Limitations in physical resources, environmental resources, personal resources (or human capital), and biopsychosocial resources (e.g., the presence of illness, genetic predispositions) combine to cause vulnerability (Aday, 2001; Leight, 2003). Poverty, limited social support, and working in a hazardous environment are examples of limitations in physical and environmental resources. People with pre-existing illnesses, such as those with communicable or infectious diseases or chronic illnesses such as cancer, heart disease, or chronic airway disease, have less physical ability to cope with stress than those without such physical problems. **Human capital** refers to all of the strengths, knowledge, and skills that enable a person to live a productive, happy life. People with little education have less human capital because their choices are more limited than those of people with higher levels of education.

The interaction among many variables causes a more powerful impact that predisposes vulnerable individuals to illness and injury. Risks come from environmental hazards (e.g., lead exposure from lead water pipes, lead-based paint from peeling walls, or paint used in toy manufacturing and melamine added to milk supplies), social hazards (e.g., crime, violence), personal behavior (e.g., diet, exercise habits, smoking), or biological or genetic makeup (e.g., congenital addiction, compromised immune status). Members of vulnerable populations often have multiple illnesses, with each affecting the other. Some members of vulnerable populations do not succumb to the health risks that impinge on them. It is important to learn what factors help these people to resist, or have **resilience** to, the effects of vulnerability. Vulnerability is a global concern, with different populations being more vulnerable in different countries.

Vulnerable people are at greater risk for poor health status. Risk is an epidemiologic term indicating that some people have a higher probability of illness than others. In the *epidemiologic triangle* as shown in Chapter 13) the agent, host, and environment interact to produce illness or poor health. This multifactor perspective aligns well with models that depict health as a result of complex personal and other environmental factors. *The natural history of disease model* explains how certain aspects of physiology and the environment, including personal habits, social environment, and physical environment, make it more likely that a person will develop particular health problems (USDHHS-CDC, n.d.b). See Chapter 13 for more information on the natural history of disease model. *The web of causation model* (USDHHS-CDC, n.d.c) can be used to depict

vulnerability and risk. Chapter 12 discusses the web of causation. Many factors increase a person's vulnerability such as the individual's living conditions, poor nutrition, and likely other factors. Vulnerability refers to general conditions such as being poor or afflicted with a stigmatizing disease such as human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDs) or mental illness. In contrast risk refers to exposure to a specific stressor.

Age imposes vulnerabilities. People at both ends of the life continuum are less able to physiologically adapt to stressors. For example, children who survive disasters may experience difficulties in later life if they do not receive adequate counseling. Examples of protective social factors include social support, self-esteem, and self-efficacy (thinking you can handle situations and cope) (Braveman & Gottlieb, 2014). Specifically, higher levels of confidence in one's ability or internal locus of control appear to protect children (particularly adolescents) from the negative effects of disaster and trauma. Persons with an internal locus of control believe that they control their behavior and do not depend entirely on external people, events, or forces to control behavior. It is the person's perception of his or her level of personal control that influences the person's decisions. Persons with a high level of internal locus of control are more likely to participate in health screenings and take responsibility for their health. That is, they believe they can control to some extent their health outcomes. For example, a woman with a high internal locus of control would participate regularly in yoga and exercise classes to increase flexibility and build strength to preserve her bone and muscle tone. Vulnerable population groups often develop an external locus of control. They may believe that events are outside their control and result from bad luck or fate. People with an external locus of control have more difficulty taking action or seeking care for health problems. They may minimize the value of health promotion or illness prevention because they do not think they have control over their health destinies. Also, people who have been abused or have experienced chronic stress may have used up a lot of the reserves that others would normally have for coping with new forms of stress.

Elderly individuals are more likely to develop active infections from communicable diseases such as the flu or pneumonia and generally have more difficulty recovering from infectious processes than younger people because of their less effective immune systems. Older people also may be more vulnerable to safety threats and loss of independence because of their age, multiple chronic illnesses, and impaired mobility.

There is often a cycle to vulnerability. Predisposing factors that lead to poor health and other outcomes can exacerbate predisposing factors, creating an additive effect. Vulnerability is associated with a heavy stress load, which creates yet another barrier to the attainment of good health. Fig. 31.3 is an illustration of a cycle of vulnerability related to homelessness.

Differences in mortality among homeless individuals illustrate how additive effects worsen outcomes and provide insight into the value of interventions designed to break the cycle, such as the Housing First initiative. Mortality rates among unsheltered homeless people are 3 times higher than people who were sheltered and 10 times higher than the general population (Roncarati et al., 2018).

Vulnerability should be considered at two levels, the individual and aggregate levels. Nurses, including public health nurses, care for both individuals and groups or populations. Group are aggregates of individuals. It is important that we not stereotype individuals based on group affiliation or characteristics. Being a member of a vulnerable group does not necessarily make an individual vulnerable. Conversely, individuals can be vulnerable even if they are not members of a vulnerable group (deChesnay, 2016).

Chronic stress can also contribute to vulnerability. Chronic stress associated with marginalization, adverse childhood experiences (ACEs), poverty, unemployment, poor education, and many other factors can lead to maladaptive physical responses and diseases (Lathrop, 2013).

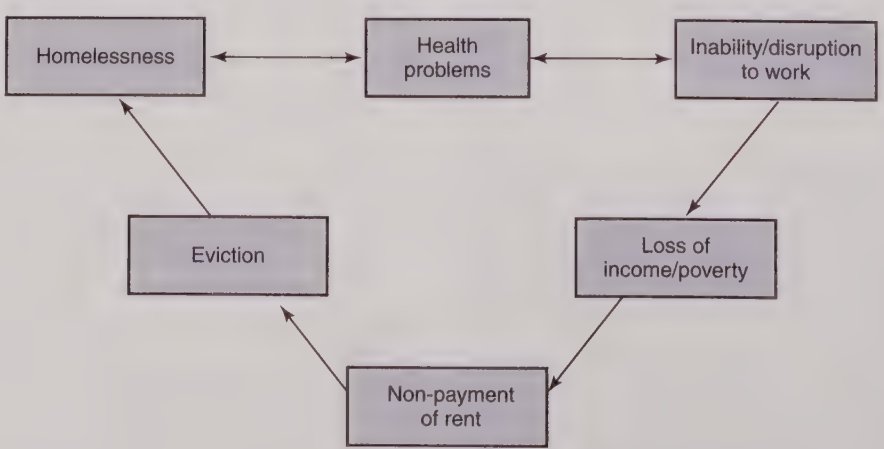

Fig. 31.3 A vicious cycle of vulnerability. (Source: Coumarelos C, Pleasence P, Wei Z: *Law and disorders: illness/disability and the experience of everyday problems involving the law,* Justice issues, no. 17, Law and Justice Foundation of NSW, Sydney. http://www.lawfoundation.net.au/ljf/site/articleIDs/187BFC9DE888BE81CA257BEA0019ECDF/$file/JI17_LawAndDisorders_FINAL_web.pdf.)

Marginalization

Vulnerable people and populations are in a marginalized, disadvantaged, or disenfranchised position. Marginalization results when people or populations are relegated to a position on the periphery of society where they have diminished importance, influence, or power. Marginalization is both a cause and outcome of vulnerability. The likelihood of developing health problems and having worse outcomes among vulnerable people and groups is higher because of general societal and environmental factors and increased exposure to risks.

Marginalized people are disconnected from mainstream society, lacking emotional ties to any group or with the larger society. Some groups such as the poor, the homeless, and migrant workers are "invisible" to society as a whole and tend to be forgotten in health and social planning. Vulnerable populations are at risk for disenfranchisement because their social supports are often weak, as are their linkages to formal community organizations such as churches, schools, and other types of social organizations. They also may have few informal sources of support, such as family, friends, and neighbors. In many ways, vulnerable groups have limited control over potential and actual health needs. In many communities, these groups are in the minority and disadvantaged because typical health planning focuses on the majority. Disadvantage also results from lack of resources that others may take for granted. Vulnerable population groups have limited social and economic resources with which to manage their health care. For example, women may endure domestic violence rather than risk losing a place for them and their children to live. Women who are among the working poor are more likely to become homeless when they leave an abusive partner. They may not be able to pay for a place to live when they lose their partner's income.

ACEs

ACEs include emotional, physical, and sexual abuse; emotional and physical neglect; mother treated violently; household substance abuse and mental illness; parental separation or divorce; and an incarcerated household member (AAP, 2014). ACEs exert negative impacts via a number of mechanisms, including disrupted neurodevelopment; social, emotional, and cognitive impairment; adoption of risky behaviors; disease; disability; social problems; and premature death (USDHHS-CDC, n.d.d).

Researchers studying ACEs conceptualized stress arrayed on a continuum. There are three major types of stress: (1) positive stress, which comes from short-lived adverse events and which children can manage with the help of supportive adults; (2) tolerable stress, which is more intense but still short-lived, such as stress arising from a natural disaster or frightening accident; or (3) toxic stress, which results from intense adverse experiences sustained over time. Stress conferred by ACEs can become toxic. Toxic stress can be profoundly destructive and last a lifetime (AAP, 2014).

Poverty

Poverty is one of the most deeply rooted and significant contributors to poor health and disparities. Adequate income facilitates (buys) access to resources that support a healthier life, including safe housing and neighborhoods, clean air and water, and nutritious food to eat. Low income is associated with low life expectancy. Someone born in 1960 in the lowest income quintile can expect to live until age 76. In contrast, the life expectancy of those in the highest quintile is 89 years (Stein & Galea, 2018a).

People who are poor are more likely to live in hazardous environments that are overcrowded and have inadequate sanitation, work in high-risk jobs, have less nutritious diets, and have multiple stressors, because they do not have the extra resources to manage unexpected crises and may not even have adequate resources to manage daily life. Poverty often reduces an individual's access to health care. In the developed countries of the world, this is more likely to be a problem for those just above the poverty line, who are not eligible for public support, whereas in developing countries poverty is correlated with decreased access to health care. The chronic stress of factors such as poverty, unemployment, and poor education can lead to maladaptive physical responses and disease (Lathrop, 2013).

The U.S. Census Bureau (Semega et al., 2017) reported that in 2016, 40.6 million Americans, or 12.7 percent, lived in poverty. The South has the highest rate of poverty (14.1 percent). Poverty rates are highest in rural areas. A review of poverty trends reveals other troubling disparities. Metrics that illustrate this point include the following: (1) pre-tax income for the poorest Americans has held steady for the past 40 years, but after-tax income has dropped due to increasing taxes, which disproportionately burden poor people (Stein & Galea, 2018b); (2) income inequality has grown (Stein & Sandro, 2018)—the disparity between the wealthiest Americans and everyone else multiplied by 27 percent between 1970 and 2016 (Kochar & Cilluffo, 2018); (3) the national minimum wage is stuck at $7.25 per hour, an amount that traps many full-time workers, depending on family size, below the wage needed to be above the federal poverty level (Koucher & Cilluffo, 2018); and (5) the real value of the current minimum wage has declined (Center for Poverty Research, 2018). The major Organisation for Economic Co-Operation and Development (OECD) countries spend on average of $1.70 for social services for every $1.00 on health services. The United States spends 56 cents per health care dollar (Butler, 2016), and there are calls from some federal policy makers to decrease social safety net spending.

Poverty among children is a particular concern. Poverty grew among children from 14 percent in 1969 to 21 percent in 2014 (AEI/Brookings, 2015). A May 2018 Save the Children report demonstrates how hard poverty hits children, particularly those who live in rural areas and the South. In the United States, 19.5 percent of children live in poverty. In rural America, 23.5 percent of children live in poverty (compared to 18.8 percent of urban children). Five states in the United States, all but one in the Southeast, have rural child poverty rates at or above 33 percent.

Children are particularly susceptible to the effects of poverty. Healthy development and learning are negatively impacted

by poverty, and poverty increases a child's exposure to risk. The effects of childhood poverty can persist across the life span and be conferred to the next generation (Save the Children, 2018).

Poverty is both a cause and an outcome of poor health. Poor health often results in lost labor income that can result in poverty, and poverty is linked with poorer health outcomes. This is another example the cyclic nature of vulnerability.

Addressing poverty will require broad-based and sustained initiatives addressing family composition (more households headed by single women are in poverty than two-parent households), work and wages, and education (AEI/Brookings, 2015). The need for this type of approach that addresses deep-rooted social problems to reduce disparities and improve health is the impetus for the *Health in All Policies* initiative (Rudolph et al., 2013).

Vulnerable Populations

A population is deemed vulnerable based on status that is unfavorable compared to other groups (deChesnay, 2016). Select examples of vulnerable populations of concern to nurses are persons who are poor, homeless, displaced, victims of abuse or neglect, rural residents, incarcerated, or have special needs or are suffering from stigmatizing diseases such as mental illness, addiction disorders, and HIV/AIDS. Other vulnerable populations include certain groups of children, pregnant teens, migrant workers, immigrants, refugees, and people at risk for infectious or communicable diseases, including persons who are HIV positive or have hepatitis B virus (HBV) or sexually transmitted diseases (STDs).

Resiliency and Hope

Objections have been raised about the use of the term *social determinants of health.* The objections stem from the connotation of the term *determinant.* The word implies that individual and population resiliency and recovery are not possible. Adopting a deterministic rather than probabilistic view of social and other influences allows us to understand important interactions that can explain to whom a factor matters most or least and the environmental conditions that interact to impact outcomes and to what degree (Simon, 2017). Useful nursing interventions to increase resilience include case finding, health education, care coordination, and policy making related to improving health for vulnerable populations.

REDUCING DISPARITIES AND IMPROVING POPULATION HEALTH OUTCOMES

Working with vulnerable populations to reduce disparities and improve population health outcomes requires informed strategies and practices. These strategies must rely on the latest evidence and be patient- and population-centric and sensitive. It is important that nurses honor the individuals and populations they work with and advocate for changes that reduce inequities, disparities, marginalization, and stigmata and improve health. Nurses have long been leaders in efforts to enhance equity.

Social-Ecological Model

The social-ecological model (SEM) is a theory-based framework that promotes understanding of the interaction of personal, social, and environmental factors that shape behavior and ultimately health (Unicef, 2009; Wendell et al., 2017). The SEM is derived from a social ecology perspective that seeks explanations for "how individuals and their environments mutually affect each other" (Wendell et al., 2017). The SEM is a tool for promoting the overarching goals which have been developed for *Healthy People 2030.* The SEM facilitates understanding of the upstream cause of health disparities. Multilevel interventions are more effective and sustainable.

The SEM includes five levels: individual, interpersonal, community, organization, and policy environment (Fig. 31.4.). Each of these levels is discussed in Table 31.2.

Advocacy and Policy Making As Caring

Advocating on behalf of individuals and populations and being engaged in policy making are essential nursing roles. **Advocacy** refers to actions taken on behalf of another.

Advocacy and policy involvement extend the caring ethos of nursing. A profession that establishes a relationship with people or groups, based on a social contract, like nursing, is morally obligated to uphold justice within its domain (Ballou, 2000; Fawcett & Russell, 2001). Nurses may function as advocates for vulnerable populations by working for the passage and implementation of policies that lead to improved public health services for these populations. For example, a nurse may serve on a local coalition for uninsured people, and another may work to develop a plan for sharing the provision of free or low-cost health care by local health care organizations and providers.

Social justice includes the concepts of *egalitarianism* and *equality.* Braveman (2014) says that at the heart of social justice is "justice with respect to the treatment of more advantaged versus less advantaged socioeconomic groups when it comes to health and health care" (p. 129). A society that subscribes to the concept of social justice would be one that values equality and recognizes the worth of all members of that society. Such a society would provide humane care and social supports for all people. Nurses who function in advocacy roles and facilitate change in public policy are intervening to promote social justice.

Nurses can be advocates for policy changes to improve social, economic, and environmental factors that predispose vulnerable populations to poor health. The legacy of the nursing profession is replete with exemplary nursing leaders who fulfilled the moral obligation to advocate on behalf of individuals and groups and understand and be involved in policy making to advance health equity.

Public Policies Advancing Health

Health in All Policies is a strategy designed to influence health and equity by addressing social determinants of health in policy.

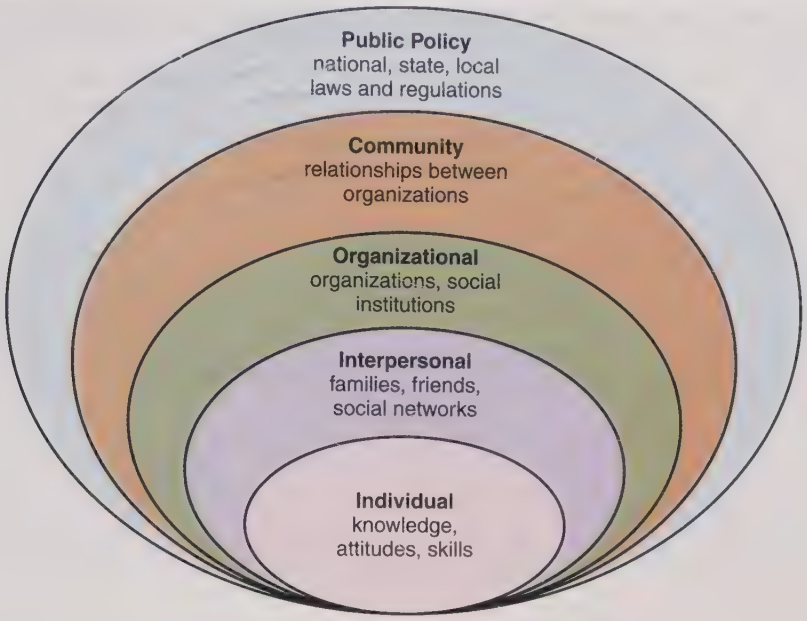

Fig. 31.4 Social-ecological model. (Modified from Centers for Disease Control and Prevention [CDC]: The social ecological model: a framework for prevention. Available at http://www.cdc.gov.)

TABLE 31.2 Social-Ecological Model Levels

Level	Description	Comments
Individual	Includes individual characteristics, traits, and identities and knowledge, attitudes, and behaviors that influence behavior change; examples: • Age • Developmental history • Education levels • Financial resources • History of abuse or trauma • Literacy • Racial and ethnic identity • Religious identity • Sexual orientation • Social status	Socioeconomic status is the most influential determinant of health. Poverty often is associated with lower educational attainment.
Interpersonal	Includes personal relationships and social networks and support systems that influence behavior and create circumstances that encourage or impede health attainment; examples: • Family • Friends • Partners • Peers • Formal and informal social networks • Co-workers • Religious networks • Customs, traditions	An individual's personal relationships and social networks have profound direct and indirect effects on health. There is mounting evidence of the adverse impact of social isolation on affected individuals and groups. The health impact of social isolation has been equated with smoking 15 cigarettes/day (Flowers et al., 2018).
Community	Includes relationships among organizations, institutions, and informational networks within a defined boundary that influence behavior of a population and their values, cultures, and customs; examples: • Built environment • Community leaders • Local businesses • Neighborhoods • Schools • Stigma • Transportation • Workplaces	The rate of mental illness among young people of color is similar to that of white, young adults, but they are less likely to be diagnosed or seek help (Primm, 2018).

Continued

TABLE 31.2 Social-Ecological Model Levels—cont'd

Level	Description	Comments
Organization	Includes development and implementation of regulations and rules that enable or thwart certain behaviors, as well as enforcement of regulation and rules; examples: • Organizations and social institutions with policies, rules, and regulations affecting the availability of support and services	National discussions about how to address gun violence in the United States is increasingly centered on the organizational level as arming school teachers is debated and large retail businesses make decisions about whether or not to sell guns.
Policy	Includes national, state, and local governmental laws, policies, and regulations; includes: • Access to prevention and health care resources • Allocation of resources and policy priorities • Social and other policies that promote or inhibit equity	Rural Americans often face challenges in accessing health care. Increasingly telehealth services are seen as one way to improve access, address health care needs, and improve patient and population health outcomes. However, the requisite broadband availability and access is frequently deficient in rural areas, which impedes the provisions of telehealth services. Policy can be used to increase the availability of broadband access in rural areas. Improved broadband access will have direct impact on telehealth services and indirect positive employment benefits.

There are numerous governmental policies that have improved conditions of vulnerable people and populations. The Seattle/King County Health Department is facilitating cross-sectoral partnerships with planning, transportation, and housing officials to integrate efforts and create synergies to enhance equity and health. Examples of recent initiatives include (1) inclusion of health-based metrics and objectives in city and county land use and transportation plans, (2) educational initiatives to improve outcomes in low-income and migrant populations and reduce the number of students expelled from school, and (3) better opportunities for physical activity in low-income neighborhoods by building trails (Wernham & Teutsch, 2014).

There are numerous governmental policies that have improved conditions and outcomes for vulnerable populations. The Social Security Act of 1935, a federal law, was designed to ensure a minimal level of support for people at risk for problems from inadequate financial resources. The Social Security Amendments of 1965 created Medicare and Medicaid to address the health care needs of older adults, people living in poverty, and disabled people. Poverty among elderly Americans declined from 35 percent in 1959 to 10 percent in 2014, in large part because of Medicare (AEI/Brookings, 2015).

Since the enactment of the Affordable Care Act in 2010, there have been states that have expanded existing Medicaid programs and other states that have not pursued expansion. This scenario has created natural experiments that allow us to look at whether Medicaid improves health outcomes. The evidence is mounting in states that have expanded Medicaid that Medicaid coverage does improve outcomes. Improvements seen in Medicaid expansion states include (1) significant increases in rates of cancer diagnoses, especially early-stage diagnosis rates, (2) increased probability of early, uncomplicated patient presentations for five common surgical procedures, (3) improvements in access to medications and other treatments for people with behavioral and mental health conditions, (4) declines in hospital lengths-of-stay, and (5) improved hypertension control (Antonisse et al., 2018).

Nursing Approaches to Advance Health Equity

Nurses have a rich legacy of promoting health equity. Florence Nightingale understood that the physical and social environments influenced the health of patients and worked hard to introduce improvements in both domains with good results. Lillian Wald, the founder of the Henry Street Settlement and mother of modern public health nursing, provided nursing care and education to the community through health promotion, including education, modification of the environment, and disease control. Dorthea Dix was a staunch advocate for indigent, mentally ill individuals whose lobbying was instrumental in policies that established mental asylums. Mary Breckenridge established the Frontier Nursing Service that was successful in improving the health of poor women and children in rural Kentucky.

There is a trend toward providing more comprehensive, family-centered services when treating vulnerable population groups. It is important to provide comprehensive, family-centered, "one-stop" services. Providing multiple services during a single clinic visit is an example of one-stop services. If social assistance and economic assistance are provided and included in interdisciplinary treatment plans, services can be more responsive to the combined effects of social and economic stressors on the health of special population groups. This situation is sometimes referred to as providing **wrap-around services**, in which comprehensive health services are available and social and economic services are "wrapped around" these services. Although this is an excellent approach to care, it is not available in all or even most areas in the United States.

It is helpful to provide **comprehensive services** in locations where people live and work, including schools, churches, neighborhoods, and workplaces. *Comprehensive services* are health services that focus on more than one health problem or concern. For example, some nurses use stationary or mobile outreach clinics to provide a wide array of health promotion, illness prevention, and illness management services in migrant camps, schools, and local communities. A single client visit may focus on an acute health problem such as influenza, but it also may include health education about diet and exercise, counseling for smoking cessation, and a follow-up appointment for immunizations once the influenza is over. The shift away from hospital-based care includes a renewed commitment to the public health services that vulnerable populations need to prevent illness and promote health, such as reductions of environmental hazards and violence and assurance of safe food and water.

Referring clients to community agencies involves much more than simply making a phone call or completing a form. Nurses should make certain that the agency to which they refer a client is the right one to meet that client's needs. Nurses can do more harm than good by referring a stressed, discouraged client to an agency from which the client is not really eligible to receive services. Nurses should help the client learn how to get the most from the referral. Nurses are critical to vulnerable populations.

Nurses are critical **safety net providers.** Safety net health providers deliver essential primary care to marginalized populations such as poor people, minority groups, homeless and uninsured people, and groups with stigmatizing illnesses and conditions such as HIV/AIDS and behavioral, mental health, and addiction disorders. Safety net facilities and providers have been referred to as *providers of last resort.*

One successful model that is associated with bridging gaps in health and health care is nurse-managed health centers (NMHCs). NMHCs are community-based primary care clinics and centers led by advanced practice registered nurses (APRNs). The hallmarks of NMHCs are the emphasis on health education and promotion, disease prevention, and the focus on underserved populations, including populations that have low incomes, may be members of minority groups, may be homeless, or may lack adequate insurance coverage, as well as other groups of vulnerable people. NMHCs are generally non-profit and usually employ a sliding scale fee schedule (Campaign for Action, 2010). NMHCs provide comprehensive care that includes referrals, follow-up, and advocacy.

There is growing recognition of the importance of the role of the registered nurse (RN) in community-based and primary care. Roles for RNs include (1) protocol-based management of chronic disease, (2) leading complex care teams, (3) care coordination, (4) management of common episodic conditions using protocols, and (5) prevention, health education/promotion, and family support (Bodenheimer & Mason, 2017).

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Quality Improvement

Use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of health care systems.

Important aspects of quality improvement include:

- **Knowledge:** Explain the importance of variation and measurement in assessing quality of care.
- **Skills:** Use quality measures to understand performance.
- **Attitudes:** Value measurement and its role in good client care.

Quality Improvement Question

Examine health statistics and demographic data in your geographic area to determine which vulnerable groups are predominant. Look on the web for examples of agencies you think provide services to these vulnerable groups. If the agency has a web page, read about the target population they serve, the types of services they provide, and how they are reimbursed for services. Learn about different agencies and share results during class. On the basis of your findings, identify gaps or overlaps in services provided to vulnerable groups in your community. Which data do these agencies collect to demonstrate the efficacy of their services? How could you deal with these gaps and overlaps to help clients receive needed services?

Prepared by Gail Armstrong, PhD, DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing.

It is important for nurses to provide culturally and **linguistically appropriate health care.** *Linguistically appropriate health care* means communicating health-related information in the recipient's primary language when possible and always in a language the recipient can understand. It also means using words that the recipient can understand. The factors that predispose people to vulnerability and the outcomes of vulnerability create a cycle in which the outcomes reinforce the predisposing factors, leading to more negative outcomes. Unless the cycle is broken, it is difficult for vulnerable populations to improve their health. Nurses can identify areas in which they can work with vulnerable populations to break the cycle. The nursing process guides nurses in assessing vulnerable individuals, families, groups, and communities; developing nursing diagnoses of their strengths and needs; planning and implementing appropriate therapeutic nursing interventions in partnership with vulnerable clients; and evaluating the effectiveness of interventions.

It is also important to consider that there can be ethical dilemmas associated with working with vulnerable populations. Ethical dilemmas that arose in an academic-community partnership designed to learn about the experiences of undocumented immigrants who sought health care in Toronto, Canada, are described in the Evidence-Based Practice box.

In some situations, the nurse works with individual clients. The nurse also develops programs and policies for populations of vulnerable persons. In both examples, planning and

EVIDENCE-BASED PRACTICE

Using an academic-community partnership, a study was conducted to understand the experiences of undocumented immigrants seeking health care in Toronto, Canada. A team composed of the principal investigator, three researchers, and a group of nine undocumented immigrants used a community-based participatory research process to examine the experiences of the immigrants. Representatives from the community-based organization (CBO) had a pre-existing, strong, and trusting relationship with the study participants. Two ethical dilemmas arose. Two of the participants thought that the researcher who was asking them questions was a spy for the Canadian Border Services Agency (CBSA). These two participants had not attended the orientation session. They were concerned when asked about their immigration status during the informed consent process. To solve this dilemma, the team decided that the CBO worker should ask for the informed consent because trust was present in that relationship. A second ethical dilemma arose when one participant told the principal investigator (PI) that she was suicidal. The PI was unprepared to deal with this information, and the team decided that in future interviews the PI would tell the participants that she was not a mental health professional. They also determined that the team needed to have access to a mental health professional in the event they learned information that needed follow-up.

Nurse Use

When ethical dilemmas arise in either research or client care, it is essential to identify them and immediately try to seek a solution. This study is a good example of how the team learned a great deal from their project. They put the project on hold in order to reflect, analyze, synthesize, and evaluate the facts.

Data from Campbell-Page RM, Shaw-Ridley MS: Managing ethical dilemmas in community-based participatory research with vulnerable populations. *Health Promot Pract* 17:485-490, 2013.

implementing care for members of vulnerable populations involve partnerships between the nurse and client and build on careful assessment. Nurses need to avoid directing and controlling clients' care because this might interfere with their being able to establish a trusting relationship and may inadvertently foster a cycle of dependency and lack of personal health control. The most important initial step is for nurses to demonstrate they are trustworthy and dependable. For example, nurses who work in a community clinic for substance abusers must overcome any suspicion that clients may have of them and eliminate any fears clients may have of being manipulated.

Nurses working with vulnerable populations may fill numerous roles, including those listed in Box 31.1. They identify vulnerable individuals and families through outreach and case finding. They encourage vulnerable groups to obtain health services, and they develop programs that respond to their needs. Nurses teach vulnerable individuals, families, and groups strategies to prevent illness and promote health. They counsel clients about ways to increase their sense of personal power and help them identify strengths and resources. They provide direct care to clients and families in a variety of settings, including storefront clinics, mobile clinics, shelters, homes, neighborhoods, worksites, churches, and schools.

BOX 31.1 Nursing Roles When Working With Vulnerable Population Groups

Case manager
Health educator
Counselor
Direct care provider
Population health advocate
Community assessor and developer
Monitor and evaluate care
Advocate
Health program planner and implementer
Participant in developing policies

CHECK YOUR PRACTICE

If you were a nurse working with families who are picking peaches in a southern state and one of the adults steps on a rusty nail, what actions would you take? What would your first action be? What additional actions might you take to assure this client of the best outcome?

The following are some examples of care to clients, families, and groups: (1) a nurse in a mobile migrant clinic might administer a tetanus booster to a client who has been injured by a piece of farm machinery and may also check that client's blood pressure and cholesterol level during the same visit; (2) a home health nurse seeing a family referred by the courts for child abuse may weigh the child, conduct a nutritional assessment, and help the family learn how to manage anger and disciplinary problems; (3) a nurse working in a school-based clinic may lead a support group for pregnant adolescents and conduct a birthing class; and (4) a nurse may work with people being treated for TB to monitor drug treatment compliance and ensure that they complete their full course of therapy.

LINKING CONTENT TO PRACTICE

Generalist and staff public health nurses should have competencies in eight domains as defined by the Quad Council Coalition of Public Health Nursing Organizations (2018). Each of the eight competencies is important in working with vulnerable populations. Public health nurses working with vulnerable populations should be able to analyze data and determine when a problem exists with an individual and within a vulnerable population group. They should be able to identify options for programs or policies that could be helpful to these populations and communicate their ideas and recommendations clearly. Public health nurses should be able to provide culturally competent interventions for individuals or for vulnerable populations. As an example, a public health nurse should be able to collect and analyze data related to the prevalence of violence among women in the community; identify key stakeholders; evaluate the cultural preferences of the population; work with others to develop a program to meet a defined need within this population, including preparation of a basic budget for the program; and ensure that the program is culturally appropriate for the population. The Council on Linkages Between Academia and Public Health Practice (2014) published a similar list for public health professionals, including but not limited to public health nurses. This list includes an emphasis on evaluation and ongoing improvement of programs. In this example, the nurse would evaluate the program developed for women who are victims of violence and work with others to develop and implement quality improvements on a regular basis.

Public health nurses also serve as population health advocates and work with local, state, or national groups to develop and implement policies that promote health. They also collaborate with community members and serve as community assessors and developers, and they monitor and evaluate care and health programs. Nurses often function as case managers for vulnerable clients, making referrals and linking them to community services. Case management services are especially important for vulnerable persons because they often do not have the ability or resources to make their own arrangements. They may not be able to speak the language, or they may be unable to navigate the complex telephone systems that many agencies establish. Nurses also serve as advocates when they refer clients to other agencies, work with others to develop health programs, and influence legislation and health policies that affect vulnerable populations.

The nature of nurses' roles varies depending on whether the client is a single person, a family, or a group. For example, a nurse might teach an HIV-positive client about the need for prevention of opportunistic infections, may help a family with an HIV-positive member understand myths about transmission of HIV, or may work with a community group concerned about HIV transmission among students. In each case, the nurse teaches individuals how to prevent infectious and communicable diseases. The size of the group and the teaching method for each group differ.

Health education is often used in working with vulnerable populations. The nurse should teach members of populations with low educational levels what they need to do to promote health and prevent illness rather than directing health education to groups that the nurse thinks might be at high risk even though there is no evidence to support the perception.

Levels of Prevention

Healthy People 2020 (USDHHS, 2010) objectives emphasize improving health by modifying the individual, social, and environmental determinants of health. One way to do this is for vulnerable individuals to have a primary care provider who both coordinates health services for them and provides their preventive services. This primary care provider may be an advanced practice nurse or a primary care physician. Another approach is for a nurse to serve as a case manager for vulnerable clients and, again, coordinate services and provide illness prevention and health promotion services. See the Levels of Prevention box for an example that relates to different vulnerable populations.

One example of primary prevention is to give influenza vaccinations to vulnerable populations that are immunocompromised (unless contraindicated). Secondary prevention is seen in conducting screening clinics for vulnerable populations. For example, nurses who work in homeless shelters, prisons, migrant camps, and substance abuse treatment facilities should know that these groups are at high risk for acquiring communicable diseases. Both clients and staff need routine screening for TB. Screening homeless adults and providing isoniazid to those who test positive for TB are examples of secondary prevention. An example of tertiary prevention is conducting a therapy group with the residents of a group home for severely mentally ill adults. Nurses who work with abused women to help them enhance their levels of self-esteem are also providing tertiary preventive activities.

LEVELS OF PREVENTION

Levels of Prevention Related to Vulnerable Populations

Primary	Secondary	Tertiary
• Provide culturally and economically sensitive health teaching about balanced diet and exercise. • Develop a portable immunization chart, such as a wallet card, that mobile population groups such as the homeless and migrant workers can carry with them.	• Conduct screening clinics to assess for things such as obesity, diabetes, heart disease, or tuberculosis (TB). • Develop a way for homeless individuals to read their TB skin test, if necessary, and to transfer the results back to the facility at which the skin test was administered.	• Develop community-based exercise programs for people identified as obese or who have increased blood pressure or increased blood glucose. • Provide directly observed medication therapy for people with active TB.

ASSESSMENT ISSUES

Nurses who work with vulnerable populations need good assessment skills, current knowledge of available resources, and the ability to plan care based on client needs and receptivity to help. They also need to be able to show respect for the client. The How To box entitled "Assess Members of Vulnerable Population Groups" lists guidelines for assessing members of vulnerable population groups.

HOW TO Assess Members of Vulnerable Population Groups

Setting the Stage

- Create a comfortable, nonthreatening environment.
- Learn as much as you can about the culture of the clients you work with so that you will understand cultural practices and values that may influence their health care practices.
- Provide a culturally competent assessment by understanding the meaning of language and nonverbal behavior in the client's culture.
- Be sensitive to the fact that the individual or family you are assessing may have other priorities that are more important to them. These might include financial or legal problems. You may need to give them some tangible help with their most pressing priority before you will be able to address issues that are more traditionally thought of as health concerns.
- Collaborate with others as appropriate; you should not provide financial or legal advice. However, you should make sure to connect your client with someone who can and will help them.

Nursing History of an Individual or Family

- You may have only one opportunity to work with a vulnerable person or family. Try to complete a history that will provide all the essential

information you need to help the individual or family on that day. This means that you will have to organize in your mind exactly what you need to ask. You should also understand why you need any information that you gather.

- It will help to use a comprehensive assessment form that has been modified to focus on the special needs of the vulnerable population group with whom you work. However, be flexible. With some clients, it will be both impractical and unethical to cover all questions on a comprehensive form. If you know that you are likely to see the client again, ask the less pressing questions at the next visit.
- Be sure to include questions about social support, economic status, resources for health care, developmental issues, current health problems, medications, and how the person or family manages their health status. Your goal is to obtain information that will enable you to provide family-centered care.
- Determine whether the individual has any condition that compromises his or her immune status, such as AIDS, or if the individual is undergoing therapy that would result in immunodeficiency, such as cancer chemotherapy.

Physical Examination or Home Assessment

- Again, complete as thorough a physical examination (on an individual) or home assessment as you can. Keep in mind that you should collect only data for which you have a use.
- Be alert for indications of physical abuse, substance use (e.g., needle marks, nasal abnormalities), or neglect (e.g., underweight, inadequate clothing).
- You can assess a family's living environment using good observational skills. Does the family live in an insect- or rat-infested environment? Do they have running water, functioning plumbing, electricity, and a telephone?
- Is perishable food left sitting out on tables and countertops? Are bed linens reasonably clean? Is paint peeling on the walls and ceilings? Is ventilation adequate? Is the temperature of the home adequate? Is the family exposed to raw sewage or animal waste? Is the home adjacent to a busy highway, possibly exposing the family to high noise levels and automobile exhaust?

Because members of vulnerable populations often experience multiple stressors, assessment must balance the need to be comprehensive while focusing only on information that the nurse needs and the client is willing to provide. Remember to ask questions about the client's perceptions of his or her socioeconomic resources, including identifying people who can provide support and financial resources. Support from other people may include information, caregiving, emotional support, and help with instrumental activities of daily living, such as transportation, shopping, and babysitting. Financial resources may include the extent to which the client can pay for health services and medications, as well as questions about eligibility for third-party payment. The nurse should ask the client about the perceived adequacy of both formal and informal support networks.

When possible, assessment should include an evaluation of clients' preventive health needs, including age-appropriate screening tests such as immunization status, blood pressure, weight, serum cholesterol, Papanicolaou (Pap) smears, breast examinations, mammograms, prostate examinations, glaucoma screening, and dental evaluations. It may be necessary to make referrals for some of these tests. Assessment should also include preventive screening for physical health problems, for which certain vulnerable groups are at particularly high risk. For example, people who are HIV positive should be evaluated regularly for CD4 cell counts and common opportunistic infections, including TB and pneumonia. Intravenous drug users should be evaluated for HBV, including liver palpation and serum antigen tests as necessary. Alcoholic clients should also be asked about symptoms of liver disease and should be evaluated for jaundice and liver enlargement. Severely mentally ill clients should be assessed for the presence of tardive dyskinesia, indicating possible toxicity from their antipsychotic medications.

Vulnerable populations should be assessed for congenital and genetic predisposition to illness and either receive education and counseling as appropriate or be referred to other health professionals as necessary. For example, pregnant adolescents who are substance abusers should be referred to programs to help them quit using addictive substances during their pregnancies and, ideally, after delivery of their infants. Pregnant women older than 35 years should receive amniocentesis testing to determine whether genetic abnormalities exist in the fetus.

The nurse should also assess the amount of stress the person or family is having. Does the family have healthy coping skills and healthy family interaction? Are some family members able and willing to care for others? What is the level of mental health in each member? Also, are diet, exercise, and rest and sleep patterns conducive to good health?

The nurse should assess the living environment and neighborhood surroundings of vulnerable families and groups for environmental hazards such as lead-based paint, asbestos, water and air quality, industrial wastes, and the incidence of crime.

Planning and Implementing Care for Vulnerable Populations

Nurses who work in community settings may have considerable involvement with vulnerable populations. The relationship with the client will depend on the nature of the contact. Some will be seen in clinics and others in homes, schools, and at work. Regardless of the setting, the following key nursing actions should be used:

- **Create a trusting environment:** Trust is essential, because many of these individuals have previously been disappointed in their interactions with health care and social systems. It is important to follow through and do what you say you are going to do. If you do not know the answer to a question, the best reply is "I do not know, but I will try to find out."
- **Show respect, compassion, and concern:** Vulnerable people have been defeated again and again by life's circumstances. They may have reached a point at which they question whether they even deserve to get care. Listen carefully, because listening is a form of respect, as well as a way to gather information to plan care.
- **Do not make assumptions:** Assess each person and family. No two people or groups are alike.
- **Coordinate services and providers:** Getting health and social services is not always easy. Often people feel like they

are traveling through a maze. In most communities a large number of useful services exist. People who need them simply may not know how to find them. For example, people may need help finding a food bank or a free clinic or obtaining low-cost or free clothing through churches or in second-hand stores. Clients often need help in determining whether they meet the eligibility requirements. If gaps in service are found, nurses can work with others to try to get the needed services established. Care for vulnerable populations requires interprofessional collaboration to meet their multiple needs. For example, nurses can work with business and public health leaders to reduce hazardous exposures, develop accessible services, and improve working conditions for low-income employees (Lathrop, 2013). Nurses may need to work with lawmakers, union leaders, urban developers, business leaders, and a range of public health and other health care workers. The case study in Box 31.2 describes a situation in which a mother faced many obstacles in getting care for her three children.

- **Advocate for accessible health care services:** Vulnerable people have trouble getting access to services. Neighborhood clinics, mobile vans, and home visits can be valuable for them. Also, coordinating services at a central location is helpful. These multiservice centers can provide health care, social services, daycare, drug and alcohol recovery programs, and case management. When working with vulnerable populations, it is a good idea to arrange to have as many services as possible available in a single location and at convenient times. This "one-stop shopping" approach to care delivery is very helpful for populations experiencing multiple social, economic, and health-related stresses. Although it may seem difficult and costly to provide comprehensive services in one location, it may save money in the long run by preventing illness.

BOX 31.2 Case Study

Felicia is a 22-year-old single mother of three children whose primary source of income is Temporary Assistance for Needy Families (TANF). She is worried about the future because she will no longer be eligible for welfare by the end of the year. She has been unable to find a job that will pay enough for her to afford childcare. Her friend Maria said that Felicia and her children can stay in Maria's trailer for a short time, but Felicia is afraid that her only choice after that will be a shelter.

Felicia recently took all three children with her to the health department because 15-month-old Hector needed immunizations. Felicia was also concerned about 5-year-old Martina, who had had a fever of 100°F to 101°F on and off for the past month. Felicia and her friends in the trailer park think that some type of hazardous waste from the chemical plant next door to the park is making their children sick. Now that Martina was not feeling well, Felicia was particularly concerned. However, the health department nurse told her that no appointments were available that day and that she would need to bring Martina back to the clinic on the next day. Felicia left discouraged because it was so difficult for her to get all three children ready and on the bus to go to the health department, not to mention the expense. She thought maybe Martina just had a cold and she would wait a little longer before bringing her back. However, she wanted to take care of Martina's problem before losing her medical card. Felicia is desperate to find a way to manage her money problems and take care of her children.

- **Focus on prevention:** Use every opportunity to teach about preventive health care. Primary prevention may include child and adult immunizations and education about nutrition, foot care, safe sex, contraception, and the prevention of injuries or chronic illness. It also includes providing prophylactic anti-tuberculosis drug therapy for HIV-positive people who live in homeless shelters or giving flu vaccine to people who are immune-compromised or older than 65 years of age. Secondary prevention would include screening for health problems such as TB, diabetes, hypertension, foot problems, anemia, or drug use or abuse. People who spend time in homeless shelters, substance abuse treatment facilities, and prisons often get communicable diseases such as influenza, TB, and methicillin-resistant *Staphylococcus aureus* (MRSA). Nurses who work in these facilities should plan regular influenza vaccination clinics and TB screening clinics. When planning these clinics, nurses should work with local physicians to develop signed protocols and should plan ahead for problems related to the transient nature of the population. For example, nurses should develop a way for homeless individuals to read their TB skin test if necessary and transfer the results back to the facility where the skin test was administered. It is helpful to develop a portable immunization chart, such as a wallet card, that mobile population groups such as the homeless and migrant workers can carry with them.
- **Know when to "walk beside" the client and when to encourage the client to "walk ahead":** At times it is difficult to know when to do something for people and when to teach or encourage them to do for themselves. Nursing actions range from providing encouragement and support to providing information and active intervention. It is important to assess for the presence of strength and the ability to problem solve, cope, and access services. For example, a local hospital might provide free mammograms for women who cannot pay. The nurse would need to decide whether to schedule the appointments for clients or to give them the information and encourage them to do the scheduling.
- **Know what resources are available:** Be familiar with community agencies that offer health and social services to vulnerable populations. Also follow up after you make a referral to make sure the client was able to obtain the needed help. Examples of agencies found in most communities are health departments, community mental health centers, voluntary organizations such as the American Red Cross, missions, shelters, soup kitchens, food banks, nurse-managed or free clinics, social service agencies such as the Salvation Army or Travelers Aid, and church-sponsored health and social services.
- **Develop your own support network:** Working with vulnerable populations can be challenging, rewarding, and at times exhausting. Nurses need to find sources of support and strength. This can come from friends, colleagues, hobbies, exercise, poetry, music, and other sources.
- In addition to the nursing actions described, the How To box entitled "Intervene With Vulnerable Populations" summarizes goals and interventions and evaluates outcomes with vulnerable populations.

HOW TO Intervene With Vulnerable Populations

Goals

- Set reasonable goals based on the baseline data you collected. Focus on reducing disparities in health status among vulnerable populations.
- Work toward setting manageable goals with the client. Goals that seem unattainable may be discouraging.
- Set goals collaboratively with the client as a first step toward client empowerment.
- Set family-centered, culturally sensitive goals.

Interventions

- Set up outreach and case-finding programs to help increase access to health services by vulnerable populations.
- Do everything you can to minimize the "hassle factor" connected with the interventions you plan. Vulnerable groups do not have the extra energy, money, or time to cope with unnecessary waits, complicated treatment plans, or confusion. As your client's advocate, you should identify possible hassles and develop ways to avoid them. For example, this may include providing comprehensive services during a single encounter, rather than asking the client to return for multiple visits. Multiple visits for more specialized aspects of the client's needs, whether individual or family group, reinforce a perception that health care is fragmented and organized for the professional's convenience rather than that of the client.
- Work with clients to ensure that interventions are culturally sensitive and competent.
- Focus on teaching skills in health promotion and disease prevention. Also, teach clients how to be effective health care consumers. For example, role-play asking questions in a physician's office with a client.
- Help clients learn what to do if they cannot keep an appointment with a health care or social service professional.

Evaluating Outcomes

- It is often difficult for vulnerable clients to return for follow-up care. Help your client develop self-care strategies for evaluating outcomes. For example, teach homeless individuals how to read their own tuberculosis (TB) skin test, and give them a self-addressed, stamped card they can return by mail with the results.
- Remember to evaluate outcomes in terms of the goals you have mutually agreed on with the client. For example, one outcome for a homeless person receiving isoniazid therapy for TB might be that the person returns to the clinic daily for direct observation of compliance with the drug therapy.

In general, more agencies are needed that provide comprehensive services with nonrestrictive eligibility requirements. Communities often have many agencies that restrict eligibility to make it possible for more people to receive services. For example, shelters may prohibit people who have been drinking alcohol from staying overnight and limit the number of sequential nights a person can stay. Food banks usually limit the number of times a person can receive free food. Agencies are often very specialized as well. For vulnerable individuals and families, this means that they must go to several agencies to obtain services for which they qualify and that meet their health needs. This is tiring and discouraging, and people may forgo help because of these difficulties.

Nurses need to know about community agencies that offer various health and social services. It is important to follow-up with the client after a referral to ensure that the desired outcomes were achieved. Sometimes excellent community resources may be available but impractical because of transportation or reimbursement issues. Nurses can identify these potential problems by following through with referrals, and they can also work with other team members to make referrals as convenient and realistic as possible. Although clients with social problems such as financial needs should be referred to social workers, it is useful for nurses to understand the close connections between health and social problems and know how to work effectively with other professionals. A list of community resources can often be found in the telephone directory or online. The following are examples of agency resources found in most communities:

- Health departments
- Community mental health centers
- American Red Cross and other voluntary organizations
- Food and clothing banks
- Missions and shelters
- Nurse-managed clinics
- Social service agencies such as Travelers Aid and the Salvation Army
- Church-sponsored health and service assistance
- Free clinics and other community services

Nurses who work with vulnerable populations often need to coordinate services across multiple agencies for members of these groups. It is helpful to have a strong professional network of people who work in other agencies. Effective professional networks make it easier to coordinate care smoothly and in ways that do not add to clients' stress. Nurses can develop strong networks by participating in community coalitions and attending professional meetings. When making referrals to other agencies, a phone call can be a helpful way to obtain information that the client will need for the visit. When possible, having an interdisciplinary, interagency team plan care for clients at high risk for health problems is effective. Obtain the clients' written and informed consent before engaging in this kind of planning because of confidentiality issues. The following list of tips can be helpful:

- Involve clients in making decisions about the kinds of services they are willing and able to use.
- Work with community coalitions to coordinate services for targeted vulnerable populations.
- Collaborate with legal counsel from the agencies involved in the coalitions to ensure that legal and ethical issues related to care coordination have been properly addressed. Examples of issues to address include privacy and security of clinical data and ensuring compliance with the Health Insurance Portability and Accountability Act of 1996 (HIPAA), contractual provisions for coordinating care across agencies, and consent to treatment from multiple agencies.
- Develop policies and protocols for making referrals, following up on referrals, and ensuring that clients receiving care from multiple agencies experience the process as smooth and seamless. The following discussion and box provide information about how to use case management with vulnerable groups.

HOW TO Use Case Management in Working With Vulnerable Populations

- Know available services and resources.
- Find out what is missing; look for creative solutions.
- Use your clinical skills.
- Develop long-term relationships with the families you serve.
- Strengthen the family's coping and survival skills and resourcefulness.
- Be the roadmap that guides the family to services, and help them get the services.
- Communicate with the family and the agencies that can help them.
- Work to change the environment and the policies that affect your clients.

Two other important categories of resources for vulnerable people are their own personal coping skills and social supports (Aday, 2001). These groups often are resourceful and creative in managing multiple stressors. Nurses can work with clients to help them identify their strengths and draw on those strengths when managing their health needs. Also, clients may be able to depend on informal support networks. Even though social isolation is a problem for many vulnerable clients, nurses should not assume they have no one who can or will help them. *Case management* involves linking clients with services and providing direct nursing services to them, including teaching, counseling, screening, and immunizing. Lillian Wald was the first case manager. She linked vulnerable families with various services to help them stay healthy (Buhler-Wilkerson, 1985). Nurses are often the link between personal health services and population-based health care. Linking, or brokering, health services is accomplished by making appropriate referrals and following up with clients to ensure that the desired outcomes from the referral were achieved. Nurses are effective case managers in community nursing clinics, health departments, hospitals, and various other health care agencies. Nurse case managers emphasize health promotion and illness prevention with vulnerable clients and focus on helping them avoid unnecessary hospitalization.

As can be seen, many of these nursing actions are in the realm of case management, in which the nurse makes referrals and links clients with other community services. In the case manager role, the nurse often is an advocate for the client or family. The nurse serves as an advocate when referring clients to other agencies, when working with others to develop health programs, and when trying to influence legislation and health policies that affect vulnerable population groups.

PRACTICE APPLICATION

Ms. Green, a 46-year-old farm worker pregnant with her fifth child, has come to the clinic requesting treatment for swollen ankles. During your assessment, you learned that she had seen the nurse practitioner at the local health department two months ago. The nurse practitioner gave her some sample vitamins, but Ms. Green lost them. She has not received regular prenatal care and has no plans to do so. Her previous pregnancies were essentially normal, although she said she was "toxic" with her last child. She also said that her middle child was "not quite right." He is in the seventh grade at age 15. Ms. Green is 5 feet 2 inches tall, weighs 180 pounds, and has a blood pressure of 160/90 mm Hg. She has pitting edema of the ankles and a mild headache.

Ms. Green says that she usually takes chlorpromazine hydrochloride (Thorazine) but has run out of it and cannot afford to have her prescription refilled. She says that she has been in several mental hospitals in the past and that she has been more agitated lately, and now has problems managing her daily activities. As her agitation grows, she says that she usually hears voices and this really makes her aggressive.

None of her children lives with her, and she has no plans for taking care of the infant. She thinks she will ask the child's father, a race track worker, to help her, because she usually travels around the country with him.

A. What additional information do you need to help you adequately assess Ms. Green's health status and current needs?

B. What nursing activities are suggested by her history, physical, and psychological descriptions?

Answers can be found on the Evolve website.

KEY POINTS

- All countries have population subgroups that are more vulnerable to health threats than the general population.
- Vulnerable populations are more likely to develop health problems as a result of exposure to risk or to have worse outcomes from those health problems than the population as a whole.
- Vulnerable populations are more sensitive to risk factors than those who are more resilient, because they are often exposed to cumulative risk factors. These populations include poor or homeless persons, pregnant adolescents, migrant workers, severely mentally ill individuals, substance abusers, abused individuals, people with communicable diseases, and people with sexually transmitted diseases.
- Factors leading to the growing number of poor people in the United States include reduced earnings, decreased availability of low-cost housing, more households headed by women, inadequate education, lack of marketable skills, welfare reform, and reduced Social Security payments to children.
- Poverty has a direct effect on health and well-being across the life span. Poor people have higher rates of chronic illness and infant morbidity and mortality, shorter life expectancy, and more complex health problems.
- Child poverty rates are twice as high as those for adults. Children who live in single-parent homes are twice as likely to be poor than those who live with both parents.
- The complex health problems of homeless people include the inability to obtain adequate rest, sleep, exercise, nutrition,

and medication; exposure; infectious diseases; acute and chronic illness; infestations; and trauma and mental health problems.

- Health care is increasingly moving into the community. This began with deinstitutionalization of the severely mentally ill population and is continuing today as hospitals reduce inpatient stays. Vulnerable populations need a wide variety of services, and because these are often provided by multiple community agencies, nurses coordinate and manage the service needs of vulnerable groups.
- Socioeconomic problems, including poverty and social isolation, physiological and developmental aspects of age, poor health status, and highly stressful life experiences, predispose people to vulnerability. Vulnerability can become a cycle, with the predisposing factors leading to poor health outcomes, chronic stress, and hopelessness. These outcomes increase vulnerability.
- Nurses assess vulnerable individuals, families, and groups to determine which socioeconomic, physical, biological, psychological, and environmental factors are problematic for clients. They work as partners with vulnerable clients to identify client strengths and needs and develop intervention strategies designed to break the cycle of vulnerability.

CLINICAL DECISION-MAKING ACTIVITIES

1. Identify nurses in your community who work with vulnerable groups. Invite these nurses to come to class and talk about their experiences. What is their typical day? What are the rewards? What are the challenges? How do they deal with frustration, competing demands, and stress?
2. Discuss welfare reform with your classmates. How does the U.S. welfare system work? Who gets welfare? What should be done to improve the system? Is your state a leader in welfare reform?
3. Suppose you are making a home visit to a person whose home is not clean. Food is everywhere, and roaches are crawling around the house. What do you do if the person asks you to sit down? What if you are offered food?

Population-Centered Nursing in Rural and Urban Environments

Angeline Bushy, PhD, RN, FAAN

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Compare and contrast definitions of *rural* and *urban*.
2. Describe residency as a continuum, ranging from farm residency to core inner city.
3. Compare and contrast the health status of rural and urban populations on select health measures.
4. Analyze barriers to care in health professional shortage areas and for underserved populations.
5. Evaluate issues related to the delivery of public health services for rural underserved populations.
6. Describe characteristics of rural and small-town residency.
7. Examine the role and scope of public health nursing practice in rural and underserved areas.
8. Evaluate two professional-client-community partnership models that can effectively provide a continuum of health care to residents living in an environment with sparse resources.

CHAPTER OUTLINE

Historic Overview
Definition of Terms
Rural-Urban Continuum
Current Perspectives
Rural Health Care Delivery Issues and Barriers to Care
Nursing Care in Rural Environments
Future Perspectives
Building Professional-Community-Client Partnerships in Rural Settings

KEY TERMS

farm residency, p. 717
frontier, p. 722
health professional shortage area (HPSA), p. 721
medically underserved, p. 731
metropolitan area, p. 718
micropolitan area, p. 718
non-core areas, p. 718
non-farm residency, p. 717
rural, p. 717
rural-urban continuum, p. 717
suburbs, p. 718
urban, p. 717

Access to health care is a national priority, especially in regions with an insufficient number of health care providers. Recruiting and retaining qualified health professionals is often difficult in underserved communities, particularly inner cities and rural areas of the United States. Until recently, however, only limited research has been undertaken on the special challenges, problems, and opportunities of nursing practice—especially public health in rural settings. This chapter presents major issues surrounding health care delivery in rural environments, which sometimes differs from that in urban or more populated settings. Common definitions for the term *rural* are discussed, as are its associated lifestyle, the health status of rural populations, barriers to obtaining a continuum of health care services, and public health nursing practice issues. Strategies are discussed to help nurses deliver more effective population-focused nursing services to clients who live in more isolated environments with sparser resources. This chapter describes rural public health nursing practice and could be used by students, nurses who practice in rural public health departments, and those who work in agencies located in urban areas that offer outreach services to rural populations in their catchment area.

HISTORIC OVERVIEW

Formal rural nursing originated with the Red Cross Rural Nursing Service (RCRNS), which was organized in November 1912. The Committee on Rural Nursing was directed by Mabel Boardman (Chair), Jane Delano (Vice-Chair), and Annie Goodrich, along with other Red Cross leaders and philanthropists (Bigbee & Crowder, 1985). Prior to the formation of the

Red Cross Rural Nursing Service, care of the sick in a small community was provided by informal social support systems. When self-care and family care were not effective in bringing about healing, this task was assigned to traditional or cultural healers, who often were women who lived in the local community. Historically, rural Americans have had many health care needs, and they may differ in some ways from those of urban populations. Problems of maldistribution of health professionals, poverty, limited access to services, lack of education, and social isolation have plagued many rural communities for generations.

The history of the RCRNS consistently moved away from its initial rural focus, as seen in its frequent name changes. Unfortunately, concern about rural health is often temporary and replaced by other areas of greater need. Hopefully, health care reform initiatives will ensure equitable access to care for rural and urban residents alike (NACRHHS, 2017a).

DEFINITION OF TERMS

Rurality: A Subjective Concept

Everyone has an idea as to what constitutes rural as opposed to urban residence. However, the two cannot be viewed as opposing entities. With the increased degree of urban influence on rural communities, the differences may not be as distinct as they may have been even a decade ago (Bureau of the Census, 2016). In general, **rural** may be defined by geographic location and population density, or it may be described in terms of the distance from (e.g., 20 miles) or the time (e.g., 30 minutes) needed to commute to an urban center. See Box 32.1 for selected terms and definitions.

Both urban and rural communities are highly diverse and vary in their demographic, environmental, economic, and social characteristics. In turn, these characteristics influence the magnitude and types of health problems that communities face. Urban counties, however, tend to have more health care providers in relation to population, and residents of more rural counties often live farther from health care resources (RHI-Hub, 2018).

Some equate the idea of rural with **farm residency**, and **urban** with **non-farm residency**, whereas others consider *rural* to be a "state of mind." For the more affluent, rural may bring to mind a recreational, retirement, or resort community located in the mountains or in lake country where one can relax and participate in outdoor activities, such as skiing, fishing, hiking, or hunting. For the less affluent, the term can impose rather grim scenes. For example, some people may think of an impoverished Indian reservation as comparable to an underdeveloped country, while others think of a migrant labor camp with several families living in a one-room shanty with no access to safe drinking water or adequate sanitation.

Just as each city has its own unique features, also it is difficult to describe a "typical rural town" because of the wide population and geographic diversity. For example, rural towns in Florida, Oregon, Alaska, Hawaii, and Idaho are different from one another, and quite different from those in Vermont, Texas, Alabama, or California. Also, there can be vast differences between rural areas within one state. Still, descriptions and definitions for *rural* tend to be more subjective and relative in nature than those for *urban*.

For example, "small" communities with populations of more than 20,000 have some features that one may expect to find in a city. Then again, residents who live in a community with a population of less than 2000 may consider a community with a population of 5000 or 10,000 to be a city. Although some communities may seem geographically remote on a map, the residents who live there may not feel isolated. Those residents believe they are within easy reach of services through telecommunication and dependable transportation, although extensive shopping facilities may be 50 to 100 miles from the family home, obstetric care may be 150 miles away, or nursing services in the district health department in an adjacent county may be 75 or more miles away (Bolin & Bellamy, 2015).

BOX 32.1 Terms and Definitions

Farm residency: Residency outside area zoned as "city limits"; usually infers involvement in agriculture
Frontier: Regions having fewer than six persons per square mile
Large central: Counties in large (1 million or more population) metro areas that contain all or part of the largest central city
Large fringe: Remaining counties in large (1 million or more population) metro areas
Metropolitan county: Regions with a central city of at least 50,000 residents
Non-farm residency: Residence within area zoned as "city limits"
Micropolitan county: Counties that do not meet SMSA (see below) criteria
Rural: Communities having fewer than 20,000 residents or fewer than 99 persons per square mile
Small: Counties in metro areas with fewer than 1 million people
Standard metropolitan statistical area (SMSA): Regions with a central city of at least 50,000 residents
Suburban: Area adjacent to a highly populated city
Urban: Geographic areas described as non-rural and having a higher population density; more than 99 persons per square mile; cities with a population of at least 20,000 but less than 50,000

Modified from Rural Health Information Hub (RHI-Hub): *What is rural?* 2018. Available at https://www.ruralhealthinfo.org.

RURAL-URBAN CONTINUUM

Frequently used definitions to describe rural and urban and to differentiate between them are provided by several federal agencies (RHI-Hub, 2018; USDA, 2017) (see Box 32.1). These definitions, which in many cases are dichotomous in nature, fail to take into account the relative nature of ruralness. Rural and urban residencies are not opposing lifestyles. Rather, the two should be conserved as a **rural-urban continuum**, ranging from living on a remote farm, to a village or small town, to a larger town or city, to a large metropolitan area with a *core inner city*. See Fig. 32.1, which describes the continuum of rural-urban residency.

Several federal agencies classify U.S. counties and county equivalents (N = 3142) according to population density, specifically, metropolitan counties (84 percent of the total population) and non-metropolitan counties (16 percent of the

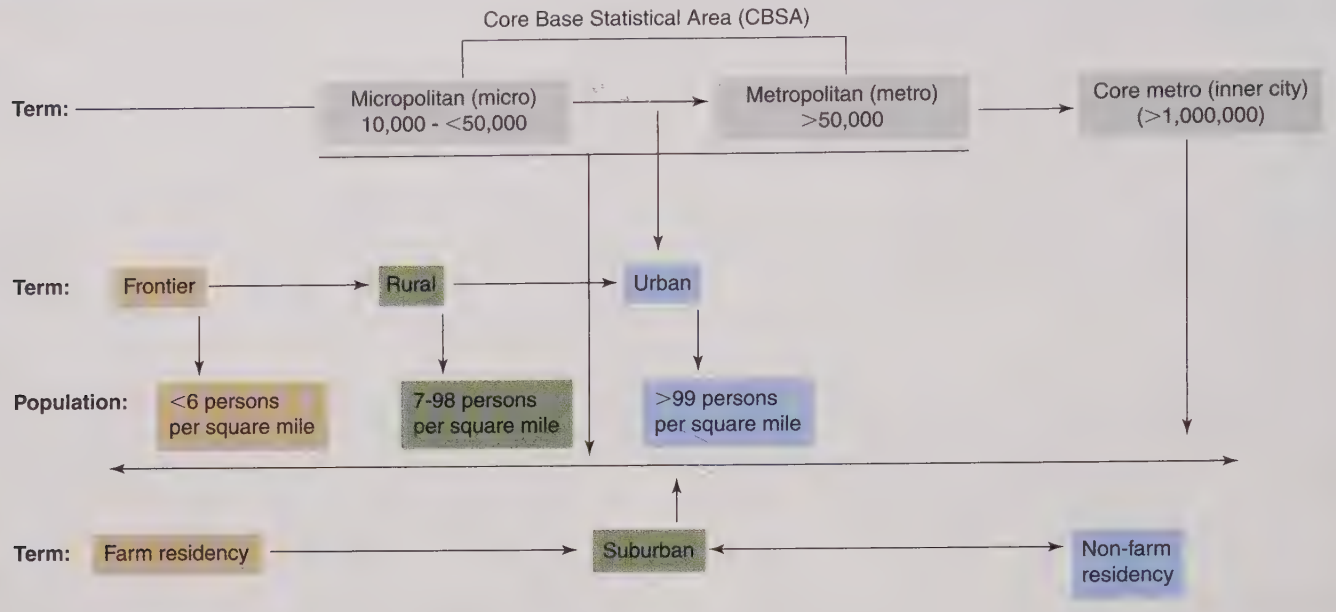

Fig. 32.1 The continuum of rural-urban residency.

total population) (RHI-Hub, 2018). The terms **metropolitan area** and **micropolitan area** (metro and micro areas) refer to geographic entities primarily used for collecting, tabulating, and publishing federal statistics. Core-based statistical area (CBSA) is a collective term for both metro and micro areas. A metro area contains a core urban area of 50,000 or more population. A micro area contains an urban core of at least 10,000 (but less than 50,000) population. Each metro or micro area consists of one or more counties containing the core urban area. Likewise, adjacent counties have a high degree of social and economic integration (as measured by commuting to work) with their urban core.

Demographically, micro areas contain about 60 percent of the total non-metro population, with an average of 43,000 people per county. In contrast, **non-core areas**, with no urban cluster of 10,000 or more residents, have on average about 14,000 residents. In general, lack of an urban core and low overall population density may place these counties at a disadvantage in efforts to expand and diversify their economic base. The designation of micro areas is an important step in recognizing non-metro diversity. The term also provides a framework to understand population growth and economic restructuring in small towns and cities that have received less attention than metro areas. Nationally and regionally, many measures of health, health care use, and health care resources among rural populations vary by the level of urban influence in a particular region.

Micro areas embody a widely shared residential preference for a small-town lifestyle—an ideal compromise between large highly populated urban cities and sparsely populated rural settings. As information about these places makes its way into government data and publications alongside metro areas in the coming years, hopefully the notion of "micropolitan" will draw increased attention from policy makers and the business community.

In recent years there has been a population shift from urban to less-populated regions of the United States. Demographers metaphorically refer to this demographic phenomenon as the "doughnut effect." That is to say, people are moving away from highly populated areas to outlying **suburbs** of urban centers. Most of the population growth has been in rural counties with a booming economy coupled with the geographic area to expand that is evident in some western and southern states (RHI-Hub, 2018).

Clearly, a notable population shift will also affect the health status and lifestyle preferences of communities in which this phenomenon occurs. As beliefs and values change over time, urban-rural differences narrow in some respects while others became more pronounced. Depending on the definition that is used, the actual rural population might vary slightly. According to Bureau of the Census estimates (2016), while about 97 percent of the land's area is rural, about 20 percent (or 60 million) of all U.S. residents live in rural settings. In this chapter, rural refers to areas having fewer than 99 persons per square mile and communities having 20,000 or fewer inhabitants.

CURRENT PERSPECTIVES

Population Characteristics

Adding to the confusion about what constitutes rural versus urban residency are the special needs of the numerous underrepresented groups (minorities, subgroups) who reside in the United States. In general, there are a higher proportion of whites in rural areas than in urban areas. There are, however, regional variations, and some rural counties have a significant number of minorities. Little is documented on the actual needs and health status of special rural populations (AHCPR, 2017; Bolin & Bellamy, 2015; USDHHS, 2013). Anthropologists note that, within a group, there often exists a wide range of lifestyles.

Consequently, even in the smallest or most remote town or village, a subgroup may behave differently and have different values about health, illness, and patterns of accessing health care. Also, a group's lifestyle may be associated with health problems that are different from those of the predominant cultural group in a given community. Background information on selected populations can be found in Chapters 8 and 31 that discuss cultural diversity and vulnerable populations.

Demographically, rural communities include a higher proportion of younger and older residents. Nurses often encounter more residents under the age of 18 and over 65 years of age in rural areas compared with an urban setting. Rural residents 18 years of age and older are more likely to be, or to have been, married than are their urban counterparts. As a group, rural adults are more likely to be widowed and have fewer years of formal education than urban adults (Bureau of the Census, 2016; CDC, 2018a; United States Census Bureau, 2010).

Although there are regional variations, rural families tend to be poorer than their urban counterparts. Comparing annual incomes with the standardized index established, more than one fourth of rural Americans live in or near poverty, and nearly 40 percent of all rural children are impoverished. Compared with those in metropolitan settings, a substantially smaller proportion of rural families are at the high end of the income scale. Accompanying the recent population shifts from urban to formerly rural areas, the average income level may change; however, no data are available at this time to substantiate this estimate. Regardless, level of income is a critical factor in whether a family has health insurance or qualifies for public insurance. Consequently, rural families are less likely to have private insurance and more likely to receive public assistance or to be uninsured (RHI-Hub, 2018).

The working poor in rural areas are particularly at risk for being underinsured or uninsured. In working poor families, one or more of the adults are employed but still cannot afford private health insurance. Furthermore, their annual income is such that it disqualifies the family from obtaining public insurance. Several factors help explain why this phenomenon occurs more often in rural settings (Bushy, 2013). For example, a high proportion of rural residents are self-employed in a family business, such as ranching or farming, or they work in small enterprises, such as a service station, restaurant, or grocery store. Also, an individual may be employed in part-time or in seasonal occupations, such as farm laborer and construction, in which health insurance often is not an employee benefit. In other situations, a family member may have a pre-existing health condition that makes the cost of insurance prohibitive, if it is even available to them. At present it remains to be seen if this situation will change with the recent health care reform. A few rural families fall through the cracks and are unable to access any type of public assistance because of other deterrents, such as language barriers, including a low level of English reading and writing even if they appear comfortable speaking the language, compromised physical status, the geographic location of an agency, lack of transportation, or undocumented worker status. Insurance, or the lack of it, has serious implications for the overall health status of rural residents and the nurses who provide services to them (AHCPR, 2017; NCHS, 2018).

Health Status of Rural Residents

Even though rural communities constitute about one fourth of the total population, the health problems and the health behaviors of the residents in them are not fully understood. This section summarizes what is known about the overall health status of rural adults and children. The health status measures that are addressed are perceived health status, diagnosed chronic conditions, physical limitations, frequency of seeking medical treatment, usual source of care, maternal–infant health, children's health, mental health, minorities' health, and environmental and occupational health risks (Bolin & Bellamy, 2015; OSHA, n.d.). Residents of rural areas suffer some of the same health problems as migrant farmworkers, as described in Chapter 34, including exposure to environmental factors and accidents.

Perceived Health Status. In general, people in rural areas have a poorer perception of their overall health and functional status than their urban counterparts. Rural residents over 18 years of age assess their health status less favorably than do urban residents. Studies show that rural adults are less likely to engage in preventive behavior, which ultimately increases exposure to risk. Specifically, they are more likely to use tobacco products and self-report higher rates of alcohol consumption and obesity; furthermore, they are less likely to engage in routine physical activity during leisure time, wear seat belts, have regular blood pressure checks, have Pap smears, complete breast self-examinations, and have colorectal screenings. Ultimately, failure to participate in health-promoting lifestyle behaviors impacts the overall health status of rural residents, their level of function, physical limitations, degree of mobility, and level of self-care activities (NCHS, 2018).

Chronic Illness. Rural adults are more likely than urban adults to have one or more of the following chronic conditions: heart disease, chronic obstructive pulmonary disease, hypertension, arthritis and rheumatism, diabetes, cardiovascular disease, and cancer. Nearly half of all rural adults have been diagnosed with at least one of these chronic conditions, compared with about one fourth of non-rural adults. Also, the prevalence of diagnosed diabetes in rural adults is about 7 out of 100, as opposed to 5 out of 100 in non-rural environments. Rural adults are more likely to have cancer (almost seven percent) compared with urban adults (about five percent). Although most cases of acquired immunodeficiency syndrome (AIDS) are still found in urban areas, the rate is increasing in some rural populations (NCHS, 2018).

Rural-urban health disparities have been documented in health status (Box 32.2) and for health behaviors (Box 32.3). For example, there are disparities in the proportion of rural adults who receive medical treatment for both life-threatening illness and degenerative or chronic conditions compared with urban adults. The proportion of rural residents who receive these treatments is high in rural versus urban areas.

BOX 32.2 Disparities Among U.S. Urban (Metropolitan) and Rural (Micropolitan) Residents' Health Status

Residents of fringe counties near large metro areas have the following:

- Lowest levels of premature mortality, partly reflecting lower death rates for unintentional injuries, homicide, and suicide
- Lowest levels of smoking, alcohol consumption, and childbearing among adolescents
- Lowest prevalence of physical inactivity during leisure time among women
- Lowest levels of obesity among adults
- Greatest number of physician specialists and dentists per capita
- Lowest percent of the population without health insurance
- Lowest percent of the population who had no dental visits

Residents in the most rural counties have the following:

- Highest death rates for children and young adults
- Highest death rates for unintentional and motor vehicle traffic–related injuries
- Highest death rates among adults for ischemic heart disease and suicide
- Highest levels of smoking among adolescents
- Highest levels of physical activity during leisure time among men
- Highest levels of obesity among adults
- Highest percent of adults with activity limitations caused by chronic health conditions
- Fewest physician specialists and dentists per capita
- Least likely to have seen a dentist
- Highest percentage of the population without health insurance

Modified from Centers for Disease Control and Prevention: *Strategies for reducing health disparities,* 2016. Available at https://www.cdc.gov; Bolin JN, Bellamy G: *Rural Healthy People: 2020,* 2015. Retrieved from https://srhrc.tamhsc.edu; Meit M, Knudson A, Gilbert T, et al.: *The 2014 update of the rural-urban chartbook,* 2014. Available at https://ruralhealth.und.edu.

Life-threatening conditions include malignant neoplasms, heart disease, cardiovascular problems, and liver disorders. Degenerative or chronic diseases include diabetes, kidney disease, arthritis, and chronic diseases of the circulatory, nervous, respiratory, and digestive systems. Chronic health conditions, coupled with their poor health status, limit the physical activities of a larger proportion of rural residents than of their urban counterparts (Bolin & Bellamy, 2015; NCHS, 2018).

Physical Limitations. Limitations in mobility and self-care are strong indicators of an individual's overall health status. Specific assessed measures on a national health survey included walking one block, walking uphill or climbing stairs, bending, lifting, stooping, feeding, dressing, bathing, and toileting. In fact, almost 10 percent of rural adults report at least three or more of these physical limitations, compared with about 6 percent of metropolitan adults. The increased prevalence of poor health status and impaired function is not necessarily attributable to the increased number of older adults found in rural areas. Similar patterns are evident in adults 18 to 64 years of age. Rural adults under 65 years of age are more likely than urban adults to assess their health status as fair to poor, and a greater percent have been diagnosed with a chronic health condition (NCHS, 2018; USDA, n.d.; USDHHS, 2013).

BOX 32.3 Rural-Urban Disparities: Lifestyle and Health Behaviors

- Residents in any rural areas are more likely to report fair to poor health status (19.5 percent) than were residents of urban counties (15.6 percent).
- Rural residents are more likely to report having diabetes (9.6 percent) versus urban adults (8.4 percent).
- Rates of diabetes are markedly higher among rural American Indians (15.2 percent) and African American adults (15.1 percent).
- Rural residents are more likely to be obese (27.4 percent) versus urban residents (23.9 percent).
- Rural black adults are particularly at risk for obesity; ranging from 38.9 percent in rural micropolitan counties to 40.7 percent in remote rural counties.
- Rural residents are less likely to meet CDC recommendations for moderate or vigorous physical activity (44 percent) versus urban residents (45.4 percent).
- Rural African American adults are less likely to meet recommendations for physical activity than other rural residents; this difference persists across all levels of rurality.

Access to Health Care Services

- Rural residents are more likely to be uninsured (17.8 percent) versus urban residents (15.3 percent).
- Hispanic adults are more likely to lack insurance, with uninsured rates ranging from 40.8 percent in rural micropolitan counties to 56.1 percent in small remote counties.
- Most rural residents (81 percent) and urban residents (79.4 percent) report having a personal health care provider. However, residents in remote rural counties were least likely to have a personal physician (78.7 percent).
- Rural white adults are more likely to have a personal health care provider than were other adults. Among Hispanic adults, the proportion with a personal provider ranged from 60.4 percent in rural micropolitan counties to 47.7 percent in remote rural counties.
- Rural adults are more likely than urban adults to defer seeking health care because of cost (15.1 percent versus 13.1 percent)
- Rural adult African Americans, Hispanics, and American Indians are more likely to report having deferred care due to cost compared with white rural residents.

Receipt of Preventive Services

- Rural women are less likely (70.7 percent) than urban women (77.9 percent) to be in compliance with mammogram screening guidelines.
- Rural women are less likely (86 percent) than urban women (91.4 percent) to have had a Pap smear within the past three years.
- Rural residents over age 50 years are less likely (57.7 percent) to have had a colorectal screening versus urban counterparts (61.4 percent).

Quality of Diabetes Care

- The proportion of adults with diabetes who reported receiving at least two hemoglobin A1c tests within the past year was low among both rural (33.1 percent) and urban residents (35 percent).
- White rural residents with diabetes were more likely than African American or Hispanic residents to receive at least two hemoglobin A1c tests in the past year.
- Only 64.2 percent of rural and 69.1 percent of urban residents with diabetes reported receiving an annual dilated eye examination.

Adapted from Centers for Disease Control and Prevention: *Strategies for reducing health disparities,* 2016. Available at https://www.cdc.gov; Bolin JN, Bellamy G: *Rural Healthy People: 2020,* 2015. Available at https://srhrc.tamhsc.edu; Meit M, Knudson A, Gilbert T, et al.: *The 2014 update of the rural-urban chartbook,* 2014. Available at https://ruralhealth.und.edu.

Based on data from national health surveys, the overall health status of rural adults leaves much to be desired. This is attributed to several factors, including impaired access to health care providers and services, coupled with other rural factors. Thus, nurses who practice in rural areas are essential in providing a continuum of care for clients. Specifically, nurses can help clients have healthier lives by teaching them how to prevent accidents, engage in more healthful lifestyle behaviors, and reduce the risk of chronic health problems. Once clients in rural environments have been diagnosed with a long-term problem, nurses can help them manage chronic conditions to achieve better health outcomes and functioning (Bolin & Bellamy, 2015; IOM, 2010).

Patterns of Health Service Use. When the use of health care services is measured, it is found that more than three fourths of adults in rural areas received medical care on at least one occasion during a year. Despite their overall poorer health status and higher incidence of chronic health conditions, rural adults seek medical care less often than urban adults. In part, this discrepancy can be attributed to scarce resources and the several other barriers cited earlier, including lack of providers in rural areas. Other reasons are discussed later under Rural Health Care Delivery Issues and Barriers to Care (AHCPR, 2017; CDC, 2017, 2018a). Nurses must be thorough in their health assessment of rural clients who may not receive regular care for chronic health conditions.

CHECK YOUR PRACTICE

When you conduct an the initial client assessment and discharge planning have you asked these questions:

- Context of residency (urban versus rural)? If rural … then …
- Occupation of the individual?
- Potential health risks associated with employment or place of residence?
- Access to health-related and support services available in the community?
- Veteran's status? If so … any actual or potential impact on health? If so, then …
- Does individual have access to veterans services?

Availability and Access to Health Care. The ability of a person to identify a usual source of care is considered a favorable indicator of access to health care and a person's overall health status. Essentially, a person who has a usual source of care is more likely to seek care when ill and adhere to prescribed regimens. Having the same provider of care can enhance continuity of care, as well as a client's perception of the quality of that care. Rural adults are more likely than urban adults to identify a particular medical provider as their usual source of care. Rural adults are more likely to receive care from general practitioners and advanced practice registered nurses (APRNs) compared to urban adults who are more likely to seek care from a medical specialist. However, this trend may be changing with health care reform, which emphasizes the importance of primary care (BHWF, 2017; Jakobs & Bigbee, 2016; IOM, 2010).

Another measure of access to care is traveling time and/or distance to ambulatory care services. Rural persons who seek ambulatory care are more likely to travel more than 30 minutes to reach their usual source of care. Extended commuting time may also be a factor for residents in highly populated urban areas and those who must rely on public transportation. Once the person arrives at the clinic or physician's office, no differences between rural and urban residents are found in the waiting time to see the provider. Also, many rural residents live on unpaved dirt roads that vehicles that transport clients to health care simply cannot reach.

In general, there is a maldistribution of health professionals among rural and urban counties. For instance, 1 out of 17 rural counties is reported to have no physician. Among rural respondents on national surveys, the ability to identify a usual site of care or a particular provider often stems from a community or county having only one, perhaps two, health care providers. The limited number of health care facilities is reinforced by the finding that nearly all rural residents who seek health care use ambulatory services that are provided in a physician's office as opposed to a clinic, community health center, hospital outpatient department, or emergency department (NACRHHS, 2017a; USDA, 2017, n.d.). One can speculate about the indicator of *usual place and usual provider*; that is to say, it suggests that rural residents are at least as well off as urban residents regarding access to care. However, this finding may be related to the fact that rural physicians tend to live and practice in a particular community for decades, thus providing care to multigenerational families who seek care from this particular provider.

Moreover, in a **health professional shortage area (HPSA)**, a physician or a nurse practitioner may provide services to residents who live in surrounding counties. One or two nurses in a public health department usually offer a full range of services for all residents in a rural catchment area of 100 or more miles from one end to the other end of a county or health district. Consequently, rural physicians and nurses frequently report, "I provide care to individuals and families with all kinds of conditions, in all stages of life, and across several generations." It should not come as a surprise that rural respondents who participate in national surveys are able to identify a usual source and a usual provider of health care (BHWF, 2018; Meit et al., 2014).

Maternal–Infant Health. Reports in the literature conflict regarding pregnancy outcomes in rural areas. Overall, rural populations have higher infant and maternal morbidity rates, especially counties designated as HPSAs, which often have a high proportion of racial minorities. Here one also finds fewer specialists, such as pediatricians, obstetricians, and gynecologists, to provide care to at-risk populations. There are extreme variations in pregnancy outcomes from one part of the country to another, and even within states. For example, in several counties located in the north-central and intermountain states, the pregnancy outcome is among the finest in the United States. However, in several other counties within those same states, the pregnancy outcome is among the worst. Particularly at risk are women who live on or near Indian reservations, are migrant workers, and are of African American descent residing in rural areas in southeastern states (Bolin & Bellamy, 2015; USDHHS, 2013).

Public health nurses recognize the interactive effects of socioeconomic factors, such as income level (poverty), education level, age, employment-unemployment patterns, and use of prenatal services, on pregnancy outcomes. There are other, less well-known health determinants, such as environmental hazards, occupational risks, and the cultural meaning placed on childbearing and child-rearing practices by a community. The interaction effects of these multifaceted factors vary and often are difficult to measure (Nelson, 2009).

Health of Children. Reports on the health status of rural children show regional variations and conflicting data. Comparing rural children with urban children under 6 years of age on the measures of access to providers and use of services reveals the following (AHCPR, 2017; Bolin & Bellamy, 2015; USDHHS, 2013):

- Urban children are less likely to have a usual provider but are more likely to see a pediatrician when they are ill.
- Like rural adults, rural children are more likely to be cared for by a general practitioner who is identified as their usual caregiver.

School nurses play an important role in the overall health status of children in the United States. The availability of school nurses in rural communities also varies from region to region. Specifically, in frontier and rural areas of the United States, school nurses usually are scarce. In part, this deficit can be attributed to limited resources associated with very low local tax revenues and shortages of health personnel in those counties. In other words, there are fewer taxpayers living in those large geographic areas. Some frontier areas have fewer than four persons per square mile and a few areas have fewer than two persons per square mile. Consequently, rural county commissioners, like their urban counterparts, must prioritize the allocation of scarce resources for essential public services such as maintaining the infrastructures of utilities, roads, bridges, and education; supporting a financially suffering county hospital; hiring a county health nurse; and offering school health services. In rural communities there are fewer resources overall, yet certain public services must be provided to local residents—albeit in many situations with aging and outdated infrastructures (RHI-Hub, 2017).

Clearly, creativity is required by both community residents and local public health care providers to resolve health care and school nursing needs. Partnership arrangements, for example, have been negotiated by two or more counties that agree to share the cost of a "district" public health nurse. Other county commissioners have forged partnerships with an agency in an urban setting and contracted for specific health care services. In both of these situations, it is not unusual for the nurse to provide services to *all* children attending *all* schools in the health district's participating counties. In some frontier states, schools may be situated more than 100 miles apart, and as many miles or more from the district health office. Because of the number of schools and distances between them, the county nurse may be able to visit each school only once or twice in a school term. Usually the nurse's visit is to update immunizations and perhaps teach maturation classes to students in the upper grades.

The health status of rural women, infants, and children is less than optimal. In part this can be attributed to inadequate preventive, primary, and emergency services to meet their particular health care needs. Scarce resources can pose a challenge to a nurse who provides care to rural residents, especially those in underserved areas. Resource deficits encourage creativity and innovation; both of these behaviors are characteristic of nursing in general and of rural nurses in particular (BHWF, 2017).

Mental Health. Like many other measures of health, the facts about the mental health status of rural people are also ambiguous and conflicting (CDC, 2018a; NACRHHS, 2017a; NCHS, 2018). Stress, stress-related conditions, and mental illness are prevalent among economically deprived populations. Increasing federal regulations imposed on agriculture, timber, and marine- and mining-related industries as well as trade agreements with other counties in the past two decades led to many job losses in rural communities. The term *farm stress* is associated with the economic downturn in the agriculture industry as it affects an individual, family, and the community. This same term or diagnosis could be applied to other communities experiencing economic recessions in their predominant enterprises, such as marine-, automobile-, and timber-related industries. Economic factors also contribute to a family's being underinsured or uninsured. Even if mental health services are available and accessible, rural residents delay seeking care when they have an emotional problem until there is an emergency or a crisis. This behavior is reflected in the lower number of annual visits for mental health services and chronic health conditions by rural residents (Bolin & Bellamy, 2015; NACRHHS, 2017b).

Mental health professionals who serve rural populations report a persistent, endemic level of depression among residents in economically stressed rural areas. They speculate this condition is exacerbated by elevated levels of poverty, geographic isolation, and an insufficient number of mental health services. Depression may also contribute to the escalating incidence of accidents and suicides, especially among rural male adolescents and young men. These incidents have increased dramatically over the last decade and continue to rise within this group, to the point of being epidemic in some small communities. Likewise, the stigma associated with mental illness remains, especially in communities having fewer health care providers to educate the public about mental and behavioral health conditions (RHI-Hub, 2018).

There are conflicting reports on the prevalence of interpersonal violence and alcohol and substance use among rural populations. These behaviors are less likely to be reported in areas where residents are related or personally acquainted. Over time, destructive coping behaviors in small, tight-knit communities may be accepted by local residents as "business as usual" for a particular family. Family problems may also be ignored if formal social services and public health services are sparse or nonexistent, or if residents do not trust the professionals who provide services at a local agency. In underserved rural areas, there are gaps in the continuum of mental health services, which, ideally, should include preventive education, anticipatory guidance, screenings, early intervention programs, crisis

and acute care services, and follow-up care. As with other aspects of health care, nurses in rural areas play an important role in community education, case finding, advocacy, and case management of client systems experiencing acute and chronic emotional and behavioral health problems (Booth & Graves, 2018; Eisenhauer et al., 2016; Montgomery et al., 2017).

Health of Minorities. As mentioned previously, a considerable number of at-risk minority groups in rural America have some rather distinctive concerns (particularly children, older adults, American Indians, Alaska Natives, Native Hawaiians, migrant workers, African Americans, immigrants, and the homeless) (CDC, 2018a; MHN, 2017; USDHHS, 2013). The rural homeless, for example, may be migrant farmworkers or local families whose homes were foreclosed. Sometimes the family may be allowed by law to continue living in the house that once was theirs. The family no longer has a means of livelihood and often remains hidden in the community with insufficient income to purchase food or other necessary services. The particular health problems of these at-risk groups are discussed in several chapters in the book. Nurses should be aware, however, that at-risk and underrepresented groups may experience some unique challenges associated with rural social structures, lifestyle, and sparse resources.

Environmental and Occupational Health Risks. A community's primary industry or industries are a determinant in the local lifestyle, the health status of its residents, and the number and types of health care services it may need. For example, four high-risk industries identified by the Occupational Safety and Health Administration (OSHA) and found in predominantly rural environments are forestry, mining, marine-related fields, and agriculture. See Table 32.1 for a description of rural groups, their typical health care needs, and their health risks or conditions. Associated health risks of these industries are machinery and vehicular accidents, trauma, selected types of cancer related to environmental factors, and allergies and respiratory conditions associated with repeated exposure to toxins, pesticides, and herbicides (NCHS, 2018; OSHA, n.d.; USDA, 2017).

For example, agriculture production industries such as farming and ranching are often owned and operated by a family. Small enterprises with a small number of employees do not fall under OSHA guidelines. For that reason, safety standards are not enforceable on most farms and ranches, since these often are family enterprises. Moreover, small businesses, such as farms, are not covered under workers' compensation insurance. Additional concerns arise because family members participate in the farm or ranch work. This means that some adults and children may work with animals and operate

TABLE 32.1 Select Health Care Needs, Risks/Conditions of Select Rural Aggregates

Rural Aggregates	Health Care Needs	Health Risks/Conditions
Farmers/ranchers	Advanced life support/emergency services	Agricultural chemicals and environmental hazards
	Oral/dental care	Dermatitis
	Obstetric/perinatal/pediatric services	Stress/depression/anxiety disorders
	Mental/behavioral health services	Respiratory conditions (e.g., farmer's lung)
	Agricultural health nurses	Accidents (vehicular/machinery)
	Geriatric specialists	Trauma-related chronic conditions
	Health promotion/illness prevention education	Dental caries/loss
	Veterans services	Interpersonal/domestic violence
	Pain management education	Pain management/opioid misuse
	Independent/progressive care living facilities for aging population	Interpersonal/domestic violence
	Home health care services	
	Interpersonal/domestic violence services	
	Women's health services	
	LGBTQ sensitive services	
American Indians	Advanced life support/emergency services	Infectious diseases (e.g., hepatitis, TB)
	Oral/dental care	Sudden infant death syndrome (SIDS)
	Obstetric/perinatal/pediatric services	Interpersonal/domestic violence
	Mental/behavioral health services	Diabetes
	Culturally appropriate substance abuse treatment programs	Alcohol/substance abuse
	Epidemiologists	Cirrhosis of the liver
	Diabetes screening and educators	Vehicular accidents
	Community health workers/education	Hypothermic/environmental injuries
	Health promotion/illness prevention education	Trauma-related injuries/chronic conditions
	Veterans services	Dental caries/loss
	Interpersonal/domestic violence services	Chronic pain management
	Women's health services	Interpersonal/domestic violence
	LGBTQ sensitive services	
	Veterans services	
	Pain management education	
	Independent/progressive care living facilities for aging population

TABLE 32.1 Select Health Care Needs, Risks/Conditions of Select Rural Aggregates—cont'd

Rural Aggregates	Health Care Needs	Health Risks/Conditions
African Americans	Community nursing health promotion and screening services	Diabetes
	Diabetes screening and educators	Hypertension
	Hypertension screening/education	Sickle cell anemia
	Prenatal and perinatal health care services	Infectious diseases (e.g., hepatitis, HIV/AIDS)
	Oncology services (education/screening/follow-up interventions)	Cancer (e.g., prostate, breast)
	HIV/AIDS prevention education/screening/follow-up care	Dental caries/loss
	Mental/behavioral health services	Depression
	Health promotion/illness prevention education	Interpersonal/domestic violence
	Veterans services	Pain management/opioid misuse
	Pain management education	
	Independent/progressive care living facilities for aging population	
	Interpersonal/domestic violence services	
	Women's health services	
	LGBTQ sensitive services	
Migrant farmworkers	Environmental protection policies (safe drinking water/sanitation)	Infectious diseases (e.g., hepatitis, typhoid, TB, HIV/AIDS, STDs)
	Community nursing/migrant health services (primary, secondary, tertiary prevention)	Environmental exposure effects of pesticides/herbicides
	Diabetes screening and educators	Otitis media (children)
	Hypertension screening/education	Substance abuse (alcohol, recreational drugs, imported medicinal/herbs)
	Maternal/child services	Dental caries/loss
	Oncology services (education/screening/follow-up interventions)	Interpersonal/domestic violence
	Mental/behavioral health services	Substandard living conditions with inadequate safe water/waste disposal
	Interpersonal/domestic violence services	Inadequate immunizations across the life span
	Women's health services	
	LGBTQ sensitive services	
	Immunizations	
Alaska Natives	Advanced life support/emergency care services	Infectious diseases (e.g., hepatitis, TB)
	Medical transport services	Dental caries/loss
	Oral/dental care	Depression
	Obstetric/perinatal/pediatric services	Interpersonal/domestic violence
	Mental/behavioral health services	Environmental health risks (e.g., exposure to toxic substances/contaminants, hypothermia)
	Culturally appropriate substance abuse treatment programs	Diabetes
	Epidemiologists	Alcohol/substance abuse
	Diabetes screening and educators	Cirrhosis of the liver
	Health promotion/illness prevention education	Vehicular accidents/trauma/long-term chronic residual effects
	Veterans services	Interpersonal/domestic violence
	Pain management education	Suicide awareness/prevention
	Independent/progressive care living facilities for aging population	
	Interpersonal/domestic violence services	
	Women's health services	
	LGBTQ sensitive services	
	Culturally sensitive grief counselors	
Coal miners	Occupational Safety and Health Administration policy/standards	Depression/substance abuse
	Mental/behavioral health services	Occupational-related accidents/trauma
	Emergency/advanced life support services	Respiratory conditions (e.g., black lung, chronic obstructive pulmonary disease)
	Occupational health nurses	Interpersonal/domestic violence
	Grief counselors	Chronic pain management/opioid misuse
	Health promotion/illness prevention education	Alcohol/substance abuse
	Veterans services	Interpersonal/domestic violence
	Pain management education	
	Independent/progressive care living facilities for aging population

dangerous machinery with minimal operating instructions on the hazards and on safety precautions. Also, many agriculture workers do not speak or read English. Consequently, agriculture-related accidents result in a sizeable number of deaths and long-term injuries, particularly among children and women. The morbidity and mortality rates associated with agriculture vary from state to state. The rising incidence of these injuries and deaths, however, has become a national concern. Nurses in rural settings can help address this problem by including farm safety content in school and community education programs (Prengaman et al., 2017).

In summary, it is risky to generalize about the health status of rural Americans because of their diversity coupled with conflicting definitions of what differentiates rural from urban residences. Many vulnerable individuals and families live in rural communities across the United States, but little is known about most of them. This information deficit is a rich area of research for nurses who practice in rural environments.

RURAL HEALTH CARE DELIVERY ISSUES AND BARRIERS TO CARE

Although each rural community is unique, the experience of living in a rural area has several common characteristics (Bushy & Winters, 2013; Montgomery et al., 2017). Barriers to health care may be associated with these characteristics (e.g., whether services and professionals are available, affordable, accessible, or acceptable to rural consumers). Box 32.4 lists characteristics of rural life.

Availability implies the existence of health services as well as the necessary personnel to provide essential services. Sparseness of population limits the number and array of health care services in a given geographic region. Lacking a critical mass, the cost of providing special services to a few people often is prohibitive, particularly in frontier states where there are an insufficient number of physicians, nurses, and other types of health care providers. Consequently, where services and personnel are scarce, these must be allocated wisely. Accessibility implies that a person has logistical access to, as well as the ability to purchase, needed services. Affordability is associated with both availability and accessibility of care. It infers that services are of reasonable cost and that a family has sufficient resources to purchase these when needed. Acceptability of care means that a particular service is appropriate and offered in a manner that is congruent with the values of a target population. This can be hampered by a client's cultural preference and the urban orientation of health professionals (AHCPR, 2017; Bushy & Winters, 2013). Box 32.5 lists barriers to health care in rural areas.

BOX 32.4 Characteristics of Rural Life

- More space; greater distances between residents and services
- Cyclical/seasonal work and leisure activities
- Informal social and professional interactions
- Access to extended kinship systems
- Residents who are related or acquainted
- Lack of anonymity
- Challenges in maintaining confidentiality stemming from familiarity among residents
- Small (often family) enterprises; fewer large industries
- Economic orientation to land and nature with industries that are extractive in nature (e.g., agriculture, mining, lumbering, marine-related, outdoor recreational activities)
- More high-risk occupations
- Town as center of trade
- Churches and schools as socialization centers
- Preference for interacting with locals (insiders)
- Mistrust of newcomers to the community (outsiders)

BOX 32.5 Barriers to Health Care in Rural Areas

- Lack of health care providers and services
- Great distances to obtain services
- Lack of personal transportation
- Unavailable public transportation
- Lack of telephone services
- Unavailable outreach services
- Inequitable reimbursement policies for providers
- Unpredictable weather and/or travel conditions
- Inability to pay for care/lack of health insurance
- Lack of "know how" to procure publicly funded entitlements and services
- Inadequate provider attitudes and understanding about rural populations
- Language barriers (caregivers not linguistically competent)
- Care and services not culturally and linguistically appropriate

Providers' attitudes, insights, and knowledge about rural populations are also important. A patronizing or demeaning attitude, lack of accurate knowledge about rural populations, or insensitivity about the rural lifestyle on the part of a nurse can make it difficult to relate to those clients. Also, insensitivity fosters mistrust, resulting in rural clients' perceiving professionals as outsiders to the community. Some nurses in rural public health practice settings express feelings of professional isolation and community nonacceptance. To address disparate views, nursing faculty members should expose students to the rural environment and the people who live there. Clinical experiences must include opportunities to provide care to clients in their natural (e.g., rural) setting to gain accurate insight about a given community (Hawkins et al., 2018).

To design population-focused programs that are available, accessible, affordable, and appropriate, nurses must implement interventions that mesh with clients' beliefs. This implies that a family and a community are actively involved in planning and delivering care for those who receive it. Nurses must have an accurate perspective on rural clients. Although the importance of forming partnerships and ensuring mutual exchange seems obvious, most current research about rural communities has been for policy or reimbursement purposes. Empirical data about rural family systems are sparse in terms of their health beliefs, values, perceptions of illness, and health care–seeking behaviors as well as what is deemed to be appropriate nursing care. Therefore, nurse scholars must assume a more active role

in implementing research on the needs of rural populations for nursing services to expand the profession's theoretical base and subsequently implement community-oriented, empirically based clinical interventions; they must understand the barriers to health care that many rural residents experience (Paré et al., 2017; Oosterbroek et al., 2017).

NURSING CARE IN RURAL ENVIRONMENTS

Theory, Research, and Practice

Information on nursing practice in small towns and rural environments is growing, and several themes have emerged as shown in Box 32.6. A nurse who practices in this setting can view each of these dimensions either as an opportunity or as a challenge.

Nationally and internationally, nurse researchers contend that existing theories do not fully explain rural nursing practice (Bell et al., 2018; Bushy & Winters, 2013; Williams et al., 2012). Their focus has been on the key concepts pertinent to nursing theory (health, person, environment, and nursing/caring) and proposed relational statements that are relevant to clients and nurses in rural environments (see the Evidence-Based Practice box). Because the focus of their research was primarily with non-Hispanic whites living in the Rocky Mountain area, care must be taken about generalizing those findings to other geographic regions and minorities. These researchers propose that rural residents often judge their health by their ability to work. They consider themselves healthy, even though they may suffer from several chronic illnesses, as long as they are able to continue working. For the rural person, being healthy is the ability to be productive. Chronically ill people emphasize emotional and spiritual well-being rather than physical wellness.

BOX 32.6 Characteristics of Nursing Practice in Rural Environments

- Variety/diversity in clinical experiences
- Broader/expanding scope of practice
- Generalist skills
- Flexibility/creativity in delivering care
- Sparse resources (e.g., materials, professionals, equipment, fiscal)
- Professional/personal isolation
- Greater independence/autonomy
- Role overlap with other disciplines
- Slower pace
- Lack of anonymity
- Increased opportunity for informal interactions with clients/coworkers
- Opportunity for client follow-up upon discharge in informal community settings
- Discharge planning allowing for integration of formal and informal resources
- Care for clients across the life span
- Exposure to clients with a full range of conditions/diagnoses
- Status in the community (viewed as prestigious)
- Viewed as a professional role model
- Opportunity for community involvement and informal health education

Adapted from Rural Health Information Hub (RHI-Hub): *What is rural?* 2018. Available at https://www.ruralhealthinfo.org. Winters C, Lee H: *Rural nursing: concepts, theory and practice*, ed. 3, New York, 2009, Springer Publishing.

EVIDENCE-BASED PRACTICE

Early on, nurse researchers at Montana State University related nursing theoretical concepts to rural practice (Long & Weinert, 1989; Winters, 2013; Winters & Lee, 2009). Since then, researchers have studied the relevance of the proposed rural nursing concepts to various populations and settings to expand the knowledge base of the profession.

- **Health:** Defined by rural residents as the ability to work. Work and health beliefs are closely related for rural Montana sample.
- **Environment:** Distance and isolation are particularly important for rural dwellers. Those who live long distances neither perceive themselves as isolated nor perceive health care services as inaccessible.
- **Nursing:** Lack of anonymity, outsider versus insider, old-timer versus newcomer. Lack of anonymity is a common theme among rural nurses who report knowing most people for whom they care, not only in the nurse-client relationship, but also in a variety of social roles, such as family member, friend, or neighbor. Acceptance as a health care provider in the community is closely linked to the outsider/insider and newcomer/old-timer phenomena. Gaining trust and acceptance of local people is identified as a unique challenge that must be successfully negotiated by nurses before they can begin to function as effective health care providers.
- **Person:** Self-reliance and independence in relationship to health care are strong characteristics of rural individuals. They prefer to have people they know care for them (informal services) as opposed to an outsider in a formal agency.

Nurse Use

In working with rural residents, it is important to know how they define their health and their environment, because their definitions may differ from yours. Understand that you may not find acceptance and trust immediately; rural residents often trust informal caregivers more than those in a formal organization.

From Bell J, Crawford R, Holloway K: Core components of the rural nurse specialist role in New Zealand. *Rural Remote Health* 18(2), 2018. Available at https://www.rrh.org.au; Rural Health Information Hub (RHI-Hub): *What is rural?* 2018. Available at https://www.ruralhealthinfo.org.

Distance, isolation, and sparse resources characterize rural life and are seen in residents' independent and innovative coping strategies. Self-reliance and independence are demonstrated through their self-care practices and preference for family and community support. Community networks provide support but still allow for each person's and family's independence. Ruralites prefer and usually seek help through their informal networks, such as neighbors, extended family, church, and civic clubs, rather than seeking a professional's care in the formal system of health care, including services such as those provided by a mental health clinic, social service agency, or health department.

Although nursing is generally similar across settings and populations, there are some unique features associated with practice in a geographically remote area or in small towns where most people know one another. The following paragraphs highlight a few of the variations that nurses in rural practice report.

A nurse's professional and personal boundaries often overlap and are diffuse. It is not unusual for a nurse to have more than one work-related role in the community. For example, a nurse may work at the local hospital or in a physician's office and may also be actively involved in managing the family farm, a local grocery store, or pharmacy. For nurses, this means that many, if not all, clients they encounter are known also as neighbors, as friends of an immediate family member, or as part of one's extended family. Associated with social informality is a corresponding lack of anonymity in a small town. Some rural nurses say, "I never really feel like I am off duty because everybody in the county knows me through my work." In part, this can be attributed to nurses being highly respected and viewed by local people as experts on health and illness. Often rural residents informally ask a nurse's advice before seeing a physician for a health problem. Rural residents may ask health-related questions when they see a local nurse (who may be a neighbor, friend, or relative) in a grocery store, at a service station, during a basketball game, or at church functions (Ortiz et al., 2018).

Nurses in rural public health practice must make decisions about the care of individuals of all ages with a variety of health conditions. They assume many roles because of the range of services they provide in a rural health care facility and because of the scarcity of nurses and other health professionals. Nurses who work in rural areas need to have skills that include technical and clinical competency, adaptability, flexibility, strong assessment skills, organizational abilities, independence, interest in continuing education, sound decision-making skills, leadership ability, self-confidence, and skills in handling emergencies, teaching, and public relations. The nurse administrator is also expected to be a jack-of-all-trades (i.e., a generalist) and to demonstrate competence in several clinical specialties in addition to managing and organizing staff within the facility for which he or she is responsible (Pavloff et al., 2017; Prengaman et al., 2017).

Rural nursing practice provides challenges, opportunities, and rewards. The way in which each factor is perceived depends on individual preferences and the situation in a given community. Challenges of rural practice sometimes include professional isolation, limited opportunities for continuing education, lack of other kinds of health personnel or professionals with whom one can interact, heavy workloads, an ability to function well in several clinical areas, lack of anonymity, and, for some, a restricted social life (Molinari & Bushy, 2012).

The most often cited opportunities and rewards in rural nursing practice are close relationships with clients and coworkers, diverse clinical experiences that evolve from caring for clients of all ages who have a variety of health problems, caring for clients for long periods of time (in some cases, across several generations), opportunities for professional development, and greater autonomy. Many nurses value the solitude and quality of life found in a rural community personally and for their own family. Others thrive on the outdoor recreational activities. Still others thoroughly enjoy the informal, face-to-face interactions coupled with the public recognition and status associated with living and working as a nurse in a small community.

Disease prevention is also an important consideration in rural communities. The Levels of Prevention box shows the levels of prevention that a nurse in a rural locale might use.

LEVELS OF PREVENTION

Rural Health

Primary Prevention

- The public health nurse partners with a women's organization in a faith community located in a small Midwestern town to instruct members on meal planning as a strategy to offset the tendency to develop diabetes in family members.
- The public health nurse advocates for policy changes regarding sexual education content (to include information on contraception that goes beyond abstinence) in the schools with the district commissioners of education.

Secondary Prevention

- The public health nurse screens congregation members of the faith community in the Midwestern town for the presence of diabetes.
- The public health nurse partners with the local critical access hospital to offer free cholesterol, blood pressure, and blood glucose screening as well as the influenza vaccine to adults attending the annual county health fair.

Tertiary Prevention

- The public health nurse collaborates with the senior center in the small community town, which provides meals on a routine basis to the elderly, to reach individuals with a diagnosis of diabetes.
- The public health nurse provides consultation on diabetic nutrition, exercise habits, foot care, and, if needed, assists clients in obtaining medications through a mail-order pharmaceutical vendor.

Although most of the publications about rural health care and nursing focus on hospital practice, much of that information is applicable to both community agencies and community-focused nursing (Davis & Droes, 1993). An early study by Case (1991) focused on work-related stressors of nursing in rural communities in Oklahoma public health departments. Anecdotal reports reinforce these same stressors are present in rural practice, including: political/bureaucratic problems and intraprofessional and interpersonal conflicts associated with inadequate communication; unsatisfactory work environment and understaffing; difficult or unpleasant nurse-client encounters, such as with relatives who refuse to deliver needed care to clients, and with clients who are hostile, apathetic, dependent, or of low intelligence; fear for personal safety; difficulty locating clients; and clients falling through the cracks of the health care system. These same stressors continue to be cited by nurses who work in rural as well as urban public health agencies. Essentially, stressors for rural nurses in general, and specifically for those in community practice, are associated with geographic distance, isolation, sparse resources, and environmental factors that characterize rurality (Pare et al., 2017).

Nursing in rural areas is characterized by physical isolation that may lend itself to any one of the following: professional isolation; scarce financial, human, and health care resources; and a broad scope of practice. Associated with personal familiarity with local residents, nurses often possess in-depth

Fig. 32.2 A hospital-sponsored health fair is one example of a community event to provide health services to individuals in a rural area.

knowledge about clients and their families. Along with the acknowledged benefits, informal (face-to-face) interactions can significantly reduce a nurse's anonymity in the community and at times be a barrier to completing an objective assessment on a client. Like urban practice, rural community nursing as shown in Fig. 32.2 takes place in a variety of locations, including homes, clinics, schools, occupational settings, and correctional facilities, and at community events such as county fairs, rodeos, civic and church-sponsored functions, and school athletic events.

Research Needs

There is a paucity of empirical studies focusing on rural nursing practice, but anecdotal reports by nurses confirm earlier studies on practice in this setting (Bushy & Winters, 2013). Specific research topics of importance to nursing practice in rural environments include the following:

1. Most nurses indicate that they enjoy practicing in rural areas and are proud of what they do. They believe that their work deserves more recognition by professional nursing organizations. Also, the retention rate of nurses in some practice settings is poor. The perspective of nurses who are dissatisfied with rural nursing provides a more complete picture of the rural experience. This information can be useful to a variety of people: other nurses who are considering rural practice, nurse managers in need of better screening tools to assess the fit between the nurse and the environment when interviewing applicants, planners of continuing nursing education programs, and faculty members who teach public health to undergraduate and graduate students.
2. More information is needed about the stressors and rewards of rural practice, in particular public health nursing. These data could lead to the development of stress management techniques to be used by nurses and their supervisors to retain nurses and to improve the quality of their workplace environment.
3. With the increasing number of rural residents in all regions of the United States, empirical data are needed on the particular nursing needs of rural client systems, especially under-represented groups, minorities, and other at-risk populations that vary by region and state.
4. A need also exists for the international perspective on the health of rural populations, and on nursing practice within the rural community. Australian, New Zealand, and Canadian nurse scholars have provided some insights into rural practice in these nations. Information is needed from less-industrialized nations as well as from those that are highly industrialized.
5. Technology increasingly is used in health care and seems to hold great potential in improving access to health care in rural and underserved areas. However, research is needed to determine the most efficient and effective way to meet the needs and preferences of rural clients, and to ensure quality.
6. Communication technology increasingly is used by institutions of higher learning to deliver educational programs to nurses who live and work some distance from campus. Empirical studies are needed to measure the most effective modalities to achieve desired learning outcomes and the impact on recruitment and retention of nurses in rural settings.
7. Rural-urban disparities in health status and health behaviors need closer examination from the nursing perspective. Evidence-based practice nursing guidelines are needed that take into consideration the rural context and preferences of residents who obtain health care in these settings.

Preparing Nurses for Rural Practice Settings

Nurses in rural practice need broad knowledge about nursing, including health promotion, primary prevention, rehabilitation, obstetrics, medical-surgical specialties, pediatrics, planning and implementing community assessments, and understanding the public health risks and needs for emergency preparedness in a particular state. A community's demographic profile and its principal industry(ies) can provide a snapshot of local social determinants that can affect health. Using demographic information, a nurse can anticipate the particular nursing skills that will be needed to care for clients in a catchment area (BHWF, 2018; Booth & Graves, 2018; Jackman et al., 2016; Nelson, 2009; Oosterbroek et al., 2017; Pavloff et al., 2017). In rural areas nurses use their knowledge of resources and their ability to coordinate formal and informal services to coordinate a continuum of services for clients even when resources are sparse and fragmentation exists in the health care delivery system (Hawkins et al., 2018).

Technology has great potential for connecting rural public health providers and consumers with resources outside of their community. The concept of *telehealth* is an expansion of the term *telemedicine*. Essentially, telemedicine more narrowly focuses on the curative aspect of health care, whereas telehealth encompasses preventive, promotive, and curative aspects of health care and can include delivery of education/information to a more distant site. Telehealth uses a variety of technology solutions such as a health care provider communicating by email with clients, ordering medications from a pharmacy, consulting with other health care providers, or accessing advanced or continuing education offered by a university located some

distance from the receiving site. More specifically, telecommunication technology could be as simple as nurses in two or more different public health settings consulting over the telephone or via computer video conferencing coordinating local health fairs, or as complex as nurse scholars collaborating with international peers on a community health–focused research project or a medical specialist located at a health science center using complex robotic surgical technology on a client who is located in another country. Regardless of the practice setting, the nurse must be computer literate and be proficient in using the communication technology that is available in that community. Increasingly, the Internet is linking nurses in rural public health practice with nursing colleagues, educators, and researchers in urban-based academic settings, thereby addressing often-cited concerns associated with professional isolation (ANCC, 2017).

FUTURE PERSPECTIVES

It is important for all people involved in providing health care in rural areas to understand the possible problems they might encounter when trying to provide the continuum of needed services in an area with a disproportionally high number of underserved persons. Those who should be involved include residents, their elected representatives, the administrators of public and private health care agencies, and members of the media. The media need to focus on public health as well as hospital care and the lack of primary care providers in rural areas. As discussed later, both case management and community-oriented primary health care (COPHC) are effective models for dealing with some of the care deficits and resolving rural health disparities.

Scarce Resources and a Comprehensive Health Care Continuum

The current fragmented health care system makes it difficult to provide a comprehensive continuum of care to populations living in areas having scarce resources, such as money, personnel, equipment, and ancillary services. In rural communities, the most critically needed services are usually preventive services, such as health screening clinics, nutrition counseling, tobacco cessation, and wellness education (Bolin & Bellamy, 2015; CDC, 2017a, 2018a, 2018b). Box 32.7 lists several health-related priorities for rural communities.

Although the nursing needs vary by community, there is generally a need in most rural areas for the following:

- School and parish nurses
- Family planning services
- Prenatal and postpartum services
- Resources for individuals diagnosed with human immunodeficiency virus (HIV)/AIDS and their families
- Emergency medical services
- Resources for families of children with special needs, including those who are physically and mentally challenged
- Mental health services
- Resources for older adults (especially the frail elderly and those with declining mental capacity) to include a continuum of residential and respite services, including adult day care, hospice, homemaker assistance, and provision of nutritional meals along with public transportation for those who remain at home

BOX 32.7 Health-Related Priorities for Many Rural Communities

- Access to care
- Cancer (screening, early intervention, oncology services)
- Diabetes (prevention, screening, tertiary care)
- Maternal–infant and children services
- Mental illness and behavioral health services
- Nutrition/obesity
- Drugs, alcohol, and substance abuse
- Use of tobacco products
- Education and an array of community-based programs
- Public health infrastructures
- Immunizations and infectious diseases
- Trauma-related injury and violence prevention
- Family planning
- Environmental and occupational health exposure education/prevention
- Emergency medical services infrastructures
- Long-term care/assistive living facilities
- Veterans services
- Safety education on outdoor recreational activities (all-terrain vehicles, water, weapons, etc.)
- Grief counseling
- High-risk occupation safety education
- Suicide awareness/prevention
- Prevention of motor vehicle accidents/injuries

Adapted from Meit M, Knudson A, Gilbert T, et al.: *The 2014 update of the rural-urban chartbook*. Available at https://ruralhealth.und.edu; Bolin JN, Bellamy G: *Rural Healthy People: 2020,* 2015. Available at https://srhrc.tamhsc.edu.

Providing a continuum of care has been further hindered by the closure of many small hospitals in the past two decades. Of those that remain, many report financial problems that could lead to closure (NACRHHS, 2017). A shortage or the absence of even one provider, most often a physician or nurse, could mean that a small hospital must close its doors. Closure of the hospital has a ripple effect on the health of local residents, other health care services, recruitment and retention of health professionals, as well as on economic development efforts in a small community (USDA, 2017a, n.d.; USDHHS, 2013).

The short supply and increasing demand for primary care providers in general, and nurses in particular, will continue for some time. To help solve this problem, elected officials and policy developers need nurses, especially those in advanced practice roles, to provide vital services in underserved areas. In an effort to effectively respond to this opportunity, nurses must be creative to ensure delivery of appropriate and acceptable services to at-risk and vulnerable populations who live in rural and underserved regions. Nurses must be sensitive to the health beliefs of clients, and then plan and provide nursing interventions that mesh with the community's cultural values and preferences.

Healthy People 2020 National Health Objectives Related to Rural Health

Because the demographic profile varies from community to community, each state has variations in the health status of its population. *Healthy People 2020,* along with *Rural Healthy People 2020* (vol. 1, vol. 2), has important implications for nurses in that a significant number of at-risk populations cited in that policy-guiding document live in rural areas across the United States (Bolin & Bellamy, 2015). Consequently, priority objectives vary, depending on population mix, health risks, and health status of residents in the state.

HEALTHY PEOPLE 2020

These selected objectives pertain to residents of both rural and urban areas:

- **AHS-3:** Increase the proportion of persons with a usual primary care provider.
- **IVP-13:** Reduce motor vehicle crash–related deaths.
- **MHMD-9:** Increase the proportion of adults with mental disorders who receive treatment.
- **HDS-2:** Reduce coronary heart disease deaths.
- **IVP-1:** Reduce fatal and nonfatal injuries.

From U.S. Department of Health and Human Services: *Healthy People 2020,* 2010. Available at https://www.healthypeople.gov.

At the local level, communities have been using *Healthy People* as a guide for action and to identify objectives and establish meaningful goals. The two-volume *Rural Healthy People 2020* focuses on particular concerns relative to vulnerable populations in rural environments (Bolin & Bellamy, 2015).

The Centers for Disease Control and Prevention's (CDC's) (2017a) *Healthy Places Initiative* addresses chronic disease prevention in both rural and urban communities. Individuals and groups at the local level collaborated with state health departments, the CDC, and other organizations to implement programs that promote and support good health in their community. This CDC initiative is a useful tool for state and local officials and health care planners to use to tailor *Healthy People* objectives to fit a community's specific needs, both rural and urban. Translating national objectives highlighted in *Healthy People 2020* (USDHHS, 2013) into achievable community health goals requires integration of the following components to ensure that services will be acceptable and appropriate for rural clients:

- Health statistics must be meaningful and understandable, and they must include appropriate process and outcome objectives that can be readily measured.
- Strategies must be designed that involve the public, private, and voluntary sectors of the community to achieve agreed-on local objectives.
- Coordinated efforts are needed to ensure that the community works together to achieve the goals.

Consider, for example, general objectives in developing a health plan for a rural county having a large population of young people. *Healthy People 2020* objectives for the county should target women of childbearing age, children, and adolescents. Priority objectives should include offering accessible prenatal care programs, improving immunization levels, providing preventive dental care instructions, implementing vehicular accident prevention and firearm safety programs, and educating teachers and health professionals for early identification of cases of interpersonal violence. On the other hand, consider a rural county that has a higher number of residents over the age of 65 years, compared with the national average. Priority objectives in the health plan should target health risks and problems of older adults in that community. Specific objectives might include developing health-promoting programs to prevent chronic health problems, or establishing community programs to meet the needs of those having chronic illness, specifically cardiovascular disease, diabetes, hypertension, and accident-related disabilities; or organizing a partnership to build progressive/assistive care residential facilities in the community. In general, the objectives in *Healthy People 2020* are pertinent to people living in all areas and not unique to rural residents. The *Healthy People 2020* box illustrates selected objectives that fit people in rural as well as more urban areas.

When implementing community-focused health plans that emerge from *Healthy People 2020,* consideration must always be given to the rural context, such as sparse population, geographic remoteness, scarce resources, personnel shortages, and physical, emotional, and social isolation. In addition to being actively involved in empowering the community and planning and delivering care, nurses play an important role in representing their community's perspective to local, state, regional, and national health planners and to their elected officials.

BUILDING PROFESSIONAL-COMMUNITY-CLIENT PARTNERSHIPS IN RURAL SETTINGS

Health care reform initiatives are focusing on cutting costs while improving access to care with equitable quality for all citizens, especially vulnerable and underserved populations. State and local grassroots organizations must be actively involved for health care reform to succeed in rural areas. Specifically, professional-client-community partnerships are essential to accomplish reform at the local level. As seen in the Linking Content to Practice box, nursing practice in rural areas is comprehensive and incorporates skills from nursing and public health. Two models have been found to be particularly useful for nurses in rural environments: case management and Community-Oriented Primary Health Care (COPHC).

Case Management

Case management is a client-professional partnership that can be used to arrange a continuum of care for rural clients, with the case manager tailoring and blending formal and informal resources. Collaborative efforts between a client and the case manager allow clients to participate in their plan of care in an acceptable and appropriate way, especially when local resources are few and far between. The Practice Application at the end of this chapter demonstrates how nursing case management can

LINKING CONTENT TO PRACTICE

As discussed, practice in rural areas relies on excellent nursing and public health skills in assessment, communication, cultural competency, problem solving, coalition building, coordination, and policy development, among others. Documents that guide the practice include the American Nurses Association Standards of Nursing Practice, the core competencies as identified by the Council on Linkages, and the Quad Council Coalition for Public Health Nursing Competencies. As one example of the congruence, consider assessment. The Council on Linkages' Core Competency of "Assess the health status of populations and their related determinants of health and illness" under their analytic assessment skills is then elaborated on by the Quad Council as a public health nursing skill of "Conducts thorough health assessments of individuals, families, communities and populations" and the public health nursing practice standard under assessment of "the public health nurse collects comprehensive data pertinent to the health status of populations" (p. XXX.) The relationship among these three sets of standards continues through all phases of the public health care provision process.

Data from American Nurses Association (ANA): *Public Health Nursing: Scope and Standards of Practice*, ed. 2, Silver Spring, MD, 2013. Available at https://www.nursingworld.org . Council on Linkages between Academia and Public Health Practice: *Core competencies for public health professionals*, 2014. Available at http://www.phf.org. Quad Council: *Public health nursing competencies*, 2018. Available at http://www.quadcouncilphn.org.

allow an older adult resident to stay at home in a rural environment if adequate supports can be provided. Outcomes are often remarkably different when case management is used. Additional information on case management is found in Chapter 25.

Community-Oriented Primary Health Care

COPHC is an effective model for delivering available, accessible, and acceptable services to vulnerable populations living in **medically underserved** areas. This model emphasizes flexibility, grassroots involvement, and professional-community partnerships. It blends primary care, public health, and prevention services, which are offered in a familiar and accessible setting. As shown in Box 32.8 the COPHC model is interprofessional, uses a problem-oriented approach, and mandates community involvement in all phases of the process.

Building professional-community partnerships is an ongoing process. The CDC *Tools and Resources for Public-Private Partnerships* (2017b) at https://www.cdc.gov offers useful information on collaborative and interprofessional initiatives in small and rural communities. At various times, nurses, other health professionals, and community leaders must assume the role of advocate, change agent, educator, expert, or group facilitator to gain both active and passive support from the community. Partnerships involve give-and-take negotiations by all participants to reach consensus. Essentially, the process begins with professionals gaining entrance into a community, establishing rapport and trust with local people, and then working together to empower the community to resolve mutually defined problems and goals. As mentioned previously, and discussed also in Chapter 16, the CDC *Healthy Places Initiative* (2017a) is an excellent resource for developing, defining, and responding to the stated goals. Because of the importance of churches and schools in a rural community, leaders from those

BOX 32.8 Community-Oriented Primary Health Care (COPHC): A Partnership Process

The steps in the COPHC process include the following:

- Define and characterize the community.
- Identify the community's health problems.
- Develop or modify health care services in response to the community's identified needs.
- Monitor and evaluate program process and client outcomes.

Modified from Centers for Disease Control and Prevention (CDC): *Tools and resources for public-private partnerships*, 2017. Available at https://www.cdc.gov.

institutions often are key players in building provider-community partnerships. The organizational phase is a priority because it forms the foundation for all other activities related to planning, implementing, and evaluating community initiatives.

As was described for case management, professional-community partnerships allow more effective identification of existing informal support systems that are accepted by rural residents. The goal is to integrate community preferences with new or existing formal services. Public input should be encouraged early in the planning process and must continue throughout the process to allow the community to feel that it has ownership in the project. This strategy can go a long way to address local residents' viewing the process as outsiders bringing another bureaucratic program into town. Strategies that nurses can use to enhance the building of partnerships in rural environments are listed in the How To Build Professional-Community-Client Partnerships box.

HOW TO Build Professional-Community-Client Partnerships

1. Gain the local perspective.
2. Assess the degree of public awareness and support for the cause.
3. Identify special interest groups.
4. List existing services to avoid duplication of programs.
5. Note real and potential barriers to existing resources and services.
6. Generate a list of potential community volunteers and professionals who are willing to assist with the project.
7. Create awareness among target groups of a particular program (e.g., individuals, families, seniors, church and recreation groups, health care professionals, law enforcement personnel, and members of other religious, service, and civic clubs).
8. Identify potential funding sources needed to implement the program.
9. Establish the community's health care priority list, and involve many community members in considering and selecting their health care options.
10. Incorporate business principles in marketing the program.
11. Measure the health system's local economic impact.
12. Educate residents about the important role the local health care system plays in the economic infrastructure of the community and the consequences of a system failure.
13. Develop local leadership and support for the community's health system through training and providing experience in decision making.

Modified from Centers for Disease Control and Prevention (CDC): *Tools and resources for public-private partnerships*, 2017b. Available at https://www.cdc.gov.

Partnership models, such as case management and COPHC, have proven to be highly effective in areas with scarce resources and an insufficient number of health care providers. Individuals and communities who are informed, active participants in planning are more likely to develop consensus about the most appropriate solution for local problems. Subsequently, involved participants are more likely to use and support that system after it is implemented. Partnership models enhance the ability of rural communities to do what they historically have done well (i.e., assume responsibility for the services and institutions that serve their residents). Knowledge about partnership models and the skills to effectively implement them are useful for nurses who coordinate services that are accessible, available, and acceptable for rural populations in their catchment area.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Quality Improvement

Use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of health care systems.

Important aspects of quality improvement include:

- **Knowledge:** Explain the importance of variation and measurement in assessing quality of care.
- **Skills:** Use quality measures to understand performance.
- **Attitudes:** Value measurement and its role in good client care.

Quality Improvement Question

Examine health statistics and demographic data in your geographic area to determine which vulnerable groups are predominant. Look on the web for examples of agencies you think provide services to these vulnerable groups. If the agency has a web page, read about the target population they serve, the types of services they provide, and how they are reimbursed for services. Learn about different agencies and share results during class. Based on your findings, identify gaps or overlaps in services provided to vulnerable groups in your community. Which data do these agencies collect to demonstrate the efficacy of their services? How could you deal with these gaps and overlaps to help clients receive needed services?

Modified from Centers for Disease Control and Prevention (CDC): *Performance management and quality improvement,* 2015. Available at https://www.cdc.gov.

PRACTICE APPLICATION

Mrs. Jones, an 89-year-old widow, was diagnosed over 10 years ago with progressive congestive heart failure. She continues to live in her beloved home of 60+ years in spite of being on continuous oxygen the last 3 years. She also has "bad knees" and gets around her house and yard with the use of a walker. Her husband of more than 60 years suddenly died 4 years ago of a heart attack while working on their farm. Their two married daughters live in California and Arkansas. The Midwestern town where she lives has about 1000 residents. The nearest hospital is more than 60 miles away from this town. Mrs. Jones's 82-year-old widowed sister, Lydia Thomas, lives a few blocks from her. Their 76-year-old brother recently entered the county nursing home located in a town 20 miles away.

Even with her dyspnea and physical limitations, Mrs. Jones is able to live alone with her dog and cat, and insists that she will not relinquish her independent lifestyle as has her brother. Yet, in the past year she has been hospitalized three times: for a bad chest cold, for a kidney infection, and after a neighbor found her lying unconscious by the picnic table in her yard. Her doctor says this episode was related to a "heart problem."

Upon being discharged from the hospital, Crystal Moore, the local home health nurse, was assigned to visit Mrs. Jones. Ms. Moore's office is based in the County Senior Center near the nursing home where the brother is a resident. He is also a client of Ms. Moore and she visits him every Wednesday. The nurse provides outreach services to all the residents in the county referred to her by a large home health agency located in the city 70 miles away. As a case manager, she works closely with the hospital's discharge planners to arrange a continuum of care for clients in the county. Nursing-related activities include coordinating formal and informal services for clients, including biomedical supplies, oxygenation, nutrition, hydration, pharmacological care, arranging for personal care, homemaker assistance, writing checks, home maintenance, emergency respite services, and home delivery of meals.

A. Describe the nursing roles that Ms. Moore uses in coordinating a continuum of care for Mrs. Jones in terms of nutrition, oxygenation, pharmaceutical and biomedical equipment, transportation, and homemaker assistance.

B. Identify formal health care and support resources that can be accessed for Mrs. Jones.

C. Identify informal support resources that might be available in the small community that could help to ensure that Mrs. Jones is safe.

D. Identify three outcomes for Mrs. Jones that can be achieved by using nursing care (case) management.

E. Select a rural community in your geographic area. Create hypothetical situations, or select real clients with real health problems (e.g., an older adult with Alzheimer's disease, a middle-aged person with cancer requiring end-of-life care, a child who is dependent on technology as a result of a farm accident). Prepare a list of services and referral agencies in that community that could be used to develop a continuum of care for each of these cases. How are these the same as, or different from, the case described in this chapter?

F. How could a public or home health nurse who is new to the community learn about formal and informal resources that could be accessed to develop a continuum of care for a rural resident for whom she cares?

Answers can be found on the Evolve site.

KEY POINTS

- There is wide diversity in the demography, economy, and geography of rural communities.
- Not all rural communities are based on an agricultural economy; most are not!
- Although many are struggling, not all rural communities are suffering economically. Some rural communities only need more extensive economic development for sustainability.
- Some rural towns are located in urban counties.
- There are wide variations in the health status of rural populations, depending on genetic, social, environmental, economic, and political factors.
- There is a higher prevalence of working poor in rural America than in more populated areas.
- There are rural-urban health disparities. Rural adults 18 years and older overall are in poorer health than their urban counterparts; nearly 50 percent have been diagnosed with at least one major chronic condition. However, they average one less physician visit each year than healthier urban counterparts.
- More than 26 percent of rural families are below the poverty level; more than 40 percent of all rural children younger than 18 years of age live in poverty.
- General practitioners and nurse practitioners are usual providers of care for rural adults and children.
- Rural residents must often travel more than 30 minutes to access a health care provider.
- Nurses must take into consideration the belief systems and lifestyles of a rural population when planning, implementing, and evaluating community services.
- Barriers to rural health care include the lack of availability, affordability, accessibility, and acceptability of services.
- Partnership models, particularly case management and community-oriented primary health care (COPHC), are effective models to provide a comprehensive continuum of care in environments with scarce resources.

CLINICAL DECISION-MAKING ACTIVITIES

1. Compare and contrast the terms *urban, suburban, rural, frontier, farm, non-farm residency,* and *metropolitan* and *micropolitan areas.*
2. Describe residency as a continuum, ranging from farm residency to core metropolitan residency.
3. Discuss economic, social, and cultural factors that affect rural lifestyle and the health care–seeking behaviors of residents who live there.
4. Identify factors that affect the accessibility, affordability, availability, and acceptability of services in the health care delivery system.
5. Compare and contrast the health status and lifestyle behaviors of rural and urban residents.
6. Summarize key nursing concepts in terms of practice in the rural context.
7. Examine the characteristics of rural community nursing practice and describe how these might differ from those of practice in more populated settings.
8. Compare and contrast challenges, opportunities, and benefits of living and practicing as a nurse in the rural environment.
9. Evaluate case management and community-oriented primary care as partnership models that can help nurses enhance the continuum of care for clients living in an environment with sparse resources.
10. Propose potential areas for rural nursing research activities. Specify research questions that focus on the professional and clinical concerns of public health nurses who practice in the rural context.

Poverty and Homelessness

Mary Kay Goldschmidt, DNP, MSN, RN, PHNA-BC

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Analyze the concept of poverty.
2. Understand the historical relationship between race, ethnicity, and poverty.
3. Describe the relationship between poverty, toxic stress, and lifelong adverse health effects.
4. Analyze the concept of homelessness.
5. Discuss the effects of homelessness on the health and well-being of individuals and families across the life span.
6. Discuss the challenges and the unique role of nurses in providing care and advocacy for poor and homeless individuals.

CHAPTER OUTLINE

Defining and Understanding the Concept of Poverty
Poverty and Health: The Impact of Toxic Stress
Defining and Understanding the Concept of Homelessness
Impact of Homelessness on Health Across the Life Span
Unique Role of the Nurse

KEY TERMS

Adverse Childhood Experiences (ACEs), p. 744
affordable housing, p. 743
chronic homelessness, p. 742
Consolidated Health Centers (CHCs), p. 750
Continuum of Care (CoC) programs, p. 743
deep poverty, p. 736
doubling up, p. 743
federal poverty level, p. 736
Housing First, p. 745
Kerner Commission, p. 738
low-income, p. 736
low-income housing, p.749
multidimensional poverty, p. 736
multigenerational poverty, p. 739
racism, p. 738
rapid re-housing, p. 745
relational health, p. 737
Shelter Plus Care, p. 749
safety net, p. 739
social determinants of health, p. 735
social exclusion, p. 737
social interconnection, p. 737
Supplemental Poverty Measure (SPM), p. 736
supportive housing, p. 749
toxic stress, p. 740
trauma-informed care, p. 745
unsheltered homeless, p. 743

Where you are born, live, and work are the most significant factors in determining your health (World Health Organization, 2008, 2018a). The social determinants of health, or "social context," are directly linked to the risk of exposure and level of susceptibility, severity, and outcome of disease resulting from infection, metabolic or genetic disorder, degenerative process, or malignancy. If you live in poverty, you are less likely to have access to healthy foods and safe neighborhoods and more likely to have lower levels of education, reduced access to and lower quality health care, engage in unhealthy behaviors, and have worse health outcomes (Centers for Disease Control and Prevention, 2018; Jarrellet al., 2014). Poverty is a foundational component of chronic disease and population health disparities. In order to improve the health of the population, a shift in focus toward addressing the social and environmental factors that contribute to poor health is essential (Levin, 2018).

It is imperative for all health care providers to understand the circumstances that create and deepen poverty, the impact of poverty on health, and how we as nurses can bring all our resources to bear on interrupting the cycle of poverty and

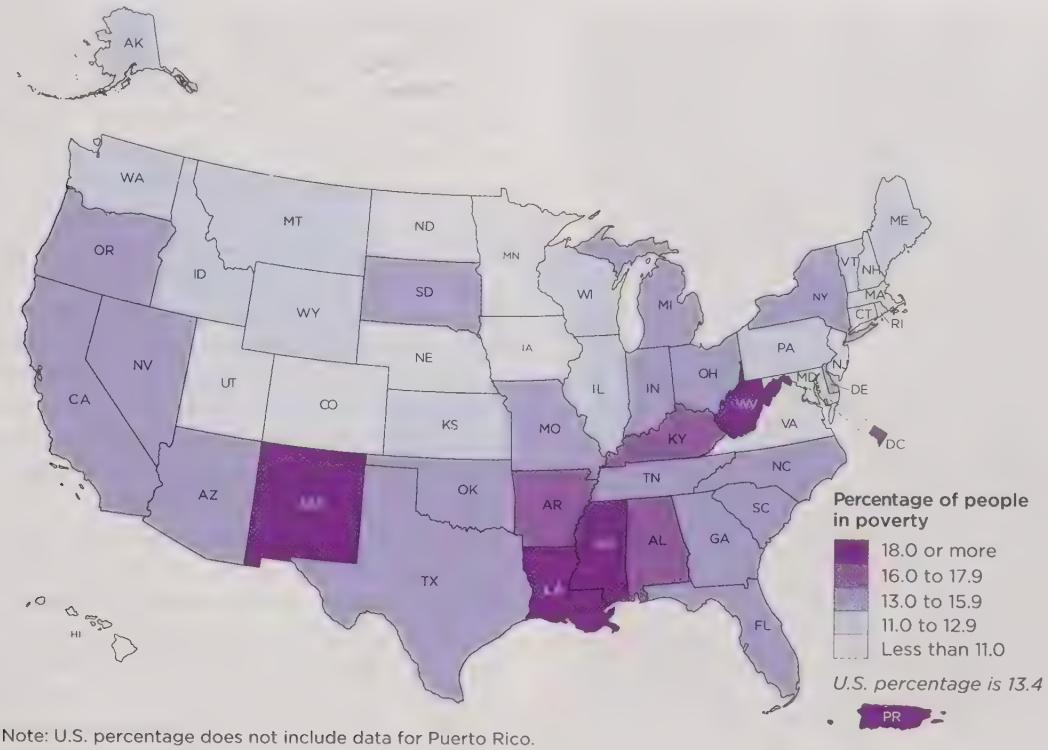
homelessness. Caring for these populations involves the development of skills and knowledge beyond that of meeting physiological needs in the health care setting. Nurses must also care for their impoverished and homeless patients at the individual, aggregate, and community level, by advocating for policies which prevent and ameliorate the health effects that arise from these conditions.

DEFINING AND UNDERSTANDING THE CONCEPT OF POVERTY

There are many ways to define and understand poverty. Historically, poverty was defined by measuring household income, the number of individuals living in the home, and a specified income poverty line. Those living below the income poverty line are considered impoverished and those above are not. An example of this approach is the Department of Health and Human Services' federal poverty level (FPL), which guides eligibility for federal assistance such as the Supplemental Nutrition Assistance Program (SNAP) and the Children's Health Insurance Program (CHIP). Table 33.1 shows the 2018 poverty guidelines for the 48 contiguous states and the District of Columbia. The method used to calculate the FPL has not fundamentally changed in the 45 years since it was developed, except for accomodating the cost of food inflation. However, families are now far more likely to have two parents working, adding childcare to the cost of living, and housing and transportation are significantly more expensive. Recent studies surmise that families need twice the amount of the FPL in order to meet basic needs. Families living below the 2018 FPL ($25,100 for a family of four) are considered poor. Familes that live at twice (200 percent) the FPL ($50,200 for a family of four) are categorized as "low-income" and those who are living at half (50 percent) the FPL ($12,550 for a family of four) are said to be living in "deep poverty" (Pascoe et al., 2016; U.S. Department of Health and Human Services, 2018).

Another example is the U.S. Census Bureau poverty threshold, which is used to calculate the number of Americans living in poverty. This calculation does not include non-cash government benefits such as public housing, SNAP, or Medicaid, and uses pre-tax dollars to establish the poverty threshold (U.S. Department of Health and Human Services, 2018). According to the 2017 Poverty Statistics Report issued by the Census Bureau, 12.7 percent of those living in the United States fall below the poverty line (United States Census Bureau, 2017). A state by state representation of individuals living below the poverty line in 2016 is shown in Fig. 33.1.

TABLE 33.1 2018 Poverty Guidelines for the 48 Contiguous States and the District of Columbia



Persons in Family/Household	Poverty Guideline
1	$12,140
2	16,460
3	20,780
4	25,100
5	29,420
6	33,740
7	38,060
8	42,380

For families/households with more than eight persons, add $4320 for each additional person.
From U.S. Department of Health and Human Services, 2018.

While both of these federal measures are important for planning and budgetary purposes, they define poverty using an income based, unidimensional, or "headcount ratio." They do not reflect geographic differences in the cost of living or the positive impact of government programs such as the Earned Income Tax Credit (EITC); nutrition program for Women, Infants and Children (WIC); public housing; and energy assistance on lifting families out of poverty. The Supplemental Poverty Measure (SPM) was developed in 2010 by the National Academy of Sciences to consider these programs when evaluating poverty and outcomes, as well as adjusting for geographic differences in the cost of living and medical care (Pascoe et al., 2016; United States Census Bureau, 2017). All of these methods provide a "snapshot" of poverty at a given point yet do not measure the impact of poverty over time. The Panel Study of Income Dynamics is an example of a longitudinal, repetitive survey instrument that has been used since 1968 to examine the effects of poverty over time.

In the 1970s, a more comprehensive view of defining poverty was developed which examines how well individuals are able to satisfy their needs. Termed the *direct method* by Amartya Sen, a Nobel prize winning economist, this approach assesses human deprivation by looking at where individuals are unable to meet basic needs. Perhaps most useful for addressing poverty at the public health level, this method measures the capacity of individuals to create their desired living circumstances and fully function in society. The concept behind this method is that poverty cannot be defined by access to economic resources alone. Increased monetary resources may improve standards of living, but only when the necessary resources can be purchased. There are other non-monetary resources needed to fully function in society, such as public education. With the direct method, resources like inner capability and the ability to achieve a desired standard of living are assessed. Individuals or populations can have multiple deprivations across monetary and non-monetary dimensions, which points to more intense levels of poverty. Each dimension is weighted so that it becomes possible to identify the most detrimental deprivations associated with poverty (Callander & Schofield, 2016; United Nations, 2015; Wagle, 2014).

This multidimensional approach to defining poverty was sanctioned by the United Nations Development Programme in 2010, using an adaptation of the Alkire-Foster (2015) counting method (Alkire et al., 2015). The resulting Multidimensional Poverty Index (MPI), which looks at poverty across the domains of health, education, and standard of living, provides a composite score which can then be used to compare poverty in other regions or globally. An individual is considered multidimensionally poor if he or she is deprived in 33 percent of MPI indicators. The MPI outcomes can also be sorted by ethnicity,

Note: U.S. percentage does not include data for Puerto Rico.

Fig. 33.1 Individuals below the poverty level by state. (From U.S. Census Bureau, 2017. Available at https://www.census.gov.)

religion, age, sex, or other classifications in order to better understand the poverty of a given population (United Nations, 2015).

In 2014, Udaya Wagle surmised that multidimensional approaches to defining poverty tended to overlook the importance of social relationships to a sense of well-being and the capability to function. Wagle points to the connection between **social exclusion** and poverty and argues for the need to evaluate the level of social interconnectedness when defining poverty. This can be established by determining the level at which "individuals *relate* with others and the broader society or polity in which they live" (Wagle, 2014). One operational indicator used to measure relational resources is to examine active participation in elections. Additional indicators are used to measure the relational dimension, as well as the economic dimension (family income with adjustments for family size) and inner capabilities dimension (educational attainment, educational degree, status of health, and occupational prestige). Wagle applied his method for defining poverty to data contained in the General Social Survey of the United States and demonstrated that a higher number of families/households are deprived of economic and relational resources than of inner capabilities, particularly among minority populations. This suggests that **social interconnection** (or lack thereof) may play a larger role in poverty than had been previously understood (Wagle, 2014).

It is important for nurses to understand the many ways to define and measure poverty so they can better understand what causes and contributes to poverty and the impact multiple deprivations can have on living a full and functional life. There is an association between multidimensional poverty, self-rated health, and chronic income poverty (Callander & Schofield, 2015; Oshio & Kan, 2014). As these methods for measuring poverty continue to evolve, they may serve as a guide to when, where, and for whom anti-poverty and health care initiatives can be most effective. For example, if a patient has a mental health disorder (health domain deficit), and also has deficits in the social/**relational health**, education, and income/monetary domains, the nurse may provide assistance by linking him or her to resources such as a mental health support group, a GED class and Temporary Assistance for Needy Families (TANF) benefits. By addressing multiple deprivations in an effective and timely way, the risk of chronic income poverty and worsening health may be interrupted (Callander & Schofield, 2015).

Historical View of Poverty in the United States

In the summer of 1967, intense rioting and looting broke out in a number of America's cities, predominantly in African American communities. The violence was so overwhelming that the National Guard was called in to restore order. Newark and Detroit were among the hardest hit cities. Milwaukee, Cincinnati, Atlanta, and Tampa were among 125 additional cities where significant episodes of violence occurred. Twenty-six people died, including women and children, and property damage was extensive. These events spurred fear, panic, and anger among Americans, and in response President Lyndon Johnson created the National Advisory Commission on Civil Disorders to investigate and report on the causes and solutions to the civil unrest. President Johnson stated: "The only genuine, long-range solution for what has happened lies in an

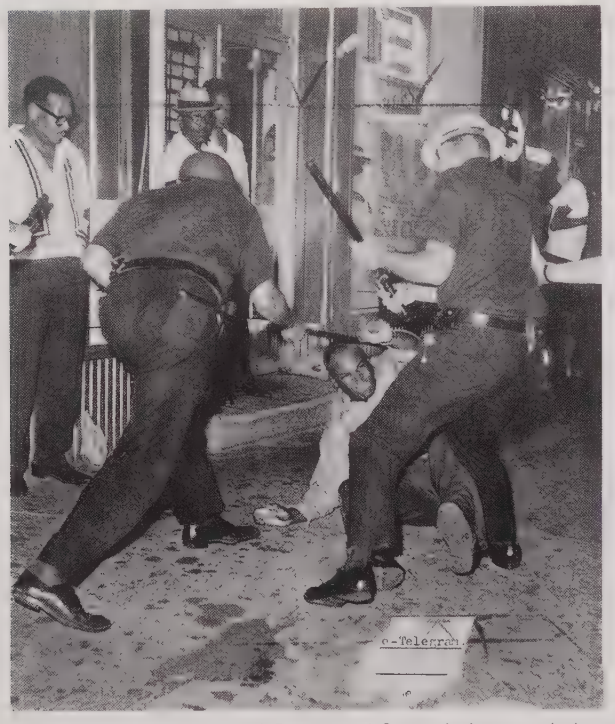


Fig. 33.2 An incident at 133rd Street and Seventh Avenue during the Harlem riot of 1964. (From Library of Congress: https://www.loc.gov.)

attack—mounted at every level—upon the conditions that breed despair and violence. All of us know what those conditions are: ignorance, discrimination, slums, poverty, disease, not enough jobs. We should attack those problems—not because we are fired by conscience. We should attack them because there is simply no other way to achieve a decent and orderly society in America" (Harris & Curtis, 2018) (Fig. 33.2).

The commission, led by David Ginsberg, began their work by holding a series of hearings and hiring staff to conduct field surveys in 23 cities. They conducted interviews and opinion surveys, and commission members visited eight cities that had been the site of rioting. Dubbed the **Kerner Commission**, the group spent an additional 44 days developing a report based on their findings. The Commission concluded that the untenable conditions under which individuals in these cities lived, and institutional **racism**, were the root causes of the violence. They pointed to African Americans migrating to cities in order to escape rural poverty between 1945 and 1965. During that time frame, jobs began moving to the suburbs along with much of the white population, leading to primarily poor and African American inner cities. Confrontation between desperate inner-city residents and majority-white police departments transpired, and hostility continued to escalate until residents erupted in significant, sustained violence in cities across the nation that police were unable to quell.

The Kerner Commission report stated that the United States was moving toward two disparate societies, one African American and one white. Segregation and poverty had created ghettoes the likes of which were unfathomable by whites, though white society was complicit in establishing, condoning, and institutionalizing these conditions. The Commission determined that in order to prevent such violence in the future, it was essential to initiate significant and sustained efforts to combat racism, poverty, unemployment, inadequate education, lack of health care, and poor housing. The Commission noted that such an initiative would require previously unheard of levels of federal funding and should not be limited to improving socioeconomic conditions. They believed that racism and discrimination should be addressed at multiple levels, and social programs should be made available to all impoverished Americans, urban or rural, African American or white, Latino, Native American, and other minorities. The Commission's report was met with a notable lack of support from President Johnson as well as among Americans, who pushed back against the concept of "white racism" and the recommendations for remedying the issues. However, a number of powerful and influential leaders such as Vice President Hubert Humphrey, Senator Robert Kennedy, and Dr. Martin Luther King, as well as the Secretary of Health, Education and Welfare, and Secretary of Labor, believed the Kerner Report accurately portrayed the problems and solutions to violence in the inner cities. President Johnson's "Great Society" initiatives continued forward momentum, and for nearly 10 years America made progress on most of the goals and solutions put forth in the Kerner report.

The Fair Housing Act of 1968 was passed following the release of the Kerner Report and four days after the death of Dr. Martin Luther King. This law prohibited discrimination on the basis of race, religion, or nationality by those selling or renting housing. Increased investment in urban and poor rural schools led to significant improvement in educational inequality, reducing the achievement gap between white and African American 13-year-olds by greater than 50 percent. Latino and African American youth attended college as often as whites by the mid-1970s. The number of Americans living below the poverty line during President Johnson's administration dropped from 22.2 percent to 12.6 percent. Had these improvements continued, the inequality gap in education would have closed by the year 2000.

The Influence of Politics on Poverty

With the advent of the Reagan administration in 1981, federal support for schools, housing, health care, and child welfare was cut, and the gains in educational achievement slowed, then halted, and eventually reversed (Harris & Curtis, 2018). Poverty rates eased upward, spiking at 15.1 percent in 1993 during the administration of President George H. W. Bush, then dropped to a low of 11.3 percent in 2000 under President Bill Clinton, rose sharply again during the George W. Bush administration, topping out in 2010 at 15.1 percent—following the Great Recession (Statista, 2018). During the administration of President Barack Obama (2009-2017), poverty dropped to 12.7 percent, where it remains today. Over the past 50 years, the United States has had a net increase in poverty of 0.1 percent (United States Census Bureau, 2017).

The greatest reductions in poverty followed President Johnson's "War on Poverty" in the mid to late 1960s and during the Clinton administration from 1993 to 2000, both of which included periods of economic expansion. During periods of

economic contraction, such as during the Great Recession (December 2007 to June 2009), poverty increases. Federal social **safety net** programs in place at the beginning of the recession reduced the population of those living in poverty by 8.9 percent. By 2012, anti-poverty programs had been expanded, reducing the alternative poverty rate by 12.7 percent (Chaudry et al., 2016).

The Changing Face of Poverty

Today, the face of poverty has changed. Adults over the age of 65 have doubled since 1966, yet the number of seniors who live in poverty has decreased, largely due to Social Security. In 2016, the highest rates of poverty occurred among children under the age of 18, followed by adults aged 18-64, during their prime income producing years. Greater than 26 percent of poor families were headed by females, who also had the lowest median income ($41,027) among family households (United States Census Bureau, 2017). Childhood poverty remains a stubborn problem with rates fluctuating over time, increasing to about 22 percent during the Great Recession and decreasing to 18 percent during the economic expansion that followed (Desilver, 2014; United States Census Bureau, 2017). Since 1966, poverty has decreased among African Americans, though the rate is still double that of whites, and poverty among Hispanics has risen to 19.4 percent (Desilver, 2014). There is significant evidence that higher poverty levels among African Americans and Hispanics are associated with disparities in educational achievement (Stanford Center on Poverty & Inequality, 2017). Americans with lower levels of education, those who are African American or Hispanic, and single mothers with children have consistently experienced higher rates of poverty over time in the United States (Chaudry et al., 2016).

Single Mothers, Women, and Children. Six out of 10 impoverished U.S. children lived in a female-led household in 2016. Of families living in poverty in the United States, those led by a single mother make up the largest group. Over twice as many female householders lived in poverty (26.6 percent) as male householders (13.1 percent) and more than five times as many as "married couple" families. Among single minority women, the rates are even higher with 34.7 percent of Hispanic and 32 percent of African American female householders living in poverty. A number of factors contribute to poverty among single mothers, but figuring centrally are the wage gap between gender and between races and ethnic groups: for women working full-time all year versus men working full-time all year, women make 84 cents for every dollar paid to men, 63 cents for African American women, 57 cents among Native women, and 54 cents on the dollar among Hispanic women. After transitioning to female, transgender women's wages fell by almost 33 percent. The gender income gap has changed little since 2007 and exists among women of all ages, education levels, and nearly all occupations. Mothers incur what is referred to as a "motherhood wage penalty" of about 7 percent lower income for each additional child, while fathers do not. The "motherhood penalty" can significantly impact minimum and low wage workers, which are primarily (58 percent) women. As a result of earning lower wages, women have lower rates of Social Security and retirement income, which can contribute to poverty among the elderly (National Women's Law Center, 2017; Semega et al., 2017).

Minorities. One out of every four African Americans or American Indians living in the United States is poor, as is one out of every five Hispanics. In 2016, poverty rates among racial and ethnic minority groups in the United States were higher for African Americans (22 percent), Hispanics (19.4 percent), and American Indians (25 percent) than they were for whites (11 percent), although the number of whites living in poverty is actually higher, commensurate with the larger population of whites. African Americans and Hispanics living in the rural South, African Americans living in the rural Northeast, and American Indians living in the rural West and urban Midwest have the highest poverty rates in the country. African Americans, Hispanics, and American Indians have historically had lower rates of educational achievement, employment, income, home ownership, and net worth (Goins et al., 2015; Running Strong for American Indian Youth, 2018; Stanford Center on Poverty & Inequality, 2017; United States Census Bureau, 2017). **Multigenerational poverty** is common among African Americans in the South, Hispanics along the border of Mexico, and American Indians who live in states with multiple reservations.

The gap in educational achievement between African Americans, Hispanics, and whites has narrowed in recent years, and high school graduation rates have improved, which is largely attributed to early childhood education programs. However, gaps continue to exist, and it is estimated that it will take 50 years before the level of academic achievement among African Americans and Hispanics is equal to that of whites. The most significant factors contributing to education inequity among these two minority groups are segregration and limited family resources. African Americans and Hispanics are far more likely to live in neighborhoods with higher concentrations of poverty, and parents are less likely to have the resources necessary to support schools, such as higher levels of education and income (Stanford Center on Poverty & Inequality, 2017). American Indians and Alaska Natives (AIAN) have lower rates of high school graduation (72 percent) compared to whites (88 percent) and African Americans (76 percent). Only 17 percent of American Indian students are able to continue their education following high school (Oliff, 2017; U.S. Department of Education, 2018).

The median income in African American and Hispanic households is about 60 percent of that for whites. While the earnings gap between African Americans and whites has decreased 32 percent in the last 40 years, African Americans have seen an overal improvement in income of only 7 percent. Fewer African Americans (41 percent) and Hispanics (45 percent) own their own homes, compared to whites (71 percent), leaving the majority of African American and Hispanic families to rent their homes, thus making them more vulnerable to eviction. The rate of eviction among Hispanic renters is significantly higher (23 percent) than the rate for African Americans (12 percent) or whites (9 percent), which is reflected in the 30 percent increase in the number of Hispanics who were

homeless and unsheltered between 2016 and 2017 (Office of Community Planning and Development, 2017; Stanford Center on Poverty & Inequality, 2017).

Housing among AIAN populations is more complex, with about 22 percent living on tribal lands and 77 percent living outside tribal lands, 60 percent of whom live in metropolitan areas. The AIAN home ownership rate overall is 54 percent, though on tribal lands the rate is higher (67 percent). Homelessness among this population is more insidious and rates may be artificially low as AIAN homeless are often sheltered by family members, which can lead to harmful effects such as taxing existing family resources and overcrowding (Pindus et al., 2017; U.S. Department of Health and Human Services, 2017; United States Interagency Council on Homelessness, 2017).

With higher rates of poverty among these three minorities, enrollment in government safety net programs such as SNAP, are generally higher, with a few exceptions. Nearly 26 percent of the AIAN population, 25.3 percent of African Americans, and 20.4 percent of Hispanics receive SNAP benefits. However, American Indians and African Americans are far less likely to enroll in Medicaid. This is referred to as a "double disadvantage effect," meaning these two minorities have higher poverty rates, yet are under-enrolled in Medicaid (Stanford Center on Poverty & Inequality, 2017).

The Elderly. Poverty among those aged 65 and older has decreased overall since 1967, though this demographic saw a statistically significant increase in poverty between 2015 and 2016. The poverty rate rose from 8.8 percent to 9.3 percent, the first such increase since 2010. There is evidence that "near poor" seniors are being pushed into poverty because of medical expenses and because Social Security is keeping fewer seniors out of poverty. A detailed analysis published in 2018 by the U.S. Census Bureau using the SPM, shows that 76 percent of seniors who entered poverty in 2016 did so because of a decrease in Social Security and/or retirement income (about $200) and an increase in medical expenses of about $500 (Fox & Pacas, 2018). Millions of older adults are considered low income because they live above the FPL ($12,140 for one person, $16,460 for two), though they have great difficulty meeting expenses and are one crisis away from sinking into poverty. Some 43 percent of single persons and 21 percent of married couples over the age of 65 rely on Social Security as 90 percent of their income, and the average Social Security benefit is $1,342.00 per month, less than $16,000 per year. The majority of seniors pay an average of $134 per year for Medicare, which is typically deducted directly from Social Security, further reducing their pay. Though a 2 percent cost of living raise has been granted for Social Security for 2018, the increase may be consumed by Medicare Part B costs (Center on Budget and Policy Priorities, 2017). The rate of poverty among seniors increases with age and is higher among women, African Americans, and Hispanics (Kaiser Family Foundation, 2018).

It is clear that the demarcation between poverty and near poverty among those aged 65 and older is fluid and precarious. A serious illness or injury can force a senior to choose between paying for medication and eating and may drop him or her below the poverty line. Food insecurity is an issue for 2.9 million households where a senior is housed, and although three out of five adults are eligible for SNAP, many are not enrolled (National Council on Aging, 2018).

Each of these vulnerable populations faces poverty for a multitude of reasons, and the approach to improving well-being is not uniform. Bringing awareness to those most at risk of poverty, as well as developing an understanding of the appropriate government safety net, faith-based, and privately funded program resources that are available, is essential to understanding the needs of these populations and the substantial link between poverty and health.

POVERTY AND HEALTH: THE IMPACT OF TOXIC STRESS

Health status is included in each of the multidimensional poverty assessment tools because it plays a significant role in the capacity to achieve and maintain a desired standard of living and a sense of well-being. Studies have shown that well-being is associated with a decreased risk of disease, illness, and injury and better immune function, longevity, and productivity. Well-being is reliant upon good health, positive social relationships, and access to basic resources such as food and shelter (National Center for Chronic Disease Prevention and Health Promotion, 2016). Families living in poverty are caught up in a vicious cycle: they are at higher risk of chronic disease, and chronic disease can drag them into a downward spiral of worsening disease and deeper poverty (World Health Organization, 2018b).

High-Risk Populations

The adverse effects of poverty on the health of children are myriad and include increased morbidity and mortality during childhood and a lifelong increased risk of cardiovascular and metabolic disease, much of which can be linked to **toxic stress.** Some 50 percent of African American children and one third of Hispanic children will develop diabetes at some point in their lives, with one in four developing prediabetes as a child (Conway, 2016). Box 33.1 outlines the impact of poverty on the health and well-being of children.

Younger children are more at risk of poverty-related toxic stress because of their vulnerability and the prevalence of poverty among this age group. The high levels of stress experienced by families living in poverty lead to consistently activated stress hormones and inflammatory mediators in children. High levels and/or prolonged exposure to hormones such as cortisol, norepinephrine, and adrenalin, coupled with mediators such as cytokine, affect the entire body and in particular, a child's developing brain. Poor impulse control and self-regulating behaviors may result from this hypervigilant stress response, which may further impair the relational health between a child and a stressed parent and other family members. As young adults, these children may engage in unhealthy behaviors such as smoking or substance abuse, in an effort to provide respite from chronic stress, which can lead to increased morbidity and

BOX 33.1 Impact of Poverty on the Health of Children

- Higher infant mortality
- Low birth weight
- Food insecurity
- Unintentional injury
- Maltreatment
- Increased frequency of asthma
- Poor dental health
- Obesity
- Reduced access to quality health care
- Violence
- Unstable or substandard housing
- Academic underachievement
- Lower quality schools
- Teen pregnancy
- Depression and conduct disorders
- Substance abuse (smoking and alcohol)
- Unsafe or non-existent recreational areas

Data from Impact of poverty on the health of children. From the American Academy of Pediatrics Committee on Psychosocial Aspects of Child and Family Health, Council on Community Pediatrics, 2016.

mortality at a young age. Children who have the benefit of good relational health and a stable family life are better able to minimize the stress response and may not experience the lifelong increased risk of chronic disease. For this reason, interventions that focus on improving parental engagement and good relational health can buffer the harm to a child's developing brain (Pascoe et al., 2016).

EVIDENCE-BASED PRACTICE

Toxic stress among children has been identified as a significant contributor to the development of chronic disease as an adult. Ameliorating the effects of toxic stress among children can be accomplished through stable, supportive relationships with adults during early childhood. Breastfeeding has been suggested as a toxic stress mitigator, beginning with the skin-to-skin contact immediately following birth. This mother-infant contact stimulates a rise in maternal oxytocin and prolactin and decreases cortisol, reducing infant allostatic load and inducing calm. Breastfeeding has been proven to aid in the establishment of maternal-infant attachment and lower the stress response in mothers and infants.

Nurse Use

Interventions that support and promote breastfeeding such as the nurse-family partnership (NFP) address disparities in breastfeeding among communities and work to decrease socioeconomic disparities for mothers and infants. NFP programs have also positively impacted such child/family outcomes as fewer child injuries related to neglect.

Data from Hallowell S, Froh E, Spatz D: Human milk and breastfeeding: an intervention to mitigate toxic stress. *Nurs Outlook* 65(1):58-67, 2017. Available from https://www.nursingoutlook.org.

The American Academy of Pediatrics (AAP) released a policy statement in 2016, outlining factors which mitigate the harmful health effects of childhood poverty. A number of government safety net programs are included in the AAP recommendations such as early identification of families in need of services, tax policies which increase family income, financial aid, comprehensive health care, early childhood education, and home visitation. Programs which provide parental support and build resilience in children are additional ameliorating influences (Pascoe et al., 2016).

Minorities. The higher rates of poverty among racial and ethnic minorities are also associated with chronic disease at an earlier age, at a higher rate, and an earlier death than among whites. Early studies suggest that poverty-related stress can lead to long-term epigenetic changes in gene expression that can impact health as early as pre-birth. African Americans are two to three times more likely to suffer from hypertension and diabetes, have higher rates of cardiovascular disease (CVD), stroke, cancer, asthma, human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS) and become victims of homicide, and are two to three times more likely to experience premature death than whites (U.S. Department of Health and Human Services, 2018a). American Indians and Alaska Natives have signficantly higher rates of infant mortality (7.6 per 100,000) than do whites (4.9 per 100,000) (U.S. Department of Health and Human Services, 2017). The major causes of illness, injury, and death are CVD, cancer, unintentional injuries, diabetes, and stroke. The AIAN population has significant risk factors for and a high prevalence of suicide, obesity, substance abuse, liver disease, sudden infant death syndrome (SIDS), and teen pregnancy. Many tribal homes do not have adequate water purification or sewage disposal systems. Access to quality health care on tribal lands is limited because of inadequate funding for Indian Health Services and the geographic isolation of many reservations (U.S. Department of Health and Human Services Office of Minority Health, 2018b).

The Hispanic population has the added difficulty of cultural and language barriers, immigration status, and often lacks insurance, which impacts the ability to access and benefit from health care services. Preventive services in particular are utilized less frequently among this ethnic group. Causes of morbidity and mortality include obesity, diabetes, asthma, CVD, cancer, stroke, chronic obstructive pulmonary disease, unintentional injuries, suicide, HIV/AIDS, and liver disease. One subgroup of the Hispanic population, Puerto Ricans, have disproportionately higher levels of low-birth-weight infants than do whites. Infant mortality, asthma, and HIV/AIDS rates are also higher among this subgroup. Hispanics have higher rates of obesity than whites, and Mexican Americans have higher rates of diabetes than other Hispanic subroups (U.S. Department of Health and Human Services Office of Minority Health, 2018c).

Nursing Intervention: Accessing the Government Safety Net

Historical analyses show that Federal social safety net programs reduce poverty. Social Security cash payments, tax credits such as the Earned Income Tax Credit (EITC), and the SNAP program (formerly known as food stamps) have had the greatest anti-poverty impact (Chaudry et al., 2016). The EITC is a tax credit offered to low-moderate income working individuals,

which reduces the tax burden or provides a refund (Internal Revenue Service, 2018). These programs increase income among those who would otherwise fall below the poverty line, and they actually lift more families out of poverty now than when they were created. Nowhere is this more evident than among impoverished children. In the mid-1960s, government policies and programs reduced childhood poverty by 1.1 percent; in the 1970s and 1980s, by 1.6 percent; and in 2016, by 2.3 percent (Chaudry et al., 2016). In 2016, child poverty hit a record low of 15.6 percent, or almost half the 1966 rate. Refundable tax credits and SNAP were the most effective policy programs for easing childhood poverty, lifting some 38 percent of children above the poverty line. These program benefits were equally distributed among African American, white, and Hispanic children.

Other government programs such as Medicaid, CHIP, and the Affordable Care Act (ACA) have proven beneficial to impoverished children by providing health insurance. Ninety-five percent of children in the United States are now insured, and studies that have examined the effect of Medicaid on children's health have shown a significant positive impact, particularly with well child and preventive services (Leininger & Levy, 2015; Shapiro & Trisi, 2017). Among children born after Medicaid was initiated, health care utilization increased, low birth weights decreased, educational outcomes improved, lower rates of poverty were noted, and lower rates of adult mortality occurred. In regions where Medicaid spending was higher and access to health care was initiated at a younger age, outcomes for adults were better and the percent of adults who saw benefit from the program was larger (Stanford Center on Poverty & Inequality, 2017).

Government safety net programs clearly function as they were intended by halting the number of Americans who would otherwise fall below the poverty line and by helping those who live below the poverty line to have a better quality of life. Critics of social safety net programs argue that government assistance disincentivizes working among impoverished individuals, yet the EITC provides benefit to low-income *working* families and the credit increases as the level of income rises—up to the maximum rate (Stanford Center on Poverty & Inequality, 2017).

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Quality and Safety Focus

Targeted Competency: Client-Centered Care

Recognize the client or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for client's preferences, values, and needs.

Important aspects of client-centered care include the following:

- **Knowledge:** Describe how diverse cultural, ethnic, and social backgrounds function as sources of client, family, and community values.
- **Skills:** Provide client-centered care with sensitivity and respect for the diversity of human experience.
- **Attitudes:** Recognize personally held attitudes about working with clients from different ethnic, cultural, and social backgrounds.

Self-awareness is a key component of providing authentic, genuine client-centered care.

In order to clarify their own values and perspectives about poverty, nurses should ask themselves the following questions about poverty and persons living in poverty:

How to Test Values and Beliefs About Poverty

- What do I believe to be true about being poor?
- Do I fully appreciate the impact racism has had on the health and well-being of minorities?
- Do I believe that people are poor because they just don't want to work? Or do I believe that society has a significant influence on one becoming poor?
- What do I personally know about being poor?
- How have family and friends influenced my ideas about being poor?
- Have I ever personally been poor?
- What do I feel when I see a hungry child? A hungry adult?
- What do I really think can be done to prevent poverty and homelessness?
- Can I effectively advocate for a client's needs if it runs counter to my personal beliefs?

Adapted from work by Gail Armstrong, PhD, DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing.

DEFINING AND UNDERSTANDING THE CONCEPT OF HOMELESSNESS

The Department of Housing and Urban Development defines "homeless" as "a person who lacks a fixed, regular, and adequate nighttime residence" (Henry et al., 2017). This definition can be expanded to cover categories of homelessness such as "chronically homeless individual" or "chronically homeless people in families," the former referring to an individual who has a disability and has either been homeless at least four times in 3 years—for a minimum of 12 months—or continuously homeless for a total of 1 year, the latter referring to a family where the head of household meets the definition of chronically homeless individual (Henry et al., 2017).

The concept of homelessness encompasses three categories: chronic homelessness, transitional, and episodic. The episodic homeless are generally marked by hardship and struggle, including chronic unemployment. These individuals move in and out of homelessness, are younger, and often have mental health and substance abuse problems. Transitional homelessness is typically caused by a catastrophic event which necessitates a short shelter stay, eventually transitioning to permanent housing. This tends to account for the majority of homelessness over time because of the high rates of turnover among this population, which edges the count higher. Finally, the chronically homeless are usually older individuals who are chronically unemployed, have some type of disability or substance abuse problem, and use the emergency shelter system as a long-term housing solution. This group makes up the smallest percent of the homeless population (National Coalition for the Homeless, 2018a).

Those who are homeless sleep at night in shelters that they often must vacate during the day. This means that during the day, they sit or stand on the street; in parks, alleys, shopping centers, and libraries; and in places such as trash bins, cardboard boxes, or under loading docks at industrial sites. Homeless persons may seek shelter in public buildings, such as

train and bus stations. Those who do not sleep in shelters may sleep in single-room-occupancy (SRO) hotels, all-night movie theaters, abandoned buildings, and vehicles. Some homeless persons choose to be unsheltered rather than live with family or stay in shelters (Choi et al., 2015; Christian & Mukarji-Connollly, 2018).

The Face of Homelessness in the United States

"On a single night in 2017, 553,742 people were experiencing homelessness in the United States" (Henry et al., 2017). Around two thirds of those people were housed in emergency shelters or transitional programs, and the remaining one third were unsheltered, meaning they slept in non-customary places such as on the street, in parks, or in an automobile. The 2017 Annual Homeless Assessment Report (AHAR) to Congress, published by the U.S. Department of Housing and Urban Development (HUD), reports that a one percent overall increase in homelessness occurred between 2016 and 2017, made up entirely of **unsheltered homeless** individuals (Henry et al., 2017). This represents the first increase in homelessness in seven years and may reflect a higher cost of renting and a lack of market availability for extremely low-income (less than 30 percent of the area median income or below FPL) housing (National Alliance to End Homelessness, 2017; U.S. Department of Housing and Urban Development, 2018a). The high rates of unsheltered homeless in the western part of the United States and in Florida correlate with the low number of units available for rent among extremely low-income households (National Alliance to End Homelessness, 2017). The number of homeless living in shelters and transitional housing declined by three percent between 2016 and 2017, a trend which has continued for the past three years, yet the number of unsheltered homeless rose by 9 percent (Henry et al., 2017).

There are two predominant ways to determine the number of people who are homeless: (1) point-in-time (PIT) counts, where the number of persons who are homeless on a given day or during a given week are counted or (2) period prevalence counts, which examine the number of people who are homeless over a given period of time. The Department of Housing and Urban Development utilizes government designated **Continuum of Care (CoC) programs** to perform an annual PIT count (conducted twice yearly in some locales) to identify and describe the U.S. homeless population. The Housing Inventory Count is used by CoC programs to define the number of beds available to serve the homeless. There were 399 CoC programs as of 2017, covering virtually all of the United States (Henry et al., 2017).

The primary causes of homelessness are a lack of **affordable housing** and insufficient housing assistance. The 2017 Housing Wage necessary to afford housing is $21.21/hour, grossly exceeding minimum wage ($7.25/hour) and well beyond the average hourly wage ($16.38/hour) of a renter. The number of families in the United States who spend greater than 50 percent of their income on housing is growing, and two thirds of those living below the poverty line receive no housing assistance. These factors have led to families becoming homeless and placed others at risk of becoming homeless (Institute for Children, Poverty and Homelessness, 2018a; National Alliance to End Homelessness, 2017; National Coalition for the Homeless, 2018b).

In recent years, questions have been raised regarding whether the PIT count adequately captures the extent of the homeless population in the United States. For example, community-based PIT counts may not include individuals or families that are "**doubling up**" with relatives or friends, or mothers who avoid being counted out of fear it may mean their children could be taken from them. This gap has been partially addressed by a U.S. Department of Education (ED) Data Express survey, which requires schools to report the number of children and families who are homeless, including those that are "doubling up" by housing with another family. These families are not considered homeless by HUD, though they do not have permanent stable housing of their own (Deck, 2017). The ED count shows dramatically higher rates of homeless families; for example, the St. Louis, Missouri, PIT count showed 460 homeless people in families, while the ED count showed 5451 homeless children. Because HUD uses the PIT count to establish the numbers of homeless individuals and families, and the U.S. Interagency Council on Homelessness (USICH) uses HUD data to report on the state of homelessness, the 2016 USICH report reflected a 23 percent decrease in homeless families between 2010 and 2016. The ED count for a similar period (2010-2014) showed a 19 percent increase in homeless students. The 2016 HUD report for 2016 counted 64,197 homeless families in the United States, while the 2016 ED report showed 1.2 million children who were homeless. This would equate to the average family consisting of 20 children! Although families who double up are temporarily housed, their problems have not been solved, and they continue to have challenges in meeting their needs and suffer psychological distress related to a lack of permanent housing (Institute for Children, Poverty and Homelessness, 2018b; National Coalition for the Homeless, 2018f).

Rural communities, despite their peaceful images, are not immune to homelessness. The problem may not be as noticeable in rural areas because homelessness is more concentrated in cities. However, homeless individuals and families living in rural areas suffer from the same issues of poverty and lack of affordable housing and the same health problems as their urban counterparts. The odds of being poor are about 1.2-2.3 times higher for those in nonmetropolitan areas. The extent of homelessness in rural areas may be less apparent because these individuals are hidden from sight, sometimes living in the woods in tents or campers, in barns or ice sheds, or they may crash on a friend's couch. Access to health care becomes more problematic because of fewer resources and transportation issues. HUD calculates the population of rural homeless at 7 percent, and the majority of this population are white, female-led homeless families with higher numbers of children under age 18 (Wiltz, 2015). The homeless in rural areas may be undercounted because estimates of this subgroup rely on service provider counts, which are often fewer in number in rural areas (National Coalition for the Homeless, 2018b).

Homelessness affects psychological, social, and spiritual well-being. Becoming homeless means more than losing a home, or a regular place to sleep and eat; it also means losing friends and family, personal possessions, and familiar surroundings. Homeless persons live in chaos, confusion, and fear. Many describe experiencing loss of dignity, low self-esteem, lack of social support, and generalized despair.

Johnstone et al. (2015) describe discrimination and exclusion of the homeless as having a negative impact on social connection and in turn, their well-being. Turning to others or being part of a cohesive group can help temper the impact of discrimination among disadvantaged groups by strengthening identity and providing social support to better deal with discrimination. A sense of group identity and connection in response to discrimination has been historically demonstrated among African Americans and women. However, even though the homeless face great stigma and discrimination, they may not coalesce around a group identity. They often do not think of themselves as similar to other homeless persons. For example, they may craft an image of being a worker, contrasting themselves with other homeless persons who do not work. In addition, the age variation and reasons for becoming homeless lead to great diversity among this population, making group identity as "homeless" even more difficult. In essence, this disadvantaged group which could derive great benefit from social connectedness and a sense of belonging may be the least likely to experience it (Johnstone et al., 2015).

Who is most likely to be homeless? The number of homeless families with children decreased by 5 percent between 2016 and 2017 and represents 33 percent of the entire homeless population, while individuals who were homeless accounted for 67 percent. The majority of homeless persons were over age 24 (69.6 percent), were more likely to be male (60.5 percent), non-Hispanic (78.4 percent), and white (47.1 percent). Victims of domestic violence and veterans also make up sizable populations within the homeless cohort. Over the past few years, efforts to address the problem of homeless veterans have increased (Henry et al., 2017)

Children and Youth. Homeless children and youth fall into one of two groups: those who are part of a homeless family and those who are "unaccompanied" by homeless family members. As is true for all homeless subpopulations, it is difficult to get an accurate count. According to the 2017 AHAR report, 9.7 percent of the overall homeless population were youth aged 18-24, and 20.7 percent were youth under 18 years of age. Those under age 18 were more likely to be sheltered (28.6 percent) than those aged 18-24 (8.8 percent). About 36,000 youth aged 18-24 were unaccompanied homeless as were 4800 youth under age 18. The majority of unaccompanied youth were male (62 percent), and the rate of unaccompanied female youth (37 percent) was higher than the rate of women among all homeless individuals (28 percent). Unaccompanied youth have a significantly higher rate of living unsheltered (55 percent) than do all homeless persons (35 percent). Causes of homelessness among youth include unstable family life and domestic violence, fractured social supports, substance abuse, mental illness, and sexual orientation and gender identity and expression (SOGIE).

The U.S. Department of Education's ED Data Express provides an estimate of the rates of homelessness among children under the age of 18 that attend public school, but these data do not capture those who are not in the public-school system or those that attempt to hide their homelessness. Adolescents are particularly reticent about identifying as homeless. They do this in an effort to blend in with their peers, or if they are unaccompanied, they may fear entering into the child welfare or criminal justice system (National Network for Youth, 2018). In 2016, there were 1.2 million homeless students in public schools, or 3 percent of the total student population, a rate that has rapidly escalated over prior years. These children are 87 percent more likely to drop out of school, which may in turn, impact graduation from high school, leaving them 4.5 times more likely to become homeless as adults (Institute for Children, Poverty and Homelessness, 2018a).

Another significant factor impacting homelessness among youth is sexual orientation or gender identity expression. An estimated 40 percent of unaccompanied homeless youth are lesbian, gay, bisexual, transgender, and queer (LGBTQ) young adults (Dashow, 2017). Among homeless youth surveyed by human services agencies that worked with LGBTQ youth in 2014, 20 percent identified as lesbian or gay, 7 percent as bisexual, 2 percent as questioning sexuality, and 3 percent as transgender. Youth of color, a subset of LGBTQ homeless who are African American, Latino/Hispanic, American Indian, or Pacific Islander, are overrepresented in the survey, suggesting this group may be at greater risk. The most frequently cited reason for LGBTQ youth homelessness was being forced from their homes or running away because of SOGIE. After addressing the primary housing needs, the second most important need cited by homeless LGBTQ youth in this study was emotional support. Some 60 percent of homeless LGBQ youth and 75 percent of homeless transgender youth have experienced physical, sexual, or emotional abuse, and 10 percent of LGBQ and 25 percent of transgender youth reported intimate partner violence. These experiences contribute to **Adverse Childhood Experiences (ACEs)** that can have lifelong health consequences (Choi et al., 2015).

In 2017, CoC programs began collecting data on homeless unaccompanied youth (under age 25) for the first time, in order to establish baseline data and better understand this population. The inaugural count showed that transgender youth, and those who did not identify as male, female, or transgender, were more likely to be unsheltered than sheltered. A significant portion of this population may choose to live on the streets to avoid harassment and violence at homeless shelters or in foster care (Christian & Mukarji-Connolly, 2018). As the youth counts continue, trends in unaccompanied youth homelessness may be used to inform policy decisions such as determining the amount and type of resources that are needed to prevent homelessness among this population and evaluating which prevention programs are successful (Henry et al., 2017).

Traumatic life events are common not only among LGBTQ homeless youth, but among all homeless youth, and the nurse

should consider the use of trauma-screening and **trauma-informed care** when working with this population (National Coalition for the Homeless, 2018c)

The Mentally Ill. One in five homeless persons has a severe mental illness, with similar rates of chronic substance abuse. Severe mental illness and substance abuse are often associated with chronic homelessness, which may be caused in part, by a lack of adequate engagement with outpatient treatment and long-term follow-up. Historically, the deinstitutionalization of mental health care was thought to be a contributing cause to the high rate of mentally ill persons who are homeless. However, a meta-analysis completed in 2016 showed that other factors may be responsible for the high rate of mentally ill homeless individuals in the United States. These factors include changes in mental health care funding in programs such as Medicaid, restrictions in Social Security and disability payments, a reduction in low-cost housing, and other social and political changes (Winkler et al., 2016).

Many homeless persons were mentally ill before becoming homeless, whereas others develop acute mental distress as a result of being homeless. Although treatment options exist, homeless persons are often unable to access mental health treatment facilities. Barriers to treatment include lack of awareness of treatment options, lack of available space in treatment facilities, inability to pay for treatment, lack of transportation, unsupportive or disrespectful attitudes of care providers, and lack of coordination of services (Roche et al., 2017). Homeless women with mental illness may face additional barriers. For example, in a recent study, women who had a history of substance use disorder (SUD) in the previous year, who also had a minor child, were far less likely to seek treatment (Upshur et al., 2018).

Veterans. A substantial percent (over nine percent) of homeless persons are military veterans. The rate of homelessness among veterans decreased by 33 percent between 2010 and 2016, largely due to a coordinated effort initiated by the U.S. Department of Veterans Affairs (VA) and HUD to engage public and private housing and service providers, and state and federal government agencies to eliminate homelessness among veterans. However, homelessness in this subgroup increased by two percent between 2016 and 2017, primarily consisting of unsheltered veterans in major cities. The majority of homeless veterans (91 percent) are male, though female veteran homelessness also rose by 7 percent during this time frame.

Veterans become homeless for many of the same reasons as non-veterans, but they are overrepresented among the homeless population, and it is thought that the experience of combat and numerous deployments may increase the risk of homelessness. Post-traumatic stress disorder (PTSD), traumatic brain injury with cognitive impairment, and other mental health issues may impair social relational health and/or negatively affect family relationships. In addition, the majority of homeless veterans are unmarried and may be socially isolated, a risk factor for homelessness. About 50 percent of veterans who are homeless have serious mental illness, and 70 percent have substance use issues.

The VA provides universal screening for all veterans who seek services through the VA health system and can be linked with housing and other appropriate services as needed, although some veterans may not be eligible for VA health services, which is dependent upon their discharge status (Henry et al., 2017; National Alliance to End Homelessness, 2018a; United States Interagency Council on Homelessness, 2018a).

A coordinated systems approach that coalesces services community-wide and uses local data to make decisions regarding resource allocation may effectively end homelessness. With this approach, "at-risk" individuals and families are quickly identified, assessed, and referred to services, in order to minimize the negative effects and interrupt a trajectory toward chronic homelessness (National Alliance to End Homelessness, 2018b). **Rapid re-housing** is one evidence-based approach to quickly re-housing the homeless, through the use of short-term rental assistance. This approach includes the provision of additional support services as needed (National Alliance to End Homelessness, 2018c). Another approach is "**Housing First**," which quickly re-houses the homeless in order to stabilize the individual/family, rather than requiring that the homeless be stabilized before they are provided housing, which has been the approach of many government and nongovernmental organization (NGO) agencies in the past. With this approach, comprehensive services are provided concurrently in order to stabilize and keep them housed continuously (Fisher, 2015; Gaetz & Dej, 2017).

Nurses may participate as community partners working within the coordinated systems approach, by using a social determinants of health screening tool to quickly identify those at risk and refer them for services (Cox, 2016). The web of causation underlying health issues needs to be addressed by nurses caring for this population. Connecting homeless clients to housing services is important, yet it is only a piece of the puzzle. A wide network of referral agencies and resources are needed to ensure that the scope of the problem is addressed (Institute for Children, Poverty and Homelessness, 2018a).

IMPACT OF HOMELESSNESS ON HEALTH ACROSS THE LIFE SPAN

Poor health is both a cause and an outcome of homelessness. Poor health can lead to work absences, job loss, financial crisis, and subsequent homelessness. Issues related to poor health are a major contributor to homelessness, with over half of personal bankruptcies in the United States due to medical issues (National Coalition for the Homeless, 2018d). Homelessness can also contribute to the risk of developing or worsening chronic disease, leading to higher mortality at a younger age. The homeless often have complex health needs and multiple morbidities, leading to high utilization of acute health services (Roche et al., 2018). They experience illness as much as six times more often than those who are housed, translating to visits at the emergency department at rates three times that of housed individuals. (National Coalition for the Homeless, 2018d; Stevenson & Purpuro, 2018).

Being homeless affects health across the life span. Imagine the effect of homelessness on pregnancy, childhood, adolescence, or older adulthood; each group has different needs. Nurses need to recognize the unique needs of homeless clients and the many factors that lead to homelessness, including joblessness; inability to maintain housing, pay utilities, and buy food; dysfunctional family life; and illness.

Mental health issues, including psychotic disorders, substance use, anxiety, PTSD, and depression, are among the most frequently cited health concerns among the homeless and are also nontraditional factors which are thought to contribute to the higher rate of cardiovascular disease (Baggett et al., 2018; Roche et al., 2018). The homeless suffer a 61 percent to 71 percent higher mortality rate from cardiovascular causes such as hypertension and ischemic heart disease than the general population, though the prevalence of hypertension is similar to those who are housed. Hypertension often goes undiagnosed or untreated, which contributes to higher CVD mortality. The high rate of tobacco use (68-80 percent) and excessive alcohol and illicit drug use add to the risk of CVD and contribute to an increased prevalence of chronic obstructive pulmonary disease, asthma, and bronchitis (Baggett et al., 2018). Diabetes also contributes to the high rates of CVD among the homeless, and lower extremity ulcerations and other foot problems are common, exacerbated by poor disease control. Foot wounds are further complicated by the many hours spent on their feet and the unsanitary conditions in which they live. (Roche et al., 2017; Stevenson & Purpuro, 2018). All of the these chronic conditions are impacted by difficulties encountered with medication adherence among the homeless, including the inability to pay for medications, store them properly, or prevent them from being stolen or lost (Baggett et al., 2018).

Infectious diseases such as HIV/AIDS, hepatitis, sexually transmitted infections (STIs) and tuberculosis are more common among the homeless than the general population. Exposure to the elements, crowded and unsanitary living conditions, malnutrition, lack of sleep, and stress place the homeless at risk for these and other infectious illnesses. Treating the homeless population effectively for these infectious diseases is particularly challenging because of difficulties getting and keeping them engaged in longitudinal treatment (Stevenson & Purpuro, 2018). Preventing infectious disease among this population is also difficult, given that visits to the emergency department or acute care facilities are a primary pathway to medical care. The focus of such care is to stabilize the emergent illness or injury, not on preventive care (Roche et al., 2018).

The HIV infection rate among the homeless ranges between 1.5 percent and 10.5 percent, depending on the subpopulation surveyed (Baggett et al., 2018). The use of intravenous drugs and risky sexual behavior, including unprotected sex and multiple partners, are contributing factors. Suboptimal HIV testing, pre-exposure prophylaxis (PrEP), and antiretroviral medication adherence negatively impact primary and secondary prevention of HIV/AIDS among the homeless (Wenzel et al., 2016).

Prolonged environmental exposure to cold environments can lead to life-threatening hypothermia, particularly when thermoregulation is impaired by age and/or abuse of drugs and alcohol. Homeless persons who lack adequate shelter are at increased risk of hypothermia due to poor mobility, poor nutrition, and mental illness or cognitive impairment. Elevated temperatures during summer can result in heatstroke and dehydration (Lane et al., 2018).

Women and Children. The rate of homeless families decreased by 5 percent between 2016 and 2017. Single, young women with limited education most often head homeless families, and in 2017, 50 percent of these mothers were African American and the remainder were white, and Hispanic (Henry et al., 2017). High rates of SUD, intimate partner violence (IPV), and pregnancy characterize this vulnerable population. In a study conducted in 2015, 62 percent of homeless women had experienced violence in childhood and adulthood, 82 percent were diagnosed with a SUD, 64 percent with major depression, and 50 percent were diagnosed with PTSD. During the study's three-year time frame, 75 percent of women had been victimized (Krahn et al., 2018; Tsaiet al., 2015). Disparities in health are higher for homeless women than for the general population of women; for example, homeless women are substantially more likely to become pregnant and experience poorer birth outcomes. Most often, these pregnancies are unintended and may be related to low levels and correct use of birth control, higher levels of sexual activity, and risky sexual encounters (Krahn et al., 2018; Thompson et al., 2016). Homeless women are less likely to have regular health care, screenings, and appropriate primary or specialty care health (Krahn et al., 2018).

The health problems of homeless children, although similar to those of poor children, are often more significant. There is a continuum of health risks among children, with those who are homeless having poorer health than children living in poverty, and those living in poverty facing greater adversity than those who do not. As with their adult counterparts, minor conditions may go untreated, resulting in higher rates of acute illness such as fever, ear infection, diarrhea, and asthma. Homeless children are at higher risk of exposure to environmental toxins such as lead. They are also at greater risk for inadequate nutrition, which can lead to delayed growth and development, failure to thrive, and conversely, obesity.

Homeless children also experience higher rates of changing schools, school absenteeism and academic progression, all of which may cause or exacerbate learning disabilities and developmental delays (Deck, 2017; Firth, 2014). While only 6.1 percent of children in "doubled up" households changed schools at least one time, 12.2 percent of the "poor but housed" group changed schools at least once, and 34.7 percent of children living in shelters changed schools more than once.

Perhaps the greatest health risk for homeless children and youth is the damaging effect of homelessness on mental health and psychological well-being. In a recent study of homeless youth drawn from the 2013 Minnesota Student Survey, 42 percent had elevated levels of emotional distress, nearly 30 percent reported self-injurious behavior such as self-mutilation, 21 percent had suicidal ideation, and over 9 percent

had attempted suicide. Female homeless youth demonstrated higher levels of emotional distress, self-inflicted behavior such as mutilation, suicidal ideation, and suicide attempts than male youth. In this particular study, homeless youth were more likely to be male, youth of color, and living in rural or non-metropolitan areas. Suicide is the second leading cause of death among all youth between ages 10 and 24 but is the leading cause of death among unaccompanied homeless youth. The lifetime prevalence of depression is almost double that of housed youth (Barnes et al., 2018).

Homeless adolescents living on the streets have greater risk-taking behaviors, poorer health status, and decreased access to health care than do teens in the general population. Homeless teens often have histories of runaway behavior and physical and sexual abuse. They are at higher risk of contracting sexually transmitted infections, including HIV, sexual exploitation, traumatic violence/victimization, unintended pregnancy, injury, tuberculosis, asthma, and death. About 25 percent of street youth and 18 percent of youth living in shelters reported a serious health problem in the previous year (Chelvakumar et al., 2016; National Conference of State Legislatures, 2016). Other contributory risk factors for youth homelessness are a poorly functioning child welfare system and adolescents who are aging out of foster care and are at high risk for becoming homeless (National Conference of State Legislatures, 2016).

The health needs of LGBTQ homeless youth are somewhat different than those of non-LGBTQ homeless youth. This population has more public health risks and is less healthy than non-LGBTQ homeless youth. Mental health tends to fare worse with higher levels of depression, anxiety, and internalizing behaviors (tendency to keep problems to oneself). Alcohol and substance abuse is often reported. Homeless transgender youth health fares worse than cis-gender (personal identity corresponds with the sex at birth) youth health, and LGBTQ youth are more likely to have experienced trafficking or sexual exploitation than heterosexual homeless youth (Choi et al., 2015).

Older Adults and the Elderly. Homeless older adults aged 50-62 have a similar level of health care needs as those 10-20 years older who are housed. Common among older homeless adults are cognitive impairments, vision and hearing difficulties, and problems with walking (National Coalition for the Homeless, 2018d). Homeless older adults have an added layer of vulnerability, including "frailty," a constellation of symptoms among the geriatric population that includes physical, psychological, and social components. Predictive of frailty among older homeless adults are age, gender, nutrition, resilience, and utilization of health care. Some 16.4 percent of the homeless adult population meet diagnostic criteria for frailty (Brown et al., 2013; Salem & Ma-Pham, 2015). During a 2015 study of frail and pre-frail homeless women who were primarily over age 50, 70 percent indicated they had fallen over the prior year, with 35 percent having fallen in the previous 30 days. The women also reported that walking on concrete was hard on the hips, and pain medication was necessary if they were going to be able to remain sober. They described a desire to obtain preventive health care such as colonoscopies and other cancer screening tests, while at the same time expressing fear of diagnostic or medical procedures. Many of the study participants had the perception that health care providers possessed an attitude which hindered their responsiveness to the needs of homeless women (Salem & Ma-Pham, 2015).

Until homeless adults reach the age of 62, when they become eligible for social safety net programs for the elderly such as subsidized housing, and at age 65 when they become eligible for Social Security and Medicare, they may not meet criteria for some government assistance programs. Even when they reach the age eligibility requirement for subsidized housing, there is a shortage of affordable housing for the elderly, with nine seniors waiting for every one currently occupied unit. The first step in addressing the health care needs of this population is to provide housing by implementing the rapid re-housing and Housing First approach (National Coalition for the Homeless, 2018d; National Coalition for the Homeless, 2018e).

In summary, homelessness negatively affects the health of persons across the life span. Nurses must be able to identify the precursors to homelessness and anticipate the effects of homelessness on physical and psychological well-being in order to be able to advocate for effective prevention (Fig. 33.3). Innovative responses to serving the health care needs of those who are homeless include nurse practitioner run clinics situated in soup kitchens, emergency night and day shelters, and other mobile health care units that bring health services to where people who are homeless congregate (Stevenson & Purpuro, 2018). Another response has been the development of respite facilities for those discharged from hospitals but are still quite vulnerable, with no

Fig. 33.3 Nurses must be able to communicate therapeutically with homeless individuals to assess their needs, create a plan of care, and effectively advocate for the patient.

home in which to return to recover from surgery or other medical procedures. Research on the effectiveness of respite care has demonstrated positive outcomes for these patients (National Health Care for the Homeless Council, 2018).

Unique Challenges and Barriers to Caring for Homeless Health. Just as people living in poverty have poor access to health care, so do homeless people. One of the topic areas in *Healthy People 2020* discusses access to health care. See the *Healthy People 2020* box for objectives that pertain to poverty and homeless persons. Even though they are at higher risk of physiological problems, homeless persons have greater difficulty accessing and understanding health care services.

HEALTHY PEOPLE 2020

The following is a sampling of goals for addressing social determinants of health among poor and homeless people:

- **AH-5.1:** Increase the proportion of students who graduate with a regular diploma, 4 years after starting 9th grade.
- **AHS-3:** Increase the proportion of persons who are unable to obtain or delay in obtaining necessary medical care, dental care, or prescription medicines.
- **HC/HIT-1.1:** Increase the proportion of persons who report their health care provider always gave them easy-to-understand instructions about what to do to take care of their illness or health condition.
- **EH-19:** Reduce the proportion of occupied housing units that have moderate or severe physical problems.
- **IVP-42:** Reduce children's exposure to violence.

From Office of Disease Prevention and Health Promotion (ODPHP): *HealthyPeople.gov: social determinants of health,* Washington, DC, 2018, ODPHP. Retrieved from https://www.healthypeople.gov.

The attitude of some health care professionals working with the homeless is a significant barrier to accessing health care. The homeless frequently cite the lack of respect and dignity with which they have been treated by providers when accessing care (Salem & Ma-Pham, 2015; Stevenson & Purpuro, 2018). Homeless persons report issues regarding communication and trust with their health care providers, particularly among women seeking gynecologic care, who may be uncomfortable with male providers. The homeless provide accounts of feeling judged and stygmatized, unheard, and rejected. In a 2018 study of homeless women seeking breast and cervical cancer screening in Canada, one woman told of routinely being turned away when seeking a primary care physician. Another reported being told she could not return to see her physician until she completed a series of diagnostic tests. Power imbalances between the homeless patient and the health care provider can be an impediment to therapeutic communication and trust building (Moravac, 2018).

Inadequate self-care is another barrier to addressing health among the homeless as they often give lower priority to health promotion and health maintenance than to obtaining food and shelter (Roche et al., 2018). They spend most of their time trying to survive. Just getting money to buy food is a major chore. In order to gather income, they may pick up odd jobs, beg, sell their blood or plasma, or sell drugs or sex for money.

Consider the case of an insulin-dependent diabetic man who lives on the street and sleeps in a shelter. His ability to get adequate rest and exercise, take insulin on a schedule, eat regular meals, or follow a prescribed diet is virtually impossible. Consider the following issues:

- How does a person buy an antibiotic without money?
- How is a child treated for scabies and lice when there are no bathing facilities?
- How does an older adult with peripheral vascular disease elevate his legs when he must be out of the shelter at 7 AM and is on the streets all day?

Preventive Services: Housing As a Nursing Intervention

The need for comprehensive, affordable, and accessible care for the nation's homeless population is huge. The federal government officially became involved with meeting the needs of the homeless in 1987 with the passage of the Stewart B. McKinney Homeless Assistance Act of 1987 (PL 100-77). Title 11 of the McKinney Act provided funding for outpatient health services; however, these services have often been insufficiently funded, and many needs go unmet. The McKinney Act grants homeless children the same access to education as permanently housed children. This act also created the U.S. Interagency Council on the Homeless (USICH) to coordinate and direct federal homeless activities. Housing assistance is available through the U.S. Department of Housing and Urban Development (2018c), which, along with many other federal agencies, funds programs to help the homeless. In the following section on prevention, an illustration is given of how to access services in a state to assist homeless persons.

The ICH is made up of the heads of 19 federal agencies that sponsor programs or activities for the homeless. The general goals of the ICH are to improve federal programs for the homeless through better coordination and linkages and by decreasing the amount of documentation required to qualify for benefits. By targeting the most vulnerable segments of the homeless population, the ICH intends to influence the problem of homelessness, particularly among children (United States Interagency Council on Homelessness, 2018b).

Essentially, the same government safety net programs available to the poor are also available to those who are homeless. Although some homeless persons are eligible for safety net programs such as Medicaid, TANF, WIC, or Social Security, they may not know they are eligible or how to apply, or they may lack the official identification necessary to apply for these benefits. Utilization rates for safety net programs among poor families and sheltered homeless families are similar, with the exception of WIC, which is underutilized among sheltered homeless families (Burt et al., 2016).

Homeless women with children under the age of five are eligible to receive nutrition assistance from the U.S. Department of Agriculture's WIC program. Persons accessing WIC benefits receive vouchers entitling them to free nutritious foods and

infant formulas from local grocers. The Supplemental Nutrition Assistance Program (SNAP) is another source of nutritional assistance for the homeless and is not limited to women with young children. The TANF cash assistance program can be a key source of income for homeless families.

Preventive services related to homelessness are focused on providing affordable, adequate housing. Typically, those who are homeless are housed in emergency shelters that are only open at night and in many cities, only on extremely cold nights. Emergency shelters are an important stopgap measure during a crisis. Those who have been homeless longer may find assistance in permanent **supportive housing.** This type of housing is subsidized by federal, state, or local governments or nonprofit organizations. Supportive housing is typically reserved for vulnerable homeless population groups, such as the chronically homeless, persons with physical and mental disabilities, women and children who are victims of abuse, and those recovering from alcohol and drug use (U.S. Department of Housing and Urban Development, 2016).

Low-income housing, if available, is accessible through Section 8 housing vouchers or through public housing. Both of these subsidized programs generally require the participant to be a U.S. citizen or eligible for immigration status, and applicants are denied housing if they have habits that might be detrimental to the housing community (U.S. Department of Housing and Urban Development, n.d.).

It is difficult to separate services for homelessness into primary, secondary, and tertiary levels of prevention because interventions related to homelessness can be assigned to more than one level. Affordable housing, for example, may qualify as primary prevention, but it could also be an important secondary or tertiary preventive intervention.

Under the public health model of preventing homelessness, strategies are aimed at risk reduction and include primary, selected, and targeted initiatives. Primary preventive services include universal, selected, and targeted prevention strategies. Universal preventive services include poverty reduction, early childhood supports, affordable and subsidized housing, and old age pensions. Selected prevention strategies focus on groups that are at higher risk related to demographic, ethnic, and other inequities. These include school-based programs for youth, and anti-discrimination and anti-oppression strategies to address disparities related to minority populations. Targeted prevention strategies are aimed at populations at higher risk of homelessness because of certain characteristics, for example, LGBTQ youth. Nurses can form networks with other health professionals to educate policy makers and the public about the value of these preventive services. These programs could prevent homelessness from occurring at all, which would prevent many of its devastating sequelae.

Secondary preventive services target persons on the verge of homelessness as well as those who are newly homeless. Examples include rapid re-housing, case management, and shelter services. Nurses can work with the homeless and near-homeless to provide education about existing services and advocate for strategies that move public policy toward providing more comprehensive services for homeless and near-homeless persons.

Tertiary prevention for homelessness focuses on minimizing the impact of homelessness and working to ensure the individual/family never experiences another episode of being homeless. An important prerequisite for population-focused nursing practice is a sound understanding of the sociopolitical milieu in which problems occur. Nurses can influence politicians and other policy makers at the federal, state, and local levels about the plight of vulnerable homeless populations in their community.

Many states have programs that provide a broad spectrum of services that may interrupt the pattern of homelessness. Several follow the guidance of a program called Shelter Plus Care (subsumed in Continuum of Care programs). **Shelter Plus Care** is a program for individuals who need housing and structured social support; the goal is to stabilize those who are homeless and help them transition into permanent housing. The program offers long-term housing and supportive services for those who are homeless and who have mental illness, are in recovery from alcohol and drug abuse, or have HIV/AIDS. It also assists people on the brink of homelessness. Before the creation of Shelter Plus Care, many low-income persons found shelters to be their only resource when faced with a housing crisis. Shelter Plus Care offers an extensive set of neighborhood-based services to help people remain in their housing. The services offered include landlord mediation, budgeting, emergency rental assistance, and job training and assistance (U.S. Department of Housing and Urban Development, 2018b).

Nurses need to understand how to apply the levels of prevention to homeless persons. When nurses advocate for preventive measures for people who are either poor or are homeless, they often do so in the local or state policy arena. Nurses working in communities often need to advocate for affordable housing, community outreach services, health services, and other assistance programs for poor and homeless persons. The HUD Exchange Homelessness Assistance website lists a range of services for homeless persons that are organized by state. Go to the website and look at the topics for homelessness. There are several useful topics in the Populations & Issues drop-down menu. In addition, you can select a state and find contact information about shelters or other assistance. Each state site offers extensive information for homeless persons, beyond housing. Although each state has some unique offerings, they typically provide information about shelters, including special shelters for victims of domestic and sexual violence. The sites generally provide information about services for homeless veterans, persons with disabilities, transitional housing for offenders who are re-entering the community; and about meals, clothing, health care, skills training, counseling, and legal assistance. Although the offerings provided by states are unique, there are three agencies common to all states: Salvation Army, United Way, and Medicaid (U.S. Department of Housing and Urban Development, 2018b).

LEVELS OF PREVENTION

Homelessness

Primary Prevention
Work with a local school district to provide the free breakfast and lunch program to all students.

Secondary Prevention
Screen public school students for homelessness or "doubling up," and connect these students and their families to comprehensive services.

Tertiary Prevention
Connect homeless students with the Summer Food Service program during the summer months when school is not in session.

Accessing Health Care

Unfortunately, health care for homeless persons tends to be fragmented and limited in scope. Health care services are available in every state through Health Care for the Homeless (HCH) services, as well as a variety of privately funded programs, yet care is often sought during an acute health crisis and care is rendered via emergency department visits (Roche et al., 2017; Stevenson & Purpuro, 2018). Safety net hospitals and publicly funded insurance programs such as Medicaid, Medicare, and the Children's Health Insurance Program often cover the costs for these visits.

Following expansion of Medicaid through the Affordable Care Act (ACA), health coverage among HCH program participants rose from 45 percent to 67 percent. However, subsequent changes to the ACA, including a work requirement in some states, may decrease the number of homeless who qualify for Medicaid. The homeless have a number of barriers to employment, including poor mental health and other physical conditions, lack of consistent work history, or a history of incarceration, all of which hinder their ability to obtain and keep work (Center on Budget and Policy Priorities, 2018; Warfield et al., 2016).

Heath Care for the Homeless has been subsumed by the **Consolidated Health Centers (CHCs)** program, which combines federally funded health centers that work with the homeless, migrant and seasonal farmworkers, public housing residents, and young children. By accessing HRSA Find a Health Center, you can explore CHCs that are located in your area and obtain directions and a phone number for the facilities. Once you have identified local facilities, you may determine the array of services available by exploring the individual facility websites.

Some of the most useful health care programs for the homeless began with grants from private funding agencies, such as the Robert Wood Johnson Foundation and the Pew Charitable Trusts. Projects funded by these agencies have followed sound public health principles by encouraging community involvement, public/private partnerships, and commitment to outreach (Institute of Medicine, 1988). Most of these projects rely heavily on nurse practitioners and physician assistants to deliver care in collaboration with physicians, nurses, and social workers. In recent years, many schools of nursing have received funding to establish nurse-managed centers for the homeless. See Chapter 20 for information on nurse managed centers Both faculty and students provide a range of services in these centers.

UNIQUE ROLE OF THE NURSE

Nurses play a critical role in the delivery of care to poor and homeless people. To be effective, nurses need strong physical and psychosocial assessment skills, current knowledge of available resources, and an ability to convey respect, dignity, and value to each person. Nurses need to be able to work with poor and homeless clients to promote, maintain, and restore health. Nurses must be prepared to look at the whole picture: the person, the family, and the community interacting with the environment. The following strategies are important to consider when working with homeless individuals, families, and populations:

- *Show respect, compassion, and concern.* Poor and homeless clients are defeated so often by life's circumstances that they may feel they do not deserve attention. Listen carefully and empathize with clients so they know you believe they are worthy of care. Because clients respond well to nursing interactions that demonstrate respect, it is helpful to use reflective statements that convey acceptance and understanding of their situation. Examples include the following: "I understand you are having difficulty taking your medications regularly because sometimes it comes down to eating instead of buying the medication, is that right?" Or another approach might be "I can see how being unable to cover the co-pay for medications would keep you from taking them regularly. Would you be open to ways in which I can help make sure you are able to do both?"
- *Create a trusting environment.* Trust is essential to the development of a therapeutic relationship with poor or homeless persons. Many clients and families have been disappointed by their interactions with health care and social systems; they become mistrustful and see little hope for change. If you don't know the answer to a question, say, "I don't know the answer, but I will try to find out. Let me make a few phone calls and I will let you know Friday." By following through and doing what they say they will do, nurses can establish trusting relationships with clients. Reliability helps to build the foundation for a trusting relationship.
- *Do not make assumptions.* A comprehensive and holistic assessment is crucial to identifying underlying needs. Just because a young mother with three preschool children misses a clinic appointment does not mean that she does not care about the health of her children. She may not have transportation or the ability to pay for services. Find out the reason for the absence and help solve the problem.
- *Coordinate a network of services and providers.* Working with poor and homeless people is challenging because of their multiple and complex needs. Many services exist, but often the people who could benefit are unaware of their existence. Developing a coordinated network of providers involves conducting a thorough assessment of the service area to identify federal, state, and local services available for poor and homeless clients. Where are the food banks and what are their hours? Where can you get clothing? What programs are available in local churches and schools? How do people access these services? What are the eligibility requirements? How helpful are the people who work at the service agencies? What service is provided to eligible individuals and

families? Nurses can identify these services and help link families with appropriate resources. In addition, a thorough assessment of available services for homeless persons in a nurse's service area can identify significant gaps in essential services. Once these gaps are identified, nurses work with other health care providers and with community members to advocate for necessary services for homeless clients.

- *Advocate for accessible health care services and affordable housing.* Poverty and homelessness create barriers that prevent access to health care services. Nurses can advocate for accessible and convenient locations of health care services. Neighborhood clinics, mobile vans, and home visits can bring health care to people unable to access care. Coordinated services such as primary care and mental health care at a central location often improves client compliance because it reduces the complexity and stress of getting to multiple places. By advocating for affordable housing, nurses are engaging a universal, primary prevention technique designed to help stabilize low-income families and prevent homelessness.
- *Focus on prevention.* Nurses can use every opportunity to provide preventive health care and health promotion teaching. Preventive health care is often overlooked among impoverished or homeless populations. Important health promotion (primary prevention) topics include child and adult immunization, and education regarding sound nutrition, foot care, safe sex, contraception, and prevention of chronic illness. Screening for health problems such as tuberculosis, diabetes, hypertension, foot problems, and anemia is an important form of secondary preventive health care among the homeless population. Knowing what other screening and health promotion services are available in the target area, such as nutrition programs, job-training and educational programs, housing programs, and legal services, is important. All these services may be included in a comprehensive nursing plan of care. See the How To box below to learn ways to evaluate the concept of homelessness.

HOW TO Evaluate the Concept of Homelessness

- What is it like to live on the streets?
- What issues might confront a young, African American, transgender youth inside a homeless shelter?
- What really causes homelessness?
- What goes through your mind when confronted with a person on the street asking for money to buy a sandwich or catch a bus? How do you respond?
- How is your response different (or not) when a young mother with children asks you for money?
- How do you react to the smell of urine in a stairwell or elevator?

- *Know when to walk beside the client and when to encourage the client to move forward on his or her own.* This area is often difficult for the nurse to implement. Nursing interventions range from extensive care activities to minimal support. At times, nursing actions include providing encouragement and support or providing information. At other times, nurses may actually call a pediatrician to set up an appointment for a sick child and may call again to see that the appointment was kept. Nurses assess patients for the presence of strengths, problem-solving and coping ability of an individual or family, while providing information on where and how to gain access to services. For example, a local hospital may provide free mammograms for uninsured women. Women who qualify for this free service may not take advantage of it because they are afraid the procedure will hurt, or they are fearful that they may have breast cancer. Nurses can find out about this important service, inform the women of the service, teach them about the importance of preventive care, and assess and deal with fear and anxiety. The challenge for the nurse becomes choosing whether to schedule the appointment for the woman or to simply provide a referral sheet, knowing that she may not follow through. The choice is not clear, but the goal is to make available a needed screening intervention without taking away the woman's right to have power over the process.
- *Develop a network of support for yourself.* Caring for poor and homeless persons is challenging, rewarding, and at times exhausting. It is important to find a source of personal strength, renewal, and hope. The people you encounter are often looking to you to maintain hope and provide encouragement. Discover for yourself what restores and encourages you. For some nurses it is poetry, music, painting, or reflective practices such as mindful meditation or yoga. For others it is a walk in a peaceful place, a weekend retreat, a good run, a workout at the gym, or meeting with other nurses who are engaged in the same work. Be attentive to your own needs, and create the time and space to restore your spirit.

CHECK YOUR PRACTICE

If you are providing services in a center for homeless families, what resources in your community would you investigate to determine if all services available to this family are being met?

The Linking Content to Practice box describes how to apply selected core public health and public health nursing competencies to the care of poor and homeless people.

LINKING CONTENT TO PRACTICE

When nurses provide care to people who are poor and/or homeless, they use the nursing process that is core to all registered nursing practice. Specifically, nurses assess by gathering a comprehensive set of data on the health status of an individual or population (standard 1); make a diagnosis and set priorities (standard 2); identify expected outcomes and develop a plan based on the population diagnosis and best practices (standard 3), and implement and evaluate the chosen plan (standards 4 and 5) (American Nurses Association, 2017).

Similarly, selected core competencies for public health professionals can be clearly used in providing care to this vulnerable population. For example, use of the ecological perspective to determine health risks of an individual or population is listed as an essential core competency in Domain 1 of the 2018 Quad Council Coalition's Community/Public Health Nursing Competencies. This perspective is used to assess the relationship of multiple determinants of health and health status as well as outcomes for vulnerable populations. In Domain 4, the competencies pertaining to cultural awareness are crucial to working with impoverished and homeless populations. It is essential that the nurse develop strategies to appropriately care for those with diverse backgrounds, taking into consideration socio-cultural and behavioral factors relative to access, availability, acceptability, and delivery of services in public health (Quad Council Coalition, 2018).

PRACTICE APPLICATION

Tonya Sims, a single mother with AIDS, lives in an apartment with seven other family members and her children, who are HIV positive. Ms. Sims does not often keep her children's numerous appointments at the immunology clinic. How do you respond?

A. Make an unsolicited telephone call or visit Ms. Sims and her family to let them know they are important and that you are thinking about them.
B. Call child protective services to report the failure of Ms. Sims to keep her children's appointments; she is noncompliant and neglectful of her children.
C. Do a more thorough assessment to determine why appointments are missed.

Answers can be found on the Evolve website.

KEY POINTS

- The definition of poverty varies depending on the source consulted. The federal government defines poverty on the basis of income and family size. The multidimensional approach takes a more holistic view, defining poverty by considering deficits across health, standard of living, and monetary domains. Newer adaptations of the multidimensional approach consider the significance of social relational health to poverty.
- Racism has played and continues to play a significant role in creating and perpetuating poverty and health inequities among minorities in the United States.
- Factors which impact the prevalence of poor persons in the United States include race and ethnicity; education level; increased substance abuse, including opioids; the number of households headed by women, who also face lower wages than their male counterparts; wage stagnation; reduced Social Security payments; and political reluctance to further advance such anti-poverty initiatives as increasing the minimum wage to a "living wage."
- Poverty affects the health status of people across the life span, and the impacts are disproportionately greater among "at-risk" populations such as single mothers, women, and children; LGBTQ youth; and minorities.
- Poor persons have higher rates of chronic disease and illness and worse outcomes, higher infant mortality, shorter life expectancy, complex multi-morbidity, and lower rates of high school graduation and home ownership.
- The impact of poverty on children is due in large part to the level of toxic stress they encounter as a result of living in poverty, which can harm the developing brain, impair relational health, and leave them at a higher lifetime risk of chronic disease and early mortality.
- Poverty affects both urban and rural communities. The poorer the community, the greater the proportion of residents who are members of a minority. Poverty may be more difficult to identify in rural communities because poor persons may be hidden from view.
- To understand the concepts of poverty and homelessness, consider the historical, political, and social factors that influence poverty and homelessness, and your personal beliefs and attitudes.
- Factors contributing to homelessness include insufficient availability of low-cost housing; poor health; mental illness; substance abuse and in particular, opioid use; lack of consistent, longitudinal treatment for mentally ill persons; intimate partner violence; and family dynamics which cause children and youth to leave home.
- The number of homeless children between 2016 and 2017 decreased by 5 percent, though the rate increased by 6.7 percent among young adults aged 18-24. Nearly 60 percent of homeless people in families were children under age 18, the vast majority of which were sheltered. The number of unsheltered homeless young adults rose by 9 percent.
- The complex health problems of homeless persons include chronic and infectious diseases; exposure to violence and trauma; and mental health problems.
- The homeless face unique challenges in caring for their health, including limited access to and ability to pay for health care, poor self-care, a limited understanding of available treatment options, and the attitude of some health care providers.
- Nurses have a critical role in assessing the health of persons who are poor and homeless and providing access to preventive care, supportive resources, and health care. Nurses bring to each client encounter the ability to assess the client's social determinants of health and to intervene in ways that restore, maintain, or promote health. By intervening early and using a coordinated systems approach, nurses can minimize the effects of poverty and halt a progression to homelessness and/or chronic homelessness.

CLINICAL DECISION-MAKING ACTIVITIES

1. Examine health statistics and demographic data to identify the rate of poverty and homelessness in your geographic area. What programs or services are available to improve social interconnectedness/relational health among impoverished or homeless populations? Parental support? Homeless youth? LGBTQ populations? What resources and agencies are available in your area to support homeless persons? What services are available from federal, state, and local sources? Identify a specific geographic region and assess this target area in terms of services for poor and homeless persons. Do a literature search to identify state-of-the-art, evidence-based interventions for poor and homeless persons. Compare the recommended programs and interventions with those available in your target area. How does your area

measure up? Give some specific recommendations about how you would fill the gaps.

2. Discuss government safety net programs with other students. How does our safety net work to reduce poverty and homelessness? Who receives TANF? Who receives SNAP? Who is eligible for supplemental security income (SSI)? How do people apply for these benefits, and are they difficult to get? What are the strengths and weaknesses of safety net programs in the United States, compared to other first world programs? What do you believe would better address the issues of poverty and homelessness in the United States? Give details of your ideas for changing our anti-poverty systems. Identify federal and state senators and representatives in your districts. Where do they stand on the issues of reducing poverty through tax credits and government safety net programs? What are the financial impacts to the general public of funding these programs? What are the impacts on individuals? What programs are needed in your community, and how could state senators and representatives support such programs?
3. Examine the specific programs identified in the preceding assessment. How and where do those who need services access them? Working with other students, make appointments with key persons in the agencies identified to find out what each agency offers, which particular aggregate is served, how clients access the services, who is eligible, how the agency receives funding, and what methods are used to evaluate the agency's ability to meet the needs of its targeted aggregates. Give some examples.
4. Identify nurses in your community who work with the homeless, medically underserved, or with other vulnerable groups. Invite these nurses to come to a class meeting to share their experiences. What constitutes a typical workday? What are the rewards and challenges of working with vulnerable populations? How do they deal with the frustrations and challenges of their work? What advice might they offer to students working with vulnerable populations? What programs do they recommend? How would they advocate for vulnerable populations in the policy arena? How would you?
5. Imagine yourself as a nurse working in a homeless shelter or making a home visit to a family in an impoverished neighborhood. How have your life experiences and education prepared you (or not) for these situations?

Migrant Health Issues

Candace Kugel, BA, MS, FNP, CNM

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Define the terms *migrant farmworker* and *seasonal farmworker,* and discuss the lifestyle and work environments that contribute to their health status.
2. Discuss the difficulties with obtaining epidemiologic and health data on this population.
3. Describe occupational and common health problems of migrant farmworkers and their families and the barriers to securing health care.
4. Evaluate programs to determine effectiveness with encouraging health-seeking and health-promoting behaviors among migrant farmworkers and their families.
5. Analyze the role of the nurse in planning and providing culturally appropriate care to migrant farmworkers and their families.
6. Advocate for legislation and policy that would improve the lives and working conditions of migrant farmworkers and their access to health care services.

CHAPTER OUTLINE

Migrant Lifestyle
Health and Health Care
Occupational and Environmental Health Risks
Common Health Problems
Children and Youth
Cultural Considerations in Migrant Health Care
Nurse-Client Relationship
Health Promotion and Illness Prevention
Role of the Nurse

pesticide exposure, p. 760
political advocates, p. 768
seasonal farmworker, p. 756
traditional beliefs and practices, p. 765

Migrant and seasonal farmworkers (MSFWs) are essential to the agricultural industry in the United States, especially with the decrease in family farms and the increase in labor-intensive crops such as vegetables, fruit, nuts, and ornamental plants. Although the availability and affordability of food in the United States depend on these individuals, their economic status and social acceptance have not reflected the importance of their work. Estimates of the numbers of MSFWs in the United States vary, with sources identifying about 1.0 to 2.7 million hired farmworkers (U.S. Department of Agriculture, 2017). Numbers vary because of divergent methodologies for estimating numbers and the inherent difficulties in counting mobile populations. Large data sources each have unique limitations prohibiting a clear picture of the MSFW population.

According to the U.S. Department of Labor (2016a), a **migrant farmworker** is a seasonal farmworker who must travel to do farmwork and is unable to return to a permanent residence within the same day. A **seasonal farmworker** returns to his or her permanent residence, works in agriculture seasonally, and does not work year-round exclusively in agriculture. The term *MSFW* also includes migrant food-processing workers, who are defined in the same way as seasonal farmworkers but

The editors of this volume and the second author (CK) wish to acknowledge the significant contributions of Marie Napolitano to the previous edition of this chapter. Even more noteworthy has been her career as an educator and advanced practice nurse working to provide health care services to farmworker families.

work in food processing and are unable to return to a permanent residence on the same day.

The National Agricultural Workers Surveys (NAWS) have been a source of data about the farmworker population since 1989, with their most recent survey of data from 2013-2014 reported in 2016 (U.S. Department of Labor, 2016a). According to the most recent NAWS data, the proportion of migrant crop farmworkers appears to be decreasing by about 25 percent in recent years, whereas that of seasonal farmworkers is increasing (Carroll, 2016). Migrant and seasonal farmworkers share many demographic, cultural, and occupational characteristics. Much of the available information on agricultural farmworkers does not distinguish between migrant and seasonal farmworkers.

The majority of MSFWs are foreign born (72 percent) and predominantly Mexican (67 percent) (Carroll, 2016). The numbers of newly arrived indigenous migrant workers from southern Mexico and Central America are increasing. These individuals are at higher risk for exploitation due to language difficulties, poverty, and fear related to their legal status. Other workers include African Americans, Jamaicans, Haitians, Laotians, and Thais. The composition of the migrant and seasonal population can vary from region to region in the United States. According to the NAWS, 53 percent of MSFWs have legal authorization to work in the United States, and less than 1 percent of farmworkers are in the United States under a guest worker visa. Foreign-born farmworkers have spent an average of 18 years working in the United States, with more than 55 percent for at least 15 years.

According to the most recent NAWS data, MSFWs are typically young, with an average age of 38 years; 18 percent are less than 25 years of age. Interestingly, considering the nature of the work, 32 percent of MSFWs are older than 45 years of age. The majority of MSFWs are male (72 percent); more than 63 percent are married with an average of two children. The proportion of women working in agriculture is gradually increasing, bringing with it additional unique health care challenges. About 39 percent live away from all family members during their agricultural work. Thirty-one percent speak English well and 27 percent cannot speak English at all, though 74 percent report that Spanish is their primary language. The average school grade completed is eighth grade.

CHECK YOUR PRACTICE

Imagine yourself attempting to deliver treatment in a migrant camp to a toddler whose pertussis culture returned positive.

The camp is located in an isolated rural community. The toddler lives in a trailer with her parents and siblings and extended family members (13 individuals). The family must also be treated as contacts. None of these individuals speak English, so you have an interpreter with you. The family has just returned from picking strawberries all day in the fields adjacent to their trailer, and they are tired and hungry.

The family is willing to give medicine to the toddler because she is sick; however, they do not understand why they must take the medicine also, because they are not sick. In addition, the family tells you that they will not be able to take the midday dose because they have no water with them at work. Walking to the drinking barrel will take too long and they will lose income.

As a nurse, what would you do?

MIGRANT LIFESTYLE

Migrant farmworkers traditionally have followed one of three migratory streams: Eastern, originating in Florida; Midwestern, originating in Texas; and Western, originating in California. As workers increasingly travel throughout the country seeking employment, however, these streams are becoming less distinct. Migrant farmworkers are employed in fruit and nut (40 percent), vegetable (21 percent), horticultural (23 percent), field (13 percent), and miscellaneous (3 percent) agricultural venues (Carroll, 2016). Eighty-five percent of farmworkers are hired directly and 15 percent are labor contracted. The cyclic nature of agricultural work, along with its dependence on weather and economic conditions, results in considerable uncertainty for migrant farmworkers. These individuals and families leave their homes with the expectation of work at certain sites. Word of mouth from friends or family, newspaper announcements, or previous employment most often determine their destinations. On arrival, however, migrant farmworkers may find that other workers have arrived first or that the crops are late, leaving the farmworkers unemployed.

Migrant farmworkers are vulnerable to forced labor (labor trafficking). According to the Polaris Project (2018) labor traffickers "use violence, threats, lies, debt bondage, or other forms of coercion to force people to work against their will in many different industries." Trafficked individuals, especially those who are undocumented, need to work but can find themselves in appalling work and housing conditions without means to leave or report, fearful of retaliation. They may owe debt to their employers or recruiters from their home countries. Federal and state legislation exist against human trafficking, but in isolated agricultural areas enforcement is difficult. Although exact numbers are not available, the agricultural sector is recognized as one of the most common labor markets that involves foreign nationals trafficked in the United States (Urban Institute, 2014). The psychological stress of working in a forced labor arrangement can result in physical and mental health problems. Certain questions can identify a victim of forced labor and can be asked as part of a nursing assessment. The National Human Trafficking Hotline (2014) created a set of suggested questions for suspected victims, which includes:

- Do you have a debt to your employer or recruiter that you can't pay off?
- Is your job or work different than you were promised?
- Is there verbal or physical abuse at work?

If a minor is identified, then child protective services and law enforcement should be notified. Richards (2014) recommended involving social workers and others in the plan to assist a trafficked minor. The minor should not be left alone until services arrive. For an adult, obtain permission to contact authorities and get a social worker or agency involved. The National Human Trafficking Resource Center hotline (888-373-7888) should be contacted.

The way of life for any migrant farmworker is stressful. Some of the challenges of the **migrant lifestyle** include leaving one's home every year, traveling, and experiencing uncertainty regarding work and housing, isolation in new communities,

Fig. 34.1 Migrant farmworkers pick and package strawberries in the Salinas Valley of central California. (David Litman/Shutterstock.com.)

and a lack of resources (Fig. 34.1). Farmworkers may be paid an hourly or piece rate, and the specifics for payment differ depending on the location and type of work. Reports of average income for farmworkers have varied. According to the NAWS 2013-2014 statistics, farmworkers reported an average hourly income of $10.19. Although many farmworker families meet the income tests for federal and state assistance programs, undocumented workers are not eligible for most of these programs; for others, changing residence from state to state, lack of knowledge and lack of access to programs impede use of program assistance.

Migrant and seasonal workers often are exempt from the protection of labor laws such as Workers' Compensation as well as from some Occupational Safety and Health Administration (OSHA) protective provisions due to allowances such as small farm exemptions. Where laws do exist to protect agricultural workers, they may be minimally enforced because of lack of staff and resources. Laws have been enacted that intend to protect farmworkers (Farmworker Justice, 2014a). These include the Fair Labor Standards Act that addresses minimum wage, overtime pay, record keeping, and child labor standards. Farms with fewer than seven workers in a calendar quarter are exempt from minimum wage requirements and farmworkers are not included in overtime pay. The Migrant and Seasonal Agricultural Worker Protection Act mandates that farm contractors, employers, and agricultural associations must disclose employment terms, post information about worker protection at the worksite, pay workers what is due and provide itemized statements, and ensure that housing complies with federal and state safety and health standards. Employers and agricultural associations have made multiple attempts to weaken or void the law.

The Occupational Safety and Health Act's Field Sanitation Standards (U.S. Department of Labor, 2008) ensure drinkable water and accessible sanitation facilities. Another set of regulations apply to H-2A guest workers, which allows agricultural employers to hire temporary workers from other countries. These laws are also difficult to enforce and can place workers in a position where they are unable to protect themselves from abusive working conditions (Farmworker Justice, 2018).

As of January 2017, the U.S. Environmental Protection Agency (EPA) implemented revisions to the Agricultural Worker Protection Standard (WPS), regulations that safeguard farmworkers from harmful exposures to pesticides (EPA, 2018). The changes include restrictions related to the age of workers who handle pesticides, training of workers, and other protective practices related to pesticide application (Migrant Clinicians Network, 2017a).

Migrant and seasonal agricultural workers are considered a unique vulnerable population because of the factors cited here, including mobility, the physical demands of their work, social and often geographic isolation, language differences, and high rates of financial impoverishment. Although MSFW problems are numerous and creating solutions is difficult, some progress has been made in improving the condition of the farmworker population. For example, the latest analyzed NAWS data showed improvement in field sanitation conditions such as the provision of drinking water, field toilets, and handwashing facilities.

Housing

Migrant farmworkers often have trouble finding available, decent, and affordable housing. Housing conditions vary among states and localities, and housing arrangements and locations and types of housing differ for migrant and seasonal farmworkers. Housing for migrant farmworkers varies by employer and by region; it can be located in camps with cabins, trailers, or houses and may be near farms. The authors have seen migrant farmworker families living in cars and tents when housing was not available. A recent trend shows that fewer employers provide on-farm housing or labor camps, and farmworkers must rely on private market housing such as apartments or motels. Although research on the current status of farmworker housing is limited, localized studies have revealed numerous violations of housing regulations, including contaminated water, infestations, non-functioning sanitation facilities, and absent fire escapes and alarms (Arcury et al., 2012).

It is widely recognized that crowded conditions, poor sanitation, and proximity to agricultural fields and pesticides are common and contribute to health risks of workers and their family members (Farmworker Justice, 2014b). Because housing may be expensive, many men may live in one house or three families may share one trailer. The health risks of overcrowded housing range from spread of infectious disease to psychosocial effects. While paying for housing during the agricultural season, many farmworker families also support a home-base household. More federal and state programs are seeking to provide private sector housing to farmworker families such as by providing grants to nonprofit agencies serving farmworkers, though insufficient funds are available to meet the demand for farmworker housing.

HEALTH AND HEALTH CARE

Research literature provides only a glimpse into the health status of migrant farmworkers. National data needed to present a clear picture of farmworkers' health status are difficult to obtain because of such factors as high annual turnover, language, mobility, and immigration status. Regional and local cross-sectional health status studies allow some insights, however. In the past, two such reports from California especially highlighted the health issues of this population: *Suffering in Silence: A Report on the Health of California's Agricultural Workers* (California Institute for Rural Studies, 2000) and *In Their Own Words: Farmworker Access to Health Care in Four California Regions* (California Institute for Rural Studies, 2001). These reports showed a population at high risk for chronic disease, poor dental health, and mental health problems; higher rates of certain diseases such as tuberculosis (TB), anemia, diabetes, and hypertension; high levels of work injuries and chemical exposures; and detrimental physical and social environments for the children. Subsequent studies have continued to support the picture of a population with health issues similar to the general population but which are exacerbated by lack of access to services, poor continuity of care, occupational safety issues, poverty, and other social determinants of health (Kugel & Zuroweste, 2010).

Access to Health Care

The **Migrant Health Act**, signed in 1962, provides funds for primary and supplemental health services to migrant workers and their families. As of 2016, these funds are dispersed to 172 community health centers across the United States that serve as models for delivery of services to a difficult-to-reach agricultural worker population. **Migrant health centers** serve almost a million individuals across the country (Health Resources and Services Administration [HRSA], 2017), though estimates show that these clinics serve less than 15 percent of the entire migrant farmworker population. Others receive medical care from private physicians, health departments or emergency departments, or they do not seek help at all.

Migrant farmworkers have limited access to health care. The NAWS findings from 2013-2014 showed that 35 percent of the farmworkers interviewed had accessed health care services in the previous two years, and factors such as gender, immigration status, migrant status, English proficiency, access to transportation, health status, and access to health care services outside of the United States were associated with health care use (U.S. Department of Labor, 2016a).

Factors that limit adequate provision of health care services include the following:

- *Lack of knowledge about services:* Because of their isolation and mobility, migrant farmworkers lack the usual sources for information regarding available services, especially if they are not receiving public benefits.
- *Inability to afford care:* According to the latest NAWS report, 35 percent of farmworkers reported that they had health insurance. The Medicaid program, which is intended to serve the poor, often is not available to migrant farmworkers. Workers may not remain in a geographic area long enough to be considered for benefits, or they may lose benefits when they relocate to a state with different eligibility standards. Their salaries may fluctuate each month, making them ineligible during the times their salaries rise. Employers may not offer health insurance. Undocumented farmworkers are not eligible for Medicaid coverage. Therefore, most migrant farmworkers lack health insurance and state program assistance, which further hinders their access to care. In addition, only 12 states require employers to provide full Workers' Compensation insurance for agricultural workers, while in the remaining states coverage is limited or optional (MCN, 2015b; FJ, 2014a).
- *Affordable Care Act or health insurance subsidies:* Although it is difficult to determine numbers, many farmworkers do not receive employer-sponsored health coverage or subsidies because of the small farm exemption and the exclusion of seasonal workers who are employed less than 120 days in the employer's tax year. Undocumented workers are excluded from any employer and individual insurance mandates.
- *Availability of services:* Immigrants are treated differently, depending on whether they were in the United States before the welfare reform legislation of 1996, and depending on the category of their immigration status. Each state determines whether to fill any or part of the services gap to immigrants. As a result, many legal immigrants and unauthorized immigrants are ineligible for services such as supplemental security income (SSI) and the Supplemental Nutrition Assistance Program (SNAP, or food stamps).
- *Transportation:* Health care services may be located a great distance from work or home, and transportation may not be available or may be too costly.
- *Hours of services:* Many health services are available only during work hours; therefore, seeking health care during work hours leads to loss of earnings and potential loss of employment.
- *Mobility and tracking:* Migrant families move from job to job, but their health care records do not typically travel with them, leading to fragmented services in such areas as TB treatment, chronic illness management, prenatal care, and immunizations. For example, health departments are known to dispense TB medications on a daily or monthly basis, and adequate treatment for TB requires 4 to 12 months of medication. The migrant farmworker who moves for work must locate new health services in order to continue treatment. The Migrant Clinicians Network (MCN) Health Network program assists mobile patients with locating care and transferring medical records when they are enrolled in the program by a health care provider. This "bridge case management" helps maintain continuity of care for TB and other conditions requiring ongoing care for a mobile population (Tschampl et al., 2016).
- *Discrimination:* Although migrant farmworkers and their families bring revenue into the community, they are often perceived as poor, uneducated, transient, and ethnically different. These perceptions foster attitudes and acts of discrimination against them.

- *Documentation:* Unauthorized individuals fear that securing services in a federally funded or state-funded clinic may lead to discovery and deportation.
- *Language:* The majority of migrant farmworkers speaks a language other than English as their first language; most speak Spanish, with a growing number speaking indigenous dialects. Although migrant health centers may hire bilingual Spanish-speaking staff, interpretation services for localized dialects may be more challenging.
- *Cultural aspects of health care:* See the section Cultural Considerations in Migrant Health Care.

OCCUPATIONAL AND ENVIRONMENTAL HEALTH RISKS

The migrant farmworker population is defined by their engagement in agricultural work, and an understanding of the **occupational health risks** and exposures of that work is therefore critical in understanding the health status and health care needs of this population. Agricultural work ranks as one of the most dangerous industries in the United States. In 2016, the occupational category of agriculture, forestry, fishing, and hunting was reported as having the highest rate of occupational injuries and illnesses (U.S. Bureau of Labor Statistics, 2017).

Heat illness fatalities have been identified as especially significant. Agricultural work is performed in conditions that are particularly high risk for heat-related illness and death (Centers for Disease Control and Prevention [CDC], 2014). In addition, working conditions, such as standing on ladders, exposure to chemicals, and using machinery, produce occupational health risks for farmworkers who may be inadequately protected or educated. The physical demands of harvesting crops 12 to 14 hours a day take their toll on the musculoskeletal system. Stooping to pick strawberries, reaching overhead while on a ladder to pick pears, or lifting heavy crates can all cause musculoskeletal pain (Moyce & Shenker, 2018). Injuries such as sprains and strains, fractures, and lacerations are especially common. Other injuries include falls; amputations; crush injuries from tractors, trucks, or other machinery; injuries related to working with livestock; acute pesticide poisoning; electrical injuries; and drowning in irrigation ponds and trenches. Naturally occurring plant substances or applied chemicals can cause irritation to the skin (contact dermatitis) or to the eyes (allergic or chemical conjunctivitis). Farmworkers also spend considerable time in the sun, which is dangerous to the skin. Infectious diseases caused by poor sanitary conditions at work and home, poor-quality drinking water, and contaminated foods can result in acute gastroenteritis and parasites. Farmworkers are at higher risk for eye injuries because of the lack of eye protection devices; lack of knowledge about prevention of eye injuries; and exposure to chemicals, pollen, and dust. Chronic eye irritation and sun exposure lead to cataracts, pterygium, and cloudy lens (Quandt et al., 2013).

The inherent dangers of farmwork are magnified by the inconsistent and inadequate safety regulations in the industry (Liebman et al., 2013). Lack of a comprehensive surveillance system makes it difficult to know the extent of all injuries within the farmworker population. Because small farms are excluded from governmental annual injury surveys and maintenance of written injury reports, injury statistics for farmworkers are incomplete (Kresge Foundation, 2012). Injuries are often unreported by farmworkers themselves for fear of loss of work and deportation, and workers are inclined to self-treat with over-the-counter remedies for injuries.

Pesticide Exposure

The majority of the North American food supply is treated with pesticides. Organophosphate (OP) pesticides make up the largest group of pesticides in current use. These pesticides are known to be potential hazards. **Pesticide exposure** risk for farmworkers includes not only the immediate effects of working in fields that are foggy or wet with pesticides, but also the unknown long-term effects of chronic exposure to pesticides. Reported incidents of occupational exposures to pesticides are monitored by the National Institute for Occupational Safety and Health (NIOSH) SENSOR-Pesticides Database (Sentinel Event Notification System for Occupational Risk). A total of 13 states participate in this reporting system, and available data from 1998-2011 reveal that half of the reported occupational pesticide exposures occur in the category of farming, forestry, and fishing (NIOSH, 2017).

The location of the migrant farmworker's dwelling near fields or orchards can also be a major source of contamination for the worker and his or her family. "Take-home exposure" occurs when chemicals on clothes worn at work come into contact with farmworker children as parents embrace or carry their children (American Academy of Pediatrics, 2012). Organophosphate pesticide metabolites have been confirmed in farmworkers and their children.

The EPA Agricultural Worker Protection Standard (WPS) requires that farmworkers be given information about pesticide exposure prevention and safety (EPA, 2018). Due to the challenges of enforcing these regulations, however, migrant farmworkers may not receive this information, they may receive ineffectual training, or they may not understand the information. Also, migrant farmworkers may have preconceived beliefs about pesticides, such as that only weak workers are harmed by them.

The use of personal protection equipment (PPE) is recommended for those who handle pesticides, and the use of such equipment is part of the WPS training. Farmworkers may not have access to protective clothing or they may be unable to afford its purchase; alternatively, they may choose to disregard precautionary procedures and behaviors (such as wearing gloves) that affect their productivity. Although the WPS is in effect to minimize pesticide risk, migrant farmworker families remain at high risk for exposure. Lack of resources for monitoring pesticide exposure, culturally inappropriate educational methods, migrants' fear of reporting violations and being fired, and language differences are just a few barriers that hinder a safer pesticide environment for migrant farmworkers (Farmworker Justice, 2013).

Not all health professionals are educated to recognize and treat pesticide illness and therefore might attribute the

farmworkers' symptoms and physical findings to other causes. See the How To box below for ways to recognize the signs and symptoms of acute pesticide exposure. For additional information, see the EPA *Recognition and Management of Pesticide Poisonings* manual (2013).

HOW TO Recognize the Signs and Symptoms of Pesticide Exposure

- Signs and symptoms of acute pesticide exposure vary according to the amount and length of time of exposure. The majority of body systems can be affected by pesticide exposure.
- Acute health effects of pesticide exposure include a wide range of symptoms, including headache, dizziness, confusion, irritability, twitching muscles, muscle weakness, seizures, respiratory symptoms (shortness of breath, difficulty breathing, and nasal and pharyngeal irritation), gastrointestinal symptoms (nausea, vomiting, diarrhea, and stomach cramps), skin rashes, eye or skin irritation, memory loss, flushing, hot sensations, difficulty with concentration, mood changes, and unconsciousness. Symptoms vary depending on whether the pesticide poisoning is mild or severe.
- Effects of chronic exposure are not entirely known but have been related to such illnesses as cancer, Parkinson disease, infertility or sterility, liver damage, and polyneuropathy and neurobehavioral problems.
- If symptoms of pesticide exposure are suspected, the nurse should develop a pesticide exposure history. A good example of an exposure form can be found at https://www.migrantclinician.org.

Data from Environmental Protection Agency (EPA): *Recognition and management of pesticide poisonings,* ed. 6, 2013: Roberts JR, Reigart JR. Available at http://npic.orst.edu.

Effects of chronic pesticide exposure are difficult to study and document, though some research findings point to health impacts related to prolonged or repeated exposure. Of particular concern is exposure of agricultural workers to the widely used insecticides classified as organophosphates (OPs), which can be absorbed through inhalation, ingestion, or skin contact. Research findings of the health impacts of exposure to these products include a wide range of neurological effects, some cancers, reproductive disorders related to endocrine disruption, and developmental disorders in children (Curtis & Sattler, 2018). In spite of these findings, policies regarding the use of these products continue to be under debate at the time of this writing.

COMMON HEALTH PROBLEMS

Migrant and seasonal farmworkers suffer from the same acute and chronic health problems as other populations in the United States. Factors related to their lifestyle and racial or ethnic group membership, however, place them at risk for certain **health disparities** compared with the general population and cause them to have more frequent and more severe health problems than the general population. Health center program data (NCFH, 2016), collected in 2016 from 165 Health Resources and Services Administration health centers serving this population, showed that hypertension, diabetes, otitis media, asthma, depression, and anxiety affected the greatest number of patients identified as agricultural workers.

MSFWs may not know that symptoms such as diarrhea or fever might indicate a more serious health problem, and they often do not seek early treatment. Lack of knowledge and, as discussed earlier, lack of access to health care services, can exacerbate treatable conditions. Undiagnosed health problems in this population such as sexually transmitted infections (STIs), cervical cancer, high blood glucose, high blood pressure, high serum cholesterol, anemia, and untreated dental problems lead to serious health problems such as heart disease, diabetes, and periodontal disease (Kresge Foundation, 2012). For children, many may experience the protective effects of the "healthy immigrant phenomenon" in infancy, though lack of access to health care services and other lifestyle factors later in childhood can lead to a higher incidence of problems such as infectious diseases, asthma, behavioral health issues, ear infections, and skin and dental problems (AAP, 2013). The lack of continuity of care and good record keeping often lead to the children being either over- or under-immunized (McLaurin & Liebman, 2012).

Women who work in agriculture experience reproductive health risks related to occupational health factors, as well as the lack of access to health care and health care information. As a result, farmworker women may experience work-related exposures and may not receive adequate prenatal care. Unfortunately, current data on migrant farmworker women and pregnancy outcomes are limited, although the lack of access to prenatal care for uninsured and undocumented women is a significant concern in the health care community (ACOG, 2015). Loss of Medicaid coverage for prenatal care for migrant women and lack of state coverage through the Children's Health Insurance Program (CHIP) in Nebraska resulted in late entry to prenatal care and an increase in pregnancy complications such as fetal abnormalities (Hopewell, 2011). Study findings have shown associations between pesticide exposures and adverse pregnancy outcomes such as low birth weight, intrauterine growth retardation (IUGR), preterm delivery, and stillbirth (ASRM, 2008). An incident that brought attention to the reproductive health risks of farmworker women occurred in 2004-2005 when four women who worked for the same company in the same fields in North Carolina and Florida during their pregnancies all experienced adverse outcomes. They gave birth within 8 weeks of each other to babies with congenital abnormalities (Calvert el al., 2007). The resulting investigation revealed numerous regulatory violations related to pesticide exposure of the women. Although it was not possible to establish a clear cause and effect relationship, this tragic outcome assisted with a heightened awareness of occupational health risk among those who care for farmworkers. See Box 34.1 for a description of the case management of a pregnant farmworker by MCN's Health Network.

Food insecurity is defined by the U.S. Department of Agriculture (2017a) as lack of access to "enough food for an active, healthy life." Ironically, access to adequate food and nutrition is a more prevalent problem for farmworkers than for the general U.S. population (Fuller, 2016). A variety of factors, including poverty, lack of transportation, and lack of access to a refrigerator and stove, contribute to food insecurity.

BOX 34.1 Case Management of a Pregnant Farmworker

MCN's Health Network is available to health care organizations to provide case management, referral, and record transfer services for patients who are likely to move during treatment. The following case illustrates how this program works for migrant women during pregnancy. Names and other details have been changed to protect patient privacy.

Xiomara was referred to Health Network in May of 2010 by a health department in a southeastern state that sent enrollment forms for this 21-year-old patient for the prenatal arm of Health Network. This referral set into motion a series of interactions that ensured that this young migrant woman would not fall through the cracks in the network of health care services for the underserved.

Once the enrollment paperwork was processed in MCN's Austin, Texas, office, the case was assigned to Gracie Castillo, one of four bilingual Health Network associates. Gracie proceeded to contact the patient, using the telephone numbers provided in the enrollment forms. The patient's sister answered the phone and was able to take a message asking the patient to return the call. Later that day the patient called back, and Gracie was able to establish a better understanding of her situation. Xiomara stated that this was her first pregnancy, she was at about three months, and she was staying temporarily at a motel. She mentioned that she was planning on moving—perhaps to Pennsylvania sometime during the summer—though she did not have an exact address at that point. She expressed concern about the cost of care involved with her pregnancy at her current location and had made an appointment at a different clinic. Gracie provided an overview of Health Network services and gave the patient a direct toll-free number to call in case immediate assistance was required.

The next step was to get medical records from the enrolling clinic. The health department had limited records, however, since they had only performed a pregnancy test and had then referred Xiomara elsewhere for prenatal care. Records were also requested from a secondary site where the patient had been seen. Xiomara called a few days later complaining that she had had some abdominal pain a few days earlier. She had gone to the clinic but was instructed to go to the emergency department since they only had an ob/gyn physician on site one day per week. She admitted that she had not gone because of concern about the cost of a hospital visit and was relieved that she was no longer having pain. Gracie was able to locate a hospital clinic in her area that was willing to work with her financial situation and arranged an appointment for Xiomara.

For two months the patient attended multiple appointments at the new location and touched base regularly with Health Network regarding her progress, and her pregnancy proceeded normally. She received appropriate lab work, an ultrasound, and also completed financial paperwork. Health Network obtained medical records from this site and included these in the patient's file.

When Gracie made a routine follow-up call to Xiomara about a month later, the patient did not answer her phone, despite numerous attempts and voicemails. It was not until three months later that the patient called Health Network reporting she had moved to another state and had recently gone to the emergency department there because of unbearable pain. She did not know her address in the new location and said she would call back when she knew exactly where she was staying. She mentioned that she would only be there for a couple of weeks. She called back with her address, and a clinic was found for her, her medical records were forwarded to this clinic, and an appointment was made. Health Network requested records and lab results for this visit a week after her appointment.

Another month passed when Xiomara did not answer her phone, but she finally returned a call in October, stating that she had just delivered a baby girl by cesarean section. She had returned to her original residence in the southeast and was concerned because of swelling, redness, and general discomfort around her surgical incision. She had attempted to make an appointment at the clinic, but the only one available was a week away. Gracie contacted the clinic to explain the situation and was able to get an appointment for the next day. Despite transportation difficulties and her husband's work demands, she was able to attend the visit and was given treatment. She recovered well and had a six-week postpartum visit, as Gracie had encouraged.

Typically Health Network considers a prenatal case to be completed after the postpartum visit takes place and all records are received. Xiomara provided an unusual opportunity for follow-up when she called Gracie four months after her baby's birth to express her appreciation for Health Network's involvement in her case. She confided that her relationship with her husband had dramatically changed after having her baby, and she was thrilled that she was no longer a victim of abuse.

According to protocol, this case was closed after being reviewed by MCN clinical staff. All notes for interactions with the patient and the various health care organizations involved in Xiomara's care are documented according to HIPAA standards. Through three moves, five health care organizations, and 43 contacts with Health Network, this patient's enrollment in Health Network reveals the impact of "bridge case management," not only through the mechanical services of scheduling appointments and transferring medical records, but also through the more personal avenue of direct communication with patients and their clinicians.

Specific Health Problems

Among the Latino population in the United States, the prevalence of diabetes is estimated to be three to five times greater than that of the general population, with higher rates of end-stage complications. Data specific to MSFWs are limited, and prevalence statistics for the Hispanic/Latino population are used as a proxy; the CDC (2017a) reported the incidence of diabetes in this population to be 8.4 per 1000 individuals, compared to 5.7 per 1000 for non-Hispanic whites. The lifestyle of migrant farmworkers makes it difficult to obtain proper nutrition, adhere to weight control measures, and procure continuity of health care and medication administration necessary for good diabetes control. The MCN Health Network assists providers with accessing information from farmworkers' previous providers who participated in the tracking program, thereby allowing for better continuity of care for diabetes (MCN, 2017b). Box 34.2 provides a brief description of an assessment with a diabetes focus for migrant farmworkers.

Disparities in both primary care and oral health services have been documented with the migrant farmworker population. Dental disease is one of the most common health problems for farmworkers of all ages. According to the CDC (2018a), Hispanic Americans experience higher rates of tooth decay and periodontal disease than do non-Hispanic whites. In an analysis of farmworkers who received care at federally funded health centers (Hu et al., 2016), it was found that 28.43 percent of MSFW patients were unable to get needed dental care, and 32.46 percent were delayed in getting needed dental care. Migrant children also have significantly lower rates of oral health treatment (NCFH, 2018a). Quandt et al. (2007) found

BOX 34.2 Example of Assessment With Migrant Farmworkers

The nurse, working with community partners and migrant camp gatekeepers, visits migrant camps to perform nutrition education (primary prevention) and to screen for diabetes (secondary prevention). If a high glucose level is obtained, the nurse refers the individual to a migrant health center or county health department clinic for a complete assessment. For those individuals in a given camp diagnosed with diabetes, the nurse plans and executes a culturally appropriate educational program on self-care for diabetes (tertiary prevention).

Fig. 34.2 Women working in agriculture face unique challenges, including sexual harassment and reproductive health risks. (David Litman/Shutterstock.com.)

that 80 percent of farmworkers in North Carolina had not received dental care in the last year, and that the few who did receive care returned to Mexico for dental care. Many of the people surveyed had inadequate knowledge of oral health and lack of access to care (and the resources to pay). Funding for increasing access to dental care has been insufficient to meet the needs of this population. Without insurance or personal resources and low Medicaid reimbursement, private dentistry is usually not an option for the farmworker.

Behavioral health issues, including depression, anxiety, post-traumatic stress disorder (PTSD), and stress, are areas of concern for migrants and may be related to isolation, discrimination, trauma, economic hardship, legal status, poor living conditions, and weather conditions that interrupt their work. MSFWs identify themselves as stressed independently of how they rate their physical health (Carvajal et al., 2014). A survey of California farmworker households (O'Connor et al., 2015) found that 22 percent of respondents reported *nervios* (a term used by some Western Hemisphere Hispanics to refer to increased susceptibility to mental stress and symptoms of nervousness). A study in North Carolina by Pulgar et al. (2016) found that almost a third of the farmworker women in their survey reported significant symptoms of depression, markedly higher than in the overall U.S. population. Related factors cited include job conditions, household responsibilities, taking care of children, and poverty. Farmworkers, especially males, are reluctant to seek mental health care.

Female farmworkers, especially the undocumented, are a vulnerable population suffering harassment and sexual abuse (Fig. 34.2). According to a landmark report by Human Rights Watch (2012), harassment and sexual abuse are so common that female farmworkers see no escape from its occurrence and believe it is part of the job. The report identified sexually charged language, unwanted touching, stalking, and rape as common occurrences. Most victims do not report these abuses, often feeling powerless; however, many who have reported have not seen their perpetrators prosecuted (Yeung & Rubenstein, 2013). Recently, the U.S. Equal Employment Opportunity Commission filed lawsuits against employers in the Northwest as a means to address sexual harassment.

Similar to behavioral health issues, drug and alcohol use in migrant communities has been identified as a significant source (or result) of stress, without a clear picture of the scope of the problem in migrant farmworker communities. One study in North Carolina showed a wide variation in drinking patterns, with 26 percent of the farmworkers surveyed abstaining from drinking and 27 percent reporting heavy drinking (Grzywacz et al., 2007). Drinking alcohol poses safety hazards for farmworkers, such as accidents while driving and workplace injuries. Alcohol can also contribute to health problems, greater risk for human immunodeficiency virus (HIV) infection, violence in camps/home sites, domestic violence, and decreased funds for personal and family needs.

The incidence rate for tuberculosis is not known for migrant farmworkers; however, Oren et al. (2016) state that they are "among the highest-risk populations for latent TB infection in the United States." According to CDC statistics (2016), in 2015, Hispanics/Latinos accounted for 28 percent of the U.S. tuberculosis cases and of the TB cases among foreign-born people, Latinos represented 32 percent in 2015. Being born outside of the United States is a significant risk factor for TB; in 2016, foreign-born individuals had a rate of 14.7 per 100,000, or 14 times higher than among native-born individuals (CDC, 2017b). The majority of migrant farmworkers are foreign-born and Hispanic/Latino. MSFWs are thus at increased risk for TB because of higher rates in their countries of origin (Latin America, Haiti, and Southeast Asia), crowded housing, and malnutrition. Required long-term treatment is difficult to complete because of mobility, fear of deportation, language barriers, and lack of access to services. Incomplete treatment contributes to resistant TB (Tschampl et al., 2016). The MCN Health Network TB tracking program fosters continuity and monitoring of TB treatment as migrant farmworkers move to different work and home sites, reporting a treatment completion rate of 83.9 percent of patients enrolled from 2005 to 2013 (MCN, 2015a).

Accurate HIV data for migrant farmworkers is also difficult to obtain; however, in the absence of adequate population-based data on farmworkers, useful inferences may be drawn from statistics collected for Latinos in the United States, a group known to be disproportionately affected and infected by HIV. Latinos make up about 18 percent of the U.S. population, but in 2015, about 23 percent of all newly diagnosed cases in the United States were among Latinos. HIV/acquired

immunodeficiency syndrome (AIDS) cases among Latinos increased by 2 percent from 2010 to 2014, according to the CDC (2018b). Risk factors for this population include lack of accurate knowledge, barriers to health care services, limited education, poverty, longer time in the United States, sharing needles for common medications such as vitamins and antibiotics, unprotected sexual activity, isolation and separation from families, available prostitution, migration across borders that results in the spread of HIV, and needle-sharing through amateur tattooing (NCFH, 2018b).

Although there is not a clear statistical picture of the health status of the MSFW population, available data do indicate that this population suffers from challenging health problems that are difficult to address. Since migrant and seasonal farmworkers experience the recognized health risk factors of poverty, stress, occupational exposures, discrimination, and poor access to care, it is clear that this is a highly vulnerable population. Nurses can play a vital role in addressing and changing this situation.

CHILDREN AND YOUTH

Migrant farmworker parents want a better future for their children. In fact, this strong desire is the catalyst for many farmworkers to leave their country of origin. These children often appear to the outsider as happy, outgoing, and inquisitive. They suffer, however, from an array of health problems, including malnutrition (vitamin A and iron deficiencies), infectious diseases (upper respiratory tract infection, gastroenteritis), dental caries (from prolonged bottle-feeding, bottle-propping, and limited access to fluoride and dental care), inadequate immunization status, pesticide exposure, injuries, overcrowding and poor housing conditions, and disruption of their social and school life, which, not surprisingly, lead to anxiety-related problems. A study of migrant farmworker children in Georgia from 2003 to 2011 found an elevated prevalence of obesity, high blood pressure, stunting, and anemia in older children (Nichols et al., 2014). Moving between states and/or being undocumented can affect migrant children's eligibility for Medicaid and the state Children's Health Insurance Program (CHIP). Children living with at least one undocumented parent experience worse health and less access to care and use of public assistance programs. Undocumented parents may be fearful of approaching health services even if their children are eligible for coverage (AAP, 2013).

Children may be separated from their farmworker parents for periods of time when parents leave for work away from the home site. Children experiencing their parents' stress with work, housing, and income when they accompany their parents can result in physical, behavioral, and emotional problems (Fig. 34.3). A survey done by Human Impact Partners (2013) found that, although 82 percent of children of undocumented immigrants in the United States are U.S. citizens themselves, the stress and fear of deportation of their patents had an impact on the mental health of the children. Twenty-nine percent of undocumented parents reported that their child felt afraid all or most of the time over the past month, compared to 12 percent for documented parents.

Fig. 34.3 Children of migrant farmworkers experience many hardships. They may have to help with the agricultural work or childcare while trying to maintain their schoolwork. (Diana Mary Jorgenson/Shutterstock.com.)

Since 2014, the United States has experienced surges of unaccompanied minors crossing into the country from Latin America in search of sanctuary and/or work, with over 60,000 arriving in 2014. Although these young people often intend to unite with family members in the United States, they bring with them an array of health concerns that arise from the hardships they have experienced in their travels (Robinson, 2015).

Children of migrant farmworkers may need to work for the family's economic survival. Migrant adolescents who work in agriculture warrant attention. Although the exact number of youth who work in the fields is not known, the National Institute for Occupational Safety and Health estimated that 266,000 youth less than age 20 were employed on U.S. farms in 2014 (NIOSH, 2014). Some adolescents accompany their parents to work or come with others such as an uncle; however, many adolescents migrate alone. Health care providers may believe that they are prohibited from caring for minor unaccompanied youth; however, they should be aware of their state's laws on minors' consent to care that could increase access to care for these youth.

Federal child labor laws have multiple exclusions for agricultural settings. The Fair Labor Standards Act (FLSA) includes restrictions based on age and hours worked. Children younger than 12 years can work on a farm with fewer than seven full-time workers. Children as young as 12 years old can work on a farm if they have parental permission or if their parent is also working on the farm. Children ages 14 or 15 may work in non-hazardous positions in agriculture but not during school hours. Youths age 16 and older may work in any farm job at any time, including performing hazardous work with no

restrictions on hours. Some additional protection is provided to children by the majority of states, such as limiting the number of hours per day and week a child can work (U.S. Department of Labor [USDOL], 2016b).

Federal law does not protect children from overworking or by limiting the hours they work outside of school. Therefore, children may work until late in the evenings or very early in the mornings every day of the week if not protected by state law or if inadequately monitored. Personal communication with Marie Napolitano and adolescent farmworkers in Oregon revealed that they were frequently too tired after working to do homework and to attend classes. They may leave school before the end of the term to travel with their families and arrive late to start school in the fall. Child farmworkers may attend three to five different schools each year as they migrate from one farm to another, and these frequent changes in schools and constant fatigue are obvious obstacles to academic success.

Availability of childcare services is a concern for farmworker parents (Liebman et al., 2017). Young children of migrant farmworkers stay home to care for younger siblings and other children. The Migrant Head Start Program is a safe, healthy, and educational option for children six weeks to five years old, though inadequate funding means there are not enough services in all locations for migrant children. The Migrant Education Program is a state- and nationally sponsored summer school program for farmworkers' children more than five years of age. This program is also not available to all eligible migrant youth, especially those living in isolated rural areas.

CULTURAL CONSIDERATIONS IN MIGRANT HEALTH CARE

To provide culturally effective care to migrant farmworkers, nurses need to be knowledgeable about the cultural backgrounds of these individuals. Because the majority of migrant farmworkers are of Mexican descent, this section focuses on Mexican culture. Although certain health beliefs and practices have been identified with the Mexican culture, the nurse must remember that beliefs and practices differ among countries as well as regions and localities of a country, and among individuals. Many of the aspects of Mexican culture described here are similar to Central American countries, though it is a multicultural region and the cultural backgrounds of Mexican and Central American immigrants vary depending on their place of origin and other factors. There are many indigenous groups in the region that speak their own group dialect and may not speak Spanish. Literacy skills may also be limited (36 percent of the NAWS respondents reported attaining a sixth grade education or less). Immigrants who are less educated, have fewer economic resources, and are from rural areas tend to possess more **traditional beliefs and practices** that are unique to their cultural background.

NURSE-CLIENT RELATIONSHIP

The nurse is considered an authority figure in the Latino culture and should show respect (*respeto*) to the individual, be able to relate to the individual on a personal level (*personalismo*), and maintain the individual's dignity (*dignidad*). Mexican individuals prefer polite, non-confrontational relationships with others (*simpatía*). At times, because of *simpatía*, individuals and families may appear to understand what is being said to them (by nodding their heads) when in actuality they do not understand. The nurse should take measures to validate understanding in these situations. The Mexican individual expects to converse about personal matters for the first few minutes of an encounter. They expect the nurse not to appear rushed and to be a good listener. Humor is appreciated, and touching as a caring gesture is seen as a positive behavior. In working with Latino migrant workers, learning some key Spanish words and phrases is an indication of a willingness to connect.

Mexican clients may not seek care with health professionals first. Instead they may consult with trusted and knowledgeable individuals in their family or community (the popular arena of care) or with folk healers (the traditional arena of care). Examples of the members of the popular arena include the *señora*, or wise, older woman living in the community; one's grandmother (*la abuela*); and the local parish priest.

Health Values

Family, in general, is a critical component of a Mexican individual's health care and social support system. In general, the female in the household is considered to be the caretaker, whereas the male is considered to be the major decision maker. Mexican women in certain families, however, have significant influence over most domestic matters, including health decisions. Grandmothers and sisters are highly significant to the wife (female) in the immediate family. They provide advice, care, and support. Not all Mexican immigrants have extended families in the United States. If not present, communication may be maintained with family in Mexico by telephone, though an effective support system for these individuals may be inadequate.

Love of their children, rather than concern for their own health, may encourage MSFW parents to adopt healthier lifestyles. An example is when the parents of a child with asthma choose to stop smoking. In Oregon, when asked if they protected themselves from pesticide exposure, Mexican migrant parents responded negatively in general. They were willing to change their behaviors, however, if their children would be protected from pesticides (Napolitano et al., 2002).

In the experience of the authors, the Mexican client may be more willing to follow the advice of another Mexican individual with a similar health problem rather than the advice of the health professional. For example, Mexican women with type 2 diabetes were more willing to ask and adopt the practices of others with diabetes than follow the redundant advice of physicians to take their medications, watch their diet, and exercise. One woman, who was unable to differentiate the symptoms of hyperglycemia and hypoglycemia, would drink a bottle of grape juice when she felt her "sugar high," as was recommended by her neighbor.

Although the majority of Mexican immigrants may identify themselves as Catholics, many Mexican individuals belong to

other religious groups. The individual's religion may influence his or her health practices such as birth control; however, the nurse cannot assume, for example, that a Catholic will not use some method of contraception. The Focus on Quality and Safety Education for Nurses box provides guidelines for client-centered care.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Patient-Centered Care

Recognize the client or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for patient's preferences, values, and needs.

Important aspects of patient-centered interventions include the following:

- **Knowledge:** Discuss principles of effective communication.
- **Skills:** Assess own level of communication skill in encounters with patients and families.
- **Attitudes:** Value continuous improvement of own communication and conflict resolution skills.

Patient-Centered Care Question

To provide patient-centered care, it is important not only to be able to communicate with the person(s) but also to understand the cultural perspectives that influence their health care practices. If you are caring for clients who live in migrant farmworker camps and you observe that they are allowing their children to work several hours both before and after they go to school, how would you approach the situation?

- Would you begin by speaking with the parents?
- Would you speak with the person who owns or manages the farm?
- What would your approach be to those with whom you speak?
- At what point would you consider involving community resources? If you choose this route, what resources would you consider?

Prepared by Gail Armstrong, PhD, DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing, based on QSEN Institute: *QSEN competencies*, 2018. Available at http://qsen.org.

Health Beliefs and Practices

In the Mexican culture, good health may be considered a gift from God. Another common perception of health is that a healthy person is one who can continue to work and maintain one's daily activities independent of symptoms or diagnosed diseases. The nurse should understand that a Mexican individual may not return for a clinic appointment because the client felt better or was capable of working that day. Likewise, Mexican immigrants may think illness is a punishment from God and may cite this belief as a rationale for why therapies have not cured them. This more commonly occurs with chronic illnesses.

There are four more common folk illnesses that a nurse may encounter with the Mexican client. These are *mal de ojo* (evil eye), *susto* (fright), *empacho* (indigestion), and *caída de mollera* (fallen fontanelle). Symptoms and treatments may vary depending on the individual's or family's origin in Mexico, and the client may be quite willing to discuss these concerns. Other cultural beliefs related to hot-cold balance, pregnancy, and postpartum behaviors (*cuarentena*) have been documented. When experiencing a folk illness, the traditional Mexican individual would prefer to seek care with a folk healer if possible. The more common healers are the *curanderos, herbalistas,* and *espiritualistas.* The most commonly used herbs are chamomile (*manzanilla*), peppermint (*yerba buena*), aloe vera, cactus (*nopales*), and wormseed or "Mexican tea" (*epazote*). Questioning the client about traditional healing practices related to a current complaint can be a helpful part of an assessment.

HEALTH PROMOTION AND ILLNESS PREVENTION

The same principles of health promotion and illness prevention apply to migrant farmworkers as to other U.S. populations. Health promotion and disease prevention may be difficult concepts for migrant workers to embrace, however, because of beliefs regarding disease causality, irregular and episodic contact with the health care system, and lower educational levels.

Health promotion begins by asking MSFW families which health topics would be of interest to them and whether they are familiar with the available resources to improve their health. Several migrant health programs have recruited current or former migrant workers to serve as outreach workers or community health workers (often referred to as *promotores* or *promotoras*) to assist in outreach and health education of the workers. Nurses can be part of the planning and training of health workers for outreach and educational programs. Evaluation to determine successful outreach educational methods can be undertaken by nurses. Such activities demonstrate the core competencies related to the domain of community dimensions of practice skills for public health nursing (Quad Council Coalition [QCC], 2018). Relevant skills include recognizing community relationships affecting health, collaborating with community partners to promote the health of the population, using group processes to advance community involvement, identifying community assets and resources, and promoting public health programs. The Linking Content to Practice box later in the chapter includes additional discussion of the Quad Council Domains of Public Health Nursing.

ROLE OF THE NURSE

The health of the MSFW population warrants a variety of actions by nurses. Working with this population can be challenging. Insufficient resources, short-term stays in a community, barriers placed by growers, discrimination, and unenforced legislation are just some of the obstacles that confront the nurse. Nurses, however, can make a difference in the health of MSFWs and their families.

In providing health care services, nurses can use primary, secondary, and tertiary prevention actions to help improve the health of migrant farmworkers, as outlined in the Levels of Prevention box. Primary prevention activities include education for the prevention of infectious diseases such as HIV, measures to reduce pesticide exposure, and immunizations in childhood and adulthood. Secondary prevention activities include screening for pesticide exposure, TB skin testing,

diabetes screening and monitoring activities, and diagnostic testing done for prenatal care. Tertiary prevention includes rehabilitation for musculoskeletal injury, especially low back pain, and treatments for lead poisoning and anemia.

LEVELS OF PREVENTION

Migrant and Farmworker Health Issues

Primary Prevention
Teach migrant workers how to reduce exposure to pesticides.

Secondary Prevention
Conduct screening for diabetes in adult farmworkers and for anemia in children in camps.

Tertiary Prevention
Educate migrant families regarding appropriate nutrition for an adult with diabetes or a child with anemia.

In this chapter, an overview of the lifestyle and health status of the MSFW population is presented. The public health nurse plays an important role in improving the health of this population. The Linking Content to Practice box reviews the core competencies for public health nursing relevant to working with MSFWs.

LINKING CONTENT TO PRACTICE

Core competencies within five of the Quad Council Coalition Domains of Public Health Nursing guide the nurse in working with migrant farmworkers. These domains are as follows: (1) Assessment/Analytic Skills, which include identifying, describing, and using data obtained from working with migrant individuals, families, and groups; (2) Policy Development/Program Planning Skills, which are directed toward knowing and applying policies, laws, and regulations toward the delivery of health programs and the protection of the migrant population; (3) Communication Skills, which are used to identify health literacy of the migrant farmworker and to communicate in a linguistic and culturally appropriate style; (4) Cultural Competency Skills, which allow the nurse to function in a culturally appropriate manner and to assist the public health organization to become more culturally competent when serving migrant farmworker families; and (5) Community Dimension of Practice Skills, which include use of community resources, establishing linkages between community partners to eliminate redundancy and better serve the migrant population, and maintaining partnerships with migrant leaders and agencies serving this population (QCC, 2018).

Nurses can screen and monitor migrant farmworkers' health. Diseases such as TB, diabetes, and hypertension are often missed in a mobile population without regular access to primary care services. Nurses can create screening programs in migrant camps and other farmworker housing. When problems are identified and treated, nurses can refer for further care and then monitor the success of medication regimens, preventive measures, and follow-up with the health care system. The nurse can provide culturally specific health promotion and disease prevention programs and materials, as well as information about referral sources when needed. The nurse can teach health promotion strategies to lay health promoters who then will educate the migrant community. The Evidence-Based Practice box describes an approach to hypertension screening by community health workers.

EVIDENCE-BASED PRACTICE

The U.S. Preventive Services Task Force (USPSTF) guidelines, as of 2015, recommend screening for high blood pressure in adults aged 18 years or older (*A* recommendation). The USPSTF recommends obtaining measurements outside of the clinical setting for diagnostic confirmation before starting treatment (Siu, 2015). As noted earlier, Latino populations experience disparities in the occurrence of hypertension and other chronic illnesses. With the additional risk factors of mobility, lack of access to care, and lack of continuity of care, the MSFW population should be a high priority for identifying and treating high blood pressure.

Research has demonstrated the value and effectiveness of community health workers in educating and motivating patients. Thompson et al. (2015) demonstrated that trained community health workers were able to assess the risk of MSFWs for diabetes and hypertension comparably to a registered nurse.

Nurse Use
Nurses have the opportunity to be involved in education, screening, and management services related to hypertension for migrant farmworkers. These services can be directed at individuals in a health care setting, in camps or other housing settings, or to groups in community settings. Additionally, nurses can design and support training for community health workers to perform education and screening for cardiovascular disease risk, since this approach has been shown to be effective in addressing the cultural context of farmworkers' knowledge and beliefs related to the benefits of identifying and treating high blood pressure.

Data from Siu AL: Screening for high blood pressure in adults: U.S. Preventive Services Task Force Recommendation statement. *Ann Intern Med* 163:778–786, 2015; Thompson RH, Snyder AE, Burt DR, et al.: Risk screening for cardiovascular disease and diabetes in Latino migrant farmworkers: a role for the community health worker. *J Community Health* 40:131–137, 2015.

Opportunities also exist for nurses to lead or participate in evaluation of the effectiveness of existing programs dedicated to all levels of prevention and treatment for farmworkers. The Clinical Decision-Making Activities at the end of the chapter explore nurses' roles in various health care delivery settings.

The health status of all people is a function of their ecology, or all that "touches" them. The nurse keeps a finger on the pulse of the community by remaining active with political and social issues that involve the client. The nurse can be a catalyst for change to assess farmworker needs continually, to direct efforts to obtain needed health care services, and to evaluate the success of those efforts. Acting as a community educator knowledgeable about how to obtain the latest information and resources, the nurse can work to assess the infrastructure and needs of the community. Follow-up on assessments by the nurse is critical. For example, the needs assessment might indicate inadequate child and adult immunizations in the migrant population, which may best be provided in the fields, camps, and schools. The nurse may instigate and lead in the creation of an immunization tracking system to share information with other counties and states as the farmworkers migrate. Outcome measures relevant to care of MSFWs are listed in the *Healthy People 2020* box.

HEALTHY PEOPLE 2020

Selected Objectives for Migrant Farmworker Populations

This box lists selected *Healthy People 2020* objectives that relate to health promotion and disease prevention in migrant farmworkers. They were selected on the basis of occupational, lifestyle, and socioeconomic factors that place migrant farmworkers and their families at unique risk for suboptimal health.

Environmental Health

- **EH-10:** Reduce pesticide exposures that result in visits to a health care facility.
- **EH-19:** Reduce the proportion of occupied housing units that have moderate or severe physical problems.

Immunization and Infectious Diseases

- **IID-29:** Reduce tuberculosis.
- **IID-30:** Increase treatment completion rate for all tuberculosis patients who are eligible to complete therapy.

Maternal, Infant, and Child Health

- **MICH-10:** Increase the proportion of pregnant women who receive early and adequate prenatal care.

Occupational Safety and Health

- **OSH-2:** Reduce nonfatal work-related injuries.
- **OSH-8:** Reduce occupational skin diseases or disorders among full-time workers.

Data from U.S. Department of Health and Human Services: *Healthy People 2020*, 2018. Available at https://www.healthypeople.gov.

Nurses can also be social and political advocates for the MSFW population. Educating communities about these individuals, collecting necessary data on their lives and health, and communicating with legislators and other policy makers at local, state, and national levels are needed actions that nurses are prepared to undertake. Migrant farmworkers have been a persistently vulnerable population, as discussed throughout this chapter, in spite of the contributions they make to our economy and our food supply. At the time of this writing, however, their status in the United States is particularly precarious due to the potent anti-immigrant climate both politically and socially. Nurses working with farmworkers can serve as a supportive and credible influence on decision makers. Box 34.3 lists selected resources for the nurse working with MSFWs.

PRACTICE APPLICATION

Maricela is 15 years old, and has accompanied her uncle and male cousin to the camp to cook and clean the cabin for them. She also works in the fields picking crops. Maricela has traveled the East Coast for six months with her uncle and cousin. Maricela is originally from Mexico, and Florida is her home base. One evening after finishing her work, Maricela asks to speak with Joan Lewis, the nurse practitioner whose medical van is parked outside the migrant camp where Maricela lives. She tells the nurse that her stomach has been hurting for a while and asks Ms. Lewis for something to stop the pain. While assessing the complaint, Ms. Lewis asks Maricela what she believes has caused the pain. Maricela is very quiet and barely responds to the nurse. She does not make eye contact with Ms. Lewis. Maricela states that she probably ate something hot that upset her stomach. She seems to be in a great hurry and says she does not want her uncle to know she stopped by the van because he would be angry. Ms. Lewis, who speaks fluent Spanish, completes her history, but Maricela does not permit the nurse to examine her abdomen. Maricela also will not talk about her last menstrual period. She asks for medicine again and gets up to leave.

A. What do you see as the important points regarding Maricela's situation?
B. What are cultural considerations that may impact the assessment of Maricela's complaint?
C. What could be the possible causes for Maricela's stomach pain? What is your rationale for each cause?

Answers can be found on the Evolve website.

KEY POINTS

- A migrant farmworker is a laborer whose principal employment involves moving from a home base to another location to plant or harvest agricultural products and lives in temporary housing. Migrant farmworkers may be single or may travel with family members.
- An estimated one to three million migrant farmworkers are in the United States. These numbers are controversial because of the inconsistency in defining farmworkers and limitations in obtaining data.
- Migrant farmworkers are considered a vulnerable population because of their lifestyle and lack of resources.
- Health problems of migrant farmworkers are linked to their work and housing environments, limited access to health services and education, and lack of economic opportunities.
- Migrant farmworkers are faced with uncertainty regarding work and housing, inadequate wages, unsafe working conditions, and lack of enforcement regarding legislation for field sanitation and safety regulations.
- Farmworkers are exposed not only to immediate risk of pesticide exposure in the fields, but also to unknown long-term effects of chronic exposure to pesticides.
- When harvesting is completed, the farmworker becomes simultaneously homeless and unemployed. Forced migration to find employment leaves little time or energy to seek out and improve living standards.
- Children of migrant farmworkers may need to work for the family's economic survival. They are most affected by the disruptive and challenging lifestyle.

CLINICAL DECISION-MAKING ACTIVITIES

1. Interview rural community leaders regarding migrant farmworkers in your area. What do business owners, teachers, clergy, politicians, and other health professionals say about this population? Can you identify misinformation or lack of information on their parts?
2. Outreach workers are personnel generally hired by an agency, such as a health department or health center, to provide services such as education to migrant persons. Lay health promoters, often former farmworkers themselves, also provide community-based education. Find out if these roles exist in your community. Interview these individuals or accompany them in their work. Compare and contrast their roles. How are they complementary? How do they overlap? How can they work together to maximize health? How are their approaches to education different (e.g., does one use a protocol or template, whereas the other uses popular education techniques)? How does the outreach worker role and the lay health promoter role compare with the nursing role? How can the nurse work with the outreach worker and the lay health promoter?
3. Find an agency that visits migrant farmworkers in their housing. Ask to accompany them on subsequent visits. What is the condition of the housing? Are there deficits that could impact the health of the inhabitants?
4. Determine eligibility for Medicaid and Aid to Families with Dependent Children services in your state. You may consult the county health department and the state health department. Do migrant workers in your state qualify for these programs?
5. Design a temporary clinic to provide health care to migrant workers in your area during crop season. What services would you provide? What hours would you operate? How would you staff the clinic? Where would you get funds?
6. Below are a few settings and RN-delivered services for migrant clients. Can you propose others?
   A. Health department (generally state and/or county funded)—Nurses monitor communicable diseases and provide treatments for outbreaks such as TB and pertussis.
   B. Migrant camps (generally funded through migrant clinics or health departments)—Nurses assess and triage, screen for disease, dispense medications under protocol, provide education, interview families, and coordinate care in conjunction with health department nurses.
   C. Migrant clinics (federally funded health centers)—Nurses work with clinics' primary care providers, lead prenatal and diabetes programs (both classes and home visits), educate regarding illnesses, and visit migrant camps to provide services or follow-up on clinic care.

Teen Pregnancy

Sharon K. Davis, DNP, APRN, WHNP-BC

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Discuss approaches that could be used in providing care to the adolescent client.
2. Identify trends in adolescent pregnancy, births, abortions, and adoption in the United States.
3. Discuss reasons that may affect whether a teenager becomes pregnant.
4. Explain some of the deterrents to the establishment of paternity among young fathers.
5. Develop nursing interventions for the prevention of pregnancy problems that adolescents are at risk for experiencing.
6. Identify nursing activities that may contribute to the prevention of adolescent pregnancy.

CHAPTER OUTLINE

Adolescent Health Care in the United States
The Adolescent Client
Trends in Adolescent Sexual Behavior, Pregnancy, and Childbearing
Background Factors
Young Men and Paternity
Early Identification of the Pregnant Teen
Special Issues in Caring for the Pregnant Teen
Teen Pregnancy and the Nurse

KEY TERMS

abortion services, p. 774
adoption, p. 776
birth control, p. 773
coercive sex, p. 777

Teen pregnancy is an area of public concern because of its significant effect on communities. Resources to support the special needs of pregnant teenagers are decreasing, and the costs of sustaining young families are prohibitive. Many teenagers who become pregnant are caught in a cycle of poverty, school failure, and limited life options. Even under the ideal circumstances of adequate finances, loving and supportive families, and good birth outcomes, a teen mother must circumvent her own necessary developmental tasks to raise her child.

There is neither a uniform reason that teens become pregnant nor a universally acceptable solution. The causes of teen pregnancy are diverse and affected by changing moral attitudes, sexual codes, and economic circumstances. Teen pregnancy places an enormous strain on the health care and social service systems. Social concern is also raised about the lost potential for young parents when pregnancy occurs, and the academic and economic disadvantages that their children will experience. Nurses are in a key position to understand how teen pregnancy affects both the individual and the community. This chapter presents a variety of issues associated with teen pregnancy and proposes nursing interventions to promote healthy outcomes for individuals and communities.

Special thanks go to Dyan Aretakis for her outstanding authoring of several editions of this chapter.

ADOLESCENT HEALTH CARE IN THE UNITED STATES

Adolescents are generally healthy, and when they seek health care it is for reasons different from those of adults or young children. The main causes of teen mortality are high-risk behaviors: motor vehicle accidents (usually including alcohol), homicide, suicide, and accidental injuries (such as falls, fires, or drowning). Teens often engage in behaviors that put them at risk for life-threatening diseases. For example, each year, one fourth of both new human immunodeficiency virus (HIV) infections and newly identified sexually transmitted diseases (STDs) occur among adolescents. During the teen years other behaviors are initiated (e.g., smoking, decreased activity, and poor nutrition) that can ultimately lead to poor health and influence behavior change that can significantly alter a young person's life (Centers for Disease Control and Prevention [CDC], 2018a). National surveys highlight the health issues facing adolescents. There have been some improvements in risk behaviors as well as a worsening of others. Among 9th to 12th graders participating in the 2017 Youth Risk Behavior Surveillance System, fewer teens reported binge drinking or riding in a car with a driver who had been drinking (CDC, 2018b). However, these and other significant risk behaviors continued at high rates. Of 9th to 12th graders, 29.8 percent reported current alcohol use, 35.6 percent had tried marijuana (19.8 percent were current users), 14 percent had taken prescription pain medication without a prescription or differently than instructed, and 39.2 percent of those who drove a car or other vehicle during the 30 days prior to their survey response had texted or emailed while driving (CDC, 2018b).

Mental health issues are also strongly associated with the adolescent years: 19 percent of students had experienced bullying on school property and 31.5 percent reported feeling sad or hopeless for more than 2 weeks; 41.1 percent of females and 21.4 percent of males reported these symptoms. Serious thought of attempting suicide was reported by 17.2 percent of the students nationwide. Suicidal thoughts with a plan existed for 13.6 percent of students, and 7.4 percent attempted suicide nationwide with a higher rate for girls (9.3 percent) than boys (5.1 percent) (CDC, 2018b).

In addition, 30.4 percent of students were either obese or overweight, 15.4 percent had not been physically active for more than 60 minutes total on a single day during the 30 days prior to filling out the survey, 43 percent played video or computer games that were unrelated to school work for three or more hours on a school day, 23.9 percent had been told they had asthma, 10.1 percent used sunscreen when they were in the sun for more than an hour, 8.8 percent had smoked cigarettes, and 13.2 percent had used a vapor product on at least one day during the 30 days prior to filling out the survey. It is the collective impact of these behaviors that not only put adolescents at risk during the teenage years but set the stage for adult morbidity and mortality from heart disease, cancer, and diabetes (CDC, 2018b).

Adolescents may not seek care for these problems for the following reasons: (1) access to health care may be hindered by a lack of transportation or health care facilities, (2) costs of care or availability of insurance, (3) lack of the belief that their visits are confidential, (4) lack of understanding of the need for health care, (5) cultural or language barriers, and (6) a limited number of professionals with expertise in dealing with teenagers who understand that sensitive topics must be broached in a nonjudgmental and supportive manner and demonstrate a desire to work with youth. Nurses who want to promote the health of adolescents by providing anticipatory guidance about peer pressure, assertiveness, and future planning need to understand adolescent behaviors, health risks, and the social context in which they live. Involvement and education of the parents about youth culture and development can promote positive and supportive parenting of teens.

THE ADOLESCENT CLIENT

Adolescents have limited experience in independently seeking health care. When they do seek care, it is often to discuss concerns about a possible pregnancy or to find a **birth control** method. These teens may also need assistance negotiating complex health care systems. Special approaches in both client interview and subsequent client education are often warranted. The behavior of adolescents toward the nurse can range from mature and competent during one visit to hostile, rude, or distant at other times because behavior often reflects intense anxiety over what the teen is experiencing.

Because client interviews usually begin with evaluation of a chief complaint, teens need to know that their concerns are heard. Health care providers may have their own opinions about what teenagers need and may fail to take the chief complaint seriously. For example, when a teen expresses ambivalence about or a desire to become pregnant, this should be discussed in depth even though the nurse may feel uncomfortable when asked to provide information to a teen about how to conceive. During this interview the nurse can provide preconception counseling and emphasize the need to achieve good health and to establish a health-promoting lifestyle before pregnancy. Health risks to the mother, as well as to fetal development, can be discussed. The nurse can encourage a young person to consider lifetime goals and discuss how parenthood might affect them. Not only does information presented this way demonstrate that the nurse has heard what the teen is saying, but it also allows the nurse to provide useful health information that may encourage the teen to examine her plans carefully, seriously, and maturely.

It is also important to pay attention to what the teen *fails* to verbalize. Knowledge of adolescent health care issues is valuable so that the nurse can anticipate other health concerns and provide an environment in which the adolescent feels safe about discussing other issues. By creating a caring and understanding atmosphere, the nurse can encourage the young person to discuss concerns about family violence, drugs, alcohol, or dating.

Discussing reproductive health care is a sensitive matter for both teens and many adults. Teens may have difficulty expressing themselves because of a limited sexual vocabulary or

embarrassment resulting from their lack of knowledge. The nurse must recognize this potential deficit and embarrassment and assist teens by anticipating concerns. It is also important to allow teens to express themselves in their own language, which may include crude or offensive words. Nurses must learn about common slang expressions and common misconceptions so they do not miss important concerns that a teenager might have. The nurse can offer more appropriate terms once trust is established.

Teens may have difficulty discussing topics that provoke a judgmental reaction, such as discussing STDs (Box 35.1). The nurse can choose neutral words to evaluate symptoms (e.g., "Has there been a change in your typical vaginal discharge?"). This approach also gives the nurse a chance to educate the young client about normal anatomy and physiology.

Considerable debate exists over whether adolescents should make reproductive health care decisions without their parents' knowledge. As seen in Box 35.2, federal law establishes the adolescent's right for access to contraceptive treatment. Obstacles to services do exist, however, and this may result in a teen not receiving contraceptive information and treatment. Obstacles can include lack of transportation to a health care facility, insufficient money to pay for services, or permission to leave school early to attend an appointment.

Although most minor teens can consent to birth control services in the United States, there is great variability in who may access and release their medical records. In recognition of the importance of confidentiality in reproductive health care, federal privacy rules were established in 2002 as follow-up to the Health Insurance Portability and Accountability Act of 1996 (HIPAA). This rule, the HIPAA Privacy Rule (or more correctly, the Standards for Privacy of Individually Identifiable Health Information), established that if a minor consented to care, then only that individual could access and release those medical records. However, the Privacy Rule also deferred to existing state law. In many states the laws specify that parents can legally access all the medical records of their minor children (Guttmacher Institute, 2018), which limits the confidentiality assurances offered to a teen seeking reproductive health care. Nurses who work with teens should be knowledgeable about state and federal laws so that they can accurately inform teenagers of their rights and limitations in seeking reproductive health care.

Abortion services for adolescents are not clearly defined. No federal protection is extended to adolescents requesting abortion services, and the adolescent's right to privacy and ability to give consent varies by state. (See Box 35.3, which describes abortion and adolescent rights. [These were the rights as of 2016. They are changing in some states so learn what is the law in your state. See Prochoice America for the latest information and for the information in your state.]) Confidential care to teenagers may mean the difference in preventing an unwanted pregnancy, an abortion, and a birth. This care can influence whether prenatal visits begin in the first trimester or in the second or third trimester. Teens have various reasons for pursuing confidential care, including seeking independence as well as serious and well-founded concerns about a parent's potential reaction (e.g., abuse or abandonment of the teen). Once nurses recognize the reason for confidential care, they can work with teens to discuss reproductive health care needs with the family. To do so, first clarify family values about sexuality and family communication styles with the teen. In a nonhealthy family, referral to community agencies (e.g., child protective services, Al-Anon) may be necessary. However, the nurse may need to honor the adolescent's need for confidentiality for an unknown period and proceed with the usual interventions, such as pregnancy testing, options counseling, and referral for clinical care.

BOX 35.1 Sexually Transmitted Diseases and Teen Pregnancy

Sexually transmitted diseases (STDs) affect 25 percent of sexually experienced teenagers each year. STDs are more easily transmitted to women than men. STD infections among women can contribute to infertility, cancer, and ectopic pregnancy. When a young woman is pregnant, these infections can cause premature rupture of membranes, premature labor, and postpartum infection. Also, the baby can be affected by all STDs in several ways: prematurity and low birth weight, febrile infection after delivery, long-term infection, and even death (e.g., exposure to viral infections such as human papillomavirus and herpes simplex virus).

The pregnant adolescent is at high risk for acquiring an STD because she may not be using barrier protection (e.g., condoms). During the pregnancy she will require periodic STD screening. STD education and counseling should accompany this screening. Information given should include ways to reduce risk, such as maintaining a mutually monogamous relationship and using latex condoms.

BOX 35.2 Reproductive Health Care and Adolescents' Rights

No federal regulation requires a young person to have parents involved in decisions on contraception services provided by federal programs. States cannot prohibit an adolescent access to contraception. Several Supreme Court decisions protect this access:

- 1965: *Griswold v. Connecticut*—the right to prevent pregnancy through the use of contraceptives is protected by the right to privacy.
- 1972: *Eisenstadt v. Baird*—the right to privacy in contraceptive use is extended to unmarried individuals.
- 1977: *Carey v. Population Services International*—the right to privacy is specifically extended to minors.

TRENDS IN ADOLESCENT SEXUAL BEHAVIOR, PREGNANCY, AND CHILDBEARING

In 2016 there were 209,809 births to women under age 20. There was an overall nine percent decline from 2015 with a new low being reached each year since 2009. Teenagers aged 15-19 had a declining birth rate in 40 states from 2015, ranging from a four percent drop in Oklahoma to a 15 percent drop in New Hampshire. Rates were essentially unchanged in 10 states (Connecticut, Delaware, Hawaii, Maine, Montana, North Dakota, Rhode Island, South Dakota, Vermont, and Wyoming) and the District of Columbia (Martin et al., 2018).

BOX 35.3 Abortion and Adolescent Rights

- *Parental consent laws:* One or both parents of a young woman who is under 18 years of age seeking an abortion must give permission to the abortion provider before the abortion is performed. These 25 states have enforceable mandatory consent and notice laws: Alabama, Arizona, Arkansas, California, Idaho, Indiana, Kansas, Kentucky, Louisiana, Maine, Massachusetts, Michigan, Mississippi, Missouri, Montana, Nebraska, New Mexico, North Carolina, North Dakota, Ohio, Pennsylvania, Rhode Island, South Carolina, Tennessee, and Wisconsin.
- *Parental notification laws:* One or both parents of a young woman seeking an abortion must be notified by the abortion provider before the abortion is performed. These laws are in 14 states: Alaska, Colorado, Delaware, Florida, Georgia, Illinois, Iowa, Maryland, Minnesota, Nevada, New Hampshire, New Jersey, South Dakota, and West Virginia.
- *Parental notification and consent laws:* One or both parents of a young woman seeking an abortion must be notified and provide consent before the abortion is performed. These laws are enforced in five states: Oklahoma, Texas, Utah, Virginia, and Wyoming.
- *The following states (12) with parental notification or consent laws permit other trusted adults to stand in for a parent:* Arizona, Colorado, Delaware, Illinois, Iowa, Maine, North Carolina, Nebraska, Pennsylvania, South Carolina, Virginia, and Wisconsin.
- *The following states (five) have laws that have been found unconstitutional and unenforceable:* California, Montana, Nevada, New Jersey, and New Mexico.
- *Judicial bypass:* In a 1979 Supreme Court decision, it was ruled that any mandatory parental consent law must allow the young woman an opportunity to be granted an exception or waiver to the law. A young woman could appeal directly to a judge, who would decide either that she was mature enough to make this decision or that the abortion would be in her best interest.

Data from National Abortion and Reproductive Rights Action League Foundation (NARAL): *Who decides? The status of women's reproductive rights in the United States,* ed. 25, Washington, DC, 2016, NARAL. Retrieved from https://www.prochoiceamerica.org.

Of these births, 17 percent were a repeat birth (Martin et al., 2018). The birth rate in the United States still remains higher than in any other Western industrialized nation (Sedgh et al., 2015). The numbers of teens who become pregnant are generally identified in the following way: by age group (e.g., younger than 15, ages 15-17, ages 18-19, and under age 20), by states, by marital status, by rates (e.g., number of pregnancies, births, and abortions per 1000 young women), and by race/ethnicity (e.g., African American, white, Hispanic/Latino).

Births to teenagers make up 5.3 percent of all births in the United States (U. S. Department of Health and Human Services [USDHHS], 2016a). Teen mothers and their children can have adverse health, economic, and social outcomes, which cost the United States about $9.4 billion annually (Romero et al., 2016). Teen birth rates increase by age, with the highest rates occurring among 19-year-olds. The 2013 U.S. birth rate for teenagers aged 15-19 dropped 57 percent from its highest point in 1991 (Martinez & Abma, 2015). Decreases in pregnancy among teens ages 15 to 17 have been attributed to reduced sexual activity (one fourth of the reduction), and the rest result from improved contraceptive use. Evidence shows that the use of long-acting reversible contraceptives can potentially help more teens avoid an unwanted pregnancy (Guttmacher, 2014). Decline in the teen birth rate varies by race, with the highest birth rates among Hispanic teens (46.3 births per 1000), then African American teens (43.9 births per 1000) and white teens (20.5 births per 1000) (USDHHS, 2016a).

In 2013 there were 448,000 pregnancies to American teens between the ages of 15 and 19 years (Kost et al., 2017). In this same year and age group, 29 percent ended in an abortion, which was a drop from 46 percent in 1985 (Kost et al., 2017). The reasons most teens give for having an abortion is that they are concerned about how a baby would change their lives. They also say that they do not think they could afford to care for a baby, and they do not feel that they are mature enough to raise a child. A sexually active teen who does not use contraceptives has a 90 percent chance of becoming pregnant within one year. Elective abortion rates for teenagers increased from the time of legalization in 1973 until 1988 and then began to decline. This decrease was caused in part by decreases in the pregnancy rate but may also have resulted from laws that required parental notification or consent for minors requesting abortion services in some states. As of July 2018, laws in 37 states required minors seeking abortions to have parental involvement in the decision (Guttmacher Institute, 2018).

HEALTHY PEOPLE 2020

Selected Objectives Related to Adolescent Reproductive Health

Objectives Related to Adolescent Health

- **HIV-13:** Increase the percent of adolescents who have been tested for HIV.

Objectives Related to Family Planning

- **FP-12:** Increase the proportion of adolescents who received formal instruction on reproductive health topics before they are 18 years old.
- **FP-13:** Increase the proportion of adolescents who talked to a parent or guardian about reproductive health topics before they are 18 years old.

Objectives Related to Maternal, Infant, and Child Health

- **MICH-8.1:** Reduce low birth weight (LBW) and very low birth weight (VLBW)
- **MICH-10:** Increase the proportion of pregnant women who receive early and adequate prenatal care.

HIV, Human immunodeficiency virus.

BACKGROUND FACTORS

Many adults have difficulty understanding why young people would jeopardize their careers and personal potential by becoming pregnant during the teen years. Adolescents, however, do not view the world in the same way as adults. Teens often feel invincible and therefore do not recognize any risk related to their behaviors or anticipate the consequences. That is, they may not think that sexual activity will lead to pregnancy. When teens become pregnant, they do not believe that the negative outcomes they are advised of could come true. Many teens believe that they are unique and different and that everything will work out fine. The developmental circumstances of

adolescence, coupled with potential background disadvantages, can magnify the problems facing the pregnant and parenting teen. Pregnant teens often express the unrealistic attitude that they can do it all: school, work, parenting, and socializing.

Babies born to teenage mothers in the United States are at risk for many of the same problems as their young mothers. These risks include school failure, poverty, and physical or mental illness (USDHHS, 2016b). Specifically, a disproportionate number of teens who give birth are poor, have limited educational achievements, and have limited opportunities within their communities for positive youth experiences (CDC, 2017a). Most teens report that their pregnancy was unplanned. They typically think that a pregnancy should be delayed until people are older, have completed their education, and are employed and married. Several factors that often contribute to pregnancy are discussed next.

Sexual Activity and Use of Birth Control

The **sexual debut**, or first experience with intercourse, for a teen has a significant impact on pregnancy risk. In 2017, among high school students who were surveyed, 39.5 percent had experienced sexual intercourse with 9.7 percent of these having four or more sexual partners (CDC, 2018b). These students answered questions about their sexual contacts, with 45.3 percent identifying contact with only the opposite sex, 1.6 percent had contact with only the same sex, and 5.3 percent had contact with both sexes (CDC, 2018b). From 2005 to 2015 there has been a linear decline in the percent of youth who have initiated sexual intercourse: male students have dropped from 46.8 percent to 41.2 percent, and female students have dropped from 45.7 percent to 39.2 percent. Ethnicity of the students having sexual intercourse was also reported for the same time period: white students dropped from 43 percent to 39.9 percent, black students dropped from 67.6 percent to 48.5 percent, and Hispanic students dropped from 51 percent to 42.5 percent (Ethier et al., 2018). The *Healthy People 2020* goal is to increase the proportion of adolescents who have never engaged in sexual intercourse by age 17 (USDHHS, 2010).

Although more teens have begun using birth control in the past 10 years, there is still progress to be made. *Healthy People 2020* addresses this with goals to increase the proportion of 15- to 19-year-olds who use condoms and a hormonal contraceptive and increase the proportion of teens who receive reproductive health information through formal instruction as well as from their parents or guardians (USDHHS, 2010). Condoms are the most commonly used method of birth control, with 68 percent of adolescent females and 80 percent of adolescent males reporting their use at first voluntary coitus. Great improvement in overall contraceptive use has occurred, with 86 percent and 93 percent of females and males, respectively, reporting that a method of contraception was used at last sex. The current recommendation for greatest protection against pregnancy and sexually transmitted infection (STI) is the use of a hormonal contraceptive, preferably **long-acting reversible contraception** (LARC), and a condom, referred to as **dual protection**. At this time only 20 percent of females and 30 percent of males reported using dual protection the last time they had sex (Guttmacher Institute, 2017). Male teens use condoms with more frequency than female teens, and African American males use condoms more often than any other group, male or female. Overall, 53.8 percent of sexually active teen couples reported that the male partner used condoms the last time they had intercourse, with the greatest use at last intercourse reported by white male teens (761.3 percent) and the lowest use reported by black female teens (47.1 percent). During 1991-2017 there was a significant increase (46.2 percent to 53.8 percent) in the use of condoms at last intercourse (CDC, 2018a).

Inadequate Contraception Knowledge

CHECK YOUR PRACTICE

You are seeing a 16-year-old patient in your office for painful menses and she did not want her mother to be present. The patient says to you, "I make my boyfriend use condoms regularly so I can't get any diseases or get pregnant."

What should you ask?

In 2012 the American College of Obstetricians and Gynecologists (ACOG) made a strong recommendation to encourage adolescents to use LARC methods—intrauterine devices and contraceptive implants. These methods are reversible and have the highest rates of continuation and prevention of pregnancy, rapid repeat pregnancy, and abortion in young women. Reports from the Contraceptive CHOICE Project, an observational clinical trial, prompted ACOG to strengthen their recommendation in 2015 when it was reported that LARC methods were 20 times more effective at preventing pregnancy in their participants (American College of Obstetricians and Gynecologists, 2015). Table 35.1 describes hormonal birth control methods and their effectiveness. As noted earlier, the use of alcohol and other substances is common among adolescents and can contribute to unplanned pregnancy. Mood-altering effects may reduce inhibitions about engaging in intercourse and interfere with the proper use of a chosen birth control method.

Peer Pressure and Partner Pressure

Peer pressure among teens is not a new phenomenon, but many of the influences have become more serious. Influence has expanded from fashion and language to cigarettes, substance abuse, sexuality, pregnancy, and sexting. Teens are more likely to be sexually active if their friends are sexually active (Gregg et al., 2018). Peers reinforce teen parenting by exaggerating birth control risks, discouraging abortion and **adoption**, and glamorizing the impending birth of the child.

Both young men and young women may think that allowing a pregnancy to happen verifies one's love and commitment for the other. In addition, young men from socioeconomically disadvantaged backgrounds may be more likely to say that fathering a child would make them feel more manly, and they are less likely to use an effective contraceptive (Farrell et al., 2017).

Other Factors

Other factors influencing teen pregnancy are a history of **sexual victimization**, family structure, parental influences, and diverse

TABLE 35.1 Hormonal Birth Control Methods Recommended for Teenagers

Method	Failure Rate With Typical Use (%/year)	Pattern of Use	Noncontraceptive Benefits
Mirena IUD Paragard IUD Liletta IUD Kyleena IUD Skyla IUD	0.2 0.8	Placed in the uterus; effective continuously for 5 years (Mirena); 10 years (Paragard); 3-5 years (Liletta); 5 years (Kyleena); 3 years (Skyla)	Less menstrual bleeding, often with amenorrhea after initial few months
Nexplanon implant	0.05	Placed subdermally in the upper arm; effective continuously for 3 years	Less menstrual bleeding
Depo-Provera	6	IM injection into either the deltoid or the gluteal muscle every 3 months	• Decreases sickle cell crisis • Decreases the seizure threshold • May become amenorrheic
NuvaRing	9	Vaginal ring inserted for 21 to 32 days; contains estrogen and progestin	For all estrogen/progestin combinations: • Risk of ovarian and endometrial cancer is reduced • May use an extended regimen to reduce menses (except Ortho Evra patch) • May improve acne • Light regular menses (except POP)
Ortho Evra transdermal patch	9	A transdermal patch that is applied to specific skin sites weekly for 3 weeks, and removed for 7 days; contains estrogen and progestin	See above
Birth control pills	9	Take pill daily. COC—estrogen and progestin; POP—progestin only ("mini pill")	See above

COC, Combined oral contraceptive pill; *IM,* intramuscular; *IUD,* intrauterine device; *POP,* progestin-only pill.
(Developed from Planned Parenthood, 2018, learn about birth control. Available at https://www.plannedparenthood.org/learn/birthcontrol.)

sexual orientations. With a history of poverty only, 16.8 percent of teens had been pregnant once by age 17. For teens with a history of poverty and reported child abuse or neglect, 28.9 percent had been pregnant by age 17 (Garwood et al., 2015). Adolescent girls with a history of sexual abuse are at risk for earlier initiation of voluntary sexual intercourse, are less likely to use birth control, are more likely to use drugs and alcohol at first intercourse, and are more likely to have older sexual partners. The prevalence of adolescents experiencing **coercive sex** or **statutory rape** is 11.3 percent (CDC, 2018b). Young women may also become pregnant as a result of forced sexual intercourse. A history of sexual victimization will influence a young woman's ability to exert control over future sexual experiences, which will affect the use of birth control and rejection of unwanted sexual experiences. Teen pregnancy is also more common among sexual minorities compared with heterosexuals, which is thought to be partially due to childhood mistreatment (Charlton et al., 2018). All these factors contribute to an increased risk for becoming pregnant. In addition, young women who have experienced a lifetime of economic, social, and psychological deprivation may think that a baby will bring joy into an otherwise bleak existence. Some mistakenly believe that a baby can provide the love and attention that her family has not provided.

Family structure can influence adolescent sexual behavior and pregnancy. While the number of single-parent families has increased in recent years, it is interesting that recent researchers found that it was not single-parent families with working mothers that had the highest risk for an unplanned teen pregnancy, but that it was adolescents who have girlfriends with early sexual activity who have a 1.63 times greater risk of getting pregnant unintentionally (Vázquez-Nava et al., 2014).

Parenting styles can influence a young woman's risk for early sexual experiences and pregnancy. Parents who are extremely demanding and controlling or neglectful and who have low expectations are least successful in instilling parental values in their children. Parents who have high demands for their children to act maturely and who offer warmth and understanding with parental rules have children more likely to exhibit appropriate social behavior and to delay early sexual experiences and pregnancy. Children of parents who are neglectful are the most sexually experienced, followed by children of parents who are very strict. Furthermore, parents who discuss birth control, sexuality, and pregnancy with their children can positively influence delay of sexual initiation and effective birth control use. Parents who do not communicate about sexuality with their teens may find them more at risk for sexual permissiveness and pregnancy (CDC, 2017b).

YOUNG MEN AND PATERNITY

Although declines among pregnant female teenagers have been seen over the past 27 years, the percent of teenage fathers increased. At first, this may seem contradictory, but it could be explained by several factors: teenage males are partnering with older women, females are partnering with older males,

paternity has been more readily ascertained by genetic testing and voluntary establishment, coordinated child support has been reinforcement, and there has been a decrease in stigma (Pirog et al., 2017).

About seven percent of males become fathers before the age of 19. Of this group, two thirds were ages 18 or 19 when they fathered their first child, and one third were less than 18 years old. These numbers may be conservative because not all teen males are aware that a partner became pregnant, nor are they always aware of the outcome of the pregnancy. A review of birth certificate information may not be helpful as many unmarried couples fail to complete the steps required for a father's name to appear. Adolescent males who become fathers are often reported to be second-generation teen parents. Studies demonstrate that they came from poor families, did poorly in school, and engaged in many high-risk behaviors such as gang membership, drugs, and early sexual involvement. These young fathers face special challenges because of concomitant social problems and limited future plans or ability to provide support. There may also be an overlap between young fatherhood and delinquency. Adolescent males who demonstrate law-breaking behaviors, alcohol or substance use, school problems, and aggressive behaviors may have difficulty developing a positive fathering role, yet they are the highest-risk group to become young fathers (Massachusetts General Hospital [MGH], 2016).

Paternity, or fatherhood, is legally established at the time of the birth for a married teen. However, it is more difficult to establish paternity among nonmarried couples. Some of the difficulty lies in the complexity of the specific state system for young men to acknowledge paternity. In some states a young man may have to work with the judicial system outside of the hospital after the birth; if he is under age 18, he may need to involve his parents.

Some young couples do not attempt to establish paternity and prefer a verbal promise of assistance for the teen mother and child. Although a verbal commitment may be acceptable when the child is born, the mother may become more inclined to pursue the establishment of paternity later when the relationship ends or for reasons related to financial, social, or emotional needs of the child. Young women who receive state or federal assistance (e.g., Temporary Assistance for Needy Families, Medicaid) may be asked to name the child's father so the judicial process can be used to establish paternity.

Young men react differently when they learn that their partner is pregnant. The reaction often depends on the nature of the relationship before the pregnancy. Many young men will accompany the young woman to a health care center for pregnancy diagnosis and counseling. A large percent of young men will continue to accompany the young woman to some prenatal visits and may even attend the delivery. These young men may also want, and need, to be involved with their children regardless of changes in their relationships with the teen mother. It is not unusual for a young man to be excluded or even rejected by the young woman's family (usually her mother). He may then begin to act as though he is disinterested when he may really feel that he cannot provide resources for his child or know how to take care of him or her (MGH, 2016) (Fig. 35.1).

Fig. 35.1 It is important to include both the teen mother and the father in teaching about child development.

Nurses can acknowledge and support the young man as he develops in the role of father. His involvement can positively affect his child's development and provide greater personal satisfaction for him and greater role satisfaction for the young mother. Young mothers who report less social support from their baby's father are more apt to be unhappy and distressed in the parenting role (Dumas et al., 2018). The immediate concerns revolve around his financial responsibility, living arrangements, relationship issues, school, and work. Establishing an opportunity to meet with the young man and both families is helpful to clarify these issues and identify roles and responsibilities. Even if the young father cannot provide financial support, emotional and physical support is still extremely important (Healthy Children Organization [HCO], 2017).

Life experiences for a young man will influence behaviors that can lead to a teen pregnancy or prevent a teen pregnancy. Adverse childhood experiences, including a history of abuse (especially physical and sexual abuse and domestic violence), mental illness and/or substance abuse in the childhood home, criminal behaviors in the home, and separated parents, have been linked to negative behaviors such as early sexual intercourse, multiple partners, and substance use. These behaviors are possible antecedents to male involvement in teen pregnancy (Chilcoat et al., 2016).

Age discrepancy between the pregnant teen and her male partner is an important consideration, even when it is only two years. It raises concern about coercion, potential or actual violence, increase in risk for STI, and exposure to greater substance and alcohol use. The greatest age discrepancies are seen with the youngest pregnant teens. Although these numbers have decreased, the risk is present with more than half of all females ages 15 and younger reporting first sexual intercourse with a male partner who is more than three years older. Protective factors that can reduce the risk of a young teen becoming

sexually involved with an older partner include living with both biological parents, greater parental education, and not being born to a teen mother (Masho et al., 2017).

EARLY IDENTIFICATION OF THE PREGNANT TEEN

Some teens delay seeking pregnancy services because they fail to recognize signs such as breast tenderness and a late period, or they are experiencing a variety of other pubertal changes. Most young women, however, suspect pregnancy as soon as a period is late. These young women may still delay seeking care because they falsely hope that the pregnancy will just go away. A teen may also delay seeking care to keep the pregnancy a secret from family members, either fearing an angry or disappointed response or expecting to be forced into a decision that may not be hers.

Nurses must be sensitive to subtle cues that a teenager may offer about sexuality and pregnancy concerns. Such cues include questions about one's fertile period or requests for confirmation that one need not miss a period to be pregnant. Once the nurse identifies the specific concern, information can be provided about how and when to obtain pregnancy testing. The nurse should determine how a teenager would react to the possible pregnancy before completing the test. If the test is negative, the nurse should take the opportunity to assess whether the young woman would consider counseling to prevent pregnancy. A follow-up visit is important after a negative test to determine if retesting is necessary or if another problem exists.

In looking at teen pregnancy from the perspective of levels of prevention, several steps could be taken. These are shown in the Levels of Prevention box.

LEVELS OF PREVENTION

Teen Pregnancy

Primary Prevention
Teach young people about sexual practices that will prevent untimely pregnancy.

Secondary Prevention
Provide services for early detection of teen pregnancy.

Tertiary Prevention
Counsel the young person or young couple about available options, including keeping the baby (and making appropriate plans to care for the child), abortion, and adoption.

A young woman with a positive pregnancy test requires a physical examination and pregnancy counseling. It is advantageous to offer these at the same time so that the counseling is consistent with the findings of the examination. The purpose of the examination is to assess the duration and well-being of the pregnancy, as well as to test for STI. The pregnancy counseling should include the following: information on adoption, abortion, and child-rearing; assessment of support systems; assessment of partner violence; and identification of the immediate concerns she might have (Marino, 2016).

The availability of affordable abortion services up to 13 weeks of gestation varies from community to community. Similarly, second-trimester services may be available locally or involve extensive travel and cost. The nurse should know about abortion services and provide information or refer the pregnant teenager to a pregnancy counseling service that can assist.

The pregnant teenager needs information about adoption, such as current policies among agencies that allow continued contact with the adopting family. Also, church organizations, private attorneys, and social service agencies provide a variety of adoption services with which the nurse should be familiar. Box 35.4 lists guidelines for adoption counseling.

Pregnancy counseling requires that the nurse and young woman explore strengths and weaknesses for personal care and responsibility during pregnancy and parenting. Young women vary in their interest in including the partner or their parents in this discussion. Issues to discuss include education and career plans, family finances and qualifications for outside assistance, and personal values about pregnancy and parenting at this time in their life. Often it is difficult to focus on counseling in any depth at the time of the initial pregnancy testing results. A follow-up visit is usually more productive and should be arranged as soon as possible.

As decisions are made about the course of the pregnancy, the nurse can make referrals to appropriate programs such as Women, Infants, and Children (WIC) program (a supplemental

BOX 35.4 Guidelines for Adoption Counseling

1. Assess your own thoughts and feelings on adoption. Do not impose your opinion on the decision-making process of teen mothers.
2. Know about state laws, local resources, and various types of adoption services.
3. Choose language sensitively. Examples follow:
   a. Avoid saying "giving away a child" or "putting up for adoption." It is more appropriate and positive to say "releasing a child for adoption," "placing for adoption," or "making an adoption plan."
   b. Avoid saying "unwanted child" or "unwanted pregnancy." A more appropriate term may be *unplanned pregnancy.*
   c. Avoid saying "natural parents" or "natural child," because the adopted parents would then seem to be "unnatural." The terms *biological parents* and *adoptive parents* are more appropriate.
4. Assess when a discussion of adoption is appropriate. It can be helpful to begin with information on adoption and then explore feelings and concerns over time. Individuals will vary in how much they may have already considered adoption, and this will influence the counseling session.
5. Assess the relationship between the pregnant teen and her partner and what role she expects him to play. Discuss the reality of this.
6. It may be helpful for a pregnant teen to talk with other teens who have been pregnant, are raising a child, have released a child for adoption, or have been adopted themselves.
7. A young woman can be encouraged to begin writing letters to her baby. These can be saved or given to the child when released to the adoptive family.

Modified from Brandsen CK: *A case for adoption,* Grand Rapids, MI, 1991, Bethany.

food program for women, infants, and children), Medicaid, and prenatal services. The young woman and her family also need to know about expected costs of care and, if there is a family insurance policy, whether it will cover the pregnancy-related expenses of a dependent child. For those without insurance, the family can apply for Medicaid or determine whether local facilities offer indigent care programs (e.g., Hill-Burton programs for assistance with hospital expenses). The nurse can also begin prenatal education and counseling on nutrition, substance abuse and use, exercise, and special medical concerns.

SPECIAL ISSUES IN CARING FOR THE PREGNANT TEEN

Pregnant teenagers are considered high-risk obstetric clients. Many of their pregnancy complications result from poverty, late entry into prenatal care, and limited knowledge about self-care during pregnancy. Nursing interventions through education and early identification of problems may dramatically alter the course of the pregnancy and the birth outcome.

Violence

Teens are more likely to experience violence during their pregnancies than adult women. Age may be a factor in their greater vulnerability to potential perpetrators that include partners, family members, and other acquaintances. Violence in pregnancy has been associated with an increased risk for substance abuse, poor compliance with prenatal care, and poor birth outcome. In the case of partner violence, young women may be protective of their partners because of fear or helplessness. Eliciting this history from an adolescent is not easy. Be sure to inquire about violence at every visit. The added risk factor of poverty along with abuse compounds the risk of teenage pregnancy. In one study 16.8 percent of teens with a history of poverty had at least one pregnancy by age 17. If poverty and abuse were reported by the teen, there was a 28.9 percent occurrence of pregnancy by age 17 (Garwood et al., 2015). Violence that began during the pregnancy may continue for several years after, with increasing severity. Teens can be so ingrained in intimate partner violence that they have cannot see symptoms of psychological distress (Bekaert & SmithBattle, 2016). The nurse must observe for physical signs of abuse, as well as for controlling or intrusive partner behavior.

Initiation of Prenatal Care

Pregnant adolescents differ remarkably from pregnant adults in initiation and compliance with prenatal care. Inadequate prenatal care has been associated with increased health risks to both the mother and the fetus. In 2016, 11.2 percent of mothers under the age of 20 years received late or no prenatal care (Martin et al., 2018). Teens have reported barriers to care, which include denial of the pregnancy, fear of telling parents, transportation, dislike of providers' care, and offensive attitudes among clinic staff toward pregnant teens (Heaman et al., 2014).

Once a teen is enrolled in prenatal care, the nurse becomes an important liaison between personnel at the clinical site and the young woman. Confusion and misunderstandings occur easily when teens do not understand what a health care provider says to them. Often these misunderstandings are based on lack of knowledge about basic anatomy and physiology. For example, a teen may be told as she gets close to term that the head of the baby is down and it can be felt. This is an alarming piece of information for a young woman who imagines the entire baby could just pop out at any time!

Cooperation between the nurse and the clinical staff can also maximize the client's compliance with special health or nutritional needs. For example, a teen who has premature contractions may be restricted to bed rest and instructed to increase fluids. The nurse who makes home visits can provide additional assessment of the teen's condition and can solve problems about self-care, hygiene, meals, and schooling.

Low-Birth-Weight Infants and Preterm Delivery

Teens are more likely than adult women to deliver infants weighing less than 5.5 lb or to deliver before 37 weeks of gestation. These low-birth-weight and premature infants are at greater risk for death in the first year of life and are at increased risk for long-term physical, emotional, and cognitive problems (Marvin-Dowle et al., 2018). For example, low-birth-weight and premature infants can be more difficult to feed and soothe. This challenges the limited skills of the young mother and can further strain relations with other members of the household, who may not know how to offer support or assistance.

The risk for low-birth-weight infants and premature births can be averted by the teen's early initiation into prenatal care. Although such births still occur, it is important to work closely with the teen mother as soon as she is identified as pregnant to try to promote compliance with prenatal care visits and self-care during the pregnancy. After the pregnancy these infants and their mothers will benefit from frequent nursing supervision to ensure that their care is appropriate and that everyone in the home is coping adequately with the strain of a small infant.

Nutrition

The nutritional needs of a pregnant teenager are especially important. First, the teen lifestyle does not lend itself to overall good nutrition. Fast foods, frequent snacking, and hectic social schedules limit nutritious food choices. Snacks, which account for about one third of a teen's daily caloric intake, tend to be high in fat, sugar, and sodium and limited in essential vitamins and minerals. Second, the nutritive needs of both pregnancy and the concurrent adolescent growth spurt require the adolescent to change her diet substantially. The growing teen must increase caloric nutrients to meet individual growth needs as well as to allow for adequate fetal growth. Third, poor eating patterns of the teen and her current growth requirement may leave her with limited reserves of essential vitamins and minerals when the pregnancy begins.

The nurse can assess the pregnant teenager's current eating pattern and provide creative guidance. Identifying good choices that a teen can consume "on the run" might include snacks of drinkable yogurt, leftover pizza, string cheese, or energy/granola bars. The teen who often eats out can boost her protein

intake at fast-food establishments by ordering milkshakes instead of soft drinks, and cheeseburgers or broiled chicken sandwiches instead of hamburgers. Adding lettuce and tomato or other sliced vegetables to burgers will improve nutrition intake along with fruit smoothies to satisfy a sweet craving (Cornforth, 2018).

Naeye (1981) was the first to introduce the idea that the pregnant teen was in direct competition for nutrients with her fetus at a time when her own nutritional needs are increasing. Improved dairy food intake does have a positive effect on increasing the birth weight for adolescent pregnancies, but more research is needed to determine appropriate dosages of nutritional intake for the best pregnancy outcomes. The nurse and adolescent should collaborate on a reasonable nutritional approach and identify individual health behavior changes that could improve the health of mother and fetus (Soltani et al., 2015).

The nurse, in collaboration with the WIC nutritionist, can determine the nutritional needs of the pregnant teenager to tailor education appropriately. Table 35.2 describes adolescent nutritional needs in pregnancy.

Weight gain during pregnancy is one of the strongest predictors of infant birth weight. Although precise weight gain goals in adolescence are controversial, pregnant adolescents who gain 25 to 35 lb have the lowest incidence of low-birth-weight babies. Babies born to teenagers may be at risk for being small for gestational age despite adequate weight gain if there is very slow gain in the first 24 weeks. Teenagers who begin the pregnancy at a normal weight should be counseled to begin weight gain in the first trimester and to average gains of 1 lb per week for the second and third trimesters. Younger teen mothers (ages 13 to 16), because of their own growth demands, may need to gain more weight than older teen mothers (ages 17 and older) to have the same-birth-weight baby. Table 35.3 shows the recommendations established by the Institute of Medicine for adolescent gestational weight gain by pre-pregnant weight categories.

It is important for the nurse to assess the attitudes of the pregnant teen about weight gain and to monitor her progress, providing feedback on adequate weight gain and counseling if weight gain is excessive. Gaining weight beyond the recommendations raises the risk for infants to be hypoglycemic, to be large for gestational age, and to have a low Apgar score, seizures, polycythemia, and a predisposition to obesity (Restall et al., 2014), Family support of the pregnant teen can be a strong influence in adequate weight gain and good nutrition during

TABLE 35.2 Adolescent Nutritional Needs During Pregnancy

Nutrient	Daily Requirement During Pregnancy[a]	Food Source
Calcium	1000 mg (increase to 1300 mg for <19-year-olds)	Macaroni and cheese; pizza; puddings, milk, yogurt; also fortified juices, water, breakfast bars and fast foods, including Taco Bell's chili cheese burrito, McDonald's Big Mac
Iron	27 mg	Meats; dried beans; peas; dark green, leafy vegetables; whole grains; fortified cereal; absorption of iron from plant foods improved by vitamin C sources taken simultaneously
Zinc	15 mg	Seafood, meats, eggs, legumes, whole grains
Folate (folic acid)	0.6 mg (prenatal vitamins contain 0.4-1.0 mg of folic acid)	Green, leafy vegetables; fruits
Vitamin A	770 mcg RAE per day Age 18 and younger 750 mcg	Dark yellow and green vegetables, fruits
Vitamin B_6	1.9 mg	Chicken, fish, liver, pork, eggs
Vitamin D	600 IU	Fortified milk products and cereals

[a]Higher ranges are especially important for the younger pregnant teen.
(American College of Obstetricians and Gynecologists, 2018. Available at https://www.acog.org/Patients?FAQs/Nutrition-During-Pregnancy.)
RAE, Retinol activity equivalent.

TABLE 35.3 Gestational Weight Gain Recommendations for Adolescents[a]

	RECOMMENDED TOTAL GAIN			
Prepregnant Weight Category[b]	kg	lb	Trimester 1 (lb)	Trimesters 2 and 3 (lb/wk)
Underweight (BMI 19.8)	12.5-18	28-40	5	1.0
Normal weight (BMI 19.9-26)	11.5-16	25-35	3	1.0
Overweight (BMI 26-29)	7.0-11.5	15-25	2	0.66
Very overweight (BMI ≥ 29)	5.0-9.1	11-20	1.5	0.5

[a]Very young adolescents (14 years of age or younger, or less than 2 years postmenarche) should strive for gains at the upper end of the range (Soltani, 2015).
[b]BMI (body mass index) is calculated as weight (in kilograms) divided by height (in meters) squared (CDC, 2018c).
From Soltani H, Duxbury A, Rundle R, Chan L: A systematic review of the effects of dietary interventions on neonatal outcomes in adolescent pregnancy, *Evid Based Mdwfry* 13(1):29–34, 2015.

the pregnancy. Nutrition education should emphasize what accounts for weight gain and how fetal growth will benefit.

Globally, iron deficiency anemia is the most common nutritional problem among both pregnant and nonpregnant adolescent females with about 50 percent of the cases being due to inadequate intake. The metabolic processes involved in tissue oxygenation are dependent upon iron (Abu-Ouf & Jan, 2015). The increased maternal plasma volume and increased fetal demands for iron (especially in the third trimester) can further compromise the adolescent. Iron deficiency in pregnancy may contribute to increased fetal **prematurity**, **low birth weight**, and low iron stores for the infant that can last for up to one year. For the mother, iron deficiency may contribute to cardiovascular stress, increased risk of urinary tract infection, sleep difficulties, decreased well-being, postpartum hemorrhage, and slower wound healing (Abu-Ouf & Jan, 2015). The nurse can reinforce the need for the teen to take prenatal vitamins during pregnancy and after the baby's birth. Vitamins should contain 30 to 60 mg of elemental iron daily. The nurse should educate about iron-rich foods and foods that promote iron absorption, such as those containing vitamin C.

Infant Care

Many adolescents have cared for babies and small children and feel confident and competent. Few teens are ever prepared, however, for the reality of 24-hour care of an infant. The nurse can help prepare the teen for the transition to motherhood while she is still pregnant. The trend toward early discharge from the hospital has made prenatal preparation even more important. The nurse can enlist the support of the teen's parents in education about infant care and stimulation. Young fathers-to-be would benefit from this education as well. Family values, practices, and beliefs about childcare may be deeply embedded and require the nurse to work gently and persuasively to challenge any that may be detrimental to an infant (HCO, 2017). For example, a family may believe that corporal punishment is a necessary component of child-rearing.

Adolescents often lack the self-confidence and knowledge required to positively interact with their infants. They may also have unrealistic expectations about their children's development (HCO, 2017). For example, they may expect their children to feed themselves at an early age or think that their children's behavior is more difficult than an adult mother might think. Teen parents often lack knowledge about infant growth and development, as seen in their limited verbal communication with their children, limited eye contact, and the tendency to display frustration and ambivalence as mothers. Over time, adolescents can improve their ability to foster their children's emotional and social growth. Children of adolescent mothers have also been found to be at risk for academic and behavior problems as they enter school. These risks can be reduced when the teen mother receives professional intervention and supervision in the area of infant social and cognitive development (The Urban Child Institute, 2014).

Abusive parenting is more likely to occur when the parents have limited knowledge about normal child development or have been victims of abuse themselves. It may also be more likely to occur among parents who cannot adequately empathize with a child's needs. Younger teens are particularly at risk for being unable to understand what their infant or child needs. This frustration may be exhibited as abusive behavior toward the child. Nurses should continually assess for child abuse risk when dealing with teens who exhibit greater psychological distress or lack social supports (McHugh et al., 2015).

After the birth of the baby the nurse should assess maternal support and observe how the mother responds to infant cues for basic needs and distress. Specific techniques that the new mother can be instructed to use in early childcare are listed in the How To box. Begin parenting education as early as possible. Adolescents who feel competent as parents have enhanced self-esteem, which in turn positively influences their relationship with their child. Recognizing these good parenting skills and providing positive feedback help a young mother gain confidence in her role (Angley et al., 2015).

HOW TO Promote Interactions Between the Teen Mother and Her Baby

The nurse can make the following suggestions to the teen mother:

1. Make eye contact with your baby. Position your face 8 to 10 inches from your baby's face and smile.
2. Talk to your baby often. Use simple sentences, but try to avoid baby talk. Allow time for your baby to "answer." This will help your baby to acquire language and communication skills.
3. Babies often enjoy when you sing to them, and this may help soothe them during a difficult time or help them fall asleep. Experiment with different songs and melodies to see which your baby seems to like.
4. Babies at this age cannot be spoiled. Instead, when babies are held and cuddled, they feel secure and loved.
5. Babies cry for many reasons and for no reason at all. If your baby has a clean diaper, has recently been fed, and is safe and secure, he or she may just need to cry for a few minutes. What works to calm your baby may be different from other babies you have known. You can try rocking, gentle reassuring words, soft music, or remaining quiet.
6. Make feeding times pleasant for both of you. Do not prop the bottle in your baby's mouth. Instead, sit comfortably, hold your baby in your arms, and offer the bottle or breast.
7. When babies are awake, they love to play. They enjoy taking walks and looking at brightly colored objects or pictures and toys that make noises, such as rattles and musical toys.

Repeat Pregnancy

Teen mothers who have a closely spaced second pregnancy, or a **repeat pregnancy**, have poorer birth, educational, and economic outcomes than teens who do not. In 2016, 17 percent of teen births in 15- to 19-year-olds were a repeat birth (USDHHS, 2016a). Teens with more than one child often are unable to finish their education or gain employment. Second children of teen mothers are often born prematurely or too small, often leading to more health problems (CDC, 2013). A *Healthy People 2020* objective is to reduce the proportion of pregnancies conceived within 18 months of a previous birth. Nurses should recognize which teens are at risk for a second teen pregnancy, such as lower educational and cognitive ability,

mental health issues, physical trauma, losses (such as death of a loved one), and substance use.

Discussions about family planning should begin during the third trimester of the current pregnancy. Nurses should review contraceptive options and help the young woman identify the methods she is most likely to use. It is helpful to determine at this time the methods she has used in the past, her satisfaction or dissatisfaction, and reasons for use or nonuse. Many teens express unrealistic goals, such as "I am never going to have sex again," or "I need a break from guys," and they may erroneously believe that they are unable to conceive for some time after the delivery. After delivery the nurse should follow up on the young woman's plan. Obstacles to obtaining contraceptives may exist, and the nurse can identify these and help problem-solve with the new mother.

Schooling and Educational Needs

Adolescents who become parents may have had limited school success before the pregnancy. However, coping with the demands of child-rearing coupled with the immaturity of the young mother may make school even less of a priority. Also, the potential for a closely spaced second birth may be lessened by a return to school. Fifty percent of teen mothers earn a high school diploma by the age of 22 years compared with 90 percent of women who did not give birth during the teen years (National Conference of State Legislators [NCSL], 2013). Federal legislation passed in 1975 prohibits schools from excluding students because they are pregnant. Greater emphasis is placed on keeping the pregnant adolescent in school during the pregnancy and having her return as soon as possible after the birth. Several factors may positively influence a young woman's return to school. These include her parents' level of education and their marital stability, small family size, whether there were reading materials at home, whether her mother is employed, and whether the young woman is African American.

A practical challenge for young parents is locating and affording quality childcare; difficulties with this may prevent the highly motivated teenager from returning to high school. In the past 30 years the percent of parenting teens who return to high school and graduate (40 percent) has improved significantly. Attendance in college, now becoming the career requisite, is still less attainable for women who had children as teenagers than for those who delayed childbearing, and less than two percent attain that college degree by the age of 30 (NCSL, 2013).

Young women who have pregnancy complications may seek home instruction. This decision is made according to regulations issued by the state boards of education. Some young women have difficulty attending school because of the normal discomforts of pregnancy or because of social and emotional conflicts associated with the pregnancy. Teens who leave school without parental or medical excuses may face legal problems because of truancy. This increases the potential for them to become school dropouts. The nurse can determine whether this has happened and try to coordinate with the school personnel (and school nurse, if one exists) to tailor efforts for a particular pregnant teen to keep her in school. Specific needs to be addressed include the following: (1) using the bathroom frequently, (2) carrying and consuming more fluids or snacks to relieve nausea, (3) climbing stairs and carrying heavy book bags, and (4) fitting comfortably behind stationary desks. Schools that are committed to keeping students enrolled are generally helpful and will assist in accommodating special needs.

TEEN PREGNANCY AND THE NURSE

Nurses can influence teen pregnancy through appropriate interventions at home and in the community.

Home-Based Interventions

Nurses can identify young women at risk for pregnancy in families currently receiving services. Younger sisters of pregnant teens were 4.8 times more likely to become pregnant themselves with an increase to 5.1 times more likely if both sister and mother had a teen birth (Wall-Wieler et al., 2016). Nurses can offer anticipatory guidance addressing sexuality issues to the parents of all preteens and teens during home visits to increase their knowledge and awareness.

Visiting the pregnant teen in her home allows the nurse to assess the facilities available at home for management of her pregnancy needs and the suitability of the environment for her child. Some specific areas to assess are adequacy of heating and cooling, a source of water, cleanliness of the home, cooking facilities, and food storage. The nurse may find it more convenient for parents and other family members to participate in education and counseling sessions in their own home. Also, the need for financial assistance and other social service support may be more easily identified. Home visiting by nurses during a young woman's pregnancy can be critical in achieving compliance with antepartum goals concerning weight gain, good nutrition, and prenatal medical concerns (Fig. 35.2).

Fig. 35.2 The teen mother and the teen's own mother can be included in health teaching.

A teen pregnancy can shift the family dynamics. Families may go through stages of reactions. First, a crisis stage may occur, characterized by many emotions and conflict. By the third trimester, a honeymoon stage may occur, with greater acceptance and understanding of the teen and the impending birth. Finally, after the infant's birth, reorganization may occur, during which conflict may emerge again over issues of childcare and the young woman's role. The nurse can facilitate family coping and resolution of these stages by treating the family as client and assessing each person's role and strengths. Ultimately, family support for a teen parent can positively influence both mother and infant (Marino et al., 2016). A balance of moderate family guidance and supplementary care supports young mothers in their parenting role rather than replacing it.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Teen Pregnancy

Targeted Competency: Evidence-Based Practice

Integrate best current evidence with clinical expertise and client/family preferences and values for delivery of optimal health care.

Important aspects of evidence-based practice (EBP) include:

- **Knowledge:** Describe EBP to include the components of research evidence, clinical expertise, and client/family values
- **Skills:** Locate evidence reports related to clinical practice topics and guidelines
- **Attitudes:** Value the need for continuous improvement in clinical practice based on new knowledge

Evidence-Based Practice Question

You are a registered nurse (RN) in a community-based health clinic conducting sports physicals for high-school aged students. You conduct a physical assessment on a female 18-year-old student, Gloria, who has been accompanied to this appointment by her mother. During the physical examination, Gloria confides in you that she is sexually active and is not currently using any form of contraception because her mother is not supportive. You ask Gloria if she would like to be using birth control, and she says that she is not sure. You provide Gloria some educational materials on various contraceptive methods.

After the examination Gloria's mother asks to speak with you privately. Gloria's mother is moderately emotional, worried that her daughter has been sexually active and might be pregnant.

- What are your legal limits around sharing information with Gloria's mother?
- Based on these limits, what information do you share with Gloria's mother?
- What might be your next step in facilitating a mother-daughter dialogue in this situation?
- Find a nursing research article about family communication with pregnant teens. Are there guidelines or outcomes from research that might be applied to this clinical scenario?
- What other patient outcome might you identify that could lead to a successful intervention in this scenario?

Prepared by Gail Armstrong, PhD, DNP, ACNS-BC, CNE, Associate Professor, College of Nursing, University of Colorado.

Community-Based Interventions

Many communities have broad-based coalitions and planning councils that facilitate a comprehensive approach to teen pregnancy. These groups usually include health care professionals, social workers, clergy, school personnel, businessmen, legislators, and members of other youth-serving agencies. Nurses play a significant role on this team by participating in or organizing community assessments, public awareness campaigns, group education (for professionals, parents, and youths), and interprofessional programs for high-risk youths. Community acceptance is more likely when there is a broad base of support for activities directed at the reduction of teen pregnancy or reduction of consequences.

LINKING CONTENT TO PRACTICE

Just as providing care to pregnant teens includes many of the *Healthy People 2020* objectives; this care is also consistent with the standards and competencies for public health professionals, including nurses. Specifically, the nurse assesses the teen population, determines priorities for nursing actions based on the assessment, develops a plan, and implements the plan by coordinating care with many appropriate agencies. In dealing with pregnant teenagers, it is essential to work with schools and many social service agencies in order to provide age-appropriate care and health education for both the teen and the baby. Skills in the core competencies such as assessment, planning, cultural competency, and communication are essential when providing care to this population.

From American Nurses Association: *Scope & standards of practice: public health nursing,* ed. 3, Silver Spring, MD, 2015, ANA; Public Health Foundation Council on Linkages: *Core competencies for public health professionals,* Washington, DC, June 26, 2014, revised and adopted, PHF.

Research has evaluated years of pregnancy prevention programs. As less funding is available, programs must stand out to receive financial support. Research summaries that can be used by communities for strategic planning are available from the Power to Decide organization's national campaign to prevent teen and unplanned pregnancy (https://powertodecide.org), based in Washington, DC. Programs that have been evaluated fall into one of three categories: programs that focus on sexual factors (this includes educational programs addressing sexual behavior and STD/HIV), programs that focus on nonsexual behaviors (service learning that matches volunteerism with a didactic component), and programs that focus on both sexual and nonsexual factors (may bring other risk behaviors and/or protective factors into the curriculum). Because there is diversity available in the programs, communities can match their characteristics and needs with a program.

Health teachers may ask nurses to provide educational materials or assistance with classroom instruction, especially in the areas of family planning, STDs, and pregnancy. Schools that do not have nurses may arrange to have a nurse from the health department available for health consultations with students during school hours. Schools may also request that nurses participate on their health advisory boards.

School-based health care clinics are operating in nearly 2000 elementary, middle, and high schools in the United States (Health Resources and Services Administration, 2017). The services offered may include counseling, referrals, and primary care services. Many middle and high school

clinics offer reproductive services, which may include contraception and abstinence counseling, pregnancy and STD testing, dispensing contraceptives, and offering prenatal care. Reproductive health counseling can be vital in efforts to increase the use of contraception, reduce teen pregnancy, and improve student attendance and high school graduation (County Health Rankings and Roadmaps, 2017). The nurse can assist school systems with designing these programs, as well as referring young women in need of reproductive health care services.

Nurses bring their knowledge about youth and reproductive behavior to any organization or group that has teens, their parents, or other professionals working with teens. Churches are becoming increasingly interested in addressing the needs of their youth, especially because teen sexual activity, pregnancy, and parenting are affecting more of their members.

EVIDENCE-BASED PRACTICE

When adolescents become parents they face challenges that set them apart from adult parents. Outcomes for teen parents and their children have been generously studied and clearly stated. What has been lacking in nursing research is a better understanding of the elements of nursing intervention that can improve these outcomes.

Previous studies have identified that pregnant and parenting adolescents can benefit from visiting nursing care on many fronts. This includes decreasing hospitalizations, emergency department visits, and repeat pregnancies; increasing spacing between births; reducing domestic violence; and more. These studies focused more on the improved outcomes rather than informing nursing on the process by which this happens.

This study adds to the data that help us understand how to help teenagers become parents. It focuses on information gathered from 30 public health nurses (PHNs) visiting pregnant and parenting teenagers. These PHNs submitted stories about their young clients, and those were analyzed to understand the basic social psychological problems experienced, as well as the basic social psychological process used by the PHN to help the adolescent attain stronger parenting skills.

Nurse Use

The data that emerged from this study confirmed that adolescents begin parenting with negative life circumstances, a poor knowledge base, and a lack of awareness of how to attain the knowledge. The elements of the PHN interventions that improved the adolescents' role as parents were wide ranging and included case management, health education, counseling, and referral. This greater understanding about the process in which PHN home visiting works is essential for targeted and effective nursing interventions (Atkinson & Peden-McAlpine, 2014).

PRACTICE APPLICATION

A local youth-serving agency requested the assistance of a nurse, Kristen Brown, in the implementation of a new high school–based program for pregnant and parenting teen girls. The primary goal of the program is to keep these teens in school through graduation. The secondary goal is to provide knowledge and skills about healthy pregnancy, labor and delivery, and parenting. After delivery, students enrolled in this program were paid for school attendance, and this money could be used to defray the costs of childcare.

A nurse from the health department was the ideal choice to conduct the educational sessions. The group met weekly during the lunch hour. The curriculum that was developed included topics from early pregnancy through the toddler years. Occasionally, Ms. Brown recruited outside speakers such as a labor and delivery nurse or an early intervention specialist.

She also met individually with each enrolled student to provide case management services. Ideally, she would ensure that each student had a health care provider for prenatal care, that each was visited at home by a nurse, that each had enrolled in WIC and Medicaid if eligible, and that both the pregnant teen and her partner knew about other parenting and support groups.

One educational session that was particularly interesting was the discussion about the postpartum course—the six weeks after delivery. There were many lively discussions about labor experiences as well as some emotional discussions about the reality of coming home with a baby and changes in the relationship with their male partner. Accurate contraception information was provided, which helped to clarify the many myths the girls had heard from friends and older women. Many girls benefited from understanding the normalcy of postpartum blues, but one young woman recognized that she had a more serious and persistent depression and privately approached the nurse for assistance.

At the end of the first school year, the dropout rate for pregnant and parenting teens was reduced by half, and preterm labor rates had also declined. The local school board and a local youth-serving agency joined together to provide financial support to continue this program for an additional two years. Ms. Brown was asked to expand the educational programs and interventions she had developed.

What are some directions in which Ms. Brown might expand the program? List four.

Answers can be found on the Evolve site.

KEY POINTS

- The provision of reproductive health care services to adolescents requires sensitivity to the special needs of this age group. This includes knowing about state laws regarding confidentiality and services for birth control, pregnancy, abortion, and adoption.
- Pregnant teenagers have a substantial percent of the first births in the United States. They are more likely to deliver prematurely and have a low-birth-weight baby. This risk can be reduced by early initiation of prenatal care and good nutrition.

- Factors that can influence whether a young woman becomes pregnant include a history of sexual victimization, family dysfunction, substance use, and failure to use birth control. Several factors may overlap.
- Nutritional needs during pregnancy can be challenged if the teenager has unhealthy eating habits and begins the pregnancy with limited reserves of vitamins and minerals. With education the adolescent can make good food choices while still snacking or eating fast foods. Weight gain during pregnancy is a significant marker for a normal-weight baby.
- Young men need special attention and preparation as they become fathers. The interventions include information about pregnancy and delivery, declaration of paternity, care of infants and children, and psychosocial support in this role.
- The pregnant teen will need support during her pregnancy and in child-rearing. Families may provide most of this support. However, many communities have a variety of services available for adolescents. These services include financial assistance for medical care, nutritional programs, and school-based support groups.
- Adolescent parents often have unrealistic expectations about their children and may not know how to stimulate emotional, social, and cognitive development. The children born to adolescents are at risk for academic and behavioral problems as they become older. Teens who receive education on normal development and childcare are more likely to avert these problems with their children.
- During a pregnancy, teenagers are expected to attend school. Homebound instruction is reserved for those with medical complications. Teen mothers who return to school and complete their education after the birth of their child are less likely to have a repeat pregnancy. Problems finding childcare and the need to have an income can create an obstacle to school return.
- Community coalitions, which include nurses, can have a significant impact on teen pregnancy. These coalitions generally have diverse representation from the community, and therefore their activities meet with more community support.

CLINICAL DECISION-MAKING ACTIVITIES

1. Become familiar with statistics on teen pregnancy, births, miscarriages, and abortions in your area, and collect information on use of prenatal care, low-birth-weight and premature deliveries, high school completion, and repeat pregnancies. Compare the trends in statistics to the impact and costs to the individual, her family, and the community.
2. Call or visit local schools, and interview the school nurse or guidance counselors about teen pregnancy. Determine what resources are available through the schools for pregnancy prevention. Assess the family life education curriculum, and identify a teaching project for nursing students. Can pregnancy prevention and parenting education be incorporated into the learning objectives in the existing school curriculum?
3. Design and offer a childbirth preparation class for pregnant teens and their support persons. Include a plan for identifying potential participants, select a site that is accessible, and develop an evaluation method. Develop teaching tools that acknowledge adolescent development.
4. Assess reproductive health care services for young men in your community. Design an awareness campaign targeting young men on paternity issues and the prevention of pregnancy. Be specific about ways to incorporate male role models and mentors.

Mental Health Issues

Anita Thompson-Heisterman, MSN, PMHCNS-BC, PMHNP-BC

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Describe the history of community mental health and make predictions about the future.
2. Discuss the prevalence of mental illness in the United States and globally.
3. Describe essential mental health services and corresponding national objectives for improving mental health.
4. Evaluate standards, models, concepts, strategies, and research findings for use in community mental health nursing practice to improve community mental health.
5. Describe the role of the community mental health nurse with individuals and with groups at risk for psychiatric mental health problems.
6. Apply the nursing process in community work with clients diagnosed with psychiatric disorders, families at risk for mental health problems, and vulnerable populations.

CHAPTER OUTLINE

Scope of Mental Illness in the United States
Systems of Community Mental Health Care
Evolution of Community Mental Health Care
Deinstitutionalization
Conceptual Frameworks for Community Mental Health
Role of the Nurse in Community Mental Health
Current and Future Perspectives in Mental Health Care
National Objectives for Mental Health Services

KEY TERMS

Because providing community services and nursing care to people suffering from mental illness or emotional distress is complex and influenced by many individual and community factors, it requires a variety of approaches. Complicating factors include (1) the scope of emotional and mental disorders; (2) uncertainty about the specific cause, cure, and treatment for the most severe mental disorders; (3) the severe chronic disabling nature of some mental disorders; and (4) the complexity of the community mental health services sector. The scarcity of resources compounds the problems and presents challenges in community mental health work.

Cultural beliefs and economics influence the amount and types of services and treatment available in various countries. However, two universal truths exist: services for people with mental disorders are inadequate in all countries, and mental illness has a significant effect on families, communities, and nations. Therefore specialized knowledge and skills about severe mental illness and mental health problems are necessary for effective nursing practice in the community. It is helpful to understand both the organization of mental health services from a historical perspective and the trends in current health care demands and delivery. Knowledge about populations at

risk for psychiatric mental health problems and understanding illness outcomes in terms of biopsychosocial consequences are even more important. Finally, it is necessary to refine and broaden nursing process skills in treatment planning to include the impact of mental illness on families and communities.

This chapter focuses on the scope of mental disorders, the development of community mental health services, the current health objectives for mental health and mental disorders, and the role of the nurse in community settings. Conceptual frameworks useful in community mental health nursing practice are also presented. Because other chapters in this book are devoted to high-risk groups such as the homeless population and those with substance abuse problems, this chapter's focus is on the variety of **mental health problems** encountered in communities, with an emphasis on populations that have long-term, **severe mental disorders** and groups that are most vulnerable to mental health problems.

SCOPE OF MENTAL ILLNESS IN THE UNITED STATES

Mental health is defined in *Healthy People 2020* (U.S. Department of Health and Human Services [USDHHS], 2010) as encompassing the ability to engage in productive activities and fulfilling relationships with other people, to adapt to change, and to cope with adversity. The World Health Organization (WHO) expands the definition, describing mental health as a state of well-being in which a person can realize his or her potential and notes that mental health is essential if a person is to have health (WHO, 2008). Mental health is an integral part of personal well-being, family and other interpersonal relationships, and contributions to community or society. Mental disorders are conditions that are characterized by alterations in thinking, mood, or behavior that are associated with distress and/or impaired functioning. Mental illness refers collectively to all diagnosable mental disorders. Severe mental disorders are determined by diagnoses and criteria that include degree of functional disability (American Psychiatric Association [APA], 2013).

Mental disorders are indiscriminate. They occur across the life span and affect persons of all races, cultures, genders, and educational and socioeconomic groups. They are a leading cause of disability and even death. One in 10 people suffer from depression and/or anxiety, affecting 676 million people worldwide, and in 2012 there were 800,000 suicides, 86 percent of these in people under age 70 (WHO, 2018). In the United States nearly 18.3 percent of adults (age 18 years and older) have a mental health condition severe enough to impair daily function, and 5.9 percent of these suffer from a **serious mental illness** such as schizophrenia (Substance Abuse and Mental Health Services Administration [SAMHSA], 2015). Nearly half of those with any mental disorder (8.1 percent) meet criteria for two disorders, mental health and substance abuse (SAMHSA, 2017). According to the Centers for Disease Control and Prevention (CDC), there were alarming and increasing rates of opioid abuse, overdoses, and suicide in the United States between 1999 and 2014 (CDC, 2016). The rate of suicide rose from 12.3 to 15.4 per 100,000 people with middle-aged adults ages 45-65 having the largest increase.

Since 2008 prevalence rates of serious mental illness among young adults ages 18-25 have increased from 3.8 to 5.9 percent, yet only half of those received any mental health treatment (SAMHSA, 2017). In 2016 between 7 and 12 percent of youth ages 12-17 had an emotional disturbance serious enough to impair function, and 20 million people over the age of 12 had a substance use disorder (SAMHSA, 2017). Adolescent mental health is a global concern as well (WHO, 2014); 14.5 percent of people over age 50 have a mental disorder, and these rates may rise as the number of older Americans increases over the next two decades. Alzheimer's disease, the primary cause of dementia, is increasing. In 2018 an estimated 5.7 million Americans had Alzheimer's disease. This number includes 5.7 million people who were 65 years or older and about 200,000 individuals under age 65 who had younger-onset Alzheimer's disease (Alzheimer's Association, 2018). The number of cases in the population doubles every 5 years of age after age 60 and is becoming a public health crisis as the baby boomer generation ages. Currently there are 53 million people with Alzheimer's disease, and by 2050 there will be 88 million. Affective disorders include major depression and manic-depressive or bipolar illness. Although bipolar illness may affect only a small proportion of the population, major depression is pervasive and is the leading cause of disability among adults ages 15 to 44. Anxiety disorders, including panic disorder, obsessive-compulsive disorder, post-traumatic stress disorder (PTSD), and phobias, are prevalent, affecting 18 percent of American adults each year. Mental disorders can also be a secondary problem among people with other disabilities. Depression and anxiety, for example, occur more frequently among people with disabilities (NIMH, 2014).

The impact of mental illness on overall health and productivity in the United States and throughout the world is often underrecognized. In the United States mental illness causes about the same amount of disability as heart disease and cancer. Despite the prevalence of mental illness, less than half of persons with a mental disorder obtain help for their illness in any part of the health care system, and the majority of persons with mental disorders do not receive any specialty mental health care. Although 65 percent of persons with the most serious mental illnesses received treatment in 2016, 35 percent did not (SAMHSA, 2017). Sixty percent of youth and 57 percent of adults received no mental health treatment. The WHO (2008) reports the global burden of mental health, substance abuse, and neurological diseases at 14 percent and noted that depression is the main cause of illness and disability in adolescents worldwide (WHO, 2014). In recognition of the lack of resources, the WHO launched a mental health global action program (mhGAP) to begin to address mental health needs (WHO, 2008). Their poster "No Health Without Mental Health" effectively describes the need to integrate physical and mental health services. Given this information, it is critical that nurses recognize and provide health services for those with mental disorders in a variety of nontraditional community settings.

In addition to diagnosable mental conditions, there is growing awareness and concern about the public health burden of stress, especially after terrorist attacks at home and globally; natural disasters, such as hurricanes, tsunamis, tornados, fires, and earthquakes; and human-made disasters such as gun violence in schools, public spaces, and communities. Strengthening the public health sector to respond to these events involves developing community mental health responses, as well as addressing physical health concerns. Community mental health nurses (CMHNs) play an important role in identifying stressful events, assessing stress responses, educating communities, and intervening to prevent or alleviate disability and disease resulting from trauma.

Although all of us are vulnerable to stressful life events and may develop mental health problems, persons with chronic and persistent mental illness have numerous problems. Mental illness is misunderstood, and those who suffer from it often experience stigma and lack of social support, which is so critical to health. Persons with mental illness are often identified by the illness as a schizophrenic instead of a person with the disease of schizophrenia. The disruptive symptoms of this illness often occur just as young persons are attempting to finish schooling and develop a career, shattering lives and driving many into a lifetime of underemployment, poverty, and lack of access to adequate health services, housing, and social supports. Many accessible and coordinated services are needed to enable people with chronic mental illness to live in the community, yet these often are not available. Despite the inadequacy of resources, advances have been made in the treatment of mental illness. Two major movements have influenced these advances: consumer advocacy and a better understanding of the neurobiology of mental illness, requiring a more integrated view of the complexity of factors involved (Macedo, 2017; Pandya & Jän Myrick, 2013). Naturally, the financing of mental health services affects access to care and influences treatment. The system known as managed care significantly affected service delivery for the past 30 years, and passage of mental health parity and national health care reform through the Patient Protection and Affordable Health Care Act have influenced mental health care more recently (Ali et al., 2016; Cowell et al., 2017; Mechanic & Olfson, 2016; Pearlman, 2013).

Consumer Advocacy

Consumer advocacy movements for people with mental illness, like those for other illnesses, came about to fulfill unmet needs and to attempt to decrease the stigma associated with mental illness. Specifically, the National Alliance for the Mentally Ill (NAMI) was the first consumer group to advocate for better services. This consumer advocacy group worked to establish education and self-help services for individuals and families with mental illness. Efforts of the NAMI gained momentum in the early 1980s. Subsequently, political groups and legislative bodies responded with direct support. One example of direct support was funding for the **Community Support Program** (CSP) by the National Institute of Mental Health (NIMH). The CSP provided grant monies to states to develop comprehensive services for persons discharged from psychiatric institutions and invited consumers to participate. These and similar efforts have helped bring consumers, families, and professionals together to work toward improvement in the treatment and care of persons with mental illness.

Neurobiology of Mental Illness

Mental illnesses are complex biopsychosocial disorders. Considerable emphasis in the past 20 years has focused on the biological basis of mental illness. The 1990s were declared the "decade of the brain" as advances in research in neurology, microbiology, and genetics led to understanding the structural and chemical complexity of the brain. Consequently, more is now known about the functions of the brain than at any time in history. We have learned that the brain is not a static organ. The concept of brain plasticity demonstrates that new learning actually changes brain structure. For example, traumatic experiences change brain biochemistry, as do significant positive experiences (Nusslock & Miller, 2016; Rosenzweig et al., 2017). This information supports the thought that both experience and psychosocial factors have effects on the etiology and on the treatment of mental illnesses. Both somatic and psychosocial interventions need to be used to treat mental illness. In addition to research, neuroradiological techniques aid diagnosis and treatment of people with psychiatric disorders. Angiography is used to screen for abnormalities of the vascular system, such as atherosclerosis and brain tumors, that can lead to behavior changes. The use of noninvasive scanning of the brain can help in making diagnoses. Computed axial tomography (CAT) scans provide a cross-sectional view of the brain, whereas nuclear magnetic resonance (NMR) imaging offers the advantage of imaging the brain from different planes. Still other techniques, such as positron emission tomography (PET) and single-photon emission computed tomography (SPECT), provide information about cerebral blood flow and brain metabolism. The information gained from these advanced technologies can lead to better understanding about mental illness and treatment and help scientists study the effects of psychotherapeutic interventions on the brain. Discoveries in psychopharmacology have also revolutionized the treatment of mental illness. New, atypical antipsychotic drugs used in the treatment of schizophrenia can improve the quality of life for many, primarily because of fewer side effects. For example, side effects of antipsychotic drugs include central and peripheral nervous system manifestations. Newer second-generation antipsychotics have reduced some of these side effects, but new adverse effects, including weight gain, insulin resistance, and dangerously high blood glucose levels, collectively known as metabolic syndrome, have created fresh concerns for consumers and providers (Rojo et al., 2015). Although psychopharmacology has dramatically improved the lives of people with severe mental illness, controversies exist about the costs of monitoring treatment. Newer antidepressant medications known as selective serotonin reuptake inhibitors (SSRIs) are now considered the first choice in the treatment of depression as well as for many anxiety disorders because they lead to good responses with fewer side effects. They are now widely prescribed by primary care physicians, as well as psychiatrists, and are some of the most prescribed

medications in the United States. Although considered safer than older agents, evidence suggests that the SSRIs may accelerate bone loss, leading to osteoporosis, and they may not be more effective than non-pharmacological interventions, such as exercise, in treating some depression (Holmes, 2016). Future directions suggest the science of pharmacogenetics might enable more individualized treatment of mental illness based on specific, genetically based responses to pharmaceuticals (Rojo et al., 2015).

SYSTEMS OF COMMUNITY MENTAL HEALTH CARE

Managed Care

Managed care is a system of managing health care to ensure access to appropriate and cost-effective services. Managed mental health care grew rapidly during the 1990s, and by 1999 nearly 80 percent of Americans were enrolled in a managed health care plan. Initially a method to control costs and access to mental health care in the private insurance sector, managed care became a significant factor in public mental health, and by the turn of the century more than half of all Medicaid recipients were enrolled in a managed mental health care plan (Mechanic & Olfson, 2016). Consumer outcomes such as health status, quality of life, functioning, and satisfaction are considerations in deciding whether services are effective.

Because one purpose of managed care was to control costs, often by substituting less costly services for more costly ones, the findings about consumer outcomes become critical. The provision of quality comprehensive services needed by persons with serious and persistent mental illness in the community is not inexpensive, but it is generally less costly than hospital care and frequent admissions. Services must fit the needs of the consumer, and outcomes research and consumer satisfaction can help guide care and policy decisions.

Changes continue to take place in mental health funding, and changes in one sector can have far-reaching consequences in many others. Although legislation was passed in 1996 ensuring parity for mental illness coverage in insurance plans, the implementation at the state level and the effects on insurance plans had been rather negligible for a variety of reasons, and further legislation (the Mental Health Parity and Addiction Equity Act) passed in 2008 to improve service access (Mechanic & Olfson, 2016).

The seemingly constant changes in mental health funding present challenges for nurses, who need to make judgments about the positive and negative outcomes of these changes on the people they care for before research findings that can be generalized to the population are readily available.

Patient Protection and Affordable Health Care Act

The Patient Protection and Affordable Health Care Act (ACA, passed in 2010) affected both access to and funding of mental health services and increased the need for CMHNs at the general and advanced practice levels (Mechanic & Olfson, 2016; Pearlman, 2013). The ACA ensured access to mental health services for 27 million more Americans who had no coverage, and an additional 35.5 million were projected to received new or improved mental health services added to existing coverage (Mechanic & Olfson, 2016; Pearlman, 2013). Preventive mental health services, such as depression and behavioral screening, are now required to be offered free of charge, and integration of mental health services into primary care is mandated (USDHHS, 2014). The ACA removed economic and geographic barriers and helped remove the stigma of mental illness through routine screening and treatment within a primary care visit. It was expected that earlier detection and treatment of mental health and substance abuse conditions would occur, thus improving the mental health of the population (Busch et al., 2013). However, despite legislation promoting greater access to care, often substance abuse treatment was not covered (Cowell et al., 2017; Ali et al., 2016). Such a major change in the manner in which services were to be provided along with the expected increase in the number of people seeking mental health care did lead to new challenges and opportunities in the delivery of care. The ACA did increase access to mental health services for many, allowed young people up to the age of 26 to stay on their parent's health plan, prohibited insurers from denying benefits due to pre-existing conditions, and promoted integration of screening and health promotion into primary care. Some provisions of the ACA have recently been changed, and the requirement of enrollment has been discontinued. The future of funding for mental health services remains unclear.

Mental Health Services

Mental health problems and mental disorders are treated by a variety of caregivers who work in diverse and loosely connected facilities. The landmark surgeon general's report on mental health, in an attempt to delineate where Americans receive mental health services, defined four major ways through which people receive assistance: (1) the specialty mental health system, both public and private; (2) the general medical or primary care sector; (3) the human service sector; and (4) the voluntary support network, including advocacy groups (USDHHS, 1999). Nurses need to understand that delivery of mental health services may occur in any of these systems. In fact, most older adults receive mental health services through the primary care sector, whereas most children and adolescents are served through human services that include schools. Those with resources, less severe mental health problems, and access to primary care are more likely to have their mental health needs addressed within the context of a visit to their primary care provider. Because of the initial influence of managed care, access to a specialist, if indicated for psychiatric treatment, had occurred via this route as well. The ACA passed in 2010 now mandates mental health screening and initiation of treatment in primary care and has had an effect on where mental health services are received or at least initiated (Mechanic & Olfson, 2016; Pearlman, 2013). In the 29 states and Washington, DC, where expansion of Medicaid occurred, insurance coverage, access to care, use of preventative services, and self-assessed health increased, particularly among low-income childless

adults (Miller & Wherry, 2017; Simon et al., 2017). Integration of behavioral and primary care systems was another benefit (Kim et al., 2017).

The **community mental health model** is the primary method of care for people with serious and persistent mental illness. Components of this model include team care, case management, outreach, and a variety of rehabilitative and recovery approaches to help prevent exacerbations of illness. In most states, services are provided through comprehensive **community mental health centers** (CMHCs). There is great variance in how each state and locality implements mental health service delivery, and each version continues to evolve in this era of health care reform and changing funding sources as the CMHCs react to societal, political, and fiscal pressures. As resources diminish, the focus narrows, and many CMHCs are unable to provide services to populations other than those with serious and persistent mental illness. It is unclear how the growing focus on integration of mental health into primary care, parity in insurance coverage, and the passage of and possible changes in the ACA will continue to impact the community mental health system of care. There has been movement toward more comprehensive, integrated, and less fragmented services and an emphasis on more utilization of mental health nurses as primary providers of care (Mechanic & Olfson, 2016).

EVOLUTION OF COMMUNITY MENTAL HEALTH CARE

Historical Perspectives

How the community has perceived the etiology of mental and emotional illness across the ages has influenced the care and treatment of persons suffering from these disorders. These patterns were often cyclical. In ancient times, mental illness was viewed as resulting from supernatural forces, and those afflicted were sometimes shunned. During the Greco-Roman era, mental and physical illnesses were seen as interrelated and resulting from physical conditions. Treatment was aimed at curing the disease by restoring balance. A return to a belief in supernatural etiologies occurred during the Middle Ages in Europe and continued in the years in which the United States was being formed into a country. These beliefs led to poor treatment of the mentally ill, including incarceration, starvation, and torture. Near the end of the eighteenth century, the revolution in mental health care known as Humanitarian Reform took place. This reform movement, influenced by Philippe Pinel (1759-1820) in France and Benjamin Rush (1745-1813) in North America, led to hospital expansion, medical treatment, and the community mental health movements (Boyd, 2018).

Before the Humanitarian Reform, persons with mental illness were often housed in jails because health and social services had not been developed. Even later, after the development of hospitals as a site of treatment, persons with mental disorders were neglected and mistreated. Although the first psychiatric hospital in the United States was built in Williamsburg, Virginia, in 1773, about 50 years passed before widespread construction of facilities in other states took place. One person in particular, Dorothea Dix, led reform efforts to correct inhumane practices (Boyd, 2018).

Dorothea Lynde Dix (1802-1887) focused attention on criminals, those with mental disorders, and victims of the Civil War. She believed that people with mental disorders needed health and social services, and her efforts influenced the improved organization of mental health services. Her work led to the development of hospitals as the primary site of care, and she influenced standards for hospital administration and nursing care. Because of her lifetime efforts, often through political action, treatment for mentally infirm persons was altered in both North America and Europe (Boyd, 2018).

Hospital Expansion, Institutionalization, and the Mental Hygiene Movement. Psychiatric hospitals constructed during the expansion era were located in rural areas and were intended for small numbers of clients. However, they soon became overcrowded with people who had severe mental disorders, older adults, and immigrants who were poor and unable to speak English. Clients were essentially separated from the community and isolated from their families. Many were institutionalized for the rest of their lives in response to both a continued fear of persons with mental disorders and a lack of community resources. **Institutionalization** of large numbers of people, combined with minimal information about cause, cure, and care, resulted in overcrowded conditions and exploitation of clients.

At the beginning of the twentieth century, institutional conditions were reported publicly in the United States by Clifford Beers, who had been hospitalized both in private and in public mental hospitals (Boyd, 2018). Beers urged reform and influenced the founding of the National Committee for Mental Hygiene. During the mental hygiene movement, attention shifted to ideas about prevention, early intervention, and the influence of social and environmental factors on mental illness. These ideas about treatment also influenced the development of multidisciplinary approaches to treatment. The mental hygiene and community mental health movements increased understanding about mental illness.

Further understanding about the scope of mental illness was gained during the conscription process for the armed services in World War II. Many of the persons screened for military service during World War II were found to have neurological and psychiatric mental health disorders. Even more military personnel required treatment for mental health problems associated with social and environmental stress during and after the war, not only in the United States but also in Europe, Russia, and Pacific Rim countries (Boyd, 2018). At the same time, the community mental health model continued to expand slowly, while populations consisting of individuals with severe mental disorders and older adult persons with dementia grew larger in the state hospitals. Demands for mental health services in communities, combined with concerns about conditions of state psychiatric hospitals, prompted federal legislation that influenced development of the community mental health concept.

Federal Legislation for Mental Health Services. The first major piece of legislation to influence mental health services in

TABLE 36.1 Legislation That Influenced Community Mental Health Services

Year	Legislation	Focus
1946	National Mental Health Act	Education and research for mental health treatment approaches began (NIMH)
1955	Mental Health Study Act	Resulted in Joint Commission on Mental Illness and Health, which recommended transformation of state hospital systems and establishment of community mental health clinics
1963	Community Mental Health Centers Act	Marked beginning of community mental health centers' concept and led to deinstitutionalization of large psychiatric hospitals
1975	Developmentally Disabled Assistance and Bill of Rights Act	Addressed the rights and treatment of people with developmental disabilities and provided foundation for similar action for individuals with mental disorders
1977	President's Commission on Mental Health	Reinforced importance of community-based services, protection of human rights, and national health insurance for mentally ill persons
1981	Omnibus Budget Reconciliation Act	Rescinded much of the 1977 commission's provisions and shifted funds for all health programs from federal to state resources
1986	Protection and Advocacy for Individuals with Mental Illness Act	Legislated advocacy programs for mentally ill persons
1990	Americans with Disabilities Act	Prohibited discrimination and promoted opportunities for persons with mental disorders
1996	Mental Health Parity Act	Attempted to address discrepancy between mental health and medical-surgical benefits in employer-sponsored health plans
2008	Mental Health Parity and Addiction Equity Act	Prohibits discrepancy in coverage between mental health and physical health benefits in employer-sponsored and private insurance plans and added substance abuse as a covered mental health condition
2010	Patient Protection and Affordable Health Care Act	Prohibits discrimination in coverage for pre-existing conditions; prohibits discontinuation of coverage because of illness

NIMH, National Institute of Mental Health.

the United States was the Social Security Act in 1935. This act, created in response to economic and social problems of the era, shifted the responsibility of care for ill people from the state to the federal government. The federal government's role expanded when the demand for mental health services increased during and after World War II. Key points of legislation that influenced the development of community mental health services are summarized in Table 36.1.

In 1946 the National Mental Health Act was passed and the **National Institute of Mental Health** (NIMH) administered its programs. Objectives included development of education and research programs for community mental health treatment approaches. The act also included financial incentives for training grants to increase the number of professional workers, including nurses, in mental health services. Education and research programs materialized readily, along with advances in science and technology and the development of psychotropic medications. In 1955 the Mental Health Study Act was passed, and the NIMH established the Joint Commission on Mental Illness and Health. Members of the commission studied national mental health needs and submitted to Congress a report entitled *Action for Mental Health.* Recommendations of the report included continued development of research and education programs, early and intensive treatment for acute mental illness, and shifting the care of severely mentally ill persons away from the large hospitals to psychiatric wards in general hospitals and to community mental health clinics. Along with prevention and intervention, community services were to include aftercare services following hospitalization for individuals with major mental illness (Boyd, 2018). The shift in the locus of care from state hospitals to community systems was begun.

The **Community Mental Health Centers Act** was passed in 1963, and the CMHC concept was formalized. Federal funds were designated to match state funds to construct CMHCs and start-up programs. CMHCs were mandated to have five basic services: inpatient, outpatient, partial hospitalization, 24-hour emergency services, and consultation/education services for community agencies and professionals. In addition, regulations encouraged states to offer diagnostic and rehabilitative precare and aftercare services (Boyd, 2018). However, many CMHCs, especially those in poor and rural areas, were unable to generate adequate money for continuing their start-up programs. Funding did not follow the client to the community. The deinstitutionalization of persons with severe mental disorders was well underway before some of these shortcomings were recognized.

DEINSTITUTIONALIZATION

Deinstitutionalization involved transitioning large numbers of people from state psychiatric hospitals to communities. The cost of institutional care was perhaps the main reason for the movement; other influences included the discovery of psychotropic medications and civil rights activism (Boyd, 2018). The goal of deinstitutionalization was to improve the quality of life for people with mental disorders by providing services in the communities where they lived rather than in large institutions. To change the locus of care, large hospital wards were closed, and persons with severe mental disorders were returned to the community to live. Many were discharged to the care of family members; others went to nursing homes. Still others were placed in apartments or other types of adult housing; some of these were supervised settings, and others were not.

Not surprisingly, as with any abrupt, dramatic change, problems related to unexpected service gaps between the hospitals and the CMHCs led to continuity-of-care problems. Although deinstitutionalization was a noble idea, resources to support the implementation were inadequate. For example, families were not prepared for the treatment responsibilities they had to assume, and yet few mental health systems offered them education and support programs. Although many older adult clients were admitted to nursing homes and personal care settings, education programs were seldom available for staff members, who often lacked the skills necessary to treat persons with mental disorders. And finally, some clients found themselves in independent settings such as rooming houses and single-room occupancy hotels with little or no supervision and few skills to manage living in the community. Clients, families, communities, and the nation suffered as poor living and social conditions were associated with mental disorders. Homelessness and placement of the mentally ill in jails and prisons also occurred. These conditions may have increased the stigma associated with persons with mental illness. The placement of persons with mental illness in nursing homes, assisted living facilities, and jails was often referred to as "**reinstitutionalization**," because it only shifted people from one institution to another. These issues prompted additional legislation and advocacy efforts.

Civil Rights Legislation for Persons With Mental Disorders

The development of CMHCs was based partially on the principle that persons with mental disorders had a right to treatment in the least restrictive environment (Boyd, 2018). Although CMHCs were less restrictive than institutions, they lacked necessary services. For example, people with severe mental disorders require daily monitoring or hospitalization during acute episodes of illness. Even though hospital services were available, many individuals expressed their rights to refuse treatment and resisted admission. Also, transitional care after discharge for those persons who were admitted to hospitals was not available in most communities. In addition to the right to refuse treatment, advocates for mentally ill individuals focused on such civil rights issues as segregated services, inhumane practices in psychiatric hospitals, and failure to include clients in treatment planning. Activism for minorities and handicapped persons also influenced civil rights legislation for persons with mental disorders. In particular, during the 1970s institutional conditions of persons with developmental handicaps prompted passage of the Developmentally Disabled Assistance and Bill of Rights Act. Other legislation shifted funding from the federal to the state level. The Mental Health Systems Act was passed in 1980 to improve mental health services. However, in 1981 when Ronald Reagan took office, the Act was repealed and replaced with a block grant program reducing the involvement of the federal government (Mechanic & Olfson, 2016). This action limited the federal leadership role, shifted more costs back to the states from the federal government, and further impeded the implementation and provision of community mental health services.

State systems of mental health services developed in unique and diverse ways and were often inadequate. In general, individuals with severe mental disorders were vulnerable and neglected and either lacked or were unable to access health and social services. In an effort to offset these problems, in 1986 the federal Protection and Advocacy for Individuals with Mental Illness Act and the State Comprehensive Mental Health Services Plan Act of 1986 were passed. Advocacy programs for mentally ill persons became part of the same state advocacy systems developed earlier under the Developmentally Disabled Assistance and Bill of Rights Act, and consumer involvement in CMHCs was mandated (Boyd, 2018). In spite of advocacy efforts and legislation, the CMHCs were unable to meet the increased and diverse demands for mental health services in their communities. The lack of services, combined with concerns about discrimination against all people with disabilities, led to additional legislation.

The **Americans with Disabilities Act** (ADA) was passed in 1990. The ADA mandated that individuals with mental and physical disabilities must not be discriminated against and must be brought into the mainstream of American life through access to employment and public services (Boyd, 2018). History reveals that past legislation promoted the rights of persons with mental disorders, but litigation was also responsible for the lack of growth, if not the decline, in community mental health services. In 1996 the Mental Health Parity Act was passed to address discrimination in insurance coverage, and in 2008 the Mental Health Parity and Addiction Equity Act (MHPAEA) was passed, prohibiting differential coverage for mental health (Hargan, 2018). The community mental health and public health nurses can advocate for clients to ensure equality in access to health services, housing, and employment.

Advocacy Efforts

Consumers, defined as persons who are current or former recipients of mental health services, along with their families have had a significant impact on mental health services. As in all areas of health care, the rights and wishes of consumers are important in planning and delivering services. However, consumers of mental health services have traditionally had difficulty advocating for themselves. In the past, treatment programs often fostered passivity in clients and excluded them from the treatment planning process. In addition, family members were responsible for care in the home, but they lacked resources and even information about treatment (Riesser & Schorske, 2013). Like persons with mental illness, family members suffered from the stigma of mental illness and public attitudes that contributed to self-advocacy problems. In contrast, self-advocacy and involvement in treatment planning fosters self-confidence, promotes participation in services, and may have a significant influence on policy decisions (Hyun et al., 2018). Consumer and family groups fostered these objectives.

Family members led self-advocacy efforts in the 1970s, when small groups organized to challenge and change mental health services. These early efforts resulted in the formation of the **National Alliance for the Mentally Ill** (NAMI), which today

BOX 36.1 Advocacy and Self-Help Organizations

- *Community Support Program (CSP):* A program of the U.S. Department of Health and Human Services (USDHHS), Substance Abuse and Mental Health Services Administration (SAMHSA), and the Center for Mental Health Services (CMHS), that developed plans for a model continuum of care, offers grants for demonstration programs including community rehabilitation projects, and provides money to states for development of consumer and family services and advocacy efforts
- *Consumer/Survivor Mental Health Research and Policy Work Group:* An endeavor sponsored by the Mental Health Statistics Improvement Program of the CMHS to initiate consumer representation in activities of the National Association of State Mental Health Program Directors (NASMHPD)
- *Mental Health America (MHA):* An organization aimed at improving mental health in the population at large, emphasizing prevention
- *National Alliance for the Mentally Ill (NAMI):* A family organization that promotes family support groups, education programs, public campaigns to reduce stigma, and advocacy for mental health policy and services at local and national levels
- *NAMI Consumers' Council:* A consumer advocacy group that advocates for improved and effective psychiatric services and consumer empowerment
- *National Mental Health Consumers' Association (NMHCA):* A consumer organization that advocates for improvements in the mental health system

has both state and local affiliates. Soon consumer groups formed to advocate for better services, changes in mental health policy, self-help programs in treatment, and empowerment. Several advocacy groups that support these consumer efforts are summarized in Box 36.1. In their assessment of resources, nurses can identify community advocacy and support groups.

CONCEPTUAL FRAMEWORKS FOR COMMUNITY MENTAL HEALTH

The community mental health principles that are the underpinnings of practice include the right to mental health services delivered in the least restrictive environment, consumer involvement in treatment, advocacy, and rehabilitative and recovery services. Biopsychosocial theories are useful to understand the multidimensional aspects of community mental health nursing. These include theories and models that explain biological processes, systems, personality, life span development, family dynamics, and stress and coping. Focusing on wellness or recovery, relapse prevention, or relapse management and helping the client reach a maximal level of function are useful for nursing practice.

Another helpful framework for community mental health practice is **systems theory**, which emphasizes the relationship between the elements of a unit and the whole. An understanding of the whole occurs through the examination of interactions and relationships that exist between the parts. A holistic view of system and subsystems can be applied in a variety of ways in community mental health practice. One example of a subsystem in a community is its cultural groups. Subsystems of the cultural groups are families; subsystems of the families are individuals. Using systems theory to explore the background, conditions, and context of situations will disclose information about the positive and negative forces that either promote or undermine the well-being of any unit in the system.

The diathesis-stress model is also useful in CMHN practice. This theory integrates the effects of biology and environment, or nature and nurture, on the development of mental illness. Certain genes or genetic combinations produce a predisposition to a disorder. When an environmental stressor challenges a predisposition to a disorder, the mental disorder may be expressed (Edmondson et al., 2014). The integration of psychosocial and neurobiological paradigms is critical to the practice of psychiatric nursing. Nurses must recognize the effects of environment and biology on people and actively work to mitigate psychosocial as well as biological stressors through teaching strategies to promote mental health and reduce stress.

Levels of Prevention

Health promotion and illness prevention are fundamental to community mental health practice as well as to national objectives for mental health (USDHHS, 2010). Therefore the concepts of primary, secondary, and tertiary levels of prevention are useful in community mental health practice (see Levels of Prevention box).

Primary prevention refers to the reduction of health risks. It involves both health promotion and disease prevention. Health promotion strategies aim to enhance the well-being of healthy populations, whereas disease prevention strategies focus on the identification of populations at risk and conditions that may cause stress and illness. Mental health promotion includes providing education about stress reduction techniques to adults in the workplace. An example is to provide mental health information about depression and eating disorders to adolescents in schools.

Secondary prevention activities are aimed at reducing the prevalence or pathological nature of a condition. They involve early diagnosis, prompt treatment, and limitation of disability. Many functions of the practitioner role are aimed at secondary prevention for individuals. These include providing individual and group psychotherapy, case management, and referral. Screening members of a community for depression during National Depression Screening Day is an example of population-based secondary prevention. Counseling, referral, and treatment interventions after traumatic incidents, such as terrorist attacks or natural disasters, are other important community interventions.

Tertiary prevention efforts attempt to restore and enhance functioning. On a community level, tertiary prevention activities might include support of affordable housing, promotion of psychosocial rehabilitation and recovery programs, and involvement in advocacy and consumer groups for persons with mental illness. Many nursing role activities in community mental health are aimed at tertiary prevention with individuals. They include working with individuals to monitor illness symptoms and treatment responses, coordinating transition from the hospital to the community, and identifying respite care options for caregivers.

Relapse management with a focus on **recovery** is central to many of the programs and activities that enhance coping skills and competence. People are much more than an illness and can, and do, recover from episodes of illness. Nurses often participate in **assertive community treatment** (ACT) programs, psychosocial rehabilitation (clubhouses), and intensive case management. ACT programs differ from intensive case management approaches in that they are based more on a medical model and team approach and provide crisis and case management services 24 hours a day, 7 days a week. They are sometimes referred to as hospitals without walls (Henwood et al., 2017). **Intensive case management models** vary across programs but generally include contact with clients several times a week by an individual case manager. Nurses have critical roles in both treatment programs, as they have the knowledge and skills to provide comprehensive biopsychosocial care.

For example, the nurse visits the client at home, checks medication, assesses physical and emotional functioning, and may take the client shopping for nutritional food. The nurse may accompany the consumer to the physician's office and serve as an advocate for the client in this setting.

As case managers, nurses work with consumers, family members, and other caregivers to foster coping and competency aimed at managing illness symptoms. The goal of managing illness symptoms is to offset relapse and promote recovery. **Relapse management** and promotion of recovery are major goals of intervention in community mental health nursing. Assessment of the frequency, intensity, and duration of symptoms for the purpose of identifying biological, environmental, and behavioral triggers that may lead to illness relapse helps the consumer manage the illness and promotes recovery. Examples of triggers are poor nutrition, poor social skills, hopelessness, and poor symptom management. Once triggers are identified, interventions aimed at fostering effective coping skills can be introduced to offset relapse of symptoms. For example, an intervention that may promote effective coping to offset social isolation is to guide the client to organized consumer group activities available in the community. Another is to promote consumer and family efforts at job training through community vocational agencies. Still another is to promote competency in family members by coordinating services that enhance their understanding of the illness, provide social support, and include respite care when needed. Finally, an alliance with the client to manage medication and side effects is an important component of relapse prevention and recovery promotion (Baker et al., 2013).

As previously discussed, scientific advances that led to the use of medications to treat mental illness revolutionized mental health care and services. Atypical antipsychotics and new antidepressants with fewer side effects have further influenced mental health care in the community. Although these new drugs have dramatically improved the lives of many people with mental disorders, they are not without problems and are not a cure. The nurse has a critical role in monitoring side effects, detecting related health problems such as diabetes, and providing education and intervention. The most effective tertiary prevention is to combine medications with other relapse management and recovery approaches, including culturally sensitive social, behavioral, and psychotherapeutic interventions (Degnan et al., 2018).

LEVELS OF PREVENTION

In Community Mental Health

Primary Prevention

- Educate populations about mental health issues.
- Teach stress reduction techniques.
- Support and provide prenatal education.
- Provide parenting classes.
- Provide support to caregivers.
- Provide bereavement support.

Secondary Prevention

- Conduct screenings to detect mental health disorders.
- Provide mental health interventions after stressful events.

Tertiary Prevention

- Provide health promotion activities to persons with serious and persistent mental illness.
- Promote support group participation for those with mental health disabilities.
- Advocate for rehabilitation and recovery services.

ROLE OF THE NURSE IN COMMUNITY MENTAL HEALTH

The role of the nurse in community mental health was shaped both by the evolution of services and by the work of nursing pioneers. Development of a knowledge base for the nursing discipline and the further expansion of mental health care services to nontraditional community sites called for more advanced community-based practitioners (American Academy of Nursing, 2012). Nursing practice standards reflect the values of the profession, describe the responsibilities of nurses, and provide direction for the delivery and evaluation of nursing care. These standards also describe the roles of nurses in both advanced and basic practice.

Advanced practice psychiatric nurses have graduate-level education. The psychiatric nurse practitioner title and role have been expanded to encompass primary care and specialty knowledge and skills. These nurses provide primary, secondary, and tertiary care to individuals, groups, families, adults, children, and adolescents. Depending on state laws, some prescribe medications and have hospital admission privileges. For example, the advanced practice nurse may see clients individually to provide psychotherapy, may prescribe medications, and may conduct physical examinations or coordinate this care with other providers in primary care settings. The blended nurse practitioner role has been a response to a shift in the health care system away from specialization and toward comprehensive services that address both physical and mental health problems.

Nurses prepared at the undergraduate level provide basic primary, secondary, and tertiary services that are equally valuable. Specific roles and functions of both mental health and

BOX 36.2 Roles and Functions in Psychiatric/Mental Health Nursing Community Practice

Roles

- Clinician
- Educator
- Coordinator

Functions

- Advocacy
- Case finding and referral
- Case management
- Community action and involvement
- Complementary interventions
- Counseling
- Crisis intervention
- Health maintenance
- Health promotion
- Health teaching
- Home visits
- Intake screening and evaluation
- Milieu therapy
- Promotion of self-care activities
- Psychiatric rehabilitation and recovery
- Psychobiological interventions

Modified from American Nurses Association, American Psychiatric Nurses Association, and International Society of Psychiatric Mental Health Nurses: *Scope and standards of psychiatric-mental health nursing,* Washington, DC, 2007, American Nurses Publishing.

community nurses at the basic level (Box 36.2) are based on clinical nursing practice and standards (American Nurses Association [ANA], 2013, 2014). The functions suggest the overlapping roles of clinician, educator, and coordinator.

Clinician

Objectives of the practitioner role are to help the client maintain or regain coping abilities that promote functioning. This involves using the nursing process to guide the diagnosis and treatment of human responses to actual or potential mental health problems (ANA, 2014). Role functions at the basic practitioner level include case management, counseling, milieu therapy, and psychobiological interventions with individuals and with groups. Clinician skills are used with individual clients in a variety of settings, including the home, and often with large groups of people in specific neighborhoods, schools, and public health districts. For example, many clients who have schizophrenia live in personal care homes. These clients require biopsychosocial interventions related to medication management, milieu management for improved social interaction, and assistance with self-care activities for community living such as use of public transportation. Also, the practitioner increasingly coordinates these activities with both the consumer and other staff members in community settings. Therefore coordination of care is often the means for promoting recovery plan outcomes and enhancing quality of life for clients. These activities can support positive outcomes for others in the community at large.

For example, family members are a primary support system for individuals with schizophrenia. Whether the client lives in a personal care home, a family residence, or another setting, counseling family members and the client about the illness may offset the stressors of caregiving. Moreover, educating the public may reduce the stigma and decrease social isolation for both clients and families, lead to public support for needed services, and decrease the costs of health care because of fewer hospitalizations. As suggested in these examples, clinician and educator roles overlap.

Educator

The educator role uses teaching/learning principles to increase understanding about mental illness and mental health. The educator role is foundational to health maintenance, health promotion, and community action. Teaching clients about illness symptoms and the benefits of medications promotes health maintenance and may reduce the risk for illness relapse. Research supports similar education programs for family members to increase their ability to monitor illness symptoms, identify events that lead to relapse, and engage in self-care (Perlick et al., 2018). The nurse may facilitate a combined support and education group for parents of children with schizophrenia or for consumers with major mental illness in weekly sessions at the community mental health center. As seen in Fig. 36.1 the CMHN, both at the basic and at the advanced level, may participate in developing educational groups and programs for consumers, families, and other providers either alone or in collaboration with other organizations such as the local affiliate of Mental Health America or NAMI. The nurse may also teach clients primary prevention skills such as parenting as shown in Fig. 36.2.

At the community level, both formal and informal teaching is important. One important objective for mental health promotion is to teach positive coping skills. Overmedicating is an example of an ineffective individual coping skill. Even when medications are properly used in treatment, the nurse requires specialized knowledge about drug interactions, pharmacokinetics, and pharmacodynamics. Factors that

Fig. 36.1 Nurse educator teaching a small group of clients. (Rawpixel Ltd, #489081731, iStock, Thinkstock.)

influence pharmacokinetics include anatomical and physiological changes that occur with aging or with coexisting mental and physical conditions. Use of nonprescription medications such as herbal remedies and over-the-counter drugs can influence pharmacokinetics. Because over one third of Americans use nontraditional remedies and many of these are specific for psychiatric conditions, nurses need to assess the use of these substances, be aware of interactions, and share this information with clients (Clarke et al., 2015). For example, people may use herbal remedies such as ginkgo biloba to improve memory, valerian to improve sleep, and St. John's wort to treat depression and these remedies may not be effective.

CHECK YOUR PRACTICE

You are the nurse at a primary care center. You are escorting a 24-year-old man to the examination room for a follow-up visit after starting treatment for depression; his gait is unsteady; and he said he did not sleep well last night but otherwise has felt fine until just now. He is visibly anxious, unable to tell you what medication he is taking and sweating profusely. His pulse is 120 beats per minute, and his blood pressure is 152/88 mm Hg. You do not know what may have caused these symptoms. What should you do?

Coordinator

Coordination of care is a basic principle of the multidisciplinary team approach in community mental health services. Yet there is often a lack of coordination as well as limited services in many communities. Therefore, at a minimum, the role of coordinator must include case finding, referral, and follow-up to evaluate system breakdown and deficits. Because of current system deficits, nurses in community mental health function as coordinators who carry out intake screening, crisis intervention, and home visits. The nurse coordinator also tries to improve the client's health and well-being by promoting independence and self-care in the least restrictive environment. For example, the nurse may teach the client how to fill a medication box or how to use relaxation techniques to reduce stress.

Fig. 36.3 Interdisciplinary mental health planning team meeting. (Digital Vision, #200297936-001, Photodisc, Thinkstock.)

Health teaching related to nutrition, smoking cessation, and sleep promotion is essential for consumers with mental illness. These functions are consistent with descriptions of clinical case management that emphasize continuity of care for individuals who need complex services and with providing information for recovery (Cheng et al., 2018).

To achieve these objectives and improve services, nurses work with a variety of professionals, including advanced practice nurses, social workers, physicians, psychologists, occupational and vocational therapists, and rehabilitation counselors (Fig. 36.3). The nurse is often the advocate for the consumer who needs assistance with making his or her needs clear and accessing both health and social services. Because non-licensed paraprofessionals are frequently involved in direct care activities, their services must be directed, coordinated, and evaluated within the context of treatment planning. Finally, coordination also involves work with individuals who may not have formal preparation but who are essential for positive treatment outcomes. These individuals include family members, shelter volunteers, consumer support groups, and community leaders who can influence development of services. For example, the nurse can teach others about mental illness and effective interventions for times when symptoms become apparent and behaviors become difficult to manage. In the coordinator role, nurses can identify and influence health system effectiveness and ineffectiveness. To assist clients in accessing community resources and services, it is as important to develop positive relationships with other community providers as it is with clients.

CURRENT AND FUTURE PERSPECTIVES IN MENTAL HEALTH CARE

Both nationally and internationally, too few mental health care services exist, and the available services are fragmented and

often difficult to access. In the United States, large segments of the population do not have basic health care services or insurance to cover both expected and unexpected illnesses. The ACA passed in 2010 closed some of the gaps in coverage, and as of March 31, 2014, an additional 8 million people had enrolled in an insurance plan. Because health insurance coverage for most Americans is linked to employment, in an economic recession when jobs are lost, insurance is often lost as well, and people are no longer able to afford health care. Also, consumers, family members, and health care providers are concerned about issues of basic treatment, continuity of care, housing, and costs for acute and long-term mental health services for persons with mental illness. As large numbers of baby boomers reach retirement age and Medicare eligibility, there is concern about whether Social Security and Medicare resources will continue to exist for older Americans. Declining state budgets and possible cuts in Medicaid funding may place community mental health services in peril. Therefore implementation of health care reform continues to be a major political, social, and economic issue. Significant alterations in the current health care delivery system are occurring and will continue. Nurses working in communities must understand the models of care, the scope of mental illness, and the national health objectives designed to promote the health and welfare of persons with mental health problems.

Managed care and the ACA, as described previously, will continue to influence the delivery of mental health services. There will be a continued focus on providing services in primary care settings, attempts to reduce inpatient stays, and a more systematic evaluation of the outcomes of the care provided. The massive growth in managed care plans dramatically reduced hospital stays but also limited access to care. Though the passage of the ACA increased access to mental health care through expansion of Medicaid, preventative services, and access for those with a previous illness, it remains unclear how it will continue to impact those with long-term care needs. Because the public mental health system is the only remaining state and federally supported treatment system for persons with serious and persistent mental disorders and Medicaid funds more than half of public mental health services, use of managed care approaches did not always provide for adequate services. The expansion of Medicaid through the ACA did improve access to mental health care for more people and improved delivery and integration of services, but the individual requirement to have insurance was challenged in a Supreme Court ruling and attempts to overturn the ACA continue. Differences in federal and state managed plans and services created barriers to care, and the dismantling of the ACA will lead to gaps in service and large holes in the safety net for vulnerable consumers suffering from mental illness.

Nurses can be important providers in community mental health because of their emphasis on wellness and health promotion, skills at teaching and case management, and lower cost for service. In communities, nurses practice primary, secondary, and tertiary prevention activities by conducting comprehensive client histories to determine health problems and interventions that improve quality of care and cost-effectiveness. In home health settings, nurses screen for ineffective coping techniques such as use of alcohol or other substances to offset the stress of traumatic life events, thereby preventing further problems and costly care. They also screen for signs of psychiatric disorders in primary care and community health care settings. Community mental health services must include access to work and school settings for families and children. These types of nursing assessments and subsequent interventions may offset costly treatment in hospital settings.

Providing the range of community services necessary to handle persistent mental illness is difficult without sufficient funds for health and social services. It is important for nurses and others working in CMHCs to recognize the impact of changes in funding, target populations, restructuring, and disagreements between professions, agencies, and levels of government. Such information enables nurses to advocate for adequate services to meet the needs of individuals with severe and persistent mental illness. The nurse can build relationships with other providers, network with other agencies, and foster interagency collaboration to improve the quality of care for clients and their families.

NATIONAL OBJECTIVES FOR MENTAL HEALTH SERVICES

The goals of the community mental health movement are consistent with the health promotion and disease prevention objectives outlined in *Healthy People 2020* (USDHHS, 2010). The *Healthy People 2020* box illustrates the primary objectives of the national health agenda for mental health promotion and illness prevention. The objectives of *Healthy People 2020* address both settings where people receive care (e.g., primary care, juvenile justice systems) and populations at risk (e.g., children, adults with mental illness, and older adults). Increasing cultural competency and consumer satisfaction with mental health services are further objectives of the national agenda for mental health.

The new millennium brought recognition of the importance of addressing mental health and mental illness as part of disease prevention. Recognition of the burden of mental illness and the status of mental health in the United States was clarified by a landmark report from the surgeon general's office, *Mental Health: A Report of the Surgeon General* (USDHHS, 1999), followed by a report from the Surgeon General's Conference on Children's Mental Health in 2000 (USDHHS, 2000). A national agenda for action described in *Healthy People 2010* and continued in *Healthy People 2020* (USDHHS, 2010) made mental health one of the 10 leading health indicators, which are chosen on the basis of relevance as a broad public health issue. The President's New Freedom Commission on Mental Health further highlighted the need to transform and heal system fragmentation to ensure access to quality mental health services. These goals of a transformed mental health system are found in Box 36.3.

Overall, the national goals of *Healthy People 2020* are to improve mental health and ensure access to quality and

BOX 36.3 New Freedom Commission's Six Goals of a Transformed Mental Health System

1. Americans will understand that mental health is essential to overall health.
2. Mental health care will be consumer and family driven.
3. Disparities in mental health care will be eliminated.
4. Early mental health screening, assessment, and referral will be common practice.
5. Excellent mental health care will be delivered, and research will be accelerated.
6. Technology will be used to access mental health care and information.

From President's New Freedom Commission on Mental Health: *Achieving the promise: transforming mental health care in America,* USDHHS Pub. No. SMA-03-3832, Rockville, MD, 2003, USDHHS.

appropriate mental health services. Approaches emphasize prevention, maintenance, and restoration of mental health and independent functioning. The standards address mental health conditions of concern across the life span and with specific populations. Nurses can (1) promote the standards in the agencies where they are employed, (2) use the standards in community assessment activities, and (3) introduce information about the standards to other groups and agencies, including local consumer and family organizations, to help prioritize mental health concerns. The following box lists selected objectives that pertain to mental health and mental disorders.

HEALTHY PEOPLE 2020

Examples of Targeted National Health Objectives for Mental Health and Mental Disorders

Goal: Improve mental health and ensure access to appropriate, quality mental health services.

- **MHMD-1**: Reduce the suicide rate.
- **MHMD-4**: Reduce the proportion of persons who experience major depressive episode (MDE).
- **MHMD-6**: Increase the proportion of children with mental health problems who receive treatment.
- **MHMD-9**: Increase the proportion of adults with mental disorders who receive treatment.
- **MHMD-10**: Increase the proportion of persons with co-occurring substance abuse and mental disorders who receive treatment for both disorders.

From U.S. Department of Health and Human Services: *Healthy People 2020 objectives,* Office of Disease Prevention and Health Promotion, Washington, DC, 2010, USDHHS.

As indicated in the definitions at the beginning of this chapter, mental health is a dynamic process, influenced by both internal and external factors, that enables and promotes the individual's physical, cognitive, affective, and social functioning. In contrast, threats to mental health create stress that undermines relationships and diminishes the individual's ability to pursue and achieve life's goals. Values and beliefs influence the allocation of resources for neighborhoods and schools and can contribute to or undermine the mental health of people in communities.

Mental health problems are manifested in many ways. Untoward incidents or even anticipated life events can diminish physical, cognitive, affective, and social functioning. For example, in most situations, an anticipated or unexpected death of a family member results in grief that may temporarily interrupt the functioning of surviving family members and produce mental distress. Given adequate support and adaptation, most persons resume their lifestyles after the death of a loved one in spite of the sadness that they are likely to experience. When people do not have adequate resources, or when bereavement is complicated because of the conditions of the situation, there is an increased risk for threats to the mental health of surviving family members. Important interventions with individuals experiencing sorrow and grief are to encourage roles and activities that promote comfort and reduce isolation. Death of a family member can affect survivors of different ages in various ways. Infants and youths may be deprived of significant nurturing and care that will result in long-term emotional deficits, whereas adults are at increased risk for stress related to role changes, and older adults are vulnerable to social isolation as relatives and friends die. In any of these situations, individual or group therapy may be indicated not only for the immediate situation, but also for prevention of longer-term problems.

However, bereavement is not the only cause of diminished mental health. Other causes include, but are not limited to, physical health problems, disabilities resulting from trauma, exposure to violence in the neighborhood, job loss and unstable employment, and unanticipated environmental disasters that result in loss. Because multiple threats to mental health exist across the life span, it is useful to organize the study of problems according to life stages along life's continuum. The box that follows provides suggestions for how nurses can recognize and teach the public the indicators of mental health issues.

HOW TO Recognize Indicators of Mental Health Issues

Community mental health nurses can recognize indicators of mental health issues and educate the public to be aware of:

- Exposure to trauma (abuse, accident, disaster, or violence)
- Withdrawal from social and pleasurable activities
- Exposure to or in temporary stressful living conditions
- Poor work or school performance, unemployment, or school dropout
- Eating or sleeping too much or too little
- Family history of mental illness or substance abuse
- Presence of a substance use disorder

From SAMHSA: *Mental health facts and resources,* 2015. Available at https://www.store.samhsa.gov.

Children and Adolescents

Healthy People 2020 objectives aim to increase the number of children screened and treated for mental health problems. Children are at risk for disruption of normal development by biological, environmental, and psychosocial factors that impair their mental health, interfere with education and social interactions, and keep them from realizing their full potential as adults. For example, children may develop depression after a

loss or behavior problems from abuse or neglect. Examples of environmental factors include crowded living conditions, violence, separation from parents, and lack of consistent caregivers. Exposure to community violence can be related to significant stress and depression in children (Sullivan and Simonson, 2016). Types of mental health problems typically diagnosed during childhood are depression, anxiety, and attention-deficit disorders. Examples of chronic disorders commonly seen are Down syndrome and autism. These problems affect growth and development and influence mental health during adolescence.

Suicide is the second leading killer of young persons between ages 15 and 34, and in most cases there was a mental or substance abuse disorder. The second objective of *Healthy People 2020* is to reduce the rate of suicide attempts by adolescents. Some of the risk factors for both adolescents and adults include prior suicide attempts, stressful life events, and access to lethal methods. Increasing the number of adolescents screened for depression in primary health care settings is a new objective of *Healthy People 2020.* Early detection and treatment of depression can help prevent suicide. In addition to depression and substance abuse, adolescent problems include conduct disorders and eating disorders.

Another objective of *Healthy People 2020* is to reduce the proportion of adolescents with eating disorders. Many CMHNs do not directly work with persons with a primary eating disorder; eating disturbances often are a symptom accompanying other conditions. Because most children are not seen in the mental health system, an important role of the CMHN is to educate other community providers, teachers, parents, and children. School nurses are in an ideal position to provide primary, secondary, and tertiary interventions for children with eating disorders. Nutrition education and early recognition, intervention, referral, and follow-up can help prevent eating disorders from becoming severe and can prevent relapses. Nurses can advocate in and beyond their communities for the provision of a nurse in all schools. This can increase the chances of early recognition of and treatment for persons with eating disorders.

Effective service expansion for children, particularly for those with serious emotional disturbances, depends on promoting collaboration across critical areas of support, including schools, families, social services, health, mental health, and juvenile justice. Better services and collaboration for children with serious emotional disturbance and their families will result in greater school retention, decreased contact with the juvenile justice system, increased stability of living arrangements, and improved educational, emotional, and behavioral development. One of the objectives of *Healthy People 2020* is to ensure that children in the juvenile justice system receive access to mental health assessment and treatment (USDHHS, 2010). Children and adolescents require a variety of mental health services, including crisis intervention and both short- and long-term counseling. Nurses working in community settings, well-child clinics, and home health can help to offset this problem through prevention, education, and inclusion of parents in program planning. Because many children and adolescents lack services or access to services, community mental health assessment activities are essential. Assessment activities include identifying types of programs available or lacking in places where children and adolescents spend time. Assessments should be performed in schools and in the homes of clients served, and also in day care centers, churches, and organizations that plan and guide age-specific play and entertainment programs. Assessment data are essential for planning and developing programs that address mental health problems prevalent from the prenatal period through adolescence. Preventing problems during these developmental periods can reduce mental health problems in adulthood.

Adults

Adults suffer from varied sources of stress that contribute to their mental health status. Sources of stress include multiple role responsibilities, job insecurity, and unstable relationships. These and other conditions can undermine mental health and contribute to serious mental illness, depression, anxiety disorders, and substance abuse. *Healthy People 2020* objectives seek to help adults access treatment in order to decrease associated human and economic costs and to reduce suicide rates (USDHHS, 2010).

At some point, virtually all adults will experience a tragic or unexpected loss, a serious setback, or a time of profound sadness, grief, or distress. Major depressive disorder, however, differs both in intensity and in duration from normal sadness or grief. Depression disrupts relationships and the ability to function and can be fatal. In 2016 there were 45,000 reported deaths by suicide. There was a substantial increase in suicide rates among adults aged 45 to 64 years between 1999 and 2014 (CDC, 2016). Many of those who kill themselves have a mental or substance abuse disorder, but in more than half of the suicides in 2015 there was no known mental health condition. Many of these deaths suggested there were relationship problems, substance use, and financial crisis. Other risk factors include prior suicide attempts, stressful life events, and access to lethal methods. Although men are more likely to die by suicide, women are twice as likely to experience depression, and women who are poor, unemployed, or victims of domestic violence are even more at risk (CDC, 2016). Available medications and psychological treatment can help 80 percent of those with depression, yet only a few seek help. Those with depression are more likely to visit a physician for some other reason, and the mental health condition may not be noted. Therefore it is imperative that nurses in all settings recognize and screen for depression. Community health nurses may provide treatment interventions. Nurses can provide mental health screening, support, and education for low-income mothers. Community health nurses at both the generalist and advanced practice levels can be instrumental in designing and developing programs to detect and reduce depression in mothers living in low-resourced communities. These interventions may be critical to ensuring improved mental health of both mothers and their children, as maternal depression is associated with negative emotional outcomes of their children (Beeber et al., 2013; Goodman & Garber, 2017).

Anxiety disorders are common both in the United States and in other countries. An alarming 31.1 percent of the adult population will experience an anxiety disorder at some time in

their lives (NIMH, 2018). Anxiety disorders may have an early onset and are characterized by recurrent episodes of illness and periods of disability. Panic disorder and agoraphobia along with depression are associated with increased risks of attempted and completed suicide.

The lifetime rates of co-occurrence of mental disorders and addictive disorders are strikingly high. About one in four persons in the United States experiences a mental disorder in the course of a year, and nearly one in three adults who have a mental disorder in their lifetime also experiences a co-occurring substance (alcohol or other drugs) abuse disorder (SAMHSA, 2017). Individuals with co-occurring disorders are more likely to experience a chronic course and to use services than are those with either type of disorder alone; however, the services are often fragmented, and treatment occurs in different segments of the system.

How can nurses intervene? The general medical sector, including primary care clinics, hospitals, and nursing homes, is typically the initial point of contact for many adults with mental disorders; for some, these providers may be the only source of mental health services. Early detection and intervention for mental health problems can be increased if persons presenting in primary care are assessed for mental health problems. Nurses who work in the general medical sector and in other community settings are in an ideal position to assess and detect mental health problems. Nurses conduct comprehensive biopsychosocial assessments and are often the professional most trusted with sensitive information by clients in these settings. The use of screening tools for depression, anxiety, substance abuse, and cognitive impairment can assist the nurse in early detection and intervention for mental health problems. The Evidence-Based Practice box identifies behavioral interventions for chronic pain, depression, and substance abuse disorders likely to be encountered in primary care.

EVIDENCE-BASED PRACTICE

A systematic review was conducted to identify behavioral interventions targeting chronic pain, depression, and substance use disorders in primary care settings.

The Cumulative Index to Nursing and Allied Health Literature, Medline, PsycInfo, and Google Scholar databases were searched to identify randomized controlled trials using a behavioral intervention with adults with at least two to three conditions.

The search yielded 1862 relevant records, and 6 met final selection criteria. A total of 696 participants were included. Though behavioral interventions varied in content, format, and duration, Mindfulness Oriented Recovery Enhancement, Acceptance and Commitment Therapy, Interpersonal Psychotherapy adapted for pain, and Cognitive Behavioral Therapy showed promising improvements across studies.

Behavioral interventions are effective for assisting patients with pain, depression, and substance abuse in primary care. Integrated delivery of interventions through group sessions, computers, and smart phones may increase patient access to treatment and reduce time, cost, stigma, distress, family burden, and health care fragmentation.

Nurse Use: In order to deliver evidence based nursing care, it is useful to be aware of the above sources to locate studies and other information to use in guiding nursing interventions.

From Barrett K, Chang YP: Behavioral interventions targeting chronic pain, depression, and substance use disorder in primary care. *J Nurs Scholarsh* 48(4):345–353, 2016.

Suicide can be prevented in many cases by early recognition and treatment of mental disorders and by preventive interventions that focus on risk factors. Thus reduction in access to lethal methods and recognition and treatment of mental and substance abuse disorders are among the most promising approaches to suicide prevention. Nurses, long respected as important population-centered providers, can work with legislators for measures to limit access to weapons such as handguns.

LINKING CONTENT TO PRACTICE

This chapter describes the role of the nurse who works with persons with mental illness in the community. The role is diverse and complex and relies on basic nursing knowledge as well as specific knowledge about mental illness. Applying this role in the community draws on many of the recommendations of nursing and public health groups. For example, the core competencies adopted by the Council on Linkages Between Academia and Public Health Practice (2014) include those related to assessment, policy development and program planning skills, communication and cultural competency skills, and involvement with the community in order to provide services effectively. The Quad Council Coalition of Public Health Nursing Organizations (2018) further develops these skills and makes clear application to nursing practice. The American Nurses Association develops and publishes scope and standards of practice documents that identify specific nursing competencies by specialty area (ANA, 2013, 2014).

Adults With Serious Mental Illness

Objectives of *Healthy People 2020* that address tertiary prevention and are targeted to persons with serious mental illness are to reduce the proportion of homeless adults who have serious mental illness, to increase their employment, and to decrease the number of adults with mental disorders who are incarcerated. Brief hospital stays and inadequate community resources have resulted in an increased number of persons with serious mental illness living on the streets or in jail. Though it is difficult to have precise data there is consensus that those with a mental illness are overrepresented. The most precise estimate based on a clinical interview is 14 percent of males and one third of females in jail suffer from a mental illness (Morabito & Wilson, 2015). Some people arrested for nonviolent crimes could be better served if diverted from the jail system to a community-based mental health treatment program with linkage to mental health services. About half of the homeless persons in the United States have a serious mental illness or a substance abuse problem, and on any given night an astonishing 60,000 are veterans (National Coalition for Homeless Veterans, 2014). Most do not have any form of employment. At present, many people with severe mental disorders live in poverty because they lack the ability to earn or maintain a suitable standard of living. Even people who live with family caregivers or in supervised housing are at risk for inadequate services because the long-term care they need often depletes human and fiscal resources. An effective approach for helping persons with serious mental illness is to partner with consumers to facilitate recovery through intensive case management. Persistent client outreach and

engagement strategies are effective in helping persons with serious mental illness recover (Fowler et al., 2018).

CMHNs are engaged in all forms of case management activities with persons with serious and persistent mental illness. They provide important case management services, coordinate resources for consumers, and function as important members of ACT programs, which provide continuous assistance to persons with mental illness. Nurses by philosophy and training promote independent living and provide support and encouragement for persons to achieve a maximal level of wellness and function. Nurses recognize the importance of the mental health benefits of meaningful work that improves self-esteem and independence. Nurses can support development of **wellness recovery action plans** at both the individual and agency levels. Nursing health promotion interventions can be provided in shelters, soup kitchens, and other places where homeless persons receive food and protection.

Older Adults

In the United States the population older than 65 years has steadily increased since the year 2000. As the life expectancy of individuals continues to grow, the number experiencing mental disorders of late life will increase. This trend will present society with unprecedented challenges in organizing, financing, and delivering effective preventive and treatment services for mental health in this population. Although many older people maintain highly functional lives, others have mental health deficits associated with normal sensory losses related to aging, failing physical health, difficulty performing activities of daily living, and social deprivation or isolation. Life changes related to work roles and retirement often result in reduced social contacts and support. Other previously described losses are associated with the death of a spouse, other family members, or friends. Reduced social networks and contacts triggered by these life events can influence mood and contribute to serious states of depression. However, depression is not a normal part of aging.

The depression rate among older adults is half that of younger people, but the presence of physical or chronic illness increases rates of depression. Depression rates for older adults in long-term care receiving care either at home or in nursing homes range from five percent to 25 percent (Haigh et al., 2018). Though overall depression rates may be lower in older adults, men over 75 still have the highest suicide rates at 42.4 per 100,000 (CDC, 2016). Alzheimer's disease and vascular conditions can cause a severe loss of mental abilities with behavioral manifestations. Nearly half of those older than age 85 have symptoms of cognitive impairment severe enough to impair function. All these conditions affect the mental health status of individuals and their family caregivers.

Older adults, because they may be dependent on others for care, are at risk for abuse and neglect. Healthy aging activities such as physical activity and establishing social networks improve the mental health of older adults. Older adults underutilize the community mental health system and are more likely to be seen in primary care or to be recipients of care in institutions. The nurse can reach them by organizing health promotion programs through senior centers or other community-based settings. Home health care nurses can assess and intervene to protect those at risk for abuse and neglect, and mental health nurses can provide stress management education for nursing home staff. Stress management for caregivers and respite daycare programs for an older adult family member can increase coping and prevent abuse. Mental health outreach services for older adults have been very effective in reducing depressive symptoms.

Most family caregivers are women who care for a spouse, an aging parent, or a child with a long-term disabling illness. These caregivers are also at risk for health disruption. The risk is particularly great for caregivers of persons with a chronic illness. Caregivers of persons with severely disabling mental disorders often have their mental health threatened by lack of social support, the stigma of the disease, and chronic strain. During stressful life events such as these, it is important for caregivers to know how to manage the many competing demands in their lives.

Activities to improve the mental health status of adults include public education programs, prevention approaches, and provision of mental health services in primary care. Specific approaches to reduce stress include use of community support groups, education about lifestyle management, and worksite programs. Nevertheless, most programs currently available for adults, families, and caregivers with health problems primarily monitor or restore health rather than prevent problems. Therefore the nurse can refer family caregivers and others to organizations such as the local NAMI for group support services. In addition, many national organizations designed for groups with specific problems (Box 36.4) have local chapters or information that can be accessed on the Internet. Some state activities expand mental health services to older adults, and *Healthy People 2020* includes objectives designed to increase services to older adults and cultural competence within the mental health system.

BOX 36.4 Examples of Sources of Information and Help for People With Mental Illness and Mental Health Problems

- Alcoholics Anonymous
- Al-Anon
- Alzheimer's Association
- American Anorexia/Bulimia Association
- American Association of Suicidology
- Anxiety Disorders Association of America
- Attention Deficit Information Network
- Children and Adults with Attention-Deficit/Hyperactivity Disorder
- Gamblers Anonymous
- National Center for Post-Traumatic Stress Disorder (it is a government agency)
- National Center for Learning Disabilities
- International OCD Foundation
- Overeaters Anonymous
- Schizophrenics Anonymous

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Quality and Safety Focus

Targeted Competency: Safety

Minimizes risk of harm to clients and providers through both system effectiveness and individual performance.

Important aspects of safety include:

- **Knowledge:** Examine human factors and other basic safety design principles, as well as commonly used unsafe practices (such as workarounds and dangerous abbreviations)
- **Skills:** Use national client safety resources for own professional development and to focus attention on safety in care settings
- **Attitudes:** Value the contributions of standardization/reliability to safety

Safety Question

Nurses engage in patient-specific interventions to keep patients safe. Nurses also regularly contribute to the development of safety approaches at the systems level. System-level approaches to safety ensure standardization of processes and a consistent methodology to addressing recurring safety concerns.

You are working as a registered nurse (RN) in home care. Your home care agency has had three patients admit to suicidal ideation and intention in the last three months. In all three situations the home care nurses handled the situations very differently, with varied success. Your manager asks you to participate in a task force to develop a standard operating procedure that all home care nurses can employ to respond to a suicidal patient in the home.

- What health care team members would be helpful in addressing the development of this standardized operating procedure?
- What evidence might you look to in developing this standardized procedure?
- How might you envision most effectively training home care nurses in this standardized approach?

Prepared by Gail Armstrong, PhD, DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing.

Cultural Diversity

To work effectively, health care providers need to understand the differences in how various populations in the United States perceive mental health and mental illness and treatment services. These factors affect whether people seek mental health care, how they describe their symptoms, the duration of care, and the outcomes of the care received. Various populations use mental health services in different ways. People may not seek mental health services in the formal system, they may drop out of care, or they may seek care at much later stages of illness, which typically costs more. This pattern of use may be the result of a community-based mental health service system that is not culturally relevant, responsive, or accessible to select populations. Although all socioeconomic and cultural groups have mental health problems, low-income groups are at greater risk because they often lack minimal resources for meeting basic physical and mental health needs.

In an effort to describe and remedy mental health disparities based on culture, a supplemental report was published to the landmark surgeon general's report on mental health (USDHHS, 2001). Caution is needed, however, when discussing differences among racial and ethnic groups in the rates of mental illness. Studies of the number of cases of mental health problems among racial and ethnic populations, while increasing in number, remain limited and often inconclusive. Discussion of the rates of existing cases must consider differences in how persons of different cultures and racial and ethnic groups perceive mental illness. Behavioral problems, often viewed in Western medicine as signs of mental illness, may be assessed differently by individuals in various racial and ethnic groups. The manner in which people of different cultures describe emotional distress may affect the detection and treatment of mental illness. With this caution in mind, along with the recognition that sample sizes for racial and ethnic groups may be limited, examination of existing large-scale studies for mental health trends and disparities among racial and ethnic groups remains important. According to the surgeon general's landmark report on culture, race, and ethnicity, the predominant minority populations in the United States are African Americans, Hispanics, Asian and Pacific Islander Americans, and American Indians, including Alaska Natives (USDHHS, 2001). A notable omission from this landmark federal report is Middle Eastern Americans, and little information could be found either in the literature or through national websites, although there is a significant and growing population, particularly in the upper Midwest. Great diversity exists among people from the Middle East, although they may share some cultural traditions with Asians, Africans, or Europeans and in some cases have been included in those classifications. However, within each of the groups identified in the federal report, there is also much diversity, as each group consists of subgroups with unique cultural differences. Therefore it is important to avoid simplification and overgeneralization in discussions about the characteristics and problems of minorities and to examine both individual and national bias. It is critical to conduct community assessments to determine unique characteristics and factors that contribute to mental health needs within specific aggregates of the population. The information presented here is intended to stimulate thinking and awareness for developing nursing activities in individual communities. Community assessments that include data about specific populations from organized agencies such as the Indian Health Service (2014) are important because assessment data can help guide role activities during all steps of the nursing process. However, the most important data comes from the individual communities.

Nurses provide a variety of primary, secondary, and tertiary prevention interventions with populations at risk that help meet the objectives for improving mental health. Consumers have historically influenced mental health services, and the health care industry increasingly is using consumer opinion to gain information on service needs and changes. Objectives of *Healthy People 2020* are to increase state tracking of consumer satisfaction with mental health services and to increase the number of states that incorporate plans addressing cultural competence. Nurses working within broad-based coalitions of consumers, families, other providers, and community leaders can help to achieve the goals of accessible, culturally sensitive, quality mental health services for all people.

African Americans. African Americans are the second largest minority population in the United States. In 2015, 25.4 percent of African Americans compared to 10.4 percent of non-Hispanic whites were living at the poverty level (USDHHS, 2016a). Ethnic and racial minorities in the United States may live in an environment of social and economic discrimination and inequality, which takes a toll on mental health and places them at risk for associated mental problems. African Americans are more likely to be exposed to, or to become victims of, violence, placing them at risk for the development of PTSD. They are overrepresented both in the homeless and correctional system populations, further increasing the risk of developing mental health problems. Although they were less likely to commit suicide, the suicide rate of young African American men rose in the previous two decades (CDC, 2016). Despite these issues, African Americans are less likely to use mental health services and may have significant negative expectations about mental health services. Nurses can promote the mental health of African Americans by integrating mental health care into primary care settings, providing services in community centers, collaborating with African American faith communities, providing education to decrease the stigma, working toward the provision of safer communities, and recruiting African Americans to work as community mental health providers.

Hispanic Americans. Hispanic Americans are the second largest minority group in America, representing 17.6 percent of the population, and by 2050 they are projected to make up 25 percent of the population (USDHHS, 2016b). Although they live primarily in the southwestern regions of the country, many have migrated to states in the Southeast and Midwest. Migrant farmworkers are also an important subpopulation among Latinos. As discussed in Chapter 34, migratory living patterns that are marked by low income, poor education, and lack of health services contribute to stressful living conditions. Nurses and nurse practitioners may be primary health care providers for migrant laborers and new immigrants. Their roles expand beyond traditional practice to encompass case management and interagency collaboration. Collaboration includes networking and referral to community mental health agencies and to advanced practice psychiatric nurses when either drug or alcohol abuse or mental illness is the primary health problem.

Hispanic Americans living in low-income urban areas are subject to many of the conditions described for low-income and disadvantaged African American families. Initially, it was reported that recent Hispanic immigrants had lower rates of depression than those born in the United States, but evidence from the CDC (2016) found suicide to be 50 percent higher than whites among young Hispanic women in grades 9-12. There are significant relationships between suicide and having a family history of suicide, physical or sexual abuse, and environmental stress. These findings suggest serious stressful living conditions for both individuals and families. Nurses working with Hispanic families need knowledge and skill in both the language and cross-cultural therapies, and they also need to include consumers in planning and evaluating mental health service delivery. Focus groups can be held to involve community members in the planning and implementation of culturally relevant mental health services.

Asian and Pacific Islander Americans. Asian and Pacific Islander Americans are a diverse and rapidly increasing population, currently representing 5.4 and 1.3 percent of the population, respectively (USDHHS, 2016c). This group includes both settled citizens and new refugees. The largest segment of this population lives in California. Whereas Asian and Pacific Islander Americans, like other minority groups, are represented in all socioeconomic strata, the lower-income groups include refugees and recent immigrants who are dealing with the displacement issues of loss, adjustment, and adaptation. Losses often involve forfeiture of family, traditions, and lifestyles for cultures that may seem alien. Adjustments and adaptations include those basic to daily living: learning new languages, laws, and monetary systems, and locating support systems. Finding support systems includes becoming acquainted with the health care delivery system. Though the suicide rate of Asian Americans is half that of white Americans, it is the ninth leading cause of death in this population (USDHHS, 2016c). Our knowledge of the mental health needs of this population is limited, because they do not seek mental health services compared to other groups. This avoidance of mental health care needs further exploration to understand the perceptions of mental health disorders. Assessment, planning, and interventions with members of this diverse group must include information about their health beliefs, a key component in any program.

Population-focused mental health nurses need to understand existing cultural barriers and help to design culturally sensitive approaches for vulnerable populations. Nurses can work to decrease the stigma of mental illness by educating minorities about the biological basis of many mental disorders. Recruitment of a culturally diverse nursing workforce may increase use of mental health services.

American Indians. American Indians represent two percent of the U.S. population. Although this is a small group, it is also diverse, with more than 573 recognized tribes and more than 200 languages. American Indians also appear to have significant rates of substance abuse, depression, and suicide particularly among the young aged 10-34. In 2014 suicide was the leading cause of death among young women and the second leading cause of death among young men. Exposures to unintentional injury, violence, and homicide are high, which results in significant rates of PTSD (Indian Health Service, 2014; USDHHS, 2016d). Use of mental health services has been difficult to determine, because only a small percent of American Indians use those provided by the Indian Health Service.

A promising intervention to address the needs of this diverse group is to build on the traditions of the specific tribe culture to foster identity and integration and enhance protective factors. A return to traditional values of community and group

support has been shown to be effective in reducing rates of substance abuse (Indian Health Service, 2014). Nurses working with American Indians, as with all population groups, need to learn the culture of the specific group and to mutually plan culturally sensitive mental health interventions at levels of primary, secondary, and tertiary prevention.

PRACTICE APPLICATION

Mr. B. is an 81-year-old white widowed man living in a rural area 20 miles from a small city. The nurse practitioner who treated Mr. B. for sinusitis referred him to the outreach nurse for an evaluation. The nurse practitioner was concerned when she noted that Mr. B. had lost weight and started to cry when talking about his wife who had died several years before. During the initial visit the nurse noted that Mr. B. weighed only 110 lb., was not sleeping, had stopped going to church, and was quite anxious and sad about his finances, his limitations from arthritis, his relationship with his 27-year-old stepson, Bart, and the possibility of nursing home placement.

The nurse conducted a suicide assessment, knowing that Mr. B. was at high risk because of his age, his mood, and the presence of guns in the home. Mr. B. stated that he had considered shooting himself, but he was reluctant to have the rifles removed at the nurse's suggestion because Bart used the guns for hunting. Mr. B. agreed to a family meeting with his stepson, and Bart agreed to remove the guns from the house. Both Mr. B. and Bart needed significant education about the biological basis of depression and the efficacy of using a new antidepressant along with support to treat his condition. Mr. B., like many older adults, did not wish to see a psychiatrist or use the community mental health system. He did agree to a trial of antidepressants, however.

The nurse, through the primary care nurse practitioner, arranged for a prescription of an antidepressant (an SSRI) that is safe for use with older adults, and Mr. B. started the medication within two weeks of the initial visit. In addition to medication and counseling, Mr. B. needed help with nutrition. Because Bart was away 10 hours a day, at work in the city, Mr. B. was alone all day. Mr. B. was not able to prepare meals because of his arthritis. The nurse arranged with the local board for aging to provide home-delivered meals. This not only helped with nutrition, but also gave Mr. B. a visit from the volunteer twice a week.

Mr. B. and Bart needed help with financial planning, as they did not want to lose the farm should Mr. B. need more assistance or nursing home placement in the future. The nurse arranged for them to talk with a social worker regarding long-term care planning.

In addition to addressing the immediate concerns, the nurse continued to provide weekly visits to Mr. B. for support and counseling, medication monitoring, and case management activities. Family meetings with Bart and Mr. B. to discuss mutual concerns were arranged every two months and as needed. The significant improvement of depressive symptoms (that is, sleep, appetite, weight, and mood) in Mr. B. was monitored both clinically and through use of a depression rating scale.

Psychological, physical, and social problems of older adults are closely intertwined and are best evaluated and treated by a multidisciplinary team. Psychiatric illness often presents first with physical symptoms, and physical limitations create further psychological distress. Older adults often prefer not to use formal mental health services, so careful assessment in primary care settings is critical to detect their mental health problems.

A. In addition to his stepson and the nurse, who else might notice if Mr. B.'s condition began to deteriorate?

B. What nursing measures are important in monitoring Mr. B.'s response to the antidepressant?

C. What secondary prevention measures did the nurse use?

D. What resources might be available for Bart should he need more information about depression?

Answers can be found on the Evolve site.

KEY POINTS

- Reform movements and subsequent federal legislation influenced the development of the current community mental health model that includes team care, case management, prevention, and rehabilitation and recovery components of service.
- During the past two decades, federal legislation in the United States focused on mainstreaming persons with mental disabilities into American life by legislating access to employment, services, and housing.
- Prevalence rates for mental health problems are very high, and people are at risk for threats to mental health at all ages across the life span. Low-income and minority groups are often at increased risk because they lack access to services and because programs may lack cultural sensitivity.
- National health objectives to promote health and services for persons who have mental health problems and severe mental disorders illustrate the scope of mental illness and provide direction for community mental health practice.
- Guidelines for attaining national health objectives were designed to help individuals at regional and local levels establish health priorities that include those for mental illness.
- The American Nurses Association standards provide a framework for the roles and functions of community mental health nurses.
- Frameworks that are useful in community mental health nursing include primary, secondary, and tertiary levels of prevention; biological theories including the effects of psychosocial factors on the brain, growth, and development; and rehabilitation and recovery models.

CLINICAL DECISION-MAKING ACTIVITIES

1. For one week, keep a list of incidents related to mental health problems that you learn about in the local media. Categorize the incidents according to age, sex, and socioeconomic, ethnic, or minority status. Which populations seem to have the most mental health problems?
2. Visit a local shelter or organization that offers temporary protection for persons with mental disorders. Determine services that are available or lacking for children, women, and men. Describe a nursing intervention that would improve services.
3. Visit with representatives of your local self-help organizations for consumers to determine their needs and the adequacy of resources for people with severe mental disorders and their caregivers; determine gaps in services. Develop a list of the agencies in your community that provide direct or indirect services for those with mental illness and their families.
4. Interview a school nurse, an occupational health nurse, an emergency department nurse, or a hospice nurse in your community to discuss types of mental health problems they see with clients in their practice settings. Determine resources that are available or lacking for primary, secondary, and tertiary prevention. Design a primary prevention intervention.
5. Interview a nurse working in a local community mental health agency to discuss roles, functions, programs, and resources available or lacking for primary, secondary, and tertiary prevention. Compare findings about prevention programs with information obtained from the preceding interview.
6. Visit a consumer-operated program or a psychosocial rehabilitation program. Interview members to learn how they view services and resources available or lacking in this setting. Describe how your attitudes about persons in recovery from mental illness changed after your visit.
7. Accompany a community mental health nurse on home visits to clients enrolled in an assertive community outreach program, and then accompany a psychiatric nurse in a home care agency. Compare and contrast how the services, funding, populations served, and philosophies of treatment differ.
8. As a class activity, arrange for a panel of speakers representing the minority populations described in this chapter. Discuss their views about the way culture shapes thinking about mental illness, and determine types of culturally sensitive services that are available or lacking in your community.
9. Review articles in at least four research journals to determine current research findings about mental disorders and mental health problems, and compare nursing care in the United States with that of other countries. Discuss the differences in mental health care between countries.

Alcohol, Tobacco, and Other Drug Problems

Mary Lynn Mathre, RN, MSN, CARN and Amber M. Bang, RN, BSN

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Analyze personal attitudes toward alcohol, tobacco, and other drug problems.
2. Differentiate among these terms: *substance use, abuse, dependence*, and *addiction*.
3. Discuss the differences among the major psychoactive drug categories of depressants, stimulants, marijuana, hallucinogens, and inhalants.
4. Explain the role of the nurse in primary, secondary, and tertiary prevention of alcohol, tobacco, and other drug problems as it relates to individual clients, their families, and special populations.
5. Evaluate the role of the nurse in primary, secondary, and tertiary prevention of alcohol, tobacco, and other drug problems as it relates to the community and national policies on drug control.

CHAPTER OUTLINE

Alcohol, Tobacco, and Other Drug Problems in Perspective
Psychoactive Drugs
Predisposing/Contributing Factors
Primary Prevention and the Role of the Nurse
Secondary Prevention and the Role of the Nurse
Tertiary Prevention and the Role of the Nurse
Outcomes

substance abuse, p. 814
tolerance, p. 816
withdrawal, p. 814

Substance abuse is the number one national health problem, causing more deaths, illnesses, and disabilities than any other health condition. Substance abuse affects not only the health of the individual user but also the health and safety of family members, coworkers, as well as the broader health of the community.

Substance abuse and addiction permeate all segments of society. As seen in *Healthy People 2020* (USDHHS, 2010), tobacco use and substance abuse are two major topic areas, with the aim of addressing numerous objectives and subobjectives both directly and indirectly related to these areas. The newer phrase *alcohol, tobacco, and other drug (ATOD) problems* rather than *substance abuse* reminds us that alcohol and tobacco represent the major drugs of abuse when discussing substance abuse, drug addiction, or chemical dependency.

This chapter begins by providing a broad perspective of ATOD problems to clarify the relevant issues. A historical overview of ATOD problems and attitudes toward ATOD users and addicted persons is examined. Relevant terms are defined to decrease confusion caused by frequent misuse of terms. The major substance categories are described in the chapter, including information on commonly used substances and current ATOD use trends. The remainder of the chapter examines the role of the nurse in primary, secondary, and tertiary prevention and describes how the nurse can improve outcomes for individuals, families, and various populations with ATOD problems when using a harm reduction model. It is important to apply nursing strategies to the *Healthy People 2020* objectives for ATOD problems.

ALCOHOL, TOBACCO, AND OTHER DRUG PROBLEMS IN PERSPECTIVE

ATOD abuse and addiction can cause multiple health problems for individuals, their families, and the community. Heavy ATOD use has been associated with many problems, including overdose; neonates with low birth weight and congenital abnormalities; accidents, homicides, and suicides; chronic diseases, such as cardiovascular diseases, cancer, lung disease, hepatitis, human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS), and mental illness; violence; and family disruption. Factors that contribute to the substance abuse problem include lack of knowledge about the drug use; the emphasis on illicit drugs and law enforcement rather than the prevention and treatment of abuse and addiction of ATODs; overprescription; lack of quality control of illegal drugs; and punitive drug laws that label certain drug users as criminals, encouraging negative attitudes and stigma toward these persons.

Historical Overview

Psychoactive drug use has been deeply ingrained in most cultures since the beginning of humanity. Often a culture encourages use of some drugs while discouraging the use of others. Caffeine, alcohol, and tobacco are socially acceptable drugs in the United States and Canada, whereas other cultures prohibit their use. People often do not recognize the amount of caffeine in the drinks that they may consume. It is generally not considered a drug, but it is important to recognize that its use should be limited (see Table 37.1). Conversely, cannabis, cocaine, and heroin use have not traditionally been accepted in mainstream U.S. society, although these substances are considered sacred or beneficial and their use is accepted in various other cultures. As a result, such cultural viewpoints concerning substances have been translated into law accordingly.

TABLE 37.1 Caffeine Content in Commonly Consumed Substances

Drink/Food/ Supplement	Amount of Drink/Food	Amount of Caffeine
Jolt cola	12 oz	71.2 mg
Mountain Dew	12 oz	55 mg
Coca-Cola	12 oz	34 mg
Diet Coke	12 oz	45 mg
Pepsi	12 oz	38 mg
7-Up	12 oz	0 mg
Brewed coffee (drip method)	5 oz	115 mg[a]
Iced tea	12 oz	70 mg[a]
Cocoa beverage	5 oz	4 mg[a]
Chocolate milk beverage	8 oz	5 mg[a]
Dark chocolate	1 oz	20 mg[a]
Milk chocolate	1 oz	6 mg[a]
Cold relief medication	1 tablet	30 mg[a]
Vivarin	1 tablet	200 mg
Excedrin extra strength	2 tablets	130 mg

[a]Denotes average amount of caffeine.
Data from U.S. Food and Drug Administration, National Soft Drink Association, Center for Science in the Public Interest. Available at http://kidshealth.org.

The United States' primary solution to various "drug problems" has been **prohibition.** During alcohol prohibition from 1920 to 1933, the United States experienced a sharp increase in violent crime and corruption among law officials as a result of the illicit marketing of alcohol. Use of distilled beverages was encouraged because of the higher profit margin per bottle of liquor than for beer or wine. The high alcohol content in illicit moonshine caused severe health problems and deaths across the United States. The alcohol prohibition was eventually recognized as a failure and repealed (Rose, 1996).

Similar problems continue to occur with the current "War on Drugs" and the more recent prohibition on cannabis, cocaine, and other drugs. The War on Drugs was coined during the Nixon administration in the 1970s as a catchphrase for the U.S. federal government's series of anti-drug policies to address drug abuse as "public enemy number one." It was during this time as well that the Controlled Substances Act was initiated and the Drug Enforcement Administration was created, launching the new era of drug control in the United States. Today, North America's rates of drug consumption and drug-related death and morbidity surpass that of any region in the world (UNODC, 2015).

Prohibitionist policies inherently support an illicit market for illegal drugs. A large body of evidence indicates that such

policies additionally do little to reduce drug consumption or production. Increased law enforcement of drug prohibition has in fact contributed to increased gun violence and high homicide rates (Werb et al., 2011). Additionally, drug prohibition laws have created mandatory sentences for drug offenders and violated civil liberties, resulting in the United States having the highest rate of incarceration in the world (World Prison Brief, 2018). As the drug war budget grows each year, most of that budget goes to law enforcement and punishment, leaving less than half for prevention and treatment (USONDCP, 2017). Furthermore, the 2018 national drug control budget reduced funding allocated for prevention, increasing funding for law enforcement and efforts to disrupt illicit drug markets. Controversially, President Trump's 2019 budget request includes a 95 percent budget cut for the Office of National Drug Control as part of the administration's strategy for addressing the national opioid crisis, shifting resources largely to the DEA to continue drug control efforts (USOMB, 2018). How this manifests for public health efforts concerning substance abuse remains to be seen.

Attitudes and Myths

Attitudes are developed through cultural learning and personal experiences. Attitudes toward ATOD problems are influenced by the way society arbitrarily categorizes drugs as either "good" or "bad." In the United States, good drugs are typically over-the-counter (OTC) drugs or those prescribed by a health care provider as *medicine,* but this makes them no less problematic or addictive. Bad drugs are the illegal drugs, and persons who use these drugs are considered criminals regardless of whether the drug has caused any problems. This harmful, arbitrary practice of moralizing certain substances has come under question in the recent shift in attitude toward cannabis as demonstrated in its legalization for recreational use in nine states and the District of Columbia.

Americans rely heavily on prescription and OTC drugs to relieve, or mask, anxiety, tension, fatigue, and physical or emotional pain. Rather than learning holistic, nonmedicinal methods of coping, many people rely on the "quick fix" and take pills to cope with their problems or difficult feelings.

Addicted persons are often viewed as immoral, weak-willed, or irresponsible persons who should try harder to help themselves. Although alcoholism was recognized as a disease by the American Medical Association in 1954 and drug addiction was recognized as a disease some years later, much of the public and many health care professionals have failed to change their attitudes to accept addicted persons as individuals suffering from illness requiring health care.

It is important for nurses to examine their attitudes toward ATOD use, abuse, and addiction before working with this health problem. To be therapeutic, the nurse must develop a trusting, nonjudgmental relationship with the client. Systematic assessment in patients for ATOD problems is based on awareness that there may be problems with both legal and illegal drugs. If the nurse's attitude toward a client with a drug abuse problem is negative or punitive, the issue may never be directly addressed or the client may be avoided. If the client senses the negative attitude of the health care provider, either by words or from tone of voice, communication may cease and information may be withheld. As always, to engage in therapeutic communication, nurses need to engage in self-awareness of their own preexisting judgments and reconcile them with the duty to provide care. It is important for nurses to realize any drug can be abused, that anyone may develop drug dependence, and that drug addiction can be successfully treated.

Myths develop over years, and if myths are not questioned, many attitudes may be formed solely on the basis of fiction rather than fact. Some common myths are as follows:

- "An alcoholic is a skid row bum"—less than 5 percent of persons with addictions fit this description.
- "If you teach people about drugs, they will abuse them"—although it is true that people may choose to use drugs if they have knowledge about them, it is more likely that people without knowledge about them will abuse them.
- "Addiction is a sin or moral failing"—addiction is recognized as a health problem involving biopsychosocial factors, and persons who use drugs do not do so with the intent to become addicted.

Paradigm Shift

We can hope to see a major shift in how the United States conceptualizes ATOD problems. The old criminal justice model is based on stereotypes, misinformation, and punishment, and it uses war tactics to fight the drug users, addicted persons, and suppliers. Campaigns have been launched using the slogans "zero tolerance" for drug users, "just say no" to drugs, and striving for a "drug-free America"—all of which vilify the drug user or drug-addicted person. However, there are still divergent opinions on the best approaches to substance abuse problems, both nationally and globally. While the Obama administration's approach to the nation's drug problem was to approach it as a public health problem rather than a criminal justice problem, the Trump administration has diverted a large portion of the drug control funding in the 2019 budget request to the Department of Justice rather than increasing funding for the Department of Health and Human Services, which focuses efforts on prevention and treatment. Meanwhile, on the international level, experts suggest that national drug policies need to be focused on health of the individual and the community rather than on law enforcement strategies. Still, many countries continue to rely on criminal justice as the main approach to substance use issues.

The **harm reduction** model is a public health approach to ATOD problems initially used in Great Britain, The Netherlands, Germany, Switzerland, and Australia, and interest in it is spreading throughout Europe and in Canada. This approach is supported by a variety of organizations, including the International Drug Policy Consortium and the World Health Organization. This public health model recognizes the following:

- Addiction is a health problem.
- Any psychoactive drug can be abused.
- Accurate information can help people make responsible decisions about drug use.
- People who have ATOD problems can be helped.

This approach accepts the reality that psychoactive drug use is endemic, and it focuses on pragmatic interventions, especially education, to reduce the adverse consequences of drug abuse and get treatment for addicted persons. The United States has already taken a harm reduction approach with tobacco and alcohol, legally sanctioned drugs. Educational campaigns are used to inform the public about the health risks of tobacco use. Warnings have appeared on tobacco product labels since 1967 as a result of the surgeon general's 1964 report on the dangers of smoking. In 1971, a ban on television and radio cigarette advertising was imposed. Consequently, cigarette smoking declined from 42 percent in 1965 to 15.5 percent in 2016; 37.8 million Americans continue to smoke (CDC, 2018a). Smoking is on the decline among 8th to 12th graders. According to *Results From the 2016 National Survey on Drug Use and Health*, past month use of any tobacco product among persons aged 12 or older decreased from 26.0 percent in 2002 to 19.1 percent in 2016, and past month tobacco use among 12- to 17-year-olds fell from 13.0 percent to 3.4 percent in that same period (SAMHSA, 2017). Similarly, education continues to address the dangers of alcohol abuse and establish guidelines for safe alcohol use. Accordingly, the percent of adolescents aged 12–17 with an alcohol use disorder dropped from 5.9 percent in 2002 to 2 percent in 2016 (SAMHSA, 2017).

Nurses need to seek the underlying roots of various health problems and plan action that is realistic, nonjudgmental, holistic, and positive. A harm reduction model for ATOD problems facilitates such an approach. See www.harmreduction.org for more resources and information concerning harm reduction (see Box 37.1 for principles for an effective drug policy).

Definitions

The terms *drug use* and *drug abuse* have virtually lost their usefulness because the public and government have narrowed the term *drug* to include only illegal drugs rather than including prescription, OTC, and legal recreational drugs. The current phrase *alcohol, tobacco, and other drugs* (ATODs) is a reminder that the leading drug problems involve alcohol and tobacco.

BOX 37.1 High-Level Principles for an Effective Drug Policy

We propose that national drug strategies should always be based on five core principles:

1. Drug policies should be developed through a structured and objective assessment of priorities and evidence.
2. All activities should be undertaken in full compliance with international human rights law.
3. Drug policies should focus on reducing the harmful consequences rather than the scale of drug use and markets.
4. Policy and activities should seek to promote the social inclusion of marginalized groups.
5. Governments should build open and constructive relationships with civil society in the discussion and delivery of their strategies.

Modified from the drug policy guide created by the International Drug Policy Consortium (IDPC), published in March 2012. Available at https://idpc.net. Each chapter of the guide fully integrates the above five core principles.

The term *substance* broadens the scope to include alcohol, tobacco, legal drugs, and even foods. **Substance abuse** is the use of any substance that threatens a person's health or impairs social or economic functioning. This definition is more objective and universal than the government's definition of drug abuse, which is the use of a drug without a prescription or any use of an illegal drug. *Misuse* of a drug refers to using prescribed drugs different from directed use. Although any drug or food can be abused or misused, this chapter focuses on **psychoactive drugs**—drugs that affect mood, perception, and thought.

Drug dependence and drug addiction are often used interchangeably, but they are not synonymous. **Drug dependence** is a state of neuroadaptation (a physiological change in the central nervous system [CNS]) caused by the chronic, regular administration of a drug; in drug dependence, continued use of the drug becomes necessary to prevent withdrawal symptoms. For example, when a person is given an opiate such as morphine on a regular basis for pain management, the amount of morphine administered needs to be gradually tapered down rather than abruptly stopped, to prevent physiological symptoms of **withdrawal**.

Drug addiction is a pattern of abuse characterized by a compulsive preoccupation with the use of a drug, securing its supply, and a high tendency to relapse if the drug is removed. This definition approximates to a severe substance use disorder as defined in the *Diagnostic and Statistical Manual of Mental Disorders,* fifth edition (DSM-5). Frequently, addicted persons are physically dependent on a drug, but there is also an added psychological component that causes the intense cravings and subsequent relapse. Furthermore, addiction is linked to physiological changes in the reward, stress, and self-control brain circuits, which may continue long after use of the drug of addiction (Goldstein et al., 2011). In general, anyone can develop drug dependence as a result of regular administration of drugs that alter the CNS; however, only a small percent of these individuals will develop an addiction. The process of becoming addicted is complex and related to several factors, including the addictive properties of the substance, family and peer influences, personality, age of first use, cultural and social factors, existing psychiatric disorders, and genetics.

Alcoholism is addiction to the drug called alcohol—increasingly referred to as a severe alcohol use disorder. Alcohol and drug addictions are recognized as illnesses under a **biopsychosocial model**. Simply stated, the disease concept of addiction identifies it as a chronic and progressive disease in which a person's use of a drug or drugs continues despite problems it causes in any area of life—physical, emotional, social, economic, or spiritual.

The DSM-5 employs the catchall phrase *substance use disorder*. This umbrella diagnosis for individuals is defined as mild, moderate, or severe and identified by the substance, such as "alcohol use disorder—moderate." The severity of the disorder for a given individual is determined by the number of diagnostic criteria that are met, which vary by substance The DSM-5 uses nine substance use disorder categories: Alcohol; Caffeine; Cannabis; Hallucinogens; Inhalants; Opioids; Sedatives, hypnotics, or anxiolytics; Stimulants; and Tobacco (American Psychiatric Association, 2013).

PSYCHOACTIVE DRUGS

Psychoactive drugs, which can alter emotions, are used for enjoyment in social and recreational settings and for personal use to self-medicate physical or emotional discomfort. Psychoactive drugs are divided into categories according to their effect on the CNS and the general feelings or experiences the drugs may induce. There are numerous ways in which drugs are categorized, as seen in the DSM-5 categories. The Internet or a pharmacology text can provide detailed information on these drug categories (e.g., **depressants**, **stimulants** [as shown in Box 37.2], **hallucinogens**, inhalants [as shown in Box 37.3], and cannabis, and a drug chart of commonly abused drugs is provided on the Evolve site for this book. This chapter focuses on alcohol, tobacco, cannabis, and opioids, since these drugs cause the greatest harm and cannabis is the most commonly used illicit drug.

BOX 37.2 Stimulants

Commonly used stimulants include caffeine, amphetamines, and cocaine. Caffeine is one of the most widely used psychoactive drugs in the world, with a U.S. daily per capita consumption of 211 mg. As seen in Table 37.1, caffeine is found in coffee, tea, chocolate, soft drinks, and various medications. Moderate doses of caffeine from 100 to 300 mg per day increase mental alertness and probably have little negative effect on health. Higher doses can lead to insomnia, irritability, tremulousness, anxiety, cardiac dysrhythmias, gastrointestinal (GI) disturbances, and headaches. Regular use of high doses can lead to physical dependence, and the withdrawal symptoms may include headaches, slowness, and occasional depression (Mayo Clinic Staff, 2017). Treating afternoon headaches with analgesics containing caffeine may in reality be preventing a withdrawal symptom from heavy morning coffee consumption.

The most commonly used illicit stimulants include cocaine and amphetamines (not prescribed). Cocaine comes from the coca shrub cultivated by South American indigenous peoples for thousands of years. Purified cocaine can be snorted, smoked, or injected. Crack is a cheap form of smokable cocaine that produces an intense high but lasts for a short period. Street cocaine ranges in purity from 50 to 60 percent and may be cut with other drugs, such as procaine or amphetamine, or any white powder, such as sugar or baby powder. High doses can cause extreme agitation, paranoid delusions, hyperthermia, hallucinations, cardiac dysrhythmias, pulmonary complications, convulsions, and possibly death (O'Malley & O'Malley, 2018c).

Amphetamines are a class of stimulants similar to cocaine, but the effects last longer and the drugs are cheaper. Amphetamines have a chemical structure similar to adrenaline and noradrenaline and are generally used to decrease fatigue, increase mental alertness, suppress appetite, and create a sense of well-being. Legally manufactured amphetamines are most commonly prescribed for attention-deficit/hyperactivity disorder (ADHD), narcolepsy, and obesity. They are popular with people who abuse these drugs to stay awake for long hours to work or study. They can be taken as pills, injected, snorted, or smoked. "Ice," the smokable form of crystal methamphetamine, is easy to manufacture on the illicit market, and its effects can last up to 24 hours (O'Malley & O'Malley, 2018b).

Chronic administration of these stimulants can lead to a neurotransmitter depletion (especially of dopamine), which results in an extreme dysphoria characterized by apathy, sadness, and anhedonia (lack of joy). Thus, these users can get caught up in a dangerous cycle of gaining an extreme high followed by an extreme low. To avoid that low, the person consumes more of the stimulant. Addicted persons who use these drugs soon are overwhelmed by their cravings and may engage in criminal activities such as theft or prostitution to get more drugs. In addition, chronic frequent use of methamphetamine can lead to "meth mouth," which describes dental caries and decay that result from dry mouth and poor oral hygiene. Individuals who abuse methamphetamine are four times as likely to have dental caries, and twice as likely to have multiple decayed, missing, or filled teeth, compared to non-abusers (Shetty et al., 2016).

BOX 37.3 Inhalants

Inhalants are often among the first drugs that young children use. The primary abusers of most inhalants are adolescents who are 12 to 17 years of age. The 2016 National Survey on Drug Use and Health found that 526,000 persons aged 12 or older had used inhalants for the first time within the past 12 months and 54.6 percent of them were under the age of 18 (SAMHSA, 2017). Use often ends in late adolescence.

Inhalants are breathable chemicals, which include gases and solvents, and they do not fit neatly into other categories. The four categories of inhalants are volatile organic solvents, aerosols, volatile nitrites, and gases. These substances are inhaled ("huffed") from bottles, aerosol cans, or soaked cloth or put into bags or balloons to increase the concentration of the inhaled fumes and decrease the inhalation of other substances in the vapor (e.g., paint particles). (See www.inhalants.org for examples of products in these categories and specific drug information.) Inhalant users can get high several times in a short period, since the inhalants are short acting and have a rapid onset. Users are predominately white. Experimental use is about equal for males and females, but males are more likely to engage in chronic use.

Depending on the dose, the user may feel slight stimulation, less inhibition, or even lose consciousness. Signs of use include paint or stains on clothes or the body; spots or sores around the mouth; red or runny eyes or nose; chemical breath odor; a drunk, dazed, or dizzy appearance; nausea and loss of appetite; and finally anxiety, excitability, and irritability. Users can die from "sudden sniffing death" syndrome, and this can occur from the 1st to the 100th time he or she uses the inhalant. This death appears to be related to acute cardiac dysrhythmia. Dangers with administration of gases increase when inhaling directly from pressurized tanks because the gas is very cold and can cause frostbite to the nose, lips, and vocal cords. Also, if a gas such as nitrous oxide is not mixed with oxygen, the user may die from asphyxiation (NIDA, 2017).

Alcohol

Alcohol (ethyl alcohol or ethanol) is the oldest and most widely used psychoactive drug in the world. In 2016, a national survey found that young people between the ages of 12 and 20 are more likely to use alcohol than to use tobacco or illicit drugs, including cannabis (SAMHSA, 2017). Youth tend to drink less often than adults, but they consume more alcohol per occasion. Nearly 90 percent of all alcohol consumed by adolescents occurs as binge drinking (Levy, 2018). In 2016, 62.5 percent of underage current drinkers were binge alcohol users. Binge drinking is defined here as having five or more drinks on one occasion for males and four or more drinks for females (SAMHSA, 2017). Alcohol abuse contributes to illness in each of the top three causes of death in the United States: heart disease, cancer, and stroke. In 2016, an estimated 20.1 million persons were classified with a substance use disorder in the past year based on criteria specified in the DSM-5. Of these, 15.1 million people aged 12 or older had an alcohol use disorder. While this number seems high, this outcome actually reflects a decrease from 2002-2014 (SAMHSA, 2017).

Alcohol abuse costs billions of dollars in lost productivity, property damage, medical expenses from alcohol-related

illnesses and accidents, family disruptions, alcohol-related violence, and neglect and abuse of children. Chronic alcohol abuse leads to profound metabolic and physiological effects on all organ systems. Gastrointestinal (GI) disturbances include inflammation of the GI tract, malabsorption, ulcers, liver problems, and cancers. Cardiovascular disturbances include cardiac dysrhythmias, cardiomyopathy, hypertension, atherosclerosis, and blood dyscrasias. CNS problems include depression, sleep disturbances, memory loss, organic brain syndrome, Wernicke-Korsakoff syndrome, and alcohol withdrawal syndrome. Neuromuscular problems include myopathy and peripheral neuropathy. Males may experience testicular atrophy, sterility, impotence, or gynecomastia, and females who consume alcohol during pregnancy may reproduce neonates with **fetal alcohol syndrome** (FAS) or fetal alcohol effects (FAE). Some of the metabolic disturbances include hypokalemia, hypomagnesemia, and ketoacidosis. Also, endocrine disturbances may result in pancreatitis or diabetes (O'Malley & O'Malley, 2018a).

The concentration of alcohol in the blood is determined by the concentration of alcohol in the drink, the rate of drinking, the rate of absorption (slower in the presence of food), the rate of metabolism, and a person's weight and sex. The amount of alcohol the average liver can metabolize per hour is equal to about ¾ oz of whiskey, 4 oz of wine, or 12 oz of beer. Fig. 37.1 shows the effects on the CNS as the **blood alcohol concentration** (BAC) increases. However, with chronic consumption, tolerance will develop, and a person can reach a high BAC with minimal CNS effects.

Alcohol use in moderation may provide health benefits by providing mild relaxation and lowering the serum cholesterol level. Controlled drinking organizations such as Moderation Management (http://www.moderation.org) provide guidelines for persons who want to have alcohol in their lives. See Box 37.4 for safe limits of alcohol consumption and Table 37.2 for standard drink equivalents.

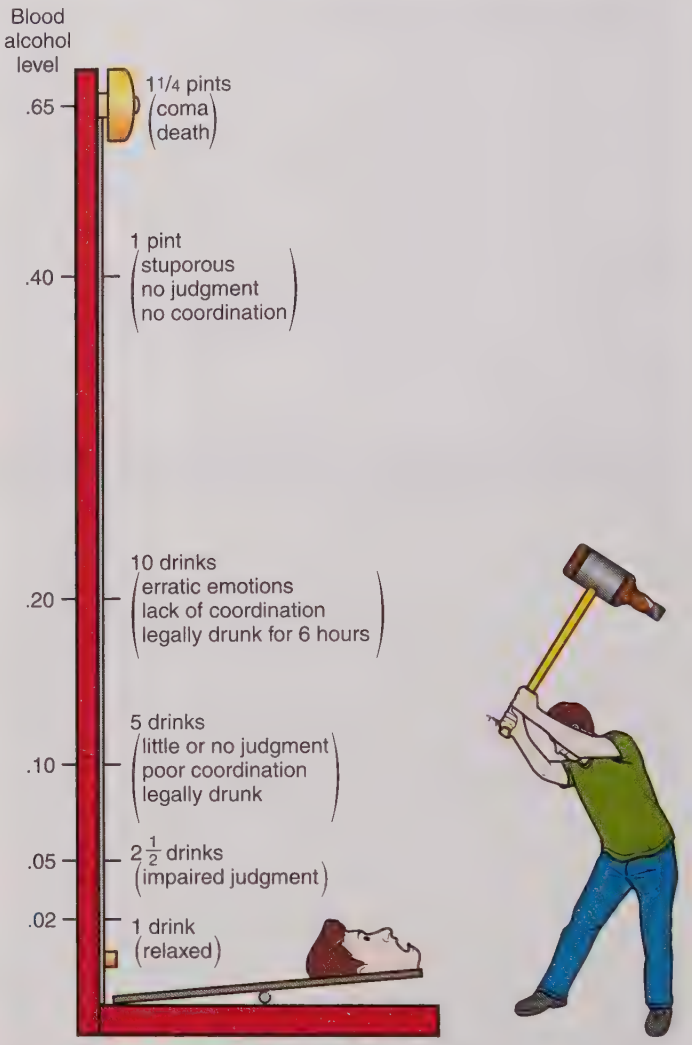

Fig. 37.1 Blood alcohol level and related central nervous system effects of a normal drinker (160-lb man) according to the number of drinks consumed in one hour. (From Kinney J: *Loosening the grip: a handbook of alcohol information,* ed. 10, New York, 2011, McGraw-Hill.)

BOX 37.4 What Are the Recommended Safe Limits for Alcohol Consumption?

For healthy men up to age 65:
- No more than 4 drinks in a day AND
- No more than 14 drinks in a week

For healthy women (and healthy men over age 65):
- No more than 3 drinks in a day AND
- No more than 7 drinks in a week

From National Institute on Alcohol Abuse and Alcoholism: *Helping patients who drink too much: a clinician's guide (update),* NIH Pub. No. 07-3769, Rockville, MD, 2005, USDHHS.

Tobacco

Smoking is the most preventable cause of death and disease in the United States, with one in five deaths attributed to cigarettes. For every person who dies from tobacco use, another 30 will suffer from at least one serious tobacco-related illness (USDHHS, 2014). Table 37.3 shows cigarette smoking–related mortality in the United States. It is estimated that more than 480,000 deaths per year are caused by complications of cigarette smoking (USDHHS, 2014). In 2016, an estimated 63.4 million Americans aged 12 or older were current (past month) users of a tobacco product. This represents 23.5 percent of the population in this age range. In addition, 51.3 million persons (19.1 percent of the population) were current cigarette smokers; 12.3 million (4.6 percent) smoked cigars; 8.8 million (3.3 percent) used snuff and chewing tobacco; and 2.3 million (0.8 percent) smoked tobacco in pipes. Young adults ages 18 to 25 reported the highest rate of current tobacco use at 23.5 percent (SAMHSA, 2017).

The economic toll from tobacco use in the United States is enormous. Cigarette smoking is responsible for more than $300 billion in annual health-related losses, with $170 billion in direct medical costs and $156 billion in lost productivity (CDC, 2018b).

Nicotine, the active ingredient in the tobacco plant, is a particularly toxic drug. To protect itself, the body quickly develops tolerance to the nicotine. If a person smokes regularly, **tolerance** to nicotine develops within hours, compared with days for heroin or months for alcohol. Pipes and

TABLE 37.2 What Is a Standard Drink?

A standard drink in the United States is any drink that contains about 14 g of pure alcohol (about 0.6 fluid oz or 1.2 tbsp). The U.S. standard drink equivalents shown here are approximate, since different brands and types of beverages vary in their actual alcohol content.

12 oz of beer or cooler	8-9 oz of malt liquor 8.5 oz shown in a 12-oz glass that, if full, would hold about 1.5 standard drinks of malt liquor	5 oz of table wine	3-4 oz of fortified wine (such as sherry or port) 3.5 oz shown	2-3 oz of cordial, liqueur, or aperitif 2.5 oz shown	1.5 oz of brandy (a single jigger)	1.5 oz of spirits (a single jigger of 80-proof gin, vodka, whiskey, etc.) Shown straight and in a highball glass with ice to show level before adding mixer[a]

12 oz 8.5 oz 5 oz 3.5 oz 2.5 oz 1.5 oz 1.5 oz

Many people do not know what counts as a standard drink and so they do not realize how many standard drinks are in the containers in which these drinks are often sold. Some examples:

For beer, the approximate number of standard drinks in
12 oz = 1
16 oz = 1.3
22 oz = 2
40 oz = 3.3

For malt liquor, the approximate number of standard drinks in
12 oz = 1.5
16 oz = 2
22 oz = 2.5
40 oz = 4.5

For table wine, the approximate number of standard drinks in a standard 750 mL (25 oz) bottle = 5

For 80-proof spirits, or "hard liquor," the approximate number of standard drinks in
a mixed drink = 1 or more[a]
a pint (16 oz) = 11
a fifth (25 oz) = 17
1.75 L (59 oz) = 39

[a]*Note:* It can be difficult to estimate the number of standard drinks in a single mixed drink made with hard liquor. Depending on factors such as the type of spirits and the recipe, a mixed drink can contain from one to three or more standard drinks.

TABLE 37.3 Cigarette Smoking–Related Mortality

Disease	Men	Women	Overall
Cancers			
Lung	74,300	53,400	127,700
Other	26,000	10,000	36,000
Subtotal	100,300	63,400	163,700
Cardiovascular Diseases and Metabolic Diseases			
Coronary heart disease	61,800	37,500	99,300
Other heart disease	13,400	12,100	25,500
Cerebrovascular disease	8,200	7,100	15,300
Other vascular disease	6,000	5,500	11,500
Diabetes mellitus	6,200	2,800	9,000
Subtotal	95,600	65,000	160,000
Respiratory Diseases			
Pneumonia/influenza	7,800	4,700	12,500
COPD	50,400	50,200	100,600
Subtotal	58,200	54,900	113,100
Total	**254,100**	**183,300**	**437,400**

COPD, Chronic obstructive pulmonary disease.
Modified from Centers for Disease Control and Prevention: *Annual cigarette smoking-related mortality in the United States.* Available at http://www.cdc.gov.

cigars are less hazardous than cigarettes because the harsher smoke discourages deep inhalation. However, pipes and cigars increase the risk of cancer of the lips, mouth, and throat.

Smoke can be inhaled directly by the smoker (**mainstream smoke**), or it can enter the atmosphere from the lit end of the cigarette and be inhaled by others in the vicinity (sidestream smoke). **Sidestream smoke** or secondhand smoke contains higher concentrations of toxic and carcinogenic compounds than mainstream smoke. Exposure to sidestream tobacco smoke has been causally linked to cancer, respiratory and cardiovascular diseases, and adverse effects on the health of infants and children (USDHHS, 2014). Sidestream smoke is only about 20 percent less dangerous than actually smoking, and most of the toxic effects occur within the first five minutes of exposure (Barnoya & Glanz, 2005). Smoking bans continue to be adopted to reduce the discomfort and health hazards among nonsmokers.

Nicotine is also used as chewing tobacco or snuff. Marketed as "smokeless tobacco," a wad is put in the mouth and the nicotine is absorbed sublingually. Higher doses of nicotine are delivered in the smokeless forms because the nicotine is not destroyed by heat. Nevertheless, this form is less addictive because nicotine enters the bloodstream less directly. Smokeless

tobacco users are 20 percent more likely to die of heart disease than nonusers, and they are at a higher risk for cancers of the mouth, pharynx, esophagus, stomach, and pancreas (Barry, 2007).

More recently, electronic cigarettes, or e-cigarettes, have gained popularity in the United States, especially among adolescents. E-cigarettes contain liquid nicotine, which is heated into a vapor and inhaled. They are the most commonly used form of tobacco among youth in the country, with 11.7 percent of high school students in 2017 reporting current use, despite only 3.2 percent of adults 18 and older reporting current use (CDC, 2017c; CDC, 2018c).

This is due in part to their availability, unhindered advertising, variety of flavors, and the belief that they are safer than cigarettes. In addition to the dangers of nicotine, studies indicate that e-cigarette smoking is associated with progression to smoking actual cigarettes, increasing the risk of smoking in vulnerable populations like adolescents (Soneji et al., 2017). While the long-term health effects of e-cigarettes are still unknown, many e-cigarette products have been found to contain known carcinogens and toxic chemicals (Hess et al., 2017).

Cannabis (Marijuana)

Cannabis (*Cannabis sativa* or *C. indica*) is the most widely used illicit drug in the United States. In 2016, a national survey found that an estimated 24 million Americans aged 12 or older were current users of cannabis (SAMHSA, 2017). Compared with other psychoactive drugs, cannabis has little toxicity and is one of the safest therapeutic agents known. Psychological dependence can occur with chronic use, but little is known about any potential physical dependence. Users enjoy a mild euphoria, a relaxed feeling, and an intensity of sensory perceptions. Some call the effect a dreamy state of consciousness in which ideas seem disconnected, unanticipated, and free flowing. Time, color, and spatial perceptions may be altered (O'Malley & O'Malley, 2018d). Side effects include dry and reddened eyes, increased appetite, dry mouth, drowsiness, and mild tachycardia. Adverse reactions include anxiety, disorientation, and paranoia.

Although the vast majority of cannabis users do not experience serious negative physical side effects, emergency departments have started to see an increase of patients suffering from cannabinoid hyperemesis syndrome. This manifests as cyclic episodes of nausea and vomiting in frequent users, resolving spontaneously within 48 hours without cannabis use and relieved only by hot baths (Lu & Agito, 2015). This phenomenon may be explained by frequent use of cannabis extracts and concentrates, which contain exponentially larger dosages of cannabinoids than traditional plant material.

In general, the greatest physical concern for chronic users is possible damage to the respiratory tract from smoking the drug, though even daily smokers do not develop obstructive airway disease. For chronic users, tolerance can develop, as well as physical dependence; however, withdrawal symptoms are benign. As with any euphoria-inducing drug, addiction can occur for some chronic users and is difficult to treat because the progression tends to be subtle.

Despite its widely accepted therapeutic effects, especially in treating chronic pain (Mucke et al., 2018), the federal government continues its total prohibition efforts. By 2018, 30 states and the District of Columbia had laws broadly legalizing marijuana in some form (see map). Additionally, several state nurses associations, the American Nurses Association, and the American Public Health Association, among other health care organizations, support access to the medicinal use of cannabis. See www.medicalcannabis.com for a full list of supporting organizations.

In the late 1980s to early 1990s, scientists discovered a complex molecular signaling system within the human body that is involved in most physiological processes, the purpose of which is to protect us from stressors and help maintain balance. This system is called the endocannabinoid system (ECS) and consists of receptors primarily in our brain (CB1 receptors) and immune system (CB2 receptors). We now know that all animals have an ECS and that we make cannabinoids (endogenous cannabinoids) that are similar in structure to the phytocannabinoids found in the cannabis plant. This new science is shedding light on human physiology and helps explain how and why cannabis has such a wide margin of safety and is helpful for such a wide array of health problems (Pacher et al., 2006; Werner, 2011). Research efforts to further elucidate the beneficial properties of Cannabidiol (CBD) continue to increase, and safer therapeutic uses of CBD have become more well-known in recent years. CBD is a cannabinoid compound found in cannabis that is not psychoactive and has been found to have antiinflammatory, anti-pain, and potentially antipsychotic properties (Burstein, 2015; Leweke et al., 2012). In light of these findings, more evidence is needed to further elucidate the beneficial properties of cannabinoids in order to harness their potential for therapeutic use in health care (Box 37.5).

Opioids

President Trump declared a public health emergency in October 2017 concerning the opioid epidemic in the United States. Opioids are the number one cause of drug overdose deaths in the country. On average, 115 Americans die every day from an opioid overdose (CDC, 2017b). Drug overdose death rates have more than tripled in the United States since 1999. In 2016, drug

BOX 37.5 Synthetic Cannabinoids

While dronabinol (Marinol) is synthetic tetrahydrocannabinol (THC) in sesame oil and approved as a Schedule III drug by the Food and Drug Administration (FDA), numerous "synthetic cannabinoids" have started to appear on the market. These synthetic cannabinoids are much stronger than the FDA-approved medication and are usually smoked or inhaled as a vapor. In the past decade, these have become an increasingly popular substance of abuse globally. There are many different formulations of synthetic cannabinoids in existence, some of which have become illegal. Many formulations, however, remain available on the legal market and are sold under names such as K2, Spice, and Black Mamba. Individuals often use synthetic cannabinoids due to the belief that they are safer because they are legal. While some report effects similar to cannabis, effects are inconsistent and may even be dangerous and fatal, depending on formulation and use (NIDA, 2018b).

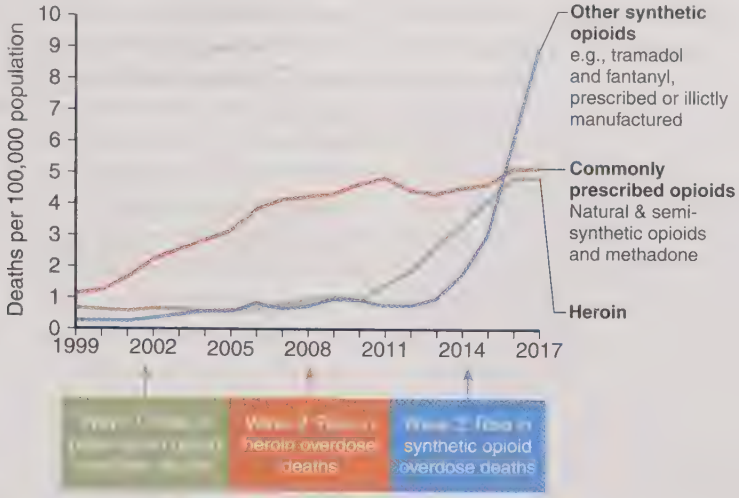

Fig. 37.2 Three waves of the rise in opioid overdose deaths. (From https://www.cdc.gov.)

overdose was the leading cause of injury death, and the third overall cause of death in the United States (CDC, 2017f). People aged 12 or older who misused prescription pain relievers in 2016 reported the most common source was from a friend or relative (53 percent) (SAMHSA, 2017). From 1999 to 2016, the drug overdose rate more than tripled, leading to 63,600 drug overdose deaths in 2016. Of these deaths, 66.4 percent involved an opioid (CDC, 2017a). It is estimated that the total economic burden of prescription opioid misuse is $78.5 billion in health care, lost productivity, addiction treatment, and criminal justice costs (Florence et al., 2016).

Opioids are primarily used for pain management by acting on opioid receptors on nerve cells to decrease pain and produce euphoria and drowsiness. Tolerance and physical dependence develop quickly, requiring a tapering down in therapy to avoid withdrawal symptoms after several days' use (O'Malley & O'Malley, 2018e).

The opioid epidemic began in 1999, primarily with the misuse of common prescription opioid drugs used to treat pain, which include hydrocodone (Vicodin), oxycodone (OxyContin, Percocet), codeine, fentanyl, and morphine (Kadian, Avinza), among others. This was in large part due to inappropriate physician prescription of these drugs, buoyed by improper marketing, lobbying, and pharmaceutical kickbacks (Dasgupta et al., 2018). In 2010, heroin overdose deaths saw a sharp increase, with the CDC reporting heroin deaths had doubled from 2010 to 2012 (CDC, 2014b). This spike occurred in part due to increasing dependency and tolerance to prescription opioids and desiring a cheaper and more potent alternative. In fact, multiple studies in 2013 found that about 80 percent of heroin users first misused prescription opioids before using heroin, which has steadily decreased in cost over the years (Muhuri et al., 2013). Yet even with this increase, still more than twice as many died from prescription opioid overdoses than heroin in 2012 (CDC, 2014a). It should also be noted that while 21-29 percent of patients prescribed opioids for chronic pain misuse them, only 8-12 percent develop an opioid use disorder, and an estimated 4–6 percent transition to heroin use (NIDA, 2018a).

The third phase of the opioid epidemic began in 2013 with the increased use of synthetic opioids (other than methadone) including tramadol, fentanyl, and fentanyl analogs such as carfentanil, which have been responsible for the bulk of opioid-related deaths since that time. Deaths from synthetic opioids doubled from 9580 in 2015 to 19,413 in 2016 (Seth et al., 2018). Fentanyl is a synthetic opioid that is 50 times more potent than heroin and 100 times more potent than morphine. Carfentanil is 5000 times more potent than heroin. Although fentanyl is produced and used legally, illegal production of fentanyl/fentanyl analogs has soared, such that most synthetic opioid overdoses today involve illicitly manufactured fentanyl, often added into counterfeit prescription opioid tablets, heroin, cocaine, or methamphetamine without the user's knowledge. While synthetic opioids were the most common drug involved in overdose deaths in 2016, 80 percent of these overdose deaths involved alcohol or another drug—most commonly another opioid (Jones et al., 2018) (Fig. 37.2).

In 2016, 35.6 percent of the population aged 18 and older reported using prescription pain relievers in the past year, although only 4.5 percent of the population reported misusing opioids, including heroin and other illicit opioids (SAMHSA, 2017). The proportion of persons who misuse opioids to the number of overdose deaths resulting from their use highlights the lethal potential of these drugs when misused. The CDC released a guideline for prescribing opioids for chronic pain to better ensure appropriate prescribing practices to reduce potential for misuse. The three main areas of focus are (1) determining when to initiate or continue opioids for chronic pain; (2) opioid selection, dosage, duration, follow-up, and discontinuation; and (3) assessing risk and addressing harms of opioid use. Increasingly, efforts are transitioning to emphasis on nonopioid pharmacological and nonpharmacological treatments for chronic pain (CDC, 2016a).

PREDISPOSING/CONTRIBUTING FACTORS

In addition to the specific drug being used, two other major variables influence the particular drug experience: set and

setting. To understand various patterns of drug use and abuse by individuals, all three factors (drug, set, and setting) should be considered.

Set

Set refers to the individual using the drug, as well as that person's expectations, including unconscious expectations, about the drug being used. A person's current health may alter a drug's effects from one day to the next. Some people are genetically predisposed to alcoholism or other drug addiction, and their chemical makeup is such that simply consuming the drug triggers the disease process. Persons with underlying mood disorders or other mental illness may try to self-medicate with psychoactive drugs. Sometimes the choice of drug exacerbates symptoms; for example, a depressed person might consume alcohol and become more depressed.

Setting

Setting is the influence of the physical, social, and cultural environment within which the use occurs. Social conditions influence the use of drugs. The fast pace of life, competition at school or in the workplace, and the pressure to accumulate material possessions are daily stressors. Pharmaceutical, alcohol, and tobacco companies are continuously bombarding the public with enticing advertisements pushing their products as a means of feeling better, sleeping better, having more energy, or just as a "treat." People grow up believing that most of life's problems can be solved quickly and easily through the use of a drug. For persons of a lower socioeconomic background, with minimal education or employment possibilities, many of life's opportunities can seem out of reach. Rather than seeking relief through holistic means or behavioral health treatment, the use of psychoactive drugs may offer a way to numb the pain or escape from a hopeless reality. They may rely on alcohol or illicit drugs, which are more readily available. For some, selling illicit drugs may appear to be the only way to support themselves and their loved ones in avoiding a future of poverty and unemployment.

Biopsychosocial Model of Addiction

Many theories have been proposed to explain the etiological factors of addiction, and no consensus exists on specific causes. These theories include the belief that addiction is a disease, a moral failing, a psychological disturbance, a personality disorder, a social problem, a dysbehaviorism, or a maladaptive coping mechanism. Different people develop addiction in different ways. For example, some alcohol-addicted persons say, "I knew I was an alcoholic from my first drink; I drank differently than others." Others have no family history of addiction, but when stressed (such as from chronic pain, significant losses, abusive relationships that lead to low self-esteem, or trauma resulting in post-traumatic stress disorder), they find that drugs may temporarily relieve their stress. Over time, heavy use of one or more drugs to cope with the stress may lead to a substance use disorder. As discussed earlier, current research focuses on the neurochemistry of addiction, which shows brain chemistry changes among addicted persons. The "just say no" approach neglects the fact that such changes to the brain's reward system may make it impossible for some already addicted individuals to do so. The biopsychosocial model provides a framework for understanding addiction as the result of the interaction of multiple factors involved in drug, set, and setting.

PRIMARY PREVENTION AND THE ROLE OF THE NURSE

The harm reduction approach to substance use disorders focuses on health promotion and disease prevention. Primary prevention for ATOD problems includes (1) the promotion of healthy lifestyles and resiliency factors and (2) education about drugs and guidelines for their use. Nurses are ideally prepared to use health promotion strategies such as promoting and facilitating healthy alternatives to indiscriminate, careless, and often dangerous drug use practices and providing education about drugs to decrease harm from irresponsible or unsafe drug use practices.

Promotion of Healthy Lifestyles and Resiliency Factors

It is possible to teach clients to have more agency in their relationships with others and how to make more beneficial decisions by looking carefully at the pros and cons of each option and the related consequences. People may turn to medications, especially psychoactive drugs, when they have persistent health problems such as difficulty sleeping, muscle tension, lack of energy, chronic stress, and mood swings. Nurses can help clients understand that medications may mask problems rather than solve them. Stress reduction and relaxation techniques along with a balanced lifestyle may be more effective than medications. Lack of sleep, improper diet, and insufficient exercise contribute to many health complaints. Assisting clients to balance their need for rest, nutrition, and exercise on a daily basis can reduce these complaints. Nurses can provide useful information to groups, assisting in the development of community recreational resources or facilitating stress reduction, relaxation, or exercise groups. Nurses can help people learn about drug-free community activities. The How To box lists community activities in which the nurse may become involved.

HOW TO Set Up Community-Based Activities Aimed at Substance Abuse Prevention

- Increase involvement and pride in school activities.
- Facilitate a peer mentorship program to discourage youth from joining gangs.
- Establish a support group for veterans.
- Organize substance-free promoting events for youth at skate parks.
- Organize a Students Against Drunk Driving (SADD) chapter.
- Mobilize parental awareness and action groups (e.g., Mothers Against Drunk Driving [MADD]).
- Establish an Al-Anon or Alateen meeting.
- Increase availability of recreational facilities.
- Curtail media messages that glamorize drug and alcohol use.
- Support and reinforce anti-drug use peer-pressure skills.
- Collaborate with community leaders to address problems related to crime, housing, jobs, and access to health care.

Lack of educational opportunities, job training, or both can contribute to socioeconomic stress and poor self-esteem, which can lead to drug use to escape the situation. Nurses can help clients identify community resources and address problems to meet basic needs rather than avoid them.

In addition to decreasing risk factors associated with ATOD problems, it is important to increase protective or resiliency factors. Prevention guidelines to teach parents and teachers how to increase resiliency in youths include the following strategies:

- Help them develop an increased sense of responsibility for their own success.
- Help them identify their talents.
- Encourage them to find inspiration in helping society rather than in consumerism.
- Provide realistic appraisals and feedback; stress multicultural competence; encourage and value education and skills training.
- Increase cooperative solutions to problems rather than competitive or aggressive solutions.

Drug Education

ATOD problems include more than abuse of psychoactive drugs. Today more than 450,000 different drugs and drug combinations are available by prescription or over the counter. Nurses have knowledge about medication administration, the benefits of drugs, and their shortcomings. Nurses can influence the health of clients by destroying the myth of good drugs versus bad drugs. This means (1) teaching clients that no drug is completely safe and that any drug can be abused, (2) helping persons learn how to make informed decisions about their drug use to minimize potential harm, and (3) teaching them to always tell their health care provider what supplements they are taking.

Drug technology is growing, yet the public receives little information about how to safely use this technology. Harm reduction as a goal recognizes that people consume drugs and that they need to know about the use of drugs and risks involved in order to make safer decisions about their drug use. Drug education should begin on an individual basis by reviewing the client's prescription medications. Clients often presume little risk is involved because a physician or nurse practitioner has prescribed the medication.

Is the client aware of any untoward interactions this drug may have with other drugs being used or with food? A common occurrence with drug users is taking drugs from different categories together or at different times to regulate how they feel, known as **polysubstance use or abuse**. For example, a person may drink alcohol when snorting cocaine to "take the edge off"; or some intravenous drug users combine cocaine with heroin (speedball) for similar reasons. Polysubstance use can cause drug interactions that can have additive, synergistic, or antagonistic effects. Indiscriminant polysubstance abuse may lead to serious physiological consequences and can be complicated for the health care professional to assess and treat. It is important to encourage clients to ask questions about their drug use. The How To box lists key information that clients should obtain before taking a drug or medication to decrease the possible harm from unsafe medication consumption.

HOW TO Determine the Relative Safety of a Drug for Personal or Client Use

Before using a drug/medication, always determine the following:

- The chemical being taken
- How and where the drug works in the body (main effects, side effects, and adverse reactions)
- The correct dosage and route of administration
- Whether there will be drug interactions, including interactions with herbal remedies or foods
- Awareness of the symptoms of a potential allergic reaction and knowing when to seek help
- If there will be drug tolerance
- If the drug will produce physical dependence

Purity of the chemical and potential for unknown additives also should be determined.

Nurses can identify references and community resources available to provide the necessary information, and they can clarify the information. User-friendly reference texts and online resources are available that describe drug interactions among medications, other drugs (including alcohol, tobacco, marijuana, and cocaine), and other substances (food and beverages); they serve as excellent guides for nurses and their clients. (See http://www.drugs.com for more information.) Clients should learn and ask questions about their prescription medications, self-administered over-the-counter drugs, including supplements and herbal remedies, and recreational drugs. This does not mean that nurses should encourage other drug use, but rather that the potential harm from self-medication can be reduced if clients have the necessary information to make more informed decisions.

Parents should seek information about their use of medications so they can act as role models for their children. It can be confusing for children and adolescents to be told to "just say no" to drugs when they see their parents trying drugs or they see drug advertisements offering to "quick fix" every health complaint or feeling of stress, anxiety, or depression with a medication. The simple "just say no" approach does not help young people for several reasons. First, children are naturally curious, and drug experimentation is often a part of normal development. Second, children from dysfunctional homes may use drugs to get attention, to escape an intolerable environment, or because a family member introduced certain drugs to them. And finally, the "just say no" approach does not address the powerful influence of peer pressure.

Drug education moved into school curriculum with Project DARE (Drug Abuse Resistance Education) in the 1980s, the most widely used school-based drug-use prevention program in the United States. This abstinence-based program uses law enforcement officers to teach the material, but studies have found that it is less effective than other interactive prevention programs and may even result in increased drug use (Pan & Bai, 2009). DARE has since added to their program a curriculum

targeting elementary and middle school students called *keepin' it REAL*, which is supported by the 2016 U.S. surgeon general's report on addiction (USDHHS, 2016).

Basic ATOD prevention programs for young people should combine efforts to increase resiliency factors with drug education. Nurses can serve as educators or as advisors to the school systems or community groups to ensure that all of these areas are addressed. Role-playing and peer facilitation is useful in teaching many of these skills.

As with much of the public health field, more online and mobile phone apps have been introduced to educate people, especially youth, about drugs and drug use. Young people are the most likely to be receptive to such mobile health (mHealth) efforts, as they may feel more comfortable using such technology than older populations. In addition, mHealth preventive interventions have the ability to reach large numbers of individuals at their convenience in comparison to in-person interventions. Although the use of such technology is still quite new in substance abuse prevention, early research points to the effectiveness of such interventions when applied in real-life, real-time contexts (Kazemi et al., 2017).

CHECK YOUR PRACTICE

As a public health nurse who works one day a week in a middle school, you are developing a program and fact sheet for eighth grade students. What are some of the age-appropriate items you would include in order to help these students know where to locate resources about alcohol and other drugs?

SECONDARY PREVENTION AND THE ROLE OF THE NURSE

Screening for health problems has long been a basic tool used by public health nurses when working with various populations. There are numerous screening tools for ATOD problems that can be used independently or integrated with broader health screening tools. When drug abuse, dependence, or addiction is identified, nurses must assist clients to understand the connection between their drug use patterns and the negative consequences on their health, their families, and the community. Brief interventions include effective strategies nurses can initiate for early intervention before a person needs more extensive or specialized treatment.

One such intervention is called Screening, Brief Intervention, and Referral to Treatment (SBIRT). SBIRT is an evidence-based practice used to identify, reduce, and prevent problematic use, abuse, and dependence on alcohol, tobacco, and other drugs. The SBIRT model was incited by an Institute of Medicine recommendation that called for community-based screening for health risk behaviors, including substance use. Primary care centers, hospital emergency departments, trauma centers, and other community settings provide opportunities for early intervention with at-risk substance users before more severe consequences occur.

- *Screening* quickly assesses the severity of substance use and identifies the appropriate level of treatment.
- *Brief intervention* focuses on increasing insight and awareness regarding substance use and motivation toward behavioral change.
- *Referral to treatment* provides those identified as needing more extensive treatment with access to specialty care.

A key aspect of SBIRT is the integration and coordination of screening and treatment components into a system of services. This system links a community's specialized treatment programs with a network of early intervention and referral activities that are conducted in medical and social service settings (http://www.integration.samhsa.gov.). Some apps have also been developed to aid health care professionals in employing SBIRT in their interactions with clients. Research points to the effectiveness of the universal application of SBIRT in the school setting for all adolescents, even outside of the clinic setting, demonstrating that it promotes continued abstinence and reduces substance use (Maslowsky et al., 2017). For example, the prevention program Brief Alcohol Screening and Intervention for College Students (BASICS) is an evidence-based intervention that has been found to return $17.61 for each dollar spent (USDHHS, 2016).

Assessing for Alcohol, Tobacco, and Other Drug Problems

In addition to the SBIRT, there are many other screening tools that can be used in order to assess for substance abuse problems. The National Institute on Drug Abuse has developed a compilation of resources for clinicians through a Physicians' Outreach Initiative called NIDAMED, including tools and resources for screening. These screening and assessment tools are available at https://www.drugabuse.gov. Of note, the Alcohol Use Disorders Identification Test (AUDIT) and Drug Abuse Screening Test (DAST) are helpful, commonly used screening instruments for health professionals.

Self-assessment screening tools are available online at http://www.alcoholscreening.org and www.drugscreening.org. These screening tools are based on the Alcohol, Smoking, and Substance Involvement Screening Test (ASSIST) developed by the World Health Organization and allow for immediate feedback. People can participate in this screening anonymously.

During any health assessment, the nurse should assess for substance abuse problems, including both self-medication practices and recreational drug use when taking a medication history. Thus, all relevant drug use history is collected and aids in the assessment of drug use patterns. Note any changes in drug use patterns over time. After obtaining a medication history, follow-up questions can determine if problems exist. The following are examples:

- If using a prescription drug, is the client following the directions correctly?
- Has the client increased the dosage or frequency above the prescription level?
- Is the person using any other prescribed or recreational psychoactive drugs, including alcohol and tobacco?
- If so, for how long and what is the dosage?

One useful assessment tool is the five A's when screening for ATOD problems: (1) Ask about use; (2) Assess amount and

pattern of use; (3) Advise about safe use as appropriate; (4) Assist with identifying help or resources; (5) Arrange for follow-up as needed.

When assessing self-medication and recreational or social drug use patterns, determine the reason the person uses the drug. Some underlying health problems (e.g., pain, stress, weight, insomnia) may be relieved by nonpharmaceutical interventions. The amount, frequency, duration of use, and the route of administration of each drug should be determined. To establish the presence of a substance abuse problem, it is necessary to determine if the drug use is causing any negative health consequences or problems with relationships, employment, finances, or the legal system. The How To box lists examples of questions to ask to determine the presence of socioeconomic problems that are often a result of substance abuse. If a pattern of chronic, regular, and frequent use of a drug exists, nurses should assess for a history of withdrawal symptoms to determine if there is physical dependence on the drug. A progression in drug use patterns and related problems warns about the possibility of addiction. **Denial** is a primary symptom of addiction. Methods of denial include the following:

- Lying about use
- Minimizing use patterns
- Blaming or rationalizing
- Intellectualizing
- Changing the subject
- Using anger or humor
- "Going with the flow" (agreeing that a problem exists, stating the behavior will change, but not demonstrating any behavior changes)

A problem should be suspected if the client becomes defensive or exhibits other behavior indicating denial when asked about alcohol or other drug use.

HOW TO Assess Socioeconomic Problems Resulting From Substance Abuse

If the client admits to use of alcohol, tobacco, or other drugs, ask the following questions:

- Do your parents, spouse, or friends worry or complain about your drinking or using drugs?
- Has a family member sought help about your drinking or using drugs?
- Have you neglected family obligations as a result of drinking or using drugs?
- Have you missed work because of your drinking or using drugs?
- Does your boss complain about your drinking or using drugs?
- Do you drink or use drugs before or during work?
- Have you ever been fired or quit because of drinking or using drugs?
- Have you ever been charged with driving under the influence (DUI) or being drunk in public (DIP)?
- Have you ever had any other legal problems related to drinking and using drugs, such as assault and battery, breaking and entering, or theft?
- Have you had any accidents while intoxicated, such as falls, burns, or motor vehicle accidents?
- Have you spent your money on alcohol or other drugs instead of paying your bills (e.g., telephone, electricity, rent)?

The Levels of Prevention box shows the levels of prevention related to substance abuse that can be used by nurses.

LEVELS OF PREVENTION

Substance Use Disorders

Primary Prevention

Provide community education to teach healthy lifestyles; focus on how to resist getting involved in substance abuse; engage individuals in activities and interests they can be passionate about.

Secondary Prevention

Institute early detection programs in schools, the workplace, and other areas in which people gather to determine the presence of substance abuse; educate individuals on how to recognize substance abuse in friends/family/coworkers.

Tertiary Prevention

Develop programs to help people reduce or end substance abuse; educate individuals who abuse drugs on safe drug use.

Drug Testing

During the 1980s, pre-employment or random drug testing in the workplace gained popularity. A person's urine, blood, saliva, or hair can be examined to test for the use of drugs. The breath can be tested for alcohol. Urine testing is the most common method of drug screening. Urine testing indicates only past use of certain drugs, not current intoxication. Thus, persons can be identified as having used a certain drug in the recent past, but the degree of intoxication and extent of performance impairment cannot be determined with urine testing. Also, most drug-related problems in the workplace are related to alcohol, and alcohol is not always included in a urine drug screen.

When is drug testing appropriate? Drug testing that follows documented impairment may help substantiate the cause of the impairment, thus serving as a backup rather than the primary screening method. It is also useful for recovering addicted persons. If part of their treatment is to abstain from psychoactive drug use, a urine test yielding positive results for a drug indicates a relapse.

Blood, breath, and saliva drug tests can indicate current use and relative amount. Any of these tests can help determine alcohol intoxication, and they are often used to substantiate suspected impairment. A serum drug screen can be useful to determine the specific drug ingested when overdose is suspected. The testing of hair is gaining attention because the results can provide a long history of drug use patterns.

Alcohol and other drug testing should be used as a clinical and public health tool, but not for harassment and punishment. For example, many people seen in trauma centers were drinking at the time of their injuries. Hence, it is recommended that breath alcohol testing should be routinely done for clients admitted to the emergency department for traumatic injuries.

Employee assistance programs (EAPs) are a beneficial service in many work settings. EAP programs can identify personal and/or work-related problems among employees and offer short-term counseling or referral to other health care providers as necessary. Such programs also offer services to employees to reduce stress and provide other forms of support to prevent substance abuse problems from developing. Nurses frequently develop and run these programs.

Often, a sizeable number of EAP clients have substance use problems, since most adults with these problems are employed. The 2016 National Survey on Drug Use and Health found that of the about 19 million adults classified with dependence or abuse, 54.5 percent were employed full time (SAMHSA, 2017).

High-Risk Groups

Identifying high-risk groups helps nurses design programs to meet specific needs and to mobilize community resources.

Adolescents. The younger a person is when beginning intensive experimentation with drugs, the more likely dependence will develop. Underage drinking is considered the most serious drug problem for youth in the United States. Findings from the 2016 National Survey on Drug Use and Health found that 19.3 percent of individuals aged 12 to 20 had used alcohol in the past month, and that 12.1 percent of those had engaged in binge alcohol use. This survey also notes these past-year drug use patterns among 12- to 17-year-olds: 15.8 percent had used illicit drugs in the past year, with 12 percent using cannabis, 0.5 percent cocaine, 0.1 percent heroin, 1.8 percent hallucinogens (including LSD, PCP, and ecstasy), 2.2 percent inhalants, 0.1 percent methamphetamine, and 5.3 percent psychotherapeutic drugs nonmedically (with 3.5 percent using pain relievers) (SAMHSA, 2017).

People who misuse illicit prescription drugs are at risk of abuse and addiction as well as overdose deaths. Many teens and college youth steal drugs from their family members or are given them by friends and family, and others buy them off the Internet. The most commonly abused opioids among teens are hydrocodone (Vicodin) and oxycodone (OxyContin), and these are sometimes crushed and snorted or injected. Friends in school share their amphetamine salts (Adderall) or methylphenidate (Ritalin) with other students, who often use them to help them study. Benzodiazepines such as diazepam (Valium) and alprazolam (Xanax) are the depressants of choice.

Students say that prescription drugs are often cheaper and easier to obtain, and some believe that they are "cleaner" or safer than illicit drugs such as cannabis or cocaine. This is increasingly untrue as synthetic opioids have made their way into counterfeit OxyContin tablets and Xanax bars. Young people generally have no idea of the toxic effects when these drugs are taken in high doses or combined.

Although risk-taking and trying new things is a normal part of adolescent development, heavy drug use during adolescence can interfere with normal brain development. Note that *Healthy People 2020* objectives SA-2 and TU-3 reduce the initiation of the use of tobacco, alcohol, and other drugs (see *Healthy People 2020* box) (U.S. Department of Health and Human Services, 2010). Family-related factors (genetics, family stress, parenting styles, child victimization) appear to be the greatest variable that influences substance abuse among adolescents. The co-occurrence with psychiatric disorders (especially mood disorders) and behavioral problems is also associated with substance abuse among adolescents, leaving peer pressure as a less influential factor. Research suggests that successful social influence-based prevention programs may be driven by their ability to foster social norms that reduce an adolescent's social motivation to begin using ATODs. One particularly effective treatment approach for adolescents is the use of family-oriented therapy (NIDA, 2014). The Quality and Safety in Nursing Education box provides information about using information management tools to develop ATOD prevention programs in a school.

Lobbying and policy changes are an important factor in primary prevention for youth as well. For example, in an attempt to limit the number of youth who use tobacco, six states and 340 localities have raised the minimum legal sale age for tobacco products to 21 years old as a result of successful campaigning ("States and Localities," 2018).

HEALTHY PEOPLE 2020

Objectives Related to Substance Abuse

- **SA-2:** Increase the proportion of adolescents never using substances.
- **SA-8:** Increase the proportion of persons who need alcohol and/or illicit drug treatment and received specialty treatment for abuse or dependence in the past year.
- **SA-14:** Reduce the proportion of persons engaging in binge drinking of alcoholic beverages.
- **SA-17:** Decrease the rate of alcohol-impaired driving (0.08+ blood alcohol content [BAC]) fatalities.

Objectives Related to Tobacco Use

- **TU-3:** Reduce initiation of tobacco use among children, adolescents, and young adults.
- **TU-11:** Reduce the proportion of nonsmokers exposed to secondhand smoke.
- **TU-14:** Increase the proportion of smoke-free homes.
- **TU-18:** Reduce the proportion of adolescents and young adults in grades 6 through 12 who are exposed to tobacco marketing.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Informatics

Use information technology to communicate, manage knowledge, mitigate error, and support decision making.

Important aspects of informatics to include:

- **Knowledge:** Identify essential information that must be available in a common database to support client care.
- **Skills:** Use information management tools to monitor outcomes of care processes.
- **Attitudes:** Value technologies that support clinical decision making, error prevention, and care coordination.

Informatics Question

You are the school nurse at a large high school in a rural, impoverished area. There has been a recent tragedy involving a senior from this high school drinking and doing other drugs while driving with friends in the car, resulting in one student death, and significant injury to the driver and another passenger. You have been asked to address use of alcohol, tobacco, and other drugs (ATOD) at this high school.

- What data should you collect to assess the scope of the ATOD problem at this school? How does the community environment impact ATOD use culture for students at the school?
- Who are some key informants you want to interview? What information will you seek from them?
- You decide that a drug and alcohol education social media campaign is needed. What data will you want to track over time to assess the effectiveness of this intervention?

Older Adults. Older adults (65 years of age and older) represent 15.2 percent of the U.S. population and are the fastest-growing segment of U.S. society, expected to represent 21 percent by the year 2030 (Ortman et al., 2014). Older adults use more prescription drugs than any other age group; 65 percent of adults aged 65 or older take three or more prescriptions drugs, and 39 percent take five or more prescription drugs (Charlesworth et al., 2015).

Alcohol and prescription drug misuse affects as many as 17 percent of adults age 60 and older. Problems with alcohol consumption, including interactions with prescribed and OTC drugs, far outnumber any other substance abuse problem among older adults (SAMHSA, 2009). A Substance Abuse and Mental Health Services Administration (SAMHSA) comprehensive screening and brief interventions guide to preventing older adult alcohol and psychoactive medication misuse/abuse is available at https://www.ncoa.org.

The increased use of prescription drugs and alcohol by older adults may be related to coping problems. Problems of relocation, loss of independence, retirement, illness, death of friends/family, and lower levels of achievement contribute to feelings of sadness, boredom, anxiety, and loneliness. Factors such as slowed metabolic turnover of drugs, age-related organ changes, enhanced drug sensitivities, a tendency to use drugs over long periods, and a more frequent use of multiple drugs (polypharmacy) all contribute to greater negative consequences from drug use among older adults. Alcohol abuse may not be identified because its effects on cognitive abilities may mimic changes associated with normal aging or degenerative brain disease. Also, depression may simply be attributed to more frequent losses rather than the depressant effects of alcohol, and the older adult may subsequently receive medical treatment for depression rather than alcoholism. Of note, it is recommended that both men and women aged 60 and older consume no more than one standard drink per day and no more than seven standard drinks per week. For older adult women, three or more drinks in a day is considered binge drinking (SAMHSA, 2012).

People Who Inject Drugs. In addition to the problem of addiction, people who inject drugs (intravenously or subcutaneously) (PWID) are at risk for other health complications. Intravenous (IV) administration of drugs always carries a greater risk of overdose because the drug goes directly into the bloodstream. With illicit drugs, the danger is increased because the exact dosage is unknown. In addition, the drug may be contaminated with other chemicals, such as sugar, starch, or quinine, or other drugs that can cause negative consequences. Often PWID make their own solution for IV administration, and any particles present can result in complications from emboli.

PWID often share needles. HIV, hepatitis C, and other bloodborne diseases can be transmitted through contaminated needles. Infections and abscesses may develop as a result of dirty needles or poor administration techniques. Although HIV incidence in PWID decreased 48 percent from 2008 to 2014, PWID continue to represent 1 in 10 new HIV diagnoses. In a change of statistical trends, fewer African Americans than whites are becoming new PWID, and whites are more likely to share needles (CDC, 2016b). Emphasis is being placed on reducing the transmission of this disease through contaminated needles. Abstinence is ideal but unrealistic for many addicted persons. Using the harm reduction model, the nurse should provide education on cleaning needles with bleach between uses and on needle exchange programs to decrease the spread of bloodborne disease. See more about this later in Safer Substance Use in Tertiary Prevention and the Role of the Nurse.

Drug Use During Pregnancy

Most drugs can negatively affect a fetus. Thus, the use of any drug during pregnancy should be discouraged unless medically necessary. *Healthy People 2020* objectives address this issue under the Maternal, Infant and Child Health topic area with several objectives that describe recommendations to improve the health of infants, such as reducing the occurrence of fetal alcohol syndrome (FAS) (MICH-25), and increasing abstinence from alcohol, cigarettes, and illicit drugs among pregnant women (MICH-11). FAS is considered the leading preventable birth defect, causing mental and behavioral impairment. In 2016 about 4.3 percent of pregnant women reported binge drinking and 0.9 percent reported heavy drinking in the past month. These low rates may be due to the extensive information available about the effects of alcohol on the fetus. With the opioid epidemic in full swing, the rates of babies born with neonatal abstinence syndrome (NAS) are also on the rise. In 2000, babies born with NAS represented 1.2 of 1000 hospital births, and by 2012 the rate had risen to 5.8 per 1000. This is equivalent to one baby born with NAS every 25 minutes (NIDA, 2015).

In 2016, the rate of past-month illicit drug use during pregnancy for women aged 15 to 44 was 6.3 percent. Tobacco remains the most-used addictive substance during pregnancy, with about 10 percent of pregnant women smoking (SAMHSA, 2017). In some states, pregnant women who are using illicit drugs are reported to child protective services because of the potential harm to the fetus.

Despite the increased focus on drug abuse interventions, many pregnant women with drug problems do not receive the help they need. This may be a result of ignorance, poverty, lack of concern for the fetus, lack of available services, and fear of the punitive consequences of revealing drug use. The fear of criminal prosecution may push addicted women farther away from the health care system, cause them to conceal their drug use from medical providers, and cause them to avoid the critical treatment and medical care that they need (Brady & Ashley, 2005).

Persons Who Use Illicit Drugs. The strategy of "just say no" to drugs is both simplistic and misleading. Indiscriminant use of "good" drugs has caused more health problems from adverse reactions, drug interactions, dependence, addiction, and overdoses than use of "bad" drugs. However, the war on drugs focuses on illicit drugs and punishes illicit drug users. The black market associated with illicit drug use puts otherwise law-abiding citizens in close contact with criminals, prevents any quality control of the drugs, increases the risk of HIV and

hepatitis as a result of needle sharing, and hinders health care professionals' accessibility to the drug user. Lack of quality control (unknown strength and purity) can cause unexpected overdoses or secondary effects of the impurities; for example, a synthetic analog of fentanyl (3-methylfentanyl) marketed as "heroin" is 6000 times as potent as morphine. Unsafe administration (contaminated needles) leads to local and systemic infections. The high cost of drugs on the black market leads to crime to support the addiction. In 2016, the highest rate of current illicit drug use was among 18- to 20-year-olds at 23.8 percent, with the next highest rate occurring among 21- to 25-year-olds at 22.8 percent (SAMHSA, 2017). See Table 37.4 for illicit drug use by race/ethnicity.

Codependency and Family Involvement

Drug addiction is often a family disease. One in four Americans experiences family problems related to alcohol abuse. People in a close relationship with the addicted person often develop unhealthy coping mechanisms to continue the relationship. This behavior is known as **codependency**—a stress-induced preoccupation with the addicted person's life, leading to extreme dependence and excessive concern with the addicted person.

Strict rules typically develop in a codependent family to maintain the relationships: don't talk, don't feel, don't trust, don't lose control, and don't seek help from outside the family. Codependents try to meet the addicted person's needs at the expense of their own. Codependency may underlie many of the

TABLE 37.4 Past Month Illicit Drug Use Among Persons Aged 12 or Older, by Age Group and Demographic Characteristics, 2015 and 2016

Demographic Characteristic	Aged 12+ (2015)	Aged 12+ (2016)	Aged 12-17 (2015)	Aged 12-17 (2016)	Aged 18+ (2015)	Aged 18+ (2016)	Aged 18-25 (2015)	Aged 18-25 (2016)	Aged 26+ (2015)	Aged 26+ (2016)

NOTE: Illicit Drug Use includes the misuse of prescription psychotherapeutics or the use of marijuana, cocaine (including crack), heroin, hallucinogens, inhalants, or methamphetamine.

NOTE: Misuse of prescription psychotherapeutics is defined as use in any way not directed by a doctor, including use without a prescription of one's own; use in greater amounts, more often, or longer than told; or use in any other way not directed by a doctor. Prescription psychotherapeutics do not include over-the-counter drugs.

[b]The difference between this estimate and the 2016 estimate is statistically significant at the .01 level. Rounding may make the estimates appear identical.

[1]The Other Employment category includes students, persons keeping house or caring for children full time, retired or disabled persons, or other persons not in the labor force.

From Substance Abuse and Mental Health Services Administration: *Results from the 2016 National Survey on Drug Use and Health: detailed tables,* NSDUH Series H-52, USDHHS Pub. No. SMA 17-5044, 2017, Rockville, MD. See Table 1.30B at https://www.samhsa.gov.

medical complaints and emotional stress seen by health care providers, such as ulcers, skin disorders, migraine headaches, chronic colds, and backaches.

When the addicted person refuses to admit the problem, the family continues to adapt to emotionally survive the stress of the addicted person's irrational, inconsistent, and unpredictable behavior. Family members consequently develop various roles that tend to be gross exaggerations of normal family roles, and they cling irrationally to these roles, even when they are no longer functional.

One of the most significant roles a family member may assume is that of an enabler. **Enabling** is the act of shielding or preventing the addicted person from experiencing the consequences of the addiction. As a result, the addicted person does not always understand the cost of the addiction and thus is "enabled" to continue to use. Although codependency and enabling are closely related, a person does not have to be codependent to enable. Anyone can be an enabler: a police officer, a boss or coworker, and even a drug treatment counselor. Health care professionals who do not address the negative health consequences of the drug use with the addicted person are enablers.

The nurse can help families recognize the problem of addiction and help them confront the addicted member in a caring manner. Whether or not the addicted family member is agreeable to treatment, the family members should be given some guidance about the literature and services that are available to help them cope more effectively. The nurse can help identify treatment options, counseling assistance, financial assistance, support services, and (if necessary) legal services for the family members. Children of ATOD abusers or addicted persons are themselves at greater risk for developing addiction and must be targeted for primary prevention.

TERTIARY PREVENTION AND THE ROLE OF THE NURSE

The nurse is in a key position to help the addicted person and his or her family. The nurse's knowledge of community resources and how to mobilize them can significantly influence the quality of care clients receive.

Safer Substance Use

Harm reduction is key in providing interventions for persons who abuse substances. There are a number of ways in which nurses can help support safer use of substances. It is important to educate clients who use drugs on how to safely use them to prevent overdose, infection, or mental health disorders. With the increase of synthetic heroin-adulterated opioids, cocaine, and methamphetamine, drug testing kits can help drug users identify when they have received a product of very low purity, meaning it contains very little of the substance they intend to use. Conversely, a person who regularly uses low-purity product may unintentionally overdose upon receiving a very high-purity product. It is also necessary to educate friends and family of drug users to recognize the signs of overdose. Public alerts concerning dangerous new formulations of substances are also significant in educating drug users so that they may make better-informed decisions.

BOX 37.6 Naloxone

Naloxone (Narcan) is a fast-acting opioid overdose reversal drug. It is available in nasal spray and injection (intramuscular and intravenous) form. Naloxone effectively removes opioids from the user's opioid receptors until it is metabolized from the system. It may be necessary to administer naloxone more than once until the individual can receive more acute medical interventions. Even in the event that naloxone is available, the Good Samaritan law protects individuals and opioid overdose victims from prosecution for drug possession charges if medical help is called.

For PWID, safe needle use prevents transmission of bloodborne disease and reduces incidence of injection-related injury and infection. Public health nurses can educate and provide resources to help PWID engage in safe needle use. Syringe exchange programs are also hugely beneficial for PWID. Such programs provide free sterile needles and syringes and safe disposal of used injection equipment. They reduce new HIV and hepatitis infections by decreasing shared syringes and needles, as well as reduce overdose deaths. Furthermore, PWID are five times as likely to enter treatment for substance use disorder when they use a syringe services program, as these sites also function as public health outreach locations. Most programs provide access to naloxone (an opioid overdose reversal drug) education, referrals, screenings, and other medical services (CDC, 2017e). See Box 37.6.

Detoxification

Detoxification is the clearing of one or more drugs from the person's body and managing the withdrawal symptoms. Depending on the particular drug and the degree of dependence, the time required may range from a few days to several weeks. Because withdrawal symptoms vary (depending on the drug used) and range from uncomfortable to life threatening, the setting for and management of withdrawal depend on the drug used.

Drugs such as stimulants or opiates may produce withdrawal symptoms that are uncomfortable but not life threatening. Detoxification from these drugs does not require direct medical supervision, but medical management of the withdrawal symptoms increases comfort to help individuals through the process. On the other hand, drugs such as alcohol, benzodiazepines, and barbiturates can produce life-threatening withdrawal symptoms. These clients should be under close medical supervision during detoxification and should receive medical management of the withdrawal symptoms to ensure a safe withdrawal. Of those who develop delirium tremens from alcohol withdrawal, 15 percent may not survive despite medical management; therefore close medical management is initiated as the blood alcohol level begins to fall.

A general rule in detoxification management is to wean the person off the drug by gradually reducing the dosage and frequency of administration. Thus, a person with chronic alcoholism could be safely detoxified by a gradual reduction in alcohol consumption. In practice, however, the switch to another drug, usually a benzodiazepine, often offers a safer withdrawal from alcohol as well as an abrupt end to the intoxication from the drug of choice. For example, chlordiazepoxide (Librium) is commonly used for alcohol detoxification. Outpatient or home detoxification for persons requiring medical detoxification

for alcohol withdrawal can be a cost-effective treatment. Nurses can monitor and evaluate the client's health status in the home environment to reduce the risk of medical complications related to alcohol withdrawal, and to provide encouragement and support for the client to complete the detoxification.

Addiction Treatment

Addiction treatment differs from the management of negative health consequences of chronic drug abuse, overdose, and detoxification. **Addiction treatment** focuses on the addiction process. The goal is to help clients view addiction as a chronic disease and assist them to make lifestyle changes to halt the progression of the disease. According to the disease theory, addicted persons are not responsible for the symptoms of their disease; they are, however, responsible for treating their disease. In 2016, 20.1 million persons aged 12 or older needed treatment for an illicit drug or alcohol use problem (7.5 percent of the persons aged 12 or older). Of these, 3.8 million persons aged 12 or older received treatment for alcohol or illicit substance use problems (SAMHSA, 2017). Fig. 37.3 shows the common reasons persons do not receive treatment.

Most treatment facilities are multidisciplinary because the intervention strategies require a wide range of approaches. Their programs involve interactions between the addicted person, family, culture, and community. Strategies include medical management, education, counseling, vocational rehabilitation, stress management, and support services. In addition, specific programs address the needs of various populations such as adolescents, pregnant women, specific ethnic groups, lesbian/gay/bisexual/transgender/queer and a plus sign to designate those not included (LGBTQ+) individuals, as well as health care professionals. The key to effective treatment is to match individual clients with the interventions most appropriate for them. Box 37.7 lists 13 fundamental principles for effective addiction treatment.

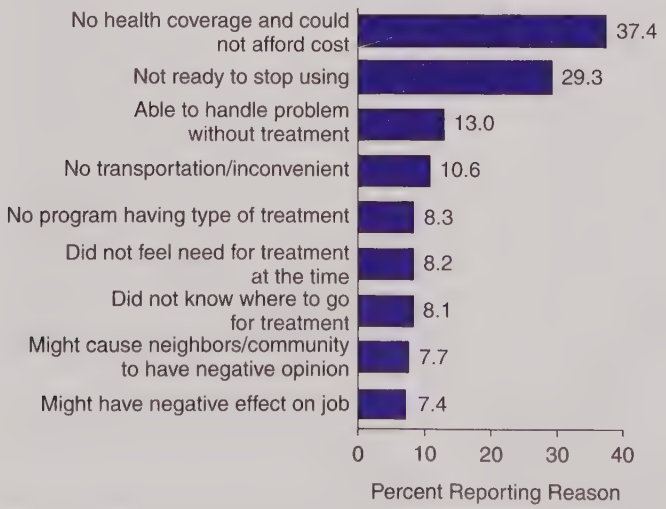

Fig. 37.3 Reasons for not receiving substance use treatment in past year among persons aged 12 or older who needed treatment but did not receive treatment and felt they needed treatment, 2016. (See Table 5.53B at https://www.samhsa.gov.) (From Substance Abuse and Mental Health Services Administration: *Results from the 2016 National Survey on Drug Use and Health: detailed tables,* NSDUH Series H-52, USDHHS Pub. No. SMA 17-5044, Rockville, MD, 2017.)

BOX 37.7 Principles of Drug Addiction Treatment

More than three decades of scientific research have yielded 13 fundamental principles that characterize effective drug abuse treatment. These principles are detailed in the National Institute on Drug Abuse's (NIDA's) *Principles of Drug Addiction Treatment: A Research-Based Guide* (2018c).

1. No single treatment is appropriate for all individuals. Matching treatment settings, interventions, and services to each client's problems and needs is critical.
2. Treatment needs to be readily available. Treatment applicants can be lost if treatment is not immediately available or readily accessible.
3. Effective treatment attends to multiple needs of the individual, not just his or her drug use. Treatment must address the individual's drug use and associated medical, psychological, social, vocational, and legal problems.
4. At different times during treatment, a client may develop a need for medical services, family therapy, vocational rehabilitation, and social and legal services.
5. Remaining in treatment for an adequate period of time is critical for treatment effectiveness. The time depends on an individual's needs. For most clients, the threshold of significant improvement is reached at about 3 months in treatment. Additional treatment can produce further progress. Programs should include strategies to prevent clients from leaving treatment prematurely.
6. Individual and/or group counseling and other behavioral therapies are critical components of effective treatment for addiction. In therapy, clients address motivation, build skills to resist drug use, replace drug-using activities with constructive and rewarding non–drug-using activities, and improve problem-solving abilities. Behavioral therapy also facilitates interpersonal relationships.
7. Medications are an important element of treatment for many clients, especially when combined with counseling and other behavioral therapies. Buprenorphine, methadone, and levo-alpha-acetylmethadol (LAAM) help persons addicted to opiates stabilize their lives and reduce their drug use. Naltrexone is effective for some opiate addicts and some clients with co-occurring alcohol dependence. Nicotine patches or gum, or an oral medication, such as bupropion, can help persons addicted to nicotine.
8. Addicted or drug-abusing individuals with coexisting mental disorders should have both disorders treated in an integrated way.
9. Medical detoxification is only the first stage of addiction treatment and by itself does little to change long-term drug use. Medical detoxification manages the acute physical symptoms of withdrawal. For some individuals it is a precursor to effective drug addiction treatment.
10. Treatment does not need to be voluntary to be effective. Sanctions or enticements in the family, employment setting, or criminal justice system can significantly increase treatment entry, retention, and success.
11. Possible drug use during treatment must be monitored continuously. Monitoring a client's drug and alcohol use during treatment, such as through urinalysis, can help the client withstand urges to use drugs. Such monitoring can also provide early evidence of drug use so that treatment can be adjusted.
12. Treatment programs should provide assessment for human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS), hepatitis B and C, tuberculosis and other infectious diseases, and counseling to help clients modify or change behaviors that place them or others at risk of infection. Counseling can help clients avoid high-risk behavior and help people who are already infected manage their illness.
13. Recovery from drug addiction can be a long-term process and frequently requires multiple episodes of treatment. As with other chronic illnesses, relapses to drug use can occur during or after successful treatment episodes. Participation in self-help support programs during and following treatment often helps maintain abstinence.

Total abstinence is the most recommended treatment goal for ATOD addiction. People who are addicted to a particular drug (e.g., cocaine) are advised to abstain from the use of all psychoactive substances. The use of another drug may simply reinforce the craving for the original drug and cause relapse. More commonly, the addiction merely transfers to the replacement substance.

Treatment may be on an inpatient or outpatient basis. In general, the more advanced the disease is, the greater the need for inpatient treatment. Inpatient treatment programs usually range from less than 1 week to as long as 90 days. Once a person has completed detoxification (considered the first phase of the treatment process), the programs use counseling and group interaction to help the client stay clean long enough for the body chemistry to rebalance. This is often a difficult time for persons recovering from addictions because they may experience mood swings and difficulty sleeping and dealing with emotions.

The goal of the educational part of the programs is to provide information about the disease and how drugs affect a person physically and psychologically. Clients are informed of the various lifestyle changes that are recommended, and they learn about tools to assist them in making these changes. Discharge planning continues throughout treatment as clients build the support systems that they will need when they leave the controlled environment of a treatment center where they will face pressures and temptations (triggers) that may lead to relapse.

Long-term residential programs, also called halfway houses, have been developed to ease the person recovering from an addiction back into society. These facilities provide continued support and counseling in a structured environment for persons needing long-term assistance in adjusting to a drug-free lifestyle. The residents are expected to secure employment and take responsibility in managing their financial obligations.

Outpatient programs are similar in the education and counseling offered, but they allow the clients to live at home and continue to work while undergoing treatment. This method is effective for persons in the earlier stages of addiction who feel confident that they can abstain from drug use and have established a strong support network. Some ways of finding an appropriate treatment program include:

1. Call SAMHSA's National Helpline for treatment referral and information at 1-800-662-HELP (4357). This service is a free, confidential, 24/7, 365 days a year helpline available in both English and Spanish for individuals and families needing help with mental and/or substance use disorders.
2. Look it up on the SAMHSA website. Their Substance Abuse Treatment Facility Locator Internet-based service provides an easy-to-use directory to help you locate (including road maps to each facility) and contact public and private treatment programs (http:/findtreatment.samhsa.gov).

For those addicted individuals unwilling or unable to completely abstain from psychoactive drugs, other medications can assist them in abstaining from their drug of choice. Currently there are three commonly used types of medication-assisted treatment (MAT) for treating opioid addiction: methadone, buprenorphine, and naltrexone. Methadone, when administered in moderate or high daily doses, produces a **cross-tolerance** to other opioids, thereby blocking their effects and decreasing the craving for the drug of choice. The advantages of methadone are that it is long acting, does not produce a "high," and is inexpensive. The oral use of methadone eliminates the danger of the spread of HIV and other bloodborne infections that commonly occur among PWID. Buprenorphine acts similarly to methadone, but is a shorter acting drug. Suboxone is a popular combination drug of buprenorphine and naloxone, preventing most users from being able to abuse it through IV use, as naloxone is poorly absorbed orally, but works well once in the bloodstream to block opioid receptors. Naltrexone is a non-opioid drug that works by inhibiting drug-induced euphoria, thereby reducing drug cravings by tapping into the reward circuit in the brain. It is also used in alcohol use disorder treatment. Although not recognized as a cure for heroin (or other opioid) addiction, MAT maintenance is a harm reduction intervention because it reduces deviant behavior and introduces addicted persons to the health care system (Volkow et al., 2014).

Recovery from addiction involves a lifetime commitment and may include periods of relapse. The addicted person must realize that modern medicine has not found a cure for addiction; therefore returning to drug use may ultimately reactivate the disease process.

EVIDENCE-BASED PRACTICE

Scavone et al. (2013) examined the use of cannabis prior to and during methadone maintenance treatment (MMT) for opioid dependence via a chart review of 91 patients undergoing MMT in Pennsylvania. They found that those opioid addicts with a history of cannabis use reported "significantly less daily expenditure on acquisition of opiates." In addition they found that those who used cannabis during induction had lower ratings of opiate withdrawal symptoms. The researchers concluded that these findings point to novel interventions for the treatment of opioid dependence that specifically target cannabinoid-opioid system interactions. This study supports earlier work by Reiman (2009), who found that many patients in a California cannabis dispensary reported using cannabis to help them get off and stay off of problematic drug use with alcohol, opioids, and other drugs of abuse. There is a marked reduction in prescriptions and dosages of opioids, as well as opioid overdose deaths, in states with medical cannabis programs, especially where dispensaries are permitted (Bachhuber et al., 2014; Liang et al., 2018; Wen et al., 2018). As of July 2018, New York, New Jersey, and Pennsylvania have allowed the use of medical cannabis to treat opioid use disorders.

Nurse Use

With the emerging understanding of the endocannabinoid system and its overall role of maintaining homeostasis, the research supports the healing properties of cannabis as it relieves withdrawal symptoms from dangerous, addictive drugs and helps addicted persons reach stabilization. This is not to say that a person may not have a problem with cannabis, but rather it is important to assess the reasons for drug use and the consequences of that use to determine whether or not the person has a substance use disorder.

Scavone JL, Sterling RC, Weinstein SP, et al.: Impact of cannabis use during stabilization on methadone maintenance treatment. *Am J Addict* 22(4):344-351, 2013.

Smoking Cessation Programs

Nearly 35 million Americans try to quit smoking each year. Fewer than 10 percent of those who try to quit on their own are able to stop for a year, and fewer than one-third of smokers who tried to quit used evidence-based cessation treatment. Interventions that involve medications and behavioral treatments allow individuals to be more successful (USDHHS, 2014). For example, nicotine replacement therapy can be used to help smokers withdraw from nicotine while focusing their efforts on breaking the psychological craving or habit. Five types of nicotine replacement products are available: nicotine gum, lozenges, and skin patches are available over the counter, and nicotine nasal spray and inhalers are available by prescription. These products are about equally effective and can almost double the chances of successfully quitting. Other treatments include smoking cessation clinics, hypnosis, acupuncture, and mobile phone apps/messaging services. The most effective way to get people to stop smoking and prevent relapse involves multiple interventions and continuous reinforcement, and most smokers require several attempts at cessation before they are successful. Many resources are available on smoking cessation programs and support groups, including those listed in Box 37.8. There is a website developed specifically for nurses to help nurses quit smoking: http://www.tobaccofreenurses.org. Smoking cessation efforts have proven to be successful for many—since 2002, the number of former smokers has been greater than the number of current smokers (CDC, 2017d).

LINKING CONTENT TO PRACTICE

Using the tools of primary, secondary, and tertiary prevention with individuals, families, and communities in whom alcohol and other drug use is an issue incorporates both public health and public health nursing guidelines and competencies. Specifically, the core competencies of the Council on Linkages Between Academia and Public Health Practice (2014) begin by identifying the analytic and assessment skills needed by public health professionals. The 12 skills in this competency category are used in providing services to the population described in this chapter. For example, you begin by assessing the "health status of populations and their related determinants of health and stress." You next move to skill #2, which is describing the "characteristics of a population-based health problem." These competencies are described through a set of eight domains. Each domain can be used with populations dealing with alcohol and other drug problems.

Similarly, the Intervention Wheel, which is the subject of Chapter 11, has many applications with this population. Many of these interventions have application with the populations described in this chapter. For example, case finding, referral and follow-up, health teaching, counseling, and policy development and enforcement are selected examples of ways in which public health nurses intervene in serving a vulnerable population with alcohol- and drug-related problems.

Support Groups

The founding of Alcoholics Anonymous (AA) in 1935 began a strong movement of peer support to treat a chronic illness. AA groups have developed around the world. Their success has led to the development of other support groups such as the following:

- Narcotics Anonymous (NA) for persons with narcotic addiction
- Pills Anonymous for persons with polydrug addictions
- Overeaters Anonymous
- Gamblers Anonymous

AA and NA help addicted people develop a daily program of recovery and reinforce the recovery process. The fellowship, support, and encouragement among members provide a vital social network for the person recovering from an addiction.

Al-Anon and Alateen are similar self-help programs for spouses, parents, children, or others involved in a painful relationship with an alcoholic. Nar-Anon is a support group for those in relationships with persons with narcotic addictions. Al-Anon family groups are available to anyone who has been affected by their involvement with an alcoholic person. The

purposes of Alateen include providing a forum for adolescents to discuss family stressors, learn coping skills from one another, and gain support and encouragement from knowledgeable peers. Adult Children of Alcoholics (ACA) groups are also available in most areas to address the recovery of adults who grew up in alcohol use disorder homes and are still carrying the scars and retaining dysfunctional behaviors.

For some persons, the AA program places too much emphasis on a higher power or focuses too much on the negative consequences of past drinking. Women for Sobriety focuses on rebuilding self-esteem, and this is often a core issue for many women with alcohol problems. (See www.womenforsobriety.org for additional information.) Rational Recovery has a cognitive orientation and is based on the assumption that ATOD addiction is caused by irrational beliefs that can be understood and overcome. See www.rational.org for additional information on this approach.

Nurse's Role

Many people with alcohol and drug addiction become lost in the health care system. If satisfactory care is not provided in one agency or the waiting list is months long, the person may give up rather than seek alternative sources of care. The nurse who knows the client's history, environment, support systems, and the local treatment programs can offer guidance to the most effective treatment modality. Brief interventions by health care professionals who are not treatment experts can be effective in helping people who abuse ATOD and addicted persons change their risky behavior. **Brief interventions** may convince these individuals to reduce substance consumption or follow through with a treatment referral. Box 37.9 describes six elements commonly included in brief interventions, using the acronym FRAMES. Strategies used with clients can vary depending on their readiness for change. Understanding the stages of change listed in Box 37.10 and recognizing which stage a client is in are important factors for determining which interventions and programs may be most helpful to the client.

After the client has received treatment, the nurse can coordinate aftercare referrals and follow up on the client's progress. The nurse can provide additional support in the home as the client and family adjust to changing roles and the stress involved with such changes. The nurse can support addicted persons who have relapsed by reminding them that relapses may well occur, but that they and their families can continue to work toward recovery and an improved quality of life.

BOX 37.9 Brief Interventions Using the FRAMES Acronym

Feedback. Provide the client direct feedback about the potential or actual personal risk or impairment related to drug use.
Responsibility. Emphasize personal responsibility for change.
Advice. Provide clear advice to change risky behavior.
Menu. Provide a menu of options or choices for changing behavior.
Empathy. Provide a warm, reflective, empathetic, and understanding approach.
Self-efficacy. Provide encouragement and belief in the client's ability to change.

From Center for Substance Abuse Treatment: *Brief interventions and brief therapies for substance abuse,* TIP 34, DHHS Pub. No. (SMA) 99-3353, Rockville, MD, 1999, USDHHS.

BOX 37.10 Stages of Change

Pre-Contemplation
At this stage, the person does not intend to change in the foreseeable future. The person is often unaware of any problem. Resistance to recognizing or modifying a problem is the hallmark of pre-contemplation.

Contemplation
At this stage, the individual is aware that a problem exists and is seriously thinking about overcoming it but has not yet made a commitment to take action. The nurse can encourage the individual to weigh the pros and cons of both the problem and the solution to the problem.

Preparation
Preparation was originally referred to as *decision making.* At this stage, the individual is prepared for action and may reduce the problem behavior but has not yet taken effective action (e.g., reduces amount of smoking but does not abstain).

Action
At this stage, the individual modifies the behavior, experiences, or environment to overcome the problem. The action requires considerable time and energy. Modification of the target behavior to an acceptable criterion and significant overt efforts to change are the hallmarks of action.

Maintenance
In this stage, the individual works to prevent relapse and consolidate the gains attained during action. Stabilizing behavior change and avoiding relapse are the hallmarks of maintenance.

Modified from DiClemente CC, Schlundt D, Gemmell L: Readiness and stages of change in addiction treatment. *Am J Addict* 13(2): 103-119, 2004.

OUTCOMES

Health promotion and risk reduction are basic concepts in nursing. Promoting a healthy environment in the home and local community provides individuals and families a nurturing environment in which to achieve optimal health. Individuals with high self-esteem and access to health care and information about the health risks related to drug use can be responsible for their personal health and make informed decisions about drug use. Nurses can assess the health of the community and its citizens, prioritize the needs, and identify local resources to collaborate with others to develop strategies that will improve the underlying health of the community.

Early identification and intervention for persons with ATOD problems can prevent many of the harmful physical, emotional, and social consequences that may occur if abuse continues and may also prevent abuse patterns from developing into addiction. The nurse needs to assess individual and community ATOD problems and target at-risk groups to develop strategies to increase assessment and provide appropriate interventions. Review the national health objectives (refer back to the *Healthy*

People 2020 box) for the tobacco and substance abuse areas and note how many can be achieved with secondary prevention strategies.

Besides saving taxpayers' money, treatment helps addicted individuals and their families recover from the devastating effects of addiction. Addicted persons and their families often become hopeless and helpless. The nurse can offer hope in affirming the addicted person's self-worth and can be the bridge to community resources to assist in treatment and recovery.

Many of these expected outcomes for ATOD problems have been lessened because a lack of funding has resulted from federal strategies that focus on law enforcement and punishment rather than on education and treatment. The greatest challenge for nurses is to influence policy makers to put the emphasis on health care for this major health problem.

PRACTICE APPLICATION

Ann Greene is a 25-year-old mother of two. Ann lives in an urban impoverished, low-income housing area where resources are limited and crime is a daily concern. Ann is a widow and has two sons, ages three and five. Her husband, who had an alcohol use disorder, was killed while driving under the influence of alcohol. Ann, who was a passenger in the accident, suffered a neck injury at the time, leaving her in severe pain. She left the hospital with a prescription for oxycodone, which she took as directed. However, as her tolerance increased, she found the prescribed amount did not sufficiently manage her pain anymore. She began to take more than the prescribed amount to adequately manage her pain, and when she returned to the emergency department to ask for a refill, she was denied and accused of being drug seeking. When she told her sister, Elise, about this, Elise offered Ann the rest of her Percocet prescription from when she had broken her ankle. At this point, Ann was taking twice as much twice as often to control the pain. She soon began buying painkillers from someone introduced to her by a friend of a friend.

During this time, Ann continued to work full time as a night-shift security guard at a factory in town, but her income could not support her obligations as a single mother in addition to her increasing demand for pills. Eventually, she found herself supplementing by smoking heroin she would get from her upstairs neighbor to take the edge off. This soon progressed to IV use. At this point, her friends and family started to notice changes in Ann's behavior. She would ask them to watch her kids but return much later than she had said she would. Her kids started to tell Elise that Ann was sleeping all the time. She would have inexplicable reasons for being unable to meet responsibilities and would leave for long periods of time to meet vague obligations.

Elise, suspecting Ann's behavior changes might be related to opioid use, confronted her about it. Ann denied it at first, but eventually confessed to letting her drug use get a little out of hand. When Elise tried to convince her to seek treatment, Ann was unwilling to go. Elise goes in to talk to a public health nurse at her local public health department to get advice on how to deal with this problem.

A. What interventions should the nurse provide for Elise?

B. What harm reduction interventions can the nurse offer Ann, knowing that she is unwilling to seek treatment at this time?

C. Knowing that there is a genetic link to addiction and being aware of the high rate of drug problems in their environment, how can the nurse help prevent Ann's children from developing substance abuse problems?

D. What are some things the prescriber should have considered before sending Ann home with a strong opioid prescription?

Answers can be found on the Evolve site.

KEY POINTS

- Substance abuse is the number one national health problem, linked to numerous forms of morbidity and mortality.
- Harm reduction is an approach to ATOD problems that deals with substance abuse primarily as a health problem rather than as a criminal problem.
- All persons have ideas, opinions, and attitudes about the use of drugs that influence their actions.
- Social conditions such as a fast-paced life, excessive stress, and the availability of drugs influence the incidence of substance use disorders.
- Important terms to understand when working with individuals, groups, or communities for whom substance abuse is prevalent are *drug dependence, drug addiction, alcoholism, psychoactive drugs, depressants, stimulants, cannabis, hallucinogens,* and *inhalants.*
- Primary prevention for substance use disorders includes education about drugs and guidelines for use, as well as the promotion of healthy alternatives to drug use either for recreation or to relieve stress.
- Nurses can help develop community prevention programs.
- Secondary prevention depends heavily on careful assessment of the client's use of drugs. Such assessment should be part of all basic health assessments.
- High-risk groups include pregnant women, young people, older adults, intravenous drug users, and illicit drug users.
- Drug addiction is often a family, not merely an individual, problem.
- Codependency describes a companion illness to the addiction of one person in which the codependent member is addicted to the addicted person.
- Brief interventions by a nurse can be as effective as treatment.
- Nurses are in ideal roles to assist with tertiary prevention for both the addicted person and the family.

CLINICAL DECISION-MAKING ACTIVITIES

1. Read your local newspaper or online news for four days and select stories that illustrate the effects of substance abuse on individuals, families, and the community. What interventions would you use? Who would you involve in your work? Are the interventions primary, secondary, or tertiary in nature? How would you evaluate your work?
2. For each of the stories in the news related to substance abuse, describe preventive strategies that a nurse might have tried before the problem reached such a dire state.
3. Looking at your local community resources directory or the Internet, identify agencies that might serve as referral sources for individuals or families for whom substance abuse is a problem.
4. Review popular magazine, television, and/or social media advertisements for alcohol, tobacco, cannabis, and other medicines (e.g., sleep aids, analgesics, laxatives, stimulants). In small groups, discuss the messages conveyed in the advertisements, and discuss the implications of client education to reduce possible harm from misuse and abuse of these substances.
5. Attend an open AA or NA meeting and an Al-Anon meeting. Go alone if possible or with an alcohol- or drug-addicted friend. As the members introduce themselves, give your first name and state, "I am a visitor." Plan to listen and do not attempt to take notes. Respect the anonymity of the persons present. Write a statement about your experience and what you learned from others at the meeting.
6. In groups of four or five, review the national health objectives in *Healthy People 2020* (see www.healthypeople.gov) under Tobacco Use and under Substance Abuse. Pick an objective from each section and brainstorm about possible community efforts a nurse could initiate to reach that objective.

Violence and Human Abuse

Jeanne L. Alhusen, PhD, CRNP, RN, FAAN, Gerard M. Jellig, EdD, and Jacquelyn C. Campbell, PhD, RN, FAAN

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Discuss the scope of the problem of violence in American communities.
2. Examine at least three factors existing in most communities that influence violence and human abuse.
3. Define the four general types of child abuse: neglect, physical, emotional, and sexual.
4. Discuss elder abuse as a crucial community health problem.
5. Discuss the principles of nursing intervention with violent families.
6. Describe specific nursing interventions with women experiencing intimate partner violence.

Violence is a serious problem in the United States. It is a leading cause of death and disability that disproportionately affects youth, low-income populations, and people of color. An estimated 65,000 individuals die each year in the United States as a result of violence-related injuries. While homicide rates have decreased over the last 20 years, homicide is the third leading cause of death for individuals 15 to 34 years of age, and the fourth leading cause of death for individuals 1 to 14 years of age (Centers for Disease Control and Prevention [CDC], 2016). Intimate partner homicide accounts for a substantial proportion of female homicide victimization. The Centers for Disease Control and Prevention (CDC) examined homicides from 18 states from 2003 to 2014 and found that over half (55.3 percent) of the homicides committed against women involved an intimate partner (Petrosky et al., 2017). Suicide is one of the top 10 leading causes of death in the United States, and the rate in the United States trended upward from 1999 through 2014. During this time period, increases in suicide rates occurred for both males and females in every age group but the oldest age group (aged 75 and older). The largest rate increases were noted among females aged 10 to 14 and males aged 45 to 64 (Curtin et al., 2016). These statistics do not account for the significant morbidity associated with interpersonal violence. For every person who dies as a result of violence, many more are injured and suffer lasting physical, sexual, and mental health sequelae. As the World Health Organization has reported, when

interpersonal violence results in large numbers of deaths, the issue is a significant public health concern necessitating attention from researchers, policy makers, health care providers, and the public (Krug et al., 2002).

Violence is an important public health nursing issue. Violence leads to significant mortality and morbidity. Communities across the United States are concerned about crime and violence rates. Medical, nursing, psychology, and social service professionals have been slow to develop an integrated response to violence that is part of their daily professional lives. As a result, the estimated 3.5 million victims of violence annually may not receive the best care possible. Nurses are in a unique position to develop community responses to violence, to influence public policy regarding violence, and to provide individuals, families, and communities with the necessary resources to mitigate violence and its consequences. Nurses represent a large group of health care providers who have an ethic of caring and value early intervention and health promotion. This can optimize individual, familial, community, and societal health outcomes.

This chapter examines violence as a public health problem and discusses how nurses can help individuals, families, groups, and communities cope with and reduce violence and abuse. Nurses work with clients in a wide variety of settings, including the home. Because nurses are in key positions to detect and intervene in community and family violence, an understanding of how community-level influences can affect all types of violence is necessary. The *Healthy People 2020* box as follows lists five objectives for reducing violence in communities.

HEALTHY PEOPLE 2020

Objectives for Reducing Violence

- **IVP-29:** Reduce homicides.
- **IVP-35:** Reduce bullying among adolescents.
- **IVP-37:** Reduce child maltreatment deaths.
- **IVP-39:** Reduce violence by current or former intimate partners.
- **IVP-40:** Reduce sexual violence.

U.S. Department of Health and Human Services (USDHHS): *Healthy People 2020: objectives,* Washington, DC, 2010, Office of Disease Prevention and Health Promotion, USDHHS.

SOCIAL AND COMMUNITY FACTORS INFLUENCING VIOLENCE

The ultimate goal is to stop violence before it begins. Identifying the factors that protect individuals or place them at a higher risk for experiencing or perpetrating violence can help focus prevention efforts. The Centers for Disease Control and Prevention uses a four-level social-ecological model to better understand violence and the complex interplay between individual, relationship, community, and societal factors. At each level, there are varied factors that increase one's risk for violence or protect an individual from experiencing or perpetrating violence. However, just as the presence of risk factors does not guarantee that an individual will experience violence, the presence of protective factors does not eliminate one's risk of violence. The overlapping rings within the model illustrate how factors at one level may influence risk and protective factors at another level (Fig. 38.1). The following section includes a discussion of selected factors that may influence violence. The Linking Content to Practice box discusses how public health nurses can collaborate in the community to prevent violence.

LINKING CONTENT TO PRACTICE

According to the Quad Council Domains of Public Health Nursing Practice (Swider et al., 2013) and the American Public Health Association (2017), public health nurses must collaborate in partnership with communities to identify and assess community needs; plan, implement, and evaluate community-based programs; and assist in the setting of policy that will contribute to the needs of the community in relationship to all types of interpersonal violence. The Quad Council competencies in the analytic assessment domain direct nurses to conduct thorough health assessments of individuals, families, communities, and populations and to develop diagnoses for the population being assessed (Swider et al., 2013). Public health nurses can help the community in many ways, as is described throughout this chapter.

Individual

The first level of the social-ecological model identifies biological and personal history factors that may increase the likelihood of an individual becoming a victim or perpetrator of violence. Demographic characteristics such as age, socioeconomic status, employment status, and educational attainment are associated with violence risk. Research also supports witnessing interparental violence, and a history of child maltreatment as risk factors for violence. Mental health disorders, including depression, anxiety, and post-traumatic stress disorder, as well as substance use disorders, are positively related to violence perpetration (Giancola, 2015; Harford et al., 2018; Jolliffe et al., 2016; Van Dorn et al., 2012).

Relationship

The second level of the social-ecological model explores how close social relationships, including relationships with peers, intimate partners, and family members, increase one's risk for violent victimization and perpetration of violence. In the cases of partner violence and child maltreatment, for example, frequent interactions or sharing a home with an abuser may increase the opportunity for violent encounters. With regard to violence among youths, research demonstrates that adolescents are significantly more likely to engage in negative activities when peers accept these behaviors (Garthe et al., 2017). Peer-based social networks are significantly related to both healthy and violent relationships. Specific to youth violence, research has demonstrated that low hyperactivity, low parental stress, strong parental supervision, positive attitude to school, and quality housing are risk-based protective factors (Jolliffe et al., 2016). Peers, intimate partners, and family members are all key influences on an individual's behavior and potential exposure to violence.

Fig. 38.1 The social-ecological model: a framework for violence prevention. (Modified from Heise LL: Violence against women: an integrated, ecological framework. *Violence Against Women* 4:262-290, 1998.)

Community

The third level of the social-ecological model examines how community contexts (e.g., schools, places of employment, neighborhoods) are associated with being victims or perpetrators of violence. With regard to neighborhoods, a high level of residential mobility, low level of neighborhood cohesion, and high population density are associated with higher levels of violence (Beyer et al., 2015). Communities with higher levels of drug trafficking or widespread social isolation are also more likely to experience violence. Community- or neighborhood-level indicators most frequently associated with violence are related to community socioeconomics such as unemployment rate, per capita income, and poverty rate. However, this also means that community protective factors may reduce one's risk of experiencing violence. Factors that increase peoples' and communities' resilience to violence include:

- Coordination of resources and support services among community agencies
- Access to mental health and substance abuse treatment services
- Support and connectedness, including connectedness to one's community, family, pro-social peers, and school

Schools are important settings for positively influencing our youth. Schools serve as a central community place of socialization, and while they can be safe havens for some youth, they can be stressful places for others. Using a nationally representative sample from 2015, 22.6 percent of youth in high school reported being involved in a physical fight over the previous year and 16.2 percent reported carrying a weapon at least once in the prior month (Centers for Disease Control and Prevention, 2016). Youth living in urban areas, particularly ethnic minority youth, are at a heightened risk for experiencing violence (McMahon et al., 2013). The importance of school climate (e.g., safety, relationships, teaching and learning practices, institutional environment) has been well established in the literature with a recent meta-analysis of 13 longitudinal studies of 5th-12th grade students demonstrating a significant relation between perceived school climate and student problem behaviors across time (Reaves et al., 2018). Thus schools represent an opportune vehicle to effect social change.

Societal

The fourth and final level of the ecological model examines the broader societal factors that influence rates of violence. These include factors that contribute to a culture that accepts violence, those that reduce inhibitions against violence, and those that both create and perpetuate disparities between different segments of society. Broader societal factors may include but are not limited to:

- Cultural norms that support violence as an acceptable means for resolving conflict
- Societal attitudes that regard suicide as an individual's choice instead of a preventable act of violence

- Cultural norms that support male dominance over women and children
- Educational, economic, and social policies that foster high levels of inequality between its citizens
- Norms that support political conflict

VIOLENCE AGAINST INDIVIDUALS OR ONESELF

The potential for violence against individuals (e.g., murder, robbery, rape, assault) or oneself (e.g., suicide) is directly related to the level of violence in the community. Persons living in areas with high rates of crime and violence are more likely to become victims than those in more peaceful areas. The major categories of violence addressed in this chapter are described in terms of the scope of the problem in the United States and underlying dynamics.

Homicide

Homicide is defined as a death resulting from the use of force against another person when a preponderance of evidence indicates that the use of force was intentional (Parks et al., 2014). Age-specific homicide rates are highest (11.7 deaths per 100,000 population) among those aged 20 to 24 years, followed by those aged 25 to 29 years (10.7 deaths per 100,000 population). Importantly, the homicide rate for males is nearly four times that of females (7.7 and 2.1 per 100,000, respectively). Non-Hispanic African Americans account for nearly half (49.6 percent) of homicide deaths and have the highest rate (15.2 deaths per 100,000 population), followed by American Indians/Alaska Natives (10.0) and Hispanics (5.1) (Parks et al., 2014). Rates of homicide for infants under the age of one year were highest among non-Hispanic African Americans and American Indians/Alaska Natives (Parks et al., 2014). Parents perpetuate the majority of homicides of children. Strangers cause 15 percent of male and 9 percent of female homicides in the United States (Catalano et al., 2009). When strangers are involved, many of these homicides are related to the illegal substance abuse network. The majority of homicides are perpetrated by a friend, acquaintance, or family member. Therefore prevention of homicide is at least as much an issue for the public health system as for the criminal justice system.

Firearm violence is a major public health issue in the United States, a country with the highest levels of firearm homicide incidences compared to other high-income countries (Richardson & Hemenway, 2011). In 2015, 72.9 percent of homicides were firearm homicides and, about 90 percent were committed with a handgun (CDC, 2016). Multiple studies have demonstrated a significant relationship between higher gun ownership at the state level and higher overall state-specific rates of firearm homicide (Fleegler et al., 2013; Siegel et al., 2013). Research has recently demonstrated that a higher proportion of household gun ownership at the state level is associated with statistically significant increased rates of nonstranger total firearm homicides. By contrast, there was not a statistically significant relationship between household gun ownership and stranger homicides, challenging the argument that gun ownership deters violent crime, particularly homicides (Siegel et al., 2014). Importantly, the number of nonfatal firearm injuries is more than double the number of deaths (CDC, 2017). While much attention has been given to the mass shootings that have occurred in the United States recently, the 88 deaths per day due to firearm-related homicides, suicides, and unintentional deaths highlight the magnitude of the issue (Hoyert & Xu, 2012).

In 2015, about 55 percent of homicides of women and 6 percent of homicides of men were committed by intimate partners, and about 55 percent of all intimate partner homicides were committed with guns (U.S. Department of Justice, 2015). Across studies, major risk factors for intimate partner homicide include previous violence, unemployment, access to firearms, estrangement, threats to kill, threats with a weapon, and a stepchild in the home (if the victim is female) (Campbell et al., 2000, 2003; Smith et al., 2014). Importantly, the risk of intimate partner homicide increases by 500 percent when a violent intimate partner has access to a firearm (Campbell et al., 2003). Many victims of intimate partner homicide are parents, and due to the nature of intimate partner homicide, which often occurs in the home, children are frequent witnesses (Lewandowski et al., 2004). Not only has one parent died; the other parent is incarcerated, has fled, or has committed suicide (Steeves & Parker, 2007). These children are confronted with significant trauma, loss, and hardship and require critical support systems.

Homicide is the leading cause of death for pregnant and postpartum women, and research has shown an overall pregnancy-associated violent death mortality rate of 4.9 per 100,000 births. Nearly two-thirds of pregnancy-associated violent deaths occur during pregnancy with the remaining occurring in the first year post partum (Palladino et al., 2011). Indeed, pregnancy-associated homicide and suicide each account for more maternal deaths than many other obstetric complications, commonly thought of as more "traditional" causes of maternal mortality. Nurses working in perinatal care environments are uniquely positioned to screen for intimate partner violence (IPV) and provide the necessary supports and referrals for those women screening positive.

Assault

The death toll from violence is staggering, yet the physical injuries and emotional costs of **assault** are equally important issues in terms of the acute health care system. Twenty-two percent of females compared with 7.4 percent of males reported injury related to physical assault. Age is the greatest risk factor for an individual's victimization through violence, and youths are at significantly higher risk. Although more males than females are victims of homicide and assault, women are more likely to be victimized by a relative, especially a male partner (Catalano et al., 2009). In some instances the response time of emergency services and the quality of treatment facilities determine whether an assault will end as a homicide. The same community measures used to address homicide are useful to combat assault. Also, nurses often care for the long-term health problems associated with assaults such as head injuries, spinal cord injuries, and stomas from abdominal gunshot wounds in a

home health care setting. In addition to providing physical care, nurses must also address the emotional trauma resulting from a violent attack by helping victims talk through their traumatic experience to try to make some sense of the violence, and by referring them for further counseling if anxiety, sleeping problems, or depression persists after the assault.

Rape

In the United States, an estimated 19.3 percent of women and 1.7 percent of men have been raped in their lifetimes (Breiding et al., 2014). The lifetime and 12-month prevalence of **rape** by an intimate partner for women was an estimated 8.8 percent and 0.8 percent, respectively. Among female victims of rape, an estimated 78.7 percent experienced this form of sexual violence before 25 years of age, and an estimated 40.4 percent before the age of 18 (Breiding et al., 2014). From 1995 to 2005, the rate of completed rape or sexual assault declined from 3.6 per 1000 females to 1.1 per 1000 females. The rate of sexual violence against females declined with age. In 2005-2010, sexual violence was committed against females aged 12 to 34 at a rate of about 4 victimizations per 1000, compared to a rate of 1.5 victimizations per 1000 for females aged 35 to 64 and 0.2 per 1000 for females age 65 or older. For all racial and ethnic groups, the rate of sexual violence was lower in 2005-2010 than it was in 1994-1998 (Planty et al., 2013). Based on data from the Bureau of Justice Statistics' National Crime Victimization Survey (NCVS), non-Hispanic white females and African American and Hispanic females had a similar rate of sexual violence over time. However, Hispanic females (1.4 per 1000) had lower rates of sexual violence than African American females (2.8 per 1000) in 2005-2010. While American Indians and Alaska Natives (4.5 per 1000) appeared to experience rape or sexual assault victimization at higher rates than females in other racial and ethnic groups, the NCVS cautions that rates are based on small sample sizes and thus should be interpreted with caution (Planty et al., 2013). From 1995 to 2010, about nine percent of all rape or sexual assault victimizations involved male victims. In 2010, the rate of rape or sexual assaults was 0.1 per 1000 for males as compared to a rate of 2.1 per 1000 for females. In 2005-2010, most rape or sexual assault victims (78 percent) knew the perpetrator, and about one-third of all rapes or sexual assaults were committed by an intimate partner (Planty et al., 2013). Because the majority of violence against women is IPV and women are raped more often by someone they know rather than by strangers, health care providers must be alert for date and marital rape. An estimated 65 percent of rapes in the United States between 2006 and 2010 went unreported to law enforcement, making rape the most underreported violent crime in the country (Langton et al., 2012).

College women are at particularly high risk for sexual victimization in the United States; an estimated 20 to 25 percent of college-aged females experience attempted rape or completed rape during their college career, yet these rates of victimization vary from campus to campus (Moynihan et al., 2011). A recent study demonstrated that female undergraduate students were more likely to be victimized than graduate students, and the vast majority of students who experienced sexual violence were victimized when they were incapacitated due to intoxication or asleep (Campbell et al., 2017). Data from the Bureau of Justice Statistics demonstrate that despite arrest rates for sexual assault remaining stable, twice as many women reported a sexual assault by an intimate partner in 2010 as compared with 1994 (Catalano, 2013). The health impact of sexual assault is highly significant. Health issues include high-risk sexual behavior, substance abuse, unintended pregnancy, depression, **post-traumatic stress disorder** (PTSD), suicidal ideation, and eating disorders (Silverman et al., 2001). Nurses are well positioned to provide victims with comprehensive care, including mental health services. Nurses can identify and refer clients who have experienced sexual assault. Advanced practice nurses are often providers of primary health care on college campuses, placing them in a unique position to educate and support students on the issue of dating violence.

Another form of rape is forced sexual initiations, with as many as 21 percent of young women in the United States whose first sexual experience is below the age of 14 reporting that this initiation was physically forced, usually by a date or boyfriend (Stockman et al., 2010). These early sexual experiences are associated with unplanned, adolescent pregnancies as well as human immunodeficiency virus (HIV)/**sexually transmitted disease** (STD) risk behaviors.

Prevention of rape, like that of other forms of human abuse, requires a broad-based community focus for educating both the community as a whole and key groups such as police, health providers, educators, and social workers. Rape rates and community-level variables such as community approval and legitimization of violence (e.g., violent network television viewing and permitting corporal punishment in schools) appear related and underscore the need for community-level intervention (Casey & Lindhorst, 2009).

Human Trafficking

Human trafficking is a significant public health issue globally, including in the United States. Human trafficking is an umbrella term that includes activities involved in recruiting, harboring, transporting or providing an individual for forced service or commercial sex acts through the use of force, deception or coercion (United Nations Office on Drugs and Crime, 2019). Due to the secretive nature of human trafficking, accurate prevalence estimates are difficult to obtain yet an estimated 50,000 women and children may be trafficked into the United States each year (Siskin & Sun, 2013). Human trafficking is the fastest growing and one of the most lucrative crimes in the United States, thus it is imperative that nurses and other health care professionals are trained in the identification, care, and supports needed for these individuals (United Nations Office on Drugs and Crime, 2019).

Human trafficking affects all races, ages, and genders; yet, women and children under the age of 18 are at heightened risk (United Nations Office on Drugs and Crime, 2019). Children are often targeted due to their earning potential, with runaway and homeless youth at greatest risk (United Nations Office on Drugs and Crime, 2019). The majority of individuals experiencing human trafficking in the United States are women or

girls, and the majority of these individuals are forced into the sex service industry (United Nations Office on Drugs and Crime, 2019).

Most trafficked individuals will come in contact with a health care provider, often through the emergency department setting, for treatment of an illness or injury at some point during their captivity. Yet, they are seldom appropriately identified as victims of trafficking (Peters, 2013). Victims are not likely to identify themselves as such for a number of reasons including fear of captor, distrust of available support systems (e.g., medical, legal, social services), uncertainty about available supports, unfamiliarity with regional language or culture, or feelings of shame about their situation (Becker & Bechtel, 2015).

Victims of human trafficking will often present to the health care system accompanied by their trafficker who may identify themselves as a family member or trusted support person. The trafficker may be male or female, and may appear to be supportive, caring, and sympathetic to the individual (Becker & Bechtel, 2015). Thus identifying trafficked individuals may be difficulty but there are "red flags" in their presentation that can be useful. A "family member" or "friend" who doesn't allow the individual to answer the health care provider's questions or consistently answers for them should raise suspicion. The individual may appear to be reluctant in describing symptoms or the events leading up to the presenting complaint; they may be vague in their responses or report inconsistencies in their responses. Individuals may not be able to provide a home address, have no identification documents, and may be unaware of the city or state in which they are receiving services.

The signs and symptoms of trafficking are multifaceted, and may occur in isolation or in combination. Physical symptoms may include, but are not limited to, unexplained bruises, burns, lacerations, bite marks, vaginal or anal tearing, sexually transmitted infections, unintended pregnancy, nutritional deficits, and substance use disorder (De Chesnay, 2013; Isaac et al., 2011; Richards, 2014). With regards to mental health issues, victims of human trafficking are at increased risk for depression, posttraumatic stress disorder, suicidal ideation or suicide attempts (Richards, 2014).

Caring for a potential victim of human trafficking requires a trauma-informed, empowering, nonjudgmental manner. The goal of the interaction should be to create a safe space and empowerment. It is critical that the health care provider can interview the patient alone thereby facilitating disclosure. Explaining that it is routine practice in a particular health care setting to interview patients alone may decrease suspicion in the captor. However, if it is difficult to obtain a one-on-one interview, it can be helpful to accompany the patient to a restroom or to a private setting for a particular reason, such as the laboratory or x-ray. If the victim does not speak English, it is critical to use a professional interpreter to assure accuracy in the assessment.

There are no validated screening questions for human trafficking, yet there are a number of questions that have been useful for health care providers to ask. These include:

- Can you come and go from your home (or job) whenever you please?
- Has anyone at home or work ever physically harmed you?
- Have you been threatened for trying to leave your job?
- Is anyone forcing you to do things you do not want to do?
- Do you have to ask permission to eat, sleep, or use the bathroom?
- Are there locks on your doors and windows that keep you from leaving?
- Have you ever been denied food, water, sleep, or medical care?
- Has anyone ever threatened your family?
- Has anyone taken away your identification papers or cards? (Crane, 2013)

If the health care provider suspects that a patient is a victim of human trafficking, it is essential to engage the assistance of a social worker or victim advocate early in the patient's care. For patients under the age of 18, a call to the state's child protective services agency is necessary. If the health care provider feels that the patient is in immediate danger, law enforcement should be contacted. If the patient isn't believed to be in immediate danger, the health care provider should notify the patient prior to engaging law enforcement on their behalf. Involving the patient may improve trust, and facilitate disclosure by the victim.

There are a number of resources available for providing care to victims of human trafficking. The National Human Trafficking Resource Center hot line (1-888-373-7888) is available to anyone with a suspicion of trafficking. It is toll free, available 24 hours/day and available in 180 languages. The Center can provide guidance on interview questions as well as indicators of potential trafficking. Importantly, it can provide access to safety resources including shelters, as well as other critical safety resources. Another helpful resource is https://polarisproject.org. This site includes an interactive map of the United States with updated listings of local organizations and resources for victims, as well as state laws regarding human trafficking.

Human trafficking is a significant issue in the United States. The physical and mental health sequelae for victims of trafficking is significant and sustained. It is critical that health care providers recognize the warning signs, acknowledging that engagement with the health care system may be one of the few opportunities for victims to escape their situations. An understanding of this issue, and supports available is key to saving lives.

Attitudes. The first priority is to change attitudes about rape and about victims or survivors. Rape is a crime of violence, not a crime of passion. The underlying issues are hostility, power, and control rather than sexual desire. The defining issue is lack of consent of the victim. When a woman or man refuses any sexual activity, that refusal means "no." People have the right to change their mind, even when they seemed initially agreeable. Pressure from physical contact, threats, or deliberate inducement of drug or alcohol intoxication is a violation of the law. The myths that women say "no" to sex when they really mean "yes" and that the victims of rape are culpable because of the way they dress or act must end.

Pornography. Although there is evidence of a relationship between the viewing of pornographic material showing violence

against women and aggressive sexual behavior, it is not clear if the relationship is causal. In other words, our current research does not yet show that viewing pornography occurs before sexual aggressiveness or that young men who are sexually violent tend to watch pornography. The current research tends to minimize the relationship between sexual assault and pornography (Ferguson & Hartley, 2009). However, there is some evidence that claims that early exposure to pornography as a child may be related to sexual offense in the future (Seto & Lalumière, 2010). Prevention programs, or more accurately labeled risk reduction or avoidance programs, also involve providing information to women about self-protection, including using self-defense procedures, avoiding high-risk locations, and safeguarding one's home against unwanted entry. Most rape prevention programs have been oriented toward women. However, men are increasingly becoming involved in rape prevention education via anti-rape websites (Masters, 2010). Many of these websites are community-based programs that promote education about violence against women and promote a positive male role model of gender equity. They often depict examples of consensual and nonconsensual sexual behaviors.

Victim or Survivor? During the act of rape, survivors are often hit, kicked, stabbed, and severely beaten. It is this violence that is most traumatic because of the survivors' fear for their lives, helplessness, lack of control, and vulnerability.

People react to rape differently, depending on their personality, past experiences, background, and support received after the trauma. Some cry, shout, or discuss the experience. Others withdraw and fear discussing the attack. During the immediate as well as the follow-up stages, victims tend to blame themselves for what happened. When working with rape victims, help them identify the issues behind self-blame. While not placing fault on survivors, teach them to take control, learn assertiveness, and therefore believe that they can take certain actions to prevent future rapes. Survivors need to talk about what happened and to express their feelings and fears in a nonjudgmental atmosphere. Survivors of drug- or alcohol-facilitated/incapacitated (DAFR/IR) rape are substantially less likely to seek health care, rape crisis, or law enforcement services compared with survivors of forcible rape. Recent research suggests that women with forced rape were nearly three times more likely than women with DAFR/IR-only to report seeking support services (Walsh et al., 2016). Public service campaigns designed to increase awareness that DAFR/IR constitutes rape, even if force is not present, may help reduce evident disparities in rape-related service seeking (Walsh et al., 2016).

In any psychological trauma, victims should be given privacy, respect, and assurance of confidentiality. They should also be told about health care procedures conducted immediately after the rape and should be linked with proper resources for ease of reporting the crime. Nurses often provide continuous care once the victim enters the health care system. Because many victims deny the event once the initial crisis is past, a single-session debriefing should be completed during the initial examination. Specially trained providers should perform the physical assessment, examination, and debriefing.

As discussed in Chapter 44, in most states, nurses trained as sexual assault nurse examiners (SANEs), a subspecialty of forensic nursing, perform the physical examination in the emergency department to gather evidence (e.g., hair samples, skin fragments beneath the victim's fingernails, evidence from pelvic examinations obtained by colposcopy) for criminal prosecution of sexual assault (Sheridan, 2004). This is an important nursing intervention because physicians may not be able to take the time required for this procedure; nurses can take advantage of this opportunity to provide therapeutic communication and support. Nurses can be trained to conduct the examination either in SANE trainings or in forensic nursing programs in many schools of nursing, and their evidence is credible and effective in resultant court proceedings (Campbell et al., 2006, 2008; Houmes et al., 2003). Nurses can lobby for changes in hospital policies and state laws to make this strategy a reality in all states.

Rape is a situational crisis for which advance preparation is rarely possible. Therefore nursing efforts are directed toward helping victims cope with the stress and disruption of their lives caused by the attack. Counseling focuses on the crisis and the concomitant fears, feelings, and issues involved. Nurses can help survivors learn how to regroup personal strengths. If PTSD occurs, professional psychological or psychiatric treatment is indicated.

Many communities have developed multidisciplinary teams, sexual assault response teams (SARTs), to coordinate response between the health care system, criminal justice system, and victim advocacy organizations to sexual assault victims. The purpose of SARTs is two-fold: to provide comprehensive, timely care and to support engagement with community services, and to collect high-quality forensic evidence (Cole, 2016). Limited evidence suggests that there are benefits of a coordinated model, including improved communication between service providers, decreased wait times at hospitals, and improved forensic evidence collection (Greeson & Campbell, 2013). Nurses must be aware of the services within their communities to assure a timely and appropriate referral to necessary service providers.

Suicide

According to the National Violent Death Reporting System (NVDRS), suicide accounted for the highest rate of violent death in 2007, taking the lives of 9245 people. Firearms accounted for 50.7 percent, hanging/strangulation/suffocation for 23.1 percent, and poisoning for 18.8 percent of suicides. Firearms (56 percent) or hanging/strangulation/suffocation (24.4 percent) were the most common form of suicide for men. Women used poisoning (40.8 percent) most frequently, followed by firearms (30.9 percent). Precipitating factors for suicide were mental health (45 percent), IPV (30 percent), and physical health problems (21.4 percent) (CDC, 2014a). The risk for death by suicide is greater than for death by homicide. Rates of completed suicide are higher for men, especially older adults, non-Hispanic whites, and Alaska Natives/American Indians (Karch et al., 2010). Affluent and educated people often have higher rates of suicide than do the economically and educationally disadvantaged except for Alaska Native/American Indian

populations, who are often poor and yet commit suicide in alarming numbers. The presence of a gun in the home is an important risk factor for both suicide and homicide (Campbell, 2007).

Suicide is the third-leading cause of death among young people ages 15 to 24. During 2005 to 2009, the highest suicide rates were among American Indian/Alaska Native males, with 27.61 suicides per 100,000, and non-Hispanic white males, with 25.96 suicides per 100,000. Of all female race/ethnicity groups, the American Indians/Alaska Natives and non-Hispanic whites had the highest rates with 7.87 and 6.71 suicides per 100,000, respectively. For American Indian youth, adverse childhood experiences, particularly witnessing a mother being abused, and historical trauma are salient risk factors for suicidality (Brockie et al., 2015). Boys and young men between the ages of 15 and 19 were five times more likely to commit suicide than females and four times more likely if between the ages of 20 and 24 (Karch et al., 2010). Attempted suicide was more prevalent for white, African American, and Hispanic females than for males of the same racial background. Leading risk factors for adolescent suicide are mental health, unintended pregnancy, and STD, especially HIV (Eaton et al., 2010). An important risk factor for actual and attempted suicide in adult women is IPV.

The majority of individuals who complete suicide have visited a health care provider in the previous month of their suicide; therefore health care providers are key for screening and intervening for individuals at risk. On a community level, nurses can be involved in a coordinated response to the prevention of suicide and the care of attempted suicides. Through their roles in public health and school nursing, they can help develop policies and protocols for suicide across the life span. Nursing care may focus on family members and friends of suicide victims. The loss of a person by suicide can arouse different feelings of grief among relatives and close friends of those who have committed suicide than the emotions they experience when death occurs from natural causes. Communicating one's feelings is an integral part of the healing process, and support groups play an important role in this healing.

FAMILY VIOLENCE AND ABUSE

Intimate partner violence (IPV), defined as physical, sexual, or psychological harm caused by a former or current intimate partner, is a major public health problem in the United States. Data from the 2011 National Intimate Partner and Sexual Violence Survey (NISVS) suggests that over 10 million women and men experience physical violence each year by a current or former intimate partner (Breiding et al., 2015). Importantly, more than one in five women (22.3 percent) and nearly one in seven men (14.0 percent) have experienced severe physical violence by an intimate partner in their lifetime (Breiding et al., 2015). The recognition of IPV is critical given it is one of the most well-established predictors of attempted or completed intimate partner homicide. The Centers for Disease Control and Prevention recently analyzed homicides from 18 states between 2003 and 2014, finding that over half (55.3 percent) of homicides committed against females in the United States involved an intimate partner (Petrosky et al., 2017).

The majority of IPV is directed at women, with the majority of IPV perpetrated by a male partner or ex-partner (Black et al., 2011). A recent integrative review synthesized results from 42 studies that examined IPV and sexual violence among sexual minorities between 1989 and 2015 (Brown & Herman, 2015). Results demonstrated that bisexual women were 1.8 times more likely to experience IPV than heterosexual women, and 2.6 times more likely to report having experienced sexual violence as compared to heterosexual women. Bisexual men were noted to also be at increased risk for IPV. A limited number of studies examined transgender people, finding they were at higher risk of IPV, with lifetime prevalence estimates ranging from 31.1 percent to 50.0 percent (Brown & Herman, 2015). Lesbian, gay, bisexual, transgender, queer (LGBTQ) IPV generally follows similar dynamics as heterosexual IPV (emotional, verbal, physical, and/or sexual violence, threats, isolation, and intimidation, in a context of one partner maintaining power and control over another) and results in similarly adverse health outcomes. As with heterosexual IPV, dynamics of power and control caused by race, gender expression, ability, immigration status, age, and class are methods of control in same-sex IPV (National Coalition of Anti-Violence Programs, 2017). LGBTQ people face many of the barriers to help seeking that non-LGBTQ people do, but they face additional barriers that are related to their sexual orientation or gender identity. These may include but are not limited to:

- Legal definitions of intimate partner violence that exclude same-sex couples
- The risks associated with "outing" oneself when seeking help and the potential for negative response from family, friends, and society
- A lack of knowledge about resources specific for LGBTQ survivors
- Potential discrimination from service providers or non-LGBTQ survivors of IPV
- Lack of knowledge or sensitivity on behalf of law enforcement officials and courts for LGBTQ people (Brown & Herman, 2015)

Recognizing the IPV survivor in the emergency department may be simple after the fact. It is unfortunate that, by the time medical care is sought, serious physical and emotional damage may have been done. Nurses are in a key position to predict and deal with abusive tendencies. By understanding factors contributing to the development of abusive behaviors, nurses can identify incidents of IPV.

Development of Abusive Patterns

Perpetrators of IPV often believe that violence within an interpersonal relationship is a normal behavior pattern (Stover et al., 2010). Factors that characterize people who become involved in IPV include upbringing, living conditions, and increased stress. Understanding how these factors influence the development of abusive behavior can help the nurse manage abusive families.

Upbringing. The most predictable factor in the background of an abuser is previous exposure to some form of violence (Whiting et al., 2009). As children, abusers were often beaten or

witnessed the beating of siblings or a parent. These children learn that violence is a suitable way to manage conflict. For both men and women, witnessing abuse as a child was associated with abuse of their children. Being financial solvent and having support tended to decrease the incidence of child abuse (Dixon et al., 2009; Whiting et al., 2009). Childhood physical punishment teaches children to use violent conflict resolution as an adult. A child may learn to associate love with violence because a parent is usually the first person to hit a child. Children may think that those who love them are also those who hit them. The moral rightness of hitting other family members thus may be established when physical punishment is used to train children, especially when it is used more than occasionally. These experiences predispose children ultimately to use violence with their own children.

As well as having a history of child abuse themselves, people who become abusers tend to have hostile personality styles and be verbally aggressive. They have often learned these characteristics from their own childhood experiences. Their parents may have set unrealistic goals, and when the children failed to perform accordingly, they were criticized, demeaned, punished, and denied affection. These children may have been told how to act, what to do, and how to feel, thereby discouraging the development of normal attachment, autonomy, problem-solving skills, and creativity (Dixon et al., 2005). Children raised in this way grow up feeling unloved and worthless. They may want a child of their own so that they will feel assured of someone's love.

Because of their experiences of trauma and to protect themselves from feelings of worthlessness and fear of rejection, abused children form a protective shell and grow increasingly hostile and distrustful of others. The behavior of potential abusers reflects a low tolerance for frustration, emotional instability, and the onset of aggressive feelings with minimal provocation. Because of their emotional insecurity, perpetrators of abuse often depend on a child or spouse to meet their needs of feeling valued and secure. When their needs are not met by others, they become overly critical. Critical, resentful behavior and unrealistic expectations of others lead to a vicious cycle. The more critical these people become, the more they are rejected and alienated from others. Abusive individuals tend to perceive that the target of their hostility is "out to get" them. These distorted perceptions can be detected when parents talk about an infant crying or keeping them up at night "on purpose" (Dixon et al., 2005).

Increased Stress. A perceived or actual crisis may precede an abusive incident. Because a crisis reinforces feelings of inadequacy and low self-esteem, a number of events often occur in a short time to precipitate abusive patterns. Unemployment, strains in the marriage, or an unplanned pregnancy may precipitate violence, especially in people with other risk factors such as a history of trauma themselves.

The daily hassles of raising young children, especially in an economically strained household, intensify an already stressed atmosphere for which an unexpected and difficult event may provoke violence. Stressful life events, poverty, and cultural values and social isolation are often associated with family violence. Crowded living conditions may also precipitate abuse. The presence of several people in a small space heightens tensions and reduces privacy; tempers flare because of the constant stimulation from others.

A significant amount of research has demonstrated the links between social support and optimal health. Conversely, social isolation is linked to poor mental and physical health and is associated with a higher risk of violence in families (Thompson, 2015). Social isolation is associated with increased stressors, less socialization of healthy parenting practices, and limited interpersonal and material resources for support. The problem may be intensified if an abusive family member tries to keep the family isolated to avoid detection. Therefore when a family chronically misses clinic or home visit appointments, nurses need to keep in mind that abuse may be present. Nurses can encourage involvement in community activities and can help neighbors reach out to neighbors to help prevent abuse.

Frequent moves disrupt social support systems, are associated with an overall increased stress level, and tend to isolate people, at least briefly. Mobility can have a serious negative effect on the abuse-prone family. These families do not readily initiate new relationships; they rely on the family for support. Resources may be unfamiliar or inaccessible to them. Because frequent moving may be both a risk factor for abuse and a sign of an abusive family trying to avoid detection, nurses should assess such families carefully for abuse.

Types of Intimate Partner and Family Violence

Because various forms of family violence and violence outside the home often occur together, nurses who detect child abuse should also suspect other forms of family violence. When older adult parents report that their (now adult) child was abused or has a history of violence toward others, the nurse should recognize the potential for elder abuse. **Physical abuse** of women is frequently accompanied by **sexual abuse** both inside and outside the marital relationship. Severe wife abusers may have a history of other acts of violence. Families who are verbally aggressive in conflict resolution (e.g., using name calling, belittling, screaming, and yelling) are more likely to be physically abusive. Although the various forms of family violence are discussed separately, they should not be thought of as totally separate phenomena.

No member of the family is guaranteed immunity from abuse and neglect. Spouse abuse, child abuse, abuse of older adults, serious violence among siblings, and mutual abuse by members all occur. Although these examples are not inclusive, they demonstrate the scope of family violence.

Child Abuse. **Child abuse** is an important cause of pediatric morbidity and mortality and is associated with significant physical and mental health sequelae that can extend into adulthood. A national survey estimated that in 2011, there were 742,000 unique reports of children and adolescents who were subjected to neglect, medical neglect, physical and sexual abuse, and emotional maltreatment. Of these children, 78 percent were victims of neglect, 18 percent were victims of physical abuse, 10 percent

were sexually abused, and 8 percent were psychologically maltreated. Except for sexual abuse, which is four times as high for girls as for boys, victims are equally distributed among abused male and female children (U.S. Department of Health and Human Services [USDHHS], 2016). Fatal cases of abuse, although less common, disproportionally affect the youngest children, with 71 percent of fatalities occurring in children less than three years of age (USDHHS, 2016).

The effects of child exposure to IPV have been recognized with research demonstrating significant associations with social, emotional, and behavioral problems (Levendosky et al., 2013). Children who are exposed to IPV are at an increased risk for depression, anxiety, and attachment disorders. Further, they exhibit more behavioral problems, including aggression and delinquency (Kimball, 2016). The consequences may last into adulthood with difficulties establishing and maintaining healthy relationships and an increased risk for perpetrating IPV. A recent systematic review demonstrated that childhood abuse and witnessing IPV in childhood and adolescence were consistent predictors of IPV perpetration and victimization for males and females (Costa et al., 2015). These findings highlight the need for resources targeting at-risk families early in life.

Poverty is a well-known risk factor for child maltreatment, and the important role of community-level poverty on nonfatal child maltreatment is increasingly recognized (Leventhal & Gaither, 2012). In 2016, the American Academy of Pediatrics published a policy statement on poverty and child health in the United States, highlighting the salient role of poverty in health disparities, including infant mortality and injury (Council on Community Pediatrics, 2016). An analysis of CDC mortality files of child abuse fatalities in U.S. children aged 0 to 4 years from 1999 to 2014 revealed that counties with the highest poverty concentration had more than three times the rate of child abuse fatalities compared with counties with the lowest poverty concentration (Farrell et al., 2017). These findings highlight that child abuse prevention efforts must recognize community poverty and related factors in contributing to violence. Child characteristics that increase one's risk of maltreatment include those that make a child more difficult to care for. Examples include children living with special health care needs, chronic illnesses, or physical or developmental disabilities (Hibbard & Desch, 2007). A child born prematurely may have unique needs, and early and prolonged separation may contribute to an increased risk of maltreatment (Wu et al., 2004). Physical aggression, difficulty following parental direction, and antisocial behaviors are more common among maltreated children. The box that follows lists ways to recognize actual or potential signs of child abuse. The How To box below lists ways to identify potentially abusive parents.

HOW TO Identify Potentially Abusive Parents

The following characteristics in couples expecting a child constitute warning signs of actual or potential abuse:

- Denial of the reality of the pregnancy, as seen in a refusal to talk about the impending birth or to think of a name for the child
- An obvious concern or fear that the baby will not meet some predetermined standard: sex, hair color, temperament, or resemblance to family members
- Failure to follow through on the desire for an abortion
- An initial decision to place the child for adoption and a change of mind
- Rejection of the mother by the father of the baby
- Family experiencing stress and numerous crises so that the birth of a child may be the last straw
- Initial and unresolved negative feelings about having a child
- Lack of support for the new parents
- Isolation from friends, neighbors, or family
- Parental evidence of poor impulse control or fear of losing control
- Contradictory history
- Appearance of detachment
- Appearance of misusing drugs or alcohol
- Shopping for hospitals or health care providers
- Unrealistic expectations of the child
- Verbal, physical, or sexual abuse of mother by father, especially during pregnancy
- Child is not biological offspring of male stepfather or mother's current boyfriend
- Excessive talk of needing to "discipline" children and plans to use harsh physical punishment to enforce discipline

From an ecological perspective, interactions among and between children, parents, family members, and the broader community may all increase the likelihood of maltreatment. Parents or caregivers with mental health concerns, limited social support, limited knowledge of normal childhood development, low sense of parenting competence, experiencing IPV, or who have non biologically related adults in the home may be at increased risk (Farrell et al., 2017; Lane, 2014). Some of the risk factors are identified in Box 38.1 (USDHHS, 2013; Zimmerman & Mercy, 2010). Importantly, several protective factors should also be noted. Social support is a key protective factor; families with higher levels of social support demonstrate lower rates of child

BOX 38.1 Determining Risk Factors for Child Abuse

Ask the following questions or observe the following behaviors to determine whether risk factors are present.

1. Are the parents unemployed?
2. Do the parents have the financial resources to care for a child?
3. Is there a support network that is willing to offer assistance?
4. Do one or both parents have a history of child abuse?
5. Is a parent a victim or perpetrator of intimate partner violence?
6. Do the parents have knowledge about child development?
7. Do one or both parents have problems with substance abuse?
8. Are the parents overly critical of the child?
9. Are the parents communicative with each other and the nurse?
10. Does the mother of the child seem frightened of her partner?
11. Does the child suffer from recurrent injuries or unexplained illnesses?

Data from Rodriguez CM: Personal contextual characteristics and cognitions: predicting child abuse potential and disciplinary style. *J Interpers Violence* 25(2):315-335, 2010; U.S. Department of Health and Human Services, Administration for Children and Families, Administration on Children, Youth and Families, Children's Bureau: *Child maltreatment, 2008*, 2010. Available at http://www.acf.hhs.gov.; Zimmerman F, Mercy JA: A better start: child maltreatment prevention as a public health priority. *Zero Three* 30(5):4-10, 2010.

maltreatment and greater use of effective parenting practices other than corporal punishment (McCurdy, 2005). A parent's sense of competence in child care practices may enable him or her to more successfully cope with the challenges associated with child rearing. Thus successfully linking parents to specific programs for the prevention of child maltreatment or referring families to community-based programs can help parents meet their children's needs.

Parents who have inadequate parenting skills or resources have more difficulty providing the care and nurturing that is needed for children to have safe, nurturing relationships. There is substantial evidence that parenting programs or behavioral family interventions that target influencing children's behavior through positive reinforcement are effective at influencing the child-rearing practices of families (Kaminski et al., 2008; Lundahl et al., 2006). Some evidence suggests that these types of support programs may also reduce or prevent physical abuse and neglect (Whitaker et al., 2005).

Foster care. When child abuse is discovered, the child is often placed in a foster home. It is the legal responsibility of the nurse to report all cases of child abuse. Ideally, the initial report begins a process in which both the child and the family can receive the care needed. Although the focus of care should be on the best interests of the child and the parents, the primary attention should be on the health and safety of the child. While in foster care the abused child should receive continuous nursing care. The nurse is often the one consistent person abused children can relate to as they are transferred from their home to foster care and hopefully back to their home. Abused children generally want to return to their parents, and the goal of most agencies is to help natural families stay together as long as it is safe for the child. However, a family preservation approach may not always keep children safe (O'Reilly et al., 2010). Often the nurse's role is to help monitor a family in which a formerly abused child is returned from foster care. Keen judgment and close collaboration with social services are necessary in these situations. The nurse must ensure the safety of the child while working with the parents in an empathetic way. The nurse's goal is to enhance parenting skills through education on child care and development, communication, and principles of social learning theory. Parents must also be given positive support and reassurance about their ability to provide proper care to their child.

One of the most distressing outcomes of child abuse is depression and other mental health problems, especially suicide. Adolescents who have been placed in the social service system many times or who move from one foster home to another are at risk for delinquency, severe depression, alcohol and substance abuse, and suicide. Nurses need to understand the dynamics of adolescent suicide and substance abuse (Fletcher, 2010; Ford et al., 2010).

Indicators of child abuse. It is essential that nurses recognize the physical and behavioral indicators of abuse and neglect. Child abuse ranges from violent physical attacks to passive neglect. Violence such as beating, burning, kicking, or shaking may lead to severe physical injury. **Passive neglect** may result in insidious malnutrition or other problems. Abuse is not limited to physical maltreatment but includes **emotional abuse** such as yelling at or continually demeaning and criticizing the child. Children who come from a family where IPV occurs are at greater risk for physical and psychological abuse and child neglect (Fletcher, 2010; Hines & Malley-Morrison, 2005; Whiting et al., 2009). The How To box provides information about ways to recognize actual or potential child abuse.

HOW TO Recognize Actual or Potential Child Abuse

Be alert to the following:

- An unexplained injury
- Skin: burns, old or recent scars, ecchymosis, soft tissue swelling, human bites
- Fractures: recent, or older ones that have healed
- Subdural hematomas
- Trauma to genitalia
- Whiplash (caused by shaking small children)
- Dehydration or malnourishment without obvious cause
- Provision of inappropriate food or drugs (alcohol, tobacco, medication prescribed for someone else, foods not appropriate for the child's age)
- Evidence of general poor care: poor hygiene, dirty clothes, unkempt hair, dirty nails
- Unusual fear of nurse and others
- Considered to be a "bad" child
- Inappropriate dress for the season or weather conditions
- Reports or shows evidence of sexual abuse
- Injuries not mentioned in history
- Seems to need to take care of the parent and speak for the parent
- Maternal depression
- Maladjustment of older siblings
- Current or history of intimate partner violence in the home

Emotional abuse involves extreme debasement of feelings and may lead the child to feel inadequate, inept, uncared for, and worthless. These children learn to hide their feelings to avoid more scorn. They may act out by performing poorly in school, becoming truant, and being hostile and aggressive. Children who are abused or who witness domestic violence can suffer developmentally (Kletter et al., 2009; Rodriguez, 2010). Major responses of adolescents to physical and sexual abuse are substance abuse, severe depression, and running away from home (Fletcher, 2010; Ford et al., 2010).

Physical symptoms of physical, sexual, or emotional stress may include hyperactivity, withdrawal, overeating, dermatological problems, vague physical complaints, stuttering, enuresis (bladder incontinence), and encopresis (bowel incontinence). Ironically, bedwetting is often a trigger for further abuse, thereby creating a vicious cycle. When a child displays physical symptoms without clear physiological origin, the nursing assessment should rule out the possibility of abuse.

Child neglect. **Child neglect** occurs when a child's basic needs are not adequately met. Basic needs include adequate nutrition, clothing, stable housing, adult supervision, protection, health care, education, love, and nurturance. The four categories of child neglect include physical, emotional, medical, and educational neglect. **Physical neglect** is failure to provide adequate food, proper clothing, shelter, hygiene, or necessary medical care and is most often associated with extreme poverty. In contrast, **emotional neglect** is the lack of the basic nurturing, acceptance, and caring essential for healthy personal

development. These children are largely ignored or treated as nonpersons, which affects the development of self-esteem. A neglected child has difficulty feeling self-worth because the parents have not shown that they value the child. Medical and educational neglect consist of the failure to provide for a child's basic medical and educational needs. Medical neglect may be due to an inability to buy basic drugs needed for common diseases. All forms of neglect may be involved when a parent fails to teach children about risky behaviors such as smoking and substance abuse (Hines & Malley-Morrison, 2005). Extreme cases of neglect are easily identified, but the majority of neglect cases are complex and lack precise identification.

Prevention and treatment of child maltreatment is challenging. In addition to addressing the consequences of poverty, substance abuse, poor mental health, and other common issues confronting families involved with child welfare, effective interventions must address the parent–child relationship. According to a national panel of child maltreatment experts, Abuse Focused Cognitive Behavioral Therapy (AF-CBT) and Parent-Child Interaction Therapy (PCIT) are two interventions that may be effective for the treatment of child maltreatment. Both are dyadic interventions, focused on altering specific patterns of interaction found in parent–child relationships (Schilling & Christian, 2014).

Sexual abuse. Child abuse also includes sexual abuse. About 1 in 4 female children and 1 in 10 males in the United States experience some form of sexual abuse by the time he or she reaches 18 years of age. It is difficult to determine the exact prevalence because not all children have the cognitive ability to describe these experiences. Rates based on reports to child protective services estimate that 50 in every 1000 children suffer from child abuse and/or neglect (USDHHS, 2016). This abuse ranges from unwanted sexual touching to intercourse. The child generally knows and trusts the person who perpetrates the sexual abuse. One-third to one-half of all sexual abuse involves a family member (Hines & Malley-Morrison, 2005; USDHHS, 2016). A child's risk for abuse is highest with parents, immediate family members, and nonrelated caregivers, although coaches, scout leaders, and even priests and other church workers have been reported as sexual abusers. The long-term effects of sexual abuse include depression, sexual disturbances, suicide, and substance abuse. Individuals with a history of both physical and sexual abuse tend to experience more severe symptoms than children who experience one form of abuse (Fletcher, 2010; Stevenson, 2009). Physically and sexually abusive parents share many of the same characteristics, including unhappiness, loneliness, and rigidity. However, sexually abused children have more gastrointestinal symptoms and post-traumatic stress disorders than physically abused children (Drossman, 2011).

Father–daughter **incest** is the type of incest most often reported; however, mothers do engage in child sexual abuse. In recent years more males have discussed their experiences of child sexual abuse. It is estimated that one in five children is a victim of child sexual abuse. Cases of father–daughter, father–son, mother–daughter, and mother–son incest have been reported (Hines & Malley-Morrison, 2005). Many cases of parental sexual abuse go unreported because victims fear punishment, abandonment, rejection, or family disruption if the problem is acknowledged. Although stepfathers are considered the most common perpetrator of father–daughter incest, we know little about female perpetrators. Incest occurs in all races, religious groups, and socioeconomic classes. Incest is receiving greater attention because of mandatory reporting laws, yet all too often its incidence remains a family secret.

Nurses must be aware of the incidence, signs and symptoms, and psychological and physical trauma of incest. Symptoms include low self-esteem, depression, anxiety, and somatic symptoms of headaches, eating and sleeping disorders, menstrual problems, and gastrointestinal distress (Drossman, 2011). Sexually abused children often exhibit premature sexual behavior, such as masturbation. Children often try to avoid or escape the abusive behavior. Avoidance can be through either behavioral or mental reactions, such as dressing to cover one's body or pretending that the abuse is not taking place. The child can escape either physically by running away or emotionally by withdrawing into other activities and thereby placing the sexual abuse in the background (Stevenson, 2009).

Adolescents may display inappropriate sexual activity or truancy or may run away from home. Running away is usually considered a sign of delinquency; however, an adolescent who runs away may be exhibiting a healthy response to a violent family situation. Therefore the assessment should include questions about sexual and physical abuse at home and a plan for appropriate intervention.

The effects of childhood sexual abuse can be mitigated by continual professional support. At different developmental stages, children may need assistance to overcome negative feelings about their own sexuality (Stevenson, 2009). Adult survivors of sexual abuse often are socially isolated and have significant health problems that need to be addressed in terms of the ongoing effects of their childhood and adult experiences (Mapp, 2006).

Abuse of Female Partners. Neither the term **wife abuse** nor the term **spouse abuse** takes into account violence in dating or cohabitating relationships or violence in same-sex relationships. IPV, a more inclusive term, refers to all kinds of violence between partners. IPV is not a rare event, with one in three women and one in four men reporting physical violence, rape, and/or stalking by a current or former intimate partner at some point in their life (Black et al., 2011). However, these figures do not include psychological forms of IPV, which also could have severe consequences. Recently, more attention has been given to female-perpetrated IPV and bidirectional violence (i.e., male-to-female violence concurrent with female-to-male violence), especially in the context of teen dating violence. Nevertheless, female victims of IPV are more likely to report severe IPV and experience more negative individual, family, and community consequences than their male counterparts, and a greater potential for intimate partner homicide (Black et al., 2011; Campbell, 2007).

IPV appears early in life. In fact, about 22 percent of victims of rape, physical abuse, and/or stalking by an intimate partner report their first experience when they were between the ages of 11 and 17. Nearly half (47 percent) report their first incident between the ages of 18 and 24 (Black et al., 2011). As in adulthood, IPV experienced by adolescents and young adults is associated with poor mental health outcomes such as depression

and suicidality, is linked to risky behaviors such as substance abuse and risky sexual behaviors, and contributes to the intergenerational transmission of interpersonal violence (Reyes et al., 2016). Adolescence is an important developmental period that should be effectively targeted to prevent violence, thus mitigating its effects into adulthood.

Signs of abuse. Abused women often have bruises and lacerations of the face, head, and trunk of the body. Attacks are often carefully inflicted on parts of the body that are disguised by clothing. This pattern of proximal location of injuries (e.g., breasts, abdomen, upper thighs, and back) rather than distal and patterned injuries (in various stages of healing, in particular configurations matching the body part or object used as a weapon) is characteristic of abuse (Campbell & Sheridan, 2004; Sheridan & Nash, 2009). When a woman has a black eye or bruises about the mouth, the nurse should ask, "Who hit you?" rather than, "What happened to you?" The latter implies that the nurse is neither knowledgeable nor comfortable with violence, and this may prompt the woman to fabricate a more acceptable cause of her injury.

Once abused, women tend to exhibit low self-esteem and depression, and even PTSD (Humphreys & Campbell, 2010). They have more physical health problems than other women, such as chronic pain (back, head, abdominal), neurological problems, problems sleeping, gynecological symptoms, urinary tract infections, and chronic gastrointestinal problems (Campbell, 2002). Victims of IPV are also at greater risk for HIV and other sexually transmitted infections (STIs), which appear to be both a risk factor and consequence of the abuse (Coker et al., 2009). In addition, female victims of IPV are more at risk for chronic diseases such as cardiovascular disease, atherosclerosis, and autonomic nervous system disorders (Symes et al., 2010). Although the focus tends to be on the victim of the abuse, it is important to note that there are health consequences to the perpetrator and children witnessing the abuse as well. These physical and mental health consequences incur health care costs that are preventable (Rivara et al., 2007).

Abuse as a process. Nursing research by Ford-Gilboe et al. (2010) suggests that there is a process of response to battering over time wherein the woman's emotional and behavioral reactions change. At first there is a great need to minimize the seriousness of the situation. The violence usually starts with a slight shove in the middle of a heated argument. If there is any physical aggression, both the man and the woman tend to blame the incident on something external such as a stressful day at work or drinking too much. The male partner usually apologizes for the incident, and as with any problem in a relationship, the couple tries to improve the situation. Although marital counseling may be useful at this early stage, it is generally contraindicated at all other stages because of the risk to the woman's safety. Unfortunately, abuse tends to escalate in frequency and severity over time, often leading to severe physical injuries and even death (Piquero et al., 2006), and the man's remorse tends to lessen. Similar power and control dynamics and risks have been documented in same-sex relationships, yet these dynamics may be more difficult to assess because screening and services for IPV are often designed for heterosexual relationships (Alhusen et al., 2010).

Because women have often been taught to take responsibility for the success of a relationship, they usually go through a period in which they try to change their behavior to end the violence. They may even blame themselves for infuriating their partner. Women who blame themselves for provoking the abuse are more likely to have low self-esteem and be depressed than those who do not blame themselves. Some women experience a moral conflict between their need to leave an abusive relationship and their sense that it is their responsibility to maintain a relationship (Edwards et al., 2015). A woman is also typically concerned about her children, which may create barriers to a woman's ability to leave or to remain out of the relationship. The frequency of abuse, severity of power and control tactics used by the perpetrator, feelings of guilt, and social and financial responsibility are additional influences on a woman's decision about how she responds to the abuse and whether she stays or leave the relationship (Rhodes et al., 2010; Sonis & Langer, 2008).

Although leaving the abusive partner may ultimately contribute to a decrease in the woman's risk for further victimization, the moment in which she leaves the relationship is the time in which there is the greatest risk for intimate partner homicide (Campbell, 2007). This creates a Catch-22 situation, in which the woman feels she will die whether she stays or leaves. Consequently, battered women often try several times to leave a relationship. The safety of the woman and her children is a nursing priority during these attempts.

EVIDENCE-BASED PRACTICE

Sharps et al. (2016) conducted a multistate longitudinal study testing the effectiveness of a structured intimate partner violence (IPV) intervention integrated into health department perinatal home visitation programs in rural and urban locations. All women (n = 239) enrolled in the randomized clinical trial were pregnant at the time of enrollment and reported a positive history of IPV in the perinatal period. The research partners included individuals from two schools of nursing, an urban East Coast health department, and 13 rural Midwestern health departments. The Domestic Violence Enhanced Home Visitation (DOVE) intervention, based on an empowerment model, combined two evidence-based interventions: a 10-minute brochure-based IPV intervention and perinatal nurse home visitation. Quantitative and qualitative data revealed that women in both the intervention group and control group demonstrated a significant decrease in IPV over time. However, women receiving the DOVE intervention had significantly lower levels of IPV than did women randomized to usual care at 24 months. Home visitors in both groups (e.g., intervention and control) were taught how to screen for IPV and how to coordinate appropriate referrals, ensuring that each woman received basic safety information.

Nurse Use

Nurses need to be able to work with survivors of IPV as well as providers within communities who work with abused women. Community-based partnerships are essential to most effectively develop and implement evidence-based IPV interventions such as DOVE. To best address IPV in a community, nurses must understand cultural differences among women who experience IPV as well as among community advocates who may also be assisting abused women. Public health nurses are well positioned to forge such partnerships and take an active role in planning, implementing, and evaluating programmatic change.

Partnering with the community. Nurses need to be able to work to address IPV on various levels of intervention. Community-based partnerships are essential collaborative actions that will assist in the reduction of IPV. To do so, nurses must understand cultural differences related to IPV, as well as the needs and strengths of the communities with which they partner. Public health nurses can take an active role in leading groups and planning, implementing, and evaluating programmatic change. There are various examples of nurse-led community partnerships to prevent and address IPV. For example, both Belknap and VandeVusse (2010) and Gonzalez-Guarda et al. (2013) partnered with community agencies, schools, and community members to identify needs and preferences for IPV prevention and services for the Hispanic/Latino community. This work has led to the development, implementation, and evaluation of dating violence prevention programs for Hispanic/Latino youth.

The CDC has launched an initiative called Dating Matters. The purpose of this program is to teach parents and adolescents about healthy relationships and to give them tools to deal with unhealthy relationships such as teen dating violence (CDC, 2014b). Dating Matters focuses on 11- to 14-year-olds in high-risk, urban communities, and includes prevention strategies for individuals, peers, families, schools, and neighborhoods. The Migrant Clinicians Network, an organization to help migrant and other poor transient workers, has developed a natural helper model for migrant workers, to work within their own community to identify and teach about IPV (Kugel et al., 2009). On the basis of models developed in the 1980s, communities are developing a coordinated response in which multiple agencies work together to assist with preventing IPV.

Screening. Given the high prevalence of IPV and the negative physical, psychological, social, and economic consequences associated with this public health problem, adolescents and adults should be screened for violence in their primary intimate relationship. The U.S. Preventive Services Task Force recommends screening women of childbearing age for IPV and referring or providing women who disclose abuse to intervention services (U.S. Preventive Services Task Force, 2013). The use of effective screening protocols, institutional support for implementing screening, initial and ongoing staff training, and access to services onsite or through a strong referral system are recommended as part of a comprehensive screening program (O'Campo et al., 2011).

Safety planning. Victims of IPV are at high risk for severe injuries and homicide, especially at the moment they decide to leave an abusive relationship (Campbell, 2007). As such, nurses should work with women victims in creating a safety plan. This plan may include the following: (1) an order of protection (a legal document to keep the abuser away from her); (2) help in getting to a safe place, such as a domestic violence shelter in an anonymous location; (3) access to individual advocacy and support groups/or the criminal justice system (Harding & Helweg-Larsen, 2009); and (4) a carefully calculated plan for escape that includes keeping a bag with a copy of important documents and other resources (e.g., keys, phone, contact information) for emergencies. Although leaving an abusive relationship has been shown to be protective in the long term (Campbell, 2007), it is important to avoid pushing women into actions they are not ready to take. Cultural factors that influence responses to IPV are also important to consider in the development of interventions addressing the safety of victims (Belknap & VandeVusse, 2010; Ward & Wood, 2009).

Batterer's interventions. The male partner may attend a program for batterers as an alternative to ending the relationship. These programs appear to be effective for some individuals. These programs are most effective if they are part of a coordinated community response, involve appropriate risk assessment and management practices, are of adequate structure (e.g., duration), are court-mandated and closely monitored, and involve training and close supervision of the staff implementing the program (Salcido Carter, 2009).

Intimate partner sexual abuse. Abused women are often forced into sexual encounters. This sexual abuse is usually but not always accompanied by physical abuse. Women who are sexually abused are at risk for STDs (Coker et al., 2009). Sexual abuse increases the risk for mental health problems for all women who are involved in physically abusive relationships. Women who experience child abuse are at even greater risk for depression than those not exposed to abuse as a child (Fogarty et al., 2009).

The belief that men have a right to force their wives to have sex comes from traditional English law that said a woman gave irrevocable and perpetual consent to her husband on marriage to have sex whenever and however he wanted. Marital rape was not considered a crime in the United States until 1993 (Yllo, 1999). Marital rape leads to serious physical and emotional damage. Women who suffer from IPV may not consider forced sex a form of abuse. It is essential when women come to the emergency department with injuries that they are assessed for the presence of both physical and sexual abuse (Bazargan-Hejazi et al., 2014).

To assess for sexual assault, the following question should be used in all nursing assessments to determine whether marital rape, date rape, or rape of a male has occurred: "Have you ever been forced into sex you did not wish to participate in?"

Abuse During Pregnancy. Abuse during pregnancy has serious implications for the health of women and their children. As a conservative estimate, 3to 8 percent of pregnant women in the United States are physically abused during pregnancy, with a larger proportion of women abused during the year before pregnancy. Even more (up to 20 percent) adolescents are abused during pregnancy than adult women (Lewis et al., 2017). IPV during pregnancy is associated with depression and PTSD both during pregnancy and in the postpartum period (Alhusen et al., 2015). The effects of IPV extend to the consequent health of the infant. There is a significant association between IPV during pregnancy and increased risk of spontaneous abortion, preterm birth, low birth weight, and small-for-gestational-age infants (Alhusen et al., 2013). Experiencing IPV in the perinatal period is associated with delayed entry into prenatal care, and inadequate prenatal care. Poor nutrition and inadequate gestational weight gain have also been associated with abuse during pregnancy (Alhusen et al., 2015). Further, women experiencing

abuse during pregnancy are more likely to smoke tobacco, drink alcohol, and use illicit substances during pregnancy as compared to their non abused counterparts (Alhusen et al., 2015). A man's control of contraception, a form of abusive controlling, may lead to unintended pregnancy and subsequent abuse. In addition, a man's refusal to use a condom places a woman at increased risk of sexually transmitted infections, including infection with HIV (Stockman et al., 2010).

All pregnant women should be screened for abuse at each prenatal care visit, and postpartum home visits should include assessment for child abuse and partner abuse. The U.S. Preventive Services Task Force updated its recommendations on screening women for IPV and concluded that screening instruments accurately identify women experiencing IPV and screening could reduce IPV and improve outcomes depending on the population screened and outcome measured (Nelson et al., 2012). Prenatal care presents a unique window of opportunity in which nurses can foster trusting relationships with pregnant women, thereby increasing the likelihood of IPV detection and mitigating its related negative consequences to both mother and child.

CHECK YOUR PRACTICE

A 23-year-old woman presents for her first prenatal care appointment. She is at 22 weeks' gestation, and her chart indicates she has missed three previously scheduled appointments. She is visibly upset during the appointment, provides short responses to your questions, and hesitates when you provide her a gown to change into. She tells you, "I am accident prone so I have a lot of bruises on my arms and abdomen." You sense that she is in an unsafe relationship.

What should you do?

Elder Abuse. The World Health Organization defines elder abuse broadly, as "a single or repeated act or lack of appropriate action, occurring within any relationship where there is an expectation of trust which causes harm or distress to an older person" (World Health Organization, 2002, p. 29). Research findings regarding the prevalence of elder abuse vary widely, depending on the population that is studied (e.g., community-dwelling elders versus those who are institutionalized), the study methods (e.g., review of service provider and protective service records versus population-based surveys of elders themselves), and the specific definition of elder abuse that was used in the research (Acierno et al., 2010; Mysyuk et al., 2013). Even the definition of who may be considered an "elder" is not consistent across research studies (Acierno et al., 2010) or across cultures (Mysyuk et al., 2013). Large, longitudinal national studies that describe the prevalence of elder abuse, its risk and protective factors, and its consequences to health over time are needed (Dong & Simon, 2011).

Regardless, it is clear that elder abuse is common. In a random-digit dial survey of 5777 community-dwelling U.S. elders at least 60 years of age, 1 in 10 reported past-year emotional, physical, or sexual mistreatment or potential neglect (i.e., an identified need for assistance that no one was addressing) (Acierno et al., 2010). Elder abuse has significant implications for public health, as it is associated with significant consequences to mental and physical health; increasing risk of physical injury; gastrointestinal, gynecological, and musculoskeletal issues; delusions, dementia, anxiety, and depression; and mortality (Daly, 2011). Elder abuse is underreported across virtually all cultures and constitutes a violation of elders' basic human rights (World Health Organization, 2002).

Types of elder abuse. Specific types of elder abuse include the following (Daly, 2011):

- *Physical abuse:* The use of physical force, potentially resulting in injury, pain, or impairment
- *Sexual abuse:* Nonconsensual sexual contact of any kind
- *Emotional abuse:* Verbal or nonverbal acts that inflict psychological anguish, pain, or distress
- *Financial or material abuse:* Illegal or improper use of the elder's money, property, or assets
- *Neglect:* Refusing or failing to fulfill one's obligations or duties to an elder
- *Abandonment:* Desertion by a caregiver or custodian

Perpetrators of elder abuse may include family members, caregivers in home or institutional settings, and intimate partners. In addition, "resident-to-resident" verbal, sexual, and/or physical aggression within long-term care settings has been described (Daly, 2011). Although resident-to-resident aggression may not clearly fall under the World Health Organization definition of elder abuse (which implies a trusting or caregiver relationship), this type of violence also has obvious potential for harm to vulnerable elders.

Prevention of elder abuse. Effectively addressing elder abuse requires the involvement of multiple sectors and disciplines. Increasing awareness and recognition of elder abuse among professionals and the public, and training of service providers, are key areas for intervention (Daly, 2011; World Health Organization, 2002), as is improving education for health professionals on management and reporting guidelines for elder abuse (Dong & Simon, 2011).

Screening for elder abuse. The U.S. Preventive Services Task Force (USPSTF) has recommended that clinicians routinely screen all women of childbearing age for IPV. In the same report, the USPSTF concluded that there is insufficient evidence to support universal screening of elders for abuse. However, the Task Force also noted that elder abuse is both common and underreported, suggesting potential benefits for universal screening, and that the existing evidence regarding the lack of harm resulting from IPV screening suggests that screening for elder abuse may also represent a small risk of harm (U.S. Preventive Services Task Force, 2013). More research is needed in this area. In the absence of support for universal screening, evidence-based guidelines for nurses published in 2010 indicate that certain groups of elders are particularly likely to benefit from assessment for abuse or risk for abuse (Daly, 2011). A systematic review of studies of community-dwelling elders by Johannesen and LoGiudice (2013) suggested that living with others (versus living alone) was correlated with overall abuse but not financial abuse; this may be another factor that warrants added attention to risk assessment.

For nurses, in-depth evidence-based guidelines for the prevention of elder abuse and numerous risk assessment tools for elder abuse are available from the University of Iowa College of Nursing's Hartford/Csomay Center for Gerontological Excellence. See https://nursing.uiowa.edu/csomay. If a nurse is working with an elder and abuse or risk of abuse is identified, the nurse should create an individualized plan of care and service, using such evidence-based practice guidelines. To be effective, these plans should focus on both the elder and his or her caregiver (Daly, 2011).

Nurses also can play a key role in facilitating primary and secondary prevention interventions. More research is needed regarding the effectiveness of such interventions, including evaluation of outcomes related to mandatory reporting laws. However, evidence to date suggests that there are a number of promising interventions, including educational programs (for elders, the general public, care providers including nursing assistants, or for mandatory reporters), home visitation, caregiver skill-building, counseling or social support interventions, respite care, and batterer intervention (for intimate partners who are violent) (Daly, 2011; U.S. Preventive Services Task Force, 2013). Nurses can also play a role in advocating for vulnerable elders with policy makers, working to ensure adequate funding of state and federal legislation that addresses elder abuse; in the United States these include the Older Americans Act, the Violence Against Women Act, and the Elder Justice Act (Dong & Simon, 2011).

NURSING INTERVENTIONS

Primary Prevention

Public health strategies for the prevention of violence, such as education, behavior change, policy implementation, and environmental support, are guided by the social-ecological model that outlines how strategies should be implemented across individual, relationship, community, and societal levels. Public health nurses can help the community in the following areas.

First, the community can take a stand against violence and make sure their elected officials and the local media consider nonviolence a priority. Public education programs can educate communities about various forms of violence and ways to get help and intervene to best support those impacted. Nurses, as community advocates, should be integral in this process. Nurses are well-positioned to advocate for legislative reform aimed at reducing violence. According to the U.S. Bureau of Justice Statistics the number of intimate partner homicides of women decreased by 26 percent between 1993 and 2008. Many experts in violence-related research attribute this decline, in large part, to the Violence Against Women Act (VAWA), first authorized by Congress in 1994, which provides funding for programs targeting interventions to reduce violence (Modi et al., 2014). Nurses are often the first people to identify survivors of violence and refer them to organizations for needed resources. Thus it is critical that nurses understand current legislation and advocate for policies that improve the health and well-being of those impacted by violence.

Communities have long been recognized as critical partners in violence prevention. High levels of collective efficacy within neighborhoods can reduce the risk of violence presumably through informal policing of community members. Nurses can work with advocacy groups to make sure law enforcement personnel deal with assault within marriage as swiftly, surely, and severely as assault between strangers (Stover et al., 2010). School nurses play a vital role in violence prevention in the school setting. School nurses work to create safe environments by collaborating with school personnel, parents, and community members. They are ideally positioned to implement educational programs about violence prevention because they are non disciplinary members of the academic team and can often establish unique rapport with students that facilitates disclosure of violence (King, 2014; National Association of School Nurses, 2018).

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Quality and Safety Focus

Targeted Competency: Teamwork and Collaboration

Function effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision making to achieve quality client care.

Important aspects of teamwork and collaboration include:

- **Knowledge:** Recognize contributions of other individuals and groups in helping client/family achieve health goals.
- **Skills:** Assume role of team member or leader, based on the situation.
- **Attitudes:** Respect the unique attributes that members bring to a team, including variations in professional orientations and accountabilities.

Teamwork and Collaboration Question

If you learned, after careful assessment of your community, that family violence is a significant community health problem, what plan of action could you take to intervene? Remember that the goal is to promote health. Are there other individuals in the community whose collaboration you could enlist? Might there be insights and assistance that could be offered by leaders in church organizations, educators in schools, primary care providers, or social workers? Outline a plan of action with objectives, timetables, implementation strategies, and evaluation plans for intervening in family violence in your community. Include the unique contributions of other team members.

Prepared by Gail Armstrong, PhD, DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing.

Second, people can take measures to reduce their vulnerability to violence by improving the physical security of their homes and learning personal defense measures. Nurses can encourage people to keep windows and doors locked, trim shrubs around their homes, and keep lights on during high-crime periods. Many neighborhoods organize crime watch programs and post signs to that effect. One sign, often posted in a window, shows a hand and indicates that people in this home will assist children who need help. Also, many neighbors informally agree to monitor one another's property and safety, and many law enforcement agencies evaluate homes for security and teach individual or neighborhood safety programs.

Unfortunately, handguns are far more likely to kill family members than intruders (Azrael et al., 2018). Firearm accidents are a leading cause of death for young children, and handguns kept in the home are easy to use when people are either depressed or very angry. A handgun is used in the majority of homicides between family members and in most suicides. Nursing assessments should include a question about guns kept in the home. The family should be made aware of the risk that a handgun holds for family members. If the family thinks that keeping a gun is necessary, safety measures should be taught, such as keeping the gun unloaded and in a locked compartment, keeping the ammunition separate from the gun and also locked away, and teaching children about the dangers of firearms. Lobbying for handgun control laws is a primary prevention effort that can significantly decrease the rate of death and serious injury caused by handguns in the United States.

Assessment for Risk Factors. Identification of risk factors is an important component of primary prevention. Although abuse cannot be predicted with certainty, several factors influence the onset and support the continuation of abusive patterns. Nurses can identify potential victims of abuse because they care for clients in a variety of settings. Factors to include in an assessment for individual or family violence, or the potential for family violence, are identified in Fig. 38.2. Both individual and familial factors must be assessed within the context of the larger community (Straus et al., 2009). Factors that must be included are found in Box 38.2.

Individual and Family Strategies for Primary Prevention. Primary prevention of violence can take place through community, family, and individual interventions (Box 38.3). Nurses, in their work with schools, community groups, employee groups, daycare centers, and other community institutions, can foster healthy developmental patterns and identify signs of potential abuse. For example, nurses may take part in media campaigns that identify risk factors for abuse. Nurses can lead in developing after-school programs and late-night programs that support young people to work toward positive goals and to develop a constructive support network. These primary prevention efforts should be broad-based, to include vulnerable youth populations such as sexual minorities, that is, a group whose sexual orientation and practices are different from the majority in a given society (Walters et al., 2013). Nurses can identify community needs and resources by capacity mapping. The identification of strengths and weaknesses can assist in determining future goals and needed interventions for the good of the community.

Primary prevention of abuse includes strengthening individuals and families so they can cope more effectively with multiple life stressors and demands, and mitigating the risk factors in the community that increase the risk of violence. Providing support and psychological enrichment to at-risk individuals and families often prevents the onset of health disruption. For example, nurses can strengthen and teach parenting abilities. A class, clinic, or home visiting services can include basic skills such as diapering, feeding, quieting, and even holding and rocking. Parents also need to learn acceptable and effective ways to discipline children so that limits are maintained without causing the child emotional or physical harm. Home visiting interventions are the most widely used parenting intervention in the United States, and their adoption is growing globally. The Nurse-Family Partnership (NFP) provides intensive prenatal and postnatal home visitation, ideally to the child's second birthday. The intervention is delivered by registered nurses to low-income first-time mothers. Research on the NFP demonstrated that there was a reduced rate of verified cases of child maltreatment among program participants during the first two years of their children's lives. Additional research has demonstrated that these effects were sustained for when the children were 15 years of age, with families in the intervention (i.e., NFP) group having significantly fewer verified child maltreatment reports over that 15-year period (Eckenrode et al., 2017).

Mutual support groups are valuable for new parents, families of children with special needs, or abused people themselves. Such groups have variable formats and can provide information, support, and encouragement to facilitate positive outcomes. Nurses can help establish such groups, refer clients, or serve as group leaders. Chapter 19 describes the role of the nurse in working with community groups.

LEVELS OF PREVENTION

Violence

Primary Prevention
Strengthen individual and family by teaching parenting skills.

Secondary Prevention
Reduce or end abuse by early screening; teach families how to deal with stress and how to have fun and enjoy recreation.

Tertiary Prevention
When signs of abuse are evident, refer client to appropriate community organizations.

Secondary Prevention

When abuse occurs, nurses can initiate measures to reduce or end further abuse. Both developmental and situational crises present opportunities for abusive situations to develop. On a community level, nurses must form collaborative relationships to provide health services for battered women (McFarlane et al., 2005). There is a critical lack of appropriate services and resources available for many violence survivors, such as LGBT persons (Walters et al., 2013); nurses are key change agents in reaching vulnerable subpopulations. Researchers must work effectively with community agencies to use current research to screen for domestic violence and to use model treatments that have a positive effect on decreasing domestic violence (Humphreys & Campbell, 2010).

Nurses can be primary leaders in the development of screening practices in the health care arena (Alhusen et al., 2013). The development of training programs for health care providers can be an effective step in identifying and treating victims of

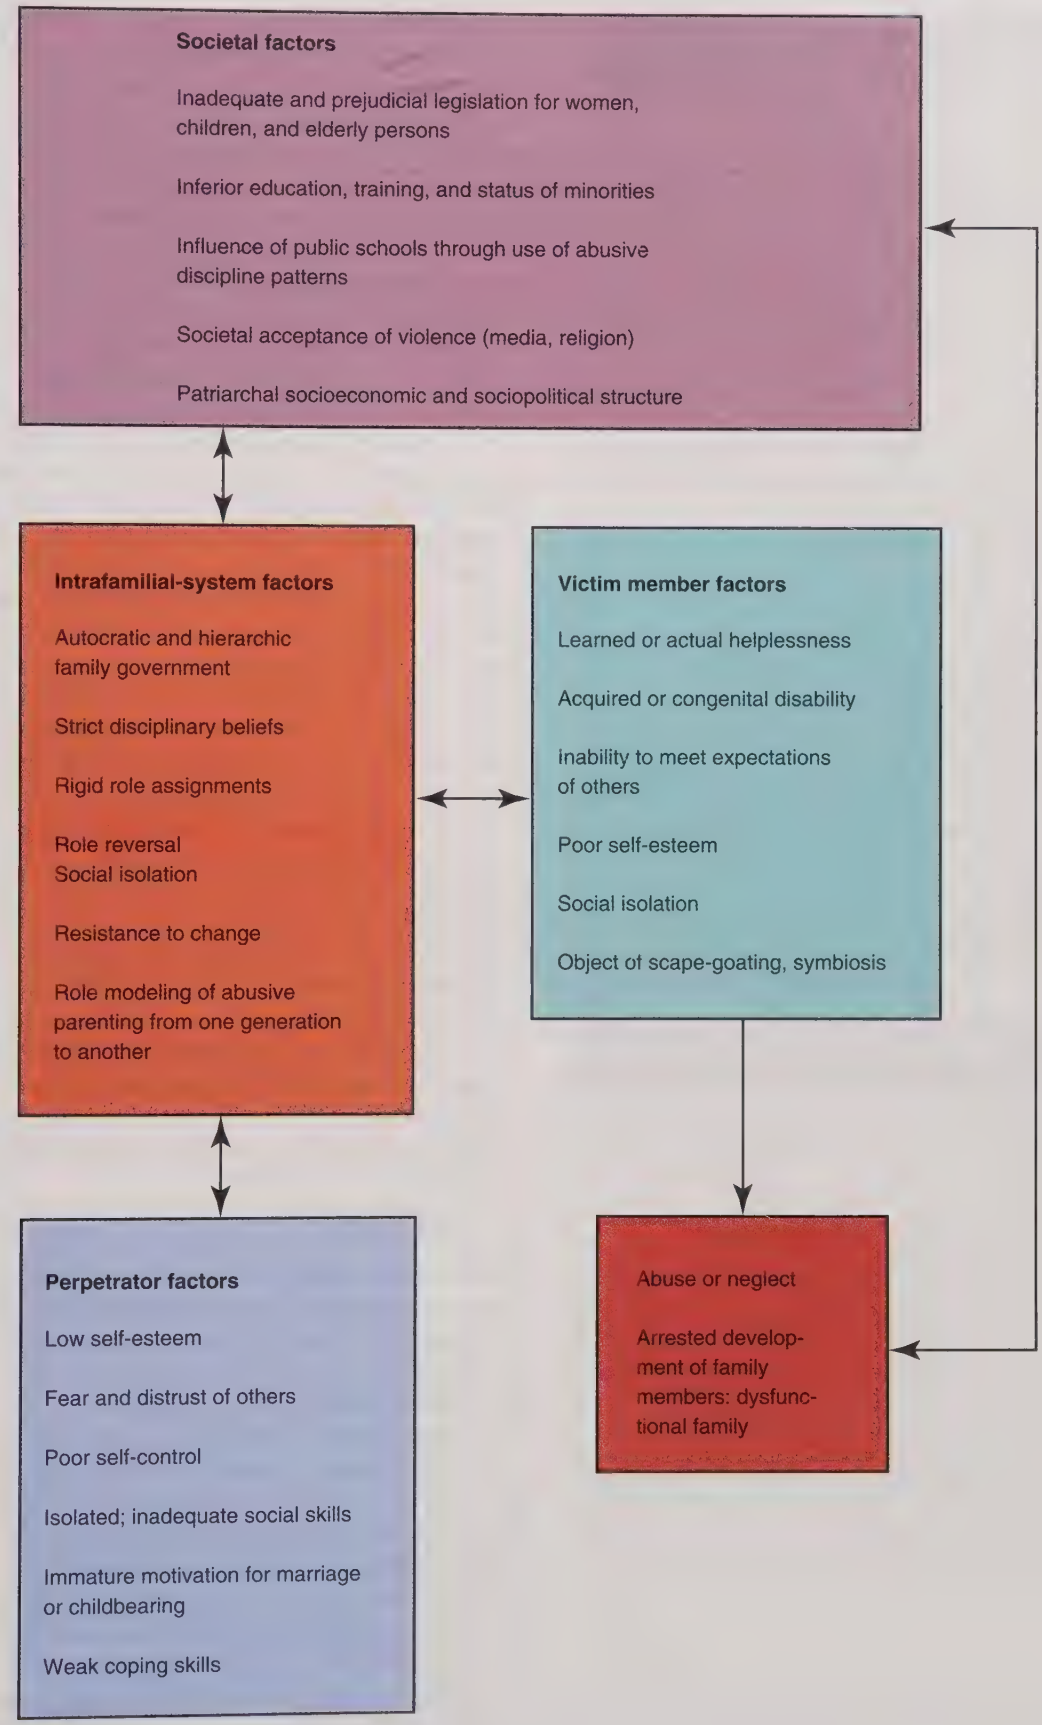

Fig. 38.2 Factors to include when assessing an individual's or a family's potential for violence.

BOX 38.2 Assessing for Violence in a Community Context

Individual Factors
- Signs of physical abuse (e.g., abrasions, contusions, burns)
- Physical symptoms related to emotional distress
- Developmental and behavioral difficulties
- Presence of physical disability
- Social isolation
- Decreased role performance within the family, and in job- or school-related activities
- Mental health problems such as depression, low self-esteem, and anxiety
- Fear of intimate others
- Substance abuse

Familial Factors
- Economic stressors
- Presence of some form of family violence
- Poor communication
- Problems with child rearing
- Lack of family cohesion
- Recurrent familial conflict
- Lack of social support networks
- Poor social integration into the community
- Multiple changes of residence
- Access to guns
- Homelessness

Community Characteristics
- High crime rate
- High levels of unemployment
- Lack of neighborhood resources and support systems
- Lack of community cohesiveness

BOX 38.3 Prevention Strategies for Violence

Individual and Family Levels
- Provide education on developmental stages and needs of children (primary).
- Teach parenting techniques (primary).
- Teach stress-reduction techniques (primary).
- Provide assessment during routine examination (secondary).
- Assess for marital discord (secondary).
- Provide counseling for at-risk parents (secondary).
- Encourage assistance with controlling anger (secondary).
- Provide treatment for substance abuse (tertiary).

Community Level
- Develop policy.
- Conduct community resource mapping.
- Collaborate with community to develop systemic response to violence.
- Develop media campaign.
- Develop resources such as transition housing and shelters.

violence. Nurses can work closely with domestic violence shelters in identifying the needs of individuals who seek sanctuary from abusive situations.

On a family level, nursing intervention can help family members discuss problems and seek ways to deal with the tension that led to the abusive situations. Injured persons must be temporarily or permanently placed in a safe location. Secondary preventive measures are most useful when potential abusers recognize their tendency to be abusive and seek help. For children, there is often a need for 24-hour child protection services or caregivers who can take care of the child until the acute family or individual crisis is resolved. Respite care is extremely important in families with frail older adult family members. Telephone crisis lines can be used to provide immediate emergency assistance to families.

Effective communication with abusive families is important. Typically, these families do not want to discuss their problems and many are embarrassed to be involved in an abusive situation. Often a lot of guilt is involved. Effective communication must be preceded by an attitude of acceptance. It is often difficult for nurses to value the worth of an individual who willfully abuses another. The behavior, not the person, must be condemned.

In addition, families do not always know how to have fun. Nurses can assess how much recreation is integrated into the family's lifestyle. Through community assessment, nurses know what resources and facilities are available and how much they cost. Families may need counseling about the value of recreation and play in reducing tension and appropriately channeling aggressive impulses.

Tertiary Prevention: Therapeutic Intervention With Abusive Families

Although it may be difficult for abusive families to form trusting relationships with health care providers, nurses can act as a case manager, coordinating the other agencies and activities involved. Principles of giving care to families who are experiencing violence include the following:
- Intolerance for violence
- Respect and caring for all family members
- Safety as the first priority
- Absolute honesty
- Empowerment

Nurses must clearly indicate that any further violence, degradation, and exploitation of family members will not be tolerated, and that all family members are respected, valued human beings. However, everyone must understand that the safety of every family member is the first priority.

Abusers often fear they will be condemned for their actions, making it difficult to maintain contact with abusive families. Although nurses convey an attitude of caring and concern for them, families may doubt the sincerity of this concern. They may avoid being home at the scheduled visit time out of fear of the consequences of the visit or an inability to believe that anyone really wants to help them. If the victim is a child, parents may fear that the nurse will try to remove the child.

Nurses are mandatory reporters of child abuse, even when only suspected, in all states. They are also mandatory reporters of elder abuse and abuse of other physically and cognitively dependent adults as well as of felony assaults on anyone in most states. The mandatory reporting laws also protect reporters

from legal action on cases that are never substantiated. Even so, physicians and nurses are sometimes reluctant to report abuse. They may be more willing to report abuse in a poor family than in a middle-class one, or they may think that an older adult or child is better off at home than in a nursing home or foster home. Referral to protective service agencies should be viewed as enlisting another source of help, rather than as an automatic step toward removal of the victim or criminal justice action. This same attitude can be communicated to families, so that reporting is done with families rather than without their knowledge and prior input. Absolute honesty about what will be reported to officials, what the family can expect, what the nurse is entering into records, and what the nurse is feeling is essential.

To further empower the family, the nurse needs to recognize and capitalize on the violent family's strengths, as well as to assess and deal with its difficulties. The nurse must use a nurse-family partnership rather than a paternalistic or authoritarian approach. Families can often generate many of their own solutions, which tend to be more culturally appropriate and individualized than those the nurse generates. Victims of direct attack need information about their options and resources, and they need reassurance that abuse is unfortunately rather common and that they are not alone in their dilemma. They also need reassurance that their responses are normal and that they do not deserve to be abused. Continued support for their decisions must be coupled with nursing actions to ensure their safety.

Nursing Actions. The nurse can meet the family's therapeutic needs in a variety of ways. Besides referral to appropriate community agencies, nurses can act as role models for the family. During clinic and home visits, nurses can demonstrate constructive adult-child interactions. Nurses often teach mothers childcare skills such as proper feeding, calming a fretful child, effective discipline, and constructive communication.

Nurses can demonstrate good communication skills and discipline by teaching both parents and children in a calm, respectful, and informative manner. Caregivers, especially those caring for children, people with special needs, or older adults, may need to learn age-appropriate expectations. It is unreasonable to expect a 14-month-old infant to differentiate between right and wrong. Children at this age do not deliberately annoy caregivers by breaking delicate pieces of china. Likewise, a person with poor sphincter control does not willingly soil clothes or bedding.

Role modeling can be used with abuse victims of all ages. When providing nursing care to abused spouses or to older adults, nurses can demonstrate communication skills, conflict resolution, and skill training. For example, adult children often become abusive toward their older parents when they become frustrated in trying to care for them. During home visits, nurses can show how to physically and psychologically care for the relative. The nurse can work with caregivers to help them develop approaches that are acceptable to the individual older adult. Assessment, creativity, and critical thinking help the nurse, family, and client learn how to meet client and family needs without causing undue stress and frustration.

BOX 38.4 Common Community Services

- Child protective services
- Child abuse prevention programs
- Adult protective services
- Parents Anonymous
- Domestic violence shelters
- Programs for children of battered women
- Community support groups
- 24-hour hotline
- Legal advocacy or information
- State/county coalition against domestic violence
- Batterer treatment
- Victim assistance programs
- Sexual assault programs
- Transition housing

Working with abusers and victims of abuse can be emotionally intensive and physically draining. Abusers present difficult clinical challenges because they are often reluctant to seek help or to remain actively involved in the helping process.

Referral is an important part of tertiary prevention. Nurses should know about available community resources for abuse victims and perpetrators. Some of these resources are listed in Box 38.4. If community attitudes and resources are inadequate, it is often helpful to work with local radio and television stations and newspapers to provide information about the nature and extent of human abuse as a community health problem. This also helps acquaint people with available services and resources. Frequently, people do not seek services early in an abusive situation because they simply do not know what is available to them. Ideally, a program or plan for abused people begins with a needs assessment to identify potential clients and to determine how to effectively serve this group. Nurses can help get programs started and provide public education.

Nursing Interventions Specific to Female Partner Abuse. Women experiencing IPV are often unlikely to voluntarily disclose their experiences unprompted. Even when women do recognize their experiences as abusive, only a small proportion seek specialized IPV services. Often, the presentation of IPV may not be obvious; rather, women may present with other complaints that could be indicators of abuse such as chronic gastrointestinal symptoms, headaches, chronic pelvic pain, sexually transmitted infections, or mental health conditions, including anxiety, depression, sleep disorders or substance use. It is therefore critical that health care providers are screening all women for IPV (Valpied & Hegarty, 2015). Despite the overall prevalence of IPV and its resultant physical and emotional health problems for women, health professionals, even those working in emergency departments, often fail to identify abused women. Some health care professionals are perceived as paternalistic, judgmental, insensitive, and less effective and helpful than they could be (Alhusen et al., 2010).

Because of the stigma and unease involved, women and health care providers may hesitate to initiate discussion about abuse. However, the majority of battered women claim they would have liked to talk about the issue with a health care professional if they were asked (Alhusen et al., 2013). Because abuse typically develops slowly, starting with minor psychological abuse and building to more severe physical incidents, victims and health care providers alike may not recognize the abuse until a severe episode occurs.

The quality of health care that a battered woman receives often determines whether she follows through with referrals to legal, social service, and health care agencies. The emergency department is the point of entry for many women in abusive relationships. Care in the emergency department is often fragmented and necessarily oriented toward addressing the most acute illness or injury. Therefore women may not be adequately assessed and often receive little or no support or referral to services to assist in dealing with the abuse. The initial response to disclosure of IPV should be one that validates her experience and provides support for her safety. It is imperative that women feel that they are believed and are not to be blamed. Nurses and other health care providers should also discuss that IPV is not an acceptable behavior and review its impact on the physical and mental health of the woman and any children. Finally, nurses should demonstrate their commitment to supporting the woman in whatever decision she makes. Even if a woman is not ready to leave an abusive relationship, a nurse's initial response will be critical in the likelihood of an abused woman returning for help (Valpied & Hegarty, 2015).

Managed care and clinic settings may be the best places to routinely screen for IPV. Ideally a clinical nurse specialist who is an expert in screening for IPV is available to coordinate efforts in the different health care settings. If battered women can be identified, perhaps effective interventions can be provided that will prevent the kind of serious injury that later results in emergency department visits or even a homicide.

However, some abused women hesitate to identify themselves as victims of domestic violence for several reasons. They may fear that revelation will further jeopardize their safety by increasing the violence, and they may also think that it will increase their sense of shame and humiliation. In addition, the nature of the systems in which victims of violence introduce themselves can be barriers. Emergency departments, clinics, managed care settings, and health departments are busy places. Staff members work hard to maintain the functioning of these facilities. Sometimes it is difficult in such chaotic settings for staff members to realize their importance as the first or only health provider to recognize violence in their clients' lives, and that women need them to take the time to deal with this issue (Straus et al., 2009).

Assessment. Assessment for all forms of violence against women should therefore take place for all women entering the health care system. The assessment should be ongoing and confidential. A thorough assessment gathers information on physical, emotional, and sexual trauma from violence, risk for future abuse, cultural background and beliefs, perceptions of the woman's relationships with others, and stated needs. Conduct the assessment in private and direct other adults who are present to the waiting area and tell them that it is policy that initially women are seen alone. Women should be asked directly if they were in an abusive relationship as a child or are currently in an abusive relationship as an adult. They should also be asked whether they have ever been forced into sex. Shame and fear often make disclosure difficult. Verbal acknowledgment of the situation and emotional and physical support assist women in talking about past or current circumstances (Valpied & Hegarty, 2015).

Women can be categorized into three groups: no, low, or moderate to high risk. Women with no signs of current or past abuse are considered at no risk. However, every future visit should include questioning a woman about whether there have been any changes in her life or whether she has additional information or questions about topics discussed at previous visits. If there is a new intimate partner in her life, she should again be screened for abuse. The Abuse Assessment Screen (AAS) is a four-question screen that has been successfully used in almost every kind of health care setting and can be downloaded from the Nursing Network on Violence Against Women International (NNVAWI) website (http://www.nnvawi.org).

Women at low risk show no evidence of recent or current abuse. Education that helps a woman gain perspective on her situation and her needs should be discussed. Resource materials including group and individual formats can be suggested. The risk level should be recorded and preventive measures and teaching should be documented.

Assessment of moderate to high risk includes evaluation of a woman's fear of both psychological and physical abuse. Lethality potential should be assessed and can be done with the Danger Assessment (DA), an instrument designed to assess the likelihood of lethality or near lethality occurring in a case of IPV (Campbell et al., 2009). The DA was developed based on data from a sample of women whose partners or ex-partners tried to kill them. The first portion of the DA assesses severity and frequency of abuse by presenting the woman with a calendar over the past year. The second part is a "yes/no" dichotomous response format of risk factors associated with intimate partner homicide such as:

- Has the physical violence increased in severity or frequency over the past year?
- Does he own a gun?
- Is he unemployed?
- Does he threaten to kill you?
- Does he ever try to choke you?
- Does he threaten to harm your children?
- Do you believe he is capable of killing you?

Based on the score, a woman's risk for intimate partner homicide is classified as low (8 or less); moderate (9-13); high (14-17), or extremely high (18 or higher). Based on the woman's score, health care providers can tailor counseling and provision of support services. The Danger Assessment is available at https://www.dangerassessment.org/ and is also available at the NNVAWI website (https://www.nnvawi.org/). In all cases, a

history of abuse and alcohol and drug use should be collected and carefully documented. The determined risk level should also be documented along with any past or present physical evidence of abuse from prior or current assault; this evidence should be photographed, shown on a body map, or described narratively. It is important that the assailant be identified in the record; this can take the form of either quotes from the woman or subjective information. These records can be very important for women in future assault or child custody cases, even if the woman is not ready to make a police report at the present time.

Many women are not ready to leave an abusive relationship at the time of screening for violence. It is important that health care providers are comfortable discussing strategies to promote a woman's safety while remaining in the abusive relationship. The discussion should also include her plan for leaving if that is what she ultimately decides; leaving an abusive relationship without a safety plan can increase a woman's danger. Strategies to consider may include keeping copies of vital records (e.g., birth certificates, Social Security cards, passports, medical information) and money hidden or with a trusted individual, discussing ways to protect any children involved, and understanding the steps for obtaining a restraining order (Paterno & Draughon, 2016). Women should also be provided with local resources such as advocacy groups, domestic violence specialists, or a local shelter. If the woman resides in an area with limited resources, such as a rural area, resources such as the National Domestic Violence Hotline (1-800-799-SAFE) and the National Sexual Assault Hotline (1-800-656-HOPE) should be made available. Determining the timing of the last abusive episode and whether sexual assault occurred is important as the jurisdictions have evidence collection time limits, often between 72 and 120 hours (Paterno & Draughon, 2016). Lists of resources such as rape crisis clinics and support groups for survivors of physical and emotional abuse should be made available.

Prevention. Prevention, public policy, and social attitudes are intertwined. Our society has taken a major step toward the secondary prevention of abuse through the establishment of programs that encourage women and children to speak about their experiences. Nurses need to support these programs further by supporting individuals and families confronted with violence. In the development of laws that punish perpetrators of child and women abuse, society has given some support to the victims of abuse. Often, however, the victims are again victimized by disbelief of their experiences, a devaluing of the effects of these assaults, and a focus on assisting the perpetrators of the crimes. Primary prevention includes a social attitudinal change. Both girls and boys need to be taught human values of interdependence, respect for human life, and a commitment to empathy and strength in the development of the human species regardless of sex, race, or socioeconomic status. We must urge continued progress toward eliminating the feminization of poverty and ensuring gender parity in economic resources. In addition, local communities must make it clear that violence against women is not tolerated. Examples of what communities can do include eliminating pornography, mandating arrests of abusers, and creating a general climate of non violence.

Abused women need assistance in making decisions and taking control of their lives. Public health nurses, prenatal nurses, Planned Parenthood, primary care, and emergency department nurses are involved with women when they can be screened for the presence or absence of abuse. There are mechanisms for routinely asking women who are either abused or at risk for abuse (Sharps et al., 2016). To intervene effectively, nurses must understand abuse as a cumulative process that must be examined as a continuum within the context of a relationship. During this process, the abuse, the relationship, and a woman's view of changes within herself require time-specific interventions. Women are often blamed and held responsible for the abuse inflicted on them by their male partners (Kennedy & Prock, 2018). When this happens, either they are assisted in a way that discounts their feelings and further devalues them, or the abuse is ignored.

Strategies for addressing education for health professionals. Various strategies have been reported that address the knowledge deficit of health practitioners on abuse issues. The National March of Dimes Birth Defects Foundation has sponsored a variety of training sessions for health professionals and produced an excellent training manual that addresses violence against women and battering during pregnancy (McFarlane & Parker, 2005). The program covers the assessment and planning of interventions to assist pregnant women in abusive relationships.

More and more nursing programs are implementing courses on how to intervene with IPV. Wallace (2009) developed and implemented a two-credit elective course focusing on attitudes, knowledge, and interventions in a structured learning environment to help nursing students acquire the expertise needed to work with women in abusive relationships. Organizations such as Futures Without Violence (https://www.futureswithoutviolence.org/) have numerous resources to support nurses in screening, and intervening in IPV. These include safety cards and other printed display material for health care settings as well as resource cards for nurses on how to assess safety, make referrals, and document findings. Additionally, there are many webinars and archived recordings on all aspects of violence that can be very helpful to health care providers caring for women, children, and families dealing with violence.

Nurses are also joining in community-based efforts to prevent and intervene with IPV and child abuse. Nurses work in public health collaborating with shelters for women, community mental health centers, criminal justice and advocacy institutions, and community-based health care. Bloom et al. (2009) developed a program to assist Latinas experiencing IPV. The program was developed specifically for the cultural and linguistic needs of the population. Emphasis was placed on assisting the Hispanic community in developing the knowledge and background to deal with the issue. At the same time, community efforts focused on expanding the knowledge base of the community at large about IPV.

PRACTICE APPLICATION

Mrs. Smith, a 75-year-old bedridden woman, became consistently rude and combative when her daughter Mary attempted to bathe her and change her clothes each morning. During a home visit, Mary told the nurse, Mrs. Jones, that she had become so frustrated with her mother on the previous morning that she had hit her. Mary felt terrible about her behavior. She stressed that her mother's incontinence made it essential that she be kept clean; her clothes had to be changed every day for her own safety and physical well-being.

A. How should Mrs. Jones respond to this disclosure?
B. What specific nursing actions should be taken?
C. What ongoing services does the nurse need to provide?

Answers can be found on the Evolve site.

KEY POINTS

- Violence and human abuse are not new phenomena, but they have increasingly become public health concerns.
- Communities throughout the United States are angry and frustrated about increasing levels of violence.
- Nurses can evaluate and intervene in incidents of community and family violence; to intervene effectively, the nurse must understand the dynamics of violence and human abuse.
- Factors influencing social and community violence include changing social conditions, economic conditions, population density, community facilities, and institutions within a community, such as organized religion, education, the mass communication media, and work.
- The potential for violence against individuals or against oneself is directly related to the level of violence in the community. Identification and correction of factors affecting the level of violence in the community constitute one way of reducing violence against family members and other individuals.
- Violence and abuse of family members can happen to any family member: spouse, older adult, child, or developmentally disabled person.
- People who abuse family members were often themselves abused and react poorly to real or perceived crises. Other factors that characterize the abuser are the way the person was raised and the unique character of that person.
- Child abuse can be physical, emotional, or sexual. Incest is a common and particularly destructive form of child abuse.
- Spouse abuse is usually wife abuse. It involves physical, emotional, and, frequently, sexual abuse within a context of coercive control. It usually increases in severity and frequency and can escalate to homicide of either partner.
- Nurses are in an excellent position to identify potential victims of family abuse because they see clients in a variety of settings, such as schools, businesses, homes, and clinics. Treatment of family abuse includes primary, secondary, and tertiary prevention and therapeutic intervention.

CLINICAL DECISION-MAKING ACTIVITIES

1. For one week, keep a log or diary related to violence.
   A. Make a note of each time you feel as though you are losing your temper. Consider what it might take to cause you to react in a violent way.
   B. Think back. When was the last time you had a violent outburst? What precipitated it? What were your thoughts? What were your feelings? How might you have handled the situation or those feelings without reacting in a violent way?
   C. During this same week, make note of the episodes of violent behaviors you observe. For example, do parents hit children in the supermarket? What seems to precipitate such outbursts? What alternatives might exist for reacting in a less violent way?
2. If you learned, after a careful assessment of your community, that family violence is a significant community health problem, what plan of action might you take to intervene? Remember that the goal is to promote health. Outline a plan of action with objectives, timetables, implementation strategies, and evaluation plans for intervening in family violence in your community.
3. Complete a partial community assessment to determine the actual incidence and types of violence in your community.
4. What resources are available in your community for victims of violence? Interview a person who works in an agency that seeks to aid victims of violence. What is the role of the agency? Do its services seem adequate? Who is eligible? Is there a waiting list? What is the fee scale?
5. Cut out all stories about violence that you find in your local newspaper every day for 2 weeks. Note the patterns. Is the majority of the violence perpetrated by strangers or family members? How are the victims portrayed? What kinds of families are involved? What kinds of stories and families get front-page treatment rather than a few lines in the back of the paper?

Advanced Nursing Practice in the Community

Sallie J. Shipman, EdD, MSN, RN, CNL, NHDP-BC, Melanie Gibbons Hallman, DNP, CRNP, CEN, FNP-BC, ACNP-BC, FAEN, and Patricia M. Speck, DNSc, APN, APRN, FNP-BC, DF-IAFN, FAAFS, FAFN, FAAN

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Discuss the historical development of the roles of the public health nurse in advanced nursing practice and the advanced nurse practitioner in public health.
2. Describe the educational requirements for population-focused advanced practice nurses.
3. Discuss certification/credentialing mechanisms in nursing as they relate to the roles of the advanced public health nurse and the advanced practice nurse.
4. Compare and contrast the various role functions and practice arenas of population-focused advanced public health nurses and advanced practice nurses in public health.
5. Explore current issues and concerns related to public health nursing practice.
6. Identify five stressors that affect nurses in expanded roles whether advanced public health nurses or nurse practitioners in public health.

CHAPTER OUTLINE

Historical Perspective
Competencies
Educational Preparation of Advanced Nursing Practice—NP Versus APHN
Credentialing
Advanced Practice Roles
Arenas for Practice
Issues and Concerns
Role Stress
Trends in Advanced Practice Nursing

third-party reimbursement, p. 865

This chapter explores the advanced nursing practice roles of both the clinical specialist in advanced public health nursing, and the advanced practice nursing specialties in the community. Why, one might ask, is this chapter in the text? For a few good reasons. One is the intent to provide the bachelor of science in nursing (BSN) student with an understanding of career opportunities that are available when continuing one's education to the graduate level. Another is for the nurse in a graduate program. The chapter provides an in-depth understanding of advanced nursing practices of both clinical specialties and advanced practice nurse roles in public health settings. The advanced nursing practice roles described in this chapter often collaborate, whether an advanced public health nurse or an advanced practice nurse. The role delineation offers excellent opportunities for two exciting careers that highlight potentials for major contributions impacting health outcomes of individuals and improving health rankings of populations of patients.

Advanced nursing practice (ANP) is broadly defined by the American Association of Colleges of Nursing (AACN) (2006) as:

> *any form of nursing intervention that influences health care outcomes for individuals or populations, including the direct care of individual patients, management of care for individuals and populations, administration of nursing and health care organizations, and the development and implementation of health policy. (p. 2)*

The **advanced nursing practice in public health** is a licensed professional nurse prepared at the master's or doctoral level to assume leadership roles by applying the nursing process and public health sciences to achieve specific public health outcomes for the community; this nurse is often referred to as an advanced public health nurse (APHN). Both the American Nurses Association (ANA, 2013) and the Association of Community Health Nursing Educators (ACHNE, 2007) refer to this specialized role as APHN; therefore APHN is the title that is used in this chapter. The APHN in the community may be an **advanced practice nurse** (APN) or a **nurse practitioner** (NP). An NP is generally a nurse with a master's or doctoral degree, who autonomously and in collaboration with health care professionals and other individuals provides a range of primary, acute, and specialty health care services (American Association of Nurse Practitioners [AANP], 2014b). The APHN and NP often work in similar settings. However, the client focuses differ. The NP's client is an individual or family, usually in a fixed setting, identifying individual or community trends in their practices, such as an outbreak of a sexually transmitted infection (STI). The NP works closely with the APHN (e.g., notifying of the STI outbreak), whose clients are individuals, families, groups at risk, or communities. The APHN's final goal is the health of the whole community (ANA, 2013; RWJF, 2017) (e.g., stopping the outbreak in the population). The APHN always has a population focus and obtains knowledge from nursing, social, and public health sciences to achieve goals of promoting and protecting the health of populations by creating conditions in which people optimize their health (ACHNE, 2007; ANA, 2013). Table 39.1 compares the functions taught to the APHN and the NP in their educational programs.

The chapter also provides a history of the educational preparation of the advanced practice nurse. The authors discuss the functions in advanced nursing practice and settings for practices, as well as issues and concerns, role negotiation, and areas of role stress relative to the APHN and the NP in the community.

TABLE 39.1 How to Distinguish Similarities and Differences in Functions of Advanced Public Health Nurses and Nurse Practitioners

Function	NP Program	APHN Program
Comprehensive assessment	Always	Often
Physiology and pharmacology	Almost always	Often
Diagnosis and management	Always	Often
Systems	Individual/family focus	More systems focused
Leadership	Usually	Almost always
Program planning and evaluation	Less often	Always in community and public health
Research	Generally	Generally

APHN, Advanced public health nurse; *NP,* nurse practitioner.
From Association of Community Health Nursing Educators (ACHNE): *Graduate education for advanced practice in community/public health nursing: at the crossroads,* Latham, NY, 2007, ACHNE; American Nurses Association (ANA): *Public health nursing: scope and standards of practice,* ed 2, Washington, DC, 2013, ANA.

HISTORICAL PERSPECTIVE

A shift in societal demands and needs resulted in changes in health care systems and nursing over the past few decades.

Trends influencing the roles of the APHN and NP include a shift from institution-based health care to population-focused health care (RWJF, 2017), improvements in technology, self-care, cost-containment measures, accountability to the client, **third-party reimbursement**, and demands for making technology-related care more responsive and client (patient) centered. Reversal of the Affordable Care Act (ACA) tax mandate in 2017 did not diminish the need for ANPs but did reverse self-reported insurance coverage trends. Rising health care costs for reduced coverage continue, and higher deductibles remain under current mandatory ACA rules.

The **clinical nurse specialist** (CNS) role began in the early 1960s and grew out of a need to improve client care. In addition to providing direct patient care, CNSs influence care outcomes by providing expert consultation for nursing staffs and by implementing improvements in health care delivery systems (National Association of Clinical Nurse Specialists, 2018). Concurrently, there was a shortage of physicians and an increasing tendency among physicians to specialize. The reduction in the number of physicians providing general medical care across the nation became a trend that continues today. Consequently, a serious and growing gap in **primary health care** (PHC) services developed, widening each decade. PHC includes both public health and primary health care services. The barriers to PHC include "(a) needed service delivery reforms to build a PHC-oriented system, (b) reforms to integrate public health initiatives into PHC settings, and (c) leadership to promote dialogue among stakeholders" (Gauld et al., 2012).

In 1965 at the University of Colorado, Dr. Loretta Ford, a nurse, and Dr. Henry Silver, a pediatrician, thought that the morbidity among medically deprived children might be decreased by nurses educated to provide well-child and sick care to children of all ages. The nursing practice for early pediatric nurse practitioners in Colorado included the identification, assessment, and management of common acute and chronic health problems, with appropriate referral of more complex problems to physicians (Silver et al., 1967). The nurse practitioner role in pediatric practice aligned with the priorities of the traditional nursing profession, which are to care for and support the well, the worried well, and the ill, offering physical care services previously provided only by physicians. Preparing nurses in the Colorado style, as primary health care providers, was responsive to the "fundamental shift in society's critical need for primary health care services," including health promotion and illness prevention (Institute of Medicine, 2011; RWJF, 2017).

Simultaneously in 1965, Duke University initiated the physician assistant (PA) role. The intent of the PA program was to attract former military corpsmen for training as "physician extenders" (Cooper et al., 1998). Often lumped with other nonphysician providers into a single category of "physician extenders," nurse practitioners and others promised to relieve the physician shortages (Wallen et al., 1982). Dr. Loretta Ford challenges the medicalization of the APN role as a physician extender by physicians in this excerpt:

> *As conceptualized, the nurse practitioner was always intended to be a nursing model focused on the promotion of health in daily living, on growth and development of children in families, and on the prevention of disease and disability. Nursing as a discipline and a profession evolved not because there was a shortage of physicians but because of societal needs. The early plans did not include preparing nurses to assume medical functions. The interests were in health promotion and disease prevention for aggregate populations in community settings, including underserved groups. These were the hallmarks of community-oriented nursing. (Ford, 1986, p. 6)*

When challenged as a threat to medical care, Wallen reported, "Patient acceptance and the quality of care rendered by these providers appear to be high" (Wallen et al., 1982). Early studies supported the report issued by the U.S. Department of Health, Education, and Welfare (now the U.S. Department of Health and Human Services [USDHHS]), *Extending the Scope of Nursing Practice* (1971), and helped convince Congress about the value of NPs as primary health care providers. The Nurse Training Act of 1971 (PL 92-158) and the comprehensive Health Manpower Training Act of 1971 (PL 92-157) provided education funding for many NP and PA programs through the 1970s and into the 1980s. Similarly, the concept of an expanded practice role for nurses was garnering interest in Canada in the 1970s. The United Kingdom followed suit in the 1980s and increased the number of advanced practice nurse programs available to educate and monitor the role's development. The number of NPs in the United States grew to a quarter million in 2018 (AANP, 2018), and while growing in numbers worldwide, the NP roles continue to experience barriers to practice and population barriers to health (Kleinpell et al., 2014).

Monitoring the roles in a variety of disciplines, graduate education for nursing began to change in the early 2000s. In 2007, the AACN called for the creation of a new nursing role—the clinical nurse leader (CNL) (AACN, 2017; AACN 2018). The **clinical nurse leader** is defined as a nurse who is a master's degree–prepared generalist who functions at the institution's microsystem level and assumes accountability for health care outcomes for a specific group of clients within a unit or area (AACN, 2018b; Commission on Nurse Certification, 2018; Foster et al., 2011). A prelicensure or licensed registered professional nurse, with graduate preparation (earned master's) from a CNL program, is an advanced nursing practice generalist, working at point of care facilitates providing direct patient care and focuses on "evidence-based practice, safety, quality, risk reduction, and cost containment" (Mohr & Coke, 2018, p. 141). The CNL is a clinical leader who, at the point of care, focuses on care coordination, outcome measurement, transitions of care, interprofessional communication, team leadership, risk assessment, implementation of best-practices based on evidence, and quality improvement.

In the 1990s, the seeds for doctoral preparation for the practicing nurse took root and early academic institutions' programs of study graduated the first practice doctorates in 1999 and 2000. By 2007, the AACN determined that the preferred preparation for advanced practice nurses' specialties should be the doctor of nursing practice (DNP) (AACN, 2017). Autonomous or freestanding schools were the first to offer a BSN-to-DNP and admit a small proportion of their applicants, who were typically part of a health professions school with doctoral research programs. Nurses with the doctor of philosophy (PhD) degree developed the first practice doctorates, and many continue to struggle with the differences between the two nursing doctorates—PhD (new knowledge) and DNP (quality improvement). Today, structural characteristics correlate with the consensus decisions to offer the BSN-to-DNP (Auerbach et al., 2015, pp. 23–24). There are stark differences between schools offering the BSN-to-DNP and those without the program of study, and many of the differences relate to capacity to offer the program of study. As more DNPs graduate, schools enlist their clinical expertise to teach in the DNP programs of study. Others offer faculty tenure tract positions to DNP graduates who demonstrate their national impact through scholarship.

COMPETENCIES

The Quad Council of Public Health Nursing Organizations, now the Quad Council Coalition, in 2003 developed a set of national public health competencies specific for public health nursing practice that reflect the *Core Competencies for Public Health Professionals* authored by the Council on Linkages Between Academia and Public Health Practice. The design for the core competencies served as a starting point for academic and practice organizations to understand, assess, and meet educational and workforce needs for health professionals practicing in public health; they were updated in 2018 (Quad Council Coalition [QCC], 2018). The Quad Council Coalition competencies are more specific to public health nursing, and the design of the tool assists agencies with language to describe workforce minimal competency for beginning positions and maximum competency needed for advancement in the employment of public health nurses. Academic settings benefit by using the competencies to prepare nurses with minimal skills as public health nurses. The competencies also are used to facilitate graduate education, agency orientation, on-the-job training, and lifelong learning (QCC, 2018) (see the Linking Content to Practice box).

The ANA, in 2013, revised and published *Public Health Nursing: Scope and Standards of Practice,* which includes population-focused standards of care in the following areas: assessment, population diagnosis and priorities, outcome identification, planning, implementation, evaluation, and standards for professional performance in ethics, education, evidence-based practice and research, quality of practice, communication, leadership, collaboration, professional practice evaluation, and resource utilization, environmental health, and advocacy. The basis of the document arose from the collaboration between the American Nurses Association and the American Public Health Association (APHA)-Public Health Nursing Section (2013). The document provided a definition and described the role of public health nursing practice. It minimally answered the following questions asked by ANA scope and standards of practice:

- **Who:** Registered Nurses (RN) and Advanced Practice Registered Nurses (APRN) comprise the "who" constituency and have been educated, titled, and maintain active licensure to practice nursing.
- **What:** Nursing is the protection, promotion, and optimization of health and abilities; prevention of illness and injury; facilitation of healing; alleviation of suffering through the diagnosis and treatment of human response; and advocacy in the care of individuals, families, groups, communities, and populations.
- **Where:** Wherever there is a client in need of care.
- **When:** Whenever there is a need for nursing knowledge, compassion, and expertise.
- **Why:** The profession exists to achieve the most positive client outcomes in keeping with nursing's social contract and obligation to society (ANA, Scope of Practice, 2018, items 1–5).

This second edition required the same rigor as the first, published in 2007. This revised edition "looks to the future of public health nursing and provides essential guidance in the form of standards and competencies for public health nurse generalist and the advanced public health nurse" (ANA, 2013). The document now includes competencies for the **advanced public health nurse** that appear at the end of each of the standards of practice. For example, under Standard 1: Assessment, additional competencies for the advanced practice nurse include the following: gathers data from multiple interdisciplinary sources as well as synthesizes qualitative and quantitative data during data analysis for a comprehensive population assessment (ANA, 2013).

EDUCATIONAL PREPARATION OF ADVANCED NURSING PRACTICE—NP VERSUS APHN

Educational preparation for the APHN includes a minimum of a master's degree and is based on a synthesis of current knowledge and research in nursing, public health, and other scientific disciplines. In addition to performing the functions of the generalist in population-focused nursing, the specialist possesses clinical experience in interprofessional planning, organizing, community empowerment, delivering and evaluating service, political and legislative activities, and assuming a leadership role in interventions that have a positive effect on the health of the community. ACHNE recommendations for graduate nursing education for the public health nurse specialty are guided by the report *Who Will Keep the Public Healthy?* (Institute of Medicine, 2003), the ANA's *Public Health Nursing: Scope and Standards of Practice* (2013), and the AACN's *Essentials of Doctoral Education for Advanced Practice Nursing* (2006). ACHNE has also identified five role characteristics of APHNs: (1) population-level health care focus; (2) ecological view; (3) responsibility for health outcomes for populations; (4) partnership and collaboration, using an interprofessional approach; and (5) leadership in practice. The identified curriculum areas

for the APHN are population-centered nursing theory and practice, interprofessional practice, leadership, systems thinking, biostatistics, epidemiology, environmental health sciences, health policy and management, social and behavioral sciences, public health informatics, genomics, health communication, cultural competence, community-based participatory research, global health, policy, and law, and public health ethics. In addition to didactic content, graduate education for the APHN includes practicum experience that takes place at the population level, is grounded in the ecological perspective, and includes the measurement of outcomes (ACHNE, 2007; RWJF, 2017).

In contrast to the APHN, educational preparation of the NP has not always been at the graduate level. Early NP programs were continuing education and certificate programs, and the baccalaureate degree was not easily attained, nor was it a requirement. At present, however, NPs are required to hold master's degrees and encouraged to obtain a practice doctorate (e.g., DNP) (AACN, 2017). The curriculum prepares NPs to perform a wide range of professional nursing functions, including assessing and diagnosing, conducting physical examinations, ordering laboratory and other diagnostic tests, developing and implementing treatment plans for some acute and chronic illnesses, prescribing medications, monitoring client status, educating and counseling clients, and consulting and collaborating with and referring to other providers (American Nurses Credentialing Center [ANCC], 2014).

In 2006, an AACN position statement supported advanced DNP education for ANPs and nurses seeking top systems and organizational roles. The eight foundational essentials for DNP programs are knowledge with a scientific underpinning, organizational and systems leadership, clinical scholarship, information systems, policy, collaboration, prevention and population health, and advanced nursing practice (AACN, 2006; AACN, 2015). Future recommendations for doctoral programs in nursing continue to be reviewed and discussed (Ketefian & Redman, 2015). The Academic Partnerships to Improve Health (APIH) is a collaborative between the AACN and the Centers for Disease Control and Prevention to help build capacity in the public health nursing workforce. The program supports faculty development in population health and connects nursing students with hands-on experiences at the community level to enhance their preparation for professional practice (AACN, 2018a; RWJF 2017).

CREDENTIALING

The American Nurses Credentialing Center (ANCC) and the American Association of Nurse Practitioners (AANP) offer certification examinations for a variety of specialties in advanced practice nursing. The purpose of professional certification is to confirm knowledge and educational expertise, but also provide recognition of professional achievement in a defined area of nursing. **Certification** is a means of assuring the public that nurses who claim to be competent at an advanced level have credentials verified through examination (ANCC, 2018). Although certification itself is not mandatory, many state boards of nursing require nurses in advanced practice, particularly those in an NP role, be nationally certified to practice.

The ANA began its certification program in 1973 and has continued to offer NP certification examinations since 1976. The ANA certification programs transitioned in 1984–1985, and ANCC began to offer certifications in 1991 in a variety of nursing specialties, primarily advanced practice nursing. Until 2009, a nurse was also certified as a generalist or as a BSN-prepared specialist in community health, and until 2017, a nurse could certify as an advanced public health nurse. However, ANCC closed both programs and currently no other certification programs exist for the APHN or PHN. Public health nursing was not the only casualty, because all rare non-NP advanced nursing practice certifications ended. Those holding non-NP certifications may maintain their certifications. In summary, since 1985, the basic qualifications for certification as an NP is a baccalaureate degree in nursing and successful completion of a formal NP program. As of 1992, a master's or higher degree in nursing is required for NP certification through the ANCC and AANP. NPs are required to maintain certification by renewing every five years.

Several nurse practitioner certifications are available at the ANCC. The examination topics vary, based on the specialty area (ANCC, 2018). The AANP also has national competency-based certification examinations in three areas: family, adult, and adult-gerontology primary care nurse practitioners (AANP, 2018a).

The certification examination for CNS in public/community health nursing was first offered in October 1990 and required a master's or higher degree in nursing with a specialization in community/public health nursing practice. Effective in 1998, eligibility requirements included holding a master's or higher degree in nursing with a specialization in community/public health nursing or holding a baccalaureate or higher degree in nursing and a master's degree in public health with a specialization in community/public health nursing. In 2009, the ANCC Commission changed the certification examination from clinical nurse specialist in public/community health to either advanced public health nursing or public health clinical nurse specialist. However, as of December 31, 2013, these examinations are no longer available. If one already holds these certifications through examination, they are renewed with professional development and practice hours. Effective January 1, 2014, an advanced public health nurse-board certified (APHN-BC) credential is obtained by the "certification through portfolio assessment" method (ANCC, 2018). However, in 2017, the APHN-BC, along with others, was no longer offered to new graduates; if certification is current, renewal is possible (ANCC, 2018). Certification is not a requirement for practice in public health nursing or advanced practice public health nursing.

ADVANCED PRACTICE ROLES

APNs holding a master's degree in nursing or DNP and specializing in public health nursing, in community health nursing, or

as a nurse practitioner have many roles, which are described here. It should be noted that the "nursing role in APPHN [advanced practice public health nursing] is not distinguished by the sites at which nurses practice, but rather by the perspective, knowledge base, and principles that focus on care of populations" (ACHNE, 2007, p. 16). The APHN's role characteristics include a focus on population health such as population and community assessment; advocacy and policy setting at the organizational, community, and state levels; ecological view for large-scale program planning and project management; and leadership and partnership building. APHNs deliver population-focused services, programs, and research (ACHNE, 2007; APHA, 2013).

Clinician

Most of the differences between the roles of the APHN and the NP are seen in clinical practice. Although the APHN's practice includes nursing directed at individuals, families, and groups, the primary responsibility is to take a leadership role in the overall assessment, planning, development, coordination, and evaluation of innovative programs to meet identified community health needs. The APHN provides the direction for population-focused health care by identifying and documenting health needs and resources in a community and in collaborating with population-focused nurse generalists, other health professionals, and consumers (ACHNE, 2007; APHA, 2013). Practicing within the role of **clinician**, the APHN involvement is in conducting community assessments; identifying needs of populations at risk; and planning, implementing, and evaluating population-focused programs to achieve health goals, including health promotion and disease prevention activities. The APHN ultimately works toward the goals of promoting and protecting the health of populations by creating conditions for optimal health (ANA, 2013; APHA, 2013).

The NP applies advanced practice nursing knowledge and physical, psychosocial, and environmental assessment skills to manage common health and illness problems of clients of all ages and genders. The NP's primary client is the individual and family. In the direct role of clinician, the NP assesses health risks and health and illness status, as well as the response to illness of individuals and families. The NP also diagnoses actual or potential health problems; decides on treatment plans jointly with clients; intervenes to promote health, to protect against disease, to treat illness, to manage chronic disease, and to limit disability; and evaluates with the client and other primary care team members about how effective and comprehensive the nursing intervention may be in providing continuity of care (AACN, 2011). Despite the setting, the practice of the nurse practitioner can be population focused. Common interventions often include community assessment and analysis, case finding, an emphasis on prevention, and participation in public policy. An advanced practice nurse in the community works in agencies or settings where the caseload consists of individuals who present themselves for services. The APHN goal is to identify others in the community who are at risk and in need of the services. Outreach activities accomplish these goals while also trying to accomplish the goals and objectives of *Healthy People 2020* (Box 39.1). Currently, planning is underway for *Healthy People 2030.*

BOX 39.1 Example of a *Healthy People 2020* Objective and Selected Advanced Practice Nursing Activities

Objective

- MHMD-1: Reduce suicide rate to no more than 10.2 suicide deaths per 100,000 people.

Activities

- Review recent literature and epidemiology of suicide.
- Provide in-service education programs to groups of health professionals related to groups at risk for suicide and related assessment and screening tools for early detection and treatment of depression.
- Become active in legislation activities related to firearm access.
- Assess individual clients for depression and suicide risk.

U.S. Department of Health and Human Services: *Healthy People 2020,* Washington, DC, 2014, U.S. Government Printing Office. Retrieved from https://www.healthypeople.gov/.

The ability of NPs to diagnose and treat increased the access to health care, teaching, and client compliance with treatment plans. State legislation guides the amounts of physician involvement in the NP's practice (AANP, 2018b). In states requiring relationships between the physician and nurse practitioner, the NP uses **protocols** or algorithms previously agreed on by the physician and the NP. The documents serve as standing orders for the management of certain illnesses. As of 2010, all states passed legislation, either partial or full, granting NPs supervisory, collaborative, or independent authority to practice. Each state has differing regulatory and legislative mandates regarding NP areas of practice authority, reimbursement, and **prescriptive authority** (Phillips, 2017). The most up-to-date information on state nurse practitioner practices and laws is available through the American Association of Nurse Practitioners (AANP) website (https://aanp.org/).

An important area for both APHNs and NPs to include in their advanced practice is health promotion/disease prevention. Within the past several decades, there has been a growing belief that the most effective way of dealing with major health problems is through prevention. Refocusing toward prevention requires the health care system to identify aggregates (populations) at risk, introduce risk reduction interventions, teach people that they control their own health, and encourage health promotion and disease prevention behaviors. The Patient Protection and Affordable Care Act (PPACA, 2010) goals continue at this printing and include improvement of the individual health care experience, reduction of the cost of health, and improvement of the health of populations; these create the potential for new public health nursing roles and responsibilities. Regardless of the outcome, public health nurses in the community (through their assessment skills, primary care focus, and system-level perspectives) are vital to the interprofessional teams necessary to ensure that all people have equitable access to high-quality care and healthy environments through health systems (APHA, 2013). The USDHHS (2014a) develops national objectives for promoting health and preventing disease.

Since 1997, this initiative, called *Healthy People* in 2000, 2010, 2020, and planning for 2030, has set and monitored national health objectives to meet a broad range of health needs, encourage collaboration across sectors, guide individuals toward making informed health decisions, as well as measure the impact of prevention activities. The *Healthy People* campaign is essential to measure outcomes for APHNs and NPs working toward the goal of a healthier nation. Nurses and advanced practice nurses also use *The Guide to Clinical Preventive Services* to address health promotion and disease prevention and 2018 *Preventive Health Care Guidelines* (CDC, 2018; USDHHS/AHRQ/USPSTF, 2014). APHNs and NPs are especially involved in helping meet the proposed objectives in equity in health care services, including access, educational and community-based programs, and public health infrastructure domains.

Population-Focused Intervention

The following example illustrates a population-focused intervention. An APHN was recently hired at a community hospital in the hospital's community health department. Traditionally, the department provided excellent health education and screening programs to individuals in the surrounding communities. However, outreach activities did not occur. After reviewing the data on attendance at community health events, the APHN developed and implemented a needs assessment in three neighboring communities not attending the events. In one neighborhood, consisting of 1800 apartments, 85 percent of the population was middle-income African Americans of all ages. The needs assessment revealed a strong interest in health promotion and disease prevention but nevertheless a lack of participation. The APHN developed a collaborative relationship with churches and community groups in the neighborhood. Health fairs and events were initiated (see the Levels of Prevention box).

LEVELS OF PREVENTION

Population-Focused APHN Activities

Primary Prevention
- Flu immunizations at churches
- Classes on breast self-examination
- Education on the need for early detection of breast cancer

Secondary Prevention
- "Men's Night Out" event with screenings for blood pressure and cholesterol (at neighborhood sites)
- Health fair at neighborhood sites with screenings

Tertiary Prevention
- Identified need and follow-up at clinics for groups with chronic diseases (diabetes, cancer, hypertension)

Educator

Nurses in advanced practice function in several indirect nursing care roles, including that of **educator.** The role of the APHN and NP includes health education within a nursing framework (as opposed to health educators, who do not have a nursing background) and professional nurse educator (faculty) roles.

The APHN identifies groups at risk within a community and implements, for example, health education interventions. The APHN and NP increase wellness and contribute to maintaining and promoting health by teaching the importance of good nutrition, physical exercise, stress management, and a healthy lifestyle. Health educators also provide education about disease processes and the importance of following treatment regimens. In addition, they provide anticipatory guidance and educate clients on the use of medications, diet, birth control methods, and other therapeutic procedures (ACHNE, 2007; ANA, 2013; APHA, 2013). They also counsel clients, families, groups, and the community on the importance of assuming responsibility for their own health. The health educators provide education to individuals, families, or groups at institutional and ambulatory levels, or home settings, or it occurs in the community with vulnerable at-risk populations. As professional nurse educators, the APHN and NP also provide formal and informal teaching of staff nurses and undergraduate and graduate students in nursing and other disciplines (Fig. 39.1). They also serve as role models by instructing (or being a preceptor to) students in advanced nursing practice in the clinical setting.

Administrator

The APHN and NP function in administrative roles. As a health **administrator,** they are responsible for all administrative matters within an agency setting. They are responsible for and have direct or indirect authority and supervision over the organization's staff and client care. In this capacity, nurses in advanced practice serve as decision makers and problem solvers. They are also involved in other business and management aspects such as supporting and managing personnel; budgeting; establishing quality control mechanisms; program planning and influencing policies; public relations; and marketing (ACHNE, 2007; Drennan, 2012; Quad Council Coalition, 2018).

Fig. 39.1 An advanced practice public health nurse leads a training session for a group of congregational nurses.

Consultant

Consultation is an important part of practice for APHNs and NPs. The consultant solves problems for and with individuals, families, or communities to improve health care delivery. Steps followed throughout the consultation process include assessing the problem, determining the availability and feasibility of resources, proposing solutions, and assisting with implementing a solution, if appropriate (AACN, 2011; APHA, 2013). The APHN and NP serve as a formal or informal **consultant** to other nurses, providing them with information on improving client care. Consultants counsel physicians and other health care providers and organizations or schools to improve the health care of clients. For example, nurse consultants are often used at the district or state level of public health departments. APHNs and NPs work closely with nurse supervisors, other NPs, and staff public health nurses to develop programs and improve the services provided to clients at clinics and in the home. Nurse consultants in the public health arena work with all other public health nurses or work in departments as members of an interprofessional team such as maternal–child health, chronic diseases, or family planning (University of Michigan Center of Excellence, 2013).

Researcher

Improvement in nursing practice depends on the commitment of nurses to developing new knowledge and refining practice improvements through application to research. Government and other funding sources now encourage research–practice partnerships, collaborating with stakeholders, for funding in the community of interest. Researchers may be academicians or may be nurses with dual PhD and practice doctorates, as well as being a practicing NP or APHN! Practicing APHNs and NPs are in ideal positions to identify researchable nursing problems for researchers that relate to the communities they serve. Collaborations are encouraged in community-based participatory research applications for funding, and when complete, the community of providers apply their research findings to the community health practice setting of interest.

All APHNs and most NPs have training in the research process and, as **researchers**, conduct their own improvement science investigations and collaborate with doctorate-prepared nurses, answering questions related to nursing practice improvement and primary health care. The acts of identifying, defining, and investigating clinical nursing problems and reporting findings encourages peer relationships with other professions and contributes to health care policy and decision making (Harne-Britner & Schafer, 2009). For example, APHNs in administrative, consultant, or practitioner roles encounter situations daily that need improvement and further investigating (e.g., noncompliance with certain public health regimens or immunization schedules). They, anecdotally or through needs assessments, identify a trend for which, if examined, population-based strategies can be implemented (see the Evidence-Based Practice box). APHNs and NPs collaborate with population-focused nurses at all levels to develop the research design, collect and analyze the data, and determine the implications for further use of nursing interventions identified and are co-authors in dissemination. APHNs play a critical role in ensuring that evidence-based research is shared and integrated into health care practice (APHA, 2013; Harne-Britner & Schafer, 2009; Issel et al., 2011).

EVIDENCE-BASED PRACTICE

Although cancer incidence and mortality are declining, cancer remains among the leading causes of death in the United States. Research shows that cancer morbidity and mortality can be reduced by early detection. However, both cancer risks and screening behavior remain understudied in the homeless population. A cross-sectional survey of homeless individuals (n = 201) was conducted. The analysis describes the demographic, psychosocial, and behavioral associations with cancer screenings and knowledge of the lung cancer screening recommendation among homeless populations

The study participants' mean age was 51.7 years; the group was largely African American (77.3 percent) and male (67.9 percent). Among women, the breast and cervical cancer screening rates were 46.5 percent (breast) and 85.1 percent (cervical). Among men, the prostate cancer screening rate was 34.2 percent. Among all participants, the colon cancer screening rate was 44 percent. Lung cancer screening knowledge was low (23.0 percent). Cancer risk behaviors were high with participation in cancer screening below national benchmarks and was associated with age, income, health status, obesity, tobacco use, and physical activity.

Nurse Use

To improve cancer survival among disparate populations, sustained community outreach is necessary to increase awareness of screening recommendations, to identify high-risk individuals, and to guide them to available resources.

Williams LB, McCall A, Looney SW, et al.: Demographic, psychosocial, and behavioral associations with cancer screening among a homeless population. *Public Health Nurs* 35(4):281-290, 2018.

ARENAS FOR PRACTICE

Regardless of where public health nurses work (e.g., schools, homes, clinics, jails, shelters, mobile vans, or after a disaster), the core interventions to accomplish the goals of promoting and protecting the health of populations are similar across all practice arenas. Positions for APHNs and NPs vary greatly in terms of scope of practice, degree of responsibility, power and authority, working conditions, and innovation. The factors and the impact on practice are influenced by nurse practice acts and other legislation (e.g., reimbursement and prescriptive privileges) that govern the legal practice in each state (Phillips, 2017). The following areas include traditional as well as alternative practice settings for APHNs and NPs.

Primary Care

Research indicates that the opportunities for APNs in primary care settings is increasing, and the trend is expected to continue (APHA, 2013; Fairman et al., 2011). Primary care settings such as private practices, large health systems, community health centers, patient-centered medical homes, and others provide various roles for the advanced practice nurse. For example, many practices employ NPs, physician's assistants, RNs,

licensed practical nurses, pharmacists, behavioral health providers, community health workers, and physicians to provide care in formal or informal team structures (Flinter et al., 2017). Over 40 years of evidence demonstrates that nurses in rigorous education programs of study in primary care from accredited academic settings produce the same high-quality providers and care, achieving equally positive health outcomes for the patient as physicians. In general, preliminary research found no appreciable differences between physicians and nurses in health outcomes for clients, process of care, resource utilization, or cost (Laurant et al., 2018).

Independent Practice

Nurses form an **independent practice** for several reasons. Reasons vary and include personal goals of access to care in remote areas, not served by others, or a professional desire to break new ground for nursing in meeting the health care needs within all communities. Today, some enter the profession for the independence, job security, and pay. It is important to investigate the state's nurse practice act to determine the limitations and laws related to the practices available for NPs. For example, NPs provide a comprehensive array of health services in states where they have legislative authority to prescribe drugs. Nurses in many states successfully lobbied for third-party reimbursement for all RNs who provide direct care services to individual clients (Phillips, 2017). The independent practice option is more likely to be chosen by APHNs and NPs in states that have established legislation to provide structure to guide their nursing practices.

Another option for APHNs and NPs interested in an entrepreneurial independent practice is to contract with physicians or organizations to provide certain services for their clients or staff. Nurses need to define a service package and market it attractively. An example for APHNs is providing a home visit to new parents after two weeks to assess the newborn, respond to parental concerns, and provide counseling and anticipatory guidance about nutrition, development, and immunization needs. This service may be marketed to pediatricians and family practice physicians who would offer or recommend the service to their clients as an option. An NP negotiates with a local school board to provide preschool children with health examinations or physical assessments before the children participate in sports. Under a contract, APHNs develop and implement health and safety programs on accident prevention and health promotion activities for small companies.

Nursing Centers

Nursing centers or nurse-managed health clinics, a type of joint practice developed by advanced practice nurses to address vulnerable populations, provide opportunities for collaborative relationships for APHNs, NPs, baccalaureate-prepared nurses, other health care professionals, and community members (National Nursing Centers Consortium, 2018). Primary health services are provided by NPs, depending on state legislation. Community APHNs, along with nurses and nursing students, focus on the neighborhood level and understand community needs. A central mission of nurse-managed clinics is community development such as health care accessibility and resources; public involvement; interprofessional practice; and health promotion and disease prevention supported by the principles of primary health care (National Nursing Centers Consortium, 2018). Nursing center models are discussed in more detail in Chapter 20.

Retail Clinics

Retail clinics are staffed primarily by NPs with convenient hours. The first retail clinic opened in Minneapolis in 2000, but their growth between 2006 and the present is substantial. They offer routine preventive and acute care services, usually covered by a protocol for consistent care between agencies. Although still generally operated by large retail pharmacies, involvement of hospital systems in retail clinic ownership is a more recent phenomenon (IOM, 2018; RAND Corp., 2016).

Faith Community Nursing/Parish Nursing

Faith community nursing, also known as **parish nursing**, is a concept that began in the late 1960s in the United States when increasing numbers of churches employed registered nurses to provide holistic, preventive health care to congregation members. Faith community nursing is a model of care that uses nurses based within faith communities such as churches and synagogues to provide health services to the members of those communities. Faith community nursing is a practice specialty that focuses on the intentional care of the spirit, promotion of an integrative model of health, and prevention and minimization of illness within the context of a faith community. Although primarily for faith community nurses and the nursing profession, it is also aimed at other health care providers, spiritual leaders, families, and members of faith communities (ANA, 2017).

The activities are complementary to the population-focused practice of APHNs, and faith community nurses either have a strong public health background or work directly with both baccalaureate-prepared nurses and APHNs. Faith community nurses positively affect client outcomes by providing health services in health promotion and disease prevention, chronic disease management, and culturally sensitive services (Roberts, 2014). See Chapter 45 for further discussion about faith community/parish nursing.

Institutional Settings

Ambulatory/Outpatient Clinics. APHNs and NPs have employment in the primary care unit of an institution (e.g., the ambulatory center or outpatient clinic). The centers/clinics generally provide hospital referral, hospital follow-up care, and health maintenance and management for nonemergency problems. The population served is usually culturally and economically diverse and represents a larger geographic area than patients served by private practices. In the outpatient settings, NPs typically practice jointly with physicians to provide acute and chronic primary care. Hospital acute care outpatient services include clinics for general medicine or family practice, or specialty-oriented clinics, such as pediatric,

obstetrical-gynecological, and ear, nose, and throat clinics. Outpatient clinics organized for chronic care are problem-oriented (e.g., hypertension, diabetes, or acquired immunodeficiency syndrome [AIDS] clinics).

Emergency Departments. Persons without access to health care, such as the medically uninsured and the homeless, often do not seek health care services until they become ill. Hospital emergency departments (EDs) are increasingly used for nonemergency primary care. Although use of an emergency department is an inappropriate use of expensive health services, it is a result of the current system, which limits access to routine and preventive health care. Emergency department care is one of the most expensive services offered in health care today (Wood et al., 2010).

Emergency services often require long waits for persons who have nonemergency problems. Fast-track/nonemergency zones or areas (sometimes called urgent care) of EDs have become commonplace to accommodate these situations. NPs in these settings see clients with nonemergent problems and provide necessary treatment and applicable counseling. APHNs also educate clients about the importance of health care and methods to gain access to the preventive health care system. APHNs, with their knowledge of community health resources, help ensure that psychosocial needs are assessed and met. APHNs often act as liaisons or mediators for community programs that serve the needs of special populations.

Long-Term Care Facilities. The elderly age group represents the fastest-growing population (especially those over 85 years of age) in the United States (Administration on Aging, 2017). The data reveal a long-anticipated trend that we are living longer, resulting in a higher percent of elderly Americans. By 2040, it is projected that 82.3 million people will be age 65 or older, twice the number of older Americans in 2000. Past statistics revealed a shortage of advanced practice nurses specializing in gerontological nursing to care for the growing older adult population (Donald et al., 2013).

Gerontology is an increasingly important field of study, and many courses are available on the health needs of older adults. APHNs and NPs with an interest in geriatrics need to continue their education in this area to increase their knowledge and skills specific to this at-risk aggregate (Donald et al., 2013). Many APHNs and NPs view long-term care facilities as exciting areas for practice and a way of increasing quality of care while containing costs for older adults and the disabled. U.S. federal legislation provides reimbursement for APHNs and NPs to provide care to clients in Medicare-certified nursing homes and to recertify eligible clients for continued Medicare coverage. In long-term care facilities where clients are not ambulatory, APHNs and NPs make regular nursing home rounds, assess the health status of clients, and provide care and counseling as appropriate. In long-term care facilities in which the residents are more ambulatory, APHNs and NPs also provides health maintenance and other primary health care services to the nursing home clients.

Industry/Occupational Health. The *Healthy People 2020* (USDHHS, 2018a) objectives include a section on occupational health and safety with goals to reduce work-related injuries and deaths. Thousands of new cases of disease and death occur each year from occupational exposures.

APHNs and NPs are increasingly useful in occupational health programs as business and industry seek ways to control their health care costs and to provide preventive and primary on-site care services. The services help reduce absences from work and increase productivity of workers. The APHN or an occupational health nurse in an industrial/occupational setting assesses the health needs of the organization based on claims data, cost-benefit health research, results of employee health screening, and the perceived needs of employee groups (Levin et al., 2013). The APHN working as an occupational health nurse can receive certification in the specialty as a Certified Occupational Health Nurse (COHN) or Certified Occupational Health Nurse-Specialist (COHN-S) (AAOHN, 2018). With their advanced administrative and clinical skills, APHNs plan, implement, and evaluate company-wide health programs. The role of the occupational health nurse is discussed in Chapter 43.

Government

U.S. Public Health Service. The U.S. Public Health Service operates the National Health Service Corps (NHSC), which places health providers in federally designated areas with shortages of health workers; and the Indian Health Service, which provides health services to American Indians.

During the 1970s, both the Corps and the Indian Health Service offered to pay to educate RNs to become nurse practitioners if they promised to work for a designated period with the Public Health Service. These programs were discontinued during the 1980s when more emphasis was placed on physician recruitment. In 1988, Congress reauthorized two loan repayment programs for the education of NPs—one with the Corps and one with the Indian Health Service. In 2009, the American Recovery and Reinvestment Act invested an additional $300 million into the Corps, hoping to double its field strength by providing more scholarships and loan repayment options for health care providers. Depending on the needs of the area, an NP employed by the Public Health Service is the only health care provider in the setting or practices with a group of providers to serve a rural, an urban underserved, or an American Indian population (USDHHS, 2018b).

Armed Services. The increased availability of physicians reduced the active recruitment of nurses to advanced degree programs by the armed forces during the 1980s. NPs are used in ambulatory clinics serving active duty and retired personnel and their dependents. Care of the war veterans with post-traumatic stress disorder, amputation, and multiple rehabilitation needs, along with integration into the community, is ongoing and essential (Military Health System, 2018). APHNs use their skills with needs assessment and program planning/evaluation to develop programs aimed at improving the health of the aggregate military population. In 2016, the U.S. Department of

Veterans Affairs (VA) granted full practice authority to NPs (U.S. Department of Veterans Affairs, 2016).

Public Health Departments. Public health departments are increasingly employing advanced practice nurses with master's degrees. These APHNs and NPs have administrative and clinical skills to work collaboratively with physicians and to manage and implement clinical services provided by the health departments. Home care and hospice services are nursing sections in many public health departments and require the services of population-oriented nurse clinical specialists.

Health departments also provide primary care services in well-child clinics, family planning clinics, and general adult primary health care clinics. A public health department uses NPs and APHNs, depending on the size of the department, the department's health priorities in the community, and financial constraints.

APHNs possess basic competencies for responding to disasters whether the health threats are natural, intentional, or technological (mass casualty incidents, unfolding infectious disease outbreaks, bioterrorism, or evolving environmental disasters). APHNs are well positioned to collaborate with leaders of the community to develop and implement systems-level preparedness and response plans for populations before, during, and after an event (Aiken, 2011; University of Michigan Center of Excellence, 2013).

CHECK YOUR PRACTICE

You have recently graduated from the BSN program at the local university. You have accepted a position as a school nurse and you are going to be working with an advanced practice public health nurse. What is the difference in your practice in the school system and the APHNs? Where will you go to find the differences in practice in your state? What do you see as your role in improving the health of the population of school children?

Schools. School health nursing, discussed in Chapter 42, involves comprehensive assessment and management of care, with emphasis on health education, to promote healthy behaviors in children and their families. Innovative practice occurs in school nursing (RWJF, 2013). APHNs and NPs are employed as school health nurses by school boards or county health departments to provide specific services to schools, such as confirming that immunization status is current; performing hearing and vision screenings; and providing many organizational, community assessment, and political functions. School-based health services are staffed by APHNs and/or nurses prepared as school, pediatric, or family nurse practitioners. Services provided by these advanced nurse practitioners include not only basic health screening but also monitoring of children with chronic health problems and finding health care for children with limited access to medical care. The nurses work collaboratively with parents, community leaders, educators, and physicians to ensure that each child within the school community receives needed services. APHNs and NPs are well suited to manage school health services if they meet specific criteria developed by individual states.

Other Arenas

Home Health Agencies. Major legislative changes in Medicare and third-party reimbursement for hospital services resulted in unprecedented growth in the home health care industry through the 1990s. Home health care is less expensive than extended hospital care and thus is an attractive option for third-party payers (Riggs et al., 2011). In addition, equipment and drug companies are developing products for home use, physicians and hospitals are exploring the development of home services, and consumers are demanding more services. Advanced practice nurses have traditionally been involved in home care in many capacities. Because of their knowledge and skills in the following areas, APHNs and NPs are well qualified to provide home health care that yields positive outcomes for clients and their families. Home health APNs engage in holistic health assessments and coordinate services with an interprofessional team for clients with complex health needs; are involved in coaching, consultation, evaluating, and using research findings; provide leadership in both the clinical and professional arenas; and collaborate interprofessionally to accomplish client goals and outcomes (Levin et al., 2013). The role of the nurse in home health is discussed in Chapter 41.

Many APNs today are practicing in telehealth environments. Telehealth is the practice of health care delivery, diagnosis, consultation, treatment, and transfer of medical data and education using interactive video, visual, audio, and data telecommunication (Kvedar et al., 2014).

Correctional Institutions. Residents of prisons and jails are a population with health needs that are met by APHNs and NPs. APHNs are an asset within prison systems, planning and implementing coordinated health programs that include health education as well as health services. Where personnel resources are limited, APHNs provide health education and counseling for inmates and/or their families to prepare prison clients for going back into the community on their release. NPs often practice in on-site health clinics at correctional institutions, providing both primary care services and health education programs (Almost et al., 2013).

ISSUES AND CONCERNS

Legal Status

The legal authority of nurses in advanced practice is determined by each state's nurse practice act and, in some states, by additional rules and regulations for practice (Phillips, 2017). In the 1970s, regulations for the direct care role performed by NPs, including diagnosis and treatment, were less defined in state nursing laws than they are today, and the legal status of NPs was being questioned. Since 1971, when Idaho revised its nurse practice act to include the practice of NPs, all 50 states have amended their nurse practice acts or revised their definitions of nursing to reflect the new nursing roles. NPs are regulated by their state boards of nursing through specific regulations (Phillips, 2017). Legislative authority to prescribe has changed dramatically in the last several years. By 2002, NPs in all states (including the District of Columbia) had prescriptive authority,

some with independent authority to prescribe and some dependent on physician collaboration (Phillips, 2017).

Reimbursement

The third-party reimbursement system in the United States, both public and private, is complicated. To practice independently or work collaboratively with physicians, NPs need to be reimbursed adequately. Because states regulate the insurance industry, available third-party private reimbursement depends in large part on state statute. Advanced practice nurses want direct access to third-party payers. The most common mechanism by which NPs get access to direct payment is through benefits-required laws. Laws also include the right to practice without being discriminated against by another provider or a health care agency (Phillips, 2014).

The Rural Health Clinic Services Act of 1977 (PL 95-210) was the first breakthrough in third-party reimbursement for nurses in primary care roles (Box 39.2). The law authorized Medicare and Medicaid reimbursement to qualified rural clinics for services provided by NPs and PAs, regardless of the presence of a physician (Wasem, 1990). The intent of the act was to improve access to health care in some of the nation's underserved rural areas; however, its use from state to state has varied dramatically. Recent legislative changes to include the coverage of services by certified nurse midwives, clinical psychologists, and social workers have improved the effectiveness of the Rural Health Clinic Services Act for reimbursement options.

In 1989, Congress mandated reimbursement for services furnished to needy Medicaid clients by a certified family nurse practitioner or certified pediatric nurse practitioner, whether or not under the supervision of a physician. With the 1997 passing of the Balanced Budget Act, NPs were directly reimbursed, regardless of geographic setting, at 85 percent of physician pay (if the service is covered under Medicare part B) (Pearson, 1998).

BOX 39.2 Landmark U.S. Legislation for Advanced Practice Nurses

- 1977: Rural Health Clinic Services Act authorized NP and PA services to be directly reimbursed when provided in a rural area.
- 1989: As part of the Omnibus Budget Reconciliation Act (OBRA), Congress recognized NPs as direct providers of services to residents of nursing homes.
- 1990: Congress established a new Medicare benefit through federally qualified health centers, where services of NPs are directly reimbursed when provided in these centers.
- 1997: Passage of the Balanced Budget Act of 1997 (PL 105-33). NPs are now be directly reimbursed, regardless of geographic setting, at 85 percent of physician pay (if the service is covered under Medicare part B).
- 2003: Individuals applying for Medicare provider numbers, such as NPs, must possess a master's degree from an NP program, as well as national certification and state licensure.
- 2010: Passage of the Patient Protection and Affordable Care Act. As a result, there will be a higher demand for primary care providers, such as NPs, with an emphasis on prevention, chronic care management, and cost-effective quality care.

NP, Nurse practitioner; *PA,* physician assistant.

Since January 1, 2003, individuals applying for Medicare provider numbers as NPs must possess a master's degree from an NP program, as well as national certification and state licensure. Once an NP has a provider number, he or she submits bills, using the standard government form, to the local Medicare insurance carrier agency for each visit or procedure.

Institutional Privileges

NPs in the community are more concerned than APHNs about **institutional privileges.** Historically, NPs experienced difficulty in obtaining hospital privileges within institutions where their patients are admitted. However, with the broadening scope of practice and professional responsibilities, more nurse practitioners are obtaining hospital privileges (often referred to as credentialing). An application process is generally required and reviewed by a credentialing board typically composed of physicians, administrators, and in some cases advanced practice providers (NPs, PAs). The criteria for nurse practitioners wishing to obtain hospital privileges vary by hospital and state; however, most hospitals require that nurse practitioners have national certification.

Employment and Role Negotiation

For APHNs and NPs to collaboratively provide comprehensive primary health care, they must understand and develop negotiating skills. Positive working relationships with health professionals, organizations, and clients require role negotiation, particularly when few guidelines exist for a role or a role is new and undeveloped. APHNs and NPs need to assess the internal politics of the organization as part of their role negotiation. Networking is another necessary skill. Forums, joint conferences, collaborative practice, and research provide opportunities to expand their functions.

Because APHNs and NPs in some locations often seek employment, as opposed to being sought by employers, assertiveness is needed. Increased financial constraints have reduced the number of job opportunities. APHNs and NPs should feel comfortable about marketing their skills. Marketing strategies should be designed to project an image that shows a nurse's individual achievement. In assessing and analyzing the needs of target markets, nurses must consider professional and institutional goals, and the target client group's goals. Methods of obtaining positions and negotiating future roles include providing **portfolios** of credentialed documents and samples of professional accomplishments such as audiovisual materials, program plans, and evaluations conducted, client education packets, and history and physical assessment tools developed. Portfolios are physical packets or web-based files that contain all these documents to showcase the nurse's abilities. APHNs and NPs should keep current portfolios containing examples of their professional activities. Names, addresses, and telephone numbers of professional and personal references should be furnished in the portfolios (but only after the referring persons have granted permission). In an electronic portfolio, or e-portfolio, information is housed on the Internet and is easily updated and shared/transmitted to employers and others. Many websites provide e-portfolio management and

services, such as Decision Critical website (https://www.healthstream.com/).

ROLE STRESS

Factors causing stress for advanced practice nurses include legal issues (as discussed previously), professional isolation, liability, collaborative practice, conflicting expectations, and professional responsibilities. APHNs and NPs want to identify self-care strategies to cope with predictable stressors, some of which are discussed here.

Professional Isolation

Professional isolation is a source of conflict for APHNs and NPs. Because they practice across all age groups, APHNs and NPs are likely to be hired in remote practice employment sites. Rural communities unable to support a physician, for example, find the NP an affordable and logical alternative for primary care services. The autonomy of practice in these sites attracts many APHNs and NPs, who fail to consider the disadvantages of isolated practice. Long drives, long hours, lack of social and cultural activities, and lack of opportunity for professional development are often experienced by these rural practitioners. These sources of stress, which leads to job dissatisfaction, can be reduced or eliminated by negotiating the employment contract to include educational and personal leaves.

Liability

All nurses are liable for their actions. Because more legal action is appearing in the judicial system, specifically concerning NPs, the importance of liability and/or malpractice insurance cannot be overemphasized (AANP, 2018b). Although malpractice insurance is not required to function as an APHN or an NP, most nurses carry their own liability insurance. It is in the best interest of APHNs and NPs to thoroughly investigate the coverage offered by various companies rather than to assume that the coverage is adequate. Practitioners who function without a physician on site are particularly vulnerable. The scope of individual APHN and NP authority determines the liability standards applied. The limits of each practitioner's authority are legislated by individual states (Phillips, 2017).

Interprofessional Collaborative Practice

The future of APHNs and NPs depends on whether they make a recognized difference in the health of families and communities, and on their ability to practice collaboratively with physicians. Interprofessional collaborative practice defines a peer relationship with mutual trust and respect. Working out a collaborative practice takes a considerable amount of time and energy. Until such practice relationships evolve within joint practice situations, the quality health care that nursing and medicine collaboratively provides will not be achieved. The arrangement demands the professional maturity to work together without territorial disputes, and the structure and philosophy of the organization must support joint practice as a mechanism for health care delivery. The growing pains of establishing such a practice produce stress for all involved; however, the results and benefits to clients and professionals are worth the effort (Interprofessional Education Collaborative Expert Panel, 2011).

Interprofessional collaborative practice for APHNs and NPs involves more disciplines than just medicine. Advanced practice nurses work with baccalaureate-prepared nurses and other nurses, social workers, public health professionals, nutritionists, occupational and physical therapists, and community leaders and members to meet their goals for the health of individuals, families, groups, and communities. To work toward the *Healthy People 2020* objectives, collaboration of multidisciplinary groups is essential. APHNs, NPs, and baccalaureate-prepared nurses provides leadership in attaining this collaborative effort.

Conflicting Expectations

Services provided by APHNs and NPs in health promotion and maintenance are often more time consuming and complex than just the management of clients' health problems. APHNs and NPs frequently experience conflict between their professional practice goals in health promotion and the need to see a required number of clients to maintain the worksite's financial goals. The problem is worsened if a facility administrator or physician views APHNs and NPs only as medical extenders and limits reimbursement to the nurse provider. A practice model that assists nurses in including health promotion and maintenance activities as well as medical case management into each client visit uses (1) flexible scheduling, (2) health maintenance flow sheets, and (3) problem-oriented recording with nursing goals and plans prominently displayed in the health record. For APHNs, program planning and evaluation based on systematic needs assessments conducted with communities are methods to show the needs and benefits of health promotion/disease prevention. Being an educator and role model in carrying out *Healthy People 2020* objectives emphasizes the importance of health promotion and disease prevention in the health care system.

Professional Responsibilities

Professional responsibilities contribute to role stress. Most states require APHNs and NPs in expanded roles to be nationally certified and to maintain certification. Recertification requires documentation of continuing education hours with composition of subject matter defined by the certifying body and often requires a prescribed minimum number of work hours in certification specialty. There are not many nurse practitioners in an area, and continuing education may not be locally available and requires travel and lodging expenses in addition to time away from the practice site. Anticipating professional responsibilities and travel expenses in financial planning decreases these concerns. Negotiating contracts with the employer for educational leave and expenses helps divert financial stress.

Quality of client care, however, cannot be measured or ensured by continuing education or the nurse's credentials.

Professional responsibility includes monitoring one's own practice according to standards established by the profession and protocols, if used, and a personal feeling of responsibility to the community. Continuous quality improvement is another professional responsibility for APHNs and NPs. This process should evaluate need, cost, and effectiveness of care in relation to client outcomes (Kelly et al., 2014).

TRENDS IN ADVANCED PRACTICE NURSING

Advanced practice nurses are prominent in multiple health care arenas today, and this is unlikely to change in the future (National Advisory Council, 2016; Van Vleet & Paradise, 2015). With the goals of the Patient Protection and Affordable Care Act (PPACA, 2010) and *Healthy People 2020* objectives, a substantial need for health care providers exists. The prominence of interprofessional education and practice, along with team-based and patient-centered care, is congruent with the PPACA and *Healthy People 2020*. APHNs and NPs have the knowledge and skills base to lead the health care team in both individual- and population-based outcomes in prevention and population health.

APHNs and NPs, in collaboration with nurses, community agencies and members, and other disciplines, have the potential to make an impact on health promotion and disease prevention at the individual, family, group, and community levels. Population-focused APHNs and NPs are in excellent positions to use the *Healthy People 2020* National Health Promotion and Disease Prevention objectives and the Healthy People in Healthy Communities model in planning their advanced practice nursing interventions

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

The Advanced Practice Nurse in the Community

Targeted Competency: Informatics

Use information and technology to communicate, manage knowledge, mitigate error, and support decision making.

Important aspects of informatics include:

- **Knowledge:** Describe examples of how technology and information management are related to the quality and safety of patient care.
- **Skills:** Use information management tools to monitor outcomes of care processes.
- **Attitudes:** Value nurses' involvement in design, selection, implementation, and evaluation of information technologies to support patient care.

Informatics Question

You are an adult/geriatric NP who has just been hired at a nursing center, where that targeted patient population is patients over the age of 65, covered by Medicare insurance. Because your nursing center provides primary care for a substantial portion of your community's Medicare population, you have been approached by the local hospital and home care agency to help them track ED visits (not resulting in admission) and hospital readmission rates, within 30 days of a hospitalization.

- What data points will you want to track to establish a preintervention baseline for these data?
- Assuming you are involved in developing an educational module for at-risk patients, families, and home care nurses, what data points will you want to track after implementing this educational module?
- Which EHR (hospital, home care, nursing center) might contain these data points?
- How might you envision shared documentation/communication among the hospital, home care agency, and nursing center to effectively manage the targeted patients?

ED, Emergency department; *EHR,* electronic health record; *NP,* nurse practitioner.
Prepared by Gail Armstrong, PhD, DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing.

LINKING CONTENT TO PRACTICE

In this chapter, emphasis is placed on the role of the advanced public health nurse (APHN) in the community and how advanced nursing practice relates to the generalist public health nurse. The Community/Public Health Nursing Competencies (Quad Council Coalition, 2018) were developed by four organizations:

Alliance of Nurses for Healthy Environments (AHNE)
Association of Community Health Nursing Educators (ACHNE)
Association of Public Health Nurses (APHN)
American Public Health Association—Public Health Nursing Section (APHA-PHN)

The competencies are categorized into eight domains and are applied to three tiers of community/public health nursing practice:

- Tier 1: Generalist community/public health nurses (C/PHN) who carry out day-to-day functions in community organizations or state and local public health organizations, including clinical, home visiting, and population-based services, and who are not in management positions
- Tier 2: Community/public health nurses with an array of program implementation, management, and/or supervisory responsibilities, including responsibility for clinical services, home visiting, and community-based and population-focused programs
- Tier 3: Community/public health nurses at an executive/senior management level and leadership levels in public health or community organizations

The domains are core areas of analytic and assessment skills, policy development/program planning, communication, cultural competency, community dimensions of practice, public health science, financial planning, evaluation and management, and leadership and systems thinking skills (Quad Council Coalition, 2018). The latter tiers include a higher-level mastery of skills and competencies. As an example, their fifth domain, Community Dimensions of Practice Skills, lists a Tier 1 competency as use formal and informal relational networks among community organizations and systems conducive to improving the health of individuals, families, and groups within communities; a Tier 2 competency as use formal and informal relational networks among community organizations and systems conducive to improving the health within programs, communities, and populations; and a Tier 3 competency as create internal and external organizational relationships, processes, and system improvements to enhance the health of populations (QCC, 2018). The Tier 2 and Tier 3 competencies/skills are clearly consistent with the APHN role and are at an advanced mastery level. This is in contrast to the generalist/staff public health nurse, where the expected level of performance mastery for this domain is more at providing care for individuals, families, and groups. Thus if an agency planned to conduct health education programs within a community, the APHN would take leadership roles in developing, implementing, and evaluating a needs assessment and interacting with community stakeholders to assist with conducting the health education programs that would be most relevant and accessible to the community.

PRACTICE APPLICATION

APHN

Martha Corley is an APHN who coordinates the aftercare services for a community hospital's early discharge clients. Martha has worked with the nursing staff to develop a nursing history form to identify family and social supports available to clients who are likely to need nursing or supportive care for a limited time after discharge. With this and additional information from head nurses, Martha visits selected clients to begin discharge planning. She consults with each client and family to validate assessed needs. The physician is also consulted about medical therapies to be continued at home. Martha has access to nurses and other resources throughout the community that accept cases on contract. She outlines the initial care plan with nurse case managers assigned to the client and receives regular progress reports. An essential aspect of her practice is to evaluate outcomes of her interventions.

Which of the following is the best example of evaluation of Martha's nursing care?

A. Assessment of client and family satisfaction with her services
B. Reported medical complications of her caseload
C. Review of related literature about home care programs
D. Collected data on hospital readmissions of her clients

Case 2: Family Nurse Practitioner

Answers can be found on the Evolve site.

KEY POINTS

- Changes in the health care system and nursing have occurred in the past few decades because of a shift in society's demands and needs.
- Trends such as a shift of health care from institution-based sites to the community, an increase in technology, self-care, cost-containment measures, accountability, third-party reimbursement, and demands for humanizing technical care have influenced the new roles of the APHN and NP.
- Educational preparation of the APHN has always been at the graduate level, whereas this has not been true of the NP; however, there are implications that both the APHN and NP have educational preparation at the Doctor of Nursing Practice level.
- Specialty certification began through the ANA in 1976 for NPs, and through the ANCC in 1990 for APHNs but is no longer available. It is not required for APHN practice at this time.
- The major role functions of the APHN and NP in community health are clinician, consultant, administrator, researcher, and educator; typically, the NP spends a greater amount of time in direct care clinical activities and less time in indirect activities than the APHN.
- Major arenas for practice for APHNs and NPs in community health include primary care practice, institutional settings, industry, government, public health agencies, schools, home health, correctional health, nursing centers, retail clinics, and health ministry settings.
- Legal status, reimbursement, institutional privileges, and role negotiation are important issues and concerns to nurses who practice in an advanced role in public health nursing.
- Major stressors for APHNs and NPs include professional isolation, liability, collaborative practice, conflicting expectations, and professional responsibilities.
- The use of *Healthy People 2020* objectives is important in emphasizing health promotion and disease prevention in advanced practice nursing and in improving the health of the nation.

CLINICAL DECISION-MAKING ACTIVITIES

1. Explore the development of the APHN and NP in the community. Give details about the differences in the roles.
2. Investigate graduate programs in public health in a state or region to determine the requirements for admission, the type of degree awarded, and whether or not APHN and/or NP preparation is available. Do the similarities and differences make sense to you? Why?
3. Review your state's nurse practice act and any rules and regulations governing advanced practice roles. Are rules different for APHNs and NPs? Give examples.
4. Negotiate a clinical observation experience with an APHN and a NP in community and public health and compare and contrast their roles. Discuss the roles as you see them with the APHN and NP. When you consider your thoughts about the roles, have you considered what the APHN and NP have told you about their roles? How has their input changed your views?

The Nurse Leader in the Community

*Lisa M. Turner, PhD, RN, PHCNS-BC**

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Explain why nurses need effective leadership, management, and consultation skills in today's public health care environment.
2. Explore what is meant by partnership and interprofessional practice and describe how these concepts are related to nursing leadership, management, and consultation.
3. Analyze what is meant by systems thinking in community-based and public health settings.
4. Describe the major competencies required to be effective as a nurse leader, manager, and consultant in community-based and public health settings.
5. Examine nursing leadership strategies to enhance client safety and reduce health care errors in community settings.
6. Explain how nurses provide leadership in care coordination in the community.

*Dr. Turner would like to acknowledge the author of this chapter in edition 8 of the text, Dr. Juliann G. Sebastian, PhD, RN, FAAN, for her many contributions that continue to appear in this chapter.

The profession of nursing has consistently ranked highly in public surveys as the most trusted profession (Gallup Inc., 2017). As such, the general public looks to nurses to act as leaders, providing guidance on health care choices. With nearly three million nurses employed in the United States (Bureau of Labor Statistics [BLS], 2018), the nursing profession has the potential to greatly influence the health of the nation. It is therefore imperative that nurses understand how to be leaders, not only with their professional colleagues, but also within their communities. Leadership as a role for nurses began to emerge as the profession became more structured in the mid-1800s, moving from a loosely defined trade to an organized, educated profession (Forrester, 2016). Florence Nightingale (1912), the founder of modern nursing, devoted a chapter in her book, *Notes on Nursing,* to what she called "petty management," defining the importance of a nurse being able to think critically, act proactively, and take charge of a situation in an efficient manner, all essential leadership skills. Since then, the concept of nursing leadership has evolved to include such qualities as developing relationships, facilitating communication between individuals and groups, providing guidance and direction, inspiring groups and organizations, and demonstrating vision (Huber, 2018). Agencies, localities, and professional organizations increasingly recognize the need for effective leadership in public health and community life.

Population-focused nurses have a responsibility to provide leadership in creating a new future for healthier communities. Members of the public ask whether better approaches to health care delivery might be developed that will ensure that all people around the world live in health-promoting communities and have access to quality health care as well as to health promotion and illness prevention services. Population-focused nurses practice in a variety of settings, including public health departments, community-based clinics, occupational health settings, schools, and **managed care organizations**. Leadership, management, and consulting skills are important to the success of client outcomes that depend heavily on cost-effective, efficient delivery of care. Care coordination and managing care transitions throughout the community, including acute and long-term care settings, are important to promoting a healthy community. Nurses need effective skills in communication, negotiation, and interprofessional practice and good leadership, management, and consultation skills, even if they do not have formal positions as managers or consultants.

Nurses must focus attention not only on the populations that are served by their organizations but also on those that are not. Because they concern themselves with the total public, their focus is always on the future and on the interacting factors that influence the health of the public. Nurses work with partnerships of community members and community organizations. **Partnerships** can be complex and require time and thoughtful attention. This chapter examines the roles and functions of nurse leaders, managers, and consultants in the twenty-first century. It emphasizes nursing leadership in public health and community-based nursing practice, personnel management, and consultation with groups and individuals.

MAJOR TRENDS AND ISSUES

Ensuring client safety and quality of care, performing evidence-based practice, eliminating disparities in health care access and outcomes, and focusing on consumer participation in and satisfaction with care are key trends in health care.

The Institute of Medicine (IOM) (2000) report titled *To Err Is Human* focused attention on the incidence of health care errors. The IOM (2001) followed this report with another one, titled *Crossing the Quality Chasm,* which offered strategies for improving the health care system. The most recent report from the IOM (2015a), titled *Improving Diagnosis in Health Care,* is a continuation of the previous landmark reports, brings attention to the need to address the occurrence of diagnostic errors to improve quality and safety in health care. The issue of reducing health care errors continues to be a topic of interest for health leaders. A 2016 study conducted by patient safety experts at Johns Hopkins found that medical errors are the third leading cause of death in the United States, noting that most of the errors represent systemic problems, including poorly coordinated care, fragmented insurance networks, the absence or underuse of safety nets, and other protocols, in addition to unwarranted variation in physician practice patterns that lack accountability (Makary & Daniel, 2016). This is a concern in the community just as in hospitals and long-term care agencies. For example, studies show that older adults living in the community are at high risk for medication errors. Sometimes this is because they are taking high-risk medications, or because they cannot read instructions for medications, or because of medication complexity (polypharmacy) and not understanding how to take medications that have been prescribed for them (Hanlon et al., 2017; Miller et al., 2017; Shade et al., 2017).

Evidence-based practice is another trend important for public health nurses. Basing clinical practice patterns and community programs on research and other forms of evidence such as best practice data is a key strategy for ensuring high-quality care. One example of evidence-based practice in a community setting is examining the impact of community-based nurse-led clinics (Randall et al., 2017). In this systematic review, the researchers evaluated the impact nurse-led clinics have on patient outcomes, patient satisfaction, patient access to services, and cost-effectiveness. The researchers concluded that the nurse-led clinics have shown a positive impact on each of the study variables, with mixed results on cost-effectiveness.

The health system in some local areas has been reorganized to provide a full continuum of services in a **seamless system of care**. Large, vertically integrated systems are able to do this. **Vertical integration** means that the system owns all of the services that clients might need (e.g., clinics, hospitals, and home health agencies). In other cases, free-standing agencies collaborate and contract with one another to achieve seamlessness. The goal is to reduce fragmentation, which should be helpful for vulnerable populations. Nurses coordinate clients' care across agencies, but this new trend in the health care system places added emphasis on relationships, such as alliances, agency partnerships, joint programs, and participation in **service delivery networks** (Allen, 2017; Berry et al., 2013).

Nurses actively participate in these groups and need good negotiating and **political skills** to be effective.

Another important trend is related to the movement toward more community partnerships (Cutts et al., 2017; Johnston & Finegood, 2015). Partnerships with community members and community agencies are essential to effective public and community health practice. The public has an increasing interest in becoming involved in planning for health services and in being active partners in their own care. Partnerships succeed when strong communication mechanisms are in place to ensure definition of needs and problems, timely problem resolution, and ongoing development of shared visions. In public and community health, the development of shared visions and goals and the operational mechanisms to make those goals a reality is the key to success. Nurses need to be able to listen well and collaborate with lay community members, whose goals and ideas may differ from those of health care professionals. Faith and community partnerships have been effective in reaching underserved populations (Cipriano, 2014). For example, in Harlem, nurses and faith leaders come together to offer health screenings, education, and improve access to health care services through the Community Health Nursing-Faith Based Partnership Program (Cipriano, 2014).

The public is increasingly using the Internet, a wide variety of publications, and lay support groups to obtain health information. People need help deciding which information is good and how best to work with their health care providers to adapt information to their own health profiles. Those with low health literacy (see Chapter 19) need special help in obtaining the health information necessary to be effective partners in health care (Batterham et al., 2016; World Health Organization, 2013).

To know whether an agency is performing as expected, nurses must be familiar with their professional standards of care, the standards held by accrediting bodies, such as The Joint Commission, and guidelines for practice, such as those published by the federal Agency for Healthcare Research and Quality and the U.S. Preventive Services Task Force (2014). Nurse leaders also need to know how to use electronic health records and management information systems to link client outcomes with clinical and administrative processes. Registries are examples of clinical databases dedicated to certain population groups, such as people with cancer, diabetes, injuries, or population groups such as women. Nurses should know how to work with the taxonomies for nursing diagnoses, interventions, and outcomes of nursing actions (Butcher et al., 2019) because these are being included in electronic health records and will help nurses identify changing health needs (Englebright et al., 2014; Gottlieb et al., 2015).

One trend that combines the idea of partnerships with a structured method for rapid performance improvement is the use of collaboratives. A **collaborative** is a group of similar organizations that agree to use common processes for providing clinical care and share certain types of data so all may learn. A well-known example is the Health Care Disparities Collaboratives (HDCs) used by the Federal Bureau of Primary Health Care. The HDCs are a nationwide initiative to improve care for people with chronic conditions (Bureau of Primary Health Care, 2014). Community health centers may apply to participate in HDCs that target certain chronic health problems, such as diabetes or cardiovascular disease.

A major trend in public health is a stronger focus on implementing the core functions of public health and providing the essential services of public health (Council on Linkages Between Academia and Public Health Practice, 2014). Competencies have been identified for generalist public/community health nurses that build on the core function and essential services (Association of Community Health Nurse Educators Education Committee, 2009; Quad Council Coalition Competency Review Task Force, 2018).

EVIDENCE-BASED PRACTICE

Spano-Szekely et al. (2016) examined the relationship between emotional intelligence (EI) and transformational leadership (TL) in nurse managers. Previous nursing studies showed that TL style managers had greater commitment from their followers than other leadership styles and that EI is a potential characteristic of TL managers. The researchers found that EI was significantly positively correlated with TL and with followership outcome measures of extra effort, effectiveness, and satisfaction. EI was significantly negatively correlated with laissez-faire leadership. Furthermore, a positive relationship was found between TL and nurse managers with advanced education and administrative certification.

Nurse Use

Nurse leaders need to consider EI characteristics when hiring nurse managers. Development and improvement of EI skills in nurses may lead to more effective leadership styles.

Spano-Szekely L, Quinn Griffin MT, Clavelle J, et al.: Emotional intelligence and transformational leadership in nurse managers, *J Nurs Admin* 46(2):101-108, 2016.

DEFINITIONS

Leadership can be defined as the process of influence that occurs between a leader and an individual, group, organization, community, or society, often by inspiring, enlivening, and engaging others to participate in the achievement of goals (Weiss & Tappen, 2015). Therefore nursing leadership refers to the influence that nurses exert on improving client health, whether clients are individuals, families, groups, or entire communities. **Management**, on the other hand, focuses on achieving organizational goals by using the managerial tasks of planning, organizing, commanding, coordinating, and motivating employees to work (Weiss & Tappen, 2015). For nurses, these resources might be people, as when a nurse coordinates an interprofessional team, or financial resources. An example of managing financial resources is when a nurse monitors the budget for an immunization program to make sure that personnel time, supplies, and equipment are being used efficiently. Nurses also manage time. For example, home health nurses must manage their time in order to provide clients with direct and indirect nursing services, such as health education and making referrals, respectively.

It is important to point out that leadership and management are two different skills. Leadership sets the direction, and

management ensures that goals will be achieved. Nurses must possess strong clinical leadership and management skills to be effective, whether or not they hold management positions.

Consultation in nursing refers to the process that occurs when a nurse works with an individual, group, organization, or community with the specific purpose of assisting them to solve actual or potential problems related to the health status of patients or to the health care organization (Franks, 2014; Ridge, 2015). Clinical consultation increasingly focuses on ways to better coordinate the care delivery process across sites of care. Population-focused nurses have a breadth of knowledge that makes them desirable consultants for colleagues both inside and outside the organizations in which they work. For example, a nurse working in a home health agency might be called on by a school nurse to give suggestions about the most effective way to intervene for a child using a respirator. Another example that occurs frequently is the informal consultation provided by nurses in the community, who help nurses working in hospitals make effective community referrals. At the population level, nurses who consult with a local health department about developing a program for obesity prevention in school-age children are focusing their efforts on a particular target population. An example would be the nurse leader of a community-based diabetes program who works with clinical colleagues in a hospital to improve the self-management education for people with diabetes.

Consultation is closely linked with the ideas of empowerment and self-management. When consultants help clients identify and work through problems and learn new skills that clients see as most important, they are enabling clients to solve more of their own problems. This is very similar to the traditional nursing philosophy of helping people solve their own problems, whether they are individuals, families, groups, or communities. Empowerment is consistent with Jean Watson's theory of human caring (Watson, 2008), in which the nurse may advocate for the client but also may assist the client to advocate for themselves (Sitman & Watson, 2018; Smith, Turkel, & Wolf, 2013).

LEADERSHIP AND MANAGEMENT APPLIED TO POPULATION-FOCUSED NURSING

Goals

Emphasizing the importance of the nurse leaders in addressing the health and well-being of populations, the Robert Wood Johnson Foundation (2017) report titled *Catalysts for Change* states that, "The key to implementing a population-focused vision of the future is strong nursing leadership, which will drive the monumental culture change required to improve health and reduce costs in our country" (p. 4). Nursing leaders work with others to ensure a healthy community. They serve as an advocate for vulnerable and high-risk populations and work toward achieving health equity, eliminating disparities, and improving the health of all groups. Nurse leaders also participate in establishing public and organizational policies and programs that promote a healthy living and working environment, and they work with interprofessional teams to design ways to coordinate care across sites and over time, in order to evaluate and continually improve health care outcomes.

One way nurses lead is by participating in advocacy and policy development at the local level. Working with others to develop policies for smoke-free public spaces is an example of promoting healthy living and working environments. Another example is collaborating with consumers and professionals from other disciplines to evaluate root causes of medication errors in home-bound elders and design a process improvement strategy to reduce errors.

Nursing managers use a systems perspective to achieve agency and professional goals for client services and clinical outcomes. Managers help personnel perform their responsibilities effectively and efficiently, and they mentor other staff members and foster lifelong learning. Furthermore, nurse managers develop new services that will enable the agency to respond to emerging community health needs, monitor health outcomes for particular population groups, and identify changes or variances suggesting new problems.

An example of how nurses show management abilities occurs when they develop plans for broad-based immunization clinics, such as smallpox vaccination clinics. Doing this in advance of confirmed bioterrorism is a way of preparing to meet an emerging community health need that achieves goals of protecting the public's health and helping personnel work effectively and efficiently. Table 40.1 shows examples of ways population-focused nurse leaders and managers facilitate primary, secondary, and tertiary preventive services.

Theories of Leadership and Management

Leadership and management theories help explain individual and group behavior as well as organizational and system dynamics. Theories that help explain and predict individual behavior often focus on employee motivation and job satisfaction. Some theories address interpersonal issues such as leadership, communication, conflict resolution, and group dynamics. Working with consumers, staff members, and other health professionals in an adult daycare facility to design a memory improvement program for participants highlights the use of these theories. This type of project requires knowledge of motivation and leadership, teamwork, change theory, and project planning, management, and evaluation. Organizational and systems theories explain issues at a broader agency or community level. These theories focus on the best ways to organize work, on how to obtain the resources necessary to accomplish agency goals, on organizational level change, on power dynamics, and understanding systems. Systems theories help explain the dynamics of rapid, interconnected change and the emergence of patterns of activity (Crowell, 2016).

Good leadership skills are essential for nurse leaders and are among the key competencies for generalist public/community health nurses recommended by the Quad Council Coalition Competency Review Task Force (2018) and for entry level public health professionals by the Council on Linkages Between Academia and Public Health Nursing Practice (2014).

The transformational leader is able to transform, or change, the situation to one that differs from the status quo

TABLE 40.1 Examples of Levels of Prevention and Population-Focused Nursing Leadership and Management

Levels of Prevention	Nursing Leadership (Sets Goals)	Nursing Management (Directs Use of Resources)
Primary (prevention of illnesses or problems before they begin)	Works with a community coalition to design a broad-based strategy for ensuring health and social needs of uninsured and underinsured populations are met. Works with nurses and interprofessional colleagues to develop goals related to preventing health care errors and ensuring client safety	Develops policies and procedures for a referral program for low-income mothers and children to obtain nutrition services. Ensures that individuals and families understand care routines to promote adherence and reduce chances of health care error
Secondary (screening for illness and treatment of health problems before they worsen)	Works with local government and health department to design lead screening and abatement programs in high-risk census tracts. Monitors data about a caseload of clients to determine whether patterns are developing that might indicate a health problem or issue needs to be resolved	Designs protocols for lead-screening program and hires staff to implement program. Works with other members of care team to design protocols to improve specific health outcomes
Tertiary (treatment of health problems to foster stabilization or delay exacerbation)	Participates on a planning commission with local health department, hospitals, police, and political leaders to update a community-wide disaster response plan that accounts for bioterrorism. Collaborates with interprofessional teams to set goals for performance improvement and rapid changes in quality of care problems	Serves as chair of a committee that organizes, staffs, and monitors budget for a smallpox vaccination program. Monitors implementation of performance improvement activities to ensure timely and appropriate completion or revision as necessary

Table developed by J. Sebastian (2010) for the eighth edition of *Public Health Nursing*.

(Fischer, 2016). Transformational leaders are sometimes found in **learning organizations**, or agencies that create cultures that support ongoing learning, experimentation, and creation of new knowledge (Roussel, Thomas, & Harris, 2016). Transformational leadership is essential to promoting a culture of safety and positive work environments for others (IOM, 2011).

Systems theories and **systems thinking** emphasize the interdependence of multiple parties. Nurses often recognize interdependence of units within an agency but may be less aware of agency interdependence. Economists analyze how distribution of resources affects policies, which players in a system will be influenced by policies, and how they will be influenced. These are called **distribution effects**. For example, if the federal government reduces money for health and social services, the clients of those services may be negatively affected. Employees of service agencies are also affected because agencies are likely to downsize to manage the reduced funding. Consequently, employees may either lose their jobs or experience wage cuts. Others likely to be affected include voluntary agencies and religious groups, which might be expected to provide more services.

Roy's adaptation model of nursing has been extended to include nursing management (Alligood, 2018). Roy argues that agencies are composed of interdependent systems. The role of nurse managers is to help the agency adapt to changing circumstances in the most effective way possible. Roy's model is particularly helpful for explaining and predicting how nurse managers and consultants can help agencies adapt to change. Nurse leaders should analyze how well interdependent units function to achieve agency goals. Furthermore, nurse leaders function as change agents because they foster agency adaptation. Complexity leadership theory accounts for the unpredictability of the behavior of people and organizations (Crowell, 2016). The combination of unpredictability and interdependence leads to disequilibrium and potentially to adaptation and growth. Communities exemplify **complex adaptive systems**. Nurse leaders must understand the analytical, political, and communication skills needed to work effectively in these systems.

Clinical **microsystems** are the systems, people, information, and behaviors that take place at the point of client care (Likosky, 2014). Evidence-based clinical improvements can be implemented quickly in a clinical microsystem that has sufficient data about the practice, information systems that support clinical decision making, and a well-functioning team. For example, nurses working in a mobile health unit are part of a clinical microsystem. The team can make rapid changes in responses to quality problems if team members work well together and the mobile health clinic has an information system that makes it possible to track population health outcomes and clinical practice patterns.

Population-focused nurse leaders should assess the systems within which they work to evaluate risks to client safety. In the community these risks might be related to communication problems, inadequate follow-up, or lack of continuity of care. Nurses should maintain accountability for the outcomes of individuals, families, and groups and should do their best to ensure that complete care is provided across the continuum and that clients feel empowered to manage their own care.

Nurse Leader and Manager Roles

First-line nurse managers may be team leaders or program directors (e.g., director of a satellite occupational health clinic or director of a small migrant health clinic), whereas mid- or executive-level nurse managers may be division directors

(including multiple programs or departments), local or state commissioners of health, or directors of large home health agencies with multiple offices. They function as coaches, facilitators, role models, evaluators, advocates, visionaries, community health program planners, teachers, and supervisors. Population-focused nurse leaders have ongoing responsibilities for the health of clients, groups, and communities, as well as for personnel and fiscal resources under their supervision. Nurse leaders may have positions as managers or they may be excellent clinicians and change agents who are seen as opinion leaders.

CONSULTATION

Goal

The goal of consultation is to help others empower themselves to take more responsibility, feel more secure, deal with their feelings and with others in interactions, and use flexible and creative problem-solving skills (Hamric et al., 2014). The functions of a consultant differ from those of a manager because consultation is typically a temporary and voluntary relationship between a professional helper and a client. The similarities between consultants and leaders are in the emphasis on empowerment and helping others develop. Consulting relationships are based on cooperation and respect between consultants and clients, who share equally in problem solving (Hamric et al., 2014).

The nurse's job responsibilities may include internal and external consultation. Internal consultants are members of the organization who work in a temporary capacity to help the client create or sustain change. For example, a nurse may be employed to consult with other nurses in the agency about client care problems or, as an employee of the health department, may serve as a consultant to a local community retirement center about the public health care needs of its residents. If the nurse is an internal consultant, the nurse is employed on a full-time salaried basis by a community agency in which the consultation takes place. If the nurse is an **external consultant**, the nurse is employed temporarily on a contractual basis by the client. The client of the external nurse consultant may be a colleague, another health provider, or a community group or agency. Consulting may occur informally when a staff nurse asks a colleague for advice or help in solving a problem. The nature of the consultation relationship, whether it is internal or external, should not change the goal of consultation.

Theories of Consultation

Several models of consultation have been developed. Although nurses often consult with individuals about their own health care, or with another nurse or health professional about the needs of an individual client, this section emphasizes population-based consultation. At this level, the nurse focuses on the needs of a group, organization, or community. The client in this case is an organization or group. Content models emphasize the role of consultant as the expert who provides specific answers to problems or issues identified by the client. This approach has the advantage of being relatively quick and often responsive to client requests, but it does not help engage the client in problem solving and learning how to address similar issues in the future (Schein, 1969, 1999, 2011, 2016). This chapter focuses on Edgar Schein's (1969, 1999) model of process consultation because it is consistent with the nursing process and with nursing values of empowering clients and collaboratively working as partners with clients. The **process model consultation** focuses on the process of problem solving and collaboration between consultant and the client. The major goal of the process model is to help the client assess both the problem and the kind of help needed to solve it (Schein, 1969, 1999, 2011). Process consultation includes assessing the underlying agency culture that influences the problem and its solution (Schein & Schein, 2016). Both consultant and client participate in the problem-solving steps that lead to changes or to actions for problem solution.

Although consultants should emphasize process consultation, they should be willing to share their expert knowledge when appropriate. Because process consultation is collaborative, Schein (2011) recommends that consultants be willing to offer opinions and advice at all stages of the consultation process. Thus although the major emphasis should be on process consultation, consultants may find it effective to integrate both context and process. Furthermore, Schein (2016) notes that for complex problems, an open, trusting relationship with the client is vital. Thus the consultant needs to be aware of the client's own view of what is going on and be adaptive to those needs.

In the process model, the consultant is a resource person whose primary goal is to provide the client with choices for decision making. Process consultation includes the same steps as the nursing process: establishing a nurse–client relationship based on trust to assess the problem, planning and implementing actions, and evaluating the outcomes of nursing interventions. Nursing interventions may be described as direct client care or as consultation activities, depending on the goal of the intervention.

Consultation may occur before a problem occurs or after a problem exists. For example, a parent–teacher council developing a school-based family center contacts the nurse to assist with options for future nursing and health care for the students and their families. The board wishes to be proactive and plan for the needs of high-risk students and families. The administrator of a minimum-security prison has found that inmates are missing work for minor health problems and that health costs are skyrocketing. The nurse is asked to help explore solutions to the problem. Prison administration is reacting to an existing problem requiring immediate intervention.

The client is identified by determining who in the situation has the problem and needs to change. The following vignette illustrates this point:

> *Barry Henderson, RN, has been asked by the pastor of his congregation to consult with the parish council regarding the potential establishment of a health ministry. Barry decides that the consultation contract needs to include representatives of the parish council and parishioners themselves to find effective answers to the question. He realizes that time would be wasted and resistance to change would still be*

present if the focus were on only one group at a time. If he met separately with the parish council, they may decide such a program should include only one set of services. The parishioners either may want a different set of services or may desire to have services and programming organized in a very different manner. For example, the parish council may be especially interested in blood pressure screening, whereas the parishioners may be interested in wellness classes to keep the congregation healthy and in-home visiting for those who are ill. After spending much energy meeting with both groups separately, Barry believes that by being a messenger between the two groups rather than a facilitator for problem solving, the consultant role has been diluted. On the other hand, by meeting with both groups together, Barry could serve as a resource, helping them explore all viewpoints and alternatives for developing the new program.

In this case, both the parish council and the parishioners are Barry's clients.

Consultation Contract

The consultation relationship is based on expectations. The consultant has expectations concerning time, money, resources, and the participation of the client in the process. Clients have expectations about what they will gain from the consultation relationship. Discussing the terms of a **consultation contract** makes expectations explicit, lessens the likelihood of violations of contract terms, and reduces the risk of additional demands being made on either party. **Contracting** involves identifying expectations and responsibilities by both parties. Some contracts are informal, verbal agreements between individuals, whereas others (such as the consulting contract) are formal, written agreements. Areas to include in the written consultation contract are as follows:

- Client and consultant goals
- The identified problem
- The time commitment
- Limitations of the contract
- Cost
- Conditions under which the contract may be broken or renegotiated
- Intervention strategies suggested
- Expected benefits for the client
- Methods of data collection to be used
- Potential interventions
- Evaluation methods to be used
- Confidentiality

Writing a contract for consultation relationships has a number of advantages. The contract terms assist the consultant in determining the number of hours that must be devoted to the interaction and in identifying needed resources and out-of-pocket expenses required to complete the interaction. **Negotiation** of the contract assists the client in identifying realistic expectations of the consultant and firmly establishes what the consultant will and will not do. The client has the opportunity during the negotiation to place limits on what the consultant can do, and the contract allows for future renegotiation of terms. Pricing methods for consultation services vary with the nature of the services. Consultants may price their services on the basis of the actual number of billable hours required to perform the service, or they may set a flat fee during the contract negotiation phase. Flat fees are more attractive to clients because they reduce uncertainty over the total cost of the consultation. They create an incentive for consultants to be efficient and to use an accurate method of estimating their services before the contract negotiation meeting.

The initial contact is made when the client or someone in a family, group, agency, or community communicates with the nurse about a potential problem that requires intervention. The communication may be a person-to-person contact during a home visit, may be written, or may occur by telephone. On initial contact, the client and the nurse have an exploratory meeting to define the problem, assess the nurse's interest and ability to help, and formulate future actions. If the nurse has little experience with the type of problem presented, the client may wish to seek assistance elsewhere. The nurse may also conclude that the situation is not within the nurse's expertise and will want to recommend someone else to work with the client.

Next, the terms of the relationship are discussed. The nurse consultant finds out what the client expects to gain from the relationship and develops terms for the interaction. Finally, in the initial exploratory meeting, the setting for the consultation is decided, the time schedule is set, the goals of the interaction are established, and the mode of intervention is chosen.

When the terms of the contract are agreed on, the data-gathering methods will be part of the agreement. Data-gathering methods used by consultants include direct observation, individual and group interviews, use of questionnaires or surveys, and tape recordings. While data are being gathered and after the diagnosis has been finalized, the nurse implements the intervention. After fulfilling the terms of the contract, the nurse must disengage or reduce the amount of involvement with the client. Decreased contacts allow each side to evaluate the effectiveness of the intervention. During disengagement, the nurse reassures the client that future interactions are possible at the client's discretion. When the agreed-on period of disengagement has passed, the relationship is terminated. The nurse typically provides the client with a written summary of the findings and recommendations resulting from the interactions during the disengagement and termination phases (Duffy et al., 2016).

An example of an internal consultative intervention follows:

The director of nursing in a local health department telephoned the state public health nursing consultant for alcohol and other substance abuse prevention and requested a meeting at the local health department. The purpose of the meeting was to help staff analyze the evidence base and develop the protocols for a community-wide substance abuse prevention program they wished to provide. Several departments within the health department had been providing different aspects of substance abuse prevention but a coordinated effort was not in place. The nurse consultant,

Paula, met with the client, Maggie, and reviewed her findings, sharing her analysis of the current situation and contributing factors. The central issue was defined as an organizational culture that did not promote interprofessional teamwork. This resulted in difficulties providing comprehensive and coordinated substance abuse prevention initiatives. Maggie then spoke with the other department directors to identify barriers and facilitators to interprofessional teamwork. Each director agreed to speak with staff in their departments to obtain their input on barriers and facilitators. One suggestion made by staff members was to hold an off-site retreat for team-based planning related to transitional care programs such as this one. Paula worked with Maggie to help develop suggestions for the agenda and logistics that Maggie shared with the other directors. The directors asked Paula to facilitate the retreat. After revision of the program plan during the retreat, Paula met with Maggie and the other directors to help them develop additional strategies to foster an organizational culture that promoted interprofessional teamwork. She maintained contact with Maggie until the updated evidence base and program plan had been approved by the health department board and termination of the consultation occurred.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Teamwork and Collaboration

Function effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision making to achieve quality patient care.

Important aspects of teamwork and collaboration include the following:

- **Knowledge:** Describe own strengths, limitations, and values in functioning as a member of a team.
- **Skills:** Initiate plan for self-development as a team member.
- **Attitudes:** Acknowledge own potential to contribute to effective team functioning.

Teamwork and Collaboration Question

You have been selected to lead a task force aimed at reducing obesity rates in your community. Although you feel you are knowledgeable about obesity prevention and have several ideas for nursing interventions to reduce the obesity rate, you feel somewhat overwhelmed to be the person in charge of the task force. What can you do to feel more confident in your new leadership role?

Answer

First, reflect on what knowledge, values, and skills you bring to the task force that are strengths and identify areas that you feel less confident in. For example, you may feel you have a good understanding of obesity prevention but lack experience in team building and conflict resolution. Next, make a plan for how you can improve your weaknesses. For example, you could attend a continuing education workshop about team building or read the current literature on strategies for conflict resolution. Consider inviting people and organizations to join your taskforce who are proficient in the areas you feel weakest in. By reminding yourself of your strengths and actively working to improve your weaknesses, you are taking the steps to seeing your potential as an effective leader on the task force.

Nurse Consultant Role

An agency whose delivery of care is similar to that of an official public health service will most likely employ a nurse who provides traditional or nursing consultation for a broad range of community health activities (e.g., a community or public health nurse clinical specialist). A community health agency that provides a program approach to the delivery of community health services, such as family planning, maternity, child health, handicapped children's services, school health, or home health, will tend to employ specialist consultants. These consultants may have skills and training in specific clinical areas (e.g., a nurse with expertise in maternal and child health). Agencies providing primary health care require a consultant with both general knowledge of public health practice and specialized knowledge in a primary care clinical area. This is also a requirement in agencies involved in long-term and home health care.

The nurse consultant employed in an official public health agency functions as an **internal consultant** to the employing agency. As a representative of the agency, the nurse provides nursing and consultation to colleagues, other disciplines, agency administration, and other health and human service agencies and/or community groups. Two primary roles of the internal consultant are resource person and facilitator.

With knowledge of available resources, the nurse consultant can identify gaps in service, identify the critical services provided by the health care delivery system, and promote services for meeting health or social needs of the population. The consultant facilitates staff nurse problem solving about individual client and family needs, health needs of a group of clients, or professional concerns and attitudes. The consultant may assist managers and administrators in solving problems about personnel, program needs, organizational goals, community relationships, and client population needs. The consultant may also facilitate communication across agencies by working with interagency **coalitions** or **alliances**.

Consultants from federal agencies are often used as external nurse consultants. The nurse consultant from the federal agency may come to the local or state agency to serve on request as facilitator or resource person helping with program planning, development, and implementation. The primary role function of this consultant is to serve as a resource person, although the consultant may facilitate movement toward identifying actual program objectives.

An example of a vital role nurse consultants can play is in helping a community agency or a coalition conduct community needs assessments and develop strategic plans and associated action plans for achieving *Healthy People 2020* goals (see the *Healthy People 2020* box) (USDHHS, 2010).

COMPETENCIES FOR NURSE LEADERS

Nurses should watch for opportunities to participate in leadership development institutes or consider ongoing formal education through advanced public health nursing degree programs. Leadership development programs are available at various levels and are provided by civic and professional organizations. Civic programs introduce participants to the full range of

HEALTHY PEOPLE 2020

Objectives Related to the Four Overarching Goals

The following are examples of some of the proposed objectives related to leadership, management, and consultation by public health nurses:

- **AHS-2:** (Developmental) Increase the proportion of persons with coverage of appropriate evidence-based clinical preventive services.
- **HC/HIT-11:** (Developmental) Increase the proportion of meaningful users of health information technology.
- **PHI-1:** Increase the proportion of federal, tribal, state, and local public health agencies that incorporate core competencies for public health professionals into job descriptions and performance evaluations.
- **PHI-14:** Increase the proportion of national and local public health jurisdictions that conduct a public health system assessment based on national performance standards.

AHS, Access to health services; *HC/HIT,* health communication/health information technology; *PHI,* public health infrastructure.
From U.S. Department of Health and Human Services: *Healthy People 2020,* Washington, DC, 2010. Available at www.healthypeople.gov.

leadership and quality-of-life issues in a community, including health, education, politics, the arts, and business. This breadth of concerns is consistent with nurses' understanding that health results from the interaction of many facets of social and economic influences. Other leadership development opportunities are provided by professional organizations (e.g., the International Honor Society for Nursing, the American Public Health Association), continuing education, and local groups. Graduate degree programs in public health nursing provide systematic academic development of public and leadership competencies and prepare nurses to sit for advanced nursing certification through the American Nurses Credentialing Center, such as the Nurse Executive Certification. Nurses should take advantage of opportunities such as these for lifelong learning and the strengthening of leadership skills.

The following section describes essential competencies that nurses must master in order to become effective leaders in the community.

Leadership Competencies

Nurses need effective leadership, interpersonal, political, organizational, fiscal, analytical, and information competencies. Some competencies are similar to those required for leadership in other clinical areas, such as good communication skills and the ability to delegate effectively. Working in the community means being able to work with populations and groups, to build coalitions and work with partnerships. Leadership essential to these roles involves identifying a shared vision and influencing others to achieve the vision, emphasizing that client needs are the basis for health services, empowering others, delegating tasks and managing time appropriately, and making decisions effectively. Public health nurse managers should be involved in developing agency-level vision, mission, and goal statements.

Empowerment. Leaders help others empower themselves to make organizations more responsive to client needs. This means removing barriers to decision making and allowing staff nurses the authority to make client decisions in "real time," as needs demand, rather than requiring nurses to obtain numerous approvals. Empowerment is more than simply increasing nurses' authority—it includes ensuring that they have the necessary knowledge, skills, and resources to effectively make the decisions for which they are held accountable. For example, nurse managers who are responsible for preparing their own department or program budgets and for approving program spending must be given the opportunity to learn budgetary concepts. Nurses are likely to feel more empowered to do their work in a less bureaucratic environment that supports clinical autonomy and collaborative professional relationships (Cordo & Hill-Rodriguez, 2017).

The concept of empowerment underpins the consulting process. Consultants assist others in identifying solutions to problems and, more importantly, in developing the ability to manage problems independently in the future.

Delegation. Effective delegation is a key competency of public health nurses. The Association of Community Health Nurse Educators Education Committee (2009) listed delegation among the basic competencies for community/public health nurses. This group noted that delegation is part of ensuring that care is appropriately coordinated within an interprofessional health care team. It has become increasingly necessary because of the complexity of care in public health and community settings (Schaffer et al., 2016).

Agency efficiency increases when tasks are assigned to the first level in the hierarchy where employees possess the necessary skills and knowledge to complete the task and where the task is related to the goals of those positions. Delegation develops others' talents and can contribute to job satisfaction. Asking a nurse in a nursing clinic for homeless families to develop a booklet describing community resources for this population helps the staff nurse learn more about community resources, the gaps that exist in local resources, and where opportunities exist for interagency collaboration. The nurse is also likely to learn about visual presentation, layout and brochure design issues, and how to present material at the appropriate reading level. Finally, delegation is an important tool in time management. A school nurse may delegate locating resources for a screening clinic to the parent-teacher association, and the time saved can be spent on developing a teaching plan for volunteers who will help with the actual screening. Strategies for delegating responsibilities are listed in Box 40.1. Fig. 40.1 provides a

BOX 40.1 Delegating Responsibility

Nurse managers share responsibility for any tasks they delegate to others. The nurse manager delegates responsibility for a task but retains final accountability for the safe, effective outcome of the task (ANA, 2016). It is critical, then, that nurse managers know that the individuals to whom they are delegating responsibility are both prepared and capable of effectively performing the tasks. Nurse managers should provide clear guidelines and plan specific times to obtain progress reports on task completion. This will allow the opportunity to manage problems as they arise and to provide staff with helpful feedback or instruction if needed.

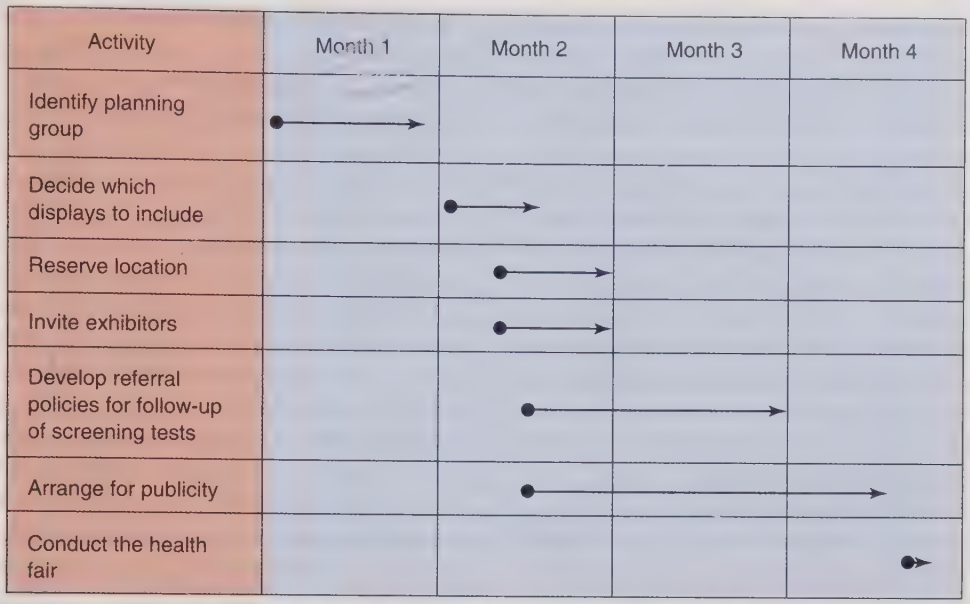

Fig. 40.1 Sample timetable for conducting a health fair.

sample timetable for conducting a health fair, showing how the nurse might decide which activities need to be completed and suggesting those that might be delegated.

Delegation has become an increasingly important skill for nurses, whether they have official roles as managers or not. As more agencies increase their use of unlicensed assistive personnel and lay community workers, nurses are increasingly delegating selected aspects of practice to others and supervising the completion of those tasks. In the National Council of State Boards of Nursing's (NCSBN's) (2016) Delegation Model, responsibilities of the employer/nurse leader, the licensed nurse, and the delegatee are outlined. Sometimes nurses mistakenly think that they are not accountable for tasks that are indirectly delegated through agency policies (e.g., policies for cross-training). However, if nursing care has been delegated, then nurses and their organizations are accountable for the safe and effective completion of that care (NCSBN, 2016). When delegating, the licensed nurse determines if the activity is appropriated based on the Five Rights of Delegation: right task, right circumstance, right person, right directions and communication, and right supervision and evaluation (NCSBN, 2016).

The first source of guidance for delegating tasks to unlicensed individuals is the state nurse practice act (NCSBN, 2016). The next source of assistance comes from specialty professional organizations. For example, the National Association of School Nurses and the ANA included care coordination and working with students, family, staff, and community members (ANA, 2017) in the standards of professional performance for school nurses. Related responsibilities include ensuring optimal outcomes and quality of care.

To delegate effectively, public health nurses must understand the differences between responsibility, accountability, and authority (NCSBN, 2016). The nurse may have the authority to delegate certain tasks to another individual or group. That individual or group accepts the responsibility to complete the task, but the nurse retains accountability to ensure the safety and quality of the outcome.

For example, a school nurse has the responsibility to assess a child with physical disabilities and develop a plan of care for that child. Selected aspects of that plan of care, such as assisting with feeding or emptying a catheter bag and recording output, could be delegated to an assistant, provided that person had received appropriate training and was competent to perform the task. This means that it is not adequate that the nurse know the individual has been certified as a nursing assistant; the nurse also needs to know that the individual is competent to safely perform the delegated task. It is important to ensure that those to whom certain tasks have been delegated have been trained to accept the responsibility and carry it out effectively. Public health nurses must also provide adequate time to plan the delegation process and to communicate with the person or group to whom a task is being delegated (NCSBN, 2016). Communication should occur throughout the process to allow for feedback and clarifications when needed. The nurse retains the legal accountability for safe client care. This responsibility may be shared with the person to whom one is delegating, but accountability is never transferred (ANA, 2016; NCSBN, 2016).

CHECK YOUR PRACTICE

You are a school nurse assigned to two elementary schools. At school A, you have four students with daily scheduled medications for attention-deficit/hyperactivity disorder, two students with prn inhalers for asthma, and one third grade student with newly diagnosed type 1 diabetes. At school B, you have three students with daily scheduled medications for attention deficit disorder, two students with severe peanut allergies with prn EpiPens, and one fourth grade student with type 1 diabetes who has an insulin pump. The schools are too far apart for you to be able to administer all scheduled medications and insulin at both schools.

- What would you do?
- What can you delegate to unlicensed assistive personnel? How will you ensure proper delegation is followed? How will you prioritize care?

Critical Thinking. Public health nursing leaders and consultants must be adept at critical thinking. Critical thinking includes analyzing and synthesizing data, using knowledge and values in making judgments, and using creative approaches in decision making and problem solving (Michelangelo, 2013; Solman, 2017). It includes reflection about the connections between sociocultural and biophysiological aspects of health status and services. Critical thinking may be fostered through the use of guided group discussions, in which group members are assisted to think about the connections just described and about the distribution effects that decisions may have on others. It is also fostered through activities to stimulate creativity, such as brainstorming. In the example below of the occupational wellness program, the nurse manager would need to critically think about ways to increase program quality.

Decision Making. Finally, a core leadership skill is the ability to make decisions effectively. Decision making and problem solving are critical aspects of nursing practice in complex clinical environments (Michelangelo, 2013; Solman, 2017). This is a two-stage process in which the nurse first must decide how much input to seek from others and second must generate alternatives for the decision and choose among the alternatives. Including others in the decision-making process is beneficial in part because others may have information and ideas that would lead to a better decision and also because others may support the decision more if they are involved in making it. This also fosters team building and collaboration, which are two competencies for public health nurses (Council on Linkages Between Academia and Public Health Practice, 2014; Quad Council Coalition Competency Review Task Force, 2018).

A decision tree can be used for selecting a leadership style that varies from a unilateral, independent decision process, to progressively more participative styles, with the most participative style involving delegating authority to a group that will be responsible for making the decision. Although many assume that autocratic decision making is not effective, in fact it may be both effective and efficient under certain circumstances, such as emergencies. In other situations, it is better to seek input from others, individually or as a group, to seek suggestions for solutions from the group, or to simply turn a problem over to a group to solve on their own.

The next stage of the decision-making process is to generate alternative solutions and to choose among those solutions. Both risk and cost are important dimensions in most situations. The goal involves low cost and low risk to clients and staff. Other dimensions might be unique to the situation. For example, if the nurse is trying to decide whether to develop an in-house wellness program for an occupational setting or to contract with a consulting group for that service, the nurse could compare the risks and benefits of both alternatives. The occupational health nurse might decide that the advantages of an in-house wellness program are that (1) it allows for staff participation in identifying key dimensions and goals and brainstorming creative solutions, (2) participants' values are built into the dimensions and goals, and (3) it allows for both creative and logical thinking processes.

Interpersonal Competencies

Nurse leaders, managers, and consultants need effective interpersonal skills in communicating, motivating, appraising and coaching, contracting, supervising, team building, and promoting diversity.

Communication. Good communication skills, including skills in the use of assertiveness techniques and conflict resolution, as well as communicating through the media and professional and scientific literature, are essential to being effective in leadership roles (Foronda et al., 2016; Vertino, 2014). Nurses have a particular challenge in communicating because many of those with whom they work may be in a different health profession or in a different field altogether. Nurses often communicate with lay workers or with the public through media outlets such as newspaper columns, television and radio interviews, blogs, and public service announcements. It is especially critical to listen carefully, to make underlying assumptions clear, and to speak in the other's language. This may mean avoiding the use of professional jargon and speaking in more commonly shared language or speaking in the listener's primary language. It is increasingly important for nurses to be bilingual or multilingual, depending on the ethnic composition of the community.

Communication must be culturally competent to be effective. Because communication involves words, tone of voice, posture, eye contact, and spatial relationships, cultural norms often influence the meanings given to different aspects of body language. For example, whereas most advise direct eye contact when communicating, in some cultures this may be viewed as aggressive, especially when the eye contact is prolonged. Some cultures prefer the closer-space relationships that may make others feel they are being crowded. Other aspects of communication are important as well, such as the appropriate place for reprimands. It is never appropriate to reprimand or criticize in public, although public praise is usually an excellent idea. Nurse managers and consultants should be sensitive to the power of written communication and be aware that, although putting a message in writing is a good way to avoid confusion, it also may be seen as aggressive, distrustful, or a bid for power. The key is to make certain that the message that is communicated is the message that was intended. Effective communication skills are listed in Box 40.2.

BOX 40.2 Effective Communication Skills

- Listen actively.
- Restate the main points.
- Speak in the listener's language.
- Maintain culturally appropriate eye contact and body language.
- Provide an appropriate environment.
- Be aware of the power of written communication.
- Use simple, direct words.
- Use "I" statements and say how you feel.
- Provide frequent feedback.
- Reflect on the meaning of the message.

Creating a Motivating Workplace. One of the more difficult skills to master is motivating other people; in fact, one cannot ever really motivate others, because motivation is internal. However, the skillful leader can create a motivating environment, working to make certain that both individual and agency goals are met to the extent possible. Sometimes individual motivation may be low because employees do not believe they have the skills necessary to achieve their goals, or they believe that the system will not allow them to do so. The effective nurse leader identifies which perceptions are inaccurate and helps individuals develop plans for improving their personal capacities for achieving goals. Although adequate salaries are important, compensation is not the only way to create a motivating environment for professionals. One home health aide supervisor is known for the high level of morale among her staff and the unusually low level of turnover. She makes a point of being available for discussion before the aides leave the agency in the morning and on their return in the afternoon. She always gives each person a birthday card, and thanks them for a job well done. For the long-term good, leaders should work with others in the community to increase salaries if they are not competitive.

Appraisal and Coaching. Employee appraisal and coaching are closely related to motivation and individual development (Mackenzie, 2013; Mone & London, 2018; Okello & Gilson, 2015). The purpose of performance evaluation is to assist employees to more effectively meet the objectives of their roles and to help them develop their potential in ways that facilitate achieving agency goals. Performance evaluation should not take place just before an annual appraisal interview is scheduled. It should be a regular part of the job, with the manager providing regular feedback on employee progress toward goals. Performance appraisal is particularly challenging for nurse managers because so many community health workers practice independently in the field. For example, nurse managers in home health must plan either to make visits with the nursing staff on a regular basis or to obtain other forms of input on employee performance, such as planning telephone or office conferences with staff.

Coaching involves working one-on-one with others to improve clinical care delivery (Westcott, 2016). With coaching, managers retain responsibility for decisions but request input and explain decisions. They support progress by helping the employee break the tasks into manageable parts, providing resources for accomplishing tasks and for acquiring the necessary skills, and praising task accomplishment. Coaching is most useful with people who may not yet be skillful in a particular area and who are not confident about their skills.

Supervision. Nurse managers who delegate tasks to others must supervise the completion of those tasks and build in mechanisms to make certain that the tasks are completed safely and effectively (ANA, 2016; NCSBN, 2016). Supervision means decision making and implementation of activities in an ongoing relationship. It may occur either on site when the nurse manager is present and while the activity is being performed, or off site when the nurse is providing care in a community setting. It is important for nurse managers to build effective means of providing off-site supervision because so many community health activities do not take place within a single agency (e.g., home health care occurs in individual homes, and school health services are provided in individual schools).

Handling criticism is a difficult skill that involves both the giving and the taking of criticism related to job performance. Nurse managers should provide constructive critique as close as possible to the time they observe a problem with an employee's job performance. Constructive criticism focuses on the behaviors necessary to meet the job expectations and helps identify sources of problems, resources for managing problem behavior, and feedback. For example, if an employee is chronically tardy, the nurse manager should speak privately with the employee about the job expectation for promptness, identify why the employee is frequently tardy, establish a behavioral goal with time frames and consequences of achieving or not achieving the goal, and assist the employee to develop a plan for achieving the goal. The employee may be unaware of the importance of being punctual and can easily change the behavior. On the other hand, a behavior modification plan may be useful to help change the behavior. Behavioral consequences may include both positive reinforcers, such as praise, and disciplinary measures, such as oral and written warnings, limited raises, suspension, and termination. Suspension and termination are normally used only with problems related to safety, inability to perform job duties, breach of confidentiality, and illegal acts; they are detailed in agency policies and procedures.

Team Building. Finally, team building and managing diversity are group-level skills needed by nurse leaders, managers, and consultants (LeBlanc, 2014; Phillips, 2016). Interprofessional teams increasingly are used to assess clients, plan client care or services, and manage quality improvement activities. Teams may include members of multiple health disciplines as, for example, with community health coalitions. They also may include people from other backgrounds, including lay community health workers. Nurse managers and consultants can facilitate team building by assisting the team to develop goals and ground rules, identifying who will fill various roles and determining how to share leadership, developing strategies for ongoing cooperation and recognition of contributions of each member, and resolving conflict.

Promoting Diversity. A key challenge to nurse managers is promoting and managing diversity in positive ways that value different perspectives and provide insights into culturally competent strategies to eliminate disparities. By 2060, the U.S. population is expected to be older (nearly one in five over the age of 65 by 2030) and more diverse, with significant increase in the number of immigrants than previous years (U.S. Census Bureau, 2018). Nurse leaders must work with others to create workplaces that build on the strengths of a diverse workforce to provide excellent health care and eliminate disparities in outcomes. Nurses should partner with schools, faith communities, health care agencies, and universities to encourage minority group members who are interested in nursing careers. This will help

build a community nursing workforce that better reflects the population as a whole (Craft-Blacksheare, 2018; Kowlowitz et al., 2018). Nurse managers must understand cultural values and norms to communicate effectively and interpret behavior accurately. They must know how to prevent any form of racial, sexual, or ethnic harassment and ensure a positive and welcoming environment in the workplace.

Power Dynamics and Conflict Resolution

Power imbalances can occur within groups, community organizations, and policy-making bodies, and affect health care professionals and community members. Managing **power dynamics** effectively requires that public health nurses understand community systems, collaboration, and strategies for providing information to empower others to work on their own behalf. Public health nurses work closely with community groups to build capacity for assessing strengths and needs, developing solutions to community health problems and promoting health and wellness, and managing long-term approaches for healthier communities. This is particularly important when working with vulnerable populations (Kyounghae et al., 2016; Ray, 2016).

Effective **conflict resolution** requires negotiation skills as well as skills in recognizing and managing power dynamics. Principled negotiation (McKibben, 2017; Rosenstein, Dinklin, & Munro, 2014) emphasizes collaborative problem solving and development of mutually agreeable ways of achieving goals. Conflict resolution strategies can result in win-win, win-lose, or lose-lose outcomes. Strategies most likely to create win-win situations include collaborating, confronting problems directly, building consensus, and ensuring that all parties have an adequate opportunity for input (McKibben, 2017; Rosenstein et al., 2014).

Population-focused nurse leaders must understand power dynamics. Because nurses possess altruistic values, they may believe that being powerful is not necessary. However, it is impossible to create health-promoting public health services without some legitimacy in decision-making arenas. Membership on community agency boards and advisory committees puts nurse managers in the position to influence service delivery.

Consultants' advice may be followed because the client feels that the consultant possesses superior knowledge or skills and is trustworthy and credible. Internal nurse consultants may have power resulting from their roles in the organization. The client may not feel obligated to implement the recommendations of external consultants. On the other hand, external consultants may be viewed as influential because of an affiliation with other well-known consultants or a national organization. The consultant's ability to persuade clients by offering reasons, new techniques, or methods of problem solving may motivate clients to follow the consultant's advice.

Organizational Competencies

Nurses use organizational skills, such as planning, organizing, implementing, and coordinating as well as monitoring, evaluating, and improving quality. Nurses use these skills when managing programs and projects and when coordinating care for individuals, families, and groups.

Planning. Planning includes prioritizing daily activities to achieve goals. It also includes long-range planning, such as working with nurses in a department to plan a new program. Planning is a collaborative activity that can involve interprofessional teams, community groups, and policy makers. Developing a shared vision, goals, and measurable objectives provides the foundation for a plan. Nurses must be able to anticipate the cost of providing nursing services to a certain population over a period of time and to develop a proposal (or a **business plan**) for a contract to provide the services. Because planning is primarily a cognitive activity, nurse managers and consultants may tend to lessen its importance and allow little time for adequate planning. However, planning is the basis for direct nursing services and it is an essential competency for population-focused nurse care (ANA, 2013; Quad Council Coalition Competency Review Task Force, 2018), so it is important to make adequate time for planning.

Several resources are available to help nurse managers and consultants plan nursing services. *Healthy People 2020* (USDHHS, 2010) defines the national health goals for the United States by the year 2020 and should be the basis for program planning. The Community Preventive Services Task Force (2018) maintains *The Community Guide* to provide evidence-based strategies for community health planning. The KU Center for Community Health Development developed and manages the *Community Tool Box* (2018a), which provides free online resources for those working to build healthier communities and bring about social change.

Organizing. Organizing involves determining appropriate sequencing and timelines for the activities necessary to achieve goals and arranging for the appropriate people to carry out the plan. Flow sheets and timetables are helpful tools that allow nurse managers and consultants to visualize how tasks are organized and to identify gaps in the planning. Fig. 40.1, as shown earlier, illustrates a timetable for conducting a health fair.

Implementing and Coordinating. Implementing and coordinating a plan includes not only following the timelines but also making certain that the relevant regulations and policies are adhered to, that activities are appropriately documented, and that the work of all team members is coordinated. One strategy that helps ensure coordination is use of an action plan (Community Tool Box, 2018b). This is a table that includes the program goals and objectives, activities to meet the objectives, identification of those responsible for each activity, the time frame for completing the activities, and the plan for evaluating achievement of the objectives. Team members should review the action plan at regular meetings and make changes as necessary. Action plans are also used to coordinate care for people with chronic illnesses such as obesity (see, e.g., Waldecker, Malpass, King, & Ridd, 2018). Nurse managers and consultants should

give sufficient attention to the change process by helping those involved identify the need for change, keeping them informed, soliciting their input, and making modifications in the plan as necessary.

Monitoring, Evaluating, and Improving. Monitoring, evaluating, and making improvements are critical to nursing services. Nurses should monitor nursing services on a regular basis and make improvements as soon as the need for improvements becomes apparent. Professional standards and the standards of various accrediting bodies guide the focus of monitoring and evaluating. The Joint Commission standards for home health and ambulatory care clinics (http://www.jointcommission.org/) provide detailed and explicit minimal standards that all such agencies should be expected to meet.

In addition to professional standards of practice available from the ANA and specialty nursing organizations, the Agency for Healthcare Research and Quality has published clinical guidelines for prevention and treatment of selected health problems, such as wound care, pain, and tobacco cessation. Using evidence-based clinical guidelines is a key way to improve the quality of care. Finally, nurses should evaluate and monitor changes in client health outcomes. Effective outcomes management programs using information systems can be applied for ongoing planning and program improvements for target populations such as women and children (Olds et al., 2014).

Fiscal Competencies

Forecasting Costs. Nurse leaders must be skilled in the area of fiscal management. Nurse managers and consultants must be able to project the cost of public health nursing services. This is especially important in today's tight economic environment because the forecast should include an assessment of the risk rating of the likely health and illness experiences of a target population. Combining community health assessment skills, epidemiologic projections, and consultation are key steps in this process and make it possible to design health programs to reduce health risks among various populations. After developing a profile of the anticipated health and illness experiences of a target population, the next step is anticipating the amount and kind of nursing resources needed by the population. These skills are basic to the development of proposals for new nursing services and contracts with external groups.

Develop and Monitor Budgets. Nurse managers have taken on more responsibility for developing and monitoring their own department budgets as agencies have decentralized. They must be able to develop a justifiable budget and monitor how actual spending compares with planned spending. Expenses commonly included in an operating budget are salaries and benefits, equipment, supplies, travel, and overhead. It is helpful to obtain staff input when developing a budget in order to make financial projections as realistic as possible. Nurse managers should review program action plans with staff to determine the resources necessary to implement the program. Combining anticipated volume, revenues, and expenses allows the nurse manager to anticipate a breakeven point for new services (i.e., determining when a new program can be expected to be financially self-sufficient).

Variance analysis means identifying the difference between actual and planned results, determining the cause of the variation, and correcting problems when they exist. Spending more than anticipated is not always negative; it may simply indicate that client or service volume was higher than anticipated. This could, however, be of concern in an agency that is fully capitated and receives a set amount of money to see a client for usually a year, regardless of the cost of the services the client needs. Additional services do not bring in additional revenues. Nurses in fully capitated environments have more opportunity than ever before to focus on health promotion and illness prevention services.

Higher expenses than planned are not always under the control of the nurse manager. For example, if the prevailing wage increases because of changes in the labor market, an agency may spend more than expected on salaries. On the other hand, spending less than predicted does not always indicate that a program is running efficiently; client volume may be down, or staff may not be providing adequate services. The most important thing for a public health nurse to do initially is to monitor expenses carefully and analyze why expenses might differ from the original plan.

For example, if a nurse manager observes that more has been spent on salaries and supplies than originally budgeted, and less on travel, should he or she think this is desirable or undesirable? To analyze the variance, the nurse should ask if the prices for labor and supplies were higher than expected or if the agency has used more nursing time or supplies than planned (Jones et al., 2018; Lim & Noh, 2015; Talley, Thorgrimson, & Robinson, 2013). The answers to these questions will help determine whether the variance resulted from factors under the manager's control, such as inefficiency, or from factors outside of the manager's control, such as higher wages or higher prices than expected. The answers will also help determine whether the variance resulted from an increase in client volume or an alteration in case mix, with the agency serving sicker clients.

Conduct Cost-Effectiveness Analysis. Regardless of the type of reimbursement system in place, nurses should be able to conduct a simple cost-effectiveness analysis of their interventions. Such analyses are not measurements of the efficiency of a program (see Chapter 23 for a discussion of this distinction) but are comparisons of the money spent for the outcomes across two or more interventions. Cost-effectiveness analyses compare alternative approaches for achieving the same goals. The nurse should measure the full costs and benefits (or savings) of each alternative intervention and construct ratios to compare the alternatives. The final result might be stated as the number of people who were able to achieve a desired health outcome (e.g., losing weight or adhering to an exercise program) for each additional dollar spent. The results of cost-effectiveness analyses sometimes raise new questions that must be analyzed. For

example, in a study of the cost-effectiveness of nurse practitioner/community health worker care management intervention to reduce cardiovascular health disparities, investigators found the patients in the intervention group had significant improvements in low-density lipoprotein (LDL) cholesterol, systolic and diastolic blood pressure (BP), and hemoglobin A1c (HbA1c) compared to those receiving usual care (Allen et al., 2014). Although Allen et al. (2014) concluded that the nurse practitioner (NP)/community health worker (CHW) care management teams were a cost-effective strategy to reduce cardiovascular risk, they also reported that those in the intervention group had higher laboratory costs and medication costs than those in the comparative group receiving usual care. What would you recommend to management in a primary care setting, based on those results?

Analytical and Information Competencies

It is increasingly important for nurses to have excellent analytical competencies and competencies in the use of information. For example, access to useful and needed data helps nurses and other health professionals monitor clinical outcomes, identify systems issues that can result in health care errors, and plan to better meet the health needs of their populations. Population-focused nurses need a good understanding of descriptive and clinical epidemiology as well as the ability to analyze graphical data displays such as histograms, flowcharts, and line graphs. Use of aids such as checklists, reminders, and clinical decision support are all good ways to improve the quality of care and prevent errors (Kihlgren et al., 2016; Massarweh et al., 2017). Because nurses are interested in identifying patterns of health problems, care delivery, and outcomes in community settings, more nurses are including nursing taxonomies (or languages) in electronic client records. Nursing leaders who participate in incorporating electronic records and information systems should have a conceptual framework to guide the project (Englebright et al., 2014; Jones & Seckman, 2018).

FUTURE OF NURSING LEADERSHIP

As noted at the beginning of this chapter, as the most trusted profession, nursing is in a position of influence. Using that power in a responsible and effective way is the task of the nurse leader.

In 2010, the IOM released its landmark report, *The Future of Nursing: Leading Change, Advancing Health.* In this report sponsored by the Robert Wood Johnson Foundation (RWJF), the committee described a vision of a transformed health care system in which quality care is accessible to the diverse populations of the United States, wellness and disease prevention are promoted, health outcomes improve, and compassionate care is provided across the life span (IOM, 2011). To achieve this health care system, the IOM (2011) recommends that the nursing workforce become prepared to "assume leadership positions across all levels" and suggests that nursing have representatives on boards, executive management teams, and in other key leadership positions. The 2015 IOM report assessing progress made on *The Future of Nursing* recommendations noted significant progress in many areas and called for more focus and attention on removing barriers to practice and care, transforming education, continued collaborating and leading by nurses, promoting diversity, and improving data sets (IOM, 2015b).

The Future of Nursing: *Campaign for Action* (2018) was convened to address the IOM's (2011) recommendations by mobilizing Action Coalitions in every state and Washington, DC, working with policy makers, health care professionals, educators, and business leaders. The *Campaign for Action* (2018) currently ties its work with the Robert Wood Johnson Foundation's (2015) *Culture of Health* vision. Convened in 2014 in response to *The Future of Nursing* report, the *Nurses on Boards Coalition* (2018) raises awareness that all boards would benefit from the nursing perspective and works towards its goal of at least 10,000 nurses on boards by 2020. By working with policy makers, government leaders at all levels, and advocacy organizations, nurse leaders have the power to change the health care system to provide accessible, quality, evidence-based care to individuals and populations. With the passage and implementation of the Affordable Care Act of 2010 (ACA), nurses have the opportunity to take a pivotal leadership role in leading the nation in transforming the health care system (Wakefield, 2013). In 2013, Kathleen G. Sebelius, Secretary of the U.S. Department of Health and Human Services, expressed the vital role nurses can play in whether or not the ACA is successful, stating nurses are "at the heart of our healthcare system" (Nurse.com News, 2013). A national survey of public health nurses (PHNs) regarding their knowledge, perceptions, and practices under the ACA concluded that PHNs are making a substantial contribution to the implementation of the health care reform act, particularly in the integration of primary care and public health, provision of clinical prevention services, care coordination, patient navigation, establishment of private-public partnerships, population health strategies, and population health data assessment and analysis (Edmonds et al., 2016). Nurse leaders are needed to provide education to individuals and communities about the ACA and assist them in navigating the health insurance marketplace. Furthermore, nurse leaders are needed to address these potential influences and to develop innovative solutions to the challenges that arise.

The Association of Public Health Nurses (APHN) released a position paper in 2016 titled *The Public Health Nurse—Necessary Partner for the Future of Healthy Communities.* This position paper acknowledges the vital role the public health nursing workforce plays in delivering essential services and impacting successful population-based outcomes. Furthermore, the report notes the important role PHN leaders have had historically in positively influencing community health and the need for PHNs to continue to provide leadership in an ever-changing health system environment, evolving and strengthening their practice with community systems.

LINKING CONTENT TO PRACTICE

This chapter emphasizes the use of leadership, management, and consultative skills and knowledge in public health nursing practice, whether one has an official leadership or consulting role or not. Use of the theories and principles of leadership, management, and consultation with public health and nursing science is key to promoting healthy communities and achieving the goals of *Healthy People 2020* (USDHHS, 2010). Entry-level public health nurses are expected to possess competencies in these areas, including communication, collaboration, team building, analysis, program planning and management, managing budgets, and understanding and implementing policies (Council on Linkages Between Academia and Public Health Practice, 2014; Quad Council Coalition Competency Review Task Force, 2018). Public health nurses focus on working with communities in addition to other staff members and colleagues, and work with broad problems and issues that require systems thinking, leadership, and building coalitions (Bekemeier et al., 2015; Olson, 2013). When a public health nurse thinks about empowerment, for example, he or she considers how to provide information and foster skill development for empowerment of other staff members and of community members. Thinking about working in partnership with community groups and policy makers influences a public health nurse's use of theories and principles of leadership, management, and consultation.

PRACTICE APPLICATION

The nurse manager of a nursing clinic in a residential facility for frail older adults approached the local college of nursing for assistance with health promotion and health monitoring activities for the residents. The facility was undergoing renovation and was expected to more than triple its capacity by the time the renovation was completed. The nurse manager thought the health promotion activities that were already in place would be inadequate to serve the growing needs. Most of the residents were more than 70 years of age and had several chronic illnesses. The residential complex was 10 to 15 miles away from health care facilities.

Shirley, the nurse manager, supervised a staff of three nurses and one homemaker aide. She contracted with a local physical therapy firm for services as needed for the residents. Shirley had asked the staff if they thought they could realistically expand their services, and they suggested consultation. The staff commented that residents needed nurses who could provide health monitoring and skilled nursing services in their apartments, because so many were increasingly homebound. Staff members were hesitant about expanding into home care themselves because they feared it would mean a cutback in the health promotion activities they currently offered. They thought the needs, and the resources that would be required to meet the needs, should be evaluated before making any final decision.

What should the staff do to complete the evaluation of the problem?

A. Call a meeting of persons affected by the problem and decide on using an internal or external consultant to help evaluate the problem.

B. Write a contract and indicate how they want the evaluation to be done.

C. Develop a plan to implement home health services because the plan would include an analysis of needs and resources.

D. Continue with their health promotion activities and decide about home health services when more resources could be identified.

Answers can be found on the Evolve site.

KEY POINTS

- Nurse leaders may function in formal roles as managers or consultants, or they may use managerial and consulting skills in their everyday clinical practice.
- Nurse leaders, managers, and consultants should work with organizations, coalitions, and community groups to design local strategies that will help achieve the *Healthy People 2020* goals.
- The goals of nursing leadership and management are (1) to achieve organization and professional goals for client services and clinical outcomes, (2) to empower personnel to perform their responsibilities effectively and efficiently, (3) to develop new services that will enable the organization to respond to emerging community health needs, and (4) to work with others for a healthy community.
- Systems thinking promotes sensitivity to the interdependence of parts of a system and the potential causes and consequences of organizational actions.
- Nurse managers may be team leaders or program directors, directors of home health agencies or community-based clinics, or commissioners of health. They function as visionaries, coaches, facilitators, role models, evaluators, advocates, community health and program planners, and teachers. They have ongoing responsibilities for clients, groups, and community health and for personnel and fiscal resources under their direction.
- The goal of consultation is to stimulate clients to take responsibility, feel more secure, deal constructively with their feelings and with others in interaction, and internalize skills of a flexible and creative nature.
- Consultation models can be categorized as content or process models. Process model consultation helps the client assess both the problem and the kind of help needed to solve the problem.
- Consultation involves seven basic phases: initial contact, definition of the relationship, selection of setting and approach, data collection and problem diagnosis, intervention, reduction of involvement and evaluation, and termination.
- Nurse consultants may function as internal consultants within an organization or external consultants outside the client organization.

- Nurse managers and consultants need a wide variety of competencies, including leadership, interpersonal, organizational, and political skills. Leadership skills include abilities to influence others to work toward achieving a vision, empower others, delegate tasks, manage time, and make decisions effectively.
- Interpersonal skills include communication, motivation, appraisal and coaching, contracting, team building, and diversity management skills.
- Organizational skills include planning, organizing, and implementing community nursing services; monitoring and evaluating services; quality improvement; and managing fiscal resources.
- Political skills are those used in negotiation and conflict management and managing power dynamics among health care teams and within the community.
- Population-focused nurses need analytical and informatics skills to be able to identify and monitor trends, improve health care safety, and evaluate outcomes.
- In general, both nurse managers and consultants must hold a minimum of a baccalaureate degree in nursing. Organizations employing nurses without this credential should help them obtain additional education in the areas of community or nursing, management theories and principles, and theories and principles of consultation.
- By working with policy makers, government leaders at all levels, and advocacy organizations, nurse leaders have the power to change the health care system to provide accessible, quality, evidence-based care to individuals and populations.

CLINICAL DECISION-MAKING ACTIVITIES

1. Discuss with your class members the implications that managed care and discounted fee-for-service preferred provider organizations have for nurse managers and consultants in community-based organizations and in the public health departments. What other implications can you think of in addition to those described in the text?
2. Draft a vision and mission statement for a nursing clinic with your classmates. Develop goals and objectives that follow the vision and mission you selected. What type of employees would you need to hire? List some of the policies and procedures you would need to have in such a clinic on the basis of your vision, mission, goals, and objectives.
3. Have several class members obtain the vision, mission, and philosophy statements from agencies in which students have community health clinical experiences. Compare these statements in terms of the agencies' target populations, basic values, and essential functions.
4. Interview one or more practicing staff nurses working with populations. Ask them to describe the activities of their jobs that could be categorized as consultation. During the interview, attempt to determine the following:
   A. How they define consultation
   B. The goals they are attempting to achieve with their consulting activities
   C. The model they seem to be applying in their consulting activities
   D. The intervention strategies they use
   E. Whether their activities are of a generalist or a specialist nature and of an internal or external consultative nature
   F. The strengths and limitations they perceive in themselves regarding their consultative functions (e.g., education, experiential, organizational, relational, economic)
5. Interview one or more nurse consultants. During the interview, attempt to determine the answers to the preceding questions. Compare the responses of the two groups (public health nurse consultants and population-focused staff nurses). Analyze the factors you think account for the similarities and differences.
6. Visit a nurse-managed clinic for underserved populations. Talk with nurses and other staff members about how they work together as a team and what they do to promote client involvement in determining needed clinic services. Develop a case analysis of the microsystem within the clinic and how clinical care delivery is continuously monitored, evaluated, and improved within the system. What recommendations might you have for strengthening the clinical information system in the clinic?

The Nurse in Public Health, Home Health, Hospice, and Palliative Care

Karen S. Martin, RN, MSN, FAAN and
Kathryn H. Bowles, RN, PhD, FAAN

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Compare different practice models for home and community-based services.
2. Summarize the basic roles and responsibilities of public health, home health, hospice, and palliative care nurses.
3. Explain the professional standards and educational requirements for nurses in public health, home health, hospice, and palliative care.
4. Describe the three components of the Omaha System.
5. Analyze how nurses in public health, home health, hospice, and palliative care use best practices, evidence-based practice, and quality improvement strategies to improve the care they provide.
6. Cite examples of trends and opportunities in public health, home health, hospice, and palliative care involving technology, informatics, and telehealth.

CHAPTER OUTLINE

Public health, home health, hospice, and palliative care nursing are rapidly expanding specialties under the broad umbrella of public health, community-oriented, and population-focused practice. When nurses practicing these specialties provide comprehensive assessment, planning, intervention, and evaluation services, they contribute to the total health of the general public as noted on the first page of this book and Chapter 1. Two additional nurse-led models are summarized in this chapter, the Nurse-Family Partnership and transitional care. Although the practice of these nurses is very diverse, **evidence-based practice** should be the goal. More details will be described later in the chapter.

For the purposes of this chapter, public health, home health, hospice, and palliative care nursing refer to a wide variety of **practice settings** and holistic services typically provided to clients of all ages by these nurses in their residences, noninstitutional settings, and some institutional settings. In general, public health and home health providers offer intermittent, skilled supportive care, treatments, and/or assistance with activities of daily living so that elders and others who are ill or have disabilities remain safe and avoid unnecessary hospitalization. Hospice and palliative care services are intended to provide comfort and meet physical, emotional, and spiritual needs to all ages. Hospice services are provided at end of life and do not include curative treatment according to Medicare rules. In contrast, palliative care is a wider range of services, is not limited to the days or weeks prior to end of life, and may include curative treatment.

A number of agencies have agreements with diverse settings, including residential and acute care facilities, so that nurses provide services in locations in addition to clients' homes. The settings include community or senior centers, libraries, corrections facilities, and work sites. As will be described later, public health, home health, hospice, and palliative care nurses and their interprofessional colleagues are employed by diverse organizations such as public health departments and voluntary, hospital-based, and proprietary organizations. Mergers, buyouts, and collaborative agreements are increasing rapidly and causing practice boundaries to blur. It is very important to note that an organization's name does not predict the types of programs and services provided.

Numerous references in this chapter describe research, finances, client personal preference, and new technology suggesting that the home is the optimal location for diverse health and nursing services (Ansberry, 2018; Buhler-Wilkerson, 2002; Gao, Maganti, & Monsen, 2017; Gorski, 2017; Marrelli, 2018a; Milone-Nuzzo & Hollars, 2017; NFP, 2017; NHPCO, 2018; Reddy, 2018; Wright, 2018). Client residences include houses, apartments, trailers, boarding and care homes, hospice houses, assisted living facilities, shelters, and cars. Home health, hospice, and palliative services are provided by formal caregivers who include nurses, social workers, physical and occupational therapists, home health aides, licensed practical nurses, chaplains, physicians, and others. Because of the nature of the practice, a team approach and **interprofessional collaboration** are required. The specific disciplines involved vary with the program, the intensity of the client and family's needs, the location of the program and home, and reimbursement.

The Triple Aim model for health care was published in 2008 (Berwick, Nolan, & Whittington, 2008). However, the primary concepts of the model have been the foundation and core values of public health, home health, and related community-based services from their inception: improve the health of populations, enhance the experience of care for individuals, and reduce the per capita cost of health care. The Triple Aim is a good strategy to encourage health promotion, prevention, and healthier lifestyles regardless of the program or setting, although all illness, including chronic illness, cannot be prevented or cured. Because the population is aging rapidly in this country and internationally, the need for services is increasing dramatically. In 2015, less than 50 million Americans were 65 years and older compared to about 98 million projected for 2060. Almost 20 million Americans may be 85 years and older in 2060 (Ansberry, 2018; Kerr et al., 2019; MedPAC, 2018; U.S. Census Bureau, 2017). Although a related concept, **population health**, is older than the Triple Aim, the term was not widely used in this country until more recently. Population health is the health status of a population of individuals, including the distribution of health status within the group (Kindig & Stoddart, 2003). According to Storfjell, Winslow, and Saunders (2017), nurses must become a well-utilized population health resource and full partner in bringing solutions to the national high cost/poor health dilemma.

Access to other health care professionals, resources, and equipment is very different when home and institutional care settings are compared. Many nurses find public health, home health, hospice, and palliative practice very rewarding because they observe the impact of their services and practice with a high degree of autonomy. Nurses who make home visits need to have good organizational, communication, critical thinking, and documentation skills. They need to understand ever-changing reimbursement regulations. Competence, integrity, adaptability, good judgment, and creativity are essential characteristics. Public health, home health, hospice, and palliative nurses need to watch for risks in the physical environment and to be savvy about their own safety as well as the safety of their clients. The Agency for Healthcare Research and Quality (AHRQ, 2017) provides rich resources about client and patient safety. It is important to stay alert and change the plan of action quickly if trouble arises when using cars or public transportation, and when inside, entering, or leaving clients' residences (Marrelli, 2018a; Milone-Nuzzo & Hollars, 2017; Schoon, Porta, & Schaffer, 2018).

When entering a residence, the public health, home health, hospice, or palliative care nurse is a guest and needs to earn the trust of the family and establish a partnership with the client and family (Fig. 41.1); more details are described later in the Practice Guidelines section. It is essential that clients and families are involved in making decisions for home-based services to be efficient and effective; this team approach may be referred to as **consumer engagement**.

Family is defined by the individual client and includes any caregiver or significant other who assists the client with care at

Fig. 41.1 Nurses are guests in clients' homes. (From www.omahasystem.org/photogallery.html. Used with permission from Karen S. Martin, RN, MSN, FAAN.)

home. Family caregiving involves transportation, helping clients meet their basic needs, and providing care such as personal hygiene, meal preparation, medication administration, and simple as well as complex treatments. Today's clients and family caregivers provide many aspects of care in the home that were previously provided in hospitals or in home by professional caregivers. Care can be confusing, challenging, stressful, burdensome, and frightening for family caregivers; many are not well-prepared for their new roles. Clients need to be monitored regularly, and some require 24-hour care. Many family caregivers need assistance to identify diverse support services that enable them to provide care while maintaining their own physical and emotional health (Ansberry, 2018; Chow & Dahlin, 2018; Diefenbeck, Klemm, & Hayes, 2017; Gao et al., 2017; Gasper et al., 2018; Gorski, 2017; Izumi, 2017; Marrelli, 2018a; Milone-Nuzzo & Hollars, 2017; NHPCO, 2018; Reddy, 2018; Wright, 2018).

HOME HEALTH CARE

Evolution of Home Health Care

Home health care provided by formal caregivers in the United States originated in the nineteenth century. In many communities, the initial programs evolved into nonprofit visiting nurse agencies and health departments. The movement expanded rapidly in the United States, resulting in the formation of 71 home health agencies prior to 1900, and 600 organizations by 1909. Additional historical details are described in Chapter 2 and other publications (Buhler-Wilkerson, 2002; Donahue, 2011).

Home health services were included as a major benefit when Medicare and Medicaid legislation was passed in 1965 and implemented in 1966. (See Chapter 5, Economics of Health Care Delivery.) Both resulted in significant changes nationally. The Medicare benefit was designed to provide intermittent, shorter visits with temporary lengths of stay to people age 65 and older who were homebound. Medicaid covered a wider range of services than Medicare and included children, pregnant women, parents of certain Medicaid-eligible children, and persons with certain disabilities. For clients who qualified for Medicare or Medicaid services, the home health agency was required to develop a plan of care for clients and obtain the signature of a physician.

During the next 30 years, the number of Medicare-certified agencies grew rapidly as a result of the aging population and prospective payment legislation that decreased the length of hospital stays. This trend changed when the Balanced Budget Act of 1997 was enacted, changing the home health payment system from a fee-for-service model to prospective payment based on a standardized assessment completed at admission. The Act prompted the closure of more than 30 percent of the country's Medicare-certified home health agencies and a dramatic decline in the number of clients served. Between 2004 and 2015, the number of agencies grew by more than 60 percent, a dramatic increase. Although the number of agencies fell slightly in 2016, the general trend is increasing growth (MedPAC, 2018; U.S. Census Bureau, 2017; Wright, 2018).

Description of Home Health Care

Home health care is a broad concept and approach to services and is at the top of the list of the fastest growing, service-providing industries in this country (BLS, 2017a). It includes a focus on primary, secondary, and tertiary prevention; the primary focus can involve aggregates, similar to those provided by other population-focused nurses. (See the Levels of Prevention box.) Initiatives involving primary and secondary prevention have always been important to home health care.

LEVELS OF PREVENTION

Home Health

Primary Prevention

The nurse (1) administers seasonal and newer strains of flu vaccine or (2) provides case management interventions so clients obtain the vaccines at convenient locations.

Secondary Prevention

The nurse monitors clients in their homes for early signs of new health problems in order to initiate prompt treatment. When the nurse works collaboratively with the physician and/or nurse practitioner, effective interventions can be provided. An example is monitoring clients for medication side effects.

Tertiary Prevention

The nurse provides instruction about dietary modifications and insulin injections to clients with new diagnoses of diabetes. Clients and their families implement the therapeutic plan to identify signs of infection, prevent complications, and maintain the highest possible level of health and self-care.

Home health nursing is "a specialty area of nursing practice that promotes optimal health and well-being for patients, their families, and caregivers within their homes and communities. Home health nurses use a holistic approach aimed at empowering patients/families/caregivers to achieve their highest levels of physical, functional, spiritual, and psychosocial health. Home health nurses provide nursing services to patients of all ages and cultures and at all stages of health and illness, including end of life" (ANA, 2014, p. 7). Home health nurses include generalist nurses, public health nurses, clinical nurse specialists, and nurse practitioners. They and their interprofessional team members provide diverse services to target populations such as new parents; clients recovering from injuries, acute illness, and surgery; frail elders; and clients managing disabilities, and chronic health problems. Some home health agencies include wellness programs, health fairs, school nurses, communicable disease prevention, and other programs that are similar to those offered by public health departments.

Home health nurses and their team members help clients and their families achieve improved health and independence in a safe environment. In addition to nursing care, the following are available to those who are Medicare eligible: physical therapy, occupational therapy, speech and language pathology, home health aide, and medical social services. Skilled nursing and **skilled nursing services** are the Medicare terms that describe the duties of the registered nurse, refer to the requirement of professional nursing judgment, and include diverse assessment, teaching, case management, and other interventions (CMS, 2016, 2018b, 2018c). Using Omaha System terms that are introduced later in this chapter, assessment involves Environmental, Psychosocial, Physiological, and Health-Related Behaviors concerns, while interventions are categorized as Teaching, Guidance, and Counseling; Treatments and Procedures; Case Management; and Surveillance (Martin, 2005; Monsen, 2018; Omaha System, 2018).

According to MedPAC (2018), about 3.4 million individuals received **Medicare-certified** home health services in 2016 that were reimbursed by the Centers for Medicare and Medicaid Services (CMS). The total number of visits exceeded 114 million, and beneficiaries averaged 33 visits during the year. About 51 percent of the visits included skilled nursing, 39 percent therapy, 10 percent home health aides, and 1 percent medical social services (MedPAC, 2018). An unknown number of additional clients received services from non-Medicare-certified agencies. The majority of home health clients were 65 years and older; more were women than men; and many had diagnoses of circulatory disease, diabetes, neurological conditions, and depression (CMS, 2016; MedPAC, 2018).

Home health agencies can be divided into the following five general categories (Fazzi, 2018; MedPAC, 2018) (Fig. 41.2).

- Official or public agencies receive tax revenue and are operated by state, county, city, or other local government units, such as health departments. Typically, official agencies also offer well-child clinics, immunizations, health education programs, and home visits for preventive health care.
- Voluntary and private agencies are nonprofit home health agencies and usually receive some funds from United Way, donations, and endowments. Currently, there are about the same number of voluntary and private agencies. Visiting Nurse Associations, AS EXAMPLE, are usually freestanding, voluntary, nonprofit organizations governed by a board of directors, and usually financed by earnings, donations, and tax-deductible contributions. Sometimes they are categorized with combination agencies because of their similar characteristics.
- Combination agencies have characteristics of both governmental and voluntary agencies. The number of combination agencies continues to decrease, although some are large agencies.
- Hospital-based agencies grew rapidly during the 1970s and 1980s when the advent of diagnosis-related groups led to earlier hospital discharges and Medicare reimbursement was encouraging. Since then, some hospitals and their home health agencies separated because of changes in reimbursement and other pressures.
- Proprietary agencies are freestanding, for-profit agencies that are required to pay taxes. Many are part of large chains. Proprietary agencies now dominate the industry and represent about 80 percent or more of all agencies. Almost all new providers are proprietary agencies.

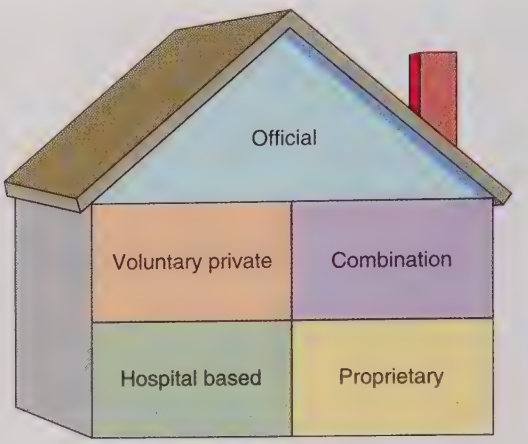

Fig. 41.2 Types of home health agencies.

In 2018, about 12,200 agencies provided Medicare services (MedPAC, 2018). Texas has more than 2000 agencies, while California and Florida have just over 1000 agencies (Fazzi, 2018). The size of individual agencies varied from those that employ a few nurses to the Visiting Nurse Service of New York with its 1525 nurses, more than 13,000 employees, 48,500 daily client census, and 1,363,488 annual visits (VNSNY, 2017, Sockolow, 2018).

Although agencies vary as to programs offered, size, administration, ownership, organization, and board structures, they must meet ever-changing licensure, certification, and accreditation **regulations** established by national and state groups. The primary source of those regulations is CMS (CMS, 2017b, 2017c, 2018b, 2018c). To be Medicare-certified and reimbursed, CMS requires that home health agencies complete a rigorous certification process, follow the rules of the Conditions of Participation (CoPs), and provide intermittent, skilled professional services

(CMS, 2017c). The rule book that agencies must follow is referred to as the Conditions of Participation (CoPs); key criteria are (1) the client must be home-bound or are unable to leave home without considerable effort; (2) services must be intermittent and include a skilled service provided by a nurse, physical therapist, or speech and language pathologist; (3) a plan of care must be initiated and followed; and (4) Medicare forms, physician orders, and client records must be completed on a timely basis.

The Conditions of Participation are lengthy, complex, and subject to change. For example, in 1999, CMS mandated the **Outcome and Assessment Information Set (OASIS)**; it has been updated several times. The current version is described later in this chapter as are other Medicare regulations, reimbursement, and accreditation details (CMS, 2017c). Beginning in 2011, physicians or allowed non-physician practitioners (nurse practitioners and physician assistants) must have a face-to-face encounter with clients prior to signing orders and initiating care (CMS, 2017c). Home health nurses must be well-informed about Medicare regulations to determine the visit frequency and timing based on their clients' conditions and communicate with physicians. Frequently, clients and their families ask nurses to help them understand their Medicare benefits.

Annual national expenditures for home health care in 2016 were $18.1 billion (Fazzi, 2018; MedPAC, 2018). During the same year, home health accounted for about 3 percent of the country's total Medicare expenditures in contrast to 49 percent for hospitals and 11 percent for skilled nursing facilities. Medicare is the largest payer for home health services. In addition to Medicare, state and local governments accounted for 15 percent of home health reimbursement, Medicaid for 24 percent, private insurance for 8 percent, out-of-pocket or private pay 10 percent, and other sources 2 percent (CMS, 2016).

HOSPICE AND PALLIATIVE CARE

Evolution of Hospice and Palliative Care

Hospice care was introduced in the United States in the 1970s by Florence Wald, often referred to as the mother of the hospice movement. Before establishing Connecticut Hospice in 1974, Dr. Wald collaborated with Dame Cicely Saunders, a British nurse, physician, and social worker who founded St. Christopher's Hospice in England in 1967 (ANA/HPNA, 2014; Wright, 2018; Zerwekh, 2006). During the same era, Dr. Elisabeth Kübler-Ross, a physician, published *On Death and Dying* (1969), a book that was widely read by the public and health care professionals. Dr. Ross described the inhumanity of a death-denying society such as the United States, the need to provide sensitive end-of-life care and involve clients in choices, and an emphasis on the quality of life (ANA/HPNA, 2014; Perry & Parente, 2017; Zerwekh, 2006).

Medicaid reimbursement for hospice care began in 1980 and Medicare in 1983; reimbursement determines many aspects of the programs, including the types and length of services. The number of Medicare-certified hospices grew from 31 in 1984 to 2323 in 2002 and to 4199 in 2015. In 2016, 1.4 million Medicare beneficiaries were enrolled in hospice care (NHPCO, 2018). Because the time of death is difficult to predict and many people in this country are reluctant to acknowledge a terminal prognosis, hospice care often begins late in the disease process. Barriers and stigmas continue to be associated with hospice for some clients, families, and physicians; because they equate hospice with hopelessness and giving up, they are reluctant to consider hospice. A number of the same people are receptive to the concept of palliative care and will accept those services (Buch & Nies, 2015; CMS, 2018c; Gasper et al., 2018; Marrelli, 2018b; NHPCO, 2018; Perry & Parente, 2017; Stober, 2017; Wright, 2018; Zerwekh, 2006).

In 1987, the first comprehensive, integrated **palliative care** program was established in the United States at the Cleveland Clinic. The focus was specialized care for those living with signs and symptoms and the stress of serious illness. Similar palliative care programs originated earlier in England (Etkind et al., 2017). In 1999, the Robert Wood Johnson Foundation funded the Center to Advance Palliative Care (CAPC) to stimulate the development of high-quality palliative care programs in hospitals and other health care settings. In 2010, the CAPC convened a consensus panel to establish criteria for palliative care assessment components at hospital admission and during the hospital stay (CAPC, 2018; Weissman & Meier, 2011). Assessment items include recent history of the illness, pain and symptom assessment, patient-centered goals of care, and transition of care plans; the goal is to help clinicians identify those individuals and their families who need palliative care. CAPC reports that the number of palliative care programs in U.S. hospitals increased from 658 in 2000 to 1831 in 2016 (CAPC, 2018).

Description of Hospice and Palliative Care

Hospice and palliative care are similar and, yet, very different. Similarities that are described throughout this chapter include a client-focused/consumer engagement approach, holistic and evidence-based practice, emphasis on ethics, communication skills, interprofessional collaboration, care coordination, focus on transitions of care, and caregiving skills that include symptom management, pain relief, and comfort. The following differences are primarily related to reimbursement requirements in this country and include the length of care and frequency and intensity of services. The goal of the hospice movement is to humanize the end-of-life experience. For hospice services, physicians need to indicate that clients have six months or less to live, and clients acknowledge that they have a terminal prognosis and select care that is comfortable, not life-extending. In contrast, the goal of palliative care is quality of life. Palliative services are not restricted based on the disease or progress and may be appropriate for those with a serious, complex illness regardless if they are expected to recover fully, live with a chronic illness for an extended time, or experience serious disease progression (ANA/HPNA, 2014; CMS, 2017b; 2018b, 2018c; Chow & Dahlin, 2018; Etkind et al., 2017; HPNA/ANA, 2007; Perry & Parente, 2017; Slipka & Monsen, 2018; U.S. Census Bureau, 2017).

The Hospice and Palliative Nurses Association (HPNA) and others suggest that palliative care is a broad term occurring over a longer period of time, and hospice is a subset with a short time period. The HPNA developed an illustration referred to as the Trajectories of Palliative Care and included it in their 2014 publication (ANA/HPNA, 2014). The title of the illustration is palliative care and represents an extended continuum of chronic serious illness to acute serious illness during which stabilization and exacerbations may occur. Services and treatment vary during this time. The continuum encompasses three segments: a longer segment that is referred to as diagnosis, limited signs and symptoms, and increasing severity of signs and symptoms; a relatively short period of hospice care and death; and a period of bereavement care for family members.

The HPNA is an umbrella organization that represents hospice and palliative nurses and other members of the team employed in home-based organizations as well as acute and long-term care, outpatient, and other settings (ANA/HPNA, 2014; ANA/HPNA, 2017). The organization's mission is to advance expert care during serious illness; it is based on four pillars of education, advocacy, leadership, and research. Nurses who are members of hospice and palliative care teams "provide evidence-based physical, emotional, psychosocial, and spiritual or existential care to individuals and families experiencing life-limiting, progressive illness" (HPNA/ANA, 2007, p. 1). The definition of hospice focuses on comfort for individuals and their families at the end of life and does not include curative treatment. The HPNA did not define their specialty in their new 2014 publication, but, instead, endorsed the National Consensus Project of Palliative Care's (NCP) definition. "Palliative care means patient and family-centered care that optimizes quality of life by anticipating, preventing, and treating suffering. Palliative care throughout the continuum of illness involves addressing the physical, intellectual, emotional, social, and spiritual needs and [facilitating] patient autonomy, access to information, and choice" (NCP, 2013, p. 9; NCP, 2018.

Both the interprofessional hospice and palliative care teams work closely together to provide comprehensive care in partnership with clients and their families. The teams include nurses, physicians, social workers, therapists, chaplains, counselors, aides, pharmacists, and volunteers; volunteers are essential team members. The Bureau of Labor (2017b) suggests that the need for employees and volunteers is increasing dramatically. Most agencies and team members consider conferences and continuing education essential to develop and renew their skills involving topics such as advance care planning, end-of-life comfort measures, new medications and treatments, therapeutic communication, compassion fatigue, spirituality, complex family dynamics, and cultural awareness. Working with clients who are dying involves unique emotional stress; hospice and palliative care programs usually address the team's well-being as well as that of the clients and families (ANA/HPNA, 2014, 2017; Buch & Nies, 2015; Diefenbeck et al., 2017; Hinds et al., 2005; Izumi, 2017; NHPCO, 2018; Slipka & Monsen, 2018; Wright, 2018; Zerwekh, 2006).

Clients and their families and friends are at the center of the hospice and palliative care teams and will be involved in advance care planning, symptom and medication management, personal care, and the use of supplies. Death produces intense emotions even when family members have prepared for it. Bereavement services that are part of hospice involve attending the funeral or other services for the deceased client, and contact at anniversaries of death, holidays, and the client's birthday for 13 months after the client's death. Hospice organizations usually offer support group opportunities for families or refer them to support groups in the area.

Palliative care has no specific federal designation as a specialty; rather it exists as a consultative discipline delivering a philosophy of care. Palliative care programs in hospitals have been growing steadily. As of 2016, 75 percent of hospitals were able to support inpatient palliative care programs, an increase from 25 percent in 2000 (Center to Advance Palliative Care [CAPC], 2018).

Palliative care clinicians must meet certain regulatory requirements when they practice in home health or other community agencies (ANA/HPNA, 2014). There are many predictions and publications that support the need for palliative care programs in the home, but very few articles or studies published about actual programs outside of acute care settings. Health care professionals, educators, researchers, organizations, and the media are making slow progress to introduce palliative care in the home without Medicare, Medicaid, or other funding sources that are available for hospice (ANA/HPNA, 2017; Chow & Dahlin, 2018; Etkind et al., 2017; Izumi, 2017; Stober (2017) conducted a literature review and found nine articles published in the last ten years; palliative care at home improved the quality of care and client outcomes including the reduction of 30-day hospital readmissions. Gasper et al. (2018) designed and conducted a quality improvement project for 13 subjects admitted to a home health care organization in Pennsylvania with a diagnosis of heart failure. Providers' skills improved with education and training, and 30-day hospital readmissions were reduced.

Hospice is a formalized, funded program in hospice and home health agencies with extensive data. For that reason, it is the focus of the following paragraphs. Initially, cancer was the primary diagnosis of most clients in hospice programs. More recently, cancer is the diagnosis of about 20-30 percent of hospice clients, and dementia, cardiac and circulatory, neurological, respiratory, and other end-stage diseases make up 70-80 percent of the diagnoses (NHPCO, 2018). More than one million clients received Medicare-certified hospice services in 2017 with an average stay of 87.8 days (MedPAC, 2018). The average length of stay will rise if home health nurses and others provide information about end-of-life hospice care to clients and families, and hospice becomes more widely accepted by the public. Most agencies are educating their nurses to recognize clients in need of hospice or palliative care and have discussions with clients and families as a strategy to decrease the hospice stigma that results in late referrals or missed opportunities. Even when nurses, physicians, and others discuss quality of life and encourage the transition from palliative services to hospice, clients and/or families may continue in denial and not accept hospice until the last several days of life. Late referrals resulting

in brief hospice stays make it difficult for the hospice team to provide comprehensive, expert, cost-effective services to clients and families. For many in this country, death is not viewed as a normal or natural part of the life cycle (Buch & Nies, 2015; Izumi, 2017; Marrelli, 2018b; NHPCO, 2018; Perry & Parente, 2017; Wright, 2018; Zerwekh, 2006).

Hospice providers can be divided into four general categories. Freestanding facilities are the most common followed by home health agencies and hospital-based facilities. Skilled nursing facilities are the least common. Many freestanding facilities are for-profit providers, similar to home health agencies. The average length of hospice service in 2016 was 71 days, and the median length was 24 days (NHPCO, 2018).

After the client acknowledges a terminal prognosis and selects comforting care rather than life-extending or curative care, hospice organizations coordinate services in partnership with the client and family and provide financial case management. According to Zerwekh (2006), hospice addresses four foci: (1) attention to the body, mind, and spirit; (2) death is not a taboo topic; (3) health care technology should be used with discretion; and (4) clients have a right to truthful discussion and participation in treatment decisions. The four types of care and the percent used are (1) routine home care with intermittent visits, 92.3 percent; (2) continuous home care when condition is acute and death is near, 1.3 percent; (3) general inpatient/hospital care for symptom relief, 6.1 percent; and (4) respite care in a nursing home of no more than 5 days at a time to relieve family members, 0.3 percent (NHPCO, 2018).

Hospice is the only Medicare benefit that includes medications, medical equipment, 24-hour/seven-day-a-week access to care, and support for family members after death. Those who receive Medicare-certified hospice services are evaluated during the 6-month period to determine if they are eligible to continue. The time period is divided into two 90-day certification periods, and is followed by an unlimited number of subsequent 60-day periods. Authorization by physicians is required for the certification periods (CMS, 2017b, 2018c; Perry & Parente, 2017).

Hospice programs are usually operated and staffed as independent entities or corporations even when they are part of a larger organization because of the specialized nature of the practice and the complex Medicare regulations and financial requirements. Similarly to home health, hospice nurses must be familiar with regulations and financial requirements; however, the OASIS is not a requirement for hospice programs as it is for home health.

Medicare, Medicaid, U.S. Department of Veterans Affairs (VA), managed care, private insurance, and private donations fund most hospice services. Medicare provides the most funds and spent 16.9 billion dollars in 2016. Hospice services account for about 6 percent of the total Medicare budget, about twice as much as home health services (CMS, 2016, 2017b, 2018c; NHPCO, 2018).

Home Care of Dying Children. "The death of a child alters the life and health of others immediately and for the rest of their lives" (Hinds et al., 2005, p. S70). The needs of dying children and their families are unique because of the degree of emotional impact, and because the young are not expected to die or precede the death of their parents. Nurses need to recognize the child's physical, cognitive, psychosocial, and spiritual development as well as the family's dynamics, cultural heritage, and spiritual beliefs. That recognition is essential to provide appropriate pain management, assist the child and family to communicate with each other, advocate for their needs in the community, and provide case management and continuity of care (Hinds et al., 2005; Kaye et al., 2015; Levine et al., 2017; Weaver et al., 2016).

Bereavement programs as described for hospice programs are especially important for families who have lost a child. Parents, grandparents, and siblings can participate in a variety of support groups offered by the hospice program or other bereavement organizations (Levine et al., 2017; Weaver et al., 2016).

HOW TO Use a Hospice Approach to Care in Any Setting

The hospice philosophy of care means providing comfort measures to individuals before death and support for their families before and after death. Individuals may be any age. Death may occur in the individual's home, a hospital setting, or an uncontrolled setting such as the community. How does one adapt nursing care in any situation? What basic skills can professional caregivers use that can be applied in any situation or setting? How do professional caregivers adapt to the death of a hospice client, inpatient death, or a sudden, unexpected death where, for example, many people have died as a result of a natural disaster or a terrorist act?

- Be prepared. Consider your own philosophy of death so that you can assist others without distraction when that time comes.
- Cultures vary in their beliefs about and responses to death. Know the differences in cultural responses so that you can effectively help people in their time of need.
- Death events cannot be totally controlled even in a hospice environment where the eventual death has been illustrated to family and friends and the dying individual before the death. Expect the unexpected and take cues from the client and the loved ones regarding their needs.
- Shock, disbelief, and crisis reactions occur even with prepared, hospice deaths. Ask family and caregivers what they need; provide them with the basics such as food or blankets; provide comfort; if it is not contraindicated, provide the family/friends with personal effects or mementos of the individual; give sensitive, caring support. Sit with them and listen.

Modified from Mistovich JJ, Karren KJ: *Prehospital emergency care*, ed. 10, Upper Saddle River, NJ, 2014, Pearson Education; Mistovich JJ, Karren, KJ: *Prehospital emergency care*, ed. 11, Upper Saddle River, NJ, 2018, Pearson Education.

ADDITIONAL NURSE-LED MODELS

The Nurse-Family Partnership and transitional care are focused on interprofessional collaboration as well as care coordination, critical thinking, best practices, and evidence-based practice. Best practices suggest using credible, established evidence from a variety of sources including research, experience, and expert clinicians; evidence-based practice suggests increased emphasis on programs of research that demonstrate consistently good outcomes (Melnyk & Fineout-Overholt, 2015; Melnyk & Gallagher-Ford, 2015). With both models, nurses have essential

roles in the provision of care, documentation of services, program development and management, outcome measurement and effectiveness analysis, and public education.

Nurse-Family Partnership

The Nurse-Family Partnership (NFP) was initiated in 1977 by a researcher, David Olds, and a nurse, Harriet Kitzman; it is probably the best known and well-funded nurse home visit specialty program in the United States (Enoch et al., 2016; NFP, 2017; Olds et al., 1997). The Partnership is a network of nurses, families, and policy makers. Nurses receive extensive orientation and provide structured education and case management during regularly scheduled home visits to pregnant women; visits continue until the children's second birthday. The goals of the program are to improve pregnancy outcomes, child health and development, and economic self-sufficiency of the families. Many rigorous studies and longitudinal, randomized controlled trials have documented numerous lifelong improvements in health outcomes that were statistically significant and economically sound. Mothers had fewer children, were more likely to become employed, and were less likely to enter the criminal justice system. Children were less likely to be abused, experience behavioral and intellectual problems by age 6, to be arrested by age 15, or to be obese. Both mothers and children demonstrated improved health and development. More fathers were present in the households. Initial recipients of care were ethnically diverse, low-income, first-time mothers and their families who lived in New York, Tennessee, and Colorado. In 2017, nurses visited more than 50,000 families in 42 states. Federal and private funding continues to increase as the program maintains successful outcomes and grows. NFP had revenues of more than 36.9 million dollars in 2017 (Enoch et al., 2016; Miller, 2015; NFP, 2017; Olds et al., 1997; Thorland et al., 2017).

Transitional Care

As a result of a fragmented health care system, increasing complexity of client care, and rising costs, transitional care has gained much needed attention in this country and internationally (Meadows et al., 2014). Transitional care is defined as "a set of actions designed to ensure the coordination and continuity of health care as clients transfer between different locations and different levels of care in the same location" (Coleman & Berenson, 2004, p. 1). Challenges to quality care originate from a lack of depth, accuracy, and timeliness of information received from the referring site; the need for complex medication reconciliation; and difficulties with communication and coordination among community-based providers.

Transitional care programs that involve home health have emerged as low- and high-intensity interventions that include, but vary from, traditional home health interventions. Low-intensity interventions include coaching, telephone follow-up, and specific disease management programs. High-intensity transitional care programs are designed for populations who have complex or high-risk health problems. An example is the Transitional Care Model, where advanced practice nurses perform transitional care from hospital to home providing in-hospital visits and discharge planning followed with home visits, primary care office visits, and telephone follow-up for one to three months after discharge (Naylor et al., 2017). Numerous studies have been conducted to test the Transitional Care Model with high-risk groups such as heart failure and dementia (Naylor et al., 2016). The research model is currently implemented in practice settings in collaboration with major insurance companies and home care agencies (Naylor et al., 2013).

Outcomes achieved with the Transitional Care Model consistently show cost savings and improvements in clinical and quality outcomes for clients receiving the intervention compared with usual care (Naylor et al., 2013). The most common outcome across all populations is a consistent reduction in readmissions to a hospital. The Transitional Care Model strategies emphasize screening in acute care for high-risk clients; engaging the elder/caregiver in designing personalized goals and the plan of care; managing symptoms; educating and promoting self-management; and collaborating with the multidisciplinary team members to assure continuity and a team approach. Both the low- and high-intensity transitional care programs have spread rapidly into practice as hospitals seek ways to avoid the financial penalties associated with higher than the national average 30-day readmission rates. The penalties are instituted through the Readmission Reduction Program enacted through the 2010 Patient Protection and Affordable Care Act (CMS, 2018e).

CHECK YOUR PRACTICE

You are working with a home health agency that is interested in defining the populations they serve. You have been asked to suggest and approach to accomplish this task. What approach would you suggest and how can you help with the task? What would you do?

POPULATION HEALTH

Population health is the health status of a population of individuals, including the distribution of health status within the group as mentioned early in this chapter and in Chapter 1. The field or emerging specialization of population health includes health status, determinants of the population's health, and policies and interventions that link those two (Kindig & Stoddart, 2003). Although the concept of population health was discussed for some years, dissemination was limited. After the concepts of the Triple Aim were widely embraced, population health began appearing more frequently in practice, education, research, health care literature, and the public press. The speed increased when CMS and private insurers began to move away from fee-for-service reimbursement and toward value-based care.

Nurses are educated to consider health issues in a large context. Nurses who work in community practice settings are involved in population health each day as they make home visits and provide care to clients and families in diverse settings. Aspects of population health are related to community assessment and windshield surveys, projects and assignments that nurses have used in community health practice and academic

settings for years (Kerr et al., 2016, 2019). Models are described elsewhere in this book (see Chapter 17). Social science professionals described a four-step approach and the associated functions, key questions, and key challenges to improve population health. The steps are reflect, assess, specify changes, and implement and evaluate (Wendel et al., 2018). Notice how similar these problem-solving steps are to the nursing process described in the next section of this chapter.

Storfjell et al. (2017) conducted a project for the Robert Wood Johnson Foundation and published an excellent report entitled *Catalysts for Change: Harnessing the Power of Nurses to Build Population Health in the 21st Century.* Their purpose was to "describe how nurses can best promote the health of the US population and reverse current health declines. The paper explores population-health related nursing roles and skills, and identifies their implications for nursing practice, education, research, and policy" (p. 2). "A population-focused nurse will move beyond the individualistic, downstream approach, viewing individuals and families in the context of their environment, and assessing how their community affects them" (p. 3). Nurses should identify and address social determinants of health, discern patterns across populations, link individuals and families to community resources, and develop broad-based interventions. Focusing on social determinants of health offers an upstream focus and offers opportunities for data mining, big data analysis, and quantifying outcomes of care (Gao et al., 2017; Gao et al., 2018; Monsen et al., 2016). According to Susan Swider (Storfjell et al., 2017), "If you think about population health and nursing practice, there is a role for nursing caring for individuals to better understand care coordination and how to assess for and address the social determinants of health. That is very much in the bailiwick of individual nursing practice. It doesn't require you to do big picture planning across large numbers of people, but it requires [the RN] to practice a bit differently" (p. 4).

Other authors have suggested practical ways that nurses can improve the health of their communities. Ross (2018) states that nurses can take action and make a difference where they learn, pray, work, and live and suggests that nurses become involved with schools, faith-based organizations, workplaces, neighborhoods, and advocacy. Duke University and the Duke University School of Nursing have developed a comprehensive, long-term plan to involve students and faculty in population health (Duke Nursing, 2018). An example of a population health approach will be described in the Medication Management section later in this chapter.

SCOPE AND STANDARDS OF PRACTICE

Nursing is a theory and practice-based profession that incorporates art and science. Examples of nursing, family, and systems theories are mentioned and summarized in other chapters of this book. Chapter 8 focuses on cultural diversity, and includes many references. In addition, Smith (2017a, 2017b) published articles that are students' and nurse educators' guides to cultural competence. Chapter 10 addresses evidence-based practice; the concept is addressed frequently in this chapter, and one example is included. Melnyk is one of the most prolific authors on this topic (Melnyk & Fineout-Overholt, 2015; Melnyk & Gallagher-Ford, 2015). Several chapters of this book describe the Quad Council Coalition's (2018) eight domains of practice; those domains are linked to information in this chapter in the Linking Content to Practice box.

The **nursing process** is the theoretical framework used by the American Nurses Association (ANA), which notes that the nursing process is the essential methodology by which client goals are identified and achieved. Their scope and standards publications, including those for home health nursing and palliative nursing, are organized according to the nursing process and contain two sections: the Standards of Care and the Standards of Professional Performance (ANA, 2013, 2014; ANA/HPNA, 2014). Publications include the six steps of the nursing process: assessment, diagnosis, outcomes identification, planning, implementation, and evaluation; the steps are linked to standards and more specific measurement criteria that are stated in behavioral objectives. The standards address quality of care, performance appraisal, critical thinking skills, education, collegiality, ethics, collaboration, research, and resource use.

OMAHA SYSTEM

The **Omaha System** was initially developed to operationalize the nursing process and provide a practical, easily understood, computer-compatible, quantifiable guide for daily use in diverse community settings. It is the only ANA-recognized terminology developed inductively by and for nurses who practice in the community (ANA, 2018).

As early as 1970, the nurses, other staff, and administrators of the Visiting Nurse Association (VNA) of Omaha, Nebraska, began addressing **nursing practice**, **documentation**, and **information management** concerns. Information management is the integration of clinical, demographic, financial, administrative, and staffing data; manipulation or processing of these data; and production of various reports that transform data into meaningful information for decision making (Martin, 2005). At that time, clinicians were not using computers, and there was no systematic nomenclature or classification of client problems and concerns, interventions, or client outcomes to quantify and measure clinical data and integrate with a problem-oriented record system.

More than 22,000 multiprofessional clinicians, educators, and researchers use Omaha System point-of-care **electronic health records (EHRs)** across the health care continuum in the United States and other countries, far beyond the initial use in community settings in the United States. About 2000 more use paper-and-pen records. EHRs are longitudinal collections of clinical and demographic client-specific data that are stored in a computer-readable format. By 2005, 85 percent of all counties in Minnesota had one or more public health or home care agencies or schools/colleges of nursing using Omaha System software. That number continues to increase as clinicians, providers, and funders want to measure the outcomes of care. During 2014, Minnesota became the first state to recommend that the Omaha System be used as a standardized terminology

in the EHRs of all community health care settings in the state. Details about Omaha System application, users, case studies, inclusion in reference terminologies, research, best practices/evidence-based practice, and listserv are described in publications and on the website (Eardley et al., 2018; Martin, 2005; Martin & Kessler, 2017; Monsen, 2018; Monsen et al., 2018; Omaha System, 2018; Topaz, Golfenshtein, & Bowles, 2014).

Description of the Omaha System

Between 1975 and 1993, the VNA of Omaha staff conducted four extensive, federally funded development and refinement research studies that established reliability, validity, and usability of the Omaha System. The result of the research was the Problem Classification Scheme, the Intervention Scheme, and the Problem Rating Scale for Outcomes. These three components of the Omaha System were designed to be used together, be comprehensive, relatively simple, hierarchical, multidimensional, and computer compatible. The Omaha System has existed in the public domain since the initial research in 1975. Because it is not held under copyright, software companies can use it as the foundation of their software without obtaining licenses or paying fees. They are expected to replicate the structure, terms, and codes as presented and cite their source (Eardley et al., 2018; Martin, 2005; Martin & Kessler, 2017; Omaha System, 2018).

As depicted in Fig. 41.3, the Omaha System conceptual model is based on the dynamic, interactive nature of the nursing or problem-solving process, the practitioner-client relationship, and concepts of diagnostic reasoning, critical thinking, and quality improvement. The client as an individual, a family, or a community appears at the center of the model. This location suggests the range of Omaha System application, client-centered care, and the essential partnership between clients and practitioners that Omaha System developers and users have embraced from the onset. The term *consumer engagement* has been used to describe this partnership, especially in acute care practice. Most nurses and other clinicians employed in community settings recognized that partnership was essential from the beginning of their employment. The outer circle is the practitioner-client relationship. Additional details about the conceptual model are described in the following paragraphs (Gao et al., 2018; Martin, 2015; Monsen et al., 2016; Omaha System, 2018).

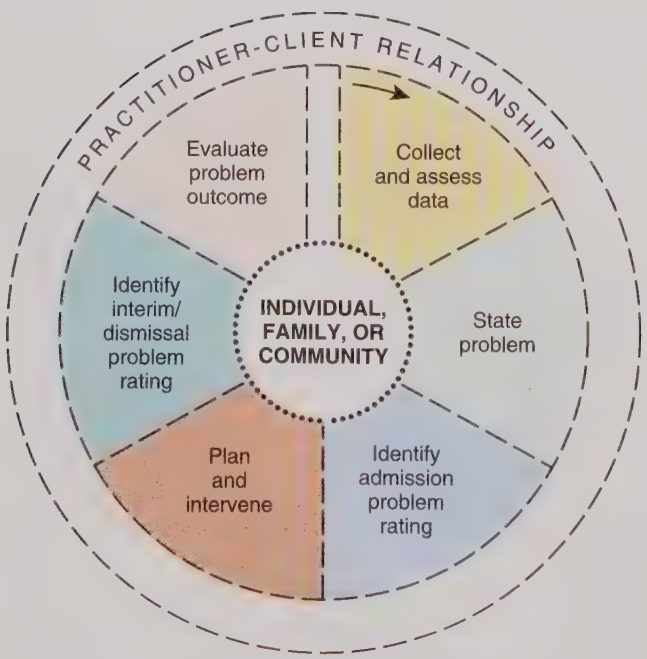

Fig. 41.3 Omaha System model of the problem-solving process. (From Martin KS: *The Omaha System: a key to practice, documentation, and information management,* reprinted ed. 2, Omaha, NE, 2005, Health Connections Press.)

Early Omaha System practice, education, and research use focused on individuals and families. The focus on the community or population level is increasingly rapidly as changes occur throughout the health care system and reimbursement (Kerr et al., 2016; Kerr et al., 2019; Monsen, 2018; Monsen et al., 2016; Monsen et al., 2018; Schoon et al., in press)

The Omaha System was intended for use by nurses and all members of the health care delivery team. The goals of the research were to (1) develop a structured and comprehensive system that could be both understood and used by members of various disciplines, and (2) foster collaborative practice. Therefore the Omaha System was designed to guide practice decisions, sort and document pertinent client data uniformly, and provide a framework for an agency-wide, multidisciplinary clinical information management system capable of meeting the daily needs of clinicians, managers, and administrators (Eardley et al., 2018; Martin, 2005; Martin & Kessler, 2017; Monsen et al., 2018; Omaha System, 2018; Quad Council Coalition, 2018).

Problem Classification Scheme. The Omaha System Problem Classification Scheme is a comprehensive, orderly, nonexhaustive, mutually exclusive taxonomy designed to identify diverse clients' health-related concerns. Its simple and concrete terms are used to organize a comprehensive assessment, an important standard of nursing practice. The Problem Classification Scheme consists of four levels. Four domains appear at the first level and represent priority areas. Forty-two terms, referred to as client problems or areas of client needs and strengths, appear at the second level. The third level consists of two sets of problem modifiers: health promotion, potential and actual, as well as individual, family, and community. Clusters of signs and symptoms describe actual problems at the fourth level. The content and relationship of the domain and problem levels depicted in Box 41.1 are further illustrated by the case example at the end of this chapter. Understanding the meaning of and relationships among the terms is a prerequisite to using the scheme accurately and consistently to collect, sort, document, analyze, quantify, and communicate client needs and strengths.

Intervention Scheme. The Omaha System Intervention Scheme is an important standard of nursing practice in providing

BOX 41.1 Domains and Problems of the Omaha System Problem Classification Scheme

Environmental Domain
Material resources and physical surroundings both inside and outside the living area, neighborhood, and broader community:
- Income
- Sanitation
- Residence
- Neighborhood/workplace safety

Psychosocial Domain
Patterns of behavior, emotion, communication, relationships, and development:
- Communication with community resources
- Social contact
- Role change
- Interpersonal relationship
- Spirituality
- Grief
- Mental health
- Sexuality
- Caretaking/parenting
- Neglect
- Abuse
- Growth and development

Physiological Domain
Functions and processes that maintain life:
- Hearing
- Vision
- Speech and language
- Oral health
- Cognition
- Pain
- Consciousness
- Skin
- Neuro-musculo-skeletal function
- Respiration
- Circulation
- Digestion-hydration
- Bowel function
- Urinary function
- Reproductive function
- Pregnancy
- Postpartum
- Communicable/infectious condition

Health-Related Behaviors Domain
Patterns of activity that maintain or promote wellness, promote recovery, and decrease the risk of disease:
- Nutrition
- Sleep and rest patterns
- Physical activity
- Personal care
- Substance use
- Family planning
- Health care supervision
- Medication regimen

From Martin KS: *The Omaha System: A key to practice, documentation, and information management*, reprinted ed. 2, Omaha, NE, 2005, Health Connections Press.

interventions. Four broad categories of interventions appear at the first level of the Intervention Scheme. An alphabetical list of 75 targets or objects of action and 1 "other" appear at the second level. Client-specific information generated by clinicians is at the third level. The contents of the category and target levels are depicted in Boxes 41.2 and 41.3, respectively. The Intervention Scheme provides the terms for care plans and services. It enables clinicians to describe, quantify, and communicate their practice, including improving or restoring health, describing deterioration, or preventing illness.

Problem Rating Scale for Outcomes. The Omaha System Problem Rating Scale for Outcomes consists of three five-point, Likert-type scales for measuring the entire range of severity for the concepts of Knowledge, Behavior, and Status. Each of the subscales is a continuum providing a framework for measuring and comparing problem-specific client outcomes at regular or predictable times, because evaluation is an important standard of nursing practice. Suggested times include admission, specific interim points, and discharge. The content and relationships of the scale are depicted in Table 41.1. Using the Problem Rating Scale for Outcomes with the Problem Classification Scheme and the Intervention Scheme creates a comprehensive problem-solving model for practice, education, and

BOX 41.2 Categories of the Omaha System Intervention Scheme

Teaching, Guidance, and Counseling
Activities designed to provide information and materials, encourage action and responsibility for self-care and coping, and assist the individual, family, or community to make decisions and solve problems.

Treatments and Procedures
Technical activities such as wound care, specimen collection, resistive exercises, and medication prescriptions that are designed to prevent, decrease, or alleviate signs and symptoms for the individual, family, or community.

Case Management
Activities such as coordination, advocacy, and referral that facilitate service delivery; promote assertiveness; guide the individual, family, or community toward use of appropriate community resources; and improve communication among health and human service providers.

Surveillance
Activities such as detection, measurement, critical analysis, and monitoring intended to identify the individual, family, or community's status in relation to a given condition or phenomenon.

From Martin KS: *The Omaha System: a key to practice, documentation, and information management*, reprinted ed. 2, Omaha, NE, 2005, Health Connections Press.

BOX 41.3 Targets of the Omaha System Intervention Scheme

anatomy/physiology	medication administration
anger management	medication coordination/ordering
behavior modification	medication prescription
bladder care	medication set-up
bonding/attachment	mobility/transfers
bowel care	nursing care
cardiac care	nutritionist care
caretaking/parenting skills	occupational therapy care
cast care	ostomy care
communication	other community resources
community outreach worker services	paraprofessional/aide care
continuity of care	personal hygiene
coping skills	physical therapy care
daycare/respite	positioning
dietary management	recreational therapy care
discipline	relaxation/breathing techniques
dressing change/wound care	respiratory care
durable medical equipment	respiratory therapy care
education	rest/sleep
employment	safety
end-of-life care	screening procedures
environment	sickness/injury care
exercises	signs/symptoms-mental/emotional
family planning care	signs/symptoms-physical
feeding procedures	skin care
finances	social work/counseling care
gait training	specimen collection
genetics	speech and language pathology care
growth/development care	spiritual care
home	stimulation/nurturance
homemaking/housekeeping	stress management
infection precautions	substance use cessation
interaction	supplies
interpreter/translator services	support group
laboratory findings	support system
legal system	transportation
medical/dental care	wellness
medication action/side effects	other

From Martin KS: *The Omaha System: a key to practice, documentation, and information management*, reprinted ed. 2, Omaha, NE, 2005, Health Connections Press.

research; the model operationalizes the nursing or problem-solving process.

PRACTICE GUIDELINES

Nursing practice is based on education, experience, and evidence. Because home health and hospice and palliative care nurses usually work with clients and their families in their homes, they must develop skills to conduct home visits efficiently, effectively, and safely (Box 41.4). A positive attitude about client-centered care, the nurse-client partnership, and consumer engagement is essential. Critical thinking skills are also essential. Effective care coordination requires familiarity with community resources. Knowledge and skills involving medications, treatments, documentation, and equipment are necessary. Excellent strategies include accompanying skilled home health, hospice, and palliative care nurses when they make home visits as well as having expert mentors. However, novice nurses also need a commitment to lifelong learning, practice, and self-evaluation (Buch & Nies, 2015; Marrelli, 2018a; Milone-Nuzzo & Hollars, 2017; Radhakrishnan et al., 2016; Schoon et al., in press; Zerwekh, 2006). The following is a brief summary of steps included in a home visit; these steps can be modified slightly for other noninstitutional settings:

- Review client data, including the referral from the intake department, hospital discharge summary, orders, and plan of care to become familiar with the client's history, purpose of the visit, and expectations.
- Contact the client or family by calling the telephone number listed on the referral information to obtain agreement for the visit, schedule the day and time, and discuss the address.
- Gather agency and Medicare forms, a nursing bag, cellular phone or pager, portable computing device, teaching materials, and supplies; understand the client's location; follow the agency policy when checking-out for the visit.
- Observe the neighborhood for resources and safety when approaching the client's home.
- Greet the client/family to begin developing a positive, appropriate professional relationship; involve them as much as possible during the visit and post-visit activities.

TABLE 41.1 Omaha System Problem Rating Scale for Outcomes

Concept	1	2	3	4	5
Knowledge: Ability of client to remember and interpret information	No knowledge	Minimal knowledge	Basic knowledge	Adequate knowledge	Superior knowledge
Behavior: Observable responses, actions, or activities of client fitting occasion or purpose	Not appropriate behavior	Rarely appropriate behavior	Inconsistently appropriate behavior	Usually appropriate behavior	Consistently appropriate behavior
Status: Condition of client in relation to objective and subjective defining characteristics	Extreme signs/ symptoms	Severe signs/ symptoms	Moderate signs/ symptoms	Minimal signs/ symptoms	No signs/symptoms

From Martin KS: *The Omaha System: a key to practice, documentation, and information management*, reprinted ed. 2, Omaha, NE, 2005, Health Connections Press.

BOX 41.4 Guidelines for Public Health, Home Health, and Hospice

- You are a guest in your client's home and neighborhood. Your behavior and your manners must convey that you recognize this role.
- Respect the client's cultural, religious, and ethnic heritage. Hesitate before contradicting that heritage. Clients are more likely to follow their heritage than your advice.
- The client may not respect your cultural, religious, and ethnic heritage. If you are a male nurse, the client may expect, and even request, a female nurse. Develop interpersonal skills—and a tough skin.
- Almost every client has family members, significant others, or friends who offer advice and can serve as either your advocate or your foe. Try to enlist them as your advocate.
- The client "owns" the health-related problem that initiated your services. That problem is just one portion of the client's past, present, and future. Thus it is the client who experiences, learns to understand, and ultimately solves the problem. It is your goal to help clients and their families become independent as quickly as possible. Talk to your peers and supervisors if you sense that you may be losing that perspective.
- Enjoy the unique autonomy and challenges of providing highly complex care in the home and community setting. Practice requires integration of high-technology skills, teaching, case management, and monitoring. Remember the need and benefits of collaboration with other members of the health care team. The nurse is usually responsible for judging whether or not the client can safely remain at home. However, data and information to support this and other decisions need to be communicated with team members orally and through the electronic health record.
- Maintain your sense of humor. You will need it!

Modified from Black JM, Hawks JH: *Medical surgical nursing*, ed. 8, St. Louis, 2009, Saunders, p. 94.

- Obtain signatures and complete needed forms.
- Provide care by completing a comprehensive assessment, identifying client problems, providing interventions, and evaluating client outcomes. Interventions may include teaching, guidance, and counseling; treatments and procedures; case management; and surveillance (Martin, 2005).
- Discuss the plan of care with the client and family during informal or formal conferences; modify as needed.
- Document some or all of the visit details in the home, preferably while using a portable computing device and an EHR.
- Discuss the next visit as well as follow-up activities and referrals.
- Proceed to the next scheduled visit after checking in, according to the agency policy.
- Complete remaining visit documentation, submit forms, coordinate referrals to other community resources, and communicate with agency colleagues, the referral source, physicians, and others as appropriate. Obtain revised orders if needed.
- Revisit to reassess the client and provide care.

Clinical Example From Community-Focused Practice

The example describes an innovative and collaborative community-focused program developed in Tucson, Arizona, by the Pima County Health Department and the Pima County Public Library. Since this program was initiated, other communities have involved nurses in their libraries (Innes, 2012; RWJF, 2013, 2018). The Pima County Public Library requested that the Health Department hire a social worker to increase safety and a welcoming environment in five high-risk libraries. Concerns included loitering, behavioral health concerns, encampment, and abandonment. Many patrons were homeless and/or had chronic diseases that were not being managed. Children and elders were left at the library by family members while they completed errands or went to work.

After a root-cause analysis was conducted and a logic model developed, the decision was made by Kathleen Malkin, Public Health Nursing Division Manager, and the Health Department and Library management staff to hire one full-time public health nurse in January 2012, a first in this country. It was decided that a nurse could better meet the identified needs of the patrons and library staff. In addition to increasing safety and a welcoming environment, a goal was to coordinate with community resource agencies to provide nutritious snacks for children and reduce hunger concerns.

During the first year, the program expanded to include five public health nurses working in six high-risk libraries. They made 180 visits to the libraries and had 2181 patron encounters. Client problems and clinician interventions were documented. The most frequently identified problems were health care supervision, nutrition, circulation, hearing, personal care, and cognition. The nurses instructed the library staff on communicable disease prevention topics. During the first year, calls made to the police and 911 were reduced by 6 percent and calls to 911 for medical emergencies were reduced by 20 percent.

In the second year, the program expanded to 13 library sites, including 2 bookmobile sites serving rural communities. Student nurses assisted the public health nurses as they completed community assessments and tailored services to the needs of each library. Working with library patrons, nurses completed 3746 encounters and 1160 assessments; 1420 health education sessions; and 192 referrals for services. They also provided health education to 76 library staff members. During the third year, nurses provided diverse health education and services to patrons. Services include assistance applying for public or private insurance, diabetes education, flu vaccine, and health education for library staff.

Using the Omaha System and an automated documentation system to capture community-level data had numerous benefits. Included were communication between the nurses and between the nurses and their health department; an evidence-based approach to practice; a standardized method of assessment, care planning, services, and evaluation; and a process that generated accurate and consistent data capable of conversion to information and useful reports.

PRACTICE LINKAGES

There are no limits to the diversity of clients who live in the community, their problems, and their strengths; the interventions that nurses provide; and the client outcome data that are

generated. Although many examples are diverse, as can be seen in the practice application, and in Box 41.7, they represent a small fraction of the actual roles and responsibilities of public health, home health, hospice, and palliative care nurses. The examples illustrate fundamental principles of professional practice: (1) a holistic approach to the steps of the nursing or problem-solving process; (2) consumer engagement or a partnership with clients as unique individuals, families, and communities; and (3) a focus on outcomes.

The following sections of the chapter are designed to increase the reader's understanding about the links between systematic best practices, evidence-based practice, and other aspects of the public health, home health, hospice, and palliative milieu. The typical nurse will not be involved with the theme of each section daily, but will over a period of months.

Setting short- and long-term goals provides criteria for evaluation and increases continuity of care and the potential for improved outcomes. Research has shown that goals set with the client rather than for the client are more successful regarding self-motivation, adherence, and attainment (Curtis et al., 2018; Zhang et al., 2015).

Outcome and Assessment Information

In 1999, the CMS mandated the collection of the Outcome and Assessment Information Set (OASIS) from all adult, nonmaternity home health clients as part of the Conditions of Participation for Medicare-certified home health agencies (CMS, 2017c). Completion of the OASIS provides a systematic, comparative measurement of client outcomes at two or more points in time. The completed OASIS improves communication about the clients' conditions among the agency's clinicians, other agency staff, and external groups; improves reimbursement; and demonstrates improved, cost-effective client outcomes as a result of home health services. CMS provides agencies with reports of their process quality (how well they follow best practices), risk-adjusted outcomes (physical and functional improvement or stabilization), and potentially avoidable events (hospitalization, new wounds). OASIS also provides data for calculating the agency's reimbursement for a particular client's episode, and promotes a standardized approach to assessment within the home care industry (Fig. 41.4) (2018a). OASIS results are publicly reported by CMS on Home Health Compare to provide comparisons of agency performance on select OASIS items such as improvement in managing daily activities and pain, treating symptoms, and preventing unplanned hospitalization (Medicare, n.d.).

The OASIS has had several revisions to improve its comprehensiveness, ease of use, reliability, and validity. The current version, OASIS-C2, was implemented on January 1, 2017, and the OASIS-D collection became available January 2019 to meet requirements within the IMPACT Act of 2014 (CMS, 2018d). Major sections include functional, physical, and service-related items each followed by a list of choices or fill-in-the-blanks (CMS, 2017c). (See Resource Tool 41.A on the Evolve website for an example of this assessment.

The OASIS is a complex and important component of home health practice. While providing care in the home, a nurse or therapist (physical, occupational, or speech and language) collects and completes the OASIS with the client and their caregivers at the start of care, after hospitalization, at the 60-day recertification date following admission, at discharge, or if transferred to a facility. It is important for clinicians to complete the OASIS accurately and consistently to reflect a client's actual status and integrate the OASIS with other portions of the agency's comprehensive assessment. They or their colleagues compare initial data to future versions as do Medicare surveyors and reimbursement reviewers. Final data from the OASIS must be submitted to CMS electronically.

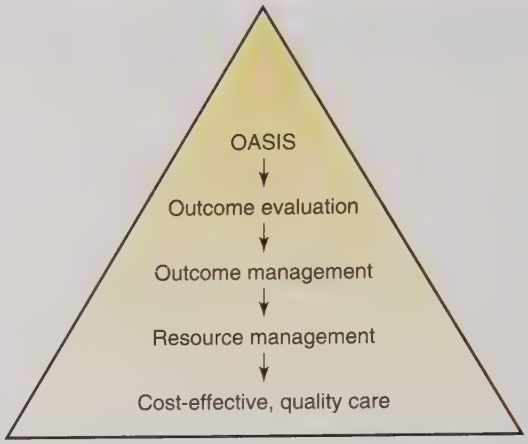

Fig. 41.4 The outcome model. *OASIS,* Outcome and Assessment Information Set. (From Centers for Medicare and Medicaid Services: *Outcome-based quality improvement [OBQI] implementation manual,* August 2010, pp. 2-9.)

The OASIS offers a challenging assignment for those who provide direct care, and one that requires extensive orientation and review. In many agencies, nurse experts serve as compliance officers to help ensure accurate and consistent completion. Not only is evidence of the quality of care related to OASIS, but so is agency reimbursement and a publicly available comparison of their client outcomes to those of other agencies. Agencies may receive sanctions or be denied payment by CMS for services provided based on claims data, audits, or surveys that reflect responses on OASIS. More recently, agencies have received Additional Development Requests (ADRs) generated by CMS. ADRs require agencies to submit extensive verification that the services they provided were essential; if verification is not adequate, agencies must initiate a legal appeal or return funds to CMS.

Target areas for emphasis on OASIS mirror clients' health challenges identified by nurses and home health agencies. Included are diabetic foot care, fall prevention, depression intervention, pain, pressure ulcers, safety, medication management, and infection control.

Box 41.5 illustrates M2001 from OASIS, one of the items related to medication management. Although all target areas are important, the latter two are of special concern to many nurses employed in hospice and palliative programs as well as diverse public health and other health care settings; they are summarized below.

BOX 41.5 Example of an Item From OASIS-C2

M2001 Drug Regimen Review: Does a complete drug regimen review indicate potential clinically significant medication issues (for example: adverse drug reactions, ineffective drug therapy, significant side effects, drug interactions, duplicate therapy, omissions, dosage errors, or noncompliance [nonadherence])?

0 No—No issues found during review [Go to M2010]
1 Yes—Issues found during review
9 NA—Patient is not taking any medications [Go to M2040]

OASIS, Outcome and Assessment Information Set.
From Centers for Medicare and Medicaid Services (CMS): *Outcome and Assessment Information Set OASIS-C2 guidance manual,* 2017. Available at http://www.cms.gov.

Medication Management

Medication management is an important component of home health practice. The goal is to assist clients and family caregivers to become independent and reliable in managing medication administration at home, and prevent adverse drug events, side effects, inadequate symptom control, and hospitalizations. However, home health clients experience many challenges, including the complexity of their chronic conditions, impaired cognitive status, inadequate coordination of their medical care, drug-drug interactions and side effects of medications, and cost. A systematic review on the frequency and causes of medication errors committed by patients or their caregivers at home revealed an incidence rate between 19 percent and 59 percent (Mira et al., 2015). Between 1988 and 2010 the median number of prescription medications used among adults aged 65 and older doubled from two to four, and the average proportion taking five or more medications tripled from 12.8 percent to 39.0 percent (Charlesworth et al., 2015). Too often, the number of medications is more than is clinically indicated, known as *polypharmacy* (Riker & Setter, 2013). This can result in side effects such as increased confusion, urinary incontinence, increased weakness, dizziness, and changes in sleeping patterns. Riker and Setter (2012, 2013) discuss how to assess for polypharmacy, its causes, and the interprofessional management of polypharmacy with emphasis on the role of the home care nurse.

Home health nurses expect to spend considerable time with medication reconciliation and management. They address medications during the initial and subsequent home visits. Unlike clients in residential settings, home health clients may or may not have all of their medications, may not take them as ordered, and may not store them appropriately. When nurses ask to see medications, they are often given a box or bag that includes current medications and ones that are extremely outdated, discontinued, or prescribed for other family members. Corbett et al. (2010) found that medication discrepancies were astoundingly widespread during the transition from hospital to home. In their study of 101 subjects, 94 percent had at least 1 discrepancy, most had an average of 3.3, and some had more; discrepancies were identified in almost all classes of medications, including those considered high risk. Reidt et al. (2014) conducted a study to explore the benefit of a pharmacist serving as a home health agency team member; findings included a positive clinical impact on clients. An excellent, comprehensive resource is the Medication Adherence Educators Toolkit, the product of a competition by schools of pharmacy (AACP/NCPA, 2013). It consists of four sections: assessing medication adherence, improving medication adherence through the use of aids, empowering patients to improve medication adherence, and resolving barriers to medication adherence. The toolkit includes evidence-based detailed information that addresses literacy, e-reminders, interprofessional practice, and cultural awareness.

Many tools are available in addition to those specific for home health nurses to assess and manage medication administration (Riker & Setter, 2013). Teaching clients to use a medication organizer for oral medications is frequently an initial intervention. However, that alone does not ensure that medications will be taken appropriately; subsequent teaching, return demonstrations, and surveillance are essential. Often the medication administration is complex with multiple drugs, in repeated dosages throughout the day, by various routes of administration.

A population health approach to medication management, for example, might be for providers to screen the medication regimen of all heart failure patients for complexity and polypharmacy. They would then work with their interdisciplinary partners (physicians and pharmacists) to simplify the medication regimen. This is also an area in need of further research and innovation. The Garfinkel "poly-de-prescribing" method shows promise. In a longitudinal, nonrandomized study of 122 older adults, they achieved significant reductions in the number of medications, and significantly less deterioration in functional, mental and cognitive status, sleep quality, appetite, sphincter control, and the number of major complications (Garfinkel, 2018).

Nurses must also understand the impact of medication management on the client and seek clients' perspectives, voices, and needs around medication adherence and management. (Zullig & Hayden, 2017) Self-efficacy, or the person's belief in their ability to manage their medications, is associated with medication adherence (Huang, Shiyanbola, & Smith, 2018) In addition, clients and caregivers need comprehensive materials about medication benefits, interactions, and side effects as well as the steps they should take to communicate that information to others (Vandermause et al., 2016). Materials need to be simple, understandable, and in the appropriate language. Clients who cannot read need graphic materials.

Another growing medication-related challenge is the management of opioid medications and overdose risk in home and community settings. A survey of community dwelling adults in the United States reported long-term opioid use in 76.9 percent of the cases (Shmagel et al., 2018). Clinicians must be aware of addiction issues; know how to safely administer antidote or direct its administration by others; and teach clients and caregivers how to safely administer, store, and dispose of narcotics (McAuley, Munro, & Taylor, 2018).

Home care agencies have policies on the safe disposal of narcotics and other pharmaceutical products. Proper disposal is

important for client, child, and environmental safety, and the nurse has a role in teaching safe disposal by the client. The Food and Drug Administration provides guidance on where and how to dispose of unused medicines through drug take-back programs or self-disposal through the trash or down the sink or toilet (FDA, 2017). Under current law, unless there is local legislation that allows disposal, home health and hospice staff are not legally permitted to handle or destroy controlled substances in the home. Pending legislation regarding the disposal of unused medication will permit disposal by clinicians if passed (NAHC, 2018).

Infection Prevention

Infection prevention is an important priority in home health and hospice practice. Infection prevention usually focuses on wound care, and invasive devices such as urinary and intravenous catheters as well as chest, tracheostomy, gastrostomy, and other tubes. Preventing infection by promoting appropriate vaccinations such as flu and pneumonia is also a priority. Most importantly, nurses need to assume that every client is potentially infected or colonized with an organism that can be transmitted, and recognize that all blood and body secretions may contain transmissible agents. They need to be familiar with the infectious process, research evidence and best practices, bag technique, personal protective equipment, cleaning equipment, medical waste management, and infection control programs. Nurses need to practice sound technique during each and every client encounter (see How To box).

HOW TO Promote Infection Prevention Standards

The practice of standard precautions means that all blood and body fluids must be treated as potentially infectious. Standard precautions are implemented to prevent exposure and infection of family caregivers and health care providers.

- Hand hygiene is the single most important practice in preventing infections. Hand hygiene should be performed before and after providing client care and before and after preparing food, eating, feeding, or using the bathroom.
- Use extreme care to prevent injuries when handling needles, scalpels, and razors. Do not recap, bend, break, or remove needles from syringes before disposal. Discard needles and syringes in puncture-resistant containers made of plastic or metal and dispose of them as directed by agency policy or community guidelines.
- Wear barrier precautions such as gloves, masks, eye covering, and gowns when contact with blood and body fluids is expected. Use masks in combination with eye protection to eliminate contact with respiratory secretions or sprays of blood or body fluids during invasive respiratory procedures or wound irrigations.
- Use aseptic technique with all sterile injection equipment.
- Double bag and discard soiled dressings or other materials contaminated with body fluids in polyethylene garbage bags.
- Clean kitchen counters, dishes, and laundry with warm water and detergent after use. Clean bathrooms with a household disinfectant.
- For clients with multidrug resistant organisms, limit the amount of nondisposable equipment brought into the home; use disposable stethoscopes, etc., when possible.

Nurses need to become familiar with evidence-based practice literature specific to infection prevention. Nurses are increasingly called upon to have a role in antibiotic stewardship (Carter et al., 2018; CDC, 2017). Guidelines exist for long-term care, but not for community-based care, providing an opportunity for nursing leadership in this area (CDC, 2017). The Centers for Disease Control and Prevention (CDC) offers a variety of materials, including guidelines to prevent the most frequent infections (CDC, 2018). Russell et al. (2018) describe home health and hospice infection prevention and control programs, lessons learned, and knowledge and attitudes toward infection control. Shang et al. have an active research agenda on infection prevention in home health care (Shang et al., 2018). Gorski (2017) is a home infusion therapy expert who has published extensively about central venous access devices (CVADs). Gorski states that infections are preventable when four topics are implemented consistently: attention to hand hygiene, site assessment and care, use of aseptic technique with all infusion-related procedures, and thorough education for the client and family. In 2014, the American Society for Parenteral and Enteral Nutrition (ASPEN) published a comprehensive set of recommendations about parenteral nutrition safety, and a publication by Ayers et al. (2014) is another good resource. Specific details about parenteral nutrition infusion and blood samples are described in the Evidence-Based Practice box.

EVIDENCE-BASED PRACTICE

The question "What practices maintain patient safety during the infusion of parenteral nutrition?" is included in ASPEN's parenteral nutrition safety publication. One of the 18 recommendations for this question is vascular access devices used for parenteral nutrition administration should not be used to obtain blood samples for laboratory tests unless no peripheral access is available. Evidence indicates that vascular access devices are a leading cause of serious adverse complications, in particular, central-line associated bloodstream infection. In addition, blood specimens drawn from vascular access devices have resulted in incorrect values and inappropriate treatment. When the recommendation was followed in recent years, infection rates were reduced substantially. Many home care organizations have added this recommendation to their protocols; all should do so.

Nurse Use

Nurses who provide parenteral nutrition care in the home should also become familiar with this comprehensive publication.

ACCOUNTABILITY AND QUALITY MANAGEMENT

Evidence-Based Quality/Performance Improvement

All providers, whether they are within community-based settings, hospitals, long-term care, or private practices, are accountable to their clients, reimbursement sources, and professional standards. Accountability is directly linked to quality or the degree to which health services for individuals, families, and communities increase the likelihood of desired health outcomes and are consistent with current professional knowledge. Florence Nightingale is often credited with establishing standards of care, demonstrating the value of evidence-based practice, and analyzing health-related outcome data successfully.

Most public health, home health, hospice, and palliative care providers have a long history of evaluating the quality of care they provided to their clients. Often, agencies use a systematic, triangulated approach in their pursuit of excellence that includes hiring qualified personnel, new employee orientation, mentoring programs, case conferences, supervisory shared visits, record audits, utilization reviews, quality studies, client satisfaction surveys, in-service education, recognition for outstanding performance, and annual evaluations. Some agencies became accredited as a way to distinguish themselves from other providers.

The sophistication of quality and performance improvement strategies used in home health, hospice, and palliative care has dramatically improved in recent years. Changes were prompted by the interest in research-based practice that has evolved into programs of research and evidence-based practice, use of computers and the Internet, guidelines developed by the National Quality Forum (2014), and the mandate from Medicare to use the OASIS and Outcome-Based Quality Improvement. Nurses should have access to current research literature, know how to critique that research, and apply it to their practice. Frameworks have been described to guide evidence-based practice projects (Levin et al., 2010; Melnyk & Fineout-Overholt, 2015).

Evaluating the quality of care professionally and legally should be done in many ways, but documentation is of special significance. The steps of the nursing process must be documented and include communication with team members, physicians, and community resources. It is through the clinical record that nurses demonstrate that they are delivering quality care and identifying strategies to improve the quality of care.

Outcome-Based Quality Improvement

Outcome measurement and cost control are the focus of the CMS **Outcome-Based Quality Improvement (OBQI)** program. Their definition of outcomes is (1) health status changes between two or more time points, where the term *health status* encompasses physiological, functional, cognitive, emotional, and behavioral health; (2) changes that are intrinsic to the client; (3) positive, negative, or neutral changes in health status; and (4) changes that result from care provided or natural progression of disease and disability, or both (CMS, 2012).

Data from OASIS-C2 are part of the two-stage CMS OBQI framework to produce various reports. The first stage, outcome analysis, enables an agency to compare its performance to a national sample, note factors that may affect outcomes, and identify final outcomes that show improvement in or stabilization of a client's condition. Comparing agency data and trends to a national sample is also known as **benchmarking**, an analysis process that has been used by many businesses but is relatively new to health care. The second stage, known as outcome enhancement, enables the agency to select specific client outcomes and determine strategies to improve care. Reports include agency–client-related characteristics (case mix), potentially avoidable events (adverse event outcomes), and end-result and utilization outcomes. The reports are for a 12-month period, the agency's previous 12-month period, and national reference or comparative data. Comparisons are risk adjusted for client differences, both over time for the agency and between the agency and the reference group. Similar to OASIS, a detailed manual describes the OBQI program; the most recent manual was published in 2012 (CMS, 2012). Due to the importance of the OASIS measures to provide information for describing the epidemiology of home health clients, reimbursement, publicly reported quality of care measures, and clinical care planning, accurate completion of the OASIS is critical. Clinicians must balance extensive documentation requirements, often using electronic devices, with building the therapeutic relationship with clients (Yang et al., 2019).

Accreditation

Home health and hospice providers participate in several different continuous quality improvement options. They may elect to meet the **accreditation** standards of one of the following groups and complete the Medicare survey according to their guidelines: the Joint Commission, the Community Health Accreditation Partner, or the Accreditation Commission for Health Care. If providers do not seek accreditation, Medicare surveyors will conduct regular reviews. In 2007, the Public Health Accreditation Board was established to offer national public health accreditation. Because some home health and hospice programs are integrated with health departments, they will participate in public health accreditation (PHAB, 2018).

After an agency applies for accreditation, a lengthy self-study must be completed that addresses all aspects of the agency's operation, and an accreditation team schedules a site visit. All three accrediting organizations review agencies' organizational structure, compliance with Medicare Conditions of Participation, care provided during home visits and documentation of those visits, and the outcomes of client care with a focus on improved health status. Site visitors accompany nurses and other clinicians on home visits to observe the steps of the problem-solving process in action. To maintain accreditation, agencies must follow guidelines and undergo periodic reviews. Some futurists predict that accreditation may become a requirement for licensure of all home health agencies.

PROFESSIONAL DEVELOPMENT AND COLLABORATION

Education, Certification, and Roles

Nurses are employed in public health, home health, hospice, and palliative care from a variety of educational and practice backgrounds. They should be educated to function at a high level of competency so that they can be relied on not only by their professional colleagues but also by the community. They have diverse roles and responsibilities in their practice settings; autonomy is a fundamental characteristic that was mentioned earlier in this chapter. Nurses are responsible for basing their practice on research evidence. A growing number of public health, home health, hospice, and palliative care nurses are

conducting research; some are members of interprofessional research teams. Their studies add to the body of knowledge for evidence-based practice, especially when the focus is on outcomes of care. The application of existing evidence and generation of new research must be priorities to increase the quality and cost-effectiveness of care (ANA, 2014; ANA/HPNA, 2014). A high-quality resource is the Alliance for Home Health Quality and Innovation, a not-for-profit organization focused on leading and sponsoring research and education on the value home health provides to clients and the entire U.S. health system (AHHQI, 2018).

The educational preparation of the 179,310 nurses employed in home health agencies varies greatly (BLS, 2017b). According to the ANA (2014), a baccalaureate degree in nursing should be the minimum requirement for entry into professional practice, and the Home Health Nursing Scope and Standards states that completion of a baccalaureate degree is the appropriate and preferred educational preparation. Roles for nurses include care management and coordination of care, education, advocacy, administration, supervision, and quality improvement. The nurse with a baccalaureate degree functions in the role of a generalist, providing skilled nursing and coordinating care for a variety of clients. Nurses with graduate degrees are prepared for roles as clinical specialists, nurse practitioners, researchers, administrators, or educators. Educational programs are increasing to prepare nurses for advanced practice roles in home health. As home health continues to expand, the need for specialized nurse clinicians will also increase to meet the highly technological and complex care needs of individuals, families, and communities. In managed care, more clinical specialists will be needed to provide a case management or population health focus and to develop programs to meet the needs of the populations served by the managed care network. For example, nurse practitioners can provide primary care to frail older adults and other homebound clients in the home.

The Hospice and Palliative Nurses Association (HPNA) offers many conferences, certification examinations, and credentialing (ANA/HPNA, 2014). There are about 14,000 credentialed registered hospice and palliative nurses. Licensed registered nurses may qualify for two levels of specialty practice certification that are differentiated by education, complexity of practice, and performance of certain nursing functions. Similar to home care, generalists provide direct care, function as educators, case managers, nurse clinicians, administrators, and other roles. The roles of the advanced practice nurse in hospice and palliative care include expert clinician, leader and facilitator of interprofessional teams, educator, researcher, consultant, collaborator, advocate, case manager, or administrator.

Interprofessional Collaboration

Typically, public health, home health, hospice, and palliative care nurses are members of interprofessional teams. The primary goal of the team is to help populations and individual clients achieve their maximum level of health, self-care, and independent functioning in a safe environment. Medicare regulations, professional organizations, and state licensing boards influence team composition and functions.

Box 41.6 and Fig. 41.5 illustrate successful interprofessional collaboration that depends on the knowledge, skills, and attitudes of each team member. When team members work collaboratively in partnership with clients, families, volunteers, and community resources, the plan of care can be implemented effectively and reinforced by all. Although each team member has a specific responsibility, any overlap in responsibilities can be beneficial for reinforcement. Team members communicate through email, phone calls, video calls, and face-to-face case conferences to review the plan of care, client progress, and team effectiveness (Marrelli, 2018a; Martin, 2005; Milone-Nuzzo & Hollars, 2017; Wright, 2018).

BOX 41.6 Factors for Successful Interprofessional Collaboration

Knowledge

1. Understand how the group process can be used to achieve group goals.
2. Understand problem solving.
3. Understand role theory.
4. Understand what other professionals do and how they view their roles.
5. Understand the differences between client levels of acuity across levels of care, including acute care, home care, ambulatory care, and long-term care.

Skills

1. Use principles of group process effectively.
2. Communicate clearly and accurately.
3. Communicate without using the profession's jargon.
4. Express self clearly and concisely in writing.

Attitudes

1. Feel confident in role as a professional.
2. Trust and respect other professionals.
3. Share tasks with other professionals.
4. Work effectively toward conflict resolution.
5. Be flexible.
6. Adopt an attitude of inquiry.
7. Be timely.

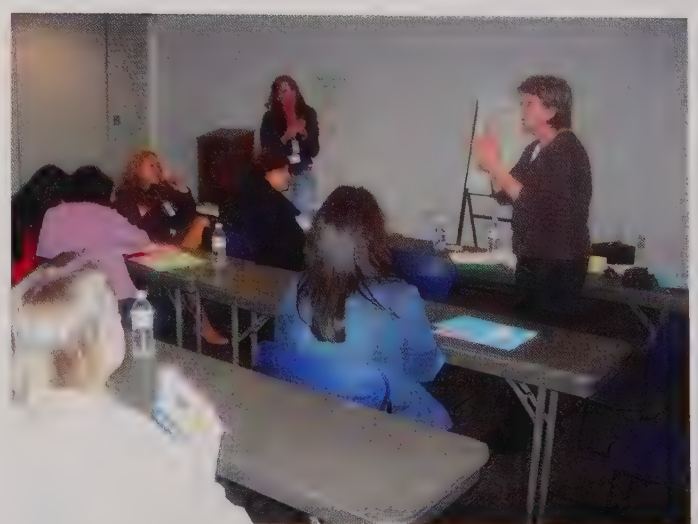

Fig. 41.5 Interprofessional team. (From www.omahasystem.org/photogallery.html. Used with permission from Karen S. Martin, RN, MSN, FAAN.)

Details about the role of nurses have been described in other sections of this chapter. Nurses often serve as the team leader or care manager in part because nursing service may be the client's primary need. Larger agencies may expand their nursing services to include wound and ostomy, intravenous, psychiatric/mental health, nurse practitioner, and other nursing specialists.

Physicians are an integral part of interprofessional teams; they submit initial and interim orders and review and sign the initial and updated plan of care. Many agencies hire a physician on a part-time basis or have an agreement with a physician who serves as a voluntary consultant. Because state laws are changing rapidly, nurse practitioners are increasingly involved and may have responsibilities similar to physicians. In addition, agencies may have specialized services such as podiatrists, pharmacists, registered dietitians, respiratory therapists, music therapists, psychologists, and chaplains.

The services of physical therapists, occupational therapists, speech and language pathologists, social workers, and home health aides are available in most agencies. They may be employed by the agency or hired through contractual agreements. Their roles are summarized below.

- Physical therapists: Provide maintenance, and preventive and restorative treatment that includes strengthening muscles, restoring mobility, controlling spasticity, gait training, and teaching active and passive resistive exercises.
- Occupational therapists: Focus on upper extremities to restore muscle strength and mobility for functional skills and performance of activities of daily living.
- Speech and language pathologists: Evaluate speech and language abilities, develop a plan of care, and teach clients to improve their communication involving speech, language, or hearing.
- Social workers: Help clients and families manage social, emotional, and environmental factors that affect their well-being through identification and referral to appropriate community resources.
- Home health aides: Provide personal care and assist with activities of daily living under the supervision of nurses or physical therapists. Home health aides or homemakers may also help with light housekeeping, laundry, meal preparation, and shopping.

LEGAL, ETHICAL, AND FINANCIAL ISSUES

The potential for human error as well as illegal and unethical activity exists in every health care organization. Examples of Medicare fraud and abuse in home health and hospice include inappropriate use of services, excessive payments to administrative staff or owners, "kickbacks" for referrals, and billing for visits and/or medical supplies that are not authorized or not provided. In addition, the complex regulations of CMS are difficult to understand and have not been interpreted consistently by Medicare surveyors.

Nurses are confronted with legal and ethical issues regularly. They need to be familiar with the living will, power of attorney for health care, and do-not-resuscitate documents. In addition, they need to be informed about local, state, and federal regulations that govern their profession and nursing license; and those that govern their employers. They need to be alert for potential problems or violations and identify solutions in a proactive manner. The privacy guidelines of the Health Insurance Portability and Accountability Act of 1996 ensure protection of clients' personal health information, include provisions about informed consent, and allow clients full access to their health care records (USDHHS, 2017).

Nurses are expected to follow professional, legal, and ethical standards to deliver care to clients, develop trusting relationships, act as client advocates, and help clients and families increase their self-advocacy skills. Because these responsibilities can produce tension, nurses need to recognize their personal values and biases to make certain they do not interfere with those of clients and families. Nurses should continually reassess client and family needs to avoid inappropriate use and overuse of services. This will become even more challenging because recent legislation has decreased an episode of home care from 60 days to 30 days (CMS, 2017a). Nurses will need to plan well and make sure clients understand the time-limited nature of their services.

The safety of clients who live alone as well as family caregiver neglect and/or abuse are ethical concerns. If the clients' needs are greater than what reimbursement allows, nurses need to talk to the clients, their families, and agency personnel to consider alternatives. In addition, many agencies have established ethics committees to assist with ethical dilemmas.

Reimbursement for home health, hospice, and palliative care is complex and tenuous; historical milestones are described earlier in this chapter, and more details about economics and reimbursement are included in Chapter 5. Medicare, state and local governments, Medicaid, and managed care are the principal funding sources for home health and hospice (NHPCO, 2016). If clients meet the eligibility criteria for the Conditions of Participation, Medicare is used as their primary payment source. When clients no longer meet those criteria and still require care, their services may be reimbursed by Medicaid, private insurance, donations, or the agency's United Way and other special needs funds. As mentioned earlier, value-based purchasing programs with bundled payments are the newest innovations in reimbursement models to affect community-based care. These innovations make partnering with acute care and other referral sources even more important, and effective collaboration among the interprofessional team is critical to achieve positive outcomes.

Nurses who work in public health, home health, hospice, and palliative care are involved with financial aspects of care to a greater extent than most other nurses. Nurses and their social work colleagues must be well informed about services available in the communities, and those that are covered by Medicare and other funding sources, and recognize how tenuous those funding sources are. Clients and families often ask for help to understand decisions about care and the numerous notices and bills that they receive. Nurses participate directly in decisions about the frequency, length, and type of client services, and their documentation needs to accurately support those decisions (Irani et al., 2018). Nurses must be knowledgeable about the reimbursement of medical supplies and should discuss problematic situations with clients, families, and agency personnel.

TRENDS AND OPPORTUNITIES

National Health Objectives

The overarching goals of the *Healthy People 2020* objectives (USDHHS, 2014) are as follows:

- Attain high-quality, longer lives free of preventable disease, disability, injury, and premature death.
- Achieve health equity, eliminate disparities, and improve the health of all groups.
- Create social and physical environments that promote good health for all.
- Promote quality of life, healthy development, and healthy behaviors across all life stages.

Nurses who work with clients and families in the home and community have opportunities to promote achievement of key objectives. They can assess client status, identify available resources and gaps to meet client needs, encourage clients and families to use resources, and coordinate care with other providers and community agencies. They can participate in numerous population-level projects and campaigns.

The *Healthy People 2020* box highlights objectives relevant to home health and hospice nurses. Note that many objectives relate to lifestyle issues. With appropriate health education, referral to community resources, and follow-up, there is a potential to reduce morbidity and mortality and decrease chronic disabilities. Nurses can make important contributions on one-to-one and population-focused levels.

HEALTHY PEOPLE 2020

Examples of National Health Objectives for the Year 2020

- **AOCBC-11:** Reduce hip fractures among older adults.
- **C-1:** Reduce the overall cancer death rate.
- **C-13:** Increase proportion of cancer survivors beyond 5 years.
- **CKD-9:** Reduce kidney failure due to diabetes.
- **HD-3:** Reduce stroke deaths.
- **HDS-1:** (Developmental) Increase overall cardiovascular health in the U.S. population.
- **HDS-5:** Reduce the proportion of persons in the population with hypertension.
- **IID-4:** Reduce invasive pneumococcal infections.

From U.S. Department of Health and Human Services: *Healthy People 2020: 2020 topics and objectives-objectives A-Z,* 2014. Available at http://www.healthypeople.gov.

Organizational and Professional Resources

It is increasingly important for nurses to be involved in political, economic, and regulatory issues at the local, state, and national levels before they affect practice and services to clients. Joining organizations, reviewing the Internet, networking with colleagues, reading professional literature, and serving on expert panels provide opportunities to become informed and influence decisions.

Nationally, several prominent home health organizations have extensive resources and websites. The National Association for Home Care & Hospice (NAHC) is a trade organization formed in 1982. A few years later, the Hospice Association of America (HAA) and NAHC developed an organizational partnership. Many agencies join as members, but nurses can also participate in the nursing section after joining as individual members. Lobbying is NAHC's primary focus; it also schedules an annual meeting and offers educational opportunities. The Visiting Nurse Association of America (VNAA), formed in 1983, has a similar focus, but membership is limited to community-based, nonprofit home health and hospice providers. Recently the VNAA and Alliance for Home Health Improvement formed an umbrella organization referred to as ElevatingHome to increase their collective influence nationally. *Home Healthcare Nurse, Home Healthcare Now, Home Health Care Management and Practice, Family and Community Health, Journal of Community Health Nursing,* and *Home Health Care Services Quarterly* are the leading journals for home health administrators, clinicians, managers, and researchers.

Hospice and palliative care organizations also have extensive resources and websites. The National Hospice and Palliative Care Organization was formed in 1978 to stimulate public and professional interest. The Hospice Foundation of America was founded in 1982; its initial mission was fundraising. The Hospice Nurses Association was formed in 1986. About 12 years later, the organization expanded and became the Hospice and Palliative Nurses Association (HPNA), and also changed the name of its national certification board. HPNA now has more than 11,000 members (HPNA, 2018). The organization schedules conferences, publishes the *Journal of Hospice and Palliative Nursing,* and offers certification and credentialing. The *American Journal of Hospice and Palliative Care, Journal of Pediatric Oncology Nursing, International Journal of Palliative Nursing, Journal of Palliative Medicine,* and other related journals address nursing practice, pain control, oncology, and medical practice.

Home health, hospice, and palliative care nurses belong to a variety of specialty organizations such as Infusion Nurses Society; Wound, Ostomy, and Continence Nurses Society; American Public Health Association; and Healthcare Information and Management Systems Society along with nurses employed in diverse settings. It is important that they share their knowledge about community-focused practice by being active members, speaking, and writing for publication.

Technology, Informatics, and Telehealth

Technology. Advances in technology, informatics, and telehealth are pervasive in health care and nursing practice. They are changing the ways in which care is provided. Many home health and hospice nurses have developed specialized technical skills with the following: wound management, parenteral nutrition, chemotherapy, intravenous therapy for hydration and antibiotics, intrathecal pain management, ventilators, ventricular assist devices, and apnea monitors. As mentioned earlier in the chapter, clients and family caregivers must learn to complete procedures and manage equipment frequently. It is the responsibility of the nurse and fellow team members to determine if such procedures and equipment can be used safely; when the answer is yes, team members must provide sufficient education,

demonstrations, and monitoring so that care continues safely and effectively. Advances in technology, informatics, and telehealth are not replacements for nurses and team members, but are tools to improve the quality and effectiveness of their practice. The tools are evolving rapidly, influencing community-based practice, and transforming home health operations.

Nursing Informatics. Nursing informatics (NI), defined as the "science and practice (that) integrates nursing, its information and knowledge, with information and communication technologies to promote the health of people, families, and communities worldwide." (Nelson & Staggers, 2018). NI is one of the most important new tools for nurses in all settings as they face urgent information management challenges, including the need for timely, reliable, and valid quantified data and information about clients, the services they receive, and their outcomes of care (Eardley et al., 2018; Monsen, 2018). They also need verbal and automated methods to communicate with other nurses and health care providers wherever they are in the community. The majority of agencies require clinicians to document care during the visit using electronic devices, rather than in their office or other location (Martin, 2005, Martin & Utterback, 2018; Monsen, 2018; Monsen et al., 2018; Yang et al., 2019).

The ANA anticipated the impact of information technology on the profession and took the first step to integrating nurse-generated data into the EHR early in the 1990s. They began to recognize standardized terminologies that could be used by nurses and other health care disciplines to describe, document, and quantify their daily practice accurately and consistently (ANA, 2014, 2018; Omaha System, 2018). The Omaha System and 11 more interface or point-of-care and reference terminologies have been recognized by the ANA. The Omaha System is an interface or point-of-care terminology; clinicians see it imbedded in their clinical documentation systems and need to learn to use it accurately and consistently.

Successful integration of nurse-generated data involves **interoperability**—the exchange of coded data and ability to use those data for multiple purposes such as quality measurement, reimbursement, and research (ANA, 2018; Bowles et al., 2013). SNOMED CT and Logical Observation Identifiers, Names, and Codes (LOINC) are examples of reference terminologies that facilitate interoperability by sharing data generated by the interface terminologies. Minnesota is the first state to recommend that health care providers use both ANA-recognized standardized point-of-care and reference terminologies. In 2014, Minnesota released their decision that the Omaha System should be the point-of-care terminology for the software used by all public health, home health, and other community-based providers (Omaha System, 2018).

Now that electronic data sets are more available and can be linked to national claims data and other rich sources of health information to form large data sets, data science is a growing methodology nurse scientists may use to capitalize on this resource (Brennan & Bakken, 2015). A form of data science, data mining is the process of discovering useful information in large data repositories (Tan et al., 2019). Through data mining, prediction models and clinical decision support systems are developed to alert clinicians of risk, changing clinical parameters, and progress and needs of their clients (Gao et al., 2018). Public health, home health, and hospice are ripe with opportunities for data science research especially when standardized data sets are used for clinical operations (Monsen et al., 2018). The OASIS data set provides a national, standardized data set to examine clients' conditions over time. OASIS linked with CMS claims data and other national data sets provide rich insights into home care practice and effectiveness (Murtaugh et al., 2017; O'Connor et al., 2014).

The sharing of information from one health care setting or provider to another is critical for community-based care, especially as clients make the transition between hospital and home. Safe, high-quality care is dependent on the sharing of information, goals of care, and care plans. Health information exchanges (HIEs) support this need and are growing in number and functionality. HIEs give care providers access to patient records from hospitals, emergency departments, skilled nursing facilities, and laboratories across the state, saving valuable time and costs associated with searching paper records, faxing, making phone calls, or re-collecting information.

The concept of meaningful use has evolved as one component of the **Merit-based Incentive Payment System (MIPS)**. MIPS combines meaningful use and other CMS quality programs, including Physician Quality Reporting System and the Value-Based Payment Modifiers into a single program to improve quality of care. MIPS promotes the use of certified EHRs that support care coordination, quality measurement, and improved patient-clinician relationships (Office of the National Coordinator for Health Information Technology, 2017b). This suggests that better health care does not come solely from the adoption of technology itself, but through the exchange and use of electronic health information to best inform clinical decisions at the point-of-care. Public health and other community-based practitioners play an important role in identifying critical information needed to conduct care and to communicate with clients, families, interprofessional team members, policy makers, and payers. They also must support the development and seek the purchase of certified EHRs that meet documentation and interoperability standards and meaningful use criteria.

Health care providers throughout the United States are rapidly converting to EHRs. The 2009 American Recovery and Reinvestment Act (ARRA), and the Health Information Technology for Economic and Clinical Health (HITECH) Act, provided reimbursement incentives for eligible professionals and hospitals to become "meaningful users" (Friedman, Parrish, & Ross, 2013). Although home health agencies were not able to obtain funding through AARA, their adoption of EHRs has also increased.

Personal health records (PHRs) are another important development (U.S. National Library of Medicine, 2018). A PHR is an electronic collection of health-related information, managed and controlled by the client rather than by clinicians and agencies. Typically, a PHR includes a health history, medications, allergies, and results from laboratory and other tests.

The Blue Button is a PHR initiative that began in 2010 by the Department of Veterans Affairs (Office of the National Coordinator for Health Information Technology, 2017a; The Blue Button, 2017). Soon after an online patient portal was launched. While their initiative is limited to veterans, many other groups use the Blue Button symbol. Usage of the Blue Button logo and brand is free but must conform to user guidelines. The goal is to encourage as many people as possible to use a Blue Button site to download their own health information.

Increasingly, individuals and families served by public health, home health, hospice, and palliative care nurses have information technology skills. They may use the Internet frequently and be well informed about diagnoses, treatments, and medications. They may also use smartphones, other mobile devices, and social media. Nurses need to inquire about their clients' skills rather than make assumptions based on their age or other factors.

Telehealth. Telehealth supports long-distance health care, client and professional health-related education, and public health and health administration using electronic information, medical devices, and telecommunications technologies (Schlachta-Fairchild et al., 2018). The technology used varies to include live videoconferencing, the Internet, store-and-forward imaging, streaming media, satellite, wireless communications, and plain old telephone systems. Telehealth equipment and program components include telephone triage and advice, and biometric telemonitoring equipment to measure vital signs, weight, cardiac function, and point-of-care diagnostics. The system may or may not include video technology for live interaction (Schlachta-Fairchild et al., 2018).

The increased availability of telehealth coincides with trends described in this and other chapters in this book: an aging population, increased chronic illness and costs, and changes in health care reimbursement by CMS and other payers. The Center for Connected Health Policy (Center for Connected Care, 2018) provides a concise overview of the current reimbursement mechanisms for telehealth. Currently, Medicare only reimburses for live-video conferencing under very specific circumstances and has restricted the types of sites that may conduct telehealth for reimbursement. To date, home health and hospice telehealth services do not qualify. However, a new chronic care management billing code provides for non–face-to-face consultation, which can include remote monitoring of chronic conditions, opening the way for collaborative management of chronic illness between home health and hospice and community-based physicians and other providers. In addition, Medicare Advantage plans (managed Medicare) do provide reimbursement under Medicare Part B for telehealth services and several bills are pending approval in Congress. Accountable care organizations and bundled payment initiatives are also able to obtain reimbursement. Medicaid plans also cover telehealth services but vary by state. These new trends promote new opportunities: public health, home health, hospice, and palliative care nurses can increasingly use innovations such as telehealth in combination with in-person visits to effectively and efficiently manage chronic conditions. They can monitor health status and symptom recognition, provide education, increase communication, and enable clients to become active partners in their own care (Madigan et al., 2013; Schlachta-Fairchild, et al., 2018).

Older adults are increasingly accepting of information technologies to help them manage their complex chronic conditions, and this information is being used for population health management. Focus groups reveal seven conditions that play an important role in acceptance of telehealth by consumers: perceived usefulness, effort expectancy, social influence, perceived security, computer anxiety, facilitating conditions, and physicians' opinions (Cimperman et al., 2013). Patients with chronic obstructive pulmonary disease reported a general satisfaction and they found the telemonitoring systems useful to help them manage their disease. Some reported difficulties in their use, which affected compliance in using the technology as prescribed (Cruz, Brooks, & Marques, 2014).

Numerous studies have confirmed that telehealth is used successfully to improve physical, emotional, and financial health outcomes for diverse home health clients. Telehealth is most commonly used and studied with heart failure patients. Fifteen systematic reviews of heart failure research published between 2003 and 2013 reported significant reductions in mortality and heart failure–related hospitalizations when using telehealth compared to usual care. However, more research is needed because the quality of studies varies, and only automated device based monitoring and mobile telemonitoring were effective (Kitsiou, Paré, & Jaana, 2015).

Telemonitoring is increasingly being used with infants, women with high-risk pregnancies, and adults with various health problems, including mental health. Smart homes are emerging to help the older adult to "age in place" (Rantz et al., 2013). Sensors can monitor activities and detect adverse events such as a fall or lack of movement and trigger a call for help. Medication management devices remind clients to take their medications, dispense medications, and send alerts to providers if devices are not accessed as expected (Marek et al., 2013). The next generation of devices is taking advantage of handheld devices such as smartphone and tablet technologies, making telemonitoring even more ubiquitous.

SUMMARY

Public health, home health, hospice, and palliative care continue to evolve with changing national policies and innovations. The need for nurses prepared to practice in these specialties is growing as the public becomes more interested in prevention, the population ages, chronic illness increases, and more care is delivered in the community. Practice will become ever more complex and diverse as individuals live longer with multiple chronic conditions and they and their families are more engaged in their care and request more choices and personalized care. Practice in this challenging environment requires a strong educational background, critical thinking skills, and a commitment to lifelong learning. The autonomy afforded by community-based practice requires strong interpersonal, communication, technological, and clinical skills. It is a good time to celebrate the past, embrace the present, and look forward to the future.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Client-Centered Care

Recognize the client or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for client's preferences, values, and needs.

Important aspects of client-centered care include:

- **Knowledge:** Demonstrate comprehensive understanding of the concepts of pain and suffering, including physiological models of pain and comfort.
- **Skills:** Elicit expectations of client and family for relief of pain, discomfort, or suffering.
- **Attitudes:** Recognize that client expectations influence outcomes in management of pain or suffering.

Client-Centered Care Question

Visit a community-based hospice or palliative care unit. Spend time observing the care provided in this setting.

1. How is care provided in this setting different from care you have seen in the acute care setting? In the home health setting?
2. Notice how nurses and nursing assistants assess pain in this environment.
3. Discuss with the nurses how they address concerns around pain and suffering with clients and families in this environment. How do nurses evaluate clients' and families' expectations around pain?
4. Discuss with the nurses differences in care approaches between a community-based hospice or palliative care versus care approaches for home hospice and palliative care. Is there additional education that is required for the client and family, because the family often provides some aspects of care for home hospice and palliative care?

Prepared by Gail Armstrong, PhD(c), DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing.

LINKING CONTENT TO PRACTICE

The Nurse in Public Health, Home Health, Hospice, and Palliative Care

The individuals, families, and communities served by public health, home health, palliative, and hospice nurses are described throughout this chapter as are the knowledge, skills, and attitudes of nurses who function well in those settings. The descriptions are evident in the text, clinical examples, boxes/figures/tables, references, and other parts of the chapter. The competencies in this chapter are congruent with the following core competencies of the Quad Council Coalition's Domains of Public Health Nursing (2018): (1) assessment analytic skills, (2) policy development and program planning skills, (3) communication skills, (4) cultural competency skills, (5) community dimensions of practice skills, (6) public health sciences skills, (7) financial planning and management skills and planning skills, and (8) leadership and systems thinking skills. Students and new graduates cannot be expected to have developed all of these skills when they begin to practice (Milone-Nuzzo & Hollars, 2017; Schoon et al., 2018, Smith, 2017a, 2017b; Wright, 2018). However, as nurses proceed in their career development and gain valuable work experience, they will progress along the novice to expert continuum.

PRACTICE APPLICATION

The first example is an individual who lives alone, the second is an individual whose family includes an involved spouse, and the third is a community client that is described in the Omaha System section of this chapter. Ideally, the student who visits Martha P. and the home health nurse who visits Mr. and Mrs. Jones use portable computing devices and document in the EHRs in the home. The public health nurses who are part of the Library Nurse Project use laptops for documentation.

Martha P. is an older woman who lives in a deteriorating home. She is a relatively typical client for a student or home health nurse to visit.

Box 41.7 consists of a story and answers designed to promote independent learning and group discussion. Note that the story and answers should be congruent: all pertinent data in the story should be reflected in the answers and all answers should match pertinent details in the story.

Mr. Jones, the second clinical example, is also a relatively typical client. After reading the example, identify the Omaha System problems, interventions, and ratings that are illustrated in the story. Discuss key characteristics of practice during this visit and an appropriate care plan for the next visit.

Mr. Jones, 70 years old, was discharged from the hospital yesterday after heart surgery for coronary artery disease and was referred to the local home health agency. Today, the home health nurse admitted him for skilled nursing care services. The nurse assessed Mr. Jones' cardiovascular status, the healing of his incisions, adjustment to his postsurgical status, and level of self-care. The nurse talked to Mr. and Mrs. Jones about exercise, nutrition, the signs and symptoms of possible postoperative cardiac problems, and their coping. Together, they looked at his medications. Mrs. Jones indicated that they were getting along well, but were concerned about the high cost of his new medications. They reviewed Mr. Jones' discharge packet. The nurse emphasized the need to maintain close communication with his physician and nurse practitioner, and the need to participate in the local exercise and nutrition rehabilitation program that they had prescribed. Mr. and Mrs. Jones indicated that they would do so. Before the visit ended, the nurse completed the necessary forms, documented the visit, and offered to call a local social service agency about financial assistance for medications. They made an appointment for the nurse's return visit.

The third clinical example was described previously in the Omaha System section of this chapter.

The home visit is the hallmark of nursing in home health and hospice. Nurses are guests when they enter a client's home and must recognize that their services can be accepted or rejected. The interpersonal relationship established during the

BOX 41.7 Martha P.: Older Woman Living in a Deteriorating Home

College of Nursing, University of Florida
Gainesville, Florida

Information Obtained During the First Visit/Encounter

Martha P. was a 93-year-old woman who lived by herself in a deteriorating house. She had kyphosis and arthritis that contributed to her unsteady gait. Martha rarely used her cane in her house, but steadied herself by holding on to furniture.

When a student nurse arrived, Martha was shivering under a thin blanket. Boxes filled with old papers were stacked along the walls. The student nurse asked Martha if she had wood for the stove that heated the house. She replied that she ran out of wood yesterday and said, "I don't know what I'm going to do, but I'm not leaving this house." She reported that people from a church had brought the last load of wood. The student asked permission to contact Concerned Neighbors, a volunteer organization that could provide firewood. Martha was pleased. The student expressed concern that the boxes of paper, especially those near the stove, were a fire hazard. "Those boxes have been there for years, and I use them to light the stove," Martha said. When the student asked if she could help Martha move the four boxes near the stove to the other wall, she grudgingly agreed.

The student nurse noted that Martha was wearing a "Lifeline necklace," a fall alert system, and asked about her history of falls. Martha described how she moved around her home and fell in the bathroom last week when she was trying to take a sponge bath. She pushed the button, and "two nice gentlemen from the fire department came to pick me up." The student and Martha walked around her house. They talked about where she fell in the past, how fortunate she was not to have injuries, and ways to decrease her risk of falling in the future. Martha was willing to have a personal care assistant visit weekly to help her with a bath and shampoo as long as there was no charge. Before leaving, the student took Martha's vital signs and blood pressure and noted that they were within normal limits. The student called Concerned Neighbors and arranged for firewood to be delivered that day; the student also telephoned a local health assistance organization to schedule a home health aide to provide personal care for the next week. Although Martha sounded grumpy, she asked the student to return.

Application of the Omaha System Problem: Residence (High Priority)

Problem Classification Scheme

Modifiers: Individual and Actual
Signs/symptoms of Actual:
- Inadequate heating/cooling
- Cluttered living space
- Unsafe storage of dangerous objects/substances

Intervention Scheme

Category: Teaching, Guidance, and Counseling
Targets and Client-specific Information: Safety (moved boxes away from stove; Martha unwilling to dispose of papers)
Category: Case Management
Targets and Client-specific Information: Other community resources (referred to Concerned Neighbors; arranged delivery of firewood)
Category: Surveillance
Targets and Client-specific Information: Home (needed wood)

Problem Rating Scale for Outcomes

Knowledge: 2—minimal knowledge (not aware/unwilling to recognize fire hazards)
Behavior: 2—rarely appropriate behavior (unable/unwilling to make changes)
Status: 2—severe signs/symptoms (residence was livable but needed changes)
Domain: Physiological

Problem: Neuro-Musculo-Skeletal Function (High Priority)

Problem Classification Scheme

Modifiers: Individual and Actual
Signs/symptoms of Actual:
- Limited range of motion
- Decreased balance
- Gait/ambulation disturbance

Intervention Scheme

Category: Teaching, Guidance, and Counseling
Targets and Client-specific Information: Mobility/transfers (ways to decrease risk of falling, absence of injuries, continue wearing "Lifeline necklace")
Category: Surveillance
Targets and Client-specific Information:
- mobility/transfers (how, when falls occurred)
- signs/symptoms—physical (falls/injuries; vital signs, blood pressure)

Problem Rating Scale for Outcomes

Knowledge: 2—minimal knowledge (knew few options to decrease falls)
Behavior: 2—rarely appropriate behavior (had not used cane in house; did wear and use "Lifeline necklace")
Status: 3—moderate signs/symptoms (activities restricted, fell last week)
Domain: Health-Related Behaviors

Problem: Personal Care (High Priority)

Problem Classification Scheme

Modifiers: Individual and Actual
Signs/symptoms of Actual:
- Difficulty with bathing
- Difficulty shampooing/combing hair

Intervention Scheme

Category: Teaching, Guidance, and Counseling
Targets and Client-specific Information: Personal hygiene (needed help with bathing, shampoo)
Category: Case Management
Targets and Client-specific Information: Paraprofessional/aide care (referred to health assistance organization for home health aide)

Problem Rating Scale for Outcomes

Knowledge: 3—basic knowledge (knew she needed to bathe, but not aware of assistance)
Behavior: 3—inconsistently appropriate behavior (tried to take a sponge bath)
Status: 3—moderate signs/symptoms (cannot bathe safely without help)

This case illustrates use of the Omaha System with a client in the home. Talk with your classmates and other colleagues about how use of the Omaha System can guide your practice and documentation and can generate aggregate data to promote high-quality home health service. Identify Martha P.'s strengths and how to maximize those when providing care.

From Martin KS: *The Omaha System: a key to practice, documentation, and information management*, Omaha, NE, 2005, Health Connections Press.

first visit is critical, as is the initial assessment of the client, support system, and environment.

A. What strategies should the nurse use to develop a positive relationship during the first visit?
B. What are the most important elements to assess in the home environment?
C. What should the nurse do to establish a partnership with the client?
D. What is necessary for the nurse to include in the client contract?
E. How can the nurse determine the client's preferred learning style?

Answers can be found on the Evolve site.

KEY POINTS

- Public health, home health, hospice, and palliative care nursing practice provided in the client's home differ from care in institutional settings. The home setting affects practice in unique ways, including establishing trust, developing care partnerships (consumer engagement), selecting interventions, collecting outcomes and data, ensuring client safety, and promoting quality.
- Family members, including caregivers and significant persons who provide assistance and/or care, are essential members of the health care team.
- Home health has its roots in public health nursing, with an emphasis on health promotion, illness prevention, and caring for people in their communities.
- Home health and hospice practice and reimbursement changed when they became major Medicare benefits.
- Five models of care are described in this chapter: public health, home health, hospice, palliative care, Nurse-Family Partnership, and transitional care. All nurses should become familiar with these models to inform clients, their families, and their communities about options and educate providers who are potential referral sources.
- Medicare-certified home health and hospice agencies are divided into various types of administrative and organizational structures. However, many aspects of nursing practice are the same in the various types.
- Standards of public health, home health, and hospice/palliative care nursing practice originate from the ANA in partnership with specialty organizations, and encourage adoption of evidence-based practice.
- Consistently demonstrating professional competency is essential for public health, home health, hospice, and palliative care nurses.
- Interprofessional collaboration is inherent in public health, home health, hospice, and palliative care.
- The Omaha System was developed and refined through a process of research. Reliability, validity, and usability were established for the entire system.
- The Omaha System is unique in that it is the only comprehensive vocabulary developed initially by and for nurses practicing in the community.
- The Omaha System consists of the Problem Classification Scheme (assessment), Intervention Scheme (care plans and services), and Problem Rating Scale for Outcomes (client change/evaluation).
- The Omaha System is designed to enhance practice, documentation, and information management. These areas are of concern to community health educators and students as well as clinicians and administrators.
- Interprofessional clinicians employed in Medicare-certified home health agencies use OASIS-C2 at designated intervals; it is the outcome measurement tool mandated by the Centers for Medicare and Medicaid Services' Conditions of Participation.
- Evidence-based quality/performance improvement is important in all home health and hospice agencies. Currently, Medicare's Outcome-Based Quality Improvement program is used for outcome measurement and cost control.
- Exciting trends and opportunities are pervasive in public health, home health, hospice, and palliative care. Many nurses are developing skills using technology, informatics, and telehealth; a commitment to lifelong learning is necessary.

CLINICAL DECISION-MAKING ACTIVITIES

1. Make a home visit with an experienced public health, home health, or hospice nurse and do the following:
   A. Evaluate the process and content of the nurse-client interaction to determine what aspects of the visit were based on evidence-based practice; describe the process of the visit.
   B. Compare actual roles and functions with the ANA scope and standards or other specialty standards as appropriate for the client population.
   C. Observe and discuss whether that nurse uses a client problem/nursing diagnosis, intervention, or outcome measurement system or framework. Is it important to use a system or framework approach? Explain.
   D. Consider the information about consumer engagement, strengths-based practice, social determinants of health, and population health described in this chapter. What examples did you observe?
2. Work with a partner or in a small group. Select a client you have visited or invent a fictitious client, and list data for a typical referral and initial visit. Independently apply the three parts of the Omaha System to the client data. Compare each portion of your selections with that of your partner or group members.
3. Make a joint home visit with another health care professional and assess as in the preceding activity. Attend a

client/family-provider conference and write a summary of the group process. Has your attitude changed after you listened to the opinions expressed by family members?

4. Review a client record. What client outcomes were met through home health care? What specific outcomes showed an improvement or a stabilizing condition?
5. Interview a public health, home health, or hospice nurse who uses electronic health records (EHRs). Ask about the advantages of EHRs and challenges associated with them. How can aggregate clinical data generated by EHRs help nurses better understand the needs of their clients? How might knowing the needs of their clinical population assist in reviewing the research literature and planning new interventions?
6. Review your state's laws governing advance directives. Consider the legal and ethical advantages and disadvantages of having such directives. How would you write an advance directive for yourself?
7. Participate in a telehomecare visit using video technology or observe the analysis of data from remote monitoring. Trace the nurse's decision making and changes in the plan of care based on the telemonitoring data. Determine what outcomes might be expected from this type of care.

The Nurse in the Schools

Erin G. Cruise, PhD, RN

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Discuss the history of school nursing and describe, compare, and contrast the professional standards and scope of practice of school nursing with those of public health nursing
2. Differentiate the roles, responsibilities, and activities of school nurses from those of nurses in other settings.
3. Describe various frameworks and models that provide the foundation for school nursing practice.
4. Discuss common health problems of children and adolescents seen in the school setting and the school nurse's support of education for children with illness and disabilities
5. Analyze the nursing care given in schools in the context of primary, secondary, and tertiary levels of prevention.
6. Anticipate future trends in school nursing.

CHAPTER OUTLINE

History of School Nursing
Federal Legislation Affecting School Nursing Practice
Standards of Practice for School Nurses
Educational and Licensure Credentials of School Nurses
Roles and Functions of School Nurses
School Health Services
School Nurses and *Healthy People 2020*
The Levels of Prevention Applied in Schools
Controversies in School Nursing
Ethics in School Nursing
Future Trends in School Nursing

School nursing is a specialty practice focused on providing health care and illness prevention to school-age children with the goal of facilitating their participation in educational opportunities (American Nurses Association [ANA] & National Association of School Nurses [NASN], 2017). School nursing services are provided to individuals within the school setting, including children, staff, and teachers. School nursing is also population focused, utilizing many of the concepts of public health nursing to prevent illness and injury and to stop the spread of disease within the school, family, and community. While school nursing has required a comprehensive approach to health care and health promotion since its inception, the practice continues to evolve and increase in complexity (Wolfe, 2013). School nurses provide leadership and coordinate health and safety programs in their schools and communities.

According to the National Center for Education Statistics, there were an estimated 50.7 million children in more than 98,000 U.S. public schools in 2017 (Institute of Education Sciences [IES]: National Center for Education Statistics [NCES], 2017). Of these, 35.6 million attended preschool, elementary, and middle schools and 15.1 million were in grades 9 through 12. In the 34,600 U.S. private schools, enrollment was predicted to be an additional 5.2 million students. School nurses provide care to these children in all school settings, as well as in their homes, correctional settings, hospitals, and during field trips, athletic competitions, and other extracurricular events (ANA & NASN, 2017).

U.S. public and private schools employ about 3.6 million teachers as well as other adult school administrators and staff such as administrative assistants, custodians, food service workers, and bus drivers (Institute of Education Sciences: National Center for Education Statistics [IES: NCES], 2017). In addition to care for children, school nurses are often asked to provide health services for these adult school staff members. This requires school nurses to have expertise in a wide variety of adult health care issues, including nutrition, medication, communicable diseases, and chronic illness (Wolfe, 2013).

This chapter will consider the history of school nursing and examine the evolving roles and activities of school nurses in modern times. Frameworks for evidence-based school nursing practice will be explained, as well as professional scope and standards of the specialty. The impact of federal regulations on the education of children and the practice of school nursing will be investigated. This chapter will also assess the relationship of public health nursing and school nursing. Different types of school health services will be examined and the levels of care required for a variety of children's health problems most commonly found in schools will be discussed. The chapter ends with a discussion of the ethical dilemmas that may arise for school nurses, and the future of nursing in the schools is predicted for ever-changing communities.

HISTORY OF SCHOOL NURSING

Origins of School Nursing

The earliest organized school health services were implemented in France in the 1830s where policies were passed to require health services and a sanitary environment for children in schools (Zaiger, 2013, p. 4). In 1874, Brussels, Belgium, employed physicians to conduct health inspections throughout the city's schools. In the 1880s and 1890s in England, a variety of volunteer nursing services were provided in the schools in London and Liverpool, with the purpose of addressing contagious disease, minor illnesses and injuries, and assessing the nutritional status of low-income children (Zaiger, 2013). While charitable funding only supported five nurses to cover the 500 elementary schools in London, the activities of these nurses significantly reduced absences. This led the London County Council to take over the funding of school nurse services by 1904 (Brainard, as cited in Zaiger, 2013, p. 5).

In the 1890s in the United States, Boston, Chicago, and New York City instituted medical inspection programs in schools to address rising levels of absenteeism due to communicable diseases, especially among immigrant and low-income populations (Rogers, 1905). Inspections were conducted by physicians without the assistance of nurses, who excluded affected children from school to prevent the spread of serious communicable and parasitic diseases among their classmates (Baker, Wald, as cited in Houlahan, 2018). However, many children were not treated due to their parents' inability to read the physicians' instructions or afford the required medications. Thus thousands of children never returned to school, yet could be found playing with their non-excluded classmates after school (Houlahan, 2018). This program did little to stem the tide of contagious disease or reduce absenteeism in New York City schools.

By 1902, the failure of the medical inspections program became more conspicuous and controversial. Lillian Wald, well known among public health authorities and charitable organizations as a strong advocate for the poor, was consulted for ideas to address plummeting school attendance in the city's poor, immigrant neighborhoods (Houlahan, 2018). Ms. Wald agreed to provide the services of Lina Rogers in the schools to assist the physicians on an experimental basis for one month.

Ms. Rogers was assigned to four schools with a total student population of 8671 students (Rogers, 1905). She conducted a thorough assessment of the schools, surrounding community, and affected families and found a lack of communication between physicians, parents, students, and school personnel (Rogers, 1905). This often led to children being readmitted to school before they had been cured of their contagious diseases, or a revolving door of returning and being sent home again (Houlahan, 2018).

Ms. Rogers worked to improve children's health by working with the physicians to screen for illness in the schools each day, providing treatment for some ailments at school, and making daily home visits to address issues that fostered the development and persistence of illness among the students. In many cases, the home environment was unsanitary or other family members were ill. Ms. Rogers educated the children and their families, administered treatments in the home, assisted with cleaning, and obtained resources for those who could not afford medications, physician visits, or cleaning supplies (Rogers, 1905).

The goal of Ms. Rogers' school nursing practice was to facilitate children's attendance at school by intervening in a timely, effective, and holistic manner to eradicate disease. As Rogers (1908) stated, these children "could least afford to lose their schooling, as they belong, almost all, to that class of wage earners who are legally allowed to work [and leave school] at the age of fourteen" (p. 967).

After the first month, Ms. Rogers' interventions were deemed so successful that the New York City Department of Health and the Department of Education agreed to provide funding to expand the program. A team of 12 school nurses, working under Ms. Rogers' direction, reduced school exclusions of children from more than 10,000 in September 1902, to 1100 in September 1903, a decrease of 98 percent in only one year (Rogers, 1905, 1908). By February 1903, the number of school nurses was increased to 27 (Houlahan, 2018).

Evolution of School Nursing Practice

Within a few years, many large cities in the United States had implemented school nurse programs, though these varied from state to state and within each state. In some communities, nurses were hired directly by the school districts. In others, local and state health department nurses provided services in schools, as well as in children's homes (Zaiger, 2013). In rural areas, services were provided by the American Red Cross Visiting Nurse Associations, the Frontier Nursing Service, and other private or charitable groups. The greatest impetus for instituting school nurse services was prevention of communicable diseases and decreasing absenteeism in schools, but health education and addressing family health needs were always part of the approach to achieving these goals.

In the early years of U.S. school nursing, services were primarily targeted at elementary-aged children and their families. However, in the 1930s, some states began to expand health programs to include high school students. Speaking at the 1936 National Organization for Public Health Nursing Convention, Foeller (1936) emphasized the importance of school nurses being qualified to deliver health education to this age group, conduct physical assessments, teach anatomy and physiology, and provide mental health services and counseling. She also promoted collaboration between the school nurse, physical education teachers, and the local health department and the importance of a thorough medical examination for all new students.

Throughout the Depression and World War II, school nursing evolved from its focus on public and community health to being mostly confined within the school walls (Apple, 2017). Some of this was due to budget constraints and some was due to changes in society. Despite evidence that school nurses' interventions decreased absenteeism and improved student engagement, thereby reducing the overall cost of educating children, many school administrators declined to pay for public health nurses to make home visits and serve the broader community. Some school districts chose to eliminate school nurses altogether. U.S. society was also evolving during this time. More women entered the workforce, requiring children to spend longer hours in school. School nurses had less time to make home visits or become involved in the community's health, as they were administering medications and providing more direct health care services to children throughout the school day (Apple, 2017).

In the 1940s and into the second half of the twentieth century, school and public health nursing experts wrestled with defining the roles, practice, and educational requirements of school nurses, as well as meeting the complex health needs of students (Zaiger, 2013). Variations in state regulations, school nurse preparation, numbers of schools and students covered by each nurse, and expectations of school administrators and parents fostered inconsistency in the practice of school nursing throughout the country. The introduction of antibiotics and immunizations meant that fewer children were attending school with communicable diseases, yet emphasis on screening, health education, supporting children with disabilities, and mental health counseling was intensified (School Nurses Branch, 1961). Teachers were increasingly expected to provide health education and first aid to students, as a way of minimizing interruptions in the classroom and maximizing the number of schools one nurse could cover. School health councils were developed in some communities to enhance collaboration among physicians, teachers and other school personnel, school nurses, public health departments, and families and address the multifaceted expectations of school health programs (Zaiger, 2013).

In 1960, the School Nurses Branch of the American Nurses Association (ANA) developed a detailed position statement that delineated functions and educational preparation of school nurses. This statement proposed a comprehensive and leadership role for school nurses in the delivery and oversight of school health programs. According to these experts, school nurses should:

- Function as the administrators of their schools' health programs.
- Identify and address health problems that may interfere with students' education.
- Foster holistic growth and development of children.
- Support children and families in obtaining the full range of health services.
- Develop policies and procedures to prevent or intervene in communicable disease outbreaks, including immunization programs.
- Collaborate with teachers in the creation and evaluation of the school's curriculum for health education.
- Engage in development of the budget for school health services.
- Serve as equal members of the faculty.
- Provide leadership in community health issues.
- Assist in researching best practices for school nursing and interventions for school health problems.
- Assist in the education of nursing students and nurses entering the field of school nursing (School Nurses Branch, 1961).

Additional functions were outlined for school nurse administrators in hiring, training, and supervising school nursing staff, as well as overseeing the school program's operations, budget, and facility improvement to enhance the effectiveness of school nursing practice. Finally, the School Nurses Branch (1961) recommended that school nurses be prepared at the baccalaureate level with additional training, experience, or graduate education specific to the field. Interestingly, this position statement aligns closely with the original 1983 *Standards of School Nursing Practice*, which have been regularly updated in

TABLE 42.1 High Points In School Nursing History

Decade	Major Events in School Nursing
1890s	English and American nurses are used in schools to examine children for infectious diseases and to teach about alcohol abuse.
1900s	Henry Street Settlement in New York City sends nurses into schools and homes to investigate children's overall health.
1910s	School nursing course added to Teachers College nursing program. School nursing spreads throughout the country.
1920s and 1930s	School nurses are employed by community health departments.
1940s	School districts employ school nurses.
1950s	Children are screened in schools for common health problems.
1960s	Educational preparation for school nurses is debated.
1970s	School nurse practitioner programs began. Increased emphasis put on mental health counseling in schools.
1980s	Children with long-term illness or disabilities attend schools. Introduction of *School Nursing: Scope and Standards of Practice* by ANA and NASN.
1990s	School-based and school-linked clinics are started. Total family and community health care is offered.
2000s	School nurses give comprehensive primary, secondary, and tertiary levels of nursing care. *The Framework for 21st Century School Nursing Practice* is adopted.

Data from Apple R.: School health is community: school nursing in the early twentieth century in the USA. *History of Education Review* 46(2):136-149, 2017; Zaiger D: Historical perspectives of school nursing. In Selekman J, editor: *School nursing: a comprehensive text*, ed. 2, Philadelphia, 2013, F.A. Davis Company, pp. 2-24.

the intervening decades, most recently in 2017 (ANA & NASN, 2017). Contemporary school nursing practice continues to evolve but remains focused on meeting the complex needs of school-age children, school staff, families, and the community.

Table 42.1 gives the highlights of school nursing history over the last century.

FEDERAL LEGISLATION AFFECTING SCHOOL NURSING PRACTICE

Federal legislation requiring that schools educate children with medical needs and disabilities has had a substantial impact on the practice of school nursing since the latter part of the twentieth century. Survival of children born prematurely increased significantly during that time. This can be correlated with an increase in children with physical, behavioral, and learning disabilities (American Academy of Pediatrics [AAP], Council on School Health, 2016). The number of children with chronic diseases, such as asthma and diabetes, is also on the rise. In the past, children with these conditions did not often survive past infancy. If they did survive, they were likely to be institutionalized rather than cared for at home and would probably not have been educated in public schools as they are now.

In 1954, the U.S. Supreme Court declared that racial segregation of schools was unconstitutional. In 1964, the Civil Rights Act strengthened laws against discrimination on the basis of race, gender, religious affiliation, or ethnic background. This trend toward equality opened the door for parents to demand civil rights for their children with disabilities under the 14th Amendment of the U.S. Constitution (Gibbons et al., 2013). In 1973, **Section 504 of the Rehabilitation Act** required that public schools and other entities receiving federal funding could not be discriminated against and children could not be denied the benefits of an education (U.S. Department of Education Office for Civil Rights [DOE-OCR], 2010).

In 1975, the **Education for All Handicapped Children Act** was passed. This law further specified the requirements for special education approaches and school health services to allow children with disabilities to reach their full potential (Yonkaitis & Shannon, 2017). This law was amended several times over the next decade, increasing eligibility for services to children ages birth to 21 years and providing financial incentives to states for early intervention programs. States were also encouraged to provide transition to work and adult life programs for disabled children as they aged out of the school system (Gibbons et al., 2013).

The **Individuals with Disabilities Education Act (IDEA)** was reauthorized in 1990 and the Americans with Disabilities Act (ADA) was also passed in 1990, further ensuring the protection of civil rights for those with disabilities, including the right to a "free and appropriate education" (FAPE) for children ages birth to 21 years of age (Gibbons et al., 2013). FAPE is interpreted to mean services are free and meet the needs of disabled children in order to promote their highest achievable level of learning and development in the least restrictive educational environment (DOE-OCR, 2010). IDEA was renamed the **Individuals with Disabilities Education Improvement Act (IDEIA)** in 2004 and extended coverage till the child turns 22 (Gibbons et al., 2013). **Individualized education plans (IEPs)** and **individualized health plans (IHPs)** are among the processes that school nurses participate in to ensure that any specialized health care needs required for disabled children to participate in FAPE are met. According to the *2016 School Health Policies and Practice Study,* 71.5 percent of states require that school nurses participate on teams developing IEPs (Centers for Disease Control and Prevention [CDC], 2016d).

IDEA is reviewed and amended periodically to determine whether it is meeting its intended goals, to strengthen access, and clarify regulations. However, in 2017, Congress found that while 40 percent of the funding for IDEA is supposed to come from the federal government, only 8 percent federal funding is currently being provided to school districts throughout the country (U.S. Government Printing Office [GPO], 2017). While Congress acknowledged the burden this places on school districts in trying to comply with the law, the amount of federal money needed to fully fund IDEA services was $10 billion annually, an amount that Congress had stated should be provided "as soon as reasonably possible, through the reallocation of non-education funds within the current budget monetary constraints" (GPO, 2017, p. 1215). In order to provide education to these medically fragile children, they must rely on the assistance of school nurses to oversee and deliver higher-level health care than was needed before the enactment of these laws. The lack of funding from the federal government makes it difficult for schools to provide adequate special educational and health care services to students covered by these laws.

Several other federal laws impact the education and health services of children in public schools. In 2015, the **Every Student Succeeds Act (ESSA)** replaced the 2001 **No Child Left Behind Act** (NCLB). NCLB required that accommodations be made to promote academic achievement for children with disabilities and those living in poverty, having limited English proficiency (LEP), or who were homeless (DOE, 2008). ESSA strengthens and clarifies these requirements but also includes regulations requiring that states must allocate a percentage of their federal funds toward "activities to support safe and healthy students" (DOE, 2018, p. 219). These activities must include education on drug use and violence prevention; comprehensive mental and behavioral health services; prevention of bullying, harassment, and suicide; and integration of health, nutrition, and safety into physical education programs. School nurses are specifically named in the ESSA as being responsible for providing instruction in healthy lifestyles and chronic disease management (DOE, 2018).

The **Child Nutrition Act** (CNA) was originally passed in 1964 to combat malnutrition and hunger among disadvantaged children and pregnant women. This law funds the National School Lunch Program, breakfast and summer food programs in schools and preschools, and food supplements for pregnant and breastfeeding women and their preschool children (U.S. Congress, 2010). The Act also establishes minimum standards for nutrition content of meals, requires decreased student access to non-nutritious foods on school grounds, and the inclusion of nutrition education, physical activity, and school wellness programs. This law has been reauthorized every five years, with the last reauthorization in 2010 as the **Healthy, Hunger-Free Kids Act** (HHFK) (U.S. Congress, 2010). By continuing to reauthorize the CNA in its various iterations, Congress and presidents have acknowledged the importance of nutrition in promoting child health, which in turn improves children's ability to engage in educational opportunities. The HHFK Act expired in 2015 due to differences between the House and Senate on policy, including nutrition standards (Food Research and Action Center, 2018). However, the HHFK/CNA programs continue as permanent law so long as Congress continues to fund them.

Health information of students in schools is protected under both the **Family Education Rights and Privacy Act (FERPA)** of 1974 and the **Health Insurance Portability and Accountability Act (HIPAA)** of 1996. FERPA covers educational records of any child in an educational setting that receives federal funding from the U.S. Department of Education (Caldart-Olson & Thronson, 2013). This includes student health records maintained by all public schools and many private schools in the United States. In general, FERPA restricts the disclosure of any information that could be used to identify the student without written permission of the parents, except within the school to school officials or teachers who have a legitimate right to know. The focus of sharing this information should be considered only to protect the health and safety of the school. On the other hand, HIPAA restricts the sharing of individual students' health information but specifically allows discussions and electronic transmission about treatment and medication between the school nurse and the child's health care providers, as long as reasonable efforts are made to protect the privacy of the student's information (Caldart-Olson & Thronson, 2013).

School nurses should stay abreast of laws and regulations that affect their practice and the health of the children in their care. Just as the School Nurses Branch recommended in 1961, school nurses must provide leadership in all health and safety-related activities in their schools. Knowing these legal requirements can help them advocate for students and their rights to a healthy and safe school environment.

Table 42.2 summarizes the effects of these laws on school nurses and schoolchildren.

TABLE 42.2 Federal Legislation Affecting School Nursing

Law	Effect on School Nurses and Children
1954 Desegregation of Schools; 1964 Civil Rights Act	Schools can no longer be segregated by race. Expanded civil rights open the door for children with disability to attend schools.
1973: PL 39-112, Section 504 of Rehabilitation Act	Children cannot be excluded from schools because of a handicap. The school must provide health services that each child needs.
1975: PL 94-142, Education for All Handicapped Children Act	All children should attend school in least restrictive environment. Requires school district's committee on handicapped to develop individualized education plans (IEPs) for children.
1992: Americans with Disabilities Act	Persons with disabilities cannot be excluded from activities.
1997: PL 105-17, Individuals with Disabilities Education Act (IDEA) with updates in 2004	Educational services must be offered by schools for all disabled children from birth through age 22 years.
2001: No Child Left Behind Act of 2001 (NCLB); 2015 Every Student Succeeds Act (ESSA)	NCLB requires all children must receive standardized education in a healthy environment. ESSA includes provisions for health and safety in schools.
2004: Child Nutrition and WIC Reauthorization Act of 2004	Every local education agency (LEA) participating in federal school meal programs must establish a local school wellness policy.
2010: Healthy, Hunger-Free Kids Act of 2010	Reform of the National School Lunch Program and National School Breakfast Program through increased funding and setting policy on nutritional quality of foods served on school grounds. Also opens eligibility requirements to improve access to the free and reduced-price lunch program.

WIC, Women, Infants, and Children program.

STANDARDS OF PRACTICE FOR SCHOOL NURSES

The professional organization for school nurses is the National Association of School Nurses (NASN), headquartered in Washington, DC. The mission of the NASN is "To optimize student health and learning by advancing the practice of school nursing" (NASN, 2018a, para. 3). NASN advances school nursing practice through education, state and national conferences, access to legal and school health resources, lobbying efforts on behalf of children and school nurses, and establishment of the *School Nursing: Scope and Standards of Practice,* which were most recently updated in 2017 (ANA & NASN, 2017). These standards "are professional expectations that guide the practice of school nursing" (ANA & NASN, 2017, p. xi). They delineate the roles, activities, ethical requirements, and standards of professionalism and practice for which school nurses are held accountable to the public.

Within the *Scope and Standards of Practice,* the *Standards of Practice* follow the nursing process: assessment, diagnosis, outcomes identification, planning, implementation, and evaluation. The *Standards of Professional Performance for School Nursing* describe the professional competencies that school nurses are responsible for. These include:

- Ethical practice
- Ensuring confidentiality of student health information
- Cultural competence
- Effective communication and interprofessional collaboration
- Continuing education to ensure current, quality, and evidence-based nursing practice
- Ongoing self-evaluation
- Appropriate and responsible utilization of resources
- School health services program management and policy development with accountability for student health
- Leadership within the school health program and community (ANA & NASN, 2017).

EDUCATIONAL AND LICENSURE CREDENTIALS OF SCHOOL NURSES

The practice of school nursing is highly complex and requires a great deal of autonomy and clinical judgment. School nurses may be required to train and supervise others and to delegate certain health care tasks to unlicensed assistive personnel. Registered nurses (RNs) can be licensed at either the bachelor of science in nursing (BSN) or associate's degree level (ADN) or in a diploma program, as long as they can pass their state board's licensure examination. The BSN curriculum includes all of the same coursework that an associate's degree or diploma does, in addition to education on leadership, management, population health, health promotion, nursing theory, health policy, and quality improvement (American Association of Colleges of Nursing, 2017). Extensive research has demonstrated that patient outcomes are improved in acute care settings when a higher percentage of nurses is prepared at the BSN level (Institute of Medicine, 2011). However, there is limited research on this specifically related to school health outcomes. Experts in the field of pediatrics and school health recommend that school nurses have a minimum licensure of RN and a minimum education level of BSN for entry into the school nursing specialty (AAP, 2016; NASN, 2016). The American Nurses Association (2013) asserts that public health nursing requires a minimum of a BSN to practice. Because school nurses care for groups of children and school personnel whose health issues may affect the greater community population, this practice is considered to be a type of public health nursing (NASN, 2016).

The NASN also recommends school nurse certification, which requires training beyond that provided in most bachelor's degree preparation (NASN, 2016). While individual states may have various requirements or pathways for certification of school nurses, certification at the national level requires licensure as an RN and a bachelor's degree in a health-related field, not necessarily nursing (National Board for Certification of School Nurses, 2018).

Despite these recommendations, school nurses across the United States vary widely in their educational preparation for assuming this critical role. According to the *Results From the School Health Policies and Practices Study* (SHPPS) (CDC, 2016), 20.7 percent of districts in the United States have no requirements related to the educational preparation of newly hired school nurses. A minimum of an ADN was required in 23.6 percent of school districts. A BSN was required in 26 percent of school districts, a significant increase from the 2012 study, which found that only 5.4 percent of newly hired school nurses were required to have a BSN (Brener et al., 2013).

Many school districts (27 percent) allow nurses with minimal education, such as licensed practical nurses (LPNs), to practice in schools (CDC, 2016d). The percentage of districts requiring RN licensure for newly hired school nurses has declined to 79 percent from about 86 percent in 2012 (Brener et al., 2013). Only 39 percent of school districts require state school nurse certification, and only 7.3 percent require national certification (CDC, 2016d). These numbers are concerning in light of the expert recommendations discussed earlier, the increasing complexity of school nursing practice, and the rising numbers of vulnerable children and families in school communities (NASN, 2016).

A 2018 study by Willgerodt, Brock, and Maughan found about 1200 advanced practice nurses (APNs) practicing in U.S. schools. These APNS may be clinical nurse specialists or nurse practitioners with specialization in pediatrics, family nursing, school nursing, or public health nursing (ANA & NASN, 2017). Some of these APNs are providing school health services at the conventional level, or they may be providing primary care services in school-based clinics (Proctor, 2013). Having APNs provide primary care may improve access to health care for families who lack a provider or health insurance, as well as minimize barriers such as transportation for families without a vehicle or employer restrictions on parents leaving work. These advanced practice nurses may be certified by professional organizations such as the ANA or their own professional organization. Most hold master's degrees in nursing (ANA & NASN, 2017).

Just as with educational and certification requirements, there is little consistency in the minimal requirements for years or types of work experience for newly hired nurses across the United States. While it is common that school nurses come to the field with prior nursing experience, it is possible for newly graduated nurses to work in the schools, depending on the entry criteria of their state and local health departments and schools. Ideally, the less experienced nurses should complete an extended orientation period until they feel comfortable practicing alone (Proctor, 2013). The *School Nursing: Scope and Standards of Practice* can provide guidance to school districts, administrators, and school nurse managers in the development of position descriptions for recruitment of new school nurses and competencies for orientation and ongoing evaluation of school nurse employees (ANA & NASN, 2017; Proctor, 2013).

ROLES AND FUNCTIONS OF SCHOOL NURSES

School nurses function in many roles within their practice. They serve as educators, counselors, consultants, case managers, and direct caregivers to children and school staff. They must coordinate the health care of many students in their schools with the health care that the children receive from their personal health care providers.

In order to ensure that school nurses can provide safe and effective care for their students, the *Healthy People 2020* Objective ECBP-5 recommends an increase in the proportion of schools that have a minimum of one full-time registered nurse for every 750 students (U.S. Department of Health and Human Services, 2018). However, as of 2016, only 10.9 percent of schools have a required minimum school nurse-to-student ratio (CDC, 2016d). The NASN (2015) supports increasing the proportion of schools served by full-time school nurses and states that "every student needs direct access to a school nurse so that all students have the opportunity to be healthy, safe, and ready to learn" (para. 10). Only one-third of schools in the United States require a full-time nurse, and fewer than 80 percent of school districts employed any school nurses as of 2016, a decline of 14 percent since 2000 (CDC, 2016d). The proportion of schools meeting the *Healthy People 2020* recommendations of one full-time nurse for every 750 students has increased from 40.6 percent in 2006 to 51.1 percent in 2014, a hopeful sign that school administrators recognize the benefits of having a school nurse provide care to their students (USDHHS, 2018). NASN (2015) and the AAP (2016) assert that there is no standardized ratio that would fit every school in every district. They propose determining school nurse-to-student ratios using a multifaceted approach, including assessment of students' health needs, social determinants of health affecting each school community, and use of evidence-based research on safe staffing and workload assignment. This is the best way to ensure that students receive the care they need and that school health programs are coordinated and implemented by qualified professionals (AAP, 2016; NASN, 2015c).

School Nurse Roles

Direct Caregiver. The school nurse functioning in the role of direct caregiver is expected to give immediate nursing care to ill or injured children or school staff members. While many people envision the school nurse caregiver role as providing minor interventions such as bandages and ice packs, nothing could be further from the truth in the majority of U.S. schools (Anderson et al., 2017). Whenever a child comes into the clinic, the school nurse must first assess the seriousness of their complaint or symptoms and then determine possible causes. Some causes are obvious, such as an injury from a fall, and some less so, such as respiratory symptoms, which could be due to communicable disease, allergies, etc. The school nurse intervenes to alleviate symptoms, provide first aid in the event of an injury, stabilize the child in an emergency situation, provide ongoing care for chronic illnesses, such as diabetes or asthma, and prevent the spread of communicable diseases (AAP, 2016). As stated earlier, many children now attend school with even more complex medical needs, requiring procedures such as intermittent catheterization, tube feeding, tracheostomy suctioning and care, and ventilator management (Shannon & Minchella, 2016; Toothaker & Cook, 2018). Some children's care needs are so time-consuming, they require the assignment of a personal or private duty nurse during the school day. This nurse assumes care for that child alone, rather than the entire student body.

Although most school nurses are in public or private schools and give care only during school hours, the nurse in boarding schools, summer camps, and detention centers provides nursing care to children 24 hours a day and seven days a week. In these residential programs, children live on the premises and may only go home for vacations or not at all if they are incarcerated. In some settings, the nurse also lives at the school and may be on call at all times. School nurses in these residential settings can impact students' academic outcomes by partnering with administrators, teachers, and families to promote a healthy school environment, adequate rest, good nutrition, regular physical activity, and comprehensive, high-quality health care services (Wernette & Emory, 2017). The nurse makes many of the health care decisions for the child and has a referral system to contact parents or guardians and other health care providers, such as physicians and psychological counselors, if needed.

Health Educator. The school nurse in the health educator role may be asked to teach children both individually and in the classroom. School nurses may provide education about disease process and management to parents and children, especially if they don't understand instructions from the primary provider (Anderson et al., 2017). School nurses provide health education to groups of children about injury and communicable disease prevention, dental hygiene, puberty, substance abuse, and nutrition, among others (AAP, 2016; Rebmann, Weaver, et al., 2018). They may be required by state or local school board policies to teach specific subjects or develop health education based on the needs of the school and parent requests.

Case Manager. The school nurse is expected to function as a case manager, helping coordinate the health care for children with complex health problems (AAP, 2016). School nurses may collaborate with the family, teachers, and administrators to ensure that health care services promote the child's ability to learn and participate in the academic environment to the

greatest extent possible. Care may be provided in the schools by physical therapists, occupational therapists, speech therapists, or other health care providers during the school day. The nurse may need to develop health care plans for children that clearly explain procedures and treatments needed for their conditions, as well as provide referrals and reports to other health care providers about children's response to treatments and interventions provided in the school (ANA & NASN, 2017).

Consultant. The school nurse is the person best able to provide health information to school administrators, teachers, and parent-teacher groups. As a consultant, the school nurse can provide professional information about proposed changes in the school environment and their impact on the health of the children. The nurse can also recommend changes in the school's policies or engage community organizations to help make the children's schools healthier places (Schaffer et al., 2016). This is a population-level role for the school nurse; the population consists of all children, families, staff, and the surrounding community.

Counselor. School nurses are reported to spend nearly one-third of their time assisting students with mental health needs (Government Accountability Office, as cited in Bohnenkamp et al., 2015). School nurses are familiar and trusted members of the school community. Children often see the nurse as a safe person in whom they may confide about problems such as bullying, physical abuse, substance abuse, grief, and suicidal thoughts. School nurses should always be alert to the potential for such problems when children come to their clinic, especially those who visit frequently with vague complaints or frequent requests to go home (Bohnenkamp et al., 2015). It is important for nurses to be honest with the child about the need to report dangerous situations to their parents, school officials, social services, and/or legal authorities. The nurse should emphasize that the child's confidentiality and privacy are central and reporting is only done as needed to protect them from harm.

Community Outreach. When participating in community outreach, nurses can be involved in community health fairs or festivals in the schools, using that opportunity to promote health through education, screenings, and immunization programs. They may be able to engage local providers, such as dentists and ophthalmologists, to provide free screenings at the school (Schaffer et al., 2015). School nurses should collaborate with area schools of nursing to provide clinical experiences for nursing students, as well as involve those future nurses in providing various health promotion and education events for the children. School nurses should attend meetings of parent-teacher associations, so they get to know the families of their students and offer education on health concerns these families raise. Attendance at school board meetings may also provide school nurses with opportunities to be seen as experts available to answer questions about school health needs, as well as concerned and engaged members of the school community.

Nurses can participate in coalitions focused on addressing a multitude of school and community health concerns from bullying and violence prevention to poverty and teenage pregnancy (Shaffer et al., 2016). They may be able to engage community faith-based and service organizations in providing food and other supplies for children living in poverty. Some school nurses coordinate weekend backpack food relief for children who only eat regularly on school days.

EVIDENCE-BASED PRACTICE

Because of the obesity epidemic in the United States, interventions to increase physical activity and reduce sedentary behaviors have become a priority for public health practitioners. This research study evaluated the feasibility and efficacy of a school nurse–delivered intervention aimed at improving diet and activity and reducing body mass index (BMI) among overweight and obese adolescents. This study used a pair-matched cluster-randomized controlled school-based trial. Six high schools were randomized into either the six-session counseling intervention or the control group. The intervention, "Lookin' Good Feelin' Good," consisted of six one-on-one school nurse–led counseling sessions conducted over 2 months during school hours. Those in the control group had six one on-one visits with the school nurse over 2 months to be weighed and review informational pamphlets on weight management. Although there was no significant difference in BMI, activity, or caloric intake between the groups at 2 months, those in the intervention group ate breakfast on more days of the week and had a lower intake of sugar than the control group.

Nurse Use

This study indicates that a school nurse–delivered obesity intervention is feasible and may improve select behaviors that may result in obesity.

Pbert L, Druker S, Gapinski MA, et al.: A school nurse-delivered intervention for overweight and obese adolescents. *J Sch Health* 83(3):182-193, 2013.

Researcher. Research on school nursing practice and impact has grown steadily over the past couple of decades. Current, ongoing research can be found on school nursing practice, staffing and workloads, educational preparation and professional development of school nurses, and the use of evidence-based practice for a host of health conditions addressed by school nurses (Allen-Johnson, 2017; NASN, 2018b; Willgerodt et al., 2018). School nurses are responsible for providing nursing care that is based on solid, evidence-based practice. School nurses can, and should, be involved in research as participants by completing surveys and questionnaires from reputable researchers and professional organizations (Maughan et al., 2016; NASN, 2018b). School nurses may also function as researchers if they are properly educated to conduct ethical and scientifically founded research, provide human subject protections if applicable, and obtain institutional review board approval from their school system or an affiliated health care or educational institution.

SCHOOL HEALTH SERVICES

School health services vary in their scope throughout the United States. However, there are common parts to the programs.

CHECK YOUR PRACTICE

While working as a student in school health you have been asked to participate in the development of a school health program for your community that emphasizes the development of healthy schools. What would you do?

Fig. 42.1 WSCC model for school health practice. *WSCC,* Whole School, Whole Community, Whole Child. (Available at https://www.cdc.gov.)

Federal School Health Programs

The federal government, through the coordination of the CDC, with an emphasis on the health of the population of children and the school community, has developed the Healthy Schools initiative, which utilizes the Whole School, Whole Community, Whole Child (WSCC) model as a framework that school health programs are encouraged to follow (CDC, 2018a) (Fig. 42.1).

CDC Healthy Schools provides funding, training, and other resources that support schools in promoting health and adopting the components of the WSCC framework. CDC Healthy Schools provided more than $15 million to the nation's schools in 2016 with the goals of eliminating health disparities, providing evidence-based health education and services, and utilizing epidemiologic surveillance and research to prevent chronic disease and decrease the spread of communicable disease (CDC, 2016a). Between 2000 and 2014, CDC Healthy Schools funding, education, and technical support significantly improved the nutritional quality of school meals. Between 2013 and 2015, CDC Healthy Schools resources helped achieve significant increases in schools that avoid selling non-nutritious foods and beverages to students and provide physical education classes one or more days a week. Nearly 100 percent of schools track chronic health problems in their students due to the support provided by this federal program (CDC, 2016a).

School Health Policies and Practices Study 2016

Since 1994, the School Health Policies and Practices Study (SHPPS) has been conducted periodically (at least every 6 years) in all 50 states and the District of Columbia to evaluate the 10 components of the WSCC model. The study also measures progress in achieving *Healthy People 2020* goals and objectives in the area of health education, disease prevention, and health promotion (CDC, 2016d). The 2016 SHPPS assessment of achievement of *Healthy People 2020* objectives for school nurse-to-student ratios and school district requirements for nurse qualifications and licensure were discussed earlier in this chapter.

The 2016 study found that the number of school districts with arrangements for school-based or off-site health centers to provide health services such as primary care, dental services, or counseling/mental health services to students decreased significantly in recent years. This is concerning

because school-based health centers (SBHCs) provide a variety of health services to children who may not have access to other community resources (Price, 2017). Having these services located at the school allows children to receive timely care and decreases time missed from class. Children whose health problems are not addressed may not be able to take full advantage of academic opportunities (Price, 2017). Having services on site may also help parents avoid missing work in order to take their children to an off-site provider. Some employers do not allow time off for such activities. School nurses can more easily assist families to get health care for their children when an SBHC is available.

According to the SHPPS (CDC, 2016d), most students in the United States were found not to be participating in the recommended 60 minutes a day of physical activity. Fewer than half of school districts had an indoor air quality management program, though more than 75 percent had policies requiring regular inspections of ventilation, heating and cooling systems, and other aspects of building integrity that could promote mold growth and other environmental contamination within school buildings. On the positive side, the SHPPS found that around 80 percent of districts prohibited all tobacco use, including vaping and e-cigarettes, by students, employees, or visitors during the school day or at school events (CDC, 2016d). Furthermore, a majority of school districts have enhanced security and safety measures in their schools, instituted disaster/crisis preparedness plans, and established programs to prevent bullying and address issues related to aggressive behaviors.

SCHOOL NURSES AND *HEALTHY PEOPLE 2020*

Many *Healthy People 2020* proposed objectives are directed toward the health of children. In addition, several point directly at the care that nurses give to children in the schools. The *Healthy People 2020* box lists the objectives that involve school-age children. These objectives are concerned with the children with disabilities in the schools, the number of children with major health problems, and the ratio of nurses to children in the schools. Nurses can accomplish the goals using the three levels of prevention, as discussed next.

THE LEVELS OF PREVENTION APPLIED IN SCHOOLS

The three levels of prevention—primary, secondary, and tertiary—have always been a part of health care in the schools (Wold & Selekman, 2013). **Primary prevention** provides health promotion and education to prevent health problems in children. **Secondary prevention** includes the screening of children for various illnesses, monitoring their growth and development, and caring for them when they are ill or injured. **Tertiary prevention** in the schools is the continued care of children who need long-term health care services, along with education within the community (Fig. 42.2).

HEALTHY PEOPLE 2020

Objectives Related to School Health and School Nursing

- **ECBP-2:** Increase the proportion of elementary, middle, and senior high schools that provide comprehensive school health education to prevent health problems in the following areas: unintentional injury; violence; suicide; tobacco use and addiction; alcohol or other drug use; unintended pregnancy, HIV/AIDS and STD infection; unhealthy dietary patterns; and inadequate physical activity.
- **ECBP-4:** Increase the proportion of elementary, middle, and senior high schools that provide school health education to promote personal health and wellness in the following areas: hand washing or hand hygiene; oral health; growth and development; sun safety and skin cancer prevention; benefits of rest and sleep; ways to prevent vision and hearing loss; and the importance of health screenings and checkups
- **ECBP-5:** Increase the proportion of elementary, middle, and senior high schools that have a full-time registered school nurse-to-student ratio of at least 1:750.
- **IID-10:** Maintain vaccination coverage levels for children in kindergarten.
- **IID-11:** Increase routine vaccination coverage levels for adolescents.
- **NW-2:** Increase the percentage of schools that offer nutritious foods and beverages outside of school meals.
- **TU-3:** Reduce the initiation of tobacco use among children, adolescents, and young adults.
- **TU-15:** Increase tobacco-free environments in schools, including all school facilities, property, vehicles, and school events.

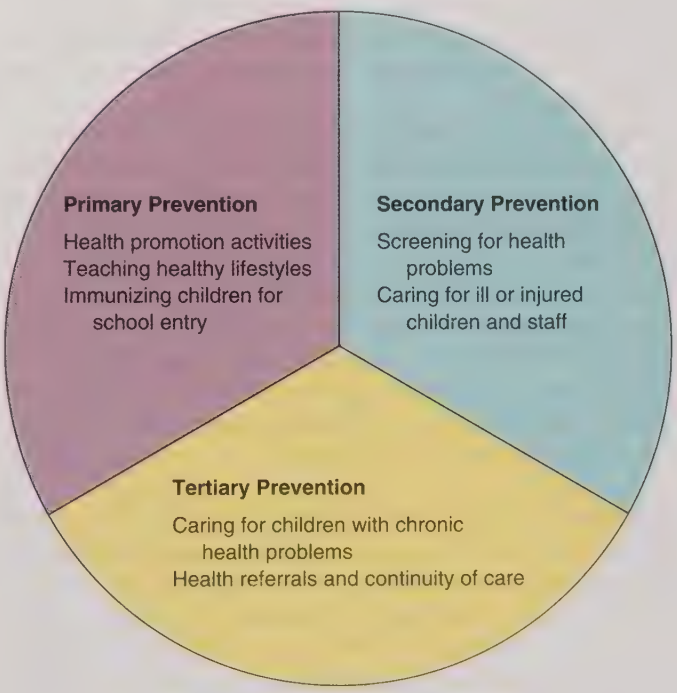

Fig. 42.2 Prevention levels in schools.

Primary Prevention in Schools

Primary prevention encompasses activities that are intended to prevent the development of illness, disease, and injury in those who are currently healthy (Wold & Selekman, 2013). The strategies for achieving primary prevention are health promotion and implementation of measures that protect people from agents that may cause disease or injury.

Health education is the most commonly used approach in health promotion. Historically, health teaching was considered "the fundamental basis of all school health work" (Struthers, as cited in Wold & Selekman, 2013). The school nurse may have the opportunity to go into the classroom to teach health promotion concepts, such as hand-washing or dental hygiene skills. This is population-level primary prevention.

School nurses also provide individual education to children who come to the school clinic for various health concerns or questions. Individual education about disease prevention may also be provided to school employees and parents (Wold & Selekman, 2013).

HOW TO Teach Young Children in School

When teaching children in preschools and elementary schools:

- Keep the lesson to no more than 10 minutes.
- Use a lot of examples, pictures, and stuffed animals in the talk.
- Always remember the developmental stage of the children when teaching them.

School nurses use the nursing process while they care for children in the schools. In their primary prevention efforts, they assess children and families to determine their level of knowledge about various health issues. Finding out whether children are at risk for preventable disease is also important. Decisions about where to focus primary prevention efforts are made by analyzing the assessments completed on all of the children in the school to determine the most pressing priorities for the school population.

School nurses address many areas of primary prevention in their practice. School programs designed to promote health, such as nutritious meals and physical education, may require consultation and education by the school nurse. Nurses can teach about healthy food choices and encourage school districts that allow vending machines to have nutritious foods instead of "junk food" available in the machines (CDC, 2016a). Other primary prevention activities may include preventing childhood injuries, preventing substance abuse behaviors, reducing risks for the development of chronic diseases, and monitoring the immunization status of children.

Prevention of Childhood Injuries. Accidents (unintentional injuries) are the leading cause of death among children and teenagers (CDC, 2016b). The school nurse educates children, teachers, and parents about preventing injuries. The CDC (2016b) provides guidelines in its *National Action Plan for Child Injury Prevention,* which school nurses can utilize to develop evidence-based educational programs to encourage children to use their seat belts or bicycle helmets to prevent injuries. Other classes can be on crossing the street, water safety, and fire safety. The school nurse, as a trusted health care provider at school, is able to quickly give information to help prevent injuries from occurring, since most injuries are preventable (Rebmann, Weaver, et al., 2018).

School nurses also provide health promotion to prevent playground injuries, which number over 200,000 injuries to children under age 14 per year (CDC, 2016c). School nurses can utilize guidelines published by the U.S. Consumer Product Safety Commission (2015) to assess their school playgrounds for equipment safety.

School sports also have the potential to cause injuries to children. The school nurse is often involved in deciding with parents and coaches on how to best prevent injuries when children are engaged in athletic activities (Rebmann, Weaver, et al., 2018). From 2015 to 2016, more than 150,000 children were seen in emergency departments from injuries sustained while riding scooters, hoverboards, or skateboards (Bandzar et al., 2018). Injuries included fractures and head injuries. School nurses can also promote the use of helmets and knee pads and work with communities to provide safe places, such as skateboard parks, for children to engage in these activities. Educating parents, children, and school personnel on safety measures to prevent any type of injury can decrease the incidence of these injuries, as well as decrease emergency department visits (Bandzar et al., 2018; Salam et al., 2016). This makes the entire community safer and decreases health care costs for all.

Substance Abuse Prevention Education. Research has found that the percentage of adolescents who report never having used substances such as alcohol, tobacco, and drugs increased between 1976 and 2014, as did the percentage of adolescents who report not having used substances in the preceding 30 days (Levy et al., 2018). However, early use of alcohol, tobacco, and drugs can lead to a plethora of health problems and carries a higher risk for addiction due to the development of the adolescent brain (National Institute on Drug Abuse, 2014). Primary prevention interventions by the school nurse include educating children and adolescents about the effects of tobacco, drugs, and alcohol on their bodies. School nurses should start early with education of children about the negative effects of street drugs (such as marijuana, cocaine, crack, and heroin), tobacco, and alcohol on their bodies and how to avoid them (NASN, 2015b).

Despite the overall decrease in use of substances, misuse of some illegal and legal drugs has remained steady or increased. Providers are seeing an increase in the use of "club drugs" such as lysergic acid (LSD), ketamine, gamma hydroxybutyrate (GHB), Rohypnol, and Ecstasy (MDMA). The school nurse can provide instruction about the serious side effects of Ecstasy, especially that it causes a very high body temperature that can lead to death. Marijuana and alcohol use have leveled off in recent years, rather than decreasing as with many other substances. Researchers postulate that this is related to easier accessibility of these substances to youth, especially with the legalization of marijuana in many states and marketing of these substances as safe and enjoyable by their powerful lobby groups (Levey et al., 2018). Students may find these substances in their homes being used by their parents. In the past decade, the abuse of opioids has reached epidemic proportions. The 2013

Partnership Attitude Tracking Study found that 23 percent of teenagers had taken prescription pain medication for nonmedical reasons at least once in their lifetimes and 16 percent had done so in the past year (Feliz, as cited in NASN, 2015b). Teaching children about the dangers of all drugs is an important responsibility of the school nurse. In addition, the school nurse can teach parents and other members of the community about the risks of substance use, ways to secure their own prescriptions and model safe use of legal substances, and how to recognize warning signs of substance abuse in their children so that early intervention can occur. Increasing everyone's awareness of these dangerous trends may lead to a decrease in abuse of those substances that is on the rise in the United States and subsequently improve the overall health of the population (NASN, 2015b).

Disease Prevention Education. The nurse has the opportunity to teach children healthy lifestyles to reduce their risk of disease later in life. For example, children can be taught ways to reduce their risk of becoming obese by teaching and reinforcing healthy nutrition and exercise (CDC, 2018d). Health education may also include ways to promote cardiovascular health, oral health, and prevent the spread of communicable diseases. The school nurse should collaborate with teachers to create evidence-based health education plans.

Dissemination of health promotion information to the parents of the children is often a challenge for the school nurse. There are many ways to increase accessibility of health information, such as providing a website or newsletter that parents can read outside of school hours without interfering with their work schedules. School nurses may consider presenting information during a parent-teacher association meeting. They could survey families for health issues they have questions or concerns about and arrange a guest speaker if the nurse is not well versed on the topic. Providing babysitters, food, and transportation to these meetings could remove barriers for families with low incomes and long workdays. By educating parents and children, the school nurse is able to promote the health of not only the schoolchildren but also the community.

Vaccinations for Schoolchildren. All states have laws that require that children receive immunizations, or vaccinations, against communicable diseases before they attend school (CDC, 2017c). School nurses must be up to date on the latest laws on immunizations for children in their own state and actively educate parents about the benefits of vaccinating their children. The CDC (2017c) provides recommendations for vaccinations, but it is up to each individual state to determine which immunizations are required for enrollment and attendance at a school or childcare facility. Vaccine requirements and exemptions laws vary from state to state (CDC, 2017c). Depending on the state's law, children may be prevented from enrolling in or attending school if they have not had the required immunizations or have not provided the required paperwork for exemptions (either for medical, religious, or philosophical/conscientious belief reasons) (CDC, 2017c). Some parents may request that their child be exempted from the required immunizations because of their belief that not all immunizations are good for their children, for medical reasons, or for religious or philosophical reasons (NASN, 2015a). The school nurse should be aware of the laws in the state regarding acceptable reasons for immunization exemption. At the same time, the nurse has the opportunity to teach parents and the rest of the community about the overall benefits to society and to their children from the use of immunizations (NASN, 2015a).

For children entering kindergarten, most state-required vaccinations include diphtheria, pertussis, and tetanus (the DTaP series); measles, mumps, and rubella (the MMR series); polio; and others. Chapters 14 and 15 have a more complete discussion of communicable diseases and immunizations in children.

The school nurse must keep a complete file of all of the children's vaccination records in order to meet the state's laws. These files will contain the student's name, date of birth, address and telephone number, parents'/guardians' names, and contact information. They will also include the student's primary health care provider's name, telephone number, and address. Most important, the information should include all the vaccinations with the dates the child received booster shots, as well as any immunizations the child may be exempted from based on medical or religious reasons (NASN, 2015a). This makes it easier for the school nurse to find out which children still need immunizations or boosters or, in the event of a vaccine preventable disease outbreak, to notify parents about the signs and symptoms of the disease, when to seek care, and the potential need to keep their children home from school until the outbreak is resolved.

The HIPAA of 1996 requires that all health information be private. This Act can present a challenge for the school nurse and personnel within the school and the school system. Teachers and school administrators as well as interprofessional health care partners may feel they have the right to know about health issues of their students. Thus they may challenge the school nurse if the nurse declines to share information to protect the child's privacy (Caldart-Olson & Thronson, 2013).

There is conflicting information on whether sharing of information about the immunization status of children between providers and school nurses is covered by HIPAA. However, the USDHHS published a statement in 2008 that protected health information may be shared between school nurses and primary providers when needed to make decisions about treatment of children in the schools (USDHHS, 2008).

The nurse will need to contact the parents to get the immunization history for the child. Written notes will need to be sent to each child's home at least one year before each new immunization is needed so that the parents have time to get the child to his or her health care provider for the shots. If the parents or guardians do not speak English, these notes will need to be translated into the family's language. If the parents have lost the information that gives the child's immunization history, they should be encouraged to contact their physician or nurse practitioner to get it.

Many problems with children not being immunized or having incomplete vaccination records may arise in families who have moved a great deal, such as those serving in the armed services or experiencing homelessness, or those who do not have a regular physician. The parents may have no idea whether the child has even received the recommended or required

vaccines. Some parents are not aware that, since the implementation of the Affordable Care Act, insurance is required to pay for certain preventive care, including childhood immunizations (Hahn, 2016). Families may also believe that, if they do not have health insurance, they will have to pay for their children's immunizations out of pocket, which can be expensive. Certain low-income families without health care insurance may qualify for federal programs that provide free immunizations to children (CDC, 2017b). Most states have their own programs to fund childhood immunizations, many through state and local public health departments, so school nurses will want to become familiar with what their state provides.

School nurses can also play an important role in immunizing children against seasonal flu. The CDC (2018e) recommends that everyone six months of age and older receive an annual seasonal influenza vaccination, especially children younger than five years of age and all children with chronic medical conditions. Vaccination against influenza should begin as soon as that season's vaccine becomes available (CDC, 2018e). During the 2009 H1N1 influenza outbreak, school nurses were at the front line of the epidemic. In fact, it was a school nurse in Queens, New York, who first notified the CDC that the influenza epidemic had reached U.S. soil (Robert Wood Johnson Foundation, 2010). School nurses were challenged to reduce the spread of this epidemic among school-age children. School nurses may administer the influenza vaccine to children at the school or work with the local public health department to do so, with the parents' permission. This has the potential to promote health within the entire community, as well as decrease costs and missed work time for parents (Fiorivant & Ward, 2018).

Secondary Prevention in Schools

Because secondary prevention involves early intervention for children when they need health care, this is the largest responsibility for the school nurse (Wold & Selekman, 2013). This includes caring for ill or injured students and school employees. It also involves screening and assessing children and referral to appropriate health agencies or providers. The school nurse uses the nursing process during secondary prevention activities. When an ill or injured child comes to the school's health office, the nurse must immediately assess the child for the degree of illness or injury.

Children seek out the school nurse for a variety of different needs:

- Headaches
- Stomachaches
- Diarrhea
- Anxiety over being separated from the parents
- Cuts, bruises, or other injuries

In addition, children may seek reassurance from the school nurse or even appear to hide in the nurse's office. This may be a result of harassment or bullying from other children in the school (John & Chewey, 2013).

Once the assessment data are gathered, the nurse determines the course of action and follows it through the implementation and evaluation phases. This occurs for direct care as well as for screening children for other health problems. If assessment indicates the child has a health problem, the school nurse continues to follow the nursing process to intervene within his or her scope of practice or to refer the child to providers who can provide the most appropriate health care.

Nursing Care for Emergencies in the School. Events that occur in or near schools may cause a crisis for children, teachers, and staff. The school nurse must have an **emergency plan** in place so that a routine can be followed when emergencies occur. Disaster planning in the schools includes becoming prepared for natural disasters (such as fire or severe weather), man-made disasters (such as school shooting or structure collapse), as well as health condition emergencies (such as asthma attack or seizure) (Rebmann, Elliott, et al., 2016). The NASN recommends that school nurses provide leadership to schools in all phases of emergency preparedness and management (Tuck et al., 2014).

The following summarizes the NASN's recommendations of the role of the school nurse during each phase of disaster planning (Tuck et al., 2014):

- Prevention/Mitigation: perform an ongoing assessment to identify hazards
- Preparedness: serve on planning groups, establish emergency response plans, provide training to school personnel
- Response: perform triage, coordinate the first-aid response team, provide direct hands-on care to victims, act as a counselor to help everyone cope with the emotional aspects of this serious event (Box 42.1)
- Recovery: provide direct support, act as liaison between community resources and those in need; school may become an emergency shelter for community-at-large

The U.S. Department of Education et al. (2013) recommend that all schools have crisis plans in place to help the children, teachers, parents, and community cope with the sudden event. **Crisis teams** are prepared to help everyone respond quickly to the crisis, to ensure the safety of the school, and to follow up on the effects of the crisis on the members of the school (Tuck et al., 2014). The crisis plan includes an administrative policy made either for the entire school district or, if the schools are large, for each individual school. The plan includes the names of the persons on the crisis team: the superintendent of the school district, the school nurse, the guidance counselor, the school psychologist or social worker, teachers, police or school

BOX 42.1 Dealing With a Disaster: Responsibilities of the School Nurse

- Provide triage.
- Communicate with emergency medical personnel.
- Assess the school community for the presence of shock and stress.
- Recommend reduced television viewing of the disaster.
- Provide grief counseling.
- Communicate with the children, parents, and school personnel.
- Follow up with assessment of children for anxiety, depression, regression, and post-traumatic stress disorder.

Modified from Doyle J.: Emergency management, crisis response, and the school nurse's role. In Selekman J, editor: *School nursing: a comprehensive text,* ed. 2, Philadelphia, 2013, F.A. Davis Company, pp. 1216-1244.

security, clergy from the community, and parents. Plans to obtain and share information can be made quickly (U.S. Department of Education et al., 2013).

The nurse can help the crisis team make a checklist for everyone to follow that explains what to do in every possible crisis situation. Then, at the end of the crisis, the crisis team will want to take time to counsel all of the people who helped in the crisis, including the teachers, emergency personnel, and parents, as well as the children. That way everyone can talk about the crisis. The crisis plan should be reviewed every year to see what parts of the plan need updating. Drills take place to act out the plan to see how it works and how it can be revised to make it more workable (Tuck et al., 2014; U.S. Department of Education et al., 2013).

Individualized emergency plans are made for all students who may have a health problem that could result in an emergency situation in the school (Tuck et al., 2014). This plan could be for the child with food allergies (e.g., to peanuts), one who has sensitivity to insect bites that could result in anaphylactic shock, or those with chronic illnesses such as asthma, diabetes, or hemophilia. The individualized emergency plan should include the student's medical history, list of medications, location of emergency medication, and list of personnel trained to administer emergency medication. It is important that the school nurse communicate with school personnel about students requiring emergency medication to ensure quick access to emergency medications at all times.

The nurse may not always be at the school and the emergency may have to be handled by a teacher, administrator, secretary, custodian, or coach (U.S. Department of Education et al., 2013). This issue is especially applicable to school nurses in rural settings, who may have several schools for which they are responsible when such schools may be far apart (Rebmann, Elliott, et al., 2016). Therefore all emergency procedures must be clearly spelled out and easily accessible to anyone in the school. Along with the procedures and an emergency manual written or obtained by the school nurse, an injury or illness log should be available for personnel to fill out so that there is an accurate record of what happened. Along with this form, procedures for notifying the parents or legal guardians about the emergency are explained. Information must be provided to parents about any actions taken for the child and where the child was sent if transfer to a hospital or other medical agency was required (Tuck et al., 2014). Good communication with parents is important to decrease their anxiety and assist them in reuniting with their children. School nurses are uniquely qualified to provide this information because they may have ongoing relationships with parents due to providing day-to-day care for their children.

Because the school nurse may have to give nursing care to a child or adult in respiratory or cardiac arrest, the nurse must have current certification in cardiopulmonary resuscitation (CPR) and the use of the automated external defibrillator (AED), which should be available to all school nurses. All 50 states have passed laws requiring that public gathering places have AEDs available, some requiring them in the schools (AED Brands, 2015). Other education in the area of emergency response would also be helpful to the school nurse, including pediatric advanced life support (PALS) or emergency nursing for pediatrics (ENPC) certification (Doyle, 2013).

Emergency Equipment in the School Nurse's Office. The school nurse needs a great deal of equipment to deal with emergencies in the school. These needs are based on the guidelines of the NASN (Doyle, 2013). The school office will need to have basic emergency items on hand (Box 42.2). Additional equipment may be obtained if a nurse is present in the school every day (see Box 42.2). Various sizes of these items are needed since children may be of different ages in the school. Another recommended item for the nurse's office includes an epinephrine auto injector kit (EpiPen auto injector) in case a child goes into anaphylactic shock after exposure to an allergen (Wahl et al., 2015). This should be locked in a medication cabinet

BOX 42.2 Emergency Items for Schools With and Without a School Nurse Present

Supplies for Schools WITHOUT a School Nurse Present

- Accessible keys to locked supplies
- Accessible list of phone resources
- Automated external defibrillator (AED) if school meets the AHA guidelines
- AED supplies stored with AED (razor, alcohol pads, dry towel, scissors, electrode pads)
- Biohazard waste bags
- Blunt scissors
- Clock with a second hand
- CPR trained staff on-site when students are on the premises
- Disposable blankets
- Emergency cards on all staff
- Emergency cards on all students
- Established relationship with local EMS personnel
- Eye protection (full peripheral glasses or goggles, face shield)
- Ice (not cold packs)
- Individual care plans/emergency plans for students with specialized needs
- First aid tapes
- Nonlatex gloves
- One-way resuscitation mask
- Cell phone or other two-way communication device
- Posters with CPR/abdominal or chest thrusts instructions
- Refrigerator or cooler
- Resealable plastic bags
- School-wide emergency operations/response plan
- Sharps container
- Soap and source of water/hand sanitizer for hand and wound cleansing
- Source of oral glucose (i.e., frosting gel, glucose tablets, juice box)
- Splints
- Staff names who have received basic first aid training
- Variety of bandages and dressings
- Water source/normal saline for wound/eye irrigation

Additional Supplies for Schools with a School Nurse Present

- C-spine immobilizers of different sizes
- Glucose monitoring device[a]

Continued

BOX 42.2 Emergency Items for Schools With and Without a School Nurse Present—cont'd

- Medications[b]
- Albuterol
- Epinephrine (auto injector preferred)
- Oxygen
- Nebulizer
- Penlight
- Self-inflating resuscitation device in two sizes (500 ml and 1 liter) with appropriate sized masks to meet needs of population being served
- Stethoscope
- Sphygmomanometer and cuffs in pediatric, adult regular, and adult large sizes
- Suction equipment (minimal source, does not have to be electric, i.e. bulb suction or v-vac type device)

AHA, American Heart Association; *CPR,* cardiopulmonary resuscitation; *EMS,* emergency medical services.
[a]Committee acknowledges challenges with maintenance and expense of test strips. Monitoring of machine must also be in compliance with CLIA (Clinical Laboratory Improvement Amendments).
[b]All medications including oxygen should be in accordance with state laws, pharmacy, and nurse practice acts.
From Tuck CM, Haynie K, Davis C: *Emergency preparedness and response in the school setting—the role of the school nurse (NASN Position Statement),* 2014. Available at https://www.nasn.org.

because of the needle in the kit. The school nurse will need to teach other school personnel how to use the EpiPen auto injector in an emergency (Wahl et al., 2015).

Gloves to meet standard precautions guidelines and a telephone available for calling emergency personnel and parents are essential. Next to the telephone, paper and pen should be available so that instructions from the emergency personnel can be written down (Doyle, 2013). The AED should be located in a central location in the school for easy access in an emergency. It should not be locked in the nurse's office but available for school staff to obtain in case the nurse is off site that day.

Giving Medication in School. The school nurse, as part of secondary prevention, may be responsible for giving medications to children during the school day (Hinkson, et al., 2017). These may include prescribed medications, over-the-counter medications that parents have asked the school's nurse to give (such as cold remedies), or vitamins (CDC, 2018b). The two most commonly administered medications in schools are those for attention-deficit/hyperactivity disorder (ADHD) and asthma (Maughan, McCarthy, et al., 2017). In all instances, the nurse should collaborate with school district administration to develop a series of medication administration policies and guidelines that allow children to receive care they need to perform well in school while following the laws and nurse practice act of the state. As part of the assessment of the health history and needs of children enrolled in the school, the school nurse should inquire of parents whether the child is taking any medications (Hinkson et al., 2017). A current, signed parental consent form, with primary care provider's approval and directions, must be provided before administering medication to any student (Hinkson et al., 2017). HIPAA requires that all of this information be kept confidential, but the consent form should include permission for the school nurse to discuss the medication and treatment plan with the prescribing provider to ensure the safety of the child (Caldart-Olson & Thronson, 2013). Nurses may also need to request permission to discuss the medication with the child's teachers so they are aware of potential side effects or adverse reactions and can alert the nurse immediately if there are any problems.

The prescribed drug must have the original prescription label on it and be in the original container to decrease the risk of errors and securely stored (Maughan, McCarthy, et al., 2017). Over-the-counter medications should also be stored securely in their original and labelled containers. Having a current drug reference in the nurse's office is important so that it can be consulted for information about any medication, or if the medication appears different, it can be matched to photographs in this reference. Nurses are expected by state law to know the mechanism of action, side effects, and implications prior to administering any medication. The child's pharmacist may also need to be contacted if there is any question about the medication appearance, dosage, or potential adverse reactions.

Delegation. Some states allow school nurses to delegate medication administration to unlicensed assistive personnel (UAP) or to a licensed practical nurse (Hinkson et al., 2017). There are several benefits and challenges associated with delegation in the school setting. On the positive side, delegation allows services to be provided in the absence of a school nurse, which is especially helpful if a nurse is covering multiple schools (Cagginello et al., 2014). Also, delegation allows children with more complex medical needs to attend school more safely, as UAPs can be trained to provide one-on-one care for some procedures. The challenge with delegation is ensuring the UAPs receive adequate training and regular supervision and monitoring of the UAP (Cagginello et al., 2014). Delegation can be done safely in the school environment provided the nurse has clear policies and procedures to follow, understands the "Five Rights of Delegation," understands the scope of practice and procedures allowed to be delegated under the state's nurse practice act, and has a trusting relationship with the UAP and school administrators (Cagginello et al., 2014).

Assessing and Screening Children at School. Children should receive screening for vision, hearing, height and weight, oral health, tuberculosis (TB), and scoliosis in the schools (Wold & Selekman, 2013). For each of these areas, the school nurse must keep a confidential record of all of the screening results for the children in the school according to HIPAA requirements. In addition, each state has different laws regarding screenings requirements, and the nurse will need to be aware of these laws.

Screening for TB in schoolchildren is required in several states prior to school entry (Wold & Selekman, 2013). It may be difficult to administer screening at school because the nurse cannot read the Mantoux test, or the TST test, until three days after

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Safety

Safety minimizes risk of harm to patients and providers through both system effectiveness and individual performance.

Important aspects of safety include:

- **Knowledge:** Describe factors that create a culture of safety (such as open communication strategies and organizational error reporting systems).
- **Skills:** Communicate observations or concerns related to hazards and errors to patients, families, and the health care team.
- **Attitudes:** Value own role in preventing errors.

Safety Question

Imagine you are working as a nurse in an elementary school. Due to budget cuts, you are only at the school two days a week. Juan, a student in the third grade, is newly diagnosed with asthma and will have an inhaler at school for emergencies. Your state allows nurses to delegate the administration of inhaler medications to unlicensed personnel. You decide to delegate the administration of Juan's emergency inhaler to his classroom teacher, Mr. Smith. What steps would you take to ensure you safely delegated this medication?

Answer

First, you would need to establish open communication between Mr. Smith and yourself. After providing the initial medication training, you should maintain open communication by checking in with Mr. Smith on a regular basis to assess his knowledge and comfort level in administering Juan's inhaler. Second, in the event that Mr. Smith gives Juan a dose from the inhaler, have a system in place to document when and why the medication was given. Emphasize the importance of such documentation to avoid medication errors/overdose and to track Juan's health condition and response to treatment. Periodically review the records to ensure that everything was documented correctly and that the medication was given for appropriate reasons. Last, in the event of a medication error, report to the proper authorities, evaluate the circumstances that led to the error, and determine what can be done differently to prevent future errors. In some circumstances, delegation may need to be withdrawn if it is determined that Mr. Smith is not capable of properly and safely administering Juan's medication.

it is administered. Often nurses are part time and may not be at the school on the day the child's test needs to be read. In some states, school nurses are required to participate in a training program to read the tests. It may be more efficient to have children screened for TB at their pediatrician's office or the local health department or prior to admission to the school (Bobo et al., 2013). If the school nurse is trained to read the test, he or she sends the results to the health clinic for follow-up. If the site is positive, it is possible the child has been exposed to TB and needs further health screening, including a chest x-ray, and treatment. A determination will need to be made about whether the child has active TB and could have spread it to other children or staff at school. In that case, the health department must be notified so that screening and prophylactic medications can be administered to all exposed individuals (Bobo et al., 2013).

The school nurse can also screen children and adolescents for hypertension, or high blood pressure. Children who develop high blood pressure are more likely to have this condition in adulthood (Cassidy-Bushrow et al., 2015). Identifying and treating hypertension early can prevent many serious, long-term health conditions. One study of more than 300 adolescents found that 14.2 percent had elevated blood pressures (Cassidy-Bushrow et al., 2015). These findings indicate the importance of the school nurse in providing effective prevention strategies related to screening, follow-up, and treatment.

Physical examinations prior to participation in a school sport are required by all 50 states (Johnson et al., 2018). While students may also obtain these physicals from their primary provider, an urgent care clinic, or a community health center, some children may not have access to a regular physician or other primary health care provider because they are uninsured or the agency is not open during hours that parents are off from work. School nurses can assist by arranging for sports physicals at school, conducting part of the screenings within their scope of practice and monitoring or assisting with the portions of these examinations being done by the school's physician or nurse practitioner. The school nurse's presence during these screenings can facilitate health education, case finding, and referrals to community resources or specialists for health problems (Johnson et al., 2018). The AAP (2016) recommends that children have regular health and developmental screenings in the school setting. The school nurse can collaborate with other school professionals to provide or facilitate such screenings as obtaining information on children's language skills, motor abilities, social skills, and behavioral health. As the children grow up, their level of physical growth can be noted as well as their sexual maturation. Dental screenings in school can also be beneficial to children to determine whether they have good oral health (Griffin et al., 2016). School nurses may arrange for dentists to provide group oral health screenings in the schools. In some states, school nurses may be able to conduct these screenings and refer children to a dentist for follow-up of suspected problems with oral health.

Screening Children for Pediculosis (Lice). School nurses are frequently called upon to screen children in their schools for pediculosis or lice infestation. Many myths abound related to risks of transmission of head lice, leading to unnecessary panic and exclusion of children from school, despite the fact that pediculosis is frequently misdiagnosed even by experienced nurses and primary care providers (Pontius, 2014). Lice do not spread disease, even though they may cause irritating symptoms, such as itching, sleep disturbance (due to itching), and sores from scratching (Smith et al., 2016). Children determined to have lice or lice eggs in their hair miss an average of four days per school year in schools with "no-nit" (no lice eggs) policies. Besides the loss to children of academic opportunity, such absenteeism costs schools hundreds of millions of dollars in annual funding and parents thousands of dollars in lost wages and treatment expenses per occurrence (Pontius, 2014).

Prevalence of lice is impossible to establish, as it is not a reportable disease and is so frequently misdiagnosed (Pontius, 2014). NASN, AAP, the Harvard School of Public Health, and the CDC recommend against no-nit policies because it is impossible for nits to be transmitted from one person to another. Nits firmly adhere to the hair shaft when they are laid by the louse, making them unlikely to come off without significant effort to remove them. Lice require human hosts to live, so if they fall off and are

not deposited on a person's head within 24 hours, they will die. Nits require the warmth of the human body to hatch. The idea that lice are a sign of poverty and poor hygiene is also a myth. Lice are found in all socioeconomic groups and are just as likely to be seen in clean hair as unwashed.

Due to the inaccuracy of results, the lack of impact on the incidence of head lice in a school, and the significant loss of educational time, the NASN, AAP, and CDC recommend against routine screening for head lice or after a case has been identified (Pontius, 2014). There is significant risk of violation of privacy rights when conducting a classroom screening. The stigma and shame associated with even false identification of head lice and subsequent exclusion from school can be emotionally and socially devastating for students and caregivers (Smith et al., 2016). Frequent or incorrect use of pediculosis treatments, especially in misdiagnosed children, can have side effects from localized irritation of the scalp, eyes, and skin to allergic reactions and neurological repercussions in susceptible persons. School nurses have a responsibility to educate parents, teachers, and school administrators about the lack of effectiveness of mass school screenings for lice and to encourage and practice evidence-based approaches to prevent or treat any cases that are found.

In the case of a suspected case of lice, the school nurse should privately screen the child and be absolutely sure that he or she is seeing live lice before recommending treatment (Pontius, 2014). When lice are seen, they have likely been on the hair for as long as a month, so to insist on immediate exclusion from the classroom will not effectively prevent transmission. School nurses should teach children, parents, and teachers how to properly prevent lice and treat cases of infestation. The nurse can do this by teaching children not to share combs and hats, and teaching parents to follow package directions exactly when treating their child with pediculocidal medications (Pontius, 2014). Parents should also remove as many nits as possible from the head with a fine-toothed comb and repeat this every few days to continue removal of any remaining nits and live lice that hatch out. Family members and other close contacts should be screened, but treatment should only be provided in the case of a definitive finding of live lice. It may be advisable to wash any bed linens and clothing worn in the past day, but spraying the house with insecticides and whole house cleaning are not currently recommended. If live lice are seen a week or more after treatment with an over-the counter product, a repeat treatment may be advisable. If live lice are still found after the second treatment, children should be referred to a primary care provider for possible prescription treatments (Pontius, 2014).

Identification of Child Abuse or Neglect. Child abuse and neglect are a serious public health concern in this country. In 2014, more than six million children were reported to authorities as suspected victims of maltreatment, with nearly half a million of these turning out to be substantiated cases and nearly 1500 children killed as a result of their abuse (Jordan, et al., 2017). Victims of child abuse have a higher risk for health issues in adulthood, such as obesity, hypertension, and mental health problems.

Child abuse and neglect often go unrecognized and are seriously underreported. Research has shown that failure to report is often due to a lack of confidence about suspicions of abuse, lack of knowledge about the effects of child maltreatment, fear of repercussions for the child, family, or reporter, and reluctance to engage with law enforcement or social services (Jordan et al., 2017). School nurses are mandated by state laws to report suspected cases of child abuse or neglect, so they may need education and training to properly recognize signs of child maltreatment and report them to the proper authorities in a timely manner. Laws for reporting differ from state to state, as do school system policies on assessment of children for injuries. School nurses must be familiar with the particular requirements for reporting in their state and school district.

When the nurse identifies a child who may be abused, or receives information from a teacher or other staff member that leads to the belief that a child has been abused, the nurse must contact the appropriate legal authorities as well as the school's principal. The nurse should be careful about asking the child too many questions or suggesting possible answers for the signs, symptoms, and complaints the child is having. A confidential file with objective assessment information should be made about the incident in case the nurse is called to testify. The nurse should contact government authorities directly and in a timely manner, usually the state or county child protection department, who will look into the suspected case (Jordan et al., 2017). In all cases, the child must be protected from harm, and those who have no right to know that child abuse or neglect is suspected should not be given any information.

Communicating With Health Care Providers. The school nurse often makes an assessment of a child that requires referral to the child's family physician or other health care provider. The findings from these assessments must be communicated accurately to the child's parent and the provider (Caldart-Olson & Thronson, 2013). The nurse must be able to disseminate the information quickly and accurately to the child's parents. Again, HIPAA privacy rules must be followed.

HOW TO Develop Good Relationships With Families

School nurses need to have good relationships with families. The school nurse can make this possible by doing the following:

- Being visible at school events.
- Sending home invitations for parents and guardians to call the nurse at any time.
- Inviting parents to visit the school health office.
- Calling parents or guardians to ask about ill children.
- Offering to help families cope with children who have long-term illnesses.
- Acting as a referral source for families with health care needs.
- Including parents and members of the community in health education activities.

One way to do this is to write a detailed report about the findings. This information can be given to the child to take home to the parents, but there may also be issues related to parental literacy (Pontius, 2013). If the concern is not an

emergency, the best way to communicate with parents may be to speak to them directly by phone or meet with them if they come to pick up their child at the end of the day. If the nurse expresses concern for the child's well-being, most parents will appreciate this personal interaction (Cornell & Selekman, 2013). Explain to the parents why the child needs to see the physician or nurse practitioner and that the child will be bringing the information home that day so they can ask the child for it at the end of the day. Verbal explanations will help in the case of low health literacy, as well as give the parent the opportunity to ask questions. The nurse may also pick up on the need for assistance during the conversation and can refer the family to community resources if they do not have a primary care provider.

Efforts to Prevent Suicide and Other Mental Health Problems. Among teenagers, more than 17 percent have considered suicide and more than 8 percent have actually attempted to take their own lives (Substance Abuse and Mental Health Services Administration [SAMHSA], 2017). Suicide is caused by complex interactions of multiple factors, such as social and environmental problems, gender identity confusion, academic problems, mental illness, bullying, and exposure to violence (Nolta, 2014). Protective factors for suicide prevention include strong family relationships, supportive religious connections, and interest in hobbies and other activities.

Suicide prevention must be addressed by school nurses. Government and professional organizations provide recommendations for reducing the incidence of suicide in teenagers. A suicide prevention program developed in one school district (see later discussion) contains ideas for the school nurse to use. Nurses can lead educational programs within the schools to emphasize coping strategies and stress management techniques for children and adolescents who have problems, and to teach about the risk factors. The school nurse can teach faculty members to look for warning signs that a student may be considering suicide. These signs include children talking about wanting to die, feelings of isolation and hopelessness, feeling anxious or depressed, giving away possessions and saying good-bye to loved ones, and demonstrating mood swings and extreme anger (National Institute of Mental Health [NIMH], 2017). The school nurse can also help organize and train peer counselors to help teenagers cope with school stresses.

Students who are expressing feelings associated with suicide risk or threaten suicide at school must be taken seriously. They should be asked directly if they are contemplating suicide, referred to mental health services within the school, encouraged to talk about their feelings, denied access to any methods of self-harm, and monitored for increasing symptoms and other risk factors (NIMH, 2017). Many states require that schools notify parents if children express intent to harm themselves. Students threatening to commit suicide should be immediately removed from any situation that is contributing to their despair. While the parents are being called, the nurse and available mental health professionals in the school should monitor and assess the student for having already made their attempt using medications or other method and if so, call for immediate emergency first responders.

In the unfortunate instance that a student commits suicide, the school nurse is called upon to help the school population, both students and teachers, cope with the death. Grief counseling should be set up and coordinated by the school nurse, usually in collaboration with guidance counselors and school administrators. In addition, further assessments can be made regarding the suicide potential among the deceased teenager's friends, since suicide clusters have been noted.

Other mental health problems may affect students. Adolescents may have early signs of mental or emotional problems such as behavioral problems in class or severe class or test anxiety. Families may be in crisis, which can translate into problems for their children. Sometimes, children with mental health issues come to the school nurse with somatic complaints and nothing can be found on assessment (Bohnenkamp et al., 2015). The nurse should be alert to the possibility that the child is experiencing emotional problems, hunger, or family problems in such cases and investigate further to find the source of the complaints.

Children who are homeless have special problems. Because these children do not have a stable address, they may have moved frequently from school to school. School nurses may need to provide assistance for obtaining medical records, make sure children are eating at school in case they are not getting meals away from school, and make referrals to community resources for financial and other assistance. Children whose parents are addicted to drugs or alcohol can also benefit from support from the school nurse, such as referrals to mental health counselors. The lack of a stable environment may increase chances that children will develop a mental or emotional problem (Bohnenkamp et al., 2015). The school nurse should be an advocate for these children and their families.

Violence at School. Results of the 2015 National Youth Risk Behavior Survey demonstrated that 6 percent of students were threatened with a weapon at school, 6 percent stayed home from school due to fears of violence, and 23 percent were in a physical fight at school (Flynn et al., 2018, p. 263). Hundreds of students reported carrying a weapon onto school grounds, and nearly two-thirds of schools reported the occurrence of at least one violent crime during the previous school year. In the past several years, there has been an increase in school shootings by students or other attackers against other students and teachers.

Bullying is at the center of attention among child and adolescent advocates. In 2015, about 20 percent of U.S. high school students experienced bullying while on school property and 16 percent were bullied online ("cyberbullying") (Wheeler et al., 2018). Bullying is defined as repetitious, unwanted, aggressive behavior intended to cause harm to another. Students with disabilities, academic problems, and speech impairments, as well as those who are lesbian, gay, bisexual, transgender, or questioning (LGBTQ) are most frequently targeted. Physical injury, social and emotional distress, suicide attempts, and even death can result from bullying. Affected students may come to the school nurse complaining of psychosomatic illnesses, such as headaches and stomachaches, due to bullying (Wheeler et al., 2018). The school nurse needs to be knowledgeable about

bullying, take students' concerns seriously, and work to protect them from aggression. School nurses should provide leadership to implement bullying prevention strategies in their schools and communities, such as increased supervision and anti-bullying policies. In an effort to reduce the prevalence of bullying, 49 states now have anti-bullying laws (USDHHS, 2017).

The school nurse's primary goal is to prevent violence from occurring and prioritize the safety of everyone on the school's campus (Flynn et al., 2018). Interventions that the nurse can implement to prevent violence include:

- Facilitate student connectedness to the school community.
- Engage parents in school activities that promote connections with their children, and foster communication, problem solving, limit setting, and monitoring of children.
- Support activities and strategies to help establish a climate that promotes and practices respect for others and for the property of others.
- Support policies of zero tolerance for weapons on school property, including school buses.
- Advocate for adult monitoring in the hallways between classes and at the beginning and end of the school day, and the assignment of staff to monitor the playground, cafeteria, and school entrances before and after school.
- Serve as positive role models, developing mentoring programs for at-risk youth and families.
- Educate students and their parents about gun safety (Flynn et al., 2018; Wheeler et al., 2018).

If violence occurs, the school nurse should do the following:

- Coordinate emergency response until rescue teams arrive;
- Provide nursing care for injured students;
- Apply crisis intervention strategies that help de-escalate a crisis situation and help resolve the conflict;
- Identify and refer those students who require more in-depth counseling services; and
- Participate in crisis intervention teams (Doyle, 2013).

By helping identify the student who might be considering school violence or by teaching students and teachers about these warning signs in students, the school nurse may be able to help prevent violent actions through education and follow-up of children who need help. The U.S. federal government has many agencies and resources that can help school nurses develop programs in their schools (U.S. Department of Education et al., 2013).

Tertiary Prevention in Schools

Using the nursing process, the school nurse gives nursing care related to tertiary prevention when working with children who have long-term or chronic illnesses or special needs. The goal of tertiary prevention is to assist children to return to their highest level of function possible after injury or illness, as well as to prevent complications (Wold & Selekman, 2013). As prevalence of chronic conditions such as asthma and diabetes increases among children, today's school nurse faces a school population that is more medically diverse than ever seen in the past (Shannon & Minchella, 2016; Toothaker & Cook, 2018; Wolfe, 2013). The school nurse should be part of the team that develops an individual education plan (IEP for students with long-term health needs that may affect their learning abilities and needs (Box 42.3).

BOX 42.3 States That Require School Nurses to Participate in Individualized Education Plans for Students

- Alabama
- Arizona
- Colorado
- Delaware
- District of Columbia
- Hawaii
- Illinois
- Indiana
- Iowa
- Louisiana
- Maryland
- Massachusetts
- Minnesota
- Mississippi
- Nevada
- New Jersey
- New Mexico
- New York
- North Carolina
- Oklahoma
- Rhode Island
- South Carolina
- Tennessee
- Texas
- Utah
- Vermont
- Virginia
- Washington
- West Virginia
- Wisconsin

Compiled from Centers for Disease Control and Prevention: *State level school health policies and practices: a state-by-state summary from the School Health Policies and Programs Study 2006,* Atlanta, 2006, CDC, USDHHS.

As discussed earlier, school nurses must have information about children's medications that need to be administered during school hours. They also need to know if children need any type of procedure, such as tracheostomy suctioning or intermittent catheterization, or therapy during the school day, such as physical or occupational therapy (Shannon & Minchella, 2016; Toothaker & Cook, 2018). If the child has a hearing or vision problem, the nurse may need to ask the teacher to seat the child in the best place in the classroom so the child can see or hear better. If a child is in a wheelchair or uses crutches, federal regulations may require that the school building itself accommodates the child's ability to get around the school and use the restrooms. It is the responsibility of the nurse to tell the school's administrators about any needs such as these.

Children With Allergies. Food and insect allergies that result in anaphylaxis are being diagnosed more frequently (Pistiner & Mattey, 2017). Anaphylaxis is a severe allergic reaction that occurs quickly and can be life-threatening. In 2017, 10,704 high school students reported having to avoid foods due to the risk of allergy (CDC, 2017a). Milk, eggs, fish, shellfish, wheat, soy, peanuts, and tree nuts account for 90 percent of serious allergic reactions in the United States (CDC, 2018d). Insect allergies may be to stinging insects, such as bees and wasps; household pests, such as cockroaches and dust mites; or biting insects, such as bedbugs and some flies (Asthma and Allergy Foundation of America, 2015).

The school nurse must take a leadership role in coordinating care for these students. The AAP has developed an allergy and anaphylaxis care plan that provides guidance for planning for and responding to allergic reactions in the school (Pistiner & Mattey, 2017). The CDC (2018c) and NASN (2014) provide toolkits, checklists, and guidelines that school nurses can utilize in planning for care of children with allergies. The school nurse must develop a plan for preventing exposure to a known

allergen and responding to an allergy emergency, collaborating with the student, the student's parents, and school personnel to determine the best plan of action (Pistiner & Mattey, 2017). Some students may have to eat at a separate table in the cafeteria that is designated allergen-free. Food and snacks in these children's classrooms may have to be restricted to items without the allergenic substance. This can result in communication challenges from parents whose children do not have allergies. The school nurse may need to help these parents understand the risks and rationale for these restrictions (Asthma and Allergy Foundation of America, 2015). Most states have laws that allow students to carry emergency medication and, if developmentally appropriate, self-administer as needed (Pistiner & Mattey, 2017). School nurses should assess children's understanding of criteria for self-administering emergency medications, ability to correctly self-administer, safe handling of needles, and when to seek help. Some states allow trained unlicensed assistive personnel to administer the emergency medication if the student is unable to do so and a nurse is not available. The school nurse must provide annual training to school personnel who are involved with the student or possibly responding to an emergency reaction (Pistiner & Mattey, 2017).

Children With Asthma. Asthma is the leading cause of children being absent from school because of a chronic illness (Cicutto et al., 2017). Children may be hospitalized with an asthma attack or they may have just returned home from the hospital. Time missed from class, either for treatment or because of absenteeism, can interfere with a child's educational progress. Asthma can also be caused by allergic triggers that affect children in the school. Possible culprits are chalk dust from the blackboards, molds or mildew in the school, or dander from pets that live in some classrooms (CDC, 2018c).

There may also be concerns about the quality of the air in the school building because many doors are shut. Indoor air pollution within schools can occur as a result of materials used in art class, woodworking, or cooking, perfumes and other scented body products, air fresheners, exhaust fumes from buses and delivery vehicles that idle near open doors or ventilation systems, outdated ventilation systems and those lacking proper maintenance, radon, mold, and secondhand smoke (U.S. Environmental Protection Agency [EPA], n.d.). The school nurse should keep track of the indoor air quality (IAQ) of the school and student complaints potentially related to IAQ so that school administrators have data about what can affect the children. Surveillance of the numbers of asthma and allergy exacerbations will help the school nurse recognize potential problems. Fig. 42.3 contains the questions developed by the EPA that the school nurse should answer regarding the air quality of the school.

The nurse uses tertiary prevention when helping children who have asthma. This includes administering, or helping them use, their inhalers or other asthma rescue medications (Cicutto et al., 2017). It also includes instructing administrators, teachers, children, and parents about asthma and ways to reduce allergens in the classroom (Asthma and Allergy Foundation of America, 2015). The nurse should determine the types of cleaning solutions used in schools. Many school systems are going with non-toxic cleaners, but many still use chemicals, such as bleach-based solutions, that can be dangerous to children if not properly stored and used (EPA, n.d.). School nurses should advocate for a transition to safer cleaning solutions and assess safe storage as part of regular school IAQ inspections (CDC, 2018e).

Children With Diabetes Mellitus. Diabetes is one of the most prevalent chronic diseases in children and adolescents, its long-term impact and the cost of treatment make it vitally important to be addressed by school nurses (Miller et al., 2016). About 132,000 people below the age of 18 years were diagnosed with diabetes as of 2015 (National Center for Chronic Disease Prevention and Health Promotion, 2017). While most of these children have type 1 diabetes, in the last couple of decades, type 2 diabetes (formerly known as adult-onset diabetes) has been reported among U.S. children and adolescents with increasing frequency (Miller et al., 2016). Case management and coordination of care are critical roles for the school nurse in caring for diabetic students (Siminerio, 2015). The school nurse must work with students' primary care provider, parents, and school personnel to establish a plan of care for managing diabetes. This includes methods of monitoring blood glucose levels and administering insulin or other medications during the school day, as well as how to respond in the event of hyperglycemic or hypoglycemic reactions (Siminerio, 2015). Emergency medications, such as glucagon, should be readily available, and staff involved with the student should be trained to administer them in case the nurse is not present in the school during an emergency. Special nutritional needs also need to be discussed with parents, teachers, and cafeteria staff. There may be significant challenges getting the child's nutritional restrictions met due to the institutional nature of most school food services and lack of education of staff about nutrition-related health concerns. The family, school nurse, and other school personnel may benefit from consultation and/or training by a diabetes educator or registered dietitian/nutritionist (Siminerio, 2015).

Children With Autism or Attention-Deficit/Hyperactivity Disorder. "Autism, or autism spectrum disorder (ASD), refers to a broad range of conditions characterized by challenges with social skills, repetitive behaviors, speech and nonverbal communication" (Autism Speaks, 2018, para. 1). Autism may also be associated with medical problems such as gastrointestinal disorders and seizures. Because most children are expected to attend some school regardless of their illness, children with autism are legally entitled to attend public schools (DOE-OCR, 2010). Children with autism are more likely to experience fragmented services leading to unmet health care needs, as well as difficulty with school accommodations for their medical, sensory, social, and educational challenges (Russell & McCloskey, 2016). Parents caring for children with special needs such as autism report a sense of guilt, emotional strain, financial hardship, social isolation, and marital difficulties. They expressed dissatisfaction and frustration with providers and schools for not collaborating with the family to meet their child's needs (Russell & McCloskey,

Health Officer/School Nurse

This checklist discusses three major topic areas:
Student Health Records Maintenance
Public Health and Personal Hygiene Education
Health Officer's Office

Instructions:
1. Read the IAQ *Backgrounder.*
2. Read each item on this Checklist.
3. Check the diamond(s) as appropriate or check the circle if you need additional help with an activity.
4. Return this checklist to the IAQ Coordinator and keep a copy for future reference.

Name: _____

Room or Area: _____

School: _____

Date Completed: _____

Signature: _____

MAINTAIN STUDENT HEALTH RECORDS

There is evidence to suggest that children, pregnant women, and senior citizens are more likely to develop health problems from poor air quality than most adults. Indoor Air Quality (IAQ) problems are most likely to affect those with preexisting health conditions and those who are exposed to tobacco smoke. Student health records should include information about known allergies and other medically documented conditions, such as asthma, as well as any reported sensitivity to chemicals. Privacy considerations may limit the student health information that can be disclosed, but to the extent possible, information about students' potential sensitivity to IAQ problems should be provided to teachers. This is especially true for classes involving potential irritants (e.g., gaseous or particle emissions from art, science, industrial/vocational education sources). Health records and records of health-related complaints by students and staff are useful for evaluating potential IAQ-related complaints.

Include information about sensitivities to IAQ problems in student health records
- Allergies, including reports of chemical sensitivities.
- Asthma.

◇ Completed health records exist for each student.
◇ Health records are being updated.
○ Need help obtaining information about student allergies and other health factors.

Track health-related complaints by students and staff
- Keep a log of health complaints that notes the symptoms, location and time of symptom onset, and exposure to pollutant sources.
- Watch for trends in health complaints, especially in timing or location of complaints.

◇ Have a comprehensive health complaint logging system.
◇ Developing a comprehensive health complaint logging system.
○ Need help developing a comprehensive health complaint logging system.

Recognize indicators that health problems may be IAQ
- Complaints are associated with particular times of the day or week.
- Other occupants in the same area experience similar problems.
- The problem abates or ceases, either immediately or gradually, when an occupant leaves the building and recurs when the occupant returns.
- The school has recently been renovated or refurnished.
- The occupant has recently started working with new or different materials or equipment.
- New cleaning or pesticide products or practices have been introduced into the school.
- Smoking is allowed in the school.
- A new warm-blooded animal has been introduced into the classroom.

◇ Understand indicators of IAQ-related problems.
○ Need help understanding indicators of IAQ-related problems.

HEALTH AND HYGIENE EDUCATION

Schools are unique buildings from a public health perspective because they accommodate more people within a smaller area than most buildings. This proximity increases the potential for airborne contaminants (germs, odors, and constituents of personal products) to pass between students. Raising awareness about the effects of personal habits on the well-being of others can help reduce IAQ-related problems.

Obtain *Indoor Air Quality: An Introduction for Health Professionals*
- Contact IAQ INFO, 800-438-4318.

◇ Already have this EPA guidance document.
◇ Guide is on order.
○ Cannot obtain this guide.

Inform students and staff about the importance of good hygiene in preventing the spread of airborne contagious diseases
- Provide written materials to students (local public health agencies may have information suitable for older students).
- Provide individual instruction/counseling where necessary.

◇ Written materials and counseling available.
◇ Compiling information for counseling and distribution.
○ Need help compiling information or implementing counseling program.

Provide information about IAQ and health
- Help teachers develop activities that reduce exposure to indoor air pollutants for students with IAQ sensitivities, such as those with asthma or allergies (contact the American Lung Association [ALA], the National Association of School Nurses [NASN], or the Asthma and Allergy Foundation of America [AAFA]). Contact information is also available in the IAQ Coordinator's Guide.
- Collaborate with parent-teacher groups to offer family IAQ education programs.
- Conduct a workshop for teachers on health issues that covers IAQ.

◇ Have provided information to parents and staff.
◇ Developing information and education programs for parents and staff.
○ Need help developing information and education program for parents and staff.

Establish an information and counseling program regarding smoking
- Provide free literature on smoking and secondhand smoke.
- Sponsor a quit-smoking program and similar counseling programs in collaboration with the ALA.

◇ "No Smoking" information and programs in place.
◇ "No Smoking" information and programs in planning.
○ Need help with a "No Smoking" program.

HEALTH OFFICER'S OFFICE

Since the health office may be frequented by sick students and staff, it is important to take steps that can help prevent transmission of airborne diseases to uninfected students and staff (see your IAQ Coordinator for help with the following activities).

Ensure that the ventilation system is properly operating
- Ventilation system is operated when the area(s) is occupied.
- Provide an adequate amount of outdoor air to the area(s). There should be at least 15 cubic feet of outdoor air supplied per occupant.
- Air filters are clean and properly installed.
- Air removed from the area(s) does not circulate through the ventilation system into other occupied areas.

◇ Ventilation system operating adequately.
○ Need help with ventilation-related activities.

☐ **No Problems to Report.** I have completed all the activities on this checklist, and I do not need help in any areas.

Fig. 42.3 Environmental Protection Agency indoor air quality checklist. (From U.S. Environmental Protection Agency: *School and child care-based asthma education programs,* 2010. Available from http://www.epa.gov.)

2016). Because many children with autism have communication problems, the school nurse can advocate for the child and collaborate with the parents to learn the most effective ways to determine and meet the child's needs. The nurse should participate on IEP teams to plan care and accommodations for children with autism. The nurse should educate teachers and other school personnel to be sure they understand how to appropriately interact with the child and what, if any, limitations autism may place on his or her participation in class or physical education activities (Rutkowski & Brimer, 2014). The nurse can give the child prescribed medications for mood or prevention of seizures. The nurse may recommend the use of sign language, picture boards, or other types of communication devices that are used by the child. In addition, the nurse can teach the parents about autism. The nurse can also help parents work with others in the health care system, such as speech-language therapists and developmental specialists, so that the child can have a positive learning experience at school (Rutkowski & Brimer, 2014).

Children with attention-deficit/hyperactivity disorder (ADHD) also attend school. In 2016, there were an estimated 6.1 million children ages 2 to 17 diagnosed with ADHD in the United States (CDC, 2018). Of these, two-thirds had another mental health or behavioral problem. Children with ADHD often have trouble sitting still, may be forgetful, have difficulty focusing on tasks or instructions, and may exhibit poor impulse control. Causes are unknown, though children exposed to environmental toxins, such as lead, and those with brain injury, prematurity, and low birth weight are more likely to be diagnosed with ADHD. School nurses may administer medications at school and may need to monitor the child for adverse reactions (Heuer & Williams, 2016). Due to their difficulty focusing, children with ADHD may need reminders to take their medications. Some medications can decrease appetite, so the school nurse can partner with parents and teachers to ensure that children do not experience nutritional deficits. Because of the behaviors common in children with ADHD, school personnel may become frustrated with them. The school nurse must advocate for the child, work with him or her to facilitate behavioral and time management skills, and encourage good communication with parents, providers, and school personnel (Heuer & Williams, 2016). Referral to mental health providers within or outside the school may be needed if the child's behaviors interfere with their ability to function and learn.

Children With Special Needs in the Schools. As discussed earlier in this chapter, children who need urinary catheterization, dressing changes, peripheral or central line intravenous catheter maintenance, tracheotomy suctioning, gastrostomy or other tube feedings, or intravenous medication also attend schools (Toothaker & Cook, 2018). The school nurse may supervise a health aide or personal care nurse who is assigned to the child to assist with complex nursing needs. In all these cases, the school nurse provides tertiary care to maintain the child's health. The nurse has the skills needed to assess the child's well-being. In addition, the nurse may have to teach another person in the school how to care for the child in case the nurse is not in the building when the child needs help (Cagginello et al., 2014). It is the responsibility of the school nurse to keep up to date with the latest health care information through in-service and continuing education programs, as well as regularly reading journals in the fields of pediatrics and school nursing.

An example of how a school nurse can help an injured child return to school after long absences follows. Enrique, a sixth-grade boy who had received serious facial burns, is preparing to return to school. Enrique is afraid of how the children will respond to the pressure mask he wears to minimize future scarring. The nurse has a meeting with Enrique's mother and the school's principal and also contacts nurses from the hospital's burn unit to determine a plan for Enrique's reentry to school. According to their plan, the school nurse first teaches a lesson to the boy's classmates about burns and their treatment. After the lesson, Enrique joined the class with the nurse and showed his classmates his face with and without his pressure mask. With the parents' and Enrique's permission, both Enrique and the nurse answered the children's questions. In addition to the education provided, changes were made in Enrique's schedule so he could be out of the sun during the school day and physical education class. The nurse found that Enrique's burns were soon forgotten and he was accepted by his friends.

Children can contract human immunodeficiency virus (HIV) from their mother before or during birth. In 2014, there were about 10,000 children diagnosed with HIV in the United States (CDC, as cited in Rasberry et al., 2017). Children with HIV or acquired immunodeficiency syndrome (AIDS) attend school and may require care from the school nurse to manage their illness and prevent complications. Because of privacy and confidentiality laws, the school nurse may not even know that the child has this disease. In some cases, the nurse may be directly notified of the child's HIV status either by the parents or physician or may suspect the diagnosis due to HIV medications being administered during the school day (Selekman, et al., 2013). In all cases, the nurse must maintain confidentiality. This means that information cannot be released to anyone, including teachers, other health professionals, other students, or staff.

School nurses should ensure that universal precautions are practiced by all personnel handling blood or body fluids of anyone at school. Most school districts are required to provide employees with bloodborne pathogens training and protective equipment under Occupational Safety and Health Administration (OSHA) (2000) regulations. These precautions can protect employees from exposure to HIV, as well as other bloodborne diseases such as hepatitis B and C. As part of regular health education in the school, the school nurse can provide education about HIV/AIDS prevention and risks to the children, school employees, and community (Rasberry et al., 2017). The school nurse should also be part of the school health advisory committee to develop an HIV/AIDS health curriculum that teaches about HIV/AIDS prevention and transmission so that children know how to protect themselves and are not afraid to go to school with children who have the disease. Nearly one-third of children report sexual activity by the time they are in high school, and more than 40 percent report not using a condom

during intercourse (Rasberry et al., 2017). School nurses should refer children who report sexual activity or sexual abuse to testing for sexually transmitted diseases, including HIV/AIDS. This requires knowing about available community resources for free or confidential testing and transportation if students do not wish to involve their parents. The nurse may be required to report to the parents and legal authorities if sexual abuse is suspected. The school nurse can encourage and assist the child in disclosing sexual activity to the parents if required by state law.

Children With DNAR Orders. As part of tertiary prevention, the school nurse cares for children with highly complex conditions and terminal diseases who attend school. The numbers of children receiving only palliative care is rising (Begley et al., 2018). These children benefit from participation in school activities, socialization with their peers, and following a daily routine. The IDEIA, as discussed earlier in this chapter, requires that children be allowed to attend school in the "least restrictive environment" (DOE-OCR, 2010). Therefore children with terminal illnesses may have **do-not-attempt-resuscitation orders** (DNAR orders) at school, and some may die at school, though this is not common (Begley et al., 2018). DNAR orders are signed by the parents and the physician according to their state's law. In some states, the courts have found that the school nurse and other school staff are bound to obey the DNAR order; however, state and local laws and school district policies vary, so school nurses should determine what is required or allowed, as well as consult legal counsel for the school district to verify support for the family's decisions.

The AAP's committees on school health and bioethics reaffirmed a set of guidelines to help school health providers and the schools decide what to do when a child with a DNAR order attends the school (AAP, 2010/2016). A formal request to the school and the school board from the parents and physician is a must regarding the written DNAR order. The school nurse should be involved in discussions regarding when to use the DNAR order. The decision not to do anything for a dying child, and how to function if the child were to suddenly face death, can be emotionally and ethically difficult. As an advocate for the child and family, school nurses should coordinate ongoing communication with parents, providers, school staff, and administrators well in advance of such an event (Begley et al., 2018).

When a child dies in school, the nurse is responsible for helping the children who witnessed the death. The nurse becomes a grief counselor and helps the children and teachers cope with the death. Further education about death and dying given by the school nurse would also help the school community cope with death in the schools (Begley et al., 2018).

Homebound Children. Even though the laws regarding disabled persons state that all children should go to school, some children cannot. Instead, they may be taught in the home or in another institutional setting such as the hospital. In these situations, the school nurse should be a liaison between the child's teacher, physician, school administrators, parents, and any nurses and other health care providers caring for the child in the home regarding the child's needs (Shannon & Minchella, 2016). The nurse participates with the child's IEP team so that it is appropriate for the child and does not remove necessary learning from the plan. The child should be allowed to go to school when he or she is able, at which point the school nurse coordinates the child's care to facilitate a smooth transition between the two settings and ensure that health care needs are met.

Pregnant Teenagers and Teenage Mothers at School. In 2015, nearly 230,000 babies were born to teenage girls between the ages of 15 and 19 (CDC, 2017b). While this is a decline of 8 percent since 2014, the United States still has a higher rate than other industrialized countries. Many teenage girls who are pregnant attend school and are protected from discrimination by Title IX of the 1972 Education Amendment Act (Disney et al., 2015). Therefore the school nurse may provide ongoing care to the mother as well as coordination of care outside the school system, including visits to the physician or nurse practitioner and assistance with setting up home school until the teen is released from medical restrictions following birth (Disney et al., 2015). Some schools provide on-site child care to encourage teen mothers to return to finish their schooling. Although this may appear to be primary prevention, it is tertiary prevention because adolescent pregnancies are considered to be high risk. Teen fathers may also require advocacy from the school nurse if they are involved with their child's care. Teen pregnancy is discussed in more detail in Chapters 28 and 35.

CONTROVERSIES IN SCHOOL NURSING

School nursing has evolved into a complex health care role, and some areas of the field still cause controversy, such as providing education on family planning and providing birth control to students in the schools where it is allowed. Although differences in opinion exist relating to sex education, reproductive services, and screening for sexually transmitted diseases in the schools, the literature supports a comprehensive approach to sexual health education (Kern et al., 2016). The school nurse should educate community members, the school board, teachers, parents, and students about the benefits of different types of services in the schools to the health of students and school personnel.

ETHICS IN SCHOOL NURSING

The school nurse may be faced with ethical issues in the schools. For example, a child may have a DNAR order that the parents wish to be used if the child dies at school (see earlier text), but following the DNAR order may be against the nurse's personal beliefs. Perhaps a girl asks the nurse where she can get an abortion and wishes to talk to the school nurse about how she feels, but the nurse is against abortions. Alternatively, a teenager asks for emergency contraception, which conflicts with the nurse's religious beliefs

or the nurse is not allowed to provide with his or her scope of practice, state laws, or school district regulations. In these cases, as in any other setting, the nurse must give nursing care to the student client according to the *School Nursing: Scope and Standards of Practice* (ANA & NASN, 2017) and the state's nurse practice act. However, if the nurse feels so strongly that he or she cannot work with the situation, another school nurse should be called for help, or the student should be referred to other health providers who can give the care the student needs. Care should never be denied or ignored; referral is a good option.

FUTURE TRENDS IN SCHOOL NURSING

The future of school nursing is strong. The amount of health care being given in the schools is increasing. In the future, school nursing may coordinate primary health care and specialist consultations for students in rural areas with limited access to care. Telecommunication may also be utilized to teach health education or to facilitate care coordination and make meetings more accessible for collaboration with other school nurses (Haynie, et al., 2017). Online resources are listed in Table 42.3. The school nurse is responsible for keeping up with the latest changes in health care and health practice so that the health of children in the schools can be enhanced by new trends in health care.

The National Association of School Nurses is looking to the future through development of the *Framework for 21st Century School Nursing Practice* (Maughan et al., 2018). This framework (Fig. 42.4) was developed by the NASN board of directors and an advisory group including school nurses and school nurse leaders. This framework integrates various models and principles that have been utilized to guide school nursing practice through the years. As the health needs of children become more complex and expectations of schools and parents grow, this framework "... provides guidance for the practicing school nurse to reach the goal of supporting student health and academic success by contributing to a healthy and safe school environment" (Maughan et al., p. 219).

LINKING CONTENT TO PRACTICE

School nurses play a primary role in the development and implementation of the CDC's WSCC model components. These components are described below and addressed throughout this chapter. The emphasis in this program design is working with the school as a population or community. This plan has 10 parts:

- *Physical education and physical activity*—The CDC (2018e) recommends that schools follow the national comprehensive physical activity framework, which includes support for regular physical activity during and outside of the school day, coordination with community, families, and school staff, and a curriculum throughout the child's school career that teaches health behaviors, sportsmanship, and other important skills related to health. Teachers of this curriculum should be licensed and certified in physical education (CDC, 2018f).
- *Nutrition environment and services*—The entire school environment should promote healthy eating, which has been shown to support student learning (CDC, 2018f). Information on nutrition and diet should be taught to all children. In addition, schools should provide healthy food choices for students in their meal programs (both breakfast and lunch). School nutrition staff should be educated to prepare food in ways that are both healthy and appetizing to encourage nutritious eating habits among staff and students. Nutrition staff should also be trained annually on safe food handling practices to decrease the risk of communicable disease outbreaks. Vending machines, school celebrations, and concession stands should offer healthy choices, following the Smart Snacks in Schools initiative, or be off limits to children, especially during the school day (CDC, 2018f). School employees, including school nurses, should model healthy eating behavior.
- *Health education*—This component includes teaching children about how to stay healthy and how to avoid becoming ill or being injured. The health education should be offered in a planned, sequential, K-12 curriculum that addresses all dimensions of health, following the National Health Education Standards (CDC, 2018f).
- *Health services*—School health services should be designed to prevent illness, promote health, and intervene in the event of illness or injury of students and school staff. Specifically, the schools can provide services to ensure access or referral to primary care, prevent and control communicable disease, provide emergency care for illness or injury, and provide educational and counseling opportunities for promoting and maintaining health across all settings (CDC, 2018f). Health services should be provided by qualified professionals, including school nurses.
- *Counseling, psychological, and social services*—This component emphasizes prevention and intervention to meet the needs of students in the areas of behavioral and mental health. School counselors, psychologists, and social workers should be qualified to provide guidance for children and their family, to alleviate barriers for children with learning needs, and provide referrals to community mental health and social services when needed (CDC, 2018f).
- *Physical environment*—The physical environment includes the school building and grounds, as well as environmental influences within and outside of the school that may impact the health of school staff and students. Indoor air quality, safe handling and use of chemicals (including pesticides and cleaning supplies), temperature and noise levels, and lighting are all addressed under this component (CDC, 2018f). This component also addresses violence and crime prevention in the schools.
- *Social and emotional school climate*—This component encompasses a safe and supportive environment for students and staff. A supportive environment fosters healthy growth and development, as well as academic achievement and healthy relationships among students.
- *Employee wellness*—Nurses often provide health care for teachers and other staff members in the schools. Staff can ask nurses about their health and obtain health education at school during their workday. This component also covers worksite safety for employees (CDC, 2018f). Nurses should be familiar with Occupational Safety and Health Administration (OSHA) guidelines for personal protective equipment, bloodborne pathogen prevention education, and healthy school environment (available from www.osha.gov). Healthy school employees are less likely to miss work and to be more productive, thereby reducing costs of finding replacements and decreasing health insurance costs for everyone.
- *Community involvement*—The school health program should contact families and community leaders to find out what health services are needed the most and how they can work together to emphasize health education, promote health in the school and community, and thereby support student learning (CDC, 2018f). Coalition building with school community partners is an important role for the school nurse, as discussed earlier in this chapter.
- *Family engagement*— Families should be made to feel welcome in the school. Their support is critical to the health and learning of their children (CDC, 2018f). Families can provide support for adequate, safe, and high-quality school health services by educating their school board representatives about children's health needs and parents' expectations for health care during the school day. Families should feel confident that privacy will be protected so they can comfortably share health and social information, as well as bring supplies and medications that may be needed to support their children's health at school.

CDC, Centers for Disease Control and Prevention; *WSCC,* Whole School, Whole Community, Whole Child.

PRACTICE APPLICATION

The elementary school principal has notified the school nurse that Melissa and John, 8-year-old twins who receive daily physical therapy for mild cerebral palsy, have transferred to the school. The nurse must comply with federal laws related to providing education and services to all children with disabilities.

A. What nursing responsibilities should the school nurse carry out?
B. What factors must be considered when the nurse coordinates the IEP and IHP plans?
C. How will this situation impact other children at school?
D. What is the central focus of Melissa's and John's education?

Answers can be found on the Evolve site.

KEY POINTS

- School nurses provide health care for children and families.
- In the early 1900s school nurses screened children for infectious diseases and educated families on prevention and treatment.
- School nursing practice has grown in complexity, becoming more holistic and adhering to professional practice standards.
- The National Association of School Nurses (NASN) is the professional organization for school nurses.
- School nurses have varying educational levels depending on state laws.
- The U.S. government supports **school-based health centers, school-linked programs**, and full-service school-based health centers.
- *Healthy People 2020* has objectives to enhance the health of children in schools and increase school nurse-to-student ratios.
- Primary prevention in schools includes health promotion and education to prevent childhood injuries, disease, and substance abuse.
- The school nurse monitors the children for all of their state-mandated immunizations for school entry.
- HIPAA privacy rules regarding the health information of children apply in schools.
- Secondary prevention involves screening children for illnesses and providing direct nursing care.
- School nurses develop plans for emergency care in the schools.
- Giving medications to children in the school must be monitored carefully to prevent errors.
- School health nurses are mandated reporters of suspected cases of child abuse and/or neglect.
- Disaster-preparedness plans should be set up for all schools with the school nurse as a member of the crisis response team.
- Tertiary prevention includes caring for children with long-term health needs, such as asthma, diabetes, and disabling conditions.
- School nurses carry out catheterizations, suctioning, gastrostomy feedings, and other complex clinical skills in schools.
- Some ethical dilemmas in the schools are related to women's health care.
- Some school nurses utilize telecommunications to coordinate health care for children and their families.

CLINICAL DECISION-MAKING ACTIVITIES

1. For the state where you live, make a list of the immunizations required for children attending schools. Then contrast this to the immunizations you received when in school. How has this changed over the years?
2. Contact the nurse in your former high school. Interview the nurse, focusing on the major focus of the role. Describe what the nurse likes best and least about the role. What changes could be made to help the nurse provide care more effectively?
3. Arrange to visit an elementary school health office during screening activities. Observe the interaction between the nurse and the children. Describe how the nurse is using the nursing process during the screening process.
4. Organize a group of nursing students to volunteer at a school health fair. Develop a health education booth for the fair. Describe how the health information can be used by the children, families, and the community.
5. Attend the annual school board meeting that discusses the budget for the next year. Analyze the budget for health services. Determine whether this will be adequate to care for the children. What issues influence the budgetary process?
6. Search the Internet to learn more about your state's health department. What trends do you see relating to health in the schools?
7. Volunteer as a participant in your school district's emergency response drill. How did the school nurse's responsibilities work to help reduce confusion and increase the provision of emergency care?

The Nurse in Occupational Health

Bonnie Rogers, DrPH, COHN-S, LNCC, FAAN

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Describe the nursing role in occupational health.
2. Discuss current trends in the U.S. workforce.
3. Use the epidemiologic model to explain work–health interactions and give examples of work-related illness, injuries, and hazards.
4. Complete an occupational health history.
5. Differentiate between the functions of the Occupational Safety and Health Administration (OSHA) and the National Institute for Occupational Safety and Health (NIOSH).
6. Explain an effective disaster plan in occupational health.

CHAPTER OUTLINE

Definition and Scope of Occupational Health Nursing
History and Evolution of Occupational Health Nursing
Roles and Professionalism in Occupational Health Nursing
Workers as a Population Aggregate
Application of the Epidemiologic Model
Organizational and Public Efforts to Promote Worker Health and Safety
Nursing Care of Working Populations
***Healthy People 2020* Document Related to Occupational Health**
Legislation Related to Occupational Health

Work can be both fulfilling and hazardous or risky. Many changes have occurred in the nature of work and workplace risks, the work environment, workforce composition and demographics, and health care delivery mechanisms. An analysis of the trends suggests that work–health interactions will continue to grow in importance, affecting how work is done, how hazards are controlled or minimized, and how health care is managed and integrated into workplace health delivery strategies. Although some workers may never face more than minor adverse health effects from exposures at work, such as occasional eyestrain resulting from poor office lighting, every industry has grappled with serious hazards (USDHHS, NIOSH, 2018). Nurses provide care to individuals to help them achieve optimal health; yet, at the same time in the course of their work, nurses face numerous hazardous substances such as blood, body fluids, or chemicals and often must lift heavy loads.

In America, work is viewed as important to one's life experiences, and most adults spend about one-third of their time at work (Rogers, 2019). Work—when fulfilling, fairly compensated, healthy, and safe—can help build long and contented lives and strengthen families and communities. No work is completely risk free, and all health care professionals should have some basic knowledge about workforce populations, work and related hazards, and methods to control hazards and improve health.

Important developments are occurring in occupational health and safety programs designed to prevent and control work-related illness and injury and to create environments that foster and support health-promoting activities. Occupational

health nurses have performed critical roles in planning and delivering worksite health and safety services, which must continue to grow as comprehensive and cost-effective services. In addition, the continuing increase in health care costs and the concern about health care quality have prompted the inclusion of primary care and management of non–work-related health problems in the health services' programs. In some settings, family services are also provided.

Health at work is an important issue for most individuals for whom the nurse provides care. With many individuals spending so much time working, the workplace, regardless of setting, has significant influence on health and can be a primary site for the delivery of health promotion and illness prevention. The home, the clinic, the nursing home, and other community sites, such as the workplace, will become the dominant areas where health and illness care will be sought.

This chapter describes the nurse's role in occupational health—working with employees and the workforce population. The focus is on the knowledge and skills needed to promote the health and safety of workers through occupational health programs, recognizing work-related health and safety, and the principles for prevention and control of adverse **work–health interactions**. The prevalence and significance of the interactions between health and work underscore the importance of including principles of occupational health and safety in nursing practice. The types of interactions and the frequent use of the general health care system for identifying, treating, and preventing occupational illnesses and injuries require nurses to use this knowledge in all practice settings. The epidemiologic triangle is used as one model for understanding these interactions, as well as risk factors, and effective nursing care for promoting health and safety among employed populations.

DEFINITION AND SCOPE OF OCCUPATIONAL HEALTH NURSING

Adapted from the American Association of Occupational Health Nurses (AAOHN) (2016), **occupational and environmental health nursing** is the specialty practice that provides for and delivers health and safety programs and services to workers, worker populations, and community groups. The practice focuses on the promotion and restoration of health, prevention of illness and injury, and protection from work-related and environmental hazards. Occupational and environmental health nurses have a combined knowledge of health and business that they blend with health care expertise to balance the requirement for a safe and healthful work environment with a healthy bottom line.

The foundation for occupational and environmental health nursing is research-based. Recognizing the legal context for occupational health and safety, this specialty practice derives its theoretical, conceptual, and factual framework from a multidisciplinary base including, but not limited to:

- Nursing science
- Medical science
- Public health sciences such as epidemiology and environmental health
- Occupational health sciences such as toxicology, safety, industrial hygiene, and ergonomics
- Social and behavioral sciences
- Management, administration, and financial principles

Guided by an ethical framework made explicit in the AAOHN *Code of Ethics* (2016), occupational and environmental health nurses encourage and enable individuals to make informed decisions about health care concerns. Confidentiality of health information is integral and central to the practice. Occupational and environmental health nurses are advocates for client(s), fostering equitable and quality health care services and safe and healthy environments in which to work.

HISTORY AND EVOLUTION OF OCCUPATIONAL HEALTH NURSING

Nursing care for workers began in 1888 and was called industrial nursing. A group of coal miners hired Betty Moulder, a graduate of the Blockley Hospital School of Nursing in Philadelphia (now Philadelphia General Hospital), to take care of their ailing coworkers and families (AAOHN, 1976). Ada Mayo Stewart, hired in 1885 by the Vermont Marble Company in Rutland, Vermont, is often considered the first industrial nurse. Riding a bicycle, Miss Stewart visited sick employees in their homes, provided emergency care, taught mothers how to care for their children, and taught healthy living habits (Felton, 1985). In the early days of occupational health nursing, the nurse's work was family centered and holistic.

Employee health services grew rapidly during the early 1900s as companies recognized that the provision of worksite health services led to a more productive workforce. At that time, workplace accidents were seen as an inevitable part of having a job. However, the public did not support this attitude, and a system for workers' compensation arose that remains today (McGrath, 1945).

Industrial nursing grew rapidly during the first half of the twentieth century. Educational courses were established, as were professional societies. By World War II there were about 4000 industrial nurses (Brown, 1981). The American Association of Industrial Nursing (AAIN) (now called the American Association of Occupational Health Nurses) was established as the first national occupational nursing organization in 1942. The aim of the AAIN was to improve industrial nursing education and practice and to promote interprofessional collaborative efforts (Rogers, 1988). Passage of several laws in the 1960s and 1970s to protect workers' safety and health led to an increased need for occupational health nurses. In particular, the passing of the landmark Occupational Safety and Health Act in 1970, which created the Occupational Safety and Health Administration (OSHA) and the National Institute for Occupational Safety and Health (NIOSH), discussed later in this chapter, resulted in a great need for nurses at the worksite to meet the demands of the many standards being implemented. Under OSHA, the Act focuses primarily on protecting workers from work-related hazards. NIOSH focuses on education and research. In 1988 the first occupational health nurse was hired by OSHA to provide technical assistance in standards development, field consultation,

and occupational health nursing expertise. In 1993 the Office of Occupational Health Nursing was established within the agency. In addition to direct health care delivery, nurses are more engaged than ever in policy making and management of occupational health services. In addition, in 1998, the AAOHN adopted the concept of environmental health as a significant component of the practice field. To this end, AAOHN has incorporated the term "environmental," as in occupational and environmental health nurse, in its documents and publications. In 1999, AAOHN published its first set of competencies in occupational health nursing, which have been updated, and established the AAOHN Foundation to support education, research, and leadership activities in occupational health nursing. Role expansion includes environmental health, total worker health, and forging sustainable relationships in the community to better improve worker health.

ROLES AND PROFESSIONALISM IN OCCUPATIONAL HEALTH NURSING

As U.S. industry has shifted from agrarian to industrial to highly technological processes, the role of the occupational health nurse has continued to change. The focus on work-related health problems now includes the spectrum of human responses to multiple, complex interactions of biopsychosocial factors that occur in community, home, and work environments. The customary role of the occupational health nurse has extended beyond emergency treatment and prevention of illness and injury to include the promotion and maintenance of health, overall risk management, care for the environment, efforts to reduce health-related costs in businesses, and total worker health. The interprofessional nature of occupational health nursing has become more critical, as occupational health and safety problems require more complex solutions. The occupational health nurse frequently collaborates closely with multiple disciplines and industry management, as well as with representatives of labor.

Occupational health nurses constitute the largest group of occupational health professionals. The most recent national survey of registered nurses indicates that there are about 19,000 licensed occupational health nurses (Health Resources and Services Administration, 2010). Occupational health nurses hold positions as nurse practitioners, clinical nurse specialists, managers, supervisors, consultants, educators, and researchers, and many occupational health nurses are employed in single-managed occupational health nurse units in a variety of businesses. The occupational health nursing role requires the nurse to adapt to an organization's needs as well as to the needs of specific groups of workers.

The professional organization for occupational health nurses is the American Association of Occupational Health Nurses. The AAOHN's mission is comprehensive. It supports the work of the occupational health nurse and advances the specialty. The AAOHN also does the following:

- Promotes the health and safety of workers
- Defines the scope of practice and sets the standards of occupational health nursing practice
- Develops the code of ethics for occupational health nurses with interpretive statements
- Promotes and provides continuing education in the specialty
- Advances the profession through supporting research
- Responds to and influences public policy issues related to occupational health and safety

The AAOHN (2012) provides the Standards of Occupational and Environmental Health Nursing Practice to define and advance practice and provide a framework for practice evaluation. The AAOHN Code of Ethics lists eight code statements based on the goal of occupational and environmental health nurses to promote worker health and safety (AAOHN, 2016). Both documents can be obtained from the AAOHN at http://www.aaohn.org.

Occupational health nurses have many roles, such as clinician, case manager, coordinator, manager, nurse practitioner, corporate director, health promotion specialist, educator, consultant, and researcher (Rogers, 2019). The majority of occupational health nurses work as solo clinicians, but additional roles are being included increasingly in the specialty practice. In many companies, the occupational health nurse has assumed expanded responsibilities in job analysis, safety, and benefits management. Many occupational health nurses also work as independent contractors and consultants or have their own businesses that provide occupational health and safety services to industry. Specializing in the field is often a requirement.

Ethical conflict is nothing new in occupational and environmental health nursing practice. Traditional concerns about confidentiality of employee health records, hazardous workplace exposures, issues of informed consent, risks and benefits, and dual duty conflicts (workers versus management) are now married with newer concerns of genetic screening, worker literacy and understanding, work organization issues, and untimely return to work (Rogers, 2019). With the current changes in health care delivery and the movement toward managed care, occupational health nurses will need increased skills in primary care, health promotion, and disease prevention. The aim of the occupational health nurse will be to devote much attention to keeping workers and, in some cases, their families healthy and free from illness and worksite injuries.

Academic education in occupational health and safety is generally at the graduate level. Training grants from NIOSH support master's and doctoral-level education with emphases in occupational health nursing, industrial hygiene, occupational medicine, and safety. These programs, shown in the resource section, are offered through NIOSH funded Occupational Safety and Health Education and Research Centers throughout the country. Certification in occupational health nursing is provided by the American Board for Occupational Health Nurses (ABOHN). ABOHN offers two basic certifications: the COHN (Certified Occupational Health Nurse) and COHN-S (Certified Occupational Health Nurse–Specialist). Eligibility for the COHN requires licensure as a registered nurse, whereas the COHN-S requires RN licensure plus a baccalaureate degree. Certification is achieved through experience, continuing education, professional activities, and examination. Those interested

in certification can view the requirements on the ABOHN website (www.abohn.org).

WORKERS AS A POPULATION AGGREGATE

The population of the United States is expected to increase from about 326 million people in 2018 to an estimated 404 million by the year 2060 (U.S. Census Bureau, 2018). In the United States in 2050, the population greater than 65 years of age is projected to reach an estimated 83.7 million people, almost double the about 43 million in 2012 (Ortman et al., 2014). In 2016, nearly 20 percent (nine million) of Americans over 65 were employed compared to about 12 percent in 2000 (Desilver, 2018). Bureau of Labor Statistics (BLS, 2018) data show total workforce projection to increase by 7.4 percent from 2016 to 2026 with workers aged 65 to 74 experiencing the fastest growth rate.

By 2024, the BLS projects the labor force will grow to 164 million civilian wage and salary workers employed in the United States (Toossi & Torpey, 2017). More than 91 percent of those who are able to work outside of the home do so for some portion of their lives. These statistics do not indicate the number of individuals who are at risk of exposure to work-related health hazards. Although some individuals may currently be unemployed or retired, they continue to bear the health risks of past occupational exposures. The number of affected individuals may be even larger, as work-related illnesses are found among spouses, children, and neighbors of exposed workers. In addition, more than seven million individuals report that they work multiple jobs (BLS, 2018).

Americans are employed in diverse industries that range in size from one to tens of thousands of employees. Types of industries include traditional manufacturing (e.g., automotive and appliances), service industries (e.g., banking, health care, and restaurants), agriculture, construction, and high-technology firms, such as computer chip manufacturers. Although some industries are noted for the high degree of hazards associated with their work (e.g., manufacturing, mines, construction, and agriculture), no worksite is free of occupational health and safety hazards. In addition, the larger the company, the more likely it is that there will be health and safety programs for employees. Smaller companies are more apt to rely on external community resources to meet their needs for occupational health and safety services.

Characteristics of the Workforce

The U.S. workplace has been changing rapidly. Jobs in the economy continue to shift from manufacturing to service. Longer hours, compressed workweeks, shift work, reduced job security, and part-time and temporary work are realities of the modern workplace. New chemicals, materials, processes, and equipment are developed and marketed at an ever-increasing pace.

As the population increases, the U.S. workforce is expected to grow as well and will become older and more racially diverse (BLS, 2018b). These changes will continue to present new challenges to protecting worker safety and health.

The demographic trends in the U.S. workforce describe a changing population aggregate that has implications for the prevention services targeted to that group. Major changes in the working population are reflected in the increasing numbers of women, older individuals, and those with chronic illnesses who are part of the workforce. Because of changes in the economy, extension of life span, legislation, and more working women, the proportion of the employed population that these three groups represent will probably continue to grow.

For example, in the late 1990s, while nearly 60 percent of all women were employed, women were predicted to account for 67 percent of the increase in the labor force in the twenty-first century (BLS, 2018). These workers tended to be married, with children and aging parents for whom they were responsible. This aggregate of workers presents new issues for individual and family health promotion, such as childcare and elder care, which can be addressed in the work environment. In 1990 more than half of the female labor force was concentrated in three areas: administrative support/clerical (26 percent), service (14 percent), and professional specialty (14 percent). Twelve percent were employed in fields such as labor, transportation and moving, machine operation, precision products, crafts, farming, construction, forestry, and fishing. In the male labor force, nearly 20 percent worked in precision production, crafts, or repair occupations, 13 percent in executive positions, 11 percent in professional specialty occupations, and 10 percent in sales. Other trends shaping the profile of the workforce include more education and mobility.

Future employment trends projected to 2026 are shown in Figs. 43.1 and 43.2. Of the 20 fastest-growing occupations in the economy, 10 are related to health care (BLS, 2018a). Health care is experiencing rapid growth, due in large part to the aging of the Baby Boomer generation, who will require more medical care. In addition, some health care occupations will be in greater demand for other reasons. As health care costs continue to rise, work is increasingly being delegated to lower-paid workers in order to cut costs. For example, tasks that were previously performed by doctors, nurses, dentists, or other health care professionals increasingly are being performed by physician assistants, nursing and medical assistants, dental hygienists, and physical therapist aides. In addition, clients increasingly are seeking home care as an alternative to costly stays in hospitals or residential care facilities, causing a significant increase in demand for home health aides. Although not classified as health care workers, personal and home care aides are being affected by this demand for home care as well.

Characteristics of Work

There has been a dramatic shift in the types of jobs held by workers. Following the evolution from an agrarian economy to a manufacturing society and then to a highly technological workplace, the greatest proportion of paid employment was in the occupations of trade, transportation, and utilities.

The nature of work has been accompanied by many new occupational hazards, such as complex chemicals, nanotechnology, nonergonomic workstation design (requiring the adaptation of the workplace or work equipment to meet the employee's

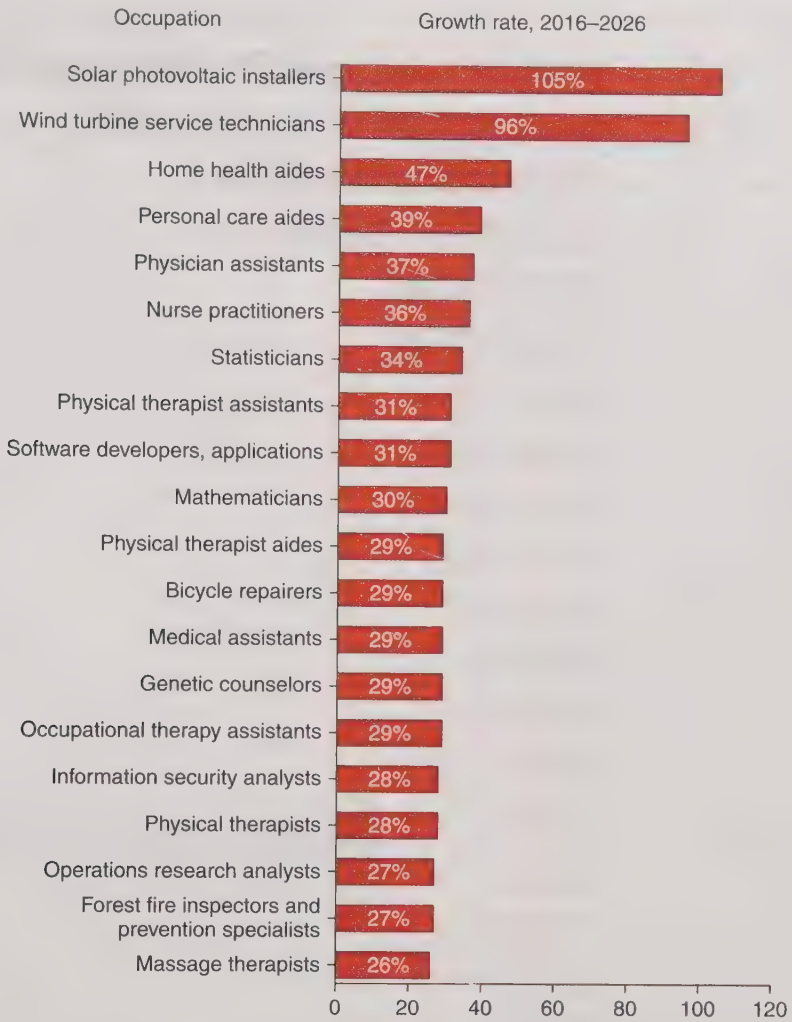

Fig. 43.1 Fastest growing occupations 2016–2026. (From Bureau of Labor Statistics, 2018. Available at https://www.bls.gov.)

health and safety needs), and many issues related to work organization such as job stress, burnout, and exhaustion. In addition, the emergence of a global economy with free trade and multinational corporations presents new challenges for health and safety programs that are culturally relevant.

Work–Health Interactions

The influence of work on health, or work–health interactions, is shown by statistics on illnesses, injuries, and deaths associated with employment.

As reported by the Census of Fatal Occupational Injuries (CFOI) (BLS, 2017s), there were 5190 fatal work injuries recorded in the United States in 2016, a seven-percent increase from the 4836 fatal injuries reported in 2015. This is the third consecutive increase in annual workplace fatalities and the first time more than 5000 fatalities have been recorded by the CFOI since 2008. The fatal injury rate increased to 3.6 per 100,000 workers from 3.4 in 2015, the highest rate since 2010. Fatal work injuries from falls, slips, or trips continued a general upward trend from 2011, increasing 6 percent in 2016 and 25 percent overall since 2011. Overdoses from the nonmedical use of drugs or alcohol while on the job increased from 165 in 2015 to 217 in 2016, a 32-percent increase. Overdose fatalities have increased by at least 25 percent annually since 2012.

Employers reported 2.9 work injuries and occupational illnesses per 100 workers in 2016 (BLS, 2017a) with 2.9 million incidents reported. Occupational injuries alone are reported to cost over $100 billion in lost wages and lost productivity, administrative expenses, health care, and other costs. This figure does not include the cost of occupational diseases. These figures are often described as the "tip of the iceberg," because many work-related health problems go unreported. However, even the recorded statistics are significant in describing the amount of human suffering, financial loss, and decreased productivity associated with workplace hazards. In 2016, there were 892,270 occupational injuries and illnesses resulting in days away from work with a median of 8 days absent (BLS, 2017b).

The high number of work injuries and illnesses can be drastically reduced. In fact, significant progress has been made in improving worker protection since Congress passed the 1970 Occupational Safety and Health Act. For example, vinyl chloride–induced liver cancers and brown lung disease (byssinosis) from

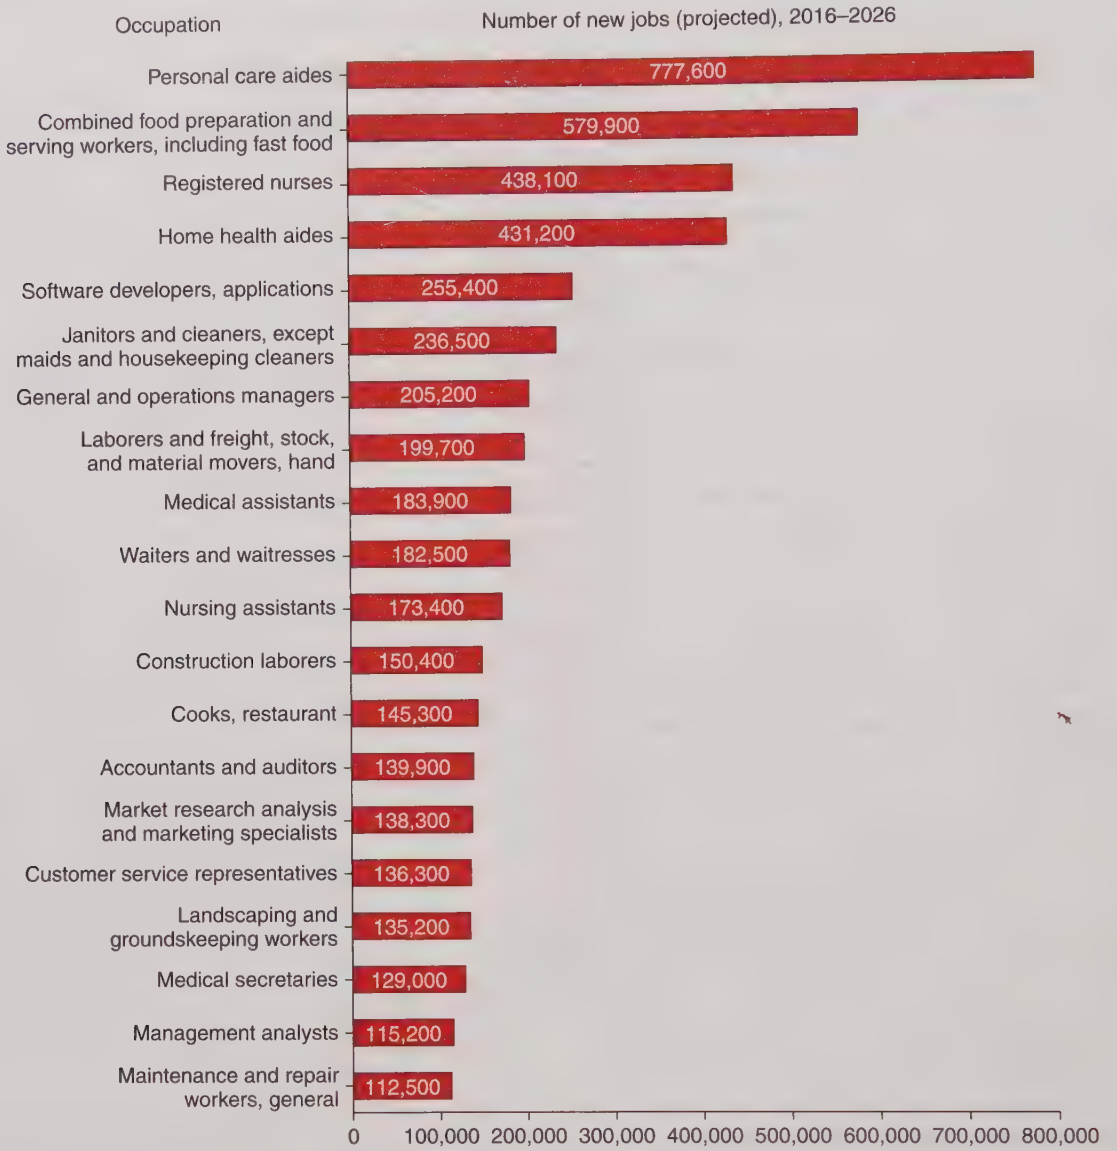

Fig. 43.2 Most new jobs (projected) 2016–2026. (From Bureau of Labor Statistics, 2018. Available at https://www.bls.gov.)

cotton dust exposure have been almost eliminated. Reproductive disorders associated with certain glycol ethers have been recognized and controlled. Fatal work injuries have declined substantially through the years. Notably, from 1970 to 1995, fatal injury rates in coal miners were reduced by more than 75 percent, and the disease prevalence was reduced by 90 percent. However, since 1995 there has been a doubling of the disease incidence (NIOSH, 2014).

The U.S. workplace is rapidly changing and becoming more diverse. Major changes are also occurring in the way work is organized, with increased shift work, reduced job security, and part-time and temporary work as realities of the modern workplace. In addition, new chemicals, materials, processes, and equipment (such as nanotechnology and fermentation processes in biotechnology) continue to be developed and marketed at an accelerating pace, creating new work-related hazards.

APPLICATION OF THE EPIDEMIOLOGIC MODEL

The Epidemiologic Triangle can be used to understand the relationship between work and health (Fig. 43.3). The reader is referred to Chapter 13, Epidemiology, for a fuller description. With a focus on the health and safety of the employed population, the **host** is described as any susceptible human being. Because of the nature of work-related hazards, nurses must assume that all employed individuals and groups are at risk of being exposed to occupational hazards. The **agents**, factors associated with illness and injury, are occupational exposures that are classified as biological, chemical, enviromechanical, physical, or psychosocial (Box 43.1). The environment includes all external conditions that influence the interaction of the host and agents. These may be workplace conditions such as temperature extremes, crowding, shift work, and inflexible management styles. The basic principle of epidemiology is that health

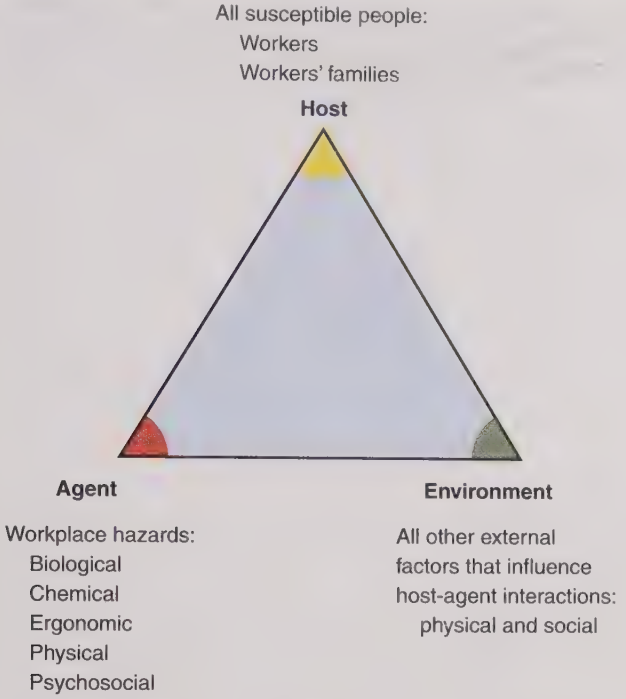

Fig. 43.3 The epidemiologic triangle.

BOX 43.1 Categories of Work-Related Hazards

Biological and infectious hazards—Infectious/biological agents, such as bacteria, viruses, fungi, or parasites, that may be transmitted via contact with infected clients or contaminated body secretions/fluids to other individuals

Chemical hazards—Various forms of chemicals, including medications, solutions, gases, vapors, aerosols, and particulate matter, that are potentially toxic or irritating to the body system

Enviromechanical hazards—Factors encountered in the work environment that cause or potentiate accidents, injuries, strain, or discomfort (e.g., unsafe/inadequate equipment or lifting devices, slippery floors, workstation deficiencies)

Physical hazards—Agents within the work environment, such as radiation, electricity, extreme temperatures, and noise, that can cause tissue trauma

Psychosocial hazards—Factors and situations encountered or associated with one's job or work environment that create or potentiate stress, emotional strain, or interpersonal problems

From Rogers B: *Occupational health nursing: concepts and practice.* In press, 2019.

status interventions for restoring and promoting health are the result of complex interactions among these three elements. To understand these interactions and to design effective nursing strategies for dealing with them in a proactive manner, nurses must look at how each of these elements influences the others.

Host

Each worker represents a host within the worker population group. Certain host factors are associated with increased risk of adverse response to the hazards of the workplace. These include age, sex, health status, work practices, ethnicity, and lifestyle factors (Rogers, 2019). For example, the population group at greatest risk for experiencing work-related accidents with subsequent injuries is new workers with less than one year of experience on the current job. Most nonfatal injuries and illnesses involving days away from work occur among new workers (the highest percentages were in mining [44 percent]; agriculture, forestry, and fishing [43 percent]; construction [41 percent]; and wholesale and retail trade [34 percent]). Thirty-five percent of injury and illness cases with days away from work occurred among workers with 5 or fewer years of service with their employer (BLS, 2017b). The host factors of age, sex, and work experience combine to increase this group's risk of injury because of characteristics such as risk taking, lack of knowledge, and lack of familiarity with the new job.

Older workers may be at increased risk in the workplace because of diminished sensory abilities, the effects of chronic illnesses, and delayed reaction times. Another population group that may be very susceptible to workplace exposure is women in their childbearing years. The hormonal changes during these years (along with the increased stress of new roles and additional responsibilities) and transplacental exposures are host factors that may influence this group's response to potential toxins.

In addition to these host factors, there may be other, less well-understood individual differences in response to occupational hazard exposures. Even if employers maintain exposure levels below the level recommended by occupational health and safety standards, 15 percent to 20 percent of the population may have health reactions to the "safe" low-level exposures (Levy et al., 2017). This group has been termed *hypersusceptible.* A number of host factors appear to be associated with this hypersusceptibility: light skin, malnutrition, compromised immune system, glucose-6-phosphate dehydrogenase deficiency, serum alpha1-antitrypsin deficiency, chronic obstructive pulmonary disease, sickle cell trait, and hypertension. Individuals who have known hypersusceptibility to chemicals that are respiratory irritants, hemolytic chemicals, organic isocyanates, and carbon disulfide may also be hypersusceptible to other agents in the work environment (Levy et al., 2017). Although this has prompted some industries to consider preplacement screening for such risk factors, the associations between these individual health markers and hypersusceptible response are speculative and require further research.

Agent

Work-related hazards, or agents (see Box 43.1), present potential and actual risks to the health and safety of workers in the millions of business establishments in the United States. Any worksite commonly presents multiple and interacting exposures from all five categories of agents. The following paragraphs discuss each of these five agents in more detail. Table 43.1 lists some of the more common workplace exposures, their known health effects, and the types of jobs associated with these hazards.

Biological Agents. Biological agents are living organisms whose excretions or parts are capable of causing human disease, usually by an infectious process. Biological hazards are common in workplaces such as health care facilities and clinical laboratories, where employees are potentially exposed to a variety of infectious agents, including viruses, fungi, and bacteria. Of particular

TABLE 43.1 Selected Job Categories, Exposures, and Associated Work-Related Diseases and Conditions

Job Categories	Exposures	Work-Related Diseases and Conditions
All workers	Workplace stress	Hypertension, mood disorders, cardiovascular disease
Agricultural workers	Pesticides, infectious agents, gases, sunlight	Pesticide poisoning, "farmer's lung," skin cancer
Anesthetists	Anesthetic gases	Reproductive effects, cancer
Automobile workers	Asbestos, plastics, lead, solvents	Asbestosis, dermatitis
Butchers	Vinyl plastic fumes	"Meat wrappers' asthma"
Caisson workers	Pressurized work environments	Caisson disease ("the bends")
Carpenters	Wood dust, wood preservatives, adhesives	Nasopharyngeal cancer, dermatitis
Cement workers	Cement dust, metals	Dermatitis, bronchitis
Ceramic workers	Talc, clays	Pneumoconiosis
Demolition workers	Asbestos, wood dust	Asbestosis
Drug manufacturers	Hormones, nitroglycerin, etc.	Reproductive effects
Dry cleaners	Solvents	Liver disease, dermatitis
Dye workers	Dyestuffs, metals, solvents	Bladder cancer, dermatitis
Embalmers	Formaldehyde, infectious agents	Dermatitis
Felt makers	Mercury, polycyclic hydrocarbons	Mercurialism
Foundry workers	Silica, molten metals	Silicosis
Glass workers	Heat, solvents, metal powders	Cataracts
Hospital workers	Infectious agents, cleansers, radiation	Infections, latex allergies, unintentional injuries
Insulators	Asbestos, fibrous glass	Asbestosis, lung cancer, mesothelioma
Jack-hammer operators	Vibration	Raynaud's phenomenon
Lathe operators	Metal dusts, cutting oils	Lung disease, cancer
Office computer workers	Repetitive wrist motion on computers	Tendonitis, carpal tunnel syndrome, tenosynovitis, eye strain

concern in occupational health is the infectious agent transmitted by humans (e.g., from client to worker or from worker to worker) in a variety of work settings. Bloodborne and airborne pathogens represent a significant class of exposures for U.S. health care workers at risk. Occupational transmission of bloodborne pathogens (including the hepatitis B and C viruses and the human immunodeficiency virus [HIV]) occurs primarily by means of needlestick injuries as well as through exposures to the eyes or mucous membranes (Dupler et al., 2013). The risk of hepatitis B virus infection following a single needlestick injury with a contaminated needle varies from 2 percent to greater than 40 percent, depending on the antigen status of the source person and the nature of the exposure. The risk of hepatitis C virus transmission depends on the same factors and ranges from 3.3 percent to 10 percent (Dupler et al., 2013).

While the number of cases and reports of tuberculosis has decreased in the United States, transmission of tuberculosis (TB) within health care settings (especially multidrug-resistant TB) continues as a major public health problem (Stewart et al., 2017). Since 1989 outbreaks of this type of TB have been reported in hospitals, and some workers have developed active drug-resistant TB. In addition, among workers in health care, social service, and correctional facilities who work with populations at increased risk of TB, hundreds have experienced tuberculin skin test conversions. Reliable data are lacking on the extent of possible work-related TB transmission among other groups of workers at risk for exposure. Many workers in these settings were employed as maintenance workers, security guards, aides, or cleaning people, who were not well protected from inadvertent exposure. Education should be provided to all health care workers, including those not having direct client care, in the proper handling and disposal of potentially contaminated linens, soiled equipment, and trash containing contaminated dressings or specimens (Gonzalez & Conlon, 2013) (see Evidence-Based Practice box).

EVIDENCE-BASED PRACTICE

The aim of this study was to investigate occupational exposures of health care workers to blood and body fluids in eastern Ethiopia (Reda et al., 2010). Health care workers still fail to adhere to standard precaution guidelines despite evidence that such a failure increases the risk of mucocutaneous blood and body fluid exposure resulting in bloodborne infection. The major infectious occupational hazards in the health care sector are hepatitis B and C viruses (HBV, HCV) and human immunodeficiency virus (HIV).

A total of 475 health care workers were surveyed working in 10 hospitals in eastern Ethiopia with an 84.4 percent response rate. Lifetime needlestick risk was 30.5 percent, and lifetime blood/body fluid exposure risk was 28.8 percent. Only 80.8 percent followed standard precautions regularly, while 46.9 percent recapped and 5.9 percent reused syringes; 44.8 percent of health care workers reported they were dissatisfied by the supply of personal protective equipment (PPE), and 70.9 percent perceived they were at risk in the workplace.

Nurse Use

Training programs and better provision of PPE are critically needed. Compliance with PPE must be emphasized along with effective teaching in infection control and safe work practice behavior.

Modified from Reda AA, Fisseha S, Mengistie B, et al.: Standard precautions: occupational exposure and behavior of health care workers in Ethiopia. *PLoS One* 5(12):e14420, 2010. doi:10.1371/journal.pone.0014420.

Chemical Agents. More than 300 billion pounds of chemical agents are produced annually in the United States. Of the about 2 million known chemicals in existence, less than 0.1 percent have been adequately studied for their effects on humans. Of those chemicals that have been linked to carcinogens, about half test positive as animal carcinogens. Most chemicals have not been studied epidemiologically to determine the effects of exposure on humans (Levy et al., 2017). As a consequence of general environmental contamination with chemicals from work, home, and community activities, a variety of chemicals have been found in the body tissues of the general population. These tissue loads may result in part from the accidental release of chemicals into the environment, such as that which occurred in Love Canal when chemicals leached out from buried industrial wastes.

In many workplaces, significant exposure to a daily, low-level dose of workplace chemicals may be below the exposure standards but may still create a potentially chronic and perhaps cumulative assault on workers' health. Predicting human responses to such exposures is further complicated because multiple chemicals often combine and interact to create a new chemical agent. Human effects may be associated with the interaction of these agents rather than with a single chemical. Another concern about occupational exposure to chemicals is reproductive health effects. Workplace reproductive hazards have become important legal and scientific issues. Toxicity to male and female reproductive systems has been demonstrated from exposure to common agents such as lead, mercury, cadmium, nickel, and zinc, as well as in antineoplastic drugs. Because data for predicting human responses to many chemical agents are inadequate, workers should be assessed for all potential exposures and cautioned to work preventively with these agents. High-risk or vulnerable workers, such as those with a latex allergy—a widely recognized health hazard—should be carefully screened and monitored for optimal health protection (Levy et al., 2017). To accurately assess and evaluate the exposure and recommend changes for abatement, it is essential that the nurse have a good understanding of the basic principles of toxicology, including routes of exposure (i.e., inhalation, skin absorption, and ingestion), dose-response relationships, and differences in effects (i.e., acute versus chronic toxicity).

Enviromechanical Agents. Enviromechanical agents are those that can potentially cause injury or illness in the workplace. They are related to the work process or to working conditions, and they can cause postural or other strains that can produce adverse health effects when certain tasks are performed repeatedly. Examples are repetitive motions, poor or unsafe workstation-worker fit, slippery floors, cluttered work areas, and lifting heavy loads. Severity of illness or injury can be estimated from the number of days away from work. In 2016 (BLS, 2017b), sprains and strains, bruises/contusions, cuts/lacerations, fractures, and multiple injuries accounted for more days away from work than for all types of injury and illness, accounting for 30 percent of total injury and illness cases.

Back pain/injury is one of the most common and significant musculoskeletal problems in the world. In 2011, back injuries and disorders accounted for 36 percent of all nonfatal occupational injuries and illnesses involving days away from work in the United States. Although the exact cost of back disorders is unknown, the estimates are staggering and in the billions per year. Regardless of the estimate used, the problem is large both in health and economic terms. Moreover, workers in six occupations accounted for 26 percent of musculoskeletal cases: nursing assistants; laborers; janitors and cleaners; heavy and tractor-trailer truck drivers; registered nurses; and stock clerks (BLS, 2011). The research on these hazards, related human responses, and prevention is evolving. The most productive strategy in preventing these exposures is redesigning the workplace and the work machinery or processes.

Physical Agents. Physical agents are those that produce adverse health effects through the transfer of physical energy. Commonly encountered physical agents in the workplace include temperature extremes, vibration, noise, lasers, radiation, and electricity. For example, vibration, which accompanies the use of power tools and vehicles such as trucks, affects internal organs, supportive ligaments, the upper torso, and the shoulder-girdle structure. Localized effects are seen with handheld power tools; the most common is Raynaud's phenomenon. The control of worker exposure to these agents is usually accomplished through engineering strategies such as eliminating or containing the hazardous agent. In addition, workers must use preventive actions, such as practicing safe work habits and wearing personal protective equipment when needed. Examples of safe work habits include taking appropriate breaks from environments with temperature extremes and not eating or smoking in radiation-contaminated areas. Personal protective equipment includes hearing protection, eye guards, protective clothing, and devices for monitoring exposures to agents such as radiation.

Psychosocial Agents. Psychosocial agents are conditions that create a threat to the psychological and/or social well-being of individuals and groups (Rogers, 2019). A psychosocial response to the work environment occurs as an employee acts selectively toward the environment in an attempt to achieve a harmonious relationship. When such a human attempt at adaptation to the environment fails, an adverse psychosocial response may occur. Work-related stress or burnout has been defined as an important problem for many individuals (Rogers, 2019). Responses to negative interpersonal relationships, particularly those with authority figures in the workplace, are often the cause of vague health symptoms and increased absenteeism. Epidemiologic work in mental health has pointed to environmental variables such as these in the incidence of mental illness and emotional disorder.

The psychosocial environment includes characteristics of the work itself, as well as the interpersonal relationships required in the work setting and shift work. About 10 percent of U.S. workers do some form of shift work that has the potential to lead to a variety of psychological and physical problems, including exhaustion, depression, anxiety, and gastrointestinal disturbance (BLS, 2018). Strategies to minimize the adverse effects of shift work are beneficial. For example, a rotating shift

allows the employee to move through a cycle of working the day shift, then the evening shift, and then the night shift over the course of several weeks, with the goal of the workforce sharing the stress of the least desirable shifts. Job characteristics such as low autonomy, poor job satisfaction, and limited control over the pace of work have been associated with an increased risk of heart disease among clerical and blue-collar workers.

Interpersonal relationships among employees and coworkers or bosses and managers are often sources of conflict and stress. Another aspect is organizational culture. This refers to the norms and patterns of behavior that are sanctioned within a particular organization. Such norms and patterns set guidelines for the types of work behaviors that will enable employees to succeed within a particular firm. Examples include following organizational norms for working overtime, expressing constructive dissatisfaction with management, and making work a top priority (USDHHS/NIOSH, 2002). These factors and the employee's response to them must be assessed if strategies for influencing the health and safety of workers are to be effective.

Nonfatal violence in the health care worker's workplace is a serious problem that is underreported. Much of the study of health care worker violence has been in psychiatric settings; however, reports in other areas such as the emergency department have been provided. Risk factors associated with this type of violence must be identified and strategies implemented to reduce the risk (Rogers et al., 2018).

Environment

Environmental factors influence the occurrence of host-agent interactions and may direct the course and outcome of those interactions. The physical environment involves the geological and atmospheric structure of an area and the source of such elements as water, temperature, and radiation, which may serve as positive or negative stressors. Although aspects of the physical environment (e.g., heat, odor, ventilation) may influence the host-agent interaction, the social and psychological environment can be equally important (Gordis, 2013).

New environmental problems continue to arise, such as an increase in industrial wastes and toxins and indoor and outdoor environmental pollution, which present opportunities for significant health threats to the working and general population. The social aspects of the environment encompass the economic and political forces affecting society and its health. This includes factors such as sanitation and hygiene practices, housing conditions, level and delivery of health care services, development and enforcement of health-related codes (e.g., occupational health and safety, pollution), employment conditions, population crowding, literacy, ethnic customs, extent of support for health-related research, and equal access to health care. In addition, addictive behaviors such as alcohol and substance abuse and various forms of psychosocial stress may be an outgrowth of negative social environments.

Consider an employee who is working with a potentially toxic liquid. Providing education about safe work practices and fitting the employee with protective clothing may not be adequate if the work must occur in a very hot and humid environment. As the worker becomes uncomfortable in the hot clothing, protection may be compromised by rolling up a sleeve, taking off a glove, or wiping the face with a contaminated piece of clothing. If the norms in the workplace condone such work practices (e.g., "Everyone does it when it's too hot"), the interventions that address only the host and agent will be ineffective; strategies to address the environment itself must be considered, such as cooling fans or minimization of exposure through job rotation. The epidemiologic triangle can be used as the basis for planning interventions to restore and promote the health of workers. These efforts are influenced by society and by organizational activities related to occupational health and safety (Rogers, 2019).

The occupational environment, within the context of the social environment, is represented by the workplace and work setting and the interactive effects of this environment on the worker. The nurse must consider the hazards and threats posed by this environment and the commitment of the employer to providing a safe and healthful workplace through use of preventive strategies and controls (e.g., engineering, substitution) (Rogers, 2019).

ORGANIZATIONAL AND PUBLIC EFFORTS TO PROMOTE WORKER HEALTH AND SAFETY

Promotion of worker health and safety is the goal of occupational health and safety programs. These programs are offered primarily by the employer at the workplace, but the range of services and the models for delivering them have been changing dramatically over the past few years. In addition to specific services, legislation at the federal and state levels has had a significant effect on efforts to provide a healthy and safe environment for all workers. Under the Occupational Safety and Health Act and because of increased public concern about worker health and safety, companies are cited for not meeting minimal occupational health and safety standards. Criminal charges have been filed against business owners when preventable work-related deaths occurred. These events have redirected an emphasis on preventive occupational health and safety programming.

Unless they have OSHA-regulated exposures, business firms are not required to provide occupational health and safety services that meet any specified standards. With few exceptions, there is no legal recourse for specific services or level of personnel provided by employers to protect worker health and safety. Therefore the range of services offered and the qualifications of the providers of occupational health and safety vary widely across industries. An important stimulus for health and safety programs is avoiding cost that can be attributed to the effectiveness of prevention services, as well as the need to support occupational health and safety and health promotion at the worksite.

On-Site Occupational Health and Safety Programs. Optimally, on-site occupational health and safety services are provided by a team of occupational health and safety professionals. The core members of this team are the occupational health nurse, occupational physician, industrial hygienist, and safety professional. In addition, more and more ergonomists are

playing an important role in the occupational health and safety team. The largest group of health care professionals in business settings is occupational health nurses; therefore the most frequently seen model is that of the one-nurse unit. This nurse collaborates with a community physician or occupational medicine physician who provides consultation and accepts referrals when medical intervention is needed. The collaboration may occur primarily through telephone contact, or the physician may be under contract with the company to spend a certain amount of on-site time each week. As companies become larger, they are likely to hire additional nurses, safety professionals, industrial hygienists, and physicians, the latter usually on a part-time or consultant basis. An increasingly popular option is to contract some health, safety, and industrial hygiene work to external providers. The largest firms often have corporate occupational health and safety professionals who set policy and participate in company decision making at the corporate level. These professionals work with the nurses employed at the individual sites within the company. Depending on the needs of the company and the workers, additional professionals may be on the occupational health and safety team, including employee assistance counselors, physical therapists, health educators, physical fitness specialists, and toxicologists.

The services provided by on-site occupational health programs range from those focused only on work-related health and safety problems to a wide scope of services that includes primary health care (Box 43.2). Increasingly employers supporting health promotion programs are offering employees incentives to stay healthy, such as gym memberships, on-site exercise facilities, or massage therapists during work hours.

BOX 43.2 Scope of Services Provided Through an Occupational Health and Safety Program

- Health/medical surveillance
- Workplace monitoring/surveillance
- Health assessments
- Preplacement
- Periodic, mandatory, voluntary assessments and services
- Transfer of clients/services
- Retirement/termination
- Executive
- Return to work
- Health promotion
- Health screening
- Employee assistance programs
- Case management
- Primary health care for workers and dependents
- Worker safety and health education related to occupational hazards
- Job task analysis and design
- Prenatal and postnatal care and support groups
- Safety audits and accident prevention
- Workers' compensation management
- Risk management, loss control
- Emergency preparedness
- Preretirement counseling
- Integrated health benefits programs

In industries that have exposures regulated by law, certain programs are required, such as respiratory protection or hearing conservation. The ability of a company to offer additional programs depends on employee needs, management's attitudes and understanding about health and safety, acceptance by the workers, and the economic status of the company. A significant increase in the number of health promotion and employee assistance programs offered in industry has occurred over the past few years. Health promotion programs focus on lifestyle choices that cause risks to health (e.g., job stress, obesity, smoking, stress responses, or lack of exercise) (O'Donnell, 2017). Employee assistance programs are designed to address personal problems (e.g., marital/family issues, substance abuse, or financial difficulties) that affect the employee's productivity. Since such efforts are cost-effective for businesses, they should continue to increase.

Similar types of occupational health and safety programs are available on a contractual basis from community-based providers. These may be offered by free-standing occupational health clinics, health maintenance organizations, hospitals, emergency clinics, and other health care organizations. In addition, consultants in each discipline work in the private sector (self-employed, in group practice, or in insurance companies) and in the public sector (in local and state health departments or departments of labor and industry). These services may be provided on-site, delivered at a specific location in the community, or offered through a mobile van that visits companies. These multiple resources have increased the options for companies that need occupational health and safety services, and they have also broadened the employment opportunities for health and safety professionals.

NURSING CARE OF WORKING POPULATIONS

The nurse is often the first health care provider seen by an individual with a work-related health problem. Consequently, nurses are in key positions to intervene with working populations at all levels of prevention (see the Levels of Prevention box). Prevention may be accomplished in the prepathogenesis period by measures designed to promote general optimal health, by protection against specific disease agents, or by the establishment of barriers against agents in the environment. These procedures have been termed *primary prevention.*

LEVELS OF PREVENTION

Occupational Health

Primary Prevention
Nurse provides education on use of personal protective equipment in the workplace to prevent injury/exposure.

Secondary Prevention
Nurse screens for hearing loss resulting from noise levels in the plant.

Tertiary Prevention
Nurse works with chronic diabetic workers to ensure appropriate medication use and blood glucose screening to avoid lost work days.

Secondary prevention may be accomplished by early diagnosis and prompt and adequate treatment. When the process of pathogenesis has progressed and the disease has advanced beyond its early stages, secondary prevention may be accomplished by means of adequate treatment to prevent sequelae and limit disability. Later, when defect and disability have been resolved, tertiary prevention may be accomplished by rehabilitation.

The occupational health nurse practices all levels of prevention (Rogers, 2019). Delivery of primary prevention services to employees is directed toward promoting health and averting a problem. In the occupational health setting, the purpose of health promotion is to maintain or enhance the well-being of individuals or groups of employees, and the company in general. This may include programs designed to enhance coping skills or good nutrition and knowledge about potential health hazards both inside and outside of the workplace.

Health protection (i.e., taking primary prevention measures) is designed to eliminate or reduce the risk of disease in order to prevent the development of an illness or injury. Walk-throughs by the occupational health nurse and/or other team members to identify workplace hazards are aimed at health protection. Specific protection programs or interventions often require active participation on the part of the employee. Participation in an immunization program, employment of personal protective equipment such as respirators or gloves, and cessation of smoking are examples of specific health protection measures.

CHECK YOUR PRACTICE

As a senior nursing student, you have been asked by the occupational health nurse to help develop a secondary prevention approach to detect the most common health problem shared by the workers at the auto plant in the local community. What would you do?
END

Secondary prevention occurs after a disease process has already begun. It is aimed at early detection, prompt treatment, and prevention of further limitations. For employees, early detection involves health surveillance and periodic screening to identify an illness at the earliest possible moment in its course, and elimination or modification of the hazard-producing situation. Interventions aimed at disability limitation are intended to prevent further harm or deterioration, and they include referral for counseling and treatment of an employee with an emotional or mental health problem whose work performance has deteriorated, as well as removal of workers from heavy-metal exposure who manifest neurological symptoms.

Tertiary prevention is intended to restore health as fully as possible and assist individuals to achieve their maximum level of functioning. Rehabilitation strategies such as return-to-work programs after a heart attack or limited duty programs after a cumulative trauma injury are examples of tertiary prevention.

Worker Assessment

The initial step of assessment involves the traditional history and physical assessment, emphasizing exposure to occupational hazards and individual characteristics that may predispose the client to the increased health risk of certain jobs. The **occupational health history** is an indispensable component of the health assessment of individuals (Rogers et al., 2018). Because work is a part of life for most people, including an occupational health history in all routine nursing assessments is essential. Many workers in the United States do not have access to health care services in their workplaces, yet it is not unusual to find health care providers in the community who have little or no knowledge about workplaces or expertise in occupation-related illnesses and injuries. Because of the large number of small businesses that do not have the resources for maintaining on-site health care, injured and ill workers are first seen in the public and private health care sector (e.g., in clinics, emergency departments, physicians' offices, hospitals, health maintenance organizations, and ambulatory care centers). Nurses are often the first-line assessors of these individuals and perhaps the only contact for education about self-protection from workplace hazards.

Identifying workplace exposures as sources of health problems may influence the client's course of illness and rehabilitation and may also prevent similar illnesses among others with potential for exposure (Levy et al., 2017). Including occupational health data into client assessments begins with recognizing the possible relationship between health and occupational factors. The next step is to integrate into the history-taking procedure some routine assessment questions that will provide the data necessary to confirm or rule out occupationally induced symptoms.

Symptoms of hazardous workplace exposures may be indicated by vague complaints involving any body system. These complaints are often similar to common medical problems. Three points that occupational health histories should include are a list of current and past jobs the client has held; questions about exposures to specific agents and relationships between the symptoms and activities at work, job titles, or history of exposures; and other factors that may influence the client's susceptibility to occupational agents (e.g., lifestyle history such as smoking, underlying illness, previous injury, or disabling condition).

Questions about the employee's occupational history can be included in existing assessment tools. The more complete the data collected, the more likely the nurse is to notice the influence of work–health interactions. All employees should be questioned about their employment history. To describe only a current status of "retired" or "housewife" may lead to the omission of needed data. The nurse should be aware that not all workers are well informed about the materials with which they work or about potential hazards. For this reason, the nurse must develop basic knowledge about all of the types of jobs held by clients and the possible hazards associated with them. Because there is an increased likelihood of multiple exposures from other environments such as the home and the community that may interact with workplace exposures, the nurse should extend the questioning to include this information.

Identifying work-related health problems should be an integrated focus of any assessment effort. A systematic approach for evaluating the potential for workplace exposures is the most effective intervention for detecting and preventing occupational health risks. Fig. 43.4 shows one short assessment tool

I. Present Job

A. What is your job title? _____

B. What do you do for a living? _____

C. How long have you had this job? _____

D. Describe the specific tasks of this job: _____

_____

E. What product or service is produced by the company where you work? _____

_____

F. Are you exposed to any of the following on your present job?

Metals	Radiation	Stress
Vapors, gases	Vibration	Others: _____
Dusts	Loud noise	
Solvents	Extreme heat or cold	

G. Do you feel you have any health problems that may be associated with your work?
If yes, describe: _____

_____

H. How would you describe your satisfaction with your job? _____

_____

I. Have any of your coworkers complained of illness or injuries that they associate with their jobs?
If yes, describe: _____

_____

II. All Past Work

Starting with your first job, please provide the following information:

Job title	Years held	Description of work	Exposures	Injuries/Illnesses	Personal protection equipment used

III. Other Exposures

A. Do you have any hobbies that involve exposure to chemicals, metals, or any of the other agents mentioned before? If yes, describe: _____

B. Are any other members of your household exposed to any of the substances listed above? If yes, describe:

_____

C. Do you live near any factories, dump sites, or other sources of pollution? If yes, describe: _____

_____

Fig. 43.4 Occupational health history form.

that can be incorporated into routine history taking. Similar questions can be included in the assessment of workers' spouses and dependents, who may receive secondhand or indirect exposure to occupational hazards.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Evidence-Based Practice

Integrates the best current clinical evidence with client and family preferences and values to provide optimal client care.

- **Knowledge:** Explain the role of evidence in determining best clinical practice.
- **Skills:** Read original research and evidence reports related to area of practice.
- **Attitudes:** Appreciate the importance of reading relevant professional journals.

Evidence-Based Practice Question

The public health nursing Quad Council competency of leadership and systems thinking skills recommends the beginning public health nurse identify organizational quality improvement initiatives that provide opportunities for improvement in public health nursing practice (2018). You are working as an occupational health nurse. You have noticed there are a lot of work days lost because of work-related injuries or exposure to some type of hazard in the workplace. In this chapter you will see which of the injuries and exposures are more likely to occur in industry. Choose one of the hazard categories and read the evidence available about this hazard category. What does the evidence suggest in terms of organizational changes that could help reduce the risk for this hazard? How can the occupational health nurse promote changes in practice using the evidence available?

Prepared by Gail Armstrong, PhD(c), DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing (updated August 2018).

During these health assessments, the nurse has the opportunity to teach about workplace hazards and prevention measures the worker can use. At the same time, the nurse is obtaining information that will be valuable in optimizing the fit between the job and the worker. Such assessments can be done during preplacement examinations before the client begins a job, on a periodic basis during employment, or when a work-related health problem or exposure becomes apparent. One important group to consider are the nearly 15 million truck drivers who face health hazards from long work hours and fatigue, shift work, sleep deprivation, chemical exposure, and sedentary work and lifestyle. Life expectancy for these workers is only 61 years, which is 16 years less than the national average (Patton, 2012). The occupational health nurse can help identify physical and psychosocial health and life-threatening issues for this workforce and develop interventions to mitigate the risk. Work-related health assessments should also be conducted when an employee is being transferred to another job with different requirements and exposures. The goal of these assessments is to identify agent and host factors that could place the employee at risk and to determine prevention steps that can be taken to eliminate or minimize the exposure and potential health problem.

When the health data from such assessments are considered collectively, the nurse may determine some patterns in risk factors associated with the occurrence of work-related injuries and illnesses in a total population of workers. For example, a nurse practitioner in a clinic noted a dramatic increase in the number of dermatitis cases among her clients. When she looked at factors in common among these individuals, she determined that they all worked at a company with solvent exposure commonly associated with dermal irritations. She worked with the union and the company to assess the environment/agent exposure to the employees and design mitigation strategies. This nursing intervention led to a safer work environment and a decrease in dermatitis in this population group. Such an approach can be used at the company, industry, and community levels. The initial collection of data and the questioning about workplace exposures are vital steps for any intervention.

Workplace Assessment

The nurse may conduct a similar assessment of the workplace itself. The purpose of this assessment, known as a **worksite walk-through** or survey, is to become knowledgeable about the work processes and the materials, the requirements of various jobs, the presence of actual or potential hazards, and the work practices of employees (Rogers et al., 2018). Fig. 43.5 shows a brief outline that can be used to guide a worksite assessment. More complex surveys are performed by industrial hygienists and safety professionals when the purpose of the walk-through is environmental monitoring using sampling techniques or a safety audit. However, most occupational health nurses have developed expertise in these areas and include such tasks as part of their functions. For all health care providers who assess workers, this information makes an important database. In addition, for the on-site health care provider, worksite walk-throughs assist the professional in developing rapport with and being seen as a credible worker among the employees.

A worksite survey begins with an understanding of the type of work that occurs in the workplace. All business organizations are classified within the North American Industry Classification System (NAICS) with a numerical code. This code, usually a two- to four-digit number, indicates a company's product and, therefore the possible types of **occupational health hazards** that may be associated with the processes and materials used by its employees. NAICS codes are used to collect and report data on businesses. For example, illness and injury rates of one company are compared with the rates of other companies of similar size with the same code to determine whether the company is having an excess of illness or injury. In addition, by knowing the NAICS code of a company, a health care professional can access reference books that describe the usual processes, materials, and by-products of that kind of company.

The nurse will want to review the work processes and work areas by jobs or locations in the workplace. These preliminary data provide clues about what hazards may be present and an understanding of the types of jobs and health requirements that may be involved in a particular industry. A description of the work environment is next and provides an overall picture of

Name of company: _____ Date: _____
Address: _____
Telephone: _____

general appearances, physical layout, and safety of the environment. Are safety signs posted and readable where needed? Is there clutter or dampness on the floor that could cause slips or falls?

A description of the employee group is necessary information to understand the demographics and the work distribution in the company. Knowing about shift work and productivity can be helpful in pinpointing potential stressors. Human resources' management and corporate commitment to health and safety are needed to develop a supportive culture for effective and efficient programming. Reviewing the status of policies and procedures and assessing opportunities for input into improving service are important to establish the organization's strength in occupational health and safety management. Gathering data about the incidence and prevalence of work-related illnesses and injuries and the cost patterns for these conditions provides useful epidemiologic trend data and helps target high-cost areas. The types of occupational safety and health services and programs are important to know. This will show whether required programs are being offered and includes health promotion and disease prevention strategies.

HOW TO Assess a Worker and the Workplace

Assessing the worker for a work-related problem is a critical practice element. You need to do the following:

- Complete general and occupational health history-taking with emphasis on workplace exposure assessment, job hazard analysis, and list of previous jobs.
- Conduct a health assessment to identify agent and host factors that interact to place workers at risk.
- Identify patterns of risk associated with illness/injury.

Assessing the work environment is necessary to determine workplace exposures that create worker health risk. You need to do the following:

- Understand the work being done.
- Understand the work process.
- Evaluate the work-related hazards.
- Gather data about incidence/prevalence of work-related illness/injuries and related hazards.
- Conduct a walk-though of the work environment.
- Examine prevention and control strategies in place for eliminating exposures.

Finally, examining control strategies that are effective in eliminating or reducing exposure is important in determining risk reduction. Control strategies follow a hierarchical approach. Engineering controls can reduce worker exposure by modifying the exposure source, such as putting needles in a puncture-proof container. Work practice controls include good hygiene and proper waste disposal and housekeeping. Administrative controls reduce exposure through job rotation, workplace monitoring, and employee training and education. Finally, personal protective control is the last resort and requires the worker to actively engage in strategies for protection such as use of gloves, masks, and gowns to prevent exposures (Rogers et al., 2018).

The more information that can be collected before the walk-through, the more efficient the process of the survey will be. After the survey is conducted, the nurse can use the information with the aggregate health data to evaluate the effectiveness of the occupational health and safety program and to plan future programs.

HEALTHY PEOPLE 2020 DOCUMENT RELATED TO OCCUPATIONAL HEALTH

In an attempt to meet the goal of attaining high-quality, longer lives free of preventable disability, injury, and premature death for Americans, health promotion and protection strategies are proposed to address the needs of large population groups such as the American workforce. As part of the *Healthy People 2020* document (USDHHS, 2010), occupational safety and health objectives were identified to promote good health and well-being among workers, including the elimination and reduction of elements in occupational environments that cause death, injury, disease, or disability. In addition, this document promotes the minimizing of personal damage from existing occupationally related illness.

HEALTHY PEOPLE 2020

Objectives Related to Occupational Health

- **OSH-1:** Reduce deaths from work-related injuries.
- **OSH-2:** Reduce nonfatal work-related injuries.
- **OSH-3:** Reduce the rate of injuries and illness cases.
- **OSH-4:** Reduce pneumoconiosis deaths.
- **OSH-5:** Reduce deaths from work-related homicides.
- **OSH-6:** Reduce work-related assault.
- **OSH-7:** Reduce the proportion of persons who have elevated blood lead concentrations from work exposures.
- **OSH-8:** Reduce occupational skin diseases or disorders among full-time workers.
- **OSH-10:** Reduce new cases of work-related noise-induced hearing loss.

Data from U.S. Department of Health and Human Services: *Healthy People 2020.* Washington, DC, 2010, U.S. Government Printing Office.

LEGISLATION RELATED TO OCCUPATIONAL HEALTH

The occupational health and safety services provided by an employer are influenced by specific legislation at federal and state levels. Although the relationship between work and health has been known since the second century (Ramazzini, 1713), public policy that effectively controlled occupational hazards was not enacted until the 1960s. The Mine Safety and Health Act of 1968 was the first legislation that specifically required certain prevention programs for workers. This was followed by the Occupational Safety and Health Act of 1970, which established two agencies, OSHA and NIOSH, each with discrete functions (Box 43.3) to carry out the Act's purpose of ensuring "safe and healthful working conditions for working men and women" (PL 91-596, 1970). The reader is also referred to Chapters 3 and 5, the Affordable Care Act, for additional information on employer mandates.

In the context of the Occupational Safety and Health Act, OSHA, a federal agency within the U.S. Department of Labor, was created to develop and enforce workplace safety and health standards and regulations on workers' exposure to potentially

BOX 43.3 Functions of Federal Agencies Involved in Occupational Safety and Health

Occupational Safety and Health Administration (OSHA)

Determines and sets standards and permissible exposure limits (PELs) for hazardous exposures in the workplace.

Enforces the occupational health standards (including the right of entry for inspection).

Educates employees and employers about occupational health and safety.

Develops and maintains a database of work-related injuries, illnesses, and deaths.

Monitors compliance with occupational health and safety standards.

National Institute for Occupational Safety and Health (NIOSH)

Conducts research and reviews findings to recommend exposure limits for occupational hazards to OSHA.

Identifies and researches occupational health and safety hazards.

Educates occupational health and safety professionals.

Distributes research findings relevant to occupational health and safety.

From U.S. Department of Health and Human Services, National Institute for Occupational Safety and Health: *National Occupational Research Agenda*. Cincinnati, OH, 2018, USDHHS.

toxic substances, enforcing these at the federal and state levels. Specific standards and information about compliance can be obtained from federal, regional, and state OSHA offices, which can be found on the OSHA website.

The **National Institute for Occupational Safety and Health (NIOSH)** was established by the Occupational Safety and Health Act of 1970 and is part of the Centers for Disease Control and Prevention (CDC). In 1996 NIOSH and its partners unveiled a 10-year **National Occupational Research Agenda (NORA)**, a framework to guide occupational safety and health research into the following decade. The NIOSH agency identifies, monitors, and educates about the incidence, prevalence, and prevention of work-related illnesses and injuries and examines potential hazards of new work technologies and practices (USDHHS, NIOSH, 2018). Subsequently, the NORA has been updated and is focused on targeted sectors to reduce the still significant toll of workplace illness and injury.

Many standards have been established by OSHA and promulgated to protect worker health. One example is the **Hazard Communication Standard.** This standard is based on the premise that while working to reduce and eliminate potentially toxic agents in the work environment, an important line of defense is to provide the work community with information about hazardous chemicals in order to minimize exposures. The Hazard Communication Standard, which was first established in 1983, requires that all worksites with hazardous substances inventory their toxic agents, label them, and provide information sheets, called safety data sheets (SDSs), for each agent. In addition, the employer must have in place a hazard communication program that provides workers with education about these agents. This education must include agent identification, toxic effects, and protective measures. Numerous standards have been established by OSHA for specific chemicals and programs. A standard familiar to all health care professionals is the *Bloodborne Pathogens Standard.*

Workers' compensation acts are important state laws that govern financial compensation to employees who suffer work-related health problems. These acts vary by state, and each state sets rules for the reimbursement of employees with occupational health problems for medical expenses and lost work time associated with the illness or injury. Workers' compensation claims and the experience-based insurance premiums paid by industry have been important motivators for increasing the health and safety of the workplace.

LINKING CONTENT TO PRACTICE

Disaster Planning and Management

Although disaster planning and management have been functions of occupational health and safety programs, this is an area of legislation that affects businesses and health professionals. The legislation of the Superfund Amendment and Reauthorization Act (SARA) requires that written disaster plans be shared with key resources in the community, such as fire departments and emergency departments. Concern about disasters—such as the terrorist attacks on the World Trade Center and Pentagon on September 11, 2001; the methyl isocyanate leak in Bhopal, India; effects of hurricanes such as Katrina and Sandy; or the community exposure to chemicals at Times Beach, Missouri, and exposure to radiation from crippled nuclear plants in Japan—has mandated more attention to disaster planning.

In occupational health, the goals of a disaster plan are to prevent or minimize injuries and deaths of workers and residents, minimize property damage, provide effective triage, and facilitate necessary business activities. A disaster plan requires the cooperation of different personnel within the company and community. The nurse is often a key person on the disaster planning team, along with safety professionals, physicians, industrial hygienists, the fire chief, and company management. The potential for disaster (e.g., explosions, floods, fires, leaks) must be identified, and this is best achieved by completing an exhaustive chemical and hazard inventory of the workplace. The safety data sheet and plant blueprints are critical for correctly identifying substances and work areas that may be hazardous. Worksite surveys are the first step to completing this inventory. The reader is also referred to Chapter 21 on the public health nurse (PHN) and disaster management.

Effective disaster plans are designed by those with knowledge of the work processes and materials, the workers and workplace, and the resources in the community. Specific steps must be detailed for actions to be put in place by specific individuals in the event of a disaster. The written plan must be shared with all who will be involved. Employees should be prepared in first aid, cardiopulmonary resuscitation, and fire brigade procedures. Plans must be clear, specific, and comprehensive (i.e., covering all shifts and all work areas) and must include activities to be conducted within the worksite and those that require community resources. Transportation plans, fire response, and emergency response services should be coordinated with the agencies that would be involved in an actual disaster. The disaster plan, emergency and safety equipment, and the first response team's abilities should be tested at least annually with a drill. Practice results should be carefully evaluated, with changes made as needed.

Continued

LINKING CONTENT TO PRACTICE—cont'd

Disaster Planning and Management

Hospitals and other emergency services, such as fire departments, should be involved in developing the disaster plan and should receive a copy of the plan and a current hazard inventory. It is imperative that the plan and hazard inventory be periodically updated. The occupational health nurse or another company representative should provide emergency health care providers with updated clinical information on exposures and appropriate treatment. It should never be presumed that local services will have current information on substances used in industry. Representatives of these agencies should visit the worksite and accompany the nurse on a worksite walk-through so that they are familiar with the operations.

In disaster planning, the nurse is often assigned or assumes the responsibility for coordinating the planning and implementing efforts, working with appropriate key people within the company and in the community to develop a workable, comprehensive plan. Other tasks include providing ongoing communication to keep the plan current; planning the drills; educating the employees, management, and community providers; and assessing the equipment and services that may be used in a disaster.

In the event of a disaster, the nurse should play a key role in coordinating the response. Principles of triage may be used as the response team determines the extent of the disaster and the ability of the company and community to respond. Post-disaster nursing interventions are also critical. Examples include identifying the ongoing disaster-related health needs of workers and community residents, collecting epidemiologic data, and assessing the cause and the necessary steps to prevent a recurrence.

Occupational health nursing is a broad, dynamic specialty practice. The Public Health Foundation provides the basis for practice, supporting a health promotion and protection and prevention model. The occupational health nurse must have interprofessional skills and linkages to provide the most effective care and service. Occupational health nurses are involved in all levels of prevention in their practice.

PRACTICE APPLICATION

An insurance company recently renovated its claims processing office area and fitted the workstation with new computers. The company's occupational health nurse noticed an increase in visits to the health unit for complaints of headaches, stiff neck muscles, and visual disturbances consistent with computer usage.

To conduct a complete investigation of this problem, the nurse assessed the workers, the agent (computer), previously existing potential agents, and the work environment. Interventions focused on designing the health hazard out of the work process, if possible. In the present example, the first level of intervention was to refit the workstation for better worker use of the computer.

Minimizing the possible hazards of the agent involved recommendations for desks, chairs, and lighting designs that would accommodate the individual worker and allow shielding of the monitor. The nursing interventions included strengthening the resistance of the host by prescribing appropriate rest breaks, eye exercises, and relaxation strategies. Recognizing that previous cervical neck injury or impaired vision may increase the risk of adverse effects from computer work, the nurse would include assessment for these factors in employees' preplacement and periodic health examinations.

For the environmental concerns, the nurse educated the manager about the health risks of paced, externally controlled work expectations and recommended alternatives.

This case is an example of which of the following?

A. The application of the occupational health history
B. A worksite assessment or walk-through
C. A work–health interaction
D. The use of the epidemiologic triangle in exploring occupational health problems

Answers can be found on the Evolve site.

KEY POINTS

- Occupational health nursing is an autonomous practice specialty.
- The scope of occupational health nursing practice is broad, including worker and workplace assessment and surveillance, case management, health promotion, primary care, management/administration, business and finance skills, and research.
- The workforce and workplace are changing dramatically, requiring new knowledge and new occupational health services.
- The type of work has shifted from primarily manufacturing to service and technological jobs.
- Workplace hazards include exposure to biological, chemical, enviromechanical, physical, and psychosocial agents.
- The Occupational Safety and Health Act of 1970 states that workers must have a safe and healthful work environment.
- The interprofessional occupational health team consists of the occupational health nurse, occupational medicine physician, industrial hygienist, and safety specialist.
- Work-related health problems must be investigated and control strategies implemented to reduce exposure.
- Control strategies include engineering, work practice, administration, and personal protective equipment.
- The Occupational Safety and Health Administration enforces workplace safety and health standards.
- The National Institute for Occupational Safety and Health is the education and research agency that provides grants to investigate the causes of workplace illness and injuries.
- Workers' compensation acts are important laws that govern financial compensation of employees who suffer work-related health problems.
- The occupational health nurse should play a key role in disaster planning and coordination.
- Academic education in occupational health nursing is generally at the graduate level.

CLINICAL DECISION-MAKING ACTIVITIES

1. Arrange to visit a local industry to observe work processes and discuss working conditions. See if you can identify the work-related hazards and make recommendations for eliminating them.
2. Interview the occupational health nurse in an industry setting and ask questions about scope of practice, job functions, and contributions to the business. Compare and contrast what you have learned about this nurse role to that of the school health nurse.
3. Contact the American Association of Occupational Health Nurses and ask what the most pressing trends are in the specialty. What are some of the complex issues related to these trends?
4. Obtain a proposed standard from the Occupational Safety and Health Administration, critique it, and submit your comments.
5. Attend a workers' compensation hearing, analyze the problem, and critique the outcome. How is your critique affected by what you thought the outcome should be?

Forensic Nursing in the Community

Laura Suzuki, PhD(c), MPH, BSN, RN, Natalie McClain, PhD, RN, CPNP, and Melissa A. Sutherland, PhD, FNP-BC

OBJECTIVES

After reading this chapter, the student will be able to do the following:

1. Describe the specialized competencies and skills of the forensic nurse within the nursing process.
2. Discuss the relationship of the forensic nurse with public health professionals in addressing injury as a public health concern.
3. List the health risks that result from incidents of injury.
4. Identify how forensic nurses deal with injuries in the three levels of prevention.
5. Discuss the health disparities that contribute to the occurrence and poor outcomes in marginalized groups who experience injury.
6. Explain the contribution of theoretical underpinnings to current models of forensic nursing practice.
7. Identify client populations and clinical arenas in the community where forensic nurses practice.
8. Define the key terms and concepts within forensic nursing theory.
9. Identify professionals who commonly work in collaboration with the forensic nurse in addressing injury care and prevention.

CHAPTER OUTLINE

Perspectives on Forensics and Forensic Nursing
Injury Prevention
***Healthy People 2020* Goals, Prevention, and Forensic Nursing**
Forensic Nursing as a Specialty Area That Provides Care in the Community
Current Perspectives

victimization, p. 982

PERSPECTIVES ON FORENSICS AND FORENSIC NURSING

Injuries resulting from crime and victimization cause pain and suffering and may cause disability, economic failure, and "distress of the human spirit" (Lynch, 2011, p. 15). However, such injuries have often taken a back seat to treatment of disease and infection. Today forensic nurses expertly care for victims of injuries, largely as a community-based specialty, from a medical as well as a legal perspective. Whether the injury is caused by intentional violence or unintentional accident, forensic nurses are involved with not only the treatment but also the prevention of injury, the leading cause of death in the first four decades of life (Centers for Disease Control and

Special thanks goes to Dr. Susan Patton who authored this chapter in the eighth edition of the textbook. Appreciation is given to Drs. Karen Landenburger and Jacquelyn Campbell for providing some content related to forensic nursing that was moved from Chapter 38, which discusses violence in the community.

Prevention [CDC], 2016). The burden of injuries to individuals ranges from minimal and brief to debilitating or fatal. The economic burden worldwide is tremendous. Each year in the United States more than 3 million people are hospitalized and 27 million people receive treatment in emergency departments as a result of violence and injuries (CDC, 2015). The total costs, for both fatal and nonfatal injuries and violence, are estimated to be more than $671 billion in medical care and lost productivity each year (CDC, 2015). Because injuries result from a wide variety of physical, environmental, and behavioral causes, risk reduction comes from a variety of approaches. Forensic nurses have a unique set of skills for dealing with injury, and these skills will be discussed in this chapter.

Forensic means pertaining to the law. **Forensic nursing** synthesizes the biopsychosocial and spiritual aspects of nursing care with an expert understanding of forensic science and the criminal justice process (International Association of Forensic Nurses, 2017). Forensic nursing has a unique body of knowledge and set of skills. It also has unique practice arenas and the client population served. The skill set is defined by the scope and standards of practice, which includes skills such as collection, documentation, and preservation of evidence and other findings that may later be used in the prosecution of a crime. Practice standards reflect care given to both the living and the dead, victims of trauma and perpetrators of crime, as well as families and affected groups within a community. Forensic nurses often have experience in emergency and trauma services and can provide an expert analysis of wounding patterns and physiological response to injury. They are able to compassionately care for individuals and families who experience emotional reactions to trauma from a variety of causes. While the majority of forensic nurses in the United States are **sexual assault nurse examiners (SANEs)**, other roles exist to care for survivors of other violent crimes, liability-related injury, and deaths. These include the clinical forensic nurse, **forensic nurse examiner** or investigator, forensic psychiatric nurse, forensic correctional nurse, legal nurse consultant, nurse attorney, and nurse coroner or death investigator (Bauman & Stark, 2015). Arenas of care include but are not limited to emergency departments and community-based urgent care clinics, offices of the medical examiner and coroner, investigative units of law enforcement and criminal justice agencies, and governmental programs of safety prevention.

Forensic nursing care largely occurs in collaboration with professionals, both within and outside of nursing, including public health professionals, epidemiologists, law enforcement and corrections officers, emergency department providers, and psychiatric practitioners. Forensic nurses may also work in conjunction with public health nurses who bring a population focus to injury prevention programs. As part of a public health approach to crime prevention and response, forensic nurses may serve as content experts, clinician advisors, and/or the clinical managers of care facilities that may contribute to a community response to injury prevention.

INJURY PREVENTION

Not surprisingly, the health determinants of injury as identified in *Healthy People 2020* mirror disease occurrence in a community. The rate of injury and crime is lower in communities that promote good health. Where inequities of resources and education exist, health disparity, violence, and other crimes rise and accidental injuries occur more often (Jackson & Vaughn, 2018). Trauma victims are overrepresented in minority, disenfranchised, and disadvantaged groups. Disparity can also be seen in the prosecution, conviction, and incarceration of individuals of minority groups in many countries. In the United States, African Americans are more than five times as likely and Hispanics twice as likely to be incarcerated as whites (Sakala, 2014). Populations that experience more disease also experience more violent as well as accidental injury and more events that lead to prosecution. The measures that improve overall health, lower risk, and reduce disparity also reduce physical and emotional injury. **Injury** now joins certain categories of disease, disability, and premature death as a major preventable health state. Reducing injury reflects the goals of *Healthy People 2020* as well as goals of other organizations such as the U.S. Public Health Service, the Centers for Disease Control and Prevention (CDC), the World Health Organization (WHO), and the International Association of Forensic Nurses (IAFN).

The National Center for Injury Prevention and Control (NCIPC), within the CDC, was established in 1997 to coordinate prevention of injuries, violence, and their consequences. NCIPC provides grants that fund prevention programs, aids in the dissemination of research findings, and maintains a website and other electronic information such as blogs, podcasts, and electronic newsletters. The NCIPC website includes a wide variety of information on injury and violence prevention, home and recreational safety, traumatic brain injury, injury data and statistics, motor vehicle safety, and opioid overdose prevention (CDC, 2018). The efforts described on this website help inform the public of the epidemiology of injury and provide resources for professionals. The database of the International Association of Forensic Nurses (http://www.iafn.org) lists over 900 facilities that provide sexual assault services in the United States, Canada, and Australia. Forensic nurse death investigators serve as trainers for the CDC's national Sudden Unexplained Infant Death Investigation program.

HEALTHY PEOPLE 2020 GOALS, PREVENTION, AND FORENSIC NURSING

The *Healthy People 2020* goals that deal with reducing injury and violence in the United States reflect the breadth of concerns and problems that result in injury, both intentional and unintentional, in communities. Objectives related to safety, violence, injury, and sexual assault are incorporated throughout the *Healthy People 2020* document. These objectives relate to injuries that are both intentional and unintentional. The box that follows lists selected objectives related to violence.

HEALTHY PEOPLE 2020

Objectives Pertaining to Injury

The following proposed objectives are examples that pertain to injury and are relevant in forensic nursing:

- **IVP-29:** Reduce homicides.
- **IVP-30:** Reduce firearm-related deaths.
- **IVP-33:** Reduce physical assaults.
- **IVP-34:** Reduce physical fighting among adolescents.
- **IVP-36:** Reduce weapon carrying by adolescents on school property.
- **IVP-40:** Reduce sexual violence (U.S. Department Health and Human Services, 2010).

From U.S Department of Health and Human Services: Healthy People 2020. Available at http://www.healthypeople.gov.

Nurses who work in the area of forensics use all three levels of prevention. For example, forensic nurses (FNs) promote safety in their involvement with projects that aim to prevent domestic violence, sexual assault, child abuse, and accidental injuries before they occur (primary prevention) and in program development and management of care centers. Community awareness of violent crimes is achieved in concert with certain programs and the community-based professionals who work there. Secondary prevention is practiced following the occurrence of injuries and crime. Forensic nurses provide direct care to both victims and perpetrators. Their expertise serves the individual as well as the community in the collection of evidence for the legal justice system. Goals of compassionate holistic care are to minimize the spiritual, psychological, physical, and social trauma, as well as the financial burden. Although the World Health Organization (WHO) guidelines recommend against routine intimate partner screening at all health encounters (WHO, 2013), the 2013 U.S. Preventive Services Task Force recommends, "that clinicians screen women of childbearing age for intimate partner violence such as domestic violence . . . ." (Feder et al., 2013; Moyer, 2013). Worth noting is that the WHO does recommend that health care providers ask about intimate partner violence (IPV) exposure in situations involving injuries or that may have been caused or complicated by IPV. FNs are often the first providers to assess a patient's medical situation and to have contact with victims.

If disability, incarceration, or death occurs, FNs provide tertiary care in settings appropriate to address rehabilitation or identify factors that have put individuals at risk. Evidence should be collected in such a way that the collection itself protects rather than destroys or alters the evidence.

LEVELS OF PREVENTION

Intentional Injury

Primary Prevention
Develop programs that promote safety and avoidance of violence, including both intentional violence and unintentional accidents.

Secondary Prevention
Provide timely, sensitive, direct care to both victims of injury and perpetrators of crime and violent behavior.

Tertiary Prevention
When injury has occurred, refer clients to appropriate community services for appropriate follow-up care and rehabilitation of the effects of trauma.

FORENSIC NURSING AS A SPECIALTY AREA THAT PROVIDES CARE IN THE COMMUNITY

Within communities, the growing prevalence of "criminal and negligence-based trauma" indicates a need for health professionals who can intercede with skills that address social justice as well as care for social offenders (Lynch, 2011, p. 17). Thus forensic nurses respond to sexual assault, drug- and alcohol-related crimes, incidents of human trafficking, elder mistreatment, child abuse, gang violence, as well as mass disaster, automobile crashes, and work-related injuries (Harris, 2013; Scannell et al., 2018). In each situation, forensic nurses look for historical, behavioral, and physical indicators that a crime has been committed and intentional injury has occurred. For example, children who are abused may have cigarette burns, bite marks, pressure sores, and other physical signs that parents may claim to be the result of accidents. Munchausen syndrome by proxy is a form of child abuse in which the primary caregiver induces or fabricates illness or clinical symptoms in a child leading to attention from medical professionals and unnecessary and at times invasive tests and interventions (Squires & Squires, 2013).

A client who is admitted to a hospital with traumatic injuries should be evaluated as to the potentially forensic nature of the injuries (Pasqualone & Michel, 2015; Filmalter, et al, 2018). Additionally, a comprehensive trauma assessment should be done, which can be used to provide teaching, referrals, and access to appropriate resources (Amar, 2016). The response to victims of assault includes a number of steps, as outlined in Box 44.1. The nurse most often comes in contact with police, victims, and perpetrators of violence or crime in the emergency department. The nurse provides a vital link between the investigative process, health care, and the court (Campbell et al., 2012; Malmgren & Leahy, 2016). Nurses should take specific actions when they come in contact with victims to ensure potential evidence is properly preserved, collected, and documented. It is important that evidence be collected in a manner that adheres to legal standards, including chain of custody requirements, in order to establish the reliability and integrity of evidence for use in court cases (Pagliaro, 2013).

BOX 44.1 Emergency Response to Assault Victims

1. Use standardized medical treatment and forensic protocols.
2. Assess for sexual assault using "forced sex" terminology rather than "rape" or "sexual assault," and call a sexual assault nurse examiner if appropriate.
3. Support privacy of assault victim.
4. Explain procedures clearly to the assault victim.
5. Document location, date, and time of assault.
6. Collect evidence in a systematic format; take pictures if necessary.
7. Take care not to destroy evidence while giving care.
8. Maintain chain of evidence.
9. Maintain evidence integrity.
10. Document the following:
    a. Injuries
    b. Emotional state
    c. Medical history
    d. Victim's account of assault
11. Identify and refer to resources that can be used after the assault.

One example of appropriate forensic care is avoid cutting through the bullet hole in the shirt when cutting a shirt off a victim who has been shot in the chest. Rather, it should be cut to the side of the hole to protect the point of origin of the bullet for later criminal investigation. The collection of DNA is a primary function of the forensic nurse and can play a significant role in criminal investigations including sexual assault (Menaker et al., 2017). It is essential that DNA be collected correctly and that elimination samples of DNA be collected from authorized people at the crime scene and from the victim (USDOJ/Office on Violence Against Women, 2013).

The most common types of evidence encountered when conducting a forensic assessment of victims of violence, including those who are raped, are clothing, footwear, bullets, bloodstains, and trace evidence such as hairs, fibers, tissue, and small pieces of metal, glass, paint, wood, or plant material (Pagliaro, 2013). In the investigation of sexual assault, an evidence kit should be used within 72 hours of the assault with specimens collected and preserved according to jurisdictional and state crime lab protocols. Only the victim or a nurse wearing protective gloves should handle the clothing. Throughout the collection process, the nurse should remain sensitive to the psychological trauma that the patient may be experiencing after an assault and maintain objectivity in recording observations and conducting the forensic exam (Jamerson & Turvey, 2014).

Amar et al. (2016) provide a useful guide to assessment of all forms of violence, including child abuse and neglect, elderly abuse, and intimate partner violence. Documentation can include written descriptions, drawings, diagrams, body charts, as well as forensic photography (Cabelus & Spangler, 2013). Written forms of documentation should be as factual, complete, and prompt as possible, avoiding the use of jargon, abbreviations, and unclear statements. Digital imaging is the most common way to take the necessary photographs. The photographs should be taken in context, using the "rule of three" guideline to capture the overall scene, a medium-range shot, and a close-up shot of the injury or potential piece of evidence (Zercie & Penders, 2013). Injuries should also be depicted on diagrams and recorded in the nurses' notes. The How To box describes how to label photographs taken after the injury.

HOW TO Label Photos

All photos should be clearly labeled with the following information:

- Client's name
- Client's medical identification number
- Client's date of birth
- The date and time of the photograph
- The name of the photographer
- The body location of the injury
- The forensic case number

From Sheridan, DJ: Legal and forensic nursing responses to family violence in Humphrey J, Campbell JC, editors: Family violence and nursing practice, Philadelphia, 2004, Lippincott Williams & Wilkins.

Forensic nurses may have expertise in alternative specialties that are combined to serve special populations. Advanced practice nurses (APNs) such as psychiatric, pediatric, geriatric, and acute care nurse practitioners bring to forensic nursing skills that allow them to provide advanced assessment and prescription of medications and treatments needed by forensic clients. Notably, forensic psychiatric nurses treat both victims of post-traumatic stress disorder and seriously emotionally disturbed clients incarcerated for violent crimes. APNs in correctional facilities may identify themselves as forensic nurses when they manage acute and chronic illness, promote wellness, and work within these systems to develop policies around legal and ethical issues.

The specialty also incorporates three subspecialties of nursing practice within the criminal justice system: forensic nurse, nurse attorney, and legal nurse consultant. Forensic nurses employed in the criminal justice arena generally provide care to individuals who are either victims of injury or perpetrators of a crime that is under investigation. **Legal nurse consultants** provide expert consultation regarding health care to attorneys in either civil or criminal court cases but do not render direct client care in that setting. Some of these situations might include medical malpractice, personal injury, workers' compensation, and probate. Nurse attorneys hold a license to practice law from a state bar association in addition to a nursing license and generally use their nursing knowledge for adjudication. **Adjudication** refers to a judicial decision or a sentence.

Finally, forensic nurses are advocates for programs that prevent injuries, which occur as a result of both intentional injury and health hazards related to environments that create injury. Relying on an understanding of epidemiology, these nurses have knowledge of occurrence as well as the mechanisms of injury in a community. Forensic nurses partner with public health professionals, including nurses, to design, implement, and evaluate projects and programs that have a forensic focus.

History of Forensic Nursing

Early writings about the evolution of modern nursing, particularly with regard to care given to victims of war, mental illness, and abuse, lay a foundation for the advent of forensic nurses in the twentieth century (Nutting & Dock, 1907). Chapter 2 discusses the history of public health nursing; this section emphasizes nursing history's linkages to forensic nursing. With public health nurses, forensic nurses celebrate the early pioneers working in communities that brought medical care to the most vulnerable and marginalized. They worked to develop national and international organizations such as the National Organization for Public Health Nursing (1912), National Society of Nurses (later the American Nurses Association [ANA], 1912), the International Congress of Nursing (1912), and the WHO (1948). These organizations were designed to give structure and standards for care and education regarding issues of violence and neglect. These issues pertain to public health, mental health, and forensic nurses who are experts in dealing with the effects of trauma, and who advocate for care of the wounded, both physically and emotionally.

Contemporary practice of forensic nursing in the United States was largely propelled by early efforts to identify and prevent child abuse and neglect and sexual assault of women. In the 1940s through the 1960s, radiologists identified fractures that they linked to assault and pediatricians began describing indicators of "battered child syndrome" (Crane, 2015). Subsequently, nurses became aware of their role in identifying

indicators of assault. In emergency departments, forensic nurses assisted in "rape" kit collection. The nurses showed compassion and competence in preserving crucial evidence and had a strong understanding of the "rape trauma syndrome" first described by Burgess in 1973. Burgess and other advanced practice nurses initiated previously undescribed care with forensic clients. The first nurse-run sexual assault clinics opened in Memphis and Minneapolis in 1974 (Speck, n.d.) with subsequent development of the first protocols for sexual assault care (Ledray, 1998). In 1985, the U.S. Surgeon General identified violence as a health care issue, and health care providers such as nurses working with victims and perpetrators of crimes, as key agents in ameliorating the effects of violence in our communities (USDHHS, HRSA, 1986). In 1990 Virginia Lynch published her dissertation on the role description and Integrated Practice Model of Forensic Nursing care of both living and deceased victims of trauma and perpetrators of crime (Lynch, 1990). By 1992, The Joint Commission began to require hospitals to develop protocols for the treatment of victims of sexual assault. At the present time, most victims of sexual assault go to emergency departments. The lack of availability of trained providers and recognition of the need for uniformity in collection and processing of evidence spurred the development of SANE programs (Simmons, 2014).

Today, the Integrated Practice Model of Forensic Nursing Science is recognized internationally as the basis for practice as well as education of forensic nurses. Following efforts to describe the unique contribution of forensic nursing (Lynch, 1986), the specialty was recognized by the American Academy of Forensic Science in 1991. The following year SANEs from the United States and Canada established the International Association of Forensic Nurses (IAFN). In 1995, the ANA designated forensic nursing as a specialty, and it is now recognized as one of the fastest growing specialties in nursing. IAFN boasts a membership of over 3700 nurses worldwide and has members in 27 countries (IAFN, 2018).

Educational Preparation

Historically, forensic nurses refined and developed their forensic skills through clinical practice and continuing education. Today, there are three primary routes for training in forensic nursing. First, nurses can gain additional skills and knowledge through continuing education courses or basic concepts introduced in generalist education. Second, certificate programs include specific content and entrance requirements, and many have clinical opportunities. Third, graduate nursing academic programs are offering minors or concentrations in forensic nursing.

Formal graduate course work on forensic nursing began at the University of Texas, Arlington, in 1986. To begin a specialty by starting with graduate preparation is both uncommon and courageous; more often content is introduced in the undergraduate studies, and graduate study assists in refining and developing the content until it is formalized in courses and majors. By 2000 there were 12 graduate programs preparing clinical nurse specialists and nurse practitioners with a focus on forensic nursing. The development of the scope and standards of practice and a core curriculum for graduate study in 2004 facilitated the development of new programs of study and formed the basis for advanced practice credentialing of students and practicing clinicians. A forensic focus in research became more prevalent in both master's and doctoral studies, which facilitated the opening of the first doctor of nursing practice (DNP) program focused on forensic nursing in 2002 at the University of Tennessee Health Science Center in Memphis. Now, new DNP programs are opening based on this model of advanced nursing practice.

The inclusion of forensic nursing content into undergraduate generalist education remains controversial. The American Association of Nurse Attorneys (TAANA) and the IAFN have recommended coursework regarding public and private legal proceedings. Students need to develop a working understanding of laws and procedures applicable to nursing practice and certain client situations, such as mandated reporting of child abuse (IAFN, 2017). In addition, nurses are prepared to care for families experiencing trauma. Many educators in the United States believe the complexity of forensic content has evolved so that the skills and competencies required to differentiate the specialty are not appropriate in a generalist educational curriculum.

Theoretical Foundations of Forensic Nursing

Humans seek stability; they seek safety from physical trauma and emotional wounding from violent relationships; and they seek protection of their finances and freedom from fears that threaten their very understanding of human existence. Theories that contribute to our understanding of what constitutes safety and well-being have been extrapolated from a variety of sources outside of nursing. Maslow, an American psychologist, developed a hierarchy of needs and desires that are seen as influencing the development of an individual toward high levels of "self-actualization" and satisfaction (Maslow, 1943). Nursing has embraced his conceptualization of the hierarchy of human need attainment. Specifically, for this chapter, it is important to consider the need for safety and the desire for security that may be threatened by injury.

In examining methods to identify the risk of injury, William Haddon, a physician and expert on automobile injury, developed a matrix that looks at factors related to personal attributes, vector or agent attributes, and environmental attributes before, during, and after an injury or death. He demonstrated that by using this framework, a person can evaluate the relative importance of different factors and design interventions (Haddon, 1972; O'Neill, 2002). Subsequently, community-based nurses such as those who work in public health and forensic nursing and, increasingly, hospital-based nurses have used the matrix to develop programs to prevent a wide variety of injuries, including burns, falls, firearm injuries, and, most recently, critical incidents from medical error.

More recently, forensic science has informed and continues to inform forensic nursing practice. This is particularly true in terms of the intricacies of evidence collection and the growing body of knowledge within criminalistics (James & Nordby, 2014). In addition, the influence of law, including structure of

the court system, federal rules of evidence, principles of witness testimony, expert opinions, and rights of citizens, has shaped the unique body of knowledge that guides the specialty from outside of nursing. Criminal justice principles and law inform practice and form the boundaries of many aspects of practice such as client consent, rules of evidence, and expert courtroom testimony.

Professional organizations outside of nursing that address large-scale health concerns such as the CDC and the WHO have contributed to nursing's understanding of injury. At the turn of the twenty-first century these organizations began a global campaign toward violence prevention that had a tremendous influence on developing a primary prevention approach within the forensic community (WHO, 2014, 2015, 2016). For example, in 2002, the CDC Injury Center developed a state-based surveillance system, the National Violent Death Reporting System (NVDRS), that compiles data on violent deaths from multiple sources. It includes all types of homicides and suicides, including child maltreatment fatalities, intimate partner homicides, deaths of law enforcement occurring in the line of duty, unintentional firearm injury deaths, and deaths of undetermined intent (CDC, 2017). Subsequently, a task force was formed to uniformly prepare individuals to conduct sudden unexplained infant death investigations. Forensic nurses practicing as death investigators served in the development of training programs that are now used nationwide. Today, the NVDRS operates in 40 states, the District of Columbia, and Puerto Rico. The system is designed to provide states and agencies with valuable data that can be used to make decisions about violence intervention and prevention activities within their communities (CDC, 2017).

In nursing, the conceptualizations that have contributed the most to forensic nursing include holism through caring; ways of knowing, including intuition and suspicion; human reaction to trauma, including the rape trauma syndrome; and models specific to forensic nursing. Hammer et al. (2013) examined the connection between the construct of caring and the unique relationship between forensic nurses and their clients. Although caring was previously recognized as the "hallmark of professional nursing" by theorists in the 1980s, Hammer et al. recognized that part of what makes forensic nursing a specialty is the manner in which caring is translated.

The caring component addresses caring for both clients and for one's self. A sense of self-worth must be cultivated and nurtured to the degree that caring is conscientious, objective, and demanding of the scientific truth. Caring must also be curious and questioning; it should be directed toward colleagues, and finally, caring should be about firm and valued concepts that inform practice (Hammer et al., 2013).

In that regard, questioning and ways of knowing, particularly intuition, are viewed as vital for a successful practice. Winfrey and Smith (1999) have described the concept of knowing as, more accurately, being suspicious in forensic nursing. Questioning also led to a greater understanding of what most would consider the unexplainable and the unimaginable: the manifestations of rape trauma syndrome (Burgess & Holmstrom, 1974), behaviors of the seriously emotionally disturbed offender (Mason & Mercer, 1998), and widespread occurrence of intimate partner violence (Campbell & Humphreys, 2011). Lynch's Integrated Practice Model of Forensic Nursing Science, as previously discussed, depicts the biopsychosocial and spiritual dimensions of nursing care with the legal expertise needed when trauma results in court-related issues. Lynch and Duval (2011) have credited several nursing theorists—including Paterson and Zderad; Conway and Hardy; Leininger, Giger, and Davidhizar; Chinn and Kramer; and Brenner—in the development of forensic nursing theory and practice. Subsequent to Lynch's efforts, Hufft (2013) described forensic nursing within the domains of nursing and delineated the theoretical foundations for advanced forensic practice. Together, these role descriptions have informed the scope and standards of practice of the forensic nurse as well as the subroles within the specialty. Knowledge, observation, and intuition are aspects of all types of forensic nursing.

Key Concepts in Forensic Nursing

The core concepts or conceptual metaphors that underlie forensic and other nursing models are not unique to nursing. Concepts when applied to the nursing process guide knowledge, skills, and attitudes found in practice. Concepts in forensic nursing theory include, but are not confined to, safety, injury, presence, perceptivity, victimization, truth, and justice.

Safety is among the five basic needs of humans identified by Maslow in his theory of self-actualization (Maslow, 1943). Maslow describes the first basic need as meeting one's physiological needs. This need is followed by safety needs, which can be affected by levels of security. The need for safety can become acute during periods of emergent trauma or chronic during periods of collective violence or chronic abuse. Until an individual is safe and wounding has healed, he or she cannot move on to higher levels of understanding and satisfaction.

Injury involves trauma or damage that is physiological, emotional, financial, spiritual, intellectual, and societal. Injury may be intentional, often known as violence, or may be unintentional. The cause may be a single source or multifaceted; it may be of human etiology or of natural causes. Making the distinction between the causes of injury is key to forensic practice. **Justice** is the concept of moral rightness based on ethics, rationality, law, natural law, fairness, and equity. As such, justice is viewed in the context of bioethics of the health care professions and the prevailing law of a particular society and culture. Therefore the fact that justice is an important goal in forensic nursing care must be viewed in the context of the environment in which the care is given.

Presence is used by nurses as a part of the humane, holistic approach to both victims of trauma and perpetrators of crime. Lynch (2011) has defined presence as "the invisible quality that commands and comforts while directing attention away from one's self and into the being of another, instilling confidence and respect in the self of that being" (p. 12).

Perceptivity, as an element of intuitiveness, is one tool the forensic nurse uses to investigate injury. Perceptivity involves an increased awareness of human behavior and environment that is interpreted by knowledge and lived experience in making expert decisions.

Truth is conceptualized as an agreement with fact or reality but also reflects characteristics such as honesty and sincerity on the part of the truth teller. Conceptualization of truth is influenced by philosophies that view it as subjective, objective, relative, or absolute. Forensic nurses hold the ideal that the results of scientific inquiry form the basis for their interactions with clients, health care systems, and the judicial system, which interact with their care; they are not influenced by personal bias or outside influence.

Victimization occurs when individuals or groups are exploited or treated unfairly, generally when there is an imbalance of power. The harm may be systematic when groups are mistreated or witness violence or it may be the result of individual attacks. Psychological responses to victimization include heightened feelings of vulnerability, depression, and anger. Juxtaposed to victimization is client empowerment, often through advocacy.

Scope and Standards of Practice

The scope and standards of practice for forensic nursing that identify the "expectations for the role and practice of the forensic nurse" were first published in 1997 and updated in 2009. The standards are delineated in each of the recognized areas: Scientific Process, Quality of Practice, Education, Professional Practice, Evaluation, Collaboration, Ethics, Research, Resource Utilization, and Leadership. Although each of these parameters helps differentiate forensic nursing from other specialties (ANA, 2017), competencies related to the scientific process, or nursing process, are perhaps the most indicative of the specialized nature of the specialty. For example:

- Assessment includes the collection of forensic data, which may involve interviewing the client for evidentiary purposes, reviewing medical legal documents, and collecting trace evidence to be used in a criminal investigation.
- Formulating a diagnosis or impression regarding the differentiation of intentional and unintentional injury is a skill that involves a unique understanding of mechanisms of injury and correlation of this with the history of the event. The impression of the forensic clinician has extraordinary legal implications beyond the realm of the health-related diagnosis.
- The identification of realistic outcomes of care is most commonly performed in collaboration with a team that frequently consists of professionals outside of nursing, including law enforcement, criminal justice, community advocates, and social service agencies. Care may reflect a decision that is humane and ensures community safety, but may not necessarily be reflective of the client's wishes.
- Formulation of the care plan involves collaboration with a team and should support the integration of clinical, human, social, and financial resources with medical-legal parameters to complete the decision-making processes.
- Implementation of the plan involves skills and techniques that are derived from sound evidence related to the applied science of both nursing and forensics. Current knowledge of both is mandated.
- Coordination of care relevant to forensic outcomes often involves including education and other strategies to prevent injuries well after the occurrence, perhaps after the death of an individual who has been injured.
- Evaluation of outcomes, particularly when viewed in aggregate, may involve dissemination of the results not only to the client and others involved in the care or situation but also to local, national, and international agencies as appropriate, for the development of laws and regulations to protect individuals in a community.

LINKING CONTENT TO PRACTICE

This chapter discusses the role of forensic nurses in the prevention and treatment of victims of violence. In addition to using the ANA competencies for practice, the forensic nurse includes the public health competencies as described in the Council on Linkages Domains and Core Competencies (2014). For example, the analytic/assessment skills that discuss assessment, data collection, and use of ethical principles are integral to this nursing role. In regard to applying ethical principles, the nurse would use them in the collection, maintenance, use, and dissemination of data and information. Clearly this skill is a part of forensic nursing.

CURRENT PERSPECTIVES

Evidence-Based Practice and Research

Evaluation of competency is required of all professions. Evaluation of nurses begins in school and continues through testing for entry-level licensure, certification examination, peer review, and personal reflection. Reflection should be on practice as well as during practice. As part of professional expectations and standards, forensic nurses are encouraged to participate in continuous quality improvement using the best evidence for practice or promising practice methods under evaluation (Meunier-Sham et al., 2013). Scientific research in forensic nursing is in its infancy. Although a large majority of the published research consists of descriptive studies of the forensic nursing role and the client populations (Orr, 2016; Valentine, 2014), there are a growing number of studies examining forensic practice and outcomes. For example, research on sexual assault response teams supports the use of these approaches to practice and recommends outcome measurement of both short-term outcomes such as client satisfaction and long-term outcomes such as prosecution rates (Campbell et al., 2014; DuMont et al., 2014). Studies in collaboration with other disciplines are currently under way to test the basis for distinctions among injuries such as bruising (Lombardi et al., 2015; Pollitt et al., 2016). Forensic nurses are producing valuable information regarding DNA sampling (Eldredge et al., 2012). Scholarly contributions to forensic nursing practice have increased since professional journals such as the *Journal of Forensic Nursing* have increased publication of forensic specific content. The following Evidence-Based Practice example describes the ways in which DNA evidence can be accurately obtained.

EVIDENCE-BASED PRACTICE

An essential step in a forensic evaluation following an alleged sexual assault is the collection of trace evidence including DNA. In addition to the history of the assault, alternative light sources (ALSs) have been used to assist examiners in identifying areas of potential DNA evidence. A common ALS used is the Wood's lamp. The goal of this project was to determine the best practice using an ALS to aid in the identification of trace DNA evidence in sexual assault forensic exams.

The authors reviewed the limited data available on this topic (seven studies) and concluded that the Wood's lamp should no longer be used as the ALS. However, ALS with wavelengths able to detect DNA should be used. Most importantly, examiners must be educated about the advantages and disadvantages and proper use of ALS. Further research is necessary on the use of ALS in forensic evaluations along with development of new techniques to assist in identification of semen in forensic exams.

Nurse Use

SANEs play a key role in providing care for victims of sexual assault. The training to become a SANE is specialized and growing in importance and the recognition of its value to victims, their families, and the criminal justice system (IAFN, 2014). Evidence-based practice ensures patients receive the highest quality of care supported by research.

SANE, Sexual assault nurse examiner.
Data from Eldredge K, Huggins E, Pugh LC: Alternate light sources in sexual assault examinations: an evidence-based practice project. *J Forensic Nurs* 8:39-44, 2012.

Certification

The scope and standards of forensic nursing practice have been used for the development of the certification examination and other credentials that are intended to demonstrate competence of the practitioner. Credentialing within forensic nursing, as with all new professional specialties, has become an increasingly important issue. Different types of credentials pertain to nursing, both within and outside the discipline. While all nurses should have an understanding of credentialing and the implications and responsibilities that accompany such a designation, it is uniquely important for FNs who maintain close relationships to both the medical and the legal communities. FNs provide care when health and the law intersect and must therefore have credentials that speak to their unique qualifications to give that specialized care (Pasqualone, 2015).

Certification examination for pediatric (SANE-P) and adolescent/adult sexual assault nurse examiners (SANE-A) is available through the International Association of Forensic Nurses. This certification along with the Legal Nurse Consultant, Corrections Nurse, Death Investigator, and Forensic Examiner are offered by other organizations to registered nurses meeting entry criteria and generally do not require a graduate degree. Forensic Nurse Examiners are most often referred to as Forensic Examiners, Medicolegal Death Investigators and Coroners, Sexual Assault Nurse Examiners, or Advanced Forensic Nurses. Advanced forensic nurse certification (AFN-BC) previously offered by the American Nurses Credentialing Center through the portfolio review method was discontinued in 2017. Graduate and undergraduate certificate programs in forensic nursing are offered at various universities as well as the American Institute of Health Care Professionals, but currently there is not a profession-wide standard certification.

ETHICAL ISSUES

Ethical considerations in the practice of forensic nursing are unique because of the implications to not only a client's health but, in some cases, his or her freedom. Practice outcomes affect individuals and families, as well as communities and society as a whole. Ethics and law are closely tied but are not equivalent. Ethical nursing practice involves adherence to law in most cases, but also to the ethics of nursing and the dictates of one's conscience (Constantino et al., 2013). Nurses maintain a different code of conduct than do other professionals. For example, law enforcement personnel answer singly to the law for their standard. Knowledge and understanding of these considerations is core to the specialty of forensic nursing (International Association of Forensic Nurses Ethics Committee, 2008).

Olsen (2013) organized ethical principles into five categories: respect for person, beneficence, distributive justice, respect for community, and contextual caring. Each of these categories reflects examples of the tension that may arise when the forensic nurse faces a dilemma imposed by conflicting interests. An overriding consideration is the need to respect each person and to develop contextual caring within the art of nursing. Respect for person means respect for autonomy while protecting vulnerable persons. The right of each human to self-determination is recognized within nursing but may not be respected by all societies. Therefore respect for human rights may involve advocacy to some degree. Laws, cultural norms, and considerations of safety, which limit the liberty of an individual, may constrain the nurse's ability to fully exercise a therapeutic relationship. Questions raised pose dilemmas in a variety of medical and psychiatric settings.

Forensic environments include courtrooms, jails, prisons, and psychiatric facilities for the criminally insane. When criminal action or trauma to an individual requires care, the need for coercion is likely. Certain situations may make medical coercion necessary. These situations include incapacity (or inability) to make decisions and making decisions that could result in harm to self or harm to others in the absence of interventions. Paternalism has been defined as "the principle that allows one person to make decisions for another" (Williams, 2007, p. 93). This may be necessary in the case of minors or older adults. Paternalistic intervention was viewed by the U.S. Supreme Court as lawful in the case of *Washington v Harper* (1990), when it ruled that mentally ill inmates could be compelled to take psychotropic medications against their will if the mental disorder is serious, the inmate is dangerous to himself, and the medication prescribed is in the inmate's best medical interest. Therefore the ability of a psychiatric forensic nurse practicing in an advanced role to make a determination of rational autonomy is crucial in questions of coercion: to make judgments without being judgmental (Martin et al., 2013).

Beneficence (care) and the complementary principle of nonmaleficence (without harm) go beyond autonomy in the

responsibility of the nurse not only to support an individual's choices but to perform actions that enhance the health of others. Nurses provide care without prejudice of the circumstance or individual characteristics. They provide care to the injured, marginalized, and poor whether the individuals are victims or offenders. Nurses who care for pregnant teens in a youth facility or collect evidence from drug addicts each hold the same ethical responsibility as described previously (Dhaliwal & Hirst, 2016; Ferszt et al., 2013). Questions may arise when the resources to achieve adequate health are not plentiful enough for all to receive adequate care. When economic restraints limit funds to process sexual assault evidentiary kits, treat victims of assault, and provide dental care to methamphetamine addicts in prison, where should the funds be applied? Principles of distributive justice address such questions in deciding what goods will be distributed to which persons in what proportions. Forensic nurses may find themselves in a policy-making position to answer such questions to ensure that their clients, given similar circumstances, are treated no better or worse than others in the application of protection and medical care. Also, when there are questions of retribution, whether withholding provisions or threatening harm, forensic nurses never participate in the punishment, however subtle, of another being.

Ethical decisions can be exceedingly difficult when the safety of a society is at risk. One approach to making decisions with respect for the community is utilitarianism, which appeals exclusively to outcomes or consequences in determining which choice to make. Williams (2009) explains:

> *Utilitarianism, with its mandate for the general good, rather than a specific interest, would place the safety of the community above the rights of any one individual. The forensic nurse expert, hired by the court to evaluate a client, as an example, testifies on behalf of society, not the individual. To that end, it may be argued that the nurse expert uses a utilitarian perspective that may not serve the interests of the client but instead, serves the interests of society. Traditional nursing mandates that the correct focus (and therefore the right moral choice) be placed on the individual. However, the burden of responsibility often shifts in forensic nursing from the individual to the community, a correct moral choice under utilitarianism (p. 50).*

During a forensic examination, the potential exists for withholding vital information in the investigation of wrongdoing. The temptation to "assist" the perceived victim's case may be justified by a desired outcome for that individual as well as the ultimate safety of a community. This dilemma of information can be carried to situations of privacy protection. The entitlement to privacy may be changed when someone's safety is at stake. If a specimen for DNA is collected during the investigation of a crime, should that information remain in the Combined DNA Index System (CODIS) for use in future crimes, regardless of the outcome of prosecution of that case and when there is the potential for repeat offense (Williams & Wienroth, 2017)? Do hospitals have the right to videotape parents who are suspected of Munchausen syndrome, or is this a violation of Fourth Amendment rights (Morrison, 1999)? When victims give information to sexual assault examiners, are they informed that records may be released to law enforcement and attorneys? Should they consent to the release of photographs that depict intimate areas of their body for anyone in law enforcement, attorneys, and juries to see, even in the name of full disclosure (Ledray, 2008)?

Finally, there are always questions regarding the relationship between forensic clients and nurses. Caring is the essence and core value of nursing (Watson, 2008). Olsen (2013) recognized that caring as well as ethics is influenced by the context of relationships and that nurses' "emotion is inextricably bound to moral good" (p. 51). Contextual caring is not synonymous with beneficence but "entreats the forensic nurse to interact with each client, whether criminal or victim, as a person within an ethical relationship of caring concern grounded in the nurse's personal values" (Olsen, 2013, p. 51). The care goes beyond the "obligatory dictates" of client rights. Unique problems are posed when the client is in denial about the role he or she plays in the problem or poses a safety risk to the nurse. In addition, forensic nurses must overcome the societal bias of establishing relationships with individuals believed to have injured another, perhaps intentionally. Finally, when personal bias or issues of conscience impair the ability to prescribe or participate in particular medical interventions, objections may be raised. Examples of situations at risk for bias in forensics include collection of trace evidence from individuals who have impaired consciousness or are coerced into consent (Constantino, et al., 2014), prescription of birth control following sexual assault, participation in capital punishment, and the use of unnecessary physical or medical restraint. Nurses and other health care professionals have well-established codes of ethics and other examined statements to guide practice and inform care (ANA, 2015; IAFN, 2008; Martin et al., 2013). It is imperative to view these statements that guide practice as a basis for conduct as well as for reflective dialogue in real client situations.

CHECK YOUR PRACICE

A mother and her seven- year -old son come to the clinic for a routine check up and for immunizations. While examining the boy, the nurse notices that he has several scratches and bruises on his upper thighs and genital area. The mother avoids eye contact with the nurse during the examination.

What actions should the nurse take?

The following two case studies demonstrate some of the aspects of forensic nursing care.

Case #1: Tamara Lynch is a six-year-old child who lives in a busy household of four children, her grandmother, mother, and stepfather. She is a client of the local pediatric clinic and has an appointment today for a school-related examination. She has been very interested in school in the past but recently her grades have declined and her mother describes her behavior as withdrawn. Shirley Meres is the pediatric nurse practitioner who has seen Tamara for her most recent health care. She too has noted the change in Tamara's affect. Based on the health history, Ms. Meres uses

CHECK YOUR PRACICE—cont'd

developmentally appropriate questions to ask Tamara about situations in which she may not feel safe or situations with adults that have made her feel uncomfortable about her body. Tamara describes repeated episodes with her stepfather during which she was inappropriately touched and fondled. The nurse meets with Tamara's mother and explains her role as a forensic nurse. She explains that Tamara will need a specialized physical examination with collection of evidence, including laboratory specimens and photographs. After obtaining permission from the mother, the evaluation is performed using enhanced lighting and visualization equipment to collect photographic evidence, and body fluids for diagnostic and forensic testing. The nurse tells Tamara and her mother that the examination is normal for her age; no indications of trauma are noted. All evidence is packed for preservation according to crime lab protocols. Following the interview and examination, Ms. Meres counsels the child and mother about predictable psychological reactions to child sexual assault and disclosure even though no evidence of abuse was found in the nurse's examination. The mother is given information on advocacy, the legal process that follows a report to law enforcement agencies, and mental health counseling that is available locally. Tamara is given an appointment at the clinic in two weeks. The nurse makes contact with law enforcement to report the child's disclosure and make arrangements for transfer of all evidence. Ms. Meres continues to follow the health care of the family in the months to follow for evaluation and prevention of common problems that present to families who experience child abuse.

Case #2: Mike Post is an 18-year-old male who is taken to the emergency department by ambulance for what appeared to be a motor vehicle collision. His condition is considered serious. Following resuscitative measures, he is pronounced dead. Staff members at the emergency department contact the medical examiner's office to report the death. Sean Miller is the forensic nurse investigator on duty who receives the call. When Mr. Miller arrives at the emergency department, he interviews paramedics and emergency department clinicians about the accident site and the appearance of the decedent on arrival. He photographs the body, clothing, and other sources of trace evidence, including items in the decedent's pockets. Mr. Miller performs a thorough examination of Mike Post and discovers a small bullet hole in the left postauricular tissue. All items are individually bagged, sealed, and labeled for further analysis by the crime laboratory. The nurse then meets with the family to explain the need for investigation of all sudden, unexpected deaths. He describes the process involved in the investigation and preparation of the body prior to transfer to a funeral home. Copies of the medical record and x-rays obtained at the facility are transported with the body for autopsy. Mr. Miller reports his findings to the forensic pathology team and law enforcement officers. The autopsy is performed and the ballistics analysis of the recovered bullet leads to the arrest of the alleged assailant. When the case goes to court, the nurse is subpoenaed to testify about the investigation and collection of evidence. The nurse maintains contact with the family to keep them informed of the progress of the case and the resources for legal and family grief counseling available in their community. See the Quality and Safety in Nursing Education box that follows to learn ways in which nurses partner with families to coordinate care.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Quality and Safety Focus

Targeted Competency: Client-Centered Care

Recognize the client or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for client's preferences, values, and needs.

Important aspects of client-centered care include:

- **Knowledge:** Describe strategies to empower clients or families in all aspects of the health care process.
- **Skills:** Assess level of client's decisional conflict and provide access to resources.
- **Attitudes:** Value active partnership with clients or designated surrogates in planning, implementation, and evaluation of care.

Client-Centered Care Question

You are an RN at a correctional facility, where system-focused updates have recently been implemented to ensure provider safety. A metal detector has been implemented that all inmates must pass through before entering the clinic. A standardized frisk procedure has also been implemented. The presence of a security guard has been standardized for all clinic visits. The clinic environment has been modified so that all sharp objects or potentially dangerous objects have been locked up. Extra surveillance cameras have been added to each clinical examination room, and panic buttons have been added as extra security for providers in each exam room.

- Which system updates might impact patients' experience of care?
- Amidst all of the identified heightened security approaches, how do you communicate client-centered care to your clients?
- How do you address client safety in this new environment?
- How do you protect client confidentiality and privacy in this new environment?

RN, Registered nurse.

Prepared by Gail Armstrong, PhD, DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing.

FUTURE PERSPECTIVES

Forensic nursing is predominantly a community-oriented specialty. Practice arenas are associated with health care facilities such as private clinics and emergency departments, criminal justice centers for victims of crime, medical examiner offices, police departments, correctional facilities, and mental health centers. What is consistent in each of these practice sites is the care of individuals who have experienced the effects of injury, either intentional or unintentional. Increasingly it is being recognized that hospitals need forensic nursing services. Clients routinely enter hospitals with conditions that have overlying legal implications (Amar, 2016). In addition, injuries occur as a result of medical incidents

and errors. Forensic nurses use their expert understanding of cause and effects of trauma and are in a position to investigate the circumstances in order to design a plan of care for individual as well as special groups of clients. They serve as a liaison between the hospital and the medical-legal community to reduce the effects of trauma.

PRACTICE APPLICATION

A 26-year-old woman arrived unaccompanied to the emergency department of an academic medical center with cuts on her face, hands, legs, and pelvic area. She was crying and said that she had been attacked and was afraid to have an examination or to provide the name of her attacker. What is the first action that the nurse should take?

A. Explain to her the importance of reporting this crime immediately.
B. Listen closely to her and reflect back to her the fear, anger, and other feelings you hear in her voice.
C. Immediately call law enforcement officials yourself.

Once you select the first action that you would take, explain your rationale and outline your exact actions.

Answers can be found on the Evolve site.

KEY POINTS

- Forensic nursing is a community-oriented specialty that addresses the prevention and treatment of accidental injury and violent crimes.
- The specialty reflects an integration of nursing, forensic science, and the law.
- Forensic nursing is needed whenever injury has legal implications.
- Forensic nurses need to maintain objectivity in rendering care to both victims of injury and perpetrators of crime.
- The scope and standards of forensic nursing practice guides forensic nurses with unique skills of the specialties such as expert courtroom testimony and documentation and security of evidence.
- Forensic nurses work in cooperation with public health professionals, including nurses, in developing programs of prevention such as automobile safety and intimate partner violence prevention.
- Educational programs for forensic nurses are offered through continuing education offerings and formal graduate degree programs.
- Credentialing for forensic nurses include pediatric and adolescent/adult sexual assault nurse examiners (SANE-A and SANE-P).

CLINICAL DECISION-MAKING ACTIVITIES

1. Think about injuries you have experienced and answer the following questions:
   A. How did the injury affect my ability to perform normal activities of my daily routine?
   B. What injury patterns did I have that would lead me to conclude it was violent or accidental?
   C. What could I have done to prevent the injury from occurring?
2. Discuss the effects of violence in your community with a fellow student. What situations exist that increase the risk that someone will be assaulted?
3. Write a list of the types of evidence that can be collected at a crime scene or in an emergency department based on a scenario of crime involving a young woman who is the victim of sexual assault.
4. In a short paragraph, explore how you might feel toward someone who commits a crime and needs nursing care. What ethical standards of nursing will influence your treatment of this individual?

The Nurse in the Faith Community

Lisa M. Zerull, PhD, RN-BC

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Define faith community nursing and holistic health promotion.
2. Differentiate between spirituality and religiosity.
3. Examine the historical roots of faith community nursing.
4. Discuss scope and standards of practice for faith community nursing.
5. Develop awareness of the nurse's role within faith communities for spiritual care, health promotion, and disease prevention.
6. Apply the nursing process in a faith community to assess, implement, and evaluate programs for healthy congregations using *Healthy People 2020* leading health indicators.

CHAPTER OUTLINE

Perspectives on Faith Community Nursing
History of Faith Community Nursing
Rationale for Faith Community Nursing as a Viable Community Health Model
Definitions in Faith Community Nursing
Faith Community Nursing Practice
Issues in Faith Community Nursing Practice
National Health Objectives and Faith Communities
Conclusion

PERSPECTIVES ON FAITH COMMUNITY NURSING

With increased incidence of chronic diseases such as hypertension and diabetes along with health concerns of obesity, substance abuse, and depression, there is a need for creative wellness initiatives in the community. One such community setting of care is the congregation or faith community as an ideal location for screening, education, and compassionate support. It is in this setting where wellness promotion efforts focus on much more than the physical needs of individuals. Rather, nursing care out of the congregation provides a comprehensive whole person approach involving care of the physical, emotional and spiritual. Faith community nurses have the knowledge, skills, and experience to offer whole person care to the wide array of persons across the life span who gather together for the purpose of worship, fellowship, and participating in specific rituals of faith.

Faith community nursing, previously call **parish nursing**, is a recognized nursing specialty practice, yet is frequently overlooked when creative strategies are needed for improving the health of individuals and the larger community. Not surprising when only 11.7 percent of nurses reported receiving adequate spiritual care training as part of their nursing education, yet 92.4 percent of nurses feel strongly that spiritual care is a legitimate part of the profession (Delgado, 2015). Nurses often confuse religious practice or religiosity with spirituality and may neglect patients' spiritual needs (O'Brien, 2017). Whereas **religiosity** relates to "a person's beliefs and behaviors associated with a specific religious tradition or denomination" (O'Brien, 2017), **spirituality** is "an individual's attitudes and beliefs related to transcendence (God) or to the nonmaterial forces of life and nature" (O'Brien, 2017). Thus additional education in spiritual care is needed to distinguish between the two and to provide an understanding of faith community nursing (Delgado, 2015).

Registered nurses working out of a faith community or congregation establish close relationships with individuals, families, and often, the larger community to coordinate programs and services that significantly affect health, healing, and wholeness (ANA/HMA, 2017; Butler & Diaz, 2017; Callaghan, 2016; Gotwals, 2016, 2018; Laming & Stewart, 2016; Young, 2016; Ziebarth, 2015, 2016). Faith community nurses balance knowledge and skill in their role to facilitate the faith community as it becomes a caring place—a place that is a source of health and **healing** for its members. Many nurses are drawn to faith community nursing because it encourages the expression of spirituality as a part of health and healing. Others are drawn to this specialty practice out of vocational calling (O'Brien, 2017).

Faith community nurses address health concerns of individuals, families, and groups of all ages (Callaghan, 2015). Like other communities, the members of faith communities experience birth and death; acute and chronic illness; growth and development; stress or dependency concerns; challenges from life transitions; and decisions regarding healthy lifestyle choices. Serving as good stewards of resources, faith community nurses encourage partnering with community health agencies as well as lay and professional church leaders to arrive at creative responses to health issues and to develop health-promoting and spiritually healing activities. The nurse serves the faith community by focusing on the needs of the individual parishioner and the overall faith community with special attention given to spiritual care support.

HISTORY OF FAITH COMMUNITY NURSING

Faith community nursing has its historical roots in the Judeo-Christian tradition with early Biblical references to women providing care to the sick and persons in need. For centuries, Catholic Sisters and Protestant women specialty trained as nurses have promoted health and cared for the sick, the poor, the fallen, and the unbelieving (Doyle, 1929; Fliedner, 1870). Likewise, parish nurses, now called faith community nurses, have followed this same tradition for more than three decades by working out of the congregation to promote whole person health—ministering to body, mind, and spirit of parishioners from the time of birth through the end of life.

In 1984, the concept of parish nursing was introduced to churches in the Chicago, Illinois, area by Lutheran chaplain Granger Westberg (1913-1999) as way of expanding existing health ministries and providing another link between faith and health (see Box 45.1, Timeline of Faith Community Nursing). Westberg described parish nursing as a way for the church to reclaim its traditional role in healing (1990). Having previous experience with setting up **holistic health centers** out of churches, Westberg fully understood that hospitals and

BOX 45.1 Timeline of Faith Community Nursing

- 1983 Pilot program with a nurse running a wellness clinic out of the congregation setting—Our Saviour Lutheran Church, Tucson, AZ.
- 1984 Parish Nurse Program partnership begun with six congregations and Lutheran General Hospital, Park Ridge, IL.
- 1986 Lutheran General Hospital establishes a Parish Nurse Resource Center to share information about health ministry and parish nursing with others.
- 1987 First Westberg Parish Nurse Symposium is held and Granger Westberg publishes book *The Parish Nurse*. Parish Nurse Resource Center becomes the *National* Parish Nurse Resource Center.
- 1989 Health Ministries Association began in Iowa.
- 1991 Marquette University offers eight-day parish nurse education program titled the *Wisconsin Model*, a curriculum later modified to become the *Foundations of Faith Community Nursing* course.
- 1995 Lutheran General merges with Evangelical Health Systems Corporation to create Advocate Health Care. National Parish Nurse Resource Center becomes the *International* Parish Nurse Resource Center.
- 1997 American Nurses Association recognizes parish nursing as a specialty practice.
- 1998 ANA/HMA publish first Scope and Standards for parish nursing. Parish Nurse Preparation Curriculum is published.
- 1999 Parish Nurse Coordinator Curriculum is published. Death of Granger Westberg (July 1913-February 1999).
- 2002 IPNRC transfers assets from Advocate Health System, Chicago, IL, to Deaconess Foundation, St. Louis, MO.
- 2004 World Forum for Faith Community Nursing is formed with 22 members from Australia, Canada, South Korea, Swaziland, and United States.
- 2005 ANA/HMA revised and published scope and standards. Nurse title changed from parish nurse to faith community nurse.
- 2011 IPNRC transfers assets from Deaconess Foundation, St. Louis, MO, to the Church Health Center, Memphis, TN. The 25th Annual Westberg International Parish Nurse Symposium is held.
- 2012 ANA/HMA publish second edition faith community nurse scope and standards.
- 2014 American Nurses Credentialing Center (ANCC) launches faith community nursing certification through portfolio. *Foundations of Faith Community Nursing* curriculum revised.
- 2016 IPNRC renamed Westberg Institute. The 30th anniversary of the Annual Westberg International Parish Nurse Symposium held in Chicago, IL.
- 2017 ANA/HMA publish third edition faith community nurse scope and standards. ANCC ends FCN certification by portfolio.
- 2018 Thirty-one countries active with faith community nursing.

ANA, American Nurses Association; *FCN,* faith community nurse; *HMA,* Health Ministries Association; *IPNRC,* International Parish Nurse Resource Center.

physicians deal with illness, yet there is a need for preventive medicine and wellness in the community and churches fit right in (1990). He also recognized that it was nurses who could have the largest impact on the delivery of whole person care within a congregation, using the nurse's broad background of health promotion, education, spiritual care, and social work (Westberg, 1985).

Westberg's rejuvenation of parish nursing in the 1980s built on the strengths of his previous work and focused on the nurse-clergy team working with individuals and their families. Nurses used their professional knowledge, skills, and experience to listen to the spoken and unspoken concerns of individuals, resulting in whole person care provision with spiritual care central to the relationship. By 1984, Westberg partnered with Lutheran General Hospital (Park Ridge, Illinois—now known as Advocate Health) on a pilot project within six Chicago-area churches (Solari-Twadell & McDermott, 2006). These partnerships established the first institutionally based paid parish nurse program between **a health system** and churches in the United States (Westberg & McNamara, 1987).

As the contemporary parish nurse movement grew, information was spread by advocates of whole person health. This resulted in the establishment of a Resource Center (International Parish Nurse Resource Center [IPNRC]) in 1986 to provide information, printed literature, and news of emerging parish nurse programs across the United States, both paid and unpaid. Through the collaborative efforts of the health system, educators, and the IPNRC, a foundational course was designed to provide basic education to prepare nurses in parish nursing. As noted in the timeline, the IPNRC moved from Illinois to Missouri and now its current home with Church Health in Memphis, Tennessee.

The need of a membership organization for a growing number of parish nurses served as a catalyst for the founding of the Health Ministries Association (HMA) 1989. The HMA provided networking and communications for nurses along with others active in health ministry. Through HMA's leadership, the American Nurses Association (ANA) recognized parish nursing as a professional nursing specialty in 1997 with the first scope and standards of practice published in 1998 (ANA/HMA 2017). The title of parish nurse was changed to faith community nurse with the 2005 revisions to the scope and standards reflective of the need to be inclusive of nurses in all faith traditions (ANA/HMA 2005). Another milestone was reached in 2014 when the American Nurses Credentialing Center (ANCC) released a nurse specialty certification by portfolio for faith community nurses; however, due to low applicant volumes combined with administrative costs, the certification was discontinued after three years (ANCC, 2017).

Another key contributor to faith community nursing is the IPNRC, whose name was changed to Westberg Institute in 2016 for a variety of reasons (Campbell, 2016). First was to honor contemporary faith community nurse founder Granger Westberg and also to support its parent organization Church Health's branding and planning future marketing strategies (Campbell, 2016). Throughout the resource center's history, the focus has remained on the provision and promotion of quality education, research, and support through curriculum, resources and continuing education opportunities.

Fig. 45.1 Parish nurse in rural Swaziland, Africa, making a home visit.

Today, faith community nursing continues to be a recognized specialty practice by the ANA complete with scope and standards to guide nursing practice and an ever increasing body of research and evidence-based practice literature. There are more than 17,000 faith community nurses across the United States and in at least 31 countries around the world such as Australia, Canada, New Zealand, Germany, Swaziland (Fig. 45.1), Ukraine, and Pakistan (Bana, 2018; Glaser, 2018; Izang, 2018; Mansour, 2018; Nicholson & Dlamini, 2018; Van Loon, 2018; Vaughan, 2018; Wordsworth, 2018; Zerull, 2018). Most countries have established resource centers, educational preparation programs, and active networks for support. The number of faith community nurses is a conservative estimate based on the number of nurses who report taking foundations courses and does not reflect the numbers of nurses who provide some form of health ministry to congregations without formal education in the specialty area (Daniels, 2016). Faith community nursing continues to evolve as a nursing specialty practice offering creative strategies for whole person health.

RATIONALE FOR FAITH COMMUNITY NURSING AS A VIABLE COMMUNITY HEALTH MODEL

Early chapters in Parts 1 and 2 of this text familiarize the reader with the historical, economic, social, political, environmental, and ethical perspectives and influences on health care. The health care delivery system is challenged to work within parameters of tighter financial constraints while addressing patients' complex health concerns and also responding to federal mandates for expensive automated systems (i.e., electronic health records) that span the continuum of care. Current health care reform reflects a shift in health care delivery from hospital to community for more comprehensive wellness-focused

programs (Briggs et al., 2017; Callaghan, 2016; Garrett Wright et al., 2015; Meyer & Holland, 2016; Sturgeon et al., 2016) and transitional care models to reduce hospital readmissions (Munning & Owen, 2018; Ziebarth, 2015, 2016; Ziebarth & Campbell, 2016). Transitional care models are defined as "care provided by a faith community nurse in a faith community to support the patient's experience of transition from one level of care to another" (Ziebarth & Campbell, 2016).

Faith community nurses are well positioned to provide lower cost and wholistic community-based care for vulnerable and underserved populations as well as collaborate with other care providers (McLean & Habicht, 2016; Young, 2016; Ziebarth, 2016).

After major hospitalizations, clients may return to their homes very sick with few, if any, care providers available. Caregivers are faced with the multiple tasks of managing finances, maintaining family responsibilities, and learning caregiving skills. Fragmented care and inadequate caregiver training and availability are problems for the disenfranchised, underserved, and uninsured, as well as for economically well-situated and better-educated persons. Families are challenged to seek the best ways to meet the multiple demands of young children, teens, and aging parents whether living in metropolitan, suburban, or rural areas.

Consumer demand for involvement in health care decisions continues to increase, and society emphasizes individual responsibility for health. Simultaneously, consumers have increased interest in their own well-being and have expressed needs for health information to be available in a variety of formats (McLean & Habicht, 2016). In addition to consumer interest and a heightened awareness of responsibility for one's own health, health care providers and managed care systems have found it financially advantageous for individuals to remain healthy and minimize unnecessary access to care. Consumers struggle to cope with the challenges of rising costs of care, decreasing reimbursement, and the complex health system demands on individuals and families.

The traditional health care delivery model will not meet the burgeoning needs of the future (Chase-Ziolek, 2015). The skills of professional nurses, such as faith community nurses, will become more important with the provision of health care services in nontraditional settings (O'Brien, 2017; Ziebarth, 2017). It is important to differentiate the unique practice of faith community nursing from other community-based specialty practices. Faith community nursing shares many similarities with home health, hospice, and public health nursing—promoting health in the community setting; however, it is set apart from other community-based nurses by its whole person health approach and care of the spirit. Nursing care is also shaped and guided by the faith community's traditions, rites, and rituals.

A primary focus of all nurses in the last few decades has been to coordinate care and to link health care providers, groups, and community resources as the client tries to understand complicated health plans. Negotiating with individuals, agencies, and community **partnerships** within the complex maze of the broader health care environment demands a knowledgeable and seasoned professional. Nurses are aware of the necessity of collaborative practices and the formation of partnerships to care for groups and individuals across the life span. These nurses recognize the need for identifying strategies to address health promotion and disease prevention at all levels. They advocate for healthy lifestyle choices in exercise, nutrition, substance use, and stress management. Nurses realize that information and guidance must be available via media, in schools, workplaces, faith communities, and residential neighborhoods. Faith community nurses partner with others such as faculty in academic settings, health care institutions, and federal agencies as they serve populations in faith communities (Opalinski et al., 2017; Power et al., 2016; Young & Smothers, 2018; Ziebarth, 2016) to help improve health outcomes.

DEFINITIONS IN FAITH COMMUNITY NURSING

The ANA describes the development of a specialty practice in nursing as nurses expanding their practice to include the knowledge and skills necessary to meet the needs of patients requiring specialty care. Faith community nursing is defined by the ANA as a specialized practice of professional nursing that focuses on the intentional care of the spirit as well as the promotion of whole person health and the prevention or minimization of illness within the context of a faith community and the wider community (ANA/HMA, 2017).

Requirements for the faith community nurse include (1) an active registered nurse license in the state in which he or she practices; (2) minimum diploma or associate degree in nursing; however, a minimum of baccalaureate degree in nursing preferred; (3) completion of an educational course to prepare for this nursing specialty practice (and ministry); (4) experience in nursing with community nursing experience preferred; (5) specialized knowledge of the spiritual beliefs and practices of the faith community served; (6) reflection of personal spirituality maturity in his or her practice; and (7) being organized, flexible, a self-starter, and a good communicator (ANA/HMA, 2017; Westberg Institute, 2018). Variation in the depth and breadth of nursing practice results from the nurse's education, experience, practice setting, and populations cared for by the nurse. For example, a nurse experienced in gerontology may seek out other nurses or health professionals in the congregation to assist with initiatives designed to support care of a teen population. Thus the faith community nurse is not required to be an expert with all populations and settings, rather is able to identify and coordinate additional resources to meet the needs.

Specialization involves focusing on nursing practice in a specific area, identified from within the whole field of professional nursing and in collaboration with specialty nursing organizations. For example the Health Ministries Association (HMA) and Faith Community Nurses International (FCNI) are identified as the two professional membership organizations for faith community nurses. Additionally, the ANA delineates the components of professional nursing practice that are

essential for any particular specialty. As the specialty continues to evolve, the valuable contributions of nurses begin to distinguish them from other care providers.

This has been true for the evolution of parish nursing. Early on, nurses involved with spiritual care struggled to find a workable definition for the role. Concerns were raised about nurses calling themselves parish nurses without any formal education—simply a nurse license and a willingness to serve their congregation. In order to validate the ministry of parish nurses to that of a recognized nursing specialty, additional education with a defined curriculum including spiritual care was created. Following much dialogue and work to validate the specialty practice, parish nursing was recognized as a nursing specialty in 1997 by the American Nurses Association (ANA/HMA, 2017).

With the 2005 revision of the *Scope and Standards of Practice,* the nurse title changed from parish nurse to faith community nurse (ANA/HMA 2005). The new title was more inclusive of diverse faith traditions and in response to international considerations (ANA/HMA 2017). **Parish nurse** was the original title chosen by Granger Westberg in the 1980s as a theological choice because it connoted service to the **congregation** and also the wider community within a geographical area. A congregation also refers to a variety of faith institutions, including churches, synagogues, temples, and mosques or other faith-based organizations (ANA/HMA 2017; Mattern, 2016). The word **parish** can mean *congregation* and also *geographical area served by a congregation.* Additional titles for nurses working out of faith communities include parish nurse, congregational nurse, health ministry nurse, crescent nurse, or health and wellness nurse (ANA/HMA, 2012, p. 7).

The **faith community nurse** is a licensed registered nurse "with well-developed clinical and interpersonal skills, a strong personal religious faith, and a desire or felt call to serve the needs of a faith community" (O'Brien, 2017, p. 335). With additional education in spiritual care of self, individuals, and groups, the faith community nurse works out of the congregational setting. It is expected that the professional registered nurse possesses competence in practice resulting from his or her application of knowledge, skills, and experience, functions with a deep understanding of the faith community's traditions, and fully integrates *care of the spirit* with care of the body and mind (ANA/HMA, 2017; O'Brien, 2017). The assumptions that underlie faith community nursing are as follows:

1. Health and illness are human experiences.
2. Health is the integration of the spiritual, physical, psychological, and social aspects of the health care consumer to create a sense of harmony with self, others, the environment, and a higher power.
3. Health may be experienced in the presence of disease or injury.
4. The presence of illness does not preclude health nor does optimal health preclude illness.
5. Healing is the process of integrating the body, mind, and spirit to create wholeness, health, and a sense of well-being when the health care consumer's illness is not cured.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

The Nurse in the Faith Community

Targeted Competency: Quality Improvement

Use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of health care systems.

Important aspects of safety include:

- **Knowledge:** Describe approaches for changing processes of care.
- **Skills:** Design a small test of change in daily work (using an experiential learning method such as plan-do-study-act).
- **Attitudes:** Value measurement and its role in good patient care.

Quality Improvement Question

You are a paid faith community nurse at a busy, urban church that partners with a regional hospital on a transitional care project to decrease readmission rates for chronically ill older adults. **Faith community nurse transitional care** is defined as *care provided by a nurse working out of the faith community to support the patient's experience of transition from one level of care to another* (Ziebarth, 2016). An alarmingly high percent of your congregation is over the age of 65 and challenged with chronic diseases of congestive heart failure (CHF) and type 2 diabetes.

As the faith community nurse you obtained additional training in transitional care at the local hospital and developed a relationship with the discharge planning team. Accepting one or two referrals every six months, you work closely with the discharge planning team and the referred individual to create the best plan of care. Beginning interventions include a wholistic assessment; medication and diabetes management review with teach-back; signs and symptoms of acute exacerbations of chronic disease; and spiritual care interventions requested by the individual such as healing presence, prayer. or scripture reading. You also accompanied the individual to primary care provider appointments for clarification of information. You want to evaluate the effectiveness of these interventions.

Step 1: What is the problem or issue that the transitional care nurse program addresses?

Step 2: Identify both short-term and long-term goals for transitional care.

Step 3: How would you document the specific program outcomes?

Step 4: Are there best practices that might inform your whole person care interventions or your collaboration with the local hospital and discharge planning team?

Step 5: How would you evaluate the short-term and long-term goals of the transitional care program?

Faith communities are organizations of groups, families, and individuals who share common values, beliefs, religious doctrine, and faith practices that influence their lives, such as a church, homeless shelter, synagogue, temple, or mosque, and that function as a patient system, providing a setting for faith community nursing (ANA/HMA, 2017). Faith communities are found all over the world wherever individuals gather for the common purpose of worship, fellowship, the giving and receiving of love, grace, and hope, as well as the invitation, not obligation, to participate in the rites and rituals of a faith tradition (Fig. 45.2). Some common examples include baptism, devotions, communion, reading of scripture, prayer, and singing. The important role of the faith community in a person's life is amplified with the recognition that it is one of the only institutions with a connection to an individual from birth through

Fig. 45.2 Religious symbols, images, rituals, and sacred places are significant to ministry.

Fig. 45.3 Prayers for healing service with ritual of laying on of hands.

death. While many recognize and receive spiritual care support in the congregation, there may not be a conscious awareness of the church being an ideal place for health promotion of body and mind.

Health ministries are visible activities, programs, and rituals of faith organized around health and healing of the congregation's membership and offered by the faith community nurse, clergy, layperson, or community resource. Health ministries may be informal or more specifically planned and encompass a gamut of activities, including home visitation, providing meals for families in crisis or upon return home after hospitalization, quilting circles, grief support groups, and prayers for healing services (Fig. 45.3) to name a few (Church Health, 2018; Patterson, 2012, 2013). Evidence suggests that health ministries potentially improve the health outcomes of all members of the faith community, including various ethnicities at higher risk for chronic disease (Asomugha et al., 2011; Horton et al., 2014). As an active member of the health ministry team, the faith community nurse emphasizes health promotion and models a visible healing presence to members of the congregation.

Faith community nurses respond to health and wellness needs of individuals, groups, and populations in fulfilling the mission of health ministry and intentional spiritual care. Services may also extend to those beyond the congregational setting, such as a food pantry, blood pressure screenings, transportation, and warm meals for those in need (Butler & Diaz, 2017; Chase-Ziolek, 2015; Garrett Wright et al., 2015). Additionally, the faith community nurse may work out of an adult daycare center, an immigrant community, a homeless shelter, an amusement park, a crisis center (Callaghan, 2015; Opalinski et al., 2017; Parker, 2018; Power et al., 2016).

According to the ANA *Scope and Standards of Practice* for all nurses (ANA/HMA, 2012), spiritual care is part of all nursing practice and acknowledges a person's sense of meaning and purpose in life, which may or may not be expressed through formal religious beliefs and practices. It is also described as a distinct type of care defined by acts of listening, compassionate presence, open-ended questions, prayer, use of religious objects, talking with clergy, guided visualization, contemplation, meditation, conveying a benevolent attitude, or instilling hope (O'Brien, 2017). Spiritual care is helping the patient make meaning out of his or her experience or find hope (Ziebarth, 2016). Unique to faith community nursing as a specialty nursing practice is the primary focus on care of the spirit, with *spirit* defined as the core of a person's being. Box 45.2 provides a detailed listing of the core interventions for care of the spirit performed by faith community nurses. The compassionate and intentional healing presence of a spiritually mature nurse with individuals or groups is vital to addressing spiritual care needs.

BOX 45.2 Nursing Interventions Classification Core Interventions for Faith Community Nursing

- Abuse Protection Support
- Active Listening
- Anticipatory Guidance
- Caregiver Support
- Coping Enhancement
- Crisis Intervention
- Culture Brokerage
- Decision-Making Support
- Emotional Support
- Environmental Management: Community
- Family Integrity Promotion
- Family Support
- Forgiveness Facilitation
- Grief Work Facilitation
- Guilt Work Facilitation
- Health Care Information Exchange
- Health Education
- Health Literacy Enhancement
- Health System Guidance
- Hope Inspiration
- Humor
- Listening Visits
- Medication Management
- Presence
- Referral
- Religious Addiction Prevention
- Religious Ritual Enhancement
- Relocation Stress Reduction
- Self-Care Assistance: IADL
- Socialization Enhancement
- Spiritual Growth Facilitation
- Spiritual Support
- Surveillance
- Sustenance Support
- Teaching: Group
- Teaching: Individual
- Telephone Consultation
- Touch
- Values Clarification

IADL, Instrumental activities of daily living.
From Bulechek G, Dochterman J, Butcher H, et al.: Core interventions for nursing specialty areas: faith community nursing. In *Nursing Interventions Classification (NIC)*, ed. 7, St. Louis, 2018.

Spiritual care is much different from **religious care**. Whereas religious care stems from the doctrine, rites, and rituals of a specific denomination or set of beliefs, spiritual care is unique to the individual's purpose in life, the fulfilling of that purpose, and living it wholeheartedly. In most denominations, religion creates a nurturing environment where groups gather for worship or defined activity and in which spirituality emerges and grows. Nurses in secular health care may not give priority to spiritual care due to lack of time (Delgado, 2015) or a reluctance to address spiritual care for fear of "stirring things up that they will not know how to address" (Jackson, 2011, p. 4), or crossing professional boundaries. With faith community nursing, intentional spiritual care is invited, expected, and appreciated.

One nurse differentiated her experiences in providing hospital care versus faith community nursing care: "I have always thought of my nursing care as being whole person in nature; however in secular settings, I had to *ask permission* to care for the spiritual needs of my patients, whereas in the congregational setting, spiritual care *is expected*. It is a rare interaction with a parishioner where prayer, a gentle touch or warm embrace are not a part of my nursing care!" (Erbach, 2005).

Holistic or whole person care relates to the relationship between body, mind, and spirit in a constantly changing environment and involves caring for the soul in a special kind of engagement that goes beyond seeing the physical patient but includes observation of the entire patient (Dossey & Keegan, 2016). The faith community nurse, supported by members of the congregation, assesses, plans, implements, and evaluates holistic care programs. The process of operationalizing holistic care is enhanced by an active **wellness committee** or **health cabinet** composed of congregation members or congregants who may or may not be health professionals (e.g., doctors, therapists, social workers) and who are fully engaged in health ministry (Patterson, 2003; Westberg, 1990). The committee is most effective when members represent the broad spectrum of the life of the church. An active wellness committee provides leadership and influence throughout the faith community; ideas come not from one individual but are generated out of a committee structure (McNamara, 2006; Patterson, 2003; Westberg, 1990). The faith community nurse uses the collective knowledge and skills of this collaborative group to provide comprehensive and effective services. The outcome is a caring congregation that understands the strong link between faith and health and supports healthy, spiritually fulfilling lives. Resources for faith community nursing can be found on this book's Evolve website.

FAITH COMMUNITY NURSING PRACTICE

Similar to public health nurses in the United States, faith community nurses identify the need for health promotion services across the life span, particularly in underserved urban and rural areas. Nurses are adept at creatively addressing gaps in the delivery of service. The congregation provides an ideal setting of care for **congregants** to benefit from health counseling and health promotion services at all levels of prevention. The following provides an overview of levels of prevention for older adult health.

LEVELS OF PREVENTION

Older Adult Health

Primary Prevention

- Hold classes for older adults on healthy eating, including food selection, preparation, and increasing socialization opportunities at mealtimes for widows/widowers.
- Promote and encourage age-appropriate activities that include daily physical exercise with increased focus on improved balance related to muscle strength, proprioception, and coordination.
- Encourage a variety of activities of individual and group interest and discourage extended inactivity.
- Encourage healthy snacks and meals for older adult gatherings and activities.
- Write faith community newsletter articles targeting topics of interest to older adults (e.g., recommended annual screenings, signs and symptoms of heart attack and stroke, medication management, Medicare benefits). Place the same health information on a bulletin board located in a high traffic area of the congregation.
- Provide an eyeglasses drive for missions, reminding older adults to get vision checks by an eye doctor at least every 1 to 2 years, and update glasses or contact lenses when vision changes.
- Provide support groups based on needs and interests (e.g., grief support/bereavement; low vision; transitions to long-term care/retirement community; Alzheimer caregivers; adults living with disabilities).
- Coordinate medication management opportunities such as inviting a pharmacist to assist in a medication review after worship.
- Initiate a walk for fun program (e.g., Walk to Emmaus)
- Host a community health fair offering resources related to whole person health.

Secondary Prevention

- Provide health assessment and counseling during home visits for health promotion such as visits after a hospitalization.
- When making home visits, identify safety concerns and make suggestions such as eliminating throw rugs, decreasing clutter, decreasing use of extension cords, and moving heat sources from flammable products such as oxygen.
- Using an attitudinal/behavioral risk survey, identify factors influencing health behaviors.
- Be available for health counseling for older adults before and after activities.

Tertiary Prevention

- Collaborate closely with ministerial team about sessions that deal with healthy nutrition, exercise with injury prevention guidelines, health concerns related to being overweight, and advantages of maintaining a healthy weight, and support, stress management, and improved quality-of-life sessions.
- Follow up and monitor health care provider's plan of care for older adults challenged with chronic disease such as diabetes, hypertension, and depression; provide education, support, and spiritual care.
- Facilitate a faith-based activities program for aging in place.
- Discuss in older adult gatherings the need for loving, caring friends and the support needed for mental health and overall well-being.

Faith community nurse services emphasize whole person health promotion and disease prevention within a supportive and caring faith community. Nurses acknowledge the inner strength and spirituality of persons and groups to enhance healing. Faith community nurses draw on knowledge and skills with communication, negotiation, collaboration, and leadership. Working with the congregation as the population group, faith community nurses attempt to include in the wellness programs those persons who are less vocal or visible in the community of faith. The spiritual dimension of health is optimized by complementing pastoral care with faith community nursing care.

Profile of the Faith Community Nurse

The practice of the faith community nurse is governed by (1) the Nurse Practice Act of the state in which the nurse practices; (2) *Nursing: Scope and Standards of Practice* (ANA, 2015); (3) *Faith Community Nursing: Scope and Standards of Practice* (ANA/HMA 2017); and (4) *Code of Ethics with Interpretive Statements* (for nurses) (ANA, 2015). According to the International Parish/Faith Community Nurse Resource Center located in Memphis, Tennessee (Church Health, 2018), the suggested requirements to be a faith community nurse include the following:

- Active registered nurse license in the state of practice
- Baccalaureate degree or higher in nursing with experience in community nursing preferred
- Completion of a foundational education course in faith community nursing
- Specialized knowledge of the spiritual beliefs and practices of the faith community
- Personal spirituality maturity in practice
- Organized, flexible, a self-starter, and a good communicator

The majority of nurses choosing to become specialized in faith community nursing are experienced and have been in practice for several years. A large survey of faith community nurses ($n = 1161$) across the United States yielded the following description:

- Average age = 55 years
- 89 percent female
- 32 percent prepared at baccalaureate level in nursing, 24 percent prepared at the diploma level, 14 percent prepared at the associate's level, 12 percent hold a master's in nursing
- 68 percent serve as unpaid staff in towns (47 percent), cities (42 percent), and metro areas (11 percent)
- Majority are from Christian faith traditions with only 2 percent of the sample Jewish; 25 percent, Lutheran; 23 percent, Roman Catholic; 16 percent, Methodist
- 17 percent have had membership in the American Nurses Association (Solari-Twadell, 2006)

Because many faith community nurses practice within their own congregation, they are considered to be a known and trusted resource. By virtue of relationship, congregants access the services of the faith community nurse with a high comfort level and awareness that information shared will be kept confidential by the nurse professional. Faith community nurses are well aware of the beliefs, faith practices, and level of spiritual maturity of the members served and link these with health and healing.

Many faith community nurses function in a part-time capacity and serve as salaried or unpaid staff. Some nurses are responsible for services for several faith communities, whereas others engage in faith community nursing as part of a full-time commitment in other capacities. For example, a nurse might be employed part-time as a public health nurse and part-time as a faith community nurse in the same community. Alternatively, a nurse employed full-time in an acute care setting may spend time serving in an unpaid capacity working in a faith community with a group of other nurses. Depending on the practice model, the nurse has a narrowly defined or a wider realm of responsibility. Faith community nurse practices may be integrated into a health care system or into practices that collaborate with related professional practice areas such as health departments or colleges of nursing. Health care systems employ **faith community nurse coordinators**, who facilitate different arrangements with several faith communities of varying backgrounds (Zerull & Solari-Twadell, 2006). Practices in which several faith community nurses are supervised by a coordinator have built-in opportunities for networking, partnering, and mentoring (Durbin et al., 2013).

As advanced practice nurse and faith community nurse practices increase in numbers and varieties of arrangements, evaluation of practice trends within the health care delivery system and the needs of society is necessary. Nursing must be accountable and responsive to those being served, as well as to those who provide opportunities to serve.

The goals for a faith community are clearly defined in the 2017 scope and standards for practice (ANA/HMA, 2017). First is the protection, promotion, and optimization of health and abilities of the congregants. Next is the prevention of illness and injury and facilitation of healing. The faith community nurse works to alleviate suffering through the diagnosis, referral, and treatment. Lastly, the faith community nurse advocates for all persons in the context of the values, beliefs, and practices of the congregation. Nurses work with a health cabinet or wellness committee to evaluate assets and areas of need in order to plan services that will attain outcomes congruent with goals established by the congregation and faith communities served.

Characteristics of Faith Community Nurse Practice

Since the early 1990s, five characteristics have been identified as central to the philosophy of faith community nursing by nursing educators and practitioners (Solari-Twadell, 2006):

1. The spiritual dimension is central to the practice. Nursing embodies the physical, psychological, social, and spiritual dimensions of clients into professional practice. Although parish nursing includes all four, it focuses on intentional and compassionate care, which stems from the spiritual dimension of all humankind.
2. The roots of the role balance both knowledge and skills of nursing, using nursing sciences, the humanities, and theology. The nurse combines nursing functions with pastoral care functions. Visits in the office, home, hospital, or nursing home often involve prayer and may include a reference to scripture, symbols, sacraments, and liturgy of the faith

community represented by the nurse. The values and beliefs of the faith community are integral to the supportive care given. Nurses also assist with worship services as appropriate within the faith community.

3. The focus of the specialty is the faith community and its ministry. The faith community is the source of health and healing partnerships, which result in creative responses to health and health-related concerns. Partnerships may be among individuals, groups, and health care professionals within the congregation. They may also be among various congregations or community agencies, institutions, or individuals. Partnerships also evolve as the congregation visualizes its health-related mission beyond the walls, stones, and steeples of its own place of worship.
4. Parish nurse services emphasize the strengths of individuals, families, and communities. Parish nurses endorse this fourth characteristic in their practice. As congregations realize the need for care and care for one another, their individual and corporate relationship with their Creator is often enhanced. This provides additional coping strength for future crisis situations within the family and community.
5. Health, spiritual health, and healing are considered an ongoing, dynamic process. Because spiritual health is central to well-being, influences are evident in the total individual and noted in a healthy congregation. Well-being and illness may occur simultaneously; spiritual healing or well-being can exist in the absence of cure.

CHECK YOUR PRACTICE

At the conclusion of the worship service you notice a long-time member of the congregation sitting alone in a back pew with her head down. Mrs. E is an 84-year-old widow whose husband died one month ago. She is well-known to you as you visited the couple's home many times over the course of his lengthy battle with cancer. She is visibly sad and withdrawn from other congregants leaving the sanctuary. You do not know if she wants to be left alone or desires the healing presence of a faith community nurse. What should you do?

Faith Community Nurse Interventions and Programs

Faith community nurses provide care to individuals, families, congregations, and communities across the life span. The practice includes the full cultural and geographic community regardless of ethnicity, lifestyle, gender, sexual orientation, or creed. The nurse incorporates faith and health, uses the nursing process in providing services to the faith community, and facilitates collaborative health ministries as an important component of the practice.

One of the first tasks of a new faith community nurse is to explore the social demographics and identify the health needs of the congregation (O'Brien, 2017). This is accomplished by selecting a congregational health needs survey available online or in print for public use (Durbin et al., 2013). In collaboration with the ministry team, the faith community nurse determines actionable priorities and then applies his or her knowledge, skills, and experience to plan health promotion and spiritual care initiatives. Often, due to limited congregational resources, the faith community nurse must conduct a resource assessment to determine feasibility when matching need with time and financial resources.

Since limited resources in faith communities often challenge program development, the faith community nurse must match need with available resources. The following set of questions helps determine what is possible to consider in advance of carrying out health promotion projects (Solari-Twadell & McDermott, 2006, p. 104):

1. What resources are needed?
2. What resources are available?
3. Which of the available resources are accessible to the nurse for the accomplishment of a specific effort or project?
4. Can the work of the project or program be accomplished with what is available and accessible?

Several images of the faith community nurse in practice highlight varying settings and professional activities. Central to all interactions is intentional care of the spirit and the healing presence of the faith community nurse. Healing presence and prayer are frequently offered in most interactions. Bulletin board displays are helpful to promote health topics of interest in hallways with high visibility. Blood pressure screenings offer therapeutic touch as well as assessment for cardiac status, social health, and overall well-being as the individual spends time with the nurse (Fig. 45.4). Informal pew-side consultations take place after worship when individuals ask health-related questions or request resource or referral information (Fig. 45.5). Young families require comprehensive support with diverse needs related to age, supportive relationships, childcare support, and parenting (Fig. 45.6). The health educator role requires creative and differing teaching strategies for the nurse based on the ages of individuals or groups being taught (Fig. 45.7). Faith community nurses may organize an annual health fair inviting community partners and service agencies to share resources and promote health ministries to parishioners

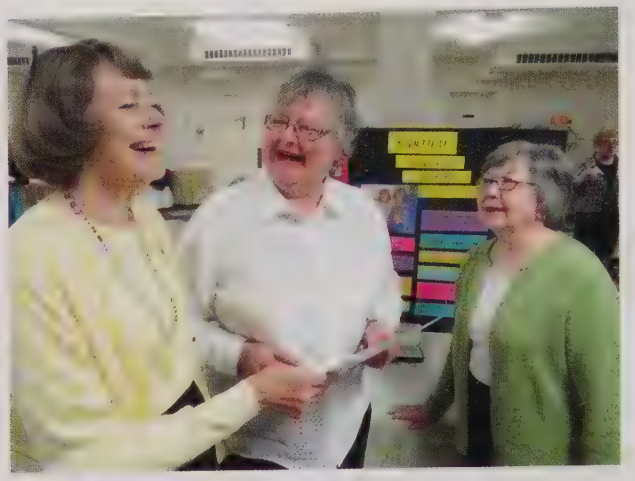

Fig. 45.8 Health fair for the congregation and community.

Fig. 45.9 Hospital visitations include care of the spirit.

of all ages (Fig. 45.8). Hospital and institutional care visits provide spiritual and emotional support when unexpected illness and health crisis may challenge coping skills and raise questions about faith and denominational theology (Fig. 45.9). In congregations with older adults, an organized bereavement/grief support group for widows and widowers may or may not be led by the faith community nurse. Depending on social ministries in place, the faith community nurse may interface with homeless persons accessing congregational resources of food or financial support. Other interventions, services, or programs provided by the faith community nurse are determined by taking into consideration specific congregation needs; the mission, vision, and strategic plan of the congregation matched with the knowledge, skills, and experience as well as time availability of the faith community nurse.

As one of the trusted members of the **pastoral care staff**, the faith community nurse will find it helpful to develop ease in inquiring about a person's spiritual journey. Assessments, whether physical or spiritual, are used to gather data for planning nursing care. Because care of the spirit is central to faith community nursing, spiritual assessment instruments are useful tools and applicable to diverse populations (Puchalski,

2018, Puchalski & Ferrell, 2010). One widely used spiritual assessment tool is constructed with sample questions and the acronym FICA:

F-Faith or beliefs: What are your spiritual beliefs? Do you consider yourself spiritual? What things do you believe in that give meaning to life?

I-Importance and influence: Is faith/spirituality important to you? How has your illness and/or hospitalization affected your personal practices/beliefs?

C-Community: Are you connected with a faith center in the community? Does it provide support/comfort for you during times of stress? Is there a person/group/leader who supports/assists you in your spirituality?

A-Address: What can I do for you? What support/guidance can health care provide to support your spiritual beliefs/practices? (Puchalski, 2018).

In addition to assessment data, history of family relationships and past association with faith communities provides background information. The nurse needs to be comfortable with questions that lead parishioners to expand on their faith beliefs. Compassionate, careful listening involves being still, reflecting, and being intentionally in the present. Being sensitive to the differing needs of personal spirituality during various points along life's journey is important to consider while guiding persons through the spiritual assessment. The nurse then also helps individuals share necessary information about spirituality needs with other health care providers and clergy as appropriate.

Faith Community Nurse Education

The registered nurse choosing to serve a faith community in a formal role should obtain additional education in the nursing specialty practice recognizing that most undergraduate nurse programs offer limited content on spiritual care. A variety of educational programs and curricula are available through health care institutions, colleges and universities, seminaries, or faith-based denominations. Education offered in classroom or online formats range from weekend to week-long curricula which may or may not award continuing education contact hours, to academic courses awarding three to six credit hours of study. Depending on the course or education sponsor, additional content may include denomination specific topics, regional community resources, complementary therapies, and transitional care to name a few.

The most widely used continuing education curriculum around the world is published by the Westberg Institute supported by Church Health in Memphis, Tennessee. Guided by the scope and standards for faith community nursing and incorporating the latest evidence in research and practice, the curriculum provides comprehensive education organized around four core values of spiritual formation, professionalism, whole person health, and community (Church Health Center, 2014). A list of available courses using this curriculum is found at https://westberginstitute.org.

Westberg Institute offers curriculum for two courses—Foundations and the Coordinator/Advanced. The Foundations course offers topics within content areas to include theology of health and healing; the nurse's role in spiritual care; use of prayer; the history, philosophy, and models of care; advocacy; assessment; beginning your ministry; working with a congregation; care coordination; communication and collaboration; documentation, ethical and legal issues; family violence; grief and loss; healing and wholeness; health promotion; and self-care (IPNRC, 2014). The Coordinator/Advanced course is designed to build on the Foundations course and offers administrative and program management content: (1) coordinator self-care; (2) working with diverse faith traditions; (3) documentation; (4) the role of the coordinator; (5) human resource management; (6) utilizing research; (7) professional development; (8) emerging trends and issues; (9) new program development; (10) growing and sustaining; (11) marketing and promoting; (12) program funding and grant writing; and (13) working with faith communities. The Advanced course equips the faith community nurse with the tools necessary to coordinate a group of faith community nurses within a congregation or a larger regional or denomination-based network.

Ongoing education for faith community nurses may be obtained locally, regionally, or internationally. At the local level, education programs are often coordinated through established networks and are institution based or university sponsored. Regionally, networks of faith community nurses may gather monthly or annually for one day or weekend program retreats. Larger conferences such as the Westberg International Symposium offered by the Westberg Institute and the annual Health Ministries Association conference provide comprehensive sessions and forums for nurses to gain new knowledge, network with others, and stay abreast of current resources, trends, and issues in the specialty practice. Additionally, there are educational programs offered by faith community resource centers around the globe such as in Germany, the United Kingdom, and Australia (Glaser, 2018; Van Loon, 2018; Wordsworth, 2018). Information about accessing faith community nursing resource centers can be found on this book's Evolve website.

Advanced practice opportunities also enrich a specialty practice. Master's-prepared nurses (with specialization in congregational leadership, congregational health, public health nursing, or holistic nursing) and nurse practitioners have found niches in faith community nursing. Universities and seminaries have developed creative and unique partnerships to provide educational opportunities for faculty and students at the undergraduate and graduate levels.

Formal educational preparation and continuing education options must continue to include the basics and enrichment courses in nursing practice, research, theology, and pastoral care (see the following How To box). In addition, the specialty practice nurse benefits from updates in the areas of public health, medicine, technology, and sensitivity awareness with the lesbian/gay/bisexual/transgender/queer (LGBTQ) community or bariatric population. Enhancing collaboration, negotiation, and coordination skills, as well as consultation, leadership, and research skills, is essential. Faith community nurses accept responsibility for ongoing professional education within nursing and ministry arenas (ANA/HMA, 2017).

HOW TO Work With Baccalaureate Nursing Students and Nursing Faculty

Baccalaureate students benefit from the integration of whole person and spiritual care in courses throughout a curriculum (Johnson et al., 2014). Additionally, a clinical practicum experience in the faith community setting provides a greater understanding of community and population-focused care. Nursing students assess community needs, plan, implement, and assist in the evaluation of programs to promote health and wellness within faith communities. When exploring the possibility of using a faith community as a clinical site for nursing students, consider the following aspects:

- *Curricular aspects:* What is the academic level of the nursing student? How are content and methods for teaching spiritual care integrated throughout the program of study, specifically in courses of assessment, health promotion, community and public health, maternal–child health, and population management? What are the course objectives? Specific unit objectives? Student learning objectives?
- *Understanding:* Nursing faculty should explore the student's knowledge of faith community nursing. What specific information about the faith community denomination and the religious rites and rituals are needed prior to the start of the student experience? Has the student reviewed the scope and standards of practice for faith community nursing?
- *Time/Students:* Consider the number of hours available for this experience and the flexibility of the student's hours with the availability of the faith community nurse. Based on the faith tradition, when will worship services (e.g., Sunday or Saturday) and planned activities take place? Can the setting accommodate one or multiple students?
- *Supervision and Evaluation:* Who will provide overall supervision of the student's activities? In what ways will the faith community nurse have input in the evaluation of the student's activities? How will the student evaluate the faith community nurse and community experience?
- *Guidelines:* Consider the guidelines needed for student safety, in-home or institutional visitation, confidentiality, and documentation. What documentation from the student and academic institution is required by the faith community?
- *Activities:* Formulate activities that include all aspects of the nursing process for the student(s) to actively participate. Identify areas from various stages of the life cycle and with varying cultural backgrounds, if possible. If required for the clinical practicum, identify a project that is feasible and realistic for the student given his or her education level, course and student learning objectives matched with the needs of the faith community.

Modified from Johnson EJ, Testerman N, Hart D: Teaching spiritual care to nursing students: an integrated model. *J Christ Nurs* 31(2): 94-199, 2014.

Models of Faith Community Nursing

Models of faith community nursing consider the organizational mission along with the influencing factors of economics, infrastructure, available personnel, and willingness of stakeholders to take some risks. Four primary models for faith community nursing are found in practice. The models are differentiated by employer and remuneration wherein the nurse is paid or unpaid.

A paid **institutional model** is supported by a health care institution (e.g., hospital, health department, or long-term care facility) where nurses are paid (salary or hourly) either by the institution or a shared salary with the congregation over time. Second is the unpaid institutional model where an institution provides soft support in the form of continuing education and spiritual development; however, the nurse is not paid a salary and is governed by the congregation who budgets for some expenses such as mileage and health education materials. Many nonprofit hospitals provide soft support to a network of faith community nurses as a partnership for promoting wellness to residents in the community and to meet requirements for tax-exempt status (Butler & Diaz, 2017). Third is the paid **congregational model** where the nurse is governed and paid by the congregation with no contractual support from any sponsoring health care institution. Fourth is the unpaid congregational model where the nurse is governed by the congregation with no contractual support from any sponsoring health care institution. When unpaid, the nurse may negotiate financial support for expenses such as gas/mileage, postage, and health promotion literature.

Pros and cons exist for each model. Paid faith community nurses tend to work more hours, more fully develop the role, and provide a stronger presence within the congregation than the unpaid parish nurse. Often with outside health care organization sponsorship, faith community nurse initiatives typically disappear during congregation transitions of transfer, retirement, or leave of absence. In all models, nurses work closely with health care professionals, pastoral care and health ministry staff, and lay volunteers.

The pursuit of faith community nursing as a specialty practice has been somewhat hindered by the larger number of unpaid nurses practicing a few hours per week or preferring to serve in a volunteer yet professional role. The ongoing question of pay is similar to the evolution of paid congregation staff for youth education and music ministry. The trend for older nurses to call themselves faith community nurses "after retirement" also sent the message of a volunteer ministry versus a professional nurse engaged in a specialty practice of nursing. Yet as faith community nurses wanting to do more in their churches can attest, financial constraints of smaller churches have prevented the creation of a paid position or increasing hours from part-time to full-time status. Regardless of the selected model, the faith community nurse uses knowledge, skills, and experience to promote whole person health of body, mind, and spirit. The ideal outcome is a caring congregation that supports healthy, spiritually fulfilling lives. Resources for faith community nursing can be found on this book's Evolve website.

Holistic Health Care

Holistic health practices emphasize nurses' and clients' commitment to optimal wellness. Such practices focus nurses and clients on seeking the meaning of wellness for the individual or situation, and on considering options from an array of therapies. Harmony between the physical, emotional, psychological, and spiritual self is sought. In addition to sharing backgrounds and functions similar to those of public health nursing, faith community nursing also parallels and benefits from commonalities and distinct practices of holistic nursing. Regardless of specialty or practice setting, nurses who practice in a holistic manner acknowledge wholeness as more than the sum of the individual parts (Dossey et al., 2016). The philosophy of holistic nursing practice (also a specialty in nursing) embraces concepts of presence,

healing, and holism. The interconnectedness of body, mind, and spirit is basic to holistic nursing and is embedded in the practice of faith community nurses. Like faith community nursing, holistic nursing emphasizes wholeness of persons across the life span.

Faith community nurses use some of the interventions commonly found in holistic nursing. Additional exploration by faith community nurses enhances practice possibilities to promote wellness and healing for practitioner and client (ANA, 2013). Both faith community nurses and holistic nurses share the skill of creating a healing environment (Dossey et al., 2016). Listening coupled with intentional compassion is basic to effective interventions. Selected interventions that are often used in both specialties of nursing are prayer, meditation, counseling, guided imagery, health promotion guidance, journaling, therapeutic touch, healing presence, and massage. Information about accessing the American Holistic Nurses Association (AHNA) can be found on this book's Evolve website.

ISSUES IN FAITH COMMUNITY NURSING PRACTICE

As a specialty practice of nursing, the faith community nurse must be alert to issues of accountability to populations served, as well as to those who entrust the nurse with the responsibility to serve a designated population. Because the role involves professional, legal, ethical, theological, and relational issues, the nurse will need to review, understand, and apply all professional parameters involved. The potential for conflicts can be reduced by the following:

- Negotiations with the pastoral staff, congregations, institutions, and the wider community must be involved in job description preparation and program planning.
- Provision of care for individuals and groups is documented and remains confidential.
- Issues such as privacy, confidentiality, group concerns, access, and record management must be discussed with the pastoral staff or the contracting agency at the outset of any program agreement.
- Discussions of health promotion activities may include the individual, the family, and the faith community leadership.

Professional Issues

A position description is a necessary tool for the defining faith community nursing practice. The description should accurately reflect the qualifications, skills, accountabilities, and responsibilities of the position. Annual and periodic evaluations of faith community nurse practice, as well as assessments and evaluations of services needed, are certainly indicated. Evaluations should include input from self, peer, congregational staff, and institutional evaluations as applicable for constructive feedback and to enhance practice.

Professional appraisal, or a portfolio, is becoming a standard in nursing practice and therefore is needed within faith community nursing. The appraisals guide the nurse's professional development as well as program development. Because the scope of faith community nursing practice is broad and focuses on the independent practice, the nurse must consider a wide variety of topics to be used in the appraisal, such as position description, professional liability, professional educational and experiential preparation, collaborative agreements, and the ability to work with lay volunteers as well as practicing and retired professionals. Abiding by the professional nursing code is understood and must be reflected in the appraisal. The nurse must also be assessed in the application of skills related to the **polity**, expectations, and mission of the particular faith community.

Nurses advocate for the health and well-being of **parishioners** and thus are in unique positions to highlight justice issues influencing local and national legislation. As the faith community reflects on the implications of legislation on their congregation and the larger denomination, the nurse contributes information to policy makers about the implications for health and well-being for the congregation, for the local community, and for the global community. Active participation in political activities contributes to health care policy changes and potential financial support for health promotion and health screening programs.

Faith community nurses face many of the same ethical issues as other nurses in different practice settings. The nurse must respect the parishioner's expectations for veracity and truth telling, advocacy, and privacy and confidentiality unless the client is in danger or laws mandate reporting of certain circumstances. However, the nurse must be keenly aware of the communal nature of the faith community—a setting where there is a commitment to pray for others, and a setting where joys and struggles are sometimes openly shared.

Documentation Issues

An ongoing challenge for faith community nurses is documenting care provision and reporting trends and outcomes. Extracting meaningful data from traditional, handwritten notes is cumbersome and labor intensive, and paper records were not designed with the accountable care requirements of today's health care system (Mayernik, 2013). Technology offers an alternative option to paper records. With advances in electronic health records, both online and stand-alone databases are widely available, though often at considerable expense that prevents many smaller faith communities from using them. Several automated documentation systems allow faith community nurses and health ministers to document, analyze, and report individual interactions, group interactions, and perceived cost savings or avoidance of interventions. Automated documentation can be accessed from any Internet capable device, including smartphones, tablets, and computers. Envision a faith community nurse visiting a parishioner at home with laptop in hand to document assessment, interventions, and plan of care or after worship service at the end of a pew looking up a medication or community resource via cell phone in answer to a health question. (See Fig. 45.5 on pew-side consultations.) As a nursing specialty practice, it is imperative that nurses document care to maintain and enhance quality of preparation and services offered, engage in evidence-based practice, network within professional organizations, and become involved in outcomes-oriented research.

According to the American Nurses Association scope and standards of practice for faith community nurses (2017), documentation should contribute to the quality of nursing practice and be kept confidential and secure while also being easily retrievable for those with permission to access. One example of an automated documentation tool for faith-based care delivery is the Henry Ford Macomb Faith Community Nursing and Health Ministry Documentation and Reporting System. The system was initially developed in 2000 to address the sponsoring health care institution's goals: (1) provide network partners (congregations and faith community nurses [FCNs]) with an easy and efficient automated documentation system; (2) meet documentation standards for professional practice; (3) allow for aggregation of data; and (4) report outcomes of faith community and health ministry initiatives with anticipated demonstration of wise and appropriate stewardship of the institutions' resources (Brown & Yore, 2013).

Legal Issues

Although the provision of nursing care in the congregational setting carries lower risk for litigation than other settings, faith community nurses engage in autonomous practice and may be involved in a legal suit. Within the legal system, the courts find no difference in the actions of nurses working in a hospital versus an alternative setting because both must adhere to the same standards of practice (ANA/HMA 2017). Therefore it is strongly recommended that the faith community nurse carry individual malpractice insurance. In addition, the faith community nurse must maintain an active nursing license, abide by the laws and regulations set forth by the state's nurse practice act, and adhere to the ANA's scope and standards for registered nurse and for specialty nurse practice (ANA, 2015; ANA/HMA, 2017). Additional legal concerns pertain to institutional contractual agreements, health records management, release of information, and volunteer liability. Resources to address legal issues of faith community practice include the faith community's legal consultant, the position statements for faith community nursing practice, and guidelines of any institutional partner (ANA/HMA, 2017).

As required by law, nurses advocate for individuals and groups. The nurse is also expected to identify and report cases of neglect, abuse, and illegal behaviors to the appropriate legal sources. The faith community nurse appropriately refers members to pastoral or community resources if the scope of the problem is not within the professional realm of the nurse. Referral is also indicated if conflict between nurse and parishioner is such that no further progress is possible. The faith community nurse who has a positive relationship that values open dialogue with the pastoral team will be supported in efforts to select the most appropriate community resource for clients.

Financial Issues

Most congregations are dependent on the contributions of their members and often operate with a limited budget for operations, salaries, and expenses. While larger congregations can support larger budgets and expanded ministries, smaller congregations are often challenged to meet expenses for operations and clergy salary. Thus there may not be sufficient funds available for a paid faith community nurse. Regardless of paid status, the faith community nurse is challenged to be creative in identifying sustainable financial support for programs as well as in finding low-cost or free resources. Considerations for planning budget may include educational and promotional materials, equipment, travel expenses, postage, continuing education, and malpractice insurance. Money, time, and human resources may limit what services or programs are offered within a faith community. Nonetheless as evidenced by the literature, faith community nurses can offer much to a congregation without additional non-salary expenses in the form of assessment, screening, health promotion, and healing presence (Alexander & Branstetter, 2017; Callaghan, 2016; Laming & Stewart, 2016; Meyer & Holland, 2016).

Future Growth

Faith community nurses can develop comprehensive, population-focused practices. They may also implement programs at beginning levels of community-based practices to ensure comprehensive care for individuals and families. The continuing challenge for nurses, other health care providers, and the communities will be to garner government, foundation, and private funding and combine it with support from volunteer activities, family involvement, and community groups to create the unique mix needed for each community. Nurses are asked to partner with community members where they live, work, attend school, and gather for worship; to closely partner with these same members to advocate for those who are powerless; to identify health and health-related needs; to detect and address those needs to prevent costly use of the health care system; and to be closely aligned with those who can implement visionary policy that improves health care for community members across the life span.

Uncovering and understanding the intricacies of the work of faith community nurses is a difficult task because minimal research on the outcomes of faith community nursing interventions has been conducted (Callaghan, 2016). The following How To box provides a general guide to program evaluation for faith community nurses. Comprehending the distinctiveness of the role of faith community nursing is important to the maturation of the specialty because it allows for a clear recognition of the work done (Solari-Twadell, 2006). Early groundbreaking research was conducted in 2002 by Solari-Twadell using the Nursing Interventions Classification (NIC) system (McCloskey & Bulechek, 2000). With data from more than 1000 parish nurses, essential or core nursing interventions were named that help differentiate the practice. A more recent review of literature conducted by Ziebarth in 2016 identified five essential attributes of faith community nursing to include (1) faith integrating; (2) disease managing and health promoting; (3) coordinating; (4) empowering; and (5) accessing health care. The research confirms that spiritual care is the hallmark of the faith community nurse's practice. Other primary interventions used daily and weekly include active listening, presence, spiritual support, emotional support, spiritual growth facilitation, humor, and hope instillation (Solari-Twadell, 2006).

HOW TO Evaluate Program Outcomes in Faith Communities

Faith community nurses plan and provide health-promotion and disease-prevention activities within faith communities. The nurses often must provide these services with limited resources of money, time, and equipment. The following model for program development and evaluation is useful in the creation of high-quality and cost-effective programs:

Step 1: What problem or issue is the program designed to address? Be specific about the problem as it guides the search for evidence-based information.

Step 2: Identify program partnerships such as regional faith community nurses, hospital, chronic disease management centers.

Step 3: Identify both short- and long-term goals. The goals help prioritize what needs to be documented, tracked, and reported.

Step 4: Document the specific program outcomes. This may include numbers of attendees, participation rates, desired changes in measurements, and any unexpected outcomes.

Step 5: Develop and implement the interventions for the program, as determined by best practices, to achieve the goals identified in Step 4.

Step 6: Evaluate the short- and long-term goals and the specific program outcomes. Share the outcome results with individuals or in aggregate form to the faith community. Disseminate findings to other faith community nurses at local, national, and international levels.

Data from Callaghan DM: Implementing faith community nursing interventions to promote healthy behaviors in adults. *International Journal of Faith Community Nursing* 2(1), 2016. Available at https://digitalcommons.wku.edu.

NATIONAL HEALTH OBJECTIVES AND FAITH COMMUNITIES

Healthy People 2020 provides evidence-based national objectives for improving the health of all Americans. The *Healthy People 2020* indicators encourage communities to support individuals and families to make informed decisions, retain a high quality of life free of preventable diseases across the life span, reduce health disparities across groups, and create environments or access to settings that promote health. Faith communities offer an ideal setting for health promotion and have long-held positions of esteem and influence in communities and where strong partnerships can be established with health care institutions and community agencies. For example, the Carter Center in Atlanta and the Park Ridge Center for Health, Faith, and Ethics in Chicago collaborated with health care professionals and leaders of faith traditions to identify the key roles faith communities have in addressing national health objectives and approaches to improving overall public health.

On a national level, multiple partnerships have been established between faith communities and federal agencies as well as high-profile not-for-profit organizations. The U.S. Department of Health and Human Services established a Center for Faith-Based and Neighborhood Partnerships, recognizing that faith communities are an ideal setting for education and health promotion initiatives (CDC, 2017). A well-known organization, the National Heart, Lung and Blood Institute, created a faith-based toolkit to promote heart health for women (Box 45.3). Notably, the American Heart Association (2016) created the *EmPowered to Serve* program designed to bring organizations together in partnership to make a positive impact around health in the faith-based community with special focus on increased physical activity, increased consumption of fruits and vegetables, reduction or limitation of sodium and sugar sweetened beverages, and improving the health of the entire family leading to improved health of the overall community.

BOX 45.3 Example of Online Faith-Based Resources

National Heart, Lung and Blood Institute Faith-Based Toolkit

This faith-based activities toolkit contains ideas and resources you can use to conduct activities to promote *The Heart Truth®* for women in your faith community. Campaign background information, faith-based resources, and other promotional and educational materials, as well as the activity ideas contained in this kit can help you formulate a plan for your own faith-based program.

Activity Ideas

Consider these ideas for planning an event to promote the heart health of women in your faith community.

- Organize a "*Red Dress* Sunday" or "*Red Dress* Sabbath" event for your place of worship. You can put a notice in the bulletin, hold an educational session, and distribute brochures and fact sheets. Also see the Ten Commandments for a Healthy Heart and Talking Points for *Red Dress* Sunday/Sabbath.
- Ask the female leader of your place of worship to become an ambassador for heart disease awareness for women in your congregation.
- Ask your ministry leader to deliver *The Heart Truth* messaging from the pulpit. Consider using Talking Points for *Red Dress* Sunday/Sabbath.
- Organize a session using *The Heart Truth for Women: A Speaker's Kit,* during a women's ministry or health ministry meeting.
- Organize a health-themed Bible study.
- Form partnerships with retail/clothing outlets to stage a *Red Dress* fashion show that donates a percent of the profit for every red dress sold to a nonprofit heart disease organization. (Sample partner outreach letter available online.)
- Incorporate a *Red Dress* theme for your women's ministry brunch or Mother's Day event.
- Organize a heart health screening event and health fair for women at your place of worship.
- Distribute *Red Dress* pins.
- Place a link to *The Heart Truth* Web pages (www.hearttruth.gov) on your place of worship's website.
- Include an article on heart disease and *The Heart Truth* in the church's newsletter/magazine.
- Consider including Ten Commandments for a Healthy Heart.
- Organize a heart healthy meal for your community.

From National Heart, Lung and Blood Institute: *Faith-based toolkit,* 2016. Available at http://www.nhlbi.nih.gov.

Recognizing that older adults are one of the fastest growing age groups in the community, including baby boomers (adults born between 1946 and 1964), a new goal was added to *Healthy People 2020—improve the health, function, and quality of life of older adults.* It is estimated that more than 37 million people in this older adult group (60 percent) will manage more than one chronic condition by 2030 (CDC, 2017). Thus older adults are at high risk for developing chronic illnesses and related disabilities such as diabetes mellitus, arthritis, congestive heart failure, and dementia. Infectious disease combined with chronic conditions is the leading cause of death among older adults (CDC, 2017). Often, acute exacerbations from one or more

illnesses require hospitalizations, frequent access to health care services, and nursing home admissions. Ultimately, the older adult may lose the ability to live independently at home. Congregations with large numbers of older adults present special needs for the faith community nurse to address in order to improve the health and well-being of this vulnerable population (see *Healthy People 2020* box).

HEALTHY PEOPLE 2020

Objectives Related to Older Adult Health in Faith Communities

Prevention

- **OA-1:** Increase the proportion of older adults who use the Welcome to Medicare benefit.
- **OA-2:** Increase the proportion of older adults who are up to date on a core set of clinical preventive services.
- **OA-6:** Increase the proportion of older adults with reduced physical or cognitive function who engage in light, moderate, or vigorous leisure-time physical activities.

Long-Term Services and Supports

- **OA-8:** Reduce the proportion of noninstitutionalized older adults with disabilities who have an unmet need for long-term services and supports.

From U.S. Department of Health and Human Services: *Healthy People 2020: older adult objectives.* Washington, DC, 2013, USDHHS.

National health objectives from *Healthy People 2020* provide a framework for health education opportunities within a faith community. These objectives, coupled with a congregational health assessment, help identify the specific health needs of a faith community. Additional considerations to determine health priorities include sociodemographic data of the membership combined with the mission, vision, polity, and strategic plan for the faith community. Often there is a wellness committee or health cabinet established in the congregation with the faith community nurse as one member. Together the team can regularly review health status objectives, make comparisons with national and specific state objectives, and prioritize initiatives to promote health, reduce risk, and prevent illness. Some examples are as follows:

- Offer regular blood pressure screening and monitoring activities focused on heart disease and stroke prevention.
- Lead age-appropriate discussion of illness prevention activities (e.g., immunizations; breast and prostate self-exam; smoking cessation; accident-free living spaces).
- Teach signs and symptoms of heart attack and stroke through newsletters, flyers placed in bathroom areas for a captive audience, and bulletin board displays in prominent well-traveled hallways.
- Coordinate healthy low-fat meals at congregation functions.
- Encourage individuals to choose healthy fruit and vegetables as snacks.
- Coordinate a series of classes for families of adolescents on stress management and sessions on the use and misuse of alcohol, tobacco, and other drugs.
- Encourage or lead a faith-based exercise program for individuals as a part of ongoing faith community activity.

EVIDENCE-BASED PRACTICE

Because of the increasing numbers of people having diabetes worldwide, interventions to increase improved glycemic control and reduction of overall health care costs have become a priority in community settings. Type 2 diabetes poses a significant health concern due to the many complications resulting from uncontrolled blood glucose levels. Community-based diabetes education provides much-needed information for individuals to better manage the disease. This research study addressed the clinical question: Following a faith-based community diabetes education program, does health coaching increase self-efficacy in people with type 2 diabetes in comparison to no additional intervention? The study utilized an experimental pre-test/post-test format for a small population of persons from several community churches. A certified diabetes educator and certified health coach collaborated with faith community nurses to provide diabetes education. Two evidence-based valid and reliable instruments were used to identify diabetes knowledge and diabetes self-efficacy. Participants were randomized into two groups with one receiving diabetes education interventions and the second receiving no intervention. Although the intervention of health coaching did not lead to significant increases in self-efficacy, the individual knowledge and self-efficacy scores improved, which may result in better self-care management of diabetes.

Nurse Use

Faith community nurses working out of the congregation setting and having additional training in diabetes management are in a unique position to assist congregants with improved glucose management. As a known and trusted health professional he or she is in a unique position to educate, support, and make appropriate referrals. As faith community nurses reach out to their surrounding community, creative strategies and collaboration with other care providers positively influence health attitudes and behaviors with resultant cost-effective strategy for screening and enhanced disease management.

Data from Meyer JL, Holland BE: Health coaching in faith-based community diabetes education. *International Journal of Faith Community Nursing* 2(1), 2016. Available at http://digitalcommons.wku.edu.

CONCLUSION

In a span of more than 30 years, parish/faith community nursing went from pilot project to recognized nursing specialty practice complete with scope and standards. The role of the faith community nurse was clearly defined, incorporating holistic health promotion and care of body, mind, and spirit to individuals and groups out of a congregational setting. A standardized curriculum for foundational and advanced preparation of faith community nurses is now widely available to help assure minimum knowledge and skills for practice. In addition, the ANCC recognizes faith community nursing as a specialty practice. Screening, monitoring, wellness education, and referrals to appropriate services are combined with a spiritual component of care to promote health and healing and fulfill the church's historic role in health and healing. Ongoing research documents favorable outcomes associated with intentional holistic health promotion to individuals, groups, and faith communities. Successful faith community nurse networks, whether institutional or congregation-based models, continue

to be established in the United States and around the world. Schools of nursing faculty are engaging in academic practice collaboration with congregations, as well as providing nursing students with exceptional community learning experiences out of the congregation. Hospitals and health systems, particularly if nonprofit, partner with faith community nurses to strengthen community connections. Careful examination of faith community nursing provides the opportunity for leaders in nursing and health policy to identify successful strategies that could improve the health and well-being of a community.

LINKING CONTENT TO PRACTICE

This chapter described individual, group, and population health out of the congregational setting. The faith community is instrumental in providing the structure, place, and resources and may intentionally seek out the vulnerable and marginalized to receive support from other community or denominational organizations closely aligned with mission and outreach activities for a common purpose. The organizations may include a health care institution, a childcare or adult daycare center, an immigrant community, a homeless shelter, an amusement park, a crisis center, a preschool, or local public schools. Depending on desired outcomes, the faith community nurse combines knowledge, skills, and experience in collaboration with others to make a difference for a larger population.

To illustrate, a faith community partners with a hospital, the local agency on aging, and a retirement community to promote older adult health. Key stakeholders gather for discussions on priorities identified from a community needs assessment completed by the hospital. The stakeholders also review suggested prevention and services objectives for older adult health from *Healthy People 2020*. The group considers baseline data and identifies desired outcomes. From discussions, activities and programs are planned, drawing from the collective human and financial resources. In this example, the faith community nurse works with hospital staff to coordinate screenings and health promotion programs held in the congregation setting and at various locations using a mobile health vehicle. Participating older adults requested additional services such as medication reviews and educational health talks on topics of depression, advance directives, and Medicare enrollment benefits. Successful disease management programs for diabetes and congestive heart failure were extended beyond the walls of the hospital into the community to reach a larger population. Hospital readmission within 30 days data were reviewed with the faith community nurses to identify creative strategies to reduce future readmissions. All services were evaluated for content and quality, as well as to track, trend, and report outcomes. As with most collaborative initiatives, more was accomplished through partnership with the congregation, and the faith community nurse was instrumental in bringing the partners together.

PRACTICE APPLICATION

The nursing process is a method that can be used for program planning and evaluation in the faith community setting. Such an approach involves congregants and faith community nurses in a dynamic endeavor to jointly learn about the members' individual health status, as well as that of the faith community, local community, and broader geographic community. Faith community nurse programs are derived in various ways. Initially, the impetus for faith community nursing may stem from an unmet health need, from members' concern about caring for vulnerable individuals or groups within the congregation, or from committee recommendations related to health and wellness issues.

Which of the following activities is most likely to increase the interest and involvement of the faith community's members?

A. Writing a contract for the services of the faith community nurse
B. Exploring the faith community's environment
C. Offering a multiple week Bible study on the topics of health, healing, and wholeness
D. Gathering information on leaders and valued activities in the congregation through focus groups of pastoral staff
E. Conducting a congregational health needs assessment survey
F. Holding a health fair
G. Attending a regional faith community nursing network meeting.

Answers can be found on the Evolve site.

KEY POINTS

- Faith community nurse services respond to health, healing, and wholeness within the context of the faith community. Although the emphasis is on health promotion and disease prevention across the life span, the central focus of practice is on the "intentional care of the spirit."
- Spiritual care is different from religious care and is an expected and welcomed component of faith community nursing care.
- Note that spiritual assessment and care can also be provided outside of a congregational setting in the larger community. Faith community nurses may work in other settings of retirement communities, faith-based amusement parks, senior centers, food pantries, and day shelters.
- Faith community nursing evolved from the historical roots of healing traditions in faith communities; early public health nursing efforts with individuals, families, and populations in the community; and more recently the professional practice of nursing.
- The faith community nurse partners with the congregational wellness committee and volunteers to plan programs that address health-related concerns within faith communities.
- The usual functions of the faith community nurse include health counseling and teaching for individuals and groups, facilitating linkages and referrals to congregation and community resources, advocating and encouraging support resources, and providing spiritual care.

- Faith community nurses collaborate to plan, implement, and evaluate health promotion activities considering the faith community's beliefs, rituals, and polity. *Healthy People 2020* objectives and health indicators offer effective frameworks for health ministry efforts of wellness committees and basic to partnering for programs.
- Nurses in congregational or institutional models enhance health ministry programs of faith communities when carefully chosen partnerships are formed within the congregation, with other faith communities, and with local health and social community organizations.
- Nurses working as faith community nurses must obtain foundational and ongoing educational and skill preparation to be accountable to those served.
- Faith community nurses document care interventions offered to individuals and groups, in addition to tracking and reporting program statistics and outcomes to validate and sustain the professional practice.
- Faith community nurses may offer additional resources to hospitals and health systems challenged to reduce 30-day hospital readmissions.
- Nurses are encouraged to consider innovative approaches to creating caring communities. These may be in individual faith communities; among several faith communities in a single locale, regionally or internationally; or in partnership with other organizations and institutions.
- To sustain oneself as a faith community nurse who provides spiritual care to support individuals, families, and communities in the healing and wholeness process, the nurse must be intentional about self-care, spiritual formation, and renewal.

CLINICAL DECISION-MAKING ACTIVITIES

1. Contact the local organization of faith communities (such as the Council of Churches or health system) to see if there is a faith community nursing network in your area. If so, make contact and arrange to spend a day with a nurse.
2. Interview the nurse about the faith community nurse role functions. Compare and contrast the nurse's answers to what you learned in this chapter.
3. Ask how the faith community nurse standards of practice are integrated into the practice. How can you verify the answer?
4. Interview the faith community nurse coordinator for a regional nurse network. Identify key questions of interest such as regional network demographics; current evidence-based practice or research; organizational and community priorities; and outcomes to name a few.
5. If possible, spend time in a variety of faith communities. Compare and contrast urban and rural settings, different faith traditions, and nontraditional settings.
6. Discuss with classmates the similarities and differences between home health care nursing, school nursing, public health nursing, and faith community nursing. Compare your answers.
7. Choose a *Healthy People 2020* indicator to implement in a faith community setting. Discuss plans for implementing the objective and evaluating the outcomes with the faith community nurse and wellness committee. What data did you use to develop a plan for implementation? How did you choose your population? How did you evaluate the outcomes of your goals and activities?
8. Interview a clergy member of a local church, temple, synagogue, or mosque in your area (preferably someone with a different background than your own). Ask the individual to elaborate on traditions of faith, health, and healing connections. Consider how you might be able to meet the unique needs of that faith community.
9. Visit a senior citizen daycare center and speak with participants about important events in their lives. Do they refer to rituals from faith traditions? Ask them about their connections to faith communities during their lives.
10. With classmates, interview a youth group leader and nurse in a local faith community about the concern of preventing risky behaviors among youths. What perspectives of this concern would the faith community nurse staff need to consider?

Public Health Nursing at Local, State, and National Levels

Lois A. Davis, RN, MSN, MA

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Define public health, public health system, public health nursing, and local, state, and national roles.
2. Identify trends in public health nursing.
3. Provide examples of public health nursing roles.
4. Differentiate the emerging public health issues that specifically affect public health nursing.
5. Describe the principles of partnerships.
6. Identify educational preparation of public health nurses and competencies necessary to practice.

CHAPTER OUTLINE

Roles of Local, State, and Federal Public Health Agencies
History and Trends in Public Health
Scope, Standards, and Roles of Public Health Nursing
Issues and Trends in Public Health Nursing
Models of Public Health Nursing Practice
Education and Knowledge Requirements for Public Health Nurses
National Health Objectives
Functions of Public Health Nurses

KEY TERMS

partnerships, p. 1009
public health, p. 1009
public health nursing, p. 1010
public health programs, p. 1009
state public health agency, p. 1011

All of public health is built on **partnerships. Public health programs** are designed with the goal of improving a population's health status. They go beyond the administration of health care of individuals to a primary focus on the health of populations. Public health programs include community health assessment and interventions based on assessment results, analysis of health statistics, public education, outreach, case management, advocacy, professional education for providers, disease surveillance and investigation, emergency preparedness and response, compliance to regulations for some institutions/agencies and school systems, and follow-up of populations. Examples of follow-up care include communicating with persons with active, untreated tuberculosis, pregnant women who have not kept prenatal visits, and parents of underimmunized children. Public health programs are frequently implemented by the development of partnerships or coalitions with other providers, agencies, and groups in the location being served. Community-Campus Partnerships for Health (CCPH) defines partnerships as "a close mutual cooperation between parties having common interests, responsibilities, privileges and power." Partnerships are built on trust, mutual respect, and the sharing of power. CCPH further emphasizes partnership approaches to health that focus on changing the conditions and environments in which people live, work, study, pray, and play (CCPH, 2018).

Box 46.1 presents principles of partnership within a public health system (CCPH, 2018). Public health nurses are skilled at developing, sustaining, and evaluating community-wide partnerships. Public health nurses are involved in these activities in various ways depending on the public health agency (local, state, or federal) and the identified needs. Public health nurses may be the partnership facilitator or a member of the partnership representing their agency.

Public health is not a branch of medicine; it is an organized community approach designed to prevent disease, promote health, and protect populations. It works across many disciplines and is based on the scientific core of epidemiology (IOM, 2003). Governmental agencies at the local, state, and federal levels are partners in the public health system that must work together to develop and implement solutions that will improve a community's health. Fig. 46.1 represents the diverse and complex network of individuals and agencies making up the public

BOX 46.1 Principles of Partnership

Community-Campus Partnerships for Health (CCPH) involved its members and partners in developing the following "principles of good practice" for community partnerships:

1. The Partnership forms to serve a specific purpose and may take on new goals over time.
2. The Partnership agrees upon mission, values, goals, measurable outcomes and processes for accountability.
3. The relationship between partners in the Partnership is characterized by mutual trust, respect, genuineness, and commitment.
4. The Partnership builds upon identified strengths and assets, but also works to address needs and increase capacity of all partners.
5. The Partnership balances power among partners and enables resources among partners to be shared.
6. Partners make clear and open communication an ongoing priority in the Partnership by striving to understand each other's needs and self-interests, and developing a common language.
7. Principles and processes for the Partnership are established with the input and agreement of all partners, especially for decision making and conflict resolution.
8. There is feedback among all stakeholders in the Partnership, with the goal of continuously improving the Partnership and its outcomes.
9. Partners share the benefits of the Partnership's accomplishments.
10. Partnerships can dissolve, and when they do, need to plan a process for closure.
11. Partnerships consider the nature of the environment within which they exist as a principle of their design, evaluation, and sustainability.
12. The Partnership values multiple kinds of knowledge and life experiences.

From Community-Campus Partnerships for Health (CCPH) Board of Directors: Position statement of authentic partnerships. *Community-Campus Partnerships for Health, 2013.* Available at https://ccphealth.org.

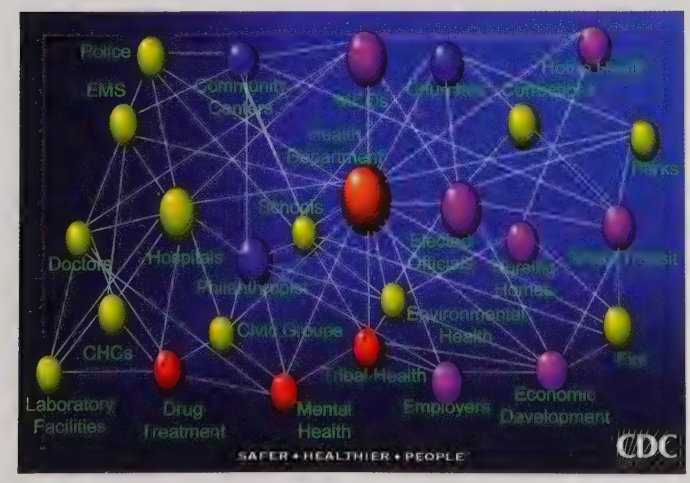

Fig. 46.1 The diverse and complex network of individuals and agencies making up the public health system. *CHC,* Consolidated Health Center; *EMS,* emergency medical services; *MCO,* managed care organization. health system (CDC, 2017). This public health system may include public, private, and voluntary entities such as the local health department, businesses, and civic associations. Public health nurses partner with interprofessional teams of people within the public health areas (Fig. 46.2), in other human services and public safety agencies, and in community-based

Fig. 46.2 Public health nurses work on multidisciplinary teams that include environmental health specialists to increase public awareness about strategies to prevent transmission of West Nile virus. (Courtesy Arlington County Department of Human Services/Public Health Division, Arlington, VA.)

organizations. The health of communities is a shared responsibility that requires a variety of diverse and often nontraditional partnerships. A critical partnership that shapes **public health nursing** practice in the United States is the interaction of local, state, and federal public health agencies.

ROLES OF LOCAL, STATE, AND FEDERAL PUBLIC HEALTH AGENCIES

In the United States, the local–state–federal partnership includes federal agencies, the state, tribal and territorial public health agencies, and the 2500 local public health agencies (Association of State and Territorial Health Officials [ASTHO]). The interaction of these agencies is critical to effectively leverage precious resources, both financial and personnel, and to protect and promote the health of populations. Public health nurses employed in all of these agencies work together to identify, develop, and implement interventions that will improve and maintain the nation's health.

Federal public health agencies develop regulations that implement policies formulated by Congress, provide a significant amount of funding to state and territorial health agencies for public health activities, survey the nation's health status and health needs, set practices and standards, provide expertise that facilitates evidence-based practice, coordinate public health activities that cross state lines, and support health services research (IOM, 2003). The U.S. Department of Health and Human Services (USDHHS) and the Environmental Protection Agency (EPA) are the federal agencies that most influence public health activities at the state and local levels (see Chapter 3 and 9). The USDHHS includes the Centers for Disease Control and Prevention (CDC), the Health Resources and Services Administration (HRSA), the Agency for Healthcare Research and Quality (AHRQ), and the Food and Drug Administration (FDA). The USDHHS is the agency that facilitates development of the nation's *Healthy People* objectives (USDHHS, 2018).

In the United States, states hold primary responsibility for protecting the public's health. Each of the states and territories has a single identified official **state public health agency** that is managed by a state health commissioner. The structure of state public health agencies varies. Some states require that the state health commissioner be a physician. A growing number of states do not limit the position to physicians but rather require specific public health experience. California, Maryland, Iowa, Oregon, Washington, and Michigan are examples of states that focus on public health experience as a requirement for the state health commissioner position. Public health nurses have been appointed to the state health commissioner positions in a number of states: California, Oregon, Washington, and Michigan. The Association of State and Territorial Health Officials defines the state public health agency as the organizational unit of the state health officer, who works in partnership with other government agencies, private enterprises, and voluntary organizations to ensure that services essential to the public's health are provided for all populations. State public health agencies are responsible for monitoring health status and enforcing laws and regulations that protect and improve the public's health. In addition to state funds appropriated by state legislatures, these agencies receive funding from federal agencies for the implementation of public health interventions, such as communicable disease programs, maternal and child health programs, chronic disease prevention programs, and injury prevention programs. The agencies distribute federal and state funds to the local public health agencies to implement programs at the community level, and they provide oversight and consultation for local public health agencies. State health agencies also delegate some public health powers, such as the power to quarantine, to local health officers.

Local public health agencies have responsibilities that vary depending on the locality, but they are the agencies that are responsible for implementing and enforcing local, state, and federal public health codes and ordinances and providing essential public health programs to a community. The goal of the local public health department is to safeguard the public's health and to improve the community's health status. The health department's authority is delegated by the state for specific functions. The duties of local health departments vary depending on the state and local public health codes and ordinances and the responsibilities assigned by the state and local governments. Usually, the local public health department provides for the administration, regulatory oversight, public health, and environmental services for a geographic area. The National Association of County and City Health Officials' (NACCHO's) operational definition of a local health department provides a description of the basic public health protections people in any community, regardless of size, can expect from their local health department. The description of local health departments includes the systems, competencies, frameworks, relationships, and resources that enable public health agencies to perform their core functions and essential services. Infrastructure categories encompass human, organizational, informational, legal, policy, and fiscal resources (NACCHO, 2014). A sample of these standards can be found in Box 46.2. As with state health departments, some states require that local health directors be physicians, whereas other states focus on public health experience. For example, public health nurses in Maryland, Kentucky, Illinois, Washington, Wisconsin, and California have held local health director positions.

BOX 46.2 Local Public Health Agency Functions

The following are selected standards by selected essential public health service performed by local public health agencies:

Essential Public Health Service 1: Monitor Health Status to Identify Community Health Problems

- Obtain data that provide information on the community's health.
- Develop relationships with local providers and others in the community who have information on reportable diseases and other conditions of public health interest and facilitate information exchange.
- Conduct or contribute expertise to periodic community health assessments in order to develop a comprehensive picture of the public's health.
- Integrate data with other health assessment and data collection efforts conducted by the public health system.
- Analyze data to identify trends and population health risks.

Essential Public Health Service 4: Mobilize Community Partnerships to Identify and Solve Health Problems

- Engage the local public health system in an ongoing, strategic, community-driven, comprehensive planning process to identify, prioritize, and solve public health problems; establish public health goals; and evaluate success in meeting the goals.
- Promote the community's understanding of, and advocacy for, policies and activities that will improve the public's health.
- Develop partnerships to generate interest in and support for improved community health status, including new and emerging public health issues.

Essential Public Health Service 7: Link People to Needed Personal Health Services and Ensure the Provision of Health Care When Otherwise Unavailable

- Engage the community to identify gaps in culturally competent, appropriate, and equitable personal health services, including preventive and health promotion services, and develop strategies to close the gaps.
- Support and implement strategies to increase access to care and establish systems of personal health services, including preventive and health promotion services, in partnership with the community.
- Link individuals to available, accessible personal health care providers.

From National Association of County and City Health Officials: *Operational definition of a functional local health department*, 2014. Available at http://www.naccho.org.

The majority of local, state, and federal public health agencies will be involved in the following:

- Collecting and analyzing vital statistics (Chapter 13)
- Providing health education and information to the population served (Chapter 19)
- Receiving reports about and investigating and controlling communicable diseases (Chapter 14)
- Planning for and responding to natural and man-made disasters and emergencies (Chapter 21)
- Protecting the environment to reduce the risk to health (Chapter 6)
- Providing some health services to particular populations at risk or with limited access to care (local public health agencies, guided by state and federal policies and goals and community needs) (Chapters 26-38)

- Conducting community assessments to identify community assets and gaps (Chapter 17)
- Identifying public health problems for at-risk and high-risk populations (Chapter 17)
- Partnering with other organizations to develop and implement responses to identified public health concerns (Chapters 16-18 and 23)

Public health nurses practice in partnership with each other at the local, state, and federal levels and with other public health staff, other governmental agencies, and the community to safeguard the public's health and to improve the community's health status. Public health agency staffs include physicians, nutritionists, environmental health professionals, health educators, various laboratory workers, epidemiologists, health planners, and paraprofessional home visitors and outreach workers. Community-based organizations include the American Red Cross, free clinics, Head Start programs, daycare centers, community health centers, hospitals, senior centers, advocacy groups, churches, academic institutions, and businesses. Other governmental agencies include the fire/emergency services department, law enforcement agencies, schools, parks and recreation departments, and elected officials. Changes in local, state, and federal governments affect public health services, and public health nursing has to develop strategies for dealing with these changes. Public health nurses facilitate community assessments to identify emerging public health concerns within communities and, based on results of community assessments, help develop programs to provide needed services.

HISTORY AND TRENDS IN PUBLIC HEALTH

A person born today can expect to live 30 years longer than a person born in 1900. Medical care accounts for 5 years of that increase. Public health practice, resulting in changes in social policies, community actions, and individual and group behavior, is responsible for the additional 25 years of that increase (USDHHS, 2010). Historically, public health nurses were valued by and important to society and functioned in an autonomous setting. They worked with populations and in settings that were not of interest to other health care disciplines or groups. Much public health service was delivered to the poor and to women and children, who did not have political power or voice. During the course of the twentieth century, public health responsibilities expanded beyond communicable disease prevention, occupational health, and environmental health programs to include reproductive health, chronic disease prevention, and injury prevention activities. As a result of Medicaid-managed care, many public health agencies were no longer providing personal health care services. Public health agencies began to shift emphasis from a focus on primary health care services to a focus on core public health activities such as the investigation and control of diseases and injuries, community health assessment, community health planning, and involvement in environmental health activities. As the twentieth century came to a close, developments in genetic engineering, the emergence of new communicable diseases, prevention of bioterrorism and violence, and the management and disposal of hazardous waste were emerging as additional public health issues (CDC, 1999). The Institute of Medicine (IOM, 2003) identified the following seven priorities for public health in the twenty-first century:

- Understand and emphasize the broad determinants of health.
- Develop a policy focus on population health.
- Strengthen the public health infrastructure.
- Build partnerships.
- Develop systems of accountability.
- Emphasize evidence-based practice.
- Enhance communication.

In supporting the 2003 IOM priorities, the National Academy of Medicine (NAM) released *Public Health 3.0: A Call to Action for Public Health to Meet the Challenges of the 21st Century* and recommended actions for public health as follows:

- Public health leaders should take on the role of chief health strategists in their communities.
- Health departments should work with private and public stakeholders in their communities to form partnerships to guide health initiatives.
- Accreditation of public health departments by the Public Health Accreditation Board (PHAB) should be encouraged and supported to assure all citizens are served by a nationally accredited health department.
- Timely, reliable, and actionable data should be accessible to communities, and clear metrics should be developed to document success of public health's practice to guide, focus, and assess the impact of prevention initiatives, which include targeting the social determinants of health and enhancing health equity.
- Public health funding should be enhanced and substantially modified by using innovative funding models to expand financial support for both infrastructure and community level work (NAM, 2017).

Public health activities at the beginning of the twenty-first century were shaped by the September 11, 2001, terrorist attacks of the World Trade Center, the Pentagon, and a field in Pennsylvania, in which thousands were murdered. However, public health nursing activities at the federal, state, and local levels were even more dramatically affected by a series of anthrax exposures that occurred shortly after the terrorist attacks. In addition to anthrax exposures in Florida and New York, one month after the attacks of September 11, thousands of workers at the Brentwood Post Office and the Senate Building in Washington, DC, were exposed to an especially virulent strain of anthrax from a contaminated letter. These exposures required public health nurses to rapidly establish mass medication distribution clinics, while also responding to frightened calls from community members and requests for information from the media.

The anthrax exposures alerted policy makers to the weakening public health infrastructure required to respond to bioterrorism events. As society grapples with the upheaval created by the reality of a bioterrorism event and an increase in violence, public health nurses learn to leverage existing authority and expertise to ensure that all critical issues threatening the

public's health are addressed. The shift of funding to support bioterrorism response efforts has the potential of weakening existing important public health programs. Nurses are well positioned to actively participate in policy decisions that will ensure that a public health infrastructure able to prevent and respond to bioterrorism will be strengthened and maintained within the context of general communicable disease surveillance and response. Public health nurses are facing issues such as unprecedented influenza, tetanus, and childhood vaccine shortages and emerging infections, such as severe acute respiratory syndrome (SARS) and the influenza A virus (H1N1) pandemic, that compete with bioterrorism activities for resources. One of these issues presented itself in the fall of 2009 and spring of 2010 when the world grappled with the lack of enough vaccine to prevent the virus from spreading across the world. (See later discussion.)

During the twentieth century, public health nurses were a major force in the nation, achieving immunization rates that accounted for the dramatic decrease in measles. A policy brief issued by All Kids Count (2000, p. 1) stated, "in 1941, more than 894,000 cases of measles were reported in the U.S. In 2013, preliminary data indicated that just 159 cases were reported—a reduction of 99.9%." Measles is still common in many parts of the world, and travelers continue to bring the disease into the United States. There have been a few measles outbreaks in recent years in the United States, primarily from unvaccinated individuals. In 2017, there were only 118 cases from 15 states reported (CDC, 2018). However, the general public is not well informed about how this immunization activity was accomplished or about its effect on improving health and lowering health care costs.

Public health nurses' difficulty in explaining the value of ongoing prevention activities can result in a decrease in resources required to ensure adequate surveillance and containment of communicable disease outbreaks. For public health services to receive adequate funding, it is necessary for the public and the government to be aware of the benefits provided to a community by public health nurses. Public health nurses must be at the table, as advocates and experts, when issues are being discussed and decisions are being made to make certain that public health programs are provided for the populations at risk. For example, as the incidence of active tuberculosis (TB) cases decreases, officials will consider shifting funds for TB control to other efforts. Public health nurses at the national, state, and local levels work together to educate officials about the importance of continuing funding for surveillance and containment efforts if the lower TB incidence rates are to be maintained. A recent public health concern is the unaccompanied immigrant children crossing the Mexican borders with no medical records. Efforts are being made to provide TB tests and to start immunizations at clinics near the border before the children migrate to other states and enter school. Public health nurses working in schools are challenged with surveillance of the immigrant students to assure the health and safety of the indigenous students and the population of the community.

The twenty-first-century public health nurse is working to develop a public health system able to monitor and detect suspicious trends and respond rapidly to prevent widespread exposure, whether the result of a deliberate or a natural epidemic. A prime example of emerging infectious diseases is severe acute respiratory syndrome (SARS), caused by a virus that brought illness and death to many in 2003. The disease spread quickly from China to other countries, being transported by airline passengers traveling internationally. The novel H1N1 influenza A virus pandemic provides another example of a natural epidemic that required a rapid, intensive, long-term response from public health nurses at the federal, state, and local levels. In 2009, the world was alerted to a new rapidly spreading influenza A virus (H1N1) when Mexico declared a state of emergency and closed schools and congregations in public settings in response to outbreaks of respiratory illness and increased reports of clients with influenza-like illness in several areas of the country (CDC, 2009). The first U.S. human cases of H1N1 were identified in April 2009 in California and Texas. On October 24, 2009, President Barack Obama declared H1N1 a national emergency in the United States. Public health nurses throughout the country shifted their activities to support the response to H1N1. Public health nurses who usually worked in areas such as family health services or school health services rapidly had to shift their focus to the H1N1 response. Family health service clinics and home-visiting services were either cancelled or scaled back to free up public health nurse time to respond to the emerging pandemic. More recent examples of diseases that have been monitored closely by public health nurses and officials are Middle Eastern respiratory syndrome (MERS) and Ebola virus. In the spring of 2014, the United States confirmed its first case of MERS-CoV, a corona virus, first reported in Saudi Arabia in 2012 (CDC, 2014a). The Ebola virus epidemic in African countries is being watched carefully by public health officials, and preventive measures are being taken to protect populations (see Chapter 14 for more on the Ebola virus outbreak in the United States).

More recently public health nurses and officials have had to educate and implement preventive measures for the Zika virus, which is contracted through mosquito bites and can be transmitted by pregnant women to their babies and additionally through sexual contact with an infected person (CDC, 2018).

SCOPE, STANDARDS, AND ROLES OF PUBLIC HEALTH NURSING

In 1920 C. E. A. Winslow defined public health as "the science and art of preventing disease, prolonging life and promoting health and efficiency through organized community effort" (Turnock, 2010, p. 10). This definition is still used in public health textbooks because it focuses on the relationship between social conditions and health across all levels of society. The IOM defines public health practice as "what we as a society do collectively to assure the conditions in which people can be healthy" (IOM, 2003, p. 28). Reflecting these definitions, the Public Health Nursing Section of the American Public Health Association defined public health nursing as "the practice of promoting and protecting the health of populations using knowledge from nursing, social and public health sciences"

(APHA, 2013, p. 1). The American Nurses Association (ANA) adds that public health nursing is a population-focused practice that works to promote health and prevent disease for the entire population. Public health nursing is a specialty practice of nursing defined by scope of practice and not by practice setting (APHA, 2013).

Additional knowledge, skills, and aptitudes are necessary for a nurse to go beyond focusing on the health needs of the individual to focusing on the health needs of populations (see Chapters 1 and 19). This additional knowledge distinguishes the public health nurse from other nurses who are practicing in the community setting. Public health nursing practices arise from knowledge gained from the physical and social sciences, psychological and spiritual fields, environmental areas, political arena, epidemiology, economics, community organization, public health ethics, community-based participatory research, and global health. The Quad Council of Public Health Nursing Organizations identified eight principles (Box 46.3) that distinguish the public health nursing specialty from other nursing specialties. Although other nurses may practice some or all of these eight principles, they are not incorporated as a core foundation of the practice in other specialties. Public health nurses adhere to all eight principles of public health nursing (APHA, 2013).

A variety of settings and a diversity of perspectives are available to nurses interested in developing a career in public health nursing. Public health nurses working at the federal, state, and local levels integrate community involvement and knowledge about the entire population with clinical understandings of the health and illness experiences of individuals and families in the population. They translate and articulate the health and illness needs of diverse, often vulnerable individuals and families in the population to planners and policy makers. As advocates, public health nurses help members of the community voice their problems and aspirations. Public health nurses are knowledgeable about multiple evidence-based strategies for intervention, from those applicable to the entire population, to those for the family and the individual. Public health nurses are directly engaged in the interprofessional activities of the core public health functions of assessment, assurance, and policy development. In any setting, the role of public health nurses focuses on the prevention of illness, injury, or disability, as well as the promotion and maintenance of the health of populations (APHA, 2013).

Public health nurses deliver services within the framework of ever-constricting resources coupled with emerging and complex public health issues. This requires the efficient, equitable, and evidence-based use of resources. The *Guide to Community Preventive Services* is a resource used by public health nurses to help determine which interventions to use (CDC, 2014b). This guide provides recommendations about the effectiveness of selected health promotion/disease prevention guidelines. Box 46.4 presents selected Task Group recommendations.

BOX 46.3 Tenets of Public Health Nursing

The following eight tenets of public health nursing distinguish public health nursing from other nursing specialties and are included in the *Scope and Standards of Public Health Nursing Practice* of the American Nurses Association (2013).

1. Population-based assessment, policy development, and assurance processes are systematic and comprehensive.
2. All processes must include partnering with representatives of the people.
3. Primary prevention is given priority.
4. Intervention strategies are selected to create healthy environmental, social, and economic conditions in which people can thrive.
5. Public health nursing practice includes an obligation to reach out to all who might benefit from an intervention or service.
6. The dominant concern and obligation is for the greater good of all the people or the population as a whole.
7. Stewardship and allocation of available resources supports the maximum population health benefit gain.
8. The health of the people is most effectively promoted and protected through collaboration with members of other professions and organizations.

Data from American Public Health Association, Public Health Nursing Section: *The definition and practice of public health nursing: a statement of Public Health Nursing Section,* Washington, DC, 2013, American Public Health Association.

BOX 46.4 How to Use Evidence to Determine Interventions

Selected Task Force on Community Preventive Services Recommendations: Vaccine-Preventable Diseases

Recommendation	Interventions
Enhancing Access to Vaccination Services	
Recommended (strong evidence)	Expanding access in medical offices or public health clinics
Recommended (strong evidence)	Reducing out-of-pocket expenses
Recommended (sufficient evidence)	Vaccination programs in WIC settings
Recommended (sufficient evidence)	Home visits
Recommended (sufficient evidence)	Vaccination programs in schools
Insufficient evidence to determine effectiveness	Vaccination in childcare centers
Increasing Community Demand for Vaccines	
Recommended (strong evidence)	Client reminder/recall systems
Recommended (strong evidence)	Multicomponent interventions that include education
Recommended (sufficient evidence)	Vaccination requirements for childcare, school, and college attendance
Insufficient evidence to determine effectiveness	Clinic-based education only
Insufficient evidence to determine effectiveness	Client or family incentives
Insufficient evidence to determine effectiveness	Client-held medical records
Insufficient evidence to determine effectiveness	Community-wide education only

WIC, Women, Infants, and Children.

Fig. 46.3 Public health nurses protect the population's health by providing immunizations. (Courtesy Arlington County Department of Human Services/Public Health Division, Arlington, VA.)

The *National Public Health Performance Standards* program (CDC, 2015), a federal, state, and local partnership, has developed evaluation instruments that can be used to collect and analyze data on the programs provided through state and local public health systems. The instruments link with the 10 essential services of public health that define the core functions of public health (see Chapter 1) and help public health nurses at state and local health departments identify which essential services are met and which need additional resources.

Public health nurses make a significant difference in improving the health of a community by monitoring and assessing critical health status indicators such as immunization levels (Fig. 46.3), infant mortality rates, and communicable diseases. On the basis of their assessment and in partnership with the community, public health nurses advocate for evidence-based interventions to respond to negative health status indicators. For example, a community assessment may indicate that a significant percent of children have hemoglobin levels below 11 mg/dL. The public health nurse will know that additional information such as blood lead levels will be needed in order to implement an appropriate intervention. Public health accreditation is being encouraged at the federal level by the Public Health Accreditation Board (PHAB, 2018) for local and state health departments to meet specific standards of practice. Community health assessments and community health improvement plans are required components for each local health department. Community partnerships are imperative for the community health assessment and plan to be a meaningful and effective tool. Public health nurses are knowledgeable about resources and agencies within the community that can be partners in the accreditation process. Public health nurses can lead the accreditation process in their communities.

Public health's shift from being the primary care provider of last resort to developing partnerships to meet the health promotion and disease prevention needs of populations has raised concerns about available health care for the uninsured and underinsured. The public health nurses' role in this ongoing shift in health care delivery is still being developed for many agencies. Public health nurses retain responsibility for assuring that all populations have access to affordable, quality health care services. They accomplish this by advocating for legislation that promotes universal health care, such as increased funding for community health centers and expansion of Medicaid eligibility criteria; and by forming partnerships with hospitals, free clinics, and other organizations to guarantee health care for all populations in the community. Case management at the community level is a renewed effort in public health nursing. Through case management activities, public health nurses link populations with needed health care providers, as well as social services providers (see Chapter 25).

Uninsured individuals seek services on a sliding payment scale from such sources as university or public hospital clinics, neighborhood health centers, nurse-managed clinics, or community-based free clinics. Public health nurses serve as a bridge between these populations and the resource needs for this at-risk group by approaching health care providers on behalf of individuals seeking medical/health services and by keeping the needs of this population on the political agenda. Frequently, low-income populations or populations with multiple chronic illnesses lack the knowledge and skills to negotiate the complex health care system. This population needs education and training in identifying their problems, approaches to self-care, and illness prevention strategies and lifestyle choices that will have an effect on their health. The public health nurse understands barriers these populations confront, such as transportation issues, language barriers, cultural differences, and difficulty understanding and following health care provider instructions.

Although vulnerable populations have always benefited from public health nursing services, the populations that are most acutely in need of public health nursing services have changed dramatically over the last couple of decades. Of particular concern are the number of young women and their partners who are substance abusers and have risky behaviors that put their pregnancy or children at high risk of injury or abuse. Public health nurses at the federal, state, and local levels have developed innovative, collaborative approaches to prepare staff to work effectively with this population. Public health nurses can cultivate community partnerships to help address the needs of this population. Needle exchange programs are an example of a community effort promoted by public health nurses that can decrease the spread of bloodborne infections for this population and provide opportunities to connect with community resources that can assist individuals who have addiction problems.

CHECK YOUR PRACTICE

Disease Prevention

A client confides that she is worried about increased violence and vandalism in her neighborhood. She suspects a group of teenagers is involved in some of these unlawful activities. She has notified the police on several occasions about fights and gunshots. A local newspaper reported an increase in bloodborne infections from intravenous drug use and unprotected sexual activity. She has found needles at the park where her children play and has observed what appear to be drug deals. She is concerned that the adolescents may be:

- Smoking marijuana or using illegal intravenous drugs
- Involved in gang activity
- Having multiple sexual partners to obtain drugs

What actions can the public health nurse take?

EVIDENCE-BASED PRACTICE

The Kentucky Health Access Nurturing Development Services (HANDS) program is a voluntary home visiting program targeting first-time pregnant mothers or parents with infants (up to 3 months old), who may have challenges such as low income, single parenthood, substance abuse problems, or have been victims of abuse or domestic violence. HANDS is designed to facilitate positive pregnancy and child health outcomes and maximize child growth and development, as well as prevent child maltreatment and improve family functioning. A trained paraprofessional or professional home visitor, such as a public health nurse or social worker, conducts prenatal and postnatal home visits with parents, performs assessments, provides parenting information, problem-solving techniques, parenting skill development; and addresses basic needs.

An analysis compared a group of 2253 prenatal mothers who were referred to the HANDS program and received at least one home visit to a group of 2253 demographically similar mothers who did not participate in HANDS. HANDS participants had lower rates of preterm delivery and low-birth-weight infants. HANDS participants also were significantly less likely to have a substantiated report of child maltreatment compared to controls. Participants in the HANDS program also had an increase in adequate prenatal care and a reduction in maternal complications during pregnancy. An additional conclusion showed pregnancy outcomes improved as the number of prenatal home visits increased. The rate of preterm births among those receiving seven or more prenatal home visits was 9.4 percent lower than the state-wide rate.

Nurse Use

HANDS program participation appears to result in significant improvements in maternal and child health outcomes, most specifically for those receiving seven or more prenatal home visits. As a state-wide, large scale home visiting program, this has significant implications for the continued improvement of maternal and child health outcomes in Kentucky (Williams et al., 2017).

ISSUES AND TRENDS IN PUBLIC HEALTH NURSING

The discovery and development of antibiotics in the 1940s, coupled with immunization programs and improvements in sanitation, contributed to the decrease in infectious disease–related morbidity and mortality during the twentieth century (CDC, 1999). Twenty-first-century issues facing public health nursing include increasing rates of drug resistance to community-acquired pathogens, societal issues such as health reform legislation, access to affordable housing, racial and ethnic disparities in health outcomes, and unequal access to health care. Additionally, behaviorally influenced issues (such as chronic diseases, violence in society, and substance abuse) and emerging infections (for example, SARS, hepatitis C, and new influenza strains, such as the H3N2 virus during the 2017 flu season [CDC, 2018]) are issues that public health nurses must help control. Community assessments need to reflect the factors that affect the populations the public health nurse serves.

For example, a major twenty-first-century public health challenge is emerging infections resulting from drug-resistant organisms. The widespread, often inappropriate use of antimicrobial drugs has resulted in loss of effectiveness for some community-acquired infections such as gonorrhea, pneumococcal infections, and tuberculosis and in increasing rates of drug resistance in community-acquired pathogens such as *Streptococcus pneumoniae, Escherichia coli,* and *Salmonella* spp. The rise in antimicrobial resistance in community and health care settings is causing alarm among public health leaders, nurses, and infectious disease experts. "Staph" infections caused by methicillin-resistant *Staphylococcus aureus* (MRSA) have received increasing attention in recent years. MRSA is a type of staph bacteria that has developed resistance to certain antibiotics, including methicillin and other more common antibiotics such as oxacillin, penicillin, and amoxicillin (CDC, 2018). Public health nurses are building partnerships, providing education, and making surveillance a top priority to prevent the spread of antimicrobial-resistant infections. Public health nurses can influence this trend by objecting to inappropriate use of antibiotics by providers and educating individuals, families, health care providers, elected officials, and the community about the dangers of misuse and overuse of antibiotics (CDC, 2018).

Societal issues such as welfare and health insurance reform will influence a population's ability to obtain preventive health services either because of limited health care providers accepting government-sponsored health care coverage or because the low-wage jobs they take do not allow time off for health care. When childcare is an issue for the welfare mother returning to work, consideration must be given to effects on the individual, family, community, and population. Public health nurses assess the problem and determine what is wrong with a system that forces parents to go to work so they can be removed from welfare rolls but that does not provide for childcare. The question to be answered by a nurse is, "What will it take to change the system?"

Partnerships and collaboration among groups are much more powerful in making change than the individual client and public health nurse working alone. As another example, the depressed, nonfunctional mother in need of counseling is a significant public health concern because the mother's, children's, and family's needs are not being met. Frequently, the problem may not be obvious to the health professional who sees this woman for the first time. Public health nurses have special preparation to help them both identify the individual's problem and look at its effects on the broader community. In this example, the children may grow to be adults with mental

health problems, and the community mental health services will need to be able to handle the increase in this population. Children may become violent adults, resulting in a need for more correctional facilities. Mothers may need additional mental health services. Children may be absent from school often and may not be able to contribute to society. They may be nonproductive in the workplace because absence from school leads to lack of skills. One problem of the single individual can place great burdens on the community.

The IOM (2002) reported that disparities in health care treatment accounted for some of the gaps in health outcomes between racial and ethnic groups. This report found that minorities received lower-quality health care than white people, regardless of insurance status, income, and severity of the condition. In 2016, the Agency for Healthcare Research and Quality released a report that includes various indicators of health care access and quality for disparate populations. The report shows areas of improvement, areas of no change, and areas that have worsened for disparate populations (AHRQ, 2016).

Public health nurses work as case managers and at the policy level to promote equal access to health care, including health literature and spoken services that reflect the community in which the services are being delivered (see Chapter 25). The public health nurse working directly as a case manager or in a clinic setting or in the community can promote ethnicity-friendly services by partnering with other community agencies such as interpreter services. Identifying and alerting the community to gaps in available services can facilitate equal access to health care. For example, some communities may appear to have an adequate number of pediatricians to meet the community's needs. However, a community assessment may reveal that the community is home to a high number of children who rely on Medicaid as payment for services or to families whose primary language is not English. Matching this information with the pediatrician population may reveal that none of the pediatricians accept Medicaid as payment for services, or they all deliver services in English only.

HOW TO Educate Nurses for Roles in Public Health: Curriculum Objectives for Public Health Nursing

The nurse should be able to do the following:

- Articulate similarities and differences between individual-focused and population-focused nursing practice.
- Describe the history and current perspectives of public health nursing practice.
- Demonstrate skills used to apply key nursing contributions to public health practice (core functions and essential services) in a community.
- Apply principles and skills of population health to practice in the public health agency.
- Use current information and communication technology in all public health agencies.
- Communicate the benefits of public health and public health nursing practice.
- Develop community partnerships that will assist in meeting the health needs of the community.

Developed by Downing, Diane: Public health nursing at local, state, and national levels. In Stanhope and Lancaster: *Public health nursing: population-centered health care in the community,* ed. 8, St. Louis, MO, 2012, Elsevier.

Population-focused public health nursing requires that public health nurses consider social determinants of health, including social and environmental factors that influence the health of communities, families, and individuals. For example, a public health nurse providing communicable disease control services for the homeless population or the refugee population will also work for policies that ensure affordable housing. A public health nurse providing case management services for a new teen mother will include ensuring that the mother returns to school; has safe, affordable housing; and has safe childcare available while she attends school. The Kentucky HANDS program is an example of a model program that considers the social determinants of health (Williams et al., 2017).

MODELS OF PUBLIC HEALTH NURSING PRACTICE

In response to the IOM (1988) report that described public health in a state of disarray and the need for all federal public health agencies to work to identify core public health functions, public health nurses have worked to develop models of practice that will operationalize the role of public health nursing. This section presents examples of models developed by local and state departments of health. These models also serve as examples of the important work that can be accomplished by local, state, and federal partnerships.

In Virginia, a statewide committee led an examination of the role of public health nursing in the context of increasing public expectation of accountability and the shift of public health nursing emphasis from clinical services to population-focused services. Their work resulted in a document that identifies public health nursing roles within the framework of the core public health functions (see Chapter 1). The work identifies the educational needs of staff that would prepare them to function effectively in the changing public health arena. Essential elements of the role were identified. These essential elements are being implemented through multiprofessional public health teams. The document includes a matrix that demonstrates the relationship of the public health functions defined by the essential elements to the public health nursing roles at the local level, as well as the role of the state in this responsibility (see Appendix F.1).

The Public Health Nursing Section of the Minnesota Department of Health (2001) developed a framework called the Intervention Wheel that defines public health nursing interventions by level of practice (see Chapter 11). Public health nurses deliver services within a framework of core interventions. The three levels of public health nursing practice are systems, community, and individual/family. The model identifies 17 population-based public health interventions delivered by public health nurses. It also identifies population-based interventions as those that do the following:

- Focus on entire populations possessing similar health concerns or characteristics
- Are guided by an assessment of health status
- Consider the broad determinants of health, such as housing, income, education, cultural values, and community capacity

- Consider all levels of prevention, with primary prevention a priority
- Consider all levels of practice (community, system, and individual/family) (see Appendix F.1)

The public health nursing practice model of Los Angeles County Department of Health describes public health nursing practice as population based. It synthesizes the 10 essential services of public health practice, principles identified by the Quad Council of Public Health Nursing Organizations and the Minnesota Department of Health, PHN Section, and tenets of the ANA *Scope and Standards of Public Health Nursing Practice.* It includes the following criteria:

- Focuses on entire populations possessing similar health concerns or characteristics
- Relies on an assessment of population health status
- Considers the broad determinants of health
- Considers all levels of prevention, with a preference for primary prevention
- Considers all levels of practice: individual/family-focused practice, community-focused practice, and systems-focused practice
- Reaches out to all who might benefit, not focusing on just those who present themselves
- Demonstrates a dominant concern for the greater good of all the people (the interest of the whole taking priority over the best interest of the individual or group)
- Creates healthy environmental, social, and economic conditions in which people can thrive (Los Angeles County Department of Public Health/Public Health Nursing, 2007)

EDUCATION AND KNOWLEDGE REQUIREMENTS FOR PUBLIC HEALTH NURSES

The Council on Linkages Between Academia and Public Health Practice (2014) examined a decade of work to identify a list of core public health competencies that represent a set of skills, knowledge, and attitudes necessary for the broad practice of public health. Initially adopted in 2001, the core competencies were revised and adopted unanimously by the Council in June 2009. The accomplishments of the Council on Linkages include not only developing the Core Competencies for Public Health Professionals to guide curriculum and workforce development but also promoting public health systems research to increase understanding of and improve public health infrastructure, as well as focusing the field on evidence-based strategies to improve worker recruitment and retention and combat emerging worker shortages. The Council is located in Washington, DC, and is staffed by the Public Health Foundation. A list of member organizations is located at http://www.phf.org.

The competencies are built around the Essential Public Health Services. This is the only consensus set of core competencies in public health that apply to all practicing public health professionals. They capture the cross-cutting competencies necessary for all disciplines that work in public health, including public health nurses, physicians, environmental health specialists, health educators, and epidemiologists. The competencies are applied to three tiers as follows: generalist, supervisor, and executive level. A detailed list of core competencies by job category and skill level is available. The core public health competencies have been applied to public health nursing (see the appendix).

LINKING CONTENT TO PRACTICE

In April 2018, the Quad Council Coalition of Public Health Nursing Organizations (QCC, 2018) released the 2018 Community/Public Health Nursing (C/PHN) Competencies. The core public health competencies are divided into the following eight domains. These eight domains are guidelines for public health departments to use in meeting standards for the public health accreditation process, which begins with a community assessment and plan conducted through collaboration with community partners.

The content related to the domains can be found in the chapters noted.

1. Analytic assessment skills: Chapters 1, 10, 11, 17 18, and 26 to 38
2. Basic public health sciences skills: Chapters 3, 6, 7, 11, 12 to 16, 21 to 25, 32
3. Cultural competency skills: Chapters 4 and 8
4. Communication skills: Chapters 19 and 25
5. Community dimensions of practice skills: Chapters 16, 17, 22, and 42 to 46
6. Financial planning and management skills: Chapter 5
7. Leadership and systems thinking skills: Chapter 40
8. Policy development/program planning skills: Chapters 9 and 23

In addition to being skilled in the areas of epidemiology, analytic assessment skills, environmental health, health services administration, cultural sensitivity, and social and behavioral science, the twenty-first-century public health nurse must be competent in areas such as community mobilization, risk communication, genomics, informatics, community-based participatory research, policy and law, global health, and public health ethics (ANA, 2013).

Many of these core public health competencies are provided by public health nurses who have learned these skills in the workplace while gaining knowledge through years of practice. Rapid changes in public health represent a challenge to public health nurses in that there is neither the time nor the staff to provide the on-the-job training needed to learn and upgrade skills and knowledge of staff. Nurses with baccalaureate or master's preparation are needed to provide a strong public health system (see Chapter 1). In 2007 and again in 2013, the ANA revised the 1999 *Scope and Standards of Public Health Nursing Practice* to reflect the increasing complexity and rapid changes faced by public health nurses. The revised standards include those that are expected of all baccalaureate degree nurses, the entry level into public health nursing practice, and the standards of the advanced practice public health nurse prepared at the master's level (APHA, 2013).

NATIONAL HEALTH OBJECTIVES

Since 1979 the U.S. Surgeon General has worked with local, state, and federal agencies, the private sector, and the U.S. population to develop objectives for preventing disease and promoting health for the nation. These objectives are

revisited every 10 years. In 2009 the proposed *Healthy People 2020* objectives were released for public comment (see the *Healthy People 2020* box).

HEALTHY PEOPLE 2020

Selected National Health Objectives Related to the Public Health Infrastructure

- **PHI-1:** Increase the proportion of federal, tribal, state, and local public health agencies that incorporate core competencies for public health professionals into job descriptions and performance evaluations.
- **PHI-4:** Increase the number of public health or related graduate degrees, post-baccalaureate certificates, and bachelor's degrees awarded.
- **PHI-13:** Increase the proportion of tribal, state, and local public health agencies that provide or assure comprehensive epidemiology services to support essential public health services.
- **PHI-14:** Increase the proportion of state and local public health jurisdictions that conduct a public health system assessment using national performance standards.
- **PHI-15:** Increase the proportion of tribal, state, and local public health agencies that have developed a health improvement plan and increase the proportion of local health jurisdictions that have a health improvement plan linked with their state plan

From U.S. Department of Health and Human Services: *Healthy People 2020: national health promotion and disease prevention objectives*, 2010. Available at http://www.healthypeople.gov.

State health departments help set local goals using the *Healthy People 2020* objectives as a framework. Knowing that public health departments do not have the resources to accomplish these goals independently, collaboration is essential to quality nursing practice and is encouraged at the local level with existing groups. New partnerships are developed related to specific goals. Communities develop coalitions to address selected objectives, based on community needs, to include all of the local community stakeholders such as social services, mental health, education, recreation, government, and businesses. Membership varies from community to community depending on that community's formal and informal structure. The groups join the coalition for a variety of reasons. For example, businesses see the value of developing a productive workforce that will be of importance to them and the community in the future. Emphasis is being placed on national accreditation for state and local public health departments. The Healthy People indicators, along with the National Public Health Performance Standards, are used as guidelines for accreditation. The Public Health Accreditation Board (PHAB) is the accrediting agency.

Public health nurses help clients identify unhealthy behaviors and then help them develop strategies to improve their health. Some of the behaviors addressed by public health nurses are tobacco use, physical activity, and obesity, all of which affect quality and years of healthy life. Public health nurses also organize the community to conduct community health assessments to identify where health disparities exist and to target interventions to address those disparities. For example, community health assessments may disclose that certain populations are at higher risk for asthma, diabetes, low immunization rates, high cigarette smoking behavior, or exposure to environmental hazards.

Some *Healthy People 2020* communicable disease areas of focus are vaccine-preventable infectious diseases, emerging antimicrobial resistance, tuberculosis infection and disease, and levels of human immunodeficiency virus (HIV), acquired immunodeficiency syndrome (AIDS), and sexually transmitted infections. To help clients reduce their risk of acquiring a communicable disease, public health nurses provide clients with instructions on the use of barrier methods of contraception and information on the hazards of multiple sexual partners and street drug use. Obtaining a complete sexual history on all clients coming to the health department for services takes special skills but is essential to determine the behaviors that have brought the client to the local health department. Education of young persons before they become sexually active has helped reduce the incidence of some sexually transmitted diseases in this population.

FUNCTIONS OF PUBLIC HEALTH NURSES

Public health nurses have many functions depending on the needs and resources of an area (Fig. 46.4). Advocate is one of the many roles of the public health nurse. As an advocate, the public health nurse collects, monitors, and analyzes data and works with the client to identify and prioritize needed services, whether the client is an individual, a family, a community, or a population. The public health nurse and the client then develop the most effective plan and approach to take, and the nurse helps the client implement the plan so that the client can become more independent in making decisions and obtaining the services needed. At the community and population levels, public health nurses promote healthy behaviors, safe water and air, and sanitation. They advocate for healthy policies at the local, state, and federal levels that will develop healthy communities (see Chapter 9).

Legislation is a public health tool used to ensure the health of populations. Implemented with extreme concern for the balance between individual rights and community rights, public policy is a critical function for the public health nurse. Examples of legislation that has successfully improved the health of populations are required immunizations for school entry, seat belt use, smoke-free environments, and bicycle and motorcycle helmet use.

Case management is a major role for public health nurses (see Chapter 25). The 2010 health reform legislation will increase the importance of the case management role as newly insured clients attempt to link with health care providers and the Nurse-Family Partnership program (2018) is expanded. Public health nurses use the nursing process of assessing, planning, implementing, and evaluating outcomes to meet clients' needs. Clear and complex communications are frequently an important component of case management. Other health and social agency providers may not be familiar with the home and community living conditions that are known to the public health nurse. It is the nurse who sees the living conditions and who can tell the story for the client or assist the individual,

Fig. 46.4 Public health nursing roles. *HIV,* Human immunodeficiency virus; *ICS,* Incident Command System; *NIMS,* National Incident Management System; *STD,* sexually transmitted disease; *STI,* sexually transmitted infection; *TB,* tuberculosis; *WIC,* Women, Infants, and Children.(Prepared by Lois Davis, RN, MSN, MA, public health clinical instructor, University of Kentucky College of Nursing, Lexington, KY.)

family, or community with the telling of their story. Case managers assist clients in identifying the services they need the most at the least cost. They also assist communities and populations in identifying and linking with services that will increase the overall population health status.

Public health nurses are a major referral resource. They maintain current information about health and social services available within the community. They know what resources will be acceptable to the client within the social and cultural norms for that group. The nurse educates clients to enable them to use the resources and to learn self-care. Nurses refer to other services in the area, and other services refer to the public health nurse for care or follow-up. For example, the mother and new baby may be referred to the public health nurse for postnatal care with postpartum home visit follow-up. School nurses often function as public health nurses because they are aware of the students' needs, have knowledge about resources in the community for referrals, and focus on preventive services.

Assessment of literacy is a large part of public health nursing. Many individuals are limited in their ability to read, write, and communicate clearly. The public health nurse has to be culturally sensitive and aware of the specific areas of unique problems of clients, such as financial limitations that may in turn limit educational opportunities. Frequently, when a person goes to a physician's office, clinic, or hospital, they are clean and neatly dressed. The assumption is made that when they nod at the health care provider it means that they understand what has been said. This is frequently not the case, but the client is embarrassed to admit that he or she does not understand what has been said. Being illiterate does not mean a person is mentally slow. It is important for the public health nurse to follow up on the many contacts the individual or family has with medical, social, and legal services to clarify what is understood and to find an answer to the questions that have not been asked by the client or answered by the services.

The public health nurse is an educator, teaching to the level of the client so that information received is information that can be used. Patience and repetitions over time are necessary to develop trust and to enable the client to use the relationship with the nurse for more information. As educator, the public health nurse identifies community needs (e.g., playground safety, hand hygiene, pedestrian safety, safe-sex practices) and develops and implements educational activities aimed at changing behaviors over time.

Public health nurses are direct primary caregivers in many situations, both in the clinic and in the community. Where the public health nurse provides primary care is determined by community assessment and is usually in response to an identified gap to which the private sector is unable to respond, coupled with an assessment of the impact of the gap in services on the health of the population. Examples include prenatal services for uninsured women, free or low-cost immunization services for targeted populations, directly observed therapy for clients with active tuberculosis, and treatment for sexually transmitted infections.

Public health nurses ensure that direct care services are available in the community for at-risk populations by working with the community to develop programs that will meet the needs of those populations. Currently, no system of outreach service in the medical models of care addresses the multiple needs of high-risk populations. High-risk populations frequently do not understand the medical, social, educational, or judicial system and the professional languages, codes of behavior, or expected outcomes of these services. Clients need a case manager, a health educator, an advocate, and a role model to enable them to benefit from these services and to teach them how to avoid complex and expensive problems in the future. The local public health nurse fills these roles and many more for this population. These are examples of the difficult clinical issues that public health nurses face in making ethical and professional decisions.

The public health nurse's role is unique and essential in many situations. Access to homes gives the nurse information that usually cannot be gathered in the hospital or clinic setting. The public health nurse learns to ask intimate questions creatively and to seek information that will facilitate case management and provide the clinical and social care needed, including other community resources. Careful attention must be paid to privacy and confidentiality in delivering public health nursing services. The credibility of the nurse and the agency depends on the professional handling of the public health information of each and every staff member.

When a disaster (see Chapter 21) occurs, public health nurses at the local, state, and federal levels have multiple roles in assessing, planning, implementing, and evaluating needs and resources for the different populations being served. Whether the disaster is local or national, small or large, natural or man-made, public health nurses are skilled professionals essential to the team. As a health care facility, the local public health department has a disaster plan, as well as a role in the local, regional, and state disaster plans. Public health nurses' roles include providing education that will prepare communities to cope with disasters and professional triage for local shelters, conducting enhanced communicable disease surveillance, planning and implementing mass dispensing sites, working with environmental health specialists to ensure safe food and water for disaster victims and emergency workers, and serving on the local emergency planning committee. Their presence may be required in other regions of the state or country to provide official public health nursing duties in a time of crisis, such as a hurricane, that requires a lengthy period of recovery. Each governmental jurisdiction has an emergency plan. The public health agency is expected to provide planning and staffing during a disaster. These local emergency preparedness plans may be multigovernmental, which requires coordination between communities. Public health nurses have a critical role in ensuring that emergency preparedness plans address the special needs of vulnerable populations such as those with disabilities or low-income populations who lack the resources to maintain the recommended three- to five-day supply of food and medication.

Essential and unique roles for public health nurses exist in the area of communicable disease control. Public health nursing skills are necessary for education, prevention, surveillance, and outbreak investigation. Public health nurses can find infected individuals; notify contacts; refer; administer treatments; educate the individual, family, community, professionals, and populations; act as advocates; and in general be state-of-the-art resources to reduce the rate of communicable disease in the community (see Chapters 14, 15, and 22). The communicable disease role is one of the most important roles for public health nursing during disasters. During the terrorist attacks on September 11, 2001, the SARS outbreak, and the novel H1N1 pandemic, public health nurses at the federal, state, and local levels immediately implemented active enhanced surveillance activities and prepared for implementation of mass dispensing sites. Information about communicable diseases seen at the local level was passed on to the state public health agency and finally to the CDC. At each step, the data were analyzed for evidence of unusual disease trends.

When October 2001 alerts from the CDC began presenting information about a photo editor in Florida who had been hospitalized with inhalation anthrax, public health nurses and hospital infection control practitioners throughout the nation increased activity. Public health response to disasters requires that resources be redirected temporarily from other programs while maintaining programs that will prevent additional outbreaks. Therefore public health nurses not normally involved in communicable disease activities can be shifted to this function. The exposures resulting from the anthrax-tainted letters presented unprecedented public health challenges. The Washington, DC, anthrax exposures resulted in thousands of possible work-related exposures, five cases of inhalation anthrax in the region, and two deaths over a period of months. Public health at the federal, state, and local levels was looked to for coordinated leadership and answers to a situation in which experience was limited and answers were uncertain.

With the first Ebola virus outbreak in the United States in Dallas, public health workers were case finding, that is, identifying contacts with the person presenting with Ebola virus. After contacts were identified, they were visited to assess them for symptoms of Ebola virus. In addition, public health workers were going door to door to see if anyone had been exposed to the virus through the identified contacts of the patient. The purpose in case finding is to be able to treat all who have symptoms to reduce the risk of a massive outbreak of a disease (CDC, June 2018).

Although communicable disease control is a core public health service, the role of the public health nurse as **incident commander** in a widespread public health emergency is a new role (see Fig. 46.5). Issues such as how to conduct mass treatment in response to a bioterrorism event, which jurisdiction is in charge, how to communicate uncertain information to the public, and who should take antibiotics for how long had to be rapidly resolved across jurisdictional and agency lines. Public health nurses often complete the Federal Emergency Management Agency (FEMA) National Incident Management System (NIMS) courses to learn about the chain of command, and participate in public emergency events (U.S. Department of Homeland Security, 2017). The anthrax exposures are typical of the nature of public health emergencies. They unfold as the communicable disease moves through communities.

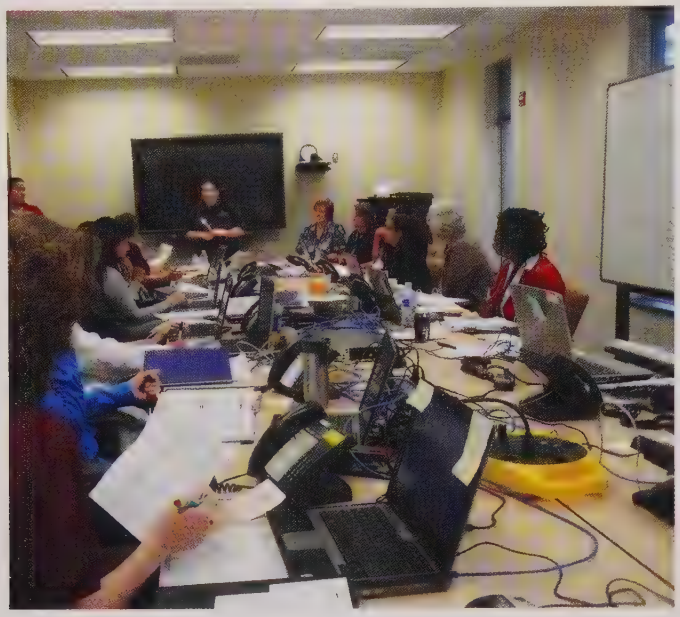

Fig. 46.5 Public health nurses respond to community-wide disease outbreaks within the framework of the incident command structure. (Courtesy Arlington County Department of Human Services/Public Health Division, Arlington, VA.)

Public health nurses are essential partners in disaster drills. In Virginia, an electrical company has a nuclear plant that requires annual multijurisdictional disaster drills. These disaster planning and practice sessions are an opportunity for local public health nurses to get to know other agencies' representatives and to let them know what public health nursing can offer. Because public health nurses are out in the communities and have assessment skills, they are essential in evaluating how the disaster was handled and making suggestions about how future events might be managed. To be most effective as disaster responders, public health nurses have to be a part of the team *before* an emergency. Knowing what type of disaster is likely to occur in a community is essential for planning. Types of disasters vary from place to place, but there is a history of past events and how they were handled, as well as resources and training from regional, state, and federal agencies. Public health nurses can help educate the public about the individual responsibilities and preparations that can be in place both for the person and for the community. The Levels of Prevention box presents additional examples of public health nurses' functions by level of prevention. Public health nurses at the local, state, and federal levels work in partnership to accomplish each function.

LEVELS OF PREVENTION

Primary Prevention

- Partnering with the community to conduct a community health assessment to identify community assets and gaps
- Partnering with the community to develop primary prevention programs in response to identified gaps
- Providing information about safe-sex practices
- Providing individual and community-based education to increase knowledge and modify perceptions of risks
- Educating daycare centers and families about the dangers of lead-based paint
- Educating daycare centers, schools, and the general community about the importance of hand hygiene to prevent transmission of communicable diseases
- Inspecting daycare centers, nursing homes, and hospitals to ensure client safety and quality of care
- Providing immunizations
- Advocating for issues such as mandatory seat belt legislation, smoke-free environments, and universal access to health care
- Providing no-charge infant car seats accompanied by classes in use of safety seats
- Identifying environmental hazards such as housing quality, playground safety, pedestrian safety, and product safety hazards, and working with the community and policy makers to mitigate the identified hazards
- Developing social networking interventions to modify community norms related to sexual risk behaviors, condom use, and abstinence
- Larvaciding against mosquitoes in areas frequented by populations 55 years of age and over
- Working with communities to develop citizen emergency preparedness plans

Secondary Prevention

- Identifying and treating clients in a sexually transmitted disease clinic
- Identifying and treating clients with TB infection and disease in a TB clinic
- Providing directly observed therapy (DOT) for clients with active TB
- Conducting lead screening activities for children
- Conducting contacting/tracing for individuals exposed to a client with an active case of TB or a sexually transmitted disease
- Conducting ongoing disease surveillance for communicable diseases and implementing control measures when an outbreak is identified
- Implementing screening programs for genetic disorders/metabolic deficiencies in newborns; breast, cervical, and testicular cancer; diabetes; hypertension; and sensory impairments in children, and ensuring follow-up services for clients with positive results
- Conducting syndromic surveillance to ensure early identification of victims of an influenza epidemic or bioterrorism event
- Providing low-cost antibiotics for treatment of Lyme disease
- Conducting enhanced surveillance for novel influenza virus infection among travelers with severe unexplained respiratory illness returning from affected countries
- Establishing mass dispensing clinics for antibiotic distribution in response to a bioterrorism event or influenza pandemic

Tertiary Prevention

- Providing case management services that link clients with chronic illnesses to health care and community support services
- Providing case management services that link clients identified with serious mental illnesses to mental health and community support services
- Educating at rehabilitation centers to help clients with stroke optimize their functioning
- Establishing an alternative treatment site for victims of a smallpox epidemic

TB, Tuberculosis.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Public Health Nursing at Local, State, and National Levels

Targeted Competency: Teamwork and Collaboration

Function effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision making to achieve quality patient care.

Important aspects of teamwork and collaboration include:

- **Knowledge:** Describe scopes of practice and roles of health care team members.
- **Skills:** Integrate the contributions of others who play a role in helping patient/family achieve health goals.
- **Attitudes:** Respect the unique attributes that members bring to a team, including variations in professional orientations and accountabilities.

Teamwork and Collaboration Question

Your state has recently been awarded funding from the Centers for Disease Control and Prevention to prevent the spread of viral hepatitis through increased testing, improving access to care, and strengthening surveillance to detect viral hepatitis transmission and disease. You are the Director of Nursing for the State Public Health Department and currently serve on the Infectious Disease Prevention (IDP) committee. The IDP committee has been given the responsibility to determine how to best utilize this new funding to effectively meet the objectives of the grant. Consider the following:

- As the Director of Nursing for the State Public Health Department, what is your role in addressing this initiative at the state level? How would your role change if you were a public health nurse working at the local health department?
- In addition to nursing, give examples of other professionals who likely serve on the IDP committee with you. Describe the role for each professional for this committee.
- Identify local and state organizations in your community that you would recommend that the IDP committee collaborate with to develop and implement a response to the identified health issue
- Through this grant, your state is addressing several objectives in the *Healthy People 2020* focus area of Immunization and Infectious Diseases. Go to the *Healthy People 2020* website and identify which specific objectives would apply to this initiative.

Prepared by Lisa Turner, PhD, RN, PHCNS-BC, Assistant Professor, Berea College Nursing Program, Berea, Kentucky.

PRACTICE APPLICATION

A retirement community in a small town reported to the local health department 24 cases of severe gastrointestinal illness that had occurred among residents and staff of the facility during the past 24 to 36 hours. It was determined that the ill clients became sick within a short, well-defined period, and most recovered within 24 hours without treatment. The communicable disease outbreak team, composed of public health nurses, public health physicians, and an environmental health specialist, was called to respond to this possible epidemic.

How should they respond to this situation? (Refer to Chapter 13 for help in answering this question.)

A. Call the Centers for Disease Control and Prevention and ask for help with surveillance.
B. Send all the ill persons in the retirement community to the hospital.
C. Evaluate the agent, host, and environmental relationships to determine the cause of the problem.
D. Close the dining room and find another source to provide food to the residents.

Answers can be found on the Evolve site.

KEY POINTS

- Local public health departments are responsible for implementing and enforcing local, state, and federal public health codes and ordinances while providing essential public health services.
- The goal of the local health department is to safeguard the public's health and improve the community's health status.
- State health departments hold primary responsibility for promoting and protecting the public's health.
- Public health nursing is the practice of promoting and protecting the health of populations using knowledge from nursing and social and public health sciences.
- Public health is based on the scientific core of epidemiology.
- Marketing of public health nursing is essential to inform both professionals and the public about the opportunities and challenges of populations in public health care.
- A driving force behind public health nursing changes is globalization that allows rapid transmission of emerging infections and the expectation that public health nurses will be active partners in emergency preparedness activities.
- Some of the roles public health nurses function in are advocate, case manager, referral source, counselor, educator, outreach worker, disease surveillance expert, community mobilizer, and disaster responder.
- Public health nurses have an important role in conducting community assessments, including partnering with the community to collect and analyze data, developing community diagnosis, and implementing evidence-based interventions.
- Public health nurses base interventions on identified health status of populations and their related determinants of health.

CLINICAL DECISION-MAKING ACTIVITIES

1. What are some of the various roles of the public health nurse in the local, state, and federal public health systems? Contrast the roles. Explain why they may be different from one another.
2. How can public health nurses prepare themselves for change? Illustrate what you mean.
3. What can today's public health nurses learn from the past practice of public health nurses? How can you verify your answer?
4. Describe collaborative partnerships that public health nurses have developed. How do partnerships help solve public health problems?
5. What are some external factors that have an effect on public health nursing? How can you deal with the complexities of these factors?
6. What are core functions used by public health nurses as they plan interventions? Do these functions make sense to you? Explain.
7. If you were a public health nurse for a day, what would you like to accomplish? Why? Is your answer supported by evidence? Be specific.
8. How would you determine the most pressing public health issue in your community? Gather several points of view from key leaders in the community.
9. Give an example of a policy change or an effect from the work of public health nurses. How did this policy make a difference in client health outcomes?

Program Planning and Design

Program planning is a process of outlining, designing, contemplating, and deliberating to develop actions to accomplish desirable goals and attain desirable outcomes.

PLANNING PROCESS

The successful program requires a lot of planning before implementation. The following need to be considered:

1. Who is in charge?
2. Who should be involved?
3. When is the best time to plan?
4. What data are needed?
5. Where should planning occur?
6. Will there be resistance?
7. Where will resistance come from?
8. Who will be early adopters?

Failing to plan can result in the inability to have a program that is viable and that will attain the goals and outcomes.

TIMETABLE

Timetables are very important to the success of planning. Two methods often used by planners are the following:

- Program Evaluation and Review Techniques (PERT)
- GANTT

PERT

The PERT method requires the planner to do the following:

- State the goal.
- List in sequence all the steps and activities for each step to accomplish the goal.
- Target dates for accomplishing each step are set.
- Diagram the process for easy use.

Student Activity

1. Go to literature and find a PERT application and diagram.
2. Draw a diagram of your program plan or a hypothetical one.
3. Be prepared to submit with end-of-module assignment.

GANTT

A GANTT chart is also a flow diagram that can be used to map out the activities needed to be accomplished so that one can maintain a timeline to achieve the goal. The GANTT chart looks much like a calendar.

Student Activity

1. Go to the literature and find a GANTT chart that has been applied to a project.
2. Complete a GANTT chart of the activities related to each objective in your project that are stated to meet the goal or do a hypothetical one.
3. Be prepared to submit at the end of the module.

PEOPLE PLANNING

To have a successful plan, one needs to involve the clients who are to be served by the program. Others to be involved are the following:

- Administrators
- Staff (providers)
- Other key stakeholders

REASONS

- Develop ownership
- Develop commitment
- Develop pride
- Develop understanding of problems
- Brainstorm
- Generate ideas

DATA PLANNING

To have a successful program, one must collect data on the following:

- Demographics of clients
- Disease statistics
- Vital statistics
- Existing similar programs
- Successes and barriers of similar programs
- Socioeconomic/environmental support
- Political issues

Student Activity

1. Find a source of data for one of the above categories.
2. Explain why it is a good data source for your program.

PERFORMANCE PLANNING

Some programs, called projects, are planned for a one-time-only event. Most programs are planned to be ongoing.

1. Question: Are problems that programs address usually solved?
   a. Explain your answer and give an example.
2. The following should be considered in planning for performance:
   a. Staff is the most expensive resource in planning.
   b. For efficiency, programs should be planned as ongoing activities.
   c. A 6-month start-up and a 5-year budget should be developed.
   d. Long-term commitment of resources to a program is essential.
   e. Planners must develop marketing tools, policies and procedures, and job descriptions before implementation.
   f. Organizational structures including committees need to be drafted.
   g. Community partners and advisory board should be planned and contacted for agreement to serve.

Priority Planning

1. Plan programs for the greatest need and the best potential for making a difference.
2. Available resources to accomplish goal no. 1 must be sought. If resources are not available, the program plan is time wasted.
3. Be a comprehensive planner.
4. Complete ongoing needs assessments to determine community changes.
5. Prioritize the greatest needs.
6. Plan new programs or change existing ones for goal no. 5.

Plan for Measurable Outcomes

1. Collect baseline data on the problem and the target population.
2. Analyze needs assessment.
3. Look at incidence and prevalence of problems.
4. Look at available services currently addressing the problem.
5. Determine the impact of the current services, using SWOT.

Evaluation Planning

1. This must begin with the needs assessment.
2. Plan for process evaluation.
3. Plan for summative evaluation.
4. Develop a timeline for evaluation to occur.
5. Develop systems for records and data collection and choose evaluation instruments.

Questions to Be Answered

1. Do you have the right people doing the planning?
2. Do you have the essential data for planning?
3. Is this the right time to plan this program?'
4. Why should evaluation occur?
5. Who should do it?
6. What data should be gathered?
7. Should evaluation occur?

Planning Models

1. Choose a model for planning your program.
2. Two models developed for program planning by the Centers for Disease Control and Prevention are PATCH and APEX.

Student Activity

1. Read about these two models.
2. Briefly explain how these models can be applied to program planning.
3. Briefly explain the model you have chosen for planning. Include the following:
   a. Definition
   b. Goal
   c. Model elements
   d. Planning process

MISSION

All programs will want to have a Mission Statement. Elements of a Mission Statement should include the following:

- Name of agency
- Name of program
- Who program serves
- Purpose of program
- Program goal
- Services offered

Student Activity

Write a Mission Statement for your program.

VISION

A Vision Statement is a brief one- or two-sentence statement that expresses the impact this program will have.

Student Activity

Write a Vision Statement for your program.

WORKSHEET FOR WRITING THE PHILOSOPHY

Questions for Discussion

What are our community's values and beliefs about health?

What is the purpose of our program?

What is our position on community involvement and responsibility for health?

What is our role in providing leadership?

Worksheet for Finding and Overcoming Obstacles

Goal:

Forces working against reaching goal (barriers/obstacles/challenges):

Forces working for reaching goal (existing resources/strengths):

Approaches to overcome obstacles:

WORKSHEET FOR WRITING OBJECTIVES

Health Issue:

Goal:

Objectives (write the most important objectives first):

1.

2.

3.

4.

CHECKLIST FOR PROGRAM PLANNING AND IMPLEMENTATION

1. Have you established a community advisory group with:
   ___ Representation of your targeted groups
   ___ The ability to provide valuable links with the community
   ___ Skills and resources that will be useful to the program
2. Have you identified community needs and concerns by way of:
   ___ Surveys/questionnaires
   ___ Focus groups
   ___ Public meetings or forums
   ___ Interested party analysis
3. Have you determined the community's priorities, taking into account:
   ___ Historical conditions
   ___ Traditional practices
   ___ Political and economic conditions
4. Have you developed program goals and objectives?
   ___ Yes
   ___ No
5. Have you decided on program strategies that:
   ___ Fit with the resources and needs of the community
   ___ Consider the beliefs, values, and practices of the community
   ___ Reflect field testing
   ___ Dispel health misconceptions
   ___ Change behavior
   ___ Change the environment
6. To implement your program, have you:
   ___ Prepared a timeline for program implementation
   ___ Listed people to be involved, and resources needed
   ___ Hired staff (preferably from the community)
   ___ Developed linkages with other community agencies, as appropriate
   ___ Planned to carry out an evaluation
7. Have you chosen appropriate methods and questions for:
   ___ Process evaluation
   ___ Outcome evaluation

Flu Pandemics

INTRODUCTION

A pandemic is a global disease outbreak. An influenza pandemic occurs when a new influenza virus emerges for which there is little or no immunity in the human population, begins to cause serious illness, and then spreads easily from person to person worldwide.

NEW FLU VIRUSES

There are four types of influenza viruses: A, B, C, and D. Human influenza A and B viruses cause seasonal influenza epidemics almost every winter in the United States. Influenza epidemics occur when there is an emergence of a new and different influenza A virus infecting people. Influenza type C infections generally cause a mild respiratory illness and are not thought to cause epidemics. Influenza D viruses predominately affect cattle and are not known to infect or cause illness in people.

Influenza viruses are constantly changing. They can change in two ways. One way they change is called *antigenic drift,* which occurs as a result of small changes in the virus as it replicates itself. The drifting is frequently enough to make a new strain of the virus unrecognizable to the human immune system as the antigenic drift accumulates, resulting in the person getting sick more than one time. For this reason, a new flu vaccine must be produced each year to combat that year's prevalent strains.

Type A influenza also undergoes infrequent and sudden changes called *antigenic shift.* Antigenic shift occurs when two different flu strains infect the same cell and exchange genetic material. The novel assortment of HA or NA proteins in a shifted virus creates a new influenza A subtype; their appearance tends to coincide with a very severe flu epidemic or pandemic.

CHARACTERISTICS AND CHALLENGES OF A FLU PANDEMIC

1. **There Will Be Rapid Worldwide Spread**
   - When a pandemic influenza virus emerges, its global spread is considered inevitable.
   - Preparedness activities should assume that the entire world population would be susceptible.
   - Countries might, through measures such as border closures and travel restrictions, delay arrival of the virus but cannot stop it.
2. **Health Care Systems Will Be Overloaded**
   - Most people have little or no immunity to a pandemic virus. Infection and illness rates soar. A substantial percentage of the world's population will require some form of medical care.
   - Nations are unlikely to have the staff, facilities, equipment, and hospital beds needed to cope with large numbers of people who suddenly fall ill.
   - Death rates are high, largely determined by four factors: the number of people who become infected, the virulence of the virus, the underlying characteristics and vulnerability of affected populations, and the effectiveness of preventive measures.
   - Past pandemics have spread globally in two and sometimes three waves.
3. **Medical Supplies Will Be Inadequate**
   - The need for vaccine is likely to outstrip supply.
   - The need for antiviral drugs is also likely to be inadequate early in a pandemic.
   - A pandemic can create a shortage of hospital beds, ventilators, and other supplies. Surge capacity at nontraditional sites such as schools may be created to cope with demand.
   - Difficult decisions will need to be made regarding who gets antiviral drugs and vaccines.
4. **There Will Be Economic and Social Disruption**
   - Travel bans, closings of schools and businesses, and cancellations of events could have major impact on communities and citizens.
   - Care for sick family members and fear of exposure can result in significant worker absenteeism.

Seasonal Flu Versus Pandemic Flu

	Seasonal Flu	Pandemic Flu
How often does it happen?	Happens annually and usually peaks between December and February	Rarely happens (three times in 20th century)
Will most people be immune?	Usually some immunity from previous exposures and influenza vaccination	Most people have little or no immunity because they have no previous exposure to the virus or similar viruses
Who is at risk for complications?	Certain people are at high risk for serious complications (infants, elderly, pregnant women, and persons with extreme obesity and certain chronic medical conditions)	Healthy people also may be at high risk for serious complications
Where can I get medical care?	Health care providers and hospitals can usually meet public and patient needs	Health care providers and hospitals may be overwhelmed Alternate care sites may be available to meet public and patient needs
Will a vaccine be available?	Vaccine available for annual flu season Usually, one dose of vaccine is needed for most people	Although the US government maintains a limited stockpile of pandemic vaccine, vaccine may not be available in the early stages of a pandemic Two doses of vaccine may be needed
Will antivirals be available?	Adequate supplies of antivirals are usually available	Antiviral supply may not be adequate to meet demand
How many people could get sick and suffer complications?	Rates of medical visits, complications, hospitalizations (https://www.cdc.gov/flu/about/disease/2014-15.htm), and death can vary from low to high CDC estimates that flu-related hospitalizations since 2010 ranged from 140,000 to 710,000, while flu-related deaths are estimated to have ranged from 12,000 to 56,000.	Rates of medical visits, complications, hospitalizations, and death can range from moderate to high Number of deaths could be much higher than seasonal flu (e.g., the estimated U.S. death toll during the 1918 pandemic [https://www.cdc.gov/flu/pandemic-resources/basics/past-pandemics.html] was approximately 675,000)
What impact will it have on schools and workplaces?	Usually causes minor impact on the general public, some schools may close, and sick people are encouraged to stay home Manageable impact on domestic and world economies	May cause major impact on the general public, such as travel restrictions and school or business closings Potential for severe impact on domestic and world economies

From Centers for Disuse Control and Prevention: How is pandemic flu different from seasonal flu? 2018. Available at https://www.cdc.gov.

PARENT FACT SHEET

The Centers for Disease Control and Prevention has developed an excellent fact sheet for parents entitled *The Flu: A Guide for Parents,* which can be retrieved from https://www.cdc.gov.

COMMUNICATIONS AND INFORMATION ARE CRITICAL COMPONENTS OF PANDEMIC RESPONSE

Education and outreach are critical to preparing for a pandemic. Understanding what a pandemic is, what needs to be done at all levels to prepare for pandemic influenza, and what could happen during a pandemic helps us make informed decisions both as individuals and as a nation. Should a pandemic occur, the public must be able to depend to its government to provide scientifically sound public health information quickly, openly, and dependably.

APPENDIX C

Friedman Family Assessment Model (Short Form)

Before using the following guidelines in completing family assessments, two words of caution. First, not all areas included below will be germane for each of the families visited. The guidelines are comprehensive and allow depth when probing is necessary. The student should not feel that every sub-area needs to be covered when the broad area of inquiry poses no problems to the family or concern to the health worker. Second, by virtue of the interdependence of the family system, one will find unavoidable redundancy. For the sake of efficiency, the assessor should try not to repeat data, but to refer the reader back to sections where this information has already been described.

IDENTIFYING DATA

1. Family Name
2. Address and Phone
3. Family Composition (see table)
4. Type of Family Form
5. Cultural (Ethnic) Background
6. Religious Identification
7. Social Class Status
8. Family's Recreational or Leisure-Time Activities

DEVELOPMENTAL STAGE AND HISTORY OF FAMILY

9. Family's Present Developmental Stage
10. Extent of Developmental Tasks Fulfillment
11. Nuclear Family History
12. History of Family of Origin of Both Parents

ENVIRONMENTAL DATA

13. Characteristics of Home
14. Characteristics of Neighborhood and Larger Community
15. Family's Geographic Mobility
16. Family's Associations and Transactions with Community
17. Family's Social Support Network (Ecomap)

FAMILY STRUCTURE

18. Communication Patterns
    - Extent of Functional and Dysfunctional Communication (Types of recurring patterns)
    - Extent of Emotional (Affective) Messages and How Expressed
    - Characteristics of Communication Within Family Subsystems
    - Extent of Congruent and Incongruent Messages
    - Types of Dysfunctional Communication Processes Seen in Family
    - Areas of Open and Closed Communication
    - Familial and External Variables Affecting Communication
19. Power Structure
    - Power Outcomes
    - Decision-Making Process
    - Power Bases
    - Variables Affecting Family Power
    - Overall Family System and Subsystem Power
20. Role Structure
    - Formal Role Structure
    - Informal Role Structure
    - Analysis of Role Models (Optional)
    - Variables Affecting Role Structure
21. Family Values
    - Compare the Family to American or Family's Reference Group Values and/or Identify Important Family Values and Their Importance (Priority) in Family
    - Congruence Between the Family's Values and the Family's Reference Group or Wider Community
    - Congruence Between the Family's Values and Family Member's Values
    - Variables Influencing Family Values
    - Values Consciously or Unconsciously Held
    - Presence of Value Conflicts in Family
    - Effect of the Above Values and Value Conflicts on Health Status of Family

FAMILY FUNCTIONS

22. Affective Function
    - Family's Need-Response Patterns
    - Mutual Nurturance, Closeness, and Identification
    - Separateness and Connectedness
23. Socialization Function
    - Family Child-Rearing Practices
    - Adaptability of Child-Rearing Practices for Family Form and Family's Situation
    - Who Is (Are) Socializing Agent(s) for Child(ren)?
    - Value of Children in Family
    - Cultural Beliefs That Influence Family's Child-Rearing Patterns

Social Class Influence on Child-Rearing Patterns
Estimation About Whether Family Is at Risk for Child-Rearing Problems and, if so, Indication of High-Risk Factors
Adequacy of Home Environment for Children's Needs to Play

24. Health Care Function
Family's Health Beliefs, Values, and Behavior
Family's Definitions of Health-Illness and Their Level of Knowledge
Family's Perceived Health Status and Illness Susceptibility
Family's Dietary Practices
Adequacy of Family Diet (recommended 24-hour food history record)
Function of Mealtimes and Attitudes Toward Food and Mealtimes
Shopping (and its planning) Practices
Person(s) Responsible for Planning, Shopping, and Preparation of Meals
Sleep and Rest Habits
Physical Activity and Recreation Practices (not covered earlier)
Family's Drug Habits
Family's Role in Self-Care Practices
Medically Based Preventive Measures (physicals, eye and hearing tests, and immunizations)
Dental Health Practices
Family Health History (both general and specific diseases—environmentally and genetically related)
Health Care Services Received
Feelings and Perceptions Regarding Health Services
Emergency Health Services
Source of Payments for Health and Other Services
Logistics of Receiving Care

FAMILY STRESS AND COPING

25. Short- and Long-Term Familial Stressors and Strengths
26. Extent of Family's Ability to Respond, Based on Objective Appraisal of Stress-Producing Situations
27. Coping Strategies Utilized (present/past)
Differences in Family Members' Ways of Coping
Family's Inner Coping Strategies
Family's External Coping Strategies
28. Dysfunctional Adaptive Strategies Utilized (present/past; extent of usage)

FAMILY COMPOSITION FORM

Name (Last, First)	Gender	Relationship	Date and Place of Birth	Occupation	Education
1. (Father)					
2. (Mother)					
3. (Oldest child)					
4.					
5.					
6.					
7.					
8.					

From Friedman, Marilyn R; Bowden, Vicky R; Jones, Elaine: *Family nursing: research, theory, and practice,* 5th Ed., ©2003. Reprinted by permission of Pearson Education, Inc., New York.

Comprehensive Occupational and Environmental Health History

WORK HISTORY

1. List your current and past longest held jobs, including the military:

Company	Dates Employed	Job Title	Known Exposures

2. Do you work full time? NO ___ YES ___ How many hours per week? ___

3. Do you work part time? NO ___ YES ___ How many hours per week? ___

4. Please describe any health problems or injuries that you have experienced in connection with your present or past jobs:

5. Have you ever had to change jobs because of health problems or injuries? YES ___ NO ___
   If yes, describe: Did any of your co-workers experience similar problems?

6. In what type of business do you currently work?

7. Describe your work (what you actually do):

8. Have you had any current or past exposure (through breathing or touching) to any of the following?

__acids	__alkalies	__arsenic	__benzene	__cadmium
__chlorinated naphthalenes	__chloroprene	__coal dust	__dichlorobenzene	__ethylene dichloride
__halothane	__isocyanates	__lead	__mercury	__nickel
__PBBs	__perchloroethylene	__phenol	__radiation	__silica powder
__styrene	__TDI or MDI	__trichloroethylene	__vibration	__welding fumes
__alcohols	__ammonia	__asbestos	__beryllium	__carbon tetrachloride
__chloroform	__chromates	__cold (severe)	__ethylene dibromide	__fiberglass
__heat (severe)	__ketones	__manganese	__methylene chloride	__noise (loud)
__PCBs	__pesticides	__phosgene	__rock dust	__solvents
__talc	__toluene	__trinitrotoluene	__vinyl chloride	__x-rays

9. Did you receive any safety training about these agents? YES ___ NO ___
   Explain:

10. Are you involved in any work processes such as grinding, welding, soldering, or polishing that create dust, mists, or fumes? YES ___ NO ___
    If yes, describe:

11. Did you use any of the following personal protective equipment when exposed?

__boots	__respirator	__welding mask
__gloves	__sleeves	__glasses/goggles
__shield	__earplugs/muffs	
__coveralls	__safety shoes	

12. Is your work environment generally clean? YES ___ NO ___
    If no, describe:

13. What ventilation systems are used in your workplace?

14. Do they seem to work? Are you aware of any chemical odors in your environment (if so, explain)?

15. Where do you eat, smoke, and take your breaks when you are on the job?

16. Do you use a uniform or have clothing that you wear only to work? YES ___ NO ___

17. How is your work clothing laundered (at home, by employer, etc.)?

18. How often do you wash your hands at work and how do you wash them (running water, special soaps, etc.)?

19. Do you shower before leaving the worksite? YES ___ NO ___

20. Do you have any physical symptoms associated with work? YES ___ NO ___
    If yes, describe:

21. Are other workers similarly affected? YES ___ NO ___

HOME EXPOSURES

1. Which of the following do you have in your home?
   __air conditioner __fireplace __electric stove
   __central heating (gas or oil) __air purifier __woodstove

2. In approximately what year was your home built?

3. Have there been any recent renovations? YES ___ NO ___
   If yes, describe:

4. Have you recently installed new carpet, purchased new furniture, or refinished existing furniture? YES ___ NO ___
   If yes, explain:

5. Do you use pesticides around your home or garden? YES ___ NO ___
   If yes, describe:

6. What household cleaners do you use? (List most common and any new products you use.)

7. List all hobbies done at your home:

8. Are any of the agents listed earlier for work exposures encountered in hobbies or recreational activities?
   YES ___ NO ___

9. Is any special protective equipment or ventilation used during hobbies? YES ___ NO ___
   Explain:

10. What are the occupations of other household members?

11. Do other household members have contact with any form of chemicals at work or during leisure activities?
    YES ___ NO ___
    If yes, explain:

12. Is anyone else in your home environment having symptoms similar to yours? YES ___ NO ___
    If yes, explain briefly:

COMMUNITY EXPOSURES

1. Are any of the following located in your community?
   __industrial plant __major source of air pollution __waste site
   __landfill __toxic spill __other_____

2. What is your source of drinking water?
   __private well __public water source __other

3. Are neighbors experiencing any health problems similar to yours? YES ___ NO ___
   If yes, explain:

KEY OCCUPATIONAL AND ENVIRONMENTAL HEALTH QUESTIONS TO BE ASKED WITH ALL HISTORIES

1. What are your current and past longest-held jobs?

2. Have you been exposed to any radiation or chemical liquids, dusts, mists, or fumes? YES ___ NO ___

3. Is there any relationship between current symptoms and activities at work or at home? YES ___ NO ___

From Pope AM, Snyder MA, Mood LH, editors: *Nursing, health, and environment: strengthening the relationship to improve the public's health*, Washington, DC, 1995, National Academy Press.

Essential Elements of Public Health Nursing

EXAMPLES OF PUBLIC HEALTH NURSING ROLES AND IMPLEMENTING PUBLIC HEALTH FUNCTIONS

This document is intended to clearly present the role of public health nurses in Virginia as members of the multidisciplinary public health team in a changing health care environment. The following matrices present the role of public health nursing in Virginia. The following definitions were used to develop these matrices.

Essential Element is taken from the National Association of City and County Health Officials' (NACCHO's) document *Blueprint for a Healthy Community.* The following public health essential elements are used as a framework to present the role of public health nursing in Virginia:

- Conducting Community Assessments
- Preventing and Controlling Epidemics
- Providing a Safe and Healthy Environment
- Measuring Performance, Effectiveness, and Outcomes of Health Services
- Promoting Healthy Lifestyles
- Providing Targeted Outreach and Forming Partnerships
- Providing Personal Health Care Services
- Conducting Research and Innovation
- Mobilizing the Community for Action

Public Health Function is defined as a broad public health activity needed to ensure a strong, flexible, accountable public health structure. It may require a multidisciplinary team to carry out.

Public Health Nurse Role is the activity the public health nurse is responsible for, either alone or as a member of a team, to accomplish the stated public health function. This can be the public health nurse at the local level or at the state level.

State Role is what public health nurses need from the state level to do their jobs (e.g., policy, aggregate data, training). This refers to any Central Office program or staff, not just nurses.

A process was implemented that would involve all public health nurses in Virginia. Although this lengthened the timeline to completion, it will ensure that the final document represents a consensus developed through creative open dialogue.

From National Association of City and County Health Officials: Blueprint for a healthy community: a guide for local health departments, Washington, DC, 1994, The Association.

ESSENTIAL ELEMENT 1: Conduct Community Assessment: Systematically collecting, assembling, analyzing, and making available health-related data for the purpose of identifying and responding to community- and state-level public health concerns and conducting epidemiologic and other population-based studies.

Public Health Function	PHN Roles	State Roles
Develop frameworks, methodologies, and tools for standardizing data collection and analysis and reporting across all jurisdictions and providers.	• Provide, review, and comment on proposed methodologies and tools for data collection. • Field-test tools and methods.	• Collaborate with professional organizations and academic and governmental institutions to develop and test tools and methods. • Provide educational opportunities in areas of and use of tools. • Work with local-level agencies to standardize definitions, data collected, etc., across jurisdictions and among all stakeholders (schools, community-based organizations, and private providers).
Collect and analyze data.	• Collaborate with the community to identify population-based needs and gaps in service. • Analyze data and needs, knowledge, attitudes, and practices of specific populations. • Identify patterns of diseases, illness, and injury and develop or stimulate development of programs to respond to identified trends.	• Provide aggregated data to the local level in a timely and accurate manner. • Provide census tract–level aggregated data to the local level. • Provide national and state comparisons to be used with local data to obtain trends and assist localities in documenting need, progress, etc., to attain standard outcomes.

ESSENTIAL ELEMENT 2: Preventing and Controlling Epidemics: Monitoring disease trends and investigating and containing diseases and injuries.

Public Health Function	PHN Roles	State Roles
Develop programs that prevent, contain, and control the transmission of diseases and danger of injuries (including violence).	• Provide community-wide preventive measures in the form of health education and mobilization of community resources. • Ensure isolation/containment measures when necessary. • Ensure adequate preventive immunizations. • Implement programs that control the transmission of diseases and danger of injuries during disasters.	• Work with local jurisdictions to develop tools such as videos, PSAs, and/or posters that local jurisdictions can use. • Work with local jurisdictions to develop disaster plans for the control of the transmission of diseases and danger of injuries during disasters. • Facilitate state-level partnerships that promote health, healthy lifestyles, and wellness (individual and family).
Develop regulatory guidelines for the prevention of targeted diseases.	• Implement regulatory measures. • Implement OSHA Guidelines for Blood Borne Pathogens and the Prevention of the Transmission of TB in Health Care Settings.	• In partnership with localities, develop regulatory guidelines. • Serve as clearinghouse or source of information.

ESSENTIAL ELEMENT 3: Providing a Safe and Healthy Environment: Maintaining clean and safe air, water, food, and facilities both in the community and in the home environment.

Public Health Function	PHN Roles	State Roles
Develop methods/tools for collection and analysis of health-related data (occurrence of mortality and morbidity relating to both communicable and chronic diseases, injury registries, sentinel event establishment, environmental quality, etc.).	• Provide reporting guidelines and consultation regarding disease prevention, diagnosis, treatment, and follow-up of cases/contacts to physicians and institutions (emergency department, university and secondary school student health, prisons, industries, etc.). • Conduct/participate in community needs assessments to determine customer/provider knowledge deficits and perceptions of need. • Provide education to individuals, providers, targeted populations, etc., in response to knowledge deficits, disease outbreaks, toxic waste emissions, etc. • Provide individual follow-up/case management of communicable diseases that are transmitted by air, water, food, and fomites (TB, hepatitis A, salmonella, staphylococcus, etc.).	• Develop standard methodology and tools for collection and analysis of health-related data. • Provide training in area of data collection and analysis. • Evaluate activities and outcomes of interactions. • Work in partnership with localities to develop program based on data analysis needs.
Develop programs that promote a safe environment in the home.	• Provide childhood lead poisoning screenings and follow-up. • Teach clients to inspect homes for safety violations and toxic substances and to practice safe behaviors; assist families to access/use available resources/safety devices. • Assess/teach regarding safe food selection, preparation, and storage. • Train/supervise volunteers/auxiliary personnel in performance of the above tasks. • Teach families that all men, women, and children have a right to a safe environment free of physical or mental abuse.	• Provide consultation and technical assistance to state/local organizations regarding laws and regulations that protect health and ensure safety. • In partnership with localities, develop and evaluate educational programs.
Develop programs that promote a safe environment in the workplace.	• Provide consultation in implementation of OSHA regulations relating to occupational exposure to diseases. • Provide educational program related to healthy lifestyles (smoking cessation, back protection, etc.). • Ensure provision of screenings for individuals to determine baselines and occurrence of infectious diseases and preventable deterioration of health and function: hearing, back soundness, lung capacity, RMS indicators, PPDs, etc. • Assist in policy/practice development to address prevention of the above. • Provide immunizations.	• Monitor and assist localities to implement prevention activities. • Assist localities in developing and evaluating educational programs. • Monitor outcomes of screening activities and evaluate interventions.

Continued

ESSENTIAL ELEMENT 3: Providing a Safe and Healthy Environment—cont'd

Public Health Function	PHN Roles	State Roles
Develop programs that promote a safe environment in the school setting.	• Provide consultation on implementation of OSHA regulations relating to occupational exposure to diseases. • Provide educational programs related to healthy lifestyles (smoking cessation, etc.). • Ensure provision of screenings for students to determine baselines and occurrence of infectious disease and preventable deterioration of health and function. • Assist in policy/practice development to address prevention of the above. • Provide immunizations.	• Develop guidelines that ensure accountability in meeting standards set forth. • Ensure that policy is developed to protect children in the school environment. • Monitor immunization status of children and provide immunizations during outbreaks and evaluate activities.
Develop programs that promote a safe environment in the community.	• Identify population clusters exhibiting an unhealthy environment; provide consultation/group education regarding preventive measures. • Participate in development of local disaster plans to ensure provision of safe water, food, air, and facilities. • Respond in time of natural disasters such as floods, tornadoes, and hurricanes. • Participate in developing plans for shelter management during disasters, especially "Special Needs" shelters that may require nursing staff.	• In times of disaster, facilitate availability of resources across jurisdictions. • Have a statewide plan. • Ensure that localities have developed plans to protect the public in time of national and/or other disasters. • Coordinate efforts statewide. • Assist localities in responding. • Evaluate efforts.
Develop and issue standards that guide regulations and mandate policy and program development.	• Survey worksites, schools, institutions, etc., for compliance to regulations that protect health and ensure safety.	• Develop a systematic evaluation tool for collection of data to measure trends.
Develop protocols to ensure accountability of all health care providers, public and private.	• Provide technical assistance (i.e., interpretation, implementation, and evaluation processes).	• Assist localities in developing standards to mandate accountability.
Provide inservice to all providers of health care services.	• Share and implement knowledge gained in inservices.	• Provide consultation/technical assistance to localities.

ESSENTIAL ELEMENT 4: Measuring Performance, Effectiveness, and Outcomes of Health Services: Monitoring health care providers and the health care system to identify gaps in service, deteriorating health status indicators, effectiveness of interventions, and accessibility and quality of personal and population-wide health services.

Public Health Function	PHN Roles	State Roles
Promote competency in public health issues throughout the health delivery system.	• Provide educational and technical assistance in areas such as case management and appropriate treatment and control of communicable diseases to the community.	• Develop appropriate regulatory, educational, and technical assistance programs. • Provide technical assistance and training to local health department for local forecasting and interpretation of data.
Collect data.	• Participate in data collection with a target population. • Ensure that the data collection system supports the objectives of programs serving the community by participating in the design and operation of data collection systems. • Collect data via surveys, polls, interviews, focus groups that will enable assessment of the community's perception of health status and understanding how the system works and how to obtain service needs.	• Work with localities (health districts, private providers, other state and local agencies) to develop standard data elements and definitions across jurisdictions and among all stakeholders, especially for consistency in coding of population-based data. • Identify data collection and analytic issues related to monitoring the impact of health system changes such as costs and benefits of record linkage, strategies for ensuring confidentiality, and strategies for analyzing trends in health within a broader social and economic context. • Advocate for uniform data collection from all managed care plans so that outcomes and health trends can be analyzed and tracked and sentinel events reported.

ESSENTIAL ELEMENT 4: Measuring Performance, Effectiveness, and Outcomes of Health Services—cont'd

Public Health Function	PHN Roles	State Roles
Analyze data to ensure accurate diagnosis of health status, identification of threats to health, and assessment of health service needs.	• Participate in a systematic approach to convert data into information that will identify gaps in service at the local and state level and will lead to action. • Monitor health status indicators to identify emerging problems and facilitate community-wide response to identified problems. • Facilitate data analysis as part of a local collaborative effort.	• Develop a systematic, integrated statewide approach to converting data into information that directs action. • Ensure that resources, such as hardware and software, to analyze data are available at the local level. • Work with localities (health districts, private providers, other state and local agencies) to address issues related to variable access to technology, confidentiality issues. • Educate and train currently employed public health nurses in areas of epidemiology and population-based services.
Monitor health status indicators for the entire population and for specific population groups and/or geographic areas.	• Identify target populations that may be at risk for public health problems such as communicable diseases, unidentified and untreated chronic diseases. • Conduct surveys or observe targeted populations such as preschools, childcare centers, and high-risk census tracks to identify health status. • Monitor health care utilization of vulnerable populations at the local and regional level.	• Develop methodology for identification, measurement, and analysis of key indicators of health care utilization of vulnerable populations.
Monitor and assess availability, cost-effectiveness, and outcomes of personal and population-based health services.	• Identify gaps in services (e.g., a neighborhood with deteriorating immunization rates may indicate lack of available primary care services). • Ensure that all receive the same quality of care, including comprehensive preventive services. • Monitor the impact of health system reforms on vulnerable populations. • Evaluate the effectiveness and outcomes of care. • Plan interventions based on the health of the overall population, not just for those in the health care system. • Identify interventions that are effective and replicable.	• Develop analyses that demonstrate the cost-effectiveness of investment in public health services. • Develop protocols and technical assistance for ensuring accountability of Medicaid managed care plans and other government-funded plans for service delivery and overall health status of their covered populations. • Identify standard theoretical, methodological, and measurement issues that are specific to population subgroups for monitoring the impact of health system changes on vulnerable populations.
Disseminate information.	• Disseminate information to the public on community health status, including how to access and use services appropriately. • Disseminate information to other health care providers regarding gaps in services or deteriorating health status indicators.	• Ensure a mechanism for public accountability of performance and outcomes through public dissemination of information and in particular ensure that underservice, a risk inherent in capitated plans, is measurable through available data. • Ensure that information is provided to communities, local health departments, managed care plans, and other appropriate state agencies.

ESSENTIAL ELEMENT 5: Promoting Healthy Lifestyles: Providing health education to individuals, families, and communities.

Public Health Function	PHN Roles	State Roles
Promote informed decision making of residents about things that influence their health on a daily basis.	• Exert influence through contact with individuals and community groups. • Accept and issue challenge of healthy lifestyles to all contacts. • Reinforce and reward positive informed decisions made for healthy lifestyles.	• Develop and monitor standards for the changes to determine changes in behavior.
Promote effective use of media to encourage both personal and community responsibility for informed decision making.	• Be a resource for the community. • Gather data and address findings as appropriate. • Work with community groups to promote accurate information for healthy lifestyle through the media. • Use current information and other agency's resources to maximize information accessible to the public.	• Assist localities to provide current information to community organizations and other state organizations. • Serve as a resource for localities and work with media.
Develop a public awareness/marketing campaign to demonstrate the importance of public health to overall health improvement and its proper place in the health delivery system.	• Provide education to special groups (e.g., local politicians, school boards, PTAs, churches, civic groups, news media) regarding the benefits of preventive health.	• Develop training activities to assist localities in marketing.
Develop public information and education systems/programs through partnerships.	• Provide educational sessions/programs to public regarding components of healthy lifestyles. • Access grants/other funding sources to promote healthy lifestyle decisions (e.g., cervical and breast cancer prevention, bike helmets, hypertension). • Provide/promote teaching for individuals and families at every opportunity (home, clinic, community settings).	• Assist localities in developing and evaluating educational programs. • Assist localities in funding. • Hold regional/state training sessions. • Evaluate outcomes and plan ongoing educational systems/programs.

ESSENTIAL ELEMENT 6: Providing Targeted Outreach and Forming Partnerships: Ensuring access to services, including those that lead to self-sufficiency, for all vulnerable populations and ensuring the development of culturally appropriate care.

Public Health Function	PHN Roles	State Roles
Ensure accessibility to health services that will improve morbidity, decrease mortality, and improve health status outcomes.	• Provide family-centered case management services for high-risk and hard-to-reach populations that focus on linking families with needed services. • Improve access to care by forming partnerships with appropriate community individuals and entities. • Increase influence of cultural diversity on system design and on access to care, as well as on individual services rendered. • Ensure that translation services are available for the non–English-speaking population. • Participate in ongoing community assessment to identify areas of concern and above needs for rules. • Provide outreach services that focus on preventing epidemics and the spread of disease, such as tuberculosis and sexually transmitted diseases.	• Provide funds in cooperation with locality. • Ensure policy development that includes case management and is culturally sensitive. • Provide adequate ongoing continuing education for staff (especially in areas common to all localities). • Participate in state-level contract development to ensure that contracts with health plans require and include incentives for health plans to offer and deliver preventive health services in the minimum benefits package. • Educate financing officials about the roles of public health both in performing core public health services and in ensuring access to personal health services.

ESSENTIAL ELEMENT 7: Providing Personal Health Care Services: Providing targeted direct services to high-risk populations.

Public Health Function	PHN Roles	State Roles
Provide direct services for specific diseases that threaten the health of the community and develop programs that prevent, contain, and control the transmission of infectious diseases.	• Plan, develop, implement, and evaluate: • Sexually transmitted disease services • Communicable disease services • HIV/AIDS services • Tuberculosis control services • Develop and implement guidelines for the prevention of the above targeted diseases.	• Establish standards/criteria for personal health care. • Work with local health departments to assist in developing infrastructure and management techniques to facilitate record-keeping and appropriate financial monitoring and tracking systems, which enable local health departments to enter into contractual arrangements for preventive health and primary care services.
Provide health services, including preventive health services, to high-risk and vulnerable populations (e.g., the uninsured working poor), and in geographic areas where primary health care services are not readily accessible or available in a privatized setting.	• Provide coordination, follow-up, referral, and case management as indicated. • Integrate supportive services (such as counseling, social work, nutrition) into primary care services. • Assess existing community medical capacity for referral and follow-up.	• Continue to work at the state and local level to build capacity of primary and preventive health services, particularly in traditionally underserved areas, to ensure availability to providers and primary care sites essential to primary care access.

ESSENTIAL ELEMENT 8: Conducting Research and Innovation: Discovering and applying improved health care delivery mechanisms and clinical interventions.

Public Health Function	PHN Roles	State Roles
Ensure ongoing prevention research relating to biomedical and behavioral aspects of health promotion and prevention of disease and injury.	• Develop outcome measures. • Identify research priorities for target communities and develop and conduct scientific and operations research for health promotion and disease/injury prevention.	• Provide training in area of measuring program effectiveness.
Implement pilot or demonstration projects.	• Develop and implement linkages with academic centers, ensuring that clients and populations who participate in research projects benefit as a result of the research.	• Support evaluations and research that demonstrate the benefits of public health, as well as the consequences of failure to support public health interventions.

ESSENTIAL ELEMENT 9: Mobilizing the Community for Action: Providing leadership and initiating collaboration.

Public Health Function	PHN Roles	State Roles
Provide leadership to stimulate development of networks or partnerships that will ensure the availability of comprehensive primary health care services to all, regardless of ability to pay.	• Advocate for improved health. • Disseminate health information. • Build coalitions. • Make recommendations for policy implementation or revision.	• Facilitate the establishment and enhancement of statewide high-quality, needed health services. • Administer quality improvement programs.
Initiate collaboration with other community organizations to ensure the leadership role in resolving a public health issue.	• Facilitate resources that manage environmental risk and maintain and improve community health. • Provide information for a community group working on impacting policy at the local, state, or federal level. • Use results of community health assessments to stimulate the community to develop a plan to respond to identified gaps in service.	• Use information-gathering techniques of assessment to assist policy/legislature activities to develop needed health services and functions that require statewide action or standards. • Recommend programs to carry out policies.

American Public Health Association Definition of Public Health Nursing

THE DEFINITION AND PRACTICE OF PUBLIC HEALTH NURSING

2013

Acknowledgments

This statement was developed by the Public Health Nursing Definition Document Task Force under the direction of the leadership of the Public Health Nursing Section of the American Public Health Association. The statement was adopted by the Public Health Nursing Section Council at the American Public Health Association Annual Meeting on November 5, 2013. The Task Force gratefully acknowledges the valuable assistance of individuals who contributed comments and recommendations throughout the development of this document.

THE DEFINITION AND PRACTICE OF PUBLIC HEALTH NURSING

A Statement of the APHA Public Health Nursing Section

2013

This document updates the 1996 American Public Health Association Public Health Nursing Section definition statement and affirms the original definition.[1] This statement addresses some of the evolving economic, health, political, and societal trends that shape the context of public health nursing practice.

Definition

Public health nursing is the practice of promoting and protecting the health of populations using knowledge from nursing, social, and public health sciences.

Public health nursing is a specialty practice within nursing and public health. It focuses on improving population health by emphasizing prevention, and attending to multiple determinants of health. Often used interchangeably with community health nursing, this nursing practice includes advocacy, policy development, and planning, which addresses issues of social justice. With a multi-level view of health, public health nursing action occurs through community applications of theory, evidence, and a commitment to health equity. In addition to what is put forward in this definition, public health nursing practice is guided by the American Nurses Association *Public Health Nursing: Scope & Standards of Practice* [2] and the Quad Council of Public Health Nursing Organizations' *Core Competencies for Public Health Nurses*.[3]

Elements of Practice

Key characteristics of practice include 1) a focus on the health needs of an entire population, including inequities and the unique needs of sub-populations; 2) assessment of population health using a comprehensive, systematic approach; 3) attention to multiple determinants of health; 4) an emphasis on primary prevention; and 5) application of interventions at all levels—individuals, families, communities, and the systems that impact their health.[4]

Public Health Nursing Perspective

Public health nursing aims to improve the health outcomes of all populations. Applying their clinical knowledge and expertise in health care from an ecological perspective, public health nurses acknowledge the complexity of public health problems and the contextual nature of health—including cultural, environmental, historical, physical, and social factors. Public health nurses apply systems-level thinking[5,6] to assess the potential or actual assets, needs, opportunities, and inequities of individuals, families, and populations and translate this assessment into action for public good.

Public Health Nursing Activities and Practice Settings

Public health nursing activities comprise the domains depicted by the *Public Health Intervention Wheel* and the *10 Essential Public Health Services*.[7,8] These activities include community collaboration, health teaching, and policy development, in response to priorities derived from ongoing, comprehensive population focused assessment. Public health nurses are members and leaders of interprofessional teams in diverse settings and in many different types of agencies and organizations including all levels of

government, community-based and other nongovernmental service organizations, foundations, policy think tanks, academic institutions and other research settings. Increasing numbers of public health nurses work in global health in an effort to promote global responsibility and connectivity. Public health nurses that work with individuals and families do so within the context of a population focus—applying a systems perspective to factors that impact health.

Determinants of Health

Eliminating population health disparities by addressing multiple determinants that lead to poor health is a national goal.[9] Public health nurses are in a position to provide leadership through public policy reform efforts, community-building, and system-level change.[10] Environmental, physical, and social determinants explain most health disparities in the United States.[11,12,13,14,15] Socioeconomic disadvantages such as poverty, low levels of education, and belonging to a racial or ethnic minority group, are more robust risk factors of poor health than a lack of access to health care or predominantly genetic factors of disease.[16,17,18] While the discipline of nursing was founded on improving environmental conditions to facilitate health at the bedside,[19] public health nurses focus on improving population health in the environments where people live, work, learn, and play.

Opportunities & Challenges

Adherence to public health nursing's key characteristics requires that the practice must evolve to address current societal needs. Public health nursing has faced multiple challenges over its history while engaging in leadership opportunities that have shaped nursing practice, addressing environmental and social justice issues, affecting population health, and exploring health promotion concepts. One example is the Patient Protection and Affordable Care Act (ACA).[20] The ACA has greatly altered the landscape for health care and health improvement in the U.S., creating the potential for new public health nursing roles and responsibilities. The ACA includes goals to 1) improve the individual health care experience; 2) reduce the cost of health care; and 3) improve the health of populations. With their positions embedded within communities, public health nurses are vital to the interprofessional teams needed to assure that all people have equitable access to high quality care and healthy environments through health system reform.[21] Their assessment skills, primary prevention focus, and system-level perspectives can assure that local and state needs are met, services and programs are coordinated, and communities are engaged.

Public health nurses are prepared to lead efforts that align emerging systems of care for population health improvement, health promotion, risk reduction, and disease prevention efforts that are within the nucleus of a reformed health system. Fewer public health nursing positions and decreased public health funding influence leadership roles and access to health care in communities.[22] Within the context of health care reform these challenges offer opportunities to emphasize a strong, well-educated public health nursing workforce to lead and carry out system coordination and change at local, state, national, and international levels.[23]

An emerging health care model that requires public health nursing leadership is the integration of primary care and public health.[24] Primary care and public health share a focus on prevention, population health, transitional care, and care coordination across settings to promote health through collaboration. With a unique focus from individuals and families to populations and systems, public health nurses are well

positioned to integrate new health system models and meet the demands of an ever-changing health system.[25]

Public Health Nursing Education

The baccalaureate degree in nursing (BSN) is recommended for entry-level public health nurses.[26] *The Essentials of Baccalaureate Education for Professional Nursing Practice* emphasize fundamental concepts for public health nursing practice such as clinical prevention, population health, health care policy, finance, and regulatory environments, and interprofessional collaboration.[27] The graduate is prepared to conduct community assessments and apply the principles of epidemiology among other competencies.

Nurses with a master's degree or higher, and with specialization in population health, demonstrate the knowledge and skills required for leadership positions. Competencies include mastery of interprofessional collaboration, health policy and advocacy, population assessment, prevention strategies, and program planning and evaluation.[28] The doctor of nursing practice (DNP) degree, with a public health emphasis, has emerged in the last decade, and provides the foundation for advanced practice in executive leadership, systems development, and the translation of research into practice. The doctor of philosophy (PhD) and other research-focused doctoral degrees remain the preparation for public health nurses to develop the science relevant to public health nursing and to generate the evidence needed to guide practice. In some states a public health nursing certification is needed to signify a nurse's specific competence and expertise in public health nursing. National advanced public health nursing certification is available via portfolio assessment through American Nurses Credentialing Center.

Summary

Public health nurses provide leadership for emerging advances in population health and health care—particularly in terms of addressing health inequities. Equipped with a baccalaureate degree or higher, public health nurses are prepared to address multiple determinants of health and participate fully in the challenges of attaining and maintaining population health. With a scope of practice that includes community-building, health promotion, policy reform, and system-level changes to promote and protect the health of populations; public health nurses have an essential role and responsibility as leaders in health improvement and promoting health equity.

American Nurses Association Scope and Standards of Practice for Public Health Nursing

STANDARDS OF CARE

Standard 1: Assessment

The public health nurse collects comprehensive data pertinent to the health status of populations.

Standard 2: Population Diagnosis and Priorities

The public health nurse analyses the assessment data to determine the diagnoses or issues.

Standard 3: Outcomes Identification

The public health nurse identifies expected outcomes for a plan specific to the population or situation.

Standard 4: Planning

The public health nurse develops a plan that prescribes strategies and alternatives to attain expected outcomes.

Standard 5: Implementation

The public health nurse implements the identified plan.

Standard 5A: Coordination of Care. The public health nurse coordinates care delivery.

Standard 5B: Health Teaching and Health Promotion. The public health nurse employs multiple strategies to promote health and a safe environment.

Standard 5C: Consultation. The public health nurse provides consultation to influence the identified plan, enhance the abilities of others, and effect change.

Standard 5D: Prescriptive Authority. Not applicable

Standard 5D: Regulatory Activities. The public health nurse participates in applications of public health laws, regulations, and policies.

Standard 6: Evaluation

The public health nurse evaluates progress toward the attainment of outcomes.

STANDARDS OF PROFESSIONAL PERFORMANCE

Standard 7: Ethics

The public health nurse practices ethically.

Standard 8: Education

The public health nurse attains knowledge and competency that reflect current practice.

Standard 9: Evidence-Based Practice and Research

The public health nurse integrates evidence and research findings into practice.

Standard 10: Quality of Practice

The public health nurse contributes to quality nursing practice.

Standard 11: Communication

The public health nurse communicates effectively in a variety of formats in all areas of practice.

Standard 12: Leadership

The public health nurse demonstrates leadership in the professional practice setting and the profession.

Standard 13: Collaboration

The public health nurse collaborates with the population and others in the conduct of nursing practice.

Standard 14: Professional Practice Evaluation

The public health nurse evaluates her or his own nursing practice in relation to professional practice standards and guidelines, relevant statutes, rules, and regulations.

Standard 15: Resource Utilization

The public health nurse utilizes appropriate resources to plan and provide nursing and public health services that are safe, effective, and financially responsible.

Standard 16: Environmental Health

The public health nurse practices in an environmentally safe, fair, and just manner.

Standard 17: Advocacy

The public health nurse advocates for the protection of the health, safety, and rights of the population.

The Health Insurance Portability and Accountability Act (HIPAA): What Does It Mean for Public Health Nurses?

Public Health Nursing Practice—definition: a specialty practice within nursing and public health. Practice focuses on improving population health by emphasizing prevention and attending to multiple determinants of health. Practice includes advocacy, policy development, and planning, which addresses issues of social justice. With a multilevel view of health, public health nursing action occurs through community applications of theory, evidence, and a commitment to health equity. The goal is to prevent disease and disability and promote and protect the health of the community as a whole.

EXPLANATION

- Federal privacy standards were created by the Department of Health and Human Services (USDHHS) to protect patients' medical records and other health information provided to health plans, doctors, hospitals, and other health care providers.
- These standards took effect on April 14, 2003.
- Standardization of electronic transactions, and the elimination of inefficient paper forms, will save the health care industry more than $29 billion in the next 10 years.

PRIVACY RULE

- Protects the confidentiality of individually identifiable health information, whether it is on paper, in computers, or communicated orally.
- Protected health information (PHI) is the name for this individually identifiable health information.
- Limits the ways that health plans, pharmacies, hospitals, and other covered entities can use patients' personal medical information.

PATIENT PROTECTIONS

- Patients should be able to see, obtain copies, and make corrections to their medical records.
- Patients should receive a notice from health care providers regarding how their personal medical information may be used by them and their rights under the privacy regulation. Patients can restrict this use.
- Limits have been set on how health care providers can use individually identifiable health information. Doctors, nurses, and other providers can share information needed to treat a patient. For purposes other than medical care, personal health information generally may not be used.
- Pharmacies, health plans, and other covered entities must obtain an individual's authorization before disclosing patient information for marketing purposes.

PUBLIC HEALTH SERVICES AND PHI

Overview: Although protection of health information is important, PHI is used for the public good by health officials to identify, monitor, and respond to disease, death, and disability among populations. Examples of ways PHI is used include public health surveillance, program evaluation, terrorism preparedness, outbreak investigations, direct health services, and public health research. Public health authorities have taken precautions in the past to protect the privacy of individuals and will continue to do so under HIPAA. The privacy rule, however, still permits PHI to be shared for important public health purposes.

PERMITTED PHI DISCLOSURES TO A PUBLIC HEALTH AUTHORITY

Without Authorization

- Reporting of disease, injury, and vital events
- Conducting public health surveillance, investigations, and interventions
- Reporting child abuse or neglect to a public health or other government authority legally authorized to receive such reports
- To a person subject to jurisdiction of the Food and Drug Administration (FDA) concerning the quality, safety, or effectiveness of an FDA-related product or activity for which that person has responsibility
- To a person who may have been exposed to a communicable disease or may be at risk for contracting or spreading a disease or condition, when legally authorized to notify the person as necessary to conduct a public health intervention or investigation
- To an individual's employer, under certain circumstances and conditions, as needed for the employer to meet the requirements

of the Occupational Safety and Health Administration, Mine Safety and Health Administration, or similar state law

HIPAA AND NURSING RESEARCH

Definitions

Covered entity: a health plan, a health care clearinghouse, or a health care provider who transmits any health information in electronic form.

Individually Identifiable Health Information (IIHI): information about an individual regarding his or her physical or mental health; the provision of health care; or the payment for the provision of health care; and which identifies the individual.

It is the covered entity's obligation not to disclose the information improperly when a researcher seeks data that includes PHI.

A covered entity can disclose IIHI for research purposes under any of the following conditions:

1. The IIHI pertains only to deceased persons.
2. The IIHI can be examined for reviews preparatory to research if it is not removed from the covered entity.
3. Information that has been de-identified can be disclosed; this information is no longer considered IIHI and thus not covered by HIPAA.
4. Data must be disclosed as part of a limited data set if the researcher has a data use agreement with the covered entity.
5. The researcher has a valid authorization from the research subject to disclose IIHI.
6. An IRB or privacy board has waived the authorization requirement.

Creating Data

Researchers may also be creating IIHI. If the researcher is part of a covered entity, any PHI obtained by any means is covered by HIPAA, and the researcher and his or her institution are bound by HIPAA regulations. Most universities with nursing schools will be hybrid entities (i.e., some parts of the university are a covered entity and some are not). Researchers should check their institution's policies.

Disclosing Data

Nurse researchers should be aware that sharing data with colleagues and students may constitute disclosures of IIHI and they should conform to HIPAA regulations. In this case, the researcher is the holder of the IIHI and can disclose it only under appropriate conditions:

1. Patients agree to specific disclosures in the initial authorization.
2. Former patients sign an additional authorization.
3. An IRB or privacy board waives the need for authorization.
4. The holder allows the colleague to review the data to prepare a research protocol if the colleague takes no information away.
5. A holder enters the data in a limited data set and signs a data use agreement with the recipient.
6. A holder de-identifies the data and shares it freely.

HEALTHY PEOPLE: 2030 UPDATE

Healthy People is a national initiative to set and monitor national health objectives with the goal of improving the health of citizens. The process began in 1979, and the current objectives are called ***Healthy People 2030***. The prior objectives, *Healthy People 2020*, envisioned a society in which all people could live long healthy lives, through the achievement of health equity, by eliminating disparities and thereby improving the health of all persons. The process of developing the national health objectives is inclusive with many points of input from the public and stakeholders. Specifically, *Healthy People* is a product that has resulted from input from many different people both from within and outside the federal government. The Secretary of Health and Human Services' Advisory Committee on National Health Promotion and Disease Prevention Objectives for 2030 developed a draft framework for *Healthy People 2030*. During a public comment period held in 2017, members of the public were invited to share their comments on the draft framework. As the result of public comments received, the Committee revised their proposed *Healthy People 2030* framework and submitted it to the HHS Secretary. HHS conducted a review of the revised *Healthy People 2030* framework proposed by the Committee. In June 2018, the HHS Secretary approved the *Healthy People 2030* framework. The framework consists of a vision, mission, foundational principles, and overarching goals with a plan of action for implementing the framework. *Healthy People 2030* is the fifth edition of Healthy People. It aims at new challenges and builds on lessons learned from its first 4 decades. Communities across the U.S. may adopt Healthy People goals and objectives. Communities, which may be as small as neighborhoods or as large as municipalities, may alter the goals and objectives to meet their own needs, and/or use them to set priorities for their region and population groups. The vision of *Healthy People 2030* is to promote a society in which all people can achieve their full potential for health and well-being across the life span.

The mission is to promote, strengthen, and evaluate the nation's efforts to improve the health and well-being of all people. The overarching goals are to:

- Attain healthy, thriving lives and well-being, free of preventable disease, disability, injury, and premature death.
- Eliminate health disparities, achieve health equity, and attain health literacy to improve the health and well-being of all.
- Create social, physical, and economic environments that promote attaining full potential for health and well-being for all.
- Promote healthy development, behaviors, and well-being across all life stages.
- Engage leadership, key constituents, and the public across multiple sectors to take action and design policies that improve the health and well-being of all.

The intent is that *Healthy People 2030* (www.healthypeople2030.gov) will further the improvement of the health and wellbeing of all people. Since the Healthy People initiative was first launched, the United States has made significant progress. Achievements include reducing major causes of death such as heart disease and cancer; reducing infant and maternal mortality; reducing risk factors like tobacco smoking, hypertension, and elevated cholesterol; and increasing childhood vaccinations. During these decades, the importance of collaborating across agencies at the national, state, local, and tribal levels and with the private and public health sectors has been demonstrated. To follow the development of the objectives for each of the overarching goals, visit the website indicated below.
