal in the aging process; however, this paradigm provides an overly simplistic understanding of aging on cognition. In a successfully aged person, parameters of cognitive function, including performance of well-practiced skills, retention of general knowledge, and recognition of familiar objects, remain stable over the lifetime. Changes in cognitive function associated with normal aging begin near the seventh decade of life and include decline in executive function, decreased attention span, difficulty reasoning in unfamiliar situations, and reduced processing of new information; still, successfully aged adults remain capable of functioning in society well beyond their 70th birthday.

SLEEP

A. Aging alters circadian patterns, resulting in changes in sleep and wakefulness. Changes in the thalamus, limbic, and reticular activating systems controlled by the hypothalamus result in a shift in normal rhythmic functions, creating sleep latency (delay in onset of sleep), reduced sleep efficiency (more time in bed when not asleep), increased nocturnal and early morning awakenings, and increased daytime sleepiness and napping. In addition, time spent in the deep and rapid eye movement stages of sleep decreases. These changes occur due to normal aging but may indicate underlying pathology (e.g., snoring or sleep apnea) or adverse drug effects.

EYES

A. Age-related changes to the eye and vision are typical and well-documented. Atrophy of periorbital fatty tissue and decreased resting tone result in ptosis or other malposition of the eyelids. Lacrimal gland changes result in reduced quantity and quality of tear production. The conjunctiva thins and may become yellow. In some adults, the cornea develops a noticeably yellow ring of fatty deposits known as arcus senilis. The iris stiffens, affecting its ability to change size, resulting in pupils that are smaller and more sluggishly responsive to light. The lens yellows and becomes opaque, scattering available light, while the retina becomes thinner due to changes ▶

in retinal photoreceptors and retinal nerve fiber thickening. Examination with the ophthalmoscope reveals narrowed and straightened blood vessels and gray and narrowed spots near the macula.

B. These anatomic differences result in commonly cited changes in vision. Dry and burning eyes result from reduced tear production, while the displacement of the lacrimal punctum may result in ineffective tear drainage and complaints of watery eyes. Changes to the iris and lens may result in difficulty reading up close (presbyopia) and other decreases in visual acuity. In addition, aged adults often experience reduced color and contrast discrimination and glare sensitivity.

C. Aging adults are at risk of three particular eye-related conditions due to normal aging. First, cataracts may develop from excessive protein accumulation in the lens over time. Cataracts appear as an opacity in the lens and interfere with the red reflex. Glaucoma results from increased intraocular pressure and may result in the gradual loss of peripheral vision. Finally, macular degeneration results from the breakdown of cells in the macula and leads to central vision loss and blindness while leaving the peripheral vision intact.

EARS

A. Ears are complex sensory organs responsible for input to the brain for hearing and balance. The ear's anatomy consists of three parts (external, middle, and inner), all of which experience changes during aging.

HEARING

A. Age-related changes affecting hearing include narrowing of the auditory canal, thickening of canal-lining hairs, and atrophy of the cerumen glands, resulting in thicker cerumen. Conductive hearing loss occurs as the tympanic membrane stiffens and calcification of ossicular joints occurs in the middle ear. Sensorineural hearing loss results from the loss of cochlear and auditory center innervation and stiffening of the basilar membrane. These age-related changes result in presbycusis, the gradual loss of hearing in both ears. Hearing loss occurs gradually and often presents as reduced ability to hear high-frequency sounds or impaired speech recognition in noisy settings. While hearing impairments may not be life-threatening, they can be disabling and negatively impact the quality of life.

BALANCE

A. The vestibule and semicircular canals of the inner ear, along with proprioceptive neurons of the central and peripheral nervous systems, coordinate balance. Sensory hair cell loss in the vestibule and changes in semicircular canal innervation impact balance in the aged adult. Aged adults often present with postural sway, complaints of vertigo, and have an increased risk of injury due to falls.

SMELL AND TASTE

A. Taste and smell are highly integrated senses allowing for sensory evaluation of the environment. Changes in their function carry significant implications for ingestion of food, personal safety, and personal hygiene. Age-related changes to these senses are incompletely understood but typically attributed to changes in the oral mucosa and nasal cavity (decrease in olfactory nerve fibers and taste buds), damage to cells throughout the life span (viral infections or environmental toxins), medication use, and diminished levels of neurotransmitters. The loss of smell impedes distinguishing spoiled foods, determining body odor, and identifying smoke in the environment. In addition, taste changes are likely to decrease interest in food and lead to weight loss.

CARDIOVASCULAR SYSTEM

A. As the cardiovascular system ages, expected changes in structure and function occur, including modest left atrial enlargement and hypertrophy and stiffening of the left ventricle, resulting in prolonged contraction time. Time in diastole lengthens to allow the stiffened ventricle longer to relax. Calcification and annular thickening of the aortic and mitral valves occur. There is a loss of pacemaker cells and fibrosis along the cardiac conduction system, leading to decreased responsiveness to adrenergic stimulation. Composition of the blood vessel changes to include increased collagen and decreased elastin, resulting in stiffer, less responsive blood vessels and coronary arteries.

B. Functional changes result from these structural changes. In general, the aged heart takes more time to recover systolic and conduction function between each beat. This is not significant while at rest; however, when stressed or at exercise, aged adults experience a decrease in maximum heart rate, cardiac output, and activity tolerance. While heart chambers enlarge, the overall heart size does not change. Valvular changes may result in nonconcerning systolic murmurs on auscultation. Due to differences in cardiac conduction, the aged adult may experience a higher rate of premature ectopic beats and are at a higher risk for atrial fibrillation. As the blood vessels stiffen, they become less responsive to baroreceptor signals and adrenergic stimulation, and the systolic blood pressure increases over time while the diastolic blood pressure remains consistent, resulting in widening pulse pressure.

RESPIRATORY SYSTEM

A. It is difficult to distinguish changes in the respiratory system solely linked to advanced age from those connected to environmental exposures over time. Changes in the respiratory status result from both changes in the lung and its ability to perform gas exchange and changes in structures assisting in ventilation. Rib and vertebrae osteoporosis and rigidities of the costal cartilage lead to limitations in thoracic movement and decreased chest wall compliance. The diaphragm flattens and becomes less efficient, resulting in pulmonary overdistention, and the recruitment of accessory muscles for adequate ventilation increases metabolic demands. Muscle weakness leads to a less vigorous cough. Age-related reductions in tracheobronchial cilia and immunoglobulin A reduce the ability to filter inhaled air and neutralize inhaled viruses.

B. Changes in the lung affect both ventilation and gas exchange. Enlargement of alveolar ducts from loss of elastic tissue results in a one-third decrease of surface area available for gas exchange. Lessened elasticity results in decreased vital capacity and increased residual volume. Changes in cardiovascular function and enlargement of the pulmonary artery lead to ventilation–perfusion mismatch; the weakened respiratory muscles become less able to move air into dependent alveoli where perfusion is greatest. Reduced effectiveness of gas exchange leads to rising carbon dioxide levels ▶

and decreasing oxygen levels in the blood, predisposing the aged adult to hypoxia and hypercapnia with less respiratory reserve capacity than when younger.

GASTROINTESTINAL SYSTEM

A. Age-related changes in the gastrointestinal (GI) system occur, although the effect on well-being is minimal. The GI tract includes all organs responsible for ingestion, digestion, absorption of nutrients, and excretion of solid waste from the body. GI-specific alterations exist; however, many changes associated with the GI system result from changes in other systems. For example, changes in the nervous system impact peristalsis and transit time, while changes in the cardiovascular system decrease mesenteric blood flow and absorption of nutrients. Specific age-related changes in the GI tract include gingival retraction and loss of teeth, decreased volume of saliva, decreased tone at the lower esophageal sphincter, reduced motility, atrophy of gastric mucosa, reduction of digestive enzyme excretion, decreased anal sphincter tone, and increased transit time (ingestion to excretion). Constipation and reflux gastritis are common complaints associated with age-related changes of the GI system.

METABOLISM AND BODY WEIGHT

A. Nutrients absorbed by the gastrointestinal system nourish the body's cells and provide energy for normal metabolic functions. As we age, the metabolism slows and the body requires less energy. In addition, hormonal changes cause the body to increase body fat stores and create less muscle mass, further decreasing the metabolic rate and increasing the chance for obesity. Throughout life, adults are encouraged to exercise most days of the week and monitor daily dietary intake to maintain a healthy body mass index between 18.5 and 24.9 kg/m^2.

ENDOCRINE SYSTEM

A. The endocrine system is a complex array of interlinked organs and glands closely linked to the nervous system. Because of the interconnectedness, it is challenging to identify gland-specific changes that occur over time. Decreases in endocrine function result in problems associated with metabolism, electrolytes, glucose, water, and minerals. Diabetes mellitus, hypothyroidism, osteoporosis, adrenal insufficiency, and various forms of hypopituitarism are some of the most common disease states associated with decreased endocrine function.

MUSCULOSKELETAL

A. The bones, muscles, and joints experience age-related changes. Calcium and mineral loss, in addition to inadequate intake of calcium and vitamin D, excessive alcohol and tobacco use, and decreased weight-bearing activity, lead to weakening of bones over time. Aging increases the chance of fracture and reduces repair speed when a fracture occurs. Joint stiffness and pain result from structure change, inflammation, and space narrowing. Muscle mass and strength decline due to hormonal changes and lack of physical activity. Muscle weakness, poor posture, joint compression, and brittle bones often reduce height by as much as 2 in. by the eighth decade of life.

GENITOURINARY SYSTEM

A. Aging of the renal system generally results in decreased efficiency of the urinary system. Kidney mass decreases and fibrotic changes occur in the parenchyma. Loss of nephrons in the renal cortex primarily affects those nephrons most important to maximal urine concentration and results in about 50% decrease in functional glomeruli in adults aged into the seventh decade of life. The nephrons remaining suffer a reduced filtering ability. Renal blood flow decreases in response to stiffened and thickened blood vessels. The loss of nephrons and decrease in blood flow result in reductions in glomerular filtration rate and creatinine clearance, leading to decreased ability to concentrate urine, manage electrolyte balance, and excrete toxic waste products. The ureters, bladder, and urethra also undergo age-related changes and include decreases in tone, elasticity, capacity, and sphincter tone, contributing to frequent urination, urinary urgency, and urinary incontinence. Females are at increased risk of urinary infections and males often experience difficulty with urination secondary to prostate enlargement.

REPRODUCTION AND SEXUALITY

SEXUALITY

A. Sexuality and intimacy are essential aspects of health and well-being throughout the life span. Decreasing hormones in both aged adults create significant and distressing changes to sexuality. There is a less rapid and extreme vascular arousal response to stimulation for both sexes. Time to orgasm increases, as does the refractory period after orgasm. Males may experience erectile dysfunction, premature ejaculation, less forceful ejaculations, and enlarging prostates. Females may experience anorgasmia, problems with arousal, and painful intercourse.

MENOPAUSE

A. Females reach menopause, the cessation of menses, commonly between their mid-40s and late 50s, with the average age at 51 years. Before menopause, the ovarian function declines, and irregular and lighter menses occur. These changes occur when the ovaries cease producing progesterone and estrogen. When this happens, reproduction is no longer possible. In addition, the hormonal changes decrease blood supply to the vagina and contribute to decreased vaginal secretion and lubrication during intercourse. Other changes associated with menopause include weakened pelvic muscles, thinning of the vaginal epithelium, and alkalinization of the vagina. These changes may lead to pain during sexual activity and increase the risk of infection.

BREAST

A. Changes to breast tissue occur as both males and females age. Postmenopausal females experience breast tissue atrophy due to decreases in sex hormones. Fibrous connective tissue replaces thinning tissue. As breast elasticity decreases, the breast decreases in size and may sag. Declining testosterone levels in males may lead to gynecomastia.

BLOOD AND BLOOD COMPONENTS

HEMATOPOIESIS

A. Outside the influence of pathology, the hematopoietic system maintains adequate function through the life span.

Baseline production and turnover of red blood cells and platelets do not change significantly; however, as with other systems, the hematopoietic ability to compensate for a loss (e.g., from phlebotomy) is less robust. Notably, platelets become hyperresponsive to thrombotic stimulators and several clotting factors increase, resulting in a slight but consistent decrease in bleeding time.

IMMUNE SYSTEM

A. The immune system weakens with aging due to a weakened ability to make antibodies to disease. The thymus gland, responsible for T-cell activating hormones, atrophies and weakens. Peripheral T-cells decrease, increasing the risk of developing infections and making infections more severe. Aged clients greatly benefit from adherence to immunization schedules recommended by the Centers for Disease Control and Prevention.

SKIN, HAIR, AND NAILS

A. Normal skin aging leads to atrophy, decreased elasticity, and impaired reparative responses. The epidermis becomes thin, flattens, and loses elasticity, leading to fine lines and wrinkles. The epidermis plays a crucial role in vitamin D synthesis, and as the epidermis thins the aged person's ability to synthesize vitamin D decreases. Skin hydration is affected as sweat, oil, and sebaceous glands become less active. The loss of subcutaneous fat tissues throughout the body reduces insulation against cold, and the loss of protective fat pads in the feet increases the risk of a foot injury. Wound healing is delayed with age. Hair changes are related to decreased follicle density and function. Hair growth slows and hair thins. Hair loss occurs most commonly in the scalp, axilla, and pubic areas. Hair color may gray and females may begin to grow facial hair. Fingernails become thin and tear easily, while toenails grow thick.

CHAPTER 2

HEALTHY LIVING FOR THE ADULT-GERIATRIC CLIENT

Ann McQueen Blair and Kathleen Bradbury-Golas

HEALTH MAINTENANCE DURING THE LIFE SPAN

A. Health maintenance involves identifying individuals at risk for health problems and encouraging behaviors that reduce these risks. An important aspect of health maintenance is client education, including teaching individuals about their risk factors for disease and ways to modify their behaviors to reduce their risks of comorbidities. Client teaching guides may be downloaded by the practitioner, filled according to the client's evaluation and needs, and given to the client.

ADULT RISK ASSESSMENT FORM

A. The Adult Risk Assessment Form (Exhibit 2.1) should be used for all adult clients to evaluate their risk for particular diseases. The practitioner should interview the client, assessing for the risk factors listed on the Adult Risk Assessment Form. The family history of first-degree relatives (parents, siblings, and children) should also be discussed because many diseases are related to genetic factors. Keep a copy of the Adult Risk Assessment Form in the front of the client's chart

CAD, coronary artery disease; DM, diabetes mellitus.

Assess the client for the following personal risk factors:

A. Coronary heart disease:
1. High-fat/high-cholesterol diet.
2. Obesity.
3. Elevated cholesterol level.
4. Stroke.
5. Hypertension.
6. Tobacco use.

B. Lung cancer:
1. High-fat/high-cholesterol diet.
2. Tobacco use.

C. Cervical cancer:
1. Early age of first intercourse.
2. Multiple sexual partners.
3. History of human papillomavirus.

D. Breast cancer:
1. Nulliparous.
2. Primigravida after the age of 35.
3. High-fat diet.

E. Colon cancer:
1. History of polyps.
2. High-fat diet.

F. Osteoporosis:
1. Less than 1 g of calcium per day.
2. History of tobacco or alcohol use.
3. Sedentary lifestyle.
4. Thin, Caucasian.
5. Female gender.

The contributions of Cheryl A. Glass to this chapter in prior editions are acknowledged here.

EXHIBIT 2.1 Adult Risk Assessment Form (*continued*)

G. **Glaucoma/visual impairment:**
   1. Family history of glaucoma.
   2. Diabetes mellitus.

H. **Sexually transmitted infections (STIs)/HIV:**
   1. Alcohol and drug use or abuse.
   2. Multiple sexual partners.
   3. Homosexual or bisexual partner.
   4. History of intravenous drug use/needle sharing.
   5. History of blood transfusion.
   6. Exposed to or history of STI.
   7. Exchanging sex for drugs or money.

I. **Substance abuse:**
   1. Alcohol or drug use history including "street drugs" and opioids.
   2. Family history of substance abuse.
   3. Stress or poor coping mechanisms.
   4. Administer the **CAGE** Assessment: Have you ever tried to **C**ut down on your alcohol/drug use? Do you get **A**nnoyed if someone mentions your use is a problem? Do you ever feel **G**uilty about your use? Do you ever have an **E**ye-opener first thing in the morning after you have been drinking or using the night before?

J. **Accidents and suicide:**
   1. Previous suicide attempt.
   2. Family history of suicide.
   3. Alcohol use.
   4. Substance use.
   5. History of depression.
   6. High-stress or "hot-reactor" personality.
   7. Male gender.
   8. Poor coping mechanisms or stress.

K. **Safety:**
   1. Does not use seat belt or car seat.
   2. Drinks and drives.
   3. Drives over the speed limit.
   4. Does not wear safety helmet if driving motorcycle.
   5. Inadequate number of smoke detectors or none in the home.

and update yearly or as needed. When complete, this tool can guide the practitioner in determining the assessment needs of each client. If using electronic medical records, a special section should be identified for risk assessment.

ADULT PREVENTIVE HEALTHCARE

A. Exhibits 2.2 and 2.3 help the practitioner identify changes in the adult client's risk factor status, make recommendations for health maintenance (e.g., immunizations, laboratory work, physical exams), and educate the client on prevention. The guide can be used as a quick reference for the practitioner to evaluate the client's adherence to preventive measures. Keep a copy of this flow sheet and guide in the front of the client's chart where they can be reviewed routinely and updated as necessary. If using electronic medical records, a special section should be identified as routine health maintenance.

ADULT-GERIATRIC SCREENING RECOMMENDATIONS

A. Health promotion includes utilization of preventive screen testing. Multiple guidelines are available for clinicians to utilize during guidance and discussion of recommendations with clients. Professional societies, the U.S. Public Health Service, and other organizations evaluate the strength of evidence and the weight of clinical research, statistical analysis, and the risk and benefits of testing to make recommendations for screening. Most of the recommendations for this section are from the U.S. Preventive Services Task Force (USPSTF) guidelines.

B. Eligibility and Medicare coverage for screening are summarized in Table 2.1.

ABDOMINAL AORTIC ANEURYSM

A. The Centers for Disease Control and Prevention (CDC) notes abdominal aortic aneurysms (AAAs) were the primary cause of death in 59% of deaths in 2019. The main risk factors for development of AAAs are age, sex, smoking, and family history. A history of smoking occurs in 75% of those with AAA. About two-thirds of people who have an aortic dissection are male. Older males who have smoked are at the highest risk of developing an AAA. Dissections and ruptures are the cause of most deaths from aortic aneurysms. An AAA is often asymptomatic; however, the symptoms may include a sharp, sudden pain in the chest; throbbing or deep pain in the back or side, and/or pain in the buttocks, groin, or legs; trouble breathing or swallowing; or syncope. Nearly two-thirds of aneurysms leading to surgery were detected as incidental findings on imaging studies performed for other indications. On physical examination, a pulsatile mass in the epigastrium where the aorta bifurcates at the umbilicus may be palpated.

B. There are several types of aneurysm: thoracic aneurysms, abdominal aneurysms, peripheral aneurysms, and those that occur in the brain, which may cause a stroke. An AAA is an enlarged ballooning area that is more than 50% of the normal diameter of the aorta. The U.S. Preventive Services Task Force (USPSTF) notes that people who are screened are about twice ▶

as likely to have AAA surgery within 3 to 5 years compared with people who are not screened. The 2019 USPSTF guideline on Abdominal Aortic Aneurysm: Primary Care Screening recommendations for AAA screening include the following:

1. Males 65 to 75 years of age who have ever smoked (100 cigarettes in a lifetime) should have a onetime ultrasound screening for AAA even if they are asymptomatic.

2. Males ages 65 to 75 years who have never smoked can be selectively offered screening by clinicians rather than routinely screening all males in this group. Screening should be based on medical history, family history, other risk factors, and client preferences.

3. The current evidence is insufficient to assess the balance of benefits and harms for the USPSTF to recommend that females ages 65 to 75 who have ever smoked be screened for AAA.

4. The USPSTF recommends that females who smoke or have never smoked should not undergo AAA screening. AAA is uncommon in older females and is very rare in females who have never smoked. The Society for Vascular ▶

STI/HIV								
Foot examination for diabetics								
Additionally, the practitioner should ensure that the client receives other healthcare as needed. Assess client's adherence to other preventive healthcare exams.								
Dental exam								
Vision/glaucoma exam								

BMI, body mass index; BP, blood pressure; PSA, prostate-specific antigen; STI, sexually transmitted infection; TSH, thyroid-stimulating hormone.

Surgery (SVS) 2018 guidelines recommend males and females older than 75 years with a history of tobacco use who are in otherwise good health and have not previously been screened with ultrasound have a onetime ultrasound screen for AAA.

5. The ultrasound is the gold standard modality for screening. CT scans are not recommended for first-line screening due to the high cost and radiation exposure.

6. Aneurysm size:

a. Small aneurysms have a diameter of < 3.0 cm.

b. Medium aneurysms have a diameter between 3.1 and 5.4 cm.

i. The SVS guidelines recommend observation for asymptomatic AAA < 5.4 cm in diameter.

c. Large aneurysms have a diameter ≥5.4 cm.

i. For asymptomatic clients, the risk of AAA rupture generally does not exceed the risk associated with elective AAA repair until aneurysm diameter exceeds 5.5 cm.

d. Very large aneurysms have a diameter ≥6.0 cm.

TABLE 2.1 MEDICARE COVERAGE AND ELIGIBILITY FOR SCREENING: CURRENT AS OF 2018

Test/Screen	Medicare Part B Coverage Eligibility
Preventive visit	"Welcome to Medicare" preventive visit available for Medicare coverage within the first 12 months of obtaining Medicare Part B • Measurement of height, weight, and blood pressure • Calculation of BMI • Simple vision test • Review of potential risk for depression and level of safety • Offer to talk about creating advance directives • Written plan on which screening, shots, and other preventive services are needed
Yearly "Wellness" visits	Annual "Wellness" visits for Medicare patients with Part B for longer than 12 months; used to develop or update a personalized prevention plan to prevent disease and disability based on current health and risk factors • Completion of an HRA • Review of medical and family history • Development or update of the list of current providers and prescriptions • Measurement of height, weight, blood pressure, and other routine measurements • Evaluation for cognitive impairment • Personalization of health advice • Listing of risk factors and treatment options • Development of screening schedule for appropriate preventive services
AAA screening	Onetime AAA ultrasound if the client meets the eligibility requirements; requires referral Risk factors for eligibility: • Family history of AAA • Male 65–75 years of age and have smoked at least 100 cigarettes/lifetime
Bone mass measurement	Covered screen once every 24 months for clients who meet the eligibility criteria: • Females whose PCP determines both of these (based on medical history and other findings): ▪ Estrogen deficient ▪ At risk of osteoporosis • X-rays showing possible osteoporosis, osteopenia, or vertebral fractures • Clients taking prednisone or steroid-type drugs or planning to begin this treatment • Clients who have been diagnosed with primary hyperparathyroidism • Clients being monitored to evaluate whether the osteoporosis drug therapy is effective Covered more often if medically necessary
Alcohol misuse screenings and counseling	Covered screen once per year for clients who meet the eligibility criteria: • Adults with Part B (including pregnant females). ▪ Use alcohol ▪ Do not meet the medical criteria for alcohol dependence • Four brief face-to-face counseling sessions per year if the following apply: ▪ Alcohol misuse determined by the PCP ▪ Competent and alert during counseling • Counseling must be provided: ▪ By a qualified PCP ▪ In a primary care setting
Cardiovascular disease (behavioral therapy)	One visit per year in PCP office or primary care clinic • Check blood pressure • Discuss aspirin use (if appropriate) • Discuss dietary information
Cardiovascular disease screening	Screening blood tests every 5 years • Cholesterol • Lipids • Triglycerides
Cervical and vaginal cancer screenings	Pap tests, pelvic exams, and clinical breast exams covered by Part B • Once every 24 months for all females • Once every 12 months if one of the following applies: ▪ High risk for cervical or vaginal cancer ▪ Childbearing age and have had an abnormal Pap test in the past 36 months

(*continued*)

TABLE 2.1 MEDICARE COVERAGE AND ELIGIBILITY FOR SCREENING: CURRENT AS OF 2018 (*CONTINUED*)

Test/Screen	Medicare Part B Coverage Eligibility
Colorectal screening	FOBT: • Coverage with a referral from a physician, physician assistant, nurse practitioner, or clinical nurse specialist Multitarget stool DNA test: • Covered once every 3 years if **all conditions** are met: ▪ 50–85 years of age ▪ No signs or symptoms of colorectal disease including, but not limited to: – Lower gastrointestinal pain – Blood in stool – Positive guaiac fecal occult blood test – Fecal immunochemical test ▪ At average risk for developing colorectal cancer, meaning: – No personal history of the following: • Adenomatous polyps • Colorectal cancer • Inflammatory bowel disease, including Crohn disease and ulcerative colitis – No family history of the following: • Colorectal cancers or adenomatous polyps • Familial adenomatous polyposis • Hereditary nonpolyposis colorectal cancer Screening flexible sigmoidoscopy: • Once every 48 months for most clients 50 years or older • If not high risk, is covered 120 months after a previous screening colonoscopy Screening colonoscopy: • Once every 24 months if at high risk for colorectal cancer • If not at high risk, is covered once every 120 months, or 48 months after a previous flexible sigmoidoscopy • A screening colonoscopy can become a diagnostic colonoscopy when: ▪ Results in biopsy or removal of a lesion or growth ▪ The biopsy or removal happens during the same visit as the screening colonoscopy Barium enema: • When utilized instead of a flexible sigmoidoscopy or colonoscopy: ▪ Coverage every 48 months if 50 years or over ▪ Coverage every 24 months and are at high risk for colorectal cancer
Dental	Routine dental care or dental procedures such as cleanings, fillings, tooth extractions, dentures, dental plates, or other dental devices not covered by Medicare
Depression screening	One depression screening per year covered by Medicare; screening must be done in a primary care setting that can provide follow-up treatment and/or referrals
Diabetes screening	Screening to test for diabetes covered by Medicare • Based on the screening test, may be eligible for two diabetes screenings each year • Screenings covered if any of the following risk factors exist: ▪ Diagnosed with prediabetes ▪ Hypertension ▪ History of abnormal cholesterol and triglycerides ▪ Obesity ▪ History of high glucose • Covers these tests if two or more of the following apply: ▪ Age 65 or older ▪ Overweight ▪ Family history of diabetes (parents, brothers, sisters) ▪ History of gestational diabetes or delivery of a baby weighing more than 9 lbs • If covered with Medicare Part B and have prediabetes, the client may qualify for diabetes prevention program services to help make health behavior changes that can prevent or delay the onset of diabetes. The program begins with at least 16 core sessions over a 6-month period, which are offered in a group setting. After the core sessions, additional monthly sessions in the diabetes prevention sessions include the following: ▪ Tips on how to get more exercise ▪ Strategies for weight control ▪ Support from people with similar goals and challenges ▪ A lifestyle coach, specially trained in motivation

(*continued*)

TABLE 2.1 MEDICARE COVERAGE AND ELIGIBILITY FOR SCREENING: CURRENT AS OF 2018 (*CONTINUED*)

Test/Screen	Medicare Part B Coverage Eligibility
DSMT	Outpatient DSMT to teach coping and management of diabetes • May cover up to 10 hours of initial DSMT; training may include 1 hour of individual training and 9 hours of group training • May also qualify for up to 2 hours of follow-up training each year if it takes place in a calendar year after the year of initial training • Training includes the following: ▪ Tips for eating healthy, being active, taking drugs, and reducing risks • Must have a written order from a PCP or other healthcare provider for certain clients with Part B who are at risk for complications from diabetes • Some exceptions apply: ▪ Group sessions are not available or if the provider notes special needs that would be better met in individual training sessions ▪ If living in a rural area, may get DSMT services from a practitioner, such as a registered dietitian in a different location through telehealth
Hepatitis C screening test	Covers one hepatitis C screening test if a PCP or practitioner orders it Also covers yearly repeat screening for certain clients at high risk who meet one of the following conditions: • High risk because they use or used illicit injection drugs • Had a blood transfusion before 1992 • Born between 1945 and 1965
HIV screening	Voluntary HIV screenings, one test once every 12 months Covered for clients who meet the criteria: • 15–65 years old • Younger than 15 or older than 65 and at increased risk • Pregnant ▪ Covered up to three times during a pregnancy ▪ Interval testing during pregnancy not defined by CMS
Immunizations	Flu shot: • Normally covers one flu shot per flu season given in the fall or winter HepB: • Clients at high or medium risk for HepB: ▪ Some risk factors noted as increased risk defined by Medicare: hemophilia, ESRD, diabetes, healthcare workers who have frequent contact with blood or bodily fluids, and other factors that increase risk for HepB (check with PCP to see if at high or medium risk) Pneumococcal shot: • One pneumococcal shot to prevent infections • A different second shot covered by Part B if it is given 1 year (or later) after the first shot • Discuss with the PCP or other healthcare providers to evaluate need for one or both shots
Lung cancer screening	A lung cancer screening with LDCT once per year for clients who meet all of the following conditions: • Age 55–77 • Asymptomatic (no signs or symptoms of lung cancer) • Either a current smoker or have quit smoking within the last 15 years • Tobacco smoking of at least 30 "pack-years" (an average of one pack a day for 30 years) • Written order from their PCP Before the first lung cancer screening, an appointment needs to be scheduled to: • Discuss the benefits and risks of lung cancer screening • Decide whether lung cancer screening is right for the client
Mammography (medical)	Screening mammogram once every 12 months (11 full months must have passed since the last screening) Diagnostic mammogram when medically necessary • Covers females with Medicare 40 years of age or older • One baseline mammogram for females with Medicare 35–39 years of age

(*continued*)

TABLE 2.1 MEDICARE COVERAGE AND ELIGIBILITY FOR SCREENING: CURRENT AS OF 2018 (*CONTINUED*)

Test/Screen	Medicare Part B Coverage Eligibility
Nutrition therapy services	MNT services and certain related services: • Can be provided by a registered dietitian or nutrition professional who meets certain requirements • Can only be referred by a PCP • MNT services may include the following: ▪ An initial nutrition and lifestyle assessment ▪ Individual and/or group nutrition therapy services ▪ Follow-up visits to check on progress managing diet • In a rural area, may be provided through telehealth; a registered dietitian or other nutrition profession, in a different location, would provide the service • MNT covered by Medicare as part of overall dialysis care if the dialysis is done in a dialysis facility • Eligibility includes clients with Part B who meet at least one of the following conditions: ▪ Have diabetes ▪ Have kidney disease ▪ Have had a kidney transplant in the last 36 months
Obesity screening and counseling	Behavioral counseling for weight loss covered by Medicare; counseling may be covered if given in a primary care setting (such as a PCP's office) • Counseling required in a primary care setting so that it can be coordinated with other care and a personalized prevention plan • Covers all clients with a BMI of 30 or more
Prostate cancer screening	All males older than 50 (beginning the day after their 50th birthday) Digital rectal examination: • Once every 12 months PSA test: • Once every 12 months
STI screening and counseling	Screening for chlamydia, gonorrhea, syphilis, and HepB • Once every 12 months • At certain times during pregnancy Up to two individual 20- to 30-minute, face-to-face, high-intensity behavioral counseling sessions covered by Medicare each year for sexually active adolescents and adults at increased risk for STIs if referred by a PCP
Smoking and tobacco use cessation	Counseling for up to eight face-to-face visits in a 12-month period performed by a qualified PCP or other Medicare-recognized practitioner All clients with Part B who use tobacco eligible for counseling
Vision	Routine eye examinations for eyeglasses or contact lenses not covered by Medicare Covers AMD testing Vision screen for glaucoma: • Glaucoma test every 12 months for clients at high risk for glaucoma: ▪ Diabetes ▪ Family history of glaucoma ▪ African Americans and those 50 years or older ▪ Hispanic Americans and those 65 years or older Vision screen for retinopathy: • Yearly exam for diabetic retinopathy • Clients on Medicare who have diabetes

Note: Consult the Medicare website for full coverage information and costs: www.medicare.gov/coverage/preventive-and-screening-services.html.

AAA, abdominal aortic aneurysm; AMD, age-related macular degeneration; BMI, body mass index; CMS, Centers for Medicare and Medicaid Services; DSMT, diabetes self-management training; ESRD, end-stage renal disease; FOBT, fecal occult blood test; HepB, hepatitis B; HRA, health risk assessment; LDCT, low-dose CT; MNT, medical nutrition therapy; PCP, primary care physician; PSA, prostate-specific antigen; STI, sexually transmitted infection.

7. Management consists of ongoing clinical evaluation and AAA surveillance and risk modification. Aneurysm surveillance from the SVS supports the following surveillance intervals:

a. Initial ultrasound screening for aortic diameter >2.5 cm but <3.0, rescreening after 10 years.

b. For AAA 3.0 to 3.9 cm, imaging at 2- to 3-year intervals.

c. For AAA 4.0 to 5.4 cm, imaging at 6- to 12-month intervals.

d. For AAA 5.0 to 5.4 cm, imaging at 6-month intervals, with surgical consult/referral for possible elective repair.

8. Aneurysm diameter is the strongest predictor of aneurysm rupture, with risk increasing markedly at aneurysm diameters >5.4 cm. Rapid expansion, which is thought to increase the risk of rupture, is defined as an increase in maximal aortic diameter ≥5 mm over a 6-month period of time or >10 mm over 1 year, using the same radiographic method of measurement. ▶

9. AAA surgical repair:

a. The decision for elective repair of asymptomatic AAA relies primarily on determining risk of rupture based on aneurysm diameter >5.4 cm. However, the diameter threshold for repair is not absolute. An elective AAA repair should also take into account the natural history of AAA and factors that increase the risk of aneurysm expansion or rupture.

b. Repair is indicated in clients with AAA who are symptomatic (tenderness or abdominal or back pain, evidence for embolization, rupture), have an AAA ≥5.4 cm, or an AAA that has expanded >0.5 cm within a 6-month interval.

c. There are two types of surgical repair:

i. Open surgical repair is the only proven intervention that has decreased AAA mortality. The open surgical repair of a large AAA has a mortality rate of 4% to 5%, with nearly one-third having pulmonary and cardiac complications.

ii. Endovascular aneurysm repair (EVAR) with stent grafts is the alternative surgical procedure to open repair. A late conversion to an open repair may be required. The overall complication rate for EVAR, including access-related issues, is approximately 10%.

d. An individualized approach to the client when choosing between open and EVAR repair needs to take into account the client's age, risk factors for perioperative morbidity and mortality, anatomic factors, and experience of the surgeon.

BONE MASS DENSITY MEASUREMENT FOR OSTEOPOROSIS

A. Osteoporosis and low bone mass are currently estimated to be a major public health threat for almost 44 million U.S. females and males 50 years of age and older. The incidence of fragility fractures increases exponentially with age, although the increase begins approximately 10 years later in males. However, the mortality rate associated with hip fractures, as well as vertebral and other major fractures, is higher in males than in females. Falls cause nearly 90% of osteoporotic fractures. Older adult clients have increased susceptibility to fractures because of other medical problems, side effects of medications, and older adults' tendency to fall. Falls cause nearly 90% of osteoporotic fractures. Fractures may cause chronic pain and disability and affect the functional ability and quality of life: Mortality and morbidity are highest with a hip fracture. For an in-depth review of osteoporosis, refer to the "Osteoporosis/Kyphosis/Fracture" section of Chapter 22.

B. The Fracture Risk Assessment Tool (FRAX) calculates the absolute fracture risk or estimates the probability of fracture. The algorithms from the FRAX calculate the probability of hip fracture and the 10-year probability of a major osteoporotic fracture (clinical spine, forearm, hip, or shoulder fracture). The FRAX assessment includes questions about age, smoking, family history of hip fracture, long-term glucocorticoid use, and low body weight. The FRAX score is used to drive decisions for testing and prescribing osteoporosis medications.

C. The Foundation for Osteoporosis Research and Education (FORE) FRAX score 10-Year Fracture Risk Calculator at riskcalculator.fore.org or at the University of Sheffield, Great Britain website at www.sheffield.ac.uk/FRAX. The National Osteoporosis Foundation (NOF) Clinician's Guide to Prevention and Treatment of Osteoporosis is available at bonehealthandosteoporosis.org.

Screening through the identification of risk factors does not diagnose osteoporosis but identifies people who require further evaluation.

D. Bone mass measurement screening is done through several tests:

1. A standard x-ray is inadequate to screen for osteoporosis.

2. The gold standard test for measurement of bone mineral density (BMD) is the use of the central dual-energy x-ray absorptiometry (DXA) of the hip and lumbar spine.

a. The central DXA of the radius bone and the peripheral bone density of the heel or another bone may be required for the morbidly obese client.

3. Quantitative ultrasonography (QUS) of the calcaneus is also utilized for measurement.

a. The measurement cutoffs for the QUS and the DXA are not interchangeable.

b. A limitation of ultrasound is that it does not reliably exclude or confirm DXA-determined osteoporosis.

c. Because of limited precision and slow rate of change of bone mass at peripheral sites, quantitative heel ultrasound cannot be reliably used to follow clients who are treated for osteoporosis.

d. An individual with a high-risk ultrasound finding needs a confirmatory DXA to determine the need for treatment based on established guidelines and as a baseline for monitoring therapy.

4. The peripheral quantitative CT (pQCT) is available but is not recommended for screening. QCT measures volumetric bone density of the spine and hip and can analyze cortical and trabecular bone separately. The application of T-scores to predict the risk of fracture has not been validated with QCT. Additionally, the test is more costly and results in greater exposure to radiation than DXA.

E. The recommendations for who to screen and screening intervals of 1 to 2 years vary by different organizations, including the NOF, the World Health Organization, and the American College of Obstetricians and Gynecologists (ACOG). ▶

The U.S. Preventive Services Task Force (USPSTF) guideline on osteoporosis screening is currently being updated (public comment closed August 2021); the USPSTF guideline is current as of July 2015. The USPSTF recommends screening for osteoporosis by sex and age:

1. Females:
   a. Age 65 years or older.
   b. The USPSTF does not define the upper age limit for screening in females because the risk of fractures increases with age.
   c. According to the draft 2018 recommendation, the USPSTF recommends screening for osteoporosis with bone measurement testing to prevent osteoporotic fractures in postmenopausal females younger than 65 years who are at increased risk of osteoporosis, as determined by a formal clinical risk assessment tool. The NOF, International Society for Clinical Densitometry (ISCD), Endocrine Society, and Canadian Osteoporosis Society recommend bone density testing for females older than 50 years with any clinical risk factors for fractures.
2. Males:
   a. Routine screening is currently a widespread practice.
   b. The USPSTF concludes that the current evidence is insufficient to assess the balance of benefits and harms of screening for osteoporosis to prevent osteoporotic fractures in males. The USPSTF found inadequate evidence that drug therapies reduce the risk of fracture in males who have no previous osteoporotic fracture.
3. The NOF, ISCD, Endocrine Society, and Canadian Osteoporosis Society recommend bone density testing for all males age 70 years or older and for males 50 to 69 years based on their risk factor profile.

CARDIOVASCULAR DISEASE AND CARDIAC SCREENING (CARDIAC CALCIUM SCORE)

A. The U.S. Preventive Services Task Force (USPSTF) has multiple screening and prevention recommendations for cardiac and cardiovascular disease (CVD). Refer to Chapter 13 for an in-depth review of cardiac conditions.

1. Screening recommendations:
   a. Screen for high blood pressure (BP) in adults 18 years of age and older.
      i. The recommendation includes measurements outside of the clinical setting for diagnostic confirmation before starting treatment.
      ii. Annual screening is recommended for adults age 40 years or older and for those who are at increased risk for high BP. Persons at increased risk include those who have high normal BP (130–139/85–89 mmHg), those who are overweight or obese, and African Americans.
      iii. Adults age 18 to 39 years with normal BP (<130/85 mmHg) who do not have other risk factors should be rescreened every 3 to 5 years. The USPSTF recommends rescreening with properly measured office BP and, if BP is elevated, confirming the diagnosis of hypertension (HTN) with ambulatory blood pressure measurement (ABPM).

The USPSTF recommends ABPM as the reference standard for confirming the diagnosis of HTN. Ambulatory BP monitoring devices record BP at regular intervals over 12 to 24 hours while the client goes about their normal activities and while sleeping. Elevated ambulatory systolic BP is consistently and significantly associated with increased risk for fatal and nonfatal stroke and cardiovascular (CV) events, independent of office BP. Ambulatory BP monitoring can be performed every year in high-risk persons and every 3 to 5 years in those at low risk (adults 18–39 years of age with no risk factors).

   b. **Lipid screening guidelines have currently been updated.** There are no sex-specific recommendations for screening for lipid disorders. The following are the age specifics for screening:
      i. The USPSTF recommends lipid screening in both males and females who are at increased risk for coronary heart disease (CHD), males aged 35 years and older, or females aged 45 years and older. Risk factors include dyslipidemia, diabetes, high BP, and smoking.
         1) 10-year CV event risk of ≥10%: Low- to moderate-dose statins are recommended.
         2) 10-year CV event risk of 7.5% to 10%: The recommendation is for selectively offering treatment using an individualized approach.
      ii. Lipid screening can also be completed in clients 20 to 35/45 years of age with increased risk for CHD. Currently, no guidelines support routine screening of lipids in young adults aged 20 to 35 years without risks of CHD.
      iii. For adults 76 years of age and older with no history of CVD, there is insufficient evidence to make a recommendation.
   c. Screen for CHD with EKG: The USPSTF found inadequate evidence to determine whether adding resting or exercise EKG to conventional risk factor assessment leads to improved risk stratification of persons to inform treatment decisions.
      i. Adults at low risk of CVD events: The USPSTF recommends against screening with resting or exercise EKG for prediction of CVD events in asymptomatic adults at low risk for CVD events.
      ii. Adults at intermediate or high risk of CVD events: Currently, there is insufficient evidence to assess the balance of benefits and harms of screening with resting or exercise EKG to prevent CVD events in asymptomatic adults at intermediate or high risk for CHD events.
   d. The current evidence is insufficient to assess the benefits and harms of screening for peripheral ▶

artery disease and CVD risk assessment with the ankle-brachial index (ABI) in adults.

i. There are no studies that provide evidence about the intervals for screening for peripheral arterial disease (PAD) with the ABI in asymptomatic clients.

ii. Evidence shows that low-dose aspirin treatment in asymptomatic clients with low ABI does not improve health outcomes and may increase bleeding.

iii. There are no trials that provide evidence on other interventions to reduce CVD events or interventions that might delay the onset of lower extremity symptoms.

e. The USPSTF recommends against screening for asymptomatic carotid artery stenosis in the general adult population.

f. The evidence is insufficient to assess the balance of benefits and harms of using nontraditional risk factors to screen asymptomatic males and females with no history of CHD to prevent CHD events. The nontraditional risk factors included in this recommendation include the following:

i. High-sensitivity C-reactive protein (hs-CRP).
ii. ABI.
iii. Leukocyte count.
iv. Fasting blood glucose level.
v. Periodontal disease.
vi. Carotid intima media thickness (CIMT).
vii. Coronary artery calcification (CAC) score on electron-beam CT (EBCT).
viii. Homocysteine level.
ix. Lipoprotein(a) level.

2. The American College of Cardiology (ACC) notes the CAC, a high-tech screen for CVD, is considered a second-tier assessment technique. Cost remains one concern, as well as the radiation risk. It is a good predictor of future cardiac disease events, which includes stroke. The calcium burden measured by CAC probably equals about one-fifth of the total atherosclerosis burden. The ACC/American Heart Association (AHA) guideline on the assessment of cardiovascular risk states that "[i]f, after quantitative risk assessment, a risk-based treatment decision is uncertain, assessment of ≥1 of the following—family history, hs-CRP, CAC score, or ABI—may be considered to inform treatment decision making."

3. Prevention recommendations with aspirin:

a. The magnitude of the CV risk reduction with aspirin use depends on an individual's initial risk for CVD events. Risk assessment for CVD should include evaluation of the following risk factors: age, sex, race/ethnicity, total cholesterol level, high-density lipoprotein (HDL) cholesterol level, systolic BP, HTN treatment, diabetes, and smoking. An online version of the ACC/AHA risk calculator can be found at too ls.acc.org/ascvd-risk-estimator-plus/#!/calculate/estimate/.

b. The recommendations for use of aspirin in the primary prevention of CVD (which are currently being updated [open for public recommendations until November 2021]) and colorectal cancer (CRC) are noted in Table 2.2.

i. The decision to initiate low-dose aspirin use for the primary prevention of CVD in adults 40 to 59 years of age who have a 10% or greater 10-year CVD risk should be an individual one. Clients who are not at risk for bleeding may benefit the most from aspirin use.

ii. The USPSTF recommends against initiating low-dose aspirin use for the primary prevention of CVD in adults age 60 years or older. Aspirin use may also result in small to moderate harms, including gastrointestinal (GI) bleeding and hemorrhagic stroke.

iii. The USPSTF concludes with moderate certainty that the benefit of aspirin use for the primary prevention of CVD events, combined with the reduced incidence of CRC, outweighs the increased risk of bleeding by a moderate amount in adults age 50 to 59 years who have a 10-year CVD risk of 10% or greater.

iv. The USPSTF concludes with moderate certainty that the benefit of aspirin use for the primary prevention of CVD events, combined with the reduced incidence of CRC, outweighs the increased risk of bleeding by a small amount in adults age 60 to 69 years who have a 10-year CVD risk of 10% or greater.

TABLE 2.2 PROPOSED USPSTF ASPIRIN USE TO PREVENT CARDIOVASCULAR DISEASE AND COLORECTAL CANCER: PREVENTIVE MEDICATION FOR ADULTS (AS OF OCTOBER 2021)

Age Range	Recommendation
Adults ages 40 to 59 years with a 10% or greater 10-year CVD risk	The decision to initiate low-dose aspirin use for the primary prevention of CVD in adults ages 40 to 59 years who have a 10% or greater 10-year CVD risk should be an individual one. Evidence indicates that the net benefit of aspirin use in this group is small. Persons who are not at increased risk for bleeding and are willing to take low-dose aspirin daily are more likely to benefit.
Adults age 60 years or older	The USPSTF recommends against initiating low-dose aspirin use for the primary prevention of CVD in adults age 60 years or older.

Notes: This recommendation applies to adults who are at increased CVD risk and at average risk for CRC. Persons who are at increased CVD risk and are known to be at increased risk for CRC (e.g., persons with a family or personal history of CRC or familial adenomatous polyposis) should consult their healthcare provider.

COLORECTAL SCREENING

A. Refer to the "Colorectal Cancer Screening" section of Chapter 14 and further review of other gastrointestinal (GI) conditions.

B. The American Cancer Society (ACS) released their 2018 updated guidelines for colorectal cancer (CRC) screening for adults with average risk. New data indicate an increasing incidence of CRC among individuals younger than age 50 years. The incidence has increased by 51% since 1994.

1. Regular CRC screening with either a high-sensitivity stool-based test or a structural (visual) examination should begin at age 45 years among adults with average risk for CRC.

2. Adults aged 50 years and older should be screened regularly for CRC.

3. Among adults with average CRC risk who are in good health and have a life expectancy of more than 10 years, CRC should be continued through age 75 years.

4. CRC screening decisions should be individualized for clients age 76 through 85 years according to client preferences, life expectancy, health status, and history of screening.

5. Continuing CRC screening is discouraged for individuals older than 85 years.

C. The following are the U.S. Preventive Services Task Force (USPSTF) recommendations for screening for CRC by age:

1. Adults age 45 to 49: The USPSTF recommends screening for CRC in adults aged 45 to 49 years.

2. Adults age 50 to 75 years:

A. The USPSTF recommends screening for CRC starting at age 50 years and continuing until age 75 years.

B. The risks and benefits of different screening methods vary.

3. Adults age 76 to 85 years:

A. The decision to screen for CRC in adults age 76 to 85 years should be an individual one, taking into account the client's overall health and screening history.

B. Adults in this age group who have never been screened for CRC are more likely to benefit.

C. Screening would be most appropriate among adults who are healthy enough to undergo treatment if CRC is detected and who do not have comorbid conditions that would significantly limit their life expectancy.

D. CRC prevention plays an important role in the overall health benefit of aspirin, but this benefit is not apparent until 10 years after aspirin therapy is started. Clients need to take aspirin for at least 5 to 10 years to realize this potential benefit, and persons with shorter life expectancy are less likely to benefit. Thus, aspirin use is more likely to have an effect when it is started and used between the ages of 50 and 59 years, with those of higher cardiovascular disease (CVD) risk. The majority of CRCs occur in people older than 50. The USPSTF guidelines recommend the use of aspirin only for adults age 50 to 59. The American College of Gastroenterology and the USPSTF agree that clients at an increased risk of CVD often have other issues associated with increased inflammation, such as diabetes, obesity, or hypertension. Those other issues increase the risk of CRC. See Table 2.2 for the USPSTF recommendation for aspirin use to prevent CVD and CRC.

DENTAL CARE

A. Research has linked infections from poor oral care from untreated cavities and gum disease to preterm birth, heart disease, diabetes, and respiratory diseases. Primary care providers are on the front line for performing oral examinations. Alcohol, drug use, smoking cigarettes, using pipes, and smokeless tobacco have been identified as among the major causes of poor oral health and partly responsible for the increase in risk of oral cancer.

B. Medicare does not cover routine dental care or dental procedures such as cleanings, fillings, tooth extractions, dentures, or other dental devices. Medicare Part A (hospital insurance) can pay for emergency or complicated dental procedures, even though dental care is not covered. Medicaid coverage for dental care varies by state. Medicare Advantage plans now cover some dental care. The Affordable Care Act (ACA) expansion of medical insurance includes coverage for dental services in children.

C. Primary care providers should provide education on good oral hygiene, including brushing, flossing, seeing a dentist at least yearly, and eating a healthy diet. The U.S. Preventive Services Task Force (USPSTF) has, however, found inadequate evidence that oral screening examinations accurately detect oral cancer or that treatment of screen-detected oral cancer improves morbidity or mortality.

D. Many dental schools provide care at reduced costs based on an individual's income. The U.S. Department of Health and Human Services Health Resources and Services Administration (HRSA) has health centers in both cities and rural areas that provide care based on income. The HRSA maintains a website to find the nearest The HRSA-funded health centers at findahealthcenter.hrsa.gov/tool.

DEPRESSION SCREENING

A. Screen for depression, regardless of risk factors, in the general adult population, age 18 years and older, including pregnant and postpartum adults. Among older adults, risk factors for depression include disability and poor health status related to medical illness, complicated grief, chronic sleep disturbance, loneliness, and history of depression. However, the presence or absence of risk factors alone cannot distinguish clients with depression from those without depression.

B. Screening is recommended by the U.S. Preventive Services Task Force (USPSTF) when staff-assisted depression care supports are in place to ensure accurate diagnosis, appropriate treatment, and appropriate follow-up.

C. There is little evidence regarding the optimal timing for screening. The optimum interval for screening for depression is also unknown. Screening all adults who have not been screened previously and using clinical judgment in consideration of risk factors, comorbid conditions, and life events are used to determine if additional screening of high-risk clients is warranted.

D. There are multiple depression screening tools:

1. The Patient Health Questionnaire (PHQ-9) is the most common screening tool used to identify depression. The tool is located at www.drugsandalcohol.ie/26814/1/Patient%20Health%20Questionnaire.pdf.

2. The Hamilton Rating Scale for Depression (HAM-D) should be administered by a healthcare professional. The tool is located at www.mdcalc.com/hamilton-depression-rating-scale-ham-d.

3. The Cornell Scale for Depression in Dementia (CSDD) is located at www.windstonehealth.com/wp-content/uploads/2015/05/Cornell.pdf.

4. The Geriatric Depression Scale (GDS) is located at www.grepmed.com/images/264/depression-geriatrics-diagnosis-geriatric-scale. The GDS (short form) is located at geriatrictoolkit.missouri.edu/cog/GDS_SHORT_FORM.PDF.

5. The Edinburgh Postnatal Depression Scale (EPDS) is located at www.fresno.ucsf.edu/pediatrics/downloads/edinburghscale.pdf.

E. All positive screening results should lead to additional assessment that considers the severity of depression and comorbid psychological problems (e.g., anxiety, panic attacks, or substance abuse), alternate diagnoses, and medical conditions.

F. Medicare Part B covers an annual depression screening for Medicare beneficiaries in primary care settings when staff-assisted depression care supports are in place to ensure accurate diagnosis, effective treatment, and follow-up, thereby facilitating and coordinating referrals to mental health treatment. Medicare does not identify a specific depression screening tool.

G. The March 2016 Institute for Clinical System Improvement (ISCI) Adult Depression in Primary Care Guideline provides practitioners with current information related to screening for depression, including an algorithm for adult depression in the primary care setting and the criteria for a major depressive episode from the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (*DSM-5;* American Psychiatric Association, 2013).

U.S. Centers for Medicare and Medicaid Services. (n.d.). *Depression screening*. http://www.medicare.gov/coverage/depression-screenings.html

DIABETES SCREENING

A. The incidence of type 2 diabetes mellitus (DM) is one of the major health problems facing the United States today and will continue to be an issue as the population ages and becomes more obese. The tests to be used for the diagnosis of diabetes are also utilized for screening for DM: fasting plasma glucose, the 2-hour plasma glucose after a 75-g glucose tolerance test, and the hemoglobin A1C tests (see the "Diabetes Mellitus" section of Chapter 24).

B. The U.S. Preventive Services Task Force (USPSTF) recommends screening in the primary care setting for abnormal blood glucose as part of cardiovascular risk assessment in adults 35 to 70 years of age who are overweight or obese and do not have obvious symptoms of diabetes. Clinicians should offer or refer clients with abnormal blood glucose to intensive behavioral counseling interventions to promote a healthful diet and physical activity. Their recommendation further states that persons who have a family history of diabetes or a history of gestational diabetes or polycystic ovarian syndrome (POS) or are members of certain racial/ethnic groups (e.g., African Americans, American Indians or Alaskan Natives, Asian Americans, Hispanics or Latinos, or Native Hawaiians or Pacific Islanders) may be at increased risk for diabetes at a younger age or at a lower body mass index (BMI). Clinicians should consider screening earlier in persons with one or more of these characteristics.

C. The following are the American Diabetes Association (ADA) screening recommendations:

1. Screening for prediabetes and type 2 DM with an informal assessment of risk factors or validated tools should be considered in asymptomatic adults.

2. Client screening should begin at age 45 years for all people. Consider testing for prediabetes in asymptomatic adults of any age with a BMI of ≥25 kg/m^2 or 23 kg/m^2 (in Asian Americans) who have one or more additional risk factors for diabetes:

a. A1C ≥5.7, impaired glucose tolerance (IGT), or impaired fasting glucose (IFG) on previous testing.
b. First-degree relative with diabetes.
c. High-risk race/ethnicity (e.g., African American, Latino, Native American, Asian American, and Pacific Islander).
d. Females who were diagnosed with gestational DM (GDM).
e. History of cardiovascular disease (CVD).

▶

f. Hypertension (>140/90 mmHg) or receiving therapy for hypertension.
g. High-density lipoprotein (HDL) <35 mg/dL and/or a triglyceride level >250 mg/dL.
h. Females with POS.
i. Physical inactivity.
j. Other clinical conditions associated with insulin resistance (e.g., severe obesity, acanthosis nigricans).

D. If the test results are normal, the ADA retesting for prediabetes and for type 2 diabetes at least at 3-year intervals is reasonable.

HEPATITIS C SCREENING

A. The U.S. Preventive Services Task Force (USPSTF) recommends offering a onetime screening for hepatitis C virus (HCV) infections to asymptomatic adults born between 1945 and 1965 without known liver disease or functional abnormalities. However, the guidelines were augmented in 2020 to include the following: (a) hepatitis C screening at least once in a lifetime for all adults aged ≥18 years, except in settings where the prevalence of HCV infection is <0.1%; and (b) hepatitis C screening for all pregnant females during each pregnancy, except in settings where the prevalence of HCV infection is <0.1%.

B. The USPSTF also recommends screening for HCV infection in persons at high risk for infection:

1. The most important risk factor for HCV infection is past or current injection drug use. Intranasal drug use is also an additional risk factor.
2. Receipt of a blood transfusion before 1992.
3. Long-term hemodialysis and hemophilia.
4. Percutaneous exposures, including unregulated tattoo.
5. High-risk sexual behaviors (multiple sex partners, unprotected sex, sex with an HCV-infected person or injection drug user, and men having sex with men [MSM]).
6. Birth to an HCV-infected mother.
7. Incarceration.

C. For those with reactive test results, the anti-HCV test should be followed with an additional, supplemental, or confirmatory test for the presence of the virus (see the "Hepatitis C" section of Chapter 14).

HIV SCREENING

A. HIV testing is a covered benefit from the Centers for Medicare and Medicaid Services (CMS) as a voluntary test every 12 months for people at increased risk and anyone asking for HIV testing. CMS also covers testing for HIV in pregnancy up to three times. The current U.S. Preventive Services Task Force (USPSTF) recommendation is that screening for HIV infection could begin at age 15 to 65 years. Teens younger than age 15 and adults older than 65 also should be screened if they are at risk for HIV infection (see the "Human Immunodeficiency Virus" section of Chapter 20). The USPSTF also recommends that all pregnant females, including those in labor who do not know their HIV status, be screened for HIV infection. High-risk factors for HIV are risky sexual practices (men having sex with men [MSM], sexual partners with HIV, bisexual, exchanging sex for drugs or money) and infected intravenous (IV) drug users. For persons over age 65, new sexual partners are at an increased risk.

B. Testing intervals are not defined by the CMS or by the USPSTF.

IMMUNIZATIONS

A. The Centers for Disease Control and Prevention (CDC) recommendations for immunizations are presented in Figure 2.1.

B. Immunizations for travel outside of the United States are recommended based on the client's health status and vaccine history, as well as the area(s) of travel. The presence of the risk of becoming ill from poor sanitary conditions, food and water sources, and endemic diseases is considered in the CDC's recommendations for travel immunizations. The CDC has an interactive tool for immunization recommendations for travel located at wwwnc.cdc.gov/travel/destinations/list.

Recommended Adult Immunization Schedule
for ages 19 years or older

UNITED STATES
2022

How to use the adult immunization schedule

1. Determine recommended vaccinations by age **(Table 1)**
2. Assess need for additional recommended vaccinations by medical condition or other indication **(Table 2)**
3. Review vaccine types, frequencies, intervals, and considerations for special situations **(Notes)**
4. Review contraindications and precautions for vaccine types **(Appendix)**

Vaccines in the Adult Immunization Schedule*

Vaccine	Abbreviation(s)	Trade name(s)
Haemophilus influenzae type b vaccine	Hib	ActHIB® Hiberix® PedvaxHIB®
Hepatitis A vaccine	HepA	Havrix® Vaqta®
Hepatitis A and hepatitis B vaccine	HepA-HepB	Twinrix®
Hepatitis B vaccine	HepB	Engerix-B® Recombivax HB® Heplisav-B®
Human papillomavirus vaccine	HPV	Gardasil 9®
Influenza vaccine (inactivated)	IIV4	Many brands
Influenza vaccine (live, attenuated)	LAIV4	FluMist® Quadrivalent
Influenza vaccine (recombinant)	RIV4	Flublok® Quadrivalent
Measles, mumps, and rubella vaccine	MMR	M-M-R II®
Meningococcal serogroups A, C, W, Y vaccine	MenACWY-D MenACWY-CRM MenACWY-TT	Menactra® Menveo® MenQuadfi®
Meningococcal serogroup B vaccine	MenB-4C MenB-FHbp	Bexsero® Trumenba®
Pneumococcal 15-valent conjugate vaccine	PCV15	Vaxneuvance™
Pneumococcal 20-valent conjugate vaccine	PCV20	Prevnar 20™
Pneumococcal 23-valent polysaccharide vaccine	PPSV23	Pneumovax 23®
Tetanus and diphtheria toxoids	Td	Tenivac® Tdvax™
Tetanus and diphtheria toxoids and acellular pertussis vaccine	Tdap	Adacel® Boostrix®
Varicella vaccine	VAR	Varivax®
Zoster vaccine, recombinant	RZV	Shingrix

*Administer recommended vaccines if vaccination history is incomplete or unknown. Do not restart or add doses to vaccine series if there are extended intervals between doses. The use of trade names is for identification purposes only and does not imply endorsement by the ACIP or CDC.

Recommended by the Advisory Committee on Immunization Practices (www.cdc.gov/vaccines/acip) and approved by the Centers for Disease Control and Prevention (www.cdc.gov), American College of Physicians (www.acponline.org), American Academy of Family Physicians (www.aafp.org), American College of Obstetricians and Gynecologists (www.acog.org), American College of Nurse-Midwives (www.midwife.org), and American Academy of Physician Associates (www.aapa.org), and Society for Healthcare Epidemiology of America (www.shea-online.org).

Report

- Suspected cases of reportable vaccine-preventable diseases or outbreaks to the local or state health department
- Clinically significant postvaccination reactions to the Vaccine Adverse Event Reporting System at www.vaers.hhs.gov or 800-822-7967

Injury claims

All vaccines included in the adult immunization schedule except pneumococcal 23-valent polysaccharide (PPSV23) and zoster (RZV) vaccines are covered by the Vaccine Injury Compensation Program. Information on how to file a vaccine injury claim is available at www.hrsa.gov/vaccinecompensation.

MAMMOGRAPHY

A. Screening mammography guidelines:

1. The 2016 U.S. Preventive Services Task Force (USPSTF) screening mammography recommendations apply to asymptomatic females age 40 years or older who do not have preexisting breast cancer or a previously diagnosed high-risk breast lesion and who are not at high risk for breast cancer due to a known underlying genetic mutation (such as a *BRCA1* or *BRCA2* gene mutation or other familial breast cancer syndrome) or a history of chest radiation at a young age.

a. The USPSTF concludes that the current evidence is insufficient to assess the benefits and harms of digital breast tomosynthesis (DBT) as a primary screening method for breast cancer.

b. In addition to false-positive results and unnecessary biopsies, all females undergoing regular screening mammography are at risk for diagnosis and treatment of noninvasive and invasive breast cancer that would otherwise not have become a threat to their health, or even apparent, during their lifetime (known as "overdiagnosis"). Beginning mammography screening at a younger age and screening more frequently may increase the risk of overdiagnosis and subsequent overtreatment.

i. Females age 40 to 49 years: The decision to start screening mammography in females prior to age 50 years should be an individual one. Females who place a higher value on the potential benefit than the potential harms may choose to begin biennial (every other year) screening between the ages of 40 and 49 years. Females with a parent, sibling, or child with breast cancer are at higher risk for breast cancer and thus may benefit more than average-risk females from beginning screening in their 40s.

ii. Females age 50 to 74 years: Biennial screening mammography is recommended.

iii. Females age 75 years or older: The current evidence is insufficient to assess the balance of benefits and harms of screening mammography in females age 75 years or older.

2. The American College of Obstetricians and Gynecologists (ACOG) 2017 recommendations for screening mammography include the following:

a. Ages 40 to 49: Offer screening mammography in the context of a shared, informed decision-making approach that recognizes the uncertainty of additional benefits and harms of clinical breast examination beyond screening mammography.

b. Ages 40 to 49: Initiate after counseling, if client desires.

c. Ages 50 to 74: Recommend screening by no later than age 50, annual or biennial.

d. Continue until 75 years. Beyond age 75, the decision to discontinue should be based on client autonomy and shared decision-making process that includes a discussion of the client's health status and longevity.

3. The 2021 American Cancer Society (ACS) mammography guideline recommendations are for clients at average risk for breast cancer. Females at high risk, due to family history, a breast condition, or other reasons, need to begin screening earlier and more often.

a. Females should have the opportunity to begin annual screening between the ages of 40 and 44 years yearly.

b. Females with an average risk of breast cancer should undergo regular screening mammograms yearly at ages 45 to 54. ▶

TABLE 2.3 CERVICAL CANCER SCREENING GUIDELINES FOR *AVERAGE-RISK* FEMALES

	Recommending Body		
	ASCCP, SGO, and ASCP 2021 Guidelines	**USPSTF 2021 Guidelines**	**ACOG 2021**
Statement about annual screening	Females of any age should not be screened annually by any screening method.	Cervical cancer screening visits are an opportunity to discuss other health problems and preventive measures.	Clients should be counseled that annual well-woman visits are recommended even if bimanual pelvic exam with cervical cancer screening is not performed at each visit. The components of the examination may vary depending on the client's age, risk factors, and physician preference. The visit is valuable in promoting prevention practices, recognizing risk factors for disease, identifying medical problems, administration of immunizations based on age and risk factors, and establishing a clinician–client relationship.
Females aged <21 years	No screening is recommended, regardless of age at sexual initiation or other risk factors.	No screening is recommended for females <21.	No screening is recommended for females <21, regardless of age at sexual initiation and other behavior-related risk factors.

(*continued*)

TABLE 2.3 CERVICAL CANCER SCREENING GUIDELINES FOR *AVERAGE-RISK* FEMALES (*CONTINUED*)

	Recommending Body		
	ASCCP, SGO, and ASCP 2021 Guidelines	**USPSTF 2021 Guidelines**	**ACOG 2021**
Females aged 21–29 years • Cytology (conventional or liquid based) alone	Cervical cytology every 3 years is recommended. HPV cotesting should not be used in females <30 years.	Cervical cytology alone **every 3 years** is recommended.	Cervical cytology **every 3 years** is recommended. Liquid-based and conventional methods of cervical cytology collection are acceptable for screening. HPV cotesting should not be used in females <30 years.
Females aged 30–65 years • Cytology (conventional or liquid based) alone OR • hrHPV cotest (cytology and HPV test administered together)	hrHPV cotesting is recommended **every 5 years**.	Cervical cytology alone is recommended **every 3 years.** OR alternatively hrHPV testing alone is recommended **every 5 years**.	Cervical cytology test alone **every 3 years** is acceptable. **OR alternatively Pap test + hrHPV cotesting every 5 years is preferred over cytology alone every 3 years.** **The FDA approved primary hrHPV testing alone every 5 years.**
When to stop screening for average-risk females	Females >65 years with adequate screening history do not need further screening.	For females >65 years, no screening is recommended for those who have had adequate prior screening and are not otherwise at high risk for cervical cancer.	• For females >65 years, no screening is recommended for those who have had adequate prior screening and are not otherwise at high risk for cervical cancer; and if no history of cervical changes **AND** either three negative Pap test results in a row or two negative cotest results in a row within the past 10 years, with the most recent test performed within the past 5 years.
Primary hrHPV testing alone	2021 ASCCP and SGO issued agreement with ACOG guidelines for use of HPV test for primary testing.	For average-risk females aged 30–65, hrHPV testing **every 5 years** is an alternative to cytology alone **every 3 years.**	Primary hrHPV testing is recommended every 5 years for females aged 30–65.
Screening posthysterectomy	Females who have had a total hysterectomy (removal of the uterus and cervix) should stop screening. Females who have had a supracervical hysterectomy (cervix intact) should continue screening according to guidelines.	No screening is recommended for females who have had a hysterectomy with removal of the cervix and do not have a history of high-grade precancerous lesions (e.g., cervical intraepithelial neoplasia grade 2 or 3) or cervical cancer.	• For females who have had a total hysterectomy with removal of the uterus and cervix and no history of cervical cancer or cervical change, no screening with routine cytology screening, and HPV testing should be discontinued and not restarted for any reason. • For females who had a hysterectomy in which the cervix was removed **AND** have a history of cervical cancer or moderate to severe cervical changes, the recommendation is to continue screening for 20 years after surgery.
Screening among those immunized against HPV 16 and 18	Females of any age with a history of HPV vaccination should be screened according to the age-specific recommendation for the general population.	The possibility that vaccination might reduce the need for screening with cytology or hrHPV testing has not been established; therefore, females who have been vaccinated should continue to be screened as recommended until further evidence accrues.	Females who have been vaccinated against HPV still need to be screened according to the same age-specific guidelines.

ACOG, American College of Obstetricians and Gynecologists; ASCCP, American Society for Colposcopy and Cervical Pathology; ASCP, American Society for Clinical Pathology; FDA, Food and Drug Administration; HPV, human papillomavirus; hrHPV, high-risk HPV testing; SGO, Society of Gynecologic Oncology; USPSTF, U.S. Preventive Services Task Force.

c. Females 55 years and older should transition to biennial screening or have the opportunity to continue screening annually.

d. Females should continue screening mammograms as long as their overall health is good and they have a life expectancy of 10 years or longer.

PAP SMEAR/PELVIC EXAMINATION

A. Human papillomavirus (HPV) increases the risk of cancer, including cervical, vulvar, vaginal, penile, and anal cancer, as well as cancer of the oropharynx. Since cervical cancer is believed to be caused by sexually transmissible HPV infections, clients who have not had sexual exposures are likely at low risk. Females older than 21 years who have not engaged in sexual intercourse may not need a Pap test depending on circumstances. The decision should be made at the discretion of the client and their physician. Females who have had sex with females are still at risk of cervical cancer.

B. Persistent infection of the uterine cervix with high-risk types of human papillomavirus (hrHPV) is required for the development of invasive cervical cancer. Infection with hrHPV is common, especially with sexually active young females; most infections are transient and spontaneously clear without clear clinical consequences. The American College of Obstetricians and Gynecologists (ACOG) joins the American Society for Colposcopy and Cervical Pathology (ASCCP) and the Society of Gynecologic Oncology (SGO) in endorsing the U.S. Preventive Services Task Force (USPSTF) 2021 cervical cancer screening clinical guidelines, recommending screening strategies with cytology or cotesting (cytology in combination with hrHPV) based on age. The guidelines recommend screening of females 21 to 65 years of age with cytology alone or cotesting with hrHPV based on age-specific guidelines. The American Cancer Society (ACS) recommends cervical cancer screening with an HPV test alone every 5 years for everyone with a cervix from age 25 until age 65. If HPV testing alone is not available, people can get screened with an HPV/Pap cotest every 5 years or a Pap test every 3 years. See Table 2.3 for cervical cancer screening recommendations for average-risk clients. Females who are infected with HIV or are otherwise immunocompromised (e.g., solid organ transplants), females previously treated for cervical intraepithelial neoplasia 2 (CIN2) or CIN3 or cancer, and females exposed to diethylstilbestrol (DES) before birth need more frequent screening.

PROSTATE CANCER SCREENING

A. Prostate cancer is one of the most common cancers in males. It is a slow-growing cancer with a lifetime risk of 11%, and the lifetime risk of dying from prostate cancer is 2.5%. The median risk of death from prostate cancer is 80 years. The risk factors for prostate cancer include:

1. Age: males older than age 50.

2. Race/ethnicity: African American (4.2%), Hispanic (2.9%), Caucasian (2.3%), and Asian and Pacific Islander males (2.1%).

3. Males who have a family history of prostate cancer.

B. Smoking is associated with a high risk of prostate cancer mortality. The U.S. Preventive Services Task Force (USPSTF) 2018 recommendations for prostate-specific antigen (PSA) screening states the following:

1. The use of digital rectal examination as a screening modality is not recommended.

2. Males age 55 to 69 years:

a. The decision to undergo periodic PSA-based screening for prostate cancer should be an individual one. Before being screened, clients should have an opportunity to discuss the potential benefits and harms with their clinician and to incorporate their values and preference in the decision.

b. In determining whether this service is appropriate in individual cases, clients and clinicians should consider the balance of benefits and harms on the basis of family history, race/ethnicity, comorbid conditions, client values, and other health needs.

c. Clinicians should not screen clients who do not express a preference for screening.

3. Males 70 years and older: The USPSTF recommends against PSA-based screening for prostate cancer, noting adequate evidence from randomized clinical trials (RCT) is consistent with no benefit of PSA-based screening for prostate cancer due to a lack of evidence on the benefits. ▶

4. Harms of screening include frequent false-positive results with subsequent overdiagnoses, which can result in overtreatment, including invasive procedures, chemotherapy, and radiation.

C. Screening for prostate cancer with PSA has been controversial because of the potential for overdiagnosis and overtreatment. The PSA may be elevated with prostate problems other than cancer, such as enlarged prostate, prostatitis, urinary tract infection, or recent ejaculation. Further testing for suspected prostate cancer includes a digital rectal examination (not a current recommendation), transrectal ultrasound, and/or a needle biopsy.

D. Active surveillance with continued observation and physical examinations has been the more common treatment choice over the past several years among males with low-risk prostate cancer and may reduce the chance of overtreatment. Active surveillance includes periodic PSA tests, physical examination, and repeated prostate biopsy, an often repeated rectal examination. Treatment includes prostatectomy surgery, radiation, cryotherapy, chemotherapy, immunotherapy, or androgen deprivation therapies. Side effects of these procedures include urinary incontinence, erectile dysfunction, and bowel dysfunction. The use of androgen deprivation therapy for localized prostate cancer is associated with erectile dysfunction, gynecomastia, and hot flashes.

SEXUALLY TRANSMITTED INFECTION SCREENING

A. Taking a thorough sexual history is the basis of identifying high-risk sexual behavior, screening, counseling, and treating sexually transmitted infections (STIs). Older adults should continue to be screened throughout their lifetime for STIs; there is no cutoff on the age of transmission of STIs. All persons who seek evaluation and treatment for STIs should be screened for HIV. Screening should be routine, regardless of whether the client reports any specific behavioral risk for HIV. The Centers for Disease Control and Prevention (CDC) recommends that persons 13 to 64 years of age be screened for HIV in all healthcare settings. Persons should be notified that testing will be performed, but retain the option to decline or defer testing. Guidelines and recommendations for HIV/AIDS for clinicians are available at the CDC website located at www.cdc.gov/hiv/guidelines/index.html. For more discussion on sexual health and treatment guidelines for STIs and HIV see the "Sexual Health Issues in the Aging Population" of Chapter 15; the full CDC STI guidelines in Chapter 18; and the "Human Immunodeficiency Virus" section of Chapter 20.

VISION SCREENS

A. Age-related changes affect the sense of sight and require screening for refractory errors, macular degeneration, glaucoma, and cataracts (see Chapter 8, "Eye Guidelines").

B. Multiple medical and systemic conditions including genetic, cardiovascular, endocrine, gastrointestinal (GI), nutritional, and metabolic disorders increase the need for a comprehensive dilated eye examination. The American Optometric Association recommends an examination every 2 years for risk-free adults between 18 and 60 years. For those at risk between 18 and 60 years of age, eye examinations are recommended every 1 to 2 years. For adults who are 61 years of age and older who are risk-free, an annual eye examination is recommended. A comprehensive eye examination for at-risk adults should occur annually or as recommended. The American Academy of Ophthalmology recommends a baseline comprehensive exam at age 40. This recommendation is for all adults with no signs or risk factors for eye disease. Based on the results of the initial screening, an ophthalmologist will prescribe the necessary intervals for follow-up exams.

PRETRAVEL HEALTH SCREENINGS

A. Pretravel consultation offers a dedicated time to prepare travelers for the health concerns that might arise during their trips. The objective is to perform an individual risk assessment, educate the traveler regarding anticipated health risks and methods for prevention, and provide immunizations for vaccine-preventable diseases and medications for prophylaxis, self-treatment, or both. Travel medicine specialists have in-depth knowledge of immunizations, risks associated with specific destinations, and the implications of traveling with underlying conditions. Therefore, a comprehensive consultation with a travel medicine expert is indicated for any traveler with a complicated health history, special risks (such as traveling at high altitudes or working in refugee camps), or exotic or complicated itineraries.

B. Effective pretravel consultations require attention to the health background of the traveler and incorporation of the itinerary, trip duration, travel purpose, and activities, all of which determine health risks.

1. Risk assessment:
   a. Medical history including underlying conditions, allergies (especially any pertaining to vaccines, egg, or latex), and medications. ▶

b. Special conditions including pregnancy, breastfeeding, disabilities, immunocompromising conditions or medications, seizure disorder, recent myocardial infarction (MI), surgery, and history of Guillain–Barré syndrome.
c. Immunization history: routine and travel vaccines.
d. Prior travel experience including malaria chemoprophylaxis, experience with altitude, and illness related to prior travel.

2. Trip details:
a. Itinerary: countries and specific regions, including the travel order of countries, as well as rural or urban travel.
b. Timing: trip duration, season of travel, time to depart.
c. Reason for travel: tourism, business, visiting friends/relatives, missionary/aid work, adoption, or seeking healthcare (medical tourism).
d. Travel style: independent travel or package tour, traveler risk tolerance, general hygiene standards at the destination, modes of transport, accommodations, and propensity for "adventurous" eating.
e. Special activities: disaster relief, medical care (providing or receiving), high altitude, diving, cruise ship, rafting or other water exposure, cycling, extreme sports, spelunking, and anticipated interactions with animals domestic and wild.

C. Assess individual risks: Many elements merit consideration in assessing a traveler's health risks (see Table 2.1). Certain travelers may confront special risks. Recent hospitalization for serious problems may lead the advisor to recommend delaying travel. Air travel is contraindicated for certain conditions, such as less than 3 weeks after an uncomplicated MI and less than 10 days after thoracic or abdominal surgery. The travel health provider and the traveler should consult with the relevant healthcare providers most familiar with the underlying illnesses.

D. Manage risk.

1. Immunizations are a crucial component of pretravel consultations, and the risk assessment forms the basis of recommendations for travel vaccines.

2. For travelers going to malaria-endemic countries, it is imperative to discuss malaria transmission, ways to reduce risk, and recommendation for chemoprophylaxis and continuation protocol of the regimen post return.

3. Travelers with underlying health conditions require attention to their health issues as they relate to the destination and activities. Travelers should be counseled on how they can find reputable medical facilities at their destination, such as using the International Society of Travel Medicine (ISTM) website (www.istm.org) or the American Society of Tropical Medicine and Hygiene website (www.astmh.org) to find suitable clinics. Any allergies or serious medical conditions should be identified on a bracelet or a card to expedite medical care in emergency situations.

4. The pretravel consultation also provides another setting to remind travelers of basic health practices during travel, including frequent handwashing, COVID-19 prevention precautions including wearing face masks and sanitizing surfaces, as well as wearing seat belts, and using car seats for infants and children. General issues such as preventing injury and sunburn also deserve mention. Written information is essential to supplement oral advice and enable travelers to review the instructions from their clinic visits; educational material is available at the Centers for Disease Control and Prevention (CDC) Travelers Health web page (www.cdc.gov/travel). Advice on self-treatable conditions may minimize the need for travelers to seek medical care while abroad.

CHAPTER 3

ADULT-GERIATRIC ASSESSMENTS

L. Douglas Smith Jr.

COMPREHENSIVE ASSESSMENT IN GERONTOLOGY

A. Adults 65 years and older will account for 20% of the total U.S. population within 10 years. Older individuals with increasingly complex chronic health conditions will account for an ever-increasing proportion of the adult and geriatric clinician's client population. While changes associated with the aging process *may* lead to progressive functional and cognitive decline, normal aging and the development of chronic disease are not synonymous. Still, the deterioration associated with aging makes it challenging to identify developing pathologies, leaves older adults vulnerable to disability and diminished quality of life, and makes it challenging to navigate the healthcare environment. The comprehensive geriatric assessment is a holistic approach to evaluating the aged person's status to develop an individualized plan of care. Personalization is imperative; the senior client may desire the care trajectory to prioritize aspects other than health outcomes and lengthened survival.

B. The evidence-based model for comprehensive geriatric assessment involves an interprofessional team performing a holistic review of the client's physical health, functional ability, psychological well-being, and socioenvironmental status. The geriatric assessment can be time- and labor-intensive. Strategies to reduce the burden of the evaluation include expanding the traditional disease-oriented visit to incorporate elements of the comprehensive assessment over multiple visits, electronic completion of screening forms before arrival, the delegation of tasks to other members of the interprofessional team, and client selection. Although parts of the assessment may be pertinent, the complete evaluation is inappropriate for clients with advanced dementia, terminal illness, and functional dependence. There is no particular evidence-prescribed instrument used; many validated tools exist. The assessment should be comprehensive while covering the four domains of physical health, functional ability, psychological well-being, and socioenvironmental status. The following includes only some of the available methods used for the assessment.

PHYSICAL HEALTH

A. The geriatric assessment does not replace the traditional physical examination; rather, it enhances the diagnostic process by elucidating information relevant to standard medical management, which clients may underreport. Therefore, clinicians must be attuned to the client's medical history and complaints while expanding the scope of the examination to search for conditions routine in older adults.

VISION AND HEARING

A. Vision and hearing impairments are common in older adults, although clients frequently fail to report these problems due to the association with normal aging. These problems may significantly impact the quality of life. Referral to a specialist (ophthalmologist or audiologist) may be appropriate, although the primary provider can initiate basic screening and workup. Assessment of visual acuity occurs with the Snellen eye chart or by asking the client questions such as "Are you having problems reading the newspapers or books?" or "Are you able to recognize faces from afar?" A hearing assessment using the whisper test or asking questions such as "Do you have problems hearing?" should occur. Family involvement with these screening questions may be invaluable as sensory loss may be less noticeable to the client. Positive screens indicate the need for further workup and intervention.

NUTRITION STATUS

A. Poor nutrition status in older adults is associated with increased health service use and mortality. Aged clients may be at increased risk for nutritional deficiency due to a host of physical and functional changes associated with normal aging. Poor nutrition may lead to unintentional weight loss or body mass index (BMI) below acceptable standards (BMI should be above 23 kg/m^2). Nutritional screening occurs using questions about weight loss or a validated instrument such as the Mini Nutritional Assessment (available at www.mna-elderly.com/sites/default/files/2021-10/mna-mini-english.pdf).

IMMUNIZATIONS

A. Aged clients are particularly at risk for preventable disease, and compliance with the recommended schedule from the Advisory Committee on Immunization Practices is encouraged. Clinicians should ensure age-appropriate immunization status for influenza, tetanus, diphtheria, pertussis, pneumococcus, and herpes zoster. Geriatric providers should monitor communications regarding ongoing immunization for coronavirus.

POLYPHARMACY

A. There is no single definition of polypharmacy, although it is often defined as using five or more medications daily. Older persons are often prescribed multiple medications by different healthcare providers, increasing their risk of drug–drug interactions and adverse drug events.

1. The older adult population takes an average of 18 prescription drugs per year.

2. One in four people aged 65 years and older receive at least one of 20 potentially drugs inappropriate for older adult clients.

3. The amount and frequency of alcohol use should be included in medication reviews:

4. An important step in evaluating *potential* polypharmacy is the assessment of new symptoms. Typical signs and symptoms suggesting polypharmacy include confusion, gait disturbance, depression, delirium, dementia, anger, forgetfulness, falls, insomnia, drowsiness, and incontinence.

5. The strongest predictor of a potentially harmful medication is the number of drug prescriptions. Exposure to multiple drugs puts clients at additive risk of each single drug and increases the risk of geriatric syndromes and their sequela for falls, depression, and cognitive impairment. Refer to Appendix C for the American Geriatrics Society's (AGS) Beers criteria for potentially inappropriate medication use in older adults. The updated Beers criteria article is available at doi.org/10.1111/jgs.15767.

6. Prescribers with insufficient geriatric care knowledge may be a significant factor in polypharmacy when medications are not thoroughly evaluated for efficacy, safety, and interactions.

7. A potential source of therapeutic duplication may occur during a transition in care between providers, consultants, or discharge from hospitalization.

8. Evaluate issues related to the client's ability to remember medication names, the reason for prescription, how often to administer, and the ability to afford medications.

9. The best method of detecting potential problems with polypharmacy is to have clients bring in all of their medications, prescription and nonprescription, in their bottles. There are several approaches to the evaluation of polypharmacy issues:

a. Schedule a "brown bag" visit to review medications and the client's understanding (see Exhibits 3.1 and 3.2).

b. A senior care pharmacist may be available in your community for a referral. Senior care pharmacists are skilled healthcare professionals who have specialized training in the medication-related needs of seniors. Typically, the senior care pharmacist does a comprehensive consultation through a one-on-one review of all medications. ▶

EXHIBIT 3.1 Checklist for Brown Bag Medication Checkup

What to check for:

A. Indication for each medication.
B. Drug interactions between medications and food.
C. Adverse drug reactions (especially those to report or how to manage them).
D. Expiration dates of medications.
E. How the client is taking their medications.
F. Physical disabilities.
G. Monitoring tests.
H. How the medication is being stored.
I. Cultural, reading level, capability.
J. Allergies.

Make sure the client understands:

A. What each medication is used for.
B. How to take each medication (e.g., with or without food, number of times per day).
C. What to expect from the medication.
D. Side effects (especially those to report or how to manage them).

Take-home messages for the client:

A. Stress the importance of proper disposal of expired or discontinued medications.
B. Clarify questions on any remaining prescriptions.
C. Explain the importance of proper storage with certain medications (e.g., nitroglycerin).
D. Remind the client to communicate with their doctor or pharmacist about any side effects of prescription medications, OTCs, or herbal supplements.
E. Suggest medication schedules and the importance of compliance.
F. Reinforce lifestyle modifications to promote well-being.

OTC, over-the-counter.

c. The Institute for Safe Medication Practices (ISMP) has published the **List of Confused Drug Names,** which includes look-alike and sound-alike drugs. The *List of Confused Drug Names* is located at www.ismp.org/Tools/confuseddrugnames.pdf.

d. Client teaching: *See Client Teaching Guide for this chapter, "Safety Issues: Medication Safety."*

10. Suggestions for safeguards to reduce risk in errors when writing a prescription include the following:

a. Use both the brand and generic names on prescriptions and labels.

b. Include the purpose of the medication on prescriptions and labels.

c. The Food and Drug Administration (FDA) approves of and the ISMP recommends using "tall man," or mixed case, letters for writing prescriptions. Tall man lettering involves highlighting the dissimilar letters in two drug names to aid in distinguishing between the two drugs. See Table 3.1 for an example of using "tall man" letters for medications on the *List of Confused Drug Names*.

11. Look for drug duplication and drug–drug interactions with prescribed medications, herbs, vitamins, and over-the-counter (OTC) drugs. Multiple websites are available for evaluation of drug interactions:

a. www.drugs.com/drug_interactions.html.

b. reference.medscape.com/drug-interactionchecker.

TABLE 3.1 EXAMPLES OF "TALL MAN" LETTERS TO PREVENT CONFUSION AND DECREASE LOOK-ALIKE PRESCRIPTION ERRORS

Drug Name/Tall Man	Confused Drug Name/Tall Man

d. www.rxlist.com/grapefruit-page3/supplements.htm.

DEPRESCRIBING

A. Deprescribing is the planned and supervised process of dose reduction or stopping medications that may cause harm or no longer provide a benefit. The strongest predictor of a potentially harmful medication is the total number of prescription drugs. The decision to stop a medicine should be weighed against the benefit. The clinician, the individual, and the family are vital partners in making an informed decision to deprescribe. Deprescribing is a trial, and medications may be restarted when appropriate.

B. Clients may combine prescribed medications with OTC medications/supplements in ways that may be harmful. Minimizing the prescribed drugs helps mitigate this risk.

C. Age-related changes occur in pharmacodynamics resulting in drug–receptor affinity, altering effective and toxic concentrations. Pharmacokinetic parameters, including drug absorption and bioavailability, distribution, and elimination, are affected by age. There is an age-related decline in serum albumin concentrations. Drug excretion by the kidneys declines; therefore, drugs excreted mainly by the kidneys may accumulate and significantly prolong the duration of action. Many older adult clients have renal impairment, but serum creatinine may not rise due to reduced muscle mass. There is no significant age-related decline in liver capacity to detoxify, metabolize, and eliminate drugs. However, medications metabolized by cytochrome P450 or similar liver enzymes may result in competitive inhibition of each other, resulting in slow clearance, drug accumulation, and toxicity.

D. Drug overdose and toxicity is a leading cause of acute confusion, particularly in older people. The risk of drug-related cognitive impairment increases with the number of medications prescribed.

E. Polypharmacy increases the risk of drug–food interaction when a food interferes with the drug's absorption or effect. For example:

1. A high-fiber diet decreases digoxin bioavailability, leading to subtherapeutic serum concentrations and an increased risk of treatment failure.

2. Potassium-rich foods may increase the risk of hyperkalemia when potassium-sparing diuretic or angiotensin-converting enzyme (ACE) inhibitors are prescribed.

F. Poor nutritional status may interfere with drug efficacy and excretion, leading to a higher risk of drug toxicity. Evaluate if the client has difficulties chewing or is altering medications by crushing because of swallowing problems. Some medicines should not be crushed because it changes the absorption or stability of the drug, causes an irritant effect, or has an unacceptable taste.

G. Medications designed to release slowly should not be crushed or chewed since the total dose will be released more rapidly than intended. A resource guide for crushing medications is available at www.ismp.org/recommendations/do-not-crush. Modified-release medications have abbreviations:

1. Long-acting (LA).
2. Controlled-release (CR).
3. Extended-release (XR).
4. Slow-release (SR).
5. Controlled delivery (CD).
6. Prolonged-release (XL).
7. When crushed, enteric-coated (EN or EC) medication loses the protection to the stomach or assurance of the drug's delivery beyond the stomach.
8. Film-coated (FC) and sugar-coated medications may require that coating to prevent rapid degradation of the medicine or to mask the taste.
9. A tablet may have a scoreline to facilitate half doses, but this does not necessarily mean it can be safely crushed.
10. *Drugs with a small therapeutic window, such as digoxin, carbamazepine, theophylline, and phenytoin, should not be crushed because of the increase in toxicity.*

H. The Beers criteria from the AGS (see Appendix C) is the most widely used geriatric resource for evaluating the safety and efficacy of medication use and includes recommendations based on a review of the literature regarding the quality of evidence, frequency and severity of harm, and availability of better treatment classes of medications, and makes recommendations for use or avoidance in older adults:

1. Benzodiazepines: Do not combine two or more other central nervous system active drugs due to increase in delirium and fall risks. Alternatives for geriatrics with anxiety include selective serotonin reuptake inhibitor (SSRI; except for paroxetine and not in clients at risk or with history or risk of falls) or the serotonin-norepinephrine reuptake inhibitor (SNRI) buspirone. Consider nonpharmacologic interventions or low-dose trazodone or melatonin for older adults with insomnia.

▶

2. Proton pump inhibitors (PPIs): Use for ≥8 weeks may be considered if the client has H2-blocker failure and a high risk of ulcer. Recommend referral to a gastroenterologist to collaborate management or deprescribing regimen if the older adult continues to use PPI for 8 to 12 weeks' duration.

3. Antihyperglycemics: Avoid thiazolidinediones (TZDs) or closely monitor geriatrics with fluid retention or risk of heart failure.

4. Antipsychotics: Geriatrics are particularly vulnerable to experience orthostatic hypotension, bradycardia, and urinary and bowel retention.

5. Cholinesterase inhibitors (ChEIs): Geriatrics are particularly vulnerable to experience orthostatic hypotension, bradycardia, and urinary and bowel retention.

I. Criteria for evaluating appropriate prescribing include the **S**creening **T**ool of **O**lder **P**eople's potentially inappropriate **P**rescriptions (STOPP) and the **S**creening **T**ool to **A**lert doctors to **R**ight **T**reatments (START). STOPP/START is an educational tool for pharmacists and prescribers. STOPP/START prescription criteria consist of a set of inappropriate combinations of medicines and disease (STOPP) and a set of recommended treatments for given conditions (START):

1. The STOPP/START Toolkit is available for use at www.cgakit.com/m-2-stopp-start.

2. The 10 most common drug classes implicated in hospital admissions for adverse drug reactions (ADRs), in the order of ADR-related admissions, are nonsteroidal anti-inflammatory drugs (NSAIDs), including aspirin, diuretics, anticoagulants, ACE inhibitors and angiotensin II receptor blockers, antidepressants, beta-blockers, opiates, digoxin, prednisolone, and clopidogrel.

3. Anticholinergic medication use is of specific concern in older people. Figure 3.1 shows the increasing adverse side effects of anticholinergic drugs. Anticholinergic drugs are mentioned explicitly in STOPP for their risk of toxicity in combination with tricyclic antidepressants, phenothiazines, benzodiazepines, neuroleptics, and antihistamines. The dangers of geriatric syndromes related to incontinence, physical impairments (gait speed and handgrip strength), falls, cognitive decline, and delirium increase incrementally as the client's anticholinergic burden increases. Cholinergic deficits may accompany aging and play a central role in the pathophysiology of Alzheimer disease.

J. Another resource for deprescribing guidelines is the Canadian Deprescribing Network (CaDeN). Their website (deprescribing.org/resources) links to free and readily available deprescribing brochures and resources. In addition, there are algorithm resources for tapering and deprescribing benzodiazepines, antipsychotics, PPIs, antihyperglycemics, ChEIs, and memantine for Alzheimer, dementia, or Parkinson, which are noted in Appendix D.

K. One of the deprescribing research links noted on the www.deprescribing.org site is Medstopper, a web-based educational tool that assists in stopping or tapering medications. The tool identifies medicines with the highest stopping priority, tapering suggestions, links to available risk calculators, and mentions whether there are Beers/STOPP criteria for the medications. Medstopper is available at medstopper.com.

FUNCTIONAL ABILITY

A. Age-related physiologic changes put aged clients at risk for declines in physical function and increased risk for falls. Determination of functional ability and fall risk occurs with assessments and screening tools. A basic evaluation includes an evaluation of a person's dependence/independence in the performance of activities of daily living (ADL), including personal self-care and community interactions. If the client cannot perform ADLs independently, identify family and other support for referrals.

ACTIVITIES OF DAILY LIVING

A. ADL evaluation of basic self-care activities includes the following:

1. Dressing: Use an open-ended question, such as "Did you dress yourself today?" Evaluate if the client can dress independently, choose weather-appropriate clothing, use buttons and zippers, and bend, grasp, and stand.

2. Eating: Evaluate if the client can use utensils, cut food, and swallow without choking.

3. Ambulating: Observation of the client entering the room and movement during the office visit evaluates if the client can walk independently, has gait abnormalities, or requires assistive devices.

4. Toileting: Evaluate if the client is continent of urine and bowel, or uses disposable undergarments, bedpan, or bedside commode. What is needed for mobility to get to the toilet? Is the client able to self-clean?

5. Hygiene: Evaluate the client's need for assistance with bathing, showering, shaving, brushing teeth, brushing hair, and other hygiene tasks.

B. The Barthel Index of ADLs is an example of an ADL assessment tool. It is located at www.sralab.org/sites/default/files/2017-07/barthel.pdf.

INSTRUMENTAL ACTIVITIES OF DAILY LIVING

A. The assessment of instrumental activities of daily living (IADL) (e.g., executive function) includes determining the ability to care for self and interact with the community. In addition, IADL consists of the ability of the client to shop and prepare food, handle finances and medications, communicate using the telephone, and perform tasks of housekeeping and laundry. The Lawton and Brody Instrumental Activities of Daily Living Scale is one of the most widely used and referenced tools (www.alz.org/careplanning/downloads/lawton-iadl.pdf).

B. Occupational and physical therapy referrals should be considered.

DRIVING ASSESSMENT FOR OLDER ADULTS

A. With the aging population, clinicians will increasingly evaluate the need for client to stop driving. The fourth edition of the American Geriatrics Society's *Clinician's Guide to Assessing and Counseling Older Drivers* (available at geriatricscareonline.org/ProductAbstract/clinicians-guide-to-assessing-and-counseling-older-drivers-4th-edition/B047#) provides decision support for clinicians.

1. Consult the Department of Motor Vehicles (DMV) in your state for information related to regulations for older drivers, including the requirement for a medical evaluation before license renewal, shorter renewal periods for aged drivers, and passing inperson vision, road, or written tests for renewal.

2. The decision to "take the keys away" is one of the significant changes impacting adult independence and self-worth. Changes in eyesight, hearing, reflex response, judgment, "pedal confusion," physical conditions, medications, and memory all impact deciding when to have the client stop driving. Family members look to healthcare providers to assist in determining whether their loved one has the capacity and ability to continue driving. The assessment begins by asking the client open-ended questions:

a. How comfortable are you driving?
b. Are you able to drive in the evening?
c. Do you drive in the rain or other bad weather?
d. Do you drive when it is rush hour?
e. Do you avoid driving on the interstate?
f. Do you ever get lost?
g. Have you ever "lost" your car? Have you had problems misplacing your keys, purse, or wallet?
h. Have you had any accidents, including minor "fender benders"?
i. Have you had any recent traffic tickets or warnings?
j. Do other drivers honk their horns when you are driving or stopped at a stop sign or signal light?
k. Do you have anyone to help you with errands?
l. Do you have any other optional transportation available, such as family and friends, senior citizen van services, taxi services, or a church van?

3. Interview family members:

a. Assess if they discussed the issue of the need to stop driving. The same questions asked to the client can be asked of the family. A three-module educational tool is available at the AARP website (www.aarp.org/auto/driver-safety/we-need-to-talk). The modular seminar covers the following subjects: "meaning of," "observing driving skills," and "planning conversations."
b. Have they been driven by their loved one, and what did they observe when they were passengers?
c. Have they noted any memory issues?
d. How active is their loved one? Have they noted any physical limitations around the home?
e. Has the family seen any dents or scraped paint on the car?

4. Evaluate alcohol consumption.

5. During a "brown bag" visit, review all medications to evaluate polypharmacy issues, drug duplication, and side effect profiles that impact driving.

6. Rereview all medical diagnoses. The client may be seeing multiple doctors, and records may not be current.

a. Vision issues: glaucoma, cataracts, macular degeneration, retinitis pigmentosa, diabetic retinopathy, abnormality of the field of vision (entire spatial area, including central and peripheral vision), visual acuity (able to distinguish details and shapes of objects, contrast sensitivity), color vision deficit, need for corrective glasses or contacts.
b. Hearing: hearing loss.
c. Neurologic disorders: Parkinson disease, multiple sclerosis, epilepsy (last seizure), syncope, Alzheimer disease, stroke (hemiparesis), cognitive impairment, and Huntington disease.
d. Heart/vascular: hypertension, unstable angina, arrhythmia, and aortic aneurysm (nonsurgical treatment).
e. Respiratory issues, including sleep.
f. Sleep issues: hypersomnia, excessive daytime sleepiness, obstructive sleep apnea.
g. Diabetes: poorly controlled diabetes/hypoglycemia. ▶

h. Psychiatric disorders and substance abuse: aggressiveness, behavioral disorders, depression, anxiety, abuse or dependence with alcohol, cannabis, and benzodiazepine use.
i. Physical limitations: amputation, range of motion, manual dexterity, arthritis, difficulties with ADL, hemiparesis.
j. Dementia/cognitive impairment.

7. Referrals:
a. Functional assessment by an occupational therapist.
b. Physical therapy.
c. Medical specialty consultation.
d. On-road assessment by the DMV.

GAIT AND MOBILITY

A. In addition to ADLs, gait speed predicts functional decline and mortality in older adults. Assessing gait speed may identify clients who need further evaluation. Additionally, it helps identify frail clients who might not benefit from the treatment of chronic asymptomatic diseases.

1. Mobility and balance are indicators of the ability to live independently.

2. The Timed Up and Go (TUG) test is a basic mobility assessment evaluating static and dynamic balance. The TUG test assesses the ability to stand from a sitting position, walk, turn, stop, and sit (see Exhibit 3.3). The provider administering the test needs a chair with armrests and a stopwatch. For client with assistive devices (e.g., cane), the device is used during the trial.
a. The client should be wearing regular shoes.
b. The test starts when the client begins rising from the chair and ends when the client is seated.
c. The client should be seated in a resting position with both arms on the chair armrests. Then, the client stands up from the chair, walks approximately 10 feet (3 m), turns around, and returns to sit down in the chair.
d. Verbal cueing through the test may be needed for a person with cognitive impairment.
e. Evaluation:
i. The expected time to complete the TUG test is between 7 and 10 seconds, indicating no balance or mobility issues.
ii. An older adult who takes 12 or more seconds to complete the TUG test is at high risk for falling.
iii. Time greater than 20 seconds indicates the need for assistance and further evaluation.
iv. Taking 30 or more seconds indicates a high risk for falls and higher dependence needs.
f. The TUG test can be repeated periodically to assess the decline in gait, mobility, and balance.

3. The Tinetti Assessment Tool measures both balance and gait. This tool is located at www.whca.org/files/2013/04/TINETTI_assessment_tool.pdf.
a. Balance:
i. Individual scores are given for tasks including sitting balance, rising, standing, balance when the examiner nudges the client, balance with eyes closed, balance ability when turning 360°, and safety when sitting down.
ii. The maximum score for the balance portion of the Tinetti test is 16 points.
b. Gait:
i. Individual scores are given for tasks/items, including the initiation of gait, step length and height of raising the feet to walk, symmetry of stepping, continual stepping, walking straight or a deviation of the path, trunk movement, and walking stance. ▶

EXHIBIT 3.3 The Timed Up and Go (TUG) Test

Patient: _____ **Date**: _____

Time: _____ a.m./p.m.

The TUG test

A. Purpose: To assess mobility.
B. Equipment: A stopwatch.
C. Directions: Clients wear their regular footwear and can use a walking aid if needed. Begin by having the client sit back in a standard armchair and identify a line 3 m or 10 ft away on the floor.

Instructions to the client:

A. When I say **"go,"** I want you to:
1. Stand up from the chair.
2. Walk to the line on the floor at your normal pace.
3. Turn.
4. Walk back to the chair at your normal pace.
5. Sit down again.
B. On the word **"go,"** begin timing.

Stop timing after the client has sat back down and record:

Time: _____ seconds.

An older adult who takes ≥12 seconds to complete the TUG test is at high risk for falling.

Observe the client's postural stability, gait, stride length, and sway.

Check all that apply: ☐ Slow tentative pace ☐ Loss of balance ☐ Short strides ☐ Little or no arm swing ☐ Steadying self on walls ☐ Shuffling ☐ En bloc turning ☐ Not using assistive device properly

Note: For relevant articles, go to www.cdc.gov/steadi/index.html.

ii. The maximum score of the gait portion of the Tinetti test is 12 points.

c. The maximum score for both the balance and gait tests of the Tinetti combined is 28 points:

i. Scores below 19 are a general indicator of high risk for falls.

ii. Scores between 19 and 24 indicate the client has a risk for falls.

4. The 30-second chair stand test is used to test leg strength and endurance (Exhibit 3.4).

5. Consider a physical therapy and/or an occupational therapy referral for gait and/or balance problems.

EXERCISE

A. Physical activity is a crucial step older adults can take to improve health. Physical activity provides many benefits: preventing muscle and bone loss, reducing the risk of falling and fractures, preventing or delaying conditions including diabetes and heart disease, reducing symptoms of anxiety and depression, and allowing prolonged independence. The second edition of the *Physical Activity Guidelines for Americans* was released in 2018 and provides evidence-based guidance to improve health through physical activity (available at health.gov/sites/default/files/2019-09/Physical_Activity_Guidelines_2nd_edition.pdf). The benefits of physical activity outweigh the possibility of adverse outcomes.

B. The National Center on Health, Physical Activity and Disability (NCHPAD) website (www.nchpad.org/Disability~and~Aging) provides information regarding exercise for clients with disabilities and conditions from acquired brain injury, arthritis, chronic fatigue syndrome, rheumatoid arthritis, and stroke.

C. Preexercise medical evaluation:

1. Before beginning a sports or vigorous exercise program, older adults should undergo screening, emphasizing the detection of cardiovascular risks.

2. When screening is suspicious for clinical pathology, additional testing is performed.

D. Key guidelines for adults 18 to 64 years:

1. Some physical activity is better than none, and adults who participate in any amount of physical activity gain some health benefits. All adults should avoid inactivity.

2. For substantial health benefits, adults should do at least 150 minutes (2 hours and 30 minutes) a week of ▶

EXHIBIT 3.4 The 30-Second Chair Stand Test

Patient: _____ **Date:** _____

Time: _____ **a.m./p.m.**

Purpose: To test leg strength and endurance.

Equipment:

A. A chair with a straight back, without armrests (seat 17-in. high).
B. A stopwatch.

Instructions to the client:

A. Sit in the middle of the chair.
B. Place your hands on the opposite shoulder crossed at the wrists.
C. Keep your feet flat on the floor.
D. Keep your back straight and keep your arms against your chest.
E. On **"go,"** rise to a full standing position and then sit back down again.
F. Repeat this for 30 seconds.

On **"go,"** begin timing.

If the client must use their arms to stand, stop the test. Record **0** for the number and score.

Count the number of times the client comes to a full standing position in 30 seconds.

If the client is over halfway to a standing position when 30 seconds have elapsed, count it as a stand.

Record the number of times the client stands in 30 seconds.

Number: _____ **Score** _____

A below-average score indicates a high risk for falls.

Chair Stand: Below-Average Scores

Age	Male	Female
60–64	<14	<12
65–69	<12	<11
70–74	<12	<10
75–79	<11	<10
80–84	<10	<9
85–89	<8	<8
90–94	<7	<4

Note: For relevant articles, go to www.cdc.gov/steadi/index.html.

moderate-intensity or 75 minutes (1 hour and 15 minutes) a week of vigorous-intensity aerobic activity. Aerobic activity should be performed in episodes of at least 10 minutes and spread throughout the week.

a. Aerobic physical activities intense enough and performed long enough to maintain or improve an individual's cardiovascular fitness include biking slowly, general gardening, using a manual wheelchair, walking briskly, and water aerobics. Vigorous activities are basketball, jumping rope, running, swimming laps, martial arts, and dancing.

b. The talk test can be used to evaluate moderate or vigorous activities. If individuals can talk but not sing, they are participating at a moderate level. If only a few words can be said without stopping to catch a breath, it is considered vigorous activity.

3. For additional and more extensive health benefits, adults should increase their aerobic physical activity to 300 minutes (5 hours) a week of moderate-intensity or 150 minutes a week of vigorous-intensity aerobic physical exercise.

4. For additional benefits, adults should also do muscle-strengthening activities that are of moderate or high intensity and involve all major muscle groups on 2 or more days a week.

E. Key guidelines for older adults:

1. The key guidelines for adults also apply to older adults. In addition, the following guidelines are only for older adults:

a. When older adults cannot do 150 minutes of moderate-intensity aerobic activity a week due to chronic conditions, they should be as physically active as their condition allows.

b. Older adults at risk for falls should do exercises that focus on balance.

c. Older adults with chronic conditions should understand how their conditions affect their ability to do regular physical activity safely.

F. Key messages for people with chronic medical conditions:

1. Adults with chronic conditions obtain important health benefits from regular physical activity.

2. When adults with chronic conditions do activity according to their abilities, physical activity is safe.

3. Adults with chronic conditions and symptoms should consult their healthcare provider about the types and amounts of activity appropriate for them.

G. Key guidelines for adults with disabilities:

1. Adults with disabilities who can should get at least 150 minutes a week of moderate-intensity or 75 minutes a week of vigorous-intensity aerobic activity, or an equivalent combination of moderate- and vigorous-intensity aerobic exercise. Aerobic activity should be performed in episodes of at least 10 minutes, and preferably it should be spread throughout the week.

2. Adults with disabilities who can do so should also do muscle-strengthening activities of moderate or high intensity that involve all major muscle groups on 2 or more days a week as these activities provide additional health benefits.

3. When adults with disabilities cannot meet the guidelines, they should engage in regular physical activity according to their abilities and avoid inactivity.

4. Adults with disabilities should consult their healthcare provider about the appropriate amounts and types of physical activity for their abilities.

5. *How to Exercise If You Have Limited Mobility: Chair Exercises and Fitness Tips for People With Injuries or Disabilities* is available at www.helpguide.org/articles/healthy-living/chair-exercises-and-limited-mobility-fitness.htm.

H. Key guidelines for safe physical activity:

1. To do physical activity safely and reduce the risk of injuries and other adverse events, people should:

a. Understand the risks and be confident that physical activity is safe.

b. Choose to do physical activity appropriate for their fitness level and health goals.

c. Increase physical activity over time whenever more activity is necessary to meet goals. Inactive people should "start low and go slow" by gradually increasing how often and how long activities are done.

d. Protect themselves by using appropriate safety gear and equipment, looking for safe environments, following rules and policies, and making sensible choices about when, where, and how to be active.

FALL ASSESSMENT

A. Among older Americans, falls are the number one cause of injuries and death from injury. Many people who fall, even if they are not injured, become afraid of falling. This fear may cause a person to cut down on their activity and become sedentary, which in turn increases weakness and risk of falls:

1. One in four people age 65 and older fall each year.

2. One out of five falls causes serious injuries such as fractures or traumatic brain injuries (TBIs).

3. Less than half of clients who have fallen talk to their healthcare provider about it.

4. The Centers for Disease Control and Prevention (CDC) also notes the following statistics:

a. Over 95% of hip fractures are caused by falls.

b. Males are more likely to die from a fall.

c. Older adults who fall are more likely to be admitted to a long-term facility for a year or longer.

B. Assess whether the client had some physical feeling precipitating the fall, such as shortness of breath, vertigo, cardiac pain/palpitations, or other signs. Evaluate if other factors, such as alcohol, medicines, and over-the-counter meds, may have been a contributing factor.

1. Did the client lose consciousness? Was the client able to get up independently?

2. What injuries occurred in previous fall(s)?

3. The interaction of multiple risk factors causes most falls. The more risk factors a person has, the greater the risk for falls. Therefore, the clinician's first focus for fall prevention is the evaluation of modifiable intrinsic and extrinsic risk factors (Table 3.2).

4. Client teaching: *See Client Teaching Guide for this chapter, "Safety Issues: Fall Prevention."*

C. The CDC has developed the Stopping Elderly Accidents, Deaths, and Injuries (STEADI) program. STEADI uses established clinical guidelines and strategies to help providers address fall risk and identify modifiable risk factors. The core elements of STEADI include screening older clients for fall risk, assessing their modifiable fall risk factors, and intervening to ▶

TABLE 3.2 INTRINSIC AND EXTRINSIC FALL RISK FACTORS

Intrinsic Risk Factors (Client Conditions)	Extrinsic Risk Factors (Environment)
History of falls (greatest risk factor) **Age >65**	Inappropriate or lack of footwear
Muscle weakness	
Gait and balance problems	
Poor vision/cataracts	Improper use or lack of assistive devices
Postural hypotension	Psychoactive medications
Fear/anxiety associated with falls Dizziness/vertigo/vestibular disorders	Environment: throw rugs, wet floors, slippery or uneven surfaces, cluttered room, lack of stair handrails, poor stair design, lack of bathroom grab bars, dim lighting or glare, obstacles, and tripping hazards (loose cords or wires)
Chronic conditions including stroke, Parkinson disease, depression, dementia, arthritis, osteoporosis, incontinence (urgent trips to the bathroom), diabetes (proprioception from diabetic peripheral neuropathy), and reduced proximal muscle strength and reaction due to vitamin D deficiency	

reduce risk using clinical and community strategies. Information about the STEADI program is located at www.cdc.gov/steadi/index.html. In addition, the CDC's National Center for Injury Prevention and Control (NCIPC) has developed an Algorithm for Fall Risk Assessment and Interventions (see Figure 3.2). The fall risk algorithm is also located at www.cdc.gov/steadi/pdf/STEADI-Algorithm-508.pdf. The *Stay Independent* brochure is found at ocagingservicescollaborative.org/wp-content/uploads/2014/07/Stay-Independent-Fall-Risk-Assessment.pdf. The Fall Risk Checklist (Exhibit 3.5) is one toolkit resource of the CDC NCIPC STEADI program that is available for clinicians.

D. When you see clients 65 and older, make the following three questions a routine part of your exam:

1. Have you fallen in the past year?
2. Do you feel unsteady when standing or walking?
3. Do you worry about falling?

If your clients answer "yes" to any of these key screening questions, they are considered at increased risk of falling. Further assessment is recommended.

PSYCHOLOGICAL WELL-BEING

A. The psychological well-being of aged adults is at risk due to the functional decline and the risk of cognitive defects associated with normal aging or pathology. Depression in adults may present atypically, and aged adults should be screened for depression. Clients should also be screened for changes in cognition and the development of dementia.

AFFECTIVE ASSESSMENT

A. Depression in older adults frequently presents atypically. It may present as apathy and cognitive impairment, disengagement with activities previously found enjoyable, or as weight loss. On the other hand, it may present as simply as adults answering questions they know the answer to as "I don't know." Beyond reductions in functional status and psychological well-being, depression results in a higher risk of suicide, increased use of healthcare services, and increased mortality in the aged adult. There are multiple validated screening tools for depression in the aging adult. Stanford University offers the Mood Assessment Scale and the Geriatric Depression Scale (GDS), both available in various languages.

1. The GDS in multiple languages is located at web.stanford.edu/~yesavage/GDS.html.
2. A web-based version of the GDS is available at www.medafile.com/GDS15.htm, and there are multiple smartphone apps with the GDS available for free.
3. Initial assessment utilizing the five-item version of the GDS can identify those at high risk for depression. This scale can be used rapidly in the office setting with yes/no responses. Two positive of five indicators suggest the full 15-point GDS should be performed.
4. Appropriate referral for psychological counseling and medication management should be considered.

COGNITIVE/DEMENTIA ASSESSMENT

A. Vitamin B_{12} deficiency is a common comorbidity in older clients, and routine assessment of vitamin B_{12} levels in older clients diagnosed with dementia is recommended.

B. Many families voice early concerns about the cognitive changes they see in their older parents and family members. Typical changes that occur with aging compared with the "10 Alzheimer warning signs" are noted in Table 3.3. ▶

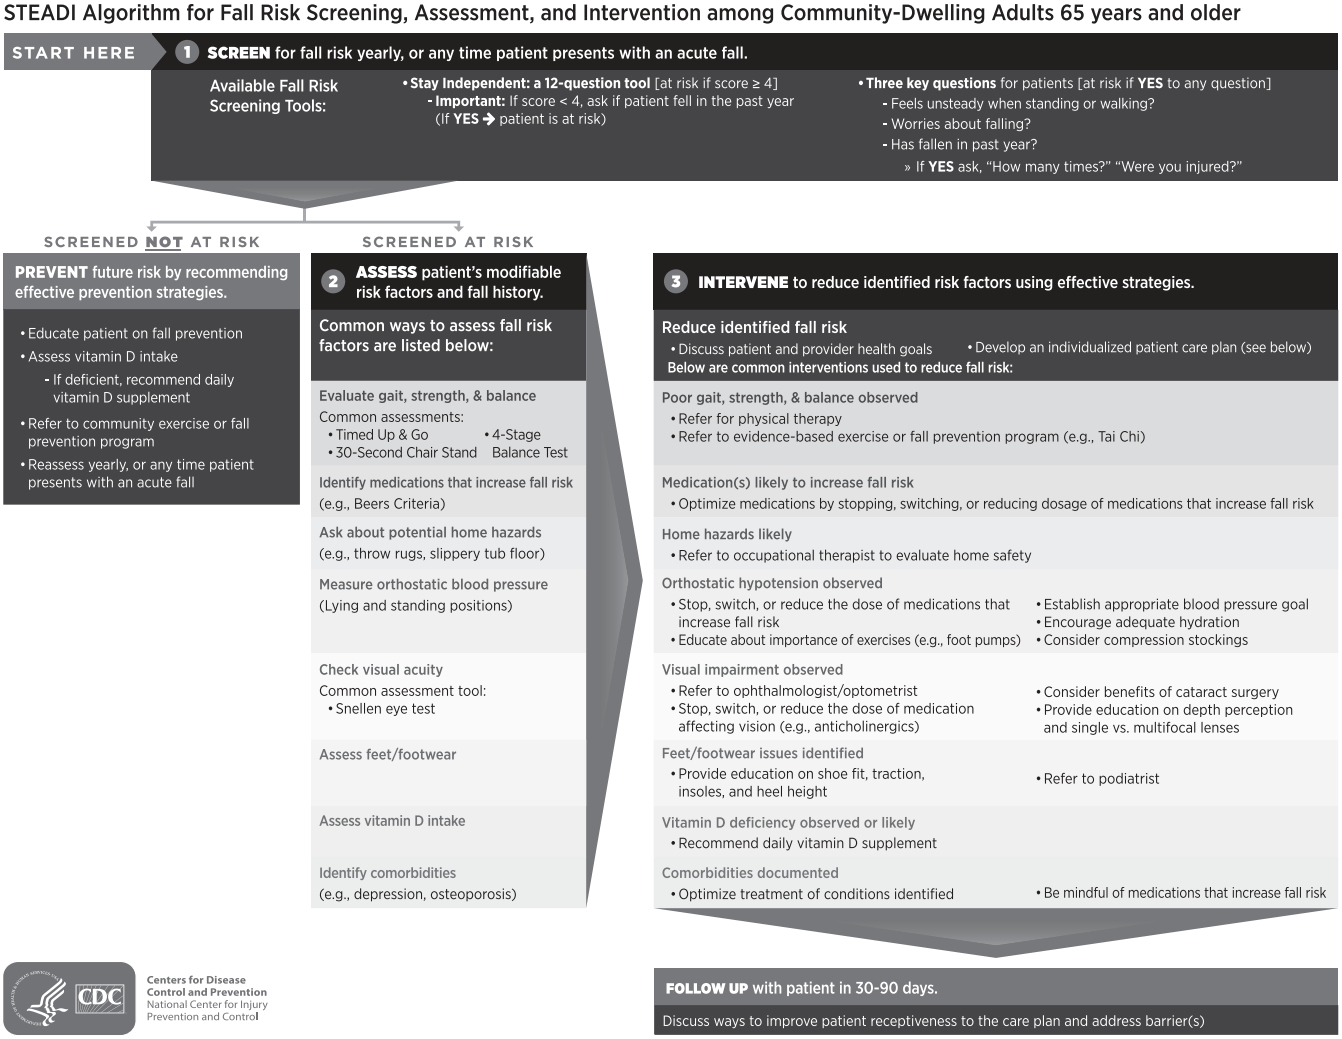

FIGURE 3.2 Centers for Disease Control and Prevention algorithm for fall risk screening, assessment, and intervention. STEADI, Stopping Elderly Accidents, Deaths, and Injuries.

Source: Centers for Disease Control and Prevention. (2019). *The Stay Independent* brochure. https://www.cdc.gov/steadi/pdf/STEADI-Algorithm-508.pdf.

C. Alzheimer disease is the most common form of dementia. Alzheimers.net notes that Alzheimer disease has seven distinct stages. For full descriptions of "What Are the 7 Stages of Alzheimer's Disease?" visit www.alzheimers.net/stages-of-alzheimers-disease.

1. Stage 1: no impairment.
2. Stage 2: very mild decline (losing keys, forgetting familiar names).
3. Stage 3: mild decline (memory and concentration problems).
4. Stage 4: moderate decline (difficulty planning dinner or paying bills on time).
5. Stage 5: moderately severe decline (unable to recall events or remember important dates).
6. Stage 6: severe decline (needs help getting dressed, personality begins to change).
7. Stage 7: very severe decline (trouble eating, swallowing, speaking, and all motor function).

D. There is no "gold standard" tool to evaluate cognitive function and impairment. An initial evaluation provides a baseline for serial surveillance and may also indicate the need for further evaluation. A yearly assessment can determine and identify a gradual decline over time. Assessments that show decline or impairment require further evaluation. The National Institute on Aging notes someone with Alzheimer disease may experience the following symptoms:

1. Getting lost.
2. Trouble handling money and paying bills.
3. Repeating questions.
4. Taking longer to complete routine daily tasks.
5. Poor judgment.
6. Losing things or misplacing them in odd places.
7. Difficulty remembering newly learned information.
8. Unfounded suspicions about family, friends, and professional caregivers.
9. Difficulty speaking, swallowing, and walking.

E. The cognitive assessment does not need to be lengthy. The Memory Impairment Screen (MIS), the General Practitioner Assessment of Cognition (GPCOG), and the Mini-Cog are the most useful in the primary care setting. These assessments require 5 minutes to administer and are very similar. ▶

EXHIBIT 3.5 Fall Risk Checklist

Patient: _____ **Date:** _____

Time: _____ **a.m./p.m.**

Fall Risk Factor Identified	Factor Present?		Notes
Fall history			
Any falls in the past year?	☐ Yes	☐ No	
Worries about falling or feels unsteady when standing or walking?	☐ Yes	☐ No	
Medical conditions			
Problems with heart rate and/or rhythm?	☐ Yes	☐ No	
Cognitive impairment?	☐ Yes	☐ No	
Incontinence?	☐ Yes	☐ No	
Depression?	☐ Yes	☐ No	
Foot problems?	☐ Yes	☐ No	
Other medical conditions (specify)?	☐ Yes	☐ No	
Medications			
Any psychoactive medications, medications with anticholinergic side effects, and/or sedating OTCs (e.g., Benadryl, Tylenol PM)?	☐ Yes	☐ No	
Gait, strength, and balance			
TUG test ≥12 seconds?	☐ Yes	☐ No	
30-second chair stand test below-average score? (See the following table.)	☐ Yes	☐ No	
Four-stage balance test full-tandem stance less than 10 seconds?	☐ Yes	☐ No	
Vision			
Acuity less than 20/40, or no eye exam in more than 1 year?	☐ Yes	☐ No	
Postural hypotension			
A decrease in systolic BP ≥20 mmHg, or a diastolic BP of ≥10 mmHg, or light-headedness or dizziness from lying to standing?	☐ Yes	☐ No	
Other risk factors (specify)

TABLE 3.3 TEN ALZHEIMER WARNING SIGNS

Issue	Common Symptoms of Early-Stage Alzheimer Disease	Typical of Aging
Memory loss	Forgetting new information and asking for the same information over and over	Forgetting names or appointments occasionally and remembering them later
Difficulty performing familiar tasks	Difficulty planning or completing everyday tasks, losing track of steps involved in preparing a meal or making a phone call	Occasionally forgetting why you came into a room or what you were planning to say
New problems with writing or speaking	Forgetting simple words or substituting unusual words, making speech or writing hard to understand	Sometimes having trouble finding the right word
Confusion with time and place	Getting lost in familiar places, forgetting where you are and how you got there, and how to get back home	Forgetting the day of the week or where you are going
Poor or decreased judgment	Dressing inappropriately for the weather, giving away large sums of money to telemarketers	Making a questionable or debatable decision from time to time
Problems with abstract thinking	Unusual difficulty performing complex mental tasks, especially relating to numbers	Finding it challenging to balance a checkbook
Misplacing things and losing the ability to retrace steps	Putting things in unusual, inappropriate places	Misplacing keys or a wallet, but being able to retrace steps to find it later
Changes in mood or behavior	Rapid mood swings, extreme confusion, anxiety, suspiciousness, dependence on a family member	Occasionally feeling sad or moody
Trouble understanding visual images and spatial relationships	Change in visual processing, difficulty reading, judging distance, and determining color or contrast, which may cause problems with driving	Vision changes related to cataracts
Withdrawing from social activities	Avoiding being social due to the changes experienced, becoming passive, sitting in front of the television for hours, sleeping more than usual, or not wanting to perform ADL	Sometimes feeling weary of work or social obligations

ADL, activities of daily living.

TABLE 3.4 SCORING THE MINI-COG ASSESSMENT TEST FOR COGNITIVE IMPAIRMENT

Three recalled words	Negative for cognitive impairment
One to two recalled words + normal CDT	Negative for cognitive impairment
One to two recalled words + abnormal CDT	Positive for cognitive impairment
Zero recalled words	Positive for cognitive impairment

CDT, clock-draw test.

F. The MIS is available on the Alzheimer's Association website at www.alz.org/media/Documents/memory-impairment-screening-mis.pdf; the MIS assessment includes:

1. Evaluation of the client's ability to recall four words: checkers, saucer, telegram, and red cross.

2. If necessary, provide category cue words for any of the four words not recalled freely.

G. The Mini-Cog assessment is a short testing tool used to detect cognitive impairment and the need for further evaluation (Table 3.4). The Mini-Cog assessment tool can be found at the Alzheimer's Association website at www.alz.org/media/Documents/mini-cog.pdf. Administration of the Mini-Cog involves three steps:

1. Ask the client to remember three unrelated words (there are six versions of word lists available). Then, ask the client to repeat the words to ensure understanding.

2. Administer the clock-draw test (CDT). See *Section II: Clock-Draw Test* for a copy of the CDT and instructions.

3. Ask the client to recall the three words from step 1.

H. An interactive program test for the GPCOG is located on the following website: www.gpcog.com.au.

I. The Mini-Mental State Examination (MMSE) or the Folstein test is a useful screening tool for cognitive impairment (available at www.fammed.usouthal.edu/Guides&JobAids/Geriatric/MMSE.pdf). It can be used to classify the severity of cognitive impairment. The 30-item tool takes 5 to ▶

10 minutes to administer. Scores greater than or equal to 24 (out of 30) indicate normal cognition. Below this, mild impairment (19–23 points), moderate impairment (10–18), or severe impairment (≤9 points) can be gauged.

SOCIOENVIRONMENTAL STATUS

A. Although factors associated with the social and environment of the aged person may not heavily impact the medical status of aged adults, they do affect the client's overall health and should be assessed. Social support systems and environmental adaptions often play a prominent role in determining whether the aged adult can stay at home or if other arrangements need to be considered. Assessment of the geriatric client's financial status allows for referral to government assistance programs that may ease the burden of staying home or acquiring assistive services when required.

PHYSICAL ENVIRONMENT

A. Due to functional and cognitive decline, the aged client may be at higher risk of environmental hazards. It is crucial to screen for use of smoke and carbon monoxide detectors. Especially when physical disability is present, assessment for stairs and access ramps is essential. Physical and occupational therapy may provide insight into the need for assistive devices such as grab bars, shower seats, lift chairs, and instructing on removing rugs to prevent falls. Identification of the mode and method of communicating in the case of emergency or accident should be clear, and consideration for a wearable alert device made when needed.

SOCIAL

A. The strength of the social support network may play a significant role in determining the client's independence. For example, identifying who the aged adult may call if assistance is needed with routine tasks is necessary or if they are unable to provide care for themselves. Discussing the social system also allows for identifying friends and loved ones the aged adult enjoys being around. These questions also will enable a transition to discuss healthcare and financial proxies if the senior adult cannot make decisions.

CULTURAL DIVERSITY AND SENSITIVITY

A. Culture is more than nationality or race. It also includes the aged, the illiterate or those lacking education, and persons with physical limitations. Culture influences a person's reasoning, decisions, and actions. It is the accumulation of learned beliefs, values, habits, and practices.

B. Cultural diversity exists when groups of different cultures coexist within an environment. Knowing that cultural differences exist and not assigning values between cultures reflects cultural sensitivity. However, significant differences may exist in how healthcare is perceived and practiced because of the differing values and beliefs regarding health and illness inherent among people of varying cultural backgrounds.

C. Contributing factors to cultural diversity:

1. Increasing immigration.
2. Efficiency in transportation and travel.
3. Increase in the homeless and poor population.
4. Increase in divorce rate and single parenting.
5. Grandparents raising grandchildren.
6. Substance abuse.
7. Violence.
8. Transgender sex changes.
9. LGBT acceptance.
10. Illiteracy.
11. Increase in non-English-proficient healthcare providers.
12. Federal regulations.
13. Physical limitations (disabilities).

D. Cultural sensitivity is the responsibility of all healthcare providers. Each office visit is an opportunity to gain more knowledge about a client's health beliefs and practices. Inadequate awareness of the client's health beliefs could lead to mistrust. This may result in barriers including inappropriate delivery of care, increased cost, and noncompliance, and may eventually lead to more barriers to healthcare access. In addition, those with physical disabilities often have unpleasant experiences with healthcare encounters, affecting their decisions to seek appropriate care. Title VI of the Civil Rights Act is particular about providing services less than the existing standard of care to anyone based on race, age, sex, color, national origin, or financial status.

E. Thoughtful considerations:

1. The provision of care without being sensitive to the needs of a culturally diverse client may suggest that the healthcare provider's values and beliefs are superior to those of the client's and may lead to a disparity in care. Implementing evidence-based guidelines to a culturally diverse population whose healthcare practices are not always based on scientific studies remains a constant challenge. The limited client involvement in care may result in noncompliance, placing clients at greater risk for health-related complications. The delay in the provision of healthcare can result in life-threatening complications.
2. Numerous resources are available throughout the literature and the internet. Preferences for educational/assessment tools are within the healthcare provider's prerogative.
3. The following are guidelines for promoting cultural sensitivity in the clinical setting:
    a. Provide a cultural diversity self-assessment.
        i. Online internet self-assessment tools, for example, the Centers for Disease Control and Prevention website (see the following section).
        ii. Download self-assessment tools from public sources (see the following section).
        iii. Use existing self-assessment tools and make necessary changes to fit the need (Exhibit 3.6).
    b. Identify the need of the population served.
        i. Understand the community and its health status.
        ii. Evaluate resources, attitudes, and barriers inside the communities and practice location.
            1) Access to resources.
            2) Notification of assistance.

3) Range of assistance options:
a) Transportation.
b) Communication; consider an interpreter (personal vs. automation):
i) Identify bilingual staff.
ii) Use a Health Insurance Portability and Accountability Act (HIPAA)-compliant medically trained translation service.
iii) Provide multilingual written materials.
c) Education (meaningful/multilingual).

c. Educate staff to cultural diversities.
i. Assessments should include client's health values and beliefs (Exhibit 3.7).
ii. Communication should be meaningful.
1) Be precise and clear.
2) Use plain language.
3) Observe facial expressions and body language.
4) Use short sentences to explain lengthy information.

d. Schedule longer appointments if needed.
e. Clarify the limitations of healthcare providers.
f. Identify alternatives offered by healthcare providers.

EXHIBIT 3.6 Cultural Diversity and Sensitivity Self-Evaluation Form

Using a scale of 1 to 5, with 1 = never and 5 = always, please answer the following questions:

Question	Response Value
1. I am comfortable with my culture and can compromise on situations without sacrificing my integrity.	
2. I think about what I say and how it may affect people with different beliefs and practices.	
3. I am aware that others may stereotype me, and I am willing to proactively get involved and share my beliefs and practices.	
4. I evaluate what the real reasons are when I encounter a conflict with the aged, the disabled, or persons of a different culture.	
5. I am aware of sensitive issues when I am around women and persons of different beliefs and races.	
6. I ask for clarification when I do not understand what others mean.	
7. I am aware of my assumptions about others who are culturally or racially different than myself and I am okay with it.	
8. I object when others tell ethnic jokes.	
9. I listen without interrupting when someone is speaking.	
10. I am comfortable forming friendships with people of different cultures.	
11. I find ways to learn more about different cultures and how to communicate effectively.	
12. I realize that flexibility and empathy allow me to evaluate persons of different cultures without imposing any judgments, which allows me to collaborate effectively.	
13. I recognize that there are ways other than mine.	
14. I accept people for who they are regardless of color, educational achievement, financial status, age, physical limitations, or gender.	
15. I don't mind apologizing if I have wronged or offended someone.	
16. I respect that others may have a different interpretation of personal space.	
17. I treat people differently than the biases and prejudices of members of my culture.	
18. I do not look down on people who do not speak English fluently or may have an accent.	
19. I understand that there are many ways to communicate.	
20. I use simple and common phrases when around older adults, those with physical limitations, or someone of a different culture who may not speak my language proficiently.	

Add up all of the numbers for a total score.

Total score: outstanding: 95–100; good: 85–94; average: 75–84; needs improvement: 74 or lower.

(This tool is intended for personal use only. It is designed to be performed as a personal self-assessment. No reliable test that measures stability, equivalence, and homogeneity has been done.)

EXHIBIT 3.7 Sample: History Form

Client: Personal, Social, and Family Information

Name _____

Date of birth _____

1. Today's date _____
2. Age _____
3. Gender: M or F. Is your answer to question number 3 based on a transgender sexual change? If no sexual change has taken place, skip questions 4 and 5.
4. Date of procedure _____
5. Type of procedure _____

Medications prescribed _____

_____

_____

Sexual orientation: heterosexual _____ gay/lesbian _____ other _____

Proficient in speaking English YES NO

Proficient in reading English YES NO

Ability to read lips YES NO

Preferred spoken language

_____

Most comfortable language when speaking

_____

Most comfortable language when reading

_____

Preferred greeting Mr. Mrs. Ms. First name

_____

Type of nonverbal communication used

_____

Eye contact

_____

Need of interpreter

_____

Relation to interpreter

_____

Quiet/use of silence

_____

Use and definition of time

_____

Use of any common signs (okay, pain, clapping)

_____

Use of comfort space

_____

Tactile use

_____

Use of cultural jargon or slang that may affect evaluation

_____

_____

Perception of pain

_____

ADVANCED CARE PLANNING

A. The assessment allows a time to review the aged adult's preferences for medical care. The discussion should involve the client's preference for the trajectory of care (e.g., life-sustaining at all costs or prioritizing quality of life and functional independence) and identification of healthcare proxies and surrogate decision-makers. The time may also be used to prepare advance directive documents or provide a referral to services to assist with these tasks. Resources such Prepare for Your Care (www.prepareforyourcare.org) and the Stanford Letter Project (med.stanford.edu/letter.html) may be helpful to the aged adult when preparing for these discussions.

CLIENT TEACHING GUIDE

SAFETY ISSUES: FALL PREVENTION

PROBLEM

A. More than one out of four people 65 years and older fall each year. A review of your home can help prevent falls. Complete a "My Falls-Free" Plan (Table 1) to help you and your caregiver identify problems and the need to have a referral to a specialist.

B. The greatest number of falls occur at night.

C. The most common times falls occur inside the home:

1. Toileting.
2. Walking to the bathroom.
3. Attempting to get out of bed.
4. Rolling out of bed.
5. Transferring from chairs.
6. Walking in the house without using assistive devices (walkers and canes).
7. Walking in hallways.

CAUSES You and your primary care provider should discuss your risk of falling. Most of the time it is a combination of factors that places you at risk for falls.

A. A previous fall makes you at the highest risk for another fall. Tell your healthcare provider if you have ever had any falls.

B. Medical problems that place you at risk for falls include arthritis, dizziness, blood pressure, diabetes, shortness of breath, heart problems, and having to go to the bathroom quickly.

C. Medicines, including over-the-counter medicines and herbals, may interact and cause problems with blood pressure, dizziness, and other side effects, which put you at risk for falls. Ask your health provider or pharmacist to review your medications.

D. Alcohol and use of recreational drugs also increase your risk for falls.

PREVENTION Review of your home to identify items that place you at risk is essential.

A. General home safety review:

1. Walk around each room to see if you have a clear path; move furniture, if needed.
2. Remove clutter.
3. Add side railings on both sides of stairs inside and outside the home.
4. Use nonslip rugs or even remove rugs to prevent tripping. Fix loose and torn carpeting.
5. Increase lighting by using higher watt bulbs and nightlights. Add an overhead light at the top and bottom of the stairway.
6. Wear shoes that fit your feet well and have solid, nonskid soles; wear shoes instead of slippers (and instead of going barefoot).
7. Coil or tape cords and wires next to walls so that you will not trip. Have an electrician put in another outlet.
8. Fix loose or uneven steps.

B. Bathroom safety review:

1. Add grab bars on the inside and outside of the shower and at least one by the toilet.
2. Add a nonslip bath mat in your tub or shower and one right outside the tub or shower.
3. Use a raised toilet seat.
4. Consider the need for a bedside commode.

C. Bedroom safety review:

1. Place a lamp close to the bed so that you do not have to reach it from the edge of the bed.
2. Use a nightlight.
3. Use comforter and blankets instead of long bedspreads that touch the floor.

D. Kitchen safety review:

1. Place bowls, plates, and spices on the lower level of your cabinets in order to get to them safely and easily.
2. Never use a chair instead of a step stool.

E. Other safety tips:

1. Discuss the need for a personal emergency response system.
2. Carry a cell phone in your pocket.
3. Use a shoulder bag, fanny pack, or a backpack purse to leave your hands free.
4. Keep emergency numbers near each phone and posted on the refrigerator.
5. Limit alcohol to one drink a day to help prevent falls.

CLIENT TEACHING GUIDE

SAFETY ISSUES: FALL PREVENTION (*CONTINUED*)

TREATMENT PLAN

A. Discuss the need for an eye examination.
B. Discuss the need for assistive devices such as canes and walkers.
C. Discuss the use of a Vial of Life to identify important information in case of an emergency (www.vialoflife.com/how_to_use_the_vial_of_life).
D. Walk two or three times a week.
E. Do balance and strengthening exercises at least three times a week.

TABLE 1 MY FALLS-FREE PLAN

Name: _____ **Date:** _____
As we grow older, gradual health changes and some medications can cause falls, but many falls can be prevented. Use this to learn what to do to stay active, independent, and falls-free.

Check "Yes" if you experience this (even if only sometimes)	No	Yes	What to do if you checked "Yes"
Have you had any falls in the last 6 months?			• Talk with your doctor(s) about your falls and/or concerns. • Show this checklist to your doctor(s) to help understand and treat your risks, and to protect yourself from falls.
Do you take four or more prescription or over-the-counter medications daily?			• Review your medications with your doctor(s) **and** your pharmacist at each visit, and with each new prescription. • Ask which of your medications can cause drowsiness, dizziness, or weakness as a side effect. • Talk with your doctor about anything that could be a medication side effect or interaction.
Do you have any difficulty walking or standing?			• Tell your doctor(s) if you have any pain, aching, soreness, stiffness, weakness, swelling, or numbness in your legs or feet—**don't ignore** these types of health problems. • Tell your doctor(s) about **any** difficulty walking, to discuss treatment. • Ask your doctor(s) if physical therapy or treatment by a medical specialist would be helpful for your problem.
Do you use a cane, walker, or crutches, or have to hold onto things when you walk?			• Ask your doctor for training from a physical therapist to learn what type of device is best for you and how to safely use it.
Do you have to use your arms to be able to stand up from a chair?			• Ask your doctor for a physical therapy referral to learn exercises to strengthen your leg muscles. • Exercise at least two or three times a week for 30 minutes.
Do you ever feel unsteady on your feet, weak, or dizzy?			• Tell your doctor and ask if treatment by a specialist or physical therapist would help improve your condition. • Review all of your medications with your doctor(s) or pharmacist if you notice **any** of these conditions.
Has it been more than 2 years since you had an eye exam?			• Schedule an eye exam every 2 years to protect your eyesight and your balance.
Has your hearing gotten worse with age, or do your family or friends say you have a hearing problem?			• Schedule a hearing test every 2 years. • If hearing aids are recommended, learn **how** to use them to help protect and restore your hearing, which helps improve and protect your balance.
Do you usually exercise less than 2 days a week (for 30 minutes total each of the days you exercise)?			• Ask your doctor(s) what types of exercise would be good for improving your strength and balance. • Find some activities that you enjoy and people to exercise with 2 or 3 days per week for 30 minutes.

CLIENT TEACHING GUIDE

SAFETY ISSUES: MEDICATION SAFETY

PROBLEM Multiple problems may occur as a result of taking more than two medicines, including drug interactions and side effects. It is very important to ask questions and ask for written instructions to make sure that you understand your medicines.

CAUSES The causes of problems with medications include the following:

A. Not understanding what each prescription is and how to take it.
B. Seeing more than one doctor for different medical conditions.
C. Using more than one pharmacy.
D. Taking some prescription medications with herbal and over-the-counter (OTC) medicines.
E. Mixing other family members' medications with yours.
F. Forgetting if you have taken your medicine and taking it again.
G. Not having a system set up to take medications as prescribed.
H. Taking someone else's medications.
I. Mixing more than one drug in one prescription bottle.
J. Some medicines need to be tapered off instead of just stopping them.

PREVENTION

A. Questions to ask your provider and pharmacist for medicines include the following:
  1. What is the medication for?
  2. What are the side effects of this medicine?
  3. How and when do you take the medication?
  4. What should you do if you miss any medicine?
  5. Can the medicine be taken with food or should it be taken on an empty stomach?
  6. Are there any foods that should not be eaten while on the medicine?
  7. Can the pill be cut in half, crushed, or chewed?
  8. How long should it be taken?
  9. Should this medicine be stored in any special way, like keeping it in the refrigerator?
  10. Is there a generic medicine that costs less?
B. Make a list of all of your medications, including any prescriptions, vitamins, herbal products, and OTC products:
  1. Eye drops, creams, patches, and inhalers are medicines.
  2. OTC products that should be listed include medicines for your bowels, headaches, stomach, and sleep.
  3. Keep your medicine list up to date by adding new medicines, taking off medicines that are no longer taken, and updating your list if the medicine dose changes.
  4. Do not stop medicines just because you feel better.
C. Once or twice a year, take a bag of all of your medications into the office to have your healthcare provider review them.
D. Store medicine in one place instead of multiple medications in the kitchen cabinets/shelves, bedroom, bathroom, and drawers.
E. Lock up your medications in a toolbox to keep them safe and to prevent others from taking your medication. Keep all medication out of reach of children.
F. Do not share medicines with anyone.
G. Keep individual family medicines separated by using a different shelf or basket.
  1. If you need to use inhalers for asthma or other lung problems, use one color basket for fast-acting inhalers and another color basket for the long-acting inhaler medicine.
H. A weekly pill container will prevent you from taking extra doses; have someone help you set up your medicines.
I. Do not mix medicines in one bottle.
J. Medicine that comes in an amber container protects the medicine from light.
K. Before throwing out an old medicine bottle, scratch out or use a marker to make personal information unreadable.
L. Ask the pharmacist how to dispose of unused and old medicines.
M. Throw out outdated medications and those that are no longer taken. The Food and Drug Administration and the White House Office of National Drug Control Policy have developed guidelines for drug disposal.

(*continued*)

From *ADULT-GERONTOLOGY PRACTICE GUIDELINES, Third Edition*. Copyright Springer Publishing Company, LLC. All Rights Reserved.

SAFETY ISSUES: MEDICATION SAFETY (*CONTINUED*)

1. Do not flush medications down the sink or toilet unless there are specific labels on the medication.
   a. Narcotic pain medicine may have instructions to flush it to reduce the danger of unintentional use or overdose.
   b. Fentanyl patches for pain should be folded in half and flushed down the toilet.

2. Use community drug-takeback programs to bring any unused drugs to a central location for proper drug disposal. Often there are designated disposal containers in police stations.

3. If the drug cannot be put down the drain/flushed or taken to a designated disposal, the following steps should be taken:
   a. Remove drugs from the original container and mix with kitty litter, coffee grounds, or other undesirable substances.
   b. Place the mixture in a sealable bag, empty can, or other container to prevent leaking.

CAREGIVER AND END-OF-LIFE ISSUES

Ann McQueen Blair

CAREGIVER SUPPORT ISSUES

A. It is estimated that 20% of the population in the United States will be classified as older adults by the year 2030. According to the Centers for Disease Control and Prevention, in 2018, 51.8% (129 million) of civilian, noninstitutionalized adults had been diagnosed with at least 1 of 10 selected chronic conditions. More specifically, 24.6% (61 million) of adults had one chronic condition and 27.2% (68 million) had ≥2 chronic conditions. Trends indicate that individuals living with chronic illness will increase as the population ages, with an estimated 50% of people 65 years of age or older having three or more chronic illnesses. These comorbid conditions are associated with increased utilization of healthcare services and risk of decreased quality of life (QOL), polypharmacy, adverse reactions, and exacerbations of illness, creating a cycle in which health may decline, care becomes more complex, and the individual can no longer live alone. Trends in healthcare, including shorter hospital stays, fewer geriatric primary care providers, and limited community resources, have negatively impacted the ability of the client to maintain living in the community without caregiver support. Therefore, along with the increase in older adults comes an increase in the number of caregivers for older adults. According to the National Alliance for Caregiving (2020), during the past year, 65.7 million Americans (or 29% of the U.S. adult population involving 31% of all U.S. households) served as family caregivers for an ill or disabled relative. The implication for healthcare providers is that the needs of the client and the caregiver should be met in order to provide optimal health services. The purpose of this section is to identify and define formal and informal caregivers (ICs), review the demographics of caregivers in the United States, examine common caregiver concerns, review assessment of caregiver health and well-being, and identify sources of support.

FORMAL AND INFORMAL CAREGIVERS

A. Caregivers are categorized as formal or informal. Formal caregivers are those who are paid to provide the care to the recipient. Formal caregivers encompass a wide variety of providers and community resources, including primary and specialty medical providers, home health providers, home aides, home companions, social services, and long-term care facilities. It is a myth that most of the care of older adults occurs in long-term care, as most caregiving is provided by informal caregivers (ICs). ICs are family, friends, or volunteers who provide uncompensated care to persons with disease or disability. This care ranges from direct care with activities of daily living (ADL), instrumental activities of daily living (IADL), transportation, household chores, medication administration, and disease management. It is important for APRNs to consider that in the current culture of healthcare the responsibility for disease management has been transferred from healthcare professionals to clients and their ICs. Additionally, one of the most important predictors of successful disease management for elder adults is the well-being of the caregiver; therefore, the needs of the IC must be identified and included in the plan of care.

INFORMAL CAREGIVER DEMOGRAPHICS

A. Informal caregivers (ICs) are a heterogeneous group of individuals who have a wide range of caregiving experiences, needs, and resources. The trend to remember is that caregivers and care recipients are getting older and that the demographics will change as the nation ages.

1. ICs provide care for an average total length of 4.6 years, although 31% of ICs reported providing care for more than 5 years.

2. The span of caregiving responsibility was 6 months to more than 10 years.

3. The average age of IC is 49.2 years and is increasing.

4. More recent estimates include the mean age of caregivers for clients who have chronic obstructive pulmonary disease (COPD), congestive heart failure (CHF), or cancer as 57 years.

5. The majority of ICs are females, and more than 50% of them are working outside of the home.

6. Almost three-fourths of ICs who worked outside of the home reported that caregiving influenced their ▶

The contributions of Carole K. H. Bartoo and Karla Schroeder to this chapter in prior editions are acknowledged here.

performance at their job, including juggling time at work to meet the demands of caregiving, turning down promotions, losing benefits, and early retirement.

7. Most ICs are married (70%), college-educated to some degree (62%), and one-fourth have trouble paying their bills.

8. The average number of hours per week spent on care provision is 20.4 hours, with a range of less than 8 hours to more than 40 hours.

9. Thirty-two percent of caregivers reported that they experienced a high burden of care, 17% reported a decline in their health, and 31% indicated that they experienced a high level of stress associated with caregiving.

10. ICs are non-Hispanic White (72%), African American (13%), Hispanic (2%), and Asian American (2%).

CARE RECIPIENT DEMOGRAPHICS

A. The average age of the care recipient is 69 and is increasing as the population of elders older than the age of 75 continues to increase.

B. Half of the care recipients live in their own home and need assistance with activities of daily living (ADL).

C. In the survey, over three-fourths of the informal caregivers reported that they desired more information from formal caregivers. The topics of interest include:

1. Home safety.

2. Balancing caregiving demands and personal needs.

3. Communication and working with healthcare professionals.

4. End-of-life (EOL) care.

5. Choosing formal caregiving services.

6. More basic information on how to care for their loved one's needs.

D. Interestingly, 30% of the survey recipients said they would turn to their medical provider for this additional information.

INFORMAL CAREGIVER CONCERNS

A. Providing care to a loved one has many benefits. The majority of informal caregivers (ICs) report that they find caregiving meaningful and rewarding; in addition, many report low levels of depression and anxiety and high levels of spiritual well-being. However, this heterogeneous group is also diverse in responses to caregiving. Some ICs do not have a positive experience. Some researchers have found that optimal caregiving outcomes are dependent on the amount of physical, emotional, and mental strain experienced by the IC. The need for ICs is great, and ICs have shown a preference for getting information from their medical providers. Medical providers need to be aware of the potential concerns ICs may have. These concerns include work–life balance, financial concerns, medication management, and caregiver health.

WORK–LIFE BALANCE

A. Caregivers face a monumental task as they are often attempting to provide care to a loved one, understand the disease process and trajectory, manage the healthcare system, and maintain their own life roles. Additional caregiver roles may include social, occupational, and personal domains. Caregivers have work, family, and community obligations, self-care needs, and leisure activity preferences. All of these should be considered when assessing caregiver response to the caregiving role. Many caregivers have stated that their own healthcare is of a less priority than that of the care recipient. Caregiving was associated with increased risk of negative health behaviors. Hoffman and Wallace (2018) proposed that a rationale for the decreased participation in preventive health activities is the demand of providing care and decreased opportunity for health-promoting activities. Therefore, it is important that ICs find balance among the multiple demands not only of life but of caregiving responsibilities.

FINANCIAL IMPLICATIONS

A. The financial implications of caregiving affect both caregivers and their employers. Employers of caregivers have reported decreased productivity due to more time missed and interruptions in workflow. Caregivers report increased expenses, decreased resources, and decreased opportunity for advancement in the workplace.

1. Of forty percent of caregivers report having to use their savings to provide care needed by their loved one.

2. Forty percent of caregivers reported cutting back on discretionary spending, while 38% reported cutting back on necessary spending.

3. Nearly one-third of caregivers report that caregiving is too expensive. Expenses incurred by caregivers include lost time at work, decreased income, and cost of direct care, including transportation, daily needs such as food and supplies, and medical expenditures. The implications of such expenditures are an increased burden for the caregiver and fewer resources for caregiving in the community. Lai (2012) found that financial implications were the largest correlating factor for increased caregiving burden.

CAREGIVER HEALTH

A. Caregiver health is another concern that APRNs should consider when assisting ICs. Hoffman and Wallace (2018) found that caregivers engaged in 28% more serious emotional distress and unhealthy behaviors than their peer noncaregivers and participated in fewer health-promoting activities.

1. Negative health behaviors include cigarette smoking, drinking regular sodas, and eating fast foods. These findings suggest that the stress associated with caregiving may lead to negative health behaviors, and the demand of caregiving may decrease the opportunity for caregivers to attend to their own health needs.

2. Common health-related sequelae of caregiving include decreased sleep quality, fatigue, poor eating habits, and less exercise.

3. Caregivers are also at risk for decreased psychological well-being. Stress, depression, and social isolation are reported by many caregivers.

PROVIDERS' ASSISTANCE WITH THE CAREGIVER

A. APRNs must actively solicit information about the health and well-being of caregivers, the caregiving requirements, and the burden associated with providing care. This conversation should be part of routine client encounters and it can be as easy as asking the question, "Are you a caregiver?"

1. Once the caregiving role has been identified, then APRNs can assess the positive and negative outcomes of caregiving. An integral understanding for the APRN to possess is that the caregiver and care recipient are a unit. The implications are that malfunction of either component in this unit can and likely will lead to poor outcomes.

2. Caregivers often report being inadequately prepared for the caregiving role. A particularly vulnerable time for this preparation is during transitions of care. There is a lack of structure and guidance from the medical community to the caregiver when care is being transitioned from a formal caregiving environment to the informal caregiving environment.

3. Caregivers are often engaged at the point of discharge. Therefore, caregivers are informed of a client's discharge from a facility without planning. Caregivers report frustration and lack of information in providing quality, often technical, care. The high rate of hospital readmission for older adults speaks to this lack of preparation for care provided postdischarge. Caregivers need information, support, and respite. The role of respite for the caregiver or the client needs to be presented when possible.

4. APRNs should seek to engage caregivers by asking about their frustrations, the caregiving demands, and their preparation for providing the needed care. Common caregiver frustrations include:

a. Lack of knowledge on how to access resources.
b. How to provide technical care.
c. How to respond to the care recipient's emotional needs.
d. How to anticipate future needs, including having an "emergency packet" of items to have on hand in case there are transitions of care.

5. The APRN will need to have knowledge of the particular client in order to adequately inform the caregiver. One goal of this assessment is to collaborate with the caregiver in order to respond to care recipient needs, train the caregiver on technical aspects of care, and provide anticipatory guidance for the trajectory of the illness or disease.

6. APRNs should also assess the well-being of the caregiver. There are several tools to assist in assessing the caregiver:

a. Caregivers should be asked about their basic needs, such as sleep, diet, healthcare, and emotional support.
b. Caregivers should be asked about their social support networks and if these social supports are adequate. This assessment can be as simple as asking if the caregiver is receiving adequate support or as complex as administering a measurement tool.
c. Caregivers should be assessed for quality of life (QOL), stress, and depression. QOL and caregiver burden measurement tools are widely available. It is important for APRNs to use this information to plan tailored interventions that will assist caregivers:

i. The five-item Geriatric Depression Scale (GDS) is a quick screening tool to use to evaluate satisfaction with life, boredom, helplessness, wanting to stay in the home instead of social interaction, and feelings of worthlessness. Each answer requires a "Yes/No" response. Further evaluation is recommended for a score of 2 or greater. A copy of the GDS assessment is available for five-item depression screener at sagelink.ca/health-care/hcp-depression/.

ii. An assessment tool such as the Patient Health Questionnaire (PHQ-9) can be used to further evaluate depression. The Likert-scale responses range from no symptoms at all to symptoms nearly every day. A copy of the PHQ-9 is available at www.apa.org/depression-guideline/patient-health-questionnaire.

1) A PHQ-9 total score of 1 to 4 indicates minimal depression.
2) A PHQ-9 total score of 5 to 9 indicates mild depression.
3) A PHQ-9 total score of 10 to 14 indicates moderate depression.
4) A PHQ-9 total score of 15 to 19 indicates moderately severe depression.
5) A PHQ-9 total score of 20 to 27 indicates severe depression.

PROVIDERS' RESPONSE TO CAREGIVER NEEDS

A. One strategy that may prove to be beneficial is for medical providers to be aware of assistive technology that will improve the provision of care.

B. Forty-five percent of informal caregivers (ICs), 45% used technology to facilitate care, including electronic mobility devices, safety alarms, personal electronic health records, and electronic communication with healthcare providers.

C. Another resource that healthcare providers need to identify and promote are healthcare policies and programs that lessen the burdens of providing care. Healthcare policies utilized by ICs included personal tax credit, a voucher program to pay minimum wage for care provided, and respite services. Availability and utilization of these resources vary by states.

CAREGIVER RESOURCES

A. Caregiver resources are becoming more widely available. As Medicare and other reimbursement agencies continue to strive to reduce readmission rates and reduce the cost of care, more attention will be paid to successful interventions that improve the health and well-being of the caregiver and the recipient.

1. Interventions that have been most successful include efforts to address physical, emotional, spiritual, and social domains.

2. Potential community resources include the primary care location, respite services, home aide services, palliative care (PC), social services, and support groups. An emerging service is geriatric care coordination.

3. The primary care location is an often overlooked resource; however, this location is the ideal site for forming the collaborative connection that will serve the caregiver and care recipient. ▶

4. Respite services may be available through care alliances and organizations. Home aide services may be available to assist the care recipient with activities of daily living; many are utilized through local home health agencies.

5. PC is helpful when learning about how to manage symptoms.

6. Social services may be of assistance to determine if local programs such as Meals on Wheels, as well as financial or housing assistance, are appropriate.

7. Support groups are effective for sharing experiences, problem-solving, and building a community of support. There are also several caregiver informational sites accessed on the internet, including the Family Caregiver Alliance (www.caregiver.org) and the National Alliance for Caregiving (www.caregiving.org).

B. Knowing the impact of family and environment is not new to nursing. Nurses have long acknowledged the significant impact of holistic care that includes not only the client but those people and places important to the client. Research about caregiving has been ongoing for decades. The impact, toll, and benefit of caregiving are well-documented. What is changing is that reimbursement for care is dependent on quality measures, and these quality measures will make their way measuring the effectiveness of caregiving. APRNs are poised to expand their role to empowering caregivers by providing knowledge, facilitating respite, and supporting caregivers.

ADVANCE DIRECTIVES

A. Decision-making is an integral concept in healthcare and has ethical roots. The ethical principle of client autonomy should be considered when thinking about the role and value of advance directives. Older adults may face a time in which they are unable to make both financial and healthcare decisions. This inability creates an ethical dilemma for family members and healthcare providers. Advance directives should give insight into what the elder would have chosen if they could still make decisions. The APRN will need to be familiar with state laws and facility regulations concerning advance directives. Families often do not understand that the state of a client's residence tethers the content and formalities of execution of advance directives. The National Hospice and Palliative Care Organization CaringInfo provides free advance directives and instructions for each state. The website link to download an individual state advance directive is www.caringinfo.org/i4a/pages/index.cfm?pageid=3289.

B. Advance directives are formal documents that enable older adults to make decisions about their future healthcare when they are no longer capable of making these decisions. The Patient Self-Determination Act of 1990 required that hospitals and other healthcare facilities provide clients with information on the purpose, execution, and documentation of an advance directive for all clients of the facility. Despite this act, many older adults do not have an advance directive. Barriers to completing an advance directive for older adults include lack of knowledge, fear of burdening family members, and desire to have the healthcare provider initiate the conversation about advance care planning. Barriers for healthcare providers include lack of time during an office visit and discomfort in initiating the conversation about advance care planning.

TYPES OF ADVANCE DIRECTIVES

A. Decision-making:

1. Decision-making includes both financial and healthcare determinations. **Adults are deemed capable of making decisions until they are proven to be incompetent. The determination of competency is a legal one and must be made by a judge.** Concerned parties may petition the court for a conservatorship (financial) or guardianship (healthcare) hearing. The court will then investigate; if the older adult is deemed unable to make decisions, then the court will appoint a conservator or a guardian to make decisions regarding finances, healthcare, or both. **It is important to know the difference between advance directives and conservatorship (guardianship); a primary difference is that the client determines who will be making decisions on their behalf when executing advance directives.** If there is no advance directive and the client is no longer capable of making decisions, then the court may have to decide who will make the decisions for the incapacitated adult.

B. Power of attorney:

1. Financial decisions include paying bills, making purchases, and selling, purchasing, or managing assets. **Healthcare decisions include treatment decisions, end-of-life (EOL) care, obtaining medical records, and many others. A competent adult has the option of creating a power of attorney (POA) or a durable POA for financial and healthcare decisions. The same person can be designated POA for both, or two separate designations can be chosen. For both the POA and the durable POA, the competent adult selects an agent who will make decisions.**

a. The POA is a collaboration between the competent adult and the agent.

i. The client retains the rights to make decisions on their own behalf. If the competent adult is subsequently determined to be incompetent, then the POA is often no longer valid and operational.

ii. If the competent adult created a durable POA and is subsequently determined to be incompetent, then the durable POA is still valid and operational. It is important to note that an agent named in a POA, or durable POA, specifically for healthcare or financial decisions and not both may be limited in their ability to make some decisions. For example, an agent of a financial durable POA may not be able to make healthcare decisions based on this document alone. A specific document for healthcare, or financial, decisions must be executed to name an agent for making decisions. These documents may not be interchangeable.

iii. It is also important to remember that the rights granted to an agent by the POA or durable POA end when the incapacitated adult dies. Therefore, an agent cannot make decisions about assets or obtain medical records for a deceased person. These rights are granted to the person, or agent, named as the executor of the person's estate. ▶

C. Living will:

1. A living will is a document created by a competent adult that specifies what treatment or medical decisions are preferred in the event that the adult becomes unable to make decisions.

a. This document is specific and will likely include preferences for resuscitation, intravenous hydration and nutrition, ventilator support, pain management, and organ donation.

b. The benefit of the document is to assist family members and medical providers in making very difficult decisions by making the wishes of the competent adult known to all parties. However, this document is not always recognized as a legally binding decision.

c. A living will does not name an agent to make healthcare decisions. A healthcare POA may be needed in addition to the living will if the living will is not recognized as a legally binding document.

d. The value of a living will should not be understated. The living will acts as a guide to assist decision-makers when making very challenging and emotionally charged decisions on behalf of the loved one.

D. Do-not-resuscitate orders:

1. A do-not-resuscitate (DNR) order is written by a medical provider in observance of the client's wishes for EOL care. A competent adult, or the agent for an incompetent adult, can make this decision and communicate it to the medical provider. The order is written by the medical provider and communicated to staff to alert all that the person does not wish to have CPR started should their heart or breathing stop. **In the absence of a DNR order, healthcare personnel may be required to start resuscitation efforts. A living will, in which a competent adult has expressed wishes against resuscitation, does not take the place of a written DNR order.**

E. MOST and POLST forms:

1. The Medical Orders for Scope of Treatment (MOST) and the Provider Orders for Life-Sustaining Treatment (POLST) forms are written orders that direct medical care based on the client's wishes. These forms are different from a living will because the MOST form is signed by the medical provider and acts as orders to direct client care. Items included on MOST/POLST forms include CPR, antibiotics, fluid, nutrition, comfort measures, and transfer to hospital if indicated. These forms are specific, created between the provider and the client, and signed by both parties. The benefit of the MOST/POLST forms is that the actions and decisions that the client and their agent have agreed upon are formalized as medical orders.

2. The National POLST Paradigm website with state legislative information is located at polst.org/programs-in-your-state.

3. The MOST and POLST forms are intended to supplement an advance directive.

The MOST and POLST forms should be updated at each transition of care.

RESOURCES FOR CREATING AN ADVANCE DIRECTIVE

A. Once a competent adult has made the decision to execute an advance directive, they may need assistance in creating the documents. Advance directives can be created without legal representation. There are many online resources available, including AARP, CaringInfo.org, and state bar associations or agencies for aging. It is important for competent adults to have a conversation with family members or others who may serve as agents to ensure that the agent is willing and able to execute the decisions of the competent adult. The optimal time for such discussions is before a medical condition threatens to incapacitate a person; however, any discussion is better than none. APRNs can assist their clients by initiating the conversation, answering questions, and providing resources.

OVERCOMING BARRIERS

A. Advance directive barriers can be characterized as barriers to creation of an advance directive and barriers to implementation of the advance directive. Spoelhof and Elliott (2012) described completion barriers as client and provider limitations.

1. Clients may have lack of interest, lack of knowledge, fear of burdening family members, and social isolation. These barriers are aptly addressed by initiating conversations at an early stage, before an illness has occurred. Clients can be approached and asked about their wishes for care should they become incapacitated during a wellness visit, or when discussing screenings for illnesses. This nonthreatening time is well-suited for information sharing.

2. Provider barriers include lack of time, lack of reimbursement, and discomfort with the topic. Hoffman et al. (2012) found that clients desire to have this discussion with healthcare providers. In addition, healthcare providers report greater satisfaction when care is congruent with client wishes.

3. Barriers to implementation include nonspecific language in the advance directive, agent issues, and advance directive accessibility:

a. The language in an advance directive should be specific and include the client's wishes for CPR, fluid, and nutrition.

b. An advance directive is also more useful if it is clear in what is meant by incapacitation, as language can make this a difficult determination. For example, it is much clearer to state that the advance directive takes effect in the event of cardiac arrest rather than in the event of no hope for recovery.

c. Agents will need to know that they have been named as healthcare proxy and to know the wishes of the client.

d. Advance directives, once completed, need to be signed by witnesses, and in some states need to be notarized. It should be easily located: the client, agent, and medical providers should have a copy of all documents. The client should keep copies of their advance directives in an easily obtainable location at their residence.

4. There are strategies to help clients and medical providers in completing the process of discussing, creating, and executing advance directives. Interactive, or group, interventions have been more successful than individual encounters for educating on the value and role of advance directives. Having ongoing discussions about the goals of care once a terminal or progressive illness has occurred is another effective means of educating clients and their healthcare agents. Another strategy is the use of advance directive facilitators to introduce and educate ▶

communities. A Values History form may be helpful in assisting the client to consider their own feelings and initiate conversations with potential healthcare agents. The Values History form was created by the Institute of Public Law and is available online. It is not a substitute for a living will or POA; however, it is a complementary document that examines one's personal beliefs in such a way as to help surrogate decision-makers during challenging and emotional EOL decision-making.

SPECIAL CONSIDERATIONS: TIMING THE ADVANCED CARE PLANNING DISCUSSION

A. Billings and Bernacki (2014) reviewed evidence about the well-timed and executed advanced planning discussion. They found the following as important elements:

1. Determining the client's understanding of their medical condition and, when gaps in understanding are found, helping the client to fill gaps and be able to verbalize their understanding of the condition.

2. Helping a client understand prognosis and clinical options, including an awareness of the trade-offs involved in choices to undergo or forego therapies.

3. Determining/discussing a client's values and goals, and using these to make choices about specific methods of life-sustaining care.

4. Involving, when appropriate, a clinician to make a recommendation based on the client's values, goals, and preferences.

5. Allowing adequate time for reflection, discussion with family, and further consultation regarding decisions made in an advanced planning discussion.

6. Creating careful documentation, conveying decisions to the family, and making decisions to other healthcare practitioners.

7. Revisiting choices regularly, especially as the medical situation changes, on hospital admission or institutional transfer.

PALLIATIVE CARE

A. In the past decade, palliative care (PC) has been in increasing demand. According to a 2010 survey, the estimated gap of available physician palliative or hospice specialists ranged between 6,000 and 18,000 physicians. This creates a need that APRNs will increasing be asked to fulfill.

B. The World Health Organization (WHO) defines PC as an approach that improves the quality of life (QOL) of clients and their families facing the problems associated with life-threatening illness through the prevention and relief of suffering by means of early identification and impeccable assessment and treatment of pain and other problems—physical, psychosocial, and spiritual. PC can be provided along with curative treatment. PC is commonly used in the treatment of cancers, but increasingly it is seen as an important service for other serious, life-limiting medical diagnoses, including renal failure, advanced chronic obstructive pulmonary disease (COPD) and congestive heart failure (CHF), and even dementia. The National Institute on Aging (www.nia.nih.gov/health/what-are-palliative-care-and-hospice-care) encourages care providers to refer older clients for a palliative consult, ideally from the point of diagnosis. If a client's disease has progressed and there are multiple hospitalizations in a year, a PC conversation is warranted and strongly encouraged. Important elements to consider in the discussion include the following:

1. PC may be provided concurrently with curative care.

2. The service can be useful in helping clients and their caregivers understand their choices for medical treatment late in life.

3. Goals of care can be discussed with greater thought and decisions can be disseminated to other key care providers at a time when healthcare needs are not urgent.

4. The topic of end-of-life takes time to be absorbed for both individuals and families and can become more "normalized" in the setting of future planning and discussion.

5. There have been no studies that have shown a decrease in survival from the palliative approach.

6. Medicare, Medicaid, and private insurance policies may cover PC fully or partially. Veterans may be eligible for PC through the Department of Veterans Affairs.

C. Research has shown PC can improve outcomes including:

1. Advance care planning.

2. Greater client and caregiver satisfaction with care.

3. Lower healthcare utilization.

D. Topics that may potentially be improved through quality PC include:

1. Preferred site of death.

2. Client mood.

3. Healthcare expenditures.

4. Caregiver QOL, mood, and burden.

5. Education regarding burdens versus benefits of treatment options.

6. A bridge to facilitate the start of hospice care when the client and their family are ready.

E. Benefits of PC:

1. Anyone with a serious illness or terminal illness can receive PC.

2. No requirement to waive traditional Medicare benefits so the client may pursue continued rehabilitation services.

3. More robust summary of current client status and prognosis.

4. Robust explanation of advance directive creation and updated Medical Orders for Scope of Treatment (MOST)/Provider Orders for Life-Sustaining Treatment (POLST) forms reviewed with family. In addition, the shift of emphasis from length of life to QOL may help in reducing unnecessary testing, reducing polypharmacy, and reducing complexity of care efforts. Coordination of care has the potential to improve through discussion of centralizing care through just one or two providers, reducing the number of specialists involved in care.

F. Timing the PC referral includes the evaluation of the client's risk of mortality. Multiple calculators are available through the ePrognosis website and are divided according to whether the client resides in the community or a nursing home, is hospitalized, or is an outpatient with advanced cancer. Other criteria include age, gender, renal function, ability to perform activities of daily living, and so forth. The ePrognosis website is located at eprognosis.ucsf.edu/calculators.php.

SPECIAL CONSIDERATIONS: HOSPICE CARE

A. Currently, most hospice clients have their costs covered through the Medicare Hospice Benefits. Ross, Sanchez-Reilly, and Healy at the University of Texas Health Science Center at San Antonio developed the Hospice Criteria Card, which provides a summary of care under Medicare eligibility (Appendix 4.1).

1. Criteria for eligibility for hospice under Medicare include the following:

a. Entitled to Part A of Medicare (Hospital Insurance).

b. Certification must specify that the individual's prognosis is for a life expectancy of 6 months or less if the terminal illness runs its normal course in accordance with the Code of Federal Regulation requirement of §418.22—Certification of terminal illness. Eligibility requires the Medicare recipient to accept palliative care instead of curative care, and the client signs a statement choosing hospice care instead of other Medicare-covered treatment for terminal illness and related conditions.

2. Duration of hospice care coverage:

a. An initial 90-day period.

b. A subsequent 90-day period, followed by if needed.

c. An unlimited number of subsequent 60-day periods.

3. Document of a hospice face-to-face (FTF) encounter by a hospice physician or a hospice nurse practitioner.

4. The Medicare Hospice Benefits has four levels of care:

a. Routine hospice care (RHC) is the most common level of hospice and provides core services of the hospice interdisciplinary team provided at the client's place of residence.

b. Continuous home care (CHC) is provided for between 8 and 24 hours to manage pain and other acute medical symptoms and is intended to maintain the terminally ill client at home during a pain or symptom crisis. Greater than 50% of care must be primarily provided by a licensed practical nurse (LPN) or registered nurse (RN). Hospice aide or homemaker service can also be used to cover the needs.

c. General inpatient care (GIP) provides for pain control and other acute symptom management, such as respiratory distress, and for imminent death when the family cannot cope at home.

d. Inpatient respite care (IRC) provides temporary relief to the client's primary caregiver. Respite care can be provided in a hospital, hospice facility, or a long-term care facility.

5. The Hospice Criteria Card outlines the eligibility criteria for a general, nonspecific, terminal illness, cancer, dementia, heart disease, HIV/AIDS, liver disease, pulmonary disease, neurologic disease, renal failure, and stroke or coma.

KEY FACTORS OF CARE IN THE ELDERLY CLIENT AT THE END OF LIFE

A. Clear explanation of the plan of care, client and family wishes, and provision of emotional support are all necessary aspects of care in the elderly client. Many times, adult children caring for parents are also taking care of their long-time partners. This adds a level of personal stress to the already emotionally burdensome situation. The following are foundational points to consider when caring for an elderly client and family at the end of life (EOL).

PHYSICAL COMFORT

A. Proper pain and symptom management: Many times clients are afraid to report pain or other symptoms. Clinicians are afraid to treat elderly clients and to overmedicate; thus, clients do not get adequate pain and symptom management.

B. Decreasing mobility, physical discomfort, and pain may cause difficulty with sitting, standing, and walking. The client may be embarrassed to ask for general assistance in completing activities of daily living (ADL). The more physical mobility decreases, the fewer tasks a person is able to complete independently, and the more the person is dependent on others.

DECISION-MAKING

A. Self-determination, also known as autonomy, respects the moral and legal rights of persons with decisional capacity to determine what will be done with their own person.

B. Respect of wishes: Clinicians may have difficulty respecting the wishes of the client when the family has other wishes.

C. Involvement of family/caregiver: Involve the client, family, and caregiver all together in the decision-making process. It helps for the family and caregivers to hear the client's requests, wishes, and perspective. Many times if the family and caregivers understand and know what the client wants, the decision-making process is much easier for all involved to complete and accept.

D. Clear documentation of goals of care: Guide the client and family through the goals of the care conversation. Clearly document and communicate the goals to the interdisciplinary group, especially consistency of care, and ensure the client and their family are supported in the decisions that have been reached.

EDUCATION

A. Discuss progression of the disease.

B. Explain the reasons for medication use, risk versus benefit, and side effects.

C. Give treatment options: Provide an honest discussion of the risk versus benefit for each treatment option.

D. Identify resources available: Utilize the social worker and case manager on the interdisciplinary team (IDT). There are many community resources available for clients. Understand a client or their family may need resources for food, medication, housing, and caregiver assistance.

E. Keep the education, goals, and plan centered on the client and on the family's goals of care. This centering is very challenging but necessary to build a trusting relationship and validate the individual experience.

EMOTIONAL SUPPORT

A. Understanding relationship dynamics.

B. Social isolation due to the effects of their disease process.

C. Caregiver fatigue.

D. Financial burden.

E. Loss of identity.

INTERDISCIPLINARY COLLABORATIVE PRACTICE

A. The palliative care (PC) IDT may include the clinician, nurse, aide, pharmacist, physical therapist, massage therapist, and nutritionist working as a complementary unit. The IDT works together to address the physical, social, spiritual, and psychological symptoms of clients with serious or life-threatening illness and their families' issues. IDT groups work to improve physical symptoms such as pain, nausea/vomiting, decreased mobility, incontinence, weakness, shortness of breath (SOB), change in body image, and other distressful symptoms. The goal is always focused on improving client and family quality of life (QOL).

B. The IDT team's initial and regular reassessment of psychological status is imperative, along with continued evolution of treatment methods. The IDT team works collaboratively with psychological and psychiatric team members to address depression, anxiety, delirium, and cognitive impairment as they directly impact clients with serious or life-threatening illness. Recognition of the need for continued social assessment and support for the PC client and family includes:

1. Initiating support services in a timely manner.
2. Involving case management in assisting with availability of community services, medication issues, financial concerns, or placement concerns.
3. Involving social workers in assisting with availability of community services, counseling, emotional support, spiritual support, and identifying barriers to care.
4. Utilizing volunteers to provide social interaction and caregiver relief.
5. Recognizing the cultural implications of care are important aspects of the client and family IDT assessment. Each individual has different cultural implications related to their specific care. Components of the cultural assessment include:
    a. Birthplace: What is the person's place of birth and what implication might this have on the client's care?
    b. Ethnic identity.
    c. Community: How does the client relate to their community?
    d. Decision-making: Who is the decision-maker for the individual: self, spouse, another person?
    e. Language of communication: Does language create a barrier? Consider things like eye contact, gender, position, and body language.
    f. Religion or spirituality: How do religion and spirituality specifically affect the individual's plan of care?
    g. Food preferences, prohibitions, or allergies.
    h. Economic situation: Can clients afford medications, food, and caregivers? Financial crisis is a major concern at EOL in the elderly population, of whom many have a fixed income.
    i. Health beliefs and practices regarding death, grief, pain, traditional therapies, care of the body, organ donation, and caregiver specifications.
        i. Does the client believe painful suffering is required?
        ii. Does the female client require a female clinician?
        iii. Is the client "refusing" an amputation of a part of the body (e.g., gangrenous toe) because the body has to remain intact in their culture?
6. Realizing spirituality does not necessarily focus strictly on religion or religious practices but rather promotes an individual's sense of well-being. Collaborative assessment for spiritual distress is completed by the IDT team. Symptoms of spiritual distress include:
    a. Feelings of abandonment.
    b. Anger.
    c. Feelings of betrayal or mistrust.
    d. Despair.
    e. Fear.
    f. Guilt.
    g. Regret.
    h. Sorrow or remorse.
    i. Depression.

▶

7. Enlisting a chaplain as an invaluable resource to help the client focus on spiritual aspects of care, provide support, and allow for a neutral conversation and reminiscence through life's journey, as well as understanding client preference of no chaplain involvement.

PHYSICAL ASPECTS OF CARE

PAIN MANAGEMENT

A. Pain is the most common symptom associated with palliative care (PC). Key concepts of pain management include the subjective nature of pain, an understanding that the symptom may not solely be physical in nature, and knowledge that pain is an experience that greatly affects the whole family unit.

B. The International Association for the Study of Pain (IASP) defines pain as a change to the nervous system and is also reflective of the individual's past pain experiences, making the pain an emotional as well as a physical experience. "Pain is an unpleasant sensory and emotional experience associated with, or resembling that associated with, actual or potential tissue damage" (IASP, 2021). At the end of life (EOL), many individuals have difficulty or are unable to communicate their pain. This occurs for several different reasons, such as delirium, dementia, aphasia, motor weakness, language barriers, and other factors. Clients who cannot verbally express pain may still be having pain and still require treatment. Often these individuals are either not treated or are inadequately managed for pain.

C. The older adult is at risk for inappropriate pain management. It is estimated that between 25% and 45% of older individuals who live in communities do not receive adequate pain management. Research presents several reasons elderly individuals continue to have untreated, undertreated, or unrecognized pain, including an atypical presentation, failure to report, chronic pain, cognitive impairments, lack of clinician knowledge, and fear.

D. Not all pain is treated the same. In order to treat pain appropriately, one must first understand the different types of pain. What follows are different types of pain, with general definitions, and how clients typically describe them.

1. Acute pain:
   a. Identified event/acute injury.
   b. Clinically described as pain lasting less than 1 month.
2. Chronic pain:
   a. The cause of chronic pain may not be easily identified.
   b. Pain persists longer than 1 month.
3. Acute on chronic:
   a. Some pain syndromes consist of chronic pain with acute exacerbations or pain crisis.
4. Nociceptive:
   a. Usually related to damage to bones, soft tissues, or internal organs.
   b. Somatic pain: aching, throbbing.
   c. Visceral pain: squeezing, cramping.
5. Neuropathic:
   a. Usually related to damage of the nervous system.
   b. Complaints of burning, tingling, shooting pain.

E. Substance abuse issues: 70% to 90% of clients with advanced disease experience pain. The American Pain Society (APS) also reports individuals with a pain score of greater than or equal to a "4" on a standard pain scale. This report has great implications for quality of life (QOL). Assessment of pain is imperative. Pain assessment begins with an in-depth history:

1. History:
   a. Identify which drugs the client has already tried, explain whether these were effective, and state what adverse effect resulted from use.
   b. Identify what medication was prescribed and if it is what dose the client is actually taking. Compare the client's information with the family's information. Discrepancies do not always mean noncompliance; there may be a lack of understanding of the medication, financial reasons, fear, or a problem with memory.
   c. Ask the client about over-the-counter (OTC) medications, recreational drugs, alcohol, and herbal products.
   d. Involve the family in conversations. They may have additional or different views/information than that of the client.
   e. Identify what types of cultural influences on pain exist.
   f. Identify the type of pain.
2. Physical assessment of pain:
   a. Identify specific site of pain if possible.
   b. Characteristics of pain: Ask client to describe pain.
   c. Onset: When did the pain begin?
   d. Duration and frequency: How long does it last; how often does the pain occur?
   e. Exacerbating factors: What makes the pain worse?
   f. Associated factors: What symptoms occur with the pain? Examples are anxiety, fear, nausea.
   g. Alleviating factors: What makes the pain better? Examples are rest, medication, relaxation, massage.
   h. Emotional state: Does the client feel frustrated, anxious, fearful, or depressed?
      i. Existential distress: Does the client have spiritual distress? Does the client need to rectify a relationship with a family member?
   i. Nonverbal pain cues:
      i. Vocal complaints: sighs, gasps, moans, groans, cries.
      ii. Facial: grimaces/winces, furrowed brow, narrowed eyes, clenched teeth, tightened lips, jaw dropped or clenched, distorted expressions.
      iii. Restlessness: constant or intermittent shifting of positions, changes in behavior, combativeness, constant hand motion.
   j. Physiologic cues: tachycardia, tachypnea, hypertension, diaphoresis, insomnia, hyperreflexia, nausea, diarrhea, dilated pupils, anorexia, vasoconstriction, cool extremities.
   k. Therapeutic intervention: Treatment of perceived pain is considered a therapeutic intervention. Treat pain before a procedure is initiated; this could be something as general as turning/repositioning or bathing at EOL. Instruct the family or other caregivers about the importance of proper pain management regarding perceived pain.
3. Pharmacology: **Pharmacologic interventions must be tailored to the individual and use the rule "start low and go slow":**
   a. Acetaminophen:
      i. Safest for long-term use in the elderly.
      ii. Good for mild to moderate pain.

▶

iii. May be used in conjunction with opioids: caution that some medications already contain acetaminophen.
iv. Avoid in clients with renal or hepatic insufficiency or alcohol dependence.
v. Maximum daily dose 3000 to 4000 mg in 24 hours.

b. Nonsteroidal anti-inflammatory drugs (NSAIDs):
i. Can be initial therapy for mild to moderate pain.
ii. Adjunct for opioids and nonopioids; when used concurrently, lower doses of opioid may be used.
iii. Useful for treatment of nociceptive pain.
iv. Should be taken in conjunction with food only to prevent risk of ulcer formation.
v. Increased risk of gastrointestinal ulceration, renal dysfunction, and impaired platelet aggregation in long-term use.
vi. Use with caution in clients with history of ulcer disease.
vii. NSAIDs are on the American Geriatrics Society (AGS) Beers criteria for potentially inappropriate medications used in the older adult population (refer to Appendix C, Tables C.1, C.2, and C.4).

c. Opioids:
i. Used for moderate to severe pain.
ii. Begin with morphine, hydromorphone, or oxycodone as these medications are easier to titrate appropriately and have fewer side effects.
iii. Morphine:
1) Clients should be carefully monitored for signs and symptoms of sedation and confusion.
2) Labs should be closely monitored for renal function.
3) Morphine should not be used in clients with renal impairment.
4) Signs of morphine metabolite buildup include sedation, confusion, and respiratory depression. These signs will appear after a few days of therapy; they are not immediate signs. If the signs of metabolite buildup appear, the opioid should be changed.
iv. Hydromorphone:
1) Metabolite buildup leads to myoclonus, hyperalgesia, and seizures.
2) Metabolite buildup is most prevalent in clients with renal failure.
3) Hydromorphone is 1:3 times more potent than morphine.
v. Oxycodone:
1) Is a synthetic opioid.
2) Long-acting and immediate-release preparations are available.
3) Medication is expensive and may be cost prohibitive for some clients.
4) Is 1.5 times more potent than morphine.
vi. Fentanyl:
1) Available in transdermal form, which is useful when clients cannot swallow or have issues with intractable nausea/vomiting.
2) Fever, cachexia, obesity, and ascites will significantly affect absorption of the medication.
3) **Fentanyl is approximately 80 times more potent than morphine. Do not use fentanyl on opioid-naïve clients.**
4) Therapy must be monitored closely, and clear education must be provided to clients and their family.
5) Therapeutic effects do not begin until 12 hours after initiation.
6) When using long-acting transdermal fentanyl, ensure the client has adequate medication and plan for breakthrough pain medication.

4. Nonpharmacologic interventions for pain:
a. When determining a plan of care for pain management, both pharmacologic and nonpharmacologic interventions should be incorporated. The plan of care should be tailored to meet the needs of the client and their family. Nonpharmacologic interventions include:
i. Massage: This can be completed by a family member or a caregiver. This can increase the therapeutic relationship and provide a sense of control for the family.
ii. Acupuncture.
iii. Tai chi.
iv. Distraction: This can be anything that distracts: reading, television something that is enjoyed.
v. Relaxation: Teaching deep-breathing techniques can be very useful for both the client and their family and can be completed together.
vi. Music therapy.
vii. Guided imagery/meditation.

5. Diagnostic testing:
a. Always evaluate whether tests should be done based on the client and family goals.
b. Laboratory data, including complete blood count (CBC) with differential, complete metabolic profile (CMP), and urinalysis labs, are useful as a baseline evaluation.
i. With narcotic use, renal function should be evaluated initially and ongoing.
c. Radiologic testing as indicated only.

6. Differential diagnoses for pain:
a. Infection.
b. Depression.
c. Anxiety.
d. Constipation.

7. Plan:
a. The National Comprehensive Cancer Network (NCCN) has outlined the following goals when assessing and managing pain:
i. Pain will be controlled at an acceptable level for both the client and the family.
ii. Distress caused by pain will be decreased for both the client and the family.
iii. The client will have a sense of control.
iv. QOL will be optimized for both the client and the family.
v. An interdisciplinary care team can be utilized.
vi. Assessment is regular and ongoing.
vii. Identify and address barriers to effective pain management.
viii. For controlled substances, implement a risk management plan.
ix. Refer the client to providers with specialized skills (interdisciplinary team):
1) Primary care.
2) Pain management.
3) Pharmacy for medication management.

▶

4) Physical therapy to promote improved QOL if applicable to goals of care.
5) Occupational therapy to promote improved QOL if applicable to goals of care.
6) Chaplain for existential pain.

SYMPTOM MANAGEMENT

ANXIETY

A. Anxiety is a common symptom and occurs in approximately 70% of individuals in hospice. It is often a predisposing factor to another symptom, such as pain or shortness of breath (SOB).

1. Causes of anxiety:
a. Fear.
b. Pain: current or unresolved.
c. SOB.
d. Past experiences.
e. Situation.
f. Preexisting anxiety disorder.
g. Delirium.
h. Anticipatory grief.
i. Advanced lung disease and periods of hypoxia.
j. Fear of death.
k. Concerns about religious beliefs, spiritual issues, and existential matters.

2. Clinical characteristics:
a. Pathologic anxiety:
i. A "life of its own."
ii. An intensity that exceeds an individual's ability to cope.
iii. Dread or intense worry.
iv. Tension, jitteriness, or restlessness.
v. Treatment nonadherence, social withdrawal, and avoidance.
vi. Inability to cope or relax.
vii. Symptoms complicated and often exacerbated by insomnia, depression, fatigue, gastrointestinal upset, dyspnea, pain, and dysphagia.

3. Assessment:
a. Begin with a complete history. Identify cause of anxiety if possible:
i. Understand client's disease process and progression. Remember anxiety is often complicated by another symptom. Identify disease processes in which symptoms may be present that may produce anxiety: congestive heart failure (CHF), chronic obstructive pulmonary disease (COPD), cancer, and anemia.
ii. Does the client have a history of psychological issues?
iii. Identify keywords during the conversation, such as fear, concern, scared, and worried.
iv. Utilize tools to help assess anxiety, including the four-item Patient Health Questionnaire for Depression and Anxiety (PHQ-4) available at www.oregonpainguidance.org/app/content/uploads/2016/05/PHQ-4.pdf or the Hospital Anxiety and Depression Scale (HADS) at kytinnitustreatment.com/wp-content/uploads/2015/06/HADS-2014.pdf.
v. Be aware that medications such as albuterol and steroids increase anxiety.
vi. Does the client have new symptoms?
vii. What is the client's knowledge of disease process and progression?
viii. Identify the client's previous healthcare and illness experiences, both positive and negative.
ix. Evaluate and understand if there are any patterns of the client's anxiety to determine if there is a cause and effect.
x. Identify the underlying cause of anxiety:
1) Physical symptoms: inability to sit still, jitteriness, depression, restlessness.
2) Emotional symptoms: edginess, feelings of impending doom, terror.
3) Cognitive difficulties: apprehension, dread, fear, obsession, uncertainty, worry.
4) Behavioral problems: avoidance, compulsions, psychomotor agitation, and potential belief of physical suffering caused from client's past behavior.
5) Autonomic symptoms: diaphoresis, diarrhea, nausea, dizziness, tachycardia, or tachypnea.

4. Diagnostic/laboratory tests:
a. Electrolytes, blood cell counts, relevant hormones, and toxicology as indicated.

5. Always evaluate diagnostic testing per the client's and family plan and goals of care.

6. Treatment is based on foundation of the anxiety.

7. Nonpharmacologic treatment is always the first-line treatment for anxiety:
a. Assess and monitor for anxiety.
b. Offer emotional support.
c. Reassure when appropriate.
d. Assess treatment response and side effects frequently.
e. Provide maximum resolution of anxiety as a goal.
f. Educate the client and their family on anxiety and treatments.
g. Provide cognitive behavioral therapy, relaxation, and distraction.
h. Encourage chaplaincy if there are spiritual and existential concerns.
i. Identify the underlying cause, if possible.

8. Pharmacologic treatment for anxiety: Consider the individual client when treating anxiety with medications using the rule "start low and go slow."
a. Lorazepam (Ativan) 0.25 to 0.5 mg two to three times a day scheduled or as needed. Maximum daily dose is 10 mg/d. May produce paradoxical agitation in clients who are elderly, demented, or brain-injured. Useful to try a small test dose first to see how the client will react to the medication. Ativan is short-acting and produces no active metabolites. It is best absorbed when given parenterally.
b. Haloperidol (Haldol) 0.5 to 1.0 mg two to three times a day scheduled or as needed. Useful if client is anxious and is unable to tolerate benzodiazepines. It may produce extrapyramidal symptoms, including akathisia. Consider dosing carefully for cachectic weight. ▶

c. Alprazolam (Xanax) 0.25 mg BID scheduled or as needed. The maximum daily dose of 6 mg/d. The extended-release alprazolam (Xanax XR) dose is 0.5 to 1.0 mg BID.

9. Plan:
a. Complete a detailed history and physical examination.
b. Discern if the cause of anxiety is psychological or physiological.
c. If fear is the cause, provide education and reassurance. Do not ignore. Validate and address the concern so that the client can directly deal with the fear.
d. Treat the underlying illness or symptom.
e. Control both the underlying symptom and the anxiety.
f. Do not assume that anxiety is inevitable and unavoidable.
g. Educate both the client and the family.
h. Ensure that the goals of the client and the family are discussed, clear, and followed.
i. Assess and reassess.

10. Differential diagnoses:
a. Depression.
b. Confusion.
c. Delirium.
d. Dementia.

11. Potential complications:
a. Difficulty making decisions.
b. Confusion.
c. Inability to intake information.
d. Agitation.
e. Difficulty controlling symptoms.

DELIRIUM

A. Delirium can be classified in two different ways: either as hyperactive or agitated delirium, or hypoactive delirium. Delirium is an acute change in the level of arousal. Accompanying characteristics include altered sleep and wake cycles, mumbling speech, memory and attention disturbances, perceptual disturbances often with delusions, and hallucinations:

1. Clinical characteristics:
a. Clouding of consciousness.
b. Altered ability to maintain attention.
c. Impairment of cognitive function.
d. Daytime sleepiness and nighttime agitation or restlessness.
e. Fluctuation of symptoms by the day or hour.

2. A careful review of the client's drug list should be done to identify potentially reversible causes of psychosis and agitation.

3. Physical examination should be performed to evaluate delirium/differentials that may cause delirium that are treatable. Treatment should be considered comfort-related actions.

4. Delirium assessment tool for end of life (EOL): **CHIMBOP:**
a. **C**: Constipation.
b. **H**: Hypovolemia, hypoglycemia.
c. **I**: Infection.
d. **M**: Medication withdrawal or side effects.
e. **B**: Bladder, catheter, bladder outlet obstruction, urinary retention.
f. **O**: Oxygen deficiency.
g. **P**: Pain.

5. Nonpharmacologic treatments:
a. Identify the possible cause of delirium and treat if indicated and part of the plan of care.
b. Establish safe, soothing, quiet environment.
c. Reduce stimuli, specifically at night; lights; sounds; and interactions. If in a hospital or facility setting, combine treatments as much as possible.
d. Ask relatives/friends/visitors to stay by client for comfort or leave to reduce stimuli.
e. Make frequent reminders of time and place to reorient if appropriate.
f. Educate caregivers about delirium, causes, and plan for treatment.

6. Pharmacologic treatments:
a. The agent of choice for most EOL clients with delirium is haloperidol (Haldol):
i. Haldol has a favorable side effect profile and can be administered safely both orally and parenterally.
ii. Starting doses are .5 to 1.0 mg orally or intravenously (IV). Use with caution and base medications on individual client needs.
iii. **BLACK BOX WARNING, which is a strict warning established by the Food and Drug Administration (FDA): Haloperidol is not approved for dementia-related psychosis because of increased mortality in elderly dementia clients on conventional or atypical antipsychotics. Most deaths were caused by cardiovascular or infectious events.**
b. Benzodiazepines should be avoided unless the source of the delirium has been identified as alcohol-sedative drug withdrawal. Benzodiazepines may also be useful when severe agitation is uncontrolled by a neuroleptic medication. Benzodiazepines can cause paradoxical worsening of confusion. The American Geriatrics Society (AGS) Beers criteria notes that benzodiazepines are associated with an increased risk of adverse effects, including an increased risk of cognitive impairment, delirium, falls, and fractures (refer to Appendix C, Tables C.1 and C.2).
c. Chlorpromazine (Thorazine) has also been used for dying clients with terminal delirium and may also be useful as an antiemetic. However, this may have higher incidence of side effects such as sedation and hypotension.
d. Although no drug has been FDA-approved for treating dementia's neuropsychiatric symptoms, atypical antipsychotics including chlorpromazine (Thorazine), olanzapine (Zyprexa), risperidone (Risperdal), and quetiapine (Seroquel) are used off-label to address agitation at EOL and are newer atypical antipsychotics. These medications are useful in the treatment of confusion and may be a drug of choice for clients with Parkinson.
e. **BLACK BOX WARNING: Atypical antipsychotics should not be used for dementia-related behaviors because of the risk versus the benefit profile caused by increased risk of cerebrovascular adverse events including stroke and a greater rate of cognitive decline and mortality** (refer to Appendix C, Table C.1).

7. Diagnostic tests/evaluation:
a. The degree of workup to seek the cause of delirium is determined by understanding the disease trajectory and overall goals of care. ▶

b. Always evaluate for the reversible cause of delirium.
c. Nonpharmacologic treatments should always be used in delirium management.

8. Plan:
a. The most important initial step is to determine the plan and goal of care.
b. Determine the cause of the delirium.
c. Determine if the cause is reversible.
d. Treat the cause if appropriate to the goals of care.
e. Educate and provide nonpharmacologic treatments.
f. Provide proper individualized medications.
g. Provide education and support for client and family.

DYSPNEA OR SHORTNESS OF BREATH

A. Dyspnea is defined as distressing SOB or abnormal breathing and is frequently referred to as a feeling of "breathlessness." Dyspnea is a subjective experience of breathing and is described as one of the most distressful symptoms. It is common in many EOL clients and serious illnesses such as lung disease, stroke, end-stage renal disease, heart disease, dementia, and cancers. Dyspnea can have severe effects on the quality of life (QOL) for both the client and their family.

1. Clinical characteristics:
a. Dyspnea can have a severe effect on functional status, affecting the person's ability to complete activities of daily living (ADL).
b. Breath sounds vary depending on the disease process.
c. Many factors improve or worsen symptoms, notably, pain, anxiety, movement, and rest.
d. Dyspnea is a subjective report and a different experience for each individual.

2. Physical examination: Evaluate for the following:
a. Jugular vein distension (JVD).
b. Bilateral crackles.
c. Respiratory rate and depth.
d. Use of accessory muscles.
e. Pain with respiratory movement.
f. Pursed-lip breathing.
g. Cyanosis.
h. Inability to speak, or only able to speak a few words, and then has to rest to breathe.
i. Heart rate >90.
j. Respiratory rate >22.
k. Restless or nonpurposeful movements, particularly at EOL or with a change in level of alertness.
l. Abdomen moves in on inspirations; can see how hard a client is working to breathe.
m. Accessory muscle use.
n. Rise in clavicles during inspiration.
o. Grunting at end of expiration.
p. Guttural sound.
q. Nasal flaring.
r. A look of fear.
s. Useful dyspnea scale for assessing SOB:
i. A respiratory distress observation scale for clients unable to self-report dyspnea:
1) pubmed.ncbi.nlm.nih.gov/20078243/.
2) homecareinformation.net/handouts/hen/Respiratory_Distress_Observation_Scale.pdf.

3. Common complaints:
a. Suffocation.
b. Inability to breathe.
c. Fear.
d. Impending doom.

4. Other signs and symptoms:
a. Anxiety.
b. Cachexia.
c. Depression.
d. Tachycardia.
e. Pain.

5. Pharmacologic treatment:
a. Medications:
i. Opioids are the first-line treatment for dyspnea. Opioids alter the client's awareness of SOB, which in turn leads to the lessening of suffering.
ii. Benzodiazepines may be used as an adjunct medication if anxiety is present with dyspnea. May also be used when opioid medication is not sufficient to treat the feelings of breathlessness.
iii. In rare cases, palliative sedation may be necessary to relieve the symptoms of dyspnea at the EOL. This is only used when all other treatment options have been exhausted and the client continues to have dyspnea.

6. Nonpharmacologic treatment:
a. Oxygen.
b. Counseling.
c. Pursed-lip breathing.
d. Energy conservation.
e. Elevated head of bed (HOB).
f. Good oral care.
g. Calm, cool, relaxed environment.
h. Movement of cool air with fans.
i. Muscle relaxation.
j. Activity grouping to conserve energy.
k. Small frequent meals to conserve energy.

7. Potential complications:
a. Uncontrolled symptoms.
b. Cyclical process: SOB produces anxiety which increases SOB, which increases anxiety, which increases SOB, and continues in a cyclical motion unless treated appropriately.
c. Infection.
d. Decreased interaction with family and friends, creating isolation and depression.
e. Increased fear or anxiety.

8. Diagnostic testing:
a. Disease process and progression evaluation.
b. X-ray if indicated.
c. Lab work if indicated.

9. Differential diagnoses:
a. COPD exacerbation.
b. Advancement of disease process.
c. Pneumothorax.
d. Anemia.
e. CHF exacerbation.
f. Anxiety.
g. Unresolved pain.
h. EOL process.

10. Plan:
a. Understand and discuss the client's and the family's goals of care.
b. Evaluate history of illness, disease process, and progression.
c. Evaluate cause.
d. Treat cause if indicated relevant to client and family goals and plan of care.
e. Treat symptoms of SOB based on cause.

▶

f. Assess and reassess effectiveness of treatment frequently.
g. Support and educate client and family.
h. Validate and identify SOB as a very distressful symptom.

ANOREXIA/CACHEXIA

A. Anorexia is defined as loss of appetite and is usually accompanied by a decrease in intake. Cachexia is defined as lack of nutrition and wasting. Both anorexia and cachexia are commonly seen in many serious illnesses and EOL processes. Many families find it difficult when a loved one will not or cannot eat and weight loss and muscle wasting continue "even though I'm trying so hard to eat." There are several causes of anorexia and cachexia, including simply not having the energy to take in the required nutrition, lack of appetite, or fullness if taking numerous medications. Lastly, at EOL, appetite naturally decreases and may also be a cause. Investigate the cause of anorexia and cachexia.

1. Common complaints:
a. Nausea.
b. Fatigue.
c. Lack of appetite.
d. Client may feel like they are taking in adequate nutrition when that is not the case. Or the client truly is taking in adequate nutrition and the body is utilizing all of the nutrition and energy for the disease process.
e. Progressive weight loss and muscle wasting.
f. Cachexia is rarely reversible in advanced illness.
g. Cachexia may be caused by metabolic abnormalities.
h. Increases distress for both the client and family.
i. Negatively impacts body image and causes body image disturbances.
j. Constant reminder of the disease process and progression.

2. Causes:
a. Oral/systemic infections.
b. Pain.
c. SOB.
d. Fatigue.
e. Constipation.
f. Nausea/vomiting/diarrhea.
g. Malabsorption.
h. Depression.
i. Medications.

3. Potential complications:
a. Fatigue.
b. Weakness.
c. Increased risk for skin breakdown.
d. Increased risk for falls.
e. Increased risk for infections.
f. Metabolic disturbances.
g. Frailty.
h. Isolation.
i. Client and family distress related to weight loss and lack of intake.

4. Physical assessment:
a. Temporal wasting.
b. Significant weight loss (5%–10% of body mass every month).
c. Decreased intake.
d. Poor skin turgor.
e. Decreased abdominal mass or fat (helpful to measure abdominal girth and track).
f. Decrease in upper arm mass or fat (helpful to measure upper arm circumference and track).

5. Pharmacologic treatment:
a. There is no single pharmacologic intervention effective for cachexia.
b. May be appropriate to try appetite stimulants:
i. Mirtazapine (Remeron) 7.5 mg may enhance appetite. If there is no effect on appetite in 6 to 8 weeks, it should be discontinued.
ii. In clients with dementia, use of Aricept can enhance the ability of some to feed themselves. Withdrawal of Aricept may lead to reduced ability to self-feed and eat at mealtimes.
iii. Megestrol acetate (MA; Megace) is on the AGS Beers list for minimal effect of weight; increased risk of thrombotic events and possible death (refer to Appendix C, Table C.1).
c. Antioxidant polyphenols from plant foods have been used for cancer-related cachexia. Polyphenols are in fresh and cooked plant foods, particularly those with rich colors, including red, purple, and black. Wine is a polyphenol-rich drink. Wine before meals may be helpful in increasing appetite.
d. Other medications used in the treatment of anorexia and cachexia include dronabinol (Marinol), corticosteroids, thalidomide, adenosine triphosphate (ATP), omega 3 fatty acids, tumor necrosis factor (TNF) inhibitor, or oxandrolone (Oxandrin).
e. In some cases, parenteral or enteral nutrition may be useful in clients who cannot swallow. However, consider risks versus benefits and each individual client, disease process, and progression. Evaluate the client and family goals and plan of care for cachexia and support these decisions.

6. Nonpharmacologic treatments:
a. Educate the client and family concerning causes of cachexia.
b. Eat small frequent meals.
c. Encourage client to eat foods that they enjoy.
d. Eat foods that are easy to chew with sauces.
e. Eliminate dietary restrictions.
f. Encourage high-calorie foods; nutritional supplements may be useful as tolerated.

7. Plan:
a. Overall, when caring for a seriously ill or EOL individual, the problem of anorexia or cachexia may be one of the most distressing to the client or the family. Eating has many emotional ties; provide support and reassurance to both client and family.
b. Constant evaluation and appropriate support and guidance are necessary.
c. Assess and reassess nutritional status.
d. Determine client and family goals and support realistic decisions.
e. Educate client and family on risk versus benefit.
f. Utilize interdisciplinary team (IDT); consult a nutritionist if appropriate.
g. Consider caloric counts.
h. Educate the client and the family about anorexia and cachexia. It is important to listen to their concerns and validate in a respectful manner. Explain that an increase in calories does not always equate with weight gain or client improvement.

▶

i. Consider palliative or hospice referral; anorexia and cachexia in serious illness are associated with decreased survival.

8. Diagnostic tests/evaluation:

a. Weigh the client standing or use a bed scale available for those who are bed-bound.

b. Measure arm/abdominal circumferences; this is particularly helpful for clients who cannot be weighed easily. Track the client's weight measurements.

c. Evaluate electrolytes as indicated.

d. Serum albumin decreases as nutritional status declines and also has a poor prognosis.

9. Special considerations:

a. Aggressive nutritional treatments in advanced illness may cause more harm than benefit due to refeeding syndrome. Refeeding syndrome is the potentially fatal shifts in fluids and electrolytes that may occur in malnourished clients receiving parenteral or enteral refeeding. High-risk clients include those who have been chronically undernourished, especially those who have diminished physiologic reserve. Seriously consider risk versus benefit before initiating aggressive nutritional treatments. The American Society for Parenteral and Enteral Nutrition (ASPEN) has clinical guidelines on their Guidelines and Clinical Resources available at aspenjournals.onlinelibrary.wiley.com/doi/10.1002/jpen.1669.

CONSTIPATION

A. Constipation is defined as the infrequent passage of stool. **The key to constipation in palliative care (PC) is prevention. Clients who are started on opioids should always have a bowel plan in place. If prevention of constipation is not treated seriously, it can lead to more complicated problems such as a preventable bowel obstruction:**

1. Common complaints:

a. Rectal pressure.

b. Straining.

c. Cramps/abdominal distension/low back pain.

d. Nausea.

e. Fullness.

2. Causes:

a. Medications:

i. Opioids.

ii. Antidepressants.

iii. Antacids.

iv. Chemotherapy.

v. Overuse of bowel stimulants.

b. Obstructive tumor.

c. Neurologic disorders.

d. Decreased or no activity.

e. Hypercalcemia/hypokalemia.

f. Spinal cord compression.

g. Surgical adhesions.

h. Dehydration.

i. Weakness.

j. Pain.

k. Depression.

3. Assessment of constipation:

a. History:

i. Characteristics of stool, appearance, and consistency.

ii. Frequency of stool.

iii. History of use of bowel medication.

iv. Fluid intake.

v. Anorexia.

vi. Presence of nausea and/or vomiting.

vii. Review all medications, including over-the-counter (OTC) and herbal products.

b. Physical assessment:

i. Inspect, auscultate, palpate, and percuss the abdomen to evaluate the presence of:

1) Bowel sounds: hyperactive, hypoactive, absent.

2) Bloating.

3) Ascites.

4) Distension.

5) Masses.

6) Pain and tenderness.

ii. Digital rectal examination:

1) Avoid in neutropenic clients.

2) Digital examination may reveal impaction, tumor, or rectocele.

3) Visual examination of the rectal area may reveal hemorrhoids, ulcerations, rectal fissures, or skin breakdown, which all make defecation painful.

4. Diagnostic tests:

a. Abdominal x-ray to rule out obstruction.

5. Differential diagnosis:

a. Obstruction.

6. Plan:

a. Written bowel plans for all clients on opioids are necessary because of constipation.

b. Prophylactic stool softeners should be used as indicated.

c. Bowel elimination should occur no less than every 3 days regardless of intake.

d. Assess and reassess.

e. Check for impaction and obstruction.

f. Educate the client and the family on constipation/bowel plan.

7. Individual/special considerations:

a. May be very embarrassing for client to address bowel problems; consider privacy, and address the issue respectfully.

b. Encourage client and/or family to discuss openly and report problems or issues/patterns in bowel elimination and output.

NAUSEA AND VOMITING

A. Nausea is a feeling and will be a subjective report, whereas vomiting will be visible with objective information. Nausea and vomiting (N&V) occurs in up to 70% of terminally ill individuals. N&V has negative effects on QOL, causing weight loss, electrolyte disturbances, isolation, frustration, anxiety, and many other associated symptoms.

B. It is important to remember that psychological or emotional factors can also cause N&V, stimulating the emetic receptors in the brain. The clinician must understand the type of N&V to treat it correctly:

1. Causes:

a. Physiologic:

i. Gastric irritation, constipation, intestinal obstruction.

ii. Liver failure, ascites.

iii. Autonomic dysfunction.

iv. Anxiety: increases gastric acid production. ▶

v. Specific treatments such as radiation, chemotherapy, or medications.
vi. Infection.
vii. Metabolic abnormalities such as renal failure or hepatic failure.
viii. Increased intracranial pressure.
ix. Vestibular disturbances.

2. Clinical characteristics and pharmacologic treatments:
a. Chemoreceptor trigger zone-based N&V:
i. Stimulated by chemotherapeutic agents.
ii. Bacterial toxins caused by infection or viruses.
iii. Metabolic products such as uremia, hypercalcemia, and infection.
iv. Opioids.
v. Radiation therapy-induced nausea.
vi. Pharmacologic: First-line treatment for chemoreceptor trigger zone N&V is a dopamine antagonist such as Phenergan or Compazine and sometimes Haldol.
b. Cerebral cortex-based N&V:
i. Anxiety.
ii. Taste.
iii. Smell.
iv. Anticipatory nausea.
v. Increased intracranial pressure.
vi. Pharmacologic: The first-line treatment for cerebral cortex N&V is administration of anxiolytics such as lorazepam or hydroxyzine.
c. Vestibular-based N&V:
i. Motion.
ii. Opioids that sensitize the vestibular center.
iii. Pharmacologic: First-line treatment for vestibular N&V involves antihistamines and anticholinergics.
d. Gastrointestinal tract-based N&V:
i. Gastric stasis or obstruction.
ii. Medications.
iii. Metastatic process.
iv. Infection.
v. Treatments.
vi. Pharmacologic treatment for gastrointestinal tract N&V: First-line treatment for gastric stasis is generic metoclopramide. Ondansetron is also useful in the treatment of N&V.

3. Assessment:
a. Obtain a thorough history that includes clear information so that the clinician can identify what type of N&V the client is exhibiting. Much like assessment for pain, the clinician has to ask many questions to properly assess the symptom of N&V.
i. What is the consistency of the emesis?
ii. What is the intensity—wrenching, belching acid?
iii. Does anything make it better or worse?
iv. How often does nausea and/or vomiting occur? Are there any patterns? It may help to have the client or family keep a symptom diary.
v. How much is the client vomiting?
vi. Are there symptoms or factors that accompany the N&V, such as dizziness or low blood sugar? Does it occur when taking medication or eating/smelling certain foods?
vii. Evaluate for constipation, impaction, or obstruction.
viii. Evaluate for uncontrolled pain, infection, or other processes.
ix. Does the client have anxiety or other emotional or existential concerns leading to N&V?

4. Diagnostic tests:
a. Labs to consider:
i. Renal and liver function tests.
ii. Electrolytes: Assess for dehydration.
iii. Urinalysis: Assess for infection.
iv. X-ray of abdomen: Check for bowel obstruction.
v. CT of head: Assess for brain metastasis.

5. Nonpharmacologic treatments for N&V:
a. Educate the client and the family to treat nausea as soon as symptoms start.
b. Teach relaxation techniques.
c. Acupuncture and acupressure techniques may be helpful.
d. Recommend music therapy.
e. Teach families and care providers about meals:
i. Serve meals at room temperature with clear fluids.
ii. Identify and avoid strong smells.
iii. Avoid large high-bulk meals; instead, eat small, frequent meals.
iv. Position the client in an upright position during meals.
v. While preparing meals, the client should avoid close proximity to the food preparation area/kitchen.
f. At times a nasogastric tube may be needed for intractable nausea and/or vomiting or unrelieved abdominal pressure to alleviate symptoms.

6. Plan for N&V control:
a. Identify the cause and type of N&V.
b. Assess and reassess the client as necessary.
c. Identify client and family goals and plan of care.
d. Provide pharmacologic interventions.
e. Educate the client and the family about nonpharmacologic interventions.

XEROSTOMIA

A. Xerostomia is defined as dry mouth, together with difficulty in mastication, swallowing, and speech. Xerostomia occurs in up to 97% of clients at EOL and greatly impairs QOL; it can be distressing to the client and family members. Management is primarily nonpharmacologic and can be completed by educating family and caregivers. This management provides families and caregivers with a means of control to "do" something, often when the individual is feeling helpless at EOL. Oral care can be a method of bonding or of resolution and is a very important aspect of client care.

1. Causes:
a. Medications:
i. Anticholinergics.
ii. Opioids.
iii. Diuretics.
b. Radiation.
c. Systemic disease.
d. Oxygen.

2. Management:
a. Identify and, if possible, correct the underlying cause.
b. Educate the client and the family on providing proper and frequent oral care. ▶

i. Brushing teeth.
ii. Cleaning tongue and lips.
iii. Keeping the mouth and lips moist.

c. Offer frequent sips of liquid, if appropriate, or frequent mouth moistening if the client cannot swallow.
d. If appropriate, soft moist foods can be offered.
e. If client is able, suggest chewing sugarless gum, use of lubricating sprays, and lozenges.
f. Maintain humidity in the room.
g. Humidify oxygen.
h. Oral care should continue even if the client is unresponsive.

3. Plan:
a. Assess for signs and symptoms of xerostomia.
b. Identify cause and correct if possible.
c. Educate client, family, and caregivers regarding proper oral care.
d. Assess and reassess as needed.

FATIGUE

A. Fatigue, or a feeling of weariness, has been reported to occur in up to 90% of cancer clients. Fatigue is also linked to many other serious illnesses such as COPD, CHF, coronary artery disease (CAD), HIV/AIDS, and advanced renal disease. Much of the treatment for fatigue is nonpharmacologic and requires the clinician to educate the client and the family. Proper assessment to determine the cause of fatigue is imperative.

1. Causes:
a. Disease states such as anemia, electrolyte imbalances, malnutrition, infection, hyperglycemia, fever, pain, organ failure, hypoxia.
b. Depression.
c. Inactivity and immobility.
d. Inadequate rest.
e. Unrelieved symptoms.
f. Medications.
g. Radiation/chemotherapy/immunotherapy.
h. Spiritual distress.

2. Assessment:
a. Obtain an adequate history by asking questions to acquire both subjective and objective information.
i. How do you feel? Are you feeling weak, tired, wiped out?
ii. How long does the fatigue last? Can you see a pattern?
iii. Have you noticed anything that makes the fatigue better or worse?
iv. Have you noticed if any of the medications or treatments make the fatigue better or worse?
v. Do you feel anxious or depressed?
vi. Do you find it difficult to concentrate?
vii. Tell me how fatigue is affecting your daily life.
viii. Walk me through a typical day.
ix. Tell me how you sleep and what that is like for you.

b. Monitor vital signs, assessing for fever, increased heart rate, weak pulse, and increased respiratory rate.
c. Assess as the client moves and talks; notice if the individual gets short of breath with very simple tasks (stating a few words, standing, walking a few steps, transferring sitting to standing).
d. Evaluate hydration status.
e. Evaluate muscle status, muscle wasting, muscle strength, and endurance.
f. Evaluate medications: Are there medications that cause sedation and fatigue? Can this be changed; if not, can the time be changed to be taken at bedtime? If not, can the client and family be instructed on how to group tasks when awake?

3. Diagnostic testing:
a. Oxygenation status hemoglobin (Hgb), complete blood count (CBC), and differential.
b. Thyroid function.
c. Electrolytes.

4. Treatments:
a. Provide assistance that will help the individual to maintain independence and functional abilities as long as possible, such as physical therapy and occupational therapy.
b. Initiate therapy as appropriate and in alignment with client goals and plan of care, such as transfusions, oxygen, and IV fluids.

5. Plan:
a. Assess for signs and symptoms of fatigue.
b. Educate client and family regarding frequent rest periods and grouping activities as much as possible in efforts to conserve energy.
c. Work with IDT to provide individualized care in efforts to maintain independence and functional ability.
d. Provide support; suggest home health or hospice aide as appropriate.
e. Assess and reassess for fatigue.

DEPRESSION

A. Depression is noted in many serious illnesses and has been reported in up to 50% of clients in the setting. The National Cancer Institute notes that, although both depression and anxiety have been frequently reported as comorbid factors in chronic medical conditions, depression is often unrecognized, undertreated, or altogether untreated. Symptoms of depression and anxiety are usually responsive to treatment, and early recognition, assessment, and diagnosis is important to improve outcomes. The client, family, and clinician should understand that depression and suicidal ideation are not normal at EOL and that symptoms should be aggressively treated.

1. Clinical characteristics:
a. Persistent feelings of helplessness, hopelessness, or inadequacy.
b. Disease-related causes of depression include:
i. Uncontrolled symptoms such as pain, anorexia, and N&V.
ii. Sleep disturbances.
iii. Sepsis, abnormal metabolic states, delirium, organic mental disorders, medication reactions.
c. Psychological issues that may lead to depression:
i. Existential factors such as fear, loss of independence, loss of control, body image disturbance, impending death.
ii. History of preexisting psychological conditions.

2. Medications:
a. Antihypertensives, analgesics, steroids, hypoglycemics, chemotherapeutics, benzodiazepines, and others.
b. Treatments such as radiation.

3. Individual situations increase the chance of depression: ▶

a. Financial, social, safety, or other issues can increase the chances of depression.
b. Assess and utilize the IDT.

4. Assessment: It may be difficult to assess for depression. Evaluate the client about mood, fear, social withdrawal, and emotional status, including:
a. Complaints of lack of appetite and weight loss with unclear cause.
b. Insomnia.
c. Decreased sexual interest.
d. Decreased interest in activities usually found pleasurable, such as reading, television, and games.
e. Feelings of helplessness and/or hopelessness.
f. Psychomotor agitation.
g. Fatigue and/or a complaint of diminished energy.
h. Ask direct questions when assessing for depression.
i. Are you depressed?
ii. How would you describe your mood?
iii. How are you sleeping?
iv. What is your energy level?
v. What do you see in your future?
1) **Ask: "Have you had thoughts of harming yourself?" The client may need immediate evaluation by a psychiatric professional if they have a lethal, precise suicide plan and the ability to carry out the plan.**

5. Pharmacologic treatment:
a. The first-line medications for treating depression are selective serotonin reuptake inhibitors (SSRIs) such as fluoxetine, paroxetine, sertraline, or citalopram.
i. Geriatric consideration: Citalopram has been best studied for safety in older adults with cardiac problems.
ii. Prozac and other SSRIs can be linked with anorexia and difficulty sleeping.
b. Other medications that may be used to treat depression include:
i. Tricyclic antidepressants such as amitriptyline. However, nortriptyline should not be used if the client has suicidal ideation.

6. Nonpharmacologic treatment measures for depression:
a. Provide mechanisms for the client to remain in control and to maintain autonomy and independence for as long as possible.
b. Encourage reminiscing, promote focusing on life's accomplishments, and help with EOL resolutions and closure with family.
c. Provide anticipatory grief counseling.
d. Provide adequate symptom relief.
e. Use cognitive behavioral techniques.

7. Plan:
a. Assess for signs and symptoms of depression.
b. Understand client diagnosis, prognosis, progression, goals, and plan of care.
c. Have clear conversation with client and family.
d. Identify depression early.
e. Treat depression appropriately, know client's history of major depressive episodes.
f. Incorporate nonpharmacologic methods and utilize IDT.
g. Educate and provide supportive relationship for client and family.
h. Ensure client safety.
i. Assess and reassess frequently.

SOCIAL ASPECTS OF CARE

A. Access to care:

1. Managing multiple chronic illnesses and disabilities is challenging in the elderly population, who require more extensive and in-depth care from providers.

2. Elderly clients require more assistance from caregivers and/or family members.

3. Care for the elderly is often episodic and unplanned. This pattern for chronic and serious illnesses causes clients to access care such as the ED. Episodic treatment in the ED is inadequate without a discharge plan. The lack of a comprehensive functional assessment during an ED visit places the elder client at risk.

4. Fragmented care puts the elder client at risk for errors caused by polypharmacy, falls, functional decline, untreated symptoms, and increased or undertreated pain and institutionalization. Using an interdisciplinary team (IDT):
a. Coordinates care and assists with follow-up care and consistency of care.
b. Reduces fragmentation of care.
c. Contains cost of care.
d. Reduces risk of polypharmacy as care is coordinated.
e. Clients who receive appropriate follow-up care have improved quality of life, receive proper education, experience fewer hospitalizations, have lower costs, and experience less client and family stress.

5. Other specific considerations when caring for elderly clients in palliative care (PC):
   a. Elderly clients need extensive family and caregiver support and care.
   b. Clients make increased demands on family and caregivers when they lose the ability to drive.
   c. As disease progresses, activities of daily living (ADL) become progressively more difficult to complete and require significant assistance from others.

6. Special considerations for client and family feelings:
   a. Older spouses may be taking care of their ill older spouses.
   b. Both the client and the family may have feelings of helplessness; they need education on tasks that can be completed, giving them a sense of control.
   c. Children and their parents experience emotional difficulty with role reversal, such as bathing their elderly parent when they are no longer able to perform general grooming activities.
   d. Feelings of resentment and/or guilt as well as depression, anxiety, and frustration may be exhibited.

B. Financial concerns:

1. Many older adults are on a fixed income, with medication expenses accounting for a significant portion of their income.

2. Older adults may have limited supplemental insurance and be unable to remain in their own homes as their disease progresses and costs rise.

3. Client and family may have lack of understanding of insurance and supplemental insurance use as situations and level of care change.

4. Placement in residential care in the last days of life may require dissolution of all assets.

BIBLIOGRAPHY

Boersma, P., Black, L. I., & Ward, B. W. (2020). Prevalence of multiple chronic conditions among US adults, 2018. *Preventing Chronic Disease*, *17*, 200130. https://doi.org/http://dx.doi.org/10.5888/pcd17.200130

SPIRITUAL, RELIGIOUS, CULTURAL, AND EXISTENTIAL ASPECTS

A. Culture greatly influences how a person and the family respond to an illness or crisis and how decisions are made within the situation. Completion of a cultural assessment is a crucial piece of client and family care. This assessment addresses many facets of a person's life and how it affects the view of life, illness, interactions, quality of life (QOL), and death. Culture includes the whole person and how that individual identifies with ethnicity, race, age, national origin, gender, religion, marital status, family, sexual orientation, professional role, current residence, community role, economic status, and educational status. This assessment shows the client and family that their culture, beliefs, and practices are important and valid.

1. Identify who the major support person or people are.

2. Identify who the decision-makers are.

3. What is the primary or preferred language? Are there language barriers to care?

4. Is it appropriate to make eye contact, touch?

5. Are there gender issues associated with communication or care/providers?

6. Ask about religion or spirituality and how they may affect care.

7. Are there specific nutritional restrictions or specific religious observations?

8. Understand the individual's economic situation. This question can be uncomfortable to ask, however, for it directly affects access to care, medications, safety, living situation, family unit, and other aspects of care.

9. Ask about health and illness beliefs and practices, traditions, routines, and rituals.

10. What types of past experiences has the individual and family had?

11. What do the client/family know about the disease, prognosis, and progression?

12. What are the beliefs and practices about pain and suffering?

13. Ask about traditional therapies, herbal medications, integrative health remedies, and other therapies:
   a. Make sure to address and include traditional therapy when able and appropriate as they are a very important part of client- and family-centered care.
   b. Clients/families may not inform clinicians if they do not believe these practices will be taken seriously or included in the plan of care.
   c. Some herbal treatments can interact with medications.
   d. Traditional therapies are often mistaken, misinterpreted, or translated as noncompliance.

14. To ensure dignity and respect, discuss care of the client's body as death approaches.

15. How do the client and the family view organ donation?

SPIRITUALITY AND RELIGION

A. Spirituality can be of value even to those who do not consider themselves religious. Spirituality provides a means to forgive and to ask for forgiveness. Religion encompasses beliefs and rituals, and includes the importance of prayer, ceremonies, and other traditions.

1. Spiritual assessment: Dr. Christina Puchalski developed the **FICA** spiritual assessment as a tool to evaluate the importance of the client's personal faith and belief system as a guide for discussion (smhs.gwu.edu/spirituality-health/sites/spirituality-health/files/FICA-Tool-PDF-ADA.pdf):
   a. **F**aith and belief.
   b. **I**mportance.
   c. **C**ommunity.
   d. **A**ddress in care.

2. Spiritual symptoms of distress: Spiritual distress often presents as many different symptoms. Often the chaplain from the interdisciplinary team (IDT) can be consulted to assist; other times, education, listening, or just being present is needed to ensure the person can validate their feelings. Common symptoms of spiritual distress include:
   a. Sense of abandonment.
   b. Direct or indirect anger.
   c. Sense of betrayal.
   d. Hopelessness or despair.
   e. Fear.
   f. Guilt.
   g. Need to seek forgiveness.
   h. Regret.
   i. Remorse.
   j. Depression.

3. Plan:
   a. Ensure cultural and spiritual assessment is completed and addressed specific to the whole person's needs.
   b. Utilize the IDT and offer the client and the family appropriate services.

COMMUNICATION

A. Communication is one of the most complicated and fundamental aspects of palliative care. Clinicians are uncomfortable with the discussions surrounding death and dying. Often the clinician believes they have failed the client as the disease progresses to the terminal phases. Communication with the client and the family must meet the needs of the client; be clear and concise, and provide the client and the family with information to make informed decisions.

1. Barriers to effective communication exist for the clinician and the client/family. These barriers include:
- a. Fear.
- b. Lack of experience.
- c. Avoidance of emotion.
- d. Insensitivity.
- e. Guilt.
- f. Disagreement with decisions.
- g. Lack of understanding of the client's culture.
- h. Lack of understanding of goals.
- i. Ethical concerns.

2. Communication tips:
- a. Build a trusting relationship.
- b. Take time to listen, be silent, and present.
- c. Be honest.
- d. Provide consistency in team communication.
- e. Coordinate care among clinicians and provide a unified, clear message.
- f. Validate client and family concerns.
- g. Understand you can give too much information; ask how much they want to know.
- h. Be sensitive.
- i. Sit down when you speak with the client and the family.
- j. Communication is not all that is "said." Body language accounts for over 80% of nonverbal communication.

3. Communication tools:
- a. Use the ask-tell-ask method of communication.
  - i. Ask the client/family to describe their understanding of the subject.
  - ii. Tell the client/family the information in a clear, concise manner without use of medical jargon.
  - iii. Ask the client/family if they understood the information presented and ask them to repeat the content back or summarize the information.
- b. Recognize and respond to emotion.
- c. Assess the client's coping style.
- d. Encourage reminiscing.
- e. Do not change the subject.
- f. Use open-ended questions.
- g. Employ useful phrases to encourage communication.
  - i. "Tell me more."
  - ii. "Tell me what you're hoping for."
  - iii. "Sometimes our hopes change; tell me yours."
  - iv. "Tell me what questions you have."
    1) "I know your family members from a medical standpoint; tell me about them as persons."
    2) "Tell me what this means for you and your life."
    3) "I know what anxiety feels like for me; tell me what it feels like for you."

ETHICS

A. The American Nurses Association's *The Nursing Code of Ethics* establishes ethical standards for the profession. While working in palliative care (PC), many difficult decisions are made. These decisions often cause clinicians moral or ethical distress. Knowing and utilizing *The Nursing Code of Ethics* allow the nurse to feel confident they are following the ethical obligations of the profession. *The Nursing Code of Ethics* with interpretive statements is available at www.nursingworld.org/coe-view-only.

APPENDIX 4.1 HOSPICE CRITERIA CARD

Hospice is a program designed to care for the dying and their special needs. All hospice programs should include:
A. **Control of pain and other symptoms** through medication, environmental adjustment, and education.
B. **Psychosocial support** for both the client and family, including all phases from diagnosis through bereavement.
C. **Medical services** commensurate with patient needs.
D. **Interdisciplinary team (IDT)** approach to patient care, patient/family support, and education.
E. Integration into existing facilities where possible.
F. Specially trained personnel with expertise in care of the dying and their families.

HOSPICE ELIGIBILITY CRITERIA
In order to be eligible to elect hospice care under Medicare, an individual must be—(a) Entitled to Part A of Medicare; and (b) certified as being terminally ill in accordance with § 418.22.

Duration of Hospice Care Coverage—Election periods:
A. An initial 90-day period;
B. A subsequent 90-day period; or
C. An unlimited number of subsequent 60-day periods.

Hospice Face-to-Face (FTF) Encounter
Must include documentation that a hospice physician or a hospice nurse practitioner had a FTF encounter with the client. This encounter is used to gather clinical findings to determine continued eligibility for hospice care. The FTF must occur within 30 calendar days prior to the start of the 3rd benefit period and every subsequent recertification period.

HOSPICE LEVELS OF CARE
Routine Home Care (RHC): Core services of hospice interdisciplinary team provided at client's home (place of residence).
Continuous Home Care (CHC): Intended to support patients and their caregivers through brief periods of crisis. CHC provides care for 8–24 hours a day. ≥50% of care must be primarily provided by an LPN or RN. Home health aide or homemaker services can be used to cover the needs.
Inpatient Respite Care (IRC): Short-term care to provide relief to family/primary caregiver. Limited to 5 consecutive days.
General Inpatient Care (GIP): Care provided in acute hospital or other setting with intensive nursing and other support outside of the home. For management of uncontrolled distressing physical symptoms (e.g., uncontrolled pain, respiratory distress) or psychosocial problems (e.g., unsafe home or imminent death when family can't cope at home).

HOSPICE PRINCIPAL DIAGNOSIS
Identify the condition that is the main contributor to the person's terminal prognosis. Non-specific diagnoses such as debility or adult failure to thrive (AFTT) may no longer be listed as a principal terminal diagnosis. Debility and AFTT can and should be listed as secondary (related) conditions to support prognosis if indicated.

TERMINAL ILLNESS: GENERAL (NON-SPECIFIC)
Terminal condition not attributed to a single specific illness.
AND
Rapid decline over past 3–6 months as evidenced by:
Progression of disease evidenced by sex, signs, and test results.
Decline in PPS to ≤50%.
Involuntary weight loss >10% and/or albumin <2.5 (helpful).

Cancer
Client meets ALL of the following:
1. Clinical findings of malignancy with widespread, aggressive, or progressive disease as evidenced by increasing symptoms, worsening lab values, and/or evidence of metastatic disease.
2. Palliative Performance Scale (PPS) ≤70%.
3. Refuses further life-prolonging therapy OR continues to decline in spite of definitive therapy.

Supporting documentation includes:
Hypercalcemia >12.
Cachexia or weight loss of 5% in past 3 months.
Recurrent disease after surgery/radiation/chemotherapy.
Signs and sex of advanced disease (e.g., nausea, requirement for transfusions, malignant ascites, or pleural effusion).

Dementia
The client has both 1 and 2.
1. Stage 7C or beyond according to the FAST Scale.
   AND
2. One or more of the following conditions in the past 12 months:
   Aspiration pneumonia.
   Pyelonephritis.
   Septicemia.
   Multiple pressure ulcers (Stage 3–4).
   Recurrent fever.
   Other significant condition that suggests a limited prognosis.
   Inability to maintain sufficient fluid and calorie intake in the past 6 months (10% weight loss or albumin <2.5 gm/dL).

(*continued*)

APPENDIX 4.1 HOSPICE CRITERIA CARD (*CONTINUED*)

Functional Assessment Scale (FAST) for Alzheimer's Type Dementia

1	No difficulty either subjectively or objectively.
2	Complains of forgetting location of objects. Subjective work difficulties.
3	Decreased job functioning evident to coworkers. Difficulty in traveling to new locations. Decreased organizational capacity.*
4	Decreased ability to perform complex task (e.g., planning dinner for guests, handling personal finances such as forgetting to pay bills).
5	Requires assistance in choosing proper clothing to wear for the day, season, or occasion (e.g., patient may wear the same clothing repeatedly, unless supervised).[a]
6	Occasionally or more frequently over the past weeks*, for the following: A. Improperly putting on clothes without assistance or cueing. B. Unable to bathe properly (not able to choose proper water temp). C. Inability to handle mechanics of toileting (e.g., forget to flush the toilet, does not wipe properly or properly dispose of toilet tissue). D. Urinary incontinence. E. Fecal incontinence.
7	A. Ability to speak limited to approximately ≤6 intelligible different words in the course of an average day or in the course of an intensive interview. B. Speech ability is limited to the use of a single intelligible word in an average day or in the course of an intensive interview. C. Ambulatory ability is lost (cannot walk without personal assistance). D. Cannot sit up without assistance (e.g., the individual will fall over if there are not lateral rests [arms] on the chair). E. Loss of ability to smile. F. Loss of ability to hold up head independently.

[a]Scored primarily on information obtained from a knowledgeable informant.

HEART DISEASE
The client has 1 and either 2 or 3.
1. CHF with **NYHA Class IV* symptoms and both:**
   Significant symptoms at rest.
   Inability to carry out even minimal physical activity without dyspnea or angina.
2. Patient is optimally treated (i.e., diuretics, vasodilators, ACEI, or hydralazine and nitrates).
3. The patient has angina pectoris at rest, resistant to standard nitrate therapy, and is either not a candidate for or has declined invasive procedures.

Supporting documentation includes:
EF ≤20%, treatment resistant symptomatic dysrhythmias, h/o cardiac related syncope, CVA 2/2 cardiac embolism, h/o cardiac resuscitation, concomitant HIV disease.

The client has either 1A or 1B and 2 and 3.
1A. CD4+ <25 cells/mcL **OR 1B.** Viral load >100,000.
AND
2A. At least one (1): CNS lymphoma, untreated or refractory wasting (loss of > 33% lean body mass), (MAC) bacteremia, progressive multifocal leukoencephalopathy, systemic lymphoma, visceral KS, Renal failure no HD, cryptosporidium infection, refractory toxoplasmosis.
AND
3A. PPS of <50%.

LIVER DISEASE
The patient has both 1 and 2.
1. End stage liver disease as demonstrated by
   A or B, and C:
   A. PT >5 sec.
      OR
   B. INR >1.5.
      AND
   C. Serum albumin <2.5 gm/dL.
      AND
2. One or more of the following conditions:

Refractory ascites, h/o spontaneous bacterial peritonitis, hepatorenal syndrome, refractory hepatic encephalopathy, h/o recurrent variceal bleeding.

(*continued*)

APPENDIX 4.1 HOSPICE CRITERIA CARD (*CONTINUED*)

Supporting documentation includes:
Progressive malnutrition, muscle wasting with decreased strength, ongoing alcoholism (>80 g ethanol/day), hepatocellular CA HBsAg positive, hep. C refractory to treatment.

PULMONARY DISEASE
Severe chronic lung disease as documented by 1, 2, and 3.
1. The client has all of the following:
   Disabling dyspnea at rest.
   Little or no response to bronchodilators.
   Decreased functional capacity (e.g., bed to chair existence, fatigue, and cough).
   AND
2. Progression of disease as evidenced by a recent h/o increasing office, home, or ED visits and/or hospitalizations for pulmonary infection and/or respiratory failure.
   AND
3. Documentation within the past 3 months ≥1:

Hypoxemia at rest on room air (p02 <55 mmHg by ABG) or oxygen saturation <88%.
Hypercapnia evidenced by pC02 >50 mmHg.
Supporting documentation includes:
Cor Pulmonale and right heart failure.
Unintentional progressive weight loss.

NEUROLOGIC DISEASE
(Criteria are very similar for chronic degenerative conditions such as ALS, Parkinson's, Muscular Dystrophy, Myasthenia Gravis, or Multiple Sclerosis.)
The client must meet at least one of the following criteria (1 or 2A or 2B):
1. *Critically impaired breathing capacity,* with all:
   Dyspnea at rest, vital capacity <30%, need O2 at rest, patient refuses artificial ventilation.
   OR
2. *Rapid disease progression* with either A or B below:
   Progression from:
   independent ambulation to wheelchair or bed-bound status
   normal to barely intelligible or unintelligible speech
   normal to pureed diet
   independence in most ADLs to needing major assistance in all ADLs.
   AND
   A. *Critical nutritional impairment* demonstrated by all of the following in the preceding 12 months:
      Oral intake of nutrients and fluids insufficient to sustain life.
      Continuing weight loss.
      Dehydration or hypovolemia.
      Absence of artificial feeding methods.
      OR
   B. Life-threatening complications in the past 12 months as demonstrated by ≥1:
      Recurrent aspiration pneumonia, pyelonephritis, sepsis, recurrent fever, Stage 3 or 4 pressure ulcer(s).

RENAL FAILURE
The client has 1, 2, and 3.
1. The client is not seeking dialysis or renal transplant.
   AND
2. Creatinine clearance* is <10 cc/min (<15 for diabetics).
   AND
   1. Serum creatinine >8.0 mg/dL (>6.0 mg/dL for diabetics).

Supporting documentation for chronic renal failure includes:
Uremia, oliguria (urine output <400 cc in 24 hours), intractable hyperkalemia (>7.0), uremic pericarditis, hepatorenal syndrome, intractable fluid overload.
Supporting documentation for acute renal failure includes:
Mechanical ventilation, malignancy (other organ system), chronic lung disease, advanced cardiac disease, advanced liver disease.

STROKE OR COMA
The client has both 1 and 2.
1. Poor functional status PPS* ≤40%.
   AND
2. Poor nutritional status with inability to maintain sufficient fluid and calorie intake with ≥1 of the following:
   ≥10% weight loss in past 6 months.
   ≥7.5% weight loss in past 3 months.
   Serum albumin <2.5 gm/dL.
   Current history of pulmonary aspiration without effective response to speech therapy interventions to improve dysphagia and decrease aspiration events.

(*continued*)

APPENDIX 4.1 HOSPICE CRITERIA CARD (*CONTINUED*)

Supporting documentation includes:
Coma (any etiology) with three of the following on the third day of coma:
Abnormal brainstem response.
Absent verbal responses.
Absent withdrawal response to pain.
Serum creatinine >1.5 gm/dL.

Palliative Performance Scale (PPS)

%	Ambulation	Activity Level Evidence of Disease	Self-Care	Intake	Level of Consciousness	Estimated Median Survival in Days*		
						A	**B**	**C**
100	Full	Normal / *no disease*	Full	Normal	Full	N/A	N/A	108
90	Full	Normal / *some disease*	Full	Normal	Full			
80	Full	Normal with effort/ *some disease*	Full	Normal or reduced	Full			
70	Reduced	Can't do normal job/ work/ *some disease*	Full	Normal or reduced	Full	145		
60	Reduced	Can't do hobbies/ housework / *significant disease*	Occasional assistance needed	Normal or reduced	Full or confusion	29	4	
50	Mainly sit/lie	Can't do any work / *extensive disease*	Considerable assistance needed	Normal or reduced	Full or confusion	30	11	41
40	Mainly in bed	Can't do any work / *extensive disease*	Mainly assistance	Normal or reduced	Full /drowsy/ confusion	18	8	
30	Bed bound	Can't do any work / *extensive disease*	Total care	Reduced	As above	8	5	
20	Bed bound	Can't do any work / *extensive disease*	Total care	Minimal sips	As above	4	2	6
10	Bed bound	Can't do any work / *extensive disease*	Total care	Mouth care only	Drowsy or coma	1	1	
0	Death	–	–	–	–	–	–	–

∗**A** = Survival post-admission to an inpatient palliative unit, all diagnoses (Virik & Glare, 2002).
B = Days until inpatient death following admission to an acute hospice unit, diagnoses not specified (Anderson, Downing, & Hill, 1996).
C = Survival post-admission to an inpatient palliative unit, cancer patients only (Morita, Tsunoda, Inoue, & Chihara, 1999).

CHAPTER 5

GERIATRIC SYNDROMES

Wesley Cook

INTRODUCTION

A. Preserving quality of life (QOL) by maintaining function is arguably the chief objective of older adult (OA) primary care. While dynamic and deeply personal, a definition of QOL that is unmoored from the OA's current health status creates unrealistic expectations with costly, cumbersome, and potentially harmful sequelae. Certain findings, referred to as geriatric syndromes, negatively impact QOL and have higher incidence and prevalence in OAs than in younger clients. Thus, the APRN interested in preserving QOL must be able to evaluate and manage these geriatric syndromes.

B. In this section, we explore geriatric syndromes both as a general concept and as a set of specific findings that cannot be pared down to a single disease, providing the APRN a framework for QOL-forward care planning. The list of individual geriatric syndromes is not codified; instead, experts expand or prune the list as they translate new knowledge into evidence-based practice. Because an exhaustive exploration of each geriatric syndrome is beyond the scope of this section, we explore eight specific syndromes, including incontinence, falls, delirium/altered mental status (AMS), weight loss, depression, pain, dementia, and impairment in activity of daily living (ADL) or instrumental activity of daily living (IADL).

DEFINITION

A. Signs and symptoms wherein the etiology is poorly understood or multifactorial.

B. Geriatric syndromes occur widely in the OA population.

C. While there is no codified definition of geriatric syndromes, this working definition highlights the key elements that set syndromes apart from diseases.

D. Approaching any geriatric syndrome simply as a syndrome that happens more frequently in OAs instead of a special codification is helpful both diagnostically and prognostically.

THE RULE OF FOURTHS

A. The Rule of Fourths "clarifies that changes often attributed to normal aging by the general public (and sometimes by medical professionals) are caused by disease, disuse, misuse, and physiology—about one-fourth of the time for each" (Warshaw et al., 2022, p. 4).

1. Incomplete to place the blame for geriatric syndromes solely on expected, physiologic changes of age.

2. Each of the four elements of decline in the OA provides a specific evaluation and management framework that reduces the APRN's decision fatigue (Table 5.1).

DIAGNOSTIC IMPLICATIONS

A. All syndromes are diagnoses of exclusion.

B. Syndromes be both frustrating and advantageous for diagnostician and the client alike:

1. Etiologic mystery and debate about their diagnostic criteria precludes a precision that makes for satisfying and economical identification of disease.

2. Syndromes hold clinicians accountable to a comprehensive workup that leaves no part of the differential unexamined as well as to a surrender of true multicomplexity where palliation is the most appropriate intervention.

C. In functionally independent OAs with low disease burden, any specific geriatric syndrome presented as an acute chief complaint should prompt a workup that assumes its etiology may be found.

D. Presuming that a syndrome is the diagnosis because the client is classified as geriatric, without ruling out a comprehensive differential diagnosis, is dangerous and unethical.

E. To help mitigate the risk of iatrogenic morbidity and mortality due to erroneous medical decision-making, a differential diagnosis is offered for the geriatric syndromes discussed in this section.

DIFFERENTIAL DIAGNOSES

A. In multicomplex or frail OAs, the presentation of geriatric syndromes is more clinically complex and frustrating.

B. Thorough workup is sometimes necessary, especially when the chief complaint is new or acutely worsened concomitantly with a chronic disease exacerbation.

C. Ruling out a reversible or treatable etiology can be paramount to maintaining QOL and reducing morbidity and mortality. As multicomplexity and frailty progress, the burdens of medical investigation can outweigh the benefits of identifying a specific etiology.

D. A palliative, symptom-based approach to interventional planning is most appropriate.

1. Diagnosing a syndrome instead of a disease is both merciful and helpful.

2. Client is comforted where curative measures would likely increase the risk of suffering.

PROGNOSTIC IMPLICATIONS

A. Clinicians remain uncomfortable and unsystematic in approaching prognosis.

B. Several standardized instruments that quantify life span based on health history and status exist; however, they can be cumbersome when used in the context of a busy clinic.

C. Prognostic scales that are useful when limited life span has been established, such as the Palliative Performance Scale, are

TABLE 5.1 THE RULE OF FOURTHS IN PRACTICE

	Disuse	Misuse	Pathology	Physiology
Context	Immobility begets immobility.	Continual injurious use of body causes permanently damage.	Illness and injury have a deleterious effect on the body. Chronic disease creates a persistently deleterious state, if insidious. Medications may cause more harm than good at a certain point in frailty.	Expected changes in the aging body.
Clinical Goal	Regain functional baseline.	Maintain current function.	Treat disease process.	Adapt to change.
Appropriate Intervention	Rehabilitation therapy aimed at regaining functional baseline given fair-to-good rehabilitation prognosis.	Rehabilitation therapy aimed at stopping misuse, maintaining current functional state, and managing client expectations considering guarded rehabilitation prognosis.	Workup and medical intervention.	Environmental adaptation and expectation management.
Questions to Consider	How can functional independence be regained with physical, occupational, or speech therapy?	How can further functional dependence be prevented with physical, occupational, or speech therapy? How can I help this client accept maintenance of current function as a goal since improvement is unlikely?	Can I find a specific cause? If not, is this presentation worsened by a disease or medical intervention present? Is it time to deprescribe rather than add an intervention?	How would a change in physical environment improve the lived experience? Would a personal care aide improve quality of life? Is occupational therapy consultation warranted?

TABLE 5.2 GERIATRIC SYNDROMES AND ASSOCIATED RISKS

Hospitalization Risk	Morbidity Risk	Mortality Risk
Geriatric syndromes increase risk of complications and functional decline of hospitalized OAs with fewer geriatric resources (Meyer et al., 2020) and increase the overall 30-day readmission risk. This increases the overall risk of hospital-associated functional decline that is noted across the OA population despite individual risk factors.	The presence of a geriatric syndrome increases the risk for other geriatric syndromes and general decline of comorbid conditions (Bare et al., 2021). Community-dwelling OAs with geriatric syndromes are less likely to self-report favorable health status (Kwon et al., 2007), placing them at higher risk for motivation loss, disordered mood, or social isolation, all of which are well-documented risks of further morbidity and mortality.	Malnutrition, impaired homeostasis (a symptom of frailty), and impaired cognition influence mortality risk more than any other geriatric syndromes (Kane et al., 2012). The presence of geriatric syndromes in the frail or high-acuity OA increases the risk of mortality compared with OAs of fair-to-good health status (Meyer et al., 2020).

OA, older adult.

often too blunt in clients not currently being considered for hospice referral.

D. An understanding of life expectancy informs the prevention and care plan:

1. New or multiple geriatric syndromes indicate a higher risk for hospitalization, morbidity, and mortality.

2. Identifying new or multiple geriatric syndromes is an indication of poor health status and overall prognosis (Table 5.2).

E. Early identification and intervention of geriatric syndromes—especially frailty, sarcopenia, malnutrition, and impaired cognition—is critical in preventing untimely mortality and worsening morbidity.

F. Clients with frailty, itself a geriatric syndrome, or multicomplexity who present with other concomitant geriatric syndromes likely have fair, guarded, or poor overall prognoses.

1. Clients should be offered an advance care planning encounter to review whether a curative or palliative plan of care best aligns with the goals of care and overall prognosis.

2. Appropriate to establish overall life expectancy using a standardized instrument, such as the *QMortality-2017 Risk Calculator* (qmortality.org/).

PREVENTION

A. Prevention of geriatric syndromes can improve QOL by maintaining functional status and reducing risk of morbidity and mortality (Table 5.3).

TABLE 5.3 GERIATRIC SYNDROME PREVENTION GOALS AND STRATEGIES BY LEVEL

	Level			
	Primary	**Secondary**	**Tertiary**	**Quaternary**
Goal	Create environmental and behavioral changes that reduce harm risk.	Discover treatable diseases and risks and treat early.	Prevent worsening of chronic disease and development of new comorbidities.	Prevent iatrogenic injury and suffering.
Strategies	Implement client education on fall mitigation strategies, expected versus pathologic and physiologic changes in aging, activity/nutrition requirements of the aging body, and community resources.	Screen clients regularly for geriatric syndromes. In addition to specific syndrome screenings discussed later, the Rapid Geriatric Assessment offers unified screening for frailty, sarcopenia, disordered nutrition, and cognitive impairment (Little, 2017).	Counsel clients and caregivers on self-management, deprescribe where possible to avoid side effects from high-risk medications, and implement rehabilitation and skilled services where rehabilitation potential is favorable.	Avoid medical interventions and screenings that offer more risk than benefit or that have low evidence of benefit.

B. Awareness of health status, whether stable or declining, can inform shared decision-making and empower clients to self-manage and self-determine.

FRAILTY AND SARCOPENIA

DEFINITION

A. The frail body is prone to deteriorate more rapidly or to a greater severity than a body that has experienced expected physiologic aging.

B. Likely the permanent effect of chronic inflammation over many years.

1. Chronic inflammation upregulates key inflammatory markers that lead to muscle wasting, hormonal dysregulation, and impaired immunity.

2. Over time, the body simply loses the ability to manage stress.

3. Chronic diseases, especially metabolic diseases, contribute to chronic inflammation exposure.

4. Additionally, sarcopenia, the reduction of lean muscle mass, leads to weakness, exhaustion, and poor reserves, eventually tipping the client into frailty.

SCREENING

A. Identifying frail OAs is an evolving concept dominated by two major models. Both models acknowledge that frail adults are particularly vulnerable to morbidity and mortality because their bodies are no longer able to maintain homeostasis when stressed. While they differ in their diagnostic criteria, each may be uniquely useful based on the specific clinical scenario (Cesari et al., 2014). Fried et al. (2001, 2021) validated a phenotype model that identifies frailty as a threshold of specific progressive signs and symptoms that point to homeostatic dysregulation. Rockland et al. (2005) validated an index model that categorizes clients as frail when they accumulate a threshold of chronic disease and functional dependencies, also framed as *multicomplexity*. Prefrailty is a precursor to frailty and may be more readily reversible. Careful attention to screening and rehabilitation for prefrailty and sarcopenia may improve the chance of the older adult returning to a state of robustness or delaying the onset of frailty (Tables 5.4 and 5.5; Warshaw et al., 2022).

FUNCTIONAL DEPENDENCE

A. Functionally independent older adults (OAs) can maintain activities of daily living (ADLs) and instrumental activities of daily living (IADLs) without assistance. ADLs are self-care tasks that must be completed to maintain control over bodily functions and needs. IADLs are self-care tasks that must be completed to participate in a community or society. Functional dependence, or the loss of ability to self-manage ADLs and IADLs without assistance, can be temporary or permanent, and it may carry significant emotional, financial, and health consequences for the OA and social system. Clients with functional dependence should be assessed for neglect and self-neglect as it may be motivation or social support-related rather than physical (Pavlou & Lachs, 2006; Pickens et al., 2006). Table 5.6 describes ADLs and IADLs, their respective screenings, and suggested management strategies.

FALL

DEFINITION

A. The World Health Organization (2021) considers any "event which results in a person coming to rest inadvertently on the ground or floor or other lower level" to be a fall.

B. Sequelae of falls include fractures—especially hip, wrist, arm, and ankle fractures—traumatic brain injury, hospitalization, fear of falling, functional decline, and death.

C. Falls are preventable and are not an inevitable part of aging. Identifying risk factors is critical to fall prevention because most falls are the result of multiple, concomitant risk factors (CDC, 2021).

RISING ANNUAL INCIDENCE

A. According to the CDC (2021), falls are the leading cause of injury-related morbidity *and* mortality for American adults

TABLE 5.4 SCREENING FOR FRAILTY

Definition (Noncodified)	Loss of ability to maintain or efficiently return to homeostasis
Clinical Significance	Reduced clinical reserve due to chronic homeostatic dysregulation High risk for hospitalization, morbidity, and mortality with minimal stress High risk for postdischarge disability Possibly reversible with appropriate intervention, more likely with prefrailty
Etiology	Phenotype model: chronic inflammation effects over time Index model: accumulation of chronic diseases and functional dependencies (van Kan et al., 2008)
Epidemiology	Frailty: 15% community-dwelling OAs (95% CI, 14%–16%) 45% of community-dwelling OAs (95% CI, 44%–47%) Higher prevalence at older ages, among females, racial and ethnic minorities, those in supportive residential settings, and persons of lower income (Bandeen-Roche et al., 2015)
Screening Tool	Phenotype model: FRAIL Scale (van Kan et al., (2008) • Fatigue: presence of fatigue most of the time over the past month • Resistance: difficulty climbing 10 steps without resting • Ambulation: difficulty walking one block • Illness: 5+ illnesses • Loss of weight: more than 5% of body weight in 1 year • Scoring: robust: 0 points, prefrail 1–2 points, frailty 3+ points Index type: DAI (Rockwood et al., 2005)
Goals of Care	Reduce mortality risk. Reverse frailty or prefrailty. Prevent tertiary admissions. Prevent/slow progression of other geriatric syndromes. Prepare the client and their family for poor prognosis and encourage. anticipatory grief.
Management	Advance care planning. Manage comorbidities. Deprescribe where appropriate. Suspend prevention activities where the benefit requires life expectancy beyond 1 to 5 years per client prognosis. Counsel on early signs of infection in frail clients (behavior changes, etc.). Establish open communication surrounding prognosis. Consult rehabilitation therapy if rehabilitation prognosis remains guarded-to-fair. Encourage comfort protocols and refer to hospice when appropriate.

DAI, deficit accumulation index; OAs, older adults.

TABLE 5.5 SCREENING FOR SARCOPENIA

Definition (Noncodified)	Age-related loss of muscle mass which presents clinically as weakness and reduced physical performance absent a pathologic etiology			
Clinical Significance	Significantly increases risk for frailty, disability, poor quality of life, falls, and mortality; presents in normal, under- or overweight OAs			
Etiology	Leading hypothesis Reduced synthesis of proteins due to chronic inflammation; other hypotheses include:			
	Physiologic	**Pathologic**	**Misuse**	**Disuse**
	Reduced androgen production Reduced motor neurons in the spinal cord	Chronic disease Increased insulin resistance	Protein intake, less than the requirements	Reduced mobility Reduced physical activity
Screening Tool	Dynamometer Grip Strength Test			
Evaluation	Diagnostic confirmations, either: • DEXA scan indicating low muscle mass, or • Bioelectrical impedance, using adjusted appendicular muscle mass for height: 2 *SD* below the mean for healthy adults diagnostic of sarcopenia • Albumin, serum, below normal limits			

(*continued*)

TABLE 5.5 SCREENING FOR SARCOPENIA (*CONTINUED*)

Goals of Care	Rule out disease/iatrogenic cause of weakness and reduced physical performance. Resolve misuse or disuse. Adapt to physiologic changes. Monitor regularly for frailty.
Management	Monitor weight regularly. Rehabilitation therapy for gait training and balance support. Social work for optimization of social support. Counsel on frailty risk and symptoms to report.

DEXA, dual-energy x-ray absorptiometry; OA, older adults.

TABLE 5.6 ADL AND IADL

Type	ADLs	IADLs
Self-care Tasks	Transferring Dressing Bathing Eating Toileting Continence	Housekeeping Food preparation Medication management Laundry Money management Phone use Transportation use Shopping
Screening	Katz Activities of Daily Living Assessment (Shelkey & Wallace, 2000)	Lawton Instrumental Activities of Daily Living Assessment (Graf, 2008)
Risk Factors	Cognitive impairment Mobility impairment Multicomplexity Hospitalization Incontinence Pressure ulcers Frailty	
Goals of Care	Prevent further functional loss. Return to functional independence where possible. Support independent function with adaptations. Maintain.	
Management	Order physical, occupational, or speech therapy consult where rehabilitation potential is not poor.	Consider occupational therapy consult where rehabilitation potential is not poor.
	Order skilled nursing home safety assessment under home health benefit if unable to make a house call. Order social work consult to assess social support system and financial means available for supportive services and to recommend appropriate support programs. Support maintenance of functional independence adaptive equipment/supplies, hiring personal care aides, and modifying the environment to abilities.	

ADL, activity of daily living; IADL, instrumental activity of daily living.

over 65. The incidence of falls has risen by 30% since 2007, contributing to more than 30,000 annual deaths, eight million annual injuries, three million ED visits, and $50 billion in healthcare expenditures. These staggering statistics do not consider the social sequelae of falls for individual older adults (OAs); a traumatic fall can mean forced retirement, loss of home, or separation from family. Given the tremendous burden and risk of falls, prevention is of paramount importance.

SCREENING

A. Encounter-based screenings (Table 5.7).

B. Stopping Elderly Accidents, Deaths, and Injuries (STEADI).

1. The CDC publishes STEADI to healthcare providers at no cost (www.cdc.gov/steadi/index.html).

2. As a comprehensive fall prevention program, STEADI aims to reduce the annual incidence of falls in OAs and by extension lower associated morbidity, mortality, and health system utilization costs. It offers standardized assessments, interventions, and counseling tools that identify and reduce multiple risk factors (Table 5.8).

DEMENTIA, DEPRESSION, AND DELIRIUM

A. While dementia, depression, and delirium may appear as discrete geriatric syndromes, their clinical presentations can often masquerade as one another. Profound depression can result in pseudodementia. Early displays of confusion in delirium might dismissed as a "bad day" in the ebb and flow of dementia manifestations. The self-neglect, social apathy, or

TABLE 5.7 ENCOUNTER-BASED SCREENINGS

Subjective	Objective
Brief Questions Include the following questions in the intake or clinical interview. Positive answers should involve further inquiry into risk factors, injury, urgent or emergent treatment, tertiary admissions, and prevention plan deficits. • Have you fallen since the last visit? • Have you fallen in the past year? • Are you afraid you are going to fall?	**TUG** • TUG ≥ 12 seconds indicates high risk of fall. • This test evaluates functional mobility by measuring the time required to stand from a chair with an armrest, walk 3 m (10 feet) away from, and return to sitting in the same chair. **30-Second Chair Stand Test** • Inability to rise from a chair without using one's arms indicates high risk of fall. • This test evaluates lower extremity strength and balance by timing a client standing from a seated position using only their legs.

TUG, Timed Up & Go.

TABLE 5.8 STOPPING ELDERLY ACCIDENTS, DEATHS, AND INJURIES

Risk Type	Environmental	Pharmacologic	Pathologic	Physiologic
Goal	Modify environment to reduce fall risk	Reduce iatrogenic fall risk	Treat and encourage adaptation to pathologies that increase fall risk	Adapt to expected changes of aging that increase risk of falls.
Strategies	Make a home visit or prescribe a skilled nurse home safety assessment using the home health benefit to assess for: • Tripping hazards: broken stairs, throw rugs, low furniture, clutter, and assistive devices not used. • Slipping hazards: slippery surfaces and improper footwear. • Balancing hazards: lack of grip bars to bathroom, shower, and stairs; and commonly used items in high cabinets requiring use of step stool. • Visibility hazards: poorly lit rooms and stairwells.	Reconcile the medication list for high fall risk medications regularly. Deprescribe or gradually dose-reduce tranquilizers, sedatives, anticholinergics, or antidepressants where possible.	Neuropathy, paresthesia, or pain to feet: Implement regular foot exams, appropriate footwear, and pain management. Generalized weakness to lower extremities causing gait or balance abnormalities: Prescribe rehabilitation therapy and assistive devices. Cognitive impairment: Coach client and their caregivers to anticipate impulsivity and to routinize the day. Delirium: Coach client and caregivers to monitor for early signs of delirium. Substance abuse: Counsel the client to quit and enroll in detoxification program.	Presbyopia: Ensure annual eye examination and appropriate corrective lenses are in place and consider distance-only glasses instead of bifocals for outdoor activities. Osteopenia/Osteoporosis: Implement calcium supplementation, vitamin D monitoring and supplementation, weight-bearing exercises, and DEXA scan. Proprioception changes: Implement weight-bearing exercises and rehabilitation therapy if warranted.

DEXA, dual-energy x-ray absorptiometry.

flattened affect of a person with undiagnosed dementia may appear as depression. Thus, understanding how each may present like the others is critical to timely diagnosis and treatment.

B. The scope of this section is to establish a cognitive framework for dementia, depression, and delirium. Definitions, risk factors, etiologies, and clinical presentations of each are alongside each other so that similarities and differences are plain (Table 5.9). Screening and treatment options specific to older adults will be briefly discussed. It is beyond the scope of this section to explore any of them fully. For a more robust discussion on dementia, see Chapter 23, Neurologic Guidelines. For a more robust discussion on depression, see Chapter 25, Psychiatric Guidelines.

POOR APPETITE AND UNINTENTIONAL WEIGHT LOSS

A. Unintentional weight loss may be attributed to gradually reduced appetite, sarcopenia, poor absorption, malignancy, cognitive decline, functional dependence without support, neglect by self or others, and other factors. Unintentionally losing 5 lbs over 3 years is a risk factor for mortality in community-dwelling (Wannamethee et al., 2005). Any unintentional loss of 5% of total body weight in 3 months or 10% in 6 months should prompt thorough investigation or consideration of hospice referral, depending on health status (Table 5.10).

TABLE 5.9 RISK FACTORS, ETIOLOGIES, AND CLINICAL PRESENTATION OF DEMENTIA, DEPRESSION, AND DELIRIUM

	Dementia	Depression	Delirium
Onset	Gradual (weeks to months)	Gradual (weeks to months)	Sudden (hours to days)
Duration	Progressive	Chronic	Acute
Characteristics	Progressive working and shortterm memory loss that worsens into: • Long-term memory loss • Executive functioning loss • Sensorimotor loss • Functional dependence • Disordered communication (see *DSM-5* for specific criteria by dementia type)	Anhedonia or depressed mood sustained for greater than 2 weeks and with at least four of the following symptoms: • Unintentional weight change • Slowness of thought or mind • Fatigue • Feeling worthless or guilty • Fogging thinking or indecisiveness • Passive death wish, suicidal ideation with or without plan, or suicide attempt (see *DSM-5*)	Acute mental status change caused by a medical condition or an adverse effect of pharmacologic interventions, reversible, manifesting as acutely disordered or disturbed: • Concentration or focus • Thinking patterns • Sensorium, especially tactile or visual hallucinations • Behavior, especially agitation with care and pressured speech (see *DSM-5*)
Aggravating Factors	Inadequate functional and social support, poorly managed comorbidities	Complicated grief, hopelessness, overwhelming stress, isolation/ loneliness, certain medications	UTI or PNA, which are the leading causes of infectious delirium in OAs
Relieving Factors	Symptom-based interventions	Appropriate therapeutic plan	Removal of causative stimulus
Treatment	Medications Lifestyle modifications Environmental modifications Functional support	Medications Psychotherapy Lifestyle modifications	Treatment of causative medical condition or deprescribing causative agent
Screening Instruments	Mini-Cog Mini-Mental State Examination Montreal Cognitive Assessment St. Louis University Mental Status Exam	Patient Health Questionnaire 9 Geriatric Depression Scale	bCAM
Evaluation and Management Pearls	Rule out other. Ensure baseline cognitive status is established and documented to ensure timely diagnosis of any delirium developed. Screen for depression to ensure that concomitant disease is properly treated. Treat dementia and ensure supportive care and a socialization plan are in place to prevent development or worsening of depression. Trend progression using the same instrument used to establish baseline.	Poorly treated or undiagnosed depression can cause pseudodementia of depression. Consider trending mental status exam of choice for improvement through depression treatment in OAs with established or suspected memory loss. Wean serotonin modulators gradually to prevent discontinuation side effects and, rarely, delirium. Distinguish psychosis from delirium by assessing for auditory hallucinations, which are seen more in psychiatric disorders, versus tactile or visual, which are seen more in delirium. Consider screening for and monitoring concomitant anxiety in clients with confirmed or suspected depression. Trend response to treatment using the same instrument used to establish baseline. SSRIs are low risk and often used as first line for OAs with depression.	Delirium increases risk of mortality; timely identification of causative stimulus is critical. Do not delay treatment for cultures if infection is highly suspected and cultures are difficult to obtain because the client could deteriorate rapidly while awaiting collection. Treat empirically per guidelines and adjust as needed. Fever is a late sign of infection in an OA; do not rely on pyrexia before clinical suspicion of infection is raised in an OA whose behavior is "off." Always reconcile the medication list when working up delirium, assessing for new prescriptions, changed doses, and unreported supplements. Terminal delirium is a common phenomenon at the end of life and can be distressing; it is the only time symptoms may be treated without an exhaustive search for causative stimulus.

bCAM, brief confusion assessment method; *DSM-5, Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition;* OA, older adult; PNA, pneumonia; SSRI, selective serotonin reuptake inhibitor; UTI, urinary tract infection.

TABLE 5.10 UNINTENTIONAL WEIGHT LOSS

Definition	Clinically significant weight loss includes: • Loss of 5% total body weight in 3 months • Loss of 10% total body weight in 6 months			
Clinical Significance	Increases risk for geriatric syndromes; may indicate neoplasm or increased risk of mortality			
Etiology	**Physiologic**	**Pathologic**	**Misuse**	**Disuse**
	Reduced taste Reduced smell Reduced elasticity of the stomach fundus Reduced absorption Increased satiety	Impaired cognition Depression CHF-related reduced cardiac output Neoplasm, especially of colon Polypharmacy Dysphagia Chemotherapy or radiation Hyperthyroid	Poor appetite	Functional dependence Inability to access or prepare food
Screening	Monitor weight/BMI annually.			
Evaluation	Monitor weight when clinical complaints or exams prompt concern for unintended weight loss. Inquire about weight changes in the clinical interview at initial, annual wellness, and chronic management encounters, in addition to when appetite and weight loss are the chief complaint(s).			
Goals of Care	Rule out disease/iatrogenic cause. Resolve misuse or disuse. Adapt to physiologic changes. Reduce barriers to adequate intake by mouth.			
Management	Obtain labs: TSH (to rule out pathologic or iatrogenic hyperthyroidism), CMP (low albumin 2/2 poor hepatic absorption or by mouth intake of protein), and fecal occult blood test x 2 to 3 (taken on different days to rule out malignant neoplasm of the colon). Optimize the management of comorbidities. Deprescribe offending or unnecessary medications. Monitor weight monthly. Consult rehabilitation therapy for dysphagia, impaired mobility, and environmental adaption assessment. Consult social work for optimization of social support. Consult a registered dietitian for nutritional recommendations. Encourage pleasure feedings.			

BMI, body mass index; CHF, congestive heart failure; CMP, comprehensive metabolic panel; TSH, thyroid stimulating hormone.

B. Conventional wisdom might lead many clients and their families to inquire about appetite stimulants or nutritional supplementation; clinically significant weight loss can be alarming. The Choosing Wisely campaign recommends against the use of megestrol acetate because it increases risk of thromboembolism, fluid retention, and death. They also caution against the use of high-protein supplements given a lack of enhanced quality of life or function. Instead, it is important to uncover any reversible etiologies and encourage pleasure feedings (Table 5.11).

PAIN

A. Poorly managed pain reduces functional independence and places clients at risk for development of other geriatric syndromes, such as poor appetite, weight loss, sarcopenia, frailty, incontinence, and impaired mobility.

B. Older adults (OAs) may underreport pain for several reasons:

1. Belief that pain is a part of "normal aging."
2. Lack of trust in the efficacy of medical interventions.
3. Fear of pain-relieving pharmaceuticals.
4. Age-related perceptions of pain.
5. Knowledge deficit of available interventions.
6. Cognitive inability to report.

C. Management of pain includes a deft understanding of cultural expectations, mastery of pain types and effective interventions by type, and attention to possible comorbidities such as depression, opiate misuse/dependence/addiction, and pain-related disuse of the affected site.

1. In cognitively intact adults, pain may be assessed using the PQRST (P, Palliative or precipitating factors; Q, quality of pain; R, region or radiation of pain; S, subjective descriptions of pain; T, Temporal nature of pain [time of pain]) mnemonic along with the number or faces scales to trend severity.
2. The Pain Assessment in Advanced Dementia (PAINAD) has been developed and verified for clients who are cognitively impaired or who cannot communicate clearly. It assesses objective findings appropriate to the OA who cannot self-advocate: breathing quality, vocalization quality, facial expression, body language, and consolability (Paulson et al., 2014).

TABLE 5.11 POOR APPETITE

Definition	Reduction in drive for oral intake of food and fluids			
Clinical Significance	Increases risk of malnutrition, involuntary weight loss, sarcopenia, constipation and related incontinence, and falls			
Etiology	**Physiologic**	**Pathologic**	**Misuse**	**Disuse**
	Reduced taste Reduced smell Reduced elasticity of stomach fundus Reduced absorption Satiety due to increased cholecystokinin	Impaired cognition Depression Polypharmacy Multicomplexity Secondary gastroparesis Pain Dysphagia	Poor oral hygiene Delayed gastric emptying 2/2 large meals Satiety due to increased adiposity releasing more leptin	Impaired mobility Reduced social support
Evaluation	Inquire about appetite changes in the clinical interview at initial, annual wellness, and chronic management encounters, in addition to when appetite and weight loss are the chief complaint(s).			
Goals of Care	Rule out disease/iatrogenic cause. Resolve misuse or disuse. Adapt to physiologic changes. Monitor regularly for clinically significant weight loss.			
Management	Consider labs as listed in Unintentional Weight Loss Management in Table 5.10. Optimize the management of comorbidities. Deprescribe offending or unnecessary medications. Monitor weight monthly. Consult rehabilitation therapy for dysphagia, impaired mobility, and environmental adaption assessment. Consult social work for optimization of social support. Consult a registered dietitian for nutritional recommendations. Counsel on behavioral interventions. Encourage pleasure feedings.			

INCONTINENCE

A. In community-dwelling older adults (OAs) up to age 85, urinary incontinence (UI) is more prevalent in females than in males, with prevalence directly correlating to age. After age 85, UI is equally burdensome for both males and females. Childbearing, surgery, obesity rates, and diabetes prevalence may contribute to the difference before age 85, but the onset of clinically significant prostate pathologies causing obstruction-based urgency or weakened sphincter tone incidence brings the male-to-female ratio with UI to nearly 1:1 (Shamliyan et al., 2009). Offermans et al. (2009) found a median prevalence rate of 58% for nursing home residents who were found to be at greater risk than community-dwelling OAs because of age, cognitive function, dementia, functional quadriplegia, and immobility, to name a few of the 45 setting-specific risk factors identified.

DEFINITION

A. UI:

1. Stress incontinence: complaint of involuntary loss of urine on effort or physical exertion, including sporting activities or on sneezing or coughing.

a. Urgency incontinence: complaint of involuntary loss of urine associated with urgency.

b. Mixed incontinence: complaints of both stress and urgency UI, that is, involuntary loss of urine associated with urgency and also with effort or physical exertion, including sporting activities or on sneezing or coughing.

c. Overflow incontinence: complaint of UI in the symptomatic presence of an excessively (over-) full bladder (no cause identified); also called "Overactive Bladder Syndrome."

d. Functional incontinence: UI related to physical barrier to using available toilet (e.g., unable to ambulate to the restroom due to loss of ambulatory or transferring independence).

B. Fecal incontinence:

1. Urgency incontinence: complaint of an involuntary loss of feces (flatus) associated with fecal urgency.

2. Passive incontinence: complaint of involuntary soiling of liquid or solid stool without sensation or warning.

3. Overflow incontinence: complaint of involuntary loss of stool due to an overfull rectum or fecal impaction.

4. Functional incontinence: fecal incontinence related to physical barrier to using the toilet (e.g., unable to ambulate to restroom due to loss of ambulatory or transferring independence).

SCREENING

A. Regular screening is recommended for all OAs to compensate for well-documented underreporting and underscreening (Wenger et al., 2007; Visser et al., 2012). Standardized instruments can be easily incorporated into annual wellness visits and previsit intake workflows completed by the medical assistant or office nurse. Standardizing screening workflows prevents incontinence from being attributed to "normal aging". Specific instruments are discussed in Table 5.12.

B. Many OAs, especially females, incorrectly attribute urinary incontinence to "normal aging" due to community messaging (Kim et al., 2019; Orsal et al., 2020; Visser et al., 2012). Standardized screening and shared decision-making

TABLE 5.12 SCREENING TOOLS FOR URINARY INCONTINENCE

Instrument	Evidence	Scope	Suggested Use
General Screening Questions (Holroyd-Leduc et al., 2008) *Unspecified UI* • "Have you had any problems with bladder or urine control?" • "Do you ever leak urine when you don't want to?" *Stress incontinence* • "Do you ever leak urine coughing, sneezing, lifting, walking, or running?" *Urgency incontinence* • *"Do you experience such a strong and sudden urge to void that you lead before reaching the toilet?"*	*Strong interrater reliability* K = 0.8 (95% CI, 0.3–0.9) *Stress UI: strong LR*[a] +LR 2.2 (95% CI, 1.6–3.2) –LR 0.39 (95% CI, 0.25–0.61) *Urgency: strong LR*[b] +LR 4.2 (95% CI, 2.3–7.6) –LR 0.48 (95% CI, 0.36–0.62)	UI identification	Online check-in, inperson check-in, or preencounter MA/LPN/RN intake New client visits Acute GYN or GU visits Annual wellness visits
ICIQ-UI SF (Hajebrahimi et al., 2012) www.iciq.net	*Strong interrater reliability* K = 0.7 *Stress UI* Sensitivity 0.636 (95% CI, 0.466–0.778) Specificity 0.826 (95% CI, 0.36–0.89) *Urge UI* Sensitivity 0.525 (95% CI, 0.402–0.645) Specificity 0.953 (95% CI, 0.871–0.984) Mixed UI Sensitivity 0.84 (95% CI, 0.653–0.936) Specificity (95% CI, 0.689–0.85)	UI identification UI QOL impact	Online check-in, inperson check-in, or preencounter MA/LPN/RN intake New client visits Acute GYN or GU visits Annual wellness visits HPI Complaint communicated during APRN interview outside of preencounter intake
IIQ (Uebersax et al., 1995) www.ohsu.edu/sites/default/files/2019-06/Female-Urology-Questionnaire-7.pdf	The short form is equally as reliable as the longer 30-item or 19-item forms, and because it is less cumbersome to implement it may be more clinically valuable.	UI QOL impact	Online check-in, in-person check-in, or preencounter MA/LPN/RN intake New client visits with established UI Chronic UI visits Annual wellness visits HPI Complaint communicated during APRN interview outside of preencounter intake Positive UI identification screening

[a]Posttest probability negatively correlates with age. [b]Posttest probability positively correlates with age.

GYN, gynecology; ICIQ-UISF, International Consultation on Incontinence Questionnaire-Urinary Incontinence Short Form; IIQ, Incontinence Impact Questionnaire; K, kappa test; GU, genitourinary; HPI, history of present illness; LPN, licensed practical nurse; LR, likelihood ratio; MA, medical assistant; QOL, quality of life RN, registered nurse; UI, urinary incontinence.

can help disabuse clients of harmful misconceptions of "normal aging."

C. Social anxiety and misconceptions about "normal aging" lead to poor reporting and undertreatment. This underreporting may be worsened by lack of screening in primary care settings (Orsal et al., 2020; Visser et al., 2012).

PLAN

A. Acute presentation: New or worsened UI in the OA without established incontinence or acutely worsened incontinence in the OA with established chronic incontinence should raise clinical suspicion of infection. New or worsened bowel incontinence should prompt a rectal history and examination to evaluate for neoplasm and neurologic alarm signs, as well as sphincter tone loss or fecal impaction (Table 5.13; Warshaw et al., 2022).

B. Chronic presentation: Equipping OAs and their caregivers with medical, behavioral, and environmental controls for incontinence of bladder or bowel improves quality of life and reduces social distress. Poorly managed incontinence increases the risk for pressure ulcers, malnutrition, falls, delirium, and functional decline (Table 5.13; Kim et al., 2019).

CONCLUSION

A. Geriatric syndromes place older adults (OAs) at risk for hospitalization, morbidity, and mortality. Early identification and management of geriatric syndromes produces the best outcomes, so incorporating regular screening into clinical practice is key. APRNs who give attention to the identification of geriatric syndromes while dispelling myths about normal aging can help OAs to self-determine, self-manage, and experience improved quality of life while reducing any caregiver role strain their lay caregivers may be experiencing.

TABLE 5.13 OBJECTIVE-BASED CARE PLANNING FOR INCONTINENCE

Goal	Rationale	Management
Identify appropriate subtype and etiology.	Discovery of precise pathophysiologic mechanism of incontinence allows for planning targeted treatment and clinical endpoint.	Standardized screening instruments Physical exam Targeted diagnostics: UA/UC, PSA, and bladder US for PVRV
Rule out "must-not-misses."	Early identification of alarm signs and symptoms reduces risk for morbidity and mortality.	UI: rule out infection, prostate malignancy, cystocele, nocturia, etc., refer as appropriate FI: rule out cauda equina syndrome, impaction, and rectocele
Treat reversible pathology/identified etiology.	Untreated reversible pathology causes place the client at risk for further morbidity or mortality and preventable social distress.	Urology/GYN referral/procedure Pharmacologic interventions Behavioral modifications: dietary modification, bladder training, toileting schedule, etc. Pelvic floor rehabilitation
Resolve social and functional barriers.	Modifying the environment for an OA with reduced mobility increases functional independence and reduces social anxiety.	Environmental modifications: urinal, bedside commode, grab bars, etc. Incontinence wearables

FI, fecal incontinence; GYN, gynecology; OA, older adult; PSA, prostate-specific antigen; PVRV, postvoid residual volume; UA, urinalysis; UC, urine culture; UI, urinary incontinence; US, ultrasound.

CHAPTER 6

PAIN MANAGEMENT GUIDELINES

Kathleen Bradbury-Golas

ACUTE PAIN

DEFINITION

A. Acute pain is defined as pain of a short, limited duration usually the result of an injury, surgery, or medical illness (disease/inflammation) that generally arises from tissue injury; however, it may be experienced even with no identifiable cause. Acute pain usually resolves when the tissue injury improves with the healing process. Most acute pain resolves in less than 6 weeks or less than 3 months.

B. General statements about pain:

1. Pain is a distressing sensory and emotional experience often associated with actual or potential tissue damage. It is an actual physical discomfort and the result of many factors including physical, emotional, psychosocial, and spiritual, along with the cultural social contexts that influence how the client expresses/tolerates the pain. Therefore, pain is multidimensional.

2. Pain is what the client says it is, "totally subjective." Clients do not always verbalize their pain but may express it in nonverbal ways. Therefore, a provider must assess the client using various methods.

3. The initial assessment of pain is to characterize the pathophysiology of the pain, identify its cause, determine its intensity, and evaluate its impact on the client's ability to function.

INCIDENCE

A. Acute pain is the most common reason for self-medication and presentation for treatment in the healthcare system. Acute pain is very individual, and if not treated properly it can have devastating physiologic and psychological effects. Because everyone experiences some type of acute pain, it is very difficult to determine the incidence and prevalence of pain. Because pain is very subjective, the client care plan needs to be individualized to meet the client's needs. Proper treatment of acute pain could prevent the development of some types of chronic pain syndromes.

PATHOGENESIS

A. Acute pain is usually the result of stimulation of the sympathetic nervous system.

B. Types of pain:

1. Nociceptive pain: normal response to peripheral tissue injury or damage (sprains, fractures).

2. Neuropathic pain: originates from injury or dysfunction of the peripheral nervous system or central nervous system structures or both (postherpetic neuralgia, diabetic neuropathy).

3. Inflammatory pain: nociceptive pain with a localized immune response due to proinflammatory mediators (arthritis).

4. Centralized/functional pain: peripheral and central sensitization with no detectable origin (fibromyalgia, headaches).

COMMON COMPLAINTS

A. Pain at the specific site.
B. Increased heart rate.
C. Increased respiratory rate.
D. Elevated blood pressure.
E. Sweating.
F. Nausea.

OTHER SIGNS AND SYMPTOMS

A. Urinary retention.
B. Dilated pupils.
C. Pallor.
D. Anxiety/depression.

SUBJECTIVE DATA

A. Elicit location of pain.
B. Note effects of pain on activities of daily living (ADLs).
C. Note intensity of pain at rest and during activity.
D. List precipitating factors.
E. Identify alleviating factors.
F. Note the quality of pain.
G. Is there radiation of pain?
H. Rate pain on a pain scale (usually on the 0–10 scale, with 0 being no pain and 10 being the worst pain).

PHYSICAL EXAMINATION

A. Check temperature, pulse, respiration, and blood pressure.
B. Inspect:
1. Observe overall appearance.
2. Note affect and ability to express self and pain.
3. Note facial grimaces with movement.
4. Note gait, stance, and movements.
5. Inspect area at pain site.
C. Auscultate:
1. Auscultate heart and lungs.
2. Auscultate neck and abdomen.
D. Palpate:
1. Palpate the affected area of pain. ▶

The contributions of Moya Cook to this chapter in prior editions are acknowledged here.

E. Percuss:
  1. Percuss chest.
  2. Percuss abdomen.

F. Perform musculoskeletal exam:
  1. Perform complete musculoskeletal exam, concentrating on the area of pain.
  2. Assess deep tendon reflexes (DTRs).

When performing a musculoskeletal exam, identify the location of pain, presence of trigger points, evidence of injury or trauma, edema, erythema, warmth, heat, lesions, petechiae, tenderness, decreased range of motion, pain with movement, crepitus, laxity of ligaments or cords, spasms, or guarding.

G. Perform neurologic exam:
  1. Perform complete neurologic exam.
  2. Identify change in sensory function, skin tenderness, weakness, muscle atrophy, and/or loss of DTRs.

DIAGNOSTIC TESTS

A. No diagnostic testing is required unless clearly indicated to rule out organic cause of pain.

B. If organic disease is suspected, diagnostic testing may include the following:
  1. CT imaging.
  2. MRI.
  3. Blood chemistries.
  4. Radiographic x-ray.
  5. Lumbar puncture.
  6. Ultrasound.
  7. Echocardiogram.

DIFFERENTIAL DIAGNOSES

A. The differential diagnoses depend on the location of the acute pain.
  1. Head:
    a. Migraine headache.
    b. Cluster headache.
    c. Temporal arteritis.
    d. Intracranial bleeding or stroke.
    e. Sinusitis.
    f. Dental abscess/infection/caries.
  2. Neck:
    a. Meningitis.
    b. Muscle strain/sprain.
    c. Whiplash injury.
    d. Thyroiditis.
  3. Chest:
    a. Pulmonary emboli.
    b. Myocardial infarction.
    c. Pneumonia.
    d. Costochondritis.
    e. Angina.
    f. Gastroesophageal reflux disease/esophagitis.
  4. Abdomen:
    a. Peritonitis.
    b. Appendicitis.
    c. Ectopic pregnancy/uterine pregnancy.
    d. Endometriosis.
    e. Pelvic inflammatory disease.
    f. Peptic ulcer.
    g. Cholelithiasis.
    h. Colitis/diverticulitis.
    i. Constipation.
    j. Gastroenteritis.
    k. Irritable bowel syndrome.
    l. Urinary tract infection, kidney stone, pyelonephritis.
    m. Prostatitis.
  5. Musculoskeletal:
    a. Muscle sprain/strain/tear.
    b. Skeletal fracture.
    c. Viral infection.
    d. Gout.
    e. Vitamin D deficiency.

PLAN

A. General interventions:
  1. Acute pain is a symptom, not a diagnosis. Try to identify the cause or source of the acute pain, depending on the location. If the pain is organic in nature, make the appropriate referral. The overall goal is to treat the acute pain appropriately.

B. Client teaching:
  1. The pain management plan must include client and family/significant other education regarding preventing and controlling pain, potential medication side effects, and preventing side effects.
  2. Discussion must include addiction concerns and a possible addiction risk assessment. Explain addiction is low when the medication is used as directed for a short duration. Explain that complete pain relief may not be achievable initially, but the overall goal is to reduce the pain, thus allowing some daily activities at home to begin recovery.

C. Pharmaceutical therapy:
  1. Source of acute pain:
    a. Visceral pain: The treatment of choice is corticosteroids, intraspinal local anesthetic, nonsteroidal anti-inflammatory drugs (NSAIDs), and opioids.
    b. Somatic pain: Treatment includes acetaminophen, cold packs, corticosteroids, localized anesthetics, NSAIDs, opioids, and tactile stimulation.
    c. Neuropathic pain: Tricyclic antidepressants (TCAs) and serotonin norepinephrine reuptake inhibitors (SNRIs) are useful in reducing pain in clients with/without depression. TCAs such as amitriptyline or imipramine can be used as first-line treatment for neuropathic pain. Anticonvulsants such as carbamazepine (Tegretol), phenytoin (Dilantin), gabapentin (Neurontin), and valproic acid (Depakene) can be useful in treating neuropathic pain but should be reserved for second-line treatment. Carbamazepine and oxcarbazepine can be used for first-line treatment of trigeminal neuralgia. Other treatments include local anesthetics, tramadol (Ultram), and glucocorticoids.

Know each medication's mechanism of action, potential adverse side effects, half-life, and drug–drug interaction potential. Always document that you have advised on potential for sedation, no driving/machinery use, or alcohol while taking medication with these potential adverse side effects.

FOLLOW-UP

A. Once the organic cause of pain has been ruled out, initial follow up is 48 to 72 hours after onset.

B. Ensure the client has access to care on a regular schedule.

CONSULTATION/REFERRAL

A. If the acute pain is organic, make the appropriate referral to a specialist.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. Failure to treat pain in the geriatric population is inhumane and increases the risk of delirium in this population.

2. Normal changes associated with the aging process require the clinician to be on high alert when using pain medications in the geriatric population. Age-associated decreases in hepatic and renal function allow for increasing serum drug concentrations and associated adverse effects.

3. Due to age-associated decreases in hepatic and renal function, it is appropriate to initiate opioid medications anywhere from 30% to 50% of the normal dose and titrate up to the desired effect.

4. Because of the risk of inciting renal failure and gastrointestinal bleeding in the geriatric population, NSAIDs should be avoided or used with extreme caution and frequent monitoring.

American Pain Society. (n.d). *Management of acute pain and chronic noncancer pain*. http://americanpainsociety.org/uploads/education/section_4.pdf

Saling, J. (2019). *Pain types and classifications*. *https://www.webmd.com/pain-management/guide/pain-types-and-classifications*.

CHRONIC PAIN

DEFINITION

A. See the "Acute Pain" section for general statements about pain.

B. Chronic pain is defined as alteration in comfort that persists longer than 3 months (or longer than the anticipated healing time).

C. The pain may be continuous or recurrent and of sufficient duration and intensity. Legitimate chronic pain interferes with a client's ability to function with normal daily activities and decreases quality of life.

D. Chronic pain can be chronic cancer pain, where there is an expected end (either with cure or death), or chronic nonmalignant pain, where there is no predictable ending or cure.

INCIDENCE

A. Pain syndromes are commonly seen in clinical practice and are the third most widespread health problem in the United States. As of 2012, chronic pain cost the American people about $635 billion a year in healthcare expenses, disability costs, and lost productivity. Approximately 50 million or 20% to 30% of adults in the United States experience chronic pain. As the U.S. population continues to age, more people develop pain-associated medical conditions (obesity, diabetes mellitus [DM]), and the average life expectancy increases, the primary care provider will be providing care for more chronic diseases and handling more chronic pain clients.

1. Females are affected more than males by 2 to 1.

2. Onset is usually in the fourth, fifth, or sixth decade and is often associated with marked functional disability.

PATHOGENESIS

A. *Skeletal muscle pain* is pain in soft tissue involving the neck, shoulders, trunk, arms, low back, hips, and lower extremities. *Myofascial pain syndrome* relates to the fascia surrounding the muscle tissue.

B. *Inflammatory pain* is caused by chemicals such as prostaglandins, leading to stimulation of the pain receptors. Examples include arthritis, infection, tissue injury, and postoperative pain.

C. *Mechanical/compressive pain* is the direct result of the muscle, ligament, and tendon causing strain, leading to stimulation of the pain receptors. Diagnosis may be based on diagnostic imaging results which may include fracture, obstruction, dislocation, or compression of tissue by tumor, cyst, or bony structure.

D. *Neuropathic pain* involves dysfunction of the somatosensory system. The most common types are diabetic neuropathy, sciatica from nerve root compression, trigeminal neuralgia, and postherpetic neuralgia.

E. *Nociceptive pain* is caused by nociceptors, a type of sensory neuron that receives the pain signal. Mechanical/compressive and inflammatory pain are examples of this type of pain. They both respond well to opioids, with the exception of arthritis. However, opioids should not be the initial management as other modalities may be just as effective.

PREDISPOSING FACTORS

A. Age 30 to 50 years.

B. Female sex.

C. History of having seen many physicians.

D. Frequent use of several nonspecific medications.

E. Depression: Major depressive disorder is the single most important prevalent chronic pain morbidity.

F. Personality, including moods, fears, expectations, coping efforts, and resources.

COMMON COMPLAINTS

A. Specific to site of pain.

B. Emotional distress related to fear, maladaptive or inadequate support systems, and other coping resources.

C. Treatment-induced complications.

D. Overuse of drugs.

E. Inability to work.

F. Financial complications.

G. Disruption of usual activities.

H. Sleep disturbances.

I. Pain becomes primary life focus.

OTHER SIGNS AND SYMPTOMS

A. Pain lasts longer than 3 months.

B. There may be anger and loss of faith or trust in the healthcare system. This type of client frequently takes too many medications, stays in bed a great deal, has seen many physicians, has lost skills, and experiences little joy in either work or play.

C. Chronic pain interferes with daily life activities. This impacts a person's self-esteem, mood, and energy level. The link between pain and psychological factors is cyclic. The more the client is in pain, the more depressed they become; this in turn leads to more pain.

SUBJECTIVE DATA

A. Elicit a clear description of the onset, location, quality, intensity, and time course of pain and any factors that aggravate or relieve it. Use the acronym OLD CARTS-U: O = onset, L = location, D = duration, C = characteristics, A = aggravating triggers, R = relieving triggers, T = timing, S = severity, U = YOU, What do YOU think is going on? What have YOU done to relieve it? ▶

B. *Self-reporting pain assessment tools* should be used early in the process of client evaluation. Use the tool at each office visit to see progression or regression. Lack of pain assessment is a barrier to good pain control. Consider the age of the client; their physical, emotional, and cognitive status; and their preference when choosing the self-reporting pain assessment tool:

1. The Verbal Rating Scale rates pain as mild, moderate, or severe.

2. The Numeric Rating Scale rates pain intensity from 0 to 10. The tool is client-friendly and quick to complete.

3. The Faces Scale is useful in pediatric and cognitively impaired clients. Multicultural translations may be downloaded at wongbakerfaces.org.

4. There are also several scales that combine different dimensions of the pain experience. Examples include the McGill Pain Questionnaire (long and short versions).

C. Determine the extent to which the client is suffering, disabled, and unable to enjoy usual activity. It is important to inquire about activities of daily living (ADLs) and functional limitations. Disability refers to the inability to do one's usual activities as a result of impairment. There is no gold standard for assessing disability as each organization has different requirements for evaluation and documentation.

D. Obtain a complete review of systems, including nausea, numbness, weakness, insomnia, loss of appetite, dysphoria, malaise, fatigue, or depression signs and symptoms.

E. Obtain a complete family and social history. Address spiritual and cultural issues. Evaluation of the risk of opioid dependence/abuse in this population is essential. There are several instruments that can be used, such as The Screening Instrument for Substance Abuse Potential.

F. Obtain the client's medical history relevant to the pain, including diagnosis, testing, treatments, and outcomes.

G. Obtain a pain history to identify the client's attitudes, beliefs, level of knowledge, and previous experiences with pain. Are previously used methods for pain control helpful? What is the client's attitude toward the use of certain pain medications? Often, the client will discuss certain adverse side effects or allergies from undesired pain medication.

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure.

B. Inspect:

1. Observe overall appearance.

2. Note affect and ability to express self and pain.

3. Note facial grimaces with movement.

4. Note gait, stance, and movements.

5. Inspect area at pain site.

C. Auscultate:

1. Auscultate heart and lungs.

2. Auscultate neck and abdomen.

D. Palpate:

1. Palpate the affected area of pain.

E. Percuss:

1. Percuss chest.

2. Percuss abdomen.

F. Perform musculoskeletal exam:

1. Perform a complete musculoskeletal exam, concentrating on the area of pain.

2. Note limitations in range of motion.

When performing a musculoskeletal exam, identify the location of pain, presence of trigger points, evidence of injury or trauma, edema, erythema, warmth, heat, lesions, petechiae, tenderness, decreased range of motion, pain with movement, crepitus, laxity of ligaments or cords, spasms, or guarding.

G. Perform neurologic exam:

1. Perform complete neurologic exam.

2. Note the client's affect and mood. Is client cooperative during exam?

3. Identify change in sensory function, skin tenderness, weakness, muscle atrophy, and/or loss of deep tendon reflexes (DTRs).

H. Perform functional assessment:

1. The baseline functional assessment provides objective measurable data on a client's physical abilities and limitations. It can be used to determine if the client's efforts are valid and complaints are reliable.

2. The information may be used to identify areas of impairment, establish specific functional goals, and measure the effectiveness of treatment interventions.

3. These objective data may be used in worker compensation cases, returning to work status, federal disability, and motor vehicle accident lawsuits.

4. Know the resources in your area that are trained to perform functional assessments. Physical therapists and occupational therapists are the best qualified to perform the assessments.

DIAGNOSTIC TESTS

A. None required unless clearly indicated to rule out the organic cause of pain.

1. Remember that pain previously diagnosed as chronic pain syndrome can be organic and vice versa. Organic causes must always be evaluated and excluded.

2. Health insurance usually requires plain radiography ordered first for muscle, inflammatory, or skeletal pain. Plain radiography will diagnose a fracture. Additional studies may be recommended by the radiologist if a lesion/abnormality is seen on plain radiography.

3. MRI and CT are ordered if the plain radiography is negative and the client continues to complain of pain.

4. Electromyography and nerve conduction studies are used to evaluate neuropathic pain. Numerous serum and urine studies should also be considered if the neuropathic pain is undiagnosed.

B. Consider using a depression assessment tool, such as the Beck Depression Inventory or the Patient Health Questionnaire 9 (PHQ-9). These tools can be administered at a subsequent appointment to follow the client's symptoms.

DIFFERENTIAL DIAGNOSES

A. Pain disorder.

B. Pain related to a disease with no cure.

C. Somatization disorder.

D. Conversion disorder.

E. Hypochondriasis.

F. Depression.

G. Chemical dependency.

H. Fibromyalgia.

PLAN

A. General interventions:

1. Treatment is multidimensional and should not be focused on pharmacologic treatment alone.

2. Offer hope and potential for improvement of pain control and of function but NOT always cure. ▶

3. The pain is real to the client, and acceptance of the problem must occur before a mutually agreed-on treatment plan can be initiated.

4. Depression is a common emotional disturbance in chronic pain clients and is treatable. Consider oral therapy. See the "Depression" section in Chapter 25.

5. Identify specific and realistic goals for therapy, such as having a good night's sleep, going shopping, or returning to work. Client discussion needs to include the idea that the goal may be reducing pain intensity, not eliminating pain.

6. Carefully assess the level of pain using available tools, such as a daily pain diary or other pain assessment scales.

7. Avoid pain reinforcement such as sympathy and attention to pain. Provide positive response to productive activities. Improving activity tolerance assists in desensitizing the client to pain.

8. Shift the focus from the pain to accomplishing daily assigned self-help tasks. The accomplishment of these tasks functions as a positive reinforcement.

B. *See Client Teaching Guide for this chapter, "Chronic Pain."*

C. Pharmaceutical therapy:

1. See Figure 6.1 for summary of medications used in pain. Medications should be based on the World Health Organization's (WHO) scale for mild to severe pain. Although this was developed for use in cancer pain, it is helpful for noncancerous chronic pain as well.

a. Skeletal muscle pain: Treatment should focus on physical rehabilitation and behavioral management. Trichloroacetic acids (TCAs) and muscle relaxants (cyclobenzaprine) may be used. There is little evidence indicating the need for opioids in the treatment of skeletal muscle pain.

b. Inflammatory pain: Nonsteroidal anti-inflammatory drugs (NSAIDs) and corticosteroids are first-line pharmaceutical interventions. Topical creams (Voltaren Gel) and solutions have been used in treating arthritis pain.

c. Mechanical/compressive pain: Opioids may be used to manage these symptoms while other measures are being taken. Referral to specialist(s) is usually indicated.

d. Neuropathic pain:

i. Gabapentin (Neurontin) and pregabalin (Lyrica) have become first-choice treatments in recent years for diabetic neuropathy and postherpetic neuralgia.

ii. TCAs and serotonin norepinephrine reuptake inhibitors (SNRIs) are extremely useful. Clients who are not depressed obtain excellent pain relief with TCAs such as amitriptyline and doxepin. Examples of antidepressants that may help with pain include but are not limited to venlafaxine (Effexor XR) and duloxetine (Cymbalta). ▶

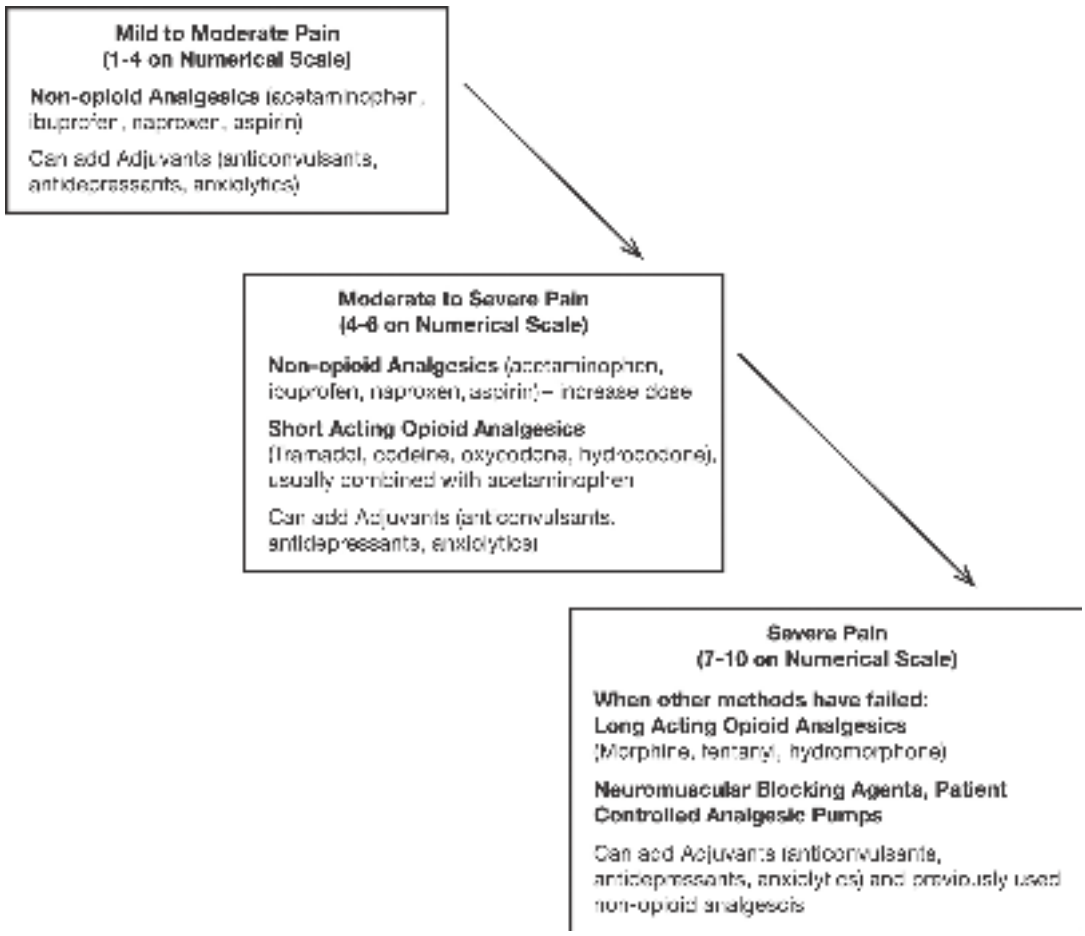

FIGURE 6.1 World Health Organization pain analgesic ladder.

Source: Adapted from World Health Organization from Anekar, A., & Casselar, M. (2021). *WHO analgesic ladder.* https://www.ncbi.nlm.nih.gov/books/NBK554435/.

iii. Anticonvulsants are useful in controlling some neuropathic pain: carbamazepine (Tegretol), phenytoin (Dilantin), and valproic acid (Depakene). **Clients need to be monitored monthly for hepatic dysfunction and hematopoietic suppression.** Blood work should be ordered on a regular basis for assessment of liver function, blood studies, and medication toxicity levels.

iv. Topical agents: Capsaicin applied three to four times per day can be used to reduce pain without significant systemic effects. Topical lidocaine 5% patches are approved for postherpetic neuralgia.

v. Carbamazepine is used as first-line treatment for trigeminal neuralgia.

vi. Opioids: Tramadol is considered a good first-line choice if an opioid is indicated. In addition to pain control, tramadol also causes serotonin reuptake inhibition similar to that seen with TCAs. **Precautions should be taken to avoid the risk of seizure disorder and serotonin syndrome when using tramadol with other selective serotonin reuptake inhibitors (SSRIs).**

e. All therapies need a 2- to 3-week trial period to adequately evaluate therapy. Some medications take longer to evaluate.

f. NSAIDs, especially cyclooxygenase (COX-2) inhibitors such as celecoxib (Celebrex), should be used for flare-ups of mild to moderate inflammatory or nonneuropathic pain. They may be used along with opioids as long as medication dosing remains within the recommended guidelines.

g. Safe opioid prescribing:

i. Opioids are often prescribed by potency, with the pure *mu* opioid the most powerful (hydromorphone, oxycodone, fentanyl, morphine).

ii. Opioids require careful client selection, titration, and monitoring.

iii. Avoid long-term, daily treatment with short-acting opioids (oxycodone, hydrocodone). For as-needed use, prescribe minimal quantities (no more than 3–7 days).

iv. After completing a full biopsychosocial assessment, start with the lowest effective dose and combine it with other pain-relieving modalities (see "Alternative interventions").

v. Check your state's prescription drug monitoring program (PDMP) prior to prescribing controlled substances, as needed and at least annually. PDMPs are state-run electronic databases that track dispensing of controlled substances. PDMPs provide clinicians with critical information about clients' narcotic prescription history and identify seeking behavior patterns.

vi. Contact the client's pharmacy for a list of current medications. The PDMP is not real time, and all current client prescriptions are available from the pharmacy.

vii. Perform urine drug screen prior to prescribing controlled substances initially, as needed, and annually. National guidelines recommend enzyme immunolinked assay (EIA) and gas chromatography/mass spectroscopy urine screen. Depending on results of urine drug screening, the provider may seek additional consultation, change medication therapy, refer for substance abuse, or discharge the client for noncompliance with the established drug contract between the prescriber and the client.

viii. A written controlled substance treatment agreement between client, provider, and clinic is recommended (informed consent). This should include full diagnosis, nature/purpose of the opioid treatment plan, complete listing of potential risk/benefits of therapy, and alternative and risks/ benefits of not receiving treatment. In addition, include the expectations of the client.

1) No other controlled substances will be prescribed by any other provider.

2) Only one pharmacy should be used when filling the prescription of the controlled substance.

3) Medication must be taken as prescribed.

4) There are no early refills on controlled substances.

5) Refills require a clinical visit for evaluation.

6) Lost/stolen prescriptions will not be refilled.

7) The client must agree to random drug screens and may be called to report to the clinic for random drug screens and/or pill counts. An example of this informed consent can be found at www.painmed.org/files/consent-for-chronic-opioid-therapy.pdf.

ix. Utilize tools such as the Addiction Behaviors Checklist, DIRE (Diagnosis, Intractability, Risk, Efficacy) score, or CAGE assessment (Have you ever tried to **C**ut down on your alcohol/drug use? Do you get **A**nnoyed if someone mentions your use is a problem? Do you ever feel **G**uilty about your use? Do you ever have an **E**ye-opener first thing in the morning after you've been drinking or using the night before?).

x. Red flags for misuse, abuse, addiction, and diversion with opioids include the following:

1) Psychiatric illness.

2) Personal history of alcohol or drug abuse or overdose.

3) Family history of alcohol or drug abuse.

4) Concurrent benzodiazepine use.

h. Ambulatory infusion pumps can be programmed to administer pain management medication continuously, intermittently, tapered, or client-controlled. Infusion pumps prescribed for clients should be overseen by a pain medicine specialist.

i. Benzodiazepines and barbiturates are not advised for treatment of chronic pain due to the high risk of substance abuse.

D. Alternative interventions:

1. Cognitive behavioral training: Examples of cognitive behavioral training include problem-solving, guided imagery, hypnosis, controlled breathing exercises, attention diversion, meditation, and yoga exercises; progressive muscle relaxation (PMR) is recommended to help relax major muscle groups.

2. Exercise: Examples of exercise include yoga exercises and PMR. PMR is recommended to help relax major muscle groups. Research indicates that yoga reduces bothersome pain after 12 weeks of regular exercise. The benefits of yoga exercise include improved strength, balance, coordination, range of motion, and reduced anxiety. Yoga ▶

instruction by a qualified teacher is a low-cost intervention. Yoga is an effective form of self-care and is an affordable way to alleviate pain. Always advise the client to start slowly and be prepared for an approach to pain management that may take several weeks of therapy.

3. Alternative therapies: Randomized controlled trials showed significant reduction in pain with alternative interventions such as music, relaxation, distraction, acupuncture, myofascial release treatments, and massage use.

4. Occupational therapy.

5. Vocational therapy.

6. Physical therapy such as noninvasive techniques, transcutaneous electrical nerve stimulation (TENS), hot or cold therapy, hydrotherapy, traction, massage, bracing, and exercise.

7. Individual and family therapy or counseling.

8. Aesthetic or neurosurgical procedures.

9. Cold laser therapy: Low light therapy stimulates healing. This therapy can be used for inflammation and has been used to stimulate healing in sprains/strains, dental ulcerations, and muscle spasms, as well as skin rejuvenation and wound healing.

10. Clients will inquire about the use of herbal products to treat chronic pain. Advise clients that these products are not regulated by the Food and Drug Administration (FDA) and may interact with current medications and cause complications. Advise clients to research all herbal products on reputable medically based websites, not blogs or chat rooms. Caution clients regarding devil's claw, feverfew, willow bark, glucosamine, and chondroitin. Discourage any use of dimethyl sulfoxide.

FOLLOW-UP

A. See clients every 4 to 6 weeks for evaluation. Reassess using the 5As: Analgesia, Activity, Adverse effects, Aberrant behaviors, and Affect.

B. Ensure the client has access to care on a regular schedule.

C. These brief visits should be regular so that care is not perceived to be dependent on escalation of symptoms.

D. Monitor for possible side effects, including sedation, pruritus, opioid-induced constipation/bowel dysfunction, nausea, and vomiting and treat as indicated.

CONSULTATION/REFERRAL

A. Consider client referral to a pain management clinic/specialist if pain control is not adequate. Interventions commonly performed at the specialty clinic include facet joint injections, percutaneous radiofrequency neurotomy, epidural corticosteroid injections, transforaminal epidural injections, and sacroiliac (SI) joint injections.

B. Consult with a physician/specialist if referral is needed for psychological counseling or if substance abuse is suspected.

C. Refer to a certified pain specialist provider if the client is taking high doses of opioids and detoxification is indicated. Buprenorphine (Subutex) is the most common medication prescribed by a certified pain specialist physician.

D. Consider rheumatology consult if a rheumatic condition is suspected.

INDIVIDUAL CONSIDERATIONS

A. Adults:

1. When prescribing pharmacologic agents, consider drug–drug interactions. When administering tramadol with use of any SSRI, educate the client regarding the possible interactions between the two medications and teach the client the signs and symptoms of serotonin syndrome and to report these signs if they occur. Avoid using this combination of medications if the client is known to have problems with metabolizing CYP2D6.

B. Pregnancy:

1. Careful consideration should be used when prescribing pain medication to clients who are pregnant. Tylenol is safe during pregnancy. NSAIDs are not recommended during pregnancy. When prescribing medications, refer to the prescribing classification of all medications for safety clarification during pregnancy.

C. Geriatrics:

1. Guidelines for assessment of pain in the geriatric population suggest the following:

a. Client self-report is the most accurate and reliable method—even for clients with cognitive impairment.

b. Consider using a narrative approach, allowing the client an opportunity to relay meaningful stories describing pain and their conclusions as to the source of their pain.

c. If clients deny "pain," try other descriptives such as "soreness" or "stings" or "aching" or "uncomfortable." Reword questions. For example, "Is there any place on your body that hurts? Please show me." "Is there anywhere inside that doesn't feel right?" "Is there any symptom that is stopping you from doing what you want to do?"

d. Educate and train clinical staff and collaborative professional teams how to recognize and engage in a conversation that will help older adults express their pain symptoms.

e. For geriatric clients who have dementia, the recommended tools are Pain Assessment in Advanced Dementia (PAINAD) and Doloplus-2.

2. Prior to prescribing medications to the geriatric client, review their current medication list for drug–drug interactions. Also, check the new medication against the Beers criteria for medications that should be avoided in the geriatric population (www.elderconsult.com/wp-content/uploads/PrintableBeersPocketCard.pdf).

3. Initiate new medications at the lowest dose and titrate slowly for the desired effect. In some cases with profound renal and hepatic insufficiency, it is not unreasonable to initiate medications at 30% to 50% lower doses than even the minimal suggested dose. Avoid extended-release products in renal and hepatically impaired clients.

4. Concerns with opioids in older adults are neurotoxicity, delirium, cognitive impairments, and increased risk of falls leading to orthopedic injury.

5. Tramadol decreases the seizure threshold and may place clients at risk of seizure-related injury. Use with caution in geriatric clients (although it may be used in clients with well-controlled seizure disorders).

6. A concern with tramadol in older adults is fall risks (fractures/injuries). Use with caution in geriatrics treated for seizures because it lowers the seizure threshold. It may be used if seizures are well controlled. Avoid extended-release product in renal-impaired geriatric clients. Instead, reduce the dose of an immediate-release product.

PAIN ASSESSMENT AND MANAGEMENT IN THE AGING POPULATION

DEFINITION

A. Persistent pain occurs quite frequently in the elderly population. However, pain is not a normal part of aging. Chronic pain is defined as having sensory/emotional changes with experience of tissue change/damage for longer than 3 months. Uncontrolled chronic pain may lead to a downward spiral for the client, progressing to alterations in physical and mental health status. Inadequate assessment and management of chronic pain may lead to a decrease in the quality of life for all clients.

COMMON PAIN SYNDROMES

A. There are many common pain syndrome that are present in older adults. Assessing for these unidentified pain syndromes may enhance the discovery of the source of pain for the client. Common pain syndromes experienced by elderly clients include fibromyalgia, gout, osteoarthritis, unidentified fractures, neuropathies, and vitamin deficiencies such as vitamin B_{12} deficiency.

INCIDENCE

A. Older adults are the fastest growing population. It is estimated that by the year 2040 there will be more than 1.3 billion people worldwide older than the age of 65. In the United States alone, there will be over 80 million people living in this age group.

PATHOGENESIS

A. Studies indicate that pain sensitivity changes and pain threshold increases with aging. Therefore, the absence of reportable pain does not mean that pain does not exist in the elderly population. As one ages, the number of neurotransmitter cell receptors in the brain diminishes as brain tissue begins to atrophy. This loss of neurons has a direct impact on pain transmission, which ultimately increases pain tolerance and disguises the presence of pain in the elderly.

PREDISPOSING FACTORS

A. Aging adult.
B. Barriers to effective pain assessment:
1. Cognitive and language impairments.
2. Comorbid chronic condition (e.g., depression, anxiety, agitation, illness, dementia, psychological disorders, and memory disorders).
3. Medications taken by the client.
4. Ineffective communication to the provider.
5. Ineffective assessment by the provider.
6. Noncompliance with medication regimen.

SUBJECTIVE DATA

A. On the initial exam, a comprehensive history is imperative when assessing for pain. Communication is a key ingredient when assessing for pain. Hearing loss, vision loss, and the inability to fill out documents (pain scales) are a few components of the assessment that can interfere with a successful interview. Adjustments should be made to ensure that communication among the client, family/significant other, and provider is clear. Clients who are not able to provide verbal information should be assessed for behaviors and physical signs of pain. Physical signs of pain may include grimacing, moaning, silence, poor eye contact, and so forth. Behaviors that may be an indicator of pain may include anxiety, agitation, confusion, depression, and isolation. Other factors to consider when assessing a client for pain include their age, medical history, surgical history, current medications, current cognitive status, and functional status. A focused history will assist in establishing a baseline status for the client.
1. Assess for communication/cognitive impairments that may interfere with the assessment. Consider communication factors, comorbid conditions/illnesses, and current medications.
2. Assess the current mood and physical state of the client (e.g., depression, anxiety, anger, illness).
3. Have the client describe the duration of pain and what time of day symptoms begin.
4. Ask the client to describe the pain, for example, crushing, stabbing, or burning.
5. Ask the client where the sensation begins and in what direction it radiates. Does pain come and go, or is it constant? What makes pain worse? What makes pain better?
6. Have the client rate pain on a scale of 0 to 10, with 0 being no pain.
7. Ask the client to complete a functional status form to assess functional abilities. Identify impairments of activities of daily living (ADLs) and note limitations.
8. Ask what medications/treatments have been used in the past for pain. Was pain improved?
9. Inquire regarding family/social support, financial resources, and concerns the client may have regarding social complexities.

PHYSICAL EXAMINATION

A. Start with vital signs: Check temperature (if applicable), pulse, respirations, and blood pressure.
B. Inspect:
1. Inspect general appearance, noting facial grimaces, frowning, body movement, and response to assisted movement.
2. Inspect site of pain for swelling and erythema.
C. Palpate:
1. Palpate specific sites of noted discomfort/pain.
2. Palpate adjacent joints/areas to site of discomfort. (Pain may also be caused from referred pain. A thorough exam of the surrounding joints/tissues should be assessed.) Note inflammation, change in skin temperature (warm/cool), and pain with palpation.
D. Perform musculoskeletal exam:
1. Perform a complete musculoskeletal exam, concentrating on the site of pain.
2. Assess range of motion, gait, and mobility. Evaluate strength, noting symmetry of strength, and/or weakness.
E. Perform neurologic exam:
1. Perform a neurologic exam on sites involved.
F. Auscultate:
1. Conduct a complete heart exam, checking for dysrhythmias. ▶

2. Conduct a complete lung exam.
3. Auscultate abdomen, noting bruits if present.

G. Mental status:
1. Assess for confusion, agitation, change in personality, anxiety, and so forth.

DIAGNOSTIC TESTS

A. Perform a Mini-Mental State Exam (MMSE) if indicated. This form is available at www.ihpa.gov.au/sites/g/files/net636/f/publications/smmse-tool-v2.pdf.

B. Perform a functional status assessment. There are many instruments that can be used; examples include the Instrumental Activities of Daily Living Scale, the 10-Minute Geriatric Screen, and the Katz Independence in Activities of Daily Living. A provider resource for assessing functional status can be found at hmsa.com/portal/provider/PRC_Guide_COA_Functional_Status_Assessment.pdf.

C. Perform the STEADI test (Stopping Elderly Accidents, Deaths & Injuries) to assess mobility and predict fall risk. Video and form information for provider and client is available at www.cdc.gov/steadi/materials.html.

D. Assess for pain using a valid method of testing for elderly clients. The Verbal Descriptor Scale (VDS) is recommended for assessment of the elderly client. Other available tools include the Faces Pain Scale and the Numeric Rating Scale. A listing of validated clinically tested tools can be found at www.practicalpainmanagement.com/resource-centers/opioid-prescribing-monitoring/list-clinically-tested-validated-pain-scales.

PLAN

A. General interventions:
1. The primary goal is to identify the source of pain. Once the source is noted, measures to improve pain should be performed.

B. Client teaching:
1. Educate the client regarding the source of pain.
2. Discuss possible sources of improving pain according to the diagnosis.
3. Depending on the source of pain, consider nonpharmacologic treatments to improve pain.

C. Special elderly considerations for pain management:
1. Nonpharmacologic treatments: Such treatments may include physical therapy, aquatic therapy, exercise, chiropractic treatments, massage, acupressure, acupuncture, transcutaneous electrical nerve stimulation (TENS), guided imagery, relaxation, hot/cold therapy, and so forth.

D. Pharmaceutical therapy:
1. Body fat, total amount of water/fluid in the body, poor nutritional status, and muscle mass all impact drug metabolism. There is a heightened sensitivity to adverse effects that results from physiologic changes, drug interactions, and drug–disease interactions.
2. Medications, such as diuretics, may influence the impact of drug distribution in the body. These factors should be considered when prescribing medications in the elderly:
a. Some changes affected by these components include onset of action, availability of the drug, and excretion of the drug.
b. Use caution when prescribing medications and repeating the dose if no response is perceived. Repeating the drug dose to obtain therapeutic results can cause adverse events and/or overdose.
c. If the drug has a slow onset, it may build up in the body and cause an overdose of the medication.
d. Aging is associated with higher steady-state concentrations of water-soluble drugs and increased half-life of fat-soluble drugs. Therefore, when prescribing medications to elderly clients, all medications should be started at the **lowest** dose possible and titrated up slowly as tolerated. Lower doses are better tolerated and potentially will lead to fewer side effects.
3. Refer to the "Chronic Pain" section for modalities and assessment for pharmacologic agents.
4. For special considerations with specific pain medications, please refer to Table 6.1.
a. Nonopioids: Acetaminophen and nonsteroidal anti-inflammatory drugs (NSAIDs) should be discussed and considered for treatment of mild pain. Assess liver and kidney function prior to administering these medications:
i. Acetaminophen: Contraindications to acetaminophen include liver failure, hepatic insufficiency, and chronic alcohol use. The maximum recommended dose of acetaminophen is 2 g per 24-hour period, which includes all Tylenol products and combination medications that include Tylenol.
ii. NSAIDs: Contraindications to NSAIDs include peptic ulcer disease, chronic kidney disease, and heart failure. Monitor closely if the client is taking other medications that may interact with the NSAID, such as corticosteroids and selective serotonin reuptake inhibitors (SSRIs). Elderly clients should only use one NSAID at a time. Advise the client to avoid using over-the-counter NSAIDs, along with prescribed NSAIDs. Elderly clients should also be advised to use a proton pump inhibitor along with the NSAID to protect the gastrointestinal system. Clients taking aspirin should not use ibuprofen while also taking aspirin. Clients prescribed these medications should be closely monitored for gastrointestinal problems (ulcers, gastroesophageal reflux), prolonged bleeding times, and adverse change in kidney function. Monitor the current use of other medications (e.g., aspirin, NSAIDs, proton pump inhibitors, Coumadin) that would interact with these medications.
b. Opioids: Opioids may be considered for treatment of moderate to severe pain when nonopioids are not effective. Proper education regarding the use of these medications is necessary to avoid misconceptions regarding the use of these drugs. Educate the client that opioids are safe medications when used properly as prescribed and that with proper use addiction can be prevented.
i. Opioids that should not be used in the elderly client include meperidine and propoxyphene. These agents may cause central nervous system toxicity if poorly metabolized by the liver.
ii. Opiates have a higher risk of falls and the client should be educated on this possibility.
c. Other medications:
i. Anticonvulsants, such as gabapentin, have been used successfully to treat neuropathic pain. Starting doses should be low and gradual titration upward can eliminate side effects and can be used successfully to treat pain. Studies have shown that doses from 2,400 to 3,600 mg/d reduce pain and improve mood and sleep disturbance. ▶

TABLE 6.1 PAIN MEDICATIONS

Classification	Examples	Special Administration/Dosing Considerations[a]
Acetaminophen	Acetaminophen	Contraindications to acetaminophen include liver failure, hepatic insufficiency, and chronic alcohol use (active/present). Do not exceed 4 g in healthy adults. Do not exceed 2 g in healthy elderly clients.
NSAIDs	Ibuprofen Naproxen Aspirin Diclofenac Meloxicam Indomethacin	Contraindications to NSAIDs include peptic ulcer disease, chronic kidney disease, and heart failure. May prolong PT. Note potential interactions with corticosteroids and SSRIs. Take only one NSAID at a time; do not use with aspirin. Consider a PPI.
NSAIDs, COX-2	Celecoxib	Use with caution due to cardiac risks (stroke and MI). Do not exceed 400 mg/d. Celecoxib is contraindicated in clients with sulfa allergy.
Tramadol (considered weak opioid)	Tramadol	Be aware of potential acetaminophen or NSAID toxicity with concurrent use of opioids. Be aware of the interactions with the use of SSRIs and risk of serotonin syndrome and seizures.
Topical agents	NSAIDs (diclofenac sodium) Lidocaine Ketamine Capsaicin	Begin with low dose and increase as tolerated. Lidocaine patches: postherpetic neuralgia. NSAIDs: localized nonneuropathic pain. Capsaicin: regional pain syndromes.
Corticosteroids	Prednisone Methylprednisolone Cortisone	Tapering for short-term use as indicated. Used for neuropathic pain and pain associated with inflammatory changes or metastatic bone pain. Not for long-term use. Avoid use in the elderly due to high side effect risk.
Muscle relaxants	Cyclobenzaprine Carisoprodol Methocarbamol Baclofen Metaxalone	Use in conjunction with NSAIDs or separately if NSAIDs are ineffective. High fall risk as muscle relaxants cause drowsiness and sedation.
Stronger opioids (short-acting)	Codeine Hydrocodone Oxycodone Morphine	Begin low with short-acting only. Increase over time. Avoid morphine in clients with renal insufficiency. Sustained release formulation only for constant pain and should be according to the recommendation of pain specialist. Be aware of potential acetaminophen or NSAID toxicity with concurrent use of opioids.
Neuropathic Pain		
Tricyclic antidepressants	Amitriptyline Imipramine Doxepin Nortriptyline Desipramine	Begin low; reevaluate and increase every 4–7 days. Order an EKG prior to starting therapy. Use with caution in clients with cardiac issues, especially conduction abnormalities. Avoid amitriptyline, imipramine, and doxepin in the elderly due to higher side effect risk (anticholinergic effects).
SNRI depressants	Duloxetine Venlafaxine Milnacipran	Duloxetine is a P450 2D6 isoenzyme inhibitor but the only one approved by the FDA as an analgesic.
Anticonvulsants	Gabapentin Pregabalin Carbamazepine	Gabapentin and pregabalin are usually well tolerated.

[a]All medications should be checked for use during pregnancy and lactation prior to prescribing.
COX-2, cyclooxygenase; FDA, Food and Drug Administration; MI, myocardial infarction; NSAID, nonsteroidal anti-inflammatory drug; PPI, proton pump inhibitor; PT, prothrombin time; SNRI, serotonin norepinephrine reuptake inhibitor; SSRI, selective serotonin reuptake inhibitor.

ii. Tricyclic antidepressants (TCAs): Nortriptyline has been shown to be successful in treating pain in elderly clients. Use with caution in clients with known cardiac conditions. Consider ordering a baseline EKG prior to beginning therapy. Avoid use if cardiac/conduction abnormalities are present. The starting dose should begin low, and a gradual increase in dose every 4 to 7 days should be prescribed as tolerated. Amitriptyline, imipramine, and doxepin should be avoided in the elderly due to a higher risk of side effects.

iii. Local anesthetics: Pain patches may be used with discretion. Lidocaine patches are useful for postherpetic neuropathy. Other pain patches may also be trialed, beginning at a low dose and titrated as tolerated. Topical NSAIDs may be used for localized nonneuropathic pain. Capsaicin and menthol topical agents have been shown to improve regional pain syndromes. Epidural injections have also been found useful in alleviating pain in older adults.

iv. Corticosteroids: Steroids may be used for neuropathic pain and pain associated with inflammatory changes or metastatic bone pain. However, great caution should be used in treating clients with steroids. Long-term use is not recommended. Significant side effects with use of steroids can occur in the elderly population in a very short period of time (such as muscle wasting, hyperglycemia). Consider other alternatives for pain control instead of steroids for elderly clients.

d. Cancer pain: The World Health Organization (WHO) recommends around-the-clock pain treatment for clients diagnosed with cancer. Cancer treatment strategies include the following:

i. Acetaminophen is the first-line treatment for mild pain.

ii. NSAIDs are recommended as second-line therapy for mild to moderate pain.

iii. Mild opioids (codeine, hydrocodone, propoxyphene, and oxycodone) are recommended for moderate pain and pain not responding to NSAIDs.

iv. Morphine may be used for severe pain and pain not responding to mild opioids. Other alternatives to morphine include hydromorphone, fentanyl, and methadone.

v. Consider adding additional medications for severe pain complicated by anxiety/mood disorders and not controlled on a single agent. Common medications that enhance the effects of analgesics include antidepressants, anticonvulsants (gabapentin), muscle relaxants, antihistamines, corticosteroids, topical creams/gels, antiarrhythmics (beta-blockers), and alpha-2 adrenergic agonists (clonidine).

CONSULTATION/REFERRAL

A. Refer all clients to a pain management specialist if considering long-term pain management.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. As many as 53% of older adults report acute pain in the preceding 3 months and 75% of these adults identify pain in more than two locations. Pain is a significant burden to the geriatric population and must be treated.

2. Asking geriatric clients about pain at night and difficulty performing ADLs is an efficient way of identifying older adults who are vulnerable to developing depression illness.

3. Older adults taking opioids for pain experience only small amounts of relief and improved function and adverse effects were three times more likely to occur. Common opioid-induced symptoms include constipation, drowsiness, nausea, headache, and confusion. Most of these effects placed the elderly client at greater risk of falls, which could lead to serious injuries. The risk-to-benefit ratio of the use of opioid medications in this population must be thoughtfully considered.

4. Integrative approaches such as yoga, massage, or chiropractic manipulation might be too strenuous for geriatrics. Tailor interventions to the individual and assess the client for osteoporosis before recommending high-impact exercises or aggressive alternative physical activities.

LOW BACK PAIN

DEFINITION

A. Painful conditions of the lower back may be categorized as follows:

1. Potentially serious disorders: acute fractures, tumor, progressive neurologic deficit, nerve root compression, and cauda equina syndrome.

2. Degenerative disorders: aging or repetitive use, degenerative disease, and osteoarthritis.

3. Nonspecific disorders: benign and self-limiting with unclear etiology.

INCIDENCE

A. Lower back pain (LBP) is commonly seen in clients from ages 20 to 29 years, with increasing incidence until age 65 years. It may be acute or chronic in nature. Chronic LBP lasts more than 3 months.

B. Approximately 70% to 80% of people experience back pain at one point in their lifetime.

C. The long-term outcome of LBP is highly favorable. However, the cost of treating LBP can be upward of $134 billion or more per year, with increasing prevalence.

PATHOGENESIS

A. Pain arises from fracture, tumor, nerve root compression, degenerative disc, osteoarthritis, and strain of the ligaments and musculature of the lumbosacral area.

PREDISPOSING FACTORS

A. Trauma causing ligament tearing; stretching of the vertebra, muscles, tendons, ligaments, or fascia.

B. Repetitive mechanical stress.

C. Tumor.

D. Exaggerated lumbar lordosis.

E. Abnormal, forward-tipped pelvis.

F. Uneven leg length.

G. Chronic poor posture due to inadequate conditioning of muscle strength and flexibility, improper lifting techniques causing excessive strain, and poor body mechanics.
H. Inadequate rest.
I. Emotional depression.

COMMON COMPLAINTS

A. Pain in the lower back area may range from discomfort to severe back pain, with or without radiation down either leg or bilaterally.

OTHER SIGNS AND SYMPTOMS

A. Ambulating with a limp.
B. Limited range of motion.
C. Posture normal to guarded.

SUBJECTIVE DATA

A. Ask the client to discuss the origin of pain. How has the pain progressed or changed since the initial injury or stress?
B. Ask the client to point to an area where pain is felt.
C. Have the client describe the pain. Is it radiating, with sharp, shooting pain down to the lower leg and feet?
D. Ask: What makes the pain worse or better? Have the client list current medications or therapies used for pain, noting the results of treatment.
E. Investigate occurrence of systemic symptoms such as fever and weight loss.
F. Explore client's medical history. Note previous trauma or overuse, tuberculosis, arthritis, cancer, and osteoporosis.
G. Inquire about symptoms such as dysuria, bowel or bladder incontinence, muscle weakness, paresthesia, and loss of sensation. Bowel or bladder dysfunction, bilateral sciatica, and saddle compression may be symptoms of severe compression of the cauda equina and necessitates an urgent workup and referral.
H. Ask the client about precipitating factors such as athletics, heavy lifting, driving, yard work, occupation, sleep habits, or systemic disease.
I. Use a pain scale to describe the worst pain and the best pain levels.

PHYSICAL EXAMINATION

A. Check temperature, pulse, blood pressure, and respirations.
B. Inspect:
  1. Observe general appearance; note discomfort and grimacing on movement and/or examination.
  2. Distraction may distinguish pain behavior from actual pathology.
  3. Note evidence of trauma with bruises, cuts, and fractures.
  4. Note posture and gait.
C. Palpate:
  1. Palpate spine and paravertebral structures, noting point tenderness and muscle spasm. Palpation elicits paravertebral tenderness and generalized tenderness over lower back to upper buttocks.
  2. Examine abdomen for masses.
  3. Palpate peripheral pulses of extremities.
D. Perform neurologic exam:
  1. Identify sensation and pain distribution.
  2. Determine motor strength and evaluate whether muscle strength is symmetrical: Upper extremity resistance is equal bilaterally.
  3. Test deep tendon reflexes (DTRs) and dorsiflexion of big toe.
E. Evaluate using the FABER test (flexion, abduction, and external rotation) or the Stork test (stand on one leg; lift the other leg and extend backward; palpate the sacroiliac joint on both sides while performing test). Back extension requires that you lie on your stomach, bring your legs upward, press your abdomen downward, and clasp your hands behind your shoulder blades (upper part of body should not be on the ground).
F. Check sensation of the perineum to rule out cauda equina syndrome.
G. Perform traction tests: straight leg raises, crossed leg raises, Yeoman Guying, and Patrick test. Musculoskeletal findings include the following:
  1. Straight leg raising and dorsiflexion of foot on affected side may reduce lower back discomfort.
  2. Elevate each leg passively with flexion at hip and extension of knee. Positive straight leg raise is radicular pain when the leg is raised 30° to 60°.
  3. Crossed leg raises: Test is positive when pain occurs in leg not being raised.
  4. Yeoman Guying: Unilateral hyperextension in prone position identifies lumbosacral mechanical disorder.
  5. Patrick test: Place heel on opposite knee and apply lateral force; check for hip or sacroiliac disease.
  6. Range of motion: Increased pain with extension often indicates osteoarthritis. Increased pain with flexion often indicates strain or injured disc.
H. Perform pelvic exam:
  1. Consider pelvic and rectal exam, if indicated. If the client has fallen on the coccyx, a rectal exam is needed to check for stability.

DIAGNOSTIC TESTS

A. Laboratory (usually unnecessary on initial exam): complete blood count, erythrocyte sedimentation rate, C-reactive protein (CRP), serum calcium, alkaline phosphatase, urinalysis, and serum immunoelectrophoresis when inflammatory conditions, neoplastic conditions, diffuse bone disease, or renal disease is suspected.
B. Radiography of spine (imaging studies not usually necessary during the first 6 weeks unless there are red flag signs/symptoms).
C. Consider the following tests (after radiography is completed):
  1. MRI to rule out disc disease and tumors.
  2. Bone scan to rule out cancer.

DIFFERENTIAL DIAGNOSES

A. Back pain secondary to musculoskeletal pain.
B. Herniated intervertebral disease.
C. Sciatica.
D. Fracture.
E. Tumor.
F. Abdominal aneurysm.
G. Pyelonephritis.
H. Metabolic bone disease.
I. Gynecologic disease.
J. Peripheral neuropathy.
K. Depression.
L. Prostatitis.
M. Spinal stenosis.
N. Osteoarthritis.
O. Osteoporosis.
P. Ankylosing spondylitis.

PLAN

A. General interventions:

1. The client should continue physical activity as tolerated. Guidelines indicate that bedrest should be avoided.

2. For acute muscle strain, have the client apply local cold packs for 20 to 30 minutes several times a day for the first 24 hours. Heat packs are recommended after the initial 24 hours of injury.

3. Chronic or recurrent pain may be treated with either ice or heat applications, whichever gives relief. Other chronic LBP treatment methods, other than pharmacology, include physical therapy, cognitive behavioral therapy, acupuncture, radiofrequency ablation, facet injections, spinal cord stimulation, and surgical intervention. Referral to the appropriate specialty provider is indicated.

B. Client teaching:

1. Give accurate information on the prognosis for quick recovery, such as continuing light physical activity, performing back-strengthening exercises, and avoiding overuse of medications.

2. Improvement occurs in most cases in a few weeks, although mild symptoms may persist.

3. Joint guidelines by the American College of Physicians and the American Pain Society recommend rehabilitative therapies for clients who do not improve after medications and self-care recommendations. Rehabilitative therapies include exercise therapy, acupuncture, massage therapy, spinal manipulation, cognitive behavioral therapy, and yoga.

4. Provide educational handouts on back exercises; *see Client Teaching Guide for* Chapter 21, *"Back Stretches."*

5. After intense pain abates, the client may perform low back exercises for range of motion and strengthening, and isometric tightening exercises of abdominal and gluteal muscles.

6. Teach client knee–chest exercises. Recommend to the client to place their back against the wall and contract abdominal and gluteal muscles with 5 to 10 repetitions four to six times per day.

7. Research indicates that yoga is beneficial for many types of back pain. Types of back pain benefited by yoga include musculoskeletal injury, herniated disc, spinal stenosis, spondylolisthesis, piriformis syndrome, arthritis, and sacroiliac joint derangement.

8. Encourage the client to perform walking exercise daily.

9. Teach relaxation techniques.

10. Encourage the client to modify work hours and job tasks.

11. Refer the client for therapeutic massage or physical therapy as needed.

12. Obesity is often related to decreased exercise and poor physical fitness with reduced trunk muscle strength and endurance. Obese clients may experience back pain with normal activity.

C. Pharmaceutical therapy:

1. Analgesics: Analgesics include acetaminophen 325 to 650 mg every 4 to 6 hours. Maximum dose is 4,000 mg/d for the average adult. Inquire of any other current medications and/or over-the-counter preparations containing acetaminophen.

2. Nonsteroidal anti-inflammatory drugs (NSAIDs), unless contraindicated due to gastrointestinal symptoms or cardiovascular disease:

a. Aspirin: 325 to 650 mg every 4 to 6 hours.

b. Ibuprofen: 400 to 800 mg every 6 to 8 hours. Maximum dose is 3.2 g/d under the care of the provider; otherwise 1.2 g/d.

c. Naproxen: 250 to 500 mg Q12H (maximum dose of 1,500 mg/d).

d. Piroxicam (Feldene): 10 to 20 mg every day (progressive response to steady state over 7 to 10 days).

e. Meloxicam (Mobic): 7.5 to 15 mg daily (maximum dose of 15 mg/d; dialysis clients only 7.5 mg/d).

f. Celecoxib (Celebrex): 100 to 200 mg BID (maximum dose of 400 mg/d).

g. Diclofenac: 50 mg two to three times per day (maximum dose of 150 mg/d).

3. Muscle relaxants:

a. Cyclobenzaprine HCl (Flexeril): 5 to 10 mg oral up to three times daily as needed.

b. Carisoprodol (Soma): 350 mg QID.

c. Methocarbamol (Robaxin): 1.5 g every day initially, then 750 to 1,000 mg every day.

d. Orphenadrine citrate (Norflex): 100 mg BID.

e. Metaxalone (Skelaxin): 800 mg three to four times a day.

FOLLOW-UP

A. If pain is severe or unimproved, follow up in 24 hours.

B. If pain is moderate, reevaluate client in 7 to 10 days.

C. See client in 2 to 4 weeks to reevaluate condition and behavioral changes.

D. Recurrences are not uncommon but do not indicate a chronic or worsening case.

CONSULTATION/REFERRAL

A. Consult with a physician/specialist when considering red flag diagnoses such as cauda equina syndrome, herniated disc, widespread neurologic involvement, carcinoma, or significant trauma.

B. Referral to a physician/specialist is recommended for clients who have symptoms indicating other conditions such as inflammatory disorders (e.g., ankylosing spondylitis, rheumatoid arthritis, iritis). Symptoms may include morning stiffness with gradual onset prior to age of 40 years, synovitis (inflammation of peripheral joints) skin rashes, and so forth.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Pregnancy is often associated with low back discomfort. This is due to the redistribution of body weight. As weight increases in the abdominal area with the growing fetus, clients tend to compensate by changing posture and tilting their spine back.

B. Adults:

1. Refer to the abovementioned material on chronic pain in the elderly. For clients older than 50 years of age presenting with no history of backache, consider a differential diagnosis of neoplasm.

2. The most common metastasis seen is secondary to the primary site of breast cancer, prostate cancer, or multiple myeloma. Pain most prominent in a recumbent position rarely radiates into the buttock or leg.

C. Geriatrics:

1. LBP is the leading cause of disability worldwide. Geriatric clients who are at the highest risk of LBP are those who had physically demanding jobs as well as those who smoke, are obese, and/or have physical/ ▶

mental comorbidities. Disabilities and costs are expected to increase in the coming decade secondary to the rising older adult population within a burdened healthcare system.

2. Studies indicate that LBP is a common reason for geriatrics to visit the ED. The prevalence of LBP is high in older adults primarily because it is underdiagnosed and/or undertreated. Approximately 60% to 80% of geriatric clients experience LBP through their lifetime, with 69% stating pain was in multiple sites, not just one. Acetaminophen is recommended as first-line treatment and management of persistent LBP.

3. Although low-dosed opioids may be considered for geriatrics with spinal pain and LBP, clinical guidelines recommend trying nonpharmacologic treatments or physical therapy/exercise adjuvant with acetaminophen first, then antidepressants/gabapentin, and lastly low-dosed opioids.

CLIENT TEACHING GUIDE

CHRONIC PAIN

You have been diagnosed with a chronic pain syndrome. This type of pain lasts longer than 3 months. This pain may be constant or it may come and go.

[ ] Apply ice (apply an ice pack to the affected area for 15 to 20 minutes) _____ times per day.

[ ] Apply heat (warm compress or heating pad 20 to 30 minutes) _____ times per day.

[ ] Physical therapy as directed _____ .

[ ] Complete the following exercises [ ] daily _____ [ ] at least three times per week [ ] as directed.

_____

[ ] Avoid caffeine in the afternoon and evening.

[ ] Rest at the beginning of the pain sequence.

[ ] You have been prescribed:

_____. Please take only as directed.

[ ] You have been prescribed a narcotic. Please follow these instructions:
A. You may need to increase fiber or take a stool softener to prevent constipation.
B. Do not drink alcohol.
C. This medication may make you drowsy or dizzy. It may impair your ability to drive or work and it may increase your risk of falling.
D. Never share this medication; keep out of reach of children and store in a safe location.

[ ] You have been referred to a pain management specialist for further evaluation and treatment.

[ ] Call your provider or go to the ED if any of the following occur:
A. Your heart rate is too slow or is fluttering too fast.
B. You develop side effects of the pain medication, such as itching, severe nausea, vomiting, or rash.
C. Your pain gets worse even though you are taking the medication correctly and as prescribed.
D. You cannot think clearly, become extremely dizzy, or begin falling more frequently.

RESOURCES Many resources on pain are available at your local library, bookstores, and on the internet. Look for a local support group in your area to join and learn how other people are coping with the condition same as yours.

There are many pain organizations available to assist clients. Clients may wish to visit the following websites for further information:
A. American Academy of Pain Management: www.aapainmanage.org.
B. American Chronic Pain Association: www.theacpa.org.
C. Arthritis Foundation: www.arthritis.org.
D. National Chronic Pain Outreach Association: www.healthcentral.com/chronic-pain/h/national-chronic-pain-outreach-association.html.
E. National Fibromyalgia Association: www.fmaware.org.
F. A nice resource available with many of the different types of logs and tools to use can be found at www.painmed.org/patientcenter/tools/.

CHAPTER 7

DERMATOLOGY GUIDELINES

Jill C. Cash and Amy C. Bruggemann

ACNE ROSACEA

DEFINITION

A. A multivariate skin disease with phenotype manifest, acne rosacea is characterized by chronic and relapsing inflammatory processes in which flushing and dilation of the blood vessels occur on the face.

INCIDENCE

A. Acne rosacea affects approximately 13 million people in the United States.

PATHOGENESIS

A. The origination and development of rosacea are poorly understood. Abnormalities in the innate immune system, inflammatory reactions to cutaneous organisms, UV exposure, genetic factors, and vascular hyperreactivity have all been identified as possible causative factors.

PREDISPOSING FACTORS

A. Tendency to flush frequently.
B. Exposure to heat, cold, or sunlight.
C. Consumption of hot or spicy foods.
D. Some topical medications, astringents, or toners.
E. Acute psychological stressors (e.g., anger, rage, embarrassment).
F. Menopausal hot flashes.
G. Hormonal changes of pregnancy.
H. Alcoholic beverages and nicotine.
I. Certain drugs, such as nicotinic acid and vasodilators.

COMMON COMPLAINTS

A. Diagnostic phenotypes:
  1. Persistent centrofacial redness that may repeatedly accentuate phymatous changes.
B. Major phenotypes:
  1. Papules.
  2. Pustules.
  3. Flushing.
  4. Telangiectasia.
  5. Ocular manifestations.
C. Secondary phenotypes:
  1. Burning.
  2. Stinging.
  3. Facial edema.

SUBJECTIVE DATA

A. Ask the client to describe the location and the onset. Was the onset sudden or gradual? How have the symptoms continued to develop?
B. Assess if the skin is itchy or painful.
C. Assess for any associated discharge (blood or pus).
D. Complete a drug history. Has the client recently taken any antibiotics or other medications?
E. Determine whether the client has used any topical medications, astringents, toners, or new skin care products.
F. Rule out any possible exposure to industrial or domestic toxins, insect bites, and possible contact with venereal disease or HIV.
G. Ask the client about close contact with others with skin disorders.
H. Identify whether exposure to heat, cold, or sunlight provokes the symptoms.
I. Ask whether eating or drinking hot or spicy foods or consumption of alcoholic beverages provokes the symptoms.
J. Identify current or smoking history.

PHYSICAL EXAMINATION

A. Check temperature, pulse, and blood pressure.
B. Inspect:
  1. Inspect skin, focusing on face and scalp.
  2. Inspect nose and paranasal structures.
  3. Inspect eyes, eyelids, conjunctiva, and cornea. **An ocular manifestation, rosacea keratitis, may cause corneal ulcers to develop.**

DIAGNOSTIC TESTS

A. None.
B. Consider skin biopsy to rule out granulomatous rosacea, if suspected.

DIFFERENTIAL DIAGNOSES

A. Clinical findings shared with centrofacial erythema:
  1. Acne rosacea.
  2. Sun-damaged skin.
  3. Seborrheic dermatitis.
  4. Acute cutaneous lupus erythematosus.
  5. Dermatomyositis.
B. Clinical findings shared with papules and pustules:
  1. Acne rosacea.
  2. Acne vulgaris.
  3. Steroid-induced acne. ▶

The contributions of Cheryl Glass to this chapter in prior editions are acknowledged here.

4. Perioral dermatitis.
5. Keratosis pilaris rubra faceii.
6. Demodicosis.
C. Granulomatous rosacea.
D. Pyoderma faciale.

PLAN

A. General interventions:
1. Identify any causative or provocative factors: heat, cold, hot or spicy foods, alcoholic beverages, nicotine, sunlight.
2. Advise washing the face with mild soap, such as Cetaphil soap, daily.
3. Avoid direct sunlight exposure; wear protective clothing/hats when outdoors. Suggest using a sunscreen with sun protection factor (SPF) 30 when exposed to sunlight.
B. Client teaching: *See Client Teaching Guide for this chapter, "Acne Rosacea."*
C. Pharmaceutical therapy:
1. Rosacea with persistent facial erythema, **no** papules or pustules:
a. Topical brimonidine 0.33% gel.
b. Oxymetazoline 1% cream.
2. Rosacea with persistent facial erythema **and** papules or pustules:
a. Mild to moderate disease:
i. Topical metronidazole gel 0.75% apply BID or 1.0% apply daily.
ii. Azelaic acid 20% cream or 15% foam apply BID.
iii. Ivermectin 1% cream apply daily.
b. Moderate to severe disease:
i. Initial treatment options:
1) Tetracycline 250 to 500 mg BID for 4 to 12 weeks.
2) Doxycycline 50 to 100 mg BID for 4 to 12 weeks.
3) Minocycline 50 to 100 mg BID for 4 to 12 weeks.
ii. Maintenance treatment:
1) Topical metronidazole gel 0.75% BID.
2) Azelaic acid cream 15% apply BID.
3. Other:
a. Do not use topical steroids. Topical steroids may worsen irritation.
b. Refractory cases may respond to isotretinoin (Accutane).

FOLLOW-UP

A. Follow up in 2 weeks to evaluate therapy.
B. See clients monthly for evaluation until maintenance is reached.
C. Relapses are common following discontinuance of antibiotics; repeat treatment.

CONSULTATION/REFERRAL

A. Consult or refer the client to a dermatologist if there is no improvement or if the client is unable to reach maintenance.
B. Provide an immediate referral to an ophthalmologist for treatment and follow-up if the eye is involved.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
1. Precautions should be used when prescribing medications for treatment during pregnancy.
2. Hormonal change can cause exacerbation. Topical preparation is first-line treatment. Metronidazole topical is thought to be safe in pregnancy.
3. The benefits of the use of steroids during pregnancy must outweigh the risks to be used. Risks of use include hypertension, intrauterine growth restriction, and diabetes.
B. Geriatrics:
1. Recent studies indicated rosacea is a systemic disorder associated with dyslipidemia, HTN metabolic disorders, cardiovascular disease, and alcohol/tobacco use, which are all prevalent in chronic kidney disease (CKD). Geriatric populations with a high rosacea severity have an increased risk of CKD and need ongoing evaluation of renal function labs: creatinine, blood urea nitrogen (BUN), and glomerular filtration rate (GFR).
2. Research suggested that rosacea is an independent risk factor for Parkinson disease through association with pathogenic mechanisms of elevated metalloproteinase activity. There was a twofold risk of Parkinson disease in clients with ocular rosacea and treatment of tetracycline appeared to reduce the risk of developing Parkinson disease. Practitioners must keep consistent skin assessments with clients who suffer from Parkinson disease and discuss treatment options with families and caregivers.
3. Monitor geriatrics for trigger medications that can worsen rosacea: vasodilators, niacin, or topical steroids.
4. Encourage elderly clients to use sunblock with titanium and/or zinc oxide on areas of the scalp with alopecia. Remind them that stress, hot/humid environments, alcohol, nicotine, spicy foods, and hot drinks can trigger a rosacea outbreak.
5. Avoidance of oil-based cosmetics and use of mild, nondrying soap is recommended.

ACNE VULGARIS

DEFINITION

A. Acne vulgaris is a disorder of the sebaceous glands and hair follicles of the skin, which are most numerous on the face, back, and chest. The sebaceous glands become inflamed and form papules, pustules, cysts, open or closed comedones, and/or nodules on an erythemic base. In severe cases, scarring can result.

INCIDENCE

A. Nearly 80% to 90% of all adults experience acne during their lifetime. Acne vulgaris, commonly seen in adolescence, may even extend into the third or fourth decade of life.

PATHOGENESIS

A. Sebum is overproduced and collects in the sebaceous gland. Sebum, keratinized cells, and hair collect in the follicle. ▶

With *Propionibacterium acnes* (also known as *Cutibacterium acnes*) present, the duct becomes clogged and lesions (noninflammatory and/or inflammatory) evolve.

PREDISPOSING FACTORS

A. Age (adolescence).
B. External irritants to skin (makeup, oils, equipment contact on skin).
C. Hormones (oral contraceptives with high progestin content).
D. Medications (lithium, halides, hydantoin derivatives, rifampin).
E. Hot, humid weather.
F. Mask use.

COMMON COMPLAINTS

A. Outbreak of pimples on face, chest, shoulders, and back that does not resolve with over-the-counter (OTC) treatment.
B. Acne rosacea: telangiectasia, flushing, and rhinophyma present.

OTHER SIGNS AND SYMPTOMS

A. Mild: comedones open (blackhead) and closed (whitehead).
B. Moderate: comedones with papules and pustules.
C. Severe: nodules, cysts, and scars.

SUBJECTIVE DATA

A. Elicit the age of onset of outbreak, duration, and course of symptoms.
B. Determine what makes the lesions worse or better.
C. Ask whether there are certain times of the month of year when lesions are better or worse.
D. Identify the client's current method of cleanser or moisturizer treatment.
E. Ask if the client has ever been treated by a provider for this problem. If so, determine the treatment and results of the treatment.
F. Assess whether other family members have this same problem.
G. Ask the client for a description of the their environment and occupation.
H. Explore with the client any current stress factors in their life.
I. Inquire about the extent of mask use and frequency of washing and/or replacement.

PHYSICAL EXAMINATION

A. Inspect:
  1. Observe skin for location and severity of lesions.
  2. Rate the severity of the lesions as mild, moderate, or severe:
    a. Mild: few papules/pustules, no nodules.
    b. Moderate: several papules/pustules, rare nodules.
    c. Severe: many papules/pustules with many nodules.
  3. Take a picture of areas of affected skin for chart and document date. Use this for future appointments as a reference to compare results for follow-up visits.

DIAGNOSTIC TESTS

A. No tests are generally required.
B. Culture lesions to rule out gram-negative folliculitis with clients on antibiotics.
C. Consider hormone testing if other primary causes of acne are considered (follicle-stimulating hormone, luteinizing hormone, testosterone levels).

DIFFERENTIAL DIAGNOSES

A. Acne vulgaris.
B. Acne rosacea.
C. Steroid rosacea.
D. Folliculitis.
E. Perioral acne.
F. Drug-induced acne.
G. Sebaceous hyperplasia.
H. Keratosis pilaris.
I. Hidradenitis suppurativa.
J. Acne cosmetica.
K. Tropical acne.

PLAN

A. General interventions:
  1. Document location and severity of lesions. Assess the quality of improvement at each office visit.
  2. The primary goal of treatment is prevention of scarring. Good control of lesions during puberty and early adulthood is required for best results. Anticipate ups and downs during the normal course and treatment.
B. Client teaching: *See Client Teaching Guide for this chapter, "Acne Vulgaris."*
  1. Instruct the client on the proper cleansing routine. The client should wash affected areas with mild soap (Purpose, Cetaphil) twice a day and apply medications as directed.
  2. Warn the client that washing the face more than two to three times a day can decrease oil production and cause drying.
  3. Discuss current stressors in the client's life and discuss treatment options.
  4. Recommend exercise routine 3 to 5 days a week.
  5. Recommend oil-free sunscreens. UV light is beneficial; however, there is a need to use with caution when retinoids and tetracycline have been prescribed.
C. Pharmaceutical therapy: **It may take 2 to 3 months before results are visible when using medications:**
  1. Mild: The treatment of choice is combination topical:
    a. Benzoyl peroxide, 2.5%, 5%, and 10%; start with 2.5% at bedtime. May graduate to 5% or 10% BID if needed, as tolerated. When ordering with Retin-A, apply the benzoyl peroxide in the morning and Retin-A at night. Combination therapy of Retin-A and/or topical antibiotic is more effective.
    b. Topical tretinoin 0.1% (Retin-A Micro); use at bedtime. Apply 20 to 30 minutes after washing skin:
      i. With Retin-A use, the client may see rapid turnover of keratin plugs.
      ii. Instruct the client to avoid abrasive soaps.
      iii. Warn the client regarding photosensitivity.
    c. Clindamycin gel 1% applied once daily.
    d. Erythromycin gel 3% applied once daily.
  2. Moderate: Use the previous topical retinoid and benzoyl peroxide medications in addition to one of the following oral medications:
    a. Doxycycline 50 to 100 mg BID or 100 mg once daily treatment of choice.
    b. Tetracycline 500 mg BID:
      i. Instruct the client to take tetracycline on an empty stomach and to avoid dairy products, antacids, and iron.
      ii. Warn the client about photosensitivity. This medication may be used as a maintenance dose at ▶

250 mg daily or every other day for clients who break out after discontinuing antibiotic therapy. No drug resistance is seen with tetracycline.

c. Minocycline 50 mg taken one to three times daily:

i. Have the client drink plenty of fluids.

ii. Central nervous system (CNS) side effects (headaches) have been seen.

d. Oral contraceptives with higher doses of estrogen have also been effective in females.

3. Severe: Medications as prescribed per dermatologist.

FOLLOW-UP

A. See clients every 6 to 8 weeks for evaluation.

1. Mild: Adjust dose depending on local irritation.

2. Moderate (oral and topical medications):

a. Adjust dose according to irritation.

b. Taper oral antibiotics with discretion and/or continue topical medications.

c. Oral antibiotics may be tapered and discontinued when inflammatory lesions have resolved.

CONSULTATION/REFERRAL

A. Consult with a physician if treatment is unsuccessful after 10 to 12 weeks of therapy or if acne is severe.

B. The client may need dermatology consultation.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Acne may flare up or improve during pregnancy, may improve in the first trimester, and worsen in the third trimester.

2. Medications preferred during pregnancy are topical agents.

3. Teratogens include tretinoin, tetracycline, and minocycline.

a. When using teratogenic medications, contraception must be practiced to avoid pregnancy to prevent severe fetal malformations.

b. Begin contraception 1 month prior to starting the medication and 1 month after finishing the medication.

B. Geriatrics:

1. Favre-Racouchot syndrome may present as acne look-alike and needs to be evaluated. The causes of this are sun exposure with aging, environmental exposures, nutrition, and skin type.

BIBLIOGRAPHY

Hauk, L. (2017). Acne vulgaris: Treatment guidelines from the AAD. *American Family Physician*, *95*(11), 740–741.

Leyden, J. J., Del Rosso, J. Q., & Webster, G. F. (2009). Clinical considerations in the treatment of acne vulgaris and other inflammatory skin disorders: A status report. *Dermatologic Clinics*, *27*, 1. https://doi.org/10.1016/j.det.2008.07.008

ATOPIC DERMATITIS

DEFINITION

A. This pattern of skin inflammation has clinical features of erythema, itching, scaling, lichenification, papules, and vesicles in various combinations. Currently, the term *eczema* is used interchangeably with *dermatitis.* Most common variants are atopic dermatitis and atopic eczema. Classification is by cause, either endogenous or exogenous.

INCIDENCE

A. Overall prevalence of all forms of eczema is about 18 in 1,000 in the United States.

B. With atopic dermatitis, 60% of those affected become afflicted between infancy and 12 years of age. It is more common in boys.

PATHOGENESIS

A. Eczema is characterized by a lymphohistiocytic infiltration around the upper dermal vessels. Epidermal spongiosis or intercellular epidermal edema and inflammation is seen.

PREDISPOSING FACTORS

A. Family history of atopic triad: dermatitis, asthma, and allergic rhinitis.

B. Exposure to allergen:

1. Common foods: cow's milk, nuts, wheat, soy, and fish.

2. Common environmental allergens: dust, mold, cat dander, and low humidity (dry air).

C. Exposure to topical medications, most commonly neomycin, lanolin, and topical anesthetics like benzocaine.

D. Skin irritants: harsh soaps, skin-care products with perfumes, chemicals and alcohol, fabrics containing wool, tight clothing.

E. Stress.

COMMON COMPLAINTS

A. Skin changes:

1. Itching, impossible to relieve.

2. Dryness.

3. Discoloration, lichenification, and scaling.

4. Skin thickening.

5. Associated bleeding and oozing skin.

OTHER SIGNS AND SYMPTOMS

A. Primary lesions, papules, and pustules that may lead to excoriation.

B. Adults will have lesions on face, trunk, neck, and genital area.

C. Other common features include infraorbital fold (Dennie sign), increased palmar creases, facial erythema, and scaling.

SUBJECTIVE DATA

A. Determine whether the onset was sudden or gradual.

B. Ask the client if the skin is itchy or painful.

C. Assess if there is any associated discharge (blood or pus).

D. Ask if the client has recently taken any antibiotics, other oral drugs, or topical medications.

E. Ask the client about use of soaps, creams, or lotions.

F. Assess for any preceding systemic symptoms (fever, sore throat, anorexia, vaginal discharge).

G. Ask the client about recent travel abroad.

H. Rule out insect bites.

I. Rule out any possible exposure to industrial or domestic toxins.

J. Elicit what precipitates itching.

K. Evaluate for increased stress level at home, work, relationships, and so forth.

PHYSICAL EXAMINATION

A. Check temperature (if indicated).

B. Inspect.

1. Inspect skin for lesions.

2. Recognize bacteria-infected eczema; *Staphylococcus aureus* is the most common pathogen. It appears with acute weeping dermatitis; crusted and small, superficial pustules.

DIAGNOSTIC TESTS

A. Culture skin lesions to determine viral, bacterial, or fungal etiology.

B. Blood work: Serum immunoglobulin E (IgE) is elevated with atopic dermatitis.

DIFFERENTIAL DIAGNOSES

A. Atopic dermatitis, acute or chronic.
B. Allergic or irritant contact dermatitis, acute or chronic.
C. Seborrheic dermatitis.
D. Ichthyosis vulgaris.
E. Bacterial/fungal infections.
F. Neoplastic disease.
G. Immunologic and metabolic disorders.
H. Psoriasis.
I. Scabies.

PLAN

A. General interventions:

1. Frequently treat the dry skin with emollients (Aquaphor, Eucerin).

2. Pat, do not rub skin.

3. Avoid wool products and lanolin preparations.

4. Keep fingernails cut short to prevent scratching/scarring skin.

5. Treatment of secondary bacterial infections may be needed as appropriate.

6. Eliminate trigger foods one at a time for 1 month to see improvement. Begin with eliminating cow's milk products. Consider soy-based foods instead.

7. Allergy testing may be considered if symptoms continue.

8. Ointments are usually recommended over creams for moisturizing.

B. Client teaching: *See Client Teaching Guide for this chapter, "Eczema."*

C. Pharmaceutical therapy:

1. Atopic: acute, adult:

a. Wet dressings with Burow solution and changed every 2 to 3 hours.

b. Topical corticosteroid:

i. Mild (low potency): desonide 0.05% or hydrocortisone 2.5% one to two times per day for 2 to 4 weeks.

ii. Moderate (medium to high potency): fluocinolone 0.025%, triamcinolone 0.1%, betamethasone dipropionate 0.05% one to two times per day up to 2 weeks.

c. Antihistamine of choice: Cetirizine HCl (Zyrtec) or diphenhydramine HCl (Benadryl).

d. Severe cases: oral steroid: prednisone 1 mg/kg (40–60 mg/d) tapered over 2 to 3 weeks.

2. Atopic: chronic, adult:

a. Short course of potent topical corticosteroid betamethasone dipropionate (Diprolene) or clobetasol propionate (Temovate) BID for 7 days.

3. Secondary bacterial infections:

a. Antibacterial treatments for secondary bacterial infections: Treat per culture and sensitivity results:

i. *S. aureus:*

1) Augmentin 875 mg PO BID for 10 to 14 days.

2) Keflex 500 mg PO QID for 10 to 14 days.

3) Erythromycin 500 mg PO QID for 10 to 14 days. OR

4) Dicloxacillin 250 mg Q6H for 10 days.

FOLLOW-UP

A. See client in office in 1 to 2 weeks and then every month until condition is stabilized.

B. Monitor the client for superimposed staphylococcal infection; may use oral erythromycin or dicloxacillin.

C. Client may be seen every 3 to 6 months thereafter for client education updates.

CONSULTATION/REFERRAL

A. Eczema herpeticum (herpes simplex type 1) may progress rapidly. Refer the client to a dermatologist.

B. Refer the client to a dermatologist if:

1. Diagnosis is uncertain.

2. Skin eruptions are severe or fail to respond to conservative treatment.

3. Second-line therapies may be required, such as phototherapy, cyclosporine, or methotrexate.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Avoid oral steroids; if needed, can use mild to moderate strength steroid cream.

2. Hormonal change can flare eczema; keep the skin moisturized.

B. Young adults and older adults:

1. Nummular eczema is commonly seen, characterized by coin-shaped vesicles and papules seen on extremities and/or trunk.

D. Geriatrics:

1. Avoid first-generation anticholinergics due to risk of confusion, dry mouth, constipation, and other anticholinergic effects or toxicity.

2. Research indicates that atopic dermatitis in older adult clients shows high rates of positivity for IgE antibodies against house dust mites and is associated with IgE allergic asthmatic exacerbations. In moderate to severe cases with geriatric clients suffering from atopic dermatitis, oral corticosteroids combined with standard treatments may be needed; however, use sparingly.

3. Avoid higher potency steroid topicals to face and skin folds of older adults and use no more than 5 to 7 days. Skin atrophy could result from overuse.

4. Avoid heat and prolonged hot showers and baths.

BENIGN SKIN LESIONS

DEFINITION

A. A benign skin lesion is a cutaneous growth with no harmful effects to the body. Benign lesions must be distinguished from the following:

1. Basal cell carcinoma (BCC): nodular tumor with pearly surface, telangiectasia on surface, and depressed center or rolled edge.

2. Squamous cell carcinoma (SCC): irregular papule, with scaly, friable, bleeding surface.

3. Malignant melanoma: asymmetric papule, with irregular border, of two or more colors, and greater than 6 mm in diameter.

INCIDENCE

A. Benign lesions are common to all races and are seen primarily in the adult and older adult populations.

PATHOGENESIS

A. The course varies depending on the specific type of lesion.

PREDISPOSING FACTORS

A. Sun exposure in the adult and older adult populations.

B. Dermatosis papulosa nigra: common in African Americans and Asians.

COMMON COMPLAINT

A. New lesion on the skin.

OTHER SIGNS AND SYMPTOMS

A. Seborrheic keratosis: Waxy papule with a stuck-on appearance is seen in adults on sun-exposed areas; they appear symmetric, 0.2 to 3.0 cm in size, with a well-demarcated border and a variety of colors (tan, black, and brown).

B. Dermatosis papulosa nigra: Hyperpigmented mole is located on face or neck; a pedunculated papule is symmetric, 1 to 3 mm in diameter.

C. Cherry angioma: Vascular papule, red to purple, is located on trunk in adults; begins in early adulthood; 1- to 3-mm diameter papules that do not blanch.

D. Solar lentigines (liver spots): Tan maculae appear on sun-exposed areas in the elderly, especially on face and hands; border is irregular and the size varies.

E. Senile sebaceous hyperplasia: Enlarged sebaceous glands appear as yellow papules on sun-exposed areas, especially on face in the elderly; papules have central umbilication and their size varies.

F. Keratoacanthoma: Sun-exposed area lesion is smooth, skin-colored or reddish in appearance, dome-shaped papule at first, then may turn and grows to 1 to 2 cm in a few weeks, with crusted interior.

SUBJECTIVE DATA

A. Identify when the client first discovered the lesion.

B. Determine whether the lesion has changed in size, shape, or color.

C. Ask if the client has discovered more lesions.

D. Elicit information regarding a family history of skin lesions or cancer.

PHYSICAL EXAMINATION

A. Inspect:

1. Observe skin; note all lesions and evaluate each for asymmetry, border, color, diameter, evolving changes, and/or elevation change.

2. Note the client's skin type.

DIAGNOSTIC TESTS

A. Benign lesions do not require any tests.

B. If unsure regarding possible malignancy, a biopsy is recommended.

DIFFERENTIAL DIAGNOSES

A. Benign skin lesion:

1. Seborrheic keratosis.

2. Dermatosis papulosa nigra.

3. Cherry angioma.

4. Solar lentigines.

5. Senile sebaceous hyperplasia.

6. Keratoacanthoma.

B. Malignant skin lesion.

PLAN

A. General interventions:

1. Reassure the client that lesions are benign. No treatment is required unless the client chooses to have the lesion removed for cosmetic purposes.

2. Lesions may be removed using cryotherapy if they are bothersome for the client.

B. Client teaching: *See Client Teaching Guide for this chapter, "Skin Care Assessment."*

C. Pharmaceutical therapy:

1. Topical 5-fluorouracil, 5% imiquimod cream (Aldara), or topical diclofenac gel may be used for benign lesions.

FOLLOW-UP

A. Routine skin exams should be performed yearly.

CONSULTATION/REFERRAL

A. Immediately refer the client to a dermatologist if malignancy is suspected or confirmed by biopsy.

INDIVIDUAL CONSIDERATIONS

A. Adults:

1. Skin lesions begin to appear in early adulthood. Encourage clients to monitor lesions over time.

B. Geriatrics:

1. Benign lesions are commonly seen in the older adult population.

a. Encourage annual/biannual skin screenings in older adult populations and the continual use of sunscreen with UVA and UVB coverage. Protective clothing and avoidance of sun exposure are highly recommended for geriatrics with a history of basal cell/benign lesions. Encourage wearing hat to cover bald spots and scalp from sun exposure as well.

b. Treatment of benign lesions for geriatrics must be balanced with client's preferences, quality of life, and life expectancy. Mohs micrographic surgery, cryosurgery, excision, photodynamic, and topical creams/solutions are acceptable treatments for geriatric clients if they choose. Monitor closely for allergic reactions or toxicity with topical medications: imiquimod (Aldara), 5-fluorouracil, and vismodegib (Erivedge).

Higgins, J. C., Maher, M. H., & Douglas, M. S. (2015). Diagnosing common benign skin tumors. *American Family Physician*, *92*(7), 601–607.

BITES

ANIMAL BITES, MAMMALIAN

DEFINITION

A. A bite from any mammalian animal to a human can be potentially dangerous. Bites from human to human are included.

INCIDENCE

A. Bites account for 2 to 5 million ED visits each year.
B. About 80% to 90% of bites are dog bites.
C. About 6% of bites are cat bites.
D. From 2% to 3% are human bites.
E. Older adults are especially prone to bites.

PATHOGENESIS

A. Mechanical trauma and break to skin and/or underlying structures.
B. Infection from transmission of bacteria:
1. *Pasteurella multocida* is primarily associated with cat bites but may also be associated with dog bites.
2. *Staphylococcus aureus, S. epidermidis*, and *Enterobacter* species can be transmitted with dog and cat bites.
3. *Streptobacillus moniliformis* can be transmitted with rat and mice bites.
4. *Streptococcus, Staphylococcus*, and *Eikenella* can be transmitted with human bites.
5. Human bites can transmit diseases such as actinomycosis, syphilis, tuberculosis, hepatitis B, and potentially HIV.
C. Rabies, an acute viral infection, may be transmitted by means of infected saliva or by an infected animal licking mucosa from an open wound. It is rarely contracted by means of airborne transmission, but this has been reported to occur in bat-infested caves.

PREDISPOSING FACTORS

A. Older adults.
B. Entering an animal's territorial space and/or surprising an animal.

COMMON COMPLAINTS

A. Bitten by an animal.
B. Pain.
C. Redness.
D. Swelling.

SUBJECTIVE DATA

A. What person or type of animal bit the client?
B. Was this a provoked or an unprovoked attack?
C. Did the client identify and contact the owner of the animal?
D. What was the behavior of the animal? Unusual, strange, or ill-appearing?
E. How much time has elapsed from being bitten to seeking treatment?
F. Did the client start any self-treatment?
G. What is the client's tetanus immunization status?
H. Review history for any prior rabies immunizations.
I. Does the client know if the animal was a domestic animal? Is the animal's vaccination status known?
J. If the bite is of human origin, determine if it is a closed-fist injury (a human bite/injury that occurs when the closed fist is injured, with teeth penetrating the skin, joint, and possibly bone, over the metacarpal heads) or plain bite.

PHYSICAL EXAMINATION

A. Check blood pressure, pulse, and respirations; observe overall respiratory status.
B. See Table 7.1.

DIAGNOSTIC TESTS

A. Refer to Table 7.1.

DIFFERENTIAL DIAGNOSES

A. Animal bite: dog, cat, human, and so forth.
1. Cat bites more frequently become infected.
2. Bites on the hand have the highest infection rates. Bites on the face have the lowest infection rates.
B. Cellulitis and abscesses.
C. High-risk potential for rabies from bites from the following: ▶

TABLE 7.1 BITES

Animal	Signs and Symptoms	Physical Exam[a]	Diagnostic Tests
Dog	Crush injury, lacerations, and abrasions	Inspect site, underlying structures, and distal neurovascular, motor, and sensory function. Palpate area. If wound is over 24 hours old, check any signs of cellulitis, lymphangitis.	If infected: laboratory—CBC, culture and sensitivity for anaerobes and aerobes
Cat	Puncture wounds, may be deep	Determine depth and extent of wound. Check for foreign bodies. If wound is over 24 hours old, check any signs of cellulitis, lymphangitis.	If sepsis suspected: laboratory—CBC, culture and sensitivity of abscess/tissue site
Rat and squirrel	Laceration, abrasions; more superficial in nature	Check for signs of infection. If wound is over 24 hours old, check any signs of cellulitis, lymphangitis.	If infected: laboratory—CBC, culture, and sensitivity
Human	Crush injury, laceration; wound in the hands (closed-fist wound)	Check for signs of infection. If the wound is over 24 hours old, check any signs of cellulitis and lymphangitis. Also, examine for fractures, air in the joint, subchondral bone defects, and osteomyelitis. Examine for full range of interphalangeal and metacarpophalangeal joints.	As above Also, take x-ray of structures underlying bite

[a] For all animal bites, check temperature.

CBC, complete blood count.

1. Skunks, foxes, raccoons, and bats are primary carriers.
2. Rabbits, squirrels, chipmunks, rats, and mice are seldom infective for rabies.
3. Properly vaccinated animals are seldom infective.

PLAN

A. General interventions:
1. Control bleeding.
2. Wound care:
   a. Immediately wash wound copiously with soap and water.
   b. Irrigate wound with saline, benzalkonium chloride (Zephiran), or 1% povidone-iodine (if the client is not allergic to iodine).
   c. May use Waterpik.
   d. Use 150 to 1,000 mL of saline solution.
   e. Direct stream on the entire wound surface.
   f. Scrub the entire surrounding area.
   g. Debride all wounds.
   h. Trim any jagged edges to prevent cosmetic and/or functional complications.
   i. Cover with dry dressing.
3. Do not suture wounds at high risk of infection:
   a. Hand bites, closed-fist injuries.
   b. Bites older than 12 hours.
   c. Deep or puncture wounds.
   d. Bites with extensive injury of surface or underlying structures.
   e. Immunocompromised clients.
   f. Lower extremity wounds in clients with venous or arterial compromise.
4. Rabies control measures:
   a. Consult with the local health department regarding risk of rabies in the area.
   b. The domestic animal should be identified, caught, and confined for 10 days of observation. If the animal develops any signs of rabies, it should be destroyed and its brain tissue analyzed. No treatment is necessary if results are negative.
   c. The wild animal should be caught and destroyed for brain tissue analysis. No treatment is necessary if the results are negative.
   d. If the bat or wild carnivore cannot be found, rabies prophylaxis is instituted.

B. Client teaching:
1. Instruct the client how to keep the site free from infection.

C. Pharmaceutical therapy:
1. Antibiotic prophylaxis:
   a. Antibiotic prophylaxis is controversial, but it is generally recommended for wounds involving subcutaneous tissues and deeper structures.
      i. Agent of choice: amoxicillin-clavulanate acid (Augmentin) 875/125 mg Q12H.
      ii. Alternatively you can prescribe (aerobic and anaerobic agents together to cover):
         1) Doxycycline 100 mg BID.
         2) Trimethoprim-sulfamethoxazole (TMP-SMX) double strength (DS) BID.
         3) Ciprofloxacin 500 to 750 mg BID.
         4) Levofloxacin 750 mg once daily.

         PLUS an anaerobic agent:
         5) Metronidazole 500 mg TID.
         6) Clindamycin 450 mg TID.
      iii. Alternatively, prescribe erythromycin (E-Mycin) 250 mg QID for 7 days.
2. Tetanus prophylaxis:
   a. Tetanus immune globulin and tetanus toxoid should be given to all clients who have had fewer than three primary immunizations.
   b. Tetanus toxoid alone can be given to those who previously have had the primary immunization, but have received a booster 5 or more years ago.
3. Rabies prophylaxis:
   a. Active immunization: Human diploid cell vaccine (HDCV), 1 mL, is given intramuscularly on the first day of treatment, and repeat doses are administered on days 3, 7, and 14. For persons with immunosuppression (corticosteroid use, immunosuppressive drugs, and immunocompromising illnesses), they will receive an additional dose on day 28.
   b. Passive immunization: Rabies immunoglobulin (RIG; human) should be used simultaneously with first dose of HDCV; the recommended dose of RIG is 20 IU/kg. Approximately one-half of RIG is infiltrated into wound and the remainder is given intramuscularly.

FOLLOW-UP

A. Evaluate the wound and change dressing in 24 to 48 hours.
B. Reevaluate as indicated. If the client is on immunoprophylaxis and has no signs of infection, see in 1 week.
C. Instruct the client to return immediately for any signs of infection.

CONSULTATION/REFERRAL

A. Refer all clients with bites in the ears, face, genitalia, hands, and feet to plastic surgery.
B. Consult with a doctor if there is suspicion of rabies.
C. Contact the local health department.
D. Wounds involving the tendon, joint, or bone require hospitalization and surgical consultation.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
1. Use appropriate antibiotic management that is safe in pregnancy.

B. Geriatrics:
1. Consider chronic conditions (chronic kidney disease, diabetes, etc.) when prescribing the client antibiotics.
2. Pet therapy has been allowed in long-term care facilities, and studies suggested that 75% did not report health and safety concerns or had policies in place for animals. Be sure to discuss pet precautions (e.g., bite prevention, how to treat bites if they occur, and safety issues) with geriatric clients, whether they live at home, assisted living, or are residents of a long-term care facility.
3. Healing time for bite wound may be delayed due to age and chronic disease state.

INSECT BITES AND STINGS

DEFINITION

A. Bites and/or stings on the skin come from commonly encountered insects, bees, hornets, wasps, mosquitoes, chiggers, ticks, fleas, and fire ants.

INCIDENCE

A. Bites are seen in all age groups, more commonly in summer months.

PATHOGENESIS

A. Some bites elicit local tissue inflammation and destruction due to proteins and enzymes in the poison or venom of the insect.

B. Serum immunoglobulin E (IgE)-mediated allergic reactions (immediate or delayed) may occur.

C. Serum-sickness reaction may appear 10 to 14 days after a sting with venom. Toxic reactions can also occur from multiple stings, yielding large inoculation of poison or venom.

D. With tick bites, exposure to Rocky Mountain spotted fever, Lyme disease, alpha-gal allergy from Lone Star tick, ehrlichiosis, and babesiosis disease may occur.

PREDISPOSING FACTORS

A. Exposure to areas of heavy insect infestations.

B. Warm weather months.

C. Outdoor exposure with barefoot and bright clothes.

D. Use of perfumes and/or colognes.

E. Previous sensitization.

COMMON COMPLAINTS

A. Local reaction: pain, swelling, and redness at site after insect bite.

B. Toxic reaction: local reaction plus headache, vertigo, gastrointestinal symptoms (nausea, vomiting, diarrhea), syncope, convulsions, and/or fever.

SUBJECTIVE DATA

A. Did the client see what bit or stung them?

B. If the client felt the bite or sting, was they bitten or stung once or multiple times?

C. How long ago did it occur?

D. Where was the client when the injury occurred (environment)?

E. Has the client ever been bitten or stung before? If so, did they have any reaction then? If so, what was the treatment?

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure. Observe overall respiratory status.

B. Inspect:

1. Inspect site of injury for local reaction; note erythema, rash, or edema.

2. Perform ears, nose, and throat exam.

C. Auscultate:

1. Assess the heart and lungs.

E. Palpate:

1. Palpate injured site.

2. Assess nodes for lymphadenopathy.

3. Perform abdominal exam, if appropriate.

DIAGNOSTIC TESTS

A. None required.

B. Consider taking skin scrapings to evaluate under microscope.

C. Consider culture if infection is suspected.

DIFFERENTIAL DIAGNOSES

A. Insect bite:

1. Bees, hornets, wasps: Local pain, redness, pruritus, and swelling occur at site. Red papules and wheals appear, enlarge, and then subside within hours. Delayed hypersensitivity occurs within 7 days with enlarged, local reaction with fever, malaise, headache, arthralgias, and lymphadenopathy. Toxicity can occur. Anaphylaxis may be seen with generalized warmth and urticaria, erythema, angioedema, intestinal cramping, bronchospasm, laryngospasm, shock, and collapse.

2. Ticks: Local redness, swelling, itching, and an enlarged area of redness and swelling may occur.

3. Mosquitoes and chiggers: Local redness, swelling, and itching occur. Delayed reaction can include edema and burning sensation.

4. Fleas: Local redness, swelling, and itching occur. Usually, papules are noted in a zigzag pattern, especially on legs and waist. Note hemorrhagic puncta surrounded by erythematous and urticarial patches.

5. Body lice: Small noninflammatory red spots, intensely pruritic, are found on waist, shoulders, axilla, and neck. Note linear scratch marks. Note secondary bacterial infection.

6. Scabies: Pruritus is the dominant symptom. Note inflammation and burrows in skin with papules and vesicles, especially in the webs of the hands and feet.

7. Fire ants: Papules appear and turn to pustules within 6 to 24 hours after bite. Watch for localized necrosis with scarring. Urticaria and angioedema can occur.

B. Allergic reaction.

C. Folliculitis.

PLAN

A. General interventions:

1. Anaphylaxis: Activate emergency medical services (EMS) immediately. With all bites and stings, treat anaphylaxis first.

2. Local reactions: Treat with analgesic of choice. Apply ice packs to site for approximately 10 minutes. Elevate affected extremities.

3. Delayed reactions: Administer antihistamines as needed. Consider corticosteroid use.

4. Routine wound care: Cleanse wound. Remove the stinger. If it is a painful sting, apply a cotton ball soaked in meat tenderizer or sodium bicarbonate paste.

5. Debride as necessary.

6. For embedded insects, apply petroleum jelly, nail polish, or alcohol over the site for 30 minutes and wait for insect or the tick to withdraw.

7. Referral to allergist–immunologist is recommended for clients with a severe systemic reaction for skin testing and to evaluate for candidacy of venom immunotherapy treatment.

8. Hospitalize the client with severe reactions.

B. Client teaching: *See Client Teaching Guide for this chapter, "Insect Bites and Stings."*

C. Pharmaceutical therapy:

1. Mild anaphylaxis:

a. Epinephrine 1:1,000 aqueous solution: 0.3 to 0.5 mL intramuscular (IM). Repeat dosing may be necessary.

b. Oral antihistamines for the next 24 hours:

i. Cetirizine 10 g once daily or loratadine 10 mg once daily.

ii. Hydroxyzine hydrochloride (Atarax) 10 to 25 mg QID.

2. Severe anaphylaxis:

a. Epinephrine 1:1,000 aqueous solution: 0.3 to 0.5 mL IM. Repeat dosing may be necessary.

b. Oxygen 2 to 4 L as needed.

c. Albuterol (Ventolin) 5 mg/mL per dose by nebulizer:

i. Adults: 2.5 mg (0.5 mL of 0.5% solution) in 2-mL saline.

3. Self-treatment for anaphylaxis (emergency treatment kits):

a. Ana-Kit (epinephrine, chlorpheniramine) contains a preloaded syringe. This will relieve respiratory distress due to bronchospasms during the allergic reaction.

b. EpiPen (epinephrine) autoinjectors are spring-loaded automatic injectors.

FOLLOW-UP

A. Follow-up in 2 weeks to evaluate effectiveness of treatment. If symptoms worsen prior to this, evaluation is needed.

REFERRAL/CONSULTATION

A. Consult with a physician when anaphylaxis occurs.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. Older adults, clients who are immobilized, those with preexisting heart disease or mast cell disorder, those being treated with certain medications (such as beta-adrenergic or angiotensin-converting enzyme [ACE] inhibitors), and those who have had a previous reaction to an insect bite are at the greatest risk of complications when an insect bite occurs.

2. Bites obtained from fire ants, bees, hornets, and wasps may result in severe stings that may even result in death. The honeybee sting is known to present the greatest risk of complications and/or anaphylaxis.

3. Occasionally, the geriatric population misinterprets symptoms of neuropathy or psychocutaneous sensations as sting/bites. Carefully assess the history of comorbidities and actively listen to the client's description. If necessary, discuss the client's descriptive symptoms with family/surrogates. If physical exam is stable and neuropathy has been ruled out or effectively treated, acknowledge the client's experience and consider psychiatric referral.

BULLOUS PEMPHIGOID

DEFINITION

A. Bullous pemphigoid is an autoimmune skin condition that occurs primarily in older adults and is characterized by blisters and/or erosive lesions of the skin or mucosa.

INCIDENCE

A. Most cases occur in adults older than 60 years of age. Studies show that during 2000 to 2005, the incidence of bullous pemphigoid was approximately 22 cases per million people, which is three times greater than in previous years.

PATHOGENESIS

A. The mechanism of the physiologic changes that occur in the body to cause bullous pemphigoid is not fully understood. It is believed to be an autoimmune disorder driven by autoantibody-mediated effects that cause damage to the epithelial basement membrane. Antibodies attach to the antigens on the basement membrane, causing inflammatory changes, resulting in separation of the epidermis from the dermis in the skin and separation of the epithelium from the subepithelial tissue in the mucous membranes, producing blister lesions on the affected tissues.

PREDISPOSING FACTORS

A. Age (adults older than 60 years).

B. Exposure to certain medications (penicillin, etanercept [Enbrel], sulfasalazine [Azulfidine], and furosemide [Lasix]).

C. UV light and radiation therapy.

COMMON COMPLAINTS

A. Large, tense blisters commonly located on the arms, legs, or trunk. Commonly seen along skin folds/creases.

B. Blisters may be asymptomatic or may be erythemic and pruritic.

OTHER SIGNS AND SYMPTOMS

A. Irritation to the oral mucosa, mouth sores, and/or bleeding gums.

B. Rash in addition to skin blisters.

C. Changes in mucous membranes of the eyes, noting redness and discomfort.

POTENTIAL COMPLICATIONS

A. Bacterial skin infection.

B. Sepsis.

C. Scarring of the mucous membranes in the mouth or eye.

SUBJECTIVE DATA

A. Ask client if there was any precipitating event prior to the outbreak of the blisters.

B. Have client describe when the blisters began and the duration of the blisters.

C. Ask client to describe the onset of the presenting lesions and the progression of the lesions.

D. Ask if the blisters are painful. If so, describe pain, such as stabbing, burning, throbbing, and so forth.

E. Rate pain on a scale of 0 to 10, with 0 being no pain.

F. List all medications currently being taken, particularly substances not prescribed. Did the blisters begin after the initiation of any new medications?

PHYSICAL EXAMINATION

A. Assess vital signs: Check temperature, pulse, respirations, and blood pressure.

B. Inspect:

1. Inspect general appearance of the skin, noting types of blisters/lesions. Note the location of the blisters, along with erythema, inflammation, or weeping. Inspect skin folds carefully.

2. Inspect the blisters for staging.

3. Inspect oral cavity for oral lesions.

4. Perform ophthalmologic exam: Inspect eyes for erythema, edema, and ulcers.

DIAGNOSTIC TESTS

A. Biopsy: skin lesion biopsy for staining and for direct immunofluorescence (DIF) studies; the gold standard for diagnosis is a positive DIF.

B. Blood tests: peripheral blood smear; elevated eosinophils and increased immunoglobulin G (IgG) levels may be present.

DIFFERENTIAL DIAGNOSES

A. Bullous pemphigoid.
B. Cellulitis.
C. Dermatitis.
D. Shingles.

PLAN

A. General interventions:
  1. Promote healing of blisters and prevent secondary bacterial infection.
  2. The goal of treatment is to control blister formation.

B. Client teaching:
  1. Inform client regarding the course of bullous pemphigoid. This skin condition may last for months or years. Therefore, treatment options are variable for all clients.
  2. Advise the client to avoid sun exposure directly on the skin.
  3. For skin care, educate the client regarding taking care of the fragile skin, avoiding injury to all sites. Tense blisters should be cleansed well with alcohol and carefully ruptured with a sterile needle. The overlying tissue from the blister should remain intact to act as a natural wound cover. Open sores should be covered with a nonadherent bandage to reduce the risk of infection.
  4. Oral blisters should be protected by avoiding spicy or hard foods, which would cause more injury to the oral ulcers.

C. Pharmaceutical therapy:
  1. First-line therapy suggested is topical steroids. Topical steroids, such as clobetasol propionate 0.05% cream, are applied to the affected area BID until inflammation, new blister formation, and pruritus have resolved for at least 2 weeks. Then gradually taper the steroid cream over the next few weeks to months.
  2. If the topical steroids are not successful, oral steroids may be used. Prednisone 0.5 to 0.75 mg/kg/d may be used as a starting dose. Oral prednisone is used until inflammation, new blister formation, and pruritus have resolved for at least 2 weeks. Then gradually taper the prednisone over the next several weeks to months.
  3. In severe cases, immunosuppressants may be prescribed to help control the lesions. These medications may include methotrexate, azathioprine (Imuran), and mycophenolate mofetil (CellCept). Using these medications may also allow weaning of the use of corticosteroids.
  4. Medications with anti-inflammatory effects may also be used, such as tetracycline and dapsone.
  5. Antibiotics and niacin may be prescribed for signs of bacterial infection. Tetracycline antibiotics may be used for mild cases. Niacin may also be prescribed, along with tetracycline, to help control gastrointestinal side effects:
    a. **Clients who do not respond should be referred to a specialist.** Clients who do not respond to steroid treatments may be prescribed biologic therapy such as intravenous (IV) rituximab by the specialist.

FOLLOW-UP

A. For clients on oral or topical treatments, recommend a follow-up appointment in 1 to 2 weeks, depending on the presentation. If signs of bacterial infection are present, then follow-up would need to be sooner.

CONSULTATION/REFERRAL

A. For all clients who present with signs of bullous pemphigoid, consult with the physician or the dermatologist for treatment options.
B. Consult with the physician if signs of bacterial infection are present. In severe cases, sepsis can develop and become life-threatening for compromised clients.
C. The physician or the dermatologist should prescribe potent medications, such as immunosuppressants.
D. Refer any client who presents with any eye involvement to the ophthalmologist.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
  1. Rarely seen in this population.

C. Geriatrics:
  1. Most commonly seen in adults older than 60 years of age. Clients who are compromised or in poor health may develop a secondary bacterial infection, which can be life-threatening.
  2. Studies suggested that eczematous dermatitis in the older adult population is possibly an early indication of a bullous pemphigoid outbreak. Because the disease is closely associated with neurodegenerative diseases, consider collaboration with a neurologist and a dermatologist for treatment management.
  3. Two categories of medications should be screened for possibly causing the development of callous pemphigoid. diabetes medications in the dipeptidyl peptidase-4 inhibitor class such as Tradjenta and psychotropic medications such as Risperidone.
  4. Recommendations for treating older adults with bullous pemphigoid:
    a. First-line clobetasol propionate 0.025% cream topically (except the face).
    b. Second-line tetracycline and nicotinamide combination therapy.
    c. Third-line PO dapsone or PO/subcutaneous methotrexate weekly.
    d. Discontinue therapy if clinical remissions last a minimum of 6 weeks and client has a negative immunofluorescence test.

Zhao, Y. C., & Murrell, F. D. (2015). Advances in understanding and managing bullous pemphigoid. *F1000Research*, *4*, 1313. https://doi.org/10.12688/f1000research.6896.1

CANDIDIASIS

DEFINITION

A. A fungal infection of the mucous membranes and/or skin, candidiasis is caused by the *Candida albicans* fungus and other fungal strains as well.

INCIDENCE

A. It occurs frequently in females, children, and older adults.

PATHOGENESIS

A. An overgrowth of *C. albicans* occurs when mucous membranes and/or skin are exposed to moisture, warmth, and an alteration in the membrane barrier.

PREDISPOSING FACTORS

A. Immunosuppression.
B. Use of antibiotics.
C. Hyperglycemia.
D. Chronic use of steroids.
E. Frequent douching by females.
F. Adults who wear dentures.
G. Urinary/fecal incontinence.

COMMON COMPLAINTS

A. Oral: persistent white patch on the tongue or roof of mouth, which may be slightly reddened with or without crevices on the tongue.
B. Vaginal: Thick, white, "cottage-cheese-like" vaginal discharge with or without vaginal itching.
C. Genital: bright, red rash with well-demarcated satellite lesions advancing to pustules or erosions in genital area.
D. Males: erythemic rash that may advance to erosions on the genitalia/scrotal area.

SUBJECTIVE DATA

A. Question the client about onset, duration, and location of lesions.
B. Determine whether the client has a history of infections.
C. Inquire into medical history and current medications.
D. Rule out the presence of any other current medical conditions.

PHYSICAL EXAMINATION

A. Inspect:
  1. Assess skin and mucous membranes for discharge and lesions.
  2. Observe location and severity of lesions. Document size, diameter, and characteristics of lesions.
B. Palpate:
  1. Palpate the lymph nodes in neck and groin.

DIAGNOSTIC TESTS

A. Vaginal and genital infections need to be evaluated for sexually transmitted infections (STIs), especially if the client is sexually active with multiple partners. Vaginal/genital culture specimen should be sent for gonorrhea/chlamydia testing.
B. Other specimens to consider include wet prep/potassium hydroxide (KOH) 10% solution, Gram stain vaginal culture for *Candida*.

DIFFERENTIAL DIAGNOSES

A. Oral candidiasis:
  1. Leukoplakia.
  2. Stomatitis.
B. Genital area:
  1. Candidiasis.
  2. Bacterial infection.
  3. Bacterial vaginosis.
  4. Chlamydia.
  5. Gonorrhea.
  6. Trichomoniasis.

PLAN

A. Client teaching:
  1. Instruct the client on how to apply medication to the skin.
  2. Advise the client to avoid scratching the site and to keep their fingernails short.
  3. Affected skin tissue should be kept cool and dry; avoid wearing tight and irritating clothing.
B. Pharmaceutical therapy: Choose *one* of the following pharmaceutical therapies:
  1. Oral:
    a. Nystatin (Mycostatin) oral suspension 100,000 U/mL QID for 7 to 10 days.
    b. Gentian violet aqueous solution, 2% for adults, one to two times per day.
    c. Lotrimin buccal troches, five times per day for 2 weeks.
  2. Topical:
    a. Nystatin cream, three to four times per day for 7 to 10 days.
    b. Mycolog-II: Apply sparingly to skin BID until resolved.
  3. Vaginal:
    a. Clotrimazole 1% cream, 5 g intravaginally for 4 to 7 days.
    b. Miconazole 2% cream, 5 g intravaginally for 7 days (over-the-counter [OTC]).
    c. Terconazole 0.8% cream, 5 g intravaginally for 3 days.
    d. Terconazole 80 mg vaginal suppository at bedtime for 3 days.
    e. Butoconazole 2% cream 100 mg intravaginal, for use one applicator, one time.
    f. Fluconazole (Diflucan) 150 mg, oral tablet one time.

FOLLOW-UP

A. None indicated unless not resolved or complications arise.

CONSULTATION/REFERRAL

A. Consult a physician if not resolved within 2 weeks.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
  1. Most effective medications for pregnant individuals are clotrimazole and miconazole.
  2. Recommend a full 7-day course of treatment during pregnancy.
B. Adults:
  1. Consider immunosuppression in all adults with oral candidiasis (HIV, diabetes, chemotherapy, leukemia).
  2. Adults with oral lesions need to be assessed for leukoplakia, especially if the client has a history of smoking or using chewing tobacco.
C. Geriatrics:
  1. Risk factors for fungal infections in older adults include denture wearers, intravascular catheters, residence in long-term care facility, renal failure, prolonged ICU stay, systemic administration of broad-spectrum antibiotics, parenteral nutrition, recent abdominal surgery, neutropenia, and use of corticosteroids.
  2. Studies posit that older adult populations are susceptible to bloodstream *Candida* infections (candidemia) characterized by a high mortality rate. To avoid candidemia, ▶

practitioners must treat fungal infections promptly, encourage prevention measures, and continually assess for relapses.

CELLULITIS AND ABSCESS

Abscess

DEFINITION

A. An abscess is a pocket of pus under the skin tissue that may invade deeper skin tissue.

PATHOGENESIS

A. An abscess develops when a collection of bacteria builds up in the tissue of the body. There may be several types of bacteria present. One common organism is methicillin-resistant *Staphylococcus aureus* (MRSA).

COMMON COMPLAINTS

A. Painful, swollen, erythemic pocket of pus under the skin tissue.

SUBJECTIVE DATA

A. Ask the client when signs and symptoms of infection, discomfort, redness, or swelling began.

B. Has the client experienced fever, chills, or other symptoms?

C. What has been used to treat the abscess? Has heat, ice, topical antibiotics, lotions, and so forth been used?

D. What treatments make the symptoms worse or better?

PHYSICAL EXAMINATION

A. Inspect:

1. Assess site of abscess.

2. Measure: length x width.

3. Note erythema, edema, warmth/fever of tissue, tenderness with palpation. Does pain radiate to other areas? If so, where?

4. Is abscess open and draining fluid? If so, note color, consistency and odor of the drainage.

DIAGNOSTIC TESTS

A. Laboratory testing (complete blood count [CBC], comprehensive metabolic panel [CMP]).

B. Open or draining abscess: culture and sensitivity, and Gram stain.

DIFFERENTIAL DIAGNOSES

A. Wound abscess.
B. Cellulitis.
C. Folliculitis.
D. Pilonidal cyst.
E. Pressure injury.
F. Necrotizing fasciitis.
G. Gas gangrene.
H. Acute gout.

PLAN

A. General interventions:

1. Incision and drainage (I&D) can successfully be performed for an uncomplicated abscess.

2. Precautions should be considered for contraindications to an I&D. These contraindications include the following:

a. Abscess location (perirectal, neck, hand, central area of the face, breasts, and in close proximity to major nerves and blood vessels).

b. Recurrent abscesses.

3. After completing the I&D, the area should be allowed to close by secondary intention.

4. Sterile packing should be inserted into the cavity for abscesses larger than 5 cm in diameter and for clients with compromised immune systems.

B. Client teaching:

1. Educate the client regarding home care for the site of the abscess. If packing is required, instruct client to return to the physician's office for packing, or consider home healthcare to perform dressing changes.

2. New packing should be replaced every 24 to 48 hours until drainage has resolved and until new granulation tissue is present.

3. Once packing is no longer necessary, the client will clean the cavity with warm, wet compress two to three times a day until healed.

C. Pharmaceutical therapy:

1. Oral antibiotic treatments: Antibiotics should be prescribed per the culture and sensitivity results if available; if not available use antibiotics that are sensitive to MRSA. See pharmacologic treatment options in the "Cellulitis" section of this chapter.

FOLLOW-UP

A. The client should return in 24 to 48 hours to evaluate the cavity and insert new packing as needed.

B. If symptoms worsen prior to follow-up, recommend that the client proceed to the ED for further assessment.

CONSULTATION/REFERRAL

A. Consult with a physician for all abscesses requiring I&D with packing.

B. Consult a physician for all abscesses that are not responding to antibiotic treatment for further evaluation.

C. See the "Cellulitis" section for other treatment options.

CELLULITIS

DEFINITION

A. Cellulitis is an acute inflammation and infection of the skin and subcutaneous tissue.

INCIDENCE

A. Cellulitis is not a reportable infection; therefore, the exact incidence is not known. However, some studies show that the incidence of cellulitis is approximately 200 individuals per 100,000 client years.

PATHOGENESIS

A. Cellulitis occurs when bacteria attack the skin tissue, which involves the dermis and subcutaneous tissue. The most common organisms causing this bacterial infection include beta-hemolytic streptococci (groups A, B, C, G, and F) and *Staphylococcus aureus*.

B. The most common organisms causing an abscess include *S. aureus* (either methicillin-susceptible *S. aureus* or MRSA [methicillin-resistant *S. aureus*]), which occur in up to 75% of cases, and group A streptococci.

C. Bacteria may invade healthy tissue but commonly occurs in damaged tissue, where there is a break in the skin, allowing invasion of the tissue that can lead to bacterial infection.

PREDISPOSING FACTORS

A. Age (adults older than 45 years, geriatrics).
B. Immunocompromised immune system.
C. Chronic medical conditions (diabetes).
D. History of intravenous (IV) drug abuse.
E. Alcoholism.
F. Peripheral vascular disease.
G. History of cellulitis.

COMMON COMPLAINTS

A. Erythema, pain, swelling, and warmth are the classic symptoms.
B. Fever, malaise, and chills.
C. Lymphadenopathy of lymph nodes adjacent to site of infection.
D. Trauma to skin tissue.

OTHER SIGNS AND SYMPTOMS

A. Drainage/discharge at wound site.
B. Erythemic streaks that progress away from the infection site.
C. Systemic signs of infection (fever, tachycardia, tachypnea, hypotension, change in mental status).

POTENTIAL COMPLICATIONS

A. Sepsis.
B. Necrosis of tissue.
C. Osteomyelitis.

SUBJECTIVE DATA

A. Ask the client if there was any activity/injury that preceded the episode.
B. Inquire regarding the onset, location, and duration of pain and symptoms. Has the area increased in size or spread to other areas?
C. Ask the client to describe pain, for example, crushing, stabbing, or burning sensation.
D. Have the client rate pain on a scale of 0 to 10, with 0 being no pain.
E. Inquire regarding any previous trauma to affected area. Have any close contacts had similar symptoms?

PHYSICAL EXAMINATION

A. Check vital signs: Check temperature, pulse, respirations, and blood pressure.
B. Inspect:
  1. Inspect general appearance of skin. Note location of involved skin and note erythemic streaking if present.
  2. Measure size (mm/cm) of skin involvement. Include pictures if applicable. Outline the erythema with a marker for ease of assessment between medical professionals as well as client if being discharged for home monitoring.
  3. Note presence of erythema, edema, and color of skin tissue involved (e.g., pink, erythemic, necrotic, pale).
C. Palpate:
  1. Palpate site for warmth, tenderness, firmness, and fluctuance.
  2. Palpate adjacent lymph nodes to assess for lymphadenopathy.
D. Auscultate:
  1. Auscultate the heart.
  2. Auscultate the lungs.

DIAGNOSTIC TESTS

A. Laboratory (blood cultures, Gram stain, culture specimen from the abscess, complete blood count [CBC] with differential, C-reactive protein [CRP] creatinine, bicarbonate, creatine phosphokinase):
  1. Blood cultures: Recommended for clients presenting with signs of systemic toxicity, extensive skin involvement, a history of comorbid conditions, history of recurrent cellulitis, and/or trauma (e.g., dog/cat bite, puncture wounds).
  2. Culture and sensitivities should be performed on clients with signs of systemic infection, severe skin impairment, history of chronic conditions, recurrent infections, and history of animal or water injury.
B. Imaging studies:
  1. Ultrasound to assess for abscess.
  2. X-ray may be performed if suspicious for osteomyelitis.
  3. CT or MRI may be considered when assessing for necrotizing fasciitis.

DIFFERENTIAL DIAGNOSES

A. Cellulitis.
B. Abscess.
C. Dermatitis.
D. Erysipelas. (This is a superficial skin infection that commonly occurs on the face, ears, and/or lower legs. It commonly presents with erythema of the skin with a distinct demarcated border commonly caused by group A *Streptococcus* bacteria. Erysipelas is more commonly seen in older adults.)

PLAN

A. General interventions:
  1. If there are signs of systemic infection, hospitalization is required.
  2. Educate the client regarding care of the site.
  3. Instruct client on reporting worsening symptoms as soon as possible to prevent sepsis.
B. Client teaching:
  1. Instruct client to keep site clean and dry, recommending elevation of extremity if applicable.

▶

2. Recommend over-the-counter (OTC) pain medications such as acetaminophen (Tylenol) or ibuprofen (Advil, Motrin) as needed for pain.

3. Advise client to notify the primary provider for the following symptoms:

a. Fever of more than 100.0°F.
b. Chills.
c. Increase in size of redness or change in size/consistency of site (i.e., abscess formation).
d. Erythemic streaks.
e. Lymphadenopathy.
f. Increase in pain.

4. Instruct the client on use of antibiotics and stress the importance of finishing the full course of prescribed antibiotics.

5. Once the infection has resolved, stress the importance of notifying the primary provider for reoccurring symptoms.

6. Recurrent cellulitis should be evaluated for the cause. Chronic underlying conditions, such as edema, should be treated to prevent future episodes. Edema may be treated with compression stocking therapy and/or use of diuretics.

C. Pharmaceutical therapy:

1. Uncomplicated cellulitis: Oral treatments include cephalexin 500 mg tablet Q6H; or dicloxacillin 500 mg tablet Q6H; or clindamycin 300 to 450 mg tablet every 6 to 8 hours. Oral medications are prescribed for 5 to 10 days.

a. Empiric treatment for MRSA should be considered for the following clients:

i. Clients who do not respond to initial treatment.
ii. Clients with signs of sepsis.
iii. Clients who have recurrent cellulitis.
iv. Clients who have a history of MRSA.

2. Cellulitis MRSA: Oral treatments include doxycycline 100 mg tablet BID or clindamycin 300 to 450 mg tablet TID or trimethoprim-sulfamethoxazole (TMP-SMX) double strength (DS) tablet BID or minocycline 200 mg tablet once, then 100 mg tablet BID or linezolid 600 mg tablet BID or tedizolid 200 mg tablet daily. Oral medications are prescribed for 5 to 10 days.

a. Dosing should be individualized according to the underlying conditions. Obese clients may have a higher failure rate if not prescribed adequate dosing.
b. Clients with purulent drainage should be treated for MRSA pending culture results.
c. Clients with renal impairment will require dosage adjustments.

3. Complicated cellulitis: IV antibiotics should be prescribed to clients with complicated cellulitis and/or erysipelas with signs of sepsis (fever/chills). Antibiotic treatments may include cefazolin, oxacillin, nafcillin, vancomycin, daptomycin, and ceftaroline.

FOLLOW-UP

A. Client needs to follow up in 24 to 48 hours for reassessment.

B. If worsening symptoms are present, recommend that the client proceed to the ED for evaluation and treatment.

CONSULTATION/REFERRAL

A. If necrotizing fasciitis is suspected, referral for a surgical consult is imperative.

B. Inpatient hospitalization is recommended for the following:

1. Hypotension.
2. Elevated creatinine level.
3. Creatine elevated two to three times over normal values.
4. CRP more than 13 mg/L.
5. Low serum bicarbonate level.
6. Elevation in CBC with left shift.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. Suppressive antibiotic therapy is recommended for clients with predisposing risk factors who have a history of recurrent cellulitis.

2. Geriatric clients are at increased risk of developing thrombophlebitis following an acute episode of cellulitis.

3. Geriatrics often develop stasis dermatitis associated with diminished circulation causing skin breakdown, which could result in cellulitis. A Doppler ultrasound will rule out blood clots. To differentiate between stasis and allergic dermatitis is to understand that cellulitis generally tends to be unilateral while allergic/contact dermatitis is usually bilateral. However, cultures and imaging will help make the definitive diagnosis.

BIBLIOGRAPHY

Spelman, D., & Baddour, L. M. (2018). Cellulitis and skin abscess in adults: Treatment. In E. L. Baron (Ed.), *UpToDate*. https://www.uptodate.com/contents/cellulitis-and-skin-abscess-in-adults-treatment

CONTACT DERMATITIS

DEFINITION

A. Contact dermatitis is a cutaneous response to direct exposure of the skin to irritants (irritant contact dermatitis) or allergens (allergic contact dermatitis):

1. Irritant contact dermatitis is a nonimmunologic response of the epidermis.

2. Allergic contact dermatitis is an immunologic response after one or more exposures to a particular agent.

INCIDENCE

A. Occurs in all ages. People who work with chemicals daily and wash their hands numerous times a day have a higher incidence of irritant dermatitis. Irritant contact dermatitis is seen in older adults due to dry skin.

PATHOGENESIS

A. Irritant contact dermatitis is caused by an alteration in the outer layer of the dermis due to exposure to chemicals, lotions, cold, dry air, soaps, detergents, or organic solvents.

B. Allergic contact dermatitis is caused by an alteration in the epidermis when, after exposure to an allergen, the immune system responds by producing inflammation of the cutaneous tissue. Common allergens include poison ivy, poison oak, sumac, nickel jewelry, hair dye, rubber and leather chemicals (latex gloves), cleaning supplies, harsh soaps, detergents, and topical medicines.

PREDISPOSING FACTORS

A. Occupation (e.g., hairdressers, nurses, housecleaners, food handlers, mechanical industry workers).

B. Jewelry.

C. Activities in yard or woods.

COMMON COMPLAINTS

A. Irritation of the skin, ranging from redness to pruritic inflammation, with possible progression of blisters:

1. Poison oak, ivy, and sumac induce classic presentation: lesions (vesicles) and papules on an erythemic base presenting in a linear fashion with sharp margins.

2. Diffuse pattern with erythema may be seen when oleoresin is contracted from pets or smoke from burning fire.

B. Exposure to some type of irritant known to the client. Round or annular lesions may have an internal cause, such as a drug reaction.

OTHER SIGNS AND SYMPTOMS

A. Chronic:

1. Erythema with thickening.

2. Scaling.

3. Fissures.

4. Inflammation; with chronic dermatitis, lichenification may occur with scales and fissures.

5. Lichenification may occur with scales and fissures.

B. Candidiasis diaper rash:

1. Bright red rash with satellite lesions at margins.

2. Inflammation and excoriations present.

3. Creases may be involved.

SUBJECTIVE DATA

A. Ask the client when irritation began and how it has progressed.

B. Elicit history of exposure to allergens.

C. Question the client regarding activity and skin contact with irritants prior to outbreak (e.g., cleaning agents, walking in woods, hobbies, change in soap/laundry detergent, shaving cream, lotions).

D. List occupation and family history of allergens.

E. Review medication list, including prescription, over-the-counter (OTC), and herbal treatments to evaluate for an interaction.

F. List medications and OTC remedies used to relieve symptoms and results.

PHYSICAL EXAMINATION

A. Check temperature (if indicated).

B. Inspect:

1. Inspect skin, noting types and locations of lesions. **Note the pattern of inflammation. The shape of irritation may mimic the shape of the irritant, such as the skin under a ring or watch, for example.**

2. Determine progression of lesions.

3. Differentiate between primary and secondary lesions.

DIAGNOSTIC TESTS

A. Consider none if source is known.

B. Wet mount (potassium hydroxide [KOH] saline) to rule out fungal infection if candidiasis is suspected.

C. Culture/sensitivity of pustules.

D. Patch test to rule out allergic contact dermatitis.

DIFFERENTIAL DIAGNOSES

A. Irritant contact dermatitis.

B. Allergic contact dermatitis.

C. Candidiasis.

D. Tinea pedis, corporis, and cruris.

E. Drug reactions.

F. Pityriasis rosea.

G. Scabies.

PLAN

A. General interventions:

1. Irritant contact dermatitis: Remove the irritating agent.

a. Topical soaks with saline or Burow solution (1:40 dilution) for weeping areas.

b. Recommend lukewarm baths (not hot) with oatmeal (Aveeno), as needed.

c. For dry erythematous skin, use Eucerin or Aquaphor ointments to rehydrate skin.

d. Remind the client to avoid scratching skin and to keep nails short.

e. Suggest use of mild soaps and cleansers.

2. Allergic contact dermatitis:

a. Instruct the client to avoid contact with the agent.

b. Have the client wash with cool water immediately after exposure.

c. Recommend lukewarm baths with oatmeal (Aveeno) three to four times per day.

d. Tell the client to apply calamine lotion after baths.

B. Client teaching: *See Client Teaching Guide for this chapter, "Dermatitis."*

C. Pharmaceutical therapy:

1. Irritant contact dermatitis:

a. Hydrocortisone 2.5% ointment three to four times per day for 2 weeks.

2. Allergic contact dermatitis:

a. Low-potency topical steroids: hydrocortisone 2.5% ointment three to four times per day for 1 to 2 weeks after blistering stage; triamcinolone acetonide 0.025% (Kenalog) ointment/cream BID.

b. Medium-potency topical steroids: triamcinolone acetonide 0.1% (Kenalog) cream BID.

c. High-potent topical steroids: fluocinonide 0.05% (Lidex) ointment three to four times per day; not to be used on face or skin folds.

d. Hydroxyzine 25 to 50 mg QID and, diphenhydramine (Benadryl) 25 to 50 mg QID.

e. If rash is severe (face, eyes, genitalia, mucous membranes), consider prednisone 60 to 80 mg/d to start and taper over 10 to 14 days.

f. Triamcinolone acetonide (Kenalog) 40 to 60 mg by intramuscular (IM) injection.

3. Secondary bacterial infections:

a. Erythromycin 250 mg QID or amoxicillin-clavulanate acid (Augmentin) 875 mg BID for 10 days.

4. Secondary candidiasis infections:

a. Miconazole nitrate 2% cream, miconazole powder, or nystatin cream.

b. Clotrimazole (Lotrimin) or ketoconazole (Nizoral) cream three to four times per day for 10 days.

c. If inflammation is present along with yeast, use Mycolog II.

d. If secondary bacterial infection is present, use mupirocin (Bactroban) ointment TID for 7 to 10 days.

FOLLOW-UP

A. None required if case is mild.

B. See client again in 2 to 3 days for severe cases, or phone to assess progress.

CONSULTATION/REFERRAL

A. Consult with a physician when steroid treatment is necessary or if worsening symptoms develop despite adequate therapy.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
  1. If medications are necessary during pregnancy, consider the gestational age of fetus and category of medication.

C. Geriatrics:
  1. Clients may only exhibit scaling as the prominent irritation rather than erythema and inflammation. Topical medications (neomycin, vitamin E, lanolin) and acrylate adhesives are common causes of contact dermatitis.
  2. Avoid first-generation anticholinergics due to risk of confusion, dry mouth, constipation, and other anticholinergic effects or toxicity.
  3. Pruritus that persists ≥6 weeks in older adult population 65 years old and older is considered a chronic dermatitis condition. Studies indicate that the aging epidermal barrier, nervous system, and immune system predispose geriatrics to a sensation of "itchiness." Topical medications are considered first-line treatment for geriatrics; however, systemic treatments might be considered after evaluation of the client's comorbid diseases.

ERYTHEMA MULTIFORME

DEFINITION

A. This dermal and epidermal inflammatory process is characterized by symmetric eruption of erythematous, iris-shaped papules ("target" lesions) and vesiculobullous lesions.

INCIDENCE

A. Erythema multiforme accounts for up to 1% of dermatology outpatient visits.
B. Adults older than 50 are rarely affected.
C. It may occur in seasonal epidemics.
D. Approximately 90% of cases of erythema multiforme minor follow a recent outbreak of herpes simplex virus (HSV)-1 or *Mycoplasma* infection.

PATHOGENESIS

A. The disorder is thought to be an immunologic reaction in the skin, possibly triggered by circulating immune complexes.

PREDISPOSING FACTORS

A. Infections: recurrent HSV, mycoplasmal infections, and adenoviral infections.
B. Drugs: sulfonamides, phenytoin, barbiturates, phenylbutazone, penicillin, and nonsteroidal anti-inflammatory drugs (NSAIDs).
C. Idiopathic: greater than 50%; consider occult malignancy.

COMMON COMPLAINTS

A. Rash with intense pruritus.
B. Nonspecific upper respiratory infection followed by rash.
C. General malaise, body aches, joint pain.
D. Fever.

OTHER SIGNS AND SYMPTOMS

A. Primary: macules, papules, plaques.
B. Secondary: erythema, dull red, target-like lesions blanch to pressure; distribution is symmetric, primarily on flexor surfaces. **Classic target lesions develop abruptly and symmetrically and are heaviest peripherally; they often involve palms and soles.**
C. Swelling of hands and feet.
D. Painful oral lesions.
E. Eye discomfort (redness, itching, burning, pain, visual changes).

SUBJECTIVE DATA

A. Ask if the client has ever been diagnosed with erythema multiforme.
B. Determine whether the onset of symptoms was sudden or gradual.
C. Assess for any associated discharge (blood or pus).
D. Identify the location of the symptoms.
E. Complete a drug history. Has the client recently taken any antibiotics or other drugs? Question the client regarding use of any topical medications.
F. Determine the presence of any preceding systemic symptoms (fever, sore throat, anorexia, vaginal discharge).
G. Rule out any possible exposure to industrial or domestic toxins.
H. Question the client concerning any possible contact with venereal disease.
I. Ask the client about any close physical contact with others with skin disorders.
J. Elicit information concerning any possible exposure to HIV.
K. Rule out sources of chronic infection, neoplasia, or connective tissue disease.
L. Inquire if client has received a COVID-19 vaccine or booster recently.

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure.
B. Inspect:
  1. Inspect the skin for lesions.
  2. Inspect the mouth and mucous membranes for lesions.
C. Palpate:
  1. Palpate the abdomen for masses and tenderness.
D. Auscultate:
  1. Auscultate the heart, lungs, and abdomen.
F. Perform neurologic exam.

DIAGNOSTIC TESTS

A. Punch biopsy of skin.
B. Complete blood count (CBC).
C. Urinalysis.

DIFFERENTIAL DIAGNOSES

A. Erythema multiforme:
  1. Erythema multiforme minor: pruritus, swelling of hands and feet, painful oral lesions.
  2. Erythema multiforme major: Fever, arthralgias, myalgias, cough, oral erosions with severe pain.
B. Urticaria.
C. Viral exanthems.
D. Stevens–Johnson syndrome (SJS): **a severe, life-threatening, systemic reaction with fever, malaise, cough, sore throat, chest pain, vomiting, diarrhea, myalgia, arthralgia, and severe skin manifestations with painful bullous lesions on mucous membranes.** ▶

E. Pemphigus vulgaris.
F. Bullous pemphigoid.
G. Other bullous diseases.
H. Staphylococcal scalded skin syndrome.

PLAN

A. General interventions:
1. Identify and treat precipitating causes or triggers.
2. Burow solution or warm compress may be used for mild cases as needed.
3. Oral lesions may be treated with saline solution, warm saltwater, and/or Mary's mouthwash (Benadryl, lidocaine, and Kaopectate).
4. Discontinue any medications suspected of precipitating symptoms.
5. Provide adequate pain relief if skin or oral lesions are painful. Lesions remain fixed at least 7 days.
6. Maintain nutrition and fluid replacement for this hypercatabolic state.
7. Consider chronic viral suppression therapy for recurrent HSV infections.
B. Client teaching: *See Client Teaching Guide for this chapter, "Erythema Multiforme."*
C. Pharmaceutical therapy:
1. Antihistamines such as Benadryl or Claritin may be used for itching.
2. Acetaminophen may be used to reduce fever and general discomfort/pain.
3. Potent topical corticosteroids include betamethasone dipropionate 0.05% or clobetasol propionate 0.05% BID for up to 2 weeks. Avoid use on face and groin.
4. Open lesions should be treated like open burn wounds. Stop offending medications that may cause blistering of the wounds and treat with steroids.
5. Oral antibiotics may be needed to control secondary bacterial skin infection.
6. Systemic corticosteroids include prednisone 40 to 60 mg daily in divided doses, tapered over 2 to 3 weeks.
7. Hospitalization for severe cases. Intravenous (IV) immunoglobulins may be needed.

FOLLOW-UP

A. See the client in office in 1 to 2 days to evaluate initial treatment.

CONSULTATION/REFERRAL

A. If client has recurrent or chronic infection, refer them to a physician.
B. Immediate consultation and/or hospital admission is critical if SJS is suspected.
C. Clients with ocular involvement should be referred immediately to an ophthalmologist.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:
1. Avoid first-generation anticholinergics due to risk of confusion, dry mouth, constipation, and other anticholinergic effects or toxicity.
2. Geriatrics taking alendronate (Fosamax) for osteoporosis therapy are at an increased risk of an adverse effect that presents as mucosa erythema multiforme. The recommendation for geriatrics taking this medication is to evaluate any hypersalivation history, swollen lips (macrocheilia), and mouth ulcers that have ill-defined borders and serofibrinous exudates. Treatment measures are local cleaning, cold compress, and clinical follow-up. Discontinue Fosamax and consider alternative treatment for osteoporosis.

FOLLICULITIS

DEFINITION

A. Folliculitis is inflammation of the superficial or deep portion of the hair follicle, causing an infection. This can be caused by bacteria, fungi, viral, or parasitic processes.

INCIDENCE

A. A very common disorder, folliculitis occurs in all ages and is seen more frequently in males.
B. *Malassezia* folliculitis is commonly seen in clients with immunosuppression, diabetes, and antibiotic use.

PATHOGENESIS

A. Bacterial organisms (most commonly *Staphylococcus aureus*) invade the follicle wall and cause an infectious process.
B. Fungal organisms, *Malassezia* folliculitis, also known as *Pityrosporum*, invade the follicle wall and cause an infectious process.

PREDISPOSING FACTORS

A. Break in the skin tissue.
B. Use of razors on skin.
C. Poor hygiene.
D. Diabetes.
E. Long-term oral antibiotic therapy for acne.
F. Exposure to hot tubs or heated swimming pools.
G. Immunosuppression.

COMMON COMPLAINT

A. Outbreak of pustules on the face, scalp, or extremities that does not resolve despite proper hygiene and care.

OTHER SIGNS AND SYMPTOMS

A. Tenderness and itching at site.
B. Furuncle (abscess): a deep pustule, tender, firm or fluctuant, found in groin, axilla, waistline, buttocks.
C. Carbuncle: a group of follicles coalescing into one larger, painful, infected area; may see fever and chills.
D. Excoriated folliculitis: chronic thickened, excoriated papules or nodules.

SUBJECTIVE DATA

A. Elicit the initial outbreak of lesions and onset and progression of lesions.
B. Identify what makes the lesions better or worse.

C. Ask the client what medications, soaps, or lotions have been used on the lesions.
D. Complete a medical history. Ask if the client has had a similar outbreak before.
E. Describe systemic symptoms if they have occurred (e.g., fever chills).
F. Does the client have a beard, shave their face, or use a razor frequently?
G. Is there a recent history of use of a hot tub? (Commonly seen 1 to 4 days after use of hot tub, whirlpool, or swimming pool.)
H. Does the client wear tight pants/jeans or use oils that clog pores in the groin area?
I. Is the client currently being treated with antibiotics for acne? (Flare of Gram-negative folliculitis may be seen with chronic use of antibiotics.)

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure.
B. Inspect:
1. Assess the skin for lesions and describe.
C. Palpate:
1. Palpate the lesions and associated lymph nodes.

DIAGNOSTIC TESTS

A. Culture and sensitivity to verify appropriate antibiotic coverage.
B. Gram stain.
C. Potassium hydroxide (KOH)/wet prep.
D. Fungal culture hair if fungi suspected (tinea of the scalp).
E. Skin biopsy for diagnosis of *Malassezia* folliculitis.

DIFFERENTIAL DIAGNOSES

A. Folliculitis.
B. Acne vulgaris.
C. Ingrown hair follicle.
D. Keratosis pilaris.
E. Contact dermatitis.
F. Papulopustular rosacea.
G. Hidradenitis suppurativa.

PLAN

A. General interventions:
1. Apply warm, moist compress to the site for comfort.
B. Client teaching: *See Client Teaching Guide for this chapter, "Folliculitis."*
1. If razors are used on the area, have the client use clean, sharp razors; throw old razors away and do not share razors. Avoid use of irritating creams or lotions on affected area.
2. Encourage proper hygiene, such as frequent washing of hands and skin with antibacterial soap.
3. Warm compress three to four times a day is encouraged at site for 15 to 20 minutes.
4. Bleach bath (1/2–1 cup of bleach to 20-L water) reduces spread of staph infection.
C. Pharmaceutical therapy:
1. Mild cases: Apply mupirocin (Bactroban) ointment to the affected area TID until resolved.
2. *S. aureus:*
a. Dicloxacillin (Dynapen) 250 to 500 mg PO QID for 7 to 10 days.
b. Cephalexin (Keflex) 250 to 500 mg PO BID for 7 to 10 days.
3. Methicillin-resistant *S.aureus* (MRSA):
a. Trimethoprim-sulfamethoxazole one to two double strength (DS) tablets BID for 7 to 10 days.
b. Doxycycline 100 mg BID for 7 to 10 days.
4. *Pseudomonas aeruginosa*:
a. Ciprofloxacin (Cipro) 500 to 750 mg PO BID for 10 days.
b. Ofloxacin 400 mg PO BID for 10 days.
5. Antistaphylococcal antibiotics:
a. Cephalexin 250 to 500 mg QID.
b. Clindamycin 150 to 300 mg QID.
c. Dicloxacillin 125 to 500 mg QID.
d. Erythromycin 250 to 500 mg QID.
6. Bacteria caused by organisms other than *Staphylococcus* may be treated for an extended period of time, 4 to 8 weeks. These areas may include axilla, chest, back, beard, and groin.
7. Severe cases may be treated with oral antibiotics with topical permethrin Q12H every other night for a 6-week period or itraconazole 400 mg daily, isotretinoin 0.5 mg/kg/d for up to 4 to 5 months with UVB light therapy. Consider dermatology referral for severe cases.
8. Treatment for *Malassezia* folliculitis is as follows:
a. Antifungal treatment: Oral antifungal medications (itraconazole, fluconazole, or ketoconazole) should be prescribed for at least 4 weeks for treatment.

FOLLOW-UP

A. If not resolved in 2 weeks, further evaluation is needed.
B. Severe cases, in which carbuncles are not improved with treatment of antibiotic therapy, may warrant incision and drainage.
C. Continue to follow every 2 weeks until resolved.
D. Test for diabetes mellitus if severe cases occur.

CONSULTATION/REFERRAL

A. Refer the client to a specialist for testing for immunodeficiency if severe cases occur or if resistance is seen.
B. Refer to a dermatologist.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:
1. Skin tissue in older adults is very thin and fragile. Precautions should be taken to avoid further breakdown. Eradicating the infection quickly and healing skin tissue are imperative to prevent long-term complications.

BIBLIOGRAPHY

Natsis, N. E., & Cohen, P. R. (2018). Coagulase-Negative staphylococcus skin and soft tissue infections. *American Journal of Clinical Dermatology*, *19*, 671. https://doi.org/10.1007/s40257-018-0362-9

HERPES SIMPLEX VIRUS TYPE 1

DEFINITION

A. Herpes simplex virus (HSV)-1 infection of the cutaneous tissue manifests itself by vesicular lesions on the mucous membranes and skin. HSV-1 is most often associated with oral lesions (mouth, lips), while HSV-2 is associated with genital lesions. The virus appears in three stages:
1. Primary.
2. Latency.
3. Recurrent infections.

INCIDENCE

A. HSV-1 is seen in clients of all ages and in equal numbers of males and females.

B. There are approximately 500,000 new cases of herpes diagnosed annually in the United States.

PATHOGENESIS

A. Viral infection can be transmitted by direct contact from a vesicular lesion or fluid (saliva) containing the virus to the skin or mucosa of another person, with an incubation period of 2 to 14 days. The trigeminal ganglia are the host of the oral virus. The virus can be reactivated, whereupon it travels along the affected nerve route and produces recurrent lesions. Common sites of infection are the lips, face, buccal mucosa, and throat.

PREDISPOSING FACTORS

A. Immunocompromised clients.

B. Prior HSV infections.

C. Exposure to virus.

COMMON COMPLAINTS

A. Painful lips, gums, and oral mucosa.

OTHER SIGNS AND SYMPTOMS

A. Primary lesion: fever, blisters on lips, malaise, and tender gums.

B. Recurrent episodes: Fever blisters with prodrome of itching, burning, and tingling sensation at site before vesicles appear.

SUBJECTIVE DATA

A. Ask questions regarding location, onset, and duration of lesions.

B. Elicit description of prodromal symptoms.

C. Ask the client if systemic symptoms occur with vesicular outbreak.

D. Determine when the initial outbreak of lesions occurred (commonly seen in childhood).

E. Inquire whether the client has been exposed to anyone with similar lesions.

F. If the lesion(s) is recurrent, ask the client if stress, skin trauma, or sun exposure stimulates outbreak of fever blisters.

PHYSICAL EXAMINATION

A. Inspect:

1. Inspect the skin, noting the location, appearance, and stage of the vesicles.

B. Palpate:

1. Palpate the lymph nodes for lymphadenopathy.

DIAGNOSTIC TESTS

A. Viral cultures.

DIFFERENTIAL DIAGNOSES

A. HSV-1.

B. Impetigo (appears as amber-colored vesicular lesions with crusting).

C. Stomatitis (appears as erythemic or erosion lesions in the mouth and lips).

D. Herpes zoster (causes vesicles that run along a single dermatome).

E. Stevens–Johnson syndrome (SJS).

F. Herpangina: Vesicles can be noted on the soft palate, tonsillar area, and uvula area, usually caused by the coxsackievirus.

PLAN

A. General interventions:

1. Comfort measures. Ice may be used to reduce swelling as needed.

2. Vaseline or other lip ointments may be applied as needed and lip ointment with sun protection factor (SPF) 30 or greater when exposed to sunlight.

B. Client teaching:

1. Educate the client regarding the disease process of HSV-1.

2. Instruct client to wash hands frequently.

3. Suggest proper care of lips to prevent drying and to reduce pain.

4. Educate regarding transmission of virus to others.

5. Teach client to expect recurrences at variable times.

C. Pharmaceutical therapy:

1. Precautions should be used when administering medication to clients who are immunocompromised and who have a history of renal insufficiency:

a. Lidocaine 2% as needed for comfort.

b. Diphenhydramine (Benadryl) elixir to rinse mouth as needed.

c. Acetaminophen (Tylenol) as needed for pain.

d. Campho-Phenique application as needed.

e. Initial episode: acyclovir 400 mg PO TID for 7 to 10 days or until resolved.

f. Recurrent episodes: Begin one of the following when prodrome begins or within 2 days of onset of lesions to get maximum effect:

i. Acyclovir 400 mg PO TID for 5 days.

ii. Acyclovir 800 mg PO BID for 5 days.

g. Other alternative antivirals: Dosage depends on renal function:

i. Famciclovir (Famvir) 750 mg PO x 1 dose.

ii. Valacyclovir (Valtrex) 2 g PO x 1 dose.

h. Suppressive therapy is recommended for clients with frequent lesions that affect everyday life:

i. Acyclovir 400 mg PO BID.

ii. Valacyclovir 500 mg PO once daily.

FOLLOW-UP

A. None needed if resolved without complications.

CONSULTATION/REFERRAL

A. Refer the client to a physician if treatment is unsuccessful or further complications arise.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Educate regarding the diagnosis of HSV-1 and precautions to take to avoid transmission to the genital area. Limit the number of sexual contacts, use a latex condom during sexual activity, use water-based lubricants (avoid oil-based lubricants), and avoid spermicides to prevent transmission. Advise the client that if a lesion in the genital area presents at any time, they are to notify their healthcare provider for testing. ▶

2. Pregnant individuals with history of human papillomavirus after 36 weeks should start suppressive therapy to avoid transmission during delivery. C-section may be the best option for delivery if flare is present.

B. Geriatrics:

1. Avoid first-generation anticholinergics due to risk of confusion, dry mouth, constipation, and other anticholinergic effects or toxicity.

2. HSV-1 has been implicated as a major component in Alzheimer disease in those who carry type 4 allele of the apolipoprotein E gene (APOE). Studies indicate that the virus remains latent in the brain of older adults and can be triggered by stress, immunosuppression, and infection. The cumulative damaging effects could further progress the disease and cognitive decline. Practitioners must look for any signs of HSV-1 outbreaks in clients suffering from Alzheimer disease and quickly treat.

3. Research does not support obtaining viral culture unless it is a first time active lesion without drying or a healed lesion.

HERPES ZOSTER (SHINGLES)

DEFINITION

A. Herpes zoster is a viral infection manifested by painful, vesicular lesions on the skin, limited to one side of the body, following one body dermatome.

INCIDENCE

A. Infection may occur at any age; however, it is more common in older adults. It is estimated by the Centers for Disease Control and Prevention (CDC) that approximately 30% of persons in the United States will experience herpes zoster in their lifetime.

PATHOGENESIS

A. After the primary episode of chickenpox (varicella zoster), the virus remains dormant in the body. Herpes zoster occurs when the varicella virus has been stimulated and reactivated in the dorsal root ganglia, producing the clinical manifestations of herpes zoster. Infection usually lasts 14 to 21 days but may be longer in older adults or debilitated clients.

PREDISPOSING FACTORS

A. Adulthood.
B. Immunocompromised clients.
C. Spinal cord trauma or injury.
D. Autoimmune disease.

COMMON COMPLAINTS

A. Prodrome: itching, burning, tingling, or painful sensation at lesion sites.
B. Active: malaise, fever, headache, pruritic rash on the skin.

OTHER SIGNS AND SYMPTOMS

A. Lesions: clusters of vesicles on an erythemic base that burst and produce crusted lesions; commonly seen on the chest and back area; distribution that typically appears along a single dermatome.
B. Motor weakness (may be seen in approximately 5% of clients).

SUBJECTIVE DATA

A. Determine onset, location, and progression of rash.
B. Ask the client about prodromal symptoms: burning, itching, tingling, or painful sensation at site prior to lesions breaking out.
C. Evaluate client status regarding immunosuppressive agents, diseases, and others.

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure.
B. Inspect:

1. Observe skin for lesions, noting characteristics and distribution.

2. Inspect eyes, ears, nose, and throat.

C. Auscultate:

1. Auscultate the heart and lungs.

DIAGNOSTIC TESTS

A. Usually none.
B. Culture vesicular lesions.
C. Consider Tzanck smear.
D. Consider and test for HIV in young clients with herpes zoster.

DIFFERENTIAL DIAGNOSES

A. Herpes zoster.
B. Varicella.
C. Poison ivy.
D. Herpes simplex virus (HSV).
E. Contact dermatitis.
F. Coxsackievirus.
G. Postherpetic neuralgia.

PLAN

A. General interventions:

1. Comfort measures. Instruct the client to apply wet dressings (Burow solution) on site for 30 to 60 minutes at least four times a day. Calamine lotions may be used as needed; oatmeal (Aveeno) bath for comfort; acetaminophen (Tylenol) as needed for malaise, temperature, and comfort.

B. Client teaching: *See Client Teaching Guide for this chapter, "Herpes Zoster (Shingles)."*

1. Educate the client regarding the rash, which usually lasts approximately 2 to 3 weeks.

2. Instruct the client to monitor for signs/symptoms of postherpetic neuralgia.

3. Instruct the client to call if symptoms worsen or do not improve, or if signs of bacterial infection occur.

4. Emphasize to the client that the virus is easily transmitted to vulnerable persons who have never had the chickenpox.

C. Pharmaceutical therapy:

1. Antiviral medications should be initiated within 24 to 48 hours after outbreak:

a. Acyclovir (Zovirax) 800 mg five times daily for 7 days.

b. Famciclovir (Famvir) 500 mg PO TID for 7 days.
c. Valacyclovir (Valtrex) 1,000 mg PO TID for 7 days.

2. Acetaminophen (Tylenol) or ibuprofen as needed for pain or discomfort.

3. Narcotics may be used for severe pain as needed.

4. Postherpetic neuralgia may be treated with the following:

a. Narcotics or other pain-relieving medications.
b. Long-term medications may be needed for control of pain.
i. Gabapentin 300 to 600 mg TID, titrate up to achieve optimal dose for relief.
ii. Amitriptyline 10 mg every bedtime or other low-dose tricyclic antidepressants; may titrate up to 50 mg every bedtime if needed for relief.

5. If secondary bacterial infection of the skin occurs, apply silver sulfadiazine (Silvadene) topically to site until resolved.

6. Use of steroids is controversial. Corticosteroids may be used with caution. May increase risk of dissemination.

FOLLOW-UP

A. As needed for complications.

B. Monitor the client for complications: postherpetic neuralgia, Guillain–Barré syndrome, motor weakness, secondary infection, meningoencephalitis, ophthalmic and facial palsy, corneal ulceration, and so forth.

CONSULTATION/REFERRAL

A. Ramsay Hunt syndrome occurs when a shingles outbreak affects the facial nerve near one of the ears. This can cause facial paralysis and hearing loss in the affected ear. Consult a physician.

B. Hutchinson sign refers to vesicles in the periorbital region. These clients require an ophthalmologist referral.

C. Consult with a physician if secondary infection occurs or if secondary complications arise.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Acyclovir and valacyclovir can be used and their safety and efficacy show no issue.

2. Advise caution on the use of the antiviral medication famciclovir during pregnancy.

B. Geriatrics:

1. Postherpetic neuralgia occurs in approximately 15% of clients. It is commonly seen in older adults.

2. The CDC recommends the shingles vaccine for those 50 years and older, irrespective of whether they have had the chickenpox or shingles infection in the past. There are two types available; the CDC recommends the recombinant vaccine (Shingrix) over the live vaccine unless contraindicated:

a. Guidelines for Shingrix: a recombinant zoster vaccine:
i. Administration dosing:
1) Two doses administered intramuscularly (IM): first dose given on day 1 and the second dose administered 2 to 6 months after the first.
ii. Indications:
1) Immunocompetent clients older than 50 years.
2) Clients who previously received the varicella vaccine and the (live) zoster vaccine. The CDC recommends waiting 5 years to administer the Shingrix vaccine if Zostavax was previously administered.
3) Clients with comorbid conditions.
iii. Contraindications:
1) Clients with known allergy to components of the vaccine.
b. Guidelines for Zostavax: a zoster live vaccine guidelines:
i. Administration dosing:
1) One-time subcutaneous injection.
ii. Indications:
1) Older than 60 years.
iv. Contraindications:
1) Clients with anaphylactic reactions to gelatin or neomycin.
2) Immunocompromised clients.
3) Planned immunosuppression.
4) Clients receiving low-dose immunosuppressive therapy.
5) Household contacts of immunocompromised hosts.

3. Geriatric red flags:

a. Avoid first-generation anticholinergics due to risk of confusion, dry mouth, constipation, and other anticholinergic effects or toxicity.
b. Avoid use of nonsteroidal anti-inflammatory drugs (NSAIDs) in clients who have chronic kidney disease stage IV or less (creatinine clearance <30 mL/min).

LICE (PEDICULOSIS)

DEFINITION

A. Pediculosis (lice) is an infestation of the louse on human beings in one of three areas:

1. Head (pediculosis capitis).
2. Pubic area (pthirus pubis).
3. Body (pediculosis corporis).

INCIDENCE

A. Pediculosis capitis is most common in children. It is estimated that head lice infestations occur in school systems anywhere from 10% to 40% of the time.

B. Pthirus pubis infestation is more common in adults.

C. Lice affect all demographics: all social, racial, and economic groups.

PATHOGENESIS

A. Head and body lice are transmitted by direct contact from person to person; this is the primary mode of transmission. The sharing of hats, combs, brushes, and so forth for transmission is controversial. The parasite hatches from an egg, or nit. Once hatched, the lice live on humans by sucking blood through the skin. The average female adult louse lives about ▶

1 month and lays seven to 10 eggs per day. The nits appear as small white eggs on the hair shaft. Nits are very difficult to remove and survive up to 55 hours after removal from the host. Body lice lay nits in the seams of clothing.

B. Pubic lice are found at the base of the hair shaft, where they lay nits. Pubic lice are transmitted through sexual contact.

PREDISPOSING FACTORS

A. Head and body lice: exposure to crowded public areas, such as schools; inability to clean and launder clothing, bed linens, and so forth.

B. Pubic lice: sexual contact with infected people.

C. Poor hygiene.

COMMON COMPLAINTS

A. Head lice: severe itching and scratching of the head, neck area, and commonly behind the ears.

B. Body lice: severe itching on the body, which may lead to secondary infections of the skin.

C. Pubic lice: severe itching of genital area.

OTHER SIGNS AND SYMPTOMS

A. Excoriated skin from intense scratching.

B. Visible lice or nits in hair, body, or clothing.

C. Papules with an erythemic base, which may develop on the genital area, axilla, chest, beard, or eyelashes.

SUBJECTIVE DATA

A. Inquire as to exposure to anyone known to have lice.

B. Identify whether the client attends a crowded environment, such as school, day care, and so forth.

C. Ask if lice and nits have been seen by the client.

D. Determine onset, duration, and course of symptoms. Ask: When were lice or nits first discovered?

E. Assess whether the client has been symptomatic (itching, scratching).

F. Inquire about social habits of cleaning, laundry, and so forth.

PHYSICAL EXAMINATION

A. Check temperature to rule out any secondary infection.

B. Inspect:

1. Inspect hair, body, pubic area, and clothing seams for nits or lice.

2. Note excoriation of skin.

3. Examine eyelashes of children.

4. Examine skin for secondary bacterial infection.

DIAGNOSTIC TESTS

A. None.

B. Culture the excoriated area if secondary bacterial infection is suspected.

DIFFERENTIAL DIAGNOSES

A. Lice.

B. Seborrheic dermatitis.

C. Scabies.

PLAN

A. General interventions:

1. Treat immediately with appropriate pediculicides (see the "Pharmaceutical therapy" section).

2. After treatment, it is imperative to remove each nit and louse; use fine-tooth comb for nit removal.

3. Evaluate the entire family for lice.

4. Treat secondary bacterial infection as needed.

B. Client teaching: *See Client Teaching Guide for this chapter, "Lice (Pediculosis)."*

1. Specific instructions need to be given to clients on how to get rid of lice and nits.

2. Reinforce good hygiene; teach not to share combs, brushes, hats, and hair accessories.

C. Pharmaceutical therapy:

1. Malathion lotion 0.5% (Ovide); pediculicidal and partially ovicidal: Leave on hair for 8 to 12 hours, then wash with a nonmedicated shampoo. A single application may be effective; repeat in 7 to 9 days if live lice are seen. Recommended for ages 6 and up.

2. Permethrin lotion 1% (Nix); pediculicidal only: Available over-the-counter (OTC). Leave on hair for 10 minutes, rinse and repeat on day 9. Recommended for ages 2 months and up.

3. Synergized pyrethrins (Rid 0.3%): Available OTC. Leave on hair for 10 minutes, rinse and repeat on day 9. Recommended for ages 2 years and up.

4. Do not use a shampoo/conditioner or conditioner before using head lice treatments. Do not wash hair for 1 to 2 days after using lice treatment regimen.

5. Pthirus pubis: permethrin (Nix) or pyrethrins; apply to the pubic area as directed.

6. Lindane (Kwell) toxicity may occur from ingestion or overuse and is exhibited by headaches, dizziness, and convulsions.

7. Eyelash manifestation: After removing nits, apply petroleum jelly to lashes three to four times a day for 8 to 10 days. **Eyelashes should never be treated with pediculicides.**

FOLLOW-UP

A. None recommended.

B. Some institutions require follow-up to evaluate whether infestation has resolved.

CONSULTATION/REFERRAL

A. If lice are a repeated problem, contact social services or the health department to have a visiting nurse or aide visit the home to evaluate home conditions and to teach the family how to prevent infestations.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Lindane (Kwell) is contraindicated during pregnancy. Permethrin topical is category B and is the only recommended for treatment of lice during pregnancy.

B. Geriatrics:

1. For adult/older adult clients with a diagnosis of lice, consider self-neglect, unsuitable living conditions, cognitive/psychiatric impairments, and/or abuse/neglect of older adults. Consider a home visit for evaluation of the client.

LICHEN PLANUS

DEFINITION

A. Lichen planus is a relatively uncommon condition of acute or chronic inflammatory dermatosis. It affects skin and mucous membranes with characteristic flat-topped, shiny, violaceous (purplish color), pruritic papules with lacy lines on the skin and milky-white papules in the mouth.

INCIDENCE

A. Lichen planus accounts for 0.1% to 1.2% of office visits to dermatologists.
B. It exhibits no racial preference.

PATHOGENESIS

A. Etiology is unknown, although it is possibly a cell-mediated immune response. Most cases remit within 7 years. Lesions may heal with significant postinflammatory hyperpigmentation.

PREDISPOSING FACTORS

A. Severe emotional stress.
B. Drugs may induce lichenoid plaques.

COMMON COMPLAINTS

A. Rash with or without pruritus.
B. Primary lesions: small, flat-topped papules or plaques that are polygonal, lightly scaly, and violaceous.
C. Secondary lesions: erythema, scales, and erosions.

OTHER SIGNS AND SYMPTOMS

A. Distribution: volar aspect of wrists, ankles, mouth, genitalia, and lumbar region.
B. Wickham striae (white, lacelike pattern on surface).
C. Scalp: atrophic skin with alopecia.
D. Nails: destruction of nail fold and bed, especially in large toe.
E. Males: lesions of glans penis.
F. Females: erosive lesions of labia and vulva.

SUBJECTIVE DATA

A. Determine whether the onset was sudden or gradual.
B. Ask the client to describe if the skin is itchy or painful.
C. Assess lesions for any associated discharge (blood or pus).
D. Identify the location(s) of the problem.
E. Complete a drug history. Ask the client if they have recently taken any antibiotics or other drugs. Ask if they have used any topical medications, lotions, or other creams.
F. Determine the presence of any preceding systemic symptoms (fever, sore throat, anorexia, or vaginal discharge).
G. Rule out insect bites.
H. Identify any possible exposure to industrial toxins, domestic toxins, or color-film-developing chemicals.
I. Ask if the client has had any possible sexual contacts with persons with HIV or sexually transmitted infections (STIs).
J. Ask if the client has had close physical contact with others with skin disorders.

PHYSICAL EXAMINATION

A. Inspect:
  1. Inspect skin and note lesion distribution.
  2. Inspect mucous membranes: buccal mucosa, tongue, and lips.
  3. Examine hair and nails.
  4. Observe genitalia.

DIAGNOSTIC TESTS

A. Dermoscopy to accentuate Wickham striae.
B. If necessary to confirm diagnosis, deep shave or punch biopsy of developed lesions.
C. HIV or STI testing if indicated.
D. Hepatitis testing should be completed to assess for hepatitis C as lichen planus has been shown to have a correlation.

DIFFERENTIAL DIAGNOSES

A. Lichen planus.
B. Lichenoid drug eruptions.
C. Leukoplakia.
D. Chronic graft versus host disease.
E. Candidiasis (thrush).
F. Lupus erythematosus.
G. Contact dermatitis.
H. Bite trauma.
I. Secondary syphilis.

PLAN

A. General interventions:
  1. Discontinue any suspected drug agent.
B. Client teaching: *See Client Teaching Guide for this chapter, "Lichen Planus."*
  1. Instruct the client that the disease may be chronic; most cases resolve spontaneously.
  2. Encourage the client to avoid severe emotional stress.
  3. Encourage the client to avoid scratching and prevent secondary infection.
  4. Reassure the client that lichen planus is not contagious.
C. Pharmaceutical therapy:
  1. Oral antihistamines to assist with pruritus: hydroxyzine hydrochloride 10 to 50 mg QID as needed for pruritus, or cetirizine HCl (Zyrtec) 10 mg daily.
  2. Medium- to high-potency topical corticosteroids:
    a. Mouth lesions: fluocinonide 0.05%, ointment or gel, two or three times daily.
    b. Body lesions: betamethasone dipropionate (Diprolene) 0.05%, triamcinolone (Kenalog), or other class 1 cream or ointment BID. **Caution clients about steroid atrophy**.
    c. Genital lesions: desonide cream 0.05% BID initially, although higher potency creams may be necessary. Topical corticosteroids should be used on genitalia in short bursts only.
    d. Hypertrophic lesions: Intralesional injections, such as injecting triamcinolone 2.5 to 10 mg/mL, 0.5 to 1 mL per 2-cm lesion, are helpful for pruritus relief. Use cautiously in dark-skinned clients due to risk of hypopigmentation. Limit the total dose to no more than 40 mg per treatment session. Injections may be repeated after 4 to 6 weeks.
  3. Oral prednisone is rarely used, but if necessary use with a short course only and taper.

FOLLOW-UP

A. See the client in 1 week for evaluation of treatment.

CONSULTATION/REFERRAL

A. Refer the client to a dermatologist if there is no response to initial treatment.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
  1. Use caution with medications prescribed.
B. Geriatrics:
  1. Red flags:
    a. Avoid first-generation anticholinergics due to risk of confusion, dry mouth, constipation, and other anticholinergic effects or toxicity.

BIBLIOGRAPHY

Trayes, K. P., Savage, K., & Studdiford, J. S. (2018). Annular lesions: Diagnosis and treatment. *American Family Physician*, *98*(5), 283–291.

PITYRIASIS ROSEA

DEFINITION

A. Pityriasis rosea is an acute, self-limiting, benign skin eruption characterized by a preceding "herald patch" followed by widespread papulosquamous lesions.

INCIDENCE

A. Pityriasis rosea is relatively common, with more than 75% of cases in individuals from 10 to 35 years of age.
B. Incidence is slightly higher in females than in males.
C. Incidence is higher during spring and autumn.

PATHOGENESIS

A. Disease is idiopathic; some evidence exists to support viral origin or autoimmune disorder.

PREDISPOSING FACTOR

A. Recent acute infection.

COMMON COMPLAINTS

A. Rash: salmon-, pink-, or tawny-colored lesions generally concentrated in lower abdominal area, but may develop on arms, legs, and rarely on the face.
B. Mild pruritus.

OTHER SIGNS AND SYMPTOMS

A. Earliest lesions may be papular but may progress to 1- to 2-cm oval plaques.
B. Long axes of oval lesions run parallel to each other, hence the term "Christmas tree distribution."
C. Preceding herald patch (2–10 cm with central clearing) closely resembles ringworm; usually appears abruptly a few days to several weeks prior to the generalized eruptive phase.

SUBJECTIVE DATA

A. Elicit information about occurrence of initial, single, 2- to 10-cm round-to-oval lesion.
B. Question the client as to known contacts with similar symptoms. Small epidemics have been identified in fraternity houses and military bases.

PHYSICAL EXAMINATION

A. Check temperature to rule out any infection.
B. Inspect:
1. Examine all body surfaces with client unclothed.
2. Look for characteristic lesions and distribution.
3. Check the mucous surfaces, palms, and soles, which are usually spared by pityriasis rosea.

DIAGNOSTIC TESTS

A. Generally, none required; however, potassium hydroxide (KOH) wet preparation may be useful to distinguish herald patch from tinea corporis.
B. If necessary to confirm diagnosis, deep shave or punch biopsy of developed lesions.
C. Order serology to rule out syphilis, if applicable.
D. If unable to identify herald patch, a serologic test for syphilis should be ordered because syphilis may be clinically indistinguishable from pityriasis rosea.
E. White blood count normal; no specific lab markers for pityriasis rosea.

DIFFERENTIAL DIAGNOSES

A. Pityriasis rosea.
B. Nummular eczema.
C. Tinea corporis.
D. Tinea versicolor.
E. Viral exanthems.
F. Drug eruptions:
1. Captopril.
2. Bismuth.
3. Barbiturates.
4. Clonidine.
5. Metronidazole.

G. Secondary syphilis.
H. Lichen planus.
I. Psoriasis.

PLAN

A. General interventions:
1. Direct sunlight to point of minimal erythema hastens disappearance of lesions and reduces itching. UVB light in five consecutive daily exposures can reduce pruritus and shorten rash, particularly if administered within the first week of eruption.
2. Not proven to be contagious and relatively harmless, so isolation is not required.

B. Client teaching: *See Client Teaching Guide for this chapter, "Pityriasis Rosea."*
1. Advise the client that the disease is self-limiting and clears spontaneously in 2 to 3 months.

C. Pharmaceutical therapy:
1. Generally, none required, but for itching the following recommendations exist:
   a. Group V topical steroids and oral antihistamines as per usual dosing.
   b. Prednisone 20 mg BID for 1 to 2 weeks in rare cases of intense itching.

FOLLOW-UP

A. None required unless secondary bacterial infection develops. Reoccurrence is unusual after disease resolution.

CONSULTATION/REFERRAL

A. Consult or refer the client to a physician when disease persists beyond 3 months.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
1. Disease has not been shown to affect fetus.

B. Geriatrics:
1. Disease rarely seen in geriatric clients. Strongly consider other differential diagnoses, particularly drug reactions.
2. Red flags:
a. Avoid first-generation anticholinergics due to risk of confusion, dry mouth, constipation, and other anticholinergic effects or toxicity.

PRECANCEROUS OR CANCEROUS SKIN LESIONS

DEFINITION

A. Skin lesions are skin cell changes that occur in the body, which may be benign, precancerous, or cancerous.

INCIDENCE

A. Actinic keratosis is the most common precancerous skin disorder, occurring in approximately 58 million Americans, which is an estimate because it is not commonly reported and/or often occurs without diagnosis.

B. Basal cell carcinoma (BCC) is the most common form of skin cancer, with approximately 400,000 new cases per year in the United States. It is often seen in the sixth or seventh decade of life.

C. Squamous cell carcinoma (SCC) accounts for 20% of all skin cancers and occurs mostly in the middle-aged and older adult populations.

D. Malignant melanoma accounts for less than 5% of all skin cancers. The median age at diagnosis is 61 years. The rate of new melanoma skin cases increased to 27.6 per 100,000 in 2008.

PATHOGENESIS

A. Actinic keratoses: A precancerous skin lesion commonly caused by damage to the skin as a result of exposure to UV rays or tanning beds. If not treated, these skin lesions may turn into a form of skin cancer, such as SCC.

B. BCC: Skin lesions that result from abnormal cells of the basal layer of the epidermis that progress into the surrounding stroma and support basal cell growth. UV rays (sunlight) are the major contributor to BCC. BCC is a slow-growing tumor that rarely metastasizes.

C. SCC: Abnormal cells of the epidermis penetrate the basement membrane of the epidermis and move into the dermis, producing SCC. This often begins as actinic keratosis that undergoes malignant change.

D. Malignant melanoma: Abnormal cells proliferate from the melanocyte system. Initially, the cells grow superficially and laterally into the epidermis and papillary dermis. After a certain period of time, the cells begin moving into the reticular dermis and subcutaneous fat. Malignant tumors occur because of the inability of the damaged cells to protect themselves from long-term exposure to UV rays.

PREDISPOSING FACTORS

A. Advanced age (older than age 50).

B. Median age of 40 years for malignant melanoma.

C. Exposure to UV light (sun exposure).

D. Fair complexion (blonde or red hair, blue, green, or gray eyes).

E. Smokers (damaged lips).

F. Skin damaged by burns and/or chronic inflammation.

G. History of blistering sunburns before 18 years of age increases risk.

COMMON COMPLAINTS

A. New lesions found on the skin.

B. Ulcer/sore that does not heal.

OTHER SIGNS AND SYMPTOMS

A. Actinic keratosis (solar keratosis): scaly, crusted lesions commonly found on sun-exposed skin areas such as the face, ears, scalp, lips, and hands that are usually rough in texture and appearance.

B. BCC: Tumors arising from the basal cell layer of the epidermis; may be seen on face and neck; may appear as an open sore, pink growth, or nodule that is greater than 1 cm and which appears shiny, pearly in color with telangiectasia; center may cave in.

C. SCC: skin lesions seen in sun-exposed areas of the skin, or skin damaged by burns or chronic inflammation; lower lip lesions common; firm, irregular papules with scaly, bleeding, friable surface like sandpaper; grows rapidly.

D. Malignant melanoma: asymmetrical tumor of skin with irregular border, variation in color, greater than 6 mm in diameter; can metastasize to any organ.

E. Bowen disease (SCC in situ): chronic, nonhealing erythemic patch with sharp, irregular borders; occurs on skin and/or the mucocutaneous tissue; resembles eczema but does not respond to steroids.

SUBJECTIVE DATA

A. Have the client identify when lesion was first noted.

B. Ask the client to describe any changes in size, color, or shape of the lesion.

C. Determine whether the client has noted any new lesions.

D. Ascertain any family history of malignant melanoma.

E. Determine the client's history of skin exposure to the sun or any other UV rays.

F. Ask the client about smoking history. If the individual smokes, ask how many packs per day.

PHYSICAL EXAMINATION

A. Inspect:
1. Perform full-body exam of the skin for lesions.
2. Note the surface, size, shape, border, color, and diameter of lesion.
3. Examine scalp and ears for lesions.

DIAGNOSTIC TESTS

A. Biopsy suspicious lesions.

DIFFERENTIAL DIAGNOSES

A. Actinic keratosis.

B. BCC.

C. SCC.

D. Malignant melanoma.

E. Solar lentigo.

F. Seborrheic keratosis.

G. Common nevus.

H. Leukoplakia.

PLAN

A. General interventions:

1. Monitor progress/change of lesions detected.

2. Biopsy any suspicious lesions. Excise lesion with narrow margins, making sure to include all margins. If biopsy results of specimen are inadequate for accurate histologic diagnosis or staging, repeat biopsy. Include all clinical history information on the pathology report with the specimen when sending to pathology.

B. Client teaching: *See Client Teaching Guide for this chapter, "Skin Care Assessment."*

1. Educate clients regarding the importance of early identification of lesions and monthly assessment of skin. The U.S. Preventive Services Task Force (USPSTF) recommends counseling adolescents and young adults less than 24 years of age regarding reducing the amount of UV radiation exposure, especially between the hours of 10 a.m. and 3 p.m. In adults older than 24 years of age, the USPSTF did not find sufficient evidence to determine the effects of counseling these clients regarding the use of sun protection.

2. Instruct clients on monthly skin evaluation. Teach the "ABCD" method of exam for changes in lesions: **A**symmetry, **B**order, **C**olor, and **D**iameter. A body map may be used to mark skin changes and monitor progress. Mark the site of the lesion on the body map, including measurements and date found. A body map can be accessed at www.skincancer.org/skin-cancer -information/early-detection/body-map.

C. Pharmaceutical therapy:

1. None indicated.

FOLLOW-UP

A. When a diagnosis is made, follow up according to diagnosis. Differentiate between benign skin lesions and malignant melanoma. Follow-up/treatment depends on diagnosis (nonsurgical vs. surgical removal for diagnosis). Surgical removal is recommended for recurrent and suspicious lesions.

CONSULTATION/REFERRAL

A. Refer all clients to a dermatologist if skin cancer is suspected.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Skin cancer screening is important during pregnancy if new lesions develop.

2. Melanoma should be assessed without delay. The same anesthetics used for adult biopsy is also safe in pregnancy. Treatment with radiation to head and neck only and use of interferon for treatment may be safe in pregnancy.

B. Geriatrics:

1. Older adults are at higher risk of skin cancer due to their decreased immune system as they age, as well as their cumulative chronic disease risk factors. Educate these clients regarding their risk factors and teach them how to assess the skin for lesions. Encourage frequent skin assessment and early diagnosis for improved outcomes.

BIBLIOGRAPHY

American Academy of Dermatology. (n.d.). *Actinic keratosis: Overview*. https://www.aad.org/public/diseases/skin-cancer/actinic-keratosis-overview#:~:text=AKs%20tend%20to%20appear%20on,to%20get%20the%20most%20sun

PSORIASIS

DEFINITION

A. A common benign, chronic, inflammatory skin disorder, psoriasis is characterized by whitish/silver scaly patches commonly seen on the scalp, knees, and elbows.

INCIDENCE

A. Psoriasis occurs in 1% to 3% of the world population.

B. Psoriasis affects 7.5 million people in the United States, with 80% of them having plaque psoriasis.

C. It occurs at any age:

1. Peak of onset seen in adolescence.

2. Young adult (16–22 years old).

3. Adult (50–60 years old).

PATHOGENESIS

A. Etiology is unknown; this is a multifactorial disease with a definite genetic component. Hyperproliferation of the epidermis and inflammation of the epidermis and dermis are seen, with epidermal transit time rapidly increased (six- to nine-fold). A T-lymphocyte-mediated dermal immune response may be due to a microbial antigen or autoimmune process.

PREDISPOSING FACTORS

A. Family history.

B. Drugs that exacerbate condition:

1. Lithium.

2. Beta-blockers.

3. Nonsteroidal anti-inflammatory drugs (NSAIDs).

4. Antimalarials.

5. Sudden withdrawal of systemic or potent topical corticosteroids.

C. Stress (common triggering factor).

D. Local trauma or irritation.

E. Recent streptococcal infection.

F. Alcohol use.

G. Tobacco use.

H. HIV association; suspected if onset is abrupt.

I. Obesity.

J. Vitamin D deficiency.

COMMON COMPLAINT

A. Dry scaly rash.

OTHER SIGNS AND SYMPTOMS

A. Pruritic and/or painful lesions.

B. Silvery scales on discrete erythematous plaques.

1. Onset commonly occurs as a guttate form with small, scattered, teardrop-shaped papules and plaques after a streptococcal infection in a young adult.

2. Larger, chronic plaques occur later in life.

C. Lesions are commonly seen on scalp, elbows, and knees, but may involve any area of the body.

D. Glossitis or geographic tongue: small pits or yellow-brown spots (oil spots).

E. Positive Auspitz sign: punctate bleeding points with removal of scale.

F. Onycholysis.

G. Stippled nails and pitting; approximately 50% of affected individuals have nail involvement.

H. Periarticular swelling of small joints of fingers and toes. **Joint pain and involvement signals psoriatic arthritis.**

I. Pustular variant with predominant involvement of hands and/or feet, including nails.

SUBJECTIVE DATA

A. Question the client regarding any predisposing factors listed earlier to identify risk factors.
B. Ask the client if there have been changes in the course of symptoms.
C. Ascertain whether the symptoms worsen in winter and clear in summer.
D. Determine site of lesion and whether the onset is sudden or painful.
E. Ask the client to describe the skin. Is it itchy or painful?
F. Assess lesions for any associated discharge (blood or pus).
G. Ask if the client is using any new soaps, creams, or lotions.
H. Rule out any exposure to industrial or domestic toxins.
I. Ask the client about any possible contact with venereal disease (sexually transmitted infections [STIs]).
J. Review whether there was close physical contact with others with skin disorders.
K. Elicit information regarding any preceding systemic symptoms (fever, sore throat, and anorexia).

PHYSICAL EXAMINATION

A. Check temperature (if indicated).
B. Inspect:
  1. Inspect skin; note type of lesion and distribution. Assess oral mucosa, nails, and nail beds.
  2. Assess joints for erythema and/or synovitis (inflammation of the synovial membrane).
C. Palpate:
  1. Palpate joints for tenderness and synovitis.

DIAGNOSTIC TESTS

A. Skin biopsy may be performed if the diagnosis remains uncertain.
B. If HIV infection is suspected, order HIV test.
C. If joint inflammation is present, consider rheumatoid factor, erythrocyte sedimentation rate, C-reactive protein, and uric acid.
D. If there is a history of streptococcal infection, order antistreptolysin O titer.

DIFFERENTIAL DIAGNOSES

A. Psoriasis.
B. Scalp: seborrheic dermatitis.
C. Body folds: candidiasis.
D. Trunk: pityriasis rosea, tinea corporis.
E. Hand dermatitis.
F. Squamous cell carcinoma (SCC).
G. Cutaneous lupus erythematosus.
H. Eczema.

PLAN

A. General interventions:
  1. This is a chronic disorder that requires long-term treatment, a high degree of client involvement, and therapy that is simple and inexpensive.
  2. Aim of treatment is control, not cure.
  3. Exposure to sunlight may be beneficial. However, a small percentage of clients worsen with exposure to sunlight.
  4. The sequence of agents for involvement of less than 20% body surface is as follows:
    a. Emollients (Eucerin cream or Aquaphor cream).
    b. Keratolytic agents (salicylic acid gel or ointment).
    c. Topical corticosteroids: Use lowest potency to control disease.
    d. Calcipotriene ointment: vitamin D analogue (calcipotriene ointment 0.005%).
    e. Anthralin: Use as short-contact therapy 1% to 3%.
    f. Coal tar (Estar, Psorigel): Use in conjunction with topical steroids or anthralin. It can be applied at bedtime or in the morning for 15 minutes and then shower off.
    g. Medicated shampoos: Useful for scalp psoriasis, in conjunction with topical steroids and other treatments.
B. Client teaching: *See Client Teaching Guide for this chapter, "Psoriasis."*
  1. Help the client understand the chronic nature of this disease characterized by flares and remission. Teach stress monitoring and control. Assist with coping techniques.
  2. A trial of a gluten-free diet may be tried to help symptoms. See Appendix B for Gluten-Free Diet.
  3. Encourage the client to reach out to the National Psoriasis Foundation for education and resources for them and their family.
C. Pharmaceutical therapy:
  1. If disease is not controlled with first agent, then an alternative agent may be tried.
    a. Mild to moderate disease: Topical steroids are first-line therapy.
    b. Emollients to start treatment (e.g., Eucerin Plus lotion or cream, Lubriderm Moisture Plus, Moisture).
    c. Scalp: Use coal tar shampoo (Zetar, T/Gel, Pentrax) in place of regular shampoo two times per week.
      i. Apply lather to scalp, allow to soak for 5 minutes, and then rinse.
      ii. If the scale is very thick, use P and S Liquid (over-the-counter [OTC]). Massage in at night and wash out in the morning.
    d. For additional treatment as needed, apply triamcinolone acetonide 0.1% (Kenalog 0.1%) lotion or equivalent to scaly, stubborn areas once or twice daily until controlled. Avoid the face.
    e. Dovonex scalp solution: Apply on dry scalp as directed.
    f. Face and skin folds: Apply hydrocortisone cream 1% sparingly up to 4 weeks, preferably no more than 2 weeks. If lesions are unresponsive, consider increasing to 2.5% and taper quickly with improvement.
    g. Body, arms, and legs: Use triamcinolone acetonide 0.025% (Aristocort A) cream BID up to 2 weeks. **Avoid normal skin.**
    h. For thick plaques, try Keralyt gel (6% salicylic acid), then corticosteroids.
    i. Coal tar (Estar gel) once or twice daily in combination with corticosteroids.
    j. Anthralin (Dritho-Creme) is beneficial as an alternate to steroid lotion for scalp psoriasis. **Avoid sunlight.**
    k. Vitamin D_3 analog (Calcipotriol), BID up to 8 weeks, is comparable to midpotency corticosteroids. **Avoid the face and skin folds.**

FOLLOW-UP

A. See the client in 2 to 3 weeks to evaluate treatment.
B. Follow up in 2 months to monitor side effects.
C. Follow-up must be individualized for each client.

CONSULTATION/REFERRAL

A. Medical management: For involvement greater than 20% of the body, refer the client to a dermatologist for the following:
  1. Light therapy with UVA and UVB. UVB light therapy is often used in conjunction with keratolytic agents.
  2. Synthetic retinoids: etretinate or acitretin.
  3. Low-dose cyclosporine or Azulfidine.
B. Refer clients with extensive disease, psoriatic arthritis, or inflammatory disease to a rheumatologist. Medications are used to suppress the immune system's response, and include adalimumab (Humira), alefacept (Amevive), etanercept (Enbrel), infliximab (Remicade), and ustekinumab (Stelara).
C. Cases of generalized pustular psoriasis of exfoliative erythroderma should be referred immediately to a dermatologist.
D. All systemic therapies should be given under supervision of a dermatologist or a rheumatologist.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
  1. Psoriasis may get better or worse during pregnancy. Use of moisturizers and emollients is strongly encouraged.
  2. Corticosteroids are safe to use if using low or medium strength. Use may cause an increase in developing stretch marks.
  3. Treatment with phototherapy is safe using broadband UVB and narrowband UVB.
  4. Avoid use of methotrexate, acitretin, and tazarotene.
B. Geriatrics:
  1. First-line therapy for mild to moderate psoriasis in the older adult population is topical treatments. Systemic steroid therapies place geriatrics at a higher risk of adverse effects, including atrophy, rebound phenomenon, tachyphylaxis, secondary skin infections, telangiectasia, and purpura.
  2. If topical treatment is not effective, before considering other treatments, do an assessment for client adherence and physical function abilities. Verify the client is using the medication correctly and consistently.
  3. If the medication is being implemented appropriately, then consider second-line treatments of systemic medications or UVB phototherapy. Second-line therapies must have a thorough review of comorbidities, any client needs for assistance, and an evaluation of functional status before initiating the systemic/phototherapy.

SCABIES

DEFINITION

A. Scabies is a contagious skin infestation by the mite *Sarcoptes scabiei.*

INCIDENCE

A. Scabies occurs mainly in individuals in close contact with many other individuals, such as nursing home residents. It is rare among African Americans.

PATHOGENESIS

A. Scabies is transmitted through close contact with an individual who is infested with the mite *S. scabiei.* Transmission may occur through sexual contact or contact with mite-infested clothing or sheets. The fertilized female mite burrows into the stratum corneum of a host and deposits eggs and fecal pellets. Larvae hatch, mature, and repeat the cycle.
B. A hypersensitivity reaction is responsible for the intense pruritus.

PREDISPOSING FACTORS

A. Close contact with large numbers of individuals.
B. Institutionalization.
C. Poverty.
D. Sexual promiscuity.

COMMON COMPLAINTS

A. Intense itching, worse at night.
B. Skin excoriation.
C. Generalized pruritus.
D. Rash.

OTHER SIGNS AND SYMPTOMS

A. Mites burrow in finger webs, wrists, sides of the hands and feet, axilla and buttocks, and in the penis and scrotum in males.
B. Discrete vesicles and papules, distributed in linear fashion.
C. Erythema.
D. Secondary bacterial infections due to scratching (pustules and pinpoint erosions).
E. Nodules in covered areas (buttocks, groin, scrotum, penis, axilla), which may have slightly eroded surfaces that persist for months after mites have been eradicated.
F. Diffuse eruption that spares face.

SUBJECTIVE DATA

A. Elicit information regarding housing conditions, close contact, or sexual contact with potentially infected individuals.
B. Question the client regarding onset, duration, and location of itching.

PHYSICAL EXAMINATION

A. Check temperature.
B. Inspect:
  1. Examine all body surfaces with client unclothed.
  2. Use a magnifying lens to identify characteristic burrows in finger webs, wrists, and penis.
  3. Inspect adult pubic area for lesions.

DIAGNOSTIC TESTS

A. Three findings are diagnostic of scabies:
  1. Microscopic identification of *S. scabiei* mites.
  2. Eggs.
  3. Fecal pellets (scybala).

B. Burrow identification: Ink the suspected area with a blue or black felt-tipped pen, then wipe with an alcohol swab. The burrow absorbs the ink, while the surface ink is wiped clean.

C. A tiny black dot may be seen at the end of a burrow, which represents the mite, ova, or feces, and can be transferred by means of a 25-gauge hypodermic needle to immersion oil on a slide for microscopic identification.

D. Place a drop of mineral oil on a suspected lesion, scrape lesion with a #15 blade, and transfer the shaved material to a microscope slide for direct examination of the mite under low power.

DIFFERENTIAL DIAGNOSES

A. Scabies.
B. Atopic dermatitis.
C. Insect bites.
D. Pityriasis rosea.
E. Eczema.
F. Seborrheic dermatitis.
G. Syphilis.
H. Pediculosis.
I. Allergic or irritant contact dermatitis.

PLAN

A. General interventions:
  1. Implement comfort measures to reduce pruritus.
  2. Treat secondary bacterial infection(s) with antibiotics.
  3. Household members should be treated simultaneously as a prophylactic measure and to reduce the chance of reinfection.
  4. The client should be advised that pruritus may continue for up to a week even with a successful treatment due to local irritation.

B. Client teaching: *See Client Teaching Guide for this chapter, "Scabies."*

C. Pharmaceutical therapy:
  1. First-line of therapy, due to its low toxicity, is 5% permethrin (Elimite cream) applied to all body areas from neck down and washed off in 8 to 14 hours. One application is highly effective, but some dermatologists recommend retreatment in 1 week.
  2. An oral dose of the anthelmintic agent ivermectin (200 mcg/kg) followed by a repeat dose in 1 to 2 weeks has been shown to be effective and to rapidly control pruritus in healthy clients and individuals with HIV.
  3. Diphenhydramine (Benadryl) 25 to 50 mg may be given PO every 4 to 6 hours if indicated for pruritus. Other nonsedating antihistamines may be used. Toxicity is usually a result of client overtreatment (failure to follow prescribed regimen). Advise the client of this danger.

FOLLOW-UP

A. Follow up in 2 weeks to assess treatment response.

CONSULTATION/REFERRAL

A. Consult or refer the client to a physician if, at 2-week follow-up, pharmaceutical therapy has been ineffective.

INDIVIDUAL CONSIDERATIONS

A. Partners:
  1. All intimate contacts within the past month and close household and family members should be treated.

B. Geriatrics:
  1. Older adults tend to have more severe pruritus despite fewer lesions.
  2. They are at risk of extensive infections due to an age-related decline in immunity.
  3. The excoriations may become severe and may be complicated by cellulitis.
  4. Red flags:
    a. Avoid first-generation anticholinergics due to risk of confusion, dry mouth, constipation, and other anticholinergic effects or toxicity.
    b. Geriatric clients who have dementia or declining functional abilities need a thorough home environment assessment and an evaluation for any issues of neglect or abuse.

SEBORRHEIC DERMATITIS

DEFINITION

A. A common chronic, erythematous, scaling dermatosis, seborrheic dermatitis occurs in areas of the most active sebaceous glands, such as the face and scalp, body folds, and presternal region.

INCIDENCE

A. Seborrheic dermatitis is very common, affecting approximately 1% to 5% of the general population.

B. Incidence is higher in HIV-infected individuals, ranging from 34% to 83%.

PATHOGENESIS

A. Etiology is unknown. There is a possibility that it is hormonally dependent, has a fungal *(Pityrosporum ovale* or *Candida albicans)* component, is neurogenic, or may reflect a nutritional deficiency.

B. Currently, it is identified as an inflammatory disorder that most probably results from a dysfunction of sebaceous glands.

PREDISPOSING FACTORS

A. Possible link between infantile and adult forms.
B. Possible familial trend.
C. High association with HIV-infected individuals.

COMMON COMPLAINTS

A. "Dandruff," dry flaky scalp.
B. Rash with "sticky flakes."

Often no presenting complaints are found on a routine physical exam.

OTHER SIGNS AND SYMPTOMS

A. Variable pruritus, often increased with perspiration and winter.

B. Oily, flaking skin on an erythemic base around ears, nose, eyebrows, and eyelids. ▶

C. Red, cracking skin in body folds, axilla, groin, or anogenital, submammary, or umbilical areas.
D. Primary lesions: plaques.
E. Secondary lesions: erythema, scales, fissures, exudate, and symmetric eyelid involvement.
F. Lesions with drainage or crusting may indicate secondary bacterial infection.
G. Distribution area in adults: scalp, eyebrows, paranasal area, nasolabial fold, chin, behind ears, chest, and groin.

SUBJECTIVE DATA

A. Identify location, onset, and progression of symptoms.
B. Ask the client to describe symptoms. Ask if the skin is itchy or painful.
C. Assess lesions for any associated discharge (blood or pus).
D. Elicit information regarding use of topical medications, soaps, creams, or lotions. Quiz client regarding any oral medications being taken.
E. Determine whether there were any preceding systemic symptoms (fever, sore throat, anorexia, or vaginal discharge).
F. Rule out any possible exposure to industrial or domestic toxins.
G. Ask the client to identify what improves or worsens this condition.

PHYSICAL EXAMINATION

A. Inspect:
  1. Inspect skin; note areas of lesions and distribution.
  2. Assess eyes for blepharitis.
  3. Inspect ears and nose.
B. Palpate:
  1. Palpate the skin, noting texture and moisture.

DIAGNOSTIC TESTS

A. None required.
B. May consider possible skin biopsy to rule out other conditions if suspicious.

DIFFERENTIAL DIAGNOSES

A. Seborrheic dermatitis.
B. Atopic dermatitis.
C. Candidiasis.
D. Dermatophytosis.
E. Histiocytosis X.
F. Psoriasis vulgaris.
G. Rosacea.
H. Systemic lupus erythematosus.
I. Tinea capitis.
J. Tinea versicolor.
K. Vitamin deficiency.
L. Impetigo.
M. Eczema.
N. Secondary syphilis.

PLAN

A. General interventions:
  1. Shampooing is the foundation of treatment.
    a. Use medicated shampoos as directed (Selsun Blue, Exsel, or Nizoral).
    b. Shampoo daily with baby shampoo using a soft brush.
    c. If scalp does not clear after 1 to 2 weeks of treatment, it is appropriate to use ketoconazole 2% cream.
  2. Seborrheic blepharitis:
    a. Hot compress plus gentle debridement with cotton-tipped applicator and baby shampoo twice a day.
    b. For secondary bacterial infection, sulfacetamide sodium 10% (ophthalmic Sodium Sulamyd).
    c. Continue treatment for several days after lesions disappear.
B. Client teaching: *See Client Teaching Guide for this chapter, "Seborrheic Dermatitis."*
C. Pharmaceutical therapy:
  1. Most shampoos should be used two times per week. Those with coal tar can be used three times per week.
  2. Medicated shampoos:
    a. Coal tar (Denorex, T/Gel, Pentrax, Tegrin) shampoo: Apply as directed.
    b. Salicylic acid (Ionil Plus, P and S) shampoo: Apply as directed.
    c. Selenium sulfide (Exsel, Selsun Blue): Shampoo daily.
    d. Ketoconazole 2% (Nizoral) cream: Apply to the affected area BID for 4 to 6 weeks.
    e. Combination shampoos: coal tar and salicylic acid (T/Sal); salicylic acid and sulfur (Sebulex). These shampoos may be used one to two times a week, alternating with other shampoos during the week. Always apply corticosteroids as thin layer only; avoid eyes.
  3. Topical corticosteroid lotions or solutions: Use in combination with medicated shampoo if 2 to 3 weeks of treatment with shampoo alone fails.
    a. Adults: scalp:
      i. Start with medium potency, for example, betamethasone valerate 0.1% lotion 20 to 60 mL BID.
      ii. If treatment is not effective in 2 weeks, increase potency, for example, fluocinonide 0.05% solution 20 to 60 mL BID, or fluocinolone acetonide 0.01% oil 120 mL nightly with shower cap.
      iii. As dermatitis is controlled, reduce to mild potency, for example, hydrocortisone 1% to 2.5% lotion 60 to 20 mL once or twice daily.
    b. Adults: face or groin:
      i. Low-potency agents, for example, hydrocortisone 1% cream or desonide 0.05% cream once or twice daily.
      ii. Consider lotion for eyebrows for easier application.
      iii. Metronidazole 1% gel on face once or twice daily.
  4. Recalcitrant disease:
    a. Add ketoconazole 2% cream (15, 30, or 60 g) every day.
    b. Sulfacetamide sodium 10%, with sulfur 5%, lotion 25 g once or twice daily.

FOLLOW-UP

A. Advise the client to call the office in 5 to 6 days to report progress.
B. The client should return to the office if no improvement is seen.

CONSULTATION/REFERRAL

A. Refer the client to a dermatologist if the condition does not clear in 10 to 14 days.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Ketoconazole is not recommended.

B. Geriatrics:

1. Seborrheic dermatitis is one of the most common inflammatory skin disorders in the older adult population. Clients with light dry skin are at greater risk of an occurrence, especially during the winter.

TINEA

DEFINITION

A. Tinea corporis (ringworm) is a fungal infection of the skin tissue (keratin) commonly seen on the trunk and extremities.

B. Tinea capitis is a fungal infection of scalp hair.

C. Tinea cruris is a fungal infection of the groin.

D. Tinea pedis is a fungal infection of the foot.

E. Tinea unguium (dermatophyte onychomycosis) is a fungal infection of the nail.

INCIDENCE

A. Tinea is a fairly common fungal infection seen in adults.

PATHOGENESIS

A. The causative fungal species varies, depending on the location of the infection. Three common organisms are *Epidermophyton, Microsporum*, and *Trichophyton.*

B. The infection can be obtained from other people, environmental contact with inanimate objects, animals (puppies, kittens), and the soil.

PREDISPOSING FACTORS

A. Exposure to person or facilities (e.g., locker rooms) infected with the fungus.

B. Poor nutrition.

C. Poor health.

D. Poor hygiene.

E. Warm climates.

F. Immunosuppression.

COMMON COMPLAINTS

A. Scaly, itchy skin.

B. When circular in shape, usually tinea corporis (ringworm).

C. When nails are thickened and yellow, usually tinea unguium.

OTHER SIGNS AND SYMPTOMS

A. Tinea capitis: erythema, scaling of scalp, with hair loss at site, in which client is asymptomatic of hair loss.

B. Tinea corporis: circular, erythematous, well-demarcated lesion on the skin with hypopigmentation at the center of the lesion; usually pruritic.

C. Tinea cruris: well-demarcated scaling lesions on groin (not scrotum) or thigh; usually pruritic.

D. Tinea pedis: scaly, erythemic vesicles on feet, between toes, and in arch, with extreme pruritus.

E. Tinea unguium (onychomycosis): thickening and yellowing of toenail or fingernail, often with other fungal infection or alone.

SUBJECTIVE DATA

A. Ask the client about onset, duration, and progression of patch or rash on skin.

B. Assess the client for other areas of skin involvement.

C. Ask if the lesion is pruritic.

D. Inquire as to the client's exposure to anyone with similar symptoms.

E. Determine whether the client has a history of similar lesions.

F. Query the client regarding predisposing factors.

G. Review with the client what remedies were used and with what results.

PHYSICAL EXAMINATION

A. Check temperature (if indicated).

B. Inspect:

1. Examine all areas of skin.

2. Note type of lesions present.

DIAGNOSTIC TESTS

A. Obtain scrapings of the border of the lesion for evaluation.

1. Potassium hydroxide (KOH).

2. Wet prep.

3. Fungal cultures.

DIFFERENTIAL DIAGNOSES

A. Tinea corporis.

B. Dermatitis.

C. Alopecia areata.

D. Psoriasis.

E. Contact dermatitis.

F. Atopic eczema.

G. Subacute cutaneous lupus erythematosus.

H. Pityriasis rosea.

PLAN

A. General interventions:

1. Identify type of lesion.

2. Identify other infected family members or sexual partners for treatment.

B. Client teaching: *See Client Teaching Guide for this chapter, "Tinea."*

1. Reinforce medication regimen for a 4- to 8-week period for resolution.

C. Pharmaceutical therapy:
1. Tinea capitis:
a. Adults: griseofulvin 500 mg PO each day for 4 to 6 weeks.
2. Tinea corporis, pedis, and cruris:
a. Clotrimazole 1% (Lotrimin) cream or econazole nitrate 1% cream, BID for 14 to 28 days.
b. Terbinafine 1% cream (Lamisil), topical; apply once or twice daily for 1 to 4 weeks.
3. Onychomycosis: Successful treatment is difficult.
a. Itraconazole (Sporanox) 100 mg, two tablets PO BID for 7 days. Repeat in 1 month, then repeat again in 1 more month.

Monitor liver function tests (LFTs) at 6 weeks after starting medication.

b. Terbinafine.
i. Fingernail: 250 mg once daily for 6 weeks.
ii. Toenail: 250 mg daily for 12 weeks.
c. Home cure: Apply Vicks VapoRub on toenail bed and cover with a sock every night at bedtime for approximately 4 to 6 months or until resolved. This treatment offers a safe, cost-effective alternative to oral medications.

FOLLOW-UP
A. A 2- to 4-week follow-up is recommended to evaluate progress.
B. When using Sporanox, monitor liver function tests (LFTs) at 6 weeks. If the medication is continued, monitoring LFTs every 6 to 8 weeks is recommended.

CONSULTATION/REFERRAL
A. Consult a physician if the infection has not improved.

INDIVIDUAL CONSIDERATIONS
A. Pregnancy:
1. Oral antifungal medications are not recommended during pregnancy.
B. Adults:
1. Tinea capitis is rare in adults.
2. Tinea cruris is more common in obese males but rare in females.
3. Transient and/or permanent hearing loss has been documented in some clients with use of itraconazole. These cases were reported when itraconazole was used with quinidine, which is contraindicated.
C. Geriatrics:
1. Itraconazole should be used cautiously in older adults.
2. Recommendation for tinea treatment with the older adult population is terbinafine due to its decreased risk for cardiac complications and drug interactions if on multiple other medications.

Trayes, K. P., Savage, K., & Studdiford, J. S. (2018). Annular lesions: Diagnosis and treatment. *American Family Physician*, *98*(5), 283–291.

TINEA VERSICOLOR

DEFINITION
A. Tinea versicolor is a fungal infection of the skin which may be chronic in nature. It is most commonly seen on the upper trunk; however, it may spread to extremities.

INCIDENCE
A. Tinea versicolor is seen most frequently in adolescents and young adults.

PATHOGENESIS
A. Tinea versicolor is a fungal infection of the skin caused by an overgrowth of *Malassezia* (formerly known as the *Pityrosporum orbiculare)*, part of the normal skin flora.
B. Discoloration of the skin is seen, forming round or oval maculae, which may become confluent.
C. Maculae range from 1 cm to very large, greater than 30 cm.

PREDISPOSING FACTORS
A. Immunosuppressed
B. Pregnancy.
C. Warm temperatures.
D. Corticosteroid therapy.
E. Genetic Predisposition.

COMMON COMPLAINTS
A. Scaly rash on the upper trunk with occasional mild itching.

OTHER SIGNS AND SYMPTOMS
A. Annular maculae with mild scaling.
B. Asymptomatic or pruritic.
C. Pink-, white-, or brown-colored rash.

SUBJECTIVE DATA
A. Ascertain when and where the rash began.
B. Have the client describe how the rash has changed.
C. Assess the client for any associated symptoms with the rash, such as itching and burning.
D. Identify what products the client has used on the skin to treat rash and with what results.
E. Elicit information regarding a history of similar rashes.
F. Query the client regarding current medications.
G. Review any medical history for comorbid conditions.

PHYSICAL EXAMINATION
A. Inspect:
1. Inspect skin and note type of lesion.
2. Examine other areas of skin for similar lesions.

DIAGNOSTIC TESTS
A. Wet prep/potassium hydroxide (KOH).
B. Wood lamp: Wood light is useful in examining skin to determine the extent of infection. Inspection of fine scales with Wood lamp reveals scales with a pale yellow-green fluorescence that contain the fungus.

C. Culture lesion: When obtaining a sample scraping, obtain sample from edge of lesion for best sample of hyphae. (Hyphae and spores have a "spaghetti and meatball" appearance.)

DIFFERENTIAL DIAGNOSES

A. Tinea versicolor.
B. Tinea corporis.
C. Pityriasis alba.
D. Pityriasis rosea: Herald patch is clue to diagnosis.
E. Seborrheic dermatitis.
F. Vitiligo.
G. Secondary syphilis.

PLAN

A. General interventions:
  1. Apply medication as directed.
C. Client teaching: *See Client Teaching Guide for this chapter, "Tinea Versicolor."*
  1. Because causative species is a normal inhabitant of skin flora, recurrence is possible.
  2. Skin pigmentation returns after infection has cleared up. This may take several months to resolve.
D. Pharmaceutical therapy:
  1. Selenium sulfide 2.5% (Selsun Blue):
    a. Advise client to shower at bedtime. Then apply selenium sulfide 2.5% cream to skin, covering entire body from chin down to toes. Leave treatment on skin for 8 to 10 hours. Shower off in the morning.
    b. A second treatment option includes applying the selenium sulfide 2.5% cream to skin lesions daily for 12 days. Leave treatment on skin for 30 minutes, then shower off.
    c. Treatment may be needed monthly until desired results are obtained. **Encourage use of Selsun Blue on entire body surface except on the face and head.**
  2. Other medications used:
    a. Clotrimazole 1% cream BID for 4 weeks.
    b. Ketoconazole 2% (Nizoral) cream daily for 14 days.
    c. Fluconazole 300 mg once weekly for 2 weeks. **When using fluconazole as treatment, caution the client regarding liver damage with toxicity.**

FOLLOW-UP

A. None required if resolution occurs.
B. Monitor liver function tests (LFTs) every 6 weeks while on oral medication.

CONSULTATION/REFERRAL

A. Consult with a physician if current treatment is unsuccessful.

INDIVIDUAL CONSIDERATIONS

A. Adults:
  1. Commonly seen in young adults.
B. Geriatrics:
  1. Rare in the geriatric population.

WARTS

DEFINITION

A. A wart is an elevation of the epidermal layer of the skin (skin tumor). Warts are caused by the human papillomavirus (HPV).

INCIDENCE

A. Warts occur in people of all ages, more commonly in children and those in early adulthood.
B. By adulthood, 90% of all people have positive antibodies to the virus.
C. Warts are seen more frequently in females than in males.

PATHOGENESIS

A. A circumscribed mass develops on the skin that is limited to the epidermal layer. The virus, papillomavirus, is located within the nucleus of the cell.
B. The virus may be transmitted by touch and is commonly seen on the hands and feet.
C. Most warts resolve without treatment within 12 to 24 months.

PREDISPOSING FACTORS

A. Skin trauma.
B. Immunosuppression.
C. Exposure to public showers, pools, locker rooms, and so forth.

COMMON COMPLAINTS

A. Bump on the skin or specific area of the body (hands, feet, arms, and legs).
B. Usually painless unless present on the bottom of the foot.

OTHER SIGNS AND SYMPTOMS

A. Common wart (verruca vulgaris): flesh-colored, irregular lesion with rough surface; black dots in center of lesion occasionally seen, which is thrombosed capillaries; can occur on any body part.
B. Filiform wart (verruca filiformis): thin, threadlike, projected papule on face, lips, nose, or eyelids.
C. Flat wart (verruca plana): flat-topped, flesh-colored papule, 1 to 3 mm in diameter, with smooth surface; seen in clusters or in a line, on face and extremities.
D. Plantar wart (verruca plantaris): firm papule, 2 to 3 cm in diameter, indented into skin with verrucous surface; painful with ambulation, when placed on ball or heel of foot.
E. Genital warts: See the topics on sexually transmitted infections in Chapter 17.

SUBJECTIVE DATA

A. Determine onset, location, and duration of wart.
B. Elicit information regarding a history of warts.
C. Identify with the client what treatment has been used in the past and what the results were. Question the client regarding ▶

length of time over-the-counter (OTC) medications were used and how aggressive they were with the treatment.

PHYSICAL EXAMINATION

A. Inspect:
  1. Assess skin for lesions, noting location, appearance, size, and surface texture of wart.
  2. Examine the entire body for other lesions.

DIAGNOSTIC TESTS

A. None indicated.

DIFFERENTIAL DIAGNOSES

A. Wart:
  1. Verruca vulgaris.
  2. Filiform wart.
  3. Verruca plana.
  4. Verruca plantaris.
B. Seborrheic keratosis.
C. Callus.
D. Molluscum contagiosum: flesh-colored group of firm papules found on the face, trunk, and/or extremities. A white core may be expressed from lesion. Lesion may be successfully removed by curettage or cryotherapy.
E. Corn.
F. Skin cancer.

PLAN

A. General interventions:
  1. Identify type of wart.
  2. Treatment is based on the type of wart.

B. Client teaching: *See Client Teaching Guide for this chapter, "Warts."*
C. Pharmaceutical therapy:
  1. Common wart:
    a. After soaking and filing wart with a nail file, apply one of the following:
      i. Salicylic acid 17% (Compound W) gel BID for up to 12 weeks, if needed. Keep site covered with adhesive and bandage.
      ii. Apply duct tape to site after treatment. Repeat this treatment every night for up to 12 weeks or until resolved.
    b. Apply cryotherapy with liquid nitrogen to the site. Repeat every 3 to 4 weeks until resolved. Apply adhesive tape over the site and keep covered.
  2. Flat wart:
    a. Retinoic acid: Apply to the site BID for 4 to 6 weeks.
    b. Imiquimod (Aldara) 5% cream may be applied by the client at home. Although labeled use is for genital warts, the client may consider off-label use at bedtime and wash off after 6 to 8 hours every other day until resolved. Precautions should be stressed regarding caustic nature of the cream to healthy skin.
  3. Plantar wart:
    a. Salicylic acid 40% (Mediplast): Apply over wart. Remove in 24 to 48 hours and remove dead skin with stone or by scraping or using nail file. Repeat every 24 to 48 hours until wart is removed. May take up to 6 to 8 weeks.
  4. Filiform wart:
    a. Apply cryotherapy with liquid nitrogen to site. Repeat every 3 to 4 weeks until resolved. Apply adhesive tape over the site and keep it covered.
    b. Refer to a dermatologist for surgical removal.
  5. Educate client to throw away emery board and nail file after each use. If using nail file, cleanse after each use with alcohol.

FOLLOW-UP

A. Follow the client every 4 to 6 weeks until resolved.

CONSULTATION/REFERRAL

A. If diagnosis is unclear, refer the client to a dermatologist for surgical excision and biopsy.

INDIVIDUAL CONSIDERATIONS

A. Warts occur in all ages but are less common in older adults. Use caution if client elects cryotherapy to treat a wart secondary to thinness of aging skin. Always assess if the client is taking aspirin or anticoagulant therapy prior to incisional removal or cryotherapy.

WOUND CARE: LOWER EXTREMITY ULCER

DEFINITION

A. Vascular ulcer:
  1. Arterial/ischemic ulcer:
    a. Skin ulcers usually found from the toes to the ankle region; ulcers fail to heal due to inadequate arterial flow.
  2. Venous ulcer:
    a. Chronic skin and subcutaneous lesions are usually found on lower extremity between the ankle and knee, thought to occur from intracellular edema or inflammatory processes.
B. Diabetic foot ulcer:
  1. Skin ulcers usually found on the plantar surface of the feet, or metatarsals, most commonly occurring from trauma or plantar pressure.

INCIDENCE

A. Diabetic foot ulcers precede over 80% of lower extremity amputations in the United States.
B. The financial burden of venous ulcers is estimated to be $2 billion per year in the United States.
C. Up to 20% of lower extremity ulcers have been shown to have mixed etiology disease.

PATHOGENESIS

A. An ulcer that is found between the knees and toes constitutes a lower extremity ulcer, and guidelines are based according to the etiology. The thing to remember with lower ▶

extremity ulcers is that they often may have more than one cause. The most common etiologies are venous insufficiency, arterial insufficiency, diabetic foot ulcer, and/or pressure.

PREDISPOSING FACTORS

A. Arterial insufficiency.
B. Congestive heart failure.
C. Coronary heart disease.
D. Diabetes.
E. Edema.
F. Dyslipidemia.
G. Obesity.
H. Age: older than 65 years.
I. Venous insufficiency.
J. Peripheral neuropathy.
K. Protein calorie malnutrition.
L. Immobility.

COMMON COMPLAINTS

A. Lower extremity or foot pain.
B. Bleeding.
C. Drainage.
D. Hyperglycemia.

SUBJECTIVE DATA

A. Ask the client to describe the location and onset. What do they think may have caused an ulcer in that area? Was the onset sudden or gradual? How have the symptoms continued to develop?
B. Assess if the area is pruritic or painful. Does the client have feeling in the area or is there a decrease in sensation noted?
C. Assess for any associated drainage. Ask about the color and if any odor is present.
D. Complete a drug history. Ask the client if they are taking any steroids or anticoagulants.
E. Has the client been treated for this location in the past? If so, ask to describe.
F. Determine whether the client has attempted to treat this at home. If yes, inquire about previous treatments and for how long.
G. Does the client have any numbness or tingling in the lower extremities? Does the client wake up at night with pain? Do they have any pain with ambulation? Do they have sensation to their feet?
H. Rule out any possible exposure to industrial or domestic toxins or insect bites.
I. Assess for iodine and sulfa allergies before starting treatment.

PHYSICAL EXAMINATION

A. Check temperature, pulse, pulse ox, respirations, and blood pressure.
B. Inspect:
1. Assess the lower extremities, feet, and metatarsals:
a. Color of the skin:
i. Assess skin, beginning at the top of the legs; move down the legs to the metatarsals for changes in color that may exhibit signs of ischemia.
ii. Hemosiderin staining may exhibit venous insufficiency.
b. Temperature of the skin.
c. Sensation of the skin.
d. Capillary refill.
e. Pulses.
f. Edema.
2. Inspect the ulcer.
a. Measure length × width × depth.
i. Undermining (destroyed tissue below the wound margin): Measure and note location, using the face of a clock to document the site of undermining: for example, 12 o'clock, 3 o'clock, 6 o'clock, or 9 o'clock.
ii. Tunneling (destroyed tissue pathway that creates dead space underneath the skin): Measure and note the location, using the face of a clock to document the site of tunneling: for example, 12 o'clock, 3 o'clock, 6 o'clock, or 9 o'clock.
b. Describe the wound bed.
i. Tissue in the wound bed:
1) Necrotic tissue, slough tissue, granulation tissue, epithelial tissue (percentage of each should together equal 100%).
ii. Drainage:
1) Amount:
a) None, scant, moderate, copious.
2) Color:
a) Serous, purulent, yellow, serosanguineous, or green.
iii. Odor:
1) Odor presence: yes or no.
iv. Periwound:
1) Intact.
2) Not intact.
a) Describe periwound. Note erythema, fever, induration, maceration, excoriation, calloused area, or epiboly (rolled edges).

DIAGNOSTIC TESTS

A. For perfusion:
1. Ankle brachial index (ABI).
2. Arterial Doppler.
3. Venous Doppler.
B. For infection:
1. Partial or full thickness:
a. Wound culture and sensitivity.
2. Full thickness with concern of underlying structure infection:
a. X-ray.
b. MRI
c. Bone scan.
C. For pathology:
1. Wound biopsy.
D. For medical management:
1. Complete blood count (CBC) basic metabolic panel (BMP).
2. Hemoglobin A1c (Hgb A1c).
3. Protein, albumin, prealbumin, and zinc level.

DIFFERENTIAL DIAGNOSES

A. Vascular ulcer:
1. Arterial/ischemic ulcer.
2. Venous ulcer.
B. Diabetic foot ulcer.
C. Abscess.
D. Atypical ulcers.
E. Dermatologic disorder.
F. Necrotizing fasciitis.
G. Skin cancers.
H. Pressure ulcer.

I. Trauma.
J. Pyoderma gangrenosum.

PLAN

A. General interventions:
1. Vascular ulcers:
a. Arterial ulcer:
i. Refer to vascular surgery for assessment to improve arterial flow.
ii. Refer to a wound care specialist.
b. Venous ulcer:
i. Establish arterial flow.
1) Refer to a vascular surgeon if deficiency is found.
ii. For signs and symptoms of infection, treat the infection first with tissue culture and sensitivity. Treat per pharmaceutical recommendations. Treat with silver alginate to the site for moderate drainage and silver gel to the site for scant drainage.
iii. Once arterial flow has been established as sufficient and infection has been ruled out, compression therapy is the mainstay of treatment for venous ulcers. Recommendations for compression therapy:
1) ABI: 0.8 to 1.0 full compression:
a) Profore.
b) Apply calcium alginate to ulcer, then wrap with an Unna Boot and cover with a Coban wrap: Change in 3 days; if tolerating well, then change weekly.
2) ABI: 0.6 to 0.8 light compression:
a) Profore Lite.
b) Apply calcium alginate to ulcer, then wrap with an Unna Boot and cover with a Coban wrap: Change in 3 days; if tolerating well, then change weekly.
2. Diabetic foot ulcer:
a. Establish arterial flow.
i. Refer to a vascular surgeon if deficiency is found.
b. For signs and symptoms of infection, use a sterile culturette to obtain a tissue culture and sensitivity first to assess what organism is present and to determine sensitivities. Treat per pharmaceutical recommendations. Treat with silver alginate to the site for moderate drainage and silver gel to the site for scant drainage.
c. Initiate offloading to site.
i. Refer to an orthotist for assessment if devices are required.
d. Treatment options:
i. To debride, cleanse with normal saline (NS), apply Santyl, and change dressing daily and as needed.
ii. To granulate an ulcer with scant drainage, cleanse with NS, apply a collagen dressing and cover with a secondary dressing, and change daily as needed.
iii. To granulate an ulcer with moderate drainage, cleanse with NS, apply calcium alginate, and change dressing daily and as needed.

B. Client teaching: *See Client Teaching Guide for this chapter, "Wound Care: Lower Extremity Ulcers."*
C. Pharmaceutical therapy:
1. If culture and sensitivity is performed, antibiotics may be used as recommended per sensitivity.

FOLLOW-UP

A. Follow up in 1 to 2 weeks to evaluate therapy.
B. See the client every 1 to 2 weeks until healing well; then may reduce to a 2- to 4-week evaluation until complete closure.

CONSULTATION/REFERRAL

A. Consult or refer the client to a wound care specialist for the following.
1. Client has extensive ulcer that you are not comfortable with:
a. Visible bone, muscle, or tendon.
2. Client has multiple medical comorbidities (especially diabetes).
3. Client is not responding to treatment of 2 to 4 weeks.
4. Ulcer is showing decline on follow-up visit.
5. Infection is present.

INDIVIDUAL CONSIDERATIONS

A. Adults:
1. Ischemic ulcers warrant immediate referral.
2. Complaints of severe pain, lack of pulse, cool digit, or new onset of purplish/bluish discolorations to the feet require immediate workup for arterial clot to lower extremity.

WOUND CARE: PRESSURE INJURIES/ULCERS

DEFINITION

A. "A pressure injury is localized damage to the skin and underlying soft tissue usually over a bony prominence or related to a medical or other device. The injury can present as intact skin or an open ulcer and may be painful. The injury occurs as a result of intense and/or prolonged pressure or pressure in combination with shear. The tolerance of soft tissue for pressure and shear may also be affected by microclimate, nutrition, perfusion, co-morbidities and condition of the soft tissue" (National Pressure Ulcer Advisory Panel, 2016).

INCIDENCE

A. Acute care: 0.4% to 38%.
B. Long-term care: 2.2% to 23.9%.
C. Home care: 0% to 17%.

PATHOGENESIS

A. Pressure ulcers occur when an area of tissue remains in surface contact for a period of time. This contact causes occlusion of microvascular vessels, which leads to tissue hypoxia and eventually may cause ischemia. Over time, a pressure ulcer is developed. The amount of time this takes is client-dependent and can be altered by physical and/or environmental factors.

PREDISPOSING FACTORS

A. Acute illness.
B. Fecal/urinary incontinence.

C. Malnutrition.
D. Weight loss.
E. Failure or inability to offload:
  1. Fracture, elevation of head of bed (HOB), lack of education, or noncompliance.
F. Chronic medical conditions.
G. Advanced age.
H. Medical devices.

COMMON COMPLAINTS

A. Pain.
B. Bleeding.
C. Drainage.

SUBJECTIVE DATA

A. Ask the client to describe the location and onset. What did they think may have caused the ulcer in the area? Was the onset sudden or gradual? How have the symptoms continued to develop?
B. Assess if the area is itchy or painful.
C. Assess for any associated drainage. Ask about the color and if any odor is noted.
D. Complete a drug history. Ask the client if they are taking any steroids or anticoagulants.
E. Has the client been treated for this location before? If so, describe treatments.
F. Determine whether the client has attempted to treat this problem at home. If yes, ask with what.
G. Rule out any possible exposure to industrial or domestic toxins or insect bites.
H. Assess for iodine and sulfa allergies before starting treatment.

PHYSICAL EXAMINATION

A. Check temperature, pulse, pulse ox, respirations, and blood pressure:
B. Inspect:
  1. Inspect the pressure ulcer/injury.
    a. Measure length × width × depth.
      i. Undermining: Measure and note location, using the face of a clock to document site of undermining: for example, 12 o'clock, 3 o'clock, 6 o'clock, or 9 o'clock.
      ii. Tunneling: Measure and note location, using the face of a clock to document site of tunneling: for example, 12 o'clock, 3 o'clock, 6 o'clock, or 9 o'clock.
    b. Describe the wound bed.
      i. Tissue in the wound bed:
        1) Necrotic tissue, slough tissue, granulation tissue, epithelial tissue (percentage of each should together equal 100%).
      ii. Drainage:
        1) Amount:
          a) None, scant, moderate, copious.
        2) Color:
          a) Serous, purulent, yellow, serosanguineous, or green.
      iii. Odor:
        1) Odor present: yes or no.
      iv. Periwound:
        1) Intact.
        2) Not intact.
          a) Erythema, fever, induration, maceration, excoriation, calloused, epiboly.

DIAGNOSTIC TESTS

A. Complete blood count (CBC).
B. Wound culture and sensitivity.
C. Wound biopsy.
D. X-ray.
E. MRI.
F. Bone scan.

DIAGNOSIS

A. Staging pressure injuries/ulcers:
  1. Deep-tissue pressure injury (DTPI):
    a. Intact or nonintact skin with persistent nonblanchable discoloration (purple, deep red, maroon) or epidermal separation revealing a blood-filled blister or darkened wound bed.
    b. Changes in pain/temperature may precede changes in skin color. Discoloration may be difficult to detect in highly pigmented skin.
    c. DTPI may be due to intense pressure and shear forces at the bone–muscle interface.
    d. The wound may resolve without tissue loss, or rapid evolution may occur to reveal extent of damage.
    e. If fascia, muscle, necrotic/subcutaneous/granulation tissue, or other underlying structures are visible, this is likely a full-thickness pressure injury (stage 3, 4, or unstageable).
    f. Do not use DTPI staging to describe neuropathic, vascular, dermatologic, or traumatic conditions.
  2. Stage 1 pressure injury:
    a. Intact skin with nonblanchable, localized erythema. Discoloration may be difficult to detect in highly pigmented skin.
    b. Changes in sensation, temperature, or firmness may precede visual changes.
    c. Do not use stage 1 to describe purple, deep red, or maroon discoloration; these may indicate DTPI.
  3. Stage 2 Pressure Injury:
    a. Partial-thickness loss of skin with exposed dermis.
    b. The wound is moist, pink or red, viable, and may present as an intact or ruptured serum-filled blister.
    c. Deeper tissues and adipose (fat) are not visible.
    d. Eschar, slough, and granulation tissue are not present.
    e. Stage 2 pressure injuries are the result of adverse microclimate or shear forces.
    f. Do not use stage 2 to describe the following:
      i. Skin tears, burns, or abrasions.
      ii. Moisture-associated skin damage (MASD), including:
        1) Incontinence-associated dermatitis (IAD).
        2) Intertriginous dermatitis (ITD).
        3) Medical adhesive-related skin injury (MARSI).
  4. Stage 3 pressure injury:
    a. Full-thickness loss of skin, with visible adipose.
    b. Granulation tissue, slough, eschar, and epibole (rolled wound edges) may be present.
    c. The extent of tissue damage varies by anatomic location; deep wounds may develop in areas of significant adiposity.
    d. Undermining/tunneling may occur.
    e. Muscle, tendon, ligament, cartilage, fascia, and/or bone are not exposed.

▶

f. Do not use stage 3 if eschar or slough obscures the depth of tissue loss; this indicates an unstageable pressure injury.

5. Stage 4 pressure injury:
a. Full-thickness loss of skin and tissue.
b. Muscle, tendon, ligament, cartilage, fascia, and/or bone are exposed or directly palpable.
c. Epibole (rolled wound edges), undermining, and/or tunneling often occur.
d. The extent of tissue damage varies by anatomic location.
e. Eschar or slough may be present. If either or both obscure the depth of tissue loss, this indicates an unstageable pressure injury.

6. Unstageable pressure injury:
a. Full-thickness loss of skin and tissue.
b. Eschar or slough obscures the extent of tissue loss; removing these will reveal a stage 3 or 4 pressure injury.
c. Do not soften or remove stable eschar (dry, adherent, intact without erythema or fluctuance) on the heel or ischemic limb unless you have established client has adequate perfusion to ensure potential for wound healing.

7. Medical device-related pressure injury:
a. This is the result of using devices intended for diagnostic or therapeutic purposes.
b. The pressure injury generally conforms to the shape or pattern of the device.
c. The injury should be staged using the staging system.

8. Mucosal Membrane Pressure Injury:
a. Found on mucous membranes with a history of medical device use at the injury's location.
b. These ulcers cannot be staged due to the anatomy of the tissue.

Source: Adapted from National Pressure Ulcer Advisory Panel (NPUAP). (2016). NPUAP pressure injury stages. www.npuap.org/resources/educational-and-clinical-resources/npuap-pressure-injury-stages/.

DIFFERENTIAL DIAGNOSES

A. Abscess.
B. Trauma.
C. Skin cancer.
D. Vascular ulcer.
E. Diabetic foot ulcers.
F. Dermatologic disorder.

PLAN

A. General interventions:
1. Identify the cause of pressure and alleviate.
2. To debride, cleanse with normal saline (NS), apply Santyl ointment, and change dressing daily and as needed throughout.
3. To granulate an ulcer with scant drainage, cleanse with NS, apply collagen, and change dressing daily as needed.
4. To granulate an ulcer with moderate drainage, cleanse with NS, apply calcium alginate, and change dressing daily as needed.

FOLLOW-UP

A. Follow up in 1 to 2 weeks to evaluate therapy.
B. See the client every 1 to 2 weeks until healing well; then may reduce to a 2- to 4-week evaluation until complete closure.

CONSULTATION/REFERRAL

A. Consult or refer the client to a wound care specialist for the following:
1. Extensive ulcer that you are not comfortable with.
2. Client with multiple medical comorbidities (especially diabetes).
3. Client not responding to treatment of 2 to 4 weeks.
4. Ulcer showing decline on follow-up visit.
5. Infection is present.

INDIVIDUAL CONSIDERATIONS

A. Adults:
1. Clients at end of life may develop pressure ulcers related to the dying process. This type of ulcer is referred to as a Kennedy terminal ulcer. These clients are treated for comfort.

B. Geriatrics:
1. Research suggests that pressure ulcers in the older adult population (especially those suffering from dementia) appear to accelerate health deterioration, which leads to lower survival and higher mortality rates. Educating the client and surrogates regarding good nutrition, fall prevention, skin care, if bed-bound or wheelchair-bound frequent position change, and meticulous wound care techniques could help reduce pressure ulcer complications and increase survival time.

Prevention and treatment of pressure ulcers/injuries: The protocol for the second update of the international Clinical Practice Guideline 2019. *Journal of Tissue Viability*, *28*(2), 51–58. https://doi.org/10.1016/j.jtv.2019.01.001

Pressure injury stages-national pressure ulcer advisory panel. (n.d.). https://npiap.com/general/custom.asp?page=PressureInjuryStages

WOUNDS OF THE SKIN

DEFINITION

A. Wounds are breaks in the external surface of the body.

PATHOGENESIS

A. Wounds can be caused by any one of innumerable objects that breach the skin. Lacerations and abrasions typically heal by a four-stage process of clotting, inflammation, skin cell proliferation, and remodeling. The most common pathogens of wound infections are *Staphylococcus aureus* and beta-hemolytic streptococcus.

PREDISPOSING FACTORS

A. Exposure to accidental or intentional injury.
B. Accident prevention failure.
C. High-risk behaviors.
D. Conditions that predispose to poor wound healing:
1. Diabetes.
2. Corticosteroid therapy.
3. Immunodeficiency.
4. Advanced age.
5. Undernourishment.
6. Comorbidities.

COMMON COMPLAINTS

A. Bleeding.

B. Pain.
C. "Cut" in the skin integrity.
D. Drainage.

OTHER SIGNS AND SYMPTOMS

A. Signs and symptoms of infection: Deep wounds and dirty wounds have increased risk of infection.
B. Soft tissue damage: Wounds with tissue necrosis have increased risk of infection.

SUBJECTIVE DATA

A. Elicit the client's description of how the wound occurred, including where and when the injury was sustained.
B. Ascertain how much time has elapsed until treatment. If 6 hours have elapsed, bacterial multiplication is likely.
C. Ask if the client is currently immunized for tetanus.
D. Complete a drug history; include any allergies to medications, anesthetics, or dressings.
E. Ask if the client is taking any medications, especially steroids or anticoagulants.
F. Assess iodine and sulfa drug allergies before starting treatment.
G. Review with the client whether anything significant in the medical history may interfere with the healing process (e.g., immunodeficiency).

PHYSICAL EXAMINATION

A. Check temperature, pulse, pulse ox, respirations, and blood pressure.
B. Inspect:
1. Inspect wound.
2. Measure wound for length × width × depth. Wounds with untidy edges may heal more slowly and with disfigurement.
3. Assess underlying bony structures.
4. Inspect for foreign objects.
C. Palpate:
1. Palpate extremities for neurovascular function and sensation.
2. Palpate tissue distal to wound.
3. Palpate lymph nodes surrounding injured area.
D. Perform neurologic exam:
1. Assess motor function distal to wound.

DIAGNOSTIC TESTS

A. Culture wound site if suspicious of infection.
B. Take x-ray films for deep or crushing wounds.

DIFFERENTIAL DIAGNOSES

A. Wound, minor.
B. Accidental self-inflicted injury.
C. Self-inflicted injury.
D. Domestic violence.
E. Bite.

PLAN

A. General interventions:
1. Wounds that require open-wound management:
a. Abrasions and superficial lacerations.
b. Wounds with great amount of tissue damage.
c. Wounds more than 6 hours old.
d. Contaminated wounds.
e. Large area of superficial skin denudation.
f. Puncture wounds.
2. For wounds that do not require sutures:
a. Cleanse the wound well with warm water and soap; remove all dirt and foreign bodies.
b. Forceful irrigation may be needed; use finepore sponge (Optipore) with a surfactant, such as poloxamer 188 (Skin-Clens). Approximate wound edges if possible, cover with xeroform and nonadherent dressing change Q72H and as needed.
c. If inflammation is present, soak and wash for 15 to 20 minutes three to four times per day. Cover with clean, dry dressing. **Do not use Steri-Strips.**
3. For wounds that require sutures:
a. Clean with warm water and soap. Irrigate with sterile saline solution.
b. Anesthetize with 1% to 2% lidocaine (Xylocaine). Do not use solution with epinephrine at fingertips, nose, or ears. Probe wound for any remaining foreign bodies. Approximate wound edges.
c. Suture the following with technique appropriate to the site:
i. Skin sutures: nonabsorbable material (e.g., nylon, prolene, silk).
ii. Subcutaneous and mucosal sutures: absorbable material (e.g., Dexon, Vicryl, or plain or chromic gut).
iii. Extremities: 4-0 nylon.
iv. Soles of feet: 2-0 nylon.
d. Cover with clean, dry dressing; change after first 24 hours.
e. Suture removal is based on location:
i. Head and trunk: 5 to 7 days.
ii. Extremities: 7 to 10 days.
iii. Soles and palms: 7 to 10 days.
f. Tetanus prophylaxis.
B. Client teaching: *See Client Teaching Guide for this chapter, "Wound Care: Pressure Injuries/Ulcers."*
C. Pharmaceutical therapy:
1. Control pain with acetaminophen (Tylenol) or ibuprofen, as needed.
2. Topical antibiotic ointments include bacitracin and neomycin.
3. Clients with severe wound contamination, involvement of structures, immunocompromised, or vascular insufficiency would be given oral antibiotics for prophylaxis:
a. Amoxicillin, clavulanate acid (Augmentin) 875 mg orally BID for 7 to 10 days.
b. With penicillin allergy, use erythromycin; 500 mg orally BID for 7 to 10 days.
4. Other alternatives include cephalexin (Keflex), cefadroxil (Duricef), ciprofloxacin.
5. Tetanus toxoid 0.5 mL by intramuscular (IM) injection in deltoid, if no booster has been administered in the past 5 years.
6. Wounds diagnosed with methicillin-resistant *S. aureus* (MRSA) should be treated with the following oral antibiotics:
a. Trimethoprim-sulfamethoxazole (Bactrim).
b. Minocycline or doxycycline.
c. Clindamycin rifampin (should be used in combination with one of the previous antibiotics).
d. Linezolid.
7. Antibiotics not recommended due to high resistance include the following:
a. Beta-lactams.

TABLE 7.2 RECOMMENDED PROTEIN NEEDS PER DAY FOR WOUND HEALING

Older adults: baseline protein needs	1.0–1.2 g/kg body weight/d
Healthy adults	0.8–1.0 g/kg body weight/d
Large burns	1.5–3.0 g/kg body weight/d (varies by extent of the burn)
Post surgery	1.0–1.5 g/kg body weight/d (varies by extent of the surgery)
Pressure ulcers/injuries	1.0–2.0 g/kg body weight/d

b. Fluoroquinolones.
c. Dicloxacillin.
d. Cephalexin.

8. Treating the nares with Bactroban Ointment BID and having the client use Hibiclens soap when showering will help prevent recurrent infections.

9. For severe cases of infection, the client requires hospitalization for aggressive antibiotic treatment.

FOLLOW-UP

A. Have the client return for evaluation and dressing change in 24 to 48 hours.

CONSULTATION/REFERRAL

A. Refer the client to a physician for the following wounds:

1. Facial wounds.
2. Subcutaneous tissue penetration.
3. Functional disturbance of tendons, ligaments, vessels, or nerves.
4. Grossly contaminated wounds.
5. Wounds requiring hospitalization or aggressive antimicrobial therapy for evidence of pyogenic abscess, cellulitis, and ascending lymphangitis.

INDIVIDUAL CONSIDERATIONS

A. Adults:

1. Adults with compromised immune systems and chronic conditions are at greater risk of developing a secondary bacterial infection.

B. Geriatrics:

1. Avoid use of nonsteroidal anti-inflammatory drugs (NSAIDs) in clients who have chronic kidney disease stage IV or less (creatinine clearance <30 mL/min).
2. Medications commonly used in the older adult population are associated with poor wound healing: cytotoxic antineoplastic agents, corticosteroids, aspirin, NSAIDs, anticoagulants, bisphosphonates, some antibiotics, anticonvulsants, angiogenesis inhibitors, and pain medications that contain morphine.

WOUND HEALING: HIGH-PROTEIN NUTRITION

A. Nutrition is an essential component in the healing of any wounds. Protein, carbohydrates, fats, vitamins, minerals, and amino acid needs are increased for tissue repair. Table 7.2 summarizes the recommended amount of protein intake needed under different circumstances for tissue repair.

1. Consult with a dietitian for medical nutrition therapy (MNT).
2. Evaluate protein intake.
3. Evaluate the client's weight.
a. Perform serial weights: Use the same scales.
b. Use diet diary or 24-hour recall.
c. The dietary and weight history is used to determine additional needs.
d. Excessive protein potentially leads to dehydration.
4. Perform lab tests.
a. Complete blood count (CBC).
b. Basic metabolic panel (BMP).
c. Protein: albumin, total protein, and prealbumin.
d. Renal: blood urea nitrogen (BUN) and creatinine.
5. Evaluate wound stage/healing.
6. Supplemental protein may be required.
a. Sources of protein:
i. **Whole eggs are considered the "gold standard" protein.**
ii. Meat: red and white meat.
iii. Fish.
iv. Liver.
v. Dairy: milk, cheese, yogurt.
vi. Soybeans.
vii. Legumes.
viii. Seeds.
ix. Nuts.
x. Grains.
b. Encourage meals and snacking, double portions of meat and eggs, commercial supplements, and fluids.
i. Eat five to six smaller meals throughout the day.
ii. Keep ready-to-eat meals and snacks.
iii. Drink shake-type beverages that contain protein, vitamins, and minerals.
iv. Add protein powder to drinks.

▶

c. Consider appetite stimulants.
d. Enteral nutrition should be considered if oral food and fluid intake is not adequate.

OTHER CONSIDERATIONS

A. Older adults have multiple risk factors for intake of insufficient protein for wound healing.
1. Financial:
a. Expense of high-protein foods.
b. Expense of oral supplemental nutrition drinks.
2. Difficulty chewing:
a. Dental problems.
b. Loose-fitting dentures.
c. Edentulous.
3. Assistive needs:
a. Inability to prepare foods.
b. Need to have a caregiver feed older adults.
c. Given inadequate time to consume food if being fed.
4. Dysphagia.
5. Anorexia.
6. Fatigue.
7. Food sensitivities and allergies.
8. Psychosocial:
a. Depression.
b. Loneliness.
B. Consultation with a dietitian for MNT, wound care specialist, social worker, occupational therapist, and behavioral health evaluations is advised.

BIBLIOGRAPHY

Prevention and treatment of pressure ulcers: Quick reference guide-EPUAP. (n.d.). https://www.epuap.org/wp-content/uploads/2016/10/quick-reference-guide-digital-npuap-epuap-pppia-jan2016.pdf

XEROSIS (WINTER ITCH)

DEFINITION

A. Xerosis, often called "winter itch," is dry skin.

INCIDENCE

A. Xerosis occurs in 48% to 98% of clients with atopic dermatitis.
B. It occurs more frequently in older adult clients.

PATHOGENESIS

A. Dry skin may fissure, appear shiny and cracked, and leave subsequent inflammatory changes.

PREDISPOSING FACTORS

A. Frequent bathing with hot water and harsh soaps.
B. Cold air.
C. Low humidity.
D. Central heating or cooling.
E. Alcohol use.
F. Poor nutrition.
G. Cholesterol-lowering drugs.
H. Systemic disease manifested by thyroid, renal, or hepatic disease, anemia, diabetes, or malignancy.

COMMON COMPLAINTS

A. Dry, rough skin, especially on legs.

OTHER SIGNS AND SYMPTOMS

A. Pruritic, scaling skin, particularly on legs, with cracks and/or fissures.
B. Pruritus may be associated with systemic disorders or other infections. **Itching of scabies is particularly intense at night**.
C. Plaques 2 to 5 cm in diameter.
D. Erythema.
E. Wheal-and-flare response typical of urticaria.

SUBJECTIVE DATA

A. Obtain the client's description of the onset of symptoms and whether it was sudden or gradual.
B. Ask the client to identify any discomfort. Ask if the skin is itchy or painful.
C. Assess lesions for any associated discharge (blood or pus).
D. Determine whether the client has recently ingested any new medicines (antibiotics, cholesterol-lowering medications, or other drugs), alcohol, or new foods.
E. Ask the client about use of any topical medications.
F. Identify any preceding systemic symptoms (fever, sore throat, anorexia, or vaginal discharge).
G. Ask the client about bathing in hot water and if they are bathing regularly.
H. Review the client's full medication history for comorbid conditions.

PHYSICAL EXAMINATION

A. Inspect:
1. Inspect the skin for lesions, noting texture of skin.
B. Palpate:
1. Palpate abdomen for masses and hepatosplenomegaly.
2. Palpate lymph nodes.

DIAGNOSTIC TESTS

A. There are no diagnostic tests for xerosis.

DIFFERENTIAL DIAGNOSES

A. Xerosis.
B. Scabies.
C. Atopic dermatitis.

PLAN

A. General interventions:
1. Hydration and lubrication of skin.
2. Assess for and treat secondary infection.
B. Client teaching: *See Client Teaching Guide for this chapter, "Xerosis (Winter Itch)."*
1. Avoid alkaline soaps: Use Dove, Basis, mild soap, or soap substitutes such as Cetaphil or Aquanil.
C. Pharmaceutical therapy:
1. Apply emollient cream or lotion (Sarna, Lac-Hydrin, or Eucerin).
2. Use over-the-counter (OTC) skin lubricants (petroleum jelly, mineral oil, or cold cream).
3. Topical corticosteroid:
a. Triamcinolone 0.025% two to four times daily or 0.1% two to three times daily; apply sparingly. Advise not to use steroid treatments any longer than 2 weeks without notifying the primary provider.
b. Hydrocortisone 1% or 2.5% two to four times daily for no longer than 2 weeks. Recommend applying a thin film and avoiding the face. ▶

4. Systemic antihistamine to control pruritus, such as diphenhydramine (Benadryl) 25 to 50 mg or hydroxyzine 25 mg every 4 to 6 hours as needed.

FOLLOW-UP

A. Follow up as indicated until resolved.

CONSULTATION/REFERRAL

A. Consult or refer the client to a dermatologist if no improvement is seen.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. Monitor the client for possible skin breakdown and/or ulceration.

2. Xerosis is common among older adult population. Several nonpharmacologic treatments to consider before using topical hydrocortisone would include increasing home environment humidity, avoiding excessive bathing and bath oils, encouraging oatmeal baths, and using emollient ointment (e.g., Aquaphor or Eucerin) and ceramide lotions (e.g., AmLactin) to smooth cracked rough skin and reduce pruritus.

CLIENT TEACHING GUIDE

ACNE ROSACEA

PROBLEM Acne rosacea is a skin condition that affects primarily the nose and face, causing redness, flushing, pimples, and bumps. The blood vessels may be more prominent on the face, causing the skin to appear reddened.

CAUSE The cause is not known but is thought to be due to the blood vessels in the face being too active, causing flushing and redness of the skin.

PREVENTION/CARE

A. Avoid rubbing or massaging the face, as it can irritate the skin.
B. Avoid alcoholic beverages.
C. Avoid using harsh soaps/creams on the face, including cosmetics that irritate the skin.
D. Wash face with a mild soap daily, such as Cetaphil or Purpose soap. Other cleansers suggested are sulfa-based cleansers (Rosanil) or benzoyl peroxide cleansers daily.
E. Protect the skin when outdoors, wearing protective clothing, as well as hats and others to shield the face. Use sunscreen with a sun protection factor (SPF) 30 or a zinc-based ointment, such as zinc oxide, on the skin for protection.
F. You may be prescribed an antibiotic by mouth or an antibiotic cream/gel to place on the skin. Use medications as prescribed by your provider.
G. Avoid using steroid creams on your face unless prescribed by your provider.
H. If your skin condition begins to affect your eyes, you need to notify your provider immediately. Do not apply any medications or creams to your eyes that have not been prescribed by your provider.

TREATMENT PLAN

A. Use antibiotics/medications as prescribed by your provider.
B. Wash face with mild cleanser daily.

Activity: As tolerated. No limitations in physical activity.

Diet:

A. Drink plenty of fluids daily.
B. Avoid alcoholic beverages.

Medications: _____

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If:

A. You have a reaction to any of the medications or cleansers prescribed.
B. Rash appears on your eyes or other new places.
C. Symptoms worsen or new signs or symptoms present before your next follow-up appointment.
D. Other: _____

Phone: _____

CLIENT TEACHING GUIDE

ACNE VULGARIS

PROBLEM Acne vulgaris refers to blackheads, whiteheads, or red nodules noted on the face, back, chest, and arms.

CAUSE Accumulation of cells and bacteria clogs the pores and stimulates an inflammatory response, resulting in papule or pustule (pimple or blackhead) formation.

PREVENTION/CARE

A. Wash area with mild soap (Purpose or Basis soap) no more than two times per day.
B. Avoid oil-based makeup and creams. Use matte-finish makeup or pore minimizer.
C. Use facial cleansers and moisturizers such as Cetaphil and Moisturel. These prevent the skin from drying out. Benzoyl peroxide 5% lotion or gel may be used at bedtime to help open pores and kill bacteria.
D. To prevent scarring, do not pick the lesions.
E. Avoid excessive sun exposure. Use oil-free sunscreen with a sun protection factor (SPF) 15 or greater.
F. Do not become frustrated if lesions return. Do not stop medications without the direction of your provider.
G. Stress can influence outbreaks of lesions. Practice exercise programs, stress management tactics, and other measures that reduce stress levels in your daily routine.
H. For mask use, wash or replace frequently.

TREATMENT PLAN

Activity: As tolerated. Physical activity encouraged.

Diet: Eat a well-balanced diet. Drink 8 to 10 glasses of water a day to help keep your skin well hydrated. Cocoa and chocolate do not have an effect on the development of acne vulgaris.

Medications: Antibiotics may need to be prescribed.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If:
A. You have a reaction to any of the medications prescribed.
B. You are unable to tolerate the prescribed medications.

CLIENT TEACHING GUIDE

DERMATITIS

PROBLEM Inflammation of the skin that occurs from contact with an irritant substance (poison ivy, soaps, etc.).

CAUSE Skin contact with irritating agent.

PREVENTION/CARE

A. Avoid aggravating agents.
B. Learn to recognize all plants (poison ivy, poison oak, etc.).
C. Flare-ups are common.
D. Avoid all known stimuli (poison ivy, soaps, etc.).
E. Do not wear tight, restrictive clothing.
F. When around irritating substances, wear gloves for protection.
G. For poison ivy, wash all clothes, shoes, pets, or other substances that may have come in contact with the poison ivy oil.

TREATMENT PLAN

Activity: As tolerated. Take cool baths as needed for itching. Oatmeal baths (Aveeno bath) help soothe the itching.

Diet: Regular diet.

Medications: Take Benadryl as needed for itching. Use calamine lotion as needed. Steroid creams may also be prescribed if the reaction is severe. Steroid dose packs may be needed if you are not getting better.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If You Have:

A. Worsening symptoms.
B. Sores on your face, eyes, or ears.
C. More redness, swelling, pain, or drainage.
D. Secondary bacterial infection.
E. Fever.
F. Other: _____

CLIENT TEACHING GUIDE

ECZEMA

PROBLEM Red, itching, scaling, and thickening of the skin occur in patches. You may have papules (bumps) with vesicles (clear fluid) that can be found especially on the hands, scalp, face, back of the neck, or skin creases of the elbows and knees.

CAUSE The cause is unknown. If it is an allergic reaction, it may be caused by foods such as eggs, wheat, milk, or seafood; wool clothing; skin lotions and ointments; soaps; detergents; cleansers; plants; tanning agents used for shoe leather; dyes; and topical medications. The risk of developing eczema increases with stress, medical history of other allergic conditions, clothing made of synthetic fabric (which traps perspiration), and weather extremes (cold, hot).

PREVENTION/CARE

A. Avoid risk factors.
B. Wear rubber gloves for household cleaning tasks.
C. Wear loose, cotton clothing to help absorb perspiration.
D. Keep fingernails short and wear soft gloves during sleep.
E. Scratching worsens eczema.
F. Bathe less frequently to avoid excessive skin dryness.
G. Use special nonfat soaps (Purpose or Basis soap) and tepid water.
H. Do not use soap on inflamed areas.
I. Lubricate the skin after bathing; avoid lubricants with alcohol in the ingredients.
J. Recommended creams include Eucerin, Keri Lotion, and Lubriderm. Steroid creams may be prescribed.
K. Avoid extreme temperature changes.
L. Avoid anything that has previously worsened the condition.

TREATMENT PLAN

Activity: No restrictions.

Diet: You may be told to try a special diet. Eliminate any foods known to cause flare-ups.

Medications: _____

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If:
A. You have a reaction to any of the medications prescribed.
B. You cannot take the medications.
C. New symptoms develop.

Phone: _____

CLIENT TEACHING GUIDE

ERYTHEMA MULTIFORME

PROBLEM An acute inflammatory disorder of the skin and mucous membranes, erythema multiforme is usually self-limited and benign.

A severe form is known as Stevens–Johnson syndrome or erythema multiforme major, and the less severe form is referred to as erythema multiforme minor.

CAUSE The cause is unknown in 50% of cases. Erythema multiforme has been associated with viral infections, particularly the herpes simplex virus; bacterial and protozoan infections; an immunologic reaction of the skin; medications (sulfonamides, penicillins, anticonvulsants, salicylates, barbiturates, nonsteroidal anti-inflammatory drugs [NSAIDs]), with reactions occurring up to 7 to 14 days after using the medication; pregnancy; premenstrual hormone changes; malignancy; or radiation therapy. Risk increases with history of erythema multiforme.

PREVENTION/CARE

A. Avoid suspected causes.
B. Seek prompt treatment of any illness or infection.
C. Prevent herpes simplex virus outbreaks by avoiding sun exposure and reducing stress.
D. Seek treatment immediately if at any time symptoms seem to be worsening or increasing.
E. Discontinue any implicated medication.
F. Apply wet dressings or soaks with Burow solution or apply lotions to soothe the skin.
G. Bathe in lukewarm to cool water three times a day for 30 minutes.
H. Monitor yourself for any eye involvement and report it to your healthcare provider immediately.
I. If mouth sores are present, use good oral hygiene (brush two to three times a day using a soft brush) and rinse frequently with cool water.
J. Hospitalization may be required if there is extensive skin involvement.

TREATMENT PLAN

Activity: As tolerated by the extent of the symptoms. Restrict yourself to bedrest if fever is present.

Diet: Usually no special diet is necessary, although if mouth sores are present a soft or liquid diet may be better tolerated. Increase fluid intake above the general 8 to 10 glasses per day.

Medications: May be prescribed to control symptoms and pain.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If:
A. You have an adverse reaction to or cannot tolerate any of the prescribed medications.
B. Symptoms worsen during treatment, or the rash does not clear in 3 weeks (usual course: rash evolves over 1–2 weeks, usually clears in 2–3 weeks, but may take 5–6 weeks).
C. New or unexplained symptoms develop.
D. You have any questions or concerns.

Phone: _____

RESOURCE American Academy of Dermatology, 9500 W Bryn Mawr Avenue, Ste 500, Rosemont, IL 60018-5216, United States, Phone: (888) 462-DERM (3376), www.aad.org

CLIENT TEACHING GUIDE

FOLLICULITIS

PROBLEM A bacterial (or fungal) infection of the hair follicle. Folliculitis is seen when a pustule develops, commonly on the arms, legs, scalp, and face (beard).

CAUSE

A. Bacterial: infection commonly caused by *Staphylococcus* bacteria.
B. Fungal: may be caused by yeast infection.

PREVENTION/CARE

A. Keep skin clean and dry.
B. Avoid warm, moist conditions.
C. Healing generally occurs in 10 to 14 days after proper treatment with medications.
D. Practice good handwashing technique, using antibacterial soaps.
E. Use clean razors daily.
F. Throw old razors away.
G. Do not share razors.
H. Shampoo scalp daily.
I. Avoid use of hot tubs or heated swimming pools.
J. Folliculitis usually resolves within 4 to 6 weeks after proper treatment.

TREATMENT PLAN

Activity: As tolerated.

Diet: Regular diet.

Medications: Topical and/or oral antibiotics as prescribed.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If:

A. You notice lesions worsening or spreading despite adequate medication treatment.
B. You have a fever higher than 101°F.
C. Your condition is not getting better.
D. You have a reaction to your medication.

CLIENT TEACHING GUIDE

HERPES ZOSTER (SHINGLES)

PROBLEM Shingles is a reactivation of the viral infection common in childhood known as chickenpox. **The virus is contagious to those who have not had chickenpox.**

CAUSE Varicella zoster virus is stimulated and produces a blister-like rash, commonly seen on the chest and trunk area. The rash is commonly confined to one side of the body.

PREVENTION There are two vaccines available for prevention of shingles. The Centers for Disease Control and Prevention (CDC) recommends the recombinant zoster vaccine (RZV; Shingrix) as the preferred vaccine for anyone age 50 years and older; however, Zostavax is also still available if there is a shortage of the preferred vaccine. Shingrix is a two-dose vaccine, given 2 months apart. Zostavax is a one-time vaccine.

TREATMENT PLAN

A. Zostavax cannot be used to treat shingles breakouts or the painful sensations (postherpetic neuralgia) after you develop shingles.
B. The shingles rash usually lasts 2 to 3 weeks; however, symptoms may persist beyond this period.
C. The goal is to relieve the itching.
D. Apply warm soaks of Burow solution three times a day to lesions.
E. Notify family and friends of active virus. Advise anyone who has had contact with you that you have shingles, especially pregnant individuals and those who have never had chickenpox.

Activity: Avoid touching the shingles. Wash your hands. Your partners should not touch the area, especially when blisters are present. Use separate bath towels.

Diet: There is no special diet for shingles.

Medications: Oral and topical medications may be prescribed to soothe the itching. Take acetaminophen (Tylenol) as needed for comfort. Antiviral medications are available to help slow down the virus if started within 48 to 72 hours after the initial outbreak. You may be prescribed medications to help with the painful sensations (neuralgia).

CDC guidelines recommend all immunocompetent adults 50 years of age and older receive the Shingrix vaccine.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If You Have:
A. Severe pain at lesion sites.
B. Any new symptoms relating to the shingles, such as excruciating pain, headaches, numbness, tingling sensation, or other symptoms.
C. Any questions regarding the shingles.
D. Any new facial involvement.

Phone: _____

RESOURCE American Academy of Dermatology, 9500 W Bryn Mawr Avenue, Ste 500, Rosemont, IL 60018-5216, United States, Phone: (888) 462-DERM (3376), www.aad.org

CLIENT TEACHING GUIDE

INSECT BITES AND STINGS

PROBLEM Insect bites or stings cause skin changes and other reactions.

A. Seek immediate help if you or a family member have any symptoms of allergic reaction or anaphylaxis, either immediately after the bite or 8 to 12 hours after the bite.

B. You may need to call 911 or your local emergency response service.

C. If you have had a previous life-threatening allergic reaction, carry an anaphylaxis kit for emergency treatment.

1. *Local skin reactions* include red bumps on the skin that usually appear within minutes after the bite or sting but may not appear for 6 to 12 hours. Itching and discomfort may occur at the site.

2. *Systemic (body) reactions* include nausea or vomiting; headache, fever, dizziness, or lightheadedness; swelling; or convulsions.

3. *Allergic reactions* include itchy eyes, facial flushing, dry cough, wheezing, and chest or throat constriction or tightness.

CAUSE Bites or stings can be caused by mosquitoes, fleas, chiggers, bedbugs, ants, spiders, bees, scorpions, and other insects.

Risk increases with exposure to areas with heavy insect infestation, warm weather in spring and summer, lack of protective measures, use of perfumes or colognes, and previous sensitization.

PREVENTION/CARE

A. Institute first-aid measures and activate emergency services if severe, life-threatening reactions occur.

B. Avoid risk factors.

C. Wear protective clothing.

D. Use insect repellents with diethyltoluamide (DEET), avoiding the head, face, eyes, and mouth.

Specific Insect Care

A. All stings: Remove the stinger.

B. Bee, wasp, yellow jacket, or hornet stings: Rub a paste of meat tenderizer and water into the site.

C. Ant bites: Rub bite with ammonia and repeat as often as necessary.

D. Spider and scorpion bites: Capture the arachnid if possible and seek medical attention.

E. Mites: Apply a petroleum product (Vaseline) until the animal withdraws from the skin.

F. Ticks: You should also be given the *Client Teaching Guide for "Lyme Disease and Removal of a Tick."*

General Care For All Bites

A. Clean wound with soap and water.

B. Apply ice pack (no ice directly on skin; use towel or cloth to protect skin).

C. Elevate and rest the affected body part.

D. Immerse affected part or apply warm water soaks to site. However, if site itches, cool water feels best.

E. For minor discomfort, you may use nonprescription oral antihistamines (Benadryl) or topical steroid preparations (hydrocortisone cream).

F. Use only low-potency topical steroid products without fluorine on the face and groin area.

G. You may be prescribed more potent, prescription medications.

TREATMENT PLAN

Activity: No restrictions.

Diet: Eat a regular diet. Maintain adequate hydration with 8 to 10 glasses of water per day.

Medications: You may be prescribed an EpiPen to use for future major reactions. You need to keep this with you at all times.

CLIENT TEACHING GUIDE

LICE (PEDICULOSIS)

PROBLEM A parasite called a louse has been found on your body or hair. Lice tend to live on the scalp, eyebrows, or genital area, or in warm moist areas of your skin. You may notice you have intense itching, swelling, or reddened areas of the skin, and sometimes even enlarged lymph glands.

CAUSE The lice bite the skin and cause intense itching. Lice and their eggs (called nits) may be difficult to see on the skin and shafts of hair. Lice look like small, 2- to 3-mm, tan-colored bugs. The eggs are tiny white eggs that stick to the hair shaft.

PREVENTION You can prevent repeated episodes of lice if you bathe daily; avoid crowded living conditions; change bed linens frequently; and do not share hats, combs, brushes, or other belongings. When family members have been in contact with others diagnosed with lice, check them closely for lice and treat as appropriate.

TREATMENT PLAN

A. Use medicated shampoo as directed.
B. Machine-wash all linens, stuffed animals, and any other items with which the lice may have come in contact.
C. Wash clothes in hot, soapy water.
D. Dry all linens in a hot dryer for at least 30 minutes.
E. Items that cannot be washed must be taken to the dry cleaner or wrapped and sealed in a plastic bag for 14 days.
F. Boil all hair accessories and clean well.
G. Do not share hats and combs.
H. Spray all furniture with appropriate products that kill all nits and lice.
I. Vacuum.

Activity: There is no activity restriction.

Diet: There is no special diet.

Medications:

A. Food and Drug Administration (FDA)-approved over-the-counter (OTC) products:
  1. Pyrethrins combined with piperonyl butoxide (Rid, Triple X, A-200, Pronto, R&C): approved for children 2 years and up. Avoid if allergic to ragweed or chrysanthemums.
  2. Permethrin lotion 1% (Nix): FDA-approved for children 2 months and older Repeat application on day 9 of initial dose.

You Have Been Prescribed to Use: _____

A. Treat as directed on the bottle.
B. After shampooing as directed, make sure to remove each single nit from each shaft of hair. Any nits left in the hair will hatch and start the cycle over again. Comb any dead or remaining live lice out of the hair with a fine-tooth comb.
C. Repeat on day 9 of initial dose.
D. Do not use a shampoo/conditioner or conditioner prior to use of the lice medications. Do not wash hair for 1 to 2 days after lice medication treatment.

You Need to Notify the Office If You Have:

A. Any questions regarding the removal of the nits and lice, or if you need any assistance. If other family members need to be evaluated, please let us know. If secondary infection occurs, call the office.
B. Precautions: Do not overuse medications or combine different head lice medications. Use only as directed. These medications are insecticides and can be dangerous if used incorrectly.

Phone: _____

CLIENT TEACHING GUIDE

LICHEN PLANUS

PROBLEM A chronic skin eruption, lichen planus is not cancerous or contagious. It frequently appears as small, slightly raised, itchy, purplish bumps with a whitish surface. Sudden hair loss from the head may occur. Lichen planus may involve the skin of the legs, trunk, arms, wrists, scalp, or penis; the lining of the mouth or vagina; and the nail beds of the toenails and fingernails.

CAUSE The cause is unknown, but it may be caused by a virus. In a few cases, this may be an adverse reaction to certain drugs. The risk of developing lichen planus increases with stress, fatigue, or exposure to drugs or chemicals.

PREVENTION/CARE Currently, there are no known preventive measures.

A. The goal of treatment is to relieve symptoms.
B. Use cool-water soaks to relieve itching.
C. Reduce stress; this may help prevent recurrences. Learn relaxation techniques or obtain counseling if necessary.
D. Speak with your healthcare provider if you suspect a drug to be the cause.

TREATMENT PLAN

Activity: No restrictions.

Diet: Eat a well-balanced diet; drink 8 to 10 glasses of water every day.

Medications: _____

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If:

A. You have a reaction to any of the prescribed medications.
B. You are unable to tolerate the prescribed medications.
C. Hair loss or nail destruction occurs.
D. New lesions appear as old lesions resolve.
E. Other: _____

Phone: _____

RESOURCE American Academy of Dermatology, 9500 W Bryn Mawr Avenue, Ste 500, Rosemont, IL 60018-5216, United States, Phone: (888) 462-DERM (3376), www.aad.org

CLIENT TEACHING GUIDE

PITYRIASIS ROSEA

PROBLEM Pityriasis rosea is a very common condition characterized by a rash, which may or may not itch. You may have noticed a large scaly patch prior to breaking out with the more generalized rash. **It is not known to be contagious and you do not need to isolate yourself.**

CAUSE The cause of pityriasis rosea is unknown.

PREVENTION Because the cause of pityriasis rosea is unknown, there are no recommended preventive measures.

TREATMENT PLAN Good hygiene and avoidance of scratching are recommended to prevent a secondary infection.

Activity: It is not necessary for you to limit your activity. Sunlight exposure to skin for short periods of time daily for 5 consecutive days will reduce itching and improve rash. Care should be taken in not burning skin with short-term exposure to the sun.

Diet: No changes are required in your diet.

Medications: You may be prescribed an antihistamine medication to take by mouth and topical steroid creams to apply to the rash itself. If the itching is severe, you may have oral steroids prescribed.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If You Have:

A. Any new symptoms.
B. Any reaction to your medication.

Phone: _____

RESOURCE American Academy of Dermatology, 9500 W Bryn Mawr Avenue, Ste 500, Rosemont, IL 60018-5216, United States, Phone: (888) 462-DERM (3376), www.aad.org

CLIENT TEACHING GUIDE

PSORIASIS

PROBLEM Psoriasis is a chronic, scaly, thickened skin disorder with frequent remissions and recurrences. The skin of the scalp, elbows, knees, chest, back, arms, legs, toenails, fingernails, and fold between the buttocks may be involved.

CAUSE The cause of psoriasis is unknown.

PREVENTION/CARE

A. There is no known prevention, but symptoms can be controlled.
B. Moving to a warmer climate might be beneficial. Severity increases with cold.
C. Maintain good skin hygiene with daily baths or showers.
D. Avoid harsh soaps.
E. Avoid skin injury, including harsh scrubbing, which can trigger new outbreaks.
F. Avoid skin dryness.
G. To reduce scaling, use nonprescription, waterless cleansers, as well as hair preparations containing coal tar (Zetar, T/Gel, Pentrax), emollients (Eucerin Plus lotion or cream, Lubriderm, Moisture Plus, Moisturel), or products containing cortisone (often prescription strength).
H. Expose the skin to moderate amounts of sunlight as often as possible. Avoid long periods in the sun to prevent sunburn.
I. Oatmeal baths may loosen scales. Use one cup of oatmeal to a tub of warm water.
J. Stress may increase outbreaks of psoriasis. Consider counseling to assist in lifestyle changes, coping, or any psychological problems caused by psoriasis.

TREATMENT PLAN

Activity: There are no activity restrictions.

Diet: Eat a well-balanced diet. You may be instructed to try a gluten-free diet. Drink 8 to 10 glasses of water per day. Avoid alcohol in your diet.

Medications: You may be prescribed the following types of medications:
A. Creams to rub on the skin:
    1. Ointments containing coal tar. These may stain clothing.
    2. Salicylic acid cream, anthralin cream, or vitamin D-like cream (calcipotriene).
    3. Topical cortisone creams may also be used for short periods of time.
B. Psoralen plus UV light (PUVA; combination of a medication and exposure to UVA light).
C. Combination of tar baths with UVB light.
D. Antihistamines to relieve itching.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If:
A. You have an adverse reaction to or cannot tolerate any of the prescribed medications.
B. Symptoms recur after treatment. Notify your healthcare provider if during an outbreak, pustules erupt on the skin and/or are accompanied by fever, muscle aches, and fatigue.
C. New, unexplained symptoms develop.
D. Other: _____

Phone: _____

For severe cases, you may be referred to a dermatologist (specialist for skin disorders).

CLIENT TEACHING GUIDE

SCABIES

PROBLEM Scabies is a common condition characterized by severe itching. You may have noticed small burrows between your fingers and in other locations, or you may have some redness and skin irritation aggravated by scratching.

CAUSE Scabies is caused by an infestation of the skin by a mite. You have contracted scabies by coming in close contact with an individual who has the condition.

PREVENTION You can prevent reinfection of scabies by following these measures:

A. Make sure all close contacts, sexual partners, family, and household contacts are treated.

B. All bedding and clothing that have touched infected skin should be machine-washed and machine-dried on the highest heat cycle.

C. Any clothing or bedding that cannot be laundered in the previously mentioned way should be placed in a plastic bag that is securely tied for at least a week. The mites cannot live this long away from human skin.

D. Coats, furniture, rugs, floors, and walls do not require any special cleaning or treatment.

TREATMENT PLAN

A. Most clients with scabies are successfully treated with only one overnight application of a cream known as scabicide.

B. You should let your practitioner know if you are pregnant or breastfeeding.

C. You may itch for up to a week even with successful treatment.

D. If you still have symptoms after 2 weeks, you should see your practitioner, who will determine if you need a second treatment.

Activity: Affected children in day care or school can return the day after treatment is completed.

Diet: There is no special diet.

Medications: The most common medications used to treat scabies include:

A. Permethrin (Elimite cream), which is applied to all body areas from the neck down and washed off in 8 to 14 hours.

B. You may be told to use Benadryl 25 to 50 mg if needed for itching.

C. Do not use it near your eyes.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If:

A. You have new symptoms.

B. You have a reaction to the medication.

C. Other: _____

CLIENT TEACHING GUIDE

SEBORRHEIC DERMATITIS

PROBLEM Seborrheic dermatitis is a skin condition characterized by greasy or dry, white, flaking scales over reddish patches on the skin. The scales anchor to the hair shafts and may itch, but they are usually painless unless complicated by infection.

CAUSE The cause is unknown. The risk of seborrheic dermatitis increases with stress; hot and humid or cold and dry weather; infrequent shampoos; oily skin and other skin disorders such as rosacea, acne, or psoriasis; obesity; Parkinson disease; use of lotions that contain alcohol; and HIV/AIDS.

PREVENTION/CARE

A. There are no specific preventive measures.
B. The goal of care is to minimize the severity or frequency of symptoms.
1. Shampoo vigorously and as often as once a day. The type of shampoo is not as important as the way you scrub your scalp. To loosen scales, scrub with your fingernails while shampooing and scrub at least 5 minutes.
2. If you suffer from minor dandruff, you may use nonprescription dandruff shampoos with selenium sulfide (Selsun Blue, Exsel) or zinc pyrithione (Zincon), as well as lubricating skin lotion.
3. For severe problems, shampoos that contain coal tar or scalp creams that contain cortisone may be prescribed.
4. To apply medication to the scalp, part the hair a few strands at a time and rub the ointment or lotion vigorously into the scalp.
5. Topical steroids may be prescribed for other affected parts of the skin.
6. Be sure to dry skin folds thoroughly after bathing.
7. Wear loose, ventilating clothing. Avoid constant cap wearing.

TREATMENT PLAN

Activity: No restrictions. Outdoor activities in the summer may help alleviate symptoms.

Diet: Eat a well-balanced diet. Drink 8 to 10 glasses of water per day. Avoid foods that seem to worsen your condition.

Medications: _____

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If:

CLIENT TEACHING GUIDE

SKIN CARE ASSESSMENT

PROBLEM Skin cancer is the most common type of cancer. In 2006, the Centers for Disease Control and Prevention (CDC) noted that the rate of skin cancer varies by the state where you live. A state map can be accessed at at www.cdc.gov/cancer/skin/statistics/state.htm.

CAUSE Skin cancer is frequently caused by damage from the UV rays of the sun. Some people are at a higher risk of developing skin cancer. Risk factors include the following:

A. Fair complexion; blond/red hair; blue, green, or hazel eye color.
B. Advanced age with sun-damaged skin.
C. A history of a severe sunburn.
D. A history of spending long hours outdoors.
E. A history of x-ray procedures for skin conditions.
F. Genetic susceptibility.

PREVENTION/CARE

A. Protect yourself and prevent sun exposure to your skin by staying out of the harmful rays as much as possible, especially between the hours of 10 a.m. and 3 p.m. This time frame accounts for approximately 70% of the harmful UV radiation.
B. If you are exposed to the sun, wear a sunscreen product with a sun protection factor (SPF) of 15 or greater at all times.
C. Wear hats that screen your face and neck, as well as your ears.
D. Clothing is available with sun-protective materials. Regular long shirts and long pants also help protect your skin.
E. Sit in the shade to rest.
F. Do not use a tanning booth.

STEPS TO TAKE TO PREVENT YOURSELF FROM HAVING SKIN CANCER

A. Examine your skin monthly.
1. Use a good light source and a mirror to see areas of your skin not clearly visible.
2. Examine your entire body closely.
3. Pay particular attention to areas that are frequently exposed to the sun, especially your face, lips, eyes, neck, scalp, and ears.
4. Monthly screening allows you to familiarize yourself with birthmarks and moles. Note the size, shape, and color of these marks. Note any changes in these marks using the "ABCDE" method:
a. Asymmetry: The shape of the mark should be noted. Any change in shape or irregularity of the mark needs to be evaluated by your healthcare provider.
b. Border: Look carefully at the border of the mark. If the border edge is ragged, notched, and not smooth, your healthcare provider needs to evaluate it.
c. Color: Note the color of moles. If you notice any change in color, or if you notice the mole to have several colors (brown, black, tan, red, etc.), you need to alert your healthcare provider.
d. Diameter: Measure the size of the mark and document it. Any change in size, especially if it is greater than 6 mm, should be brought to the attention of your healthcare provider.
e. Elevation: Note elevation of the lesion, change in size, and any evolving changes of the lesion. You need to alert your healthcare provider if changes occur.
5. You should also evaluate lesions on your skin for any type of change. If the lesions begin bleeding or hurting, or change in texture or in any other way, your healthcare provider needs to evaluate the change.
6. Be alerted to any skin ulcers that do not heal within 1 month. Also, any new moles or lesions need to be evaluated by your healthcare provider for proper diagnosis of the type of lesion.

TINEA

PROBLEM Tinea is a fungal infection of the skin that can be found on any part of the body. It is not uncommon to have more than one tinea fungal infection at a time:

A. Tinea pedis (athlete's foot).
B. Tinea cruris (jock itch).
C. Tinea capitis (ringworm on the head).
D. Tinea unguium (onychomycosis of the nails).
E. Tinea corporis (ringworm on the trunk or extremities).

CAUSE The fungus is transmitted by direct contact. It can be transmitted from objects, shoes, locker rooms, animals, and people.

PREVENTION/CARE

A. Use good hygiene, including not sharing hairbrushes and combs.
B. Keep skin cool and dry.
C. Wear shoes in locker rooms and pools.
D. Wear loose-fitting clothing.
E. Treat pets' skin problems adequately. Ringworm is often blamed on cats but it can come from almost any animal, including horses, rabbits, dogs, and pigs.
F. Infections of fingernails and toenails may require prescription medications.

TREATMENT PLAN

Activity: As tolerated. Some contact sports may increase getting tinea (football and wrestling).

Diet: There is no special diet.

CLIENT TEACHING GUIDE

TINEA VERSICOLOR

PROBLEM A yeast infection of the skin, tinea versicolor may cause color changes of the skin, commonly on the chest, back, shoulders, arms, and trunk. During the summer, these spots usually appear pale and do not tan. During the winter, the spots may appear pinker or darker than the normal skin color.

CAUSE Tinea versicolor is caused by an increased production of yeast on the skin, which is influenced by warm, moist conditions. It is common to have recurring episodes.

PREVENTION/CARE

A. Air-dry skin as much as possible.
B. Apply medication as directed.
C. Patches on skin (color changes) may take several weeks to be resolved.
D. Monthly treatments may help prevent recurrences.

TREATMENT PLAN

Activity: There are no activity restrictions with tinea versicolor.

Diet: There is no special diet.

Medications:
A. Apply Selsun Blue shampoo or other medication as directed.
B. Most medications may be washed off of skin 30 minutes after application.
C. Selsun Blue shampoo may be used daily on the affected skin for 2 weeks.
D. Keep shampoo out of the eyes and the genital area.
E. Leave it on skin for about 20 minutes and then rinse it off.

CLIENT TEACHING GUIDE

WARTS

PROBLEM A wart is a raised, rough growth projecting from the skin, which can be contagious.

CAUSE Warts are caused by a viral infection that stimulates the cells of the skin to multiply rapidly, resulting in an outward growth.

PREVENTION/CARE

A. Wash hands well.
B. Avoid scratching or picking warts. Warts bleed easily.
C. Some warts go away spontaneously without any treatment after time.
D. Medications may be prescribed.

To Enhance Destruction

A. Soak wart in warm water 10 to 15 minutes a day.
B. After soaking, use an emery board to file wart down.
C. Apply over-the-counter (OTC) medication (Compound W) as prescribed to site.
D. Duct tape may be applied over wart.
E. Perform these steps every night until resolved.
F. Warts may reappear at the same spot or in other areas.
G. Cryotherapy or "freezing" is another treatment option. Discuss this with your healthcare provider.

TREATMENT PLAN

Activity: There are no activity restrictions for warts.

Diet: There are no special diets for warts.

Medications: _____

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If:

A. You develop an infection at the site of the wart.
B. Other: _____

Phone: _____

CLIENT TEACHING GUIDE

XEROSIS (WINTER ITCH)

PROBLEM Xerosis is severely chapped skin that becomes cracked, fissured, and inflamed. It can appear anywhere on the body, but it is seen most commonly on the legs.

CAUSE Xerosis is caused by insufficient oil on the skin's surface, which allows water to evaporate through the skin. Oil in the skin decreases with aging, excessive bathing, and excessive rubbing of the skin. An environment with low humidity also promotes dryness of the skin.

PREVENTION/CARE

A. Reduce water loss from the skin.
   1. Reduce the frequency and duration of baths or showers; use tepid water.
   2. Use soap sparingly.
   3. Avoid detergent soaps.
   4. Pat skin dry rather than rubbing.
   5. Apply skin lubricants (Lac-Hydrin, Eucerin, etc.) to dry skin before chapped areas become inflamed.
   6. Use ultrasonic, cool-mist humidifiers if the air is very dry.
   7. Clean the humidifier daily.
   8. Oil (such as Nivea) in the bathwater may be helpful.
   9. Apply lubricants after bathing when possible to trap additional moisture before evaporation occurs.

B. Apply hand cream four to eight times a day to hands and twice daily on the trunk and extremities.

TREATMENT PLAN

Activity: No restrictions. Avoid long-term exposure to drying environments.

Diet: Eat a well-balanced diet; drink 8 to 10 glasses of water per day.

Medications: _____

You Have Been Prescribed: _____

CHAPTER 8

EYE GUIDELINES

Jill C. Cash and Nancy Pesta Walsh

BLEPHARITIS

DEFINITION

A. Blepharitis is dryness and flaking of the eyelashes, resulting from an inflammatory response of the eyelid. It is considered a chronic condition exhibiting intermittent exacerbations of worsening redness and irritation of the eyelid.

INCIDENCE

A. Blepharitis affects all age and ethnic groups. Current studies indicate the mean age of clients affected with blepharitis is 50 years, and clients with staphylococcal blepharitis are approximately 42 years old and primarily female.

PATHOGENESIS

A. Seborrheic: excessive shedding of skin cells and blockage of glands.
B. *Staphylococcus:* the most common bacteria found, responsible for bacterial infection of lid margin.
C. Commonly seen with altered lipid protection and increased bacterial colonization of the ocular surface and eyelids.
D. Allergic dermatitis (contact dermatitis), eczema, psoriasis.

PREDISPOSING FACTORS

A. Diabetes.
B. *Candida*.
C. Seborrheic dermatitis.
D. Acne rosacea.
E. Eczema.
F. Aging.
G. Clients who wear contact lens and have acquired giant papillary conjunctivitis.

COMMON COMPLAINTS

A. Burning and itching.
B. Lacrimal tearing.
C. Photophobia.
D. Recurrent eye infections, styes, or chalazia.
E. Dry, flaky secretions on lid margins and eyelashes.
F. Gritty sensation to both eyes.
G. Dry eyes.

OTHER SIGNS AND SYMPTOMS

A. Seborrheic blepharitis: lid margin swelling and erythema, flaking, nasolabial erythema, and scaling.
B. *Staphylococcus aureus* blepharitis: erythema/edema, scaling, burning, tearing, itching, and recurrent stye or chalazia.
C. May have dandruff of scalp and eyebrows.

SUBJECTIVE DATA

A. Elicit onset and duration of signs and symptoms.
B. Note sensations of itching, burning, or pain in the eye.
C. Ask: What makes signs and symptoms worse? What makes signs and symptoms better?
D. Any change in soaps, creams, lotions, or shampoos?
E. Has the client had similar signs and symptoms in the past?
F. Note any visual change or pain since the last eye exam.
G. Note contributing factors involved, if present. These should include smoking, allergen exposure, contact lenses, and use of retinoid products.
H. Ask about risk for foreign bodies or contact with toxins transferred from hands to eyelids (occupational exposures).

PHYSICAL EXAMINATION

A. Inspect:
  1. Inspect eyes, noting extraocular eye movements (EOMs).
  2. Examine sclera, pupil, iris, and fundus.
  3. Examine eyes for red reflex and corneal light reflex.
  4. Note erythema or edema on lid margin; note dryness, scaling, and flakes.
  5. Examine for foreign body or corneal abrasion.
  6. Assess vision using Snellen chart.

DIAGNOSTIC TESTS

A. None; however, cultures of eyelid margins may be warranted if signs/symptoms indicate.

DIFFERENTIAL DIAGNOSES

A. Blepharitis:
  1. *S. aureus.*
  2. Seborrheic.
  3. *Demodex folliculorum.*
B. Conjunctivitis.
C. Squamous cell carcinoma.
D. Stye (hordeolum).
E. Chalazion.
F. Upper respiratory infection.
G. Sinusitis with periorbital involvement.

PLAN

A. General interventions:
  1. Assess the client and rule out bacterial infection and vision changes.
  2. Clients with frequent recurrent blepharitis need further follow-up with an ophthalmologist. ▶

The contributions of Mellisa Hall to this chapter in prior editions are acknowledged here.

B. Client teaching:
1. Wash eyelids with antibacterial soap and water. Use over-the-counter (OTC) eyelid scrub product or baby shampoo.
2. Apply warm compress to eye for comfort daily for approximately 10 to 20 minutes.
3. Stop use of contacts until the eye is healed. Avoid eye makeup while lids are inflamed.
4. Encourage good hygiene for prevention of recurrent episodes.
C. Pharmaceutical therapy:
1. Apply erythromycin ophthalmic ointment or azithromycin ophthalmic solution to margin of eye at bedtime, taking care not to contaminate the medication bottle. Bacitracin is an alternative but has been associated with contact dermatitis.
2. Oral antibiotics for severe blepharitis not responding to topical antibiotics: tetracycline 250 mg PO QID for 4 weeks; alternative: doxycycline 100 mg PO BID, or oxacillin 250 mg QID for 4 weeks (contraindicated during pregnancy and lactation).
3. Consider long-term treatment with doxycycline if infections reoccur.
4. Topical glucocorticoids, while having a role in treatment, should be prescribed only by an ophthalmologist due to potential side effects.
5. Consider use of topical cyclosporine ophthalmic drops such as Restasis.

FOLLOW-UP

A. Recommend follow-up with a primary provider in 1 to 2 weeks.
B. Consider referral to an eye specialist for recurrent episodes of blepharitis.

EMERGENT ISSUES/INSTRUCTIONS

A. Same-day referral to an ophthalmologist should be arranged for clients with severe eye pain, redness, light sensitivity, vision changes, corneal concerns, or symptoms not responding to initial therapy.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:
1. If symptoms are unilateral only, client should be evaluated by an ophthalmologist as blepharitis is a bilateral condition. Unilateral cases may be associated with malignancy.
2. Azithromycin may lead to abnormalities of heart electrical rhythm; use with caution in clients at high risk of cardiovascular disease.
3. Geriatric clients who often rub their eyes and have a history of meibomian gland dysfunction or keratoconus (thinning, protruding cornea) will tend to suffer from blepharitis disease progression. Erythromycin ointment is recommended as a first-line treatment if staphylococcal infection is present. Keep eyes moistened during the day with artificial tear formulations and ophthalmic gel solutions at night (e.g., Systane gel drop lubricant).
4. Clear lids with gentle cleaning with dandruff shampoo or applying tea tree oil to lids; referral if no improvement within 6 weeks.

CATARACTS

DEFINITION

A. A cataract, an opacity of the crystalline lens of the eye, causes progressive, painless loss of vision (functional impairment). Presenile and senile cataract formation is painless and progresses throughout months and years. Cataracts are frequently associated with intraocular inflammation and glaucoma.

INCIDENCE

A. Cataracts are the most common cause of blindness in the world.
B. Of people older than 60, 95% have cataracts without visual disturbance.
C. Of people older than 40, 50% have significant visual loss due to cataracts.
D. Prevalent cases in the United States are 61% female and 39% male.
E. The National Institutes of Health projected that by year 2030 approximately 40 million U.S. citizens are expected to suffer from cataracts and approximately 50 million people by 2050.

PATHOGENESIS

A. Age-related changes of the lens of the eye result from protein accumulation, which produces a fibrous thickened lens that obscures vision.

PREDISPOSING FACTORS

A. Age.
B. Trauma.
C. Medications (e.g., topical or systemic steroids, major tranquilizers, or some diuretics).
D. Medical diseases (e.g., diabetes mellitus, metabolic syndrome, Wilson disease, hypoparathyroidism, glaucoma, congenital rubella syndrome, chronic anterior uveitis).
E. Chronic exposure to UVB light (including sunlight).
F. Down syndrome.
G. Low antioxidant vitamin use.
H. Alcohol use.
I. Smoking.
J. Lower educational level.
K. Poor nutrition and sedentary lifestyle.
L. Lead exposure.
M. Family history.

COMMON COMPLAINTS

A. Decreased vision, including reading road signs or small print.
B. Blurred or foggy vision, "ghost" images.
C. Inability to drive at night.

OTHER SIGNS AND SYMPTOMS

A. Initial visual event can be a shift toward nearsightedness.
B. Visual impairment can be more marked at distances, with abnormal visual acuity exams.
C. Severe difficulty with glare.
D. Altered color perception.
E. Frequent falls or injuries.

SUBJECTIVE DATA

A. Review the onset, course, and duration of visual changes, including altered day or night vision and nearsighted versus farsighted vision. Rule out diplopia or hemianopia.
B. Assess whether involvement is in one or both eyes.
C. Determine what improves vision—use of glasses or use of extra light.
D. Review the client's medical history and current medications.
E. Review the client's history for traumatic injury.
F. Discuss the client's occupation and leisure activities to determine exposure to UV rays.
G. Review lifestyle choices that would identify risk of cataract formation.

PHYSICAL EXAMINATION

A. Inspect:
1. Conduct a funduscopic examination.
a. Check red reflex and opacity.
i. A bright red reflex is seen in the normal eye.
ii. Cataract formation is seen by the disruption of the red reflex.
iii. Lens opacities appear as dark areas against the background of the red-orange reflex.
b. Examine color of opacity. For brunescent cataracts, the nucleus acquires a yellow-brown coloration and becomes progressively more opaque.
c. Check retinal abnormalities, hemorrhage, scarring, and drusen (small yellow deposits).
d. Examine extraocular movements and papillary reactivity.

DIAGNOSTIC TESTS

A. Perform visual acuity exam.
B. Perform peripheral vision exam.
C. Perform slit-lamp exam to determine the exact location and type of cataract.
D. Perform dilated eye exam (performed by an ophthalmologist).

DIFFERENTIAL DIAGNOSES

A. Cataracts.
B. Glaucoma.
C. Age-related macular degeneration (AMD). AMD causes vision loss that is symptomatically similar to cataracts.
D. Diabetic retinopathy.
E. Temporal arteritis.
F. Cerebral vascular accident.
G. Central nervous system (CNS) lesions or neurodegenerative conditions.

PLAN

A. General interventions:
1. Monitor the client for increased interference of visual impairment on their lifestyle.
2. Cataracts do not need to be removed unless there is impairment of normal, everyday activities.
3. Surgery is the definitive treatment; however, modification of glasses may improve vision adequately to defer surgery. Contact lenses are optically superior to glasses.
B. Client teaching:
1. Prevention is important. Teach the client to use protective eyewear to prevent trauma and sun exposure.
2. Discuss modifiable lifestyle behaviors that increase the risk of cataract formation.
3. Wear a hat with a visor to protect eyes when outdoors.
4. Vitamins: Lutein and zeaxanthin are associated with reduced cataract formation in elderly females.
5. Clients may not be aware of Medicare coverage for surgical removal. Referring them to Medicare.gov will help them understand costs of surgical intervention.

FOLLOW-UP

A. Surgical removal is indicated if the visual disturbance is interfering with the client's life, such as causing falls or prohibiting reading.

CONSULTATION/REFERRAL

A. Refer client for ophthalmologic consultation.
B. Clients should be followed by an optometrist or an ophthalmologist to monitor the cataract for increased size and progressive visual impairment.
C. Contact a social worker or community resources as needed.

INDIVIDUAL CONSIDERATIONS

A. Adults:
1. Cataracts are most commonly seen after the age of 60.
2. Clients complaining of visual disturbance should be screened for cataracts.
B. Geriatrics:
1. More than half of Americans ≥80 years old have cataracts or have had cataract surgery. Cataracts in older adults tend to present as a yellow-brown color on the lens. Clients may report a problem with identifying blues, blacks, and purples. Other complaints include cloudy/blurry vision, faded colors, glare, halo around lights (home appliances or headlights), poor night vision, and double/multiple images.
2. After 60 years of age, implement a comprehensive dilated eye exam at least once every 2 years.
3. Interventions for geriatrics include the following:
a. Reduction of UV light exposure. Encourage older adults to wear sunglasses and wide-brim hats.
b. Smoking cessation and reduce/avoid alcohol use.
c. Surgery: diagnostic preoperative indications for geriatrics:
i. EKG for clients with heart disease to determine stability.
ii. Potassium and creatinine levels for clients on diuretics (renal function).
iii. Glucose trends during stress/infections with diabetics in order to prepare any short-term medicine changes.
iv. Close monitoring for clients taking scheduled anticoagulant/antiplatelet medications.
4. Secondary cataracts may develop after long-term steroid use. Be sure to monitor clients who have chronic obstructive pulmonary disease (COPD) or rheumatoid arthritis (RA)/autoimmune disorders and who have been taking daily steroids ≥1 year.

CHALAZION

DEFINITION

A. Chalazion is a chronic lipogranulomatous inflammation of a meibomian gland located in the eyelid margin. It differs from a hordeola in that it is a result of gland obstruction rather than an infection. Inflammation occurs from occlusion of the ducts.

INCIDENCE

A. The incidence is unknown.

PATHOGENESIS

A. Meibomian glands secrete the lipid layer of the tear film that covers and protects the eye. When the glands become blocked, the oil or lipid extrudes into the surrounding tissue, causing formation of a painless, rubbery nodule.

PREDISPOSING FACTORS

A. Chalazion may occur as a secondary infection of the surrounding tissues (stye). Chalazia occur more frequently in clients with blepharitis and rosacea.

COMMON COMPLAINTS

A. Swelling, nontender palpable nodule, usually pea-sized, inside lid margin or eye.
B. Discomfort or irritation due to swelling.

OTHER SIGNS AND SYMPTOMS

A. Tearing.
B. Feeling of a foreign body in the eye.
C. If infection is present, the entire lid becomes painfully swollen.

SUBJECTIVE DATA

A. Review onset of symptoms, their course and duration, and any concurrent visual disturbance.
B. Question the client regarding possible foreign body or trauma to the eye.
C. Elicit the quality of pain or tenderness of the eyelid.
D. Review past eye problems and the treatment received.
E. Question for eye tearing, discharge, or matting.
F. Question for employment duties and hobbies predisposing to foreign bodies.

PHYSICAL EXAMINATION

A. Check temperature.
B. Inspect:
  1. Inspect the eye, sclera, and conjunctiva for a foreign body, erythema, vessel injection, discharge, matting, inflammation of the eyelids, or pterygium.
  2. Check for red- or gray-colored subconjunctival mass in the upper and lower eyelid.
C. Palpate:
  1. Palpate eyelid for masses, foreign-body sensation, and tenderness.
  2. Check for preauricular adenopathy. Usually a hard, nontender nodule is found on the middle portion of the tarsus, away from the lid border; it may develop on the lid margin if the opening of the duct is involved. Some chalazia continue to increase in size and can cause astigmatism by putting pressure on the eye globe.
  3. Chalazia may become acutely tender; however, note the difference between the chalazia and the stye, which is found on the lid margin.

DIAGNOSTIC TESTS

A. Perform visual acuity exam.

DIFFERENTIAL DIAGNOSES

A. Chronic dacryocystitis.
B. Hordeolum.
C. Blepharitis.
D. Xanthelasma.
E. Cellulitis of the eyelid.

PLAN

A. General interventions:
  1. Small chalazia do not usually require treatment.
  2. Warm, moist compress may be applied for 15 minutes four times a day.
B. Client teaching:
  1. Instruct client regarding use of warm compress and good handwashing.
  2. Use of baby shampoo and lid massage may be helpful.
C. Pharmaceutical therapy:
  1. Antibiotic treatment is not recommended as chalazion is a granulomatous condition. However, if infected, give doxycycline 100 mg PO BID for 10 days, OR minocycline 50 mg daily for 10 minutes. If unable to take tetracycline, metronidazole is recommended.
  2. Intrachalazion corticosteroid injection by an ophthalmologist may be considered.

FOLLOW-UP

A. For large chalazia, follow up with client in 1 week and then evaluate the client every 2 to 4 weeks.

CONSULTATION/REFERRAL

A. Refer to an ophthalmologist for incision and curettage if the chalazion does not resolve spontaneously.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:
  1. To prevent the development of infected chalazion, have the client routinely remove makeup at night and gently wash eyes. Encourage washing their hands frequently during the day.
  2. Nonpharmacologic treatments include warm compress for 20 to 30 minutes (rewetting washcloth every 5–10 minutes), applying a gentle massage, discontinuing use of contact lens and eye makeup until healed, and encouraging clients to keep hands clean and to not rub their eyes.
  3. Pharmacologic treatments common in geriatrics include short-term nonsteroidal anti-inflammatory drugs (NSAIDs) for pain and inflammation and Tobradex ointment three to four times a day for 1 week (combination of an antibiotic and an anti-inflammatory).
  4. Recurrent chalazion in the elderly should be biopsied to rule out malignancy.

CONJUNCTIVITIS

DEFINITION

A. Conjunctivitis is inflammation of the conjunctiva. All conjunctivitis is erythemic, but not all erythemic eyes are conjunctivitis. Differential diagnosis is key in the diagnosis.

INCIDENCE

A. Conjunctivitis may be subdivided into viral, bacterial, allergic, and nonallergic subcategories. Viral conjunctivitis is the most common type of conjunctivitis.

PATHOGENESIS

A. Primarily, four types of conjunctivitis are observed:
  1. Bacterial (*Staphylococcus aureus*, *Corynebacterium*, *Pseudomonas*, *Moraxella*, *Haemophilus influenzae*, *Streptococcus pneumoniae*, *Neisseria gonorrhoeae*, and *Chlamydia*).
  2. Viral (adenovirus, coxsackievirus, herpes zoster ophthalmicus, and enteric cytopathic human orphan [ECHO] viruses).
  3. Allergic (seasonal pollens or allergic exposure).
  4. Nonallergic (commonly related to mechanical or chemical trauma).

PREDISPOSING FACTORS

A. Contact with another person with a diagnosis of conjunctivitis.
B. Exposure to sexually transmitted infection (STI).
C. Other atopic conditions (allergies).
D. Mechanical or chemical injury.

COMMON COMPLAINTS

A. Red eyes.
B. Eye drainage.
C. Itching (with allergic conjunctivitis).
D. Matting upon awakening.

OTHER SIGNS AND SYMPTOMS

A. Bacterial:
  1. Fast onset, 12 to 24 hours of copious purulent or mucopurulent discharge.
  2. Burning, stinging, or gritty sensation in eyes.
  3. Crusted eyelids upon awakening, with swelling of the eyelid.
  4. Usually starts out unilaterally; may progress to bacterial infection.
  5. Bacterial conjunctivitis may present as beefy red conjunctiva.
B. Viral:
  1. Symptoms may begin in one eye and progress to both eyes.
  2. Tearing of eyes.
  3. Sensation of foreign body.
  4. Systemic symptoms of upper respiratory infection (runny nose, sore throat, sneezing, fever).
  5. Preauricular or submandibular lymphadenopathy.
  6. Photophobia, impaired vision.
  7. Primary herpetic infection: vesicular skin lesion, corneal epithelial defect in form of dendrite, uveitis.
C. Allergic:
  1. Itchy, watery eyes, bilateral.
  2. Seasonal symptoms.
  3. Edema of eyelids without visual change.
  4. With allergic conjunctivitis, hyperemia of eyes is always bilateral and giant papillae on tarsa may be seen.
  5. May also see eczema, urticaria, and asthma flare.
D. Nonallergic (mechanical or chemical):
  1. Itchy, watery eyes, unilateral or bilateral.
  2. Frequent causes may include smoke, dust, vapors, and foreign objects.
  3. Tearing.
  4. Vision obstructed from blurring or tearing.

SUBJECTIVE DATA

A. Elicit onset, duration, and course of symptoms.
B. Question client regarding presence of discharge upon awakening.
C. Elicit changes in vision since symptoms began.
D. Determine whether there has been any injury or trauma to the eye, including foreign body.
E. Assess whether these symptoms have appeared before.
F. Rule out exposure to anyone with conjunctivitis.
G. Ask client about any new events, such as use of contact lenses or change in contact lenses or solutions.
H. Review client and family history of allergies.
I. Question the client regarding pain and rate on a pain scale.

PHYSICAL EXAMINATION

A. Check temperature.
B. Inspect:
  1. Observe eyes for color and foreign objects. Perform complete eye exam, including acuity exam.
  2. Note lid edema.
  3. Assess pupillary reflexes.
  4. Examine eyelids and periorbital skin for erythema, vesicles, inflammation, or tenderness.
  5. Inspect ears, nose, and throat.
C. Auscultate:
  1. Auscultate heart and lungs.
D. Palpate:
  1. Palpate preauricular lymph nodes and anterior and posterior cervical chain lymph nodes.

DIAGNOSTIC TESTS

A. Gram stain testing for discharge/exudate extracted from eyes if gonococcal infection is suspected.
B. Culture if gonococcal or chlamydial infection is suspected, recurrent conjunctivitis, or treatment-resistant infection.
C. Perform fluorescein stain of eye if foreign body or corneal abrasion/ulceration is suspected.
D. Test visual acuity with the Snellen chart. Assess peripheral vision and extraocular eye movements (EOMs).

DIFFERENTIAL DIAGNOSES

A. Conjunctivitis.
B. Corneal abrasion.
C. Blepharitis.
D. Drug-related conjunctivitis.
E. Herpetic keratoconjunctivitis.
F. Iritis.
G. Gonococcal or chlamydial conjunctivitis.
H. Angle-closure glaucoma.
I. Keratitis.
J. Foreign body.

PLAN

A. General interventions:

1. Distinguish between bacterial, allergic, nonallergic, and viral infection.

2. Consider other diagnoses as earlier if eye pain is noted.

B. Client teaching: *See Client Teaching Guides for this chapter, "Conjunctivitis" and "How to Administer Eye Medications."*

1. Cool compress to affected eye should be applied several times a day.

2. Clean eyes with warm, moist cloth from inner to outer canthus to prevent spreading infection.

3. Encourage good handwashing with antibacterial soap.

4. Instruct on the proper method of instilling medication into eye.

5. Instruct the female client to discard all eye makeup, including mascara, eyeliner, and eye shadow, worn at the time of the infection.

6. Teach the client the difference between bacterial, allergic, nonallergic, and viral infections. Educate according to appropriate diagnosis.

7. If using aminoglycoside or neomycin ointments or drops, use caution and monitor closely for reactive keratoconjunctivitis.

8. Contact lens wearers should be prescribed a fluoroquinolone to cover for *Pseudomonas*.

9. Bacterial conjunctivitis is contagious up to 24 hours after starting medication.

10. Viral conjunctivitis is contagious for 48 to 72 hours, but may last up to 2 weeks. This is typically self-limiting and does not require antibiotic treatment.

11. Discuss general eye protection against recurrent exposures or trauma.

C. Pharmaceutical therapy:

1. Bacterial:

a. Aminoglycosides: These should be avoided due to risk of reactive keratoconjunctivitis.

b. Polymyxin B: Trimethoprim/polymyxin B sulfate (Polytrim) ophthalmic ointment in each eye QID for 7 days. Polymyxin B/bacitracin (Polysporin) drops may also be used, 1 gtt Q3H for 7 to 10 days.

c. Macrolides: Erythromycin (Ilotycin) ophthalmic ointment 0.5% in each eye QID for 7 days.

d. Fluoroquinolones: Ciprofloxacin 0.3% Q2H for 2 days, then Q4H for 5 days; moxifloxacin (Vigamox) 0.5% 1 gtt TID for 7 days. (Due to concerns of resistance, fluoroquinolones should be reserved for treatment of bacterial conjunctivitis primarily in contact wearers.)

2. Viral:

a. Trifluridine 1% drops are indicated for ocular herpes, one drop Q2H while awake; no more than nine drops per day; use for 10 to 14 days. Clients suspected with ocular herpes should benefit from a same-day referral to an ophthalmologist as permanent vision loss can be a sequela of herpes conjunctivitis.

b. Ganciclovir 0.15% gel one drop five times a day until epithelial heals and then TID for 1 week.

c. Oral antiviral medications (trifluridine, valacyclovir) may be used for herpes simplex keratitis. Herpes zoster ophthalmicus is often treated with acyclovir, famciclovir, or valacyclovir and lessens symptoms if started within 72 hours of onset of symptoms. **Clients should receive same-day referral** for consideration of treatment of ocular herpes.

3. Allergic:

a. Topical antihistamines/mast cell stabilizer:

i. Azelastine HCl (Optivar): for adults, one drop to the affected eye BID.

ii. Olopatadine HCl (Pataday) 0.2%: one drop to the affected eye daily.

iii. Olopatadine HCl (Patanol) 0.1%: one drop BID to the affected eye.

b. Mast cell stabilizer:

i. Cromolyn sodium (Crolom) ophthalmic solution: one to two drops four to six times daily.

c. Topical nonsteroidal anti-inflammatory drugs (NSAIDs):

i. Ketorolac tromethamine (Acular) 0.5%: for adults, one drop QID; this is used for severe symptoms of atopic keratoconjunctivitis.

d. Artificial tears can be used four to five times daily.

e. Oral antihistamines may be used in severe cases (loratadine or diphenhydramine HCl).

4. Concurrent conjunctivitis and otitis media should be treated with a systemic antibiotic; no topical eye antibiotic is needed.

FOLLOW-UP

A. If complete resolution occurs within 5 to 7 days after proper treatment, follow-up is not needed.

B. If client continues to have equal or worsening symptoms after 48 to 72 hours of treatment or if different symptoms appear, then follow-up and a same-day referral to an ophthalmologist are recommended.

CONSULTATION/REFERRAL

A. Consult or refer client to a physician if they are not responding to treatment within 48 to 72 hours.

B. Same-day referral if client is suspected of having periorbital cellulitis, iritis, keratitis, herpes zoster ophthalmicus, or acute angle-closure glaucoma.

C. Refer to an eye specialist if client has vision change or eye pain, is not responding to treatment, or if sight-threatening red flags are present.

1. Reduced visual acuity with onset of symptoms.

2. Observation of a ciliary flush.

3. Photophobia.

4. Severe foreign-body sensation.

5. Corneal opacity.

6. Fixed pupil.

7. Severe headache associated with nausea.

INDIVIDUAL CONSIDERATIONS

A. Partners:

1. Check partners for gonorrhea and chlamydia when an adolescent or adult presents with gonococcal or chlamydial conjunctivitis.

B. Pregnancy:

1. In pregnancy, change in hormones and the immune system make the client more susceptible to eye infections, especially if there are young children in the house as vectors.

2. Apply cool compress, practice good hand hygiene, and if the client has allergic conjunctivitis Pataday and Optivar are safe to use during pregnancy.

3. If antibiotic drops are needed, erythromycin (predominantly gram-positive coverage) and polymyxin B (gram-negative coverage) are safe during pregnancy.

C. Geriatrics:

1. Lid or lacrimal sac edema or proptosis with conjunctivitis is a red flag to further investigate for cellulitis or an orbital tumor.

2. First-line treatment for conjunctivitis in geriatrics is erythromycin ointment/drops. Second-line is ciprofloxacin 0.3% solution.

3. If signs/symptoms of purulent discharge do not improve within 48 hours after initiating antibiotics, refer to an ophthalmologist.

4. Avoid diphenhydramine secondary to risks of confusion, constipation, blurred vision, delirium, dry mouth, and other anticholinergic symptoms. This may be considered only for acute treatment of a severe allergic reaction.

CORNEAL ABRASION

DEFINITION

A. A corneal abrasion is a defect of the corneal epithelial tissue, either superficial or deep.

INCIDENCE

A. In the United States, there are 2,000 work-related eye injuries daily, approximately 2.4 million annually.

B. One-third of these eye injuries require treatment in an ED or by an ophthalmologist.

PATHOGENESIS

A. Injury from trauma occurs to the epithelial tissue of the cornea.

PREDISPOSING FACTORS

A. Trauma to the eye caused by a human fingernail, contact lens, animal paws, makeup applicators, UV light burns from tanning beds or welding arcs, tree branches, wood or metal particles, children's toys, or sports injuries.

B. A history of surgical trauma, causing globe weakening.

C. A history of spontaneous corneal erosions.

COMMON COMPLAINTS

A. Sudden onset of eye pain.

B. Foreign-body sensation in the eye.

C. Watery eye.

D. Mild photophobia.

OTHER SIGNS AND SYMPTOMS

A. Change in vision/blurred vision.

B. Redness, swelling, inability to open the eye.

SUBJECTIVE DATA

A. Elicit the onset, duration, and course of symptoms; note any history of similar symptoms.

B. Question the client regarding visual changes (blurred, double, or lost vision, or loss of a portion of the visual field).

C. Question the client regarding the mechanism of injury and how much time has elapsed since the injury (minutes, hours, or days). Ask: What is their occupation, do they work with wood or metal, what sports are involved, or what hobbies predispose them to injury? Were goggles being worn and are they routinely worn during the sport or activity?

D. Review the client's history of exposure to herpetic outbreaks.

E. Determine the degree of pain, if any, and check for headache, photophobia, redness, itching, or tearing.

F. Ascertain whether the client wears contact lenses or glasses and for what length of time.

G. Ask if the client has tried any treatments before presentation to the office. If so, what?

H. Rule out the presence of any other infections, such as sinus infection. **Conjunctival discharge signifies an infectious etiology**.

I. Ask about foreign-body sensations.

J. Rule out farm injury due to risk of bacterial keratitis.

PHYSICAL EXAMINATION

A. Check vital signs: blood pressure, pulse, temperature.

B. Inspect:

1. Observe *both* eyes.

2. Test visual acuity and pupil reactivity and symmetry.

3. Observe cornea surface with direct illumination, noting shadow on surface of iris.

4. Perform funduscopic exam.

5. Evert eyelids for cornea inspection.

6. Inspect for foreign body and remove if indicated.

7. Perform fluorescein stain to visualize changes in epithelial lining. Cobalt blue light or Wood lamp should be used for visualization.

8. Consider slit-lamp examination to rule out traumatic hyphema or open globe injuries.

DIAGNOSTIC TEST

A. Perform fluorescein stain test: **An epithelial defect that stains with fluorescein is the hallmark symptom**.

DIFFERENTIAL DIAGNOSES

A. Corneal abrasion.

B. Corneal foreign body.

C. Acute angle glaucoma.

D. Herpetic infection (herpes simplex virus [HSV]): HSV is associated with decreased corneal sensation.

E. Recurrent corneal ulceration.

F. Ulcerative keratitis.

G. Spontaneous corneal erosion.

PLAN

A. General interventions:

1. Superficial or smaller corneal abrasions should not be patched. ▶

2. For deeper or larger abrasions and if a foreign body is ruled out, apply a patch that prevents lid motion for 24 hours. Patching is not recommended for pain control as it has the potential to delay healing.

3. Pressure patch is no longer recommended.

B. Client teaching: *See Client Teaching Guide for this chapter, "How to Administer Eye Medications."*

1. Discuss the use of protective eyewear and prevention of future ocular trauma in clients with a history of use of power tools or hammering.

2. Advise the client to not use/wear contact lenses until the eye is completely healed.

C. Pharmaceutical therapy:

1. Antibiotic drops or ointment: **Never instill antibiotic ointment if there is a possibility of a perforation. Patch the eye and refer the client to a physician or ophthalmologist:**

a. Erythromycin 0.5% ointment, 1/2-in. ribbon twice a day to four times a day for 7 days.

b. Sulfacetamide sodium ophthalmic solution 10% (Sulamyd), one to two drops instilled into the lower conjunctival sac every 2 to 3 hours during the day; may instill Q6H during the night for 5 to 7 days.

c. Sulfacetamide sodium (Sulamyd) ophthalmic solution or ointment interacts with gentamicin. Avoid using them together.

d. Para-aminobenzoic acid (PABA) derivatives reduce sulfacetamide's action. Wait for half to 1 hour before instilling sulfacetamide.

e. Sulfacetamide precipitates when used with silver preparations. Avoid using them together.

f. Polymyxin B sulfate (Polytrim) 10,000 U, bacitracin zinc 500 U/g ophthalmic ointment (Polysporin), a small ribbon of ointment applied into the conjunctival sac four to six times daily for 7 to 10 days.

g. Bacitracin 500 U/g ointment, 1/2-in. ribbon twice a day to four times a day for 7 to 10 days.

h. Contact lens wearers are often colonized with *Pseudomonas* and should be treated with either a fluoroquinolone or an aminoglycoside. Ciprofloxacin 0.3% solution one to two drops QID for 3 to 7 days; ofloxacin 0.03% one to two drops every 30 minutes on days 1 to 2, Q1H on days 3 to 7, and QID on days 7 to 9; gentamycin 0.3% solution one to two drops QID for 3 to 5 days; or tobramycin (Tobrex) ointment or drops QID for 3 to 5 days.

2. Analgesics: Oral nonsteroidal anti-inflammatory drugs (NSAIDs) or topical analgesics should be used sparingly for the first 24 hours. Diclofenac (Voltaren) 0.1% solution in the eye QID as needed or ketorolac (Acular) 0.5% solution in the eye QID as needed.

3. Avoid use of home prescriptions that will interfere with the healing process.

4. Avoid use of medications containing steroids. These products may increase the risk of superinfection and may slow down the healing process.

5. The length of therapy may vary but should be continued until the client is symptom-free for 24 hours.

FOLLOW-UP

A. Reevaluate the client **within 24 hours**. Cornea usually heals within 24 to 48 hours.

B. If the client is still symptomatic in 48 hours, a same-day referral to an ophthalmologist is warranted.

CONSULTATION/REFERRAL

A. Immediate referral to an ophthalmologist is required for large or central lesions or deep or penetrating wounds. If ophthalmology referral cannot be arranged, the client should be treated at the ED.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Retinal detachment should be considered as a source of eye pain and visual loss, especially in females with severe pregnancy-induced hypertension (HTN).

B. Adults:

1. Encourage protective eyewear for sports (including hockey, soccer, baseball, and basketball) and when using any power equipment or tools.

2. Clients with corneal abrasions secondary to contact lenses are at higher risk of bacterial keratitis. Injuries secondary to contact lenses should be evaluated to rule out a corneal infiltrate or ulcer. If this condition is observed, the client is at risk of *Pseudomonas* keratitis, an ocular emergency.

3. These clients should never receive an eye patch, should be covered with a topical ophthalmic agent that has *Pseudomonas* coverage, and should be evaluated by an ophthalmologist.

C. Geriatrics:

1. Research indicates that eye surgery is successful in the majority of older adult clients, secondary to advancement in technological microsurgery procedures. However, as demand for refractory surgery rises, corneal abrasions are also increasing as a complication of postsurgical ocular procedures.

2. Geriatric clients may not remember details of eye trauma event and should be evaluated for corneal abrasion if there are complaints of pain and photophobia.

DACRYOCYSTITIS

DEFINITION

A. Infection or inflammation of the lacrimal sac, or dacryocystitis, can be acute or chronic.

B. Dacryocystitis is usually secondary to obstruction of the nasolacrimal duct.

INCIDENCE

A. The incidence is unknown in adults. Dacryocystitis is more common in children than in adults.

B. In adults, dacryocystitis is more common in females and after the age of 40. Females comprise 70% to 83% of cases, with a peak age of 60 to 70 years.

C. Caucasians tend to be more affected than other races because their lacrimal canal is longer and is inclined to deviate.

PATHOGENESIS
A. Bacterial infection of the lacrimal sac is most commonly caused by *Staphylococcus*, *Streptococcus*, *Haemophilus*, and *Pseudomonas*. Methicillin-resistant *Staphylococcus aureus* is more common in acute dacryocystitis.

PREDISPOSING FACTORS
A. Nasal trauma.
B. Deviated septum.
C. Nasal polyps.
D. Congenital dacryostenosis.
E. Inferior turbinate hypertrophy.

COMMON COMPLAINTS
A. Pain in the eye.
B. Redness.
C. Swelling.
D. Fever.
E. Tearing.
F. Visual change.

OTHER SIGNS AND SYMPTOMS
A. Purulent exudate may be expressed from the lacrimal duct.

SUBJECTIVE DATA
A. Elicit the onset, course, and duration of symptoms. Are symptoms bilateral or unilateral?
B. Review the client's activity when the symptoms began to determine if etiology is chemical, traumatic, or infectious.
C. Review other presenting symptoms, such as fever and discharge.
D. Review the client's history for previous episodes. Note treatments used in the past.
E. Review history for a recent herpes simplex virus (HSV) or fever blister.
F. Review ophthalmologic history.
G. Review medications.
H. Review blood glucose in diabetics.

PHYSICAL EXAMINATION
A. Check temperature, pulse, and blood pressure.
B. Inspect:
1. Assess both eyes.
2. Check peripheral fields of vision and sclera.
3. Evaluate conjunctiva for distribution of redness, ciliary flush, and foreign bodies.
4. Inspect lid margins: Evaluate for crusting, ulceration, and masses.
C. Palpate:
1. Palpate lacrimal duct and surrounding bony structures. Discharge can be expressed from the tear duct with application of pressure.

DIAGNOSTIC TESTS
A. Check visual acuity.
B. Culture any discharge.
C. Obtain plain radiographs if foreign body is suspected.
D. Obtain CT to evaluate trauma, suspected tumor, and orbital cellulitis.

DIFFERENTIAL DIAGNOSES
A. Dacryocystitis.
B. Chalazion.
C. Blepharitis.
D. Xanthoma.
E. Bacterial conjunctivitis.
F. Hordeolum.
G. Foreign body.
H. Orbital cellulitis.
I. Preseptal cellulitis.
J. Complications of sarcoidosis.

PLAN
A. General interventions:
1. Apply warm, moist compress at least four times per day.
2. Instruct the client to discard old makeup, including mascara, eyeliner, and eye shadow, used prior to infection.
3. Consider avoiding use of contacts and switch to their glasses.
B. Client teaching: *See Client Teaching Guide for this chapter, "How to Administer Eye Medications."*
1. Advise client to perform proper handwashing and cleaning.
C. Pharmaceutical therapy:
1. Coverage should be aimed at gram-positive organisms. Empiric coverage should include both gram-positive and Gram-negative coverage. Augmentin is a good choice.
2. Acute dacryocystitis:
a. Clindamycin 300 mg Q6H for 7 to 10 days depending on response.
b. Erythromycin 250 mg QID for 7 days.
c. Dicloxacillin 250 mg QID for 7 days.
3. Acute dacryocystitis with orbital cellulitis requires hospitalization with intravenous (IV) antibiotics.

FOLLOW-UP
A. Follow up in 3 days for reevaluation.

CONSULTATION/REFERRAL
A. Acute dacryocystitis: Abrupt onset with erythema, warmth, swelling, and pain of the lacrimal duct should be managed on the same day by an ophthalmologist.
B. Chronic dacryocystitis: Refer the client to an ophthalmologist for irrigation and probing if needed.
C. Lab studies are generally performed by an ophthalmologist.

INDIVIDUAL CONSIDERATIONS
A. Adults/Geriatrics:
1. Referral to an ophthalmologist for acute and chronic condition.

DRY EYES

DEFINITION
A. Insufficient lubrication of the eye, or dry eyes, is due to a deficiency of any one of the major components of the tear film.
B. Defects in tear production are uncommon but may occur in conjunction with systemic disease. Presence of systemic disease should be evaluated.

INCIDENCE

A. Increased incidence of dry eyes in the elderly is due to decreased rate of lacrimal gland secretions. It has been estimated as a concern in as many as 30% of people 50 years of age and older.

B. The elderly population is vulnerable to dry eye disease due to their decreased rate of lacrimal gland secretions.

PATHOGENESIS

A. Decreased production of one or more components of the tear film results in dry eyes. The tear film comprises three layers:

1. An outermost lipid layer, excreted by the lid meibomian glands.

2. A middle aqueous layer, secreted by the main and accessory lacrimal glands.

3. An innermost mucinous layer, secreted by conjunctival goblet cells.

B. A defect in production of the aqueous phase by lacrimal glands causes dry eyes (keratoconjunctivitis sicca). The condition most often occurs as a physiologic consequence of aging, and it is commonly exacerbated by dry environmental factors. It may also develop in clients with connective tissue disorders.

C. In Sjögren syndrome, the lacrimal glands become involved in immune-mediated inflammation.

D. Mucin production may decline in the setting of vitamin A deficiency.

E. Loss of goblet cells can occur secondary to chemical burns.

PREDISPOSING FACTORS

A. History of severe conjunctivitis.

B. Eyelid defects such as fifth or seventh cranial nerve palsy, incomplete blinking, exophthalmos, and lid movement hindered by scar formation.

C. Drug-induced conditions, including use of anticholinergic agents:

1. Phenothiazine.

2. Tricyclic antidepressants.

3. Antihistamines.

4. Diuretics.

5. Isotretinoin (Accutane).

D. Systemic diseases such as rheumatoid disease, Sjögren syndrome, and neurologic disease.

E. Environmental factors such as heat (wood, coal, gas), air conditioners, winter air, and tobacco smoke.

F. Use of contacts.

G. Increasing age and associated loss of androgens.

H. Lipid abnormalities.

COMMON COMPLAINTS

A. Ocular fatigue.

B. Foreign-body sensation in the eye.

C. Itching, burning, irritation, or dryness sensation in the eye.

D. Redness.

E. Eye discharge.

F. Heavy eyelid sensation.

OTHER SIGNS AND SYMPTOMS

A. Photophobia.

B. Cloudy, blurred vision.

C. Rainbow of color around lights. Acute angle-closure glaucoma can present with a red, painful eye; cloudy, blurred vision and a rainbow of color around lights; dilatation of the pupil; and nausea and vomiting.

D. Bell palsy, signs of stroke, or other conditions that affect the blinking mechanism.

SUBJECTIVE DATA

A. Elicit onset, duration, and frequency of symptoms.

B. Note factors that worsen or alleviate symptoms.

C. Note medical history for systemic conditions and strokes.

D. List current medications, noting anticholinergic drugs and isotretinoin (Accutane) use.

E. Note whether the client wears contact lenses or glasses and ask for what length of time.

F. Review occupational and home exposure to irritants, allergens, and fans.

G. Assess whether the client produces tears. Note eye drainage amount, color, and frequency.

H. Review history of any ocular disease, surgeries, or autoimmune disorders.

I. Ask about dry mouth (as another symptom in association with Sjögren syndrome).

J. Confirm no foreign-body sensation or risk of exposures to foreign bodies.

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure.

B. Inspect:

1. Observe and evaluate *both* eyes.

2. Conduct a detailed eye exam. Check the eye, lid, and conjunctiva for masses, corneal abrasions, foreign bodies, and redness.

3. Check pupil reactivity and corneal clarity. The corneal reflex should be checked if there is concern for neuroparalytic keratitis or facial nerve palsy.

4. Complete a funduscopic exam. Check for completeness of lid closure as well as position of eyelashes.

5. Examine mouth for dryness.

6. Inspect skin for butterfly rash.

C. Palpate:

1. Palpate lacrimal ducts for drainage.

2. Invert upper lid and check for foreign body or chalazion.

3. Check sinuses for tenderness.

4. Palpate thyroid.

5. Palpate joints for warmth and redness or inflammation.

DIAGNOSTIC TESTS

A. There is no "gold standard" for the diagnosis of dry eye syndrome. Clinical diagnosis using a thorough history and physical exam should be considered. Validated questionnaires include the following:

1. Ocular Surface Disease Index (OSDI).

2. Impact of Dry Eye on Everyday Life (IDEEL).

3. Salisbury Eye Evaluation (SEE) Questionnaire.

B. A Schirmer test has variable results between examiners. To perform Schirmer test, use Whatman no. 41 filter paper, 5 mm by 35 mm. A folded end of filter paper is hooked over the lower lid nasally and the client is instructed to keep their eyes lightly closed during the test. Wetting is measured after 5 minutes; less than 5 mm is usually abnormal.

C. Slit-lamp exam.

DIFFERENTIAL DIAGNOSES

A. Dry eyes.

B. Stevens–Johnson syndrome.

C. Sjögren syndrome: The triad of chronic dry mouth, dry eyes, and arthritis suggests Sjögren syndrome. Facial telangiectasias, parotid enlargement, Raynaud syndrome, and dental caries are associated features. Clients complain first of burning ▶

and a sandy, gritty, foreign-body sensation, particularly later in the day.
D. Systemic lupus erythematosus.
E. Scleroderma.
F. Ocular pterygium.
G. Superficial pemphigoid.
H. Vitamin A deficiency.

PLAN

A. General interventions:
1. If no ocular disease is present, reduce environmental dryness by use of a room humidifier, eliminate fans, and reduce screen time, for a 2-week trial.
2. Apply artificial tear substitutes and nonprescription drops.
3. Consider stopping medications being used that may be contributing to dry eye symptoms.
4. Caution should be used when using over-the-counter (OTC) allergy medications, if allergy is a contributing cause. Topical antihistamines may exacerbate the condition over time or cause systemic side effects in the elderly.
B. Client teaching: *See Client Teaching Guide for this chapter, "How to Administer Eye Medications."*
C. Pharmaceutical therapy:
1. Topical artificial tears one or two drops QID, preferably one without preservatives (e.g., TheraTears, dry eye therapy, and Tears Naturale).
2. Drops may be instilled as often as desired.
3. Cyclosporine ophthalmic drops 0.05% or 0.01% one drop BID have been shown to reduce symptoms of dry eye. Six weeks of treatment may be needed before an effect is appreciated. OTC artificial tears may be used in addition.
4. Oral antioxidants and omega-3 fatty acids have shown some promise in reducing symptoms of dry eye.
5. Lifitegrast 5% one drop to each eye Q12H. This is usually ordered by ophthalmology.

FOLLOW-UP

A. Reevaluate the client in 2 weeks.

CONSULTATION/REFERRAL

A. Refer the client to an ophthalmologist if symptoms are unrelieved at 2-week follow-up.
B. Make an immediate referral for red eye, visual disturbance, or eye pain.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:
1. The rate of lacrimal gland secretions diminishes with aging; therefore, the elderly are at an increased risk of developing dry eye.
2. Angiotensin-converting enzyme (ACE) inhibitors may reduce the risk of dry eye syndrome in some clients. Consider treatment with ACE inhibitors for hypertension (HTN) as appropriate in clients.
3. Assess use of OTC antihistamines and decongestants that can cause dry eye.
4. Evaluate for autoimmune disorders, including rheumatoid arthritis, scleroderma, and thyroid disorder, as well as possible vitamin D and vitamin A deficiencies.
5. Rule out neurogenerative disorders such Parkinson disease as symptoms of dry eyes.
6. Consider environmental adjustments, room humidifiers, and goggles/moisture chambers to fit eyewear (wear occasionally), and instruct older adults to frequently blink to increase natural eye lubrication. Keep eyes moistened during the day with artificial tear formulations and with ophthalmic gel solutions at night (e.g., Systane gel drop lubricant).

EXCESSIVE TEARS

DEFINITION

A. Excessive tears disorder is an overproduction of tears. Complaints vary from watery eyes to overflowing tears that run down the cheeks, a condition known as epiphora.

INCIDENCE

A. The incidence is unknown. Previous research has reported the highest incidence of excessive tearing is in individuals between 50 and 70 years old and is more prevalent in females.

PATHOGENESIS

A. The most common cause is reflex overproduction of tears (as occurs in the elderly) due to a deficiency of the tear film.
B. Lacrimal pump failure and obstruction of the nasolacrimal outflow system are other causes of excessive tears.
C. Canalicular infections may be caused by *Actinomyces israelii* (*Streptothrix*) and *Candida*.

PREDISPOSING FACTORS

A. Blepharitis (inflammation of the eyelid).
B. Allergic conjunctivitis (infectious or foreign body).
C. Exposure to cold, air conditioning, or dry environment.
D. Lid problems: impaired pumping action of the lid motion due to seventh nerve palsy or conditions that stiffen the lids, such as scars or scleroderma.
E. Lid laxity from aging or ectropion (sagging of the lower lid).
F. Sinusitis.
G. Atopy.
H. Age: increased incidence in the elderly due to an overproduction of tears by the lacrimal gland.
I. Congenital obstruction.

COMMON COMPLAINTS

A. Watery eyes or tears running down cheeks are common complaints.

OTHER SIGNS AND SYMPTOMS

A. Unilateral tearing: obstructive etiology.
B. Bilateral tearing: environmental irritants.

SUBJECTIVE DATA

A. Inquire about onset, course, and duration of symptoms. Note frequency of excessive tearing. ▶

B. Ascertain whether this is a new symptom or whether the client has a history of similar complaints. Ask how it was treated and what the response was to treatment(s).
C. Determine severity. Do the tears run down the cheek?
D. Ascertain whether tearing is unilateral or bilateral.
E. Review common environmental predisposing factors.
F. Question the client regarding vision changes.
G. Review medical history.
H. Review recent history for sinus infections or drainage, facial fractures, and surgery.
I. Confirm no pain associated with condition.

PHYSICAL EXAMINATION

A. Inspect:
1. Evaluate *both* eyes.
2. Observe the lid structure and motion.
3. Conduct a dermal exam to rule out butterfly rash.
4. Confirm pupil reactivity.
5. Perform a funduscopic exam for vascular changes.
B. Palpate:
1. Apply gentle pressure over the lacrimal sac to check drainage.
2. Invert upper lid to check for foreign body.
3. Palpate face for sinus tenderness.

DIAGNOSTIC TEST

A. Culture any drainage expressed from the lacrimal sacs.

DIFFERENTIAL DIAGNOSES

A. Excessive tears.
B. Dendritic ulcer: Early symptoms are tears running down cheeks associated with a foreign-body sensation.
C. Congenital glaucoma.
D. Dacryocystitis (purulent discharge).
E. Reflex tearing caused by dry eye.
F. Blepharitis.

PLAN

A. General interventions:
1. Eliminate identifiable irritants.
2. Treatment is aimed mainly at the underlying condition (e.g., ocular infection).
3. Dacryocystitis is treated with hot compress at least four times a day and with systemic antibiotics.
B. Client teaching:
1. Instruct the client on the application of compress if dacryocystitis is suspected.
2. After pathology is ruled out, reassure the client excessive tearing is common and more frequent with aging.
C. Pharmaceutical therapy:
1. None required for diagnosis of excessive tears without infectious pathology.
2. Dacryocystitis:
a. Erythromycin 250 mg QID for 7 days.
b. Dicloxacillin 250 mg QID for 7 days.

FOLLOW-UP

A. See client in 48 to 72 hours to evaluate symptoms, especially if antibiotic therapy was needed for infection.

CONSULTATION/REFERRAL

A. Clients unresponsive to treatment should be promptly referred to an ophthalmologist.
B. Consider referral for lid malposition or nasolacrimal duct obstructions.

INDIVIDUAL CONSIDERATIONS

A. Adults:
1. Consider mental health support if condition alters self-image and limits socialization.
B. Geriatrics:
1. Encourage geriatric clients to protect eyes when traveling (airplanes, dry environments, and hot rooms during winter) and when facing exposure to windy areas, bright sunlight, and abrupt temperature changes. All these sources could easily cause older adults with dry eyes to excessively tear.
2. If shielding/protective measures do not resolve the symptom, further evaluate for infection or blocked tear duct. Common causes of increased tear production in geriatrics are dry eyes, allergic sinusitis, and upper respiratory infections.
3. How to determine dry eyes versus obstruction (excessive tears vs. nasolacrimal drainage) is as follows: If tears do not run down the cheeks, then it most likely is dry eyes. If tears run down the cheeks, then it most likely is nasolacrimal drainage. Unexplained excessive tears (epiphora) in geriatric clients will need to be referred to a specialist for further evaluation to rule out tumors or abscess.

Patel, J., Levin, A., & Patel, B. C. (2021). *Epiphora*. *StatPearls NCBI Resources*. https://www.ncbi.nlm.nih.gov/books/NBK557449/
Worak, S., Bengzon, A., Law, S., Roy, H., Pelton, R., & Camara, J. (2018). *Nasolacrimal duct obstruction and epiphora*. Epiphora: Ophthalmology. *MedScape*, e1–e17. https://emedicine.medscape.com/article/1210141-overview

EYE PAIN

DEFINITION

A. Sensation of pain may affect the eyelid, conjunctiva, or cornea.

INCIDENCE

A. Unknown. Pain in the eye is most often produced by conditions that do not threaten vision.

PATHOGENESIS

A. The external ocular surfaces and the uveal tract are richly innervated with pain receptors. As a result, lesions or disease processes affecting these surfaces can be acutely painful.
B. Pathology confined to the vitreous, retina, or optic nerve is rarely a source of pain.

PREDISPOSING FACTORS

A. Eyelids: inflammation such as hordeolum (stye), trichiasis (in-turned lash), and tarsal foreign bodies.
B. Conjunctiva: viral and bacterial conjunctivitis or allergic conjunctivitis; or toxic, chemical, and mechanical injuries.
C. Cornea: keratitis (inflammation of the cornea) accompanying trauma, infection, exposure, vascular disease, or decreased lacrimation; microbial keratitis from contact use. If blood vessels invade the normally avascular corneal stroma, vision may become cloudy. Severe pain is a prominent symptom; movement of the lid typically exacerbates symptoms.

COMMON COMPLAINTS

A. Eye pain (sharp, dull, deep): The quality of the pain needs to be considered. Deep pain is suggestive of an intraocular problem. Inflammation and rapidly expanding mass lesions may cause deep pain. Displacement of the globe and diplopia may ensue. ▶

B. Eye movement may cause sharp pain due to meningeal inflammation (the extraocular rectus muscles insert along the dura of the nerve sheath at the orbital apex). Most cases are idiopathic, but 10% to 15% are associated with multiple sclerosis.

OTHER SIGNS AND SYMPTOMS

A. Symptoms may be unilateral or bilateral.
- **1.** Eyelids:
  - a. Tenderness.
  - b. Foreign-body sensation.
  - c. Redness.
  - d. Edema.
- **2.** Conjunctiva:
  - a. Mild burning.
  - b. Foreign-body sensation.
  - c. Itching (allergic).
- **3.** Cornea:
  - a. Burning.
  - b. Foreign-body sensation.
  - c. Considerable discomfort.
  - d. Reflex photophobic tearing.
  - e. Pain exacerbated by blinking.
  - f. Pain relieved with pressure holding the lid shut. With a foreign body or a corneal lesion, pain is exacerbated by lid movement and relieved by cessation of lid motion.
- **4.** Sclera:
  - a. Redness or vessel injection.
- **5.** Uveal tract (uveitis or iritis):
  - a. Dull, deep-seated ache and photophobia.
  - b. Profound ocular and orbital pain radiating to the frontal and temporal regions accompanying sudden elevation of pressure (acute angle-closure glaucoma).
  - c. Vagal stimulation with high pressure may result in nausea and vomiting.
  - d. Usual history of mild intermittent episodes of blurred vision preceding onset of throbbing pain, nausea, vomiting, and decreased visual acuity.
  - e. Halos around light.
- **6.** Orbit:
  - a. Deep pain with inflammation and rapidly expanding mass lesions.
  - b. Eye movement causing sharp pain due to meningeal inflammation.
- **7.** Sinusitis:
  - a. Secondary orbital inflammation and tenderness on extremes of eye movement.

SUBJECTIVE DATA

A. Review the onset, duration, and course of symptoms. Inquire regarding the quality of pain.
B. Review any predisposing factors such as trauma or a foreign object. Ask: Was the onset sudden or gradual?
C. Note reported changes in visual acuity or color vision.
D. Note aggravating or alleviating factors.
E. Determine whether the eye pain is bilateral or unilateral.
F. Review history for herpes, infections, and toxic or chemical irritants.
G. Review history for glaucoma and previous eye surgeries or treatments.
H. Assess the client for any other symptoms, such as migraine headache, sinusitis, or tooth abscess.
I. Inquire whether the client has lost a large amount of sleep or slept with contact lenses.
J. Inquire whether they have been exposed to a large amount of UV light or sunlight (vacation, tanning beds).
K. Review history for any other medical problems, such as lupus, sarcoidosis, or inflammatory bowel disease.

PHYSICAL EXAMINATION

A. Inspect:
- **1.** Evaluate *both* eyes.
- **2.** Test visual acuity and color vision.
- **3.** Observe for extraocular eye movements (EOMs) and visual fields.
- **4.** Check the eye, lid, and conjunctiva for masses, foreign bodies, and redness.
- **5.** Check pupil reactivity and corneal clarity.
- **6.** Conduct a funduscopic exam for disc abnormalities.
- **7.** Perform ear, nose, and throat exam.

B. Palpate:
- **1.** Palpate lacrimal ducts for drainage.
- **2.** Palpate sinuses for tenderness.
- **3.** Invert upper lid and check for foreign body or chalazion.
- **4.** Palpate the periorbital skin for tenderness.

DIAGNOSTIC TESTS

A. Fluorescein stain.
B. Measurement of intraocular pressure (IOP).

DIFFERENTIAL DIAGNOSES

A. Eye pain.
B. Hordeolum.
C. Chalazion.
D. Acute dacryocystitis.
E. Irritant exposure.
F. Conjunctival infection.
G. Corneal abrasion.
H. Foreign body or other trauma.
I. Ulcers.
J. Ingrown lashes.
K. Contact lens abuse.
L. Scleritis.
M. Acute angle-closure glaucoma: Fixed, midposition pupil, redness, and a hazy cornea may be present.
N. Uveitis.
O. Referred pain from extraocular sources such as sinusitis, tooth abscess, tension headache, temporal arteritis, and prodrome of herpes zoster.
P. Iritis.
Q. Bacterial keratitis.
R. Temporal arteritis.
S. Cluster headache.
T. Optic neuritis.
U. Orbital cellulitis.

PLAN

A. General interventions:
- **1.** The initial task is to be sure that there is no threat to vision.
- **2.** Treatment modality depends on the underlying cause of eye pain.

B. Client teaching: *See Client Teaching Guide for this chapter, "How to Administer Eye Medications."*

C. Pharmaceutical therapy:
  1. Medication depends on the underlying cause.

FOLLOW-UP
A. Follow-up depends on the underlying cause.

CONSULTATION/REFERRAL
A. Any change in visual acuity or color vision requires an urgent ophthalmologic consultation (same-day referral).

INDIVIDUAL CONSIDERATIONS
A. Geriatrics:
  1. Common pain medications for geriatric eye pain:
    a. Acular 0.5% one drop three to four times a day (maximum 2 weeks). Caution on risk of bleeding secondary to nonsteroidal anti-inflammatory drug (NSAID) classification.
    b. Lidocaine ophthalmic gel 3.5% (Akten) two drops to ocular surface or tetracaine 0.5% eye drops one drop to ocular surface. These anesthetic medications are usually implemented in-clinic for severe pain or applied prior to an ocular procedure/surgery.

GLAUCOMA, ACUTE ANGLE CLOSURE

DEFINITION
A. Acute angle-closure glaucoma is an ocular emergency caused by elevations in intraocular pressure (IOP) that damage the optic nerve, leading to loss of peripheral fields of vision; this leads to loss of central vision, resulting in blindness.

INCIDENCE
A. Acute angle-closure glaucoma is the second leading cause of blindness in the United States. Ten percent of glaucoma cases are due to angle-closure glaucoma. Approximately 5% to 15% of the population develop some form of glaucoma.

PATHOGENESIS
A. The essential pathophysiologic feature of glaucoma is an IOP that is too high for the optic nerve. Increased IOP increases vascular resistance, causing decreased vascular perfusion of the optic nerve and ischemia. Light dilates the pupil, causing the iris to relax and bow forward. As the iris bows forward, it comes into contact with the trabecular meshwork and occludes the outflow of aqueous humor, resulting in increased IOP.

PREDISPOSING FACTORS
A. Narrow anterior ocular chamber.
B. Prolonged periods of darkness.
C. Drugs that dilate the pupils (e.g., anticholinergics).
D. Advancing age.
E. African American heritage.
F. Family history.
G. Trauma.
H. Neoplasm.
I. Corticosteroid therapy.
J. Neovascularization.
K. Female sex.
L. Hyperopia (farsightedness).

COMMON COMPLAINTS
A. Ocular pain.
B. Blurred vision, decreased visual acuity, "cloudiness" of vision.
C. "Halos" around lights at night.
D. Neurologic complaints (headache, nausea, or vomiting).

OTHER SIGNS AND SYMPTOMS
A. Red eye with ciliary flush. Ciliary flush is a red or purple ring that surrounds the cornea which expands beyond the ring.
B. "Silent blinder" is a nickname used for glaucoma. It causes extensive damage before the client is aware of visual loss.
C. Dilated pupil.
D. Hard orbital globe.
E. No pupillary response to light.
F. Increased IOP (normal IOP is 10–20 mmHg).

SUBJECTIVE DATA
A. Review the onset, course, and duration of symptoms; note visual changes in one or both eyes. Do symptoms get worse in early evening?
B. Review medical history and medications, including over-the-counter (OTC) products.
C. Review family history of glaucoma.
D. Determine whether there has been any difficulty with peripheral vision, any headache photophobia, or any visual blurring.
E. Rule out presence of any chemical, trauma, or foreign bodies in the eye.
F. Review any recent history of herpes outbreak.
G. Ask the client whether this has ever occurred before, and if so how it was treated.
H. Determine if IOP has been measured in the past.

PHYSICAL EXAMINATION
A. Check blood pressure.
B. Inspect:
  1. Examine both eyes.
  2. Rule out foreign bodies.
  3. Inspect for redness, inflammation, and discharge.
  4. Check pupillary response to light.
  5. Note redness around the iris, if the pupil is dilated, and if the cornea appears cloudy.
  6. Inspect anterior chamber of eye by holding penlight laterally and directing toward nasal area. Shallow chamber will cast a shadow on the nasal side of the iris.
  7. Facial symmetry.
  8. Cranial nerves.
  9. Strength of upper/lower extremities.

▶

10. Funduscopic exam: This may reveal notching of the cup and a difference in cup-to-disc ratio between the two eyes.

C. Palpate:

1. Palpate the globe of the eye, which will feel firm on palpation.

DIAGNOSTIC TESTS

A. Check visual acuity and peripheral fields of vision.

B. Measure IOP with a tonometer. Normal level is 10 to 21 mmHg; IOP in acute angle-closure glaucoma is often 30 to 50 mmHg. Tonometer exam is not recommended if external infection is present.

C. Slit-lamp exam: edematous and/or cloudy cornea.

D. Gonioscopy (gold standard) using a slit lamp. Exam typically performed by optometrist or ophthalmologist.

DIFFERENTIAL DIAGNOSES

A. Acute angle-closure glaucoma.

B. Acute iritis.

C. Acute bacterial conjunctivitis.

D. Iridocyclitis.

E. Corneal injury.

F. Foreign body.

G. Herpetic keratitis.

H. Cerebrovascular accident (CVA).

PLAN

A. General interventions:

1. Severe attacks can cause blindness in 2 to 3 days. Same-day referral is critical if angle-closure glaucoma is suspected. Vision loss is irreversible. Treatment is aimed at preventing further vision loss**. Seek medical attention immediately to prevent permanent vision loss**.

2. Frequency of attacks is unpredictable.

3. All pressure changes greater than 21 mmHg need further evaluation from an ophthalmologist.

B. Client teaching: *See Client Teaching Guide for this chapter, "How to Administer Eye Medications."*

C. Pharmaceutical therapy:

1. Management **must be instituted by an ophthalmologist**. If evaluation and treatment by an ophthalmologist are projected to be greater than 1 hour, initial treatment to lower pressures should be considered with the following:

a. Timolol maleate 0.5%.
b. Pilocarpine (Pilocar) 2%.
c. Apraclonidine 1%.

D. Surgical intervention:

1. Surgery is indicated if IOP is not maintained within normal limits with medications or if there is progressive visual field loss with optic nerve damage.

2. Surgical treatment of choice is peripheral iridectomy: excision of a small portion of the iris whereby the aqueous humor can bypass the pupil.

3. Laser peripheral iridotomy: creates on opening in the peripheral iris to reduce pressures against the optic nerve.

FOLLOW-UP

A. Annual eye exams by an ophthalmologist are necessary to monitor IOP and treatment efficacy.

CONSULTATION/REFERRAL

A. All clients should be referred to an ophthalmologist *immediately* for measurement of IOP, acute management, and possible surgical intervention (laser peripheral iridectomy).

INDIVIDUAL CONSIDERATIONS

A. Adults:

1. Females normally have slightly higher IOPs than males.

2. Asians may have higher IOPs than African Americans and Caucasians.

3. Individuals older than age 40 should have their IOP measured periodically. Every 3 to 5 years is sufficient after a stable baseline is established for the client.

B. Geriatrics:

1. Incidence increases with age, usually in those older than 60.

2. Medications that have anticholinergic properties may adversely affect clients with narrow-angle glaucoma. These medications are used to treat diseases such as the following:

a. Asthma/chronic obstructive pulmonary disease (COPD): ipratropium bromide (Atrovent) or tiotropium bromide (Spiriva).
b. Incontinence/overactive bladder: tolterodine (Detrol), fesoterodine (Toviaz), darifenacin (Enablex), solifenacin (Vesicare), and oxybutynin (Ditropan).
c. Gastrointestinal problems: cimetidine (Tagamet).
d. Muscle spasms: orphenadrine and trihexyphenidyl.
e. Depression: selective serotonin reuptake inhibitors (SSRIs) such as fluoxetine (Prozac) and paroxetine (Paxil), and tricyclic antidepressants such as amitriptyline (Elavil) and imipramine (Tofranil).
f. Allergies: antihistamines OTC that contain diphenhydramine.
g. Nausea: promethazine (Phenergan).
h. Anxiety: hydroxyzine (Vistaril).
i. Colds: medications containing ephedrine.

3. Use caution when using medications containing sulfonamide-containing drugs, such as topiramate (Topamax), acetazolamide (Diamox Sequels), quinine (Qualaquin), tetracycline (Sumycin), and trimethoprim-sulfamethoxazole (Bactrim).

4. Chronic use of oral steroids may affect open-angle glaucoma and should be avoided if possible.

5. Long-term use of steroids may also increase the risk of developing cataracts.

HORDEOLUM (STYE)

DEFINITION

A. Hordeolum is an infection of the glands of the eyelids (follicle of an eyelash or the associated gland of Zeis [sebaceous] or Moll gland [apocrine sweat gland]), usually caused by *Staphylococcus aureus*.

1. If swelling is under the conjunctival side of eyelid, it is an internal hordeolum. ▶

2. If swelling is under the skin of the eyelid, it is an external hordeolum.

INCIDENCE

A. The incidence is unknown; it is more common in children and adolescents than in adults.

B. Clients with recurrent blepharitis, seborrheic dermatitis, rosacea, diabetes, and hyperlipidemia are at an increased risk of hordeola development.

PATHOGENESIS

A. Acute bacterial infection of the meibomian gland (internal hordeolum) or of the eyelash follicle (external hordeolum) is usually caused by *S. aureus*.

PREDISPOSING FACTORS

A. Age: commonly seen in adults.

B. Meibomian gland dysfunction.

C. Rosacea.

COMMON COMPLAINTS

A. Eye tenderness.

B. Sudden onset of a purulent discharge.

C. Painful bump on the edge of the eyelid.

OTHER SIGNS AND SYMPTOMS

A. Redness and swelling of the eye.

SUBJECTIVE DATA

A. Review the onset, course, and duration of symptoms.

B. Determine whether there is any visual disturbance.

C. Note whether this is the first occurrence. If not, ask how it was treated before.

D. Evaluate how much pain or discomfort the client is experiencing.

E. Review the client's history for chemical, foreign body, and/or trauma etiology.

F. Review the client's medical history and medications.

G. Does the client have a history of rosacea or frequent meibomian gland dysfunction?

PHYSICAL EXAMINATION

A. Inspect:

1. Examine both eyes; note redness, site of swelling, and amount and color of discharge.

2. Evert the lid and check for pointing.

3. Assess sclera and conjunctivae for abnormalities.

4. Inspect ears, nose, and throat.

B. Palpate:

1. Palpate eye for hardness and expression of discharge.

2. Evaluate for preauricular adenopathy.

DIAGNOSTIC TESTS

A. Test visual acuity.

B. Discharge can be cultured but is usually treated presumptively.

DIFFERENTIAL DIAGNOSES

A. Hordeolum.

B. Chalazion: the main differential diagnosis, which points to the conjunctival side of the eyelid and does not usually affect the margin of the eyelid.

C. Blepharitis.

D. Xanthoma.

E. Bacterial conjunctivitis.

F. Foreign body.

G. Basal cell carcinoma/sebaceous cell carcinoma.

PLAN

A. General interventions:

1. Most lesions will drain without any treatment. Warm compress and massage to the area may help facilitate drainage.

2. Lid scrubs with a mild baby shampoo may promote drainage.

3. Larger, persistent lesions may require antibiotic therapy. Contain the infecting pathogen. Crops occur when the infectious agent spreads from one hair follicle to another.

B. Client teaching: *See Client Teaching Guide for this chapter, "How to Administer Eye Medications."*

1. Apply warm compress to eye 10 to 15 minutes four times a day for comfort.

2. Instruct on proper eyelid hygiene and good handwashing.

3. Clients should discard all eye makeup, including mascara, eyeliner, and eye shadow.

C. Pharmaceutical therapy:

1. If hordeolum does not resolve with warm compress within 5 days or if multiple sites are infected:

a. Erythromycin ophthalmic 0.5% ointment 1 cm to affected eye up to six times daily.

b. If crops of sties occur, some clinicians recommend a course of tetracycline to stop recurrences (consult with a physician).

c. If cellulitis of the surrounding tissue is suspected, oral antibiotics that cover *Staphylococcus* are recommended. Oral antibiotics recommended include cephalexin and erythromycin.

FOLLOW-UP

A. Have client telephone or visit the office in 48 hours to check response.

B. If crops occur, diabetes mellitus must be excluded. Perform blood glucose evaluation.

C. Recommended follow-up appointment in 2 weeks.

CONSULTATION/REFERRAL

A. Hordeolum may produce a diffuse superficial lid infection, preseptal cellulitis, requiring referral to an ophthalmologist.

B. If hordeolum does not respond to topical antimicrobial treatment, refer the client to an ophthalmologist for possible incision and drainage if indicated.

C. Recurrent lesions should be referred to an ophthalmologist for further evaluation and treatment (biopsy) for possible basal cell carcinoma or sebaceous cell carcinoma.

INDIVIDUAL CONSIDERATIONS

A. Adults:

1. Recurrent lesions should be referred to a specialist for evaluation and workup for possible carcinoma.

2. Hordeolums are benign infections and usually respond in 1 to 2 weeks with proper treatment. If lesion has not resolved, further workup is recommended.

3. Address underlying conditions such as rosacea, frequent blepharitis, uncontrolled diabetes, and high cholesterol to prevent recurrent hordeolum in these clients.

B. Geriatrics:

1. Nonpharmacologic treatments include warm compress for 20 to 30 minutes (rewetting washcloth every 5–10 minutes), applying gentle massage, discontinuing wearing contact lens and eye makeup until healed, and encouraging clients to keep hands clean and to not rub their eyes. ▶

2. Pharmacologic treatments common in geriatrics include short-term nonsteroidal anti-inflammatory drugs (NSAIDs) for pain and inflammation and Tobradex ointment three to four times a day for 1 week (combination of an antibiotic and an anti-inflammatory), which would be contraindicated if coexistent with fungal or viral ocular infection.

Carlisle, R. T., & Digiovanni, J. (2015). Differential diagnosis of the swollen red eyelid. *American Family Physician*, *15*(92), 106–112. https://www.aafp.org/afp/2015/0715/p106.html

MACULAR DEGENERATION

DEFINITION

A. Macular degeneration (MD) is the result of age-related changes of the macula (central retina) that result in loss of central vision. MD is the leading cause of blindness in the United States.

INCIDENCE

A. The risk of MD increases with age, with risk starting as early as age 50. It is estimated that MD will affect 2.95 million people by 2025. Currently, 25% of people 75 years of age have some degree of MD and 14% of people older than the age of 84 years struggle with visual loss due to MD. With progressive MD in one eye, the opposite eye has greater than 40% risk of visual loss within 5 years.

PATHOGENESIS

A. There are two types of MD:

1. Dry type (nonneovascular) is secondary to retinal atrophy. The initial cause of the atrophic changes is unclear.

2. Wet type (neovascular) is secondary to abnormal vascular growth in the subretinal space. Immune-mediated inflammation is believed to play a major role in MD.

PREDISPOSING FACTORS

A. Age.
B. Smoking.
C. Family history.
D. Cardiovascular disease.
E. Dietary fat.
F. Cataract surgery.
G. Aspirin use.
H. Excessive alcohol intake (greater than three drinks per day).
I. White race.
J. Obesity.

COMMON COMPLAINTS

A. Gradual loss of vision in one or both eyes.
B. Scotoma (dark patch in the center of the visual field).
C. Distorted straight edges (appearing curved or irregular).

POTENTIAL COMPLICATIONS

A. Blindness resulting in functional impairments.
B. Depression secondary to visual loss.
C. Isolation.

SUBJECTIVE DATA

A. Review the onset, duration, and course of symptoms.
B. Was the change in vision sudden or gradual?
C. Ask if vision loss was unilateral or bilateral?
D. Was distance or near vision affected?
E. Determine family history of MD.
F. Review history of eye disorders and previous eye surgeries or treatments.
G. Review date of last eye exam, including dilation.
H. Review medical history, including current medications.
I. Determine the amount of change in activities of daily living (ADL) due to visual impairment.
J. Ask about perceived safety concerns and history of falls.

PHYSICAL EXAMINATION

A. Check vital signs, including blood pressure.
B. Inspect:

1. Symmetry of eyes and obvious deformities.

2. Pupil symmetry and response to light and accommodation.

3. Assessment of fields of vision and extraocular movements.

4. Funduscopic assessment observing for drusen bodies.

5. Snellen and Rosenbaum screening.

6. Observation of entropion or ectropion.

7. Observation of pterygium.

DIAGNOSTIC TESTS

A. Imaging of dry eye MD (performed by an ophthalmologist or an optometrist).

1. Fluorescein angiogram.

2. Optical coherence tomography.

3. Indocyanine green angiography.

4. Autofluorescence.

B. Imaging of wet eye MD (performed by an ophthalmologist or an optometrist).

1. Fluorescein angiography.

2. Indocyanine green angiography.

3. Optical coherence tomography.

DIFFERENTIAL DIAGNOSES

A. MD.
B. Presbyopia.
C. Cataracts.
D. Glaucoma.
E. Diabetic retinopathy.

PLAN

A. General interventions:

1. Referral to eye specialist for formal diagnosis and prescription for corrective lenses.

2. Discussion of eye health, including routine eye exams and prevention of injury.

B. Client teaching:

1. Prevention: Encourage a healthful diet of fruit, green leafy vegetables, fish, and nuts.

2. Discuss the importance of antioxidants, vitamin C 500 mg, vitamin E 400 IU, lutein 10 mg, zeaxanthin 1 mg, zinc oxide 80 mg, cupric oxide 2 mg, zeaxanthin 2 mg, and omega-3 fatty acids 1,000 mg. These supplements are thought to retard the progression of MD. Beta carotene has been removed from the list of recommendations due to the increased risk of lung cancer, particularly in smokers.

3. Stress the importance of routine eye exams. ▶

4. Emphasize the need to control blood sugar if diabetic and blood pressure if hypertensive.
5. Stress the importance of eye protection, including sunglasses.
6. Healthy lifestyle choices, including an active lifestyle and smoking avoidance, reduce the risk of MD.

C. Pharmaceutical therapy:
1. Ranibizumab, aflibercept, or bevacizumab intravitreal injections may be used by a specialist for treatment.

CONSULTATION/REFERRAL

A. Referral to an optometrist or ophthalmologist is required for accurate diagnosis and treatment.

INDIVIDUAL CONSIDERATIONS

A. Adults:
1. Corrective lenses, additional visual aids, good lighting, and visual rehab should all be considered to reduce functional impairments and isolation from MD.
2. Eye exams are covered, under certain circumstances, by Medicare. Clients can receive up-to-date coverage information at Medicare.gov.

B. Geriatrics:
1. The following link is a web-based age-related macular degeneration (AMD) update page which emphasizes the geriatric's point of view regarding AMD and how practitioners may help meet clients' needs and create shared-decision care plans: www.webrn-maculardegeneration.com/.
2. Current research posits that use of anticholinergic medication for at least 3 months is associated with an increase of AMD (as evidenced by a high Anticholinergic Burden Score). The suggested component contributing to primary lesions of AMD was increase of amyloid-beta deposits from anticholinergic use.
3. Geriatric clients who suffer from AMD have double the rate of depression compared with those without the disease. Evaluate for anxiety, depression, and quality of life issues every annual visit and treat appropriately.
4. Review safety precautions with driving, ambulating, and within the home environment, and examine the ability to perform ADLs at home/work or activities such as shopping, sports, and so forth.
5. Promote dietary modifications that research has suggested to prevent/improve AMD: water-rich foods, vitamin C, zinc oxide, lutein, and fish oil.
6. Vascular endothelial growth factor (VEGF) inhibitors (Avastin and Lucentis) reduce neovascularization, are monthly treatments, and might maintain vision for up to 2 years. Complications include uveitis, increased intraocular pressures, cataracts, and retinal detachment.

REFRACTIVE DISORDERS

DEFINITION

A. Clear vision occurs when the cornea and the crystalline lens bend (refract) light appropriately onto the retina. Refractive errors occur when any component of the optical system malfunctions. Refraction errors are common and correctable. Refractive errors include ametropia (including myopia, hyperopia, astigmatism) and presbyopia.

INCIDENCE

A. Refractive disorders affect more than one-third of people 40 years or older. Myopia and astigmatism are the two most prevalent refractive disorders. Myopia (nearsightedness) is more common in Caucasians and Asians. Astigmatism and presbyopia increase with aging.

PATHOGENESIS

A. Emmetropia (normal refraction) begins in childhood and continues into early adulthood. The etiology of poorly developed emmetropization is unknown.

PREDISPOSING FACTORS

A. Myopia:
1. Genetic predisposition.
2. Reading for long periods.
3. Medications (sulfonamides, diuretics, and cholinergics), the adverse effects of which are reversible with discontinuing medication.
4. Diabetes.
5. Trauma.
6. Excessive accommodation.
7. Cataracts.
8. Older maternal age at birth or maternal smoking.

B. Hyperopia:
1. Trauma.
2. Anticholinergic medications.

COMMON COMPLAINTS

A. Fear of driving or performing usual, common activities due to decreased visual acuity.

POTENTIAL COMPLICATIONS

A. Motor vehicle accidents.
B. Increased risk of falls and hip fractures.
C. Isolation due to fear of leaving familiar environment.

SUBJECTIVE DATA

A. Review the onset, duration, and course of symptoms.
B. Was the change in vision sudden or gradual?
C. Determine family history of refractive disorders.
D. Review history of eye disorders and previous eye surgeries or treatments.
E. Review date of last eye exam, including dilation.
F. Review medical history, including current medications and history of diabetes.
G. Determine if client has used over-the-counter (OTC) corrective lenses and duration of use.
H. Has there been a change in vision associated with headaches?
I. Ask about the amount of up-close work, including reading, computer use, factory assembly, and sewing.
J. Determine the amount of change in activities of daily living (ADLs) due to visual impairment.
K. Ask about perceived safety concerns and history of falls.

PHYSICAL EXAMINATION

A. Check vital signs, including blood pressure.
B. Inspect:
1. Symmetry of eyes and obvious deformities.
2. Pupil symmetry and response to light and accommodation.
3. Assess fields of vision and extraocular movements.
4. Funduscopic assessment.
5. Snellen and Rosenbaum screening.
6. Observe for entropion or ectropion.
7. Observe for pterygium.

DIAGNOSTIC TESTS

A. Phoropter (performed by an optometrist or ophthalmologist).

DIFFERENTIAL DIAGNOSES

A. Cranial nerve dysfunction (cranial nerves II, III, and VI).
B. Transient ischemic attack (TIA)/cerebrovascular accident (CVA).
C. Trauma (if sudden unilateral reduction in acuity).
D. Glaucoma.
E. Space-occupying intracranial lesion.
F. Age-related macular degeneration.
G. Diabetic retinopathy.
H. Cataracts.

PLAN

A. General interventions:
1. Refer to an eye specialist for formal diagnosis and prescription for corrective lenses.
2. Discuss eye health, including routine eye exams and prevention of injury.
B. Client teaching:
1. Importance of routine eye exam.
2. Importance of control of blood sugars if diabetic and blood pressure if hypertensive.
3. Importance of eye protection, including quality sunglasses.

CONSULTATION/REFERRAL

A. Referral to an eye specialist is required for accurate diagnosis following initial eye screening.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
1. Increase in estrogen and progesterone in pregnancy is associated with vision change of myopia or hyperopia.
2. Advanced maternal age, higher parity, regular television watching, and computer use contribute to refractory changes seen.
B. Adults:
1. Refraction errors are more common with aging, especially myopia, presbyopia, and astigmatism. At 40 years of age, clients should expect presbyopic changes.
2. Diabetic retinopathy, although not a refractive error, is a leading cause of blindness. Clients should receive an annual ophthalmic exam.
3. Eye exams are covered under certain circumstances by Medicare. Clients can receive up-to-date coverage information at Medicare.gov.
C. Geriatrics:
1. Safe driving: age-related vision changes to evaluate and discuss with older adults ≥60 years old:
a. Ability to see road sign clearly decreases.
b. The vehicle's instrument panel becomes blurry and it is difficult to quickly adjust from road to panel.
c. Challenges in judging distances.
d. Color perception changes.
e. Night vision ability decreases.
f. Pain and difficulty adjusting to sunlight/headlights.
g. Peripheral vision loss.
2. Avoid wearing eyeglasses or sunglasses with wide frames or side-arm temples that could restrict vision.
3. Suggest handheld or stand magnifiers when viewing labels or doing tasks such as sewing, puzzles, nail hygiene, and so forth. Consider video magnification for computers/monitors. Avoid overuse of eyes, causing "tired eyes." Consider using talking timepieces, audio books, and apps that read aloud internet news and social media comments.
4. Allow geriatric clients to express feelings of vision loss and assist with eyesight solutions to assure safety and quality of life.

RETINOPATHY

DEFINITION

A. Retinopathy is damage of retinal blood vessels most commonly due to pathology secondary to hyperglycemia (diabetic retinopathy). There are two major categories of retinopathy: nonproliferative and proliferative. Retinopathy is further classified into nonproliferative stages—mild, moderate, severe, and very severe—and proliferative stages—early, high risk, and severe. Symptoms do not present until late in the disease process. Retinopathy is a risk marker of higher rates of morbidity and mortality from cardiovascular disease.

INCIDENCE

A. Diabetic retinopathy is the leading cause of blindness of adults between the ages of 25 and 74 years, occurring in 77.3% of those with type 1 diabetes and 25.1% of those with type 2 diabetes.

PATHOGENESIS

A. Nonproliferative retinopathy is due to nerve fiber damage, retinal hemorrhages, microaneurysms, or tortuous/dilated retinal vessels.
B. Proliferative retinopathy is due to neovascularization vessel growth that produces harmful changes in the retinal bed, including preretinal or vitreous hemorrhages, fibrosis, and retinal detachment.
C. Macular edema may occur during any stage of retinopathy.

PREDISPOSING FACTORS
A. Diabetes, including gestational diabetes.
B. Uncontrolled hypertension (HTN).
C. Smoking.
D. Chronic kidney disease.
E. Dyslipidemia.

COMMON COMPLAINTS
A. Visual impairments are not common until pathologic changes are well established.
B. "Curtain falling" or floaters may be mentioned in vitreous hemorrhage.

POTENTIAL COMPLICATIONS
A. Loss of independence due to visual impairments.
B. Loss of employment.
C. Motor vehicle accidents.
D. Isolation due to fear of leaving familiar environment.
E. Depression.

SUBJECTIVE DATA
A. Review the onset, duration, and course of symptoms.
B. Was the change in vision sudden or gradual?
C. Discuss home glucose monitoring and results.
D. Review history of eye disorders and previous eye surgeries or treatments.
E. Review date of last eye exam, including dilation.
F. Review medical history, including current medications and year of onset of diabetes or HTN.
G. Determine if client has used over-the-counter (OTC) corrective lenses for self-treatment and determine duration of use.
H. Determine the level of change in activities of daily living (ADLs) due to visual impairment.

PHYSICAL EXAMINATION
A. Check vital signs, including blood pressure.
B. Inspect:
1. Symmetry of eyes and obvious deformities.
2. Pupil symmetry and response to light and accommodation.
3. Assessment of fields of vision and extraocular movements.
4. Funduscopic assessment.
5. Snellen and Rosenbaum screening.

DIAGNOSTIC TESTS
A. Funduscopic exam, dilated.
B. Fluorescein angiography (performed by an optometrist or ophthalmologist).
C. Hemoglobin A1c.

DIFFERENTIAL DIAGNOSES
A. Diabetic retinopathy.
B. Hypertensive retinopathy.

PLAN
A. General interventions:
1. Identify the possible diagnosis of retinopathy and refer to an eye specialist for formal diagnosis.
2. Panretinal laser photocoagulation for proliferative retinopathy (ophthalmology).
3. Vitreous surgery (ophthalmology).
4. Clients diagnosed with diabetes are encouraged to improve their glucose levels.
B. Client teaching:
1. Advise the client on the importance of routine eye exams.
2. Discuss the importance of good control of blood sugar if diabetic and blood pressure if hypertensive.
3. Lifestyle modifications: smoking cessation, weight loss, dietary changes, reduction of alcohol.
4. Proliferative diabetic retinopathy clients need to avoid any exercise that may raise blood pressure due to increased risk of retinal hemorrhage or detachment.
C. Pharmaceutical therapy:
1. None. The client is followed by an ophthalmologist.

CONSULTATION/REFERRAL
A. Referral is required for accurate diagnosis following initial funduscopic screening.

INDIVIDUAL CONSIDERATIONS
A. Adults:
1. Retinopathy is the leading cause of blindness between the ages of 25 and 74. Clients should receive an annual ophthalmic exam.
2. Retinopathy can be slowed based on the stage of progression. Early diagnosis is key to sight-saving intervention.
B. Geriatrics:
1. The highest risk factors for older adult retinopathy are uncontrolled diabetes, uncontrolled HTN, and smoking. Retinopathy changes can start when client is in the prediabetic phase of Type 2 diabetes
2. Vascular endothelial growth factor (VEGF) inhibitors are becoming first-line treatment for retinopathy. These medications (Avastin and Lucentis) can cause macular edema (swelling of the central part of the eye), which is associated with retinopathy (ischemia and vitreous hemorrhage).
3. Manage glycemic levels specifically related to comorbidities and the client's life expectancy. (Individuals in hospice have less stringent glycemic control.) Keep client's blood pressure ≤140/80.

SUBCONJUNCTIVAL HEMORRHAGE

DEFINITION
A. Subconjunctival hemorrhage presents as blood patches in the bulbar conjunctiva.

INCIDENCE
A. Subconjunctival hemorrhage may be seen in adults after forceful exertion (coughing, sneezing, childbirth, strenuous lifting). Subconjunctival hemorrhages account for approximately 3% emergent visits in the United States, and males have a higher prevalence than females. The true incidence is unknown secondary to many cases not being reported.

PATHOGENESIS
A. Subconjunctival hemorrhage occurs when the small blood vessels in the conjunctiva rupture from force or injury. When this occurs, the blood leaks out from the vessel, causing a red staining of the sclera. This may appear as a dark red spot on ▶

the white part of the eye. This disorder is believed to be secondary to increased intrathoracic pressure that may occur from forces such as pushing during labor and delivery, vomiting, excessive coughing, or with physical exertion.

PREDISPOSING FACTORS

A. Local trauma.
B. Systemic hypertension (HTN).
C. Acute conjunctivitis.
D. Vaginal delivery.
E. Severe coughing.
F. Severe vomiting.
G. Long-term hemodialysis.

COMMON COMPLAINT

A. Red-eyed appearance without pain.

OTHER SIGNS AND SYMPTOMS

A. Bright red blood in plane between the conjunctiva and sclera.
B. Usually unilateral.
C. Normal vision.

SUBJECTIVE DATA

A. Identify onset and duration of symptoms.
B. Elicit information about trauma to the eye; is it due to severe coughing or vomiting?
C. Identify history of conjunctivitis or HTN.
D. Review medications for anticoagulant or antiplatelet use, including over-the-counter (OTC) herbal products.

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure (rule out HTN).
B. Inspect:
  1. Observe eyes.
  2. Inspect ears, nose, and mouth.
  3. Inspect skin for bruises, petechiae, or other trauma.
  4. Assess for signs of trauma or abuse. **Blood in the anterior chamber (hyphema) can result from injury or abuse**.
C. Percuss:
  1. Percuss abdomen for hepatosplenomegaly.
E. Other physical examination components are dependent on etiology.

DIAGNOSTIC TESTS

A. Perform visual screening.
B. Test extraocular movements (EOMs) and peripheral vision.

DIFFERENTIAL DIAGNOSES

A. Subconjunctival hemorrhage.
B. Systemic HTN.
C. Blood dyscrasia.
D. Trauma to eye.
E. Conjunctivitis.
F. Hyphema.
G. Abuse.

PLAN

A. General interventions:
  1. Reassure the client that the hemorrhage is not damaging to the eye or vision and that the blood reabsorbs on its own over several weeks.
  2. A slit-lamp exam may be performed to rule out any ocular trauma.
B. Client teaching:
  1. Educate the client regarding safety to prevent trauma to the eye.
C. Pharmaceutical therapy:
  1. None.

FOLLOW-UP

A. If subconjunctival hemorrhage recurs, evaluate the client further for systemic HTN or blood dyscrasia.

CONSULTATION/REFERRAL

A. Consult or refer the client to a physician if hyphema is noted, if glaucoma is suspected, or if the client has additional eye injuries.

INDIVIDUAL CONSIDERATIONS

A. Adults:
  1. Always measure blood pressure to rule out systemic HTN.
B. Geriatrics:
  1. Research indicates that the common causes of elderly subconjunctival hemorrhage are HTN and use of aspirin. It occurs most often with geriatric males and primarily observed in the nasal region of the eye.
  2. Always measure blood pressure to rule out systemic HTN.
  3. Consider evaluation for blood dyscrasia.
  4. Assess clotting times if client is taking warfarin (Coumadin) or other products interfering with coagulation.

UVEITIS

DEFINITION

A. Uveitis, also known as iritis, is inflammation of the uveal tract (iris, ciliary body, and choroid) and is usually accompanied by a dull ache and photophobia due to irritative spasm of the pupillary sphincter.

INCIDENCE

A. The true incidence is unknown. Approximately 15% of clients with sarcoidosis present with uveitis. Of all cases 48% to 70% are considered idiopathic.
B. Older adults, females, smokers, and those with gastrointestinal (GI) inflammatory diseases have a higher prevalence of uveitis.

PATHOGENESIS

A. The cause is unknown. Underlying causes include infections, viruses, and arthritis.

PREDISPOSING FACTORS

A. Collagen disorders.
B. Autoimmune disorders.
C. Ankylosing spondylitis.
D. Sarcoidosis.
E. Juvenile rheumatoid arthritis.

F. Lupus.
G. Reiter syndrome.
H. Behcet syndrome.
I. Syphilis.
J. Tuberculosis.
K. AIDS.
L. Crohn disease.
M. Lyme disease.
N. Cerebral vasculitis.

COMMON COMPLAINTS

A. Eye pain: painless to deep-seated ache.
B. Photophobia.
C. Blurred vision with decreased visual acuity.
D. Black spots.
E. Eye redness.

OTHER SIGNS AND SYMPTOMS

A. Unilateral or bilateral symptoms:
1. Unilateral: The pupil is smaller than that of the other eye due to spasm.
B. Ciliary flush.
C. Pupillary contraction.
D. Nausea and vomiting with vagal stimulation.
E. Halos around lights.
F. Hypopyon (pus in anterior chamber).
G. Limbal flush with small pupil.

SUBJECTIVE DATA

A. Elicit the onset, course, duration, and frequency of symptoms. Are symptoms bilateral or unilateral?
B. Identify the possible causal activity or agent (chemical, traumatic, or infectious etiologies).
C. Review the client's history of uveitis and other ophthalmologic disorders.
D. Review any associated fever, rash, headache, weight loss, joint pain, back pain, oral ulcers, or genital ulcers.
E. Review full medical history for comorbid conditions.

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure.
B. Inspect:
1. Assess both eyes for visual acuity and peripheral fields of vision.
2. Check sclera and conjunctiva.
C. Other physical and mental health assessments need to be completed related to comorbid conditions.

DIAGNOSTIC TESTS

A. Slit-lamp test: Slit-lamp examination reveals cells in the anterior chamber and "flare," representing increased aqueous humor protein. Inflammatory cells, called keratic precipitates, can collect in clusters on the posterior cornea.
B. Penlight examination: Flashlight examination shows a slightly cloudy anterior chamber in the uveitic eye.

DIFFERENTIAL DIAGNOSES

A. Uveitis: usually idiopathic, but may be associated with many systemic and ocular diseases.
B. Acute angle-closure glaucoma.
C. Retinal detachment.
D. Central retinal artery occlusion.
E. Endophthalmitis.

PLAN

A. General interventions:
1. Treat underlying cause as indicated.
2. Provide immediate referral to an ophthalmologist due to possible complications of cataracts and blindness.
B. Client teaching:
1. Inform the client that recurrent attacks are common and also require immediate attention.
2. Advise the client to notify the provider if eye pain, change of vision, or other new symptoms occur.
C. Pharmaceutical therapy:
1. Medications are given by an ophthalmologist.
2. Uveitis and colitis often flare simultaneously; oral steroids are effective for both.

FOLLOW-UP

A. A client with uveitis needs a follow-up with an ophthalmologist.

CONSULTATION/REFERRAL

A. The client should be referred *immediately* to an ophthalmologist for evaluation and intervention.

INDIVIDUAL CONSIDERATIONS

A. Adults:
1. Recurrent uveitis may be a sign of another systemic condition. Other conditions include infections (bacterial, spirochetal, viral, fungal, and parasitic infections), inflammatory diseases including spondyloarthropathies (ankylosing spondylitis, psoriatic arthritis, reactive arthritis), inflammatory bowel disease, multiple sclerosis, and the use of new medications. Further workup should be performed for recurrent uveitis.
B. Geriatrics:
1. Research has indicated that uveitis is strongly associated with immunosuppression and autoimmunity disorders such as ankylosing spondylitis, gout, psoriasis, and rheumatic diseases, which are prevalent among the geriatric population.
2. With noninfectious/treatment-resistant uveitis, refer to an ophthalmologist/rheumatologist for collaborative management. Monoclonal tumor necrosis factor inhibitors (TNFi) such as adalimumab (Humira) and infliximab (Remicade) are demonstrating safety and efficacy with no statistically significant differences.
3. A natural possible treatment for uveitis is taking a multivitamin.
4. Difficult-to-treat and nonresponding uveitis can be treated by ophthalmology with slow-release implantable steroid.

CLIENT TEACHING GUIDE

CONJUNCTIVITIS

PROBLEM You have an infection of the eye, or conjunctivitis, which causes redness, itching, drainage from the eye, and crusting on the eyelids.

CAUSE Bacteria, viruses, or allergies can cause eye infections.

PREVENTION

A. Wash your hands frequently.
B. Avoid persons with conjunctivitis, such as pinkeye.
C. Avoid known allergens.

TREATMENT PLAN

A. All types:
  1. Wash your hands frequently, especially after touching the eyes, to avoid spread.
  2. Use cool compress on the eyes as needed.
  3. Wash crusting eyelids with baby shampoo daily.
  4. Wipe the eyes from inner to outer corners.
B. Bacterial: Bacterial conjunctivitis is contagious up to 24 hours after starting medication.
C. Viral: Viral conjunctivitis is contagious for 48 to 72 hours, but may last up to 2 weeks.

Activity: As tolerated.

Diet: As tolerated.

Medications: No medications are prescribed for viral infections. You will be given instructions on how to use eye drops or eye ointment.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If You Have:
A. A reaction to your medication.
B. Trouble seeing.
C. New symptoms, including pain in your eye or increased redness.
D. Other: _____

Phone: _____

CLIENT TEACHING GUIDE

HOW TO ADMINISTER EYE MEDICATIONS

PROBLEM You have been prescribed a medication for your eye(s). It is very important that you know the correct way to use your eye medication.

CAUSE You have been diagnosed with_____.

PREVENTION The health of your eyes is important.

A. Use good handwashing techniques and try not to rub your eyes with your fingers.
B. Clean your contact lenses regularly with contact cleaning solution. Do not put your contacts in your mouth to moisten. Change and remove your contacts as recommended by the manufacturer.
C. Wear sunglasses in bright sunshine.
D. Use eye goggles when working and playing sports to ensure extra protection.
E. Change your eye makeup often. Mascara, eye shadow, and eyeliner grow bacteria. Do not share makeup.

TREATMENT PLAN

A. Correct use of your medication is important.
B. You may or may not require an eye patch or shield.

How to Apply Eye Ointment

A. Always wash your hands before placing medication in your eyes.
B. Gently pull down the lower eyelid.
C. Make a small pocket between the eyeball and the eyelid.
D. If you have someone helping to put your eye ointment in the lower lid pocket, look up and away while they put in the medicine.
E. Do not let the tube of medicine touch the eye or eyelid.
F. Squeeze a thin ribbon of the medication into the pocket of the eyelid.
G. Start at the inner fold of the eye going from the nose to the outer eye.
H. Let go of the eyelid and blink to spread the medication.

How to Instill Eye Drops

A. Always wash your hands before placing medication in your eyes.
B. Gently pull down the lower eyelid.

FIGURE 1 How to instill eye drops into the eye.

CLIENT TEACHING GUIDE

HOW TO ADMINISTER EYE MEDICATIONS (*CONTINUED*)

C. Make a small pocket between the eyelid and the eyeball.
D. If you have someone helping to put eye drops in the lower lid pocket, look up and away while they put in the medicine.
E. Do not let the bottle of medication touch the eye or eyelid.
F. Squeeze the prescribed number of drops of the medicine into the pocket of the eyelid.
G. Let go of the eyelid and blink (or tell the client to blink) to spread the medication (Figure 1).

Activity: No restrictions are required unless you require eye surgery; then you will be given specific instructions about the amount of activity allowed.

Diet: No restrictions.

Medications: _____

You Have Been Prescribed: _____

You Need to Use the Medicine: _____

You Need to Notify the Office If:
A. You are unable to put in the medication yourself or get help from others.
B. You are not better 24 to 48 hours after starting the medication.
C. Your vision is worse after using the medication.
D. You have an allergic reaction to the medicine.
E. Other: _____

Phone: _____

CHAPTER 9

EAR GUIDELINES

Jill C. Cash and Emily Y. Brignola

ACUTE OTITIS MEDIA

DEFINITION

A. Acute otitis media (AOM) is inflammation of the middle ear associated with an acute bacterial infection of the middle ear. There is usually a rapid onset of symptoms.

INCIDENCE

A. AOM commonly occurs in children ages 12 months or less, but it may also be seen in adults and geriatric clients.

PATHOGENESIS

A. Obstruction of the eustachian tube can lead to middle ear effusion and infection. Contamination of this middle ear fluid often results from a backup of nasopharyngeal secretions. The most common bacterial pathogens in adults are *Streptococcus pneumoniae* and *Haemophilus influenzae*.

PREDISPOSING FACTORS

A. Recurrent otitis media (three or more episodes in the past 6 months).
B. Previous episode of otitis media or upper respiratory infection (URI) within the past month.
C. Medical condition that predisposes to otitis media (e.g., Down syndrome, AIDS, cystic fibrosis, cleft palate, immune disorders, and craniofacial abnormalities).
D. Native American/Inuit heritage.
E. Exposure to tobacco smoke and air pollution.
F. History of allergies.

COMMON COMPLAINTS

A. Otalgia.
B. Decreased or muffled hearing.
C. Ear fullness.
D. Fever may or may not be present.

OTHER SIGNS AND SYMPTOMS

A. Sleeplessness within past 48 hours.
B. Decreased appetite.
C. Acute hearing loss.
D. URI symptoms.
E. Mastoiditis presenting with a swollen and red mastoid.
F. Perforated tympanic membrane (TM; sudden severe pain followed by immediate relief of pain with fluid drainage from the ear).
G. Cholesteatoma (saclike structure in the middle ear accompanied by white, shiny, greasy debris).

SUBJECTIVE DATA

A. Elicit the onset and duration of symptoms.
B. Inquire whether the client recently had (or has concurrently) a URI.
C. Determine whether the client has any change in hearing.
D. Assess the client for any otorrhea (ear drainage) from the ear(s).
E. Question the client or their caregiver regarding risk factors.
F. Identify the client's history of otitis media.

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure.
B. Inspect:
  1. Observe the canal and auricle for redness, deformity, drainage, or foreign body.
  2. Inspect the TM position to determine if it is neutral and whether landmarks are visible, retracted, full, or bulging.
  3. Observe ears for decreased or absent TM mobility (with pneumatic otoscope).
  4. Inspect nose, mouth, and throat.
C. Auscultate:
  1. Auscultate heart and lungs.

DIAGNOSTIC TESTS

A. Tympanometry is a test that measures how easily the TM vibrates. Tympanogram shows flat or type B curve.
B. A diagnostic audiogram should be done in clients with persistent otitis media (≥3 months' duration).
C. Consider complete blood count if the client appears toxic with a high fever.

DIFFERENTIAL DIAGNOSES

A. Chronic otitis media.
B. Otitis media with effusion (OME).
C. URI.
D. Mastoiditis.
E. Otitis externa.
F. Eustachian tube dysfunction (ETD).
G. Cholesteatoma (saclike structure in the middle ear usually accompanied by chronic foul-smelling ears, otorrhea, and progressive hearing loss).
H. Spontaneous TM rupture.
I. Herpes zoster infection.
J. Other deep space head/neck infections.

The contributions of Kathleen Bradbury-Golas to this chapter in prior editions are acknowledged here.

PLAN

A. General interventions:

1. Pain relief with acetaminophen or ibuprofen. Auralgan may be used for a topical pain relief.

B. Client teaching:

1. Stress the importance of taking antibiotics as prescribed and finishing the prescription as ordered. If pain, fever, or other symptoms do not improve in 48 to 72 hours, then the client should notify the provider for further evaluation.

C. Pharmaceutical therapy:

1. Drug of choice: First-line therapy for adults with mild infection is amoxicillin-clavulanate (Augmentin) 875 to 125 mg orally BID. For severe infection (fever, severe pain, hearing loss, etc.) or those with infections resistant to *S. pneumoniae,* amoxicillin 1,000 mg with clavulanate 62.5 mg, extended-release, orally BID (for lower weight clients and/or those with milder infections), OR amoxicillin 2,000 mg with clavulanate 125 mg, extended-release, orally BID (for higher weight clients and/or those with more severe infections), is recommended.

2. If amoxicillin-clavulanate cannot be used, amoxicillin 500 mg orally TID or 875 mg orally BID may be used as an alternative first-line therapy.

3. For penicillin allergy, cephalosporins are used.

a. Cefdinir 300 mg orally Q12H or 600 mg orally daily for 5 to 7 days.

b. Cefpodoxime 200 mg orally Q12H for 5 to 7 days.

c. Cefuroxime 500 mg orally Q12H for 5 to 7 days.

d. Ceftriaxone 1 to 2 g intravenously or 1 g intramuscularly once daily for 3 days.

4. Other alternatives for clients known to have severe allergy to beta-lactam antibiotics include doxycycline or a macrolide.

a. Doxycycline 100 mg Q12H.

b. Clarithromycin 500 mg orally Q12H.

c. Azithromycin 500 mg orally as a single dose on day 1, then 250 mg orally on days 2 to 5 or clarithromycin 500 mg orally BID for 5 to 7 days.

5. Trimethoprim-sulfamethoxazole is not used due to high rate of resistance among *H. influenzae* and *S. pneumoniae* and because it is not effective against group A *Streptococcus*. Similarly, clindamycin is not used because it has no activity against *H. influenzae.*

6. Antibiotic treatment is recommended for all adults and geriatric clients diagnosed with AOM.

FOLLOW-UP

A. Recheck the client in 2 weeks to evaluate for resolution of the infection. Documentation of the resolution of the ear infection is valuable information if infections are recurrent.

B. If fever, pain, hearing loss, or other new symptoms present or if the client did not improve in 48 to 72 hours, then a follow-up appointment is recommended.

CONSULTATION/REFERRAL

A. Consult or refer the client to a specialist (otolaryngologist) if they appear septic or are diagnosed with mastoiditis.

B. A client with persistent otitis media with a hearing loss of 20 dB or more should be referred to an otolaryngologist.

C. A client with a chronic TM perforation after recurrent or severe episodes of AOM should be referred to an otolaryngologist.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Do not use sulfa medications (sulfonamides) in pregnant clients.

B. Geriatrics:

1. Elderly clients may present with OME and/or AOM secondary to blocked eustachian tube and/or an URI.

2. Bullous myringitis is a condition in which blisters are visible on the TM, which can cause significant pain. Bullous myringitis may be caused by a viral, bacterial, or mycoplasmal infection.

3. Otitis media may cause inflammation of petrous bone adjacent to middle ear (mastoiditis), which could become critical for elderly in terms of further hearing loss, uncontrolled pain, and increased confusion.

4. Geriatrics are particularly vulnerable to recurrent otitis media (minimal of three relapses in 6 months or minimal of four annual infections).

5. Prevention strategies for the elderly are (a) to control modifiable risk factors such as smoking cessation and diabetes control and (b) sufficiently treat each ear infection as soon as possible.

CERUMEN IMPACTION (EARWAX)

DEFINITION

A. Cerumen is defined as a mixture of ear secretions and dead epithelial cells which migrate laterally and often mix with hair. Cerumen occurs naturally in the external auditory canal (EAC) and is a protective mechanism of the ear that maintains homeostasis by lubricating the ear canal, removing debris, and providing bactericidal protection. Excessive accumulation of cerumen can cause a partial or complete obstruction of the EAC, leading to discomfort and associated conductive hearing loss (CHL).

INCIDENCE

A. Certain individuals are at increased risk of excessive earwax due to overproduction or inability of the ear to clear itself. The populations most likely to be diagnosed with cerumen impaction include the elderly, young children, those with mental disabilities, and institutionalized clients. The incidence in nursing home clients may be as high as 60%.

B. Approximately 12 million office visits per year occur for cerumen extraction in the United States.

PATHOGENESIS

A. With age, the normal self-cleaning mechanisms of the ear fail. Cilia, which have become stiff, cannot remove cerumen and dirt from the ear canal. Placing cotton swabs, paper clips,▶

bobby pins, and other objects into the EAC may also impact cerumen.

PREDISPOSING FACTORS

A. Age (decreased function of ear cilia).
B. Use of hearing aids or earbuds.
C. Recurrent otitis externa.
D. Dermatologic conditions of the external canal.
E. Previous audiologic surgeries.
F. Keratosis obturans.
G. Use of cotton swabs or other objects to clean the EAC.

COMMON COMPLAINTS

A. Dryness and itching of ear canal.
B. Dizziness/unsteadiness.
C. Otalgia.
D. Hearing loss.
E. Fullness in the ear.
F. Chronic cough.
G. Tinnitus.

SUBJECTIVE DATA

A. Elicit onset, duration, and laterality of symptoms.
B. Elicit history of cerumen impaction.
C. Question the client regarding the method used to clean the ears.
D. Determine personal or family history of anatomic deformity.
E. Assess for any physical barriers to wax extrusion, such as cotton swabs, hearing aids, or devices utilized to protect hearing (earplugs).

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure.
B. Inspect:
  1. Observe ears for thick, light to dark brown wax occluding the auditory canal.
  2. Observe tympanic membrane (TM) if possible. Perforated TM is associated with otitis media.
  3. Inspect nose and throat.
C. Auscultate:
  1. Auscultate heart and lungs.

DIAGNOSTIC TESTS

A. Cerumen impaction is diagnosed with direct visualization of an otoscope.
B. When hearing loss is the primary subjective complaint, you may consider a hearing assessment. Expected outcomes associated with cerumen impaction include CHL of 35 to 40 dB and positive Rinne (tuning fork test reveals bone conduction greater than air conduction in affected ear).

DIFFERENTIAL DIAGNOSES

A. Cerumen impaction.
B. Foreign body in the ear canal.
C. Otitis externa: White, mucus-like ear discharge is associated with otitis externa.

PLAN

A. General interventions:
  1. If experienced in removal of cerumen impaction and chooses to proceed with cerumenectomy, the clinician may elect to obtain written informed consent prior to performing this procedure. Remove impaction by means of lavage or curettage. Be sure to inspect the canal and TM after removal of the cerumen. Document the client's hearing before and after removal of cerumen.
  2. If initial management is unsuccessful or for severe cerumen impaction, consider otolaryngology consult for microscopic cerumenectomy.
B. Client teaching: *See Client Teaching Guide for this chapter, "Cerumen Impaction (Earwax)."*
  1. Instruct the client to avoid cleaning their own ears. Advise not to clean ears with cotton swabs, bobby pins, and so forth. Using these devices pushes the wax further into the ear canal and can worsen symptoms.
  2. Instruct clients to avoid ear candling.
C. Pharmaceutical therapy:
  1. None indicated.

FOLLOW-UP

A. If cerumen is removed, no immediate follow-up is required. Consider having the client return in 4 to 6 weeks to recheck their ears for cerumen.

CONSULTATION/REFERRAL

A. Consult or refer the client to a specialist (otolaryngologist) when cerumen cannot be safely removed.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:
  1. Cerumen impaction is common in older adult and geriatric clients secondary to the atrophic cilia and dry epithelium of the ear canal.
  2. The use of hearing aids and earbuds can also contribute to wax buildup and cause wax to be pushed further into the canal. Persons using hearing aids or earbuds should be evaluated for wax buildup as indicated.
  3. To prevent uncertainty and fears, the elderly with hearing loss need to be reminded that as a liquid treatment/water is held for 15 minutes in the canal, cerumen expands and might temporarily cause further hearing loss. Continue to encourage the client during any treatment and, if necessary, have the nurse stay with client during the wait time.

A., Yanagisawa, K., & Cunningham, E. R. (2017). Clinical practice guideline (Update): Earwax (Cerumen impaction). *Otolaryngology–Head and Neck Surgery*, *156*(Suppl. 1), S1–S29. https://doi.org/10.1177/0194599816671491

HEARING LOSS

DEFINITION

A. Impaired hearing (complete or partial hearing loss) results from interference with the conduction of sound, its conversion to electrical impulses, or its transmission through the nervous system. There are three types of hearing loss: ▶

1. Conductive hearing loss (CHL; defect in the conductive pathway of the ear).
2. Sensorineural hearing loss (SNHL; defect in the inner ear, cochlea, or auditory nerve (cranial nerve VIII).
3. Mixed hearing loss (MHL; combined conductive and sensorineural hearing loss).

INCIDENCE

A. Hearing loss is the most prevalent sensory deficit in the United States. Approximately 30 million (12.7%) individuals in the United States have bilateral hearing loss and 48 million (20.3%) have hearing loss in at least one ear.
B. Approximately 43% of persons aged 65 to 84 years have hearing loss.
C. Globally, approximately 538 million individuals experience hearing loss that is considered to be disabling.

PATHOGENESIS

A. *CHL (air–bone gap)* occurs when sound is not conducted effectively and presents with a diminution of volume, particularly low tones and vowels. It may be caused by one of the following:
1. Otologic processes such as chronic or serous otitis media, otitis externa, foreign body, cerumen impaction, or trauma to the middle ear.
2. Otosclerosis disorder of the architecture of the bony labyrinth, which fixes the footplate of the stapes in the oval window.
3. Exostoses: bony excrescences of the external auditory canal.
4. Tympanic membrane (TM) perforation.
5. Cholesteatoma: growth of squamous epithelium in the middle ear space.
6. Glomus tumors: benign, highly vascular tumors derived from normally occurring glomera of the middle ear and jugular bulb.
7. Congenital malformations such as microtia and/or atresia.

B. *SNHL* occurs after damage to the inner ear or vestibulocochlear nerve and characteristically produces impairment of the high-tone perception. It is usually bilateral and symmetrical.
1. Presbycusis is hearing loss associated with aging and is the most common cause of diminished hearing in the elderly; onset is bilateral, symmetric, and gradual.
2. Noise-induced hearing loss is due to chronic exposure to sound levels in excess of 85 to 90 dB.
3. Drug-induced hearing loss can be caused by aminoglycoside antibiotics, furosemide, ethacrynic acid, quinidine, chemotherapeutic agents such as cisplatin, and high-dose aspirin.
4. Ménière disease produces a fluctuating, unilateral, low-frequency impairment usually associated with tinnitus, a sensation of fullness in the ear, and intermittent episodes of vertigo.
5. Acoustic neuroma is a benign tumor of cranial nerve VIII (rare).
6. Sudden deafness can derive from head trauma, skull fracture, meningitis, otitis media, scarlet fever, mumps, congenital syphilis, multiple sclerosis, and perilymph leaks or fistulas.
7. Infectious, autoimmune, or postinflammatory processes.

PREDISPOSING FACTORS

A. Acoustic or physical trauma.
B. Ototoxic medications (e.g., aminoglycosides, aspirin, radiation therapy, chemotherapy).
C. Changes in barometric pressures/barotrauma.
D. Recent upper respiratory infection (URI).
E. Pregnancy.
F. Otosclerosis.
G. Nasopharyngeal cancer.
H. Serous otitis media/middle ear effusion/eustachian tube dysfunction (ETD).
I. Cerumen impaction.
J. Foreign body in the ear.

COMMON COMPLAINTS

A. Partial or total hearing loss.
B. Associated tinnitus.
C. Difficulty understanding the television, phone conversations, and people talking.
D. Aural fullness, ear pressure.

SUBJECTIVE DATA

A. Elicit the onset, duration, progression, and severity of the symptoms. Note whether symptoms are bilateral or unilateral.
B. Obtain the client's history of past or recent trauma.
C. Review the client's occupational and recreational exposure to risk factors.
D. Review the client's medical history and medications, including over-the-counter (OTC) drugs and prescriptions.
E. Review the client's family medical history.
F. Review the client's history for recent URI or ear infections, especially for chronic ear infections.
G. Elicit data about any previous hearing loss, how it was treated, and how it affected daily activities. There is often a history of ear disease with CHL.
H. Review the client's other symptoms, such as dizziness, fullness or pressure in the ears, and noises.
I. Review what causes difficulty with hearing, high tones versus low frequencies. Can the client hear people talking, the television at normal volume, doorbells ringing, telephone ringing, and watch ticking?

PHYSICAL EXAMINATION

A. Inspect:
1. Examine both ears for comparison.
2. Externally inspect ears for discharge; note color and odor. Obstruction of the auditory canal by impacted cerumen, a foreign body, exostoses, external otitis, otitis media with effusion (OME), or scarring or perforation of the eardrum due to chronic otitis may be present.
3. Conduct otoscopic examination to observe the auditory canal for cerumen impaction or foreign body.
4. Inspect TM for color, landmarks, contour, perforation, and acute otitis media (AOM). A reddish mass visible through the intact TM may indicate a high-riding jugular bulb, an aberrant internal carotid artery, or a glomus tumor.

B. Palpate:
1. Palpate auricle and mastoid area for tenderness, swelling, or nodules.
2. Check lymph nodes if infection is suspected.

C. Perform neurologic exam:
1. Perform Weber and Rinne tests.
   a. In the Weber test, the tuning fork is perceived more loudly in the ear with CHL.
   b. The Rinne test shows that bone conduction is better than air conduction (it is normal when air conduction is greater than bone conduction).

DIAGNOSTIC TESTS

A. Audiogram screening in primary setting.
B. Air insufflation for TM mobility.
C. Diagnostic pure-tone audiometry (hearing test) with tympanometry (used to evaluate the TM and the middle ear status) performed by an audiologist.
D. CT scan of temporal bones or MRI of the brain and internal auditory canals after consultation with an otolaryngologist.

DIFFERENTIAL DIAGNOSES

A. Congenital hearing loss.
B. Traumatic hearing loss.
C. Ototoxicity.
D. Presbycusis.
E. Ménière syndrome.
F. Acoustic neuroma.
G. Cholesteatoma.
H. Infection.
I. Cerumen impaction.
J. Otitis externa.
K. Foreign body in the ear.
L. Tumors.
M. Otosclerosis.
N. Perforation of TM.
O. Serous otitis media.
P. Hypothyroidism.
Q. Paget disease.

PLAN

A. General interventions:
  1. Treat any primary cause (e.g., remove impacted cerumen, ETD).
B. Client teaching:
  1. Harmful noise levels should be avoided.
  2. Individual hearing protection devices should be utilized in all clients exposed to occupational noise.
C. Pharmaceutical therapy:
  1. Treat primary condition if applicable.

FOLLOW-UP

A. If hearing loss is identified and cause is not immediately treatable, refer the client to otolaryngology for further evaluation.

CONSULTATION/REFERRAL

A. Any sudden onset of hearing loss requires immediate referral.
B. The client should be referred to an otolaryngologist for an extensive workup when the primary cause cannot be identified.
C. Referral should be made to a hearing aid specialist for hearing evaluation and treatment as indicated (e.g., hearing aids).

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:
  1. Impaired hearing among the elderly is common and can lower the quality of life. Up to 80% of those over 85 years have hearing loss.
  2. People with seriously impaired hearing often become withdrawn or appear confused.
  3. Subtle hearing loss may go unrecognized.
  4. Impacted cerumen is very common in the elderly and can be a source of hearing loss.
  5. Hearing loss in the elderly affects both peripheral and central auditory systems. The highest frequencies are predominantly impacted, which is the area vital to understanding spoken words.
  6. Geriatrics with depression and dementia significantly benefit from cochlear implants. Studies have suggested that the enhanced amplification improved behavioral health issues and quality of life. There is a 1% failure rate. Client selection criteria are the following:
    a. Moderate to severe bilateral SNHL.
    b. Unilateral deafness with/without ipsilateral tinnitus.
    c. Benefit from hearing aids less than expected.
    d. No medical contraindication with anesthesia and no active ear infections.
    e. Family/surrogate support, motivation, and appropriate expectations.
  7. Communicating with the elderly who have hearing loss:
    a. Ask what is their preference in communication.
    b. Stand/sit 2 to 3 feet away with client sitting in front of a wall to reflect sound.
    c. Speak slowly toward the better ear using a lower pitched voice (do not shout).
    d. Rephrase rather than repeat sentences, and pause between each phrase/idea as needed.
  8. Elderly clients with dexterity challenges may benefit with user-friendly hearing aid models such as behind-the-ear or in-the-ear types.
  9. Clients with advanced cognitive deficits might need specific aids attached to the device and fastened to clothing to prevent loss of hearing aid. Audiologists would assist families/surrogates with safety measures for these attachments.

OTITIS EXTERNA

DEFINITION

A. Otitis externa is an inflammation of the external ear canal that commonly produces pruritus, pain, and purulent discharge. It may be acute (rapid onset generally within 48 hours of symptoms) or chronic depending on the underlying pathogenesis. It may or may not involve the tympanic membrane (TM).

INCIDENCE

A. Otitis externa is seen in persons of all ages (lifetime incidence is up to 10%).
B. Both sexes are equally affected.
C. The incidence is higher during summer months. Of otitis externa visits, 44% occur between the months of June and August.
D. Clients with asthma, allergic rhinitis, atopic dermatitis, or other chronic skin disorders are more likely to experience recurrent otitis externa.
E. All varieties of otitis externa, with the exception of necrotizing otitis externa, are common.

PATHOGENESIS

A. Acute diffuse otitis externa (swimmer's ear): Characterized by rapid onset (1–2 days) of symptoms including otalgia (often severe), external auditory canal swelling, possible otorrhea, and/or cellulitis of the pinna/adjacent skin. Bacteria causes 90% of cases. *Pseudomonas* is the most common bacterial infection (67%), followed by *Staphylococcus* and *Streptococcus*. Infection can also be fungal *(Aspergillus*, 90%). Bacterial or fungal invasion is usually preceded by trauma to the ear canal, aggressive cleaning of the naturally bactericidal cerumen, or frequent submersion in water (swimming).

B. Chronic otitis externa: Condition generally results from a persistent, low-grade infection and inflammation with *Pseudomonas*.

C. Eczematous otitis externa: Otitis externa is associated with primary coexistent skin disorder such as atopic dermatitis, seborrheic dermatitis, and psoriasis.

D. Necrotizing or malignant otitis externa: Invasive *Pseudomonas* infection results in skull base osteomyelitis. Cranial nerve palsies (of cranial nerves VII, IX, and XII) and periostitis of the skull base have been associated with necrotizing otitis externa. Necrotizing or malignant otitis externa is a life-threatening condition that occurs in diabetic or immunocompromised clients. It is most commonly seen in the immunocompromised or diabetic geriatric client.

PREDISPOSING FACTORS

A. Exposure to a moist or humid environment (frequent swimming).

B. Ear trauma from scratching, foreign object, or vigorous cleaning.

C. Use of a hearing aid or earplugs.

D. Primary skin conditions, such as eczema.

E. Immunocompromised, malnourished, or comorbid conditions.

COMMON COMPLAINTS

A. Otalgia.

B. Itching.

C. Erythematous and swollen external canal.

D. Purulent discharge.

E. Hearing loss from edema and obstruction of canal with drainage.

OTHER SIGNS AND SYMPTOMS

A. Plugged ear sensation (aural fullness).

B. Tenderness to palpation (tragus, pinna, or both) that is disproportionate to what may be expected based on visual inspection.

SUBJECTIVE DATA

A. Elicit the onset, duration, and intensity of ear discomfort.

B. Inquire into the client's history of ear infections.

C. Determine whether the client notes any degree of hearing loss.

D. Question the client about recent exposure to immersion in water (swimming).

E. Determine if the client wears hearing aids, earplugs, or other devices that may impact the ear canal.

F. Question the client as to ear canal cleaning practices and any recent trauma to canal.

PHYSICAL EXAMINATION

A. Temperature.

B. Inspect:

1. Carefully examine the ear with an otoscope due to its extreme tenderness.

2. Observe the ear for erythematous and edematous external canal; look for otorrhea and debris.

3. Observe the TM, which may appear normal.

4. Inspect the nose and throat.

C. Auscultate:

1. Auscultate the heart and lungs.

D. Palpate:

1. Apply gentle pressure to tragus and manipulate pinna to assess for tenderness.

2. Palpate preauricular, postauricular, and lateral cervical lymph nodes.

DIAGNOSTIC TESTS

A. Examine ear canal scrapings and drainage under microscope for hyphae (if fungal infection is suspected from history or ineffective topical therapy).

DIFFERENTIAL DIAGNOSES

A. Otitis externa.

B. Acute otitis media (AOM).

C. Chronic suppurative otitis media.

D. Cholesteatoma.

E. Mastoiditis.

F. Referred pain (wisdom tooth eruption).

G. Herpes zoster oticus (vesicular eruptions in the ear canal are associated with herpetic otitis externa).

PLAN

A. General interventions:

1. The primary treatment goals are to reduce pain and inflammation and to treat the underlying organism.

2. In extreme cases, the client's ear canal may be blocked by edema or drainage, preventing passage of ear drops. Cautiously irrigate the canal and insert a cotton ear wick (approximately 1 in. long for adults) by gently rotating it to allow passage of drops. Consider referral for abnormal or extensive cases.

B. Client teaching: *See Client Teaching Guide for this chapter, "Otitis Externa."*

1. The client should be advised to keep water out of the ear during treatment, which typically lasts 1 week. During this time, bathing or showering is permitted with earplugs or a cotton ball coated with petroleum jelly inserted into the ear to block water passage into the ear canal.

2. Clients with appropriately treated uncomplicated acute otitis externa generally show signs of improvement within 48 to 72 hours.

C. Pharmaceutical therapy:

1. Oral antibiotics are indicated only if there is an associated otitis media and should not be used alone for otitis externa.

2. For early, mild cases associated with swimming in which the primary symptom is pruritus, homemade preparations of 50% isopropyl alcohol and 50% vinegar or acetic acid/aluminum acetate can be used as a drying agent and to create an unsatisfactory environment for *Pseudomonas* growth.

3. For mild infection, use topical therapy with acidifying agent such as Vosol or Vosol HC, which includes a glucocorticoid therapy. Instill five drops in the ear canal three to four times daily. (Vosol and Vosol HC are contraindicated with perforated eardrum; Vosol HC is contraindicated with viral otic infections.)

4. For moderate infection, use of an acidifying agent, antibiotic, and glucocorticoid therapy (CiproDex) is suggested. Other alternatives include ciprofloxacin (Cipro HC) and ofloxacin (Floxin). Potentially ototoxic ototopical aminoglycosides (Neomycin and Polymyxin) should be avoided if the integrity of the TM is in question.

a. If fungal infection is suspected, clotrimazole and betamethasone dipropionate lotion (Lotrisone) can be used for fungal infections if TM is intact. Nystatin 100,000 units/mL or clotrimazole topical solutions may also be used for *Candida* or yeast infections.

b. Acyclovir is the treatment of choice for herpes simplex or herpes zoster.

5. Severe or resistant infections in healthy clients may require additional management with oral antibiotics and antifungals. In addition, oral antibiotics should be considered as an adjunct to topical therapy in clients who are immunocompromised, malnourished, or have comorbidities, including associated otitis media and/or cellulitis of the outer ear:

a. Ciprofloxacin for pseudomonal infections; dicloxacillin or cephalexin for staphylococcal infections.

b. Itraconazole (Sporanox) for treatment of otomycosis (fungal otitis externa).

6. Use of acetaminophen or ibuprofen should be adequate for pain control. Pain uncontrolled by these medications should be a red flag for serious infection and warrants immediate referral.

FOLLOW-UP

A. Usual follow-up is within 3 to 5 days to assess improvement. Recheck in 1 to 2 weeks.

B. If wicking is required, the wick should be removed within 3 to 5 days, once the swelling is reduced. It is common for the wick to spontaneously fall out as the swelling improves. Upon reduction of swelling, clients can then instill ototopical drops directly into the ear canal.

CONSULTATION/REFERRAL

A. Any client suspected of necrotizing otitis externa requires immediate referral due to the potential life-threatening complications of osteomyelitis.

B. Consult or refer the client to an otolaryngologist or ED if osteomyelitis is suspected.

C. For complications (e.g., abscess, mastoiditis, and meningitis), refer to the ED for emergent treatment.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. Ramsay Hunt syndrome, also known as herpes zoster oticus, occurs when the shingles virus breaks out near the ear, affecting cranial nerves V, IX, and X, causing painful blisters/rash near the ear and/or the external ear canal. Facial paralysis, change in taste perception, and/or hearing loss in the affected ear may occur. Symptoms may include shingles rash near the ear and/or inside the external ear canal, ear pain, change in taste, hearing loss, ringing in the ear, dizziness, and/or facial paralysis near the ear/mouth. Prompt treatment with antiviral medications is recommended to prevent permanent damage to the nerve. Hearing loss and facial paralysis are commonly temporary but may also be permanent. Nerve damage may occur. Referral to an otolaryngologist for evaluation is recommended.

2. Malignant otitis externa is found mostly in the elderly and/or diabetics. Treatments include surgical removal of dead tissue, antibiotics, and hyperbaric oxygen treatment (HBOT), if the client is determined a candidate.

3. There is an increased risk of otitis externa with diabetic geriatrics. The primary goal is to keep blood glucose controlled and to monitor ear canals frequently.

4. The elderly population are apt to clean their ears more often than younger adults secondary to dry itchy skin. Frequent cleansing may alter the immune response and pH balance of the external canal, predisposing to risk of otitis externa infection.

Clinical practice guideline: Acute otitis externa. *Otolaryngology-Head and Neck Surgery*, *150*(Suppl. 1), S1–S24. https://doi.org/10.1177/0194599813517083

OTITIS MEDIA WITH EFFUSION

DEFINITION

A. Otitis media with effusion (OME) is a noninfectious asymptomatic middle ear fluid without signs of bacterial infection.

INCIDENCE

A. OME is seen in persons of all ages.

B. OME often follows an acute upper respiratory infection (URI) or recent diagnosis of acute otitis media (AOM).

C. The middle ear effusion typically resolves without treatment in more than 80% of all clients. Although symptoms can sometimes continue for up to 12 weeks, the majority of clients will have complete symptom resolution by 4 weeks.

D. Approximately 2.2 million new cases of OME are diagnosed in the United States each year.

PATHOGENESIS

A. The effusion may be sterile fluid secondary to URI and eustachian tube dysfunction. It may be residual fluid after an episode of AOM.

PREDISPOSING FACTORS

A. Recent AOM.
B. Concurrent or recent URI.
C. Chronic sinusitis.
D. Allergies.
E. Craniofacial predisposition.
F. Smoking or exposure to secondhand smoke.
G. History of middle ear infections.
H. Barotrauma.

COMMON COMPLAINTS

A. Ear pain.
B. Increased pressure sensation in the ears.
C. Recent hearing loss/muffled hearing.

OTHER SIGNS AND SYMPTOMS

A. A sense of fullness in the ears.
B. Dizziness/unsteadiness.
C. Tinnitus.

SUBJECTIVE DATA

A. Elicit onset, laterality, and duration of symptoms.
B. Inquire about recent history of otitis media or URI.
C. Inquire about subjective hearing loss.
D. Determine if the client has a history of frequent otitis media.

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure.
B. Inspect:
  1. Inspect ears, noting fluid level, serous middle fluid, and a translucent, amber, gray membrane with decreased mobility.
  2. Inspect nose, mouth, and throat.
C. Auscultate:
  1. Auscultate heart and lungs.
D. Palpate:
  1. Palpate head, neck, and lymph nodes in the head, chin, and neck.
E. Perform neurologic examination:
  1. Perform Weber and Rinne tests with tuning fork.

DIAGNOSTIC TESTS

A. Pneumatic otoscopy reveals decreased mobility. **Assessment with pneumatic otoscopy is strongly recommended**.
B. Tympanometry is a test that measures how easily the tympanic membrane (TM) vibrates. Type A tympanograms are normal; type B tympanograms indicate a hypercompliant TM (e.g., middle ear effusion); type C tympanograms indicate negative middle ear pressure.

DIFFERENTIAL DIAGNOSES

A. OME.
B. AOM.
C. Cerumen impaction or foreign body.
D. Otitis externa.
E. Cholesteatoma.
F. Myringitis.
G. Tympanosclerosis.

PLAN

A. General interventions:
  1. Client should be monitored closely for resolution of effusion without treatment within several weeks.
  2. Clients with persistent OME (>12 weeks) should be referred to an otolaryngologist for a hearing evaluation and possible tympanostomy tubes as indicated.
  3. Maneuvers such as intermittent autoinsufflation may be helpful for more symptomatic clients (persistent aural fullness, minimal to moderate discomfort) in helping relieve the symptoms until the effusion resolves.
B. Client teaching: *See Client Teaching Guide for this chapter, "Otitis Media With Effusion."*
C. Pharmaceutical therapy:
  1. Use of nasal corticosteroids and nasal antihistamines may be helpful in clients with OME.
  2. Systemic decongestants can be used.

FOLLOW-UP

A. Recheck the client's ears after 4 weeks to monitor for spontaneous resolution. If no resolution is noted, schedule a follow-up appointment.

CONSULTATION/REFERRAL

A. Consult or refer the client to an otolaryngologist if treatment is not effective or if the client has a persistent effusion (at least 3 months) along with a hearing loss of 20 dB or more.
B. Consider referring the client to an otolaryngologist prior to 12 weeks if they do not have the usual underlying risk factors associated with OME.
C. Consider earlier referral to an otolaryngologist when the OME is bilateral due to potential increased hearing loss.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:
  1. OME in geriatrics is an ominous sign that needs thorough investigation. A pharyngeal congestion could spread to the eustachian tubes, causing a pressure increase in the middle ear that forms serous effusion. Often these infections stem from a virus and most erupt from a URI.
  2. The prognosis tends to be poor for the elderly if their immune system is compromised. In this population, it could lead to permanent hearing loss, endocarditis, or septicemia. Prevention and immediate effective treatment are paramount in avoiding complications.

PRESBYCUSIS

DEFINITION

A. A sensorineural hearing loss (SNHL) associated with aging.
B. Symmetrical progressive hearing loss over many years; gradual.
C. Affects the high frequencies of hearing first.

INCIDENCE

A. Hearing loss is common in the elderly and increases with age. Presbycusis affects more than half of adults by age 75 years, most adults over the age of 80, and nearly all adults who are 90 or older.
B. Males tend to be affected slightly earlier and experience more impairment, possibly related to higher levels of noise exposures.
C. The World Health Organization estimates there will be 1.2 billion people over 60 years old worldwide who will suffer significantly from presbycusis by 2025.

PATHOGENESIS

A. Multiple factors of heredity, cumulative noise exposure, and age-related physiologic changes to the ear are thought to be factors in the degree of hearing loss. Although presbycusis is multifactorial, physiologic changes in the cochlea have been identified as the primary underlying mechanism of decreased hearing.

PREDISPOSING FACTORS

A. Age.
B. Family history (genetics).
C. Ototoxic medications (e.g., gentamicin and aspirin).
D. Cumulative noise exposure.
E. Cardiovascular disease (hypertension [HTN] and hyperlipidemia).
F. Smoking.
G. Immunologic disorders.
H. Hormonal factors (estrogen).

COMMON COMPLAINTS

A. Partial hearing loss.
B. Difficulty understanding the television, phone conversations, and people talking.
C. Difficulty in background noises.
D. Tinnitus.

SUBJECTIVE DATA

A. Elicit the onset, duration, progression, and severity of the symptoms. Note whether symptoms are bilateral or unilateral.
B. Review the client's family history.
C. Review the client's occupational and recreational exposure to noise.
D. Review the client's medical history for cardiovascular disease, HTN, and hyperlipidemia.
E. Ask specifically about all medications, including over-the-counter (OTC) drugs and prescriptions.
F. Review the client's history for recent upper respiratory infection (URI), or ear infections, especially for chronic ear infections.
G. Elicit data about any previous hearing loss, how it was treated, and how it affected daily activities. There is often a history of ear disease with conductive hearing loss.
H. Review the client's other symptoms, such as dizziness, fullness or pressure in the ears, and noises.
I. Review what causes difficulty with hearing, high tones versus low frequencies. Can client hear people talking, the television at normal volume, doorbells ringing, telephone ringing, and watch ticking?

PHYSICAL EXAMINATION

A. Inspect:
  1. Examine head, neck, and ears for signs of trauma, asymmetry, masses, or edema.
  2. Externally inspect ears for discharge; note color and odor. Obstruction of the auditory canal by impacted cerumen, a foreign body, exostoses, external otitis, otitis media with effusion (OME), or scarring or perforation of the eardrum due to chronic otitis may be present.
  3. Conduct otoscopic examination to observe the auditory canal for cerumen impaction or foreign body.
  4. Inspect tympanic membrane (TM) for color, landmarks, contour, perforation, and acute otitis media (AOM). A TM that is opaque rather than translucent can be a variation of normal in elders and is not related to hearing loss.
B. Common screening tests:
  1. Whispered voice: From 2 feet behind the client, the examiner whispers words or short phases while occluding one ear at a time.
  2. Client report: Ask the client, "Do you have difficulty hearing?"
  3. Screening version of the Hearing Handicap Inventory for the elderly.
  4. Weber and Rinne tests to differentiate conductive from SNHL: The Weber test reveals conductive hearing loss when sound travels toward the poor ear. SNHL is present when sound travels toward the good ear. This screening test is performed by striking a tuning fork and then placing it on the middle of the head. The client is then asked where sound is being heard from—the left ear, the right ear, or equal in both ears. Normal results are reflected by sound being heard equally in both ears. The Rinne tuning fork test reveals bone conduction greater than air conduction in the affected ear (abnormal). The Rinne test is performed by placing the struck tuning fork against the mastoid bone. Begin counting or timing the interval from the start to when the client can no longer hear. Continue counting or timing the interval to determine the length of time sound is heard by air conduction. Air-conducted sound should be heard twice as long as bone-conducted sound after bone conduction stops.

DIAGNOSTIC TEST

A. Audiogram in primary setting.

DIFFERENTIAL DIAGNOSES

A. Presbycusis.
B. Sudden SNHL.
C. Ototoxicity.
D. Ménière syndrome.
E. Acoustic neuroma.
F. Cholesteatoma.
G. Chronic otitis media.
H. Cerumen impaction or foreign body.

PLAN

A. General interventions:
  1. All clients with suspected hearing loss should undergo formal testing.
  2. Goals are to prevent further hearing loss and assist the client in lifestyle changes that increase quality of life.
B. Client teaching:
  1. Let clients know that a follow-up with a specialist is important to identify the correct diagnosis.
  2. Summarize treatment options of aural rehabilitation, hearing aids and, when applicable, cochlear implants.
  3. Assess for and teach clients the consequences of excessive environmental noise; consider protective mechanisms such as earplugs.
C. Nonpharmaceutical therapy:
  1. Aggressive management of comorbidities such as HTN and hyperlipidemia may slow progression of hearing loss.
  2. Evaluate for polypharmacy and the role it may play in hearing loss. Specifically assess for ototoxic medications. Eliminate when possible.

FOLLOW-UP

A. Stress the importance of follow-up with the audiologist and otologist. Often the client does not pursue viable options that would improve quality of life.

CONSULTATION/REFERRAL

A. The client should be referred to an otolaryngologist immediately for sudden, severe, or rapidly progressing hearing loss and hearing loss that is unilateral; associated with pain, bleeding, or drainage; or involves other neurologic deficits.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. Studies have strongly suggested that music training and education among the elderly positively affected presbycusis and were important factors in slowing deterioration of music perception and perhaps speech intelligibility.

2. The elderly may "try out" OTC hearing aids. Studies have strongly suggested that these OTC devices are not efficient secondary to ineffective volume control, high equivalent input noise, and irregular frequency response. Encourage clients to talk about their feelings regarding hearing loss and their motivation to improve it with appropriate auditory devices. This will help build a foundational willingness from the client for a consultation/referral.

3. Impaired hearing among the elderly is common and can lower quality of life. Individuals with significantly impaired hearing may become withdrawn or appear confused.

4. Impacted cerumen is common in the elderly.

TINNITUS

DEFINITION

A. The word "tinnitus" comes from the Latin *tinnire*, which means "to ring." Tinnitus is the perception of an auditory sensation such as hissing, sizzling, or ringing in the absence of external stimuli. Sounds can be constant or intermittent and vary in intensity from client to client. The tinnitus can also be categorized as rhythmical or pulsatile and corresponding with a heartbeat (this may suggest a vascular origin).

B. Primary tinnitus is defined as tinnitus that is idiopathic and may or may not be associated with sensorineural hearing loss (SNHL). Secondary tinnitus is defined as tinnitus that is associated with an underlying cause other than SNHL (e.g., cerumen impaction, middle ear disease, eustachian tube dysfunction, Meniere disease, and vestibular schwannoma).

INCIDENCE

A. Tinnitus is a very common medical problem that affects an estimated 50 million people in the United States.

B. Prevalence is similar between males and females and is known to increase with age.

PATHOGENESIS

A. Tinnitus is poorly understood and there is wide disagreement on the pathophysiology. It is best described as a nonspecific manifestation of pathology of the inner ear, cranial nerve VIII, or the central auditory mechanism. There is a strong association between tinnitus, stress, anxiety, and depression.

PREDISPOSING FACTORS

A. High levels of noise exposure, either recreational or occupational.

B. Otologic conditions:

1. Neoplasms.
2. Hearing loss.
3. Cerumen impaction.
4. Otitis media/middle ear effusion.
5. Mastoiditis.
6. Labyrinthitis.
7. Tympanic membrane (TM) perforations.
8. Acoustic trauma.

C. Neurologic conditions:

1. Vertigo.
2. Migraines.
3. Epilepsy.
4. Meningitis.
5. Multiple sclerosis.
6. Jugular bulb anomaly: Compression of the ipsilateral jugular vein abolishes the objective tinnitus of a jugular megabulb anomaly.

D. Trauma to head or neck or issues with temporomandibular joint (TMJ) disorder.

E. Immune system disorders such as rheumatoid arthritis, systemic lupus erythematosus, or systemic sclerosis.

F. Endocrine influences such as diabetes, hypothyroidism, and pregnancy.

G. Psychological disorders:

1. Anxiety.
2. Depression.
3. Posttraumatic stress disorder.
4. High stress.

H. Hypertension.

I. Ototoxic drugs: More than 130 medications are known to cause tinnitus or hearing loss. Clients should be assessed for concurrent use of multiple ototoxic medications, especially when other risk factors are present. The most common broad categories include the following:

1. Analgesics.
2. Antibiotics.
3. Antineoplastics and immunosuppressives.
4. Diuretics.
5. Corticosteroids.

COMMON COMPLAINTS

A. Ringing.
B. Roaring.
C. Buzzing.
D. Clicking.
E. Hissing.
F. Hearing loss.
G. Fluttering.

OTHER SIGNS AND SYMPTOMS

A. "Muffled" hearing.
B. Change in own voice, lower pitch.

SUBJECTIVE DATA

A. Review the onset, duration, course, and type of symptoms; note whether they are bilateral, unilateral, or centralized.

B. Determine the frequency and quality of sound; is the ringing constant, intermittent, or pulsating?

C. Review all medications, including over-the-counter (OTC) drugs and prescriptions.

D. Determine if there is a family history of tinnitus, hearing loss, or neurofibromatosis.

E. Ask whether the client has experienced recent physical or emotional trauma. Inquire about recent/current stressors the client has experienced.

F. Inquire about any history of ontologic disorders, either acute or chronic.

G. Ask about associated symptoms:

1. Headache.
2. Hearing loss.
3. Noise intolerance.
4. TMJ.
5. Vertigo.

H. Review work, hobbies, and music habits for noise levels (potential damage).

I. Assess the date of last hearing exam and determine whether there was any known hearing loss.

J. Review whether client uses cotton-tipped swabs or other small objects for ear cleaning.

PHYSICAL EXAMINATION

A. General: The goal of the physical exam is to evaluate for the most common known causes of tinnitus.

B. Inspect:

1. Observe the external ear for discharge; note color and odor.
2. Conduct otoscopic exam of the auditory canal for cerumen impaction or foreign body.
3. Inspect the TM for color, landmarks, contour, perforation, and acute otitis media (AOM).

a. The landmarks (umbo, handle of malleus, and the light reflex) should be visible on a normal exam.
b. The TM should be pearly gray in color and translucent.
c. A bulging TM is more conical, usually with a loss of bony landmarks and a distorted light reflex.
d. A retracted TM is more concave, usually with accentuated bony landmarks and a distorted light reflex (pathologic conditions in the middle ear may be reflected by the characteristics of the TM).

C. Auscultate:

1. Assess for bruits or murmurs over the ear canal, auricular areas, neck, and chest.

D. Palpate:

1. Palpate auricle and mastoid area for tenderness, swelling, or nodules.
2. Palpate the TMJ for tenderness or crepitus.

E. Perform visual exam:

1. Inspect for papilledema.
2. Assess for visual field changes and for nystagmus.

F. Perform neurologic exam:

1. Assess all cranial nerves.
2. First evaluate how the client responds to your questions.
3. Clients who speak in a monotone or with erratic volume may have hearing loss.
4. Check the client's response to a soft whisper (should respond at least 50% of the time).
5. Perform Rinne and Weber tests.

DIAGNOSTIC TESTS

A. When tinnitus is acute (<3 weeks) and has no associated neurologic deficits or hearing loss, consider audiometry. Any focal neurologic findings warrant an MRI and/or prompt physician referral. Tinnitus lasting longer than 3 weeks should be referred to an otolaryngologist. Appropriate diagnostics are influenced by intermittent hearing loss, vertigo, abnormal physical exam findings, pulsatile quality, and unilateral presentation.

DIFFERENTIAL DIAGNOSES

A. Tinnitus.

B. Hearing loss that could be related to multiple otologic conditions:

1. Cerumen impaction.
2. Foreign body.
3. AOM.
4. Ménière disease.
5. Presbycusis.
6. Cholesteatoma.

C. TMJ syndrome.

D. Ototoxicity.

E. Central nervous system lesion.

PLAN

A. General interventions:

1. Assess for underlying cause of tinnitus.
2. Refer to an otolaryngologist for tinnitus lasting longer than 3 weeks.

B. Client teaching: *See Client Teaching Guide for this chapter, "Tinnitus."*

1. Educate the client regarding techniques/therapies to improve symptoms of tinnitus, such as sound therapy, interventions to reduce distress such as counseling, and cognitive behavioral therapy (mindfulness meditation, biofeedback). Consider hearing aids for clients with hearing loss and tinnitus.
2. Encourage the client to attend therapy sessions as indicated.

C. Pharmaceutical therapy:

1. Medications do not have a beneficial role in the treatment of tinnitus. There are no medications to "cure" tinnitus.

FOLLOW-UP

A. Length of follow-up depends on whether the client has an identified and/or treatable cause of tinnitus. Typically no specific follow-up is required for tinnitus unless a treatable problem is identified.

CONSULTATION/REFERRAL

A. Consult with an otolaryngologist as indicated.

B. Referral of an anxious client to the otolaryngologist may be necessary to assure the client that everything has been explored and that there is no serious or correctable underlying condition.

C. Any client with a history of head trauma should be referred to an otolaryngologist because in rare cases tinnitus may be associated with an acoustic neuroma, arteriovenous fistula, or an aneurysm of the intrapetrous portion of the internal carotid artery.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. Tinnitus onset later in life tends to be more abrupt and distressing than with younger adults. It is important to monitor this population closely for comorbid anxiety/depression, psychosocial changes, and sleep pattern disruptions.

2. Ringing in the ears can be a severe distraction that could increase the risk of unexpected accidents and falls.

3. Geriatrics with arterial bruits, venous hums, shunts, and high cardiac output are particularly vulnerable to exacerbative tinnitus. Monitor for social isolation and conversational withdrawal. Encourage referral for cochlear implants to those who have long-term tinnitus with profound hearing loss.

CLIENT TEACHING GUIDE

CERUMEN IMPACTION (EARWAX)

PROBLEM A buildup of earwax in the external ear canal that may cause itching, pain, dizziness, ear ringing, aural fullness, and/or temporary hearing loss.

CAUSE Earwax production is a normal, healthy process of the gland of the ear. Earwax is produced to protect the ear from infection and trauma. The wax is continuously being produced and removed from the ear on its own mechanism. Ears are self-cleaning organs. However, at times, an overproduction of wax may build up and remain in the external ear canal. With age, the normal mechanisms of the ear for removing earwax are decreased. This is called cerumen impaction. Use of cotton swabs to remove earwax can push the wax further into the ear and cause problems deeper into the ear canal.

PREVENTION Do not use cotton swabs, paper clips, bobby pins, or other objects to clean your ears. These can damage the ear canal and lead to an external ear infection and/or cause further impaction.

TREATMENT PLAN

A. It is generally safe to clean the external ears with a wet washcloth. The external ear that is visible to the eye is the only part of the ear that should be cleaned with a wet washcloth.

B. In general, it is preferable to allow your healthcare provider or your otolaryngologist to clean your ears. Do not try to remove the earwax on your own because of the chance of damaging your eardrum or creating an environment for bacteria to grow. Never stick any kind of tool into your ear. This will usually push the wax further into your ear canal, making removal more difficult for your healthcare provider.

Activity: As tolerated.

Diet: As tolerated.

Medications: _____

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If:

A. You are unable to hear.
B. You have colored drainage or fluid draining from your ears.
C. You run a fever.
D. You have dizziness.
E. Other: _____

Phone: _____

CLIENT TEACHING GUIDE

OTITIS EXTERNA

PROBLEM Your practitioner has diagnosed you with a condition known as otitis externa, sometimes also referred to as "swimmer's ear." This is a common condition characterized by itching in the ear, sometimes followed by ear pain, swelling, and drainage of the ear canal. Difficulty hearing may also occur. The eardrum is rarely affected.

CAUSE Otitis externa occurs from irritation to the external canal of the ear. The most common causes of otitis externa are long exposure to water in the ear canal after frequent swimming and too vigorous cleaning of the wax from your ears. It may involve either a bacterial or a fungal infection.

PREVENTION You may prevent future problems with otitis externa by following these measures:

A. Clean the outer ear only as needed. Do not use cotton-tipped swabs or any other device to clean down into the ear canal. Usually, wax is just pushed deeper into the canal with this method and the canal may be traumatized by the instrument used.

B. For swimmers or others susceptible to frequent recurrences of otitis externa, it may be helpful to dry the ear canals with a blow dryer on a low setting after exposure to water. You may also instill a solution of isopropyl alcohol (rubbing alcohol) in the ear twice daily and after every submersion in water. Do not instill rubbing alcohol into the ear if the ear is infected or if there is a hole in the eardrum.

C. Earplugs may be beneficial to swimmers with recurrences of otitis externa.

TREATMENT PLAN For the most common bacterial infections associated with otitis externa, antibiotic/steroid ear drops are usually prescribed. For fungal infections associated with otitis externa, antifungal/steroid ear drops are usually prescribed. Frequent cleanings by an otolaryngologist may be required to remove infection. For both bacterial and fungal infections associated with otitis externa, the ear should be kept dry until it is healed (including no swimming). To bathe or shower, first coat cotton balls with petroleum jelly and use them to plug the ears.

Activity: Avoiding moisture accumulation in the ear is important. Bathing and hair washing are permitted as previously described. Continue with dry ear precautions until cleared by your healthcare provider.

Diet: No changes are required in your diet.

Medications:

A. Ear drops are used to treat otitis externa.

B. The drops should be applied down the ear canal's opening, moving the earlobe back and forth to help the ear drops pass downward.

C. In severe cases, oral antibiotics may be given.

You Have Been Prescribed: _____

You Need to Instill _____ **Drops Into the Affected Ear** _____ **Times Per Day.**

You Need to Notify the Office If You:

A. Have symptoms that worsen or do not seem to be improving.

B. Have a fever over 100.8°F.

C. Have increased pain, redness, or swelling in the ear or around the ear or face.

D. Are unable to instill ear drops into the ear due to swelling of the ear canal.

E. Other: _____

Phone: _____

CLIENT TEACHING GUIDE

OTITIS MEDIA WITH EFFUSION

PROBLEM You have inflammation of the middle ear with effusion, which is the presence of fluid in the middle ear without infection.

CAUSE The middle ear fluid can remain behind the tympanic membrane after you have been treated for an ear infection (otitis media). The eustachian tube is blocked and the fluid behind the ear is not draining out properly. Symptoms may include difficulty hearing and a feeling of fullness in the ear.

TREATMENT PLAN

A. Determine if you are having increased difficulty hearing.
B. Make accommodations for the hearing loss, such as reducing or eliminating external noises while having a conversation clearly and loudly.
C. If you have a buildup of fluid in the middle ear for longer than 12 weeks or you notice a significant or increasing hearing deficit, you should receive a hearing evaluation.
D. Follow up with a healthcare provider as instructed to avoid complications and/or permanent hearing loss.

Activity: There is no activity restriction.

Diet: There is no special diet.

Medications: Middle ear fluid often resolves without treatment within 3 months. Nasal spray steroids and nasal spray antihistamines (Astelin) are sometimes prescribed and can improve the time that is taken for the fluid to resolve. These medications should be taken exactly as directed. Antibiotics are likely not needed.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If You Have:
A. Fever.
B. Decreased appetite.
C. Decreased activity level.
D. Ear pain.
E. Noticed a change in hearing loss or speech development.
F. Any other new symptoms that occur.
G. Other: _____

Phone: _____

CLIENT TEACHING GUIDE

TINNITUS

PROBLEM Tinnitus is an irritating noise or sound that is heard in one or both ears, commonly referred to as a buzzing, humming, or ringing noise.

CAUSE Tinnitus is poorly understood and the cause is not known. It probably originates in the brain and not the ear. There is a strong association between tinnitus, stress, anxiety, and depression. Stressors include emotional, physical (comorbidities), environmental, and so forth. You do not have to have hearing loss to have tinnitus.

TREATMENT PLAN

A. Hearing evaluation will be performed to determine if there is hearing loss.
B. A CT or MRI may be performed to evaluate for the cause of the tinnitus.
C. Rest, exercise, and mindfulness meditation are encouraged to reduce stress, anxiety, and depression, which can worsen symptoms of tinnitus.

Activity: There is no activity restriction.

Diet: Some foods may make the tinnitus worsen. Therefore, reducing the amount of sodium, nicotine, alcohol, and caffeine (tea, coffee, soft drinks) is encouraged.

Medications: Avoid aspirin. Aspirin has been known to aggravate the symptoms of tinnitus.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If You Have:
A. Fever.
B. Ear pain.
C. A change in hearing loss or speech development.
D. Dizziness.
E. Any other new symptoms that occur.
F. Other: _____

Phone: _____

CHAPTER 10

NASAL GUIDELINES

Jill C. Cash and Sarah Hendershott Taylor

ALLERGIC RHINITIS

DEFINITION

A. Allergic rhinitis is a chronic or recurrent condition characterized by nasal congestion, clear nasal discharge, sneezing, nasal itching, conjunctival itching, and periorbital edema. It usually occurs seasonally after exposure to allergens (same time every year, associated with pollen count) or may be perennial (year-round, related to indoor inhalants, animal dander, and mold). Although these classifications can occur distinctly, clients may also have combined seasonal and perennial allergic rhinitis. "Allergic" suggests that a specific immunoglobulin E (IgE) antibody mediates the condition.

INCIDENCE

A. Prevalence varies according to geographic region; 10% to 30% of adults have allergic rhinitis. In 70% of cases, allergic rhinitis develops before age 20.

B. Intranasal corticosteroid sprays are recommended for adolescents 12 years of age or older as initial treatment, instead of combination therapy with antihistamines and/or leukotriene antagonists.

C. Sleep-disturbed breathing is one of the most significant sequelae of allergic rhinitis.

PATHOGENESIS

A. This is an IgE-mediated inflammatory disease involving nasal mucosa; IgE antibodies bind to mast cells in the respiratory epithelium, and histamine is released. This results in naso-ocular inflammation, leading to congestion, rhinorrhea, sneezing, and pruritus. The nasal allergic response has an immediate and late phase. The immediate phase peaks 15 to 30 minutes after allergen exposure and the late phase peaks 6 to 12 hours after exposure.

PREDISPOSING FACTORS

A. Genetic predisposition to allergy (especially for individuals with eczema or asthma).

B. Exposure to allergic stimuli: pollens, molds, animal dander, dust mites, and indoor inhalants.

COMMON COMPLAINTS

A. Nasal congestion/obstruction.
B. Sneezing.
C. Clear rhinorrhea.
D. Cough from postnasal drip.
E. Sore throat.
F. Itchy, puffy eyes with tearing.

OTHER SIGNS AND SYMPTOMS

A. Dry mouth from mouth-breathing, snoring.
B. Sleep disturbance due to difficulty with breathing, leading to malaise/fatigue.
C. Itchy nose.
D. Decrease/loss of smell and taste.
E. Eczema.
F. Shortness of breath, difficulty breathing, and wheezing.
G. Headache.
H. Halitosis.

SUBJECTIVE DATA

A. Ask about onset, course, and duration of symptoms.
B. Inquire about the characteristics of nasal discharge.
C. Inquire about exposure to people with similar symptoms.
D. Ask about seasonal impact on symptoms.
E. Inquire about other diseases caused by allergens, such as asthma, eczema, and urticaria.
F. Rule out pregnancy.
G. Ask female clients about their birth control method, specifically birth control pills.
H. Review exposure to irritants.
I. Ask about any past or recent nasal trauma.

PHYSICAL EXAMINATION

A. Check vital signs: temperature, blood pressure, pulse, and respirations.
B. Inspect:
1. Examine face. Note Dennie lines (skin folds under the eyes) and allergic salute (transverse crease on the nose from chronic rubbing).
2. Examine eyes and conjunctivae.
   a. Tearing, red and swollen eyelids, and allergic shiners (dark circles under eyes from venous congestion in maxillary sinuses) are seen with allergies.
   b. Palpebral conjunctiva pale and swollen, bulbar conjunctiva is injected.
3. Examine ears, nose, and throat.
   a. Red, dull, bulging, perforated tympanic membrane is seen with otitis media.
   b. Nasal redness, swelling, polyps, and enlarged turbinates are seen with upper respiratory infection (URI). Mucosa appears pale blue, boggy with clear discharge in chronic allergies.
   c. Cobblestone appearance in pharynx, tonsils, adenoids, and turbinates is seen in chronic allergies.
   d. Use otoscope light to transilluminate under superior orbital ridge of frontal sinus cavity and also maxillary ▶

The contributions of Kathleen Bradbury-Golas to this chapter in prior editions are acknowledged here.

sinus cavity to assess for fluid in sinus cavity. Healthy sinuses contain air and light up symmetrically.

C. Palpate:

1. Palpate face and frontal maxillary sinuses for tenderness.

2. Examine head and neck for enlarged lymph nodes.

D. Percuss:

1. Percuss sinus cavities and mastoid bone.

2. Percuss chest for consolidation.

E. Auscultate:

1. Auscultate heart and lungs.

DIAGNOSTIC TESTS

A. Diagnosis may be made from history and physical. Other diagnostic tests include the following:

1. Best test: skin prick–puncture method to detect allergen sensitization.

2. Serum tests for allergen-specific IgE antibodies (e.g., IgE immunoassay).

DIFFERENTIAL DIAGNOSES

A. Allergic rhinitis.

B. URI.

C. Medication-induced rhinitis (consider systemic medications, nasal decongestants, or cocaine abuse).

D. Sinusitis.

E. Nasal polyps.

F. Work-related (e.g., irritant, corrosive).

G. Endocrine conditions such as hypothyroidism.

H. Influenza.

PLAN

A. General interventions:

1. Avoid allergens (most effective treatment).

2. Keep bedroom as allergen-free as possible. Implement changes in work and home environments; consider removing upholstery and carpets to reduce reservoirs for dust mites.

B. Client teaching: *See Client Teaching Guide for this chapter, "Allergic Rhinitis."*

C. Pharmaceutical therapy:

1. Topical therapy:

a. Topical corticosteroids are the single most effective maintenance therapy for allergic rhinitis. They have been proven more effective than oral or topical antihistamines. They are first-line agents for older adults.

i. Fluticasone propionate (Flonase), 50 mcg/spray, two sprays each nare daily.

ii. Mometasone (Nasonex), 50 mcg/spray, two sprays each nare daily.

iii. Beclomethasone (Qnasl), 80 mcg/spray, two sprays each nare daily.

iv. Budesonide (Rhinocort), 32 mcg/spray, two sprays each nare daily.

v. Triamcinolone (Nasacort), 55 mcg/spray, two sprays each nare daily.

vi. Fluticasone furoate (Flonase Sensimist), 27.5 mcg/spray, two sprays each nare daily.

b. Topical antihistamine: *Consider these options in place of oral antihistamine for older adults.*

i. Azelastine hydrochloride (Astelin), 0.1% or 0.15% spray, one to two sprays each nare, one to two times daily.

ii. Olopatadine (Patanase), 665 mcg/spray, two sprays each nare, BID.

c. Other agents:

i. Nasal saline:

1) Nasal spray or irrigations help lavage irritants from the mucosa.

2) Saline gel can help lubricate nasal mucosa to help prevent dryness.

ii. Ipratropium bromide (Atrovent nasal), 0.03% spray, two sprays each nare, two to three times daily.

1) Useful in decreasing rhinorrhea.

iii. Oxymetazoline (Afrin), 0.05% spray, one to two sprays each nare, one to two times daily.

1) **Must not use longer than 3 days due to rebound congestion.**

2) Decongestants are NOT recommended as monotherapy in chronic treatment but can help with severe nasal congestion.

iv. Phenylephrine (Neo-Synephrine), 1% spray or drops, two sprays/drops in each nare Q4H.

1) Therapy should not last longer than 3 days.

2) Decongestants are NOT recommended as monotherapy in chronic treatment but can help with severe nasal congestion.

2. Oral therapy:

a. Antihistamines (H_1 receptor antagonists) are the preferred agent. Several may need to be tried before an effective one is found. Drugs may also need to be switched occasionally to prevent tolerance. *Avoid first-generation, sedating antihistamines in older adults.*

i. Cetirizine (Zyrtec), 10 mg daily.

ii. Levocetirizine (Xyzal), 5 mg daily.

iii. Loratadine (Claritin), 10 mg daily.

iv. Fexofenadine (Allegra), 180 mg daily.

FOLLOW-UP

A. Client should return for follow-up visit in 2 to 3 weeks if necessary, earlier if symptoms worsen after 3 days of treatment.

CONSULTATION/REFERRAL

A. Refer the client to an allergist if symptoms continue and interfere with daily activities.

B. Allergist may prescribe immunotherapy following identification of offending allergens.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Over-the-counter (OTC) antihistamines such as diphenhydramine HCl (Benadryl) may be used for up to 5 days.

2. OTC decongestants such as oxymetazoline HCl (Afrin) may be used up to 3 days.

B. Geriatrics:

1. Beers considerations:

a. Antihistamines are effective for this population; however, there are more side effects and drug interactions in this group. Consider age and possible drug–drug interactions when prescribing medications for allergic rhinitis.

b. Anticholinergic effects in older adults are sedation, bladder/bowel retention, confusion, delirium, high risk of falls, and being prone to accidents.

c. Acetylcholinesterase inhibitors often prescribed for cognitively impaired geriatrics will increase anterior rhinorrhea.

d. Best tolerated medications for the elderly population that offer fewer side effects include the following:
i. Intranasal steroid sprays.
ii. Nasal saline rinse and spray.
iii. Most second-generation antihistamines, such as cetirizine, fexofenadine, and loratadine.
iv. Topical (nasal) antihistamine sprays.
v. Limited Benadryl might be appropriate for an acute, severe allergic reaction.

2. Studies show that sleep disordered breathing is more prevalent in the elderly with allergic rhinitis. Sleep efficiency was lower and waking after sleep onset was longer. It is imperative that clinicians obtain a thorough sleep history and assess for any signs/symptoms of sleep deprivation and decreased cognitive alertness with this population to maintain safety and quality of life.

3. The elderly population tends to be undertreated. Nasal steroid sprays are first-line agents and minimally sedating antihistamines can be used. Note that some may experience adverse anticholinergic side effects and starting with lower doses should be considered. Topical antihistamines are a good option and may be initiated prior to trial of oral antihistamines.

4. Common allergens for geriatrics with persistent allergic rhinitis are house dust mites, pet dander, and cockroach allergens. Assessment of elderly home environments and living conditions could initiate improved avoidance measures and reduce the risk of allergic outbreaks.

EPISTAXIS

DEFINITION

A. Epistaxis is a nosebleed or hemorrhage from the nose. This can be classified as anterior or posterior, depending on the source of bleeding.

INCIDENCE

A. Nosebleeds occur in approximately 60% of Americans at least once in their lifetime. However, fewer than 10% will seek medical care for a nosebleed. In the adult population, most cases occur between the ages of 45 and 65.

PATHOGENESIS

A. Epistaxis is caused by disruption of the nasal mucosa. More than 90% of nosebleeds are related to local irritation rather than underlying anatomic lesions and are self-limiting. Most start in the anterior nasal cavity (Kiesselbach plexus).

B. Posterior bleeds arise most commonly from the sphenopalatine artery and result in significant hemorrhage. Posterior nosebleeds require prompt referral to ED for care by an otolaryngologist and possible nasal packing, cautery, and/or hospital admission.

C. Nosebleeds more commonly occur during the winter months. They may also be associated with other conditions such as upper respiratory infections (URIs) or allergic rhinitis.

PREDISPOSING FACTORS

A. Local trauma, usually from nose picking.
B. Acute inflammation from a URI (e.g., common cold, acute sinusitis, and allergic rhinitis).
C. Vigorous nose-blowing.
D. Inhalation of chemical irritants.
E. Drying and crusting of nasal septum.
F. Trauma.
G. Cocaine use.
H. Pregnancy.
I. Neoplasm.
J. Systemic causes:
1. Bleeding disorders (most common).
2. Hypertension.
3. Heart failure.
4. Anticoagulation.

COMMON COMPLAINT

A. Common complaint is unusually severe or recurrent nosebleeds.

OTHER SIGNS AND SYMPTOMS

A. Anterior epistaxis:
1. Unilateral.
2. Continuous, mild/moderate bleeding from nasal septum.
B. Posterior epistaxis:
1. Brisk (arterial) bleeding.
2. Blood flowing into pharynx (indicates a more serious problem).

SUBJECTIVE DATA

A. Inquire about amount, duration, and frequency of bleeding. Ask about what side the bleeding started.
B. Ask about use of oral anticoagulants, aspirin, or aspirin-containing compounds (e.g., Pepto-Bismol, aspirin, Excedrin).
C. Ask about recent or current URIs, family history of abnormal bleeding, recent surgery, or trauma.
D. Rule out pregnancy.
E. Ask about possible foreign body in the nose.
F. Ask about cocaine use or occupational exposure to irritants or chemicals.
G. If the client has a history of nosebleeds, how did the client treat previous nosebleeds?
H. Has the client ever been evaluated for a blood clotting abnormality, such as thrombocytopenia or platelet dysfunction?
I. Does the client complain of bruising easily, melena, or heavy menstrual periods?
J. Ask about family history of bleeding disorders, such as hemophilia or von Willebrand disease.

PHYSICAL EXAMINATION

A. Check temperature, blood pressure (check for orthostatic hypertension), pulse, and respirations. **If nasal packing is required, take precaution and monitor client closely for vasovagal episode during insertion of nasal packing.**
B. Inspect:
1. Check airway patency with client sitting and leaning forward. ▶

2. Observe skin, mucous membranes, and conjunctiva for rash, pallor, purpura, petechiae, and telangiectasias.
3. Perform full eye exam, noting pupillary response.
4. Examine nose for septal perforations and ulcerations, which indicate cocaine use. Collagen diseases (such as lupus) are occasionally responsible for ulceration. Epistaxis is rare in hemophiliacs without trauma but is characteristic of von Willebrand disease.
5. Examine nasal discharge: A unilateral foul discharge with blood indicates a foreign body in the nose.
6. After bleeding has stopped:
a. Inspect nasal mucosa for color, discharge, masses, lesions, and swelling of turbinates.
b. Inspect the nasal septum for alignment, septal perforation, and crusting.

C. Auscultate:
1. Auscultate heart and lungs.

D. Palpate:
1. Check for enlarged lymph nodes in the neck to rule out sarcoidosis, tuberculosis, or malignancy.

E. Percuss:
1. Percuss sinuses.

DIAGNOSTIC TESTS

A. None required unless the client has recurrent or severe blood loss.
B. Drug screen, if indicated.
C. Hematocrit and hemoglobin if bleeding is severe.
D. Complete blood count (CBC) with differential.
E. Platelets, prothrombin time (PT), and partial thromboplastin time (PTT) if bleeding disorder is suspected.
F. Sinus films if recurrent sinus pain, tenderness, bleeding, or if nasal mass is suspected.

DIFFERENTIAL DIAGNOSES

A. Epistaxis.
B. Foreign body.
C. Septal deformity or perforation.
D. Nasal tumors or mass.
E. Coagulation disorder (von Willebrands disease).
F. Drug-induced coagulopathy.
G. Hypertension.
H. Pregnancy.

PLAN

A. General interventions:
1. The main goal is to stop bleeding or reduction of recurrence.

B. Client teaching: *See Client Teaching Guide for this chapter, "Nosebleeds."*

C. Treatment/management:
1. To control *anterior* bleeding:
a. Have client sit and lean forward to prevent swallowing of blood.
b. Initial tamponade:
i. Soak a cotton pledget in phenylephrine (Neo-Synephrine) or oxymetazoline (Afrin); place this plug into bleeding nostril and hold *bilateral* pressure over nasal alae for 10 to 15 minutes without releasing pressure.
ii. Remove and check for bleeding.
iii. If this fails, chemical cautery may be needed.
c. Cautery:
i. Only do cautery if bleeding site is visualized.
ii. Warn client that this may be a little painful. Anesthetize mucous membrane by applying cotton soaked with 2% lidocaine, lidocaine with epinephrine, or 4% cocaine.
iii. Apply silver nitrate by applying applicator tip to the site of bleeding for no longer than 10 seconds until a white precipitate forms. While silver nitrate needs moisture to work, it will only work on a relatively bloodless surface.
iv. Avoid overzealous cautery, which can lead to ulceration and perforation.
v. Avoid cautery of both sides of the septum, which can lead to tissue necrosis.
vi. If bleeding continues, repeat initial tamponade and cautery, then place a small amount of oxidized regenerated cellulose (Surgicel) against the bleeding artery. **If client continues to have high-flow epistaxis, nasal packing may need to be performed in emergency setting.**
vii. If bleeding stops, give client antibiotic ointment to apply gently with fingertip or cotton swab TID for 3 days. Saline gel or Vaseline can also be used.
2. To control *posterior* bleeding:
a. Have client sit and lean forward to prevent swallowing of blood.
b. As it can be difficult to determine the source of epistaxis, try to control bleeding first with the above steps of topical vasoconstrictor and anesthetic, then apply pressure.
c. **Consult a physician. The client needs ED care immediately due to rapid blood loss.**
d. Monitor vital signs (blood pressure and pulse) and order hematocrit; blood type and crossmatch may be needed.

FOLLOW-UP

A. Anterior epistaxis: as needed.
B. Posterior epistaxis: needs admission to hospital and referral to an otolaryngologist.

CONSULTATION/REFERRAL

A. Anterior epistaxis: Referral to an otolaryngologist is recommended for unsuccessful cessation of hemorrhage or persistent, recurrent epistaxis despite interventions.
B. Posterior epistaxis: Refer to a physician and/or otolaryngologist immediately.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
1. Nosebleeds are common.
2. Suggest use of saline spray to keep mucous membranes moist and use humidifier at bedtime.
3. Follow use of saline spray with Vaseline applied with Q-tip daily to prevent recurrent nosebleeds.

B. Geriatrics:
1. In the geriatric population, epistaxis is classically associated with hypertension, arteriosclerosis, coagulation disorders, chronic anemia, angina pectoris, and cerebral hemorrhages. Be sure to ask if the client has been prescribed daily aspirin or other anticoagulation and review education with client/family regarding the benefits as well as the risks.
2. Applying lipid-based lubricant on rims of nostrils to maintain mucosal moisture may cause lipoid pneumonia in the elderly. Use saline/water-based lubricant instead.
3. Although epistaxis with geriatrics may indicate an underlying serious condition, it might also be benign, related to natural aging: inflammation of mucosa, injury ▶

(scratching too hard), dryness, or side effects from medications.

NONALLERGIC RHINITIS

DEFINITION

A. Nonallergic rhinitis is rhinitis without an identifiable etiology and without an immunoglobulin E dependent component. It is characterized by nasal congestion, postnasal drainage, rhinorrhea, and sneezing, and is associated with some degree of autonomic dysregulation. It is classified in various ways: idiopathic, vasomotor, atrophic, geriatric, drug-induced, gustatory, occupational, or rhinitis of pregnancy.

INCIDENCE

A. Nonallergic rhinitis may be responsible for 17% to 52% of all rhinitis cases in adults.

B. Of nonallergic rhinitis clients, 70% present with symptoms after 20 years of age (whereas a majority of allergic rhinitis clients present before the age of 20).

PATHOGENESIS

A. No single theory of pathogenesis for chronic nonallergic rhinitis has been determined, but it can be divided into noninflammatory and inflammatory. It is a diagnosis of exclusion.

B. Clients exhibit clinical hypersensitivity of nasal mucosa to certain odors and irritants.

C. Atrophic and geriatric rhinitis result from progressive atrophy of nasal mucosa.

D. Overuse of topical nasal decongestants or cocaine and some systemic medications can result in nasal dysfunction.

E. Rhinitis of pregnancy results from hormonal changes; symptoms abate with delivery.

PREDISPOSING FACTORS

A. Adulthood.

B. Abrupt changes in temperature, odors, and emotional stress.

C. Other predisposing factors depend on type (e.g., overuse of medications, side effects of systemic medications, and occupational environment).

COMMON COMPLAINTS

A. Nasal congestion.

B. Sneezing.

C. Clear rhinorrhea.

D. Coughing.

E. Symptoms are often exacerbated by weather conditions.

SUBJECTIVE DATA

A. Ask about the onset, duration, and course of symptoms. Clinical history is the **most important** tool used to make distinction between allergic and nonallergic rhinitis.

B. Inquire about the color and other characteristics of nasal discharge.

C. Ask about other discomforts and exposure to people with similar symptoms.

D. Inquire about seasonal impact on symptoms, effect of weather changes on symptoms, previous treatments, and results.

E. Rule out pregnancy. Ask female clients about birth control method, specifically contraceptives.

F. Ask about use of prescription drugs, over-the-counter (OTC) drugs (especially aspirin), and illicit drugs (cocaine).

G. Review medical history for other respiratory problems, such as asthma, emphysema, or chronic bronchitis.

PHYSICAL EXAMINATION

A. Check temperature and blood pressure.

B. Inspect:

1. Observe general appearance.
2. Inspect conjunctivae for "allergic shiners" (dark circles under eyes), tearing, and eyelid swelling.
3. Examine ears for signs of otitis media (red, bulging, perforated tympanic membrane, and purulent drainage).
4. Examine nose for redness, swelling, polyps (soft, pedunculated, nontender, pale-gray smooth structures), enlarged turbinates, foreign objects, septal deviation, septal perforation (sign of cocaine abuse), ischemia, mucosal injury, atrophy, and "cobblestoned" pharyngeal mucosa (sign of allergy). **However, none of these findings are diagnostic and the mucosa may appear relatively normal in nonallergic rhinitis.**

C. Auscultate:

1. Auscultate heart and lungs.

D. Percuss:

1. Percuss sinus cavities and mastoid process.
2. Percuss chest for consolidation.

E. Palpate:

1. Palpate face for sinus tenderness.
2. Palpate head and neck for enlarged lymph nodes.

DIAGNOSTIC TESTS

A. Nonallergic rhinitis is a diagnosis of exclusion. Diagnosis is based on characteristic history and physical exam, as well as absence of clinical allergy to aeroallergens.

B. Skin testing for allergies may be done to exclude allergic rhinitis.

DIFFERENTIAL DIAGNOSES

A. Nonallergic rhinitis.

B. Allergic rhinitis.

C. Upper respiratory infection (URI).

D. Foreign body.

E. Sinusitis.

F. Deviated septum.

G. Tumor.

H. Nasal polyps.

I. Endocrine conditions such as hypothyroidism and pregnancy.

J. Drug use: oral contraceptives, aspirin, alpha-adrenergic blockers, cocaine, and nasal decongestant overuse.

PLAN

A. General interventions:

1. Identify triggers and address alleviating triggers with avoidance/minimization.

B. Client teaching:

1. Teach the client the significance of individual triggers for nonallergic rhinitis. Encourage use of a journal to learn personal triggers.

2. Avoid triggers such as smoking, smoke-filled rooms, wood-burning stoves/fireplaces, sprays, and perfumes.

3. Other triggers may include weather changes, hormonal changes, and medications.

4. Teach methods of treatment and identify treatments that work best for the client.

5. Encourage use of neti pot or nasal saline flush with warm saline water daily to cleanse sinus cavity. Cleansing the sinus cavity daily will help remove foreign materials inhaled and will also help with tissue edema. Clean pot after each use and allow to air-dry.

C. Pharmaceutical therapy:

1. Monotherapy versus combination therapy:

a. Clients with mild disease may be adequately treated with intranasal corticosteroid or intranasal antihistamine spray. For clients who are more symptomatic, clinical evidence has shown combination therapy to be more effective, with both daily intranasal corticosteroid and antihistamine spray.

b. Topical corticosteroids:

i. Fluticasone propionate (Flonase), 50 mcg/spray, two sprays each nare daily.

ii. Mometasone (Nasonex), 50 mcg/spray, two sprays each nare daily.

iii. Beclomethasone (Qnasl) 80 mcg/spray, two sprays each nare daily.

iv. Budesonide (Rhinocort), 32 mcg/spray, two sprays each nare daily.

v. Triamcinolone (Nasacort), 55 mcg/spray, two sprays each nare daily.

vi. Flonase furoate (Flonase Sensimist), 27.5 mcg/spray, two sprays each nare daily.

c. Topical antihistamine:

i. Azelastine hydrochloride (Astelin), 0.1% or 0.15% spray, two sprays each nare one to two times daily.

ii. Olopatadine (Patanase), 665 mcg/spray, two sprays each nare BID.

2. If rhinorrhea is the dominant or only symptom (such as in gustatory rhinitis or rhinitis in older adults), recommend anticholinergic nasal spray:

a. Ipratropium (Atrovent) 0.03% or 0.06%, two sprays each nare, two to three times daily.

3. Decongestants: Oral and nasal decongestants are NOT recommended unless antihistamines and nasal steroids have failed. Examples include oral pseudoephedrine and nasal oxymetazoline (Afrin).

a. **Therapy should not continue longer than 3 days to prevent effects of rebound congestion.**

FOLLOW-UP

A. Clients receiving chronic therapy for rhinitis should be seen every 3 to 12 months, depending on severity of symptoms.

CONSULTATION/REFERRAL

A. Consult with a physician if symptoms continue despite treatment.

B. If treatment fails, refer the client to an allergist for testing and/or ear, nose, and throat specialist to consider surgical approaches for clients with severe, chronic nonallergic rhinitis.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Reassure pregnant clients that rhinitis is a common hormonal response. Nonallergic rhinitis is not contagious and cannot cross the placenta.

B. Geriatrics:

1. Obstructive sleep apnea is associated with allergic and nonallergic rhinitis. Obtain a thorough sleep history and look for any signs/symptoms of sleep deprivation and/or decreased cognitive alertness.

Lieberman, P. L. (2020). Chronic nonallergic rhinitis. In J. Corren (Ed.), *UpToDate*. Wolters Kluwer. https://www.uptodate.com/contents/chronic-nonallergic-rhinitis?search=nonallergic%20rhinitis&source=search_result&selectedTitle=1~63&usage_type=default&display_rank=1#H19

Peden, D. (2020). An overview of rhinitis. In J. Corren (Ed.), *UpToDate*. Wolters Kluwer. https://www.uptodate.com/contents/an-overview-of-rhinitis?search=nonallergic%20rhinitis&source=search_result&selectedTitle=2~63&usage_type=default&display_rank=2

SINUSITIS

DEFINITION

A. Sinusitis (often referred to as rhinosinusitis) is inflammation of the mucous membranes and the paranasal sinuses. It may be acute, subacute, or chronic.

1. Acute sinusitis: abrupt onset of inflammation and/or infection with symptom resolution after therapy, lasting less than 4 weeks.

2. Subacute sinusitis: persistent symptoms despite therapy, lasting 4 to 12 weeks.

3. Chronic sinusitis: episodes of prolonged (>12 weeks) inflammation and/or infection.

INCIDENCE

A. Sinusitis is very prevalent, affecting millions of people in the United States each year. It is estimated that one in seven individuals in the United States will experience an episode of acute sinusitis each year. Incidence is higher among females, and among all adults it is highest in those aged 45 to 64. Chronic sinusitis affects between 5% and 12% of the general population.

PATHOGENESIS

A. Etiology of acute rhinosinusitis involves factors such as environmental, anatomic, and systemic. These factors can occur at the same time and predispose clients not only to acute sinusitis but also to the development of chronic sinusitis.

B. The most common cause of acute sinusitis is viral infection, with the most common causes being rhinovirus, influenza virus, and parainfluenza virus. Acute bacterial rhinosinusitis occurs in 0.5% to 2% of all sinusitis episodes. The most common bacterial organisms are *Streptococcus pneumoniae, Haemophilus influenzae*, and *Moraxella catarrhalis*. If acute sinusitis infections are not resolved or become recurrent, *Staphylococcus aureus* or *Pseudomonas aeruginosa* can become dominant.

C. The transition from viral to bacterial has been studied extensively and is thought to be secondary to decreased mucociliary clearance and consequent colonization of bacteria on retained mucus secretion from the obstruction of outflow. The sinonasal mucosa inflammation from the triggering agent stuns the cilia and mucus remains trapped in the sinuses, and ▶

bacteria proliferate. Anatomic abnormalities can also interfere with normal mucociliary clearance and can prolong illness.

D. Other causes of acute sinusitis are fungi, dental abscess, and autoimmune reactions. Fungal sinusitis tends to occur in immunosuppressed clients.

PREDISPOSING FACTORS

A. Recent upper respiratory infection (URI).
B. Allergic rhinitis.
C. Cigarette smoke (firsthand or secondhand).
D. Air pollutant exposure.
E. Sinonasal anatomy (septal deviation, septal spurs, turbinate hypertrophy, Haller cells, adenoidal hypertrophy, or obstructive mass).
F. Ciliary dysfunction (as in Kartagener syndrome and cystic fibrosis).
G. Dental anatomy/abscess.
H. Asthma.
I. Neoplasms.
J. Immunodeficiency (often associated with recurrent acute or chronic sinusitis).
K. Trauma.
L. Diving and swimming.
M. Air travel or rapid changes in altitude.

COMMON COMPLAINTS

A. Mucopurulent rhinorrhea.
B. Headache and/or facial pain.
C. Dental or ear pain.
D. Loss of smell (anosmia).
E. Nasal congestion.

OTHER SIGNS AND SYMPTOMS

A. Fever (mostly associated with acute sinusitis).
B. Malaise or fatigue.
C. Cough.
D. Periorbital edema.
E. Halitosis.
F. Snoring, mouth-breathing.
G. Hyponasal speech.

POTENTIAL COMPLICATIONS

A. Consider immediate ear, nose, and throat referral.
  1. Meningitis (symptoms are increased fever, stiff neck).
  2. Preseptal or orbital cellulitis.
  3. Subperiosteal or intracranial abscess.
  4. Epidural abscess.
  5. Cavernous sinus thrombosis (acute thrombophlebitis due to infection in the area where veins drain into the cavernous sinus).
  6. Osteomyelitis of the sinus bones.

SUBJECTIVE DATA

A. Elicit onset, duration, and course of symptoms. Have symptoms lasted longer than 10 days or longer than 12 weeks?
B. Inquire whether seasons affect symptoms.
C. Ask the client about recent URI and how it was treated. Did the client receive antibiotics? Did the client finish the full course of antibiotics?
D. Ask about allergies.
E. Inquire about recent dental problems, especially dental abscesses.
F. Find out what home therapies and over-the-counter (OTC) medications the client tried before the office visit.
G. Ask if the client took a trip recently, especially by airplane.
H. Inquire whether the client was swimming or diving recently.
I. Review the client's medical history for cystic fibrosis, asthma, nasal abnormalities (e.g., deviated septum), and other respiratory problems.

PHYSICAL EXAMINATION

A. Check temperature, blood pressure, pulse, and respirations.
B. Inspect:
  1. Observe eyes for periorbital swelling, "allergic shiners" (dark circles under eyes), tearing, and signs of orbital cellulitis (conjunctival edema, drooping lid, decreased extraocular motion, and vision loss).
  2. Examine ears.
  3. Inspect the nose for erythema, edema, discharge, lack of nostril patency, septal deviation and polyps, and presence of a foreign body.
  4. Transilluminate maxillary and frontal sinuses in a darkened room. Absence of light reflection is not definitive.
  5. Examine the mouth and pharynx for erythema and tonsillar enlargement, check teeth for uneven surfaces (sign of grinding), and check retropharynx for evidence of postnasal drip.
C. Auscultate:
  1. Auscultate heart and lungs.
D. Palpate:
  1. Palpate all sinuses for pain and tenderness.
    a. Frontal sinusitis: pain on palpation of forehead.
    b. Maxillary sinusitis: the cheeks are tender, or the client may present with jaw and tooth pain.
    c. Ethmoid sinusitis: swelling and tenderness in the eyelids and surrounding tissue.
  2. Palpate neck for lymphadenopathy.
E. Perform neurologic exam:
  1. Evaluate for signs of meningeal irritation, assessing for Brudzinski sign, Kernig sign, and nuchal rigidity.

DIAGNOSTIC TESTS

A. Diagnosis is usually made through history and physical.
B. If the disease is refractory to initial treatment or becomes recurrent or chronic, further investigation may be necessary.
  1. Rule out immunodeficiencies (cystic fibrosis, Wegener granulomatosis, sarcoidosis, Churg–Strauss syndrome).
  2. Skin testing for allergies.
  3. Nasal endoscopy to detect abnormalities of the nasal passage (polyps, pus). Culture can be obtained for culture-directed antimicrobial treatment.
  4. Sinus CT is the best imaging method for viewing paranasal sinuses and reveals extent of inflammation and disease. CT is not recommended for routine investigation for acute rhinosinusitis. It is recommended for chronic and recurrent sinusitis, for clients in immunocompromised state, or if there is concern for complications (e.g., fungal sinusitis, disease extending outside of the sinus cavities).

DIFFERENTIAL DIAGNOSES

A. Sinusitis.
B. Headache (cluster, migraine).
C. Rhinitis (allergic or nonallergic).
D. Temporomandibular joint disease.
E. Trigeminal neuralgia.
F. Cerebral spinal fluid rhinorrhea.
G. Tumor/neoplasm.
H. Autoimmune disease.
I. Odontogenic disease.

PLAN

A. General interventions:

1. Teach client to avoid smoking and secondhand smoke.

2. Drinking extra fluids helps loosen secretions and hydrate the body.

3. Encourage the client to use medications as prescribed. OTC medications such as antihistamines and decongestants should be used with caution.

4. Application of warm, moist compress to the face several times a day will help with discomfort.

5. Humidifiers should be used daily. Advise client to clean humidifiers on a regular basis.

6. Nasal saline to the nares three times a day will help keep nasal passages moist.

B. Client teaching: *See Client Teaching Guide for this chapter, "Sinusitis."*

C. Pharmaceutical therapy:

1. Initial treatment with antibiotics should be 5 to 7 days, and if not improving on initial therapy can extend to 10 to 14 days.

a. First-line treatment: Augmentin 875 mg BID or 500 mg TID.

b. At risk of pneumococcal resistance or failed initial therapy (older than 65 years, recent hospitalization, recent use of antibiotics in the past month, or immunocompromised client): Augmentin 2,000 mg BID.

c. Beta-lactam allergy: doxycycline 100 mg BID or 200 mg daily.

d. Respiratory fluoroquinolone can be considered as alternative for penicillin-allergic clients but should be reserved for those who have no alternative treatment options: levofloxacin 750 mg or 500 mg daily or moxifloxacin 400 mg daily.

e. The same antibiotics can be used for chronic sinusitis, but treatment should last 3 to 4 weeks.

2. Oral and topical decongestants may be used to correct the underlying edematous mucosa (use cautiously with hypertension).

a. Oxymetazoline (Afrin) 0.05% spray, one to two sprays each nare, one to two times daily. DO NOT use longer than 3 days.

b. Phenylephrine (Neo-Synephrine) 1% spray or drops, one to two sprays/drops each nare Q4H.

c. Pseudoephedrine HCl 30 to 60 mg up to TID.

d. Nasal saline spray throughout the day and saline irrigation BID.

3. Intranasal corticosteroid sprays may be used to decrease nasal inflammation.

a. Fluticasone propionate (Flonase), 50 mcg/spray, two sprays each nare daily.

b. Mometasone (Nasonex), 50 mcg/spray, two sprays each nare daily.

c. Beclomethasone (Qnasl) 80 mcg/spray, two sprays each nare daily.

d. Budesonide (Rhinocort), 32 mcg/spray, two sprays each nare daily.

e. Triamcinolone (Nasacort), 55 mcg/spray, two sprays each nare daily.

f. Flonase furoate (Flonase Sensimist), 27.5 mcg/spray, two sprays each nare daily.

4. Antihistamines are recommended to block histamine production in response to the allergy triggers and prevent allergy symptoms.

a. Cetirizine (Zyrtec), 10 mg daily.

b. Levocetirizine (Xyzal), 5 mg daily.

c. Loratadine (Claritin), 10 mg daily.

d. Fexofenadine (Allegra), 180 mg daily.

FOLLOW-UP

A. Recheck the client in 5 to 7 days after initial therapy, and if no improvement consider extending therapy or alternative therapy.

B. If the client is not improving and may be resistant to antibiotics, they may be switched to a different antibiotic for 14 days.

CONSULTATION/REFERRAL

A. Admit the client to the hospital if they have signs and symptoms that the disease has spread intracranially or intraorbitally.

B. Refer the client to an otolaryngologist if they do not improve in 4 weeks or after failed medical therapy.

C. Refer the client to an otolaryngologist for suspected neoplasm, abscess, osteomyelitis, meningitis, or sinus thrombosis.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Amoxicillin/Augmentin are the desired antibiotics for use during pregnancy.

2. Clients who are allergic to penicillin should be treated with azithromycin.

3. Doxycycline and fluoroquinolones are NOT recommended during pregnancy.

B. Geriatrics:

1. Nose-blowing precautions should be used for clients currently prescribed warfarin (Coumadin) and/or aspirin and other anticoagulants.

2. Avoid use of trimethoprim-sulfamethoxazole (TMP-SMX) with warfarin because the medication can cause a significant increase in prothrombin time (PT)/international normalized ratio (INR). Also avoid TMP-SMX in clients taking angiotensin-converting enzyme inhibitor or angiotensin receptor blocker or clients with decreased creatinine clearance to avoid hyperkalemia.

3. Inappropriate antibiotic therapy with geriatrics can cause significant risks and adverse effects that include drug interactions and contraindications, side effects related to polypharmacy, age-related metabolisms, risks of multidrug-resistant organisms, and *Clostridium difficile*:

4. Home treatment suggestions for geriatrics:

a. Safe (reliable brand) home humidifier with automatic shutoff and adequate weight balance to prevent hot steam spillage and avoid burns.

b. Drinking plenty of water or hot/cold herbal teas—staying well hydrated.

c. Placing a warm, moist washcloth over nose and sinuses.

d. Using gentle saline rinses; or while showering, breathing in steam an extra couple of minutes.

e. Minimizing exposure to allergens (dust and dander).

CLIENT TEACHING GUIDE

ALLERGIC RHINITIS

PROBLEM Allergic rhinitis is a chronic or recurrent condition. Common symptoms are nasal congestion, sneezing, and clear nasal discharge. It is not contagious, so you cannot catch it from anyone and you cannot spread it to others.

CAUSE You are having an allergic response after being exposed to an allergen.

PREVENTION

A. The best prevention is to avoid things you know you are allergic to, for example, smoke (cigarette, cigar, wood smoke), pollens and molds, animal dander, dust mites, and indoor inhalants such as hair spray and other aerosol spray products.
B. Target your bedroom as "allergy free" by removing carpets, damp mopping the floors weekly, hanging washable curtains instead of blinds, removing books and stuffed animals, using foam pillows, and encasing the pillows and mattress in plastic.
C. Do not blow your nose too frequently or too hard. It may cause your eardrum to perforate (tear). Blow through both nostrils at the same time to equalize the pressure.
D. Use tissues when you blow your nose. Dispose of them and then wash your hands. If no tissue is available, do the "elbow sneeze" into the bend of your arm (away from your open hands). Always wash your hands.

TREATMENT PLAN

A. Use the air conditioner in your house and car to reduce exposure to pollens.
B. Use an air filtration system in your house or buy a small one for your bedroom.
C. Dust your house often, using a cloth and cleaner or polish to keep dust from flying.
D. Allergy testing may need to be done if you have had allergies for a long time. Ask your healthcare provider about a consultation with an allergist.

Activity: There are no activity restrictions. However, you may want to exercise indoors during the spring, summer, and fall when pollen counts are high.

Diet: Eat well-balanced meals. Drink at least six to eight glasses of liquid a day.

Medications: Common medications used include antihistamines, decongestants, and nasal sprays.
A. Antihistamines: Some antihistamines may cause drowsiness; use with caution. You may consider using a different antihistamine during the day that does not cause drowsiness.
B. Decongestants: Decongestants may increase blood pressure and may also interact with other medications. Please consult with your provider before using these medications.
C. Nasal sprays: Nasal saline spray is safe to use several times a day. Nasal decongestant sprays may be used for a short period of time. Do NOT use longer than 3 days to prevent rebound side effects from this medication. Consult with your provider if using a nasal decongestant spray.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If:
A. You experience trouble breathing or catching your breath.
B. You have asthma and your symptoms worsen.
C. Your symptoms are not any better after using the medications for 3 complete days.
D. Your nasal discharge changes to a greenish color.
E. Other: _____

Phone: _____

CLIENT TEACHING GUIDE

NOSEBLEEDS

PROBLEM Most nosebleeds stop within 10 minutes. **If you have trouble breathing with a nosebleed, *call 911***.

CAUSE Nosebleeds may be caused by several problems:
A. Trauma from nose picking or forcefully blowing the nose.
B. Chronic sinus infections.
C. Allergies.
D. Drugs, including over-the-counter medications such as aspirin and Pepto-Bismol, or street drugs such as snorted cocaine.
E. Exposure to irritants.

PREVENTION
A. Avoid picking your nose. Keep fingernails trimmed short.
B. Do not blow your nose too frequently or too hard (it may also cause eardrum tearing).
C. Blow your nose through both nostrils at the same time to equalize pressure.
D. Use a humidifier in your home, or place a container of water near the radiator.
E. Keep the inside of your nose moist and promote healing with a nasal saline spray or gel.
F. Avoid smoking and secondhand smoke.

TREATMENT PLAN
A. If you experience a nosebleed, take these steps:
  1. Sit up and lean forward.
  2. Apply pressure to the bridge of your nose for 10 to 15 minutes to stop the blood flow.
  3. If the bleeding continues, spray Afrin into your nostril.
  4. If the bleeding still continues, lightly soak a cotton ball with the nasal spray, insert it into your nose, and press.
  5. If the bleeding stops, use nasal saline spray and gel to keep the area moist and promote healing. Avoid picking your nose or hard nose-blowing.
B. If the bleeding continues, seek medical care.

Activity: Avoid or limit the following activities for 3 to 5 days after a nosebleed:
A. Heavy lifting.
B. Straining.
C. Bending over from the waist.
D. Very hot showers.

Diet: Avoid hot, spicy foods for 3 to 5 days after a nosebleed.

Medications: Avoid medications that increase bleeding, such as aspirin and Pepto-Bismol.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If:
A. Bleeding does not stop with pressure or nasal spray applied to the bleeding site.
B. You keep having nosebleeds (more than two in a week or four in a month).
C. Other: _____

Phone: _____

CLIENT TEACHING GUIDE

SINUSITIS

PROBLEM Sinusitis (sinus infection) is classified as an acute, subacute, or chronic condition. In acute sinusitis, the infection is resolved after treatment. In subacute sinusitis, there is a persistent, yellow to green nasal discharge despite treatment. In chronic sinusitis, episodes of prolonged inflammation continue longer than 3 months despite treatment.

CAUSE Sinusitis occurs when the mucous lining in your sinus cavities becomes inflamed and infected with viruses, bacteria, or allergen. This can occur after a cold or tooth abscess.

PREVENTION

A. If you have a tooth abscess, see your dentist and finish all your antibiotics.
B. Do not blow your nose too frequently or too hard. It may cause your eardrum to perforate (tear). Blow through both nostrils at the same time to equalize pressure.
C. To prevent spreading germs to others, cover your mouth when you cough.
  1. Use tissues when you blow your nose. Dispose of them and then wash your hands.
  2. If no tissue is available, do the "elbow sneeze" into the bend of your arm (away from your open hands).
D. Always wash your hands after coughing or using tissues.

TREATMENT PLAN

A. Avoid smoking and secondhand smoke.
B. Use steam inhalation to liquefy secretions.
C. Use a room humidifier. Keep your humidifier clean—it can grow bacteria.

Activity: There are no activity restrictions; however, diving, swimming, and flying may increase the occurrence of symptoms or make them worse. Make sure to get plenty of rest each day.

Diet: Eat a healthy diet. Drink at least 8 to 10 glasses of liquid every day.

Medications: Take all of your prescribed antibiotics (if indicated), even if you feel better.

Over-the-counter medications:
A. Pain relievers: ibuprofen (Advil) or acetaminophen (Tylenol) as needed for facial pain.
B. Antihistamines: Some antihistamines may cause drowsiness. Use with caution. You may consider using an antihistamine during the day that does not cause drowsiness.
C. Decongestants: Decongestants may increase blood pressure and may also interact with other medications. Please consult with your provider before using these medications.
D. Nasal sprays: Nasal saline spray is safe to use in the nose several times a day. Nasal decongestant sprays may be used for a short period of time. Do NOT use longer than 3 days to prevent rebound side effects from this medication. Consult with your provider if you are using a nasal decongestant spray.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Call the Office If:
A. Your eyelids begin to swell or droop, or you experience decreased vision.
B. You have stiffness in your neck or increased fever.
C. You have asthma and you are getting worse.
D. You begin vomiting and are unable to keep down your antibiotic.
E. You are a diabetic and your blood sugars are elevated, or you notice ketones in your urine.
F. Other: _____

Phone: _____

CHAPTER 11

THROAT AND MOUTH GUIDELINES

Jill C. Cash and Kathleen Bradbury-Golas

DENTAL ABSCESS

DEFINITION

A. A dental abscess is a space infection of the gingival or periodontal tissues.

INCIDENCE

A. The incidence is unknown.

PATHOGENESIS

A. An abscess occurs when bacteria gain access into the gingiva or periodontal tissues. Dental infections are often polymicrobial and usually caused by anaerobic gram-negative rods and gram-positive cocci.

PREDISPOSING FACTORS

A. Poor dental hygiene.
B. Dental caries.
C. Low socioeconomic status.
D. Poor nutrition.
E. Physical and mental disabilities.

COMMON COMPLAINTS

A. Throbbing pain at infected site that may radiate to jaw, ears, cheek, neck, head.
B. Swelling (gingival edema).
C. Difficulty chewing with tooth due to pain.

OTHER SIGNS AND SYMPTOMS

A. Fever.
B. Warmth, redness.
C. Loss of appetite.
D. Heat and cold sensitivity.
E. Halitosis.
F. Trismus (unable to open mouth).

POTENTIAL COMPLICATIONS

A. The risk of complications increases with valvular disease. The following are complications:
1. Sepsis.
2. Leukocytosis associated with facial cellulitis.
3. Hematogenous dissemination to native or prosthetic heart valves, joints, or other devices.
4. Osteomyelitis of the jaw.

SUBJECTIVE DATA

A. Elicit information from the client regarding onset, duration, location, and quality of pain.
B. Note radiation of pain as well as alleviating or aggravating factors.
C. Note if pain is brought on by contact with hot, cold, or sweet substances; this may indicate periapical abscess or dental caries.
D. Ask if the client has a fever. If so, ask how high and for how long.
E. Inquire about history of mitral valve prolapse or rheumatic fever.

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure.
B. Inspect:
1. Inspect teeth for caries, mobility of teeth or protrusion from sockets, and gum disease.
2. Examine teeth for erosion, enamel decalcification, diminished tooth size, discoloration, and sensitivity to temperature changes.
C. Palpate:
1. Palpate neck and submental area for enlarged, tender lymph nodes.
D. Percuss:
1. Percuss all teeth. Tenderness is diagnostic of an abscess.
E. Auscultate:
1. Auscultate heart and lungs.

DIAGNOSTIC TESTS

A. CT.
B. X-ray (consider panoramic).
C. Serum labs: complete blood count (CBC) with differential.

DIFFERENTIAL DIAGNOSES

A. Dental abscess.
B. Periodontal disease.
C. Cellulitis.
D. Peritonsillar abscess.

PLAN

A. General interventions:
1. Treat immediate infection.
2. Refer to a dentist for immediate evaluation and treatment.
B. Client teaching:
1. Advise client to apply a heating pad to painful facial area for comfort.
2. Advise soft diet until pain resolves.

3. Review daily dental care and hygiene with client. Recommend regular brushing and dental flossing after meals, use of fluoride and/or antimicrobial mouth rinse, smoking cessation, reducing sugar intake, and regular dental appointments.

4. Chlorhexidine 0.12% oral mouth rinse may be used for gingivitis.

C. Pharmaceutical therapy:

1. Drug of choice: amoxicillin-clavulanic acid (Augmentin) 875 mg BID for 7 to 14 days. Dental consultation required.

2. Other medications (penicillin-allergic clients):

a. Clindamycin (Cleocin) 300 to 450 mg orally Q8H until dental consultation.

b. Cephalexin (Keflex) 500 mg Q6H until dental consultation.

c. **Levofloxacin plus metronidazole if clindamycin-resistant.**

3. For discomfort and fever: ibuprofen (Advil) 400 to 600 mg orally every 6 to 8 hours, not to exceed 1,200 mg/d. Tylenol 500 mg orally every 4 to 6 hours may be used for clients with renal impairment. Consider renal function when prescribing nonsteroidal anti-inflammatory drugs (NSAIDs) to older adults and geriatric clients.

FOLLOW-UP

A. Follow up 2 to 3 days after dental exam to evaluate results, as needed.

CONSULTATION/REFERRAL

A. Advise the client to see a dentist promptly, even if pain resolves.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Clients may safely have dental procedures during pregnancy.

2. X-ray films may be taken with lead shield over the client's abdomen.

3. Epinephrine and nitrous oxide should not be used during dental procedures.

4. Tetracycline should not be used; it causes staining of fetal bones and teeth.

B. Geriatrics:

1. Two primary oral factors with older adults' propensity for dental abscess are the following:

a. Xerostomia: hypofunction of salivary glands, medications (antihypertensives, antidepressants, antipsychotics), and diabetes.

b. Facial pain: root caries and reduced masticatory ability (could lead to malnutrition), which lowers the body's immune system.

2. Observational studies indicate that the elderly population with remaining teeth tend to have less dental abscesses or periodontal problems. They performed appropriate physical functioning, were less frail, and maintained better oral healthcare. These factors decrease the risk of health problems and infections that arise during the aging process.

3. When oral healthcare educational programs are implemented to geriatrics (in the community setting or long-term care facility), plaque levels improve and there is decreasing trend in gingival bleeding/infections. Chlorhexidine 0.12% mouth rinse may be used for gingivitis. Encourage elderly clients and their families to maintain oral healthcare and visit a dentist regularly.

BIBLIOGRAPHY

Menegas, S., Moayedi, S., & Torres, M. (2021). Abscess management: An evidence-based review for emergency medicine clinicians. *Journal of Emergency Medicine (0736-4679)*, *60*(3)310–320. https://doi-org.proxy.library.vanderbilt.edu/10.1016/j.jemermed.2020.10.043

DYSPHAGIA

DEFINITION

A. Dysphagia is defined as difficulty swallowing.

1. Oropharyngeal dysphagia is defined as difficulty with the initial task of swallowing, which can be accompanied by choking, coughing, or a food block in the pharynx.

2. Esophageal dysphagia is defined as difficulty swallowing after initiation of swallowing, feeling food lodged in the esophagus. A motor disorder occurs when there is difficulty swallowing solids and/or liquids. This can be intermittent or progressive. A mechanical obstruction occurs when there is difficulty swallowing solids, which may be nonprogressive or progressive:

a. Nonprogressive disorders include an esophageal ring or eosinophilic esophagitis.

b. Examples of progressive disorders include peptic stricture (chronic heartburn is present) and esophageal/gastric cardia cancer.

3. Odynophagia is defined as pain with swallowing.

INCIDENCE

A. Dysphagia affects approximately 300,000 to 600,000 persons annually.

B. Approximately 15% of the elderly population are affected by dysphagia.

PATHOGENESIS

A. In advancing age, muscle strength and the range of motion of swallowing decline, which may impact the effectiveness of swallowing. A decrease in oral secretions, taste changes, and smell acuity may also impact the effectiveness of swallowing.

PREDISPOSING FACTORS

A. Age (elderly).

B. Neurologic conditions such as stroke, myasthenia, multiple sclerosis, Parkinson disease, and so forth.

C. Dementia.

D. Trauma or radiation to neck and head.

COMMON COMPLAINTS

A. Difficulty with swallowing.

B. Reflux of food/liquid into the nose.

OTHER SIGNS AND SYMPTOMS

A. Weight loss.

B. Nutritional deficiency.

C. Refusal to eat.

POTENTIAL COMPLICATIONS

A. Malnutrition.

B. Pneumonia.

SUBJECTIVE DATA

A. Ask the client if they have difficulty swallowing when initiating the swallow or a few seconds after trying to swallow. ▶

B. Does difficulty swallowing occur at every meal or snack? If so, is it getting worse?
C. Is it difficult to swallow solid foods, liquids, or both? Difficulty swallowing solids and liquids occurs when a motility disorder of the esophagus is present. Difficulty swallowing solids that generally progresses to liquids is commonly caused by a mechanical obstruction.
D. When swallowing occurs, does the client experience coughing or reflux, or does food go up through the nose?
E. Can the client identify a site where food commonly gets lodged?
F. Has the client noticed any change in appetite? Weight loss or weight gain? Nausea, vomiting, diarrhea, constipation, change in stools, heartburn, or chest pain?
G. Has the client started any new medications that have caused indigestion or reflux? Common medications that may cause reflux include bisphosphonates, ferrous sulfate, potassium chloride, ascorbic acid, tetracycline, and NSAIDs.
A. Does the client have a history of dry mouth/dry eyes indicating salivary production change (e.g., medications causing dry mouth/eyes include anticholinergics, antihistamines, and antihypertensive medications; radiation to head/neck; new diagnosis of Sjögren syndrome)?

PHYSICAL EXAMINATION

A. Check vital signs: temperature, pulse, respirations, and blood pressure.
B. Inspect:
  1. Inspect the oral cavity for lesions, ulcers, and poor dentition. Note muscle weakness or paralysis in movement of tongue.
  2. Inspect head and neck for any masses.
  3. Inspect face for muscle weakness and neck for swallowing difficulty.
  4. Assess all cranial nerves, focusing on cranial nerves V, VII, X, XI, and XII.
C. Palpate:
  1. Palpate the neck and supraclavicular lymph nodes for adenopathy or palpable masses.
D. Auscultate:
  1. Heart.
  2. Lungs.

DIAGNOSTIC TESTS

A. Upper endoscopy.
B. Barium swallow.
C. Motility testing.

DIFFERENTIAL DIAGNOSES

A. Oropharyngeal dysphagia.
B. Esophageal dysphagia.
C. Odynophagia.
D. Achalasia (decreased peristalsis in the distal esophagus and loss of relaxation of the lower esophageal sphincter while swallowing).

PLAN

A. General interventions:
  1. Identify the cause of dysphagia and treat accordingly.
B. Client teaching:
  1. Educate the client regarding the possible causes of dysphagia.
  2. Stress the importance of nutrition and educate the client and their family about dietary alternatives to maintain nutrition and prevent weight loss.
  3. Discuss potential diagnostic testing necessary to identify the cause of dysphagia.
C. Dietary management:
  1. Depending on the diagnosis and treatment, dietary management—solids versus liquids—will need to be discussed with the client and their family.
  2. A modified food diet should be provided to the client and their family, prepared with a nutritionist and dietitian.
D. Pharmaceutical therapy:
  1. H2 blockers and proton pump inhibitors may be prescribed to help control acid reflux.
  2. If infection of the esophagus is suspected, antibiotics may be considered.
  3. Calcium channel blockers may help with esophageal spasms.

CONSULTATION/REFERRAL

A. Refer to gastroenterology for screening tests required for diagnosis.
B. Refer to a speech or swallowing specialist for assessment and education regarding swallowing exercises. Swallow rehabilitation may be suggested.
C. Refer to a dietitian/nutritionist for alternative food options and education on proper nutrition and prevention of weight loss.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:
  1. Dysphagia may occur in conditions such as systemic sclerosis and Sjögren syndrome.
  2. Dysphagia is commonly seen after long-term intubation.
  3. For the older adult population, consider cancer in the differential diagnosis if the client is noted to have anemia and/or weight loss.
  4. Neurologic origin is the most common cause of oropharyngeal dysphagia and can be efficiently managed by the client in collaboration with a clinical swallow specialist.
  5. Screen all geriatric clients for dysphagia because the swallowing reflex is regarded as a normal age-related occurrence. Any difficulties would render further studies as well as initiate education for diet and mechanical exercises to prevent aspiration and other complications.
  6. Recommend safe swallowing techniques to geriatric clients, which could include multiple small swallows, chin-tuck when swallowing, dietary modifications, avoiding rushed/forced eating, sitting upright 90°, and a review of safe administration of medications and practices that are unsafe (such as crushing enteric-coated tablets).
  7. A speech therapist or a clinical swallow specialist would manage any food consistency changes unique to the client's needs and degree of swallowing challenges.

Lauridsen, M. K., Bang Møller, L., & Ulrich Pedersen, P. (2021). Psychometric properties of tools for initial screening for oropharyngeal dysphagia in older people: A scoping review protocol. *JBI Evidence Synthesis*, *19*(8), 1948–1953. https://doi-org.proxy.library.vanderbilt.edu/10.11124/JBIES-20-00245

EPIGLOTTITIS

DEFINITION

A. Epiglottitis is inflammation and swelling of the epiglottis and is a medical emergency.

INCIDENCE

A. Epiglottitis usually occurs in children between ages 2 and 8 years, but may also occur in adults. The incidence of epiglottitis has decreased since the *Haemophilus influenzae* vaccine was introduced.

PATHOGENESIS

A. Epiglottitis is almost always caused by *H. influenzae* (25%), although *Streptococcus pneumoniae* and *S. pyogenes* have also been implicated. Other noninfectious causes include physical trauma, thermal injury to the epiglottitis, and/or ingesting caustic agents.

PREDISPOSING FACTORS

A. Upper respiratory infection.
B. Trauma to the mucosa in the nasopharynx tissue from a viral infection or from injury from food being swallowed.
C. Hypertension.
D. Diabetes mellitus.
E. Substance abuse.
F. Immune deficiency.

COMMON COMPLAINTS

A. Sudden onset of fever.
B. Sudden onset of dysphagia.
C. Sudden onset of drooling.
D. Sudden onset of muffled voice.

OTHER SIGNS AND SYMPTOMS

A. Difficulty with breathing and/or respiratory distress.
B. Stridor.
C. Very ill appearance.
D. Sore throat.
E. Change in voice (muffled voice commonly called a "hot potato voice," as if the client is struggling with a mouthful of hot food).

SUBJECTIVE DATA

A. Determine onset, duration, and course of illness.
B. Has breathing been labored?
C. Is breathing interfering with the client's ability to eat or drink?
D. Has the client had a fever?
E. Has the client had trouble swallowing or talking?

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure.
B. Inspect:
1. Observe overall appearance.
2. Check nail beds and lips for cyanosis.
3. Note drooling or difficulty swallowing.
4. Note breathing pattern and rhythm.
5. Note cough if present.
6. Direct exam of the throat can be attempted if there is no concern about compromising the airway. If airway compromise is of concern, do not examine the throat; airway occlusion may result.
C. Auscultate:
1. Auscultate heart and lungs.

DIAGNOSTIC TESTS

A. Lateral neck radiograph confirms diagnosis. However, this test may delay establishment of airway.

DIFFERENTIAL DIAGNOSES

A. Epiglottitis.
B. Foreign-body aspiration.
C. Retropharyngeal abscess.

PLAN

A. General interventions:
1. Immediately transfer to the ED for evaluation and hospitalization.
2. While awaiting transport to hospital, establish patent airway, start oxygen, and assemble airway equipment.
3. Insert intravenous (IV) access for fluids and antibiotic administration.
4. If respiratory arrest occurs, you may not be able to see the airway to intubate. An Ambu bag and mask may work temporarily, but nasogastric (NG) tube insertion may be necessary to prevent gastric distension.
5. Prompt recognition and appropriate treatment usually result in rapid resolution of swelling and inflammation.
B. Client teaching:
1. Educate client and family that epiglottitis is a medical emergency.
2. If client has drooling and no cough, diagnosis is most likely epiglottitis.
C. Pharmaceutical therapy (in-hospital treatment):
1. IV fluids.
2. Antibiotics; IV antibiotics after physician consultation.
3. Blood and epiglottis cultures obtained prior to starting antibiotics.
4. Drug of choice:
a. First-line antibiotic therapy includes use of third-generation cephalosporins, which include ceftriaxone (Rocephin) and ampicillin/sulbactam (Unasyn).
b. If unable to use these due to allergy and so forth, other alternatives include chloramphenicol, cefuroxime (Ceftin), and clindamycin (Cleocin).

FOLLOW-UP

A. Follow-up care occurs in the hospital.
B. An airway specialist should evaluate the client in the operating room.

CONSULTATION/REFERRAL

A. If you suspect epiglottitis, consult with the physician/specialist immediately.
B. The client should be transferred to the ED for treatment and care.
C. Maintain a patent airway while transferring the client to the ED.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:
1. Epiglottitis may induce intractable vomiting. Geriatrics are at high risk of aspiration pneumonia and must be monitored closely.
2. Although rare, poor oral healthcare may cause esophageal inflammation and tongue-base abscess that could cause obstruction. Presentation mirrors epiglottitis: pain, neck swelling, drooling, dyspnea, and respiratory compromise. Promote appropriate mouth care to prevent epiglottitis and infections.

ORAL CANCER, LEUKOPLAKIA

DEFINITION

A. Oral cancer is cancer of the buccal mucosa, tongue, gingiva, hard palate, soft palate, or lips. White patches, known as leukoplakia, or red, velvety patches, known as erythroplakia, on the buccal mucosa may indicate premalignant lesions.

INCIDENCE

A. Oral cancer is primarily seen in older adults. Approximately 90% of oral cancers are diagnosed as squamous cell carcinoma. The male to female predominance is 2 to 1; oral cancer is higher in African American than Caucasian adults. The death rate is fairly high for oral cancer; it is secondary to the cancer being diagnosed in the late stages of development.

B. There were over 49,000 Americans newly diagnosed with oral cancer in 2017 and 9,000 deaths will occur each year.

C. Oral cancer represents 3% of all newly diagnosed cancers and 2% of all cancer-related deaths.

D. The frequency of oral cancer of cheek and gum rises 50-fold among long-term users of smokeless tobacco.

E. Clients diagnosed with oral cancer are at greater risk of developing cancer in another part of the body, such as the lung, larynx, esophagus, and other sites. Therefore, follow-up exams are recommended for the remainder of the client's life.

PATHOGENESIS

A. Pathogenesis is unknown; 50% of oral cancers already have metastasized at time of diagnosis. The following factors are involved:

1. Use of tobacco in all its forms is highly correlated with risk of oral cancer.

2. Risk of oral cancer is also high with heavy alcohol consumption. Whether this is due to a direct effect of alcohol on the oral mucosa or to associated smoking or vitamin deficiency remains unclear.

3. Chronic iron deficiency leading to Plummer–Vinson syndrome is known to alter mucosal tissues, and this change may be related to increased risk of oral cancer. Research has shown that a diet low in fruits and vegetables contributes to oral cancer.

4. Epstein–Barr virus and papillomavirus have been found in cells of the tongue manifesting oral hairy leukoplakia, a hyperplastic change found in AIDS clients. Human papillomavirus (HPV) is found in approximately 20% to 30% of cases of oral cancer.

5. Occupational hazards also exist from sun exposure. It is estimated that 30% of those with oral cancer worked outdoors.

PREDISPOSING FACTORS

A. Male sex (although leukoplakia is more common in females).

B. Age older than 40 years for males and older than 50 years for females.

C. African American ancestry.

D. Smoking or use of other tobacco products, including such smokeless products as snuff and dip.

E. Alcohol consumption.

F. Sun exposure.

G. Poor diet, deficient in vitamins A, C, and E, and high in salted or smoked meats, fats, and oils.

H. Previous cancer.

COMMON COMPLAINTS

A. Oral sores that do not heal; this is what most commonly leads clients to seek medical care.

B. Poorly fitting dentures.

C. Bleeding mucosa or gingiva without apparent cause.

D. Difficulty swallowing, usually indicating more advanced disease.

E. Altered sensations: burning or numbness, usually indicating more advanced disease.

F. Leukoplakia (50% occur on tongue) or erythroplakia.

OTHER SIGNS AND SYMPTOMS

A. No symptoms, possibly.

B. Decreased appetite related to altered taste.

C. Increased salivation.

D. Sore throat.

E. Foul breath odor.

F. Oral or neck mass.

G. Lymphadenopathy.

SUBJECTIVE DATA

A. Review onset, course, and duration of symptoms. Question the client regarding altered taste, sensations, difficulty swallowing, and foul breath.

B. Evaluate for risk factors. See the "Predisposing Factors" section.

C. Ask the client about history of cancer and treatments.

D. Review the client's use of tobacco products, including age of onset, amount of daily use, and quit dates.

E. Evaluate client's amount of alcohol intake, including age of onset, amount of daily use, and quit dates.

F. Review the client's general health history for other chronic conditions.

G. Review the client's medication history, including prescription and over-the-counter drug use, especially aspirin.

H. Take client's dental history, including previous gum surgery, how long ago dentures were fitted, and if they always fit well.

I. Establish client's usual weight. Is there any weight loss related to altered taste, and if so how much and in what length of time?

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, blood pressure, and weight.

B. Inspect:

1. Observe general appearance.

2. Note quality of voice patterns.

3. Note odor of breath.

4. Inspect lips, gums, tongue, buccal mucosa for swelling, discoloration, bleeding, asymmetry, texture, limited movement of tongue, abnormal ulcerations, leukoplakia, and erythroplasia. Take out dentures first.

5. Assess for tenderness or pain in mouth/tongue.

a. Leukoplakia ranges from slightly raised, white, translucent areas to dense, white, opaque plaques, ▶

with or without adjacent ulceration. Normal intraoral mucosa is pinkish or salmon-colored.

b. Mucosal erythroplasia is red, inflammatory, or erythroplastic mucosal changes. It appears smooth, granular, and minimally elevated, with or without leukoplakia, and persists more than 14 days.

c. Erythroplakia may mimic inflammatory lesions, but can be differentiated by failure of the affected area to blanch with light pressure. **Erythroplakia is a malignant change seen as a red, velvety, plaque-like lesion on mucous membrane.**

d. Other oral lesions appear black, blue, or brown.

e. Inspect the tongue, oropharynx (soft palate, lingual aspect of the retromolar trigone, anterior tonsillar pillar), and floor of the mouth.

f. Cancer of the lip is a lesion that fails to heal.

g. Signs and symptoms of cancer of the tongue are swelling, ulceration, areas of tenderness or bleeding, abnormal texture, and limited movement.

C. Palpate:

1. Palpate mouth for masses. Try to remove or scrape patches.

2. Palpate lymph nodes: cervical (anterior/posterior chain), submandibular, sublingual, and submental, pre-/postauricular; check nodes for size, firmness, and tenderness.

D. Auscultate:

1. Auscultate lungs and heart: The lungs are the most frequently involved extranodal metastatic site.

DIAGNOSTIC TESTS

A. Check serum blood for HIV, if indicated.

B. Stain the oral lesion with toluidine blue: Lesion stains dark blue after rinsing with acetic acid. Normal tissue does not absorb the stain.

C. Perform biopsy for persistent lesions (>2 weeks): It is essential to differentiate from blue-black lesion of malignant melanoma.

D. Perform chest radiography to rule out metastasis.

E. Consider CT, MRI, or bone scan to rule out metastasis.

DIFFERENTIAL DIAGNOSES

A. Oral leukoplakia.
B. Actinic keratosis.
C. Periapical abscess.
D. Gingivitis.
E. Periodontitis.
F. Lichen planus.
G. Oral candidiasis.
H. Discoid lupus.
I. Pemphigus vulgaris.

PLAN

A. General interventions:

1. If oral cancer is suspected, refer to a physician or otolaryngologist/dentist for evaluation.

2. Suspicious lesions should have biopsy.

3. Leukoplakia ranges from slightly raised, white, translucent areas to dense, white, opaque plaques, with or without adjacent ulceration. Normal intraoral mucosa is pinkish or salmon-colored.

4. Mucosal erythroplasia is red, inflammatory, or erythroplastic mucosal changes. It appears smooth, granular, and minimally elevated, with or without leukoplakia, and persists more than 14 days.

5. Erythroplakia may mimic inflammatory lesions, but can be differentiated by failure of the affected area to blanch with light pressure.

6. Cancer of the lip is a lesion that fails to heal.

B. Client teaching:

1. Advise the client to stop smoking and stop using oral tobacco products.

2. Advise the client to reduce/eliminate alcohol consumption.

3. Encourage routine dental care and exams.

4. Review dietary intake and educate the client regarding benefits of increasing dietary intake of vitamins A, C, and E. Encourage client to reduce dietary intake of foods that are high in salt, smoked meats, fats, and oils.

5. Recommend wearing sunscreen/lip balm with sun protection factor (SPF) of 15 or greater.

C. Pharmaceutical therapy:

1. Erythroplakia does not respond to antifungal therapy.

2. For mouth pain, topical anesthetic or Magic mouthwash (common compounded solution includes Maalox/diphenhydramine/lidocaine combined at a 1:1:1 ratio).

FOLLOW-UP

A. If immediate biopsy is not indicated, ask the client to return for reevaluation in 2 weeks, after eliminating irritants and noxious agents.

CONSULTATION/REFERRAL

A. Refer the client to an otolaryngologist and/or dentist for immediate biopsy for deeply ulcerative or fungating lesions. Follow-up treatment may include one or more of the following: wide excision, radical neck dissection, radiation, and chemotherapy.

INDIVIDUAL CONSIDERATIONS

A. Adults:

1. The American Cancer Society recommends that people between age 20 and 40 undergo an oral cancer screening every 3 years and that those older than 40 years be screened every year. Oral screening should be considered annually in adults who use tobacco and/or alcohol.

B. Geriatrics:

1. Oral cavity cancer within the geriatric population predominantly arises between 50 and 70 years old secondary to susceptibility to mucosal disorders. Natural aging process decreases salivary secretion and risks ulceration and mucosa breakdown, which eventually lead to immune system dysfunction. This increases risk of a potential malignant disorder.

2. Evidence-based research indicated that mortality was reduced when clients over 65 years old with leukoplakia were screened and diagnosed with oral cavity cancer at an early stage.

3. A chronically dry mouth (xerostomia) affects quality of life, reduces adequate ingestion of foods, causes burning sensations and taste disturbances, and increases risk of malnutrition.

4. Thoroughly evaluate any oral pain with the geriatric population to rule out oral cancer. Normal age-related changes include yellowing/darkening of teeth, thickening composition/abrasion, gingival recession leading to root caries, and reduced sensitivity secondary to the number ▶

of blood vessels entering the tooth, which decreases the enamel.

5. Precancerous lesions might be subtle and asymptomatic. Meticulously examine lateral borders of tongue, lips, and floor of mouth, where oral cancer most commonly occurs. A lesion may be white or dull red and will progress to ulceration.

PHARYNGITIS

DEFINITION

A. Pharyngitis is inflammation of the pharynx and surrounding lymph tissue.

INCIDENCE

A. Pharyngitis is the fourth most common condition seen in medical practice. Group A *Streptococcus* accounts for approximately 5% to 15% of adults who present for evaluation and treatment of pharyngitis. Viral pharyngitis accounts for approximately 40% to 60% of all cases of sore throat.

PATHOGENESIS

A. Pharyngitis may be due to viral, bacterial, and fungal agents, as well as other atypical agents:

1. Approximately 50% to 80% of cases of sore throat are viral. Viral agents include rhinoviruses/adenoviruses, coxsackievirus, enteric cytopathic human orphan (ECHO) viruses, and Epstein–Barr virus.

2. Approximately 3% to 36% of cases of sore throat are bacterial. Bacterial agents include group A beta-hemolytic streptococcus (GAS), *Neisseria gonorrhoeae*, and *Corynebacterium diphtheriae*.

3. The fungal source is *Candida albicans*.

4. Atypical agents include *Mycoplasma pneumoniae* and *Chlamydia trachomatis* (rare).

5. Noninfectious causes include allergic rhinitis, postnasal drip, mouth-breathing, mechanical/caustic agents, and trauma.

PREDISPOSING FACTORS

A. Cigarette smoking.
B. Allergies.
C. Upper respiratory infections.
D. Oral sex.
E. Drugs (antibiotics and immunosuppressants).
F. Debilitating illnesses (such as cancer) that can cause *C. albicans* to proliferate.
G. Recent exposure to a person testing positive for GAS.

COMMON COMPLAINTS

A. Sore and/or scratchy throat.
B. Fever.
C. Headache.
D. Malaise.
E. Tonsillar exudate.
F. Anterior cervical lymph node swelling.
G. Skin rash.
H. Bacterial pharyngitis symptoms include acute onset of sore throat, anterior cervical lymphadenopathy/tenderness, tonsillar exudate, skin rash, fever.

OTHER SIGNS AND SYMPTOMS

A. Oral vesicles.
B. Fatigue.
C. Dysphasia, hoarseness.
D. Abdominal pain.
E. Vomiting.
F. Viral pharyngitis symptoms include cough, fever, malaise, nasal congestion, oral ulcers, coryza, conjunctivitis.

POTENTIAL COMPLICATIONS

A. Without proper antimicrobial treatment, streptococcal pharyngitis can lead to serious complications such as the following:

1. Suppurative adenitis with tender, enlarged lymph nodes.
2. Scarlet fever.
3. Peritonsillar abscess.
4. Glomerulonephritis.
5. Rheumatic fever.

SUBJECTIVE DATA

A. Ask the client about onset, course, and duration of symptoms. Ask about dyspnea or dysphagia.
B. Inquire about mouth lesions, rhinorrhea, cough, drooling, and fever.
C. Ask about malaise, headache, fatigue, and fever; these are symptoms of mononucleosis.
D. Take a sexual history, if indicated. Ask if family members or sexual partners have the same signs and symptoms. Pharyngeal gonorrhea has no symptoms, so high-risk clients should be tested.
E. Ask whether symptoms have caused decreased intake of food and fluid.
F. Determine history of heart disease, strep pharyngitis, rheumatic fever, and other respiratory diseases such as asthma, emphysema, and chronic allergies.
G. If rash is present, find out when it first occurred and if it has spread.
H. Ask about signs and symptoms of urinary tract infection and pyelonephritis.
I. Ask about a history of herpes, immunosuppressive disorders, and steroid use.
J. Review immunization history.

PHYSICAL EXAMINATION

A. Check temperature and blood pressure, if indicated.
B. Inspect:

1. Observe general appearance.
2. Examine the mouth, pharynx, tonsils, and hard and soft palate for vesicles and ulcers, candidal patches, erythema, ▶

hypertrophy, exudate, and stomatitis. Check the gum and palate for petechiae and tongue for color and inflammation.

3. Examine the ears, nose, and throat. Assess patency of airway if tonsils are enlarged.

4. Inspect skin for rashes:

a. Pastia lines are petechiae present in a linear pattern along major skin folds in axillae and antecubital fossa that are seen with GAS.

b. Erythema marginatum, caused by GAS, is an evanescent, nonpruritic, pink rash mainly on the trunk and extremities. It may be brought out by heat application.

C. Auscultate:

1. Auscultate the heart and lungs.

D. Percuss:

1. Percuss abdomen, especially spleen area.

2. Percuss the chest.

E. Palpate:

1. Palpate lymph nodes, especially of the anterior and posterior cervical chains, axilla, and groin.

2. Palpate abdomen for organomegaly and suprapubic tenderness.

3. Palpate back for costovertebral angle (CVA) tenderness.

F. Perform neurologic exam:

1. Check for nuchal rigidity and meningeal irritation.

G. Use the Modified Centor Clinical Prediction Rule for group A streptococcal infection (Table 11.1).

TABLE 11.1 MODIFIED CENTOR CLINICAL PREDICTION RULE

Points	Criteria
+1	Tonsillar exudates present
+1	Tender anterior chain cervical adenopathy
+1	Absence of a cough
+1	Fever by history
+1	3–14 years of age
0	15–44 years of age
–1	≥45 years of age
Total score	

Once scored: If 4 points, + predictive value of 80%, treat empirically. If 2 to 3 points, positive predictive value of 50%, complete rapid strep antigen, treat as group A beta-hemolytic *Streptococcus* positive. If 0 or 1 point, positive predictive value of 20%, do not test, treat empirically only, with follow-up as needed.

DIAGNOSTIC TESTS

A. Rapid strep test; if negative, perform throat culture and sensitivity.

1. Throat culture is recommended if the client has been exposed to an area at high risk of GAS, has history of acute renal failure (ARF), immunosuppression-compromised, or has close contact with clients with ARF or immunosuppression. **Throat culture and sensitivity is the gold standard for diagnosis**.

B. Monospot test.

C. Complete blood count (CBC) with differential.

D. COVID-19 screening recommended if illness appears viral.

E. HIV and gonorrhea culture recommended for sexually transmitted infection concerns.

F. Blood cultures if sepsis is suspected.

G. Radiograph of neck if possible trauma.

DIFFERENTIAL DIAGNOSES

A. Pharyngitis.

B. COVID-19.

C. Stomatitis.

D. Rhinitis.

E. Sinusitis with postnasal drip.

F. Epiglottis.

G. Peritonsillar abscess.

H. Mononucleosis.

I. Herpes simplex.

J. Coxsackie A virus.

K. *C. diphtheriae.*

L. Trench mouth.

M. Vincent angina.

N. *C. albicans.*

O. HIV.

PLAN

A. General interventions:

1. Clients with a history of rheumatic fever and those who have a household member with a documented group A streptococcal infection need immediate treatment without prior testing.

2. Herpangina is characterized by small oral vesicles on the fauces and soft palate caused by the coxsackievirus.

3. Herpes causes vesicles and small ulcers (stomatitis) of the buccal mucosa, tongue, and pharynx.

4. Trench mouth (gingivitis) and necrotic tonsillar ulcers (Vincent angina) cause foul breath, pain, pharyngeal exudate, and a gray membranous inflammation that bleeds easily.

5. *C. albicans* (thrush) may be painful and causes cheesy, white exudate on the tongue and inside cheeks.

6. Oral candidiasis may be the first symptom of HIV.

7. Peritonsillar cellulitis causes inflamed, edematous tonsils, grayish-white exudate, high fever, rigors, and leukocytosis. Peritonsillar abscess (palpable mass) may also develop.

8. Mononucleosis causes tonsillar exudates in 50% of clients; 33% develop petechiae at junction of hard and soft palate.

9. *C. diphtheriae* causes a whitish-blue pharyngeal exudate "pseudomembrane" that covers the pharynx and bleeds if removal is attempted.

10. COVID-19 symptoms include fever, cough, difficulty breathing, congestion, sore throat for a few days, and loss of taste/smell. Self-isolation recommended per Centers for Disease Control and Prevention guidelines.

11. Do not put instruments in the airway if you suspect epiglottitis.

B. Client teaching: *See Client Teaching Guide for this chapter, "Pharyngitis."*

1. Recommend rest, fluids, and staying well-hydrated.

2. Avoid contact with others for 24 hours after starting antibiotics.

3. Treat symptomatically: ibuprofen/acetaminophen as needed for body aches/sore throat/fever. Warm saltwater gargles/throat lozenges for sore throat. Sterilize toothbrush or buy new toothbrush.

4. Take antibiotics/medication as prescribed. ▶

5. Call for fever not responding to medication/treatment, worsening symptoms, or not improving in the next 3 to 4 days.

6. Call 911 for difficulty with breathing, throat/neck swelling, drooling, or other severe symptoms.

7. If concerns of mononucleosis, advise no contact sports until diagnosis is made to prevent injury to the spleen.

C. Pharmaceutical therapy:

1. Drug of choice: Prescribe one of the following penicillins for bacterial pharyngitis:

a. Penicillin V potassium (Pen-Vee-K): 500 mg BID for 10 days.

b. Amoxicillin: 500 or 875 mg BID for 10 days.

c. Penicillin G benzathine: 1.2 million units intramuscular (IM) injection, one dose.

d. Cephalexin: 500 mg BID for 10 days.

2. If the client is allergic to penicillin:

a. Clindamycin: 600 mg TID for 10 days.

b. Azithromycin: 500 mg on day 1 followed by 250 mg daily on days 2 to 5.

c. Clarithromycin: 250 mg BID for 10 days.

3. Recurrent bacterial pharyngitis:

a. Clindamycin: 600 mg TID for 10 days.

b. Penicillin and rifampin: penicillin V 500 mg BID for 10 days.

c. Amoxicillin-clavulanic acid: 500 mg Q8H or Q12H for 10 days; or 875 mg Q12H for 10 days; not for use in creatinine clearance less than 30 mL/min.

d. Penicillin G benzathine: 1.2 million units IM injection, plus one dose of rifampin 600 mg/d orally for 4 days.

4. For severe symptoms:

a. Single-dose corticosteroids, dexamethasone, may be prescribed; however literature/evidence of use is limited.

5. For pharyngeal gonorrhea:

a. Ceftriaxone (Rocephin) 500 mg to 1 g by IM injection (provider should prescribe to cover for *C. trachomatis* as well).

6. For *M. pneumoniae* and *C. trachomatis*:

a. Erythromycin (E-Mycin) 250 mg orally three to four times daily for 10 days or azithromycin 1 g orally single dose or doxycycline 100 mg orally BID for 7 days.

7. For pharyngeal candidiasis in the immunocompromised client:

a. Oral nystatin suspension (100,000 U/mL): 15 mL by swish-and-swallow method QID.

b. Clotrimazole troche: 10 mg held in the mouth for 15 to 30 minutes three to five times daily for 7 to 10 days.

FOLLOW-UP

A. If symptoms do not improve in 3 to 4 days, advise client to call/return for evaluation.

B. Treat sexual partners of those diagnosed with pharyngeal gonorrhea.

CONSULTATION/REFERRAL

A. Consult a physician/specialist if client has severe dysphagia or dyspnea, signaling possible airway obstruction.

B. Refer the client to an otolaryngologist if peritonsillar abscess is noted.

INDIVIDUAL CONSIDERATIONS

A. Recommendations include treating clients with oral antibiotics for 10 days to eradicate infection. For clients who are not able to tolerate oral antibiotics, penicillin G benzathine may be given via IM route.

B. Geriatrics:

1. Acetaminophen for sore throat is treatment of choice for the geriatric population.

2. Antibiotic treatment for pharyngitis is warranted if client is ≥65 years old with an acute cough and has two or more of the following criteria: hospitalized in the past year, diabetic, congestive heart failure, and on glucocorticoid therapy. If the client is ≥80 years old with pharyngitis and cough, treat with antibiotic if one or more of the latter criteria applies.

3. Older adult clients with chronic illnesses (such as diabetes, congestive heart failure, and skin diseases) who have pharyngitis caused by GAS are at an increased risk of bacteremia and more likely to die from complications.

4. Viral pharyngitis with symptoms of runny nose, stuffy chest, congestion, cough, and red/itchy eyes should be treated symptomatically and avoid antibiotics.

STOMATITIS, RECURRENT APHTHOUS STOMATITIS

DEFINITION

A. Stomatitis is tender, round, discrete, oval, shallow, 1- to 5-mm ulcers in the oral cavity. The ulcers are gray-white or yellow, on nonkeratinized skin, and surrounded by erythematous halos. They typically involve the labial and buccal mucosa and tongue, and adjacent tissue appears healthy.

B. Major recurrent aphthous stomatitis (RAS) has larger, deeper ulcers, lasts a longer period of time, usually recurs up to four times a year, and frequently leaves scars. It can cause significant dysphagia.

INCIDENCE

A. Stomatitis affects 20% to 50% of the population. It is very common in North America.

PATHOGENESIS

A. Cause is poorly understood. Genetic, immunologic, viral, or nutritional causes are possible.

PREDISPOSING FACTORS

A. Minor trauma.

B. History of RAS.

C. Possible nutritional deficiency in iron, vitamin B_{12}, folic acid, or zinc.

D. Hormonal changes.

COMMON COMPLAINT

A. Painful sore in mouth.

OTHER SIGNS AND SYMPTOMS

A. Burning sensation in mouth for 24 to 48 hours before lesions appear. ▶

SUBJECTIVE DATA

A. Elicit history of aphthous stomatitis.
B. Ask the client about prodrome of burning or stinging in the mouth.
C. Elicit information regarding previous illness and trauma.
D. Inquire regarding nutritional intake and dietary (balanced meals) and oral supplements (B_{12}, folic acid, and zinc).

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure.
B. Inspect:
  1. Inspect mouth for ulcers.
  2. Inspect ears, nose, and throat.
  3. Inspect skin, especially palms and soles, for lesions; indicates hand-foot-and-mouth disease.
C. Auscultate:
  1. Auscultate the heart and lungs.

DIAGNOSTIC TESTS

A. There is no specific diagnostic testing for stomatitis.
B. Consider herpes simplex virus (HSV) culture if HSV is considered for diagnosis.
C. If syphilis is of concern, order serum rapid plasma reagin (RPR).

DIFFERENTIAL DIAGNOSES

A. Aphthous stomatitis.
B. Herpetic stomatitis.
C. Behçet disease.
D. Crohn disease.
E. HIV.
F. Kawasaki syndrome.
G. Hand-foot-and-mouth disease.

PLAN

A. General interventions:
  1. Avoid spicy, salty, or hot foods.
  2. Encourage cold foods, such as fluids, ice pops, and so forth to help with pain.
  3. Avoid hard, sharp food that is difficult to chew.
  4. Recommend using a soft-bristle toothbrush when brushing teeth. Sodium lauryl sulfate found in toothpaste may delay healing time.
  5. Consider monitoring clients with RAS for systemic / autoimmune disorders such as Behçet disease, Grave disease, Hashimoto thyroiditis, systemic lupus erythematosus (SLE), gout, rheumatoid arthritis, and ankylosing spondylitis.
B. Client teaching: *See Client Teaching Guide for this chapter, "Aphthous Stomatitis."*
C. Pharmaceutical therapy:
  1. Mouthwash made of diphenhydramine (Benadryl), with Kaopectate, or Maalox or sucralfate, and viscous lidocaine three to four times a day. Tell the client not to swallow medication.
  2. Sucralfate (Carafate) suspension one teaspoon QID may be used to swish in mouth and spit out for oral comfort.
  3. Topical corticosteroids, such as dexamethasone, triamcinolone, fluocinonide, or clobetasol, are highly recommended. For severe cases, systemic corticosteroids may be needed, for example, glucocorticoid gel such as fluocinonide gel (Lidex) 0.05% two to four times a day, one of which is always at bedtime.
  4. Orabase with or without triamcinolone acetonide (Kenalog) applied to ulcer two to four times a day until healed.
  5. Immunomodulatory agents, antimicrobials, and anesthetic agents may also be used.

FOLLOW-UP

A. Follow-up as needed for treatment of recurrences.

CONSULTATION/REFERRAL

A. Refer the client to, or consult with, a physician/specialist if ulcers are deeper or larger than 1 to 5 mm, if Kawasaki disease is suspected, or if no improvement is seen with adequate treatment.
B. Any lesion lasting longer than 3 weeks should be evaluated by a dentist or oral surgeon to rule out cancer.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
  1. Avoid use of fluocinonide and triamcinolone acetonide (Kenalog) in pregnant or nursing clients.
B. Adults:
  1. Consider underlying immunologic conditions in clients who have recurrent oral ulcers.
C. Geriatrics:
  1. Ask older adult clients about their dentures, if there is adequate fit (looseness or too tight), and if there is any pain.
  2. Dentures should be removed and cleaned at least once daily. Encourage clients to remove dentures at night.
  3. Oral inflammation and denture-related stomatitis have recently been linked through evidence-based research with the pathogenesis of cardiovascular disease (atherosclerosis and hypertension). Geriatric clients must be screened for denture-related stomatitis and immediate antifungal treatment is advised.
  4. Nutritional challenges in the older adult population can lead to stomatitis and aphthous ulcers. Assess chewing ability. Evaluate geriatric clients for iron, B_{12}, and folic acid deficiencies.

THRUSH

DEFINITION

A. Thrush is a fungal infection of the oral cavity and/or the pharynx caused by *Candida*.

INCIDENCE

A. Approximately 9% to 31% of clients with AIDS and 20% of clients diagnosed with cancer will have thrush.

B. Healthy adults may also experience an episode of thrush; however, these adults usually have other risk factors, such as the frequent use of inhaled steroids and/or use of oral antibiotics/steroids.

PATHOGENESIS

A. Thrush is an overgrowth of yeast cells, *Candida albicans*, on the oral mucosa, which leads to desquamation of the epithelial cells, creating a pseudomembrane over the normal oral mucosa. Other species of yeast cells may include *C. glabrata*, *C. krusei*, and *C. tropicalis*.

PREDISPOSING FACTORS

A. Use of broad-spectrum antibiotics.
B. HIV.
C. Prolonged steroid use (systemic or inhaled corticosteroids).
D. Cancer treatments (radiation/chemotherapy).
E. Dentures.
F. Malnutrition.

COMMON COMPLAINTS

A. Soreness and pain in the mouth.
B. White plaque coating the buccal mucosa, palate, tongue, or oropharynx.

OTHER SIGNS AND SYMPTOMS

A. Erythemic, sore tongue, buccal mucosa, or oropharynx.

SUBJECTIVE DATA

A. Determine onset, duration, and course of illness.
B. Has the client used antibiotics or other medications in the previous weeks?
C. Does the client use inhaled or systemic steroid on a daily basis?
D. Has the client had difficulty swallowing?
E. Does the client wear dentures?

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure.
B. Inspect:
1. Inspect oral cavity for white, curd-like plaques that cannot be removed.
2. Inspect ears, nose, and throat.

DIAGNOSTIC TESTS

A. Gram stain or potassium hydroxide (KOH) performed on scraping specimen of lesions. Diagnosis is confirmed with the presence of yeast and pseudohyphae. Gram stain or KOH testing is recommended for recurrent infections.
B. If treatment prescribed is not working, fungal culture should be sent for diagnosis.

DIFFERENTIAL DIAGNOSES

A. Thrush.
B. Esophageal candidiasis (hallmark symptom is odynophagia or pain with swallowing).
C. Stomatitis.
D. Aphthous ulcer.
E. Hairy leukoplakia.

PLAN

A. General interventions:
1. Instruct the client/family on proper use and cleaning/rinsing of inhalers/dentures to prevent reoccurrence of thrush.
2. Instruct client on the use of oral medications to treat thrush.
B. Client teaching: *See Client Teaching Guide for this chapter, "Thrush."*
C. Pharmaceutical therapy:
1. Oral candidiasis: nystatin (Mycostatin) oral suspension (400,000–600,000 units) 4 to 6 mL QID for 7 to 10 days. Place medication in front of the mouth on each side. Rub directly on plaques with a cotton swab. Nystatin pastilles: 200,000-unit lozenge QID for 7 to 14 days, or swish and swallow 500,000-unit QID for 14 days or two 500,000-unit tablets TID for 14 days.
2. Clotrimazole troche (Mycelex): 10 mg five times daily for 14 days; monitor for side effects.
3. Fluconazole: for adults, 400 mg once (load dose), then 200 mg daily for 14 days.
4. Mary's magic mouthwash (diphenhydramine, nystatin, Maalox—equal amounts of each) may be used for maintenance once thrush has resolved. Swish and spit this mouthwash one to three times a day as needed. If painful, viscous lidocaine can also be added.

FOLLOW-UP

A. Advise the client to telephone the office if there is no improvement, if thrush lasts more than 10 days, or if there is unexplained fever.

CONSULTATION/REFERRAL

A. Consult a physician/specialist if thrush does not resolve with adequate antifungal treatment.
B. Immunosuppressed clients are at higher risk of developing systemic dissemination and candidal esophagitis. Consult a physician if this is suspected.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:
1. Ask older adult clients about their dentures, if there is adequate fit (looseness or too tight), and if there is any pain.
2. Dentures should be removed and cleaned at least once daily. Encourage clients to remove dentures at night.
3. Oral inflammation and denture-related stomatitis have recently been linked through evidence-based research with the pathogenesis of cardiovascular disease (atherosclerosis and hypertension). Geriatric clients must be screened for denture-related stomatitis and immediate antifungal treatment is advised.
4. Nutritional challenges in the older adult population can lead to stomatitis and aphthous ulcers. Assess chewing ability. Evaluate geriatric clients for iron, vitamin B_{12}, and folic acid deficiencies.
5. Certain conditions may cause overgrowth of *Candida* thrush and/or increase occurrences of aphthous stomatitis in the geriatric population, which could include use of steroid inhaler, tobacco use, systemic steroid/antibiotics, ▶

radiation/chemotherapy, food allergies, asthma, diabetes or other endocrine disorders, anxiety, and lack of sleep.

6. If pain is involved, evaluate client's food/drink intake, weight, and nutritional status.

CLIENT TEACHING GUIDE

APHTHOUS STOMATITIS

PROBLEM Aphthous stomatitis refers to tender ulcers in the mouth that recur.

CAUSE The cause is unknown, but possible causes include diet (lack of iron, zinc, or B vitamins), menstrual or hormonal changes, and viruses.

TREATMENT PLAN

A. Use an over-the-counter gel, such as Anbesol or Orajel, four times daily.
B. You may be prescribed a mouthwash made of diphenhydramine (Benadryl), Maalox, and lidocaine or fluocinonide gel to "swish" in your mouth two to four times daily.

Activity: No restrictions are required.

Diet:
A. Avoiding spicy, salty, or hot foods may help.
B. Using a straw when drinking may reduce pain.
C. Cold foods may be easier to tolerate.
D. Avoid hard or sharp food.
E. Use a soft toothbrush.

Medications: _____

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If You Have:
A. Worse symptoms than seen at the office visit today.
B. Ulcers that do not heal in approximately 1 to 2 weeks.
C. Other: _____

Phone: _____

From *ADULT-GERONTOLOGY PRACTICE GUIDELINES, Third Edition*. Copyright Springer Publishing Company, LLC. All Rights Reserved.

CLIENT TEACHING GUIDE

PHARYNGITIS

PROBLEM Pharyngitis (sore throat) is a condition that occurs when your throat becomes inflamed.

CAUSE The inflammation can be caused by a virus, a bacterium, or a fungus. Other noninfectious causes include postnasal drip, allergies, mouth-breathing, and trauma.

PREVENTION

A. Avoid sick people and crowds. Stay at home if you are sick.
B. Cover your mouth when coughing.
C. Do not share a drinking glass, kiss, or have close contact with anyone who has an upper respiratory infection.
D. Gargle with warm saltwater frequently. Use over-the-counter pain medications (such as acetaminophen or ibuprofen) for pain relief.

TREATMENT PLAN

A. Hot tea, soup, and throat lozenges soothe your throat.
B. Use disposable tissues when sneezing and when blowing your nose. If no tissue is available, do the "elbow sneeze" into the bend of your arm (away from your open hands). Dispose of the tissues and then wash your hands.
C. Avoid smoking and secondhand smoke.

Activity: If you have strep throat, do not return to school or work until you have completed a full 24 hours of antibiotic. Rest or nap as often as possible while you are sick. If diagnosed with strep throat, please change your toothbrush to prevent reinfection after treatment.

Diet: Eat a healthy diet. If swallowing is difficult, eat soft foods such as ice cream, Jell-O, pudding, and soup. Avoid salt and spicy foods. Increase your fluid intake to 10 to 12 glasses a day.

Medications: You will be prescribed antibiotics if you have a bacterial infection. If your sore throat is caused by a virus, antibiotics would not help. Do not share your prescription medications with other family members who are also sick. They need a full prescription, too. Many other medications are available over the counter, such as throat lozenges and cough suppressants.

You Have Been Prescribed: _____

You Need to Take: _____

If you are prescribed antibiotics, complete all of the doses.

You Need to Notify the Office If:
A. You have difficulty breathing because of the sore throat or enlarged tonsils.
B. Your symptoms are worse after 24 hours of antibiotics.
C. You are unable to keep down your antibiotic because of vomiting.
D. You develop a rash or itching after starting the antibiotic.
E. You are a diabetic and your blood glucose is high, or you have ketones in your urine.
F. Other: _____

Phone: _____

CLIENT TEACHING GUIDE

THRUSH

PROBLEM Oral thrush is characterized by white patches that coat the inside of the mouth and tongue. It mainly affects adults with risk factors such as a compromised immune system, use of frequent antibiotics, and/or chronic use of steroid inhalers.

CAUSE Thrush is caused by a yeast called *Candida*, which grows rapidly on the lining of the mouth and tongue. It may also occur after a course of antibiotic medication.

PREVENTION

A. Avoid overuse of antibiotics.
B. Clean inhalers and dentures daily. Use a denture cleaner daily. You may soak the dentures overnight in the denture cleaner. Rinse dentures well before putting them into your mouth. Rinse your mouth after inhaled steroid use.
C. Practice good oral hygiene daily.
D. Change your toothbrush or sanitize the toothbrush when diagnosed with thrush to prevent reinfecting the mouth with yeast.
E. Rinse your mouth after using steroid inhaler.

TREATMENT PLAN

A. Try to remove any large plaques with a moistened cotton-tipped applicator or gauze pad.
B. Cleanse the mouth before giving medication. The use of salt or warm saltwater (with iodized salt or baking soda) helps relieve irritation, as well as creates a poor environment for fungal growth.
C. Place the medication in the front of the mouth on each side.
D. Rub it directly on the plaques with a cotton swab.

Diet: As tolerated. Limit foods high in sugar and yeast products such as beer, wine, and bread. Increase diet to include yogurt and products that contain *acidophilus*.

Medications: Nystatin is an oral medication used to treat thrush. Nystatin suspension four times a day after meals or 30 minutes prior to eating. Patches should improve within 2 to 3 days of using the medication.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If:
A. You have difficulty with eating or drinking because of pain.
B. Symptoms do not improve or thrush lasts longer than 10 days.
C. Unexplained fever occurs.
D. Secondary infection occurs in the mouth (pain, tenderness, sores).
E. Other: _____

Phone: _____

CHAPTER 12

RESPIRATORY GUIDELINES

Audra Malone Cave

ASTHMA

DEFINITION

A. Asthma is a chronic airway inflammation characterized by recurrent episodes of wheezing, breathlessness, chest tightness, and cough, particularly at night and in the early morning. Episodes are associated with widespread, variable, often reversible airflow obstruction and bronchial hyperresponsiveness when airways are exposed to various stimuli or triggers. Asthma is responsible for lost school days, lost productivity, and presenteeism.

B. Classifications of asthma:

1. Mild intermittent:
- a. Symptoms of cough, wheezing, chest tightness, or difficulty breathing less than or equal to two per week.
- b. Flare-ups are brief, but intensity may vary.
- c. Nighttime symptoms less than or equal to two per month.
- d. No symptoms between flare-ups.
- e. Lung function test: forced expiratory volume in 1 second (FEV_1) is 80% or more above normal values.
- f. Peak flow has less than 20% variability from morning to next morning, or from morning to night, day-to-day.

2. Mild persistent:
- a. Symptoms of cough, wheezing, chest tightness, or difficulty breathing three to six times a week.
- b. Flare-ups may affect activity level.
- c. Nighttime symptoms three to four times a month.
- d. Lung function test FEV_1 is above 60% but below 80% of normal values.
- e. Peak flow has more than 30% variability.

3. Moderate persistent:
- a. Symptoms of cough, wheezing, chest tightness, or difficulty breathing daily.
- b. Flare-ups may affect activity level.
- c. Nighttime symptoms five or more times a month.
- d. Lung function test FEV_1 is above 60% but below 80% of normal values.
- e. Peak flow has more than 30% variability.

4. Severe persistent:
- a. Symptoms of cough, wheezing, chest tightness, or difficulty breathing are continual.
- b. Frequent nighttime symptoms.
- c. Lung function test FEV_1 is 60% or less of normal values.
- d. Peak flow has more than 30% variability.

INCIDENCE

A. Asthma affects 25 million people in the United States.

B. Asthma rates in the general population are increasing, including in developed countries.

C. Up to 80% of those with asthma also suffer from persistent rhinitis.

D. Asthma is often associated with other comorbid conditions, including gastroesophageal reflux disease (GERD) and obesity.

E. The diagnosis is more common in adult females than males.

F. Puerto Ricans, African Americans, Filipinos, and Irish Americans have higher rates than other ethnicities.

G. Asthma control and asthma outcomes are worse for lower socioeconomic groups.

PATHOGENESIS

A. Asthma arises from a complex cycle of processes initiated by airway inflammation resulting from physical, chemical, and pharmacologic agents (e.g., environmental irritants, allergens, furry animals, cockroaches, dust mites, pollens and mold, cold air, viral respiratory infections, and exercise). It progresses to airway hyperresponsiveness, bronchoconstriction, airway wall edema, chronic mucus plug formation, and chronic airway remodeling.

PREDISPOSING FACTORS

A. Family history.

B. Coexisting sinusitis, nasal polyps, and sensitivity to aspirin or other nonsteroidal anti-inflammatory drugs (NSAIDs).

C. Exposure to wood dust, metals, and animal products in the workplace.

D. Premenstrual asthma (PMA).

E. Smoking.

F. Early menarche.

G. Obesity.

H. Postmenopausal hormone replacement therapy.

I. Viral respiratory infections.

J. Gastroesophageal reflux.

K. Triggers:

1. Exposure to allergens.

2. Upper airway viral infection.

3. Medications: Beta-blockers, angiotensin-converting enzyme (ACE) inhibitors, cyclooxygenase (COX) inhibitors, aspirin, and NSAIDS may induce symptoms.

4. Exercise.

5. Situational factors: cold air, laughter, strong odors, air pollution, smoke exposure, pregnancy.

6. Foods.

The contributions of Melissa A. Hall to this chapter in prior editions are acknowledged here.

7. Hormones.
8. GERD.

COMMON COMPLAINTS

A. Recurrent cough (worse at night and early morning).
B. Recurrent wheezing.
C. Recurrent shortness of breath (SOB) or dyspnea.
D. Recurrent chest tightness (may worsen with moderate activity).

OTHER SIGNS AND SYMPTOMS

A. Nocturnal awakening from symptoms.
B. Variation of symptoms with seasons or environment.
C. Chest discomfort, tightness with moderate activity.

SUBJECTIVE DATA

A. Ask about onset, duration, pattern, and course of symptoms.
B. Inquire about sudden severe episodes of coughing, wheezing, and SOB and whether precipitating factors can be identified.
C. Ask whether the client has chest colds that take more than 10 days to resolve.
D. Ask if the client is a smoker, how much, for how long, and if interested in quitting.
E. Ask whether symptoms seem to occur during certain seasons or during exposure to the following environmental irritants:
1. Tobacco smoke.
2. Perfume.
3. Household pets.
4. Fireplaces.
5. Wood-burning stoves.
6. Mold.
7. Dust mites.
8. Cockroaches.
9. Occupational triggers.

F. Find out how often coughing, wheezing, or SOB awakens the client.
G. Ask if symptoms are caused or exacerbated by moderate exercise or physical activity.
H. Determine family history of asthma, allergies, and eczema.
I. Determine if the client is pregnant or has medical problems. In pregnancy, treatment is based on the same step therapy as in nonpregnant client.
J. Administer the asthma control test. The test is available online at www.asthma.com. A score greater than 20 points indicates the client's asthma is well-controlled. A scores of 16 to 19 points indicates the client's asthma is not well-controlled.
K. Evaluate if the client has ever been tested for allergies.
L. Ask how many times the client has gone to the ED or had to be hospitalized for an asthmatic attack.
M. Ask how many times they have been on oral steroids during the past year.
N. Review all medications including over-the-counter (OTC) and herbal supplements and their effectiveness for asthma control.
O. Ask if prescription or OTC inhalers are used and to what extent.

PHYSICAL EXAMINATION

A. Check temperature, blood pressure (BP), pulse, respirations, and pulse oximetry. Measure the client's height, weight, body mass index (BMI), and waist circumference because obesity is associated with asthma.
B. Inspect:
1. Observe comfort with respiratory pattern, skin tones, and use of accessory muscles of breathing.
2. Observe for hyperexpansion of thorax and signs that accessory muscles are being used (retractions, nasal flaring) or stridor.
3. Note appearance of hunched shoulders and/or chest deformity.
4. Inspect the ears, nose, and throat. Evaluate the presence of enlarged tonsils and adenoids, and nasal polyps.
5. Inspect the skin for eczema, dermatitis, or other irritation that might signal allergy.
6. Observe for allergic shiners and pebbled conjunctiva.
7. Observe for digital clubbing.

C. Auscultate:
1. Auscultate lung sounds. Note wheezing during normal expiration and prolonged expiration, which is seen with asthma.
2. Listen to all lung fields for an asymmetric wheeze.
3. Auscultate heart rate.

D. Percuss:
1. Percuss the lung fields.

DIAGNOSTIC TESTS

A. Spirometry is the gold standard. Peak flow meter measurements are not a substitute for spirometry. Evaluate the forced vital capacity (FVC) and FEV1 before and after the client inhales a short-acting bronchodilator.
B. Chest radiograph (CXR) is not recommended unless there is a compelling reason or suspicion for an alternative diagnosis and complete blood count (CBC) to assess for infection or eosinophilia.
C. Check peak expiratory flow rate (PEFR) after inhalation of short-acting beta-2 agonist (SABA). Diagnosis is confirmed if:
1. There is a 15% increase in PEFR after 15 to 20 minutes.
2. PEFR varies more than 20% between arising and 12 hours later in clients taking bronchodilators (or 10% without bronchodilators).
3. There is a greater than 15% decrease in PEFR after 6 minutes of running or exercise.

D. Consider a bronchial provocation test with histamine or methacholine for nondiagnostic spirometry.

DIFFERENTIAL DIAGNOSES

A. Asthma.
B. Chronic obstructive pulmonary disease (COPD).
C. GERD.
D. Congestive heart failure (CHF).
E. Cough secondary to medications such as an ACE inhibitor or beta-blocker.
F. Pneumonia.
G. Pulmonary embolism.
H. Laryngeal dysfunction.
I. Benign and malignant tumors.
J. Vocal cord dysfunction.
K. Obstructive sleep apnea (OSA).
L. Tuberculosis (TB).
M. Postviral syndrome.
N. Obesity.
O. Allergic rhinitis.
P. Aspiration.

PLAN

A. General interventions:

1. Review proper medication dosages. Short- and long-term agents come in several formulations: nebulizer, metered-dose inhaler (MDI), and a dry powder inhaler (DPI).

2. Demonstrate correct use of inhalers, spacers, and nebulizers. If the client does not use correct technique when using these devices, medication does not get delivered to the bronchioles and therefore the client may believe the medication does not work. Most often the medication works well when delivered to the bronchioles correctly. *See Client Teaching Guide for this chapter, "How to Use a Metered-Dose Inhaler."* The easiest delivery mechanism should be considered for the elderly.

3. Stress the importance of using a peak flow monitor at home to monitor progress of the disease. *See Client Teaching Guide for this chapter, "Asthma Action Plan and Peak Flow Monitoring."*

4. SABA is used for rescue from acute symptoms. Ask the client to state or identify which inhaler they use for "rescue."

5. Use of a SABA more than twice a week for symptom relief indicates the client has inadequate asthma control and needs an inhaled corticosteroid (ICS) as controller therapy.

6. Stress the need for an asthma action plan. *See Client Teaching Guide for this chapter, "Asthma Action Plan and Peak Flow Monitoring."*

B. Client teaching: *See Client Teaching Guide for this chapter, "Asthma."*

1. Asthma is more difficult to control in obesity. Weight reduction should be included in the treatment plan for obese clients with asthma; even 5% to 10% weight loss can improve asthma control.

C. Pharmaceutical therapy:

1. Drugs are prescribed in a stepwise fashion for the type of asthma. The amount of medication used depends on the severity of asthma.

2. Prior to any medication/dosage changes, evaluate if the client has been doing incorrect inhaler technique for medication delivery and monitor the client's compliance with use of medications.

3. Reevaluate the client's modifiable risk factors (e.g., smoking, weight) and evaluate if symptoms are due to comorbid conditions, for example, allergic rhinitis.

4. The 2021 Global Initiative for Asthma (GINA) guidelines outline the medication classes for the approach to Steps 1 to 5.

5. See Table 12.1 for a list of medications for asthma. The following treatments are recommended:

a. Step 1:
   i. Low-dose ICS-formoterol as needed.
   ii. SABA as needed for rescue medication; may be used Q4H as needed to treat exacerbation.
   iii. GINA guidelines add low-dose ICS-formoterol taken when the rescue inhaler is used as another option to prevent exacerbations.

b. Step 2:
   i. Preferred controller: low-dose ICS-formoterol as needed for symptoms and prior to exercise.
   ii. Alternative controller options:
      1) Daily low-dose ICS with SABA as needed for symptoms. GINA prefers low-dose ICS because adherence to daily ICS therapy may be low, predisposing clients to severe exacerbations if SABA is the only treatment the client is using.
      2) **Low-dose ICS taken whenever SABA is taken.**
      3) **Combination low-dose ICS and long-acting beta-2 agonist (LABA).**
      4) Leukotriene receptor antagonist (LTRA).
      5) OR low-dose ICS daily or low-dose ICS-formoterol as needed for clients with seasonal symptoms. Start the medication when symptoms begin and continue for 4 weeks.
   iii. Reliever: Continue to use SABAs as "rescue" as needed.

c. Step 3: Prior to stepping up to step 3, verify client medication administration technique, medication adherence, and potential triggers.
   i. Low-dose ICS-formoterol daily and as needed for symptoms: Maximum daily dose of budesonide formoterol is 72 mcg metered dose and 54 mcg delivered dose. Maximum daily dose of beclometasone formoterol is 48 mcg metered dose and 36 mcg delivered dose.
      1) ICS-formoterol used as needed for rescue has not been studied with ICS-LABA control regimens and should not be recommended.
   ii. Other controller options:
      1) ICS-LABA with SABA as needed for symptoms.
      2) Sublingual allergen immunotherapy (SLIT).
      3) Medium-dose ICS.
      4) Low-dose ICS plus either a leukotriene modifier or a low-dose sustained-release theophylline.
   iii. Reliever: Continue to use SABAs as "rescue" as needed OR low-dose ICS/formoterol.

d. Step 4: Assess medication administration technique, adherence, and exposure to triggers.
   i. Preferred controller: medium-dose ICS-formoterol with low-dose ICS-formoterol as needed for symptoms.
      1) Maximum daily dose of budesonide formoterol is 72 mcg metered dose and 54 mcg delivered dose. Maximum daily dose of beclometasone formoterol is 48 mcg metered dose and 36 mcg delivered dose.
      2) Medium-dose ICS with LABA and SABA for symptoms.
      3) Add a long-acting muscarinic inhibitor (LAMA) for persistent symptoms.
      4) SLIT for persistent symptoms with allergy component.
   ii. Other controller options:
      1) Medium-dose ICS plus either an LTRA or add theophylline.
      2) Tiotropium by mist inhaler is an add-on treatment for clients with a history of exacerbation (not indicated for children <12 years).
   iii. Reliever: Continue to use SABAs as "rescue" as needed OR low-dose ICS/formoterol.

e. Step 5: Refer for expert investigation and add-on treatments.
   i. Add-on treatments include the following:
      1) Tiotropium by mist inhaler for clients with a history of exacerbations (≥12 years of age). ▶

TABLE 12.1 MEDICATIONS FOR ASTHMA AND COPD (BY CLASS/ALPHABETICAL ORDER)

Brand	Generic	Drug Classification	Availability
SABA, for Rescue/Fast-Acting Rescue			
AccuNeb	Albuterol	Beta-2 agonist	Nebulizer
Albuterol	Albuterol sulfate	Beta-2 agonist	Inhaler solution Nebulizer Syrup
Alupent Combivent	Metaproterenol Ipratropium + albuterol	Beta-2 agonist Combination anticholinergic + beta-2 agonist	Oral Oral aerosol Nebulizer MDI
Brethine	Terbutaline sulfate	Beta-2 agonist	Tablet
Fenoterol Maxair Autohaler	Ipratropium + fenoterol Pirbuterol acetate	Beta-2 agonist Beta-2 agonist	Inhaler MDI Oral syrup
ProAir HFA inhaler	Albuterol	Beta-2 agonist	MDI
Proventil HFA inhaler	Albuterol	Beta-2 agonist	MDI
Tornalate Ventolin HFA	Bitolterol Albuterol sustained-release	Beta-2 agonist Beta-2 agonist	Aerosol Inhaler solution MDI
Vospire ER	Albuterol	Beta-2 agonist	ER tablet
Xopenex	Levalbuterol tartrate	Beta-2 agonist	HFA inhaler Concentrate solution for nebulizer
LABA, for Maintenance/Long-Acting Control (Partial List)			
Advair Diskus	Fluticasone + salmeterol	Combination-steroid + LABA	Dry powder Diskus MDI-HFA inhaler
AirDuo RespiClick Arcapta Breo Ellipta Brovana	Fluticasone, salmeterol Indacaterol Fluticasone, vilanterol Arformoterol	Corticosteroid + LABA Long-acting beta-1 agonist Corticosteroid + LABA Beta-2 agonist	Inhaler Nebulizer DPI Nebulizer
Dulera Foradil Aerolizer	Mometasone, formoterol Formoterol fumarate	Corticosteroid + LABA, LABA	Inhaler Nebulizer Dry powder Diskus
Perforomist	Formoterol solution	Beta-2 agonist	Nebulizer
Serevent Diskus Symbicort	Salmeterol Budesonide, formoterol	LABA LABA	Dry powder Diskus Pressurized MDI
Aerobid and Aerobid M	Flunisolide	ICS	MDI MDI with menthol
Alvesco	Ciclesonide	ICS	MDI
Asmanex	Mometasone	ICS	Twisthaler dry powder
Beclovent	Beclomethasone dipropionate	ICS	Dipro powder inhaler
Dulera Flovent HFA	Mometasone furoate + formoterol, fluticasone	Combination corticosteroid + LABA ICS	MDI MDI (also available as a DPI as Flovent Diskus)
Pulmicort	Budesonide	ICS	Flexhaler and respules
QVAR	Beclomethasone	ICS	MDI
Symbicort Breo Ellipta	Budesonide + formoterol Fluticasone + vilanterol	Combination corticosteroid + LABA Combined corticosteroid + LAMA	MDI DPI

TABLE 12.1 MEDICATIONS FOR ASTHMA AND COPD (BY CLASS/ALPHABETICAL ORDER) (*CONTINUED*)

Brand	Generic	Drug Classification	Availability
Leukotriene Modifiers: Nonsteroidal Anti-Inflammatory			
Accolate	Zafirlukast	Leukotriene modifier	Tablet
Singulair	Montelukast	Leukotriene modifier	Chew tablet and granules
Zyflo	Zileuton	Leukotriene modifier	Filmtab
Anticholinergics/LAMA			
Anoro Ellipta Atrovent HFA	Umeclidinium + vilanterol Ipratropium	Anticholinergic/LABA Antimuscarinic/antispasmodic	DPI MDI and nebulizer
DuoNeb	Ipratropium + Albuterol	Combination antimuscarinic/antispasmodic + beta-2 agonist	Nebulizer
Seebri Neohaler Spiriva with HandiHaler Tudorza Pressair Incruse Ellipta	Glycopyrrolate Tiotropium Aclidinium Umeclidinium	Long-acting antimuscarinic Antimuscarinic/antispasmodic Anticholinergic Anticholinergic	DPI Dry powder Diskus DPI DPI
Interleukin-5 Antagonists			
NUCALA	**Mepolizumab**	**Interleukin-5 antagonists**	**Injection**
CINQAIR	**Reslizumab**	**Interleukin-5 antagonist**	**Injection**
Mast Cell Stabilizer			
Intal	Cromolyn sodium	Mast cell stabilizer	MDI
Tilade Gastrocrom	Nedocromil Cromolyn	Mast cell stabilizer Mast cell stabilizer	MDI MDI
Methylxanthine			
Aminophylline Theo-24	Theophylline + ethylenediamine Theophylline sustained-release	Methylxanthines respiratory smooth muscle relaxant Methylxanthines respiratory smooth muscle relaxant	Tablet Tablet
Anti-IgE (IgE Blocker) Monoclonal Antibody			
Xolair	Omalizumab	IgE blocker-immunomodulator	Subcutaneous injection
Systemic Corticosteroids: Used as a Short-Term "Burst" for Control			
Deltasone	Prednisone	Systemic corticosteroid	Tablet
Medrol	Methylprednisolone	Systemic corticosteroid	Tablet
Prelone	Prednisolone	Systemic corticosteroid	Tablet
PDE4 Inhibitors			
Daliresp	Roflumilast	Selective PDE4	Tablet

COPD, chronic obstructive pulmonary disease; DPI, dry powder inhaler; ER, extended-release; HFA, hydrofluoroalkanes; ICS, inhaled corticosteroid; IgE, immunoglobulin E; LABA, long-acting beta-2 agonist; LAMA, long-acting muscarinic antagonists; MDI, metered-dose inhaler; PDE4, phosphodiesterase 4; SABA, short-acting beta-2 agonist.

2) Anti-immunoglobulin E (IgE; subcutaneous [SC] omalizumab) for severe allergic asthma (≥6 years of age).

3) Anti-interleukin 5 for severe eosinophilic asthma (SC mepolizumab or SC benralizumab for ≥12 years of age or intravenous [IV] reslizumab for ≥18 years of age).

4) Sputum-guided treatment, if available, improves outcomes.

ii. Other controller options:

1) Some clients may benefit from low-dose oral corticosteroid (OCS) but long-term systemic side effects commonly occur.

iii. Reliever: Continue to use SABAs as "rescue" as needed OR low-dose ICS/formoterol.

▶

f. Mild to moderate asthma:
   i. Leukotriene modifiers are used to reduce the need for short-acting, inhaled beta-2 agonists. They are also an alternative to low-dose ICS for clients with mild persistent asthma.
g. Exercise-induced bronchospasm:
   i. Short-acting inhaled beta-2 agonists, two inhalations shortly before exercise, are effective for 2 to 3 hours.
   ii. LABA, two inhalations, is effective 10 to 12 hours. LABA should be used cautiously unless combined with an ICS.
h. Hypertension and asthma:
   i. Drug of choice is a calcium channel blocker. Asthmatics also tolerate diuretics well.
i. Theophylline can cause cardiac arrhythmias; therefore, use it with caution and always follow up with theophylline levels.
j. Always ask about asthma before prescribing NSAIDs, including aspirin—aspirin-exacerbated respiratory disease (AERD).
k. Vaccinations:
   i. Influenza vaccine should be administered annually to asthmatics.
   ii. Pneumococcal vaccines are recommended for clients age 19 and older with chronic lung disease, including asthma.

FOLLOW-UP

A. After acute episodes, follow up within 1 to 2 hours or next day to monitor improvement until client is stable.

B. For clients with mild intermittent or mild persistent asthma under control for at least 3 months, assess and follow up at least every 6 months to assess risk factors, provide education, and reinforce positive behaviors.

C. Gradually reduce medication dosage. If control is not achieved, consider increasing dosage after reviewing medication technique, compliance, and environmental control.

EMERGENT ISSUES/INSTRUCTIONS

A. If the client's SOB is not relieved by two inhalations of their SABA, or they are reading in the Red Zone of their peak flow, they should understand this signals a medical emergency and should call emergency medical service (EMS).

B. Clients should clearly state or show you their SABA used for "rescue."

CONSULTATION/REFERRAL

A. Consider hospitalization for clients with acute episodes who do not completely respond to treatment within 1 to 2 hours.

B. If all therapies fail—including a short burst of prednisone—refer the client to an asthma specialist.

C. Consult with a physician when the client is pregnant or has other medical problems, or when standard treatment is ineffective.

D. Refer if the client presents with atypical symptoms.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Risks of uncontrolled asthma far outweigh risks to mother or fetus from drugs used to control the disease.

2. Step therapy should be followed in pregnancy according to guidelines for adults.

3. Classes of drugs that cause risk include decongestants, antibiotics (tetracycline, sulfonamides, and ciprofloxacin), live virus vaccines, immunotherapy (if doses are increased), and iodides. Always weigh benefits against risks because adequate fetal oxygen supply is essential. The obstetrician should be consulted.

4. If corticosteroids are necessary, recommend aerosolized forms due to their lower systemic effects. Prednisone and methylprednisolone are preferred and should be prescribed at minimum effective doses.

5. Do not prescribe inhaled triamcinolone because it is teratogenic.

6. Drugs recommended during pregnancy:
   a. A beta-2 agonist, such as terbutaline, is preferred: two inhalations Q4H as needed up to eight inhalations per day. Regular daily use suggests a need for additional medications.
   b. Cromolyn: two inhalations QID as initial therapy for clients needing regular medication.
   c. Regular inhaled beclomethasone if cromolyn is not effective.
   d. Regular oral theophylline if beclomethasone is not effective.
   e. Oral prednisone if all other therapies fail: 1 week of 40 mg/d, followed by 1 to 2 weeks of tapering.

7. Leukotriene inhibitors should be prescribed in pregnancy only if clearly needed:
   a. Accolate is excreted in the breast milk and should not be prescribed to mothers who are breastfeeding.
   b. Fetal anomalies have been reported with Zyflo.

B. Geriatrics:

1. Asthma may be underdiagnosed in the elderly due to poor perception, an assumption that dyspnea is normal in old age, lack of fitness, or reduced activity.

2. Asthma may be overdiagnosed in the elderly through confusion with SOB due to left ventricular failure or ischemic heart disease.

3. Respiratory viruses may be a common trigger for the first episode of asthma in the geriatric client.

4. While obesity is a risk factor for asthma in geriatrics, malnutrition (e.g., undernutrition) may play an important a role as a risk factor for asthma.

5. Elderly clients with dementia are generally unable to perform the FVC and FEV1 diagnostic tests. In the elderly with dementia, consider COPD in older adults who have any of the following factors. The greater the number of factors, the more likely COPD is present:
   a. Dyspnea that is progressive or worse with exercise.
   b. Chronic cough, either productive or nonproductive.
   c. History of chronic exposure to tobacco smoke, smoke from heating fuels, dust, or chemicals.
   d. Family history of COPD.

6. Treatment is the same as with younger clients, with inhaled steroids the mainstay and oral steroids reserved for severe episodes. The elderly have more adverse effects from inhaled ICS.

7. Chronic steroid use requires careful monitoring for complications including cataracts, increased intraocular pressure, hyperglycemia, and accelerated loss of bone mass.

8. Inhaled anticholinergics and beta-2 agonists are second-line treatment.

9. Consider nebulized treatments for older adults in the following conditions who may not be able to appropriate use inhalers:
   a. Decreased manual dexterity due to arthritis or reduced grip strength. ▶

b. Cognitive impairment: Difficulty coordinating the required activation/inhalation steps to achieve proper penetration of medication into the lungs.

10. Theophylline is rarely effective in the elderly. Asthma medications may have increased adverse effects in the elderly or may aggravate coexisting medical conditions, requiring medication adjustments. Also consider drug interactions and drug and disease interactions.

11. For older adults who are cognitively intact or mildly impaired, or have manual dexterity/decreased grip strength, spacing chambers may be used to assist in the proper delivery of inhaled medications.

12. Depression plays an important role in asthma management; geriatrics especially should be monitored for depression and its effect on chronic management.

BRONCHITIS, ACUTE

DEFINITION

A. Acute bronchitis is inflammation of the tracheobronchial tree. Bronchitis is nearly always self-limited in the otherwise healthy individual. Generally, the clinical course of acute bronchitis lasts 10 to 14 days. The cause is usually infectious, but allergens and irritants may also produce a similar clinical profile. Asthma can be mistaken as acute bronchitis if the client has no history of asthma.

INCIDENCE

A. Bronchitis is more common in fall and winter in relation to the common cold or other respiratory illness. It occurs in males more frequently than in females. Fewer than 5% of clients with bronchitis develop pneumonia. It is one of the most common conditions seen in outpatients. Bronchitis is listed as the sixth most common reason for office visits to a medical provider.

PATHOGENESIS

A. Most attacks are caused by viral agents, such as adenovirus, influenza, parainfluenza viruses, and respiratory syncytial virus (RSV).

B. Bacterial causes (account for only 6% of acute bronchitis cases) include *Bordetella pertussis, Mycobacterium tuberculosis, Corynebacterium diphtheriae*, and *Mycoplasma pneumoniae. B. pertussis* should be considered in adults with persistent coughs.

PREDISPOSING FACTORS

A. Viral infection.
B. Upper respiratory infection (URI).
C. Exposure to cigarette smoke.
D. Exposure to other irritants.
E. Allergens.
F. Chronic aspiration/gastroesophageal reflux disease (GERD).
G. Immunocompromised and frailty.

COMMON COMPLAINTS

A. The most common symptom initially is a dry, hacking, or raspy-sounding cough. The cough then loosens and becomes productive.

OTHER SIGNS AND SYMPTOMS

A. Sore throat.
B. Rhinorrhea or nasal congestion.
C. Rhonchi during respiration.
D. Low-grade fever.
E. Malaise.
F. Retrosternal pain during deep breathing and coughing.
G. Decreased/lack of appetite.
H. Headache.
I. Dyspnea.

SUBJECTIVE DATA

A. Ask about onset, duration, and course of symptoms. Note duration of cough symptoms.
B. Is cough productive?
C. Is there substernal discomfort?
D. Is there malaise or fatigue?
E. Has client had a fever?
F. Does client smoke? (Smoking aggravates bronchitis.)
G. A review of occupational history may be important in determining whether irritants play a role in symptoms.
H. Assess for symptoms of gastroesophageal reflux.
I. If diabetic, ask about home blood glucose readings.
J. Ask about recent cold symptoms.

PHYSICAL EXAMINATION

A. Check temperature, pulse, and blood pressure (BP). Consider pulse oximetry. Evaluate general appearance.
B. Inspect:
  1. Observe overall appearance, including level of consciousness (LOC).
  2. Inspect eyes, ears, nose, and throat (pharynx may be injected).
  3. Transilluminate sinuses.
C. Palpate:
  1. Palpate the lymph nodes, maxillary, and frontal sinuses.
D. Auscultate:
  1. Auscultate in all lung fields for crackles, wheezing, and rhonchi.

DIAGNOSTIC TESTS

A. Consider chest x-ray to exclude pneumonia if fever, tachycardia, or tachypnea is present.

DIFFERENTIAL DIAGNOSES

A. Bronchitis.
B. URI.
C. Asthma.
D. Sinusitis.
E. Cystic fibrosis (CF).
F. Aspiration.
G. Respiratory tract anomalies.
H. Foreign-body aspiration.
I. Pneumonia.

▶

J. Chronic obstructive pulmonary disease (COPD) and emphysema.
K. Pertussis.
L. GERD.
M. Malignancy.
N. Heart failure.
O. Postnasal drip.
P. Medications (angiotensin-converting enzyme inhibitor).

PLAN

A. General interventions:
1. Primarily supportive and should ensure the client is adequately oxygenating.
2. Instruct the client to increase fluid intake.
3. Suggest humidity and mist therapy.
4. Avoid irritants, such as smoke.
B. Client teaching: *See Client Teaching Guide for this chapter, "Bronchitis, Acute."*
C. Pharmaceutical therapy:
1. Acetaminophen (Tylenol) for fever and malaise.
a. Adults: 625 to 1,000 mg orally Q4H not to exceed 4 g/d.
2. Expectorants such as guaifenesin with dextromethorphan (Robitussin DM, Humibid DM, Mytussin) to treat minor cough from bronchial/throat irritation. Cough suppressants including opiates are rarely appropriate and include risk of sedation in elderly.
3. Among otherwise healthy individuals, antibiotics have not demonstrated to be beneficial for acute bronchitis and are against the Centers for Disease Control and Prevention (CDC) current recommendations. Symptoms can persist for up to 4 weeks.
4. Albuterol (Ventolin) for clients with wheezes or rhonchi or for clients with a history of bronchoconstriction.
a. Two puffs every 4 to 6 hours or 2 to 4 mg PO three to four times a day.

FOLLOW-UP

A. Follow up if symptoms persist for more than 3 weeks. Educate on symptoms that warrant sooner follow-up, such as fever, dyspnea, and bloody sputum.
B. Recommend yearly influenza vaccinations.
C. Ensure older adults have both pneumonia vaccinations recommended by the CDC.

EMERGENT ISSUES/INSTRUCTIONS

A. Clients should understand to call the office or go to the ED if shortness of breath (SOB) develops.

CONSULTATION/REFERRAL

A. In uncomplicated cases, mucus production decreases and cough disappears in 7 to 10 days. If symptoms persist, refer the client to a physician.
B. Refer the client if you note respiratory distress or worsening condition.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:
1. Use of handheld bronchodilator should be demonstrated. Older adults who are cognitively intact or mildly impaired may be unable to use standard inhalers. Spacing chambers may be used to assist in proper delivery of inhaled medications. Nebulized treatments should also be considered for the following issues:
a. Decreased manual dexterity due to arthritis or reduced grip strength.
b. Cognitive impairment: difficulty coordinating the required activation/inhalation steps to achieve proper penetration of medication into the lungs.
2. Geriatric red flags:
a. Monitor elderly clients for complications such as pneumonia. The elderly have a greater morbidity and mortality rate and may present with confusion or loss of appetite only.
b. Follow-up may be needed every 24 hours to ensure improvement and to assess changes associated with sepsis.

Smith, M. P., Lown, M., Singh, S., Ireland, B., Hill, A. T., Linder, J. A., Irwin, R. S., & CHEST, Expert Cough Panel. (2020). Acute cough due to acute bronchitis in immunocompetent adult outpatients: CHEST expert panel report. *CHEST*, *157*(5), 1256–1265. https://doi.org/10.1016./j.chest.2020.01.044

BRONCHITIS, CHRONIC

DEFINITION

A. Chronic bronchitis is excessive mucus secretion with chronic or recurrent productive cough occurring in 3 successive months a year for 2 consecutive years.
B. Others limit the definition to a productive cough that lasts more than 2 weeks despite therapy.
C. Clients with chronic bronchitis have more mucus than normal due to either increased production or decreased clearance. Coughing is the mechanism for clearing excess secretion.

INCIDENCE

A. The incidence of chronic bronchitis is uncertain. There is a lack of definitive diagnostic criteria and there is considerable overlap with asthma. Visits for bronchitis are second only to visits for otitis media and are slightly more common than for asthma.
B. The prevalence of chronic bronchitis increases with age.
C. The rates of chronic bronchitis are highest in African American and Caucasian ethnicities.

PATHOGENESIS

A. Mucociliary clearance is delayed due toexcess mucus production and loss of ciliated cells, leading to a productive cough.
B. The bacteria most often implicated are *Streptococcus pneumoniae, Haemophilus influenzae, Mycoplasma pneumoniae*, and *Moraxella catarrhalis.*
C. Specific occupational exposures are associated with symptoms of chronic bronchitis, including coal, cement, welding fumes, organic dusts, engine exhausts, fire smoke, and secondhand smoke.

PREDISPOSING FACTORS

A. Cigarette smoking.
B. Cold weather.
C. Acute viral infection.
D. Chronic obstructive pulmonary disease (COPD)/emphysema.

E. Occupational exposure to other airborne irritants.
F. Chronic, recurrent aspiration or gastroesophageal reflux.
G. Allergies.
H. Immunosuppression.
I. Frailty.

COMMON COMPLAINTS

A. Worsening cough: hacking, harsh, or raspy sounding.
B. Changes in color (yellow, white, or greenish), amount, and viscosity of sputum.
C. "Rattling" sound in chest.
D. Dyspnea/breathlessness.
E. Wheezing.

OTHER SIGNS AND SYMPTOMS

A. Difficulty breathing and retrosternal pain during a deep breath or cough.
B. Rapid respirations.
C. Fatigue.
D. Headache.
E. Loss of appetite.
F. Fever.
G. Myalgias.
H. Arthralgias.
I. Sleep disturbance due to cough.

SUBJECTIVE DATA

A. Determine the onset, course, and duration of illness.
B. Is the client having trouble breathing?
C. Has there been a fever?
D. How is the client's appetite? Is the client drinking enough fluids?
E. Does the client smoke, or is the client exposed to secondhand smoke?
F. Review occupational history to evaluate exposure to irritants.
G. Does the client have a history of asthma?

Chronic bronchitis has a long history of a productive cough and late-onset wheezing. Clients with asthma with a chronic obstruction have a long history of wheezing with a late onset of productive cough.

H. Is there chest pain in any certain area?
I. When was the client's last illness?
J. Determine blood glucose levels if diabetic.
K. Determine the frequency of short-acting beta-2 agonists (SABA) inhaler use and effectiveness.
L. Determine any confusion or lack of appetite (especially in advanced age).
M. Assess the severity of symptoms using the modified Medical Research Council (mMRC) Dyspnea Scale or the COPD Assessment Test (CAT) or the Refined ABCD Assessment Tool.
N. Review medications. There is mixed evidence on the safety of beta-blockers and gabapentinoids as each may increase the risk of breathlessness.

PHYSICAL EXAMINATION

A. Check temperature, pulse, blood pressure (BP), respirations, and pulse oximetry.
B. Inspect:
1. Observe overall appearance, including signs of respiratory distress.
2. Inspect eyes, ears, nose, and throat.
a. Pharynx may be injected.
b. Conjunctivitis suggests adenovirus.
3. Transilluminate sinuses.
4. Assess skin turgor and mucous membranes for dehydration.
5. Assess nutritional status as cachexia may be noted in advanced disease.
C. Auscultate:
1. Auscultate the lungs in all fields. Lung sounds may sound normal to scattered, bilateral crackles, rhonchi, or large airway wheezing.
2. Auscultate heart.
D. Percuss:
1. Percuss the chest.
E. Palpate:
1. Anterior/posterior cervical lymph nodes.
2. Maxillary and frontal sinuses.

DIAGNOSTIC TESTS

A. Clients with uncomplicated respiratory illness need little, if any, laboratory evaluation.
B. Pulse oximetry.
C. Sputum culture to identify bacteria.
D. Chest radiograph (CXR) may help exclude other diseases or complications.
E. Pulmonary function studies may be indicated.
F. EKG and pulmonary function tests (PFTs) may be required for COPD clients.
G. Consider C-reactive protein(CRP) to help guide the decision to start antibiotics. Low CRP may be an indicator that antibiotics are not necessary.

DIFFERENTIAL DIAGNOSES

A. Chronic bronchitis.
B. Acute bronchitis.
C. Asthma.
D. Sinusitis.
E. Cystic fibrosis (CF).
F. Bronchiectasis.
G. Central airway obstruction.
H. Pneumonia.
I. Lung cancer.
J. Aspiration syndrome.
K. Gastroesophageal reflux.
L. Tuberculosis (TB).
M. Foreign body.
N. Heart failure.

PLAN

A. General interventions:
1. Rest during early phase of illness.
2. Encourage stopping smoking and staying away from secondhand smoke.
3. Suggest exercise for clients with COPD.
4. The client's goal is to improve symptoms and to reduce cough and production of sputum.
5. Inform the clients that increased sputum production may occur after smoking cessation and that they may have airway reactivity (wheezing), especially seen in asthmatics.
6. Discuss the clients's choices of advance directives preferably before exacerbation occurs.
B. Client teaching: *See Client Teaching Guide for this chapter, "Bronchitis, Chronic."*
C. Dietary management:
1. Increase fluids unless contraindicated.
2. Eat nutritious food.

D. Pharmaceutical therapy:

1. Bronchodilators should be considered for bronchospasm.

a. Albuterol sulfate (Proventil, Ventolin):

i. Adults: metered-dose inhaler (MDI) actuations (90 mcg/actuation) inhaled every 4 to 6 hours.

2. Analgesics and antipyretics are used to control fever, myalgias, and arthralgias.

3. Consider oral steroids to reduce inflammation.

a. Adults: 5 to 60 mg/d PO.

b. Tapering steroids is not necessary with short courses.

4. Inhaled corticosteroid (ICS) may be effective.

a. Beclomethasone (QVAR): available as an MDI that delivers 40 or 80 mcg/actuation:

i. 40 to 80 mcg inhaled PO BID; not to exceed 320 mcg BID.

b. Fluticasone (Flovent HFA, Flovent Diskus): available as MDI (44, 110, or 220 mcg/actuation) and Diskus powder for inhalation (50, 100, or 250 mcg/actuation):

i. Adults:

1) MDI: 88 mcg inhaled PO BID; not to exceed 440 mcg BID.

2) Diskus: 100 mcg inhaled PO BID; not to exceed 500 mcg BID.

5. Antibiotics for bacterial infection (two of the following should be present to consider antibiotics: dyspnea, increased cough, or purulent sputum).

a. Amoxicillin-clavulanic acid (Augmentin) 250 to 500 mg PO Q8H.

b. Doxycycline 100 mg PO Q12H.

c. Macrolide antibiotics such as erythromycin or azithromycin.

d. Suspected *Pseudomonas* coverage for 65 or older with cardiac disease: levofloxacin 500 mg daily.

FOLLOW-UP

A. Follow up if there is no improvement in 3 to 4 days after starting therapy.

B. Recommend yearly influenza vaccinations and vaccinations against pneumonia.

EMERGENT ISSUES/INSTRUCTIONS

A. Client should understand to seek emergency care should their shortness of breath (SOB) worsen, in accordance with the Advance Directive.

CONSULTATION/REFERRAL

A. Refer clients with respiratory distress to a physician. If respiratory failure occurs (rare), hospitalization may be needed.

B. Refer clients with COPD to a physician or pulmonary specialist.

C. Pulmonary rehab should be considered once recovered.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. Follow-up may be needed every 24 hours to ensure improvement and to assess for worsening clinical presentation and assessment for developing sepsis.

2. Use of handheld bronchodilator should be demonstrated. Older adults who are cognitively intact or mildly impaired may be unable to use standard inhalers. Spacing chambers may be used to assist in proper delivery of inhaled medications. Nebulized treatments should also be considered for the following issues:

a. Decreased manual dexterity due to arthritis or reduced grip strength.

b. Cognitive impairment: difficulty coordinating the required activation/inhalation steps to achieve proper penetration of medication into the lungs.

3. The client's choice for aggressive care, including ventilation, should be noted in the chart and shared with family members.

DynaMed. *COPD*. EBSCO Information Services. Https://www-dynamed-com.frontier.idm.oclc.org/condtion/copd

CHRONIC OBSTRUCTIVE PULMONARY DISEASE

DEFINITION

A. Chronic obstructive pulmonary disease (COPD) is a progressive, chronic, expiratory airway obstruction due to chronic bronchitis or emphysema. The relief of bronchoconstriction due to inflammation has some reversibility. Chronic bronchitis is a chronic productive cough lasting 3 months during 2 consecutive years, after all causes of chronic cough have been excluded. Emphysema is an abnormal, permanent enlargement (hyperinflation) of the air sacs, as well as the destruction of the elastic recoil. Many clients have both types of air restriction symptoms of chronic bronchitis and emphysematous destruction leading to COPD. Clients with asthma whose airflow obstruction is completely reversible are not considered to have COPD. When asthmatic clients do not have complete reversible airflow obstruction, they are considered to have COPD.

B. Irreversible airflow obstruction is a key factor in the client's disability. The goal of COPD management is to improve daily quality of life (QOL) and the recurrence of exacerbations. Smoking cessation continues to be the most important therapeutic intervention.

C. The Global Initiative for Chronic Obstructive Lung Disease (GOLD) staging criteria are as follows:

1. Stage I—mild obstruction: forced expiratory volume in 1 second (FEV_1) greater than 80% of predicted value, some sputum, and chronic cough.

2. Stage II—moderate obstruction: FEV_1 between 50% and 80% of predicted value, shortness of breath (SOB) on exertion, and chronic symptoms.

3. Stage III—severe obstruction: FEV_1 between 30% and 50% of predicted value, dyspnea, reduced exercise tolerance, and exacerbations affecting QOL.

4. Stage IV—very severe obstruction chronic respiratory failure: FEV_1 less than 30% of predicted value; or moderate obstruction: FEV_1 less than 50% of the predicted value; and chronic respiratory failure.

5. Comorbidities commonly seen with COPD include hypertension, cardiac disorders including atrial fibrillation and heart failure, diabetes/metabolic syndrome, gastrointestinal disorders, lung cancer, depression, and osteoporosis.

INCIDENCE

A. Approximately 16 million people in the United States have been diagnosed with COPD. It is the third leading cause of death in the United States. Since 2011, COPD has been more commonly seen in females than in males. The exact worldwide prevalence is unknown as up to 50% of people with low lung function are undiagnosed.

PATHOGENESIS

A. Chronic bronchitis leads to the narrowing of the airway caliber and increase in airway resistance. Mucus gland enlargement is the histologic hallmark of chronic bronchitis.

B. In emphysema, loss of the air sac's elastic recoil causes air limitation. Emphysema caused by smoking is the most severe in the upper lobes. Most clients with COPD have smoked one pack of cigarettes a day for 20 or more years before the symptomatic dyspnea, cough, and sputum appear.

PREDISPOSING FACTORS

A. Cigarette smoking.

B. Occupational, environmental, or atmospheric pollutants:

1. Dust.

2. Chemical fumes.

3. Secondhand smoke.

4. Air pollution.

C. Genetic factor: alpha-1 antitrypsin (AAT) deficiency.

D. Recurrent or chronic lower respiratory infections or disease (childhood and as adult).

E. Age (most common after the fifth decade of life).

F. Females and Native Americans/Alaskan Natives have higher risk.

G. History of asthma.

H. Unemployment, including retirement.

I. Single status (divorced, widowed, or separated).

J. Less than high school education.

COMMON COMPLAINTS

A. Chronic cough and colorless sputum, usually worse in the morning.

B. Dyspnea with exertion, progressing to dyspnea at rest.

C. Wheezing.

D. Difficulty speaking or performing tasks.

E. Weight loss (decrease in fat-free mass).

OTHER SIGNS AND SYMPTOMS

A. Pursed-lip breathing.

B. Use of accessory muscles.

C. Tripod position.

D. Barrel chest.

E. Cyanosis (fingertips, tip of nose, around lips).

F. Tachypnea.

G. Tachycardia.

H. Difficulty speaking or performing tasks.

I. Jugular venous distension.

J. Abnormal, diminished, or absent lung sounds.

K. Mental status changes.

L. Anxiety and depression.

M. Pulmonary hypertension.

N. Cor pulmonale.

O. Left-sided heart failure.

SUBJECTIVE DATA

A. Ask the client about past respiratory problems and infections. Do they currently have fever, chills, or other signs of infection?

B. Ask about onset of cough and characteristics of sputum (amount, color, and presence of blood).

C. Determine cigar use and cigarette pack-year history (pack/day times the number of years smoked) and current interest in quitting.

D. Inquire about exposure to occupational or environmental irritants.

E. How far can the client walk before becoming breathless? Is there more breathlessness when the client walks on a slight incline? Have symptoms caused lost work days or productivity?

F. Does the client become breathless or tired when performing activities of daily living (ADL)?

G. Ask about insomnia, anxiety, restlessness, edema, and weight change.

H. How many pillows does the client sleep on? Do they have to sleep in a recliner or sitting up?

I. Assess the client's ability to perform ADL and instrumental activities of daily living (IADL), including grooming and personal hygiene, performing chores around the house, shopping, cooking, and driving.

J. Ask about alcohol use.

K. Review all medications, including over-the-counter (OTC) and herbal products.

L. Review further assessment questions based on existing comorbidities.

M. Depression screening.

N. Inquire about use of ED or need for hospitalization. Previous ventilation?

PHYSICAL EXAMINATION

A. Record temperature, blood pressure (BP), pulse, respirations, and pulse oximetry. The respiratory rate increases proportionally with disease severity. Take height and weight to calculate the body mass index (BMI). **The client may have a normal examination early in the disease.**

B. Inspect:

1. Observe general appearance: skin color, affect, posture, gait, and amount of respiratory effort when walking and speaking; note increased anterior–posterior chest diameter.

2. Examine sputum: Frothy pink signals pulmonary edema. Hemoptysis is seen in tuberculosis (TB).

3. Examine lips, fingertips, and nose for cyanosis. (Finger clubbing is not characteristic of COPD.)

4. Observe the neck for distended veins and peripheral edema (advanced disease).

5. Check for pursed-lip breathing and use of accessory muscles.

C. Auscultate:

1. Auscultate the heart.

2. Auscultate lungs for wheezes, crackles, decreased breath sounds, and prolonged forced expiratory rate.

3. Assess for vocal fremitus (vibration) and egophony (increased resonance and high-pitched bleating quality). Air trapping causes air pockets that do not transmit sound well. Absent vesicular lung sounds are a distinctive characteristic of COPD.

4. Auscultate carotids for bruits.

D. Percuss:

1. Percuss the chest for presence of hyperresonance and for signs of consolidation.

E. Palpate:

1. Palpate the neck and the superior and inferior clavicular spaces for lymphadenopathy.

2. Palpate the chest.

3. Palpate/percuss abdomen for organomegaly.

4. Grade dependent edema.

F. Mental status:

1. Assess for decreased level of consciousness (LOC).

G. Perform 6-minute walking distance (6MWD) testing to evaluate oxygen desaturation.

H. Further physical examinations are dependent on comorbidities. ▶

DIAGNOSTIC TESTS

A. Spirometry is the gold standard for diagnosing COPD. Pulmonary function tests (PFTs) are used to diagnose, determine severity, and follow the disease progression of COPD. Perform spirometry before and after using bronchodilator.

1. FEV1 is used as an index to airflow obstruction and evaluates the prognosis in emphysema.
2. Forced vital capacity (FVC).
3. FEV1/FVC ratios less than 0.70.

B. Chest radiograph (CXR; not required to diagnose COPD but rules out other diagnoses).

C. Complete blood count (CBC): Evaluate polycythemia due to chronic hypoxia.

D. Sputum specimen for culture.

E. If the client is younger than 40 years of age or has a family history of early onset of emphysema, measure AAT levels.

F. Arterial blood gas (ABG) for baseline.

G. EKG: Note sinus tachycardia and atrial arrhythmias.

H. Two-dimensional echocardiogram is used to evaluate secondary pulmonary hypertension.

I. Chest CT is an alternative imaging study for emphysema; however, it is not required as a diagnostic tool. Low-dose CT should be recommended as appropriate for annual lung cancer screening.

J. Perform a purified protein derivative (PPD) test if TB is suspected.

K. Brain natriuretic peptide (BNP).

L. Theophylline level (if applicable).

DIFFERENTIAL DIAGNOSES

A. COPD.
B. Asthma.
C. Heart failure.
D. Bronchiectasis.
E. Pulmonary edema.
F. TB.
G. AAT deficiency.
H. Pneumonia.
I. Pulmonary embolism.
J. Cystic fibrosis.
K. Cancers.
L. Central airway stenosis.
M. Diffuse panbronchiolitis (predominately seen in those of Asian descent).
N. Obliterative bronchiolitis.

PLAN

A. General interventions:

1. Educate and encourage active participation in the plan of care, including medication adherence.
2. A smoking cessation plan is an essential part of a comprehensive treatment plan. Develop a smoking cessation plan; assess readiness to quit. Set a quit date; encourage a group smoking cessation program. Pharmacotherapy and nicotine replacement reliably increase long-term smoking abstinence rates. **Discuss smoking at every subsequent visit. The effectiveness and safety of e-cigarettes as a smoking cessation aid are uncertain at this time.** *See Client Teaching Guide for Chapter 25, "Nicotine Dependence."*
3. The GOLD guidelines note a five-step program for smoking intervention:
   a. ASK: Systematically identify all tobacco users at every visit; *EVERY* client at *EVERY* clinic visit; is queried about tobacco use status.
   b. ADVISE: Strongly urge all tobacco users to quit in a clear, strong, and personalized manner.
   c. ASSESS: Determine willingness and rationale of the client's desire to make a quit attempt. Ask every tobacco user if they are willing to make a quit attempt at this time (e.g., within the next 30 days).
   d. ASSIST: Aid in quitting, make a quit plan, provide practical counseling, provide educational materials, and help the client obtain social support. Pharmacotherapy if appropriate.
   e. ARRANGE: Schedule a follow-up contact either in person or by telephone.
4. Consider pulmonary rehabilitation for all stages of COPD. Pulmonary rehab programs vary in format and length. Most programs use a small group format and include the following:
   a. Education about symptoms, medications, and oxygen.
   b. Supervised exercise classes and instruction.
   c. Breathing techniques.
   d. Nutritional counseling.
   e. Emotional health support.
5. The selection of inhalers is dependent on the client's age and ability to use the inhaler. Clients should be evaluated as to their coordination and inspiration abilities necessary to use inhalers; otherwise, aerosol medication via a nebulizer is the best delivery method.
6. Have the client bring in their medication/spacers to demonstrate correct use.
7. Consider group visits for teaching sessions.

B. Client teaching: *See Client Teaching Guide for this chapter, "Chronic Obstructive Pulmonary Disease."*

1. Advise to stay away from secondhand smoke and limit exposure to other pulmonary irritants, including aerosols/vapors and extreme temperature changes.
2. Advise exercise with provider approval.
3. Educate and counsel the client regarding advance directives.

C. Dietary management:

1. About 25% of COPD clients are malnourished due to coexisting medical conditions, depression, and inability to shop for or prepare food.
2. Suggest a low-carbohydrate diet. High-carbohydrate intake may increase respiratory work by increasing CO_2 production.

D. Pharmaceutical therapy: Treatment guidelines are based on spirometry. Prior to any medication/dosage changes, monitor the client's compliance (see Table 12.1).

1. Key points for use of bronchodilators:
   a. Long-acting beta-2 agonists (LABAs) and long-acting muscarinic agonists (LAMAs) are preferred over short-acting agents except for clients with only occasional dyspnea.
   b. Clients may start on a single long-acting bronchodilator or dual long-acting bronchodilator therapy. Clients with persistent dyspnea on one bronchodilator should be escalated to two.
   c. Inhaled bronchodilators are recommended over oral bronchodilators.

▶

d. Theophylline is not recommended unless other long-term treatment bronchodilators are unavailable or unaffordable. Theophylline has a narrow therapeutic range and frequent toxicity.

The target theophylline concentration is 5 to 10 µg/mL. Prescribing theophylline requires weight-based dosing. Dosage adjustment therapy is based on serum theophylline concentrations. Monitor theophylline level whenever there is a new illness, worsening chronic illness, or a change in medications that may alter theophylline clearance (e.g., fever >102°F sustained for ≥24 hours or altered liver function including hepatitis). Check drug interactions using an online checker: www.rxlist.com/drug-interaction-checker.htm.

i. Dosage should be titrated up. Titration steps include the following: the starting dose; after 3 days, *if tolerated*, increase dose; and after 3 more days, *if tolerated and if needed*, increase dose.

ii. Common side effects of theophylline include loss of appetite, abdominal pain, diarrhea, weight loss, restlessness, tremor, insomnia, headache, lightheadedness, dizziness, and sweating.

iii. Instruct the client to call 911 and get emergency medical help for severe headache, hyperglycemia, severe or persistent vomiting, cardiac arrhythmias, seizures, or confusion.

2. Key points for anti-inflammatory agents:

a. Long-term monotherapy with inhaled corticosteroid (ICS) is not recommended.

b. Long-term treatment with ICS may be considered in association with LABA in clients with a history of exacerbations despite appropriate treatment with long-acting bronchodilators.

c. Long-term therapy with oral corticosteroids is not recommended.

d. For clients with exacerbations despite LABA/ICS or LABA/LAMA/ICS, chronic bronchitis and severe to very severe airflow obstruction, the addition of a phosphodiesterase 4 (PDE4) can be considered.

Peak flow meters should not be used to diagnose or monitor COPD.

3. GOLD 1 (mild: FEV1 ≥80% predicted): The client may be unaware they have COPD. Give influenza vaccine and pneumococcal vaccines and and use anticholinergics or short-acting beta-2 agonists (SABA) bronchodilators as needed.

4. GOLD 2 (moderate: 50% ≤ FEV1 < 80% predicted): Give influenza vaccine, pneumonia vaccines, SABA bronchodilators as needed, plus long-acting anticholinergics or beta-2 bronchodilator(s) (LABA) plus cardiopulmonary rehabilitation.

5. GOLD 3 (severe: 30% ≤ FEV1 <50% predicted): Give influenza vaccine, pneumonia vaccines, SABA bronchodilators as needed, plus long-acting anticholinergic or beta-2 bronchodilator(s), plus cardiopulmonary rehabilitation, plus inhaled glucocorticoid steroids if client has repeated exacerbations.

6. GOLD 4 (very severe: FEV1 <30%): Give influenza vaccine, pneumonia vaccines, SABA bronchodilator as needed, plus long-acting anticholinergic or beta-2 bronchodilator(s), plus cardiopulmonary rehabilitation, plus inhaled glucocorticoid steroids if repeated exacerbations, plus long-term oxygen therapy (if the client meets the criteria for O_2). To qualify for home oxygen therapy, Medicare guidelines require the PaO_2 to be less than 55 mmHg or the resting oxygen saturation to be below 88% on room air.

7. For maximum effectiveness, utilization of a spacer/holding chamber for inhalers should be encouraged, especially in the elderly or those with difficulty activating metered-dose inhalers (MDIs).

8. Administer pneumonia vaccine in clients 65 years and older or beginning at age 19 if immunocompromised or chronic respiratory condition is present. Consider revaccination every 5 to 10 years in high-risk clients.

a. Sequential administration of the pneumococcal conjugate vaccine (PCV13) and pneumococcal polysaccharide vaccine (PPSV23) is recommended (download the Centers for Disease Control and Prevention's (CDC) guide at: www.cdc.gov/vaccines/vpd/pneumo/downloads/pneumo -vaccine-timing.pdf). In the vaccine-naive client, give PCV13 first, then the PPSV23 12 months later.

b. In older adults who received PPSV23 at the age of 65 or older, give PCV13 in 1 year or more.

c. In older adults who received PPSV23 BEFORE the age of 65, give PCV13, then 5 years after the initial PPSV23 give a second PPSV23.

d. Give a onetime second dose of PPSV23 in persons with chronic renal failure or nephrotic syndrome, functional or anatomic asplenia, or immunocompromising conditions.

Administer yearly flu vaccine. Trivalent or quadrivalent influenza vaccine is essential for all COPD clients. Those 65 years of age or older should receive high-dose trivalent vaccine. Give the client the vaccine in late September, at least 6 weeks before the flu season.

9. Prescribe pharmacologic agents/nicotine replacement therapy (NRT) for smoking cessation according to client preference:

a. Nicotine chewing gum produces better quit rates than counseling alone.

b. Transdermal nicotine patches have a long-term success rate of 22% to 42%.

c. The use of vapor nicotine products should be discussed as their long-term adverse effects on lung function are unknown.

d. Use of an antidepressant, such as bupropion sustained-release (Zyban), has been shown to be effective in smoking cessation by reducing the enjoyment of smoking, reducing withdrawal symptoms, and limiting weight gain. Bupropion may be used in combination with NRT. Begin dosing 1 week before quit date.

i. Days 1 to 3 of treatment: 150 mg every morning.

ii. Day 3 until the end of treatment: 150 mg BID, at least 8 hours apart.

iii. The duration of treatment should be for 7 to 12 weeks. If the client has not quit smoking after 7 to 12 weeks, it is unlikely that they will quit during that attempt so treatment should be discontinued and the treatment plan reassessed.

iv. Medication doses and/or frequency interval are required for renal and mild hepatitis impairment.

v. Moderate to severe hepatic impairment: 150 mg every other day.

e. Varenicline (Chantix) is a partial agonist selective for alpha-4, beta-2 nicotinic acetylcholine receptors. (Chantix is currently off the market as of June 2021. It was pulled from the market by the manufacturer due to having higher levels of nitrosamines, which may be ▶

carcinogenic. Generic forms are available.) Varenicline mimics the effect of nicotine; therefore, it reduces the urge to smoke and relieves withdrawal symptoms. It blocks or blunts the effect of nicotine if the person relapses and has a cigarette. Review the client's history of renal impairment, psychiatric disorders, seizure history/risk, alcohol use, and cardiovascular disease.

10. Antibiotics are not recommended in COPD clients except with acute exacerbation; symptoms of increased dyspnea, increased sputum volume, and increased sputum purulence; or changes in cough, fever, or other evidence of an infection such as an infiltrate on CXR. Antibiotics are prescribed for COPD clients on mechanical ventilation.

11. Mucolytic agents have small benefits and are not usually recommended.

12. Antitussives are not recommended.

13. Cardioselective beta-blockers are not contraindicated in COPD. A noncardioselective beta-blocker may contribute to bronchospasm.

14. Long-term oxygen has been shown to increase survival in clients with severe resting hypoxemia. Target oxygen saturation is 88% to 92%. Refer to a medical supply company if long-term oxygen or assistive devices are needed. To qualify for home oxygen therapy, Medicare guidelines require the PaO2 to be less than 55 mmHg or the resting oxygen saturation to be below 88% on room air.

FOLLOW-UP

A. For acute exacerbations, follow up on the same day or the following day.

B. Follow up stable, chronic COPD every 1 to 2 months, depending on the client's needs.

C. Serial PFTs may help guide therapy and offer prognostic information.

D. Reevaluate clients on oxygen therapy in 1 to 3 months after starting oxygen, including their current smoking status with oxygen in the home.

E. Evaluate for osteoporosis; bone mineral density is lower in COPD clients.

F. Monitor body weight.

EMERGENT ISSUES/INSTRUCTIONS

A. Monitor theophylline levels due to the drug's potential for toxicity.

1. Instruct the client to call 911 and get emergency medical help for severe headache, hyperglycemia, severe or persistent vomiting, cardiac arrhythmias, seizures, and confusion.

CONSULTATION/REFERRAL

A. Consult with a physician if the client has acute respiratory decompensation, severe cor pulmonale (jugular venous distension, hepatomegaly, dependent peripheral edema, ascites, or pleural effusion).

B. Refer the client to a pulmonary specialist for rehabilitation, if available:

1. Outpatient education for the client and the family.

2. Exercise training.

3. Breathing retraining, that is, pursed-lip breathing and huff coughing.

4. Correct administration of medications.

C. Refer to a registered dietitian (RD) to provide medical nutrition therapy (MNT). RDs focus on the prevention and treatment of weight loss associated with COPD and other comorbidities.

D. Send to a pulmonologist for evaluation for continuous positive airway pressure (CPAP) or bilevel positive airway pressure (BiPAP).

E. Send to a pulmonologist to evaluate for surgical intervention, such as bullectomy, lung volume reduction surgery, or lung transplantation.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. COPD is rare except in AAT deficiency.

2. Monitor drug treatment for potential teratogenic effects.

B. Adults:

1. Sexual dysfunction is common in clients with COPD; encourage other ways to display affection.

2. Adults with COPD have twice the incidence and prevalence of disability compared with those without COPD. The association between COPD and disability is as strong as that for other chronic diseases, including stroke, diabetes, and heart disease. Monitor access to social support systems.

C. Geriatrics:

1. Presentation may be atypical.

2. Appearance or progression of one or more of these geriatric syndromes in a client with COPD is a red flag for poor outcomes. Monitor for the following:

a. Incontinence: difficulty in getting to the bathroom due to exertional dyspnea or equipment such as oxygen.

b. Falls: dizziness with exertion, often related to ADLs such as dressing and bathing; hazards, such as tripping over oxygen tubing.

c. Weight loss: SOB contributes to appetite loss and reduced ability to meet daily nutritional needs.

d. COPD is a disease requiring skills in self-management. Efforts to identify cognitive impairment and early deficits in self-care may be as important as other areas of COPD care.

3. Testing:

a. Elderly clients with dementia are generally unable to perform the FVC and FEV_1 diagnostic tests.

4. Medication administration:

a. Handheld MDIs, dry powder, or other types of inhalers cannot be used effectively in adults with cognitive impairment, reduced manual dexterity, or decreased hand grip strength and poor hand–eye coordination.

b. Clients should demonstrate use of their inhaler. If there are concerns, nebulizer therapy should be prescribed to improve the benefit of pharmacotherapy.

c. Clients should have annual flu vaccination and pneumococcal vaccinations according to the CDC guidelines. The 13- and 23-valent vaccines should be given sequentially. Download a guide to the sequential administration according to individual health considerations at: www.cdc.gov/vaccines/vpd/pneumo/downloads/pneumo-vaccine -timing.pdf.

5. Adults with COPD have twice the incidence and prevalence of disability compared with those without COPD. The association between COPD and disability is as strong as that for other chronic diseases, including stroke, diabetes, and heart disease. Monitor access to social support systems.

6. Discuss the trajectory of illness, living wills, advance directives, and resuscitation status early, before a crisis ▶

occurs. Make sure clients understand the potential for prolonged mechanical ventilation and potential need for tracheostomy should they become ventilator–dependent. Encourage clients to discuss their preferences with their family.

7. Beers list caution: theophylline:

a. Theophylline is on the Beers list of drugs to use with caution in the geriatric population related to cardiovascular, renal, hepatic, insomnia, and peptic ulcers.

i. Theophylline has a drug–drug interaction with cimetidine, increasing the risk of theophylline toxicity, and should be avoided (refer to Appendix C [Beers Criteria], Table C.4.)

GOLD 2020 pocket guide-goldcopd.org. www.goldcopd.org(n.d.). https://goldcopd.org/wp-content/uploads/2020/03/GOLD-2020-POCKET-GUIDE.1.0_FINAL-WMV.pdf

COMMON COLD/UPPER RESPIRATORY INFECTION

DEFINITION

A. The common cold is a self-limiting acute respiratory tract infection (ARTI) resulting from viral infection of the upper respiratory tract. It is also called acute nasopharyngitis. ARTI is characterized by mild coryzal symptoms, rhinorrhea, nasal obstruction, headache, sore throat, myalgia, and sneezing.

INCIDENCE

A. Upper respiratory tract infections are among the most frequent reasons for office visits. However, the true incidence is not known because clients treat themselves with over-the-counter (OTC) and home remedies and there is seasonal and geographic variability. Most adults have two to three colds a year.

B. ARTIs cause 40% of lost workdays.

PATHOGENESIS

A. Over 25% to 80% of ARTIs are caused by a rhinovirus (>100 antigenic serotypes). Other viral agents include coronavirus (10%–20%), respiratory syncytial virus (RSV), adenoviruses (5%), influenza viruses (10%–15%), and parainfluenza viruses. Incubation period is 1 to 5 days, with viral shedding lasting up to 2 weeks.

B. Rhinoviral infections are chiefly limited to the upper respiratory tract but may cause otitis media and sinusitis.

PREDISPOSING FACTORS

A. Exposure to airborne droplets.

B. Direct contact with virus by touching hands or skin of infected people or by touching surfaces they touched and then touching eyes or nose.

C. Very young or old ages.

D. Smoking, which increases risk by 50%.

E. Crowded conditions such as long-term care facilities and college dormitories.

COMMON COMPLAINTS

A. Low-grade fever.

B. Generalized malaise.

C. Nasal congestion and discharge (initially clear, then yellow and thick).

D. Sneezing.

E. Sore throat or hoarseness.

F. Watery and/or inflamed eyes.

OTHER SIGNS AND SYMPTOMS

A. Headache.

B. Cough.

SUBJECTIVE DATA

A. Elicit the onset, course, and duration of symptoms.

B. Inquire about color and other characteristics of nasal discharge and sputum. **Purulent nasal discharge after 14 days signals bacterial sinusitis.**

C. Inquire about other discomforts and exposure to people with similar symptoms.

D. Review allergens, seasonal problems, and exposure to irritants and smoke.

E. Review history for other respiratory problems, such as asthma, chronic bronchitis, and emphysema.

F. Determine the frequency of similar symptoms, including the last ARTI.

G. Note symptoms that may indicate more significant competing diagnosis (respiratory distress, altered mental status, vomiting, dehydration, rash, stiff neck).

H. Ask about immune compromise.

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure (BP). Check pulse oximetry as needed.

B. Inspect:

1. Observe general appearance.

2. Inspect eyes. Note "allergic shiners," tearing, and eyelid swelling.

3. Observe ears, throat, and mouth. Otitis media is indicated by redness and bulging of tympanic membrane, or by membrane perforation with drainage.

4. Inspect nose for nasal redness, swelling, polyps, enlarged turbinates, septal deviation, and foreign bodies.

5. Transilluminate the sinuses.

a. Group A streptococci: tonsillar enlargement, exudates, palatine petechiae.

b. Allergies: "cobblestoned" pharyngeal mucosa.

c. Mononucleosis: About half of clients with mononucleosis develop tonsillar exudates and about one-third develop petechiae at the junction of the hard and soft palate, which is highly suggestive of the disease or coinfection with group A beta-hemolytic strep.

C. Auscultate:

1. Auscultate all lung fields. Note decreased breath sounds, rales, or wheezing.

2. Auscultate heart.

D. Percuss:

1. Percuss sinus cavities and mastoid process of temporal bone to rule out otitis media.

2. Percuss chest for consolidation.

3. Percuss the abdomen for organomegaly.

E. Palpate:

1. Palpate face for sinus tenderness.

2. Examine head and neck for enlarged, tender lymph nodes.

DIAGNOSTIC TESTS

A. Diagnosis may be made from history and physical. Because common cold manifestations are so prevalent, an aggressive workup is rarely necessary.

B. Consider rapid strep test if the client has symptoms, positive exam findings, or recent exposure.

C. Consider throat culture if the client has negative rapid strep and is symptomatic or has positive exam findings.

D. Consider testing for influenza A and B.

E. Chest x-ray is not indicated in the absence of physical findings consistent with pneumonia, with comorbid conditions, or with symptoms greater than 3 weeks.

DIFFERENTIAL DIAGNOSES

A. Upper respiratory infection (URI).
B. Allergic rhinitis.
C. Foreign body.
D. Sinusitis.
E. Influenza.
F. Group A strep pharyngitis.
G. Otitis media.
H. Pneumonia.
I. Acute bronchitis.
J. Immunocompromised if history of excessive ARTIs.
K. Asthma.

PLAN

A. General interventions:

1. Supportive care with rest and fluids.

2. Controlled trials reveal minimal therapeutic benefits of vitamin C for treatment and prevention of colds. Zinc has no proven benefit. Echinacea has not shown any differences in rates of infection or severity of symptoms when compared with placebo. Validation and standardization of herbal products have not been completed.

B. Client teaching: *See Client Teaching Guide for this chapter, "Common Cold."*

C. Pharmaceutical therapy:

1. The American College of Chest Physicians released clinical practice guidelines in 2006 for the management of cough.

2. Antibiotics are ineffective in treating viral infection.

3. Corticosteroids may actually increase viral replication and have no impact on cold symptoms.

4. Topical decongestants for rhinorrhea and nasal congestion:

a. Intranasal ipratropium bromide 0.06% two sprays, each nostril, three to four times daily.

b. Intranasal cromolyn sodium one spray, each nostril, three to four times daily.

c. Pseudoephedrine (Afrin) nasal spray 0.05% two to three sprays per nostril BID or phenylephrine (Neo-Synephrine) nasal spray 0.25% to 1% two to three sprays per nostril Q4H as needed. Limit use to 2 to 3 days maximum to avoid rebound rhinitis.

5. Oral decongestants such as pseudoephedrine (Sudafed) have no proven benefits and the side effects can be problematic in the elderly.

6. Analgesics, such as acetaminophen (Tylenol) and ibuprofen (Advil), may be used for headache relief.

7. Cough suppressants are not recommended as side effects outweigh benefits. Dextromethorphan can be used for cough suppression to improve sleep as needed.

8. Colds have no allergic mechanism, so antihistamines are ineffective. The atropine-like drying effect from antihistamines may exacerbate congestion and obstruct the upper airway by impairing mucus flow.

FOLLOW-UP

A. None recommended unless symptoms persist longer than 7 days from onset or the client develops symptoms of lower respiratory infection.

CONSULTATION/REFERRAL

A. Consult a physician if the client has been reevaluated and given a new treatment plan but still has symptoms.

B. Make a same-day referral to an otolaryngologist if tonsillar abscess is suspected.

INDIVIDUAL CONSIDERATIONS

A. Adolescents:

1. Dextromethorphan may be used as a recreational drug with potential for abuse.

B. Geriatrics:

1. Potential benefits from cold preparations do not outweigh the risks, including sedation and urinary retention.

BIBLIOGRAPHY

DynaMed. *Upper Respiratory Infection (URI) in Adults and Adolescents. EBSCO Information Services*. https://www-dynamed-com.frontier.idm.oclc.org/condition/upper-respiratory-infection-uri-in-adults-and-adolescents-18

COUGH

DEFINITION

A. Coughing is a mechanism that clears the airway of secretions and inhaled particles. The act of coughing has the potential to traumatize the upper airway (e.g., vocal cords). A chronic cough is one that lasts longer than 8 weeks.

B. Because coughing can be an affective behavior, psychological issues must be considered as a cause or effect of coughing.

INCIDENCE

A. Data on the incidence of coughing are not available. However, most healthy people do not cough and the main reason for coughing is airway clearance. A chronic cough is the most common presenting symptom in adults who seek medical treatment in an ambulatory setting. Chronic cough is present in 10% to 20% of adults.

PATHOGENESIS

A. Stimulation of mucosal neural receptors in the nasopharynx, ears, larynx, trachea, and bronchi can produce a cough, as can acute inflammation and/or irritation of the respiratory tract. Cough is a reflex response that is mediated by the medulla but is subject to voluntary control. There is clear evidence that vagal afferent nerves regulate involuntary coughing.

B. Pertussis (whooping cough) is caused by the bacterium *Bordetella pertussis*.

C. The **pathogenic triad of chronic cough** responsible for 92% to 100% of chronic coughs is as follows:

1. Upper airway cough syndrome (UACS), previously referred to as postnasal drip syndrome.

2. Asthma.

3. Gastroesophageal reflux disease (GERD).

PREDISPOSING FACTORS

A. Pharyngeal irritants including postnasal drainage.
B. Foreign-body aspiration.
C. Tuberculosis (TB; persons in prisons and nursing homes and immigrants from endemic areas of TB).
D. Psychogenic factors.
E. Mediastinal or pulmonary masses.
F. Congestive heart failure (CHF).
G. Cystic fibrosis (CF).
H. Congenital malformations.
I. Viral bronchitis.
J. Asthma (sole symptom in 28%).
K. *Mycoplasma* infection.
L. UACS, previously referred to as postnasal drip.
M. Chronic sinusitis.
N. Allergic rhinitis.
O. Environmental irritants.
P. GERD.
Q. Chronic bronchitis.
R. Pulmonary edema.
S. Medications, including angiotensin-converting enzyme (ACE) inhibitors.
T. Impacted cerumen and external otitis.
U. Nonasthmatic eosinophilic bronchitis (NAEB; 13%–33%).
V. Swallowing dysfunction in the elderly.

COMMON COMPLAINTS

A. A common complaint is a cough that interferes with activities of daily living (ADL) and sleeping, leading to a decrease in the client's quality of life (QOL).
B. Pertussis cough is uncontrollable and violent. Following coughing, a "whooping" sound follows with a deep breath.

OTHER SIGNS AND SYMPTOMS

A. Fatigue.
B. Rhinitis.
C. Epistaxis.
D. Tickle in throat.
E. Pharyngitis.
F. Night sweats.
G. Dyspnea.
H. Fever.
I. Sputum production.
J. Hoarseness.

SUBJECTIVE DATA

A. Elicit information about onset, duration, and course of the cough. Was onset recent or gradual? **Does the cough occur at night? Nocturnal cough may be caused by chronic interstitial pulmonary edema and may signal left-sided heart failure. Cough caused by asthma is also worse at night. Morning cough with sputum suggests bronchitis.**
B. Inquire about the cough's characteristics. For example, is it productive, dry, bronchospastic, brassy, wheezy, strong, or weak? If it is productive, is it bloody or mucoid? What is the color, consistency, odor, and amount of sputum or mucus? Dry, irritative cough suggests viral respiratory infection. Severe or changing cough should be evaluated for bronchogenic carcinoma. Rusty-colored sputum suggests bacterial pneumonia. Green or very purulent sputum is due to degeneration of white cells. HIV cough also produces purulent sputum.
C. Inquire whether the cough is associated with eating and choking episodes. Wheezing or stridor with coughing may indicate a foreign body or aspiration.
D. Ask whether the cough is associated with postnasal drip, which produces a chronic cough, clear sputum, edematous nasal mucosa, and a "cobblestoned" pharyngeal mucosa.
E. Find out if the cough is associated with heartburn or a sour taste in the mouth, indicating GERD.
F. Ask about precipitating factors, such as exercise, cold air, or laughing. Also ask about alleviating factors. Cough from asthma can be triggered or exacerbated by exposure to environmental irritants, allergens, cold, or exercise.
G. Ask about current and previous work. Is the client exposed to occupational and environmental irritants, such as dust, fumes, or gases? If so, what are the type, level, and duration of exposures?
H. Ask about family history of respiratory illness, such as CF or asthma.
I. Is the client a smoker? If so, how much do they smoke and how long have they smoked? Are they interested in cessation? Are they exposed to secondhand smoke? How much of the day? **Smoking is the main cause of chronic cough**.
J. Find out the date of the client's last tuberculin skin test. Note recent exposure to TB.
K. Inquire about any exposure to the flu.
L. Does the client have a history of heart problems?
M. Does the client have a history of respiratory problems or other medical problems? Chronic bronchitis is a major cause of chronic cough and sputum production. Cough may also be an early sign of lung cancer; in late stages, cough occurs along with weight loss, anorexia, and dyspnea.
N. Review medications such as ACE inhibitors. Cough related to ACE inhibitors usually subsides within 2 weeks, but the median time is up to 26 days.
O. Is there weight loss or worsening dyspnea?
P. Exposure to TB. (Confined living conditions? Incarceration?)
Q. Ask about pain in the back or bony skeleton.
R. Ask of any previous screening for lung cancer (as appropriate) with low-dose CT.

PHYSICAL EXAMINATION

A. Record temperature, blood pressure (BP), respirations, heart rate, and weight. Compare previous changes in weight.
B. Inspect:
  1. Observe general appearance for cyanosis, difficulty breathing, use of axillary muscles, and finger clubbing.
  2. Examine ears, nose, and throat.
C. Auscultate:
  1. Auscultate heart and lungs.
D. Percuss:
  1. Percuss sinus cavities and mastoid process.
  2. Percuss chest and lungs for consolidation.
E. Palpate:
  1. Palpate face for sinus tenderness.
  2. Examine head and neck for lymph nodes, masses, and jugular vein distension (JVD).

DIAGNOSTIC TESTS

A. Testing can be held to a minimum by careful review of history and physical exam.
B. White blood cell (WBC) if infection suspected.
C. HIV test if suspected.
D. Sputum for eosinophils, Gram stain, and/or culture. ▶

E. Mantoux test if indicated.
F. Chest radiograph (CXR) for hemoptysis, dyspnea, fever, chest pain, or weight loss.
G. Pulmonary function testing/spirometry.
H. Methacholine challenge to rule out asthma.
I. Esophageal pH monitoring to rule out GERD.
J. CT with consideration of contrast scan if necessary (the radiologist may need to determine).

DIFFERENTIAL DIAGNOSES

A. Environmental irritants:
  1. Cigarette, cigar, or pipe smoking.
  2. Pollutants (wood smoke, smog, burning leaves, etc.).
  3. Dust.
  4. Lack of humidity.
  5. Chemical exposure in home or workplace, including illicit substances.
B. Lower respiratory tract problems:
  1. Lung cancer.
  2. Asthma.
  3. Chronic obstructive lung disease (includes bronchitis).
  4. Interstitial lung disease.
  5. CHF.
  6. Pneumonitis.
  7. Bronchiectasis.
  8. Foreign body or aspiration.
  9. Tracheal–esophageal fistula.
  10. Pulmonary embolism.
  11. Pulmonary edema.
  12. Pneumonia.
C. Upper respiratory tract problems:
  1. Chronic rhinitis.
  2. Chronic sinusitis.
  3. Disease of external auditory canal.
  4. Pharyngitis.
D. Medication-induced cough from ACE inhibitors.
E. Extrinsic compression lesions:
  1. Adenopathy.
  2. Malignancy.
  3. Aortic aneurysm.
F. Psychogenic factors.
G. Gastrointestinal problems such as reflux esophagitis.
H. Genetic problems such as CF.

PLAN

A. General interventions:
  1. If sputum is purulent, obtain a sample for examination.
  2. Clients with chronic obstructive pulmonary disease (COPD) and CF should be taught huffing as an adjunct to other methods of sputum clearance.
B. Client education: *See Client Teaching Guide for this chapter, "Cough."*
C. Pharmaceutical therapy:
  1. The risk of cough suppressants outweighs the benefits of use.
  2. Antibiotics should not be prescribed for coughs unless a bacterial infection is suspected.
  3. Therapy depends on various acute inflammatory and chronic irritating processes and on cause of cough. Refer to applicable sections of this chapter, such as "Asthma" and "Tuberculosis," and see the "Gastroesophageal Reflux Disease and Dyspepsia" section of Chapter 14.
  4. Inhaled or oral antihistamines could be considered if cough is related to allergic rhinitis. Potential side effects versus benefits should be considered, especially in the elderly.

FOLLOW-UP

A. The client with a normal CXR and no risk factors for lung cancer (e.g., smoking or occupational exposure) can be followed expectantly without further testing.
B. In clients whose cough resolves after cessation of ACE inhibitors and for whom there is a compelling reason to treat with these agents, substitution with an angiotensin II receptor blocker (ARB) is recommended.
C. See applicable sections for specific diagnoses.
D. Pertussis vaccination booster should be administered to all adults according to the Centers for Disease Control and Prevention (CDC) adult vaccine guidelines. Pertussis cases should be reported to the local health department.

CONSULTATION/REFERRAL

A. Consult a physician if symptoms persist after treatment. Reevaluate client in 2 weeks if they are no better.
B. When a cough lasts more than 2 weeks without another apparent cause and is accompanied by paroxysms of coughing, posttussive vomiting, and/or an inspiratory whooping sound, the diagnosis of a *B. pertussis* infection should be made unless another diagnosis is proven.
C. Clients whose condition remains undiagnosed after a workup and therapy may need referral to a cough specialist.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
  1. Cough may be an early symptom of pulmonary edema. Watch intrapartum clients for signs of edema.
B. Adolescents:
  1. Dextromethorphan has been associated with abuse potential.
C. Geriatrics:
  1. The risk of side effects from over-the-counter (OTC) cough suppressants should be discussed with the client.
  2. Elderly clients with dementia are generally unable to perform the forced vital capacity (FVC) and forced expiratory volume in 1 second (FEV1) diagnostic tests. In the elderly with dementia, consider COPD in older adults who have any of the following factors. The greater the number of factors, the more likely COPD is present:
    a. Dyspnea that is progressive or worse with exercise.
    b. Chronic cough, either productive or nonproductive.
    c. History of chronic exposure to tobacco smoke, smoke from heating fuels, dust, or chemicals.
    d. Family history of COPD.

DYSPNEA

DEFINITION

A. Dyspnea occurs when a client experiences any level of breathing discomfort. The symptom is often associated with pulmonary disorders and cardiac ischemia and is a significant predictor of mortality. The risk of experiencing dyspnea increases with age. Up to 37% of people older than the age of 70 experience dyspnea. Treatment is directed at identifying and managing the underlying pathologic concern.

INCIDENCE

A. Dyspnea affects up to half of clients seen in hospitals and up to one-fourth of clients seeking outpatient care.
B. Millions of clients living at home experience chronic dyspnea related to pulmonary and cardiac morbidities.
C. Between three and four million ED visits annually are due to some level of dyspnea.
D. Dyspnea is associated with cardiovascular disease (the leading cause of death in the United States) and pulmonary disease (asthma and chronic obstructive pulmonary disease [COPD], affecting more than 25 million).

PATHOGENESIS

A. Respiration is controlled by peripheral chemoreceptors in the carotid bodies and aortic arch the central chemoreceptors in the medulla.
B. Chemoreceptors are stimulated by a drop in partial pressure of oxygen in arterial blood, a drop in pH, and a change in pCO_2 levels.
C. Additional receptors play a role in maintaining oxygenation, including mechanoreceptors in the upper airway, pulmonary receptors, and chest wall receptors.
D. Breathing discomfort occurs when a client recognizes hypoxia and hypercapnia. Dyspnea is experienced due to physical, psychological, social, and environmental factors.
E. For adequate gas exchange to occur, oxygen must reach the alveoli from the environment. If any part of the airway is compromised, including the alveolar beds, the process is dysfunctional to some degree.
F. In addition to intact respiratory receptors and a clear airway for gas exchange, the act of breathing also requires muscular strength and adequate hemoglobin levels to transport oxygen.

PREDISPOSING FACTORS

A. Asthma.
B. COPD.
C. Interstitial lung disease.
D. Cardiovascular disease.
E. Deconditioning/obesity.
F. Severe anemia.
G. Foreign body.

COMMON COMPLAINTS

A. Difficulty breathing or the sensation of "air hunger."
B. Change in respiratory pattern.
C. Potential wheezing.
D. Weakness.
E. Fatigue.
F. Functional disability.

OTHER SIGNS AND SYMPTOMS

A. Chest tightness.
B. Rapid or shallow breathing.
C. Breathing feels "heavy."
D. Chronic dyspnea is associated with depression.
E. Severe, acute dyspnea is associated with a sensation of impending death.
F. Headache.
G. Anorexia.

POTENTIAL COMPLICATIONS

A. Hypoxemia.
B. pH imbalance.
C. Cardiac dysrhythmias.
D. Confusion.

SUBJECTIVE DATA

A. Determine the onset, duration, and course of dyspnea.
B. Determine if any short-acting beta-2 agonist (SABA; rescue) inhaler was used, the name, quantity used, effectiveness, and when it was last used.
C. Establish medical history, including pulmonary, cardiac, neuromuscular, or hematologic impairments.
D. Determine smoking history, including inhalation of illicit substances (methamphetamines).
E. Rate the degree of dyspnea on a dyspnea scale.
F. Ask the client to list all medications currently being taken, including oral or aerosolized herbal products.
G. Ask about exposures to caustic substances, including fumes, smoke, carbon monoxide in the home or workplace, and occupational exposures to inhaled toxins.
H. Is there associated cough or wheezing?
I. Ask of any pain in chest wall, mental confusion, or extreme fatigue.
J. Determine if there is a history of anxiety or panic episodes.
K. Ask about use of emergency services or need for hospitalization due to dyspnea.
L. Consider if the client has established advance directives and made any change from previous directives.

PHYSICAL EXAMINATION

A. Check temperature, blood pressure (BP) pulse, pulse oximetry, level of consciousness (LOC), and ability to speak in complete sentences without obvious air hunger.
B. Inspect:
  1. Inspect general appearance, noting degree of dyspnea and the respiratory pattern.
  2. Check trachea for deviations.
  3. Inspect for use of accessory muscles of breathing.
  4. Inspect skin for pallor, cyanosis, bruising, open wounds, petechiae, and turgor.
  5. Inspect facial features for fear, lethargy, or angioedema.
  6. Inspect legs for edema.
  7. Capillary refill.
C. Palpate:
  1. Palpate chest wall for tenderness/injury.
  2. Palpate radial and peripheral pulses for amplitude and rhythm.
  3. Palpate chest wall for crepitus.
D. Auscultate:
  1. Cardiac for rhythm, S3/S4.
  2. Lungs in all fields for adventitious sounds.
  3. Abdomen for distension.

DIAGNOSTIC TESTS

A. EKG shows inverted T waves, ST-segment elevation, and Q waves. One normal EKG initially does not always rule out myocardial infarction (MI); perform serial EKGs if MI suspected.
B. Arterial blood gas (ABG).
C. Chest x-ray.
D. Complete blood count (CBC) with differential.
E. Comprehensive metabolic panel (glucose, electrolytes, renal and hepatic functions).
F. Brain natriuretic peptide (BNP).
G. Thyroid-stimulating hormone (TSH).
H. Pulmonary function tests (PFTs).

DIFFERENTIAL DIAGNOSES

A. Acute MI.
B. Pulmonary embolus.

C. Aortic dissection.
D. Pneumothorax.
E. Poisoning (secondary to inhaled elicit substances or unintentional: carbon monoxide).
F. Asthma, uncontrolled.
G. COPD exacerbation.
H. Pulmonary fibrosis.
I. Pulmonary edema.
J. Neuromuscular dysfunction.
K. Respiratory suppression secondary to medication overdose.
L. Anemia.
M. Anxiety/panic episode.
N. Developing pregnancy with gravid uterus.
O. End-stage heart failure.
P. Pulmonary hypertension.
Q. Lung cancer.
R. Progression of morbid obesity and deconditioning.
S. Aspiration or foreign body.
T. Allergic response/angioedema.

PLAN

A. General interventions:
1. The treatment of dyspnea is determined by the underlying etiology.
2. If coronary heart disease (CHD) is present:
a. Make sure client is aware of signs and symptoms of MI.
b. Make sure client knows to seek medical attention or dial 911 if signs and symptoms occur.
c. Encourage CPR training for the family and/or close friends.
B. Client teaching:
1. Educate the client about modifying controllable risk factors for pulmonary and cardiovascular disease. Smoking cessation should be addressed at each client encounter.
2. Discuss the benefits of cardiovascular exercise.
3. Client should carry fast-acting nitroglycerin at all times and know how to use it.
C. Dietary management:
1. If applicable, counsel client on benefits of weight loss to comfort of breathing.
2. Encourage well-balanced meals and adequate fluid intake.
D. Pharmaceutical therapy:
1. Oxygen should be delivered based on client status. For conscious clients in outpatient settings, oxygen is most effectively delivered through a nonrebreather mask. The hypoxic drive is not a consideration for limiting oxygenation in acute emergencies.
2. When MI is suspected, give aspirin 160 to 325 mg (four 81-mg baby aspirin) chewed or swallowed as soon as possible. Enteric-coated aspirin delays absorption and therefore is not recommended.
3. For bronchodilation, a SABA should be delivered by inhaler or nebulization.
4. Further intervention must be under the direction of a specialist after a full evaluation.

FOLLOW-UP

A. Follow-up is determined by the client's condition and primary diagnosis. Timely follow-up is essential and is based on individual client considerations. In the elderly who live alone, next-day follow-up should be considered if the client will not be hospitalized.

EMERGENT ISSUES/INSTRUCTIONS

A. If you suspect MI as the cause of dyspnea, refer the client through emergency medical service (EMS) for immediate ED evaluation.
B. For suspected pulmonary emboli or dissecting aneurysms, client should be transported by EMS.

CONSULTATION/REFERRAL

A. Consultation for chronic dyspnea with a pulmonologist if lung disorder.
B. Consultation with appropriate specialist if cardiac, neuromuscular, or hematologic disorder.
C. Referral to pulmonary and/or cardiac rehabilitation services.
D. Referral to occupational therapy for functional rehabilitation

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
1. For optimal oxygenation, clients with a gravid uterus should be placed on their left side while they are receiving supplemental oxygen.
2. Obstetric referral is recommended for significant dyspnea during pregnancy.
3. Control of asthma or any chronic lung disorder is crucial as the mother must maintain adequate oxygenation to sustain the fetus.
B. Geriatrics:
1. Frailty is a risk marker of morbidity and mortality for all causes of dyspnea. The differential list for dyspnea is lengthy and covers multiple systems. A thorough review of systems and physical exam is required to differentiate the final diagnosis.
2. Adult vaccination guidelines from the Centers for Disease Control and Prevention should be followed for prevention; these are available at www.cdc.gov/vaccines/schedules/downloads/adult/adult-combined-schedule.pdf.
3. The primary care provider should be aware of the client's choices in worsening dyspnea. Advance directives should be available on the outpatient medical record.
4. Consideration for hospice or palliative care services should be recommended to support the client and the family early in the course of progressive dyspnea and chronic illness.

EMPHYSEMA

DEFINITION

A. Emphysema is an abnormal dilation and destruction of alveolar ducts and airspaces distal to the terminal bronchioles. Lung function slowly deteriorates over many years before the illness develops. Emphysema is one of the chronic obstructive pulmonary diseases (COPDs)—a term that refers to conditions characterized by continued increased resistance to expiratory airflow. Chronic bronchitis, emphysema, and asthma comprise COPD. Chronic bronchitis and emphysema with airflow obstruction commonly occur together. ▶

B. There are three morphologic types of emphysema:
1. Centriacinar emphysema: associated with long-term smoking; primarily involves the upper half of the lungs.
2. Panacinar emphysema: found predominantly in the lower half of the lungs; this is observed in clients with alpha-1 antitrypsin (AAT) deficiency.
3. Paraseptal emphysema: involves the distal airway.

INCIDENCE

A. Emphysema typically occurs in people older than age 50, with peak occurrence after the age of 65.
B. The prevalence of emphysema is 20.2 cases per 1,000.
C. The prevalence is greater in Caucasians than other ethnicities.
D. Emphysema is slightly greater in females (21.4/1,000) than in males (19.0/1,000).

PATHOGENESIS

A. Decreased gas exchange occurs due to focal destruction limited to the airspaces distal to the respiratory bronchioles, causing airway obstruction, hyperinflation, loss of lung recoil, and destruction of the alveolar–capillary interface.

PREDISPOSING FACTORS

A. Long-term cigarette smoking.
B. Occupational and environmental exposure to toxic agents:
1. Dust.
2. Chemical fumes.
3. Secondhand smoke.
4. Air pollution.
5. Gases.
C. Alpha-1 protease inhibitor deficiency.
D. Intravenous (IV) drug use secondary to pulmonary vascular damage from the insoluble fillers (e.g., cornstarch, cotton fibers, cellulose, talc).
E. Connective tissue disorders (e.g., Marfan syndrome and Ehlers–Danlos).
F. HIV.

COMMON COMPLAINTS

A. Gradually progressing exertional dyspnea.
B. Chronic cough.
C. Wheezing.
D. Fatigue.
E. Weight loss.

OTHER SIGNS AND SYMPTOMS

A. Cough with mild to moderate sputum production and clear to mucoid sputum.
B. Early morning cough.
C. Shortness of breath (SOB).
D. Tachypnea.
E. Use of accessory muscles for breathing, pursed-lip breathing, *prolonged* expiration.
F. Barrel chest (increased anterior to posterior chest diameter).
G. Flushed skin.
H. Clubbed fingers.
I. Decreased libido.
J. Thin, wasted appearance.
K. Wheezing, particularly during exertion and exacerbations of emphysema.
L. Functional impairment related to dyspnea.
M. Depression.

SUBJECTIVE DATA

A. Elicit information about onset, duration, and course of symptoms.
B. Determine if the client is a smoker. Determine cigar use and cigarette pack-year history (pack/day times the number of years smoked). If so, how much and for how long? Evaluate exposure to secondhand smoke. How much of the day? Are they interested in quitting?
C. Ask about current and previous work. Is the client exposed to occupational and environmental irritants, such as dust, fumes, or gases? If so, what are the type, level, and duration of exposures?
D. Inquire about the cough's characteristics. Is it productive, dry, bronchospastic, brassy, wheezy, strong, or weak?
E. Question the client about episodes of tachypnea, frequency of respiratory infections, and incidence of angina during exertion.
F. Does the client have a hereditary disease (e.g., cystic fibrosis [CF] or AAT deficiency), asthma, nasal abnormalities (e.g., deviated septum), or other respiratory problems?
G. Determine the last tuberculin skin test and recent risk for tuberculosis (TB) exposure.
H. Find out the client's usual weight and assess how much weight loss has occurred and over what time period.
I. Evaluate current vaccination status for pneumonia and influenza.
J. Review all medications, including over-the-counter (OTC) and herbal products.
K. Assess the client's ability to perform activities of daily living (ADL) and instrumental activities of daily living (IADL), including grooming and personal hygiene, performing chores around the home, shopping, cooking, and driving.
L. Ask about alcohol use.
M. Screen for depression.
N. Ask about frequency of use of short-acting beta-2 agonists (SABA) and effectiveness.
O. Inquire about use of ED or need for hospitalization. Previous ventilation?
P. Assess severity of symptoms using the modified Medical Research Council Dyspnea Scale and the COPD Assessment Test.

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, blood pressure (BP), and weight for changes. Consider pulse oximetry.
B. Inspect:
1. Observe general appearance; note flushed skin color, use of accessory muscles, pallor around lips, pursed-lip breathing, barrel chest (lung hyperinflation), and thinness.
2. Assess for peripheral edema.
3. Perform dermal examination: Note finger clubbing and cyanosis.
4. Observe mental status and psychiatric concerns, including depression.
C. Auscultate:
1. Auscultate heart.
2. Auscultate lungs for wheezes, crackles, and decreased breath sounds (generally diffuse decreased breath sound).
3. Assess for vocal fremitus (vibration) and egophony (increased resonance and high-pitch bleating quality). Air trapping causes air pockets that do not transmit sound well.
D. Percuss:
1. Percuss chest for presence of hyperresonance and signs of consolidation.
2. Percuss abdomen for organomegaly.

E. Palpate:
1. Palpate the neck and the superior and inferior clavicular spaces for lymphadenopathy.
2. Palpate abdomen for organomegaly.
3. Grade dependent edema.
F. Further physical examinations are dependent on comorbidities.
G. Mental status:
1. Assess for decreased level of consciousness (LOC).

DIAGNOSTIC TESTS

A. Pulse oximetry: blood gases if indicated. Baseline should be considered as early in disease process as client presents.
B. AAT to rule out hereditary deficiency.
C. Tuberculin skin test.
D. Pulmonary function tests (PFTs) reveal increased total lung capacity with poor respiratory expulsion and increased respiratory volume.
E. EKG reveals sinus or supraventricular tachycardia.
F. Chest radiograph (CXR) reveals hyperinflation, flat diaphragm, and enlarged heart.
G. Sputum evaluation and/or culture.

DIFFERENTIAL DIAGNOSES

A. Emphysema.
B. Chronic bronchitis.
C. Chronic asthma.
D. Bronchiectasis.
E. CF.
F. Chronic asthmatic bronchitis.
G. TB.
H. AAT deficiency.
I. Congestive heart failure (CHF).

PLAN

A. General interventions:
1. Medical management: Supplemental oxygen therapy is indicated if the client has a resting PaO2 less than 55 mmHg or a PaO2 less than 60 mmHg, along with right heart failure or secondary polycythemia. The goal is to achieve a PaO2 of greater than 55 mmHg (usually 1–3 L/min).
B. Client teaching: *See Client Teaching Guide for this chapter, "Emphysema."*
1. Develop a smoking cessation plan: Assess readiness to quit. Set a quit date and encourage a group smoking cessation program. A smoking cessation plan is an essential part of a comprehensive treatment plan.
2. The Global Initiative for Chronic Obstructive Lung Disease (GOLD) guidelines note a five-step program for smoking intervention:
a. ASK: Systematically identify all tobacco users at every visit; *EVERY* client at *EVERY* clinic visit is queried about tobacco-use status.
b. ADVISE: Strongly urge all tobacco users to quit in a clear, strong, and personalized manner.
c. ASSESS: Determine willingness and the rationale of the client's desire to make a quit attempt. Ask every tobacco user if they are willing to make a quit attempt at this time (e.g., within the next 30 days).
d. ASSIST: Aid in quitting, make a quit plan, provide practical counseling, provide educational materials, and help the client obtain social support. Pharmacotherapy if appropriate.
e. ARRANGE: Schedule a follow-up contact either in person or by telephone.
C. Pharmaceutical therapy:
1. Prescription medication and nicotine replacement reliably increase long-term smoking abstinence rates. **The effectiveness and safety of e-cigarettes as a smoking cessation aid are uncertain at this time.**
2. *See Client Teaching Guide for Chapter 25, "Nicotine Dependence."*
3. Nicotine chewing gum produces better quit rates than counseling alone.
4. Transdermal nicotine patches have a long-term success rate of 22% to 42%.
5. The use of vapor nicotine products should be discussed as their long-term adverse effects on lung function are unknown.
6. The use of an antidepressant such as bupropion sustained-release (Zyban) has been shown to be effective in smoking cessation by reducing the enjoyment of smoking, reducing withdrawal symptoms, and limiting weight gain. Bupropion may be used in combination with nicotine replacement therapy (NRT). Begin dosing 1 week before quit date.
a. Days 1 to 3 of treatment: 150 mg every morning.
b. Day 3 until the end of treatment: 150 mg BID, at least 8 hours apart.
c. Duration of treatment should be for 7 to 12 weeks. If the client has not quit smoking after 7 to 12 weeks, it is unlikely that they will quit during that attempt so treatment should be discontinued and the treatment plan reassessed.
d. Medication doses and/or frequency intervals are required for renal and mild hepatitis impairment.
e. Moderate to severe hepatic impairment: 150 mg every other day.
7. Varenicline (Chantix) is a partial agonist selective for alpha-4, beta-2 nicotinic acetylcholine receptors. Varenicline mimics the effect of nicotine; therefore, it reduces the urge to smoke and relieves withdrawal symptoms. It blocks or blunts the effect of nicotine if the person relapses and has a cigarette. Review the client's history of renal impairment, psychiatric disorders, seizure history/risk, alcohol use, and cardiovascular disease. (Chantix is currently off the market due to high levels of nitrosamine, which is said to be carcinogenic.)
8. Oral and inhaled medications are used for clients with stable emphysema to reduce dyspnea and improve exercise tolerance. GOLD guidelines recommend medications based on the results of symptom severity assessments. **Prior to any medication/dosage changes, monitor the client's compliance (see Table 12.1). A spacer/chamber device should be used to improve drug delivery and reduce adverse effects.**
a. Bronchodilators decrease muscle tone in both the small and large airways thereby, increasing ventilation. This category includes beta-adrenergic agents, methylxanthines, and anticholinergics.
i. Albuterol (Proventil, Ventolin), a beta-2 agonist, relaxes the smooth muscle with little effect on cardiac muscle contractility. Albuterol is available as a liquid for nebulizers, and as a metered-dose inhaler (MDI) and dry powder inhaler (DPI).
ii. Metaproterenol (Alupent), a beta-2 agonist, relaxes the smooth muscle with little effect on cardiac muscle contractility. Metaproterenol is available as liquid for nebulizer, MDI, and DPI.

iii. Levalbuterol (Xopenex) is a selective beta-2 agonist that is also used for treatment or prevention of bronchospasm.

iv. Ipratropium (Atrovent) is chemically related to atropine with antisecretory properties. It is used on a fixed schedule with a beta-agonist.

v. Salmeterol (Serevent) relaxes the smooth muscles and can relieve bronchospasm. It may also facilitate expectoration. The bronchodilating effect lasts longer than 12 hours. It is used on a fixed schedule in addition to regular use of anticholinergic agents.

vi. Formoterol (Foradil) is a beta-agonist with rapid onset and long duration. The bronchodilating effects last longer than 12 hours. Formoterol is used on a fixed schedule in addition to regular use of anticholinergic agents.

vii. Tiotropium (Spiriva) is a quaternary ammonium compound that elicits anticholinergic/antimuscarinics effects with inhibitory effects on M3 receptors on airway smooth muscles, leading to bronchodilation. It is available as a capsule dosage form containing dry powder for oral inhalation via HandiHaler.

viii. Theophylline (aminophylline, Theo-24, Theo-Dur, Slo-Bid) potentiates exogenous catecholamines and diaphragmatic muscular relaxation, which stimulates bronchodilation. Theophylline has a narrow therapeutic range and frequent toxicity.

The target theophylline concentration is 5 to 10 µg/mL. Prescribing theophylline requires weight-based dosing. Dosage adjustment therapy is based on serum theophylline concentrations. Monitor theophylline level whenever there is a new worsening chronic illness, or a change in medications that may alter theophylline clearance (e.g., fever >102°F sustained for ≥24 hours or altered liver function including hepatitis). Check drug interaction using an online checker: www.rxlist.com/drug-interaction-checker.htm.

1) Dosage should be titrated up. Titration steps include the following: the starting dose; after 3 days, *if tolerated*, increase dose; and after 3 more days, *if tolerated and if needed*, increase dose.

2) Common side effects of theophylline include loss of appetite, abdominal pain, diarrhea, weight loss, restlessness, tremor, insomnia, headache, lightheadedness, dizziness, and sweating.

3) Instruct the client to call 911 and get emergency medical help for severe headache, hyperglycemia, severe or persistent vomiting, cardiac arrhythmias, seizures, or confusion.

a) Aclidinium (Tudorza Pressair) is an M1 to M3 muscarinic agonist (long-acting muscarinic agonists [LAMAs]). It inhibits M3 receptors, leading to muscle relaxation and subsequent bronchodilation.

b. Corticosteroids attempt to moderate the inflammatory component. They should only be added to a regimen that includes a long-acting bronchodilator:

i. Fluticasone inhaled: vasoconstrictive and anti-inflammatory activity.

ii. Budesonide inhaled.

c. Phosphodiesterase 4 (PDE4) inhibitors: Selective PDE4 inhibitors reduce exacerbations, improve dyspnea, and increase lung function in clients with severe COPD.

d. Oral steroids should be used to treat outpatients with acute exacerbations. Corticosteroids reduce mucosal edema, inhibit prostaglandins that cause bronchoconstriction, and increase responsiveness to bronchodilators. Taper dose as soon as bronchospasm is controlled. A minority of clients who respond to oral steroids can be maintained on long-term inhaled steroids.

e. In clients with emphysema, chronic infection or colonization of the lower airways is common. The goal of antibiotic therapy is not to eliminate the organisms, but to treat acute exacerbations. If infection is present, give one of the following:

i. Macrolides (azithromycin) are preferred for clients with COPD exacerbation.

ii. Augmentin 500 mg orally BID.

iii. Doxycycline 100 mg orally BID.

iv. Trimethoprim-sulfamethoxazole 80 to 160 mg orally Q12H.

v. If *pseudomonas* is considered, levofloxacin 500 mg daily.

f. Mucolytic agents in clinical practice are not recommended currently due to a lack of evidence on their benefit.

g. Trivalent influenza vaccine is essential for all COPD clients.

Administer yearly flu vaccine. High-dose trivalent or quadrivalent influenza vaccine is essential for all COPD clients. Those 65 years of age or older should receive high-dose trivalent vaccine. Give the client the vaccine in late September, at least 6 weeks before the onset of flu season.

h. Administer pneumonia vaccine in clients 65 years and older, or beginning at age 19 if immunocompromised or chronic respiratory condition is present. Consider revaccination every 5 to 10 years in high-risk clients. Download a guide to sequential administration according to individual health considerations at www.cdc.gov/vaccines/vpd/pneumo/downloads/pneumo-vaccine-timing.pdf.

i. Sequential administration of the pneumococcal conjugate vaccine (PCV13) and pneumococcal polysaccharide vaccine (PPSV23) is recommended (download the Centers for Disease Control and Prevention's [CDC] guide at www.cdc.gov/vaccines/vpd/pneumo/downloads/pneumo-vaccine-timing.pdf). In the vaccine-naive client, give PCV13 first, then the PPSV23 12 months later.

ii. In older adults who received PPSV23 at age 65 or older, give PCV13 in 1 year or more.

iii. In older adults who received PPSV23 BEFORE the age of 65, give PCV13, then 5 years after the initial PPSV23 give a second PPSV23.

iv. Give a onetime second dose of PPSV23 in persons with chronic renal failure or nephrotic syndrome, functional or anatomic asplenia, or immunocompromising conditions.

i. AAT is needed for significant antitrypsin deficiency (<80 mg/dL). Clients get weekly or monthly infusions. Consult with a physician before therapy. A history of smoking rules out candidacy. ▶

FOLLOW-UP

A. If the client is acute, contact by phone in 24 to 48 hours and consider immediate referral.

B. Monitor the client's body weight.

C. Serial PFTs may help guide therapy and offer prognostic information.

D. Monitor theophylline levels due to the drug's potential for toxicity. Adverse effects, including nausea and nervousness, are the most common. Other adverse effects include abdominal pain with cramps, anorexia, tremors, insomnia, cardiac arrhythmia, and seizures. Theophylline doses: 100 to 200 mg every 6 to 8 hours.

EMERGENT ISSUES/INSTRUCTIONS

A. Monitor theophylline levels due to the drug's potential for toxicity.

1. Instruct the client to call 911 and get emergency medical help for severe headache, hyperglycemia, severe or persistent vomiting, cardiac arrhythmias, seizures, and confusion.

CONSULTATION/REFERRAL

A. If the client's condition remains acute after 48 hours of treatment, consider immediate referral to a physician.

B. Refer the client to a social worker for help in getting Meals on Wheels, handicapped parking, and finding other community resources.

C. A consultation with a pulmonary specialist is recommended.

D. Pulmonary rehabilitation should be considered early in the disease process. Pulmonary rehab programs vary in format and length. Most programs use a small group format and include the following:

1. Education about symptoms, medications, and oxygen.
2. Supervised exercise classes and instruction.
3. Breathing techniques.
4. Nutritional counseling.
5. Emotional health support.

INDIVIDUAL CONSIDERATIONS

A. Adults:

1. Sexual dysfunction is common in clients with COPD.

B. Geriatrics:

1. Older adults are at higher risk for restrictive lung diseases. Therapy follows the underlying cause. These diseases fall into four broad categories:

a. Intrinsic: idiopathic pulmonary fibrosis, radiation-induced, drug-induced, postinflammatory lung fibrosis, connective tissue disease.
b. Extrinsic: kyphosis/kyphoscoliosis and obesity.
c. Neuromuscular: amyotrophic lateral sclerosis (ALS), thyroid disorders, adrenal disorders, postpolio syndrome, vitamin D deficiency.
d. Central nervous system disorders: Parkinson disease, multisystemic atrophy, multiple sclerosis, progressive supranuclear palsy.

2. Discuss course of disease, living wills, advance directives, and resuscitation status early, before a crisis occurs. Encourage the client to discuss their preferences with their family.

3. Older adults may be unable to use standard inhalers for the following reasons:

a. Decreased manual dexterity due to arthritis, reduced grip strength, tremors, muscle weakness, and poor hand–eye coordination.
b. Cognitive impairment: difficulty coordinating the required activation/inhalation steps to achieve proper penetration of medication into the lungs.
c. Clients should demonstrate use of their inhaler. If concerns, nebulizer therapy should be prescribed to improve the benefit of pharmacotherapy.

4. Beers list caution:

a. **Theophylline**: theophylline is on the Beers list of drugs to use with caution in the geriatric population related to cardiovascular, renal, hepatic, insomnia, and peptic ulcers.
b. Theophylline has a drug–drug interaction with multiple medications, increasing the risk of theophylline toxicity. For example, theophylline has a drug–drug interaction with cimetidine (refer to Appendix C [Beers Criteria], Table C.4.)

INFLUENZA (FLU)

DEFINITION

A. Influenza is a common, acute, viral infection that is a self-limiting, febrile illness of the respiratory tract. Illness is spread person-to-person, primarily by respiratory secretions that can be spread from infected persons through sneezing, coughing, talking, and self-inoculation of secretions through direct contact routes. Influenza is one of the top 10 causes of death in the United States when it occurs with pneumonia.

INCIDENCE

A. Epidemics occur yearly, primarily in the winter months, in both the northern and southern hemispheres. Travelers should be reminded that the flu season is different by hemisphere and can occur on cruise ships. Attack rates may be as high as 10% to 20% of the population. Mortality is highest in the geriatric population older than 65 years of age, except during pandemics when 50% of influenza deaths occur in individuals younger than 65 years of age. Extraordinarily high attacks have occurred in the institutionalized and crowded populations.

PATHOGENESIS

A. Influenza A and B are viruses that have the ability to undergo periodic antigenic changes of their envelope glycoproteins, the hemagglutinin and neuraminidase. Among influenza A viruses that infect humans, there are three major subtypes of hemagglutinins (H1, H2, and H3) and two subtypes of neuraminidases (N1 and N2). Influenza A outbreaks typically start abruptly, peak over 2 to 3 weeks, and last approximately 2 to 3 months. H1N1 (swine flu) is an influenza A virus. ▶

B. The avian flu was an N5N1 and H7N7 viral infection associated with recent exposure to dead or ill poultry. Following exposure, the incubation period for human H5N1 infection was 7 days or less. Clusters of human-to-human transmission of avian flu had a typical incubation period of 3 to 5 days.

C. Influenza B outbreaks are generally less extensive and less severe. Outbreaks associated with the B virus have been reported in schools, military camps, nursing homes, and cruise ships.

D. *Haemophilus influenzae* is a gram-negative coccobacillus. *H. influenzae* is an invasive bacterial disease that can cause meningitis, otitis media, sinusitis, epiglottitis, septic arthritis, occult febrile bacteremia, cellulitis, pneumonia, and empyema; occasionally, this virulent organism causes neonatal meningitis.

E. The incubation period for *H. influenzae* is from between 18 and 72 hours to 5 days after exposure. The exact period of communicability for *H. influenzae* is unknown, but may be for as long as the organism is present in the upper respiratory tract.

PREDISPOSING FACTORS

A. The primary mode of spread is via exposure to viral strain respiratory secretions from respiratory droplets (coughing or sneezing) and direct contact with contaminated surfaces.

1. Adults:
   a. Aged older than 65 years (dependent on the viral strain).
   b. Pregnancy.
   c. High-exposure jobs: teachers, healthcare workers, police, and firefighters.
   d. Recent illnesses or state that has lowered resistance (stress, excessive fatigue, poor nutrition).
   e. Immunosuppression from drugs, illness, or chronic illness (transplant recipients, lung disease, heart disease).
   f. Crowded living conditions, including military camps and institutions such as nursing homes.
   g. Travel in endemic areas.
   h. Avian flu: exposure to dead or ill poultry.
   i. Obesity.

COMMON COMPLAINTS

A. Clinical manifestations of influenza depend on age and previous experience with the influenza virus.

B. Rapid-onset respiratory illness is the most common complaint.

C. Abrupt onset of fever and/or chills.

D. Joint pain.

E. Headache.

F. Conjunctivitis (avian flu).

OTHER SIGNS AND SYMPTOMS

A. Upper respiratory congestion (watery eyes, clear nasal drainage, headache, sore throat, and hoarseness).

B. Malaise or fatigue.

C. Anorexia.

D. Swollen lymph nodes.

E. Nonproductive cough (persisting for weeks).

F. Muscle aches.

G. Gastrointestinal symptoms.

H. Febrile seizures.

I. Otitis media.

SUBJECTIVE DATA

A. Review the onset, course, and duration of symptoms, especially myalgia and malaise.

B. Query the client if they have had a flu shot and when the last flu vaccination was received.

C. Review symptoms of other family members or coworkers who are also ill.

D. Review for recent travel location and use of cruise ships or planes.

E. Evaluate living conditions for exposure risks.

F. Is the client a smoker?

G. Review all medications, including over-the-counter (OTC) and herbal products. Has the client taken any medications for the symptoms?

H. Does the client have a history of asthma or chronic obstructive pulmonary disease (COPD)?

I. Is the client immunocompromised (e.g has HIV, is a transplant recipient, or is on chemotherapy)?

J. What other medical comorbidities, such as diabetes, does the client have?

K. In clients 65 and older, is illness associated with new-onset confusion, which may indicate sepsis?

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure (BP).

B. Inspect:

1. Observe overall appearance for pallor and for any respiratory distress.
2. Assess hydration status of mucous membranes.
3. Conduct an eye, ear, nose, and throat exam.
4. Assess skin for rashes, petechiae, and turgor.

C. Auscultate:

1. Auscultate the lung fields, observing for wheezing and crackles.
2. Auscultate the heart.

D. Palpate:

1. Palpate the neck and lymph nodes: preauricular, posterior auricular, submental and sublingual, anterior cervical chain, and supraclavicular nodes.

E. Perform neurologic exam:

1. Assess the level of consciousness (LOC).
2. Assess for nuchal rigidity.
3. Assess for meningeal signs.
   a. Signs of meningeal irritation include nuchal rigidity.
   b. Positive Brudzinski and Kernig signs (Figures 12.1 and 12.2):
      i. Brudzinski sign: Place the client supine and flex the head upward. Resulting flexion of both hips, knees, and ankles with neck flexion indicates meningeal irritation.
      ii. Kernig sign: Place the client supine. Keeping one leg straight, flex the other hip and knee to a bent knee to form a 90° angle. Slowly extend the lower leg. This places a stretch on the meninges, resulting in pain and spasm for the hamstring muscle. Resistance to further extension can be felt.

DIAGNOSTIC TESTS

A. Usually none required. However, if the client appears ill, consider the following:

1. White blood cell (WBC) and complete blood count (CBC).
2. Viral RNA cultures: Obtain during the first 72 hours of illness because the quality of virus shed subsequently ▶

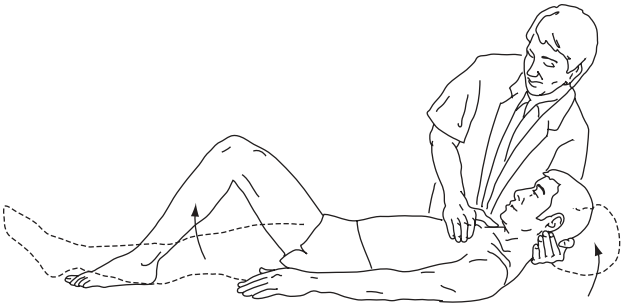

FIGURE 12.1 Brudzinski sign.

FIGURE 12.2 Kernig sign.

decreases rapidly. There is some evidence that a throat sampling yields an improved specimen. Nasopharyngeal secretions obtained by swab or aspirate should be placed in an appropriate transport medium for culture.

3. Rapid antigen test (usually less sensitive in the detection of influenza A than the polymerase chain reaction [PCR]; a negative rapid diagnostic test should be confirmed with a viral culture or other means).

4. Monospot test: **Monospot test is negative with the flu and positive with mononucleosis.**

5. Chest radiograph (CXR; only if pneumonia is suspected).

6. Sputum culture (complications only).

7. Lumbar puncture (complications only).

8. Rapid plasma reagin (RPR) test (for high-risk HIV factors): negative RPR to rule out syphilis.

9. PCR assay (can differentiate between influenza subtypes and offers high sensitivity and specificity but is not readily available for clinical use).

DIFFERENTIAL DIAGNOSES

A. Influenza:
- **1.** Influenza A.
- **2.** Influenza B.
- **3.** Avian flu (H5N1).
- **4.** H1N1 (swine flu).

B. Pneumonia.
C. Bronchitis.
D. Mononucleosis.
E. Early HIV.
F. Severe acute respiratory syndrome (SARS).
G. Meningitis.

PLAN

A. General interventions:

1. Management is usually treatment of symptoms.

2. Encourage flu vaccine for clients in susceptible populations prior to flu season.

3. Clients should expect to have a persistent cough and malaise after the initial acute phase.

B. Client teaching**:** *See Client Teaching Guide for this chapter, "Influenza (Flu)."*

C. Pharmaceutical therapy:

Influenza can alter the metabolism of certain medications, especially theophylline, possibly resulting in the development of toxicity from high serum concentrations.

1. Acetaminophen (Tylenol) as needed for fever.

2. Nonsteroidal anti-inflammatory drugs (NSAIDs) as needed for body aches.

3. Amantadine and rimantadine (class of medications known as adamantanes) are not recommended for antiviral treatment or chemoprophylaxis of currently circulating influenza A virus strains.

4. Antivirals started within the first 48 hours confer the greatest benefit. Antiviral therapy recommendations vary by type of influenza, age group, renal function, and risk factor. To prescribe the most current antiviral therapy, refer to the Centers for Disease Control and Prevention (CDC) website for the most up-to-date recommendations: www.cdc.gov/flu/professionals/antivirals/summary-clinicians.htm.

5. The recommended duration of treatment is 5 days. Longer treatment regimens may be necessary in persons with immunosuppression or for hospitalized clients.

6. Zanamivir (Relenza):
- a. This is not recommended for persons with underlying airway disease, including asthma or COPD.
- b. Zanamivir is for uncomplicated acute illness due to influenza A or B in adults who have been symptomatic for no more than 2 days.
- c. See Table 12.2 for the recommended dosage and schedule of influenza antivirals for treatment and chemoprophylaxis.

7. Oseltamivir (Tamiflu):
- a. For adults and adolescents 13 years of age or older who have been symptomatic for no more than 2 days.
- b. Preferred treatment for pregnant clients. Pregnant clients are recommended to receive the same antiviral dosing as those who are not pregnant.
- c. See Table 12.2 for the recommended dosage and schedule of influenza antivirals for treatment and chemoprophylaxis.

8. Vaccination:
- a. Flu vaccine should not be administered to persons allergic to eggs.
- b. The vaccine should be administered in the autumn prior to the flu season, at least 6 weeks before the onset of the season.
- c. Influenza vaccines may be administered concurrently with other live or inactivated vaccines.
- d. **Immunization is the major means of influenza prevention.** Each year the vaccine is produced with influenza strains. The vaccine may be trivalent or quadrivalent formulations. ▶

TABLE 12.2 RECOMMENDED DOSAGE AND SCHEDULE OF INFLUENZA ANTIVIRAL MEDICATIONS[A] FOR TREATMENT[B] AND CHEMOPROPHYLAXIS[C]

Antiviral Agent		Age Group (Years)	
		13–64	≥65
Zanamivir	Treatment, influenza A and B	10 mg (two inhalations) BID	10 mg (two 5–mg inhalations) BID
	Chemoprophylaxis, influenza A and B	10 mg (two inhalations) once dailyBID	10 mg (two 5-mg inhalations) BID
Oseltamivir	Treatment, influenza A and B	75 mg BID	75 mg BID
	Chemoprophylaxis, influenza A and B	75 mg once daily	75 mg once daily
Peramivir	Treatment, influenza A and B	600 mg IV × one dose	600 mg IV once
	Chemoprophylaxis, influenza A and B	N/A	N/A

[a]Zanamivir is manufactured by GlaxoSmithKline (Relenza inhaled powder). Zanamivir is approved for treatment of persons older than 7 years of age and approved for chemoprophylaxis of persons older than 5 years of age. Zanamivir is administered through oral inhalation by using a plastic device included in the medication package. Clients will benefit from instruction and demonstration of the correct use of the device. Zanamivir is not recommended for persons with underlying airway disease. Oseltamivir is manufactured by Roche Pharmaceuticals (Tamiflu—tablet). Oseltamivir is approved for treatment or chemoprophylaxis of persons 1 year of age or older Oseltamivir is available for oral administration in 30-45- and 75-mg capsules and liquid suspension.

[b]The recommended duration for antiviral treatment is 5 days. Longer treatment courses can be considered for clients who remain severely ill after 5 days of treatment.

[c]The recommended duration is 10 days when administered after a household exposure and 7 days after the most recent known exposure in other situations. For control of outbreaks in long-term care facilities and hospitals, the Centers for Disease Control and Prevention recommends antiviral chemoprophylaxis for a minimum of 2 weeks and up to 1 week after the most recent known case was identified.

IV, intravenously; N/A, not approved.

This information is based on data published by the Food and Drug Administration (FDA), available at www.fda.gov/Drugs/DrugSafety/InformationbyDrugClass/ucm100228.htm.

e. Two types of administration of the vaccine are available:
   i. Inactivated influenza vaccine (IIV), previously called trivalent inactivated vaccine (TIV), is administered intramuscularly.
   ii. Live attenuated influenza vaccine (LAIV) is administered intranasally. The LAIV is available for adults up to 49 years of age.

f. A high-dose influenza vaccine is also available for adults older than 65 years.

g. The recommended site of vaccination in adults is the deltoid muscle.

h. Oseltamivir (Tamiflu) should not be administered with a LAIV within 2 weeks prior to or 48 hours after treatment.

FOLLOW-UP

A. Schedule a follow-up visit within 2 to 5 days if symptoms do not improve:

1. People at highest risk for influenza complications:
   a. All persons 50 years of age and older.
   b. Anyone with chronic pulmonary (including asthma) or cardiovascular (except isolated hypertension), renal, hepatic, neurologic, hematologic, or metabolic disorders, including diabetes mellitus.
   c. Persons who have immunosuppression, including immunosuppression caused by medications or HIV infection.
   d. Persons who are or will be pregnant during the influenza season.
   e. Residents of nursing homes and other long-term care facilities.
   f. American Indians and Alaska Natives.
   g. Persons who are morbidly obese (body mass index [BMI] ≥40).

B. Monitor the client for pulmonary and neurologic complications.

C. Because antiviral resistance patterns can change over time, clinicians should monitor local antiviral resistance surveillance data. Local and state health departments are the points of contact for information about current influenza.

EMERGENT ISSUES/INSTRUCTIONS

A. Clients demonstrating the following should receive same-day ED evaluation:

1. Respiratory compromise.

2. Neurologic changes including obvious central nervous system (CNS) involvement.

3. Profound dehydration or alterations in vital signs.

CONSULTATION/REFERRAL

A. Refer the client to a physician or a neurologist for any complications.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. The American College of Obstetricians and Gynecologists (ACOG) in their 2018 Committee Opinion notes that the flu vaccine is an essential element of preconception, prenatal, and postpartum care.

2. Pregnancy predisposes the client to an increased risk for influenzal pneumonia.

3. Immunization of pregnant persons is considered safe at any stage of pregnancy with the IIV.

4. LAIV, available as an intranasal spray, is not recommended for those who are pregnant but is safe for postpartum clients. ▶

5. The inactivated vaccine is safe for breastfeeding mothers and their infants.

6. Zanamivir is the antiviral of choice for pregnancy dut to its limited systemic absorption.

7. Oseltamivir is used in pregnancy for those with asthma secondary to a higher risk for complications.

B. Adults:

1. Persons with high-exposure occupations such as teachers, healthcare workers, police, and firefighters should consider yearly immunization. Vaccine should be offered/administered to persons with chronic metabolic diseases, renal dysfunction, HIV infection, and immunosuppression.

C. Geriatrics:

1. Ninety percent of flu-related deaths and half of flu-related hospitalization occur in people age 65 and older. Pneumococcal pneumonia and influenza are significant causes of mortality and morbidity in the elderly.

2. Factors that contribute to more severe infections include general frailty, decreased functional reserve, weakened immune systems, decreased lung compliance, and decreased respiratory muscle strength, all due to advancing age.

3. Influenza vaccine is recommended yearly for clients older than the age of 60. The vaccine should be especially encourage in nursing home residents and clients with cardiopulmonary disease.

4. Older adults are at very high risk for complications and death from influenza. Tamiflu (Oseltamivir) is the preferred antiviral therapy.

5. For those with a positive flu test, 75 mg Q12H × 5 days if renal function is known to be normal. For stage 3 chronic renal impairment (creatinine clearance [CrCl] 30–60), give 30 mg Q12H × 5 days. For severe renal impairment (CrCl < 30), 30 mg once daily × 5 days. In end-stage renal disease (ESRD) clients on hemodialysis, give 30 mg immediately, then 30 mg after each hemodialysis cycle for 5 days.

6. For those with exposure to influenza, give prophylaxis: with normal renal function, give 75 mg; daily; for those with CrCl 30 to 60, give 30 mg daily. In hemodialysis, 30 mg immediately, then 30 mg after every other dialysis. For exposure from close contacts within a household, treat for 10 days. In institutional settings, give for 14 days or up to 7 days after the last known case.

7. Geriatric red flags: Geriatric clients with influenza may have worsening of any of the following geriatric syndromes:

a. Weight loss related to anorexia with viral illness.
b. Delirium/confusion due to illness.
c. Falls related to orthostasis with viral illness.

OBSTRUCTIVE SLEEP APNEA

DEFINITION

A. Obstructive sleep apnea (OSA) is the periodic reduction (hypopnea) or cessation (apnea) of breathing due to a narrowing or occlusion of the upper airway during sleep. OSA has been linked to motor vehicle accidents, cardiac diseases, stroke, diabetes, depression, sexual dysfunction, inattention, poor work performance, and visceral obesity. OSA is also associated with nocturnal cardiac arrhythmias and chronic and acute cardiac events, and is a risk factor for strokes. OSA worsens in the supine sleeping position. Either of the two following conditions is diagnostic of OSA:

1. The presence of 15 or more apneas, hypopneas, or respiratory effort-related arousals per hour of sleep in an asymptomatic client. More than 75% of the apneas and hypopneas must be obstructive.

2. Five or more obstructive apneas, obstructive hypopneas, or respiratory effort-related arousals per hour of sleep in a client with symptoms or signs of disturbed sleep. More than 75% of the apneas or hypopneas must be obstructive.

INCIDENCE

A. The incidence of OSA in the morbidly obese population is between 38% and 88%.

B. Obesity adds a fourfold added risk for disordered breathing.

C. OSA is the most common sleep-related breathing disorder and is increasing in prevalence due to increasing rates of obesity.

D. OSA is more common in males than in females.

PATHOGENESIS

A. Increased tissue thickness of the structures of the tongue and soft tissues in the pharyngeal cavity that decreases the passageway for air to the trachea is thought to be the mechanism of OSA. At night, the muscles of the oropharynx relax , resulting in the relative obstruction of the airway. Obesity and hypertrophy of the tonsils and/or adenoids play a major role in OSA. Clients with severe OSA left untreated have a two- to threefold risk for all-cause mortalities.

PREDISPOSING FACTORS

A. Obesity.
B. Increased neck circumference.
C. Age: increases with age and plateaus in the sixth decade.
D. Sex: male.
E. Postmenopausal females.
F. Hypothyroidism.
G. Tonsillar hypertrophy.
H. Alcohol.
I. Craniofacial abnormalities.
J. Medications:

1. Benzodiazepines.
2. Antipsychotics.
3. Opioid analgesics.
4. Beta-blockers.
5. Barbiturates.
6. Antihistamines.
7. Sedative antidepressants.

K. Allergic rhinitis.

L. Genetic conditions (e.g., Down syndrome, Pierre Robin anomalies, and Marfan syndrome).

▶

M. Ethnic (e.g., African American, Asian, Hispanic, American Indians, Pacific Islanders).
N. Acromegaly.
O. Smoking.
P. End-stage renal disease.
Q. Pregnancy.
R. Congestive heart failure (CHF).
S. Chronic obstructive pulmonary disease (COPD).

COMMON COMPLAINTS

A. Daytime sleepiness.
B. Loud snoring, gasping, or snorting during sleep.
C. Fatigue.
D. Insomnia.

OTHER SIGNS AND SYMPTOMS

A. Adults:
1. Asymptomatic: Clients may not recognize they have OSA because they are able to go to sleep anytime.
2. Restless sleep.
3. Dry mouth or sore throat.
4. Lack of physical or mental energy.
5. Falling asleep when watching television, reading, or driving/riding in a car.
6. Morning headaches.
7. Decreased libido and impotence.
8. Cognitive deficits.
9. Depression.
10. Mood disorders.

SUBJECTIVE DATA

A. Does the client feel sleepy during the day? Is daytime sleepiness a problem?
B. Does the client struggle to stay awake during the day?
C. Does the client take naps? How often and for how long?
D. Does the client feel physically and mentally exhausted?
E. Does the client's bed partner complain about snoring, gasping, choking sensation, or snorting?
F. Ask the Epworth Sleepiness Scale questions related to how often the client dozes off or falls asleep (in contrast to just feeling tired). Each situation is scored from 0 = would never doze, to 1 = a slight chance of dozing, 2 = moderate chance of dozing, and 3 = a high chance of dozing. There are eight situations to which the client responds:
1. Sitting and reading.
2. Watching television.
3. Sitting inactive in a public place (e.g., a theater or a meeting).
4. As a passenger in a car for an hour without a break.
5. Lying down to rest during the day when circumstances permit.
6. Sitting and talking to someone.
7. Sitting quietly after lunch without alcohol.
8. In a car, while stopped for a few minutes in traffic.
G. Ask client to list all medications currently being taken, particularly substances not prescribed, including over-the-counter (OTC) and herbal products.
H. Review alcohol use.
I. Males who present with sleep disorders should also be questioned about the presence of erectile dysfunction.

PHYSICAL EXAMINATION

A. Check blood pressure, pulse, respirations, height, weight, body mass index (BMI), neck and waist circumference.
B. Inspect:
1. Inspect of face for deformities.
2. Perfom oropharynx examination for:
a. Peritonsillar narrowing or hypertrophy.
b. Tongue (evaluate for macroglossia).
c. Elongated or enlarged uvula.
d. Palate (high arch or narrow palate).
3. Measure neck circumference (>16 in. in females or 17 in. in males).
4. Perfom nasal examination:
a. Look for septal deviation and nasal polyps.
5. Inspect for signs of pulmonary hypertension or cor pulmonale:
a. Jugular venous distension.
b. Peripheral edema.
C. Palpate:
1. Thyroid gland.
D. Auscultate:
1. Heart and lungs.
E. Mental status:
1. Assess for confusion, flat affect, level of attention/alertness, and somnolence.

DIAGNOSTIC TESTS

A. Polysomnography (PSG) is the standard method of diagnosis. The apnea hypopnea index (AHI) or the respiratory disturbance index (RDI) is used to quantify hypopneas and classify the degree of sleep disturbance:
1. Full-night PSG (gold standard).
2. Split-night PSG.
3. Home testing with portable monitors.

Clients with cardiac, respiratory, or neurologic disease may be at the greatest risk for central sleep apnea, and the American Academy of Sleep Medicine (AASM) does not recommend the use of portable monitors for diagnosis in these clients.

B. Routine lab work is not helpful in the confirmation or exclusion of OSA.

DIFFERENTIAL DIAGNOSES

A. OSA.
B. Primary snoring.
C. Narcolepsy.
D. Restless legs syndrome.
E. Swallowing disorder.
F. Nocturnal seizures.
G. Gastroesophageal reflux disease (GERD).
H. Obesity hypoventilation syndrome.
I. Sleep deprivation, including shift-work disorder.
J. Neurodegenerative disease (e.g., Parkinson, dementia, Alzheimer).
K. Substance abuse.
L. Alcoholism.
M. Asthma.
N. Central sleep apnea.

PLAN

A. General interventions:
1. Continuous positive airway pressure (CPAP) and bilevel positive airway pressure (BiPAP) are the mainstay of treatment of moderate to severe OSA. Treatment with CPAP and BiPAP is required at all times during the night and during naps.
B. Client teaching: *See Client Teaching Guide for this chapter, "Sleep Apnea."*

1. Educate the client about modifying controllable risk factors such as keeping diabetes and hypertension under control, diet, weight loss, exercise, and stopping smoking.

2. Behavioral strategies include sleeping in a nonsupine position using a positioning device (e.g., alarm, pillow, backpack, and tennis ball are used for positional therapy).

C. Dietary management:

1. Encourage dietary changes and exercise to promote weight loss.

2. Even a modest weight loss of 10% to 20% has been associated with an improvement.

D. Nonsurgical treatment:

1. Oral appliances (OAs) require a thorough dental examination.

a. Custom-made OAs may improve airway patency during sleep by enlarging the upper airway and/or by decreasing the upper airway collapse.

b. Mandibular repositioning appliances (MRAs) cover the upper and lower teeth and hold the mandible in an advanced position.

c. Tongue-retaining devices (TRDs) hold the tongue in a forward position without mandibular repositioning.

2. Avoid alcohol even during daytime due to central nervous system (CNS) depression and worsening apnea.

3. Avoid prescribing medications with sedating properties unless the benefit outweighs worsening sleep apnea (anticonvulsants for seizure control may not be avoided as benefits outweigh risk).

4. Encourage smoking cessation. *See Client Teaching Guide for* Chapter 25*, "Nicotine Dependence."*

E. Surgical treatment:

1. Tracheostomy can eliminate OSA but not central hypoventilation syndromes. This procedure should be considered only when other options have failed or when it is considered necessary by clinical urgency.

2. Maxillary-mandibular advancement (MMA) is indicated when the client cannot tolerate/refuses CPAP and an OA is not appropriate/effective.

3. Multilevel or stepwise surgery (MLS) is a combined procedure or serves as a stepwise multiple surgery.

4. Bariatric surgery's weight loss has been effective in improving sleep efficiency and REM sleep. The severity of presurgical OSA determines the degree to which OSA improves postbariatric surgery.

5. Radiofrequency ablation (RFA) is for treatment of mild to moderate OSA when the client cannot tolerate/refuses CPAP and an OA is not appropriate/effective.

6. Laser-assisted uvulopalatoplasty is not recommended for OSA.

FOLLOW-UP

A. There is no standard for recommending repeat PSG testing or a CPAP titration study after significant weight loss.

CONSULTATION/REFERRAL

A. Refer client to a dentist for an OA.

B. Refer client to a pulmonologist for management of therapy and/or surgical treatment.

C. Refer client to a cardiologist as needed.

D. If client is uninsured, refer to a social worker for assistance in treatment purchases as needed.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. OSA in older people is associated with worsening cardio-cerebrovascular, cognitive, and functional outcomes.

2. Fatigue, poor focus, and irritability can be sometimes attributed to dementia and treatment for any sleep breathing problem may improve some or all of those symptoms.

3. The use of positive pressure airway devices must be thoughtfully considered for clients with cognitive dysfunction and neuromuscular weakness. Clients who use CPAP should be instructed to travel with their device.

BACTERIAL COMMUNITY–ACQUIRED PNEUMONIA

DEFINITION

A. Pneumonia is inflammation and consolidation of lung tissue due to a bacterial pathogen. The causative agent and the anatomic location classify pneumonia. It is not uncommon to have acute viral and bacterial pneumonia concurrently.

B. Other types of pneumonia and pulmonary inflammation occur secondary to smoking, exposure to chemicals or fungi, near drowning, and recurrent aspiration with gastroesophageal reflux.

C. Hospitalization is recommended in severe cases of pneumonia.

D. The Pneumonia Severity Index Calculator is a tool to estimate pneumonia mortality and assist in determining whether the client should best be treated in the inpatient or outpatient setting. See www.mdcalc.com/psi-port-score-pneumonia-severity-index-cap.

INCIDENCE

A. Pneumonia is a leading cause of death in clients older than 65 years.

B. Bacterial pneumonia is more prevalent in the very old and very young.

C. A higher mortality rate occurs in persons with immunodeficiency, comorbid conditions, abnormal vital signs, and virulent pathogens.
D. The incidence rate also varies by pathogens.

PATHOGENESIS

A. Pneumonia results from inflammation of the alveolar space. Lobar pneumonia has four stages:
1. Vascular congestion and alveolar edema within the first 24 hours of infection.
2. Red hepatization (2–3 days), characterized by erythrocytes, neutrophils, and fibrin within the alveoli.
3. Gray hepatization (2–3 days), characterized by a gray-brown to yellow color secondary to exudate.
4. Resorption and restoration of the pulmonary architecture. A rub may still be auscultated due to the fibrinous inflammation.
B. Bacterial causes include *Streptococcus pneumoniae* (the most common pathogen), *Haemophilus influenzae* type b (the second most common pathogen), *Staphylococcus aureus, Legionella, Chlamydia trachomatis, C. pneumoniae, Mycoplasma pneumoniae, Pseudomonas, Klebsiella*, and *Pneumocystis jirovecii* pneumonia (PCP) in clients with HIV.

PREDISPOSING FACTORS

A. Advanced age.
B. Impaired mentation.
C. Smoking.
D. Chronic obstructive pulmonary disease (COPD).
E. Alcoholism.
F. Aspiration.
G. Heart failure.
H. Diabetes.
I. Heart disease.
J. Crowded conditions (dormitories, long-term care centers).
K. Immunodeficiency.
L. Congenital anomalies.
M. Abnormal mucus clearance.
N. Lack of immunization.
O. Measles.
P. Indoor air pollutants from cooking or heating with wood.
Q. History of pneumonia.
R. Lung cancer.
S. Malnutrition.
T. Medications: immunosuppressives, oral corticosteroids, Proton Pump Inhibitor, and H2 antagonist.

COMMON COMPLAINTS

A. Acute onset of the following symptoms:
1. Fever.
2. Shaking chills.
3. Dyspnea, rapid, labored breathing.
4. Cough.
5. Rust-colored sputum.

OTHER SIGNS AND SYMPTOMS

A. Increased respiratory rate (tachypnea).
B. Chest pain, localized.
C. Upper respiratory infection (URI) symptoms such as pharyngitis.
D. Headache.
E. Nausea.
F. Vomiting.
G. Vague abdominal pain.
H. Diarrhea.
I. Myalgia.
J. Arthralgias.
K. Anorexia.
L. Change in level of consciousness (LOC), including confusion.

SUBJECTIVE DATA

A. Determine the onset, duration, and course of illness.
B. Has the client had fever or shaking chills?
C. Has there been breathing trouble? Are the breathing problems interfering with eating and drinking?
D. If diabetic, obtain take-home blood sugar readings.
E. Is there a cough? Is the cough productive? What color is the sputum?
F. Are any other family members ill?
G. Has the client ever been hospitalized for pneumonia or respiratory distress before?
H. Review the history for any chronic or comorbid conditions, including malignancy.
I. Has the client ever been immunized for influenza or pneumonia?
J. Review all medications, including over-the-counter (OTC) and herbal products. Specifically review whether the client has been on any antibiotics in the past 3 months. Recent exposure to an antibiotic is a risk factor for antibiotic resistance. Continued or repeated use of that class of antibiotics is not recommended.
K. Ask about change in sexual partners (including the elderly) for risk of HIV or chlamydia infections.
L. Review immunizations.
M. Ask about recent travel.
N. Review occupational risk factors.

PHYSICAL EXAMINATION

A. Check temperature, blood pressure (BP), pulse, and weight.
1. In the elderly the BP can be low; this is a consideration for sepsis.
B. Inspect:
1. Observe overall appearance. Does the client appear ill? Consider the clinical presentation, age of the person, and history. Assess mental status.
2. Observe breathing pattern and the use of accessory muscles, grunting, retractions, and tachypnea.
3. Obtain a pulse oximetry to assess oxygen saturation. **An Oxygen saturation less than 92% is an indicator of severity and the need for oxygen therapy.**
4. Check the nail beds and lips for cyanosis.
5. Examine the eyes, nose, ears, and throat.
6. Examine skin for turgor and mucous membranes for dehydration.
C. Auscultate:
1. Auscultate heart.
2. Auscultate lungs for the following (auscultate the bases first in geriatric clients):
a. Crackles (present in 80% of clients), wheezes, and decreased breath sounds.
b. Whispered pectoriloquy (increased loudness of whisper during auscultation).
c. Egophony (client's "e" sounds like "a" during auscultation).
d. Bronchophony (voice sounds louder than usual).
3. Auscultate abdomen (usually hypoactive bowel sounds). ▶

D. Percuss:
1. Percuss chest to identify areas of consolidation or dullness.
E. Palpate:
1. Palpate chest for tactile fremitus (increased conduction when client says "99").
2. Palpate lymph nodes for adenopathy.
3. Palpate sinuses for tenderness. Sinusitis is a sign of *Mycoplasma* infection.

DIAGNOSTIC TESTS

A. The World Health Organization (WHO) defines pneumonia solely on the basis of clinical findings observed by inspection and timing of respirations.
B. Chest radiograph (CXR):
1. Infiltrates confirm diagnosis. False negatives result from dehydration, evaluation in first 24 hours, and infection.
2. Ordering a posterior, anterior, and lateral CXR ensures adequate visualization for diagnosis.
C. Complete blood count (CBC) with differential.
D. BUN, creatinine level, and glomerular filtration rate (GFR) if acute renal failure secondary to dehydration or sepsis is a concern.
E. Cultures:
1. Blood cultures if critically ill, immunocompromised, or for persistent symptoms.
2. Sputum cultures are reserved for very ill clients for unusual presentations.
F. Consider rapid viral testing.
G. Consider skin testing for tuberculosis (TB) for high-risk exposure risk.
H. Acute phase reactants: C-reactive protein greater than or equal to 48 may favor diagnosis of community acquired pneumonia over exacerbation of chronic lung disease. Procalcitonin level may help differentiate bacterial from nonbacterial pneumonia.
I. Consider metabolic panel to assess renal and liver functions.

DIFFERENTIAL DIAGNOSES

A. Pneumonia:
1. Bacterial pneumonia.
2. Viral pneumonia.
3. Aspiration pneumonia.
4. Chemical-induced pneumonia.
5. Fungal pneumonia (especially in immunocompromised or diabetes out of control).
B. Asthma.
C. Bronchitis/bronchiolitis.
D. Pertussis.
E. Heart failure.
F. Pulmonary embolus.
G. Empyema and abscess.
H. Aspiration of foreign body.

PLAN

A. General interventions:
1. Encourage rest during acute phase.
2. Encourage the client to avoid smoking/secondhand smoke.
3. A vaporizer may be used to increase humidity.
4. Encourage good handwashing or use of hand sanitizer.
5. Severity of symptoms and safety of home environment should be part of the assessment for inpatient versus outpatient treatment.
6. Chest physiotherapy is not prescribed for pneumonia.
B. Client teaching: *See Client Teaching Guide for this chapter, "Pneumonia, Bacterial."*
C. Dietary management:
1. Encourage a nutritious diet with increased fluid intake.
D. Pharmaceutical therapy:
1. *S. pneumoniae* is the most common bacterial pathogen, and resistance against antibiotics is a concern. Resistance is seen more commonly in:
a. Age greater than 65 years.
b. Use of a beta-lactam antibiotic or fluoroquinolones in the past 6 months.
c. Alcoholism.
d. Chronic illness/comorbidities.
e. Immunosuppression therapy or illness.
f. Exposure to a child at a day-care center.
2. The Pneumonia Severity Index Calculator should be used prior to initiation of antibiotic therapy; it is available at www.mdcalc.com/psi-port-score-pneumonia-severity-index-cap.
3. Treatment with antibiotics is empirical. Oral therapy should continue 7 to 10 days.
a. If antimicrobials have not been used in the past 3 months:
i. Amoxicillin 1g orally TID.
ii. **Macrolide antibiotics (azithromycin) in areas with less than 25% community resistance to macrolide.**
iii. Doxycycline.
b. If antimicrobials have been used in the past 3 months:
i. Respiratory quinolones.
ii. Augmentin or high-dose amoxicillin.
c. Chronic comorbidities:
i. Monotherapy with respiratory fluoroquinolones.
ii. Combination therapy with amoxicillin -clavulanate OR cephalosporin PLUS macrolide or doxycycline.
4. Administer acetaminophen (Tylenol) for fever.
5. Avoid cough suppressants. Suppression of a cough may interfere with airway clearance.
6. Vaccines:
a. Pneumococcal vaccine is recommended for anyone older than the age of 19 with chronic lung disease, including asthma; immunocompromised adults; and in the elderly 65 years and older.

FOLLOW-UP

A. Clients should know the signs of increasing respiratory distress and seek immediate medical attention.
B. Follow up by telephone in 24 hours.
C. If there is no improvement after 48 hours on antibiotics, the client is advised to call back.
D. Schedule a return visit in 2 weeks for evaluation, unless elderly and living alone: Follow up in person within a week.
E. Clients older than 60 years and those who smoke should follow up with a CXR in 4 to 6 weeks. However, if the client is younger than 60 years, a nonsmoker, and feels well at 6-week follow-up, there is no need to follow up with a CXR.

EMERGENT ISSUES/INSTRUCTIONS

A. Clients demonstrating the following should receive same-day ED evaluation:
1. Respiratory compromise.

2. Neurologic changes including obvious central nervous system involvement.
3. Profound dehydration or alterations in vital signs.

CONSULTATION/REFERRAL

A. Clients who are immunocompromised or have signs of toxicity or hypoxia may need hospitalization. Refer them to a physician.
B. If the client is in any level of respiratory distress, dehydrated, or hypoxemic, consult with or refer the client to a physician/hospital.
C. Poor prognostic signs that require referral are age older than 65 years, respiration rate greater than or equal to 30 breaths per minute, systolic BP less than 90 or diastolic BP less than 60, temperature greater than 101°F, altered mental status, extrapulmonary infection, and white blood cell (WBC) less than 4,000 or greater than 30,000.
D. Physician consultation is needed for suspected PCP.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
1. The annual U.S. rate of antepartum community-acquired pneumonia (CAP) is 0.5 to 1.5 per 1,000 pregnancies.
2. Perinatal mortality may increase slightly due to associated increase in prematurity. Pneumonia puts older mothers at high risk of maternal death.
3. The symptoms of bacterial pneumonia are the same in pregnancy.
4. CXRs are acceptable in pregnancy to diagnose pneumonia.
B. Geriatrics:
1. Mortality rates from pneumonia are highest in geriatric groups.
2. Geriatric clients may present initially with confusion only, not with typical signs and symptoms of younger clients, and unable to mount a fever.
3. Older adults may remain afebrile in 20% of cases or more.
4. Up to half may not exhibit leukocytosis, but 95% have a left shift.
5. Aspiration pneumonia is more common as people age. Right lower lobe infiltration may indicate aspiration.
6. Avoid overuse of antibiotics. Antibiotics are indicated:
a. In an otherwise healthy older adult if fever of 102°F or greater is present, and/or respiratory rate is greater than 25.
b. In the absence of fever, in older adults with COPD and increased cough/purulent sputum.
c. In afebrile older adults without COPD if there is a new/increased cough, a respiratory rate greater than 25, rigors, or new-onset delirium.
7. Geriatric red flags: Geriatric clients with bacterial pneumonia may have worsening of any of the following geriatric syndromes:
a. Weight loss related to anorexia with viral illness.
b. Delirium/confusion due to illness.
c. Falls related to orthostasis with viral illness.

M., Restrepo, M. I., & Whitney, C. G. (2019). Diagnosis and treatment of adults with community acquired pneumonia. An official clinical practice guideline of the American thoracic society and infectious disease society of America. *American Journal of Respiratory and Critical Care Medicine*, *200*(7), e45–e67. https://doi.org/10.1164/rccm.201908-1581ST

PNEUMONIA (VIRAL)

DEFINITION

A. Viral pneumonia is inflammation and consolidation of lung tissue due to a viral pathogen.
B. Hospitalization is recommended for clients who are significantly immunocompromised and the frail elderly.

INCIDENCE

A. Viral pneumonia accounts for a small portion of pneumonia cases in adult pneumonia. It is not uncommon to have concurrent viral and bacterial infections.
B. Elderly persons have the highest rate of influenza-associated hospitalizations.

PATHOGENESIS

A. Pneumonia results from inflammation of the alveolar space and may compromise air exchange. Viral pneumonia is caused by influenza viruses, parainfluenza virus, adenovirus, and respiratory syncytial virus (RSV).
B. Influenza is the most common cause of viral pneumonia in adults.
C. Viruses and bacteria are spread from a cough or sneeze.
D. Pneumonia can also be spread via blood.

PREDISPOSING FACTORS

A. Age extremes.
B. Frailty or immunocompromised conditions.
C. Exposure to viral illness.
D. Lack of immunization.

COMMON COMPLAINTS

A. Fever.
B. Cough.
C. Dyspnea.
D. Tachypnea.
E. Wheezing (more common in viral pneumonia).

OTHER SIGNS AND SYMPTOMS

A. Upper respiratory prodrome.
B. Poor appetite.
C. Malaise/lethargy.
D. Myalgia.
E. Muscle aches.
F. Headache.
G. Fatigue.
H. Chest pain/tightness.

SUBJECTIVE DATA

A. Determine onset, duration, and course of illness.
B. Has the client had fever, cough, and upper respiratory infection?
C. Have there been any flulike symptoms?
D. Has there been any labored breathing?
E. Has there been a cough? Is it a productive cough? What color is the sputum?
F. Are the breathing problems affecting the ability to eat or drink?
G. Has the client had nausea, vomiting, or diarrhea?
H. Review if the client is up to date on immunizations.
I. Review all medications, including over-the-counter (OTC) and herbal products.

J. If diabetic, ask about home blood glucose readings/control.
K. Is there localized pain in chest?
L. Ask about pneumonia history.
M. Ask about pneumonia and influenza vaccine history.

PHYSICAL EXAMINATION

A. Check temperature, blood pressure (BP), pulse, respirations, and pulse oximetry. **Observe the level of consciousness (LOC).**
B. Inspect:
1. Observe overall appearance. Is the client septic? Consider the clinical presentation, age of person, and history.
2. Observe respiratory pattern, grunting, nasal flaring, retractions, and use of accessory muscles.
3. Check pulse oximetry. **An Oxygen saturation less than 92% is an indicator of severity and the need for oxygen therapy.**
4. Check nail beds and lips for cyanosis.
5. Examine eyes, ears, nose, and throat.
C. Auscultate:
1. Auscultate heart.
2. Auscultate lungs for the following (auscultate the bases first in geriatric clients):
a. Crackles, decreased breath sounds.
b. Whispered pectoriloquy (the client's whispered sounds are louder than normal).
c. Egophony (client's "e" sounds like "a").
d. Bronchophony (voice sounds louder than usual).
D. Percuss:
1. Percuss chest for dull sound (consolidation).
E. Palpate:
1. Palpate lymph nodes for swelling.
2. Palpate chest for tactile fremitus (increased conduction when client says "99").
3. Palpate sinuses.

DIAGNOSTIC TESTS

A. Chest radiograph (CXR), which reveals interstitial, perihilar, or diffuse infiltrates.
B. Complete blood count (CBC) with differential.
C. Rapid viral tests per nasal swab.
D. Sputum Gram stain if indicated.

DIFFERENTIAL DIAGNOSES

A. Viral pneumonia.
B. Bacterial pneumonia.
C. Varicella pneumonia.
D. Herpes pneumonia.
E. Cytomegalovirus pneumonia.
F. Pertussis.
G. Asthma.
H. Bronchitis/bronchiolitis.
I. Sinusitis.
J. Foreign-body obstruction.
K. Aspiration.
L. Fungal pneumonia (especially in the immunocompromised).
M. Severe acute respiratory syndrome (SARS).
N. Middle East respiratory syndrome coronavirus (MERS-CoV).
O. Avian flu.
P. Pulmonary tuberculosis (TB).

PLAN

A. General interventions:
1. Instruct the client to rest during acute phase.
2. Avoid smoking or secondhand smoke.
3. Require respiratory isolation; may use facial masks.
4. Encourage good handwashing or use of hand sanitizer.
5. Chest physiotherapy is not prescribed for pneumonia.
B. Client teaching: *See Client Teaching Guide for this chapter, "Pneumonia, Viral."*
C. Dietary management:
1. Encourage fluids and nutritious diet.
D. Pharmaceutical therapy:
1. Antiviral agents have limited support for efficacy. Treatment should be targeted based on viral etiology.
a. Oseltamivir, zanamivir, peramivir, and baloxavir are recommended and started within 24 to 48 hours of onset of fever and symptoms.
b. Amantadine and rimantadine have high levels of resistance and are not recommended.
c. Acyclovir (Zovirax) for herpes viruses is administered as an intravenous (IV) infusion.
2. Clients with viral pneumonia who are superinfected with bacterial organisms require antibiotic therapy.
3. Avoid cough suppressants. Suppression of a cough may interfere with airway clearance.
4. Give acetaminophen (Tylenol) for fever.
5. Immunizations:
a. **Recommend the pneumonia and influenza vaccines for prevention.**
i. Administer pneumonia vaccine in clients 65 years and older, or beginning at the age of 19 if immunocompromised or chronic respiratory condition is present. Consider revaccination every 5 to 10 years in high-risk clients.
ii. Sequential administration of the pneumococcal conjugate vaccine (PCV13) and pneumococcal polysaccharide vaccine (PPSV23) is recommended (download the Centers for Disease Control and Prevention [CDC] guide at www.cdc.gov/vaccines/vpd/pneumo/downloads/pneumo-vaccine-timing.pdf). In the vaccine-naive client, give PCV13 first, then the PPSV23 12 months later.
iii. In older adults who received PPSV23 at the age of 65 or older, give PCV13 in 1 year or more.
iv. In older adults who received PPSV23 BEFORE the age of 65, give PCV13, then 5 years after the initial PPSV23 give a second PPSV23.
v. Give a onetime second dose of PPSV23 in persons with chronic renal failure or nephrotic syndrome, functional or anatomic asplenia, or immunocompromising conditions.

Administer yearly flu vaccine. Trivalent or quadrivalent influenza vaccines are available. Give the client the vaccine in late September, at least 6 weeks before the flu season. Yearly flu vaccination information is available on the CDC website.

FOLLOW-UP

A. Signs and symptoms may vary greatly according to the viral pathogen, severity of disease, and the client's age:
1. Instruct the client to return to the clinic if no improvement is seen after 48 hours on antiviral agents. ▶

2. Follow up by phone in 24 hours.
3. Consider follow-up at 2 weeks if bronchoconstriction is noted on exam.

EMERGENT ISSUES/INSTRUCTIONS

A. Clients demonstrating the following should receive same-day ED evaluation:
1. Respiratory compromise.
2. Neurologic changes including obvious central nervous system (CNS) involvement.
3. Profound dehydration or alterations in vital signs.

CONSULTATION/REFERRAL

A. Consult a physician if viral pneumonia is strongly suspected.
B. Consult a physician if the client is pregnant.
C. Consult a physician or transfer to the hospital if the client is in respiratory distress, dehydrated, or hypoxemic.
D. Consider consultation with a pulmonologist.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
1. Ribavirin, a class X drug, is contraindicated in pregnancy.
2. Acyclovir is given in the third trimester at 10 mg/kg IV Q8H for 5 days.
3. The varicella zoster immune globulin (VZIG) may be considered in pregnancy.
4. The measles virus is a live attenuated virus and should not be given during pregnancy.
5. Pneumonia during pregnancy is associated with higher morbidity rates. Physician consultation is advised.
B. Geriatrics:
1. Mortality rates from pneumonia are highest in geriatric groups.
2. Geriatric clients may present initially with confusion only, not with typical signs and symptoms of younger clients, and unable to mount a fever.
3. Geriatric clients in communal living situations should adhere to vaccination guidelines for pneumococcus, influenza, and COVID-19.
4. Geriatric red flags: Geriatric clients with viral pneumonia may have worsening of any of the following geriatric syndromes:
a. Weight loss related to anorexia with viral illness.
b. Delirium/confusion due to illness.
c. Falls related to orthostasis with viral illness.

M., Restrepo, M. I., & Whitney, C. G. (2019). Diagnosis and treatment of adults with community acquired pneumonia. An official clinical practice guideline of the American thoracic society and infectious disease society of America. *American Journal of Respiratory and Critical Care Medicine*, *200*(7), e45–e67. https://doi.org/10.1164/rccm.201908-1581ST

TUBERCULOSIS

DEFINITION

A. Tuberculosis (TB) is an infectious disease. It is a granulomatous disease caused by *Mycobacterium tuberculosis*, *M. bovis*, and other mycobacteria. Humans are the only reservoirs for *M. tuberculosis*. TB may involve multiple organs, including the lungs, liver, spleen, kidney, eyes, brain, spine, and bone.
B. In most immunocompetent individuals, macrophages are successful in containing the bacilli, and the infection is self-limited and often subclinical. As many as 5% of adults with primary TB are asymptomatic, with approximately 41% of cases worldwide being undiagnosed. When the pulmonary macrophages are unable to contain the bacilli, it leads to clinically apparent infection-progressive primary TB.
C. Postprimary (reactivation) TB occurs when the initial infection is successfully contained by the pulmonary macrophages, with bacilli remaining viable within the macrophages. Infection results when the host's immune status (T cells) is compromised.
D. Clients with fever of unknown origin, failure to thrive, significant weight loss, or unexplained lymphadenopathy should be evaluated for TB.
E. The lungs are the most common site for the development of TB; 85% of symptomatic clients present with pulmonary complaints.

INCIDENCE

A. TB is a worldwide infection and is considered a global public health emergency by the World Health Organization (WHO). One-third of the world population are infected:
1. The WHO reports more than nine million new cases of TB every year.
2. TB can affect any age group. Over 60% of the cases are 25 to 40 years old.
3. TB is the leading cause of death in those infected with HIV.
4. The incidence of TB in the United States is 2.9 cases per 100,000 population.
5. Due to the high risk among immigrants, California, New York, Texas, and Florida accounted for half of the TB cases reported in the United States.
B. Postprimary TB is a significant cause of worldwide morbidity and mortality. Pulmonary morbidity results from a chronic cough, hemoptysis, fibrosis, superinfection, bronchial stenosis, repeated pulmonary infections, or empyema. Morbidity also arises from chronic TB osteomyelitis, chronic renal insufficiency, and central nervous system (CNS) TB.

PATHOGENESIS

A. Mycobacteria are non spore-forming, slow-growing bacilli. TB infection occurs by means of inhalation of airborne bacillus droplets from an infected host. The development of an infection depends on prolonged exposure (weeks) to an individual with active pulmonary TB. Bacilli travel through the pulmonary lymphatics or enter the vascular system and are disseminated to the brain, meninges, eyes, bones, joints, lymph nodes, kidneys, intestines, larynx, and skin. The incubation period from infection to a positive skin test reaction is 2 to 10 weeks, although disease may not occur for many years or may never occur. The risk of disease is greatest within 2 years following infection.

PREDISPOSING FACTORS

A. Exposure to someone with active disease, including household contact.
B. High-risk groups: minorities, birth in TB-endemic country, prisoners, nursing home residents, teachers, indigents, migrant workers, and healthcare providers.
C. HIV infection is one of the most significant risk factors for TB.
D. Steroid therapy, cancer chemotherapy, and hematologic malignancies increase the risk of TB. ▶

E. Tumor necrosis factor-alpha (TNF-alpha) antagonists used for rheumatoid arthritis, psoriasis, and other autoimmune disease are associated with a significant risk for TB. **Prior to beginning any TNF-alpha treatment, a TB skin test should be administered**.
F. Non-TB infections such as measles, varicella, and pertussis may activate quiescent TB.
G. Smoking.
H. Malnutrition.
I. Alcoholism.
J. Intravenous (IV) drug abuse.
K. Congenital TB (rare).
L. Poverty.

COMMON COMPLAINTS

A. Fever (usually low grade at onset but becoming marked with progression of disease).
B. Malaise.
C. Weight loss/difficulty gaining weight.
D. Cough.
E. Night sweats.
F. Chills.
G. Occasional hemoptysis.
H. Fatigue.
I. Anorexia.

OTHER SIGNS AND SYMPTOMS

A. Pulmonary TB: fatigue, irritability, and undernutrition, with or without fever and cough.
B. Glandular TB: chronic cervical adenitis.
C. Meningeal TB: fever and meningeal signs, and positive cerebrospinal fluid.
D. Skeletal TB: back pain or stiffness, lower extremity paralysis, and tuberculous arthritis, which usually involves only one joint (most often the hip or knee, followed by the ankle, elbow, wrist, and shoulder).
E. Genitourinary TB: flank pain, dysuria, frequent urination, pen-painful scrotal mass, prostatitis, orchitis, or epididymitis; in females symptoms mimic pelvic inflammatory disease.
F. Gastrointestinal TB: referable to the infected site including nonhealing ulcers in the mouth or anus, difficulty swallowing (esophageal disease), abdominal pain mimicking peptic ulcer disease, malabsorption, pain, diarrhea, or hematochezia.

SUBJECTIVE DATA

A. Determine onset, duration, and course of illness.
B. Review symptom history: fever, night sweats, chills, or cough.
C. Review history of weight loss.
D. Review exposure history to someone who has TB and the date of past screening.
E. What is the client's living situation?
F. Review travel history to endemic areas with TB, including China, Pakistan, the Philippines, Thailand, Indonesia, Bangladesh, and the Democratic Republic of Congo.
G. Review HIV status or need for testing.

PHYSICAL EXAMINATION

A. A complete physical examination is mandatory. Physical findings of pulmonary TB are not specific and are usually absent in mild or moderate disease.
B. Record temperature, respirations, pulse, blood pressure (BP), and weight. Compare weight with previous readings in the past 12 months.
C. Inspect:
  1. Observe overall appearance.
  2. Check skin for pallor.
  3. Inspect eyes, ears, nose, and throat. Evaluate for nonhealing ulcers in the mouth or anus.
D. Auscultate:
  1. Auscultate heart.
  2. Auscultate lungs and chest for the following:
    a. Rales in upper posterior chest.
    b. Bronchophony (voice sounds louder than usual).
    c. Whispered pectoriloquy: Client's whispered sounds are louder than normal.
E. Percuss:
  1. Percuss chest.
F. Palpate:
  1. Palpate for lymphadenopathy, usually anterior or posterior cervical and supraclavicular nodes. Less commonly involved lymph nodes include submandibular, axillary, and inguinal lymph nodes.
  2. Palpate to evaluate hepatosplenomegaly.
G. Perfom neurologic examination:
  1. Evaluate the presence of nuchal rigidity.
  2. Assess deep tendon reflexes.

DIAGNOSTIC TESTS

A. Diagnosis is based on a combination of purified protein derivative (PPD) skin testing, serum testing with interferon-gamma release assays (IGRAs), and sputum cultures. Bronchoscopy may be required to obtain specimens. Clients with primary TB may not undergo imaging; however, conventional chest radiograph (CXR) may be performed, and 15% of clients with primary TB have normal CXR findings.
B. Clients with progressive primary or postprimary TB may need a CT to evaluate parenchymal involvement, satellite lesions, bronchogenic spread, and miliary disease. MRI may be ordered to evaluate complications, such as the extent of thoracic wall involvement with empyema.
C. Tuberculin skin test using the Mantoux test is the recommended method. Dosage of 0.1 mL or 5 tuberculin units (TU) of PPD should be injected intradermally into the volar aspect of the forearm using a 27-gauge needle. A wheal should be raised and should measure approximately 6 to 10 mm in diameter. Skilled personnel should read the test in 48 to 72 hours after administration. Measure the amount of induration and not the erythema. Measure transverse to the long axis of the forearm (Table 12.3).
  1. Sputum culture with acid-fast smear; nasopharyngeal secretions and saliva are not acceptable.
D. The Food and Drug Administration has approved Quantiferon TB Gold as an alternative TB test for detecting both TB and latent TB infection.
E. Annual Mantoux tests for those at high risk are recommended. There is no need to repeat PPD once the client has reacted and had a positive PPD. A two-step test is recommended for initial screening only.
F. Anteroposterior (AP) and lateral CXR films: "Snowstorm" appearance indicates miliary TB; segmental consolidation and hilar adenopathy are common; pleural effusion may be present.
G. Complete blood count (CBC) with differential.
H. IGRA test.
I. HIV testing as indicated by risk factors to guide management.
J. Pregnancy test (if indicated) to guide management.

TABLE 12.3 INTERPRETATION OF MANTOUX TUBERCULIN SKIN TEST

Positive Reaction—Induration Size	Risk Factors
5 mm or more	Close contact with known or suspected TB; immunosuppressive conditions (e.g., HIV); on immunosuppressive medications; or an abnormal chest x-ray—consistent with active TB, previously active TB, or clinical evidence of the disease
10 mm or more	High-risk categories (e.g., homeless, HIV-infected, users of illicit drugs, residents in nursing homes, incarcerated, or institutionalized); travel histories to high-prevalence areas of world
15 mm or more	Any age without any risk factors for TB

TB, tuberculosis.

DIFFERENTIAL DIAGNOSES

A. TB.
B. Bronchiectasis.
C. Asthma.
D. Histoplasmosis.
E. Coccidioidomycosis.
F. Blastomycosis.
G. Malignancies.
H. Other pulmonary infections.
I. Aspiration pneumonia.

PLAN

A. General interventions:
1. Report all suspected and confirmed cases of TB to the local health department.
2. Directly observed therapy (DOT) is mandatory for treatment of clients with coexistent HIV disease, those with multidrug-resistant (MDR) TB, and those who may be noncompliant.
B. Client teaching:
1. Educate clients regarding compliance to therapy, adverse effect of medications, and follow-up care.
C. Pharmaceutical therapy:
1. The American Thoracic Society (ATS) and the Centers for Disease Control and Prevention (CDC) provide standard guidelines for therapy:
a. Refer to the CDC for up-to-date guidelines on treatment: www.cdc.gov/tb/publications/guidelines/treatment.htm. Medication protocols vary and include the following first-line agents: isoniazid (INH), rifampin (Rifadin), pyrazinamide (Tebrazid), and ethambutol (Etibi):
i. INH (Laniazid, Nydrazid) dosing:
1) Adults: 5 to 10 mg/kg PO; not to exceed 300 mg/d.
ii. Rifampin (Rifadin) dosing:
1) Adults: 600 mg PO every day.
iii. Pyrazinamide (Tebrazid) dosing:
1) Adults: 15 to 30 mg/kg PO every day; not to exceed 2 g/d.
iv. Ethambutol (Myambutol) dosing:
1) Adults with no previous anti-TB therapy: 15 mg/kg PO every day.
2) Adults with previous therapy: 25 mg/kg PO every day.
b. Compliance with drug regimen is most important.
c. Drug resistance averages 5% to 10% nationally and is increasing.
d. The Bacillus Calmette-Guerin (BCG) vaccine is available in TB-endemic countries for prevention of childhood TB-related meningitis and miliary TB. BCG is a live vaccine. BCG does not prevent infection with *M. tuberculosis*.

FOLLOW-UP

A. Regular follow-up every 4 to 8 weeks to ensure compliance and to monitor the adverse effects and response of the medications.
B. Repeat CXR may be performed after 2 to 3 months of therapy to observe the response to treatment of clients with pulmonary TB.
C. Consider monitoring liver enzymes monthly in the following clients:
1. Severe or disseminated TB.
2. Concurrent or recent hepatic disease or hepatobiliary tract disease from other causes.
3. Those receiving high doses of INH (10 mg/kg/d) in combination with rifampin, pyrazinamide, or both drugs.
4. Those who are pregnant or within the first 6 weeks postpartum.
5. Clinical evidence of hepatotoxic effects.

CONSULTATION/REFERRAL

A. An infectious disease consultation for management of affected clients.
B. Reportable illness to the county health department.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
1. Manage TB on a case-by-case basis with a physician.
2. Chemotherapy must be started immediately after the first trimester to protect both mother and fetus:
a. First-line agents recommended by the American Academy of Pediatrics include INH, rifampin, and ethambutol.
b. Streptomycin is contraindicated in pregnancy.
3. All pregnant persons on INH therapy should receive pyridoxine.
4. Pregnant persons are at increased risk for INH-induced hepatotoxicity.
5. The mother who has current disease but is noncontagious at delivery does not require separation from their infant. These mothers can also breastfeed.
6. The mother who has current disease and is contagious at delivery requires separation from their infant until the mother is noncontagious.
B. Geriatrics:
1. Geriatrics, no matter the ethnic group or gender identity, represent the largest reservoir of TB infection, especially in developed nations. The institutionalized geriatric client is at particular risk for both reactivation of latent TB and development of new infection. ▶

2. Baseline acute/chronic disease processes, malnutrition, and normal changes associated with aging make the diagnosis of TB difficult. Clinical features may be atypical, nonspecific, and mimic concomitant age-related diseases.

3. Treatment of TB in the geriatric population is difficult due to adverse drug reactions and drug-to-drug interactions.

4. Treatment priorities include treatment of associated chronic diseases, minimization of invasive procedures, limitation of polypharmacy, and appropriate nutrition support.

CLIENT TEACHING GUIDE

ASTHMA

PROBLEM Asthma is a chronic condition with wheezing, coughing, breathlessness, and chest tightness.

CAUSE The most common cause is inflammation that results from exercise or exposure to environmental irritants, allergens, furry animals, cockroaches, dust mites, pollens and molds, cold air, or viral respiratory infections.

PREVENTION

A. You have asthma and so are encouraged to get the flu vaccine every year.
B. Always keep your quick-relief (rescue) inhaler with you.
C. Asthma is more difficult to control in obesity. Weight reduction, even 5% to 10% of weight loss, can improve asthma control.
D. You may be able to prevent frequent recurrences of asthma by following these asthma trigger avoidance strategies:
1. Dust mite allergens: Wash bedding weekly in hot water and dry it in a hot dryer. Encase pillows and mattresses in airtight covers. Remove carpets, especially from your bedroom. Avoid use of fabric-covered furniture, especially for sleeping.
2. Cockroach allergens: Clean your house thoroughly. Use poison bait or traps. Do not leave food or garbage exposed.
3. Animal fur allergens: Avoid keeping house pets, or at least do not allow them in sleeping areas.
4. Smoke allergens: Avoid smoking, contact with tobacco smoke, smoke from wood-burning stoves or fireplaces, and unvented stoves or heaters.
5. Outdoor pollens and molds: Keep windows closed when pollen or mold counts are high.
6. Indoor mold: Reduce dampness in your home by using a dehumidifier. Clean damp areas often. Remove carpets that are laid on concrete.
7. Other irritants: Avoid perfumes, cleaning agents, and sprays.

TREATMENT PLAN You should also be given the *Client Teaching Guides "Asthma Action Plan and Peak Flow Monitoring"* and *"How to Use a Metered-Dose Inhaler."*

Activity:
A. If cold air causes symptoms, wear a scarf over your mouth and nose if you must go outside during the winter.
B. Avoid vigorous exercise if this causes asthma symptoms. Learn to recognize activities that trigger your breathing problems.
C. Make an asthma action plan to follow. Copy the plan and place it on the refrigerator, take a copy of your action plan to school, and give each coach a copy of your asthma action plan.
D. Color-code your inhalers with tape or markers; for example, use green tape for quick-relief inhalers and blue tape for long-acting inhalers.

Diet: There are no diet restrictions unless you have found a food that causes an allergic reaction and trouble with breathing.

Medications: Cough medicines should not be used for asthma symptoms.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If You Have:
A. A peak flow reading below 60% of your personal best number that does not return to the yellow or green zone after taking your medication.
B. Other: _____

Phone: _____

RESOURCE A Patient's Guide to Aerosol Drug Delivery: http://www.copd-alert.com/AerosolDrug.pdf

From *ADULT-GERONTOLOGY PRACTICE GUIDELINES, Third Edition*. Copyright Springer Publishing Company, LLC. All Rights Reserved.

CLIENT TEACHING GUIDE

ASTHMA ACTION PLAN AND PEAK FLOW MONITORING

A peak flow meter is a device that measures how well air moves out of your lungs. This measurement is referred to as your "peak expiratory flow" (PEF).

HOW TO USE A PEAK FLOW METER

A. Place the indicator at the bottom of the numbered scale.
B. Stand up.
C. Take a deep breath, filling your lungs as deeply as possible.
D. Place the mouthpiece in your mouth and close your lips around it. Do not put your tongue inside the hole.
E. Blow into the mouthpiece as hard and fast as you can. It is important to give this your best effort.
F. Write down the number on the indicator. If you cough or make a mistake, do not record that number—do it over again.
G. Repeat steps A through F two more times.
H. Write down the highest number of the three attempts. This is your PEF.

CALCULATING YOUR PERSONAL BEST PEAK FLOW NUMBER

This number is the highest peak flow number you can achieve over a 2- to 3-week period when your asthma is under good control (when you do not have any symptoms). To find this number, take peak flow readings.

A. Twice daily for 2 to 3 weeks.
B. When you wake up and between noon and 2 p.m.
C. Before and after taking your quick-relief medication.
D. Or as directed by your healthcare provider.

THE PEAK FLOW ZONE SYSTEM

Once you have determined your personal best peak flow number, your healthcare provider can give you the numbers that let you know what medications to take based on your PEF. The numbers are set up like a traffic light system (red, yellow, and green).

Green zone (80%–100% of your personal best number): signals good control. No asthma symptoms are present, and you should take your medication as usual.

Yellow zone (50%–80% of your personal best number): signals caution. You may be having an episode of asthma that requires an increase in your medications.

Red zone (below 50% of your personal best number): signals a medical alert. You must use your "fast" inhaler to help open up your airways right away and call your healthcare provider immediately if your peak flow number does not return to the yellow or green zone and stay there.

Use the following Asthma Action Plan, which specifies what medications you should take when you are in each zone, and also use the self-assessment diary provided in Table 12.4.

ASTHMA ACTION PLAN

A. My personal best PEF is _____.
B. When I am in the ***green zone***, PEF above _____, I should continue to take my regularly scheduled asthma medications. They are:
1. _____
2. _____
3. _____

C. When I am in the ***yellow zone***, PEF between _____ and _____, I should add the following to my regularly scheduled medications:
1. _____
2. _____
3. _____

D. When I am in the ***red zone***, PEF below _____, I should immediately take the following rescue medication and contact my healthcare provider:

CLIENT TEACHING GUIDE

PNEUMONIA BACTERIAL

PROBLEM Pneumonia is a lung infection that causes fluid to collect in the air sacs. You may have a fever, cough, or trouble breathing.

CAUSE Respiratory bacteria or viruses cause pneumonia.

PREVENTION

A. Although the flu vaccine will not keep you from getting bacterial pneumonia, a flu vaccine is recommended every year.
B. There are two types of pneumonia vaccines. People older than 65 years of age, people who smoke, younger people with chronic lung disease, and people with other medical conditions may receive vaccines to prevent pneumococcal pneumonia.
C. You may be given one of the pneumonia vaccines at the same time as you get the flu vaccine.
D. Avoid contact with people with respiratory illnesses.

TREATMENT PLAN

A. Use a cool-mist humidifier. Clean the humidifier daily.
B. Do not smoke, and avoid smoke-filled rooms.
C. Cover your mouth when you cough and cover your nose when you sneeze.
D. Use tissues when you blow your nose. Throw away tissues as soon as they are used.
E. If no tissue is available, do the "elbow sneeze" into the bend of your arm/sleeve of your shirt.
F. Wash your hands frequently with soap and water or use hand sanitizer.

Activity: Rest during the early phase of the illness.

Diet: Eat a nutritious diet. Drink 8 to 10 glasses of water a day.

Medications:

A. Do not use cough suppressants if your cough produces sputum. Use them only for a dry, nonproductive cough.
B. Acetaminophen (Tylenol) may be used for fever or body aches.
C. Antibiotics are given for pneumonia that is caused by bacteria. Take your medication as directed.
D. Finish all of your antibiotics even though you may feel better.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If You Have:

A. Increased difficulty breathing.
B. Fever after 48 hours on an antibiotic.
C. Blood in your sputum.
D. Worsening discomfort or fatigue.
E. Trouble keeping your antibiotic down.
F. Diabetes and your blood sugars are elevated, or you notice ketones in your urine while you are sick.
G. Other: _____

Phone: _____

Follow-up appointment on: _____

CLIENT TEACHING GUIDE

BRONCHITIS, ACUTE

PROBLEM Acute bronchitis is a lung infection followed by a productive cough.

CAUSE Respiratory viruses cause bronchitis.

PREVENTION

A. Although the flu shot does not prevent acute bronchitis, you are encouraged to take the flu vaccine every year.
B. Avoid exposure to other people with respiratory illnesses.
C. Do not smoke, and avoid secondhand smoke and other smoke-filled environments.
D. Avoid air pollutants, such as wood smoke, solvents, and cleaners.
E. Cover your nose and mouth when you sneeze or cough.
F. Use tissues when you blow your nose.
G. Throw away all tissues as soon as they are used. If no tissue is available, do the "elbow sneeze" into the bend of your arm/sleeve of your shirt.
H. Use good handwashing techniques with soap and water or hand sanitizer.

TREATMENT PLAN

A. Humidity and mist may be helpful.
B. Always clean the humidifier daily to prevent bacteria from growing.
C. Twenty minutes several times a day in a steamy bathroom may provide relief.

Activity: Rest is important since you have been diagnosed with bronchitis; increase activity as tolerated when the fever subsides.

Diet: Eat a nutritious diet. Drink 8 to 10 glasses of water daily.

Medications:

A. Acetaminophen (Tylenol) may be used to relieve discomfort.
B. For a nonproductive cough, take cough suppressants if recommended. You may be prescribed a cough medicine or be told the best kind to buy in the drugstore.
C. Since a virus almost always causes acute bronchitis, **antibiotics will rarely be needed to get better.**

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If You Have:

A. No improvement after 48 hours.
B. Worsening symptoms.
C. High fever, chills, chest tightness or pain, or shortness of breath.
D. Symptoms that last longer than 3 weeks.
E. Diabetes and your blood sugars are elevated, or you notice ketones in your urine while you are sick.
F. Other: _____

Phone: _____

CLIENT TEACHING GUIDE

BRONCHITIS, CHRONIC

PROBLEM Chronic bronchitis is an upper respiratory infection followed by a productive cough. To be diagnosed with chronic bronchitis, you need to have had the symptoms 3 months for 2 years in a row.

CAUSE Both viruses and bacterial infections cause chronic bronchitis.

PREVENTION

A. A yearly flu vaccine is recommended because the flu may lead to bronchitis.
B. There are two pneumonia vaccines. Pneumonia vaccines are recommended for people older than 65 years of age, younger people who smoke, and for people with chronic respiratory conditions and other medical conditions.
C. You may be given one of the pneumonia vaccines at the same time as you get the flu vaccine.
D. Avoid exposure to others with respiratory illnesses.
E. Do not smoke, and avoid secondhand smoke and smoke-filled environments.
F. Avoid other air pollutants, such as wood smoke, solvents, and cleaners.
G. Use good handwashing techniques and use hand sanitizers.
H. Use tissues for the mucus coughed up. Dispose of the tissues after use.
I. Cover your mouth when you cough. If you do not have a tissue, the "elbow sneeze" into the bend of your arm/into your sleeve will prevent you from spreading your illness.

TREATMENT PLAN

A. Humidity and mist may be helpful.
B. Always clean the humidifier daily to prevent bacterial growth.
C. Twenty minutes several times a day in a steamy bathroom may provide relief.
D. If continuing to smoke, do your best to reduce the amount.

Activity: Rest during the early stage of the illness, then increase activity as tolerated when the fever subsides. It is not uncommon to feel tired for several weeks.

Diet: Eat a nutritious diet. Drink 8 to 10 glasses of water daily.

Medications:

A. Acetaminophen (Tylenol) may be used to relieve fever and discomfort.
B. You may be prescribed an inhaler to help your breathing.
C. You may be prescribed steroids to help with the inflammation of your lungs. The steroids may be given by an inhaler or as a pill.
D. It is very important that you use the inhaler properly so that the medicine can go into your lungs. A teaching sheet on how to use an inhaler is available.
E. You may also be prescribed an antibiotic for a bacterial infection. Take all of your antibiotics even if you feel better.
F. You may be prescribed a cough suppressant to take at night to help you rest. However, coughing up the mucus is very important to clear out your "windpipes."

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If You Have:

A. No improvement after 48 hours.
B. Worsening symptoms.
C. High fever, chills, chest tightness or pain, or shortness of breath.
D. Symptoms that last longer than 3 weeks after taking all of your antibiotics.
E. Diabetes and your blood sugars are elevated, or you notice ketones in your urine while you are sick.
F. Other: _____

CLIENT TEACHING GUIDE

CHRONIC OBSTRUCTIVE PULMONARY DISEASE

PROBLEM Chronic obstructive pulmonary disease (COPD) is a chronic, progressive, debilitating disease of the lungs that does not have a cure. Most people have a combination of emphysema and chronic bronchitis. Persons with COPD usually have some of the following symptoms: cough (usually productive), shortness of breath at rest or with exertion, wheezing, decreased energy level, and weight loss.

CAUSE COPD is most commonly associated with cigarette smoking. COPD is also caused by long-term exposure to pulmonary irritants in the environment (e.g., coal dust). Repeated respiratory infections may also contribute to the development of COPD.

PREVENTION

A. Avoid smoking and exposure to secondhand smoke.
B. Avoid exposure to environmental irritants, including pollution, household cleaning products, and smoke from fires.

TREATMENT PLAN

A. Stopping smoking is the most important treatment. Talk to your healthcare provider about support for stopping. It is never too late to stop smoking. You should also be given the *Client Teaching Guide "Nicotine Dependence."*
B. Get the flu vaccine every year.
C. There are two pneumococcal vaccines; you may need to be given both vaccines.
D. You may be given one of the pneumonia vaccines at the same time as you get the flu vaccine.
E. Reduce your exposure to lung irritants and extremely hot and cold air temperatures.
F. Begin an exercise program with your healthcare provider's approval. Walking is a good aerobic exercise. Begin with a pace that is tolerable and easy to maintain, then increase the duration and intensity of the exercise as tolerated. Stop if you experience shortness of breath or chest pain. A realistic goal may be 5 to 10 minutes a day, eventually increasing to 30 to 40 minutes a day.
G. Use a spacer/holding chamber to help you inhale all of your medicine. Spacers help you place more of your medicine in your lungs instead of at the back of your throat and mouth. Keep your spacer clean. You should also be given the *Client Teaching Guide "How to Use a Metered-Dose Inhaler."*
H. Use slow, deep breathing or pursed-lip breathing when you are short of breath. Breathe out like you are blowing out a candle.
I. Ask your healthcare provider if you are a candidate for low-flow oxygen treatment when shortness of breath occurs at night and causes insomnia and restlessness.
J. If you are prescribed theophylline to help control your respiratory systems, your blood level needs to be monitored.

Activity: Group activities together, such as planning shopping with going to the post office. Schedule rest periods throughout the day. Exercise programs should help increase activity tolerance.

Diet: Good nutrition is important. Six small, high-calorie meals a day are suggested. Avoid excessive intake of carbohydrates, especially simple carbohydrates like candy, soda, and potato chips. Milk and milk products increase the production of mucus. Ask your healthcare provider to refer you to a dietitian if nutritional problems persist.

Medications: _____

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If:
A. Your mucus changes color or increases in amount, or if the consistency is becoming thicker.
B. Your wheezing or shortness of breath is getting worse after you start your medication.
C. You are having trouble walking or talking because of your shortness of breath.
D. Other: _____

Phone: _____

You should have a follow-up appointment in 3 months unless you worsen before then.

CLIENT TEACHING GUIDE

COMMON COLD

PROBLEM The common cold is swelling of the mucous membranes of the respiratory tract. Most people complain of feeling tired and have a runny or stopped-up nose, a sore throat, hoarseness, and watery and/or red eyes. You may have a low-grade fever or no fever at all.

CAUSE A virus usually causes the common cold.

PREVENTION

A. The flu vaccine is recommended to be taken every year.
B. Colds are spread from one person to another through hand-to-hand contact and contact with air droplets from sneezing, coughing, and talking.
C. Practice good handwashing techniques with soap and water or hand sanitizers.
D. Do not drink from the same glass after others.
E. Cover your mouth and nose when you sneeze or cough.
F. Use tissues when you blow your nose. Dispose of them and then wash your hands.
G. If no tissue is available, do the "elbow sneeze" into the bend of your arm/shirt sleeve (away from your open hands). Always wash your hands.

TREATMENT PLAN

A. Using a humidifier for your bedroom or inhaling steam helps keep the mucous membranes of your nose from drying.
B. Discuss using saline nose drops.
C. Secondary infections of the respiratory tract (sinuses, lungs) may occur. If these do occur, then antibiotic therapy may be needed.
D. Zinc preparations are not recommended for an acute cough caused by the common cold.

Activity: There are no activity restrictions. Frequent rest periods or naps can help with fatigue.

Diet: Eat well-balanced meals and snacks. Drink extra liquids (10–12 glasses a day). Warm fluids, such as tea and soups, can increase the rate of mucus flow and provide some symptom relief.

Medications: Antibiotics are not prescribed for a cold, but they may be prescribed for a secondary infection. All cold medications are available over the counter. Please consider the side effects of these products, as side effects can be greater than any benefit. If you choose to use them, take as directed.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If:
A. You experience pain that is getting worse in your ears, sinuses, throat, neck, or chest.
B. You have green or yellow nasal drainage.
C. Your temperature is higher than 100.4°F.
D. You are a diabetic and your blood sugars are elevated, or you notice ketones in your urine while you are sick.
E. Other: _____

From *ADULT-GERONTOLOGY PRACTICE GUIDELINES, Third Edition*. Copyright Springer Publishing Company, LLC. All Rights Reserved.

CLIENT TEACHING GUIDE

COUGH

PROBLEM Coughing is an important defense mechanism your body uses to clear your airways of mucus and inhaled particles.

CAUSE A cough is often associated with other respiratory symptoms and may be a sign of infection. Coughing is often related to environmental or chemical irritants such as smoking.

PREVENTION

A. The flu vaccine is recommended each year; however, the flu vaccine does not prevent a cough.
B. Coughing cannot be prevented, but you do have some voluntary control over it.
C. Occasionally, medications can cause a cough. Therefore, review all medications with your healthcare provider.

TREATMENT PLAN

A. Stop smoking, including exposure to secondhand smoke. At the minimum, maintain a smoke-free bedroom.
B. Using a room humidifier may be helpful. Keep your humidifier clean—it can grow bacteria.
C. Change heating and air conditioning filters often to reduce environmental irritants.
D. Coughing for several minutes may tire you, so you may need extra rest.

Activity: No activity restrictions.

Diet: Drink at least 10 to 15 glasses of liquids a day.

Medications: _____

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If:
A. You have difficulty breathing.
B. You cough up blood.
C. You develop other symptoms besides coughing, such as green sinus drainage and/or a sore throat.
D. You cannot sleep due to coughing.
E. You develop a fever over 101°F.
F. Other: _____

Phone: _____

From *ADULT-GERONTOLOGY PRACTICE GUIDELINES, Third Edition*. Copyright Springer Publishing Company, LLC. All Rights Reserved.

CLIENT TEACHING GUIDE

EMPHYSEMA

PROBLEM Emphysema is a chronic lung disease and is incurable. Emphysema can only be managed; the goal of treatment is to improve the activities of daily living and the quality of life by preventing symptoms and by preserving optimal lung function.

CAUSE Cigarette smoking increases the risk of chronic obstructive pulmonary disease (another name for several lung diseases) by about 30 times. *You should also be given* the *Client Teaching Guide "Nicotine Dependence."*

PREVENTION Emphysema cannot be prevented once lung changes have taken place.

TREATMENT PLAN

A. Stop smoking—it causes more lung irritation, mucus/sputum production, and coughing. It is never too late to quit smoking.
B. Get a flu shot every year.
C. There are two types of pneumonia vaccinations to reduce your risk for pneumonia.
D. One of the pneumonia shots can be given at the same time as the flu shot.
E. If you are prescribed theophylline to help control your respiratory systems, your blood level needs to be monitored.
F. Eliminate other lung irritants, such as wood smoke, secondhand smoke, hairspray, paint, bleach, and other chemicals found at home. Avoid sweeping and dusting, and stay indoors when air pollution or pollen counts are high.
G. Pulmonary rehabilitation may be ordered. Exercising is a very important component of pulmonary rehabilitation, as well as learning breathing techniques.
H. Report respiratory infections to your healthcare provider as soon as possible.
I. Use postural drainage: Lean over the side of the bed, rest your elbows on a pillow placed on the floor, and cough as someone gently pounds on your back.
J. Stay indoors during extremely hot or cold weather. If you must be outside in the cold, cover your nose and face. Use an air conditioner in hot weather.
K. Avoid people who have respiratory illnesses; also avoid crowds and poorly ventilated areas.
L. Oxygen therapy may be ordered if you have trouble breathing.
M. Use community resources such as Meals on Wheels, a handicap parking tag, or parking stickers.
N. You may be asked to talk to a social worker.

Activity:
A. Pace yourself to avoid shortness of breath.
B. Follow a daily exercise plan. Start with three to four times a day, each lasting 5 to 15 minutes. Start at half-speed and build up.
C. Sexual dysfunction can occur due to lack of physical energy and trouble breathing. Find other ways to show affection, such as kissing, hugging, or massage.

Diet:
A. If you do not have congestive heart failure, drink 3 L of fluid a day—equal to one-and-a-half large soda bottles.
B. Avoid dairy products; they increase mucus/sputum production.
C. Eat five to six small meals a day. Big meals feel like pressure on your stomach and lungs.
D. Avoid foods that cause gas and stomach discomfort.
E. Use oxygen during meals, if necessary; take your time eating, rest between bites, and avoid hard-to-chew foods because eating may tire you. Rest before and after eating if you have shortness of breath.
F. Eat a high-protein diet with a good balance of vitamins and minerals.
G. Avoid excessively hot or cold foods and drinks that may start an irritating cough.

CLIENT TEACHING GUIDE

HOW TO USE A METERED-DOSE INHALER

USING AN INHALER To receive the proper dose from your inhaler, you must use good technique. Your healthcare practitioner may provide you with a drug-free practice inhaler. Practice the following steps until you are comfortable administering your inhalant:

A. Shake the inhaler well immediately before each use.

B. Using a spacer helps to deliver more medication to your lung (not just the back of your mouth).

C. Remove the cap from the mouthpiece. Hold the inhaler upright. Make sure the medication canister is firmly inserted into the plastic holder (actuator).

D. The first time you use your new inhaler (or if it has been 1 month or longer since the your last use), test-spray four times into the air.

E. Breathe out through your mouth to the end of a normal breath.

F. Position the mouthpiece about 1 to 2 in. in front of your open mouth. Or you may close your lips in a tight seal around the mouthpiece.

G. Open your mouth widely (unless you are using the second method) and position your head in a neutral position.

H. While breathing in slowly and deeply, firmly depress the container once.

I. Continue breathing in slowly until your lungs are full.

J. Once you have breathed in fully, hold your breath for 10 seconds or as long as you can.

K. If you need a second puff of the same medication, wait a minimum of 1 minute before repeating steps A through J. If you are using a different inhaler for the second puff, wait at least 5 minutes before using the second inhaler.

OTHER TIPS

A. If you are taking a steroid inhalant, rinse your mouth and throat with water after each dose.

B. When you are short of breath, use your bronchodilator ("rescue medicine") first; then wait about 5 minutes before using your steroid inhaler. The rescue inhaler opens your airways so more of the steroid medication reaches your lungs.

C. Keep the inhaler clean. Once a week, remove the medication canister from the actuator and wash the actuator in warm, soapy water. Rinse and allow to air-dry. Replace the medication canister in the holder and re-cap the mouthpiece.

D. Always check the expiration date on your inhaler and make sure to refill your prescription before the medication expires.

E. Color-code your inhalers with tape or markers; for example, use green tape for quick-relief inhalers and blue tape for long-acting inhalers.

CLIENT TEACHING GUIDE

INFLUENZA (FLU)

PROBLEM Influenza (flu) is an acute, self-limiting, febrile illness of the respiratory tract. You are contagious for 24 to 48 hours before feeling the symptoms, and you are contagious up to 7 days after symptoms begin. Coughing and sneezing spread the flu.

CAUSE There are many flu viruses. Stress, excessive fatigue, poor nutrition, recent illness, crowded places, and immunosuppression from drugs or illness lower your resistance to these viruses.

PREVENTION

A. Although the flu vaccine neither prevents nor causes the flu, the flu vaccine is recommended every year.
B. Avoid unnecessary contact with sick persons, including in crowded areas.
C. To keep the flu from spreading:
  1. Cover your mouth when coughing or sneezing.
  2. Use tissues when you blow your nose. Dispose of them and then wash your hands.
  3. If no tissue is available, do the "elbow sneeze" into the bend of your arm/shirt sleeve (away from your open hands).
  4. Do not share drinking glasses.
  5. Wash your hands with soap and water or use hand sanitizer.

TREATMENT PLAN

A. Rest.
B. Drink lots of fluids.
C. Run cool-mist vaporizer.
D. Take tepid sponge baths in warm water to prevent chilling and shivers.
E. Gargle with warm saltwater for a sore throat.
F. Use warm compress or heating pad on low for aching muscles.

Activity: Stay in bed for at least 24 hours after your fever is gone.

Diet: You may not be hungry, but you do not need to be on a special diet for the flu. Drink plenty of liquids (at least 10 glasses a day).

Medications:
A. Antibiotics do not help the flu since it is a virus.
B. Special medications shorten the flu. They must be started within 2 days of contracting the flu.

You Have Been Prescribed to Shorten Your Flu Symptoms: _____

You Need to Take: _____

You Have Been Prescribed for Your Fever: _____

You Need to Take: _____

You Have Been Prescribed for Your Respiratory Symptoms: _____

You Need to Take: _____

You Have Been Prescribed a Cough Suppressant: _____

You Need to Take: _____

You Need to Notify the Office If You Have:
A. Thick, green nasal drainage.
B. Ear pain.
C. Increase in fever or cough.
D. Shortness of breath or chest pain.

CLIENT TEACHING GUIDE

INFLUENZA (FLU) (*CONTINUED*)

E. Blood when you cough.
F. Neck pain or stiffness.
G. New or unexplained symptoms.
H. No need to urinate (longer than 8 hours while awake without the need to urinate).
I. Diabetes and your blood sugars are elevated, or you notice ketones in your urine while you are sick.
J. Other: _____

Phone: _____

From *ADULT-GERONTOLOGY PRACTICE GUIDELINES, Third Edition*. Copyright Springer Publishing Company, LLC. All Rights Reserved.

CLIENT TEACHING GUIDE

PNEUMONIA, VIRAL

PROBLEM Viral pneumonia is an infection of the lung that causes fluid in the air sacs. You may have fever, cough, or difficulty breathing.

CAUSE Respiratory viruses cause viral pneumonia and bacteria.

PREVENTION

A. Although the flu vaccine does not prevent pneumonia, a yearly flu shot is recommended.
B. There are two types of pneumonia vaccines. The pneumonia vaccines help prevent pneumonia caused by bacteria. If you are older than 65 years, smoke, and have chronic respiratory illness or certain medical conditions, the pneumonia vaccines are recommended.
C. You may be given one of the pneumonia vaccines at the same time as you get the flu vaccine.
D. Avoid contact with people with respiratory illnesses.

TREATMENT PLAN

A. Use a cool-mist humidifier and clean it daily.
B. Take deep breaths and cough frequently to clear secretions from the lungs.
C. Avoid smoking and exposure to secondhand smoke.
D. Cover your mouth when you cough and cover your nose when you sneeze.
E. Use tissues when you blow your nose. Throw away tissues as soon as they are used.
F. If no tissue is available, do the "elbow sneeze" into the bend of your arm/sleeve of your shirt.
G. Practice good handwashing techniques with soap and water or use of hand sanitizers.

Activity: Rest frequently during the early phase of the illness. Fatigue may continue for up to 6 weeks.

Diet: Eat a nutritious diet. Drink to 10 glasses of water a day.

Medications:

A. Take acetaminophen (Tylenol) for fever, discomfort, and headache.
B. Do not take cough suppressants. It is important for you to cough and get up any mucus.
C. Antibiotics are not given for a viral infection. If you have a bacterial infection, then you may be put on an antibiotic.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If You Have:

A. Increased difficulty breathing.
B. Fever over 101°F or fever that persists after 48 hours of antibiotics.
C. Worsening discomfort.
D. Shortness of breath.
E. Blood in sputum.
F. Nausea, vomiting, or diarrhea.
G. Diabetes and your blood sugars are elevated, or you notice ketones in your urine while you are sick.
H. Other: _____

Phone: _____

You should be seen for a follow-up appointment on: _____

CLIENT TEACHING GUIDE

SLEEP APNEA

PROBLEM You have been diagnosed with sleep apnea. During sleep, your tongue and throat relax, causing less air to go down into your lungs. When you sleep and snore, you have short periods when you stop breathing and may wake up gasping for breath. Your bed partner may shake you awake because of your loud snoring or may notice that you have stopped breathing. The sleep apnea makes you very tired, leading you to take daytime naps.

CAUSES

A. Being overweight and having a "thick neck" can cause sleep apnea.
B. As you get older, you are more likely to have sleep apnea.
C. After menopause, females may start having sleep apnea.
D. If you have not had your tonsils removed, they may be part of the problem as your tongue and throat relax.
E. Alcohol and some medicines cause sleep apnea.
F. Allergies may also cause some sleep apnea.

PREVENTION

A. There is no way to prevent sleep apnea once you have it.
B. One way to help your sleep apnea is to lose weight.

TREATMENT PLAN

A. Review all of your medicines and any herbal products with your healthcare provider.
B. You may be told to sleep with your head up on two pillows, use a tennis ball under your pillow, or even sleep with a backpack under your pillow. This holds your head up higher and prevents your tongue from making your windpipe smaller.
C. You may also need a mouthpiece to help your tongue from relaxing when you sleep. Your dentist will need to help you find the best one.
D. You may be sent to a lung specialist to help with your treatment.
E. You may be told you need to have a sleep study to check out and measure how often you stop breathing at night.
F. After your sleep study, your lung specialist may order you to have a sleep machine called continuous positive airway pressure (CPAP) or biphasic positive airway pressure (BiPAP).
    1. The sleep machine uses nose tubing, a nasal mask, or a full face mask.
    2. The machine is small and portable.
    3. Your CPAP machine can be taken through the airport.
    4. You will have a supplier send you more tubing, machine filters, and breathing tubes/masks on a regular schedule.
G. Continuing to use the prescribed treatment for sleep apnea is important to your overall health.

Activity:
A. You will continue to need to sleep with your head higher, use the mouthpiece, or use the sleep machine to keep from having sleep apnea.
B. Exercise; losing even a small amount of weight will help with sleep apnea.
C. Stop smoking. You should be given the *Client Teaching Guide "Nicotine Dependence."* **It is never too late to quit smoking**.
D. Avoid alcohol, especially near your bedtime.

Diet: There is no special diet for sleep apnea, but losing weight helps.

Medications: There are no medicines for sleep apnea.

You Need to Notify the Office If:
A. Your bed partner complains that your snoring or sleep apnea has worsened.
B. You want to make an appointment to discuss having a sleep study.
C. You are having difficulty with your sleep machine or other equipment.
D. Other: _____

CHAPTER 13

CARDIOVASCULAR GUIDELINES

Debbie A. Gunter and Laura A. Petty

ACUTE MYOCARDIAL INFARCTION

DEFINITION

A. Acute myocardial infarction (MI) is a prolonged lack of myocardial oxygenation leading to necrosis of a portion of the heart muscle. It is caused by atherosclerotic coronary artery disease (CAD), which alone or in association with other factors causes complete blockage of one of the coronary arteries.

INCIDENCE

A. The estimated annual incidence of heart attack in the United States is 605,000 new attacks and 200,000 recurrent attacks. The average age at the first heart attack is 66 years for males and 70 years for females. Approximately every 42 seconds, an American will have a heart attack. Despite a marked decrease in incidence and mortality during the past three decades, MI continues to be the leading cause of death in this country, accounting for one-fourth of all fatalities. More females die from heart disease than males.

PATHOGENESIS

A. Abrupt coronary artery occlusion is the primary cause of most MIs. Occlusions can result from atherosclerotic plaque, intracoronary thrombus formation, or arterial spasm.

PREDISPOSING FACTORS

A. Hypercholesterolemia: increased low-density lipoprotein (LDL) and decreased high-density lipoprotein (HDL).
B. Hypertriglyceridemia.
C. Premature familial onset of coronary heart disease (CHD), formerly called CAD, before the age of 55.
D. Smoking.
E. Hypertension (HTN).
F. Obesity.
G. Sedentary lifestyle.
H. Diabetes mellitus.
I. Aging.
J. Stress.

COMMON COMPLAINTS

A. Primary complaint: pain somewhere in the chest, often described as worst pain ever experienced.
B. Nausea.
C. Vomiting.
D. Diaphoresis.
E. Indigestion.

OTHER SIGNS AND SYMPTOMS

A. Pain in abdomen, arm, back, jaw, and neck.
B. Chest heaviness or tightness.
C. Anxiety.
D. Cough.
E. Dyspnea.
F. HTN or hypotension.
G. Weakness, light-headedness, syncope.
H. Pallor.
I. Orthopnea.
J. Fatigue.
K. Malaise.

POTENTIAL COMPLICATIONS

A. Arrhythmias.
B. Heart failure (HF).
C. Cardiogenic shock.
D. Rupture of left ventricular (LV) papillary muscle.
E. Ventricular septal rupture.
F. Pericarditis or Dressler syndrome.
G. Ventricular aneurysm.
H. Thromboembolism.
I. Death.

SUBJECTIVE DATA

A. Ask the client if they were participating in some type of activity and what it was that brought about or preceded the episode of chest pain.
B. Ask the client to describe the duration of pain and what time of day symptoms began.
C. Ask the client to describe pain, for example, crushing, stabbing, or burning.
D. Ask the client where sensation began and in what direction it radiates.
E. Identify the degree of pain by using a pain scale of 0 to 10, with 0 being no pain.
F. Ask the client to list all medications currently being taken, particularly substances not prescribed and illicit drugs such as cocaine.

PHYSICAL EXAMINATION

A. Clients presenting with acute chest pain should be quickly assessed for the need to call emergency services/911 for immediate transport to the hospital.
B. Check pulse, respirations, blood pressure (BP), and pulse oxygenation.
C. Inspect:
1. Inspect general appearance, noting dyspnea and weakness.
2. Inspect skin for pallor and diaphoresis.
3. Inspect legs for edema.
4. Inspect chest wall for visible pulsations.
5. Inspect neck for jugular vein distension.
6. Observe nail beds for signs of cyanosis and note capillary filling time. ▶

D. Palpate:
1. Palpate abdomen for organomegaly.
2. Palpate peripheral pulses in legs.
3. Palpate femoral pulses.
E. Auscultate:
1. Auscultate carotid arteries.
2. Auscultate abdomen.
3. Conduct a complete heart exam, checking for dysrhythmias.
4. Conduct a complete lung exam.
F. Mental status:
1. Assess for confusion and anxiety.

DIAGNOSTIC TESTS

A. EKG shows inverted T waves, ST-segment elevation, and Q waves. **One normal EKG initially does not always rule out MI; perform serial EKGs if MI is suspected.**
B. Laboratory testing:
1. Cardiac biomarkers/enzymes.
2. Troponin level: Troponin is a protein that is released when necrosis of the cardiac muscles occurs.
3. Creatine kinase (CK): Creatine kinase-muscle/brain (CK-MB) levels increase 3 to 12 hours after the chest pain begins, peak at 24 hours, and return to normal in 48 to 72 hours.
4. Myoglobin: Urine myoglobin levels rise 1 to 4 hours after the chest pain begins.
5. Complete blood count (CBC).
6. Chemistry profile.
7. Lipid profile.
8. C-reactive protein (CRP) and inflammatory markers.
C. Cardiac imaging:
1. Coronary angiogram.

DIFFERENTIAL DIAGNOSES

A. Acute MI.
B. Unstable angina pectoris.
C. Aortic dissection.
D. Pulmonary embolism (PE).
E. Pericarditis.
F. Esophageal spasm.
G. Pancreatitis.
H. Biliary tract disease.

PLAN

A. General interventions:
1. Educate the client and the family regarding the signs and symptoms of an acute MI.
2. Long-term care and treatment should be reinforced at each client visit.
B. Client teaching:
1. Educate the client about modifying controllable risk factors, such as keeping diabetes and HTN under control, diet, exercise, and smoking cessation.
2. If known CHD is present:
a. Instruct the client on signs and symptoms of an acute MI.
b. Advise the client to have a plan in seeking medical attention or dialing 911 if signs and symptoms occur.
c. Advise the client to carry nitroglycerin at all times and to take the nitroglycerin at the first sign of chest pain. If there is no relief after 5 minutes, 911 should be called. Nitroglycerin may be repeated every 5 minutes times three doses.
d. Encourage CPR training for family members and close friends.
e. Exercise regimen: Encourage routine exercise for the client most days of the week, such as walking, treadmill use, and so forth, once released by the cardiologist.
f. Advise smoking cessation as indicated. Encourage support groups, classes, and smoking cessation aids as indicated. *See Client Teaching Guide for Chapter 25, "Nicotine Dependence."*
C. Dietary management:
1. Counsel the client on nutrition and low-fat, low-cholesterol, and low-sodium diets. Recommend Dietary Approaches to Stop Hypertension (DASH) diet and lifestyle changes. Provide dietary handouts on the DASH diet and a low-fat/low-cholesterol/low-sodium diet. See Appendix B for the DASH diet.
E. Pharmaceutical therapy:
1. When MI is suspected, give aspirin 160 to 325 mg (four 81-mg baby aspirin) chewed or swallowed as soon as possible. Enteric-coated aspirin delays absorption and is therefore not recommended.
2. Instruct the client on how to take sublingual nitroglycerin tablets and other medications.
3. Nitrates: Give nitroglycerin sublingually 0.2 to 0.6 mg every 5 minutes for ischemic chest pain in the absence of hypotension.
4. If pain persists after three doses of nitroglycerin:
a. Morphine sulfate intravenously (IV) 2 to 4 mg repeating every 5 minutes until pain resolves. Dose may be increased to 2 to 8 mg per dose as tolerated. Monitor side effects such as nausea/vomiting, dizziness, hypotension, and respiratory depression.
5. Oxygen therapy: 2 to 4 L per nasal cannula.
6. If there are no contraindications (bradycardia, HF, second- or third-degree heart block, asthma, shock), beta-blockers may be started IV during the acute phase and changed to oral therapy during the course of treatment.
7. Fibrinolytic therapy may be used for clients with suspected MI with ST-elevation myocardial infarction (STEMI) or non-ST-elevation myocardial infarction (NSTEMI) with left bundle branch block.
8. After an MI, if the client is not currently on a statin, a statin should be started.

FOLLOW-UP

A. Follow-up is determined by client's needs, severity of acute MI, and whether complications are present.

EMERGENT ISSUES/INSTRUCTIONS

A. If MI is suspected, refer client for immediate hospitalization.
B. Administer four aspirin 81 mg swallowed or chewed while waiting for emergency medical service (EMS).

CONSULTATION/REFERRAL

A. According to the American College of Cardiology/American Heart Association (ACC/AHA) guidelines for management of a client who is a candidate for reperfusion who is seen at a percutaneous coronary intervention (PCI)-capable hospital, this client should be sent to the cath lab for primary PCI in less than or equal to 90 minutes. If the client is at a facility that is non-PCI capable, then a transfer should be made to a PCI facility as soon as possible and in less than or equal to 120 minutes. If the time lapse will be greater than 120 minutes, then it is recommended to administer fibrinolytic therapy within 30 minutes of arrival.
B. Follow up with cardiologist as scheduled when discharged from the hospital.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. The approach to older adults with MI is similar to that of younger adults with the following considerations:

a. NSTEMI is more common than STEMI in older adults. Recurrent MI and post-MI HF are more common in the geriatric population.

b. **Geriatric adults are more likely to complain of dyspnea, fatigue, and dizziness, than typical coronary type chest pain, and may present with altered mental status or shortness of breath.**

c. Even when classic ischemic precordial discomfort is present, it tends to be less severe and less well-defined.

d. Older clients are more likely to have "silent" MIs, often delaying diagnosis and hospital admission for this cohort.

2. Pharmacotherapy for geriatric clients post-MI is similar to treatment strategies aimed toward younger individuals with the following considerations, taking into account normal age-related declines in renal function:

a. An older adult (over age 65) treated for an acute coronary syndrome (MI or angina) should discontinue nonsteroidal anti-inflammatory drugs (NSAIDs). NSAIDs (other than aspirin) as these are independent risk factors for cardiovascular disease.

b. **Aspirin is no longer recommended as primary prevention for older adults.** Unless contraindicated, older adults who have had an MI should take aspirin, a beta-blocker, and an angiotensin-converting enzyme inhibitor (ACEI).

c. Long-acting nitrates (e.g., isosorbide mononitrate) or long-acting calcium channel blockers (CCBs) may be used for chronic angina if beta-blockers are contraindicated.

3. Beers criteria precautions:

a. Use nitrates with caution due to an increased risk for syncope.

b. Avoid nondihydropyridine CCBs in HF with reduced ejection fraction due to increased risk of fluid retention and exacerbation of HF.

ARRHYTHMIAS

DEFINITION

A. Arrhythmias are abnormal heart rhythms. The following are the common types:

1. Bradycardia: heart rate less than 60 beats per minute (bpm); impulse originates in the sinoatrial (SA) node.

2. Tachycardia: heart rate greater than 100 to 160 bpm; impulse originates in the SA node.

3. Supraventricular tachydysrhythmias (SVTs): heart rate greater than 100 bpm; originates in the following:

a. Atrioventricular nodal reentrant tachycardia (AVNRT), which is an intranodal reentry by means of fast and slow conduction pathways within the atrioventricular (AV) junction.

b. Orthodromic atrioventricular reentrant tachycardia (AVRT), which is a tachycardia across accessory pathways associated with preexcitation.

4. Atrial fibrillation (AF): chaotic electrical activity caused by rapid discharges from numerous ectopic foci in atria. Atrial rate is difficult to count. There are three types of AF:

a. Paroxysmal AF occurs in clients who usually have normal sinus rhythm (NSR). There may be an episode of faulty electrical signals and rapid heart rate. This usually starts suddenly and stops on its own. Symptoms can be mild or severe and usually stop in less than 24 hours, but may last for several days.

b. Chronic AF occurs in clients who have a permanent fibrillation rather than brief episodes of symptoms.

c. Premature ventricular contractions (PVCs) are impulses that form within the Purkinje network (see the "Atrial Fibrillation" section of this chapter).

INCIDENCE

A. SVTs are the most common cardiac arrhythmias presenting to healthcare providers.

B. AVNRT accounts for 60% to 70% of all SVTs.

C. AVRT accounts for 30% to 40%.

D. AF is the most common cardiac tachydysrhythmia, affecting approximately 2% of the general population. Prevalence increases with age to 5% of those older than age 69. The presence of AF is associated with a fivefold increase in risk of morbidity, a twofold increase in mortality, and an increased incidence of embolic stroke.

E. PVCs are common and their frequency increases with age.

PATHOGENESIS

A. Bradycardia: Dominance of the parasympathetic nervous system, with excessive vagal stimulation to the heart, causes decreased heart rate of sinus node discharge.

B. Tachycardia: Dominant sympathetic nervous system stimulation of the heart or vagal inhibition results in positive chronotropic, dromotropic, and inotropic effects.

C. AVRT: The most classic form of this SVT is Wolff–Parkinson–White (WPW) syndrome. Reentry occurs in a loop using atrial myocardium, the AV node–His–Purkinje system, ventricular myocardium, and an accessory AV connection. During sinus rhythm, antegrade conduction through the accessory connection depolarizes the myocardium earlier than would occur by conduction through the AV node–His–Purkinje system, preexcitation is present, and a delta wave (slurring of initial deflection of the QRS complex) is usually seen on the surface 12-lead EKG. ▶

D. AVNRT: The most common form is antegrade conduction, which occurs through a pathway with a short effective refractory period (ERP) and a longer conduction time. This pathway is often referred to as the slow pathway.

E. AF: Multiple, rapid impulses from many foci depolarize the atria in a totally disorganized manner. In the chaos, no P waves, no atrial contraction, loss of atrial kick, and a totally irregular ventricular response occur. The atria quiver, which leads to formation of mural thrombi and potential embolic events.

F. PVCs: These originate in the ventricles as a result of increased irritability in those cells.

PREDISPOSING FACTORS

A. Bradycardia:
- **1.** Increased vagal tone.
- **2.** Decreased sympathetic drive.
- **3.** Ischemia to SA node.
- **4.** Drugs: digitalis, propranolol, sedatives, propylthiouracil (PTU) or Tapazole, aminophylline, caffeine, alcohol, nicotine, and sympathomimetics.
- **5.** Normal variant in athletes.
- **6.** Normal body response to insult.
- **7.** Atrial enlargement.
- **8.** Acute myocardial infarction (MI).
- **9.** Congestive heart failure (CHF).
- **10.** Rheumatic heart disease.
- **11.** Hypertensive heart disease.
- **12.** Thyroid disease.
- **13.** Hypothermia.
- **14.** Electrolyte abnormality.
- **15.** Acidosis.
- **16.** Infection.

B. Tachycardia:
- **1.** Decreased vagal tone.
- **2.** Increased sympathetic tone.
- **3.** MI.

C. SVT:
- **1.** Digitalis toxicity.
- **2.** Catecholamines.

D. AF:
- **1.** Myocardial ischemia.
- **2.** Thyrotoxicosis.

E. PVC:
- **1.** Stress.
- **2.** Myocardial ischemia.

COMMON COMPLAINTS

A. Symptoms may not be present; however, the client may note irregular heartbeat.

B. Palpitations.

C. Chest discomfort.

D. Shortness of breath (SOB).

E. Dizziness.

F. Diaphoresis.

G. Weakness.

H. Syncope.

I. Nausea.

SUBJECTIVE DATA

A. Obtain an accurate health and medical history.

B. Explore precipitating factors, such as emotional stress, alcohol or drug use, and hot tub or bath use.

C. Inquire about the onset and duration of symptoms, also noting the age of the client when symptoms began.

D. Explore whether the client has had concomitant weight loss, mood changes, and tremor, which are often associated with hyperthyroidism.

E. Carefully determine the number of previous episodes of palpitations or symptoms and what treatment, if any, was initiated.

F. Review all medications including prescription, over-the-counter (OTC), and herbal products.

PHYSICAL EXAMINATION

A. Check pulse, respirations, blood pressure (BP), and weight.
- **1.** Sinus bradycardia: pulse rate decreased.
- **2.** EKG: normal.
- **3.** Sinus tachycardia:
  - a. Pulse regular.
  - b. Systolic blood pressure (SBP) constant.
- **4.** AF:
  - a. Pulse irregular.
  - b. SBP changing.
- **5.** AVNRT:
  - a. Pulse regular; AV block usual.
  - b. SBP constant; electrical alternans rare.
- **6.** AVRT:
  - a. Pulse regular; AV block not present.
  - b. SBP constant; electrical alternans common, especially at high heart rates.
- **7.** PVC: pulse diminished or absent.

B. Inspect:
- **1.** General appearance:
  - a. Is the client in respiratory distress? Note SOB, chest pain, dyspnea.
  - b. Does the client look apathetic? This is a sign of a thyroid problem.
- **2.** Inspect the skin for flushing or pallor.
- **3.** Examine the eyes, noting lid lag.
- **4.** Assess the neck for jugular vein distension or thyromegaly:
  - a. With sinus tachycardia, neck vein pulsation is normal.
  - b. With AF, neck vein pulsation is irregular; assess for thyromegaly.
  - c. AVNRT: Assess the neck veins for "frog sign," in which the atria contract against closed AV valves, producing rapid, regular, expansive venous pulsation in the neck, resembling the rhythmic puffing motion of a frog.
  - d. AVRT: Assess for frog sign.

C. Auscultate:
- **1.** Auscultate the neck for carotid artery bruits and the heart for abnormal heart sounds. Heart rhythm may be regular or irregular, depending on type of dysrhythmia. Have the client perform a vagal maneuver (Valsalva maneuver). If the vagal maneuver responds to rapid heart rate and the cycle is broken, it is likely the client has AVRT. If it does not respond, it is possible the client has AVNRT.
  - a. Sinus bradycardia:
    - i. Rate less than 60 bpm.
    - ii. Rhythm regular.
  - b. Sinus tachycardia:
    - i. Rate equals 160 to 200 bpm.
    - ii. Rhythm regular; gradual onset and cessation.
    - iii. Constant loudness of first heart sound.
  - c. AF:

▶

i. Rate: Atrial rate is nonmeasurable and ventricular rate is variable, usually rapid at onset.
ii. Rhythm: Atrial and ventricular rhythms are irregular.
iii. Loudness of first heart sound changes.

d. AVNRT:
i. AV block is usually present.
ii. Loudness of first heart sound is constant.

e. AVRT:
i. AV block is not present.
ii. Constant loudness of first heart sound.

f. PVC:
i. Rate depends on underlying rhythm.
ii. Rhythm: Prematurity interrupts regularity of the rhythm.

DIAGNOSTIC TESTS

A. EKG.
B. Drug screen:
1. Digitalis.
2. Aminophylline.
3. Illicit drugs.
C. Electrolytes.
D. Arterial blood gas (ABG) if indicated.

DIFFERENTIAL DIAGNOSES

A. Multifocal atrial tachycardia.
B. Sinus tachycardia with multiple premature atrial contractions.
C. Atrial flutter.
D. Ventricular tachycardia.
E. AV blocks.

PLAN

A. General interventions:
1. Remove as many predisposing factors as possible.
2. Stop smoking.
B. Client teaching:
1. Teach relaxation techniques.
2. Teach the client and their family signs of hemodynamic compromise, including rapid heart rate, unexplained weight gain, worsening dyspnea on exertion, and decreased exercise tolerance.
3. Teach and reassure the client about long-term medication therapy and its side effects.
4. Educate the client and their family regarding safety, dietary restrictions, and complications that may occur (bleeding) with the use of anticoagulant therapy.
5. Discuss the need for a pacemaker/defibrillator or surgical ablation.
C. Pharmaceutical therapy:
1. Initial treatment is usually prescribed by a physician.
2. Selection of treatment modality should be based on the underlying pathophysiology.
3. For reentrant cases (AVNRT, AVRT), agents that block the reentrant circuit are more effective.
a. Digitalis.
b. Beta-blockers.
c. Calcium channel blockers (CCBs).
4. Episodes caused by increased automaticity are treated with the following:
a. Quinidine gluconate (Quinaglute).
b. Procainamide HCl (Procan SR).
c. Disopyramide phosphate (Norpace CR).
5. Chronic AF is treated with anticoagulants such as warfarin sodium (Coumadin).
a. Start therapy as soon as possible if a history of underlying heart disease is present.
b. Evaluate prothrombin time (PT)/international normalized ratio (INR) on a regular basis to monitor for therapeutic response to warfarin sodium treatment.

FOLLOW-UP

A. Clients who have their first episode of AF should return to the clinic within 24 to 48 hours for reevaluation.
B. Clients on antiarrhythmic agents should have liver enzymes measured during the first 4 to 8 weeks of therapy.
C. Clients with risk factors for developing cardiac complications to therapy should have EKG during the first weeks of therapy and every 3 to 6 months thereafter.
D. Monitor clients on digoxin carefully for digitalis toxicity.
E. Caution the clients regarding interactions of medications with digitalis.

CONSULTATION/REFERRAL

A. Consult a physician when questions arise about the difference between a narrow and wide QRS complex.
B. Consult a physician if the client has an abnormal EKG pattern, refractory AF, suspicion of WPW syndrome, or sick sinus syndrome.

EMERGENT ISSUES/INSTRUCTIONS

A. Clients with chest pain and/or hemodynamic instability should be referred to an ED or call 911 immediately.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
1. Digitalis is safe during pregnancy.
C. Geriatrics:
1. Over 50% of AF occurs in the percentage (6%) of the population older than 75 years of age.
2. The prevalence of AF increases with age.
3. Advanced age and female sex are potent risk factors for stroke.
4. Use the CHA_2DS_2-VASc risk calculator to estimate the risk of stroke in nonvalvular AF. In older adults with a CHA_2DS_2-VASc score less than 2, it is unlikely a stroke reduction benefit can be achieved with the use of oral anticoagulants. The risk of treatment may outweigh the benefit for those with a low CHA_2DS_2-VASc score. A CHA_2DS_2-VASc risk calculator is available at www.globalrph.com/chad2.htm.
5. Prior to prescribing anticoagulant therapy, it is important to assess bleeding risk in older adults. The HAS-BLED (Hypertension, Abnormal liver/ renal function, Stroke history, Bleeding history or predisposition, Labile INR, Elderly, Drug/alcohol usage) bleeding risk score can be used specifically when considering the use of warfarin (not validated in other anticoagulant therapy). It assesses the 1-year risk of a major bleed in clients with AF. A HAS-BLED risk calculator is available at www.globalrph.com/has-bled-score.htm.
6. Direct thrombin inhibitor anticoagulants provide alternatives to warfarin but are not without limitations. Most are related to renal function and an increased risk of bleeding:
a. Pradaxa (dabigatran) is listed in the Beers criteria to be used with caution in adults aged 75 or older and those with creatinine clearance (CrCl) less than 30 due to an association with an increased risk for ▶

gastrointestinal (GI) bleeds (refer to Appendix C, Table C.1).

b. Eliquis (apixaban): Use half the regular dose (2.5 mg BID) in those aged 80 and older who weigh less than 60 kg. In those with a CrCl greater than 1.5, use the half-regular dose if *either* over the age of 80 *or* if weight is less than 60 kg. Beers criteria: AVOID use in those aged 65 and older who have a CrCl less than 25 mL/min.

7. The routine use of mechanical interventions and devices in older AF clients remains to be clearly established. Left atrial appendage occlusion may be considered in clients with AF who are at increased risk of stroke and have a contraindication to anticoagulation.

8. Lenient rate control with concomitant anticoagulation is a reasonable therapeutic strategy in older individuals with limited symptoms.

ATHEROSCLEROSIS AND HYPERLIPIDEMIA

DEFINITION

A. Atherosclerosis is a systemic disease characterized by lipid deposition and smooth muscle cell migration and proliferation in the intima of the larger arteries. Atheromatous changes lead to thrombotic stroke, peripheral vascular disease (PVD), atherosclerosis cardiovascular disease (ASCVD), and myocardial infarction (MI).

B. Hyperlipidemia is an elevation in serum lipoproteins and a major risk factor in the development of cardiovascular disease (CVD). The two main lipids in the blood are cholesterol and triglyceride. Cholesterol is a relatively insoluble lipid that is necessary for cell membrane formation, steroid and bile salt production, and the development of nerve sheaths. Cholesterol is composed of three clinically significant components: high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), and very-low-density lipoprotein (VLDL). Triglyceride is found in VLDL particles, but its role in atherosclerosis is not clear.

C. The atherosclerotic buildup of lipids, cholesterol, calcium, and cellular debris within the intima of the blood vessels causes plaque formation, vascular remodeling, and acute and chronic obstruction of the lumen of the blood vessels, which in turn decreases blood flow, causing myocardial ischemia and decreased oxygen to other vital organs.

D. In 2019, the American College of Cardiology (ACC) and the American Heart Association (AHA) published a revised and comprehensive set of guidelines on the primary prevention of CVD. A web-based calculator is available to help estimate 10-year and lifetime risks for ASCVD in individuals without a history of ASCVD (tools.acc.org/ASCVD-Risk-Estimator-Plus/#!/calculate/estimate/).These risk tools are used to drive conversations on client risk factors for ASCVD, potential benefits, negative aspects of risk, and client preferences regarding initiation of relevant therapies. The assessment of ASCVD risk factors is recommended every 4 to 6 years in adults 20 to 79 years of age who are free from ASCVD. Long-term and lifetime risk information may be used to motivate therapeutic lifestyle changes (TLCs) and to encourage adherence to these changes and pharmacologic therapies.

INCIDENCE

A. Atherosclerosis begins in childhood with the development of fatty streaks. The incidence of atherosclerotic diseases increases with age. CVD causes one in four deaths reported each year in the United States. The annual direct cost of CVD is estimated at $273 billion and the overall cost of CVD is estimated at $444 billion annually.

B. The leading risk factors for CVD are hypertension (HTN), high cholesterol, and smoking.

1. HTN can increase arterial wall tension, potentially leading to disturbed repair processes and aneurysm formation.

2. Cigarette smoking is associated with an increase in multiple inflammatory markers, including C-reactive protein (CRP), interleukin-6, and tumor necrosis factor.

PATHOGENESIS

A. Atherosclerosis is in part attributed to the deposition of cholesterol and lipoproteins in arterial smooth muscle cells. Dietary factors, obesity, drugs, and genetic defects in lipoprotein particle metabolism influence lipid and lipoprotein concentrations in blood.

B. Primary hyperlipoproteinemias are either due to single-gene disorders transmitted by simple dominant or recessive mechanisms, or to multifactorial disorders with complicated inheritance patterns.

C. Secondary hyperlipoproteinemias (such as in thyroid disease and diabetes mellitus) occur as part of a constellation of abnormalities in certain metabolic pathways. The association between atherosclerosis, CVD, and hypercholesterolemia is well-documented. HDL-C comprises about one-fourth of the total serum cholesterol and acts as a scavenger, removing cholesterol from peripheral tissues and returning it to the liver, which produces a favorable cardioprotective effect. Elevated HDL-C levels are desirable. HDL-C levels more than 60 mg/dL are a negative risk factor for CVD; those below 35 mg/dL are a major risk factor for CVD.

D. LDL-C constitutes 70% of the total serum cholesterol. It is the most atherogenic cholesterol subgroup. LDL-C particles interact with platelets, damaged arterial endothelium, and smooth muscle cells in the process of plaque formation. LDL-C levels of 160 mg/dL or greater are associated with an increased number of cardiac events.

E. VLDL accounts for a small amount of total serum cholesterol and is responsible for carrying triglycerides from the liver. Its role in atherogenesis is uncertain, but an inverse relationship has been observed between VLDL and HDL-C.

PREDISPOSING FACTORS

A. High-risk factors for CVD events (CVD risk equivalent):

1. Clinical CVD.

2. Symptomatic carotid artery disease.

3. Peripheral arterial disease (PAD).

4. Abdominal aortic aneurysm.

B. Presence of major risk factors (other than LDL-C):

1. Age is the strongest risk factor for the development of CVD.

a. Age older than 45 years for males and older than 55 years for females.
b. Older adults experience a higher morbidity and mortality.

2. Cigarette smoking.
3. Low HDL-C level, less than 40 mg/dL.
4. Family history of early CVD: MI or sudden cardiac death younger than 55 years in the father or other male first-degree relative, and before age 65 in the mother or other female first-degree relative.
5. HTN (blood pressure [BP] >140/90 mmHg or on antihypertensive medication).
6. Sedentary lifestyle.
7. Obesity.
8. Metabolic syndrome.
9. Diabetes.
10. Chronic inflammation.

HDL-C of greater than 60 mg/dL is equal to "negative" risk factor and removes one risk factor from the total count.

COMMON COMPLAINTS

A. There are no complaints or symptoms associated with atherosclerosis and hyperlipidemia. Most lipid abnormalities are detected by routine laboratory testing or as part of a cardiovascular evaluation.

SUBJECTIVE DATA

A. Ask the client if there is a history of CVD.
B. Discuss their medical history, including predisposing factors for CVD.
C. Have the client list current medications, including over-the-counter (OTC) and herbal products.
D. Have the client discuss their current diet and exercise routine.
E. Explore the client's social habits, including use of alcohol and tobacco.

PHYSICAL EXAMINATION

A. Check pulse, respirations, BP, height, and weight. Calculate body mass index (BMI) at each subsequent visit. An adult BMI calculator and teen BMI calculator are located at www.cdc.gov/healthyweight/assessing/bmi.
B. Inspect:
1. Perform funduscopic exam: Examine eyes for premature arcus cornealis, which is a gray opaque line around the cornea caused by lipoid degeneration, and for lipemia retinalis, which is a pale retina with white blood vessels caused by excess serum lipids due to VLDL of more than 2,000 mg/dL or alcoholism.
2. Inspect skin for xanthomas, which appear as red-brown or yellow papules, nodules, or plaque, caused by lipid deposits from high VLDL. Tendinous xanthomas are found on Achilles tendons, patellae, and hands.
3. Inspect joints for Achilles tendonitis and arthritis.
C. Palpate:
1. Palpate abdomen for hepatomegaly or splenomegaly.
2. Palpate neck and thyroid.
D. Auscultate:
1. Perform a complete heart exam.
2. Perform a complete vascular exam.

DIAGNOSTIC TESTS

A. Laboratory testing:
1. Lipid profile and lipoprotein analysis (Table 13.1).
2. Complete blood count (CBC).
3. Complete metabolic panel (CMP).
4. Thyroid function studies to exclude disorders of the thyroid.
5. CRP.
6. Hemoglobin A1C (if appropriate).
B. Tests/imaging:
1. Treadmill stress test.
2. Nuclear stress test.
3. Echocardiogram.
4. Ultrasound.
5. CT.
6. Coronary angioplasty.

DIFFERENTIAL DIAGNOSES

A. Assess client for the following secondary causes of ASCVD and hyperlipidemia:
1. Atherosclerosis.
2. Hyperlipidemia.
3. Diabetes mellitus.
4. Hypothyroidism.
5. Nephrotic syndrome.
6. Porphyria.
7. Obesity.
8. Obstructive liver disease.
9. Diuretic use.

TABLE 13.1 ATP III CLASSIFICATION OF LDL, TOTAL, AND HDL CHOLESTEROL (MG/DL)

Determine Lipoprotein Levels. Obtain Complete Lipoprotein Profile After 9- to 12-Hour Fast.	
LDL Cholesterol: Primary Target of Therapy	
<100	Optimal
100–129	Near optimal/above optimal
130–159	Borderline high
160–189	High
>190	Very high
Total Cholesterol	
<200	Desirable
200–239	Borderline high
>240	High
HDL Cholesterol	
<40	Low
>60	High
Triglycerides	
<149	Good
150–199	Borderline
>200	High
>500	Very high

ATP, Adult Treatment Panel; HDL, high-density lipoprotein; LDL, low-density lipoprotein.

PLAN

A. General interventions:

1. TLCs, including exercise, diet, and weight management, are recommended for all clients.

2. Increased physical activity. The 2013 ACC/AHA guidelines on lifestyle management outline the newest physical activity recommendations advising adults to engage in 40 minutes of aerobic physical activity three to four times a week. The aerobic exercise should involve moderate-to-vigorous intensity to reduce BP, LDL-C, and non-HDL-C. Refer to Chapter 3 for further exercise recommendations from the *2008 Physical Activity Guidelines for Americans* for key guidelines for adults 18 to 64 years, older adults, people with chronic medical conditions, and adults with disabilities.

B. Dietary management:

1. Advise the client that diet modification is the first line of therapy for hyperlipidemia.

2. Explain the cholesterol-lowering diet. Give dietary recommendation sheets. See Appendix B for low-fat/low-cholesterol and the Dietary Approaches to Stop Hypertension (DASH) diets.

C. Client teaching: *See Client Teaching Guide for Chapter 25, "Nicotine Dependence."*

1. Weight reduction:

a. Explain that weight reduction in clients who are more than 20% over ideal body weight can lower LDL-C and triglyceride levels.

2. Other key dietary recommendations include the following:

a. Reduce intake of saturated fats and trans fats. Aim for 5% to 6% of calories from saturated fat.

b. Increase intake of poly and monounsaturated fats.

c. Increase intake of soluble fiber (psyllium supplement).

d. Limit intake of alcohol: one drink per day for females and two drinks per day for males.

e. Increase intake of plant stanols and sterols (1 oz of Promise Activ or Benecol spread per day).

f. Increase intake of omega-3 fatty acids from marine sources (salmon or tuna twice a week or supplements).

g. Follow the DASH, Mediterranean, or AHA diet.

h. Lower sodium intake. Consume no more than 2,400 mg/d of sodium. Further reduction to 1,500 mg/d of sodium is associated with greater reduction in BP.

D. Pharmaceutical therapy: **Use clinical judgment when deciding potential benefits, possible side effects, and costs of drug treatment**:

1. Drug of choice: HMG-CoA reductase inhibitors (statins):

a. Statins suppress the activity of the key enzyme in cholesterol synthesis in liver; they are highly effective in lowering LDL-C but can cause liver toxicity, myositis, rhabdomyolysis, and low.

b. There are four major groups that benefit from statins:

i. Individuals with presence of clinical ASCVD, including acute coronary syndromes, history of MI, stable or unstable angina, coronary or other arterial revascularization, stroke, transient ischemic attack (TIA), or PAD.

ii. Individuals with primary elevations of LDL-C greater than 190 mg/dL.

iii. Individuals 40 to 75 years of age with diabetes and LDL-C of 70 to 189 mg/dL and without clinical ASCVD (refer to Chapter 24 for statin therapy for diabetes).

iv. Individuals without clinical ASCVD or diabetes who are 40 to 75 years of age with an LDL-C of 70 to 189 mg/dL and an estimated 10-year ASCVD risk of 7.5% or higher.

c. **ASCVD events are reduced by using the maximum tolerated statin intensity in those groups shown to benefit. The expert panel defines intensity of statin therapy on the basis of the average expected LDL-C response to a specific statin and dose. The intensity levels are "high-intensity," "moderate-intensity," and "lower-intensity" statin therapy. Full statin treatment recommendations for primary and secondary prevention as well as the high/moderate/low-intensity statin therapy from the 2013 ACC/AHA guidelines on the treatment of cholesterol are available at www.ahajournals.org/doi/10.1161/JAHA.116.004909.**

d. Monitor liver function tests (LFTs) before therapy begins and 4 to 6 weeks after starting drug therapy. Then check at 6- to 12-month intervals or more frequently, if necessary.

e. Discontinue medications if abnormal lab values or adverse symptoms appear.

f. Use caution when using statins and other medications. Avoid concomitant drugs such as erythromycin, nicotine, azole antifungals, clofibrate, and gemfibrozil.

g. The use of statins in older adults over age 75 remains controversial. See the "Individual Considerations" section on geriatrics.

2. Category X drugs:

a. **Statins are category X drugs and are contraindicated in pregnancy.**

3. Nonstatin drug therapy (see Table 13.2 for nonstatin drugs that affect cholesterol):

a. Bile acid sequestrants bind bile acids in the gastrointestinal (GI) tract; lower moderately elevated LDL-C by 20%; and may cause constipation, bloating, and poor absorption of other drugs. Bile acid sequestrant therapy is not recommended if triglycerides are greater than 300 mg/dL.

b. Nicotinic acid or niacin: broad-spectrum lipid regulating agent. Niacin has been documented to exhibit anti-inflammatory properties (reduction of lipoprotein-associated phospholipase A2 and CRP). Discuss possibilities of flushing. Niacin is contraindicated in chronic liver disease and severe gout. The niacin-treated subjects in the Atherothrombosis Intervention in Metabolic Syndrome With Low HDL/High Triglycerides: Impact on Global Health (AIM-HIGH) clinical trial had a trend toward increased stroke incidence.

c. Fibric acid derivatives are highly effective in lowering triglycerides, and lower VLDL-C, cause modest reduction in LDL-C, and raise HDL-C.

i. The combination of niacin with other lipid-lowering drugs has been shown to reduce progression and promote regression of coronary and carotid atherosclerosis and improve clinical outcomes.

ii. Fibrates may cause GI distress, rash, pain, blurred vision, anemia, and gallstones.

iii. Fibrates may inhibit insulin and oral hypoglycemic absorption and potentiate oral anticoagulants. ▶

TABLE 13.2 NONSTATIN DRUGS AFFECTING LIPOPROTEIN METABOLISM

Drug Class	Agents and Daily Doses	Lipid/Lipoprotein Effects	Side Effects	Contraindications
Bile acid sequestrants	Cholestyramine (4–16 g), colestipol (5–30 g), colesevelam (1,875–3,750 mg)	LDL-C ↓15%–30% HDL-C ↑3%–5% TG no change or increase	GI distress Constipation Decreased absorption of other drugs	Absolute: • Dysbetalipoproteinemia • TG >400 mg/dL Relative: • TG >200 mg/dL
Nicotinic acid	Immediate-release (crystalline) nicotinic acid (1.5–3 g), extended-release nicotinic acid (Niaspan; 500 mg–2 g), sustained-release nicotinic acid (1–2 g)	LDL-C ↓5%–25% HDL-C ↑15%–35% TG ↓20%–50%	Flushing Hyperglycemia Hyperuricemia (or gout) Upper GI distress hepatotoxicity	Absolute: • Chronic liver disease • Severe gout Relative: • Diabetes • Hyperuricemia • Peptic ulcer disease
Fibric acid	Gemfibrozil (600 mg BID), fenofibrate (145–200 mg), clofibrate (500–2,000 mg)	LDL-C ↓5%–20% (may be increased in patients with high TG) HDL-C ↑10%–20% TG ↓20%–50%	Dyspepsia Gallstones Myopathy	Absolute: • Severe renal disease • Severe hepatic disease
PCSK9 inhibitors.	Alirocumab (75–150 mg Q 2 weeks or 300 mg Q 4 weeks), evolocumab (140 mg Q 2 weeks or 420 mg Q 4 weeks)	LDL-C ↓43%–64%	Arthralgias Headache Limb pain Fatigue	Absolute: • Prior sensitivity reaction to either medication
Cholesterol absorption inhibitors	Ezetimibe (Zetia) (10 mg Q day)	LDL-C ↓13%–20%	Diarrhea Back pain Abdominal pain	Absolute: • None Serious: • Cyclosporine

GI, gastrointestinal; HDL-C, high-density lipoprotein cholesterol; LDL-C, low-density lipoprotein cholesterol; TG, triglycerides.

FOLLOW-UP

A. Measure client's total cholesterol 4 weeks after initiation of diet and then at 3- to 4-month intervals.

B. If initiating medication therapy, obtain baseline blood work, including fasting lipid profile with LFTs and a CBC. Recheck tests 4 to 6 weeks after starting drug therapy. Then check at 6- to 12-month intervals or more frequently, if necessary.

CONSULTATION/REFERRAL

A. Refer to a dietitian for nutritional counseling for dietary modifications.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. The use of statin therapy for primary prevention of ASCVD in those over age 75 remains controversial. The use of the 10-year ASCVD risk calculator almost always exceeds the guideline-recommended treatment threshold in this population. However, there is little evidence that statins provide primary prevention in older adults.

2. The risk of side effects when using statins increases with age (myalgias, elevated liver enzymes, cognitive impairment).

3. The American Diabetes Association recommends statins as primary prevention in older adults with diabetes, even in those with no previous CVD who are over age 75.

4. There is compelling evidence supporting the use of statins for secondary prevention in individuals older than 75. Much the same as younger adults, adults over age 75 with clinical ASCVD have been shown to have a reduction in the risk for secondary events when a statin is used.

5. Because of a number of barriers, the rates of participation in physical activity are low among many older adults. Older adults who are isolated, frail, have mobility limitations or disabilities, and have fewer resources available may be particularly vulnerable to the effects of inactivity. Chronic pain and arthritis could represent additional barriers to physical activity among populations who are already at high risk of poor health outcomes associated with low levels of physical activity.

ATRIAL FIBRILLATION

DEFINITION

A. Atrial fibrillation (AF) is the irregular and rapid heart rhythm caused by abnormal electrical impulses. These impulses make the heart's upper chambers (the atria) beat chaotically and out of sync with the heart's lower chambers (the ventricles),p resulting in poor circulation of blood throughout the body.

B. Classification of AF:

1. Paroxysmal AF:

a. Also called intermittent AF.

b. AF that is self-terminating usually within 48 hours or with intervention within 7 days of onset.

2. Persistent AF:

a. AF that is sustained greater than 7 days.

b. Usually requires pharmacologic and/or cardioversion to restore sinus rhythm.

3. Long-standing persistent AF:

a. Continuous AF for greater than 12 months.

4. Permanent AF:

a. Persistent AF in which rhythm control strategies are no longer effective (such strategies are not utilized to restore sinus rhythm).

5. Nonvalvular AF:

a. The term used to reference clients with paroxysmal, persistent, or permanent AF who do not have valvular heart disease (e.g., rheumatic mitral stenosis, a mechanical or prosthetic heart valve, or mitral valve prolapse [MVP]).

6. "Lone" AF:

a. The term used historically to refer to younger clients without clinical or echocardiographic evidence of cardiopulmonary disease, hypertension (HTN), or diabetes.

INCIDENCE

A. AF is the most common heart arrhythmia. The prevalence of AF in adults who are ≥65 years of age increased 5% per year from 1993 to 2007. More than 750,000 hospitalizations in the United States annually list AF as the primary admitting diagnosis. An estimated 150,000 deaths per year in the United States are attributed to AF. Clients with AF are hospitalized twice as often and are three times more likely to have multiple admissions. As of 2017, an estimated 2.7 million and 6.1 million American adults have AF. It is estimated that by 2030 more than 12 million Americans will have AF. AF is more common in males than in females and more common in Caucasians than other ethnicities.

PATHOGENESIS

A. Multiple impulses travel throughout the atria, yielding continuous electrical activity and an atrial rate in excess of 300 beats per minute (bpm). The impulses enter the atrioventricular node in a completely random manner. A small percentage of the impulses are conducted to the ventricle, which results in a lower ventricular rate, usually 100 to 180 bpm, and an irregularly irregular rhythm. This leads to ineffective atrial contractions, a decrease in cardiac output, and an increased risk of thrombus formation.

PREDISPOSING FACTORS

A. Increased age:

1. Approximately 1% of all AF clients are less than 60 years of age.

2. Approximately one-third of all AF clients are older than 80 years.

B. Ischemic heart disease (IHD).

C. HTN.

D. Rheumatic heart disease.

E. Valvular heart disease:

1. Mitral valve stenosis.

2. Mitral regurgitation.

3. Tricuspid regurgitation.

4. Left ventricular hypertrophy (LVH).

F. Heart failure (HF).

G. Myocardial infarction (MI).

H. Hyperthyroidism.

I. Obstructive sleep apnea (OSA).

J. Obesity.

K. Pericarditis.

L. Myocarditis.

M. Electrocution.

N. Pneumonia.

O. Pulmonary embolism (PE).

P. Cardiothoracic surgery.

Q. Diabetes mellitus.

R. Smoking.

S. Excessive alcohol use.

T. Recent cardiac surgery, including heart transplantation.

U. Pulmonary diseases (related to hypoxia):

1. Chronic obstructive pulmonary disease (COPD).

2. Bronchitis, acute or chronic.

3. Asthma.

4. Emphysema.

V. Electrolyte imbalances:

1. Hyperkalemia and hypokalemia.

2. Hypercalcemia and hypocalcemia.

3. Hypermagnesemia and hypomagnesemia.

W. Factors that can trigger episodes of AF:

1. Physical or emotional stress.

2. Nicotine.

3. Caffeine.

4. Alcohol.

5. Exercise.

COMMON COMPLAINTS

A. Palpitations.

B. Angina.

C. Fatigue.

D. Dyspnea at rest or on exertion.

E. Vertigo or dizziness.

F. Disorientation.

G. Confusion.

H. Syncope.

I. Headache.

J. Urinary frequency or urgency.

K. Anxiety.

L. Asymptomatic presentation, most often seen in the elderly and in clients with permanent AF.

POTENTIAL COMPLICATIONS

A. Stroke:

1. The risk of stroke increases four to five times during an episode of AF.

2. An AF-related stroke is more likely to be severe than a non-AF-related stroke.

B. HF:

▶

1. The risk of HF increases three times in the presence of AF.

C. Dementia:

1. The risk of dementia increases two times in the presence of AF.

D. Mortality:

1. Overall mortality increases two times in the presence of AF.

2. There is increased mortality in individuals who have other cardiovascular conditions or procedures, specifically HF, MI, coronary artery bypass surgery (CAB), stroke, and HTN.

E. PE.

F. Peripheral emboli:

1. These may present as an ischemic extremity or ischemic bowel.

SUBJECTIVE DATA

A. Ask the client what activity brought about or preceded the episode.

B. Have the client describe the duration of symptoms and what time of day the symptoms began.

C. Ask the client to describe their symptoms.

D. Ask the client whether any previous episodes have occurred.

E. Ask the client to list all medications, over-the-counter (OTC), and herbal products currently being taken or recently stopped:

1. Medications with links to AF:

a. Common complications with AF:

i. Theophylline (theophylline anhydrous; Theo-24, Elixophyllin).

ii. Digoxin (Lanoxin).

iii. Quinidine (quinidine gluconate; Nuedexta).

iv. Tricyclic antidepressants (TCAs).

b. Rare complications with AF:

i. Donepezil hydrochloride (Aricept).

c. Questionable complications with AF:

i. Bisphosphonates (alendronate, risedronate, etidronate).

F. Ask client to quantify their smoking history, alcohol history, and caffeine intake.

PHYSICAL EXAMINATION

A. Clients presenting with acute cardiovascular episode should be quickly assessed for the need to call emergency services/911 for immediate transport to the hospital.

B. Early screening is key. Current guidelines strongly suggest that all clients who present with breathlessness, palpitations, syncope, chest discomfort, and/or stroke symptoms have their pulse checked for irregularities and a 12-lead EKG.

C. Check vital signs: blood pressure (BP), pulse, and respirations. Count heart rate for 1 full minute.

1. Check orthostatic BP: sitting, standing, and lying down.

D. Inspect:

1. Inspect overall physical appearance, noting any distress.

2. Inspect the neck: Check jugular vein distension and pulsations:

a. **Provoking maneuvers (e.g., carotid massage) should only be performed by a cardiologist.**

3. Inspect extremities: Note edema, pallor, and cyanosis.

4. Perform a funduscopic exam: Note hemorrhage, exudates, and papilledema to determine the presence of a malignant HTN.

E. Palpate:

1. Palpate extremities for peripheral pulses in the arm and groin; determine rate and regularity.

2. Assess capillary refill.

3. Palpate carotid arteries for thrills and heaves.

F. Auscultate:

1. Auscultate heart: While client is sitting, standing, and in left lateral recumbent positions, note normal and extra heart sounds (S3 and S4).

a. S4 is not present during AF.

2. Auscultate neck for carotid bruits.

3. Auscultate lungs: Note the presence of wheezing and crackles.

G. Additional areas for physical examination:

1. Assess for focal neurologic deficits (orientation, unilateral weakness, dysarthria).

DIAGNOSTIC TESTS

A. Complete blood count (CBC), basic metabolic panel (BMP; including electrolytes, blood glucose, blood urea nitrogen [BUN], creatinine), magnesium, and liver function tests (LFTs).

B. Thyroid profile and lipid profile.

C. Brain natriuretic peptide (BNP) and N-terminal pro-brain natriuretic peptide (NT-proBNP).

D. Cardiac profile (including troponin, creatine phosphokinase [CPK] test, creatine kinase-muscle/brain [CK-MB]).

E. Serum drug levels, digoxin, amiodarone, and quinidine (if applicable).

F. International normalized ratio (INR), if applicable.

G. Creatinine clearance (CrCl).

H. 12-lead EKG, required to confirm the AF diagnosis.

I. Two-dimensional echocardiogram.

J. Transesophageal echocardiogram (TEE), most sensitive and specific test to detect left atrial (LA) thrombi and identify features associated with an increased risk of LA thrombus formation and subsequent systemic embolism.

K. Chest x-ray.

L. Exercise stress test or thallium stress test, if exercise-induced arrhythmia or coronary artery disease (CAD) is suspected.

M. Holter monitoring.

N. Evaluation of sleep apnea.

DIFFERENTIAL DIAGNOSES

A. AF.

B. MI.

C. IHD.

D. HF.

E. Mitral stenosis.

F. HTN.

G. Hyperthyroidism.

H. Digitalis intoxication.

I. Acute infections.

PLAN

A. General interventions:

1. The goal of therapy is to improve the client's quality of life by reducing morbidity and prolonging survival.

B. Client teaching: *See Client Teaching Guide for this chapter, "Atrial Fibrillation."*

1. Encourage weight loss, smoking cessation, and stress management. ▶

2. Educate clients about the adverse effects of their anticoagulant and antiarrhythmic medications.

3. Instruct clients taking anticoagulants, including Coumadin (warfarin), to take steps to lessen their risk of falls. Some examples include well-fitting footwear, removing rugs from the home, nightlights between the bed and bathroom, and grab bars in the bathroom.

4. Educate clients with implanted defibrillators and pacemakers about their susceptibility for external electrical fields and avoidance of exposure.

5. Prevention:

a. Control other chronic medical conditions, that is, HTN, diabetes, HF, pulmonary diseases, and hyperlipidemia.

C. Dietary management:

1. Counsel client on proper nutrition, specifically a low-fat, low-cholesterol, and low-sodium diet. Give diet handouts.

2. Educate clients taking Coumadin (warfarin) regarding dietary modifications to prevent variations in INR levels.

D. Pharmaceutical therapy:

1. Anticoagulant therapy:

a. Note: The CHA_2DS_2-VASc score evaluates the risk of ischemic stroke in clients with AF. To calculate a CHA_2DS_2-VASc score, go to clincalc.com/cardiology/stroke/chadsvasc.aspx. In general, the lower the score, the stronger the consideration for oral anticoagulation. The one exception to this is when the client has a score of 1 due to gender alone.

b. Goal of therapy: prevention of thromboembolism:

i. Warfarin sodium (Coumadin, Jantoven): Beers criteria caution: AVOID warfarin in older clients also taking amiodarone due to risk of elevated INRs and subsequent bleeds. AVOID warfarin in older adults who use nonsteroidal anti-inflammatory drugs (NSAIDs) due to risk of gastrointestinal (GI) bleed (refer to Appendix C, Tables C.3 and C.4):

1) Doses: 1, 2, 2.5, 3, 4, 5, 6, 7.5, and 10 mg tablets.

2) A warfarin dose calculator is located at www.globalrph.com/warfarin_calc.htm.

3) Review all medications that may affect the anticoagulant effects of warfarin. GlobalRPH is a resource with a list of medications that both increase and decrease the INR (www.globalrph.com/warfarin_drug_interactions.htm). Because antibiotics can have a significant effect on both decreasing and increasing the INR (especially Bactrim, Cipro, and erythromycin), INRs should be checked at least twice weekly through the duration of antibiotic therapy.

4) The incidence of anticoagulation with warfarin often declines as age advances due to the increased risk of falls, bleeding, and other adverse events.

ii. Dabigatran (Pradaxa): Beers criteria caution (age 65 and older): AVOID use in older adults with CrCl less than 30 due to increased risk of bleeds:

1) Pradaxa 75, 110, and 150 mg tablets:

a) Dosage indications based on CrCl:

i) CrCl greater than 30 mL/min: 150 mg, taken BID.

ii) CrCl of 15 to 30 mL/min: 75 mg, taken BID.

iii. Rivaroxaban (Xarelto): Beers criteria caution (age 65 and older): Reduce dose in older adults with CrCl 30 to 50 and AVOID in older adults with CrCl less than 30:

1) Xarelto 2.5, 10, 15, and 20 mg tablets:

a) Dosage indications based on CrCl:

i) CrCl greater than 50 mL/min: 20 mg with evening meal.

ii) CrCl of 15 to 50 mL/min: 15 mg with evening meal.

iv. Apixaban (Eliquis): Beers criteria caution (age 65 and older): AVOID in older adults with CrCl less than 25:

1) Eliquis 2.5 and 5 mg tablets:

a) Dosage indications: The recommended dose is 2.5 mg, taken BID in clients who fit any of the following criteria:

i) 80 years of age or older.

ii) Weight greater than or equal to 60 kg (132 lbs).

iii) Serum creatinine greater than or equal to 1.5 mg/dL.

2. Antiplatelet therapy:

a. Goal of therapy: prevention of thromboembolism; modest preventive effect:

i. Clopidogrel bisulfate (Plavix):

1) 75 mg (daily dose) and 300 mg (single loading dose).

ii. Aspirin:

1) 81 and 325 mg tablets:

2) Beers criteria caution:

a) Use aspirin with caution in older adults over the age of 80 with no history of cardiovascular disease (CVD): There is no clear evidence that aspirin provides primary prevention for cardiac events, but there is a risk for GI bleeds.

b) In adults 65 and older, avoid use of greater than 325 mg due to risk of GI bleed, unless other alternatives are not effective and the client can take a gastroprotective agent.

c) In adults older than 75 years, or adults older than 65 taking corticosteroids, anticoagulants, or antiplatelet agents, there is an increased risk of upper GI bleeds. The use of proton pump inhibitors (PPIs) reduces but does not eliminate risk. The risk of GI bleed increases with duration of use of NSAIDs, including high-dose aspirin (ASA). At 1 year, the risk is 2% to 4% and this increases with each subsequent year.

3. Combined anticoagulant and antiplatelet therapies:

a. Prescription of both antiplatelet medications (Plavix and aspirin) in addition to an anticoagulant is referred to as triple therapy. Triple therapy is commonly used to prevent complications when two or more of the following conditions are present:

i. AF.

ii. Mechanical valve prosthesis.

iii. Drug-eluting coronary stent.

b. Triple therapy is linked to an increase in bleeding complications ranging from mild to life-threatening.

4. Heart rate control therapy:
   a. Goal of therapy: varies based on client age but typically involves achieving a ventricular rate between 60 and 80 bpm at rest and 90 and 115 bpm during moderate exercise.
   b. Beta-blockers:
      i. Acebutolol (acebutolol hydrochloride; Sectral): 200 and 400 mg capsules.
      ii. Atenolol (Tenormin): 25, 50 (scored), and 100 mg tablets.
      iii. Betaxolol (betaxolol hydrochloride; Betoptic, Betoptic S): 10 and 20 mg tablets, all scored.
      iv. Bisoprolol (bisoprolol fumarate; Zebeta): 5 (scored) and 10 mg tablets.
      v. Metoprolol (metoprolol tartrate; Lopressor, Toprol XL): 50 and 100 mg tablets, all scored.
      vi. Nadolol (Coreg, Corgard): 20, 40, and 80 mg tablets, all scored.
      vii. Propranolol (propranolol hydrochloride; Hemangeol, Inderal LA, Inderal XL, InnoPran XL): 10, 20, 40, 60, and 80 mg tablets, all scored.
      viii. Sotalol (sotalol hydrochloride; Betapace, Sorine): 80, 120, and 160 mg tablets, all scored.
      ix. Timolol (timolol maleate; Blocadren): 5, 10 (scored), and 20 mg (scored) tablets.
   c. Calcium channel blockers (CCBs):
      i. Amlodipine (amlodipine besylate; Norvasc): 2.5, 5, and 10 mg tablets.
      ii. Diltiazem (diltiazem hydrochloride; Cardizem): 30, 60 (scored), 90 (scored), and 120 mg (scored) tablets.
      iii. Felodipine: 2.5, 5, and 10 mg tablets.
      iv. Isradipine: 2.5 and 5 mg tablets.
      v. Nicardipine (nicardipine hydrochloride):
         1) 20 and 30 mg capsules.
         2) Cardene SR: 30, 45, and 60 mg capsules.
      vi. Nifedipine (Procardia): 10 and 20 mg capsules.
      vii. Nimodipine: 30 mg capsules.
      viii. Nisoldipine (Sular): 8.5, 10, 17, 20, 25.5, 30, 34, and 40 mg tablets.
      ix. Verapamil (verapamil hydrochloride; Calan Tarka): 40, 80 (scored), and 120 mg (scored) tablets.
   d. Digoxin (Lanoxin):
      i. Beers criteria caution: Digoxin should be avoided as first-line therapy for AF and should not be prescribed in daily doses greater than 0.125 mg: 0.125 and 0.25 mg tablets, all scored.
5. Heart rhythm control therapy:
   a. Goal of therapy: maintenance of a normal rhythm and suppression of AF:
      i. Sodium channel blockers:
         1) Disopyramide (Norpace): 100 and 150 mg capsules.
         2) Quinidine (quinidine gluconate): 200 and 300 mg tablets, all scored.
      ii. Potassium channel blockers:
         1) Amiodarone (amiodarone hydrochloride; Cordarone, Pacerone, Nexterone).
            a) Beers criteria caution: Amiodarone should be avoided as first-line therapy for AF unless the client has HF or substantial LVH: 200 mg tablet, scored.
         2) Dofetilide (Tikosyn): 125, 250, and 500 mcg capsules.
         3) Dronedarone (Multaq).
            a) Beers criteria caution: Dronedarone should be avoided in clients with permanent AF or with severe of recently decompensated HF: 400 mg tablet.
         4) Sotalol (sotalol hydrochloride; Betapace): 80, 120, and 160 mg tablets, all scored.

E. Surgical therapies:
   1. Ablation therapy:
      a. Goal of therapy: prevention of recurrent AF.
      b. Preferred clinical characteristics include the following:
         i. Symptomatic paroxysmal AF.
         ii. Failure of one or more antiarrhythmic medications.
         iii. Normal to mildly dilated atria.
         iv. Normal to mildly reduced ventricular function.
         v. Absence of severe pulmonary disease.
      c. The long-term efficacy of ablation therapy requires further study, especially with regard to clients with HF and structural heart disease.

FOLLOW-UP

A. AF clients should be comanaged with a physician.
B. AF that is resistant to routine therapy should always be followed by a cardiologist.
C. Lab monitoring as indicated by the client's anticoagulant and antiarrhythmic medications:
   1. CrCl for clients taking Pradaxa and Xarelto.
   2. INR for clients taking Coumadin. Multiple medications affect the anticoagulant property of Coumadin.
D. Follow-up is determined by client's needs, frequency of AF reoccurrence, and the presence of other medical conditions.
E. After defibrillator or pacemaker placement, monitor clients utilizing regular follow-up appointments and EKGs to identify failure of implanted device, thromboembolism, lead dislodgment, infection, and complicating arrhythmias.

EMERGENT ISSUES/INSTRUCTIONS

A. Clients should go to the ED if they have any of the following symptoms:
   1. Palpitations or a fluttering in their chest.
   2. Chest pain.
   3. Weakness or extreme tiredness.
   4. Shortness of breath (SOB) at rest or with activity.
   5. Dizziness.
   6. Disorientation.
   7. Confusion.
   8. Passing out or losing consciousness.
   9. Severe headache.
   10. Frequent urination or a compelling urge to urinate.
   11. Anxiety or panic symptoms.
   12. Sudden weakness in an arm or leg.
   13. Sudden change in vision.
   14. Trouble speaking or understanding others.
   15. If taking an anticoagulant and have any of the following symptoms:
      a. Nosebleed that will not stop with pressure.
      b. Coughing up blood.
B. Clients should contact the office if they are taking an anticoagulant medication and have any of the following symptoms:
   1. Vomiting or other illness causes them to miss more than one dose of their medications.
   2. Vomit that is bright red or dark and that looks like coffee grounds or grape jelly. ▶

3. Blood in their bowel movements that looks black or tarry in color.
4. Heavy periods.

C. Clients should contact the office if they are experiencing any new symptom(s) not present at their last office visit.

CONSULTATION/REFERRAL

A. If you suspect an acute cardiovascular episode, refer client for immediate hospitalization to initiate thrombolytic therapy, cardioversion, hypertensive management, and additional diagnostic testing.

B. Refer to cardiology as indicated by client's clinical situation, specifically the frequency of AF reoccurrence and the presence of other complex medical conditions.

C. AF that is resistant to routine therapy should always be followed by a cardiologist.

CAROTID ARTERY STENOSIS

DEFINITION

A. Carotid artery stenosis is the narrowing of one or both of the carotid arteries.

B. Classification of carotid artery stenosis:
1. Moderate:
   a. Less than 69% narrowing.
2. Severe:
   a. 70% to 99% narrowing.

INCIDENCE

A. Moderate carotid artery stenosis:
1. Prior to age 70: male, 4.8%; female, 2.2%.
2. After age 70: male, 12.5%; female, 6.9%.

B. Severe carotid artery stenosis:
1. All ages: both sexes: 1.7%.

C. Severe asymptomatic carotid artery stenosis:
1. After age 80: male, 3.1%; female, 0.9%.

PATHOGENESIS

A. As the human body ages, the artery walls become thicker and less flexible (atherosclerosis). The plaques, also known as atheromas, can develop on the interior artery wall. Over time, the buildup of plaque reduces blood flow to the brain. The arterial narrowing also increases the risk of thrombus formation and subsequent stroke risk.

PREDISPOSING FACTORS

A. Nonmodifiable factors:
1. Age:
   a. Male: increased risk prior to age 75.
   b. Female: increased risk after age 75.
2. Personal or family history of any of the following:
   a. Stroke.
   b. Angina.
   c. Myocardial infarction (MI).
   d. Peripheral arterial disease (PAD).

B. Modifiable factors:
1. Hypertension (HTN).
2. Hypercholesterolemia.
3. Diabetes mellitus.
4. Obesity.
5. Tobacco abuse.
6. Sedentary lifestyle.

COMMON COMPLAINTS

A. Asymptomatic carotid artery stenosis:
1. Often there are no symptoms.

B. Symptomatic carotid artery stenosis:
1. Focal neurologic symptoms, acute onset:
   a. Monoparesis or hemiparesis.
   b. Sensory alterations:
      i. Paresthesias.
   c. Speech disturbance:
      i. Expressive aphasia.
      ii. Receptive aphasia.
      iii. Changes in speech pattern or vocal quality (dysprosody).
   d. Visual changes:
      i. Blurred vision.
      ii. Blindness in one eye, partial or complete.
      iii. Visual field loss: specifically contralateral homonymous hemianopsia.
      iv. Dimming of vision.
   e. Constructional apraxia (i.e., inability to perform purposeful movements).
2. Vertigo and syncope are symptoms not generally caused by carotid artery stenosis.

POTENTIAL COMPLICATIONS

A. Cerebrovascular accident (CVA).

B. Transient ischemic attack (TIA).

C. Death.

D. Comorbidities that increase complication risk:
1. Age: older than 80 years.
2. New York Heart Association (NYHA) III or IV heart failure (HF).
3. Left ventricular ejection fraction (LVEF): less than 30%.
4. Class III or IV angina pectoris.
5. Coronary artery disease (CAD): left main coronary artery.
6. CAD: multivessel.
7. Planned cardiac surgery within 30 days.
8. History of MI within 4 weeks.
9. Severe chronic lung disease (e.g., chronic obstructive pulmonary disease [COPD], bronchitis, emphysema, asthma).

SUBJECTIVE DATA

A. Ask client to describe any new neurologic symptoms.
  1. Further determine the frequency, intensity, and duration of the symptoms.
B. Ask client to list all medications currently being taken, including over-the-counter (OTC) substances.

PHYSICAL EXAMINATION

A. Clients presenting with acute neurologic symptoms indicative of a stroke (e.g., paresis, speech or swallowing difficulty, visual field loss) should be quickly assessed for the need to call emergency services/911 for immediate transport to the hospital.
B. Check vital signs: blood pressure (BP), pulse, and respirations.
C. Inspect:
  1. Inspect overall physical appearance, noting any distress.
  2. Eyes: Assess papillary reflex bilaterally and perform a funduscopic exam, noting arterial occlusions or ischemic retinal damage.
D. Auscultate:
  1. Neck: carotid bruits, bilaterally:
    a. Studies have shown that carotid bruits have a poor predictive value in asymptomatic clients but are more indicative of CAD. However, the presence of a bruit should still be documented.

DIAGNOSTIC TESTS

A. Noninvasive testing:
  1. Carotid Doppler/duplex ultrasound.
  2. Carotid magnetic resonance angiogram (MRA).
  3. CT angiography (CTA).
B. Invasive testing:
  1. Cerebral angiography with contrast:
    a. **The gold standard for determination of carotid artery stenosis.**

DIFFERENTIAL DIAGNOSES

A. Monoparesis:
  1. TIA.
  2. CVA/stroke.
  3. Multiple sclerosis.
  4. Separated shoulder.
  5. Fractured limb.
B. Hemiparesis:
  1. TIA.
  2. CVA/stroke.
  3. Multiple sclerosis.
  4. Spinal tumor.
C. Sensory alterations (paresthesias):
  1. TIA.
  2. CVA/stroke.
  3. Peripheral neuropathy.
  4. Cervical spinal stenosis.
  5. Lead poisoning.
  6. Lyme disease.
  7. Wernicke syndrome.
  8. Multiple sclerosis.
D. Speech disturbance (aphasia):
  1. TIA.
  2. CVA/stroke.
  3. Myasthenia gravis.
  4. Brain tumor.
E. Speech disturbance (speech pattern or vocal quality; e.g., dysprosody):
  1. TIA.
  2. CVA/stroke.
  3. Brain tumor.
F. Visual changes:
  1. TIA.
  2. CVA/stroke.
  3. Retinal detachment.
  4. Ocular migraine.
  5. Cataracts.
  6. Giant cell arteritis.
  7. HTN.
  8. Macular degeneration.
  9. Sarcoidosis.
  10. Glaucoma.
  11. Brain tumor.
G. Constructional apraxia:
  1. TIA.
  2. CVA/stroke.
  3. Brain tumor.

PLAN

A. General interventions:
  1. The goal of therapy is to improve the client's quality of life by reducing morbidity and prolonging survival.
  2. The estimated risk of stroke within 5 years when utilizing medical management is 11.8% versus the risk of perioperative death, which is 6.4%.
B. Client teaching:
  1. Educate client about modifying controllable risk factors such as HTN, diabetes, hypercholesterolemia, obesity, tobacco abuse, and sedentary lifestyles.
  2. If known carotid artery stenosis is present:
    a. Make sure client is aware of signs and symptoms of TIA and stroke.
    b. Make sure client knows to seek medical attention or dial 911 if signs and symptoms occur.
C. Dietary management:
  1. Counsel client regarding appropriate change to their diet (e.g., low-fat, low-cholesterol, and low-sodium diet if applicable).
  2. Reinforce teaching with nutrition/diet handouts.
  3. Consider referral to a registered dietitian.
D. Pharmaceutical therapy:
  1. Antiplatelet therapy:
    a. Aspirin:
      i. Taken prior to carotid endarterectomy (CEA) surgery and for at least 3 months postoperatively.
      ii. Dosage: 81 to 325 mg/d.
      iii. Use caution when prescribing higher dose aspirin therapy in older adults. See geriatrics discussion under the "Individual Considerations" section.
  2. Additional pharmaceutical therapies:
    a. Hypertensive therapy:
      i. BP goal: less than 140/90.
    b. Hyperlipidemia therapy:
      i. Low-density lipoprotein cholesterol (LDL-C) goal (primary): less than 100 mg/dL.
      ii. LDL-C goal (secondary): less than 70 mg/dL.
    c. Tobacco cessation therapy.
E. Surgical therapies:
  1. CEA:
    a. Goal of therapy: stroke risk reduction.

b. Preferred clinical characteristics:
i. Recent TIA or CVA within 6 months and ipsilateral stenosis between 70% and 99% (severe):
1) CEA is recommended.
2) Morbidity/mortality: less than 6%.
ii. Recent TIA or CVA within 6 months and ipsilateral stenosis between 50% and 69% (moderate):
1) CEA is recommended after analysis of other factors that include age, gender, and comorbidities.
2) Morbidity/mortality: less than 6%.
iii. Ipsilateral stenosis less than 50%:
1) No indication for CEA surgery.
c. Pharmaceutical therapy and CEA:
i. Aspirin:
1) Recommendations: Take prior to CEA surgery and for at least 3 months postoperatively unless contraindicated.
2) Dosage: 81 to 325 mg/d.
ii. Other available antiplatelet agents do not have standardized dosage or frequency regimens established for postoperative CEA clients.

2. Carotid angioplasty/stenting (CAS):
a. Goal of therapy: stroke risk reduction.
b. Preferred clinical characteristics:
i. Symptomatic clients with stenosis less than 70% as determined by noninvasive imaging or less than 50% as determined by conventional contrast angiography.
ii. Symptomatic clients with stenosis greater than 70% in which surgical access via CEA would be difficult or history indicates an increased complication risk (e.g., radiation-induced stenosis and restenosis of a prior CEA).
iii. Ipsilateral stenosis less than 50%:
1) No indication for CAS surgery.
c. Pharmaceutical therapy and CAS:
i. Acetaminophen (aspirin):
1) Recommendations: Take prior to CEA surgery and for at least 3 months postoperatively unless contraindicated.
2) Dosage: 81 to 325 mg/d.
ii. Clopidogrel (Plavix):
1) Recommendations: 300 mg loading dose on operative day and 75 mg/d after stenting.
iii. Other available antiplatelet agents do not have standardized dosage or frequency regimens established for postoperative CAS clients.

3. Contraindications to carotid surgery:
a. Chronic total occlusion of the stenosed artery.
b. Clients with severe disability related to prior CVA.

FOLLOW-UP

A. Follow-up with cardiology and vascular surgery is determined by client's needs and the presence of other medical conditions.

EMERGENT ISSUES/INSTRUCTIONS

A. Clients presenting with acute neurologic symptoms indicative of a stroke (e.g., paresis, speech or swallowing difficulty, visual field loss) should be quickly assessed for the need to call emergency services/911 for immediate transport to the hospital.

CONSULTATION/REFERRAL

A. Referral to a registered dietitian is indicated for additional teaching regarding dietary modifications.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:
1. Beers criteria: aspirin cautions:
a. Use aspirin with caution in older adults over age 80 with no history of cardiovascular disease (CVD): There is no clear evidence that aspirin provides primary prevention for cardiac events, but there is a risk for gastrointestinal (GI) bleeds. The routine use of aspirin as primary prevention is not recommended.
b. In adults 65 and older, avoid use of greater than 325 mg of aspirin due to risk of GI bleed, unless other alternatives are not effective and the client can take a gastroprotective agent.
c. In older adults more than 75 years old, or adults older than 65 taking corticosteroids, anticoagulants, or antiplatelet agents, there is an increased risk of upper GI bleeds. The use of proton pump inhibitors (PPIs) reduces but does not eliminate risk.
d. The risk of GI bleed increases with duration of use of nonsteroidal anti-inflammatory drugs (NSAIDs), including high-dose aspirin (ASA). At 1 year, the risk is 2% to 4%, and this increases with each subsequent year.

CHEST PAIN

DEFINITION

A. Chest pain is a localized sensation of distress or discomfort that may or may not be associated with actual tissue damage.

INCIDENCE

A. Chest pain is one of the most common complaints of adult clients. Causes can range from minor disorders to life-threatening diseases, so every client must be assessed carefully.

PATHOGENESIS

A. Cardiac etiology: ischemia, atherosclerosis, inflammation, or valvular problems due to angina, myocardial infarction (MI), pericarditis, endocarditis, dissecting aortic aneurysm, or mitral valve prolapse (MVP; see Table 13.3).
B. Musculoskeletal etiology: muscle strain and inflammation due to costochondritis, chest wall syndrome, cervicodorsal arthritis, or intercostal myositis.

TABLE 13.3 COMPARISON OF COMMON CHEST PAIN ETIOLOGIES

Condition	Pain Findings	Associated Symptoms	Precipitating Factors	Relieving Factors	Physical Findings	Diagnostic Tests	Treatment Modalities
Cardiac stable angina	Substernal, tight, and dull pressure, usually lasts longer than 15 minutes		Exertion, cold, emotional stress	Rest, nitroglycerin, Valsalva maneuver	Sinus tachycardia, bradycardia, xanthomas, signs of HF	Resting EKG, stress EKG, cardiac enzymes, echo, angiogram	ASA, BB, nitrates, CCB
Prinzmetal angina (variant)	Substernal, achy, tight, and dull pressure		Often occurs at rest; may awaken from sleep	Nitroglycerin	Same as stable angina	Resting EKG, angiogram	ASA, nitrates, CCB
MI	Precordial, substernal, severe, crushing, squeezing, lasts >15 minutes	Dyspnea, sweating, dizziness, radiation to neck/arm/jaw, N&V, cough, fever, unstable V/S	Oxygen	Not relieved by nitroglycerin	S3 or S4 murmur, tachycardia, bradycardia pericardial friction rub, hyper/hypotension	EKG, serial CK enzymes, echo, radionuclide studies	Analgesia, reperfusion, prevention, and treatment complications limit infarcts Thrombolytic therapy for acute MI
MVP	Usually not substernal, often knifelike, may last 1–3 hours	Palpitations, fatigue, light-headed, arrhythmia, syncope		Recumbent position, BB, nitroglycerine	Midsystolic click and/or murmur, thin body status, SOB	Echo, EKG	Usually none, BB if palpitations or ventricular ectopy becomes disabling
Hypertrophic cardiomegaly	Similar to angina	Dyspnea with exertion, arrhythmia, light-headed, syncope	May be increased by nitroglycerin, exertion	BB, squatting	Systolic murmur, increased upright position, Valsalva maneuver, more forceful PMI	EKG, CXR, echo, Doppler, cardiac catheterization	BB, CCB, possible pacing and myomectomy, exercise restriction
Pericarditis	Retrosternal, sharp or dull, sudden onset, long duration, radiates to one side of the trapezius	Fever, myalgia, anorexia, anxiety, recent viral infection		Sitting up, leaning forward	Friction rub, SVT1, tachypnea, crackles, signs of cardiac tamponade	EKG, echo, CBC, ESR	Hospitalize, rule out purulent process, analgesics

(*continued*)

TABLE 13.3 COMPARISON OF COMMON CHEST PAIN ETIOLOGIES (*CONTINUED*)

Condition	Pain Findings	Associated Symptoms	Precipitating Factors	Relieving Factors	Physical Findings	Diagnostic Tests	Treatment Modalities
Endocarditis	Usually dull, retrosternal, may radiate to back	Fever, night sweats, joint pain, back pain, weight loss, headache, murmur			Systolic–diastolic murmur, petechiae, Osler modes, Roth spots, neck vein distension, pleural or pericardial rub, pain in extremities, splenomegaly, hematuria	CBC, ESR, blood cultures, echo	Hospitalization, for antibiotic therapy
GI esophageal spasm	May be identical to angina		Alcohol or cold liquids	May be relieved by nitroglycerin		Esophageal manometry	Nitroglycerin, anticholinergics, esophageal dilation
Esophagitis	Burning, tightness	Heartburn, water brash	Overeating, alcohol, recumbent position	Antacids	May have slight to moderate epigastric tenderness	Esophagoscopy	Lifestyle modification, antacid, H2 blocker, PPI, promotility agent
Musculoskeletal costochondritis	Sharp, sometimes pleuritic, parasternal costochondral pain		Sneezing, cough on deep inspiration, twisting motions, reaching overhead		Erythema at sites of tenderness, positive pinpoint tenderness at costochondral junctions	CXR to rule out other causes	NSAIDs, ASA, ibuprofen, naproxen, heat application

ASA, aspirin; BB, beta-blocker; CBC, complete blood count; CCB, calcium channel blocker; CK, creatine kinase; CXR, chest x-ray; ESR, eosinophilic sedimentation rate; GI, gastrointestinal; HF, heart failure; MI, myocardial infarction; MVP, mitral valve prolapse; NSAIDs, nonsteroidal anti-inflammatory drugs; N&V, nausea and vomiting; PMI, point of maximal impulse; PPI, proton pump inhibitor; SOB, shortness of breath; SVT, supraventricular tachycardia; V/S, vital signs

C. Neurologic etiology: nerve inflammation and/or compression due to herpes zoster and nerve root compression.
D. Gastrointestinal (GI) etiology: structural defects, inflammation, or infection due to gastroesophageal reflux disease (GERD), hiatal hernia, esophageal spasm, pancreatitis, cholecystitis, or peptic ulcer disease (PUD).
E. Pleural etiology: inflammation, distension, or compression of pleural membranes due to pneumonia, pulmonary embolus, pulmonary hypertension (HTN), spontaneous pneumothorax, and lung and mediastinal tumors.
F. Psychogenic etiology: stress due to anxiety, depression, or panic disorders.

PREDISPOSING FACTORS

A. These vary depending on the etiology of pain.

COMMON COMPLAINTS

A. Primary complaint: pain somewhere in the chest.
B. "Levine sign": placing the fist to the center of the chest to demonstrate pain.
C. Fatigue.
D. Cough.
E. Indigestion.
F. Dyspnea.
G. Syncope.
H. Palpitations.
I. Profound fatigue.

OTHER SIGNS AND SYMPTOMS

A. Pain may be typical of angina and MI.
B. Musculoskeletal pain may be relieved by position change, aggravated by body movement, reproducible, or caused by injury or trauma.
C. Neurologic pain is associated with skin lesion if herpes zoster is the causative agent.
D. GI pain may be associated with meals, certain positions, belching, or an acid "brash" taste in mouth, or it may be referred to other sites.
E. Pleural pain is usually accompanied by cough, upper respiratory infection (URI) symptoms, or shortness of breath (SOB).
F. Psychogenic pain or pressure along with SOB and dizziness may be associated with a specific event or time.

SUBJECTIVE DATA

A. How long has the client had chest pain?
B. Has the client ever been treated for chest pain? What treatments, tests, and medications (such as nitroglycerin) were used?
C. What precipitates and relieves the client's chest pain?
  1. Precipitating factors: exertion, taking a deep breath, eating, cold, stress, and sexual intercourse.
  2. Alleviating factors: resting, eating, taking an antacid, taking nitroglycerin, and positional change.
D. Inquire about the characteristics of pain.
  1. Location: neck, throat, chest, epigastric area, and shoulder.
  2. Radiation: neck, throat, shoulder, lower jaw, and upper extremity.
    a. **Radiation to one or both arms is a predictor of acute MI.**
    b. **Chest pain that radiates between the scapulae may be due to aortic dissection.**
  3. Quality: squeezing, pressure, strangling, fullness, heavy weight, tightening, constriction, and ripping/tearing (acute aortic dissection).
  4. Intensity: abrupt onset, gradually getting worse, dull, or insidious.
  5. Duration: seconds, minutes, hours, or years.
  6. Frequency: intermittent, occurs every morning/evening.
E. Are other associated symptoms present?
F. Discuss any risk factors the client may have for cardiac disease: smoking, hyperlipidemia, HTN, sedentary lifestyle, diabetes, and family history.
G. Review medical history as noted earlier.
H. Review all medications, including prescription (such as sildenafil), over-the-counter (OTC), and herbal products.
I. Review recreational/illicit drug use.
J. Inquire about any new physical labor if musculoskeletal etiology is suspected.
K. Has the client had any trauma (including domestic violence)?
L. Has the client had a recent infection?

PHYSICAL EXAMINATION

A. Check temperature (if infection is suspected), pulse, respirations, blood pressure (BP), and pulse oximetry.
B. Inspect:
  1. Inspect general appearance:
    a. Appearance of discomfort/distress.
    b. Any appearance of respiratory distress.
    c. Evaluate jugular venous distention (JVD).
    d. Note client position: sitting, lying, squatting. Relief of chest pain with recumbency suggests MVP; relief with squatting suggests hypertrophic cardiomyopathy. Noncardiac chest pain may be present along with cardiac chest pain.
  2. Inspect skin for diaphoresis, jaundice, pallor, herpes zoster lesions, rash, or cyanosis.
  3. Inspect the chest wall for herpes zoster lesions or signs of trauma.
  4. Inspect eyes by performing funduscopic exam.
  5. Inspect legs for signs of phlebitis: unilateral swelling, cyanosis, venous stasis, and diminished pulses.
  6. Inspect neck for enlarged thyroid and lymph nodes, midline trachea, and JVD.
C. Palpate:
  1. Palpate chest wall for tenderness and swelling. Chest pain present in only one body position is usually not cardiac in origin.
  2. Palpate abdomen for masses, tenderness, bounding pulses, organomegaly, and ascites.
  3. Palpate femoral and distal pulses.
D. Auscultate:
  1. Auscultate carotid arteries for bruits.
  2. Auscultate lungs for crackles, wheezes, equal breath sounds, and pleural rub.
  3. Auscultate abdomen for bruits and bowel sounds.
  4. Auscultate heart for murmurs, rubs, clicks, irregularities, or extra sounds.
E. Perform neurologic exam:
  1. Perform this exam if neurologic etiology is suspected.

DIAGNOSTIC TESTS

A. Testing depends on information collected in the exam. A normal physical exam, EKG, and/or lab test results in a client with chest pain does not rule out coronary heart disease (CHD). Typical tests include the following:
  1. EKG.
  2. Chest radiography, whenever diagnosis of chest pain is not clear.
  3. Echocardiogram.

▶

4. Stress test.
5. Cardiac catheterization.
6. Barium tests.
7. Endoscopy to rule out GI etiology.
8. Esophageal pH, low.
9. Lab tests:
   a. Troponin I or T.
   b. Myoglobin.
   c. Creatine kinase (CK).
   d. Creatine kinase-muscle/brain (CK-MB) isoenzyme: may be useful if the initial troponin determination is abnormal for suspected reinfarction.
   e. C-reactive protein (CRP).
   f. B-type natriuretic peptide (BNP) for clinical findings/risk of heart failure.
   g. D-dimer for suspected venous thrombotic event (deep vein thrombosis [DVT] or pulmonary embolism [PE]).

DIFFERENTIAL DIAGNOSES

A. Cardiac causes:
1. CHD:
   a. Acute MI: chest pain lasting more than 15 minutes.
   b. Unstable angina pectoris.
   c. Stable angina pectoris.
   d. Prinzmetal, or variant, angina.
2. Valvular heart disease:
   a. MVP.
   b. Aortic stenosis.
3. Cardiomyopathies:
   a. Hypertrophic.
   b. Dilated.
   c. Restrictive.
4. Pericarditis.
5. Endocarditis.
6. Aortic dissection.

B. Noncardiac causes:
1. Pulmonary causes:
   a. Pneumonia.
   b. Pleurisy.
   c. PE.
   d. Pulmonary HTN.
   e. Pneumothorax.
   f. Tracheobronchitis.
   g. Lung cancer.
2. GI causes:
   a. GERD.
   b. Esophageal spasm.
   c. PUD.
   d. Pancreatitis.
   e. Cholecystitis.
   f. Flatulence.
3. Rheumatology causes:
   a. Fibromyalgia.
   b. Costochondritis.
   c. Arthritis.
4. Chest wall causes:
   a. Rib fracture.
   b. Muscle strain.
   c. Cervical or thoracic spine disease.
   d. Metastatic bone disease.
   e. Breast conditions.
5. Neurologic causes:
   a. Herpes zoster.
   b. Postherpetic pain syndrome.
   c. Nerve root compression.
6. Psychogenic causes:
   a. Panic disorder.
   b. Generalized anxiety.
   c. Depression.
   d. Somatoform disorders.

PLAN

A. General interventions:
1. Direct management toward primary disorder causing the symptom.

C. Client teaching:
1. Teach the client about medications.
2. Encourage CPR training for the client's family and/or close friends for clients with coronary artery disease (CAD).
3. Explain to the client and their family when and how to call 911 and the importance of going to the ED immediately so that thrombolytic therapy can be considered. A positive response to nitroglycerin does not confirm the presence of CAD.

D. Pharmaceutical therapy:
1. Cardiac pain: nitroglycerin.
2. GI pain: H2 blocker and proton pump inhibitors (PPIs).
3. Musculoskeletal pain: nonsteroidal anti-inflammatory drugs (NSAIDs).
4. Psychogenic pain:
   a. Selective serotonin reuptake inhibitors (SSRIs).
   b. Tricyclic antidepressants (TCAs).
   c. Benzodiazepines.

FOLLOW-UP

A. Follow clients with CAD for an indefinite period of time to detect the recurrence or progression of disease.
B. Other follow-up depends on the etiology of chest pain.

EMERGENT ISSUES/INSTRUCTIONS

A. Refer clients exhibiting signs or symptoms of acute MI or aortic dissection to the closest ED and/or call 911.
B. Refer clients with hemodynamic instability to the closest ED and/or call 911.

CONSULTATION/REFERRAL

A. Consult a physician when chest pain is cardiac in origin. If a cardiac origin is found in a pregnant client, schedule a cardiology consultation as soon as possible for comanagement.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
1. Evaluate chest pain in the same manner as in nonpregnant clients.
2. Rule out pregnancy-induced hypertension (PIH) and HELLP (hemolysis, elevated liver enzymes, low platelets) syndrome when a third-trimester client presents with upper epigastric/chest pain.

B. Geriatrics:
1. Frail elderly clients often do not present with the "typical" symptom complex of chest pain. Frequently, the only symptoms of acute MI are lethargy, decreased level of consciousness (LOC), crackles, congestive heart failure (CHF), persistent cough, or hypotension.
2. The following signs and symptoms may be the primary presentation in the frail older person for many acute illness states:
   a. Confusion.
   b. Self-neglect.

▶

c. Falling.
d. Incontinence.
e. Apathy.
f. Anorexia.
g. Dyspnea.
h. Fatigue.

3. Prescribe medications for frail elderly clients based on their creatinine clearance and then slowly taper upward to the desired effect.

4. Assess for polypharmacy (considered to be greater than five to nine medications consumed on a daily basis) and medication interactions; side effects may account for or worsen many of the symptoms and geriatric syndromes described previously (refer to the "Polypharmacy" and "Deprescribing" sections of Chapter 3).

CHRONIC VENOUS INSUFFICIENCY AND VARICOSE VEINS

DEFINITION

A. Peripheral vascular disease (PVD) is a general term that encompasses all occlusive or inflammatory diseases that occur within the peripheral arteries, veins, and lymphatics. These conditions include peripheral arterial disease (PAD), deep vein thrombosis (DVT), superficial thrombophlebitis, lymphedema, and chronic venous diseases. Chronic venous diseases include chronic venous insufficiency (CVI) and varicose veins.

INCIDENCE

A. CVI:

1. It is estimated that six to seven million adults in the United States have CVI. CVI is twice as common in females as in males.

2. Peak incidence is seen in females over 50 years of age.

3. CVI is the most common cause of the 2.5 million leg ulcerations in the United States.

B. Varicose veins:

1. More than 24 million Americans have varicose veins. They are usually thought to be more common in females; however, there is a higher incidence in males, especially African American males.

PATHOGENESIS

A. CVI: Venous insufficiency is caused by dysfunctional valves that allow valvular reflux and subsequently venous hypertension (HTN) and impaired circulation. In CVI, persistent ambulatory venous HTN leads to obstruction of venous flow, which produces local tissue anoxia, inflammation, and at times even tissue necrosis. This process eventually causes subcutaneous fibrosing panniculitis and additional venous and lymphatic outlet obstruction.

B. Varicose veins: Varicose veins are a form of CVI. The same dysfunctional valves that cause valvular reflux and subsequently venous HTN in CVI also cause varicose veins. This influx of volume and pressure causes the vessel walls to weaken, causing the veins to dilate, elongate, twist, and bulge.

PREDISPOSING FACTORS

A. CVI:

1. Age >30 years.
2. Sex, being female.
3. Prolonged standing or sitting.
4. History of DVT.
5. Stature, more common in tall persons.
6. Obesity.
7. Sedentary lifestyle.
8. Family history.
9. History of multiple pregnancies.
10. HTN.

B. Varicose veins:

1. Genetics:
a. Risk increases to 90% if both parents have varicose veins.
b. If one parent is affected, the risk increases by 25% for males and 62% for females.
2. Age.
3. Pregnancy.
4. Prolonged standing.
5. Restrictive clothing.
6. Obesity.
7. Ligamentous laxity:
a. History of hernia(s).
b. Flat feet.
8. Smoking.
9. History of superficial or deep vein clots.

COMMON COMPLAINTS

A. CVI:

1. Extremity edema.
2. Pain worse when standing, usually dull, aching, or cramping.
3. Pain improved with elevation.
4. Itching sensation.
5. Feeling of heaviness in extremity.
6. Hyperpigmentation.
7. Thickening and hardening of the skin.
8. Ulcerations.

B. Varicose veins:

1. Pain, usually burning, aching, or itching.
2. Blue veins that protrude above the surface of the skin.
3. Leg fatigue.
4. Edema.
5. Symptoms worsening toward the end of the day.
6. Leg heaviness.

POTENTIAL COMPLICATIONS

A. CVI:

1. Cellulitis.
2. Peripheral neuropathy.
3. Varicose veins.
4. Abscess.
5. Ulceration.
6. Stasis dermatitis.
7. DVT.

▶

B. Varicose veins:
- **1.** Stasis dermatitis.
- **2.** Stasis ulceration.
- **3.** Petechial hemorrhage.
- **4.** Chronic edema.
- **5.** Superficial thrombophlebitis.
- **6.** Hyperpigmentation.
- **7.** Eczema.
- **8.** DVT.

SUBJECTIVE DATA

A. Ask client when the symptom(s) were first noticed.
B. Have client describe duration of symptoms.
C. Ask client to describe pain, for example, crushing, stabbing, or burning.
D. Ask the client what makes the symptoms better and what makes them worse.
E. Have client rate pain on a scale of 0 to 10, with 0 being no pain.
F. Ask client to list all medications currently being taken, particularly substances not prescribed and illicit drugs such as cocaine.
G. Review recent history of invasive procedures or surgery.
H. Review medical history for heart disease, diabetes, HTN, and DVT.
I. Ask client if they have an increase in the size of lower extremities after being on their feet. Discern if one leg is worse than the other.

PHYSICAL EXAMINATION

A. CVI:
- **1.** Check vital signs.
  - a. Check blood pressure (BP) and document resting heart rate, respirations, temperature (if indicated), height, and weight.
- **2.** Inspect:
  - a. Inspect extremity for edema, hyperpigmentation, erythema, difference in temperature.
  - b. Inspect and document any varicosities.
- **3.** Palpate:
  - a. Palpate distended veins, noting tenderness.
  - b. Perform the cough impulse test to determine turbulent retrograde flow.
  - c. Perform the tap test to determine if the great saphenous vein is distended with blood.
- **4.** Auscultate:
  - a. Auscultate the heart: rate, rhythm, heart sounds, murmur, and gallops.
  - b. Auscultate lungs: lung sounds in all fields.
- **5.** Clinical, Etiology, Anatomy, and Pathophysiology (CEAP) clinical classification of CVI made based on the following:
  - a. Class C0: no visible signs of venous disease.
  - b. Class C1: telangiectasis or reticular veins (e.g., small visible blood vessels with no protrusion).
  - c. Class C2: visible varicose veins.
  - d. Class C3: edema without skin changes noted.
  - e. Class C4: skin discoloration/pigmentation.
  - f. Class C5: healed venous ulceration.
  - g. Class C6: active venous ulceration.

B. Varicose veins:
- **1. Clients presenting with any of the following should be quickly assessed for the need to call emergency services/911 for immediate transport to the hospital:**
  - a. **A bleeding varicosity with eroded surrounding skin.**
  - b. **A varicosity that has bled and is at risk for bleeding again.**
  - c. **An ulceration that is worsening and/or painful despite treatment.**
- **2.** Check vital signs.
  - a. Check BP and document resting heart rate, respirations, temperature (if indicated), height, and weight.
- **3.** Inspect:
  - a. Inspect skin for superficial veins that are raised above the skin's surface; client should be standing.
  - b. Inspect extremity for edema, hyperpigmentation, and eczema.
- **4.** Palpate:
  - a. Palpate distended veins, noting tenderness.
- **5.** Auscultate:
  - a. Auscultate heart: rate, rhythm, heart sounds, murmur, and gallops.
  - b. Auscultate lungs: lung sounds.
- **6.** CEAP clinical classification of varicose veins made based on the following:
  - a. Class C0: no visible signs of venous disease.
  - b. Class C1: telangiectasis or reticular veins (e.g., small visible blood vessels with no protrusion).
  - c. Class C2: visible varicose veins.
  - d. Class C3: edema without skin changes noted.
  - e. Class C4: changes in skin and subcutaneous tissue.
    - i. Class C4A: pigmentation or eczema.
    - ii. Class C4B: lipodermatosclerosis (panniculitis) or atrophie blanche.
  - f. Class C5: healed venous ulceration.
  - g. Class C6: active venous ulceration.

DIAGNOSTIC TESTS

A. CVI:
- **1.** Trendelenburg test.
- **2.** Perthes test.
- **3.** Doppler ankle–brachial index (ABI).
- **4.** Duplex venous ultrasound.

B. Varicose veins:
- **1.** Trendelenburg test.
- **2.** Perthes test.
- **3.** Duplex venous ultrasound.

DIFFERENTIAL DIAGNOSES

A. CVI:
- **1.** DVT.
- **2.** Ulceration.
- **3.** Infection.
- **4.** Peripheral artery disease (PAD).
- **5.** Varicose veins with risk of hemorrhage.

B. Varicose veins:
- **1.** Arthritis.
- **2.** Peripheral neuritis.
- **3.** Nerve root compression.
- **4.** Telangiectasia.
- **5.** DVT.
- **6.** Inflammatory liposclerosis.

PLAN

A. General prevention of CVI and varicose veins:
- **1.** Avoid prolonged standing or sitting. ▶

2. Exercise on a regular basis.
3. Encourage smoking cessation, weight loss, and exercise, if applicable.
4. Encourage strategies to better manage other chronic medical conditions that directly affect the progression of PAD, that is, diabetes, dyslipidemia, obesity, and HTN.

B. CVI:
1. Nonpharmaceutical therapy:
   a. Extremity elevation.
   b. Compression stockings.
   c. Exercise.
   d. Venous ulcerations treated with wound care and compression therapy.
      i. Compression therapy is the primary mode of management and has demonstrated venous ulcer healing rates as high as 97%.
2. Pharmaceutical therapy:
   a. Diuretics: management of edema, short-term administration:
      i. Hydrochlorothiazide.
   b. Antiplatelet: may increase the speed of healing to ulcerations:
      i. Aspirin: 325-mg tablet.
         1) Beers criteria caution:
            a) Use aspirin with caution in adults older than age 80 with no history of cardiovascular disease (CVD): There is no clear evidence that aspirin provides primary prevention for cardiac events, but there is a risk for gastrointestinal (GI) bleeds.
            b) In adults 65 and older, avoid use of greater than 325 mg due to risk of GI bleed, unless other alternatives are not effective and the client can take a gastroprotective agent.
            c) In adults older than 75 years, or adults older than 65 taking corticosteroids, anticoagulants, or antiplatelet agents, there is an increased risk of upper GI bleeds. The use of proton pump inhibitors (PPIs) reduces but does not eliminate risk. The risk of GI bleed increases with duration of use of nonsteroidal anti-inflammatory drugs (NSAIDs), including high-dose aspirin (ASA). At 1 year, the risk is 2% to 4% and this increases with each subsequent year.
   c. Systemic antibiotics: management of infection in persons demonstrating an increase in pain, erythema, or increase in size of ulceration.
3. Surgery:
   a. Venous ablation, for clients who continue to be symptomatic after 6 months of nonpharmacologic therapies. The types of ablation are chemical, thermal, and mechanical.

C. Varicose veins:
1. Client teaching: *See Client Teaching Guides for this chapter, "Chronic Venous Insufficiency" and "Varicose Veins."*
   a. If prolonged standing is required, shift weight from one leg to the other.
   b. Do not sit with legs dependent.
2. Nonpharmaceutical therapy:
   a. Extremity elevation.
   b. Compression stockings.
   c. Exercise.
3. Surgery:
   a. Radiofrequency ablation.
   b. Endovenous laser therapy.
   c. Phlebectomy.
   d. Sclerotherapy and foam sclerotherapy.
   e. Vein ligation and vein stripping.
   f. Valvuloplasty, valvuloconstruction, valve transplantation, and valve transposition.
   g. Subfascial endoscopic perforator surgery, Linton operation, and percutaneous ablation of perforators.

FOLLOW-UP

A. Follow-up is determined by client's needs, frequency and intensity of symptoms, and the presence of other medical conditions.
B. PVD manifesting persistent symptoms should always be followed by a cardiologist.

EMERGENT ISSUES/INSTRUCTIONS

A. Clients should go to the ED if they have any of the following symptoms:
1. **A bleeding varicosity with eroded surrounding skin.**
2. **A varicosity that has bled and is at risk for bleeding again.**
3. **An ulceration that is worsening and/or painful despite treatment.**
4. **A change in color of a foot or hand.**

B. Clients should contact the office if they are experiencing any of the following:
1. **Fever over 101°F.**
2. **Increased redness, pain, tenderness to touch, swelling, and/or warmth.**
3. **New wound or sore on the affected arm or leg.**
4. **If taking an antiplatelet therapy and have any of the following symptoms:**
   a. **Vomiting or other illness causes them to miss more than one dose of their medications.**
   b. **Vomit that is bright red or dark and looks like coffee grounds or grape jelly.**
   c. **Blood in their bowel movements that looks black or tarry in color.**

C. Clients should contact the office if they are experiencing any new symptom(s) not present at their last office visit.

CONSULTATION/REFERRAL

A. If you suspect acute limb ischemia (ALI), refer client for immediate hospitalization to obtain diagnostic testing to determine the presence of a thrombus and restore circulation to the affected extremity.
B. If chronic limb ischemia (CLI) has led to ulceration and/or superimposed infection, hospitalization is indicated to initiate wound care consultation and diagnostic testing to determine the degree of arterial occlusion.
C. Referral to a cardiologist is indicated in the presence of persistent PVD symptoms.
D. Referral to a podiatrist becomes necessary to trim toenails and assess client for properly fitting shoes.
E. Referral to pain management is indicated if pain is resistant to treatment.

INDIVIDUAL CONSIDERATIONS

A. Nonambulatory clients:
1. Using rocking chairs is a possible substitute for persons unable to participate in a walking program.

B. Geriatrics:

1. Compression stockings and elevating the legs are first-line treatments for lower extremity venous insufficiency in older adults.

2. Use of diuretics solely to reduce ankle edema requires a careful consideration of risks versus benefits. If the edema is not linked with serious harmful symptoms like rapid weight gain indicating decompensated congestive heart failure (CHF), respiratory compromise, or lower extremity infection such as cellulitis, the treatment itself may contribute to more harmful effects such as hypotension, incontinence, or dehydration.

3. Use caution when prescribing aspirin therapy in older adults. See the "Atrial Fibrillation" section of this chapter, under "Pharmaceutical Therapy"; see also Appendix C, Table C.1.

4. Be alert to signs and symptoms of depression related to immobility and pain.

DEEP VEIN THROMBOSIS

DEFINITION

A. Peripheral vascular disease (PVD) is a general term that encompasses all occlusive or inflammatory diseases that occur within the peripheral arteries, veins, and lymphatics. PVD includes deep vein thrombosis (DVT). DVT is a condition in which a thrombus forms in one or more veins. DVT greatly increases the risk of pulmonary embolism (PE).

INCIDENCE

A. The Centers for Disease Control and Prevention (CDC) estimates that as many as 900,000 Americans are diagnosed with a first-time DVT or PE annually and between 60,000 and 180,000 deaths annually are directly or indirectly attributed to DVT or PE.

B. The Vascular Disease Foundation states that approximately 5% of the world's population will have a DVT during their lifetime.

PATHOGENESIS

A. Changes within the venous system precipitate the formation of a DVT. These changes are formally called the Virchow triad. This triad includes hypercoagulability, venous stasis, and injury to the vessel wall. At least two of the triad must be present for a DVT to form. Essentially, an injury to the vessel wall causes inflammation that attracts platelets, especially in a state of altered coagulation. The thrombus that forms spreads in the direction of blood flow and additional layers of platelets are added to the thrombus as time progresses. As it grows, the vessel becomes further occluded and the client becomes symptomatic.

PREDISPOSING FACTORS

A. Age 60 years and older.
B. Hip or femur fracture.
C. Recent surgery, especially cardiac or extremity surgery.
D. Prolonged inactivity/immobility.
E. Pregnancy.
F. Medication:
  1. Hormone replacement therapy (HRT).
  2. Oral contraceptives.
  3. Tamoxifen.
G. Smoking.
H. Obesity.
I. Cancer.
J. Inherited hypercoagulable conditions.

COMMON COMPLAINTS

A. Note: Symptoms of a DVT are usually unilateral and have a sudden onset.
  1. Extremity edema.
  2. Extremity pain.
  3. Increased temperature of extremity.
  4. Change in color or extremity.
  5. Asymptomatic, depending on the size and location of the thrombus.

POTENTIAL COMPLICATIONS

A. PE.
B. Arterial embolism with arteriovenous shunting.
C. Myocardial infarction (MI).
D. Chronic venous insufficiency (CVI).
E. Postphlebitic syndrome.
F. Phlegmasia cerulea dolens.

SUBJECTIVE DATA

A. Ask client when the symptom were first noticed.
B. Have client describe duration of symptoms.
C. Ask client to describe pain (e.g., crushing, stabbing, or burning).
D. Ask the client what makes the symptoms better and what makes them worse.
E. Have client rate pain on a scale of 0 to 10, with 0 being no pain.
F. Ask client to list all medications currently being taken, particularly substances not prescribed and illicit drugs such as cocaine.
G. Review recent history of invasive procedures or surgery.

PHYSICAL EXAMINATION

A. Clients presenting with acute shortness of breath (SOB) and/or chest pain should be quickly assessed for the need to call emergency services/911 for immediate transport to the hospital.
B. Clients presenting with symptoms of DVT that include cyanosis of the distal extremity should be quickly assessed for the need to call emergency services/911 for immediate transport to the hospital.
C. Check vital signs.

▶

1. Check blood pressure (BP) and document resting heart rate, respirations, height, and weight.

D. Inspect:
1. Assess for signs of erythema, increased temperature, and edema.
2. Assess for a Homans sign (i.e., calf pain with forced plantar flexion).
3. Assess for Moses or Bancroft sign (i.e., pain when calf muscle is compressed forward against the tibia).
4. Assess Lisker sign (i.e., pain upon tibial percussion).

E. Palpate:
1. Palpate pulses distal to affected area, noting symmetry.
2. Palpate capillary refill.
3. Palpate extremity for tenderness. Do not perform deep palpation.

F. Auscultate:
1. Auscultate heart: rate, rhythm, heart sounds, murmur, and gallops.
2. Auscultate lungs: lung sounds in all fields.

DIAGNOSTIC TESTS

A. Serum laboratory testing:
1. D-dimer.
2. Complete blood count (CBC) with differential.
3. Coagulation panel (prothrombin time [PT], partial thromboplastin time [PTT], international normalized ratio [INR]).
4. Testing for idiopathic DVT: Add factor V Leiden, homocysteine, G20210A prothrombin, factor VIII, lupus anticoagulant, protein C and S levels, anticardiolipin antibodies, and antithrombin.

B. Compression ultrasound.

C. MRI, if thrombus is suspected in the pelvic veins or vena cava.

D. Venography, not utilized often due to expense and risk of phlebitis.

DIFFERENTIAL DIAGNOSES

A. DVT.
B. Cellulitis.
C. Fracture.
D. Lymphedema.
E. Congestive heart failure (CHF).
F. Vein compression (caused by enlarged lymph nodes or mass).
G. Filariasis.
H. Allergic reaction, localized.
I. Compartment syndrome.

PLAN

A. Client teaching: *See Client Teaching Guide for this chapter*, "*Deep Vein Thrombosis*":
1. Clients taking Coumadin should be educated regarding foods that are high in vitamin K.
2. Avoid prolonged standing or sitting.
3. Avoid crossing the legs.
4. Gradually resume normal activity.
5. Avoid immobility.
6. Exercise on a regular basis.
7. Stop smoking.
8. Wear compression stockings frequently.
9. Encourage strategies to better manage other chronic medical conditions that directly affect the progression of peripheral arterial disease (PAD), that is, diabetes, dyslipidemia, obesity, and hypertension (HTN).

B. Nonpharmaceutical therapy:
1. Compression stockings.

C. Pharmaceutical therapy:
1. Thrombolytics: administered in the inpatient setting.
2. Anticoagulants:
   a. Heparin, intravenous (IV): administered in the inpatient setting.
   b. Warfarin sodium (Coumadin; Jantoven):
      i. Doses: 1, 2, 2.5, 3, 4, 5, 6, 7.5 , and 10 mg tablets.
      ii. See the "Atrial Fibrillation" section for specifics on Coumadin therapy.
3. Low-molecular-weight heparin (LMWH):
   a. Enoxaparin sodium (Lovenox):
      i. Doses (multidose vial): 300 mg/3 mL.
      ii. Doses (prefilled syringe): 30 mg/0.3 mL, 40 mg/0.4 mL, 60 mg/0.6 mL, 80 mg/0.8 mL, 100 mg/mL, 120 mg/0.8 mL, and 150 mg/mL.
   b. Dalteparin sodium (Fragmin):
      i. Doses (multidose vial): 95,000 IU/9.5 mL.
      ii. Doses (by injection): 2,500 IU/0.2 mL, 5,000 IU/0.2 mL, 7,500 IU/0.3 mL, 10,000 IU/0.4 mL, 10,000 IU/mL, 12,500 IU/0.5 mL, 15,000 IU/0.6 mL, and 18,000 IU/0.72 mL.
4. Novel anticoagulants:
   a. Rivaroxaban (Xarelto):
      i. 2.5, 10, 15, and 20 mg tablets.
      ii. Dosage indications based on creatinine clearance (CrCl).
         1) CrCl >50 mL/min: 20 mg with evening meal.
         2) CrCl of 15 to 50 mL/min: 15 mg with evening meal.
   b. Apixaban (Eliquis):
      i. 2.5 and 5 mg tablets.
      ii. Dosage indications:
         1) Recommended dose is 2.5 mg, taken BID in clients who fit any of the following criteria:
            a) 80 years of age or older.
            b) Weight ≥60 kg (132 lbs).
            c) Serum creatinine ≥1.5 mg/dL.
   c. Edoxaban (Savaysa):
      i. 15, 30, and 60 mg tablets.
      ii. Dosage indications:
         1) CrCl between 15 and 50 mL/min: 30 mg, once daily.
         2) CrCl >95 mL/min: Do not prescribe.
   d. Betrixaban (Bevyxxa):
      i. 40 and 80 mg.
      ii. Initial dose of 160 mg, then maintenance dose of 80 mg daily, with the duration of therapy being 35 to 42 days.
5. Thrombin inhibitors:
   a. Bivalirudin (Angiomax): 250 mg per vial, add 5 mL of sterile water for injection; recommended IV bolus of 0.75 mg/kg followed by an infusion of 1.75 mg/kg/hr.
   b. Argatroban (Acova): 2 mcg/kg/min in constant infusion until PTT is 1.5 to 3 times the initial baseline PTT value.
   c. Dabigatran etexilate mesylate (Pradaxa):
      i. 75, 110, and 150 mg tablets.
      ii. Dosage indications based on CrCl:
         1) CrCl >30 mL/min: 150 mg, taken BID.
         2) CrCl of 15 to 30 mL/min: 75 mg, taken BID.
   d. Thrombate III (antithrombin III).
6. Specific factor Xa inhibitor:

a. Fondaparinux sodium (Arixtra):
i. Doses: 2.5 mg/0.5 mL, 5 mg/0.4 mL, 7.5 mg/0.6 mL, and 10 mg/0.8 mL by injection.

D. Surgery:
1. Insertion of vena cava filter to prevent PE.
2. Venous thrombectomy.

FOLLOW-UP

A. Follow-up is determined by client's needs, frequency and intensity of symptoms, and presence of other medical conditions.
B. DVT manifesting persistent symptoms should always be followed by a cardiologist.
C. Clients taking anticoagulants are best followed by an anticoagulant clinic and/or cardiologist.

EMERGENT ISSUES/INSTRUCTIONS

A. Clients should go to the ED if they have any of the following symptoms:
1. Sudden SOB.
2. Chest pain.
3. A change in color of a foot or hand.
4. If taking an anticoagulant and have any of the following symptoms:
a. **Nosebleed that will not stop with pressure.**
b. **Coughing up blood.**

B. Clients should contact the office if they are experiencing any of the following:
1. Fever over 101°F.
2. Increased redness, pain, tenderness to touch, swelling, and/or warmth.
3. New wound or sore on the affected arm or leg.
4. If taking an anticoagulant and have any of the following symptoms:
a. **Vomiting or other illness causes them to miss more than one dose of their medications.**
b. **Vomit that is bright red or dark and looks like coffee grounds or grape jelly.**
c. **Bright red blood in their stools, or black, tarry stools.**

C. Clients should contact the office if they are experiencing any new symptom(s) not present at their last office visit.

CONSULTATION/REFERRAL

A. If you suspect acute limb ischemia, refer client for immediate hospitalization to obtain diagnostic testing to determine the presence of a thrombus and restore circulation to the affected extremity.
B. If chronic limb ischemia has led to ulceration and/or superimposed infection, hospitalization is indicated to initiate wound care consultation and diagnostic testing to determine the degree of arterial occlusion.
C. Referral to a cardiologist is indicated in the presence of persistent PVD symptoms.
D. Refer to pain management if pain is resistant to treatment.
E. Refer to a registered dietitian as indicated by the client's understanding of dietary modification necessary to improve status of risk factors.

INDIVIDUAL CONSIDERATIONS

A. Nonambulatory clients:
1. Using rocking chairs is a possible substitute for persons unable to participate in a walking program.
B. Geriatrics:
1. Be alert to the following geriatric syndrome: depression related to immobility and pain.

HEART FAILURE

DEFINITION

A. Heart failure (HF) is failure of the heart to pump sufficient blood to meet the metabolic demands of the tissues. The 2017 focused update of the 2013 guidelines from the American College of Cardiology/American Heart Association (ACC/AHA) addresses management of heart failure with reduced ejection fraction (HFrEF) and heart failure with preserved ejection fraction (HFpEF). These guidelines include the following:
1. HFrEF:
a. Ejection fraction (EF) less than 40%, due to weak, inefficient systolic contractions. The left ventricular ejection fraction (LVEF) is a measurement of systolic failure.
b. S3 ventricular gallop rhythm commonly occurs.
c. Systolic failure is often the result of coronary heart disease (CHD) and/or myocardial infarction (MI).
d. It can result from right- or left-sided failure, or both.
2. HFpEF:
a. EF greater than 50%, but with poor compliance of the ventricle, which impedes ventricular diastolic filling (the ventricle is unable to relax).
b. There are two subgroups:
i. HFpEF borderline (or intermediate): clients with an EF of 41% to 49%.
ii. HFpEF with EF greater than 40% who previously had HFrEF (EF <40%), but improvement or recovery was noted in EF.
c. The client may be asymptomatic for years.
d. HF presents with the same symptoms of systolic failure, pulmonary congestion, and peripheral edema.
e. S4 atrial gallop rhythm commonly occurs.

INCIDENCE

A. HFrEF incidence is higher in older females, chronic hypertension (HTN), obesity, left ventricular (LV) hypertrophy, cardiomyopathy, excessive alcohol use, end-stage chronic obstructive pulmonary disease (COPD), valvular disorders, anemia, renal failure, atrial fibrillation (AF), coronary artery disease (CAD), or diabetes. ▶

B. Approximately 5.7 million people in the United States have HF. By the year 2030, the AHA estimates that there will be a 46% increase in HF in clients with chronic diseases.
C. Americans over 40 have a 20% lifetime risk of developing HF.
D. There are 650,000 new clients diagnosed yearly.
E. The 5-year mortality rate is 50% from the time of diagnosis and the 1-year mortality increases to 50% if the client has multiple admissions for HF in the same year.
F. There are one million hospitalizations per year, and according to the Centers for Medicare and Medicaid Services (CMS) the rate of readmissions within 1 month nationally is 23% to 25%.
G. The current cost to treat HF exceeds $30 billion yearly, and it is also estimated that the costs of direct client care (e.g., healthcare services, hospitalizations, medications) for these clients with chronic disease will increase to approximately $53 billion by the year 2030.

PATHOGENESIS

A. Injuries to the myocardium may cause loss of functioning muscle. Compensatory mechanisms, including cardiac hypertrophy and neurohumoral processes, lead to adverse long-term effects. An inotropic insult results in incomplete emptying (systolic failure), and a compliance abnormality results in incomplete filling (diastolic failure). Most HFs have some degree of both abnormalities.

PREDISPOSING FACTORS

A. Atherosclerotic heart disease.
B. MI.
C. Rheumatic heart disease involving mitral and aortic valves.
D. Cardiomyopathies.
E. Hypertensive heart disease.
F. Aortic stenosis or regurgitation.
G. Thyrotoxicosis.
H. Pregnancy-related disorders, such as multiple births with preexisting heart disease.
I. Volume overload.
J. Beta-blockers or other cardiac depressants.
K. Pulmonary embolism (PE).
L. Systemic infection.
M. Arrhythmias.
N. Renal disease.

COMMON COMPLAINTS

A. Clients are assigned the New York Heart Association (NYHA) classifications by their tolerance of physical activity and shortness of breath (SOB). This classification may change according to the progression or regression of their cardiovascular disease (CVD; Table 13.4).
B. Dyspnea on exertion.
C. Hemoptysis.
D. Fatigue.
E. Cough.
F. Orthopnea.
G. Edema/weight gain.
H. Paroxysmal nocturnal dyspnea.
I. Nausea.
J. Right upper abdominal pain or fullness.
K. Chest pain.
L. Palpitations.

TABLE 13.4 FUNCTIONAL CLASSIFICATION FOR HEART FAILURE

Functional Class	Activities	Objective Assessment
Functional capacity class I Objective assessment A	No limitation No undue fatigue, palpitation, dyspnea, or angina with ordinary activity	No objective evidence of CV disease
Functional capacity class II Objective assessment B	Slight limitations Fatigue, palpitation, SOB, and angina with ordinary physical activity	Objective evidence—minimal CV disease
Functional capacity class III Objective assessment C	Marked limitations No discomfort at rest Fatigue, palpitation, SOB, and angina with less than usual activities	Objective evidence—moderately severe CV disease
Functional capacity class IV Objective assessment D	Inability to do physical activity without discomfort Symptoms present at rest and become worse with activity	Objective evidence—severe CV disease

CV, cardiovascular; SOB, shortness of breath.

Source: Reprinted with permission from www.heart.org. ©1994 American Heart Association, Inc.

OTHER SIGNS AND SYMPTOMS

A. Hemoptysis.
B. Bibasilar crackles.
C. S3 gallop.
D. Murmurs.
E. Exercise intolerance.
F. Weakness.
G. Cough.
H. Orthopnea.
I. Nocturnal dyspnea.
J. Tachycardia.
K. Pallor.
L. Cyanosis.
M. Anorexia.
N. Constipation.
O. Jugular venous distention (JVD).
P. Hepatomegaly.
Q. Hepatojugular reflux (HJR).
R. Murmurs.
S. Exercise intolerance.

SUBJECTIVE DATA

A. Ask the client if they have difficulty breathing.
B. Ask how many pillows they sleep on. Does the client need to sit up in a recliner to sleep?
C. Inquire about how often they wake up at night with SOB.
D. Inquire about how far the client can walk without getting SOB. Have the client describe their routine activities of daily living and how well they tolerate each activity.
E. Discuss the client's history of heart disease, heart attack, HTN, or hyperlipidemia.

F. Ask the client about current medications, as well as prescription, over-the-counter (OTC), and herbal products.
G. Question the client regarding all symptoms found in the "Common Complaints" section.
H. Discuss drug and alcohol history.
I. Has the client ever been treated for cancer/chemotherapy, and how long ago?
J. What is the client's usual weight? Have they experienced more symptoms if they have pedal edema?
K. Does the client have a cough? (Consider angiotensin-converting enzyme inhibitors (ACEIs) as the cause.)

PHYSICAL EXAMINATION

A. Check pulse, respirations, blood pressure (BP), pulse oximetry, height, and weight.
1. Check BP sitting, standing, and lying down.
2. Be alert for abnormal vital signs: hypotension, narrow or wide pulse pressure, tachycardia, bradycardia, and tachypnea.
3. Calculate body mass index (BMI).
4. On all subsequent visits, note weight gain of more than 1 lb per day over 3 consecutive days or 3 lbs in 1 day.
B. Inspect:
1. Inspect overall physical appearance. Is the client in distress?
2. Inspect skin: Note pallor, cyanosis, and temperature.
3. Inspect neck: Check jugular veins for distension.
4. Inspect extremities: Note edema, cyanosis, pallor, and ulcers.
C. Palpate:
1. Palpate abdomen for hepatomegaly and HJR.
2. Palpate extremities for peripheral pulses.
3. Palpate chest wall for displaced point of maximal impulse (PMI), lifts, heaves, and thrills.
D. Auscultate:
1. Auscultate heart for murmurs; tachycardia; S1, S3, or S4 gallops; and other abnormalities.
2. Auscultate lungs: Note moderate-to-severe crackles/rales and other abnormal sounds.
3. Auscultate the neck and carotid arteries.
E. Mental status:
1. Check mental status because confusion may occur, especially in the elderly.

DIAGNOSTIC TESTS

A. Two-dimensional echocardiography with Doppler to evaluate LVEF.
B. Radionuclide ventriculography may be used to measure LVEF and LV volumes.
C. Coronary angiography.
D. Anterior/posterior chest x-ray.
E. EKG for clients with suspected arrhythmia, ischemia, or cardiac disease. Identify acute and old EKG changes to rule out pathologic Q wave, ST-segment elevation, and LV hypertrophy.
F. Natriuretic peptides (brain natriuretic peptide or N-terminal pro-brain natriuretic peptide).

DIFFERENTIAL DIAGNOSES

A. HF:
1. HFrEF.
2. HFpEF:
a. HFpEF borderline clients with an EF of 41% to 49%.
b. HFpEF clients with an EF greater than 40% who previously had HFrEF (EF, 40%) with improvement noted in EF.
B. Renal disease or nephrotic syndrome.
C. Liver disease.
D. Asthma.
E. COPD: To distinguish between progressing HF and a COPD exacerbation when both conditions are present, the presence of weight gain and an S3 gallop indicates HF, not COPD.

PLAN

A. General interventions according to the 2017 focused update of the ACC/AHA guidelines for HF:
1. Determine the etiology of the failure state and treat appropriately.
2. Treat HF stages:
a. Stage A: Treat/manage the client's underlying conditions (HTN, AF, hyperlipidemia, diabetes, tobacco cessation, obesity, substance abuse [alcohol, cocaine, etc.]).
b. Stage B: Begin ACEIs or angiotensin receptor blockers (ARBs), if intolerant to ACEIs, along with beta-blockers for clients with HFrEF. Add statin therapy if client has a history of MI. If the client has signs of water retention or has a history of water retention, diuretics should be started.
c. Stage C: HFrEF: implantable cardioverter defibrillators and cardiac resynchronization therapy:
i. Digoxin may be added if the client is still symptomatic and has been optimized on guideline-directed therapy to help manage symptoms.
ii. Hydralazine and isosorbide dinitrate are indicated for African American clients with HFrEF, clients with kidney dysfunction, or clients who cannot take ACEI or ARB therapy.
iii. Aldosterone receptor antagonist may be considered in the following scenarios:
1) HFrEF less than 30% or 30% to 35% with QRS greater than 130 ms.
2) Post-MI with EF less than 40% + (HF symptoms or diabetes) NYHA II symptoms, and serum creatinine less than 2.5 mg/dL (glomerular filtration rate [GFR] >30 mL/min), and serum potassium less than 5.
iv. Angiotensin receptor-neprilysin inhibitors (ARNIs) help prevent degradation of natriuretic peptides, bradykinin, and other vasoactive peptides. Research shows a reduction in composite endpoints of cardiovascular death or hospital admissions by 20%.
1) Prior to starting, a washout of the previous ACEI is needed. Do not start within 36 hours of last dose of an ACEI.
d. Stage D: advanced treatments such as cardiac transplant, mechanical support, home-based inotropic therapy, and/or hospice care.
3. The goal of therapy is to improve the client's quality of life by reducing symptoms, decreasing morbidity, and prolonging survival.
B. Client teaching:

▶

1. Teach the client to weigh daily at the same time, on the same scale, and in the same clothing. The client is to call if there are gains of more than 2 to 3 lbs in 1 day or more than 5 lbs in 1 week:
   a. Develop a plan of care for the client to increase the diuretic dosing for edema/weight gain to reduce dyspnea and prevent hospitalization. The directions could be to take an extra dose of the diuretic each day for several days until the weight gain, swelling, or symptoms improve.
2. Encourage weight loss if overweight.
3. Recommend regular, moderate exercise as long as dyspnea is not induced. Encourage exercise even though the client may only tolerate a few minutes of walking to increase endurance and strengthen muscles.
4. Encourage smoking cessation.
5. Encourage medication adherence. Instruct the client about all medications and possible side effects. Do not use OTC medicines without consulting the provider. Nonsteroidal anti-inflammatory drugs (NSAIDs) are contraindicated in HF.
6. Utilize continuous positive airway pressure (CPAP) or bilevel positive airway pressure (BiPAP) for nighttime sleep and naps for treatment of obstructive sleep apnea (OSA).

C. Dietary management:
1. Read food labels for sodium content.
2. Teach dietary modifications, especially salt restriction of 2,000 to 3,000 mg/d for HFrEF and HFpEF. Less than 2,000 mg/d of sodium is recommended in clients with moderate to severe HF symptoms.
3. Fluid restriction is not recommended unless the client is classified as stage D or is diagnosed with hyponatremia, with sodium levels less than 130 mEq/L. Restrict fluid intake to 2,000 mL/d or less for clients with chronic fluid retention despite use of diuretics and sodium restrictions.
4. Alcohol consumption should be limited to one glass of beer or wine per day. This amount should be counted in the daily fluid restriction.
5. See Appendix B for the Dietary Approaches to Stop Hypertension (DASH) diet (Tables B.1–B.5).
6. Other diet changes include low-fat/low-cholesterol and the use of the following:
   a. Monounsaturated fats, which decrease cholesterol:
      i. Canola oil.
      ii. Olive oil.
   b. Polyunsaturated fats, which decrease cholesterol but not as well as monounsaturated fats:
      i. Vegetable and fish oils.
      ii. Corn, safflower, peanut, and soybean oils.
   c. Avoid saturated fats:
      i. Animal fats and some plant fats.
      ii. Butter and lard.
      iii. Coconut oil and palm oil.

D. Pharmaceutical therapy:
1. Therapy is based on extent of cardiac impairment and severity of symptoms. Medication regimens include a combination of the following classes: diuretics, ACEIs (ARBs if unable to tolerate ACEIs), cardioselective beta-blockers, inotropic agents such as digoxin, vasodilators, nitrates, and anticoagulants if there is an increased risk of thrombus formation. In general, calcium channel blockers (CCBs) are not used in HF management.
2. Drug classifications for antihypertensive and cardiac medication are noted in Table 13.5.
3. Drugs that should be avoided and/or used with caution in HF because they cause exacerbations or are at high risk for adverse reactions include the following:
   a. NSAIDs: increased renal dysfunction, edema, impaired response to ACEI.
   b. Cyclooxygenase (COX-2) inhibitors: increased rate of HF and increased mortality.
   c. Aspirin: interaction between aspirin (ASA) and ACEI and interference with benefits of beta-blockers on LVEF.
   d. Metformin: increased risk of lethal lactic acidosis.
   e. Thiazolidinediones: fluid retention that may precipitate HF.
   f. CCBs: some data on possible effect on systolic dysfunction.
   g. Antidepressants tricyclic antidepressants (TCAs) and selective serotonin reuptake inhibitors (SSRIs): major adverse cardiovascular events including HF, MI, stroke, and cardiovascular death.
   h. Phosphodiesterase inhibitors (PDE3, PDE4, and PDE-5): increased mortality.
   i. Antiarrhythmic: negative inotropic activity and further reduction in LV function can impair the elimination and result in toxicity of the antiarrhythmic.
   j. Chemotherapy: many are cardiotoxic.
   k. Androgens-testosterone patch: edema that may accelerate the rate of HF.
   l. Theophylline serum levels may increase and cause toxicity due to acute decompensation of HF.
   m. Sodium bicarbonate and Fleet Phospho-Soda contain significant quantities of sodium.
   n. Herbal/supplements may also affect HF.
4. Biventricular pacing or an implantable defibrillator may be necessary for advanced HF.
5. Advanced HF therapies can include the following:
   a. Inotropic therapy in hospital and at home.
   b. Implanted mechanical-assist devices as a bridge to transplantation or as a destination therapy.
   c. Heart transplantation.
6. Discuss the client's desire for an evaluation as a heart transplant candidate.
7. Pneumonia vaccination as well as yearly influenza immunization should be encouraged.
8. Discuss the need for compassionate care/hospice when HF does not respond despite maximal therapy.

FOLLOW-UP

A. HF clients should be comanaged with a physician.

B. Close follow-up is essential if the client is to be maintained as an outpatient.

C. Appointments every 1 to 2 weeks may be necessary, with additional appointments depending on the client's symptoms, such as increasing SOB, inability to lie flat to sleep, nocturnal moist cough, and increase in daily weight.

D. Lab monitoring is required for electrolytes, blood urea nitrogen (BUN), creatinine, proteinuria, and digoxin level.

CONSULTATION/REFERRAL

A. Consult a physician when the client requires the next level up in pharmacologic management.

B. Consult a cardiologist for staging and hospital management. ▶

TABLE 13.5 ANTIHYPERTENSIVE AND CARDIAC MEDICATIONS (SORTED ALPHABETICALLY)

Brand Name	Generic Name	Drug Class
Accupril	Quinapril	ACE inhibitor
Aceon	Perindopril erbumine	ACE inhibitor
Adalat CC	Dihydropyridine/nifedipine	CCB
Aldactazide	Spironolactone + HCTZ	Combination: K + sparing + thiazide
Aldactone	Spironolactone	Diuretic: K + sparing
Altace	Ramipril	ACE inhibitor
Amiloride/HCTZ	Amiloride/HCTZ	Combination + diuretic
Atacand	Candesartan cilexetil	ARB
Atacand HCT	Candesartan + HCTZ	Combination: ARB + diuretic
Avalide	Irbesartan + HCTZ	Combination: ARB + diuretic
Avalide Avapro	Irbesartan + HCTZ Irbesartan	Combination: ARB + diuretic ARB
Azor	Amlodipine + olmesartan	CCB + ARB
Benicar	Olmesartan medoxomil	ARB
Benicar HCT	Olmesartan + HCTZ	Combination: ARB + diuretic
Betapace	Sotalol	Beta-blocker/class II and III antiarrhythmic
Betapace AF	Sotalol	Class II and III antiarrhythmics
Betaxolol Bidil	Betaxolol HCL isosorbide dinitrate + hydralazine	Beta-blocker: cardioselective nitrate + diuretic
Bumex	Bumetanide	Loop diuretic
Bystolic	Nebivolol	Beta-blocker: cardioselective
Caduet	Amlodipine + atorvastatin	CCB/amlodipine/atorvastatin
Calan	Verapamil	CCB/antianginal
Calan SR	Verapamil	CCB
Capoten	Captopril	ACE inhibitor/CHF
Capozide	Captopril + HCTZ	Combination: ACE + diuretic
Cardizem LA	Diltiazem	CCB
Cardura	Doxazosin	Alpha-1 receptor antagonist (alpha-blocker)
Catapres	Clonidine	Central alpha agonist
Cleviprex	Dihydropyridine	CCB
Cordarone	Amiodarone	Class II and III antiarrhythmics
Coreg CR	Carvedilol	Beta-blocker: noncardioselective/CHF
Corgard	Nadolol	Beta-blocker: noncardioselective/antianginal
Corlanor	Ivabradine	Hyperpolarization-activated cyclic nucleotide-gated channel blocker
Corzide	Nadolol + HCTZ	Combination: beta-blocker (noncardioselective) + diuretic
Covera HS	Verapamil	CCB/antianginal

(*continued*)

TABLE 13.5 ANTIHYPERTENSIVE AND CARDIAC MEDICATIONS (SORTED ALPHABETICALLY) (*CONTINUED*)

Brand Name	Generic Name	Drug Class
Cozaar	Losartan	ARB
Demadex	Torsemide	Loop diuretic
Digoxin	Digoxin	Cardiac glycoside/antiarrhythmic
Dilacor XR	Diltiazem	CCB/antianginal
Dilatrate SR	Isosorbide dinitrate	Nitrate
Diovan	Valsartan	ARB/CHF class II–IV
Diovan HCT	Valsartan + HCTZ	Combination: ARB + diuretic
Diuril	Chlorothiazide	Thiazide diuretic
Dutoprol Dyazide	Metoprolol extended-release + HCTZ Triamterene + HCTZ	Beta-blocker (cardioselective) + thiazide Combination: K + sparing + thiazide
Dynacirc CR	Isradipine controlled-release	CCBr
Edarbi	Azilsartan	ARB
Edarbyclor	Azilsartan + chlorthalidone	ARB + diuretic
Edecrin	Ethacrynic acid	Loop diuretic
Entresto	Sacubitril + valsartan	Neprilysin inhibitor + ARB
Exforge	Amlodipine + valsartan	CCB + ARB
Fosinopril HCTZ	Various hydrochlorothiazide	ACE inhibitor, thiazide diuretic
Hytrin	Terazosin	Alpha-1 blocker
Hyzaar	Losartan potassium + HCTZ	Combination: ARB + diuretic
Imdur	Isosorbide dinitrate	Nitrate
Inderal	Propranolol	Beta-blocker: noncardioselective/antianginal/antiarrhythmic
Inderide	Propranolol + HCTZ	Combination: beta-blocker (noncardioselective) + diuretic
InnoPran XL	Propranolol HCL extended-release	Beta-blocker: noncardioselective
Inspra	Eplerenone	Aldosterone receptor blocker: mineralocorticoid selective/CHF
Ismo	Isosorbide dinitrate	Nitrate
Isoptin SR	Verapamil	CCB
Kerlone	Betaxolol	Beta-blocker: cardioselective
Lanoxin	Digoxin	Cardiac glycoside/antiarrhythmic
Lasix	Furosemide	Loop diuretic
Levatol	Penbutolol sulfate	Beta-blocker: noncardioselective
Lopressor	Metoprolol tartrate	Beta-blocker: cardioselective/antianginal
Lopressor HCT	Metoprolol + HCTZ	Combination: beta-blocker (cardioselective) + diuretic
Lotensin	Benazepril	ACE inhibitor
Lotensin HCT	Benazepril + HCTZ	Combination: ACE + diuretic
Lotrel	Amlodipine + benazepril	Combination: CCB + ACE inhibitor
Mavik	Trandolapril	ACE inhibitor/CHF

(*continued*)

TABLE 13.5 ANTIHYPERTENSIVE AND CARDIAC MEDICATIONS (SORTED ALPHABETICALLY) (*CONTINUED*)

Brand Name	Generic Name	Drug Class
Maxzide	Triamterene + HCTZ	Combination: K + sparing + thiazide
Mexitil	Mexiletine	Class IB antiarrhythmic
Micardis	Telmisartan	ARB
Micardis HCT	Telmisartan + HCTZ	Combination: ARB + diuretic
Microzide	HCTZ	Diuretic
Minitran	Nitroglycerin	Nitrate
Monoket	Isosorbide dinitrate	Nitrate
Monopril	Fosinopril	ACE inhibitor/CHF
Multaq	Dronedarone	Antiarrhythmic
Nicardipine	Various	CCB
Nitro-BID	Nitroglycerin	Nitrate
Nitro-Dur	Nitroglycerin	Nitrate
Nitrolingual	Nitroglycerin	Nitrate
Nitrostat	Nitroglycerin	Nitrate
Normodyne	Labetalol	Beta-blocker
Norpace	Disopyramide	Antiarrhythmics: class I-ventricular
Norvasc	Amlodipine	CCB/antianginal
Pindolol	Pindolol	Beta-blocker: noncardioselective
Plendil	Felodipine	CCB
Prinivil	Lisinopril	ACE inhibitor/CHF
Prinzide	Lisinopril + HCTZ	Combination: ACE inhibitor + thiazide diuretic
Procanbid	Procainamide	Antiarrhythmics: class Ia-ventricular
Procardia XL	Nifedipine	CCB/antianginal
Quinidine gluconate	Various	Antiarrhythmics: class I atrial and ventricular
Quinidine sulfate	Various	Antiarrhythmics: class I atrial and ventricular
Ranexa	Ranolazine	Antianginal
Rythmol	Propafenone	Antiarrhythmics: class Ic-ventricular
Sectral	Acebutolol	Beta-blocker: cardioselective
Sular	Nisoldipine	CCBr
Tambocor	Flecainide	Antiarrhythmics: class Ic-ventricular
Tarka	Trandolapril + verapamil	Combination: ACE + CCB
Tekamlo	Aliskiren + amlodipine	Direct renin inhibitor + DHP CCBr
Tekturna	Aliskiren	Direct renin inhibitor
Tekturna HCT	Aliskiren + HCTZ	Direct renin inhibitor + thiazide diuretic
Tenex	Guanfacine	Central alpha agonist

(*continued*)

TABLE 13.5 ANTIHYPERTENSIVE AND CARDIAC MEDICATIONS (SORTED ALPHABETICALLY) (*CONTINUED*)

Brand Name	Generic Name	Drug Class
Tenoretic	Atenolol + chlorthalidone	Combination: beta-blocker (cardioselective) + diuretic
Tenormin	Atenolol	Beta-blocker: cardioselective/antianginal
Teveten	Eprosartan	ARB
Teveten HCT	Eprosartan + HCTZ	Combination: ARB + diuretic
Thalitone	Chlorthalidone	Antihypertensive/diuretic
Tiazac	Diltiazem	CCB/antianginal
Tikosyn	Dofetilide	Class III antiarrhythmic
Timolide	Timolol maleate + HCTZ	Combination: beta-blocker (noncardioselective) + diuretic
Toprol XL	Metoprolol	Beta-blocker: cardioselective/antianginal/CHF class II or III
Trandate	Labetalol	Beta-blocker: noncardioselective
Tribenzor	Olmesartan + amlodipine + HCTZ	ARB + CCB + thiazide diuretic
Twynsta	Telmisartan + amlodipine	ARB + CCB
Uniretic	Moexipril + HCTZ	Combination: ACE + diuretic
Univasc	Moexipril	ACE inhibitor
Valturna	Aliskiren + valsartan	Direct renin inhibitor + ARB
Vaseretic	Enalapril + HCTZ	Combination: ACE + diuretic
Vasotec	Enalapril	ACE inhibitor/CHF with digitalis and diuretics
Verelan PM	Verapamil	CCB
Zaroxolyn	Metolazone	Diuretic: quinazoline
Zebeta	Bisoprolol	Beta-blocker: cardioselective
Zestoretic	Lisinopril + HCTZ	Combination: ACE + diuretic
Zestril	Lisinopril	ACE inhibitor/CHF with digitalis and diuretics
Ziac	Bisoprolol + HCTZ	Combination: beta-blocker (cardioselective) + diuretic

ACE, angiotensin-converting enzyme; ARB, angiotensin II receptor blocker; CCB, calcium channel blocker; CHF, congestive heart failure; DHP, dihydropyridine; HCL, hydrochloride; HCTZ, hydrochlorothiazide, HR, heart rate, SA node, sinoatrial node.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. HF is uncommon in healthy females without coexisting heart disease.

2. Pregnancy in a client with heart disease is considered high risk.

3. Refer to a high-risk obstetrician.

B. Adults:

1. The 5-year survival rate is about 50% for both males and females.

2. Predictors of poor outcome include an EF of less than 25%, ischemic etiology, ventricular arrhythmias, serum sodium greater than 130 mEq/L, poor functional class, low cardiac index, and high filling pressures.

C. Geriatrics:

1. Common signs and symptoms of HF are less specific in older adults and atypical symptoms may predominate.

2. Age-associated changes in pharmacokinetics must be taken into account when prescribing drugs for HF.

3. Effective communication among health professionals, clients, and families is necessary.

4. Given the life-limiting nature of HF in frail older adults, it is critical for clinicians to discuss end-of-life issues with clients and their families as soon as possible. The Medicare hospice benefit is granted to clients who have been certified by two physicians to have a life expectancy of 6 months or less if their terminal illness runs its natural course. The criteria for determining that HF is terminal are:

a. NYHA class III (symptomatic with less than ordinary activities) or IV (symptomatic at rest).

b. LVEF less than or equal to 20%.

c. Persistent symptoms despite optimal medical management.

d. Inability to tolerate optional management because of hypotension with or without renal failure.

5. Geriatric red flag:

a. For the older adult with existing cognitive, functional, or mobility impairments, the nurse practitioner (NP) should practice special consideration of the following geriatric syndromes if adding or increasing a diuretic:
   i. Incontinence.
   ii. Falls.
      1) Avoid diuretics after 4 p.m. to reduce the risk of falls from attempting to get to the bathroom during the night. Discuss ways the client can adjust fluid intake and toileting habits. Alert the client that avoidance of incontinent episodes by reducing oral intake could result in dehydration and/or urinary tract infection.

HYPERTENSION

DEFINITION

A. Discord exists between the American College of Cardiology/American Heart Association (ACC/AHA) (2017) and the Eighth Joint National Committee (JNC 8) guideline (2014) as to the definition and stages of hypertension (HTN). The JNC 8 guideline provided more permissive (higher) blood pressure (BP) goals, especially for those 60 and older. The newer AHA/ACC guideline defines HTN as a systolic blood pressure (SBP) of 130 mmHg or more, a diastolic blood pressure (DBP) of 80 mmHg or more, or describes a condition in which a person is taking antihypertensive medications.

B. Resistant HTN is defined as follows:

1. BP that is not at target despite a three-drug regimen, including an angiotensin-converting enzyme inhibitor (ACEI) or an angiotensin receptor blockers (ARBs) + a calcium channel blocker (CCB) + a diuretic appropriate for the client's glomerular filtration rate (GFR).

2. Controlled BP while taking four or more medications is also considered resistant HTN.

C. Standing and supine BPs should be measured before the initiation of combination antihypertensive therapy. Orthostatic (postural) hypotension is diagnosed when, within 2 to 5 minutes of quiet standing, one or more of the following is present:

1. At least a 20 mmHg fall in systolic pressure.

2. At least a 10 mmHg fall in diastolic pressure.

3. Symptoms of cerebral hypoperfusion, such as dizziness.

D. The average nocturnal BP is approximately 15% lower than daytime values. Failure of BP to fall by at least 10% during sleep is called "nondipping" and is a stronger predictor of adverse cardiovascular outcomes than daytime BP.

E. Isolated systolic hypertension (ISH) is defined when the SBP is greater than or equal to 140, with the DBP normal or below normal (<90 mmHg). ISH usually affects the elderly, increasing their risk of stroke or myocardial infarction (MI).

F. Isolated diastolic hypertension (IDH) is defined as a diastolic pressure greater than or equal to 90 mmHg, with a systolic pressure less than 140 mmHg. IDH is more common in younger males who are overweight/obese and in individuals younger than 40 years.

G. Malignant HTN is marked HTN with retinal hemorrhages, exudates, or papilledema. Malignant HTN is usually associated with diastolic pressures above 120 mmHg.

INCIDENCE

A. Worldwide, HTN affects about one billion people and is the leading preventable risk factor for premature death and disability worldwide.

B. Approximately one in three adults in the United States have HTN.

C. The incidence of resistant HTN is rising. The data indicate a 21.7% incidence.

D. African American females have the highest death related to HTN (37.7 deaths per 100,000 population).

PATHOGENESIS

A. Over 90% of cases have no identifiable cause, thus constituting the category of primary or essential HTN. The remaining 10% of cases have the following secondary causes.

1. Renal causes:
   a. Glomerulonephritis.
   b. Pyelonephritis.
   c. Polycystic kidney disease.

2. Endocrine causes:
   a. Primary hyperaldosteronism.
   b. Pheochromocytoma.
   c. Hyperthyroidism.
   d. Cushing syndrome.

3. Vascular causes:
   a. Coarctation of aorta.
   b. Renal artery stenosis.

4. Obstructive sleep apnea (OSA).

5. Chemical-/medication-induced HTNs:
   a. Oral contraceptives.
   b. Nonsteroidal anti-inflammatory drugs (NSAIDs).
   c. Decongestants.
   d. Antidepressants.
   e. Sympathomimetics.
   f. Corticosteroids.
   g. Lithium.
   h. Ergotamine alkaloids.
   i. Cyclosporine.
   j. Monoamine oxidase inhibitors (MAOIs), in combination with certain drugs or foods.
   k. Appetite suppressants, in combination with certain drugs or foods.
   l. Cocaine.
   m. Amphetamines.

PREDISPOSING FACTORS

A. When making a diagnosis, consider not only the absolute BP reading, but also the presence or absence of other cardiovascular risk factors. Factors include the following:

1. Family history of HTN.

2. Obesity.

3. Alcohol consumption.

4. Stress.

▶

5. Sedentary lifestyle.
6. African American ancestry.
7. Male sex.
8. Age older than 30 years.
9. Excessive salt intake.
10. Medications.
11. Drug use.

COMMON COMPLAINT

A. HTN is asymptomatic in the majority of clients.

OTHER SIGNS AND SYMPTOMS

A. Headaches.
B. Advanced disease: organ-specific complaints with end-organ damage.
C. Retinopathy.

POTENTIAL COMPLICATIONS

A. Cerebrovascular accident (CVA).
B. MI.
C. Renal failure.
D. Heart failure (HF).
E. Peripheral arterial disease (PAD).

SUBJECTIVE DATA

A. Ask the client about any family history of HTN or cardiac or renal disease.
B. Ask if the client has ever been diagnosed with HTN or cardiac or renal disease.
C. Ask if the client ever had any high BP readings.
D. Ask if the client has ever been treated for any of the earlier problems.
E. Ask about other risk factors, such as smoking, drinking, high-fat intake, obesity, and/or diabetes.
F. Inquire about the client's lifestyle, exercise regimen, work environment, and stress level.
G. Ask the client about symptoms that suggest secondary etiology:
1. Palpitations, headache, diaphoresis (pheochromocytoma).
2. Anxiety, weight gain or loss (thyroid abnormality).
3. Muscle weakness, polyuria (primary aldosteronism).

H. Find out if the client is taking drugs that elevate BP (noted under the "Pathogenesis" section).
I. Ask if the client feels nervous when having their BP taken in the office ("white coat HTN").
J. Review current medications, including prescription, over-the-counter (OTC), and herbal products.
K. Review current recreational/illicit drug use.

PHYSICAL EXAMINATION

A. Check pulse, BP, height, weight, waist circumference, and distribution of body fat. Calculate body mass index (BMI).
1. The diagnosis of HTN is made after averaging two or more properly measured readings at each of two or more visits after an initial screen.
2. When client's SBP and DBP fall into two different categories, use the higher category to classify their BP.
3. For accurate measurement, use correct size of cuff for client (adult, large adult, or thigh cuff).

B. Inspect:
1. Observe overall appearance.
2. Conduct funduscopic exam; look for papilledema, exudates, arteriovenous nicking, anterior nicking.
3. Inspect the neck for jugular vein distension.
4. Observe for pedal edema.

C. Palpate:
1. Palpate the neck; check thyroid for enlargement.
2. Palpate the abdomen for masses or organomegaly.
3. Palpate the extremities; assess peripheral pulses and note edema.
4. Assess deep tendon reflexes (DTRs).

D. Auscultate:
1. Auscultate heart, noting the point of maximal impulse (PMI).
2. Auscultate lungs; check for bronchospasm and rales.
3. Auscultate neck; assess carotid arteries for bruits.

DIAGNOSTIC TESTS

A. Hematocrit.
B. Liver function tests (LFTs), lactate dehydrogenase (LDH), uric acid.
C. Chemistry profile.
D. Fasting lipid profile (total and high-density lipoprotein [HDL] cholesterol and triglycerides).
E. Urinalysis for proteinuria.
F. Estimated GFR.
G. EKG.
H. If history, physical exam, or lab tests indicate the need, obtain the following:
1. Intravenous pyelography (IVP).
2. Renal arteriogram.
3. Plasma renin.
4. Catecholamines.
5. Chest radiography.
6. Aortogram.
7. Ultrasonography.
8. Sleep study.

I. Monitor potassium levels if on ACEIs/ARBs or spironolactone.

DIFFERENTIAL DIAGNOSES

A. Primary HTN.
B. Secondary HTN.
C. Drug-induced HTN.
D. White coat syndrome.

PLAN

A. General interventions (Table 13.6):
1. Advise overweight clients to lose weight. Loss of as little as 10 lbs reduces BP in many clients. ▶

TABLE 13.6 WHELTON 2017 HIGH BLOOD PRESSURE CLINICAL PRACTICE GUIDELINE CLASSIFICATIONS

BP Classification	SBP (mmHg)	DBP (mmHg)
Normal	<120	*And* <80
Pre-HTN	120–129	>80
Stage 1 HTN	130–139	*Or* 80–89
Stage 2 HTN	≥140	*Or* ≥90

BP, blood pressure; DBP, diastolic blood pressure; HTN, hypertension; SBP, systolic blood pressure.

2. Advise the client to limit or discontinue alcohol intake.
3. Encourage the client to stop smoking.
4. Encourage increased physical activity. The 2017 ACC/AHA guidelines on lifestyle management outline the newest physical activity recommendation, which advises adults to engage in 40 minutes of aerobic physical activity three to four times a week. The aerobic exercise should involve moderate to vigorous intensity.
5. Encourage some form of relaxation technique.

B. Client teaching:
1. Stress asymptomatic nature of disease.
2. Stress importance of ongoing monitoring and treatment under the direction of a healthcare provider.
3. Review risk factors for cardiac, renal, and cerebrovascular disease and possible preventive measures.
4. The ACC maintains the CardioSmart Patient Education Portal for an online BP and other heart conditions management tool to educate and motivate clients. ACC's CardioSmart is a free resource located at www.cardiosmart.org. CardioSmartTXT *PREVENT* is a 6-month program of health tips and reminders sent via two text messages a week. CardioSmartTXT *QUIT* is a 2-month program to assist clients in smoking cessation. Four text messages are sent a day with information and assistance with smoking cessation.

C. Dietary management:
1. Review specific dietary measures. Give dietary recommendation sheets. See Appendix B for low-fat/low-cholesterol and Dietary Approaches to Stop Hypertension (DASH) diets.
2. Diet alone will only make the smallest incremental change in BP; therefore, it should be combined with lifestyle modification and lower sodium intake; stopping smoking, weight loss, and exercise are essential.
3. It is essential for the client/family to read labels for sodium, fat content, and serving sizes.
4. Other dietary changes include low-fat/low-cholesterol diets and limiting fats:
a. Use monounsaturated fats to decrease cholesterol:
i. Canola oil.
ii. Olive oil.
b. Use in limited quantities: Polyunsaturated fats decrease cholesterol but not as well as monounsaturated fats:
i. Vegetable and fish oils.
ii. Corn, safflower, peanut, and soybean oils.
c. Limit saturated fats:
i. Animal fats and some plant fats.
ii. Butter and lard.
iii. Coconut oil and palm oil.

D. Pharmaceutical therapy:
1. If lifestyle changes alone are not adequate to control HTN, consider drug therapy. Medication doses are dependent on age, ethnicity, and comorbid conditions. Most clients will require two or more medications to control their BP. Consider starting antihypertensives and/or diuretics (see Table 13.5 for drugs and classifications). The JNC 8 recommendations were released in 2014 for initiation and BP goals (Table 13.7). The JNC 8 published an extensive algorithm for treatment of HTN. The algorithm is available at jama.jamanetwork.com/solr/searchresults.aspx?q=jnc8&fd_JournalID=67&f_JournalDisplayName=JAMA&SearchSourceType=3.

TABLE 13.7 MODIFIABLE AND NONMODIFIABLE RISK FOR CONTROL OF HYPERTENSION

Modifiable	Nonmodifiable
Sedentary lifestyle	Age
Smoking	Gender
Diet	Ethnicity
Lipid control	Diabetes
Sodium intake	Postmenopausal
Alcohol intake	Family history
Obesity	

2. The 2017 guidelines released by the AHA, the ACC, and the Centers for Disease Control and Prevention (CDC) recommend medication classifications for treatment of HTN in the presence of medical conditions (Table 13.8).
3. Antihypertensive/diuretics should be started low and increased if there is inadequate response to initial therapy and nonadherence is ruled out. Consider the following:
a. Increasing drug dose.
b. Substituting another drug.
c. Adding a second drug from another class; a diuretic is recommended if one is not already being used.
d. **Beta-blockers are no longer first-line antihypertensive agents. Atenolol may increase central aortic pressure.**
e. **ACEIs and ARBs are critical medications to prescribe and titrate to maximum dose as a first-line medication in people with renal disease, diabetes, and proteinuria.**
4. If response is still inadequate, add a second or third drug or a diuretic if one has not already been tried.
5. Evaluate the client for secondary causes if severe HTN is resistant to therapy.
6. Resistant HTN; rule out all inadequate response to the three-drug therapy (ACEI or ARB or CCB + diuretic).
a. "White-coat" HTN: Have the client begin to take and record their BP at home and report the values.
b. Use of size-appropriate BP cuffs on obese clients.
c. Nonadherence to therapy, including side effects, medication regimen too complex, and/or cost/affordability.
d. Volume overload due to excessive salt intake, progressive renal damage, fluid retention from BP reduction, and inadequate diuretic therapy.
e. Drug problems, such as dose too low, wrong type of diuretic, inappropriate combinations, rapid inactivation, drug actions, and interactions.
f. Associated conditions, such as smoking, obesity, sleep apnea, insulin resistance, ethanol intake greater than 30 mL (1 oz) per day, panic attacks, chronic pain, and organic brain syndrome.
g. Adding spironolactone can decrease SBP by an average of 25 mmHg and DBP by an average of 12 mmHg in resistant hypertensive clients.
7. Treat with decongestants very cautiously. Pseudoephedrine HCl (Sudafed) has the least cardiovascular effect. ▶

TABLE 13.8 WHELTON 2017 HIGH BLOOD PRESSURE CLINICAL PRACTICE GUIDELINE

Ethnicity/Population	Age (Years)	Begin Initiation of Pharmacologic Treatment to Lower Blood Pressure	Blood Pressure Goals for Treatment	Other Comments
General population	>60	Initiate therapy for SBP ≥130 mmHg or DBP ≥80 mmHg.	Treat to goal of SBP <130 mmHg and DBP <80 mmHg.	If pharmacologic treatment results in a lower achieved SBP and treatment is well-tolerated, treatment does not need to be adjusted.
General population	<60	Initiate therapy to lower BP at SBP ≥130 mmHg.	Treat to goal of SBP <130 mmHg.	
General population	<60	Initiate therapy to lower BP at DBP ≥80 mmHg.	Treat to goal of DBP <80 mmHg.	
Clients with chronic kidney disease	>18	Initiate therapy to lower BP at SBP ≥130 mmHg or DBP ≥80 mmHg.	Treat to goal of SBP <130 mmHg and DBP <80 mmHg.	
Clients with chronic kidney disease (regardless of race or diabetes status)	>18			Initial or add-on antihypertensive therapy should include an ACEI or ARB to improve kidney outcomes.
Clients with diabetes	>18	Initiate therapy to lower BP at SBP ≥130 mmHg or DBP ≥80 mmHg.	Treat to goal of SBP <130 mmHg and DBP <80 mmHg.	The American Diabetes Association criteria differ from all else in that their guidelines remain treating diabetics with hypertension to an SBP goal of <140 mmHg and to a DBP of <80 mmHg.
General non-Black population including those with diabetes				Initial antihypertensive therapy should include a thiazide-type diuretic, CCB, ACEI, or ARB.
General Black population including those with diabetes				Initial antihypertensive therapy should include a thiazide-type diuretic or CCB.

ACEI, angiotensin-converting enzyme inhibitor; ARB, angiotensin receptor blocker; BP, blood pressure; CCB, calcium channel blocker; DBP, diastolic blood pressure; SBP, systolic blood pressure.

8. Diuretics may worsen gout and diabetes.
9. Beta-blockers are contraindicated in asthma, HF, and heart block.
10. Use diltiazem HCl (Cardizem) and verapamil HCl (Calan) cautiously in HF or block.
11. ACEIs may cause coughing.
12. Abrupt cessation of therapy with a short-acting beta-blocker, such as propranolol, or the short-acting alpha-2-agonist clonidine can lead to a potentially fatal withdrawal syndrome. Gradual discontinuation of these agents over a period of weeks should prevent this syndrome.

FOLLOW-UP

A. If drug therapy is initiated, see the client again in 2 to 4 weeks for follow-up.
B. Once the client is stable, see them every 3 to 6 months.
C. Evaluate the client yearly, including uric acid, creatinine, and potassium.
D. Review and discuss drug therapy compliance, effectiveness, and adverse reactions (including effect on sexual activity) at each visit.
E. Home and ambulatory blood pressure monitoring (ABPM) is an adjunctive tool for management of HTN.
1. BP tracking apps are available on iTunes for the iPhone, iPod touch, and iPad.
2. BP tracking apps for Android are available on Google Play and Amazon Appstore.
3. A printable BP tracker log is located at organizedhome.com/sites/default/files/image/pdf/health_blood_pressure_tracker.pdf.
F. Consider sleep study for diagnosis of OSA (see the "Obstructive Sleep Apnea" section of this chapter).
G. Clients with elevated BP without diabetes, chronic kidney disease (CKD), or cardiovascular disease should be treated by nonpharmacologic therapy (e.g., diet, sodium reduction, weight loss, exercise, smoking cessation) and should be evaluated annually.

EMERGENT ISSUES/INSTRUCTIONS

A. Consult a physician if the client is having an acute hypertensive emergency: DBP greater than 130 mmHg.

CONSULTATION/REFERRAL

A. If the client is pregnant, consult a physician before prescribing medications. Many antihypertensive drugs are harmful to the fetus.

B. Consult/comanage with a physician if the client needs more than three drugs for therapy.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy. Refer to Chapter 16, "Obstetrics Guidelines."

1. HTN may be either chronic or pregnancy-induced.

2. HTN is considered chronic if it is present before pregnancy or diagnosed prior to the 20th week of gestation.

3. Pregnancy-induced hypertension (PIH) is diagnosed if SBP increases 30 mmHg or more, or if DBP increases 15 mmHg or more, compared with BP readings before the 20th week of gestation. When BP readings are not known, a reading of 140/90 or higher is considered abnormal.

4. Maternal as well as fetal mortality and morbidity improve with treatment.

B. Geriatrics:

1. The Whelton 2017 general guideline for clients older than 60 is to treat when BP is greater than 130/80. HTN in the elderly places the client at risk for coronary events, stroke, HF, and PAD.

2. The JNC-8 guideline on managing HTN in adults older than 60 is to treat BP to a goal less than 150/90:

a. Avoid SBP less than 130 mmHg and DBP less than 60 mmHg due to effects on cerebral perfusion.

3. Elderly persons with HTN are more likely to develop orthostatic and postprandial hypotension, which may result in falls or syncope.

a. Evaluate side effects including dizziness and sedation. Beta-blockers may cause depression or confusion in the elderly and are no longer recommended.

b. Check for orthostatic BP changes.

4. The general approach to drug therapy in the geriatric population is to start low and go slow. Specific drug choices should be determined by comorbidities, side effects, and costs:

a. Start at low doses, with slow titration up to goal.

5. Check the Beers list for harmful drugs in the geriatric population. A printable pocket card is available for download at www.americangeriatrics.org/files/documents/beers/PrintableBeersPocketCard.pdf.

6. To avoid hyperkalemia in the elderly, potassium-sparing diuretics should not be given with ACEI or ARBs.

7. Geriatric red flag:

a. If adding or increasing diuretics to manage BP in clients with existing cognitive, functional, or mobility impairment, the nurse practitioner (NP) should practice special consideration of the following geriatric syndromes:

i. Incontinence.

ii. Falls.

1) Avoid diuretics after 4 p.m. to reduce the risk of falls from attempting to get to the bathroom during the night. Discuss ways the client can adjust fluid intake and toileting habits. Alert the client that avoidance of incontinent episodes by reducing oral intake may result in dehydration and/or urinary tract infection.

LYMPHEDEMA

DEFINITION

A. Peripheral vascular disease (PVD) is a general term that encompasses all occlusive or inflammatory diseases that occur within the peripheral arteries, veins, and lymphatic system. Lymphedema is a chronic condition caused by the accumulation of lymphatic fluid in the interstitial tissue.

INCIDENCE

A. Almost one million Americans have lymphedema, and the incidence worldwide is projected to approach 100 million.

PATHOGENESIS

A. Lymphedema occurs when lymph fluid is unable to flow in a normal manner and accumulates in an extremity. The propensity for lymphedema can be inherited or caused by another condition such as lymphangitis, malignancy, filariasis, removal of lymph nodes, and major trauma or burns.

PREDISPOSING FACTORS

A. Cancer.

B. Radiation therapy.

C. Surgical removal of lymph nodes.

D. Parasitic infection (filariasis).

E. Congenital disorder involving the structure of the lymph system:

1. Milroy disease.

2. Meige disease.

F. Obesity.

G. Surgical implantation of pacemaker or arteriovenous shunt.

H. Systemic diseases (hyperthyroidism, hypertension, renal or cardiac disease).

I. Vascular disease (chronic venous insufficiency [CVI] or postthrombotic syndrome).

J. Sedentary lifestyle.

COMMON COMPLAINTS

A. Severe edema that is consistent with the distal aspect of the extremity.

B. Hard skin over an edematous area.

C. Loss of range of motion.

POTENTIAL COMPLICATIONS

A. Infection, including lymphangitis and cellulitis.
B. Lymphangiosarcoma.

SUBJECTIVE DATA

A. Ask client when the symptom were first noticed.
B. Have client describe duration of symptoms.
C. Review any history of cancer, radiation, and chemotherapy.
D. Review recent history of invasive procedures or surgery.
E. Ask client to list all medications currently being taken, particularly substances not prescribed and illicit drugs such as cocaine.
F. Ask client to describe any pain.
G. Ask the client what makes the symptoms better and what makes them worse.
H. Have client rate discomfort on a scale of 0 to 10, with 0 being comfortable.

PHYSICAL EXAMINATION

A. Check vital signs.
  1. Check blood pressure, resting heart rate, respirations, temperature, height, weight, and body mass index.
B. Inspect:
  1. Assess for signs of erythema, increased temperature, and edema.
C. Palpate:
  1. Palpate lymph nodes distal and proximal to the site.
  2. Palpate pulses distal and proximal in all extremities.
  3. Palpate extremity for tenderness.
D. Auscultate:
  1. Heart: rate, rhythm, heart sounds, murmur, rub, and gallops.
  2. Lungs: lung sounds in all fields.

DIAGNOSTIC TESTS

A. Serum laboratory tests: complete blood count (CBC) with differential and brain natriuretic peptide (BNP).
B. CT scan of the affected extremity.
C. Doppler ultrasound of the affected extremity.
D. MRI.
E. Lymphoscintigraphy.
F. Additional tests to monitor coexisting systemic and/or vascular disease.

DIFFERENTIAL DIAGNOSES

A. Unilateral limb edema:
  1. Lymphedema.
  2. Venous insufficiency.
  3. Deep vein thrombosis or postthrombotic syndrome.
  4. Arthritis.
  5. Baker cyst.
  6. Presence or reoccurrence of cancer.
B. Symmetrical limb edema:
  1. Congestive heart failure (CHF).
  2. CVI.
  3. Renal dysfunction.
  4. Hepatic dysfunction.
  5. Hypothyroidism (myxedema).
  6. Medication-induced edema.
  7. Lipedema.

PLAN

A. Client teaching: *See Client Teaching Guide for this chapter, "Lymphedema."*
  1. Protect your arm or leg while recovering from cancer treatment.
  2. Avoid heavy lifting, if it is an arm.
  3. Avoid strenuous exercise.
  4. Avoid heat on your arm or leg.
  5. Avoid tight clothing.
  6. Inspect the affected limb daily. Note any cracks or cuts that increase the risk of infection and treat as directed.
  7. Apply lotion daily to protect and prevent dry skin.
  8. Avoid burns to the skin.
  9. Take extra care when shaving and use a clean razor on clean skin.
  10. Use insect repellent to prevent insect bites, which could become infected.
  11. Wash skin daily with a mild soap and dry skin carefully paying special attention to any skin folds.
  12. Prevent excessive sun exposure by applying sunscreen or wearing appropriate clothing to cover skin.
B. Nonpharmaceutical therapy: consists of two phases of complex decongestive therapy (CDT).
  1. Intensive reduction phase:
    a. Duration: usually past 2 to 4 weeks for severe lymphedema. If lymphedema is mild to moderate, it is possible to skip to the maintenance phase of the CDT.
    b. Steps of CDT in the intensive reduction phase:
      i. Low-stretch bandages (an adjustable compression garments).
      ii. Manual lymphatic drainage (MLD): MLD consists of gentle, skin-stretching movements performed by a certified therapist.
      iii. Sequential gradient pump: This is a durable medical equipment that provides gentle massage that mimics MLD.
      iv. Exercises: A physical therapy referral for a home exercise plan would be appropriate. A home exercise plan would likely include resistance bands or light weights and walking.
      v. Skincare and risk precautions: See the "Client Teaching" section earlier.
  2. Maintenance phase:
    a. Duration: lifelong, although the frequency of the treatments can be tailored to the symptoms.
    b. Steps of CDT in the maintenance phase:
      i. Compression garments.
      ii. Exercises in the form of a home exercise plan.
      iii. Skincare and risk precautions: See the "Client Teaching" section earlier.
      iv. MLD, if required.
      v. Sequential gradient pump, if required.
C. Surgery:
  1. Lymphaticovenous anastomosis (LVA): surgical attachment of nonfunctional lymph nodes to the venous system, thereby allowing for drainage of access fluid.
  2. Vascularized lymph node transfer (VLNT): transplantation of functional lymph nodes into an extremity to restore lymphatic function.
  3. Suction assisted protein lipectomy (SAPL): a treatment in which suction is used to remove lymphatic solids and fatty deposits. This surgery is most commonly used to treat those who are poor candidates for LVA and/or VLNT.

FOLLOW-UP

A. Follow-up is determined by client's needs, frequency and intensity of symptoms, and presence of other medical conditions. ▶

B. PVD manifesting persistent symptoms should always be followed by a cardiologist.

EMERGENT ISSUES/INSTRUCTIONS

A. Clients should contact the office if they are experiencing any new symptom(s) not present at their last office visit.

B. Clients should contact the office if they have any of the following symptoms:

1. Fever over 101°F.

2. Increased redness, pain, tenderness to touch, and/or warmth in the affected arm or leg.

3. New pain, swelling, or warmth in an arm or leg.

CONSULTATION/REFERRAL

A. If you suspect acute limb ischemia (ALI), refer the client for immediate hospitalization to obtain diagnostic testing to determine the presence of a thrombus and restore circulation to the affected extremity.

B. If chronic limb ischemia has led to ulceration and/or superimposed infection, hospitalization is indicated to initiate wound care consultation and diagnostic testing to determine the degree of arterial occlusion.

C. Referral to a cardiologist is indicated in the presence of persistent PVD symptoms.

D. Referral to a certified lymphedema therapist and physical therapist is indicated to best manage chronic lymphedema.

E. Referral to physical therapy is indicated to teach a home exercise program.

MURMURS

DEFINITION

A. A murmur is turbulent blood flow through the heart as a result of one or more of the following etiologies:

1. Narrow valve opening, stenosis.

2. Incomplete valve closure, regurgitant or insufficient blood flow.

3. Abnormal opening through chambers, atrial or ventricular septal defect (VSD).

4. Rapid blood flow through normal valve structures; occurs during pregnancy, with increased physiologic demand states, such as thyrotoxicosis.

5. No abnormality; occurs in clients with thin chest walls.

INCIDENCE

A. Innocent heart murmurs are quite common. They affect 40% to 45% of children and about 10% of adults at some point during their lifetime. Innocent heart murmurs are more common in females during pregnancy. Abnormal heart murmurs occur most often in people who have certain heart conditions, such as a defective heart valve (e.g., aortic stenosis, mitral regurgitation).

PATHOGENESIS

A. Pathogenesis depends on specific etiology, but rheumatic heart disease, calcific changes, ischemic insults, congenital abnormalities, and degenerative diseases can all contribute to the development of a murmur.

COMMON COMPLAINTS

A. Often no symptoms are present and murmur is found on routine examination.

B. Complaints with advanced valvular disease:

1. Chest pain.

2. Dyspnea.

3. Palpitations.

4. Shortness of breath (SOB).

5. Exercise intolerance.

6. Postural light-headedness.

SUBJECTIVE DATA

A. Has the client ever been diagnosed with a murmur?

B. Did the client have frequent strep infections as a child?

C. Ask the client about any recent viral infections.

D. Question the client about chest pain, SOB, palpitations, diaphoresis, light-headedness, or syncope, especially with exertion.

E. Ask the client if any family members had sudden cardiac death before age 55.

PHYSICAL EXAMINATION

A. Check temperature, if indicated, pulse, respirations, and blood pressure (BP).

B. Inspect:

1. Inspect the chest for lifts and heaves.

C. Palpate:

1. Palpate the chest for lifts, heaves, and thrills.

E. Auscultate:

1. Auscultate heart for splitting of heart sounds, clicks, rubs, and murmurs; use bell and diaphragm of stethoscope to auscultate client in left lateral, supine, standing, sitting (and leaning forward), and squatting positions and after having them run in place or do jumping jacks for 2 to 3 minutes.

a. A new, systolic, regurgitant murmur in the setting of an acute myocardial infarction (MI) may indicate a ruptured papillary muscle and possible cardiogenic shock.

b. When a new murmur is audible, differentiate the location, timing, quality, intensity, and duration. Note if radiation to neck, axilla, or back is present.

c. Note location of murmur:

i. Aortic: second right intercostal space (ICS) next to the sternum.

ii. Pulmonic: second left ICS next to sternum.

iii. Tricuspid: fifth left ICS next to sternum.

iv. Mitral: fifth left ICS at midclavicular line.

d. If murmur is heard, have the client squat, stand, and/or perform the Valsalva maneuver. Squatting will increase the blood to the heart and increase the left ventricle blood volume and stroke volume, which will increase the sound of the murmur. Standing and the Valsalva maneuver will provide the opposite, in which the venous return will drop and decrease the ventricle size and stroke volume and soften the sound of the murmur.

e. If the sound of the murmur occurs in the opposite action, softer when squatting and louder when standing or during the Valsalva maneuver, consider hypertrophic cardiomyopathy or mitral valve prolapse (MVP) as the diagnosis.

2. Auscultate the neck and axilla for radiation.

DIAGNOSTIC TESTS

A. EKG.

B. Echocardiogram.

C. Chest radiography.

DIFFERENTIAL DIAGNOSES

A. Major differentiation should be in the description of the murmur, as this aids in identification of the murmur.

1. Timing:

a. Identify when the murmur occurs in the cardiac cycle.

b. Systolic murmurs may or may not be normal.

i. Occurs between the "S1" lub and the "S2" dub.

c. Diastolic murmurs are always abnormal.

i. Occurs between the "S2" dub and the "S1" lub.

2. Quality: Is the sound harsh, blowing, musical, rumbling, vibratory, or soft?

3. Intensity: Murmurs are usually graded on a 6-point scale:

a. Grade I: barely audible.

b. Grade II: audible but soft.

c. Grade III: easily audible without thrill.

d. Grade IV: easily audible, thrill usually palpable.

e. Grade V: audible with only the rim of the stethoscope on the chest wall.

f. Grade VI: audible with the stethoscope barely off the chest wall; thrill present.

4. Duration: Identify the location and timing in the specific phase of the cardiac cycle:

a. Holosystolic: throughout systole.

b. Holodiastolic: throughout diastole.

c. Midsystolic: midway between S1 and S3.

d. Middiastolic: midway between S2 and S1.

e. Decrescendo: starts loud at the beginning, then tapers off.

f. Crescendo: starts soft at the beginning, then gets louder.

5. Radiation: Murmur can be heard in another place, such as the neck, back, left axilla, or across precordium. Sound usually radiates in the direction of blood flow.

6. Location: Identify location on chest wall where murmur is heard the best. Identify site: apex, pulmonary area, tricuspid, and aortic areas. Radiation murmur may also include axilla, left fourth ICS, or base of heart.

7. Configuration: intensity of the murmur over time: Does it plateau, crescendo, decrescendo, or crescendo–decrescendo?

8. Systolic murmurs: Systolic murmurs are benign or pathologic:

a. Early systolic murmurs:

i. Mitral regurgitation: holosystolic, blowing may be loud; located at the fifth ICS and radiates to left axilla/back; heard best in the left lateral position and sudden squatting; intensity decreases with the Valsalva maneuver and standing.

ii. Tricuspid regurgitation: holosystolic, heard in left lower sternal border or apex when right ventricle is enlarged; intensity increases with inspiration and decreases with expiration; straight leg raises may increase intensity; may also see hepatojugular reflux (HJR).

iii. Physiologic: early to midsystolic, low-pitch normal S1 to S2, located at left lower sternal edge at third to fourth ICS; heard best with bell and in supine and disappears when sitting up or holding breath; commonly seen in pregnancy and infection.

b. Midsystolic to late systolic murmurs:

i. Aortic stenosis: loud, hard crescendo–decrescendo at second right ICS and radiates to neck; heard best leaning forward, increases with leg raise and lying flat; decreases with Valsalva and handgrip standing.

ii. Pulmonic stenosis: prolonged, loud S2 or crescendo–decrescendo, usually greater than 3/6 at second ICS and radiates to neck; increases with inspiration.

iii. Hypertrophic cardiomyopathy (aortic outflow obstruction): peaks at midsystole; loud, harsh tone at left, lower sternal border that may radiate to the neck; increases with Valsalva maneuver and standing, decreases with sudden squatting; note carotid upstroke brisk.

c. Late systolic murmurs:

i. MVP: midsystolic click heard before late systolic murmur, heard best at fifth left ICS; heard best with diaphragm; sitting or squatting may increase intensity.

ii. Tricuspid valve prolapse: heard over the left lower sternal border, delayed onset of murmur with inspiration secondary to an increase in the right ventricular volume.

9. Diastolic murmurs: Murmurs are always pathologic.

a. Early diastolic murmur:

i. Aortic regurgitation: high-pitch faint, decrescendo may start with S2 at third left ICS and radiates down sternal edge; heard best leaning forward, holding breath; increases with sudden squatting or handgrip; may hear displaced point maximal intensity, S3, bounding pulse.

ii. Pulmonary regurgitation: valvular, dilation of valve annulus, congenital defect (tetralogy of Fallot, VSD), and pulmonic stenosis; best heard over left second/third ICS; may sound high-pitched with "blowing" sound in clients with hypertension (HTN); may be pansystolic, having decrescendo configuration.

b. Middiastolic murmur:

i. Mitral stenosis: rumbling extends beyond middiastole at fifth ICS, heard best using the bell of the stethoscope; increases with left lateral position; may hear snap after S2.

ii. Tricuspid stenosis: increased flow across the tricuspid valve, heard best at the left sternal border; identified by its increase in intensity of the murmur with inspiration (Carvallo sign); commonly seen with mitral stenosis.

PLAN

A. General interventions:

1. Major therapeutic goals are to preserve quality of life, increase life expectancy and exercise capacity, and reduce risk of complications. ▶

2. Activity restriction is not necessary in clients with asymptomatic valvular disease.

B. Client teaching:

1. Reassure the client regarding specific diagnosis.

2. Counsel the client regarding their specific condition.

3. Teach the client signs and symptoms to report to the health provider, including chest pain, SOB, difficulty breathing, and so forth.

C. Medical and surgical management:

1. Clients who need progressive increases in medications to control symptoms may be candidates for valve replacement surgery.

D. Pharmaceutical therapy:

1. The American College of Cardiology/American Heart Association (ACC/AHA) 2014 guidelines do not recommend routine endocarditis antimicrobial prophylaxis treatment for common valvular lesions, including a bicuspid aortic valve, acquired aortic or mitral valve disease (including MVP with regurgitation), and hypertrophic cardiomyopathy with latent or resting obstruction.

2. Endocarditis prophylaxis treatment: cardiac conditions:

a. Prophylactic treatment is recommended for high-risk cardiac condition abnormalities. Specific cardiac conditions include the following:

i. Prosthetic cardiac valve or prosthetic material used for cardiac valve repair.

ii. Previous infective endocarditis.

iii. Certain congenital heart diseases, such as cyanotic congenital heart disease that has not been repaired; a congenital heart disease that has been repaired with an artificial material or device for 6 months after repair; and repaired congenital heart defects with continued problems such as leaks or insufficient flow at the prosthetic device or adjacent to the repair.

iv. Postcardiac transplant valvulopathy.

b. Procedures for high-risk clients previously mentioned who require prophylaxis treatment:

i. All dental procedures with manipulation of gingival tissue or periapical region of teeth or perforation of the oral mucosa.

ii. Incision or biopsy of respiratory mucosa or any invasive procedure of the respiratory tract system.

iii. Procedures that include infected skin or musculoskeletal tissue.

iv. Preventive treatment with antibiotics is not recommended for procedures that include the reproductive tract, urinary tract, or gastrointestinal (GI) tract.

c. Antibiotic prophylactic regimens include single dose 30 to 60 minutes prior to the procedure:

i. Amoxicillin 2 g PO, intramuscular (IM), or intravenous (IV) for adults.

ii. Ampicillin 2 g IM or IV or 50 mg/kg IM or IV.

iii. Allergy to penicillin: cephalexin 2 g PO for adults.

iv. Azithromycin or clarithromycin 500 g for adults.

v. If allergic to these, consider cefazolin or ceftriaxone 1 g IM or IV or clindamycin 600 mg IM or IV for adults.

d. Other pharmaceutical treatments depend on the specific valvular abnormality.

i. Mitral stenosis: The mitral valve has a narrowing that does not allow adequate blood to the left ventricle during diastole, usually due to rheumatic heart disease. Mitral heart disease is the most commonly seen valve effect with rheumatic heart disease.

ii. Diuretics such as furosemide (Lasix) or hydrochlorothiazide (HydroDiuril) are used to control edema.

iii. Digoxin (Lanoxin) or beta-blockers are used to control atrial fibrillation (AF) and irregular heart rate.

iv. Warfarin (Coumadin) and the antiplatelet agent aspirin (Bayer) are used to prevent clotting.

v. MVP: Echocardiogram is the recommended test for diagnosis of MVP. Usually no medications are recommended except when symptomatic and required.

1) Beta-blockers (e.g., atenolol) may be used for palpitations.

2) Diuretics should be avoided in clients who are volume-reserved.

3) Oral contraceptives should be avoided in females who exhibit neurologic symptoms.

vi. Mitral regurgitation: diuretics, digitalis, and afterload-reducing agents for congestive heart failure (CHF):

1) Aortic stenosis.

2) Diuretics are used for CHF.

3) Avoid vasodilators; they may result in profound, irreversible hypotension.

4) Echocardiograms should be performed every 6 to 12 months to follow progression of narrowing of the left ventricle across the aortic valve.

vii. Aortic regurgitation: Afterload-reducing agents, digitalis, and diuretics are recommended.

FOLLOW-UP

A. Most clients with valvular disease should be evaluated at least once a year.

B. Clients on oral anticoagulation drugs need monthly follow-up or as needed prothrombin time (PT)/international normalized ratio (INR).

CONSULTATION/REFERRAL

A. Consult a physician if the client is diagnosed with a new murmur or exercise-induced symptoms during a sports physical.

B. Refer clients with newly diagnosed murmurs to a cardiologist after obtaining echocardiogram results.

C. Drug therapy should be initiated according to diagnosis and symptoms.

D. Onset of AF with rapid ventricular response is an indication for immediate hospitalization.

E. Refer clients with systemic embolization to a physician for emergent anticoagulation therapy and chronic oral anticoagulant therapy. Discuss the possibility of valve replacement with a cardiologist.

F. If a new murmur is diagnosed in a pregnant them with a history of cardiac disease, refer them to a physician immediately.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
  1. The development of a new, "high-flow" murmur in a healthy client is not uncommon due to physiologic changes occurring during pregnancy.

B. Geriatrics:
  1. Aortic stenosis, which is a systolic murmur, occurs in about 2% of people older than the age of 65. It occurs more often in males than in females.
  2. Symptoms of aortic stenosis in the elderly may include the following:
    a. Chest discomfort: The chest pain may get worse with activity and reach into the arm, neck, or jaw. The chest may also feel tight or squeezed.
    b. Cough, possibly bloody.
    c. Breathing problems when exercising.
    d. Becoming easily tired.
    e. Feeling the heart beat (palpitations).
    f. Fainting, weakness, or dizziness with activity.
  3. A systolic murmur, heard best in the aortic area, may indicate aortic sclerosis due to aging of the aortic valve rather than true aortic stenosis.

Otto, C., & Nishimura, R. (2021). 2020 ACC/AHA guideline for the management of patients with valvular heart disease a report of the American College of Cardiology/American Heart Association Joint Committee on clinical practice guidelines developed in collaboration with and endorsed by the American Association for Thoracic Surgery. American Society of Echocardiography, Society for Cardiovascular Angiography and Interventions, Society of Cardiovascular Anesthesiologists, and Society of Thoracic Surgeons. *Journal of the American College of Cardiology*, *77*, e25–e197.

PALPITATIONS

DEFINITION

A. Palpitations are a feeling or an unpleasant awareness of the heartbeat in the chest. It may be described as feeling a sensation of the heart "flip-flopping" or feeling a "rapid flutter" of the heart.

INCIDENCE

A. The incidence of palpitations may range from 1% to 8% of clients in a general practice setting.

PATHOGENESIS

A. Palpitations may be caused by the following:
  1. Increase in stroke volume or contractility.
  2. Sudden change in heart rate or rhythm.
  3. Unusual cardiac movement within thorax.
  4. Hyperkinetic states, which cause constant pounding.
  5. Valvular heart disease that produces large stroke volumes.
  6. Catecholamine release during anxiety or panic attacks.

PREDISPOSING FACTORS

A. Cardiac defects.
B. Severe anemia.
C. Hyperthyroidism.
D. Pregnancy.
E. Fever.
F. Anxiety.
G. Stimulants, such as caffeine and certain drugs.
H. Emotions, such as fear.
I. Exertion.
J. Diabetes mellitus and insulin reaction.

COMMON COMPLAINTS

A. Palpitations are often described as a turning over or flopping sensation in the chest, but symptoms vary enormously.
B. Most clients are free of palpitations at the time of the exam.

OTHER SIGNS AND SYMPTOMS

A. Fluttering in the chest.
B. Shortness of breath (SOB).
C. Pounding in the chest and neck.
D. Diaphoresis.
E. Light-headedness.
F. Anxiety or fear.

SUBJECTIVE DATA

A. Ask the client when symptoms first presented, including age, and how they have changed.
B. Have the client describe the characteristics of the palpitations, such as rapid, regular, irregular, or slow.
C. Ask the client what precipitates the palpitations. Does anything terminate them, or do they go away on their own?
D. Inquire whether symptoms occur or change with position (standing, bending over, lying down, left lateral decubitus position) and/or exercise.
E. Ask the client about other symptoms associated with the palpitations, such as dizziness or syncope.
F. Ask how often the episodes occur and how long each lasts.
G. Discuss any previous treatments for this condition and the results.
H. Ask the client about risk factors for coronary heart disease (CHD) and cardiac history.
I. Obtain a complete list of medications the client is currently taking, including over-the-counter (OTC) and herbal products:
  1. Specifically question the client's use of OTC decongestants and diet pills.
  2. Are there any new medications or changes in routine medications?

PHYSICAL EXAMINATION

A. Check pulse (count the pulse for 1 full minute), respirations, and blood pressure (BP).
B. Inspect:
  1. Inspect overall appearance.
  2. Inspect the skin for diaphoresis and pallor.
  3. Inspect the neck for thyromegaly or jugular vein distension.
  4. Inspect the legs for edema.
C. Palpate:
  1. Palpate the skin for temperature and dryness.
  2. Palpate the lower extremities for edema and calf tenderness.
  3. Palpate the neck for thyroid enlargement.
D. Auscultate:
  1. Auscultate the heart for abnormal rhythms. Auscultate heart sitting, standing, and left lateral decubitus position. Ask client to walk quickly down the hallway and back and then auscultate heart in all positions again.
  2. Auscultate the lungs.
  3. Auscultate the neck and carotid arteries for bruits.
E. Mental status:

1. Does the client appear light-headed, anxious, or fearful?

DIAGNOSTIC TESTS

A. Diagnostic testing is highly recommended for clients with an arrhythmia or at risk for an arrhythmia, and clients who are anxious and want to explore the causes of their symptoms. The following testing is recommended:

1. Hemoglobin to rule out anemia, if suggestive on exam.

2. Thyroid-stimulating hormone (TSH) to rule out hyperthyroidism, if suggestive on exam.

3. EKG during episode, if possible.

4. Ambulatory monitoring if symptoms continue, either 24-hour Holter monitor or client-activated transtelephonic monitoring.

5. Treadmill test if palpitations are provoked by exercise.

DIFFERENTIAL DIAGNOSES

A. Palpitations are secondary to an underlying problem, such as anxiety, medications, or cardiac or pulmonary origin.

PLAN

A. General interventions:

1. Provide reassurance if the palpitations result from a neurotic concern.

B. Client teaching:

1. Caution the client to avoid any factors that trigger episodes. Factors may include stress, exercise, foods, and medications.

2. Teach the client the vagal maneuver, which is effective in halting palpitations.

C. Medical and surgical management:

1. Correct any underlying problem (e.g., cardiac or pulmonary).

2. Treat medical conditions accordingly.

3. Management of arrhythmias should be monitored by a cardiologist.

D. Pharmaceutical therapy:

1. Discontinue all nonessential medications that could cause palpitations.

FOLLOW-UP

A. Depending on the etiology of palpitations and the existence of comorbid conditions, the prognosis in clients with no underlying cardiac disease is generally favorable.

CONSULTATION/REFERRAL

A. Consult a physician if the client has a history of palpitations leading to syncope or near syncope, angina-like chest pain, or dyspnea. These clients are candidates for referral to a cardiologist and/or inpatient evaluation. Refer any client with an arrhythmia to a cardiologist.

B. Hemodynamically compromised clients need prompt hospital admission.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. Elderly individuals are at increased risk for adverse effects from antiarrhythmic medications.

2. If drug treatment is necessary, lower doses should be initiated and titrated slowly to desired effect.

3. Polypharmacy (variously defined as the use of more than five to nine medications) may be the cause of cardiac-related symptoms.

4. Use caution when prescribing aspirin therapy in older adults.

PERIPHERAL ARTERIAL DISEASE

DEFINITION

A. Peripheral arterial disease (PAD) is a circulatory disorder characterized by the buildup of plaque on the interior surface of arteries. These plaques harden and narrow the diameter of the arteries, which reduces the volume of blood circulating to internal organs and extremities. The arteries affected by PAD include all arteries in the body, with the exception of the cerebral and coronary arteries. The decreased circulation seen in PAD can also be caused by nonatherosclerotic conditions. Some of these conditions are arteritis, trauma, radiation damage, and fibromuscular dysplasia. Symptoms of PAD can occur in the upper or lower extremities.

B. Classification of PAD:

1. Asymptomatic PAD:

a. No symptoms but the presence of risk factors or a new diagnosis of a common coexisting disease (coronary artery disease [CAD] or cerebrovascular disease) should prompt further evaluation.

2. Intermittent claudication (IC):

a. Discomfort (e.g., cramping or pain) with physical exertion that remits within 10 minutes of rest.

3. Chronic limb ischemia (CLI):

a. Pain at rest with a nonhealing wound, skin ulceration, or gangrene.

b. Onset is defined as chronic (i.e., ≥2 weeks).

4. Acute limb ischemia (ALI):

a. Pain at rest in a pale, pulseless extremity that is usually cold (poikilothermia) and has paresthesias and/or paralysis.

b. Onset is defined as acute (i.e., <2 weeks).

C. Other conditions contained within PAD:

1. Buerger disease (thromboangiitis obliterans): a disease manifested by inflammation, peripheral edema, and microthrombi, leading to gangrene of the hands and feet; usually caused by tobacco abuse and clients are thought to have a genetic predisposition to develop this condition.

2. Raynaud syndrome: a vasospastic disorder manifested by a response in the extremities to cold temperatures or stress where pallor, cyanosis, numbness, and/or pain are experienced.

3. Leriche syndrome: the triad of claudication, absent or diminished femoral pulses, and erectile dysfunction.

INCIDENCE

A. Approximately 8 million adults in the United States have PAD. This correlates to 20% of Americans older than 80 years of age.

B. PAD is more common in males than in females.

C. PAD is more common in clients of African and Hispanic descent when compared with the non-Hispanic White population.

▶

PATHOGENESIS

A. PAD is most commonly precipitated by atherosclerosis. An atherosclerotic plaque develops in response to turbulent blood flow on the endothelial cells of the vessel wall. The plaque contains inflammatory cells and a thrombogenic lipid core that is covered by a fibrous cap. When the fibrous cap is disturbed, the lipid core can precipitate to development of a thrombus and lead to occlusion of the vessel.

PREDISPOSING FACTORS

A. Smoking.
B. Diabetes.
C. Dyslipidemia.
D. Hypertension (HTN).
E. Obesity.
F. Atherosclerotic disease in another vascular bed (e.g., coronary, carotid, subclavian, renal, mesenteric artery stenosis, or abdominal aortic aneurysm).
G. Age.
  1. Age ≥65 years, increased occurrence.
  2. Age 50 to 64 years, with family history of PAD or risk factors for atherosclerosis (e.g., diabetes, smoking history, hyperlipidemia, and/or HTN).
  3. Age <50 years, with diabetes and one additional risk factor for atherosclerosis (e.g., coronary, carotid, subclavian, renal, mesenteric artery stenosis, and abdominal aortic aneurysm).

COMMON COMPLAINTS

A. Pain with activity is commonly characterized as cramping and/or aching:
  1. Upper extremity pain in the forearm, hand, and digits.
  2. Lower extremity pain in the foot, calf, hip, thigh, and/or buttocks:
    a. Foot pain is most common in tibial or peroneal artery stenosis.
    b. Calf pain is most common with superficial femoral or popliteal artery stenosis.
    c. Thigh pain is most common in aortoiliac and common femoral artery stenosis.
    d. Hip and buttock pain are most common with aortoiliac arterial stenosis.
B. Pain at rest.
C. Calf weakness or fatigue.
D. Numbness or tingling.
E. Dizziness with upper extremity exertion.
F. Syncope with upper extremity exertion.
G. Extremity ulceration.

OTHER SIGNS AND SYMPTOMS

A. Decreased peripheral pulses.
B. Blanching of the affected limb with elevation.
C. Ulcerations or infection on distal aspects of extremities.
D. Erectile dysfunction.

POTENTIAL COMPLICATIONS

A. Nonhealing lower extremity ulcerations.
B. Infection.
C. Amputation.
D. Common coexisting diseases:
  1. CAD; also known as coronary heart disease (CHD).
  2. Cerebrovascular disease.
  3. Subclavian artery stenosis.

SUBJECTIVE DATA

A. Ask client what activity brought about or preceded the episode or whether it occurs at rest. If ambulation was the precipitating factor, how far was the client able to walk?
B. Have client describe duration of pain and what time of day the symptoms began.
C. Ask client what alleviates their pain.
D. Ask client whether any previous episodes have occurred.
E. Ask the client to list all medications, including over-the-counter (OTC) and herbal products currently being taken or recently stopped.
F. Ask client to quantify their smoking history.
G. Ask client if they have medical history of myocardial infarction (MI) or cerebrovascular accident (CVA).
H. Ask client if they have any history of impotence or erectile dysfunction.

PHYSICAL EXAMINATION

A. Clients presenting with ALI should be quickly assessed for the need to call emergency services/911 for immediate transport to the hospital.
  1. Symptoms of ALI as evidenced by the six Ps: pain, pallor, paresthesia, paralysis, pulseness, and poikilothermia (the inability to maintain a constant core temperature).
B. Check vital signs.
  1. Check blood pressure (BP) in both upper extremities.
    a. A difference in systolic blood pressure (SBP) of 10 mmHg or greater in upper extremities is associated with upper extremity PAD and cerebrovascular disease.
    b. A difference in SBP of 15 mmHg or greater in upper extremities is associated with lower extremity PAD.
  2. Check BP in both lower extremities.
  3. Document resting heart rate, respirations, height, and weight.
C. Inspect:
  1. Perform a funduscopic exam: Check for retinal vascular changes that indicate a retinal vascular occlusion, such as macular edema and neovascularization.
    a. Macular edema is the swelling of the central part of the retina.
    b. Neovascularization is the growth of abnormal vessels secondary to decreased perfusion of the retina.
  2. Inspect abdomen for a pulsating abdominal mass.
  3. Inspect extremities. Note edema, pallor, and cyanosis. Note color of extremities in dependent and elevated positions (e.g., elevation pallor and dependent rubor).
  4. Inspect distal skin, hair, and nails. Note any temperature discrepancies or trophic changes that are indicative of ischemia.
  5. Assess lower extremities for any ulcerations or diffuse erythema.
  6. Assess for Homans sign (i.e., calf pain with forced dorsiflexion).
  7. Assess whether pain occurs when affected limb is elevated.
D. Palpate:
  1. Palpate pulses, noting symmetry:
    a. Bilateral upper extremities (brachial and radial).
    b. Abdominal (aorta).
    c. Bilateral groin (femoral).
    d. Bilateral lower extremity pulses (popliteal, dorsalis pedis, and posterior tibialis).
  2. Palpate capillary refill.

▶

3. Perform an Allen test: Occlude the radial and ulnar arteries with the fist closed. Open the hand and then release one of the occluded arteries. Repeat but release the other artery. Each time, prompt capillary refill should occur.

4. Palpate neck for carotid bruits.

5. Palpate the abdominal aorta, noting any lateral pulsation, which is indicative of an aortic aneurysm.

E. Auscultate:

1. Auscultate heart: Assess rate, rhythm, heart sounds, murmur, and gallops.

2. Auscultate the carotids, abdomen, and bilateral groin for bruits.

3. Auscultate lungs: Assess lung sounds, noting any sign of heart failure (HF).

DIAGNOSTIC TESTS

A. Doppler ankle–brachial index (ABI).

1. Interpretation of ABI ratios:

a. 1.00 to 1.29: normal.

b. 0.91 to 0.99: borderline PAD.

c. 0.41 to 0.90: mild to moderate PAD.

d. 0.00 to 0.40: severe PAD.

B. Basic metabolic panel (BMP; including blood urea nitrogen [BUN], creatinine, sodium, and potassium).

C. Lipid profile.

D. C-reactive protein (CRP), homocysteine, and D-dimer.

E. EKG (12-lead).

F. Doppler ultrasound.

G. Abdominal ultrasound.

H. Treadmill testing.

I. CT angiography (CTA).

J. Magnetic resonance angiogram (MRA).

K. Arteriography, ordered and performed by a surgeon.

DIFFERENTIAL DIAGNOSES

A. PAD.

B. Venous stasis.

C. Venous obstruction/claudication.

D. Spinal stenosis.

E. Nerve root compression.

F. Arthritis of the hip.

G. Peripheral neuropathy.

H. Arteritis.

PLAN

A. General interventions.

1. The goal of therapy is to improve the client's quality of life by reducing morbidity and prolonging survival.

B. Client teaching: *See Client Teaching Guide for this chapter, "Peripheral Arterial Disease."*

1. Encourage smoking cessation, weight loss, and exercise, if applicable.

2. Encourage strategies to better manage other chronic medical conditions that directly affect the progression of PAD, that is, diabetes, dyslipidemia, obesity, and HTN.

3. Proper foot care:

a. Instruct client to wear proper-fitting shoes that protect the feet.

b. Inspect inside of shoes before donning.

c. Encourage client to inspect feet daily for signs of trauma or infection.

d. Instruct client to dry their feet well, including between toes, after bathing.

4. Prevention:

a. Control other chronic medical conditions, that is, diabetes, dyslipidemia, HTN, and obesity.

C. Dietary management:

1. To manage dyslipidemia and HTN, counsel the client on nutrition and low-fat, low-cholesterol, and low-sodium diet.

2. To manage diabetes, counsel the client on diabetic diet and carbohydrate counting.

3. To manage infection related to PAD, counsel the client on high-calorie, high-protein diet. Consider the addition of vitamins and minerals to promote wound healing, specifically zinc and vitamins C and A.

4. Give diet handouts and/or refer to a registered dietitian.

D. Pharmaceutical therapy:

1. Goal of therapy: prevention of thromboembolism.

a. Pentoxifylline (Trental):

i. 400 mg tablet.

1) Dosage indications based on creatinine clearance (CrCl):

a) CrCl less than 10 mL/min: 400 mg, taken once a day.

b) CrCl of 10 to 50 mL/min: 400 mg, taken BID.

c) CrCl greater than 50 mg/min: 400 mg, taken TID.

b. Cilostazol (Pletal):

i. 50 mg and 100 mg tablets.

1) **Warning: Metabolites of Pletal are inhibitors of phosphodiesterase III and are contraindicated in clients with congestive heart failure (CHF) of any severity.**

2) Dosage indications:

a) 50 mg, taken BID if taken in coadministration with ketoconazole, itraconazole, erythromycin, and diltiazem.

b) 100 mg, taken BID at least half an hour before or 2 hours after breakfast and dinner.

ii. 81 and 325 mg tablets, taken once daily.

c. Clopidogrel bisulfate (Plavix):

i. 75 mg, taken once daily.

d. Aspirin (acetylsalicylic acid; Ecotrin).

i. Beers criteria caution:

1) Use aspirin with caution in older adults older than 80 years with no history of cardiovascular disease (CVD): There is no clear evidence that aspirin provides primary prevention for cardiac events, but there is a risk for gastrointestinal (GI) bleeds.

2) In adults older than 65 years, avoid use of greater than 325 mg due to risk of GI bleed, unless other alternatives are not effective and the client can take a gastroprotective agent.

3) In adults older than 75 years, or adults older than 65 taking corticosteroids, anticoagulants, or antiplatelet agents, there is an increased risk of upper GI bleeds. The use of proton pump inhibitors (PPIs) reduces but does not eliminate risk. The risk of GI bleed increases with duration of use of nonsteroidal anti-inflammatory drugs (NSAIDs), including high-dose aspirin (ASA). At 1 year, the risk is 2% to 4% and this increases with each subsequent year.

2. Risk factor reduction:
   a. Manage dyslipidemia.
      i. Low-density lipoprotein cholesterol (LDL-C) goal: less than 100 mg/dL and less than 70 mg/dL for clients at high risk for CAD.
   b. Manage HTN.
      i. BP goal in clients without diabetes: less than 140/90 mmHg.
      ii. BP goal in clients with diabetes or chronic kidney disease: less than 130/80 mmHg.
   c. Manage diabetes.
      i. Hemoglobin A1C goal: less than 7.0%.

E. Surgical therapies:
1. Considered in clients with pain at rest, tissue loss, or significant physical limitations that prevent exercise.
   a. Bypass.
   b. Stenting.
   c. Angioplasty/percutaneous transluminal angioplasty.

F. Nonsurgical therapies:
1. Smoking cessation program.
2. Daily walking program.
   a. Instruct the client to walk to the point of pain, then stop and resume walking when pain remits.
   b. Medical clearance may need to be obtained for the client to exercise.

FOLLOW-UP

A. PAD manifesting persistent symptoms should always be followed by a cardiologist.

B. Follow-up is determined by the client's needs, frequency and intensity of symptoms, and the presence of other medical conditions.

EMERGENT ISSUES/INSTRUCTIONS

A. Clients should contact the office if they have any of the following symptoms:
1. **Worsening pain in arm or leg.**
2. **Fever over 101°F.**
3. **Any change in feeling of a hand or foot.**
4. **Any change in the color of a hand or foot.**
5. **Difficulty walking.**
6. **Vomiting or other illness that causes them to miss more than one dose of their medications.**
7. **If taking an antiplatelet therapy and have any of the following symptoms:**
   a. **Vomit that is bright red or dark and looks like coffee grounds or grape jelly.**
   b. **Blood in their bowel movements that looks black or tarry in color.**

B. Clients should contact the office if they are experiencing any new symptom(s) not present at their last office visit.

CONSULTATION/REFERRAL

A. If you suspect ALI, refer client for immediate hospitalization to obtain diagnostic testing to determine the presence of a thrombus and restore circulation to the affected extremity.

B. If CLI has led to ulceration and/or superimposed infection, hospitalization is indicated to initiate wound care consultation and diagnostic testing to determine the degree of arterial occlusion.

C. Refer to a cardiologist in the presence of persistent PAD symptoms.

D. Refer to a vascular surgeon for further evaluation of angioplasty, stenting, or bypass surgery.

E. Refer to a podiatrist to trim toenails and assess client for proper-fitting shoes.

F. Refer to pain management if pain is resistant to treatment.

G. Refer to a registered dietitian as indicated by the client's understanding of dietary modification necessary to improve status of risk factors.

INDIVIDUAL CONSIDERATIONS

A. Nonambulatory clients:
1. Using rocking chairs is a possible substitute for persons unable to participate in a walking program.

B. Geriatrics:
1. Refrain from aggressive therapies such as percutaneous or surgical revascularization in stenosis unless claudication or critical limb ischemia is present.
2. Review comorbid conditions, such as renal function, GI bleed risk, and polypharmacy prior to prescribing pharmaceutical therapy. The risk/benefit ratio is varied in older and frail adults and nonpharmacologic therapy may be the best choice depending on individual considerations (see the "Deprescribing" section of Chapter 3).
3. Be alert to signs and symptoms of depression related to immobility and pain.

SUPERFICIAL THROMBOPHLEBITIS

DEFINITION

A. Superficial thrombophlebitis occurs when venous turbulence, static, or coagulability allows microthrombi to form in the presence of vessel wall (endothelial) injury, which triggers an inflammatory response in a superficial vein.
1. Most superficial thrombophlebitis occurs in the lower extremity but may also occur in the breast and penis (Mondor disease).
2. Superficial thrombophlebitis may also occur in the upper extremities and neck secondary to invasive ▶

intravenous (IV) catheters used in medical procedures and medication administration.

3. Generally, superficial thrombophlebitis is usually benign and self-limiting, but may persist for a period of time (3–4 weeks or longer) before resolution.

B. Superficial thrombophlebitis with an infection is referred to as a "septic thrombophlebitis."

INCIDENCE

A. With pregnancy, there is approximately a four- to fivefold increase of phlebitis over a nonpregnant female. Eighty percent of thromboembolic events in pregnancy are venous (0.5–2.0 per 1,000).

B. The prevalence of superficial thrombophlebitis ranges from 4% to 7% in clients with an indwelling catheter.

C. Superficial phlebitis is common after a vein radiofrequency or laser ablation.

PATHOGENESIS

A. Superficial thrombosis is caused by infection, abuse of IV drugs, chemical irritation from overuse of IV route for diagnostic tests and drugs, and/or trauma. Several episodes of superficial thrombosis can signal an underlying problem, such as carcinoma of the pancreas and hemoglobinopathies.

B. Thrombi in the upper extremities commonly have iatrogenic causes, such as IV catheters.

C. Superficial thrombophlebitis during pregnancy through the first 6 weeks postpartum is linked to a reduced fibrinolytic state.

PREDISPOSING FACTORS

A. Previous thrombophlebitis is the highest risk factor for recurrence.

B. Hypercoagulability, such as pregnancy (50% of events) through 6 weeks postpartum (50% of events).

C. History of polyarteritis nodosa, thromboangiitis obliterans (Buerger disease), or Behçet disease.

D. Hemoglobinopathies:

1. Factor V Leiden mutation.
2. Protein C deficiency.
3. Protein S deficiency.
4. Prothrombin gene mutation.
5. Antithrombin III deficiency.
6. Factor XII deficiency.

E. Estrogen therapy, especially high-dose hormone replacement therapy.

F. Malignancy (especially in the tail of the pancreas).

G. Systemic lupus erythematosus with a positive anticardiolipin antibody.

H. Sepsis.

I. Recent surgery.

J. Long bone trauma.

K. Recent IV catheter access.

L. Prolonged immobilization.

M. Obesity, specifically with a body mass index exceeding 25 kg/m^2.

N. Varicose veins or venous stasis.

O. Age older than 60.

P. Stroke.

Q. Myocardial infarction (MI).

R. Family history of deep vein thrombosis (DVT).

S. Smoking.

T. Hypertension (HTN).

U. Infection.

V. IV drug abuse.

COMMON COMPLAINTS

A. Warm, tender, inflamed vessel with palpable cord.

B. Discoloration: redness along the course of the superficial vein in the acute phase with progression to a brown pigmentation in the chronic phase.

C. Tenderness or pain localized to the affected vein.

OTHER SIGNS AND SYMPTOMS

A. Fever/no fever.

B. Localized edema.

POTENTIAL COMPLICATIONS

A. Superficial thrombophlebitis extending into the deep venous system.

B. DVT.

C. Conversion to suppurative thrombophlebitis:

1. Metastatic abscess formation.
2. Septicemia.
3. Septic emboli.

SUBJECTIVE DATA

A. Query the client regarding onset, duration, and intensity of symptoms.

B. Ask the client about fever or other related symptoms.

C. Obtain a thorough medical history and account of recent physical activity.

D. Ask the client about any recent experience of any type of injury.

E. Inquire whether the client has ever had similar symptoms or previous thrombophlebitis. If so, discuss previous treatment and therapy used and the results.

F. Review current medications: prescription, over-the-counter (OTC), and herbal products.

1. **Ask specifically about oral contraceptives and hormone therapy.**

G. Review the client's occupation for sedentary lifestyle.

H. Review any recent plane travel.

I. Review history for recent invasive procedures.

PHYSICAL EXAMINATION

A. Check temperature (if indicated with inflammation), pulse, respirations, and blood pressure (BP).

B. Inspect:

1. Assess overall appearance. Evaluate for the presence of respiratory distress.
2. Inspect extremities, noting erythema and edema.
3. Assess for increased warmth over the affected vein.

C. Auscultate:

1. Auscultate heart, noting rate, rhythm, heart sounds, murmurs, and gallops.
2. Auscultate lungs for lung sounds in all fields.

D. Palpate:

1. Palpate extremities; check all pulses, including femoral, posttibial, pedal, and radial.
2. Palpate extremities for tenderness and palpable cord.
3. Palpate lymph nodes distal and proximal to the site.
4. Test for Homans sign in lower extremities bilaterally if DVT is suspected.

DIAGNOSTIC TESTS

A. Duplex ultrasound identifies the presence, location, and extent of the venous thrombosis.

B. Doppler ultrasound. ▶

C. Magnetice resonance venography (MRV), which is noninvasive and sensitive for diagnosis but may not be readily available.

D. Laboratory tests are ordered dependent on the clinical situation.

1. Complete blood count (CBC) with differential.

2. Screening for hypercoagulability should not be considered for one episode of superficial thrombophlebitis.

3. Screening for hypercoagulability should be considered for recurrent superficial thrombophlebitis.

4. Blood cultures.

DIFFERENTIAL DIAGNOSES

A. Thrombophlebitis.
B. Varicose veins.
C. Cellulitis.
D. Strained muscle.
E. Insect bites.
F. Erythema nodosum.
G. Cutaneous polyarteritis nodosa.
H. Kaposi sarcoma.
I. Hyperalgesic pseudothrombophlebitis.

PLAN

A. General interventions:

1. The goal is to offer comfort, time for healing, and prevent an evolution into the deep venous system.

a. Prescribe supportive hose/compression stockings.
b. Have the client apply heat and elevate the extremity for varicose veins or superficial thrombophlebitis.
c. Prescribe bedrest for superficial thrombophlebitis.
d. DVT: Hospitalization is required.
e. Instruct clients with thrombophlebitis to discontinue oral contraceptives and hormone replacement.
f. Alternative forms of birth control recommended by the American Congress of Obstetricians and Gynecologists (ACOG) include the following:

i. Intrauterine device (IUD), including IUDs that contain progestin.
ii. Progestin-only oral contraceptives.
iii. Progestin-only implants.
iv. Barrier methods.
v. Surgical procedures: vasectomy and tubal ligation.

B. Client teaching: *See Client Teaching Guides for this chapter, "Superficial Thrombophlebitis" and "Varicose Veins."*

1. Advise all clients to stop smoking.

2. Instruct the client to avoid prolonged sitting or standing and not to cross or massage their legs.

3. Advise the client to avoid constrictive clothing, such as knee-high hosiery.

C. Pharmaceutical therapy:

1. Nonsteroidal anti-inflammatory drugs (NSAIDs) are used for treatment of pain. No NSAID has been identified as superior for treatment.

2. The use of anticoagulation therapy for treatment of lower extremity superficial thrombophlebitis is controversial. Unfractionated heparin and low-molecular-weight heparin (LMWH) are both used for treatment to reduce risk of DVT and/or recurrent phlebitis.

3. The American College of Chest Physicians recommends anticoagulation for clients with lower extremity superficial thrombophlebitis at increased risk of thromboembolism. This is defined as an affected venous segment greater than or equal to 5 cm in proximity (≥5 cm) to the deep venous system and positive medical risk factors. The American College of Chest Physicians' full evidence-based clinical practice guidelines on antithrombotic therapy are available at journal.chestnet.org/article/S0012-3692(15)00335-9/pdf.

4. Antibiotics, if infection is suspected.

D. Surgery:

1. Biopsy.

2. Vein ablation, only if symptoms are significant and persistent.

3. Vein ligation, only if symptoms are significant and persistent.

FOLLOW-UP

A. Schedule an appointment for clients with superficial thrombophlebitis to return in 7 to 10 days or earlier as needed. Repeat physical examination as needed to evaluate resolution or progression of the thrombophlebitis.

B. Periodic follow-up is needed to monitor clients on anticoagulation therapy.

C. After acute problem is resolved, consider laboratory evaluation for hypercoagulation syndrome (e.g., protein C, protein S, and antithrombin III).

D. Monitor bone loss with a dual-energy x-ray absorptiometry (DEXA) scan with prolonged use of heparin.

E. Screening all females for thrombophilias before starting oral contraceptives is not recommended by the ACOG.

F. Females with a history of thrombosis who have not had a complete evaluation should be tested for both antiphospholipid antibodies and inherited thrombophilias.

EMERGENT ISSUES/INSTRUCTIONS

A. Clients should contact the office if they have any of the following symptoms:

1. Worsening pain in an arm or leg.
2. Fever over 101°F.
3. Any temperature change in a hand or foot.
4. Any change in feeling of a hand or foot.
5. Any change in the color of a hand or foot.
6. Difficulty walking.
7. Vomiting or other illness that causes them to miss more than one dose of their medications.

B. Clients should contact the office if they are experiencing any new symptom(s) not present at their last office visit.

CONSULTATION/REFERRAL

A. If septic thrombophlebitis or DVT is diagnosed, refer the client to a physician.

B. Hospitalization is required to initiate heparin therapy.

C. Comanage pregnancy with an obstetrician.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Routine anticoagulation therapy for all pregnant individuals is not recommended. Therapeutic anticoagulation is recommended for clients with acute thromboembolism during the current pregnancy or those at high risk of thrombosis, such as individuals with mechanical heart valves.

2. Warfarin and NSAIDs are contraindicated.

3. Heparin is the preferred anticoagulant in pregnancy. Neither unfractionated heparin nor LMWH crosses the placenta.

4. Warfarin, LMWH, and unfractionated heparin do not accumulate in breast milk and do not induce an ▶

anticoagulant effect in the infant and therefore are considered compatible with breastfeeding.

B. Geriatrics:

1. Chronic NSAID use is contraindicated in the geriatric population. Short-term use requires caution in certain populations due to the risk for cardiovascular disease (CVD) and kidney injury.

2. The overall prognosis is poor for geriatric clients with septic thrombophlebitis.

3. Static or seated exercise therapy or even the use of a self-propelled wheelchair (using the feet to walk with wheelchair forward) or a rocking chair may provide an activity substitute for persons unable to participate in a walking program.

4. Be alert to the geriatric syndrome of depression related to immobility and pain.

SYNCOPE

DEFINITION

A. Syncope is a brief, sudden loss of consciousness and muscle tone secondary to cerebral ischemia, or inadequate oxygen or glucose delivery to brain tissue. Recovery is spontaneous.

INCIDENCE

A. Syncope is a common problem in all age groups. Between 12% and 48% of healthy young adults have lost consciousness (one-third following trauma), but most do not seek medical attention. Adults older than age 75 in long-term care facilities have a 7% annual incidence of syncope and 30% have had previous episodes. Syncopal episodes account for approximately 1% to 6% of hospital admissions and 3% of ED visits.

PATHOGENESIS

A. The most common cause of syncope is inadequate cerebral perfusion caused by one of the following:

1. Vasomotor instability associated with a decrease in systemic vascular resistance and/or venous return. The following may cause syncope:

a. Vasovagal episodes.

b. Situational syncope, from coughing, micturition, and defecation.

c. Medications:

i. Vasodilators.

ii. Antiarrhythmics.

iii. Diuretics.

iv. Neurologic agents.

v. Glucose-regulating drugs.

vi. Impotence therapy.

2. Decrease in cardiac output caused by blood flow obstruction within the heart or pulmonary circulation or by arrhythmias. This may be caused by the following:

a. Aortic, pulmonic, and mitral stenosis.

b. Idiopathic hypertrophic subaortic stenosis (IHSS) or hypertrophic obstructive cardiomyopathy (HOCM).

c. Pump failure.

d. Subclavian steal syndrome.

e. Seizures.

3. Focal or generalized decrease in cerebral perfusion leading to transient ischemia due to cerebrovascular disease:

a. Carotid arterial disease.

4. Metabolic abnormalities:

a. Hypoglycemia.

b. Hypocarbia and hypoxia usually do not result in syncope unless they are profound, although consciousness may be altered.

5. Psychiatric illnesses associated with syncope include the following:

a. Generalized anxiety.

b. Panic attacks.

c. Major depressive disorders.

6. Unexplained cause.

PREDISPOSING FACTORS

A. Advanced age, caused by altered regulation of cerebral blood flow and/or systemic arterial pressure due to aging process and increased medication use.

B. Other factors, depending on etiology.

C. Medication use (previously noted).

COMMON COMPLAINTS

A. Dizziness.

B. Light-headedness.

C. Fainting with no memory of events.

OTHER SIGNS AND SYMPTOMS

A. Neuroautonomic regulations:

1. Event triggered by changing position, turning head, or wearing tight collars.

2. Nausea, warmth, diaphoresis, or weakness 1 hour after eating.

B. Cardiac causes:

1. Exercise-induced palpitations, chest pain, and shortness of breath (SOB), with no warning prior to episode.

C. Neurologic causes:

1. Vertigo.

2. Diplopia.

3. Facial paresthesias.

4. Ataxia.

5. Auditory, visual, or vestibular disturbances.

D. Metabolic or endocrine causes:

1. Restlessness.

2. Anxiety.

3. Confusion.

4. No recent food intake, low glucose level.

E. Psychiatric:

1. Graceful fainting in presence of an audience.

SUBJECTIVE DATA

A. Inquire if the client ever experienced similar symptoms or episodes before. If so, when and at what age did it begin?

B. Ask the client or witness of the episode to give a detailed description of loss of consciousness. Was loss of consciousness complete, and if so for how long? What was the posture of the client before, during, and after the event? Did it ▶

occur abruptly, or were there symptoms leading up to the event?

C. Question the client regarding events leading up to the episode, noting prodromal symptoms such as headache, aura, nausea/vomiting, light-headedness, diaphoresis, feeling, or warmth.

D. Obtain a detailed account of symptoms during and after the episode, noting mental status. Did the client recover on their own, or did the client require assistance? Were there any associated symptoms that occurred during the event? SOB, chest pain, loss of bowel, or bladder control?

E. If syncope has occurred in the past, are there any events that precipitate an episode? Exertion, exercise, coughing, or standing quickly?

F. Obtain a detailed medication history, addressing prescribed and over-the-counter (OTC) drugs, alcohol, and illicit preparations.

G. Review the client's medical history.

PHYSICAL EXAMINATION

A. Check temperature, if indicated, pulse, respirations, and blood pressure (BP).

1. Measure BP and pulse in both arms and legs. Note BP differences between the arms.

2. Measure BP several times during a 2-minute period with the client standing.

3. Check for orthostatic hypotension, which is defined as a drop of 20 mmHg or more in systolic blood pressure (SBP) on standing.

a. First, measure BP after the client lies supine for 5 to 10 minutes.

b. Then have the client stand and measure BP several times during a 2-minute period.

4. Inspect the range of motion in the neck.

B. Palpate:

1. Palpate the abdomen, noting pulsatile expansion.

C. Auscultate:

1. Auscultate the heart with position changes. Note murmurs or extra heart sounds to rule out structural disease. Identify dysrhythmias such as bradycardia, supraventricular tachycardia, tachycardia, atrioventricular (AV) blocks, atrial fibrillation (AF), bundle branch blocks, and sinus pauses or arrests.

2. Auscultate the carotid arteries.

3. Auscultate the abdomen for bruits.

D. Perform neurologic exam:

1. Perform a complete exam, if indicated, including assessing cranial nerves II to XII, Babinski reflex, and gait.

E. Mental status:

1. Assess mental health, if indicated.

DIAGNOSTIC TESTS

A. The 2017 American College of Cardiology/American Heart Association (ACC/AHA) guideline for syncope recommends the following diagnostic tests based on history and physical findings:

1. If carotid sinus syndrome is suspected, carotid sinus massage can be attempted. Avoid in clients with history of transient ischemic attack (TIA) or stroke in the past 3 months and in clients with carotid bruits. Recommend physician or cardiology specialist assistance when performing carotid massage along with continuous cardiac monitoring. Use caution when performing carotid sinus massage. Please consider contraindications, complications, and guidelines for performing procedure.

2. Echocardiogram for clients with a history of heart disease, structural heart disease, or syncope secondary to cardiovascular cause (known heart disease), family history of unexplained sudden death in the family, syncope with exertion or supine, abnormal EKG, sudden onset of palpitation prior to syncope, or arrhythmia on EKG.

3. EKG for clients with suspected arrhythmia or cardiac disease. Identify acute and old EKG changes to rule out pathologic Q wave, ST-segment elevation, and left ventricular (LV) hypertrophy.

4. Orthostatic challenge test if syncope is related to position change or suspect reflex mechanism.

5. Neurologic/serum laboratory testing for other concerns of nonsyncopal loss of consciousness. Laboratory testing includes chemistry profile, thyroid-stimulating hormone (TSH), and free T4. Consider a glucose tolerance if diabetes is suspected. Brain natriuretic peptide may be useful to evaluate cardiac versus noncardiac causes of syncope.

6. Chest radiography, for essential baseline data. Wide mediastinum signals aortic dissection.

7. In-hospital monitoring is recommended for unstable clients in life-threatening conditions.

8. Holter monitor for 24 to 48 hours.

9. External event monitor.

10. Exercise testing is recommended for clients with syncope that occurs during, or quickly after, cessation of exercise. Echocardiogram is recommended prior to this testing.

11. Cardiac catheterization.

12. Lung scan.

13. Treadmill test.

14. Electrophysiologic studies are recommended for clients with unexplained syncope.

DIFFERENTIAL DIAGNOSES

A. Irregular neuroautonomic regulations:

1. Neurocardiogenic causes.

2. Situational causes, such as coughing, defecation, diving, micturition, sneezing, swallowing, trumpet playing, vagal stimulation, weightlifting, postprandial state.

3. Orthostatic causes:

a. Hyperadrenergic state.

b. Hypoadrenergic state, primary or secondary autonomic insufficiency.

c. Carotid sinus syncope.

d. Cardioinhibitory state.

e. Vasodepressor stimulation.

f. Mixed.

B. Cardiac causes:

1. Mechanical causes, such as aortic dissection, aortic stenosis, atrial myxoma, cardiac tamponade, global myocardial ischemia, hypertrophic cardiomyopathy, mitral stenosis, myocardial infarction (MI), prosthetic valve dysfunction, pulmonary embolism (PE), pulmonary hypertension (HTN), pulmonary stenosis, and Takayasu arteritis.

2. Electrical causes, such as AV block, long QT syndrome, pacemaker, sick sinus syndrome, supraventricular tachyarrhythmias, and ventricular tachyarrhythmias.

C. Neurologic causes:

1. Neuralgias: glossopharyngeal, trigeminal. ▶

2. Normal pressure hydrocephalus.
3. Subclavian steal.
4. Vertebrobasilar artery disease: compression, migraine, and TIA.

D. Metabolic or endocrine causes: hypoadrenalism, hypoglycemia, hyponatremia, hypothyroidism, and hypoxia.

E. Psychiatric causes: anxiety, hysteria, major depression, panic disorder, somatization, and hyperventilation syndrome.

PLAN

A. General interventions:
1. Management is directed at primary cause of the episode.

B. Client teaching:
1. If the client has orthostatic hypotension, suggest that they wear elastic stockings, change positions slowly, sleep with the head of the bed elevated, and exercise their legs before standing.
2. If syncope is induced by situations, warn the client to avoid or alter their approach to such precipitating events.
3. If the client has prodromal symptoms, such as nausea, light-headedness, pallor, sweating, or palpitations, advise them to lie down when they occur.
4. If the client has hypersensitive carotid sinus reflex, recommend that they loosen their collar.
5. Instruct client to avoid prolonged standing. If they cannot avoid it, they should contract their calf muscles to increase venous blood flow.
6. Some driving restrictions exist for clients at risk of recurrent syncope. Driving restrictions are enforced by state law. Review restrictions with the client and the family as indicated by diagnosis.

C. Dietary management:
1. If not contraindicated, instruct clients with orthostatic hypotension to use salt liberally.

D. Pharmaceutical therapy for neurocardiogenic syncope includes the following:
1. Nonpharmacologic methods suggested:
a. Avoid volume depletion.
b. Maintain adequate sodium levels by increasing salt intake in their diet.
c. Wear thigh-high elastic support hose with 30 to 40 mmHg pressure.
d. Orthostatic training is also recommended two times a day.
2. Drugs of choice: beta-blockers (Inderal 80–160 mg/d, metoprolol 50–100 mg/d) for vasovagal syncope.
3. Fludrocortisone acetate (Florinef Acetate), a corticosteroid, may be used alone or with beta-blockers. Initial dosage is 0.1 to 0.4 mg/d; this may be increased gradually to 1.0 to 2.0 mg/d.
4. Other drugs include anticholinergic agents (disopyramide 100–200 mg BID sustained-release), and selective serotonin reuptake inhibitors (SSRIs; Zoloft 50 mg/d, Prozac 20 mg/d, Paxil 20 mg/d).

FOLLOW-UP

A. Scheduling of return visits depends on the etiology and severity of syncope and on whether the client has been placed on medications.

CONSULTATION/REFERRAL

A. Consult with or refer the client to a physician when cardiac or neurologic involvement is suspected.

B. Consult with or refer the client to a physician if medication therapy is required.

INDIVIDUAL CONSIDERATIONS

A. Adults:
1. In young adult athletes, be aware of symptoms of Marfan syndrome.
2. In older adults, coronary atherosclerosis may present along with syncope.

B. Geriatrics:
1. The most common cause of syncope in the elderly is postural hypotension, which can be due to a combination of factors, both intrinsic and extrinsic. This is often the impetus for falls.
2. Intrinsic factors can include noncompliant arteries, reduced skeletal muscle pumping action of venous return due to physical inactivity, and aging of the sinoatrial node and conduction system due to progressive atherosclerosis and/or structural heart disease.
3. The most common extrinsic factor involves medications that lower BP and cause vasodilation of blood vessels. Nurse practitioners (NPs) should routinely evaluate their geriatric client's cardiac medications and reduce doses or deprescribe when appropriate.
4. In the elderly, syncope often has more than one cause. For example, the combination of taking several heart and BP drugs and standing for a long period of time may lead to syncope even though no single factor might cause it.

CLIENT TEACHING GUIDE

ATHEROSCLEROSIS AND HYPERLIPIDEMIA

PROBLEM Hyperlipidemia (excess lipids in the blood) is often referred to as "hardening of the arteries." The excess lipids increase your risk of developing heart disease and heart attacks.

CAUSE Elevated blood cholesterol levels lead to plaque formation in the walls of the major arteries in the body. The higher the level of low-density lipoprotein (LDL), or "bad" cholesterol, the greater the chance of developing heart disease. On the other hand, the higher the level of high-density lipoprotein (HDL), or "good" cholesterol, the lower the risk of heart disease.

PREVENTION/TREATMENT PLAN Lowering your risk of heart disease involves the following:

A. Diet changes to lower your bad cholesterol (LDL) and raise your good cholesterol (HDL).
B. Lose weight. Start with losing 5 to 10 lbs.
C. Start or increase your physical activity. Walking is a good exercise to start getting active.
D. Other ways to modify your risk factors:
  1. Stop smoking. **It is never too late to stop smoking.**
  2. Control your blood pressure.
  3. If you are a diabetic, control your blood sugar level.

Activity: Regular exercise, such as walking vigorously for 30 minutes three times a week, increases your good cholesterol levels, lowers blood sugar, and promotes weight loss.

Diet: Follow the Dietary Approaches to Stop Hypertension (DASH) and low-fat/low-cholesterol diet.

A. Reduce total fat calories and cholesterol.
B. Reduce total saturated fats and replace with monounsaturated fats, such as canola oil, olive oil, and margarine.
C. Increase fiber with oatmeal, bran, or fiber supplements.
D. Increase daily intake of fruits and vegetables.
E. Try garlic, soy protein, and vitamin C to help lower LDL cholesterol.

Medications: You may be prescribed a medicine to lower your cholesterol. You will need to come to the doctor's office and have your blood drawn to monitor your liver and cholesterol levels.

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If You Have:

A. Chest pain.
B. Shortness of breath or trouble breathing while exercising.
C. Abdominal pain.
D. Muscle pain or weakness.

CLIENT TEACHING GUIDE

ATRIAL FIBRILLATION

PROBLEM Atrial fibrillation (AF) is the condition that causes the upper chambers of the heart (the atria) to beat faster and irregularly (also called fibrillation). The upper chambers of the heart do not beat at the same time as the lower chambers (the ventricles). When AF occurs, blood clots can form in the heart and then travel to the brain, causing a stroke.

CAUSES AF is caused by a malfunction of the heart's pacemaker. Many things can cause the heart's pacemaker to malfunction, including excessive alcohol intake, emotional stress, physical stress, recent heart surgery, medication side effects, and a long list of medical conditions. These medical conditions include coronary artery disease, leaky heart valves, high blood pressure (BP), heart failure, heart attack, thyroid disease, infections, inflammation around the heart, sleep apnea, obesity, and lung diseases such as chronic obstructive pulmonary disease, bronchitis, asthma, and emphysema.

PREVENTION

A. Stop smoking. Discuss smoking cessation with your healthcare provider. **It is never too late to stop smoking.**
B. Reduce or eliminate intake of alcohol and caffeine.
C. Lose weight. Discuss losing weight with your healthcare provider.
D. Make a list of your current medical conditions and current medications. Keep an updated copy in your wallet.
E. When traveling:
  1. Always travel with enough of your medication to last through your vacation plus an additional 3 days.
F. Take all of your medications as prescribed. If you become ill and are unable to take your medications, call your healthcare provider's office.

TREATMENT PLAN

A. Take your medications as ordered by your healthcare provider.
B. Effectively manage all other medical conditions, paying special attention to cholesterol, BP, thyroid disease, sleep apnea, and any lung diseases.
C. Follow up with your primary healthcare provider and/or cardiologist on a regularly scheduled basis.
D. If you are on a blood thinner that requires regular blood work, make sure you get your blood checked on the schedule set by your healthcare provider.

Activity: Get regular exercise, after discussing the type and frequency of exercise that is safe for you with your healthcare provider.

Diet: Eat a balanced, low-fat, and low-salt diet in addition to dietary guidelines suggested by your healthcare provider.

Medications: _____

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office in Case of the Following:

A. Seek care in the ED if you have any of the following symptoms:
  1. Palpitations or a fluttering in the chest.
  2. Chest pain.
  3. Weakness or extreme tiredness.
  4. Shortness of breath at rest or with activity.
  5. Dizziness, disorientation, confusion, or headache.
  6. Passing out or losing consciousness.
  7. Frequent urination or a compelling urge to urinate.
  8. Anxiety or panic symptoms.
  9. Sudden weakness in an arm or leg.
  10. Sudden change in vision.
  11. Trouble speaking or understanding others.

CHRONIC VENOUS INSUFFICIENCY

PROBLEM Chronic venous insufficiency (CVI) is a condition in which blood has difficulty flowing back to the heart from the arms or legs. This usually occurs when the valves along the inside of the veins are damaged and allow blood to flow backward. The pooling of blood leads to swelling, pain, a heavy feeling, darkening of the skin, and infections. Without treatment, CVI can lead to blood clots and serious infections that could lead to amputation.

CAUSES Many things may increase the chance of having CVI. Some, like gender, age, or how tall you are, cannot be changed. Others can be changed; these include prolonged standing or sitting and excessive weight.

PREVENTION

A. Avoid standing or sitting for long periods of time.
B. If overweight or obese, lose weight. Discuss what you can do to lose weight with your healthcare provider.

TREATMENT PLAN

A. Take your medications as ordered by your healthcare provider.
B. Wear compression stockings. Put them on before getting out of bed in the morning. Take them off just before going to bed at night.
C. Raise the affected arm or leg whenever lying down to improve pain and swelling.
D. Avoid standing or sitting for long periods of time.
E. Follow up with your primary healthcare provider on a regularly scheduled basis.

Activity:

A. Get regular exercise. Discuss what type and frequency of exercise is safe for you with your healthcare provider.
B. Exercise leg muscles by pumping your ankles when sitting. Rocking in a rocking chair is another option.

Diet: Discuss the type of diet that best suits your needs with your healthcare provider: diabetic diet, low-fat diet, low-cholesterol diet, and/or low-sodium diet.

Medications: _____

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If You Have the Following:

A. Seek care in the ED if you have a change in color of a foot or hand.
B. Contact the office if you are experiencing any of the following:
1. Fever over 101°F.
2. Increased redness, pain, tenderness to touch, swelling, and/or warmth.
3. New wound or sore on the affected arm or leg.
4. Sudden shortness of breath.
5. Chest pain.
6. If taking aspirin or a blood thinner and have any of the following symptoms:
   a. Vomiting or other illness that causes you to miss more than one dose of your medications.
   b. Vomit that is bright red or dark and looks like coffee grounds or grape jelly.
   c. Blood in your bowel movements that looks black or tarry in color.
   d. Severe headache.
   e. Sudden weakness in an arm or leg.
   f. Memory loss or confusion.
   g. Sudden change in vision.
   h. Trouble speaking or understanding others.

C. Contact the office if you are experiencing any new symptom(s) not present at your last office visit.

CLIENT TEACHING GUIDE

DEEP VEIN THROMBOSIS

PROBLEM You have inflammation or a blood clot in one of the veins in your body. Phlebitis is inflammation, and thrombosis means a blood clot. Symptoms include the following:

A. Pain.
B. Fever.
C. Swelling.
D. Tenderness in the affected leg or arm.
E. The vein may feel somewhat "hard" to touch.

CAUSE Blood clots form because of bedrest, surgery, a heart attack, a severe illness, and birth control pills. A blood clot can also form after breaking a hip or leg, pregnancy, with cancer, and with some medications.

TREATMENT PLAN/CARE

A. If you have phlebitis, you may be given an anti-inflammatory medicine.
B. Some clients need to go to the hospital and get intravenous (IV) medicine to break up the clot.
C. You may be given blood thinners either as a pill or by self-injection.
D. Be sure to take all of the medicines given as directed to help with the blood clot.
E. Do not smoke: This worsens your condition. **It is never too late to stop smoking.**
F. If you currently take any hormones, such as birth control pills, your healthcare provider may talk to you about stopping them.
G. Manage all other medical conditions, especially high blood pressure, diabetes, and high cholesterol, and try to lose any extra weight.
H. Follow up with your primary healthcare provider and/or cardiologist on a regularly scheduled basis.

Activity:

A. Get out of bed as soon as possible after surgery.
B. While in bed, perform range-of-motion exercises with your legs.
C. Exercise leg muscles by pumping your ankles when sitting.
D. Do not sit with your legs crossed.
E. Avoid standing or sitting for long periods of time.
F. Do not wear tight clothing, such as knee-high hosiery.
G. Wear special supportive hosiery called compression stockings. Put them on before getting out of bed in the morning and take them off before going to bed at night.
H. When traveling:
    1. Try to take rest breaks on a regular basis.
    2. Continue to do the ankle pumping exercise when in the car or on the plane.
    3. Wear loose-fitting clothes that are comfortable.
    4. Avoid drinking alcohol.
    5. Drink plenty of fluids unless you are instructed not to do so by your healthcare provider.
    6. Ask your healthcare provider if you should wear compression stockings.
I. Wear a MedicAlert bracelet if you are put on blood thinners; you will notice that you bruise more easily while on your blood thinner.
J. You may need to come back to the office to have your labs drawn.

Diet:

A. Discuss the type of diet that best suits your needs: diabetic, low-fat, low-cholesterol, and/or low-sodium.
B. If you are taking the blood thinner Coumadin, you will be given a list of foods that should not be eaten. These foods interfere with how the blood thinner works.
C. Avoid alcohol.

CLIENT TEACHING GUIDE

LYMPHEDEMA

PROBLEM Lymphedema is the backup of fluid in the lymphatic system into an arm or leg. The fluid causes severe swelling, which restricts movement and can lead to infection and, in rare cases, a form of cancer called lymphangiosarcoma.

CAUSES Many factors can cause lymphedema. These include a diagnosis of cancer treated with radiation, surgical removal of lymph nodes, infection, and disorders from birth that affect the structure of the lymph system.

PREVENTION

A. Protect your arm or leg while recovering from cancer treatment.
B. Avoid heavy lifting, if it involves an arm.
C. Avoid strenuous exercise.
D. Avoid heat on your arm or leg.
E. Avoid tight clothing.
F. Inspect the affected limb daily. Note any cracks or cuts that increase the risk of infection, and treat as directed.
G. Apply lotion daily to protect and prevent dry skin.
H. Avoid burns to the skin.
I. Take extra care when shaving and use a clean razor on clean skin.
J. Use insect repellent to prevent insect bites, which could become infected.
K. Wash skin daily with a mild soap and dry skin carefully paying special attention to any skin folds.
L. Prevent excessive sun exposure by applying sunscreen or wearing appropriate clothing to cover skin.

TREATMENT PLAN

A. Raise the affected arm or leg when lying down to reduce pain and swelling.
B. Wear compression stockings. Put them on before getting out of bed in the morning. Take them off just before going to bed at night.
C. Apply lotion every day to the affected area.
D. Check the affected area every day and report any skin changes to your healthcare provider, especially any cracks or cuts.
E. Follow up with your primary healthcare provider and other specialty providers on a regularly scheduled basis.

Activity:

A. Get regular exercise. Discuss with your healthcare provider or physical therapist what type and frequency of exercise is safe for you.
B. Exercise leg muscles by pumping your ankles when sitting. Rocking in a rocking chair is another option.

Diet:

A. Discuss with your healthcare provider the type of diet that best suits your needs: diabetic diet, low-fat diet, low-cholesterol diet, and/or low-sodium diet.

Medications: _____

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If You Have:

A. Fever greater than 101°F.
B. Increased redness, pain, tenderness to touch, and/or warmth in the affected arm or leg.
C. New pain, swelling, or warmth in an arm or leg.
D. Other: _____

CLIENT TEACHING GUIDE

PERIPHERAL ARTERIAL DISEASE

PROBLEM Peripheral arterial disease is a condition in which fatty deposits build up on the inside of the vessels that carry blood to the hands and feet. This makes it difficult for blood to travel to hands and feet, causing pain with activity and when resting. If these blockages increase in size, the pain will also worsen; infections can also occur, which could lead to amputation.

CAUSES Many things cause these fatty deposits to build up inside arteries. Some factors such as age, gender, and genetics cannot be changed. Others can be changed; these include smoking, diabetes, high cholesterol, high blood pressure (BP), and excessive weight.

PREVENTION

A. Stop smoking. **It is never too late to stop smoking.**
B. To prevent injury that could progress into an infection, do the following:
  1. Wear well-fitting shoes that protect your feet.
  2. Look and feel inside your shoes before putting them on.
  3. Look at your feet daily for any signs of injury or infection.
  4. Dry feet well after bathing, including between toes.
  5. Do not trim your own toenails or shave off calluses. A healthcare provider should do this for you to prevent infection.
  6. Do not use a heating pad or hot water on your hands or feet to keep warm. Wear gloves or socks instead.

TREATMENT PLAN

A. Take your medications as ordered by your healthcare provider.
B. Effectively manage all other medical conditions, paying special attention to cholesterol, BP, diabetes, and obesity.
C. Follow up with your primary healthcare provider and/or cardiologist on a regularly scheduled basis.

Activity:

A. Get regular exercise, after discussing with your healthcare provider the type and frequency of exercise that is safe for you.

Diet:

A. Discuss the type of diet that best suits your needs: diabetic diet, low-fat diet, low-cholesterol diet, and/or low-sodium diet.
B. Follow the dietary guidelines suggested by your healthcare provider.

Medications: _____

You Have Been Prescribed: _____

You Need to Take: _____

You Need to Notify the Office If You Have the following:

A. Contact the office if you have any of these symptoms:
  1. Worsening pain in arm or leg.
  2. Fever over 101°F.
  3. Any temperature change in a hand or foot.
  4. Any change in feeling of a hand or foot.
  5. Any change in the color of a hand or foot.
  6. Difficulty walking.
  7. Vomiting or other illness that causes you to miss more than one dose of your medications.
  8. If taking aspirin and have any of the following symptoms:
    a. Vomit that is bright red or dark and looks like coffee grounds or grape jelly.
    b. Blood in your bowel movements (BMs) that looks black or tarry in color.
B. Contact the office if you are experiencing any new symptom(s) not present at your last office visit.

CLIENT TEACHING GUIDE

SUPERFICIAL THROMBOPHLEBITIS

PROBLEM Superficial thrombophlebitis occurs when a vein is irritated or injured. The portion of the vein that is affected can develop a blood clot or become infected, causing redness, swelling, and pain. If untreated, the infection and/or blood clot can progress into a life-threatening condition such as sepsis, deep vein thrombosis, or pulmonary embolism.

CAUSES Many things can cause irritation and injury to veins. These include a recent intravenous line placed during a hospital stay, infection, some medications, and pregnancy. Some risk factors cannot be changed, such as genetics, whereas others can be changed, including inactivity and excessive weight.

PREVENTION

A. Avoid standing or sitting for long periods of time.
B. If you smoke, stop or reduce the amount you smoke. **It is never too late to stop smoking.**
C. If overweight or obese, lose weight. Discuss what you can do to lose weight with your healthcare provider.

TREATMENT PLAN

A. Take your medications as ordered by your healthcare provider.
B. Raise the affected arm or leg when lying down to improve pain and swelling.
C. Warm compress to the affected area may improve pain.
D. Wear compression stockings. Put them on before getting out of bed in the morning. Take them off just before going to bed at night.
E. Avoid standing or sitting for long periods of time.
F. Follow up with your primary healthcare provider on a regularly scheduled basis.

Activity:

A. Get regular exercise. Discuss with your healthcare provider what type and frequency of exercise is safe for you.
B. Exercise leg muscles by pumping your ankles when sitting. Rocking in a rocking chair is another option.

Diet:

A. Discuss with your healthcare provider the type of diet that best suits your needs: diabetic diet, low-fat diet, low-cholesterol diet, and/or low-sodium diet.

Medications: _____

You Have Been Prescribed: _____

You Need To Notify the Office If You Have Any of the Following:

A. Worsening pain in an arm or leg.
B. Fever over 101°F.
C. Sudden shortness of breath.
D. Chest pain.
E. New pain, swelling, change in color, or temperature in an arm or leg.
F. Difficulty walking.
G. Vomiting or other illness that causes you to miss more than one dose of your medications.
H. If you are taking a blood-thinning medication and have any of the following symptoms:
  1. Vomit that is bright red or dark and looks like coffee grounds.
  2. Bright-red blood in your stools, or black, tarry stools.
  3. Severe headache.
  4. Sudden weakness in an arm or leg.
  5. Memory loss or confusion.
  6. Sudden change in vision.
  7. Trouble speaking or understanding others.

CLIENT TEACHING GUIDE

VARICOSE VEINS

PROBLEM Varicose veins are caused when the valves inside the veins are damaged and allow blood to flow backward instead of toward the heart. This backflow of blood increases the pressure in the vein, leading to pain and swelling; this makes them more visible. Varicose veins can worsen and increase the risk of blood clots, infection, bleeding, and changes to the skin.

CAUSES There are many factors that increase the chance of developing varicose veins. Some, such as age and genetics, cannot be changed. Some can be changed; these include prolonged standing, restrictive clothing, excessive weight, and smoking.

PREVENTION

A. Avoid prolonged standing. If prolonged standing is required, shift weight from one leg to the other.
B. When possible, prop your feet up instead of keeping both feet on the floor or letting them hang down.
C. Stop smoking. Discuss smoking cessation with your healthcare provider.

TREATMENT PLAN

A. Raise the affected arm or leg when lying down to improve pain and swelling.
B. Wear compression stockings. Put them on before getting out of bed in the morning. Take them off just before going to bed at night.
C. Avoid standing or sitting for long periods of time.
D. Follow up with your primary healthcare provider on a regularly scheduled basis.

Activity:

A. Get regular exercise. Discuss with your healthcare provider what type and frequency of exercise is safe for you.
B. Exercise leg muscles by pumping your ankles when sitting. Rocking in a rocking chair is another option.

Diet:

A. Discuss with your healthcare provider the type of diet that best suits your needs: diabetic diet, low-fat diet, low-cholesterol diet, and/or low-sodium diet.
B. If you are taking the blood thinner Coumadin, ask your healthcare provider about which foods are high in vitamin K and whether you should limit those foods in your diet.

EMERGENT ISSUES/INSTRUCTIONS

A. Seek care in the ED if you have any of the following symptoms:
1. **A bleeding varicosity with eroded surrounding skin.**
2. **A varicosity that has bled and is at risk of bleeding again.**
3. **An ulceration that is worsening and/or painful despite treatment**.

CHAPTER 14

GASTROINTESTINAL GUIDELINES

L. Douglas Smith Jr., Ann McQueen Blair, and Justin Calabrace

ABDOMINAL PAIN

DEFINITION

A. Abdominal pain is a common and nonspecific complaint. The evaluation of abdominal pain is challenging for clinicians as it may represent a benign complaint, or it may herald significant abdominal pathology. The responsibility of clinicians is to determine if clients can be observed and treated symptomatically or if they require further investigation and referral to a specialist. Pain in the abdomen is secondary to problems relating to abdominal organs, and it is categorized as follows:

1. Acute pain: pain of less than a few days that has worsened progressively until presentation.
2. Chronic pain: pain lasting greater than 12 weeks and remaining unchanged over a period of months to years. Recurrent abdominal pain is also included in this category.
3. Subacute pain: pain lasting from a few days to several weeks.
4. Emergent pain: pain that lasts 3 hours or longer, accompanied by a fever or vomiting.

B. Pain may be categorized by the following descriptions:

1. Visceral pain is usually dull and aching in character.
2. Parietal pain is sharp and well-localized.
3. Referred pain is aching and perceived to be near the surface of the body.

INCIDENCE

A. Abdominal pain is a common complaint. While there is significant variance among the literature, as many as 50% of adults will complain of abdominal pain at some point. Gastroenteritis and irritable bowel syndrome (IBS) are the most common causes of acute pain, and chronic stool retention is the most common cause of chronic pain. Other causes of abdominal pain include the following:

1. Acute appendicitis: occurs 233:100,000.
2. Acute cholecystitis: varies according to age, sex, and ethnic origin.
3. Intestinal obstruction, usually small intestines: accounts for 20% of acute abdominal conditions.
4. Pregnancy-associated abdominal pain: ectopic pregnancy, miscarriage, and abruptio placentae.

PATHOGENESIS

A. Pathogenesis depends on the origin of pain. Pain may result from inflammation, ischemia, distension, altered motility, obstruction, or ulceration.

PREDISPOSING FACTORS

A. Abdominal trauma.
B. Motor vehicle accidents with trauma such as ruptured spleen.
C. Dietary intolerances.
D. Pregnancy.
E. Torsion.
F. Psychogenic pain.
G. Sickle cell disease.
H. Infection.
I. Diabetes.
J. Vascular disease.
K. Congenital or acquired abdominal abnormalities.

COMMON COMPLAINTS

A. Clinical presentation of abdominal pain is determined in part by the site of the involvement:

1. Acute or chronic onset of pain.
2. Vomiting.
3. Diarrhea.

OTHER SIGNS AND SYMPTOMS

A. Referred shoulder pain.
B. Fever.
C. Nausea and/or projectile vomiting.
D. Rigid abdomen.
E. Abdominal distension.
F. Constipation or diarrhea.
G. Guarding.
H. Rebound tenderness.
I. Biliary pain and right subcostal tenderness.
J. Anorexia.
K. Periumbilical discomfort; consider appendicitis if, within 2 to 12 hours, pain localizes in right lower quadrant (RLQ) at McBurney point.
L. Dysuria.
M. Abdominal mass; do not overlook the possibility of pregnancy as the cause of a mass.
N. Melena (most common in peptic ulcer disease [PUD]).
O. Tachycardia.

SUBJECTIVE DATA

Evaluate for a "surgical abdomen," defined as a rapidly worsening pathology in the absence of surgical intervention that will result in a poor prognosis. Clients should not eat or drink while a diagnosis of a surgical abdomen remains under consideration. Once a surgical abdomen has been excluded, the remainder of the evaluation will be guided by the chronicity of symptoms, along with the location of pain.

The contributions of Cheryl A. Glass and Kathy R. Reese to this chapter in prior editions are acknowledged here.

A. Review onset, duration, course, and quality of pain:
1. When did the pain start?
2. What were you doing when the pain started?
3. Has this ever occurred before?
4. What was the primary diagnosis?
5. What was the previous treatment and was it effective?
6. Is there anyone else having the same symptoms in your home?
7. Review the progression of pain.
B. Determine pain rating on a 10-point scale, with 0 being no pain and 10 being equivalent to the worst pain the client has ever felt.
C. Qualify the duration of pain in minutes, hours, days, weeks, or months. Does the pain interfere with sleep?
D. Review the pattern of pain:
1. Review aggravating factors.
2. Review alleviating factors.
3. Does the pain radiate?
4. Does the pain have any relationship to food intake?
E. Questions specific to females:
1. Determine the client's last menstrual period (LMP).
2. Has the client had a hysterectomy or tubal ligation?
3. Does the client have a recent history of dyspareunia or dysmenorrhea that suggests pelvic pathology?
4. Is there any history of physical abuse?
5. What type of contraception is used? Specifically evaluate for an intrauterine device (IUD).
F. Review the client's current medications and drug history, especially antibiotic, laxative, acetaminophen, aspirin, and nonsteroidal anti-inflammatory drug (NSAID) use. Clients taking corticosteroids may have a significant masking of pain.
G. Rule out abdominal trauma from domestic violence, motor vehicle accidents, falls, or assaults.
H. Review bowel habits and note changes: constipation, diarrhea, anorexia, food intolerance, nausea, vomiting, or bloating.
I. Review the client's history for sickle cell disease. Any individual of African American or Mediterranean descent presenting with leg or abdominal pain should be questioned regarding sickle cell disease or trait.
J. Review urinary function. Is there any urinary frequency, urgency, dysuria, flank pain, or back pain? If the client is male, do they have any hesitancy, difficulty starting the urine stream, nocturia, low urinary volume, or any lower abdominal distension indicating urinary retention?
K. Review alcohol intake/history.
L. Has the client had any unexplained weight loss?
M. Evaluate sexual activity to rule out potential sexually transmitted infection (STI):
1. Evaluate if clients have new partners.
2. Are their partners experiencing any symptoms?

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure (BP); include orthostatic BP.

Tachycardia or hypotension may be signs of a ruptured aortic aneurysm, septic shock, gastrointestinal (GI) hemorrhage, ectopic pregnancy, or volume depletion. Absence of a fever in the older adults or immunosuppressed does not exclude a serious illness or infection.

B. Inspect:
1. Observe general appearance: facial expressions, walk, skin turgor; refusal to move/writhing; note grimacing during exam.
2. Perform eye and oral exam to rule out iritis and aphthous ulcers of the mouth (extraintestinal manifestations of inflammatory bowel disease [IBD]).
3. Examine the abdomen for the presence of a hernia at the umbilicus, groin, or near the site of prior surgical incisions.
4. Examine the abdomen for overt masses or pulsations.
5. Examine the eyes and skin for jaundice.
6. Observe for any bruising or other signs of domestic violence in the "bathing suit" areas: breasts, abdomen, back that would be easily covered with clothes.
C. Auscultate:
1. Auscultate for bowel sounds in all four quadrants of the abdomen.
2. Evaluate heart and lungs.
3. Listen for bruits of aorta, iliac, and renal bruits.
D. Percuss:
1. Percuss abdomen for tympanic and dullness sounds.
E. Palpate:
1. Palpate abdomen for masses, rebound tenderness, and peritoneal signs:
a. Before palpating the abdomen, ask the client to bend the knees and place hands at sides to help with relaxation of the wall musculature.
b. Older adults may lack classical peritoneal signs of rebound and guarding.
2. Check the abdomen for tender pulsatile mass at midline; it may indicate abdominal aortic aneurysm (AAA).
3. Palpate back; check for cerebrovascular accident (CVA) tenderness.
4. Perform a bimanual examination in females regardless of whether the client has had a hysterectomy or is postmenopausal:
a. Evaluate the size and symmetry of the uterus.
b. Evaluate the adnexal areas for presence of appropriately sized, mobile ovaries. A fixed, painful adnexal mass is suggestive of an endometrioma or tubo-ovarian abscess.
c. Endometriosis is suggested by localized tenderness in the cul-de-sac or uterosacral ligaments, palpable tender nodules, pain with uterine movement, or tender fixation of adnexal or uterus in a retroverted position.
5. Check for obturator sign, or abdominal pain in response to passive internal rotation of the right hip from 90° angle hip–knee flexion position. A positive sign indicated pain secondary to irritation of obturator muscle with inflamed appendix.
6. Assess psoas sign or increased abdominal pain occurring when the client attempts to raise their right thigh against the pressure of your hand placed over their right knee. Pain is caused by inflammation of the psoas muscle in acute appendicitis.
F. Rectal exam:
1. Perform a rectal exam, including testing of stool for occult blood. **Failure to perform a rectal examination in clients with undifferentiated abdominal pain can lead to misdiagnosis.**

DIAGNOSTIC TESTS

A. In all individuals of childbearing age, assume the client is pregnant until proven otherwise. Vaginal bleeding with or without abdominal pain should prompt a transvaginal ultrasound and a serum human chorionic gonadotropin (HCG).
B. Complete blood count (CBC) with differential.
C. Comprehensive metabolic profile (CMP). ▶

D. Amylase.
E. Lipase.
F. Urinalysis; consider culture.
G. Stool guaiac or fecal immunoassay test for occult blood.
H. Plain x-ray abdomen; x-ray with oral contrast for certain indications.
I. CT abdomen/pelvis.
J. Abdominal ultrasonography; may be limited in scope depending on indication (e.g., right upper quadrant [RUQ] if hepatic or gall bladder pathology suspected).
K. *Helicobacter pylori* fecal antigen.
L. Coproporphyrin, if lead poisoning is suspected.
M. Chest x-ray.
N. GI series radiography.
O. Endoscopy.
P. Sigmoidoscopy.
Q. Barium enema (BE): Avoid with suspected obstruction.
R. Consider endoscopic retrograde cholangiopancreatography (ERCP) to visualize the distal common bile duct.
S. EKG to evaluate for cardiac etiology.
T. Blood cultures for clients with abdominal pain associated with either fever or hypothermia or when sepsis is suspected.

DIFFERENTIAL DIAGNOSES

A. Location and duration of abdominal pain can often help significantly in narrowing the differential diagnosis.

1. RUQ pain:
   a. Acute cholecystitis and biliary colic:
      i. Biliary tract: increased serum amylase.
      ii. Ascending cholangitis: fever and jaundice in a client with RUQ pain.
      iii. Acute cholecystitis: maximal pain in the RUQ or epigastrium, radiating to the scapular region, accompanied by nausea, vomiting, and fever without jaundice. "Murphy's sign," or tenderness to palpation during an inspiratory pause, may be seen with acute cholecystitis. RUQ tenderness to percussion or pressure of the gallbladder is also a suggestive finding.
      iv. Ketoacidosis: presents with severe abdominal pain in 8% of instances and may be accompanied by emesis and an elevated white cell count. Acute intra-abdominal events such as cholecystitis may be the precipitant of ketoacidosis, as well as metabolic abnormalities including diabetic, starvation, and alcoholic ketoacidoses.
   b. Acute hepatitis.
   c. Hepatic abscess.
   d. Hepatomegaly due to congestive heart failure (CHF).
   e. Perforated duodenal ulcer (DU).
   f. Acute pancreatitis; bilateral pain.

Pancreatitis is accompanied by an increased serum lipase.

   g. Herpes zoster.
   h. Myocardial ischemia.
   i. Pleural or pulmonary pathology (e.g., pneumonia, pulmonary embolism [PE], or empyema).

2. RLQ pain:
   a. Appendicitis: often begins with symptoms of dull, steady, periumbilical pain and anorexia before localizing to the RLQ at McBurney point.
   b. Regional enteritis.
   c. Leaking aneurysm.
   d. Ruptured ectopic pregnancy.
   e. Twisted ovarian cyst.
   f. Pelvic inflammatory disease (PID).
   g. Ureteral calculi.
   h. Incarcerated, strangulated inguinal hernia.
   i. Endometriosis.
   j. Meckel diverticulitis.
   k. Abdominal wall hematoma.

3. Left upper quadrant (LUQ) pain:
   a. Gastritis.
   b. Acute pancreatitis: epigastric pain that is relatively sudden, boring to the back, and associated with nausea, vomiting, and anorexia.
   c. Splenic enlargement, rupture, infarction, aneurysm.
   d. Myocardial ischemia.
   e. Left lower lobe pneumonia.
   f. Renal colic: radiates to the groin.

4. Left lower quadrant (LLQ) pain:
   a. Sigmoid diverticulitis.
   b. Regional enteritis.
   c. Leaking aneurysm.

AAA may present with a tender pulsatile mass at the abdominal midline. Vascular disorders such as acute arterial insufficiency, due to atherosclerosis or embolus, may present with severe abdominal pain in acute pathology or exacerbation, though may more commonly present with mild, constant pain for several days in a subacute or chronic presentation. Dissection or rupture of an AAA produces severe acute abdominal pain and often radiates to the back or genitalia.

   d. Ruptured ectopic pregnancy.

Rupture of the fallopian tube generally causes sudden, acute, and localized abdominal pain. Internal hemorrhage causes syncope and referred shoulder pain, caused by phrenic nerve irritation. Diagnosis before tubal rupture may be difficult because symptoms and physical findings mimic other conditions such as appendicitis.

   e. Incarcerated ovarian cyst.
   f. PID.
   g. Ureteral calculi.
   h. Incarcerated, strangulated inguinal hernia.

5. Generalized abdominal pain:
   a. Trauma:
      i. **Any person with a possible blow to the abdomen should have orthostatic BP taken, careful palpation of the abdomen, serial abdominal circumferences measured, and be considered for abdominal imaging. Serial hemoglobin (Hgb) and hematocrit (Hct) measurements should be obtained, if necessary.**
      ii. In abdominal trauma, the spleen is the most commonly injured organ, especially in blunt abdominal trauma; the onset can be immediate or delayed.
      iii. Nontraumatic splenic rupture is often associated with acute infectious mononucleosis.
   b. Intestinal obstruction: obstruction that develops slowly over weeks to months may be relatively subtle in presentation.

Acute obstruction presents with severe "colicky" pain or pain that is wavelike in nature; it makes the pain relentless.

   c. Peritoneal irritation: severe pain due to the rich innervation of the parietal peritoneum. Focal injury results in well-localized discomfort that is described as a sharp aching or burning. ▶

d. Metabolic disturbances may mimic intra-abdominal etiologies.

Porphyria and lead poisoning sometimes simulate bowel obstruction because they can cause cramping, abdominal pain, and hyperperistalsis.

e. Nonspecific dysfunctional abdominal pain and psychogenic abdominal pain are diagnoses of exclusion.

PLAN

A. General interventions:

1. If necessary, prepare the client for emergency transport and hospitalization.

2. Management and follow-up of other causes of abdominal pain are variable and depend on diagnosis.

B. Client teaching: *See Client Teaching Guide for this chapter, "Abdominal Pain":*

1. Counsel the client with chronic or recurrent abdominal pain to keep a pain diary that includes activity, foods, and other pain triggers; duration of pain; and what provides relief of symptoms.

C. Pharmaceutical therapy:

1. Treatment depends on the findings from the history, physical, and testing, as well as the clinical diagnosis.

FOLLOW-UP

A. Variable, depending on diagnosis.

B. Review pain diary.

CONSULTATION/REFERRAL

A. Consult the physician or surgeon for the client with acute abdominal pain and pain related to abdominal trauma.

B. For the obstetric client, consult a physician for any bleeding or abdominal pain.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. There is no evidence that acute intra-abdominal surgical emergencies are more common during pregnancy if ectopic pregnancy is excluded:

2. The presence of peritoneal signs, rebound tenderness, and abdominal guarding is never normal in pregnancy.

3. Bleeding complications include the following:

a. First trimester: miscarriage and ectopic pregnancy.

b. Second and third trimester: abruptio placentae.

4. Physiologic changes of pregnancy may affect the presentation and evaluation of abdominal pain. The enlargement of the uterus can impede physical examination, affect the normal location of pelvic and abdominal organs, and mask or delay peritoneal signs. (Refer to section "Appendicitis" in this chapter.)

5. Severe preeclampsia: The clinical manifestations of liver involvement include RUQ or midepigastric pain, elevated transaminases, and, in severe cases, subcapsular hemorrhage or hepatic rupture.

B. Adults:

1. Obesity distorts the abdominal exam, making organ palpation or pelvic examination difficult.

2. With males older than age 40 and females older than age 50, suspect cardiac origin when presenting with epigastric pain. Consider obtaining EKG for this age group.

Although myocardial infarction (MI) "classically" presents with anterior chest pressure or pain, the client may also have a gastritis or heartburn sensation, coupled with nausea and diaphoresis.

C. Geriatrics:

1. Delirium is a common early sign of acute illness or infection in older adults. It is more common in clients with existing cognitive impairment. Intra-abdominal pathology should be considered for clients presenting with altered mental status. Additional information regarding the evaluation of altered mental status and delirium are available in Chapter 23, "Neurologic Guidelines".

2. Older adults may have a vague or atypical presentation of pain, including fatigue and chest pain, varying in location, severity, and presence of a fever or nonspecific findings on examination:

a. Classic findings of acute peritonitis, rebound tenderness, and local rigidity occur less in older adults.

b. For dementia or noncommunicative clients, the American Medical Directors Association has endorsed the Pain Assessment in Advanced Dementia (PAINAD) Scale, which scores the following items:

i. Breathing: Examples include normal, labored, hyperventilation.

ii. Negative vocalization: Examples include moaning, negative language, crying.

iii. Facial expression: Examples include smiling, frowning, grimacing.

iv. Body language: Examples include relaxed, tense, rigid, or striking out.

v. Consolability: Examples include extent to which a caregiver is able to console, distract, or reassure.

3. In an older client, a similar presentation to IBD with abdominal pain and a change in bowel habits can be the first sign of colon cancer.

4. AAA is observed almost exclusively in older adults. Risk increases with each decade after 65:

a. Approximately 5% to 10% of males 65 years and older have an AAA.

b. Maintain a high index of suspension in clients who present with a clinical picture suggestive of renal colic or musculoskeletal back pain.

5. Older adults with urinary tract infection (UTI) are less likely to have dysuria, frequency, or urgency.

6. Clients older than 65 years have a 30% to 50% risk of gallstones and may not present with significant pain; less than half have fever, vomiting, or leukocytosis.

7. Fever and an elevated white blood cell (WBC) count occur in less than half of older adults with diverticulitis. Only about 25% with diverticulitis present with a guaiac positive stool.

8. The incidence of PUD is more common in older adults due to the availability and use of NSAIDs. The most common presenting symptom with PUD in older adults is melena.

9. Although the older adults may state they are having loose liquid stool, evaluate for fecal impaction. Diarrhea rather than constipation is sometimes the only complaint due to the collection of liquid stool distending the proximal colon and passing around the obstructing stool.

10. MI and pneumonia also commonly present as vague abdominal complaints in the older adults.

11. Weight loss/appetite suppression: Weight loss is a predictor of mortality. Clinically significant weight loss is considered to be 5% loss of usual body weight in 3 months or 10% in 6 months. Dehydration is more common in the older adults. Signs of dehydration include confusion, ▶

muscle weakness, fever, dizziness, poor skin turgor, hypotension, and tachycardia:

a. Monitor weight patterns/body mass index (BMI). (Caution: BMI is not used to identify loss of muscle mass.)

b. Monitor both serum albumin and anemia: Hypoalbuminemia and anemia are not necessarily associated with low bodyweight. They can be caused by decreases in liver protein synthesis:

i. Serum albumin concentration is commonly recommended.

ii. Hgb, prealbumin, and transferrin.

iii. Cholesterol.

12. Depression: Anxiety and depression are common in IBD and are factors that lead to decreased health-related quality of life.

13. Due to polypharmacy, a full review of medications, herbals, and over-the-counter (OTC) drugs should be undertaken to identify medications that should be avoided in the geriatric population, duplicate medications, and medications that are able to be decreased or deprescribed.

APPENDICITIS

DEFINITION

A. Appendicitis is acute inflammation of the appendix caused by obstruction of the appendiceal lumen. There is no single sign, symptom, or diagnostic test that accurately confirms the diagnosis of inflammation. Perforation is rare in the first 12 hours, but the rate of perforation increases after 72 hours. Prompt, early diagnosis and operative intervention is the goal of treatment. The differential diagnoses for appendicitis include all abdominal sources of pain.

INCIDENCE

A. Acute appendicitis occurs at a rate of 29:100,000. It is most common between the ages of 10 and 30, with a slight male predominance. It is the most common condition in children (1%–8%) and during pregnancy (0.06%–0.1%) that requires emergency abdominal surgery. One in every 2,000 adults older than age 65 will develop appendicitis.

PATHOGENESIS

A. Foreign bodies, fecal material, tissue hypertrophy, strictures, or a bend or twist on the organ may cause obstruction of the appendix. The obstruction causes colicky pain. Bacterial invasion causes inflammation and leads to gangrene and perforation. The most common bacteria are *Escherichia coli*, *Pseudomonas*, *Bacteroides fragilis*, and *Peptostreptococcus* species.

PREDISPOSING FACTORS

A. Pregnancy.
B. Torsion.
C. Abdominal trauma.
D. Male, age 10 to 30.
E. Recent gastrointestinal (GI) infection.
F. Low-fiber diet.
G. Positive family history.

COMMON COMPLAINTS

The classic history of anorexia and periumbilical pain followed by nausea, right lower quadrant (RLQ) pain, and vomiting occurs in only 50% of cases.

A. Adults:

1. Generalized or localized abdominal pain in the epigastric or periumbilical areas. Within 2 to 12 hours, pain localizes in RLQ at McBurney point, and intensity increases.

2. Pain typically develops before vomiting.

3. Nausea and/or vomiting (may be projectile).

4. Anorexia signals organic cause of abdominal pain.

5. Nonspecific symptoms including indigestion, flatulence, change in bowel habits, and malaise.

6. The location of the appendix is altered in pregnancy.

7. The location of pain can vary according to the position of the appendix and the region that is inflamed.

B. Older adults are less likely to present with anorexia, RLQ pain, fever, or leukocytosis.

OTHER SIGNS AND SYMPTOMS

A. Rigid abdomen.
B. Changes in pulse (tachycardia), breathing (tachypnea), or skin temperature concerning for developing sepsis.
C. Involuntary guarding.
D. Rebound tenderness.

SUBJECTIVE DATA

A. Evaluate for a "surgical abdomen," defined as a rapidly worsening prognosis in the absence of surgical intervention. Clients should not eat or drink while a diagnosis of a surgical abdomen remains under consideration. Once a surgical abdomen has been excluded, the remainder of the evaluation will be guided by the chronicity of symptoms along with the location of pain:

B. Review onset, duration, course, and quality of pain. Has pain ever occurred before? If so, what was the primary diagnosis? What was the previous treatment and was it effective?

C. Qualify the duration of pain in minutes, hours, days, weeks, or months. Does it interfere with sleep? Is there a pattern to the pain?

D. Have the client rate the pain on a 10-point pain scale, with 0 being no pain and 10 being the worst pain the client has ever felt.

E. Review the pattern of pain:

1. Review aggravating factors.

2. Review alleviating factors.

3. Does the pain radiate?

4. Does the pain have any relationship to food?

F. Questions specific to females:

1. Determine the client's last menstrual period (LMP) to rule out pregnancy. ▶

2. What type of contraception is used? Specifically evaluate for an intrauterine device (IUD).

3. Has the client had a hysterectomy or tubal ligation?

4. Does the client have a recent history of dyspareunia or dysmenorrhea that suggests pelvic pathology?

G. Review current medications and drug history, especially antibiotic and laxative use. Clients taking corticosteroids may have a significant masking of pain.

H. Rule out abdominal trauma, motor vehicle accidents, falls, and assault.

I. Discuss bowel habits, including any changes, such as constipation or diarrhea, anorexia, food intolerance, nausea and vomiting, bloating.

J. Ask the client about urinary frequency, urgency, dysuria, flank pain, and back pain. In males, ask about hesitancy, difficulty starting the urine stream, nocturia, low urinary volume, or lower abdominal distension (urinary retention).

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure (BP), including orthostatic BP. Often, temperature is greater than 101°F.

B. Inspect:

1. Observe general appearance: facial expressions (grimace during exam), walk, skin color and turgor, level of consciousness, and acuity level of pain.

2. Inspect abdomen for surgical scars.

3. Observe for any bruising or other signs of domestic violence in the "bathing suit" area: breasts, abdomen, or back that would be easily covered by clothes.

C. Auscultate:

1. Auscultate the abdomen for presence of bowel sounds and bruits.

2. Auscultate heart and lungs.

D. Palpate: Note guarding with exam:

1. Palpate the abdomen:

a. Ask the client to bend their knees to help relax the abdominal wall musculature. Place arms at sides.

b. Note any rebound tenderness which indicates peritonitis. ***Perform at the end of the exam*** **because positive response produces pain and muscle spasm that can interfere with subsequent exam.**

2. Palpate back; note cerebrovascular accident (CVA) tenderness.

3. Check for obturator sign, or abdominal pain in response to passive internal rotation of right hip from 90° angle hip–knee flexion position. A positive sign indicates pain secondary to irritation of obturator muscle with inflamed appendix.

4. Assess psoas sign or increased abdominal pain occurring when the client attempts to raise their right thigh against the pressure of your hand placed over their right knee. Pain is caused by inflammation of the psoas muscle in acute appendicitis.

5. Check for the Apley rule; the farther from the navel the pain, the more likely it is organic in origin.

6. Check for Rovsing sign, or referred pain to the RLQ with palpation of the left lower quadrant (LLQ).

7. The location of the appendix and pain is altered during pregnancy (Figure 14.1).

E. Percuss:

1. Percuss abdomen.

F. Rectal exam:

1. Perform rectal exam. Although not demonstrated to show clear clinical benefit in cases of appendicitis, clients with a retrocecal appendicitis might experience more pain during a rectal examination.

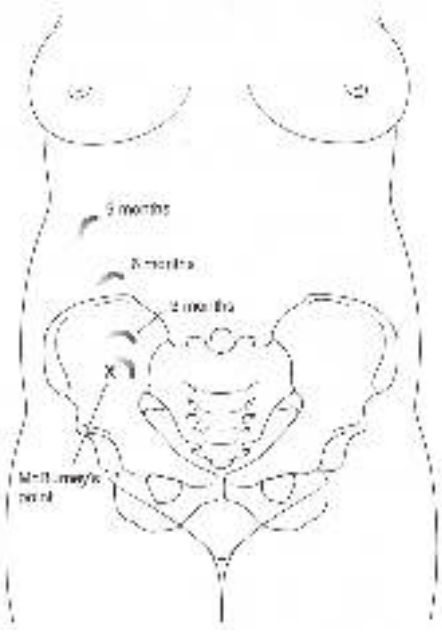

FIGURE 14.1 The position of the appendix alters during pregnancy, and so must the site of incision to gain access.

DIAGNOSTIC TESTS

A. Serum human chorionic gonadotropin (HCG): Pregnancy should be excluded in all individuals of childbearing age. Assume the client is pregnant until proven otherwise.

B. Complete blood count (CBC) with differential—80% of appendicitis cases present with leukocytosis.

C. C-reactive protein (CRP).

D. Urinalysis, to rule out urinary disorders.

E. Abdominal ultrasonography; any person with trauma to abdomen should have abdominal ultrasound. A finding of appendiceal diameter greater than 6 mm is the most suggestive ultrasound finding.

F. CT scan with contrast; significant findings include appendiceal diameter of greater than 6 mm, appendiceal wall enhancement or thickening of greater than 2 mm, periappendiceal fat stranding.

G. MRI may be used as an alternative diagnostic test in pregnancy to avoid exposure to ionizing radiation. Appendiceal diameter of greater than 7 mm is considered significant.

H. Guaiac stool for occult blood.

DIFFERENTIAL DIAGNOSES

A. The appendix has no fixed position. Duration of pain can help significantly in narrowing differential diagnosis. Nonspecific dysfunctional abdominal pain and psychogenic abdominal pain are diagnoses of exclusion:

1. GI:

a. Appendicitis.

b. Ruptured appendix: findings of white blood cell (WBC) greater than 15,000 and fever 103°F or greater. Twenty percent of perforations occur in less than 24 hours from onset and 65% occur in greater than 48 hours.

c. Cecal diverticulitis: presents similar to appendicitis. Right-sided diverticulitis occurs in 1.5% of individuals from Western countries but is more frequent in the Asian population.

d. Meckel diverticulitis: occurs in younger clients but presentation is similar to acute appendicitis. ▶

e. Regional enteritis or ileitis: associated with infection; presents with diarrhea.
f. Crohn's disease (CD)/inflammatory bowel disease (IBD): presents with more chronic symptoms along with fatigue.
g. Incarcerated groin hernia.
h. Abdominal wall hematoma.
i. Bowel obstruction.
j. Intestinal malrotation.
k. Intussusception.
l. Parasitic infection.
m. Constipation.
n. Leaking abdominal aneurysm.

2. Gynecologic:
a. Pelvic abscess: secondary to pelvic inflammatory disease (PID) and usually occurs with vaginal discharge.
b. PID: worse with intercourse and usually occurs with vaginal discharge.
c. Ruptured ovarian cyst: usually worse with exertion and can cause bleeding.
d. Mittelschmerz: timing related to ovulation.
e. Ovarian torsion.
f. Endometriosis.
g. Ectopic pregnancy.
h. Endometritis: associated with fever, vaginal discharge, and usually occurs after a procedure or delivery.
i. IUD.

3. Urologic:
a. Ureteral calculi/renal colic.
b. Testicular torsion.
c. Epididymitis.

PLAN

A. Client teaching: *See Client Teaching Guide for this chapter, "Abdominal Pain."*

B. Medical and surgical management:

1. Appendectomy is the current standard of care for management of appendicitis, and especially perforated appendicitis.

C. Pharmaceutical therapy:

1. Multiple studies have examined whether surgery can be delayed for nonperforated appendicitis. Several meta-analysis and systemic reviews have concluded that for a very small minority of clients with previous surgical complication or severe phobia, delayed appendectomy may be appropriate. Clients should be warned that as many as 50% of clients with delayed appendectomy may develop recurrent symptoms and require emergent surgery at a later time.

2. The use of antibiotics prior to surgery is warranted to decrease the rate of wound infection.

3. Most episodes of appendicitis fall into the category of mild-to-moderate community-acquired intra-abdominal infections without factors for resistance or treatment failure. Antibiotics chosen should cover streptococci, nonresistant Enterobacteriaceae, and anaerobes.

4. Do not give antipyretics to mask fever.

5. Do not administer cathartics because they may cause rupture.

FOLLOW-UP

A. Postoperative follow-up is with the surgeon.

CONSULTATION/REFERRAL

A. Physician consultation and possible emergency transport and hospitalization are often required.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Any abdominal pain or bleeding in the first 8 weeks after a missed menstrual period must be considered a symptom of possible *ectopic pregnancy*.

2. The identification of intra-abdominal masses may be compromised by the enlarged uterus, but this problem may be partially obviated by examining the client in the lateral position.

3. The intestinal tract is progressively displaced upward, outward, and backward during pregnancy; bowel sounds are best heard lateral or superior to the uterus.

B. Adults:

1. Obesity distorts abdominal exam, making organ palpation or pelvic exam difficult.

2. Immunocompromised clients are susceptive to infection. They may not exhibit the typical signs and symptoms of appendicitis; only mild tenderness on exam.

3. The CT exam is useful in the immunocompromised client for diagnosis, although inflammatory changes may be less prominent.

C. Geriatrics:

1. Older adults adults tend to have a diminished inflammatory response, resulting in a less remarkable history and physical examination. For this reason, they more frequently present with perforation. Be aware of vague symptoms, such as milder pain, less pronounced fever, and leukocytosis with shift to left on differential.

2. A redundant sigmoid colon may also cause right-sided pain from sigmoid disease.

3. Older clients have an increased risk of colonic malignancy as the cause for their RLQ pain. Consider CT **and** colonoscopy in clients older than 40 presenting with symptoms of appendicitis, especially if CT scan is negative for obvious etiology.

BOWEL OBSTRUCTION

DEFINITION

A. Bowel obstruction occurs when the flow of intestinal contents is disrupted along the course of the large or small bowel. Although a more common occurrence in the small bowel, 25% of obstructions occur in the large bowel. The obstructions can occur in two ways:

1. Mechanical: can be partial or complete; occurring insidiously or acutely:
a. Mass/stricture.
b. Adhesions.
c. Volvulus.

d. Intussusception.
e. Congenital anomalies.
f. Fecal impaction.
g. Diverticular disease.

2. Functional: due to altered physiology of the intestines.

B. Intestinal pseudo-obstruction related to nerve and muscle disorders:

1. Parkinson disease.
2. Multiple sclerosis.
3. Hirschsprung disease.
4. Diabetes.
5. Medications.

C. Small bowel obstruction can be characterized as follows:

1. Partial or complete:
a. Simple.
b. Strangulated.

D. The absence of bowel activity, stool and flatus, is a predictor of complications, such as ischemia, necrosis, or perforation.

E. Metabolic disturbances may mimic intra-abdominal etiologies.

Porphyria and lead poisoning sometimes simulate bowel obstruction because they can cause cramping, abdominal pain, and hyperperistalsis.

INCIDENCE

A. In clients with a history of abdominal surgery, the postsurgical incidence is around 9%.

B. In clients without a history of abdominal surgery, the incidence is 3% to 9%.

C. The small bowel is implicated in 75% to 80% of all intestinal obstructions.

D. Average age 65 to 70 in both males and females.

1. Volvulus occurs in the sigmoid colon or cecum in greater than 95% of cases. Typically presents during ages 60 to 80 with other chronic medical and neuropsychologic conditions.

PATHOGENESIS

A. Obstruction can be caused by extrinsic (outside the bowel wall), intrinsic (in the bowel wall), or intraluminal factors. Blockages can be complete or incomplete.

B. With obstruction, dilation of the bowel wall occurs proximally, leading to edema, fluid accumulation, and loss of absorptive function. Emesis can create metabolic alkalosis due to loss of electrolytes. With intensifying distention, the vessels within the wall of the intestines become compromised, leading to reduced perfusion, resulting in ischemia or the tissue and possible necrosis and perforation.

C. Peritoneal irritation: Severe pain due to the rich innervation of the parietal peritoneum. Focal injury results in well-localized discomfort that is described as a sharp aching or burning.

PREDISPOSING FACTORS

A. Cancer:

1. Colorectal cancer (CRC; 30%).
2. Pancreatic.
3. Ovarian.
4. Prostatic neoplasm.

B. Previous radiation therapy.

C. Prior abdominal surgery.

D. Prior colorectal resection.

E. Inflammatory bowel disease (IBD; Crohn's or ulcerative colitis).

F. Abdominal wall hernias.

G. Structural abnormality:

1. Volvulus.
2. Fecal impaction.

H. Rectal stenosis.

I. Endometriosis.

J. Tuberculosis.

K. Lymphogranuloma venereum.

L. Medications:

1. Opioids.
2. Tricyclic antidepressants.

COMMON COMPLAINTS

Acute obstruction presents with severe paroxysmal "colicky" pain or pain that is wavelike in nature; it makes the pain relentless. Systemic signs—fever, tachycardia, hypotension, altered mental state—may be associated with strangulation.

CARDINAL SYMPTOMS

A. Abdominal pain.

B. Distention.

C. Severe and obstinate constipation.

OTHER SIGNS AND SYMPTOMS

A. Nausea and vomiting (may be bile-colored emesis in small bowel obstruction).

B. Focal abdominal pain can indicate peritoneal irritation caused by ischemia or necrosis.

C. Pain occurring in the lower pelvis can be due to rectal tenesmus, indicating rectal obstruction.

D. Pencil thin bowel movements (BMs).

E. Obstructions may develop slowly over weeks to months; may be relatively subtle in presentation.

SUBJECTIVE DATA

A. The history should focus on the identification of risk factors:

1. Review the location, onset, location, onset, characteristics, associated factors, timing, exacerbating factors, and severity of symptoms.
2. Is the client able to pass stool and flatus?
3. Is the client able to keep liquids down?
a. When was the last fluid intake?
b. Is the client urinating?
4. Does the client have any of the following as noted in "Predisposing Factors"?
a. Cancer(s), previous radiation therapy.
b. Does the client have a diagnosis of IBD?
c. Has the client had recent surgeries or a colon resection?
d. Has the client had gastroenteritis? Is any other family member ill?
e. Has the client ever had a colonoscopy and been diagnosed by diverticular disease?
5. Review all medications, over-the-counter (OTC), and herbal products. Does the client have a history of chronic opioid use?

PHYSICAL EXAMINATION

A. Check temperature, blood pressure (BP) sitting and standing, pulse, respirations, height, and weight to calculate a body ▶

mass index (BMI). (Dehydration is manifested by tachycardia and orthostatic hypotension.)

B. Inspect:

1. Clients with complications from obstruction appear acutely ill.

2. Check mucous membranes for signs of severe dehydration.

3. Evaluate presence of abdominal distention.

4. Surgical scars indicating past abdominal surgeries.

5. Hernias: incisional or groin.

C. Auscultate:

1. Abdomen all four quadrants: High-pitched bowel sounds indicate acute obstruction followed by muffling of the bowel sounds as distention progresses; finally, the bowel sounds become hypoactive. Evaluate for ascites.

2. Heart.

3. Lungs.

D. Palpate:

1. Abdomen: Identify mass (abscess, volvulus, tumor) or hernia.

2. Check for hepatosplenomegaly.

3. Evaluate rebound tenderness.

E. Percussion:

1. Abdomen:

a. Tympany of the abdomen due to distention; tympany over the liver suggests free intra-abdominal air.

b. Dullness of the abdomen over fluid-filled dilated loops.

c. Tenderness to percussion can indicated peritonitis.

F. Rectal examination:

1. Rectal examination identifies rectal mass; check for occult blood.

G. Neurologic exam.

DIAGNOSTIC TESTS

A. Laboratory studies:

1. Complete blood count (CBC) with differential.

2. Metabolic profile.

3. Blood urea nitrogen (BUN)/creatinine levels (may be elevated in dehydration due to vomiting).

4. Urinalysis.

5. Guaiac any stool from the rectal examination.

B. Imaging:

1. Abdominal x-ray. (Relevant findings include dilated loops of bowel or a size difference between the proximal and distal bowel with the proximal being dilated and the distal appearing collapsed.)

2. Chest radiograph: used to assess for aspiration in clients who have been vomiting.

3. Ultrasound.

4. Endoscopy.

5. CT:

a. Significant findings include increased thickening of bowel wall greater than 3 mm, mesenteric edema, abdominal ascites, and submucosal edema or hemorrhage.

b. Target sign, whirl sign, and venous cutoff sign are all radiologic findings suggestive of specific etiology.

6. Magnetic resonance (MR) enterography is useful with low-grade bowel obstruction is suspected.

DIFFERENTIAL DIAGNOSES

A. Bowel obstruction:

1. Small bowel obstruction: The most common etiologies are adhesions, hernias, and malignancy.

2. Large bowel obstruction: The most common etiologies are tumor, adhesions, and volvulus.

B. Nonobstructive motility disorder:

1. Paralytic ileus.

2. Pseudo-obstruction.

C. Constipation.

D. Fecal impaction.

E. Porphyria.

F. Lead poisoning.

PLAN

A. General interventions:

1. Treatment depends on the location and severity of the obstruction.

2. Clients with suspected bowel obstruction should be kept NPO to avoid gastric distention. Hospitalized clients may benefit from nasogastric (NG) tube placement with low-intermittent wall suction.

3. The crampy abdominal pain of bowel obstruction does not generally respond to pharmacologic therapy. Use of opioids is discouraged except among clients with cancer.

4. There is a subset of clients with partial bowel obstruction who may be managed with medical observation for 12 to 24 hours by a specialist or surgeon.

B. Pharmaceutical therapy:

1. Treatment depends on the findings from the history, physical, and testing, as well as the clinical diagnosis.

FOLLOW-UP

A. Variable, depending on diagnosis.

EMERGENT ISSUES/INSTRUCTIONS

A. All clients identified as having a complete bowel obstruction should be admitted to the hospital for consideration of surgical exploration.

B. Without treatment, abdominal pain can increase as a result of bowel perforation and ischemia.

CONSULTATION/REFERRAL

A. Surgical consult.

B. Depending on the urgency, consult with a gastroenterologist.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. Signs of dehydration include confusion, muscle weakness, fever, dizziness, poor skin turgor, hypotension, and tachycardia.

2. Delirium is a common early sign of acute illness or infection in the older adults. It is more common in clients with existing cognitive impairment. At a minimum, clients and family should be asked if the client has experienced episodes of altered mental status:

3. Older adults have a diminished sensorium, allowing pathology to advance to a dangerous point prior to symptom development:

a. The level of pain is much less severe at presentation and continues to be at a lower level of pain.

B. Although older adults may state they are having loose liquid stool, evaluate for fecal impaction. Diarrhea rather than constipation is sometimes the only complaint due to the collection of liquid stool distending the proximal colon and passing around the obstructing bolus.

CELIAC DISEASE

DEFINITION

A. Celiac disease, previously known as celiac sprue, is an immune-mediated disorder triggered by ingestion of gluten, a storage protein contained in three grains: wheat, barley, and rye. Clients with celiac disease are unable to tolerate gliadin, the alcohol soluble fraction of gluten. The disease primarily affects the small intestine in those genetically susceptible. Onset of symptoms depends on the amount of gluten in the diet. Dietary nonadherence is the chief cause of persistent or recurrent symptoms. (See Appendix B, "Gluten-Free Diet.")

B. Celiac disease is a common cause of chronic malabsorption due to injury to the small intestine resulting in loss of absorptive surface area and decrease in digestive enzymes, leading to impaired absorption of fat-soluble vitamins, iron, and potentially vitamin B_{12} and folic acid.

C. A substantial number of clients are misdiagnosed as having irritable bowel syndrome (IBS) for years prior to the diagnosis of celiac disease.

D. The complications from celiac disease include osteopenia, osteoporosis, infertility, short stature, delayed puberty, anemia, and gastrointestinal (GI) malignancies and non-Hodgkin lymphoma (NHL).

INCIDENCE

A. Celiac disease can occur at any stage of life. Its prevalence is approximately 1% of the general population in North America. The highest incidence (5%) is noted in the sub-Saharan African population. The true incidence is undetermined due to asymptomatic disease and underdiagnosis.

B. Newly diagnosed clients with celiac disease should inform their first-degree family members of their increased risk of celiac disease and the American College of Gastroenterology (ACG) recommendation for screening.

C. Celiac disease is strongly associated with autoimmune conditions, including type 1 diabetes, Addison disease, and thyroiditis, as well as genetic syndromes, including Down syndrome, Williams syndrome, and Turner syndrome.

D. Liver disease and Crohn's disease (CD) share widespread risk factors. Liver disorders such as autoimmune hepatitis, elevation of liver enzyme levels, primary biliary cirrhosis, nonspecific hepatitis, primary sclerosing cholangitis (PSC), and nonalcoholic fatty liver disease (NAFLD) have been reported in clients with CD.

PATHOGENESIS

A. Both immune and genetic factors play a role in the intestinal reaction to gluten ingestion. After the gluten fragment is ingested and absorbed, broken into fragments by tissue transglutaminase, an immune complex is formed in genetically prone individuals. The formation of the complex then stimulates both cellular and humoral immunity, leading to production of autoantibodies, which attack enterocytes causing atrophy, and inflammatory cytokines, which cause mucosal inflammation and villous atrophy. Celiac disease primarily affects the mucosal layer of the small intestine. The classic celiac lesion is noted in the proximal small intestine.

B. Hallmark histologic findings include presence of intraepithelial lymphocytes in the jejunum, duodenum, or both; crypt hyperplasia; villous atrophy.

C. The Marsh Classification is used to describe the progressive histologic stages of celiac disease. Note: Marsh 1 and Marsh 2 may be seen in sow's and cow's milk allergies.

1. Marsh 0: preinfiltrative stage (normal).
2. Marsh 1: infiltrative lesion (increased intraepithelial lymphocytes).
3. Marsh 2: hyperplastic lesion (type 1 plus hyperplastic crypts).
4. Marsh 3: destructive lesion (type 2 plus villous atrophy of progressively more severe degrees [termed 3a, 3b, and 3c]).
5. Marsh 4 (atrophic–hypoplastic): total villous atrophy, crypt hypoplasia.

PREDISPOSING FACTORS

A. Female.

B. Infectious diarrheal episode or other intestinal disease (e.g., rotavirus).

C. Genetic disorders:

1. Down syndrome (8%–12%).
2. Type 1 diabetes (10%).
3. Turner syndrome (2%–10%).
4. Williams syndrome (8.2%).

D. Strong hereditary component (10% in first-degree relatives; 2% in second-degree relatives).

E. The introduction of gluten before 4 months of age is associated with an increased development of disease.

F. Autoimmune thyroid disorders (Hashimoto thyroiditis and Graves disease).

G. Selective immunoglobulin A (IgA) deficiency.

COMMON COMPLAINTS

A. Asymptomatic.
B. Chronic diarrhea or explosive watery diarrhea.
C. Foul-smelling voluminous stools.
D. Anorexia.
E. Abdominal distention/bloating/flatulence.
F. Abdominal pain.
G. Poor weight gain or weight loss.
H. Vomiting.
I. Steatorrhea (malabsorption of ingested fat).

OTHER SYMPTOMS

A. Behavioral changes, including irritability.
B. Dehydration.
C. Lethargy.
D. Constipation.
E. Failure to thrive (FTT).
F. Short stature and delayed puberty.
G. Dermatitis herpetiformis/skin disorders.
H. Arthritis.
I. Seizures.
J. Weakness and fatigue.
K. Dental enamel hypoplasia of permanent teeth.
L. Iron deficiency anemia unresponsive to treatment.
M. Bruising/bleeding tendency.
N. Osteopenia/osteoporosis.
O. Hair loss.
P. Lactose intolerance.
Q. Aphthous stomatitis.

SUBJECTIVE DATA

A. Review the onset, duration, course, type of symptoms, and aggravating or alleviating factors.
B. Review the client's weight history.
C. Evaluate family history for celiac disease or members with similar histories.
D. Review current medications and drug history, especially antibiotic, laxative, and herbal products.
E. Review bowel habits and note changes: constipation, diarrhea, anorexia, and/or food intolerance.
F. Review the client's tolerance to lactose products.

PHYSICAL EXAMINATION

A. Check vital signs, including height and weight. Follow serial changes in body mass index (BMI).
B. Inspect:
  1. Observe general overall appearance.
  2. Oral examination to evaluate glossitis, dry mucosal membranes (dehydration), and the presence of oral aphthae.
  3. Examine the skin for the presence of dermatitis herpetiformis, a blistering rash involving the scalp, neck, elbows, knees, and buttocks.
  4. Evaluate the abdomen for the presence of bloating and protuberant "potbelly."
  5. Evaluate the client's weight loss, including muscle wasting.
C. Auscultate:
  1. Auscultate for bowel sounds.
D. Percuss:
  1. Percuss abdomen.
E. Palpate:
  1. Palpate the abdomen for masses, rebound tenderness, and peritoneal signs:
    a. Before palpating the abdomen, ask the client to bend their knees and place hands at sides to help with relaxation of the wall musculature.
F. Rectal examination:
  1. Perform a rectal examination, including testing stool for occult blood.

DIAGNOSTIC TESTS

A. Screening of the general population for celiac disease in asymptomatic persons is not recommended by the U.S. Preventive Services Task Force. However, screening of high-risk populations such as those individuals with a positive family history is recommended.
B. The confirmation of a diagnosis of celiac disease is based on the combination of findings from the medical history, physical examination, serology, and upper endoscopy, with histologic analysis of multiple biopsies of the duodenum. **All testing should be performed while clients are following a gluten-rich diet.**
C. Endoscopy for duodenal biopsies is the standard and a critical component for diagnosing celiac disease.
D. Screening and monitoring test for celiac disease. See Table 14.1 for celiac disease tests and possible results:
  1. Tissue transglutaminase antibody (tTG), IgA class: 95% sensitive, 95% specific:
    a. Primary test ordered to screen for celiac disease.
    b. Used for monitoring and evaluating the effectiveness of treatment.
    c. Antibody levels should fall when gluten is removed from the diet.
  2. Total IgA: IgA deficiency is more common in clients with celiac disease.
  3. Anti-tTG antibodies, immunoglobulin G (IgG).
  4. Deamidated gliadin peptide antibodies (anti-DGP, IgA).
  5. Antigliadin antibodies (AGA) IgA.
  6. IgA endomysial antibody (EMA): less frequently ordered, measures same as the anti-tTG.
  7. Antireticulin antibody (ARA): rarely ordered.
  8. Anti-F-actin: ordered if the disease has been diagnosed; evaluates the severity of intestinal damage. May be used for monitoring.
E. Complete blood count (CBC) and electrolytes.
F. Aspartate transaminase (AST) and alanine transaminase (ALT): Liver enzymes normalize on a gluten-free diet.
G. Prothrombin time (PT) may be prolonged with malabsorption of vitamin K.
H. C-reactive protein (CRP).
I. Erythrocyte sedimentation rate (ESR).
J. Total protein.
K. Albumin.
L. Calcium.
M. Iron, transferrin, and ferritin.
N. Vitamin B_{12}, folate levels, and vitamin D. ▶

TABLE 14.1 WHAT DOES THE TEST RESULT MEAN? SOME CELIAC DISEASE TESTS AND RESULTS

Anti-tTG Antibodies, IgA	Total IgA	Anti-tTG Antibodies, IgG	Anti-DGP, IgA	AGAs-IgG	Diagnosis
Positive	Normal				Presumptive celiac disease
Negative	Normal	Negative	Negative	Negative	Symptoms not likely due to celiac disease
Negative	Low	Positive	Negative	Positive	Possible celiac disease (false-negative anti-tTG, IgA, and anti-DGP are due to a total IgA deficiency)
Negative	Normal	Negative	Positive	Positive/negative	Possible celiac disease (may be seen in children younger than 3 years old)

AGAs, antigliadin antibodies; DGP, deamidated gliadin peptide; IgA, immunoglobulin A; IgG, immunoglobulin G; tTG, tissue transglutaminase.

Source: Reprinted with permission from American Association for Clinical Chemistry. (2017, December 4). Celiac disease antibody tests. *Lab Tests Online*. https://labtestsonline.org/tests/celiac-disease-antibody-tests.

O. Stool culture, ova, and parasites.
P. Fecal fat.
Q. Bone density (bone mineral density improves on gluten-free diet).
R. Human leukocyte antigen (HLA) haplotypes.
S. Colonoscopy if bloody stools or symptoms of colitis.
T. Sweat test to exclude cystic fibrosis (CF).
U. Radiograph, including barium swallow study with a small bowel follow-through, is usually nonspecific and is not indicated.

DIFFERENTIAL DIAGNOSES

A. Celiac disease.
B. Microscopic colitis.
C. Food allergies.
D. Inflammatory bowel disease (IBD):
  1. CD.
  2. Ulcerative colitis (UC).
E. Immunodeficiency disorders.
F. Gastroenteritis (viral or bacterial).
G. Parasites.
H. Fungal infection.
I. IBS.
J. Malabsorption.
K. Lymphomas of the small intestine.
L. Pancreatic exocrine dysfunction.

PLAN

A. General interventions:
  1. Lifelong adherence to a gluten-free diet is the only accepted treatment for celiac disease:
    a. Gluten-free dietary instructions should be given and reinforced.
    b. Reinforce the need to read all food labels.
    c. Stress that wheat-free is not the same as gluten-free.
  2. The ACG recommends a referral to a registered dietitian to receive a thorough nutritional assessment and education on a gluten-free diet. A gluten-free diet should be maintained for life. Numerous apps are available for download to smartphones to aid the client in dietary selections.
  3. Monitor for nutritional deficiencies including iron, B vitamins, and vitamin D. Substitute flours are not fortified with B vitamins. Supplement with iron, folate, and vitamin B_{12} as needed.
  4. Screen for osteoporosis.
  5. Keep a food/symptom diary to eliminate trigger foods. See Appendix B, "Gluten-Free Diet."
  6. Gluten has been identified in dietary supplements, over-the-counter (OTC) medications, nonfood items such as lipstick and envelope adhesive, and food items with gluten additives such as condiments. Gluten is also found in the fillers of pill capsules.
  7. Gluten rechallenge is not generally recommended unless the diagnosis remains uncertain.
  8. HLA-DQ2/DQ8 genotyping for genetic risk factors should not be used for routing screening or testing.
B. Pharmacology:
  1. Vitamin and calcium supplements.
  2. Bisphosphonates for osteoporosis.
  3. Corticosteroids may be prescribed for rapid control of symptoms.

FOLLOW-UP

A. After the diagnosis of celiac disease and implementation of a strict gluten-free diet, follow up in 4 to 8 weeks or earlier if the client has other comorbidities.
B. The Celiac Disease Guideline Committee recommends repeating the measurement of tTG after 6 months of a gluten-free diet.
C. Newly diagnosed clients with celiac disease should undergo testing and treatment for micronutrient deficiencies. Deficiency testing should include, but not be limited to, iron, folic acid, vitamin D, and vitamin B_{12}.
D. Refer for dietary consultation with a nutritionist with experience in gluten-free diets.
E. Consider allergy testing.

CONSULTATION/REFERRAL

A. If the gluten-free diet fails or the client experiences new symptoms, a systematic evaluation is required to elucidate other sources of villous inflammation.
B. Endocrine consultation for clients with Hashimoto thyroiditis and celiac disease.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
  1. Clients with untreated celiac disease are at risk for preterm birth, low birthweight babies, recurrent loss, and reduced fertility.
B. Geriatrics:
  1. Older adults may present with nonspecific GI symptoms, abdominal discomfort, bloating, constipation, or dyspepsia.
  2. Diarrhea may be mild or intermittent in older adults.
  3. Celiac disease is the most common cause of steatorrhea in people older than 50 years of age and the second most common cause in people older than 65 years.
  4. Iron-deficiency anemia may also be a presenting symptom. Anemia is present in 60% to 80% of older adults with celiac disease.
  5. Autoimmune thyroid disorders are common with older adults with celiac. The majority present with hypothyroidism.
  6. The risk for NHL is increased in people with celiac disease age 50 years and older.
  7. Due to polypharmacy a full review of medications, herbals, and OTC drugs should be undertaken to identify medications that should be avoided in the geriatric population, duplicate medications, and medications that are able to be decreased or deprescribed. Refer to section on deprescribing in Chapter 3, "Adult-Geriatric Assessments".
  8. For older adults with existing celiac disease, nurse practitioner (NPs) should practice special consideration for the following geriatric syndromes:
    a. Falls:
      i. Ataxia and neuropathy are two main neurologic complications of celiac disease, placing older adults at a higher risk for falls.
      ii. Older adults may rush to get to their toilet and pull their garments down with episodes of diarrhea, thereby placing themselves at increased risk for falls.
      iii. Up to 70% of adults and older adults with celiac disease have osteopenia and therefore are at increased risk for fractures.
    b. Weight loss/appetite suppression:
      i. Because of GI distress, abdominal discomfort, and diarrhea, older adults are at increased risk of avoiding eating.
      ii. Monitor weight patterns/BMI.

CHOLECYSTITIS

DEFINITION

A. Cholecystitis is the acute or chronic inflammation of the gallbladder. Acute cholecystitis is associated with stone formation (cholelithiasis) in 90% of all cases, causing obstruction and inflammation. Biliary sludge is a feature of chronic cholecystitis.

B. Following a cholecystectomy, stones may recur in the bile duct.

INCIDENCE

A. Gallbladder disease afflicts more than 20 million people (10%–20% of adults) in the United States. Most clients have asymptomatic gallbladder disease; however, 20% progress to experiencing acute biliary symptoms. Once acute symptoms develop, there is a 30% chance of persistent recurrences, and therefore acute cholecystectomy is the recommended treatment for symptomatic clients. Mortality related to acute cholecystitis is 5% to 10%, with the highest risk for clients older than age 60. The most common complication of acute cholecystitis is the development of gallbladder gangrene (20%), with the potential for subsequent perforation (2%). Gangrenous cholecystitis is most common in older clients, diabetics, or clients who delay treatment.

PATHOGENESIS

A. Cholecystitis occurs subsequent to bile stasis, bacterial infection, ischemia, or cystic obstruction by a gallstone. Acute cholecystitis is related to the impaction of a calculus in the neck of the gallbladder in approximately 90% of cases. Spontaneous resolution may occur after the reestablishment of cystic duct patency.

B. *Escherichia coli* is the primary microorganism in 80% of cholecystitis infections. Other pathogens include *Enterobacter, Enterococcus*, and *Klebsiella*. Positive culture rates range from 22% to 46%.

C. Estrogen-induced alteration in bile salts may favor stone formation. Stones occur when cholesterol supersaturates the bile in the gallbladder and precipitates out of the bile. Cholesterol stones are the most common type of gallstones in the United States.

D. Pigment stones occur when free bilirubin combines with calcium. Pigment stones are found in clients with cirrhosis, hemolysis, and infections in the biliary tree.

E. Acalculous cholecystitis is associated with infection and local inflammation. Formation of gallstones is not necessary for the obstruction of the bile duct.

PREDISPOSING FACTORS

A. Female.

B. Sudden starvation/prolonged fasting.

C. Medications:

1. Cholesterol-lowering drugs: Stone formation increases in users of cholesterol-lowering drugs, which are known to increase biliary cholesterol saturation.

2. Thiazide diuretics.

3. Ceftriaxone.

4. Cyclosporine.

5. Opiate narcotic analgesics.

6. Estrogen usage (oral contraceptives [OCPs] and hormone therapy [HT]): Stone formation increases in users of contraceptives and estrogens, which are known to increase biliary cholesterol saturation.

7. Octreotide.

D. Bile acid malabsorption.

E. Genetic predisposition: Native Americans and those of Chinese or Japanese descent have a high incidence.

F. Total parenteral nutrition (TPN).

G. Obesity.

H. Status postbariatric surgery. (Clients who have had either the Roux-en-Y or laparoscopic banding surgeries are at increased risk for gallstones.)

I. Pregnancy secondary to elevated progesterone.

J. Increasing age.

K. Hemolytic anemia.

L. Diabetes.

M. Hepatic cirrhosis.

N. Biliary tree infections.

COMMON COMPLAINTS

A. Abrupt, severe abdominal pain lasting greater than 6 hours.

B. Constant aching pain or gnawing pain in the right upper quadrant (RUQ), right subcostal region, with radiation to the back and right shoulder.

C. Nausea and vomiting.

OTHER SIGNS AND SYMPTOMS

A. Anorexia.

B. Heartburn.

C. Upper abdominal fullness.

D. Biliary colic: sudden onset of severe pain in the epigastrium or right hypochondrium that subsides relatively slowly. Tenderness may remain for days.

E. Fat intolerance.

F. Fever (low-grade).

G. Mild jaundice (20%).

H. Complicated disease such as an abscess or perforation; symptoms includes more severe localized persistent pain, tenderness, fever, chills, and leukocytosis.

I. Chronic diarrhea (4–10 bowel movements [BMs] every day for at least 3 months).

SUBJECTIVE DATA

A. Review the onset, location, duration, course, and quality of pain.

B. Use a pain rating scale, such as a 10-point pain scale, with 0 being no pain and 10 being equivalent to the worst pain the client has ever felt. Determine progression of the pain as well.

C. Review any alleviating factors, such as antacids, and any worsening factors, such as deep inspiration.

D. Review any pain radiating to the jaw, neck, shoulder, or arm.

E. Review onset of pain in relation to last meal and foods ingested.

F. Ask the client about recurrent history of epigastric pain. ▶

G. Obtain history and demographic data that may indicate the risk factors for biliary disease.
H. Review the date of the client's last menstrual period (LMP), and if they are pregnant establish gestational age.

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, and blood pressure (BP). Tachycardia, increased fever, and elevated white blood cell (WBC) are markers of inflammatory disease.
B. Inspect:
1. Observe general appearance, walking, and facial expressions such as grimacing during the examination. Overall appearance is generally unremarkable between attacks; ill appearance occurs during acute attack.
2. Observe skin turgor and color (15% have jaundice).
3. Clients generally remain still during exam due to peritoneal inflammation, which aggravates pain with movement.
C. Auscultate:
1. Heart.
2. Lung fields.
3. Abdomen for bowel sounds.
D. Percuss:
1. Percuss abdomen.
E. Palpate:
1. Palpate the abdomen; check for tenderness in the RUQ, especially with inspiration; assess for guarding and rebound tenderness.
2. Check Murphy sign. Positive Murphy sign is inspiratory arrest secondary to extreme tenderness when subhepatic area is palpated during deep inspiration.
F. Rectal exam, if indicated.

DIAGNOSTIC TESTS

A. Laboratory tests:
1. Complete blood count (CBC) with differential.
2. Amylase.
3. Alkaline phosphate.
4. Bilirubin.
5. Aspartate transaminase (AST).
6. Alanine transaminase (ALT).
7. Urinalysis to rule out pyelonephritis and renal calculi.
8. Pregnancy test if childbearing age.
9. Stool for occult blood to rule out bleeding.
B. Radiography:
1. Ultrasonography: study of choice and can often establish the diagnosis. Assess for presence of gallstones, gallbladder wall thickening (>4–6 mm), and sonographic Murphy sign.
2. Cholescintigraphy (hepatobiliary iminodiacetic acid [HIDA]) scan is indicated if the diagnosis is uncertain after an ultrasound.
3. Magnetic resonance (MR) cholangiography: sensitive for stone in cystic duct.
4. CT scan.
5. Endoscopic retrograde cholangiopancreatography (ERCP) and percutaneous transhepatic cholangiography (PTC).
6. Chest radiography to rule out pneumonia.
C. EKG to rule out myocardial infarction (MI).

DIFFERENTIAL DIAGNOSES

A. Acute cholecystitis.
B. Biliary colic: caused by contraction of the gallbladder after a fatty meal pressing a stone toward the orifice of the cystic duct. Distinguishing features of biliary colic include pain that peaks after several hours and then totally resolves (<4–6 hours). No associated fever, nausea, vomiting, or leukocytosis. Usually clients with acute cholecystitis have experienced episodes of biliary colic in the past, which can complicate diagnosis.
C. Acute pancreatitis.
D. Appendicitis.
E. Peptic ulcer disease (PUD)/perforation.
F. Acute hepatitis.
G. Pneumonia or pleurisy.
H. MI.
I. Renal calculi or other pathology associated with the right kidney.
J. Gastroesophageal reflux disease (GERD).
K. Pregnancy: urolithiasis, pyelonephritis.
L. Functional bowel disorders including nonulcerative dyspepsia, irritable bowel syndrome (IBS): pain predominant, functional gallbladder disorder.
M. Sphincter of Oddi dysfunction.
N. Intra-abdominal abscess.
O. Fitz-Hugh–Curtis syndrome: perihepatitis caused by gonococcal infection.

PLAN

A. General interventions:
1. Clients with a single episode of biliary colic (pain <4–6 hours with full resolution) are reasonable candidates for expectant management as long as they continue to be free of recurrent pain.
B. Client teaching:
1. No activity restriction is required.
2. Treatment depends on acuteness, severity, and frequency of attack(s). Heat may be used as needed for pain. If pain continues to worsen, have the client contact their healthcare provider. Hospitalization and/or surgery may be required depending on the severity of the attack.
C. Dietary management:
1. Counsel the client to avoid fatty foods.
2. Encourage the client to avoid fasting and starvation diets, which make the bile even more lithogenic.
D. Surgical management:
1. Cholecystectomy is recommended for symptomatic clients with positive findings on imaging. **The standard of care is the laparoscopic cholecystectomy.** Conversion from a laparoscopic procedure to an open surgical procedure is approximately 5%.
2. Clients are admitted to the hospital for intravenous (IV) fluid replacement, pain control, and antibiotics. Interventional therapy depends on client's risk factors for surgery and severity of symptoms.
3. Conservative treatment includes IV antibiotics, bowel rest, and an interventional cholecystectomy 6 to 8 weeks later.
4. A WBC count above 15,000 cells/μL indicates a nonresolving inflammation and is a predictor of treatment failure after 24 to 48 hours of conservative observation. Other predictive factors of failed conservative treatment include the following:
a. Age greater than 70 years.
b. Diabetes.
c. Distended gallbladder.
5. Percutaneous drainage (cholecystostomy) is reserved for clients who fail conservative treatment, or as a salvage procedure for high-risk clients.
6. Extracorporeal shockwave lithotripsy. ▶

E. Pharmaceutical therapy:

1. Nonsteroidal anti-inflammatory drugs (NSAIDs) are recommended for pain control.

2. Anticholinergics are not helpful.

3. Oral bile acid therapy decreases the amount of cholesterol produced by the liver and absorbed by the intestines. This therapy is reserved for poor surgical candidates who are at high risk for developing recurrent gallstones. Bile acid is not prescribed for calcified radio-opaque or radiolucent bile pigment stones or those with urgent need for surgery:

a. Actigall (Ursodiol):

i. Dissolution of stones: 8 to 10 mg/kg/d in two to three divided doses.

ii. Prevention therapy 300 mg BID.

b. Urso (Ursodiol) 250 mg tablets also available as Urso Forte 500 mg tablets:

i. 13 to 15 mg/kg/d in two to four divided doses.

FOLLOW-UP

A. See the client at next pain attack to reevaluate.

B. Surgical follow-up in 2 weeks.

C. Clients on oral bile acid therapy should follow up with serial ultrasound at 6 and 12 months, and 1 to 3 months after dissolution of the stone. AST and ALT should be measured at the start of therapy and every 6 months thereafter.

CONSULTATION/REFERRAL

A. For acute attack, consult a physician for possible surgical consultation referral.

B. Refer the client for elective cholecystectomy when they have documented gallstones and recurrent biliary colic or a history of complications from gallstone disease, such as pancreatitis.

C. Refer to a gastroenterologist for consideration of ERCP. The ERCP is the most common procedure for detecting and managing bile duct stones and may be performed before, during, or after gallbladder removal.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. RUQ pain in pregnancy differential includes preeclampsia, pancreatitis, and appendicitis.

2. In the absence of pancreatitis, maternal mortality should be rare and fetal loss is generally estimated to be no more than 5%. However, if secondary pancreatitis is present, maternal mortality is 15% and fetal loss is reported as high as 60%.

B. Geriatrics:

1. Signs and symptoms may be nonspecific and vague.

2. Localized tenderness may be the only presenting sign.

3. The response of Murphy sign may be diminished in older adults.

4. Persistent elevated WBC more than 15,000 suggests refractory disease and should play a central role in clinical follow-up for older adults with acute cholecystitis.

5. Early cholecystectomy is advocated for older adults with gallstone disease. The most important risk factor for postoperative morbidity and mortality is advanced age.

6. Gallstones occur in nearly 25% of females in the United States by the age of 60 and as many as 50% by age 75. Only about 20% of males have gallstones by their 70s.

CIRRHOSIS OF THE LIVER

DEFINITION

A. Cirrhosis is the final stage of a pathologic process within the liver that leads to fibrosis and replacement of normal hepatic tissue with structurally abnormal nodules known as regenerative nodules. It is considered irreversible, but in mild cases has been shown to be reversible with treatment of the underlying condition. The scarring is most often caused by long-term exposure to toxins including alcohol and viral infections.

B. The natural history of liver cirrhosis (LC) is an asymptomatic compensated phase followed by a decompensated phase, marked by the development of overt clinical signs; the most frequent are ascites (5%–10%), bleeding, encephalopathy, and jaundice. Following the first appearance of any of these, the disease usually progresses more rapidly toward death or need for liver transplantation. The development of hyponatremia (serum sodium concentration <130 mmol/L in clients with cirrhosis) carries an ominous prognosis, as it is associated with increased morbidity and mortality.

C. Once decompensation has occurred, cirrhosis becomes a systemic disease, with multiorgan/system dysfunction. Cirrhosis also leads to an increased risk of developing hepatocellular carcinoma (HCC).

D. The concept of diagnosis of cirrhosis is changing from the documentation of histologic F4 fibrosis to the identification of clients truly at risk of developing complications.

1. Prevention of cirrhosis can be accomplished by the primary care provider by screening for alcohol abuse, viral hepatitis, and risk factors for development of nonalcoholic steatohepatitis (NASH).

2. Management of cirrhosis involves identifying preexisting hepatic disease, avoiding further injury to the liver, and managing the complications.

INCIDENCE

A. In the United States, chronic liver disease (CLD) and cirrhosis are the 12th leading cause of death, with about 1.5% of deaths per year and with a higher incidence in males. The transition from compensated asymptomatic cirrhosis to decompensated cirrhosis occurs at a rate of about 5% to 7% per year. The three most common causes of cirrhosis are chronic alcoholism, chronic hepatitis C virus (HCV), and nonalcoholic fatty liver disease (NAFLD).

B. Alcoholic liver disease (ALD) is one of the main causes of CLD worldwide and accounts for up to 48% of cirrhosis associated deaths in the United States.

1. Clients with ALD are at increased risk of developing HCC, with a lifetime risk of 3% to 10% and an annual risk of about 1%. Alcohol is also a frequent cofactor in clients with other type of liver disease where it accelerates hepatic fibrosis. Long-term heavy alcohol users remain at ▶

risk for advanced liver disease with alcoholic steatohepatitis (ASH), cirrhosis, and HCC.

2. Diagnosis of ALD requires documentation of chronic heavy alcohol use and exclusion of other causes of liver disease. Approximately 1 in 12 adults have alcohol use disorder (AUD), defined as consumption of more than three drinks per day in males and more than two drinks in females, or binge drinking defined by the National Institution of Alcoholism and Alcohol Abuse as more than five drinks in males and more than four drinks in females consumed over a 2-hour period.

3. Obesity and cigarette smoking are risk factors for HCC in clients with ALD.

4. Most clients with ALD present for medical care after they have developed jaundice or complications of cirrhosis.

C. NAFLD is a condition of excessive fat storage; there are two types: simple fatty liver and NASH.

1. Simple fatty liver (nonalcoholic fatty liver [NAFL]) has the presence of fat but little or no inflammation or liver cell damage. Simple fatty liver typically does not progress to cause liver damage or complications.

2. NASH causes inflammation and liver cell damage in addition to fatty liver. NASH may lead to cirrhosis or HCC.

D. Cirrhosis is complicated by bleeding from portal hypertension and also by portal vein thrombosis (PVT). PVT occurs in approximately 20% to 50% of clients with cirrhosis, particularly advanced cirrhosis. PVT is a hallmark of poor outcome. PVT vascular complications include increase of portal hypertension and bleeding risk, and higher complications in the early postliver transplantation period. At this time, clinical and laboratory variables to adequately assess the thrombotic risk in LC are limited. A meta-analysis shows than anticoagulants are efficacious and safe for treatment of PVT in clients with cirrhosis, but suggest the need of planning interventional clinical trials.

PATHOGENESIS

A. CLD resulting from various underlying etiologies causes death of hepatocytes, triggering an increase in hepatic enzymes. This process results in chronic inflammation, which over time leads to fibrosis of the liver. Fibrosis is a precursor to cirrhosis, or the replacement of normal liver parenchyma with regenerative nodules. Activation of hepatic stellate cells (HSCs) is a pivotal event in fibrosis. Defenestration and capillarization of liver sinusoidal endothelial cells are major contributing factors to hepatic dysfunction in LC. Activated Kupffer cells destroy hepatocytes and stimulate the activation of HSCs. Repeated cycles of apoptosis and regeneration of hepatocytes contribute to pathogenesis of cirrhosis.

B. The liver's ability to metabolize bilirubin is compromised, leading to elevated bilirubin levels. The liver's ability to synthesize clotting factors is reduced, creating elevated bleeding times. As the liver becomes increasingly fibrotic, the pressure in the portal system increases the risk of esophageal varices and gastrointestinal (GI) bleeding.

PREDISPOSING FACTORS

A. Toxicity:

1. Alcohol abuse.

2. Medications:

a. Methotrexate use.

b. Acetaminophen.

B. Inflammation:

1. Hepatitis C.

2. Hepatitis B.

3. Autoimmune hepatitis.

4. Sarcoidosis.

5. Schistosomiasis, syphilis, brucellosis.

C. Genetic:

1. NASH.

2. Hemochromatosis.

3. Primary biliary cirrhosis.

4. Primary sclerosing cholangitis (PSC).

5. Alpha-1 antitrypsin deficiency.

6. Wilson disease.

7. Hereditary hemorrhagic telangiectasia.

8. Polycystic liver disease.

9. Celiac disease. (Liver disease and Crohn's disease (CD) share widespread risk factors. Liver disorders such as autoimmune hepatitis, elevation of liver enzyme levels, primary biliary cirrhosis, nonspecific hepatitis, PSC, and NAFLD have been reported in clients with CD.)

D. Congestive heart failure (CHF): right-sided.

E. Budd–Chiari syndrome: a rare condition through which the venous outflow from the liver is blocked through either narrowing of the vessels or by thrombotic occlusion.

F. Idiopathic portal fibrosis.

COMMON COMPLAINTS

A. Clients can present with symptoms of cirrhosis or complications from cirrhosis.

1. Symptoms of cirrhosis include the following:

a. Abdominal distention.

b. Jaundice.

c. GI bleeding.

2. Complications include the following:

a. HCC.

b. Hepatic encephalopathy (HE): caused by the inability of the liver to metabolize toxic products; can vary in severity from mild barely perceptible symptoms (grade 1) to coma (grade 4).

c. Ascites.

d. Acute GI bleeding.

e. Bacterial peritonitis.

f. Hepatorenal syndrome.

g. Hepatopulmonary syndrome.

h. Hepatic hydrothorax.

i. Portopulmonary hypertension.

OTHER SIGNS AND SYMPTOMS

A. Nonspecific: anorexia, weight loss, weakness, and fatigue.

B. Pruritus.

C. Digital clubbing.

D. Dark-colored urine.

E. Sleep disturbances: indicative of encephalopathy.

F. Due to alteration in hormones, females develop anovulation and amenorrhea, whereas males develop hypogonadism and gynecomastia.

G. Decreased blood pressure (BP): sometimes noted with a previously hypertensive client.

SUBJECTIVE DATA

A. Inquire regarding duration of symptoms, associated factors, progression of symptoms, location of pain, severity of symptoms, and any exacerbating factors noted by the client or family. ▶

B. Review the client's medical history with attention to immunization status, prior infections, and hepatic disease.

C. Has the client had a liver biopsy? If yes, when and what were the results?

D. Has the client been treated for hepatitis B or hepatitis C?

1. How long ago was the client treated?

2. Did the client complete therapy? If not, why?

3. What was the client's response to therapy (e.g., nonresponder, relapser)?

E. Review the client's medication list including prescription and over-the-counter (OTC) medications. Note any hepatotoxic drugs, particularly methotrexate. See Table 14.2 for a nonexhaustive list of herbal and nutritional supplemental products that the client may be using for cirrhosis.

F. Review the client's surgical history.

G. Does the client have a history of varices? If yes, has any procedure been done including banding or a transjugular intrahepatic portosystemic shunt (TIPS)?

H. Review the client's social history including alcohol use, sexual preference and behavior, drug use (particularly history of intravenous [IV] drug use), international travel, and dietary history.

I. Review the client's family history, particularly for inheritable disease.

J. Review for presence of HE:

1. Moderate encephalopathy signs and symptoms include difficulty thinking, personality changes, poor concentration, confusion, forgetfulness, poor judgment, problems with handwriting or other small hand movements, and fetor hepaticus breath odor.

2. Severe encephalopathy signs and symptoms include lethargy, altered mental status, confused speech, seizures, severe personality changes, and extrapyramidal signs (Parkinson-like state).

K. Perform a thorough review of systems because decompensated cirrhosis affects many other organ systems.

TABLE 14.2 HERBAL AND NUTRITIONAL SUPPLEMENTS USED IN LIVER DISEASE

Sho-saiko-to (Xiao-Chai-Hu-Tang)	Bupleurum (*Bupleurum chinense, Bupleurum kaoi*)
Salvianolic acid B	Oxymatrine
Milk thistle (*Silybum marianum*)	MitoQ (Coenzyme Q10)
Licorice root (*Glycyrrhiza glabra*)	Long pepper (*Fructus Piperis Longi*)
Dandelion (*Taraxacum officinale*)	Japanese knotweed (*Polygonum cuspidatum*)
Asian ginseng (*Panax ginseng*)	Cordyceps (*Cordyceps sinensis*)
Chinese privet (*Ligustrum lucidum*)	Angelica (*Angelica archangelica*)
Reishi mushroom (*Ganoderma lucidum*)	Centella (*Centella asiatica*)
Kudzu (*Pueraria lobate*)	Fringe tree (*Chionanthus virginicus*)
SAMe (nutritional supplement)	Holy basil (*Ocimum sanctum L.*)
Phosphatidylcholine (nutritional supplement)	Liver Dr.

PHYSICAL EXAMINATION

A. Check BP, pulse, respirations, height, and weight to calculate body mass index (BMI). Observe for decrease in weight or reduction in BP.

B. Screening tests:

1. Substance abuse screening.

a. CAGE questionnaire for detecting alcoholism is available at www.hepatitisc.uw.edu/page/substance-use/cage.

b. Alcohol Use Disorders Inventory Test (AUDIT) at every visit. The AUDIT tool is available at www.hepatitisc.uw.edu/page/substance-use/audit-c.

2. Screen for depression at each visit. The Patient Health Questionnaire-9 (PHQ-9) calculator is located at www.mdcalc.com/phq-9-patient-health-questionnaire-9.

3. Screen for generalized anxiety disorder (GAD) for clients with ALD. The GAD questionnaire is available at adaa.org/screening-generalized-anxiety-disorder-gad.

4. Cognitive testing for mental status/signs of encephalopathy includes the following:

a. The clock-draw test (CDT); refer to Section II: Procedures, "Clock-Draw Test."

b. Clinical Hepatic Encephalopathy Staging Scale (CHESS): nine items ranging from normal (0) to deep coma (9). A copy of the CHESS is available at www.liver.ca/wp-content/uploads/2018/02/HE-Staging-Scale-CHESS-ENG.pdf.

c. The Stroop Color and Word Test (SCWT). In the most common version, clients are required to read three different tables as fast as possible. Clients read names of colors (color-words) printed in black (W) and name different color patches (C). Conversely the name color-word (CW) are printed in inconsistent color ink (e.g., "red" is printed in green ink). In this incongruent condition, the client is required to name the color of the ink instead of reading the word. The EncephalApp Stroop Test is available for download for Apple iOS from www.encephalapp.com and is available for Android systems through Google Play.

C. Inspect:

1. Observe overall appearance including gait and coordination, including evaluation for fetor hepaticus breath odor noted with HE, described as a distinctive strong, musty smell like a combination of rotten eggs and garlic.

2. Observe skin for jaundice and telangiectasia.

3. Inspect eyes for scleral icterus.

4. Check palms for presence of palmar erythema.

5. Inspect distal extremities for peripheral edema and clubbing.

6. Assess for gross asymmetries across the abdomen. Note any abdominal distention or protrusion.

7. Assess chest wall for presence of gynecomastia.

8. Inspect abdominal wall for presence of dilated vessels.

9. Inspect for gynecomastia and small testes.

D. Auscultate:

1. Evaluate presence of bowel sounds in all quadrants.

2. Listen over the area of the liver for and bruits or venous hums.

E. Palpate:

1. Palpation of the abdomen can be significant for a firm nodular liver; hepatomegaly may or may not be present.

2. Palpate for splenomegaly. ▶

3. Assess the abdominal distention for ascites, which can occur with a fluid wave. A positive test is noted when "a shock wave" of fluid moves against the fingertips pressed along the flank of the abdomen as the fluid is pushed from one side of the abdomen to the other by the force of a tap along the opposite flank:
   a. Grade 1, mild ascites, is only detectable by ultrasound.
   b. Grade 2, moderate ascites, manifests by moderate symmetrical distension of the abdomen.
   c. Grade 3, large or gross ascites, is manifested by marked abdominal distension.
4. Palpate the scrotum to evaluate size of the testes.

F. Percuss:
1. Percuss the costal margins for dullness. Begin percussion over the lungs and move from the area of resonate lung sounds to the areas of dullness. Mark the area of change. Start in the right lower quadrant (RLQ), repeating the same process. Measure the vertical distance from the top to the bottom. You can also use palpation to determine the lower border.

G. Neurologic exam:
1. Cranial nerve examination (refer to Section II: Procedures, "Neurologic Examination") for testing of sensations, temperature, and vibratory sensation.
2. Test for asterixis: Asterixis is the involuntary flapping of the wrist in a symmetric or asymmetric pattern with wrist extension. This test can also be elicited by the examiner pressing the client's wrists into hyperextension and then removing the pressure.

DIAGNOSTIC TESTS

A. Liver biopsy is still considered the gold standard to identify the typical features of cirrhosis. However, alternative diagnostic methods have been validated in comparison with liver biopsy and have a good diagnostic accuracy for the diagnosis of cirrhosis:
1. Currently, the most important and frequent scenario that requires a mandatory liver biopsy is the differentiation between severe alcoholic hepatitis and decompensated alcoholic cirrhosis, because at the present time there are no specific clinical signs or noninvasive methods to differentiate between the two conditions.
2. Liver biopsy remains key in the case of suspected NASH-related liver disease and in cholestatic and autoimmune CLD.
3. Noninvasive testing:
   a. Ultrasound-based techniques.
      i. Transient elastography (Fibroscan).
      ii. Point shear-wave elastography.
      iii. Two-dimensional (2D) shear wave elastography.
      iv. Ultrasound and Doppler.
   b. Clinical calculators:
      i. Fibrosis-4 (FIB-4) calculator: (www.hepatitisc.uw.edu/page/clinical-calculators/fib-4).
      ii. Echosense FibroMeter.
      iii. Aspartate aminotransferase (AST)/aspartate platelet ratio index (APRI): www.hepatitisc.uw.edu/page/clinical-calculators/apri.

B. Platelet count, although never used alone, is used to look for portal hypertension.

C. AST/alanine transaminase (ALT) index: elevated but may be normal in cases of advanced liver disease.

D. AST/platelet ratio index.

E. Serum prothrombin time (PT)/international normalized ratio (INR): Elevation indicates a decline in the liver's ability to produce clotting factors.

F. Complete blood count (CBC): anemia, leukopenia, thrombocytopenia.

G. Total bilirubin: elevation.

H. Alkaline phosphatase (ALP): elevated two to three times upper limit of normal.

I. Gamma-glutamyl transpeptidase (GGT): elevated.

J. Albumin: hypoalbuminemia.

K. Sodium: hyponatremia.

L. Creatinine: elevated.

M. Alpha-fetoprotein: marker for HCC. Used for monitoring CLD and development of HCC.

N. Urine drug screen (if indicated).

O. Imaging:
1. Ultrasound: noted earlier.
2. Abdominal contrast-enhanced CT scan. (Not routinely used for diagnosis of cirrhosis as similar information is obtained with ultrasound without exposure to excessive radiation.)
3. MRI:
   a. Abdominal contrast-enhanced MRI.
   b. Magnetic resonance elastography.
   c. Magnetic resonance angiography (MRA).

P. Endoscopy to visualize presence of varices. Noninvasive methods especially transient elastography are also being done to stratify the risk of varices.

Q. A diagnostic paracentesis is warranted to rule out spontaneous bacterial peritonitis.

R. Child–Pugh score for cirrhosis mortality estimates cirrhosis severity using total bilirubin, albumin, INR, presence/absence of ascites, and presence/absence of encephalopathy. An online calculator is available at www.hepatitisc.uw.edu/page/clinical-calculators/ctp.

S. Model of End-stage Liver Disease (MELD) score is used to estimate the severity and likely survival of clients awaiting liver transplantation. Factors include creatinine, bilirubin, INR, sodium, and recent dialysis. A score of 10 or greater indicates need for referral to hepatology. MELD exceptions (meaning these conditions are automatically given a score of 22 or greater) include HCC, hepatopulmonary syndrome, portopulmonary hypertension, and hepatic artery thrombosis. An online calculator is available at www.hepatitisc.uw.edu/page/clinical-calculators/meld.

DIFFERENTIAL DIAGNOSES

A. Cirrhosis.

B. HCC.

C. Budd–Chiari syndrome.

D. PVT.

E. Splenic vein thrombosis.

F. Inferior vena cava obstruction.

G. Sarcoidosis.

H. Schistosomiasis.

PLAN

A. Immunizations:
1. Clients should be up to date on all immunizations including hepatitis A and hepatitis B, if they are not already immune. Pneumococcal pneumonia and influenza are also recommended by the Centers for Disease Control and Prevention (CDC). ▶

B. Client teaching: avoidance of hepatotoxins:

1. Alcohol: Long-term mortality is related to severity of underlying liver disease and is dependent on abstinence from alcohol. Prolonged abstinence is the most effective strategy to prevent disease progression and treatment of the underlying AUD. Active alcoholism and previous alcohol use with less than 6 months of abstinence may be a contraindication to liver transplantation center's policy.

2. Clients with obesity or chronic HCV should avoid consumption of alcohol.

3. Counsel clients to stop smoking.

4. Counsel clients that OTC medications, including Tylenol or medications containing Tylenol, should not be taken.

5. Nonsteroidal anti-inflammatory drugs (NSAIDs) should not be used in clients with ascites.

6. Supplements: Many supplements are hepatotoxic.

7. Clients with hypovolemic hyponatremia have a fluid restriction (1,000 mL/d is recommended).

C. Pharmaceutical therapy: Because cirrhosis is the result of an underlying process, pharmaceuticals are directed at the causative agent (if applicable) or are used for supportive care of the complication:

1. The client's medications should be dose-adjusted for hepatic impairment.

2. The use of diuretics, antibiotics, beta-blockers, and anticoagulants is indicated in the treatment of ascites, bacterial peritonitis, portal vein hypertension and PVT, respectively. Lactulose and rifaximin therapy are used in the management on HE.

3. The use of proton pump inhibitors (PPIs) is generally avoided if possible due to their association with increased rates of bacterial peritonitis.

4. Angiotensin-converting enzyme (ACE) inhibitors, angiotensin II antagonists, or alpha-1 adrenergic receptor blockers should not generally be used in clients with ascites due to increased risk of renal impairment.

5. Aminoglycosides are discouraged in the presence of ascites; they are associated with an increased risk of acute kidney injury (AKI).

D. Diet: Refer to a dietician:

1. A moderate restriction of sodium intake (4.6–6.9 g of salt) is recommended in clients with moderate, uncomplicated ascites. This is generally equivalent to a no added salt diet with avoidance of preprepared meals.

2. Diets with a very low sodium content should be avoided because this is associated with diuretic-induced complications and can endanger a client's nutritional status.

3. Four to seven small frequent meals per day due to anorexia and nausea.

4. Ensure the diet contains adequate protein from a variety of sources.

EMERGENT ISSUES/INSTRUCTIONS

A. Clients presenting with acute GI bleeding should be hospitalized and undergo an urgent endoscopy.

B. Clients with moderate or severe alcohol withdrawal should be hospitalized. Severe forms of alcohol withdrawal include delirium tremens, generalized seizures, coma, cardiac arrest, and death.

FOLLOW-UP

A. Follow-up visit frequency is dependent on the severity of cirrhosis as determined by the MELD score:

1. Less than 10: every 6 to 12 months.

2. 11 to 18: every 3 months.

3. 19 to 24: every month.

4. 25 or greater: every week.

B. Monitor:

1. Lab: Monitor liver enzymes, renal function, electrolytes, blood count, and alpha fetoprotein:

a. Development of HCC with ultrasonography every 6 months.

2. Encephalopathy: This is indicated by personality change, change in consciousness, and sleep disturbance.

3. Ascites: A therapeutic paracentesis is needed for symptom relief of tense ascites.

4. Esophageal varices and acute GI bleeding through frequent endoscopy: Frequency is determined by severity of varices.

5. Bacterial peritonitis.

CONSULTATION/REFERRAL

A. Hepatology consultation:

1. Indicated for all clients whose diagnosis remains unclear after history, physical, serologic tests, and imaging.

2. Indicated for clients with cirrhosis in which the causative agent requires treatment, such as hepatitis C.

3. Clients in need of secondary prophylaxis of esophageal variceal hemorrhage and treatment of refractory ascites, or those for whom paracentesis is ineffective, should be evaluated for a TIPS insertion.

4. Indicated for clients who would benefit from liver biopsy. Liver biopsy is avoided if the biopsy will not change the management of condition, such as a late-stage diagnosis.

5. MELD score should be calculated at the time of the diagnosis and recalculated frequently during management. Referral to a transplant center is indicated for a MELD score 10 or greater.

B. Clients with cirrhosis are best managed by an interdisciplinary team including drug and alcohol addiction specialists.

C. Dietary consultation.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. Older clients are at greater risk for delirium tremens with alcohol withdrawal.

COLORECTAL CANCER SCREENING

DEFINITION

A. Screening for colorectal cancer (CRC) has increased early detection and has allowed for early intervention of premalignant localized cancer. There are multiple screening guidelines. ▶

Table 14.3 outlines current recommendations for colorectal screening for adults at average risk from the U.S. Preventive Task Force (USPTF), the American Cancer Society (ACS), and the U.S. Multi-Society Task Force (MSTF) on CRC. There are two categories of screening:

1. Stool-based testing.
2. Direct visualization tests.

INCIDENCE

A. In the United States, CRC is the second leading cause of cancer-related death in both males and females.
B. Americans have a 5% lifetime risk of CRC.
C. CRC is rare before age 40 years.
D. Ninety percent of the cases of CRC occur after 50 years. The majority of cases are diagnosed between 65 and 74, with the average age of diagnosis at 68 and the average age of death at 73.
E. African Americans have a higher overall incidence rate and younger mean age at onset of CRC:

1. Lower screening rates.
2. Higher CRC incidence rate.
3. Earlier mean age at onset.
4. Worse survival and late-stage presentation.
5. Higher proportion of cancers before age 50.

F. Up to 20% of CRC in the United States are associated with smoking.
G. Obesity is associated with colon cancer but not increases in rectal cancer. Abdominal obesity is a stronger risk factor than truncal obesity or body mass index (BMI).

PATHOGENESIS

A. The usual pathogenesis is the development of a slow-growing adenomatous polyp followed by onset of dysplasia and finally cancerous cells.

PREDISPOSING FACTORS

A. Age: 50 years and older.
B. Male.
C. African American.
D. Family history/genetic: accounts for 20% of all CRCs:

1. Familial adenomatous polyposis (FAP).
2. Nonpolyposis CRC: Lynch syndrome.
3. MUTYH-associated polyposis (MAP).
4. Family history outside of genetic factors.

E. Smoking and moderate to heavy alcohol use (on average three drinks or more daily).
F. Obesity.

TABLE 14.3 CRC SCREENING RECOMMENDATIONS FOR ADULTS AT AVERAGE RISK

	U.S. Preventive Services Task Force: 2016	American Cancer Society: 2018	U.S. MTSF[a] on CRC: 2017
Ages for screening	Start screening at age 50. Stop screening at 75. The decision to be screened after 75–85 should be made on an individual basis taking into account the client's overall health and screening history. Screening after age 85 is not recommended.	Start screening at age 45. For adults with average CRC risk, in good health, and with a life expectancy of more than 10 years, screening should continue through age 75 years. The decision to be screened for clients aged 76–85 years should be individualized to client preference, life expectancy, health status, and history of screening. Screening after 85 is not recommended.	• Start screening at age 50. • Limited evidence supports screening African Americans at 45 years. • Stop screening at age 75 or have <10 years of life expectancy. • Persons without prior screening should be considered for screening up to age 85, depending on age and comorbidities. • Colonoscopy and FIT are recommended as the cornerstones of screening regardless of how screening is offered.
Highly sensitive gFOBT	Annual	Annual	No recommendation
Highly sensitive FIT	Annual	Annual	Annual
FIT fecal DNA	Every 1 or 3 years[b]	No recommendation	Every 3 years
MT-s DNA test		Every 3 years	No recommendation
FSIG	Every 5 years OR the FSIG and FIT DNA recommendation	Every 5 years	Every 5–10 years
FSIG and FIT DNA	FSIG every 10 years plus FIT every year	No recommendation	No recommendation
Colonoscopy	Every 10 years	Every 10 years	Every 10 years[c]
CT colonography (virtual colonoscopy)	Every 5 years	Every 5 years	Every 5 years

[a]MSTF represents the American College of Gastroenterology, the American Gastroenterological Association, and the American Society for Gastrointestinal Endoscopy.

[b]FIT DNA testing suggested by manufacturer.

[c]Colonoscopy offered first, FIT should be offered to clients who decline colonoscopy.

CRC, colorectal cancer; FIT, fecal immunochemical test; FSIG, flexible sigmoidoscopy; gFOBT, guaiac-based fecal occult blood test; MT-s DNA, multitargeted stool DNA; MTSF, Multi-Society Task Force.

G. Diet high in red meat and fats.
H. Personal history of prior adenomatous polyps or isolated CRC.
I. Inflammatory bowel disease (IBD: Crohn's disease [CD] and ulcerative colitis [UC]).
J. Diabetes/insulin resistance.
K. History of renal transplantation.
L. History of abdominal radiation.

COMMON COMPLAINTS
A. Asymptomatic screening.

SUBJECTIVE DATA
A. Review the client's age and risk factors to discuss screening for CRC.
B. Review family history of CRC.
C. Review smoking history and alcohol consumption.
D. Review the client's diet, evaluating red meat, processed meats, and lack of grains, fruits, and vegetables.
E. Review all medications currently being taken, including over-the-counter (OTC) and herbal products.

PHYSICAL EXAMINATION
A. Examinations are not required for discussion on colorectal screening testing.
B. A physical examination and vital signs should be taken as indicated for other presenting complaints.

DIAGNOSTIC TESTS
A. Stool-based testing:
1. Guaiac-based fecal occult blood test (gFOBT).
2. Fecal immunochemical test (FIT).
3. FIT fecal DNA.
4. Multi-targeted stool DNA test (MT-sDNA).

B. Direct visualization tests:
1. Flexible sigmoidoscopy.
2. **Colonoscopy: The American College of Gastroenterology (ACG) recommends the colonoscopy as the preferred strategy for screening.**
3. CT colonography (virtual colonoscopy).

C. Serum, urine, and capsule endoscopy are NOT recommended for CRC screening.

DIFFERENTIAL DIAGNOSES
A. None related to screening.

PLAN
A. Client teaching:
1. Educate client about modifying controllable risk factors with diet, exercise, smoking cessation, and low or no consumption of alcohol (on average one or less drinks per day).
2. Discuss the procedures and the preparation needed for each test.

B. Pharmaceutical therapy:
1. Bowel prep for flexible sigmoidoscopy and colonoscopy depends on the test, client's age, and other comorbidities.
2. Refer to Chapter 2, Table 2.2 for the U.S. Preventive Services Task Force (USPSTF) recommendations for aspirin use to prevent cardiovascular and colorectal disease recommendations by age range.

FOLLOW-UP
A. Follow-up CRC screening is determined by family history, underlying risk factors, results of the prior screening test, and the test used for screening.
B. Clients with classic FAP (>100 adenomas) should be advised to have genetic counseling.
C. Nonsteroidal anti-inflammatory drugs (NSAIDs) have been associated with a decrease in the risk of developing CRC. There is insufficient evidence to recommend the use of NSAIDs as a prevention strategy.

CONSULTATION/REFERRAL
A. Refer to a gastroenterologist and/or surgeon as indicated.

INDIVIDUAL CONSIDERATIONS
A. Geriatrics:
1. Medicare Part B covers colorectal screening tests. See Chapter 2, "Healthy Living for the Adult-Geriatric Client," for the full Medicare coverage guidelines.

BIBLIOGRAPHY
Shaukat, A., Kahi, C. J., Burke, C. A., Rabeneck, L., Sauer, B. G., & Rex, D. K. (2021, March 1). ACG clinical guidelines: Colorectal cancer screening 2021. *American Journal of Gastroenterology*, *116*(3), 458–479. https://doi.org/10.14309/ajg.0000000000001122

CONSTIPATION

DEFINITION
A. Constipation means infrequent and difficult defecation of hard stools and a sensation of incomplete evacuation or straining. Constipation may also refer to a decrease in the volume or weight of stool, and the need for enemas, suppositories, or laxatives to maintain bowel regularity. Constipation is a symptom, not a disease.
B. The lower limit of normal stool frequency is three bowel movements (BMs) a week. The Rome consensus criterion defines constipation as two or more of the following occurring over a period of 3 months: two or fewer stools weekly, sensation of straining, sensation of incomplete evacuation or sensation of obstruction or blockage, and/or the need for digital removal of stool.
C. Classification of constipation includes the following:
1. Primary constipation:
   a. Normal-transit constipation (most common).
   b. Functional constipation (slow transit).
   c. Defecatory disorders.
2. Secondary constipation:
   a. Dietary deficiency.
   b. Structural obstruction.
   c. Systemic: related to endocrine, neurologic, or connective tissue disorder.

INCIDENCE
A. The incidence of constipation is 16% among all adults and 33% in clients older than 60 years of age. Constipation is commonly self-reported. Constipation occurs in more than 50% of clients with colorectal cancer (CRC); it is usually a symptom of advanced disease, but it may be the presenting complaint.

PATHOGENESIS
A. Constipation can be caused by an alteration of the filling of the rectum by colonic transportation and/or reflex defecation of stool.
B. Lack of exercise and prolonged bedrest decrease propulsion of bowel contents.
C. During pregnancy, progesterone has a relaxing effect on the muscles of the gastrointestinal (GI) tract and causes a decrease in peristalsis. The compression of the intestines by the enlarging uterus causes constipation during pregnancy. ▶

D. Habitual use of laxatives is associated with impaired colonic motor activity and has the potential of producing hypokalemia.
E. Hypokalemia can produce a generalized ileus and is most often seen in clients who take diuretics.
F. Psychiatric disease and psychosocial distress have important roles. The exact mechanisms by which emotional difficulties lead to constipation remain unclear, but their contribution is widely recognized.
G. Drugs (Table 14.4).

PREDISPOSING FACTORS

A. Insufficient nutrition:
  1. Low-fiber diet.
  2. Low fluid intake.
B. Neurologic causes:
  1. Spinal cord injury.
  2. Parkinson disease.
  3. Multiple sclerosis.
  4. Aganglionosis (Hirschsprung disease).
  5. Sacral nerve trauma/tumor.
C. Sedentary lifestyle/impaired mobility.
D. Laxative abuse.
E. Travel.
F. Ignoring urge to defecate.
G. Drug use (individual medications and polypharmacy).
H. Pregnancy, especially third trimester.
I. Psychosocial problems:
  1. Depression.
  2. Sexual abuse.
  3. Unusual attitudes to food and bowel function.
  4. Obsessive/compulsive.
J. Extremes of ages: Infants and geriatrics.
K. Hypothyroidism.
L. CRC.
M. Irritable bowel syndrome (IBS).
N. Pelvic floor disorders:
  1. Impaired function of the pelvic floor and/or external sphincter.
  2. Pelvic floor obstruction.
  3. Rectal prolapse.
  4. Enterocele and/or rectocele.
  5. Rectal intussusception.

TABLE 14.4 DRUGS AND CLASSIFICATIONS THAT CAUSE AND INCREASE CONSTIPATION

Anticholinergics (atropine, antidepressants, neuroleptics, antiparkinsonian drugs, antispasmodics)	Opiates
Antipsychotics	Cholestyramine (binds bile salts)
Anticonvulsants	Antacids (aluminum hydroxide and calcium carbonate)
Antihistamines	Iron supplements
Antihypertensives (calcium channel blockers, clonidine, hydralazine, MAOIs, methyldopa)	NSAIDs
Diuretics	Ganglionic blockers

NSAIDs, nonsteroidal anti-inflammatory drugs; MAOIs, monoamine oxidase inhibitors.

COMMON COMPLAINTS

A. Hard, infrequent stools.
B. Straining.
C. Inability to defecate when desired.
D. Need for digital manipulation to facilitate evacuation.

OTHER SIGNS AND SYMPTOMS

A. Hard, pebbly, rocklike stools.
B. Painful defecation.
C. Abdominal pain/distention.
D. Weight loss.
E. Blood in stools.

POTENTIAL COMPLICATIONS

A. A rectal prolapse of the mucosa is pink and looks like a doughnut or rosette. Complete prolapse involving the muscular wall is larger and red, and has circular folds.
B. Anal fissure.
C. Hemorrhoidal disease.
D. Pelvic floor damage in females.
E. Rectal ulceration.
F. Fecal impaction.
G. Bowel obstruction.
H. Fecal incontinence (FI).
I. Megacolon.
J. Volvulus.
K. Urinary retention.
L. Syncope.
M. Anal fistula.

SUBJECTIVE DATA

A. Review the onset, duration, and course of symptoms:
  1. Is constipation a chronic or acute problem?
  2. If there has been a change in bowel habits, was it gradual or sudden?
  3. What feature does the client rate most distressing?
B. Review bowel habits:
  1. Does the client have a regular time for defecation?
  2. Review size, color, consistency, and frequency of stools.
  3. Is there any blood?
  4. Are there any periods of diarrhea?
  5. How often are laxatives being used and what doses?
  6. Are suppositories and enemas also required?
  7. Does the client have the urge to defecate?
  8. Does the client have a sensation of incomplete evacuation?
  9. Does the client need to digitally remove stool?
C. Review the client's daily diet and fluid intake. Has there been any dietary change?
D. Review the client's medication history: prescription and over-the-counter (OTC; refer to Table 14.4).
E. Review the client's daily physical activity.
F. Review the client's psychosocial history of stress, depression, anxiety, and coping mechanisms.
G. Review the client's other health problems such as diabetes, depression, hypothyroidism, and hypercalcemia.
H. Review family history of constipation and CRC.
I. Review surgical history.

PHYSICAL EXAMINATION

A. Check pulse, respirations, blood pressure (BP), and weight. Check temperature if indicated.
B. Inspect:
  1. General overall assessment of nutritional status.
  2. Examine the skin for pallor and signs of dehydration and hypothyroidism. ▶

3. Evaluate for presence of hernias.
4. Inspect anus, including the position, presence of perianal erythema, hemorrhoids, and skin tags.
5. Observe for signs of fecal soiling.
6. Examine the lower back to rule out spinal lesions: hairy or hyperpigmented patches, gluteal fold asymmetry, cutaneous dimples, sinus tracts, and lipomas.
7. The American Gastroenterology Association (AGA) notes that the client should be in the left lateral position with the buttocks separated to evaluate:
   a. Observe the descent of the perineum during simulated bowel evacuation.
   b. Observe the elevation during a squeeze aimed at retention of stool.
   c. During the simulated defecation, the anal verge should be observed for any patulous opening or prolapse of anorectal mucosa.

C. Auscultate:
1. Auscultate abdomen for bowel sounds. Auscultation of the abdomen should precede any palpation or percussion due to the changes in intensity and frequency of sounds after manipulation. Bowel sounds may be high pitched or absent in the presence of constipation.

D. Percuss:
1. Percuss the abdomen.

E. Palpate:
1. Palpate the abdomen for masses, tenderness, distension, and fecal mass.
2. Palpate the liver and spleen.

F. Digital rectal exam:
1. Examine the rectum for masses, hemorrhoids, fissures, fistula, prolapse, inflammation, and anal warts.
2. Evaluate for impaction, hard stool in ampulla.
3. Perform an anal "wink" reflex test by a light pinprick or scratch.
4. Evaluate sphincter tone:
   a. Disordered innervation of the anus is indicated by finding that the anal canal opens wide when the puborectalis muscle is pulled posteriorly.
   b. Evaluate the resting tone of the sphincter and squeezing effort.
   c. Instruct the client to "expel the examination finger" to evaluate the force of expulsion.

G. Neurologic examination:
1. Perform a neurologic examination for tone, strength, and reflexes to search for focal deficits and delayed relaxation phase of the ankle jerks, suggestive of hypothyroidism.

H. Pelvic examination:
1. Perform pelvic examination to evaluate a prolapse or rectocele. Evaluate when the client is at rest and with straining.

I. Mental status:
1. Perform mental status examination, checking for signs of depression and somatization.

DIAGNOSTIC STUDIES

A. No tests are required for the diagnosis of chronic constipation.

B. Because laboratory tests have demonstrated low sensitivity for indicating a cause for constipation, unless there are alarm symptoms (as defined as follows), initial treatment may consist of alterations in the diet and activity level, and addition of laxatives. The following are alarm symptoms:
1. Weight loss of greater than 10 lbs.
2. Rectal bleeding or positive test for occult blood.
3. Abdominal pain.
4. Inability to pass flatus.
5. Vomiting.
6. Change in bowel habits in a client older than 50 years.
7. Positive family history of CRC or inflammatory bowel disease (IBD).

C. If a trial of lifestyle modifications and/or laxatives is unsuccessful, further investigation is warranted.

D. Laboratory tests:
1. Complete blood count (CBC).
2. Thyroid studies.
3. Potassium and calcium. **Clients taking diuretics should have serum potassium checked. Hypokalemia may reduce bowel contractility and produce an ileus.**
4. Serum glucose to rule out diabetes.
5. Stool for occult blood.

E. Radiographs:
1. Plain abdominal radiographs may be useful to evaluate stool burden and assess for obstruction or megacolon.
2. Barium enema (BE) to evaluate megacolon and redundant sigmoid colon.

F. Endoscopic:
1. Flexible sigmoid.
2. Colonoscopy (especially if the client is older than 50 or has had abrupt onset of constipation).
3. CT colonography.

G. Anorectal function tests if there is no response to a trial of laxatives:
1. Balloon expulsion.
2. Colonic transit.
3. Anorectal manometry.
4. Defecography.
5. Electromyography (EMG): anal surface.

DIFFERENTIAL DIAGNOSES

A. Constipation.
B. Intestinal obstruction: Acute onset of constipation requires ruling out an ileus, especially when accompanied by abdominal discomfort.
C. Hypothyroidism.
D. Psychosocial dysfunction.
E. Fecal impaction.
F. Neurologic disorders.
G. Multiple sclerosis.
H. Spinal cord injury.
I. Cancer.
J. Drug use.
K. Celiac disease: Constipation is often the presenting complaint in Crohn's disease (CD).
L. Diabetes (chronic dysmotility).
M. IBS: constipation predominant.

PLAN

A. Client teaching: *See Client Teaching Guide for this chapter, "Tips to Relieve Constipation."*
1. Encourage the client to exercise. Both exercise and dietary fiber stimulate the natural wavelike contraction of the colon that trigger the urge to defecate.
2. Reassure the client that recommended dietary changes and exercise help with constipation.
3. Aim to reduce dependency on laxatives. Warn chronic laxative users that it may take 4 to 6 weeks before spontaneous BMs return.
4. Provide education regarding potential complications of long-term constipation.
5. Encourage defecation after meals, especially in the morning hours when colonic motility is most pronounced. ▶

6. Ask the client to keep a stool diary to bring to their next appointment. A BM record is available at www.nhsggc.org.uk/media/241191/nhsggc-bristol-stool-chart.pdf.

B. Dietary management:

1. See Appendix B, "High-Fiber Diet."

C. Medical management of idiopathic constipation:

1. Treatment of constipation is symptomatic and should begin with lifestyle and dietary changes:

a. Direct relationship between fiber intake, water intake, and fecal output. Fiber goal is 20 to 35 g daily.

b. Use of bulk-forming laxatives encouraged first. These agents include psyllium (Metamucil), methylcellulose (Citrucel), calcium polycarbophil (Fibercon), and wheat dextrin (Benefiber). Of these choices, psyllium or methylcellulose produce the best subjective results. All bulk-forming agents produce inconsistent objective results.

c. Nonbulk-forming laxatives may be initiated:

i. Surfactants: Colace: generally used short term.

ii. Osmotics: polyethylene glycol (PEG; MiraLax): may be used long term but may produce electrolyte imbalances in the older adults or clients with renal disease.

iii. Stimulants: bisacodyl, senna: may be added every other day or every third day to the previous choices. The intensity of the action of stimulant laxatives is dose-related. A large dose of any stimulant laxative can produce serious adverse effects including severe cramps, dehydration, and hypokalemia. There is concern that chronic, long-term use of stimulant laxatives can lead to loss of colon function (cathartic colon).

2. Evaluate and stop medications, if possible, that cause constipation.

3. Mineral oil, also known as liquid paraffin, should be used with caution if the client is at risk for aspiration or accidental inhalation secondary to the risk of aspiration pneumonia. Mineral oil interacts with fat-soluble vitamins and anticoagulants.

D. Medical management of severe or refractory constipation:

1. Suppository: bisacodyl or glycerin; used for defecatory dysfunction since the products liquify stool and relieve obstruction.

2. Fecal impaction may require manual fragmentation followed by enema to relieve the situation. Enemas should not be given routinely to treat constipation because they disrupt normal defecation reflexes and the client becomes dependent. After manual disimpaction, mineral oil/warm water enema is used to soften the remaining stool and evacuate the rectum. PEG solution may then be administered orally daily with the intention of stimulating one BM every day to every other day. Investigation to ascertain the initial cause of constipation should be undertaken.

3. Manual removal of fecal impaction can stimulate the vagus nerve and cause syncope and tachycardia. It is contraindicated in the following conditions:

a. Pregnancy.

b. After genitourinary, rectal, perineal, abdominal, or gynecologic surgery.

c. Myocardial infarction (MI), coronary insufficiency, pulmonary embolism (PE), congestive heart failure (CHF), or heart block.

d. GI or vaginal bleeding.

e. Blood dyscrasias or bleeding disorders.

f. Hemorrhoids, fissures, and rectal polyps.

TABLE 14.5 LAXATIVES

Bulk laxatives	Psyllium (Konsyl, Metamucil) polycarbophil Malt soup extract (Maltsupex) Methylcellulose (Citrucel) Calcium polycarbophil (FiberCon) Wheat dextrin (Benefiber)
Saline laxatives	Magnesium hydroxide (Milk of Magnesia) Magnesium citrate Fleet Phospho-Soda
Lubricating agents (emollient)	Magnesium citrate Mineral oil
Stimulant laxatives	Docusate Bile acids Bisacodyl (Dulcolax) Castor oil Senna Cascara Aloes
	Rhubarb Ex-Lax Senokot Correctol
Osmotic agents	Magnesium and phosphate salts Lactulose (Kristalose) Sorbitol Polyethylene glycol (Colyte, Glycolax, MiraLax)
	Glycerin suppositories

E. Pharmaceutical therapy:

1. Bulk-forming agents (Table 14.5) reduce abdominal pain and improve stool consistency. These should be used if an increase in dietary fiber does not work. They act by causing retention of fluid and increasing fecal mass. They must be taken with plenty of fluids to prevent formation of an obstructing bolus. Flatulence and abdominal distension may occur, but long-term use is safe.

2. Stimulant laxatives (see Table 14.5) act by directly stimulating the colonic nerves. Suppositories are faster (20–60 minutes) versus oral laxatives (8–12 hours).

3. Osmotic laxatives (see Table 14.5) act by retaining fluid in the bowel by osmosis, changing the water distribution in the feces. Good hydration is important. Clients who need to limit their sodium intake, such as those with CHF, renal disease, and hypertension, should not use osmotic laxatives that contain sodium.

4. Newer agents:

a. Lubiprostone (Amitiza): chloride channel activator; indicated for use in IBS with constipation predominant (IBS-C), opioid-induced constipation (OIC), and chronic idiopathic constipation (CIC). Dosing adjustments are required for hepatic impairment. The effectiveness of Amitiza has not been established for a diphenylheptane opioid (e.g., methadone).

b. Linaclotide (Linzess): guanylate cyclase C agonist; indicated for IBS-C and CIC.

c. In 2018 the U.S. Food and Drug Administration (FDA) accepted a new drug application for prucalopride (Resolor). Prucalopride, a high affinity, selective serotonin type 4 (5-hydroxytryptamine [5-HT4]) receptor agonist, is a GI prokinetic agent that stimulates colonic peristalsis, increasing bowel motility associated with CIC. ▶

5. When severe depression requires the use of antidepressants, the least constipating agent should be selected (i.e., one with minimal anticholinergic activity).

6. Treat other identified causes, for example, hypothyroidism.

F. Multidisciplinary referrals:

1. Pelvic floor physiotherapy may be offered. The pelvic floor retraining involves teaching the client to relax their pelvic floor muscles during straining and to correlate relaxation and pushing to achieve defecation.

2. Biofeedback has been effective for short-term treatment of intractable constipation and for treatment of FI. Biofeedback has been shown to improve rectoanal coordination during defecation and symptoms of constipating despite reduced laxative use.

FOLLOW-UP

A. Repeat assessment in 4 to 6 weeks. Ask the client to keep a stool diary and bring it in for subsequent appointments.

B. If there is no evidence of obstruction, anemia, or occult blood loss, follow the client expectantly for a few weeks on a conservative program that includes increased dietary fiber and increased exercise, and follow stool guaiac.

C. Failure to improve may indicate a serious underlying cause and need for referral.

EMERGENT ISSUES/INSTRUCTIONS

A. Acute onset of constipation is considered a red flag in the geriatric population.

B. Fever, abdominal pain, inability to pass flatus, and abdominal distention may be a sign of bowel obstruction and require immediate evaluation.

CONSULTATION/REFERRAL

A. Consider consultations with a gastroenterologist, gynecologist, or psychologist/psychiatrist as indicated.

B. Surgical consultation may be required for slow-transit constipation. Total colectomy with ileorectal anastomosis may be required when there is failure of aggressive, prolonged trials of laxatives, fiber, and prokinetic agents.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Constipation is very common in pregnancy secondary to progesterone and the enlarging uterus (see "Pathogenesis").

2. Constipation that results from iron supplementation can be avoided by increasing the intake of fluid and high-fiber foods, and increasing physical activity such as walking.

3. Bulking agents and lactulose will not enter breast milk. Senna, in large doses, will enter breast milk and may cause diarrhea and colic in infants.

B. Adults:

1. The most common cause of chronic constipation in adults is failure to initiate defecation.

2. Diabetics should avoid stimulant laxatives such as lactulose and sorbitol. Their metabolites may influence blood glucose levels.

C. Geriatrics:

1. Constipation in older individuals is not a result of aging; instead it is considered a geriatric syndrome. Nurse practitioner (NPs) should practice special consideration of this symptom.

2. Constipation is usually related to an increase in constipating factors such as chronic illnesses, immobility, dietary factors, medications, neurologic factors, and psychiatric conditions.

3. An important diagnostic concern in older adults is the possibility of constipation being due to a colonic neoplasm. More than 25% of clients with colorectal carcinomas present with constipation.

4. Check for a fecal impaction, especially in older adults with a history of chronic constipation. Fecal impaction ranks as one of the major sources of anorectal discomfort among older adults and bedridden. Chronic, incomplete evacuation leads to formation of an obstructing bolus of desiccated hard stool in the rectum.

5. Diarrhea rather than constipation is sometimes the only complaint due to the collection of liquid stool distending the proximal colon and passing around the obstructing bolus.

6. Beers Criteria caution: A full review of medications, herbals, and OTC drugs should be undertaken to identify medications that should be avoided in the geriatric population, duplicate medications, and medications that are able to be decreased or deprescribed. (Refer to section on deprescribing in Chapter 3, "Adult-Geriatric Assessments"):

a. Refer to Appendix C: Beers Criteria, Table C.1 to identify drugs that have highly anticholinergic side effects and are potentially inappropriate medications for use in older adults, including the following:

i. First-generation antihistamines.
ii. Antispasmodics.
iii. Antidepressants.
iv. Opioids.
v. Calcium channel blockers.
vi. Anticonvulsants.
vii. Muscle relaxants.

CROHN'S DISEASE

DEFINITION

A. Crohn's disease (CD) is a chronic, progressive, destructive inflammatory bowel disorder with both intestinal and extraintestinal manifestations. It produces focal, asymmetric, transmural inflammation, ulceration, and fibrosis, resulting in malabsorption. CD can involve any segment of the gastrointestinal (GI) tract from the mouth to the anus; the terminal ileum and colon are the most common sites:

1. CD is subclassified based on age, location (ileal, colonic, ileocolonic, or upper GI), and clinical presentation (nonstricturing/nonpenetrating to penetrating) using the Montreal classification.

2. Older adults with inflammatory bowel disease (IBD) can be subdivided into two groups:

a. Older adults with onset of IBD at a late age (late-onset IBD).

b. Older adults with long-standing IBD; first diagnosed as having IBD at a younger age (long-standing IBD).

B. The disease is chronic, relapsing, and incurable. CD is characterized by episodes of remission and exacerbation. The most frequent cause of death in persons with IBD is the primary disease, followed by malignancy and thromboembolic disease. Symptoms of CD do not correlate well with the presence of active inflammation and therefore should not be the sole guide for therapy. The diagnosis is usually established by objective evaluation with endoscopic finding in a client with a compatible clinical history. Objective evidence for disease activity should be sought before administering medication that may have significant adverse effects.

C. Up to 80% of clients with CD undergo surgery at some point during their clinical course. Indications for surgery include stricture, intractable or fulminant disease, anorectal disease, and intra-abdominal abscess. Surgical procedures include bowel resection and ileal pouch–anal anastomosis (IPAA). The 10-year cumulative risk of a major abdominal surgery in CD is 30% in the biologic era of treatment. The 10-year risk of a second resection after the first is 30% to 35%.

D. The lifetime risk of fistula development is 20% to 40%.

E. The incidence of adenocarcinoma in clients with CD is higher than in the general population. Lymphoma is also increased, especially in clients with IBD treated with azathioprine (AZA; 6-mercaptopurine [6-MP]).

INCIDENCE

A. The incidence rate ranges from 3.1 cases per 100,000 to 20.2 cases per 100,000. An estimated one to two million people in the United States have ulcerative colitis (UC) or CD. The incidence of IBD has been reported to be highest in Jewish populations. IBD is very prevalent among the American Jewish population—four to five times that of the general population.

B. The peak incidence of CD is most common in late adolescence to the third decade of life. Another peak occurs in persons aged 50 to 80 years. It is arguable if the increased incidence later in life is due to prior misdiagnosis or actual development of new disease. Ten to fifteen percent of cases of IBD are diagnosed in clients older than 60 years of age.

C. CD may involve the entire GI tract; note the incidence according to the location:

1. 80% have small bowel involvement, usually in the distal ileum. In severe cases of ileitis, complications may include fistulas or an abscess in the right lower quadrant (RLQ) of the abdomen.
2. 50% have ileocolitis (involving both the ileum and colon). This type is associated with significant weight loss.
3. 20% have disease limited to the colon, with roughly one-half having sparing of the rectum.
4. A small percentage has predominant involvement of the mouth (aphthous ulcers) or gastroduodenal area; fewer have involvement of the esophagus (odynophagia and dysphagia) and proximal small bowel.
5. One-third have perianal disease (perianal pain, drainage from large skin tags, anal fissures, perirectal abscesses, and anorectal fistulae).
6. 15% to 20% have arthralgias. Arthritis is the most common complication.

PATHOGENESIS

A. Pathogenesis is multifactorial and remains unclear. Dysregulation of the immune system, changes in the composition of intestinal flora, and presence of genetic susceptibility combine to produce inflammation of the mucosal lining of the intestinal tract, resulting in ulceration, edema, bleeding, and fluid and electrolyte loss.

B. The 2018 American Gastroenterology Association (AGA) guidelines note genetic testing is not indicated to establish the diagnosis of CD. There are currently 200 genetic foci that are being studied to determine their role in the pathogenesis of IBD. CD and UC share approximately 70% of their genes, indicating a close relationship between the two processes.

PREDISPOSING FACTORS

A. Age between 15 and 35 years and another peak at 50 to 80 years.

B. Genetic predisposition/family history of CD:

1. First-degree relative 5- to 20-fold increased risk.
2. 70% incidence in identical twins versus 5% to 10% in nonidentical twins.
3. Jewish populations.

C. Smoking exacerbates disease activity and accelerates disease recurrence.

D. Obesity: unclear if there is increased risk but complications are more severe and frequent.

E. Physical activity: lower risk in active individuals.

F. Dysbiosis: antibiotic use (particular metronidazole and quinolones); presence of infection.

G. Breastfeeding history: three to four times increased risk in clients that were not breastfed.

H. Medications: Use of tretinoin, nonsteroidal anti-inflammatory drugs (NSAIDs), and oral contraceptives have all been implicated in the development of Crohn's, although the relationship remains unclear.

I. History of appendectomy: Some studies show a protective benefit after appendectomy.

J. Psychosocial factors.

K. Sleep duration.

COMMON COMPLAINTS

A. The following hallmark/cardinal symptoms occur in about 80% of clients.

1. Abdominal pain, the classic location being in the RLQ (appendicitis-like):
   a. Abdominal pain often worsens postprandially.
2. Diarrhea, chronic or nocturnal.
3. Fatigue: very prevalent; thought to arise from inflammation, anemia, and vitamin and mineral deficiencies.
4. Constitutional symptoms at presentation:
   a. Fever.
   b. Weight loss/anorexia.
   c. Growth failure (Younger ages).

OTHER SIGNS AND SYMPTOMS

A. Symptoms vary depending on the location of the intestinal tract and extent of disease.

1. Constipation: early sign.
2. Bowel urgency and sense of incomplete evacuation.
3. Rectal bleeding.
4. Abdominal mass.
5. Night sweats.
6. Pallor/anemia.
7. Perianal discomfort or soft or semiliquid irritating rectal discharge.
8. Recurrent fissures and fistulas, abscesses sometimes extending to skin.
9. Folate deficiency.
10. Menstrual irregularities/amenorrhea.

▶

11. Extraintestinal symptoms: classic:
- a. Arthropathy (both axial and peripheral).
- b. Dermatologic:
  - i. Pyoderma gangrenosum.
  - ii. Erythema nodosum.
- c. Ocular:
  - i. Uveitis.
  - ii. Scleritis.
  - iii. Episcleritis.
- d. Hepatobiliary disease:
  - i. Primary sclerosing cholangitis (PSC).
- e. Other extraintestinal complications:
  - i. Thromboembolic (venous and arterial).
  - ii. Metabolic bone diseases.
  - iii. Osteonecrosis.
  - iv. Cholelithiasis.
  - v. Nephrolithiasis.

12. Other immune-mediated diseases associated with CD include asthma, chronic bronchitis, pericarditis, psoriasis, celiac disease, rheumatoid arthritis, and multiple sclerosis.

SUBJECTIVE DATA

A. Ask about onset, duration, and course of symptoms. Have any of the presenting symptoms occurred at any time in the past (flares of CD may have gone undiagnosed in the past)?

B. Review the client's history and extent of diarrhea, including frequency, consistency, color, quantity, and odor of stools. Evaluate if there is blood, mucus, pus, or food particles in the stools.

C. Inquire about recent travel to foreign countries.

D. Ask the client if diarrhea represents a change in bowel habits. Is there nocturnal diarrhea?

E. Ask the client what makes the diarrhea worse or better.

F. Inquire about previous GI surgery.

G. Review the client's usual weight and any history of weight loss. If weight loss has occurred, how many pounds? How is the client's appetite?

H. Review family history of CD, colon cancer, UC, and malabsorption syndrome.

I. How has the duration of current complaints affected the client's work or usual social activities?

J. Review for duration and extraintestinal symptoms, including the following:
- **1.** Urinary complications: renal calculi.
- **2.** Sclerosing cholangitis: fatigue and jaundice.
- **3.** Skin diseases:
  - a. Erythema nodosum: painful, tender, raised, purple lesion on the tibia.
  - b. Pyoderma gangrenosum: inflamed patch of skin that has progressed to ulceration.
  - c. Herpetic lesions related to immune suppression.
- **4.** Arthritic symptoms.

K. Review medications, especially antibiotics and NSAIDs.

L. Review the client's current tobacco/cigarette use.

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, blood pressure (BP). Measure height and weight to calculate body mass index (BMI).

B. Inspect:
- **1.** Observe general appearance, noting pallor, wasting, cachectic appearance, ecchymosis, skin ulcerations, jaundice, and signs of Kaposi sarcoma.
- **2.** Inspect the head and neck for aphthous ulcers, glossitis, stomatitis, and poor dentition.
- **3.** Inspect the abdomen for surgical scars.
- **4.** Order eye examination for uveitis.
- **5.** Inspect joints for warmth and redness.

C. Auscultate:
- **1.** Auscultate the abdomen for altered bowel sounds (obstruction).

D. Palpate:
- **1.** Palpate the neck for goiter and lymphadenopathy.
- **2.** Palpate the abdomen for distension, ascites, tenderness rebound, guarding, and masses.
- **3.** Palpate for hepatomegaly in RLQ.
- **4.** Palpate the joints for tenderness.

E. Rectal exam:
- **1.** Check anal sphincter for tags, control, and discharge.
- **2.** Palpate for masses, fissures, fistulas, and inflammation.
- **3.** Perform digital rectal examination to assess for anal strictures and rectal mass.

F. Neurologic exam:
- **1.** Assess for signs of vitamin B_{12} deficiency, including tingling sensation and numbness in hands or feet.

DIAGNOSTIC TESTS

A. Laboratory tests:
- **1.** Complete blood count (CBC) with differential.
- **2.** Electrolytes and albumin.
- **3.** Erythrocyte sedimentation rate (ESR)/C-reactive protein (CRP).
- **4.** Serum cobalamin (vitamin B_{12}).
- **5.** Serum iron studies.
- **6.** Folate.
- **7.** Liver enzymes and functioning tests (international normalized ratio [INR]) and bilirubin.
- **8.** HIV.
- **9.** Celiac antibody testing should be considered.
- **10.** Thiopurine methyltransferase (TPMT) activity should be assessed before AZA or MP.

B. Stool studies:
- **1.** Fecal calprotectin should be considered to help differential the presence of IBD from irritable bowel syndrome (IBS).
- **2.** Guaiac.
- **3.** Stool culture.
- **4.** *Clostridioides difficile* toxin assay.
- **5.** Ova and parasites.

C. Imaging:
- **1.** Abdominal flat plate radiography; assess dilated loops of bowel.
- **2.** Barium enema (BE):
  - a. Classic "string sign": narrow band of barium flowing through an inflamed or scarred area in terminal ileum; differentiates CD from UC.
  - b. "Rectal sparing": suggests CD in the presence of inflammatory changes in other parts of the colon.
  - c. "Thumbprinting": indicates mucosal inflammation (may be seen on flat plate of abdomen).
  - d. "Skip lesions": areas of inflammation with normal-appearing areas.
- **3.** Small bowel follow-through GI series.
- **4.** Fistulogram: used to guide the surgical correction.
- **5.** CT or MRI scan of the abdomen and pelvis (limited use in IBD but may detect fistulae).

D. Procedures with/without biopsy:
- **1.** Colonoscopy: Mucosa has characteristic cobblestone appearance. ▶

2. Flexible sigmoidoscopy with biopsy reveals "skip areas" in colon, significant small bowel involvement, fistulas, and granulomas.

3. Upper endoscopy: Aphthous ulcerations occur in the stomach and duodenum in 5% to 10% of clients.

4. Capsule enteroscopy: The major risk is the potential for the camera to become lodged at the point of stricture and requires operative intervention.

5. Skin biopsy.

E. Tuberculin purified protein derivative (PPD) skin test: prior to initiation of biologic therapy.

DIFFERENTIAL DIAGNOSES

A. CD.
B. UC.
C. Appendicitis.
D. Colon cancer.
E. IBS.
F. Anorexia nervosa.
G. Perianal abscess.
H. Intestinal protozoan and bacterial etiologies.
I. Food poisoning.
J. Cytomegalovirus (CMV).
K. Intestinal tuberculosis (TB).
L. Diverticulitis with colitis.

PLAN

A. General interventions:

1. CD should be managed jointly with a gastroenterologist, colorectal surgeon, and specialists such as a rheumatologist, pharmacist, and nutritionist.

B. Client teaching: *See Client Teaching Guide for this chapter, "Crohn's Disease and Ulcerative Colitis."*

1. Smokers should be counseled to stop smoking. Active smoking cessation programs should be encouraged. *See Client Teaching Guide for* Chapter 25, *"Nicotine Dependence."*

C. Dietary management:

1. Adequate nutrition is critical to promotion of healing. Sufficient protein and calories limit the stress on an inflamed and often strictured bowel.

2. Clients with cramps and diarrhea should alter the fiber content of their diets. Diet should include high fiber, low fat (see Appendix B, "Dietary Recommendations").

3. Those with steatorrhea benefit from decrease in fat intake to less than 80 g/d. Give the client a copy of the low-fat/low-cholesterol diet (see Appendix B, "Dietary Recommendations").

4. An empiric trial of restricting milk products may terminate diarrhea due to lactase deficiency.

5. Clients with severe diarrhea may require partial bowel rest, which removes the stimulus that food has on bowel motility and secretion.

6. Elemental diet preparations, such as Ensure, Sustacal, or Isocal, have been found to induce remission, improve symptoms, and decrease disease activity in clients with acute disease.

7. Total parenteral nutrition (TPN) is used when the client's oral intake is not adequate or when surgery is indicated.

8. Pretreatment screening for TB, using Mantoux (a PPD) skin testing, is needed prior to initiation of immunomodulators and thiopurines.

D. Immunization status:

1. International consensus guidelines recommend vaccinating clients on or likely to begin immunosuppressive therapy for control of their IBD.

2. Immunizations with inactivated vaccines should be brought up to date and rigorously maintained during treatment, including a yearly inactivated influenza, meningococcus, hepatitis B if not immune, and pneumococcal vaccine given periodically (5-yearly).

3. Check varicella titers prior to treatment with immunomodulators and reimmunize if titers are low.

4. If required, live vaccines (polio, rubella, and yellow fever) should be given at least 3 weeks before immunosuppressive therapy or 3 months after stopping the therapy.

E. Medical and surgical management.

1. Surgery does not cure the client and is reserved for intractable disease, perforation, obstruction, or severe bleeding.

2. The objective of surgery is to remove grossly involved bowel and to spare as much normal-appearing bowel as possible.

3. Postoperative recurrence rates are estimated at 30% to 50% per decade and are inversely related to preoperative disease duration.

F. Pharmaceutical therapy. The medical management of CD can be divided into treatment of mild Crohn's and moderate to severe Crohn's and further subdivided into management of an acute exacerbation and maintenance of remission. In acute exacerbation, triggers such as underlying infection, fistula, perforation, and other pathology must be ruled out prior to the intravenous (IV) administration of glucocorticoids. The goal of chronic therapy is the remission of bowel inflammation. Therapies include the following:

1. Vitamin, mineral, and folic acid supplements are necessary for proper healing and avoidance of secondary complications, such as bone disease and anemia:

a. Client should take a multiple vitamin containing about five times the normal daily vitamin requirements.

b. Sulfasalazine is effective in treating symptoms of CD. Folic acid supplementation is required for clients on sulfasalazine because it impairs folic acid absorption.

c. Vitamin B_{12} replacement is required for clients who have ileal surgery.

d. Vitamin D, 4,000 international unit (IU), is required for clients with steatorrhea.

2. Loperamide is recommended for symptomatic relief of diarrhea that occurs either prior to maintenance of remission or during acute flares only for mild CD.

3. Stepwise medication approach (Table 14.6):

a. Aminosalicylates (5-ASA) are a mainstay of therapy for mild CD due to their anti-inflammatory activities and rapid absorption throughout the small intestines. Several formulations are available for targeting a specific region of the bowel.

b. Corticosteroids are used if IBD fails to respond to 5-ASA. Corticosteroids should be tapered as rapidly as possible as they do not have a role in maintaining remission. The 2018 AGA guidelines recommend controlled ileal release budesonide at a dose of 9 mg once daily and is effective and should be used for induction of symptomatic remission for clients with mild-to-moderate ileocecal CD. However, budesonide should not be used to maintain remission of CD beyond 4 months.

c. Immunomodulatory agents may be initiated for moderate or severe Crohn's refractory to corticosteroids or in Crohn's that exhibits frequent flares that require steroids. These agents require monitoring of ▶

TABLE 14.6 MEDICATIONS FOR CROHN'S DISEASE AND ULCERATIVE COLITIS

5-ASA: anti-inflammatory activities and rapid absorption throughout the GI tract			
		Induction Therapy	**Maintenance Therapy**
Sulfasalazine (Azulfidine)	Treatment of mild to moderate UC, and as adjunctive therapy in severe UC; converted to mesalamine in the colon	**UC and CD** Initial 1–2 g/d in divided doses Gradual increase to 3–4 g/d in divided doses	**UC** For prolongation of the remission period between acute attacks 2–4 g/d in divided doses
Balsalazide (Colazal)	Mild to moderately active CD Release delayed until the terminal ileum and cecum; converted to mesalamine in the colon	**UC and CD** 6.75 g/d in divided doses; duration 8–12 weeks	**UC and CD** Safety and effectiveness not established beyond 12 weeks
Mesalamine (Asacol)	Targeted for release in the distal ileum and colon	**UC and CD** 2.4–4.8 g/d in divided doses	**UC and CD** Maintenance: 2.4–4.8 g/d in divided doses
Mesalamine (Pentasa)	Mild to moderate disease; released in the duodenum to the distal colon	**UC and CD** 4 g/d in divided doses for up to 8 weeks	**UC and CD** 2–4 g/d in divided doses
Mesalamine (Apriso)	Locally acting aminosalicylates 24-hour delayed and extended-release; release occurring at a pH ≥ 6, then prolonged throughout the colon	**UC** 1.5–3 g/d in divided doses	**Maintenance of Remission of UC** 1.5 g/d
Mesalamine suppository (Canasa)	Specific to the rectum and distal colon	**Ulcerative Proctitis Rectal Suppository** One 500 mg suppository rectally BID OR one 1,000 mg rectally at night; suppositories to be retained 1–3 hours to achieve maximal benefit	**Maintenance of Remission of Ulcerative Proctitis Rectal Suppository** One 500 mg suppository rectally BID OR one 1,000 mg rectally at night; suppositories to be retained 1–3 hours to achieve maximal benefit
Mesalamine retention enema (Rowasa)	Specific to the rectum and distal colon	**Retention Enema** 60 mL (4 g) at bedtime, retained overnight (8 hours)	**Retention Enema** 60 mL (4 g) at bedtime, retained overnight (8 hours)
Corticosteroids: nonspecifically suppress the immune system; mainstay of treatment for active flares			
Budesonide (Uceris; Entocort EC).	Treatment of mild to moderate CD involving the ileum and/or ascending colon; released in the distal small intestine and right colon	**UC and CD** 9 mg daily for up to 8 weeks; TAPER to 6 mg daily for 2 weeks prior to complete cessation; for recurring episodes of active CD, a repeat 8 week course can be given	**UC and CD** Maintenance of clinical remission of mild to moderate CD of ileum and/or ascending colon 6 mg/d up to 3 months; maintenance treatment beyond 3 months with no proven substantial clinical benefit
Prednisone (most common oral steroid used) Methylprednisolone (IV)	Used in acute treatment but are not preventive; IV steroids used in clients with severe disease that requires hospitalization	**UC and CD** Varied dosage and length of treatment. Steroids not to be stopped abruptly; tapering should begin concomitantly with initiating other treatments to maintain remission	**UC and CD** Not for maintenance therapy
		Induction Therapy	**Maintenance Therapy**
Hydrocortisone enemas (Cortenema) Hydrocortisone acetate foam and steroid suppositories (Cortifoam, ProctoFoam-HC)	Colonic disease: proctitis requiring topical/rectal formulations.	**UC and CD Enema**: one nightly at HS; usual length of treatment 2–3 weeks **Suppository**: one BID (a.m. and p.m.); severe proctitis may require using a suppository TID or using two suppositories BID **Foam**: one applicator once daily or Q12H for 2–3 weeks, then one applicator every other day if needed	**UC and CD** Dosage and length of treatment based on medical treatment and response to treatment

(*continued*)

TABLE 14.6 MEDICATIONS FOR CROHN'S DISEASE AND ULCERATIVE COLITIS (*CONTINUED*)

Immunomodulatory Agents: • **Thiopurines (azathioprine, 6-MP are effective and should be considered for use for steroid sparing in CD. Both are effective therapies and should be considered for treatment of CD for maintenance of remission (2018 AGA recommendations).** • **AGA recommends using MTX should be considered for alleviating signs and symptoms in clients with steroid-dependent CD and for maintaining remission. Consensus opinion currently does not favor using MTX as monotherapy.**			
6-MP (Purinethol)	Slow-onset: onset of therapy noted after 3–6 months	**CD** Weight-based dosage and response to therapy 1.5 mg/kg/d	**CD** Weight-based dosage and response to therapy 1.5 mg/kg/d
Azathioprine (Imuran): used off-label for UC and CD	Converts to its active form 6-MP; slow-acting and can take up to 3 months to work	**UC and CD** Weight-based dosage and response to therapy 2.5 mg/kg/d.	**UC and CD** Weight-based dosage and response to therapy 2.5 mg/kg/d
MTX folic acid antagonist	Improvement generally in 3–6 weeks; however, full benefit may not be seen for 12 weeks	**CD** 15–25 mg once a week by injection; clients also need to take folic acid 1 mg/d	**CD** 15 mg per week; clients also need to take folic acid 1 mg/d
Biologics: TNF-Alpha Blocker • **The AGA states that using combination therapy of infliximab with immunomodulators (thiopurines) is more effective than treatment with either immunomodulator monotherapy or infliximab monotherapy in clients who are naïve to those agents.** • **The AGA recommends using anti-TNF-alpha for CD refractory to thiopurines and MTX.** • **The AGA recommends anti-TNF-alpha be used to treat CD that is resistant to treatment with corticosteroids.**			
Infliximab (Remicade) IV infusion	Moderate to severe CD with fistulizing CD or resistance to steroids and conventional therapy	**CD** 5 mg/kg IV over 2 hours at 0, 2, and 6 weeks	**CD** 5 mg/kg every 8 weeks thereafter; if no response by week 14, consider discontinuing therapy
Antiadhesion Molecule			
Natalizumab (Tysabri) Distribution restricted and available only through a close monitored program known as TOUCH	Moderate to severe CD for clients who failed anti-TNF therapy	**CD** 300 mg every 4 weeks; given by IV infusion over 1 hour; discontinuation after 12 weeks based on individual response/ protocol	**CD** 300 mg IV monthly; restricted distribution
Antibiotics: used for treatment of bacterial infections that cause abscesses and can be helpful in treatment of fistulas			
Ciprofloxacin (Cipro)		**UC and CD** Varied dosage and length of treatment	**UC and CD** Varied dosage and length of treatment
Metronidazole (Flagyl)		**UC and CD** Varied dosage and length of treatment	**UC and CD** Varied dosage and length of treatment

5-ASA, aminosalicylates; 6-MP, 6-mercaptopurine; AGA, American Gastroenterology Association; CD, Crohn's disease; GI, gastrointestinal; HS, at bedtime; IV, intravenous; MTX, methotrexate; TNF, tumor necrosis factor; UC, ulcerative colitis.

Source: Adapted from the 2018 American College of Gastroenterology Clinical Guideline: Management of Crohn's Disease in Adults. http://gi.org.

blood counts due to hematologic toxicity. A 3% incidence of pancreatitis, allergic reactions, infections, and marrow toxicity is associated with their use. The main drawback to the use of AZA and 6-MP is their slow onset. The effect of therapy is noted after 3 to 6 months of treatment. The 2018 AGA guidelines recommend TPMT testing should be considered before initial use of AZA or 6-MP.

d. Biologic agents: Tumor necrosis factor (TNF)-alpha blocker: initial biologic. Infliximab and adalimumab are indicated for both remission induction and maintenance of remission:

i. Infliximab (Remicade).
ii. Adalimumab (Humira).
iii. Certolizumab: not indicated to induce remission.
iv. Anti-interleukin 12/23: ustekinumab (Stelara): alternative to TNF-alpha blocker.
v. Anti-integrin.
vi. Vedolizumab (Entyvio): useful in clients over 60.
vii. Natalizumab (Tysabri).

e. Antibiotics are utilized in adults for management of perianal disease or inflammatory mass (metronidazole, ciprofloxacin). Metronidazole and ciprofloxacin should ▶

not be used as primary therapy for luminal inflammatory CD.

f. **NSAIDs may exacerbate disease activity and should be avoided when possible.**

FOLLOW-UP

A. Have the client record their weight daily to monitor changes.

B. Assess frequency and consistency of stools to evaluate volume losses and effectiveness of therapy.

C. Instruct clients on self-medication and to call a physician if fever develops, diarrhea worsens, bleeding occurs, or abdominal pain becomes marked.

D. Monitoring clients on 5-ASA should include CBC at least twice a year and urinalysis at least annually.

E. Monitoring clients on 6-MP requires frequent monitoring, including CBC and aminotransferase levels (alanine transaminase [ALT] and AST) before treatment, and again at 2, 3, 8, and 12 weeks after initiating therapy. When stable, monitor every 3 months thereafter, and 2 to 3 weeks after a change in dosage.

F. Monitoring clients on methotrexate (MTX) includes a CBC and aminotransferases as with 6-MP/thiopurine therapies.

G. Periodic bone mineral density assessment is recommended for clients on long-term corticosteroid therapy (longer than 3 months). Osteopenia should be treated aggressively. The primary intervention includes dietary counseling and supplementation to ensure adequate intake of vitamin D and calcium.

H. Annual ophthalmologic examinations are recommended for clients on long-term corticosteroids.

I. Clients who are using corticosteroids should be monitored for glucose intolerance and other metabolic abnormalities.

CONSULTATION/REFERRAL

A. Refer the client to a gastroenterologist initially for evaluation. Treatment requires multidisciplinary management with a gastroenterologist and other subspecialists, including a nutritionist, surgeon, rheumatologist, ophthalmologist, and social workers.

B. Promptly hospitalize for parenteral management clients who are toxic, bleeding heavily, in severe pain, or too sick to obtain adequate nutrition orally.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Active disease at the time of conception is associated with increased incidence of miscarriage and postpartum exacerbation. It may also predispose the client to other maternal and prenatal risks, such as premature labor, small-for-gestational-age babies, and stillbirth.

2. Sulfasalazine and steroids are safe and effective during nursing or pregnancy.

3. Clients on prednisone should receive supplementary steroids during labor and delivery, as well as during other highly stressful times.

4. Counsel clients to attempt pregnancy only when the disease has been quiescent for several months.

5. Withholding sulfasalazine for 2 to 3 days before delivery may be advisable to minimize neonatal jaundice due to bilirubin displacement.

6. MTX is a U.S. Food and Drug Administration (FDA) category X drug.

B. Geriatrics:

1. Unexplained diarrhea, weight loss, and perianal disease in older adults should arouse suspicions regarding CD. Older adults have worse outcomes due to delayed presentation and comorbid conditions. The older adult is more likely to be more malnourished, anemic, and hypovolemic with higher transfusion requirements and with longer postoperative hospital stays especially after surgery. Dehydration is more common in older adults. Signs of dehydration include confusion, muscle weakness, fever, dizziness, poor skin turgor, hypotension, and tachycardia.

2. Diagnostic delay is more common in older adults. The differential diagnosis for older clients includes the following:

a. Diverticulitis and diverticular bleeding.
b. Ischemic colitis.
c. Microscopic colitis.
d. Infectious colitis.
e. NSAID-induced ulcerations, strictures, and perforation.
f. Radiation colitis (most commonly gynecologic, rectal, and prostate cancers).

3. Older adults tend to have CD confined to the distal colon, with only 40% having proctitis.

4. With an increase in cancers in older adults with CD, it is imperative to evaluate and exclude cancer before beginning immunosuppressant or biologic therapies. Older clients with CD are at increased risk for cancers, including those cancers found in the following:

a. Small intestines.
b. Pancreas.
c. Endocrine glands.
d. Kidney.
e. Stomach.
f. Lung and non-Hodgkin lymphoma (NHL) and nonmelanoma skin cancer.

5. Review CD therapies, with comorbid conditions in mind, due to side effects, interactions between medications, need for increased laboratory monitoring (e.g., INR as well as digoxin levels and phenytoin levels), and risk of infections.

6. Anti-TNF-alpha agents are contraindicated in clients with New York Heart Association (NYHA) class III and IV heart failure (HF).

7. Age is currently not a contraindication to performing an IPAA. Older adults with good anal sphincter function and adequate cognitive ability are better surgical candidates for the IPAA procedure.

8. The incidence of a deep vein thrombosis (DVT) is higher in older adults.

9. Due to polypharmacy a full review of medications, herbals, and over-the-counter (OTC) drugs should be undertaken to identify medications that should be avoided in the geriatric population, duplicate medications, and medications that are able to be decreased or deprescribed. (Refer to section on deprescribing in Chapter 3, "Adult-Geriatric Assessments.")

CYCLOSPORIASIS

DEFINITION

A. Cyclosporiasis is a one-cell parasite that infects the upper small intestines. Causes of cyclosporiasis include consuming infected water or produce (fresh fruits, especially raspberries and vegetables) or exposure to the organism during travel to countries where it is endemic.

B. It manifests as protracted and relapsing gastroenteritis. The clinical syndrome consists of explosive watery diarrhea, nausea, anorexia, weight loss, fatigue, and abdominal cramps that may persist for 7 days to several weeks, with a waxing and waning course.

C. In an immunocompromised host, onset is insidious and the condition becomes chronic; the shedding of oocysts continues indefinitely. Symptoms associated with cyclosporiasis are more severe in HIV/AIDS clients.

D. The oocysts are resistant to most disinfectants used in food and water processing and can remain viable for prolonged periods.

INCIDENCE

A. Cyclosporiasis affects approximately 16,000 persons per year in the United States among 76 million cases of foodborne diarrhea. It is endemic in other regions of the world.

B. Most outbreaks in the United States and Canada have been associated with consumption of imported fresh produce. Most cases are diagnosed between May and August. Reported cases increased between summer 2016 and summer 2017.

C. It affects all ages.

D. In the United States, one-third of cases occur in international travelers, one-third of cases are acquired without travel, and one-third occur without known risk factors.

E. The highest incidences are in Guatemala and Peru, with other countries in Central America, South Americana, Asia, and the Caribbean also contributing to reported cases among travelers.

PATHOGENESIS

A. Infection is caused by an 8- to 10-μm spore-forming coccidian protozoan called *Cyclospora cayetanensis*. Transmission of oocysts is by the oral–fecal route. The incubation period ranges from 2 days to 2 weeks after excretion, depending on temperature and humidity.

PREDISPOSING FACTORS

A. Incompetent or compromised immune system (e.g., infection with HIV).

B. Travel to underdeveloped or tropical countries.

C. Ingestion of contaminated food or water.

D. Contact with animals that carry the parasite.

COMMON COMPLAINTS

A. Abrupt, profuse, malodorous, watery diarrhea.

B. Nausea.

C. Vomiting.

D. Anorexia.

E. Substantial weight loss.

F. Flulike symptoms.

G. Abdominal cramps and bloating.

OTHER SIGNS AND SYMPTOMS

A. Asymptomatic: common among individuals residing in endemic regions.

B. Low-grade fever.

C. Nausea and vomiting.

D. Profound fatigue.

E. Yellow-to-khaki-green stools.

F. Flatus.

G. Dehydration.

SUBJECTIVE DATA

A. Review onset, duration, and course of symptoms. Is diarrhea acute or chronic?

B. Question the client about travel to areas known for *Cyclospora*, such as Guatemala, Haiti, Puerto Rico, Pakistan, India, Mexico, Nepal, New Guinea, and Peru.

C. Review the client's intake of medications and other substances that can cause diarrhea, especially antibiotics, laxatives, quinidine, magnesium-containing antacids, digitalis, loop diuretics, antihypertensives, alcohol, caffeine, herbal teas, and sorbitol-containing (sugar-free) gum and mints.

D. Ask about the nature of the client's bowel movements (BMs), including frequency, consistency, volume, and presence of blood, pus, or mucus.

E. Review associated symptoms that need evaluation: fever, abdominal pain, and anorexia.

F. Ask the client if other family members or sexual contacts are also ill.

G. Establish the client's normal weight and any recent weight loss. How much weight was lost and over what period of time?

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, blood pressure (BP; vital signs are normal in most cases), and height and weight to calculate body mass index (BMI).

B. Inspect:

1. Inspect general appearance for signs of illness and dehydration:
   a. Inspect mucous membranes.
   b. Note the presence of decreased skin turgor.

C. Auscultate:

1. Auscultate the abdomen for bowel sounds in all quadrants.

D. Palpate:

1. Palpate the abdomen for masses, rebound tenderness, guarding; may exhibit right upper quadrant (RUQ) pain (biliary disease).
2. Palpate lymph nodes for enlargement.

E. Rectal exam.

DIAGNOSTIC TESTS

A. Identification may be made by microscopic examination of a stool preparation by modified acid-fast staining, fluorescence microscopy, or review of wet mounts of stool by experienced microscopists. Finding large numbers of white cells suggests an inflammatory or invasive diarrhea. The following tests are done:

1. Acid-fast Ziehl–Neelsen stained slide of stool: 8 to 10 micron *Cyclospora* oocysts are visible.
2. Stool culture for ova and parasites: Parasites are passed intermittently, so three or more stools on alternating days should be examined. Specific requests to assess for *Cyclospora* is necessary.
3. Endoscopy with small bowel biopsy.

DIFFERENTIAL DIAGNOSES

A. Cyclospora infection.

B. Giardiasis.

▶

C. Malabsorption.
D. *Escherichia coli* infection: *E. coli* causes diarrhea within hours of ingesting contaminated food. Confirm by checking if others were affected.
E. Irritable bowel syndrome (IBS): Leukocyte-free mucus is the hallmark of IBS.
F. Viral diarrhea.
G. Lactose intolerance.
H. Other bacterial infections, for example, *Shigella, Salmonella*, and *Campylobacter.*
I. Cholera.
J. Inflammatory bowel disease (IBD; Crohn's disease (CD) or ulcerative colitis [UC]).
K. Cryptosporidium: retain acid-fast stain but are smaller, only 5 microns.

PLAN

A. General interventions:
1. Advise the client to tell household members and sexual contacts to seek medical examination and treatment.
2. Children and caregivers with diarrhea should be excluded from childcare centers until they become asymptomatic.
3. Fresh produce should always be washed thoroughly before it is eaten.
B. Client teaching: *See Client Teaching Guide for this chapter, "Diarrhea."*
1. Discuss safe sexual practices.
2. Teach contact precautions to those caring for diapered and/or incontinent children.
C. Dietary management:
1. Tell the client to increase fluids. Fluid replacement is the basic approach to prevent dehydration from diarrhea.
2. Tell the client to restrict milk products to rule out lactose intolerance.
3. Give the client a copy of a diet to control nausea and vomiting. See Appendix B, "Nausea and Vomiting Diet Suggestions."
D. Pharmaceutical therapy:
1. The drug of choice is trimethoprim-sulfamethoxazole (TMP-SMZ). It can reduce shedding and stop diarrhea within 2 days:
a. Adults:
i. Immunocompetent host: TMP 160 mg/SMZ 800 mg tablet orally BID for 7 to 10 days.
ii. Immunocompromised host: TMP 160 mg/SMZ 800 mg tablet orally QID for 10 days, followed by prophylaxis with TMP 160 mg/SMZ 800 mg orally three times per week.
2. For sulfa allergic clients: nitazoxanide (500 mg BID for 7 days)
3. Ciprofloxacin (Cipro): Treatment failures have been reported:
a. Adults: Cipro 500 mg orally BID for 7 to 10 days for acute infection.
b. Adults: prophylaxis in HIV: cipro 500 mg orally three times a week.

FOLLOW-UP

A. See the client in 1 week to verify continuing clinical improvement.
B. If diarrhea persists 2 weeks or more, a second evaluation is indicated.
C. Report cases of cyclosporiasis to the health department.

CONSULTATION/REFERRAL

A. Consult an infectious disease specialist and/or gastroenterologist if the client has no symptom relief after completing therapies or has a prolonged or severe case.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
1. TMP-SMZ is a pregnancy category C drug. Use during pregnancy if the potential benefit outweighs the risk to the fetus.
2. TMP-SMZ should be avoided near term due to the potential for hyperbilirubinemia and kernicterus in the newborn.
B. Geriatrics:
1. Use of bactrim in the geriatric adult should coincide with monitoring of renal function and after evaluation of med list to ensure no interactions.

DIARRHEA

DEFINITION

A. Diarrhea is characterized by an abnormally high fluid content in the stool. Generally, diarrhea also involves an increase in the frequency of bowel movements (BMs), which can range from four to five to more than 20 times a day. Diarrhea may be an acute onset or chronic/persistent diarrhea.
1. Acute diarrhea is usually self-limited; the most common complication of diarrhea is dehydration and malabsorption.
2. Chronic diarrhea is defined as lasting longer than 14 days.

INCIDENCE

A. The incidence of diarrhea is unknown.
B. The incidence of *Clostridioides difficile* infection is approximately 7%, and 28% of clients who were hospitalized have positive cultures for the organism. *C. difficile*-associated diarrhea has a mortality rate as high as 25% in the frail older adults.
C. Be aware that *C. difficile* can occur among clients in the community who have been treated with antibiotic therapy or antineoplastic agents with antibacterial activity.

PATHOGENESIS

A. The increased water content in diarrhea stools is due to an imbalance in the physiology of the small and large intestinal processes. See Table 14.7 for organisms that cause diarrhea.

PREDISPOSING FACTORS

A. Enteric infections.
B. Females have a higher incidence of *Campylobacter species* infections.
C. Institutional: day care and skilled nursing facilities.
D. Food: raw or contaminated food.
E. Contaminated water or inadequate chlorinated water supply.
F. Travel.
G. Chemotherapy or radiation induced.
H. Vitamin deficiencies (niacin and folate).

TABLE 14.7 ORGANISMS THAT CAUSE DIARRHEA

Viral organisms	Rotavirus
	Norovirus
	Adenovirus
	Calicivirus
	Astrovirus
	Ebola
Invasive bacteria	*Escherichia coli*
	Klebsiella
	Clostridioides difficile
	Clostridium perfringens
	Shigella
	Salmonella
	Campylobacter
	Cholera
	Yersinia
	Plesiomonas
	Aeromonas
Parasites	*Giardia*
	Entamoeba organisms
	Cryptosporidium
	Giardia lamblia

I. Vitamin toxicity (C, niacin, and vitamin B_3).
J. Ingestion of heavy metals (copper, tin, or zinc) or toxins.
K. Ingestion of plants, mistletoe, or mushrooms.
L. Antibiotics.
M. Immunodeficiency.

COMMON COMPLAINTS

A. Frequent watery stool.
B. Foul-smelling stools (fat malabsorption).
C. Flatulence.
D. Abdominal cramping.

OTHER SIGNS AND SYMPTOMS

A. Lethargy.
B. Fever.
C. Nausea and vomiting.
D. Currant jelly stool (blood and mucus).
E. Anorexia.
F. Dehydration in adults:
  1. Thirst.
  2. Less frequent urination.
  3. Dark urine.
  4. Dry skin.
  5. Fatigue.
  6. Dizziness.
  7. Light-headedness.

SUBJECTIVE DATA

A. Review the onset of diarrhea stools. What is the normal stool pattern?
B. Review the consistency, color, volume, and frequency of the stools.
C. Review dietary intake of raw foods, contaminated food, and nonabsorbable sugars, including lactulose or lactose in lactose malabsorbers. Review the use of artificial sweeteners such as sorbitol.
D. Review any contact with others who may have the same symptoms.
E. Have any of the stools contained blood?
F. Review travel history, including camping vacations.
G. Review medication history, including vitamins, herbal production, laxatives, antacids that contain magnesium, opiate withdrawal, Olestra, and methylxanthines (caffeine, theobromine, and theophylline):
  1. Specifically inquire about the use of antibiotics in the previous 2 to 3 months (*C. difficile* may develop as late as 10 weeks after stopping antibiotics).
H. Review any food allergies and history of lactose intolerance.
I. Evaluate the presence of other symptoms such as fever and abdominal pain.

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, blood pressure (BP; standing and sitting), and weight.
B. Inspect:
  1. Observe the client's general overall appearance, the presence of lethargy or depressed consciousness, or grimace during exam.
  2. Evaluate muscle tone, skin turgor, reduced muscle, and fat mass.
  3. Examine mouth, lips, and mucous membranes for signs, symptoms, and severity of dehydration.
  4. Perianal examination for skin breakdown, erythema, and fissures.
C. Auscultate:
  1. Assess heart and lungs.
  2. Auscultate the abdomen in all four quadrants.
  3. Assess the presence of borborygmi (significant increase in peristaltic action that may be audible and/or palpable).
D. Percuss:
  1. Percuss abdomen.
E. Palpate:
  1. Palpate the abdomen for masses, guarding, rebound tenderness, and peritoneal signs.
  2. Palpate for lymphadenopathy.
F. Rectal examination:
  1. Perform a rectal examination, including testing of stool for occult blood.

DIAGNOSTIC TESTS

A. Stool specimens for evaluation of the following:
  1. *C. difficile*: reserved for clients having more than three loose stools per 24 hours and/or with risk factors including recent hospitalization, use of antibiotics, or advanced age:
    a. Enzyme immunolinked assay (EIA) tests: glutamate dehydrogenase (GDH) antigen and toxin detection, which detects toxin A, toxin B, or both.
    b. Nucleic acid amplification test (NAAT): polymerase chain reaction (PCR) test that detects presence of pathogenic strain of *C. difficile*.

2. Fecal leukocytes.
3. Blood tests:
a. Complete blood count (CBC): White blood cells (WBCs) may be elevated.
b. Electrolytes.
c. Albumin.
4. Bacterial culture.
5. Ova and parasites.
6. Giardia antigen.
7. Fecal calprotectin: indicates colonic inflammation.
8. Fecal alpha-1 antitrypsin levels: useful in chronic diarrhea.
9. Specific lab requests must be made to identify *Campylobacter, Aeromonas*, and *Yersinia. Listeria* should be suspected with outbreaks of nonbloody, febrile diarrhea in the setting of negative stool testing.

B. A colonoscopy for intestinal biopsy for chronic or protracted diarrhea or clients with AIDS should be done. A sigmoidoscopy alone may not reveal any abnormality.
C. Abdominal ultrasound to identify intussusception.
D. Abdominal CT.
E. Hydrogen breath test for lactose/fructose intolerance.

DIFFERENTIAL DIAGNOSES

A. Diarrhea: infectious etiology.
B. Inflammatory bowel disease (IBD):
1. Crohn's disease (CD).
2. Ulcerative colitis (UC).
C. Cystic fibrosis (CF).
D. Giardiasis.
E. Protozoan.
F. Malabsorption syndromes.
G. Intussusception.
H. Stool impaction.
I. Irritable bowel syndrome (IBS).
J. Meckel diverticulum.
K. Intolerance to lactose, carbohydrates, and protein.
L. Antibiotic-associated diarrhea.
M. Pseudomembranous colitis.
N. Toxic megacolon.
O. Appendicitis.
P. Celiac disease.

PLAN

A. Client teaching: *See Client Teaching Guide for this chapter, "Diarrhea."*
1. Examination of stools for ova and parasites should be done every other day or every 3 days.
2. Rehydration with oral fluids for each diarrhea stool. Administer small amounts at frequent intervals. Solution should contain water, salt, and sugar. Diluted fruit juices or flavored soft drinks, broths, or soups should be sufficient with mild cases of diarrhea. Gatorade-type solutions may be sufficient for mild cases, but for more severe cases oral rehydration solution (Rehydralyte or Ceralyte) should be considered. Intravenous (IV) fluids should be used for severe hypovolemia.
3. Hold foods until hydration is completed. Dietary modifications are poorly validated in studies; however, the use of saltine crackers, boiled vegetables or starches, and bananas is generally supported in clients with nausea, vomiting, or anorexia.
4. Use antibiotics (or the discontinuation of antibiotics in the case of *C. difficile)* or antiparasitic agents, depending on the etiology. Empiric use of antibiotics is not recommended as most cases of diarrhea are viral. However, in cases of severe and/or bloody diarrhea, especially with fever, the benefit of the antibiotic likely outweighs the risk.
5. The use of probiotics, *Lactobacillus GG* (I, A) and *Saccharomyces boulardii* (II, B), has been found to be effective in repopulating or maintaining the colonic gut flora. They may reduce the spread of rotavirus.
6. Encourage proper hygiene and food preparation to prevent spread and future infections.
7. Water should be boiled for at least 1 minute if contamination is suspected.

B. Pharmaceutical therapy:
1. Antiprotozoal: nitazoxanide (Alinia) 500 mg Q12H for 3 days.
2. HIV/AIDS: crofelemer (Fulyzaq) for noninfectious diarrhea in adults on antiretroviral therapy; 125 mg tablet BID.
3. Antidiarrheals.
a. Loperamide (Imodium):
i. Initially 4 mg, then 2 mg after each loose stool. Maximum dose 16 mg/d. Stop in 48 hours if diarrhea is not relieved.
ii. Chronic diarrhea: initially 4 mg, maintenance 4 to 8 mg/d; reevaluate if no improvement in diarrhea in 10 days at 16 mg/d.
b. Bismuth subsalicylate (Kaopectate) 262 mg/15 mL, take 30 mL every 30 to 60 minutes if needed; maximum four doses per day. Slower onset of action compared with loperamide; however, more useful in clients with fever and dysentery.
c. Diphenoxylate HCL (Lomotil) two tablets or 10 mL QID until diarrhea is controlled; maintenance, two tablets or 10 mL per day. Increased risk of cholinergic side effects.
4. *C. difficile* treatment:
a. Stop antibiotics.
b. Avoid antiperistaltic agents.
c. Initial occurrence:
i. Vancomycin 125 mg QID for 10 days. OR
ii. Fidaxomicin (Dificid) 200 mg orally BID for 10 days. OR
iii. Metronidazole 500 mg TID for 10 to 14 days if the other two choices are unavailable.
d. First recurrence:
i. Fidaxomicin 200 mg orally for 10 days, OR 200 mg orally BID for 5 days followed by once every other day for 20 days.
ii. Vancomycin in a tapered and pulsed regimen (i.e., 125 mg orally QID for 10–14 days, followed by 125 mg orally BID for 7 days, followed by 125 mg orally daily, followed by 125 mg orally every 2–3 days for 2–8 weeks) OR 125 mg orally QID for 10 days.
iii. Bezlotoxumab 10 mg/kg IV given once during above as adjunctive treatment.
e. Second and subsequent recurrence:
i. Fidaxomicin: 200 mg PO BID for 10 days OR 200 mg orally BID for 5 days followed by once every other day for 20 days.
ii. Vancomycin in taper/pulsed regimen (see above for example). OR
iii. Vancomycin followed by rifaximin. Vancomycin 125 mg PO QID for 10 days, then rifaximin 400 mg PO TID for 20 days.

iv. Consider fecal microbiota transplantation (FMT).

f. Fulminant disease: any occurrence or recurrence accompanied by hypotension/shock, ileus, or megacolon.

i. Consider consultation with infectious disease and surgical specialist.

ii. Vancomycin 500 mg PO QID AND metronidazole 500 mg IVQ8H.

iii. If ileus present, consider FMT or recall vancomycin.

FOLLOW-UP

A. Follow-up depends on the severity of diarrhea and the age of the client.

B. Leukocytosis of increasing severity in hospitalized clients should prompt a clinical evaluation for *C. difficile* infection.

CONSULTATION/REFERRAL

A. Evaluate the need for a surgical consultation (fulminant colitis, peritonitis, or toxic megacolon) or one with an infectious disease specialist or a gastroenterologist.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. Diarrhea rather than constipation is sometimes the only complaint due to the collection of liquid stool distending the proximal colon and passing around the obstructing bolus.

2. Review any hospitalizations within the past 72 hours as a cause of diarrhea. Traditionally *C. difficile* infections occur in an institutional setting; however, community-acquired infection is not uncommon.

3. Advanced age is a risk factor for *C. difficile* infection.

4. Due to polypharmacy, a full review of medications, herbals, and over-the-counter (OTC) drugs should be undertaken to identify medications that should be avoided in the geriatric population, duplicate medications, and medications that are able to be decreased or deprescribed. (Refer to section on deprescribing in Chapter 3, "Adult-Geriatric Assessments.")

5. Beers Criteria caution:

a. Medications for constipation and those for diarrhea are on the American Geriatrics Society 2015 medications to be avoided. Refer to Appendix C, "Beers Criteria."

Johnson, S., Lavergne, V., Skinner, A. M., Gonzales-Luna, A. J., Garey, K. W., Kelly, C. P., & Wilcox, M. H. (2021, September 7). Clinical practice guideline by the Infectious Diseases Society of America (IDSA) and Society for Healthcare Epidemiology of America (SHEA): 2021 focused update guidelines on management of *Clostridioides difficile* infection in adults. *Clinical Infectious Diseases*, *73*(5), e1029–e1044. https://doi.org/10.1093/cid/ciab549

DIVERTICULOSIS AND DIVERTICULITIS

DEFINITION

A. Diverticulum is the saclike protrusion of mucosa through the muscular colonic wall. Protrusions occur in weakened areas of the bowel wall. Diverticulosis is the presence of diverticula within the colon, but it does not imply a pathologic condition and may remain asymptomatic. Diverticulitis occurs when the diverticula become plugged and inflamed. Diverticular bleeding occurs due to injury of the blood vessel within the diverticulum and subsequent rupture into the lumen. Diverticular disease occurs over a continuum including simple asymptomatic diverticular disease, uncomplicated symptomatic diverticulitis, and complicated symptomatic diverticulitis. Complicated diverticulitis includes problems arising from abscess, perforation, fistula, peritonitis, and sepsis.

B. An increased risk of developing diverticular disease is associated with a diet that is high in red meat and total fat content. This risk can be reduced by a diet high in fiber content, especially with fruits and vegetables (cellulose; see Appendix B, Table B.7).

C. Diverticulosis is often diagnosed as an incidental finding on a barium enema (BE) or sigmoid/colonoscopy.

D. Recurrent attacks of diverticulitis can result in the formation of scar tissue, leading to narrowing and obstruction of the colonic lumen.

INCIDENCE

A. Diverticulosis is very common and increases with age:

1. Prevalence by age:

a. 20% by age 40.

b. 60% by age 60.

C. No significant difference in prevalence by sex. Male preponderance in diverticular clients less than 50 years old and female preponderance in clients over 70 years of age.

D. Diverticulosis becomes symptomatic in 70% of cases. It leads to diverticulitis in 5% to 25% and is associated with bleeding in 5% to 15%. The sigmoid colon is commonly affected in Western countries, whereas right-sided involvement is more commonly seen among Asian entities.

E. Diverticulitis can be separated into two groups:

1. Simple, with no complications; responds to treatment such as dietary changes without the need for surgery.

2. Complicated, with abscesses, fistula, obstruction, perforation, and peritonitis leading to sepsis; usually requires surgery.

PATHOGENESIS

A. The formation of diverticula is multifactorial. Clients with diverticula have been shown to have higher colonic segmental pressures, which cause the mucosa to herniate through the colonic wall. The increased pressure might be due to upregulation of smooth muscle receptors and, combined with production of abnormal collagen, luminal narrowing, abnormal elastin deposits within the colonic wall, leads to the development of herniation. Diverticulitis occurs due to micro- or macroperforation of the diverticular wall, which is a result of persistent increased pressure and retained food particles that erode the wall. The perforation is followed by inflammation and localized necrosis. Diverticular bleeding occurs when the blood vessel contained within the diverticulum becomes weakened due to structural repositioning and ruptures into the colon lumen.

PREDISPOSING FACTORS

A. Advanced age.

B. Obesity (84%–96%).

C. Dietary factors:

1. Low residue.

2. High red meat and total fat content.

D. Complicated diverticular disease is increased in the following:

1. Smokers.

2. Chronic nonsteroidal anti-inflammatory drugs (NSAIDs) use.

3. Acetaminophen use (especially paracetamol).

E. Physical inactivity.

F. Indication that genetics are a predisposing factor:

1. Left-sided diverticula is predominant in the United States.
2. Right-sided (cecal) diverticula is predominant in Asia.

COMMON COMPLAINTS

A. Diverticulosis is usually asymptomatic.
B. Painless rectal bleeding is the hallmark of diverticular bleeding, with intermittent passage of maroon or bright red blood.
C. Common diverticulitis symptoms:
1. Left lower quadrant (LLQ). pain.
2. Constipation.

OTHER SIGNS AND SYMPTOMS

A. Back pain.
B. Flatulence.
C. Periodic abdominal distension.
D. Borborygmi, or loud, prolonged gurgles caused by hyperactive intestinal peristalsis.
E. Diarrhea.
F. Nausea or vomiting.
G. Dysuria.
H. Tenderness on palpation, possible guarding.
I. Low-grade fever.

SUBJECTIVE DATA

A. Review onset, duration, and course of symptoms, including size, color, consistency, and frequency of stools.
B. Ask the client if constipation is a chronic or acute problem, and if it alternates with diarrhea.
C. Review the client's daily diet and fluid intake.
D. Ask the client about medication use, including iron supplements, NSAIDs, and acetaminophen, steroids, and opiates.
E. Inquire about the color, amount, and frequency of rectal bleeding. Does the client strain when having a bowel movement (BM)?
F. Review the client's history of pain with defecation.

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, blood pressure (BP), and weight.
B. The physical examination may be relatively unremarkable but most commonly reveals abdominal tenderness or a mass.
C. Inspect:
1. Observe the general overall appearance for signs of pain.
2. Inspect the abdomen in detail, assessing for distension.
D. Auscultate:
1. Abdomen. Absent bowel sounds suggest peritoneal inflammation.
E. Percuss:
1. Abdomen.
F. Palpate:
1. Palpate the abdomen for rebound tenderness or masses signaling possible abscess and tenderness.
2. Palpate beneath right costal arch, checking for Murphy sign or pain on deep inspiration.
G. Rectal exam:
1. Evaluate for hemorrhoids, masses, fissures, fistulas, inflammation, and stool in ampulla.

DIAGNOSTIC TESTS

A. Labs:
1. Complete blood count (CBC): Leukocytosis supports the diagnosis of diverticulitis.
2. Comprehensive metabolic profile (CMP): evaluates kidney function, liver enzymes, and electrolytes.
3. Urinalysis: Sterile pyuria may occur.
4. Stool studies are only indicated for clients with diarrhea and are rarely indicated.
5. Human chorionic gonadotropin (HCG) in all females of childbearing age.
6. C-reactive protein (CRP) to assess for inflammation.
7. Stool hemoccult or fecal immunoassay.
B. Imaging:
1. CT contrasted of the abdomen and pelvis.
2. Ultrasonography can show bowel wall thickening, abscess (with/without gas bubbles).
3. MRI is acceptable to avoid radiation.
4. Abdominal radiography shows abnormality in 30% to 50% of symptomatic clients.
5. BE after infection subsides. Caution: A BE during the acute phase may increase intraluminal pressure and cause bowel perforation.
C. Endoscopy:
1. Colonoscopy.
2. Proctosigmoidoscopy.

DIFFERENTIAL DIAGNOSES

A. Diverticulitis.
B. Diverticulosis.
C. Acute appendicitis.
D. Bowel obstruction.
E. Ischemic colitis.
F. Colon cancer.
G. Hemorrhoids.
H. Constipation or impaction.
I. Inflammatory bowel disease (IBD).
J. Urologic disorder: pyelonephritis.
K. Pelvic inflammatory disease (PID).
L. Ectopic pregnancy.

PLAN

A. General interventions:
1. Clients who have evidence of complicated diverticulitis (with perforation, fistula, obstruction, or abscess) need to be admitted to hospital and treated as inpatients. All inpatients are treated with intravenous (IV) fluid support, IV antibiotics, and pain control. Depending on the complication, other interventions may be undertaken by a specialist.
2. Clients who have uncomplicated diverticulitis but one of the following findings should also be treated as inpatients: microperforation, fever over 102.5°F, significant leukocytosis, severe pain, inability to tolerate oral intake, immunosuppression, significant comorbidities, poor support system, or outpatient treatment failure.
3. Clients with uncomplicated diverticulitis and none of the earlier characteristics may be treated as outpatients.
B. Pharmaceutical therapy:
1. Antibiotic therapy should be continued for 7 to 10 days. Choices include the following:
a. Cipro 500 mg Q12H + metronidazole 500 mg Q8H or levaquin 500 mg daily + metronidazole.
b. Bactrim DS one tablet Q12H + metronidazole 500 mg Q8H.
c. Augmentin 875 mg Q12H or Augmentin 500 mg Q8H. ▶

d. Moxifloxacin 400 mg daily if beta-lactam and/or metronidazole not tolerated.

i. Check local resistance patterns. If resistance is greater than 10% to one agent, choose alternative regimen.

C. Dietary treatment:

1. Outpatient diet: There is no evidence to support dietary restrictions during acute episode of diverticulitis.

2. Long-term dietary management:

a. High-fiber diet, including bran, beans, fruits, and vegetables.

b. Bulk agents if unable to tolerate bran.

c. There is no evidence in the research to support the avoidance of foods such as corn, seeds, or nuts.

D. Relapse:

1. Approximately one-third of clients with an initial episode of diverticulitis will experience a second episode and one-third of those clients will progress to have a third recurrence.

2. Whereas surgical management used to be considered based on the number of episodes of diverticulitis, currently surgical management is not dependent on the number of uncomplicated episodes but rather the presence of a complicating problem.

3. There is no evidence to support the idea that uncomplicated episodes progress or worsen over time.

FOLLOW-UP

A. Outpatients should be reevaluated after 3 days of therapy and every week until resolution of symptoms. Generally, reimaging is not indicated or recommended.

B. A colonoscopy should be performed from 6 weeks after recovery to evaluate the extent of the diverticulosis/rule out other manifestations such as colon cancer.

EMERGENT ISSUES/INSTRUCTIONS

A. Arrange for prompt hospitalization and surgical consultation if the client's temperature rises above 102.5°F, the client's pain worsens, peritoneal signs develop, or white blood cell (WBC) continues to rise. Surgery consultation is required for abscess, peritonitis, obstruction, fistula, or failure to improve after several days of medical management.

CONSULTATION/REFERRAL

A. Consult a physician if the client has mild diverticulitis: temperature less than 101°F; WBC less than 13,000 to 15,000.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. For the older adult with existing diverticulosis, nurse practitioner (NPs) should practice special consideration of the following *geriatric syndromes*:

a. Pain: Poorly relieved pain is an important cause of functional impairment at any age group:

i. Older adults have a diminished sensorium, allowing pathology to advance to a dangerous point prior to symptom development.

ii. Older adults with abdominal pain may present with altered mental status. Cognitive impairment can make assessment and diagnosis of pain more difficult.

iii. For dementia or noncommunicative clients, the American Medical Directors Association has endorsed the Pain Assessment in Advanced Dementia (PAINAD) Scale, which scores for the following items:

1) Breathing: Examples include normal, labored, hyperventilation.

2) Negative vocalization: Examples include moaning, negative language, crying.

3) Facial expression: Examples include smiling, frowning, grimacing.

4) Body language: Examples include relaxed, tense, rigid, or striking out.

5) Consolability: Examples include extent to which a caregiver is able to console, distract, or reassure.

ELEVATED LIVER ENZYMES

DEFINITION

A. Liver function tests (LFTs) used to determine the health of the liver, but are not direct measures of its function. The liver has excretory, metabolic, protective, detoxification, hematologic, and circulatory functions. LFTs may be abnormal even in clients with a healthy liver. Normal laboratory chemistry values may vary according to age, gender, ethnicity, blood group, and postprandial state, as well as other factors such as exercise and pregnancy. Uses for common liver chemistry tests (Table 14.8) include the following:

1. Assessing the severity of hepatocellular injury.

2. Evaluating cholestatic problems.

3. Following the trend of hepatic disease.

4. Diagnosing for the presence of latent liver disease (e.g., differential diagnosis of ascites or hematemesis).

5. Screening for suspected cases during outbreaks of infective hepatitis.

6. Making differential diagnosis of the different types of jaundice.

7. Screening persons exposed to hepatotoxic drugs. A wide variety of drugs are associated with liver disease and require monitoring of liver function, including carbamazepine, methyldopa, minocycline, macrolide antibiotics, nitrofurantoin, statins, sulfonamides, terbinafine, chlorpromazine, and methotrexate. In addition, drugs can cause fatty liver and steatohepatitis and vascular injury. Methotrexate treatment requires special care, to prevent dose-dependent liver fibrosis, and noninvasive markers of fibrosis should be monitored. Although statins can lead to drug-induced liver injury, this is very rare, with studies demonstrating they are safe in clients with preexisting abnormal liver enzymes.

INCIDENCE

A. The incidence of elevated liver enzymes is undetermined. Abnormal elevations of serum liver chemistries may occur in 1% to 4% of the asymptomatic population.

TABLE 14.8 LIVER CHEMISTRY TESTS AND IMPLICATIONS

Liver Chemistry Test	Clinical Implication of Abnormality
ALT	Hepatocellular damage
AST	Hepatocellular damage
ALP	Cholestasis, infiltrative disease, or biliary obstruction
Albumin	Synthetic function
Alpha-fetoprotein	Cancer marker when elevated
Bile acids: urine bile salts, bile pigments, and urobilinogen	Cholestasis or biliary obstruction, impaired hepatic update or secretion, or portal systemic shunting
Bilirubin: serum total, direct and indirect bilirubin	Cholestasis, impaired conjugation, or biliary obstruction
Cholesterol, serum triglycerides	Lipoprotein production and metabolism, chronic cholestasis
Fibrinogen	Liver damage/cirrhosis, acute liver insufficiency, poisoning
GGT	Cholestasis or biliary obstruction, malignant involvement in hepatocellular disease, more sensitive than other enzymes in alcoholism
Hepatitis surface antigen, IgM, antibody, RNA, genotype, viral load	Differentiation of type of hepatitis
LDH	Hepatocellular damage not specific for hepatic disease
Total proteins, albumin globulin, (A/C ratio)	Hepatitis, advanced liver disease
PT	Synthesis function in hepatocellular disease, fulminate hepatitis
Plasma ammonia	CNS dysfunction/toxicity or end-stage liver disease
5NT	Cholestasis or biliary obstruction
Urea	End-stage liver disease

5NT, 5′-nucleotidase; A/C, albumin, creatinine; ALP, alkaline phosphatase; ALT, alanine transaminase; AST, aspartate transaminase; CNS, central nervous system; GGT, gamma-glutamyl transpeptidase; IgM, immunoglobulin M; LDH, lactate dehydrogenase; PT, prothrombin time.

PATHOGENESIS

A. Pathogenesis varies by diagnosis.

PREDISPOSING FACTORS

A. Predisposing factors are dependent on the suspected or known medical diagnosis.

COMMON COMPLAINTS

A. Asymptomatic.
B. Pruritus.
C. Jaundice.
D. Ascites.
E. Fatigue.
F. Weight loss.
G. Change in the color of urine (dark) or stools (clay-colored).
H. Abdominal pain.
I. Nausea/vomiting.

SUBJECTIVE DATA

A complete medical history is the single most important part of the evaluation of a client with elevated LFTs.

A. Due to polypharmacy, a full review of medications, herbals, and over-the-counter (OTC) drugs should be undertaken to identify medications that should be avoided in the geriatric population, duplicate medications, and medications that are able to be decreased or deprescribed.

B. Determine the duration of LFT abnormalities (if known).

C. Review the presence of accompanying symptoms, including arthralgias, myalgias, rash, abdominal pain, fever, pruritus, and changes in the color of urine or stool.

D. Has the client experienced any anorexia or weight loss? Over what period of time did weight loss occur?

E. Review parenteral exposures, including transfusions (especially if occurred prior to 1992), intravenous (IV) and intranasal drug use, tattoos, and sexual history.

F. Review the client's recent travel history: food, sexual history, regions of travel, purpose of travel, exposure to other sick contacts.

G. Review the client's exposure to people with jaundice.

H. Review the client's occupational and recreational history and possible exposure to hepatotoxins.

I. Review the client's history of alcohol consumption. Significant alcohol intake is generally considered greater than 210 g alcohol per week in a male or greater than 140 g alcohol per week in a female occurring over at least a 2-year period. Fourteen grams of alcohol are contained in a 12-oz beer, 5 oz of wine, or 1.5 oz of liquor.

J. Evaluate the gestational age of pregnancy. Hemolysis, elevated liver enzymes, and low platelets (HELLP) syndrome is generally present in the mid-second trimester or third trimester of pregnancy.

PHYSICAL EXAMINATION

A. Temperature (if infection is suspected), pulse, respirations, blood pressure (BP), and height and weight to calculate body mass index (BMI).

B. Inspect:

1. Observe for temporal and proximal muscle wasting.

2. Perform eye and mouth (mucous membranes) examination for icterus.

3. Perform skin examination for icterus, spider nevi, palmar erythema, presence of caput medusae (the presence of dilated veins seen on the abdomen; noted with cirrhosis of the liver and portal hypertension).

4. Evaluate the presence of gynecomastia.

5. Observe for the presence of jugular venous distension (JVD), a sign of right-sided heart failure (HF) that suggests hepatic congestion.

C. Auscultate:

1. Heart.

2. Lungs.

D. Percuss:

1. Abdomen.

E. Palpate:

1. Abdominal examination:

a. Evaluate the presence of hepatomegaly; focus on the size and consistency of the liver.

b. Evaluate the presence of splenomegaly; focus on the size of the spleen. An enlarged spleen is most easily appreciated with the client in the right lateral decubitus position.

c. Assess for ascites: Note presence of a fluid wave or shifting dullness.

d. Assess for an abdominal mass.

2. Lymph nodes: Evaluate lymphadenopathy.

3. Conduct testicular examination for testicular atrophy (increased estrogen/reduced testosterone).

DIAGNOSTIC TESTS

A. The particular LFT tests ordered are related to the suspected or identified medical diagnosis. Table 14.9 shows common serologic tests for viral hepatitis.

B. The pattern of elevated liver biochemistries suggests the underlying cause:

1. Elevation of aminotransferases indicates hepatocyte injury.

2. Elevation of alkaline phosphatase (ALP) indicates cholestasis.

3. Changes in albumin and/or prothrombin time (PT) indicate interruption in the synthesis process.

C. The magnitude of the elevation can indicate the underlying cause:

1. Aspartate transaminase (AST): Alanine transaminase (ALT) of greater than 2:1 indicates alcohol-related disease. If the AST:ALT is greater than 3:1, the chance of alcohol-related disease is at 96%.

2. AST and ALT normal to two times upper limit normal (ULN) indicates chronic hepatitis B or C.

3. AST and ALT less than four times ULN occurs in nonalcoholic hepatic disease.

4. AST less than eight times ULN and ALT less than five times ULN indicates alcoholic hepatic disease.

5. AST and ALT greater than 25 times ULN indicates acute viral hepatitis.

6. AST and ALT greater than 50 times ULN indicates ischemic hepatitis.

TABLE 14.9 SEROLOGIC TESTS FOR HEPATITIS

Virologic Test	Usual Clinical Implication of a Positive Test
Hepatitis A-IgM	Positive in acute hepatitis A
Hepatitis A-IgG	Positive in response to previous hepatitis A infection or vaccination
HBsAg	Positive during active hepatitis B infection
Hepatitis B surface antibody	Positive in response to previous hepatitis B infection or vaccination
Hepatitis B core antibody-IgM	Positive during active hepatitis B infection
Hepatitis B core antibody-IgG	Positive in response to current or prior hepatitis B infection
HBV-DNA	Positive during active hepatitis B infection
Hepatitis Be antigen	Positive test indicates replicative state of wild-type hepatitis B infection
Hepatitis Be antibody	Positive after replicative state of wild-type hepatitis B infection
HBV viral load	Assess hepatitis B virology
HCV-antibody ELISA	Positive during or after hepatitis C infection
HCV RIBA	Positive during or after hepatitis C infection
HCV-RNA	Positive during hepatitis C infection
HCV viral load	Assess hepatitis C virology
HCV genotype	Genotyping is used for evaluation of the length of therapy

ELISA, enzyme-linked immunosorbent assay; HBsAg, hepatitis B surface antigen; HBV, hepatitis B virus; HCV, hepatitis C virus; IgG, immunoglobulin G; IgM, immunoglobulin M; RIBA, recombinant immunoblot assay.

DIFFERENTIAL DIAGNOSES

A. Table 14.10 shows differential diagnoses with elevated liver enzymes.

PLAN

A. General interventions:

1. The clinical significance of any liver chemistry test abnormality must be interpreted in the context of the clinical situation. All abnormalities should be confirmed before additional tests are added. Follow-up blood chemistries can vary according to the nature of the initial elevation:

a. An elevated ALP should be rechecked with additional testing with gamma-glutamyl transpeptidase (GGT) or fractionated ALP to determine if the elevation is related to hepatic disease or from an outside location such as bone.

b. An elevated bilirubin should be fractionated to determine if it is conjugated or unconjugated.

c. Serology for viral hepatitis, viral infections, autoimmune disease, muscular disease, Wilson disease, and pregnancy may also be added according to the client's history and exam.

d. Abdominal ultrasound should be undertaken.

e. If the source is not obvious by laboratory testing and ultrasonography, liver biopsy is recommended.

2. Clients with marked abnormalities of liver tests, or with signs and symptoms of chronic liver disease (CLD) or hepatic decompensation (e.g., ascites, encephalopathy, coagulopathy, or portal hypertension), should be evaluated and treated in a more expeditious manner than asymptomatic clients.

B. Client teaching:

1. Lifestyle modifications, including discontinuance of medications and alcohol, weight loss, and dietary changes, can be recommended as appropriate.

FOLLOW-UP

A. Follow-up testing for elevated LFTs, including abdominal/liver ultrasonography, CT, MRI, and liver biopsy, is dependent on the risk factors for disease, symptoms and history, and physical finding of the suspected or identified medical diagnosis. A liver chemistry test that is normal does not ensure that the client is free of liver disease. If a laboratory error is suspected, the laboratory test should be repeated.

CONSULTATION/REFERRAL

A. Refer to gastroenterology or hepatology any client with persistent elevation of aminotransferases greater than two times ULN or of ALP greater than 1.5 times ULN.

B. Referral to infectious disease specialist as indicated.

INDIVIDUAL CONSIDERATIONS

A. Adults:

1. Pregnancy: HELLP syndrome is a severe form of pregnancy-induced hypertension (PIH or preeclampsia). It may occur anywhere from the mid-second trimester to immediate postpartum. HELLP syndrome occurs in 0.2% to 0.6% of pregnancies. The etiology is unknown. The presence of laboratory abnormalities confirms the diagnosis. Treatment of HELLP syndrome will not be covered. However, the laboratory abnormalities that are noted include the following:

a. Hemolytic anemia.

b. Proteinuria.

c. Serum AST level (>70 IU/L).

d. Low platelet count (<10,000 cells/mL).

e. Serum lactate dehydrogenase (LDH) level (>600 IU/L).

f. Total bilirubin level (>1.2 mg/dL).

B. Geriatrics:

1. Elevated liver enzymes are common in older adults:

a. One in six of the general population aged 75 and above have at least one elevated liver test of AST, ALP, or bilirubin. ▶

TABLE 14.10 DIFFERENTIAL DIAGNOSIS WITH ELEVATED LIVER ENZYMES

Infiltrating diseases of the liver • Sarcoidosis • TB • Fungal infection • Amyloidosis	• Lymphoma • Metastatic malignancy • Hepatocellular carcinoma
Acute viral hepatitis (A-E, EBV, CMV, herpes)	Wilson disease (genetic disorder of biliary copper excretion)
Cholestasis disease	Acute bile duct obstruction
Chronic hepatitis B and C	Hemolysis
Steatosis/NASH	Rhabdomyolysis
Hereditary hemochromatosis	Thyroid disorders
Medication/herbal-induced	Strenuous exercise-induced changes
Alpha-1 antitrypsin deficiency	Pregnancy: HELLP syndrome
Cirrhosis	Toxin(s) exposure
Celiac disease	Acute Budd–Chiari syndrome
Alcohol-related liver injury	Anorexia nervosa

EBV, Epstein–Barr virus; CMV, cytomegalovirus; HELLP syndrome, hemolysis, elevated liver enzymes, and low platelets; NASH, nonalcoholic steatohepatitis; TB, tuberculosis.

2. Elevated liver enzymes levels (mainly ALT, GGT, and ALP but not AST) are positively associated with the prevalence of metabolic syndrome in older adults.

3. A history of diabetes and an assessment of dementia were associated with both elevated AST and ALP, with a history of heart attack associated only with increased ALP.

C., Verne, J., Walmsley, M., & Yeoman, A. (2018, January). Guidelines on the management of abnormal liver blood tests. *Gut*, *67*(1), 6–19. https://doi.org/10.1136/gutjnl-2017-314924

FECAL INCONTINENCE

DEFINITION

A. Fecal incontinence (FI) is the involuntary loss of bowel function, ranging from an occasional leakage of mucus or stool when passing flatus to complete loss of bowel control. There are three classifications of FI:

1. Passive incontinence: characterized by impaired awareness of the need to defecate prior to the incontinent episode.

2. Urge incontinence: characterized by the desire to retain fecal material followed by an incontinent episode.

3. Fecal seepage: leakage of fecal material after normal evacuation of stool:

a. Overflow incontinence secondary to fecal impaction.

b. Reservoir secondary to diminished colonic or rectal capacity.

c. Rectosphincteric dysfunction: structural or neurologic damage to the anal sphincter.

INCIDENCE

A. Incidence is dependent on the population studied. Overall incidence is 7.7%, with a range from 2% to 21%. The American College of Gastroenterology (ACG) estimates that more than 18 million Americans have FI. Due to the embarrassing nature of the problem, it is often underreported.

B. Up to 21% of institutional clients have FI. It is the second most common cause of nursing home placement.

C. Incidence increases with age, female gender, and institutionalization.

D. Literature notes 7% incidence of coexisting fecal and urinary incontinence among females and a 4% incidence of FI alone.

PATHOGENESIS

A. FI is a multifactorial problem, and generally a deficiency in one area does not lead to incontinence. Stool continence requires the ability to hold stool (sphincter function), the ability to sense the presence of stool in the rectum (anorectal sensation), the ability to relax and hold the stool (rectal compliance), the mental capabilities to recognize the urge, and the physical ability to go to the toilet, as well as colonic transit of a stool with volume and consistency.

PREDISPOSING FACTORS

A. Fecal impaction/constipation.

B. Diarrhea (viral/bacteria etiology).

C. Obstetrics:

1. Forceps delivery.

2. Episiotomy.

3. Vaginal tears.

4. Large baby (>9.5 lbs).

D. Neurologic/spinal etiology of rectosphincter dysfunction:

1. Lumbar disc herniation with subsequent cauda equina syndrome.

2. Spinal cord injury.

3. Multiple sclerosis.

4. Spina bifida.

5. Meningocele/myelomeningocele.

6. Imperforated anus.

7. Diabetes.

8. Stroke.

E. Trauma.

F. Hemorrhoids/hemorrhoidectomy.

G. Rectocele.

H. Rectal prolapse.

I. Dementia.

J. Radiation for rectal/pelvic cancer.

K. Inflammatory bowel disease (IBD).

L. Inactivity (constipated-related bowel control problems).

M. Vitamin B_{12} deficiency.

N. Hypothyroidism.

O. Severe learning disability.

P. Urinary incontinence.

Q. History of postmenopausal hormone use.

COMMON COMPLAINTS

A. Leakage of mucus/stool when passing flatus.

B. Uncontrolled passing of stool.

OTHER SIGNS AND SYMPTOMS

A. Inability to get to the toilet in time.

SUBJECTIVE DATA

A. Ask about the following bowel-related issues:

1. When did the FI start and how often does the client have bowel control problems?

2. Is the client incontinent of mucus, liquid, and/or solid stools? Do they leak a little or have full incontinence?

3. Is the client able to control passing gas?

4. Does the client have an urge to have a bowel movement (BM) or just have loss of control?

5. Are hemorrhoids present?

6. What foods make the FI worse?

7. Does the client have to do a self-rectal evacuation of stool? How often?

8. Does the client have anal intercourse? How often? Use of penetrating objects?

9. Is there a history of impaction?

10. Does the client wear a pad or an adult diaper?

B. Obtain a detailed obstetrical history:

1. Number of vaginal deliveries.

2. Use of forceps.

3. Infant birth weights and pelvic floor trauma.

4. Need for episiotomy for each vaginal delivery.

5. Presence of vaginal tears.

6. Stool incontinence after deliveries.

C. Has the client been diagnosed with Crohn's or ulcerative colitis (UC)? Is the client currently under treatment? Is the client compliant with their treatments?

D. Review full medical history, especially for diabetes, pelvic radiation, neurologic disease, and back injury. ▶

E. Inquire about urinary incontinence.
F. Review surgical history, including pelvic/rectal surgeries.
G. Review all medications currently being taken, including over-the-counter (OTC) and herbal products. Specifically, evaluate for laxative abuse and recent antibiotic use.
H. Are any other family members ill?
I. Has the client recently traveled or gone camping, which would identify infectious causes? (Refer to entries on diarrhea and infectious diseases.)

PHYSICAL EXAMINATION

A. Check temperature (if applicable), pulse, respirations, blood pressure (BP), and weight.
B. Inspect:
1. Inspect general appearance.
2. Examine the back and lower limbs.
3. Inspect the perianal area for fecal matter, dermatitis, excoriation, fistula, abscess, rectal prolapse, hemorrhoids, and scars.
4. Evaluate if the anal sphincter is open or closed at rest.
C. Auscultate:
1. Auscultate the abdomen.
D. Palpate:
1. Palpate all quadrants of the abdomen to evaluate distension, tenderness, and masses.
E. Anorectal examination: A negative digital rectal examination does not rule out proximal impaction:
1. Evaluate anal stenosis, resting tone.
2. Check presence of impacted stool.
3. Assess the puborectalis muscle by palpating the posterior anal canal:
a. Ask the client to bear down as if having a BM. (An intact puborectalis displaces the examining finger anteriorly.)
b. Ask the client to squeeze the provider's finger.
4. Stroke the perianal skin bilaterally to check for an anal "wink" anocutaneous reflex.
F. Pelvic examination:
1. Perform pelvic examination to evaluate the presence of a cystocele, rectocele, enterocele, vaginal prolapse, and fistula.
H. Mental status:
1. Make a cognitive assessment, such as the Mini-Mental State Examination (MMSE).
2. Assess for depression with Patient Health Questionnaire-2 (PHQ-2) or Patient Health Questionnaire-9 PHQ-9) screening tool.

DIAGNOSTIC TESTS

A. Stool studies to rule out infectious etiology (refer to section "Diarrhea" in this chapter).
B. Abdominal x-ray.
C. Sigmoidoscopy/colonoscopy: Flexible sigmoidoscopy is reserved for clients younger than age 40.
D. Rectal manometry.
E. Anorectal ultrasound.
F. Defecography/proctography.
G. MRI.
H. Anal electromyography (EMG).
I. Balloon expulsion test.
J. Thyroid function tests.
K. Hydrogen breath tests to evaluate lactose/fructose intolerance.

DIFFERENTIAL DIAGNOSES

A. FI.
B. Constipation/fecal impaction.
C. Diarrhea secondary to infectious etiology.
D. IBD.
E. Postradiation therapy.

PLAN

A. General interventions:

Optimal treatment of FI is dependent on identifying the underlying cause of the symptoms. The goal of therapy is to reduce the number of stools and increase the consistency. The best prevention of FI is an empty rectum.

B. Client teaching: *See Client Teaching Guide for this chapter, "Fecal Incontinence."*
1. Discuss keeping a stool diary for a week. A BM record is available at www.hct.nhs.uk/media/1067/bristol-stool-chart.pdf.
2. Discuss keeping a food diary for a week to assist in identifying any foods that cause, trigger, or worsen FI such as coffee, fatty or greasy foods, dairy products (lactose intolerance), sugar-free gum/artificial sweeteners, and cured/smoked meats.
3. Discuss a high-fiber diet. Give client a dietary sheet on a high-fiber diet (see section "High-Fiber Diet" of Appendix B).
4. Discuss the need for additional fluids, 8 to 10 glasses of water, to help prevent constipation. Caffeine, carbonated beverages, alcohol, and milk may cause diarrhea.
5. Discuss the need for manual disimpaction.
6. Remove physical barriers that prevent getting to the bathroom; if mobility an issue, consider bedside commode.
7. Discuss tips to help deal with bowel incontinence/hygienic measures:
a. Use the toilet before leaving home.
b. Identify public restrooms before they are needed.
c. Carry a bag of supplies and change clothes as soon as possible.
d. Pants with elastic are easier to pull down than pants that have buttons.
e. Wear disposable underwear/absorbent pads.
f. Use water without soap; soap dries and irritates.
g. Use baby wipes.
h. Use a moisture-barrier cream, such as zinc oxide.
i. Use fecal deodorant to disguise odor.
C. Conservative treatment:
1. Bowel retraining program:
a. Schedule defecation throughout the day, especially after meals.
2. Biofeedback:
a. **Biofeedback requires the ability to comprehend and follow directions, motivation, and cooperation:**
i. Auditory or visual feedback for reeducation of the pelvic floor muscles.
ii. Rectal sensitivity training utilizing a rectal balloon.
iii. Anal sphincter exercises.
3. Pelvic floor exercises (Kegel exercises).
4. Anal plug can be irritating and is most effective for clients with decreased anal sensation.
D. Dietary management:
1. Counsel the client on nutrition and low-fat, low-cholesterol, and low-sodium diets. Give diet handouts. ▶

E. Pharmaceutical therapy:

1. Solutions containing magnesium, phosphate, or citrate should be used with caution or avoided, especially with clients who have heart failure (HF), or chronic renal failure secondary to the absorption of these electrolytes increases fecal impaction:

2. Mainstay of treatment: loperamide hydrochloride (Imodium): 2 to 4 mg two or three times a day to control symptoms. Maximum daily dose for loperamide is 16 mg.

3. Diphenoxylate hydrochloride/atropine (Lomotil):

a. Contains an opioid Schedule V medication under the Controlled Substance Act. May produce sedation and dizziness.

b. Two tablets QID until diarrhea is controlled, or if liquid Lomotil 10 mL up to four times a day.

c. Maintenance dose two tablets per day.

4. Bulking agents to increase formed stools (used for diarrhea and constipation): may worsen incontinence in clients with decreased rectal compliance but is useful in clients with low-volume loose stools:

a. Methylcellulose (Citrucel): one to two tablespoons daily.

b. Psyllium (Metamucil): Dose varies per client; start with one scoop powder or six pills per day.

5. Fecal impaction:

a. Polyethylene glycol (MiraLax).

b. Enemas (predictable and have a timely response).

c. Suppositories (e.g., glycerine).

d. Laxatives.

6. Manage and treat underlying disease(s) if present, including *Clostridioides difficile* and IBD (see related entries).

F. Medical management:

1. Sacral nerve stimulator: In 2013, the U.S. Food and Drug Administration (FDA) approved the Medtronic InterStim Therapy System.

2. Injectable nonabsorbable bulking agent: hyaluronic acid/dextranomer (Solesta)-tissue bulking agent given by submucosal injection:

a. Indicated as an option for FI treatment for clients older than 18 years of age having failed conservative treatment or not good surgical candidate.

b. Administered by trained providers who hold a certification on the Solesta procedure.

G. Surgical management:

1. Surgical management is dependent on the findings of the history, physical, diagnostic testing, failure of conventional therapies, and client consent. Options include sphincteroplasty or colostomy.

FOLLOW-UP

A. Follow-up is determined by client's needs, severity of acute FI, and whether complications are present.

CONSULTATION/REFERRAL

A. Refer to a gastroenterologist for an endoscopy and if diagnosis is still in question.

B. Refer to a colorectal surgeon.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. FI is the second leading cause of institutionalization of older adults.

2. Polypharmacy with constipating drugs and laxative overuse are common reasons for FI in older adults. Conduct a full review of medications, herbals, and OTC drugs should be undertaken to identify medications that should be avoided in the geriatric population, duplicate medications, and medications that are able to be decreased or deprescribed. (Refer to section on deprescribing in Chapter 3, "Adult-Geriatric Assessments.")

3. Many older adults experience FI as a result of fecal impaction and subsequent overflow. Reduced fluid intake is a common factor for constipation in older adults:

a. Impaired thirst perception.

b. Urinary incontinence.

c. Limited access to liquids due to immobility.

d. Removal of fecal impaction involves a three-step program:

i. Disimpaction by manual removal or with use of enema.

ii. Titration to appropriate dose of oral polyethylene glycol to promote one BM at least every other day.

iii. Maintenance therapy to reduce the risk of reoccurrence.

4. For the older adult with existing FI, a nurse practitioner (NP) should practice special consideration of the following *geriatric syndromes*:

a. Delirium is a common early sign of acute illness or infection in older adults. It is more common in clients with existing cognitive impairment. Dehydration is more common in older adults. Signs of dehydration include confusion, muscle weakness, fever, dizziness, poor skin turgor, hypotension, and tachycardia. Diminished thirst mechanism and decreased body water exacerbate dehydration.

b. At a minimum, clients and family should be asked if the client has experienced episodes of altered mental status:

i. The Brief Confusion Assessment Method (bCAM) is a well-documented assessment for delirium. It is available at www.mnhospitals.org/Portals/0/Documents/ptsafety/LEAPT%20Delirium/HELP%20Program%20CAM%20Flowsheet.pdf.

c. Falls: Consistently assess for falls. Discuss the risk of dizziness or light-headedness when standing:

i. At the minimum, older adults should be asked how many times they have fallen since their last visit. A reported fall should trigger questions about whether the fall led to injury, a visit to urgent care or hospital ED, or a hospital admission:

1) Many falls occur en route to the bathroom when the client hurries and may not be able to remove their pants and undergarments in time.

ii. Clients who use pads or adult diapers should be informed of risks associated with infrequent changing. Because of the high cost of absorbent pads and undergarments, infrequent changing is common and contact dermatitis and candidal rashes may develop. If these occur, clients should be encouraged to change pads/garments more frequently, and avoid wearing absorbent garments overnight and instead should use mattress/bedding pads.

iii. Safety measures to reduce falls in the home include removing small area carpets, keeping night lights along the path to the bathroom, and installing a toilet seat or nearby grab bars. ▶

d. Depression: Anxiety and depression are common in FI and are factors that lead to isolation and decreased health-related quality of life. A depression screen should be done at each office visit:

i. An online PHQ-9 is available at www.mdcalc.com/phq-9-patient-health-questionnaire-9.

ii. The Geriatric Depression Scale, Short Form, a 15-item questionnaire that can be quickly applied in the clinical setting, is available at https://www.apa.org/depression-guideline/patient-health-questionnaire.pdf.

e. Weight loss/appetite suppression: Weight loss is a predictor of mortality. Clinically significant weight loss is considered to be 5% loss of usual body weight in 3 months or 10% in 6 months:

i. Due to gastrointestinal (GI) distress, abdominal discomfort, and diarrhea, older adults are at increased risk of avoiding eating.

ii. Monitor weight patterns/body mass index (BMI). (Caution: BMI is not used to identify loss of muscle mass.)

iii. Monitor both serum albumin and anemia: Hypoalbuminemia and anemia are not necessarily associated with low bodyweight. They can be caused by decreases in liver protein synthesis:

1) Serum albumin concentration is commonly recommended.

2) Hemoglobin (Hgb), prealbumin, and transferrin.

3) Cholesterol.

5. Beers Criteria caution:

a. Diphenoxylate/atropine predisposes older adults to significant side effects, including falls, mental status changes, and urinary retention.

GASTROENTERITIS, BACTERIAL AND VIRAL

DEFINITION

A. Bacterial and viral gastroenteritis is an acute inflammation of the gastrointestinal (GI) mucosa of the middle or lower intestine. It is primarily an acute, self-limited illness that resolves in a week or less. The illness is usually accompanied by nausea, vomiting, diarrhea, fever, and generalized abdominal pain, but can occur with diarrhea alone. Immunocompromised clients can develop unremitting or fatal symptoms from gastroenteritis.

INCIDENCE

A. Gastroenteritis is very common, occurring in all age groups. Epidemic outbreaks of bacterial gastroenteritis occur in groups who have ingested contaminated food. Viral excretion can begin before symptoms. Gastroenteritis is responsible for an estimated eight million healthcare visits and 250,000 hospitalization a year. There are 19 to 20 million annual gastroenteritis illnesses in the United States annually.

PATHOGENESIS

A. Gastroenteritis is commonly due to infectious agents: viruses, bacteria, and parasites (Table 14.11). There are four viral agents: rotavirus, norovirus, enteric adenovirus, and astrovirus. Exotoxins produced by some organisms induce hypersecretion or increased peristalsis, resulting in diarrhea or vomiting. Bacteria such as *Escherichia coli* and *Salmonella* penetrate and invade the gastric mucosa and lead to diarrhea accompanied by fever and fecal leukocytes. Viruses destroy enterocytes of the upper jejunal villi, often producing secondary lactose intolerance.

PREDISPOSING FACTORS

A. Travel to areas where cholera or *Giardia* is epidemic:

1. Ingestion of raw or undercooked seafood or drinks containing cholera-contaminated ice or water.

2. Ingestion of *Giardia*: contaminated water supplies.

B. Ingestion of food contaminated with *Salmonella* or *Shigella.* Foods that are often implicated are domestic fowl and eggs, custard-filled pastries, processed meats, foods warmed on steam tables, poultry, red meat, raw seafood, raw milk, rice, and bean sprouts due to the following:

1. Inadequate cooking time and temperatures.

2. Poor hygiene, lack of handwashing.

3. Improper storage of food.

4. Ingestion of fruits and vegetables contaminated by an infected person or by animal products.

C. Infection by person-to-person spread:

1. Day-care centers: Rotavirus can be found on toys and hard surfaces.

2. Overcrowded environment, inadequate healthcare or education.

3. Schools/dormitories. ▶

TABLE 14.11 INFECTIOUS AGENTS CAUSING GASTROENTERITIS

Causative Agent	Incubation Period
Noroviruses	12 hr–2 d
Escherichia coli	24–72 hr
Campylobacter	2–5 d
Staphylococcus	1–6 hr
Shigella	8–24 hr
Botulism	12–36 hr
Giardia lamblia	7–21 d
Salmonella	6–72 hr
Rotaviruses	1–3 d
Adenovirus	5–8 d
Clostridium perfringens	10–12 hr
Clostridioides difficile	Variable
Listeria species	20 hr

4. Nursing homes.
5. Banquet halls, cruise ships.

D. Contact with *Salmonella*-infected turtles, iguanas, and other reptiles kept as pets.

E. Seasonal outbreaks:
1. Rotavirus and astrovirus occur from October to April.
2. Adenovirus occurs throughout the year.
3. Norovirus occurs throughout the year but tends to increase in cooler months (December–February).

COMMON COMPLAINTS

A. Abrupt onset of nausea and vomiting.
B. Abrupt onset of diarrhea.
C. Fever, sometimes.

OTHER SIGNS AND SYMPTOMS

A. Explosive flatulence.
B. Cramping abdominal pain.
C. Abdominal tenderness.
D. Frequent watery diarrhea.
E. Mucoid stools with or without blood.
F. Tenesmus.
G. Myalgia.
H. Headache.
I. Weakness.
J. Malaise.

SUBJECTIVE DATA

A. Review onset, duration, and course of symptoms, including presence of abdominal pain and frequency of bowel movements (BMs). Ask the client if anyone else in the family or coworkers have the same symptoms.

B. Ask the client about travel history, including travel by cruise ships or travel to foreign countries and camping with ingestion of water from streams, springs, or untreated wells. Inquire regarding exposure to animals.

C. Ask the client about crowded or unsanitary living conditions, use of day-care centers, and institutional living.

D. Take a 24-hour diet history, including ingestion of prunes or beans.

E. Review diarrhea history:
1. How many stools?
2. How frequent are the diarrhea stools?
3. What color is the stool?
4. Does the stool contain mucus?
5. Has there been blood in the stool?
6. Does the client have tenesmus (constant feeling for the need to pass stool)?

F. Inquire about other symptoms, such as fever or respiratory problems.

G. If the client is an infant, ask caregiver about activity level, irritability, sleep pattern, fluid intake, and number of wet diapers.

H. Review drug history intake, including laxatives, antacids, antibiotics, quinine, or anticancer medications.

I. Has the client been vaccinated with the rotavirus vaccine?

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, blood pressure (BP), and weight:
1. Bacterial infections: temperatures between 101°F and 102°F.
2. Viral infections: temperatures of 103°F and above.
3. Note hypotension and tachycardia.

B. Inspect:
1. Inspect general appearance; note if the client is very ill.
2. Assess hydration status. Signs of dehydration:
   a. Mild: slightly dry buccal mucous membranes, increased thirst, decreased urine output.
   b. Moderate: sunken eyes, loss of skin turgor, dry buccal mucous membranes, decreased urine output.
   c. Severe: signs of moderate dehydration and one or more of the following: rapid thready pulse, tachypnea, lethargy, and postural hypotension.

C. Auscultate:
1. Abdomen for bowel sounds; note hyperactive bowel sounds, absent or hypoactive bowel sounds (common with botulism), and borborygmi.

D. Palpate:
1. Abdomen for diffuse tenderness, slight distension, masses, rebound tenderness, and spasm.

E. Rectal exam:
1. Check for masses, fissures, inflammation, perianal erythema, or stool in ampulla.

F. Neurologic exam:
1. Check for dizziness, difficulty swallowing, and other neurologic signs.
2. Neurologic signs and symptoms indicate botulism and require emergency intervention.

DIAGNOSTIC TESTS

A. No immediate lab tests are required if dehydration is absent or mild and the client feels well except for frequent diarrhea.

B. Complete blood count (CBC) with differential: Serologic studies may fail to differentiate between bacterial and viral pathogens.

C. Sedimentation rate: elevated with infections or inflammation

D. Electrolytes, sodium, chlorides, potassium, and blood urea nitrogen (BUN).

E. Blood gases to assess acid–base balance, if indicated.

F. Blood cultures, if indicated.

G. Stool for guaiac, leukocytes, ova, and parasites; test specimens three times, every other day. Stool guaiac is usually negative in viral infections, positive in invasive bacterial infections. Large numbers of white cells in stool suggest inflammatory or invasive diarrhea, such as occurs with *Shigella, Salmonella, Campylobacter*, invasive *E. coli*, or *Entamoeba.* Mononuclear cells in stool are characteristic of salmonellosis.

H. Stool culture if blood or mucus, fever more than 24 hours, or leukocytes are present.

I. Special cultures for *Campylobacter* and cholera are required.

J. Urinalysis: excludes urinary tract infection (UTI) as cause of nonspecific diarrhea; urine-specific gravity to assess dehydration.

K. Sigmoidoscopy: Skip bowel prep with presentation of gross blood, large numbers of leukocytes in stool, or severe illness.

L. Culture food from suspected foci for *Salmonella.*

M. Real-time reverse transcriptase-polymerase chain reaction (RT-qPCR) is the most widely used assay for detecting norovirus in stool, vomitus, and environmental specimens. The best detection is in stool specimens.

DIFFERENTIAL DIAGNOSES

A. Gastroenteritis, bacterial and viral.
B. Acute viral hepatitis.

▶

C. Acute appendicitis.
D. Cholecystitis.
E. Irritable bowel disease (IBD; ulcerative colitis [UC]/Crohn's disease [CD]).
F. Pelvic inflammatory disease (PID).
G. Bowel obstruction for other causes.
H. Colorectal cancer (CRC).
I. Irritable bowel syndrome (IBS).
J. Microscopic colitis.
K. Malabsorption syndrome.
L. Postcholecystectomy syndrome.
M. Medication-induced.
N. Laxative abuse.

PLAN

A. General interventions:

1. Meticulous handwashing is the single most important measure to decrease transmission. Hand sanitizers are an option when access to soap or clean water is limited.

2. Advise the client to begin bedrest with progression to regular activities.

3. If the client is diapered and/or incontinent, tell the client or caregiver to adhere strictly to contact precautions. Alcohol-based handwashing may decrease the spread.

4. Diaper-changing areas should be separate from food preparation areas.

5. Chlorine-based disinfectants inactivate rotavirus and may prevent disease transmission from contact with environmental surfaces.

B. Client teaching: *See Client Teaching Guide for this chapter, "Diarrhea."*

C. Dietary management:

1. There are no specific dietary restrictions for clients diagnosed with acute gastroenteritis. As tolerated, food intake should be advised. Small meals and low-residue foods are better tolerated. Soup, saltines, broiled or boiled salted starches (oats/cereal/potatoes), and bananas are good choices.

2. Hydration is one of the most important factors in the prevention of complications. For most clients, use of sports drinks, diluted juices, or broth is sufficient. Oral rehydration solutions may be implemented for moderate to severe cases.

3. See section "Nausea and Vomiting Diet Suggestions" of Appendix B.

D. Pharmaceutical therapy:

1. The primary treatment for viral gastroenteritis is fluid replacement. There are no specific antiviral pharmaceutical therapies. Intravenous (IV) rehydration of fluids and electrolytes may be required in severe dehydration as evidenced by dry mucous membranes, hypotension, tachycardia, or mental status changes.

2. Antibiotics may or may not be prescribed according to the bacterial source. Antimicrobial therapy is not indicated for uncomplicated (noninvasive) gastroenteritis because therapy does not shorten duration of the disease and can prolong duration of excretion of *Salmonella* organisms.

3. Antidiarrheal therapy delays transit time and can reduce the severity and duration of abdominal cramping; however, it may prolong the course of some bacterial diarrhea such as *Shigella* and *E. coli*. In otherwise healthy clients younger than 65 years of age, if diarrhea is moderate to severe or if clinical signs of dehydration are evident, short-term (1–2 days) use of loperamide may be used to facilitate oral rehydration.

4. An antiemetic such as ondansetron (Zofran), which does not cause sedation, may be useful for 1 to 2 days if vomiting is severe enough to prevent oral rehydration.

5. Review all medications, herbal, and over-the-counter (OTC), to decrease or deprescribe other medications that may be triggering diarrhea.

EMERGENT ISSUES/INSTRUCTIONS

A. Refer clients to a hospital immediately if they have dehydration, rebound tenderness, severe abdominal pain, neurologic symptoms, and intussusception.

FOLLOW-UP

A. Tell the client to return if the condition worsens or if signs and symptoms have not abated in 48 to 72 hours. However, diarrhea due to *Salmonella* may be expected to persist for up to 2 weeks.

B. If diarrhea persists for 1 or more weeks, have the client return for a secondary evaluation. Stool studies, white blood cell (WBC), renal function, and electrolytes are warranted at this time.

C. Twenty-five percent of affected clients will have long-lasting bowel changes after recovering from gastroenteritis. A small percentage of these clients will develop postinfectious IBS.

D. Reporting surveillance systems:

1. In 2009, the Centers for Disease Control and Prevention (CDC) launched the National Outbreak Reporting System (NORS) and updated in 2017 to collect information on outbreaks of foodborne, waterborne, and enteric disease that is spread from person to person, animals, environmental surfaces, and other ways by public health agencies.

2. In 2009, the CDC developed CaliciNet for public health and food regulator laboratories to submit outbreaks to a national database.

3. New Vaccine Surveillance Network (NVSN).

4. Foodborne Disease Active Surveillance Network (FoodNet).

CONSULTATION/REFERRAL

A. Refer any client with diarrhea longer than 7 days that has had no response to usual treatment.

B. Refer an immunocompromised client.

INDIVIDUAL CONSIDERATIONS

A. Adults:

1. Those with concomitant chronic debilitating disease are at a higher risk of mortality. Closely monitor clients with immunodeficiency, IBD, valvular heart disease, diabetes mellitus, renal impairment, rheumatoid arthritis, systemic lupus erythematosus (SLE), and clients taking immunosuppressants, corticosteroids, or diuretics.

B. Geriatrics:

1. Older adults are at a higher risk of mortality secondary to dehydration. Diminished thirst mechanism and decreased body water exacerbate dehydration. Signs of dehydration include confusion, muscle weakness, fever, dizziness, poor skin turgor, hypotension, and tachycardia.

a. At a minimum, clients and their family should be asked if the client has experienced episodes of altered mental status.

i. The Brief Confusion Assessment Method (bCAM) is a well-documented assessment for delirium. It is available at deliriumnetwork.org/wp-content/uploads/2018/05/bCAM.pdf.

2. Due to polypharmacy, a full review of medications, herbals, and OTC drugs should be undertaken to identify medications that should be avoided in the geriatric ▶

population, duplicate medications, and medications that are able to be decreased or deprescribed. (Refer to section on deprescribing in Chapter 3, "Adult-Geriatric Assessments.")

3. New residents to nursing/group homes should be isolated from ill clients.

4. For the older adult with existing diarrhea, nurse practitioner (NPs) should practice special consideration of the following *geriatric syndromes*:

a. Falls:

i. Consistently assess for falls. Discuss the risk of dizziness or light-headedness when standing due to orthostatic hypotension and due to weakness.

ii. Many falls occur en route to the bathroom when the client hurries and may not be able to remove their pants and undergarments in time.

iii. At the minimum, older adults should be asked how many times they have fallen since their last visit. A reported fall should trigger questions about whether the fall led to injury, a visit to urgent care or hospital ED, or a hospital admission.

iv. Safety measures to reduce falls in the home include removing small area carpets, keeping night lights along the path to the bathroom, and installing a toilet seat or nearby grab bars.

v. Durable medical equipment such as a bedside commode may be considered.

vi. Clients who use pads or adult diapers should be informed of risks associated with infrequent changing. Because of the high cost of absorbent pads and undergarments, infrequent changing is common and contact dermatitis and candidal rashes may develop. If these occur, clients should be encouraged to change pads/garments more frequently, and avoid wearing absorbent garments overnight and instead should use mattress/bedding pads.

b. Delirium is a common early sign of dehydration, acute illness, or infection in older adults. It is more common in clients with existing cognitive impairment.

c. Weight loss/appetite suppression: Weight loss is a predictor of mortality. Clinically significant weight loss is considered to be 5% loss of usual body weight in 3 months or 10% in 6 months:

i. Monitor weight patterns/body mass index (BMI). (Caution: BMI is not used to identify loss of muscle mass.)

ii. Monitor both serum albumin and anemia: Hypoalbuminemia and anemia are not necessarily associated with low body weight. They can be caused by decreases in liver protein synthesis:

1) Serum albumin concentration is commonly recommended.

2) Hemoglobin (Hgb), prealbumin, and transferrin.

3) Cholesterol.

GASTROESOPHAGEAL REFLUX DISEASE AND DYSPEPSIA

DEFINITION

A. The American College of Gastroenterology (ACG) defined gastroesophageal reflux disease (GERD) as symptoms or complications resulting from the reflux of gastric contents into the esophagus or beyond, into the oral cavity (including larynx) or lung.

B. GERD is considered a normal physiologic process in healthy infants, children, and adults. Most episodes last less than 3 minutes, and most often occur 30 to 60 minutes after meals and with reclining positions. GERD is present when the episodes, more than twice a week, cause troublesome symptoms or complications.

C. The ACG and Canadian Association of Gastroenterology (CAG) Clinical Guideline: Management of Dyspepsia was released in 2017 and updated in 2021. Dyspepsia is defined as predominant epigastric pain lasting at least a month. This can be associated with any other upper gastrointestinal (GI) symptoms such as epigastric fullness, nausea, vomiting, or heartburn, provided epigastric pain is the client's primary concern. Functional dyspepsia (FD) refers to clients with dyspepsia where endoscopy and other tests, where relevant, have ruled out organic pathology that explains the client's symptoms:

1. A very large population of clients will present after self-medicating with antacids, bicarbonate soda, and over-the-counter (OTC) medications. Proton pump inhibitors (PPIs) are currently available by prescription and OTC (Table 14.12).

INCIDENCE

A. GERD is very common; the estimated global presence is 8% to 33%. GERD affects all ages and both genders. Daily heartburn typically occurring postprandially has been estimated to affect 17% to 65% of the normal adult population. ▶

TABLE 14.12 PROTON PUMP INHIBITORS (PPIS)

PPI	Available Dosages
Omeprazole (Prilosec)	Capsules: 10, 20, and 40 mg
Lansoprazole (Prevacid)	Capsules: 15, 20, and 30 mg delayed-release Oral suspension, capsules, and SoluTab
Rabeprazole (Aciphex)	Tablets: 20 mg delayed-release Sprinkles 5 and 10 mg capsules
Pantoprazole (Protonix)	Capsules: 20 and 40 mg Oral suspension: 30 mg
Esomeprazole (Nexium)	Capsules: 20 and 40 mg Oral suspension: 20 and 40 mg
Dexlansoprazole (Dexilant)	Sustained-release tablets: 30 and 60 mg
Omeprazole + sodium bicarbonate (Zegerid)	Capsules: omeprazole 20 and 20 mg plus 300 mg Na+ Oral suspension: omeprazole 20 and 40 mg plus 460 mg Na+

Reflux esophagitis affects over 50% of females at some time during pregnancy. It is estimated that 30% to 90% of asthmatics have GERD. Barrett esophagus, which affects fewer than 1% of adults, is commonly associated with GERD.

B. Approximately 40% of the population have symptoms of dyspepsia globally. Dyspepsia is more common in females, smokers, and those taking nonsteroidal anti-inflammatory drugs (NSAIDs).

PATHOGENESIS

A. GERD is relaxation or incompetence of the lower esophagus persisting beyond the newborn period. Relaxation of the lower esophageal sphincter (LES) allows reflux of gastric acid and pepsin into the distal esophagus. Heartburn occurs when reverse peristaltic waves cause regurgitation of acidic stomach contents into the esophagus. Anatomic abnormalities such as a hiatal hernia predispose persons to GERD. Improper diet and nervous tension are also precipitating factors.

B. GERD has been identified as a trigger for asthma, possibly by the activation of vagal reflexes and/or microaspiration. Asthma may promote GERD, and GERD may provoke asthma. Some asthma medications may reduce LES tone, further complicating the picture. Conversely, a client with GERD may experience pulmonary disease as a response to the esophageal acid exposure.

PREDISPOSING FACTORS

A. Obesity.
B. Consuming large meals.
C. Pregnancy.
D. Emotional stress.
E. Increased abdominal pressure from tight clothes, straining to lift or defecate, or swallowing air.
F. Ingesting drugs that promote LES relaxation; slow gastric emptying can directly affect the mucosal lining (see Table 14.12).
G. Foods that promote LES relaxation:
  1. Alcohol.
  2. Chocolate.
  3. Peppermint.
  4. Garlic and onions.
  5. Fatty, spicy, and fried foods.
H. Smoking: increases stomach acid and LES pressure.
I. Ingestion of caustic agents such as lye.
J. Infection by agents, such as *Candida*, herpes simplex, or cytomegalovirus (CMV), which directly attack the esophageal mucosa.
K. Compromised immunity, from AIDS, diabetes, or chemotherapy.
L. Asthma.

COMMON COMPLAINTS

A. Heartburn.
B. Regurgitation of fluid or food.
C. Chest pain.

OTHER SIGNS AND SYMPTOMS

A. Retrosternal aching or burning.
B. Nocturnal aspiration, water or "acid" brash.
C. Harsh taste in the mouth upon awakening.
D. Chronic cough, especially at bedtime.
E. Hoarseness.
F. Globus sensation.
G. Nausea.
H. Dental erosion.

SUBJECTIVE DATA

A. Review onset, duration, and course of heartburn or other symptoms.
B. Review medication history, including OTC medication and herbals:
  1. Has the client been taking OTC antacids, H2 blockers, or OTC PPIs?
  2. How long has the client been using these OTCs?
  3. Is the client taking drugs that induce symptoms (refer to Table 14.13)?
C. Ask the client about alleviating and aggravating factors.
D. Review the client's habits, including smoking and alcohol intake.
E. Inquire about other symptoms, such as weight loss, dysphagia, blood loss, regurgitation, and diarrhea.
F. Establish the client's usual weight to determine extent of problem.
G. Ask the client about any history of asthma.
H. Ask the client about any history of Crohn's disease (CD; mucosal damage).
I. Review the client's dietary history for bulimia.
J. Ask about any history of celiac disease or family history of autoimmune disorders.

PHYSICAL EXAMINATION

A. Check pulse, respirations, and blood pressure (BP), and measure height and weight to calculate the client's body mass index (BMI).
B. General observation of respiratory distress.
C. Inspect:
  1. Examine throat and evaluate mouth for dental erosion.
  2. Assess swallowing ability.
D. Auscultate:
  1. Evaluate the presence of wheezing in the lungs.
  2. Auscultate the heart.
  3. Evaluate the abdomen in all four quadrants.
E. Palpate:
  1. Palpate abdomen for the presence of hepatosplenomegaly and masses.
  2. Assess the abdomen for tenderness or distension.
F. Rectal exam (if indicated for any history of hematemesis or melena).

DIAGNOSTIC TESTS

A. Clinical findings and history alone usually confirm the diagnosis in the vast majority of reflux sufferers.
B. *Helicobacter pylori* testing.

TABLE 14.13 COMMONLY USED MEDICATIONS THAT CAN IMPEDE ESOPHAGEAL FUNCTION, RETARD GASTRIC EMPTYING, OR CAUSE DIRECT ESOPHAGEAL MUCOSAL INJURY

Antibiotics	Bisphosphonates
Anticholinergics	Dopamine agents
Anticonvulsants	Ferrous sulfate
Antihypertensives	Lithium
Antiretrovirals	Nicotine
Ascorbic acid	Nitrates
Aspirin and NSAIDs	Potassium chloride
Benzodiazepines	Progesterone
Beta agonists	Xanthines (Theophylline)

NSAIDs, nonsteroidal anti-inflammatory drugs.

C. The 2021 ACG and CAG clinical guidelines for dyspepsia related to endoscopy state:

1. Clients 60 years or over with dyspepsia should have an endoscopy to exclude upper GI neoplasia.

2. For clients under age 60, an endoscopy should not be done to investigate alarm features for dyspepsia to exclude upper GI neoplasia.

3. Clients younger than 60 years with dyspepsia should have a noninvasive *H. pylori* test and treatment if possible. (Refer to section "Peptic Ulcer Disease" in this chapter for *H. pylori* treatment.)

D. The 2021 American Gastroenterology Association (AGA) guidelines for GERD state:

1. Endoscopy is not required for the presence of typical GERD symptoms but is recommended for the presence of alarm symptoms or for screening clients at high risk for complications.

2. Endoscopy with biopsy is usually the first diagnostic tool in cases of caustic ingestion or suspected infectious etiology.

3. The ACG does not recommend an endoscopy to establish the diagnosis of GERD-related asthma, chronic cough, or laryngitis.

E. The Lyon Consensus (2020) statement suggests various questionnaires present similar sensitivity and specificity compared with accurate gastroenterologic evaluations. Related to endoscopy, Lyons Consensus notes when GERD symptoms do not respond to empiric PPI an endoscopy is advised to both evaluate for GERD complications and to detect potential alternative diagnoses that might redirect therapy. Barrett esophagus or peptic stricturing is considered confirmatory evidence of GERD.

1. Motility and pH monitoring:

a. The ACG and CAG guidelines on motility studies state the following:

i. Recommend against routine motility studies for clients with FD.

ii. Suggest motility studies for selected clients with FD where gastroparesis is strongly suspected.

b. The AGA states ambulatory 24-hour pH monitoring: Prolonged monitoring is the best clinical tool for diagnosing GERD in asthmatics. However, it is very expensive and not universally available.

c. The Lyon Consensus states reflux monitoring demonstrates GERD pathology, evident as either excessive esophageal acid exposure time (AET) or reflux episodes, rather than the mechanics. However, wireless pH monitoring is expensive, limiting its availability.

F. Upper GI series or barium contrast radiography is not used to diagnose GERD but rules out anatomic abnormalities of the upper digestive tract.

G. Guaiac test for occult blood: Bleeding may accompany reflux esophagitis and be slow and chronic, resulting in iron deficiency anemia, or brisk, resulting in hematemesis. GERD may not be obvious to the clinician when obtaining a client history, especially in an asthma client with confounding respiratory symptoms.

DIFFERENTIAL DIAGNOSES

A. GERD.
B. Dyspepsia.
C. Cancer: gastric or esophageal.
D. Peptic ulcer.
E. Eosinophilic esophagitis (EE).
F. Esophageal spasm.
G. Myocardial infarction (MI)/angina.
H. Gallbladder disease.
I. Infections: CMV, herpes simplex virus, and *Candida.*
J. Ingestion of caustic substance.
K. Self-induced vomiting/bulimia.
L. Pyloric stenosis.
M. Autoimmune skin disorders affecting the esophagus.
N. Food allergy.

PLAN

A. General interventions:

1. Management depends on cause and severity of symptoms.

B. Client teaching: *See Client Teaching Guide for this chapter, "Gastroesophageal Reflux Disease (GERD)."*

C. Dietary management:

1. Weight loss is advised for overweight or obese clients with GERD symptoms.

2. At present, there are no supporting data for special dietary precautions; however, an elimination diet of key trigger foods helps to identify triggers.

D. Medical and surgical management:

1. The Nissen fundoplication is a surgical procedure used to treat GERD in asthmatics. It improves the antireflux barrier and provides a lasting solution. Because it is not always successful, it is reserved for severe cases. The Nissen operation is often performed as a laparoscopic procedure.

2. Surgical therapy is not recommended for clients who do not respond to PPI therapy.

3. The ACG guidelines note that surgical therapy is as effective as medical therapy for carefully selected clients with chronic GERD when performed by an experienced surgeon.

4. Clients on NSAIDs who experience upper gastric pain including reflux need to be referred for endoscopy as soon as possible.

E. Pharmaceutical therapy:

PPIs are used for dyspepsia, GERD, and EE and are considered the "gold standard" of treatments.

1. Guidelines related to PPI therapy:

a. The AGA and CAG guidelines related to PPI therapy:

i. Dyspepsia clients under the age of 60 should have empirical PPI therapy if they are *H. pyloric*-negative or remain symptomatic after *H. pylori* eradication therapy.

ii. Tricyclic antidepressants (TCA) or prokinetic therapies for clients younger than 60 with dyspepsia can be tried if a trial of PPI is ineffective or the clients did not respond to *H. pylori* eradication therapy.

iii. The ACG and CAG guidelines recommend PPI, TCA, and prokinetic therapy in this order for clients who fail therapy or are *H. pylori*-negative.

b. The AGA guidelines state the following:

i. Histamine-2 receptor antagonists (H2 blockers) are effective in managing milder, infrequent GI symptoms. Tolerance occurs with chronic use of H2 blockers. Several H2 blockers are currently available as prescription and OTC: nizatidine (Axid), famotidine (Pepcid), and cimetidine (Tagamet).

ii. Rule out cardiac/noncardiac chest pain before institution of PPI therapy (see section "Chest Pain" in Chapter 13).

iii. The target of pharmaceutical therapy is improvement in quality of life by the reduction/relief of symptoms and healing of erosive esophagitis.

iv. Initiation of a PPI should be prescribed once a day, before the first meal of the day. For maximal pH control, the traditional delayed-release PPI should be administered 30 to 60 minutes before a meal.

v. Management of GERD and dyspepsia should be tailored to the frequency, severity, and duration of symptoms. On-demand or self-directed therapy has been shown to be effective; however, a client's use and response should be evaluated.

vi. Long-term use of acid suppression therapy without a diagnosis is not advised.

vii. Long-term therapy should be titrated down to the lowest effective dose based on symptom control.

2. Adverse side effects of PPIs:

a. The potential adverse effects of acid suppression include the increased risk of community-acquired pneumonia, osteoporosis/osteopenia, vitamin B_{12} deficiency and hypomagnesium, and GI infections, including *Clostridioides difficile*-associated diarrhea.

b. Avoid the concomitant use of clopidogrel (Plavix) with PPIs due to the significant reduction of the antiplatelet activity of clopidogrel.

c. PPIs interact with warfarin, phenytoin, and diazepam:

i. Monitor the therapeutic effect of warfarin and phenytoin.

ii. Clients may experience a relapse in their GERD symptoms after discontinuance and therefore may need to be tapered off or use a stepdown approach with an antacid or an H2 blocker.

3. The ACG guidelines do not recommend the use of integrated and alternative medicines.

FOLLOW-UP

A. Noncardiac chest pain due to GERD should have a diagnostic evaluation before institution of therapy.

B. Empiric treatment with a PPI may be attempted for a short period except for clients presenting with any alarm symptoms. Schedule a return visit in 1 to 2 weeks to evaluate the relief of symptoms.

C. Clients having frequent relapses and failure to adequately respond to long-term OTC H2 blockers and PPI use should have an endoscopic evaluation.

D. The need for prescribed long-term PPI treatment or the presence of alarm symptoms requires a gastroenterology consultation.

E. Consider bone density studies for clients with long-term PPI use.

EMERGENT ISSUES/INSTRUCTIONS

A. Alarm symptoms:

1. Dysphagia (difficulty swallowing).
2. Unintentional weight loss.
3. Predominant upper abdominal pain.
4. Hematemesis (vomiting blood).
5. Melena (black feces/blood stool).
6. Odynophagia (painful swallowing).
7. Severe symptoms.

B. Clients on NSAIDs who experience upper gastric pain including reflux need to be referred for endoscopy as soon as possible.

CONSULTATIONS

A. Referral is necessary if the client fails to improve after trying two different medications, or if the client has dysphagia, recent weight loss, or blood loss.

B. PPI nonresponders need to be referred for evaluation.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Underlying causes in pregnancy are diminished gastric motility and displacement of stomach by enlarging uterus.

2. Rule out pregnancy-induced hypertension (PIH); evaluate the client immediately for signs and symptoms of sudden-onset discomfort with no relief from antacids (PIH or HELLP [hemolysis, elevated liver enzymes, and low platelets] syndrome).

B. Geriatrics:

1. GERD prevalence increases with age and may be associated with a hiatal hernia.

2. Prolonged reflux results in esophagitis and may lead to stricture development. Chronic recurrence may develop into Barrett syndrome.

3. Treatment of GERD is the same as for general adults; however, do diagnostic testing in short time sequence secondary to stricture and cancer in the older adults.

4. Atypical symptoms are common presentations in the older adults:

a. Vomiting.
b. Anorexia.
c. Dysphagia.
d. Respiratory symptoms.
e. Belching.
f. Hoarseness.
g. Postprandial fullness.

5. Beers Criteria cautions for PPIs:

a. Due to polypharmacy, a full review of medications, herbals, and OTC drugs should be undertaken to identify medications that should be avoided in the geriatric population, duplicate medications, and medications that are able to be decreased or deprescribed. Evaluate if the client has difficulties with chewing or if the client is altering medications by crushing due to swallowing difficulties. Some medications should not be crushed because it alters the absorption or stability of the medication, causes an irritant effect, or has unacceptable taste. (Refer to section on deprescribing in Chapter 3, "Adult-Geriatric Assessments.")

b. **When prescribing to older adults, use the lowest dose, for the shortest period of time.**

c. PPIs interact with medications that are commonly taken in the older population, including warfarin, phenytoin, and diazepam. PPIs also reduce the antiplatelet effect of clopidogrel:

i. Monitor the therapeutic effect of warfarin and phenytoin.

d. PPIs are on the American Geriatrics Society 2019 Beers Criteria for potential inappropriate medication use in older adults. (Refer to Appendix C, Table C.1.) Avoid scheduled use of PPIs for greater than 8 weeks unless needed for high-risk clients. PPIs are associated with the following:

i. Osteoporosis/osteopenia, prolonged exposure may increase of fractures.
ii. Community-acquired pneumonia.
iii. *C. difficile* infections and diarrhea.
iv. Vitamin B_{12} deficiency and hypomagnesium.

e. See Appendix D for the PPI deprescribing algorithm from deprescribing.org.

GIARDIA INTESTINALIS

DEFINITION

A. *Giardia intestinalis* is the leading parasitic cause of diarrhea. Infestation can lead to malabsorption by coating large areas of the small bowel, particularly the lower duodenum and upper jejunum. Most people infected with *G. intestinalis* remain asymptomatic, and most infections are self-limited.

INCIDENCE

A. Giardiasis has a worldwide distribution and is especially prevalent in the United States and overseas. It is common in areas where water supplies are contaminated by human sewage. The age-specific prevalence of giardiasis is highest in children 1 to 5 years and in adults 35 to 39 years of age. The peak onset occurs annually during early summer through early fall.

PATHOGENESIS

A. *G. intestinalis* is a flagellated protozoan. The infective form is the cyst. Humans are the principal reservoir of infection, but *Giardia* can infect dogs, cats, beavers, and other animals that can contaminate water with feces containing cysts.

B. People become infected either directly, by hand-to-mouth transfer of cysts from feces of an infected person (e.g., childcare), or indirectly, by ingestion of fecal-contaminated water or food. Most community-wide epidemics result from contaminated water supplies.

C. The incubation period is 1 to 3 weeks, with an average of 7 to 10 days. The infective form is the cyst with infection limited to the small intestine and the biliary tract. Disease is communicable for as long as the infected person excretes cysts.

D. Symptoms may last 2 to 6 weeks in otherwise healthy people.

PREDISPOSING FACTORS

A. 50% to 75% of outbreaks occur in childcare settings.
B. Travel to endemic areas.
C. Subjection to unsanitary food handling.
D. Exposure to contaminated water supplies (lakes, rivers, springs, ponds, streams, or wells):
1. Swallowing water from a swimming pool that is underchlorinated.
E. Hikers and campers.
F. Oral/anal and oral/genital sexual contact.
G. Immunocompromised individuals are at high risk.

COMMON COMPLAINTS

A. Acute complaints:
1. Explosive, foul-smelling diarrhea.
2. Mucus in stools, bulky stools.
3. Upper abdominal pain or discomfort.
4. Flatulence.
5. Nausea.
6. Anorexia.
7. Weight loss.

OTHER SIGNS AND SYMPTOMS

A. Chronic complaints:
1. Intermittent loose stools (but not diarrhea).
2. Steatorrhea.
3. Increased flatulence or distension.
4. Vague abdominal discomfort.
5. Fatigue related to anemia.
6. Profound weight loss (10%–20% of body weight).
7. Malabsorption.
8. Urticaria.

SUBJECTIVE DATA

A. Review onset, duration, and course of symptoms. Is diarrhea acute or chronic?
B. Ask the client about travel to areas known for giardiasis.
C. Work exposure such as day-care or orphanage worker.
D. Review recreational exposure to water sources, swimming pools, lakes, ponds, rivers, and so forth.
E. Review the client's intake of medications and other substances that can cause diarrhea, especially antibiotics, laxatives, quinidine, magnesium-containing antacids, excess alcohol, caffeine, herbal teas, digitalis, loop diuretics, antihypertensive agents, and sorbitol-containing (sugar-free) gums and mints.
F. Review the nature of the client's bowel movements (BMs), including frequency, consistency, volume, and presence of blood, pus, or mucus.
G. Does diarrhea have any relationship to meals? Onset of diarrhea within hours of ingesting a potentially contaminated food is suggestive of bacterial infection such as *Escherichia coli;* this is confirmed by checking if others were similarly affected.
H. Ask the client about associated symptoms that need evaluation, such as fever, abdominal pain, or rash.
I. Ask the client if other family members or sexual contacts are also ill.
J. Establish the client's normal weight, and if any weight has recently been lost, review amount and over what period of time.

PHYSICAL EXAMINATION

A. The physical examination may reveal no specific finding. ▶

B. Check temperature, pulse, respirations, blood pressure (BP). Measure height and weight to calculate body mass index (BMI).
C. Inspect:
1. General appearance for signs of dehydration; include evaluation of mucous membranes.
D. Auscultate:
1. Abdomen for bowel sounds in all quadrants.
E. Palpate:
1. Palpate the abdomen for masses, tenderness, guarding, and rebound. Clients with periumbilical or right lower quadrant (RLQ) pain and copious volumes of watery stool are likely to have a small bowel etiology.
2. Palpate lymph nodes for enlargement.
F. Rectal exam.

DIAGNOSTIC TESTS

A. Routine blood tests, complete blood count (CBC), and electrolytes are usually normal.
B. The Centers for Disease Control and Prevention (CDC) recommends collecting three stool specimens from clients over several days for more accurate test results to rule out other pathogens. **Parasites are passed intermittently, so examine stools on alternating days.**
C. Test of choice is direct fluorescence antibody (DFA); also available: enzyme immunolinked assays (EIAs) kit, microscopy with trichrome staining.
D. Mucus stool for leukocytes: Mucus free of leukocytes is the hallmark of irritable bowel syndrome (IBS); a large number of white cells suggests inflammatory or invasive diarrhea.
E. Endoscopy to identify cyst in duodenal fluid or small bowel tissue.

DIFFERENTIAL DIAGNOSES

A. Giardiasis.
B. Malabsorption.
C. *E. coli* infection.
D. IBS.
E. Viral diarrhea.
F. Lactose intolerance.
G. Other bacterial infections, such as *Shigella, Salmonella*, and *Campylobacter.*
H. Crohn's disease (CD).
I. Sprue, celiac disease, gluten intolerance.

PLAN

A. General interventions:
1. Advise adult workers with diarrhea to stay away from day-care centers until they become asymptomatic.
2. Advise the client's household and sexual contacts to seek medical examination and treatment.
B. Client teaching: *See Client Teaching Guide for this chapter, "Diarrhea."*
1. Discuss safe sexual practices.
2. Recommend contact precautions for duration of illness for diapered and/or incontinent children.
3. People with diarrhea caused by *Giardia* should not use recreational water venues, including swimming pools, for 2 weeks after symptoms resolve.
4. Avoidance of alcohol during treatment should be avoided secondary to disulfiram-like effect.
C. Dietary management:
1. Instruct the client or caregiver to prevent dehydration from diarrhea by increasing fluids.
2. Advise restricting milk products to rule out lactose intolerance. Post-*Giardia* lactose occurs in up to 40% of clients.
3. Instruct backpackers, campers, and people likely to be exposed to contaminated water to avoid drinking directly from streams. To make water safe for drinking, boil the water, or use chemical disinfection or filtration. Boiling water is the most reliable method to make water safe for drinking.
D. Pharmaceutical therapy:
1. Treatment of asymptomatic carriers is not generally recommended.
2. Tinidazole and nitazoxanide are the drugs of choice for treatment:
a. Tinidazole (Tindamax):
i. Adults: 2-g single dose.
ii. Only available in tablet form; it may be crushed by a pharmacist and mixed with flavored syrup.
b. Nitazoxanide (Alinia) has the advantage of treating other intestinal parasites:
i. Age 12 years and older: 500 mg tablet Q12H or 25 mL oral suspension Q12H with food for 3 days.
3. Metronidazole (Flagyl): duration of treatment 5 to 7 days:
a. 500 mg orally BID for 5 to 7 days. OR
b. 250 mg orally TID for 5 to 7 days.
c. For lactating females, alternative dosing is a 2-g single dose, with interruption of breasting feeding for 12 to 24 hours.
d. Available in tablets; oral suspension may be prepared by a pharmacist.
4. Albendazole:
a. 400 mg daily for 5 days.
b. Available in tablets or suspension.
c. Active against other parasites.
5. Paromomycin (Humatin), a nonabsorbable aminoglycoside, is recommended for treatment of symptomatic infection in pregnant females in the second and third trimesters:
a. Adults: 10 mg/kg orally TID for 5 to 10 days.
6. Furazolidone: 100 mg orally QID for 7 to 10 days.
7. Quinacrine: 100 mg orally TID for 5 days.

FOLLOW-UP

A. Relapses after treatment are common, especially in immunocompromised clients:
1. Persistent symptoms may be attributed to drug resistance, noncompliance with dosing, or immunosuppression.
B. If diarrhea persists for 2 weeks or more, secondary evaluation is indicated. Stools should be examined again for blood, leukocytes, and parasites.
C. A repeat course of antimicrobials may be needed for clients with an established diagnosis of giardiasis.
D. Schedule follow-ups at 6 weeks and 6 months after treatment, as indicated.
E. Giardiasis is a nationally notifiable disease. Cases should be reported to the local or state health departments.

CONSULTATION/REFERRAL

A. Consult a physician if the client has no relief of symptoms after completion of therapies.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Treatment of clients during pregnancy is recommended. Giardiasis in pregnancy is associated with dehydration, malabsorption, or severe symptoms.

2. Malabsorptive symptoms may persist because regeneration of functioning intestinal mucosa requires time.

3. Medications to treat giardiasis in pregnancy would include metronidazole and nitazoxanide; the agents that should not be used is Tindamax (first trimester) and no use of quinacrine, Humatin, albendazole, and use with caution furazolidone.

B. Geriatrics:

1. Anemia, weight loss, and anorexia have been the most prominent signs in older adults.

HEMORRHOIDS

DEFINITION

A. Hemorrhoids are clusters of vascular tissues, smooth muscle, and connective tissue of the anal canal. Internal hemorrhoids are above the anorectal line and covered by rectal mucosa. Hemorrhoids can be found at any position of the rectum. Internal hemorrhoids are graded by severity (Table 14.14).

B. External hemorrhoids are below the anorectal line, covered by anal skin, and appear as painless, flaccid skin tags (Figure 14.2).

C. Complications of hemorrhoids include thrombosis, secondary infection, ulceration, abscess, and incontinence.

D. Although rectal bleeding is commonly associated with hemorrhoids, it may be a symptom of other disease processes, such as colorectal cancer (CRC), inflammatory bowel disease (IBD), other colitides, diverticular disease, and angiodysplasia.

INCIDENCE

A. The incidence of hemorrhoids is estimated at 4.4% worldwide. Clients tend to present after utilization and failure of over-the-counter (OTC) treatments. Hemorrhoids are common in people between 45 and 65 years of age. They are uncommon in people younger than age 20, except secondary to pregnancy.

TABLE 14.14 SEVERITY OF HEMORRHOIDS USED TO GUIDE TREATMENT OPTIONS

Grade	Severity
I	The hemorrhoids bleed but do not prolapse.
II	The hemorrhoids prolapse upon defecation but reduce spontaneously.
III	The hemorrhoids prolapse upon defecation and must be reduced manually.
IV	The hemorrhoids are prolapsed and cannot be reduced manually.

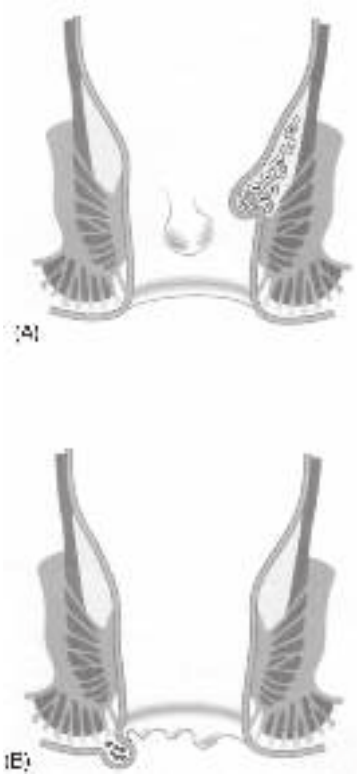

FIGURE 14.2 Internal and external hemorrhoids. (A) Internal hemorrhoid: Covered by a thin sheet of tissue called mucous membrane, an internal hemorrhoid bulges into the rectal opening and may sink a bit during bowel movements. (B) External hemorrhoid: Covered by skin, an external hemorrhoid protrudes from the rectum.

PATHOGENESIS

A. External hemorrhoids develop from the ectoderm and are covered by squamous epithelium.

B. Internal hemorrhoids develop from the embryonic endoderm and are lined with columnar epithelium of anal mucosa.

C. Mechanism is unknown. Prolapse may be initiated by shearing force from passage of large firm stool, by increased venous pressure from portal hypertension or pregnancy, or by straining that occurs with lifting or defecation.

PREDISPOSING FACTORS

A. Pressure and straining with stool associated with constipation.
B. Chronic diarrhea.
C. Pelvic congestion.
D. Poor pelvic musculature.
E. Pregnancy.
F. Episiotomy.
G. Portal hypertension, cirrhosis.
H. Low-fiber diet.
I. Sedentary jobs.
J. Loss of muscle tone due to advanced age.
K. Anal intercourse.
L. Obesity.
M. Colon malignancy.
N. Rectal surgery.
O. Inflammatory bowel disease.

COMMON COMPLAINTS

A. Cardinal features:
  1. Bleeding: painless, bright red bleeding with defecation (internal).
  2. Anal pruritus.
  3. Prolapse.
  4. Pain related to thrombosis.

OTHER SIGNS AND SYMPTOMS

A. Visible prolapsed mass.
B. Incomplete defecation.
C. Leakage of feces (internal hemorrhoids).
D. Excessive moisture.
E. Weakness or fatigue, with anemia.

SUBJECTIVE DATA

A. Review onset and duration of symptoms, especially history of rectal bleeding, prolapse, issues of hygiene, and pain.
B. Review the quantity, color, and timing of any rectal bleeding (bright red, dripping, streaks on toilet paper).
C. Review the client's history of hemorrhoids and treatments, including surgery.
D. Ask the client about recent pregnancy, liver disease, and constipation.
E. Inquire about the client's job and level of daily activity.
F. Review the client's sexual practices for anal intercourse.
G. Review the client's dietary history for fluid intake and sources/amount of fiber.
H. Ask about bowel habits, including frequency, consistency, and ease of evacuation.
I. Review a detailed family history, with emphasis on intestinal disease.
J. Review client's history of coagulation and immune status.

PHYSICAL EXAMINATION

A. Check temperature (if indicated), pulse, respirations, and blood pressure (BP). Measure height and weight to calculate body mass index (BMI).
B. Inspect:
  1. Observation of rectal area for skin tags, prolapse, irritation, fissures, and condyloma:
    a. Internal hemorrhoids are usually not visible unless prolapsed.
    b. External hemorrhoids protrude with straining or standing.
    c. In order to observe and evaluate hemorrhoids/prolapse, ask the client to strain down like they are having a bowel movement.
  2. Using anoscopy, visualize internal rectum for hemorrhoids, masses, or fissures (approximately 20% have concomitant anal fissures).
C. Palpate:
  1. Palpate abdomen for masses and tenderness.
  2. Internal hemorrhoids are usually not palpable unless thrombosed.
D. Rectal examination:
  1. Perform digital rectal examination. (Topical anesthetics may be needed to reduce discomfort from the examination.)
    a. Evaluate rectal tone.
    b. Palpate the prostate.
E. Neurologic examination:
  1. Evaluate the presence of an anal wink (reflexive contraction of the external anal sphincter upon stroking of the skin).

DIAGNOSTIC TESTS

Full evaluation of the large bowel with colonoscopy is recommended for clients with significant abdominal symptoms, weight loss, change in bowel habits, age older than 50, or other risk factors for colonic malignancy.

A. Complete blood count (CBC; hematocrit [Hct] and hemoglobin [Hgb] to evaluate anemia if bleeding is present and also evaluates presence of infection).
B. Anoscopy reveals internal hemorrhoids as bright red to purplish bulges. **Digital rectal examination alone can neither diagnose nor exclude internal hemorrhoids; anoscopy is mandatory.**
C. Sigmoidoscopy and/or flexible sigmoidoscopy.
D. Colonoscopy or CT colonography is reserved for bleeding atypical from hemorrhoids.
E. Air-contrast barium enema (BE) for atypical bleeding.

DIFFERENTIAL DIAGNOSES

A. Hemorrhoids.
B. Condyloma acuminata.
C. Rectal prolapse.
D. Rectal bleeding due to one of the following:
  1. Colorectal cancer.
  2. Polyps.
  3. Anal fissure.
  4. Fistula.
  5. Perianal abscess.
  6. IBD, including ulcerative colitis (UC) and Crohn's disease (CD).
  7. Diverticulitis.
  8. Pelvic tumor.

PLAN

A. General interventions:
  1. No treatment is necessary if the client is asymptomatic, except for maintaining regular bowel habits and performing comfort measures.
B. Client teaching: *See Client Teaching Guides for this chapter, "Hemorrhoids" and "Tips to Relieve Constipation."*
C. Dietary management:
  1. High-fiber diet and an adequate fluid intake are recommended by the American College of Gastroenterology (ACG) as the first-line treatment. High-fiber diet and adequate fluid intake should be continued indefinitely to maintain a soft bulky stool that can be passed without straining (see Appendix B, "High-Fiber Diet").
D. Medical and surgical management:
  1. Use warm sitz baths up to three times a day for irritation and pruritus.
  2. Conservative treatment for thrombosed hemorrhoid includes lying prone and applying ice pack to area.
  3. Incision and evacuation of thrombosis or clot may be performed under local anesthesia. Other treatments for thrombosed hemorrhoids noted in clinical trials have included the following:
    a. Topical nitroglycerin 0.2% topical ointment for temporary analgesia. The most common side effect was headache.
    b. Topical nifedipine: Use with caution due to hypotension.
    c. Injection of botulinum toxin has been used for treatment of chronic anal fissures if no response to conservative or pharmacologic treatment.

4. Symptomatic grade I, grade II, and some grade III hemorrhoids may be treated by the following:

a. Rubber band ligation is the treatment of choice for grades I and II hemorrhoids. Rubber band ligation is the most widely used and is associated with fewer complications than surgery:

i. Rubber band ligation is generally contraindicated in clients with advanced cirrhosis due to the risk of profound secondary bleeding following the procedure. Injection sclerotherapy and hemorrhoidectomy are used in refractory cases.

ii. Rubber band ligation is not recommended in clients with current use of anticoagulant or antiplatelet drugs due to the risk of secondary bleeding. Conservative therapy is the mainstay.

b. Bipolar, infrared, and laser coagulation (may require more than one treatment).

c. Sclerotherapy and cryotherapy are used infrequently.

d. Stapled hemorrhoidopexy can be performed in clients with grade III hemorrhoids.

5. External hemorrhoids usually do not require surgical therapy except in cases of thrombosis. For selective grade III and grade IV internal and strangulated hemorrhoids that fail medical and nonoperative therapies, surgical treatment is required:

a. **Stapled hemorrhoidopexy has a faster recovery but has a higher recurrence rate.**

b. **Hemorrhoidectomy is the treatment of last choice because it requires hospitalization and an extended recovery period, and it risks compromising competence of the anal sphincter.**

6. Hemorrhoidectomy complications include the following:

a. Urinary retention.
b. Urinary tract infection (UTI).
c. Fecal impaction.
d. Pain.
e. Hemorrhage.
f. Stricture formation (1%) or sphincter damage (rare).
g. Nonhealing wound.
h. Fistula formation.
i. Anal leakage.

7. AIDS is a contraindication to nonsurgical procedures; conservative therapy is recommended, especially if immunosuppressed.

E. Pharmaceutical therapy:

1. Drug of choice: bulk-forming agents such as psyllium seed (Metamucil), methylcellulose (Citrucel), or calcium polycarbophil (Fibercon), one to three teaspoons in 8 oz of liquid TID. Maintenance dose is one to three teaspoons after dinner.

2. Plant-based soluble fiber, (Benefiber) containing wheat dextrose and cellulose, 2 teaspoons powder with 4 to 8 oz of water 2 to 3 x a day or 3 tablets up to three times a day.

3. Stool softener: docusate sodium (Colace) or docusate calcium (Doxidan) 100 mg TID.

4. For irritation and pruritus, topical creams and anesthetics are found in OTC products such as Anusol, pramoxine HCl (Tronolane Cream), Preparation H, and topical hydrocortisone preparations.

5. Acetaminophen is the drug of choice for pain.

FOLLOW-UP

A. None necessary if resolution occurs and the client is asymptomatic.

B. Reevaluate the client in 2 weeks for further treatment if symptoms persist.

C. Evaluate the client with an intervention in 7 to 10 days.

EMERGENT ISSUES/INSTRUCTIONS

A. The onset of urinary retention and fever immediately after an office-based procedure may be the initial sign of perianal sepsis and mandates emergent client evaluation.

CONSULTATION/REFERRAL

A. Refer the client with acute thrombosis of external hemorrhoids to a physician.

B. Refer the client to a colorectal surgeon if hemorrhoids bleed repeatedly, prolapse, produce intractable pain, or are thrombosed, and if 3 to 5 consecutive days of treatment do not provide relief.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Hemorrhoids are common in pregnancy. Most clients revert to their previous asymptomatic state after pregnancy.

2. Conservative treatment is recommended with excision of thrombosed external hemorrhoids only if necessary.

3. Surgical treatment is contraindicated in pregnancy due to the risk of inducing labor.

4. Labor, which results in pressure on the pelvic floor by the presenting part of the fetus and the expulsive efforts of the mother, may aggravate hemorrhoids, causing protrusion and inflammation during the puerperium. Hemorrhoids may be pushed back after delivery to prevent them from becoming swollen and painful.

B. Geriatrics:

1. Hemorrhoids are common in older adult with intermittent and low-volume hematochezia, which often only coats the stool.

2. Prolapse of rectal mucosa is more common in older adults.

3. Older adults are at an increased risk of lower gastrointestinal (GI) bleeding secondary to the increased incidence of comorbid illness and more polypharmacy (anticoagulants and nonsteroidal anti-inflammatory drugs [NSAIDs]). Colonoscopy is recommended in the geriatric population to exclude malignancy or other underlying disease.

HEPATITIS A

DEFINITION

A. Hepatitis A is an acute self-limited illness with inflammation of the liver caused by a viral infection. Hepatitis A virus (HAV) is spread by viral shedding. Acute cases of hepatitis A are reportable to the public health department.

B. Case definition: an acute illness with a discrete onset of any sign or symptoms consistent with acute viral hepatitis (e.g., fever, headache, malaise, anorexia, nausea, vomiting, diarrhea, ▶

and abdominal pain) AND either jaundice or elevated serum alanine aminotransferase (ALT) or aspartate transaminase (AST) levels.

C. The average incubation period is 28 days (range 15–50 days).

D. The highest titers of HAV in the stool of infected clients occur 1 to 2 weeks before onset of illness (jaundice or elevation of liver enzymes), during which time clients are most likely to transmit infection. Risk subsequently diminishes and is minimal in the week after onset of jaundice. Up to 70% of clients will have jaundice. Persons with chronic liver disease (CLD) are at risk for fulminant hepatitis.

E. Duration of HAV infection is typically 8 weeks, but prolonged disease, as long as 6 months, can occur in 10% to 15% of symptomatic clients.

F. The major methods of prevention include improved sanitation of water sources, improved hygiene practice prior to food preparation and diaper changes, immunization with the hepatitis A vaccine, and administration of immune globulin (IG).

G. Hepatitis A does not reoccur because immunoglobulin G (IgG) antibodies to HAV provide lifelong protection.

INCIDENCE

A. From 30% to 35% of acute hepatitis cases in the United States are due to HAV. In developing countries, where infection is endemic, most people are infected during the first decade of life. Multistate HAV outbreaks have recently occurred in the United States:

1. September 2021: Famous Anthony's restaurants, 14 infected people ate at three of the sites according to the Virginia Department of Health.

2. August 2016: multiple states, linked to frozen strawberries and in Hawaii linked to raw scallops.

3. March 2017 to 2018: multiple states among people who used drugs and/or people who are homeless.

B. Outbreak in custodial institutions accounts for about 10% to 15% of reported HAV in the United States.

C. The incidence of mortality from HAV is 0% to 2%. The single most important determinant of illness severity is age; a direct correlation between increasing age and the likelihood of adverse events is present. Most deaths from acute HAV occur in persons older than 50 years.

PATHOGENESIS

A. HAV is a small, RNA enterovirus classified as a member of the picornavirus group. Viral replication depends on hepatocyte uptake and synthesis, and assembly occurs exclusively in liver cells. Transmission of HAV is person-to-person, primarily by the fecal–oral route and parenterally. The incubation period is 15 to 50 days, with an average of 25 to 30 days.

B. Common-source, food- and waterborne epidemics have occurred, including several caused by shellfish contaminated with human sewage. Nosocomial outbreaks have occurred as a result of shedding of HAV from infected, asymptomatic neonates, children, or adults.

PREDISPOSING FACTORS

A. Primarily, infections in the United States result from travel to another country where HAV transmission is common.

B. Person-to-person transmission contact through the fecal–oral route:

1. Contact with a child who attends a childcare center (especially with children in diapers).

2. Sex among men who have sex with men (MSM).

3. Vertical transmission from mother to fetus (limited).

4. Personal contact with a newly arriving international adoptees with high or intermediate hepatitis A endemicity.

5. Injection and noninjection drug users.

C. Exposure to contaminated food or water:

1. Uncooked foods contaminated with HAV.

2. Cooked foods that are not heated to temperatures that are capable of killing the virus.

3. Foods contaminated after cooking (infected food handlers).

4. Freezing does not inactivate HAV.

5. Waterborne outbreaks from poor sanitation. In the United States, outbreaks of HAV caused by flooding have not been documented.

COMMON COMPLAINTS

A. Malaise.

B. Anorexia.

C. Nausea.

D. Low-grade fever.

E. Jaundice: icteric phase (70% of older children and adults):

1. Tea-colored urine.

2. Clay-colored stool.

3. Abdominal pain.

4. Pruritus.

5. Enlarged liver.

F. Fatigue.

G. Joint pain.

OTHER SIGNS AND SYMPTOMS

A. Adults: severe, prolonged course with fatigue, headache, vomiting, and symptoms noted earlier.

B. Relapsing hepatitis A is more common in older adults. There generally has been a protracted course of symptoms and a relapse of symptoms following an apparent resolution.

SUBJECTIVE DATA

A. Review duration, onset, and severity of symptoms, including specifics about urine or stool color changes.

B. Ask the client about family members and sexual contacts with similar symptoms.

C. Review the client's history of blood transfusions, intravenous (IV) drug use, and alcohol abuse.

D. Inquire about occupational exposure.

E. Ask the client about recent international travel, eating off street carts potentially not sanitized or exposure to newly arrived international adoptees.

F. Review immunization status.

G. Review medications for a possible Tylenol overdose or ecstasy use as a cause of acute drug-induced liver injury.

PHYSICAL EXAMINATION

A. Check temperature (acute illness), pulse, respirations, blood pressure (BP), and weight.

B. Inspect:

1. Note general appearance.

2. Inspect the skin for slight jaundice or rash.

3. Inspect mucous membranes and nail beds.

4. Inspect eyes for yellow sclera.

C. Auscultate:

1. Lung fields, all quadrants of the abdomen.

2. Heart.

▶

D. Percuss:
  1. Abdomen.
E. Palpate:
  1. Palpate all quadrants of the abdomen for masses, liver tenderness, and hepatosplenomegaly (about 10% of cases).

DIAGNOSTIC TESTS

A. Nucleic acid testing (NAT) is the gold standard for diagnosis of viremic stages of hepatitis infection.
B. Because the clinical characteristics are the same for all types of acute viral hepatitis, HAV must be confirmed by a positive serologic test for immunoglobulin M (IgM) antibody to HAV (anti-HAV) or the case must meet the clinical case definition and occurs in a person who has an epidemiologic link with a person who has laboratory-confirmed hepatitis A (e.g., household or sexual contact with an infected person during the 15–50 days before the onset of symptoms):
  1. Serum IgM presents at onset of illness and disappears within 4 months, generally indicating current or recent infection. However, it may persist for 6 months or longer.
  2. Presence of IgG anti-HAV antibodies without virus-specific IgM indicates past infection and immunity.
C. Liver function studies, including ALT, AST, lactate dehydrogenase (LDH), and alkaline phosphatase (ALP).
D. Bilirubin, direct and indirect.
E. Complete blood count (CBC).
F. Prothrombin time (PT).
G. Imaging studies are usually not indicated for hepatitis A infection. An ultrasound may be used to exclude other pathology.

DIFFERENTIAL DIAGNOSES

A. HAV.
B. Mononucleosis.
C. Cancer.
D. Obstructive jaundice.
E. Alcoholic hepatitis or cirrhosis.
F. Hepatotoxic drug use:
  1. Drug-induced liver injury (e.g., excessive Tylenol, Ecstasy).
  2. Drug-induced hypersensitivity reaction (e.g., sulfasalazine hypersensitivity).
G. Food poisoning.
H. Exclusion of other hepatitis types.
I. Cytomegalovirus (CMV).
J. Acute HIV infection.

PLAN

A. General interventions:
  1. Contact precautions are recommended for diapered and/or incontinent clients for 1 week after onset of symptoms.
  2. Children and adults with acute HAV infection should be excluded from school, work, and childcare centers for 1 week after onset of illness.
  3. Hepatitis A is self-limiting and does not require therapy. Treatment is supportive:
    a. Limit activities secondary to malaise.
    b. Alcohol consumption is not advised.
    c. Adults who work as food handlers should not work for 1 week after onset of the illness.
  4. Encourage strict handwashing.
B. Client teaching: *See Client Teaching Guide for this chapter,"Jaundice and Hepatitis."*
  1. Teach the client that major methods for prevention are improved sanitation (e.g., of water sources and in food preparation) and personal hygiene.
  2. Food and travel precautions include the following:
    a. Avoid uncontrolled water resources: Use bottled water, boil water, or add iodine to inactivate the virus.
    b. Avoid raw shellfish.
    c. Avoid uncooked foods.
    d. All fruits should be washed and peeled.
  3. HAV can be killed by cleaning with a freshly prepared solution of 1:100 dilution of bleach to water.
C. Dietary management:
  1. Encourage optimum nutrition.
D. Pharmaceutical therapy:
  1. HAV vaccine preexposure is preferred in all populations unless contraindicated.
  2. Immune globulin (IG; GamaSTAN S/D): preexposure administration is 0.02 mL/kg, two doses intramuscularly (IM).
  3. Travel preexposure prophylaxis to endemic areas:
    a. Up to 1 month of travel: 0.1 mL/kg.
    b. Up to 2 months of travel: 0.2 mL/kg.
    c. 2 months of travel or longer: repeat dose of 0.2 mL/kg every 2 months.
  4. Persons who have been exposed recently to HAV and who have not been vaccinated should be administered one dose of single-antigen hepatitis A vaccine or IG as soon as possible, **within 2 weeks after exposure:**
    a. Healthy persons aged ≥12 months who have been exposed to HAV within the prior 14 days and have not previously completed the two-dose HepA vaccine series should receive a single dose of HepA vaccine as soon as possible. In addition to HepA vaccine, IG (0.1 mL/kg) may be administered to persons aged >40 years depending on the providers' risk assessment. For long-term immunity, the HepA vaccine series should be completed with a second dose at least 6 months after the first dose; the second dose is not necessary for postexposure prophylaxis (PEP).
    b. Persons aged ≥12 months who are immunocompromised and persons with chronic liver disease who have been exposed to HAV within the prior 14 days and have not previously completed the two-dose HepA vaccine series should receive both IG (0.1 mL/kg) and HepA vaccine simultaneously in a different anatomic site as soon as possible after exposure. For long-term immunity, the HepA vaccine series should be completed with a second dose at least 6 months after the first dose; the second dose is not necessary for PEP.
    c. For infants aged <12 months and persons for whom vaccine is contraindicated (who are allergic to a vaccine component) should receive IG (0.1 mL/kg) instead of vaccine as soon as possible and within 2 weeks after exposure.
    d. Postexposure prophylaxis with IG is also recommended for the following:
      i. Household and sexual contacts of infected persons.
      ii. Newborn infants of HAV-infected mothers.
      iii. Childcare center staff, children, and their household contacts.
      iv. Students when transmission within school is documented.
      v. Staff in institutions and hospitals.

TABLE 14.15 DOSAGES AND SCHEDULES FOR HEPATITIS A VACCINES

HAVRIX				
Licensed dosages and schedules for HAVRIX[a]				
Age	**Dose (ELISA units)[b]**	**Volume (mL)**	**Number of Doses**	**Schedule (Months)[c]**
12 months–18 years	720	0.5	2	0, 6–12
≥19 years	1,440	1.0	2	0, 6–12
VAQTA				
Licensed dosages and schedules for VAQTA[d]				
Age	**Dose (U)[e]**	**Volume (mL)**	**Number of Doses**	**Schedule (Months)[f]**
12 months–18 years	25	0.5	2	0, 6–18
≥19 years	50	1.0	2	0, 6–18
TWINRIX				
Licensed dosages and schedules for TWINRIX[g]				
Age	**Dose (ELISA Units)[h]**	**Volume (mL)**	**Number of Doses**	**Schedule[i]**
≥18 years	720	1.0	3	Standard dosing schedule 0, 1, 6 months
≥18 years	720	1.0	4	Accelerated dosing schedule 0, 7, 21–30 days + 12 months

[a]Hepatitis A vaccine, inactivated, GlaxoSmithKline.

[b]Enzyme-linked immunosorbent assay units.

[c]0 months represents timing of the initial dose; subsequent numbers represent months after the initial dose.

[d]Hepatitis A vaccine, inactivated, Merck & Co., Inc.

[e]Units.

[f]0 months represents timing of the initial dose; subsequent numbers represent months after the initial dose.

[g]Combined hepatitis A and hepatitis B vaccine, inactivated, GlaxoSmithKline.

[h]Enzyme-linked immunosorbent assay units.

[i]This four-dose schedule enables clients to receive three doses in 21 days; this schedule is used prior to planned exposure with short notice and requires a fourth dose at 12 months.

vi. People who ingested HAV-contaminated food or water within 2 weeks of last exposure.

5. Vaccines:
- a. Two inactivated HAV vaccines, Havrix and Vaqta, are available in the United States.
- b. Twinrix is a combination hepatitis A (Havrix) and hepatitis B (Engerix-B) vaccine available in the United States for ages 18 years or older (Table 14.15).

6. HAV vaccine is recommended for the following:
- a. Children 2 years and older in defined and circumscribed communities with high endemic rates and/or periodic outbreaks of HAV infection.
- b. Clients with chronic lung disease.
- c. Homosexual and bisexual males.
- d. Users of injections and illicit drugs.
- e. Those with occupational risk of exposure, such as handlers of nonhuman primates and persons working with HAV in a laboratory setting.
- f. Travelers who need preexposure immunoprophylaxis.
- g. Clients with clotting factor disorders such as hemophilia.

7. HAV vaccine is potentially indicated for the following:
- a. Childcare center staff and children.
- b. Clients and staff in custodial care institutions.
- c. Hospital personnel.
- d. Food handlers; **however, routine HAV for food handlers is not recommended.**
- e. Clients with hemophilia.

8. HAV vaccine may be administered simultaneously with other vaccines, but it should be given in a separate syringe and at a separate site.

9. The need for an additional hepatitis A booster beyond the two-dose primary immunizations has not been established.

10. Immune response in immunocompromised clients such as those with HIV may be suboptimal. The vaccine ▶

is inactivated; therefore, no special precautions are needed when vaccinating immunocompromised clients.

11. Vaccine side effects are generally mild and may include the following:

a. Local pain at the immunization site.

b. Localized induration at the injection site.

12. Tylenol may be administered for fever and arthralgia but is strictly limited to a maximum dose of 3 to 4 g/d in adults.

13. Antiemetic agents as needed for nausea and vomiting.

FOLLOW-UP

A. Dehydration may require hospital admission.

B. Follow-up in 2 weeks for reevaluation.

C. Check for hepatitis B immunity and vaccinate.

D. Acute hepatitis A is reportable to the public health department.

E. Prolonged cholestasis may follow an acute infection.

CONSULTATION/REFERRAL

A. Consult a physician if necessary.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Pregnant females recently exposed to HAV should receive prophylactic gamma globulin.

2. HAV is an inactivated vaccine and is considered safe during pregnancy.

3. HAV infection during pregnancy is associated with increased risk of premature labor and delivery.

B. Adults:

1. In the United States, the lowest rate of HAV infection is in people older than 40.

C. Geriatrics:

1. Older adults have greater numbers of HAV antibodies, resulting in fewer cases.

2. Symptoms are usually vague. Fatigue, pruritus, and the classic symptoms of jaundice, hepatomegaly, and liver tenderness are commonly absent in older adults.

3. Diagnostic test results in older adults include elevated bilirubin, lower or normal transaminase and ALP, and normal ultrasonography.

4. Older adults with acute HAV are likely to have more profound hepatocellular dysfunction with frequent jaundice and coagulopathy, as well as a higher incidence of complications such as prolonged cholestasis, pancreatitis, and ascites.

HEPATITIS B

DEFINITION

A. The hepatitis B virus (HBV) causes inflammation of the liver. Acute HBV infection cannot be distinguished from other forms of acute viral hepatitis on the basis of clinical signs and symptoms or nonspecific laboratory findings. Acutely infected clients may be asymptomatic or symptomatic. The likelihood of developing symptoms of acute hepatitis is age-dependent.

B. The presence of hepatitis B surface antigen (HBsAg) establishes the diagnosis of hepatitis B. Chronic HBV (CHB) versus acute infection is defined as the presence of HBsAg in serum for at least 6 months. Diagnostic criteria and clinical terms are available at the 2018 American Association for the Study of Liver Disease (AASLD) website located at www.aasld.org/publications/practice-guidelines.

C. The levels of serum alanine transaminase (ALT) and HBV DNA as well as liver fibrosis are important predictors of long-term outcome for decisions for antiviral treatment as well as treatment response.

D. Staging of liver disease severity using a liver biopsy or noninvasive tests such as elastography is important in guiding surveillance and assisting with treatment decisions.

E. Ten genotypes of HBV have been identified (A through J):

1. HBV genotypes A to H have been found in the United States, with genotypes A, B, and C being most prevalent.

F. Guidelines for monitoring clients who are CHB who are not currently on treatment as well as the management of CHB special populations are available on the AASLD website.

G. The Advisory Committee on Immunization Practices (ACIP) recommends that the following people receive hepatitis B vaccination:

1. All infants.

2. Unvaccinated children younger than 19 years.

3. People at risk for infection by sexual exposure:

a. Sex partners of HbsAg-positive persons.

b. Sexually active people who are not in a long-term, mutually monogamous relationship (e.g., persons with more than one sex partner during the previous 6 months).

c. People seeking evaluation or treatment for a sexually transmitted infection (STI).

d. Men who have sex with men (MSM).

4. People at risk for infection by percutaneous or mucosal exposure to blood:

a. Current or recent injection drug users.

b. Household contacts of people who are HbsAg-positive.

c. Residents and staff of facilities for developmentally disabled people.

d. Healthcare and public safety personnel with reasonably anticipated risk for exposure to blood or blood-contaminated body fluids.

e. Individuals on hemodialysis, including peritoneal dialysis and home dialysis.

f. People with diabetes age 19 to 59 years; persons with diabetes age >60 years at the discretion of the treating clinician.

5. International travelers to countries with high or intermediate levels of endemic HBV infection (HbsAg prevalence of ≥2%).

6. People with hepatitis C infection.

7. People with chronic liver disease (CLD; cirrhosis, fatty liver disease, alcoholic liver disease [ALD], autoimmune hepatitis, and an ALT or aspartate transaminase [AST] level greater than twice the upper limit of normal).

8. HIV-infected persons.

9. People who are incarcerated.

10. All other people seeking protection from HBV infection.

INCIDENCE

A. The majority of children and adults with CHB in the United States are immigrants, have immigrant parents, or became exposed through other close household contacts.

B. In 2016, the Centers for Disease Control and Prevention (CDC) noted the overall incidence of HBV was one case per 100,000. In 2019, 5.9 cases per 100,000 population; 47% occurred among persons aged 30 to 49 years.

C. HBV is more severe among adults older than 60 years.

D. Approximately 95% of adults recover completely from HBV infection and do not become chronically infected.

E. Approximately 25% of those who become chronically infected during childhood and 15% of those who become chronically infected after childhood die prematurely from cirrhosis or liver cancer, and the majority remain asymptomatic until onset of cirrhosis or end-stage liver disease.

PATHOGENESIS

A. HBV is a hepadnavirus. HBV-related liver injury is largely caused by immune-mediated mechanisms mediated via cytotoxic T-lymphocyte lysis of infected hepatocytes. The virus is transmitted through perinatal, percutaneous, sexual exposure, and close person–person contact body fluids, such as wound exudates, semen, cervical secretions, and saliva that are HBsAg-positive. It is not transmitted by the fecal–oral route or by water. Blood and serum contain the highest concentration of virus; saliva contains the lowest.

B. The incubation period is 45 to 160 days (2–5 months), with an average of 120 days. An infected person can infect others 4 to 6 weeks before symptoms appear and for an unpredictable time thereafter.

C. The production of antibodies against HBsAg confers protective immunity and can be detected in clients who have recovered from HBV or in those clients who have been vaccinated. The immunoglobulin M (IgM) subtype indicates an acute infection or reactivation. Immunoglobulin G (IgG) subtype indicates chronic infection.

PREDISPOSING FACTORS

A. Higher prevalence populations born in regions of high or intermediate HBV prevalence of ≥2% including (the percentage is the area of the country) Africa, Asia, South Pacific, Middle East, Eastern and Western Europe, North America/Alaskan Eskimos, Mexico and Central America, Australia, and the Caribbean.

B. United States born persons not vaccinated as an infant whose parents were born in regions with high HBV endemicity (≥8%).

C. MSM.

D. Drug use, sharing needles.

E. Occupational exposure to blood or blood-contaminated body fluids.

F. Household, needle-sharing, and sexual contacts of HbsAg-positive persons.

G. Perinatal exposure, by vertical infection.

H. Receiving blood transfusions or blood products for hemophilia.

I. End-stage renal disease, including predialysis, hemodialysis, peritoneal dialysis.

J. Staffing or residing in institutions.

K. International travel.

L. Incarceration in long-term correction facilities.

M. Percutaneous contact with inanimate objects contaminated with HBV; virus can survive 1 week or longer.

COMMON COMPLAINTS

A. The following symptoms occur in the acute phase of HBV:

1. Anicteric hepatitis: asymptomatic (majority of clients).
2. Icteric hepatitis: associated with a prodromal period:
   a. Anorexia.
   b. Nausea and vomiting.
   c. Low-grade fever.
   d. Myalgia.
   e. Fatigue.
   f. Aversion to food and cigarettes.
   g. Intermittent, mild to moderate right upper quadrant (RUQ) and epigastric pain.
   h. Tea-colored urine.
   i. Clay-colored bowel movements (BMs).
3. Hyperacute, acute, and subacute hepatitis symptoms:
   a. Hepatic encephalopathy (HE).
   b. Somnolence.
   c. Disturbances in sleep pattern.
   d. Mental confusion.
   e. Coma.

B. The following symptoms occur in the chronic phase of HBV:

1. Asymptomatic: may be healthy carriers without any evidence of active disease.
2. During the replicative state, common symptoms are:
   a. Fatigue.
   b. Anorexia.
   c. Nausea.
   d. Mild upper quadrant pain or discomfort.
   e. Hepatic decompensation.

OTHER SIGNS AND SYMPTOMS

A. Icteric phase (10 days after the appearance of constitutional symptoms and lasts for 1–3 months):

1. Jaundice of sclera and skin.
2. Tea-colored urine.
3. Clay-colored stools, often precede jaundice.
4. RUQ tenderness.
5. Hepatomegaly.

SUBJECTIVE DATA

A. Review onset, duration, course, and severity of symptoms. Ask the client for specifics about urine and stool color.

B. Ask the client about other family members and sexual contacts with similar symptoms.

C. Review family history of hepatocellular carcinoma (HCC).

D. Discuss the client's history of blood transfusions, tattoos, incarceration, intravenous (IV) drug use, and alcohol abuse.

E. Ask about high-risk sexual practices.

F. Review the client's occupational exposure.

G. Inquire about recent international travel.

H. Establish the client's usual weight; note amount of any weight lost and over what length of time.

I. Has the client ever had a liver biopsy?

J. Review for a history of variceal bleeding.

K. Ask if the client has ever been treated for any type of hepatitis?

1. How long ago was the client treated?
2. Did the client complete therapy? If not, why?
3. What was the client's response to therapy (e.g., nonresponder, relapser)?

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, blood pressure (BP), and height and weight to calculate body mass index (BMI).
B. Inspect:
  1. Observe general appearance, muscle wasting, ascites, and peripheral edema.
  2. Inspect the skin for tattoos and piercings, jaundice, palmar erythema, rash, spider nevi, spider angioma, and dehydration.
  3. Inspect the eyes for yellow sclera.
  4. Inspect the mucous membranes and nail beds for clubbing and cyanosis.
  5. Evaluate for the presence of gynecomastia and small testes.
C. Auscultate:
  1. Auscultate lung fields and the heart.
  2. Auscultate all quadrants of the abdomen. Evaluate for an abdominal bruit.
D. Percuss:
  1. Abdomen.
E. Palpate:
  1. Palpate all quadrants of the abdomen for masses, liver enlargement or tenderness, characteristics of cirrhosis, and hepatosplenomegaly.
  2. Palpate the lymph nodes for lymphadenopathy.
  3. Palpate for testicular atrophy.

DIAGNOSTIC TESTS

A. Diagnostic test for HBV antigens and antibodies (Table 14.16).
B. Complete blood count (CBC) with platelets.
C. Complete liver panel:
  1. AST/ALT.
  2. Total bilirubin.
  3. Prothrombin time (PT)/international normalized ratio (INR).
  4. Albumin.
D. Alkaline phosphatase (ALP).
E. Other viral infection markers.
F. Alpha-fetoprotein (AFP; rule out other causes of liver disease).
G. Gamma-glutamyl transpeptidase (GGT).
H. Serum iron levels (screen for hemochromatosis).
I. Thyroid profile.
J. Blood glucose/A1C.
K. After HBV confirmation:
  1. HBV genotype.
  2. HBV DNA viral load.
L. Serum fibrosis panel:
  1. Aspartate platelet ratio index (APRI): AST-to-platelet ratio index used for estimating hepatic fibrosis. Online calculator can be found at: www.hepatitisc.uw.edu/page/clinical-calculators/apri.
  2. Fibrosis-4 (FIB-4) is an index for estimating hepatic fibrosis based on a calculation derived from AST, ALT, platelet concentrations, and age. Online calculator can be found at www.hepatitisc.uw.edu/page/clinical-calculators/fib-4.
  3. FibroTest (FibroSure): commercial biomarker test that uses the results of six blood markers to estimate hepatic fibrosis.
M. Imaging:
  1. Ultrasonography: FibroScan: Transient shear-wave elastography measures liver stiffness as a surrogate for fibrosis.
  2. CT or MRI to help exclude biliary obstruction.
N. Liver biopsy to assess the severity of disease.
O. Pregnancy testing before antiviral therapy.
P. Before oral antiviral therapy is introduced, all clients should be screened for HIV.
Q. Hepatitis C virus (HCV) and HIV testing to rule out coinfection.

DIFFERENTIAL DIAGNOSES

A. Hepatitis B.
B. Exclusion of other types of hepatitis (A, C, D, E, viral, or autoimmune hepatitis).
C. Infectious mononucleosis.
D. Hepatotoxic drug ingestion, for example, chloramphenicol, acetaminophen, or methyldopa.
E. Metastatic cancer to the liver.
F. Alcoholic cirrhosis.
G. Hemochromatosis.
H. Wilson disease.

PLAN

A. General interventions:
  1. Before any form of HBV therapy is started, and optimally at the first presentation, the client needs to be provided with information about the natural history of chronic ▶

TABLE 14.16 DIAGNOSTIC TESTS FOR HEPATITIS B ANTIGENS AND ANTIBODIES

Factors to Be Tested	HBV Antigen or Antibody	Indication
HBsAg	HBsAg	Detects acutely or chronically infected; antigen used in hepatitis B vaccine
Anti-HBs	Antibody to HBsAg	Identifies resolved HBV infections; determines immunity after immunization
HBeAg	HBeAg	Identifies at risk of transmitting HBV
Anti-HBe	Antibody to HBeAg	Identifies lower risk of transmitting HBV
Anti-HBc	Antibody to HBcAg; IgM (HBcAg)	Identifies acute, resolved, or chronic HBV infection; anti-HBc not present after immunization
IgM anti HBc	IgM antibody to HBcAg	Identifies acute or recent HBV infections (includes HBsAg-negative during the window phase of infection)

HB, hepatitis B; HBcAg; hepatitis B core antigen; HBeAg, hepatitis B e-antigen; HBsAg, hepatitis B surface antigen; HBV, hepatitis B virus; IgM, immunoglobulin M.

hepatitis B infection and the fact that most infections remain entirely without symptoms even in those with severe disease, so there is a need for regular lifelong monitoring.

B. Client teaching: *See Client Teaching Guide for this chapter, "Jaundice and Hepatitis."*

1. Instruct the client to avoid sexual activity until they are free of HBsAg.

2. Recommend abstinence or minimal alcohol consumption. More than seven drinks of alcohol per week for females and more than 14 drinks per week for males are associated with an increase of cirrhosis and HCC.

3. Any blood spills should be cleaned using 1:10 dilution of bleach to water for disinfecting the area. Gloves should be worn when cleaning up any blood spills.

4. There are no dietary restrictions with acute and chronic hepatitis (without cirrhosis).

5. Diets for decompensated cirrhosis, portal hypertension, or encephalopathy are prescribed:

a. Low-sodium diet (1.5 g/d).

b. High-protein diet (white-meat protein, e.g., pork, turkey, and fish).

c. Fluid restriction of 1.5 L/d in the presence of hyponatremia.

C. Pharmaceutical therapy:

1. The goal of treatment is to prevent progression to cirrhosis, hepatic failure, and hepatocellular cancer:

a. Primary prevention includes vaccination. Vaccination is up to 95% effective. Immunizations schedules are located on the CDC website. https://www.cdc.gov/hepatitis/hbv/hbvfaq.htm#D4.

i. There are three single-antigen hepatitis B vaccines (ENGERIX-B, RECOMBIVAX BH, and HEPLISAV-B).

ii. There are three combination vaccines:

1) PEDIARIX: combined hepatitis B; diphtheria, tetanus, acellular pertussis (DTaP); and inactivated poliovirus (IPV) vaccine. Cannot be administered before age 6 weeks or after age 7 years.

2) TWINRIX: combined hepatitis A and hepatitis B vaccine. Recommended for persons age ≥18 years who are at increased risk for both hepatitis A virus (HAV) and HBV infections.

3) **Vaxelis**: combination diphtheria, tetanus, acellular pertussis, IPV, *Haemophilus influenzae* type b, and hepatitis B.

iii. There is one three-antigen hepatitis B vaccine (PreHevbrio).

b. If serum HBV DNA exceeds 1,000 IU/mL, antiviral therapy is recommended. See Table 14.17 for current HBV therapy:

i. All clients need to be screened for HIV prior to antiviral therapy.

ii. Females need to have a pregnancy test prior to therapy.

iii. All antivirals require close monitoring due to side effect profiles.

iv. Dose adjustment is required in the presence of renal impairment, dialysis, and is used with caution in clients with a history of pancreatitis.

c. Orthotopic liver transplantation (OLT) is the treatment of choice for clients with fulminant hepatic failure who do not recover and for clients with end-stage liver disease.

d. Immunize against hepatitis A for individuals with CHB if not already immune.

FOLLOW-UP

A. Laboratory monitoring:

1. Screening should be performed using both HBsAg and anti-HBs.

2. Screening for anti-HBc (hepatitis B core antigen) to determine prior exposure is not routinely recommended:

a. Test in clients who have HIV infection.

b. Test persons about to initiate HCV or anticancer and other immunosuppressive therapy or renal analysis and in donated blood.

3. Monitor liver function (ALT) every 3 to 6 months for active disease.

4. Monitor HBeAg every 3 to 6 months dependent on ALT levels.

5. Monitor CBC and creatinine every month (1–2 days prior to treatment).

6. Monitor HBV DNA viral load every 3 to 6 months when the client is on treatment in the reactivation phase.

B. Laboratory, physical examination, and psychosocial evaluation are required for antiviral therapy:

1. Monitor for mental dysfunction related to interferon (IFN), including depression, psychosis, aggressive behavior, hallucinations, violent behavior, suicidal ideation, suicide attempt, and homicidal ideation (rare), even without history of psychiatric illness.

C. Risk of exposure to HBsAg ceases when antigen disappears from the bloodstream, usually within 6 to 8 weeks of infection.

D. HBV reactivation is the abrupt reappearance or rise in HBV DNA in a client with previously inactive or resolved hepatitis B. It is often accompanied by a flare in disease activity with elevation of liver enzymes with or without symptoms, and can be severe, resulting in death.

1. Clients at highest risk for HBV reactivation:

a. Clients undergoing cancer chemotherapy.

b. Clients taking immunosuppressive therapy including the following:

i. Black box warning for rituximab and other drugs that target B lymphocytes.

ii. High-dose steroids.

iii. Anti-tumor necrosis factor (TNF) agents.

c. Clients with HIV who have discontinued HBV active antiviral drugs.

d. Clients undergoing solid organ or bone marrow transplantation.

e. Clients coinfected with hepatitis C.

CONSULTATION/REFERRAL

A. Clients with persistently elevated serum transaminase concentrations (exceeding twice the upper limits of normal), as well as those with elevated serum alpha-fetoprotein concentrations or abnormal ultrasounds, should be referred to a gastroenterologist for further management.

B. Clients who are coinfected with HBV or HIV or have end-stage renal disease should be referred to and managed by a hepatologist, infectious disease provider, or gastroenterologist for treatment.

C. Clients with decompensated cirrhosis should be referred for consideration of liver transplantation.

D. HBV-infected pregnant clients with cirrhosis should be managed by a high-risk OB practice and should be treated with tenofovir disoproxil fumarate (TDF) to prevent decompensation.

TABLE 14.17 APPROVED ANTIVIRAL THERAPIES FOR ADULTS WITH CHRONIC HEPATITIS B: AASLD 2018 HEPATITIS B GUIDANCE

Drug	Dose in Adults	Monitoring on Treatment	Pregnancy Category
Preferred			
Peg-IFN-alpha-2a	180 mcg weekly	Test for HIV before treatment initiation CBC every 1–3 months TSH every 3 months Lactic acid levels if clinical concern (decompensated cirrhosis only) Clinical monitoring for autoimmune ischemia, neuropsychiatric, and infectious complications	C Avoid in pregnancy and when breast feeding
Entecavir	0.5 mg daily Dose 1 mg daily if client is lamivudine experienced of if they have decompensated cirrhosis	Test for HIV before treatment initiation CBC every 1–3 months TSH every 3 months Lactic acid levels if clinical concern (decompensated cirrhosis only) Clinical monitoring for autoimmune ischemia, neuropsychiatric, and infectious complication	C Avoid in pregnancy and when breast feeding
Tenofovir TDF	300 mg daily	Test for HIV before treatment initiation Creatinine clearance at baseline If at risk for renal impairment, creatinine clearance, serum phosphate, urine glucose, and urine protein at least annually Consider bone density study at baseline and during treatment in clients with history of fracture or risks for osteopenia Lactic acid levels if there is clinical concern	B Safe in pregnancy up to 28 weeks of pregnancy
TAF Tenofovir alafenamide	25 mg daily	Test for HIV before treatment initiation Assess serum creatinine, serum phosphorus, creatinine clearance, urine glucose, and urine protein before initiating and during therapy in all clients as clinically appropriate Lactic acid levels if there is clinical concern	Insufficient human data for assignment of drug-associated risk of birth defects and miscarriage
Nonpreferred			
Lamivudine	100 mg daily	Test for HIV before treatment initiation Amylase if symptoms of pancreatitis are present Lactic acid levels if there is clinical concern	C Not recommended during the first 3 months of pregnancy; should be used only during pregnancy if benefit outweighs the risk to fetus
Adefovir	10 mg daily	Test for HIV before treatment initiation Creatinine clearance at baseline If at risk for renal impairment, creatinine clearance, serum phosphate, urine glucose, and urine protein at least annually Consider bone density study at baseline and during treatment in clients with history of fracture or risks for osteopenia Lactic acid levels if there is clinical concern	C During pregnancy only if benefit outweighs the risk to the fetus*; avoid in breastfeeding*
Telbivudine	600 mg daily	Test for HIV before treatment initiation Creatine kinase if symptoms are present Clinical evaluation if CK and myopathy are present Lactic acid levels if there is clinical concern	B

Note: In 2015, the U.S. Food and Drug Administration replaced the pregnancy risk designation by letters A, B, C, D, and X with more specific language on pregnancy and lactation. This new labeling is being phased in gradually, and to date only TAF includes these additional data.

AASLD, American Association for the Study of Liver Disease; CBC, complete blood count; CK, creatine kinase; IFN, interferon; TAF, tenofovir alafenamide; TDF, tenofovir disoproxil fumarate; TSH, thyroid-stimulating hormone.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Clients should receive HBsAg testing during each pregnancy:

a. Those who are HBsAg-positive should have HBV DNA testing.

b. Prenatal HBsAg testing of all pregnant females is recommended to identify newborns who require immediate postexposure prophylaxis.

c. Extra care is necessary to evaluate the mother to ensure that the infant receives hepatitis B immune globulin (HBIG) and HBV vaccine within 12 hours of birth (Table 14.18).

2. Pregnancy and lactation are not a contraindication to vaccination. No adverse effect on developing fetus has been observed when pregnant females are vaccinated against HBV.

3. Antiviral therapy in the third trimester is recommended for pregnant females with serum HBV DNA > 200,000 IU/mL:

a. TDF is the preferred therapy for prevention of mother-to-child transmission.

b. Antiviral therapy given for prevention of mother-to-child transmission is recommended to be discontinued at the time of delivery or up to 4 weeks postpartum:

i. Pregnant clients who stop antiviral therapy at or early after delivery should be monitored for up to 6 months after delivery for hepatitis flares and seroconversion.

ii. Long-term follow-up should be continued to assess the need for future antiviral therapy.

c. Antiviral drug labels do not recommend breastfeeding while on therapy; however clinical studies support the safety of these drugs during breastfeeding.

B. Adults:

1. Most HBV infections are acquired in adolescence or adulthood, largely as a result of IV drug use, sexual contact, or occupational or household exposure. HBV infection is associated with other sexually transmitted diseases, including syphilis.

2. Clients who have received a blood transfusion should refrain from blood donation for 6 months, the incubation period for HBV. Blood should never be donated if the client is a hepatitis B carrier or was infected with hepatitis C.

C. Geriatrics:

1. Vaccination against HBV is recommended in older adults at risk for infection, including all nursing home residents.

2. HBV is more severe among adults older than 60 years:

a. There is substantial decrease in liver mass, in the number of hepatocytes, and in the portal blood flow, which results in alteration of metabolism. There are significant reductions in up to 30% to 40% in parenchymal volume, liver blood flow, and perfusion

b. Older adults have a higher rate of mortality than younger clients, reflecting in part a higher prevalence of comorbid conditions such as diminished immune response, metabolic derangement, nutritional deficiencies, and greater cumulative exposure to environmental hepatotoxins.

c. Those who do develop the disease have a greater tendency to deteriorate into chronic liver failure or HCC:

i. The risk of cirrhosis in highly linked to the HBV DNA level.

3. Liver transplant programs may have relative contraindication inclusion criteria for liver transplant for ages more than 65 to 70 years.

HEPATITIS C

DEFINITION

A. Hepatitis C is an inflammation of the liver caused by the hepatitis C virus (HCV). HCV has signs and symptoms ▶

TABLE 14.18 POSTEXPOSURE HEPATITIS B PROPHYLAXIS AFTER PERCUTANEOUS EXPOSURE

Exposed Person	HBsAg- Negative	Unknown or Not Tested	Treatment When Source Is HBsAg-Positive
Unimmunized	Initiate hepatitis B vaccine series	Initiate hepatitis B vaccine series	Administer one dose of HBIG 0.06 mL/kg IM; then initiate hepatitis B vaccine series
Previously immunized: known responder	No treatment	No treatment	No treatment
Previously immunized: known nonresponder	No treatment	If known high-risk source, treat as if source was HBsAg-positive	Administer one dose of HBIG 0.06 mL/kg IM; then initiate reimmunization or HBIG (two doses) hepatitis B vaccine series
Previously immunized: response unknown	No treatment	Test exposed person for anti-HBs; if adequate, no treatment; if inadequate, administer vaccine booster	Test exposed person for anti-HBs and administer vaccine booster dose; two additional doses should be administered to complete three-dose reimmunization series

HB, hepatitis B; HBIG, hepatitis B immune globulin; HBsAg, hepatitis B surface antigen; IM, intramuscular.

often undistinguishable from those of hepatitis A or B (HAV or HBV). The disease tends to be asymptomatic to mild and has an insidious onset. Acute fulminate infection is rare. The major feature of HCV is its propensity to become chronic.

B. Multiple (6) HCV genotypes and subtypes exist. It is possible for a person to be infected with more than one genotype. The genotype is a major factor in the effectiveness of the client's response to therapy.

C. The development of chronic hepatitis and its complications increase with several factors, including older age at acquisition, HBV coinfection, HIV coinfection, excessive alcohol consumption, and male sex.

D. HCV is the leading cause of nonalcoholic hepatic failure and cirrhosis, and the cause of 90% of posttransfusion hepatitis. Primary hepatocellular carcinoma (HCC) also occurs in these clients.

E. No vaccine for hepatitis C is available and therefore prevention of HCV depends on reducing the risk of exposure.

F. Council of State and Territorial Epidemiologists (CSTE) Position Statements for *Acute Hepatitis C*:

1. Clinical criteria for acute HCV:

a. An illness with discrete onset of any sign or symptom consistent with acute viral hepatitis (e.g., fever, headache, malaise, anorexia, nausea, vomiting, diarrhea, and abdominal pain).

AND

i. Jaundice.

OR

ii. A peak elevated serum alanine transaminase (ALT) level greater than 200 IU/L during the period of acute illness.

2. Laboratory criteria for acute HCV:

a. A positive test for anti-HCV.

b. HCV detection test:

i. Nucleic acid testing (NAT) for HCV RNA positive (including qualitative, quantitative, or genotype testing).

ii. A positive test indicating presence of HCV antigen(s).

3. Criteria to distinguish a new case from an existing case of acute HCV:

a. A new acute case is an incident acute hepatitis C case that meets the case criteria for acute hepatitis C and has not previously been reported.

b. A new probable acute case may be reclassified as a confirmed acute case if a positive NAT for HCV RNA or a positive HCV antigen(s) test is reported within the same year.

c. A confirmed acute case may be classified as a confirmed chronic case if a positive NAT for HCV RNA or a positive HCV antigen is reported 1 year or longer after acute case onset.

d. A confirmed acute case may not be reported as a probable chronic case (i.e., HCV antibody positive, but with an unknown HCV RNA NAT or antigen status).

4. Case classification for acute HCV:

a. Probable:

i. A case that meets clinical criteria and has a positive anti-HCV antibody test, but has no reports of a positive HCV NAT or positive HCV antigen tests.

AND

ii. Does not have test conversion within 12 months or has no report of test conversion.

b. Confirmed:

i. A case that meets clinical criteria and has a positive HCV detection test (HCV NAT or HCV antigen).

OR

ii. A documented negative HCV antibody, HCV antigen, or NAT laboratory test result followed within 12 months by a positive result of any of these tests (test conversion).

G. Council of State and Territorial Epidemiologists (CSTE) Position Statements for *Chronic Hepatitis C:*

1. Clinical criteria for chronic HCV:

a. No available evidence of clinical and relevant laboratory information indicative of acute infection (as noted earlier).

b. Most HCV-infected persons are asymptomatic; however, many have CLD, which can range from mild to severe.

2. Laboratory criteria for diagnosis of chronic HCV:

a. A positive test for anti-HCV.

b. HCV detection test for acute HCV:

i. NAT for HCV RNA positive (including qualitative, quantitative, or genotype testing).

ii. A positive test indicating presence of HCV antigen(s).

3. Criteria to distinguish a new case from an existing case of chronic HCV:

a. A new chronic case is an incident chronic hepatitis C case that meets the case criteria for chronic hepatitis C and has not previously been reported.

b. A confirmed acute case may not be reported as a probable chronic case (i.e., HCV antibody positive, but with an unknown HCV RNA NAT or antigen status).

4. The Centers for Disease Control and Prevention (CDC) 2020 case classification for chronic HCV:

a. Probable:

i. A case that does not meet clinical criteria or has no report of clinical criteria.

AND

ii. Has presumptive laboratory evidence.

AND

iii. Has no documentation of anti-HCV or RNA test conversion within 12 months AND

iv. Does not have HCV RNA detection reported.

b. Confirmed:

i. A case that does not meet clinical criteria or has no report of clinical criteria.

AND

ii. Has confirmatory laboratory evidence.

AND

iii. Has no documentation of anti-HCV or HCV RNA test conversion within 12 months.

INCIDENCE

A. The World Health Organization (WHO) estimates that more than 117 million individuals worldwide with hepatitis C and 58 million are chronically infected with HCV. Annually, 1.5 million individuals are newly infected with hepatitis C.

B. Of every 100 people infected with HCV, approximately:

1. 75 to 85 will go on to develop chronic infection.

2. 10 to 20 will go on to develop cirrhosis over a period of 20 to 30 years.

3. Rates of progression to cirrhosis are increased in the presence of a variety of factors: males more than females, ▶

age greater than 50 years, alcohol, nonalcoholic fatty liver disease (NAFLD), HBV or HIV coinfection, immunosuppressive therapy.

C. Among clients with cirrhosis, there is:

1. 1% to 5% annual risk of HCC.

2. 36% annual risk of hepatitic decompensation, for which the risk of death in the following year is 15% to 20%.

D. Approximately 15% to 25% of people clear the HCV virus without treatment and do not develop chronic infection. **Although they are no longer infected, they will still test positive for antibodies to HCV (anti-HCV):**

1. Predictors of spontaneous clearance include jaundice, elevated ALT level, hepatitis B surface antigen (HBsAg) positivity, female sex, younger age, HCV genotype 1, and host genetic polymorphisms, most notably those near the IL28B gene.

E. HCV infection becomes chronic in approximately 75% to 85% of cases. A person infected with HCV mounts an immune response to the virus, but replication of the virus during infection can result in changes that evade the immune response. This may explain how the virus establishes and maintains chronic infection.

F. Seroprevalence rates among individuals vary according to their associated risk factors. The highest rates occur in persons with large or repeated direct percutaneous exposure to blood or blood products, such as intravenous (IV) drug users and clients with hemophilia who have received multiple blood transfusions prior to 1990.

G. Seroprevalence among pregnant clients in the United States in 2018 was estimated at 1% to 2.5%. Maternal–fetal (vertical) transmission only ranges from 3% to 10%. Risk for transmission is highest among individuals with a high viral load at delivery. Maternal coinfection with HIV has been associated with increased risk of perinatal transmission of HCV RNA.

H. Serum anti-HCV antibody and HCV RNA have been detected in colostrum. However, although only a limited number of clients have been studied, the rate of transmission among breastfed infants is the same as among bottle-fed infants.

PATHOGENESIS

A. HCV is a small, single-stranded RNA virus with a lipid envelope and is a member of the Flavivirus family. It is a bloodborne virus, and the most common modes of infection are through exposure to small quantities of blood injection drug use, unsafe injection practices, and transfusion of unscreened blood and blood products.

B. The WHO also notes that one of the most common transmissions is in the reuse or inadequate sterilization of medical equipment, especially syringes and needles in healthcare settings.

C. Sexual transmission of HCV is uncommon except with high-risk behavior.

D. The incubation period averages 6 to 7 weeks, with a range of 2 weeks to 6 months. The time from exposure to the development of viremia generally is 1 to 2 weeks.

PREDISPOSING FACTORS

A. All people with HCV-RNA in their blood are considered to be infectious. The following groups are at high risk for HCV infection and should be tested:

1. IV drug users who have shared needles.

2. Intranasal cocaine users, presumably resulting from epistaxis and shared equipment.

3. Hemophiliacs, hemodialysis clients, and those who received blood transfusions before 1992.

4. Recipients of solid organ transplants prior to 1992.

5. Healthcare workers with percutaneous exposures.

6. Individuals with multiple sexual partners.

7. Transmission among contacts living with infected persons may occur with percutaneous or mucosal exposure to blood.

8. Infants of infected mothers, by vertical transmission.

9. HCV is more common in males than females.

10. Tattooing, body piercing, and acupuncture with unsterile equipment.

11. HIV.

12. Incarceration.

COMMON COMPLAINTS

A. Chronic HCV: asymptomatic unless there is progressive inflammation and complications from cirrhosis.

B. Malaise.

C. Anorexia.

D. Nausea.

E. Myalgia.

F. Fever.

G. Abdominal pain.

OTHER SIGNS AND SYMPTOMS

A. Jaundice (occurs in fewer than 20% of clients).

B. Hepatomegaly is present in one-third of clients with an acute infection.

C. Ascites.

D. Spider nevi.

E. Dark urine.

F. Clay-colored stools.

SUBJECTIVE DATA

A. Review duration, onset, and severity of symptoms.

B. Ask the client about other family members and sexual contacts with similar symptoms.

C. Review family history of hepatocellular carcinoma (HCC).

D. Review the client's history of blood transfusions, tattoos, incarceration, IV drug use, and alcohol abuse.

E. Ask the client about occupational exposure to blood and bodily secretions.

F. Ask about high-risk sexual practices.

G. Inquire about recent international travel.

H. Establish the client's usual weight; note amount of any weight lost and over what length of time.

I. Review for a history of variceal bleeding.

J. Ask if the client has been treated for any type of hepatitis:

1. How long ago was the client treated?

2. Did the client complete therapy? If not, why?

3. What was the client's response to therapy (e.g., nonresponder, relapser)?

K. Has the client had any testing for cirrhosis/liver biopsy? What testing and when?

L. Review HIV status.

PHYSICAL EXAMINATION

A. Check temperature (acute infection), pulse, respirations, blood pressure (BP), and height and weight to calculate body mass index (BMI).

B. Inspect:

1. Observe general appearance, muscle wasting, edema, and demeanor. **Administer a depression self-assessment tool at each visit when on HCV therapy.** ▶

2. Inspect the skin for jaundice, rash, dehydration, palmar erythema, excoriations, spider nevi, and tattoos/piercings.
3. Inspect the eyes for yellow sclera.
4. Inspect mucous membranes and nail beds for clubbing and cyanosis.
5. Inspect for gynecomastia and small testes.

C. Auscultate:
1. Auscultate lung fields and heart.
2. Auscultate all quadrants of the abdomen and evaluate for abdominal bruit.

D. Percuss:
1. Abdomen.

E. Palpate:
1. Palpate all quadrants of the abdomen for masses, liver enlargement or tenderness, characteristics of cirrhosis, and hepatosplenomegaly, which occurs in about 10% of cases.
2. Palpate the lymph nodes for lymphadenopathy and enlarged parotid.

DIAGNOSTIC TESTS

A. Complete blood count (CBC) with platelets.
B. Complete liver panel:
1. Aspartate aminotransferase (AST)/ALT.
2. Total bilirubin.
3. Prothrombin time (PT)/international normalized ration (INR).
4. Albumin.
C. Alkaline phosphatase (ALP).
D. Other viral infection markers, especially hepatitis B virus (HBV) and HIV.
E. Alpha-fetoprotein (AFP; rule out other causes of liver disease).
F. Gamma-glutamyl transferase (GGT).
G. Thyroid profile.
H. A1C.
I. After HBV confirmation:
1. HBV genotype.
2. HBV DNA viral load.
J. Serum fibrosis panel:
1. AST-to-platelet ratio index (APRI): used for estimating hepatic fibrosis. Online calculator can be found at: www.hepatitisc.uw.edu/page/clinical-calculators/apri.
2. Fibrosis-4 (FIB-4) is an index for estimating hepatic fibrosis based on a calculation derived from AST, ALT, platelet concentrations, and age. Online calculator can be found at www.hepatitisc.uw.edu/page/clinical-calculators/fib-4.
3. FibroTest (FibroSure): commercial biomarker test that uses the results of six blood markers to estimate serum hepatic fibrosis markers.
K. Imaging:
1. Ultrasonography: FibroScan: Transient shear-wave elastography measures liver stiffness as a surrogate for fibrosis.
2. CT or MRI to help exclude biliary obstruction.
L. Liver biopsy to assess the severity of disease.
M. Pregnancy testing before and during antiviral therapy.
N. The in-depth initial and follow-up testing for HCV is located at the American Association for the Study of Liver Disease (AASLD) and Infectious Diseases Society of America (IDSA) website at www.hcvguidelines.org/evaluate. These guidelines are dynamic; therefore, the website should be accessed frequently.

DIFFERENTIAL DIAGNOSES

A. Hepatitis C.
B. Hepatitis A.
C. Hepatitis B.
D. Alcoholic liver disease (ALD).
E. Drug toxicities.
F. Opportunistic infections associated with HIV infection.
G. Infectious hepatitis (viral, bacterial, fungal, and parasitic).
H. Autoimmune diseases.

PLAN

A. General interventions:
1. Discuss the possibility of transmission to others, and tell the client to refrain from donating blood, organs, tissues, or semen and from sharing toothbrushes and razors.
2. All clients with chronic HCV should be immunized against hepatitis A and hepatitis B.
3. Any blood spills should be cleaned using a 1:10 dilution of bleach to water for disinfecting the area. Gloves should be worn when cleaning up any blood spills.
4. The WHO recommends that alcohol screening and behavioral interventions for people with moderate to high alcohol intake should be instituted.
5. The CDC recommends that anyone born between the years of 1945 and 1965 be tested for HCV one time as serum screening.

B. Client teaching: *See Client Teaching Guide for this chapter, "Jaundice and Hepatitis."*
1. Counsel the client to avoid hepatotoxic medications and alcohol:
a. Recommend abstinence or minimal alcohol consumption. More than seven drinks of alcohol per week for females and more than 14 drinks per week for males are associated with an increase of cirrhosis and HCC. Alcohol-free beers with limitations still contain some alcohol per beer.

C. Pharmaceutical therapy:
1. Treatment is aimed at inhibiting HCV replication and eradicating infection. Pharmaceutical regimens are quickly evolving as new medications come to the market. The AASLD and IDSA guidelines break down therapy and management in detail by genotype/subtypes, presence of cirrhosis, whether a client is treatment-naïve or treatment-experienced, and medications and length of therapy.
2. The guidelines are located at www.hcvguidelines.org/contents.
3. The guidelines also include the management of unique populations including clients with HIV/HCV coinfection, clients with decompensated cirrhosis, clients who develop recurrent HCV infection postliver transplant, clients with renal impairment, kidney transplant clients, management of acute HCV infection, HCV in pregnancy and children, management of chronic HCV infection, HCV in people who inject drugs, men who have sex with men (MSM), and testing and treatment in correctional facilities.

FOLLOW-UP

A. Refer to AASLD/IDSA current guidelines on testing, managing, and treating hepatitis C at www.hcvguidelines.org/references/aasldidsa-2020.

CONSULTATION/REFERRAL

A. Referrals include gastroenterologist, hepatologist, infectious disease, psychiatrist, endocrinologist, neurologist, hematologist, dietitian, and social workers.

B. Clients who are coinfected with HBV or HIV or have end-stage renal disease should be referred to and managed by a hepatologist, infectious disease provider, or gastroenterologist for treatment.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Routine serologic testing of pregnant clients for HCV infection is not recommended. Clients with significant risk factors for HCV should be offered antibody screening.

2. According to current guidelines of the U.S. Public Health Service and the American Academy of Pediatrics, maternal HCV infection is not a contraindication to breastfeeding. HCV-positive mothers should consider abstaining from breastfeeding if their nipples are cracked or bleeding.

3. The method of delivery has not been shown to increase the risk of vertical transmission of HCV. Cesarean delivery is reserved for obstetric indications.

B. Adults:

1. Infected persons with steady partners do not need to change their sexual practices. However, they should be informed of the possible risk of transmission and of what precautions to use to prevent transmission.

2. Persons with multiple partners should be advised to reduce the number of partners and to use condoms to prevent transmission.

C. Geriatrics:

1. As the population ages, the cases of HCV will increase more in older adults than in other age groups.

2. There is substantial decrease in liver mass, in the number of hepatocytes, and in the portal blood flow, which results in alteration of metabolism. There are significant reductions up to 30% to 40% in parenchymal volume, liver blood flow, and perfusion.

3. Older adults have a higher rate of mortality than younger clients, reflecting in part a higher prevalence of comorbid conditions such as diminished immune response, metabolic derangement, nutritional deficiencies, and greater cumulative exposure to environmental hepatotoxins.

4. Older age is an independent factor associated with a lower likelihood of being considered for antiviral therapies:

a. Adults over 60 have a higher prevalence of comorbidities, particularly cardiovascular, renal, pulmonary, and hematologic diseases.

b. Older adults are less likely to accept antiviral treatment.

c. Discontinuation of therapy and reductions are more frequently required in this age group.

d. Older adults have a faster progression to fibrosis.

5. Liver transplant programs may have relative contraindication inclusion criteria for liver transplant for ages more than 65 to 70 years.

HERNIAS, ABDOMINAL

DEFINITION

A. A hernia is the protrusion of a peritoneum-lined sac through some defect in the abdominal wall. Abdominal wall hernias are the most common surgical procedure. Hernias are a leading cause of disability and work loss. Types include the following:

1. Umbilical hernia: occurs when the intestinal muscles fail to close around the umbilicus, allowing the omentum and/or intestines to protrude into the weaker area.

2. Incisional hernia: caused by a defect in the abdominal musculature that develops after a surgical incision.

3. Epigastric hernia: protrusion of fat or omentum through the linea alba between the umbilicus and the xiphoid. Epigastric hernias are generally less than 2 cm in diameter.

4. Diastasis recti: acquired hernia most often due to pregnancy and obesity. The right and left rectus muscles separate, but there is no facial defect.

5. Obturator hernia: follows the path of the obturator nerves and muscles.

INCIDENCE

A. Umbilical hernias are common and often asymptomatic and may be present in up to 25% of the population when examined by ultrasound imaging. Umbilical hernias are more common in African American infants, females, and older adults. This type of hernia has a higher risk of incarceration and strangulation and therefore a greater mortality because the large bowel is frequently entrapped.

B. Epigastric hernias are most common in males 20 to 50 years old.

C. Incisional hernias typically are noted in the early postoperative period; however, there is an increase in incisional hernias during pregnancy. These iatrogenic hernias occur in 2% to 10% of abdominal operations. In addition to hernias, separation of the recti abdominis muscles (diastasis recti) is often caused by pregnancy or obesity.

D. Obturator hernias occur more commonly in females. Females have a larger canal diameter, which is noted predominantly in thin older adult females.

PATHOGENESIS

A. Incisional hernias are due to failure of fascial tissues to heal and close.

B. Epigastric hernias are defects in the abdominal midline between the umbilicus and the xiphoid process. They are usually related to a congenital weakness, increased intra-abdominal pressure, surrounding muscle weakness, or chronic abdominal wall strain.

C. An umbilical hernia is caused by failure of the umbilical ring to obliterate after birth. In the infant, the umbilical ring often closes spontaneously within the first 1 to 2 years of life. Increased abdominal pressure or congenital defects cause ▶

abdominal hernias that allow abdominal contents to protrude through the opening defect. In adults with an umbilical hernia, obesity increases the danger of incarceration.

PREDISPOSING FACTORS

A. Congenital predisposition.
B. Male.
C. Obesity.
D. Multiparity.
E. Cirrhosis and ascites.
F. Trauma or straining.
G. African American ancestry.
H. Chronic cough; can precipitate or worsen herniation.
I. Previous abdominal surgery.
J. Straining, coughing, and sneezing.
K. Straining with chronic constipation.
L. Incisional hernia factors:
  1. Smoking.
  2. Connective tissue disorder.
  3. Infection.
  4. Malnutrition.
  5. Immunosuppressive medications.
M. Age: Obturator hernias occur predominantly in older adults.
N. Maternal smoking is associated with an increased prevalence of omphalocele and gastroschisis.

COMMON COMPLAINTS

A. Asymptomatic: may only be detected on routine physical examination:
  1. Swelling or fullness at the hernia site.
  2. Varying degrees of discomfort.
  3. The only sign of a hernia may be increased irritability.
  4. Bulge of abdomen or of a previous scar.
B. Symptoms aggravated by cough and straining.

OTHER SIGNS AND SYMPTOMS

A. Incisional: bulge through incision wall (may be intermittent).
B. Epigastric: small, usually painless subcutaneous mass.
C. Umbilical:
  1. Adult: vague, intermittent pain; palpable mass.
D. Reducible or irreducible: Signs and symptoms are related to the degree of pressure of their contents rather than to size. Most clients are asymptomatic or complain of only mild pain.
E. Strangulated: colicky abdominal pain, nausea, vomiting, abdominal distension, hyperperistalsis.

SUBJECTIVE DATA

A. Review onset, duration, and course of symptoms.
B. Ask the client about previous abdominal surgeries, wound infection, and pregnancies.
C. Review history of straining, trauma, or physical labor.
D. Determine if the client has signs and symptoms of strangulation of entrapped bowel: pain, nausea, vomiting, distension, and fever.
E. Determine if the client can reduce hernia.
F. Ask the client whether the hernia is enlarging and uncomfortable.
G. Review the client's bowel history, specifically constipation.
H. Review the client's history for chronic obstructive pulmonary disease (COPD)/chronic cough.
I. Review the client's history for symptoms of obstructive uropathy where flow of urine is blocked causing injury to one or both kidneys.
J. Review how the hernia affects the client's activities of daily living (ADLs).

PHYSICAL EXAMINATION

A. Examination is the same for all types of abdominal hernias. Perform exam while the client is standing and supine. History and physical examination are the best means of diagnosing hernias.
B. Check temperature (if indicated), pulse, respirations, and blood pressure (BP).
C. Inspect:
  1. Inspect contour and symmetry of the abdomen for bulges or masses. The bulge may be asymmetric.
  2. Inspect irreducible hernias for discoloration, edema, and ascites.
  3. Assess:
    a. Have the client perform Valsalva maneuver while standing.
    b. Have the client lie supine, lift head from exam table, and then bear down to tense abdomen.
D. Auscultate:
  1. Abdomen in all quadrants for bowel sounds.
E. Percuss:
  1. Liver.
  2. Spleen.
  3. Abdomen.
F. Palpate:
  1. Palpate the entire abdomen for masses, hepatomegaly, and ascites. Umbilical hernias may be obscured by subcutaneous fat.
  2. Palpate the groin.
  3. Palpate the hernia to try to gently reduce it.

DIAGNOSTIC TESTS

A. None required if the hernia is easily reducible (depending on the type of hernia).
B. Complete blood count (CBC): white blood count (WBC) increased, hematocrit (Hct) increased.
C. Electrolytes: Na+ increased or decreased.
D. Abdominal radiography reveals abnormally high levels of gas in bowel.
E. Ultrasonography, if strangulation is suspected.
F. CT scan of the abdomen and pelvis may be indicated.

DIFFERENTIAL DIAGNOSES

A. Abdominal hernia.
B. Diastasis recti.
C. Ascites.
D. Abdominal wall tumor or cyst.
E. Bowel obstruction.

PLAN

A. General interventions:
  1. Assess type of hernia and further diagnostics that are recommended.
B. Client teaching:
  1. Discuss the hernia and available options for treatment.
  2. Teach the client signs and symptoms of strangulation.
  3. Instruct the client to refrain from heavy lifting.
  4. Advise the client to wear a support garment.
C. Medical and surgical management:

Reduction should not be attempted if there are signs of inflammation or obstruction. Reduction of a strangulated bowel leads to persistent ischemia or necrosis with no clinical improvement.

1. Try to reduce hernia unless strangulated. See Section II: Procedures, "Hernia Reduction (Inguinal/Groin)."

a. Easily reducible: Abdominal contents can be easily returned to their original compartment. Allows symptomatic relief.

b. Incarcerated: cannot be returned to its original compartment. The incarcerated tissue may be bowel, omentum, or other abdominal contents.

c. Strangulated: surgical emergency—blood supply to the herniated tissue is compromised.

2. Do not try to reduce strangulated hernias because reduction can cause gangrenous bowel to enter peritoneal cavity.

3. A truss fits snugly over a hernia to prevent abdominal contents from entering the hernial sac. It does not cure a hernia and is used only when the client is not a surgical candidate.

4. Surgery may be done laparoscopically or through an open procedure and by sutured or mesh repair, depending on the age of the person, type and size of the hernia, and the presence of strangulation.

FOLLOW-UP

A. Instruct the client to call the office if fever or severe pain occurs. Otherwise, no follow-up is required unless for postoperative repair. Postoperative follow-up is with the physician who performed the surgery.

EMERGENT ISSUES/INSTRUCTIONS

A. Consult a physician or send the client to the ED if the client has abdominal tenderness, discoloration, or edema at the site; fever; or signs of bowel obstruction.

CONSULTATION/REFERRAL

A. A surgical consultation may be warranted.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. Incisional hernias are more common during pregnancy due to increased intra-abdominal pressure.

2. Bowel obstruction secondary to previous scarring may also be seen and is most common when the uterus emerges from the pelvis early in the second trimester, when the uterus is maximally distended at term, and in the immediate puerperium when the uterus promptly decreases in size.

3. Maternal smoking has been associated with an increased prevalence of omphalocele and gastroschisis.

B. Geriatrics:

1. Because of the anatomic position of the obturator hernia, the presentation is more common as a bowel obstruction than as a protrusion of bowel contents.

a. The geriatric population is more prone to develop electrolyte and acid–base imbalances from obstruction.

2. The geriatric population has a higher rate of ventral hernias attributed to the loss of muscle strength in the anterior abdominal wall and the prevalence of comorbidities that lead to an increased intra-abdominal pressure.

HERNIAS, PELVIC

DEFINITION

A. Hernia is the protrusion of a peritoneum-lined sac through some defect from one anatomic space to another. As shown in Figure 14.3, there are three types of pelvic (inguinal) hernias distinguished by presentation:

1. Indirect: protrudes through internal inguinal ring; can remain in canal, exit external ring, or pass into scrotum; unilateral or bilateral.

2. Direct: protrudes through external inguinal ring; located in region of Hesselbach triangle; rarely enters scrotum.

3. Femoral: protrudes through femoral ring, femoral canal, and fossa ovalis.

INCIDENCE

A. The lifetime risk of development of a groin hernia is estimated at 25% for males and 2% for females.

B. Indirect inguinal hernias are the most common type of hernia. They affect both sexes. Indirect hernias occur at the extreme of ages, from 0.25% at 18 years of age to 4.2% at 75 to 80 years of age.

C. Direct inguinal hernias are less common than indirect inguinal hernias. They occur more often in males and are more common in those older than age 40. Primary inguinal hernias occur in 1% to 5% of infants and in 9% to 10% of those born prematurely.

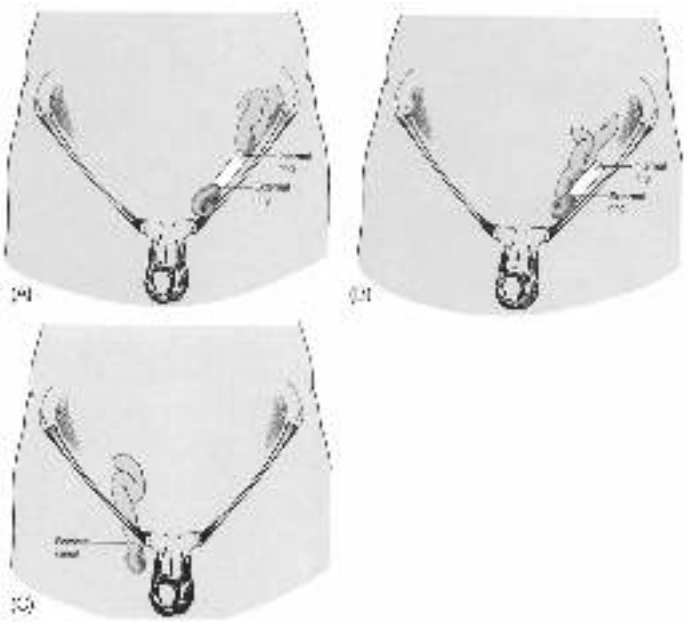

FIGURE 14.3 Pelvic hernias. (A) Indirect hernia comes down the canal and touches the fingertip on exam. (B) Direct hernia bulges anteriorly and pushes against the side of the finger on exam. (C) Femoral hernia protrudes through the femoral ring, femoral canal, and fossa ovalis, so the inguinal canal is empty on exam.

D. Femoral hernias are the least common type of hernia (<5% of groin hernias):

1. 35% to 40% of femoral hernias are not diagnosed until the client presents with strangulation or bowel obstruction.

2. They occur more often in females.

3. The incidence steadily increases with age and is higher among clients with recurrent hernias.

4. Right-sided presentation is more common than left.

E. Among inguinal hernias, a sliding component is found in 3%; they are overwhelmingly on the left side (left-to-right ratio, 4.5:1). Sliding hernias are much more common in males than in females, and the predominance increases with age.

F. Primary perineal hernias occur most often in older adult multiparous females.

PATHOGENESIS

A. Pelvic hernias occur because there is a potential space for protrusion—commonly of the bowel but occasionally of the omentum.

1. Indirect and direct hernias arise along the course that the testicle travels as it exits the abdomen and enters the scrotum during intrauterine life. Indirect hernias may be due to a congenital defect in which the processus vaginalis remains patent.

2. Femoral hernias occur at the fossa ovalis, where the femoral artery exits the abdomen.

PREDISPOSING FACTORS

A. Pregnancy.
B. Straining.
C. Age.
D. Obesity.
E. Sex.
F. Repetitive stress/hard physical labor.
G. Congenital defect.
H. Premature birth.
I. Chronic cough/chronic obstructive pulmonary disease (COPD).
J. Chronic constipation.
K. Family history of hernia.
L. History of an abdominal aortic aneurysm (AAA).
M. Straining to urinate.
N. Previous inguinal hernia or hernia repair.
O. Collagen vascular disease.
P. Peritoneal dialysis.

COMMON COMPLAINTS

A. Bulging or swelling localized in the groin or scrotum.
B. Dull ache in lower abdomen or groin.
C. Swelling of labia majora in females.
D. Bowel obstruction symptoms may be present with an incarcerated hernia.

OTHER SIGNS AND SYMPTOMS

A. Ability to reduce hernia.
B. Exacerbation on standing, straining, or coughing.
C. Strangulation.
D. Systemic toxicity secondary to ischemic bowel is possible. Signs of sepsis include fever, tachycardia, hypotension, vomiting, and confusion.

1. Colicky abdominal pain.

2. Extreme tender groin mass.

3. Hyperperistalsis.

4. Edema.

5. Discoloration.

SUBJECTIVE DATA

A. Review time of onset, duration, course of hernia, and swelling.
B. Review any symptoms and quality of pain. Blatant pain with hernias is unusual, and its presence should raise the possibility of incarceration or strangulation.
C. Ask the client about history of straining, trauma, physical labor, and pregnancy.
D. Inquire about symptoms of obstruction or strangulation of entrapped bowel: pain, nausea, and vomiting. Groin pain and tenderness are generally absent in strangulated femoral hernias.
E. Determine if the client has or can reduce the hernia.
F. Review irritating (e.g., exercise, straining, cough) and alleviating factors.
G. Review bowel habits and patterns, particularly constipation.
H. Evaluate history of COPD and cough.

PHYSICAL EXAMINATION

A. Physical examination is the same for all types of hernias and is directed at determining the type of hernia and whether it is reducible, incarcerated, or strangulated. Perform the exam while the client is standing and supine. Palpation is best done with the client standing:
B. Check temperature (if indicated), pulse, respirations, and blood pressure (BP).
C. Inspect:

1. Inspect for discoloration and edema of the herniated area.

2. Inspect for visible hernia. Instruct the client to perform Valsalva maneuver to increase intra-abdominal pressure.

3. Perform transillumination of the scrotum to evaluate any bowel contents.

4. Inspect for presence of ascites.

D. Auscultate:

1. Abdomen for bowel sounds.

E. Palpate:

1. Palpate the groin for lymphadenopathy, masses, and tenderness. *The right side is more commonly affected in both males and females*:

a. Males: Using the second or third finger, invaginate the scrotal skin, with and without cough and strain. There will be some degree of pressure with this maneuver, but a true hernia can typically be felt as a "silky" impulse tapping against the finger. Palpate the scrotum: Scrotal lump is either soft or unusually firm.

b. Females: Visually examine for a bulge, and then place two or three fingers across the inguinal canal and ask the client to bear down or cough to elicit the characteristic bulge or impulse. Palpate the labia for swelling: either soft or unusually firm.

DIAGNOSTIC TESTS

A. History and physical examination remain the best means of diagnosing hernias.
B. Perform ultrasonography for abdominal masses and strangulation.
C. MRI appears to be able to differentiate inguinal and femoral hernias with high sensitivity.
D. Sigmoidoscopy is not recommended as a screening test.
E. Plain abdominal x-rays are of limited value in evaluating an incarcerated hernia. ▶

F. Karyotyping should be considered when a testicle is palpable in the inguinal canal or found at herniorrhaphy in phenotypic females.
G. Routine laboratory work is not recommended.

DIFFERENTIAL DIAGNOSES

A. Inguinal or pelvic hernia.
B. Acute conditions:
1. Testicular torsion causes sudden, excruciating pain in or around the testicle, which may spread to the lower abdomen; the pain may get worse with standing. Other signs and symptoms include swelling, rising of the affected testicle, nausea, vomiting, fever, and fainting or light-headedness.
2. Epididymitis.
C. Nonacute conditions:
1. Testicular tumor.
2. Muscle strain.
3. Hip arthritis.
4. Undescended testicle.
5. Hydrocele.
6. Varicocele.
7. Spermatocele.
8. Lymphadenopathy.
D. Bowel obstruction.

PLAN

A. General interventions:
1. Evaluate hernia and determine diagnostic testing and referral options.
B. Client teaching:
1. Instruct the client to call the office right away if they find a lump or swelling in the scrotum, even if it is small or painless. Testicular tumors are usually painless.
2. Discuss condition and treatment options with the client:
a. Surgery is the only effective treatment.
b. Watchful waiting rather than surgical repair is an option if the client is asymptomatic as long as they are aware of the risk and understands the need for prompt attention should symptoms of complication occur.
c. Watchful waiting is not recommended in females, given their higher prevalence of femoral hernias, which are associated with a high risk of strangulation.
d. Nonsurgical therapy for groin hernias is the use of a truss. There are insufficient data to determine the efficacy of trusses in controlling symptoms. A truss has the potential risk of bowel constriction; prolonged use of a truss can lead to atrophy of the spermatic cord or fusion to the hernial sac.
3. Instruct the client on signs of strangulation.
4. Instruct the client to avoid heavy lifting and straining to have bowel movements (BMs) because they increase intra-abdominal pressure.
C. Medical and surgical management:
1. Gently reduce a groin hernia while the client lies supine with hips slightly flexed to relax the abdominal muscles. See Section II: Procedures, "Hernia Reduction (Inguinal/Groin)."

FOLLOW-UP

A. Preoperative:
1. Excessive waiting time for elective repair increases the risk of strangulation, bowel resection, and mortality, especially with older clients.
B. Postoperative evaluation for hernia recurrences as needed:
1. Immediately from repair.
2. Greater than 6 months and up to 5 years from repair.
3. Late recurrences beyond 5 years from the repair.

EMERGENT ISSUES/INSTRUCTIONS

A. Strangulated hernias are nonreducible, and blood supply to protruded tissue is compromised. Refer clients for immediate surgical intervention.
B. Instruct the client to return to the office if fever, severe pain, or strangulation occurs.

CONSULTATION/REFERRAL

A. Refer clients with femoral hernias to a physician. These hernias need to be repaired as soon as possible due to increased risk of incarceration and strangulation.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
1. Preexisting groin hernias may become more symptomatic during the first trimester of pregnancy. The symptoms must be differentiated from round ligament pain. Umbilical hernia may become worse in pregnancy due to increased intra-abdominal pressure.
B. Geriatrics:
1. Groin hernias are one of the most frequently encountered pathologies occurring in old age, secondary to the presence of constipation, coughing, abdominal fat deposit, and loss of strength of the abdominal wall.
2. Signs and symptoms of prostatism are frequently present in males with hernias and may require relief before herniorrhaphy.
3. The higher rate of comorbidities and the usage of general anesthesia increase the risk of complications in the older client.
4. For the older adult with existing pelvic hernias, nurse practitioner (NPs) should practice special consideration of the following *geriatric syndrome*:
a. Pain: Poorly relieved pain is an important cause of functional impairment at any age group:
i. Older adults have a diminished sensorium, allowing pathology to advance to a dangerous point prior to symptom development.
ii. Older adults with abdominal pain may present with altered mental status. Cognitive impairment can make assessment and diagnosis of pain more difficult.
iii. For dementia or noncommunicative clients, the American Medical Directors Association has endorsed the Pain Assessment in Advanced Dementia (PAINAD) Scale, which scores the following items:
1) Breathing: Examples include normal, labored, hyperventilation.
2) Negative vocalization: Examples include moaning, negative language, crying.
3) Facial expression: Examples include smiling, frowning, grimacing.
4) Body language: Examples include relaxed, tense, rigid, or striking out.
5) Consolability: Examples include extent to which a caregiver is able to console, distract, or reassure.

BIBLIOGRAPHY

American Hernia Society(AHS). https://www.americanherniasociety.org

HIATAL HERNIA

DEFINITION

A. Hiatal hernia occurs when portions of the stomach or other abdominal cavity organs herniate through the esophageal hiatal of the diaphragm. The client may be asymptomatic, and the herniation may be found incidentally in the diagnostic evaluation of other problems. There are four types of hiatal hernia:

1. Type I: sliding hernia. A portion of the stomach, gastroesophageal (GE) junction, slides in and out of the hiatus. The fundus of the stomach remains below the GE junction.

2. Type II: paraesophageal hernia. The gastric fundus of the stomach slides through the hiatus and lies next to the esophagus.

3. Type III: combined. Combination of sliding and paraesophageal hiatus hernia.

4. Type IV: complex paraesophageal hernia. The stomach, small and large bowels, spleen, pancreas, or liver are pushed up into the chest through a large defect.

INCIDENCE

A. The frequency of hiatal hernias increases with age, from 10% in clients younger than 40 years to 70% in clients older than 70 years.

B. Sex: Hiatal hernias are more common in females.

C. The most common hiatal hernia is the type I sliding hernia (95%).

D. Type II through type IV hernias make up the remaining 5% and are referred to as paraesophageal hernias (PEH).

E. The least common herniation is type II.

PATHOGENESIS

A. The exact cause of a hiatal hernia is unknown. It is known for the widening of the GE junction and/or laxity of the phrenoesophageal (gastrosplenic and gastrocolic ligaments). A hiatal hernia may also be a congenital defect.

PREDISPOSING FACTORS

A. Obesity.
B. Pregnancy.
C. Cough (chronic).
D. Straining with lifting or straining to have bowel movement.

COMMON COMPLAINTS

A. Asymptomatic (found incidentally, on upper endoscopy or other radiographic imaging being performed for other problems).
B. Heartburn.
C. Upper abdominal pain.
D. Vague, intermittent chest discomfort or pain.
E. GE reflux or "acid brash."
F. Trouble swallowing.
G. Choking.

OTHER SIGNS AND SYMPTOMS

A. Burping.
B. Hiccups.
C. Coughing.
D. Vomiting blood.
E. Blood in stools.
F. Weight loss.

POTENTIAL COMPLICATIONS

A. Strangulation/incarceration.
B. Gastric volvulus.
C. Perforation.
D. Respiratory compromise secondary to the hernia.

SUBJECTIVE DATA

A. Ask client what activity brought about or preceded the episode.

B. What are alleviating and aggravating factors?

C. Review medical history for a diagnosis of gastroesophageal reflux disease (GERD):

1. If the client has a diagnosis of GERD, has the client been prescribed and are they taking proton pump inhibitors (PPIs)?

2. Has the client had an esophagogastroduodenoscopy (EGD)? Was a hiatal hernia noted at the time of the procedure?

D. Review medical history for cardiac diagnosis.

E. Ask the client to list all medications currently being taken, including herbals and over-the-counter (OTC) medications. Specifically review whether the client is taking OTC antacids, H2 blockers, or OTC PPIs.

PHYSICAL EXAMINATION

A. Check pulse, respirations, and blood pressure (BP). Measure height and weight to calculate body mass index (BMI).

B. Inspect:

1. Inspect general appearance and observation of respiration, noting any distress.

2. Assess swallowing ability.

C. Auscultate:

1. Auscultate abdomen in all four quadrants.

2. Conduct a complete heart and lung exam.

D. Palpate:

1. Palpate upper gastric region for tenderness or distension.

2. Palpate abdomen for organomegaly or masses.

E. Rectal examination (if indicated for hematemesis or blood in the stool).

DIAGNOSTIC TESTS

A. The 2013 Society of American Gastrointestinal and Endoscopic Surgeons (SAGES) guidelines recommend tests should be done to diagnose hiatal hernia only if they will change clinical outcome.

1. Barium swallow (identifies anatomy and size of hernia).

2. Esophagogastroduodenoscopy (EGD).

3. High-resolution manometry.

4. CT scan.

5. Large hiatal hernias may cause iron deficiency anemia:

a. Complete blood count (CBC).
b. Iron.
c. Ferritin.

DIFFERENTIAL DIAGNOSES

A. Hiatal hernia.
B. GERD.
C. Cholecystitis.
D. Esophageal spasm.
E. Angina pectoris.
F. Coronary artery disease.
G. Cancer (gastric or esophageal).

PLAN

A. General interventions:

1. Management depends on the cause and severity of symptoms. Asymptomatic sliding hernias do not require surgical repair. Management of sliding hernias with reflux includes managing symptoms of GERD.

B. Client teaching:

1. Educate client about modifying controllable risk factors, such as keeping diabetes and hypertension under control, diet and weight control, exercise, and stopping smoking.

C. Dietary management:

1. There is no specific diet for a hiatus hernia; however, dietary modifications for GERD are encouraged.
2. Food should be cut up into small bite-sized pieces and thoroughly chewed.

D. Pharmaceutical therapy:

1. There is no medication specific for a hiatal hernia; however, symptomatic acid reflux can be treated by neutralizing acid with antacids or by blocking acid secretion with H2 receptor blocking agents for more potent PPIs:
   a. PPIs increase the risk of *Clostridioides difficile* infection.
   b. PPIs are associated with bone loss and fractures.

E. Medical and surgical management:

1. Surgical repair is not indicated in the absence of reflux disease.
2. Age and client comorbidities should be considered in the routine elective repair of completely asymptomatic PEH.
3. The SAGES guidelines recommend that, during operations for Roux-en-Y gastric bypass (RYGB), sleeve gastrectomy, and placement of adjustable gastric bands, all hiatal hernias should be repaired.
4. All symptomatic types II to IV PEH should be repaired, especially in the presence of acute obstructive symptoms or volvulus:
   a. There are three major types of surgical repair: Nissen fundoplication, Belsey fundoplication, and Hill repair. These procedures offer relief in 80% to 90% of clients.

FOLLOW-UP

A. Follow-up is determined by client's needs, severity of symptoms, and whether complications are present.

EMERGENT ISSUES/INSTRUCTIONS

A. An emergent surgical repair of a hiatal hernia is required in clients with a gastric volvulus, uncontrolled bleeding, obstruction, strangulation, perforation, and respiratory compromise.

CONSULTATION/REFERRAL

A. Consider a surgical consultation for hiatus repair for:

1. Clients who have no relief from PPIs.
2. Pulmonary complications that are linked to GERD, including asthma and recurrent aspiration pneumonia.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. The incidence of a hiatal hernia increases due to the increase in intra-abdominal pressure from the uterus. In pregnancy, the most common type of hernia is hiatal hernia present in 15% to 20% of pregnancies, appearing during the second trimester.

B. Geriatrics:

1. For the older adult with existing GERD, nurse practitioner (NPs) should practice special consideration of the following *geriatric syndromes*:
   a. Falls:
      i. Consistently assess for falls. PPIs are associated with osteopenia/osteoporosis.
      ii. At the minimum, older adults should be asked how many times they have fallen since their last visit. A reported fall should trigger questions about whether the fall led to injury, a visit to urgent care or hospital ED, or a hospital admission.
      iii. Safety measures to reduce falls in the home include removing small area carpets, keeping night lights along the path to the bathroom, and installing a raised toilet seat or nearby grab bars. *See Client Teaching Guide for Chapter 3, "Safety Issues: Fall Prevention."*
   b. Weight loss/appetite suppression: Weight loss is a predictor of mortality. Clinically significant weight loss is considered to be 5% loss of usual body weight in 3 months or 10% in 6 months.
   c. Due to gastrointestinal (GI) distress, abdominal discomfort, and diarrhea, older adults are at increased risk of avoiding eating.
   d. Monitor weight patterns/BMI. (Caution: BMI is not used to identify loss of muscle mass.)
   e. Monitoring both serum albumin and anemia: Hypoalbuminemia and anemia are not necessarily associated with low bodyweight. They can be caused by decreases in liver protein synthesis:
      i. Serum albumin concentration is commonly recommended.
      ii. Hemoglobin (Hgb), prealbumin, and transferrin.
      iii. Cholesterol.
2. Beers Criteria cautions for PPIs:
   a. Due to polypharmacy, a full review of medications, herbals, and OTC drugs should be undertaken to identify medications that increase symptoms of GERD, medications that should be avoided in the geriatric population, duplicate medications, and medications that are able to be decreased or deprescribed. (Refer to section on deprescribing in Chapter 3, "Adult-Geriatric Assessments.")
   b. Prescribe the lowest dose for the shortest amount of time.
   c. PPIs are on the American Geriatrics Society 2021 Beers Criteria for potential inappropriate medications use in older adults. (Refer to Appendix C, Table C.1.) Avoid scheduled use of PPIs for greater than 8 weeks unless needed for high-risk clients. PPIs are associated with the following:
      i. Osteoporosis/osteopenia, prolonged exposure may increase of fractures.
      ii. Community-acquired pneumonia.
      iii. *C. difficile* infections and diarrhea.
      iv. Vitamin B_{12} deficiency and hypomagnesium.
   d. See Appendix D for the PPI deprescribing algorithm from deprescribing.org.

BIBLIOGRAPHY

American Hernia Society(AHS). https://www.americanherniasociety.org

IRRITABLE BOWEL SYNDROME

DEFINITION

A. Irritable bowel syndrome (IBS) is the most common of the gastrointestinal (GI) motility disorders. IBS is responsible for significant direct and indirect healthcare costs. It is a chronic relapsing functional disturbance of intestinal motility marked by a common symptom complex that includes bloating and abdominal pain or discomfort associated with defecation.

B. Bladder dysfunction has been identified in 50% of clients with IBS. Clients commonly transition between subgroups.

C. According to the Rome III criteria, IBS is the presence of recurrent abdominal pain or discomfort at least 3 days/mo that occurs in association with altered bowel habits over a period of at least 3 months.

D. IBS is defined by symptom-based diagnostic criteria, in the absence of detectable organic causes. Rome III criteria for IBS is related to stool characteristics:

1. IBS with diarrhea predominant (IBS-D): loose stools (small volume, pasty/mushy or watery) more than 25% of the time and hard stools less than 25% of the time.

2. IBS with constipation (small, hard, pellet like stools) predominant (IBS-C): hard stools more than 25% of the time and loose stools less than 25% of the time.

3. IBS with alternating bouts of constipation and diarrhea, mixed or cyclic pattern (IBS-M): both hard and soft stools more than 25% of the time.

E. On clinical grounds, other subclassifications are used:

1. Based on symptoms:

a. IBS with predominant bowel dysfunction.
b. IBS with predominant pain.
c. IBS with predominant bloating.

2. Based on precipitating factors:

a. Postinfectious (PI-IBS).
b. Food-induced (meal-induced).
c. Stress-related.

INCIDENCE

A. IBS is common, accounting for about 50% of GI complaints seen by healthcare professionals, and is a major cause of morbidity in the United States. Studies suggest nearly 20% of all adults suffer from some form of the condition; however, only a fraction seek medical help. IBS is recognized in children; symptoms consistent with IBS are reported in 16% of students age 11 to 17 years. IBS is not described in preschool-age children.

B. The condition affects between 5% and 10% of healthy people at any one point in time and, in most people, runs a relapsing and remitting course.

C. IBS with diarrhea is more common in males.

D. IBS with constipation is more common in females.

E. The prevalence is lower in people aged 50 years or older.

F. The American College of Gastroenterology (ACG) has recognized IBS as a key component of Gulf War syndrome.

PATHOGENESIS

A. IBS has an absence of detectable pathology, and laboratory tests are unrevealing. The understanding of IBS has evolved from a disturbance in bowel motor activity to a more integrated understanding of visceral hypersensitivity and brain–gut interaction. It is thought to be both a normal response to severe stress and a learned visceral response to stress:

1. Nonpropulsive colonic contractions lead to IBS-C predominant.

2. Increased contraction in the small bowel and proximal colon with diminished activity in the distal colon lead to IBS-D predominant.

3. Most clients with functional disorders appear to have inappropriate perception of physiologic events and altered reflex responses in different gut regions.

4. The brain–gut transmitters act at different sites in the brain and gut and lead to varied effects on GI motility, pain control, emotional behavior, and immunity. Serotonin plays a critical role in the regulation of GI motility, secretion, and sensation. Studies have shown that IBS may be related to an imbalance in mucosal serotonin and 5-hydroxytryptamine (5-HT) availability caused by defects in 5-HT production, serotonin receptors, or serotonin transport.

PREDISPOSING FACTORS

A. Age:

1. IBS mainly occurs between the ages of 15 and 65 years:

a. 50% of IBS occur prior to age 35.
b. 40% of IBS occur between ages 35 and 50.

B. Sex:

1. Females are two to three times more likely to have IBS.

C. Emotional factors and situational stress.

D. Prior GI infection-induced IBS.

E. Genetics is considered a factor.

F. Carbohydrate intolerance may produce significant symptoms.

COMMON COMPLAINTS

A. Chronic relapsing stool pattern:

1. Diarrhea, over three loose stools per day. OR

2. Alternation of diarrhea with constipation. Diarrhea is typically small in volume, has visible mucus, and may follow a hard movement by a few hours. OR

3. Constipation: less than three bowel movements (BMs) per week.

B. Feeling of incomplete evacuation.

C. Abdominal distension and bloating.

D. Straining with BMs.

E. Aching or cramps in periumbilical or lower abdominal region.

F. Pain relief with BM.

OTHER SIGNS AND SYMPTOMS

A. Change in bowel function.

B. Clear mucous stool.

C. Pain may be precipitated by meals.

D. Pain radiates to left chest or arm, from gas in splenic flexure. Nocturnal pain is unusual and is considered a warning sign.

E. Flatulence.

F. Nausea.

G. Anxiety.

H. Depression.

I. Preoccupation with bowel symptoms.

J. Extraintestinal symptoms:

1. Dysmenorrhea.

2. Urinary frequency, urgency, and incomplete bladder emptying.

3. Impaired sexual function and dyspareunia.

4. Fibromyalgia.

K. Menses may exacerbate IBS symptoms.

SUBJECTIVE DATA

A. Review pattern of main symptoms, including onset, duration, and usual course.
B. Ask the client what are the predominant symptoms: abdominal pain, diarrhea, or constipation.
C. Review the client's history for stress factors and ask if recurrent symptoms occur in relation to them.
D. Ask what other symptoms occur with the pain, diarrhea, or constipation, such as bloating, blood in stool, or nighttime BMs. **Bleeding, weight loss, and nocturnal diarrhea are not characteristic of IBS. IBS symptoms disappear during sleep.**
E. Establish client's normal weight history, and determine amount of weight loss, if any, over what time period.
F. Review the client's diet, including the following:
1. Response to milk or lactose products.
2. Artificial sweeteners.
3. Alcohol intake.
4. Irregular or inadequate meals.
5. Insufficient fluid intake.
6. Excessive fiber intake.
7. Obsession with dietary hygiene.
8. Response to gluten (wheat, barley, rye) ingestion.

G. Inquire about the client's prescription, herbal, and over-the-counter (OTC) medications. Ask specifically about the use of laxatives.
H. Review travel and food history for dominant history of diarrhea.
I. Ask the client if there is a family history of colon cancer, ulcerative colitis (UC), Crohn's disease (CD), or malabsorption.
J. Is there any fever accompanying lower abdominal pain?
K. What is the relation of symptoms to menstruation?

PHYSICAL EXAMINATION

A. Check temperature (if indicated), pulse, respirations, and blood pressure (BP). Measure height and weight to calculate a body mass index (BMI).
B. Inspect:
1. Observe general appearance. Does the client appear anxious or depressed?
2. Inspect abdominal contour for masses and bulges.

C. Auscultate:
1. Abdomen for bowel sounds; note whether they are normal or mildly hyperactive.

D. Percuss:
1. Abdomen for tympany or dullness.

E. Palpate:
1. Abdomen:
   a. Evaluate the abdomen for mild tenderness, rigidity, guarding, and masses.
   b. Evaluate for hepatosplenomegaly.
   c. Evaluate for lymphadenopathy.

F. Rectal exam:
1. Check for masses and tenderness.
2. Obtain stool for diagnostic tests.
3. Rectal exam is normal with IBS.

DIAGNOSTIC TESTS

A. The ACG Task Force on IBS recommends that individuals younger than 50 years of age who do not have alarm features need not undergo routine colonic imaging. Individuals with IBS symptoms who have alarm features, such as anemia or weight loss, or those who are older than 60 years of age should undergo colonic imaging to exclude organic disease.

TABLE 14.19 ROME III DIAGNOSTIC CRITERIA FOR IBS

Onset of symptoms at least 6 months before diagnosis. Recurrent abdominal pain or discomfort for more than 3 days per month during the past 3 months.

At least two of the following features:
A. Improvement with defecation.
B. Association with a change in frequency of stool.
C. Association with a change in stool form.

B. Diagnosis of IBS is usually suspected on the basis of the client's history and physical examination without additional tests (Table 14.19).
C. Diagnostic tests are performed to exclude organic disease that may masquerade as IBS:
1. Complete blood count (CBC).
2. Sedimentation rate or C-reactive protein.
3. In clients presenting with chronic diarrhea, the American Gastroenterology Association (AGA) suggests against the use of erythrocyte sedimentation rate or C-reactive protein to screen for IBD.
4. Serum potassium, if the client is on diuretics; hypokalemia may reduce bowel contractility and produce an ileus.
5. Blood glucose, if diarrhea predominates; rule out diabetes mellitus, which may present as diarrhea due to diabetic gastroenteropathy.
6. Thyroid function study.
7. Stool specimen: Culture for leukocytes and fat, ova and parasites, and occult blood. **Leukocyte-free mucus is a hallmark of IBS.**
8. Stool cultures for *Clostridioides difficile* toxin assay, if clinically indicated.
9. Barium enema (BE) and/or proctosigmoidoscopy for severe signs and symptoms, after consultation or referral.
10. Celiac serology, if appropriate.
11. Mucosal biopsy is appropriate if a colonoscopy or sigmoidoscopy is performed.
12. Esophagogastroduodenoscopy (EGD) and distal duodenal biopsy in clients with diarrhea should be considered to rule out celiac disease, tropical sprue, giardiasis, and for clients in whom abdominal pain and discomfort are located more in the upper abdomen.
13. Hydrogen breath test to evaluate lactose intolerance and small intestinal bowel overgrowth (SIBO).

DIFFERENTIAL DIAGNOSES

A. IBS.
B. Refer to Table 14.19 for common and red flag differential diagnoses for IBS:
1. Inflammatory bowel disease (IBD):
   a. CD.
   b. UC.
2. Viral or bacterial gastroenteritis or acute diarrhea due to protozoa or bacteria.
3. Diverticulitis.
4. GI neoplasm.
5. Medications:
   a. Laxative abuse.
   b. Drug(s) side effects.

C. Lactose insufficiency/deficiency.
D. Diabetes.
E. Celiac spruce/gluten etiology.

▶

F. Endometriosis/pelvic inflammatory disease (PID).
G. Zollinger–Ellison syndrome.

PLAN

A. General interventions:
1. Advise the client to keep a diary of events of BMs and precipitating factors. A BM record is available at www.nhsggc.org.uk/media/241191/nhsggc-bristol-stool-chart.pdf.
2. Encourage the client to quit smoking because nicotine may aggravate symptoms.
3. Recommend daily exercise to reduce stress.
4. Stress management should be encouraged, including counseling, tapes, meditation, and yoga.
B. Client teaching: *See Client Teaching Guide for this chapter, "Irritable Bowel Syndrome."*
C. Dietary management:
1. Encourage lifestyle changes and dietary modification first. Prescribe a high-fiber diet.
2. Tell the client to avoid foods that aggravate the bowel. Avoid gas-producing foods, such as broccoli, beans, onions, garlic, and so forth. Advise to follow a low FODMAP (fermentable oligosaccharides, disaccharides, monosaccharides, and polyols) diet. See Appendix B, "Dietary Recommendations," for the FODMAP diet. When diarrhea predominates, dietary review is essential for clues of intolerance to lactose or sorbitol.
3. Referral to registered dietary nutritionist (RDN) to collaborate with making dietary changes.
4. Reassess frequently if dietary changes are improving symptoms and/or client is compliant with diet.
D. Pharmaceutical therapy:
1. Advise the client to stop all nonessential medications that may affect bowel function, especially irritant laxatives. Avoid narcotics, depressants, and other long-term drug use if possible.
2. Recommend eliminating sorbitol-containing candy and restricting lactose-containing milk products.
3. Drug of choice: psyllium hydrophilic mucilloid (Metamucil) one tablespoon per day in 8 oz of juice or water, followed with another 8 oz of liquid. This treats both diarrhea and constipation.
4. Pain relief:
a. Opiates should be avoided due to the risk of dependence and addiction in chronic conditions.
b. Nonsteroidal anti-inflammatory drugs (NSAIDs) have an undesirable side effect on the GI tract.
c. Antispasmodics and anticholinergic agents (IBS-D predominant):
i. Hyoscyamine (Levsin, Levbid):
1) Levsin 0.125 to 0.25 mg (one to two tablets) orally or sublingual Q4H; not to exceed 12 tablets a day.
2) Levbid 0.375 to 0.75 mg orally BID.
3) Hyoscyamine is available in immediate-release, extended-release, time capsules, biphasic tablets, elixir, and drop formulations.
ii. Dicyclomine (Bentyl) 20 to 40 mg QID; discontinue if not effective within 2 weeks or if 80 mg daily is associated with adverse effects. Also available in intramuscular formulation.
d. Tricyclic antidepressants for diarrhea predominant IBS. *Tricyclics should be avoided for constipated clients*:
i. Amitriptyline (Elavil) 10 mg every bedtime initially, titrate up slowly to 75 mg/d at bedtime as needed.
ii. Desipramine (Norpramin) 10 mg every bedtime initially, titrate up slowly up to 75 mg/d.
iii. Imipramine (Tofranil) 10 to 50 mg orally every bedtime.
5. Selective serotonin reuptake inhibitors (SSRIs):
a. Paroxetine (Paxil) 10 to 60 mg/d.
b. Citalopram (Celexa) 5 to 60 mg/d.
6. Antidiarrheals:
a. Opiate-derived antidiarrheals are reserved for very severe cases secondary to the potential for abuse.
b. Loperamide (Imodium):
i. Adults: 2 to 12 mg orally divided into BID/TID doses; doses differ greatly among individuals.
c. Alosetron (Lotronex), a 5-HT3 receptor antagonist, is indicated for females with severe IBS-D predominant. Starting dose is 0.5 mg BID; may increase to 1 mg BID after 4 weeks of starting dose. Discontinue if no relief after 4 weeks of 1-mg dosing.
7. Laxatives and stool softeners (IBS-C predominant) along with dietary measures and fiber supplements:
a. Mineral oil 15 to 45 mL orally daily or divided into TID dosing.
b. Stimulant laxatives may be necessary intermittently for short periods, but prolonged use of stimulant laxatives should be avoided.
c. Lactulose is a colonic acidifier that promotes laxation. Transit time through the colon may be slow; 24 to 48 hours may be required to produce a BM. The usual dose is 1 to 2 tablespoons daily. Lactulose contains galactose and lactose and should be used with caution for clients with diabetes.
8. Lubiprostone (Amitiza), a selective C-2 chloride-channel activator, is indicated for females 18 years and over with IBS-C predominant. 8-µL doses BID with food and water:
a. Lubiprostone should not be used in clients with mechanical bowel obstruction or preexisting diarrhea.
b. Clients should have a documented negative pregnancy test before starting therapy and should be advised to use contraception when taking lubiprostone.
9. Probiotics.
10. Linaclotide (LINZESS), a guanylate cyclase-C (GC-C) agonist, was recently released to market for both IBS-C and chronic idiopathic constipation (CIC).
11. Eluxadoline (Viberzi), a mu-opioid receptor agonist, is indicated for IBS-D predominant. There are two recommended dosings:
a. Dosing is 100 mg tablet BID taken with food.
b. The alternative dosing is 75 mg BID taken with food for clients with the following conditions:
i. Do not have a gallbladder.
ii. Unable to tolerate 100 mg BID.
iii. Are receiving concomitant OATP1B1 inhibitor, such as the lipid-lowering drug gemfibrozil and its metabolite gemfibrozil 1-O-beta.
iv. Have mild or moderate hepatic impairment.
c. If a dose is missed, clients should not compensate by taking two doses at once.

FOLLOW-UP

A. Reevaluate the effectiveness of treatment in 2 weeks. Treatment may be challenging for symptom management and numerous tests may be inconclusive, but rule out pathology.

B. If symptoms persist without relief, have the client return as needed.

C. Return if diarrhea lasts more than 2 weeks on medication therapy.

CONSULTATION/REFERRAL

A. Refer to a gastroenterologist for red flag symptoms:

1. Red flag features that require referral to a specialist for endoscopic evaluation include:

a. Increased rectal bleeding.
b. Weight loss.
c. Unexplained iron-deficiency anemia.
d. Abdominal symptoms during the night.
e. Strong family history of bowel disorders (e.g., colon cancer, celiac sprue, IBD).

B. Alosetron (Lotronex) is prescribed under a restricted distribution program through a gastroenterologist.

C. Consult a physician if all treatment options fail.

D. Consider a psychiatric consultation, if indicated, for anxiety, depression, somatization, and symptom-related fears.

INDIVIDUAL CONSIDERATIONS

A. Adults:

1. Annual rectal examination and sigmoidoscopy are recommended after age 50.

2. When constipation predominates, rule out malignancy, particularly in clients older than age 40 who have weight loss or a family history of colon cancer.

B. Geriatrics:

1. For the older adult with existing IBS, nurse practitioners (NPs) should practice special consideration of the following *geriatric syndromes*:

a. Depression: Anxiety and depression are common in IBS and are factors that lead to decreased health-related quality of life. A depression screen should be done at each office visit:

i. An online Patient Health Questionnaire-9 (PHQ-9) is available at www.mdcalc.com/phq-9-patient-health-questionnaire-9.

ii. The Geriatric Depression Scale, Short Form, a 15-item questionnaire that can be quickly applied in the clinical setting, is available at web.stanford.edu/yesavage/GDS.english.short.html.

b. Pain: Poorly relieved pain is an important cause of functional impairment at any age group:

i. Older adults have a diminished sensorium, allowing pathology to advance to a dangerous point prior to symptom development.

ii. Older adults with abdominal pain may present with altered mental status. Cognitive impairment can make assessment and diagnosis of pain more difficult.

iii. For dementia or noncommunicative clients, the American Medical Directors Association has endorsed the Pain Assessment in Advanced Dementia (PAINAD) Scale, which scores the following items:

1) Breathing: Examples include normal, labored, hyperventilation.

2) Negative vocalization: Examples include moaning, negative language, crying.

3) Facial expression: Examples include smiling, frowning, grimacing.

4) Body language: Examples include relaxed, tense, rigid, or striking out.

5) Consolability: Examples include extent to which a caregiver is able to console, distract, or reassure.

2. Beers Criteria caution:

a. A full review of medications, herbals, and OTC drugs should be undertaken to identify medications that should be avoided in the geriatric population, duplicate medications, and medications that are able to be decreased or deprescribed. (Refer to section on deprescribing in Chapter 3, "Adult-Geriatric Assessments.")

b. Refer to Appendix C, Table C.1 to identify drugs that have highly anticholinergic side effects and are potentially inappropriate medications for use in older adults, including the following:

i. First-generation antihistamines.
ii. Antispasmodics.
iii. Antidepressants.
iv. Opioids.
v. Calcium channel blockers.
vi. Anticonvulsants.
vii. Muscle relaxants.

JAUNDICE

DEFINITION

A. Jaundice is a yellow tinge of the skin or mucous membranes. It is a symptom, not a disease. The diagnostic approach begins with gathering a comprehensive history, physical examination, and screening labs. The differential diagnosis is formulated, and further testing may be warranted. The onset of jaundice usually prompts the client or family to seek medical attention. Jaundice can reflect a medical emergency secondary to massive hemolysis, ascending cholangitis, unconjugated hyperbilirubinemia in the neonatal period, and fulminant liver failure.

INCIDENCE

A. Incidence is variable according to pathogenesis, age, and population.

PATHOGENESIS

A. The mechanism responsible for jaundice includes excess bilirubin production, decreased hepatic uptake, impaired conjugation, intrahepatic cholestasis, extrahepatic obstruction, and hepatocellular injury (Table 14.20). However, it ▶

TABLE 14.20 CLASSIFICATION OF JAUNDICE ACCORDING TO BILE PIGMENT AND BY MECHANISM

Unconjugated Hyperbilirubinemia	Conjugated hyperbilirubinemia
Increased/overproduction of bilirubin	Hepatocellular injury/disease
Impaired/decreased hepatic uptake of bilirubin	Intrahepatic cholestasis
Impaired/decreased conjugation	Extrahepatic cholestasis (biliary obstruction)

is important to recognize that more than one mechanism can be operating in a given case (i.e., sickle cell anemia and HIV).

1. Excess bilirubin production results from accelerated red cell destruction. The excessive amounts of hemoglobin (Hgb) and resultant bilirubin released into the bloodstream overwhelm the liver's normal capacity for uptake, and an unconjugated hyperbilirubinemia ensues.

2. With decreased uptake and conjugation, there is often a concurrent, acquired illness such as infection, cardiac disease, or cancer. Hereditary conditions, such as Gilbert and Crigler–Najjar syndromes, are responsible.

3. Intrahepatic cholestasis may occur at a number of levels: intracellularly (e.g., hepatitis), at the canalicular level (when estrogen-induced), at the ductule (phenothiazine exposure), at the septal ducts (primary biliary cirrhosis), and at the intralobular ducts (cholangiocarcinoma).

4. Extrahepatic obstruction occurs when stone, stricture, or tumor blocks the flow of bile within the extrahepatic biliary tree. A history of gallstones, biliary tract surgery, or malignancy may be elicited.

PREDISPOSING FACTORS

A. Previous blood transfusion.
B. Travel to an area endemic for hepatitis.
C. Raw shellfish consumption.
D. Intravenous (IV) drug abuse.
E. High-risk sexual practices.
F. Family history of episodic jaundice.
G. History of gallstones.
H. Biliary obstruction/previous biliary tract surgery.
I. Alcoholism.
J. Chemical exposure.
K. Sickle cell disease.
L. Pregnancy (intrahepatic cholestasis).
M. Cancer.

COMMON COMPLAINTS

A. Pruritus.
B. Dark, tea-colored urine, from conjugated bilirubinuria.
C. Light, clay-colored stools, from absence of bile.
D. Fatigue.
E. Right upper quadrant (RUQ) pain.

OTHER SIGNS AND SYMPTOMS

A. Enlarged liver.
B. Splenomegaly.
C. Fever.
D. Chills.
E. Gastrointestinal (GI): appetite loss, weight loss, abdominal pain, nausea, or vomiting.
F. Ascites.
G. Shortness of breath.
H. Palpitations.
I. Ecchymosis.
J. Steatorrhea, severe.
K. Asterixis (tremor).
L. Myalgias.
M. Malaise.

SUBJECTIVE DATA

A. Review onset, duration, and course of symptoms.
B. Review medication history for drugs/herbals that may induce jaundice (Table 14.21).
C. Inquire about recent blood transfusions. Are there any known blood disorders in the client's family history?
D. Ask about contact with a person who has an infection, such as infectious hepatitis.
E. Ask about unprotected sexual activity/HIV status.
F. Review ingestion of potentially contaminated food or water, including *Amanita* mushrooms, milk, or shellfish.
G. Ask about the client's exposure to any toxic chemicals, such as carbon tetrachloride, chloroform, phosphorus, arsenic, ethanol, or halothane (Fluothane).
H. Review the client's history of nonsterile needle punctures.
I. Review the client's medical/surgical history for gallstones, hepatitis, tumor, pancreatitis, Wilson disease, Budd–Chiari syndrome, liver surgery, or transplantation. Is there a family history of gallstones?
J. Ask how much alcohol the client has ingested over the years, as well as daily intake of alcohol.
K. Ask about dark urine or white or clay-colored stool.
L. Inquire about dyspepsia, anorexia, nausea, vomiting, RUQ or epigastric pain, or pain radiating to the back or shoulder blade. Ask what the relationship of pain is to eating. ▶

TABLE 14.21 DRUGS AND HERBALS ASSOCIATED WITH JAUNDICE

ACE inhibitors
Acetaminophen (Tylenol)
Alkylated steroids
Aminobenzoic acid
Antibiotics
Antidiabetic drugs
Arsenic
Barbiturates
Chlorpromazine
Ethinyl estradiol/OCPs/hormone replacement
Herbal medications (e.g., Jamaican bush tea)
INH
Mercaptopurine (Purinethol)
Methyldopa (Aldomet)
Monoamine oxidase inhibitors
Paracetamol (acetaminophen)
Perphenazine (Trilafon)
Phenothiazine derivatives
PTU
Probenecid
Rifampin
Sulfonamides
Tamoxifen
TPN

ACE, angiotensin-converting enzyme; INH, isoniazid; OCPs, oral contraceptives; PTU, propylthiouracil; TPN, total parenteral nutrition.

M. Inquire about fever, fatigue, malaise, loss of vigor and strength, easy bruising, and weight loss.
N. Review travel history.

PHYSICAL EXAMINATION

A. Check temperature, pulse, respirations, blood pressure (BP), and weight. Marked weight loss accompanied by jaundice suggests carcinoma of the head of the pancreas or metastatic disease obstructing the common duct. Note breath odor for fetor hepaticus (breath of the dead).
B. Inspect:
1. Inspect skin, mouth, palms, and sclera for yellow tinge. Severe jaundice may cause greenish tinge from oxidation of bilirubin to biliverdin:
a. In fair-skinned people, discoloration is most evident on the face, trunk, and sclera (sclera icterus).
b. In dark-skinned people, discoloration is most evident in sclera and roof of mouth.
c. Jaundice is most noticeable in natural sunlight. In artificial or poor light, it may be hard to detect.
2. Inspect the skin for spider angiomata, rashes, or scratches from severe itching due to pruritus, and for bruising or petechiae.
3. Inspect the palms for erythema or overt bleeding.
4. Inspect the chest for gynecomastia.
C. Auscultate:
1. Heart.
2. Lungs.
3. Abdomen.
D. Palpate:
1. Abdomen for tenderness, masses, liver enlargement in RUQ, and ascites:
a. Extrahepatic obstruction and intrahepatic cholestasis may be identical in presentation.
b. Tenderness is minimal unless cholangitis or rapid distension occurs.
c. Splenomegaly is unlikely except in primary biliary cirrhosis.
d. Gallbladder may be palpable (Courvoisier sign) when there is gradual development of the biliary tree. Sudden onset of pain results from passage of stone that becomes wedged into common duct; fever and sepsis shortly thereafter indicate cholangitis.
e. Malignancy usually presents as a rock-hard mass.
f. Absence of abdominal pain does not rule out obstruction, especially when it develops slowly from tumor growth or primary biliary cirrhosis.
g. Advanced hepatocellular disease is indicated by a small liver, signs of portal hypertension (ascites, splenomegaly, prominent abdominal venous pattern), asterixis, peripheral edema (from hypoalbuminemia), spider angiomata, gynecomastia, palmar erythema, and testicular atrophy.
E. Percuss:
1. Abdomen.
F. Neurologic exam:
1. Note level of consciousness.
2. Note asterixis, or flapping tremor elicited when arms are extended and wrists are dorsiflexed.
G. Rectal exam:
1. Check for masses and occult blood.

DIAGNOSTIC TESTS

A. The diagnostic approach begins with a careful history and physician examination, and screening laboratory studies. A differential is formulated, and appropriate further testing is performed to narrow the diagnosis.
B. Initial laboratory tests:
1. Serum bilirubin: direct, indirect (unconjugated), and total; clinically, jaundice becomes noticeable when levels reach 2.0 to 2.5 mg/dL:
a. Intrahepatic cholestasis and extrahepatic obstruction: elevated conjugated bilirubin, elevated serum alkaline phosphatase (ALP); mild to moderate rise in transaminase.
b. Gilbert syndrome is the most common cause of decreased uptake and unconjugated hyperbilirubinemia. It is a benign disorder that produces recurrent self-limited episodes of mild jaundice. Typically, the unconjugated fraction rises to no more than 1.5 to 3.0 mg/100 mL. In Gilbert syndrome, fasting and minor illness can precipitate jaundice.
2. ALP: Biliary obstruction or intrahepatic cholestasis is commonly exhibited by increased ALP out of proportion to aminotransferases.
3. Aspartate transaminase (AST)/alanine transaminase (ALT):
a. Elevation of ALT and AST may indicate liver cell damage or may be caused by opiates and aspirin.
b. Aspirin may also decrease AST and ALT.
4. Prothrombin time (PT):
a. PT may be prolonged due to malabsorption, but it is reversible by vitamin K injection.
b. Prolonged PT unresponsive to parenteral vitamin K strongly suggests hepatocellular failure.
c. Cholestasis and obstruction may also produce prolongation of PT but can be reversed by vitamin K.
d. Phenazopyridine (Pyridium) may cause a false-positive bilirubin result.
C. Other laboratory testing as needed:
1. Total serum protein.
2. Serum albumin and globulin:
a. Albumin decreases with cirrhosis and chronic hepatitis.
b. Globulin increases with cirrhosis, chronic obstructive jaundice, and viral hepatitis.
c. To interpret albumin level, consider dietary intake and sources of possible protein loss.
3. Cholesterol.
4. Lactate dehydrogenase (LDH).
5. Gamma-glutamyl transpeptidase (GGT).
6. Serum ammonia.
7. Bile acids radioimmunoassay: Elevated levels indicate hepatic disease.
8. Serologic tests for viral hepatitis.
9. Serum iron, transferrin, and ferritin to evaluate hemochromatosis.
10. Serum ceruloplasmin levels to evaluate Wilson disease.
11. Alpha-1 antitrypsin activity to evaluate alpha-1 antitrypsin deficiency.
12. Urine for bilirubin: Bilirubinuria may be an early sign of liver disease:
a. Collect specimens over a 2-hour period after lunch.
b. Place specimen in a dark brown container and send to lab immediately to prevent decomposition.
D. Abdominal ultrasound is considered the screening procedure of choice. More selective imaging procedures are ordered based on clinical evaluation.
E. Other imaging procedures:

1. Endoscopic ultrasound.
2. Hepatobiliary iminodiacetic acid (HIDA) scan: uses radioactive isotopes.
3. Oral cholecystography.
4. Endoscopic retrograde cholangiopancreatography (ERCP).
5. Percutaneous transhepatic cholangiography (PTC).
6. Helical CT.
7. Magnetic resonance cholangiopancreatography (MRCP) is an alternative to ERCP.
8. Liver biopsy may be indicated for definitive diagnosis.

DIFFERENTIAL DIAGNOSES

A. Jaundice is a symptom, not a diagnosis.
B. Cancer of pancreas.
C. Obstruction of biliary tract.
D. Icteric phase of hepatitis.
E. Cirrhosis.
F. Right-sided heart failure (HF).
G. Chronic hemolysis from prosthetic heart valve.

PLAN

A. General interventions:
1. Management depends on primary diagnosis. Most clients can be managed on an ambulatory basis, unless they are unable to maintain hydration or begin to show evidence of severe hepatocellular failure.
B. Pharmaceutical therapy:
1. Cholestyramine 2 to 8 g orally BID may be used to help relieve itching. Cholestyramine is ineffective with complete biliary obstruction.

FOLLOW-UP

A. See the client 2 to 4 weeks after initial diagnosis and referral.
B. Subsequent routine evaluations are related to primary diagnosis.

EMERGENT ISSUES/INSTRUCTIONS

A. Hospital admission is mandatory when jaundice is complicated by a fever and peritoneal signs are indicative of cholangitis. IV antibiotics and prompt surgical consultation are required.

CONSULTATION/REFERRAL

A. Consult with a gastroenterologist familiar with liver disease and needle biopsy techniques when hepatocellular disease is suspected; when there is evidence of hepatic failure, portal hypertension, or encephalopathy; or when jaundice persists longer than 3 months.
B. Consultation with a gastroenterologist, surgeon, or radiologist experienced in evaluation of jaundice can be very useful when there is clinical suspicion of extrahepatic obstruction.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
1. Viral hepatitis is the most frequent cause of jaundice in pregnancy.
2. Intrahepatic cholestasis in pregnancy is associated with modest maternal risks, including increased risk of peripartum bleeding and increased likelihood of subsequent cholelithiasis.
3. Cholestyramine resin, generally 4 g every 4 to 6 hours, has been reported to afford some relief of pruritus in 50% of affected females, presumably by removing a portion of the bile acids by irreversible binding in the gut.
4. Pregnant clients who take cholestyramine are at increased risk for depletion of vitamin K-dependent coagulation factors and should be followed with serial PT times. Such clients should also receive prophylactic vitamin K supplementation. If PT becomes prolonged, medication should be discontinued.
B. Geriatrics:
1. The most frequent cause of jaundice in clients older than 65 years is *cholelithiasis*.
2. The second most frequent cause of jaundice for clients 65 years and older is cancer, especially of the gallbladder.
3. Painless jaundice in older adults with weight loss and a mass, but with minimal pruritus, suggests biliary obstruction caused by cancer.
4. Drugs that are highly metabolized by cytochrome P450 or similar liver enzymes may result in competitive inhibition of each other, resulting in slow clearance, drug accumulation, and toxicity. Due to polypharmacy, a full review of medications, herbals, and over-the-counter (OTC) should be done for medications (monotherapy or in combination) that are hepatoxic and should be avoided in the geriatric population.

Jaundice as a diagnostic and therapeutic problem: a general practitioner's approach. *Digestive diseases (Basel Switzerland)*, *40*(3), 362–369. https://doi-org.proxy.library.vanderbilt.edu/10.1159/000517301

MALABSORPTION

DEFINITION

A. Malabsorption syndrome is a group of signs and symptoms occurring as a result of digestive problems and absorption of nutrients. There may be a resultant decrease in absorption of fat-soluble vitamins A, D, E, and K. Poor absorption of carbohydrates, minerals, and proteins may also occur.
B. The presentation of malabsorption varies from severe overt symptoms with weight loss to discrete oligosymptomatic changes in hematologic/laboratory tests that are found incidentally. Malabsorption can result from congenital defects or from acquired defects, such as bariatric surgery, and may be either global or partial. The degree of nutrient malabsorption from bariatric surgery is dependent on the type of bariatric procedure.

INCIDENCE

A. Affects millions worldwide, but given the many etiologies it is difficult to determine the exact incidence and prevalence.

PATHOGENESIS

A. Deficiency of intestinal enzymes: lactase deficiency.
B. Inadequate digestion caused by diseases of the pancreas (such as cystic fibrosis [CF]), gallbladder, liver, and biliary systems.
C. Change in bacteria that normally live in the intestinal tract. ▶

D. Disease of intestinal walls, such as helminths (worms) or parasites, tropical sprue, and celiac disease.
E. Surgery that reduces the intestinal tract, decreasing the area for absorption, such as bariatric surgery.
F. Intolerance to gluten, or celiac sprue.
G. Atrophic gastritis results in hypochlorhydria and achlorhydria. The body does not produce enough pepsin and hydrochloric acid to release the food-bound vitamin B_{12} from protein.

PREDISPOSING FACTORS

A. Lactose deficiency:
  1. Incidence is increased in African Americans, Indians, and Asians.
  2. People of Jewish descent typically have onset in adulthood.
B. Family history of malabsorption or CF.
C. Use of drugs, such as mineral oil or other laxatives.
D. Excess alcohol consumption.
E. Travel to foreign countries.
F. Intestinal surgery:
  1. Partial or total gastrectomy.
  2. Small bowel resections (jejunum, ileum, ileocecal).
  3. Partial or total resection of the pancreas.
G. Chronic pancreatitis:
H. Advanced age (increased risk for malabsorption and malnutrition).
I. Long-term adherence to a strict vegetarian or vegan diet (exclusion of all forms of animal protein, including eggs and dairy products).
J. HIV infection.

COMMON COMPLAINTS

A. Diarrhea, stools pale, greasy, and copious.
B. Foul-smelling stools, frequently with mucus.
C. Weight loss despite adequate food intake.
D. Gas or vague abdominal discomfort.
E. Anorexia.

OTHER SIGNS AND SYMPTOMS

A. Early malabsorption:
  1. Minimal weight loss.
  2. Softer, more frequent stools.
  3. Steatorrhea; stools "float" due to increased trapped gas.
  4. Abdominal discomfort.
  5. Bloating.
B. Later signs: symptoms mentioned plus the following:
  1. Marked weight loss.
  2. Foul-smelling, bulky, greasy stools.
C. Malabsorption of fats and carbohydrates: previous symptoms plus the following:
  1. Foul-smelling, bulky, greasy, "sticky" stools that may be difficult to flush down the toilet.
  2. Ecchymosis.
  3. Bone pain.
  4. Glossitis.
  5. Muscle tenderness.
  6. Cramping in lower abdomen after bowel movement (BM).
D. Malabsorption of lactose:
  1. Nausea and bloating.
  2. Cramps.
  3. Diarrhea after ingesting more than customary intake of milk products.
  4. Absent or mild weight loss and steatorrhea.
  5. Good appetite.
E. Edema: with severe protein depletion/calorie malnutrition.
F. Ecchymosis and bleeding disorders secondary to vitamin K malabsorption.
G. Vitamin malabsorption:
  1. Generalized motor weakness (pantothenic acid, vitamin D).
  2. Peripheral neuropathy (thiamine).
  3. Sense of loss for vibration and position (cobalamin).
  4. Night blindness (vitamin A).
  5. Seizures (biotin).

SUBJECTIVE DATA

A. Review onset, duration, and course of symptoms. Are there any other family members with the same history/symptoms?
B. Ask the client about dietary intake history.
C. Review any changes in BMs and stool characteristics.
D. Inquire about recent travel to areas known for giardiasis or other parasites.
E. Document weight loss, how much, and over what period of time.
F. Review previous gastrointestinal (GI) surgery, including bariatric procedures and reversals, small bowel resections, and partial or total resection of the pancreas.
G. Ask the client about signs and symptoms of inflammatory bowel disease (IBD), such as easy bruising, paresthesia, and sore tongue.
H. Ask about any irradiation treatment.

PHYSICAL EXAMINATION

A. Check pulse, respirations, and blood pressure (BP; may have orthostatic hypotension). Check height and weight to calculate body mass index (BMI) in order to follow serial weight loss.
B. Inspect:
  1. Observe general appearance, noting wasting and apathetic appearance.
  2. If the client experiences a BM after the examination, observe the stool for volume, appearance, presence of blood, mucus, and the presence of gross worms/parasites.
  3. Inspect the skin for ecchymosis, jaundice, pallor, surgical scars, stigmata of hyperthyroidism or hepatocellular failure, or signs of Kaposi sarcoma. Alopecia or seborrheic dermatitis may be present.
  4. Inspect the ears, nose, and throat for glossitis, stomatitis, aphthous ulcers, poor dentition, and goiter.
C. Auscultate:
  1. Auscultate the heart for tachycardia.
  2. Auscultate the abdomen in all four quadrants for bowel sounds, noting borborygmi.
D. Percuss:
  1. Percuss abdomen.
E. Palpate:
  1. Palpate all lymph nodes; look for lymphadenopathy.
  2. Palpate the abdomen for organomegaly, focal tenderness, masses, distension, and ascites.
F. Neurologic exam:
  1. Assess for signs of vitamin B_{12} deficiency, including motor weakness, peripheral neuropathy, or ataxia.
G. Rectal exam:
  1. Note tenderness, discharge, blood, and stool.

DIAGNOSTIC TESTS

A. Assessment of stool fat: qualitative assessment on a single specimen.

▶

B. Quantitative assessment of a 72-hour stool collection while the client is following a 100 g of fat diet.
C. Sudan III stain: performed on a spot stool sample and is sensitive for malabsorption.
D. Increased fecal fat: test for celiac disease.
E. Abdominal ultrasound.
F. Colonoscopy to evaluate and obtain biopsies.
G. Endoscopy to evaluate and obtain biopsies.
H. Barium studies.
I. Consider CT of the abdomen.
J. Endoscopic retrograde cholangiopancreatography (ERCP) helps to document malabsorption due to pancreatic or biliary-related disorders.
K. Breath tests for carbohydrate malabsorption.
L. Complete blood count (CBC) and electrolytes.
M. Serum iron, vitamin B_{12}, and folate concentrations.
N. Prothrombin time (PT): may be prolonged due to vitamin K deficiency.
O. Vitamin levels: Vitamins A, D, E, and K may be decreased.
P. Total protein: may be decreased.
Q. Albumin: may be decreased.
R. Serum amylase.
S. Stool for ova and parasites; obtain on alternate days for three or more specimens because parasites are passed intermittently.
T. Serum immunoglobulin A (IgA): used to rule out IgA deficiency.
U. Three-stage Schilling test (vitamin B_{12} deficiency) identifies the cause of B_{12} deficiency. However, it is rarely used now due to B_{12} and methylmalonic acid availability. The administration of oral or injectable B_{12} is commonly ordered.

DIFFERENTIAL DIAGNOSES

A. Malabsorption.
B. AIDS.
C. Alcoholism.
D. Worms or parasites.
E. CF.
F. Celiac disease.
G. Failure to thrive (FTT).
H. Crohn's disease (CD).
I. Tropical sprue.
J. Side effect from bariatric surgery.
K. Disaccharidase deficiencies (lactase).
L. Fructose intolerance.
M. Lactose intolerance.
N. Milk or protein allergy.
O. Whipple disease.
P. Zollinger–Ellison syndrome.
Q. Chronic pancreatitis.
R. Cirrhosis.

PLAN

A. General interventions:
1. Treatment depends on underlying cause.
B. Client teaching: *See Client Teaching Guide for this chapter, "Lactose Intolerance and Malabsorption."*
C. Dietary management:
1. In most clients, diet modification or dietary supplements restore health.
D. Pharmaceutical therapy:
1. Vitamin supplements: Fat-soluble vitamins A, D, and K are most likely to be depleted. Supplements help prevent malnutrition, even though caloric intake may be replenished:
a. Vitamin A: 25,000 to 50,000 U/d orally.
b. Vitamin D: 30,000 U/d orally.
c. Vitamin K: 4 to 12 mg/d orally.
d. Vitamin B_{12}: 1,000 g/mo by intramuscular (IM) injection.
2. Enzyme replacements: These replace endogenous exocrine pancreatic enzymes and aid in digestion of starches, fat, and proteins. Pancreatic supplements are typically expressed in U.S. Pharmacopeia Convention (USP) units. One international unit (IU) is equivalent to approximately two to three USP units:
a. Pancreatin: Doses vary with the condition being treated. Oral doses are given before or with meals or each snack. They may also be given in divided doses at 1- to 2-hour intervals throughout the day**. Use with extreme caution in clients with a known hypersensitivity to pork products:**
i. Malabsorption syndrome: 8,000 to 24,000 USP units of lipase activity occasionally up to 36,000 units of lipase activity may be required. Considerable dosage variation exists, partly due to the susceptibility of pancreatin to acid–peptic inactivity in the upper GI tract.
ii. Functional indigestion: 1,200 to 2,400 USP of lipase activity.
b. Pancrelipase (Creon, Pancrease, Ultrase, Viokase): This must be given with each meal or snack:
i. Adults: one to three capsules or tablets orally with meals; titrate dose to desired clinical response.
3. Antispasmodics:
a. Anticholinergic agents are used to reduce the cholinergic stimulation of colonic activity that occurs in response to a meal.
b. Drug of choice: dicyclomine hydrochloride (Antispas), 10 to 20 mg orally before meals.
4. Iron and folic acid supplementation are usually required for celiac disease.
5. Calcium and magnesium supplementation are required after extensive small intestinal resection.
6. Antibiotic therapy for bacterial overgrowth.
7. Corticosteroids and anti-inflammatory agents to treat regional enteritis.

FOLLOW-UP

A. If exam is normal, observe the client for 1 month and have the client keep a diary of food intake and weight.
B. For persistent malabsorption, monitor for osteoporosis/bone mass with a dual-energy x-ray absorptiometry (DEXA) scan.

EMERGENT ISSUES/INSTRUCTIONS

A. Any client with weight loss of 15 kg is likely to have a life-threatening condition and requires prompt consultation and hospitalization.

CONSULTATION/REFERRAL

A. Consult a gastroenterologist when malabsorption is documented by 72-hour stool fat assessment.
B. Consider a dietary consultation.
C. Refer back to the bariatric surgeon/center, depending on surgical complications from bariatric surgery.
D. Consider a referral for allergy testing for milk and proteins.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. Weight loss/appetite suppression: Weight loss is a predictor of mortality. Clinically significant weight loss is considered to be 5% loss of usual body weight in 3 months or 10% in 6 months

2. Individuals 65 years of age and older are more likely to develop a vitamin B_{12} deficiency because they are at risk for both malabsorption and malnutrition.

3. The frail older adults may have dietary insufficiency due to:

a. Cognitive disabilities.
b. Social isolation, depression, bereavement.
c. Physical impairment/mobility limitations.
d. Poor dentition:
   i. Poor-fitting dentures.
   ii. Edentulous.
e. Poverty.
f. Loss of the sense of taste.
g. Inability to prepare meals.
h. Lack of assistance feeding.
i. Too little time to eat/be fed.

BIBLIOGRAPHY

NAUSEA AND VOMITING

DEFINITION

A. Nausea and vomiting are common symptoms for many conditions and diseases; several terms describe the symptoms (Table 14.22).

1. Hyperemesis gravidarum is a condition of persistent, uncontrollable vomiting that begins in the first weeks of pregnancy and may continue throughout pregnancy.

2. Chronic nausea and vomiting is defined as at least 1 month in duration.

3. Complications of nausea and vomiting include fluid depletion, hypokalemia, and metabolic alkalosis.

4. Vomiting is also considered a protective mechanism to remove harmful ingested substances.

INCIDENCE

A. Nausea and vomiting are very common, and the etiology is dependent on the disease/condition.

B. During pregnancy, 50% to 95% of females experience nausea and/or vomiting; 50% have both nausea and vomiting. Onset after the initial 9 weeks of pregnancy should direct especially careful evaluation for another cause within the differential diagnoses of nausea and vomiting in nonpregnant clients. Hyperemesis gravidarum occurs in 1 in every 0.5% to 2% of pregnancies. Severe hyperemesis requires hospitalization in 0.3% to 2% of pregnancies.

C. Approximately one-third of surgical clients have nausea and/or vomiting after general anesthesia.

D. The incidence of nausea and/or vomiting subsequent to cancer treatment is high.

PATHOGENESIS

A. Protective mechanisms are activated by numerous gastrointestinal (GI) and non-GI causes. Normal function of the upper GI tract involves an interaction between the gut and the central nervous system (CNS).

B. Nausea and vomiting in pregnancy are related to increased hormones, including human chorionic gonadotropin (HCG), estrogen, and progesterone, as well as decreased gastric motility and relative hypoglycemia that result from a night-long fast.

PREDISPOSING FACTORS

A. Acute nausea and vomiting.

1. Medications: digitalis toxicity, opiate use, anesthetic, chemotherapy agents, drug withdrawal, nicotine/nicotine patches, antibiotics, hormones, and antivirals.

2. Ketoacidosis.

3. Pregnancy or hormones.

4. Binge drinking.

5. Hepatitis.

B. Recurrent or chronic nausea and vomiting.

1. Psychogenic vomiting.

2. Metabolic disturbances.

3. Gastric retention.

4. Bile reflux.

5. Pregnancy.

6. Radiation.

7. Gastroparesis.

TABLE 14.22 DEFINITIONS OF TERMINOLOGY USED TO DESCRIBE NAUSEA AND VOMITING

Anorexia	Loss of desire to eat; a true loss of appetite
Early satiety	Fear of being full after eating an unusually small quantity of food
Nausea	The unpleasant sensation of the imminent need to vomit, usually referred to the throat or epigastrium; a sensation that may or may not ultimately lead to vomiting
Regurgitation	The act by which food is brought back into the mouth without the abdominal and diaphragmatic muscular activity that characterizes vomiting
Retching	Spasmodic respiratory movements against a closed glottis with contraction of the abdominal musculature without expulsion of any gastric contents, referred to as "dry heaves"
Rumination	Chewing and swallowing of regurgitated food that has come back into the mouth through voluntary increase in abdominal pressure within minutes of eating or during eating; rumination may be accompanied by weight loss and bulimia
Sitophobia	Fear of eating because due to subsequent or associated discomfort
Vomiting	Forceful oral expulsion of gastric contents associated with contraction of the abdominal and chest wall musculature

C. Nausea and vomiting with abdominal pain.
- **1.** Viral gastroenteritis.
- **2.** Acute gastritis.
- **3.** Food poisoning.
- **4.** Peptic ulcer disease (PUD).
- **5.** Acute pancreatitis.
- **6.** Small bowel obstruction.
- **7.** Acute appendicitis.
- **8.** Acute cholecystitis.
- **9.** Acute cholangitis.
- **10.** Acute pyelonephritis.
- **11.** Inferior myocardial infarction (MI).

D. Nausea and vomiting with neurologic symptoms.
- **1.** Increased intracranial pressure (ICP).
- **2.** Midline cerebellar hemorrhage.
- **3.** Vestibular disturbances.
- **4.** Migraine headaches.
- **5.** Autonomic dysfunction.
- **6.** Head trauma.
- **7.** Multiple sclerosis.

COMMON COMPLAINTS

A. "Queasy" sensation.
B. Food aversion.
C. Inability to retain food or liquids.

OTHER SIGNS AND SYMPTOMS

A. Increased salivation.
B. Bitter taste, "acid brash": indicates ulcer or small bowel obstruction.
C. Weight loss.
D. Dehydration.
E. Sweating.
F. Fast pulse.
G. Pale skin.
H. Rapid breathing.
I. Light-headedness.

SUBJECTIVE DATA

A. Review onset, duration (acute or chronic problem?), and course of symptoms, including the quality (projectile?) and quantity of emesis. What were the color, taste, and consistency of the emesis? Was blood present?
- **1.** Vomiting bright red blood indicates a hemorrhage—*peptic ulcer.*
- **2.** Dark red blood indicates a hemorrhage—*esophageal or gastric varices.*
- **3.** Coffee grounds material is indicative of digested blood from a slowly bleeding gastric ulcer or duodenal ulcer (DU).
- **4.** Vomiting fecal material is a sign of distal *small bowel obstruction* and blind-loop syndrome.
- **5.** Explosive projectile vomiting is associated with increased ICP such as with meningitis.

B. Ask the client about other symptoms, including pain, fever, diarrhea, and headache.
C. Inquire if other family members are also ill and what their symptoms are.
D. Review the timing of vomiting in relation to meals, time of day, odors, and activity. Does vomiting occur before or after food intake?
E. Ask the client about medication intake such as antibiotics, chemotherapy, herbals, digitalis, opiates, and birth control pills.
F. Ask about self-image, binge eating, and self-induced emesis.
G. Review any exposure to hepatitis or travel to places with poor sanitation and outbreaks of cholera.
H. Review the client's medical history for vertigo, head injury, jaundice, diabetes, hypertension, and pregnancy.
I. Inquire about first day of last period and birth control method used.
J. Establish usual weight. Has there been any recent weight change, how many pounds, and over what period of time?
K. Ask about the client's history of diabetes, gallbladder disease, ulcer disease, or cancer.

PHYSICAL EXAMINATION

A. Check temperature (if indicated), pulse (which should be checked both standing and lying down), respirations, blood pressure (BP), and weight.
B. Inspect:
- **1.** Observe general overall appearance of skin for pallor and signs of dehydration. Tenting of skin when it is rolled between your thumb and index finger may indicate dehydration.
- **2.** Inspect for signs of autonomic insufficiency. Postural hypotension, lack of sweat, and blunted pulse and BP responses to Valsalva maneuver suggest autonomic dysfunction and a bowel motility problem as the underlying etiology of nausea and vomiting. Postural hypotension indicates marked volume depletion or circulatory collapse.
- **3.** Oral exam: Inspect mouth, teeth, and gums. Pay particular attention for dental enamel erosion as a sign of bulimia.

C. Palpate:
- **1.** Palpate the abdomen for masses, distension, tenderness, signs of peritonitis, and organomegaly.
- **2.** Palpate the back; note costovertebral angle (CVA) tenderness.

D. Percuss:
- **1.** Percuss the abdomen.

E. Auscultate:
- **1.** Auscultate the abdomen for bowel sounds in all quadrants.
- **2.** Auscultate the heart and lungs.

F. Rectal exam (if indicated).
G. Neurologic examination (if indicated).

DIAGNOSTIC TESTS

A. The cause of an acute episode of nausea and vomiting is typically determined through a detailed history and physical examination. Only if the cause is unclear should further diagnostic tests be performed.
B. Urine: ketones, specific gravity, pregnancy test, culture and sensitivity, if indicated.
C. Serum labs: multiple chemistry profile, including amylase, electrolytes, blood urea nitrogen (BUN), creatinine, glucose, and transaminase.
D. Drug screen.
E. Hepatitis panel.
F. Upper GI.
G. Ultrasonography:
- **1.** Obstetric ultrasound to rule out multiple gestation and/or molar pregnancy if persistent nausea and vomiting, especially after 16 weeks' gestation.
- **2.** Upper abdominal ultrasound, if clinically indicated, to evaluate the pancreas and/or biliary tree.

H. Stool for occult blood.

▶

I. Endoscopy.
J. CT scan.
1. Head CT scan, if indicated.
2. Abdominal CT if appendicitis is suspected.
K. Gastric scintigraphy, to rule out gastroparesis if indicated.
L. EKG if chest pain/MI is suspected.

DIFFERENTIAL DIAGNOSES

A. See "Predisposing Factors."

PLAN

A. General interventions:
1. Assess hydration status. Proceed to intravenous (IV) hydration and antiemetics until ketones clear.
B. Dietary management:
1. See Appendix B, "Dietary Recommendations."
C. Pharmaceutical therapy (not an exhaustive list):
1. Antiemetics:
a. Dextrose/fructose/phosphoric acid solution (Emetrol); available over the counter:
i. Adults: 15 to 30 mL PO at 15-minute intervals (not to exceed five doses)
ii. Tell the client not to dilute the drug or take fluids 15 minutes before or after taking the medication.
iii. Diabetics should be instructed not to use without consulting their provider.
iv. If nausea continues despite medication, contact healthcare provider.
b. Promethazine (Phenergan):
i. Drug of choice for gastroenteritis.
ii. Adults: 25 to 50 mg PO or per rectum every 4 to 6 hours.
c. Trimethobenzamide (Tigan):
i. Used for gastroenteritis and motion sickness.
ii. Adults: 300 mg orally three or four times daily.
iii. Adults: 200 mg IM three or four times daily.
d. Prochlorperazine (Compazine):
i. Adults: 5 to 10 mg three or four times daily; spansules 15 mg Q12H; suppositories 25 mg BID.
2. Outpatient IV hydration in pregnancy: 1 L lactated Ringer solution to correct dehydration and restore electrolyte balance. Check urine ketones after first liter to determine if additional liter is necessary to clear ketones.
3. 5-hydroxytryptamine (5-HT3, or serotonin) antagonists are utilized for nausea related to chemotherapy and postoperative nausea and vomiting. 5-HT3 drugs are available in oral, IV, and transdermal formulations. Consult a prescribing reference for current dosing/formulations:
a. Ondansetron (Zofran).
b. Granisetron (Sancuso and Kytril).
c. Palonosetron (Aloxi).
d. Dolasetron mesylate (Anzemet).
4. Dronabinol (Marinol), cannabinoid 2.5, 5, and 10 mg capsules are indicated for refractory nausea and vomiting associated with chemotherapy. Therapy is individualized before and after chemotherapy.

FOLLOW-UP

A. Tell the client to call or visit the office in 24 hours to check response and nutritional intake.

EMERGENT ISSUES/INSTRUCTIONS

A. First priority is to rule out acute surgical etiology such as bowel obstruction and peritonitis.
B. ***If overdose is suspected, contact 1-800-222-1222, the American Association of Poison Control Centers, the local poison control center, or the ED immediately.***

CONSULTATION/REFERRAL

A. Consult a physician and hospitalize the client promptly if there is evidence of bowel obstruction; increased ICP; or another GI, neurologic, or metabolic emergency.
B. Hyperemesis gravidarum is the most severe form of nausea and vomiting in pregnancy. Hyperemesis gravidarum may require hospitalization to correct fluid and electrolyte imbalance, and nutritional deficiencies.
C. Call for a psychiatric consultation for suspected psychogenic nausea and vomiting.
D. If postural hypotension occurs, especially in older adults, hospital admission for parenteral fluid and electrolyte replacement is indicated.
E. Endocrinologist, gastroenterologist, and surgical consultations for treatment, consideration, and placement of a gastric stimulator for diabetic gastroparesis.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:
1. Determine whether the client is ingesting nonfood substances, such as starch, clay, or toothpaste, which would indicate pica.
2. Intractable nausea and vomiting require ultrasonography to rule out hydatidiform mole.
3. Emetrol, promethazine (Phenergan), and prochlorperazine (Compazine) may be used during pregnancy.
4. The only Food and Drug Administration (FDA)-approved drug for treating nausea and vomiting in pregnancy is doxylamine/pyridoxine. Antihistamines, promotility agents (e.g., metoclopramide), Emetrol, promethazine (Phenergan), and prochlorperazine (Compazine) may be used during pregnancy. In cases of refractory to standard therapy, ondansetron and steroids may be considered.
5. Uncorrected hyperemesis gravidarum can result in severe electrolyte imbalance and possible hepatic and renal damage. The major concern for fetal well-being is uncorrected ketosis, which may result in fetal abnormalities or death in early pregnancy.
6. Tell the client to eat toast or a dry cracker; to eat small, frequent meals and snacks; to drink fluids separately from meals; and to avoid fatty, fried, greasy, or spicy foods and foods with strong odors.
B. Geriatrics:
1. There should be a low threshold for hospitalization of older adults to treat dehydration and correction of fluid and electrolyte imbalance.
2. Use of the lower dose ranges of an antiemetic is sufficient for most older adults due to their susceptibility to hypotension and neuromuscular reactions. Dosages should be increased more gradually in older adults.
3. For the older adult with existing nausea and vomiting, nurse practitioners (NPs) should practice special consideration of the following *geriatric syndromes*:
a. Delirium is a common early sign of acute illness or infection in older adults. It is more common in clients with existing cognitive impairment. Dehydration is more common in older adults. Signs of dehydration include confusion, muscle weakness, fever, dizziness, poor skin turgor, hypotension, and tachycardia. ▶

Diminished thirst mechanism and decreased body water exacerbate dehydration.

i. At a minimum, clients and their family should be asked if the client has experienced episodes of altered mental status.

ii. The Brief Confusion Assessment Method (bCAM) is a well-documented assessment for delirium. The bCAM is available at www.mnhospitals.org/Portals/0/Documents/ptsafety/LEAPT%20Delirium/HELP%20Program%20CAM%20Flowsheet.pdf.

b. Weight loss/appetite suppression: Weight loss is a predictor of mortality. Clinically significant weight loss is considered to be 5% loss of usual body weight in 3 months or 10% in 6 months:

i. Due to GI distress, abdominal discomfort, diarrhea, older adults are at increased risk of avoiding eating.

ii. Monitor weight patterns/body mass index (BMI). (Caution: BMI is not used to identify loss of muscle mass.)

iii. Monitoring both serum albumin and anemia: Hhypoalbuminemia and anemia are not necessarily associated with low bodyweight. They can be caused by decreases in liver protein synthesis.

1) Serum albumin concentration is commonly recommended.
2) Hemoglobin, prealbumin, and transferrin.
3) Cholesterol.

c. Falls: Consistently assess for falls. Discuss the risk of dizziness or light-headedness when standing.

i. At the minimum, older adults should be asked how many times they have fallen since their last visit. A reported fall should trigger questions about whether the fall led to injury, a visit to urgent care or hospital ED, or a hospital admission. Safety measures to reduce falls in the home include removing small area carpets, keeping night lights along the path to the bathroom, installing a toilet seat or nearby grab bars. *See Client Teaching Guide for Chapter 3, "Safety Issues: Fall Prevention."*

C., Ayad, S., Beagley, L., Candiotti, K., Englesakis, M., Hedrick, T. L., Kranke, P., Lee, S., Lipman, D. … Philip, B. K. (2020). Fourth consensus guidelines for the management of postoperative nausea and vomiting. *Anesthesia and Analgesia*, *131*(2), 411–448. https://doi-org.proxy.library.vanderbilt.edu/10.1213/ANE.0000000000004833

PANCREATITIS

DEFINITION

A. Acute pancreatitis is defined as an inflammatory pancreatic condition characterized by local injury, systemic inflammatory response, and possibly organ failure. The most common causes of acute pancreatitis are gallstones and alcohol use.

B. Pancreatitis is subdivided into several categories based on the 2012 Atlanta Classification of acute pancreatitis including:

1. Mild acute pancreatitis:
   a. No organ failure, local or systemic complications.
2. Moderately severe acute pancreatitis:
   a. Organ failure that resolves within 48 hours. AND/OR
   b. Local or systemic complications without persistent organ failure:
      i. Local complications of acute pancreatitis include:
         1) Acute peripancreatic fluid collections.
         2) Pancreatic pseudocysts.
         3) Acute necrotic collections.
         4) Walled-off pancreatic necrosis.
3. Severe acute pancreatitis: persistent organ failure greater than 48 hours.
4. Interstitial edematous acute pancreatitis.
5. Necrotizing acute pancreatitis.
6. Organ failure and systemic complications of acute pancreatitis.

INCIDENCE

A. Pancreatitis is the most common gastroenterologic condition resulting in hospitalization.

B. In the United States, the incidence is 600 to 700 per 100,000 people, with an approximate 1% mortality rate. The peak age of acute pancreatitis is in the fifth and sixth decades; however, mortality increases with age, pancreatitis, organ failure, or pancreatic necrosis.

C. The most common causes are alcohol use and gallstones. However, the incidence is on the rise in part due to hypertriglyceridemia and metabolic syndrome.

PATHOGENESIS

A. Pancreatitis involves localized destruction in the pancreas and systemic inflammatory response. There is also a genetic predisposition for pancreatitis.

B. The inciting event is the premature activation of trypsinogen to trypsin. Normal feedback mechanisms that prevent over accumulation or early release of digestive enzymes are impaired. Accumulation of digestive enzymes creates injury to the pancreas.

C. Impairment can occur at any point along the pathway of digestive enzymes, from injury of the acinar cells that produce digestive enzymes, to early release of enzymes from their transport mechanism, to problems involving the release along the brush border of the duodenum.

D. Once injury occurs, the inflammatory response ensues and causes increased vascular permeability of pancreas, leading to hemorrhage and edema. Necrosis of the tissue can then occur.

E. Mediators of this event are released into the bloodstream, leading to bacteremia, acute respiratory distress syndrome, pleural effusion, gastrointestinal (GI) hemorrhage, and renal failure.

F. Immune-mediated toxicity is thought to be the cause of amino salicylates and sulfonamides, direct toxicity with diuretics, and accumulation of toxic metabolites with valproate and pentamidine.

G. Drug-induced; common drugs include azathioprine, erythromycin, simvastatin, itraconazole, lamivudine, olanzapine, and sulfasalazine.

PREDISPOSING FACTORS

A. Alcohol use.
B. Gallstones.

C. The mnemonic **IT HURTS BADLE** can be used to identify other predisposing factors:
- **1. I**nfectious (bacterial, viral, and parasitic).
- **2. T**umor.
- **3. H**ypercalcemia and hypertriglyceridemia.
- **4. U**lcer (penetrating).
- **5. R**enal failure.
- **6. T**rauma.
- **7. S**tricture.
- **8. B**iliary tract obstruction.
- **9. A**lcohol or anatomic abnormality.
- **10. D**rugs.
- **11. L**ipids: hypertriglyceridemia.
- **12. E**ndoscopic retrograde cholangiopancreatography (ERCP; postprocedure).

COMMON COMPLAINTS

A. Cardinal symptoms:
- **1.** Characteristic abdominal pain located in the epigastrium or left upper quadrant (LUQ), acute onset and steadily progressive; described as steady, boring and dull; radiating into the back or flank, occurring with nausea and anorexia.

OTHER SIGNS AND SYMPTOMS

A. Fever.
B. Dehydration.
C. Tachycardia/tachypnea.
D. Abdominal bloating and distention.
E. Diarrhea.
F. Fatigue.
G. Jaundice.

SUBJECTIVE DATA

A. Elicit information regarding onset, duration, location and characteristics of pain, aggravating and alleviating symptoms, radiation of the pain, and severity of symptoms.
B. Obtain the client's medical history with thorough review of systems.
C. Review all of the client's prescription and over-the-counter (OTC) medications and herbals.
D. Inquire regarding the client's social habits:
- **1.** Alcohol use (how much, how often, over what length of time).
- **2.** Smoking (how much, how often, what length of time).
- **3.** Assess hobbies and occupation to assess risk of toxin exposure.
- **4.** Inquire regarding surgeries and recent procedures, especially an ERCP.

E. Inquire about familial pancreatitis.
F. Review bowel habits and note changes: constipation, diarrhea, anorexia, food intolerance, nausea, vomiting, or bloating.

PHYSICAL EXAMINATION

Evaluate for a "surgical abdomen," defined as a rapidly worsening prognosis in the absence of surgical intervention. Once a surgical abdomen has been excluded, the remainder of the evaluation will be guided by the cause, chronicity of symptoms, along with the location of pain.

A. Check temperature, blood pressure (BP; hypotension in severe cases), pulse (tachycardia), respirations (tachypnea), and height and weight to calculate body mass index (BMI). Notice any weight loss.
B. Inspect:
- **1.** Observe overall appearance: facial expressions, demeanor with walking, refusal to move/writhing; note grimace during exam.
- **2.** Assess for signs of dehydration, including confusion, muscle weakness, fever, dizziness, poor skin turgor, dry mucous membranes, hypotension, and tachycardia.
- **3.** Observe for jaundice and skin changes:
  - a. Sclera icterus.
  - b. Skin:
    - i. Ecchymosis due to hemorrhage:
      - 1) Grey–Turner sign: back/flank.
      - 2) Cullen sign: abdominal/periumbilical.
    - ii. Xanthomas: hypertriglyceridemia.

C. Auscultate:
- **1.** Heart.
- **2.** Lungs:
  - a. Rales may be present if the client has atelectasis due to shallow respirations or pneumonia.
  - b. Decreased breath sounds due to pleural effusions.
- **3.** Abdomen: Assess for bowel sounds in all four quadrants. Diminished bowel sounds; possibly tinkling bowel sounds due to distention.

D. Palpate:
- **1.** Neck: parotid mass if pancreatitis is secondary to mumps infection.
- **2.** Abdomen examination:
  - a. Classic: tenderness in the epigastrium.
  - b. Palpate for hepatomegaly and splenomegaly, rebound tenderness, and peritoneal signs.
  - c. Older adults may lack classic peritoneal signs of rebound and guarding.

E. Percuss:
- **1.** Abdomen for hepatomegaly or splenomegaly. Tympany may be present with a distended abdomen.

F. Neurologic exam
- **1.** Assess for mental status changes which could be indicative of encephalopathy, impending coma, or shock.

DIAGNOSTIC TESTS

A. Laboratory:
- **1.** Serum amylase and lipase: in all clients suspected of acute pancreatitis. A threefold elevation of serum lipase or amylase is identified by the American College of Gastroenterology as one of the three clinical features necessary for diagnosis, along with classic pain consistent with acute pancreatitis and abdominal imaging consistent with acute pancreatitis (ultrasound, CT, or MRI):
  - a. Lipase has a higher diagnostic accuracy compared with amylase as the serum lipase levels are elevated for a longer period of time.
  - b. Amylase for clients with hypertriglyceridemia may be falsely low.
- **2.** C-reactive protein (CRP) on admission and daily for the first 72 hours after admission.
- **3.** Complete blood count (CBC).
- **4.** Comprehensive metabolic profile (CMP).
- **5.** Liver function tests: alanine transaminase (ALT), aspartate transaminase (AST), lactate dehydrogenase (LDH), triglycerides.
- **6.** Blood urea nitrogen (BUN) and creatinine.
- **7.** Arterial blood gases.

B. EKG: Assess for acute coronary syndrome.
C. Imaging:
- **1.** X-ray:

a. Chest: for pneumonia or pleural effusion.
b. Abdominal plain films: to assess for free air.

2. Ultrasound should be performed in all clients at baseline to assess the biliary tract to determine if there is presence of gallstones and/or a stone in the common bile duct (CBT).

3. CT abdomen with contrast:
a. Selective use when there is a broad differential diagnosis that includes acute pancreatitis or suspected local complications suggested on ultrasound.
b. Assessment of local complications 48 to 72 hours after the onset of symptoms.
c. Contraindications to CT with contrast include renal dysfunction and allergy to the contrast medium.

4. Magnetic resonance cholangiopancreatography (MRCP): reserved for severe cases with an elevation of liver enzymes and CBD is not visualized adequately or is found to be normal on ultrasound.

5. ERCP: within 24 to 72 hours in clients with acute gallstone pancreatitis associated with bile duct obstruction or cholangitis.

DIFFERENTIAL DIAGNOSES

A. Pancreatitis.
B. Causes of acute abdomen:
1. Cholecystitis.
2. Appendicitis.
3. Ectopic pregnancy.
4. Ischemic bowel.
5. Small or large bowel obstruction.
6. Perforated viscus.
C. Infectious origin:
1. Abscess.
2. Pyelonephritis.
3. Viral: HIV, cytomegalovirus (CMV), Epstein–Barr, mumps, Coxsackie.
4. Bacterial: *Campylobacter jejuni, Legionella, Mycobacterium tuberculosis, Mycoplasma, Shigella.*
5. Parasitic: *Ascaris lumbricoides*, Cryptosporidium, Microsporidia.
D. GI pathology:
1. Esophagitis.
2. Esophageal rupture.
3. Peptic ulcer disease (PUD).
4. Bowel perforation.
5. Bowel obstruction.
E. Cardiovascular pathology:
1. Acute coronary syndrome.
2. Aortic dissection.
F. Hepatic pathology: hepatitis (all types).
G. Renal pathology: nephrolithiasis.
H. Pancreatic cancer (increases at age 40 years or older).

PLAN

A. General interventions:
1. Acute pancreatitis management is dependent not only on the etiology of the illness but more importantly on the severity. Acute pancreatitis can range from mild and self-limited to life-threatening.
2. Clients diagnosed with acute pancreatitis are managed inpatient. For severe cases, defined by organ failure, ICU admission is necessary.
3. Once the diagnosis is confirmed, rapid assessment of hydration status is warranted. Fluid resuscitation is critical within the first 24 hours to prevent complications.
4. Risk assessment should be performed to determine the severity of pancreatitis; results guide further management. There are several risk assessment tools available:
a. Calculation of an Acute Physiologic Assessment and Chronic Health Evaluation (APACHE) II score on admission and daily for the first 72 hours after admission. An APACHE II calculator is located at www.globalrph.com/apacheii.htm.
b. Ranson's Criteria in Acute Pancreatitis-Prognostic Implication located at www.globalrph.com/ransons.htm.
5. For mild pancreatitis, fluid resuscitation, pain management, and supportive care are recommended. Generally, mild pancreatitis is self-limited.
6. Although lipase and amylase measurement can assist in diagnosing pancreatitis, following the levels during treatment is not recommended.
B. Pharmaceutical therapy:
1. Antibiotics are not indicated unless an extrapancreatic infection exists.
C. Diet:
1. Enforcing a strict NPO diet is unnecessary for a client with mild acute pancreatitis. Once abdominal pain, nausea, and vomiting resolve, they may begin a low-fat diet as tolerated.

FOLLOW-UP

A. Reevaluate in the office posthospitalization: For mild cases, following with the primary care provider is recommended. However, for moderately severe or severe cases, follow-up with the specialist is recommended.
B. Monitor for increasing pain, anorexia, recurrence of nausea and vomiting, dyspnea or tachycardia, fever, weight loss, or jaundice.
C. Lab follow-up: It is not recommended to repeat amylase and lipase. Lab follow-up is dependent on the etiology of pancreatitis. For instance, following serum transaminases, alkaline phosphatase, bilirubin if biliary obstruction is the cause, or following a lipid profile if due to hypertriglyceridemia.
D. Follow up with specialist (e.g., surgeon, hepatologist, gastroenterologist, oncologist, infectious disease specialist) as directed.
E. For clients who developed pancreatitis from alcohol abuse, continued counseling and referral into an alcohol treatment program are indicated. Clients should be counseled at follow-up visits regarding the importance of continual abstinence from alcohol to prevent the development of chronic pancreatitis.
F. Clients who smoke should be counseled on cessation because smoking is an independent risk factor for development of pancreatitis.
G. Long-term management of acute pancreatitis involves eliminating the causative factor to prevent recurrence.
H. Recurrence rate of biliary pancreatitis is 60% and usually occurs within 6 weeks. Therefore, cholecystectomy at time of hospitalization or within 4 weeks of discharge is recommended.

CONSULTATION/REFERRAL

A. Dependent on etiology.
B. Endocrinology: hypercalcemia, hypertriglyceridemia, or resulting pancreatic insufficiency.
C. Rheumatology: autoimmune pancreatitis.
D. Gastroenterology/surgery: abscess, hemorrhage, pseudocyst, cholecystectomy.
E. Infectious disease: underlying infection.

INDIVIDUAL CONSIDERATIONS

A. Geriatrics:

1. Delirium is a common early sign of acute illness or infection in older adults. It is more common in clients with existing cognitive impairment. At a minimum, clients and their family should be asked if the client has experienced episodes of altered mental status:

a. The Brief Confusion Assessment Method (bCAM) is a well-documented assessment for delirium. The bCAM is available at www.mnhospitals.org/Portals/0/Documents/ptsafety/LEAPT%20Delirium/HELP%20Program%20CAM%20Flowsheet.pdf.

2. Older adults have a diminished sensorium, allowing pathology to advance to a dangerous point prior to symptom development:

a. The level of pain is much less severe at presentation and continues to be at a lower level of pain.

b. Older adults may present with altered mental status. Cognitive impairment can make assessment and diagnosis of pain more difficult. For dementia or noncommunicative clients, the American Medical Directors Association has endorsed the Pain Assessment in Advanced Dementia (PAINAD) Scale, which scores the following items:

i. Breathing: Examples include normal, labored, hyperventilation.

ii. Negative vocalization: Examples include moaning, negative language, crying.

iii. Facial expression: Examples include smiling, frowning, grimacing.

iv. Body language: Examples include relaxed, tense, rigid, or striking out.

v. Consolability: Examples include extent to which a caregiver is able to console, distract, or reassure.

PEPTIC ULCER DISEASE

DEFINITION

A. Peptic ulcer disease (PUD) is circumscribed ulceration of the gastrointestinal (GI) mucosa occurring in areas exposed to acid and pepsin. The client's ulcer history tends to predict future behavior and risk of future complications. Complications include bleeding ulcer, perforation, and obstruction.

B. The stomach is divided on the basis of its physiologic functions into two main portions. The proximal two-thirds, the fundic gland area, acts as a receptacle for ingested food and secrete acid and pepsin. The distal third, the pyloric gland area, mixes and propels food into the duodenum and produces the hormone gastrin. "Peptic" lesions may occur in the esophagus (esophagitis), stomach (gastritis), or duodenum (duodenitis).

C. There is often no correlation between the presence of an active ulcer, noted by endoscopy, and symptoms. The disappearance of symptoms does not guarantee ulcer healing.

INCIDENCE

A. The annual incidence of peptic ulcer is estimated to range from 0.1% to 1.8%. The ulcer incidence in *Helicobacter pylori*-infected individuals is about 1% per year. The recurrence rate is 50% to 80% during the 6 to 12 months following the initial ulcer healing, although relapses are not always symptomatic. Some peptic ulcers heal spontaneously, and 2% to 20% of clients have multiple simultaneous ulcers.

B. From 16% to 31% of ulcers are caused by nonsteroidal anti-inflammatory drugs (NSAIDs). Epidemiologic studies show that risks of peptic ulcer and death are three to six times higher among people who take NSAIDs.

C. Cigarette smokers are twice as likely to develop ulcers as nonsmokers.

D. Increased prevalence in males and people with chronic conditions.

PATHOGENESIS

A. Although the precise mechanisms of ulcer formation remain incompletely understood, the process appears to involve the interplay of acid production, pepsin secretion, bacterial infection, and mucosal defense mechanisms. Excess acid production is the hallmark of duodenal ulcer (DU) disease. Pepsin secretion is also elevated in DU disease.

B. The relation of aspirin and other NSAIDs to ulcer disease is due largely to the drugs' potent inhibition of gastric mucosal prostaglandin synthesis. In addition to prostaglandin inhibition, many NSAID preparations produce acute diffuse mucosal injury by means of a direct erosive effect.

PREDISPOSING FACTORS

A. *H. pylori* infection is the most common cause of ulceration.

B. Use of NSAIDs, especially aspirin, ibuprofen, and naproxen, is associated with acute erosive gastritis.

C. Smoking.

D. Genetic factors: family history of ulcer disease.

E. Age:

1. DU occurs between ages 25 and 75.

2. Gastric ulcer (GU) occurs between ages 55 and 65.

F. Sex:

1. The male-to-female ratio for gastritis is 1:1.

2. The male-to-female ratio for peptic ulcers is 2:1.

G. Excessive alcohol consumption, which stimulates acid secretion.

H. Medications:

1. Corticosteroids potentiate ulcer risk in clients who use NSAIDs concurrently.

2. Anticoagulants, such as warfarin.

3. Bisphosphonates.

4. Spironolactone.

5. Selective serotonin reuptake inhibitors (SSRIs).

I. Improper diet, irregular meals, and skipped meals.

J. Severe physiologic stress:

1. Burns.

2. Central nervous system (CNS) trauma.

3. Surgery.

4. Severe medical illness:
   a. Cirrhosis.
   b. Chronic obstructive pulmonary disease (COPD).
   c. Renal failure.
   d. Crohn's disease.

K. Other causes:
1. Radiation-induced ulcer.
2. Chemotherapy-induced ulcer.
3. Vascular insufficiency.
4. Duodenal obstruction.

L. Zollinger–Ellison syndrome.
M. Bile reflux.
N. Illicit drugs: crack cocaine.

COMMON COMPLAINTS

A. Perforated peptic ulcer presents with a sudden severe onset of sharp abdominal pain.
B. Pain described as aching, boring, gnawing, or burning feeling.
C. Epigastric pain in right upper quadrant (RUQ) and left upper quadrant (LUQ) of the abdomen or occasionally below breast.
D. Pain that awakens the client at night or in early morning.

OTHER SIGNS AND SYMPTOMS

A. Asymptomatic.
B. GI distress 1 to 3 hours after a meal, on an empty stomach.
C. Pain relieved by food, antacids, or vomiting.
D. Nausea and vomiting.
E. Hematemesis.
F. Chest discomfort.
G. Blood in stools, "grape jelly" or maroon-colored stools.
H. Loss of appetite or weight.
I. Weight gain; those with DU may eat more to ease pain.
J. Anemia.

OTHER SIGNS AND SYMPTOMS

A. Massive bleeding:
1. Acute, bright red hematemesis or large amount of melena with clots in the stool, or "grape jelly" stool.
2. Rapid pulse, drop in blood pressure, hypovolemia, and shock.

B. Subacute bleeding:
1. Intermittent melena or coffee-ground emesis.
2. Hypotension.
3. Weakness and dizziness.

C. Chronic bleeding:
1. Intermittent appearance of blood.
2. Increased weakness, paleness, or shortness of breath.
3. Occult blood.

SUBJECTIVE DATA

A. Ask the client to describe onset, duration, type, and location of pain. Does it occur at any special time, for example, before meals, after meals, or during the night?
B. Has the client had a previous ulcer? What was the treatment; if oral treatment was prescribed, did the client complete the therapy?
C. Have the client describe what alleviates pain, such as taking antacids, and what worsens pain, such as use of aspirin, oral steroids, or NSAIDs.
D. Review associated symptoms, such as nausea, vomiting, and heartburn.
E. Ask the client if any first-degree relatives have ulcers.
F. Inquire whether the client is a smoker. If so, how much and for how long?
G. Ask the client about alcohol consumption: How much and for how long?
H. Inquire whether any blood has ever been vomited or passed in stool. If so, have the client describe it.
I. Take the client's dietary history, including time of meals, frequency of skipped meals, weight loss, and so forth.
J. Review all medications, including a review of over-the-counter (OTC) and herbal products such as ginkgo biloba; special attention should be taken to inquire about aspirin and NSAIDs.
K. Obtain medical history of associated diseases, such as cirrhosis, pancreatitis, arthritis, COPD, and hyperparathyroidism.
L. If the client suspects blood in stool, ask if there has been a change in bowel pattern, presence of abdominal pain or tenderness, and what kind of food, such as red beets, the client recently ingested.

PHYSICAL EXAMINATION

A. Check temperature (if indicated), pulse, respirations, blood pressure, and weight.
B. Inspect:
1. Overall appearance of client.

C. Auscultate:
1. Abdomen for bowel sounds.

D. Percuss:
1. Abdomen for hepatosplenomegaly.

E. Palpate:
1. Abdomen for tenderness, rigidity, masses, and liver or spleen enlargement.

F. Rectal exam:
1. Check for tenderness and masses.
2. Take stool specimen.

DIAGNOSTIC TESTS

A. Complete blood count (CBC).
B. Stool for occult blood.
C. Coagulation studies.
D. Testing for *H. pylori:*
1. **Endoscopy with biopsy is the most accurate test.**
2. Rapid urease test is the diagnostic test of choice.
3. Urea breath test (UBT).
4. Serum test for *H. pylori* antibodies.
5. Stool *H. pylori* antigen testing: more accurate than antibody testing and less expensive.

E. Radiography with barium meal.
F. Mucosal biopsy, after GI consultation, to rule out cancer.
G. Fasting gastrin level (screening for Zollinger–Ellison syndrome).
H. Proton pump inhibitors (PPIs) are associated with osteopenia/osteoporosis; depending on the length of therapy, consider a dual-energy x-ray absorptiometry (DEXA) scan.

DIFFERENTIAL DIAGNOSES

A. PUD.
B. Gastroesophageal reflux disease (GERD).
C. Zollinger–Ellison syndrome: Fasting serum gastrin level 500 pg/mL in the presence of acid hypersecretion is diagnostic.
D. Cancer:
1. Gastric lymphoma.
2. Gastric cancer.
3. Pancreatic cancer.

E. Pancreatitis (acute or chronic).

▶

F. Myocardial ischemia.
G. Abdominal aneurysm.
H. Diverticulitis.
I. Drug-induced dyspepsia:
1. Theophylline.
2. Digitalis.
J. Crohn's disease (CD) involving the stomach or duodenum.
K. Gastric infections.
L. Cholelithiasis.

PLAN

A. General interventions:
1. Goals are to alleviate pain, promote healing, limit complications, and prevent recurrences while minimizing the costs and side effects of treatment:
B. Client teaching: *See Client Teaching Guide for this chapter, "Management of Ulcers."*
1. Encourage the client to stop taking NSAIDs, unless medically indicated:
a. If NSAID use is unavoidable, the lowest possible dose and duration and cotherapy with a PPI based on triple therapy are recommended.
2. Smoking cessation should be highly encouraged at each visit.
C. Dietary management:
1. Advise the client to avoid alcohol; coffee, including decaffeinated; and other caffeine-containing beverages because they stimulate acid secretion (see section "Bland Diet" in Appendix B).
D. Medical and surgical management:
1. Diagnostic evaluation of the ulcer is by means of endoscopy.
2. Test for *H. pylori* (carbon isotope-UBT, blood test for antibodies to *H. pylori*, stool test, or gastric biopsy at the time of esophagogastroduodenoscopy [EGD]):
a. A single negative *H. pylori* test should be interpreted cautiously, especially in the face of active bleeding. Blood in the stomach can alter the pH indicator in the rapid urease test. False-negatives are likely, and additional testing for *H. pylori* is essential.
b. Concurrent use of a PPI, antibiotics, or bismuth will cause a false-negative test.
3. Surgery remains an option for treatment of refractory disease and complications. The most serious indications for surgery include brisk bleeding of 6 to 8 units of blood in 24 hours, recurrent bleeding episodes, perforation, gastric outlet obstruction refractory to medical therapy, and failure of a benign GU to heal after 15 weeks. Emergency intervention may be required, such as withholding food and oral fluids, starting an intravenous (IV), placing a nasogastric (NG) tube, providing oxygen therapy, or performing a blood transfusion. If life-threatening bleeding occurs, treat shock.
E. Pharmaceutical therapy:
1. The treatment of a peptic ulcer begins with the eradication of *H. pylori* in infected individuals. Empiric therapy for the infection is reasonable for uncomplicated cases in the absence of NSAID use. Documenting infection, even in clients with known ulcers, is an essential step prior to initiating antimicrobial therapy:
a. Triple therapy anti-*H. pylori* regimen PPI + amoxicillin + clarithromycin:
i. PPI-based regimen (choose one):
1) Rabeprazole (Aciphex) 20 mg BID; total treatment duration 7 days.
2) Esomeprazole (Nexium) 40 mg once a day; total treatment duration 10 days.
3) Lansoprazole (Prevacid) 30 mg BID; total treatment duration 14 days.
ii. Amoxicillin 1,000 mg BID.
iii. Clarithromycin 500 mg BID.
b. Quadruple therapy–Helidac therapy (sold in a combination pack), oral doses QID for 14 days:
i. Choose standard-dose PPI, or ranitidine 150 mg BID x 14 days.
ii. Metronidazole (Flagyl) 250 mg QID x 14 days.
iii. Tetracycline 500 mg QID x 14 days.
iv. Bismuth subsalicylate 525 mg (two chewable tablets) QID x 14 days.
2. Antisecretory therapy is the mainstay of therapy in uninfected clients and is used for maintenance therapy in selected cases. Full doses of H2 receptor antagonist provide effective initial therapy; however, PPIs are more effective.
3. Clients with uncomplicated, small (<1 cm) DU or GU who have received adequate treatment for *H. pylori* probably are asymptomatic and do not need any further therapy directed at ulcer healing. Maintenance acid suppression with a PPI for 1 year following *H. pyloric* eradication is recommended for clients with a complicated DU. If the ulcer is giant (>2 cm), showing densely fibrosed ulcer beds, or if the client is a high-risk client with a protracted history, then the client should be kept on a PPI until a follow-up endoscopy is performed:
a. H2 receptor antagonist-based therapy: Split dose, evening, and nighttime therapy are all effective. In the United States, cimetidine, ranitidine, and famotidine are approved for GU healing. H2 receptor antagonist-based regimens are not U.S. Food and Drug Administration (FDA)-approved treatment regimens. Choose one antibiotic combination (amoxicillin + clarithromycin OR metronidazole + tetracycline as noted above) for 2 weeks and add one of the following:
i. Cimetidine (Tagamet) 400 mg orally BID or 800 mg at bedtime for 6 to 8 weeks.
ii. Ranitidine (Zantac) 150 mg BID or 300 mg at bedtime for 6 to 8 weeks.
iii. Famotidine (Pepcid) 20 mg orally BID or 40 mg at bedtime for 6 to 8 weeks.
iv. Nizatidine 150 mg orally BID or 300 mg at bedtime for 6 to 8 weeks.
b. PPIs are effective in inducing ulcer healing. The PPIs are the most potent inhibitors of gastric acid secretion. Once-daily dosing is generally sufficient for acid inhibition; however, a second dose may be necessary and should be given before the evening meal. Once-daily PPI dosing inhibits acid output by 66% after 5 days. Optimal dosing is immediately before breakfast:
i. Omeprazole (Prilosec/Zegerid) 20 to 40 mg every morning for 4 weeks.
ii. Esomeprazole (Nexium) 20 to 40 mg every morning for 4 to 8 weeks.
iii. Lansoprazole (Prevacid) 15 to 30 mg every morning for 4 weeks.
iv. Dexlansoprazole (Kapidex) 30 to 60 mg every morning for 4 to 8 weeks.

v. Pantoprazole (Protonix) 20 to 40 mg every morning for 4 weeks.
vi. Rabeprazole (Aciphex) 20 mg every morning for 4 weeks.
vii. Dexlansoprazole (Dexilant) 60 mg every morning for 8 weeks.

c. PPIs should not be given concomitantly with prostaglandin, or other antisecretory agents due to the marked reduction in their effects. An H2 antagonist can be used with a PPI if given after a sufficient interval between their administrations; the minimal times have not been established. The H2 antagonist could be given at bedtime for breakthrough symptoms after a morning dose of a PPI.

d. Combination products currently on the market:
i. Omeclamox-Pak: omeprazole 20 mg (two caps), amoxicillin 500 mg (four caps), and clarithromycin 500 mg (two tabs) per Pak. Take omeprazole 20 mg, amoxicillin 100 mg, and clarithromycin 500 mg BID. Treatment is 10 days.
ii. Prevpac: lansoprazole 30 mg (two caps), amoxicillin 500 mg (four caps), and clarithromycin 500 mg (two caps) per Pak. Take lansoprazole 30 mg, amoxicillin 1,000 mg, and clarithromycin 500 mg BID Treatment is 10 or 14 days.

4. Sucralfate (Carafate) 1 g orally QID, 1 hour before meals and at bedtime; maintenance therapy is 1 g BID. Sucralfate is not recommended for *H. pylori* or NSAID ulcers.

5. Misoprostol (Cytotec, a prostaglandin analogue) is effective for peptic ulcers due to NSAID use; peptic ulcers respond well to misoprostol 100 to 200 mcg orally QID.

FOLLOW-UP

A. Therapeutic trial of lifestyle changes combined with an H2 receptor antagonist, sucralfate, or omeprazole for 1 to 2 weeks should provide relief. Reevaluate the client after 2 weeks, and if symptoms are improved prescribe a full course of 6 to 8 weeks.

B. Reevaluate the client again at 8 weeks, after the full course of therapy is completed.

C. Consider repeating breath test to confirm eradication of *H. pylori.*

D. Some authorities advocate routine endoscopic or radiologic documentation of healing. However, no studies show this to be cost-effective in uncomplicated cases in which symptoms resolve within 4 to 6 weeks and do not recur.

E. For refractory GU—that is, persistent pain after 8 weeks despite a full medical regimen or unresponsive to treatment for *H. pylori*—endoscopic examination and biopsy are needed, especially in clients older than age 40 who are at increased risk of gastric cancer. Barium study is not sufficient because even malignant ulcers may shrink in size in response to therapy.

F. Evaluate refractory cases for Zollinger–Ellison syndrome, especially when there are multiple ulcers, occurrences in unusual places, marked abdominal pain, or a secretory diarrhea.

G. There is an increased risk of osteoporotic fracture from the long-term use of PPIs.

H. Clients beginning long-term NSAID therapy should first be tested for *H. pylori*.

EMERGENT ISSUES/INSTRUCTIONS

A. Admit the client to a hospital when symptoms of hemorrhage, penetration, perforation, or gastric outlet obstruction are present.

CONSULTATION/REFERRAL

A. Consult both a surgeon and a gastroenterologist.

B. Refer clients with recurrences or refractory disease to a physician for evaluation for *H. pylori* infection by endoscopy or breath test. If present, eradicate with a 2-week course of triple therapy.

INDIVIDUAL CONSIDERATIONS

A. Pregnancy:

1. The drugs misoprostol and ranitidine are abortifacients. They cross the placental barrier and are excreted in breast milk and are contraindicated in pregnancy or suspected pregnancy. Use in sexually active clients of childbearing age should be done with proper warning and detailed client education.

B. Adults:

1. DUs are more common in people between ages 45 and 54; GUs, between 55 and 64 years.

2. Clients older than age 40 are at greater risk of gastric cancer and should undergo either an upper GI series or endoscopy to document the nature and location of lesions when there is strong clinical suspicion of ulcer disease.

3. Gastritis not associated with reflux is present in 75% of people older than age 50.

C. Geriatrics:

1. Silent disease is particularly common among older adults and those using NSAIDs.

2. Lethargy, confusion, slurred speech, agitation, and visual hallucinations have been reported with cimetidine, particularly in older adults.

3. In older adults, DU symptoms remain classic with early morning awakening to pain, then quick relief by food or antacids. GU symptoms are less obvious, with burning or gnawing pain experienced in <50% of older adults.

4. Anemia may be the only symptom of gastric cancer. Cancer must always be considered and confirmed by endoscopy with biopsy.

5. For the older adult with existing PUD, nurse practitioner (NPs) should practice special consideration of the following *geriatric syndromes*:

a. Delirium is a common early sign of acute illness or infection in older adults. It is more common in clients with existing cognitive impairment. Dehydration is more common in older adults. Signs of dehydration include confusion, muscle weakness, fever, dizziness, poor skin turgor, hypotension, and tachycardia. Diminished thirst mechanism and decreased body water exacerbate dehydration:
i. At a minimum, clients and their family should be asked if the client has experienced episodes of altered mental status:
1) The Brief Confusion Assessment Method (bCAM) is a well-documented assessment for delirium. The bCAM is available at www.mnhospitals.org/Portals/0/Documents/ptsafety/LEAPT%20Delirium/HELP%20Program%20CAM%20Flowsheet.pdf.
ii. Pain: Poorly relieved pain is an important cause of functional impairment at any age group: ▶

1) Older adults have a diminished sensorium, allowing pathology to advance to a dangerous point prior to symptom development.
2) Older adults with abdominal pain may present with altered mental status. Cognitive impairment can make assessment and diagnosis of pain more difficult.
3) For dementia or noncommunicative clients, the American Medical Directors Association has endorsed the Pain Assessment in Advanced Dementia (PAINAD) Scale, which scores the following items:
a) Breathing: Examples include normal, labored, hyperventilation.
b) Negative vocalization: Examples include moaning, negative language, crying.
c) Facial expression: Examples include smiling, frowning, grimacing.
d) Consolability: Examples include extent to which a caregiver is able to console, distract, or reassure.
e) Body language: Examples include relaxed, tense, rigid, or striking out.

b. Falls: Consistently assess for falls. PPIs are associated with osteopenia and osteoporosis and place the client at an increased risk of fractures.
i. At the minimum, older adults should be asked how many times they have fallen since their last visit. A reported fall should trigger questions about whether the fall led to injury, a visit to urgent care or hospital ED, or a hospital admission.
ii. Safety measures to reduce falls in the home include removing small area carpets, keeping night lights along the path to the bathroom, and installing a toilet seat or nearby grab bars.
iii. *See Client Teaching Guide for Chapter 3, "Safety Issues: Fall Prevention."*

6. Beers Criteria caution:
a. Due to polypharmacy, a full review of medications, herbals, and OTC drugs should be undertaken to identify medications that should be avoided in the geriatric population, duplicate medications, and medications that are able to be decreased or deprescribed (refer to deprescribing section in Chapter 3, "Adult-Geriatric Assessments.").
b. When prescribing to older adults, use the lowest dose, for the shortest period of time.
i. Avoid prescribing a long-acting NSAID, such as indomethacin (Indocin) and piroxicam (Feldene).
c. PPI:
i. PPIs are on the American Geriatrics Society 2015 Beers Criteria for potential inappropriate medications use in older adults. (Refer to Appendix C, Table C.1). Avoid scheduled use of PPIs for >8 weeks unless needed for high-risk clients. PPIs are associated with the following:
1) Osteoporosis/osteopenia, prolonged exposure may increase of fractures.
2) Community-acquired pneumonia.
3) *Clostridioides difficile* infections and diarrhea.
4) Vitamin B_{12} deficiency and hypomagnesium.
d. See Appendix D for the PPI deprescribing algorithm from deprescribing.org.
e. Due to other medications they take for comorbid health conditions, older adults are especially at risk with the combination of NSAIDs and the following:
i. Aspirin.
ii. Clopidogrel (Plavix).
iii. Dabigatran (Pradaxa).
iv. Dipyridamole (Persantine).
v. Prasugrel (Effient).
vi. Ticlopidine (Ticlid).
vii. Warfarin (Coumadin).
viii. Corticosteroids.

POSTBARIATRIC SURGERY LONG-TERM FOLLOW-UP

DEFINITION

A. The number of obese people in the United States has more than doubled in the past 50 years. The traditional management of obesity, a combination of diet, exercise, and behavioral modification, often results in moderate success with limited sustainability. Increasing prevalence of obesity combined with improvements in surgical weight-loss procedures and improved insurance coverage has resulted in exponential growth of the number of people opting for surgical management. Individuals who undergo surgical weight-loss procedures have unique healthcare needs and require lifelong follow-up. Although the bariatric treatment team is the ideal source of follow-up and monitoring, primary care providers can play a critical role and need to be cognizant of the unique needs of this population.

B. The primary mechanism of action for surgical weight-loss procedures is either restriction or a combination of restriction and malabsorption (Table 14.23). All procedures have some form of restriction that reduces the volume of food that can be ingested. Restriction can occur by means of a physical barrier such as a laparoscopic adjustable gastric band (LAGB; Figure 14.4), or an intragastric balloon (Figure 14.7), or by removing a portion of the digestive tract such as with the gastric sleeve (GS; Figure 14.5). Malabsorptive procedures cause weight loss by changing the way nutrients are absorbed, which is accomplished by removing portions of the stomach and/or small intestine and sometimes by rerouting the digestive tract (Roux-en-Y; Figure 14.6). The success of surgical weight loss is defined by initial weight loss, maintenance of weight loss, and prevention of complications. Success is directly related to the aftercare a person receives.

INCIDENCE

A. According to the 2015 to 2016 National Health and Nutrition Examination Survey (NHANES), the prevalence of obesity is 39.8%; among adults aged 40 to 59 years, the prevalence is higher (42.8%). The American Society for Metabolic and Bariatric Surgery (ASMBS) reports an estimated 228,000 weight-loss operations were performed in 2017. About 90% of surgical weight-loss procedures are performed laparoscopically now. The most common procedures performed today include the gastric bypass, GS, adjustable gastric band, and biliopancreatic diversion with duodenal switch. The intragastric balloons were U.S. Food and Drug Administration (FDA) ▶

TABLE 14.23 SURGICAL WEIGHT-LOSS PROCEDURES AND MECHANISM OF ACTION

Procedure	Mechanism of Action	Advantages	Disadvantages
LAGB; Figure 14.4	Restriction	No cutting or rerouting of digestive tract Reversible and adjustable Lowest risk of nutritional deficiencies	Slower (more gradual) weight loss Greater chance of failure to lose 50% of excess weight Foreign device in body; slippage and erosion possible Highest rate of reoperation
GS; Figure 14.5	Restriction and some malabsorption	No rerouting Hormonal hunger suppression, appetite reduction, and increased satiety	Not reversible Potential for nutrient deficiencies Higher complication rate than LAGB
RYGB; Figure 14.6	Restriction and malabsorption	Reduces appetite, enhances satiety Better initial and long-term weight loss compared with LAGB	Long-term nutritional-deficiency risk Lifelong adherence to diet and supplementation required Higher complication rate compared with LAGB and GS
BPD/DS	Malabsorption and some restriction	Greatest weight loss overall Reduces appetite, improves satiety Most effective for treatment of diabetes mellitus	Greatest risk of nutritional deficiencies Strict lifetime adherence to diet and supplements Highest complication rate
Intragastric balloons; Figure 14.7	Restriction	Approved for BMI 30–40 Placed endoscopically performed under conscious sedation or general sedation Can be adjunctive therapy to achieve weight loss reduction prior to bariatric surgery	Designed to remain implanted for 6 months and allow adjustment in fluid volume to address client symptoms and weight loss plateaus

BPD/DS, biliopancreatic diversion with duodenal switch; GS, gastric sleeve; LAGB, laparoscopic adjustable gastric band; RYGB, Roux-en-Y gastric bypass.

FIGURE 14.4 Laparoscopic adjustable gastric band.

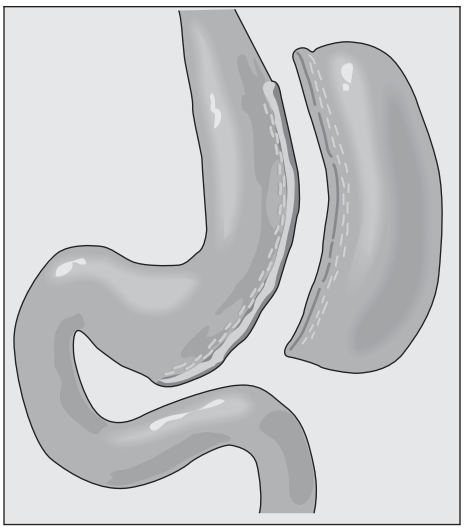

FIGURE 14.5 Sleeve bypass procedure with stomach resection.

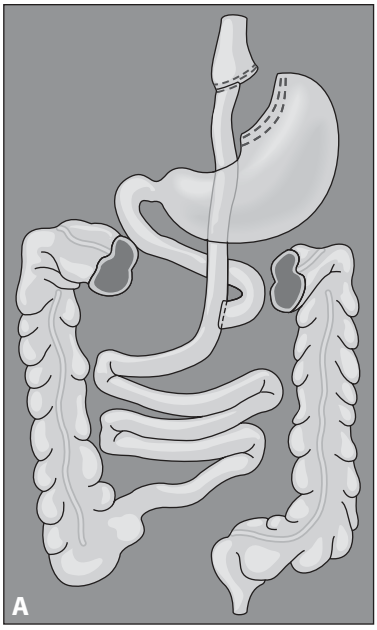
approved in 2015; only about 2.75% were done in 2017. The intragastric balloon is a temporary weight loss procedure with placement only for 6 months.



PATHOGENESIS

A. The pathogenesis of obesity is reviewed under "Obesity" (Chapter 24). Significant improvements in the safety of surgical weight-loss procedures in recent years result from improved surgical techniques, accreditation, and the use of laparoscopy. The overall mortality rate is about 0.5%. The incidences of complications vary by surgical procedure. Postoperative complications may occur immediately or may occur many years after surgery. Nutritional deficiencies are by far the most common long-term complication.

PREDISPOSING FACTORS

A. Higher body mass index (BMI).
B. Noncompliance with bariatric diet and exercise.
C. Lack of follow-up with healthcare professionals.
D. Obesity-related health problems:
  1. Sleep apnea.
  2. Diabetes.
  3. Arthritis.

▶

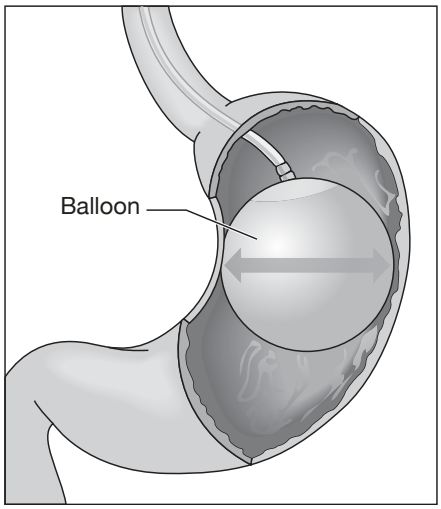

FIGURE 14.7 Intragastric balloon.

4. Hypertension.
5. Gastroesophageal reflux disease (GERD).

E. Complexity and type of surgery.

COMMON COMPLAINTS

A. Functional and nutritional:

1. Dumping syndrome usually occurs within 30 minutes of eating high-fat/high-sugar foods and involves flushing, sweating, light-headedness, tachycardia, palpitations, nausea, diarrhea, and cramping.

2. Hypoglycemia occurs 1 to 3 hours after eating high-carb meals and involves shakiness, anxiety, sweating, chills, clamminess, confusion, rapid heart rate, dizziness, hunger, and nausea.

3. New or exacerbated reflux is more common with a GS.

4. Vitamin deficiencies or toxicities (Table 14.24):

a. Most common:

i. Iron deficiency: fatigue, lethargy, pica, food cravings.

ii. Iron toxicity: gastrointestinal (GI) irritation, nausea, vomiting, indigestion, constipation, diarrhea.

iii. Protein deficiency: weakness, decreased muscle mass, brittle hair, generalized edema.

iv. Folate deficiency: fatigue, palpitations, sore tongue, diarrhea, restless legs.

v. Calcium deficiency: usually silent, hyperparathyroidism.

vi. Calcium toxicity: constipation, nausea, vomiting, dry mouth, loss of appetite.

vii. Vitamin D deficiency: spasms/twitching of eyes, burning in mouth, sweating, weakness.

viii. Vitamin B_{12} deficiency: fatigue, burning lips/mouth, rapid heart rate, palpitations, sore tongue, weakness, mood changes, neurologic changes.

b. Less common:

i. Thiamine (B1) deficiency: usually in first 3 months postop, often a result of vomiting, blurred or double vision, difficulty swallowing, rapid heart rate, fatigue, confusion, memory loss, burning feet, leg weakness, amnesia.

ii. Zinc deficiency: loss of smell, diminished sense of taste, poor wound healing, skin rashes or roughness, hair loss, poor appetite, lethargy, grooved or deformed nails, canker sores.

iii. Magnesium deficiency: hyperexcitability, cramps, tremors, fasciculation, spasms, fatigue, loss of appetite, apathy, confusion, insomnia, irritability, poor memory.

iv. Selenium deficiency (very rare): signs of hypothyroidism (selenium is necessary for conversion of thyroxine into its active form, triiodothyronine).

v. Selenium toxicity (rare): hair loss, abnormal nails, dermatitis, peripheral neuropathy, nausea, diarrhea, fatigue, irritability, garlic odor of breath.

5. Surgical complications:

a. Short term:

i. Anastomotic leak: <1% to 3% with Roux-en-Y gastric bypass (RYGB).

ii. GI hemorrhage, bleeding: 0.5% to 2%.

iii. Wound infection: more common with open approach.

iv. Thromboembolism: deep vein thrombosis (DVT), pulmonary embolism (PE), <1%.

v. Anastomotic strictures: typically within first 3 months, nausea and/or vomiting.

vi. Acute distention of the distal stomach.

vii. Respiratory insufficiency, pneumonia.

▶

TABLE 14.24 MOST COMMON NUTRIENT DEFICIENCIES IN POSTBARIATRIC SURGERY

Nutrient	Protein	Iron	Folate	Calcium	Vitamin B_{12}	Vitamin D
Assay	Serum albumin <3.5 mg/dL May need prealbumin and serum creatinine levels also	Iron saturation <10% Serum ferritin <10 ng/mL or iron saturation <7% regardless of ferritin value	Serum folic acid	Total and ionized calcium Phosphorus 24-hr urinary calcium excretion Intact serum parathyroid hormone Bone density	Serum B_{12} level May need methylmalonic acid level also	25 (OH)D3 <30 ng/mL
Incidence	18%–25% after malabsorptive procedures	6%–50%	1%–10%	10%–25%	5%–25%	Up to 63%
Complications and symptoms	Anemia Edema Alopecia Asthenia (weakness, decreased muscle mass, brittle hair, generalized edema)	Microcytic, hypochromic anemia (pallor, fatigue, poor capillary refill, palpitations, pica, brittle hair)	Megaloblastic or macrocytic anemia (palpitations; fatigue; diarrhea; smooth, sore tongue) Neural tube defects May aggravate B_{12} deficiency	Secondary hyperparathyroidism Enhanced bone loss Metabolic bone disease (tetany, tingling, cramping)	Megaloblastic anemia with macrocytosis Neuropathy Cognitive dysfunction (glossitis, constipation, diarrhea, neurologic changes, depression, dementia)	Myopathy Secondary hypocalcemia
Recommended daily amount for prevention	1.1–1.5 g/kg ideal body weight/d 10%–35% of total energy intake should be from protein	45–60 mg/d from multivitamins and iron supplements for malabsorptive procedures Menstruating females may need more	400 mcg/d	1,200–1,500 mg/d of calcium citrate from food and supplements	500 mcg/d oral for band 1,000 mcg/d oral for malabsorptive procedures; may need 500–1,000 mcg/mo intramuscular	At least 3,000 IU of oral D3 daily, better to titrate to therapeutic level
Treatment dosing	If previous options are not effective, may need parenteral nutrition	150–200 mg of elemental iron BID, preferably with vitamin C	1,000 mcg/d for 3 months	2,000 mg/d with adequate vitamin D supplementation	Depends on the level of deficiency Recheck levels after 3–6 months of repletion	6,000–10,000 IU/d or 50,000 IU/wk up to 50,000 IU/d Recheck level every 3 months

Source: Adapted from Becker, D. A., Balcer, L. J., & Galetta, S. L. (2012). The neurological complications of nutritional deficiency following bariatric surgery. *Journal of Obesity, 2012*. https://doi.org/10.1155/2012/608534; Handzlik-Orlik, G., Holecki, M., Orlik, B., Wylezol, M., & Dulawa, J. (2015). Nutrition management of the post-bariatric surgery patient. *Nutrition in Clinical Practice: Official Publication of the American Society for Parenteral and Enteral Nutrition, 30*(3), 383–392. https://doi.org/10.1177/0884533614564995; and Kerner, J. (2014). Nutrition support after bariatric surgery. *Support Line, 36*(3), 9–20.

b. Long term:
   i. Band slippage: abdominal pain, acid reflux, regurgitation, or dysphagia.
   ii. Band erosion: may be asymptomatic, abdominal pain, GI bleeding, weight loss, abdominal sepsis.
   iii. Intestinal obstruction: caused by internal hernias, adhesions, and anastomotic stenosis—colicky central abdominal pain, nausea, vomiting, abdominal distention, absolute constipation.
   iv. Hepatobiliary complications: rapid weight loss associated with gallstone formation.
   v. GI bleeding: rare and usually caused by ulceration.
   vi. Marginal ulcers: abdominal pain, vomiting, bleeding, or anemia.
   vii. Micronutrient deficiencies.

OTHER SIGNS AND SYMPTOMS

A. Expected weight loss:
   1. LAGB: initial loss of 40% to 50% of excess body weight in 3 to 5 years. Expected maintenance <50%.
   2. GS: initial loss of >50% of excess body weight in 3 to 5 years. Expected maintenance >50%.
   3. RYGB: initial loss of 60% to 80% of excess body weight in 1 year. Expected maintenance >50%.
   4. Biliopancreatic diversion with duodenal switch (BPD/DS): initial loss of 60% to 70% of excess body weight in 1 year. Expected maintenance of 60% to 70%.
   5. Intragastric balloons: loss of about 10% to 15% of body weight typical during the 6 months following intragastric ▶

balloon placement. Expected maintenance: The gastric balloon is only placed for 6 months then removed.

B. Weight regain of up to 20 lbs is common after 2 years.

C. Constipation and/or diarrhea may occur, depending on the procedure.

D. Weight loss of <25% of excess body weight is considered a surgical failure and may be revised.

E. Even if weight loss is adequate, clients may express disappointment and/or depression related to rate or amount of weight lost.

F. Nausea and vomiting after LAGB may indicate need for band adjustment.

SUBJECTIVE DATA

A. Review onset and duration of symptoms.

B. Elicit the date of surgery, type of surgery, and any reoperations or complications.

C. Review previous highest weight and amount of excess weight lost since surgery.

D. Evaluate the location and level of pain/discomfort.

E. Evaluate the overall psychosocial changes since surgery.

F. Review a 24-hour food recall, choices of healthy foods, skipping meals, food aversion (e.g., red meat), and intolerance.

G. Review medications and supplement use.

PHYSICAL EXAMINATION

A. Check height, weight, waist, and hip circumference. Calculate BMI, waist-to-hip ratio, pulse, respirations, and blood pressure. Check temperature if infection is suspected.

B. Inspect:

1. Examine the skin, evaluate surgical site(s), evaluate redness, and tenderness.

2. Oral/dental examination.

3. Evaluate for dehydration.

4. Eye examination: Evaluate eye movement (thiamine deficiency).

5. Evaluate gait.

6. General overview of personal presence and affect.

C. Auscultate:

1. Auscultate the heart and lungs.

2. Auscultate the abdomen for bowel sounds.

D. Palpate:

1. Abdomen:

a. Evaluate for the presence of tenderness.

b. Evaluate for masses.

E. Neurologic examination:

1. Perform neurologic examination, including checking deep tendon reflexes (DTRs), sense of smell, and Babinski reflex (vitamin B_{12} deficiency).

DIAGNOSTIC TESTS

A. Annual recommended laboratory testing for all procedures:

1. Complete blood count (CBC) with differential.

2. Liver function tests.

3. Glucose.

4. Creatinine.

5. Electrolytes.

B. Annual laboratory testing suggested for LAGB, recommended for all other procedures:

1. Iron/ferritin.

2. Vitamin B_{12}.

3. Folate.

4. Calcium.

5. Intact parathyroid hormone (PTH).

6. 25-hydroxy vitamin D.

7. Albumin/prealbumin.

C. Optional labs that may be required based on symptoms:

1. Zinc.

2. Copper.

3. Vitamin B_1.

4. Vitamin B_6.

5. Vitamin A every 24 months and beyond.

D. Other labs as appropriate for condition and prevention:

1. Monitor HgA1c and blood glucose closely in clients with diabetes. Diabetes has resolved after bariatric surgery in some clients.

2. Lipid profile.

E. Abdominal ultrasound.

F. CT scan abdomen.

G. Doppler ultrasound of limb for suspected DVT.

H. Pulmonary ventilation/perfusion scan for suspected pulmonary embolus.

I. Bone mineral density (DEXA) scan: recommended annually until stable after malabsorptive procedures.

J. Endoscopy as needed for abdominal complaints.

DIFFERENTIAL DIAGNOSES

A. Postoperative surgical complication(s):

1. Infection.

2. Abdominal pain.

3. Fascial dehiscence.

4. DVT.

5. Bowel obstruction.

6. Band slippage.

7. Anastomosis leakage.

8. Stomal stenosis/stricture.

B. Cholecystitis.

C. Dumping syndrome.

D. Food intolerance.

E. Gastric ulcer (GU).

F. Gastroenteritis.

G. Vitamin deficiency.

H. Malnutrition/protein deficiency.

I. Incisional hernia.

J. Osteoporosis.

PLAN

A. General interventions:

1. Lifelong follow-up is required after bariatric surgery. Ideally, clients should follow up with their surgical group, but many do not. Primary care providers are well-positioned to capture those lost to follow-up. Continuous reinforcement of good nutritional habits is important.

B. Client teaching:

1. Many complications can be prevented by adhering to diet and lifestyle recommendations:

2. Supplements are required lifelong; strict adherence will prevent deficiencies.

3. Dumping syndrome can be prevented by avoiding foods that trigger it, such as high-sugar and/or high-fat foods. Clients can keep food diaries to identify triggers.

4. Hypoglycemia can usually be prevented by careful monitoring of carbohydrate intake.

5. Surgery does not replace the need for a balanced diet or exercise. Approximately 150 minutes of moderate activity each week is recommended, though safety and tolerance differ so exercise recommendations should be individualized. Any activity is better than none. ▶

6. Exercise is important in counteracting adverse effects on muscle mass and bone density.

7. Food should be chewed thoroughly and consumed slowly. Liquids should be avoided 30 minutes before and after meals. Avoid eating and drinking liquids simultaneously.

8. Protein is important for maintaining muscle mass during rapid weight loss and avoiding hunger during maintenance. Between 60 and 100 g of protein daily is recommended. Limit carbohydrate intake to 50 g/d or less. Limiting carbohydrate intake reduces risk of weight regain by preventing rebound hunger.

9. To prevent dehydration, as well as reduce the risk of kidney stones and constipation, encourage 64 oz of fluids daily.

10. Stress, boredom, and emotions often affect eating habits. Identifying problems and seeking help early are important.

11. Support groups can be a vital source of education and social support, both of which are key to weight loss and maintenance.

12. Weight plateaus are common and normal. This is the body's way of trying to establish a new set point. Do not be discouraged by plateaus. Consistency is key to overcoming them.

13. Adequate sleep and successful stress management are also key to successful weight loss and maintenance.

C. Pharmaceutical therapy:

1. Medication absorption can be altered after bariatric surgery. Evaluate need for adjustments of medication dosing, especially diabetic, psychiatric, and antihypertensive medications, as well as any medication with a narrow therapeutic window.

2. Clients may require alternate formulations of medications, including crushed, chewable, liquid, patches, intramuscular, or subcutaneous. Long-acting, extended-release, or enteric coated medications may not be absorbed as well and may need to be switched to immediate release.

Drugs with a small therapeutic window such as digoxin, carbamazepine, theophylline, and phenytoin should not be crushed due to the increase in toxicity.

3. Medications designed to release slowly should not be crushed or chewed because the full dose will be released faster than expected. A resource guide for crushing medications is available at www.ismp.org/recommendations/do-not-crush.

4. Universal postoperative supplementation (Table 14.25):

a. Multivitamin and mineral supplementation:
   i. LAGB: one daily.
   ii. All other procedures: two daily (take each dose at a separate time).
   iii. Tablets, chewable, or liquid.

b. Calcium:
   i. LAGB, GS, RYGB1, 200 to 1,500 mg daily from food and supplements.
   ii. BPD/DS: 1,800 to 2,400 mg daily from food and supplements.
   iii. Calcium citrate should be taken in divided doses (23 doses of 500 mg).
   iv. Chewable or liquid.

c. Vitamin D_3 (all procedures):
   i. 3,000 IU daily, titrate to therapeutic level.
   ii. Vitamin D should be taken with the calcium supplement.

d. Iron:
   i. 18 mg/d elemental iron.
   ii. RYGB, SG, BPD/DS 45 to 60 mg daily from multivitamin plus additional supplementation.
   iii. Menstruating females: 45 to 60 mg/d.
   iv. Iron should be taking separately at least 2 hours apart from calcium supplements.
   v. Iron should not be taken with milk products.

e. Vitamin B_{12} (cobalamin):
   i. Oral or sublingual: 350 to 500 mcg/d.
   ii. Intranasal: 1,000 mcg/wk.
   iii. Intramuscular 1,000 mcg/mo.

f. Folate (folic acid):
   i. 400 to 800 mcg/d.
   ii. Females of childbearing age: 800 to 1,000 mcg/d.

g. Vitamin A:
   i. LAGB: 5000 IU/d.
   ii. RYGB or SG: 5,000 to 10,000 IU/d.
   iii. BPD/DS: 10,000 IU/d.

h. Vitamin E: (all procedures) 15 mg/d.

i. Vitamin K:
   i. LAGB, SG or RYGB: 90 to 120 mcg/d.
   ii. BPD/DS: 300 mcg/d.

j. Zinc:
   i. SG or LAGB: 8 to 11 mg/d.
   ii. RYGB: 8 to 22 mg/d.
   iii. BPD/DS: 16 to 22 mg/d.

k. Copper:
   i. SG or LAGB: 1 mg/d.
   ii. RYGB or BPD/DS: 2 mg/d.

5. Long-term anticoagulation may be needed for DVT/PE prophylaxis.

6. Nonsteroidal anti-inflammatory drugs (NSAIDs) and corticosteroids should be avoided to reduce the risk of marginal ulcers.

D. Psychosocial changes:

1. Bariatric surgery often results in dramatic lifestyle and body changes and may require significant psychosocial adjustments for the client as well as their friends and family:

a. Monitor for depression/anxiety, body image concerns, and social support.

b. Alcoholism can be a concern after bariatric surgery. Less alcohol is needed to elevate blood alcohol levels and blood alcohol levels are sustained longer after bariatric surgery.

FOLLOW-UP

A. Bariatric surgery requires lifelong follow-up, ideally by a multidisciplinary team of healthcare providers. Initial follow-up schedules are set by the surgeon. Long-term follow-up (after the first 2 years) is usually provided for by the bariatric surgery program.

B. Medications with narrow therapeutic windows and medication are dosed based on weight should be evaluated frequently.

C. Annual laboratory and diagnostic testing is required (refer to "Diagnostic Tests"). Early recognition of nutritional deficiencies can prevent permanent damage and even death.

D. Chronic disease management (particularly diabetes, lipids, and bone disease) can be simpler or more complex after bariatric surgery, depending on the client's adherence to lifestyle and nutritional recommendations. ▶

TABLE 14.25 ROUTINE SUPPLEMENTATION BASED ON TYPE OF GASTRIC BYPASS SURGERY

Supplement	Gastric Band	Gastric Sleeve	Gastric Bypass	BPD/DS
Multivitamin plus mineral	One daily	Two daily	Two daily	Two daily
Calcium	1,200–1,500 mg daily from food and calcium citrate divided doses	1,200–1,500 mg daily from food and calcium citrate divided doses	1,200–1,500 mg daily from food and calcium citrate divided doses	1,200–1,500 mg daily from food and calcium citrate divided doses
Vitamin D	3,000 IU daily; titrate to therapeutic level	3,000 IU daily; titrate to therapeutic level	3,000 IU daily; titrate to therapeutic level	3,000 IU daily; titrate to therapeutic level
Iron	Not usually necessary	45–60 mg/d from multivitamin plus additional supplement	45–60 mg/d from multivitamin plus additional supplement	45–60 mg/d from multivitamin plus additional supplement
Vitamin B_{12}	Not usually necessary	As needed to maintain levels in the form best tolerated	As needed to maintain levels in the form best tolerated	As needed to maintain levels in the form best tolerated

BPD/DS, biliopancreatic diversion with duodenal switch.

CONSULTATION/REFERRAL

A. Bariatric surgeon for surgical complications, revisions.
B. Surgeon for cholecystectomy (preferably bariatric surgeon or general/GI surgeon experienced in the care of bariatric clients).
C. Gastroenterology consult.
D. Nutrition consultation and/or counseling.
E. Psychologist consultation.
F. Physical therapy/exercise specialist.
G. Support group.

INDIVIDUAL CONSIDERATIONS

A. Females:
  1. All females of childbearing age should receive adequate folate supplementation and be given contraception and preconception counseling.
  2. Oral contraceptives (OCPs) may not be as effective after bariatric surgery due to changes in absorption.
B. Pregnancy:
  1. Pregnancy should be delayed for 12 to 18 months after bariatric surgery or however long it takes for weight loss to stabilize.
  2. Bariatric surgeon consult may be required.
  3. Increased folic acid may be needed preconception to reduce risk of neural tube defects.
  4. Increased vitamin supplementation may be necessary during pregnancy. Vitamin A should be limited to 5,000 IU daily.
  5. Gastric band may need to be adjusted during pregnancy.
  6. Serial ultrasounds may need to be done to follow fetal growth.
C. Geriatrics:
  1. Discussion of bariatric surgery in older adults (over 60 years of age) is controversial. However, the client should not be denied bariatric surgery due to age. Mortality rate was 0.01%, complication rate ranged from 9.7% to 14.7%. At 1-year follow-up, excess weight loss was approximately 53.77%, with improvement of diabetes by 54.5%, hypertension improvement 42.5%, and cholesterol improvement 41.2%.

ULCERATIVE COLITIS

DEFINITION

A. Ulcerative colitis (UC) is one of the two inflammatory bowel diseases (IBDs), along with Crohn's disease (CD). UC is limited to the colon; it extends proximally from the anal verge in an uninterrupted pattern to a part of or the entire colon. Extracolonic manifestations also include uveitis, pyoderma gangrenosum, pleuritis erythema nodosum, ankylosing spondylitis, and spondyloarthropathies. Refer to Table 14.26 for the definition of severity of UC.
B. Neither UC nor CD should be confused with irritable bowel disease (IBD), which affects the motility of the colon. Smoking is negatively associated with UC; the relationship is reversed in CD. The general course of UC is intermittent exacerbations and remissions. In severe cases, surgery may be required. The choice of treatment depends on disease activity and extent of pathology, client acceptability, and mode of drug delivery.
C. Histologically, most of the pathology of UC is limited to the mucosa and submucosa. The severity of UC is defined by the following:
  1. Pan-ulcerative (total colitis): extensive disease with evidence of UC proximal to the splenic flexure. Massive ▶

TABLE 14.26 DEFINITION OF SEVERITY OF ULCERATIVE COLITIS

Mild UC	• ≤4 bloody stools/d with or without blood • No systemic toxicity • Normal ESR • Mild abdominal pain or cramping
Moderate UC	• >4 bloody stools/d • No signs of systemic toxicity • Pulse <90 beats/min • Temperature <37.5°C (99.5°F) • Hemoglobin >10.5 g/dL • ESR <30 mm/hr • Moderate abdominal pain
