separation of, 100, 105–109
subunits of, 55
tagging for destruction, 703–705
translocation of, 940–941
unfolding of, 59, 59f
Proteoglycans
in cartilage, 340–341, 340f
defined, 338
properties of, 339–340
structural roles, 339–340
Proteolysis, 142, 753
Proteolytic activation, 223–228
apoptosis by, 224
of chymotrypsinogen, 224–225, 224f
zymogens, 225f, 226
Proteolytic enzymes
activation of, 223–228
in blood clotting, 228–229
chymotrypsinogen as, 224, 224f
in digestion, 224–225
function of, 143
inhibitors of, 226–228
Proteomes, 125–126
Proteomics, 125

Prothrombin, 228–229, 229f
Proton abstraction, 193
Proton dissociation, 18
Proton gradients
    across thylakoid membrane, 599–602
    in ATP synthesis, 562–569
    biochemical processes and, 579–581
    cytochrome *bf* contribution to, 596, 596f
    formation of, 548–549
    in oxidative phosphorylation, 458, 458f, 543, 548–549, 562–569
    in photosynthesis, 592
    photosystems and, 593–599
    power transmission by, 579–581, 581f
Proton shuttle, 193, 194f
Proton transport, 558–559, 559f
Proton-motive force
    ATP forms without, 565–566, 565f
    energy in, 599
    in oxidative phosphorylation, 543, 562–563, 563f, 565–567, 565f
    in photosynthesis, 599
Proto-oncogenes, 433
Protoplasts, 296
Protoporphyrin IX, 786, 787f
Protospacer-adjacent motif (PAM), 294
Proviral DNA, 290
Proximal histidine, 73, 79, 79f
Prusoff, William, 987
Pseudo-first-order reactions, 152
Pseudogenes, 283–284
Pseudosubstrate sequence, 222
Psi (ψ) angle, 45, 45f, 46f
Psoralens, 866, 866f
P-type ATPases
    defined, 384

as evolutionarily conserved, 387–388
roles of, 387–388
SERCA, 384–387
Puffer fish, genome of, 286–287
Pumps
ATP-driven, 384
calcium ion, 384–387, 385f
defined, 384
ion gradients, 382
MDR, 388
Na^+–K^+, 384, 387, 387f
purification of, 384
Pur repressor, 954f, 955
Pure noncompetitive inhibition, 166, 168f
Purine catabolism, 809f
Purine nucleotide synthesis, 783, 797–801
AMP in, 799–800, 799f
control of, 807–808, 808f
de novo pathway for, 796f, 797, 797f, 798–799, 798f, 799t
enzymes of, 800
GMP in, 799–800, 799f
5-phosphoribosyl-1-pyrophosphate (PRPP) in, 797, 807–808
phosphorylation in, 797–799, 798f
ribose phosphate in, 797
salvage pathway for, 797, 800
Purine nucleotides, 792, 797
Purine synthesis, 799–800, 799f
Purinosomes, 800, 800f
Puromycin, 943, 943t, **943f**
PurZ, 801, 801f
Pyran, 327
Pyranose, 327, 327f, 329–330
Pyridoxal phosphate enzymes
bond cleavage in, 712, 712f

reaction choice, 711–712, 711f, 712f
stereoelectronic effects, 712, 712f
Pyridoxal phosphate (PLP)
in amino acid degradation, 709–710, 711–712
in glycogen metabolism, 643–645, 644f
in Schiff-base intermediates formation, 709–710
in Schiff-base linkage, 769
structure of, **709**, **711f**
Pyridoxamine phosphate (PMP), 710, 710f, **710**, 769f, 770
Pyridoxine (vitamin B_6), 463t, 464f, 709–710, **709**
Pyrimidine nucleotide synthesis, 783, 793–797
carbamoyl phosphate in, 793f, 794
control of, 807
cytidine triphosphate (CTP) in, 796
de novo pathway for, 792, 792f, 796
glutamine in, 796
mono-, di-, and triphosphates in, 796
orotate in, 794–795
5-phosphoribosyl-1-pyrophosphate (PRPP) in, 779, 795
regulation of, 807
salvage pathway for, 796–797
substrate channeling in, 794
Pyrimidine nucleotides
defined, 792
recycling of, 796–797
Pyrimidines, 866, 866f
Pyrosequencing, 284, 285f
Pyrrolidine rings, 37, 54, 54f
Pyruvate
alcohols, formation from, 486–487
in amino acid degradation, 712–713, 718, 719, 719f
in amino acid synthesis, 769
in ATP formation, 484–485
carboxylation of, 501–502, 535

conversion into phosphoenolpyruvate, 484, 501–503, 502f
fates of, 486, 486f
formation of, 484–485, 719, 719f
glucose conversion into, 485–486
in glycolysis, 473, 473f, 476f, 485–486, 486f
in ligation reactions, 467
metabolism disruption, 535–536
oxaloacetate synthesis from, 467
reduction of, 487, 487f
structure of, **101**, **159**, **712**
Pyruvate carboxylase
in citric acid cycle, 534–535
in gluconeogenesis, 500f, 501–502, 501f, 502f
Pyruvate carboxylase deficiency (PCD), 510–511
Pyruvate decarboxylase, 486
Pyruvate dehydrogenase, 531–533, 532f, 535
diabetic neuropathy from inhibition of, 532–533
Pyruvate dehydrogenase complex, 515, 516
of *B. stearothermophilus*, 520f
carbon dioxide production, 518–521
in citric acid cycle, 516, 517–521, 518f, 520f, 522f, 531–533, 531f, 532f
components of, 518–521, 520f
of *E. coli*, 518t
mechanism, 518–520, 519f
reactions of, 520–521, 522f
regulation of, 531–532, 531f
response to energy change, 531, 532f
Pyruvate dehydrogenase, in citric acid cycle, 531–533
Pyruvate dehydrogenase phosphatase, 531
Pyruvate kinase
in glycolysis, 494, 495f, 496–497, 497f
liver and glycolysis and, 496–497, 496f
muscle and glycolysis and, 494

Pyruvate kinase isozyme (PKM), 633
Pyruvate kinase M, 498

Q cycle
    defined, 555
    in respiratory chain, 555–556, 555f
Q pool, 553
Q-cytochrome c oxidoreductase, 549, 549f, 550t
    defined, 554–555
    in respiratory chain, 554–555
    structure of, 554f, 555
Quantitative PCR (qPCR), 287, 287f
Quaternary protein structure, 34, 55, 55f
Quinones
    oxidative states of, 550–551, 550f
    in photosynthesis, 592, 592f
    ubiquitous, 561
Quinonoid intermediate, 710

R groups, 35, 37f. *See also* Amino acid side chains
R state of hemoglobin, 78, 78f, 79
Racemizations, 711
Raf, 432
Ramachandran, Gopalasamudram, 45
Ramachandran plot
    for angles of rotation, 46f
    β strands, 48f
    defined, 45–46
    for helices, 47, 47f
Random-coil conformation, 56
Ras
    activation of, 432, 432f
    affixation to cytoplasmic face, 218
    GTPase activity of, 432
    in protein kinase cascade initiation, 432–433

Ras genes, 271
Rate constants, 152
RBP4, 737
R-carvone, **436**
Reaction centers
accessory pigments and, 602–605, 603f, 604f
bacterial, 591f, 592–593, 592f, 593f
chloroplasts and, 590–591, 591f
cyclic electron flow in, 592–593
defined, 590
photosystem I, 597–598, 597f
photosystem II, 594–596, 594f
Reaction rates
defined, 152
enzymes and, 148, 148f
kinetics as study of, 152
rate constants, 152
Reactions
acid–base, 17–18
ATP hydrolysis, 204, 204f
bimolecular, 152
in Calvin–Benson cycle, 611–620, 617f
carbonic anhydrases and, 190–194
of citric acid cycle, 528
deleterious, 480
DNA ligase, 849–850, 849f
double-displacement, 160–161
elongation, 692
enzyme acceleration of, 148–151
equilibrium, 146–147
equilibrium constant of, 146
in fatty acid oxidation, 673t
in fatty acid synthesis, 684–689, 686t, 687f
first-order, 152

free-energy difference of, 145
of gluconeogenesis, 504t
group-transfer, 465–466
hydrolytic, 466
isomerization, 467
ligation, 467
multiple-substrate, 159–161
oxidation-reduction, 465
oxygenase, 614–615, 614f
pentose phosphate pathway, 627–630, 629f, 630f
pseudo-first-order, 152
reduction potentials of, 548
second-order, 152
sequential, 159–160
standard reduction potentials of, 547t
transaldolase, 629–630, 630f, 631f
transketolase, 627–628, 629f, 631f
velocity versus substrate concentration, 149, 149f
Reactive oxygen species (ROS)
accessory pigments and, 604
defined, 560
DNA damage and, 865
exercise and, 561
glucose 6-phosphate dehydrogenase in protection against, 634–635
pathological conditions that may entail injury, 560t
release prevention, 74
source of, 677
Reactive substrate analogs, 170, 170f
Real-time PCR, 287
RecA, 872–873, 957
Receptor tyrosine kinase, 426
Receptor-mediated endocytosis, 375–376, 375f, 376f, 829, 829f
Receptors, 413
Reclinomonas americana, 545

Recognition helix, 951
Recognition sequence, 194
Recognition sites (sequences)
in cognate and noncognate DNA, 197–199, 198f, 199f
defined, 194
distortion of, 198, 198f
EcoRV endonuclease, 197f, 198
structure of, 197, 197f
Recombinant DNA
formation of, 272–273
manipulation of, 272
Recombinant DNA technology
amino acid sequence information, 123
in biology, 272–281
blotting techniques in, 265, 266–267, 267f
cloning in, 277–278
cohesive-end method in, 272, 273f
complementary DNA (cDNA) in, 278–279, 278f, 279f
complete genome, 282–287, 282f
disease-causing mutations, functional effects of, 271–272
in disease-causing mutations identification, 271–272
DNA probes in, 266–267, 268–269
DNA sequencing in, 265, 267–268
DNA synthesis in, 268–269, 268f
electroporation in, 296, 296f
eukaryotic genes, 287–296
functional effects of disease-causing mutations and, 271–272
gel electrophoresis in, 266–267, 266f
gene disruption in, 290–294, 291f, 292f, 294f
gene expression analysis in, 287–289, 287f, 288f
gene insertion into eukaryotic cells, 289–290
gene therapy in, 296
genome comparison, 286–287, 286f
genome sequencing, 282–283
genomic libraries in, 277–278, 277f, 278f

human genome, 283–284, 283f
λ phage in, 275–276, 276f
mutation creation, 279–281
in mutation identification, 271–272
next-generation sequencing methods, 284–286, 285f, 286f
in plants, 295–296, 295f
plasmids in, 274–275
polymerase chain reaction (PCR) in, 265, 269–270, 269f, 270f
in protein purification, 112
restriction-enzyme analysis in, 265–266, 272–273
RNA interference in, 294–295, 295f
solid-phase approach in, 268–269, 268f
tools of, 265–272
transformed into animal cells, 289–290
transgenic animals in, 290, 291f
vectors in, 274–276
Recombinant human insulin, 995. *See also* Insulin

phosphodiester bonds, formation of, 882–884
prokaryotic, 881, 881f
promoter sites in, 886–887

in proofreading, 885
structure of, 881, **881f**
subunits of, 886
in transcription, 881–890
types of, 894–895, 894t
RNA processing
eukaryotic pre-rRNA, 899f, 900
of pre-mRNA, 899f, 900–901, 901f
in transcription of eukaryotes, 892–893, 908, 908f
tRNA, 898–899, 901f
RNA sequences, comparison of, 314, 314f, 315b, 316f
RNA splicing, 901–902, 902f. *See also* Splicing
RNA-DNA hybrid
backtracking, 885, 885f
during elongation, 888, 888f
lengths of, 885
separation, 885, 885f
translocation, 885, 885f
RNA-induced silencing complex (RISC), 295, 295f
RNA-seq, 289
Rodbell, Martin, 425b
Rods, 438, 438f
Rofecoxib (Vioxx), 997
Rotational catalysis in ATP synthase, 567, 567f
Rotenone, 577, 577f
rRNA (ribosomal RNA)
in base pairing, 927
folding of, 928
in structural scaffolding, 928
transcription of, 898–899, 899f, 900f
in translation, 927–928, 928f
Rubisco
in Calvin–Benson cycle, 611–615, 612f, 613f, 614f, 621
defined, 611
magnesium ion in, 612–613, 613f

oxygenase reaction, 613f, 614–615, 614f
structure of, 611–612, 612f

S_1 pockets, 185, 185f, 186
Saccharomyces cerevisiae, 283, 488, 881f, 958
Salicin, 980
Salicylic acid, 980, **980**
Salmonella test, 871–872, 871f
Salmonella typhimurium, 579–580, 579f
Salt fractionation, 110
Salting out, 102–103
Salvage pathways. *See also* Nucleotide synthesis
defined, 792, 792f
for IMP and GMP synthesis, 811
purine, 797, 800
pyrimidine, 796–797
Sample half-cell, 546
Sandwich ELISA, 115, 115f
Sanger, Frederick, 43, 267, 282
Sanger dideoxy method, 267, 267f
Sarcin-ricin loop (SRL), 931
Sarcoplasmic reticulum Ca^{2+} ATPase. *See* SERCA

Sarin, **182**
SARS-CoV-2, 89, 89f, 100, 880, 881. *See also* COVID-19
Saturated fatty acids, 679
S-carvone, **436**
Schiff bases
in amino acid degradation, 709–711, 711f
in amino acid synthesis, 766, 767f
in aminoacrylate, 779, **779**
linkage with PLP, 644f
in retinal, 438f
in transaldolase reaction, 629–630, 630f, 631f

Scissile bond, 185, 185f
Scoring system, 307, 307f
Screening libraries, 982–983, 983f
Screw sense, 47, 47f
scRNA-seq, 289
Scurvy, 63, 756–757
SDS (sodium dodecyl sulfate), 106
SDS–polyacrylamide gel electrophoresis (SDS-PAGE), 106–107, 107f, 109, 110, 363, 363f
Second Law of Thermodynamics, 13–15
Second messengers, 413–414, 413f, 421–422, 424–425
Secondary active transport, 390
Secondary antibody, 116
Secondary assays, 982
Secondary protein structure, 34, 46–50, 52, 58t
Secondary transporters, 390–392, 390f, 391f
Second-order reactions, 152
Secretory pathway, 939
Secretory proteins, 940, 940f
Sedimentation coefficients, 111
Sedimentation equilibrium, 111
Sedoheptulose 7-phosphate, **627**
Selectins, 347
Selectivity filter, 396, 397f
Self-splicing, 909–912
    defined, 909
    example of, 910, 910f
    intron structure, 910f
    mechanism, 910, 911f
Sense (+) strand, 884
Sensory systems
    evolution of, 441–442, 441f
    7TM receptor and, 436–437, 436f
    signal transduction and, 435–442, 436f
Sequence alignment

with conservative substitution, 307f
defined, 303
distant evolutionary relationships, 305–308
with gap insertion, 303, 304f
of hemoglobin, 307f, 308f
homologous sequences, 308–309
of identities only versus Blosum-62, 307f
of leghemoglobin, 307, 307f, 308f
of repeated motifs, 311–312, 312f
scoring system, 307f
shuffling and, 304f, 305, 305f
statistical analysis of, 302–305
statistical comparison of, 305, 305f
three-dimensional structures in evaluation of, 311
Sequence comparison methods, 302, 310
Sequence identities, 303
Sequence template, 311
Sequential model
allosteric enzymes, 215
of hemoglobin-oxygen binding, 78–79, 78f
Sequential reactions, 159–160
SERCA
defined, 384
P-type ATPase, 384–387
pumping by, 385–386, 385f
structure of, 385–386
Serine, **41f**, 719, 719f
in catalytic triads, 183–185, 183f
in chymotrypsin, 181–182, 182f
in cysteine synthesis, 772, 776
defined, 38
from glycine, 719, 719f
in glycine synthesis, 772
pyruvate formation from, 719, 719f
in sphingolipid synthesis, 819, 819f, **819**

sphingosine from, 783
structure of, **38f**, 41, 41f
synthesis of, 772, 776
Serine dehydratase, 712
Serine hydroxymethyltransferase, 772
Serine kinases, 219–220, 220t
Serine phosphatases, 431
Serine protease inhibitors, 226–227
Serine proteases
catalytic strategies of, 179, 183–185
convergent evolution and, 313, 313f
Serotonin, synthesis of, 783, **783f**, 785, 785f
Serpins, 226–227
Seven-transmembrane-helix (7TM) receptor
defined, 415
G proteins and, 424–425, 425f
in glycogen metabolism, 652, 652f
ligand binding to, 415–418
in olfaction, 436–437
phosphoinositide cascade activation, 420–421, 420f, 421f
sensory systems and, 436–437, 436f
in signal termination, 419f
in signal transduction, 415f, 419f, 420–421
70S initiation complex, 931, 931f
70S ribosomes, 927, 927f, 929f, 931
Severe Acute Respiratory Syndrome (SARS), 26
Severe combined immunodeficiency (SCID), 809–810
SgRNA (single guide RNA), 293, 293f
Shaker channel, 394, 399, 399f
Shaker gene, 394
Shape complementarity, 847–848, 847f
Shemin, David, 786
Shikimate in amino acid synthesis, 776–779
Shine, John, 930
Shine–Dalgarno sequences, 930

Short interspersed elements (SINES), 284
Shuffled sequences, 304f, 305, 305f
Sialic acids, **332f**, 819
Sick sinus syndrome, 405
Sickle-cell anemia, 21, 23, 44, 83, 83f
Sickled red blood cells, 83f
Side chains
    amino acid. *See* amino acid side chains
    hydrophilic, 52
    hydrophobic, 52
    polypeptide chains, 42, 42f, 52
Side effect, 987, 997
Sigma (σ) subunit, 886–887, 887f, 890–892
Sigmoid oxygen-binding curve, 76
Sigmoidal curve, 215, 215f
Sigmoidal kinetics, 212, 212f, 215
Signal peptidase, 940
Signal sequence, 940
Signal transduction, 412–442
    abnormalities in cancer, 433, 434, 434f, 435f
    adaptor proteins in, 428
    β-adrenergic receptor in, 415, 415f, 416f, 419f
    calcium ions in, 420–422, 422f
    calmodulin in, 420, 423, 423f
    cAMP in, 412, 418–419
    cross talk, 414
    defects, 433–435
    defined, 412
    EGF signaling, 431–433
    epidermal growth factor (EGF) in, 414f, 431–433, 432f, 433f
    epinephrine in, 414–425, 414f, 416f, 419f
    function of, 413, 414f
    G proteins in, 415–418, 417f
    in glycogen metabolism, 651–653

GTPases and, 433
in hearing, 440–441, 441f
insulin in, 414f, 425–431, 742–743, 742f, 744f
molecular circuits, 413–414
monoclonal antibodies as inhibitors, 434, 434f
nucleotides in, 792
in olfaction, 436–437, 436f, 437f
overview of, 413–414, 413f
primary messenger, 413
principles of, 413–414, 414f
protein kinase A in, 418–419, 424
protein kinases in, 433
Ras in, 432, 432f
second messengers, 413–414, 413f, 421–422, 424
sensory systems and, 435–442, 436f
7TM receptors, 415f, 419f, 420–421
in vision, 437–439, 439f
Signal-recognition-particle (SRP), 940, 940f
Sildenafil, 980, **980f**
Simple diffusion, 382
Single guide RNA (sgRNA), 293, 293f
Single-cell RNA-seq, 289
Single-molecule methods, 15–17, 16f
Single-molecule Michaelis–Menten equation, 164
Single-molecule studies, enzyme, 162–165, 163f
Single-particle analysis, 135
Single-stranded DNA, 266
Single-stranded-binding protein (SSB), 858, 858f
Sinoatrial (SA) node, 405
Site-directed mutagenesis, 187–188, 187f, 280, 280f
Sliding DNA clamp, 857, 857f
Slow-twitch muscle fibers, 649, 747
Small G proteins, 432
Small interference RNA (siRNA), 295, 295f, 972
Small nuclear ribonucleoprotein particles (snRNPs), 903–906, 903f

Small nuclear RNA (snRNA), 903–906
Small nucleolar ribonucleoprotein (snoRNPs), 899
Small subunit (30S) of ribosomes, 927, 927f, 929f, 931
Smell. *See* Olfaction
Smooth endoplasmic reticulum (SER), 667, 668f, 939
SNARE proteins, 376, 376f
Snell, Esmond, 770b
SOD1 gene, 272
Sodium dodecyl sulfate (SDS)
    in gel electrophoresis, 105f, 106–107
    PAGE, 106–107, 107f
Sodium ion channels, 396–397
    inactivation of, 399–400
    paddles, 404
    purification of, 394
    selectivity filter, 397f
Sodium ions, 393
Solid-phase DNA synthesis, 268–269, 268f
Solid-phase peptide synthesis, 127–129, 128f
Somatostatin, 735t
Sonicating, 360
Sos, 432, 432f
Southern, Edwin, 266
Southern blotting, 266, 267f, 290
Space-filling models, 76f
Special pair, 591, 592, 592f
Specific activity, 101
Specificity, dissociation constants and, 93–94
Specificity constant, 158–159
Sperm whale myoglobin, 73
Sphingolipids
    ceramide and, 819, 819f
    defined, 819
    diversity and, 821

gangliosides, 819
synthesis of, 819, 819f
Sphingomyelin, 359f
defined, 357, 819
structure of, **357f**, **820f**
Sphingosine, 356
defined, 357
structure of, **357f**, **819**
synthesis of, 783, **783f**
Spike protein, 89, 89f
Spliceosomes, 902
assembly and action, 903–906, 905f
catalytic center, 905, 905f
defined, 902
mRNA precursors and, 903–904
structure of, **904f**
Splicing
alternative, 906–907, 907f, 907t
branch points in, 902, 903f
catalytic center, 905, 905f
defined, 902
group I, 910, 911f
group II, 911, 911f, 912
mechanism, 902f, 905f
mRNA precursors, 903–906
mutations affecting, 906, 906f
pathways comparison, 911f
self-splicing and, 909–912, 910f, 911f
sites of, 902f, 903–906
snRNPs in, 903–906
spliceosomes in, 902–906, 905f
transesterification in, 902–903, 903f, 905f
Splicing factors, 903
Split-pool synthesis, 982–983, 983f, 984f
Squalene

cyclization of, 824–825, 825f
synthesis of, 823, 824–825, 824f, 825f
Squalene synthase, 823
SREBP (sterol regulatory element binding protein), 756, 825–827, 826f, 830
SREBP cleavage activating protein (SCAP), 826–827, 826f
SRP receptor, 940, 940f, 941f
Stable radicals, 803–804, 804f
Standard free-energy change, 146–147, 147b, 147t
Standard reference half-cell, 546
Staphylococcus aureus, 172–173, 173f, 979
Starch, 335, **336f**, 618
Starvation, metabolic adaptations in, 752–754, 753t
Statins, 166, 833
Stator, 566
Steady-state assumption
defined, 152–153
in enzyme kinetics, 152–153
Steady-state system, 152–153
Stearoyl CoA desaturase, 692, 693f

Termination utilization substance (Tus), 860
Ternary complex, 159
Terpenes, 840, 840f
Tertiary protein structure, 34, 50–54, 310–311, 310f
Testosterone, 70–71, 71f, **71**, 834, 838, **838f**
Tetracycline, 943t
Tetrahydrobiopterin, 723
Tetrahydrofolate, 773f
in amino acid synthesis, 772–774, 773f
defined, 772
one-carbon groups carried by, 773f, 773t
Tetrahymena, 909, 910f, 911
Tetrapyrrole, 786
Tetraubiquitin chain, **704f**
Tetrodotoxin, **394**
Tetroses, 325
TFIID protein complex, 896–898, 897f
Thalassemia, 906, 906f
Therapeutic index, 993
Thermodynamics
of coupled reactions, 449, 451–452
laws of, 12–14, 734
of metabolism, 448–449
Thermogenin, 576

Thermus aquaticus, 270, 881f
Thiamine (vitamin B_1), 463t, 535, 756
Thiamine pyrophosphate (TPP), 615
in citric acid cycle, 518–519, 519f
deficiency, 535
defined, 535
structure of, **518**
in transketolase reaction, 629, 629f
Thioester intermediate, 481, 481f, 482, 483f
Thioesterase, 689
Thioesters, 462
Thioether groups, 36
Thiol groups, 39
Thioredoxin, 601
in Calvin–Benson cycle, 621–622, 621t, **621f**
enzyme activation by, 622f
enzymes regulated by, 621t
Thioredoxin reductase, 803
30S initiation complex, 931, 931f
3D genome, 863
Three-dimensional structure
conservation of, 310–311, 310f
convergent evolution, 313
repeated motifs, 312
RNA sequences, 314, 314f, 315b
in sequence alignment evaluation, 311
tertiary structure and, 310–311
in understanding evolutionary relationships, 308
Threonine
defined, 38
degradation of, 721–722
pyruvate and, 719
structure of, **38f**
synthesis of, 781

Threonine deaminase, 721–722, 780–781, 780f, **781f**
Threonine dehydratase, 712, 721
Threonine kinases, 219–220, 220t
Threonine operon, 969, 969f
Threonyl-tRNA synthetase, 922–923, **923f**
Threshold effects, 215f, 216
Thrombin, 143, **143f**
    antithrombin and, 232
    in blood clotting, 228–229, 231
    dual function of, 231
    inhibitors of, 232
Thromboxane synthase, 693
Thromboxanes, 693, 693f
Thunnus alalunga, 551
Thylakoid membranes, 594f
    defined, 588
    pH gradient across, 599
    photosynthesis in, 588–589
    photosystem II, 596f
    photosystem II and, 594
    proton gradient across, 599–602
    stacked, 605, 605f
    unstacked, 605, 605f
Thylakoid spaces, 588–589, 599
Thylakoids, 588
Thymidine, 796
Thymidine kinase, 796–797
Thymidine monophosphate (TMP), 804, 805f
Thymidine phosphorylase, 796
Thymidylate
    blocking synthesis of, 805–807, 806f
    defined, 804
    synthesis of, 804–805, 805f
Thymidylate synthase, 804, 805f
Thymine, 796

in DNA repair, 868–869
structure of, **4**, **5**, **5f**
synthesis of, 774
Thyroxine, **963**
Thyroxine, synthesis of, 783, **783f**
Time-of-flight (TOF) mass analyzer, 119, 119f
Tip links, 441, 441f
Tissue factor pathway inhibitor (TFPI), 232
Tissue factor (TF), 228
Titin, 43
Titration, 19
Toll-like receptors (TLRs)
defined, 84
extracellular domain of, 85
illustrated, 85f
PAMPs and, 85f
Topoisomerases
bacterial, 855–857
defined, 853–854
type I, 854–855, 854f
type II, 854, 855–857, **855f**, 856f
Topoisomers, 853, 853f
Torpedo marmorata, 401, 401f
Torsion angles, 45
Tosyl-l-phenylalanine chloromethyl ketone (TPCK), 170, **170**, **170f**, 171
Toxicity, drug, 992–993, 993f
Tractability, 978
Trans configuration, peptide bonds, 44–45, 45f
Trans fat, 679
Trans unsaturated fatty acids, 679
Transacetylase, 520–521, 521f
Transaldolase
in pentose phosphate pathway, 626–628, 629–630, 630f
reactions, 629–630, 630f, 631f
Transaminases

in amino acid degradation, 708–713
defined, 708
mechanism, 710, 710f
Transamination
in amino acid degradation, 709–711
amino acid synthesis by, 767, 769–770, 769f, 770f
Schiff-base intermediates in, 710
Transcription
ATP hydrolysis in, 905
in bacteria, 886, 935, 935f
chemistry of, 882
defined, 881
elongation, 882, 884, 884f, 888, 888f
in eukaryotes, 892–893, 892f
in gene expression, 935, 950
initiation of, 882
mRNA processing and, 908, 908f
nuclear hormone receptors in, 963–965
overview of, 881
in prokaryotes, 892f
promoters in, 882, 886, 886f
proofreading in, 885
regulation of, 890–898, 892f
repression of, 967
rho in, 889–890, 889f, 890f
riboswitches in, 891, 891f
RNA polymerases in, 881–890
of rRNA, 898–899, 899f, 900f
self-splicing in, 909–912, 910f, 911f
splicing in, 880, 902f, 903–906, 903f, 905f
stages of, 882
start site, 886
termination of, 882, 888–890, 889f, 890f
upstream promoter element (UPE) in, 886, 895

Transcription activator-like effector nucleases (TALENs), 292–293, 292f, 293f
Transcription bubbles
defined, 882
elongation at, 888, 888f
schematic representation, 888f
structure of, **883f**
Transcription factors
activation domain, 960
defined, 291, 896, 959
DNA-binding domains of, 958–960
ethanol metabolism and, 756
in eukaryotes, 896–898, 897f, 958–960
in gene expression, 958–960
nuclear hormone receptor, 963–964, 964f
in prokaryotes, 958
regulatory domains of, 960
Transcription in eukaryotes, 890–898
in bacteria versus, 892, 892f
CAAT box in, 896, 896f
carboxyl-terminal domain (CTD) in, 894
control of, 892–893
downstream core promoter element (DPE) in, 896
enhancers in, 898
eukaryotic promoter elements, 896f
GC box in, 896, 896f
initiation of, 892, 896–898, 897f
initiator element (Inr) in, 896
microRNAs in, 902f, 908
nuclear membrane in, 892
pre-mRNA processing and, 899–900, 901f, 908, 908f
products of, 898–909
RNA editing in, 908–909, 909f
RNA polymerases in, 896f
RNA processing and, 892–893, 908, 908f

splicing in, 905f
TATA box in, 896, 896f
transcription factors in, 896–898, 897f
translation and, 892, 892f
upstream promoter element (UPE) in, 895
Transcription initiation, 882
in bacteria, 886
de novo, 884–885
in eukaryotes, 892, 896–898, 897f
Transcription repressors, 960
Transcriptome, 288
Transducin, rhodopsin and, 439
Transduction, 290, 413
Transesterification reactions, 902–903
Transfection, 289
Transferases, 143t
Transferred DNA (T-DNA), 296
Transferrin, 376, 970
Transferrin receptor, 376, 376f, 970
Transferrin-receptor mRNA, 970–971, 970f
Transgenic mice, 290
Transglutaminase, 230
Transition state
ATP hydrolysis, 202–203
in catalysis, 149
collapse of, 151
defined, 148
formation facilitation of, 148–151
symbol, 148
Transition-state analogs, 169, 169f, 173f, 202, 202f
Transketolase, 535, 615
in Calvin–Benson cycle, 616, 616f, 618
in pentose phosphate pathway, 626–628, 629f
reaction, 628–629, 629f, 631f
Translation, 47, 917–921

accuracy of, 917–918, 917t
activation sites, 922–923, 923f
adenylation in, 921–922
aminoacyl-tRNA synthetase in, 921–926
anticodons in, 919–921, 921f
in bacteria, 930, 931f, 935, 935f, 936–937
base pairing in, 919–920, 927–928, 928f
codon-anticodon interactions in, 921
codons in, 920–921, 921f
defined, 917
direction of, 935
elongation factors in, 931–932, 931f, 937
in eukaryotes, 892, 892f, 936–937, 937f
eukaryotic initiation of, 936–937, 937f
formylmethionyl-tRNA in, 930, 930f
in gene expression, 935
initiation factors, 931, 931f
initiation of, 929–930, 930f, 931f, 936–937
initiation sites, 929–930, 930f
mRNA in, 937
organization in, 937
overview of, 916–917
peptide bond formation in, 932–933, 933f
proofreading in, 923–925, 924f, 970–971
reading frame, 931
release factors in, 935–936, 935f
ribosomes in, 921, 926–939
rRNA in, 927–928, 928f
Shine–Dalgarno sequences in, 930
signaling in, 940–941
termination of, 935–936, 935f, 937
translocation in, 933–935, 934f
tRNA in, 918–920, 929, 930f, 936–937
wobble hypothesis and, 920–921, 920t
Translesion polymerases, 864–865

Translocase, 934
Translocation
inhibition by antibiotics, 943–944, 944f
mechanism of action, 934
of proteins, 940–941
RNA-DNA hybrid, 885, 885f
signal sequences in, 940–941, 940f, 941f
in translation, 933–935, 934f
Translocon, 940–941
Transmembrane helices, 367–369
Transport vesicles, 941–942
Transporters
ABC, 388–390, 388f, 389f, 999
antiporters, 390, 390f
ATP-ADP, 572–573, 572f, 573f
dicarboxylate, 573, 573f
glucose, 390, 474, 474t, 498, 498t
glucose 6-phosphate, 661
mitochondrial, 572–573, 572f, 573f

phosphate, 572, 573f
in photosynthesis, 589–593, 589f
secondary, 390–392
symporters, 390, 390f
tricarboxylate, 573, 573f
uniporters, 390, 390f
Transverse diffusion, 370, 370f
Trastuzumab (Herceptin), 114, 434
Tree of life, 3f
Triacylglycerol synthesis, 815–821
Triacylglycerol synthetase complex, 816
Triacylglycerols
in adipose tissue, 753
defined, 666–668
electron micrograph of, 666f

as energy source, 692
in fatty acid metabolism, 668–669, 669f
hydrolysis of, 499
pancreatic lipases and, 667f
structure of, **666**
synthesis of. *See* Triacylglycerol synthesis
transport of, 827–829
Tricarboxylic acid (TCA) cycle. *See* Citric acid cycle
Triglycerides. *See* Triacylglycerols
Trimethoprim, 807, **807**
Trinucleotide repeats, 869, 869f
Triose phosphate isomerase deficiency (TPID), 509–510
Triose phosphate isomerase (TPI)
catalytic mechanism of, 479f, 480
in glycolysis, 478–480, 479f
structure of, **479f**
Trioses, 325
Triple helix of collagen, 54f
tRNA (transfer RNA)
acceptor stem, 919
anticodons of, 918, 919–920
bases, 919–920
CCA terminal region of, 919, 919f
charged, 921
codons in, 920–921
common features of, 918–920
defined, 918
extra arm, 919
helix stacking in, 919, 919f
initiator, 936–937
inosine in, 921
molecule design, 918–920, 919f
precursors of, 900f, 919
recognition sites on, 925, 925f

RNA polymerase III and, 900
RNA processing, 898–899, 901f
structure of, **918f**, 919, 919f, **919f**
synthetase recognition of, 925, 925f
in translation, 918–920, 929, 930f, 936–937
translocation of, 933–935, 934f
wobble hypothesis and, 920–921, 920t
Trombone model, 859, 859f
Troponin complex, 419
Trp operon, 968, 968f
TRPV1, 136
Trypanosomes, 909
Trypsin, 143, **143f**
catalytic triad in, 186–187, 186f
chymotrypsin and, 186, 186f
defined, 226
generation of, 226
S_1 pockets, 186f
S_1 pockets of, 186f
structure of, 186f
Trypsin inhibitor, 226–228, 227f
Trypsinogen, 226
Tryptophan, 718, **724**
in alanine, 719
degradation of, 724, 724f
nicotinamide from, 783
as precursor for neurotransmitters, 785, 785f
serotonin from, 783
structure of, 37–38, 37f, **37f**
synthesis of, 778–779, 778f
Tryptophan synthase, 779, **779f**
Tryptophan synthetase, 794
Ts elongation factor (EF-Ts), 932
t-SNARE, 942

T-to-R equilibrium, 216–217, 216f, 217f
T-to-R state transition, ATCase, 214f, 215
T-to-R transition, 78f, 80–81
Tu elongation factor (EF-Tu), 931–932, 931f
Tuberculosis (TB), 538, 707
Tumor hypoxia, 498
Tumor-inducing (Ti) plasmids, 295–296, 295f
Tumor-suppressor genes, 433, 434, 870
Turnover number, 157, 157t
Twin studies, 23, 24t
Twist in supercoiling, 852f, 853
2′, 3′-dideoxy analog, 267, **267**
Two-dimensional electrophoresis, 108–109, 108f, 109f
Two-dimensional NMR, 133–135
Twofold rotational symmetry, 197, 197f
Type 1 diabetes
    defined, 741
    glucagon excess in, 746
    insulin insufficiency in, 746
    metabolic derangements in, 746
    treatment for, 746
Type 2 diabetes
    defined, 741
    exercise and, 746
    metabolic syndrome and, 743, 743f
    treatments for, 660, 745
Type I muscle fibers, 649
Type I topoisomerases, 854–855, 854f
Type II topoisomerases, 854, 855–857, **855f**, 856f
Type IIb muscle fibers, 649
Typing-monkey analogy, 60, 60f
Tyrosine phosphatases, 431
Tyrosine, 718
    defined, 38

degradation of, 723–724, 724f
from phenylalanine, 768, 769
phenylketonuria and, 728
as precursor for neurotransmitters, 785f
structure of, **38f**, **40t**, **162**, **724**
synthesis of, 776–777, 778f
thyroxine from, 783
Tyrosine kinases, 219–220, 426, 427f, 428f
Tyrosine phosphatase IB, 743
Tyrosinemia, 727t
Tyrosyl radical, 802f, 803, 804
Tyrosyl-tRNA synthetase, 924

Ubiquinol, 553–554, 672
Ubiquinone, 550, 672
Ubiquinone reductase, 672
Ubiquitin
conjugation, 703–704, 704f
defined, 703
pathway, 707
in protein tagging, 703–705
research in, 708b
structure of, **703f**
Ubiquitination, 704–705
Ubiquitin-conjugating enzyme (E2), 703, 704f
Ubiquitin-protein ligase (E3), 703–705, 704f
Ubiquitin-activating enzyme (E1), 703, 704f
UDP (uridine diphosphate), 656
UDP-galactose 4-epimerase, 491
UDP-glucose
defined, 490, 653, 792
in galactose conversion, 491
in glycogen synthesis, 654–655
synthesis of, 653–654
UDP-glucose pyrophosphorylase, 653

Ultracentrifugation, 111
Ultraviolet light, and DNA damage, 866, 866f
UMP kinase, 796
Uncompetitive inhibition, 166, 167f, 168f. *See also* Enzyme inhibition

Vitamin B_7 (biotin), 463t, 501, 501f
Vitamin B_9 (folic acid), 463t
Vitamin B_{12}, 463t, 677b
as coenzyme, 676–677, 676f, 678
corrin ring and cobalt atom, 676–677
in fatty acid metabolism, 676–677

Vitamin C (ascorbic acid)
deficiency, 464t
deficiency of, alcohol related, 756–757, 757f
forms of, 757, 757f
function of, 464t
Vitamin D (calcitriol)
biochemical role, 839, 840
cholesterol as precursor, 839–840
deficiency, 464t, 840
function of, 464t
synthesis of, 839–840, 839f
Vitamin E (α-tocopherol), 464t
Vitamin K
in blood clotting, 231, 231f, 464t
deficiency, 464t
structure of, **231f**
in γ-carboxyglutamate formation, 231, 231f
Vitamins
coenzyme, 463–464, 463t
defined, 463
evolution of, 464
metabolism of and ethanol, 756–757
noncoenzyme, 464t
in reducing homocysteine levels, 776
V_{max}, 156. *See also* Maximal rate
Voltage-gated ion channels, 398–399, 399f
von Gierke disease, 660–661, 661t

proteolytic activation, 226, 226f
secretion of, 224, 224f

Extended Descriptions

The cover page of the book titled “Biochemistry, Tenth edition” is shown
Logo of W. H. Freeman Macmillan learning
Structures of cell membrane and associated proteins
Reactions and its corresponding graph and related questions
Incomplete purification table along with the percent yield equation
New case study Mile High Stadium and Silent Killer: Hemoglobin Dysfunction
Logo of Macmillan learning
FIGURE 6.18 The active site of human carbonic anhydrase II includes a bound zinc ion
Photograph and a snippet of the accompanying text of a short profile of a scientist
FIGURE 12.38 Many cells take up molecules by receptor-mediated endocytosis
FIGURE 15.6 The sources of ATP change as exercise duration increases, even within the first few seconds
FIGURE 16.36 The Cori cycle allows the liver to better support other tissues, such as skeletal muscle
FIGURE 1.1 Despite tremendous biological diversity, there is remarkable similarity in the molecules that make up living organisms
Examples of metabolites
FIGURE 1.2 A possible timeline for biochemical evolution shows that life on Earth began approximately 3.5 billion years ago
FIGURE 1.3 The relationships of all modern organisms can be displayed on a tree of life with just three major branches
Structures of the four nitrogenous bases of D N A
FIGURE 1.4 The covalent structure of DNA is a linear polymer of monomeric units

FIGURE 1.5 The double helix has two antiparallel strands
FIGURE 1.6 The nitrogenous bases in DNA form specific Watson–Crick base pairs
FIGURE 1.7 Once separated, each strand of the DNA double helix can act as a template for the generation of its partner strand
FIGURE 1.8 When two DNA strands with complementary sequences are mixed, they spontaneously assemble to form a double helix
Resonance structures of adenine
FIGURE 1.9 Electric dipoles can form a variety of noncovalent interactions
FIGURE 1.10 Hydrogen bonds are weak noncovalent interactions between specific hydrogen atoms and lone pairs of electrons
An example of hydrogen bonding
FIGURE 1.11 The energy of a van der Waals interaction varies and is most favorable at the van der Waals contact distance
Electric dipole in a water molecule
FIGURE 1.12 The structure of ice involves extensive hydrogen bonding
FIGURE 1.13 The hydrophobic effect is due to the behavior of water molecules
FIGURE 1.14 Ionic interactions among phosphate groups oppose the formation of the DNA double helix
Example of a reversible reaction
FIGURE 1.15 Optimal base stacking allows many weak, but favorable, van der Waals contacts that drive double- helix formation
FIGURE 1.16 Double-helix formation entails a loss of entropy
FIGURE 1.17 DNA double-helix formation can be probed at the single-molecule level
A table corresponding to the experiments based on double helix formation
FIGURE 1.19 A plot of the running average of the number of experimental repetitions observing double-helix formation reveals eventual convergence on a stable value
Dissociation of water
FIGURE 1.20 DNA strands are separated by the addition of a base

Reversible reaction of guanine
FIGURE 1.21 Buffers resist changes in pH over a narrow pH range
FIGURE 1.22 Added hydrogen ions protonate buffer components rather than remaining free
Reversible deprotonation reaction of phosphoric acid
FIGURE 1.23 The cost to sequence a human genome has decreased dramatically over the past two decades
FIGURE 1.24 DNA sequences vary more within populations than they do between populations
FIGURE 1.25 Genomic information can confirm locations of ancestry
FIGURE 1.26 The human microbiome comprises many different bacterial and fungal species
FIGURE 1.27 Protein folding is primarily dictated by the specific sequence of amino acids
FIGURE 1.28 The similarities between hemoglobin sequences from different species provide evidence for a molecular clock
FIGURE 1.29 There are a variety of possible career paths for those involved in biochemical research
Fused structure of a benzene ring with a 5-membered heterocyclic ring
Types of insulin structure
FIGURE 2.1 The structure of a protein determines its function
FIGURE 2.2 Some proteins form complex assemblies
FIGURE 2.3 Conformational changes allow flexibility in protein function
FIGURE 2.4 The l and d isomers of amino acids are mirror images of each other
FIGURE 2.5 The ionization state of amino acids is altered by changes in pH
FIGURE 2.6 The hydrophobic amino acids have nonpolar R groups
FIGURE 2.7 The polar amino acids have polar but uncharged R groups at physiological pH
FIGURE 2.8 Histidine can bind or release protons near physiological pH

FIGURE 2.9 Two amino acids are positively charged at physiological pH. The guanidinium group in the arginine side chain is shown in red
FIGURE 2.10 Two amino acids are negatively charged at physiological pH
Ionization of an alpha-carboxyl group.
Ionization of an alpha-carboxyl group.
Ionization of a histidine amino acid
Reversible reaction of ammonia
Ionization of a mercapto group
Ionization of a hydroxyl group
Reversible reaction of ammonia
Ionization of an amine group
FIGURE 2.11 Some amino acids are not found in proteins because they are too reactive
FIGURE 2.12 The formation of the peptide bond linking two amino acids is accompanied by the loss of a molecule of water
FIGURE 2.13 Amino acid sequences have direction
FIGURE 2.14 A polypeptide chain consists of a constant backbone and variable side chains
FIGURE 2.15 The formation of a disulfide bond from two cysteine residues is an oxidation reaction
FIGURE 2.16 The primary structure of bovine insulin is its amino acid sequence
FIGURE 2.17 Peptide bonds are planar and have partial double-bond character
Peptide bond resonance structures
FIGURE 2.18 For most amino acids, the trans configuration of the peptide bond is strongly favored because of steric clashes that arise in the cis isomer.
FIGURE 2.19 For peptide bonds between proline and its preceding residue, cis bonds are as likely as trans bonds
FIGURE 2.20 The structure of each amino acid in a polypeptide adjusts by rotation about two single bonds
FIGURE 2.21 A Ramachandran plot shows that not all φ and ψ values are possible without collisions between atoms

FIGURE 2.22 Various depictions of an alpha helix reveal several of its key features
FIGURE 2.23 In an alpha helix, hydrogen bonds form between the CO group of residue I and the NH group of residue i + 4
FIGURE 2.24 Both right- and left-handed helices lie in regions of allowed conformations in the Ramachandran plot
FIGURE 2.25 There are two common ways to draw α helices. (A) A ribbon depiction. (B) A cylindrical (rod) depiction
FIGURE 2.27 β strands occupy an allowed region of the Ramachandran plot
FIGURE 2.28 The side chains of a beta strand project alternately above and below the plane of the strand
FIGURE 2.29 In an antiparallel beta sheet, adjacent beta strands run in opposite directions
FIGURE 2.30 In a parallel β sheet, adjacent β strands run in the same direction
FIGURE 2.31 In a mixed beta sheet, the beta strands have a combination of parallel and antiparallel pairings
FIGURE 2.32 The twisted shape of some beta sheets is more evident in a schematic depiction of strands
FIGURE 2.33 Fatty acid-binding protein is rich in beta sheets
FIGURE 2.34 In a reverse turn, the CO group of residue i of the polypeptide chain is hydrogen bonded to the NH group of residue i + 3
FIGURE 2.35 Loops are found on protein surfaces
FIGURE 2.36 Myoglobin folds into a compact structure
FIGURE 2.37 Hydrophobic amino acids are preferentially distributed in the interior of myoglobin.
FIGURE 2.38 Porin, found in the hydrophobic environment of the membrane, exhibits an “inside out” amino acid distribution
FIGURE 2.39 The helix-turn-helix motif is a supersecondary structural element found in many DNA-binding proteins
FIGURE 2.40 Domains are compact regions within proteins that are connected by flexible polypeptide segments

FIGURE 2.41 The alpha-helical coiled coil adopts an extended structure
FIGURE 2.42 Heptad repeats from each helix in a coiled-coil protein interact with one another
FIGURE 2.43 The amino acid sequence of a part of a collagen chain reveals that every third residue is a glycine.
FIGURE 2.44 A single strand of a collagen triple helix adopts an extended conformation
FIGURE 2.45 Glycine residues form the interior of the collagen triple helix
FIGURE 2.46 Quaternary structure refers to the arrangement of multiple polypeptide chains
FIGURE 2.47 Human hemoglobin is composed of an alpha 2 beta 2 tetramer
FIGURE 2.48 Viral coat proteins adopt complex quaternary structures with many copies of relatively few unique subunits
Urea and beta-mercaptoethanol
FIGURE 2.49 Bovine ribonuclease is a single polypeptide chain with four intramolecular disulfide bonds
FIGURE 2.50 Beta-Mercaptoethanol disrupts disulfide bonds
FIGURE 2.51 Ribonuclease is denatured with urea and β-mercaptoethanol
FIGURE 2.52 Native ribonuclease can be re-formed from scrambled ribonuclease in the presence of a trace of beta-mercaptoethanol
FIGURE 2.53 Many sequences can adopt alternative conformations in different proteins
FIGURE 2.54 The transition from folded to unfolded state is abrupt
FIGURE 2.55 At the denaturation midpoint, half the molecules are fully folded and half are fully unfolded
FIGURE 2.56 In the analogy of the typing monkey, the desired result is achieved more rapidly if individual correct keystrokes are retained
FIGURE 2.57 The proposed folding pathway of chymotrypsin inhibitor-2 demonstrates the nucleation-condensation model
FIGURE 2.58 The folding funnel depicts the thermodynamics of protein folding.

FIGURE 2.59 AlphaFold represents a significant step forward in protein folding prediction.
FIGURE 2.60 The structure of the Aβ amyloid fibril reveals its extensive β sheet network
FIGURE 2.61 The extent of amyloid fibril aggregation in the brain can predict the progression of Alzheimer disease
FIGURE 2.62 Posttranslational modifications to proteins include covalent attachments.
FIGURE 2.63 GFP is modified posttranslationally by the chemical rearrangement of three amino acids
Structure of 5-membered heterocyclic pentagonal ring
Structure of substituted benzene ring
Branched structure of substituted carboxylate ion
Branched structure of substituted carboxylate ion
Structure of a polypeptide
Structure of an amino acid
Structure of a substituted 5-membered heterocyclic pentagonal ring
Ball-and-stick model of an amino acid derivative
Ball-and-stick model of an amino acid derivative
Ball-and-stick model of an amino acid derivative
Ball-and-stick model of an amino acid derivative
Ball-and-stick model of an amino acid derivative
An image showing a large number of penguins
FIGURE 3.1 Comparing the percentage of receptor R bound to ligand L with the concentration of added L reveals how tightly R binds L
FIGURE 3.2 The binding of L to R can be characterized by L1/2
FIGURE 3.3 Estrogens are hormones that are bound by estrogen receptors
FIGURE 3.4 The steroid hormones β -estradiol and testosterone appear quite similar, yet receptors recognize the molecules as distinct
FIGURE 3.5 Proteins such as estrogen receptors include binding pockets that are complementary to the shapes of specific ligands
FIGURE 3.6 Even subtle features of ligands can be recognized

FIGURE 3.7 Dissociation and association are constantly occurring, even at equilibrium where the concentrations of all species are constant
FIGURE 3.8 Half saturation of human myoglobin occurs when the partial pressure of oxygen is 2 torr
FIGURE 3.9 The structure of myoglobin consists primarily of α helices surrounding a heme molecule
FIGURE 3.10 The structure of heme comprises four pyrrole rings that use their nitrogen atoms to bind to a central iron atom
FIGURE 3.11 Oxygen binding changes the position of the heme iron ion
FIGURE 3.12 The complex between iron and oxygen in myoglobin can be described by two resonance structures
FIGURE 3.13 Bound oxygen is stabilized through a hydrogen bond between the distal histidine and one of the oxygen atoms
FIGURE 3.14 Carbon monoxide can bind to the iron ion in myoglobin, blocking the oxygen-binding site
FIGURE 3.15 Hemoglobin is an assembly of four subunits, each of which is very similar to myoglobin
FIGURE 3.16 The oxygen-binding curve for hemoglobin, with its sigmoid (S-like) shape, is markedly different from that for myoglobin
FIGURE 3.17 Cooperativity enhances oxygen delivery by hemoglobin
FIGURE 3.18 Oxygen delivery by hemoglobin responds to exercise
FIGURE 3.19 Substantial quaternary structural changes occur in hemoglobin upon oxygen binding
FIGURE 3.20 A concerted model can explain cooperative oxygen binding by hemoglobin
FIGURE 3.21 The sigmoid oxygen-binding curve of hemoglobin can be seen as a combination of the T state binding curve and the R state binding curve
FIGURE 3.22 A sequential model can account for oxygen-binding cooperativity
FIGURE 3.23 Oxygen binding causes the iron to move into the porphyrin

FIGURE 3.24 The movement of the distal histidine and its associated α helix upon oxygen binding drives cooperativity
Structure of 2,3-Bisphosphoglycerate
FIGURE 3.25 The oxygen-binding curves for pure hemoglobin and hemoglobin in red blood are markedly different
FIGURE 3.26 2,3-Bisphosphoglycerate binds in the central cavity within deoxyhemoglobin
FIGURE 3.27 Fetal red blood cells obtain oxygen from maternal red blood cells by virtue of fetal hemoglobin's lower affinity for 2,3-BPG
FIGURE 3.28 Lowering the pH decreases the oxygen affinity of hemoglobin and facilitates the release of oxygen into metabolically active tissues
FIGURE 3.29 Ionic interactions involving the β chain C-terminal histidine are responsible for some of the pH sensitivity of hemoglobin oxygen affinity
FIGURE 3.30 The presence of carbon dioxide decreases the oxygen affinity of hemoglobin, even beyond the effect due to a decrease in pH
Formation of carbamate
FIGURE 3.31 Carbon monoxide is rapidly transferred from carboxyhemoglobin to N g b-H64Q
FIGURE 3.34 Two molecules of hemoglobin S interact through hydrophobic patches
FIGURE 3.35 The structure of the LRR domain from TLR3 reveals how many LRR units come together to form a structure with binding surfaces for potential partners
Thymine and uracil
FIGURE 3.36 The innate immunity component TLR3 recognizes its PAMP, a double stranded RNA
FIGURE 3.37 Immunoglobulin sequences include regions of extensive sequence variability
FIGURE 3.38 The immunoglobulin fold consists of a pair of β sheets linked by a disulfide bond

FIGURE 3.39 An IgG molecule has a Y-shaped structure comprising two identical arms with hypervariable regions at the end
FIGURE 3.40 Immunoglobulin G molecules can be cleaved into two F ab fragments and one F c fragment by treatment with papain
FIGURE 3.41 The structure of an F ab fragment reveals how the six hypervariable loops come together to form a binding surface
FIGURE 3.42 The structure of a complex between lysozyme and a specific F ab fragment reveals how the binding surface on the F ab interacts with the antigen
FIGURE 3.43 Five classes of immunoglobulin have the same light chain combined with a different heavy chain (γ, α, μ, δ, or ε)
FIGURE 3.44 Antibodies elicited against the spike protein of SARS-CoV-2 can bind to this protein and block the ability of the virus to infect cells
FIGURE 3.45 The structure of the extracellular domain of a class I MHC protein reveals a deep groove
FIGURE 3.46 In class I MHC proteins, peptides can bind in the groove
FIGURE 3.47 Each MHC class I protein presents peptides with some recurring features
FIGURE 3.48 The T-cell receptor recognizes specific class I MHC complexes, contacting both the MHC protein and the bound peptide
FIGURE 3.49 Binding can be monitored by measuring the fraction of receptors with ligand bound as a function of the amount of ligand added
FIGURE 3.50 At high enough concentrations, ligands with lower affinity for a receptor can compete for binding with high-affinity ligands
FIGURE 3.50 At high enough concentrations, ligands with lower affinity for a receptor can compete for binding with high-affinity ligands
Binding of a receptor to its ligand with the forward and reverse reaction rates
FIGURE 3.51 At equilibrium, the rates of the forward and reverse reactions are the same

FIGURE 3.52 A rate constant reflects the distribution of reaction times at the single molecule level
Binding of oxygen by hemoglobin
Two graphs for myoglobin and hemoglobin
Reversible reaction of oxygen binding in arthropods
Structure of choline
Structure of spermine
Structure of inositol Penta phosphate
Structure of indole
Ribbon diagram of SARS-CoV-2 spike protein bound to angiotensin-converting enzyme 2 and immunofluorescence photomicrographs of infected cells
Chemical equation for oxidation of lactate to pyruvate
FIGURE 4.1. Schematic illustration of differential centrifugation and photomicrographs of the pellets obtained at each step
FIGURE 4.2. Schematic illustration of dialysis to separate proteins from small molecules
FIGURE 4.3. Schematic illustration of gel-filtration chromatography to separate proteins on the basis of their size
FIGURE 4.4. Schematic illustration of ion-exchange chromatography to separate proteins based on their net charge
Chemical structure of ionized carboxymethyl group and protonated diethylaminoethyl group bound to cellulose or agarose bead
FIGURE 4.5. Schematic illustration of affinity chromatography to separate proteins based on their binding to a specific ligand
FIGURE 4.6. Graph showing H P L C mediated protein separation with high resolving power
FIGURE 4.7. Schematic illustration of polyacrylamide gel electrophoresis
FIGURE 4.8. Cross-linking reaction for polyacrylamide gel formation
Chemical structure of sodium dodecyl sulfate
FIGURE 4.9. Photograph of stained polyacrylamide gel showing protein bands
FIGURE 4.10. Electrophoresis graph for protein mass determination

FIGURE 4.11. Electrophoretic analysis for monitoring the progress of protein purification
FIGURE 4.12. Schematic illustration of isoelectric focusing mediated separation of proteins
FIGURE 4.13. Schematic illustration and actual image of two-dimensional gel electrophoresis for separation of complex protein mixtures
FIGURE 4.14. Photographic results of two dimensional gel electrophoresis showing alterations of protein level in normal and cancerous tissue
FIGURE 4.15. Schematic illustration of polyclonal and monoclonal antibodies with different number of epitopes
FIGURE 4.16. Schematic illustration of monoclonal antibody production
FIGURE 4.17. Schematic illustration of indirect and sandwich ELISA for antigen or antibody detection
FIGURE 4.18. Schematic illustration of western blotting to detect specific proteins
FIGURE 4.19. Schematic illustration of co-immunoprecipitation for the detection of protein binding partners
FIGURE 4.21. Fluorescence microscopy mediated detection of changes in protein localization inside a cell
FIGURE 4.23. Schematic illustration of MALDI-TOF mass spectrometer for measurement of ionized samples based on their mass-to-charge ratio
FIGURE 4.24. Mass spectrum obtained through MALDI-TOF mass spectrometry
FIGURE 4.25. Method of Edman degradation for peptide sequencing
FIGURE 4.26. Peptide sequencing with the help of tandem mass spectrometry
FIGURE 4.27. Use of overlapping peptides to establish the order of sequenced peptides
FIGURE 4.28. Use of reduction and alkylation reactions for the separation of disulfide-linked polypeptides before sequencing
FIGURE 4.29. Ribbon diagram and units of calmodulin protein

FIGURE 4.30. Mass spectrum showing peptide mass fingerprinting
Chemical structure of f Met peptide
FIGURE 4.31. Chemical structure of 8-arginine vasopressin and 1-Desamino-8-D-arginine vasopressin
FIGURE 4.32. Steps of solid-phase peptide synthesis involving repeated coupling and deprotection
Chemical structures of t-Butyloxycarbonyl amino acid and 9-Fluorenylmethyloxycarbonyl
Chemical structure of dicyclohexylcarbodiimide
FIGURE 4.33. Native chemical ligation reaction for linking two synthetic peptides
FIGURE 4.34. Schematic illustration of the fundamental steps of x-ray crystallography experiment
FIGURE 4.35. X-ray diffraction pattern of a protein crystal
FIGURE 4.36. Electron density map of a protein to determine position of atoms in the crystallized protein
FIGURE 4.37. Electron density map of a protein at different resolutions
FIGURE 4.38. Graph depicting different spin states of a nucleus in N M R spectroscopy
FIGURE 4.39. One-dimensional superscript 1 H NMR spectra shows chemical shift of protons in a sample
FIGURE 4.40. Identification of closely placed protons in a polypeptide due to nuclear overhauser effect
FIGURE 4.41. NOESY spectrum for a protein
FIGURE 4.42. Calculation of structures based on N M R constraints
FIGURE 4.43. Family of related structures produced by N M R spectroscopy
FIGURE 4.44. Projections of a protein complex captured through cryo-E M
Two-dimensional electrophoresis gel showing separation results
Chemical structure of phenylthiohydantoin derivative
Three different protein gels showing different banding patterns
Reaction showing cleavage of cystine by performic acid to produce two molecules of cysteic acid

Chemical equation showing the hydration of carbon dioxide
Chemical equation showing the hydrolysis of a peptide bond
Chemical equation showing the hydrolysis of ester bond
FIGURE 5.1. Chemical structures showing the high specificity of enzymes for their substrates and chemical reactions
Reaction catalyzed by nucleoside monophosphate kinase
Hypothetical chemical reaction
Chemical equation showing the conversion of dihydroxyacetone phosphate into glyceraldehyde-3-phosphate
FIGURE 5.2. Graphical representation of the unperturbed equilibrium point of a reaction in the presence and absence of an enzyme
Calculation of equilibrium constants for catalyzed and uncatalyzed reaction
FIGURE 5.3. Graphical representation of the enzyme-mediated acceleration of a reaction by lowering of the free energy of activation
FIGURE 5.4. Graphical representation of the maximal velocity attained by an enzyme-catalyzed reaction as the substrate concentration increases
FIGURE 5.5 Ribbon diagram and ball-and-stick model show a substrate surrounded by the active site residues of cytochrome P 450 enzyme
FIGURE 5.6. Ribbon diagram and schematic representation of the primary structure depict the coming together of distantly located amino acids in the active site of a folded protein
FIGURE 5.7. Hydrogen bonding between the side chains of active site residues and the substrate
FIGURE 5.8. Schematic illustration of the lock and key model and the induced-fit model
FIGURE 5.9. Graphical representation of the relation between initial velocity and substrate concentration
Model proposed by Michaelis and Menten for enzyme catalysis
Enzyme catalysis
FIGURE 5.10. Graphical representation of Michaelis-Menten kinetics
Reaction catalyzed by alcohol dehydrogenase
Reaction catalyzed by aldehyde dehydrogenase

FIGURE 5.11. The Lineweaver–Burk plot
Chemical structure of the side chain of valine
Chemical structure of the side chain of phenylalanine
Bisubstrate reaction
Chemical equation showing the oxidation of lactate to produce pyruvate
Cleland notation for the conversion of pyruvate into lactate
Chemical equation showing the conversion of creatine into phosphocreatine
Cleland notation for the conversion of creatine into phosphocreatine
Double displacement reaction between aspartate and alpha-ketoglutarate
Cleland notation for the conversion of aspartate into glutamate
FIGURE 5.12. Graphical representation of the allosteric enzyme activity
Graphical representation of the relation between enzyme activity and temperature
Chemical reaction showing the conversion of tyrosine into dopaquinone
FIGURE 5.13. Schematic illustration and graphical representation of molecular heterogeneity
FIGURE 5.14. Schematic illustration of the stochastic behavior of a single-enzyme molecule
Chemical equation showing the conversion of carbohydrate galactose to galactose
FIGURE 5.15. Chemical reaction showing the formation of a highly fluorescent product
FIGURE 5.16. Lineweaver-Burk plot comparing single-molecule kinetic studies and ensemble studies
FIGURE 5.17. Scatter plot indicating heterogeneity of beta-galactosidase at molecular level
FIGURE 5.18. Schematic illustration showing the binding of different types of reversible inhibitors to the enzyme
Chemical structure of sulfanilamide and P A B A

FIGURE 5.19. Michaelis–Menten plot showing the activity of a competitive inhibitor
FIGURE 5.20. Lineweaver–Burk plot depicts competitive inhibition
FIGURE 5.21.Michaelis–Menten plot showing the activity of an uncompetitive inhibitor
FIGURE 5.22. Lineweaver–Burk plot distinguishing uncompetitive inhibition
FIGURE 5.23. Michaelis–Menten plots show the activity of pure noncompetitive inhibitor
FIGURE 5.24. Lineweaver–Burk plot distinguishing a pure noncompetitive inhibition
FIGURE 5.25. The chemical structure of the transition state of a reaction and its analog
FIGURE 5.26. Schematic illustration of irreversible inhibition of an enzyme by D I P F, a group specific reagent
FIGURE 5.27. The chemical structure of the natural substrate of chymotrypsin and an affinity label that binds to chymotrypsin
Lineweaver–Burk plot shows enzyme activity at different concentrations of molecule X
FIGURE 5.28 Chemical structure and ball-and-stick model of penicillin and benzylpenicillin respectively
FIGURE 5.29. Schematic representation of a section of peptidoglycan in Staphylococcus aureus
FIGURE 5.30. Similar chemical structures of penicillin and transition state (R prime-D-Ala-D-Ala peptide) of the transpeptidase reaction
FIGURE 5.31. Schematic illustration showing the formation of penicilloyl-enzyme complex
Enzyme catalysis
Graphical representation of the reaction progress for two different reactions
Forward and reverse rate constants for the conversion of S into P
Protein binding to a small molecule and the formula for K subscript d
Michaelis–Menten plot
Double-reciprocal plots for three different enzyme concentrations
Michaelis–Menten curves for asparaginase from different sources

Sequential conversion of A to D
Photograph of a chess board and ball-and-stick model of an enzyme
Hydrolysis of a peptide
Chemical reaction
FIGURE 6.1. Chemical structure of a peptide with highlighted target amino acids and bonds cleaved by chymotrypsin
FIGURE 6.2. Schematic illustration of the irreversible inactivation of chymotrypsin by D I P F
Molecular structures of malathion and sarin
FIGURE 6.3. Chemical reaction for monitoring chymotrypsin action
FIGURE 6.4. Graphical representation of the two kinetic phases of chymotrypsin activity
FIGURE 6.5. Schematic illustration of hydrolysis by chymotrypsin
FIGURE 6.6. The ribbon diagram of chymotrypsin with active site serine residue
FIGURE 6.7. Schematic illustration of a catalytic triad in the active site of chymotrypsin and the polarization of hydroxyl group of serine residue
FIGURE 6.8. Schematic illustration of the mechanism of peptide hydrolysis
FIGURE 6.9. Schematic illustration of oxyanion hole-mediated stabilization of a tetrahedral intermediate formed during chymotrypsin catalysis
FIGURE 6.10. Space-filling model of the specificity pocket of chymotrypsin
FIGURE 6.11. Structure of a molecule
FIGURE 6.12. Similar structures of chymotrypsin and trypsin
FIGURE 6.13. Spacing filling models and schematic illustrations of the S 1 pockets of chymotrypsin, trypsin, and elastase
FIGURE 6.14. Ball-and-stick model of catalytic triad and oxyanion hole of subtilisin
FIGURE 6.15. Bar graph shows the activity of subtilisin enzyme for different mutations of the catalytic triad
FIGURE 6.16. Schematic illustration of the different catalytic strategies of (A) cysteine proteases, (B) aspartyl proteases, and (C)

metalloproteases
FIGURE 6.17. Ribbon diagram and ball-and-stick model of H I V protease with inhibitor indinavir
Reversible chemical reactions depicting the formation of carbonic acid
FIGURE 6.18. Ribbon diagram of carbonic anhydrase roman number 2 and the ball-and-stick model of its active site
FIGURE 6.19. Graphical representation of the dependence of carbonic anhydrase activity on p H
FIGURE 6.20. Reversible reaction consisting of one reactant and two products is shown
FIGURE 6.21.Electron density map of carbonic anhydrase active site and C O 2 binding site
FIGURE 6.22. Mechanism for the hydration of carbon dioxide by carbonic anhydrase
FIGURE 6.23. Chemical reaction shows the reversible deprotonation of water molecule bound to carbonic anhydrase active site and the ratio of rate constants for protonation and deprotonation
FIGURE 6.24. Reversible reaction shows the deprotonation of the zinc-bound water molecule in carbonic anhydrase aided by buffer
FIGURE 6.25. Graphical representation of the rate of carbon dioxide hydration by carbonic anhydrase as a function of buffer concentration
FIGURE 6.26. Schematic illustration of histidine 64 residue of carbonic anhydrase roman number 2 acting as a proton shuttle
FIGURE 6.27. Chemical reaction shows the restriction enzyme-mediated hydrolysis of phosphodiester bond
Two reversible reactions consisting of two reactants and two products are shown
Chemical reaction for the direct hydrolysis of D N A
Series of reversible reactions consisting of two reactants, two products, and an intermediate product are shown
FIGURE 6.28. Schematic representation of Eco R V cleavage site in a D N A sequences

FIGURE 6.29. Schematic illustration of the inversion of the stereochemical configuration of phosphorus atom after cleavage of D N A by Eco R V
FIGURE 6.30. Ball-and-stick model of the bridge formed by M g superscript 2 plus ion between the enzyme and substrate
FIGURE 6.31. Two fold rotational symmetry of recognition site for Eco R V
FIGURE 6.32. The ribbon diagram of Eco R V bound to a cognate D N A and the ball-and-stick model of C G and A T base pair
Ball-and-stick model of cognate D N A from Eco R V complex
FIGURE 6.34.Ribbon diagram illustrates the positions of the nonspecific and the cognate D N A within Eco R V
FIGURE 6.35. Energy level diagram showing D N A distortions due to an increase in binding energy
FIGURE 6.36. Schematic illustration of the methylation of the recognition sequence of Eco R V
FIGURE 6.37. Ball-and-stick model of asparagine 185 residue of Eco RV and methylated adenine hydrogen bonded to thymine
Reversible reaction consisting of two reactants and two products is shown
FIGURE 6.38. Schematic illustration of the structure of myosin
FIGURE 6.39. Schematic illustration of A T P bound to the myosin molecule
The structure of transition state of A T P
FIGURE 6.40. Ball-and-stick model of a transition-state analog of myosin
FIGURE 6.41. Chemical reaction shows the serine 236 mediated attack of water molecule on gamma-phosphoryl of A T P
FIGURE 6.42. Schematic illustration compares the overall structures of the myosin A T P ase domain with bound A T P and that with the transition-state analog A D P–vanadate
Chemical equation of A T P hydrolysis in the presence of with O superscript 18 labeled water
FIGURE 6.43. Schematic illustration of the reversible hydrolysis of A T P within the active site of myosin

FIGURE 6.44. Ribbon diagram and schematic illustration of actin filament
FIGURE 6.45. Graphical representation of the position of a single dimeric myosin roman number 5 molecule and a model of the movement of the dimeric molecule
FIGURE 6.46. Schematic illustration of the steps involved in the movement of myosin along an actin filament
FIGURE 6.47. Schematic illustration of the structure of myosin assembly in muscle
Chemical structure of the amide substrate of chymotrypsin
Molecular structure of the aldehyde derivative of the substrate of elastase
Chemical structure of a molecule A
Enzyme catalyzed reaction
A chemical reaction representing the committed step of pyrimidine synthesis
Graphical representation of the inhibition of A T C ase by C T P
Graph of the rate of formation of N-carbamoylaspartate as a function of aspartate concentration
Chemical reaction of p-Hydroxymercuribenzoate with a crucial cysteine residue of aspartate transcarbamoylase
Schematic illustration of the top and side views of the catalytic subunit trimer of A T C ase
Chemical equation for the formation of an intermediate compound in the A T C ase catalytic pathway and the structure of its analog P A L A
The ribbon structure of the catalytic trimer of A T C ase and the active site residues of one of the catalytic subunits bound to P A L A
Schematic illustration of the tense and relaxed states of A T C ase
Graphical representation of the change of state in a cooperative enzyme as a function of substrate concentration
Graphical representation of the velocity of reaction as a function of substrate concentration for allosteric and Michaelis-Menten enzymes
Schematic illustration of the stabilization of T state of A T C ase by C T P

A schematic illustration of the equilibrium between the R and T states of A T C ase
Graphical representation of the different effects of A T P and C T P on A T C ase kinetics
Schematic illustration of the timing of expression of isozymes of lactate dehydrogenase and their tissue specific concentrations respectively
Chemical structure of acetylated lysine
Chemical reaction of the phosphorylation of an amino acid residue catalyzed by a protein kinase enzyme is shown
Chemical reaction of dephosphorylation of a phosphorylated protein catalyzed by a protein phosphatase enzyme
Schematic illustration of the range of free energy between phosphorylated and dephosphorylated proteins
Chemical structure of cyclic adenosine monophosphate
A schematic illustration of the binding of c A M P to the regulatory subunits of P K A
Schematic illustration of the secretion of zymogens by acinar cells of the pancreas
Schematic illustration of the activation of chymotrypsinogen by proteolysis
Schematic illustration of the conversion of chymotrypsinogen into chymotrypsin
A flow chart of the cascade of activation of zymogens initiated by the activation of trypsin
The ribbon structures of free pancreatic trypsin inhibitor and the pancreatic trypsin inhibitor bound to trypsin
Chemical reaction of the oxidation of methionine to methionine sulphoxide
Schematic illustration of an enzymatic cascade leading to the clotting of blood
Schematic illustration of the protein domains of prothrombin
Schematic illustration of the binding of calcium ions to the g l a domain of prothrombin
Schematic illustration of the structure of fibrinogen

Schematic illustration of the cleavage of fibrinogen by thrombin to initiate fibrin clot formation
Cross-linking reaction between glutamine and lysine residue
Chemical structure of vitamin K and warfarin
Chemical reactions showing the synthesis of gamma-carboxyglutamate
Graph depicts the velocity curve of an allosteric enzyme and the effect of negative modifier
Graphical representation of the fraction of enzyme in the R state and the fraction of substrate-bound active sites as a function of substrate concentration.
Schematic illustration of a metabolic pathway
Three vertical bar graphs showing the results of control group (no inhibitor), P K A inhibitor, and P K G inhibitor
Graphical representation of the reaction rate as a function of the mole ratio of P A L A to A T C ase
Photograph of a family of dogs is accompanied by a ribbon diagram of a zinc finger protein bound to D N A
Schematic representation of central dogma
FIGURE 8.1. Schematic representation of the structure of nucleic acids
FIGURE 8.2. Chemical structures of ribose and deoxyribose found in R N A and D N A respectively
FIGURE 8.3. The chemical structure of D N A and R N A
FIGURE 8.4. Chemical structures of different purines are pyrimidines
FIGURE 8.5. Chemical structures of a nucleoside and a nucleotide
FIGURE 8.6. Photomicrograph compares the size of an E.coli cell to its coiled genome
FIGURE 8.7. Photomicrograph of the stained chromosomes of female Indian muntjac
FIGURE 8.8. Simplified schematic representation of a nucleic acid strand
FIGURE 8.10. The Watson–Crick model of double-helical D N A
FIGURE 8.11. Base-pairing of nucleotide bases

FIGURE 8.12. Schematic representation of the side view of D N A reveals the stacking of base pairs within the double helix
FIGURE 8.13. Schematic representation of the different structural forms of D N A
FIGURE 8.14. The structures of the sugars in the A and B forms of D N A
FIGURE 8.15. The major and minor grooves of a D N A double helix
FIGURE 8.16. Two photomicrographs show the relaxed and supercoiled forms of circular bacterial D N A
FIGURE 8.17. Stem-loop structures formed in single-stranded D N A and R N A molecules
FIGURE 8.18. Schematic representation of complex structure adopted by R N A molecule
FIGURE 8.19. Bands obtained by density-gradient centrifugation and corresponding graphs for N superscript 14 and N superscript 15 D N A
FIGURE 8.20. D N A banding pattern detected by density-gradient centrifugation across 4 generations
FIGURE 8.21. Schematic representation of the semi-conservative mode of D N A replication
FIGURE 8.22 Single-stranded DNA absorbs light more effectively than does double-helical DNA
Reaction catalyzed by D N A polymerase
FIGURE 8.23. Schematic illustration of D N A polymerization using the saw-tooth schematic
FIGURE 8.24 DNA polymerases catalyze the strand-elongation reaction in the 5'-to-3' direction
FIGURE 8.25. Schematic representation of D N A synthesis from R N A template in retroviruses
Reaction catalyzed by R N A polymerase
FIGURE 8.26. Ribbon structure of R N A polymerase
FIGURE 8.27. Schematic representation of the elongation of the R N A strand catalyzed by R N A polymerase using D N A as a template
FIGURE 8.28. Sequences of m R N A strand, template D N A strand, and coding D N A strand

FIGURE 8.29. Schematic representation of the prokaryotic and eukaryotic promoter sites
FIGURE 8.30. Stem-loop structure at the 3 prime end of an E.coli m R N A transcript
FIGURE 8.31. Schematic representation of mRNA in eukaryotes modified after transcription
FIGURE 8.32. Structure of a t R N A molecule
FIGURE 8.33. The structure of amino acyl-t R N A
FIGURE 8.34. Graphical representation of arginine codon usage preference in different species
FIGURE 8.35. Schematic representation of the prokaryotic and eukaryotic start signals for protein synthesis
FIGURE 8.36. Schematic illustration of structure of the beta-globin gene
FIGURE 8.37. Schematic representation of the splicing of a beta-globin m R N A
FIGURE 8.38. Schematic representation of the location of splice sites in an m R N A
FIGURE 8.39 The tissue plasminogen activator (TPA) gene was generated by exon shuffling
FIGURE 8.40. Schematic illustration of membrane-bound and soluble antibody molecules generated by alternative splicing

Three-dimensional structure of Cas 9 endonuclease
Cleavage site of a restriction enzyme
Cleavages sites for five different restriction endonucleases
Photograph of electrophoresis gel slab with stained D N A fragments
Schematic illustration of the steps of southern blotting
Schematic illustration of the steps of chain-terminating D N A sequencing method

Chemical Structure of 2 prime, 3 prime-dideoxy analog
Stepwise illustration of the Phosphite triester method of oligonucleotide synthesis
Structure of a deoxyribonucleoside 3 prime phosphoramidite with D M T and beta C E attached
Schematic illustration of the steps of the first cycle of Polymerase Chain Reaction
Schematic illustration of multiple cycles of Polymerase Chain Reaction
Photograph of gel electrophoresis slab of P C R in a forensic case
Schematic illustration of cohesive-end method of D N A ligation
Schematic illustration of addition of cohesive ends to a D N A fragment
Schematic illustration of unique restriction sites in a polylinker sequence of a plasmid
Schematic illustration of the steps of insertional inactivation of genes for identification of colonies
Structure of an expression vector
Schematic illustration of the lytic and lysogenic pathways of infection in lambda phage
Steps of development of mutant lambda phage to be used as cloning vector
Oligonucleotide probe designed from a target sequence
Schematic illustration of the creation of genomic library from a whole genome digest
Schematic illustration of the screening of a genomic library for a specific gene
Schematic illustration of double-stranded c D N A preparation from m R N A using reverse transcriptase
Schematic illustration of the screening of colonies in a c D N A library that express a protein of interest
Schematic illustration of designing a bacteria to express proinsulin by infection with proinsulin c D N A
Schematic illustration of site-directed mutagenesis in P C R
Schematic illustration of cassette mutagenesis

Schematic illustration of the application of P C R to generate mutations
Mapped genome of Haemophilus influenzae
The set of human chromosomes with the location of genes associated with important biochemical pathways marked
Schematic illustration of pyrosequencing
Light generation during the pyrosequencing process
Chemical reactions catalyzed by apyrase
Different approaches used in next-generation sequencing methods
Comparison of human and mouse genomes
Graphs depicting results of a quantitative P C R
Schematic illustration of the steps of D N A microarray analysis
Heat map of a microarray analysis of tumors
Micrograph of a cloned plasmid D N A being injected into a fertilized mouse egg
Schematic illustration of foreign D N A insertion by homologous recombination
Consequences of myogenin knockout in mice
Schematic illustration of non-homologous end joining and homology directed repair of D N A
Recognition of individual bases in D N A by TALE repeats
Schematic illustration of the introduction of double-stranded break into D N A by Z F N or TALEN
Structure of single guide R N A
Schematic illustration of D N A cleavage by CRISPR-Cas system
Mechanism of R N A interference
Schematic illustration of the steps of introduction of foreign D N A into plant cell by electroporation
Electrophoresis gel slab
Banding pattern in southern, northern, and western blots
Four chromatograms of the alpha chain variants of hemoglobin
Map of hypothetical p SAP plasmid
A time versus temperature plot
Cleavage sites in a D N A segment
Electrophoresis gel slab

Sequencing chromatogram
Cleavage sites of K p n roman number 1 and A c c 6 5 roman number 1.
Microarray data
FIGURE 10.1 Homologs can be divided into two classes
FIGURE 10.2 The amino acid sequences of human hemoglobin (chain) and human myoglobin will be used to demonstrate sequence alignments
FIGURE 10.3 Amino acid sequences are compared by sliding one sequence past the other, one amino acid at a time
FIGURE 10.4 Scoring method
FIGURE 10.6 Comparison of alignment scores reveals the statistical significance of an unshuffled alignment
FIGURE 10.7 The Blosum-62 substitution matrix enables scoring based on amino acid similarity
FIGURE 10.8 Conservative and nonconservative substitutions yield very different scores in the Blosum-62 matrix
FIGURE 10.9 Counting conservative substitutions reveals strong similarity between α-hemoglobin and myoglobin
FIGURE 10.10 Alignment using Blosum-62 can uncover more distant evolutionary relationships
FIGURE 10.11 Alignment of human myoglobin and lupine leghemoglobin reveals many conservative substitutions
FIGURE 10.12 Related protein sequences can be rapidly identified using online BLAST searches
FIGURE 10.13 Three-dimensional structure is more conserved than primary structure
FIGURE 10.14 The structures of actin and a large fragment of heat shock protein 70 (Hsp70) reveal an unexpected relationship
FIGURE 10.15 Internal repeats can be identified using a self-alignment
FIGURE 10.16 Mammalian chymotrypsin and bacterial subtilisin are examples of convergent evolution
FIGURE 10.17 RNA sequence alignments provide insights into structure based on conservation of base-pairing. (A) A comparison of

sequences in a part of ribosomal RNA taken from a variety of species
Sequences of R N A fragments
Sequences of R N A fragments
Sequences of R N A fragments
Stem loop structure of R N A
FIGURE 10.18 Sequence alignments enable the construction of an evolutionary tree
FIGURE 10.21 Proteins encoded within the G. sulphuraria genome with high homology to prokaryotic sequences are suggestive of horizontal gene transfer
FIGURE 10.22 DNA sequence comparisons enable the placement of Neanderthals and Denisovans on an evolutionary tree
FIGURE 10.23 Evolution can be studied in the laboratory setting
FIGURE 10.24 A conserved secondary structure is common to RNA molecules selected for ATP binding
FIGURE 10.25 Experimental molecular evolution yields an ATP-binding RNA molecule
Evolutionary tree of similar genes
Sequence of two proteins
Sequence alignments
An evolutionary tree
Structures of dihydroxyacetone, D-glyceraldehyde, and L-Glyceraldehyde
Classification of isomers
Molecular structures of common monosaccharides
Formation of hemiacetal from aldehyde and alcohol
Chemical structure of pyran
Formation of alpha-D-Glucopyranose and beta-D-Glucopyranose from D-Glucose
Formation of hemiketal from ketone and alcohol
Chemical structure of furan
Formation of alpha-D-Fructofuranose from D-Fructose
Four distinct ring structures adopted by D-fructose in solution
The ring structures of common monosaccharides
Structure of the chair and boat forms of beta-D-glucopyranose

Chair form of beta-D glucopyranose with steric hinderance
Structures of C-3 endo and C-2 endo forms of a puckered furanose ring
Oxidation of glucose
Chemical structures of alpha-D-Methylglucopyranose and adenosine monophosphate
Chemical structures of beta-L-Fucopyranose, beta-D-Acetylgalactosamine, beta-D-Acetylglucosamine, and sialic acid
Chemical structures of glucose 6-phosphate (G-6 P), dihydroxyacetone phosphate (D H A P), glyceraldehyde 3-phosphate (G A P)
Chemical structure of maltose
Chemical structures of sucrose, alpha-Lactose, and alpha-maltose
Chemical structures of acarbose (Precose) and miglitol (Glyset)
Chemical structure of glycogen
Straight chain of cellulose and bent structure of starch and glycogen
Chemical structure of galacturonic acid
Chemical structure of chitin repeating unit
Chemical structures of N-linked G l c N A c and O-linked G a l N A c
Schematic illustrations of N-linked oligosaccharides
Schematic illustration of erythropoietin with oligosaccharides linked to amino acid residues
Structure of beta-D-acetylglucosamine
Structures of chondroitin 6-sulfate, keratan sulfate, heparin, dermatan sulfate, and hyaluronate
An electron micrograph and schematic representation of proteoglycan
Schematic illustrations depict the mucoprotein and an oligosaccharide bound to the V N T R region of the protein
Structure of dolichol phosphate
Chemical structure of isoprene
Schematic illustration of protein sorting in the Golgi complex
Glycosyltransferase reaction
Schematic illustration of the structures of O antigen, A antigen, and B-antigen

Ribbon diagram of cholera toxin bound to O antigens depicted as ball-and-stick models
Stepwise formation of mannose 6-phosphate residue
Mass spectrums for the characterization of oligosaccharides
Ribbon diagram and ball and stick model depict the calcium ion mediated binding of C-type lectin to carbohydrates
Schematic illustrations depict the entry and exit of influenza virus from host cell
Chemical structures of beta L-Galactopyranose and beta L-Glucopyranose
Chemical structures of D-Erythrose, D-Ribose, D-Glyceraldehyde, Dihydroxyacetone, D-Erythrulose, D-Ribulose, and D-Fructose
Chemical structure of raffinose
Graphical representation of G A G concentration versus time in days
Space-filling model of sphingomyelin and scanning electron micrograph of the myelin sheath
Chemical structures of palmitate and oleate
Numbering of carbon atoms in a fatty acid chain
Structure of linolenate
Schematic representation of a phospholipid molecule
Chemical structure of phosphatidate
Chemical structures of common phosphoglycerides located in the membrane
Structures of serine, ethanolamine, choline, glycerol, and inositol
Structures of sphingosine and sphingomyelin
Chemical structure of cerebroside
Chemical structure of cholesterol
Structure of membrane lipid of the archaeon Methanococcus jannaschii
Space filling models of phosphoglyceride, sphingomyelin, and an archaeal lipid; and shorthand depiction of membrane lipid labeled (A) and (B) respectively
Schematic illustration of micelles
Schematic illustration of lipid bilayer
Schematic illustration of liposome

Production of liposomes containing glycine
Experimental study of the properties of planar bilayer membranes
The permeability coefficients (P) of ions and molecules in a lipid bilayer
Schematic illustration of the wrapping of Schwann cell membrane around an axon and an electron micrograph of myelin sheath around the axon
S D S gel patterns of membrane proteins from different cell types
Membrane proteins interact with lipid bilayers in different ways
Schematic illustration of the view of bacteriorhodopsin through the membrane and cytoplasmic side
Amino acid sequence of the membrane spanning helices of bacteriorhodopsin
Schematic illustration of the side view and periplasmic view of porin protein from Rhodopseudomonas blastica
Secondary structure of porin protein from Rhodopseudomonas blastica
Ribbon structure of prostaglandin H 2 synthase-1 attached to the membrane surface
Step-wise formation of prostaglandin H 2 from arachidonate
Ribbon structure of prostaglandin H 2 synthase-1 containing a hydrophobic channel
Acetyl group transfer to serine residue of prostaglandin H 2 synthase 1 by aspirin
Structures of S-Palmitoyl cysteine, C-terminal S-farnesyl cysteine methyl ester, and Glycosylphosphatidylinositol (G P I) anchor
Hydropathy plot for glycophorin A and the amino acid sequence and disposition of glycophorin A
Hydropathy plot for porin
Schematic representation of fluorescence bleaching and recovery and a graphical representation of fluorescence intensity versus time
Schematic illustration of lateral and transverse diffusion in lipid bilayer
Graph showing the melting temperature of a phospholipid membrane
Space-filling models labeled (A) and (B)

Schematic illustration of cholesterol inserted in lipid bilayer
Lipid raft and human monocytic cell stained with a fluorescent dye
Transport of ions by N a superscript plus-K superscript plus transport system in the lipid bilayer
Structure of the plasma membrane of gram positive and gram negative bacteria and their photomicrographs
Schematic illustration of nuclear and surrounding E R
Schematic representation and photomicrographs of the steps of receptor-mediated endocytosis
Fusion of vesicles to the plasma membrane to release neurotransmitter
Schematic illustration of receptor-mediated endocytosis of transferrin receptor and iron
Schematic illustration of the initiation of membrane fusion
Chemical structure of a fatty acid
Chemical structure of platelet-activating factor (P A F)
Different ways in which membrane proteins interact with lipid bilayers
Hydropathy plots of different proteins A, B, and C
Graphical representation of the fluidity of fatty acids in a phospholipid bilayer as a function of temperature
Bar graphs depict the effect of ibuprofen and indomethacin on prostaglandin H 2 synthesis
Two graphs depict the variation of free energy as a function of concentration ratio and membrane potential respectively
Chemical structure of phoshorylaspartate
Schematic representation of a conformational change of pump proteins during transport of a molecule
Schematic structure of S E R C A P-type A T P ase and the ball-and-stick model of amino acid residues in the transmembrane domain bound to calcium
Conformational change in the structure of S E R C A P-type A T P ase
Conformational change of S E R C A during a catalytic cycle
Chemical structure of digoxin and chemical reaction inhibited by cardiotonic steroids

Schematic structure of multidrug-resistance protein and bacterial lipid transport protein
Open and closed forms of bacterial lipid transporter M s b A
Mechanism of transport of molecules by A B C transporters
Schematic representation of antiporter, symporter, and uniporter
Side view and bottom view of E.coli lactose permease
Mechanism of transport of lactose by lactose permease
Graphical representation of action potential
Patch-clamp technique
Result of patch-clamp experiment
Sructure of Tetrodotoxin
Structural features of sodium and calcium channels, shaker potassium channel, and bacterial potassium channel
Different views of the bacterial potassium ion channel
Space-filling model of a potassium ion channel
Selectivity filter of potassium ion channel
Desolvation and resolvation energy of potassium and sodium ions
Calcium channel and sodium channel
Model of K superscript plus channel ion transport
View through the pore and side view of the voltage-gated potassium channel
Closed and open voltage-gated potassium channel
Graph of membrane current versus time after depolarization
Mechanism of channel inactivation
Structure of acetylcholine
Schematic representation of synapse
Model of acetylcholine receptor and a view of the receptor from outside the cell
Opening of the acetylcholine receptor due to ligand binding
Schematic representation of equilibrium potential
Graphs for membrane potential and current flow and schematic representation of the states of ion channels during an action potential
Graph depicts the percentage of activated H C N 4 channels as function of potential
Structure and orientation of connexon

Side and bottom view of aquaporin
Electrophysiological recordings of cells
Graphs depicting membrane potential in the presence or absence of a drug or compound
A graph and a photograph
Generalized signal-transduction pathway
Chemical structure of different secondary messengers
Physiological outcomes of different signal transduction pathways
Chemical structure of epinephrine
Schematic representation of 7 T M helix receptor
Schematic representation of the side view and top view of the beta-2 adrenergic receptor
Stabilization of the active conformation of beta-adrenergic receptor
Signaling pathway initiated by epinephrine
Ribbon diagram and schematic representation of the G protein subunits
Beta-2 A R bound to G protein and G D P and receptor bound forms of alpha subunit
Schematic representation of adenylate cyclase and ribbon diagram of adenylate cyclase bound to G subscript alpha S subunit
Flowchart shows events leading to cardiac muscle contraction
G protein resetting
Termination of beta-adrenergic receptor signaling
Cleavage of phosphatidylinositol 4,5-bisphosphate
Protein kinase C activation
Ball-and-stick model of calcium ion bound to oxygen atoms
Structure of Fura-2
Fluorescence spectra of Fura-2 and photographs of calcium ions spreading across an egg cell
E F hand motif
Conformational change in the apo form of calmodulin and its binding to protein kinase
Flow chart show events leading to smooth muscle contraction
Signal transduction by G protein beta gamma dimer

Generalized signaling pathway involving the three classes of G protein alpha subunits
Structure of adenosine
Chemical structure of caffeine
Graphical representation of glucose and insulin levels post meal
Insulin ribbon structure
Insulin receptor
Chemical reaction catalyzed by tyrosine kinase
Unactivated form of insulin receptor kinase
Conformational change in insulin receptor
Activation of insulin receptor
Schematic representation of the common amino acid sequence in I R S-1 and I R S-2
Formation of phosphatidyl 3,4,5-trisphosphate
Insulin signaling pathway
Ribbon diagram of the inactive conformation of P D K 1 and comparison of the activation loops of inactive and active forms
Insulin signaling pathway
Ribbon diagram of epidermal growth factor
Extracellular domain of the E G F receptor and its dimerization upon E G F binding
E G F receptor signaling
E G F signaling pathway
E G F receptor bound to cetuximab
Photomicrographs show the panel of breast cancer cells expressing normal and high levels of H E R 2
Formation of b c r- a b l gene
Ribbon structure of A b l kinase bound to imatinib
Structures of benzaldehyde, 3-methylbutane-1-thiol, geraniol, zingiberene, R-Carvone, and S-Carvone
Olfactory signal-transduction cascade
The structures of four sets of closely related compounds
Distinct patterns of olfactory-receptor activation
Electromagnetic spectrum

Structures of 11-cis-Retinal and 11-cis-Retinal connected to lysine through Schiff base
Scanning electron micrograph and schematic representation of retinal rod cells
Graphical representation of light absorption by rhodopsin
Isomerization of 11-cis-retinal in presence of light
Visual signal transduction
Absorption spectra of different light receptors from human cone cells
Scanning electron micrograph of stereocilia bundle on hair cells
Micrograph of tips of two stereocilia
Hair cell signal detection
Phylogenetic tree
Photograph shows several fruits and vegetables
Flow Chart for the cleavage of membrane lipid
Structure of A T P
Percentage of binding capacity of the receptor as a function of hormone concentration
Stimulation of adenylate cyclase as a percentage of maximum hormone concentration
Distinct patterns of olfactory-receptor activation
Flow chart depicting the transformation of glucose to pyruvate
Node diagram depicting metabolic pathways are interconnected series of enzyme-catalyzed reactions
Chemical reactions and their respective standard free energy changes
Structures of A T P, A D P, and A M P
A T P hydrolysis and standard free energy changes
Reversible reactions catalyzed by nucleoside monophosphate kinase and nucleoside diphosphate kinase
Reaction with its standard free energy change
Standard free energy changes of A T P and glycerol-3-phosphate hydrolysis
Structure of Glycerol 3-phosphate
Four resonance structures of orthophosphate separated by two-way arrows

Graphical representation of the compounds with high phosphoryl-transfer potential that can be used to make A T P from A D P
Structure of creatine phosphate
Structure of creatine
Graphical representation of the sources of A T P change as exercise duration increases
A T P and A D P cycle
Free energy of oxidation of single-carbon compounds increases with the degree of hydrogen saturation from most energy on the left to least energy on the right
Structures of glucose and saturated fatty acids
Reaction for oxidation of glyceraldehyde 3-phosphate to 3-Phosphoglyceric acid
Reaction for the formation of 1,3-Bisphosphoglycerate
Reaction for the formation of 3-phosphoglyceric acid
Proton gradients formed in the biological membrane using energy from either sunlight or chemical oxidation can power A T P synthesis
Three stages of extraction of energy from food to form A T P in aerobic organisms
Reaction for the formation of N A D H
Structure of oxidized forms of N A D superscript plus and N A D P superscript plus
Reaction for the formation of F A D H 2
Structure of flavin adenine dinucleotide
Reaction for the formation of reduced form (F A D H 2) from oxidized form (F A D)
Reaction for the biosynthesis of fatty acids
Structure of Acyl C o A and Acetyl C o A
Structure of coenzyme A
Reversible reaction depicts the formation of acetate from acetyl C o A and its standard free energy change
Structures of oxygen esters and thioesters
Structures of water-soluble B vitamins
Formation of Fumarate from Succinate
Formation of oxaloacetate from malate

Formation of glucose 6-phosphate and A D P
Hydrolytic reaction
Formation of Glyceraldehyde 3-phosphate from Fructose 1, 6-Bisphosphate
Formation of Phosphoenolpyruvate (P E P) from 2-Phosphoglycerate
Equilibrium reaction depicts the formation of isocitrate from citrate
Equilibrium reaction depicts the formation of oxaloacetate from pyruvate
Graphical representation of energy charge versus relative rate of A T P synthesis
Structure of Arginine phosphate
Reaction catalyzed by aldolase
Structures of Ethanol and Acetaldehyde
Structures of Lactate and Pyruvate
Structure of Succinate and Fumarate
Structure of Oxalosuccinate and Isocitrate
Structure of Malate and Oxaloacetate
Graphical representation of delta G for the hydrolysis of A T P varies as a function of the M g superscript 2 plus concentration
Schematic illustration of sources of A T P for muscle contraction
Schematic representation of glucose metabolism
Two stages of glycolytic pathway
Stage 1 of glycolytic pathway
Reversible conversion of glucose to glucose 6-phosphate
Conformational change in hexokinase upon glucose binding
Conversion of glucose 6-phosphate to fructose 6-phosphate
Reversible conversion of fructose 6-phosphate to fructose 1, 6-bisphosphate
Reversible conversion of fructose 1, 6-bisphosphate to dihydroxyacetone phosphate and glyceraldehyde 3-phosphate
Reversible conversion of dihydroxyacetone phosphate to glyceraldehyde 3-phosphate
Ribbon diagram of triose phosphate isomerase
Catalytic mechanism of triose phosphate isomerase
Conversion of enediol intermediate into methyl glyoxal

Stage 2 of glycolytic pathway
Reversible conversion of glyceraldehyde 3-phosphate to 1,3-bisphosphoglycerate
Chemical reactions depict the oxidation of an aldehyde and formation of acyl-phosphate production
Graphs depicting free energy profiles
Ribbon diagram of G A P D H
Catalytic mechanism of G A P D H
Chemical reaction shows the conversion of 1,3-bisphosphoglycerate to 3-phosphoglycerate
Conversion of 3-phosphoglycerate to pyruvate
Transfer of phosphoryl group from histidine residues of an enzyme to 3-phosphoglycerate
Removal of phosphoryl group from 2,3-bisphosphoglycerate
Conversion of phosphoenolpyruvate to pyruvate
Step 6 of glycolysis
Different fates of pyruvate molecule
Conversion of pyruvate to ethanol
Ball-and-stick model of zinc ion in the alcohol dehydrogenase active site and its binding partners
Reoxidation of N A D H
Chemical reaction shows the conversion of pyruvate to lactate
Regeneration of N A D superscript plus during lactic acid fermentation
Entry of additional sugars in the glycolytic pathway
Entry of fructose into the glycolytic pathway in the liver
Irreversible conversion of galactose to galactose 1-phosphate
Formation of U D P-glucose from galactose 1-phosphate and U D P-glucose
Chemical reaction shows the conversion of galactose to galactitol
Photographs comparing healthy eye and cataract affected eye
Breakdown of lactose into galactose and glucose
Ribbon diagram of E.coli phosphofructokinase
Graphical representation of the inhibition of phosphofructokinase activity

Flowcharts depict glycolysis regulation
Chemical structure of fructose 2, 6-bisphosphate and flow chart depicting allosteric activation of phosphofructokinase
Structure of fructose 2, 6-bisphosphate
Graphs depict fructose 1, 6-bisphosphate synthesis with respect to fructose 6-phosphate concentration
Regulation of pyruvate kinase activity
Pretherapy and post therapy PET scans
Hypoxia-induced gene expression alteration in tumors
Gluconeogenesis pathway
Formation of dihydroxyacetone phosphate from glycerol
Formation of oxaloacetate from pyruvate
Structures of biotin and carboxybiotin covalently bound to the epsilon-amino group of a lysine
First stage of pyruvate carboxylation
Final stage of pyruvate carboxylation
Ribbon diagrams of pyruvate carboxylase subunits
Formation of phosphoenolpyruvate from oxaloacetate
Transport of malate produced in the mitochondrial matrix to the cytoplasm and its conversion to oxaloacetate
Formation of free glucose in E R lumen
Step 6 of gluconeogenesis
Reciprocal regulation of glycolysis and gluconeogenesis
Schematic representation and ribbon diagram of the domains of P F K 2 slash F B P ase 2
Hormonal regulation of synthesis and degradation of fructose 2, 6-bisphosphate
Different rates of operation of a A T P-driven cycle
Cori cycle
Cooperation between glycolysis and gluconeogenesis during a sprint
Structure of methylglyoxal
Activity of P F K and F B P ase in different bumblebee species
Schematic representation of the citric acid cycle
Structure of acetyl coenzyme A or acetyl C o A
Electron micrograph and schematic illustration of a mitochondrion

Citric acid cycle
Citric acid cycle and oxidative phosphorylation in a mitochondrion
Connection between glycolysis and citric acid cycle
Structure of thiamine pyrophosphate (T P P) and lipoic acid
Stepwise conversion pyruvate to acetyl C o A
Formation of hydroxyethyl-T P P
Mechanism of E 1 decarboxylation reaction
Oxidation of hydroxyethyl-T P P
Formation of acetyl C o A
Regeneration of oxidized lipoamide
Structure of lipoamide
Photograph of bacterial pyruvate dehydrogenase complex
Ribbon diagram of a subunit of the transacetylase trimer
Activity of pyruvate dehydrogenase complex
Formation of citrate from oxaloacetate
Space filling model shows the binding of oxaloacetate to citrate synthesis
Citrate synthase mechanism
Conversion of citrate to isocitrate
Ribbon diagram of citrate synthase and ball-and-stick model of its iron-sulfur cluster connected to citrate and side chains of amino acids
Conversion of isocitrate to alpha-ketoglutarate
Oxidative decarboxylation of alpha-ketoglutarate
Conversion of succinyl C o A into succinate
Mechanism of action of succinyl C o A synthetase
Sequential reaction showing conversion of succinate to oxaloacetate
Conversion of fumarate into L-malate
Citric acid cycle
Conversion of glucose to C O 2 and fatty acids
Regulation of pyruvate dehydrogenase complex activity
Response of pyruvate dehydrogenase complex to changes in the energy of the cell
Regulation of citric acid cycle
Fates of the intermediates of citric acid cycle

Inhibition of pyruvate dehydrogenase by arsenite and its reversal by 2,3-dimercaptopropanol
Glyoxylate cycle
Structure of 2-vinyl-isocitrate
Structure of homopyruvoyl-modified isocitrate lyase
Structure of malonate
Structure of oxaloacetate
Colony-forming units in mice lungs in the weeks after an infection
Colony-forming units in mice lungs in the weeks after an infection
Schematic representation of proton flow across A T P synthase
Oxidative phosphorylation
FIGURE 18.2 Mitochondria (A) An electron micrograph and (B) a diagram
FIGURE 18.3 Redox potential can be precisely measured
FIGURE 18.4 Components of the electron-transport chain
FIGURE 18.5 Quinones can have three different oxidation states, two of which are stable
FIGURE 18.6. The three-dimensional structure of cytochrome c is remarkably conserved among distantly related species
FIGURE 18.7 Three different types of iron–sulfur clusters are commonly found in biological systems
FIGURE 18.8 Flavins have two oxidation states
FIGURE 18.9 Electron transfer through NADH-Q oxidoreductase is coupled to proton transfer reactions
Structure of reduced ubiquinone
FIGURE 18.10 Q-cytochrome c oxidoreductase is a homodimer, with each monomer consisting of 11 distinct polypeptide chains
FIGURE 18.11 The Q cycle allows the safe transfer of electrons from Q H 2 to cytochrome c
Chemical structure of copper ion bonded to histidine residue covalently linked to a tyrosine residue
FIGURE 18.12 The structure of bovine cytochrome c oxidase reveals 13 polypeptide chains and numerous electron carriers
Structure of heme A

FIGURE 18.13 The mechanism of cytochrome c oxidase prevents early oxygen release
FIGURE 18.14 Two metals form a peroxide bridge in cytochrome c oxidase
FIGURE 18.15 Proton transport by cytochrome c oxidase has two components
FIGURE 18.16 Electrons flow via two pathways through the electron-transport chain
FIGURE 18.17 Three complexes of the ETC associate to form the respirasome
Conversion of superoxide radical by enzyme superoxide dismutase
FIGURE 18.18 The superoxide dismutase mechanism has two phases
FIGURE 18.19 Proteins dramatically improve the rate of electron transfer
FIGURE 18.20 The chemiosmotic hypothesis states that electron-driven proton transport and ATP synthesis are coupled
FIGURE 18.21 The chemiosmotic hypothesis is supported by experiments using bacterial proton pumps
FIGURE 18.22 The structure of ATP synthase reveals a complex molecular rotational motor
FIGURE 18.23 Mitochondrial ATP synthase forms homodimers
FIGURE 18.24 ATP synthase assists in the formation of cristae
FIGURE 18.25 ATP-synthesis is catalyzed by ATP synthase
FIGURE 18.26 ATP forms without a proton-motive force but is not released
FIGURE 18.27 ATP synthase nucleotide-binding sites cycle through distinct conformational states
FIGURE 18.28 The binding-change mechanism involves the cycling of all three β subunits through three conformations
FIGURE 18.29 The ATP-driven rotation in ATP synthase has been directly observed
FIGURE 18.30 Components of the proton-conducting unit of ATP synthase include two half channels and a critical charged residue
FIGURE 18.31 Proton motion across the membrane drives rotation of the c ring

FIGURE 18.32 Protons must travel around the c ring to cross the membrane
FIGURE 18.33 An overview of oxidative phosphorylation shows the spatial relationship of the components
FIGURE 18.34 The glycerol 3-phosphate shuttle allows for rapid rates of oxidative phosphorylation at the cost of energetic efficiency
FIGURE 18.35 The malate–aspartate shuttle preserves all the chemical potential energy of cytoplasmically generated NADH
FIGURE 18.36 The ATP-ADP translocase catalyzes the exchange of entry of ADP and ATP
FIGURE 18.37 Structurally homologous mitochondrial transporters
FIGURE 18.38 ATP synthase depends upon the rest of the ATP synthesome, as well as the ETC and CAC
FIGURE 18.39 Mechanism of heat generation by U C P-1
FIGURE 18.40 P E T scan results of the uptake and distribution of F superscript 18-fluorodeoxyglucose in adipose tissue
FIGURE 18.41 Inhibitors of the electron transport chain
FIGURE 18.43 The flagellar motor is a complex structure containing as many as 40 distinct types of proteins
FIGURE 18.44 Rotation of the flagellum involves proton half-channels like ATP synthase
FIGURE 18.45 Proton gradient as an interconvertible form of free energy
Absorption spectra of the reduced and oxidized forms of cytochrome c
Results of an experiment using the X F technology
Phototrophic halobacteria are visible from the air in salt ponds near the San Francisco Bay and a schematic shows electron excitation and its transfer to acceptor
FIGURE 19.1 Phototrophy can be accomplished by the cooperation of just two proteins
FIGURE 19.2 The light reactions of oxygenic photosynthesis generate both A T P and reducing power
FIGURE 19.3 The anatomy of a chloroplast reveals complex membrane-enclosed structures

FIGURE 19.5: Structure of Chlorophyll alpha
FIGURE 19.6 Chlorophyll a has a distinct absorbance spectrum in the visible range
FIGURE 19.7 The absorption of light leads to the excitation of an electron from its ground state to a higher energy level
FIGURE 19.8 The key to photosynthesis is photoinduced charge separation
FIGURE 19.9 The photosynthetic reaction center in a nonsulfur purple bacterium is a large complex with many electron-carrying groups and one special pair
FIGURE 19.10 In the reaction center of nonsulfur purple bacteria, electrons flow from the special pair to a quinone
FIGURE 19.11 Cyclic electron flow in the bacterial reaction center allows the generation of A T P but not reducing power
FIGURE 19.12 In green plants, electrons can flow through two photosystems
Structures of Plastoquinone and Plastoquinol
FIGURE 19.13 Photosystem II is a large membrane protein complex with many chlorophyll molecules, one special pair, and the water-oxidizing complex
FIGURE 19.14 In photosystem II, electrons flow from manganese atoms to plastoquinone
FIGURE 19.15 The core of the water-oxidizing complex includes four manganese ions and one calcium ion
FIGURE 19.16 Four photons are required to generate one oxygen molecule after the first cycle
FIGURE 19.17 The model for the water-oxidizing complex explains the light-flash experiments
FIGURE 19.18 Photosystem II releases protons into the thylakoid lumen and takes them up from the stroma
FIGURE 19.19 Electron flow through cytochrome bf contributes to the proton gradient
FIGURE 19.20 Photosystem I is a protein complex with numerous chlorophyll molecules and one special pair.
FIGURE 19.21 In photosystem I, electrons flow to ferredoxin

FIGURE 19.22 Ferredoxin is an electron-carrying, iron-sulfur protein
FIGURE 19.23 Ferredoxin–N A D P + reductase transfers electrons from the protein ferredoxin to N A D P +
FIGURE 19.24 The “Z” scheme of photosynthesis is the linear path of electrons from H 2 O to N A D P +
FIGURE 19.25 Photosynthesis and oxidative phosphorylation have a similar layout but differ in a number of ways
Reversible reaction catalyzed by ferredoxin-thioredoxin reductase
FIGURE 19.26 Cyclic photophosphorylation allows A T P production without a need for an electron source
Structure of chlorophyll b
FIGURE 19.27 Chlorophylls a and b absorb light maximally at different wavelengths
Structure of Lycopene and beta carotene
FIGURE 19.28 Resonance energy transfer allows electrons to transfer energy over a distance
FIGURE 19.29 Energy is transferred from accessory pigments to reaction centers
FIGURE 19.30 Photosynthetic assemblies are differentially distributed in the stacked and unstacked regions of thylakoid membranes
FIGURE 19.31 Photovoltaic cells can drive artificial photosynthesis
FIGURE 19.32 Optogenetics allows neurons to be controlled using light
Graph depicts atmospheric C O 2 measured at Mauna Loa, Hawaii
FIGURE 20.1 The Calvin–Benson cycle consists of three stages
Sequential conversion of ribulose 1,5-bisphosphate to 3-phosphoglycerate
FIGURE 20.2 The enzyme ribulose 1,5-bisphosphate carboxylase slash oxygenase (Rubisco) comprises 16 subunits
Formation of carbamate from the lysine side chain and its binding to a magnesium ion
FIGURE 20.3 C O 2 fixation by magnesium-coordinated ribulose 1,5-bisphosphate
FIGURE 20.4 In stage 1 of the Calvin–Benson cycle, 3-phosphoglycerate is formed

FIGURE 20.5 The enediolate on Rubisco can react with oxygen in a wasteful side reaction
FIGURE 20.6 Photorespiration consumes O 2 and produces C O 2
FIGURE 20.8 In stage 2 of the Calvin–Benson cycle, hexose phosphate is formed
Aldose and ketose formation
Ketose formation
FIGURE 20.9 Five-carbon sugars are formed from six-carbon and three-carbon sugars
FIGURE 20.10 In stage 3 of the Calvin–Benson cycle, ribulose 1,5-bisphosphate is regenerated
FIGURE 20.11 The full Calvin–Benson cycle process for converting three molecules of C O 2 to dihydroxyacetone phosphate is complex
FIGURE 20.12 Carbohydrates are stored as sucrose
Conversion of crotonyl-C o A to ethylmalonyl-C o A and butyryl-C o A
FIGURE 20.13 Scientists have engineered artificial photosynthesis using alternative C O 2 fixation pathways
FIGURE 20.14 Light regulates the Calvin–Benson cycle
FIGURE 20.16 Thioredoxin can activate enzymes by reducing them
FIGURE 20.17 The C 4 pathway can concentrate C O 2
FIGURE 20.21 The pentose phosphate pathway consists of an oxidative and a nonoxidative phase
FIGURE 20.22 The oxidative phase of the pentose phosphate pathway yields two molecules of NADPH
Formation of ribose 5-phosphate
Reactions catalyzed by transketolase
Reaction catalyzed by transketolase
Formation of xylulose 5-phosphate
Reaction catalyzed by transaldolase
Reaction catalyzed by transketolase
FIGURE 20.23 The transketolase reaction takes place on thiamine pyrophosphate
FIGURE 20.24 The transaldolase reaction involves a Schiff base intermediate

FIGURE 20.25 For transketolase and transaldolase, a carbanion intermediate is stabilized by resonance
FIGURE 20.26 The pentose phosphate pathway can operate in four modes
Structure of reduced glutathione
Structure of pamaquine
Structure of primaquine
FIGURE 20.27 Fava beans produce a pyrimidine glycoside
Conversion of oxidized glutathione to reduced glutathione catalyzed by glutathione reductase
FIGURE 21.3 The fundamental structure of glycogen is a linear polymer with occasional branches
FIGURE 21.4 Glucose 6-phosphate can have many metabolic fates
Cleavage of glucose 1-phosphate residue from glycogen with n residues
FIGURE 21.5 Glycogen phosphorylase forms a homodimer with a pyridoxal phosphate (P L P) group in each active site
FIGURE 21.6 P L P forms a Schiff-base linkage with lysine
FIGURE 21.7 The mechanism of phosphorylase involves P L P and the formation of a carbocation
FIGURE 21.8 Glycogen remodeling requires three distinct catalytic activities
Action of alpha-1, 6-glucosidase
FIGURE 21.9 Phosphoglucomutase transfers a phosphoryl group to the substrate
FIGURE 21.10 Phosphorylase exists in two distinct quaternary states
FIGURE 21.11 Phosphorylase is regulated by phosphorylation
FIGURE 21.12 Liver phosphorylase is allosterically inhibited by glucose
FIGURE 21.13 Muscle phosphorylase is allosterically regulated by A T P, A M P, and glucose 6-phosphate
Amino acid sequence of glucagon
Structure of epinephrine
FIGURE 21.14 Phosphorylase kinase is activated by calcium ions and hormonally controlled phosphorylation

FIGURE 21.15 Glycogen breakdown is controlled by the combined effects of multiple hormones in a tissue specific manner
FIGURE 21.16 Glycogen degradation is stimulated by hormone binding to 7 T M receptors
Structure of uridine diphosphate glucose (U D P-glucose)
Formation of U D P-glucose from glucose 1-phosphate and U T P
Synthesis of U D P-glucose and the hydrolysis of pyrophosphate and the resulting reaction
Elongation of glycogen molecule by 1 glucose residue
FIGURE 21.17 Action of a branching enzyme
FIGURE 21.18 A cross section of a glycogen molecule reveals the basic branching structure
FIGURE 21.19 Glycogen metabolism is regulated in part by hormone-triggered cyclic A M P cascades
FIGURE 21.20 Glycogen synthesis is regulated by protein phosphatase 1 (P P 1)
FIGURE 21.21 P P 1 is regulated by hormonally controlled cascades
FIGURE 21.22 Insulin inactivates glycogen synthase kinase
FIGURE 21.23 Blood glucose regulates liver-glycogen metabolism
FIGURE 21.24 Glucose regulates liver-glycogen metabolism
FIGURE 21.25 An electron micrograph of a muscle cell from a patient with Pompe disease reveals enlarged lysosomes
Western blot photograph shows the separation of samples of glycogen
Western blot photograph shows the separation of samples of glycogen isolated from a cell line
Synthesis and degradation of fatty acids
Structure of triacylglycerol
FIGURE 22.2 Breakdown of triacylglycerol into monoacylglycerol and fatty acids by lipase
Structure of glycocholate
FIGURE 22.4 Fat absorption and transport is a complex process involving multiple proteins
Hydrolyzation of triacylglycerol to yield glycerol and isolated fatty acids

FIGURE 22.5 Triacylglycerols in adipose tissue are converted into free fatty acids in response to hormonal signals
FIGURE 22.6 Lipolysis generates fatty acids and glycerol
Stepwise conversion of glycerol to D-Glyceraldehyde 3-phosphate
Thioester linkage formation between fatty acid and coenzyme A
Structure of acyl adenylate
Conversion of fatty acid to acyl adenylate and acyl adenylate to acyl C o A
Formation of acyl carnitine from acyl C o A and carnitine
FIGURE 22.7 Acyl carnitine translocase mediates the entry of acyl carnitine into the mitochondrial matrix
FIGURE 22.8 The reaction sequence for the degradation of fatty acids has four sequential steps
Sequential transfer of electrons from substrate to ubiquinone
FIGURE 22.9 Each round of fatty acid degradation removes two carbons
FIGURE 22.10 The degradation of a monounsaturated fatty acid involves an additional enzymatic step
FIGURE 22.11 Multiple additional enzymes are necessary to oxidize polyunsaturated fatty acids
FIGURE 22.12 The final product of odd-numbered fatty acid degradation is converted into a C A C intermediate
FIGURE 22.13 Coenzyme B 12 (cobalamin) is a class of molecules with a complex structure
FIGURE 22.14 Cobalamin enzymes catalyze specific rearrangement reactions
FIGURE 22.15 Cobalamin enzymes accomplish homolytic bond cleavage to form a radical
FIGURE 22.16 Succinyl C o A is formed from methylmalonyl C o A by a rearrangement reaction
FIGURE 22.17 The active site of methylmalonyl C o A mutase reveals how radical formation is accomplished
FIGURE 22.18 Initiation of peroxisomal fatty acid degradation requires a flavoprotein

FIGURE 22.19 Ketone bodies are formed from acetyl C o A primarily in the liver
FIGURE 22.20 Pathway Integration: The liver supplies ketone bodies to the peripheral tissues
FIGURE 22.21 Acetoacetate can be used as a fuel to drive A T P formation
Formation of acetoacetate from D-3-hydroxybutyrate
FIGURE 22.22 Diabetic ketosis results when insulin signaling is impaired
FIGURE 22.23 The steps in fatty acid degradation and synthesis are chemically similar
FIGURE 22.24 Phosphopantetheine group in acyl carrier protein and coenzyme A
FIGURE 22.25 Like beta-oxidation, saturated fatty acid synthesis consists of four steps
FIGURE 22.26 Mammalian fatty acid synthase is a large, dimeric, multidomain protein complex
FIGURE 22.27 One catalytic cycle of mammalian fatty acid synthase consists of seven steps
FIGURE 22.28 Acetyl C o A can be transferred from the mitochondrial matrix to the cytoplasm
FIGURE 22.29 Pathway Integration: Fatty acid synthesis requires the cooperation of various pathways in different cellular compartments
FIGURE 22.30 Desaturation of fatty acids by an electron transport chain in the E R membrane
FIGURE 22.31 Several eicosanoid hormones are produced from arachidonate by distinct enzymatic pathways
FIGURE 22.32 Structures of different eicosanoids
FIGURE 22.33 Inhibition and activation of acetyl C o A carboxylase
FIGURE 22.35 The catalytic activity of acetyl C o A carboxylase depends upon the concentration of citrate
Acetyl C o A containing radioactive carbon and hydrogen atoms
Relationship between carnitine acyltransferase 1 activity and concentration of carnitine

Relationship between carnitine acyltransferase 1 activity and concentration of palmitoyl C o A
Relationship between carnitine acyltransferase 1 activity and concentration of malonyl C o A
Effect of various amounts of soraphen A on fatty acid synthesis
Effect of various amounts of soraphen A on fatty acid oxidation
Effect of various amounts of soraphen A on phospholipid synthesis
Effect of different concentrations of soraphen A on the viability of cancer cells
Schematic representation of the absorption of protein digestion products by a cell
FIGURE 23.1 The products of protein digestion are absorbed by the small intestine
FIGURE 23.2 Ubiquitin is a small, compact protein with seven lysines
Isopeptide bond between ubiquitin and the side chain of lysine residue of the target protein
FIGURE 23.3 Ubiquitin conjugation requires three enzymes
FIGURE 23.4 In a tetraubiquitin chain, four ubiquitin molecules are linked by isopeptide bonds
FIGURE 23.5 The 20 S proteasome is barrel-shaped and made up of 28 homologous subunits
FIGURE 23.6 The 26 S proteasome consists of one 20 S and two 19 S subunits
FIGURE 23.7 The proteasome and other proteases generate free amino acids
FIGURE 23.8 Proteasomes have become more complex in eukaryotes
Structure of bortezomib
Structure of H T 1171
Oxidative deamination in the liver
Transfer of the alpha-amino group from an alpha-amino acid to an alpha-ketoacid
Formation of alpha-ketoglutarate from glutamate
Conversion of an ammonium ion into urea in terrestrial vertebrates
Reversible conversion of P L P (phenol) to P L P (phenolate)
Formation of external aldimine from internal aldimine

FIGURE 23.9 Transaminations proceed through three steps to form P M P
Structure of pyridoxamine phosphate
FIGURE 23.10 The active site of aspartate aminotransferase reveals P L P bound to a lysine through a Schiff-base linkage
FIGURE 23.11 P L P enzymes labilize one of three bonds at the alpha-carbon atom of an amino acid substrate
FIGURE 23.12 Stereoelectronic effects determine specific bond cleavage
FIGURE 23.13 Bond orientation in the active site determines bond cleavage in different P L P enzymes
Deamination of serine
FIGURE 23.14 PATHWAY INTEGRATION: The glucose–alanine cycle allows muscle cells to use amino acids as fuel
FIGURE 23.15 The urea cycle eliminates both nitrogen and carbon waste products
Formation of carbamoyl phosphate from bicarbonate
Reaction catalyzed by N-acetylglutamate synthase
Reaction catalyzed by ornithine transcarbamoylase
Reaction catalyzed by argininosuccinate synthetase
Reaction catalyzed by argininosuccinase
Reaction catalyzed by arginase
FIGURE 23.16 Nitrogen metabolism is integrated with other pathways
FIGURE 23.17 Argininosuccinase deficiency can be managed by supplementing the diet with arginine
FIGURE 23.18 Both carbamoyl phosphate synthetase and ornithine transcarbamoylase deficiencies can be treated the same way
Structure of uric acid
FIGURE 23.19 The carbon skeletons of all 20 proteogenic amino acids enter central metabolism as just seven different molecules
FIGURE 23.20 Pyruvate is the metabolic entry point for the carbon skeletons from three-carbon amino acids
FIGURE 23.21 Four amino acids produce carbon skeletons that enter central metabolism as alpha-ketoglutarate
FIGURE 23.22 Stepwise conversion of histidine to glutamate

FIGURE 23.23 The degradation pathways for proline and arginine converge on a common intermediate
FIGURE 23.24 Succinyl C o A is formed from methionine, isoleucine, threonine, and valine
FIGURE 23.25 Methionine catabolism proceeds through the formation of S A M
Conversion of threonine to propionyl C o A
Conversion of leucine to isovaleryl C o A
Conversion of isovaleryl C o A to beta-methylglutaconyl C o A
Conversion of beta-methylglutaconyl C o A to acetyl C o A and acetoacetate
Reaction catalyzed by phenylalanine hydroxylase
Irreversible conversion of quinonoid dihydrobiopterin to tetrahydrobiopterin
FIGURE 23.26 Phenylalanine and tyrosine degradation produce both acetoacetate and fumarate
FIGURE 23.27 Tryptophan degradation requires multiple oxygenases and numerous steps
Structure of 2-methylbutyryl C o A
Structure of butyryl C o A
Beta-oxidation of 2-methylbutyryl C o A
Hydration and oxidation steps of beta-oxidation
Thiolysis of the product of the oxidation step of beta-oxidation
Conversion of homogentisate to a highly colored polymer
FIGURE 23.28 Urine has long been used to diagnose diseases due to the excretion of unusual biochemical products
Conversion of alpha-ketoacid to 2,4-dinitrophenylhydrazone derivative
Conversion of phenylalanine to phenylpyruvate

Variation of percentage of digestion of pentapeptide with minutes of incubation

Photograph of an event and schematic representation of integration of metabolic pathways for glucose homeostasis
Coordinated use of nutrient pools to maintain homeostasis
FIGURE 24.2 Signal molecules originating from the gut induce feelings of satiety in the brain
FIGURE 24.3 Leptin suppresses appetite by affecting the brain
FIGURE 24.4 Adipokines help to maintain systemic lipid and glucose homeostasis
FIGURE 24.5 Suppressors of cytokine signaling (S O C S) regulate insulin receptor function
FIGURE 24.6 Glycolysis and gluconeogenesis are reciprocally regulated
FIGURE 24.7 Insulin signaling activates A k t using the second messenger P I P 3
FIGURE 24.8 The storage capacity of fat tissue can be exceeded in obesity
FIGURE 24.9 Excess fat can disrupt signal-transduction pathways and lead to insulin insensitivity
FIGURE 24.10 Insulin release by the pancreas is regulated by blood-glucose concentration, using A T P as a second messenger
Irreversible reaction catalyzed by creatine kinase
FIGURE 24.11 Running velocity decreases dramatically as a function of the duration of the race
FIGURE 24.12 An idealized representation of fuel use and RQ illustrates major changes as a function of aerobic exercise intensity
FIGURE 24.13 Exercise results in mitochondrial biogenesis and enhanced fat metabolism
FIGURE 24.14 Biochemical adaptations to exercise vary over a range of time scales
FIGURE 24.15 The blood concentrations of ketone bodies glucose, and fatty acids during starvation
FIGURE 24.16 Fuel use during prolonged starvation changes after fat mass is depleted
FIGURE 24.17 Formation of 4-hydroxyproline requires ascorbate
Structure of ascorbic acid, ascorbate, and dehydroascorbic acid

Relation between blood-lactate levels, oxygen consumption, and heart rate during exercise of increasing intensity
Reaction sequence depicting the assimilation of N 2
FIGURE 25.1 The nitrogenase complex fixes nitrogen to ammonia
FIGURE 25.2 The F e protein, or reductase, transfers elections of high reducing power
FIGURE 25.3 The M o F e protein, or nitrogenase, catalyzes the reduction of N 2 to N H 3
Formation of glutamate
Formation of protonated Schiff base
Formation of glutamate from alpha-ketoglutarate
FIGURE 25.4 Glutamate chirality is established by hydride transfer to the Schiff base
Conversion of glutamate to glutamine
Irreversible reaction catalyzed by phenylalanine hydroxylase
FIGURE 25.6 Essential and nonessential amino acids can be distinguished by the required number of biosynthetic steps
FIGURE 25.7 Transamination is a critical step in the biosynthesis of most amino acids
FIGURE 25.8 Proton addition during transamination establishes amino acid stereochemistry
Conversion of aspartate to asparagine
Conversion of glutamate to glutamic gamma-semialdehyde
Formation of arginine and proline from glutamate
Formation of serine from 3-phosphoglycerate
Formation of glycine from serine
FIGURE 25.9 Tetrahydrofolate is an important carrier of activated one-carbon units
FIGURE 25.10 Interconversion of one carbon units attached to tetrahydrofolate
Formation of S-adenosylmethionine from methionine
Formation of homocysteine from S-adenosylmethionine
Reaction catalyzed by methionine synthase
FIGURE 25.11 The activated methyl cycle enables regeneration of methionine

Formation of alpha-ketobutyrate and cysteine
FIGURE 25.12 Chorismate is formed from phosphoenolpyruvate and erythrose 4-phosphate
Structure of glyphosate
FIGURE 25.13 Phenylalanine and tyrosine are formed in the prephenate branch
FIGURE 25.14 Tryptophan is formed in the anthranilate branch
Structure of 5-phosphoribosyl-1-pyrophosphate
FIGURE 25.15 Tryptophan synthase contains two remotely positioned catalytic domains
Reaction between Schiff base of aminoacrylate and indole
FIGURE 25.16 Tryptophan synthase uses substrate channeling to prevent loss of the indole intermediate
Inhibition of the first irreversible step of a biosynthetic pathway
FIGURE 25.17 3-Phosphoglycerate dehydrogenase is a homotetramer
FIGURE 25.18 Threonine deaminase is regulated by feedback inhibition and activation
FIGURE 25.19 The regulatory domains of 3-phosphoglycerate dehydrogenase and threonine deaminase are related structurally
Inhibition of enzymes by different products of a pathway
FIGURE 25.20 The three aspartokinases from E. coli have different regulatory domains
Structure of tyrosine residue modified by adenylylation
FIGURE 25.21 Glutamine synthetase is regulated by covalent modification
FIGURE 25.22 A diverse array of biomolecules are derived from amino acids
FIGURE 25.23 Glutathione structure
FIGURE 25.24 Ribbon diagram of glutathione peroxidase
FIGURE 25.25 Regeneration of selenolate active site after peroxide cleavage
FIGURE 25.26 Generation of nitric oxide from arginine
FIGURE 25.27 Tyrosine is a precursor for the catecholamines
FIGURE 25.28 The neurotransmitters serotonin and melatonin are synthesized from tryptophan

FIGURE 25.29 The origins of atoms in heme were revealed by isotope-labeling studies
Formation of delta-aminolevulinate
FIGURE 25.30 Heme is synthesized from eight molecules of delta-aminolevulinate
FIGURE 25.31 Heme is degraded into biliverdin and bilirubin
Structure of tryptophan
Formation of proline from ornithine
Schematic representation of a branched pathway
Ribbon diagram of A T P grasp domain
FIGURE 26.1 Nucleotides can be synthesized by de novo and salvage pathways
FIGURE 26.2 Pyrimidine nucleotides can be synthesized de novo
FIGURE 26.3 Carbamoyl phosphate synthetase 2 includes sites for three reactions
Formation of carbamic acid from bicarbonate
Formation of carbamoyl phosphate from carbamic acid
FIGURE 26.4 The three active sites of carbamoyl phosphate synthetase 2 are linked by a channel through which intermediates pass
Formation of orotate from carbamoyl phosphate
Reaction catalyzed by P R P P synthetase
Formation of orotidylate
Formation of uridylate from orotidylate
Formation of C T P from U T P
Structure of acyclovir
FIGURE 26.5 Purine nucleotides can be synthesized de novo
Formation of 5-phosphoribosyl-1-amine from P R P P
Activation of the carbonyl oxygen atom followed by the displacement of the phosphoryl group by a nucleophile
FIGURE 26.6 The de novo purine biosynthesis pathway involves nine steps
FIGURE 26.7 Inosinate can be converted to A M P and G M P
FIGURE 26.8 Hela cells in the presence and absence respectively of purine in the medium

Structure of inosinate
Structure of 2-aminoadenine
FIGURE 26.9 The nucleotide containing 2-aminoadenine is synthesized from deoxyguanylate
FIGURE 26.10 Ribonucleotide reductase uses a radical mechanism to produce deoxyribonucleotides
Oxidation of N A D P H coupled with the reduction of ribose substrate
FIGURE 26.11 The ribonucleotide reductase R 2 subunit contains a stable free radical on a tyrosine residue
FIGURE 26.12 Thymidylate synthase catalyzes the addition of a methyl group to d U M P to form T M P
Reduction of dihydrofolate to tetrahydrofolate
FIGURE 26.13 Enzymes crucial for nucleotide synthesis are anticancer drug targets
FIGURE 26.14 Fluoruracil acts by suicide inhibition
Generalized structure of aminopterin and methotrexate
Structure of trimethoprim
Regulation of aspartate transcarbamoylase
FIGURE 26.15 Purine biosynthesis is regulated at many steps
FIGURE 26.16 Ribonucleotide reductase is highly regulated to balance the pool of deoxyribonucleotides
FIGURE 26.17 Purines are catabolized for excretion
Structure of allopurinol
Structure of azaserine
Action of statins on cholesterol level and photograph of medicines targeting lipid biosynthesis
FIGURE 27.1 Phosphatidate is a key intermediate in lipid biosynthesis
A reaction depicting the conversion of glycerol 3-phosphate to phosphatidate
A reaction depicting the conversion of phosphatidate to triacylglycerol
Conversion of phosphatidate to C D P diacylglycerol
Conversion of C D P diacylglycerol to phosphatidylinositol and C M P
Structure of diphosphatidylglycerol (cardiolipin)
Conversion of ethanolamine to phosphatidylethanolamine

Formation of phosphatidylcholine
Structure of sphingosine
FIGURE 27.2 Biosynthesis of ceramide involves four steps
FIGURE 27.3 The ganglioside G subscript M 1 consists of five monosaccharides linked to ceramide
FIGURE 27.4 Ceramide can be converted into sphingomyelin, cerebroside, and gangliosides
Conversion of ganglioside G subscript M 2 to ganglioside G subscript M 3
FIGURE 27.6 Phosphatidic acid phosphatase is a key regulatory enzyme in lipid synthesis
FIGURE 27.7 Isotope-labeling experiments have revealed the source of carbon atoms in cholesterol synthesized from acetate
FIGURE 27.8 3-Hydroxy-3-methylglutaryl C o A has different fates
FIGURE 27.9 Mevalonate is converted into isopentenyl pyrophosphate
Structure of isoprene
Formation of dimethylallyl pyrophosphate from isopentenyl pyrophosphate
FIGURE 27.10 Condensation reactions build carbon–carbon bonds that eventually form the cholesterol skeleton
FIGURE 27.11 Two molecules of farnesyl pyrophosphate are linked to form squalene
FIGURE 27.12 Squalene cyclization leads to the steroid skeleton in the form of lanosterol
FIGURE 27.13 Cholesterol is formed from lanosterol
FIGURE 27.14 S R E B P regulates gene expression in response to cholesterol levels

Extended description for The cover page of the book

titled “Biochemistry, Tenth edition” is shown

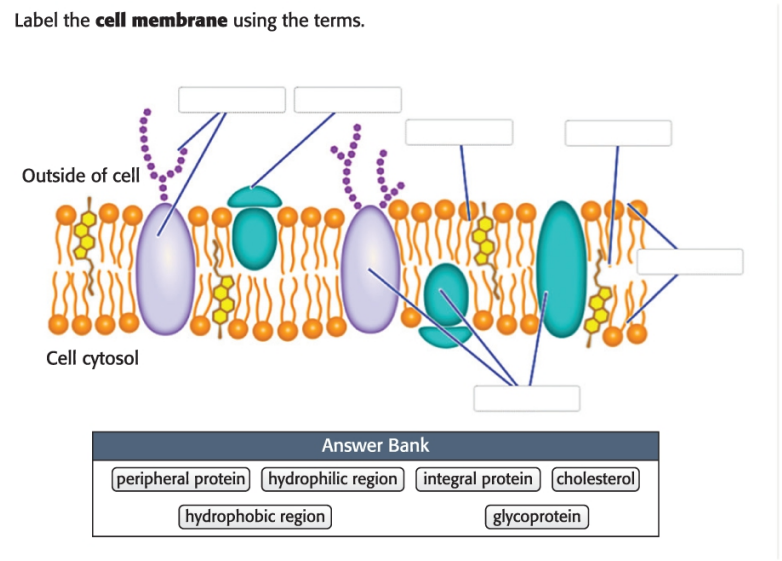
An illustration of the chemical structure of the D N A double helix is depicted as observed when looked at from the terminus.

The names of the author are listed as follows:

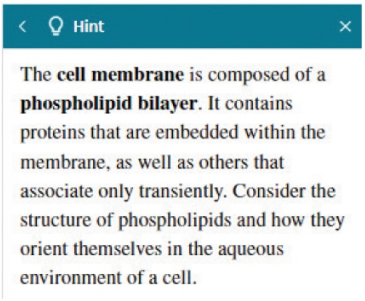
Jeremy M. Berg
Gregory J. Gatto, Jr.
Justin L. Tymoczko
Lubert Stryer

The logo of Macmillan learning is in the lower right corner.

Return to The cover page of the book titled “Biochemistry, Tenth edition” is shown



Extended description for Logo of W. H. Freeman Macmillan learning



The logo includes two parts: the emblem and the wordmark. The emblem depicts a stylized open book and also resembling sea gulls or waves. Next to it, there is the phrase "w.h. freeman Macmillan learning". W.H. Freeman is in lowercase letters and is highlighted in black. Macmillan learning is below W.H. Freeman, in smaller font with letters M and L capitalized, highlighted in red.

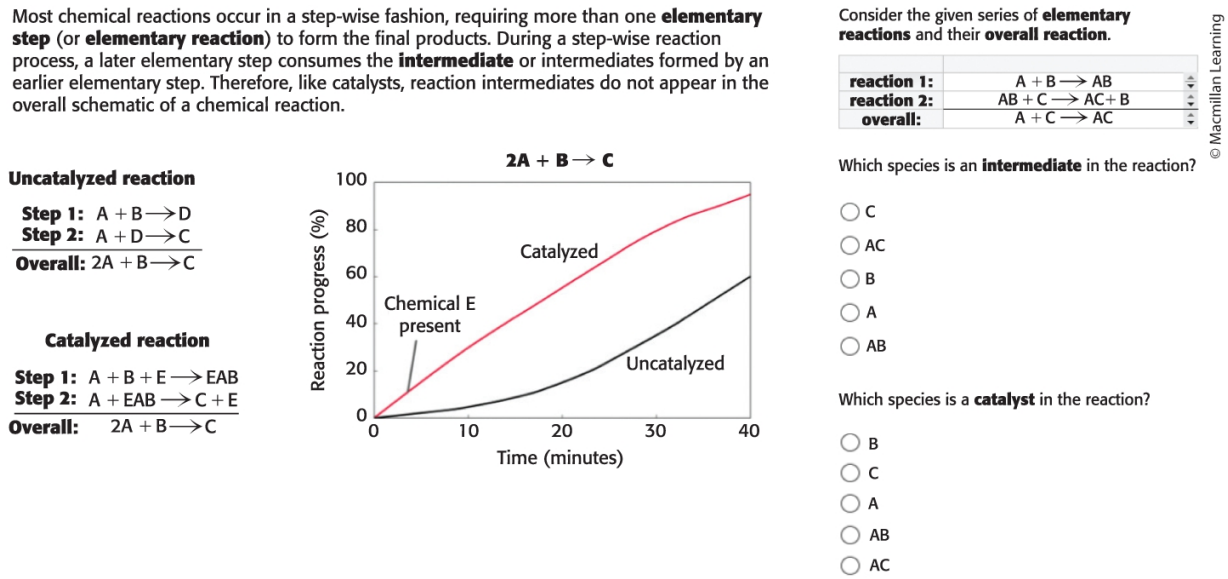
Extended description for Structures of cell membrane and associated proteins

© Macmillan Learning

First illustration: The schematic diagram shows the cell membrane composed of the phospholipid bilayer that separates the outside of the cell from the cell cytosol. The phospholipid bilayer is represented as small orange spherical structures arranged adjacent

to each other at intervals and bordering the layer above and below. The orange spherical structures are marked by a blank rectangular box. Each sphere is bound to a pair of stalks. The stalks of both spherical layers face each other toward the center and are marked by a blank rectangular box. Numerous proteins are shown embedded at an interval across the phospholipid bilayer of the cell membrane. The illustration shows an oval-shaped purple membrane-bound protein with a branched chain formed by a series of hexagonal molecules extending from the top of the protein toward the outside of the cell. The oval protein with a branched hexagon chain is marked by a blank rectangular box. Numerous fused yellow hexagonal structures with branches extending from them occurring at intervals are marked by a blank rectangular box and are shown spanning either the top half or bottom half of the phospholipid bilayer. The turquoise oval-shaped protein spanning the top half of the phospholipid bilayer is bound with a flat elliptical turquoise structure on the top toward the outside of the cell is marked by a blank rectangular box. The second oval-shaped purple membrane-bound protein with two branched chains formed by a series of hexagonal molecules extending from the top of the protein toward the outside of the cell. The second turquoise oval-shaped protein spanning the bottom half of the phospholipid bilayer is bound with a flat elliptical turquoise structure on the bottom toward the cell cytosol. An oblong oval turquoise protein spans the phospholipid bilayer of the membrane. The second purple oval protein, second turquoise protein, and oblong oval turquoise protein are collectively marked by a blank rectangular box.

The Answer bank terms provided inside the box are peripheral protein, hydrophilic region, integral protein, cholesterol, hydrophobic region, and glycoprotein. Label the cell membrane using the terms.



Second illustration: The schematic diagram shows the cell membrane composed of the phospholipid bilayer that separates the outside of the cell from the cell cytosol. The phospholipid bilayer is represented as small orange spherical structures arranged adjacent to each other at intervals and bordering the layer above and below. The orange spherical structures are marked by a rectangular box labeled “hydrophilic region.” Each sphere is bound to a pair of stalks. The stalks of both spherical layers face each other toward the center and are marked by a rectangular box labeled “hydrophobic region.” Numerous proteins are shown embedded at an interval across the phospholipid bilayer of the cell membrane. The illustration shows an oval-shaped purple membrane-bound protein with a branched chain formed by a series of hexagonal molecules extending from the top of the protein toward the outside of the cell. The oval protein with a branched hexagon chain is marked by a rectangular box labeled “glycoprotein.” Numerous fused yellow hexagonal structures with branches extending from them occurring at intervals are marked by a rectangular box labeled “cholesterol” and are shown spanning either the top half or bottom half of the phospholipid bilayer. The turquoise oval-shaped protein spanning the top half of the phospholipid bilayer is bound with a flat elliptical turquoise structure on the top toward the outside of the cell and is marked by a rectangular box labeled “peripheral protein.” The second oval-shaped purple membrane-bound protein with two branched chains formed by a series of hexagonal molecules extending from the top of the protein toward the outside of the cell. The second turquoise oval-shaped protein spanning the bottom half of the phospholipid bilayer is bound with a flat elliptical turquoise structure on the bottom toward the cell cytosol. An oblong oval turquoise protein spans the phospholipid bilayer of the membrane. The second purple oval protein, second turquoise protein, and oblong oval turquoise protein are collectively marked by a rectangular box labeled “Integral protein.”

A hint box is provided on the right that reads “The cell membrane is composed of a phospholipid bilayer. It contains proteins that are embedded within the membrane, as well as others that associate only transiently. Consider the structure of phospholipids and how they orient themselves in the aqueous environment of a cell.”

A feedback box on the bottom right reads “One or more terms are misplaced. Integral proteins, such as transporters, extend into the membrane. Other proteins, called peripheral proteins because of their locations, have functions such as helping move substances to other parts of the cell.”

Return to Structures of cell membrane and associated proteins

Extended description for Reactions and its corresponding graph and related questions

The paragraph text at the top of the left window reads,

Most chemical reactions occur in a step-wise fashion, requiring more than one elementary step (or elementary reaction) to form the final products. During a step-wise reaction process, a later elementary step consumes the intermediate or intermediates formed by an earlier elementary step. Therefore, like catalysts, reaction intermediates do not appear in the overall schematic of a chemical reaction.

Below the paragraph text, there are two steps uncatalyzed and catalyzed reactions along with a graph.

The uncatalyzed reaction reads,

Step-1: A plus B, right arrow, D

step-2: A plus D, right arrow, C

An underline below these steps gives the sum of step reactions which reads overall: 2 A plus B, right arrow, C.

The catalyzed reaction reads,

Step-1: A plus B plus E, right arrow, E A B

step-2: A plus E A B, right arrow, C plus E

An underline below these steps gives the sum of step reactions which reads overall: 2 A plus B, right arrow, C.

The graph is drawn for the overall reaction 2 A plus B, right arrow, C. The horizontal axis of the graph is labeled Time (in minutes). The vertical axis is labeled reaction progress (in percent). The horizontal axis ranges from 0 to 40 in increments of 10 units. The vertical axis ranges from 0 to 100 in increments of 20 units. The graph shows two curves. A red line curve for Catalyzed reaction starts from (0, 0) rises linearly till (33, 80), rises with a decreasing slope, and then terminates at (40, 95). A point on the curve at (3, 10) is labeled "Chemical E present". A black concave-up curve for uncatalyzed reaction starts from (0, 0), rises almost linearly till (13, 8), then curves up through (15, 11), (20, 18), and (25, 22). It then again rises linearly till (40, 56).Note: all numerical values in the graph are approximated.

The right-side window reads as follows:

Consider the given series of elementary reactions and their overall reaction.

Reaction-1: A plus B, right arrow, A B

Reaction-2: A B plus C, right arrow, A C plus B

overall: A plus C, right arrow, A C.

Below these reactions, there are two M C Q problems based on the reactions.

First problem:

Which species is an intermediate in the reaction?

1. C

2. A C

3. B

4. A

5. A B

Second problem:

Which species is a catalyst in the reaction?

1. B

2. C

3. A

4. A B

5. A C

Return to Reactions and its corresponding graph and related questions

Extended description for Incomplete purification table along with the percent yield equation

Complete the purification table: % yield

$$\% \text{ yield} = \frac{\text{total activity in step}}{\text{total activity step 1}} \times 100$$

step (procedure)	total protein (mg)	activity (units)	specific activity (units/mg)	% yield	purification factor
crude extract	20,000	4,000,000	200	100	
precipitation (salt)	5,000	3,000,000	600	75	
precipitation (pH)	4,000	1,000,000	250		
ion-exchange chromatography	200	800,000	4,000		
affinity chromatography	50	750,000	15,000		
size-exclusion chromatography	45	675,000	15,000		

The end user needs to fill the table using the percent yield equation. percent yield equals Start Fraction total activity inches step over total activity step 1 End Fraction multiplied by 100.

The table consists of 6 columns and 6 rows. The headings of the columns are as follows: step (procedure), total protein (milligrams), activity (units), specific activity (units per milligram), percent yield, and purification factor. The row entries are as follows.

Row 1: step (procedure): crude extract. total protein (milligrams): 20,000. activity (units): 4,000,000. specific activity (units per milligram): 200. percent yield: 100. Note: A human entry of 100 is shown here indicating that this value is calculated using the equation. purification factor: Blank.

Row 2: step (procedure): precipitation (salt). Note: A curved blue arrow points from Row 1 step (procedure) entry Crude extract to precipitation (salt). total protein (milligrams): 5,000. activity (units): 3,000,000. Note: This value is encircled in blue. specific activity (units per milligram): 600. percent yield: 75. Note: A human entry of 75 is shown here indicating that this value is calculated using the equation. purification factor: Blank.

Row 3: step (procedure): precipitation (pH). total protein (milligrams): 4,000. activity (units): 1,000,000. specific activity (units per milligram): 250. percent yield: Blank. purification factor: Blank.

Row 4: step (procedure): ion-exchange chromatography. total protein (milligrams): 200. activity (units): 800,000. specific activity (units per milligram): 4,000. percent yield: Blank. purification factor: Blank.

Row 5: step (procedure): affinity chromatography. total protein (milligrams): 50. activity (units): 750,000. specific activity (units per milligram): 15,000. percent yield: Blank. purification factor: Blank.

Extended description for New case study Mile High Stadium and Silent Killer: Hemoglobin Dysfunction

Mile High Stadium and the Silent Killer
Case Study on Hemoglobin Regulation and Dysfunction
By Justin Hines, Lafayette College

Photo Credit: Zoonar /A. Kravchenko /AGE Fotostock

Act 1 - Trouble at Mile High Stadium

Gino had hemoglobin on the mind. He had been embarrassed earlier when he failed to remember how pH was related to oxygen transport in the human body.

As an undergraduate in his junior year who hoped to go to medical school, Gino's day job shadowing emergency room physician Dr. Rose Smith was otherwise going well. But the routine patient visits were interrupted when he saw a large crowd gathered just outside in the hospital lobby. Most had flowers, but some, strangely, were carrying footballs and wearing jerseys.

"Dr. Smith, what's that all about?" Gino pointed to the noisy crowd.

"Oh that... yes, we have a patient up on three recovering from a sickle cell attack."

"But why so many people?" asked Gino. "And why do some have footballs? Is it a child or something?"

"No, actually he's an NFL star... plays defensive end. Most of those people are just fans. He played a game last night here in Denver at the new Mile High Stadium. The combination of vigorous exercise from sprinting all over a 100-yard field and the fact that the game was here in Denver triggered a sickle cell crisis. He'll probably never play in Denver again."

"He has sickle cell anemia and plays in the NFL??!"

"Actually, he has sickle cell *trait*, meaning he is heterozygous for the sickle cell allele, HbS. Some people with sickle cell trait can be top athletes. But, the right conditions can still bring about a crisis."

A photograph shows the Mile High Stadium. A text beside the photograph reads:

Mile High Stadium and the Silent Killer Case Study on Hemoglobin Regulation and Dysfunction By Justin Hines, Lafayette College

Act 1 - Trouble at Mile High Stadium

Gino had hemoglobin on the mind. He had been embarrassed

earlier when he failed to remember how pH was related to

oxygen transport in the human body.

As an undergraduate in his junior year who hoped to go to medical school, Gino's day job shadowing emergency room physician Dr. Rose Smith was otherwise going well. But the routine patient visits were interrupted when he saw a large crowd gathered just outside in the hospital lobby. Most had flowers, but some, strangely, were carrying footballs and wearing jerseys.

SPORTS

"Dr. Smith, what's that all about?" Gino pointed to the noisy crowd.

"Oh that. yes, we have a patient up on three recovering from a sickle cell attack."

"But why so many people?" asked Gino. "And why do some have footballs? Is it a child or something?"

"No, actually he's an N F L star. plays defensive end. Most of those people are just fans. He played a game last night here in Denver at the new Mile High Stadium. The combination of vigorous exercise from sprinting all over a 100-yard field and the fact that the game was here in Denver triggered a sickle cell crisis. He'll probably never play in Denver again."

"He has sickle cell anemia and plays in the N F L??!"

"Actually, he has sickle cell trait, meaning he is heterozygous for the sickle cell allele, H b S. Some people with sickle cell trait can be top athletes. But, the right conditions can still bring about a crisis."

"What does playing in Denver, Colorado have to do with sickle cell?"

"Oh Gino. you really need to go back and review your stuff on hemoglobin again. this is all straight out of undergraduate biochemistry !"

Extended description for Logo of Macmillan learning

The logo includes two parts: the emblem and the wordmark. The emblem depicts a stylized open book and also resembling sea gulls or waves. Next to it, there is the phrase "Macmillan learning" in lowercase letters. Macmillan is highlighted in red and learning is in black. Below it the different centers of macmillan are shown which are: Austin, Boston, New York, and Plymouth.

Return to Logo of Macmillan learning

Extended description for FIGURE 6.18 The active site of human carbonic anhydrase II includes a bound zinc ion

© Macmillan Learning

The three-dimensional ribbon diagram of human carbonic anhydrase 2 is composed of antiparallel beta-strands and a few coiled alpha-helices connected by thin thread-like loops. The core of the enzyme is composed of antiparallel beta-strands. The active site of the enzyme is present between the beta-strands and thread-like loops. It contains a zinc ion bound to the active site residues.

The ball-and-stick model shows a central Z n superscript 2 plus ion connected to the imidazole rings of three histidine residues. Z n superscript 2 plus ion is depicted as a green sphere and is connected above with an H 2 O molecule. The histidine residues are composed of black, blue, white, and red spheres. The model highlights the residues H i s 96, H i s 119, and H i s 94.

Extended description for FIGURE 12.38 Many cells take up molecules by receptor-mediated endocytosis

Credit: *Top*: Republished with permission of Company of Biologists, from Membrane remodeling in clathrin-mediated endocytosis. Volker Haucke, Michael M. Kozlov, J Cell Sci (2018) 131 (17): jcs216812. Figure 1. Permission conveyed through Copyright Clearance Center, Inc.; *Bottom*: Schmid SL. Reciprocal regulation of signaling and endocytosis: Implications for the evolving cancer cell. J Cell Biol. 2017 Sep 4;216(9):2623-2632. doi: 10.1083/jcb.201705017. Epub 2017 Jul 3. PMID: 28674108; PMCID: PMC5584184. Copyright © 2017 Schmid. Illustration by Marcel Mettlen. Used with permission.

The figure shows photomicrographs of receptor-mediated endocytosis on the top and corresponding steps of receptor-mediated endocytosis below.

The first micrograph shows the surface of the cell.

In the second micrograph, the surface begins to invaginate slightly.

In the third micrograph, the invagination becomes prominent.

In the fourth micrograph, the neck of the invagination starts to get closer.

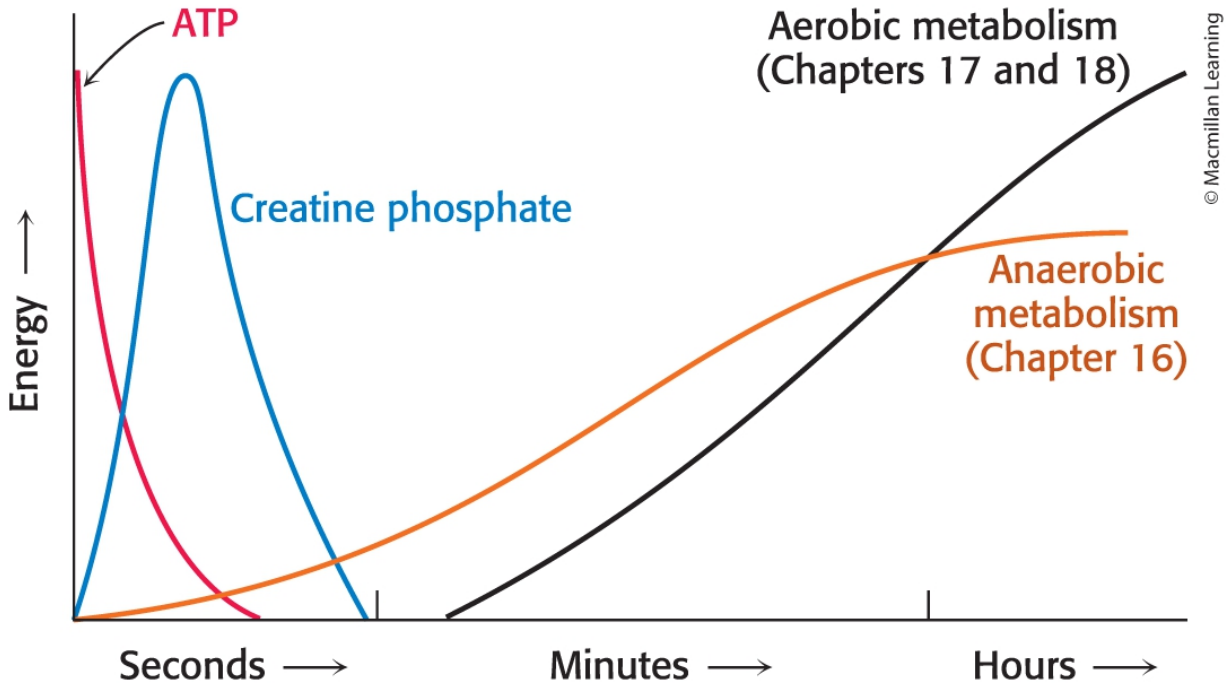
In the fifth micrograph, the completely invaginated membrane appears as a sphere inside the cell.

The schematic illustration of the corresponding steps of receptor-mediated endocytosis is shown below the micrographs.

The lipid bilayer of the membrane consists of two parallel layers of lipids. Each lipid molecule has the yellow extensions aligned together and forms the core of the bilayer. The blue spheres are located away from each other.

Step 1: The plasma membrane forms a slight invagination. A clathrin molecule attaches to the inner surface of the invagination.

Step 2: The invagination becomes slightly deeper by concave folding, and the inner surface of the invagination is lined by a series of clathrin molecules. The invagination is labeled clathrin-coated pit. The clathrin molecule is depicted as a box-like structure fused to a sphere on the bottom left and bottom right.



Step 3: The invagination becomes prominent as a U-shaped structure.

Step 4: The invagination becomes spherical and its neck is continuous with the membrane. Several spherical bead-like structures called dynamin zip the neck of the spherical invagination.

Step 5: The dynamin spheres are released and a spherical structure surrounded by a lipid bilayer and clathrin coating is released into the intracellular space.

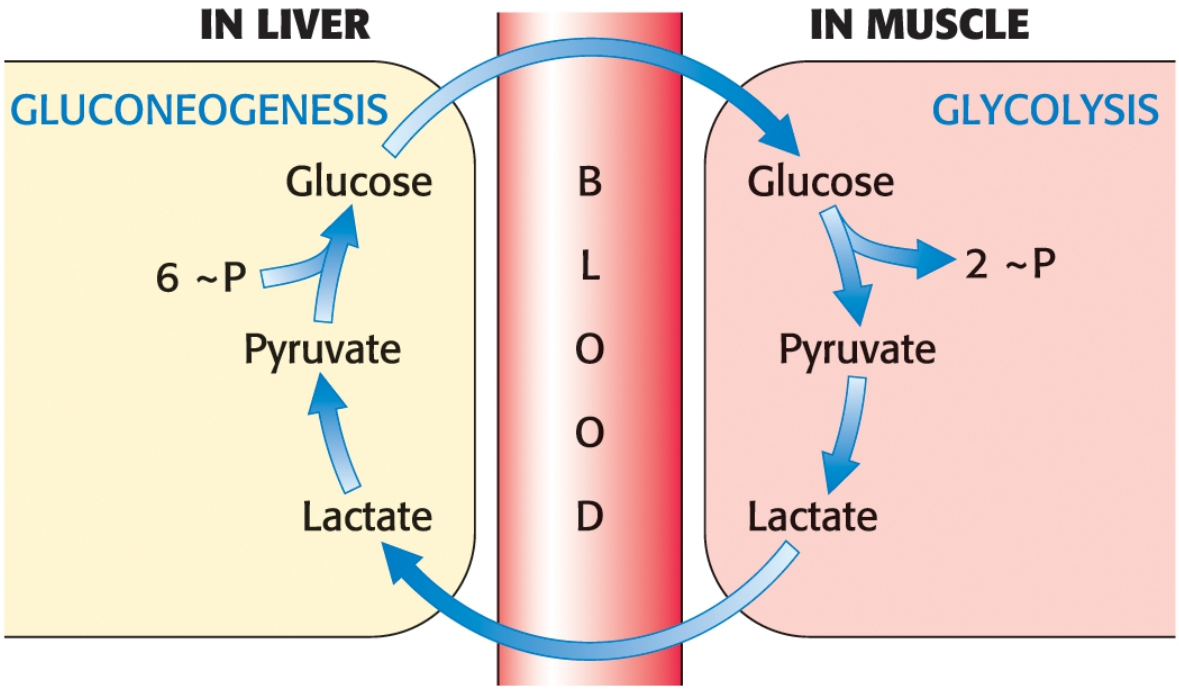
Extended description for FIGURE 15.6 The sources of ATP change as exercise duration increases, even within the first few seconds



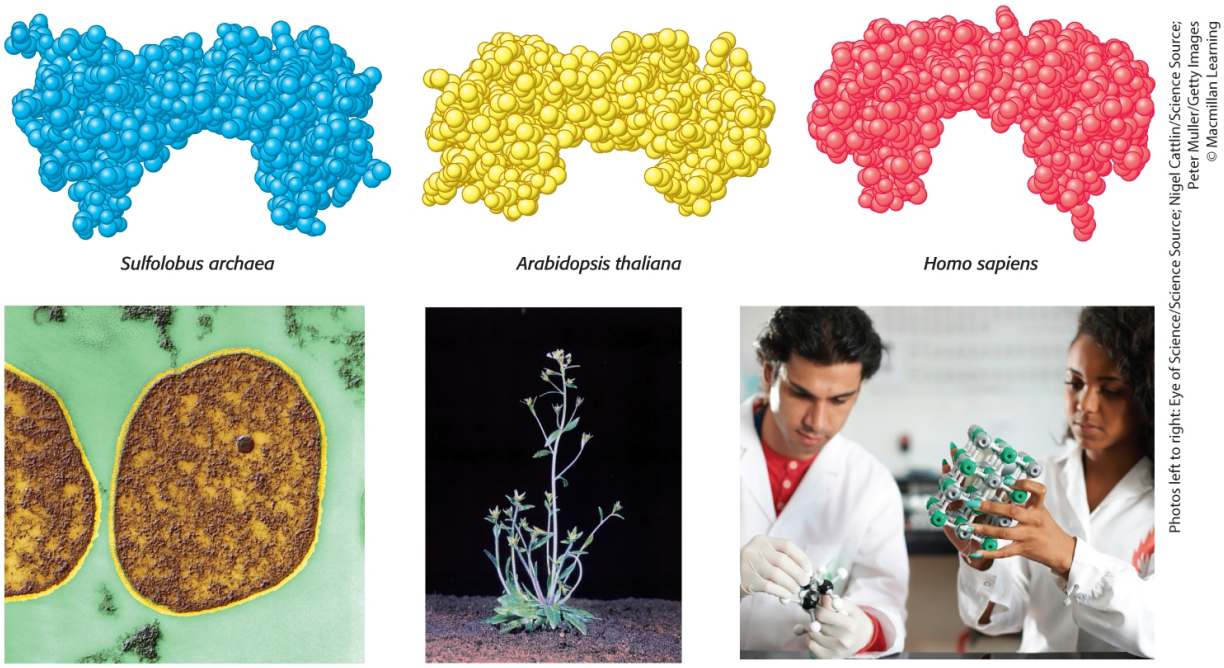
The vertical axis is labeled Energy indicated by an upward arrow. The horizontal and vertical axes intersect at the bottom left. The horizontal axis contains two markings from left to right. The first interval between the vertical axis and the first marking is labeled Seconds indicated by a rightward arrow. The second interval between the first and the second markings is labeled Minutes indicated by a rightward arrow. The third interval between the second and the third marking is labeled Hours indicated by a rightward arrow. A red curve representing A T P starts on high value of Energy on the vertical axis and falls concave upward to intersect the horizontal axis in the seconds interval. A blue curve representing Creatine phosphate starts at the intersection of the axes, rises almost linearly to a peak at high value of energy, and falls

concave upwards to intersect the horizontal axis at the first marking. An orange curve representing Anaerobic metabolism (Chapter 16) starts at the intersection of the axes, rises with an increasing slope till a low to mid value of energy, and rises further with a decreasing slope to mid value of energy in the hours interval. A black curve representing Aerobic metabolism (Chapters 17 and 18) starts on the horizontal axis to the right of the first marking, rises with an increasing slope till a low to mid value of energy, and rises further with a decreasing slope to mid value of energy in the hours interval.

Return to FIGURE 15.6 The sources of ATP change as exercise duration increases, even within the first few seconds

Extended description for FIGURE 16.36 The Cori cycle allows the liver to better support other tissues, such as skeletal muscle

© Macmillan Learning



The illustration shows three different compartments. The central compartment is labeled blood and is long and cylindrical. The left compartment is a rounded half-rectangle labeled “IN LIVER.” The right compartment is also a rounded half-rectangle labeled “IN MUSCLE.” Each conversion is shown by sequential curved arrows.

In muscle, glycolysis is depicted as follows: Step 1: Glucose is converted into pyruvate coupled with the release of 2, wavy line, P represents 2 nucleoside triphosphates. Step 2: Pyruvate is further converted into lactate. Step 3: The lactate travels from the muscle compartment to the liver compartment through the blood compartment.

In the liver, gluconeogenesis is depicted as follows: Step 1: Lactate is converted into pyruvate. Step 2: Pyruvate is further converted into glucose with the coupled entry of 6, wavy line, P which represents 6 nucleoside triphosphates. Step 3: The glucose molecule travels back to the muscle compartment through the blood compartment.

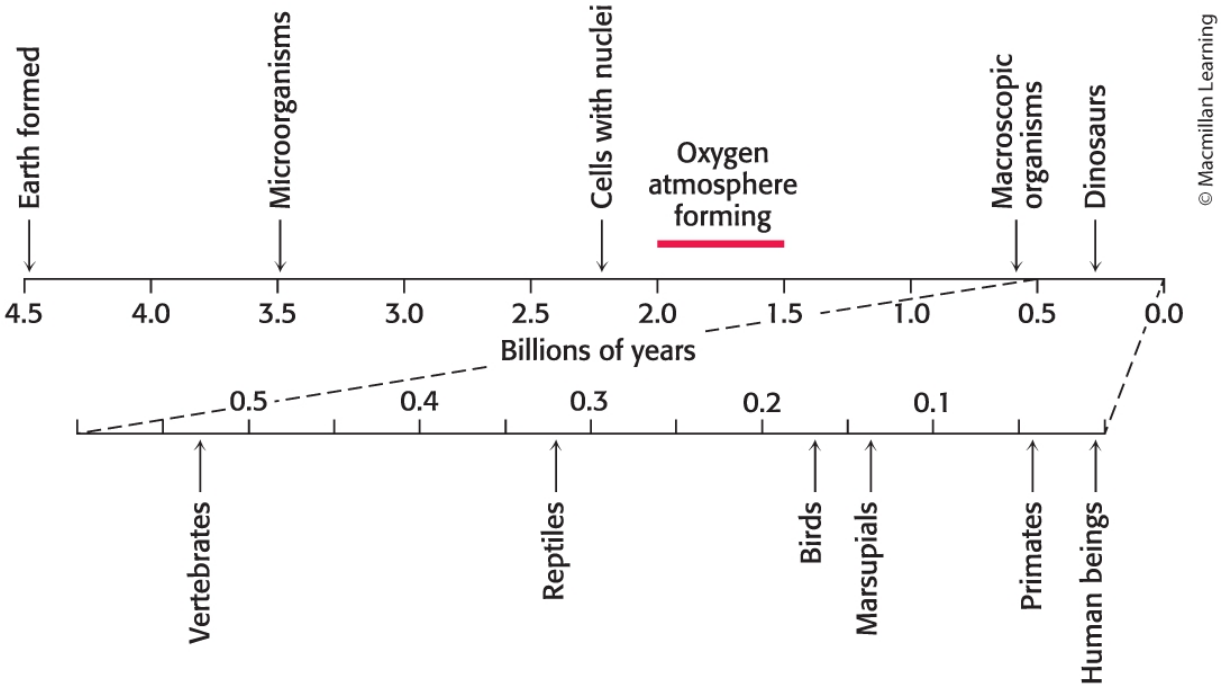
Extended description for Examples of metabolites



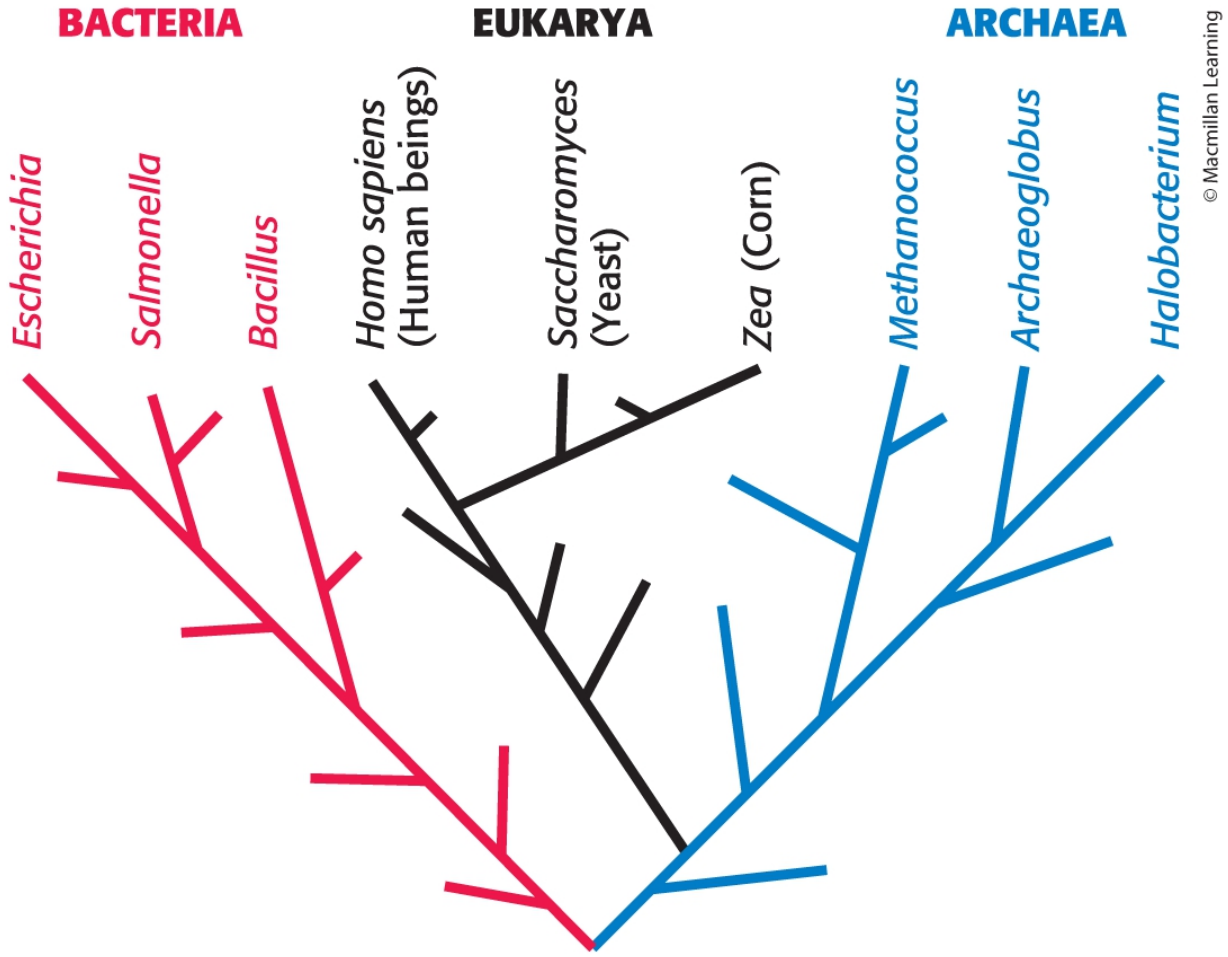
Glucose: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top-right vertex. C 1, C 2, and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above. C 2 and C 3 are toward the observer.

Glycerol: A central C atom is single bonded to C H 2 O H above and below, O H on the left, and H on the right.

Return to Examples of metabolites

Extended description for FIGURE 1.2 A possible timeline for biochemical evolution shows that life on Earth began approximately 3.5 billion years ago

The main timeline ranges from 4.5 to 0.0 billion years in decrements of 0.5 units. The following events are indicated on the timeline:



1. Earth formed: 4.5 billion years
2. Microorganisms: 3.5 billion years
3. Cells with nuclei: 2.2 billion years
4. Oxygen forming atmosphere: Between 2.0 and 1.5 billion years
5. Macroscopic organisms: 0.6 billion years
6. Dinosaurs: 0.3 billion years

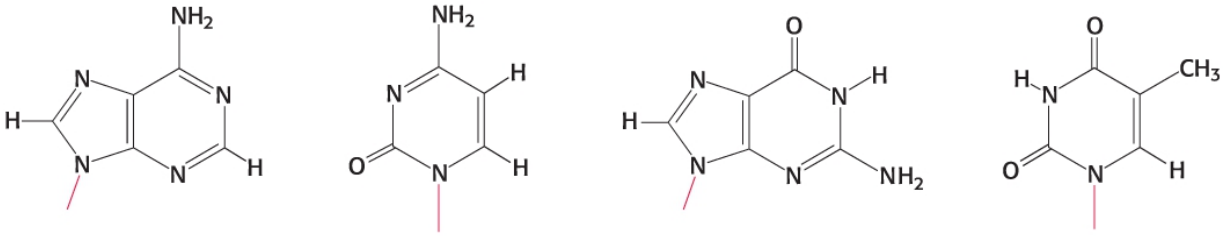
A second timeline is shown below the main timeline, ranging from 0.6 to 0.0 billion years in decrements of 0.1 units. This timeline indicates the times of emergence of classes of animals as follows:

1. Vertebrates: 0.53 billion years
2. Reptiles: 0.32 billion years
3. Birds: 0.17 billion years
4. Marsupials: 0.14 billion years
5. Primates: 0.04 billion years
6. Human beings: 0.01 billion years

Return to FIGURE 1.2 A possible timeline for biochemical evolution shows that life on Earth began approximately 3.5 billion years ago

Extended description for FIGURE 1.3 The relationships of all modern organisms can be displayed on a tree of life with just three major branches

The tree begins at a point and has two main branches extending toward the upper left and upper right, respectively.



The branch toward the upper left pertains to Bacteria and ends at *Escherichia*. Two sub-branches extend from the main branch. One is closer to *Escherichia* and ends at *Salmonella* followed by the other that ends at *Bacillus*.

The branch toward the upper right pertains to Archaea and ends at *Halobacterium*. Two sub-branches extend from the main branch. One is closer to *Halobacterium* and ends at *Archaeoglobus* followed by the other that ends at *Methanococcus*.

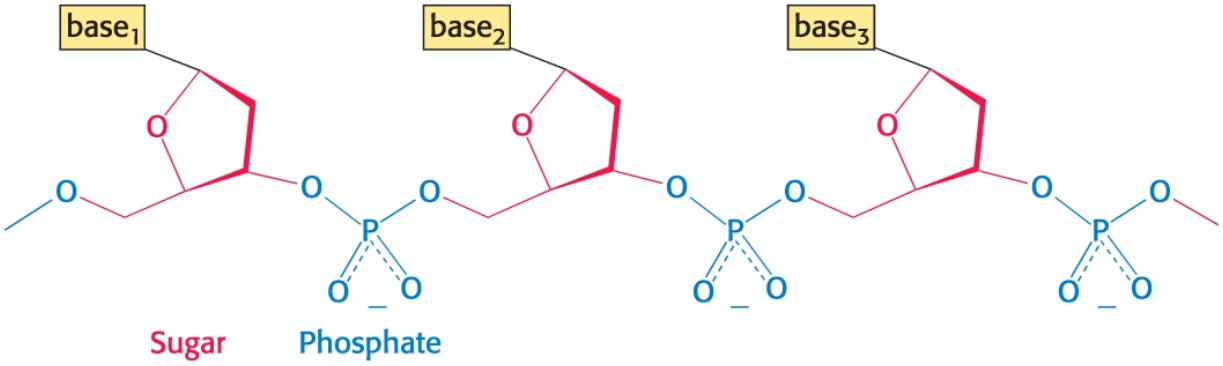
The branch for Archaea contains a major sub-branch pertaining to Eukarya. The sub-branch extends from the base of the Archaea branch and extends toward the upper left to end at *Homo sapiens* (Human beings) such that it is close to *Bacillus*. A smaller sub-branch from the *Homo sapiens* sub-branch extends toward the upper right to end at *Zea* (Corn) such that it is close to *Methanococcus*. A small sub-branch on the *Zea* branch midway between *Homo sapiens* and *Zea* extends upward pertaining to *Saccharomyces* (yeast).

Return to FIGURE 1.3 The relationships of all modern organisms can be displayed on a tree of life with just three major branches

Extended description for Structures of the four nitrogenous bases of D N A

Adenine (A) has the following structure: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 2 N and 3 C atoms. The first N atom, highlighted, occupies the first position, which is the bottom-left vertex, and the second N atom occupies the third position, which is the top-left vertex. A double bond is present between C 1 and the second N atom and between C 2 and C 3. C 1 is single bonded to H. This ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation that consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the top-right vertex, and the second N atom occupies the third position, which is the bottommost vertex. A double bond is present between C 1 and the second N atom and between C 4 and the first N atom. C 1 is single bonded to H, and C 4 is single bonded to N H 2. The two rings are fused to each other such that C 2 and C 3 of the 5-membered ring are the C 3 and C 2 of the 6-membered ring, respectively.

Cytosine (C) has the following structure: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. The first N atom, highlighted, occupies the first position, which is the bottommost vertex, and the second N atom occupies the third position, which is the top-left vertex. A double bond is



present between the second N atom and C 2 and between C 3 and C 4. C 1 is double bonded to O, C 2 is single bonded to N H 2, and C 3 and C 4 are each single bonded to H.

Guanine (G) has the following structure: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 2 N and 3 C atoms. The first N atom, highlighted, occupies the first position, which is the bottom-left vertex, and the second N atom occupies the third position, which is the top-left vertex. A double bond is present between C 1 and the second N atom and between C 2 and C 3. C 1 is single bonded to H. This ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation that consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the top-right vertex, and the second N atom occupies the third position, which is the bottommost vertex. A double bond is present between C 1 and the second N atom. The first N atom is single bonded to H, C 1 is single bonded to N H 2, and C 4 is double bonded to O. The two rings are fused to each other such that C 2 and C 3 of the 5-membered ring are the C 3 and C 2 of the 6-membered ring, respectively.

Thymine (T) has the following structure: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. The first N atom, highlighted, occupies the first position, which is the bottommost vertex, and the second N atom occupies the third position, which is the top-left vertex. A double bond is present between C 3 and C 4. C 1 is double bonded to O, the second N atom is single bonded to H, C 2 is double bonded to O, C 3 is single bonded to C H 3, and C 4 is single bonded to H.

Return to Structures of the four nitrogenous bases of D N A

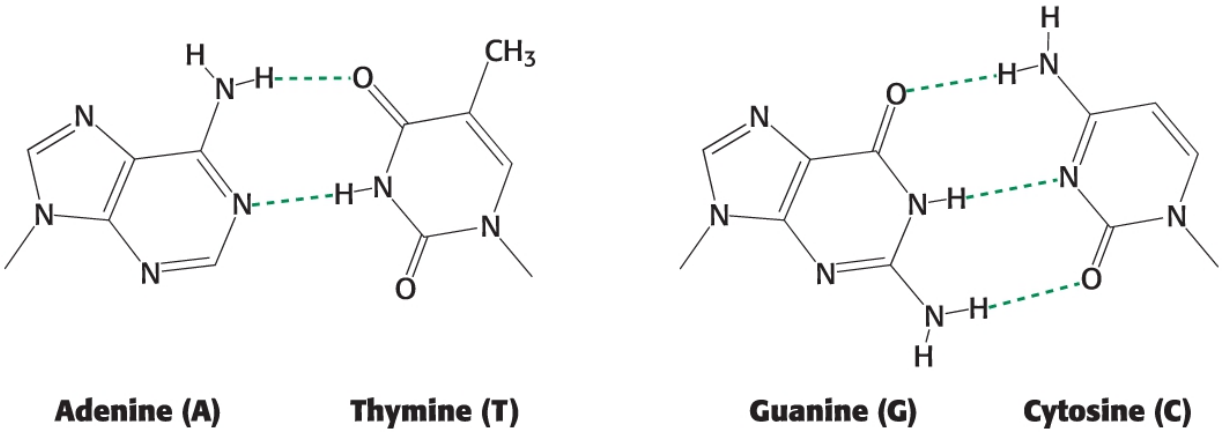
Extended description for FIGURE 1.4 The covalent structure of DNA is a linear polymer of monomeric units

Three sugar molecules are joined in a linear chain via phosphate groups.

The sugar has the following structure: A heterocyclic pentagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position which is the leftmost vertex. C 1 of each sugar molecule is single bonded to a base. The first sugar molecule is bonded to base 1, the second sugar molecule is bonded to base 2, and the third sugar molecule is bonded to base 3.

The phosphate group has the following structure: A central P is single bonded to O on the upper left and O on the upper right. P is partially double bonded to O on the lower left and O on the lower right by means of a straight line and a dotted line. The phosphate group carries a negative charge. The single bonded to O on the upper left is single bonded to C 3 of a sugar molecule on the left. The single bonded to O on the upper right is single bonded to a C H 2 group on the lower right. The C H 2 group is single bonded to C 4 of the next sugar molecule on the upper right.

Return to FIGURE 1.4 The covalent structure of DNA is a linear polymer of monomeric units



Extended description for FIGURE 1.5 The double helix has two antiparallel strands

Two ribbon-like strands of D N A are shown to be twisted to form a double-helix structure. A rightward arrow along one strand (red) and a leftward arrow along the other strand (blue) represent the antiparallel nature of the strands. Vertical lines, colored green, purple, orange, and yellow, between the two strands, show complementary bonding between the nitrogenous bases of the two strands.

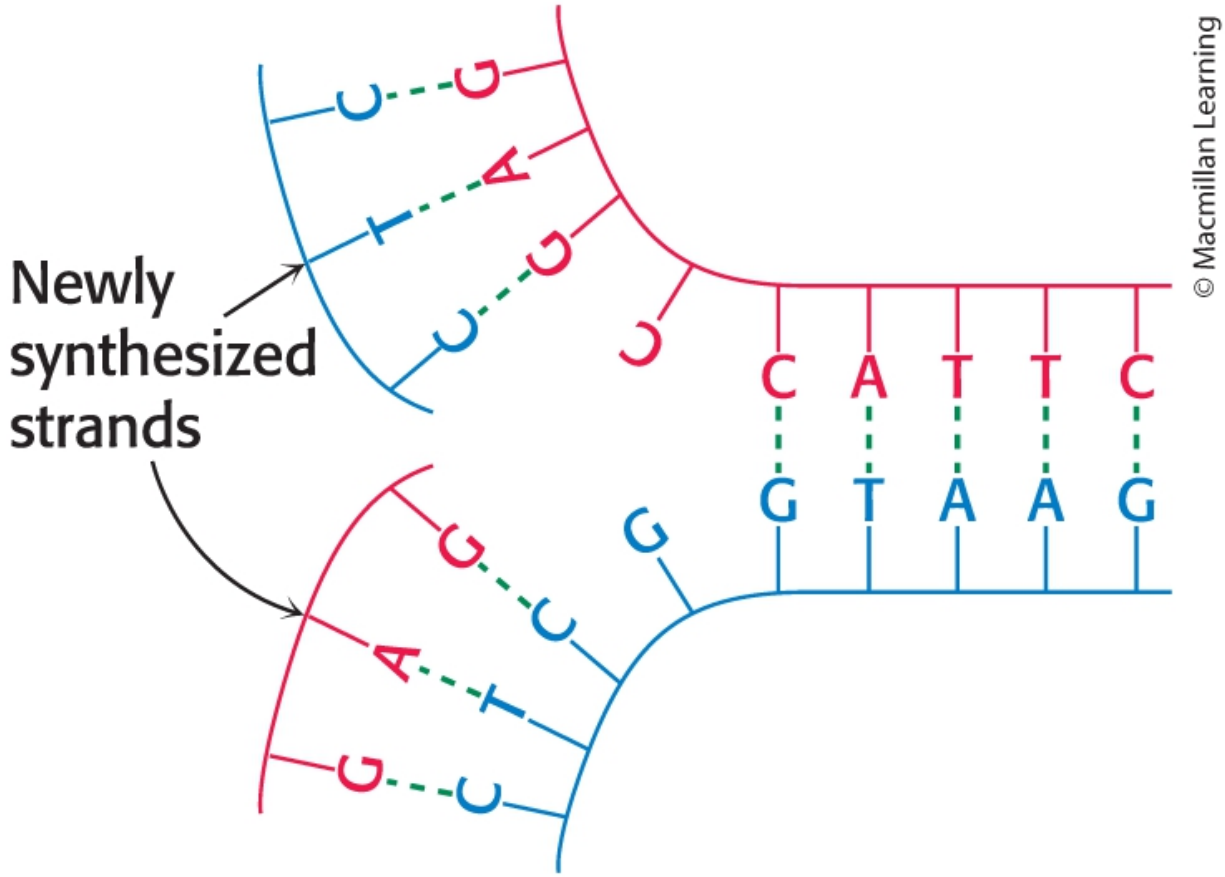
Return to FIGURE 1.5 The double helix has two antiparallel strands

Extended description for FIGURE 1.6 The nitrogenous bases in DNA form specific Watson–Crick base pairs

Adenine (A) has the following structure: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 2 N and 3 C atoms. The first N atom occupies the first position, which is the bottom-left vertex, and the second N atom occupies the third position, which is the top-left vertex. A double bond is present between C 1 and the second N atom and between C 2 and C 3. The first N atom is single bonded to C H 3 in the form of a line. This ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation that consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the top-right vertex, and the second N atom occupies the third position, which is the bottommost vertex. A double bond is present between C 1 and the second N atom and between C 4 and the first N atom. C 4 is single bonded to N. This N atom is single bonded to H on the upper left and H on the upper right. The two rings are fused to each other such that C 2 and C 3 of the 5-membered ring are the C 3 and C 2 of the 6-membered ring, respectively.

Thymine (T) has the following structure: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the bottom-right vertex, and the second N atom occupies the third position, which is the bottom-left vertex. A double bond is present between C 3 and C 4. C 1 is double bonded to O, the second N atom is single bonded to H, C 2 is double bonded to O, C 3 is single bonded to C H 3, and the first N atom is single bonded to C H 3 in the form of a line.

A dashed green line is drawn between the first N atom of the 6-membered ring in adenine and the H single bonded to the second N atom in thymine. A second dashed green line is drawn between the H on the upper right in adenine and the O atom double bonded to C 2 in thymine.



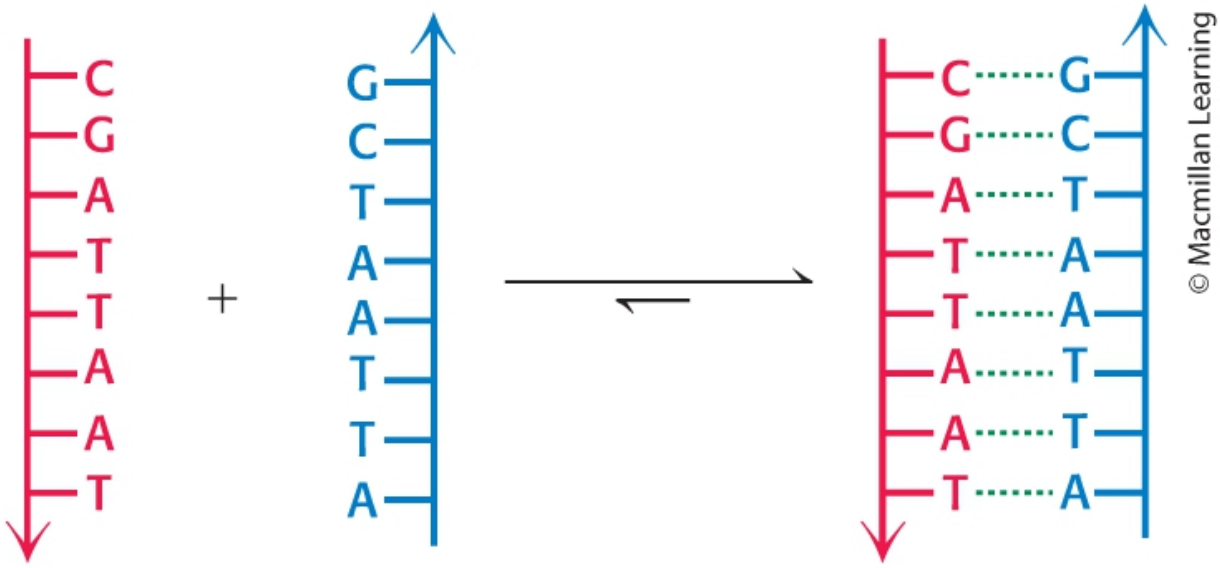
Guanine (G) has the following structure: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 2 N and 3 C atoms. The first N atom occupies the first position, which is the bottom-left vertex, and the second N atom occupies the third position, which is the top-left vertex. A double bond is present between C 1 and the second N atom and between C 2 and C 3. The first N atom is single bonded to C H 3 in the form of a line. This ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation that consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the top-right vertex, and the second N atom occupies the third position, which is the bottommost vertex. A double bond is present between C 1 and the second N atom. The first N atom is single bonded to H. C 1 is single bonded to N. This N atom is single bonded to H on the upper right and H on the lower left. C 4 is double bonded to O. The two rings are fused to each other such that C 2 and C 3 of the 5-membered ring are the C 3 and C 2 of the 6-membered ring, respectively.

Cytosine (C) has the following structure: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. The first N atom, highlighted, occupies the first position, which is the bottom-right vertex, and the second N atom occupies the third position, which is the bottom-left vertex. A double bond is present between the second N atom and C 2 and between C 3 and C 4. The first N atom is single bonded to C H 3 in the form of a line. C 1 is double bonded to O. C 2 is single bonded to N. This N atom is single bonded to H above and H on the lower left.

A dashed green line is drawn between the O atom double bonded to C 4 of the 6-membered ring in guanine and the H atom on the lower left single bonded to N bound to C 2 in cytosine. A second dashed green line is drawn between the H atom single bonded to first N atom of the 6-membered ring in guanine and the second N atom in cytosine. A third dashed green line is drawn between the H on the upper right single bonded to N bound to C 1 in guanine and the O atom double bonded to C 1 in cytosine.

Return to FIGURE 1.6 The nitrogenous bases in DNA form specific Watson–Crick base pairs

Extended description for FIGURE 1.7 Once separated, each strand of the DNA double helix can act as a template for the generation of its partner strand

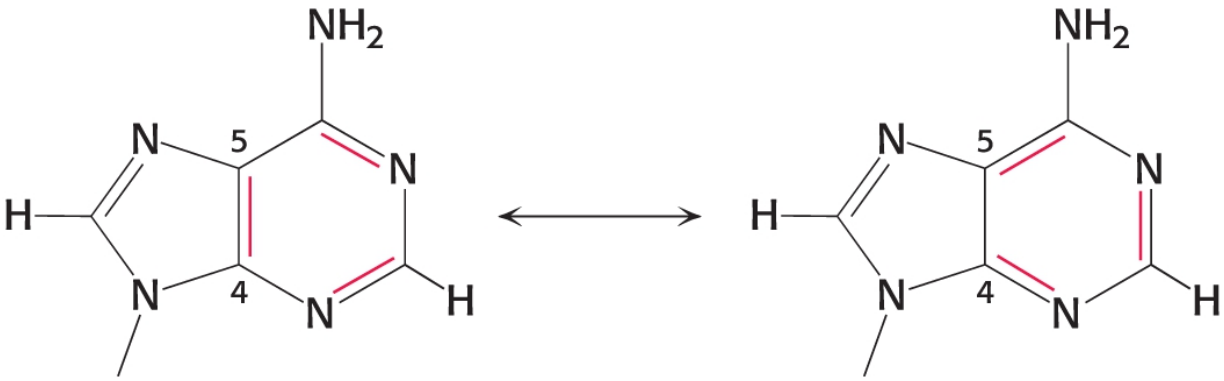


© Macmillan Learning

The parent D N A is illustrated to have two antiparallel strands of D N A held together by complementary base pairing between via hydrogen bonds represented by dashed green lines. The parent strands are shown to separate on the left end, forming a fork. The separated parent strands are each bonded to newly synthesized strands by complementary base pairing via hydrogen bonds represented by dashed green lines.

Return to FIGURE 1.7 Once separated, each strand of the DNA double helix can act as a template for the generation of its partner strand

Extended description for FIGURE 1.8 When two DNA strands with complementary sequences are mixed, they spontaneously assemble to form a double helix

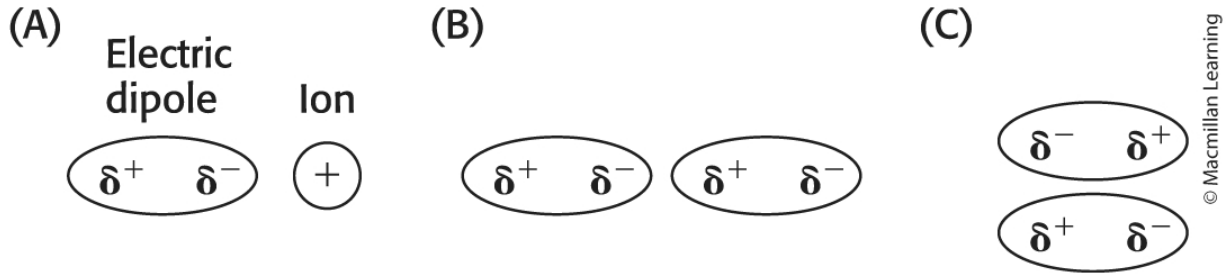


The reversible reaction consists of two reactants and one product. The product side is more preferred in the reaction.

The first reactant is a single stranded D N A (red) having a downward orientation. The second reactant is a single stranded D N A (blue) having an upward orientation. The corresponding nitrogenous bases of the two strands are complementary to each other. The product is a double stranded D N A formed by complementary base pairing of nitrogenous bases of the two reactant D N A strands. The two D N A strands are antiparallel to each other.

Return to FIGURE 1.8 When two DNA strands with complementary sequences are mixed, they spontaneously assemble to form a double helix

Extended description for Resonance structures of adenine



The first resonance structure is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 2 N and 3 C atoms. The first N atom occupies the first position, which is the bottom-left vertex, and the second N atom occupies the third position, which is the top-left vertex. C 2 and C 3 are numbered 5 and 4, respectively. A double bond is present between C 1 and the second N atom. The first N atom is single bonded to C H 3 in the form of a line. C 1 is single bonded to H. This ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation that consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the top-right vertex, and the second N atom occupies the third position, which is the bottommost vertex. A highlighted double bond is present between C 1 and the second N atom, C 2 and C 3, and C 4 and the first N atom. C 1 is single bonded to H, and C 4 is single bonded to N H 2. The two rings are fused to each other such that C 2 and C 3 of the 5-membered ring are the C 3 and C 2 of the 6-membered ring, respectively.

The second resonance structure is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 2 N and 3 C atoms. The first N atom occupies the first position, which is the bottom-left vertex, and the second N atom occupies the third position, which is the top-left vertex. C 2 and C 3 are numbered 5 and 4, respectively. A double bond is present between C 1 and the second N atom. The first N atom is single bonded to C H 3 in the form of a line. C 1 is single bonded to H. This ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation that consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the top-right vertex, and the second N atom occupies the third position, which is the bottommost vertex. A highlighted double bond is present between the first N atom and C 1, the second N atom and C 2, and C 3 and C 4. C 1 is single bonded to H, and C 4 is single bonded to N H 2. The two rings are fused to each other such that C 2 and C 3 of the 5-membered ring are the C 3 and C 2 of the 6-membered ring, respectively.

Extended description for FIGURE 1.9 Electric dipoles can form a variety of noncovalent interactions

Part (A): An oval capsule labeled electric dipole is illustrated with a delta plus charge at its left end and a delta minus charge at its right end. A circle labeled ion carrying a positive charge is illustrated to the right of the electric dipole.
Part (B): Two oval capsules representing electric dipoles are illustrated side-by-side. The first dipole carries a delta plus charge at its left end and a delta minus charge at its right end. The second dipole carries a delta plus charge at its left end and a delta minus charge at its right end.
Part (C): Two oval capsules representing electric dipoles are illustrated one below the other. The dipole at the top carries a delta minus charge at its left end and a delta plus charge at its right end. The dipole at the bottom carries a delta plus charge at its left end and delta minus charge at its right end.

Return to FIGURE 1.9 Electric dipoles can form a variety of noncovalent interactions

Extended description for FIGURE 1.10 Hydrogen bonds are weak noncovalent interactions between specific hydrogen atoms and lone pairs of electrons

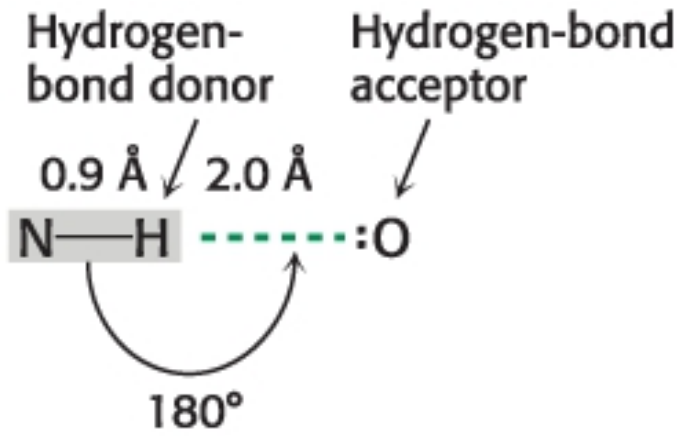
Pair 1:

Hydrogen-bond donor: H, single bond, H. The first H carries a delta minus charge and the second H carries a delta plus charge.
Hydrogen-bond acceptor: N with a lone pair of electrons and a delta minus charge.
A dashed green line is drawn between the second H and the N with a lone pair of electrons.

Pair 2:

Hydrogen-bond donor: N, single bond, H.
Hydrogen-bond acceptor: O having a lone pair of electrons.
A dashed green line is drawn between H and O.

Pair 3:



Hydrogen-bond donor: O, single bond, H.
Hydrogen-bond acceptor: N having a lone pair of electrons.
A dashed green line is drawn between H and N.

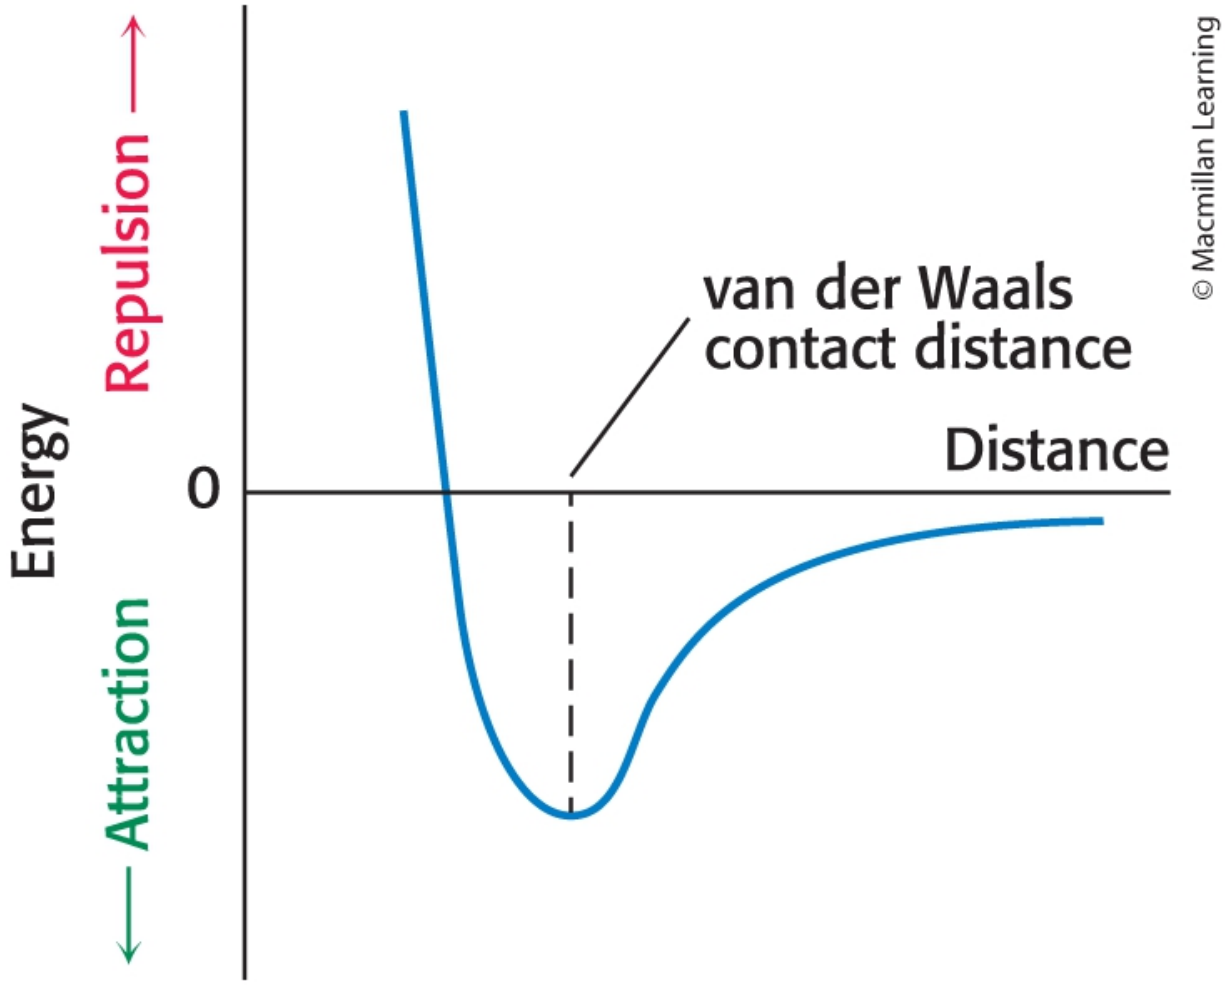
Pair 4:

Hydrogen-bond donor: O, single bond, H.
Hydrogen-bond acceptor: O having a lone pair of electrons.
A dashed green line is drawn between the O bonded to H and the O with a lone pair of electrons.

Return to FIGURE 1.10 Hydrogen bonds are weak noncovalent interactions between specific hydrogen atoms and lone pairs of electrons

Extended description for An example of hydrogen bonding

Hydrogen-bond donor: N, single bond, H. The bond length of the single bond is 0.9 Angstrom.



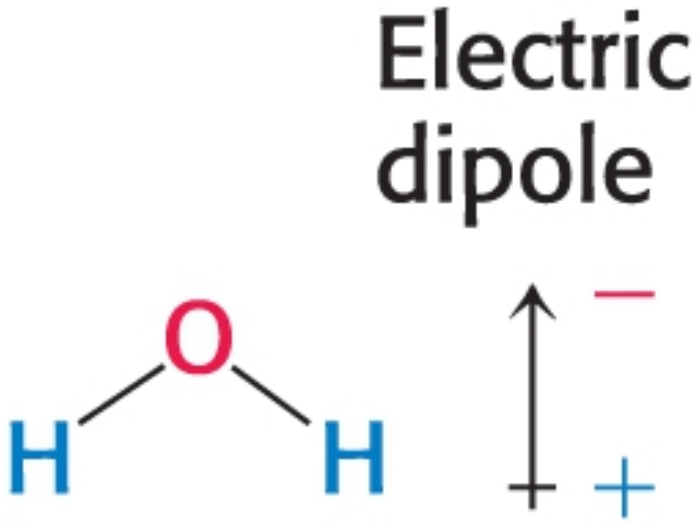
Hydrogen-bond acceptor: O with 2 lone pairs of electrons.

A dashed green line is drawn between H and O representing a hydrogen bond. The bond length of the hydrogen bond is 2.0 Angstrom.

The angle between the single bond between N and H and the hydrogen bond is 180 degrees.

Return to An example of hydrogen bonding

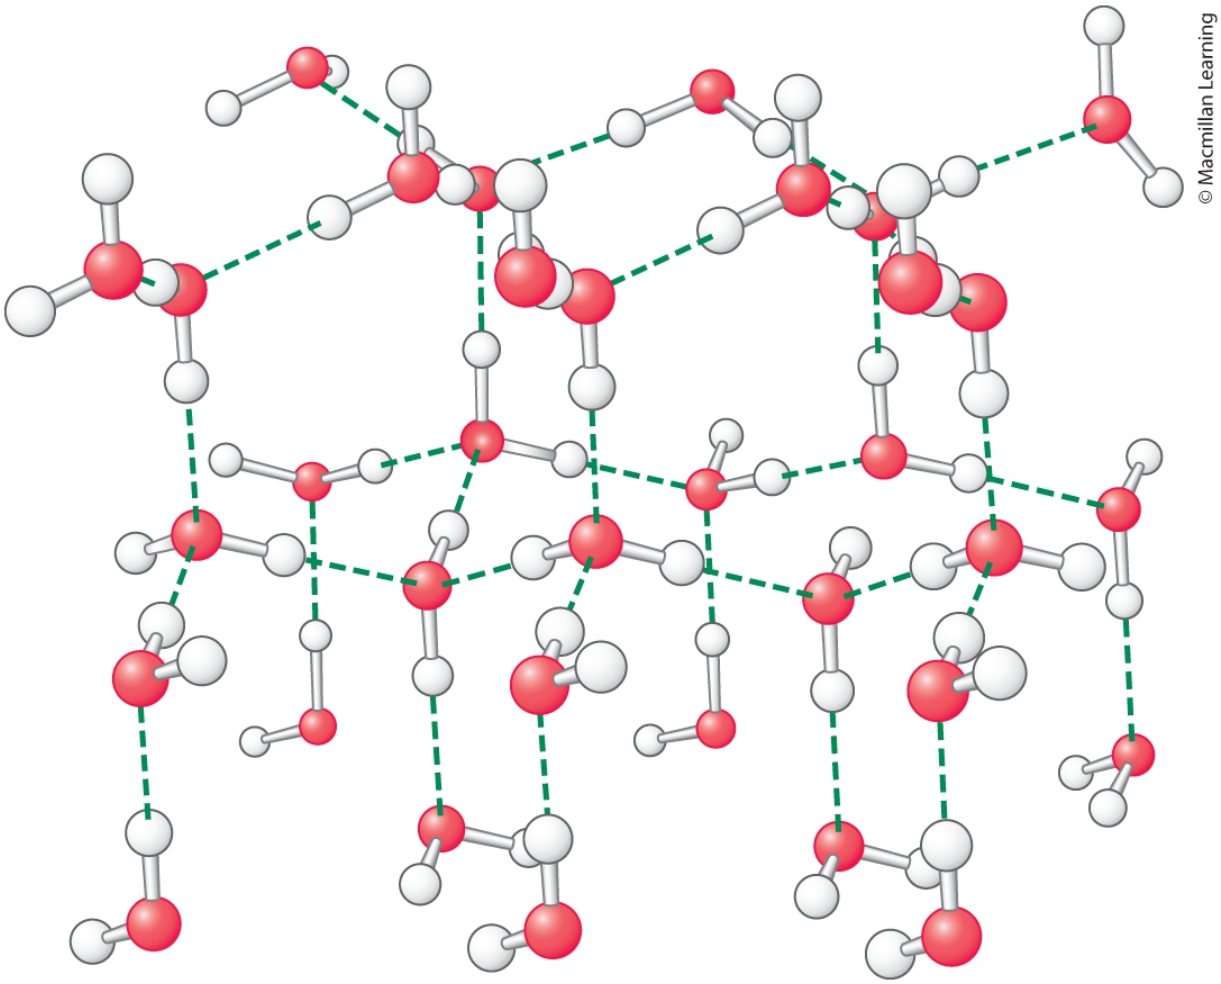
Extended description for FIGURE 1.11 The energy of a van der Waals interaction varies and is most favorable at the van der Waals contact distance



The horizontal axis is labeled Distance, and the vertical axis is labeled Energy with the positive vertical axis pertaining to Repulsion and the negative vertical axis pertaining to Attraction. The intersection of the axes is labeled 0. A curve starts at a point close to 0 distance and high on the repulsion axis and drops steeply to a point further on the distance axis and the midpoint of the attraction axis. The curve then rises gradually and becomes almost

parallel to the distance axis. The point on the distance axis that corresponds to the point of dip is labeled van der Waals contact distance.

Return to FIGURE 1.11 The energy of a van der Waals interaction varies and is most favorable at the van der Waals contact distance

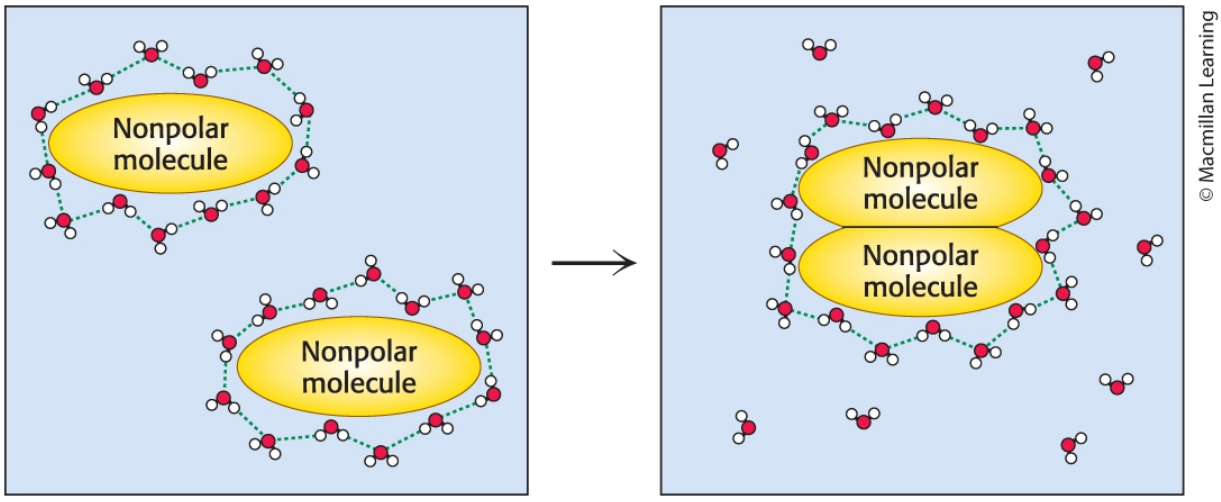


Extended description for Electric dipole in a water molecule

A central O atom is single bonded to H on the lower left and lower right. An upward arrow with a crossed tail is labeled electric dipole. The arrow tip is at O and carries a negative charge. The tail is at the H atoms and carries a positive charge.

Return to Electric dipole in a water molecule

Extended description for FIGURE 1.12 The structure of ice involves extensive hydrogen bonding

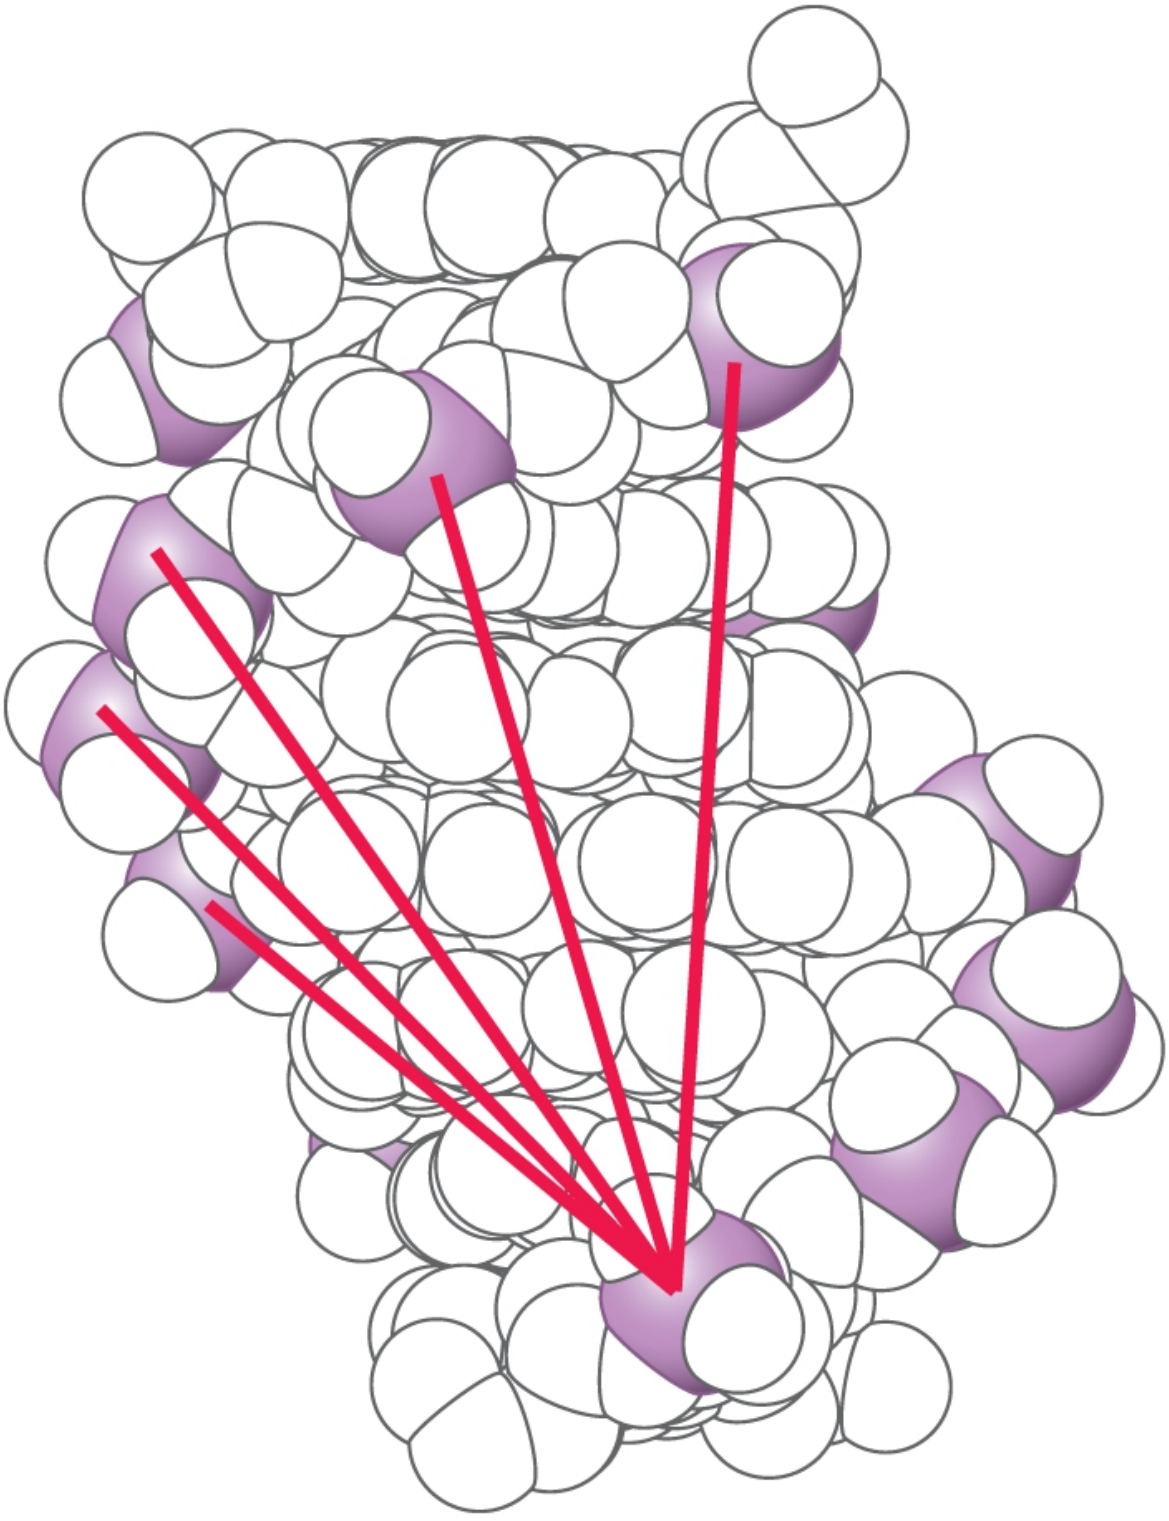


Ice is illustrated to be made up of water molecules. The ball-and-stick model of water molecules is as follows: A red sphere representing an O atom is bonded to a white sphere representing an H atom on the lower left and on the lower right. Dashed green lines are drawn between H and O atoms of adjacent water molecules, forming hexagonal shapes. Two parallel sheets of such fused hexagons are illustrated. Dashed green lines are drawn between H

and O atoms of adjacent water molecules of the top and the bottom sheet. The dashed green lines represent hydrogen bonds.

Return to FIGURE 1.12 The structure of ice involves extensive hydrogen bonding

Extended description for FIGURE 1.13 The hydrophobic effect is due to the behavior of water molecules



Two stages are shown as follows:

Stage 1: Two ovals labeled nonpolar molecules are shown far apart. Each nonpolar molecule is surrounded by ball-and-stick models of water molecules. Dashed green lines are drawn between the O atoms and H atoms of adjacent water molecules.
Stage 2: The nonpolar molecules are shown to aggregate together, one on top of the other. Ball-and-stick models of water molecules are shown to surround the aggregated nonpolar molecules. Dashed green lines are drawn between the O atoms and H atoms of adjacent water molecules. Some water molecules are shown to be suspended freely in the solution.

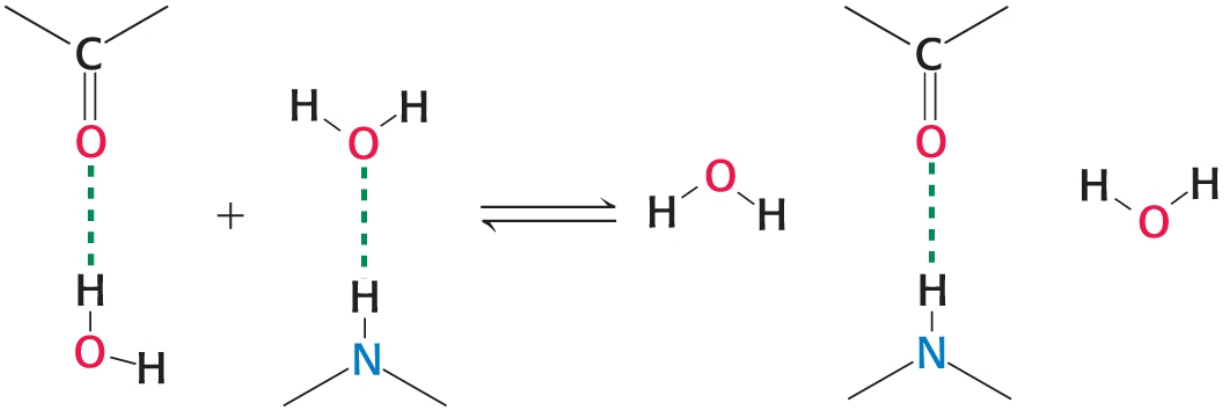
Extended description for FIGURE 1.14 Ionic interactions among phosphate groups oppose the

formation of the DNA double helix



© Macmillan Learning

The space-filling model of a D N A double-helix structure is shown. The P atoms are represented by purple spheres and the other atoms are represented by white spheres. Red lines from one purple sphere are drawn to purple spheres of the groove above.

Return to FIGURE 1.14 Ionic interactions among phosphate groups oppose the formation of the DNA double helix

Extended description for Example of a reversible reaction

The reaction consists of three reactants and three products.

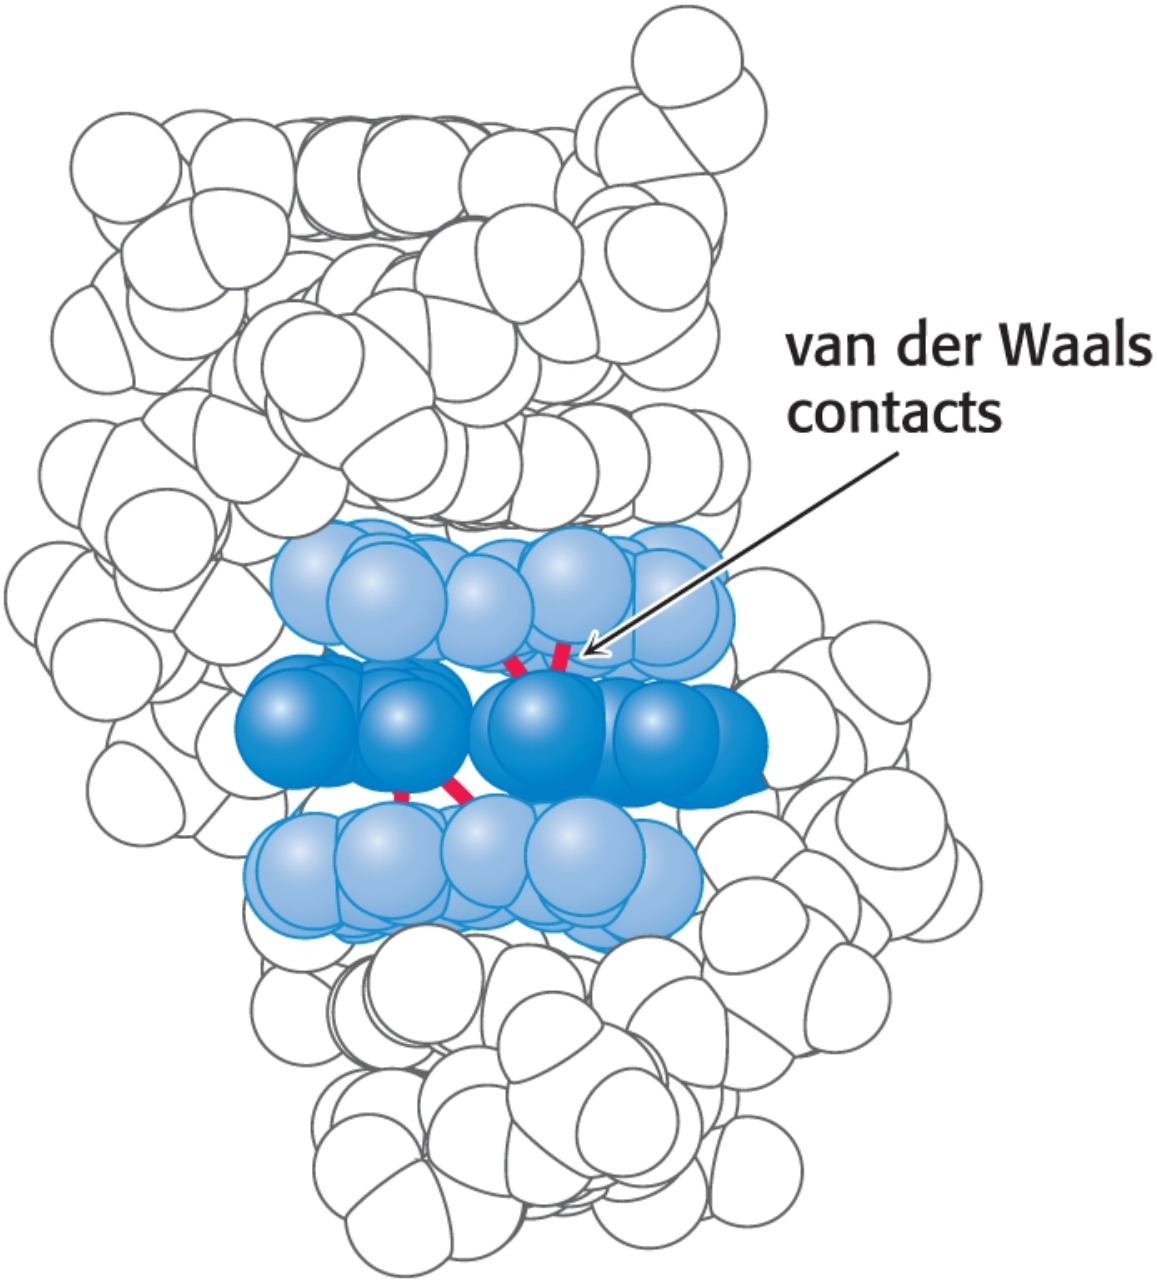
The first reactant has the following structure: A central C atom is single bonded to C H 3 on the upper left and C H 3 on the upper right each in the form of a line. The central C atom is double bonded to O, highlighted in red, below.

The second reactant has the following structure: A central O atom, highlighted in red, is single bonded to H above and H on the lower right. The second reactant is placed below the first reactant. A dashed green line is drawn between the O atom of the first reactant and the H above of the second reactant.

The third reactant has the following structure: A central N atom, highlighted in blue, is single bonded to C H 3 on the lower left and C H 3 on the lower right each in the form of a line. The central N atom is single bonded to H above.

Another molecule of the second reactant is placed above the third reactant. A dashed green line is drawn between the O atom of the second molecule and the H atom above of the third reactant.

The first product has the following structure: A central O atom, highlighted in red, is single bonded to H on the lower left and H on the lower right.



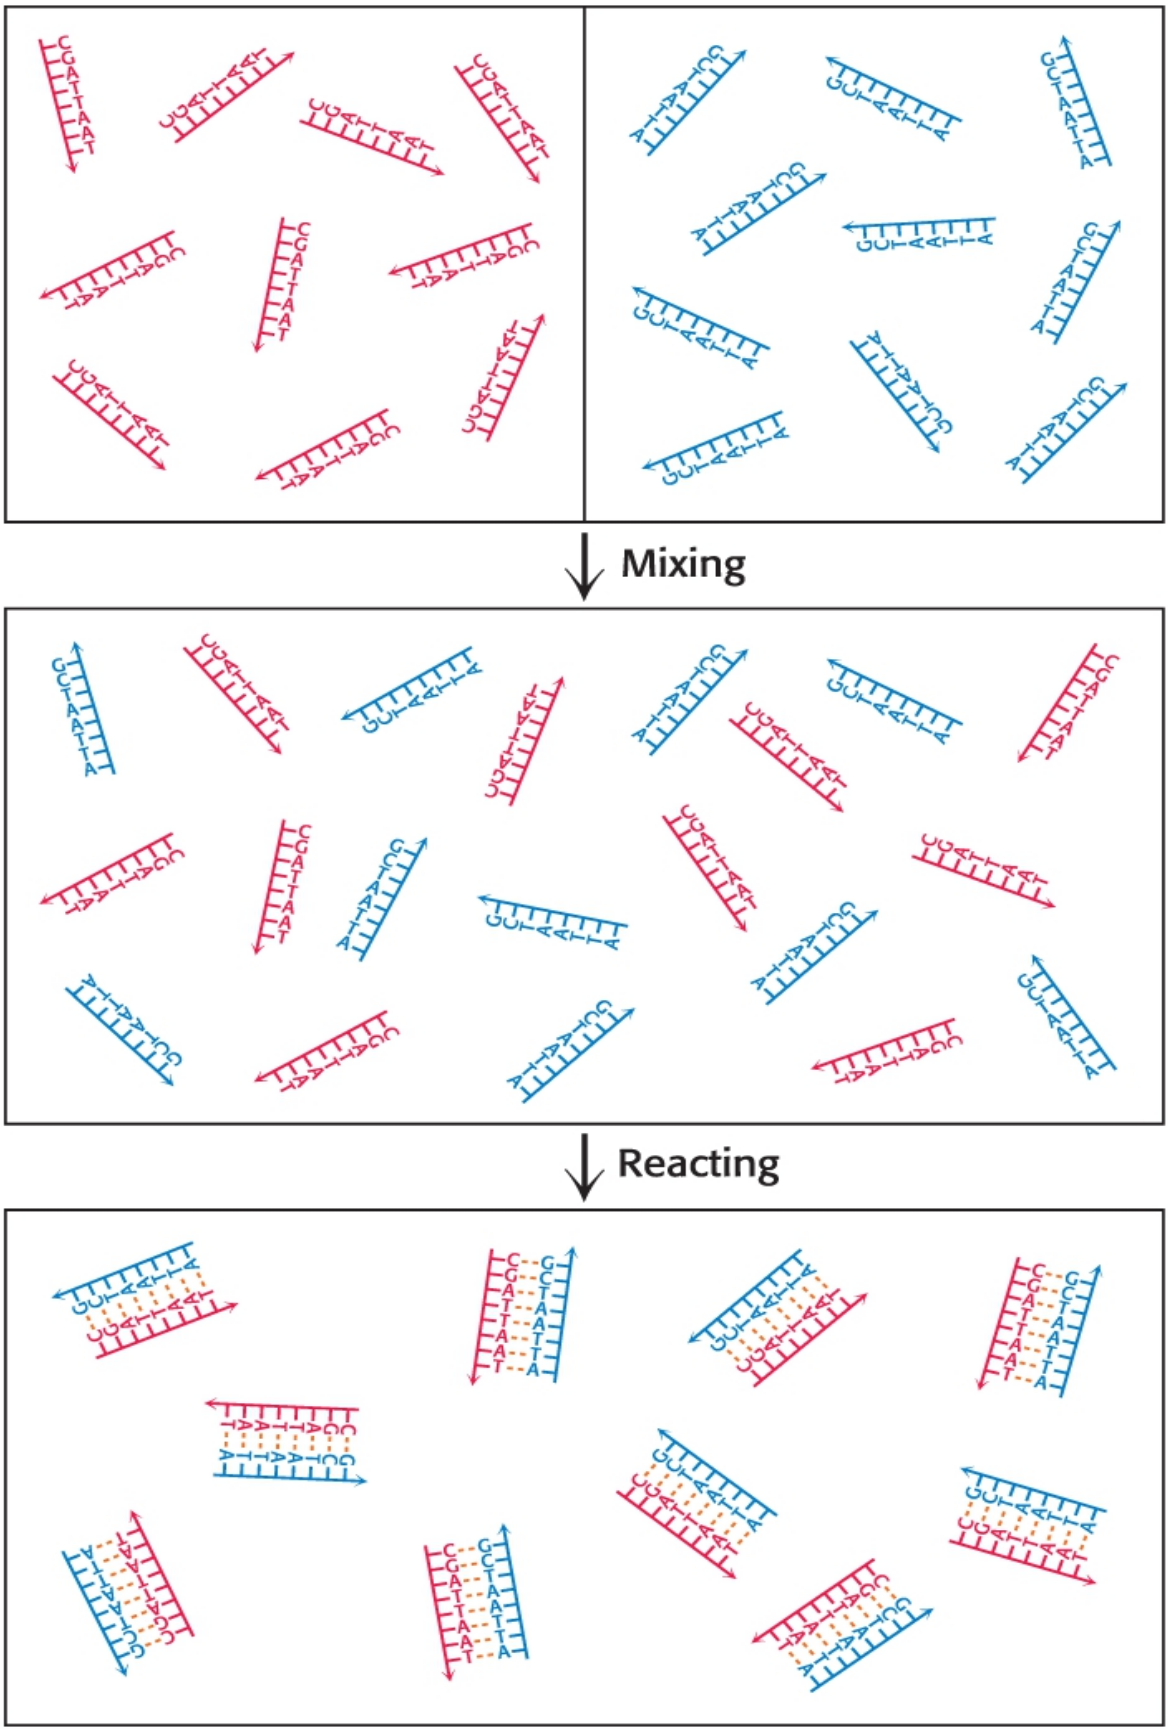
The second product is made of two molecules connected by a dashed green line. The first molecule has the following structure: A central C atom is single bonded to C H 3 on the upper left and C H 3 on the upper right each in the form of a line. The central C atom is double bonded to O, highlighted in red, below. The second molecule is placed below the first molecule and has the following structure: A central N atom, highlighted in blue, is single bonded to C H 3 on the lower left and C H 3 on the lower right each in the form of a line. The central N atom is single bonded to H above. The dashed green line is drawn between the O atom of the first molecule and the H atom above of the second molecule.

The third product has the following structure: A central O atom, highlighted in red, is single bonded to H on the upper left and H on the upper right.

The dashed green lines represent hydrogen bonds.

Return to Example of a reversible reaction

Extended description for FIGURE 1.15 Optimal base stacking allows many weak, but favorable, van der Waals contacts that drive double- helix formation



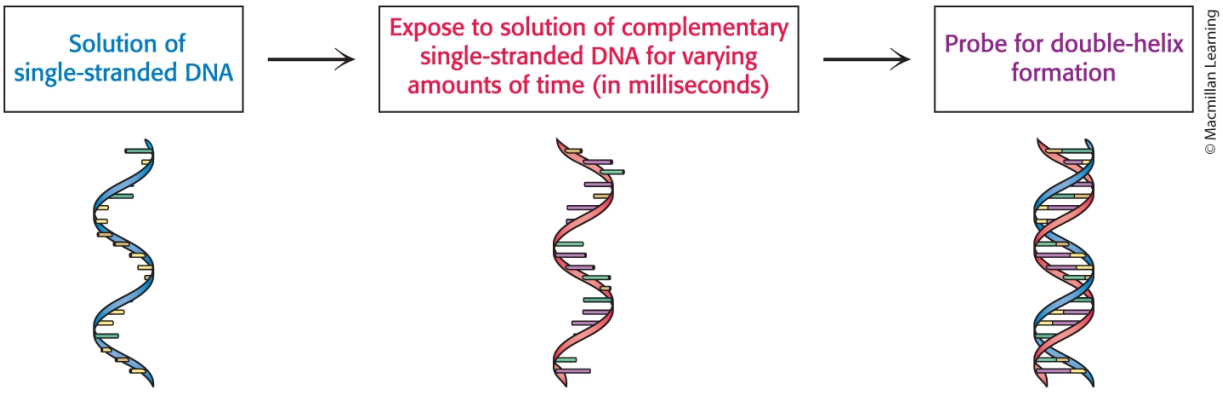
© Macmillan Learning

The space-filling model of a D N A double-helix structure is shown. In the middle portion, adjacent bases are shown to stack one on top of the other, forming three stacked layers. Atoms of the top and bottom layers are colored light blue and the atoms of the middle layer are colored dark blue. Short red lines labeled van der Waals contacts are drawn between spheres of two adjacent layers.

Return to FIGURE 1.15 Optimal base stacking allows many weak, but favorable, van der Waals contacts that drive double- helix formation

Extended description for FIGURE 1.16 Double-helix

formation entails a loss of entropy



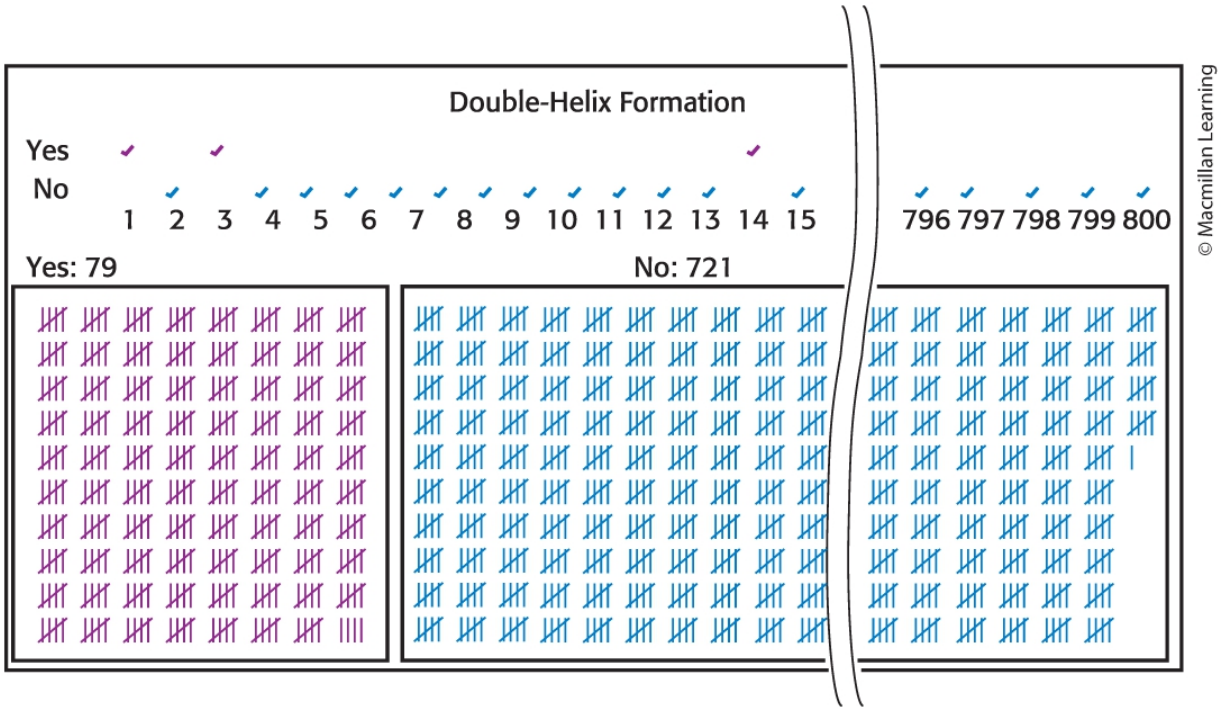
© Macmillan Learning

The process involves 2 steps as follows:

Step 1, mixing: Two solutions are shown. The first solution contains red single-stranded D N A molecules. The second solution contains blue single-stranded D N A molecules. The two solutions are shown to mix together.
Step 2, reacting: A complementary red and a blue strand of D N A are shown to come together to form a duplex.

Return to FIGURE 1.16 Double-helix formation entails a loss of entropy

Extended description for FIGURE 1.17 DNA double-helix formation can be probed at the single-molecule level

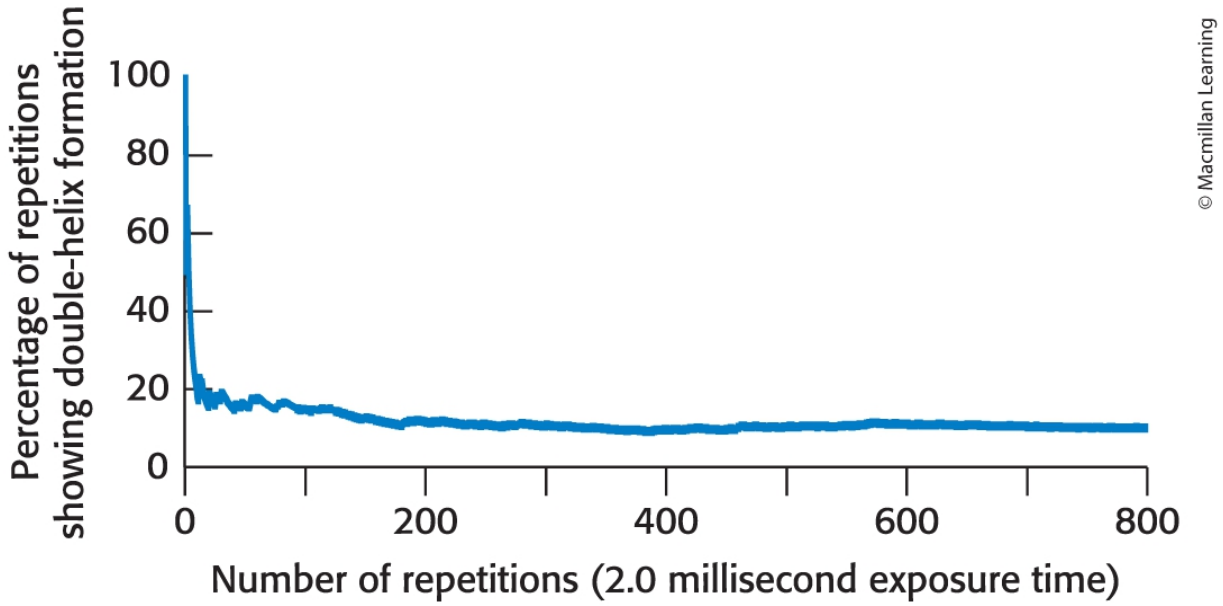


The process involves 3 steps as follows:

Step 1: Solution of single-stranded D N A. A blue helical single-stranded D N A is shown. The sugar-phosphate backbone is represented by a blue ribbon-like structure. The nitrogenous bases are represented by short blue lines, perpendicular to the backbone. Step 2: Expose to a solution of complementary single-stranded DNA for varying amounts of time (in milliseconds). A red helical single-stranded D N A molecule is shown. The sugar-phosphate backbone is represented by a red ribbon-like structure. The nitrogenous bases are represented by short red lines, perpendicular to the backbone. Step 3: Probe for double-helix formation. The red and blue helical single-stranded D N A molecules are shown to come together to form a D N A double helix by complementary base pairing. The red and the blue ribbon-like backbones of the single-stranded D N A molecules are shown to twist together to form a double helix. Adjacent complementary nitrogenous bases of the two strands are shown to join together, forming a ladder-like pattern.

Return to FIGURE 1.17 DNA double-helix formation can be probed at the single-molecule level

Extended description for A table corresponding to the experiments based on double helix formation



The table has a common heading titled Double-Helix Formation. A row labeled Yes followed by a row labeled No are shown for the individual trials ranging from 1 to 800.

A tally box for Yes ticked for trials 1, 3, and 14 is shown. The number of times the result was a Yes for the detection of a double helix is 79.

A tally box for No ticked for all trials except 1, 3, and 14 is shown. The number of times the result was a No for the detection of a double helix is 721.

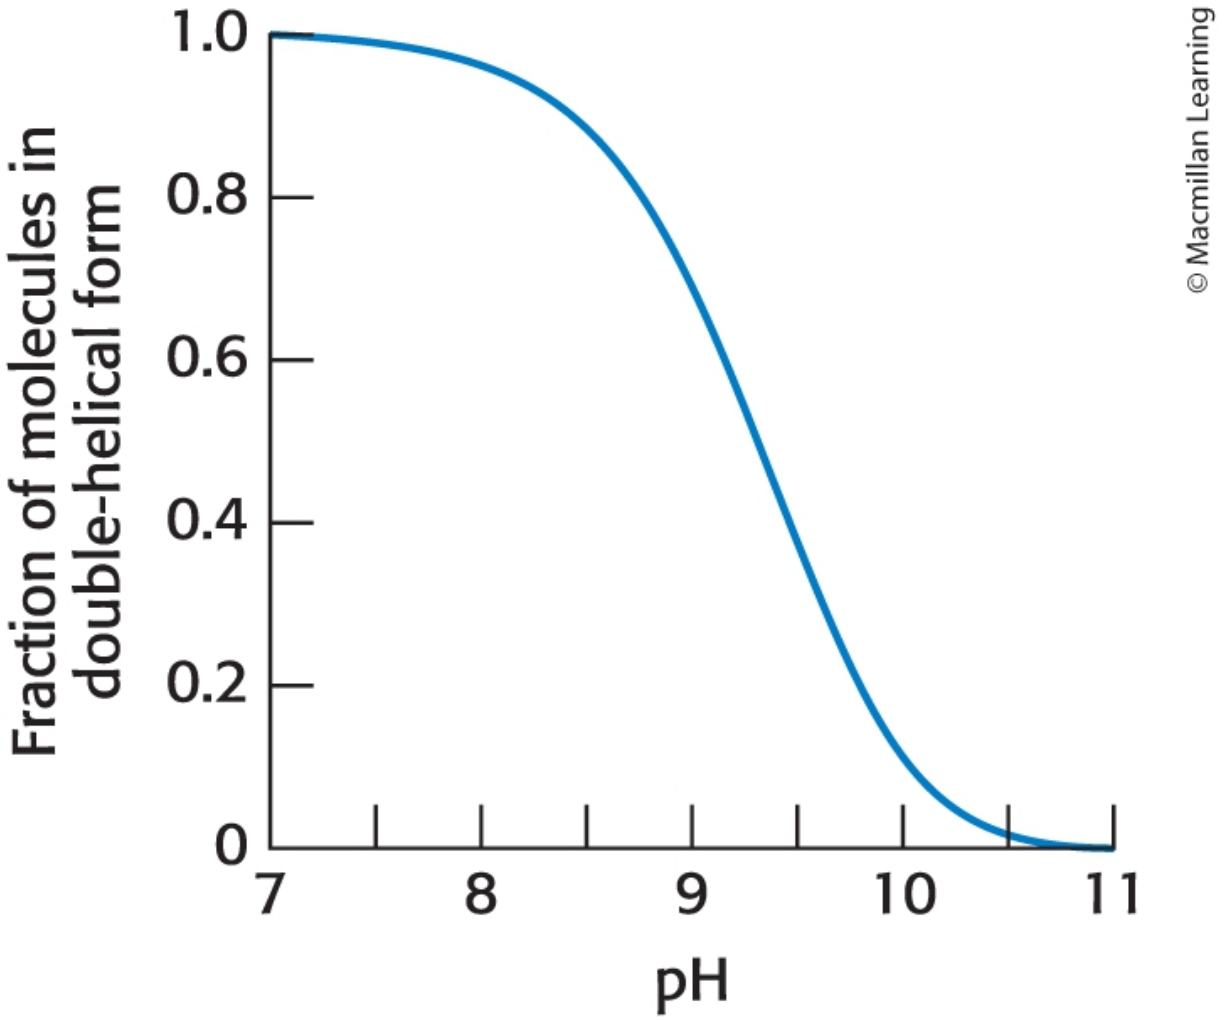
[Return to A table corresponding to the experiments based on double helix formation]

Extended description for FIGURE 1.19 A plot of the running average of the number of experimental repetitions observing double-helix formation reveals eventual convergence on a stable value

© Macmillan Learning

The horizontal axis is labeled Number of repetitions (2.0 millisecond exposure time) and ranges from 0 to 800 in increments of 100 units. The vertical axis is labeled Percentage of repetitions showing the double-helix formation and ranges from 0 to 100 in increments of 20 units. A plotline starts at (0, 100) and sharply drops to (10, 20), followed by a gradual decline to nearly (800, 10).

Return to FIGURE 1.19 A plot of the running average of the number of experimental repetitions observing double-helix formation reveals eventual convergence on a stable value



Extended description for Dissociation of water

The reaction consists of one reactant and two products. The reactant is H 2 O. A reversible reaction arrow leads to the products. The first product is H superscript plus. The second product is O H superscript minus.

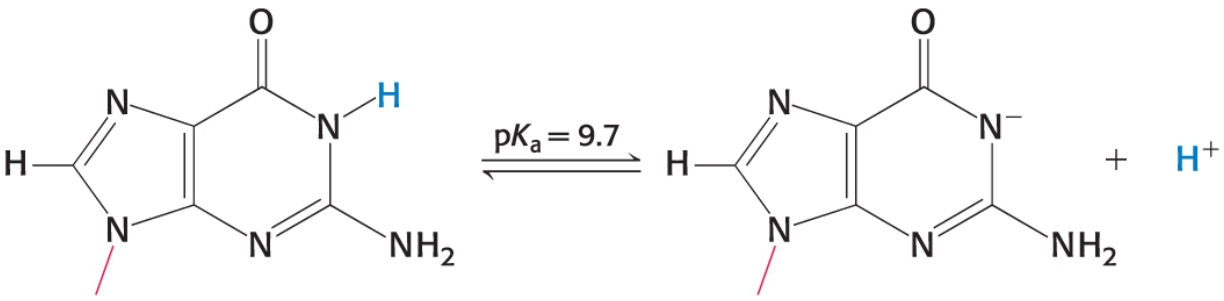
Extended description for FIGURE 1.20 DNA strands are separated by the addition of a base



© Macmillan Learning

The horizontal axis is labeled p H and ranges from 7 to 11 in increments of 1 unit. The vertical axis is labeled Fraction of molecules in double-helical form and ranges from 0 to 1.0 in increments of 0.2 units. A curve starts at (7, 1.0), gradually drops to (9, 0.9), followed by a sharp decline to nearly (11, 0). The curve has an inverted S-shape.

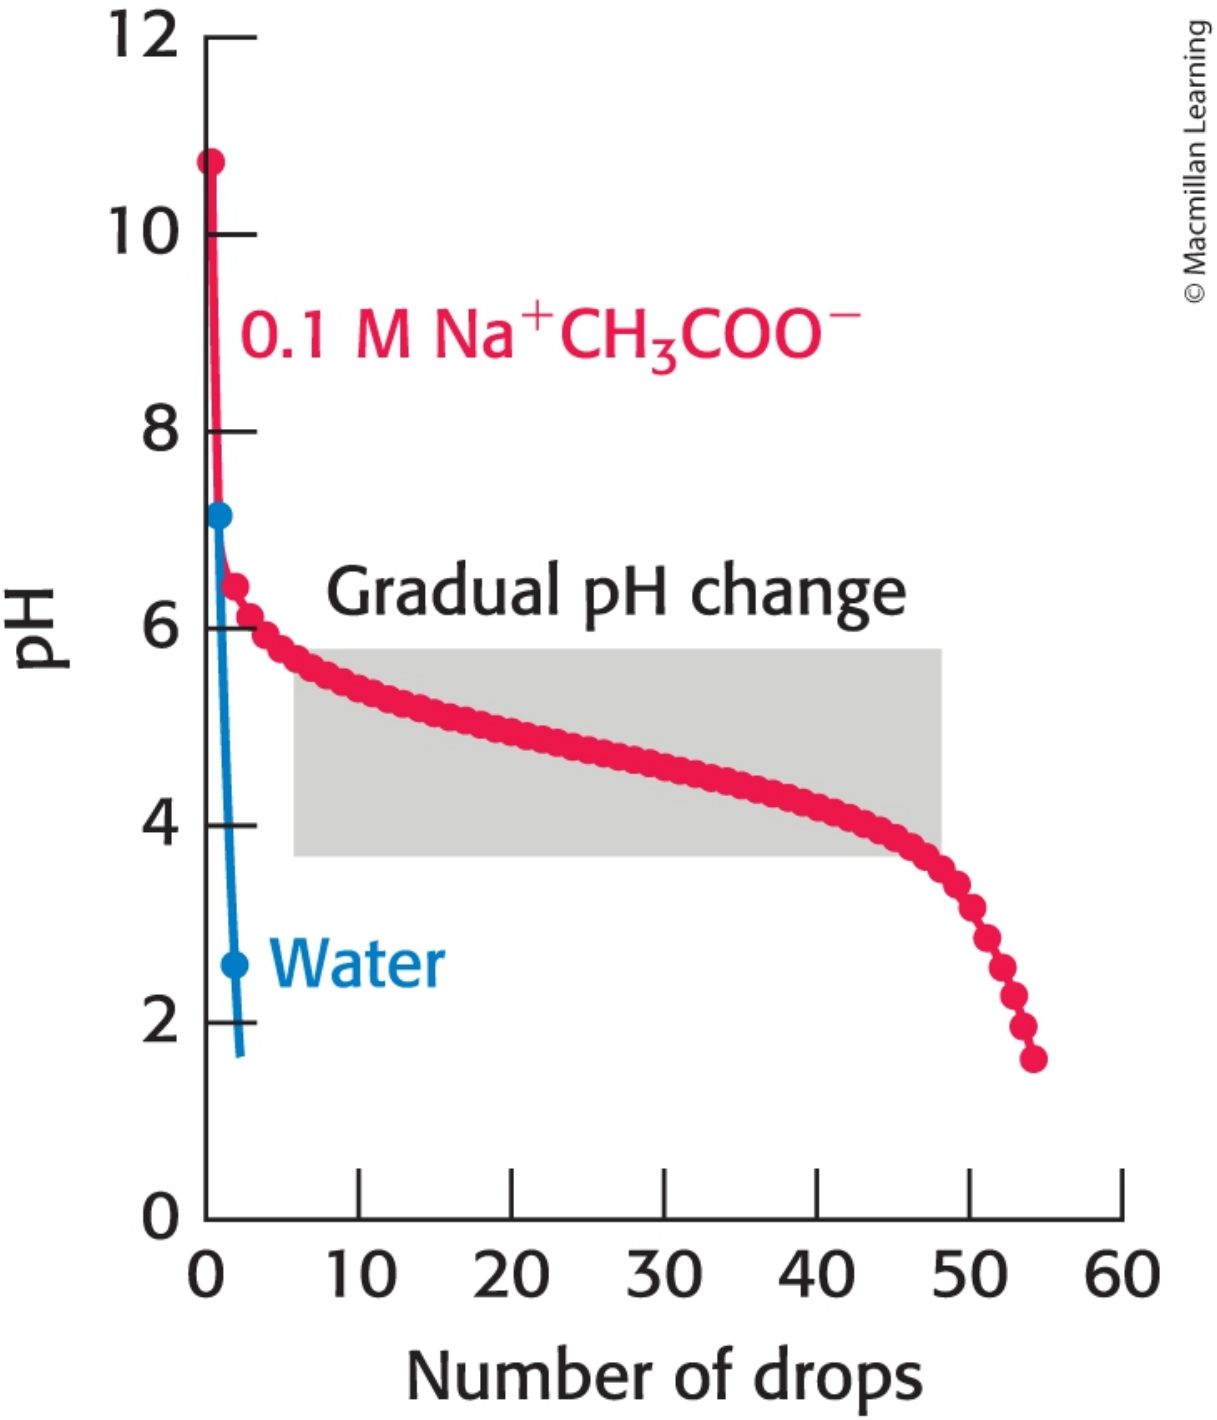
Return to FIGURE 1.20 DNA strands are separated by the addition of a base

Extended description for Reversible reaction of guanine

Guanine (G)

The reaction consists of one reactant and two products.

The reactant labeled Guanine (G) has the following structure: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 2 N and 3 C atoms. The first N atom occupies the first position, which is the bottom-left vertex, and the second N atom occupies the third position, which is the top-left vertex. A double bond is present between C 1 and the second N atom and between C 2 and C 3. The first N atom is single bonded to C H 3 in the form of a red line. C 1 is single bonded to H. This ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation that consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the top-right vertex, and the second N atom occupies the third position, which is the bottommost vertex. A double bond is present between C 1 and the second N atom. The first N atom is single bonded to H (highlighted in blue), C 1 is single bonded to N H 2, and C 4 is double bonded to O. The two rings are fused to each other such that C 2 and C 3 of the 5-membered ring are the C 3 and C 2 of the 6-membered ring, respectively.



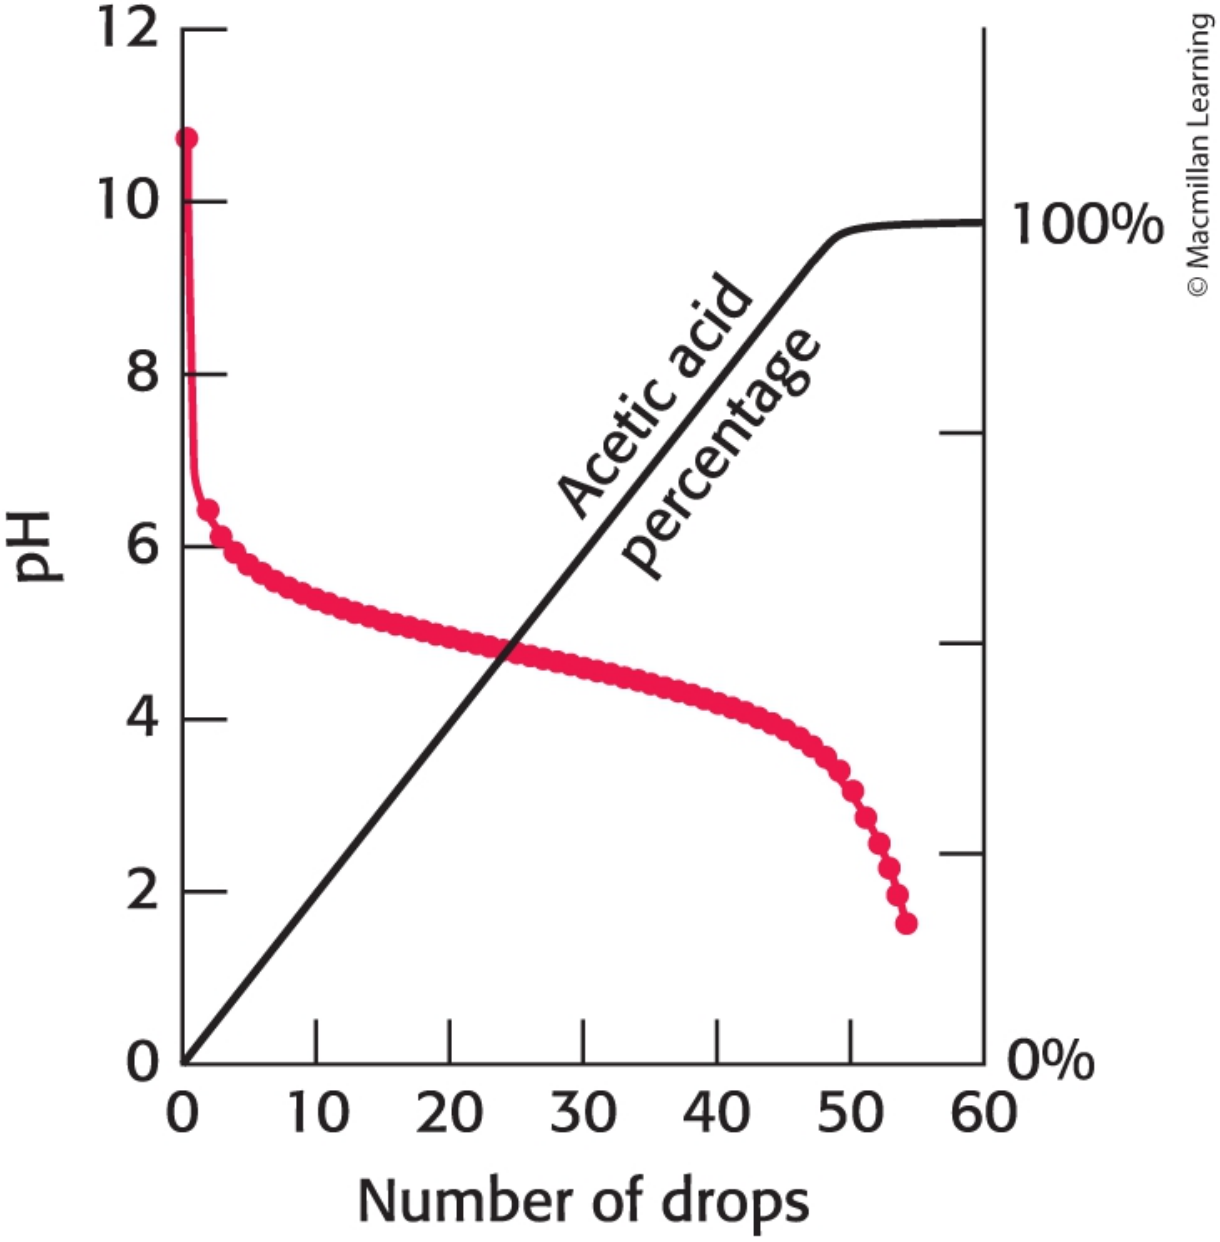
The reaction arrow is labeled p K subscript a equals 9.7.

The first product has the following structure: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 2 N and 3 C atoms. The first N atom occupies the first position, which is the bottom-left vertex, and the second N atom occupies the third position, which is the top-left vertex. A double bond is present between C 1 and the second N atom and between C 2 and C 3. The first N atom is single bonded to C H 3 in the form of a red line. C 1 is single bonded to H. This ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation that consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the top-right vertex, and the second N atom occupies the third position, which is the bottommost vertex. A double bond is present between C 1 and the second N atom. The first N atom carries a negative charge. C 1 is single bonded to N H 2, and C 4 is double bonded to O. The two rings are fused to each other such that C 2 and C 3 of the 5-membered ring are the C 3 and C 2 of the 6-membered ring, respectively.

The second product is H superscript plus, highlighted in blue.

Return to Reversible reaction of guanine

Extended description for FIGURE 1.21 Buffers resist changes in pH over a narrow pH range



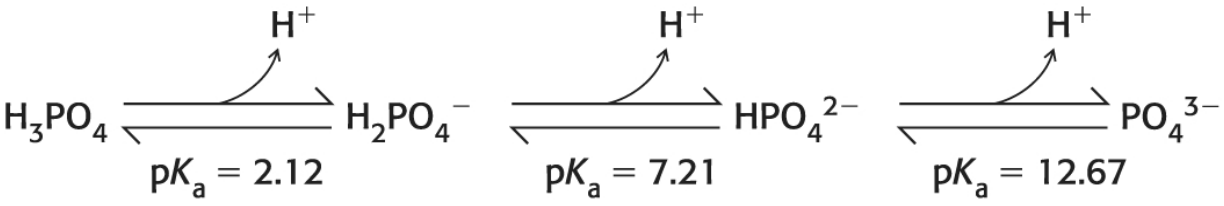
© Macmillan Learning

The horizontal axis is labeled Number of drops and ranges from 0 to 60 in increments of 10 units. The vertical axis is labeled p H and ranges from 0 to 12 in increments of 2 units.

Water: The trend line starts at (1, 7) and sharply drops to (2, 2.5).
0.1 M N a superscript plus C H 3 C O O superscript minus: The trendline starts at nearly (1, 11), sharply drops to (2, 6.5), gradually declines to nearly (50, 3.5), followed by a drop to nearly (55, 1.5).
A rectangle labeled Gradual p H change encloses the curve between 8 and 50 along the horizontal axis and between 5.5 and 6.5 along the vertical axis.

Return to FIGURE 1.21 Buffers resist changes in pH over a narrow pH range

Extended description for FIGURE 1.22 Added hydrogen ions protonate buffer components rather than remaining free



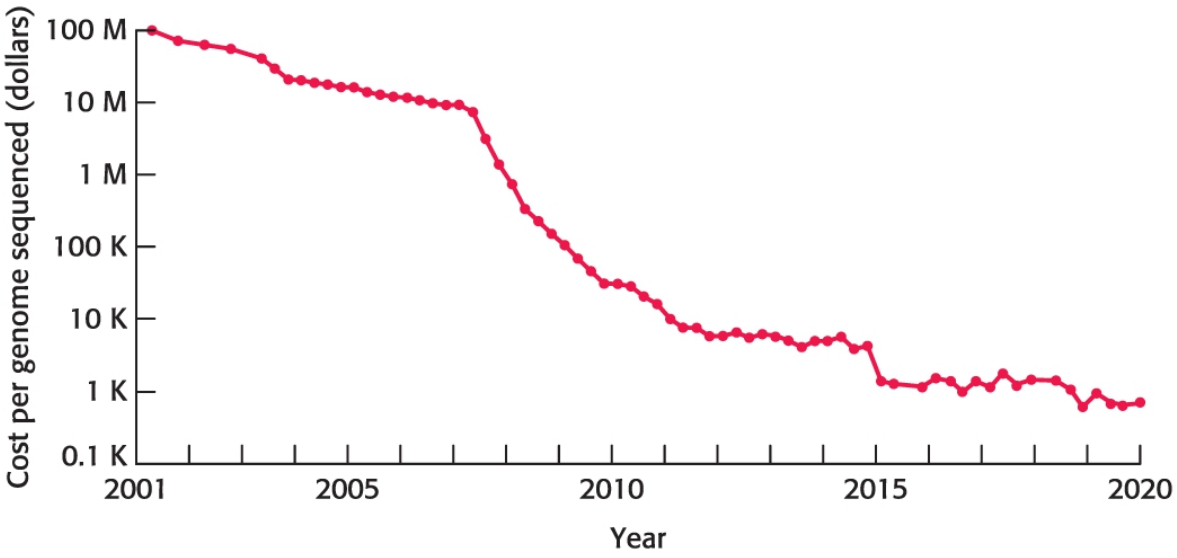
The horizontal axis is labeled Number of drops and ranges from 0 to 60 in increments of 10 units. The left vertical axis is labeled p H and

ranges from 0 to 12 in increments of 2 units. the right vertical axis represents acetic acid percentage and ranges from 0 percent to 100 percent.

Change in p H: The trendline starts at nearly (1, 11), sharply drops to (2, 6.5), gradually declines to nearly (50, 3.5), followed by a drop to nearly (55, 1.5).
Acetic acid percentage: The curve starts at (0, 0 percent), rises to nearly (50, 100 percent), and then runs parallel to the horizontal axis.

Return to FIGURE 1.22 Added hydrogen ions protonate buffer components rather than remaining free

Extended description for Reversible deprotonation reaction of phosphoric acid



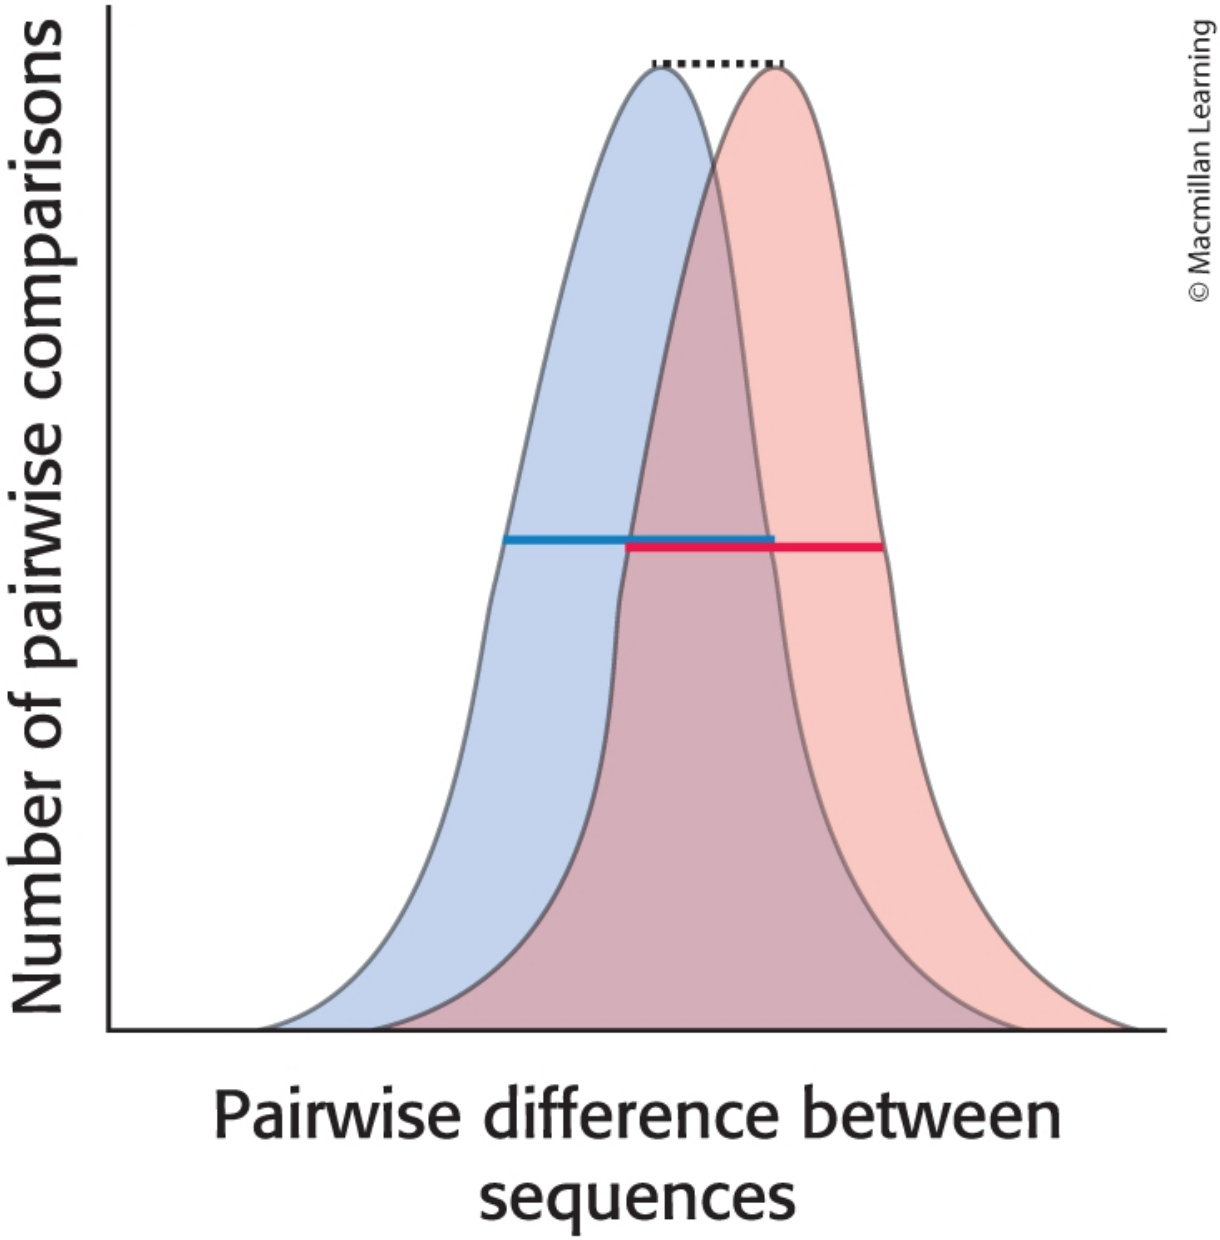
The first reactant is H 3 P O 4. One H superscript plus ion is lost to form the product, H 2 P O 4 superscript minus ion. The reaction arrow is labeled p K subscript a equals 2.12.

The product of the first reaction is the reactant of the second reaction. One H superscript plus ion is lost to form the product, H P O 4 superscript 2 minus ion. The reaction arrow is labeled p K subscript a equals 7.21.

The product of the second reaction is the reactant of the third reaction. One H superscript plus ion is lost to form the product, P O 4 superscript 3 minus ion. The reaction arrow is labeled p K subscript a equals 12.67.

Return to Reversible deprotonation reaction of phosphoric acid

Extended description for FIGURE 1.23 The cost to sequence a human genome has decreased dramatically over the past two decades

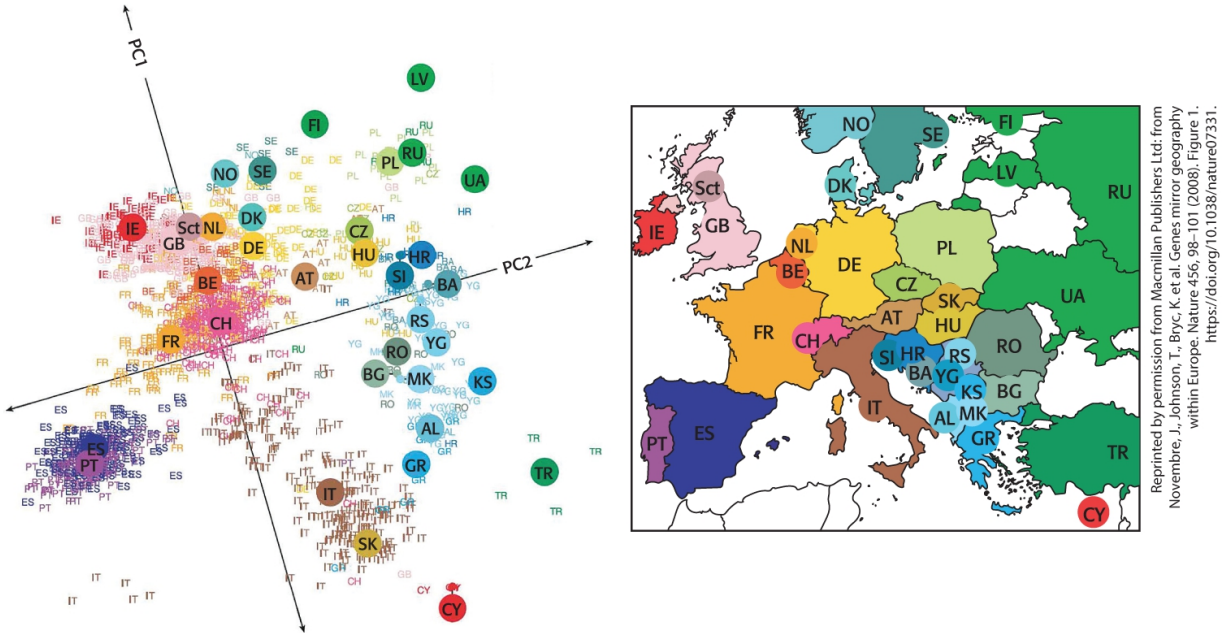


© Macmillan Learning

The horizontal axis is labeled Year and ranges from 2001 to 2020 in increments of 5 units. The vertical axis is labeled Cost per genome sequenced (dollars) and ranges from 0.1 K to 100 M in geometric increments of 10 units. A trendline starts at (2001, 100 M), gradually drops to nearly (2007, 10 M), followed by a decline to (2020, 0.1 K) with minor fluctuations.

Return to FIGURE 1.23 The cost to sequence a human genome has decreased dramatically over the past two decades

Extended description for FIGURE 1.24 DNA sequences vary more within populations than they do between populations



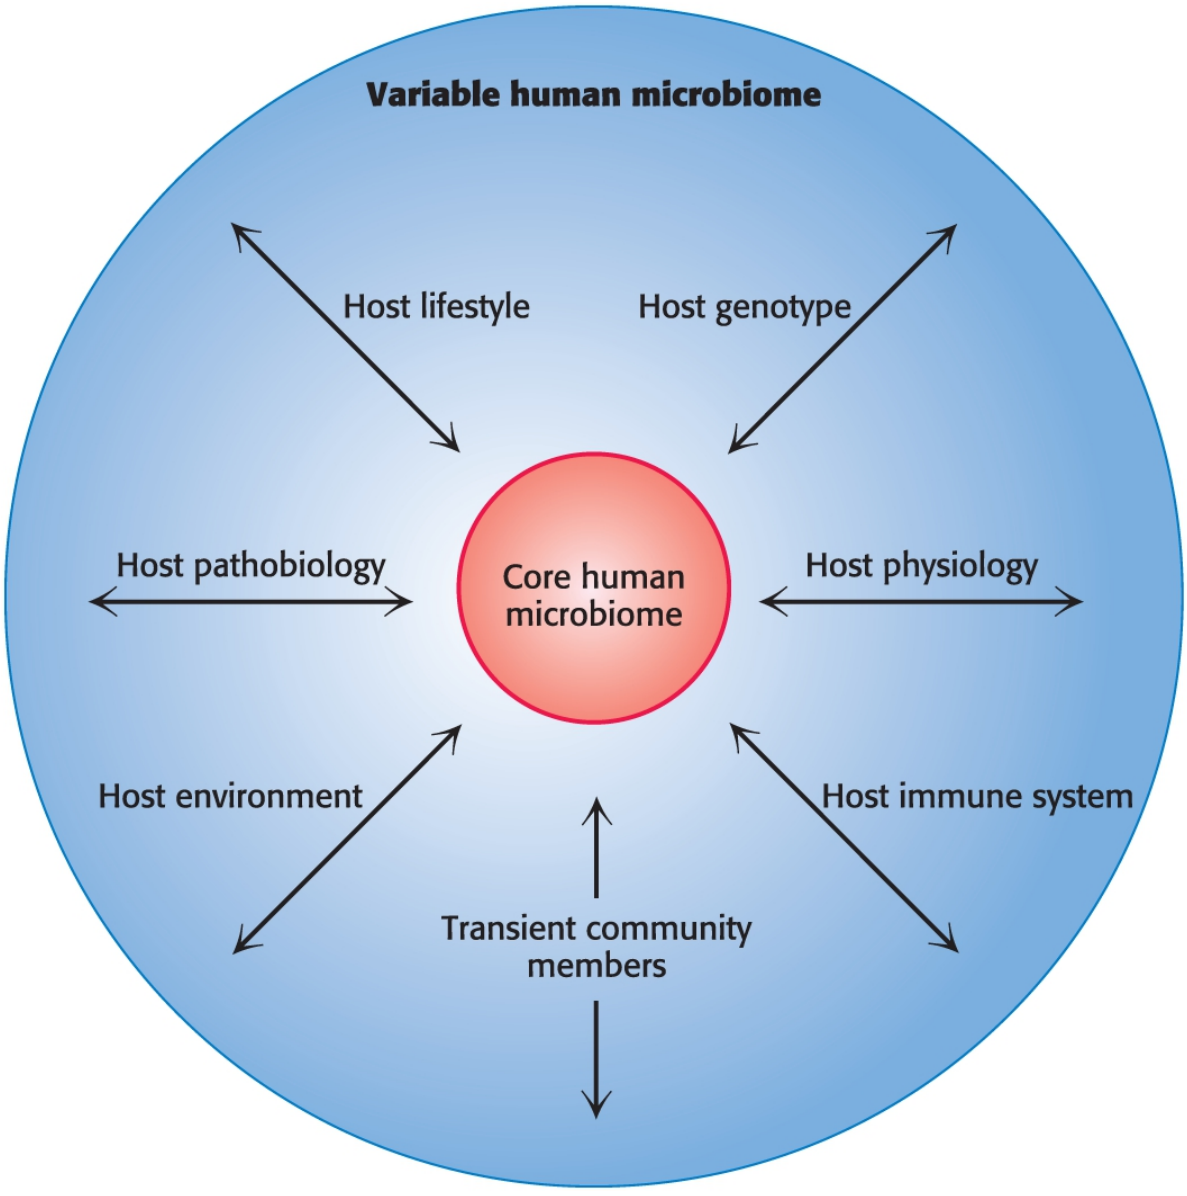
The horizontal axis is labeled Pairwise difference between sequences. The vertical axis is labeled Number of pairwise

comparisons. A blue bell-shaped curve has a peak corresponding to the upper end of the vertical axis. A red bell-shaped curve partially overlaps with the blue curve on the blue curve's left and has the same peak height. A black horizontal line is drawn between the peaks of the two curves. A blue horizontal line is drawn through the middle of the blue curve. A red horizontal is drawn through the middle of the blue curve. The red and the blue lines are longer than the black line.

Return to FIGURE 1.24 DNA sequences vary more within populations than they do between populations

Extended description for FIGURE 1.25 Genomic information can confirm locations of ancestry

A map of Europe is color-coded as follows:



Poland, the Czech Republic, Ukraine, Turkey, Latvia, and Russia are colored in shades of green.
Romania, Bulgaria, Greece, Serbia, Hungary, etcetera are colored in shades of blue.
Italy is colored brown. France, Germany, Denmark, the Netherlands are colored in shades of yellow.
Portugal is colored purple.
Spain is colored indigo.
Ireland is colored red.
Scotland and Great Britain are colored in shades of pink.
Norway, Sweden, and Denmark are colored in shades of turquoise.

Statistical analysis shows a coordinate plane with mutually perpendicular axes. the vertical axis is labeled P C 1 and the

horizontal axis is labeled P C 2. The axes are slightly tilted to the left. Scatterplots on the plane roughly reproduce the map of Europe.

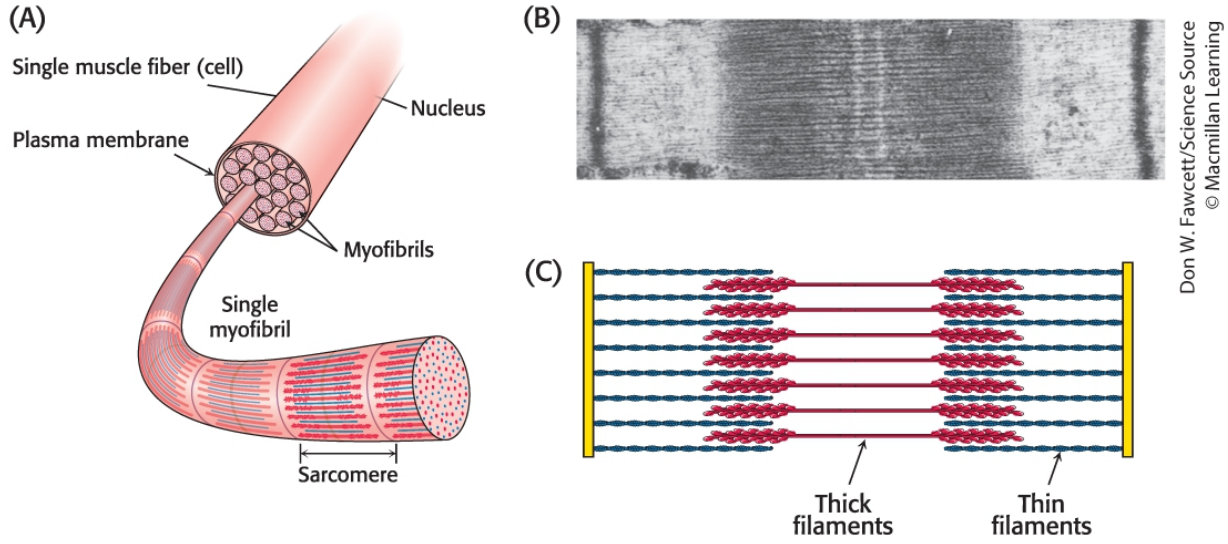
Extended description for FIGURE 2.1 The structure of a protein determines its function



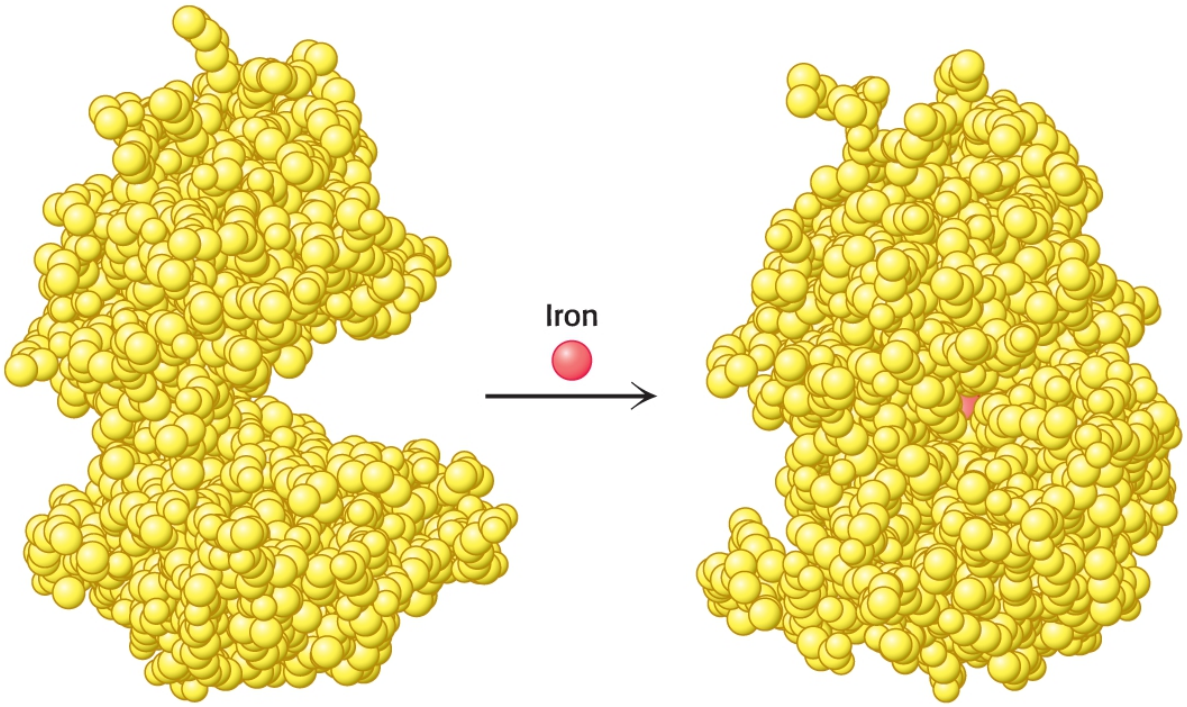
© Macmillan Learning

A rod-shaped structure labeled D N A is surrounded by a ring shaped-protein made up of multiple small spheres. Half of the ring on the left is colored red, and the other half on the right is colored yellow.

Return to FIGURE 2.1 The structure of a protein determines its function

Extended description for FIGURE 2.2 Some proteins form complex assemblies

Part (A): A single muscle fiber (cell) is magnified. It is a multinucleate cell surrounded by a cell membrane and contains numerous myofibrils. A magnified view of a myofibril shows it to be a highly ordered assemblage of thick myosin and thin actin filaments. One short unit of myofibril is labeled sarcomere. The cross-section of the myofibril near the middle of a sarcomere shows how actin and myosin filaments are organized in three dimensions. Each myofibril is formed by many such contracting sarcomere units.



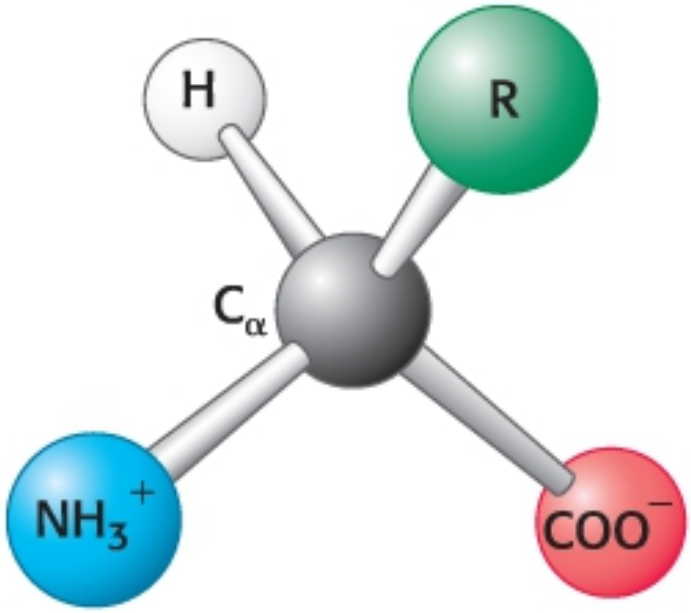
Part (B): The micrograph shows a thin light gray vertical strip in the middle flanked by two thick dark gray regions on both sides. The dark gray regions are followed by a thick light region which is followed by a thin dark gray line.

Part (C): The structure of a single sarcomere is represented as a two-dimensional line diagram. Two parallel vertical yellow bars are shown some distance apart. Blue parallel horizontal lines labeled

thin filaments extend from the yellow bars toward the middle. Parallel horizontal red lines labeled thick filaments are illustrated in the middle section. Small grape-like red structures emerge from the ends of the thick filaments and extend partially into the space between two adjacent thin filaments.

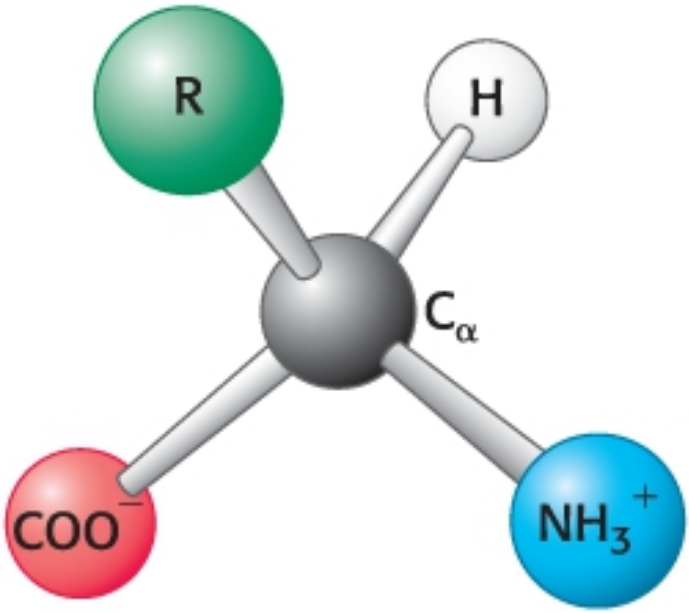
Return to FIGURE 2.2 Some proteins form complex assemblies

Extended description for FIGURE 2.3 Conformational changes allow flexibility in protein function



© Macmillan Learning

The starting 3-dimensional structure of the protein is illustrated to be roughly a C-shape. Upon binding of iron, represented by a red sphere, the protein undergoes a conformational change. The resultant 3-dimensional structure of the protein loses its C-shape with the iron atom at the center.



Return to FIGURE 2.3 Conformational changes allow flexibility in protein function

Extended description for FIGURE 2.4 The l and d isomers of amino acids are mirror images of each other

Glycine (G l y, G): Arrangement of bonds: A central C atom is wedge bonded to H on the upper right, dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right. Fischer projection: A central C atom is single bonded to H above and H

below, C O O superscript minus on the right, and N H 3 superscript plus on the left. Alanine (A l a, A): Arrangement of bonds: A central C atom is wedge bonded to C H 3 on the upper right, dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right. Fischer projection: A central C atom is single bonded to C H 3 above, H below, C O O superscript minus on the right, and N H 3 superscript plus on the left.

Proline (P r o, P): Arrangement of bonds: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 N and 4 C atoms. The N atom bound to H 2 occupies the first position, which is the bottom left vertex. C 3 is wedge bonded to C 4. C 4 is dash bonded to H on the upper left and single bonded to C O O superscript minus on the lower right. Fischer projection: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 N and 4 C atoms. The N atom bound to H 2 and carrying a positive charge occupies the first position, which is the bottom left vertex, and C atoms occupy the remaining positions. C 1, C 2, and C 3 are each bound to H 2. C 4 is single bonded to C O O superscript minus on the right and H below.

Valine (V a l, V): Arrangement of bonds: A central C atom is wedge bonded to C 2 of a 3-carbon alkane chain on the upper right, dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right. Fisher projection: A central C atom is single bonded to H below, C O O superscript minus on the right, N H 3 superscript plus on the left, and C above. The C above is single bonded to H on the left and C H 3 above and C H 3 on the right.

Leucine (L e u, L): Arrangement of bonds: A central C atom is wedge bonded to C 1 of a 3-carbon alkane chain on the upper right, dash bonded to H on the upper left, single bonded to N H 3 superscript

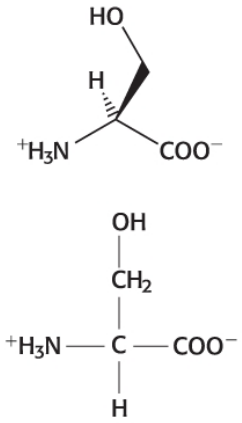
plus on the lower left, and single bonded to C O O superscript minus on the lower right. C 2 of the alkane chain in single bonded to C H 3 on the upper right. Fisher projection: A central C atom is single bonded to H below, C O O superscript minus on the right, N H 3 superscript plus on the left, and C H 2 above. C of the C H 2 above is single bonded to a central C atom above. The central C atom above is single bonded to H on the left, C H 3 above and C H 3 on the right.

Isoleucine (I l e, I): Arrangement of bonds: A central C atom is wedge bonded to C 1 of a 2-carbon alkane chain depicted as a line structure using 1 line on the upper right, dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right. C 1 of the alkane chain is marked with an asterisk and dash bonded to C H 3 on the right. C 2 of the alkane chain is single bonded to C H 3 on the upper right. Fisher projection: A central C atom is single bonded to H below, C O O superscript minus on the right, N H 3 superscript plus on the left, and a central C atom above. The central C atom above is single bonded to H on the left, C H 2 above, and C H 3 on the right. The C H 2 above is single bonded to C H 3 above.

Methionine (M e t, M): Arrangement of bonds: A central C atom is wedge bonded to C 1 of a 2-carbon alkane chain depicted as a line structure using 1 line on the upper right, dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right. C 2 of the alkane chain is single bonded to S on the upper right which is single bonded to C H 3 on the upper left. Fischer projection: C H 3, single bond, S, single bond, C H 2, single bond, C H 2, single bond, C, single bond, H in a vertical manner. C 4 is single bonded to N H 3 superscript plus on the left and C O O superscript minus on the right.

Tryptophane (T r p, W): Arrangement of bonds: A central C atom is wedge bonded to C H 2 on the upper right, dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right. C H 2 is single bonded to C 3 of 5-membered heterocyclic pentagonal ring in a vertical orientation on the upper left consisting of 1 N and 4 C atoms. The N atom bound to H occupies the first position, which is the top left vertex. A double bond is present between C 3 and C 4. The pentagonal ring is fused to a benzene ring in a horizontal orientation with C 1 occupying the rightmost vertex. The benzene ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. The two rings are fused together such that C 1 and C 2 of the pentagonal ring are C 4 and C 3 of the benzene ring, respectively. The two rings are shown in red. Fisher projection: A central C atom is single bonded to H below, C O O superscript minus on the right, N H 3 superscript plus on the left, and C H 2 above. C in the C H 2 above is single bonded to C 3 of a 5-membered heterocyclic pentagonal ring in a vertical orientation on the upper left consisting of 1 N and 4 C atoms. The N atom bound to H occupies the first position, which is the top left vertex, and C atoms occupy the remaining positions. C 4 is bound to H and double bonded to C 3. The pentagonal ring is fused to a benzene ring in a horizontal orientation with a C atom occupying each vertex. C 1, C 4, C 5, and C 6 are each bound to H. The ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. The two rings are fused together such that C 1 and C 2 of the pentagonal ring are C 4 and C 3 of the benzene ring, respectively. The two rings are shown in red.

Phenylalanine (P h 2, F): Arrangement of bonds: A central C atom is wedge bonded to C H 2 on the upper right, dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right. C H 2 is single bonded to C 2 of a benzene ring in a horizontal



orientation with C 1 occupying the rightmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. Fischer projection: A central C atom is single bonded to H below, C O O superscript minus on the right, N H 3 superscript plus on the left, and a C H 2 above. The C H 2 above is single bonded to C 3 of a benzene ring in a vertical orientation with C 1 occupying the topmost vertex with a C atom occupying each vertex. C 1, C 2, C 4, C 5, and C 6 are each bound to H. The ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1.

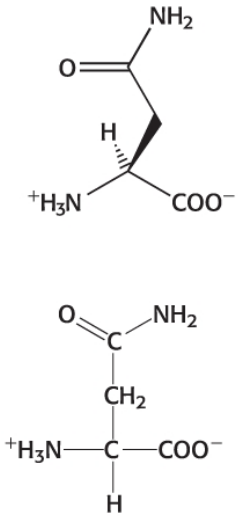
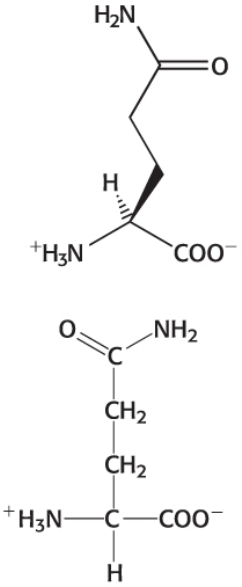
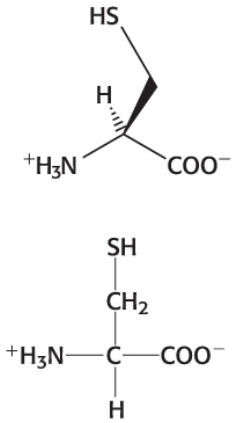
Serine (Ser, S)



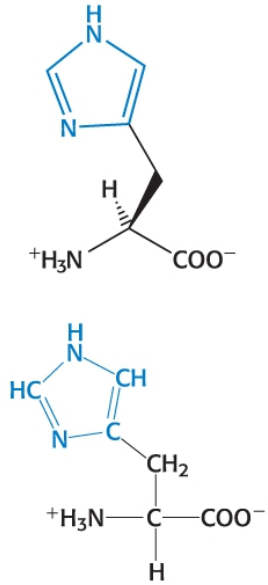
Threonine (Thr, T)



Tyrosine (Tyr, Y)



Asparagine (Asn, N)



Glutamine (Gln, Q)

Cysteine (Cys, C)

Histidine (His, H)

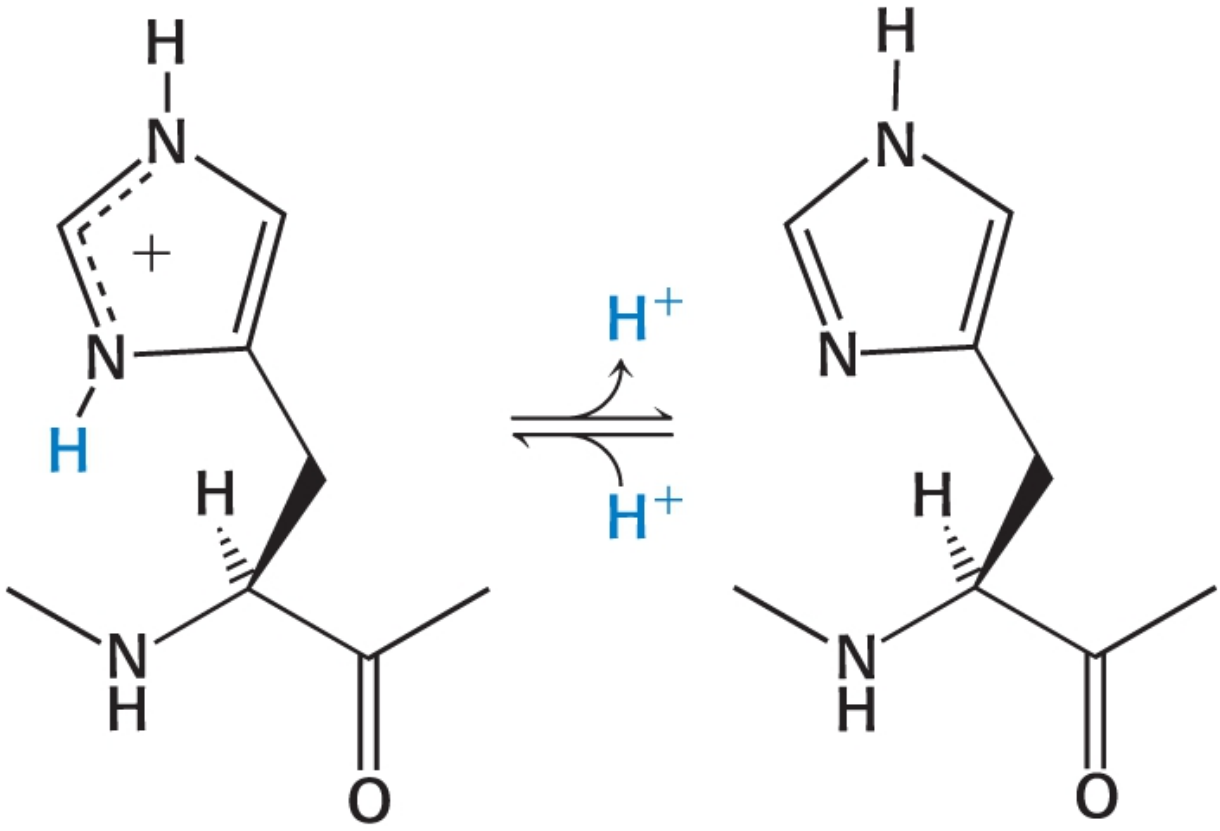
Serine (S e r, S): Arrangement of bonds: A central C atom is wedge bonded to C H 2 on the upper right, dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right. C H 2 is single bonded to O H on the upper left. Fischer projection: A central C atom is single bonded to H below, single bonded to N H 3 superscript plus on the left, single bonded to C H 2 above, and single bonded to C O O superscript minus on the right. C H 2 is single bonded to O H above.

Threonine (T h r, T): Arrangement of bonds: A central C atom is wedge bonded to C H on the upper right marked with an asterisk, dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right. C H is single bonded to O H on the upper left and dash bonded to C H 3 on the right. Fischer projection: A central C atom is single bonded to H below, single bonded to N H 3 superscript plus on the left, single bonded to a central C atom above, and single bonded to C O O superscript minus on the right. The C atom above is single bonded to O H above, single bonded to H on the left, and single bonded to C H 3 on the right.

Tyrosine (T y r, Y): Arrangement of bonds: A central C atom is wedge bonded to C H 2 on the upper right, dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right. C H 2 is single bonded to C 2 of a benzene ring in a horizontal orientation with C 1 occupying the rightmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 5 is single bonded to O H. Fischer projection: A central C atom is single bonded to H below, single bonded to N H 3 superscript plus on the left, single bonded to a C H 2 above, and single bonded to C O O superscript minus on the right. The C H 2 above is single bonded to C 3 of a benzene ring in a vertical

orientation with C 1 occupying the topmost vertex and a C atom occupies each vertex. The ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1, C 2, C 4, C 5, and C 6 are each bound to H. C 5 is single bonded to O H.

Asparagine (A s n, N): Arrangement of bonds: A central C atom is wedge bonded to C 1 of 2-carbon alkane chain depicted as a line structure using one line on the upper right, dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right. C 2 of the alkane chain is double bonded to O on the left and single bonded to N H 2 on the upper right. Fisher projection: A central C atom is single bonded to H below, single bonded to N H 3 superscript plus on the left, single bonded to a C H 2 above, and single bonded to C O O superscript minus on the right. The C H 2 above is single bonded to a central C atom above. The central C atom above is double bonded to O on the upper left and single bonded to N H 2 on the upper right.



Glutamine (G l n, Q): Arrangement of bonds: A central C atom is wedge bonded to C 1 of 3-carbon alkane chain depicted as a line structure using 2 zigzag lines on the upper right, dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right. C 3 of the alkane chain is double bonded to O on the right and single bonded to N H 2 on the upper left. Fisher Projection: A central C atom is single bonded to H below, single bonded to N H 3 superscript plus on the left, single bonded to a C H 2 above, and single bonded to C O O superscript minus on the right. The C H 2 above is single bonded to C H 2 above which is single bonded to a central C atom above. The central C atom above is double bonded to O on the upper left and single bonded to N H 2 on the upper right.

Cysteine (C y s, C): Arrangement of bonds: A central C atom is wedge bonded to C H 2 on the upper right, dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right. C H 2 is single bonded to S H on the upper left. Fischer projection: A central C atom is single bonded to H below, single bonded to N H 3 superscript plus on the left, single bonded to a C H 2 above, and single bonded to C O O superscript minus on the right. The C H 2 above is single bonded to S H above.

Histidine (H I s, H): Arrangement of bonds: A central C atom is wedge bonded to C H 2 on the upper right, dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right. C H 2 is single bonded to C 3 of a 5-memebered heterocyclic pentagonal ring in a vertical orientation consisting of 2 N and 3 C atoms, on the upper left. The first N atom occupies the first position, which is the bottom left vertex. The second N bound to H occupies the third position, which is the topmost vertex. A double bond is present between the first N and C 1 and C 2 and C 3. Fischer projection: A central C atom is single bonded to H below, single bonded to N H 3 superscript plus on the left, single bonded to a C H 2 above, and single bonded to C O O superscript minus on the right. The C H 2 above is single bonded to C 3 of a 5-memebered heterocyclic pentagonal ring in a vertical orientation consisting of 2 N and 3 C atoms, on the upper left. The first N atom occupies the first position, which is the bottom left vertex. The second N bound to H occupies the third position, which is the topmost vertex, and the C atoms occupy the remaining positions. C 1 and C 2 are each bound to H. A double bond is present between the first N and C 1 and C 2 and C 3.

Return to FIGURE 2.7 The polar amino acids have polar but uncharged R groups at physiological pH

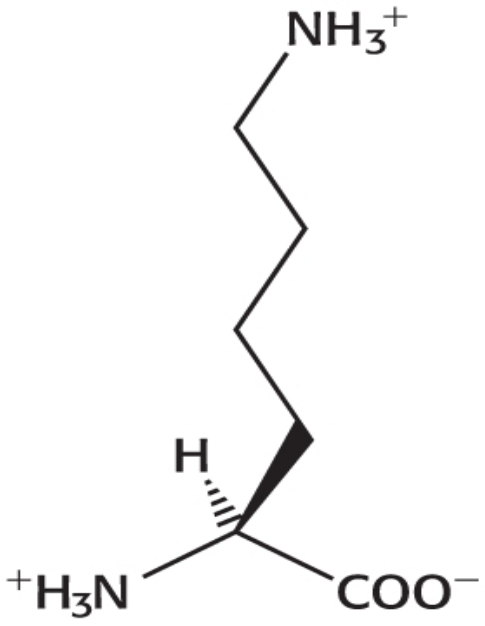
Extended description for FIGURE 2.8 Histidine can bind or release protons near physiological pH

The reaction consists of one reactant and one product. The reactant has the following structure: A 1 N and 4 C heteronuclear alkane chain is depicted as a line structure using 4 zigzag lines. The N atom bound to H occupies the second position. C 3 is double bonded to O below. C 2 is dash bonded to H on the upper left and wedge bonded to C H 2 on the upper right. C H 2 is single bonded to C 3 of a 5-memebered heterocyclic pentagonal ring in a vertical orientation on the upper left consisting of 2 N and 3 C atoms. The first N atom single bonded to H occupies the first position, which is the bottom left vertex. H atom is highlighted in blue. The second N atom single bonded to H occupies the third position, which is the topmost

vertex. A double bond is present between C 2 and C 3. A partial double bond is present across the first N atom, C 1, and the second N atom of the ring represented as a dotted line. A plus sign is shown across the dotted line.

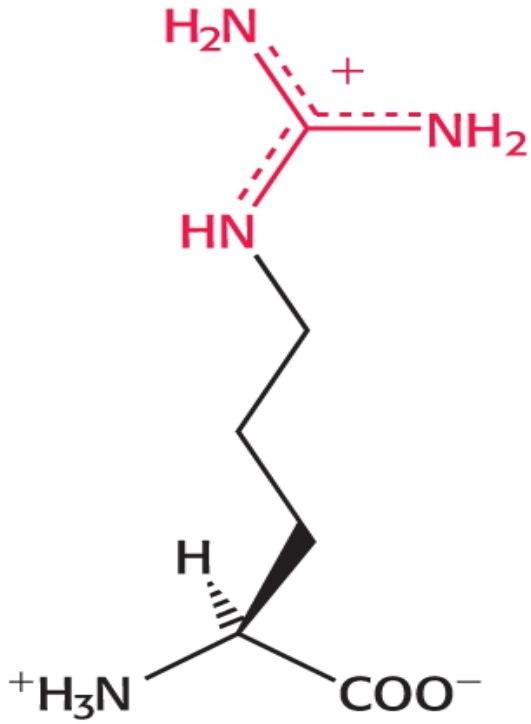
An H superscript plus ion highlighted in blue is eliminated in the forward reaction.

The product has the following structure: A 1 N and 4 C heteronuclear alkane chain is depicted as a line structure using 4 zigzag lines. The N atom bound to H occupies the second position. C 3 is double bonded to O below. C 2 is dash bonded to H on the upper left and wedge bonded to C H 2 on the upper right. C H 2 is single bonded to C 3 of a 5-memebered heterocyclic pentagonal ring in a vertical orientation on the upper left consisting of 2 N and 3 C atoms. The first N atom occupies the first position, which is the bottom left vertex. The second N atom single bonded to H occupies the third position, which is the topmost vertex. A double bond is present between the first N atom and C 1 and C 2 and C 3.

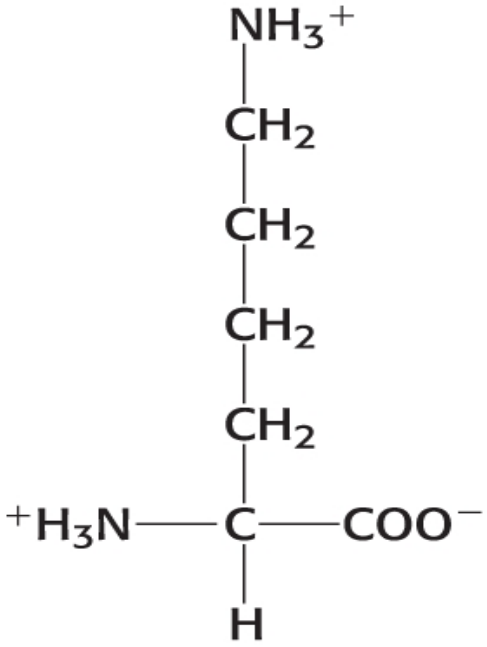


An H superscript plus ion highlighted in blue is added in the backward reaction.

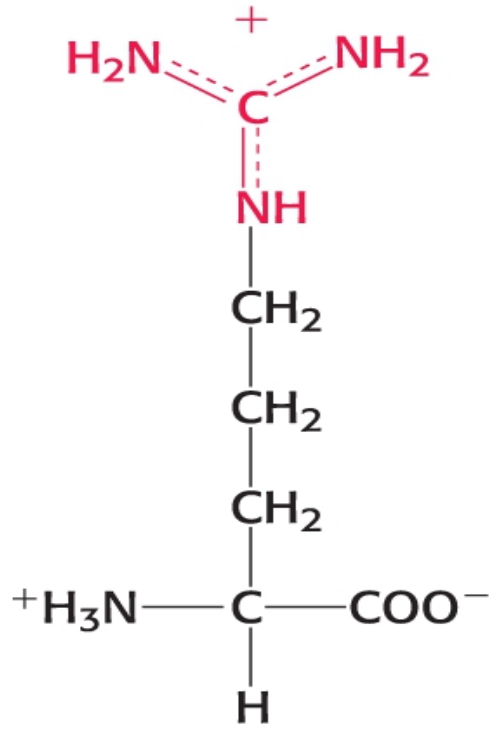
Return to FIGURE 2.8 Histidine can bind or release protons near physiological pH



Extended description for FIGURE 2.9 Two amino acids are positively charged at physiological pH. The



guanidinium group in the arginine side chain is shown in red



Lysine
(Lys, K)

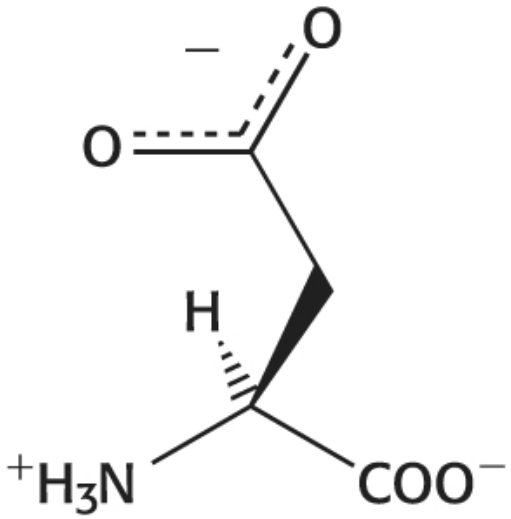
Arginine
(Arg, R)

The first structure of lysine (L y s, K) is as follows: A 5-carbon alkane chain is depicted as a line structure in vertical orientation using 4 zigzag lines. C 1 is single bonded to N H 3 superscript plus on the upper right. C 4 is wedge bonded to C 5 on the lower left. C 5 is dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right.

The second structure of lysine is as follows: N H 3 superscript plus, single bond, C H 2, single bond, C H 2, single bond, C H 2, single bond, C H 2, single bond, C, single bond, H in a vertical orientation. C 5 is single bonded to N H 3 superscript plus on the left and C O O superscript minus on the right.

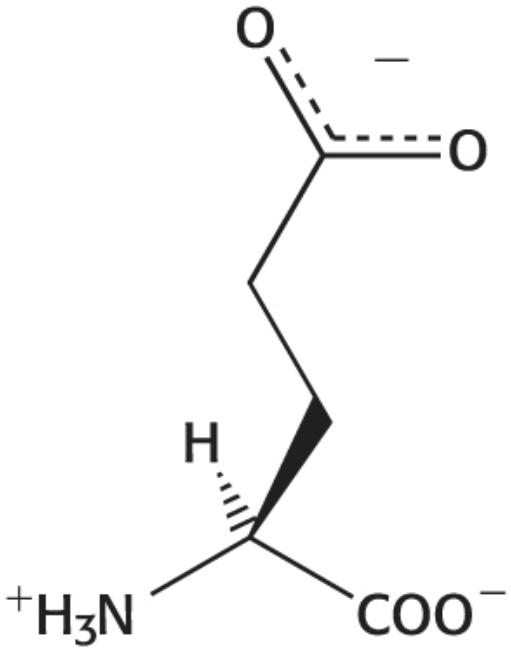
The first structure of arginine (A r g, R) is as follows: A 1 N and 5 C heteronuclear alkane is depicted as a line structure in vertical orientation using 5 zigzag lines. N occupies the second position and is bound to an H atom. C 1 is single bonded to N H 2 on the right and N H 2 on the upper left. A V-shaped dashed line goes from the N H 2 on the upper left to the N H 2 on the right. A plus sign is present at the center of the dashed line. A dashed line is present between C 1 and the N atom of the alkane chain. The N H 2 groups, dashed lines, plus sign, N H group of the alkane chain are highlighted in red. C 4 is wedge bonded to C 5 on the lower left. C 5 is dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right.

The second structure of arginine is as follows: C, single bond, N H, single bond, C H 2, single bond, C H 2, single bond, C H 2, single bond, C, single bond, H in a vertical orientation. C 1 is single bonded to N H 2 on the upper left and single bonded to N H 2 on the upper right. A V-shaped dashed line goes from the N H 2 on the upper left to the N H 2 on the upper right. A plus sign is present at

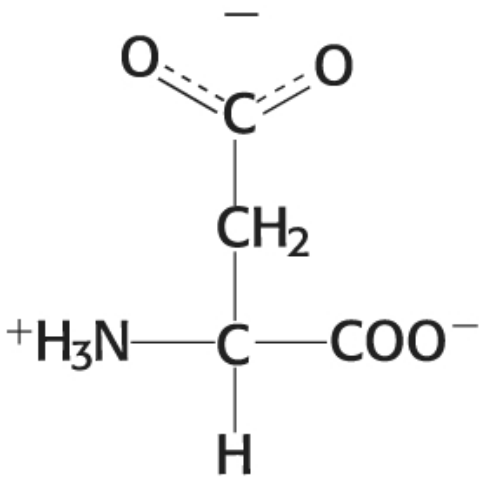


the center of the dashed line. A dashed line is present on the right of the single bond between C 1 and the first N atom of the alkane chain. The N H 2 groups, dashed lines, plus sign, N H group are highlighted in red. C 5 is single bonded to N H 3 superscript plus on the left and single bonded to C O O superscript minus on the right.

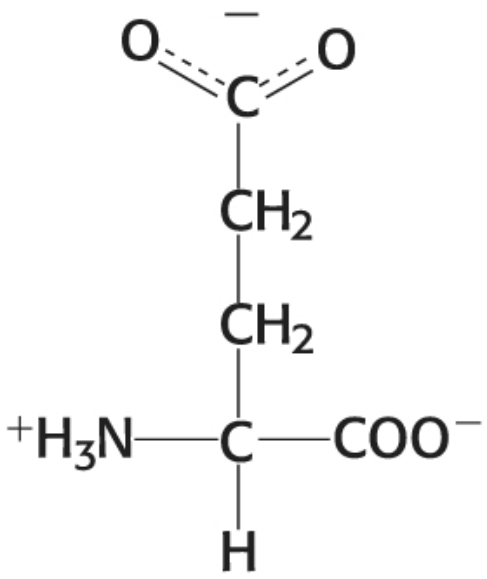
Return to FIGURE 2.9 Two amino acids are positively charged at physiological pH. The guanidinium group in the arginine side chain is shown in red



Extended description for FIGURE 2.10 Two amino acids



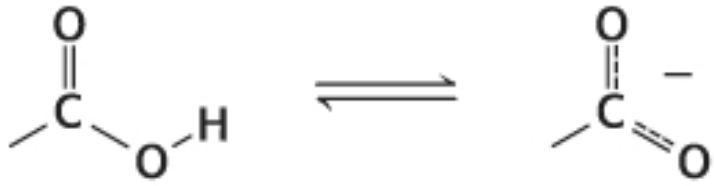
are negatively charged at physiological pH



Aspartate (Asp, D)

Glutamate (Glu, E)

The first structure of aspartate (A s p, D) is as follows: A central C atom is single bonded to a C atom on the upper left and wedge bonded to a C atom on the lower left. C on the upper left is single bonded to an O atom on the upper right and O on the left. A V-shaped dashed line connects the two O atoms. A minus symbol is shown between the two O atoms. C on the lower left is dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left and C O O superscript minus on the lower right.



The second structure of aspartate is as follows: C, single bond, C H 2, single bond, C, single bond, H in a vertical orientation. C 1 is single bonded to an O atom on the upper left and upper right. A V-shaped dashed line connects the two O atoms. A minus symbol is shown between the two O atoms. C 3 is single bonded to N H 3 superscript plus on the left and C O O superscript minus on the right.

The first structure of glutamate (G l u, E) is as follows: A 3-carbon alkane chain is depicted as a line structure using 3 zigzag lines in a vertical orientation. C 1 is single bonded to an O atom on the upper left and upper right. A V-shaped dashed line connects the two O atoms. A minus symbol is shown between the two O atoms. C 3 is wedge bonded to a central C atom on lower left. This C atom is dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left and C O O superscript minus on the lower right.

The second structure of glutamate is as follows: C, single bond, C H 2, single bond, C H 2, single bond, C, single bond, H in a vertical orientation. C 1 is single bonded to an O atom on the upper left and upper right. A V-shaped dashed line connects the two O atoms. A minus symbol is shown between the two O atoms. C 4 is single bonded to N H 3 superscript plus on the left and C O O superscript minus on the right.

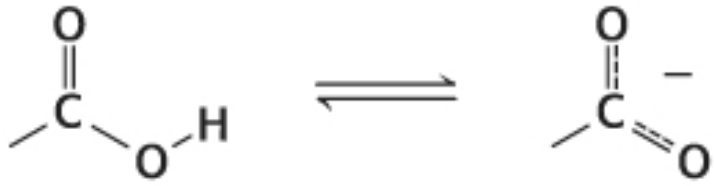
Extended description for Ionization of an alpha-carboxyl group.

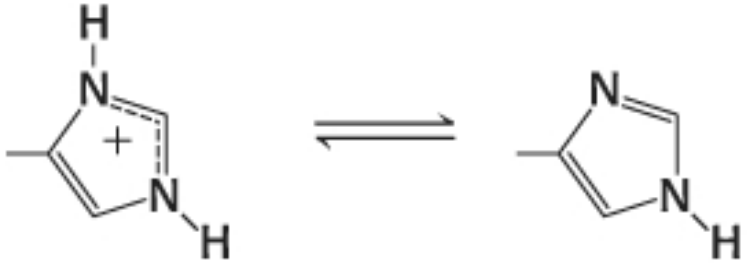


The reaction consists of one reactant and one product. The reactant has the following structure: A central C atom is single bonded to O on the lower right and double bonded to O above. The C atom has an open single bond on the lower left. The O atom on the lower right is single bonded to H on the upper right.

The product has the following structure: A central C atom is single bonded to O on the lower right and single bonded to O above. The C atom has an open single bond on the lower left. A dashed line is present between C and O on the lower right and C and O above. A minus sign is present adjacent to this dashed line.

Return to Ionization of an alpha-carboxyl group.

Extended description for Ionization of an alpha-carboxyl group.

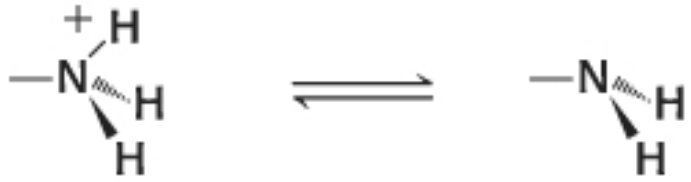


The reaction consists of one reactant and one product. The reactant has the following structure: A central C atom is single bonded to O on the lower right and double bonded to O above. The C atom has an open single bond on the lower left. The O atom on the lower right is single bonded to H on the upper right.

The product has the following structure: A central C atom is single bonded to O on the lower right and single bonded to O above. The C atom has an open single bond on the lower left. A dashed line is present between C and O on the lower right and C and O above. A minus sign is present adjacent to this dashed line.

Return to Ionization of an alpha-carboxyl group.

Extended description for Ionization of a histidine amino acid



The reaction consists of one reactant and one product. The reactant has the following structure: A 5-membered heterocyclic pentagonal is in a vertical orientation and consists of 2 N and 3 C atoms. The first N atom is single bonded to H and occupies the first position, which is the topmost vertex. The second N atom is single bonded to H and occupies the third position, which is the bottom right vertex. C 2 is double bonded to C 3. A partial double bond is present across the first N, C 1, and the second N. C 3 has an open single bond on the left. A positive charge is shown inside the ring.

The product has the following structure: A 5-membered heterocyclic pentagonal is in a vertical orientation and consists of 2 N and 3 C atoms. The first N atom occupies the first position, which is the topmost vertex. The second N atom is single bonded to H and occupies the third position, which is the bottom right vertex. A double bond is present between the first N atom and C 1 and C 2 and C 3. C 3 has an open single bond on the left.

Extended description for Reversible reaction of ammonia

The reaction consists of one reactant and one product. The reactant has the following structure: A central N superscript plus is wedge bonded to H on the lower right, dash bonded to H on the right, and single bonded to H on the upper right. It has an open single bond on the left. The product has the following structure: A central N atom is wedge bonded to H on the lower right, dash bonded to H on the right. It has an open single bond on the left.

Return to Reversible reaction of ammonia

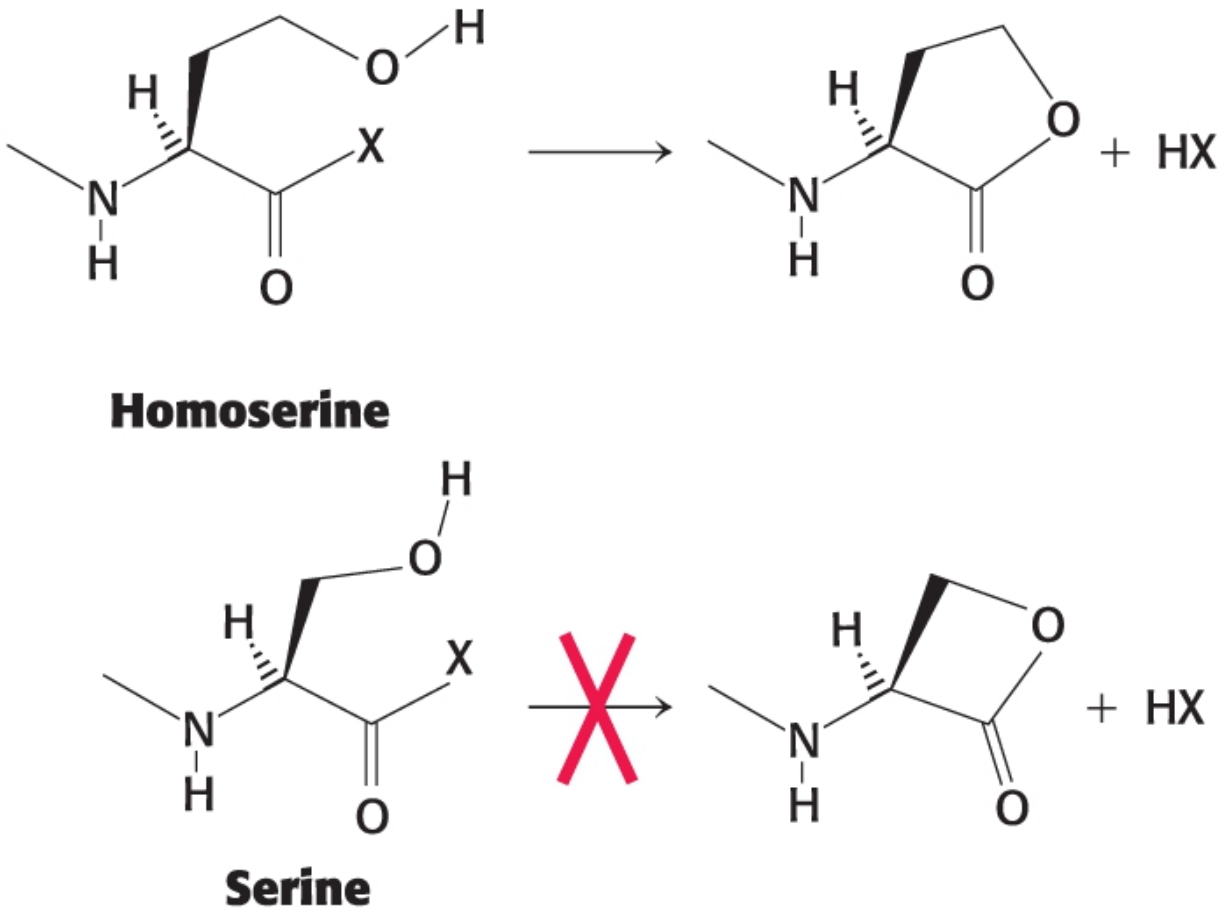
Extended description for Ionization of an amine group

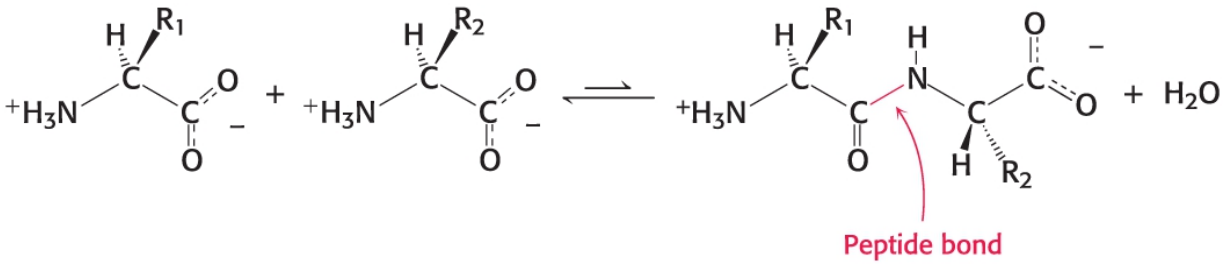


The reaction consists of one reactant and one product. The reactant has the following structure: A central C atom is single bonded to N on the left, single bonded to N on the upper right, and single bonded to N on the lower right. The N on the left has two open single bonds on the upper left and lower left. The N on the upper left is single bonded to H on the upper right and single bonded to H on the lower right. The N on the lower right is single bonded to H on the right and single bonded to H on the lower left. A partial double bond is present across the central C atom and each N atom, respectively. The central C atom carries a positive charge.

The product has the following structure: A central C atom is single bonded to N on the left, double bonded to N on the upper right, and single bonded to N on the lower right. The N on the left has an open single bond on the lower left and is single bonded to H on the upper left. The N on the upper right is single bonded to H above. The N on the lower right is single bonded to H on the right and single bonded to H on the lower left.

Return to Ionization of an amine group

Extended description for FIGURE 2.11 Some amino acids are not found in proteins because they are too reactive



Cyclization of homoserine: The reaction consists of one reactant and two products. The reactant has the following structure: A 1 N and 3 C heteronuclear alkane chain is depicted as a line structure using 3 zigzag lines. N single bonded to H below occupies the second position. C 3 is double bonded to O below and single bonded to X on the upper right. C 2 is dash bonded to H on the upper left and wedge bonded to C 1 of a 2-carbon alkane chain depicted as a line structure using one line. C 2 of the second chain is single bonded to O on the

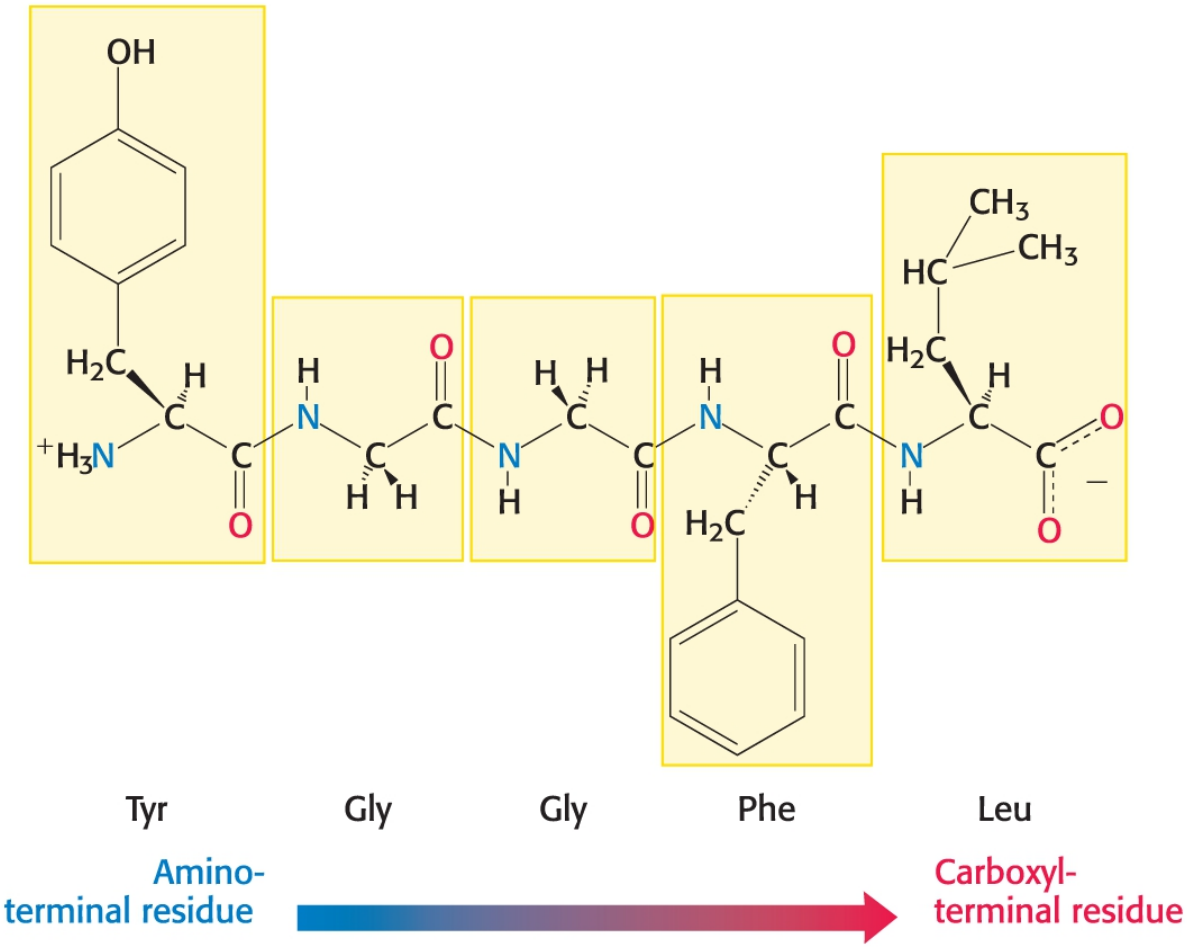
lower right which is single bonded to H on the upper right. The first product has the following structure: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 1 O and 4 C atoms. O occupies the first position, which is the rightmost vertex. C 1 is double bonded to O below. C 2 is wedge bonded to C 3. C 2 is dash bonded to H on the upper left and single bonded to N which is single bonded to H below and C H 3 on the upper left in the form of a line. The second product is H X.

Cyclization of serine: The reaction consists of one reactant and two products. The reactant has the following structure: A 1 N and 3 C heteronuclear alkane chain is depicted as a line structure using 3 zigzag lines. N single bonded to H below occupies the second position. C 3 is double bonded to O below and single bonded to X on the upper right. C 2 is dash bonded to H on the upper left and wedge bonded to C H 2 on the upper right. C H 2 is single bonded to O on the right which is single bonded to H on the upper right. The first product has the following structure: The first product has the following structure: A 4-membered heterocyclic ring is in a horizontal orientation and consists of 1 O and 3 C atoms. O occupies the first position, which is the rightmost vertex. C 1 is double bonded to O below. C 2 is wedge bonded to C 3. C 2 is dash bonded to H on the upper left and single bonded to N which is single bonded to H below and C H 3 on the upper left in the form of a line. The second product is as follows: H X. The reaction arrow is crossed out.

Return to FIGURE 2.11 Some amino acids are not found in proteins because they are too reactive

Extended description for FIGURE 2.12 The formation of the peptide bond linking two amino acids is accompanied by the loss of a molecule of water

The reaction consists of two reactants and two products. The first reactant has the following structure: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C on the lower right, dash bonded to H on the upper left, and wedge bonded to R 1 on the upper right. The C on the lower right is single bonded to O on the upper right and single bonded to O below. A partial double bond is present between the C and O below and the C and O on the upper right. The C on the lower right carries a negative charge.



The second reactant has the following structure: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C on the lower right, dash bonded to H on the upper left, and wedge bonded to R 2 on the upper right. The C on the lower right is single bonded to O on the upper right and single bonded to O below. A partial double bond is present between the C and O below and the C and O on the upper right. The C on the lower right carries a negative charge.

The backward reaction is more preferred than the forward reaction as indicated by the reversible reaction arrow.

The first product has the following structure: Superscript plus H 3 N, single bond, C, single bond, C, single bond, N, single bond, C, single bond, C, single bond, O. The chain is shown in a zigzag manner. The single bond between C 2 and N is highlighted in red and labeled peptide bond. C is dash bonded to H on the upper left and wedge bonded to R 1 on the upper right. C 2 is double bonded to O below. C 3 is wedge bonded to H on the lower left and dash bonded to R 2 on the lower right. C 4 is single bonded to O above and carries a negative charge. A partial double bond is present between C 4 and O above and the C 4 and O on the lower right. The second product is H 2 O.

Return to FIGURE 2.12 The formation of the peptide bond linking two amino acids is accompanied by the loss of a molecule of water

Extended description for FIGURE 2.13 Amino acid sequences have direction

© Macmillan Learning

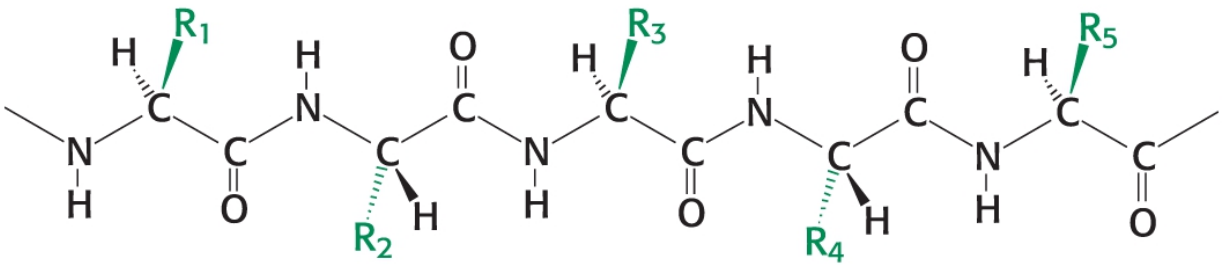
The polypeptide chain has the following sequence: Tyrosine, Glycine, Glycine, Phenylalanine, and Leucine. The amino acids are linked by peptide bonds. The structure of tyrosine is as follows: A central C atom is single bonded to C on the lower right, single bonded to N H 3 superscript plus on the lower left, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. N is highlighted in blue. C of C H 2 is single bonded to C 4 of a benzene ring in a vertical orientation above, with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 1 and

C 2, C 3 and C 4, and C 5 and C 6. C 1 of the benzene ring is single bonded to O H. The C on the lower right is double bonded to O below and single bonded to N of the glycine residue. O is highlighted in red.

Glycine has the following structure: A central C atom is single bonded to N on the upper left, single bonded to C on the upper right, wedge bonded to H on the lower right, and dash bonded to H on the lower left. N is single bonded to H above and is highlighted in blue. The C on the upper right is double bonded to O above and single bonded to N of the second glycine residue. O above is highlighted in red.

The second glycine residue has the following structure: A central C atom is single bonded to N on the lower left, single bonded to C on the lower right, wedge bonded to H on the upper left, and dash bonded to H on the upper right. N is single bonded to H below and highlighted in blue. The C on the lower right is double bonded to O below and single bonded to N of the phenylalanine residue. O below is highlighted in red.

Phenylalanine has the following structure: A central C atom is single bonded to N on the upper left, single bonded to C on the upper right, wedge bonded to H on the lower right, and dash bonded to C H 2 on the lower left. N is highlighted in blue. C in C H 2 is single bonded to C 1 of a benzene ring in a vertical orientation below, with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. N is single bonded to H above. The C on the upper right is double bonded to O above and single bonded to N of the leucine residue. O above is highlighted in red.

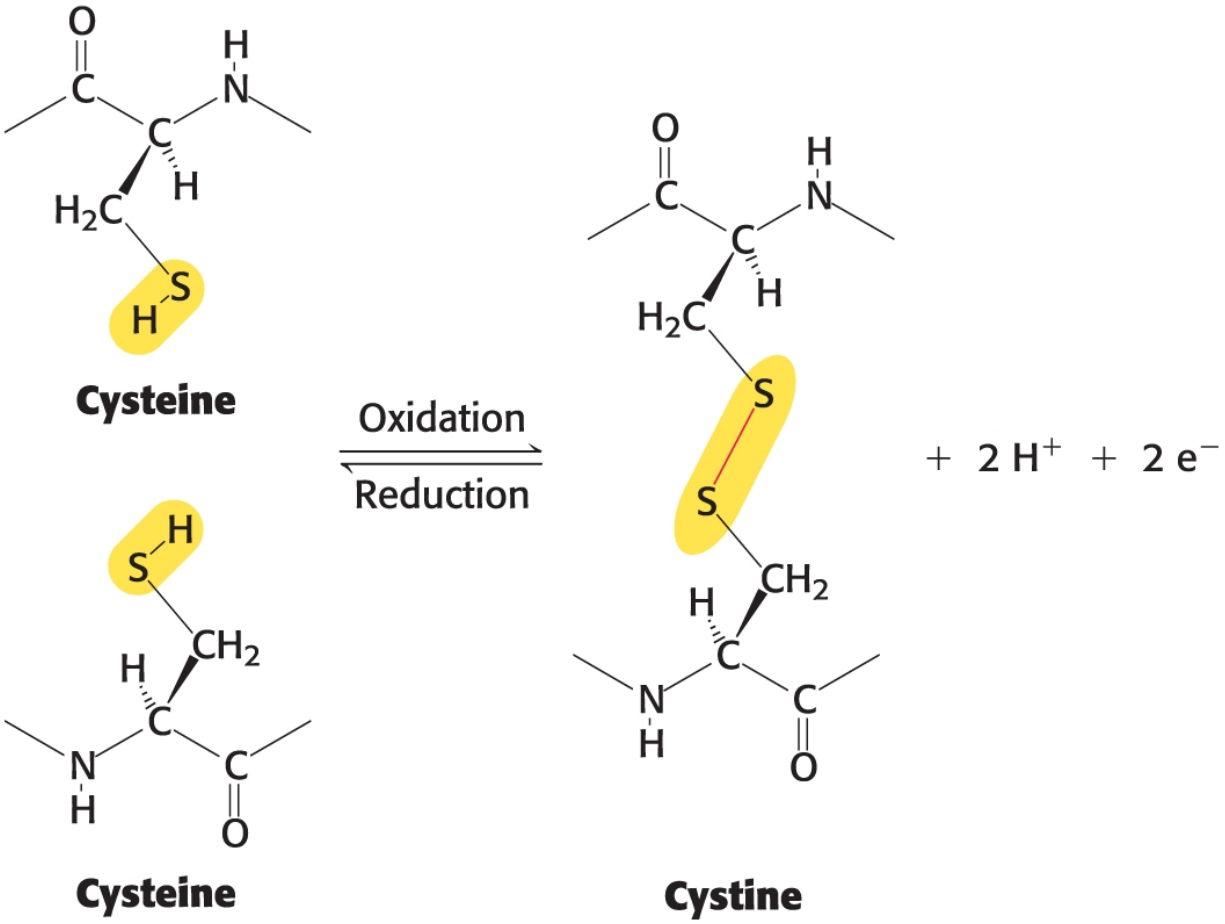


Leucine has the following structure: A central C atom is single bonded to C on the lower right, single bonded to N on the lower left,

wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. C in C H 2 is single bonded to C H above. C in C H is single bonded to C H 3 on the right and single bonded to C H 3 on the upper right. N is single bonded to H below and is highlighted in blue. C on the lower right is single bonded to O on the upper right and single bonded to O below. A partial double bond is present across the O on the upper right, C, and the O below. The C atom carries a negative charge. Both O atoms are highlighted in red.

A right-pointing arrow from the tyrosine residue to the leucine residue has a color gradient from blue to red. The tail of the arrow at tyrosine is labeled amino-terminal residue. The arrowhead at the leucine residue is labeled carboxyl-terminal residue.

Return to FIGURE 2.13 Amino acid sequences have direction



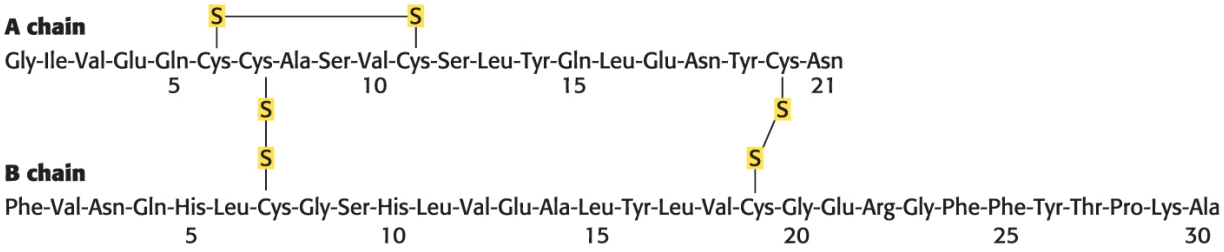
Extended description for FIGURE 2.14 A polypeptide chain consists of a constant backbone and variable side chains

The structure is as follows: open single bond, N, single bond, C, single bond, C, single bond, N, single bond, C, single bond, C, single bond, N, single bond, C, single bond, C, single bond, N, single bond, C, single bond, C, single bond, N, single bond, C, single bond, C, open single bond. The chain is shown in a zigzag manner. The first, third, and fifth N atoms are each single bonded to H below. The second and the fourth N atoms are each single bonded to H above. C 1, C 5, and C 9 are dash bonded to H on the upper left and wedge bonded to R 1, R 3, and R 5 on the upper right, respectively. C 3 and C 7 are wedge bonded to H on the lower right and dash bonded to R 2 and R 4 on the lower left, respectively. C 2, C 7, and C 10 are each double bonded to O below. C 4 and C 8 are each double bonded to O above. The R groups are highlighted in green.

Return to FIGURE 2.14 A polypeptide chain consists of a constant backbone and variable side chains

Extended description for FIGURE 2.15 The formation of a disulfide bond from two cysteine residues is an oxidation reaction

The reaction consists of one reactant and three products. The reactant is two molecules of cysteine amino acids. The structure of first cysteine amino acid is as follows: A 1 N and 2 C heteronuclear alkane chain is depicted as a line structure using 2 zigzag lines. N atom occupies the third position. N is single bonded to H above. N atom has an open single bond on the lower right. C 1 is double bonded to O above. C 1 has an open single bond on the lower left. C 2 is wedge bonded to C H 2 on the lower left and dash bonded to H

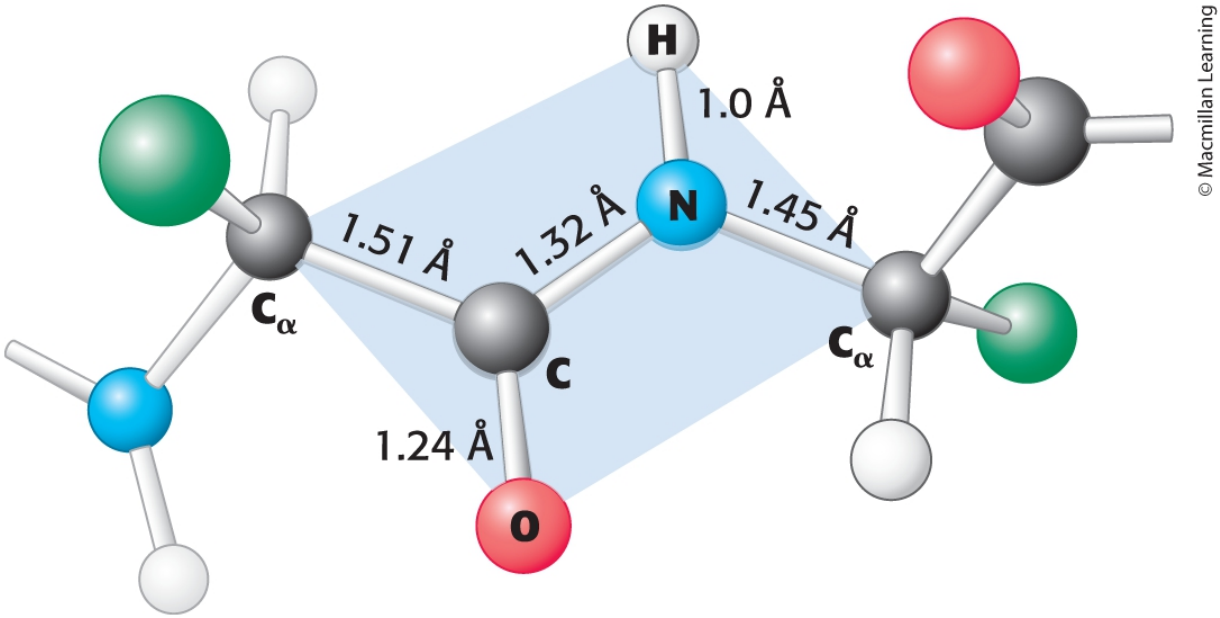


on the lower right. C H 2 on the lower left is single bonded to S on the lower right. S is single bonded to H on the lower left. S, single bond, H is highlighted in yellow. The structure of the second cysteine amino acid is as follows: A 1 N and 2 C heteronuclear alkane chain is depicted as a line structure using 2 zigzag lines. N atom occupies the first position. N is single bonded to H below. N atom has an open single bond on the upper left. C 1 is wedge bonded to C H 2 on the upper right and dash bonded to H on the upper left. C H 2 on the upper right is single bonded to S on the upper left. S is single bonded to H on the upper right. S, single bond, H is highlighted in yellow. C 2 is double bonded to O below. C 2 has an open single bond on the upper left.

The forward reaction arrow is labeled oxidation and the backward reaction arrow is labeled reduction.

The three products are one molecule of cystine, 2 H superscript plus ions, and 2 e superscript minus. The structure of cystine is as follows: A 1 N and 2 C heteronuclear alkane chain is depicted as a line structure using 2 zigzag lines. N atom occupies the third position. N is single bonded to H above. N atom has an open single bond on the lower right. C 1 is double bonded to O above. C 1 has an open single bond on the lower left. C 2 is wedge bonded to C H 2 on the lower left and dash bonded to H on the lower right. C H 2 on the lower left is single bonded to S on the lower right. S is single bonded to another S on the lower left. S, single bond, S is highlighted in yellow. The second S is single bonded to a C H 2 group on the lower right. This C H 2 is part of a second heteronuclear alkane chain. C H 2 is wedge bonded to C 1 of the second alkane chain. C 1 is wedge bonded to H on the upper left. The heteronuclear alkane chain consists of 1 N and 2 C atoms. N occupies the first position and is single bonded to H below. N has an open single bond on the upper left. C 2 is double bond to O below and has an open single bond on the upper right.

Return to FIGURE 2.15 The formation of a disulfide bond from two cysteine residues is an oxidation reaction



Extended description for FIGURE 2.16 The primary structure of bovine insulin is its amino acid sequence

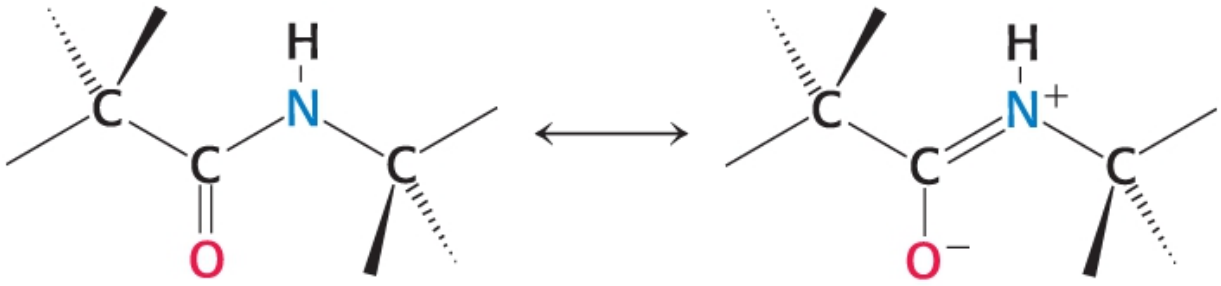
Chain A is made up of 21 amino acids, and B chain is made up of 30 amino acids. Cysteine as the sixth and the eleventh position of chain A are each single bonded to S above. A single bond is present between the two S atoms above. Cysteine at the seventh position of chain A is single bonded to S below. This S is single bonded to S below, which is single bonded to cysteine at the seventh position of chain B below. Cysteine at the twentieth position of chain A is single bonded to S below. This S is single bonded to another S on the lower left, which is single bonded to cysteine at the nineteenth position of chain B below.

Return to FIGURE 2.16 The primary structure of bovine insulin is its amino acid sequence

Extended description for FIGURE 2.17 Peptide bonds are planar and have partial double-bond character

© Macmillan Learning

Two amino acids are linked together by a peptide bond shown on the same plane. The amino acids are represented using ball-and-stick models. In the ball-and-stick model, black spheres represent carbon atoms, blue spheres represent nitrogen atoms, white spheres represent hydrogen atoms, red spheres represent oxygen atoms, and green spheres represent side chains.



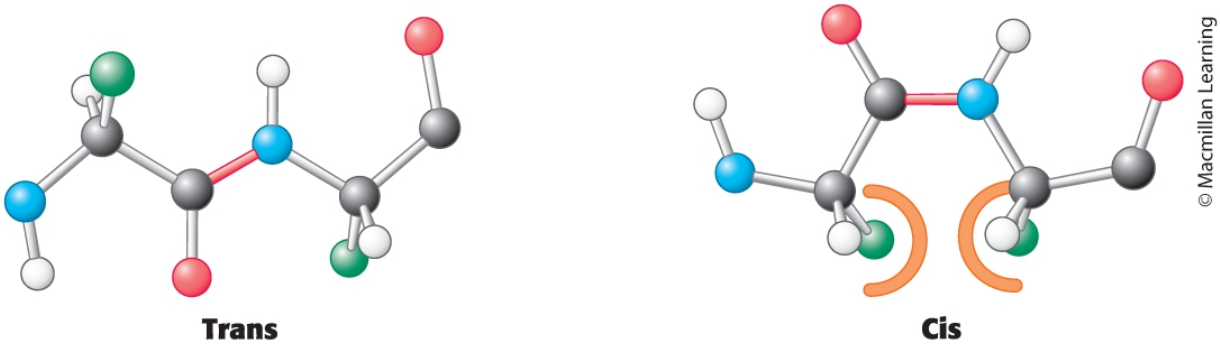
The first amino acid has the following structure: A central black sphere labeled C alpha is connected to a blue sphere on the lower left, another black sphere labeled C on the lower right, a large green sphere above and toward the observer, and a small white sphere above and away from the observer. The blue sphere is connected to a small white sphere below, and the black sphere on the lower right is connected to a red sphere labeled O below.

The second amino acid has the following structure: A central black sphere labeled C alpha is connected to a blue sphere on the upper left, another black sphere on the upper right, a large green sphere on the lower right and away from the observer, and a small white sphere below and toward from the observer. The blue sphere is connected to a small white sphere above labeled H and the black sphere labeled C in the previous amino acid. The black sphere on the upper right is connected to a red sphere labeled O toward the observer.

The bond length between C in the first amino acid and N in the second amino acid is 1.32 Angstrom. The bond length between C alpha and C in the first amino acid is 1.51 Angstrom. The bond length between C and O in the first amino acid is 1.24 Angstrom. The bond length between N and H in the second amino acid is 1.0 Angstrom. The bond length between N and C alpha in the second amino acid is 1.45 Angstrom.

Return to FIGURE 2.17 Peptide bonds are planar and have partial double-bond character

Extended description for Peptide bond resonance structures



Peptide-bond resonance structures

The first resonance structure is as follows: Open single bond, C, single bond, C, single bond, N, single bond, C, open single bond. The chain is shown in a zigzag manner. N is single bonded to H above. N is highlighted in blue. C 1 has an open wedge bond on the upper right and an open dash bond on the upper left. C 2 is double bonded to O below. O is highlighted in red. C 3 has an open wedge bond on the lower left and an open dash bond on the lower right.

The second resonance structure is as follows: Open single bond, C, single bond, C, double bond, N superscript plus, single bond, C, open single bond. The chain is shown in a zigzag manner. N superscript plus is single bonded to H above. C 1 has a wedge bond on the upper right and a dash bond on the upper left. C 2 is single bonded to O superscript minus below which is highlighted in red. C 3 has a wedge bond on the lower left and a dash bond on the lower right.

Return to Peptide bond resonance structures

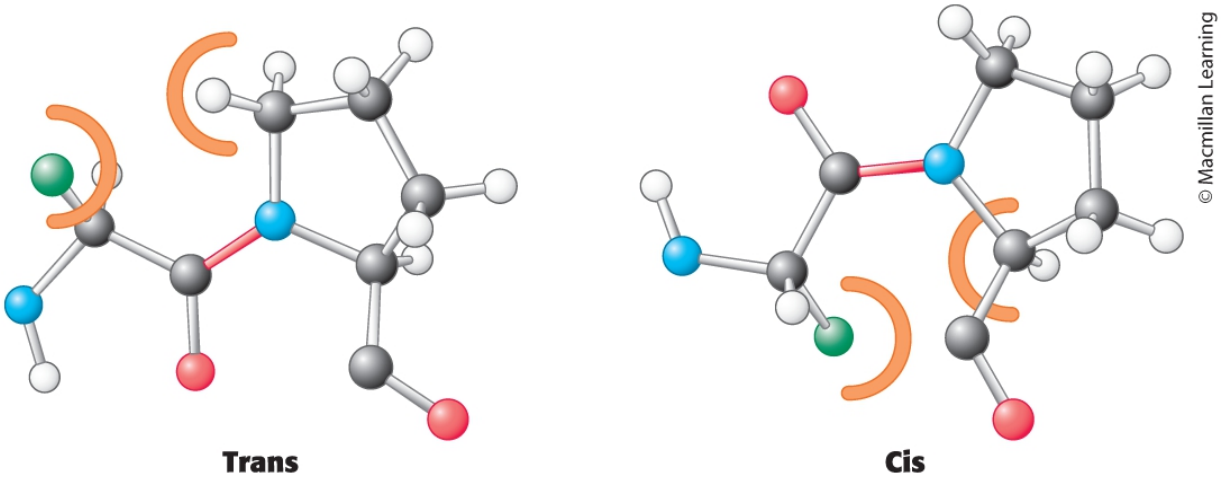
Extended description for FIGURE 2.18 For most amino acids, the trans configuration of the peptide bond is strongly favored because of steric clashes that arise in the cis isomer.

Trans: Two amino acids are linked together by a peptide bond highlighted in red. The amino acids are represented using ball-and-stick models. In the ball-and-stick model, black spheres represent carbon atoms, blue spheres represent nitrogen atoms, white spheres represent hydrogen atoms, red spheres represent oxygen atoms, and green spheres represent side chains.

In the first amino acid, a central black sphere is connected to another black sphere on the lower right, a blue sphere on the lower left, a green sphere above and toward the observer, and a white sphere above and away from the observer. The blue sphere is connected to a white sphere below. The black sphere on the lower right is connected to a red sphere below and connected to a blue sphere in the second amino acid on the upper right.

In the second amino acid, a central black sphere is connected to a blue sphere on the upper left, a black sphere on the upper right, a green sphere below and away from the observer, and a white sphere

below and toward the observer. The blue sphere is connected to a white sphere above. The black sphere on the upper right is connected to a red sphere above.



Cis: Two amino acids are linked together by a peptide bond highlighted in red. The amino acids are represented using ball-and-stick models. In the ball-and-stick model, black spheres represent carbon atoms, blue spheres represent nitrogen atoms, white spheres represent hydrogen atoms, red spheres represent oxygen atoms, and green spheres represent side chains.

In the first amino acid, a central black sphere is connected to a blue sphere on the left, a black sphere on the upper right, a green sphere on the lower right and away from the observer, and a white sphere below and toward the observer. The blue sphere is connected to a white sphere above. The black sphere on the upper right is connected to a red sphere on the upper left and connected to a blue sphere in the second amino acid on the upper right.

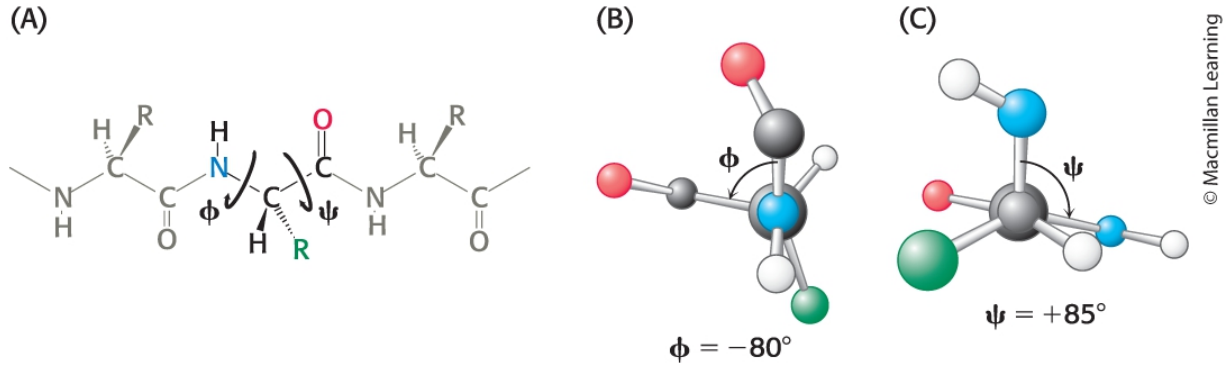
In the second amino acid, a central black sphere is connected to a blue sphere on the upper left, a black sphere on the upper right, a green sphere on the lower left and away from the observer, and a white sphere below and toward the observer. The blue sphere is connected to a white sphere on the upper right. The black sphere on the upper right is connected to a red sphere above. Orange semicircles are drawn around the side chains.

Return to FIGURE 2.18 For most amino acids, the trans configuration of the peptide bond is strongly favored because of steric clashes that arise in the cis isomer.

Extended description for FIGURE 2.19 For peptide bonds between proline and its preceding residue, cis bonds are as likely as trans bonds

Trans: Proline and the amino acid residue are linked together by a peptide bond highlighted in red. The amino acids are represented using ball-and-stick models. In the ball-and-stick model, black spheres represent carbon atoms, blue spheres represent nitrogen atoms, white spheres represent hydrogen atoms, red spheres represent oxygen atoms, and green spheres represent side chains.

In the first amino acid, a central black sphere is connected to another black sphere on the lower right, a blue sphere on the lower left, a green sphere on the upper left and toward the observer, and a white sphere above and away from the observer. The blue sphere is connected to a white sphere below. The black sphere on the lower right is connected to a red sphere below and connected to a blue sphere of a heterocyclic pentagonal ring on the upper right. The 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 blue and 4 black spheres. The blue sphere occupies the first position, which is the bottom left vertex. Each black sphere



except for the one at the bottommost vertex is connected to two white spheres. The black sphere at the bottommost vertex is connected to a white sphere away from the observer and another black sphere below which is connected to a red sphere on the lower right. Orange semicircles are drawn around the green sphere of the first amino acid and the white spheres are connected to the black sphere at the top right vertex.

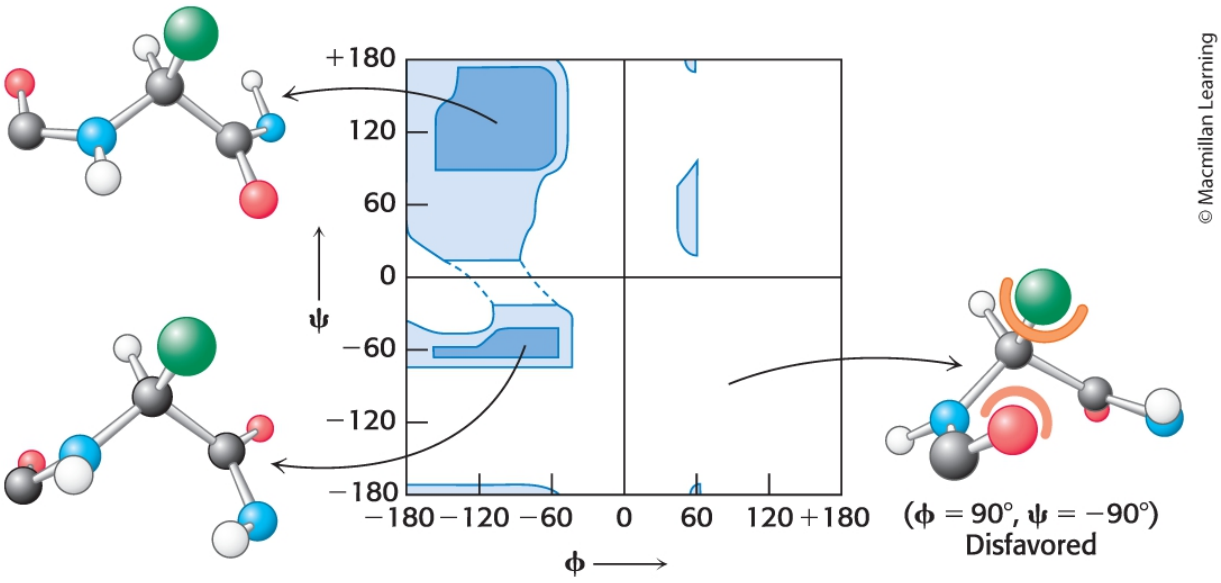
Cis: Proline and the amino acid residue are linked together by a peptide bond highlighted in red. The amino acids are represented using ball-and-stick models. In the ball-and-stick model, black spheres represent carbon atoms, blue spheres represent nitrogen atoms, white spheres represent hydrogen atoms, red spheres represent oxygen atoms, and green spheres represent side chains.

In the first amino acid, a central black sphere is connected via rods to a blue sphere on the left, a black sphere on the upper right, a green sphere on the lower right and away from the observer, and a white sphere below and toward the observer. The blue sphere is connected to a white sphere above. The black sphere on the upper right is connected to a red sphere on the upper left and connected to a blue sphere of a heterocyclic pentagonal ring on the right. The 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 1 blue and 4 black spheres. The blue sphere occupies the first position, which is the leftmost vertex. Each black sphere except for the one at the bottom left vertex is connected to two white spheres. The black sphere at the bottom left vertex is connected to a white sphere away from the observer and another black sphere on the lower left, which is connected to a red sphere on the lower right. Orange semicircles are drawn around the green sphere of the first amino acid and the white spheres are connected to the black sphere at the bottom left vertex.

Return to FIGURE 2.19 For peptide bonds between proline and its preceding residue, cis bonds are as likely as trans bonds

Extended description for FIGURE 2.20 The structure of each amino acid in a polypeptide adjusts by rotation about two single bonds

Part (A): Open single bond, N, single bond, C, single bond, C, single bond, N, single bond, C, single bond, C, single bond, N, single bond, C, single bond, C, open single bond. The first and the third N atoms are each single bonded to H below. The second N atom is single bonded to H above and is highlighted in blue. C 1 and C 5 are each dash bonded to H on the upper left and wedge bonded to R on the upper right. C 2 and C 6 are double bonded to O below. C 4 is double bonded to O above which is highlighted in red. C 3 is wedge bonded to H on the lower left and dash bonded to R on the lower right, which is highlighted in green. A rotating curved arrow around the single bond between C 3 and the second N is labeled phi. Another rotating curved arrow around the single bond between C 3 and C 4 is labeled psi.



Part (B): A ball-and-stick model shows a central black sphere connected to a blue sphere in the front, a black sphere on the upper left, a small white sphere on the upper right away from the observer, and a green sphere on the lower right. The black sphere on the upper left is connected to a red sphere on the upper left. The blue

sphere is connected to a black sphere above and a small white sphere below. The black sphere above is connected to a red sphere above. The angle between the black sphere connected to the blue sphere and the black sphere connected to the central black sphere is labeled phi. Phi equals negative 80 degrees.

Part (C): A ball-and-stick model shows a central black sphere connected to a black sphere in the front, a red sphere on the left and away from the observer, and a blue sphere on the lower right. The blue sphere is connected to a small white sphere on the lower right. The black sphere in the front is connected to a blue sphere above, a small white sphere on the lower right, and a green sphere on the lower left and toward the observer. The blue sphere above is connected to a small white sphere on the upper left and toward the observer. The angle between the blue sphere above and the blue sphere on the lower right is labeled psi. Psi equals positive 85 degrees.

Return to FIGURE 2.20 The structure of each amino acid in a polypeptide adjusts by rotation about two single bonds

Extended description for FIGURE 2.21 A Ramachandran plot shows that not all φ and ψ values are possible without collisions between atoms

© Macmillan Learning

The Ramachandran plot consists of a horizontal axis and a vertical axis. The horizontal axis is labeled phi and has markings ranging from negative 180 to positive 180 in increments of 60 units. The vertical axis is labeled psi and has markings ranging from negative 180 to positive 180 in increments of 60 units.

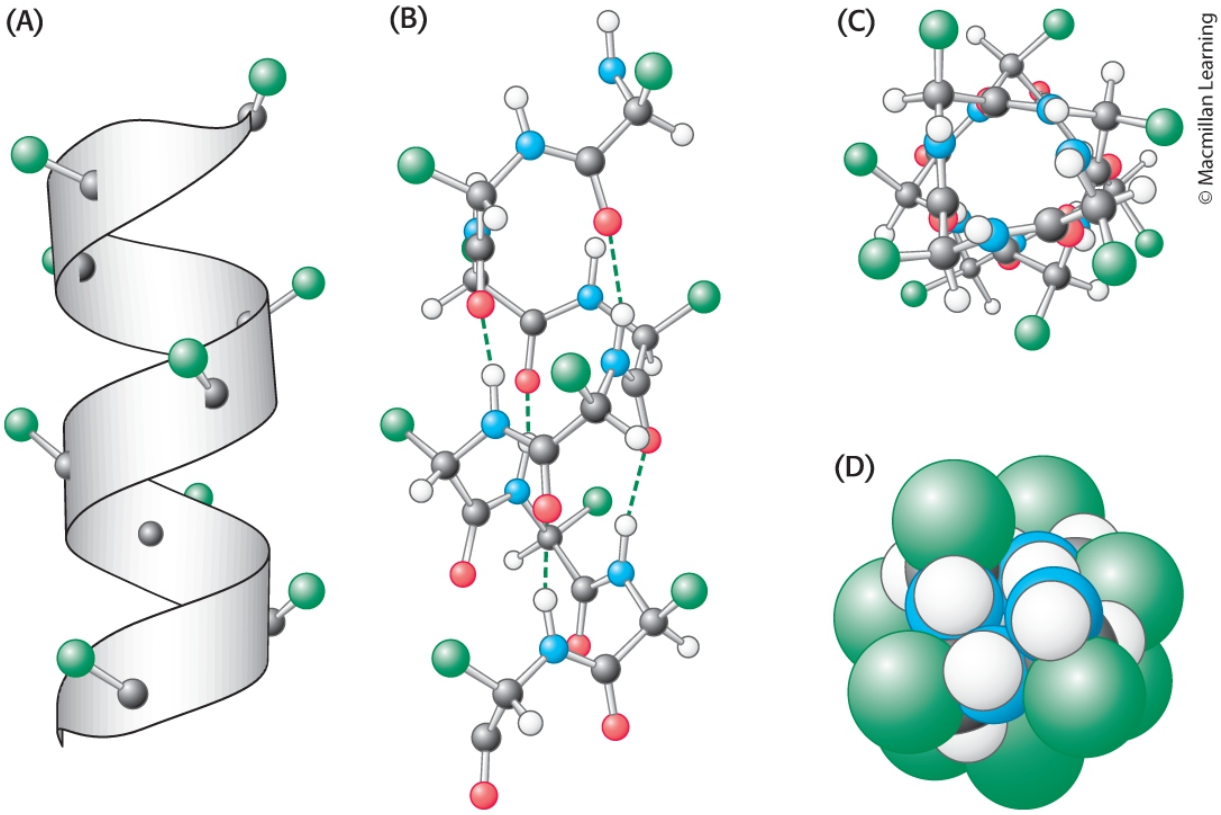
The plot is divided into four quadrants with the help of a horizontal and a vertical line. The horizontal line begins from the marking 0 on the vertical axis. The vertical line begins from the marking 0 on the horizontal axis. The first quadrant is located at the top left. The second quadrant is located at the top right. The third quadrant is located at the bottom left. The fourth quadrant is located at the bottom right.

The first quadrant contains a light blue region that spans from a point just above 0 to positive 180 on the vertical axis and negative 180 to a point after negative 60 on the horizontal axis. The left side of the bottom portion of the light blue region narrows down from a point just below the positive 60 on the vertical axis. The right side of the bottom portion of the light blue region narrows down from a point between the positive 60 and positive 120 on the vertical axis. The bottom side of the light blue region spans from a point before negative 120 marking to a point before negative 60 on the horizontal axis. Within the top portion of the light blue region, a square-shaped dark blue region with an indentation on the top left is present. It spans from the midpoint of positive 120 and 60 to a point just below positive 180 on the vertical axis and a point before negative 120 to a point just after negative 60 on the horizontal axis.

An arrow from the dark blue region points toward a molecule depicted using a ball-and-stick model. The structure of the molecule is as follows: A black sphere is connected to another black sphere on the lower right, a blue sphere on the lower left, a green sphere on the upper right, and a white sphere on the upper left. The green sphere is toward the observer and the white sphere is away from the observer. The black sphere on the lower right is connected to a blue sphere on the right and a red sphere below. The red sphere is toward the observer. The blue sphere is away from the observer and is connected to a white sphere that is away from the observer. The blue sphere on the lower left is connected to a black sphere on the right and a white sphere in the center. The white sphere is toward the observer. The black sphere is connected to a red sphere above. The red sphere is away from the observer.

In the second quadrant, a tiny light blue region pointed downward is located on the top left at negative 180 above the positive 60 marking on the horizontal axis. An elongated light blue region is present on the bottom left. It has a pointed tip on the top. It spans from a point

just above 0 to a point below positive 120 on the vertical axis and two closely spaced points between 0 and 60 on the horizontal axis.



In the third quadrant, a narrow rectangular-shaped light blue region is present. This light blue region has a concave depression on the top left. It spans from a point just below negative 60 to a point below 0 on the vertical axis and negative 180 to a point just after negative 60 on the horizontal axis. The two pointed edges on the top right portion of the rectangular light blue region are connected to the corresponding two pointed edges on the bottom side of the light blue region in the first quadrant by two dashed lines. Within the light blue region, a smaller dark blue region is present. The dark blue region has a shape similar to the blue region. It spans from a point just below negative 60 to a point above negative 60 on the vertical axis and a point after negative 180 to a point just after negative 60 on the horizontal axis.

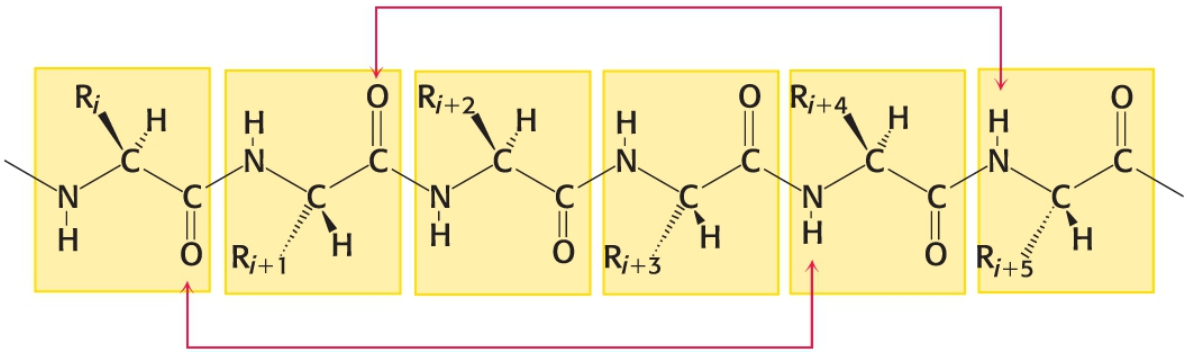
An arrow from the dark blue region points toward a molecule depicted using a ball-and-stick model. The structure of the molecule is as follows: A black sphere is connected to another black sphere on the lower right, a blue sphere on the lower left, a green sphere on the upper right, and a white sphere on the upper left. The green sphere is toward the observer. The white sphere is away from the observer. The black sphere on the lower right is connected to a blue sphere on the lower right and a red sphere on the upper right. The red sphere is away from the observer. The blue sphere is toward the observer and is connected to a white sphere on the lower left. The white sphere is toward the observer. The blue sphere on the lower left is connected to a white sphere toward the observer and a black sphere on the lower left. The black sphere on the lower left is connected to a red sphere behind. A narrow light blue region is located at the bottom left of the third quadrant. It spans from negative 180 to a point just above negative 180 on the vertical axis and negative 180 to negative 60 on the horizontal axis.

In the fourth quadrant, a tiny light blue pointed region is located at positive 60 on the horizontal axis. An arrow from the middle of the white region points toward a molecule depicted using a ball-and-stick model. The structure of the molecule is as follows: A black sphere is connected to a green sphere on the upper right, a white sphere on the upper left, a black sphere on the lower right, and a blue sphere on the lower left. The green sphere is toward the observer and is surrounded by a thick orange semi-circular line. The white sphere is away from the observer. The black sphere on the lower right is connected to a white sphere on the lower right, a blue sphere on the lower right and away from the observer, and a red sphere behind. The blue sphere on the lower left is connected to a white sphere on the left and a black sphere toward the observer. The black sphere is connected to a red sphere on the upper right. The red sphere is surrounded by a thick red semi-circular line. Note: phi is equal to 90 degrees, psi is equal to negative 90 degrees, disfavored.

Return to FIGURE 2.21 A Ramachandran plot shows that not all φ and ψ values are possible without collisions between atoms

Extended description for FIGURE 2.22 Various depictions of an alpha helix reveal several of its key features

Part (A): A ribbon-like structure forms a vertical helical structure. Green spheres connected to black spheres are attached to the helix at equal distances from top to bottom.



Part (B): A side-view of the ball-and-stick model of an alpha helix is illustrated. black spheres represent carbon atoms, blue spheres represent nitrogen atoms, white spheres represent hydrogen atoms, red spheres represent oxygen atoms, and green spheres represent side chains. Green dashed lines are drawn between the N H and C O groups of adjacent turns.

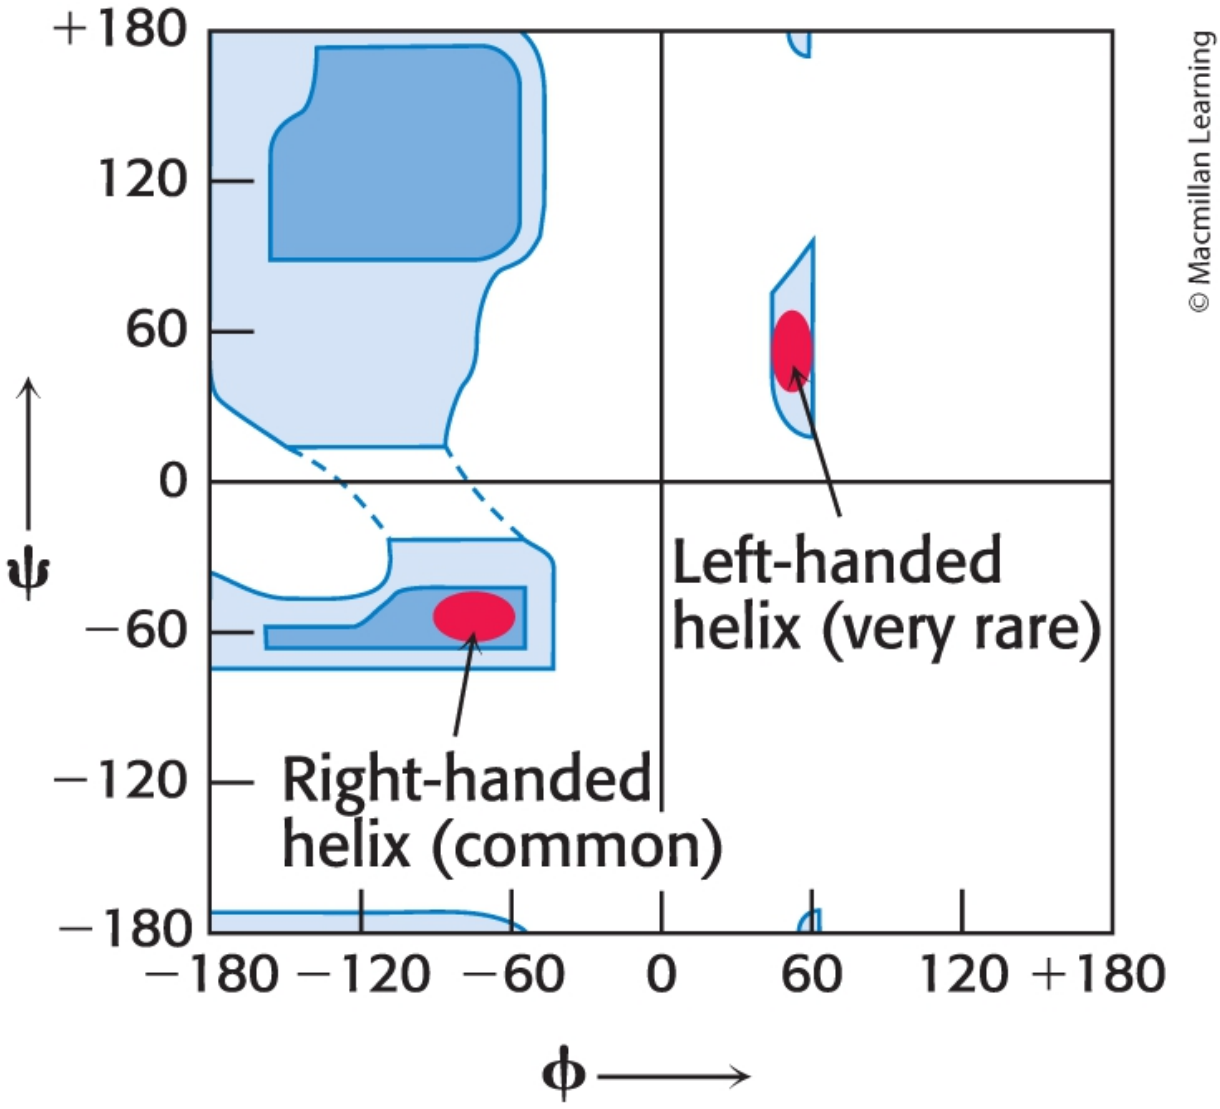
Part (C): An end-view of an alpha-helix shows a ring-like structure in which the side chains of the amino acids are oriented toward the periphery. Black spheres represent carbon atoms, blue spheres represent nitrogen atoms, white spheres represent hydrogen atoms, red spheres represent oxygen atoms, and green spheres represent side chains.

Part (D): An end-view of a space-filling model of an alpha-helix shows blue spheres fused to white spheres at the center and large green spheres at the periphery. Blue spheres represent nitrogen atoms, white spheres represent hydrogen atoms, and green spheres represent side chains.

Return to FIGURE 2.22 Various depictions of an alpha helix reveal several of its key features

Extended description for FIGURE 2.23 In an alpha helix, hydrogen bonds form between the CO group of residue I and the NH group of residue i + 4

Six amino acid residues are connected in a linear chain by peptide bonds. The basic structure of the peptide linkage between two amino acids is as follows: In the first amino acid, a central C atom is single bonded to C on the lower right, single bonded to N on the lower left, dash bonded to H on the upper right, and wedge bonded to R subscript i on the upper left. N is single bonded to H below and has an open single bond on the upper left. The C on the lower right is double bonded to O below and single bonded to N of the next amino acid.



In the next amino acid, a central C atom is single bonded to C on the upper right, single bonded to N on the upper left, dash bonded to R subscript i plus 1 on the lower left, and wedge bonded to H on the lower right. N is single bonded to H above. C on the upper right is double bonded to O above and single bonded to N of the next amino acid.

Two such pairs of amino acids are linked in a series. The respective side chains of the next four amino acids are R subscript i plus 2, R

subscript i plus 3, R subscript i plus 4, and R subscript i plus 5. A double headed red arrow is shown between the O atom in the second amino acid and the H bonded to N above in the sixth amino acid. A double headed red arrow is shown between the O atom in the first amino acid and the H bonded to N below in the fifth amino acid.

Return to FIGURE 2.23 In an alpha helix, hydrogen bonds form between the CO group of residue I and the NH group of residue i + 4

Extended description for FIGURE 2.24 Both right- and left-handed helices lie in regions of allowed conformations in the Ramachandran plot

The Ramachandran plot consists of a horizontal axis and a vertical axis. The horizontal axis is labeled phi and has markings ranging from negative 180 to positive 180 in increments of 60 units. The

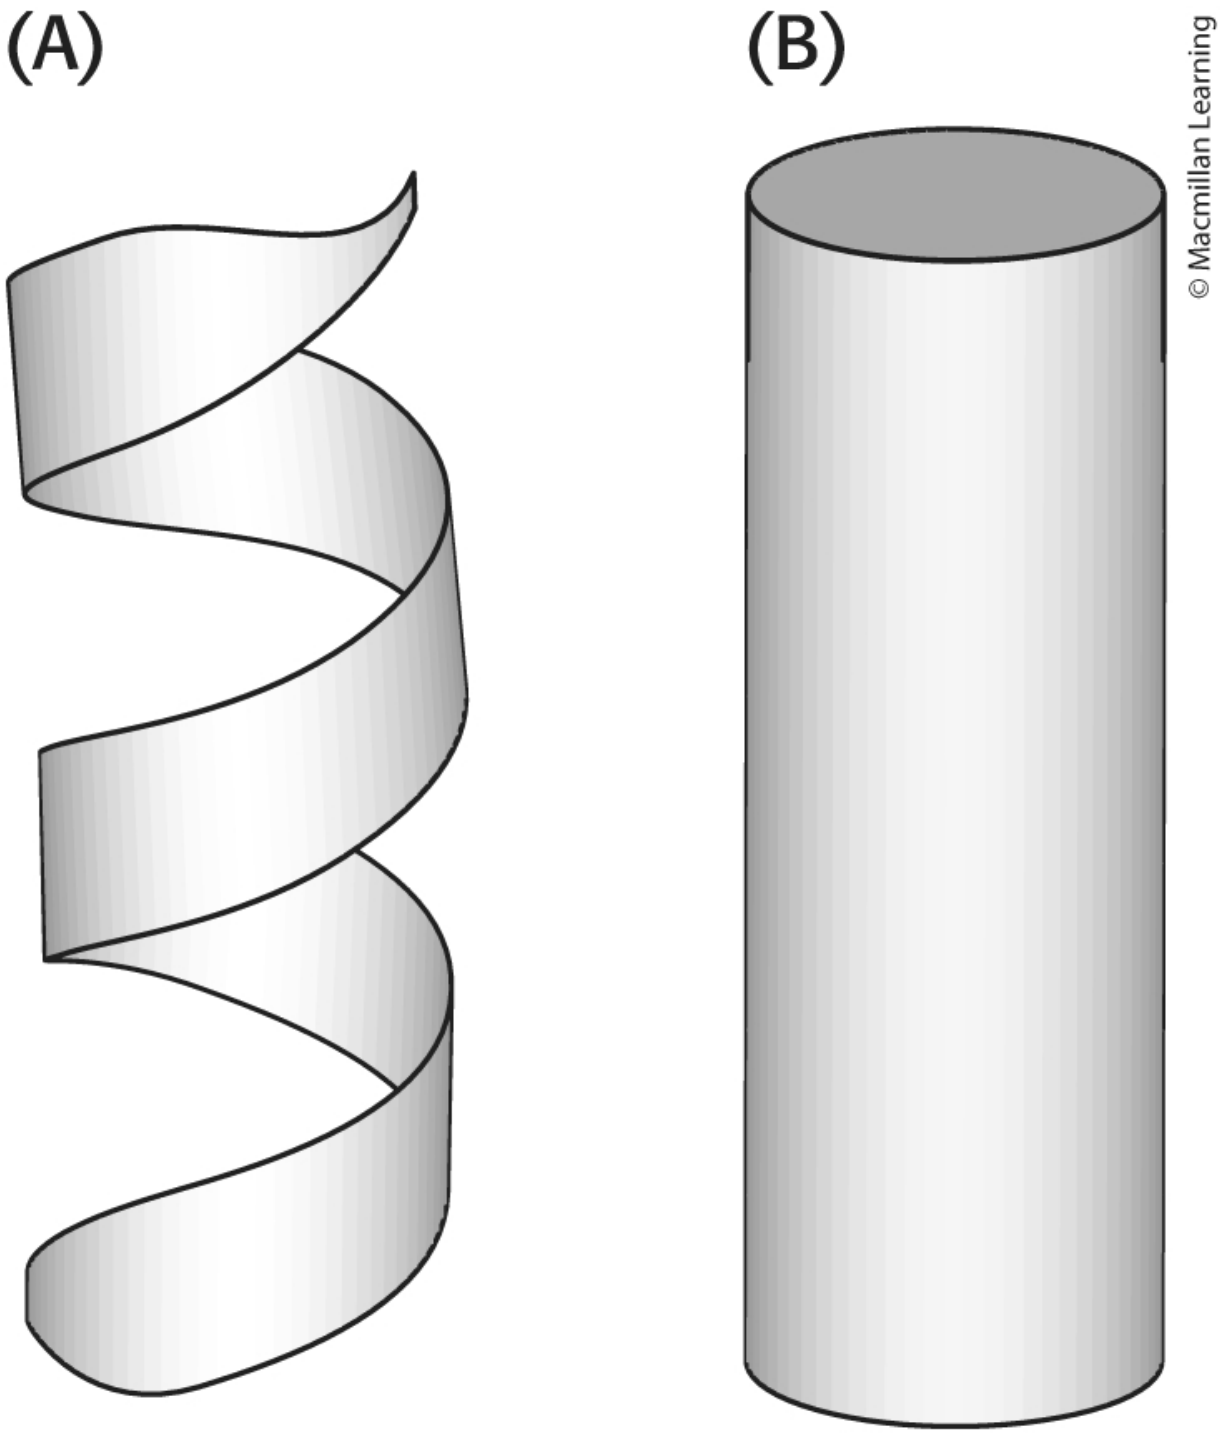
vertical axis is labeled psi and has markings ranging from negative 180 to positive 180 in increments of 60 units.

The plot is divided into four quadrants with the help of a horizontal and a vertical line. The horizontal line begins from the marking 0 on the vertical axis. The vertical line begins from the marking 0 on the horizontal axis. The first quadrant is located at the top left. The second quadrant is located at the top right. The third quadrant is located at the bottom left. The fourth quadrant is located at the bottom right.

The first quadrant contains a light blue region that spans from a point just above 0 to positive 180 on the vertical axis and negative 180 to a point after negative 60 on the horizontal axis. The left side of the bottom portion of the light blue region narrows down from a point just below the positive 60 on the vertical axis. The right side of the bottom portion of the light blue region narrows down from a point between the positive 60 and positive 120 on the vertical axis. The bottom side of the light blue region spans from a point before negative 120 marking to a point before negative 60 on the horizontal axis. Within the top portion of the light blue region, a square-shaped dark blue region with an indentation on the top left is present. It spans from the midpoint of positive 120 and 60 to a point just below positive 180 on the vertical axis and a point before negative 120 to a point just after negative 60 on the horizontal axis.

In the second quadrant, a tiny light blue region pointed downward is located at the top left at negative 180 above the positive 60 marking on the horizontal axis. An elongated light blue region is present at the bottom left. It has a pointy tip on the top. It spans from a point just above 0 to a point below positive 120 on the vertical axis and two closely spaced points between 0 and 60 on the horizontal axis. Within the elongated region, a red circular region labeled left-handed helix (very rare) is present. The red region fits inside the

elongated region. The red region spans from a point below positive 60 to a point just above positive 60 on the vertical axis.



In the third quadrant, a narrow rectangular-shaped light blue region is present. This light blue region has a concave depression on the top left. It spans from a point just below negative 60 to a point below 0 on the vertical axis and negative 180 to a point just after negative 60 on the horizontal axis. The two pointed edges on the top right portion of the rectangular light blue region are connected to the corresponding two pointed edges on the bottom side of the light blue region in the first quadrant by two dashed lines. Within the light blue region, a smaller dark blue region is present. The dark blue region has a shape similar to the blue region. It spans from a point just below negative 60 to a point above negative 60 on the vertical axis and a point after negative 180 to a point just after negative 60 on the horizontal axis. Within the dark blue region, a red circular region labeled right-handed helix (common) is present on the right. The red region fits inside the dark blue region. It spans between a point before negative 60 to negative 60 on the horizontal axis. A narrow light blue region is located at the bottom left of the third quadrant. It spans from negative 180 to a point just above negative 180 on the vertical axis and negative 180 to negative 60 on the horizontal axis.

In the fourth quadrant, a tiny light blue pointed region is located at positive 60 on the horizontal axis.

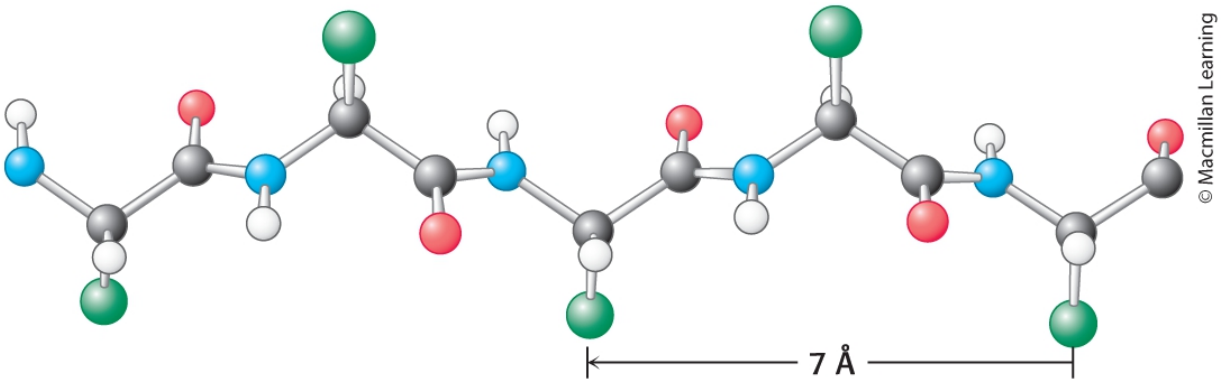
Extended description for FIGURE 2.27 β strands occupy an allowed region of the Ramachandran plot

The Ramachandran plot consists of a horizontal axis and a vertical axis. The horizontal axis is labeled phi and has markings ranging from negative 180 to positive 180 in increments of 60 units. The vertical axis is labeled psi and has markings ranging from negative 180 to positive 180 in increments of 60 units.

The plot is divided into four quadrants with the help of a horizontal and a vertical line. The horizontal line begins from the marking 0 on the vertical axis. The vertical line begins from the marking 0 on the horizontal axis.

The first quadrant is located at the top left. The second quadrant is located at the top right. The third quadrant is located at the bottom left. The fourth quadrant is located at the bottom right. The first quadrant contains a light blue region that spans from a point just above 0 to positive 180 on the vertical axis and negative 180 to a point after negative 60 on the horizontal axis. The left side of the bottom portion of the light blue region narrows down from a point just below the positive 60 on the vertical axis. The right side of the bottom portion of the light blue region narrows down from a point between the positive 60 and positive 120 on the vertical axis. The bottom side of the light blue region spans from a point before negative 120 marking to a point before negative 60 on the horizontal axis. Within the top portion of the light blue region, a square-shaped dark blue region with an indentation on the top left is present. It spans from 90 to a point just below positive 180 on the vertical axis and negative 150 to a point just after negative 60 on the horizontal axis. Within the dark blue region, a small square-shaped red region labeled beta strands is present. The red region spans from a point below positive 180 to a point below positive 120 on the vertical axis and a point just before negative 120 to a point before negative 60 on the horizontal axis.

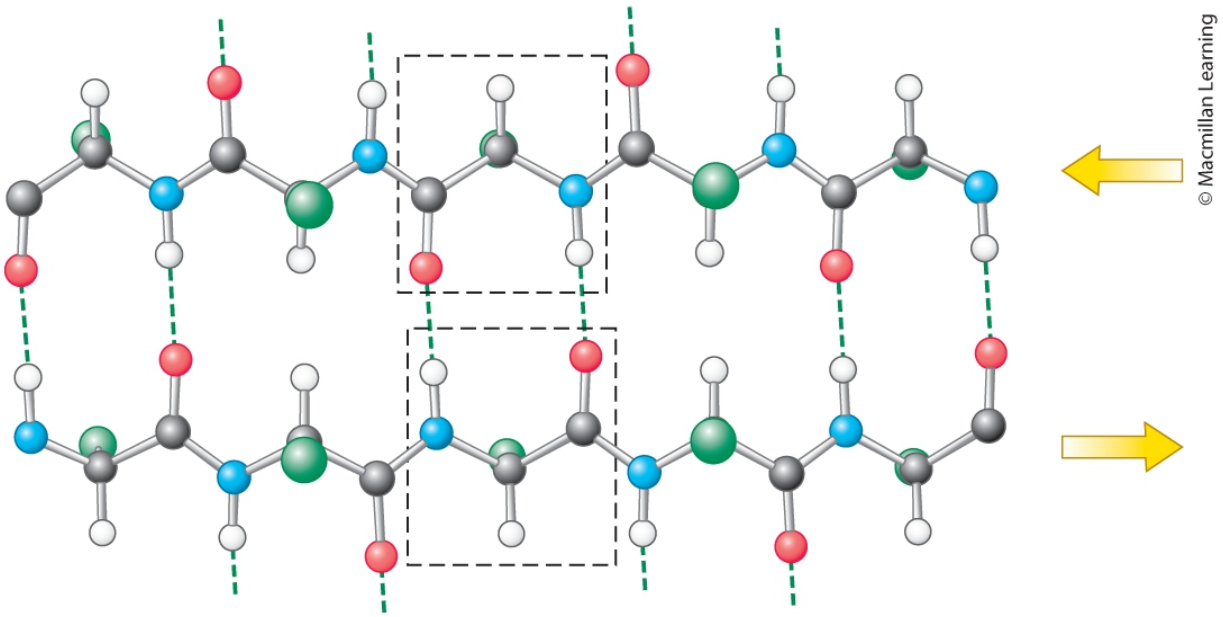


In the second quadrant, a tiny light blue region pointed downward is located on the top left at negative 180 above the positive 60 marking on the horizontal axis. An elongated light blue region is present on the bottom left. It has a pointy tip on the top. It spans from a point just above 0 to a point below positive 120 on the vertical axis and two closely spaced points between 0 and 60 on the horizontal axis.

In the third quadrant, a narrow rectangular-shaped light blue region is present. This light blue region has a concave depression on the top left. It spans from a point just below negative 60 to a point below 0 on the vertical axis and negative 180 to a point just after negative 60 on the horizontal axis. The two pointed edges on the top right portion of the rectangular light blue region are connected to the corresponding two pointed edges on the bottom side of the light blue region in the first quadrant by two dashed lines. Within the light blue region, a smaller dark blue region is present. The dark blue region has a shape similar to the light blue region. It spans from a point just below negative 60 to a point above negative 60 on the vertical axis and a point after negative 180 to a point just after negative 60 on the horizontal axis. A narrow light blue region is located at the bottom left of the third quadrant. It spans from negative 180 to a point just above negative 180 on the vertical axis and negative 180 to negative 60 on the horizontal axis.

In the fourth quadrant, a tiny light blue pointed region is located at positive 60 on the horizontal axis.

Return to FIGURE 2.27 β strands occupy an allowed region of the Ramachandran plot



Extended description for FIGURE 2.28 The side chains of a beta strand project alternately above and below the plane of the strand

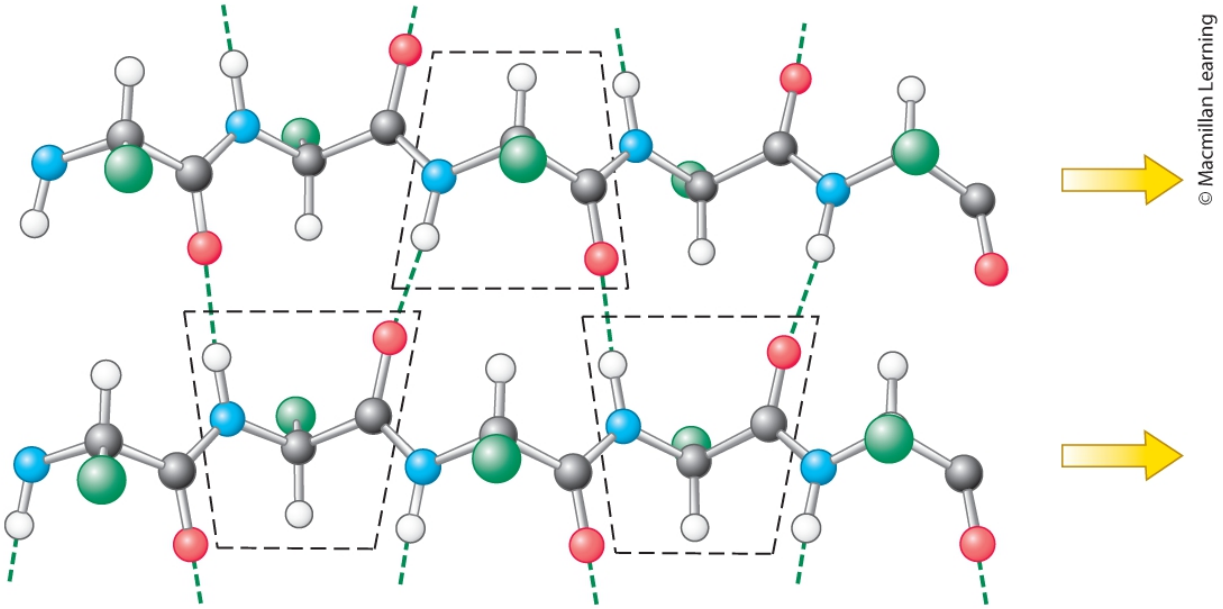
The ball-and-stick model is represented by a central black sphere connected to a blue sphere on the upper left and a black sphere on the upper right. The blue sphere is connected to a small white sphere. The second black sphere is connected to a red sphere. The central black sphere is connected to a small white sphere above and away from the observer and a large green sphere below. The second black sphere of one amino acid is connected to the blue sphere of the adjacent amino acid. Five such amino acids are linked such that the side chains of the adjacent amino acids are facing in vertically opposite directions. The distance between the side chains of two amino acids in alternate positions is 7 angstrom.

Return to FIGURE 2.28 The side chains of a beta strand project alternately above and below the plane of the strand

Extended description for FIGURE 2.29 In an antiparallel beta sheet, adjacent beta strands run in opposite directions

The structure of the ball-and-stick model is as follows: C atoms are depicted as black spheres, R groups are depicted as green spheres, H atoms are depicted as small white spheres, amino groups are depicted as small blue spheres, and carboxyl groups are depicted as small red spheres. The C and the N atoms form the zigzag-shaped backbone of the structure. Two peptide chains are shown above each other.

The first chain starts with a black sphere connected to another black sphere on the lower left, a blue sphere on the lower right, a white sphere above, and a green sphere behind. The blue sphere on the lower right is connected to a white sphere below and a black sphere on the upper right. The black sphere on the upper right is connected to a red sphere above and a black sphere on the lower right. The



black sphere on the lower right is connected to a green sphere toward the observer, a white sphere below, and a blue sphere on the upper right.

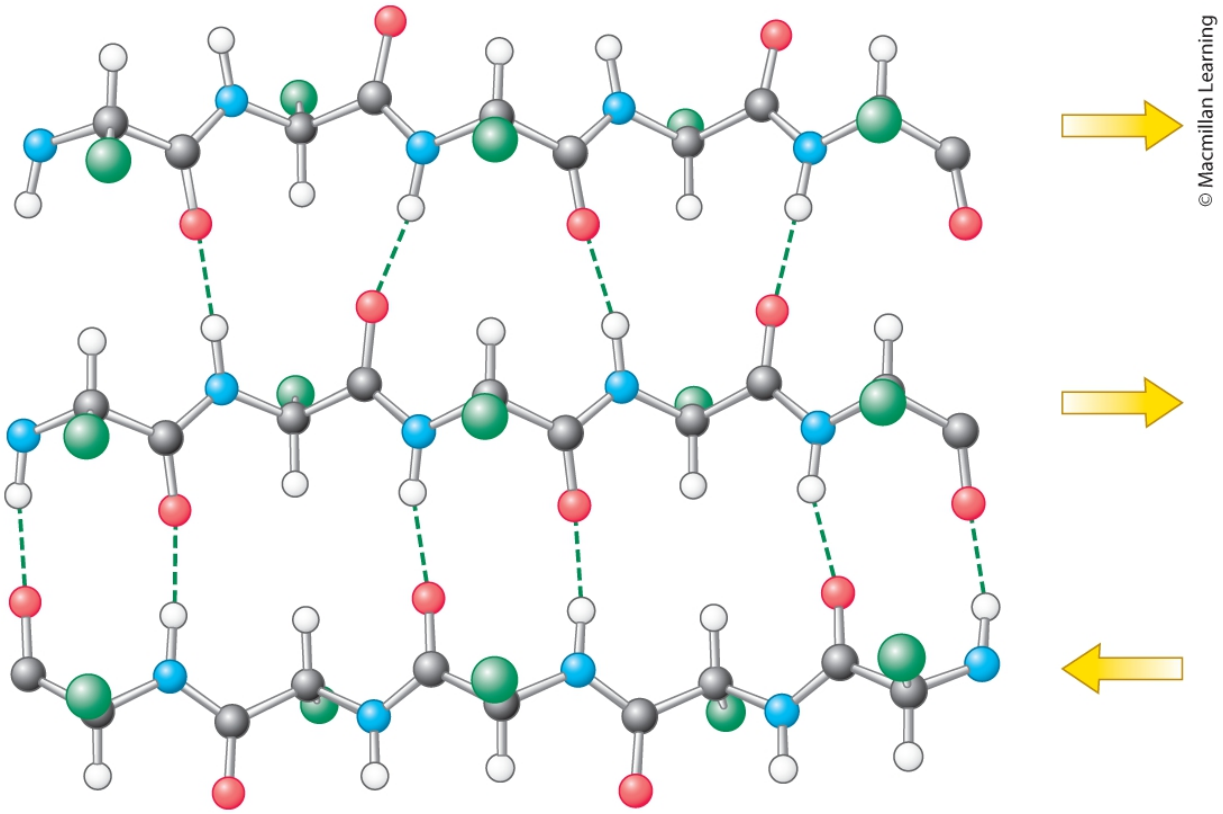
These structures are present in an alternating manner in the first peptide. A rightward pointing arrow is present at the right of the first peptide chain. Vertical dashed lines arise upward from the first red sphere, second white sphere, second red sphere, and fourth white sphere. The second peptide chain starts with a black sphere connected to a blue sphere on the upper left, a black sphere on the upper right, a white sphere below, and a green sphere behind. The blue sphere on the upper left is connected to a white sphere above. The black sphere on the upper right is connected to a blue sphere on the lower right and a red sphere above. The blue sphere is connected to a black sphere on the upper right and a white sphere below. The black sphere on the upper right is connected to a black sphere on the lower right, a white sphere above, a green sphere toward the observer.

These structures are repeated alternately. A leftward pointing arrow is shown at the right of the second peptide chain. Vertical lines arise downward from the second white sphere, first red sphere, fourth white sphere, and second red sphere. Vertical dashed lines arising in the downward direction from the first red sphere, white sphere, second red sphere, third white sphere, third red sphere, and fifth white sphere located below the plane of the first peptide chain connect with the first white sphere, first red sphere, third white sphere, second red sphere, second red sphere, and third red sphere, respectively, located above the plane of the second peptide chain. The third molecule from the left is enclosed within dashed square boxes in both the chains.

Return to FIGURE 2.29 In an antiparallel beta sheet, adjacent beta strands run in opposite directions

Extended description for FIGURE 2.30 In a parallel β sheet, adjacent β strands run in the same direction

The structure of the ball-and-stick model is as follows: C atoms are depicted as black spheres, R groups are depicted as green spheres, H atoms are depicted as small white spheres, amino groups are depicted as small blue spheres, and carboxyl groups are depicted as small red spheres. The C and N atoms form the zigzag backbone of the structure. Two peptide chains are shown one above the other. Both the chains have the same structure.



A black sphere is connected to another black sphere on the lower right, a blue sphere on the lower left, a white sphere above, and a green sphere toward the observer. The blue sphere on the lower left is connected to a white sphere below. The black sphere on the lower right is connected to a red sphere below and a blue sphere on the upper right. The blue sphere on the upper right is connected to a white sphere above and a black sphere on the lower right. The black

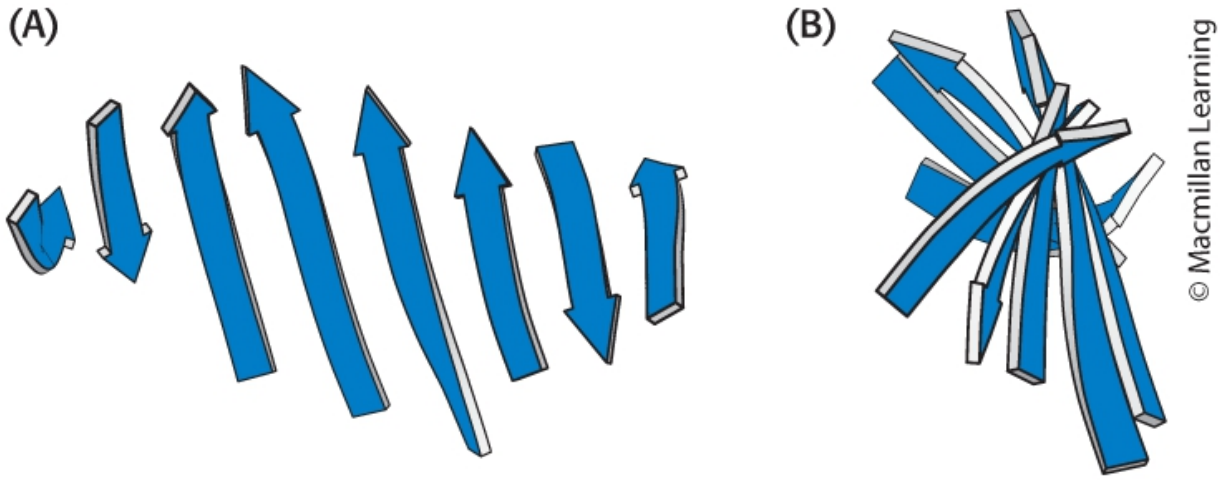
sphere is connected to a green sphere behind, a white sphere below, and a black sphere on the upper right.

These structures are present in an alternating manner in both the peptide chains. A right-pointing arrow is present at the right of both the peptides. Vertical dashed lines arise upward from the second white sphere above, the first red sphere, the fourth white sphere, and the second red sphere located above the plane of the first peptide. Vertical dashed lines arise downward from the first white sphere, first red sphere, third white sphere, second red sphere, fifth white sphere, and third red sphere located below the plane of the second peptide. Vertical dashed lines arising in the downward direction from the first red sphere, third white sphere, second red sphere, fifth white sphere, located below the plane of the first peptide connect with the second white sphere, first red sphere, fourth white sphere, second red sphere, and second red sphere, respectively, located above the plane of the second peptide chain. The third molecule from the left in the first peptide is enclosed within dashed boxes. The second and the fourth molecule from the left in the second peptide are enclosed within dashed boxes.

Return to FIGURE 2.30 In a parallel β sheet, adjacent β strands run in the same direction

Extended description for FIGURE 2.31 In a mixed beta sheet, the beta strands have a combination of parallel and antiparallel pairings

Three peptide chains are shown one below the other. The ball-and-stick model of an amino acid unit is as follows: Black spheres represent carbon atoms, blue spheres represent nitrogen atoms, white spheres represent hydrogen atoms, red spheres represent oxygen atoms, and green spheres represent side chains.



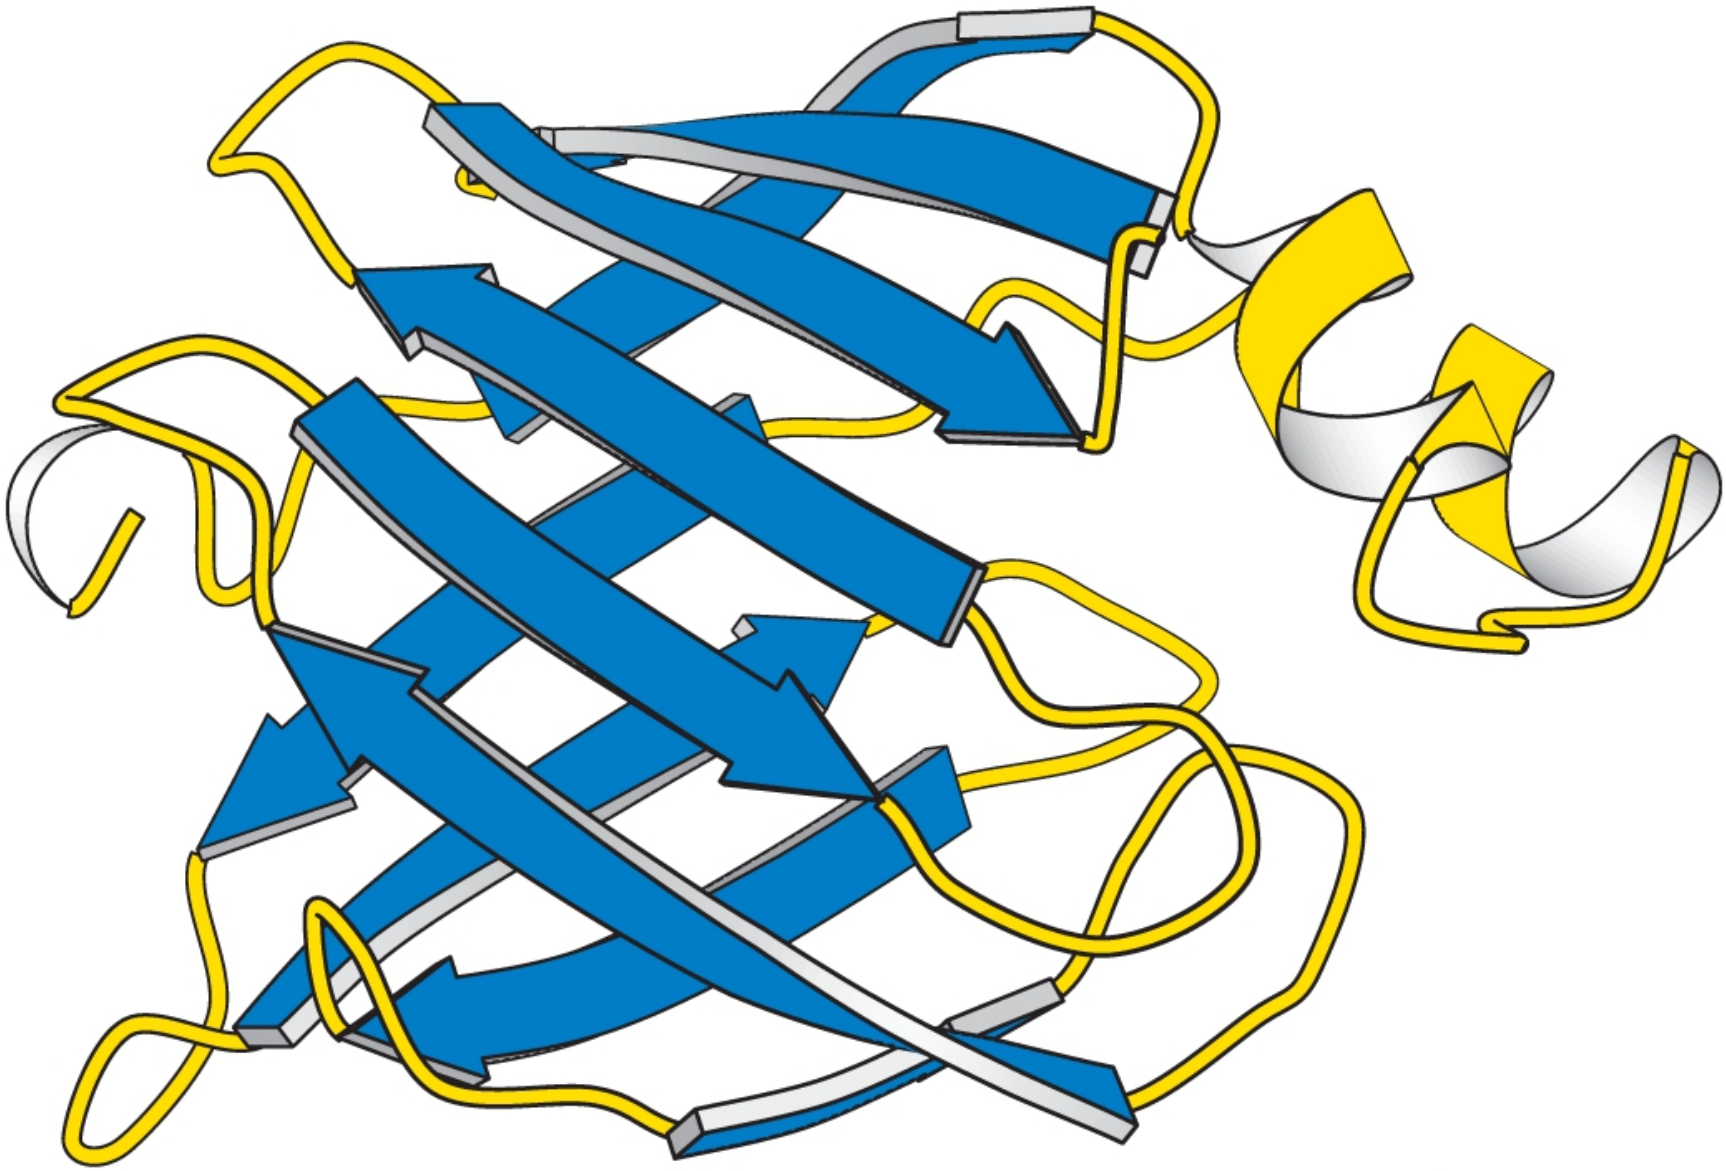
A black sphere is connected to another black sphere on the lower right, a blue sphere on the lower left, a white sphere above, and a green sphere toward the observer. The blue sphere on the lower left is connected to a white sphere below. The black sphere on the lower

right is connected to a red sphere below and a blue sphere on the upper right. The blue sphere on the upper right is connected to a white sphere above and a black sphere on the lower right. The black sphere is connected to a green sphere behind, a white sphere below, and a black sphere on the upper right.

The first and the second peptide chains are parallel to each other, and the third peptide chain is anti-parallel to the first two strands. Green dotted lines are drawn between a red and a white sphere of two peptide chains in close proximity. A right pointing arrow next to the first and the second chain indicates that the carboxy terminals of the peptide chains are oriented to the right. A left pointing arrow next to the third chain indicates that the carboxy terminal of the peptide chain is oriented to the left.

Return to FIGURE 2.31 In a mixed beta sheet, the beta strands have a combination of parallel and antiparallel pairings

Extended description for FIGURE 2.32 The twisted shape of some beta sheets is more evident in a schematic depiction of strands



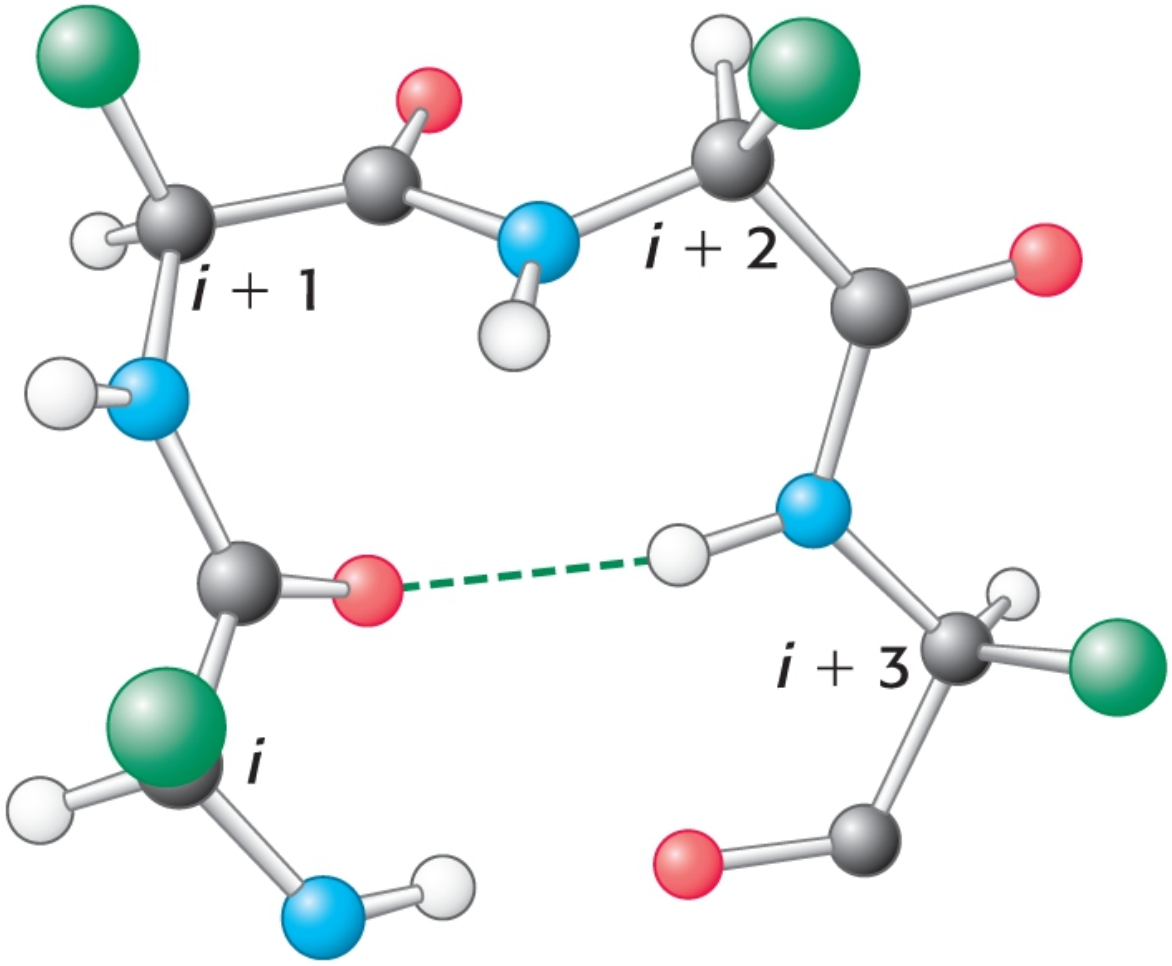
Part (A): Eight broad blue arrows are placed side by side. The first and the last arrows are twisted upward and are the shortest. The arrows look longer as they go from the ends to the middle. This diagram shows the twisted shape of beta sheets as seen from the front.

Part (B): Eight broad blue arrows are placed in a line from the front to back. The arrows gradually bend to the left from the right, from front to back. This diagram shows the twisted shape of beta sheets as seen from the side.

Return to FIGURE 2.32 The twisted shape of some beta sheets is more evident in a schematic depiction of strands

Extended description for FIGURE 2.33 Fatty acid-

binding protein is rich in beta sheets



© Macmillan Learning

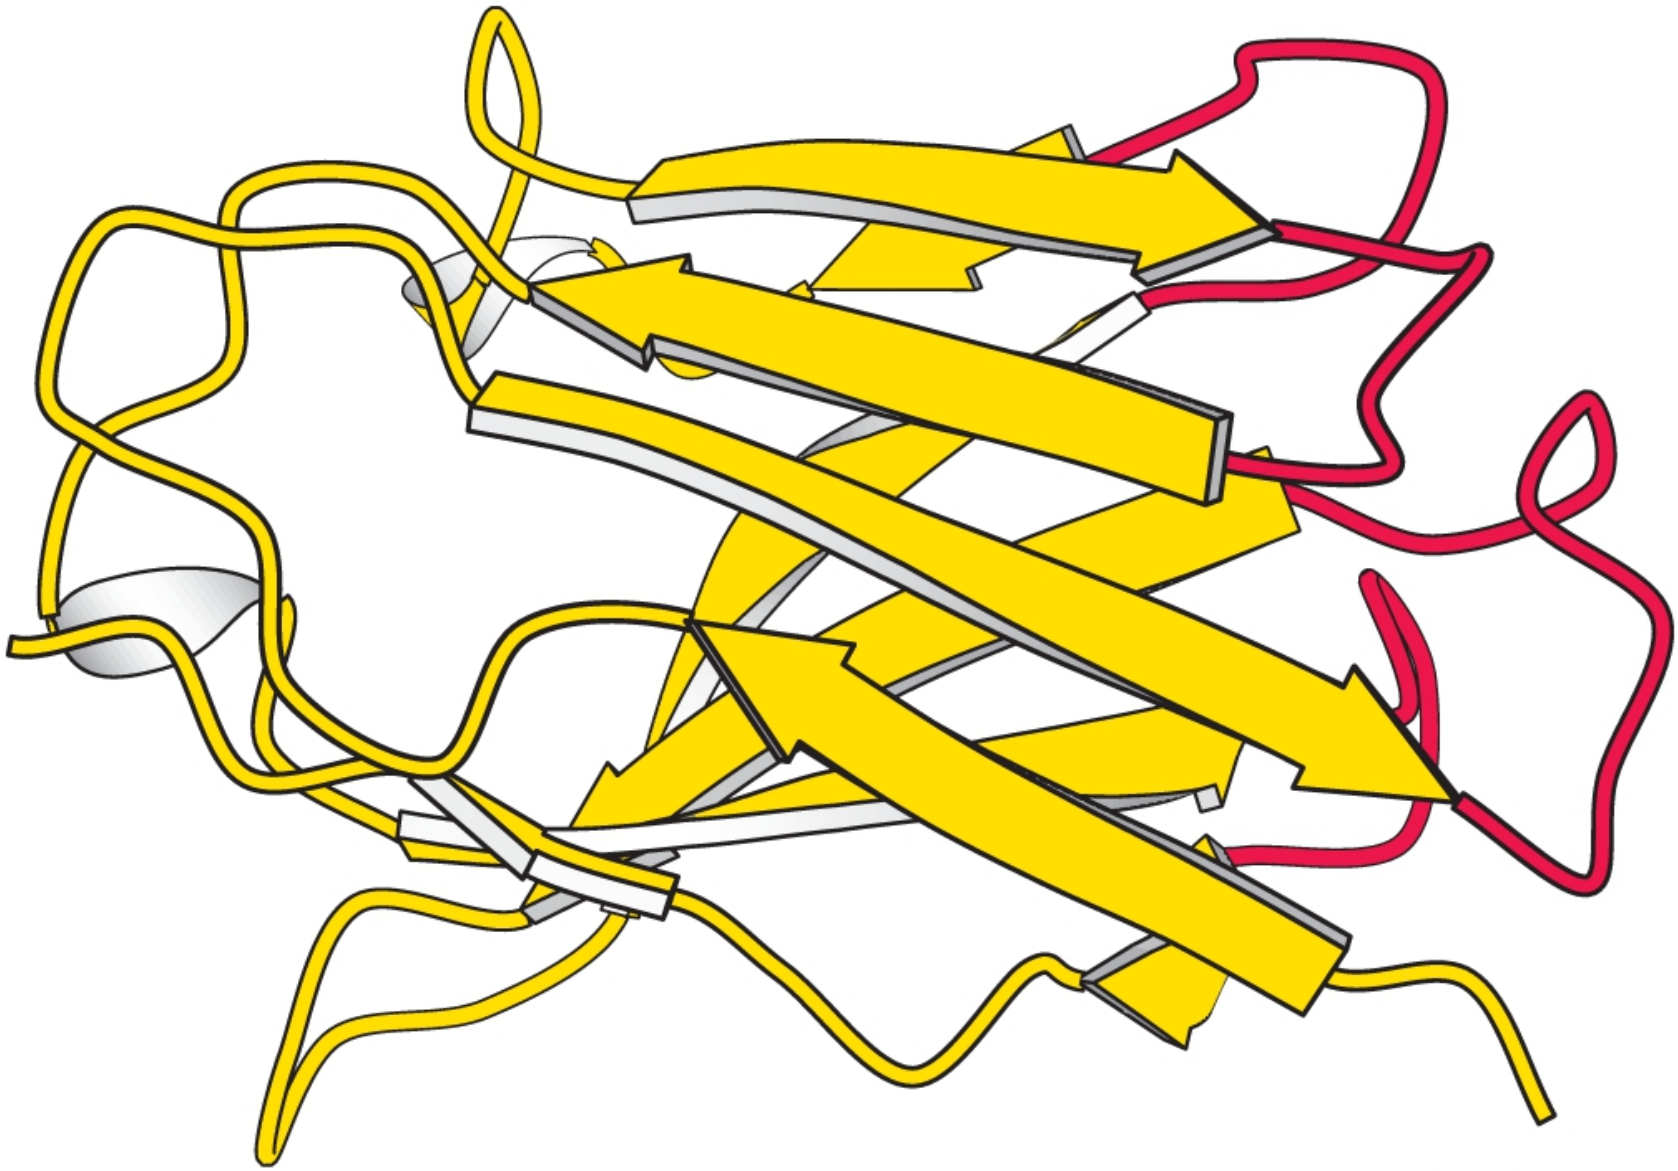
Broad blue arrows representing beta-sheets are arranged around an axis forming a barrel-like structure. The adjacent strands are oriented in opposite directions and connected by short tread-like loops. One of the arrows is connected to a yellow helix.

Return to FIGURE 2.33 Fatty acid-binding protein is rich in beta sheets

Extended description for FIGURE 2.34 In a reverse turn, the CO group of residue i of the polypeptide chain is hydrogen bonded to the NH group of residue i + 3

© Macmillan Learning

The ball-and-stick model of the residues in a reverse turn is shown. Each residue has the following structure: A central black sphere is connected to a black sphere on the lower right and a blue sphere on the lower left. The central black sphere is connected to a small white sphere away from the observer and a large green sphere above and toward the observer. The other black sphere is connected to a red sphere and the blue sphere is connected to a small white sphere.



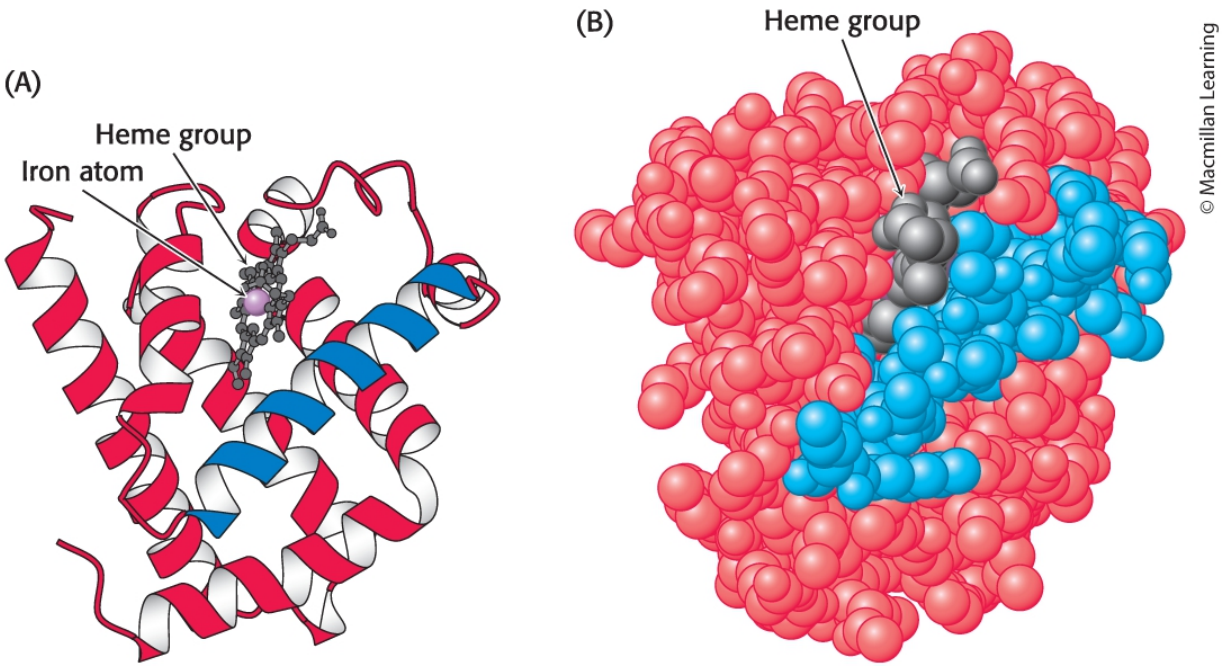
The second black sphere of one residue is connected to the blue sphere of the next residue.

Four such residues form an inverted U-shaped turn. The residues are labeled i, i plus 1, i plus 2, and i plus 3 in a clockwise direction, starting from the residue on the lower left. A dotted line is drawn between the red sphere of the first residue (i) and the small white sphere connected to the blue sphere of the fourth residue (i plus 3).

Return to FIGURE 2.34 In a reverse turn, the CO group of residue i of the polypeptide chain is hydrogen bonded to the NH group of residue i + 3

Extended description for FIGURE 2.35 Loops are found

on protein surfaces

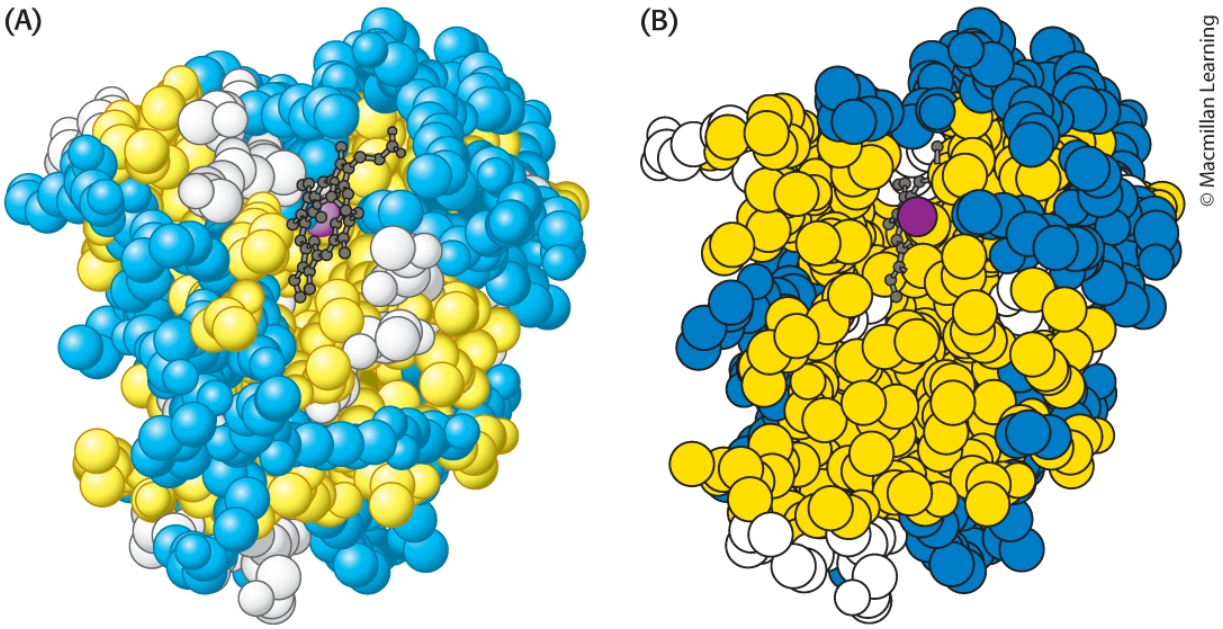


© Macmillan Learning

Antiparallel beta-sheets are shown at the center with the help of thick yellow arrows pointing in the upward and downward directions. The head and tail of the adjacent beta-strands at the bottom are connected by yellow thread-like structures forming curvy loops. The head and the tail of the adjacent beta-strands at the top are connected by red thread-like structures forming curvy loops.

Return to FIGURE 2.35 Loops are found on protein surfaces

Extended description for FIGURE 2.36 Myoglobin folds into a compact structure



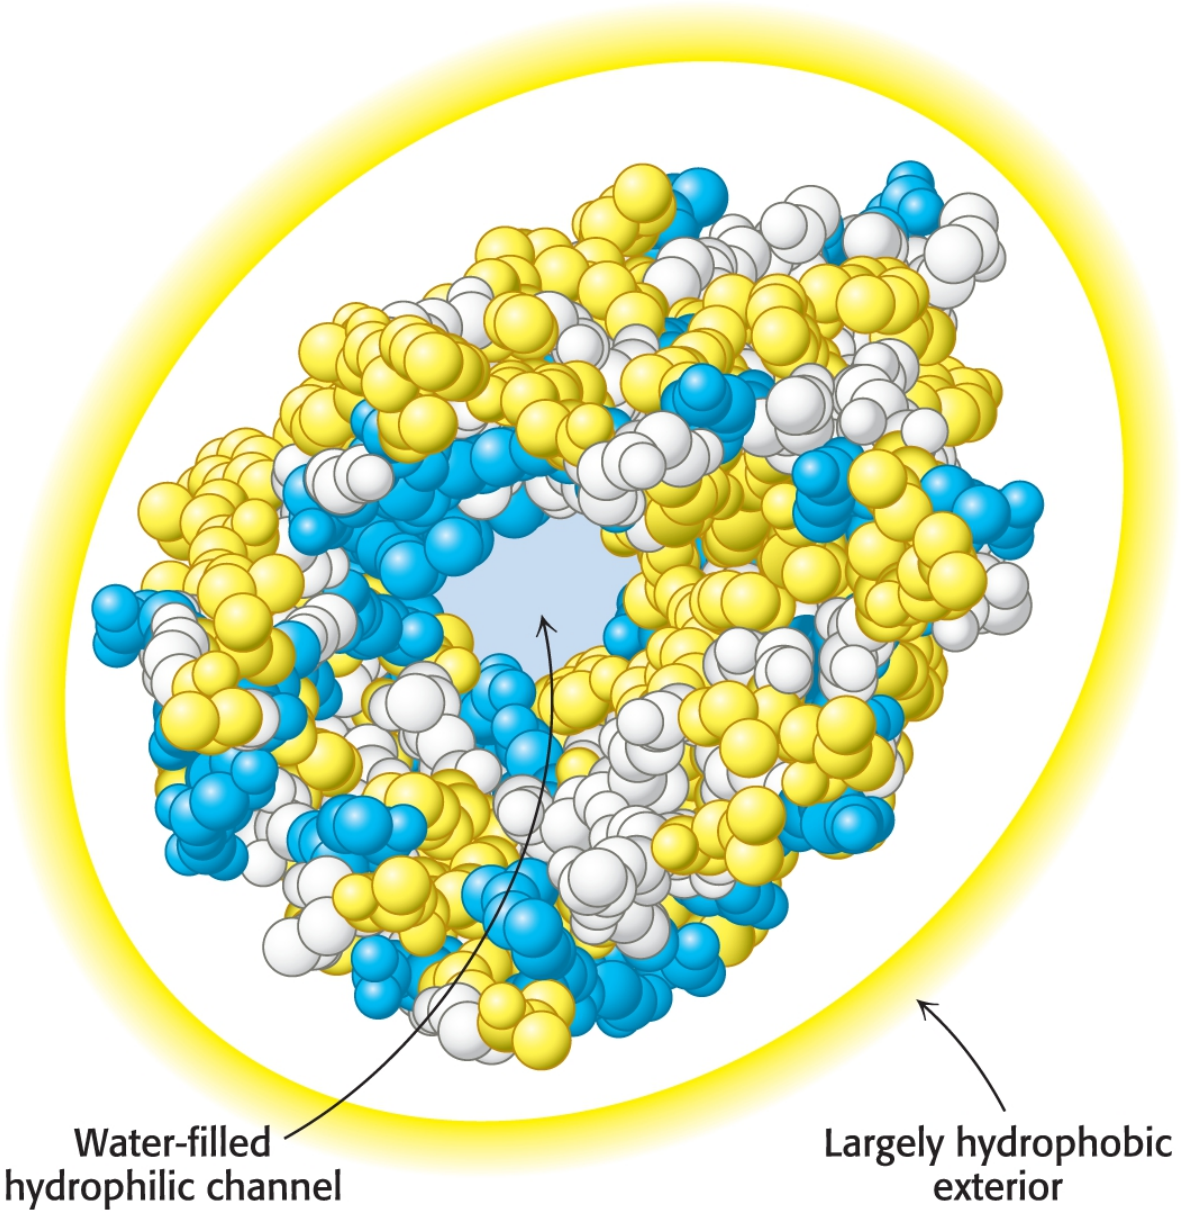
Part (A): The ribbon diagram of myoglobin is composed of six cylindrical spiral ribbons connected by thread-like loops. Four long red spiral ribbons are arranged vertically in a slanting orientation. They rest on the floor made up of one horizontal red spiral ribbon. A blue spiral ribbon crosses three vertical spiral ribbons diagonally. A molecule is present between the second and the third vertical spiral ribbon. It contains a central iron atom depicted as a light purple sphere. Several tiny black spheres cluster around the iron atom and are labeled heme group.

Part (B): The space-filling model of myoglobin is composed of red, black, and blue spheres. The red spheres form most of the myoglobin molecule. They form a broad and elongated structure. A thick cluster of blue spheres passes diagonally from the upper right

to the lower left of the myoglobin molecule. A small cluster of black spheres is present above the middle of the blue cluster and is labeled heme group.

Return to FIGURE 2.36 Myoglobin folds into a compact structure

Extended description for FIGURE 2.37 Hydrophobic amino acids are preferentially distributed in the interior of myoglobin.

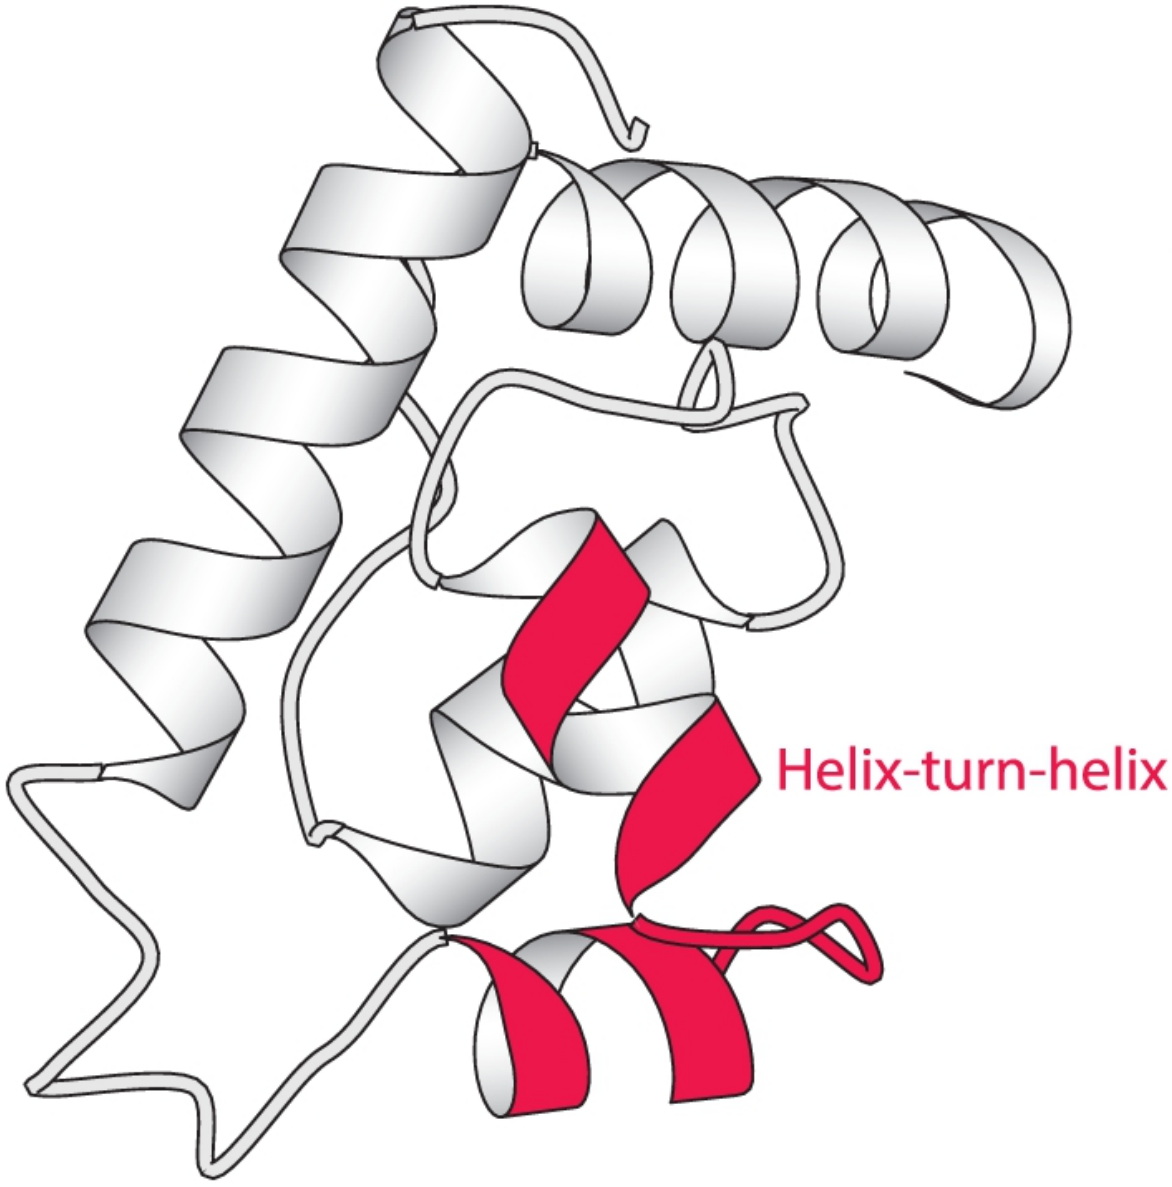


Part (A): The three-dimensional structure is roughly circular. The atoms are represented as spheres. The hydrophobic amino acids are shown in yellow, charged amino acids are shown in blue, and others are shown in white. The surface of the protein is covered with blue spheres interspaced with yellow and white spheres. A cluster of small black spheres at the center encloses a purple sphere.

Part (B): The cross-section of myoglobin shows a purple circle at the center. Most of the interior of the protein is filled with yellow circles.

Return to FIGURE 2.37 Hydrophobic amino acids are preferentially distributed in the interior of myoglobin.

Extended description for FIGURE 2.38 Porin, found in the hydrophobic environment of the membrane, exhibits an “inside out” amino acid distribution



© Macmillan Learning

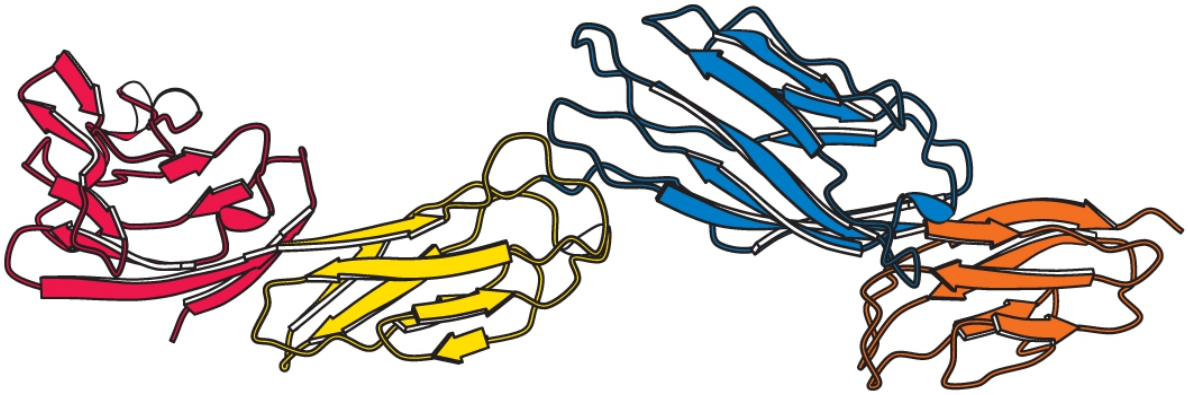
The structure is donut-shaped. The periphery of the structure is mostly made up of yellow spheres, which make up of hydrophobic

amino acids. The region around the central void is mostly made up of blue spheres which make up hydrophilic amino acids. The yellow and blue spheres are interspaced with white spheres. The void at the center is labeled water-filled hydrophilic channel. A circle around the protein is labeled largely hydrophobic exterior.

Return to FIGURE 2.38 Porin, found in the hydrophobic environment of the membrane, exhibits an “inside out” amino acid distribution

Extended description for FIGURE 2.39 The helix-turn-helix motif is a supersecondary structural element found in many DNA-binding proteins

© Macmillan Learning



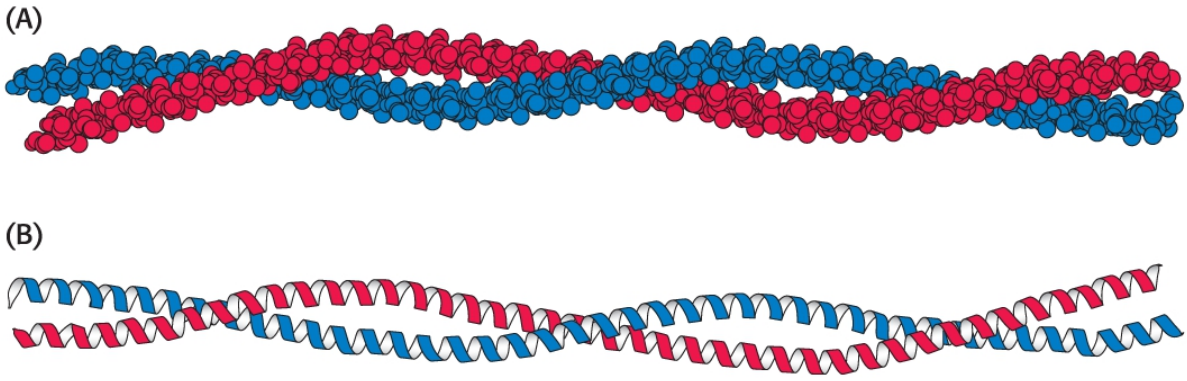
The diagram consists of 3 cylindrical white spiral ribbons. One ribbon is longer than the other two ribbons. One of the short ribbons is present horizontally on the top right of the long ribbon.

The second short ribbon is present vertically on the bottom right of the long ribbon. These ribbons are connected by thread-like loops.

A set of two short cylindrical red spiral ribbons are present in front of the short ribbon. These red spiral ribbons are arranged such that one red spiral ribbon forms a horizontal floor on which the second red spiral ribbon rests in a slanting orientation. These red spiral ribbons are connected by a red thread-like structure that forms a knotted loop. The short red spiral ribbons and the knotted loop are labeled helix-turn-helix.

Return to FIGURE 2.39 The helix-turn-helix motif is a supersecondary structural element found in many DNA-binding proteins

Extended description for FIGURE 2.40 Domains are compact regions within proteins that are connected by flexible polypeptide segments



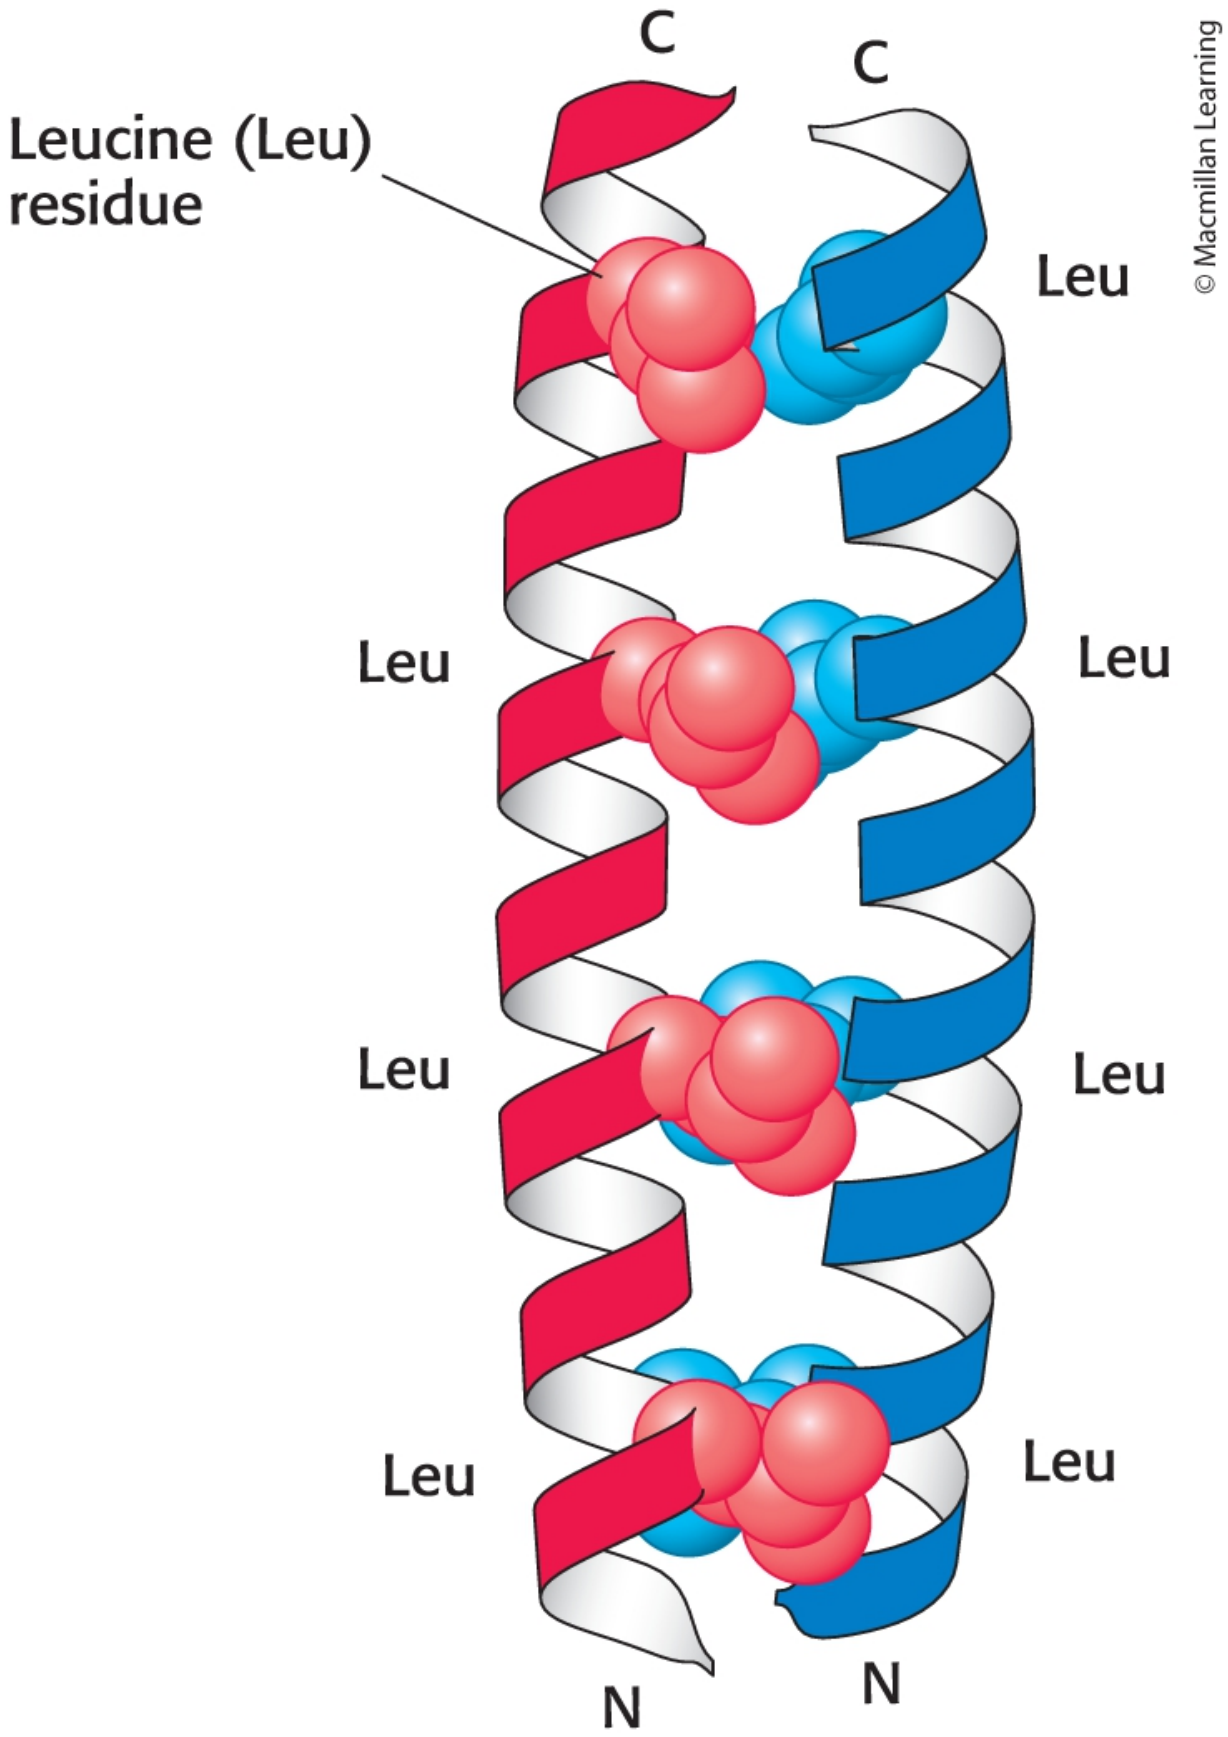
© Macmillan Learning

A set of 4 antiparallel beta-sheets are shown. The antiparallel beta-strands in each beta-sheet are shown as thick arrows pointing in opposite directions. The head and tail of the adjacent antiparallel beta-strands are connected by long, curved thread-like structures.

Return to FIGURE 2.40 Domains are compact regions within proteins that are connected by flexible polypeptide segments

Extended description for FIGURE 2.41 The alpha-helical coiled coil adopts an extended structure

© Macmillan Learning



Part (A): Two alpha helices are made of red and blue spheres representing atoms, respectively. The two helices twist around each other to form a coiled structure.

Part (B): The two alpha helices are represented using two red and blue ribbons. The two ribbons twist around each other to form a coiled structure.

Return to FIGURE 2.41 The alpha-helical coiled coil adopts an extended structure

Extended description for FIGURE 2.42 Heptad repeats from each helix in a coiled-coil protein interact with

one another

© Macmillan Learning

Two protein helices are shown running parallel to each other. The left helix is red, and the right helix is blue. The helices have opposite turns, and the top terminals are labeled C, and the bottom terminals are labeled N. Four sets of four red spheres attached to the red helix interact with four sets of four blue spheres of the blue helix. Each set of spheres represents a leucine residue.

Return to FIGURE 2.42 Heptad repeats from each helix in a coiled-coil protein interact with one another

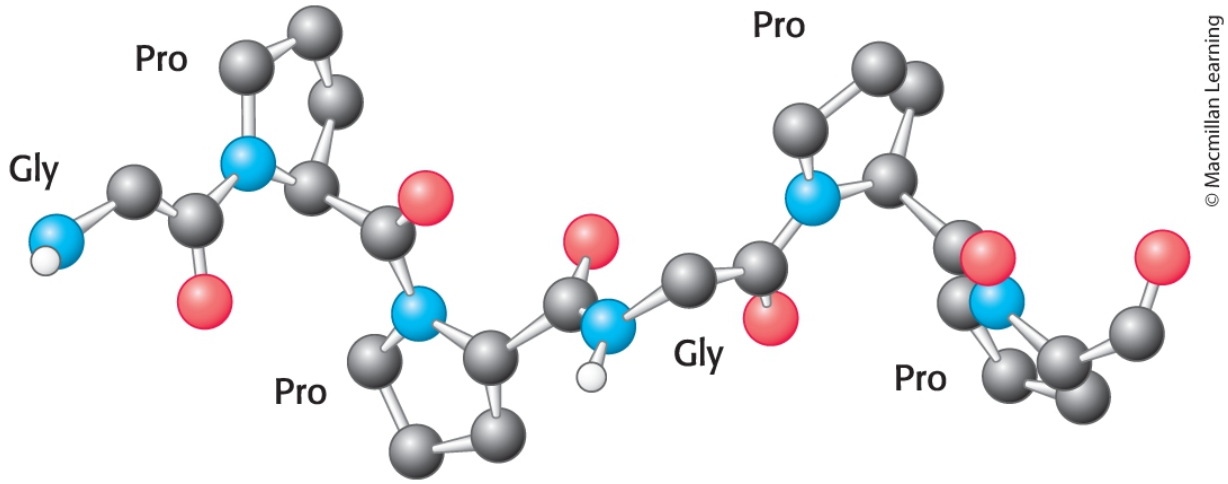
The first sequence starts from the thirteenth residue: Glycine, Proline, Methionine, Glycine, Proline, Serine, Glycine, Proline, Arginine

The second sequence starts from the twenty-second residue: Glycine, Leucine, Hydroxyproline, Glycine, Proline, Hydroxyproline, Glycine, Alanine, Hydroxyproline

The third sequence starts from the thirty-first residue: Glycine, Proline, Glutamine, Glycine, Phenylalanine, Glutamine, Glycine, Proline, Hydroxyproline

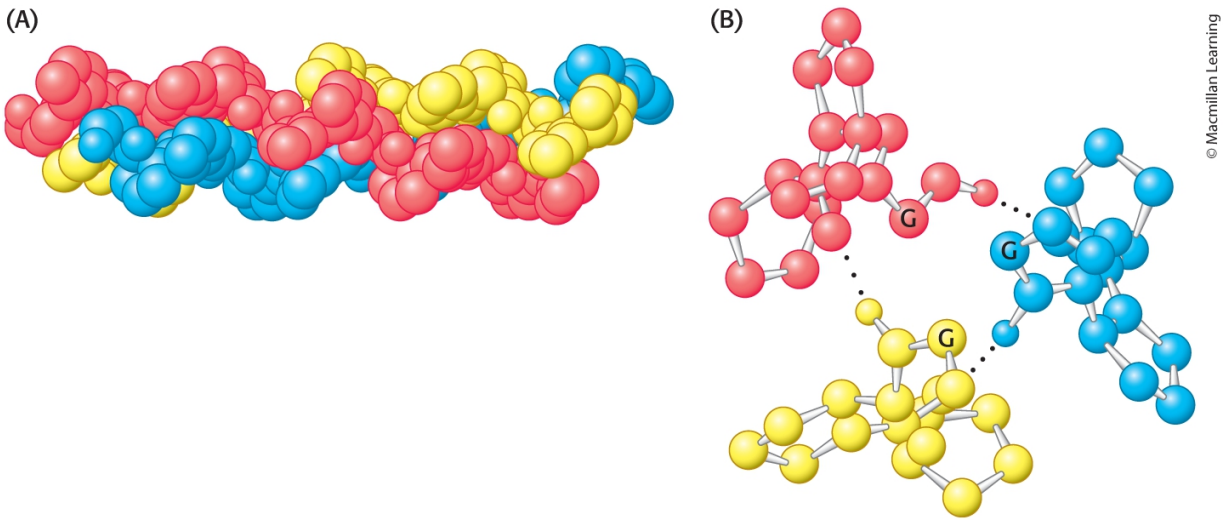


The fourth sequence starts from the fortieth residue: Glycine, Glutamine, Hydroxyproline, Glycine, Glutamine, Hydroxyproline, Glycine, Alanine, Serine

The fifth sequence starts from the forty-ninth residue: Glycine, Proline, Methionine, Glycine, Proline, Arginine, Glycine, Proline, Hydroxyproline

The sixth sequence starts from the fifty-eighth residue: Glycine, Proline, Hydroxyproline, Glycine, Lysine, Asparagine Glycine, Aspartic acid, Aspartic acid

Return to FIGURE 2.43 The amino acid sequence of a part of a collagen chain reveals that every third residue is a glycine.

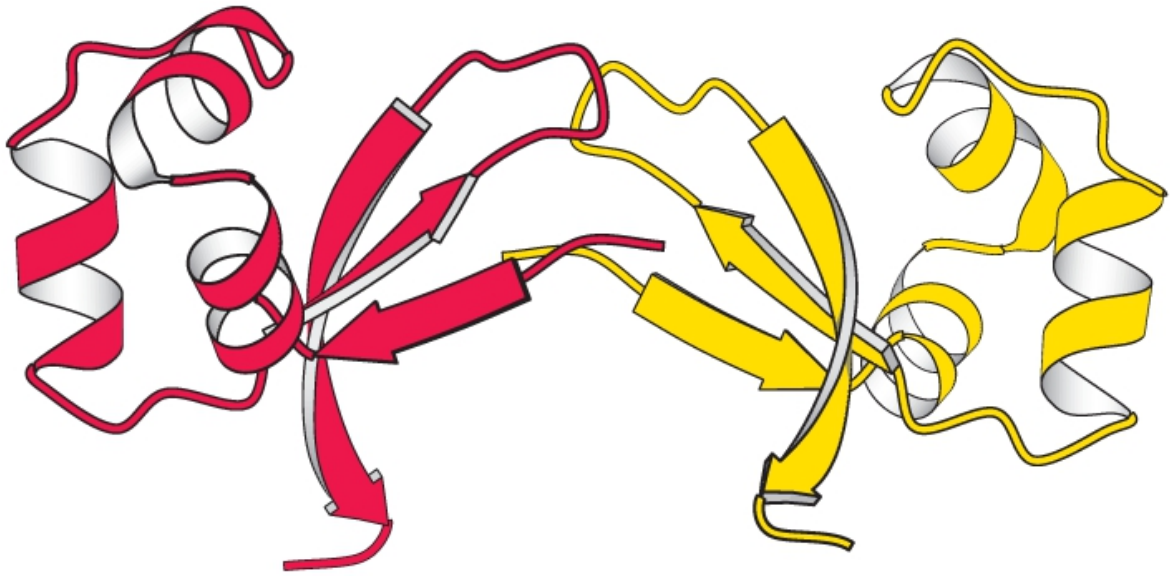


Extended description for FIGURE 2.44 A single strand of a collagen triple helix adopts an extended conformation

In the ball-and-stick model, the C atoms are represented as black spheres, oxygen atoms as red spheres, and nitrogen atoms as blue spheres. The sequence of the strand is as follows: Glycine, Proline, Proline, Glycine, Proline, Proline.

Return to FIGURE 2.44 A single strand of a collagen triple helix adopts an extended conformation

Extended description for FIGURE 2.45 Glycine residues form the interior of the collagen triple helix

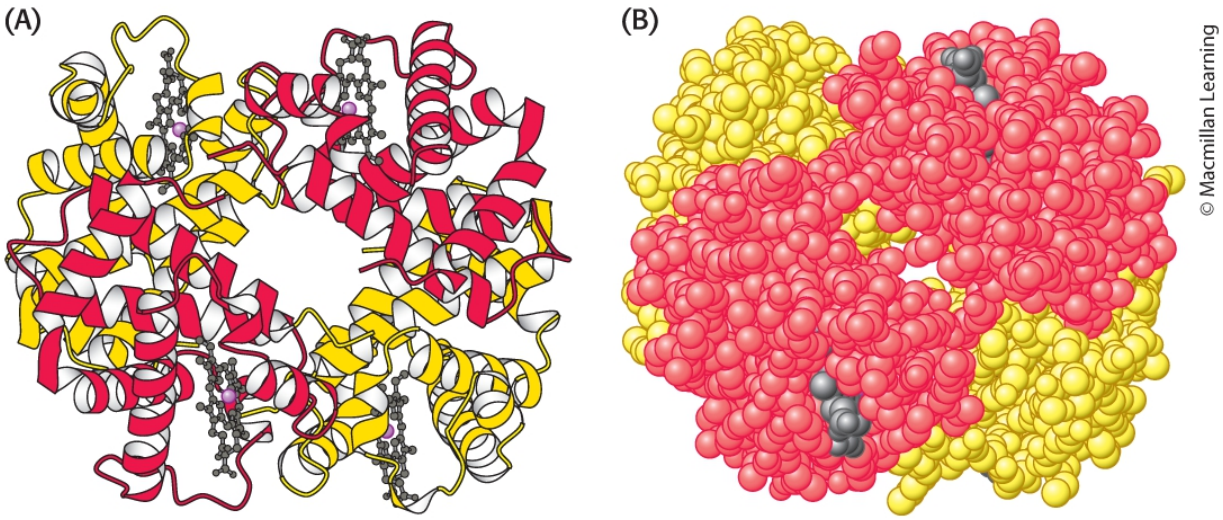


Part (A): Three chains of red, blue, and yellow spheres, respectively, are twisted forming a triple helical structure.

Part (B): A cross-section of a collagen triple-helix is shown. Glycine and pyroline residues of the red, blue, and yellow strands are shown arranged in a circle. Dotted lines representing hydrogen bonds are drawn between the adjacent stands. The alpha-C atoms of glycine residues of each strand are labeled and are oriented to the center of the triple-helix. The pyrrolidine rings of the proline residues are oriented toward the periphery.

Return to FIGURE 2.45 Glycine residues form the interior of the collagen triple helix

Extended description for FIGURE 2.46 Quaternary structure refers to the arrangement of multiple polypeptide chains



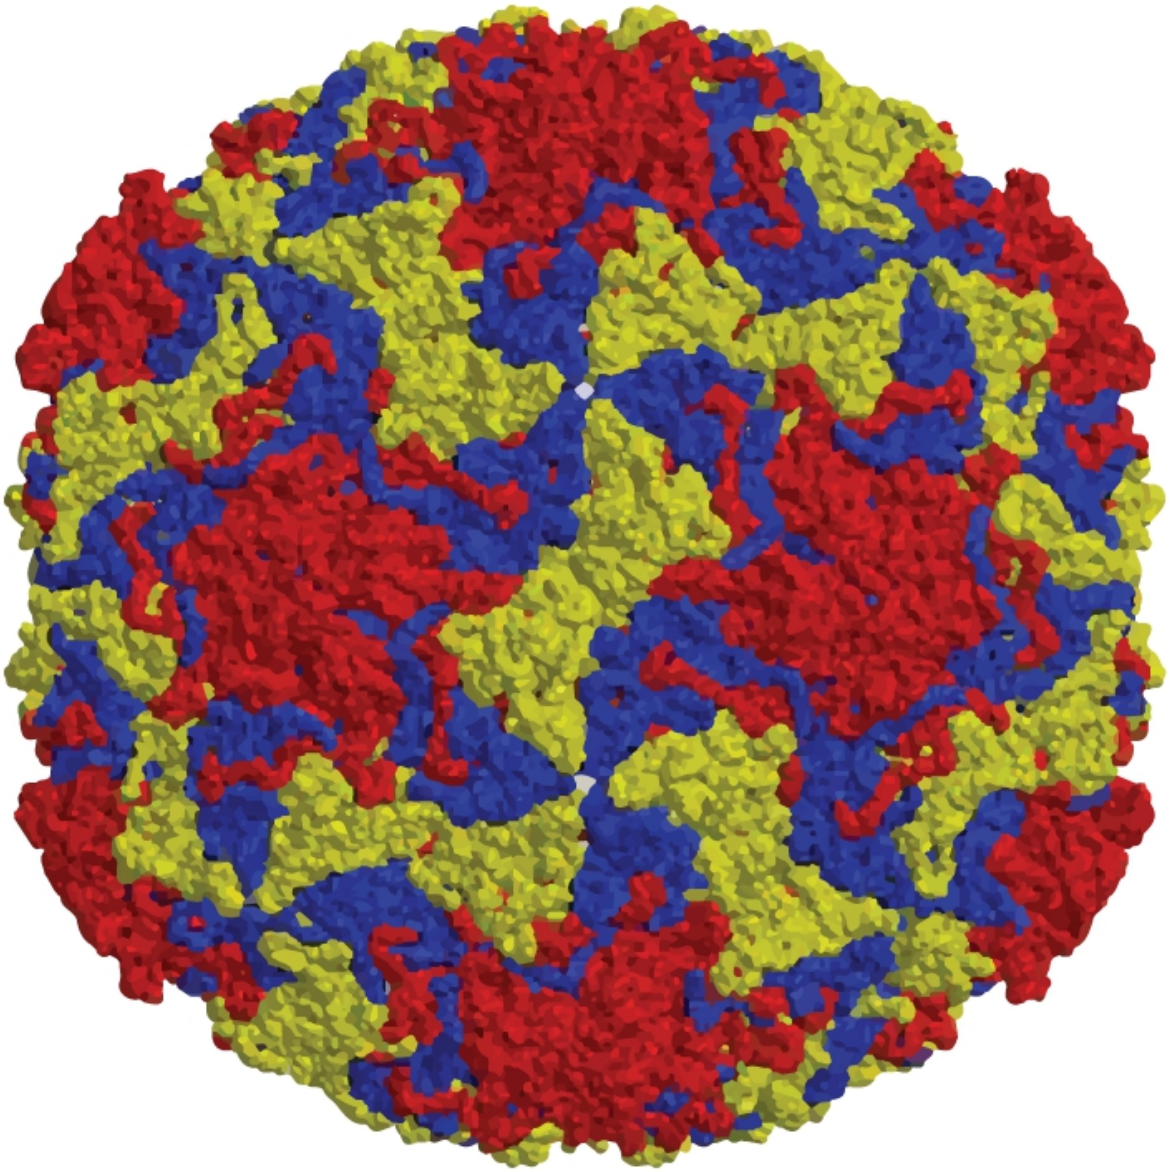
The homodimer consists of two identical structures facing each other. The first structure consists of two cylindrical spiral ribbons on the left. The cylindrical spiral ribbons are connected by narrow and wavy thread-like structures on the top. A thread from the left spiral connects it to the tail of a beta-sheet arrow on the right. The beta-sheet is composed of a pair of antiparallel beta-strands. The antiparallel beta-strands are depicted as thick arrows pointing in opposite directions.

The head and tail of the arrows are connected by a thread-like structure on the top. The downward-facing head of one arrow is attached to a free short thread-like structure. A thread from the right spiral connects to the head of a beta-strand arrow. The tail of the beta-strand arrow has a free short thread-like structure. The beat sheets of the first structure face the beat-sheets of the second

structure. The second structure is a mirror image of the first structure.

Return to FIGURE 2.46 Quaternary structure refers to the arrangement of multiple polypeptide chains

Extended description for FIGURE 2.47 Human hemoglobin is composed of an alpha 2 beta 2 tetramer

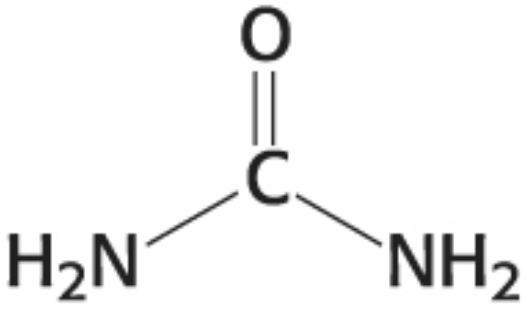


Part (A): Four similar units mainly composed of alpha helices are shown to aggregate together forming a donut shape. Out of the four units, two units are yellow and two units are red. A red unit is adjacent to a yellow unit. At the center of each unit is a heme group represented as a purple sphere enclosed in a cage of small black spheres.

Part (B): The space-filling model shows the same structure as described above. The units are made up of red and yellow spheres, respectively.

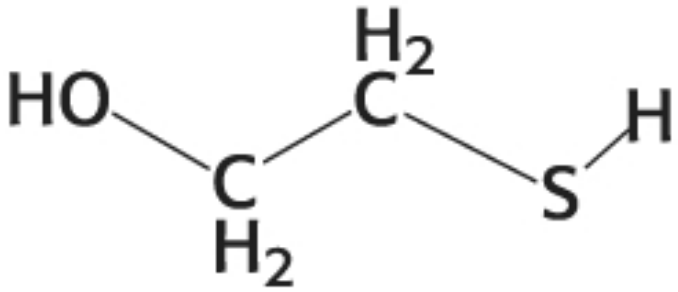
Return to FIGURE 2.47 Human hemoglobin is composed of an alpha 2 beta 2 tetramer

Extended description for FIGURE 2.48 Viral coat proteins adopt complex quaternary structures with many copies of relatively few unique subunits



© Macmillan Learning

The quaternary structure has a hexagonal shape. The vertices of the hexagon are curved. Large blue star-shaped patches are present against a yellow background. The star-shaped patches have irregular

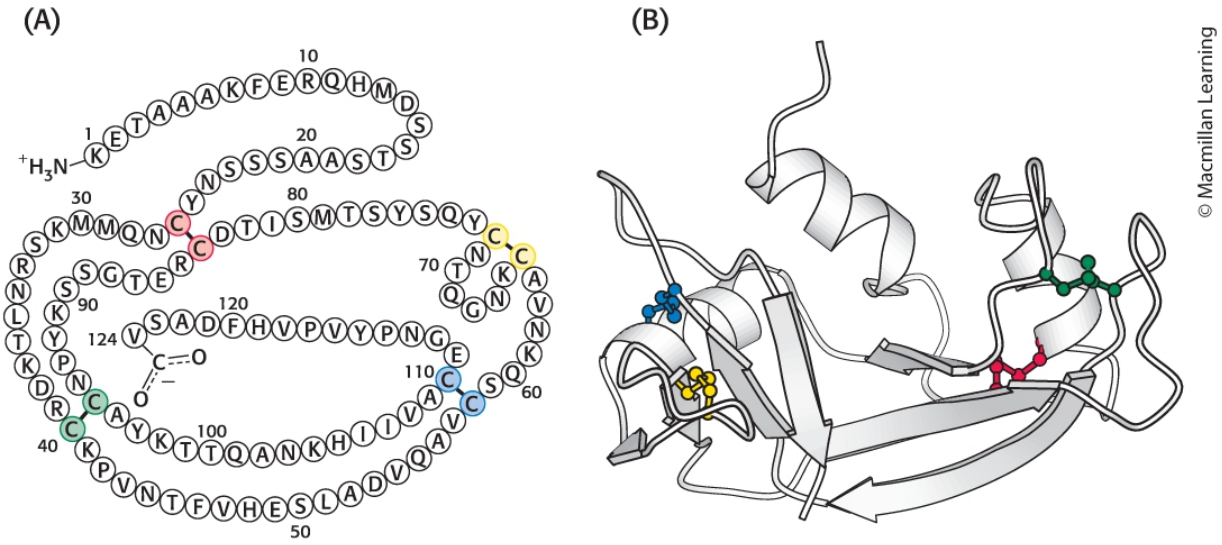


margins. Within the star-shaped patches, red patches are present at the center. All the patches have a rough bumpy texture.

Return to FIGURE 2.48 Viral coat proteins adopt complex quaternary structures with many copies of relatively few unique subunits

Extended description for Urea and beta-mercaptoethanol

Urea

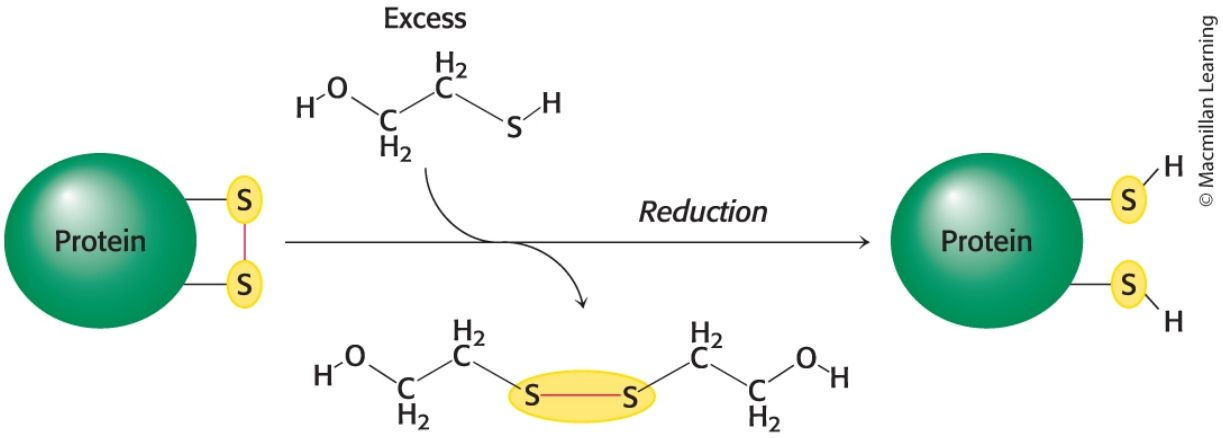


β-Mercaptoethanol

The structure of urea is as follows: A central C atom is single bonded to N H 2 on the lower left and N H 2 on the lower right, and double bonded to O above. The structure of beta-mercaptoethanol is as follows: O H, single bond, C, single bond, C, single bond, S, single bond, H in a zigzag manner. Both C atoms are bound by H 2.

Return to Urea and beta-mercaptoethanol

Extended description for FIGURE 2.49 Bovine ribonuclease is a single polypeptide chain with four intramolecular disulfide bonds



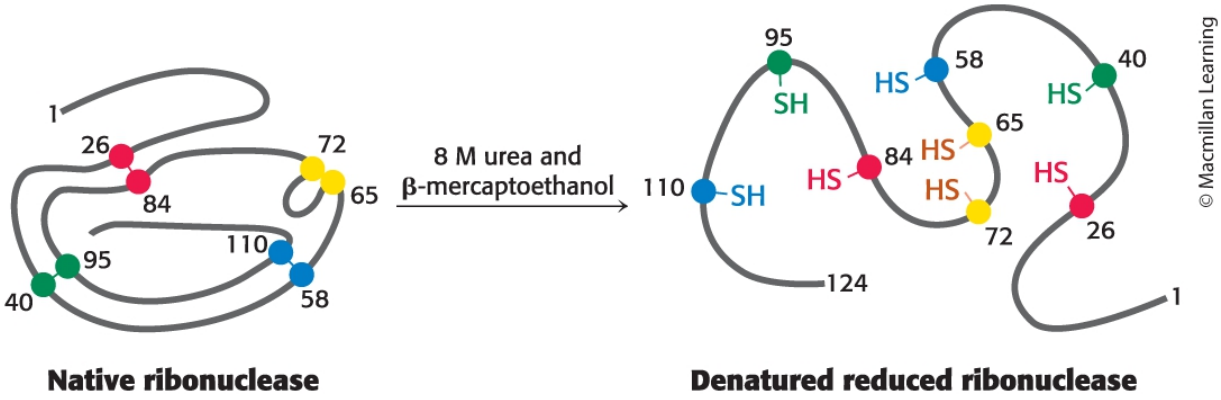
Part (A): The primary structure of bovine ribonuclease is illustrated as a string of circles representing amino acid residues folding into a roughly spiral shape. Some non-adjacent cysteine residues in the chain are linked to each other. Residue 26 is linked to residue 84, residue 40 is linked to residue 95, residue 110 is linked to residue 58, and residue 72 is linked to residue 65.

Part (B): The three-dimensional structure forms a roughly U-shape. It consists of some alpha-helices represented by helical ribbon-like structures and some beta sheets represented by broad arrows. These structures are connected by short thread-like loops. The linked cysteine residues are represented as clusters of red, yellow, green, and blue spheres.

Return to FIGURE 2.49 Bovine ribonuclease is a single polypeptide chain with four intramolecular disulfide bonds

Extended description for FIGURE 2.50 Beta-Mercaptoethanol disrupts disulfide bonds

The reaction consists of two reactants and two products. The first reactant has the following structure: A large green sphere labeled protein has two S atoms linked to it on its side. A red disulfide bond is present between the two S atoms. S atoms are highlighted in yellow. The second reactant is in excess and has the following structure: C H 2 is single bonded to C H 2 on the upper right. C 1 is single bonded to O on the upper left which is single bonded to H on the lower left. C 2 is single bonded to S on the lower right which is single bonded to H on the upper right.



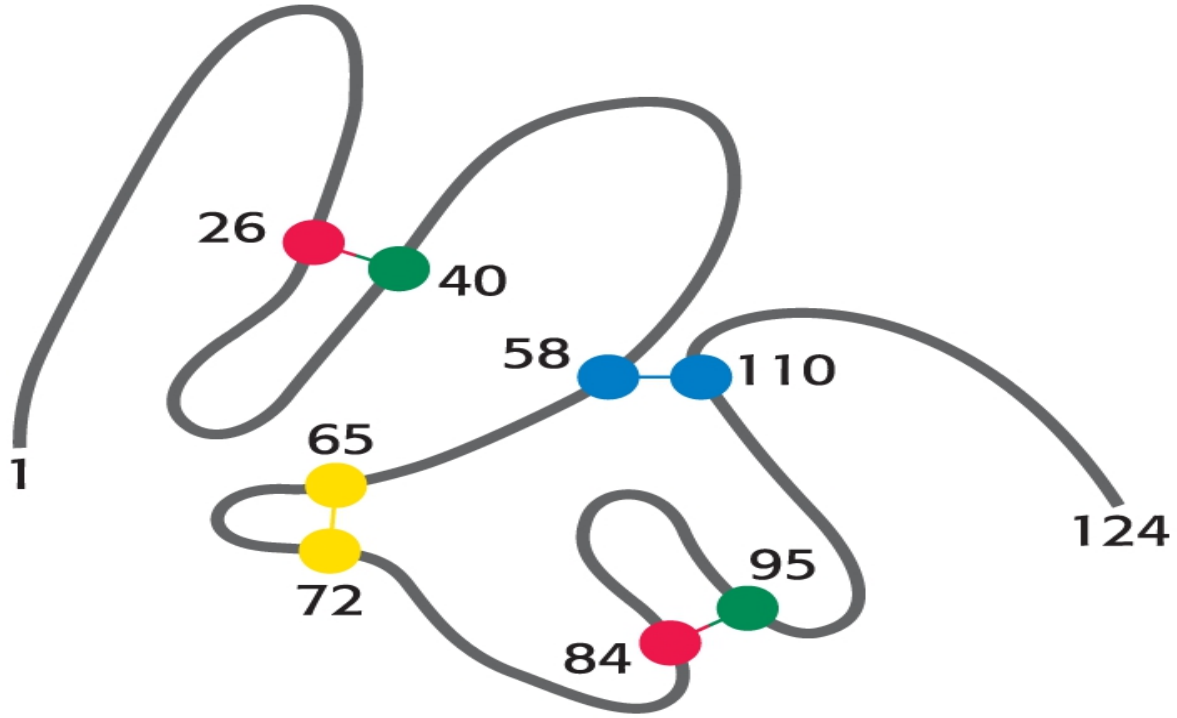
The reaction arrow is labeled reduction.

The first product has the following structure: A large green sphere labeled protein has two S atoms linked to it on its side. The S atoms are each single bonded to H atoms to the right, which are pointing away from each other. S atoms are highlighted in yellow. The second product has the following structure: Two molecules of the second reactant are placed side-by-side such that the respective S atoms are

facing each other. The S atoms are single bonded to each other highlighted in red and the bonding is shown within a yellow sphere.

Return to FIGURE 2.50 Beta-Mercaptoethanol disrupts disulfide bonds

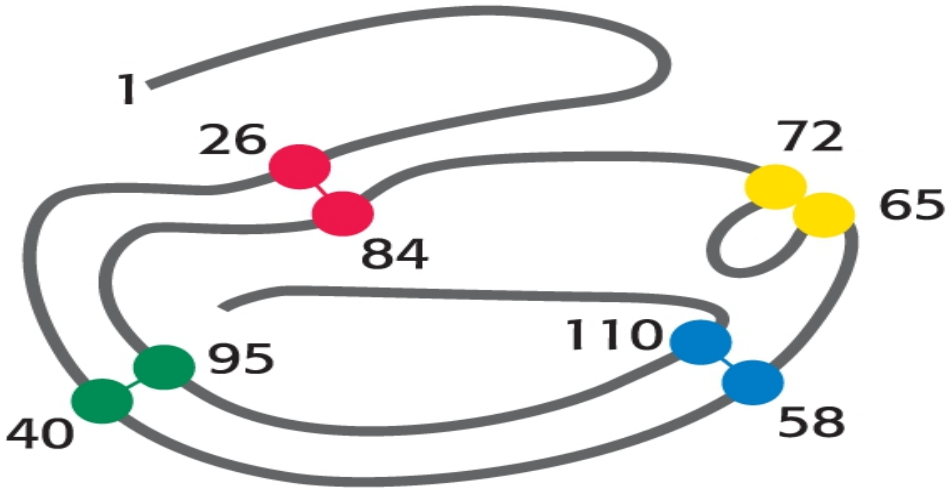
Extended description for FIGURE 2.51 Ribonuclease is denatured with urea and β-mercaptoethanol



The reactant is native ribonuclease and is depicted as a curved gray line that folds inwards to form a loose coiled structure. The markings on the gray line from the extreme top end to the interior are as follows: 1, 26, 40, 58, 65, 72, 84, 95, and 110. The markings located adjacently are 26 and 84, 40 and 95, 65 and 72, and 58 and 110. The line makes an inward loop at the point of contact between the markings 65 and 72. The reaction arrow is labeled 8 M urea and beta-mercaptoethanol.

The product is denatured reduced ribonuclease and is depicted as a curved gray line that starts from the bottom left, forms two large loops, and ends at the bottom right. The markings on the gray line from the extreme right end to the extreme left end are 1, 26, 40, 58, 65, 72, 84, 95, 110, and 124. The markings 26, 40, 58, 65, 72, 84, 95, and 110 are each connected to an S H group.

Return to FIGURE 2.51 Ribonuclease is denatured with urea and β-mercaptoethanol



Extended description for FIGURE 2.52 Native ribonuclease can be re-formed from scrambled

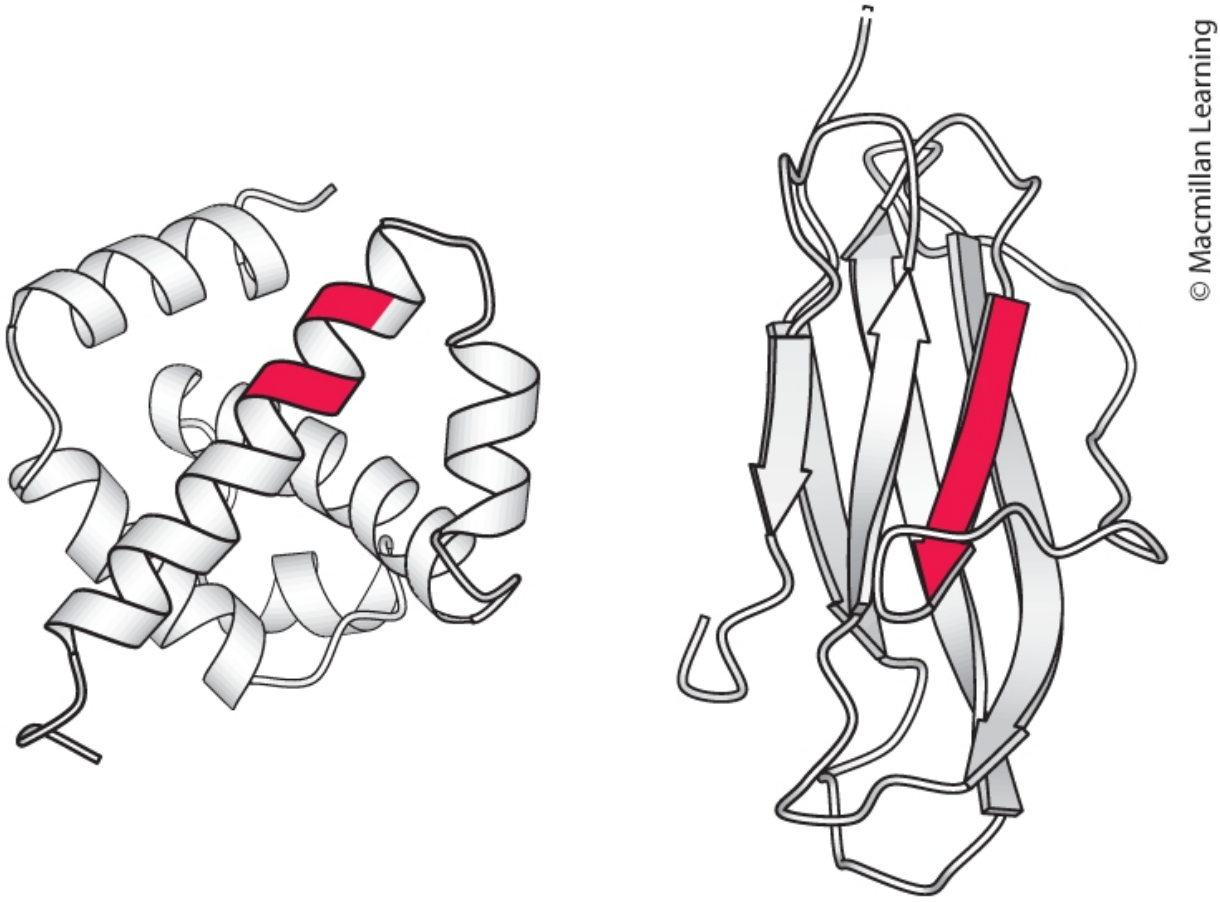
ribonuclease in the presence of a trace of beta-mercaptoethanol

Scrambled ribonuclease

Trace of
β-mercaptoethanol

Native ribonuclease

© Macmillan Learning

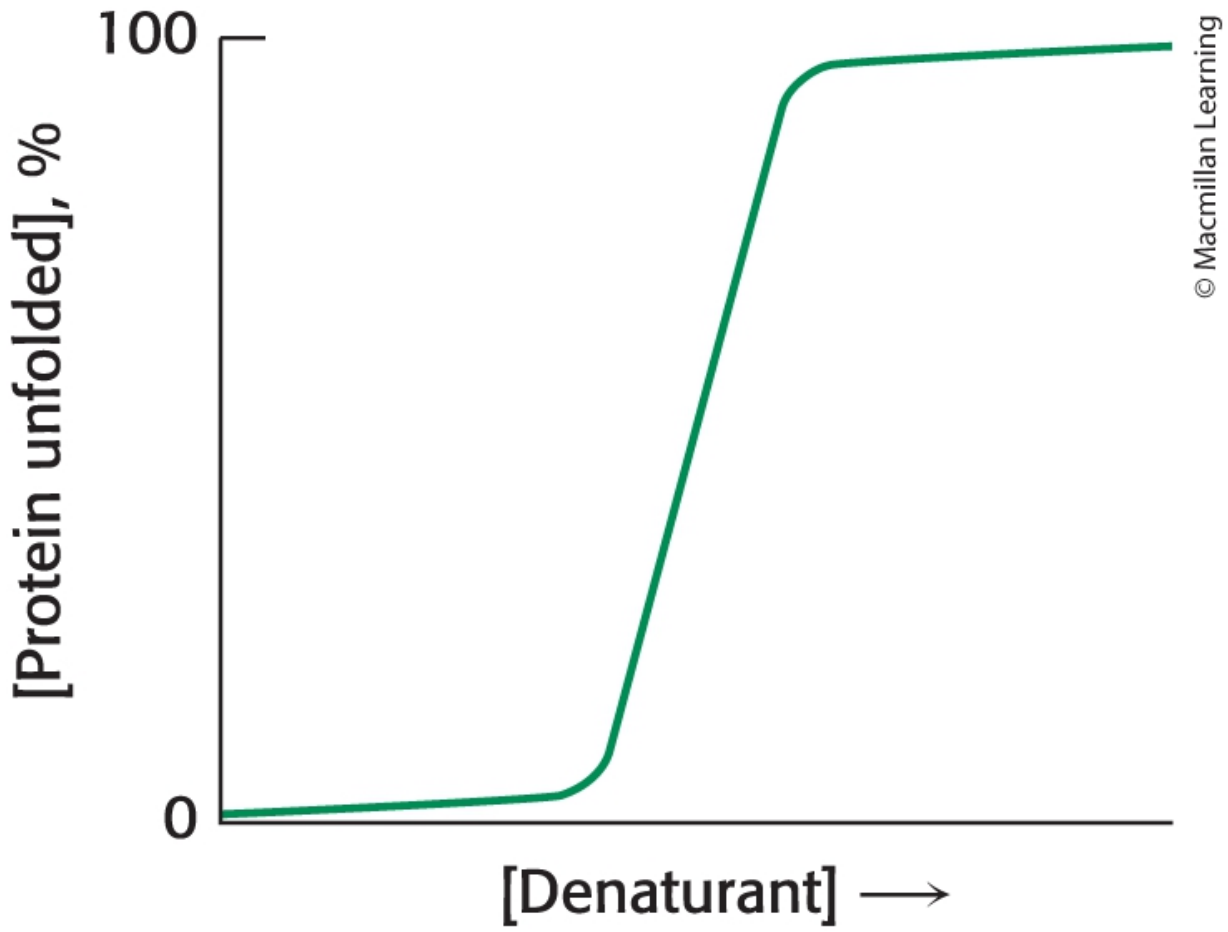


Scrambled ribonuclease is represented as a long string of amino acids. Residues 26 and 84 are highlighted in red. Residues 40 and 95 are highlighted in green. Residues 65 and 72 are highlighted in yellow. Residues 58 and 110 are highlighted in blue. Residue 26 is linked to residue 40. Residue 65 is linked to residue 72. Residue 58 is linked to residue 110. Residue 84 is linked to residue 95.

A downward arrow labeled trace of beta-mercaptoethanol points from scrambled ribonuclease to native ribonuclease.

In the native ribonuclease, residue 26 is linked to residue 84, residue 40 is linked to residue 95, residue 110 is linked to residue 58, and residue 72 is linked to residue 65. The amino acid string folds into a roughly spiral shape.

Return to FIGURE 2.52 Native ribonuclease can be re-formed from scrambled ribonuclease in the presence of a trace of beta-mercaptoethanol

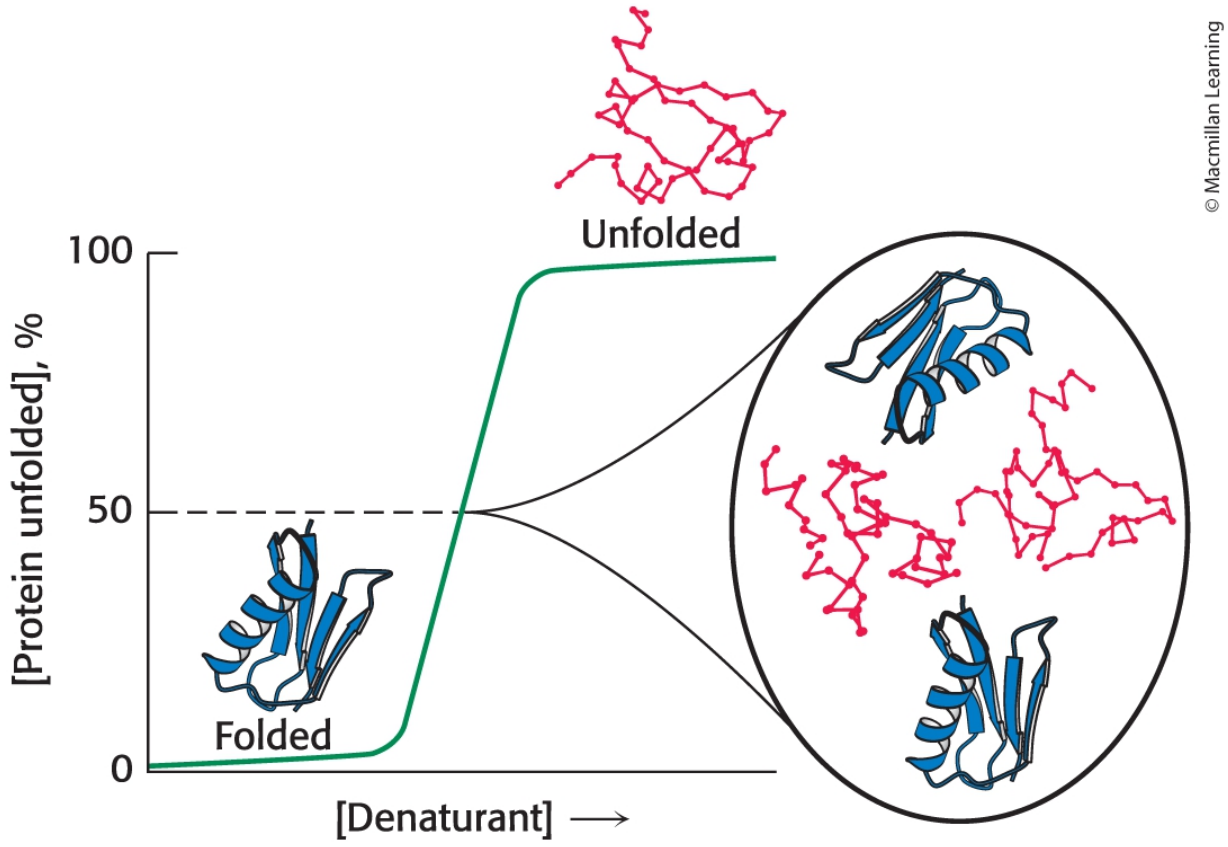


Extended description for FIGURE 2.53 Many sequences can adopt alternative conformations in different proteins

In the first protein, several alpha helices are connected by short thread-like loops. A short segment of one of the alpha helices is highlighted in red. In the second protein, several beta strands are connected by short thread-like loops. A short segment of one of the beta strands is highlighted in red. Both the red regions have the same amino acid sequences.

Return to FIGURE 2.53 Many sequences can adopt alternative conformations in different proteins

Extended description for FIGURE 2.54 The transition from folded to unfolded state is abrupt



The horizontal axis is labeled concentration of denaturant and increases from left to right. The vertical axis is labeled concentration of protein unfolded, percentage and has two markings: 0 and 100. The marking 0 is located at the bottom and the marking 100 is located at the top of the vertical axis.

A curve begins at the 0 mark on the vertical axis and moves horizontally toward the right. It rises steeply toward the right at a point just before the mid point of the horizontal axis. The curve

continues rising until it reaches just below the 100 mark on the vertical axis. It then moves horizontally toward the right at a point after the mid point of the horizontal axis. The curve gradually reaches the 100 marking on the vertical axis.

Return to FIGURE 2.54 The transition from folded to unfolded state is abrupt

Extended description for FIGURE 2.55 At the denaturation midpoint, half the molecules are fully folded and half are fully unfolded

© Macmillan Learning

The horizontal axis is labeled concentration of denaturant and a rightward arrow indicates increasing concentration. The vertical axis is labeled concentration of protein unfolded, percentage and ranges from 0 to 100 in increments of 50 units. An S-shaped curve starts at the origin, gradually rises to nearly 5 percent, followed by a steep rise to nearly 100 percent, and then remains constant.

A diagrammatic representation of a folded protein with intact alpha helices and beta pleats is indicated near the lower arm of the curve. A diagrammatic representation of a completely unfolded protein is

represented as a folded string with no alpha helices or beta pleats indicated near the upper arm of the curve. A dotted line passing through the midpoint of the curve at 50 percent is drawn, and a corresponding diagram shows two folded proteins and two unfolded proteins.

Return to FIGURE 2.55 At the denaturation midpoint, half the molecules are fully folded and half are fully unfolded

Extended description for FIGURE 2.57 The proposed folding pathway of chymotrypsin inhibitor-2 demonstrates the nucleation-condensation model

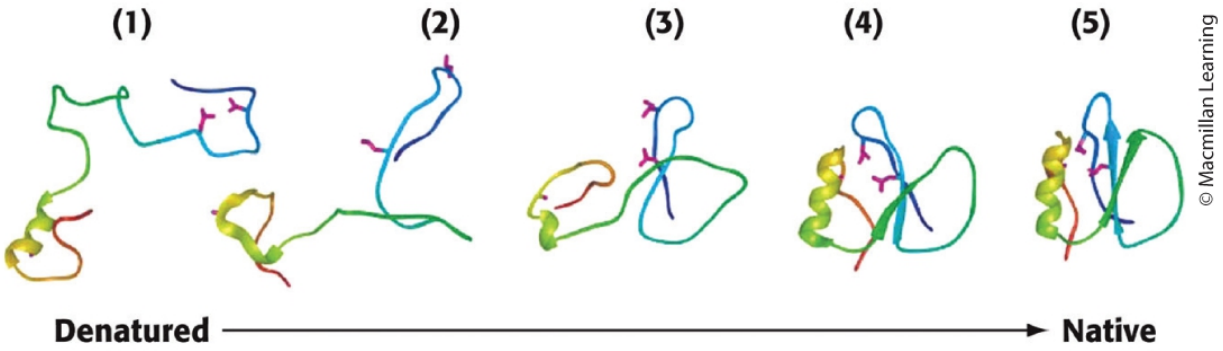

Diagram (1) consists of a cylindrical spiral ribbon. It is connected to a thread-like structure forming curved waves. This thread-like structure is present in a horizontal orientation. Two Y-shaped structures are present on the top right end of the thread-like structure. The spiral ribbon is connected to a smaller curved thread-like structure.

Diagram (2) shows a thread-like structure in a vertical orientation with a horizontal bottom. The cylindrical spiral ribbon is inverted such that it is connected to a smaller curved thread-like structure at the top.

Diagram (3) shows a thread-like structure in a more coiled form.

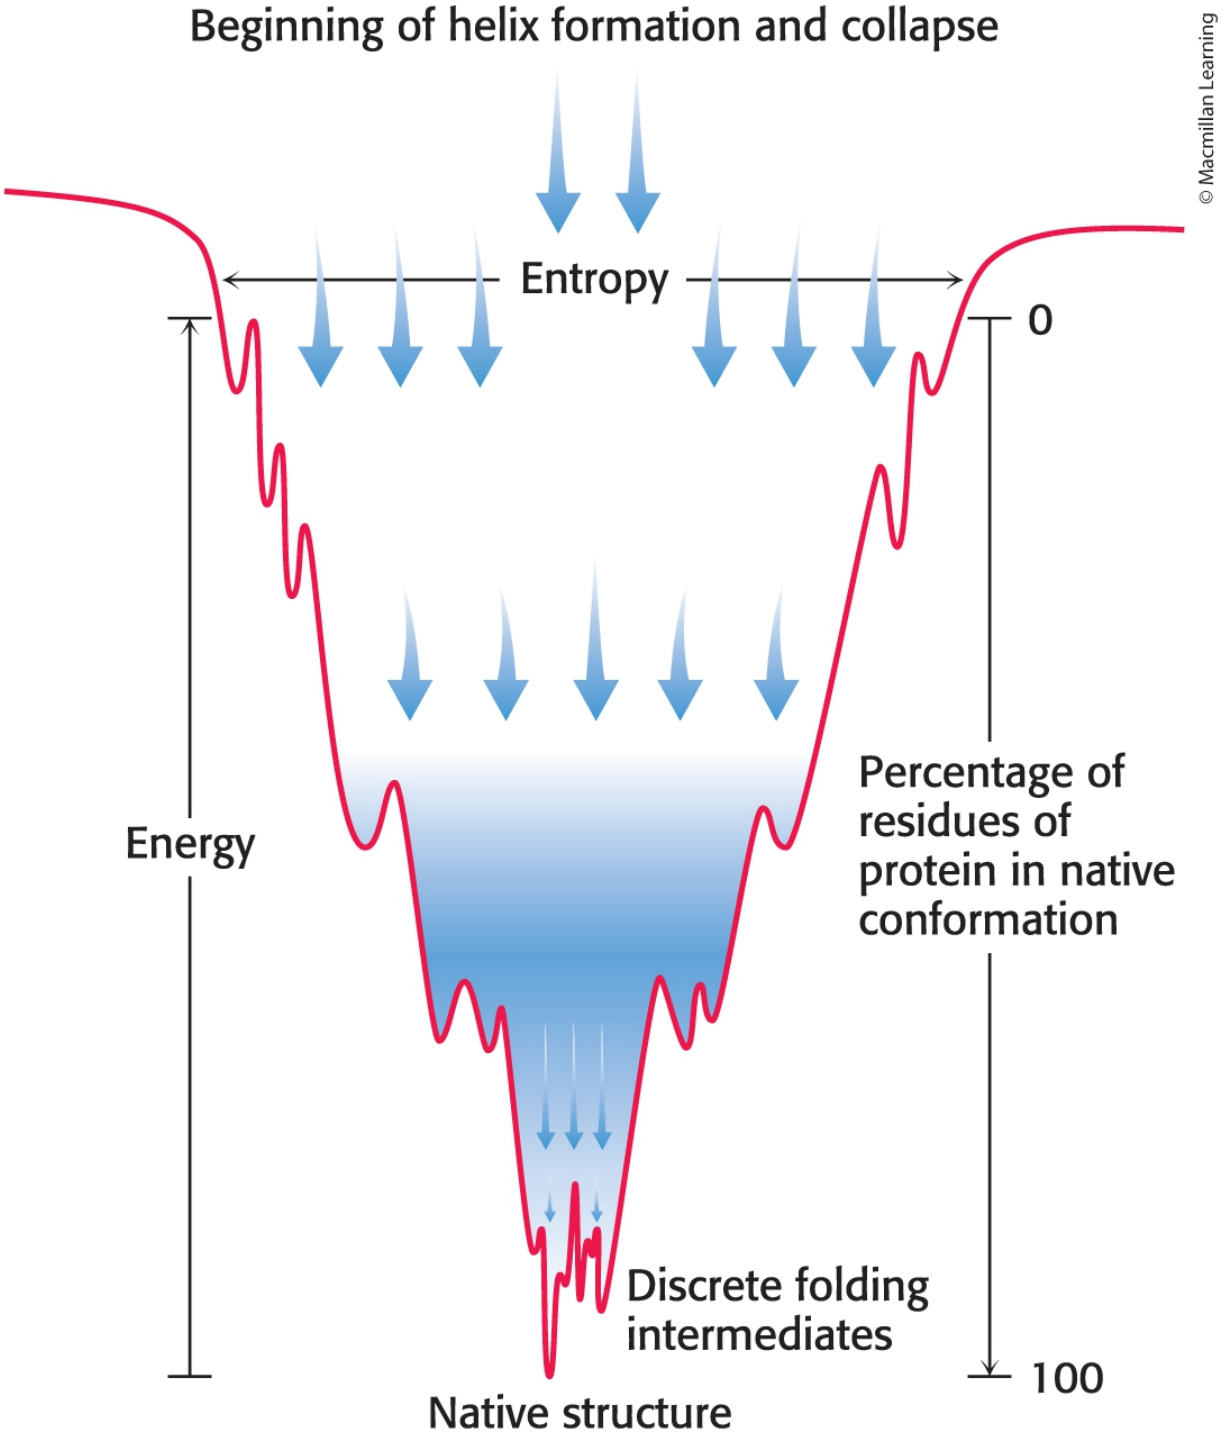

Diagram (4) shows the cylindrical ribbon having three turns. The thread-like structure is relatively more coiled.

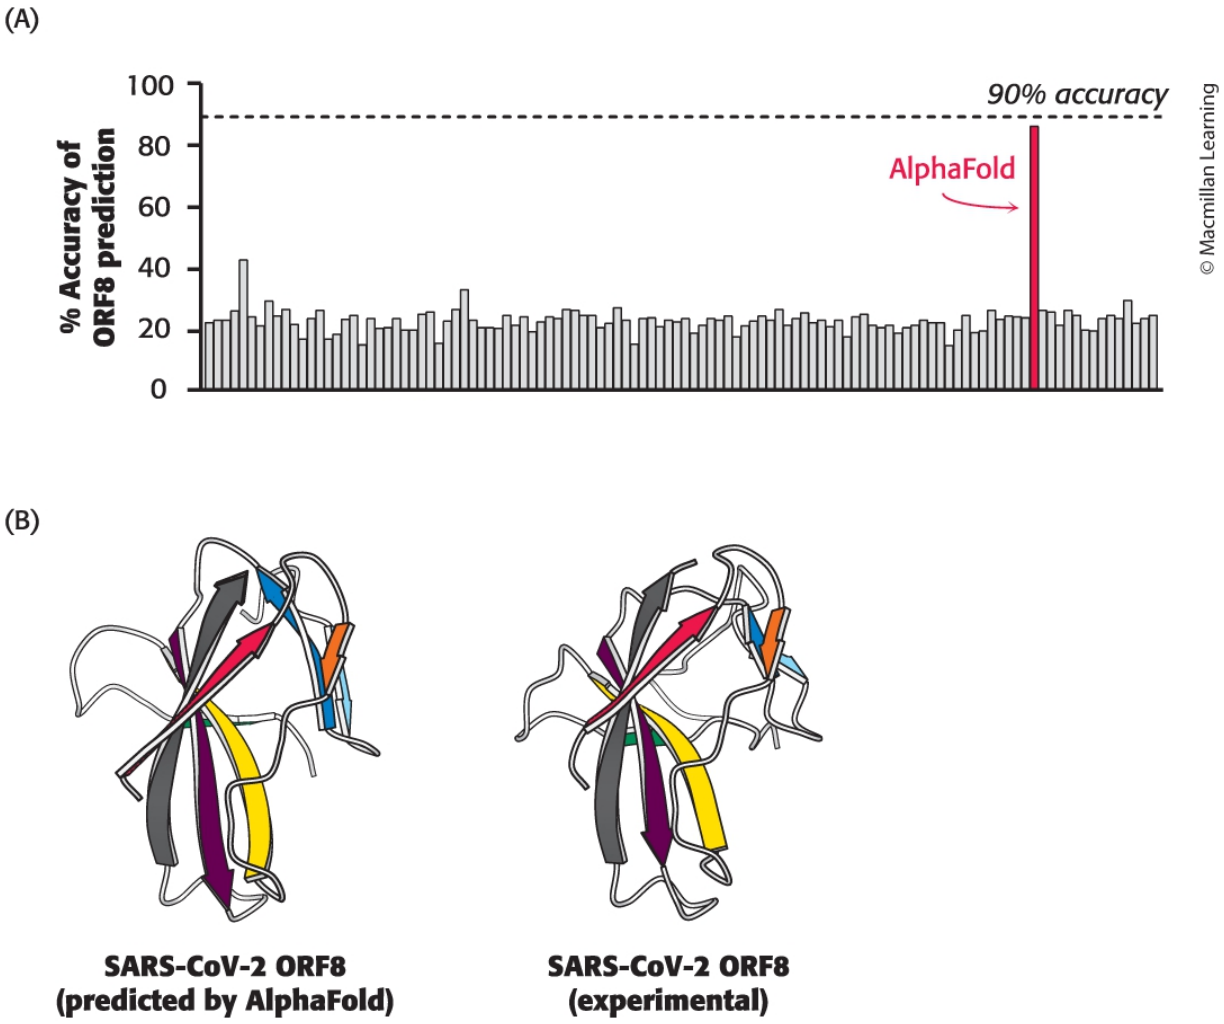
Diagram (5) shows the spiral ribbon and the thread-like structure close together in a more compact form.

A rightward pointing arrow below spans from the diagram (1) to diagram (5). The head of the arrow is labeled native and the tail of the arrow is labeled denatured. The figure illustrates a ball-and-stick model of a parallel beta sheet.

Return to FIGURE 2.57 The proposed folding pathway of chymotrypsin inhibitor-2 demonstrates the nucleation-condensation model

Extended description for FIGURE 2.58 The folding funnel depicts the thermodynamics of protein folding.

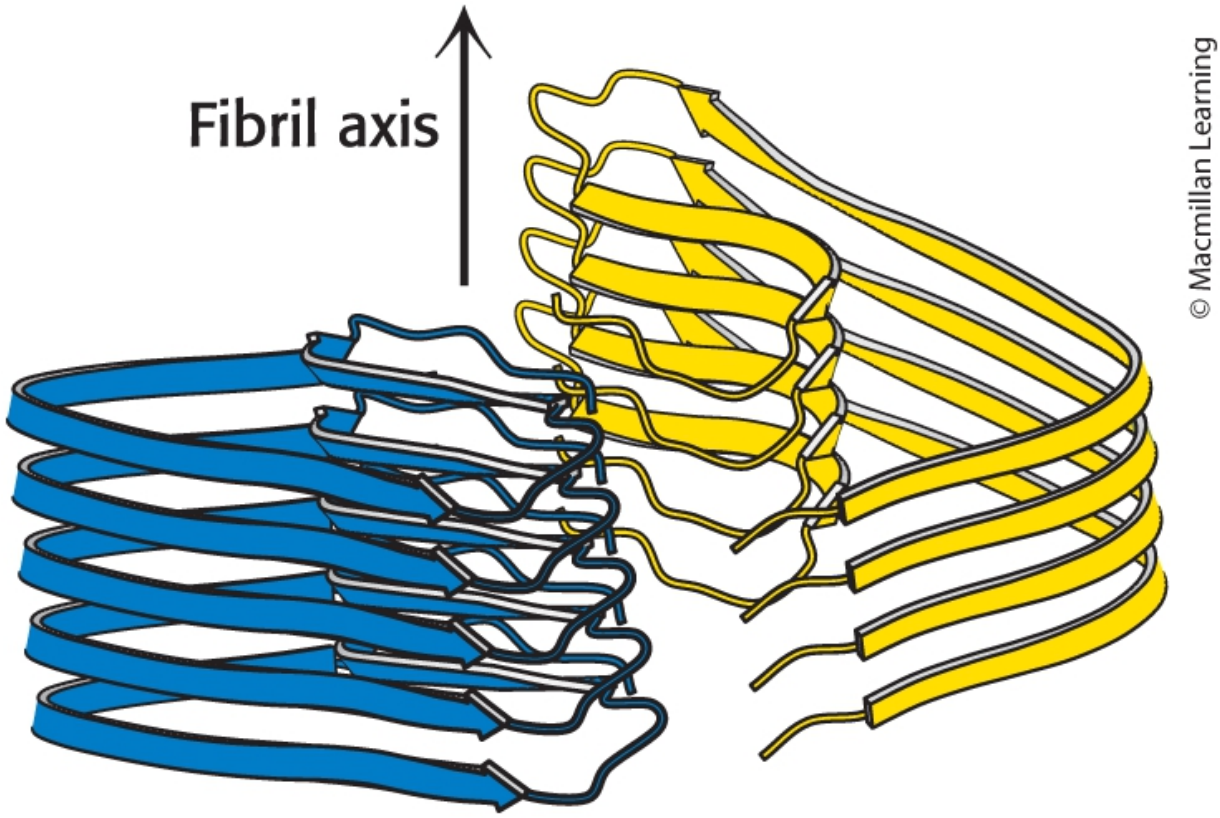


A funnel-shaped curve is illustrated with minor fluctuations and is labeled native structure. Two arrows pointing down are shown above the mouth of the funnel and are labeled the beginning of helix formation and collapse. A double-headed arrow spanning across the widest portion of the mouth of the funnel at the top is labeled entropy. Downward arrows are drawn from the mouth. The tip of the funnel is labeled discrete folding intermediates.

An upward arrow pointing from the tip of the funnel to the mouth of the funnel is labeled energy. A downward arrow pointing from the mouth of the funnel to the tip of the funnel at the bottom is labeled the percentage of residues of protein in native conformation and ranges from 0 to 100 from top to bottom. The mid-section of the funnel is colored blue which gradually gets lighter toward the tip. Downward arrows are indicted in this region pointing to the tip of the funnel.

Return to FIGURE 2.58 The folding funnel depicts the thermodynamics of protein folding.

Extended description for FIGURE 2.59 AlphaFold represents a significant step forward in protein folding prediction.



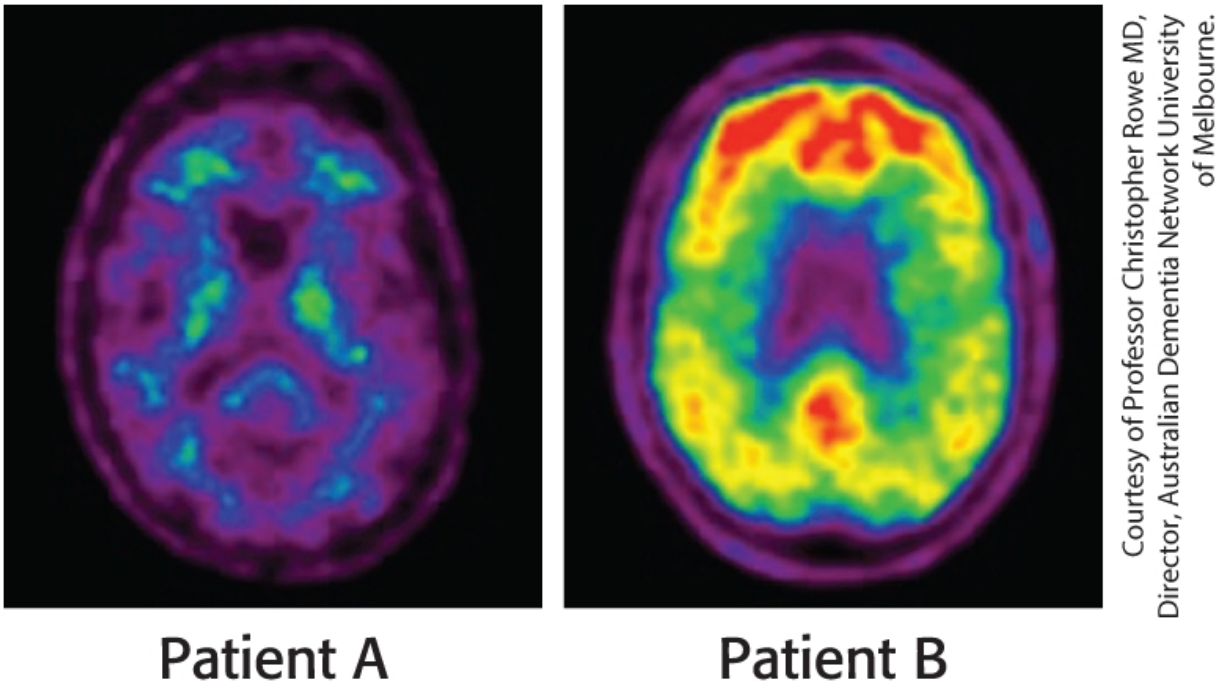
Part (A): The vertical axis is labeled percentage accuracy of O R F 8 prediction and ranges from 0 to 100 in increments of 20 units. Multiple data bars are shown along the horizontal axis and all lie below 45 percent. A red bar labeled alphaFold peaks at an accuracy of 90 percent.

Part (B): Two structures of the S A R S-Co V-2 O R F 8 are made up of beta sheets connected by short loops. The structure predicted by alphaFold is very similar to the experimentally determined structure.

Return to FIGURE 2.59 AlphaFold represents a significant step forward in protein folding prediction.

Extended description for FIGURE 2.60 The structure of the Aβ amyloid fibril reveals its extensive β sheet network

© Macmillan Learning



5 antiparallel beta sheets are shown on the left in blue. The peptides are depicted as thick arrows. The peptides are arranged one above the other and are curved at the center. The peptides on the outer side point toward the right. The peptides on the inner side point toward the back. The head of the outer peptides is connected to the corresponding tails of the inner peptides. Blue narrow thread-like structure connects the peptides.

4 antiparallel beta sheets are shown on the right in yellow. The peptides are arranged one above the other and are curved at the

center. The peptides on the outer side point toward the back. They are curved near the tail that faces the observer. The peptides on the inner side point toward the front. The head of the outer peptides is connected to the corresponding tails of the inner peptides. A yellow narrow thread-like structure connects the peptides. Short threads arise from the tails of the outer peptides. An upward arrow labeled fibril axis is present between the two sets of beta sheets.

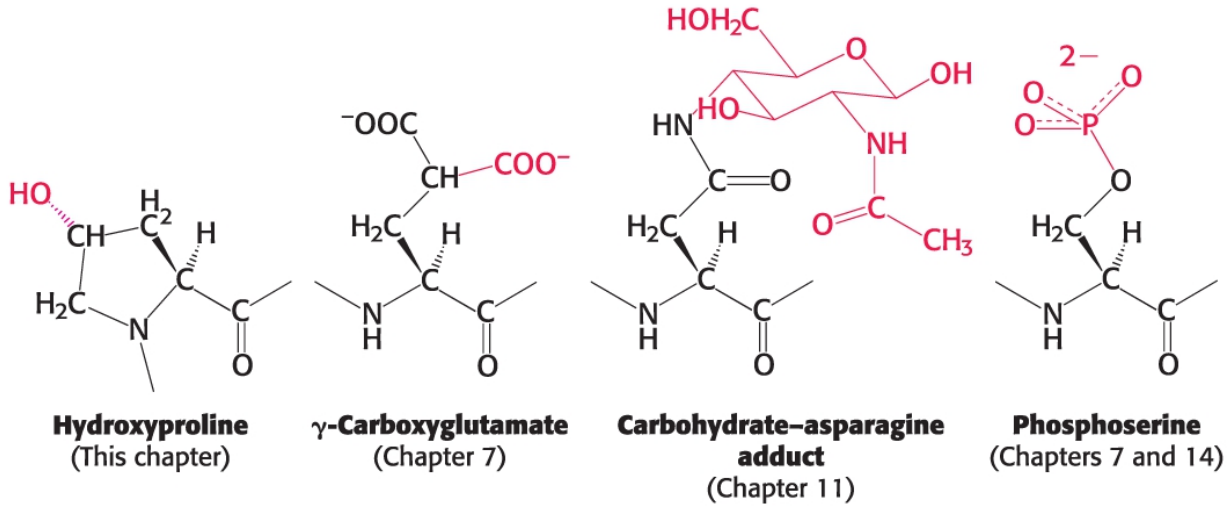
Extended description for FIGURE 2.61 The extent of amyloid fibril aggregation in the brain can predict the progression of Alzheimer disease



Patient A: Light green signal is detected in certain small regions in the brain indicating minimal accumulation of A beta fibrils.

Patient B: Green, yellow, and red signals are detected in major areas of the brain indicating a high accumulation of A beta fibrils.

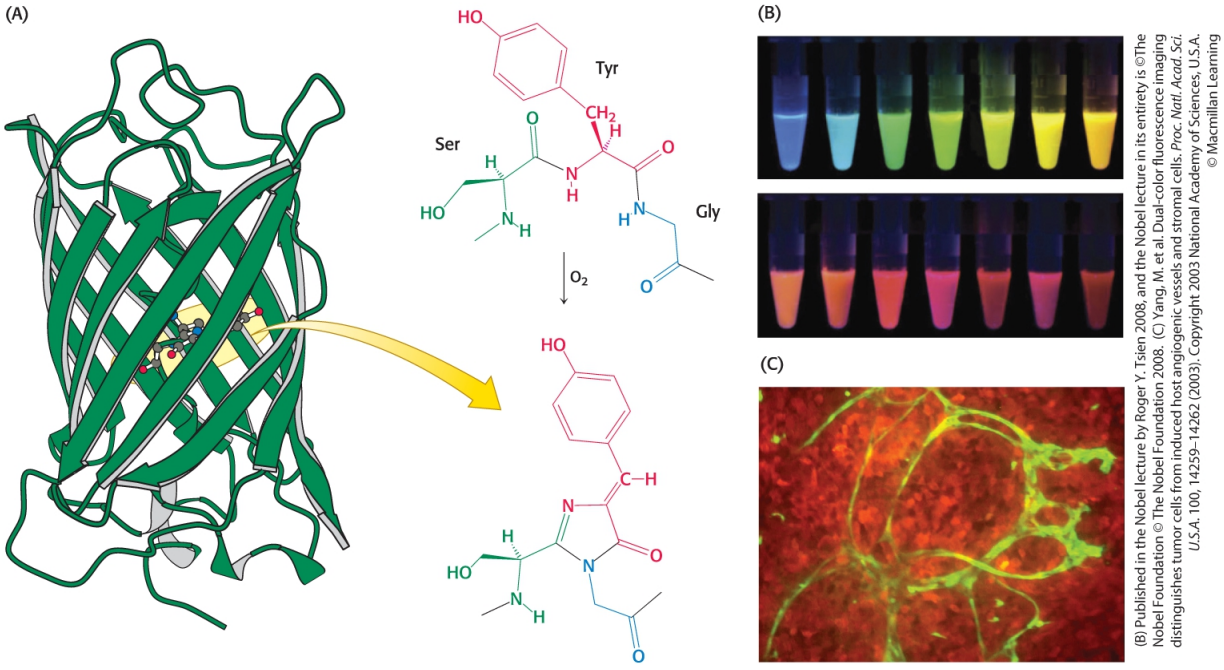
Return to FIGURE 2.61 The extent of amyloid fibril aggregation in the brain can predict the progression of Alzheimer disease

Extended description for FIGURE 2.62 Posttranslational modifications to proteins include covalent attachments.

Hydroxyproline (This chapter): A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 1 N and 4 C atoms. The N atom occupies the first position, which is the bottom right vertex and the C atoms occupy the remaining positions. N has an open single bond. C 1 and C 3 are each bound to H 2. C 2 is bound to H and dash bonded to O H highlighted in red. C 4 is dash bonded to H on the upper right and a central C atom on the lower right. The central C atom is double bonded to O below and has a single bond on the upper right.

Gamma-Carboxyglutamate (Chapter 7): A central C atom is single bonded to N H on the lower left, single bonded to C on the lower right, dash bonded to H on the upper right, and wedge bonded to C H 2 on the upper left. N in N H has an open single bond on the upper left. The C on the lower right is double bonded to O below and has an open single bond on the upper right. C H 2 is single bonded to C

H on the upper right. C H is single bonded to C O O superscript minus on the upper left. C H is single bonded to C O O superscript minus, highlighted in red, on the upper right.



Carbohydrate-asparagine adduct (Chapter 11): A central C atom is single bonded to N H on the lower left, single bonded to C on the lower right, dash bonded to H on the upper right, and wedge bonded to C H 2 on the upper left. N in N H has an open single bond on the upper left. The C on the lower right is double bonded to O below and has an open single bond on the upper right. C H 2 is single bonded to C on the upper right which is double bonded to O on the right. C is single bonded to N H on the upper left which is single bonded to C 4 of a carbohydrate group, highlighted in red on the upper right. The carbohydrate group consists of a 5-membered heterocyclic ring in a chair conformation. The ring consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C atoms are numbered in a clockwise direction from O. C 2 and C 5 are close to each other. C 4 occupies the top left vertex. C 1 is single bonded to O H on the upper right. C 2 is single bonded to N H on the lower right. C 3 is single bonded to O H on the upper right. C 4 is single bonded to N H of asparagine on the lower left. C 5 is single bonded to C H 2 O H on the upper right. N H single bonded to C 2 is single bonded to a central C atom below. The central C atom is double bonded to O on the lower left and single bonded to C H 3 on the lower right.

Phosphoserine (Chapter 7 and 14): A central C atom is single bonded to N H on the lower left, single bonded to C on the lower right, dash bonded to H on the upper right, and wedge bonded to C H 2 on the upper left. N in N H has an open single bond on the upper left. The C on the lower right is double bonded to O below and has an open single bond on the upper right. C H 2 is single bonded to O on the upper right which is single bonded to P of a phosphate group carrying a negative 2 charge, highlighted in red, on the upper left.

The phosphate group consists of a central P atom with three resonating double bonds to O on the left, upper left, and upper right.

Return to FIGURE 2.62 Posttranslational modifications to proteins include covalent attachments.

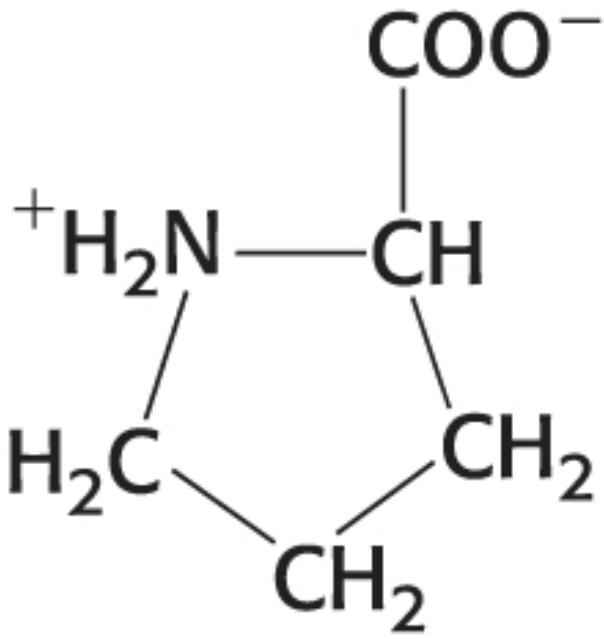
Extended description for FIGURE 2.63 GFP is modified posttranslationally by the chemical rearrangement of three amino acids

Part (A): The G F P molecule is depicted using a ribbon diagram. It consists of a hollow cylindrical barrel-like structure formed by antiparallel beta-sheets. The beta-strands pass diagonally across the length of the barrel. The head and tail of the adjacent beta-strand are connected by curved thread-like structures. A cylindrical spiral ribbon is present below the barrel and is connected to it through a thread-like structure. A ball-and-stick model of a molecule is shown inside the barrel. The structure of the molecule is shown on the right. The molecule is produced by the oxidation of a tripeptide composed of serine, tyrosine, and glycine. The structure of the tripeptide is as follows: The serine molecule consists of a 3-carbon alkane chain depicted as a line structure using 2 zigzag lines. C 1 is single bonded to O H on the lower left. C 1 is wedge bonded to C 2. C

2 is dash bonded to H above and single bonded to N below. This N is single bonded to H on the lower right and C H 3 on the lower left in the form of a line. C 3 is double bonded to O above and single bonded to N on the lower right. This N is single bonded to H below and single bonded to the C atom of the tyrosine amino acid. The C atom is single bonded to H on the upper right and wedge bonded to C H 2 on the upper left. C H 2 is single bonded to the C 3 of a benzene ring in a vertical orientation. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, C 6 and C 1. C 6 of the benzene ring is single bonded to O H. The C atom of tyrosine is single bonded to C on the lower right. This C is double bonded to O on the upper right and single bonded to N atom of glycine. N is single bonded to H on the lower left and C on the lower right. The C atom is single bonded to C below. This C is double bonded to O on the lower left and single bonded to C H 3 on the lower right in the form of a line. A downward reaction arrow labeled O 2 is shown below the tripeptide.

The structure of the product is as follows: A central C atom is wedge bonded to C H 2 on the upper left that is single bonded to O H on the lower left. The central C atom is dash bonded to H above and single bonded to N below. This N is single bonded to H on the lower right and C H 3 on the lower left in the form of a line.

The central C atom is single bonded to C 1 of a 5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 2 N and 3 C atoms. The first N atom occupies the first position, which is the bottom left vertex. The second N atom occupies the second position, which is the top left vertex. A double bond is present between C 1 and the second N atom. C 3 is double bonded to O. The first N atom is single bonded to C 1 of a 3-carbon alkane chain depicted as a line structure using 2 zigzag lines. C 2 of the alkane chain is double bonded to O below. C 2 of the pentagonal ring is double bonded to C on the upper right. This C is single bonded to



H on the right and C 2 of a benzene ring in a horizontal orientation on the upper left. The benzene ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, C 5 and C 6. C 5 of the benzene ring is single bonded to O H.

Part (B): Two black rectangles are shown. In the first rectangle, seven Eppendorf are adjacently placed. Each Eppendorf is half-filled with a solution that displays fluorescence. From left to right, the first and the second Eppendorf's show light blue and dark blue fluorescence, respectively. The third and the fourth Eppendorf's display light green and yellowish-green fluorescence, respectively. The fifth, sixth, and seventh Eppendorf show yellowish green, dark yellow, and orangish-yellow fluorescence, respectively. In the second rectangle, seven Eppendorf are adjacently placed. Each Eppendorf is half-filled with a solution that displays fluorescence. From left to right, the first and the second Eppendorf show light orange and dark orange fluorescence, respectively. The third and the fourth Eppendorf display orangish pink and pink fluorescence, respectively. The fifth, sixth, and seventh Eppendorf show purplish orange, purplish pink, and reddish-orange fluorescence, respectively.

Part (C): A photomicrograph shows a background composed of tiny bright red cells. An irregular tubular network that forms a large circle in the center having branch-like extensions is present among these cells. This tubular network is bright green colored.

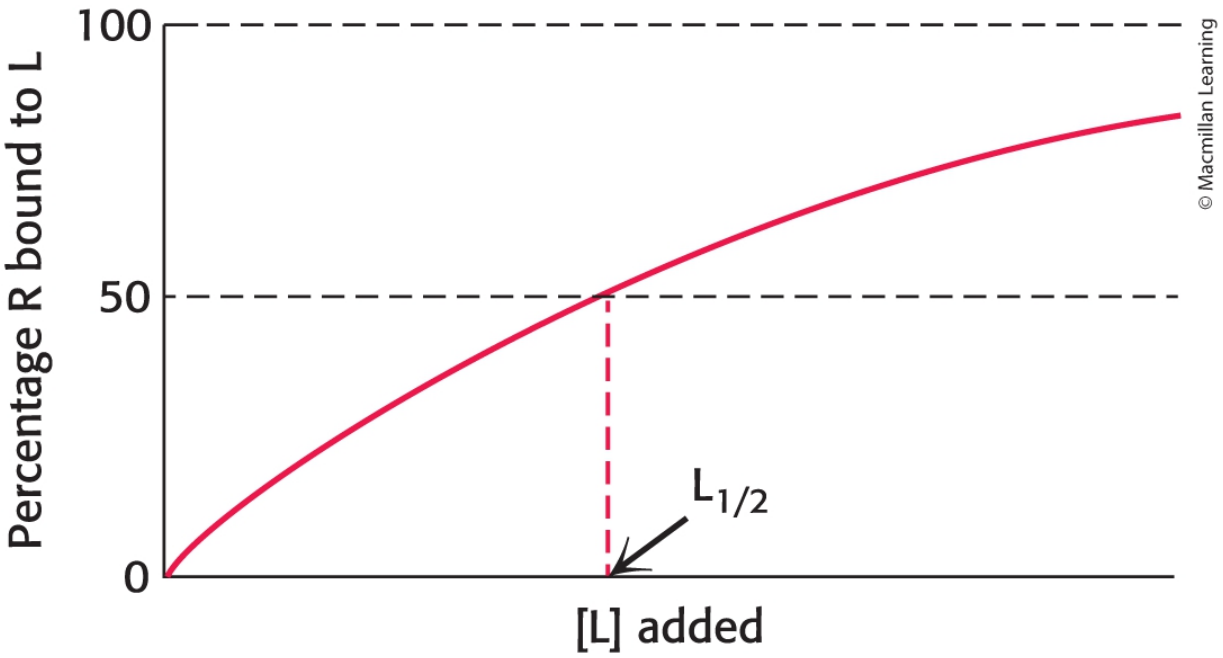
The receptor protein is shown in blue. It consists of several alpha-helices located adjacent to one another. They are connected by short thread-like loops. The target protein is shown in yellow, below the receptor protein. It consists of four alpha helices in a horizontal orientation above an anti-parallel beta-sheet. The beta-strands and alpha-helices are connected by short thread-like loops. A thread moves from the alpha-helix of the target protein into the center of the receptor protein. The terminal of this thread contains a short peptide depicted using a ball-and-stick model.

Return to An image showing a large number of penguins

Extended description for FIGURE 3.1 Comparing the percentage of receptor R bound to ligand L with the concentration of added L reveals how tightly R binds L

The horizontal axis is labeled concentration of L added. The vertical axis is labeled the percentage of R bound to L and ranges from 0 to 100 in increments of 50 units. R is receptor and L is ligand.

Three curves are shown on the graph. The first curve is labeled very tight binding. The curve begins at the origin and moves gradually to the upper right linearly until it reaches 100 on the vertical axis at very little concentration of ligand added. The curve then moves horizontally toward the right till the end of the horizontal axis.



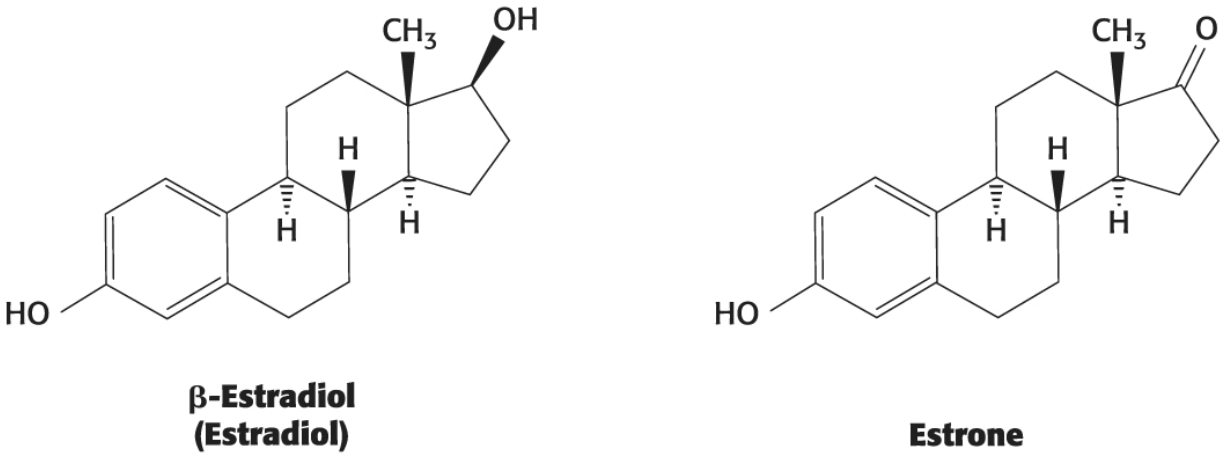
The second curve is labeled intermediate binding. The curve begins at the origin and moves gradually to the upper right until it reaches

approximately 80 percent on the vertical axis at the highest concentration of L added, and ends at the end of the horizontal axis.

The third curve is labeled very weak binding. The curve begins at the origin and overlaps with the horizontal axis along its way toward the right. The curve slightly rises above the horizontal axis near the end to reach approximately 1 percent on the vertical axis.

Return to FIGURE 3.1 Comparing the percentage of receptor R bound to ligand L with the concentration of added L reveals how tightly R binds L

Extended description for FIGURE 3.2 The binding of L to R can be characterized by L1/2



The horizontal axis is labeled concentration of L added. The vertical axis is labeled percentage R bound to L and ranges from 0 to 100 in increments of 50 units.

The curve begins at 0 and moves gradually upward to the right until it reaches approximately 80 percent on the vertical axis at the highest concentration of L added. A dotted horizontal line arises from the markings 50 and 100 on the vertical axis till the end of the horizontal axis. At the point of intersection between the horizontal line from the marking 50 and the curve, a red dotted vertical line extends till the horizontal axis. The point of contact of the red dotted line and the horizontal axis is labeled L superscript StartFraction 1 over 2 EndFraction.

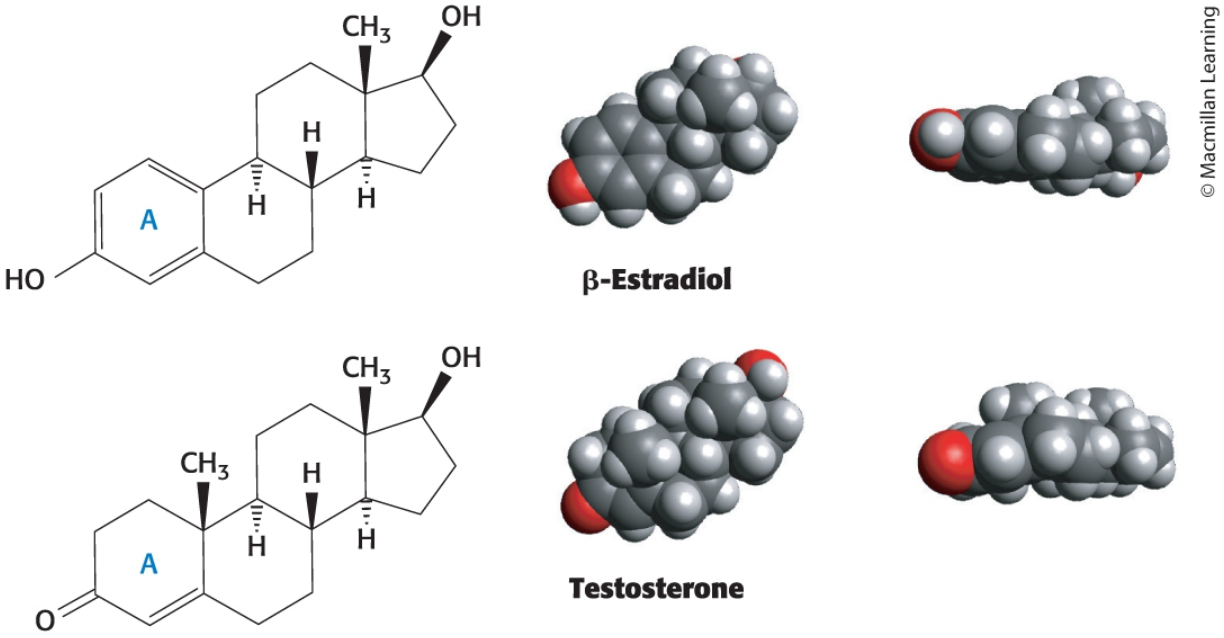
Extended description for FIGURE 3.3 Estrogens are hormones that are bound by estrogen receptors



The structure of beta-estradiol or estradiol is as follows: A benzene ring, two hexagonal rings, and a pentagonal ring are fused together. The benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 5 is single bonded to O H on the lower left. The benzene ring is fused on the right to the first 6-carbon hexagonal ring in a vertical orientation with C 1 occupying the topmost vertex. The rings are fused together such that C 2 and C 3 of the benzene ring are C 6 and C 5 of the hexagonal ring, respectively. C 1 is dash bonded to H below. This hexagonal ring is fused to the second 6-carbon hexagonal ring in a vertical orientation with C 1 occupying the topmost vertex on the upper right. The rings are fused together such that C 1 and C 2 of the first ring are C 5 and C 4 of the second ring, respectively. C 2 is wedge bonded to C H 3 above. C 3 is dashed bonded to H below. C 4 is wedge bonded to H above. The second hexagonal ring is fused on the right to the 5-carbon pentagonal ring in a horizontal orientation with C 1 occupying the rightmost vertex. The two rings are fused together such that C 2 and C 3 of the second hexagonal ring are C 4 and C 3 of

the pentagonal ring, respectively. C 5 is wedge bonded to O H on the upper right.

The structure of estrone is as follows: A benzene ring, two hexagonal rings, and a pentagonal ring are fused together. The benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 5 is single bonded to O H on the lower left. The benzene ring is fused on the right to the first 6-carbon hexagonal ring in a vertical orientation with C 1 occupying the topmost vertex. The rings are fused together such that C 2 and C 3 of the benzene ring are C 6 and C 5 of the hexagonal ring, respectively. C 1 is dash bonded to H below. This hexagonal ring is fused to the second 6-carbon hexagonal ring in a vertical orientation with C 1 occupying the topmost vertex on the upper right. The rings are fused together such that C 1 and C 2 of the first ring are C 5 and C 4 of the second ring, respectively. C 2 is wedge bonded to C H 3 above. C 3 is dashed bonded to H below. C 4 is wedge bonded to H above. The second hexagonal ring is fused on the right to the 5-carbon pentagonal ring in a horizontal orientation with C 1 occupying the rightmost vertex. The two rings are fused together such that C 2 and C 3 of the second hexagonal ring are C 4 and C 3 of the pentagonal ring, respectively. C 5 is double bonded to O on the upper right.

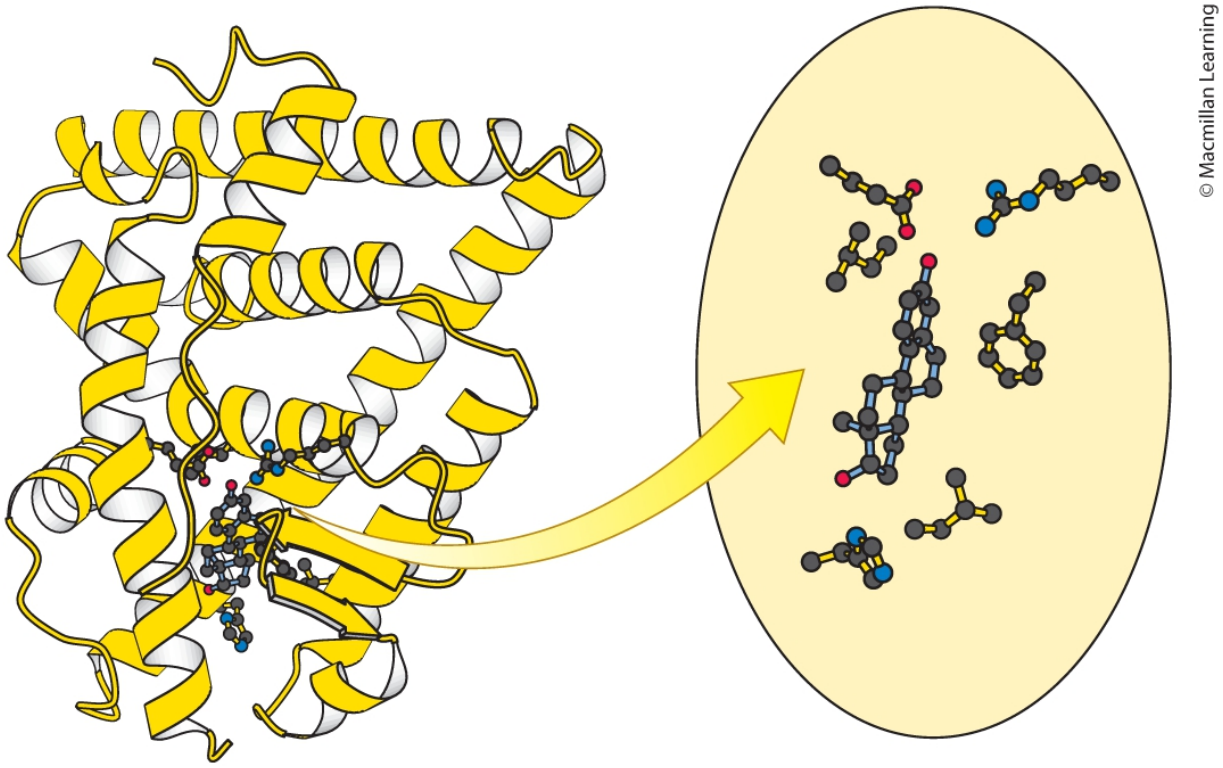
Return to FIGURE 3.3 Estrogens are hormones that are bound by estrogen receptors

Extended description for FIGURE 3.4 The steroid hormones β -estradiol and testosterone appear quite similar, yet receptors recognize the molecules as distinct

The structure of beta-estradiol is as follows: A benzene ring, two hexagonal rings, and a pentagonal ring are fused together. The benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. The center of the ring is labeled A. C 5 is single bonded to O H on the lower left. The benzene ring is fused on the right to the first 6-carbon hexagonal ring in a vertical orientation with C 1 occupying the topmost vertex. The rings are fused together such that C 2 and C 3 of the benzene ring are C 6 and C 5 of the hexagonal ring, respectively. C 1 is dash bonded to H below. This hexagonal ring is fused to the second 6-carbon hexagonal ring in a vertical orientation with C 1 occupying the topmost vertex on the upper right. The rings are fused together

such that C 1 and C 2 of the first ring are C 5 and C 4 of the second ring, respectively. C 2 is wedge bonded to C H 3 above. C 3 is dashed bonded to H below. C 4 is wedge bonded to H above. The second hexagonal ring is fused on the right to the 5-carbon pentagonal ring in a horizontal orientation with C 1 occupying the rightmost vertex. The two rings are fused together such that C 2 and C 3 of the second hexagonal ring are C 4 and C 3 of the pentagonal ring, respectively. C 5 is wedge bonded to O H on the upper right.

The structure of testosterone is as follows: Three hexagonal rings and a pentagonal ring are fused together. A 6-carbon hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. A double bond is present between C 3 and C 4. The center of the ring is labeled A. C 5 is double bonded to O on the lower left. C 2 is wedge bonded to C H 3 above. The first hexagonal ring is fused on the right to the second 6-carbon hexagonal ring in a vertical orientation with C 1 occupying the topmost vertex. The two rings are fused together such that C 2 and C 3 of the first ring are C 6 and C 5 of the second hexagonal ring, respectively. In the second hexagonal ring, C 1 is dash bonded to H below. The second hexagonal ring is fused on the upper right to the third 6-carbon hexagonal ring in a vertical orientation with C 1 occupying the topmost vertex. The two rings are fused together such that C 1 and C 2 of the second ring are C 5 and C 4 of the third ring, respectively. C 4 is wedge bonded to H above. The third hexagonal ring is fused to the 5-carbon pentagonal ring in a horizontal orientation with C 1 occupying the rightmost vertex. The two rings are fused together such that C 2 and C 3 of the third hexagonal ring are C 4 and C 3 of the pentagonal ring, respectively. C 3 is dash bonded to H below. C 4 is wedge bonded to C H 3 above. C 5 is wedge bonded to O H on the upper right.



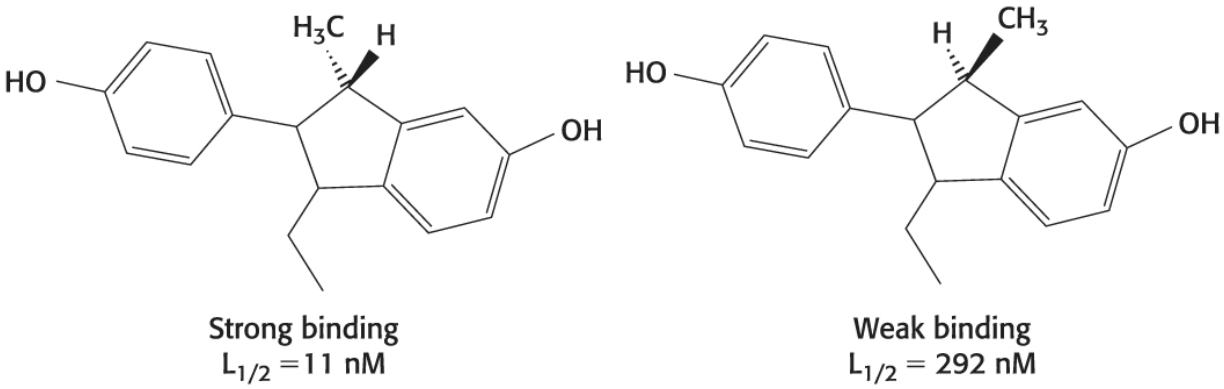
Two views of the space-filling model of both beta-estradiol and testosterone are shown. Beta-estradiol in the first view is depicted as a cluster of dark grey and light grey spheres. A red sphere is present

on the lower left. Beta-estradiol in the second view is depicted as a linear cluster of dark grey and light grey spheres. The red sphere is located on the left and away from the observer.

Testosterone in the first view is depicted as a cluster of dark and grey spheres. A red sphere is located on the upper right end and lower left end. The upper right red sphere is located away from the observer. Testosterone in the second view is depicted as a linear cluster of dark grey and light grey spheres. A red sphere is located on the left and toward the observer.

Return to FIGURE 3.4 The steroid hormones β -estradiol and testosterone appear quite similar, yet receptors recognize the molecules as distinct

Extended description for FIGURE 3.5 Proteins such as estrogen receptors include binding pockets that are complementary to the shapes of specific ligands



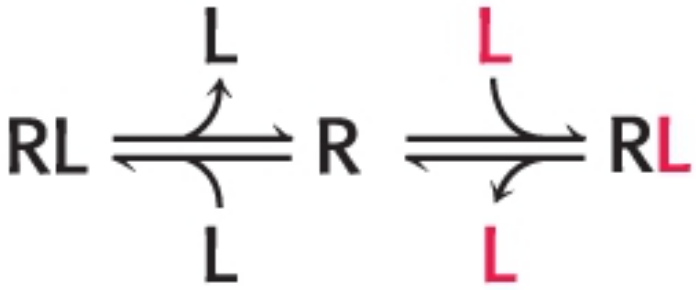
© Macmillan Learning

The estrogen receptor consists of 8 alpha helices and two beta-pleats in an antiparallel orientation. The alpha helices are connected by short thread-like loops. Two alpha helices are present in a horizontal orientation one above the other. The ends of the top alpha helix are connected to the alpha helix below. The left alpha helix moves toward the right to form a horizontal platform below the bottom horizontal alpha helix. The right alpha helix and a vertical alpha helix in front of the left alpha helix join near their end to create a pocket for an alpha helix on the ligand binding. The pocket is lined by amino acids depicted as ball-and-stick models. The ligand-

binding pocket of the receptor is enlarged that shows the estrogen at the center surrounded by side chains of amino acids.

Return to FIGURE 3.5 Proteins such as estrogen receptors include binding pockets that are complementary to the shapes of specific ligands

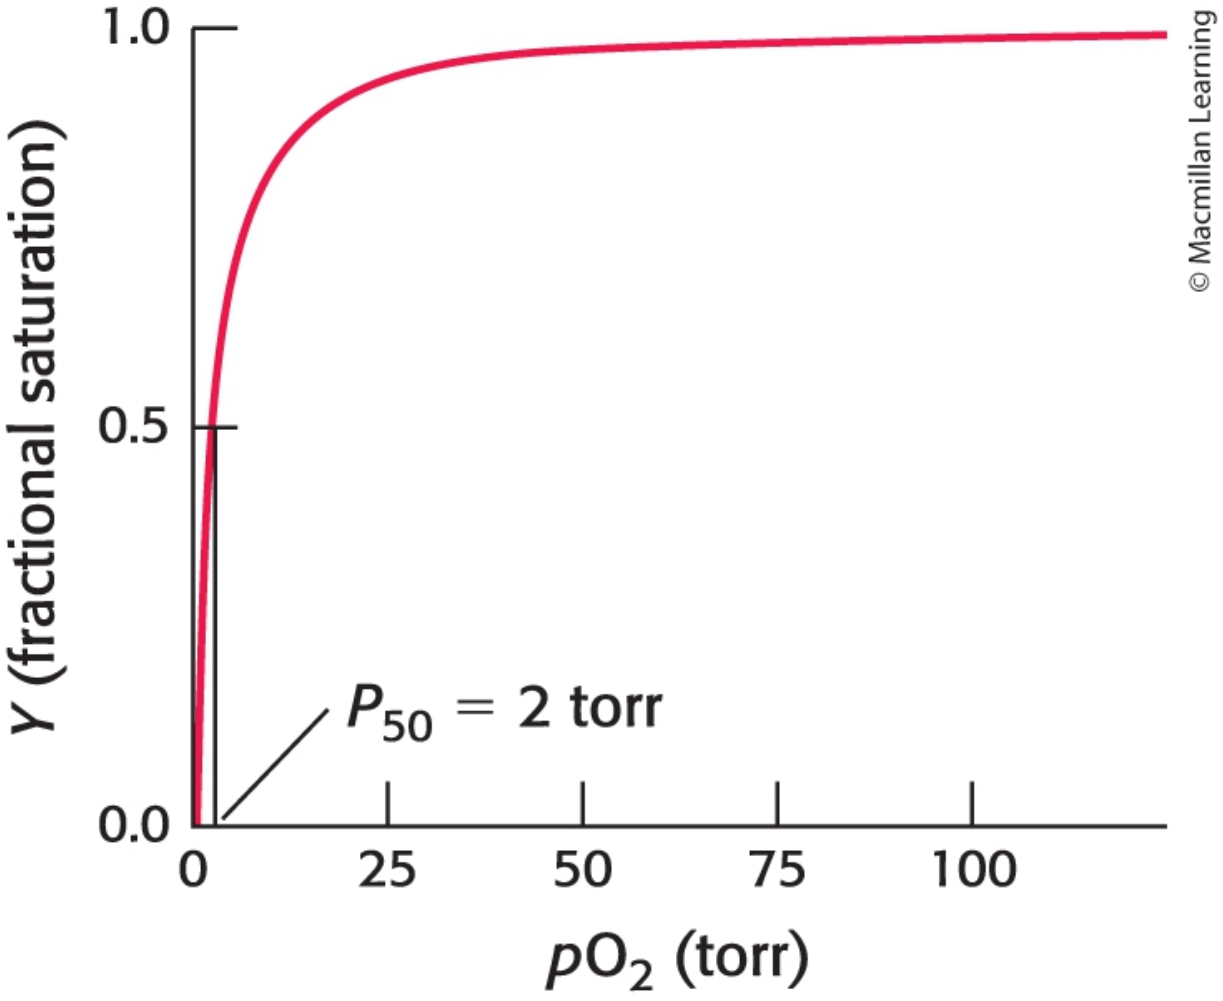
Extended description for FIGURE 3.6 Even subtle features of ligands can be recognized



The structure of the first synthetic ligand is as follows: A benzene ring is in a horizontal orientation with C 1 occupying the rightmost vertex. The ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 4 is single bonded to O H on the left. C 1 is single bonded to C 5 of a 5-carbon pentagonal ring in a vertical orientation, with C 1 occupying the topmost vertex. C 1 of the pentagonal ring is dash bonded to C H 3 on the upper left and wedge bonded to H on the upper right. C 4 is single bonded to C H 2 in the form of a line on the lower left. C of this C H 2 is single bonded to C H 3 in the form of a line on the lower right. The pentagonal ring is fused to a benzene ring on the right in a vertical orientation, with C 1 occupying the topmost vertex. The rings are fused together such that C 2 and C 3 of the pentagonal ring are C 6 and C 5 of the benzene ring, respectively. The ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 2 is single bonded to O H on the upper right. Note: Strong binding, L subscript StartFraction 1 over 2 EndFraction equals 11 n M.

The structure of the second synthetic ligand is similar to the synthetic ligand on the left, except that the C 1 of the pentagonal ring is dash bonded to H on the upper left and wedge bonded to C H 3 on the upper right. Note: Weak binding, L subscript StartFraction 1 over 2 EndFraction equals 292 n M.

Return to FIGURE 3.6 Even subtle features of ligands can be recognized

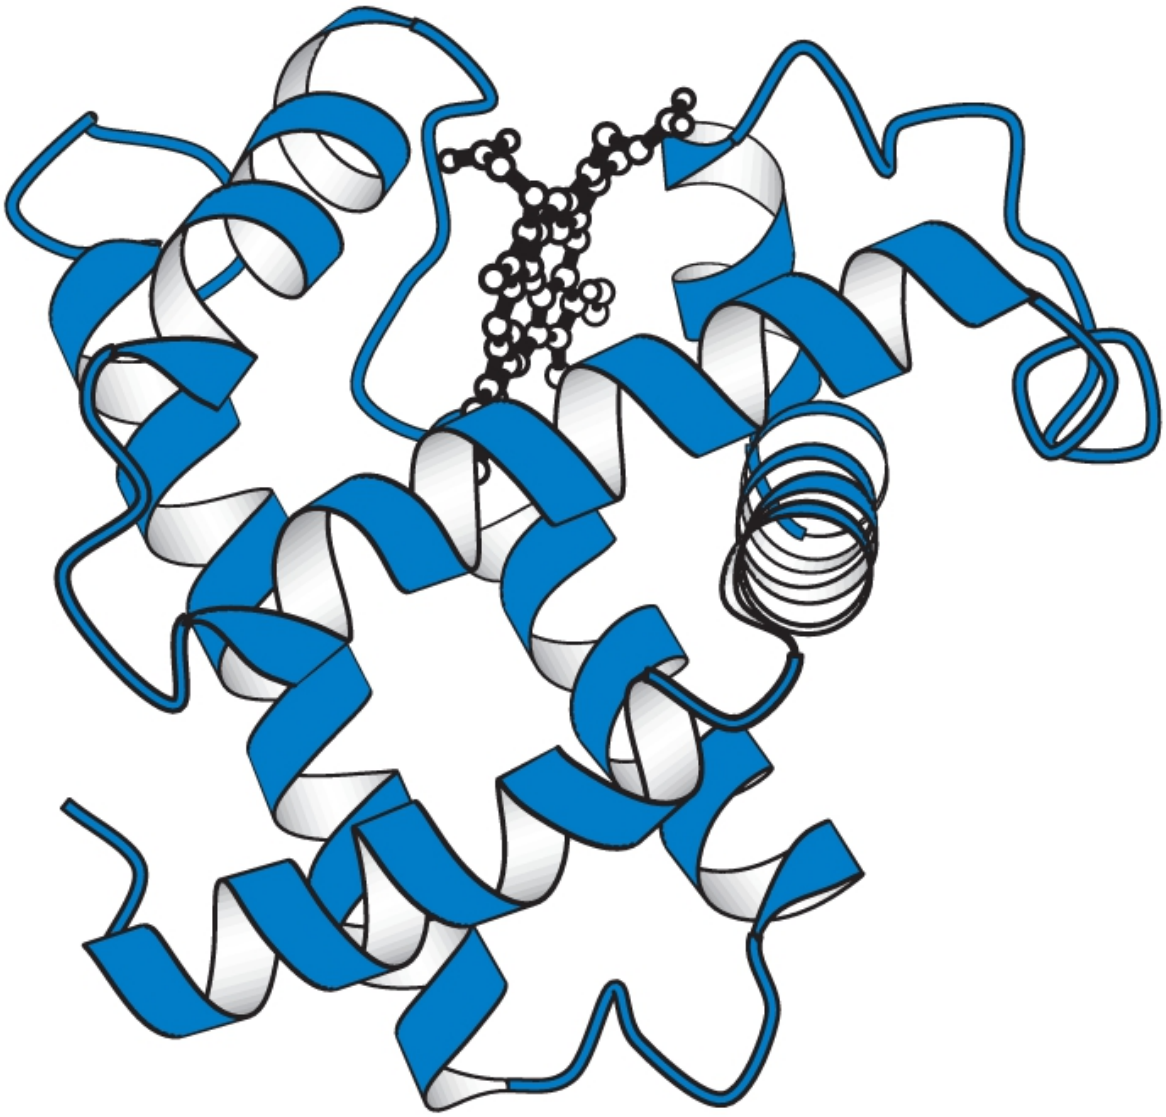


Extended description for FIGURE 3.7 Dissociation and association are constantly occurring, even at equilibrium where the concentrations of all species are constant

The receptor is depicted as R, the ligand is depicted as L, and the receptor-ligand complex is depicted as R L. The reversible reaction is a two-step reaction. The overall reaction shows reactant R L dissociates to produce R, which again gives R L. In the first step, L is eliminated in the forward reaction to give R and added in the backward reaction. In the second step, L is added in the forward reaction to give R L (L highlighted in red) and eliminated in the backward reaction to give R. L in the second step is highlighted in red.

Return to FIGURE 3.7 Dissociation and association are constantly occurring, even at equilibrium where the concentrations of all species are constant

Extended description for FIGURE 3.8 Half saturation of human myoglobin occurs when the partial pressure of oxygen is 2 torr



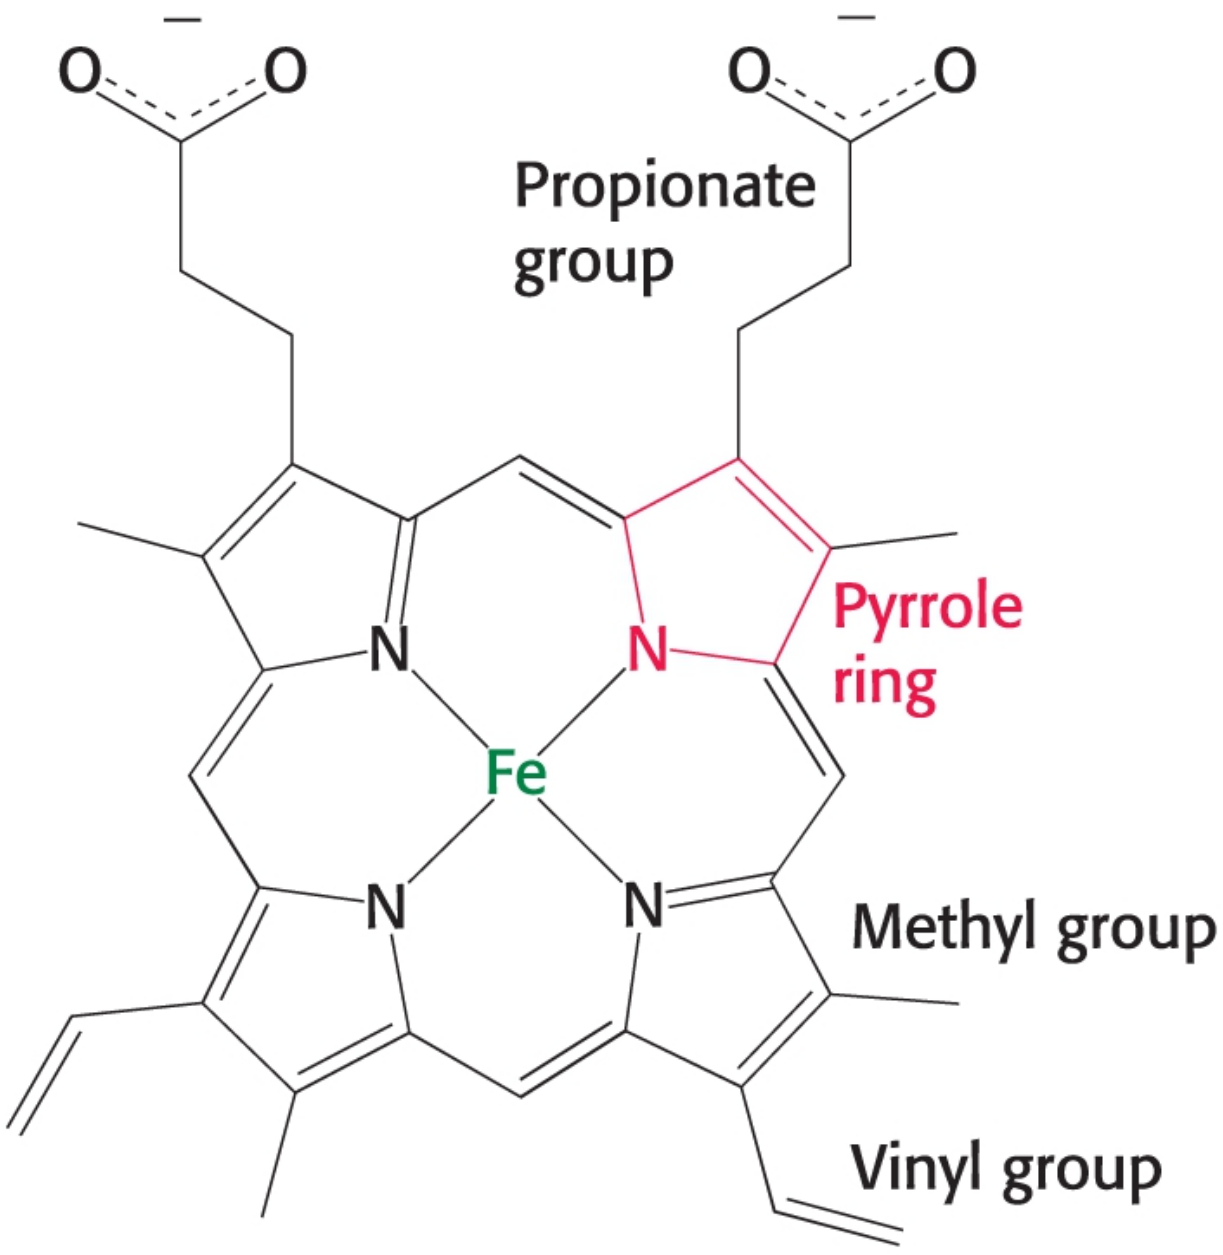
The horizontal axis is labeled p O subscript 2 (torr) and ranges from 0 to 100 in increments of 25 units. The vertical axis is labeled Y (fractional saturation) and ranges from 0.0 to 1.0 in increments of 0.5 units.

A curve shown on the graph has a hyperbolic shape. It begins at the origin and moves upward to point (2, 0.5). It then continues to the

upper right until it reaches approximately point (25, 0.9). The curve then moves horizontally toward the right till the end of the horizontal axis.

Return to FIGURE 3.8 Half saturation of human myoglobin occurs when the partial pressure of oxygen is 2 torr

Extended description for FIGURE 3.9 The structure of myoglobin consists primarily of α helices surrounding a heme molecule



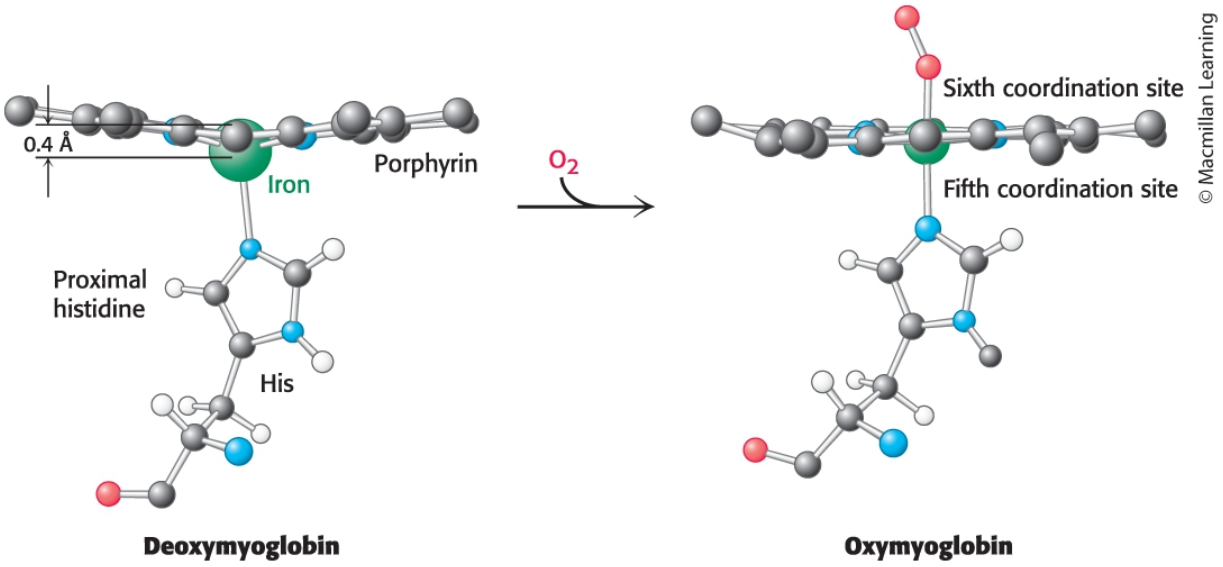
© Macmillan Learning

Myoglobin

The myoglobin protein is composed of 8 alpha-helices connected by short thread-like loops forming a compact globular structure. The heme molecule is depicted as a ball-and-stick model composed of white spheres. It is located inside a pocket having a long diagonal alpha-helix at the base and flanked by two short alpha-helices.

Return to FIGURE 3.9 The structure of myoglobin consists primarily of α helices surrounding a heme molecule

Extended description for FIGURE 3.10 The structure of heme comprises four pyrrole rings that use their nitrogen atoms to bind to a central iron atom



Heme (Fe-protoporphyrin IX)

Heme has the following structure: A central F e atom is single bonded to the N atom of a 5-membered heterocyclic ring on the upper right, lower right, lower left, and upper left, respectively. The 5-membered heterocyclic pentagonal ring consists of 1 N and 4 C atoms in different orientations. N occupies the first position, and N atoms of each ring face inward. The adjacent rings are connected to a common C H group in the middle. The ring is labeled pyrrole ring. In the ring on the lower right, C 2 is single bonded to a C H 3 in the form of a line, and C 3 is single bonded to a vinyl group. In the ring on the upper right, C 2 is single bonded to C 1 of a 3-carbon alkane chain depicted as a line structure using 2 zigzag lines. C 3 of this chain is partially double bonded to O on the upper right and upper left. A negative charge is present between the two O atoms. This group is labeled propionate group.

Return to FIGURE 3.10 The structure of heme comprises four pyrrole rings that use their nitrogen atoms to bind to a central iron atom

Extended description for FIGURE 3.11 Oxygen binding changes the position of the heme iron ion

In the ball stick model, carbon atoms are represented as black spheres, N atoms are represented as blue spheres, oxygen atoms are represented as red spheres, H atoms are represented as white spheres, and the iron atom is represented as a large green sphere.

The reaction consists of two reactants and one product. The first reactant is deoxymyoglobin. The ball-and-stick model shows the side view of the flat porphyrin ring. The black spheres connected to one another are visible to the observer. The ring contains a central green sphere slightly below the plane of the ring. The distance between the center of the green sphere and the plane of the ring is 0.4 Angstrom. The green sphere is connected to a blue sphere located at the topmost vertex of a heterocyclic pentagonal ring of histidine molecule. The black spheres are located at the top right vertex, bottom left vertex, and top left vertex of the ring. The second blue sphere is located at the bottom right vertex. The black sphere at the

top right vertex is connected to a white sphere. The black sphere at the top left vertex is connected to a white sphere. The blue sphere at the bottom right vertex is connected to a white sphere. The black sphere at the bottom left vertex is connected to another black sphere below. This black sphere is connected to a white sphere on the left and right. The black sphere below is connected to another black sphere located toward the observer. This black sphere is connected to a white sphere on the left and a blue sphere on the right. The black sphere located toward the observer is connected to another black sphere below which is connected to a red sphere on the left.

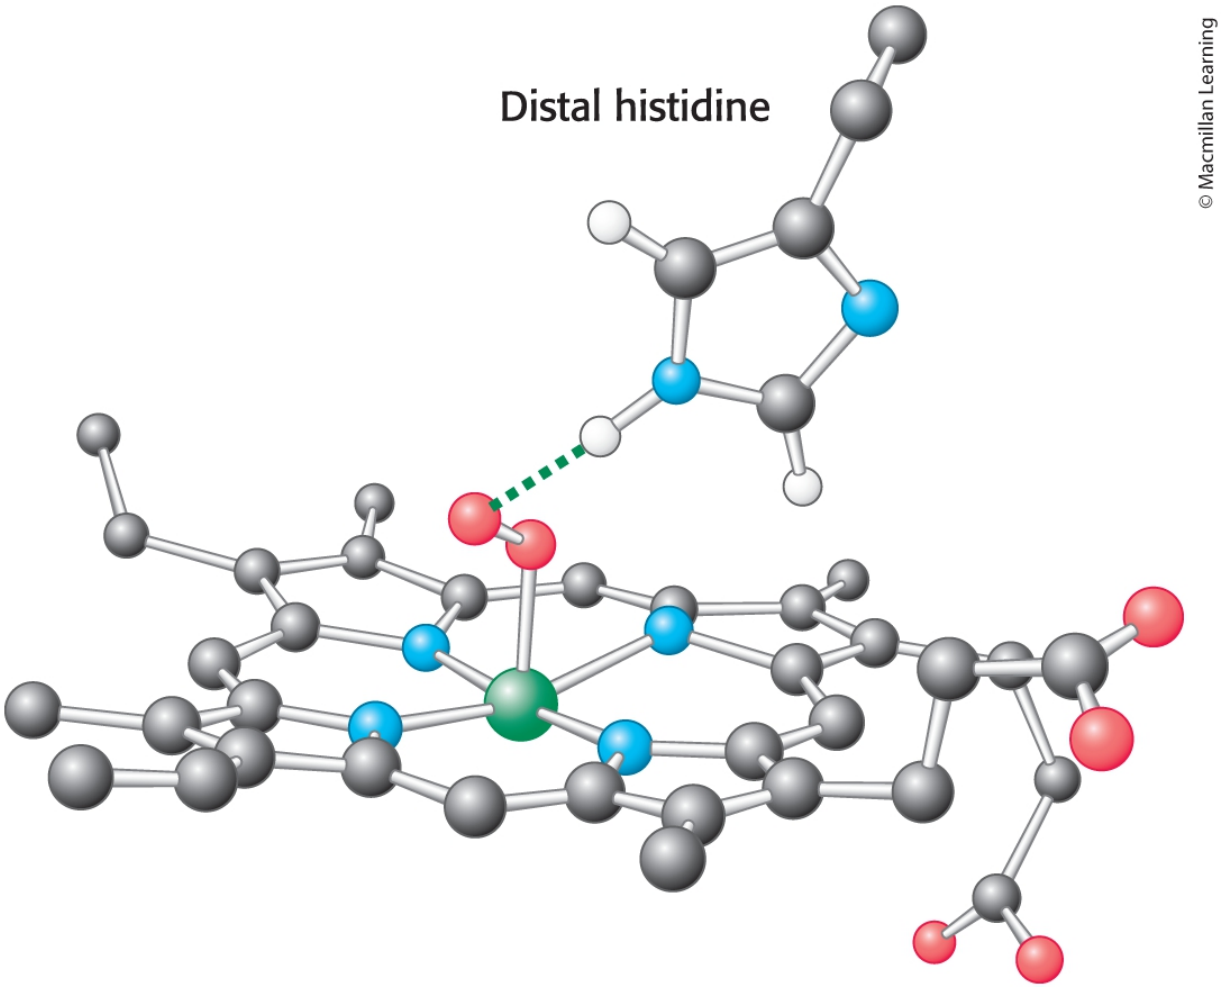
The second reactant is O 2 written over the reaction arrow.

The product is oxymyoglobin. The ball-and-stick model shows the side view of the flat porphyrin ring. The black spheres connected to one another are visible to the observer. The ring contains a central green sphere slightly in the plane of the ring. The green sphere is connected to a red sphere above the plane of the ring. This connection is labeled the sixth coordination site. This red sphere is connected to another red sphere on the upper left. This connection is labeled the fifth coordination site. The green sphere is connected below to a blue sphere located at the topmost vertex of a heterocyclic pentagonal ring of histidine molecule. The black spheres are located at the top right vertex, bottom left vertex, and top left vertex of the ring. The second blue sphere is located at the bottom right vertex. The black sphere at the top right vertex is connected to a white sphere. The black sphere at the top left vertex is connected to a white sphere. The blue sphere at the bottom right vertex is connected to a white sphere. The black sphere at the bottom left vertex is connected to another black sphere below. This black sphere is connected to a white sphere on the left and the right. The black sphere below is connected to another black sphere located toward the observer. This black sphere is connected to a white sphere on the left and a blue sphere on the right. The black

sphere located toward the observer is connected to another black sphere below which is connected to a red sphere on the left.

Return to FIGURE 3.11 Oxygen binding changes the position of the heme iron ion

Extended description for FIGURE 3.12 The complex between iron and oxygen in myoglobin can be described by two resonance structures



The first resonance structure is as follows: F e superscript 2 plus is single bonded to O above. O is double bonded to O on the upper right. The O atoms and the double bond are highlighted in red.

The second resonance structure is as follows: F e superscript 3 plus is single bonded to O above. O is partially double bonded to O superscript minus on the upper right. O atom, O superscript minus atom, and the partial double bond are highlighted in red and labeled superoxide ion.

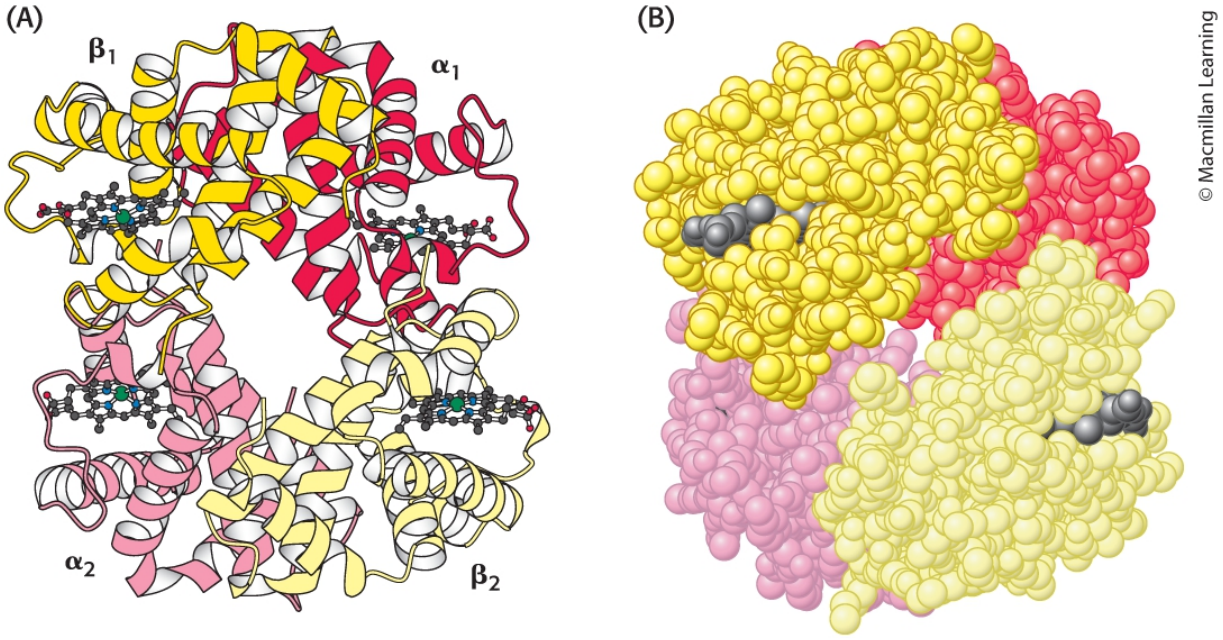
In the ball-and-stick model, carbon atoms are represented as black spheres, nitrogen atoms are represented as blue spheres, oxygen atoms are represented as red spheres, hydrogen atoms are depicted as white spheres, and the iron atom is depicted as a large green sphere.

The heme ring is flat and its top view is shown. A central green sphere is connected to a blue sphere on the upper left, lower left, upper right, and lower right. These blue spheres are a part of pyrrole rings located on the upper left, upper right, lower left, and lower right of the green sphere. The skeleton of the pyrrole ring is composed of 1 blue sphere and 4 black spheres. The side chain of the upper right and lower right rings contains a chain of 3 black spheres in which the terminal black sphere is connected to one red sphere on either side. The rings are connected through a black sphere. One black sphere on the upper left vertex of the upper left ring and the bottom left vertex of the lower left ring is connected to a chain of two black spheres. One black sphere at the topmost vertex of the upper left ring and the topmost vertex of the upper right ring is connected to a black sphere above. One black sphere at the top left vertex of the lower left ring and the bottommost vertex of the lower right ring is connected to a black sphere.

The central green sphere is connected to a red sphere above the plane of the ring. This red sphere is connected to another red sphere on the upper left. The red sphere on the upper left is connected to a white sphere on the upper right by a dotted lined. The white sphere is connected on the upper right to a blue sphere located on the bottom left vertex of a heterocyclic pentagonal ring of distal histidine consisting of 3 black spheres and two blue spheres. The black spheres are located at the topmost vertex, bottom right vertex, and top right vertex. The second blue sphere is located at the top right vertex. The black sphere at the lower right and upper left vertices are connected to a white sphere. The black sphere at the topmost vertex is connected to a chain of two black spheres above.

Return to FIGURE 3.13 Bound oxygen is stabilized through a hydrogen bond between the distal histidine and one of the oxygen atoms

Extended description for FIGURE 3.14 Carbon monoxide can bind to the iron ion in myoglobin, blocking the oxygen-binding site



In the ball-and-stick model, carbon atoms are represented as black spheres, nitrogen atoms are represented as blue spheres, oxygen atoms are represented as red spheres, hydrogen atoms are represented as white spheres, and the iron atom is represented as a large green sphere.

The heme ring is flat and its top view is shown. A central green sphere is connected to a blue sphere on the upper left, lower left, upper right, and lower right. These blue spheres are part of pyrrole rings located on the upper left, upper right, lower left, and lower right of the green sphere. The skeleton of the pyrrole ring is composed of 1 blue sphere and 4 black spheres. The side chain of the upper right and lower right rings contain a chain of 3 black spheres in which the terminal black sphere is connected to one red sphere on either side. The rings are connected through a black sphere. One black sphere at the top left vertex of the upper left ring and the bottom left vertex of the lower left ring is connected to a chain of two black spheres. One black sphere at the topmost vertex the upper left ring, and the topmost vertex of the upper right is connected to a black sphere above. One black sphere at the top left vertex of the lower left ring and bottommost vertex of the lower right ring is connected to a black sphere.

The central green sphere is connected to a black sphere above the plane of the ring. This black sphere is connected to a red sphere on the upper left. The heterocyclic pentagonal ring in distal histidine is shown above the heme ring. It consists of 3 black spheres and 2 blue spheres. The black spheres are located at the topmost vertex, bottom right vertex, and top right vertex. The first and second blue spheres are located at the top right and bottom left vertex. The black spheres at the bottom right and top left vertices are connected to a white sphere. The blue sphere at the bottom left vertex is connected to a white sphere. The black sphere at the topmost vertex is connected to a chain of two black spheres above.

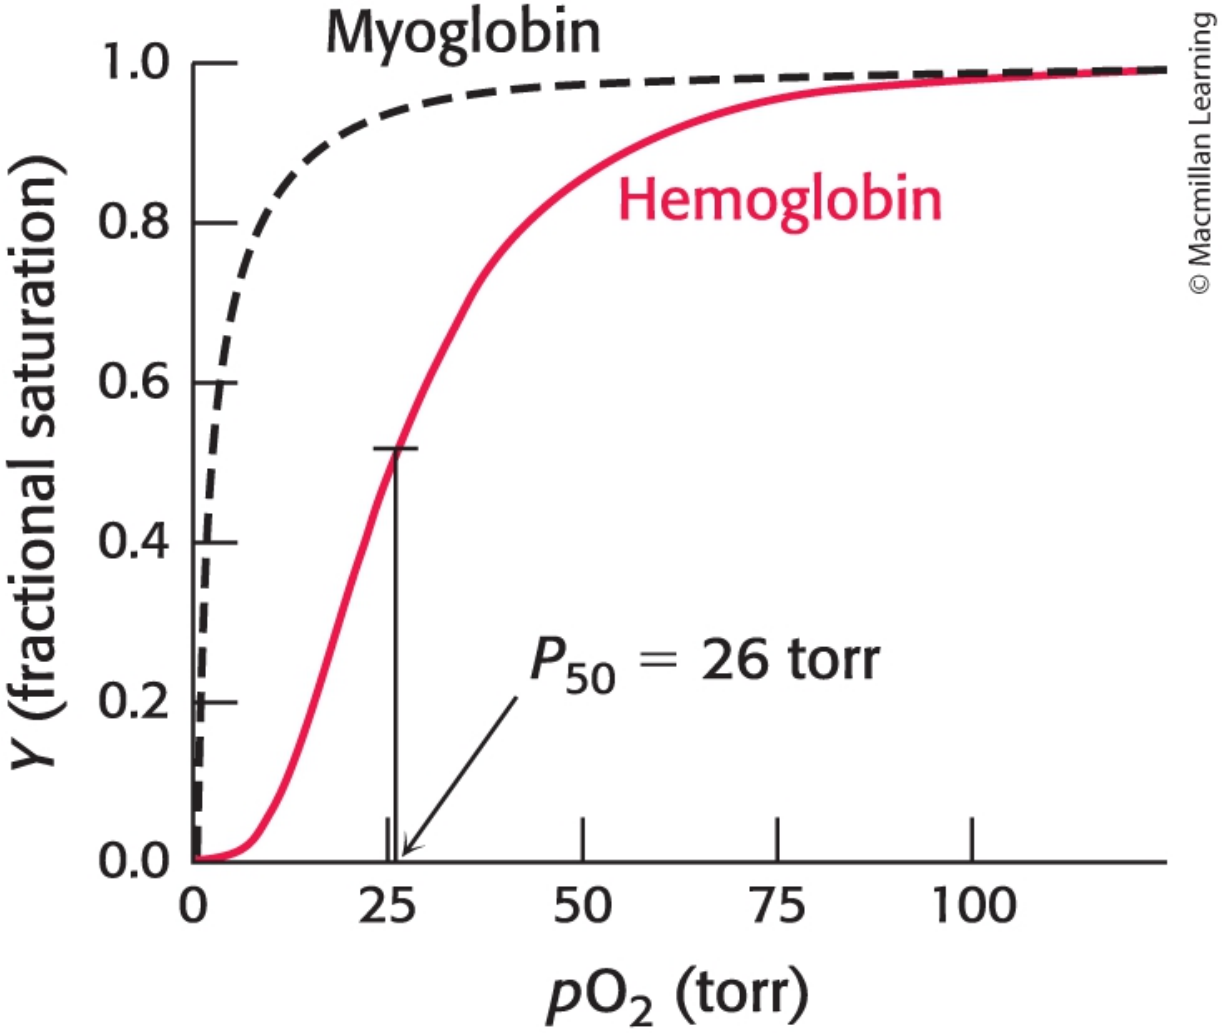
Extended description for FIGURE 3.15 Hemoglobin is an assembly of four subunits, each of which is very similar to myoglobin



© Macmillan Learning

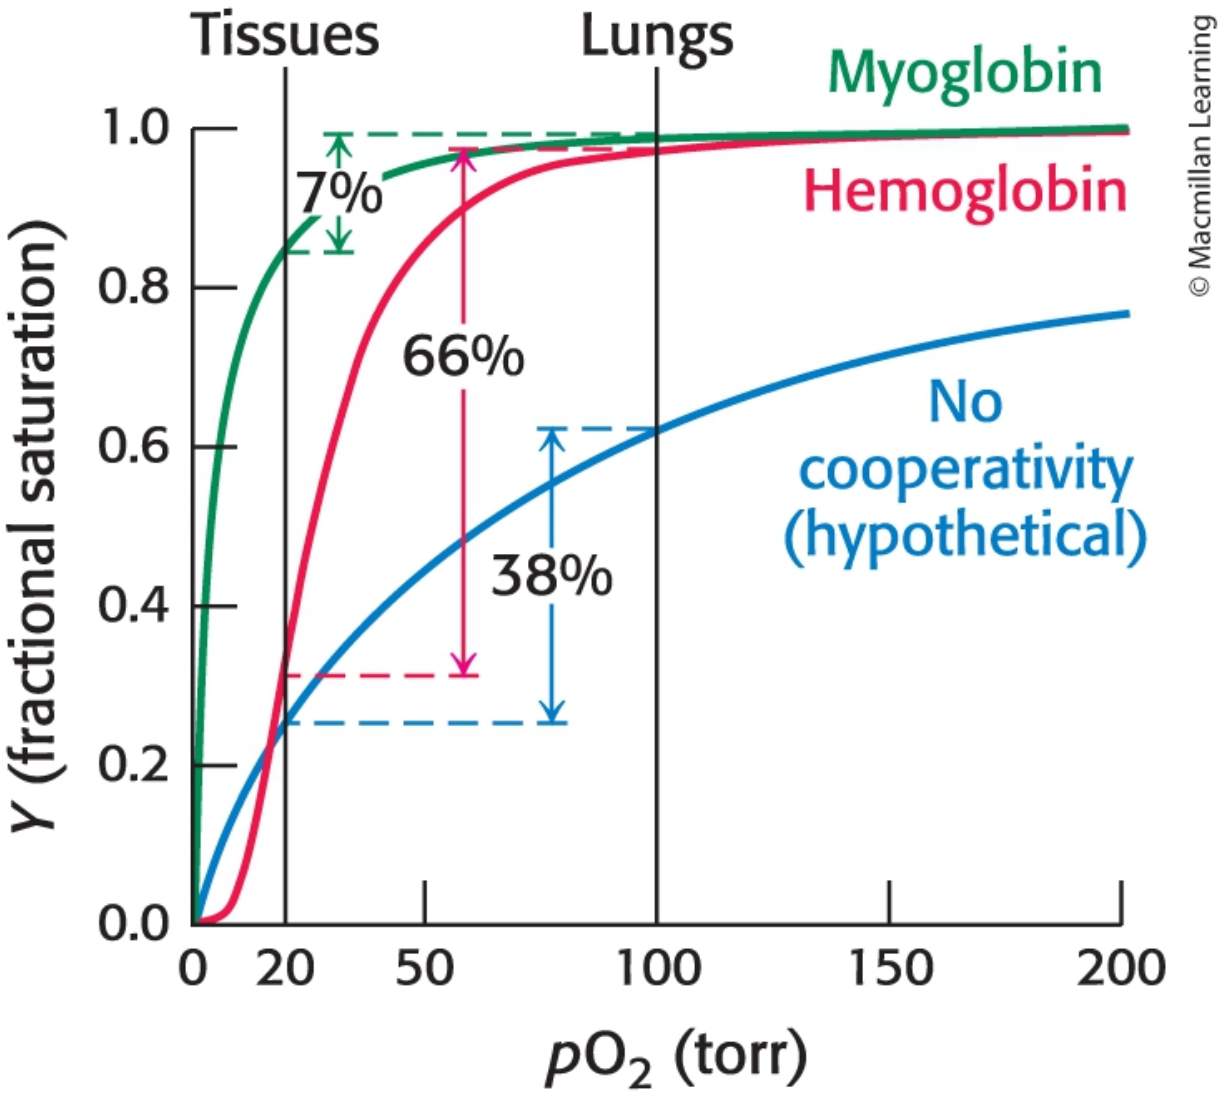
1. Part (A): Four units composed of alpha helices aggregate together form a donut shape with a hollow center. Out of the four units, the first unit on the upper left is dark yellow, the second unit on the upper right is red, the third unit on the lower right is light yellow, and the fourth unit on the lower left is pink. At the center of each unit is a heme group represented as a green sphere enclosed in a cage of small black spheres.
2. Part (B): The space-filling model shows a globular compact structure. It consists of four subunits that are dark yellow, red, light yellow, and pink. The dark yellow subunit located on the upper left has a cluster of dark yellow spheres. The red subunit on the upper right has a cluster of red spheres. The light yellow subunit on the lower right has a cluster of light yellow spheres. The pink subunit on the lower left has a cluster of pink spheres.

A small cluster of black spheres is embedded in the left and right ends of the dark yellow and light yellow subunits, respectively.

Return to FIGURE 3.15 Hemoglobin is an assembly of four subunits, each of which is very similar to myoglobin

Extended description for FIGURE 3.16 The oxygen-binding curve for hemoglobin, with its sigmoid (S-like) shape, is markedly different from that for myoglobin

The horizontal axis is labeled p O subscript 2 (torr) and ranges from 0 to 100 in increments of 25 units. The vertical axis is labeled Y (fractional saturation) and ranges from 0.0 to 1.0 in increments of 0.2 units.



The oxygen binding curve for myoglobin has a hyperbolic shape. The curve begins at the origin and moves to the upper right until it reaches approximately point (25, 0.9). The curve then rises to 0.98 Y and moves horizontally to the right.

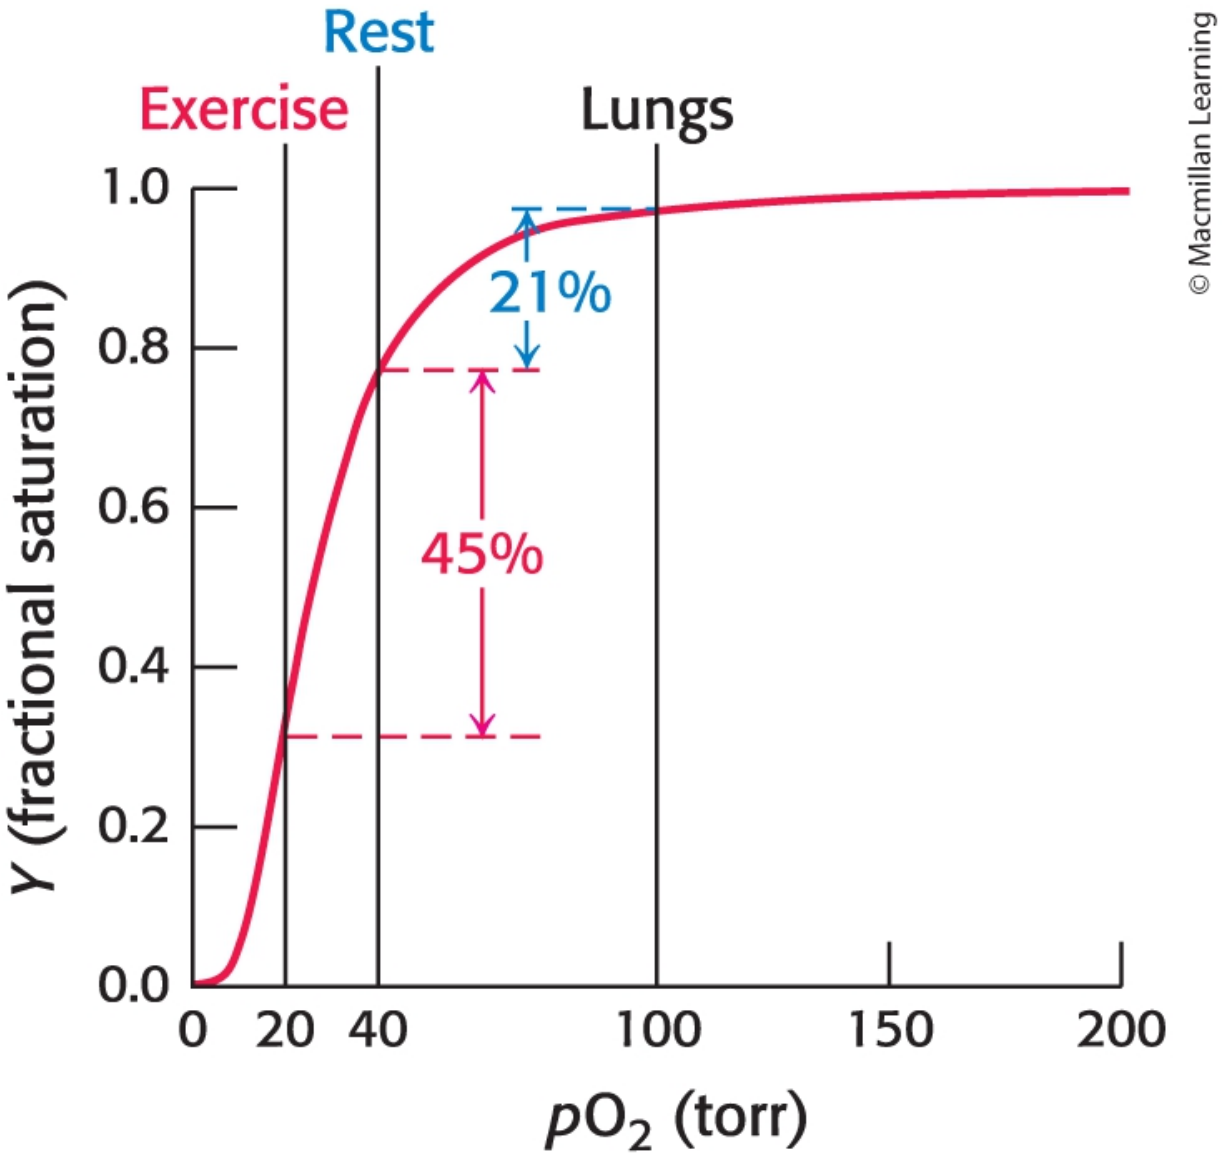
The oxygen binding curve for hemoglobin has a sigmoidal shape. It begins at the origin and moves horizontally to the right until approximately 2 torr. The curve then rises and moves toward the upper right until it reaches approximately point (75, 0.9). It then moves horizontally toward the right and merges with the myoglobin curve at approximately at 87.5 torr.

A vertical line begins at 26 torr and intersects with the hemoglobin curve. This line is labeled P subscript 50 is equal to 26 torr.

Return to FIGURE 3.16 The oxygen-binding curve for hemoglobin, with its sigmoid (S-like) shape, is markedly different from that for myoglobin

Extended description for FIGURE 3.17 Cooperativity enhances oxygen delivery by hemoglobin

The horizontal axis is labeled p O subscript 2 (torr) and ranges from 0 to 200 in increments of 50 units. The vertical axis is labeled Y (fractional saturation) and ranges from 0.0 to 1.0 in increments of 0.2 units. A vertical line begins at 20 torr on the horizontal axis and is labeled tissues. Another vertical line begins at 100 torr on the horizontal axis and is labeled lungs.



The oxygen binding curve for myoglobin has a hyperbolic shape. It begins at the origin and moves to the upper right until it reaches approximately point (25, 0.9). The curve then moves horizontally to the right. The region at which the curve makes a transition in the horizontal direction has a double-headed vertical arrow that spans from approximately markings 0.82 to 1.0 on the vertical axis. This arrow is labeled 7 percent.

The oxygen binding curve for hemoglobin has a sigmoidal shape. It begins at the origin and moves horizontally to the right until approximately 2 torr. The curve then rises and moves to the upper right until it reaches approximately point (75, 0.9). It then moves horizontally to the right and merges with the myoglobin curve at approximately at 110 torr. A double-headed vertical arrow spans from approximately markings 0.3 to 0.98 on the vertical axis at approximately 60 torr. This arrow is labeled 66 percent.

The oxygen binding curve for non-cooperative (hypothetical) protein begins at the origin. It rises upward in a curved manner and reaches approximately point (200, 0.78). A double-headed vertical arrow spans from approximately markings 0.25 to 0.6 on the vertical axis at approximately 75 torr. It is labeled 38 percent.

Return to FIGURE 3.17 Cooperativity enhances oxygen delivery by hemoglobin

Extended description for FIGURE 3.18 Oxygen delivery by hemoglobin responds to exercise

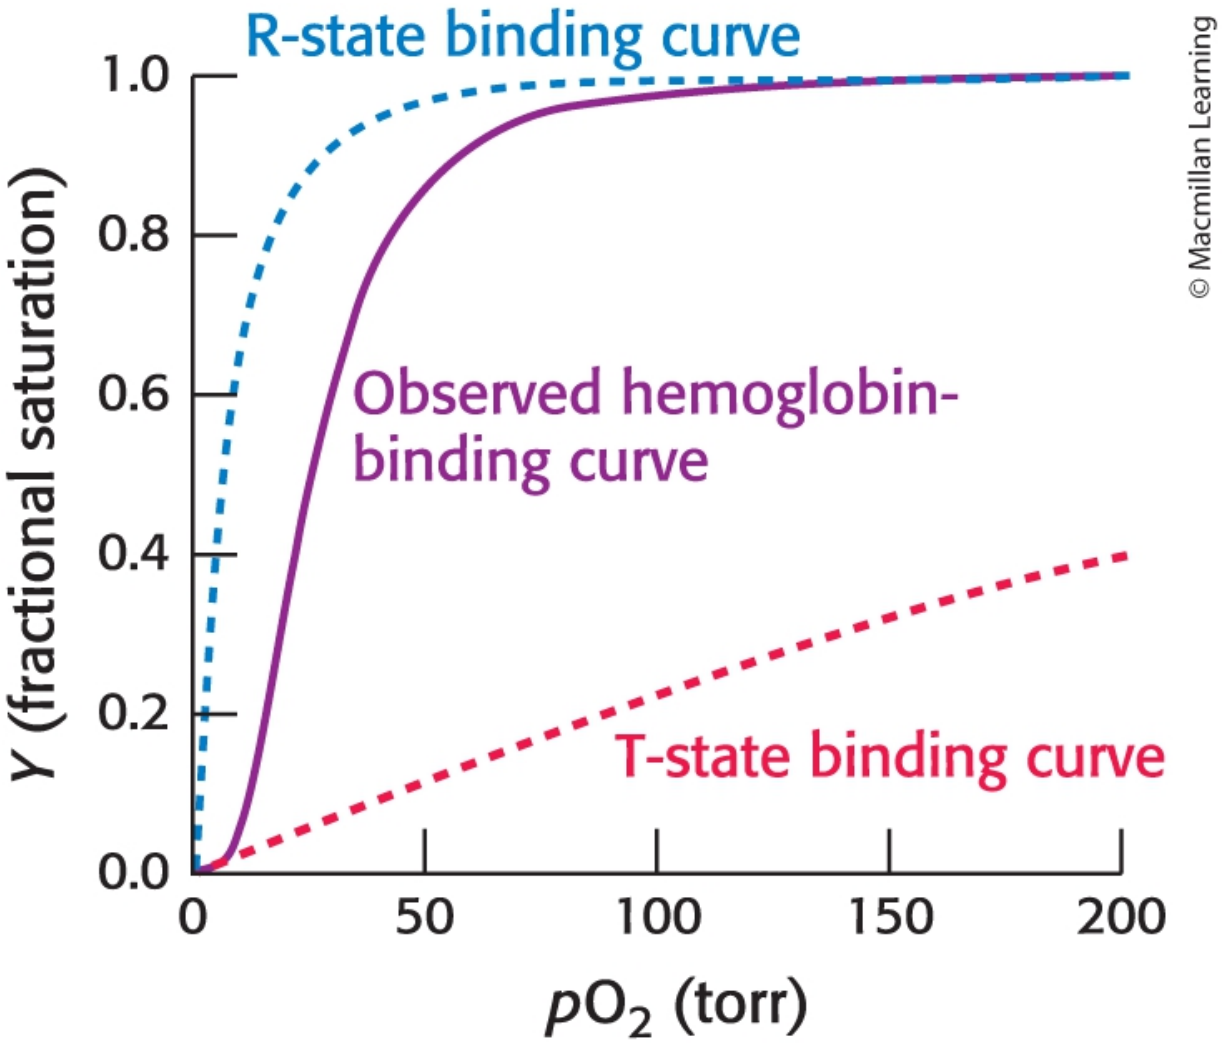
Five reversible T states are shown. Each T state is depicted as a square composed of two columns and two rows. Five reversible R states are shown below. Each R state is depicted as a cluster of four circles such that two circles are located side-by-side above and two circles below side-by-side touching each other. The T and R states are interconvertible.

The first T state is an empty square with two columns and two rows. A reversible reaction arrow is shown below and on its right. The right arrow is labeled K subscript T and shows the formation of the second T state. The arrow below is labeled T state strongly favored and shows the formation of the first R state.

The second T state is a square containing O 2 in the first row of the first column. The remaining rows and columns are empty. A reversible reaction arrow leads to the third T state.

The third T state is a square containing O 2 in the first and second row of the first column. The remaining rows and columns are empty. A reversible reaction arrow leads to the fourth T state.



The fourth T state is a square containing O 2 in the first and second rows of the first column and the second row of the second column. A reversible reaction arrow leads to the fifth T state.

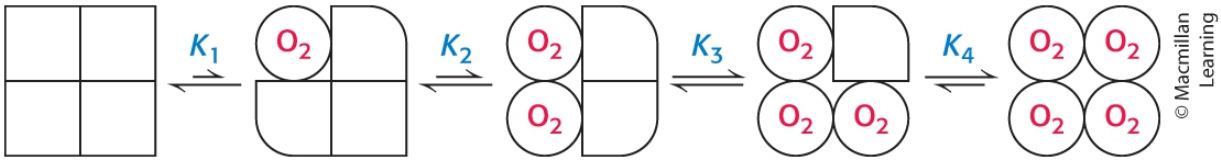
The fifth T state is a square containing O 2 in all the rows and columns. A reversible reaction arrow below is labeled R state strongly favored. It shows the formation of the fifth R state.

The first R state has all the circles empty. A reversible reaction arrow labeled K subscript R leads to the second R state. The second R state contains O 2 in the first circle of the top row. The remaining circles are empty. A reversible reaction arrow leads to the third R state. The third R state contains O 2 in the first circle of the top row and the first circle of the bottom row. The remaining circles are empty. A reversible reaction arrow leads to the fourth R state. The fourth R state contains O 2 in the first circle of the top row and both circles of the bottom row. The second circle of the top row is empty. A reversible reaction arrow leads to the fifth R state. The fifth R state contains O 2 in all the circles.

Return to FIGURE 3.20 A concerted model can explain cooperative oxygen binding by hemoglobin

Extended description for FIGURE 3.21 The sigmoid oxygen-binding curve of hemoglobin can be seen as a combination of the T state binding curve and the R state binding curve

The horizontal axis is labeled p O subscript 2 (torr) and ranges from 0 to 200 in increments of 50 units. The vertical axis is labeled Y (fractional saturation) and ranges from 0.0 to 1.0 in increments of 0.2 units.



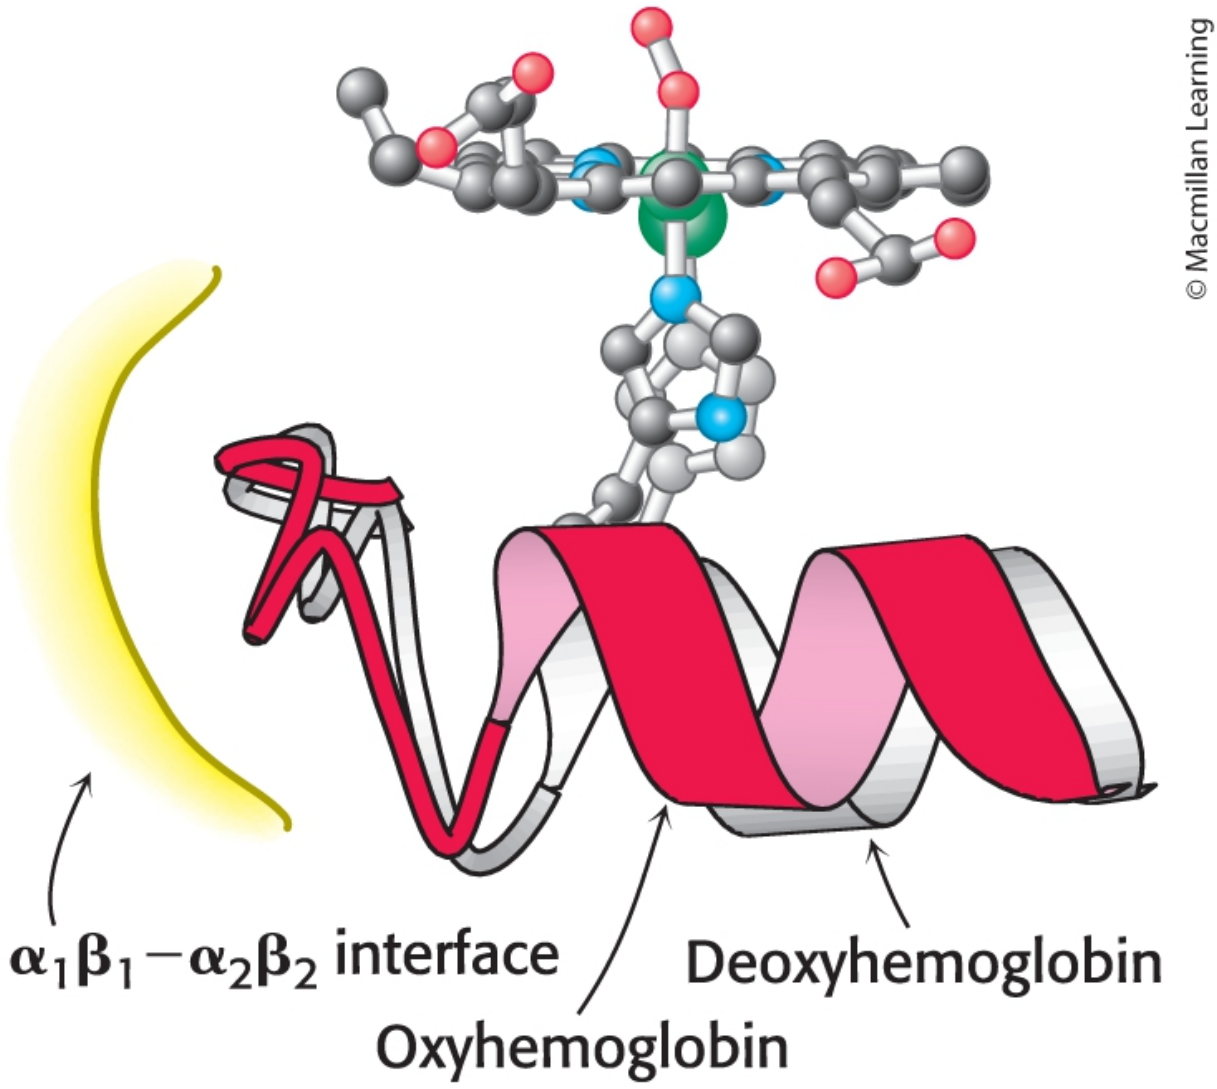
The R-state binding curve has a hyperbolic shape. The curve begins at the origin and moves to the upper right until it reaches approximately point (25, 0.9). The curve then reaches 0.98 Y and moves horizontally toward the right.

The observed hemoglobin oxygen binding curve has a sigmoidal shape. The curve begins at the origin and moves horizontally toward the right until approximately 2 torr. The curve then rises and moves toward the upper right until it reaches approximately point (60, 0.9). It then moves rises to 0.98 Y and moves horizontally toward the right to merge with the R-state binding curve at approximately 120 torr.

The T-state binding curve is a diagonal straight line that begins at the origin. It moves toward the upper right until it reaches the point (200, 0.38).

Return to FIGURE 3.21 The sigmoid oxygen-binding curve of hemoglobin can be seen as a combination of the T state binding curve and the R state binding curve

Extended description for FIGURE 3.22 A sequential model can account for oxygen-binding cooperativity



Five reversible states of hemoglobin are shown. The first state is depicted as an empty square composed of two rows and two columns. A reversible reaction arrow labeled K subscript 1 leads to the second hemoglobin state. The second hemoglobin state consists of a circle at the top left. The circle contains O 2. The top right and bottom left boxes of the square have a curved corner at the top right and bottom left, respectively. The bottom right box is square-shaped. A reversible reaction arrow labeled K subscript 2 leads to the third hemoglobin state.

The third hemoglobin state consists of a circle at the top left and bottom left. These circles contain O 2. The top right and bottom right boxes have a curved corner at the top right and bottom right, respectively. A reversible reaction arrow labeled K subscript 3 leads to the fourth hemoglobin state.

The fourth hemoglobin state consists of a circle at the top left, bottom left, and bottom right. These circles contain O 2. The top right box has a curved corner at the top right. A reversible reaction arrow labeled K subscript 4 leads to the fifth hemoglobin state. It consists of a circle at the top left, top right, bottom left, and bottom right. All the circles contain O 2.

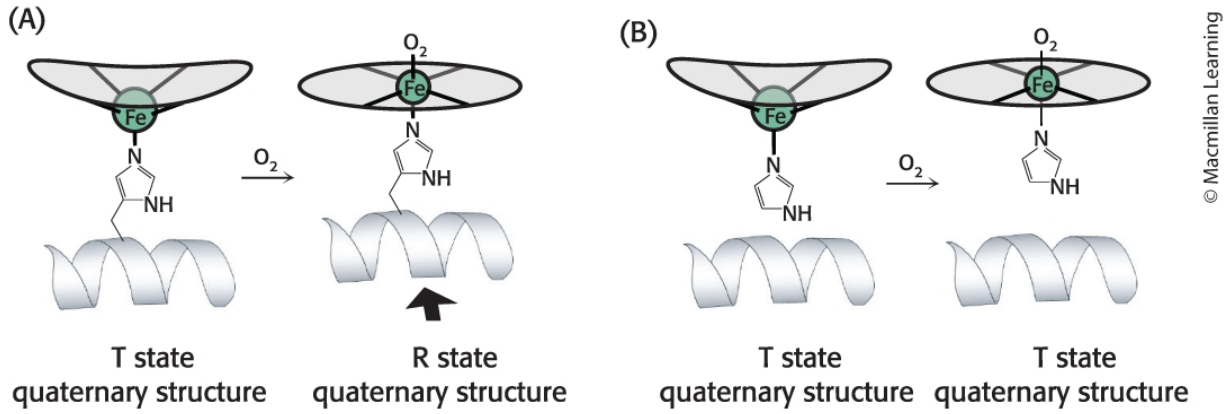
Deoxyhemoglobin is depicted as a grey horizontal helix, and oxyhemoglobin as a red horizontal helix. Grey and red thread like loops are shown at the left end of the deoxyhemoglobin and oxyhemoglobin helices, respectively. The deoxyhemoglobin molecule is shown behind the oxyhemoglobin molecule.



A ball-and-stick model of the proximal histidine and heme rings is shown on the top of both the molecules. The proximal histidine above the deoxyhemoglobin molecule is composed of a ring of 5 grey spheres. The bottom left grey sphere is connected to the deoxyhemoglobin helix below. The proximal histidine above the oxyhemoglobin molecule is composed of a ring of 3 black and 2 blue spheres. The black sphere on the bottom left is connected to a black sphere on the lower left. The topmost blue sphere of the proximal histidine of oxyhemoglobin is connected to a central green sphere of the heme ring.

This green sphere is located in the plane of the heme ring and connected to a red sphere above. The red sphere above is connected to another red sphere on the upper left. The topmost grey sphere of the proximal histidine of deoxyhemoglobin is connected to the central green sphere of the heme ring. This green sphere is located slightly below the plane of the heme ring. The proximal histidine of deoxyhemoglobin is located below the proximal histidine of oxyhemoglobin. The heme ring is depicted as a flat cage-like structure composed of a skeleton of black spheres.

A brown curved line is shown on the left of the oxyghemoglobin and deoxyhemoglobin molecule. The left region of the line is highlighted in yellow and labeled alpha 1 beta 1- alpha 2 beta 2 interface.

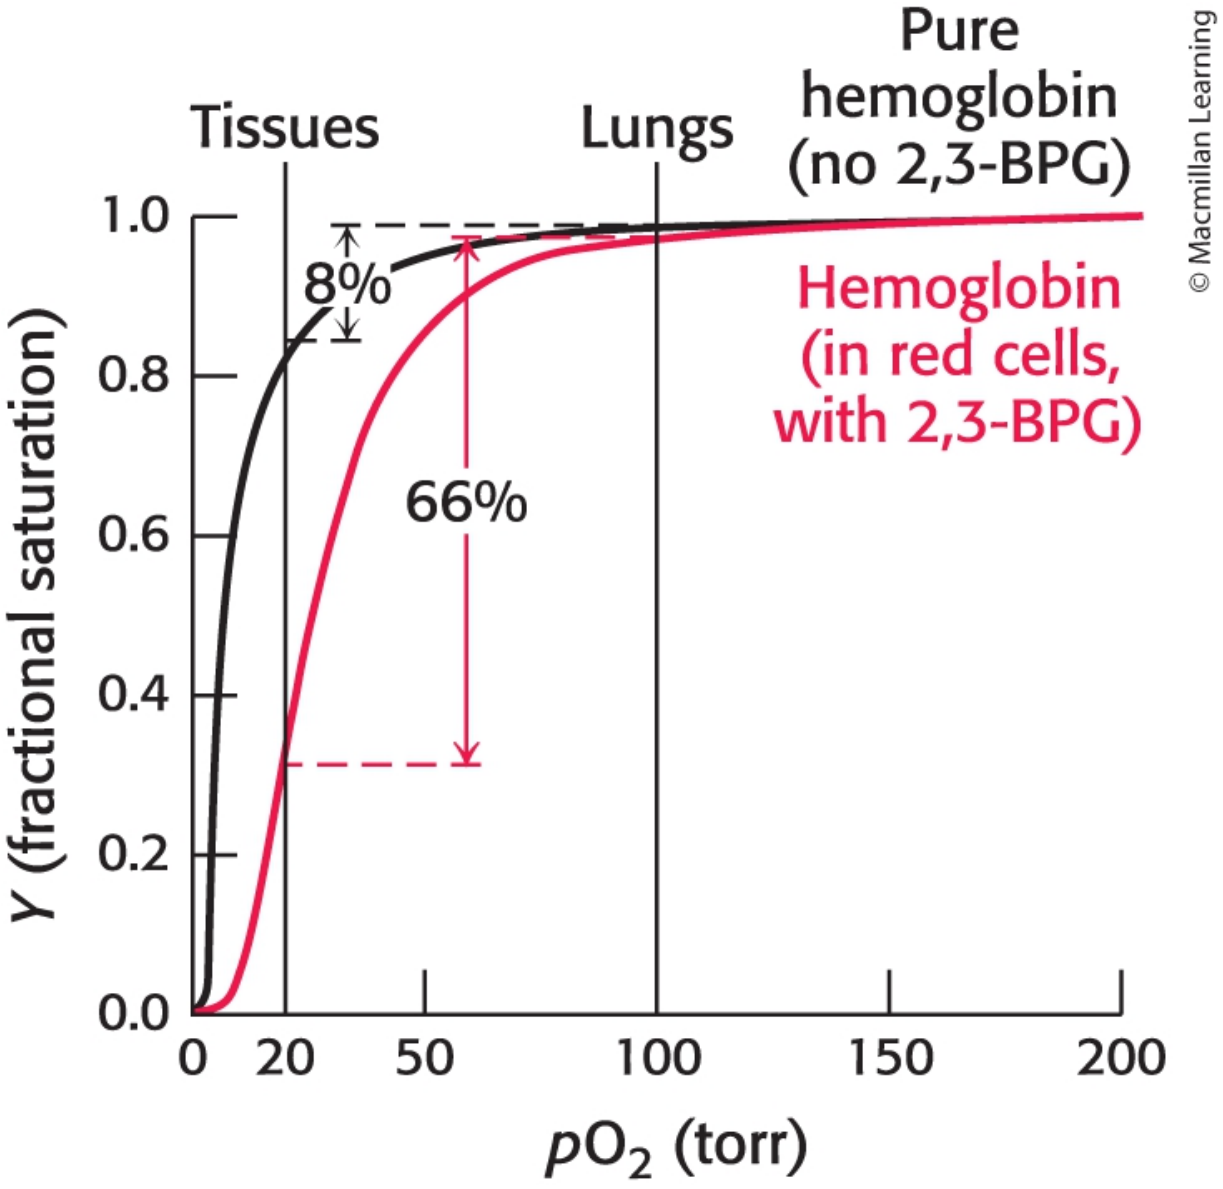
Extended description for Structure of 2,3-Bisphosphoglycerate



2,3-Bisphosphoglycerate (2,3-BPG)

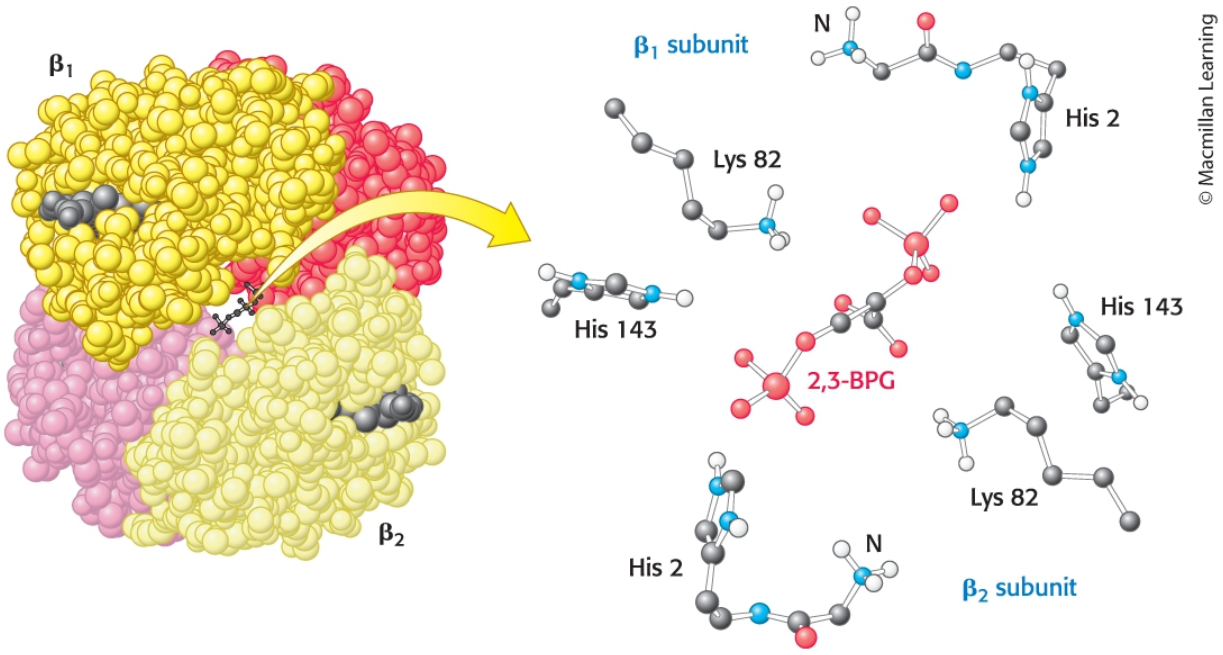
2,3-Bisphosphoglycerate (2,3-B P G) has the following structure: A 2 O and 2 C heteronuclear alkane chain is depicted as a line structure using 3 zigzag lines. The first O atom occupies the first position and the second O atom occupies the fourth position. The first O atom is single bonded to P on the lower left. P is partially double bonded to O on the upper left, O on the lower left, and O on the lower right. A charge of negative 2 is present between the oxygen atoms on the upper left and lower left. C 2 is wedged bonded C on the upper left and dash bonded to H on the upper right. This C atom is partially double bonded to O on the upper left and O on the upper right. A negative charge is present between the two O atoms. The second O

atom is single bonded to P on the upper right. P is partially double bonded to O on the upper left, O on the upper right, and O on the lower right. A charge negative 2 is present on the top of the oxygen atom at the upper right. Except for the alkane chain and the H atom on C 2 are highlighted in red.

Return to Structure of 2,3-Bisphosphoglycerate

Extended description for FIGURE 3.25 The oxygen-binding curves for pure hemoglobin and hemoglobin in red blood are markedly different

The horizontal axis is labeled p O subscript 2 (torr) and has markings 0, 20, 50, 100, 150, and 200. The vertical axis is labeled Y



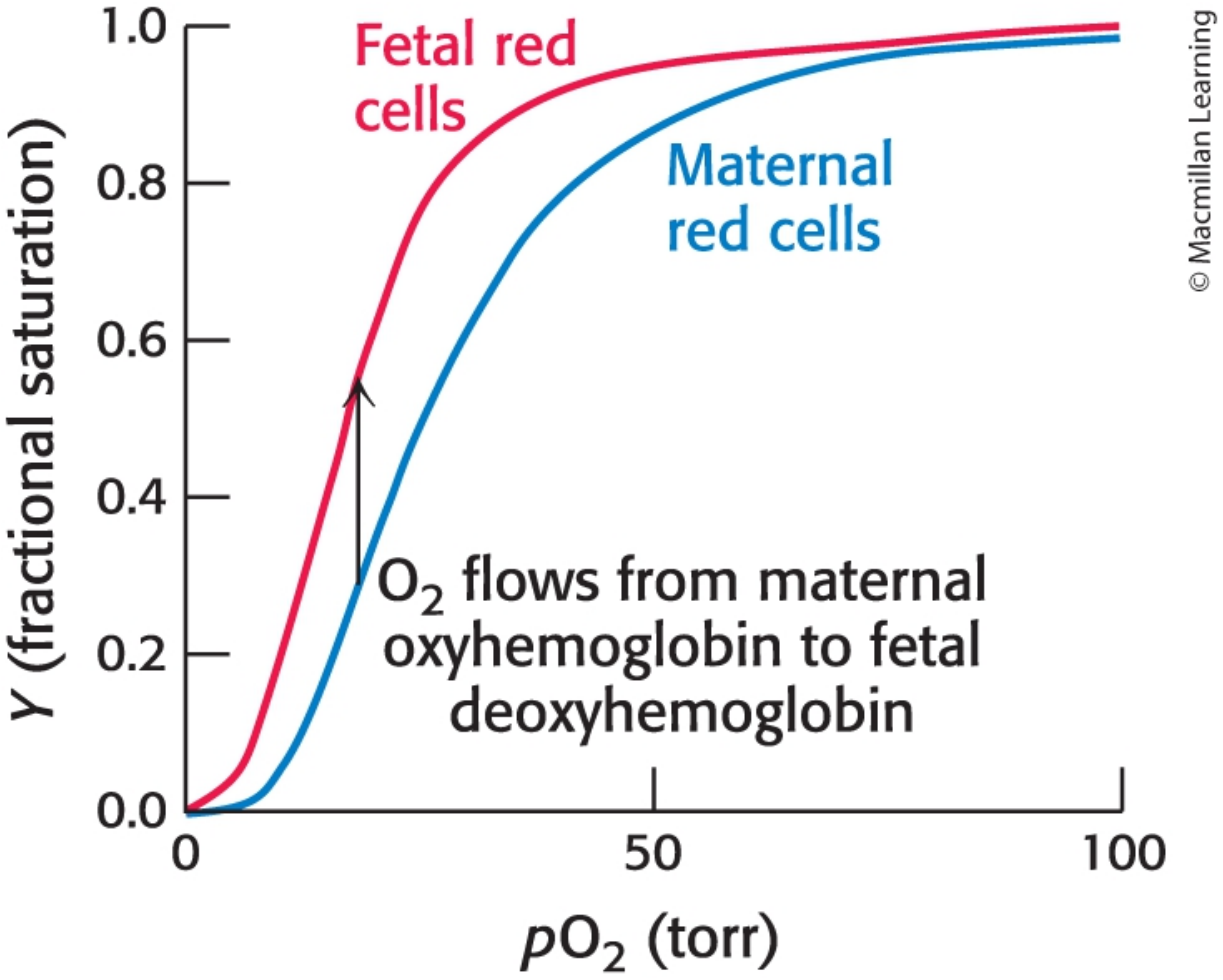
(fractional saturation) and ranges from 0.0 to 1.0 in increments of 0.2 units.

A vertical line begins at 20 torr and is labeled tissues. Another vertical line begins at 100 torr and is labeled lungs. The oxygen binding curve for pure hemoglobin (no 2, 3-B P G) has a hyperbolic shape. It begins at the origin and moves upward to the right until it reaches approximately point (35, 0.9). The curve then moves horizontally to the right. The region at which the curve makes a transition in the horizontal direction has a double-headed vertical arrow that spans from approximately 0.82 Y to 1.0 Y. This arrow is labeled 8 percent on the right of the vertical line labeled tissues.

The oxygen binding curve for hemoglobin (in red cells, with 2, 3- B P G) has a sigmoidal shape. It begins at the origin and moves horizontally to the right until approximately 2 torr. The curve then rises and moves upward to the right until it reaches approximately point (70, 0.9). It then moves horizontally to the right and merges with the pure hemoglobin curve at approximately at 110 torr. A double-headed vertical arrow spans from approximately 0.3 Y to 0.98 Y on the pure hemoglobin curve at approximately 60 torr. This arrow is labeled 66 percent.

Return to FIGURE 3.25 The oxygen-binding curves for pure hemoglobin and hemoglobin in red blood are markedly different

Extended description for FIGURE 3.26 2,3-Bisphosphoglycerate binds in the central cavity within deoxyhemoglobin



The space-filling model shows a globular compact structure of deoxyhemoglobin. It consists of four subunits that are dark yellow, red, light yellow, and pink in color. The dark yellow subunit located at the upper left is labeled beta 1, and is composed of a cluster of the dark yellow sphere. The red subunit located at the upper right is composed of a cluster of red spheres. The light yellow subunit located at the lower right is labeled beta 2 and is composed of a cluster of light yellow spheres. The pink subunit located at the lower left is composed of a cluster of pink spheres. A small cluster of black spheres is embedded in the left and the right end of the dark yellow and the light yellow subunits, respectively. There is a free space at the center of the deoxyhemoglobin molecule.

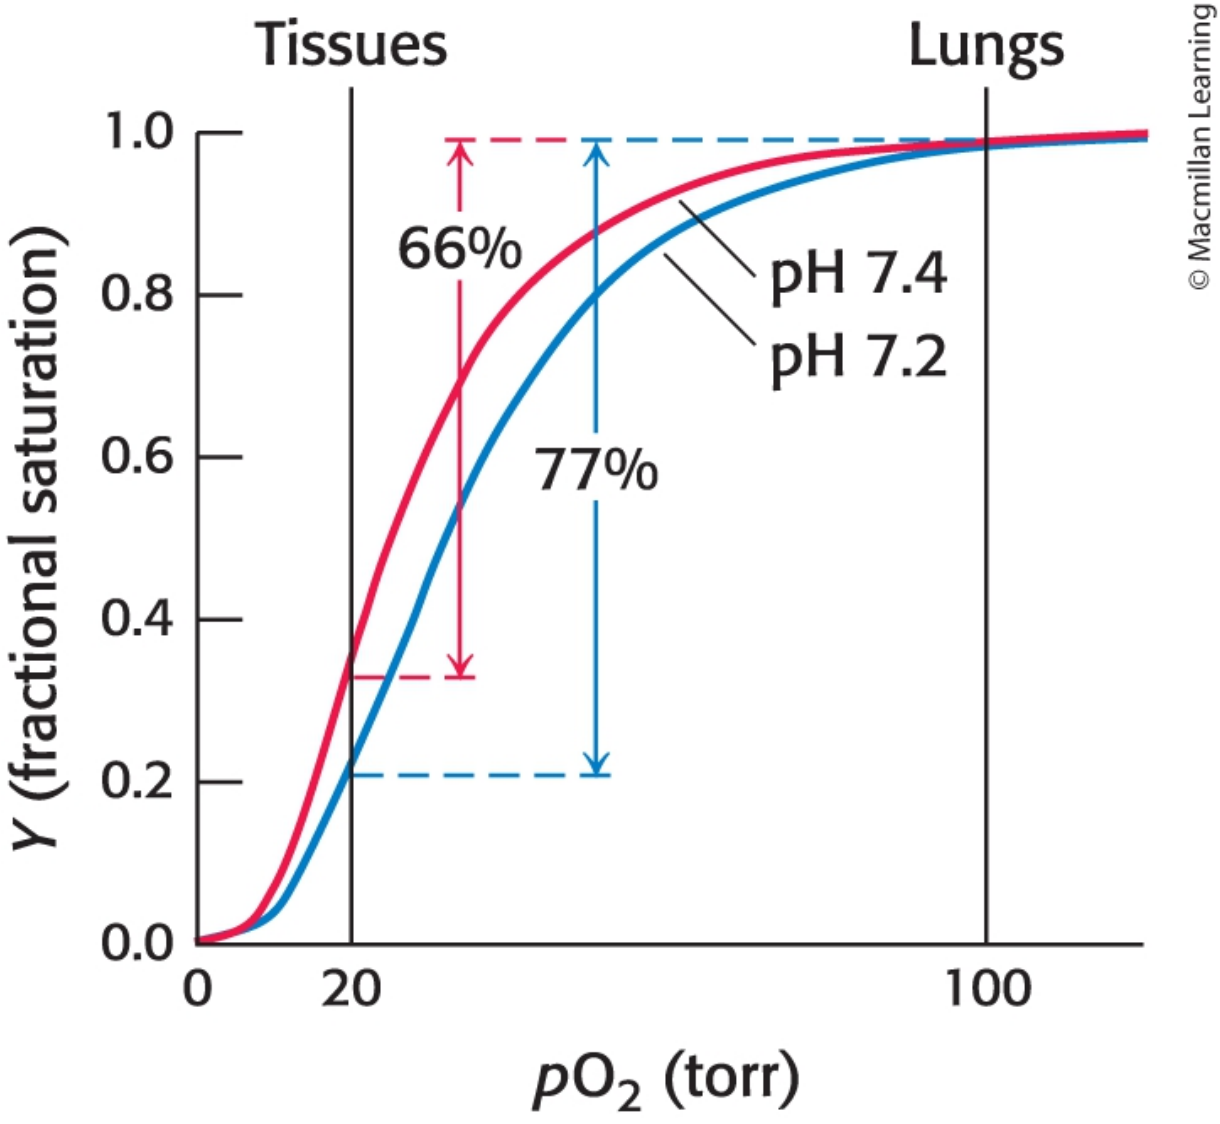
This space is the central cavity and is enlarged on the right. The enlarged figure shows a ball-and-stick model of 2, 3- B P G composed of red and black spheres in a diagonal orientation at the center. It is surrounded by the amino acid residues histidine 2, histidine 143, lysine 82, histidine 2, histidine 143, and lysine 82 from the bottom left to the bottom right. Histidine 2, histidine 143, and lysine 82 at the bottom left, left, and top left is part of the beta 1 subunit. The remaining histidine 2, histidine 143, and lysine 82 are part of the beta 2 subunit.

Return to FIGURE 3.26 2,3-Bisphosphoglycerate binds in the central cavity within deoxyhemoglobin

Extended description for FIGURE 3.27 Fetal red blood cells obtain oxygen from maternal red blood cells by virtue of fetal hemoglobin's lower affinity for 2,3-BPG

© Macmillan Learning

The horizontal axis is labeled p O subscript 2 (torr) and ranges from 0 to 100 in increments of 50 units. The vertical axis is labeled Y (fractional saturation) and ranges from 0.0 to 1.0 in increments of 0.2 units.



Two curves labeled fetal red cells, and maternal red cells are shown. The fetal red cell curve begins at the origin and moves upward to the

right to reach approximately point (4, 0.05). It moves steeply upward till approximately point (40, 0.98). The curve then moves horizontally to the right. A point on this curve approximately at point (20, 0.52) is labeled O 2 flows from maternal oxyhemoglobin to fetal deoxyhemoglobin.

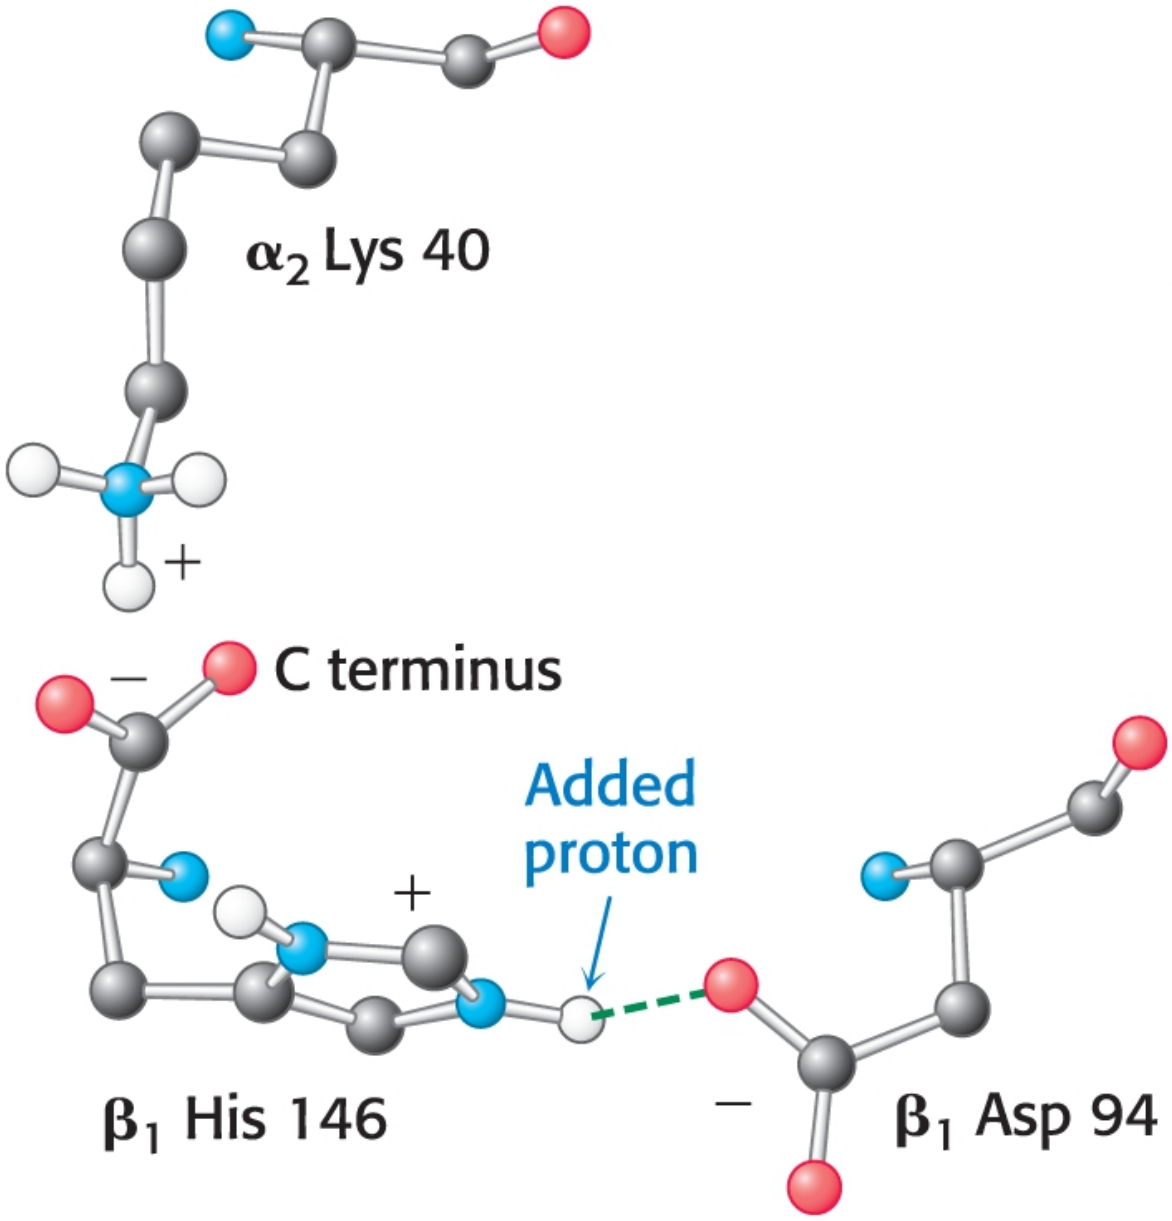
The maternal red cells curve begins at the origin and moves horizontally to the right until approximately 6 torr. The curve then rises and moves upward on the right of the fetal red cells curve until it reaches approximately point (75, 0.98). It then moves horizontally to the right below the fetal red cells curve.

Return to FIGURE 3.27 Fetal red blood cells obtain oxygen from maternal red blood cells by virtue of fetal hemoglobin's lower affinity for 2,3-BPG

Extended description for FIGURE 3.28 Lowering the pH decreases the oxygen affinity of hemoglobin and facilitates the release of oxygen into metabolically active tissues

The horizontal axis is labeled p O subscript 2 (torr) and has markings 0, 20, and 100. Markings 20 and 100 are at a greater distance than markings 0 and 20. The vertical axis is labeled Y

(fractional saturation) and ranges from 0.0 to 1.0 in increments of 0.2 units.



A vertical line begins at 20 torr and is labeled tissues. Another vertical line begins at 100 torr and is labeled lungs. The oxygen binding curve for hemoglobin at p H 7.4 has a sigmoidal shape. It begins at the origin and moves upward to the right until it reaches approximately point (70, 0.98). The curve then rises to 1.0 Y and moves horizontally toward the right.

The oxygen binding curve for hemoglobin at p H 7.2 has a sigmoidal shape. This curve is located toward the right of the oxygen binding curve for hemoglobin at p H 7.4. It begins at the origin, merges with the first curve, and moves almost horizontally toward the right until approximately 8 torr. The curve then rises and moves upward to the right until it reaches approximately point (70, 0.9). It then moves horizontally toward the right and merges with the first curve at approximately at 90 torr.

A double-headed vertical arrow spans from approximately 0.3 Y to 1.0 Y at approximately 35 torr. This arrow is labeled 66 percent. Another double-headed vertical arrow spans from approximately 0.2 Y to 1.0 Y at approximately 50 torr. This arrow is labeled 77 percent.

Return to FIGURE 3.28 Lowering the pH decreases the oxygen affinity of hemoglobin and facilitates the release of oxygen into metabolically active tissues

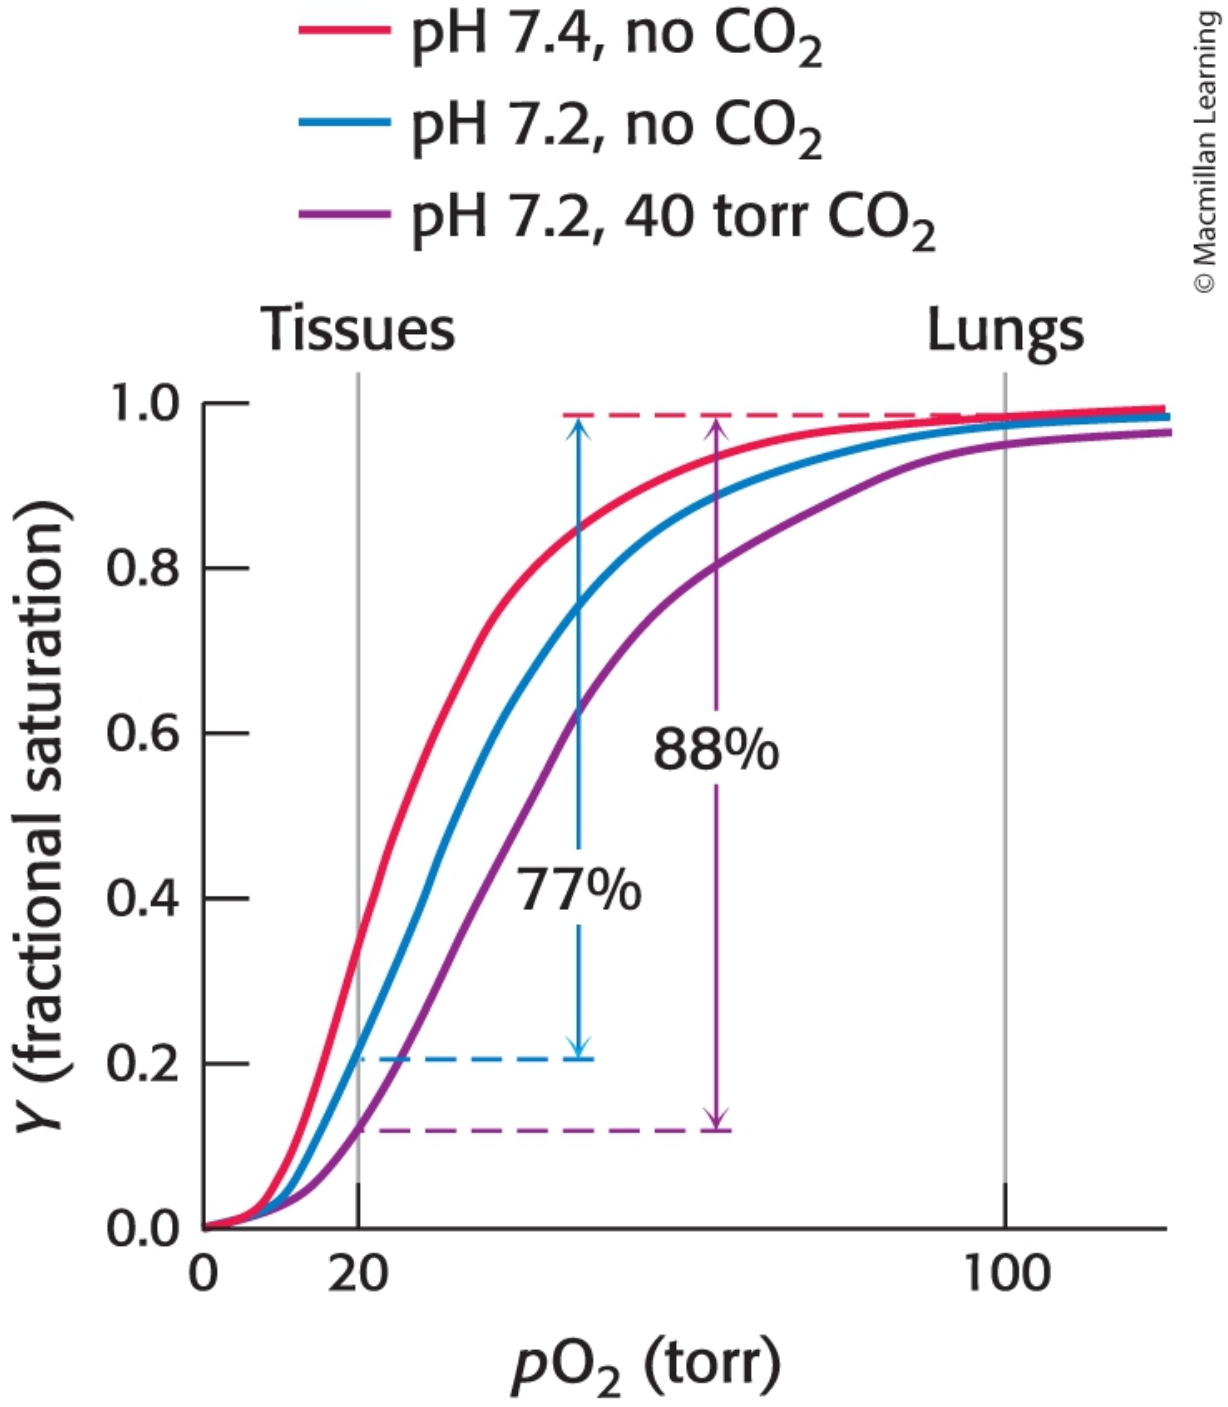
Extended description for FIGURE 3.29 Ionic interactions involving the β chain C-terminal histidine are responsible for some of the pH sensitivity of hemoglobin oxygen affinity

© Macmillan Learning

In the ball-and-stick model, C atoms are represented as black spheres, N atoms are represented as blue spheres, O atoms are represented as red spheres, and H atoms are represented as white spheres.

The C-terminal of the beta 1 chain consisting of aspartic acid 94 and histidine 146 is shown. Aspartic acid 94 consists of a chain of 4 black spheres connected in a zigzag manner. The first black sphere from the left is connected to a red sphere on the upper left and lower left. A negative charge is present between the two red spheres. The third black sphere is connected to a blue sphere on the left. The fourth black sphere is connected to a red sphere on the upper right. The red sphere on the upper left is connected through a dashed line to a white sphere labeled added proton on the left. The white sphere is connected to a blue sphere located at the leftmost vertex of a flat heterocyclic pentagonal ring consisting of 2 blue and 3 black spheres. The second blue sphere is located at the top left vertex and connected to a white sphere. The remaining positions are occupied by black spheres. A positive charge is present above the black sphere on the top right vertex of the ring.

The black sphere on the bottom left vertex is connected to another black sphere on the left. This black sphere is connected to a vertical chain of two black spheres. The bottom black sphere of this chain is connected to a blue sphere on the right. The top black sphere of this chain is connected to a red sphere on the upper left and upper right. This region is labeled C terminus. A negative charge is present between the two red spheres. The lysine 40 side chain of the alpha 2 chain is shown above the C terminus of the beta 1 chain.



The structure of this side chain is as follows: A central blue sphere is connected to a white sphere on the left, below, and right. A positive charge is present between the white spheres on the right and bottom. The blue sphere is connected above to a chain of 3 black

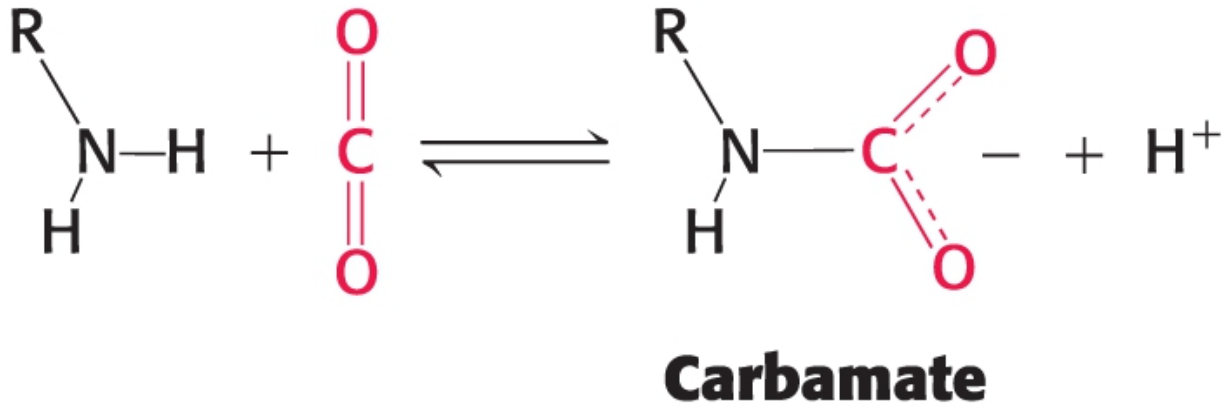
spheres in a vertical orientation. The topmost black sphere of the chain is connected to a zigzag chain of 3 black spheres on the right. The rightmost black sphere of the chain is connected to a red sphere on the right. The second black sphere of the chain is connected to a blue sphere on the left.

Return to FIGURE 3.29 Ionic interactions involving the β chain C-terminal histidine are responsible for some of the pH sensitivity of hemoglobin oxygen affinity

Extended description for FIGURE 3.30 The presence of carbon dioxide decreases the oxygen affinity of

hemoglobin, even beyond the effect due to a decrease in pH

The horizontal axis is labeled p O subscript 2 (torr) and has markings 0, 20, and 100. The vertical axis is labeled Y (fractional saturation) and ranges from 0.0 to 1.0 in increments of 0.2 units.



A vertical line begins at 20 torrs and is labeled tissues. Another vertical line begins at 100 torrs and is labeled lungs. The oxygen binding curve for hemoglobin at p H 7.4 and no C O 2 is depicted using a red line. The oxygen binding curve for hemoglobin at p H 7.2 and no C O 2 is depicted using a blue line. The oxygen binding curve for hemoglobin at p H 7.2 and 40 torr C O 2 is depicted using a purple line. All the curves have a sigmoidal shape.

The red curve begins at the origin and moves horizontally to the right until 8 torrs. It then moves upward to the right until it reaches approximately point (70, 0.98). The curve then rises to 1.0 Y and moves horizontally to the right. The blue curve begins at the origin, merges with the red curve, and moves almost horizontally to the right until approximately 10 torrs. The curve then rises and moves upward to the right until it reaches approximately point (70, 0.9). It then moves horizontally to the right and merges with the red curve approximately at 90 torrs. The purple begins at the origin merges with the red and blue curves and moves almost horizontally to the right until approximately 12 torrs. The curve then rises and moves upward to the right until it reaches approximately point (90, 0.9). It then moves horizontally to the right below the blue curve.

A double-headed vertical arrow spans from approximately 0.2 Y to 1.0 Y at approximately 65 torrs. This arrow is labeled 77 percent. Another double-headed vertical arrow spans from approximately 0.1 Y to 1.0 Y at approximately 60 torrs. This arrow is labeled 88 percent.

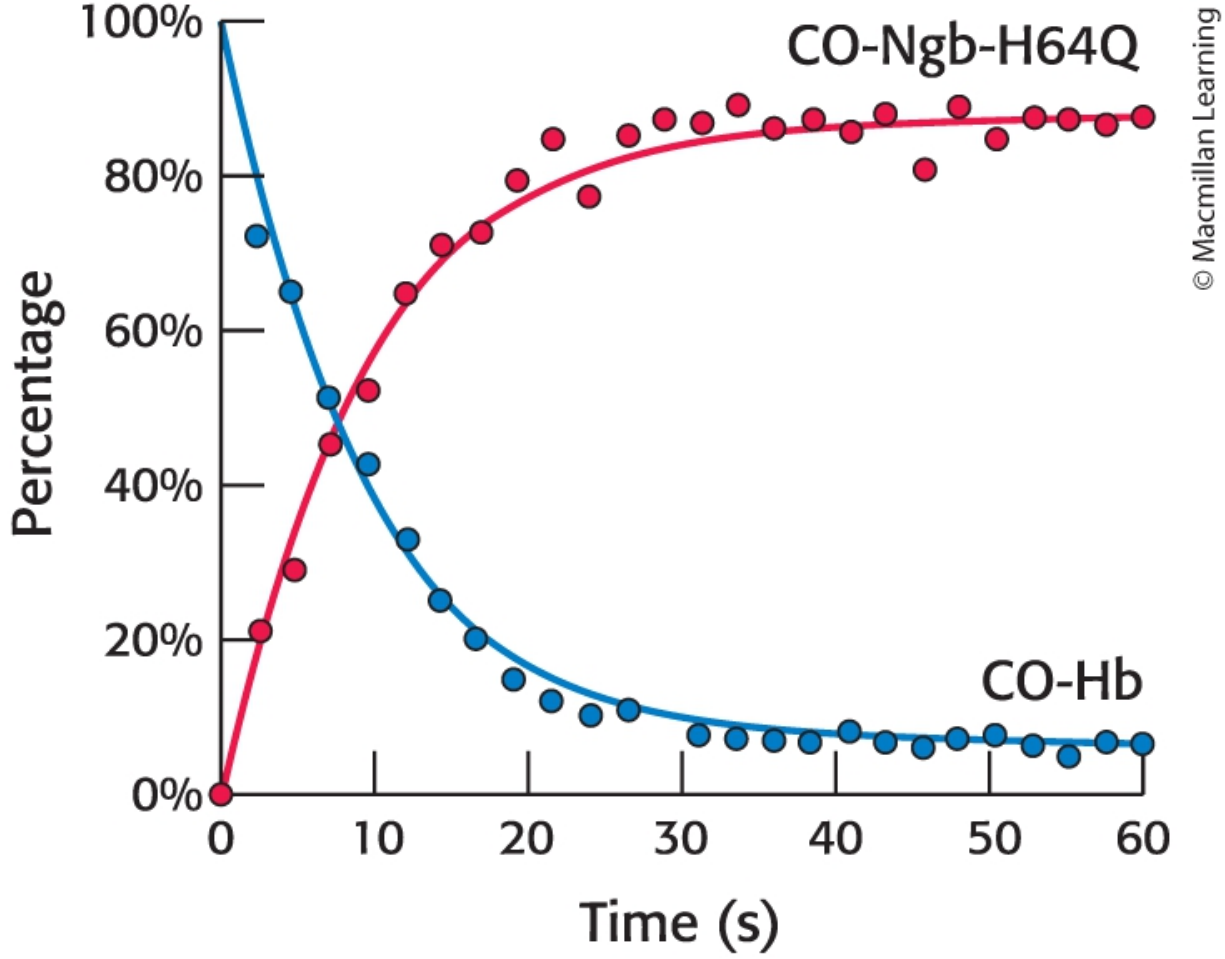
Extended description for Formation of carbamate



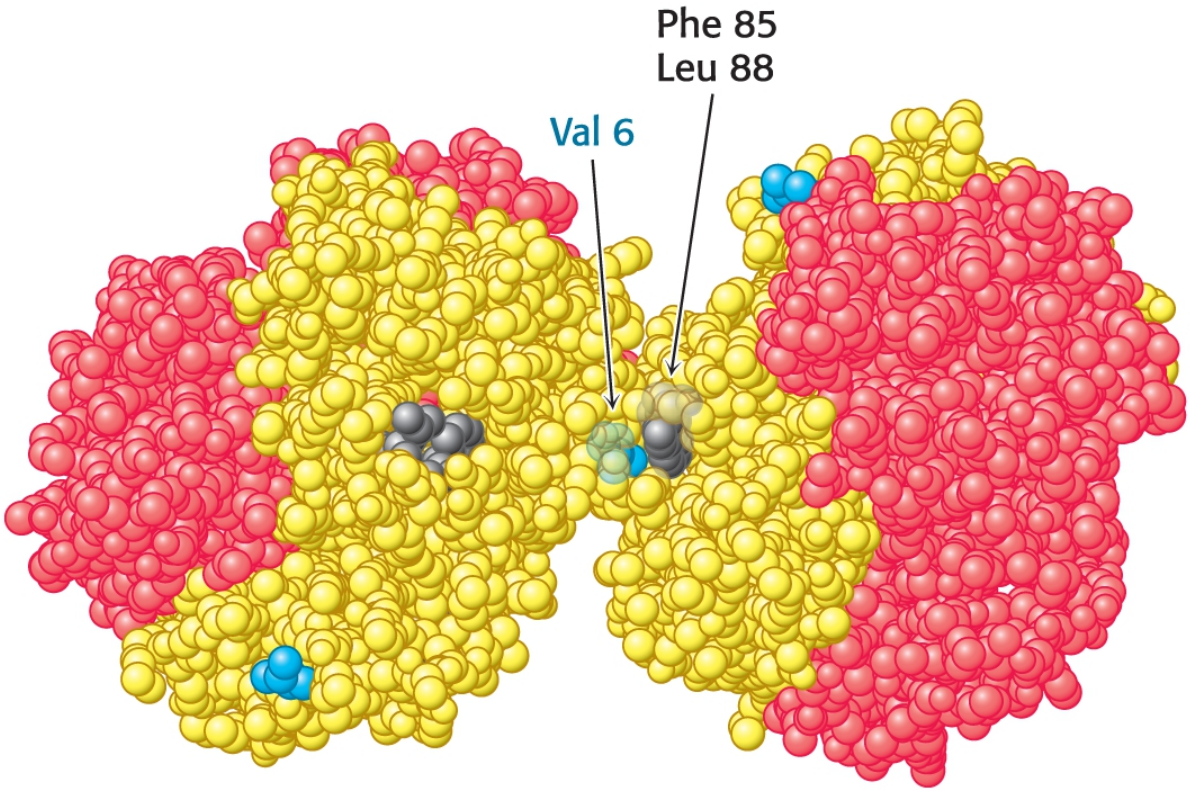
The reversible reaction consists of two reactants and two products. The first reactant has the following structure: N, single bond, H. N is single bonded to R on the upper left and single bonded to H on the lower left. The second reactant has the following structure: O, double bond, C, double bond, O in a vertical orientation. The second reactant is highlighted in red.

The first product labeled carbamate has the following structure: N, single bond, C. N is single bonded to R on the upper left and single bonded to H on the lower left. C is partially double bonded to O on the upper right and lower right. A minus sign is present between the two O atoms. The C atom and the two O atoms are highlighted in red. The second product is H superscript plus.

Return to Formation of carbamate

Extended description for FIGURE 3.31 Carbon monoxide is rapidly transferred from carboxyhemoglobin to N g b-H64Q

The horizontal axis is labeled time (s) and ranges from 0 to 60 in increments of 10 units. The vertical axis is labeled percentage and ranges from 0 to 100 in increments of 20 units.



Two curves are shown on the graph. The first curve is labeled C O - H b. It begins at 100 percent on the vertical axis and moves downward toward the lower right until it reaches approximately

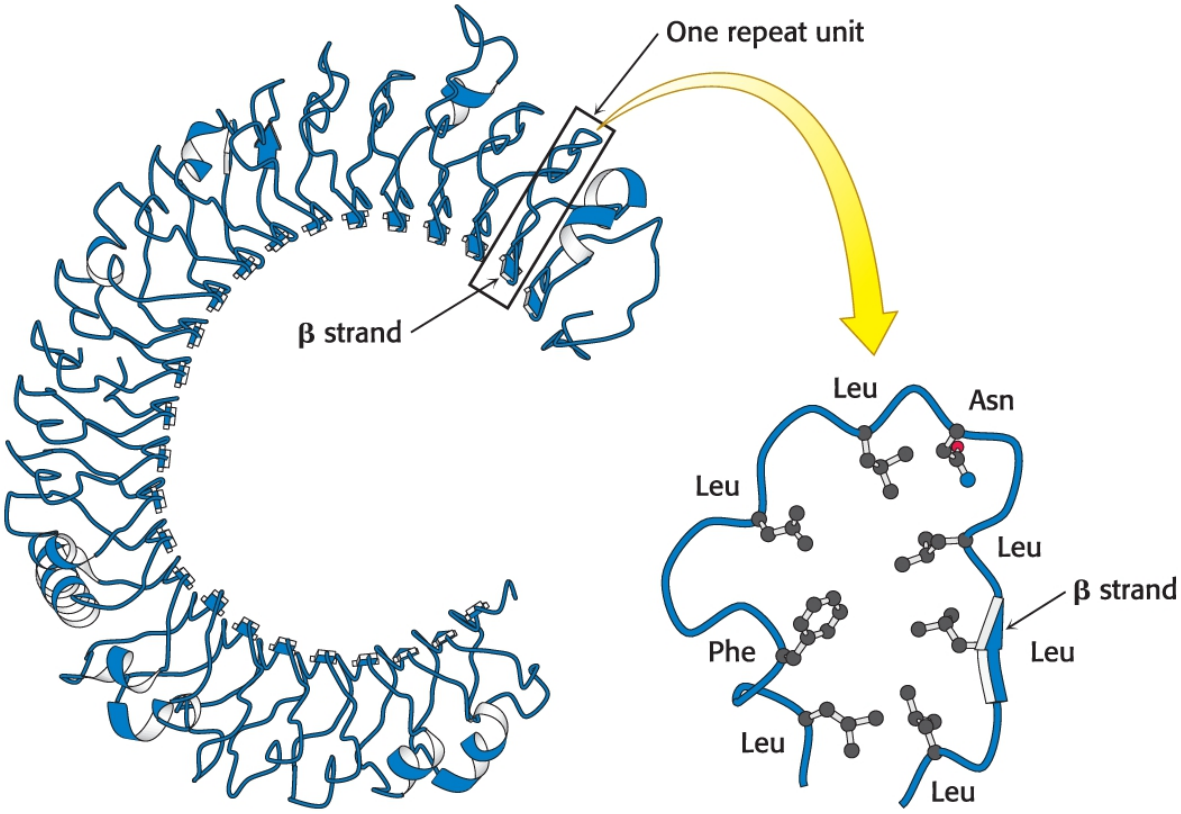
point (40, 10). It forms a curved slope between 10 to 30 seconds. At 10 seconds, the percentage is approximately 30. At 20 seconds, the percentage is approximately 18. At 30 seconds, the percentage is approximately 11 percent. After 40 seconds, the curve moves horizontally toward the right and ends at the end of the horizontal axis. Several points are marked on and around the curve.

The second curve is labeled C O - N g b - H 6 4 Q. It begins at the origin and moves to the upper right until it reaches approximately point (30, 82). It forms a curved slope between approximately 12 seconds and 30 seconds. At 10 seconds, the percentage is approximately 58. At 20 seconds, the percentage is approximately 79. At 30 seconds, the percentage is 81. Several points are marked on and around the curve.

Return to FIGURE 3.31 Carbon monoxide is rapidly transferred from carboxyhemoglobin to N g b-H64Q

Extended description for FIGURE 3.34 Two molecules of hemoglobin S interact through hydrophobic patches

© Macmillan Learning



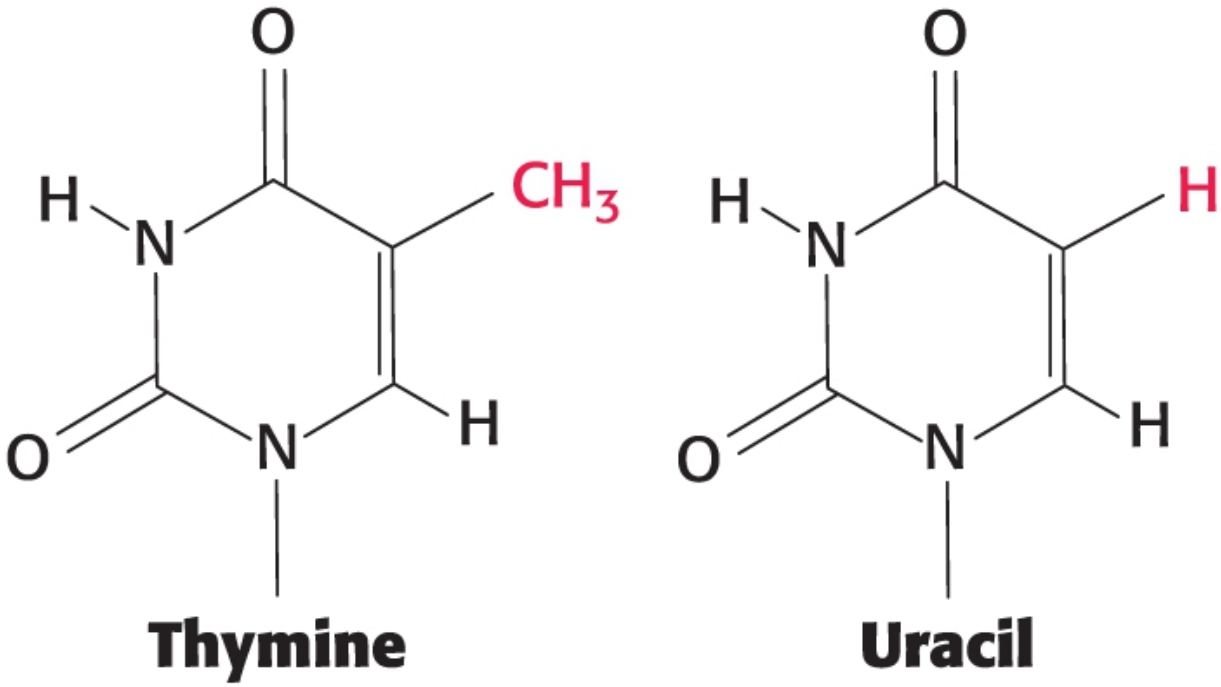
The space-filling model shows a globular compact structure of two hemoglobin S molecules side-by-side. Both structures consists of two subunits that are dark yellow and red. A small cluster of four blue spheres is located at the bottom of the dark yellow subunit of the left hemoglobin S molecule. A small cluster of three blue spheres is located at the top of the dark yellow subunit of the right hemoglobin S molecule.

A small cluster of black sphere is located at the center of the dark yellow subunit of left hemoglobin S molecule. The dark yellow subunits of the two hemoglobin S molecules face each other and are attached at the center. Valine 6, phenylalanine 85, and leucine 88 are

located at the point of attachment of the two subunits. Valine is depicted as a small cluster of light blue transparent spheres. Phenylalanine and leucine are depicted as small clusters of transparent gray spheres.

Return to FIGURE 3.34 Two molecules of hemoglobin S interact through hydrophobic patches

Extended description for FIGURE 3.35 The structure of the LRR domain from TLR3 reveals how many LRR units come together to form a structure with binding surfaces for potential partners



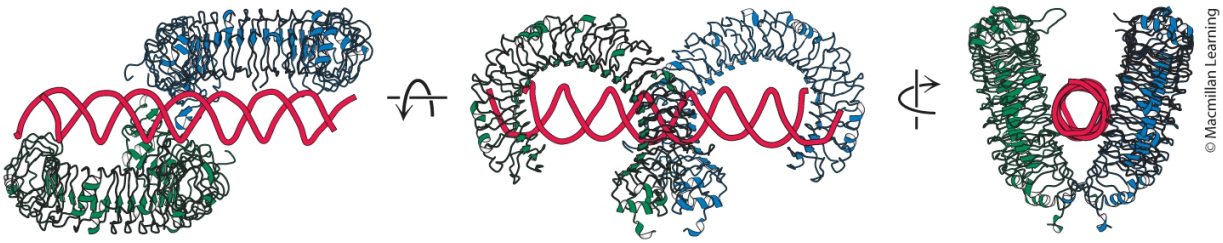
© Macmillan Learning

The L R R domain is depicted as a large C-shaped structure composed of several L R R repeats. Each L R R unit is composed of a beta-strand at the base connected to a circular loop-like structure above. The structure of the L R R unit is enlarged to show a circular loop with an open bottom. A beta-strand in an upward orientation is at the bottom right of the loop. From the bottom left to the bottom right, the order of amino acids is leucine, phenylalanine, leucine, leucine, asparagine, leucine, leucine, and leucine. The beta-strand is below the leucine residue. The beta-strand also contains a leucine

residue. A leucine residue is at the bottom right end of the loop below the beta-strand. The side chains of the amino acid residues face the hollow interior of the loop. They are depicted as a ball-and-stick model.

Return to FIGURE 3.35 The structure of the LRR domain from TLR3 reveals how many LRR units come together to form a structure with binding surfaces for potential partners

Extended description for Thymine and uracil



The structure of thymine is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the bottommost vertex. The second N atom occupies the third position, which is the top left vertex. The first N atom has an open single bond below. The second N atom is single bonded to H on the upper left. A double bond is present between C 3 and C 4. C 1 is double bonded to O on the lower left. C 2 is double bonded to O above. C 3 is single bonded to C H 3 on the upper right which is highlighted in red. C 4 is single bonded to H on the lower right.

The structure of uracil is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the bottommost vertex. The second N atom occupies the third position,

which is the top left vertex. The first N atom has an open single bond below. The second N 2atom is single bonded to H on the upper left. A double bond is present between C 3 and C 4. C 1 is double bonded to O on the lower left. C 2 is double bonded to O above. C 3 is single bonded to H on the upper right which is highlighted in red. C 4 is single bonded to H on the lower right.

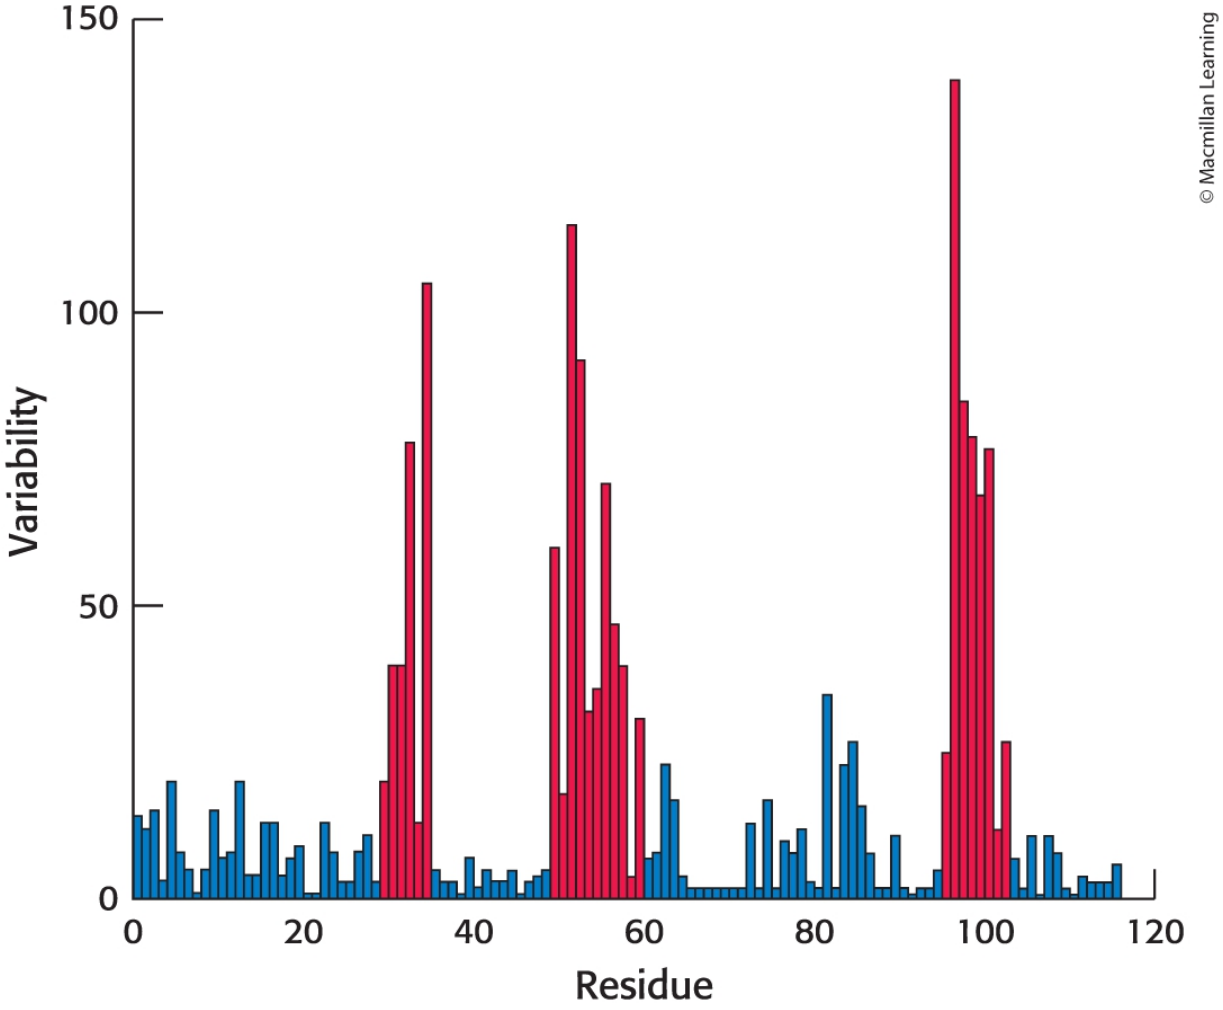
Extended description for FIGURE 3.36 The innate immunity component TLR3 recognizes its PAMP, a double stranded RNA

First view: The side view of a double-stranded R N A in horizontal orientation is shown. It is sandwiched between two extracellular domains of T L R 3 protein in a horizontal orientation. The blue domain is on the upper right of the R N A molecule. The green domain is on the lower left of the R N A molecule. The domains are composed of beta-sheets and alpha helices. Long thread-like loops connect these secondary structures. The bottom left portion of the beta-sheet of the top blue domain moves into the center of the helix. The top right portion of the beta-sheet of the bottom green domain moves into the center of the helix.



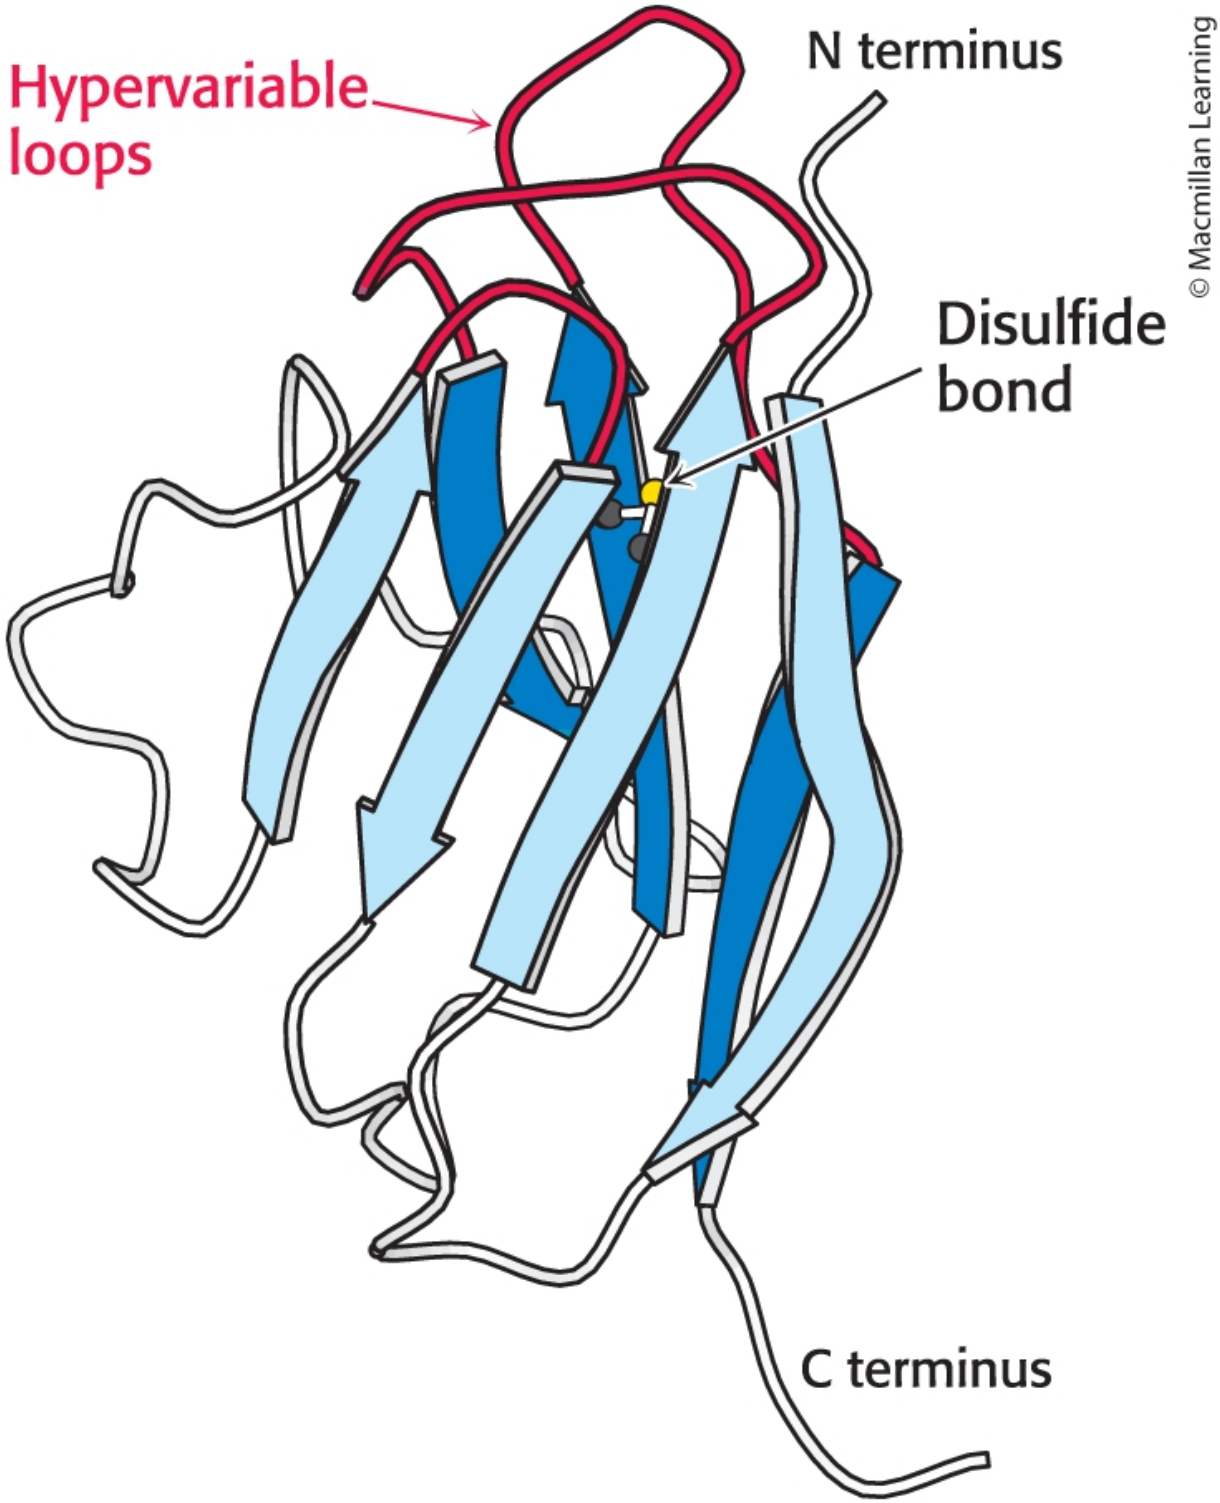
Second view: The first view rotates 180 degrees in an anti-clockwise direction across the horizontal plane to form the second view. It consists of a double-stranded R N A in a horizontal orientation. The green and blue domains form an arch-shaped structure on the upper left and upper right of the R N A helix such that the left portion of the green domain and the right portion of the blue domain merge at the center of the R N A helix. They continue downward and diverge below the R N A helix.

Third view: The second view rotates 180 degrees in a clockwise direction across a vertical plane to form the third view. The top view

of the R N A helix is shown in the center such that it consists of a coiled circular structure. It is flanked by the green domain on the left and the blue domain on the right each in a vertical orientation. The domains are slightly slanted such that they touch at their lower terminals below the R N A helix.

Return to FIGURE 3.36 The innate immunity component TLR3 recognizes its PAMP, a double stranded RNA

Extended description for FIGURE 3.37 Immunoglobulin sequences include regions of extensive sequence variability



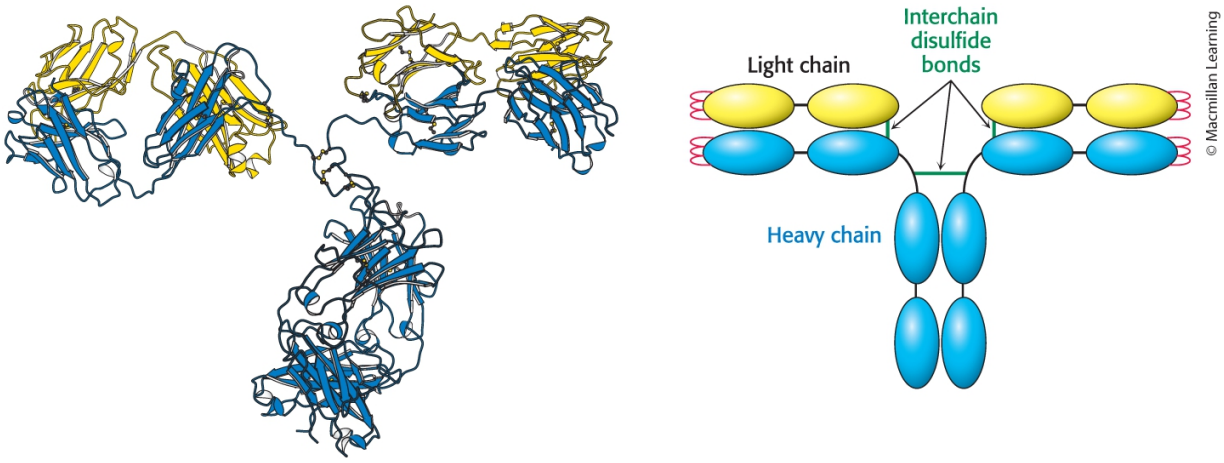
The horizontal axis is labeled residue and ranges from 0 to 120 in increments of 20 units. The vertical axis is labeled variability and ranges from 0 to 150 in increments of 50 units. Several blue and red bars are shown on the graph. The red bars are clustered between 30 to 35 residues, 50 to 60 residues, and 95 to 102 residues. All the blue bars and several red bars show variability much less than 50. The

red bar show variability greater than 50 at the residue 33, 50, 53, 56, 97, 98, 99, and 100 and greater than 100 at residue 35, 52, and 96.

Return to FIGURE 3.37 Immunoglobulin sequences include regions of extensive sequence variability

Extended description for FIGURE 3.38 The immunoglobulin fold consists of a pair of β sheets

linked by a disulfide bond



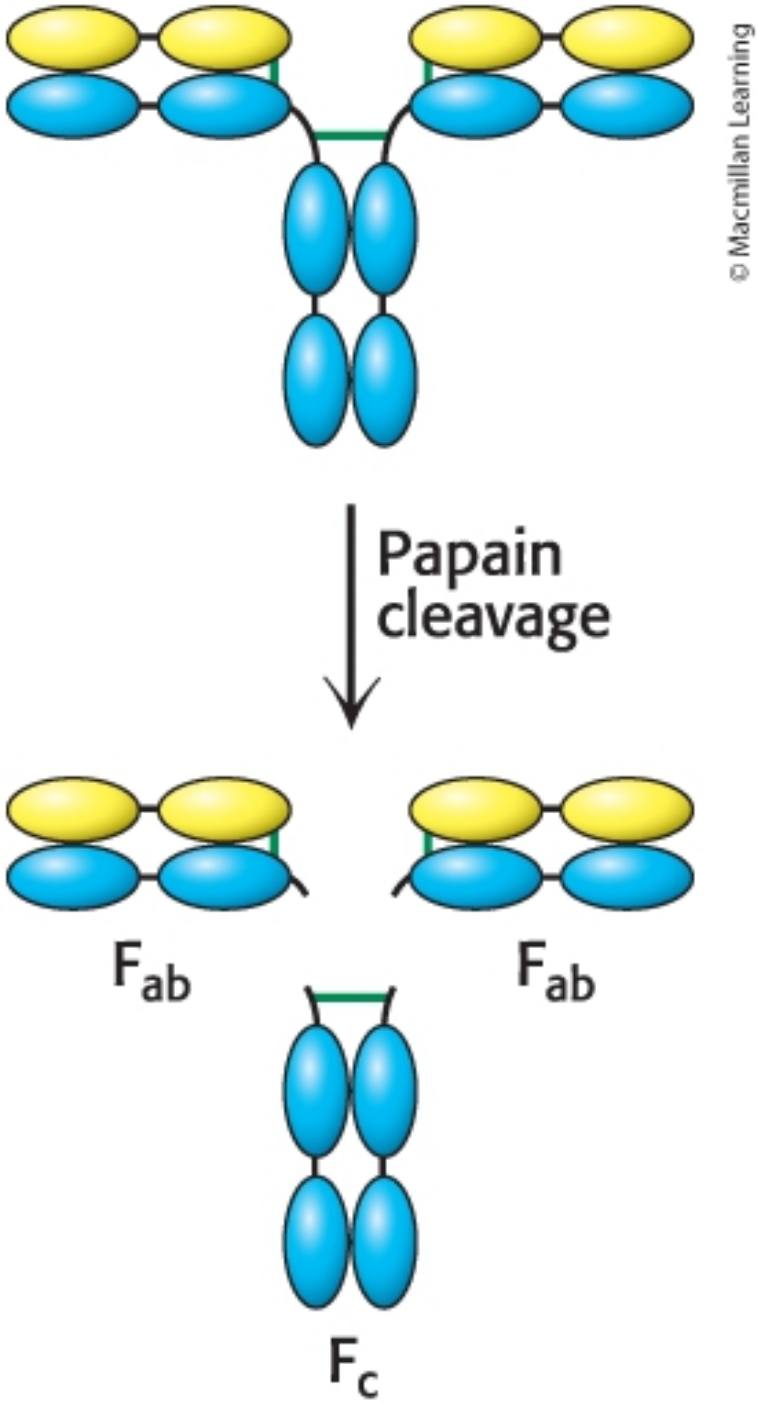
The immunoglobulin fold consists of a pair of an anti-parallel beta-sheet containing 7 beta-strands. The vertical beta-strands are alternately oriented in the upward and the downward directions. They are depicted as thick light blue and dark blue arrows. Short thread-like loops connect the beta-strands. The red loops at the top are labeled hypervariable loops. White loops are located at the bottom. A white short thread at the top of a beta-strand oriented downward is labeled N terminus. A white short thread at the bottom of another beta-strand oriented downward is labeled C terminus.

A ball-and-stick model labeled disulfide bond is shown above the immunoglobulin fold. It consists of a small yellow sphere above connected to a black sphere on either side.

Return to FIGURE 3.38 The immunoglobulin fold consists of a pair of β sheets linked by a disulfide bond

Extended description for FIGURE 3.39 An IgG molecule has a Y-shaped structure comprising two identical arms with hypervariable regions at the end

The immunoglobulin G molecule is depicted as a T-shaped structure. The vertical part of the molecule labeled heavy chain is composed of two layers located side-by-side, and each layer is composed of two blue ovals in a vertical orientation. The left and right arms of the molecule labeled light chain consists of a layer of two yellow ovals located above the layer of two blue ovals, each in a horizontal orientation. There is a space between the two arms. The ovals are connected with lines.



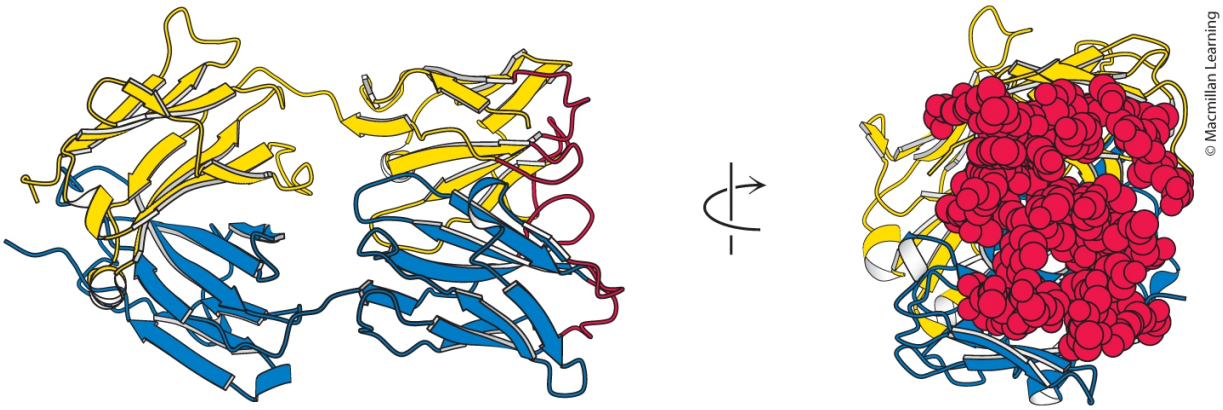
A vertical line connects the left yellow oval of the top layer to the left blue oval of the bottom layer of the left arm and the left yellow oval of the top layer with the left blue oval of the bottom layer of the right arm. A horizontal line connects the two layers of the vertical chain. These lines are labeled interchain disulfide bonds.

The ribbon diagram of the I g G molecule is depicted as a Y-shaped structure. The two arms of the Y-shaped structure are composed of 2

pairs of beta-sheets connected by thread-like loops. Each pair consists of a yellow beta-sheet located above a blue beta-sheet. The thread-like structure from both the pairs connects below to a pair of a blue beta-sheet. The pair consists of a blue beta-sheet located above another blue beta-sheet. These beta sheets are connected by thread-like loops.

Return to FIGURE 3.39 An IgG molecule has a Y-shaped structure comprising two identical arms with hypervariable regions at the end

Extended description for FIGURE 3.40 Immunoglobulin G molecules can be cleaved into two F ab fragments and one F c fragment by treatment with papain



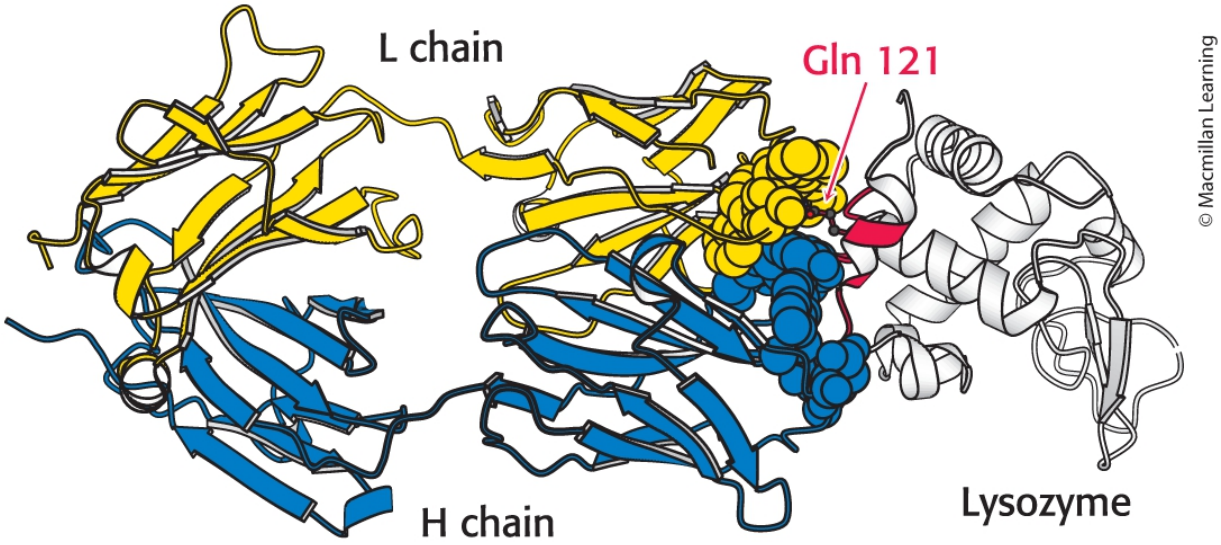
© Macmillan Learning

The immunoglobulin G molecule is depicted as T-shaped structure. The vertical part of the molecule is composed of two layers located side-by-side, and each layer is composed of two blue ovals in a vertical orientation. The left and right arms of the molecule consists of a layer of two yellow ovals located above the layer of two blue ovals, each in a horizontal orientation. There is an empty space between the two arms.

The ovals are connected with lines. The products of papain cleavage are two F subscript ab fragments and one F subscript c fragment. The F subscript ab fragment consists of a layer of two yellow ovals located above the layer of two blue ovals, each in a horizontal orientation. The F subscript c fragment consists of two layers located side-by-side, and each layer is composed of two blue ovals in a vertical orientation.

Return to FIGURE 3.40 Immunoglobulin G molecules can be cleaved into two F ab fragments and one F c fragment by treatment with papain

Extended description for FIGURE 3.41 The structure of an F ab fragment reveals how the six hypervariable loops come together to form a binding surface



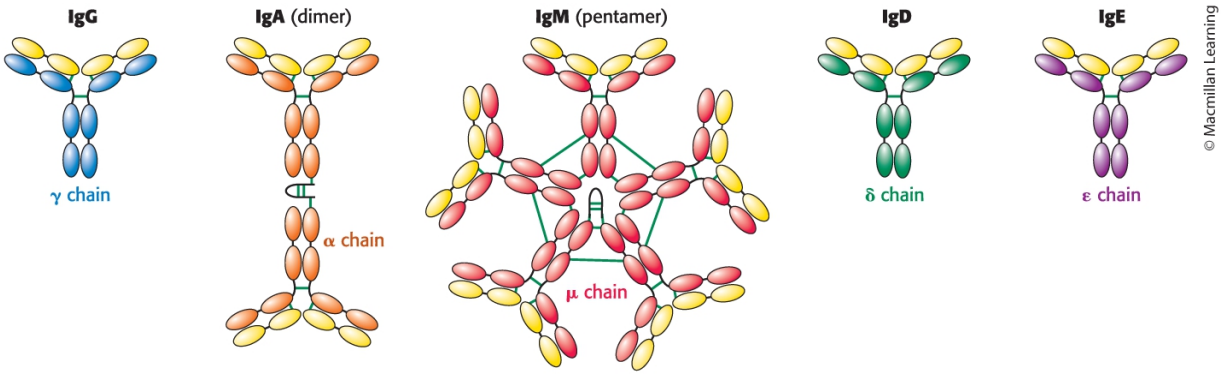
Side view: Two pairs of beta-sheets are connected by thread-like loops. Each pair consists of a yellow anti-parallel beta-sheet above a blue anti-parallel beta-sheet. Thread-like structures from both the pairs connect them. The red loop-like structures are present on the right of the right pair of beta-sheet.

End view: The side view is rotated 180 degrees across the vertical plane to form the end view. It consists of a pair of anti-parallel beta-sheets. Their surface is covered with clumped red spheres.

Return to FIGURE 3.41 The structure of an F ab fragment reveals how the six hypervariable loops come together to form a binding surface

Extended description for FIGURE 3.42 The structure of a complex between lysozyme and a specific F ab fragment reveals how the binding surface on the F ab interacts with the antigen

© Macmillan Learning



Two pairs of beta-sheets are connected by thread-like loops. Each pair consists of a yellow anti-parallel beta-sheet above a blue anti-parallel beta-sheet. Thread-like structures from both the pairs connect them. The top yellow beta sheets are labeled L chain. The bottom blue beta sheets are labeled H chain. A loop on the right of the yellow beta-sheet of the right pair contains a cluster of yellow spheres. One yellow sphere is labeled glutamine 121.

A loop on the right of the blue beta-sheet of the right pair contains a cluster of blue spheres. The lysozyme molecule consists of 5 alpha-helices, of which 2 are large and 3 small. These helices are connected to an anti-parallel beta-sheet composed of two beta-strands through long thread-like loops. One large and two small

alpha-helices of lysozyme interact with the cluster of yellow and blue spheres.

Return to FIGURE 3.42 The structure of a complex between lysozyme and a specific F ab fragment reveals how the binding surface on the F ab interacts with the antigen

Extended description for FIGURE 3.43 Five classes of immunoglobulin have the same light chain combined with a different heavy chain (γ,α, μ, δ, or ε)

The immunoglobulins are depicted as T-shaped structures.

I g G: The vertical region of the molecule labeled gamma chain is composed of two layers one above the other. Each layer is composed of two blue ovals in a vertical orientation. The left and right arms of the molecule are composed of a layer of two yellow ovals in a horizontal orientation located above a layer of two blue ovals in a horizontal orientation. The ovals are connected by vertical and horizontal lines.

I g A (dimer): The vertical region of the molecule labeled alpha chain is composed of two layers one above the other. Each layer is composed of two orange ovals in a vertical orientation. The left and right arms of the molecule are composed of a layer of two yellow ovals in a horizontal orientation located above a layer of two orange ovals in a horizontal orientation. The ovals are connected by lines. Vertical and horizontal lines connect the ovals. This entire structure constitutes an I g A monomer. It is connected below to another I g A monomer in an inverted orientation through a U-shaped pin-like

structure in a horizontal orientation. Two vertical lines are present inside the U-shaped structure.

I g M (pentamer): The vertical region of the molecule labeled mu chain is composed of two layers one above the other. Each layer is composed of two pink ovals in a vertical orientation. The left and right arms of the molecule are composed of a layer of two yellow ovals in a horizontal orientation located above a layer of two pink ovals in a horizontal orientation. The ovals are connected by lines. Vertical and horizontal lines connect the ovals. This entire structure constitutes an I g M monomer. The vertical regions of five different I g M monomers are organized such that they occupy the vertices of a pentagon. The bottom layer of the vertical region of the I g M monomer on the bottom left and bottom right vertices are connected through an inverted U-shaped pin-like structure. Two horizontal lines are present inside the U-shaped structure.

I g D: The vertical region of the molecule labeled delta chain is composed of two layers one above the other. Each layer is composed of two green ovals in a vertical orientation. The left and right arms of the molecule are composed of a layer of two yellow ovals in a horizontal orientation located above a layer of two green ovals in a horizontal orientation. The ovals are connected by lines. Vertical and horizontal lines connect the ovals.

I g E: The vertical region of the molecule labeled epsilon chain is composed of two layers one above the other. Each layer is composed of two purple ovals in a vertical orientation. The left and right arms of the molecule are composed of a layer of two yellow ovals in a horizontal orientation located above a layer of two purple ovals in a horizontal orientation. The ovals are connected by lines. Vertical and horizontal lines connect the ovals.

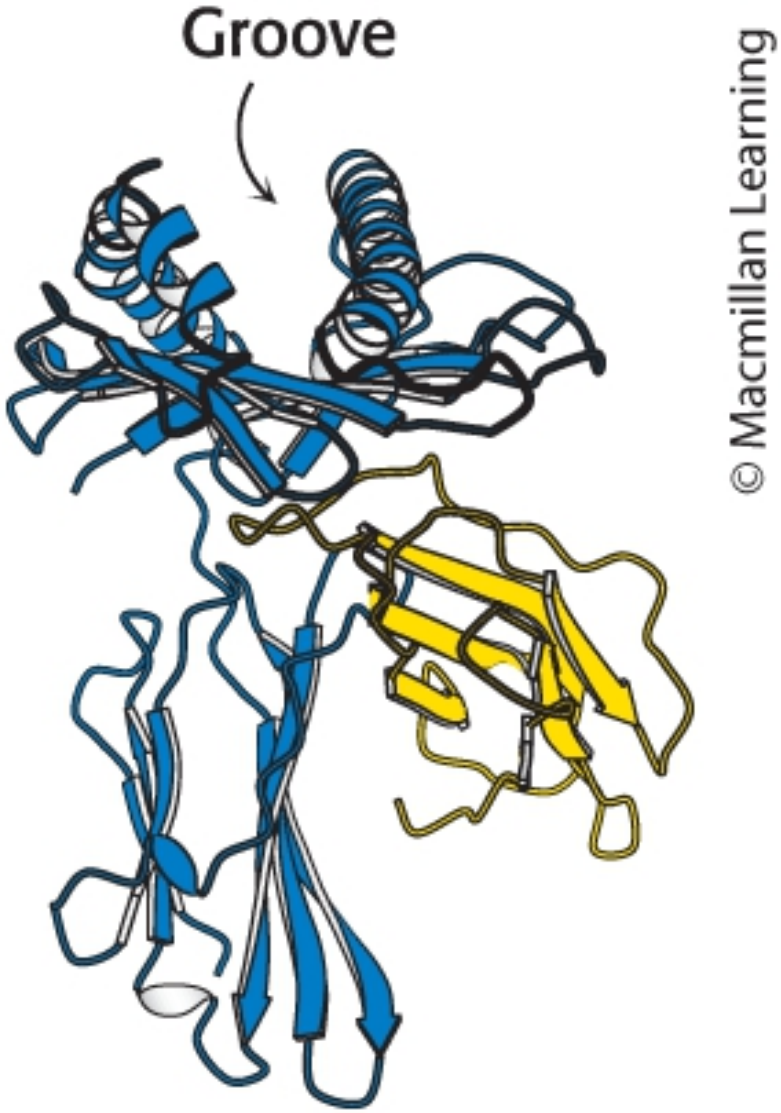
Extended description for FIGURE 3.44 Antibodies elicited against the spike protein of SARS-CoV-2 can

bind to this protein and block the ability of the virus to infect cells

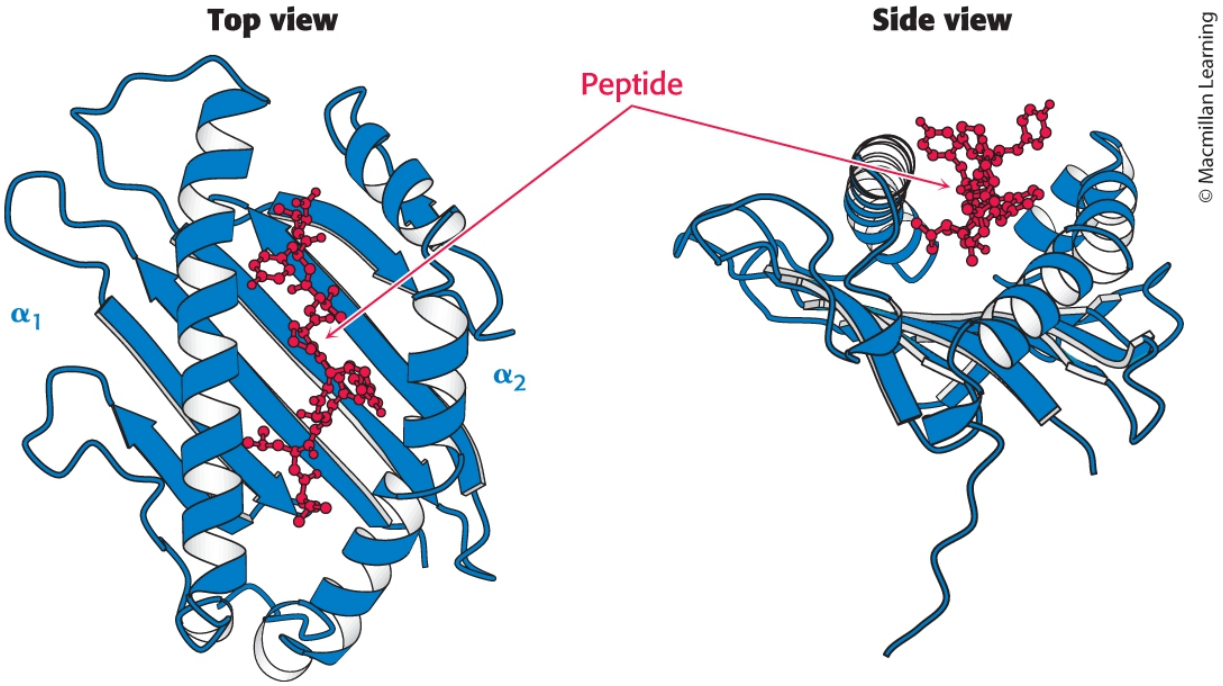


© Macmillan Learning

The trimeric spike protein consists of several vertically orientated alpha-helices that form its core. Some helices are at the bottom surface. Anti-parallel beta-sheets are at the top surface, top left surface, left surface, top right surface, right surface, and at the bottom. The beta-sheets at the top surface, top right surface, and right surface form a concave depression. Thread-like loops from the surface of the top right beta-sheet touch the beta-strands of the blue beta-sheet of the left pair of the F subscript a b fragment.

Return to FIGURE 3.44 Antibodies elicited against the spike protein of SARS-CoV-2 can bind to this protein and block the ability of the virus to infect cells

Extended description for FIGURE 3.45 The structure of the extracellular domain of a class I MHC protein reveals a deep groove

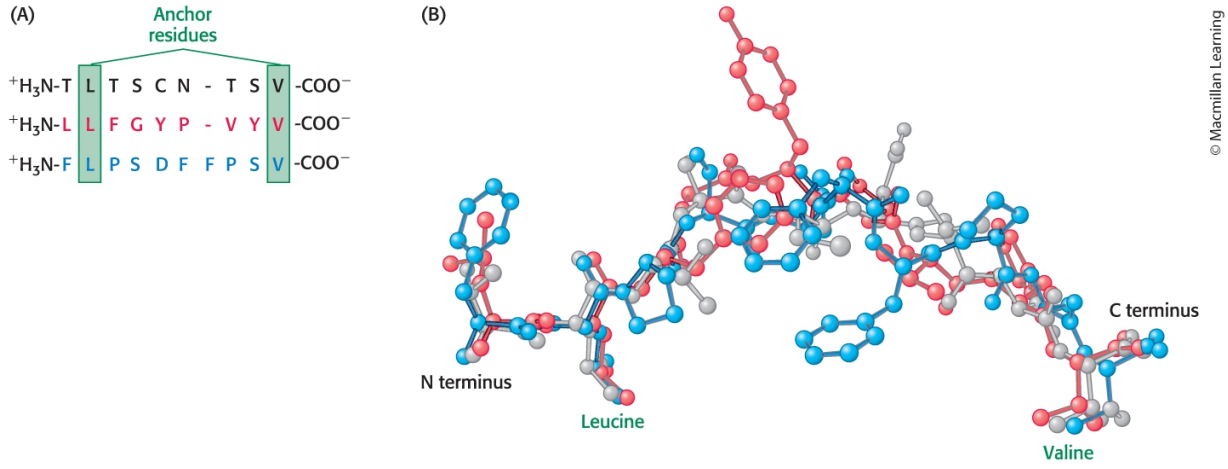


The extracellular domain is composed of two distinct polypeptides shown in yellow and blue. The blue polypeptides consist of two adjacent anti-parallel beta-sheets containing beta-strands in a vertical orientation. These are connected at the top to a flat anti-

parallel beta-sheet in a horizontal orientation. Two alpha-helices on the left and an alpha helix on the right, flank a deep groove at the top center of the horizontal beta-sheet. The beta sheets are interconnected by short thread-like loops. The yellow polypeptide is located on the right of the junction between the top horizontal and the bottom vertical beta-sheets of the blue polypeptide. It is composed of an anti-parallel beta-sheet in a horizontal orientation. Short-thread-like loops connected the individual beta-strands.

Return to FIGURE 3.45 The structure of the extracellular domain of a class I MHC protein reveals a deep groove

Extended description for FIGURE 3.46 In class I MHC proteins, peptides can bind in the groove

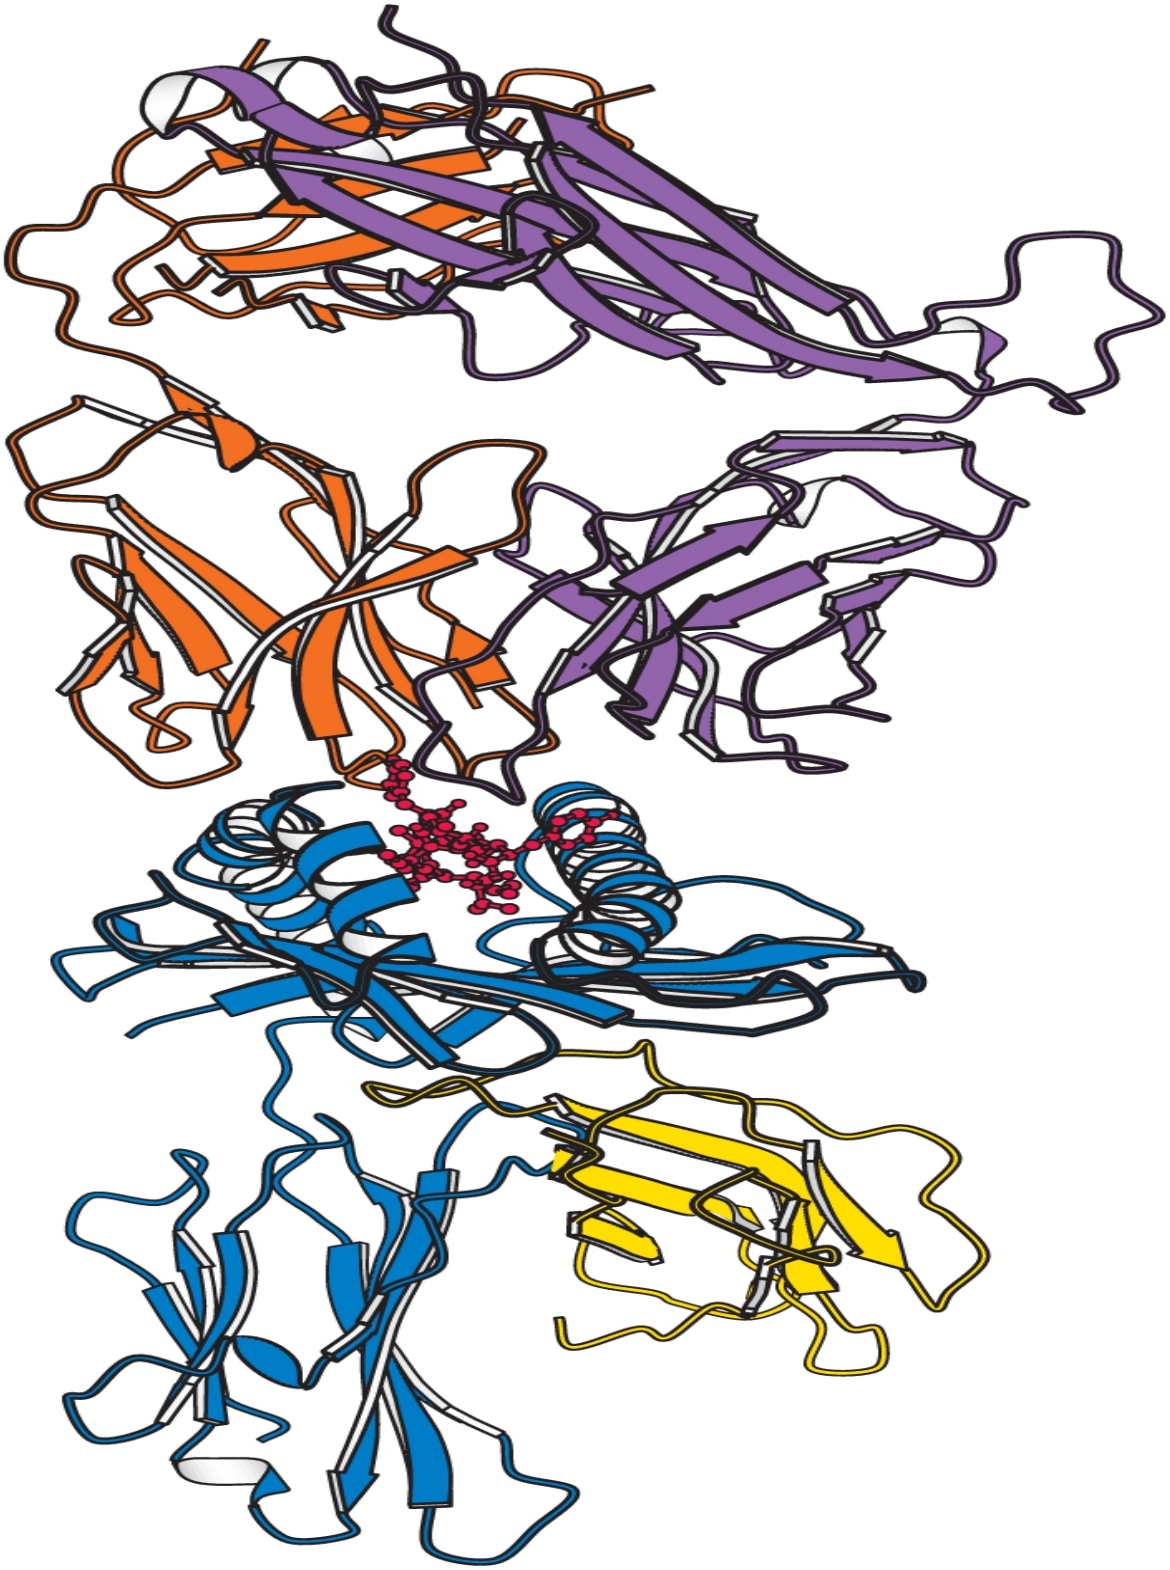


Top view: Two alpha-helices flank an anti-parallel beta-sheet in a diagonal orientation. The left alpha-helix labeled alpha 1 is longer than the right alpha-helix. The right alpha-helix labeled alpha 2 is smaller and is connected on the top to a shorter helix. The beta-strands of the beta-sheet are connected by long thread-like loops. A peptide in a vertical orientation is between the alpha helices in front of the beta-sheet.

Side view: A flat beta-sheet is shown. Two alpha helices are shown on its top such that they create a central groove. Peptide is shown inside the groove created the alpha-helices.

Return to FIGURE 3.46 In class I MHC proteins, peptides can bind in the groove

Extended description for FIGURE 3.47 Each MHC class I protein presents peptides with some recurring features



1. Part (A): The sequence of the first peptide is as follows: Superscript plus H 3 N, single bond, T, L T, S, C, N, dash, T, S, V, single bond, C O O superscript minus. The sequence of the second peptide is as follows: Superscript plus H 3 N, single bond, L, L, F, G, Y, P, dash, V, Y, V, single bond, C O O superscript minus. The sequence of the third peptide is as follows: Superscript plus H 3 N, single bond, F, L, P, S, D, F, F, P, S, V, single bond, C O O superscript minus. From the left, the second and tenth residue of each peptide are highlighted in green and labeled anchor residues.
2. Part (B): Three overlapping ball-and-stick models of the three peptides are shown. It shows that the N-terminus, C-terminus, and the side chains of leucine and valine residues are at the same position. The remaining structure is different due to the presence of different side chains of different amino acid residues at the corresponding positions of the peptides.

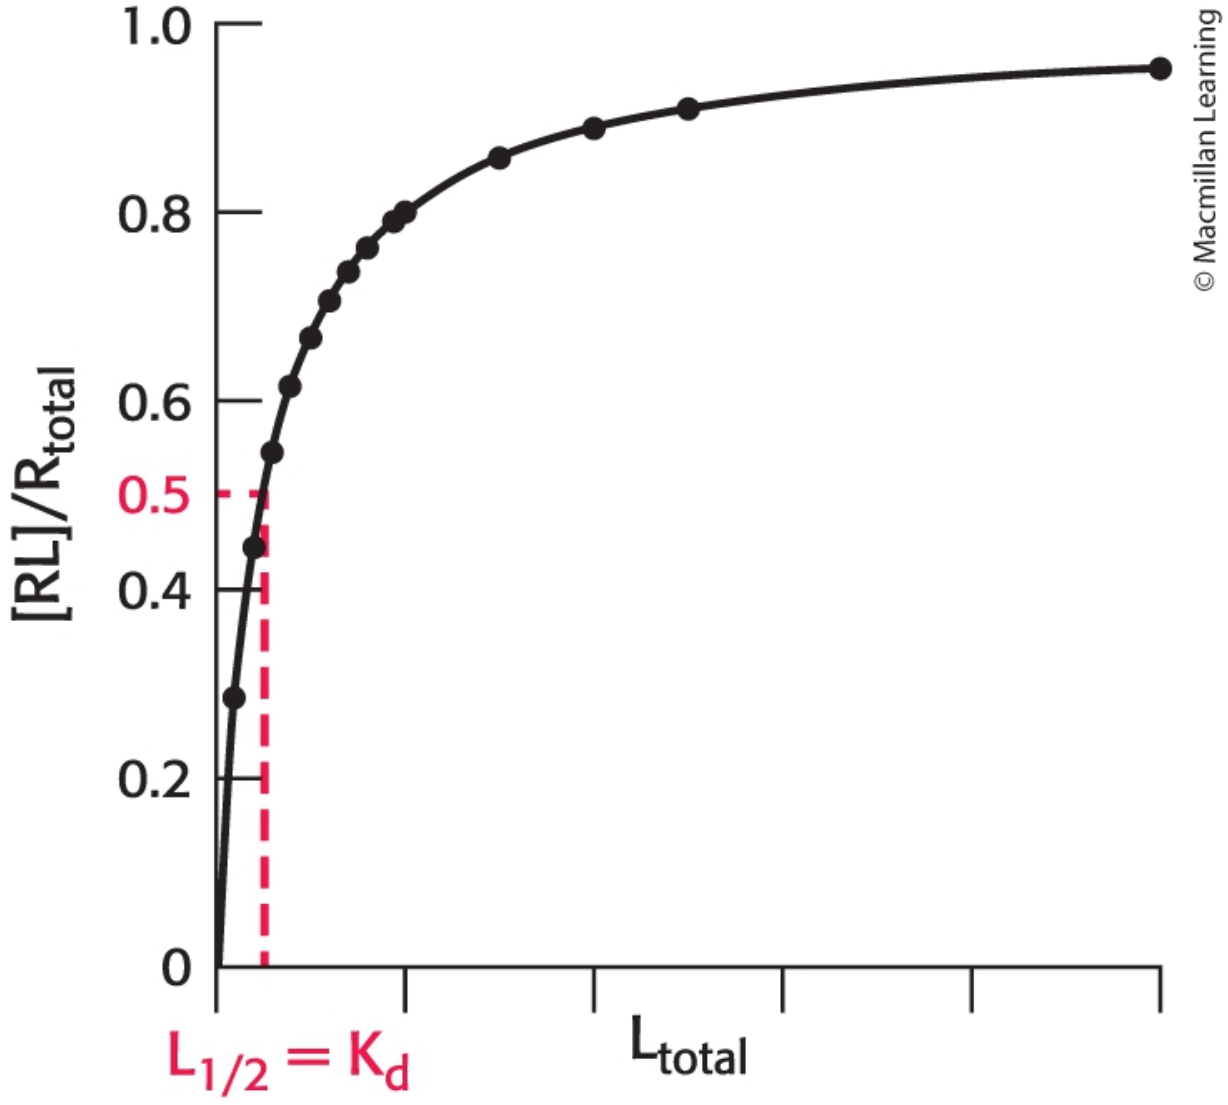
Return to FIGURE 3.47 Each MHC class I protein presents peptides with some recurring features

Extended description for FIGURE 3.48 The T-cell receptor recognizes specific class I MHC complexes,

contacting both the MHC protein and the bound peptide

T-cell receptor

MHC class I



© Macmillan Learning

The M H C class 1 complex is composed of two distinct polypeptides shown in yellow and blue. The blue polypeptides consist of two adjacent anti-parallel beta-sheets containing beta-strands in a vertical orientation. These are connected at the top to a flat anti-parallel beta-sheet in a horizontal orientation. Two alpha helices on the left and an alpha helix on the right flank a deep groove at the top center of the horizontal beta-sheet. The beta sheets are interconnected by short thread-like loops.

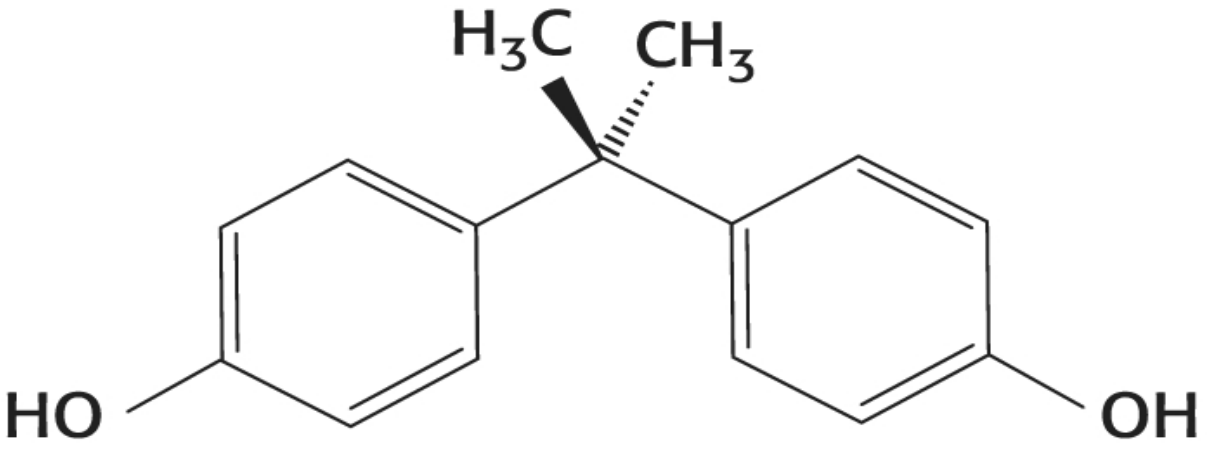
The yellow polypeptide is on the right of the junction between the top horizontal and bottom vertical beta-sheets of the blue polypeptide. It is composed of an anti-parallel beta-sheet in a horizontal orientation. Short thread-like loops connect the individual beta-strands. The T-cell receptor is above the M H C class 1 complex. It consists of two pairs of beta-sheets one above the other. In each pair, an orange anti-parallel beta-sheet on the left is associated with a purple anti-parallel beta-sheet on the right. Short thread-like loops connect the beta-strands of the beta-sheets.

Return to FIGURE 3.48 The T-cell receptor recognizes specific class I MHC complexes, contacting both the MHC protein and the bound peptide

Extended description for FIGURE 3.49 Binding can be monitored by measuring the fraction of receptors with ligand bound as a function of the amount of ligand added

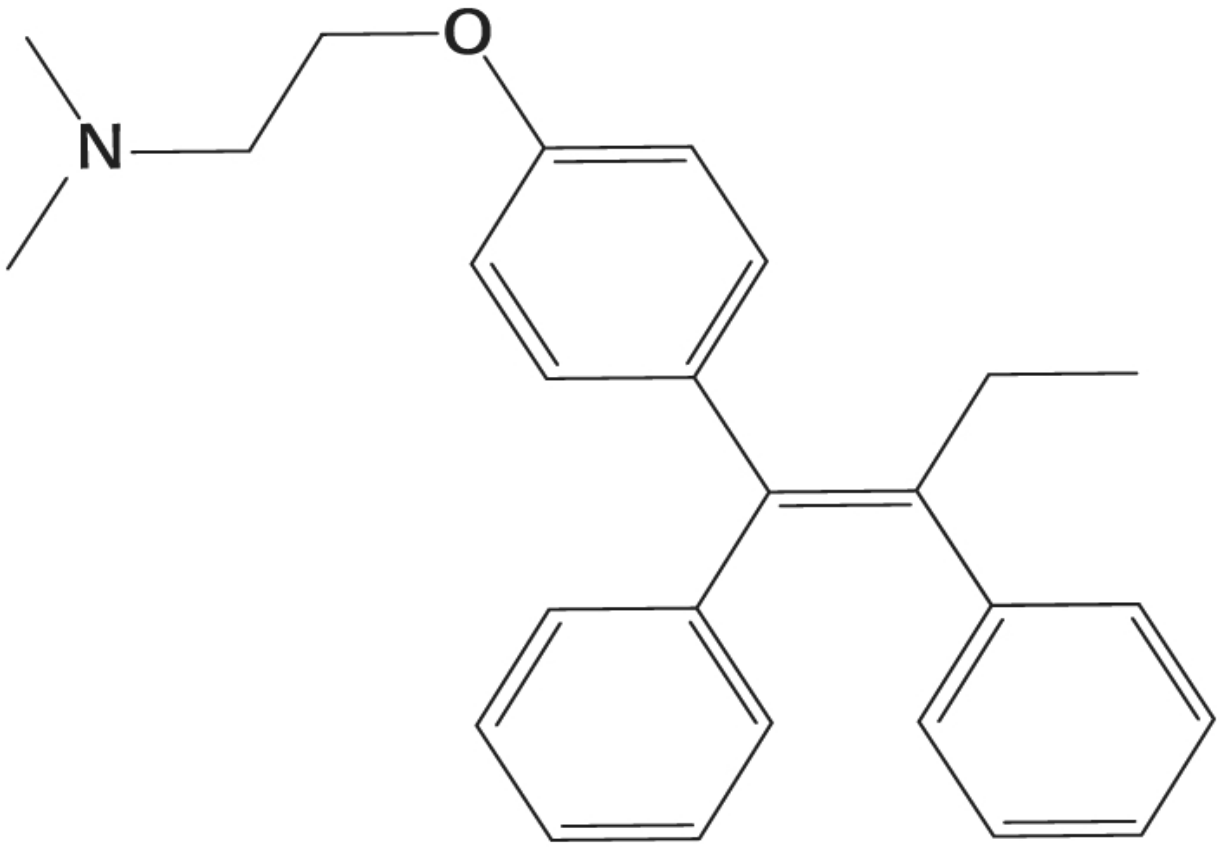
The horizontal axis is labeled L subscript total and has 5 unlabeled equidistant markings. The vertical axis is labeled StartFraction

concentration of R L over R subscript total EndFraction and ranges from 0 to 1.0 in increments of 0.2 units.



A hyperbolic curve begins at the origin and moves gradually to the upper right. It forms a curve between the markings 0.7 and 0.9 on the vertical axis. The curve then moves almost horizontally after the second marking on the horizontal axis till the end of the horizontal axis. Several points are marked on the curve represented as thick black dots.

A red dotted line starts from the 0.5 marking on the vertical axis and intersects the curve. At the point of intersection, a red dotted vertical line moves toward the horizontal axis. The point of intersection of the vertical line with the horizontal axis is labeled L subscript StartFraction 1 over 2 EndFraction equals K subscript d.

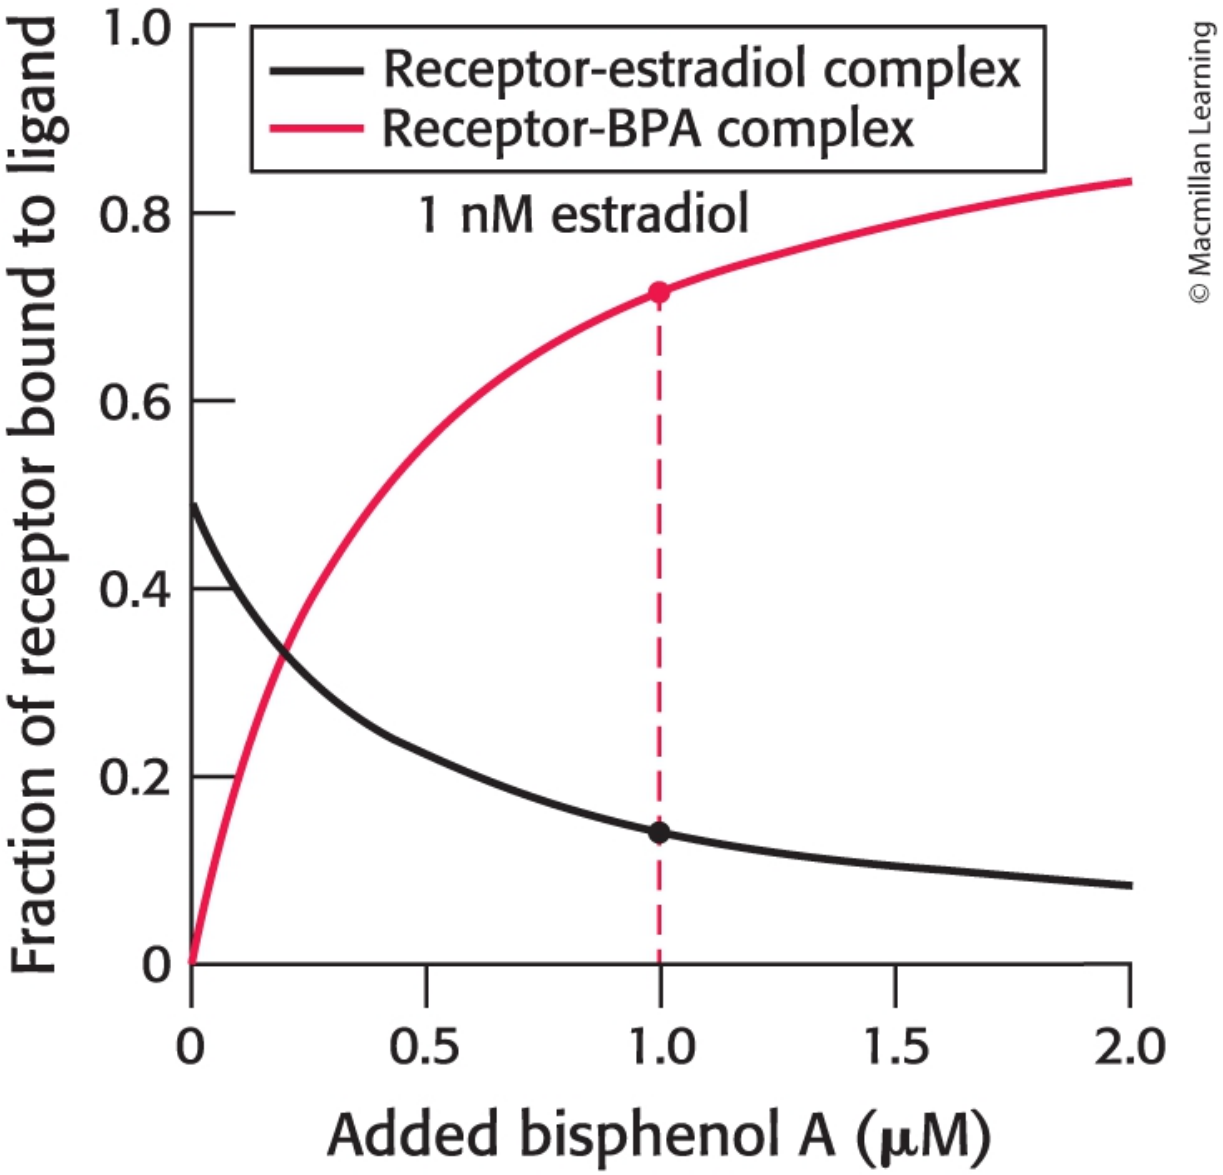


Return to FIGURE 3.49 Binding can be monitored by measuring the fraction of receptors with ligand bound as a function of the amount of ligand added

Extended description for FIGURE 3.50 At high enough concentrations, ligands with lower affinity for a

receptor can compete for binding with high-affinity ligands

Bisphenol A (BPA)



Tamoxifen

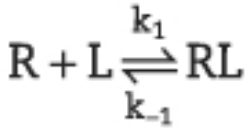
Bisphenol A (B P A) has the following structure: A benzene ring is in a vertical orientation, with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 5 is single bonded to O H on the lower left. C 2 is single bonded to a central C atom on the upper right. This C is single bonded on the lower right to C 5 of a second benzene ring in a vertical orientation, with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. The central C atom is wedge bonded to C H 3 on the upper left and dash bonded to C H 3 on the upper right. C 3 of the second benzene ring is single bonded to O H on the lower right.

Tamoxifen has the following structure: A benzene ring is in a horizontal orientation, with C 1 occupying the rightmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 5 is single bonded to O on the upper left. This O is single bonded on the left to C 1 of a 2-carbon alkane chain depicted as a line structure using 1 line. C 2 of the chain is single bonded to a central N atom on the left. This N atom is single bonded to C H 3 on the upper left and C H 3 on the lower left, each in the form of a line. C 2 of this ring is single bonded on the lower right to C 1 of a 2-carbon alkene chain depicted as two parallel lines. C 2 of this chain is single bonded to C 1 of a second 2-carbon alkane chain depicted as a line structure using 1 line. C 1 and C 2 of the alkene chain are each single bonded to a benzene ring on the lower left and the lower right, respectively. The benzene ring is in a horizontal orientation, with C 1 occupying the rightmost vertex. The ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1.

Return to FIGURE 3.50 At high enough concentrations, ligands with lower affinity for a receptor can compete for binding with high-affinity ligands

Extended description for FIGURE 3.50 At high enough concentrations, ligands with lower affinity for a receptor can compete for binding with high-affinity ligands

The horizontal axis is labeled added bisphenol A (micro molar) and ranges from 0 to 2.0 in increments of 0.5 units. The vertical axis is

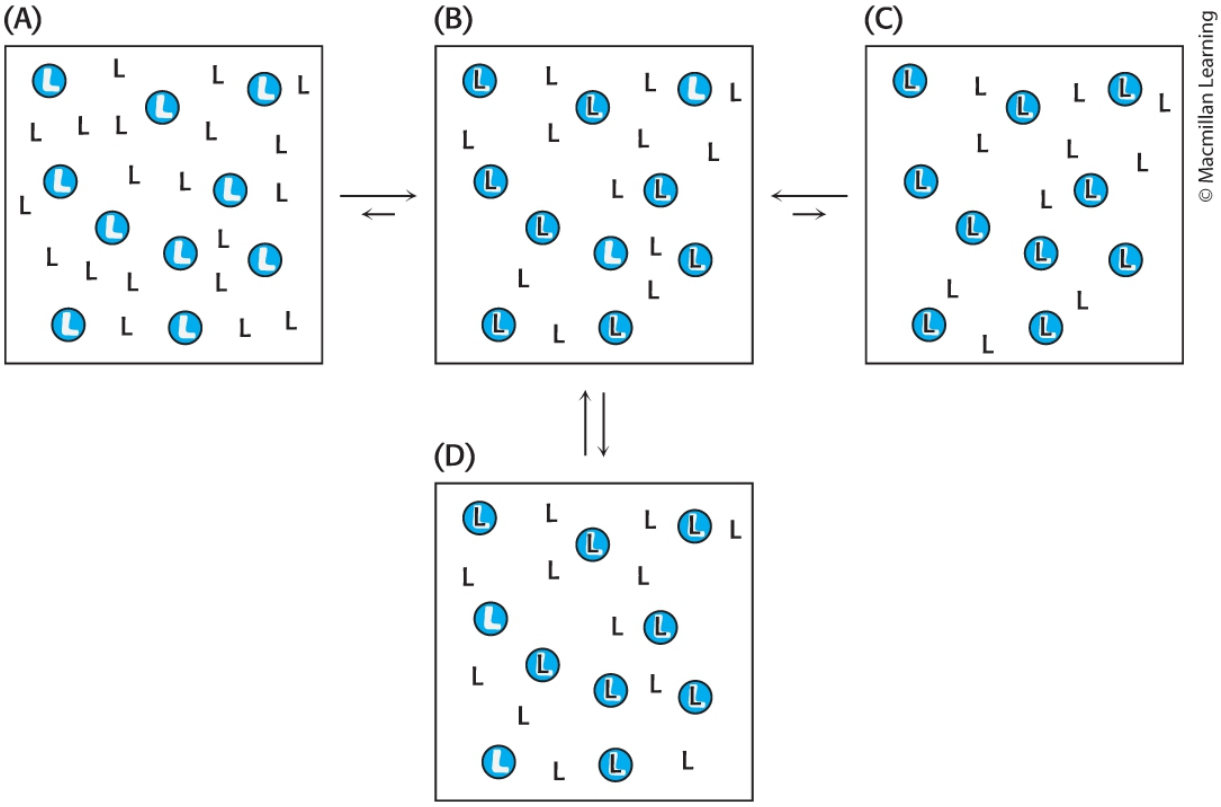


labeled fraction of receptor bound to ligand and ranges from 0 to 1.0 in increments of 0.2 units.

A curve for receptor-estradiol complex begins approximately at point (0, 0.48) and then moves down to the lower right until it reaches point (1.0, 0.14). It then gradually moves down to the right until it reaches point (2.0, 1.0).

The curve for receptor-B P A complex begins at the origin. The curve moves upward to the right till point (1.0, 0.7). The curve moves gradually upward to the right until it reaches point (2.0, 0.84). A dotted vertical line begins from 1.0 on the horizontal axis, intersects the two curves, and is labeled 1 nanomolar estradiol.

Return to FIGURE 3.50 At high enough concentrations, ligands with lower affinity for a receptor can compete for binding with high-affinity ligands

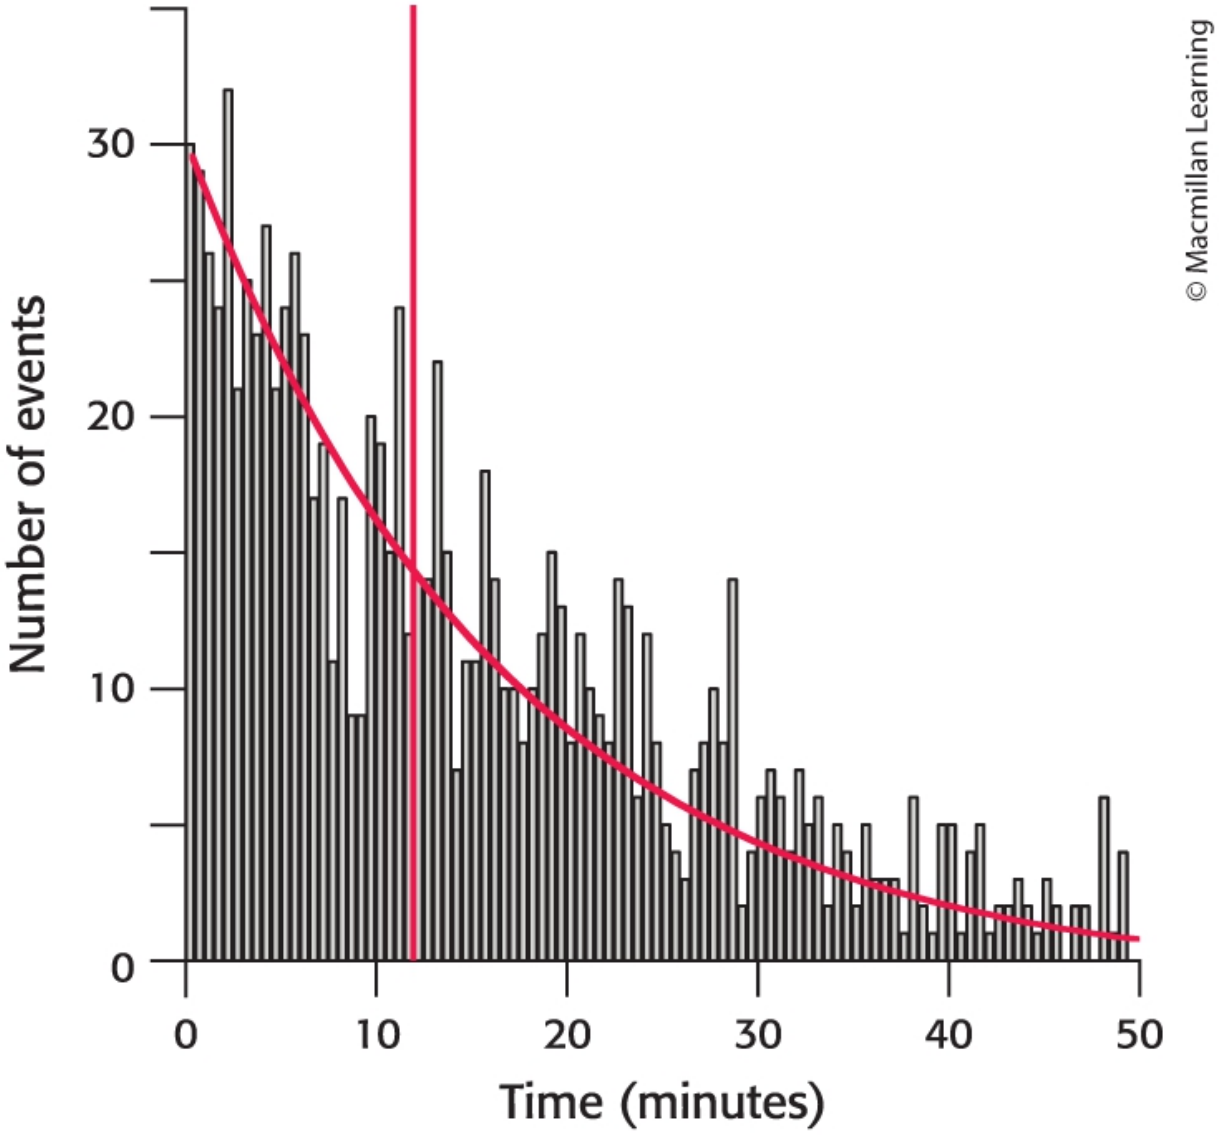


Extended description for Binding of a receptor to its ligand with the forward and reverse reaction rates

The reaction has two reactants and one product. The reactants are R and L. The product is R L. The forward reaction rate shown above the top forward arrow is lowercase K subscript 1. The reverse reaction rate shown below the bottom backward arrow is lowercase k subscript minus 1.

Return to Binding of a receptor to its ligand with the forward and reverse reaction rates

Extended description for FIGURE 3.51 At equilibrium, the rates of the forward and reverse reactions are the same



Each part consists of a square containing blue circles and several L letters. Parts (A) and (B), (B) and (C), and (B) and (D) are interconvertible shown by reversible reaction arrows.

1. Part (A): 10 blue circles labeled L are present randomly inside the square. These L labeling are shown in white. The L letters depicted in black exceed the number of blue circles, and present randomly around the circles.
2. Part (B): 8 black L letters occupies the L labeling inside 8 blue circles. The L labeling of two blue circles are empty.

3. Part (C): 10 black L letters occupies the black L labeling in all the circles.
4. Part (D): 8 black L letters occupies the L labeling inside 8 blue circles. The L labeling of two blue circles are empty.

Return to FIGURE 3.51 At equilibrium, the rates of the forward and reverse reactions are the same

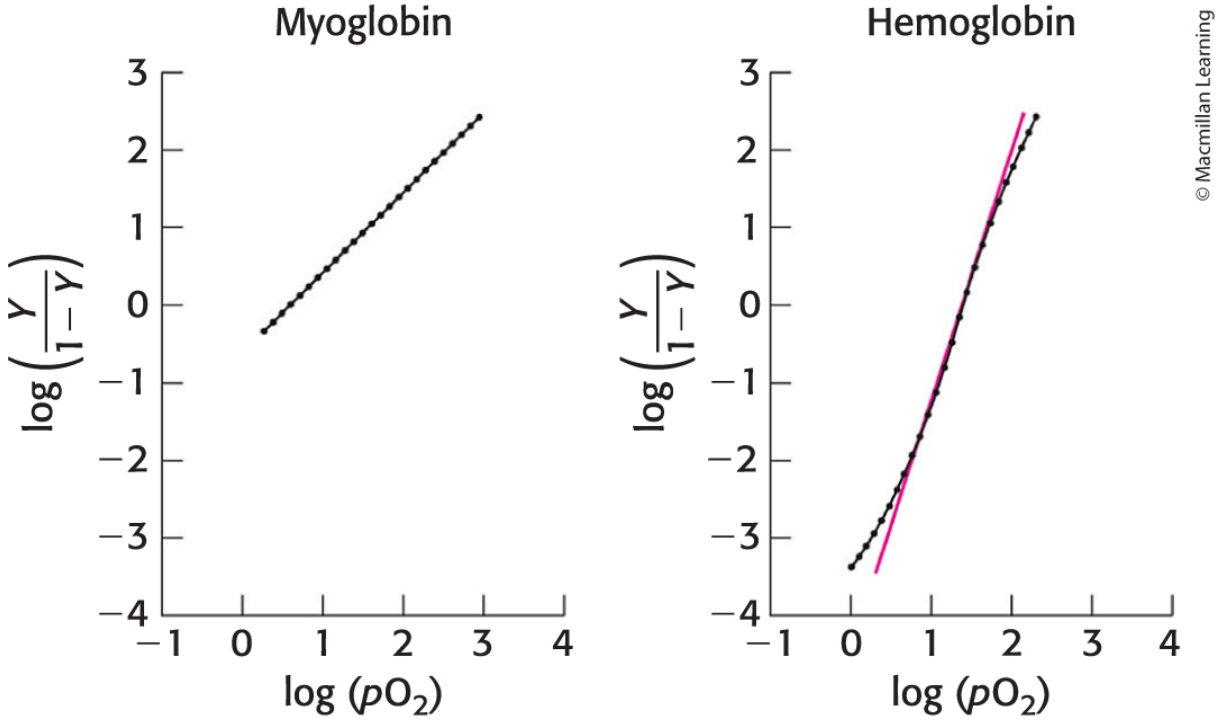
Extended description for FIGURE 3.52 A rate constant reflects the distribution of reaction times at the single molecule level

© Macmillan Learning

The horizontal axis is labeled time (minutes) and ranges from 0 to 50 in increments of 10 units. The vertical axis is labeled number of events and ranges from 0 to 30 in increments of 10 units.

Several bars are shown at different times. The number of events decreases as time increases. A red curve begins from 30 events and gradually moves toward the lower right to read approximately 2 events at 50 minutes. A red vertical line originates from the base of the bar located at 12 minutes and goes beyond 30 events.

Return to FIGURE 3.52 A rate constant reflects the distribution of reaction times at the single molecule level



Extended description for Binding of oxygen by hemoglobin

The reaction consists of two reactants and one product. The first reactant is H b. The second reactant is n O 2. A reversible reaction arrow leads to the product. The product is H b open parenthesis O 2 close parenthesis with subscript n.

The reversible reaction consists of two reactants and one product. The first reactant has the following structure: A central C u atom is single bonded to the N atoms of three heterocyclic pentagonal rings above, below, and on the left. The structure of the pentagonal ring is as follows: A 5-membered heterocyclic pentagonal ring consists of 2 N and 3 C atoms. Three such rings are oriented in different directions. The first N atom occupies the first position and the second N atom occupies the third position. A double bond is present between the first N atom and C 1 and C 2 and C 3. C 2 has an open single bond.

Two molecules of the first reactant are used. The second molecule is the mirror image of the first molecule. The second reactant is O 2.

The product has the following structure: O, single bond, O is arranged in a vertical orientation. Each O atom is single bonded to a common C u atom on either side. The two molecules of the reactant are connected through an O 2 molecule.

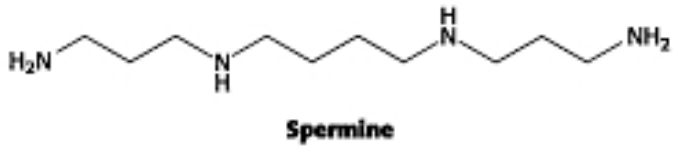
Extended description for Structure of choline

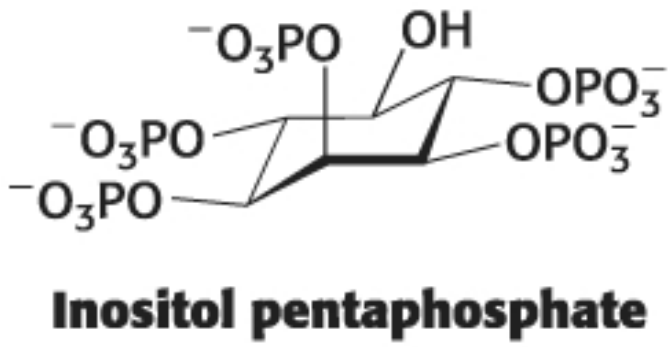


Choline

The structure of choline is as follows: A 2-carbon alkane chain is depicted as a line structure using 1 line. C 1 is single bonded to O H on the lower left. C 2 is single bonded to N superscript plus on the upper right. The N atom is single bonded to C H 3 on the upper right, dash bonded to C H 3 on the lower right, and wedge bonded to C H 3 below.

Return to Structure of choline

Extended description for Structure of spermine

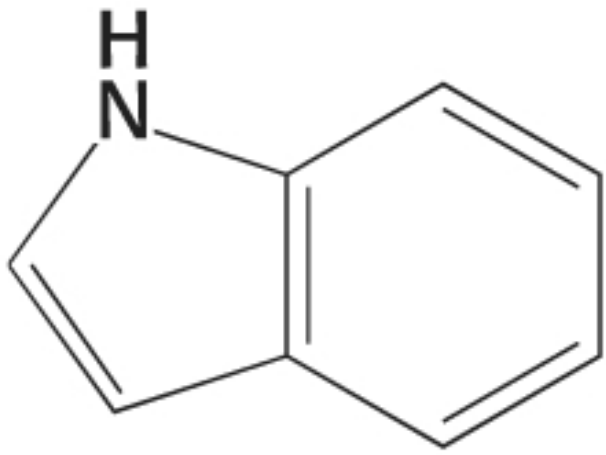


Spermine

The structure of spermine is as follows: A 2 N and 10 C heteronuclear alkane chain is depicted as a line structure using 11 zigzag lines. The first N atom occupies the fourth position and the second N atom occupies the ninth position. C 1 is single bonded to N H 2 on the lower left. Each N atom is bound to H. C 10 is single bonded to N H 2 on the upper right.

Return to Structure of spermine

Extended description for Structure of inositol Penta phosphate

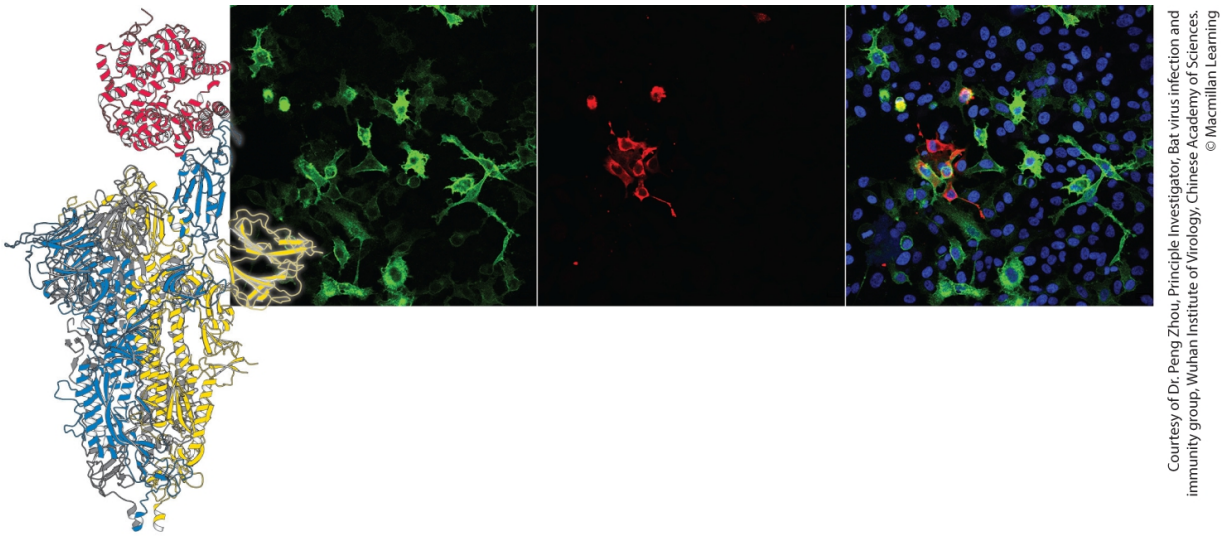


Inositol pentaphosphate

Inositol Penta phosphate has the following structure: A 6-carbon ring in horizontal orientation is shown as a boat conformation. C 1 occupies the top right vertex. C 3 and C 6 are close to each other. C 4 occupies the bottom left vertex. C 1, C 2, C 3, C 4, and C 5 are each single bonded to O P O 3 superscript minus. C 6 is single bonded to O H. The ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are toward the observer.

Return to Structure of inositol Penta phosphate

Extended description for Structure of indole



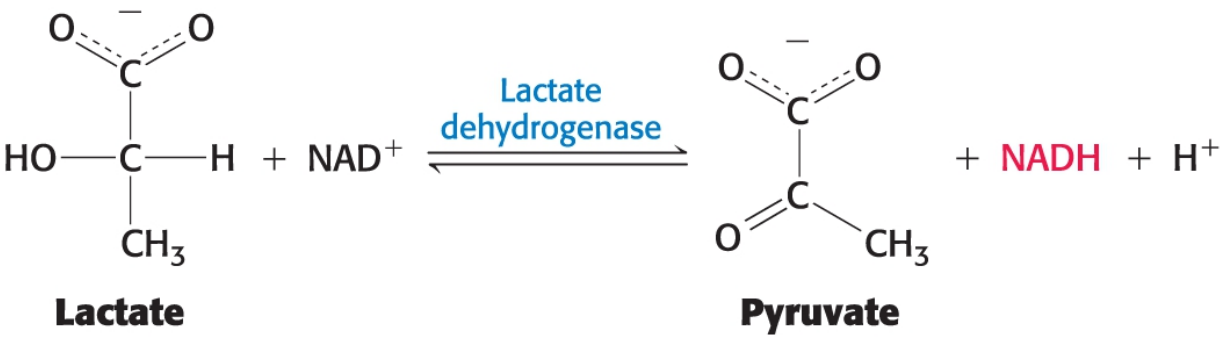
Indole

Indole has the following structure: A 5-membered pentagonal ring and a benzene ring are fused together side-by-side. The 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 1 N and 4 C atoms. N occupies the first position, which is the top left vertex and is bound to H. A double bond is present between C 3 and C 4. The pentagonal ring is fused to the benzene ring in a vertical orientation, with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. The two rings are fused together such that C 2 and C 3 are C 6 and C 5 of the benzene ring, respectively.

Return to Structure of indole

Extended description for Ribbon diagram of SARS-CoV-2 spike protein bound to angiotensin-converting enzyme 2 and immunofluorescence photomicrographs of infected cells

Courtesy of Dr. Peng Zhou, Principle Investigator, Bat virus infection and immunity group, Wuhan Institute of Virology, Chinese Academy of Sciences.
© Macmillan Learning



The spike protein is shown to be composed of beta strands connected by short loops. It has an elongated structure.

The three immunofluorescence micrographs are as follows:

The first micrograph shows cells expressing the angiotensin-converting enzyme 2 labeled in green.
The second micrograph shows virus particles labeled in red and concentrated toward the left.
The third micrograph is a combined image of the first two. Nuclei of the cells are visible and are labeled in blue.

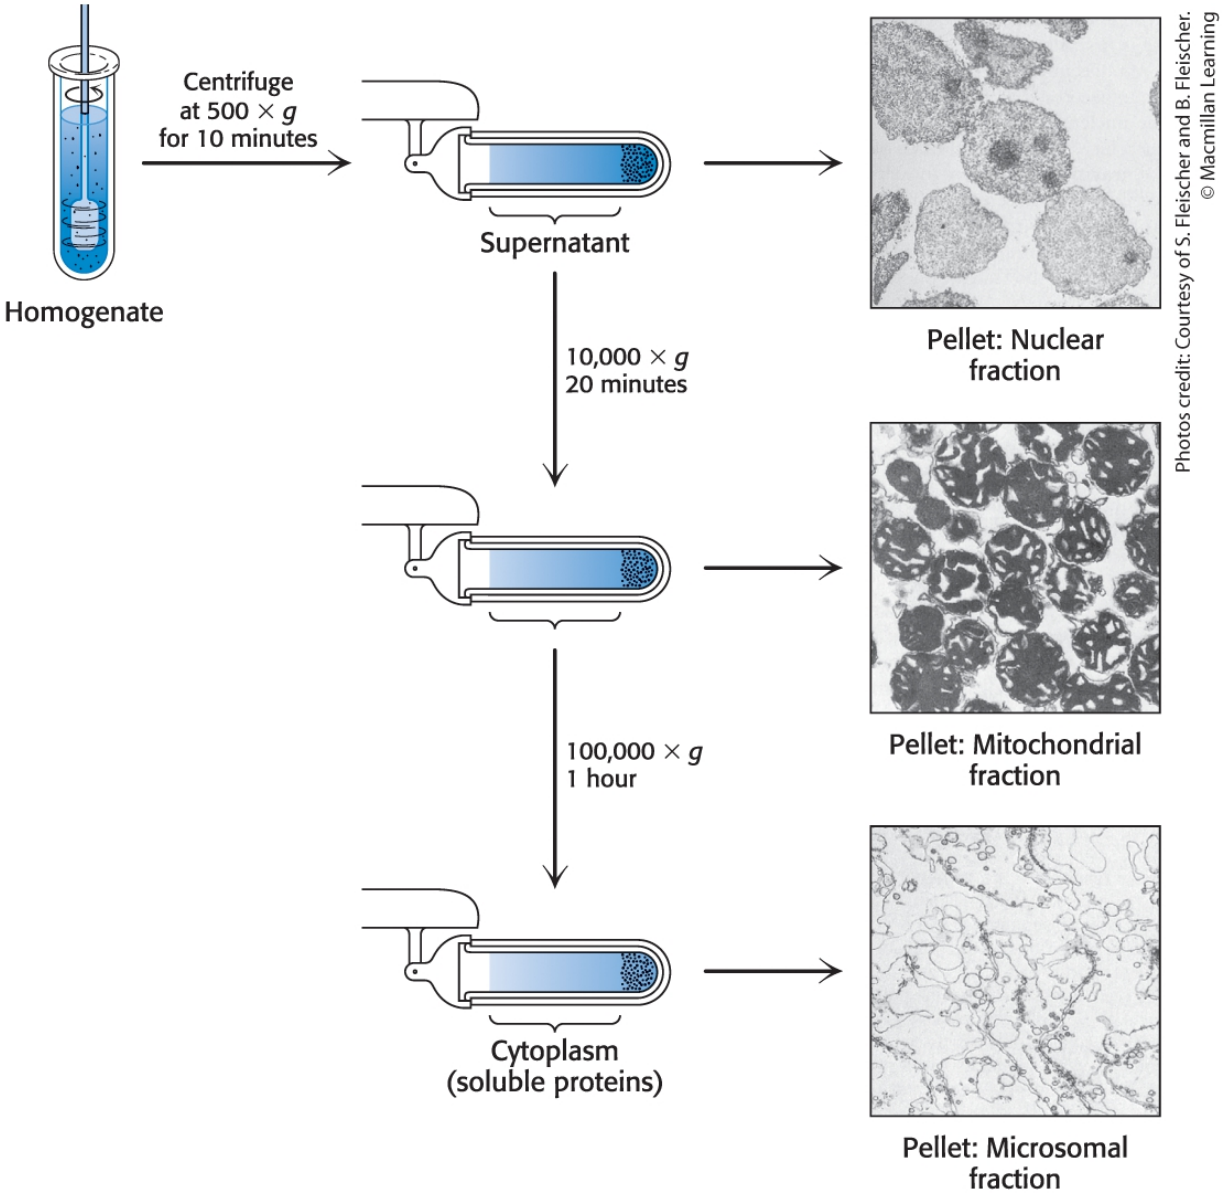
Return to Ribbon diagram of SARS-CoV-2 spike protein bound to angiotensin-converting enzyme 2 and immunofluorescence photomicrographs of infected cells

Extended description for Chemical equation for oxidation of lactate to pyruvate

The reversible reaction consists of two reactants and three products.

The first reactant is lactate and has the following structure: H O, single bond, C, single bond, H. C is single bonded to C H 3 below and single bonded to C above which is partially double bonded to O on the upper left and partially double bonded to O on the upper right. The C O O group above carries a negative charge.

The second reactant is N A D superscript plus.



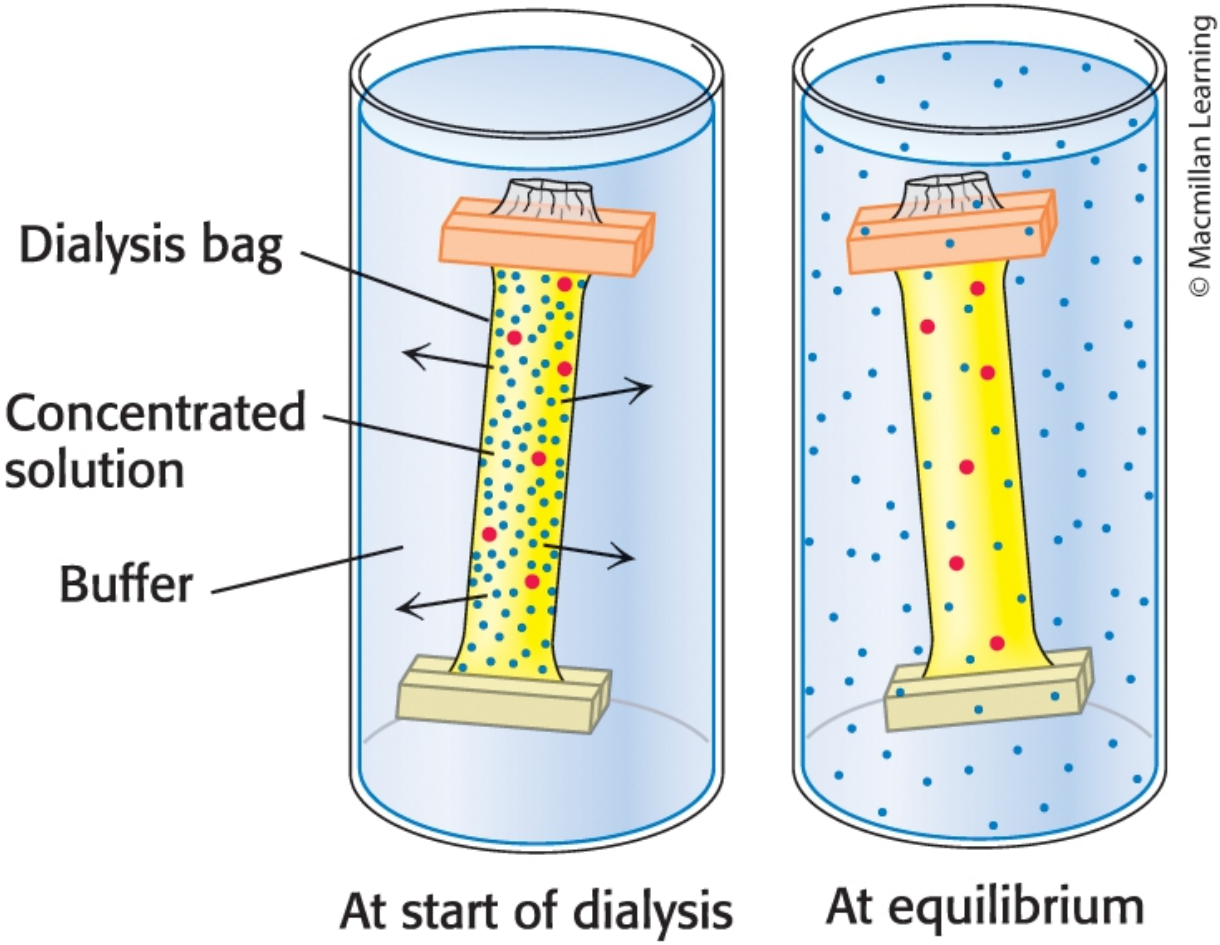
The first product has the following structure: A C atom is single bonded to C above. C 1 is single bonded to C H 3 on the lower right and double bonded to O on the lower left. C 2 is partially double bonded to O on the upper left and partially double bonded to O on the upper right. The C O O group above carries a negative charge.

The second product is N A D H.

The third product is H superscript plus ion.

Return to Chemical equation for oxidation of lactate to pyruvate

Extended description for FIGURE 4.1. Schematic illustration of differential centrifugation and photomicrographs of the pellets obtained at each step

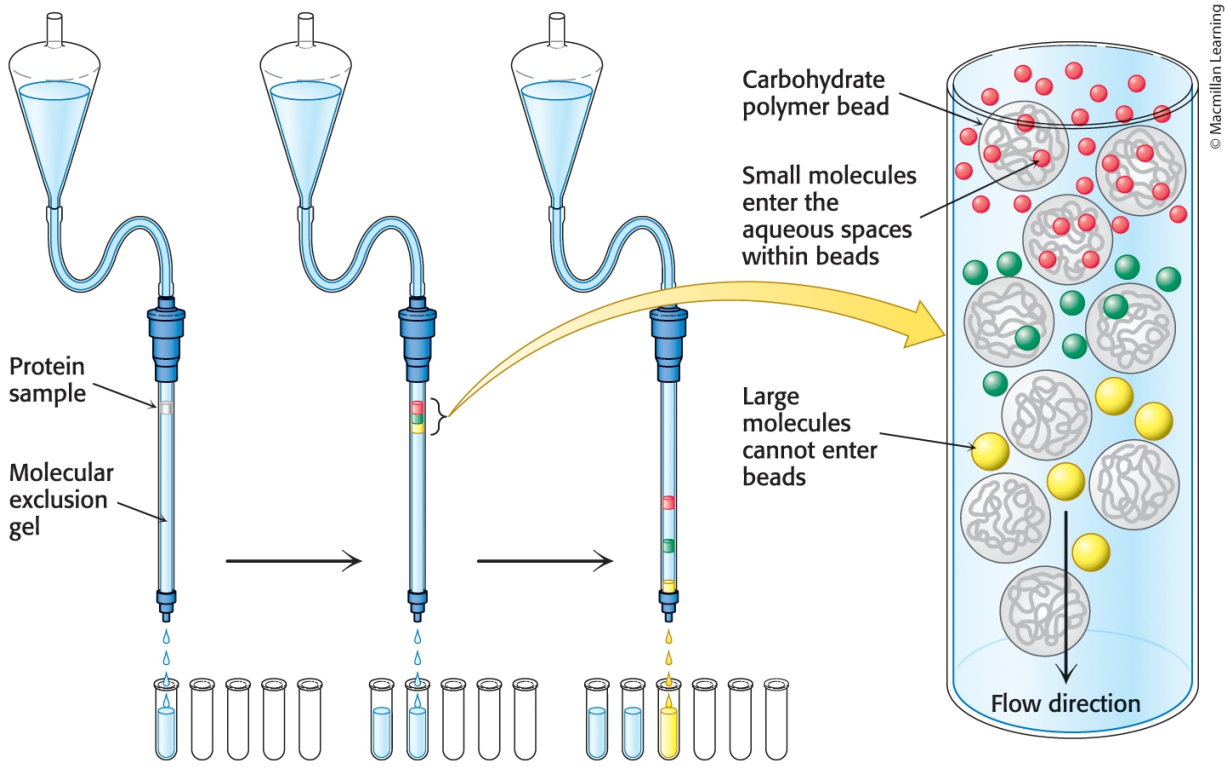


1. A test tube homogenizer containing a cell homogenate is shown. The homogenate is then centrifuged at 500 g for 10 minutes.

2. A centrifuge tube is shown in a horizontal orientation. It has a pellet at the base and the fluid supernatant fills the rest of the tube. A corresponding micrograph is labeled "Pellet: Nuclear fraction." It shows conglomerates comprising chromatin and other nuclear material.
3. The supernatant is then again centrifuged at 10,000 g for 20 minutes.
4. The centrifuge tube is shown in a horizontal orientation which contains supernatant and a pellet. A corresponding micrograph is labeled "Pellet: Mitochondrial fraction." It shows conglomerates comprising several mitochondria.
5. The supernatant is then again centrifuged at 10,000 g for 20 minutes.
6. The supernatant is then again centrifuged at 100,000 g for 1 hour.
7. The centrifuge tube is shown in a horizontal orientation which contains supernatant and a pellet. The supernatant is labeled "Cytoplasm (soluble proteins)." A corresponding micrograph is labeled "Pellet: Microsomal fraction." It shows small bead-like particles.

Return to FIGURE 4.1. Schematic illustration of differential centrifugation and photomicrographs of the pellets obtained at each step

Extended description for FIGURE 4.2. Schematic illustration of dialysis to separate proteins from small molecules



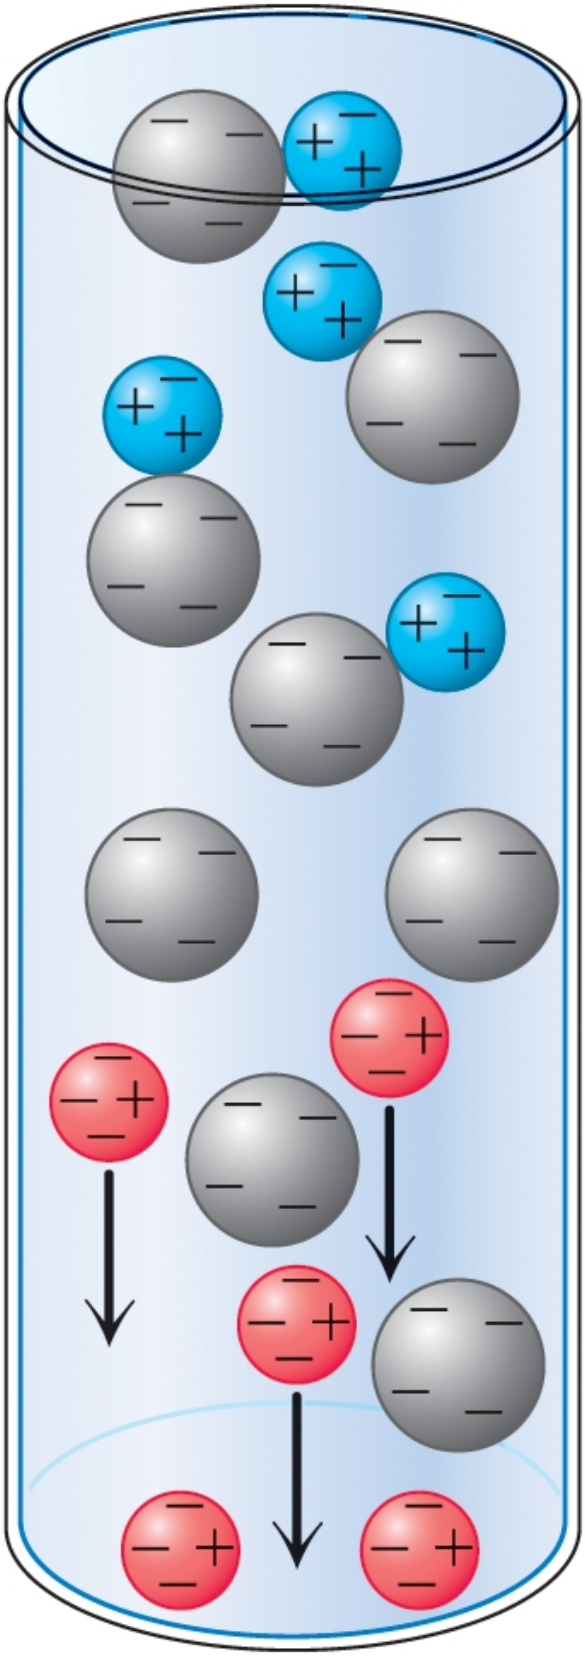
At the start of dialysis: A container filled with a buffer is shown. A column labeled "Dialysis bag" is shown suspended in the buffer and clipped on both ends. Several small blue dots interspaced with moderately sized green dots and larger red dots are shown inside the dialysis bag and is labeled "Concentrated solution." Outward arrows are directed from the concentrated solution in the dialysis bag toward the buffer outside.

At equilibrium: The blue dots earlier inside the dialysis bag are now shown to be in the buffer. On the green and red dots are shown to remain in the dialysis bag.

Return to FIGURE 4.2. Schematic illustration of dialysis to separate proteins from small molecules

Extended description for FIGURE 4.3. Schematic illustration of gel-filtration chromatography to separate proteins on the basis of their size

Three stages of the chromatographic separation technique is shown.



The first stage shows a funnel drip. A swan-neck tube from the funnel drip is connected to a vertical column. The apparatus is filled with molecular exclusion gel. A small white section is seen in the column and is labeled "Protein sample." The contents passing through the column is collected in a test-tube below.
The second stage shows the column having three consecutive sections colored red, green, and yellow. The contents passing through the column is collected in a test-tube below. A magnified view of these sections is shown. It shows the column filled with spherical beads labeled "Carbohydrate polymer beads." The flow

direction is indicated from the top to bottom. Small red spheres are shown at the top of the column and a callout reads, "Small molecules enter the aqueous spaces within beads." Moderate sized green beads are shown in the middle portion of the column. Larger yellow spherical beads are shown is the bottom portion of the column and a callout reads, "Large molecules cannot enter beads." The third stage shown the three colored segments separate along the length of the column. The yellow molecules are shown to be collected in a test-tube below.

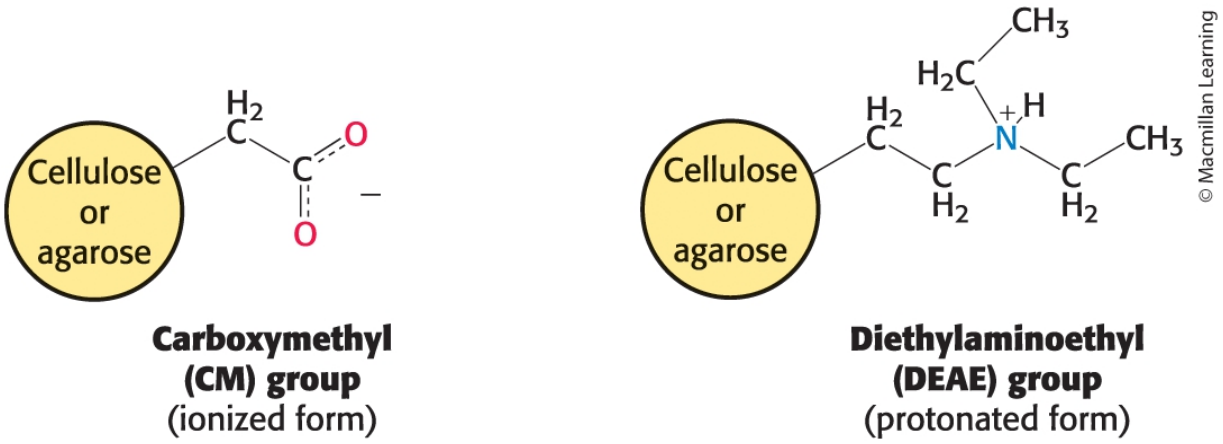
Extended description for FIGURE 4.4. Schematic illustration of ion-exchange chromatography to

separate proteins based on their net charge

Positively charged protein binds to negatively charged bead



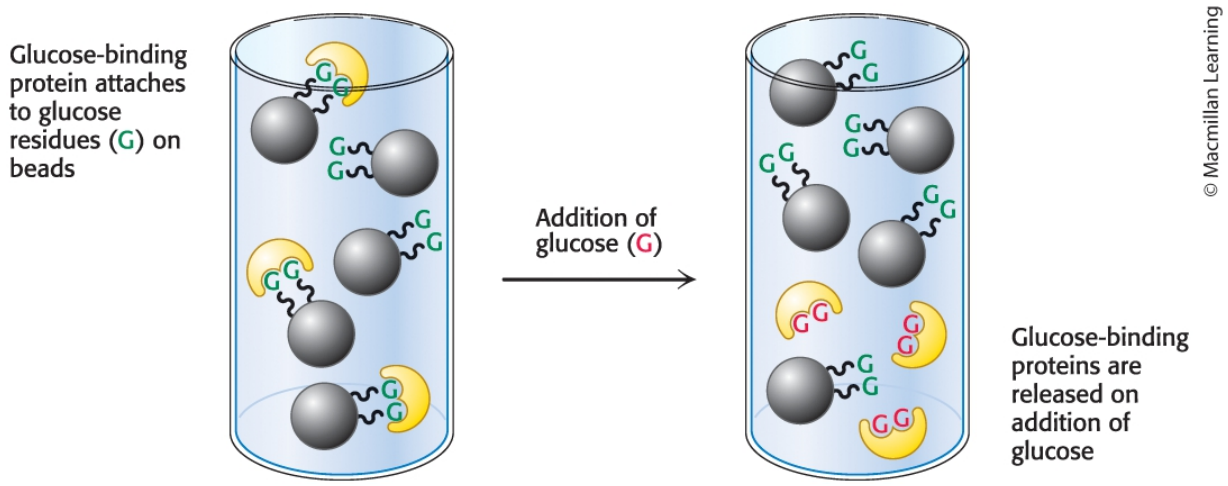
Negatively charged protein flows through

© Macmillan Learning

A column is shown to contain negatively charged beads. Blue spheres carrying a net positive charge are shown to adhere to the beads. A callout reads, "Positively charged protein binds to negatively charged bead." Red spheres carrying a net negative charge are shown to elute out of the column. A callout reads, "Negatively charged protein flows through."

Return to FIGURE 4.4. Schematic illustration of ion-exchange chromatography to separate proteins based on their net charge

Extended description for Chemical structure of ionized carboxymethyl group and protonated diethylaminoethyl group bound to cellulose or agarose bead



Carboxymethyl (C M) group (ionized form): C, single bond, C. C 1 is bound to H 2 and single bonded to a large bead labeled "Cellulose or agarose" on the lower left. C 2 is partially double bonded to O on the upper right and partially double bonded to O below. The terminal C O O group carries a negative charge.

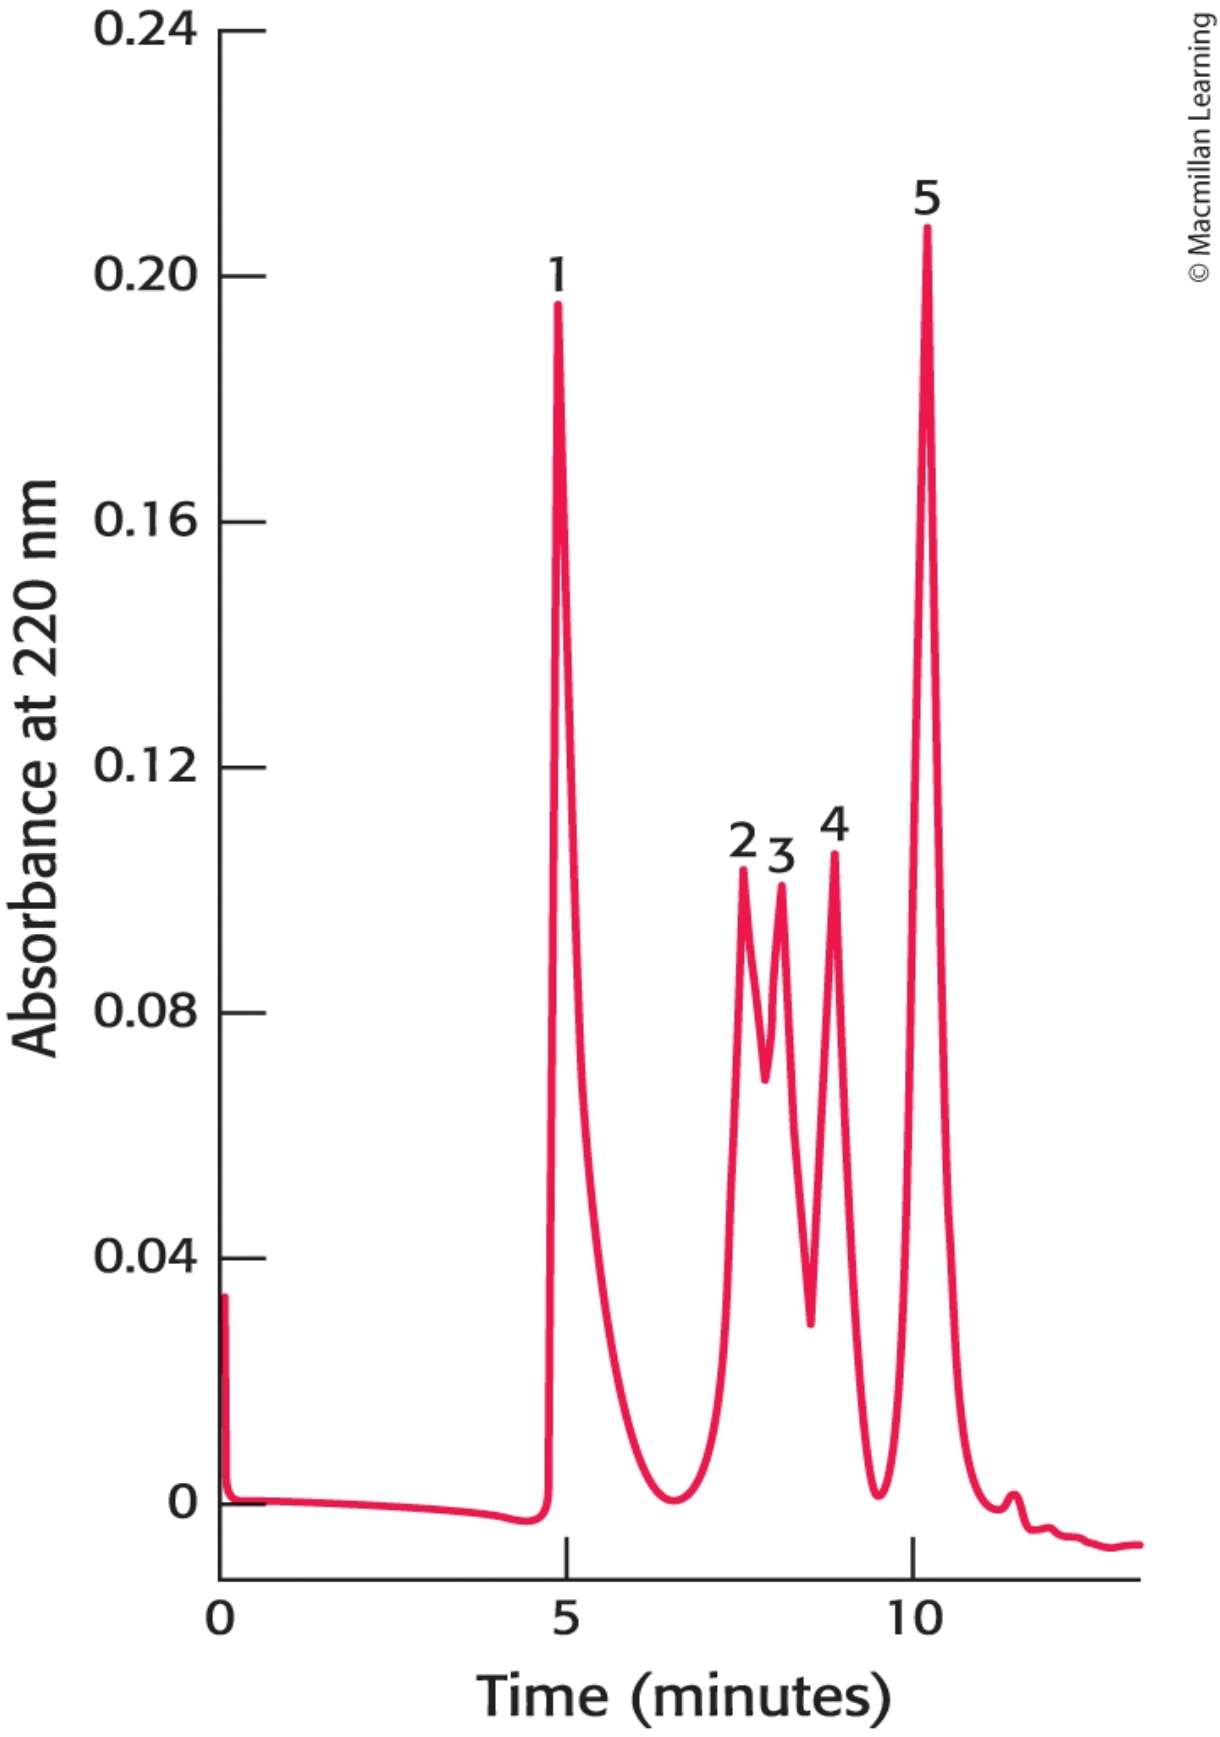
Diethylaminoethyl (DEAE) group (protonated form): C, single bond, C, single bond, N, single bond, C, single bond, C H 3. C 1, C 2, and C 3 are each bound to H 2. C 1 is single bonded to a large bead labeled "Cellulose or agarose" on the lower left. N carries a positive charge and is single bonded to h on the upper right and single bonded to C H 2 on the upper left which is further single bonded to C H 3 on the upper right.

Return to Chemical structure of ionized carboxymethyl group and protonated diethylaminoethyl group bound to cellulose or agarose

bead

Extended description for FIGURE 4.5. Schematic illustration of affinity chromatography to separate proteins based on their binding to a specific ligand

A column is shown to contain spherical beads with glucose residues (shown in green) covalently attached to their surface. Crescent-shaped proteins, concanavalin A, are shown to attach to these glucose residues on the beads. A callout reads, "Glucose-binding protein attaches to glucose residues on beads."



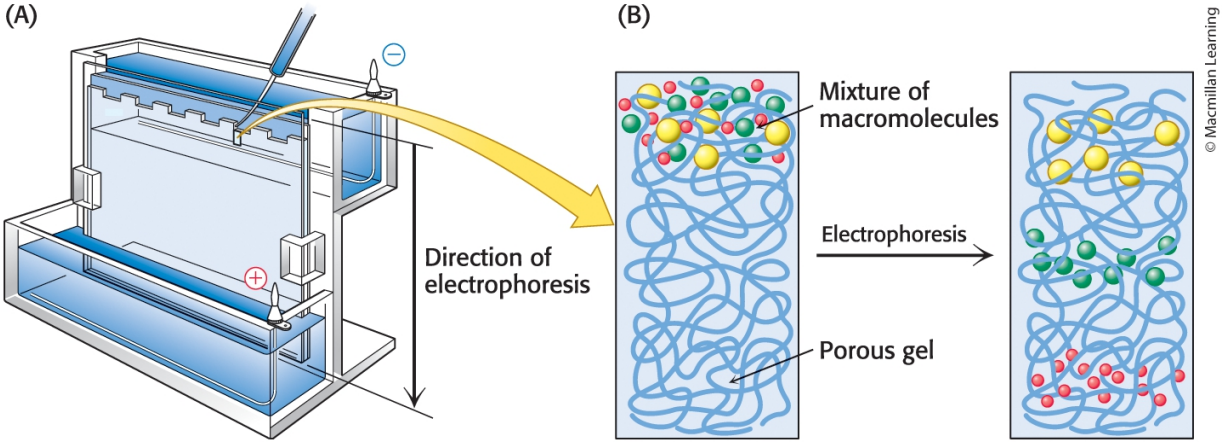
Glucose (shown in red) is shown to be added to the column.

After addition of glucose, the proteins are shown to detach from the beads and bind to the added glucose. A callout reads, "Glucose-binding proteins are released on addition of glucose."

Return to FIGURE 4.5. Schematic illustration of affinity chromatography to separate proteins based on their binding to a specific ligand

Extended description for FIGURE 4.6. Graph showing H P L C mediated protein separation with high resolving

power



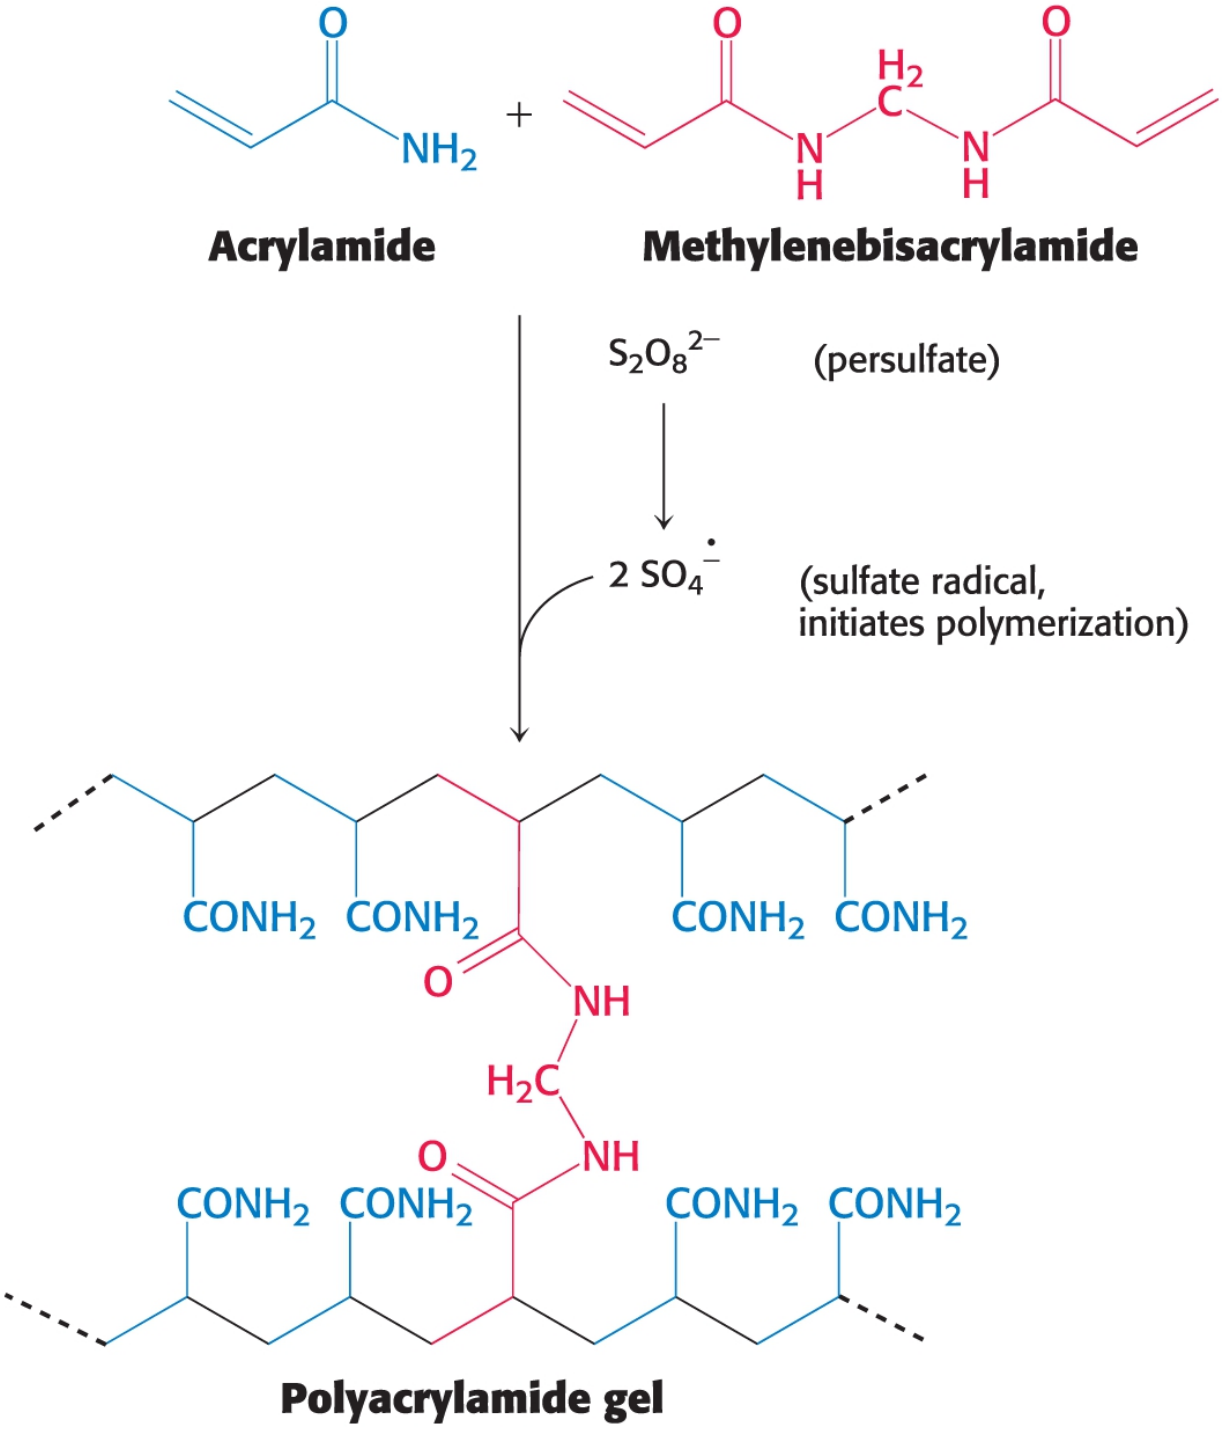
© Macmillan Learning

The horizontal axis is labeled Time (minutes) and ranges from 0 to 10 in increments of 5 units. The vertical axis is labeled Absorbance at 220 n m and ranges from 0 to 0.24 in increments of 0.04 units. Five peaks are labeled on the graph from 1 through 5 as follows:

Peak 1 at (5, 0.20)
Peak 2 at (7.5, 0.10)
Peak 3 at (8, 0.95)
Peak 4 at (9, 0.10)
Peak 5 at (10, 0.21)

Return to FIGURE 4.6. Graph showing H P L C mediated protein separation with high resolving power

Extended description for FIGURE 4.7. Schematic illustration of polyacrylamide gel electrophoresis



Part (A): A polyacrylamide gel electrophoresis set-up is shown. The gel is mounted vertically. It has several small wells at the top into which the sample is shown to be loaded by a pipette. The direction of electrophoresis is shown to be from the top to bottom. A tank with a buffer is present at the top, behind the gel. This has a negative electrode. Another tank with a buffer is present at the bottom, in front of the gel. This has a positive electrode.

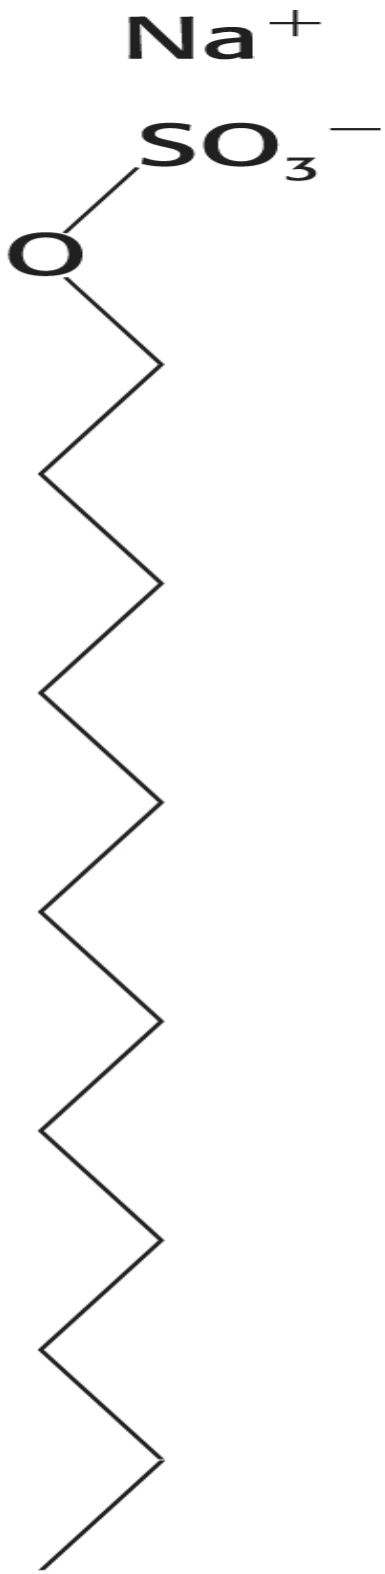
Part (B): A magnified view of the well loaded with the sample is shown. It shows a mesh-like matrix made up of intertwined rope-like structures. Pockets in the matrix is labeled "Porous gel". A mixture of macromolecules are shown at the top portion of the gel and consists of large yellow spheres, moderate-sized green spheres, and small red spheres. A rightward arrows from this is labeled "Electrophoresis" which points at the separated macromolecules. The large yellow spheres are shown to be trapped toward the top of the gel. The intermediate-sized green spheres are trapped in the middle. The small red spheres are trapped at the bottom of the gel.

Return to FIGURE 4.7. Schematic illustration of polyacrylamide gel electrophoresis

Extended description for FIGURE 4.8. Cross-linking reaction for polyacrylamide gel formation

The first reactant is Acrylamide and has the following structure: A 3-carbon alkene chain is depicted as a line structure using 2 zigzag lines. C 1 is double bonded to C 2. C 3 is double bonded to O above and single bonded to N H 2 on the lower right.

The second reactant is Methylenebisacrylamide and has the following structure: A 3-carbon alkene chain is depicted as a line structure using 2 zigzag lines. C 1 is double bonded to C 2. C 3 is double bonded to O above and single bonded to N bound to H on the lower right. N is single bonded to C bound to H 2 on the upper right. C is single bonded to N bound to H on the lower right. N is single bonded to C 1 of a 3-carbon alkene chain depicted using 2 zigzag lines on the upper right. C 1 is double bonded to O above. C 2 is double bonded to C 3.



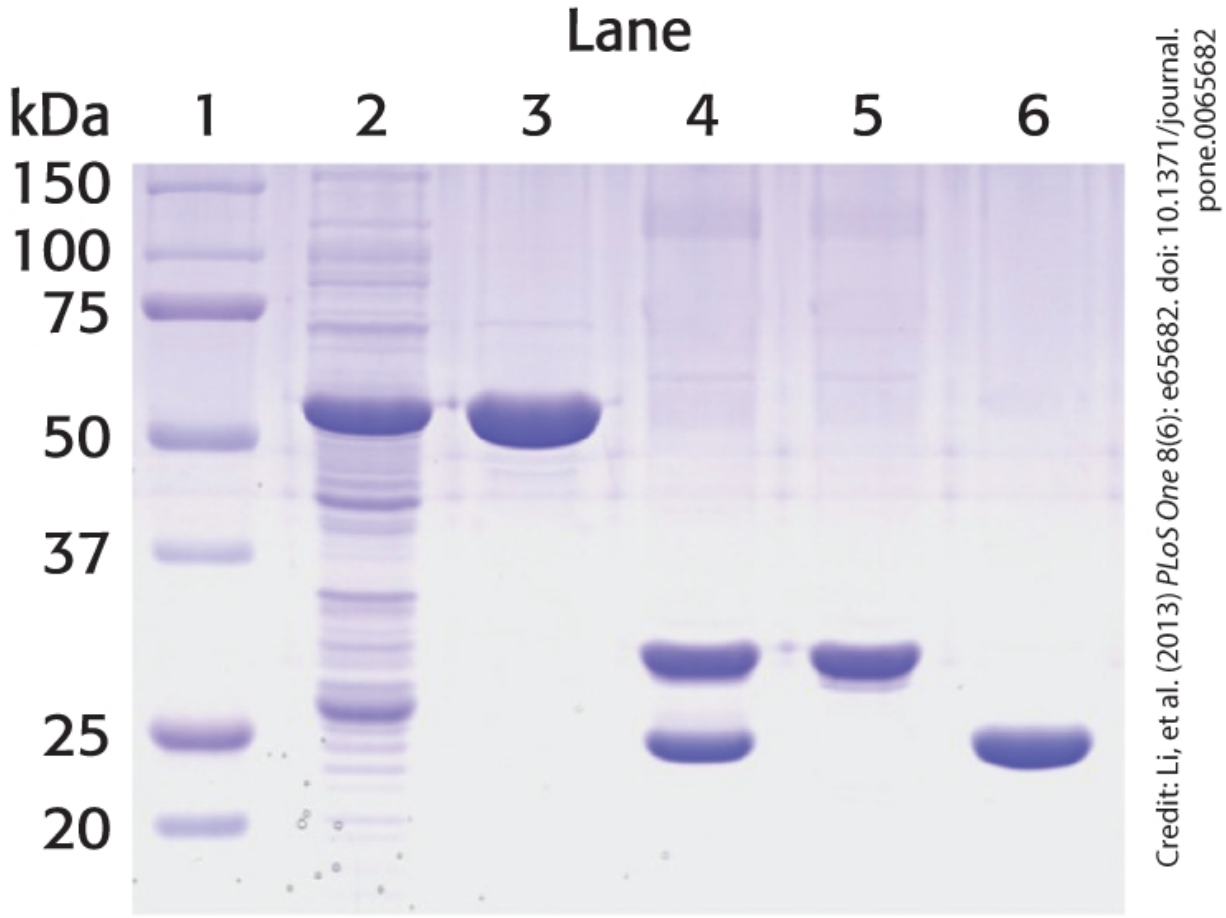
S 2 O 8 superscript 2 minus (persulfate) is shown to form 2 S O 4 superscript minus with a lone electron (sulfate radical). The sulfate radical is indicated to initiate polymerization.

The product is Polyacrylamide gel which has the following structure: A polymeric units is shown to consist of a 10-carbon alkane chain depicted as a line structure using 9 zigzag lines. C 2, C 4, C 8, and C 10 are each single bonded to C O N H 2 below. C 6 is single bonded to a C atom below. The C atom is double bonded to O on the lower left and single bonded to N H on the lower right. N H is single bonded to C H 2 on the lower left which is single bonded to N H on the lower right. N H is single bonded to a central C atom on the lower left which is double bonded to O on the upper left and single bonded to C 6 of another 10-carbon alkane chain below. The alkane chain is depicted as a line structure using 9 zigzag lines. C 2, C 4, C 8, and C 10 are each single bonded to C O N H 2 above. The group linking the two alkane chains is highlighted in red.

Return to FIGURE 4.8. Cross-linking reaction for polyacrylamide gel formation

Extended description for Chemical structure of sodium

dodecyl sulfate

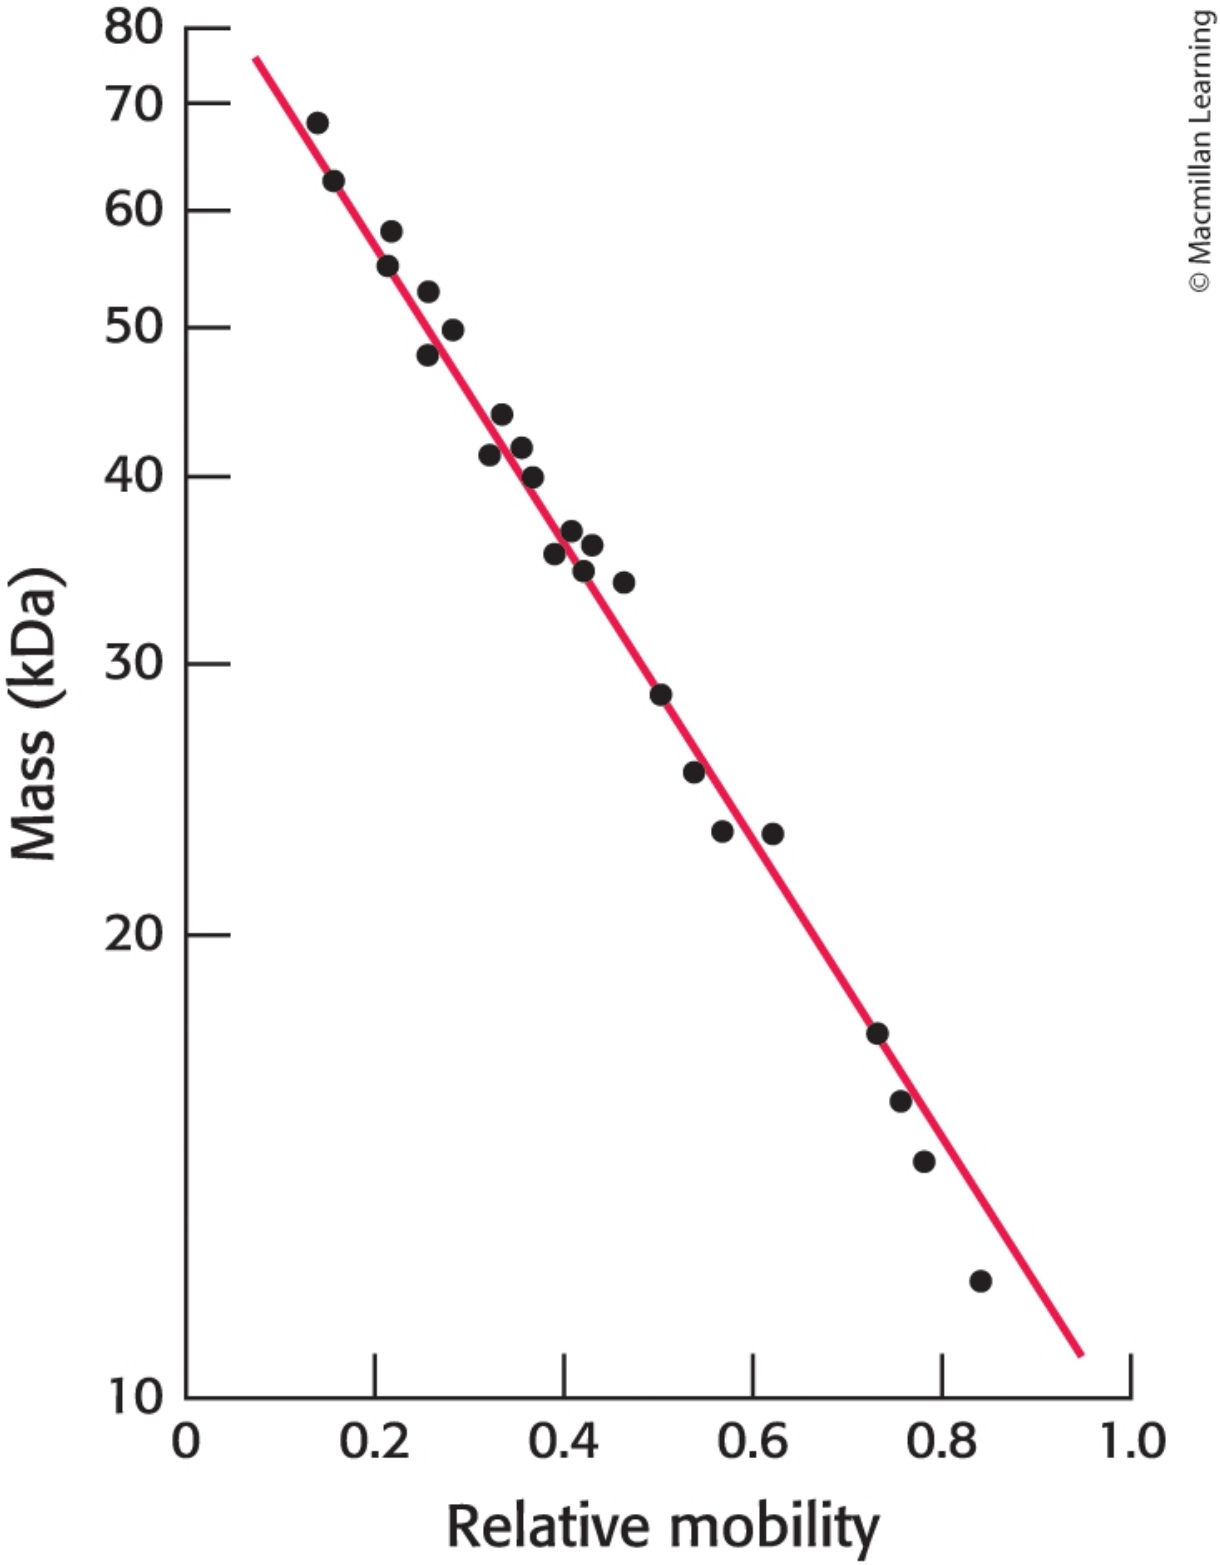


Sodium dodecyl sulfate (SDS)

The structure of sodium dodecyl sulfate (S D S) is as follows: S O 3 superscript minus is single bonded to O on the lower left. O is single bonded to C 1 of a 12-carbon alkane chain depicted as a line structure using 11 zigzag lines. N a superscript plus is present above S O 3 superscript minus as a counter-ion.

Return to Chemical structure of sodium dodecyl sulfate

Extended description for FIGURE 4.9. Photograph of stained polyacrylamide gel showing protein bands



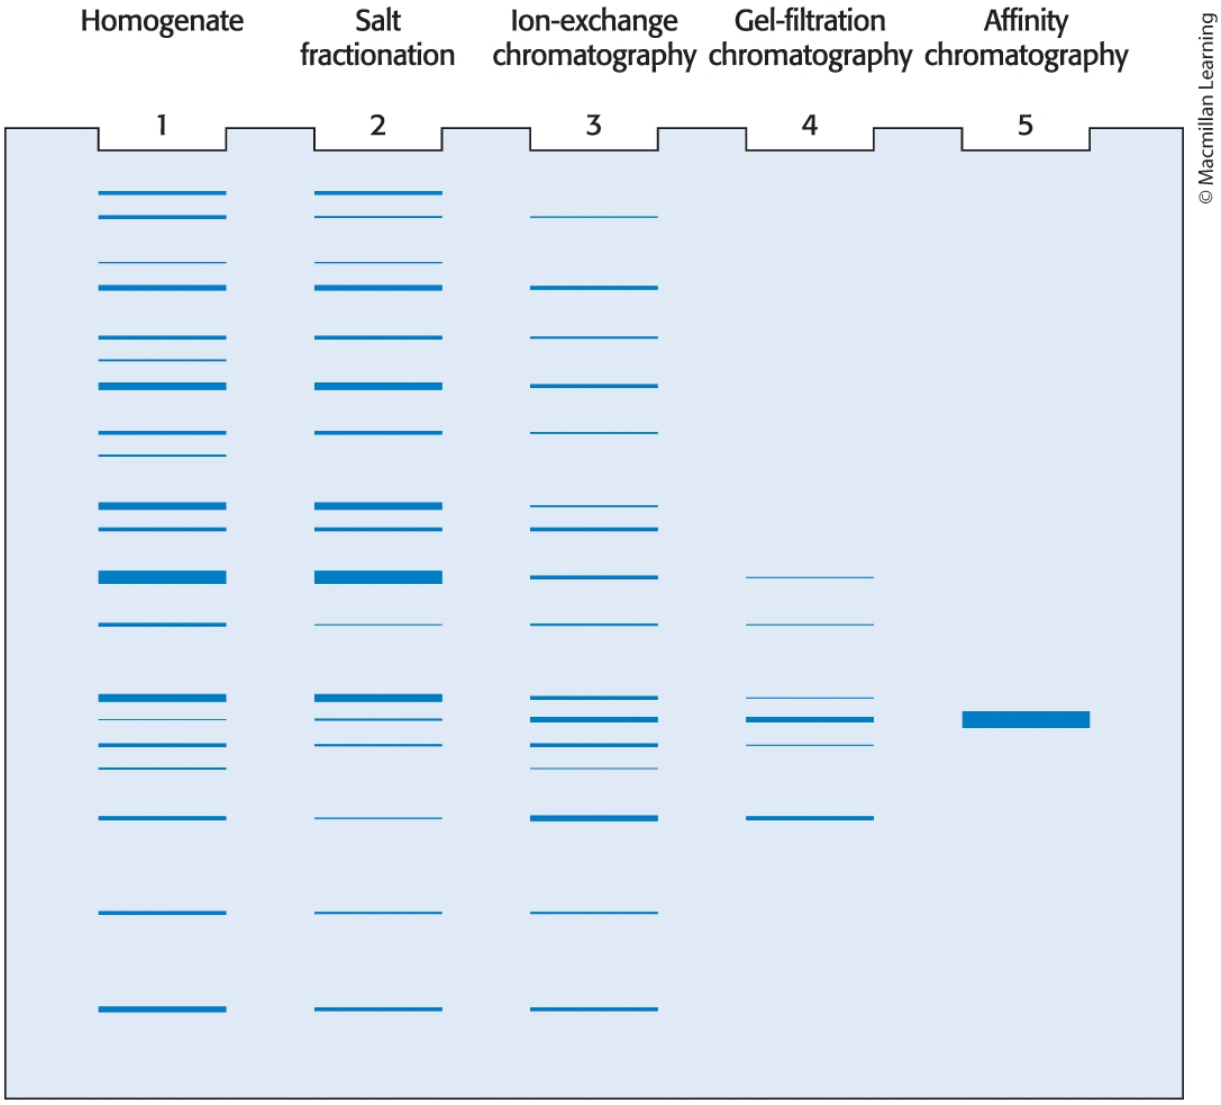
Credit: Li, et al. (2013) *PLoS One* 8(6): e65682. doi: 10.1371/journal.pone.0065682

The photograph shows six vertical lanes that are labeled 1 through 6. Lane 1 is shown to represent a protein ladder which functions as a reference. It contains proteins of various sizes ranging from 20 to 150 kilo Dalton, from bottom to top. The rest of the lanes show the separate proteins in the samples. Some of the bands appear significantly darker than the rest.

Return to FIGURE 4.9. Photograph of stained polyacrylamide gel showing protein bands

Extended description for FIGURE 4.10. Electrophoresis

graph for protein mass determination

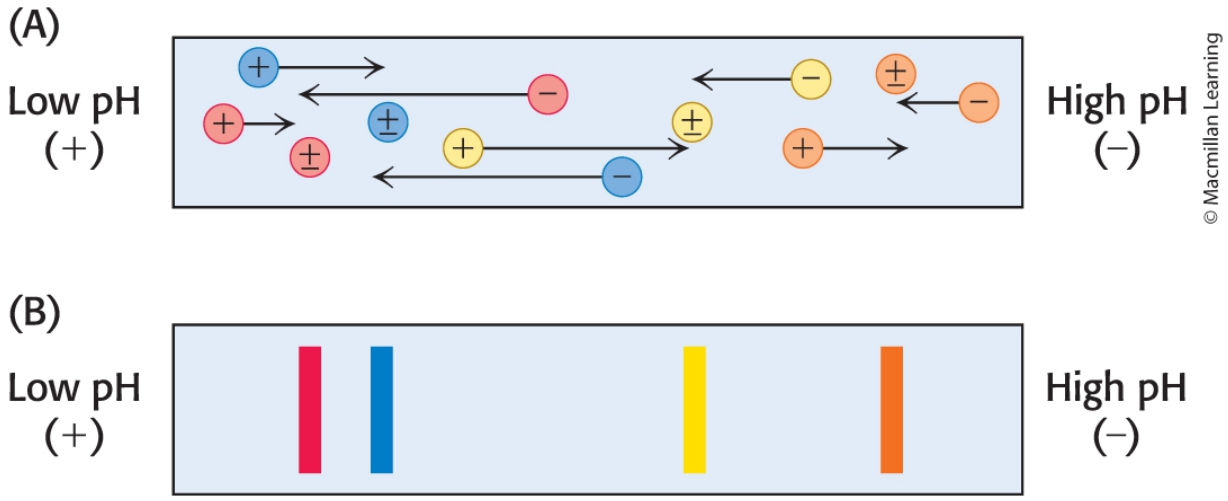


© Macmillan Learning

The horizontal axis is labeled Relative mobility and ranges from 0 to 1.0 in increments of 0.2 units. The vertical axis is labeled Mass (kilo Dalton) and ranges from 10 to 80 in unequal increments. The trendline has a negative slope which starts at (0.1, 75) and ends at (0.95, 11). Plot points are shown to lie near the trendline.

Return to FIGURE 4.10. Electrophoresis graph for protein mass determination

Extended description for FIGURE 4.11. Electrophoretic analysis for monitoring the progress of protein purification

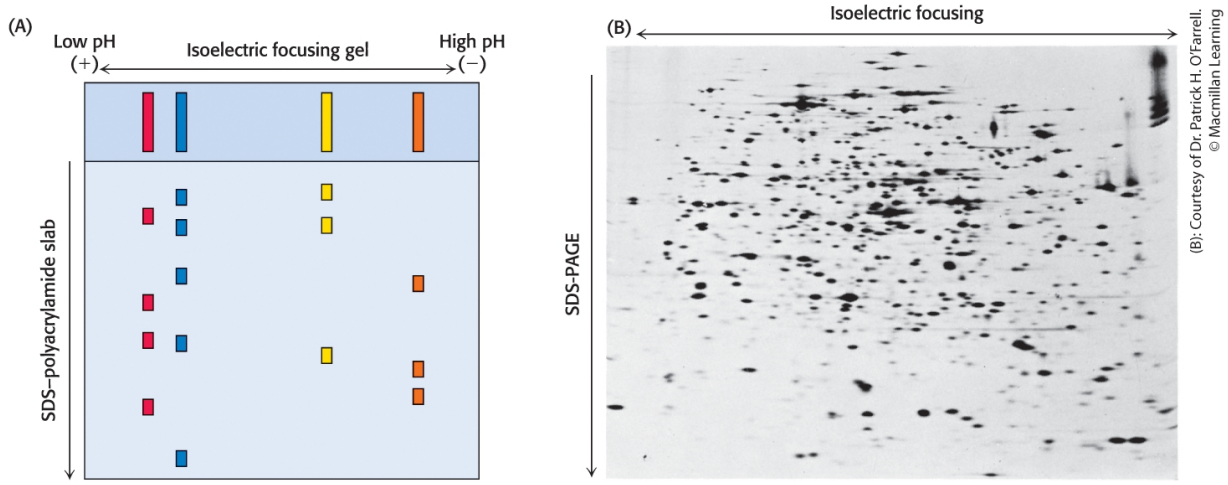


The gel is shown to have 5 lanes, from left to right, labeled Homogenate, Salt fractionation, Ion-exchange chromatography, Gel-filtration chromatography, and Affinity chromatography.

The band corresponding to the protein of interest is shown be present approximately in the middle. The number of bands obtained at each subsequent step is shown to decrease. The band corresponding to protein of interest is shown to get thicker along the purification process. In the final lane, only the band corresponding to the protein of interest is visible.

Return to FIGURE 4.11. Electrophoretic analysis for monitoring the progress of protein purification

Extended description for FIGURE 4.12. Schematic illustration of isoelectric focusing mediated separation of proteins



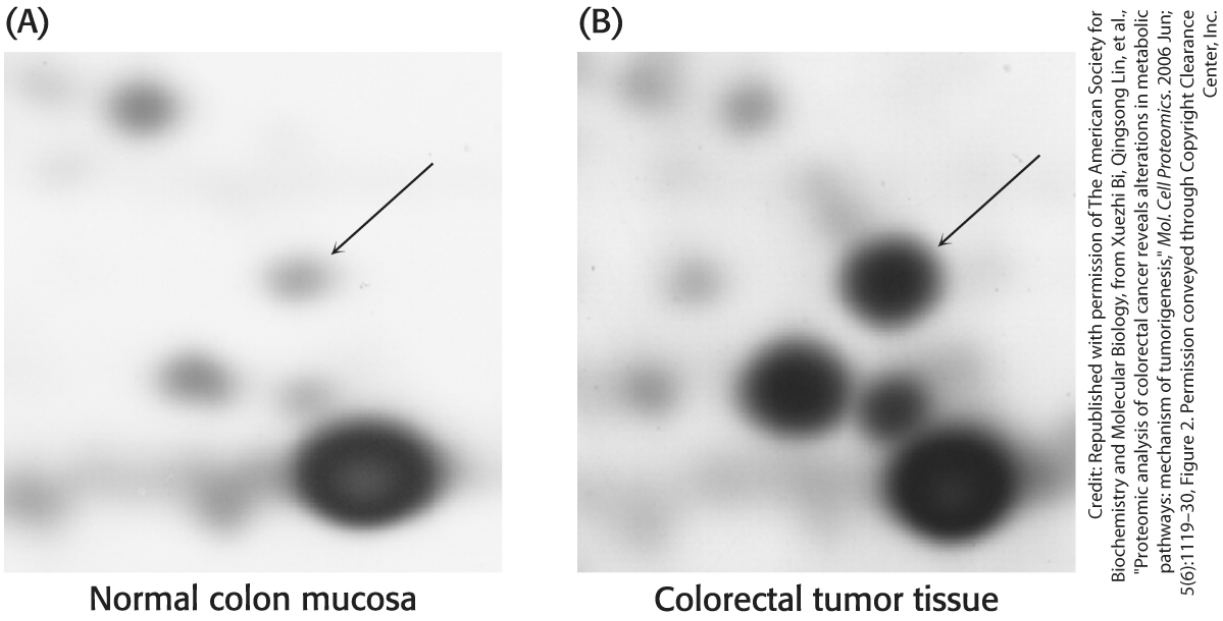
© Macmillan Learning

Part (A): A p H gradient is shown across the gel. The left end is labeled low p H (plus) and the right end is labeled high p H (minus). Several red, blue, yellow, and orange spheres are shown carrying the following charges: positive, negative, and both positive and negative. The spheres carrying a positive charge are shown to migrate toward the right terminal. The spheres carrying a negative charge are shown to migrate toward the left terminal. Spheres carrying both positive and negative charges are shown to remain stagnant.

Part (B): Several vertical protein bands are shown along the gel. Red and blue bands are present closer to the positive left terminal. An orange band is present closer to the negative right terminal. A yellow band is present almost in the middle but slightly closer to the right terminal.

Return to FIGURE 4.12. Schematic illustration of isoelectric focusing mediated separation of proteins

Extended description for FIGURE 4.13. Schematic illustration and actual image of two-dimensional gel electrophoresis for separation of complex protein mixtures



Part (A): The figure illustrates an isoelectric focusing gel slab at the top joined to a larger S D S-polyacrylamide gel slab at the bottom. A double-headed arrow is shown above the isoelectric focusing gel, indicating that the separation is horizontal. A downward arrow is shown along the S D S-polyacrylamide gel, indicating that the separation is vertical. A p H gradient is shown across the gel. The left end is labeled low p H (plus) and the right end is labeled high p H (minus). Several vertical protein bands are shown along the gel. Red and blue bands are present closer to the positive left terminal. An orange band is present closer to the negative right terminal. A yellow band is present almost in the middle but slightly closer to the right terminal. Below each band, corresponding small separated segments are shown in the S D S-polyacrylamide gel.

Part (B): A photograph of two-dimensional gel electrophoresis shows several dark spots corresponding to respective proteins. The

spots are mostly present in the middle portion and toward the top half of the gel.

1. A mouse is shown to be injected with antigen.

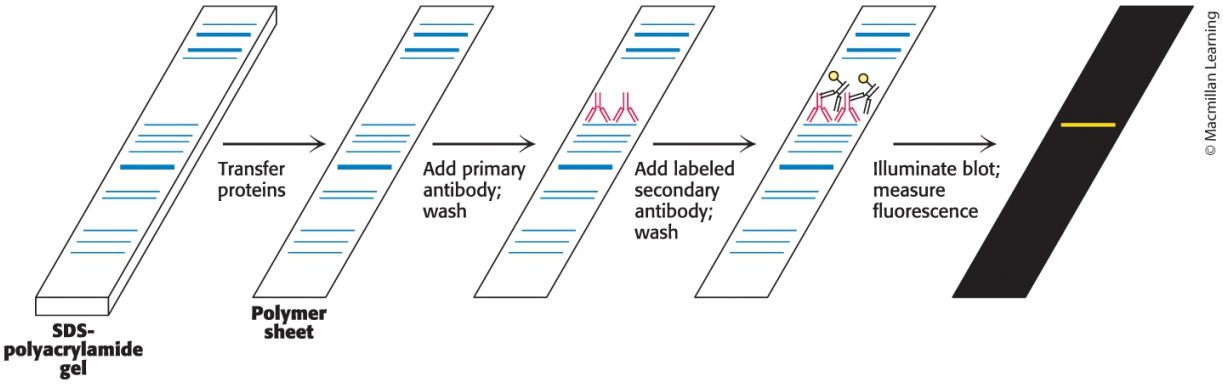
2. Spherical red spleen cells are shown to be harvested from the mouse.
3. Myeloma cell line is shown to be expanded by cell culture.
4. Spherical blue myeloma cells are shown to be obtained from the cell culture.
5. A tube filled with polyethylene glycol is shown. The tube is shown to contain the spleen and myeloma cells which fuse to produce hybrid cells. The hybrid cells are shown to be half blue and half red.
6. The hybrid cells are selected and grown.
7. The cells making antibody of desired specificity and selected.
8. A cell culture flask is shown to be used to propagate desired clones.
9. The clones are shown to be grown in mass culture of injected into mouse to induce tumors. Antibodies are obtained from both the mass culture and the tumor induced mouse.

Return to FIGURE 4.16. Schematic illustration of monoclonal antibody production

Extended description for FIGURE 4.17. Schematic illustration of indirect and sandwich ELISA for antigen or antibody detection

Part (A): Indirect ELISA.

1. Antigen-coated well: A well containing a buffer is shown. The floor of the well is shown to be coated with red spherical antigens. The well is then washed.
2. Specific antibody binds to antigen: Arms of the Y-shaped antibodies are shown to bind to antigens in the well. The well is then washed.
3. Enzyme-linked antibody binds to specific antibody: An arm of Y-shaped secondary antibody is shown to bind to the stem of the primary antibody bound to antigens. The stem of the

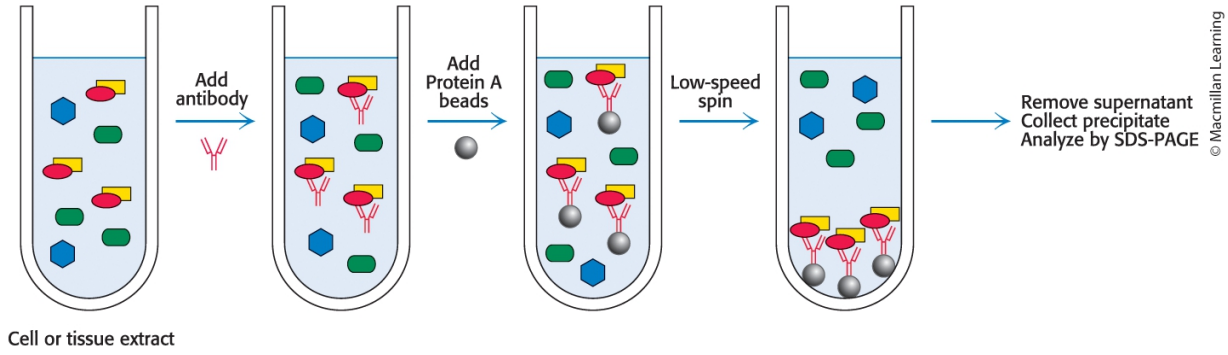


secondary antibody is linked to an enzyme. The well is then washed.
4. Substrate is added and converted by enzyme into colored product; the rate of color formation is proportional to the amount of specific antibody: The enzyme linked to the antibody-antigen complex is shown to convert the substrate to a yellow colored product.

Part (B): Sandwich ELISA.

1. Monoclonal antibody-coated well: well containing a buffer is shown. The floor of the well is shown to be coated with Y-shaped antibodies. The well is then washed.
2. Antigen binds to antibody: Red spherical antigens are shown to bind to the arms of the antibodies. The well is then washed.
3. A second monoclonal antibody, linked to enzyme, binds to immobilized antigen: The arms of the Y-shaped secondary antibody are shown to bind to the antigens bound to the primary antibody. The stem of the secondary antibody is linked to an enzyme. The well is then washed.
4. Substrate is added and converted by enzyme into colored product; the rate of color formation is proportional to the amount of specific antibody: The enzyme linked to the antibody-antigen complex is shown to convert the substrate to a yellow colored product.

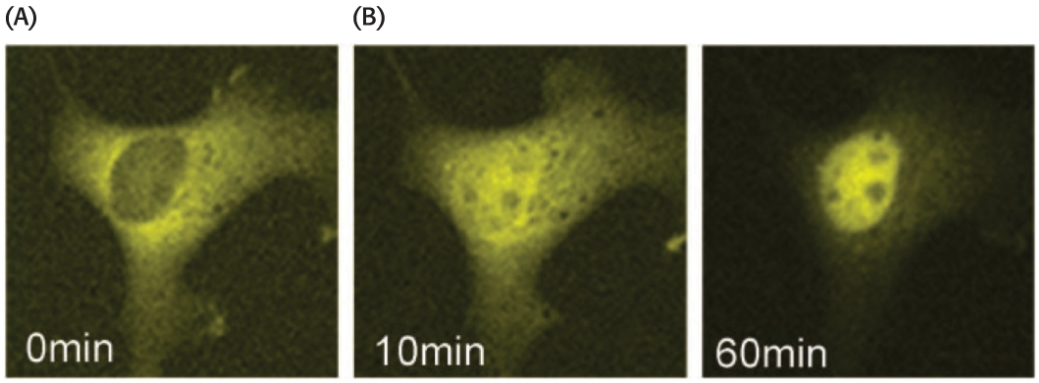
Return to FIGURE 4.17. Schematic illustration of indirect and sandwich ELISA for antigen or antibody detection



Extended description for FIGURE 4.18. Schematic illustration of western blotting to detect specific proteins

1. A long slab of S D S-polyacrylamide gel I shown. Several horizontal bands of proteins are shown on the gel. The bands are of varying thickness.
2. The proteins are shown to transferred to a polymer sheet. The bands on the polymer sheet have the exact same arrangement and thickness as those on the gel.
3. Y-shaped primary antibodies are added to the sheet. The antibodies are shown to bind specifically to only one band on the sheet. The sheet is then washed.
4. Labeled Y-shaped secondary antibodies are shown to be added to the sheet. These secondary antibodies are show to bind to the primary antibodies. The sheet is then washed.
5. The immunoblot is illuminated. Only the antibody-bound protein band is visible as a bright yellow band against a dark background. The fluorescence is measured.

Return to FIGURE 4.18. Schematic illustration of western blotting to detect specific proteins



Extended description for FIGURE 4.19. Schematic illustration of co-immunoprecipitation for the detection of protein binding partners

A test tube is shown to contain a cell or tissue extract. Several particles are seen as follows: a blue hexagon, a green oval, a red oval fused to a yellow rectangle. Y-shaped antibody are shown to be added to the tube. The antibodies are shown to bind to the ovals fused to the rectangles. Spherical Protein A beads are shown to bind to the stem of the antibodies. The antibodies bound to the beads and the protein of interest are shown to precipitate at the bottom of the tube upon low-speed spin. The supernatant is removed and the precipitate is analyzed by SDS-PAGE.

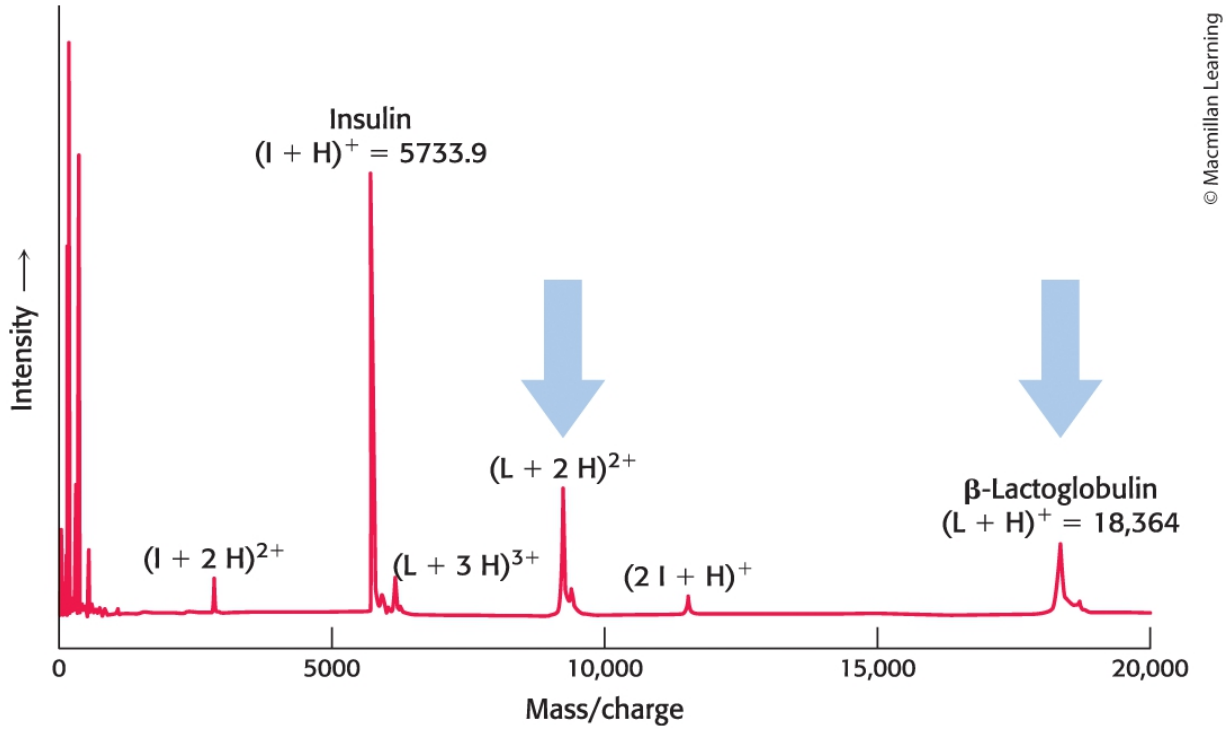
Extended description for FIGURE 4.23. Schematic illustration of MALDI-TOF mass spectrometer for measurement of ionized samples based on their mass-to-charge ratio



A laser is projected as a rectangular slab labeled "Beam splitter." A laser beam passes through the beam splitter to enter a glass prism in front of the beam splitter. A fraction of the laser pulse is directed down from the beam splitter to a clock that starts time. The laser beam is refracted inside the prism and then it hits a plate in the ionizer where the protein sample is ionized. This ionizing setup consists of a small plate inside a cylindrical enclosure. The ionized sample from this small plate then passes through central apertures of a series of larger discs. This setup of the discs inside the enclosure is labeled "Ion source." The enclosure is connected to a long tube with a smaller diameter labeled "Flight tube." Ions are shown to pass through this tube. Lighter ions pass ahead of the heavier ions to reach the detector at the other end of the flight tube. The detector is connected to a transient recorder which records the

time of flight of the ions (T O F). The recorder is connected to the clock.

A magnified view of the plate where the sample is ionized is shown. The sample is shown to be present on a matrix and the laser beam is shown to hit the sample.

Return to FIGURE 4.23. Schematic illustration of MALDI-TOF mass spectrometer for measurement of ionized samples based on their mass-to-charge ratio

Extended description for FIGURE 4.24. Mass spectrum obtained through MALDI-TOF mass spectrometry

The horizontal axis is labeled Mass over charge and ranges from 0 to 20,000 in increments of 5000 units. The vertical axis is labeled intensity. The following peaks are observed:

1. open parenthesis I plus 2 H close parenthesis superscript 2 plus at 2700 has a short peak
2. open parenthesis I plus 2 H close parenthesis superscript plus equals 5733.9 at 5500 has a very tall peak and is labeled insulin
3. open parenthesis L plus 3 H close parenthesis superscript 3 plus at 6000 has a short peak
4. open parenthesis L plus 2 H close parenthesis superscript 2 plus at 9000 has a relative taller peak and has a bold arrow pointing at it

5. open parenthesis 2 I plus H close parenthesis superscript plus at 12000 has a short peak
6. open parenthesis L plus H close parenthesis superscript plus at 18,500 has a relatively taller peak and is labeled beta-lactoglobulin. It has a bold arrow pointing at it.

Return to FIGURE 4.24. Mass spectrum obtained through MALDI-TOF mass spectrometry

Extended description for FIGURE 4.25. Method of Edman degradation for peptide sequencing

1. Stage 1: A peptide chain is shown to consist of 5 amino acid residues. The first two are labeled in blue and green respectively. An arrow points down to the next stage and is labeled “Labeling.”
2. Stage 2: A red triangle is shown to be connected to the first residue. An arrow points down to the next stage and is labeled “Release.”
3. Stage 3: The red triangle connected to the first amino acid residue is shown to separate from the peptide. An arrow points down to the next stage and is labeled “Labeling.”
4. Stage 4: A red triangle is shown to be connected to the second residue of the shortened peptide. An arrow points down to the next stage and is labeled “Labeling.”
5. Stage 5: The red triangle connected to the second amino acid residue is shown to separate from the peptide.

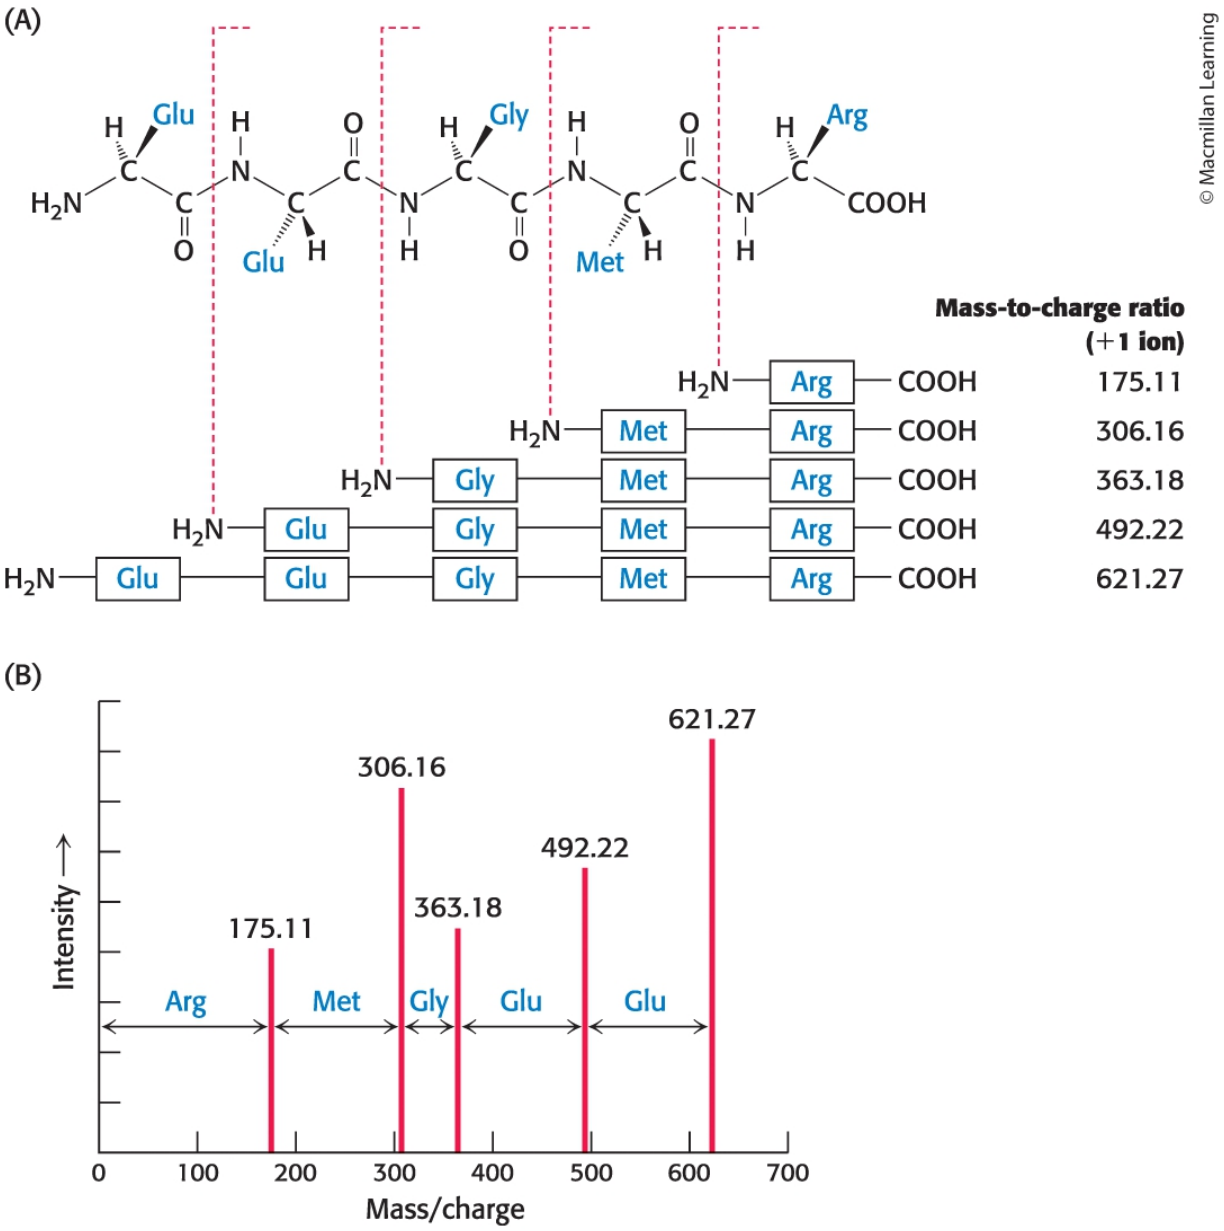
The steps until stage 3 are labeled “First round” and the steps preceding these are labeled “Second round.”

The steps involved in the first round are shown as two reactions:

The first reactant is Phenyl isothiocyanate which has the following structure: A benzene ring in a horizontal orientation consists of three alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to N on the right which is double bonded it C on the lower right. C is double bonded to S on the lower right.

The second reactant is the peptide chain with the first two residues being alanine and glycine followed by aspartic acid, phenylalanine, arginine, and glycine. Alanine has the following structure: A central C atom is single bonded to N H 2 on the upper left, single bonded to C H 3 on the lower left, wedge bonded to H on the lower right, and single bonded to a central C atom on the upper right. The central C atom on the upper right is double bonded to O above and single bonded to N on the glycine residue. Glycine has the following structure: A central C atom is single bonded to N H on the lower left, wedge bonded to H on the upper left, dash bonded to h on the upper right, and single bonded to a central C atom on the lower right. The central C atom is double bonded to O below and single bonded to the aspartic acid residue. The reaction arrow is labeled “Labeling.”

The product has the following structure: A benzene ring in a vertical orientation consists of 3 alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to N H on the upper right which is single bonded to a central C atom below. The central C atom is double bonded to S below and single bonded to N of the alanine residue of the peptide.



The reaction arrow from this product is labeled “release.”

The first product has the following structure: A benzene ring in a horizontal orientation consists of three alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to the first N of a 5-membered pentagonal ring in a vertical orientation. The pentagonal ring consists of 2 N and 3 C atoms. the first N atom occupies the first position which is the rightmost vertex. The second N bound to H occupies the third position which is the leftmost vertex. C 1 occupies the topmost vertex and is double bonded to S. C 2 is dash bonded to H on the right and wedge bonded to C H 3 on the lower right. C 3 is double bonded to O on the lower left. This product is labeled P T H alanine.

The second product is the shortened peptide consisting of glycine, aspartic acid, phenylalanine, arginine, and glycine.

Return to FIGURE 4.25. Method of Edman degradation for peptide sequencing

Extended description for FIGURE 4.26. Peptide sequencing with the help of tandem mass spectrometry

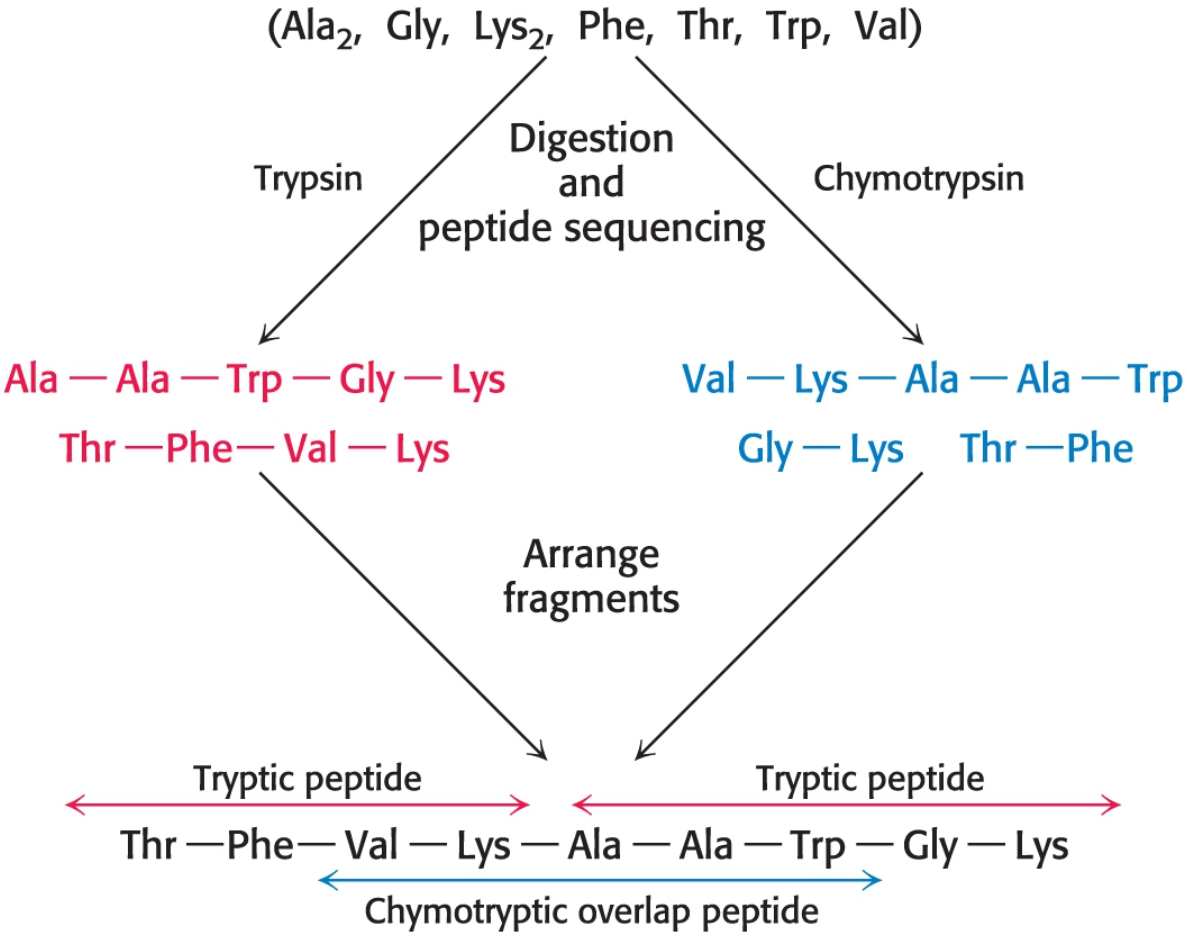
© Macmillan Learning

Part (A): A peptide is shown to have the following sequence from the amino to the carboxy terminal: Glutamic acid, Glutamic acid,

Glycine, Methionine, Arginine.

The mass to charge ratio (plus 1 ion) for the fragmented peptide is as follows:

Arginine: 175.11
Methionine, Arginine: 306.16
Glycine, Methionine, Arginine: 363.18
Glutamic acid, Glycine, Methionine, Arginine: 492.22
Glutamic acid, Glutamic acid, Glycine, Methionine, Arginine: 621.27



Part (B): A mass spectrum is shown. The horizontal axis is labeled mass over charge and ranges from 0 to 700 in increments of 100 units. The vertical axis is labeled intensity. The peaks are observed as follows:

The first peak (175.11) is at 185. The horizontal distance between the vertical axis is this peak is labeled Arginine.
The second peak (306.16) is at 305. The horizontal distance between the first peak is this peak is labeled Methionine.
The third peak (363.18) is at 370. The horizontal distance between the second peak is this peak is labeled Glycine.
The fourth peak (492.22) is at nearly 500. The horizontal distance between the third peak is this peak is labeled Glutamic acid.
The fifth peak (621.27) is at 615. The horizontal distance between the first peak is this peak is labeled Glutamic acid.

The peaks are of varying heights.

Return to FIGURE 4.26. Peptide sequencing with the help of tandem mass spectrometry

Extended description for FIGURE 4.27. Use of overlapping peptides to establish the order of sequenced peptides

© Macmillan Learning

A peptide sequence is as follows: Alanine subscript 2, Glycine, Lysine subscript 2, Phenylalanine, Threonine, Tryptophan, Valine

The peptide is digested and sequenced.

Trypsin digestion yields the following two sets of peptides:

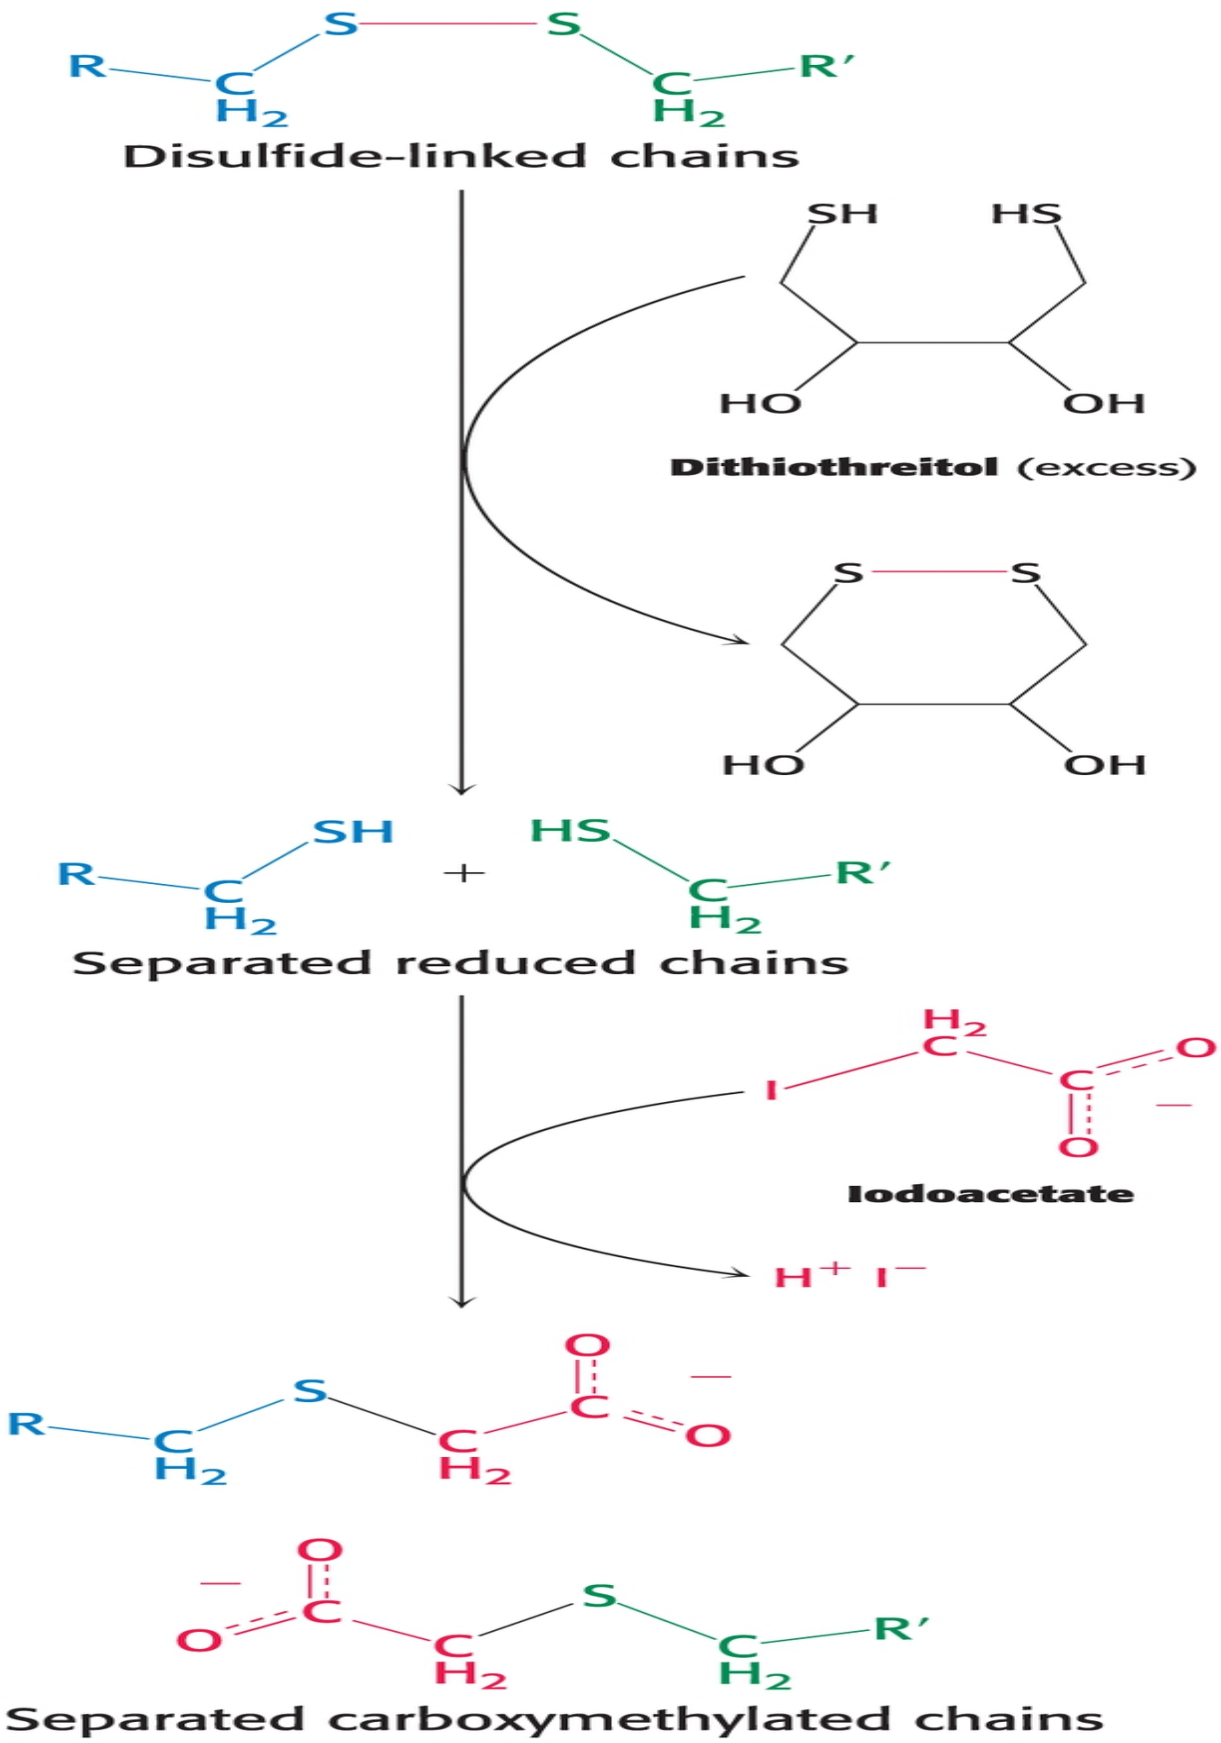
Alanine, Alanine, Tryptophan, Glycine, Lysine

Threonine, Phenylalanine, Valine, Lysine

Chymotrypsin digestion yields the following three sets of peptides:

Valine, Lysine, Alanine, Alanine, Tryptophan
Glycine, Lysine
Threonine, Phenylalanine

After arranging the fragments obtained by both the digestions, the following sequence is obtained:



Threonine, Phenylalanine, Valine, Lysine, Alanine, Alanine, Tryptophan, Glycine, Lysine

Residue 1 to 4 and 5 to 9 are labeled tryptic peptide. Residue 3 to 7 are labeled chymotryptic overlap peptide.

Return to FIGURE 4.27. Use of overlapping peptides to establish the order of sequenced peptides

Extended description for FIGURE 4.28. Use of reduction and alkylation reactions for the separation of disulfide-

linked polypeptides before sequencing

Disulfide-linked chains
Dithiothreitol (excess)
Separated reduced chains
Iodoacetate
Separated carboxymethylated chains

The first reactant is disulphide-linked chains which has the following structure: A central C atom bound to H 2 is single bonded to R on the left and single bonded to s on the upper right. S is single bonded to S on the right. The second S is single bonded to a C bound to H 2 on the lower right which is single bonded to R dash on the right. The disulphide bond is highlighted in red. The group to the left of the disulphide link is shown in blue and the group to the right is shown in green.

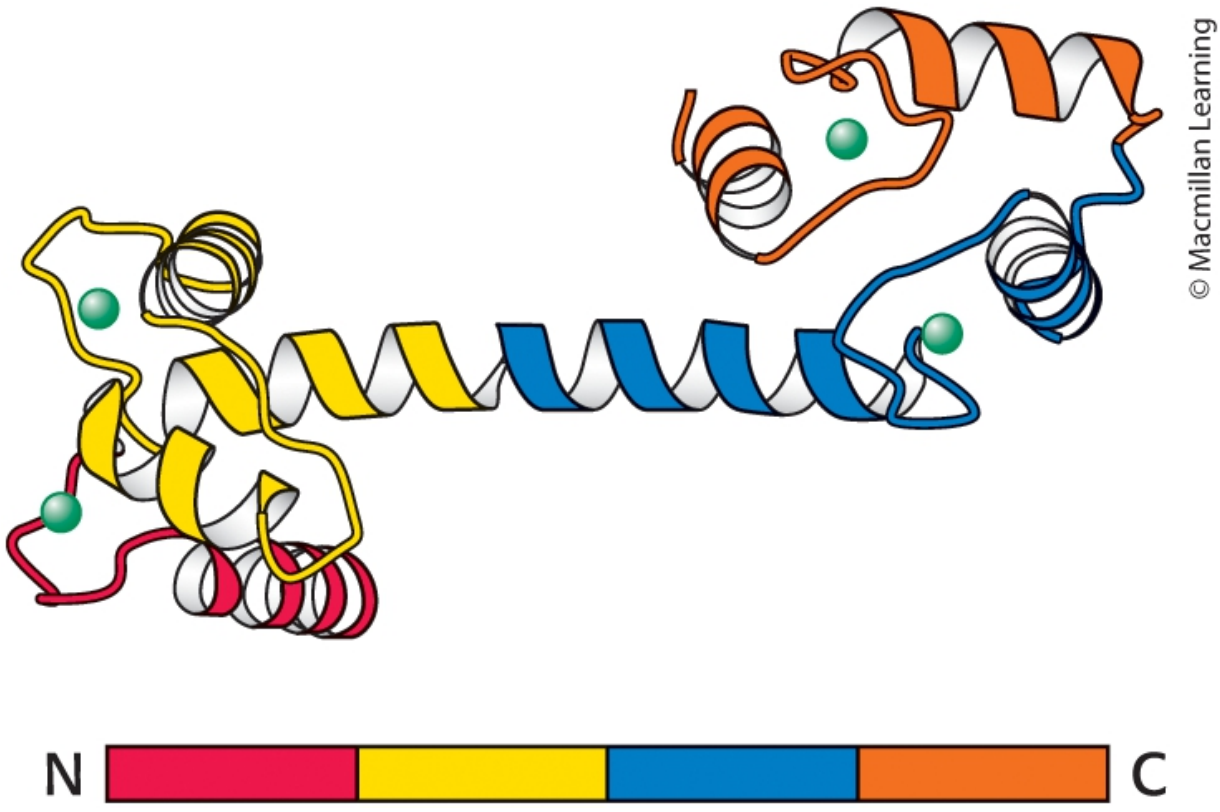
The formation of disulphide link in dithiothreitol (excess) is shown next to the reaction arrow. The structure of dithiothreitol is as follows: A 4-carbon alkane chain is depicted as a line structure using 3 zigzag lines such that it forms an U-shape. C 1 and C 4 are each single bonded to S H above. C 2 is single bonded to O H on the lower left. C 3 is single bonded to O H on the lower right. The product shows a single bond representing the disulphide linkage between the two S atoms.

The reaction leads to the formation of separated reduced chains.

The first product has the following structure: A central C atom bound to H 2 is single bonded to R on the upper left and S H on the upper right. This is shown in blue.

The second product has the following structure: A central C atom bound to H 2 is single bonded to S H on the upper left and single bonded to R dash on the upper right. This is shown in green.

A reaction arrow from these products leads to the separated carboxymethylated chains. The conversion of iodoacetate to H I is shown next to the reaction arrow. The structure of iodoacetate is as follows: I is single bonded to C bound to H 2 on the upper right which is single bonded to C on the lower right. C is partially double



bonded to O below and partially double bonded to O on the upper right. The C O O group carries a negative charge. The converted product is H superscript plus I superscript minus. The components of this conversion are shown in red.

The first product of the alkylation reaction has the following structure: A central C atom bound to H 2 is single bonded to R on the upper left and S on the upper right. This is shown in blue. S is single bonded to C bound to H 2 on the lower right which is single bonded to C on the upper right. C is partially double bonded to O above and partially double bonded to O on the lower right. The C O O group carries a negative charge. This is shown in red.

The second product of the alkylation reaction has the following structure: A central C atom bound to H 2 is single bonded to S on the upper left and single bonded to R dash on the upper right. This is shown in green. S is single bonded to C bound to H 2 on the lower left which is single bonded to c on the upper left. C is partially double bonded to O above and partially double bonded to O on the lower left. The C O O group carries a negative charge. This is shown in green.

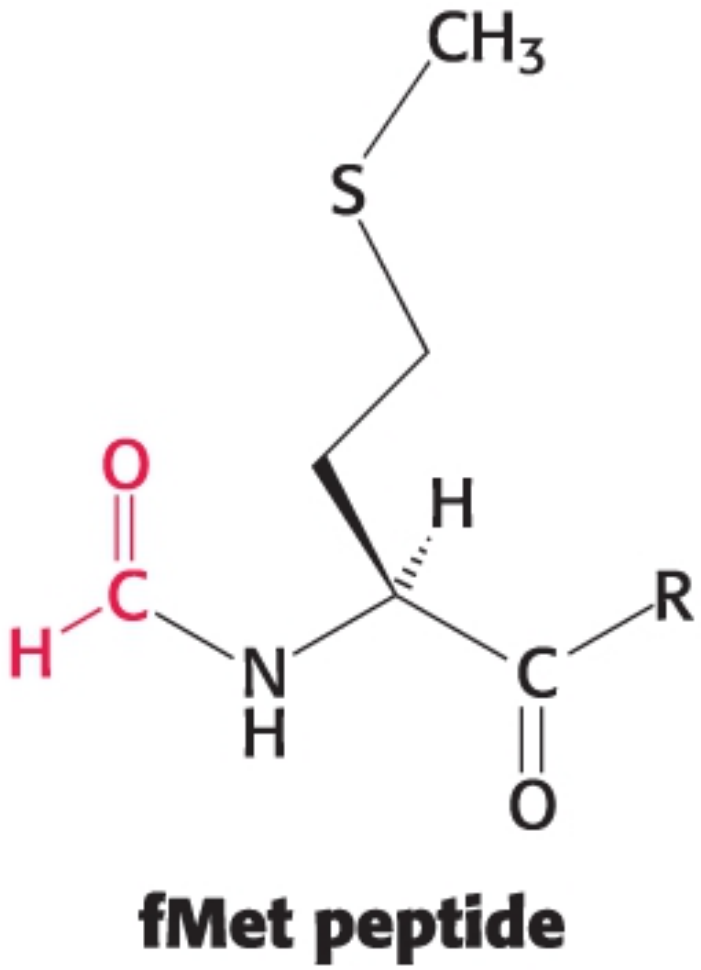
Extended description for FIGURE 4.30. Mass spectrum showing peptide mass fingerprinting



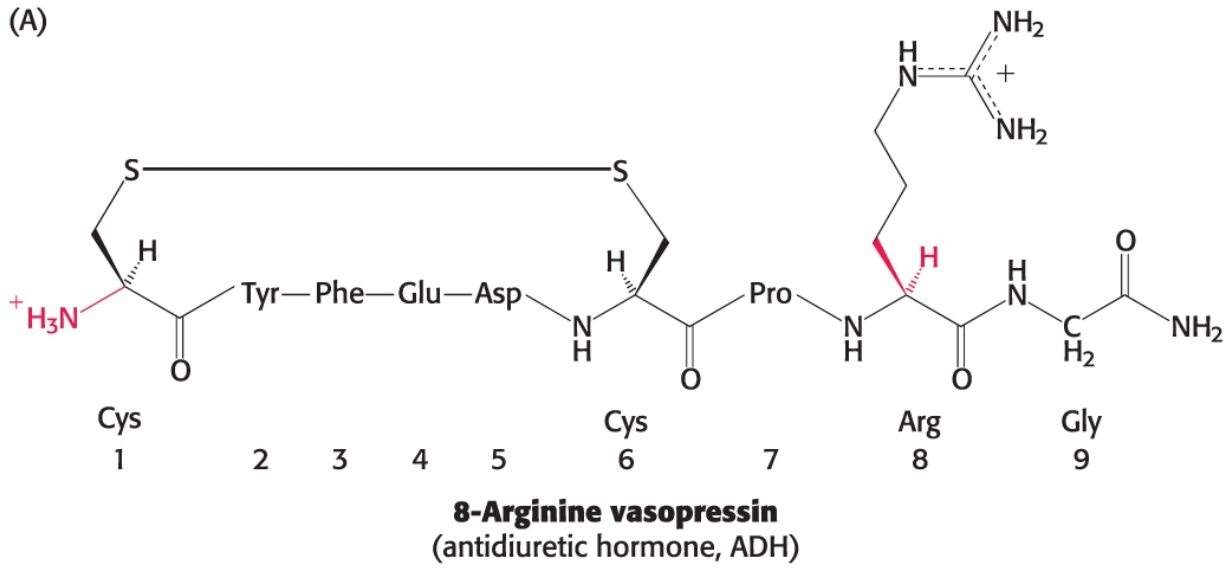
The horizontal axis is labeled mass over charge. The vertical axis is labeled Intensity. Several peaks of varying heights are seen in the spectrum. The following are indicated:

Blue triangle: Nup 120 p
Red diamond: Kap 122 p
Green circle: Kap 120 p

The peaks with the blue triangles are significantly taller than the rest. The peaks for the other two proteins are low lying.

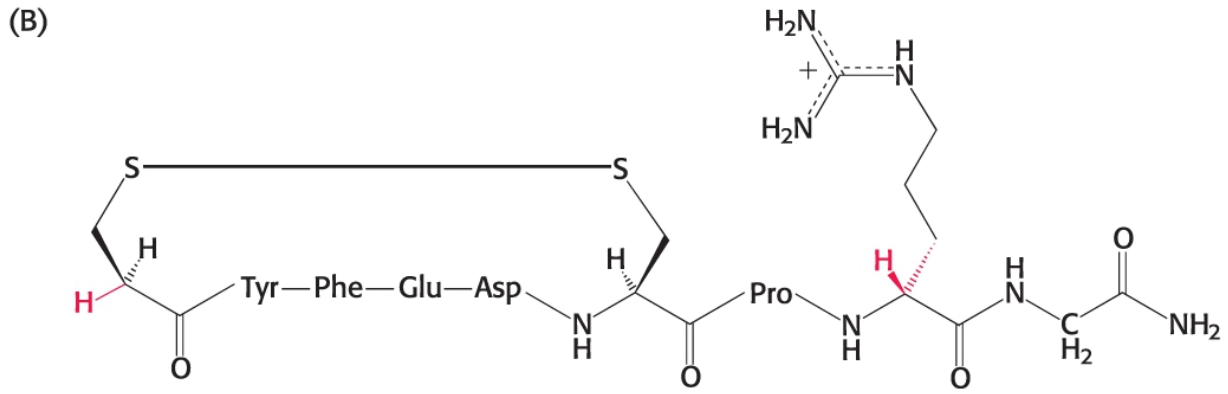
Return to FIGURE 4.30. Mass spectrum showing peptide mass fingerprinting

Extended description for Chemical structure of f Met peptide



fMet peptide

The structure is as follows: A C atom is dash bonded to H on the upper right, single bonded to C on the lower right, single bonded to N H on the lower left, and wedge bonded to C 1 of a 3-membered heteronuclear alkane chain above. The alkane chain consists of 2 C and 1 S atoms and is depicted by a line structure using 2 zigzag lines. The S atom occupies the third position and is single bonded to C H 3 on the upper right. The C on the lower right is single bonded to R on the upper right and double bonded to O below. The N on the lower



left is single bonded to a C atom on the upper left which is single bonded to H on the lower left and double bonded to O above. The C O H group is highlighted in red.

Return to Chemical structure of f Met peptide

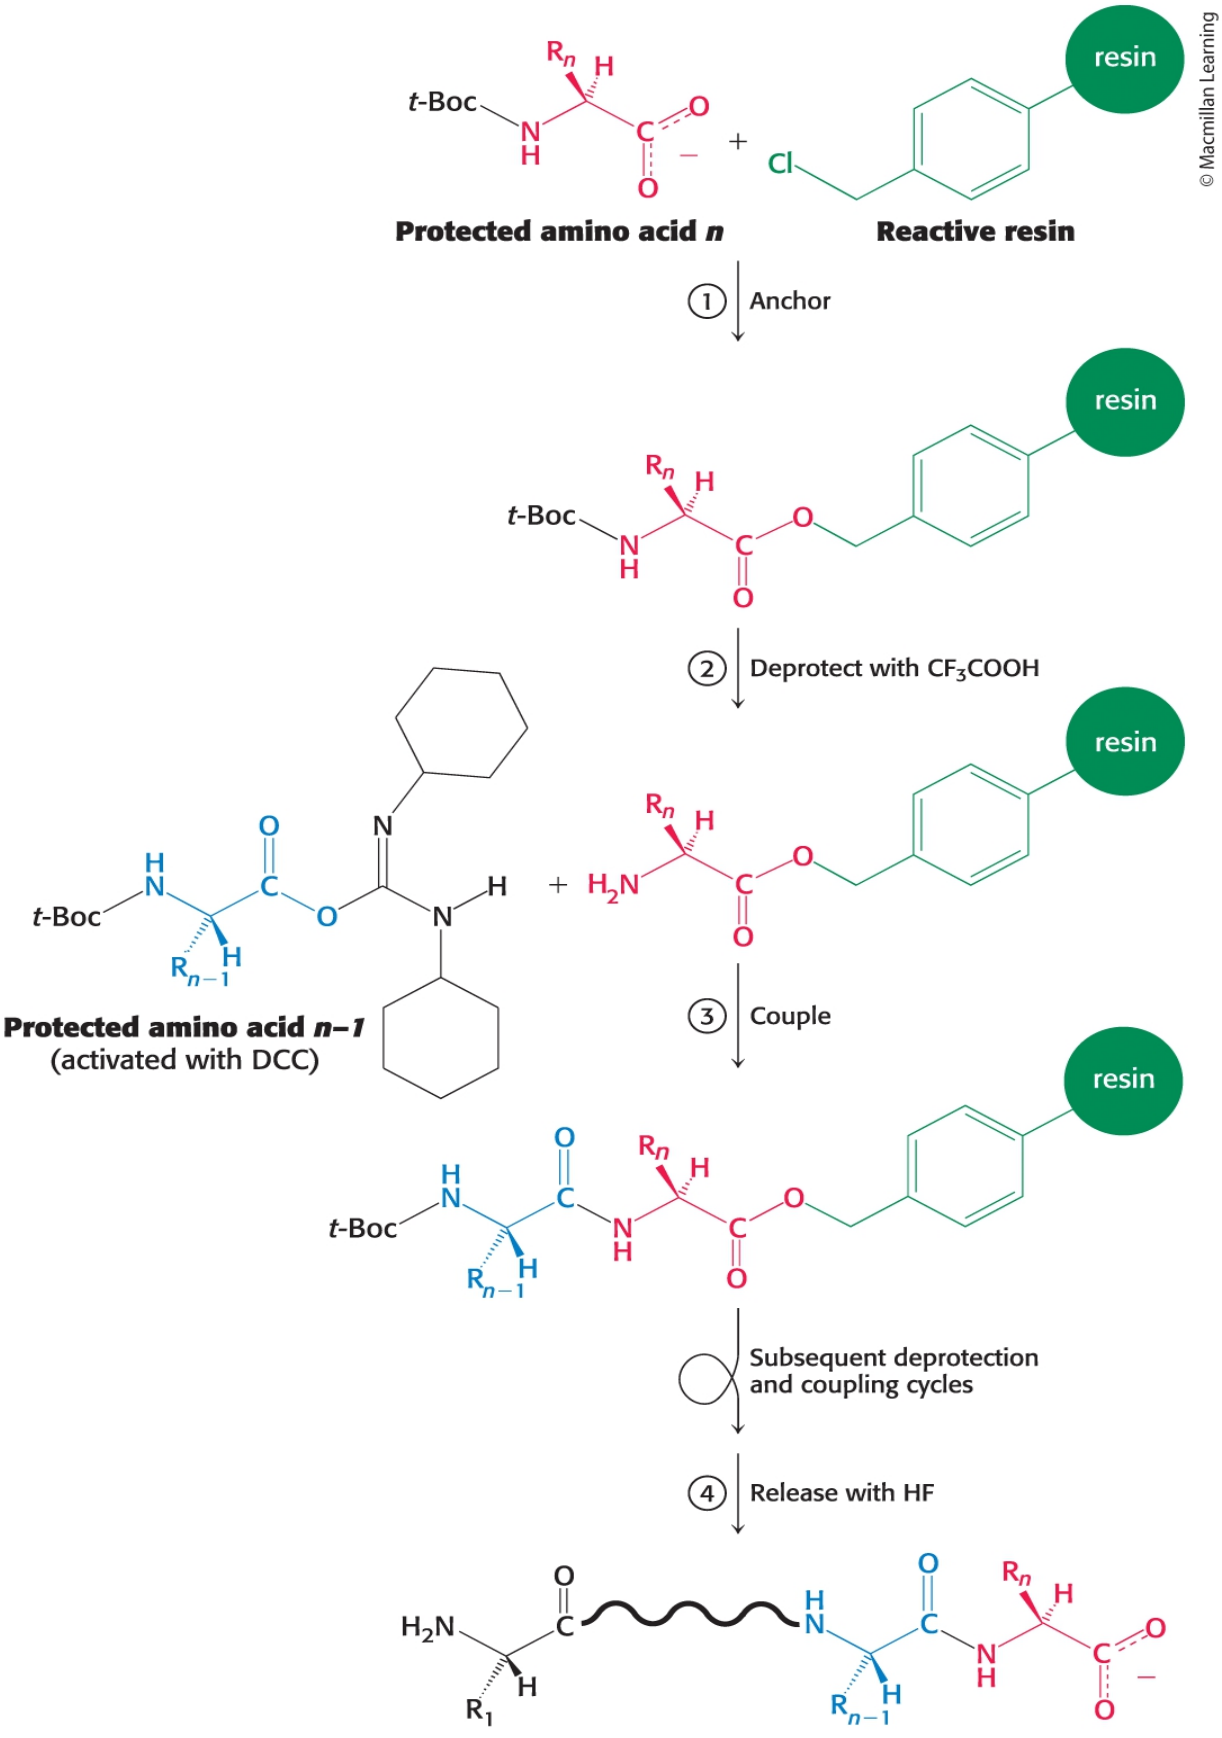
Extended description for FIGURE 4.31. Chemical structure of 8-arginine vasopressin and 1-Desamino-8-D-arginine vasopressin

8-Arginine vasopressin
(antidiuretic hormone, ADH)

1-Desamino-8-D-arginine vasopressin
(Desmopressin)

The structure of antidiuretic hormone (A D H), 8-Arginine vasopressin is as follows: It consists of 9 amino acid residues- Cysteine, Tyrosine, Phenylalanine, Glutamic acid, Aspartic acid, Cysteine, Proline, Arginine, Glycine. The structure of cysteine is as follows: a central C atom is single bonded to C on the lower right,

single bonded to N H 3 superscript plus on the lower left, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C atom on the lower right is double bonded to O below and single bonded to Tyrosine at the second position. C H 2 is single bonded to S on the upper right. This S atom is single bonded to S of the cysteine residue at the sixth position. Cysteine has the following structure: a central C atom is single bonded to C on the lower right, single bonded to N H on the lower left, wedge bonded to C H 2 on the upper right, and dash bonded to H on the upper left. C on the lower right is double bonded to O below and single bonded to proline at the seventh position. C H 2 is single bonded to S on the upper left which is bonded to S of cysteine at the first position. Arginine at the eighth position has the following structure: A central C atom is single bonded to C on the lower right, single bonded to N H on the lower left, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. C on the lower right is double bonded to O below and single bonded to N H of glycine at the ninth position. C H 2 on the upper left is single bonded to C 1 of 3-carbon alkane chain depicted as a line structure using two zigzag lines. C 3 of the alkane chain is single bonded to N bound to H on the upper right. N is partially double bonded to C on the right which is partially double bonded to N H 2 on the upper right and partially double bonded to N H 2 on the lower right. This group carries a positive charge. Glycine at the ninth position has the following structure: A central C H 2 group is single bonded to N H on the upper left and single bonded to C on the upper right. C on the upper right is single bonded to N H 2 on the lower right and double bonded to O above.



The structure of 1-Desamino-8-D-Arginine vasopressin, Desmopressin, is as follows: It has the same structure at A D H except for the position of the side chain of arginine at the eight position. The central C atom of arginine is wedge bonded to H on the upper left and dash bonded to C 1 of 3-carbon alkane chain

depicted as a line structure using two zigzag lines. C 3 of the alkane chain is single bonded to N bound to H on the upper left. N is partially double bonded to C on the left which is partially double bonded to N H 2 on the upper left and partially double bonded to N H 2 on the lower left. This group carries a positive charge.

Return to FIGURE 4.31. Chemical structure of 8-arginine vasopressin and 1-Desamino-8-D-arginine vasopressin

Extended description for FIGURE 4.32. Steps of solid-phase peptide synthesis involving repeated coupling

and deprotection

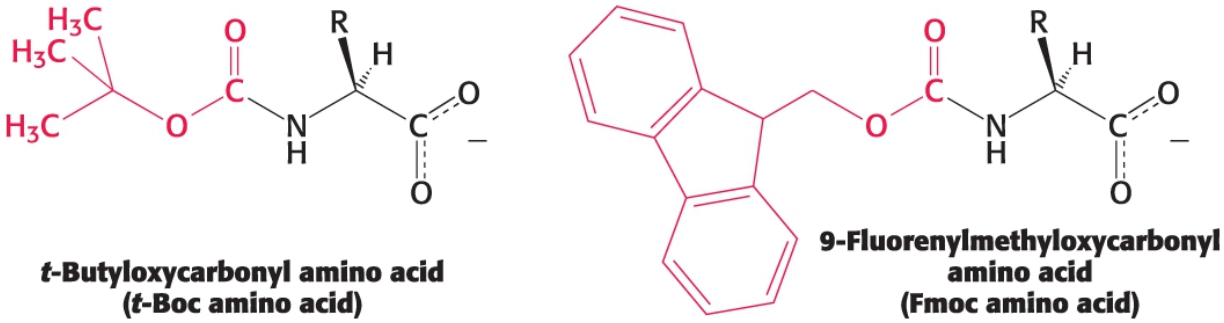
© Macmillan Learning

Step 1: Anchor. The first reactant is Protected amino acid n, which has the following structure: A central C atom is single bonded to N H on the lower left, single bonded to C on the lower right, dash bonded to H on the upper right, and wedge bonded to R n on the upper left. N H is single bonded to t-B o c on the upper left. The C on the lower right is partially double bonded to O on the upper right and partially double bonded to O below. The C O O group carries a negative charge. The second reactant is Reactive resin, which has the following structure: A benzene ring in a vertical orientation consists of 3 alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to a resin. C 5 is single bonded to C H 2 which is single bonded to C l on the upper left. The product has the following structure: A central C atom is single bonded to N H on the lower left, single bonded to C on the lower right, dash bonded to H on the upper right, and wedge bonded to R n on the upper left. N H is single bonded to t-B o c on the upper left. The C on the lower right is single bonded to O on the upper right and double bonded to O below. The O on the upper right is single bonded to C H 2 on the lower right. C H 2 is single bonded to C 5 of a benzene ring in a vertical orientation. It consists of 3 alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to a resin.

Step 2: Deprotect with C F 3 C O O H. The product of step 1 is the reactant here. The first product is Protected amino acid m minus 1 (activated with D C C), which has the following structure: A central C atom is single bonded to N H on the upper left, single bonded to C on the upper right, wedge bonded to H on the lower right, and dash bonded to R n minus 1 on the lower left. N H is single bonded to t-B o c on the lower left. C on the upper right is double bonded to O above and single bonded to O on the lower right. The O on the lower right is single bonded to C on the upper right which is double bonded to N above and single bonded to N on the lower right. The N above is single bonded to C 3 of a 6-carbon hexagonal ring in a

horizontal orientation. The N on the lower right is single bonded to H on the upper right and single bonded to C 1 of a 6-Carbon hexagonal ring below. The second product has the following structure: A central C atom is single bonded to N H 2 on the lower left, single bonded to C on the lower right, dash bonded to H on the upper right, and wedge bonded to R n on the upper left. The C on the lower right is single bonded to O on the upper right and double bonded to O below. The O on the upper right is single bonded to C H 2 on the lower right. C H 2 is single bonded to C 5 of a benzene ring in a vertical orientation. It consists of 3 alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to a resin.

Step 3: Couple. The products of step 2 are the reactants of step 3. The product has the following structure: A central C atom is single bonded to N H on the upper left, single bonded to C on the upper right, wedge bonded to H on the lower right, and dash bonded to R n minus 1 on the lower left. N H is single bonded to t-B o c on the lower left. C on the upper right is double bonded to O above and single bonded to N H on the lower right. N H is single bonded to a central C atom on the upper right. This C atom is wedge bonded to R n on the upper left, dash bonded to H on the upper right, and single bonded to C on the lower right. The C on the lower right is single bonded to O on the upper right and double bonded to O below. The O on the upper right is single bonded to C H 2 on the lower right. C H 2 is single bonded to C 5 of a benzene ring in a vertical orientation. It consists of 3 alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to a resin.



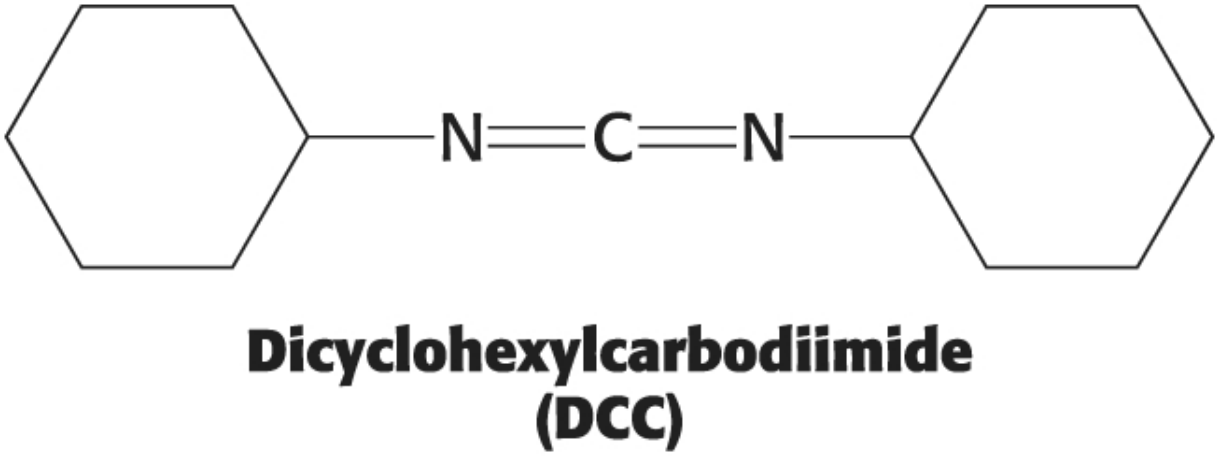
This product undergoes subsequent deprotection and coupling cycles.

Step 4: Release with H F. The product has the following structure: A central C atom is single bonded to N H 2 on the upper left, dash

bonded to R 1 on the lower left, wedge bonded to H on the lower right, and single bonded to C on the upper right. The C on the upper right is double bonded to O above and linked to N H of a peptide by a wavy bond. The second last amino acid has a central C atom single bonded to N H on the upper left, dash bonded to R n minus 1 on the lower left, wedge bonded to H on the lower right, and single bonded to C on the upper right. The C on the upper right is double bonded to O above and single bonded to N H of the last amino acid. The last amino acid has a central C atom single bonded to N H on the lower left, wedge bonded to R n on the upper left, dash bonded to H on the upper right, and single bonded to C on the lower right. The C on the lower right is partially double bonded to O on the upper right and partially double bonded to O below. This C O O group carries a negative charge.

Return to FIGURE 4.32. Steps of solid-phase peptide synthesis involving repeated coupling and deprotection

Extended description for Chemical structures of t-Butyloxycarbonyl amino acid and 9-Fluorenylmethyloxycarbonyl

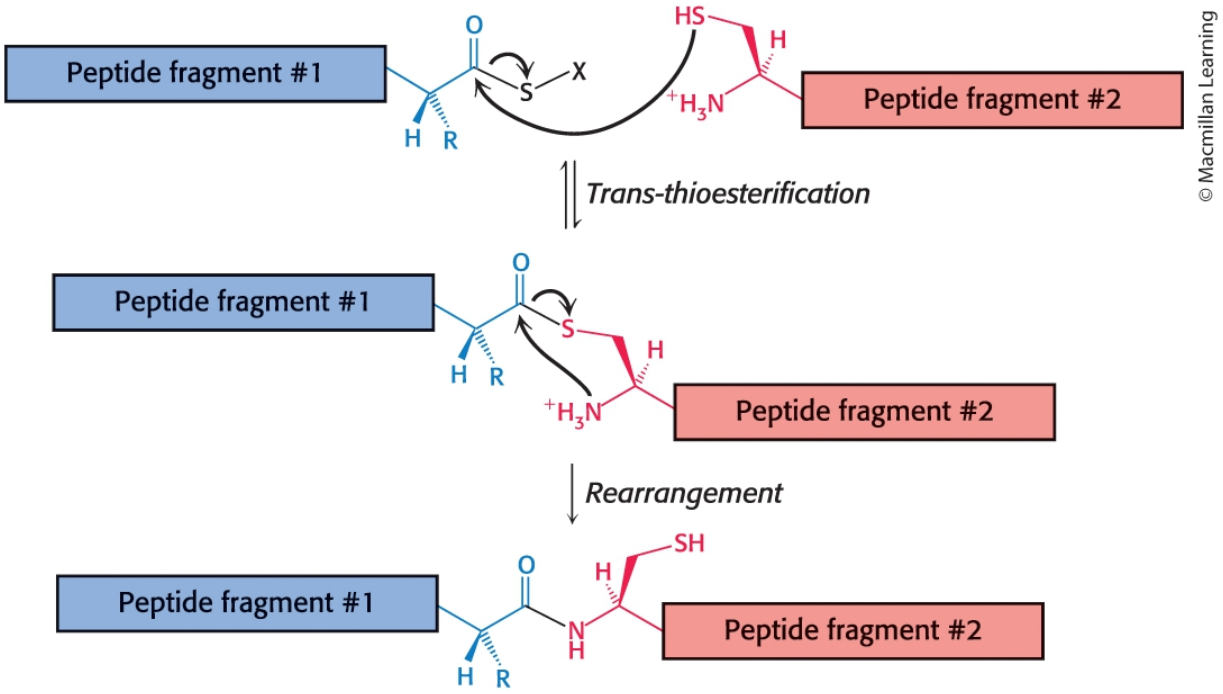


t-Butyloxycarbonyl amino acid has the following structure: A central C atom is single bonded to N bound to H on the lower left, single bonded to C on the lower right, dash bonded to H on the upper right, dash bonded to R on the upper left. The C on the lower right is partially double bonded to O on the upper right and partially double bonded to O below. The C O O group carries a negative charge. N is single bonded to C on the upper left which is double bonded to O above and single bonded to O on the lower left. The O on the lower left is single bonded to a central c atom on the upper left. The central C atom is single bonded to C H 3 on the lower left, single bonded to C H 3 on the upper left, and single bonded to C H 3 above. This entire group bonded to The amino acid is shown in red.

9-Fluorenylmethyloxycarbonyl has the following structure: A central C atom is single bonded to N bound to H on the lower left, single bonded to C on the lower right, dash bonded to H on the upper right, dash bonded to R on the upper left. The C on the lower right is partially double bonded to O on the upper right and partially double bonded to O below. The C O O group carries a negative charge. N is single bonded to C on the upper left which is double bonded to O

above and single bonded to O on the lower left. The O on the lower left is single bonded to a C H 2 group on the upper left. C H 2 is single bonded to C 2 of a 5-membered pentagonal ring in a vertical orientation. The ring consists of 5-C atoms. The pentagonal ring is fused to a benzene ring in a vertical orientation such that C 1 and C 5 of the pentagonal ring are C 3 and C 4 of the benzene ring, respectively. The benzene ring consists of 3 alternating double bonded between C 1 and C 2, C 3 and C 4, and C 5 and C 6. The pentagonal ring is fused to a second benzene ring in a horizontal orientation such that C 3 and C 4 of the pentagonal ring are C 6 and C 5 of the benzene ring, respectively. The benzene ring consists of 3 alternating double bonded between C 1 and C 2, C 3 and C 4, and C 5 and C 6. The entire group bonded to the amino acid is shown in red.

Return to Chemical structures of t-Butyloxycarbonyl amino acid and 9-Fluorenylmethyloxycarbonyl



Extended description for Chemical structure of dicyclohexylcarbodiimide

Dicyclohexylcarbodiimide, D C C, has the following structure: C 1 of a 6-carbon hexagonal ring in a horizontal orientation is single bonded to N. N is double bonded to C on the right which is double bonded to N on the right. The second N is single bonded to C 4 of a 6-Carbon hexagonal ring in a horizontal orientation.

Return to Chemical structure of dicyclohexylcarbodiimide

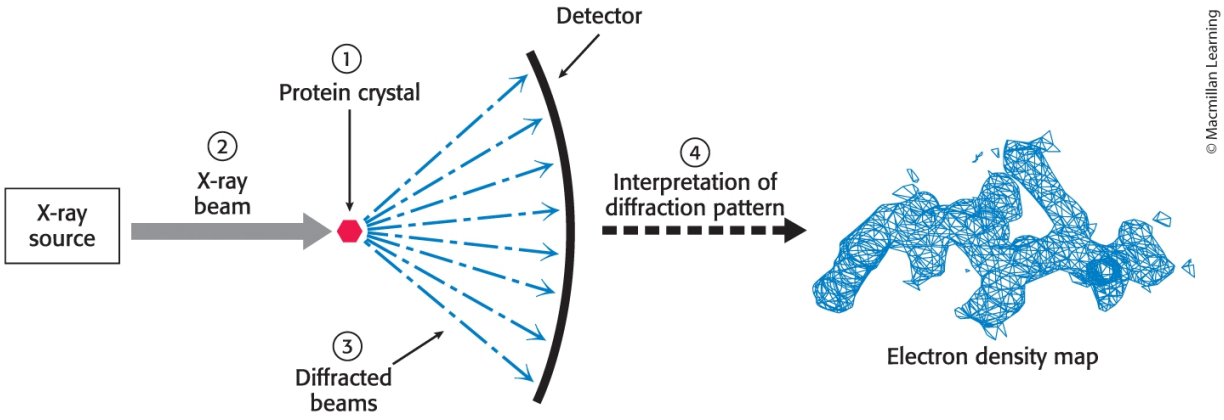
Extended description for FIGURE 4.33. Native chemical ligation reaction for linking two synthetic peptides

© Macmillan Learning

The first reactant is Peptide fragment number 1 which has the following structure: A central C atom is single bonded to C on the upper right, dash bonded to R on the lower right, wedge bonded to H on the lower left, and has a single bond on the upper left. The C on the upper right is double bonded to O above and single bonded to S on the lower right which is single bonded to X on the upper right. The second reactant is Peptide fragment number 2 which has the following structure: A central C atom is single bonded to N H 3 superscript plus on the lower left, wedge bonded to C H 2 on the upper left, dash bonded to H on the upper right, and has a single bon on the lower right. The C H 2 on the upper right is single bonded to S H on the left.

An arrow points from S H of peptide fragment number 2 to the C double bonded to O on peptide fragment number 1. Another arrow points from the C double bonded to O on peptide fragment number 1 to S of the same fragment.

A reversible reaction arrow from these reactants is labeled Trans-thioesterification.



In the product, S of the first fragment is single bonded to C H 2 of the second fragment.

A reaction arrow from this product is labeled Rearrangement.

In the product of rearrangement, the C double bonded to O of the first fragments is single bonded to N H of the second fragment. In the second fragment, the central C atom is dash bonded to H on the upper left and wedge bonded to C H 2 on the upper right which is single bonded to S H on the right.

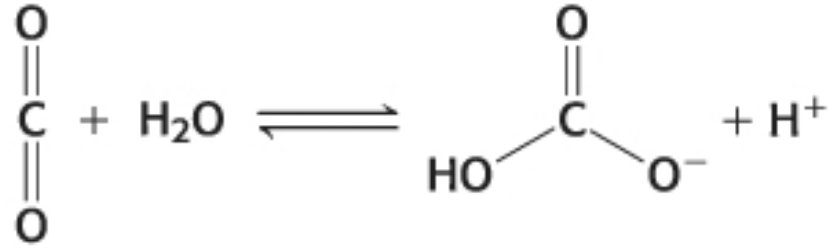
Extended description for Reaction showing cleavage of cystine by performic acid to produce two molecules of cysteic acid

The reactant has the following structure: A central C atom is single bonded to N H on the upper left, wedge bonded to C H 2 on the upper right, dash bonded to H on the lower right, and single bonded to C on the lower left. The N H on the upper right has a single bond on the upper right. The C on the lower left is double bonded to O on the left and has a single bond on the lower right. C H 2 on the upper right is single bonded to S on the lower right. S is single bonded to

another S on the right. The second S is single bonded to C H 2 on the lower right. C H 2 is single bonded to a central C atom on the upper right. The central C atom is dash bonded to H on the upper left, single bonded to C on the upper right, and single bonded to N H on the lower right. The C on the upper right is double bonded to O on the right and has a single bonded on the upper left. The N H on the lower right has a single bond on the lower left.



The reaction arrow is labeled Performic acid, which has the following structure: H, single bond, C, single bond, O, single bond, O, single bond, H. C is double bonded to O above.

The products are labeled Cysteic acid. The first product has the following structure: A central C atom is single bonded to N H on the upper left, wedge bonded to C H 2 on the upper right, dash bonded to H on the lower right, and single bonded to C on the lower left. The N H on the upper right has a single bond on the upper right. The C on the lower left is double bonded to O on the left and has a single bond on the lower right. C H 2 on the upper right is single bonded to S O 3 superscript minus on the lower right.

The second product has the same structure as the first product but is flipped along its axis.

Extended description for Chemical equation showing the hydration of carbon dioxide

The reaction is reversible and consists of two reactants and two products. The first reactant has the following structure: A central C atom is double bonded to O above and below. The second reactant is H 2 O. The first product has the following structure: A central C atom is single bonded to O superscript minus on the lower right, single bonded to O H on the lower left, and double bonded to O above. The second product is H superscript plus ion.

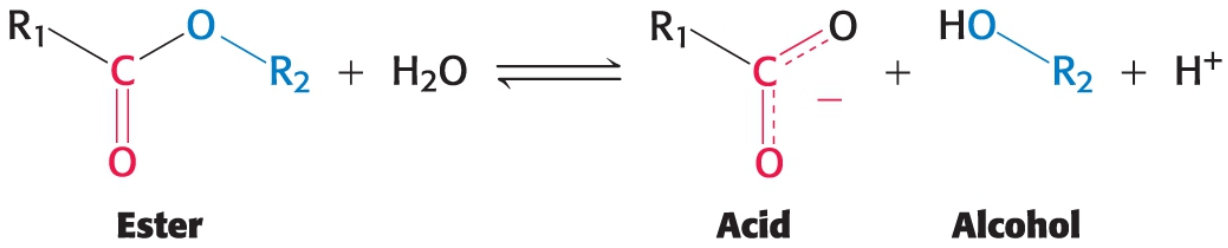
Return to Chemical equation showing the hydration of carbon dioxide

Extended description for Chemical equation showing the hydrolysis of a peptide bond

The reaction is reversible and consists of two reactants and two products.

The first reactant is a peptide which has the following structure: A 2 N and 4 C heteronuclear alkane chain is depicted as a line structure using 5 zigzag lines. The N atoms occupy the first and fourth position. The first N atom is single bonded to H below. It has a zigzag line on the upper left. C 1 is wedge bonded to R subscript 1 on the upper left and dash bonded to H on the upper right. C 2 is double bonded to O below and is highlighted in red. The second N atom is bound to H above and highlighted in blue. C 3 is dash bonded to R subscript 2 on the lower left and wedge bonded to H on the lower right. C 4 is double bonded to O above. It has an open single bond on the lower right.

The second reactant is H 2 O.



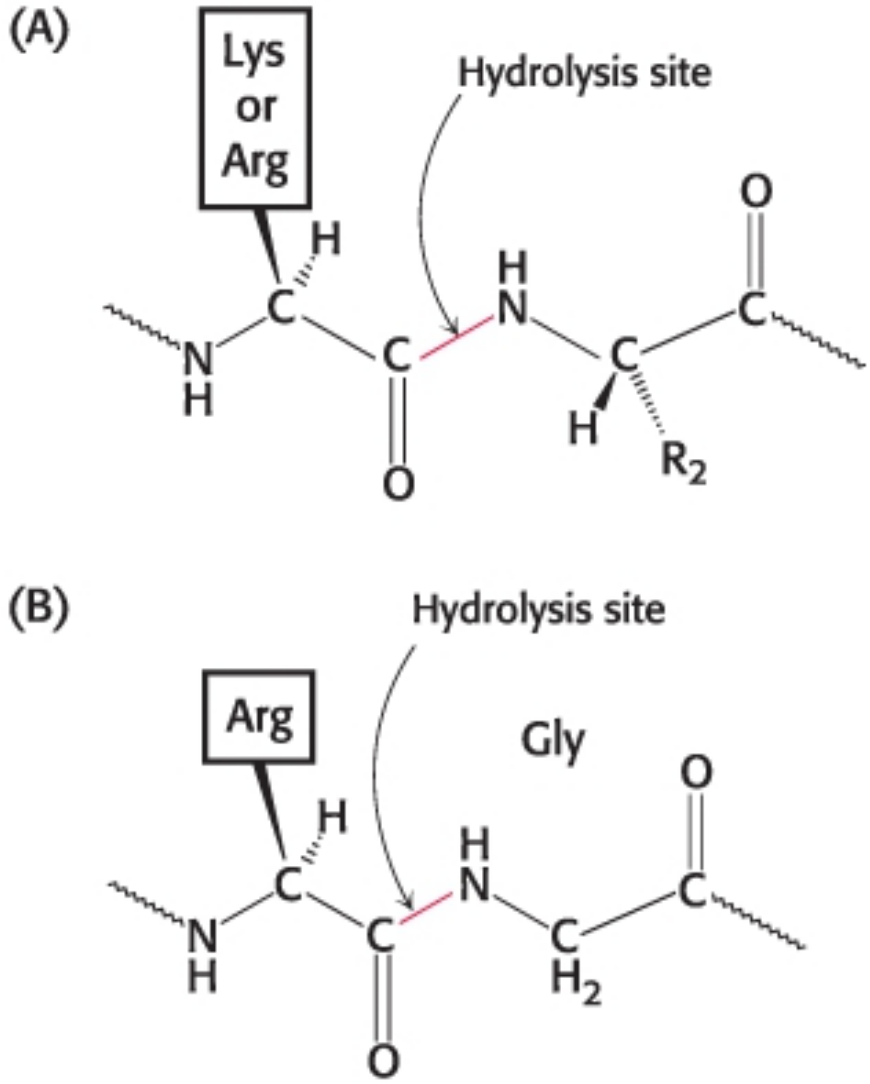
The first product is the carboxyl component which has the following structure: A 1 N and 2 C heteronuclear alkane chain is depicted as a line structure using 2 zigzag lines. The N atom occupies the first position and is single bonded to H below. It has an open single bond on the upper left. C 1 is wedge bonded to R subscript 1 on the upper

left and dash bonded to H on the upper right. C 2 is single bonded to O below and on the upper right with a resonance bond shared between C and the O atoms. C 2 and its associated bonds are highlighted in red.

The second product is the amino component which has the following structure: A 1 N and 2 C heteronuclear alkane chain is depicted as a line structure using 2 zigzag lines. The N atom occupies the first position. It is bound to H 3 superscript plus. This N H 3 superscript plus group is highlighted in blue. C 1 is dash bonded to R subscript 2 on the lower left and wedge bonded to H on the lower right. C 2 is double bonded to O above. It has zigzag line on the lower right.

Return to Chemical equation showing the hydrolysis of a peptide bond

Extended description for Chemical equation showing the hydrolysis of ester bond



The reaction is reversible and consists of two reactants and three products. The first reactant is an ester and has the following structure: A central C atom is single bonded to R subscript 1 on the upper left, single bonded to O on the upper right, and double bonded to O below. The O atom on the upper right is single bonded to R subscript 2 on the lower right. C, double bond, O is highlighted in red while O, single bond, R subscript 2 is highlighted in blue. The second reactant is H 2 O.

The first product is an acid that has the following structure: A central C atom is single bonded to R subscript 1 on the upper left and single bonded to O below and on the upper right with a resonance bond shared between C and the two O atoms. The C and O atom below and their associated bonds are highlighted in red. The second product is an alcohol which has the following structure: O H, single bond, R subscript 2. The O atom of the O H group, single bond, and R subscript 2 are highlighted in blue. The third product is H superscript plus ion.

Return to Chemical equation showing the hydrolysis of ester bond

Extended description for FIGURE 5.1. Chemical structures showing the high specificity of enzymes for their substrates and chemical reactions

Part (A): It shows the structure of a peptide and hydrolysis site cleaved by trypsin.

The structure of the peptide is as follows: A 2 N and 4 C heteronuclear alkane chain is depicted as a line structure using 5

zigzag lines. The N atoms occupy the first and fourth positions. The first N atom is bound to H below. It has a zigzag line on the upper left. C 1 is wedge bonded to either lysine or arginine on the upper left and dash bonded to H on the upper right. C 2 is double bonded to O below. The second N atom is single bonded to H above. C 3 is dash bonded to R subscript 2 on the lower right and wedge bonded to H on the lower left. C 4 is double bonded to O above. It has a zigzag line on the lower right. The single bond between C 2 and the second N atom is labeled hydrolysis site and is highlighted in red.

Part (B): It shows the structure of a peptide and hydrolysis site cleaved by thrombin.

The structure of the peptide is as follows: A 2 N and 4 C heteronuclear alkane chain is depicted as a line structure using 5 zigzag lines. The N atoms occupy the first and fourth positions. The first N atom is single bonded to H below. It has a zigzag line on the upper left. C 1 is wedge bonded to arginine on the upper left and dash bonded to H on the upper right. C 2 is double bonded to O below. The second N atom is bound to H above. C 3 is single bonded to H 2 below. C 4 is double bonded to O above. It has a zigzag line on the lower right. The single bond between C 2 and the second N atom is labeled hydrolysis site and is highlighted in red. There is a glycine residue above C 3.

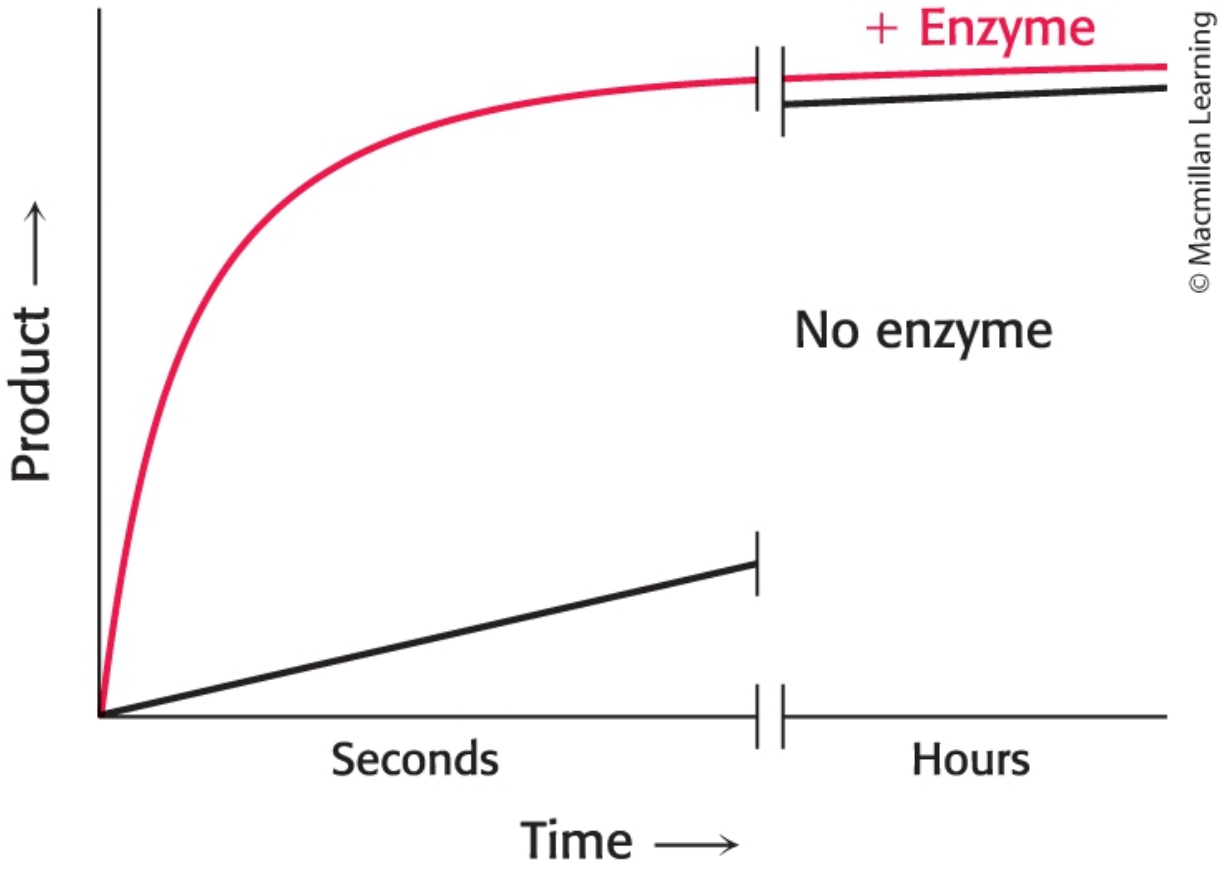
Extended description for Chemical equation showing the conversion of dihydroxyacetone phosphate into glyceraldehyde-3-phosphate



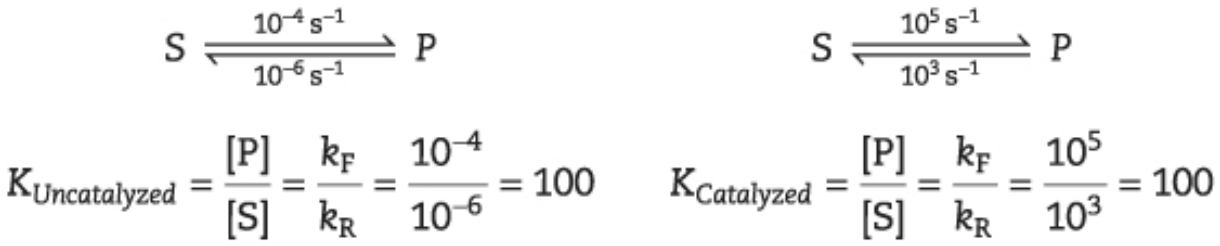
The reaction is reversible and consists of one reactant and one product.

The reactant is dihydroxyacetone phosphate (D H A P) and has the following structure: A three-carbon alkane chain is depicted as a line structure using two zigzag lines. C 1 is single bonded to O H on the upper left and bound to H 2 below. C 2 is double bonded to O above. C 3 is single bonded to O P O 3 superscript 2 minus on the upper right and bound to H 2 below.

The product is glyceraldehyde 3-phosphate (G A P) and has the following structure: A three-carbon alkane chain is depicted as a line structure using two zigzag lines. C 1 is double bonded to O on the upper left and single bonded to H below. C 2 is dash bonded to O H on the upper left and wedge bonded to H on the upper right. C 3 is single bonded to O P O 3 superscript 2 minus on the upper right and bound to H 2 below.

Return to Chemical equation showing the conversion of dihydroxyacetone phosphate into glyceraldehyde-3-phosphate

Extended description for FIGURE 5.2. Graphical representation of the unperturbed equilibrium point of a reaction in the presence and absence of an enzyme



The horizontal axis is labeled time. The first half of this axis is labeled seconds and the second half is labeled hours. The two halves are separated by an axis break. The vertical axis is labeled product.

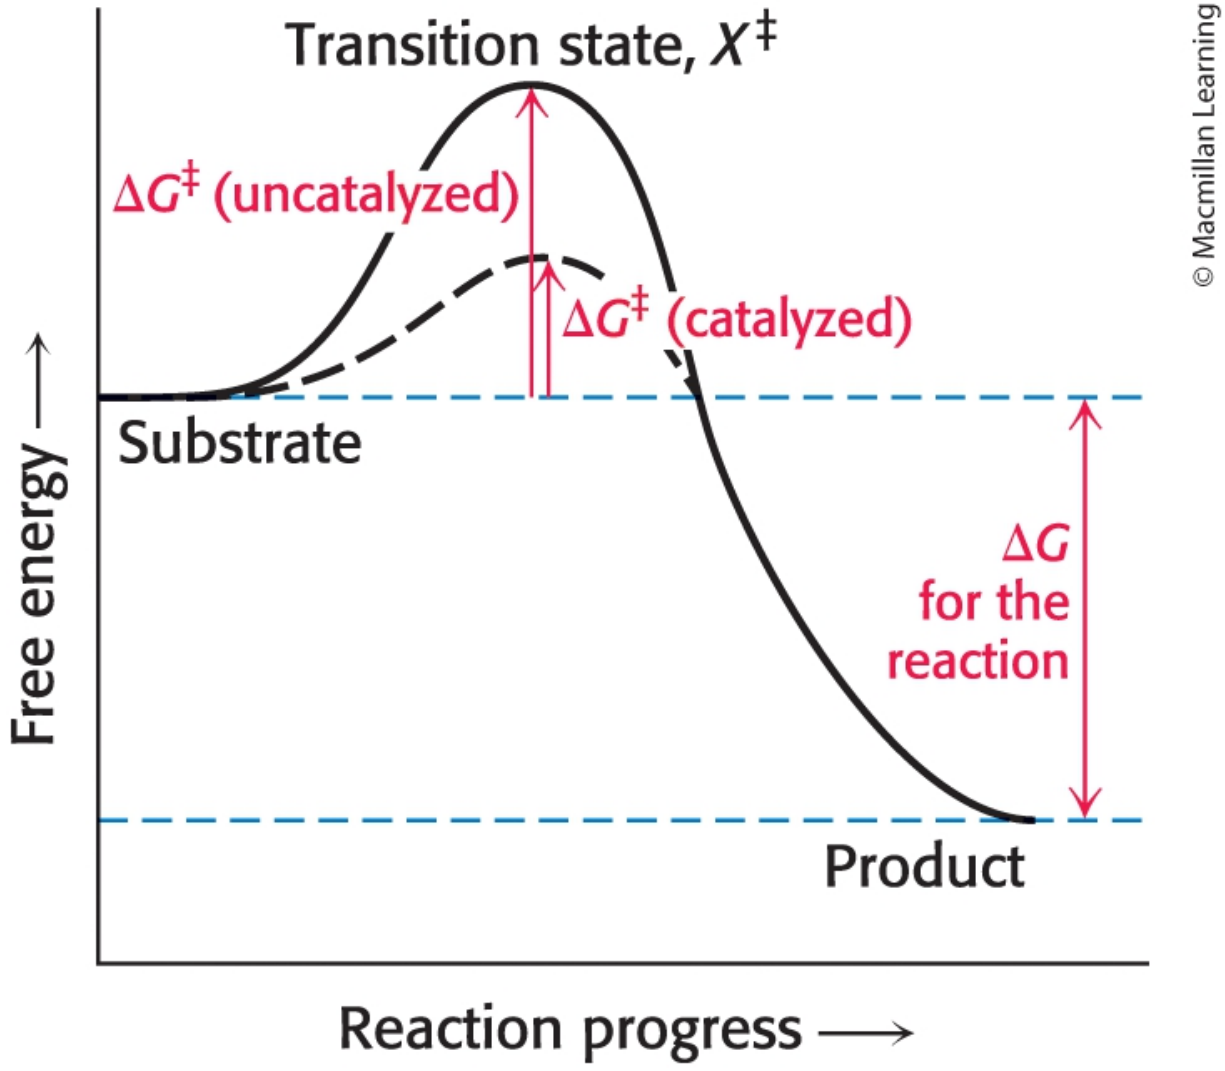
In the presence of an enzyme, the product formation curve rises rapidly (up to roughly 95 percent) in the seconds phase and then plateaus in the hours phase. In the absence of an enzyme, the product formation curve rises linearly up to less than the half of the product concentration at the end of the seconds phase. A break is

shown as short vertical line at the tip of the straight line. The remaining product is formed in the hours phase. It is depicted as a straight horizontal line, just below the plateau of the first curve in the hours phase. Both curves still terminate at the same point.

Return to FIGURE 5.2. Graphical representation of the unperturbed equilibrium point of a reaction in the presence and absence of an enzyme

Extended description for Calculation of equilibrium constants for catalyzed and uncatalyzed reaction

The first reaction shows the reversible conversion of S to P. The top forward arrow is labeled 10 superscript minus 4 baseline s superscript minus 1. The bottom backward arrow is labeled 10 superscript minus 6 baseline s superscript minus 1.



The calculation of K subscript uncatalyzed is depicted as follows: K subscript uncatalyzed baseline equals the concentration of P over concentration of S equals StartFraction lowercase k subscript F over lowercase k subscript R EndFraction equals 10 superscript minus 4 over 10 superscript minus 6 equals 100.

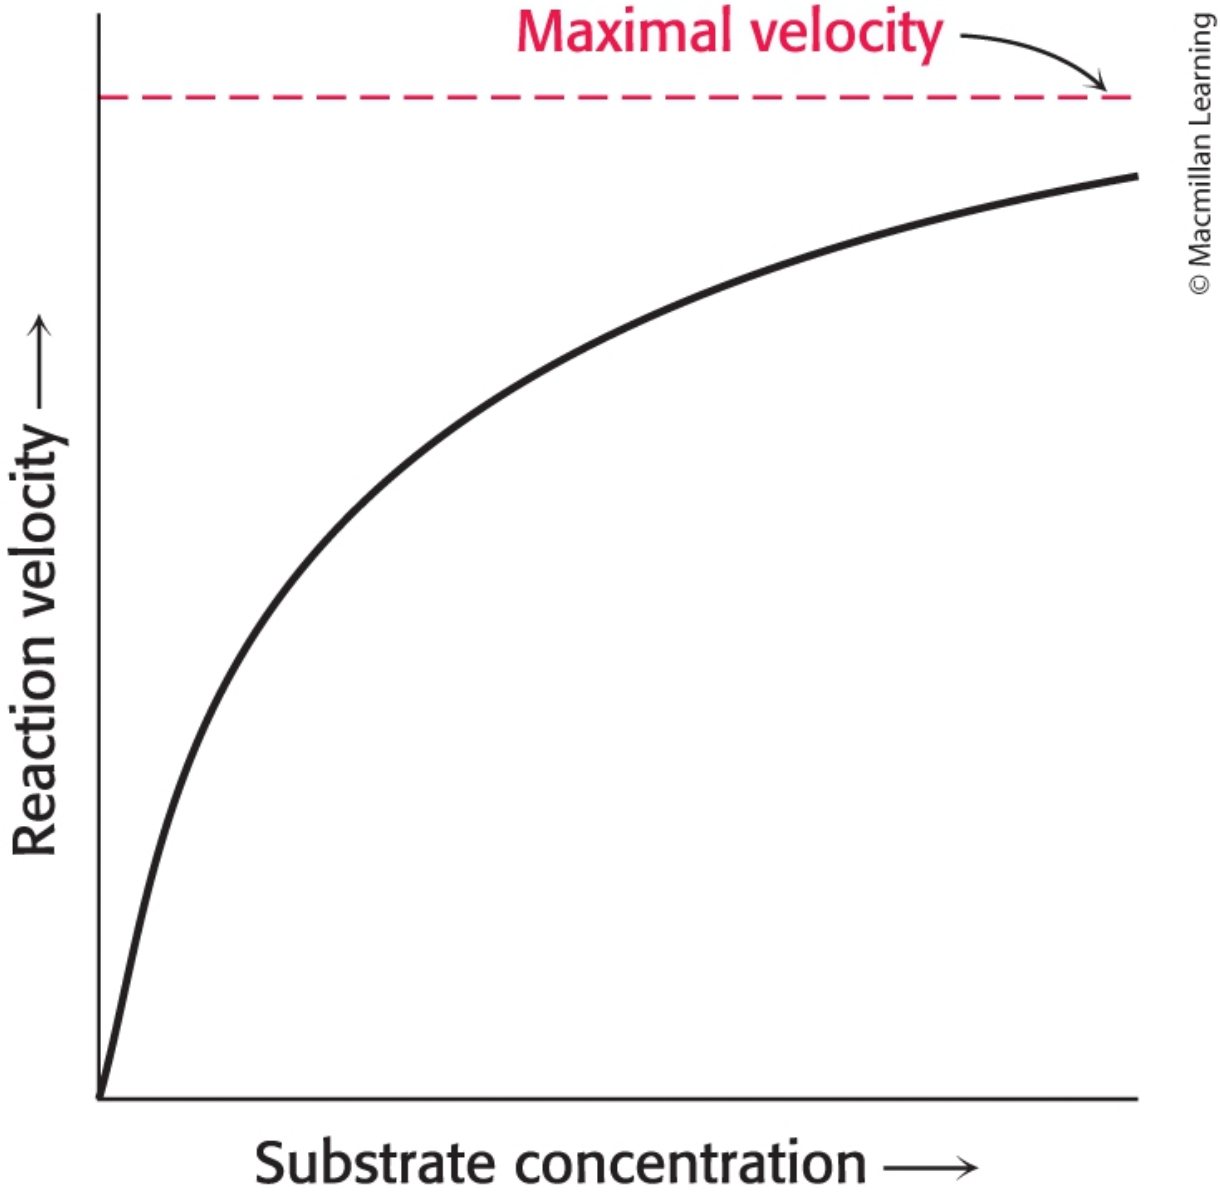
The second reaction shows the reversible conversion of S to P. The top forward arrow is labeled 10 superscript 5 baseline s superscript minus 1. The bottom backward arrow is labeled 10 superscript 3 baseline s superscript minus 1.

The calculation of K subscript catalyzed is depicted as follows: K subscript catalyzed baseline equals the concentration of P over concentration of S equals StartFraction lowercase k subscript F over lowercase k subscript R EndFraction equals 10 superscript 5 over 10 superscript 3 equals 100.

Return to Calculation of equilibrium constants for catalyzed and uncatalyzed reaction

Extended description for FIGURE 5.3. Graphical representation of the enzyme-mediated acceleration of a reaction by lowering of the free energy of activation

The horizontal axis is labeled reaction progress. The vertical axis is labeled free energy. Two dashed lines run parallel to the horizontal axis. The first line is extremely close to the horizontal axis and is labeled product on the extreme right. The second line is located just



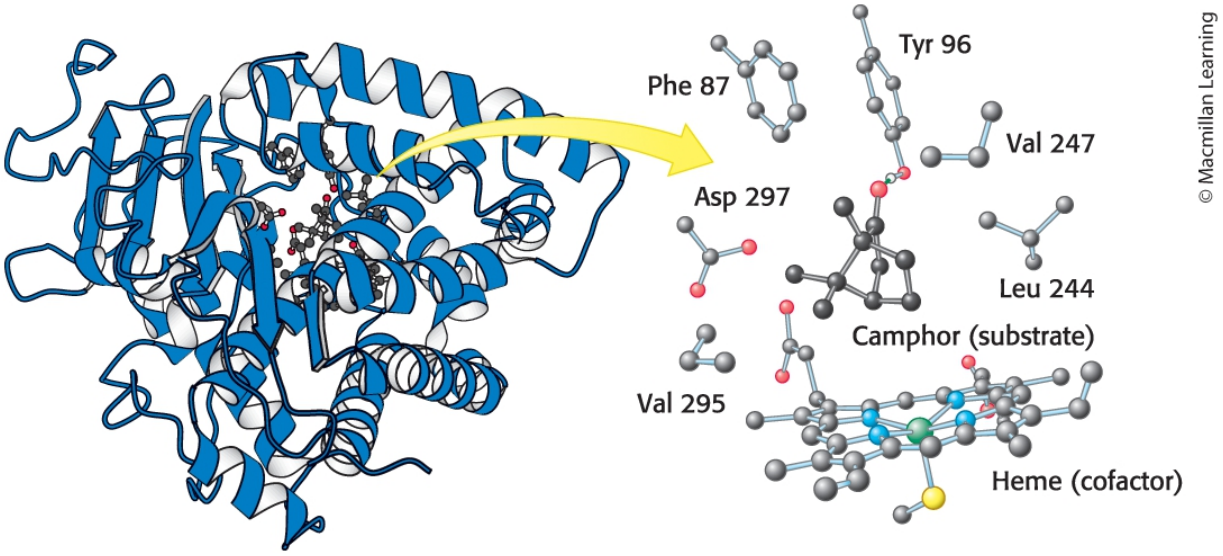
above the mid point of the vertical axis and is labeled substrate on the extreme left. The distance between two lines is labeled delta G for the reaction.

A solid curve labeled delta G superscript double dagger (uncatalyzed) is present. It rises steadily from the substrate line at the start of the reaction to a highest free energy labeled transition state, X superscript double dagger. This state is achieved in the middle of the reaction. The curve then falls to the product line by the end of the reaction.

A dashed curve labeled delta G superscript double dagger (catalyzed) is also present. It follows the same path as the solid curve, but only attains half the height of the peak of the solid curve.

Return to FIGURE 5.3. Graphical representation of the enzyme-mediated acceleration of a reaction by lowering of the free energy of activation

Extended description for FIGURE 5.4. Graphical representation of the maximal velocity attained by an enzyme-catalyzed reaction as the substrate concentration increases



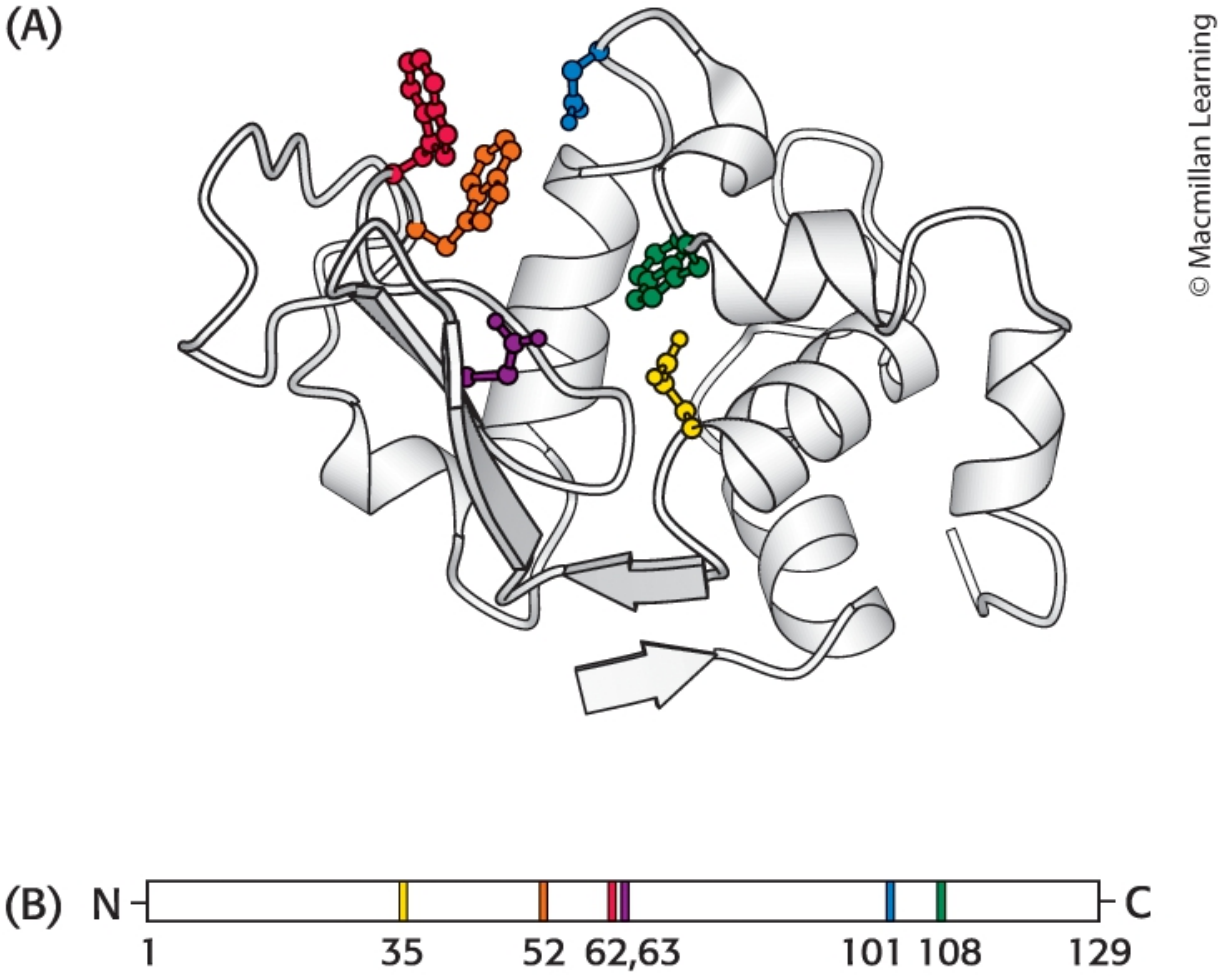
The horizontal axis is labeled substrate concentration. The vertical axis is labeled reaction Velocity. A dashed line parallel to the

horizontal axis is labeled maximal velocity. It is located at the highest reaction velocity.

An upward convex curve rises rapidly from the origin and plateaus just below the maximal Velocity line.

Return to FIGURE 5.4. Graphical representation of the maximal velocity attained by an enzyme-catalyzed reaction as the substrate concentration increases

Extended description for FIGURE 5.5 Ribbon diagram and ball-and-stick model show a substrate surrounded by the active site residues of cytochrome P 450 enzyme



© Macmillan Learning

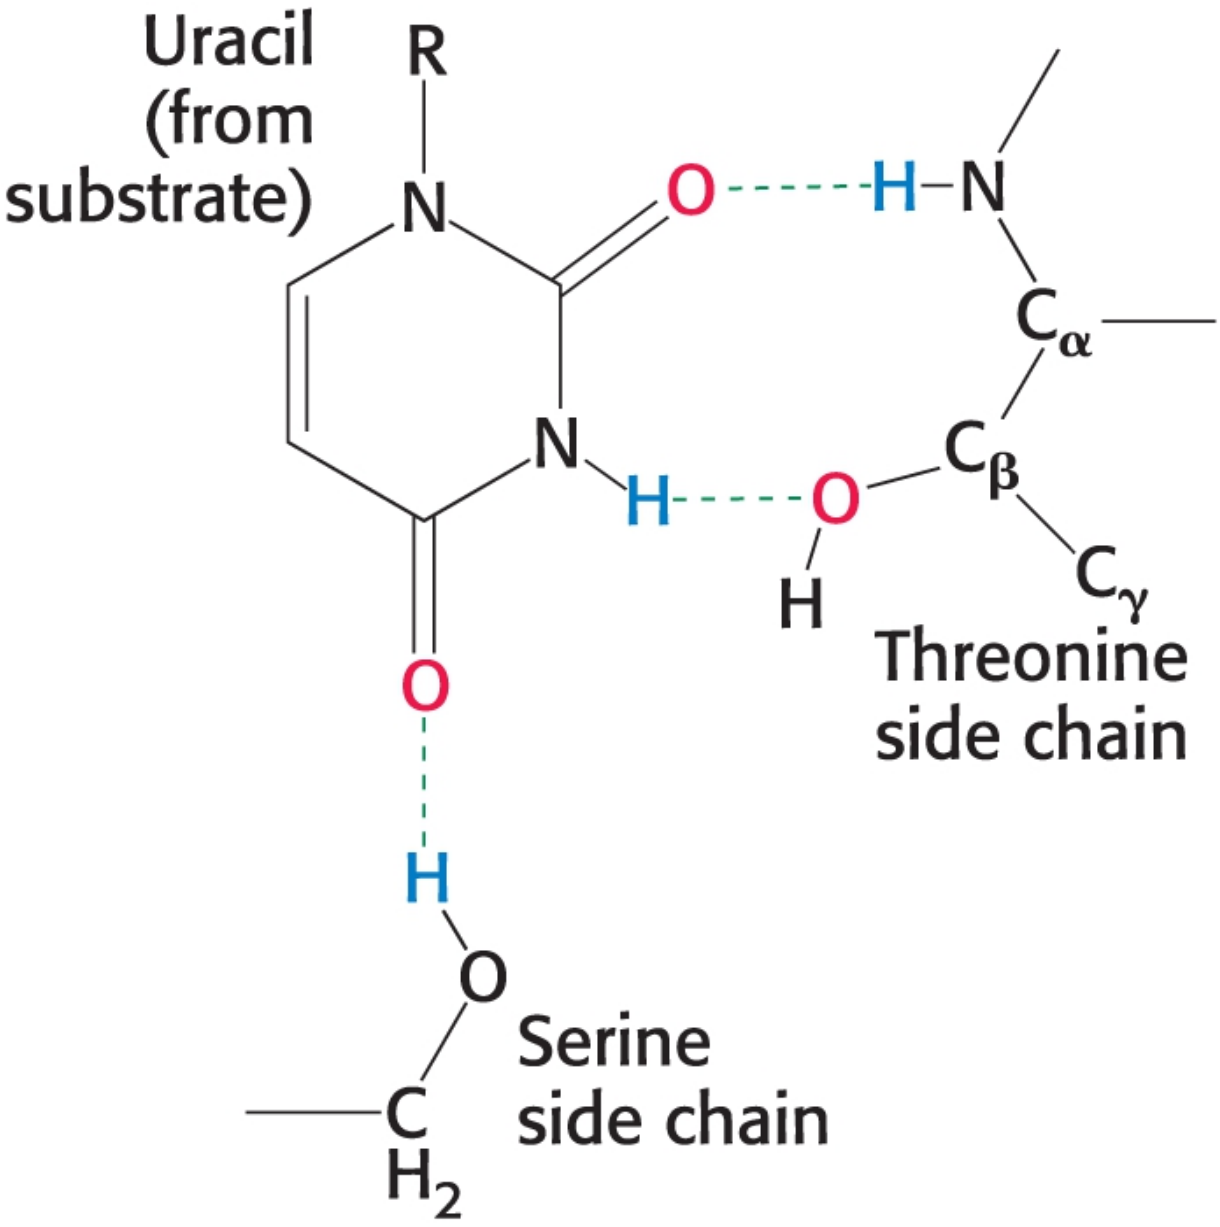
Ribbon diagram: The protein structure consists of interconnected motifs such as ribbon-shaped alpha helices and arrow-shaped beta sheets. The ball-and-stick model of camphor, the substrate, is shown as several interconnected black spheres. It is located inside a cavity located between the alpha helices and beta-sheets.

Ball and stick model: One black sphere of camphor is connected to a chain of a red, white, and red sphere, which is then connected at the top to a residue labeled T y r 96. A planar arrangement of interconnected black, spheres labeled Heme (cofactor) is present below the substrate. Heme contains four blue spheres inside the interconnected network of black spheres. The blue spheres are connected to a single green sphere at the center. Various residues labeled V a l 295, A s p 297, P h e 87, V a l 247, and Le u 244 are present around the substrate from bottom left to bottom right.

Return to FIGURE 5.5 Ribbon diagram and ball-and-stick model show a substrate surrounded by the active site residues of cytochrome P 450 enzyme

Extended description for FIGURE 5.6. Ribbon diagram and schematic representation of the primary structure depict the coming together of distantly located amino acids in the active site of a folded protein

© Macmillan Learning



(A): The ribbon diagram of lysozyme consists of interconnected motifs such as ribbon-shaped alpha helices and arrow-shaped beta-sheets. The alpha helices and the beta-strands are connected by thread-like loops. The active site residues are shown as different clusters composed of interconnected colored spheres. Each cluster has a different color like red, orange, blue, purple, green, and

yellow. They are located on different alpha-helices, thread-like loops, and beta-strand. They are brought together by the folding of the protein.

(B): The primary structure of lysozyme is depicted as a horizontal narrow rectangular structure. It is made up of 129 and its left and right end are labeled N and C respectively. It has the markings 1, 35, 52, 62, 63, 101, 108, and 129 to show the location of different amino acid residues. The residues 35, 52, 62, 63, 101, and 108 are shown as tiny vertical bars having yellow, orange, red, purple, blue, and green colors respectively.

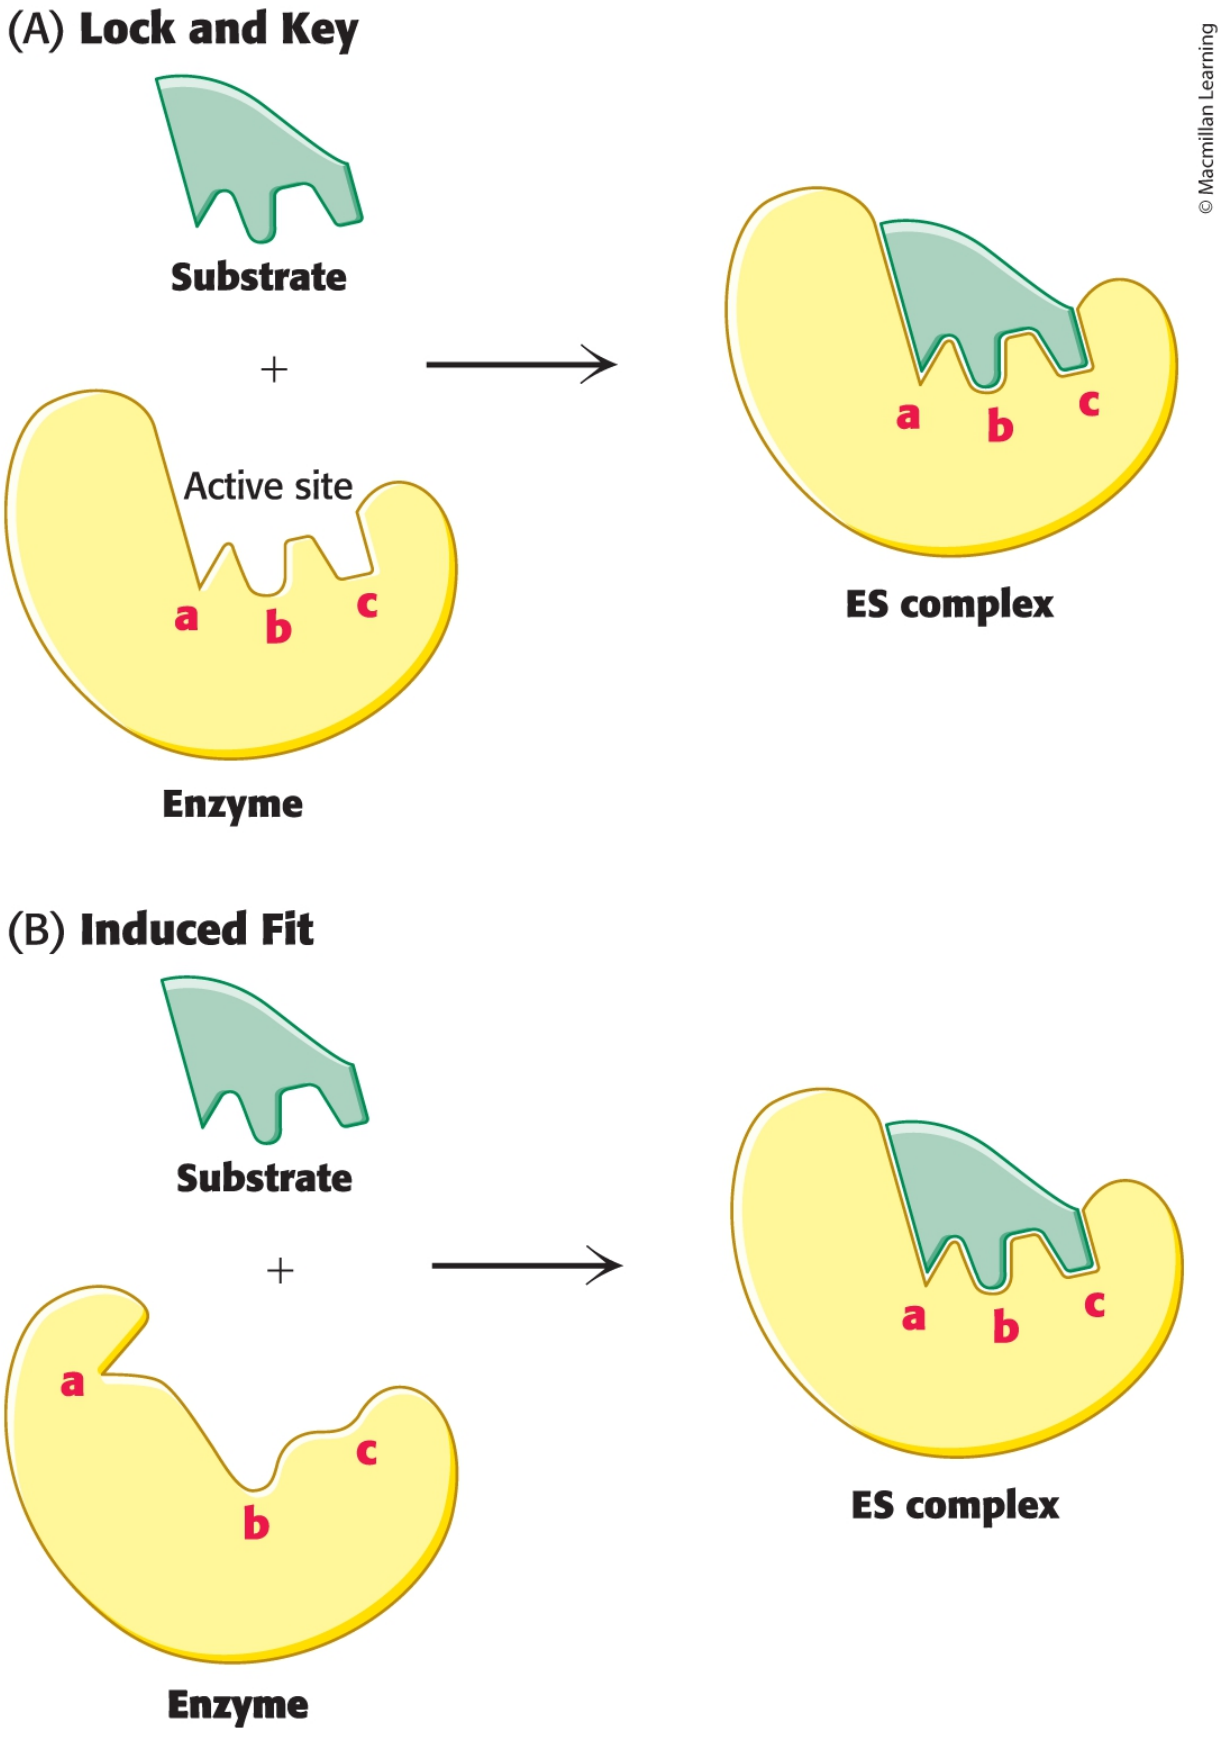
Return to FIGURE 5.6. Ribbon diagram and schematic representation of the primary structure depict the coming together of distantly located amino acids in the active site of a folded protein

Extended description for FIGURE 5.7. Hydrogen bonding between the side chains of active site residues and the substrate

Three interacting compounds are shown:

1. Uracil (from substrate): A heterocyclic hexagonal ring composed of 2 N and 4 C is present in a vertical orientation. The first N atom occupies the first position, which is the topmost vertex. The second N atom occupies the third position, which is the bottom right vertex. A double bond is present between C 3 and C 4. The first N atom is single bonded to R above. C 1 is double bonded to O on the upper right. The second N atom is single bonded to H on the lower right. C 2 is double bonded to O below.

2. Threonine side chain: A 1 N and 3 C heteronuclear alkane chain is depicted as a line structure using 3 zigzag lines. It is present in a vertical orientation. The N atom occupies the first position, C 1 is represented as C subscript alpha, C 2 is represented as C subscript beta, and C 3 is represented as C subscript gamma. The N atom is single bonded to H on the left. It has an open single bond on the upper right. C subscript alpha has an open single bond on the right. C subscript beta is single bonded to O on the lower left. This O is single bonded to H on the lower left.



3. Serine side chain: H, single bond, O, single bond, C H 2 is present in a vertical orientation. C has an open single bond on the left.

A dashed line connects the O atom double-bonded to C 2 of the uracil component with the first H atom of the serine side chain. A second dashed line connects the O atom double-bonded to C 1 of the uracil component with the H atom single bonded to the first N atom of the threonine side chain. A third dashed line connects the H atom single bonded to the second N atom of the uracil component with the O atom single bonded to the C subscript beta of the threonine side chain.

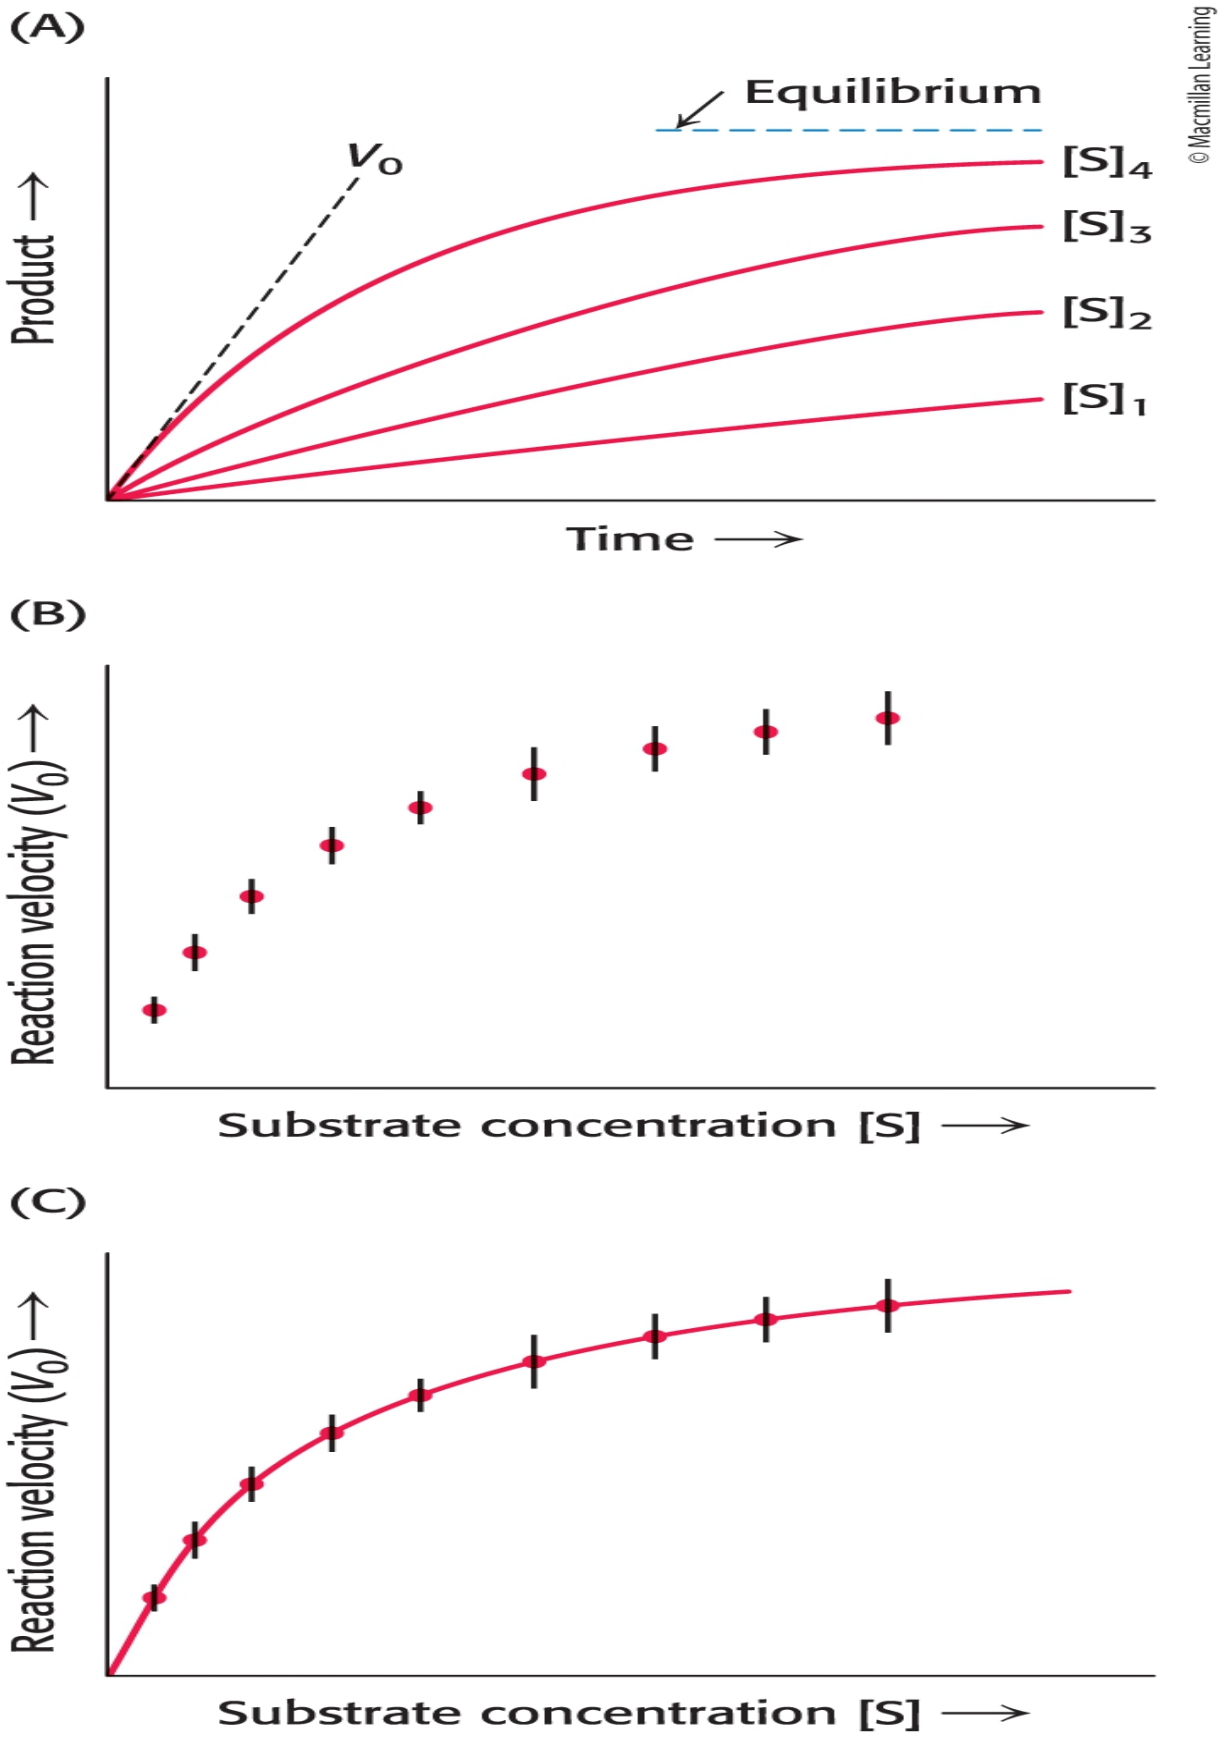
Extended description for FIGURE 5.8. Schematic illustration of the lock and key model and the induced-

fit model

© Macmillan Learning



(A) Lock and Key Model: The substrate and the active site of the enzyme are perfectly complementary to each other such that the three projections of the substrate fit perfectly in the three grooves of the enzyme active site labeled a, b, and c. The enzyme and substrate combine to form an E S (enzyme-substrate) complex.

(B) Induced Fit Model: The substrate and the active site of the enzyme are originally not perfectly complementary to each other. The enzyme later modifies shape of its active site such that the three projections of the substrate fit perfectly in the three grooves of the active site. The enzyme and substrate combine to form an E S complex.

Return to FIGURE 5.8. Schematic illustration of the lock and key model and the induced-fit model

Extended description for FIGURE 5.9. Graphical representation of the relation between initial velocity

and substrate concentration

© Macmillan Learning

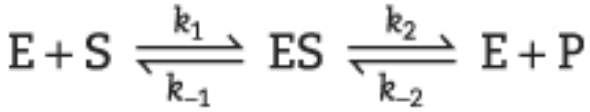
Graph (A): The horizontal axis is labeled time. The vertical axis is labeled product. A dashed line labeled equilibrium runs parallel to the horizontal axis at the highest concentration of product on the vertical axis. A dashed straight line labeled V naught rises steeply from the origin at an angle of roughly 60 degrees. The graph consists of four curves:

1. substrate concentration subscript 1: The curve is a straight line that rises gradually from the origin at an angle of roughly 15 degrees. It stops at a product concentration much less than half of the maximum product concentration given in the vertical axis.

2. substrate concentration subscript 2: The curve is a straight line that rises gradually from the origin at an angle of roughly 20 degrees. It then plateaus slightly in the end. It stops at a product concentration just below half of the maximum product concentration given in the vertical axis.

3. substrate concentration subscript 3: The curve is a straight line that rises gradually from the origin at an angle of roughly 45 degrees. It then plateaus slightly in the end. It stops at a product concentration just above half of the maximum product concentration given in the vertical axis.

4. substrate concentration subscript 4: The curve is slightly hyperbolic. It rises gradually from the origin at an angle of roughly 60 degrees. It then plateaus slightly in the second half of the graph just below the equilibrium point.

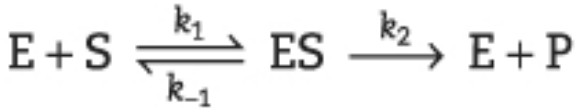


(B) The graph is a scatterplot. The horizontal axis is labeled substrate concentration substrate concentration. The vertical axis is labeled Reaction velocity (V naught). The data points are presented such that they form an upward convex curve that starts from the

origin and plateaus at the highest reaction velocity, in the upper right corner of the graph.

(C) The graph is a scatterplot. The horizontal axis is labeled Substrate concentration substrate concentration. The vertical axis is labeled Reaction velocity (V naught). The data points are presented such that they form an upward convex curve similar to graph (B). They start from the origin and plateau at the highest reaction velocity, in the upper right corner of the graph. A line connects the data points.

Return to FIGURE 5.9. Graphical representation of the relation between initial velocity and substrate concentration



Extended description for Model proposed by Michaelis and Menten for enzyme catalysis

The chemical equation is depicted as follows: E plus S is reversibly converted into E S. The top forward arrow is labeled lowercase k subscript 1. The bottom backward arrow is labeled lowercase k subscript minus 1. E S is further reversibly converted into E plus P. The top forward arrow is labeled lowercase k subscript 2. The bottom backward arrow is labeled lowercase k subscript minus 2.

Return to Model proposed by Michaelis and Menten for enzyme catalysis

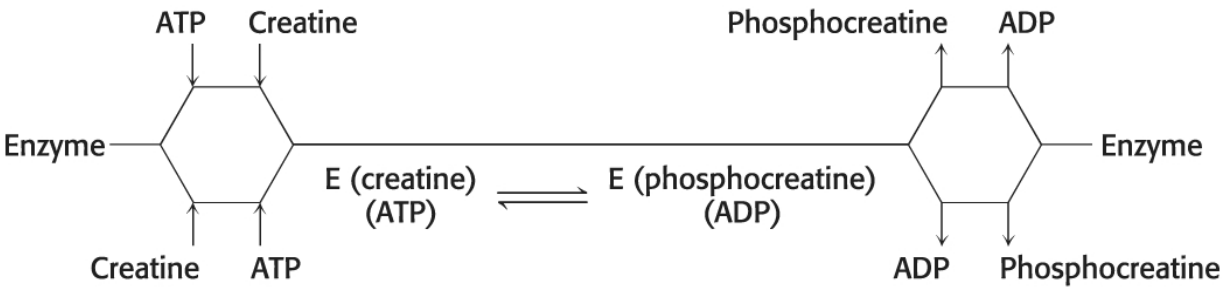
Extended description for Chemical equation showing the conversion of creatine into phosphocreatine

The reaction is reversible and consists of two reactants and two products.

The first reactant is creatine and has the following structure: A 1 N and 3 C heteronuclear alkane chain is depicted as a line structure using 4 zigzag lines. The N atom occupies the third position. The C atoms occupy the remaining positions. C 1 is single bonded to an O atom below and on the upper left with a resonance bond shared between them. This end of the molecule carries an overall negative charge. C 2 is bound to H 2. The first N atom is single bonded to C H 3 below. C 3 is single bonded to an N H 2 group above and on the lower right with a resonance bond shared between them. This end of the molecule carries an overall positive charge.

The second reactant is an A T P molecule.



The first product is phosphocreatine and has the following structure: A 2 N and 3 C heteronuclear alkane chain is depicted as a line structure using 4 zigzag lines. The first N atom occupies the third position and the second N atom occupies the fifth position. The C atoms occupy the remaining positions. C 1 is single bonded to an O atom below and on the upper left with a resonance bond

shared between them. This end of the molecule carries an overall negative charge. C 2 is bound to H 2. The first N atom is single bonded to C H 3 below. C 3 is single bonded to an N H 2 group above. The second N atom is bound to H and single bonded to a central P atom on the upper right. P atom is single bonded to an O superscript 2 minus ion above, and an O atom on the right and the lower right. Resonance bonds are shared between central P atom and O atoms.

The second product is an A D P.

Return to Chemical equation showing the conversion of creatine into phosphocreatine

Extended description for Cleland notation for the conversion of creatine into phosphocreatine

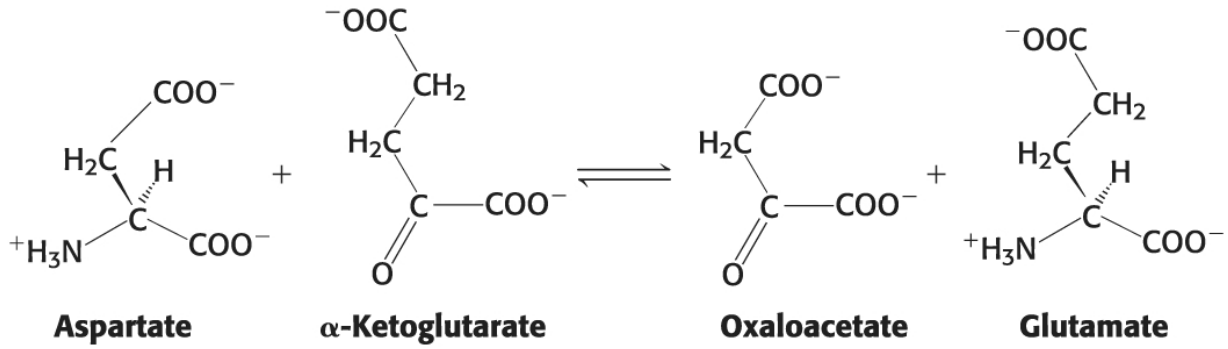
The mechanism observes the following sequence:

1. Enzyme

2. Addition of either A T P or Creatine

3. Addition of either Creatine or A T P.

4. The reversible conversion of the E (enzyme), creatine, and A T P into E, phosphocreatine, and A D P.



5. Removal of either A D P or phosphocreatine.

6. Removal of either phosphocreatine or A D P.

7. Release of enzyme.

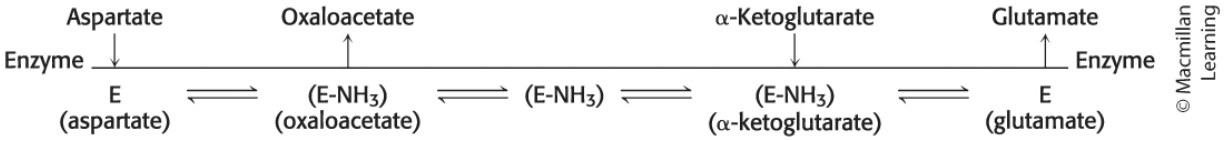
[Return to Cleland notation for the conversion of creatine into phosphocreatine]

Extended description for Double displacement reaction between aspartate and alpha-ketoglutarate

The reaction is reversible and consists of two reactants and two products.

The first reactant is aspartate and has the following structure: A central C atom is single bonded to C O O superscript minus group on the lower right, single bonded to N H 3 superscript plus on the lower left, dash bonded to H on the upper right, and wedge bonded to C H 2 on the upper left. The C H 2 group is further single bonded to another C O O superscript minus group on the upper right.

The second reactant is alpha-ketoglutarate and has the following structure: A three carbon alkane chain is depicted as a line structure using two zigzag lines in a vertical orientation. C 1 is single bonded to a C O O superscript minus group on the right and double bonded to an O atom on the lower left. C 2 is bound to H 2. C 3 is bound to H 2 and single bonded to another C O O superscript minus group on the upper left.



The first product is oxaloacetate and has the following structure: A central C atom is single bonded to a C O O superscript minus group on the right and double bonded to an O atom on the lower left. C 2 is

bound to H 2 and single bonded to another C O O superscript minus group on the upper right.

The second product is glutamate and has the following structure: A central C atom is single bonded to C O O superscript minus group on the lower right, single bonded to N H 3 superscript plus on the lower left, dash bonded to H on the upper right, and wedge bonded to C H 2 on the upper left. The C H 2 group on the upper left is single bonded to another C H 2 group on the upper right which is further single bonded to another C O O superscript minus group on the upper left.

Return to Double displacement reaction between aspartate and alpha-ketoglutarate

Extended description for Cleland notation for the conversion of aspartate into glutamate

The mechanism observes the following sequence:

1. Enzyme

2. Addition of aspartate

3. Formation of an enzyme-aspartate complex.

4. The reversible conversion of the enzyme-aspartate complex into an enzyme-N H 3-oxaloacetate complex or enzyme-N H 3 complex.

5. Removal of oxaloacetate.

6. Addition of alpha-ketoglutarate.

7. The reversible conversion of the enzyme-N H 3 complex into an enzyme-N H 3-alpha-ketoglutarate complex.

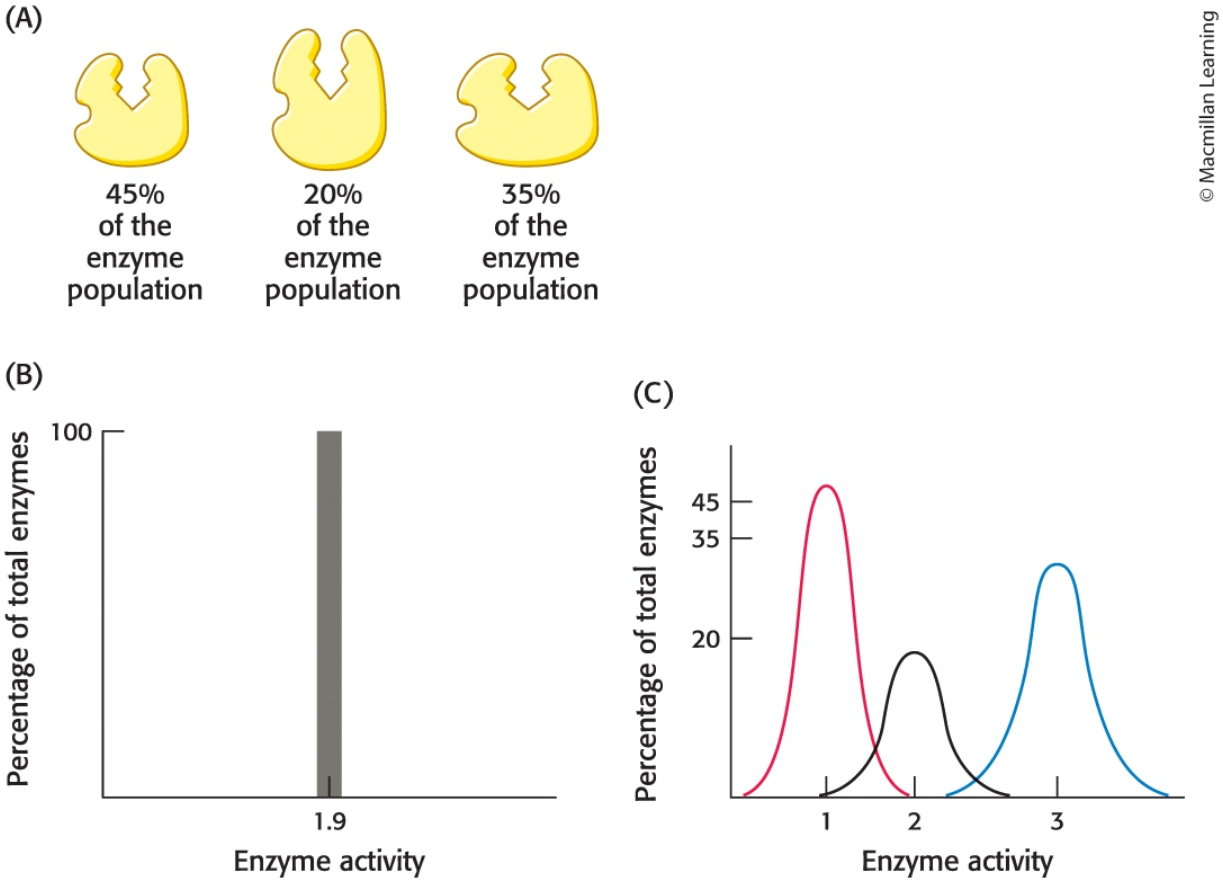
Extended description for Chemical reaction showing the conversion of tyrosine into dopaquinone

The reaction consists of three steps, each with one reactant and one product. The initial two steps are catalyzed by tyrosinase.

Step 1: The reactant is tyrosine and has the following structure: A benzene ring is present in a vertical orientation with C 1 occupying the topmost vertex. Alternating double bonds are present between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 5 atom of the benzene ring is single bonded to O H. C 2 atom of the ring is single bonded to C 1 atom of a 3 carbon alkane chain depicted as a line structure using 2 zigzag lines. C 2 atom of the chain is single bonded to N H 2 below. C 3 atom of the chain is double bonded to O above and single bonded

to O H on the lower right. The reaction is catalyzed by the enzyme tyrosinase.



The product is dihydroxyphenylalanine and has the following structure: A benzene ring is present in a vertical orientation with C 1 occupying the topmost vertex. Alternating double bonds are present between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 5 is single bonded to O H on the lower left. C 6 is single bonded to O H on the upper left. C 2 atom of the ring is single bonded to C 1 atom of a 3 carbon alkane chain depicted as a line structure using 2 zigzag lines. C 2 atom of the chain is single bonded to N H 2 below. C 3 atom of the chain is double bonded to O above and single bonded to O H on the lower right.

Step 2: The reactant is Dihydroxyphenylalanine. The reaction occurs in catalyzed by tyrosinase. The product is dopaquinone and has the following structure: A 6 C hexagonal ring is present in a vertical orientation with C 1 occupying the topmost vertex. Double bonds are present between C 1 and C 2 and C 3 and C 4. C 5 is double bonded to O on the lower left. C 6 is double bonded to O on the upper left. C 2 atom of the ring is single bonded to C 1 atom of a 3 carbon alkane chain depicted as a line structure using 2 zigzag lines. C 2 atom of the chain is single bonded to N H 2 below. C 3 atom of the chain is double bonded to O above and single bonded to O H on the lower right

Step 3: The reactant is dopaquinone. The product is melanin.

Return to Chemical reaction showing the conversion of tyrosine into dopaquinone

Extended description for FIGURE 5.13. Schematic illustration and graphical representation of molecular heterogeneity

© Macmillan Learning

Part (A): Three of the major shapes used by enzymes are shown:

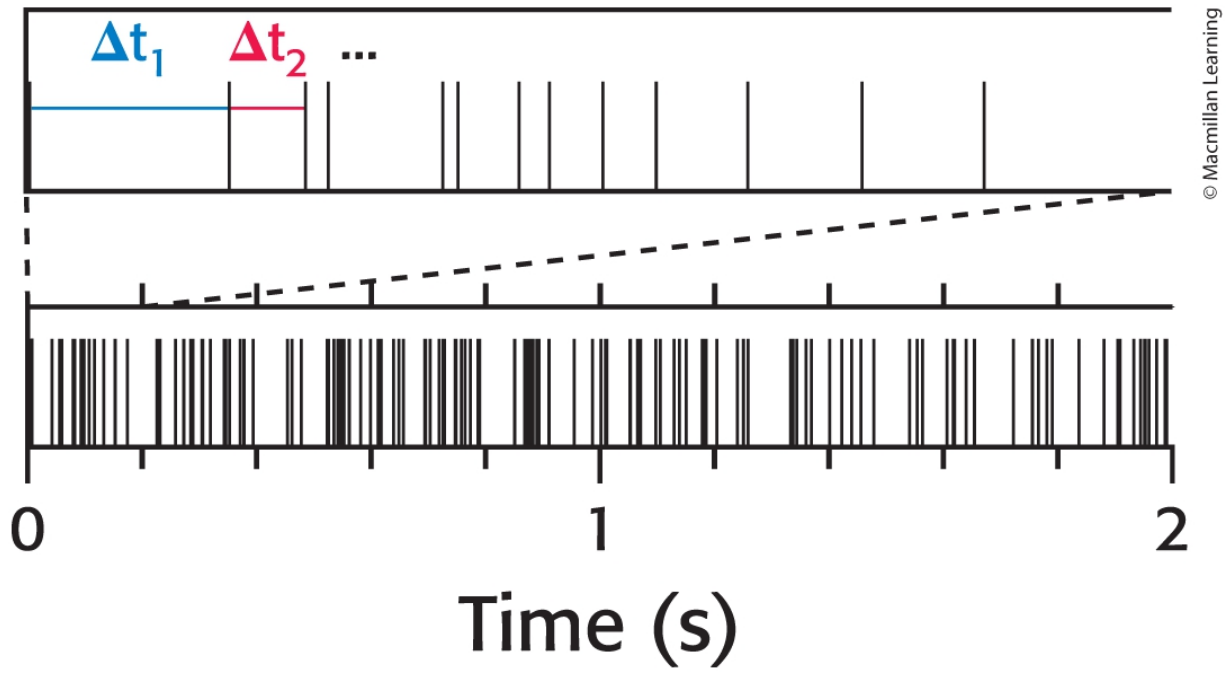
1. Roughly square-shaped: 45 percent of the enzyme population.

2. Elongated in height: 20 percent of the enzyme population.

3. Elongated in width: 35 percent of the enzyme population.

Part (B): A bar graph is shown. The horizontal axis is labeled enzyme activity and is marked 1.9 at the midpoint. The vertical axis is labeled percentage of total enzymes. It has the marking 100 at the top. At the 1.9 unit mark, a vertical bar having a height of 100 units is shown.

Part (C): A graph containing three curves is shown. The horizontal axis is labeled enzyme activity. It has marking ranging from 0 to 3 in increments of 1 unit. The vertical axis is labeled percentage of total enzymes. It has markings 20, 35, and 45. The graph consists of three bell-shaped curves:

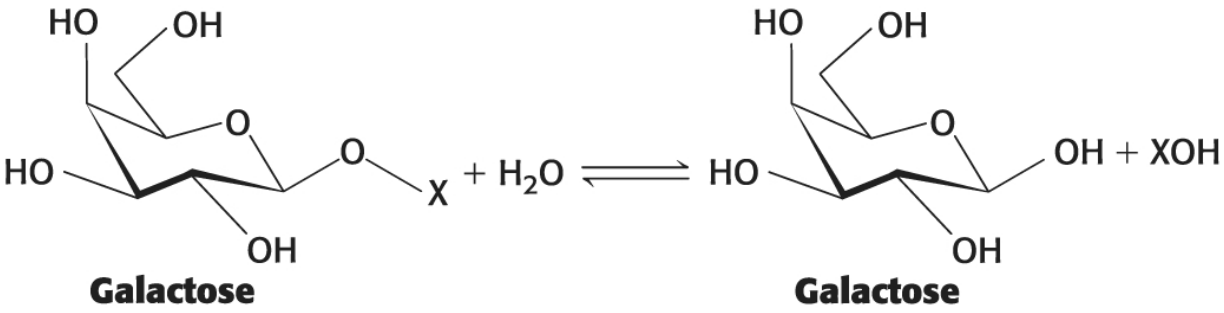


1. The first curve rises rapidly from the origin, peaks at (1, 45), and falls to (2, 0).

2. The second rises rapidly from (1,0), peaks at (2, 19), and falls to (2.5, 0).

3. The third curve rises rapidly from (2.3, 0), peaks at (3, 33), and falls to (3.5, 0).

Return to FIGURE 5.13. Schematic illustration and graphical representation of molecular heterogeneity



Extended description for FIGURE 5.14. Schematic illustration of the stochastic behavior of a single-enzyme molecule

A horizontal barcode like image is shown. It consists of several short thick and thin vertical lines. The barcode is divided into 10 sections. The horizontal axis is labeled time (s) that ranges from 0 to 2 in increments of 1 unit. The initial section of the barcode is enlarged on the top. It consists of vertical lines separated by irregular gaps. Variable time increments labeled delta t subscript 1, delta t subscript 2 are shown in the enlarged view. The gap between the distantly placed first and second vertical line is labeled delta t subscript 1. The gap between the closely spaced second and third line is labeled delta t subscript 2.

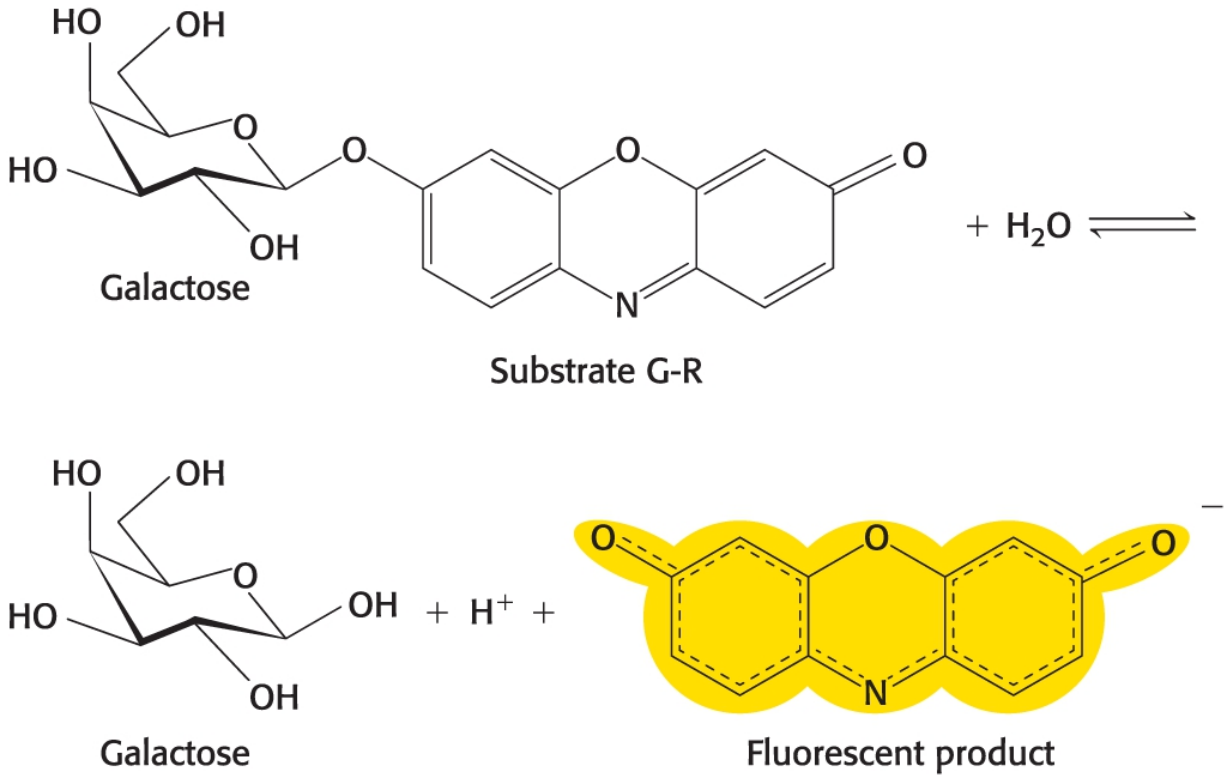
Return to FIGURE 5.14. Schematic illustration of the stochastic behavior of a single-enzyme molecule

Extended description for Chemical equation showing the conversion of carbohydrate galactose to galactose

The reaction is reversible and consists of two reactants and two products.

The first reactant is labeled galactose and has the following structure: A six-membered heterocyclic ring consisting of 1 O and 5 C atoms is in a chair conformation. O atom occupies the top-right vertex. C 1 is single bonded to O on the upper right. This O atom is single bonded to X on the lower right. C 2 is single bonded to O H on the lower right. C 3 is single bonded to O H on the upper left. C 4 is single bonded to O H above. C 5 is single bonded to C H 2 on the upper left in the form of a line. This C H 2 is single bonded to O H on the upper right.

The second reactant is H 2 O.



The first product is also labeled galactose and has the following structure: A six-membered heterocyclic ring consisting of 1 O and 5 C atoms is in a chair conformation. O atom occupies the top-right vertex. C 1 is single bonded to O H on the upper right. C 2 is single bonded to O H on the lower right. C 3 is single bonded to O H on the upper left. C 4 is single bonded to O H above. C 5 is single bonded to

C H 2 on the upper left in the form of a line. This C H 2 is single bonded to O H on the upper right.

The second product is X O H.

Return to Chemical equation showing the conversion of carbohydrate galactose to galactose

Extended description for FIGURE 5.15. Chemical reaction showing the formation of a highly fluorescent product

The reaction is reversible and has two reactants and three products.

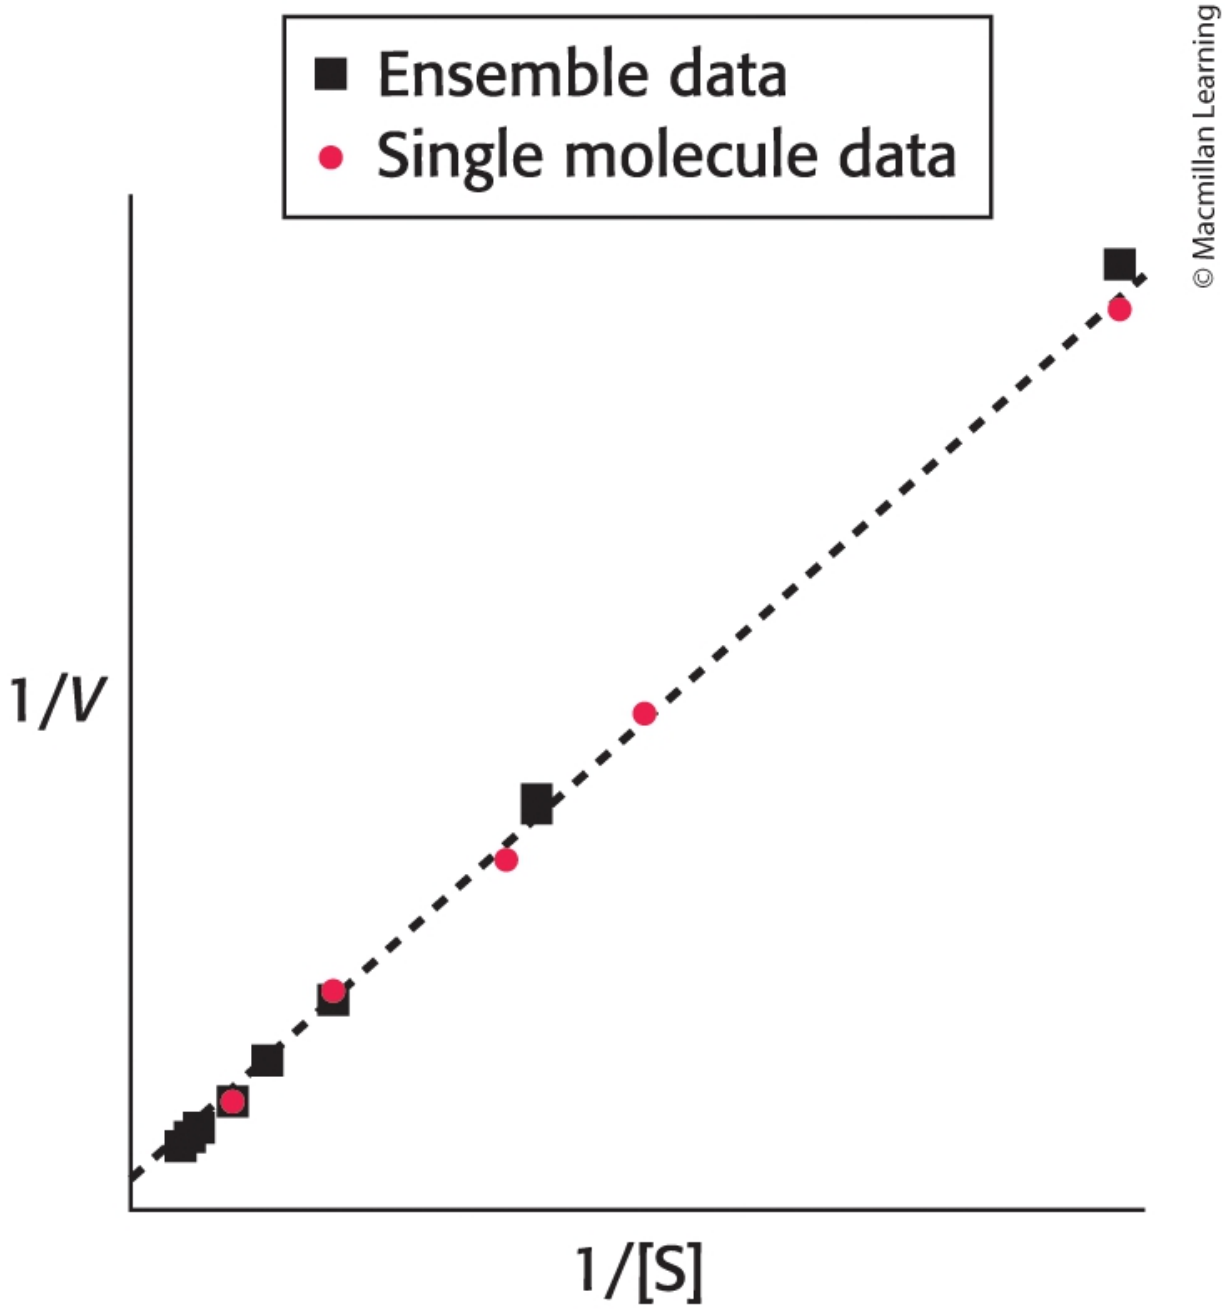
The first reactant is the substrate G-R molecule. It is composed of three fused rings connected to a galactose molecule.

The galactose molecule has the following structure: A six-membered heterocyclic ring consisting of 1 O and 5 C atoms is in a chair conformation. O atom occupies the top-right vertex. C 2 is single bonded to O H on the lower right. C 3 is single bonded to O H on the upper left. C 4 is single bonded to O H above. C 5 is single bonded to

C H 2 on the upper left in the form of a line. This C H 2 is single bonded to O H on the upper right.

The fused rings have the following structure: A 6 C hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. A double bond is present between C 1 and C 2 and C 3 and C 4. C 1 is single bonded to O on the upper left. This O atom is single bonded to the C 1 atom of the galactose molecule. This hexagonal ring is fused on the right to a 6-membered heterocyclic hexagonal ring such that C 2 and C 3 of the first ring are C 4 and C 3 of the second ring respectively. The second ring consists of 1 O, 1 N, and 4 C atoms. O occupies the first position, which is the topmost vertex. N occupies the second position, which is the bottom-most vertex. A double bond is present between C 2 and N atoms. The second hexagonal ring is fused on the right to a third 6 C hexagonal ring such that C 1 and C 2 of the second ring are C 6 and C 5 respectively of the third ring. C 1 occupies the topmost vertex of the third ring. A double bond is present between C 3 and C 4, and C 6 and C 1. C 2 is double bonded to O on the upper right.

The second reactant is H 2 O.



The first product is galactose which has the following structure: A six-membered heterocyclic ring consisting of 1 O and 5 C atoms is in a chair conformation. O atom occupies the top-right vertex. C 2 is single bonded to O H on the lower right. C 3 is single bonded to O H on the upper left. C 4 is single bonded to O H above. C 5 is single bonded to C H 2 on the upper left in the form of a line. This C H 2 is single bonded to O H on the upper right.

The second product is H superscript plus ion.

The third product is labeled fluorescent product and has the following structure: A 6 C hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. The resonating bonds in the ring are depicted as a dashed hexagon inside the ring. C 6 is bonded to the O atom on the upper left through a resonance bond. This hexagonal ring is fused on the right to a 6-membered heterocyclic hexagonal ring such that C 2 and C 3 of the first ring are C 4 and C 3 of the second ring respectively. The second ring consists of 1 O, 1 N, and 4 C atoms. O occupies the first position, which is the topmost vertex. N occupies the second position, which is the bottom-most vertex. A resonance bond is present between C 2 and N, and N and C 3. The second hexagonal ring is fused on the right to a third 6 C hexagonal ring such that C 1 and C 2 of the second ring are C 6 and C 5 respectively of the third ring. C 1 occupies the topmost vertex of the third ring. The resonating bonds in the ring are depicted as a dashed hexagon inside the ring. C 2 is bonded to O on the upper right through a resonance bond.

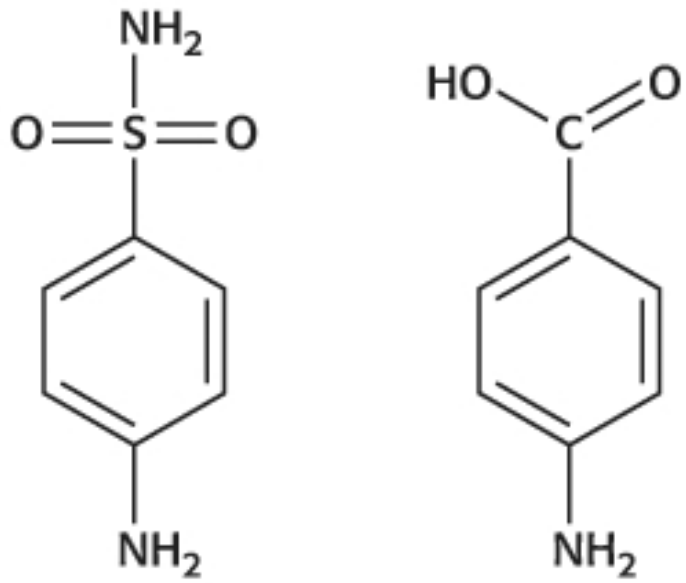
Extended description for FIGURE 5.18. Schematic illustration showing the binding of different types of

reversible inhibitors to the enzyme

© Macmillan Learning

Part (A) The substrate fits perfectly inside the groove of the enzyme molecule.



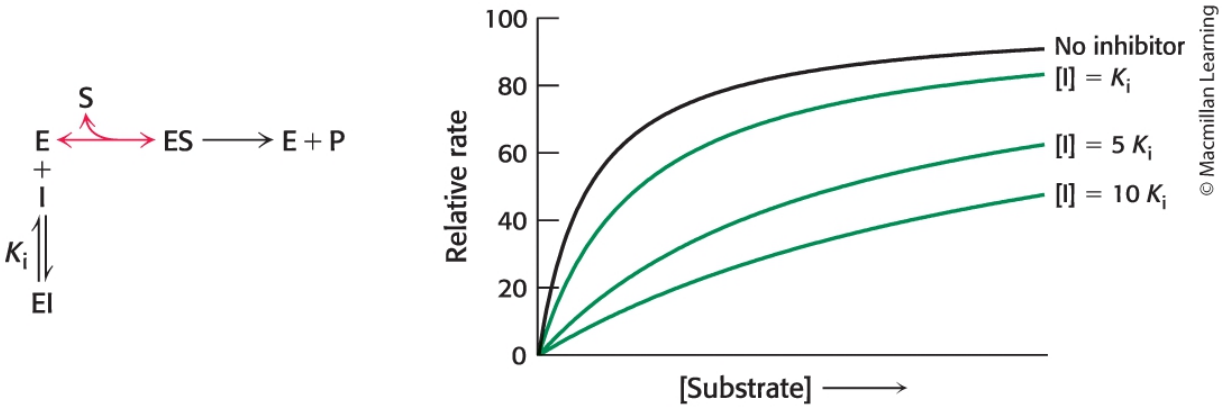
(B) The competitive inhibitor is not the perfect fit for the enzyme groove but fits well enough to block the substrate.

(C) The uncompetitive inhibitor fits perfectly on a different groove of the enzyme. This groove is located above the main groove bound by the substrate.

(D) The noncompetitive inhibitor fits perfectly on a different groove located on the side of the enzyme. This changes the shape of the main groove designated for the substrates. The substrate binds to the main groove but does not fit perfectly into it.

Return to FIGURE 5.18. Schematic illustration showing the binding of different types of reversible inhibitors to the enzyme

Extended description for Chemical structure of sulfanilamide and P A B A



Sulfanilamide **PABA**

Sulfanilamide: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. Alternating double bonds are present between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to a central S atom above. This S atom is single bonded to N H 2 above and double bonded to O on the left and right. C 4 is single bonded to N H 2 below.

P A B A: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. Alternating double bonds are present between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to a central C atom above. This C atom is single bonded to O H on the upper left and double bonded to O on the upper right. C 4 is single bonded to N H 2 below.

Return to Chemical structure of sulfanilamide and P A B A

Extended description for FIGURE 5.19. Michaelis–Menten plot showing the activity of a competitive inhibitor

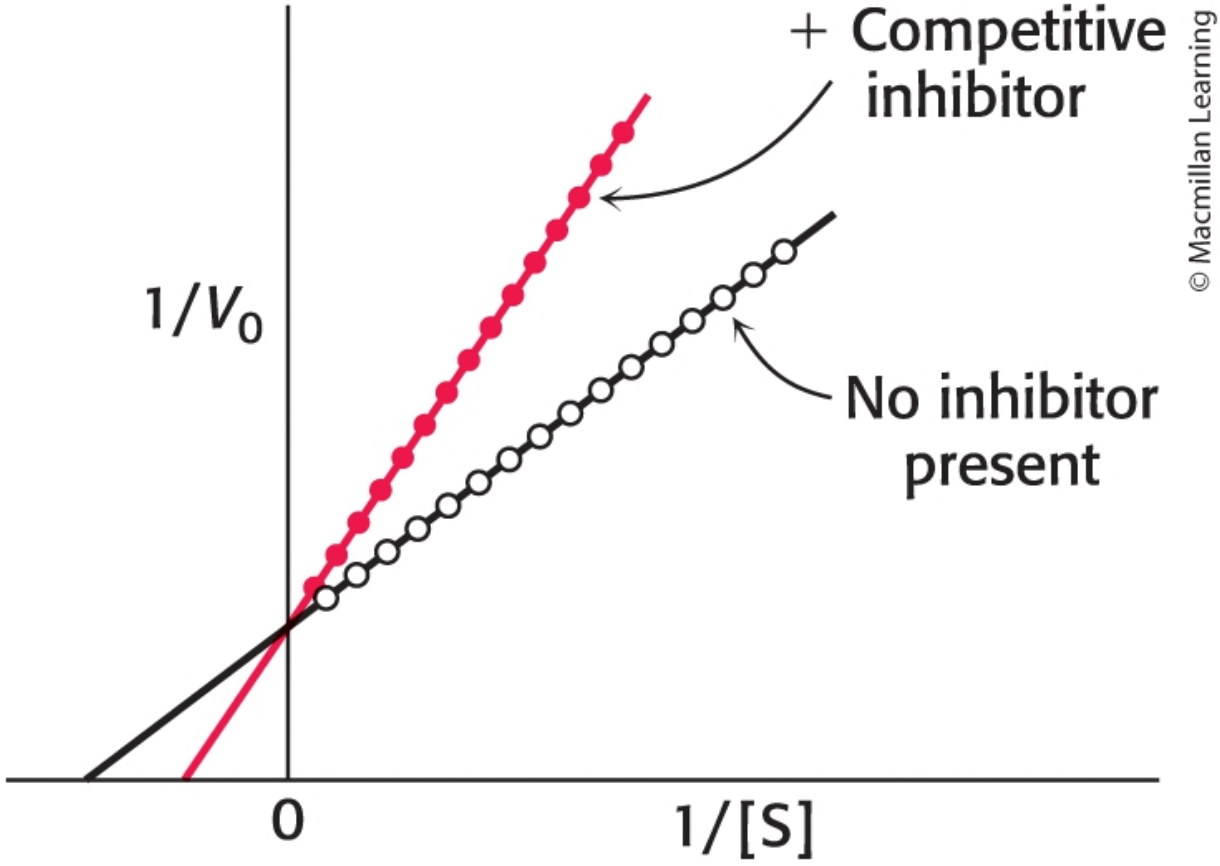
The horizontal axis is labeled concentration of substrate. The vertical axis is labeled relative rate. It has markings ranges from 0 to 100 in increments of 20 units. Four curves are shown:

1. No inhibitor: The curve rises rapidly to 75 units on the vertical axis then plateaus at around 85 units.

2. Concentration of I equals K subscript i: The curve rises rapidly to 60 units and then plateaus around 80 units.

3. Concentration of I equals 5 K subscript i: The curve rises almost linearly to 60 units.

4. Concentration of I equals 10 K subscript i: The curve rises almost linearly to approximately units.



Two equations are shown that depict the two reactions that an enzyme may undergo:

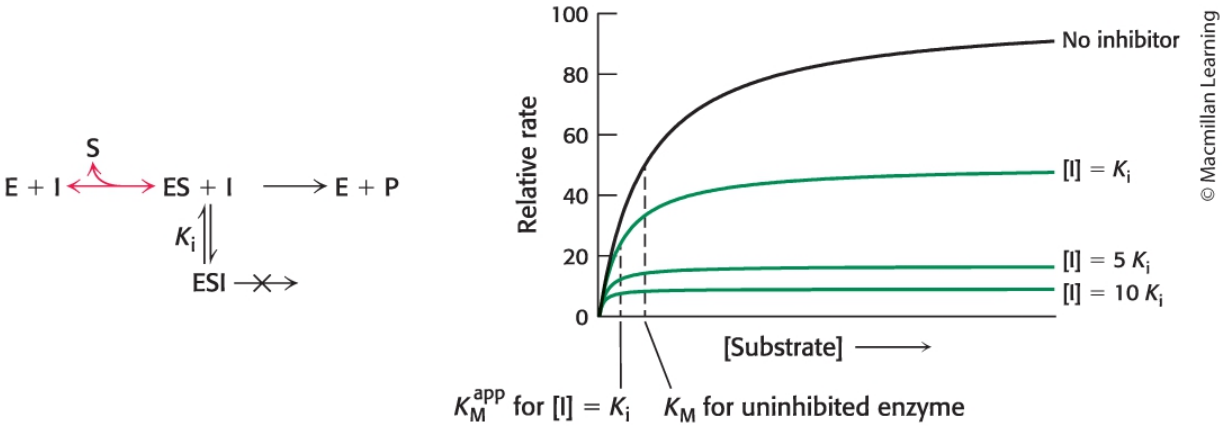
1. E, double-headed arrow and removal of S, E S, forward reaction arrow, E plus P.

2. E plus I, reversible reaction arrow in the presence of K subscript i, E I.

Return to FIGURE 5.19. Michaelis–Menten plot showing the activity of a competitive inhibitor

Extended description for FIGURE 5.20. Lineweaver–Burk plot depicts competitive inhibition

The horizontal axis is labeled StartFraction 1 over substrate concentration EndFraction. The vertical axis is labeled 1 over V naught. Two straight line plots are shown:



No inhibitor present: A straight line with a linear slope runs from a point on the negative side of the horizontal axis. It crosses the vertical axis into the positive quadrant.

Competitive inhibitor: A straight line with a steeper slope runs from a point slightly closer to the origin, on the negative side of the

horizontal axis. It crosses the vertical axis into the positive quadrant.

Return to FIGURE 5.20. Lineweaver–Burk plot depicts competitive inhibition

Extended description for FIGURE 5.21.Michaelis–Menten plot showing the activity of an uncompetitive inhibitor

The horizontal axis is labeled substrate concentration. The vertical axis is labeled relative rate. It has markings ranging from 0 to 100 in increments of 20 units. Four hyperbolic curves are shown:

1. No inhibitor: The hyperbolic curve rises rapidly to 75 units on the vertical axis and then plateaus around 85 units on the vertical axis.

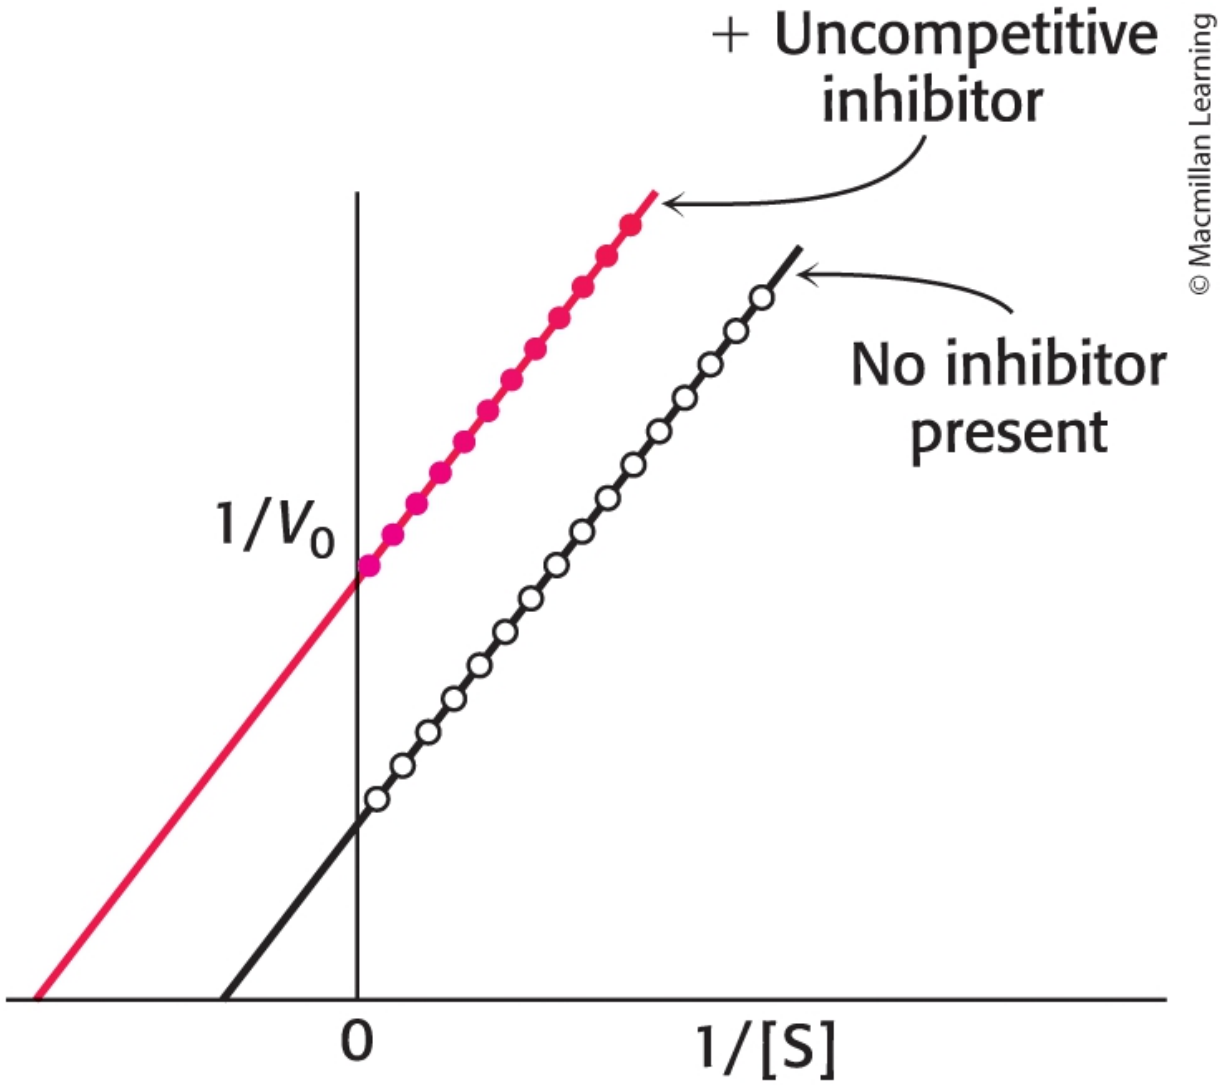
2. Concentration of I equals K subscript i: The hyperbolic curve rises rapidly to 40 units on the vertical axis and then plateaus at the same value.

3. Concentration of I equals 5 K subscript i: The hyperbolic curve rises to 10 units on the vertical axis and then plateaus at the same value.

4. Concentration of I equals 10 K subscript i: The hyperbolic curve rises to around 7 units on the vertical axis and then plateaus at the same value.

A dashed vertical line rises from the horizontal axis, near the origin, and intersects with curve 2 at approximately 25 units. This line is labeled K superscript app subscript M for concentration of I equals K subscript i.

Another dashed vertical line rises from the horizontal axis, on the right of the first dashed line, and intersects with the first curve at approximately 50 units. This line is labeled K subscript M for uninhibited enzyme.



Two equations are shown that depict the two reactions that an enzyme may undergo:

1. E plus I, double-headed arrow and removal of S, E S plus I, forward arrow, E plus P.

2. E S plus I, reversible reaction arrow in the presence of K subscript i, E S I, forward reaction arrow crossed out.

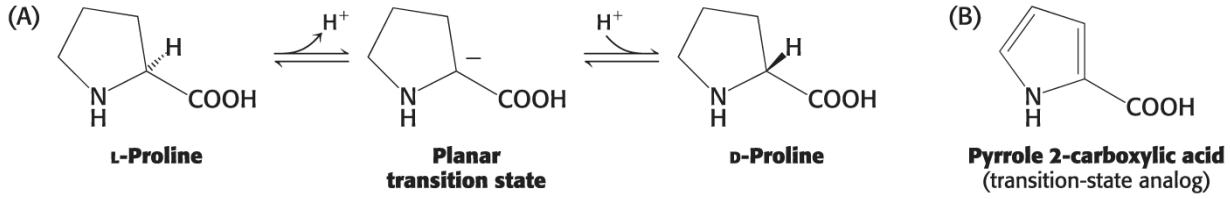
Extended description for FIGURE 5.24. Lineweaver–Burk plot distinguishing a pure noncompetitive inhibition

© Macmillan Learning



The horizontal axis is labeled StartFraction 1 over substrate concentration EndFraction. The vertical axis is labeled 1 over V naught. Two straight line plots are shown:

No inhibitor present: A straight line with a linear slope runs from a point on the negative side of the horizontal axis. It crosses the vertical axis into the positive quadrant.

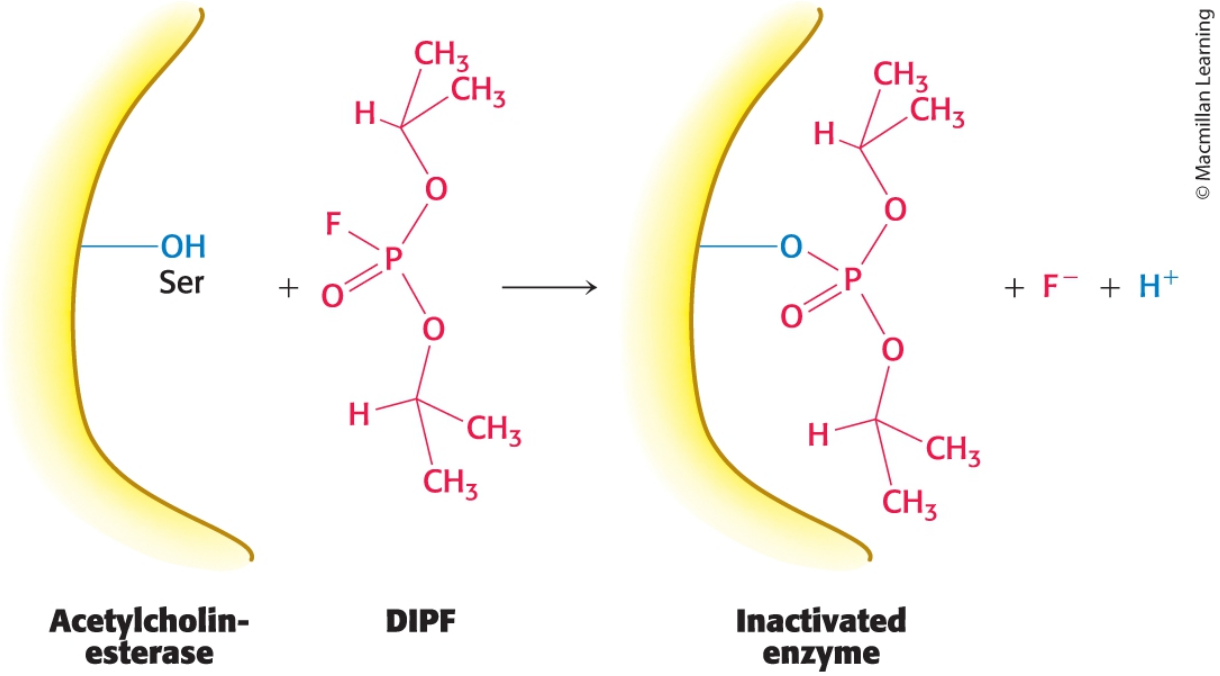
Noncompetitive inhibitor: A straight line with steeper slope runs from the same point on the negative side of the horizontal axis. It crosses the vertical axis into the positive quadrant.

Return to FIGURE 5.24. Lineweaver–Burk plot distinguishing a pure noncompetitive inhibition

Extended description for FIGURE 5.25. The chemical structure of the transition state of a reaction and its analog

Part (A) The reaction consists of two steps:

Step 1: This reaction is reversible and consists of one reactant and one product. The reactant is L-Proline and has the following structure: A five-membered heterocyclic pentagonal ring consisting of 1 N and 4 C atoms is in a vertical orientation. N atom occupies the first position, which is the bottom-most vertex. The N atom is bound to H. C 4 is single bonded to C O O H on the lower right and dash bonded to H on the upper right. The product is labeled planar transition state and has the following structure: A five-membered heterocyclic pentagonal ring consisting of 1 N and 4 C atoms is in a vertical orientation. N atom occupies the bottom-most vertex. The N atom is bound to H. C 4 is single bonded to C O O H on the lower right and carries a negative charge. H superscript plus ion is released as a byproduct in this reaction.



Step 2: This reaction is reversible and consists of one reactant and one product. The reactant is labeled planar transition state. The product is D-Proline and has the following structure: A five-membered heterocyclic pentagonal ring consisting of 1 N and 4 C atoms is in a vertical orientation. N atom occupies the bottommost vertex and is bound to H. C 4 is single bonded to C O O H on the

lower right and wedge bonded to H on the upper right. H superscript plus ion is consumed in this reaction.

Part (B) Pyrrole 2-carboxylic acid (transition-state analog): A five-membered heterocyclic pentagonal ring consisting of 1 N and 4 C atoms is in a vertical orientation. N atom occupies the bottom-most vertex and is bound to H. A double bond is present between C 1 and C 2, and C 3 and C 4. C 4 is single bonded to C O O H on the lower right.

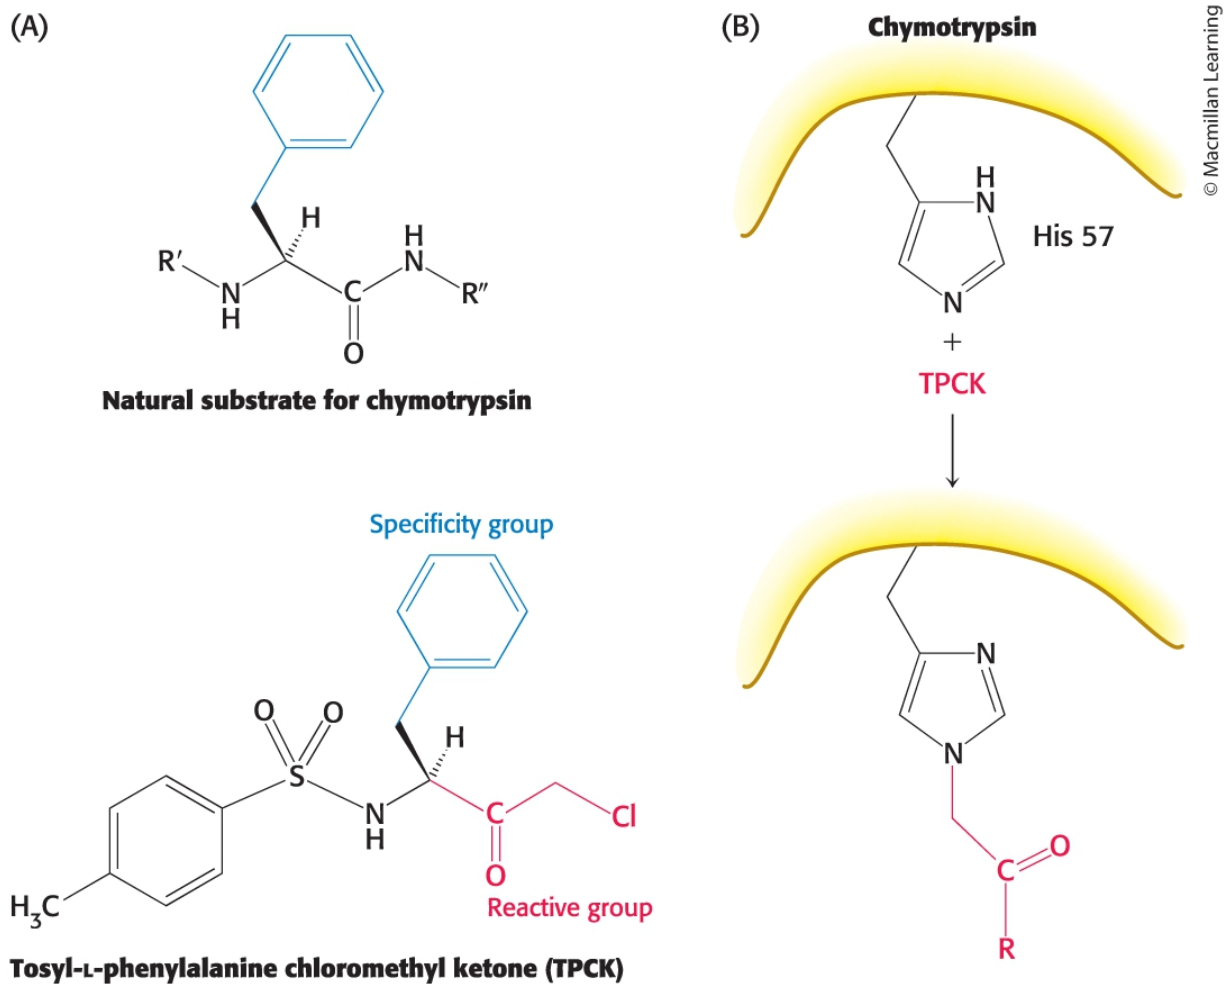
Extended description for FIGURE 5.26. Schematic illustration of irreversible inhibition of an enzyme by D I P F, a group specific reagent

© Macmillan Learning



The acetylcholinesterase enzyme is depicted as a vertical curved line with a yellow highlight. It is connected to O H of a serine residue at the center. O H group is highlighted in blue.

Diisopropylphosphofluoridate (D I P F) has the following structure: A 2 O, 1 P, and 2 C heteronuclear alkane chain is depicted as a line structure using 4 zigzag lines in a vertical orientation. The O atoms occupy the second and fourth positions. P atom occupies the third position. C 1 is single bonded to C H 3 above, on the upper right and H on the upper left. The P atom is single bonded to F on the upper left and double bonded to O on the lower left. C 2 is single bonded to C H 3 below, on the lower right, and H on the lower left. The entire molecule is highlighted in red.

The product is labeled Inactivated enzyme and has the following structure: The O atom (blue) of the O H group of the serine residue loses its H atom and forms a single bond with the P atom of D I P F (red) which has lost its F atom. The second product is F superscript minus which is highlighted in red. The third product is H superscript plus which is highlighted in blue.

Return to FIGURE 5.26. Schematic illustration of irreversible inhibition of an enzyme by D I P F, a group specific reagent

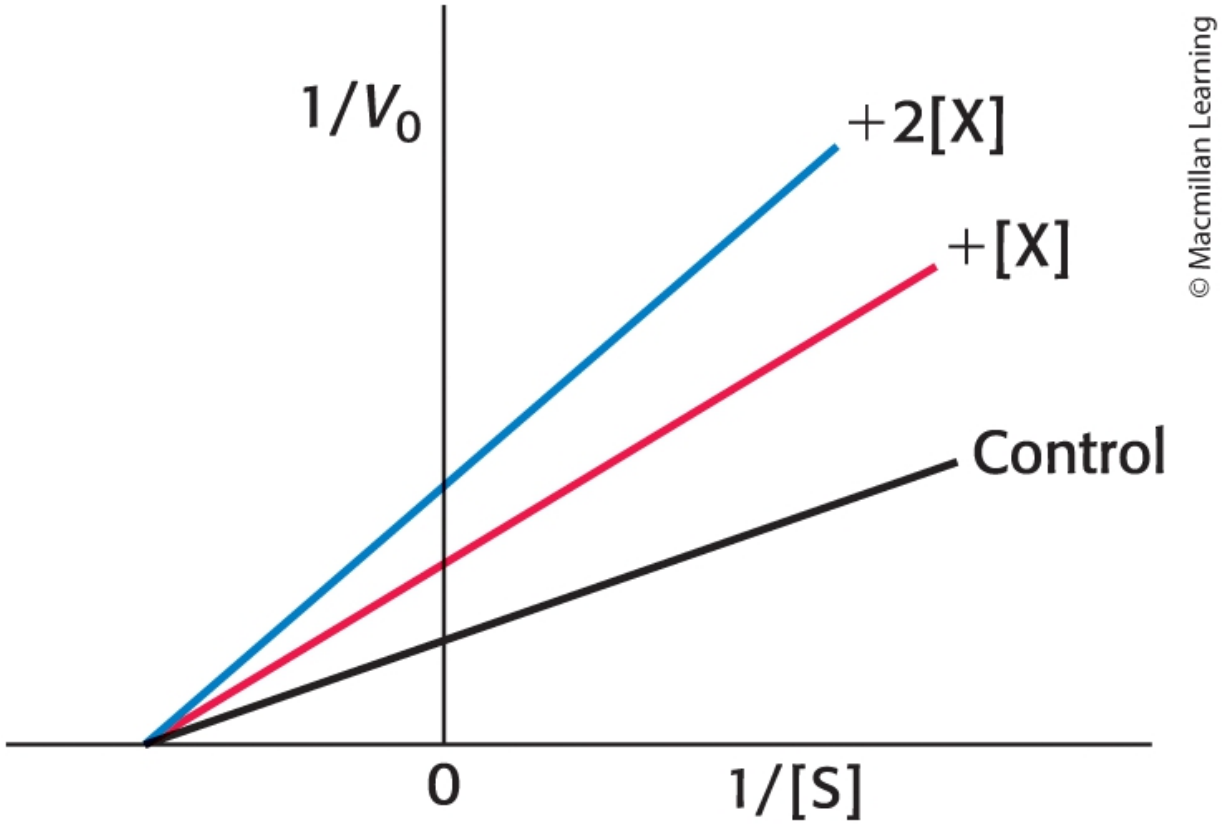
Extended description for FIGURE 5.27. The chemical structure of the natural substrate of chymotrypsin and an affinity label that binds to chymotrypsin

Part(A) Chemical structures:

1. The natural substrate for chymotrypsin: A 2 N and 2 C heteronuclear alkane chain is depicted as a line structure using 3 zigzag lines. The N atoms occupy the first and fourth positions while the C atoms occupy the remaining positions. The first N atom is bound to H below and single bonded to R prime on the upper left. C

1 is dash bonded to H on the upper right and wedge bonded to a C atom on the upper left. The wedge bonded C atom is single bonded to C 4 of a benzene ring in a vertical orientation. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 of the heteronuclear chain is double bonded to O below. The second N atom is bound to H above and single bonded to R double prime on the lower right. The benzene ring and the single bond at C 4 are highlighted in blue.

2. Tosyl-L-phenylalanine chloromethyl ketone (T P C K): A 1 S, 1 N and 3 C heteronuclear alkane chain is depicted as a line structure using 4 zigzag lines. The S atom occupies the first position and is double bonded to O on the upper right and the upper left. It is single bonded to C 2 of a benzene ring in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 5 of this ring is single bonded to C H 3 on the lower left. The N atom occupies the second position in the alkane chain and is bound to H. C 1 is dash bonded to H on the upper right and wedge bonded to a C atom on the upper left. This C atom is single bonded to C 4 of a benzene ring in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C6. C 2 of the heteronuclear chain is double bonded to O below. C 3 is single bonded to C l on the lower right. The benzene ring and the single bond at C 4 are highlighted in blue and collectively labeled specificity group. C 2 and C 3 of the chain, along with their associated bonds, are highlighted in red and labeled reactive group.



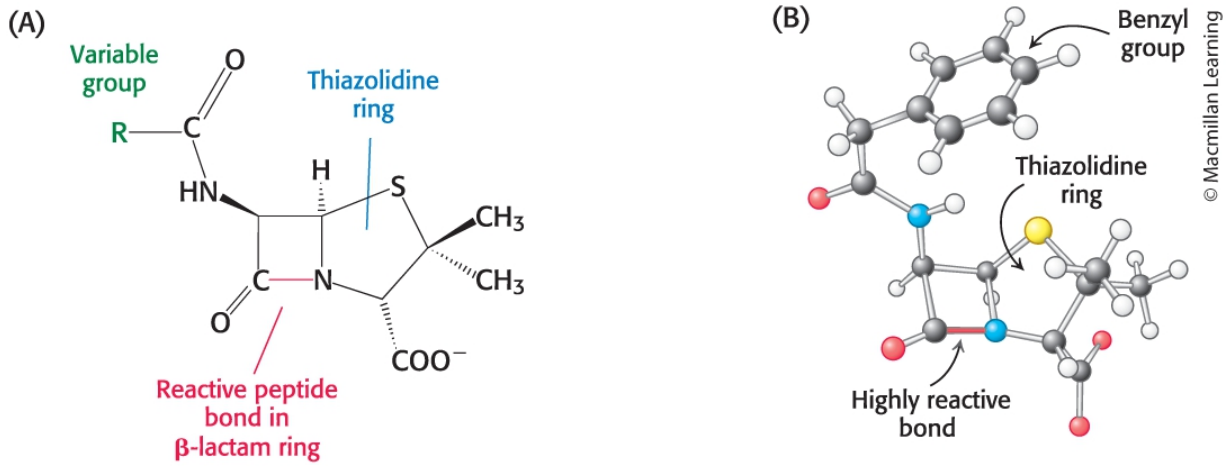
(B) The histidine residue of the chymotrypsin molecule is labeled His 57 and has the following structure: A five membered heterocyclic pentagonal ring consisting of 2 N and 3 C atoms is in a horizontal orientation. The first N atom occupies the first position, which is top left vertex. The second N atom occupies the third

position, which is the bottom-most vertex. C 1 occupies the bottom right vertex. A double bond is present between C 1 and the second N atom and C 2 and C 3. The second N atom is bound to H. C 3 is single bonded to C H 2 in the form of a line which in turn is connected to chymotrypsin. The chymotrypsin molecule is depicted as an upward curved line with a yellow highlight.

The His 57 residue reacts with T P C K and undergoes the following modification. The modified product consists of a five-membered heterocyclic pentagonal ring composed of 2 N and 3 C atoms is in a horizontal orientation. The first N atom occupies the first position, which is the top right vertex. The second N atom occupies the third position, which is the bottom-most vertex. A double bonds are present between the first N atom and C 1, and C 1 and C 3. The second N atom is single bonded to C H 2 below in the form of a line which is further single bonded to a C atom below. This C atom is double bonded to O on the upper right and single bonded to R below. The modified portion is also highlighted in red.

Return to FIGURE 5.27. The chemical structure of the natural substrate of chymotrypsin and an affinity label that binds to chymotrypsin

Extended description for Lineweaver–Burk plot shows enzyme activity at different concentrations of molecule X



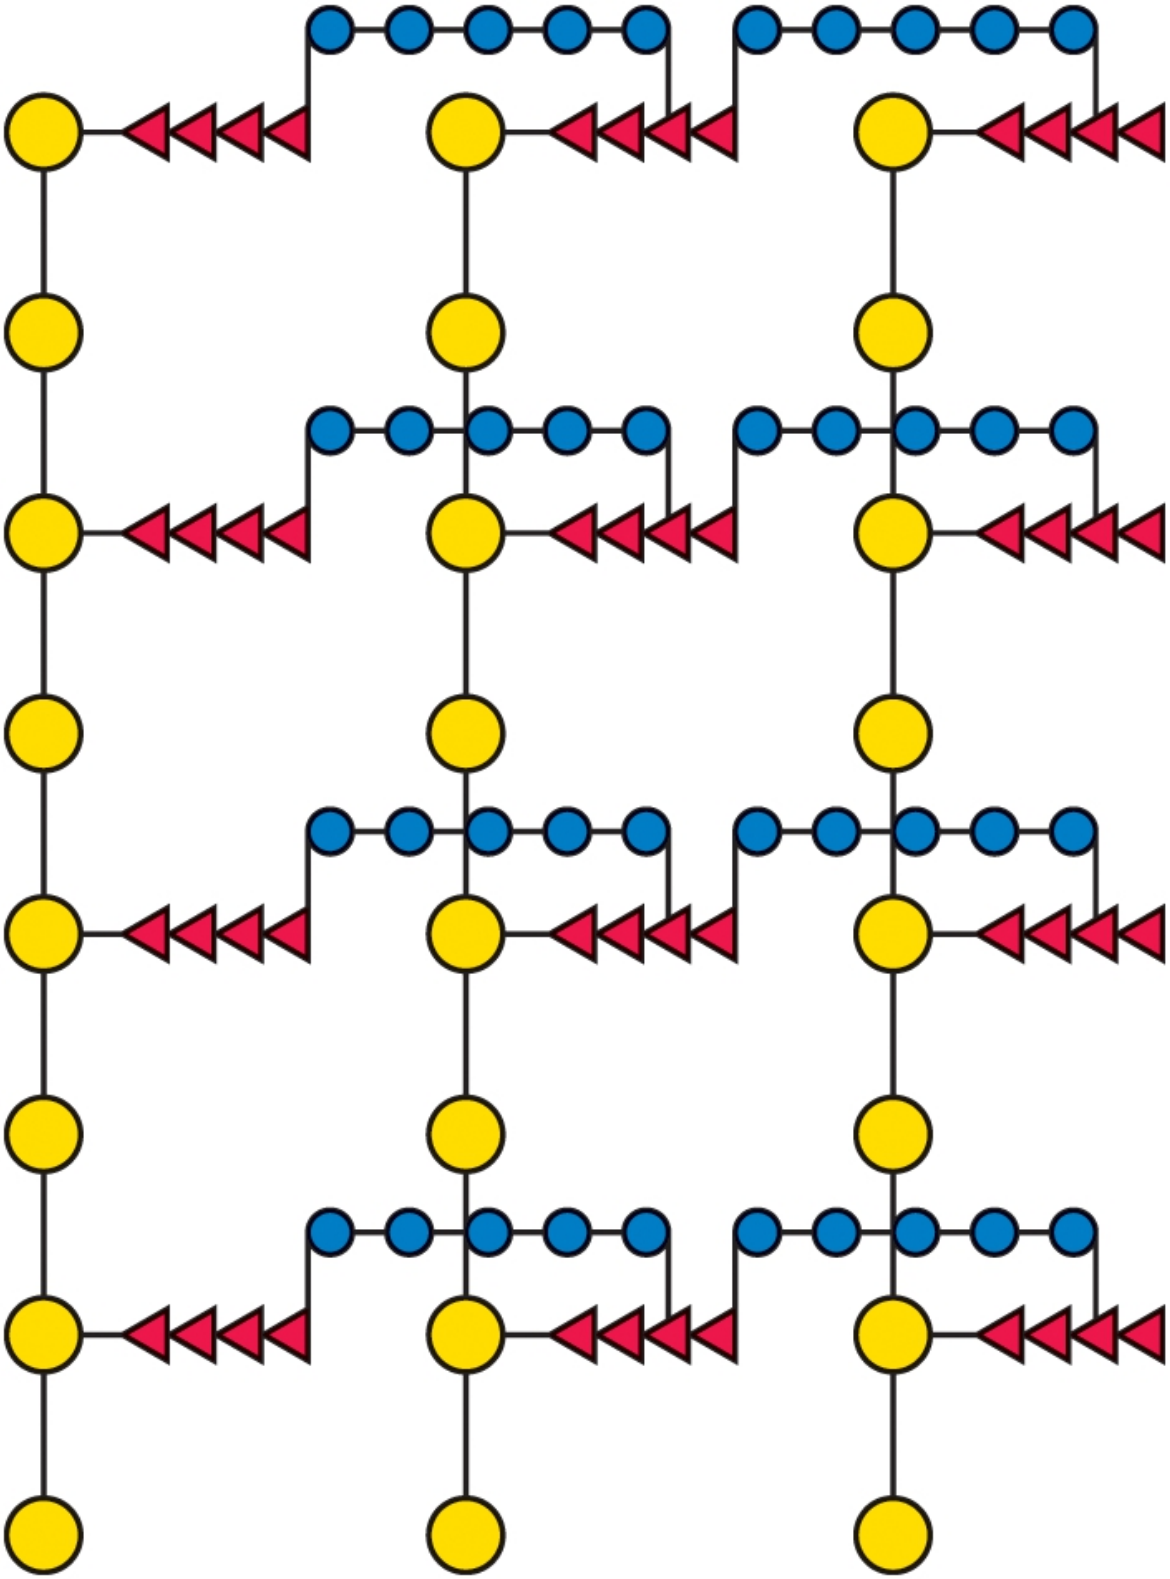
The horizontal axis is labeled StartFraction 1 over substrate concentration EndFraction. The vertical axis is labeled 1 over V naught. Three straight-line plots are shown:

Control: A straight line with a linear slope runs from a point on the negative side of the horizontal axis. It crosses the vertical axis into the positive quadrant. Plus concentration of X: A straight line with a steeper slope runs from the same point on the negative side of the horizontal axis. It crosses the vertical axis into the positive quadrant.

Plus 2 concentration of X: A straight line with an even steeper slope runs from the same point on the negative side of the horizontal axis. It crosses the vertical axis into the positive quadrant.

Return to Lineweaver–Burk plot shows enzyme activity at different concentrations of molecule X

Extended description for FIGURE 5.28 Chemical structure and ball-and-stick model of penicillin and benzylpenicillin respectively



Part (A): A central C atom is single bonded to R (variable group) on the left, double-bonded to O on the upper right, and single bonded to N H on the lower right. N is wedge bonded to C 2 of a 1 N and 3 C heterocyclic quadrilateral ring. N occupies the first position, which is the bottom right vertex. C 1 occupies the bottom left vertex and is double bonded to O on the lower left. The bond between C and N is labeled reactive peptide bond in the beta-lactam ring. The quadrilateral ring is fused to a 1 S, 1 N, and 3 C containing heterocyclic pentagonal ring labeled thiazolidine ring such that C 3 and N of the quadrilateral ring are C 1 and N respectively of the pentagonal ring. The pentagonal ring is in a horizontal orientation. N occupies the first position, which is the bottom right vertex. S occupies the topmost vertex. C 1 is dash bonded to H above. C 2 is wedge bonded and dash bonded to a C H 3 group on the upper right and lower right, respectively. C 3 is dash bonded to C O O superscript minus on the lower right.

(B) In the ball-and-stick model, C atoms are depicted as black spheres, N atoms are depicted as blue spheres, O atoms are depicted as red spheres, H atoms are depicted as small white spheres, and S atom is depicted as a yellow sphere. A benzyl group composed of a ring of 6 black spheres is present in the position of the variable group R. All black spheres except one are connected to a white sphere. The remaining structure of the molecule is similar to (A) except atoms are replaced by spheres. The highly reactive bond is highlighted in red and the thiazolidine ring is shown with an arrow.

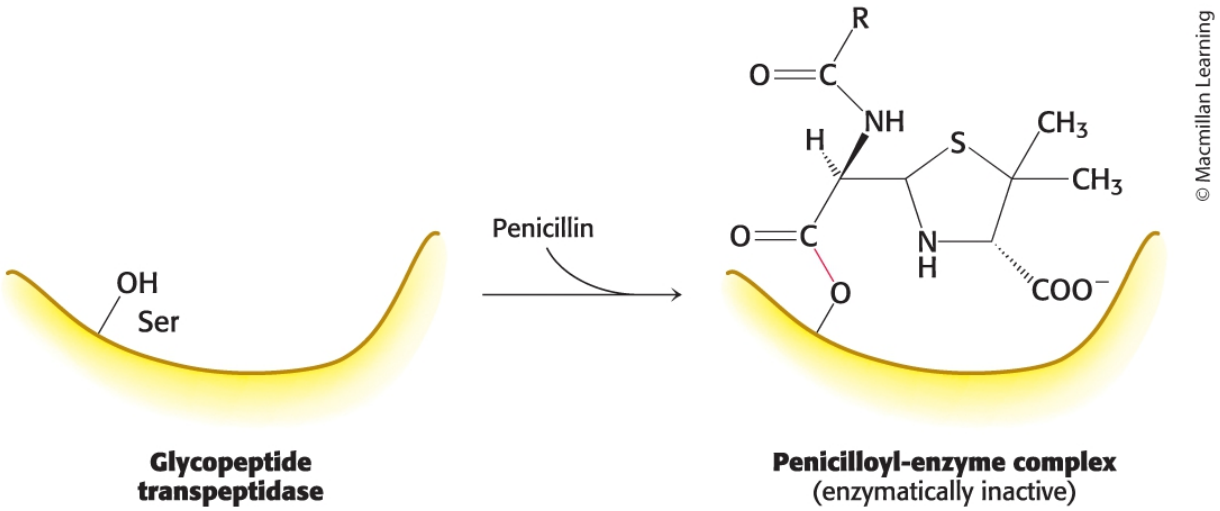
Extended description for FIGURE 5.30. Similar chemical structures of penicillin and transition state (R prime-D-Ala-D-Ala peptide) of the transpeptidase reaction

Penicillin **R′-D-Ala-D-Ala peptide**



Penicillin: A central C atom is single bonded to R on the left, double-bonded to O on the upper right, and single bonded to N H on the lower right. N is wedge bonded to C 2 of a 1 N and 3 C heterocyclic quadrilateral ring. N occupies the first position, which is the bottom right vertex. C 1 occupies the bottom left vertex and is double bonded to O on the lower left. The bond between C and N is labeled reactive bond. The quadrilateral ring labeled beta-lactam ring is fused to a 1 S, 1 N, and 3 C containing heterocyclic pentagonal ring such that C 3 and N of the quadrilateral ring are C 1 and N respectively of the pentagonal ring. The pentagonal ring is in a horizontal orientation. N occupies the first position, which is the bottom right vertex. S occupies the topmost vertex. C 1 is single bonded to H above. C 2 is wedge bonded and dash bonded to a C H 3

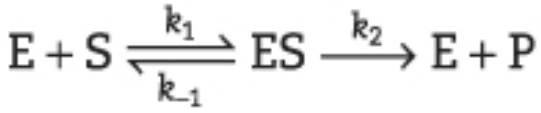
group on the upper right and lower right, respectively. C 3 is dash bonded to C O O superscript minus on the lower right.

R prime-D-Ala-D-Ala peptide: R prime, single bond, N, wedge bond, C is present in a zigzag manner. N is bound to H. C is single bonded to C H 3 on the right and single bonded to C below in the form of a vertical line. The C atom below is double bonded to O on the lower left, and single bonded to N on the right. This part of the molecule is labeled D-Ala. The N atom is bound to H and is single bonded to C on the lower right in the form of a line. The C atom is single bonded to C H 3 on the upper right and dash bonded to C O O superscript minus below. This part of the molecule is also labeled D-Ala.

Return to FIGURE 5.30. Similar chemical structures of penicillin and transition state (R prime-D-Ala-D-Ala peptide) of the transpeptidase reaction

Extended description for FIGURE 5.31. Schematic illustration showing the formation of penicilloyl-enzyme complex

The reaction consists of one reactant and one product.



The reactant is an enzyme labeled glycopeptide transpeptidase. It is depicted as a downward curved horizontal line with a yellow highlight. A serine residue with an available O H group is connected to the enzyme. The reaction occurs in the presence of penicillin.

The product is labeled penicilloyl-enzyme complex (enzymatically inactive) and has the following structure: A 1 N and 3 C heteronuclear alkane chain is depicted as a line structure using 3 zigzag lines. It is present in a vertical orientation. The N atom occupies the second position. C 1 is double bonded to O on the left and single bonded to R on the upper right. The N atom is bound to H and wedge bonded to C 2. C 2 is dash bonded to H on the upper left, and single bonded to C 1 of a five-membered heterocyclic pentagonal ring in a horizontal orientation. The ring consists of 1 S,

1 N, and 3 C atoms. N atom occupies the first position, which is the bottom left vertex. It is bound to H. S atom occupies the first position, which is the topmost vertex. C 2 of this ring is single bonded to C H 3 on the upper right and on the right. C 3 is dash bonded to C O O superscript minus on the lower right. C 3 of the heteronuclear alkane chain is double bonded to O on the left. The O atom of the serine residue of glycopeptide transpeptidase loses its H bond and forms a single bond with the C 3 atom of the heteronuclear alkane chain.

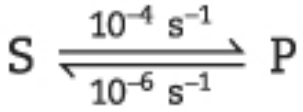
Extended description for Graphical representation of the reaction progress for two different reactions

© Macmillan Learning

The horizontal axis is labeled reaction progress. The vertical axis is labeled free energy. Two energy levels are shown in each case.

(A): The first level is extremely close to the right end of the horizontal axis and is labeled Product. The second level is at four times the height of the product level and is located above the left end of the horizontal axis. It is labeled substrate.

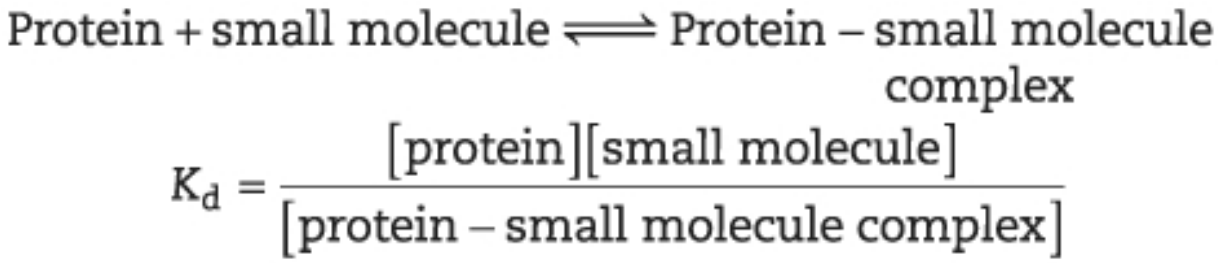


A solid curve rises steadily from the substrate level at the start of the reaction to a higher level in the middle of the reaction and forms a peak. The curve then falls to the product level by the end of the reaction.

(B): The first level is extremely close to the left end of horizontal axis and is labeled Substrate. The second level is at four times the height of the substrate level, above the right end of the horizontal axis, and is labeled product.

A solid curve rises rapidly from the substrate level at the start of the reaction to a higher level in the middle of the reaction and forms a peak. The curve then falls slightly to the product level by the end of the reaction.

Return to Graphical representation of the reaction progress for two different reactions

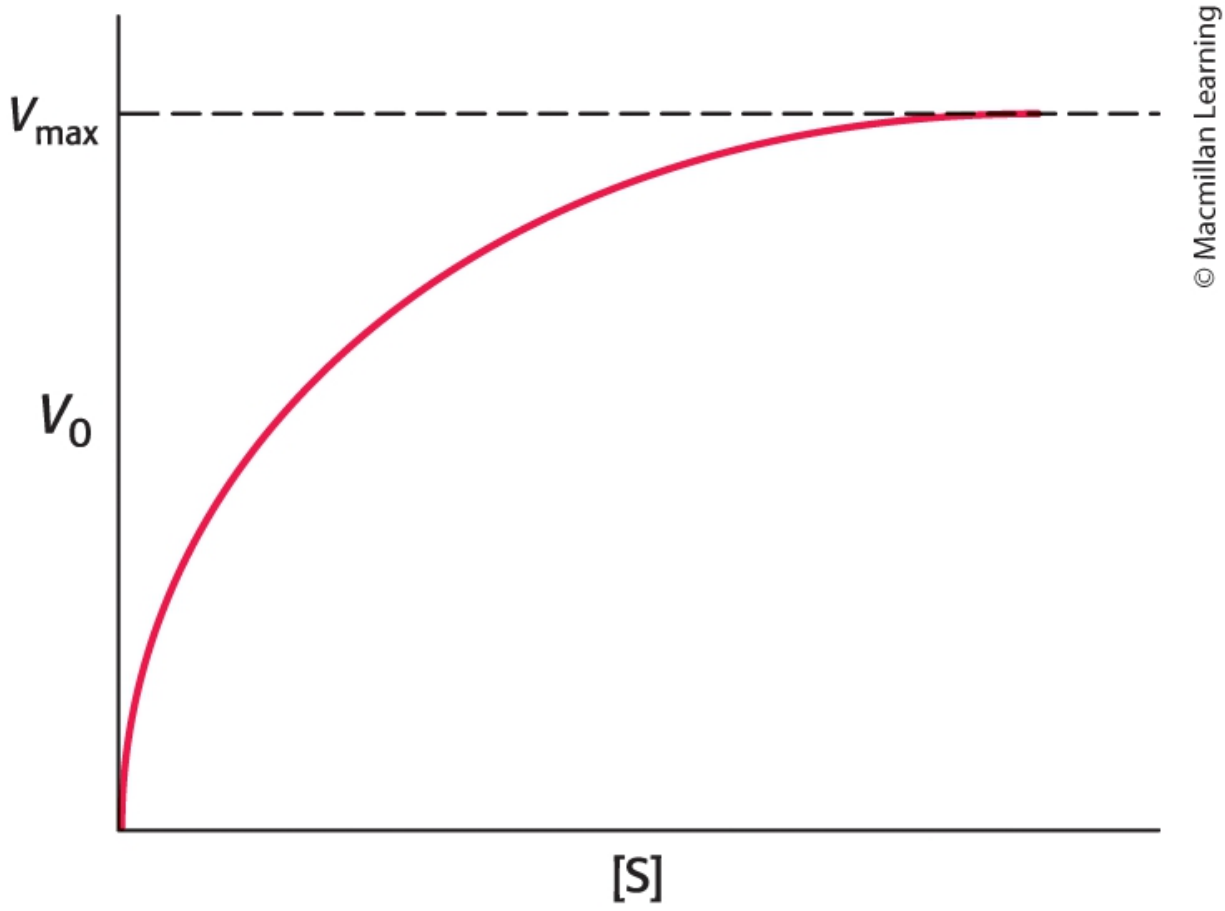


Extended description for Forward and reverse rate constants for the conversion of S into P

The reaction shows the reversible conversion of S to P. The forward rate constant shown above the forward arrow is 10 superscript minus 4 baseline s superscript minus 1. The reverse rate constant shown below the backward arrow is 10 superscript minus 6 baseline s superscript minus 1.

Return to Forward and reverse rate constants for the conversion of S into P

Extended description for Protein binding to a small molecule and the formula for K subscript d

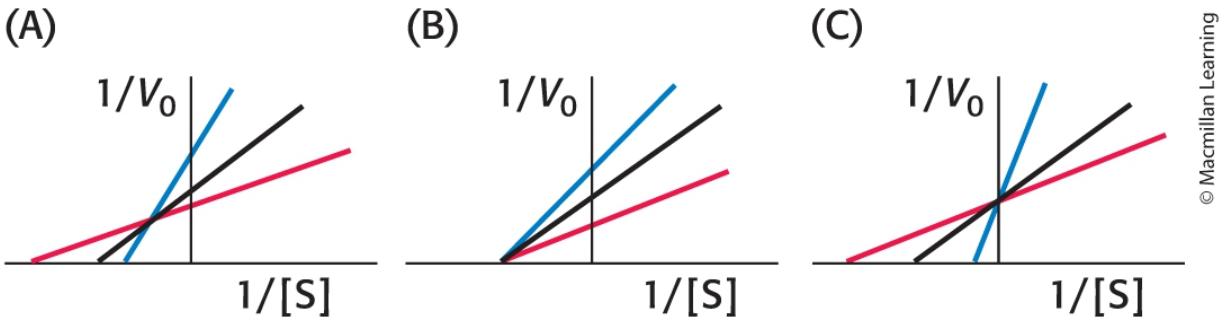


The chemical reaction consists of two reactants and one product. The first reactant is protein. The second reactant is small molecule. A reversible reaction arrow leads to the product. The product is the protein-small molecule complex.

The formula for K subscript d is as follows:

K subscript d equals StartFraction concentration of protein into concentration of small molecule over concentration of protein-small molecule complex EndFraction.

Return to Protein binding to a small molecule and the formula for K subscript d



Extended description for Michaelis–Menten plot

The graph shows an upward convex curve. The horizontal axis is labeled substrate concentration. The vertical axis is labeled V naught. A dashed line labeled V subscript max runs parallel to the horizontal axis at the highest point of the vertical axis. An upward convex curve starts from the origin and plateaus near the dashed-line at a high substrate concentration.

Return to Michaelis–Menten plot

Extended description for Double-reciprocal plots for three different enzyme concentrations

© Macmillan Learning

The horizontal axis is labeled StartFraction 1 over substrate concentration EndFraction. The vertical axis is labeled StartFraction 1 over V naught EndFraction. Three straight line plots are shown in each graph:

(A) All the straight lines intercept each other at a point to the left of the vertical axis, just above the origin.

Red: A straight line runs from a point on the negative side of the horizontal axis. It crosses the vertical axis into the positive quadrant.

Black: A steeper straight line from a point slightly closer to the origin, on the negative side of the horizontal axis. It crosses the vertical axis into the positive quadrant.

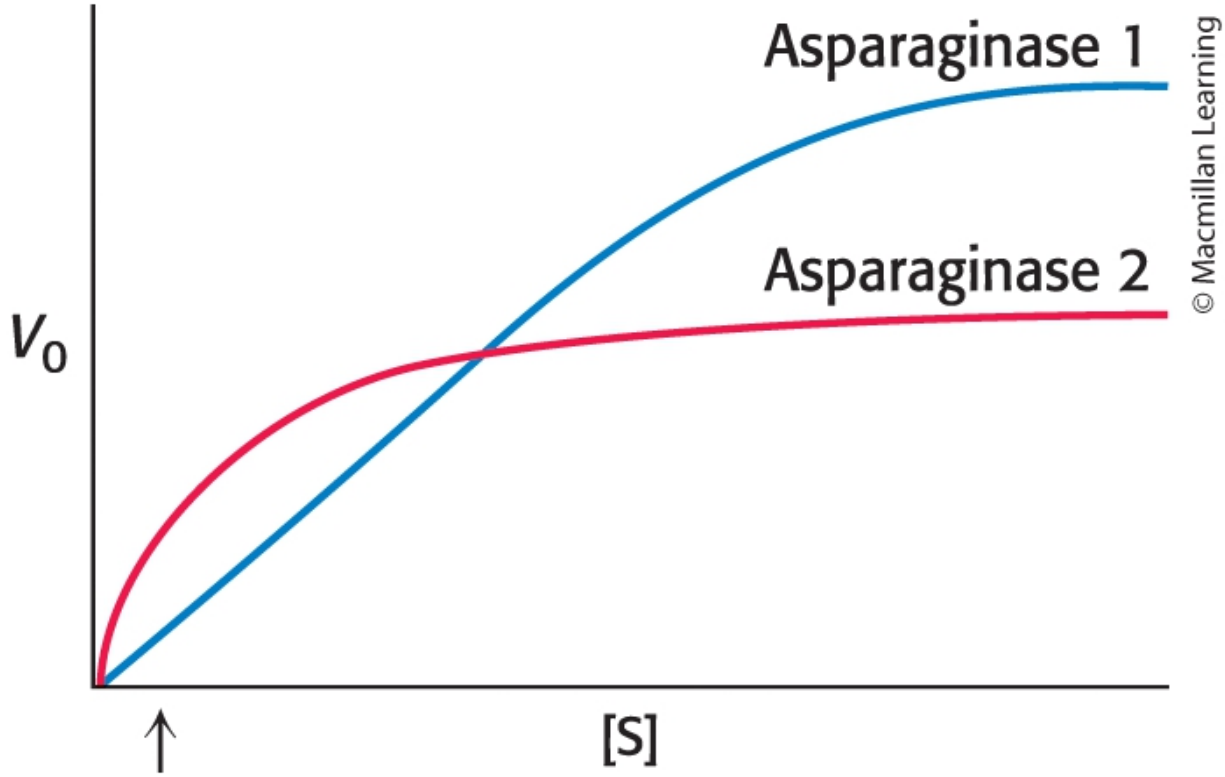
Blue: An even steeper straight line runs from a point even closer to the origin, on the negative side of the horizontal axis. It crosses the vertical axis into the positive quadrant.

(B) Red: A straight line runs from a point on the negative side of the horizontal axis. It crosses the vertical axis into the positive quadrant.

Black: A steeper straight line runs from the same point on the negative side of the horizontal axis. It crosses the vertical axis into the positive quadrant.

Blue: An even steeper straight line runs from the same point on the negative side of the horizontal axis. It crosses the vertical axis into the positive quadrant.

(C) All the straight lines cross the vertical axis at the same point.



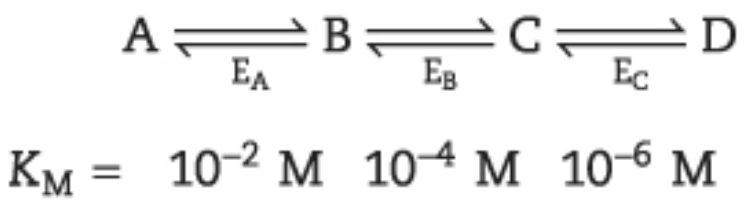
Red: A straight line runs from a point on the negative side of the horizontal axis. It crosses the vertical axis into the positive quadrant.

Black: A steeper straight runs from a point slightly closer to the origin, on the negative side of the horizontal axis. It crosses the vertical axis into the positive quadrant.

Blue: An even steeper straight line runs from a point slightly even closer to the origin, on the negative side of the horizontal axis. It crosses the vertical axis into the positive quadrant.

Return to Double-reciprocal plots for three different enzyme concentrations

Extended description for Michaelis–Menten curves for asparaginase from different sources



The horizontal axis is labeled substrate concentration. The vertical axis is labeled V naught. A hyperbolic curve and a line curve are shown:

1. Asparaginase 1: The line curve rises linearly until three-fourth of the maximum value of V naught on the vertical axis, and then plateaus at the highest concentration of substrate.

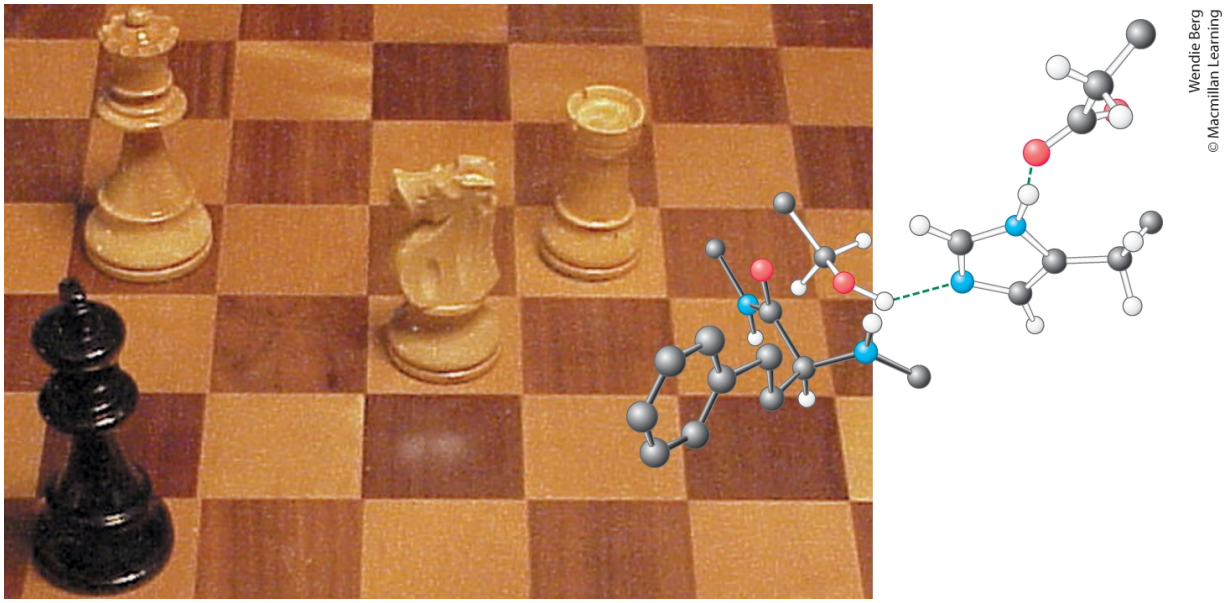
2. Asparaginase 2: The hyperbolic curve rises rapidly until one-half of the value of V naught on the vertical axis, and then plateaus at a substrate concentration less than half of the maximum value.

Return to Michaelis–Menten curves for asparaginase from different sources

Extended description for Sequential conversion of A to D

The pathway is depicted as follows: A is reversibly converted into B. The bottom backward arrow is labeled E subscript A. B is then reversibly converted into C. The bottom backward arrow is labeled E subscript B. C is further reversibly converted into D. The bottom backward arrow is labeled E subscript C.

The value of K subscript M for the different enzymes is as follows:



E subscript A: 10 superscript minus 2 molar.

E subscript B: 10 superscript minus 4 molar.

E subscript C: 10 superscript minus 6 molar.

Return to Sequential conversion of A to D

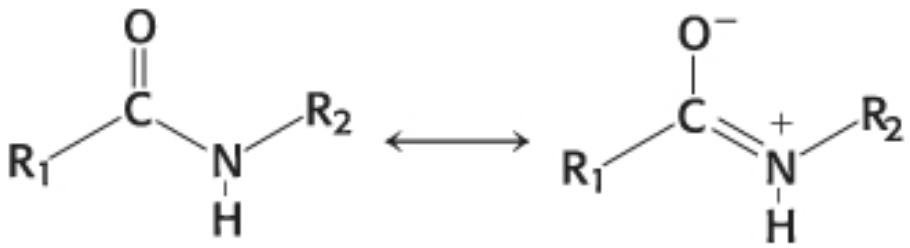
Extended description for Hydrolysis of a peptide

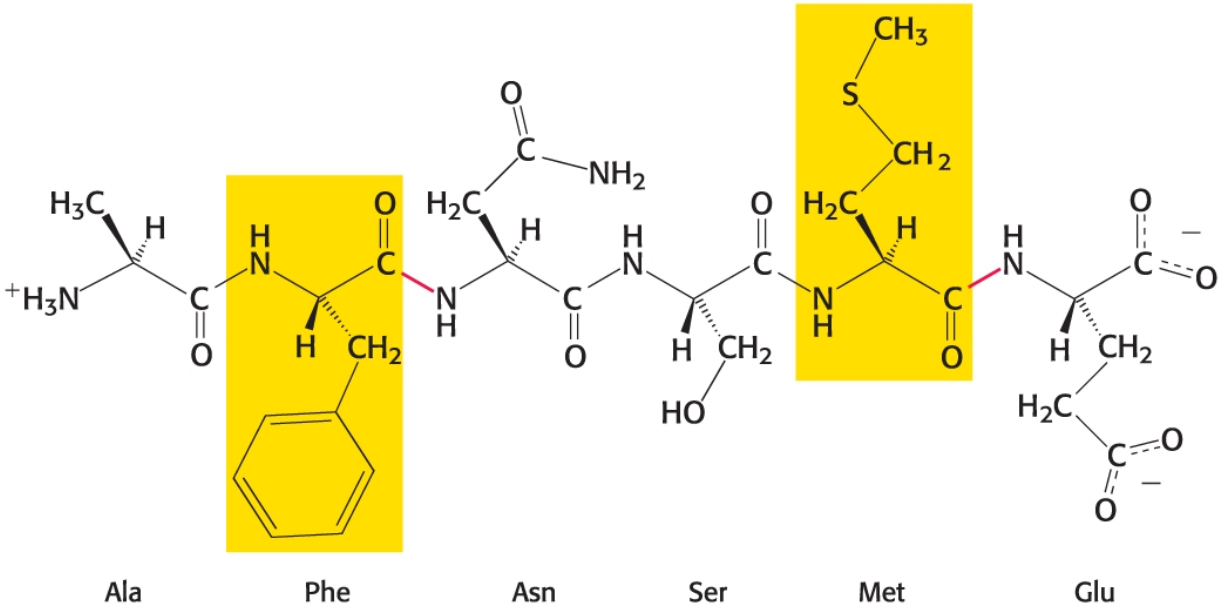


The hydrolysis reversible reaction consists of two reactants and two products.

The first reactant has the following structure: A central C atom is double bonded to O above, single bonded to R subscript 1 on the lower left, and N on the lower right. N is single bonded to R subscript 2 on the upper right and H below. The second reactant is H 2 O.

The first product has the following structure: A central C atom is single bonded to R subscript 1 on the left. The central C atom is single bonded to O on the upper right and shares a resonance bond with O. The central C atom is single bonded to a second O atom on the lower right and shares a resonance bond with the second O atom. The second product has the following structure: R subscript 2, single bond, N H 3 superscript plus.

Return to Hydrolysis of a peptide



Extended description for Chemical reaction

The reaction consists of one reactant and one product. The first reactant has the following structure: A central C atom is double bonded to O above, single bonded to N on the lower right, and single bonded to R subscript 1 on the lower left. The N atom on the lower right is single bonded to R subscript 2 on the upper right and H below. The product has the following structure: A central C atom is single bonded to O superscript script minus above, double-bonded to N superscript plus on the lower right, and single bonded to R subscript 1 on the lower left. The N atom on the lower right is single bonded to R subscript 2 on the upper right and H below.

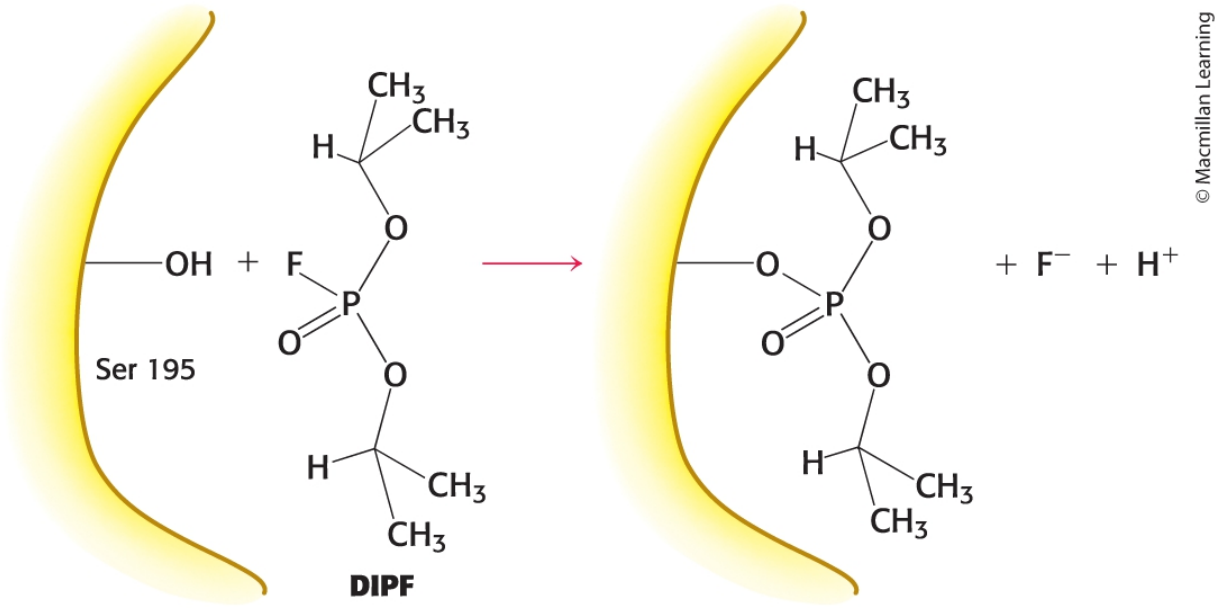
Extended description for FIGURE 6.1. Chemical structure of a peptide with highlighted target amino acids and bonds cleaved by chymotrypsin

The peptide is composed of amino acids A l a, P h e, A s n, S e r, M e t, and G l u.



The structure of the peptide is as follows: A 5 N and 1 2 C heteronuclear alkane chain is depicted as a line structure using 16 zigzag lines. The first N bound to H occupies the third position. The second N bound to the H atom occupies the sixth position. The third N bound to H occupies the ninth position. The fourth N bound to H occupies the twelfth position. The fifth N bound to H occupies the fifteenth position. C 1 is wedge bonded to C H 3 on the upper left, dash bonded to H on the upper right, and single bonded to N H 3 superscript plus on the lower left. C 2 is double bonded to O below. C 3 is wedge bonded to H on the lower left and dash bonded to C H 2 on the lower right. C H 2 is single bonded to C 6 of a benzene ring in

a horizontal orientation with C 1 occupying the rightmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 4 of the alkane chain is double bonded to O above. C 5 of the alkane chain is dash bonded to H on the upper right and wedge bonded to C H 2 on the upper left. C H 2 is single bonded to a central C atom on the upper right. The central C atom is double bonded to O on the upper left and single bonded N H 2 on the lower right. C 6 is double bonded to O below. C 7 is wedge bonded to H on the lower left and dash bonded to C H 2 on the lower right. C H 2 single bonded to O H on the lower left. C 8 is double bonded to O above. C 9 is dash bonded to H on the upper right and wedge bonded to C H 2 on the upper left. C H 2 is single bonded to C H 2 on the upper right, which is again single bonded to S on the upper left. S is single bonded to C H 3 on the upper right. C 10 is double bonded to O below. C 11 is dash bonded to C H 2 on the lower left and wedge bonded to H on the lower right. C H 2 is single bonded to C H 2 on the lower left, which is again single bonded to C on the lower right. This C atom is partially double bonded to O on the upper right and O lower left. C 12 is partially double bonded to O above and O on the lower right. This C O O group has a net negative charge.

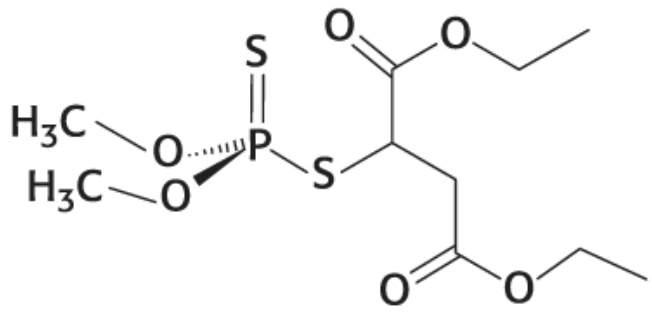
P h e amino acid highlighted in yellow includes the first N atom, C 3, and its associated benzene ring. M e t amino acid highlighted in yellow includes the fourth N atom, C 9 and its associated chain, and C 10. The single bond between C 4 and second N atom and C 10 and fifth N atom is highlighted in red.

Return to FIGURE 6.1. Chemical structure of a peptide with highlighted target amino acids and bonds cleaved by chymotrypsin

Extended description for FIGURE 6.2. Schematic illustration of the irreversible inactivation of chymotrypsin by D I P F

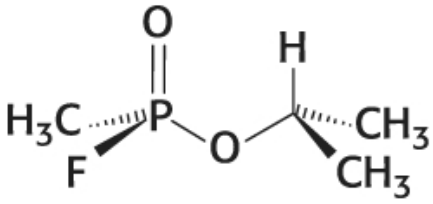
The irreversible inactivation of chymotrypsin by D I P F is shown as a chemical reaction consisting of two reactants and three products.

The first reactant is S e r 195 bound to the enzyme. The enzyme is depicted as a vertical concave surface with a yellow highlight. The O H group of S e r 195 is single-bonded to the enzyme. The second reactant is D I P F which has the following structure: A 1 P, 2 O, and 2 C heteronuclear alkane chain is depicted as a line structure using 4 zigzag lines. The first O atom occupies the second position and the second O atom occupies the fourth position. The P atom occupies the third position. C 1 is single bonded to C H 3 on the lower right, and below, and single bonded to H on the lower left. The P atom is single-bonded to F on the upper left and double-bonded to O on the



lower left. C 2 is single bonded to C H above, upper right, and single bonded to H on the left.

A forward reaction arrow is shown.

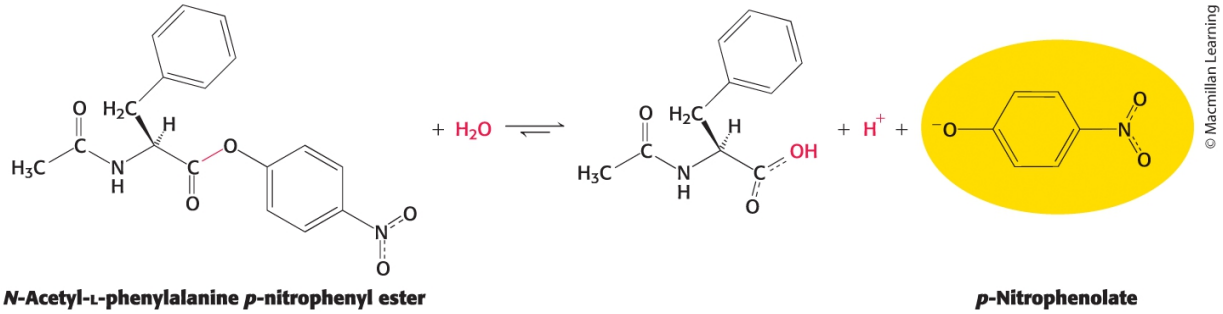


The first product consists of D I P F bound to the enzyme. It has the following structure: The O atom of the S e r 195 residue loses its H atom and forms a single bond with the P atom of D I P F which has lost its F atom. The second product is F superscript minus ion. The third product is H superscript plus ion.

Return to FIGURE 6.2. Schematic illustration of the irreversible inactivation of chymotrypsin by D I P F

Extended description for Molecular structures of malathion and sarin

Malathion



Sarin

The structure of malathion is as follows: A 1 P, 1 S, and 2 C heteronuclear alkane chain is depicted as a line structure using 3 zigzag lines. P atom occupies the first position. S atom occupies the second position. P is double bonded to S above, dash bonded O, single bond, C H 3 on the left, and wedge bonded to O, single bond, C H 3 on the lower left. C 1 is single bonded above to C 1 of another 1 O and 3 C heteronuclear alkane chain depicted as a line structure using 3 zigzag lines. O atom occupies the second position. C 1 is double bonded to O on the upper left. C 2 of the main chain is single bonded below to C 1 a 1 O and 3 C heteronuclear alkane chain depicted as a line structure using 3 zigzag lines. O occupies the second position. C 1 is double bonded to O on the lower left.

The structure of sarin is as follows: A 1 P, 1 O, and 1 C heteronuclear alkane chain is depicted as a line structure using 2 zigzag lines. P occupies the first position. O occupies the second position. P is double bonded to O above, dash bonded to C H 3 on the left, and wedge bonded to F on the lower left. C 1 is single bonded to H above, dash bonded to C H 3 on the lower right, and wedge bonded to C H 3 below.

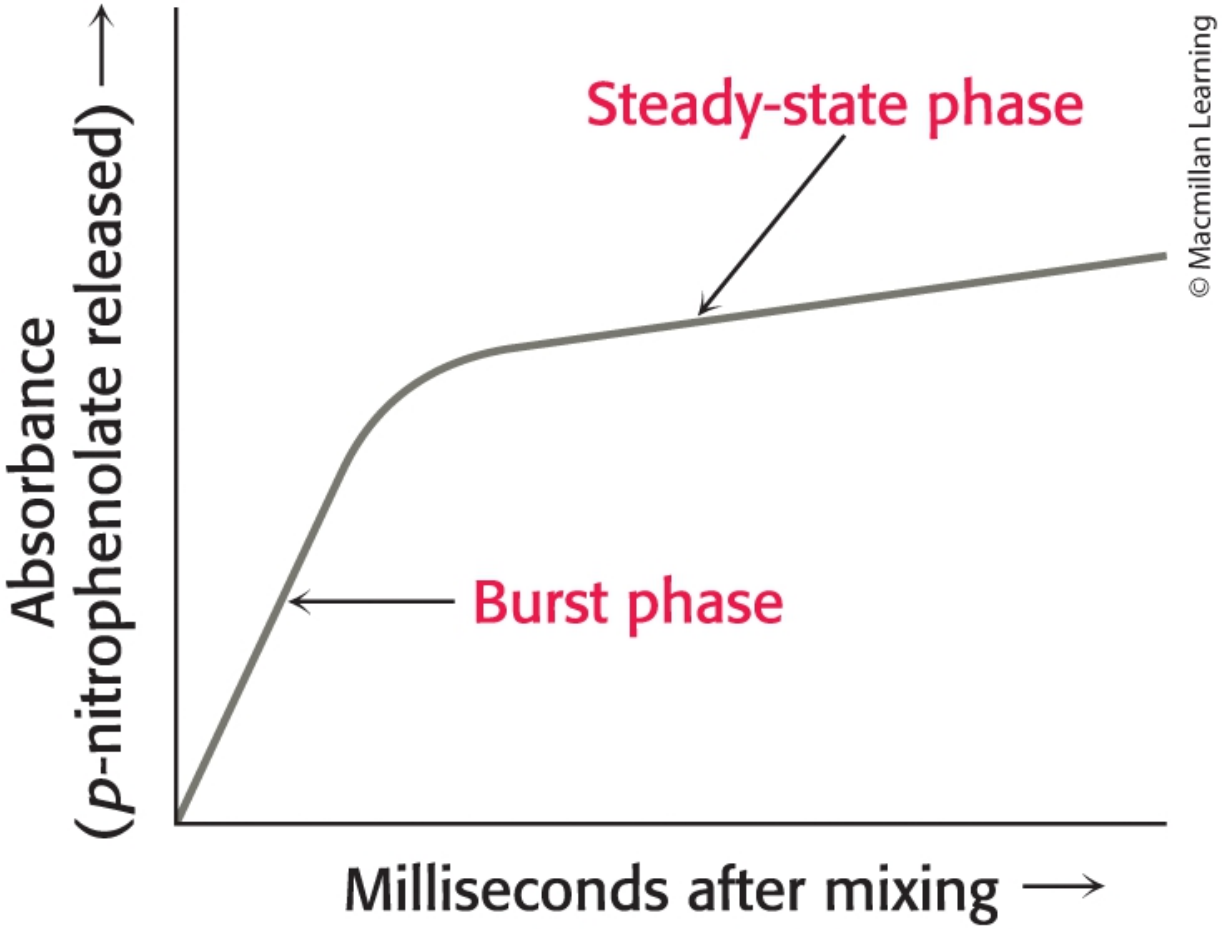
Return to Molecular structures of malathion and sarin

Extended description for FIGURE 6.3. Chemical reaction for monitoring chymotrypsin action

The reaction consists of two reactants and three products.

The first reactant is N-Acetyl-L-phenylalanine p-nitrophenyl ester has the following structure: A 1 N and 4 C heteronuclear alkane chain is depicted as a line structure using 4 zigzag lines. N occupies the third position and is bound to H. C 1 is bound to H 3. C 2 is double bonded to O above. C 3 is dash bonded to H on the upper right and wedge bonded to C H 2 on the upper left. C H 2 is single bonded to C 3 of a benzene ring in a horizontal orientation with C 1 occupying the right most vertex. The ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 4 of the heteronuclear chain is single bonded to O on the upper right and double bonded to O below. The O atom on the upper right is single bonded to C 6 of a benzene in a vertical orientation with C 1 occupying the topmost vertex. Alternating double bonds are present between C 1 and C2, C 3 and C 4, and C 5 and C 6. C 3 of the benzene ring is single bonded to N on the lower right. The N atom is single bonded to O on the upper right and O below with a resonance bond shared between them.

The second reactant is a H 2 O.

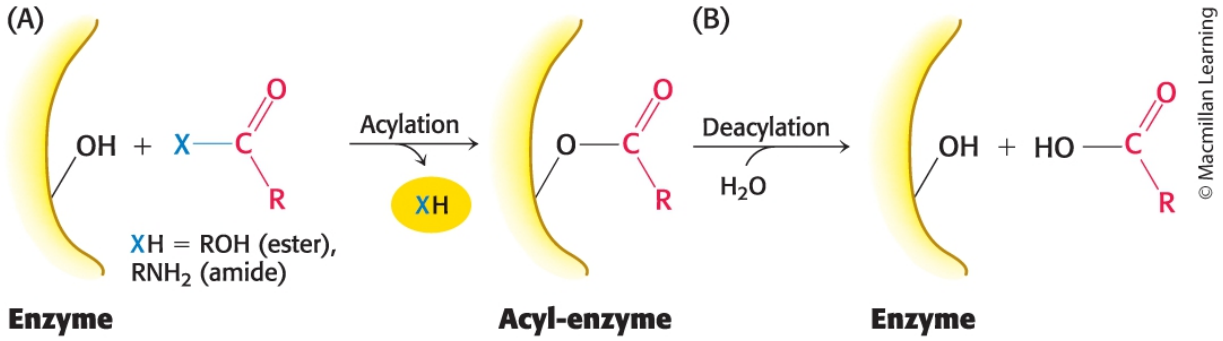


The structure of the first product is as follows: A 1 N and 4 C heteronuclear alkane chain is depicted as a line structure using 4 zigzag lines. N occupies the third position and is bound to H. C 1 is bound to H 3. C 2 is double bonded to O above. C 3 is dash bonded to H on the upper right and wedge bonded to C H 2 on the upper left. C H 2 is single bonded to C 3 of a benzene ring in a horizontal orientation with C 1 occupying the right most vertex. The ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 4 of the heteronuclear alkane chain is single bonded to O H on the upper right and O on the lower left with a resonance bond shared between them.

The second product is H superscript plus ion.

The third product is p-Nitrophenolate whose structure is as follows: A benzene ring is in a horizontal orientation with C 1 occupying the rightmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 1 is single bonded to N on the right. The N atom is single bonded to O on the upper right and O on the lower right with a resonance bond shared between them. C 4 is single bonded to O superscript minus on the left. The entire molecule is enclosed in a yellow circle.

Return to FIGURE 6.3. Chemical reaction for monitoring chymotrypsin action



Extended description for FIGURE 6.4. Graphical representation of the two kinetic phases of chymotrypsin activity

The horizontal axis is labeled milliseconds after mixing. The vertical axis is labeled absorbance (p-nitrophenolate released). A black curve begins at origin moves gradually toward the upper right in a straight line and is labeled burst phase. The curve then moves almost horizontally and very slowly reaches the upper right and is labeled steady-state phase.

Return to FIGURE 6.4. Graphical representation of the two kinetic phases of chymotrypsin activity

Extended description for FIGURE 6.5. Schematic illustration of hydrolysis by chymotrypsin

The chymotrypsin enzyme is depicted as a vertical concave surface with a yellow highlight.

Part (A): It shows the formation of an acyl-enzyme intermediate in an acylation reaction.

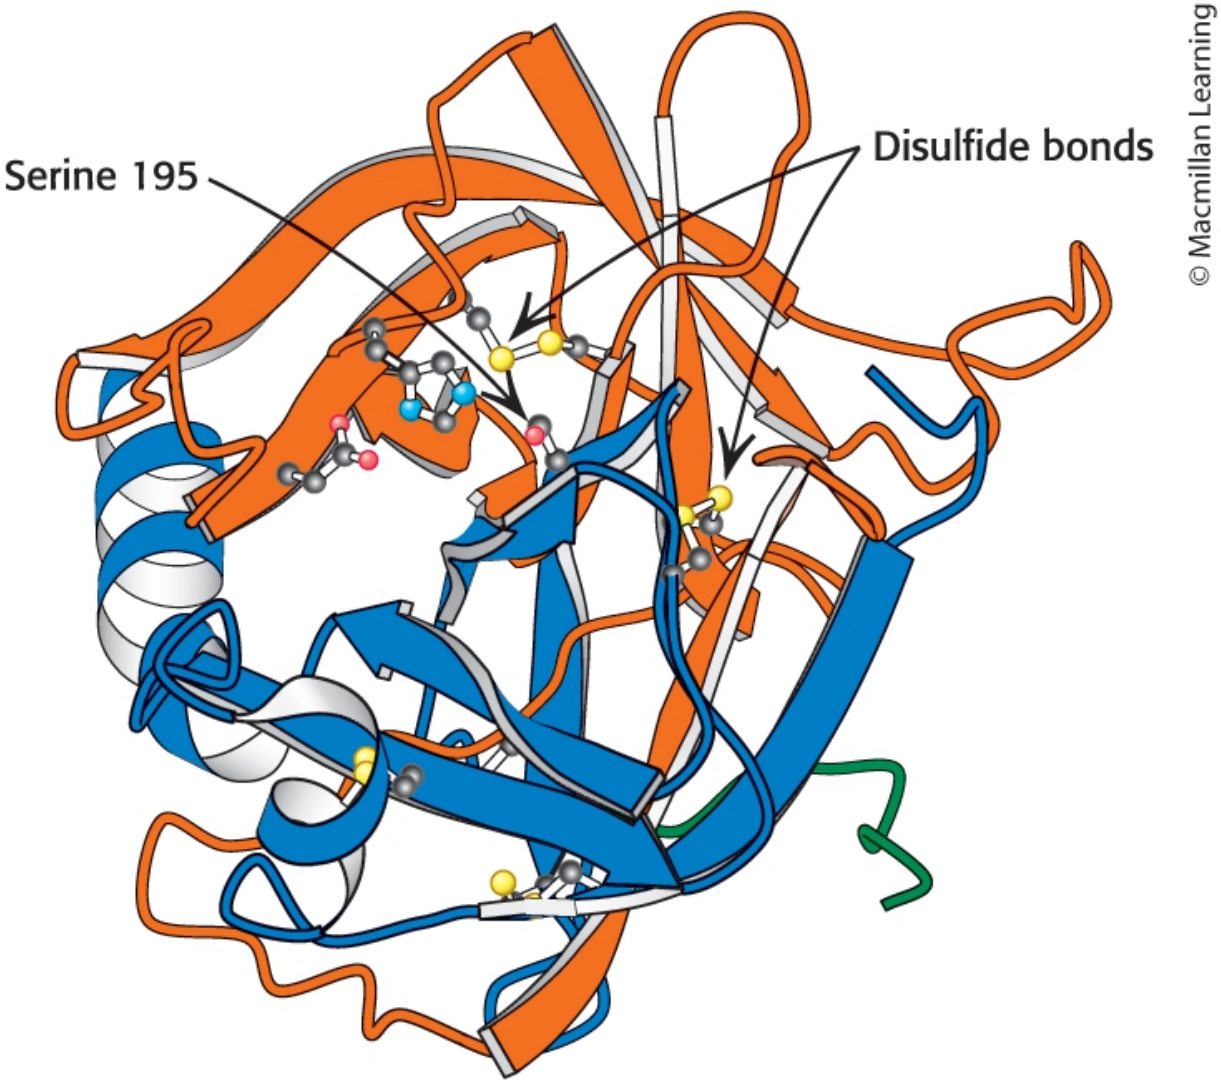
The structure of the first reactant is as follows: The chymotrypsin enzyme single bonded to an O H group in the concave depression is shown. The structure of the second reactant is as follows: A central C atom is single double bonded to O on the upper right, single bonded to R on the lower right, and X on the left. X is highlighted in blue color.

Note: X H equals R O H (ester) and R N H 2 (amide).

A forward reaction arrow is labeled acylation and X H leaves the reaction.

The structure of acyl-enzyme is as follows: A central C atom is double bonded to O on the upper right, single bonded to R on the

lower right, and single bonded to O on the left. The O atom on the left is single bonded to the enzyme.



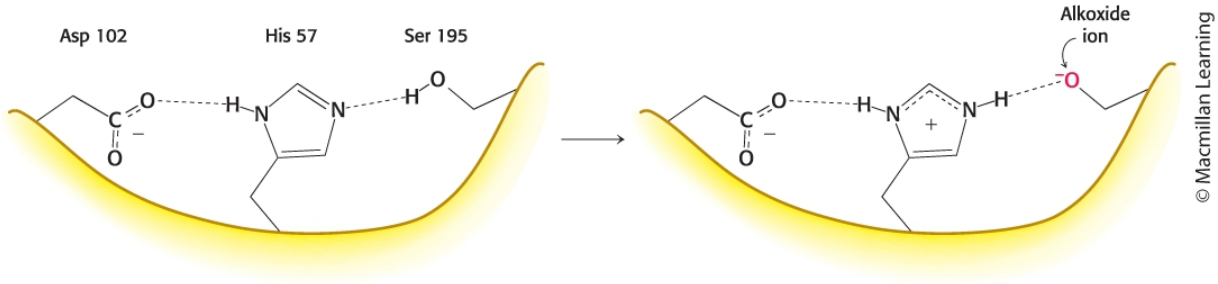
Part (B): The acyl-enzyme is converted into a free enzyme by deacylation reaction.

A forward reaction arrow is labeled deacylation. H 2 O enters the reaction.

The structure of the first product is as follows: The enzyme molecule single bonded to an O H group is shown. The structure of the second product is as follows: A central C atom is double bonded to O on the upper right, single bonded to R on the lower right, and single bonded to O H on the left.

Return to FIGURE 6.5. Schematic illustration of hydrolysis by chymotrypsin

Extended description for FIGURE 6.6. The ribbon diagram of chymotrypsin with active site serine residue

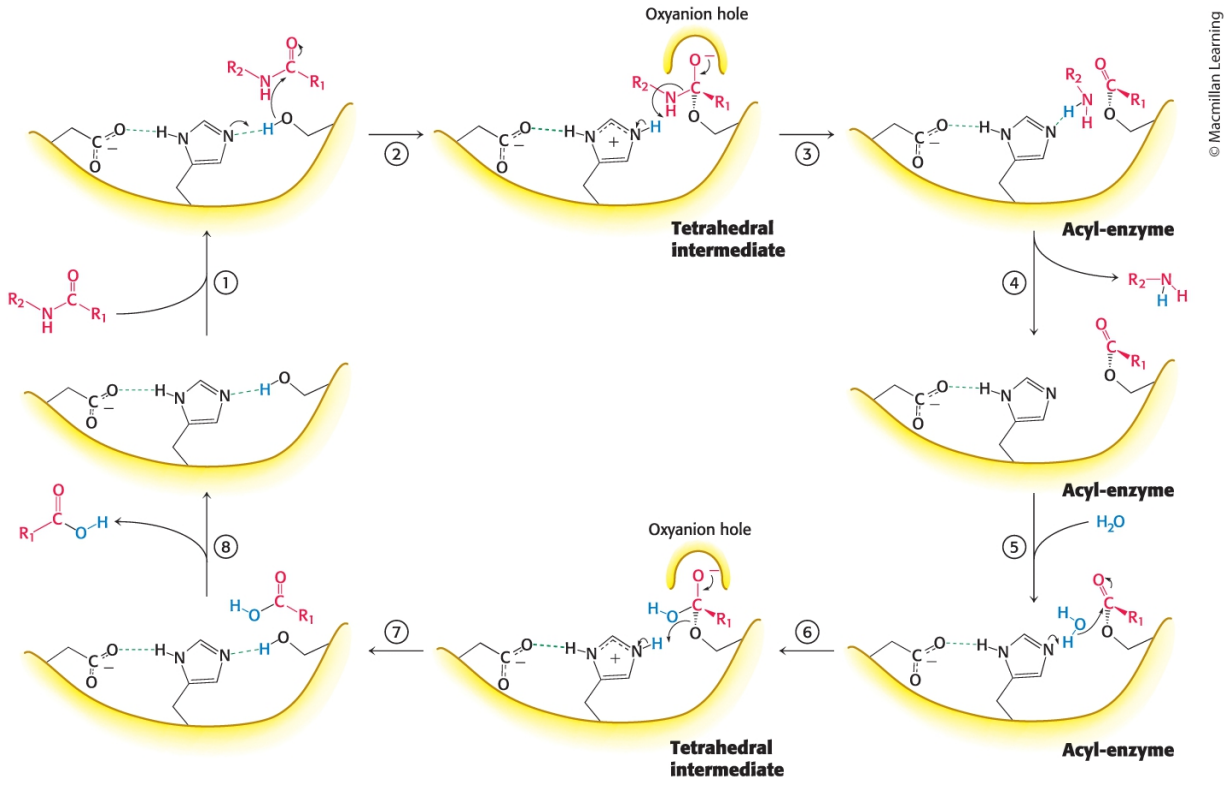


The chymotrypsin consists of three chains. The three chains of chymotrypsin are represented in orange, blue, and green colors. The orange and blue chains consist of beta-strands and alpha-helix connected by a thread-like loop. Serine 195 is located in a cleft on

the surface of chymotrypsin. The ball-and-stick models of disulfide bonds are shown at the top and rightmost region of chymotrypsin.

Return to FIGURE 6.6. The ribbon diagram of chymotrypsin with active site serine residue

Extended description for FIGURE 6.7. Schematic illustration of a catalytic triad in the active site of chymotrypsin and the polarization of hydroxyl group of serine residue



The enzyme is depicted as a concave surface with a yellow highlight. The catalytic triad consists of A s p 102, H i s 57, and S e r 195 residues. The A s p 102 residue consists of a central C atom partially bonded to O on the upper right and O below. The C O O group has a net negative charge. C is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single-bonded to the enzyme. The O atom on the upper right is hydrogen-bonded to an H atom. The H atom is single bonded to the first N atom of H i s 57 residues. The H i s 57 residue consists of a 5-membered heterocyclic pentagonal ring in a vertical orientation consisting of 2 N and 3 C atoms. The first N atom occupies the first position, which is the top-left vertex. The second N atom occupies the third position, which is the top-right vertex. C 1 occupies the topmost vertex. A double is present between C 1 and second N and C 2 and C 3. C 3 is single bonded to C H 2 on the lower left in the form of a line. C H 2 is single-bonded to the enzyme. The second N is hydrogen-bonded to an H atom on the upper right. The H atom is again single bonded to O of S e r 195 residue on the upper right. The O atom is single-bonded to C H 2 on the lower right in the form of a line. C H 2 is single-bonded to the enzyme.

A forward reaction arrow shows the polarization of the O H group of S e r 195 residue. The second N atom of H is 57 residue is single-bonded to H on the upper right. This H atom is hydrogen-bonded to O superscript minus ion of S e r 195 side chain. O superscript minus ion is labeled alkoxide ion.

Return to FIGURE 6.7. Schematic illustration of a catalytic triad in the active site of chymotrypsin and the polarization of hydroxyl group of serine residue

Extended description for FIGURE 6.8. Schematic illustration of the mechanism of peptide hydrolysis

The mechanism is shown in a series of 8 irreversible steps. The enzyme active site is depicted as a concave surface with a yellow highlight. The active site of the enzyme contains a catalytic triad composed of aspartate, histidine, and serine interconnected by hydrogen bonds.

Step 1:

A peptide with the following structure enters the active site: A central C atom is double bonded to O above, single bonded to R 1 on the lower right, and single bonded to N on the lower left. N is bound to H below and single bonded to R 2 on the upper left.

The second N atom of the heterocyclic pentagonal ring of histidine donates electrons toward the hydrogen-bonded H atom. An arrow from the single bond between the H and O atom of serine residue points toward the central C atom of the peptide. An arrow from the C atom points toward the double-bonded O atom.

Step 2:

A Tetrahedral intermediate is formed.

The pentagonal ring of histidine acquires a net positive charge. The second N of the ring becomes single bonded to H. An arrow from the H atom points toward the N atom. The central C atom is single bonded to O superscript minus above. O superscript minus is located inside an oxyanion hole. An arrow from the O superscript minus atom points toward the C atom. A counter-clockwise arrow points from the single bond between N and C of the peptide toward the H atom bound to N.

Step 3:

An acyl-enzyme complex is formed.

The second N atom of the pentagonal ring of histidine becomes hydrogen-bonded to H. This H atom is single-bonded to N of the peptide. N is single bonded to R 2 above and H below. The bond between N and C of the peptide is broken. C atom becomes dashed bonded to O atom of a serine residue. C is double bonded to O above and wedge bonded to R 1 on the lower right.

Step 4:

A molecule having the following structure leaves the active site: R 2, single bond, N. N is single bonded to H below and H on the lower right. The second N of the pentagonal ring of the histidine residue is not bonded to any atom.

Step 5:

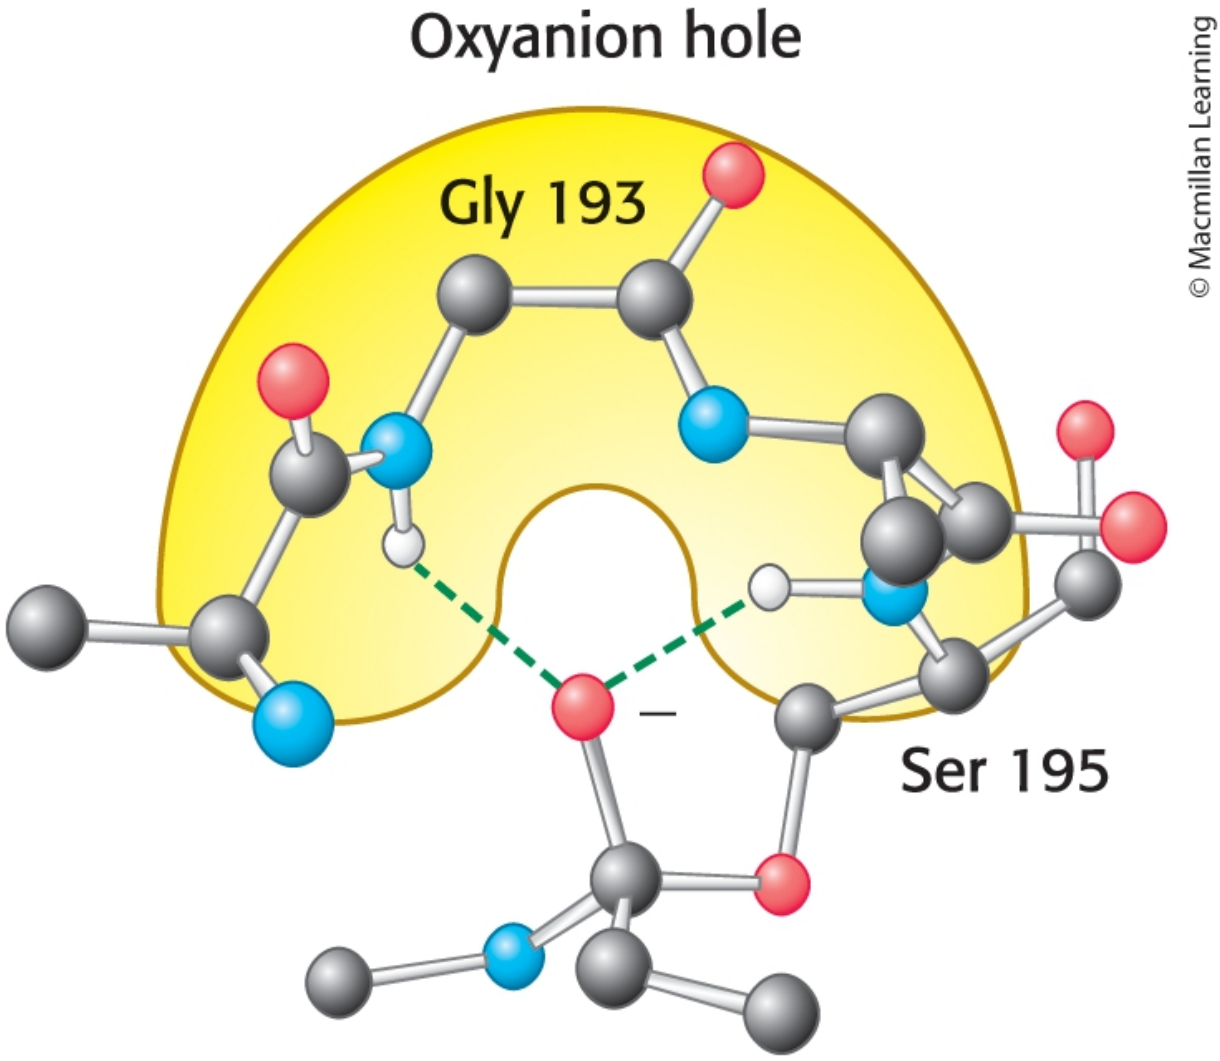
H 2 O molecule enters the active site. The second N of the pentagonal ring of histidine transfers electrons toward the H atom of a H 2 O molecule. An arrow from the single bond between this H and O atom points toward a C atom dash bonded to the O atom of a serine residue. An arrow points from this C atom to double-bonded O above.

Step 6:

A tetrahedral intermediate is formed.

C atom is a single bonded O superscript minus which is located inside an oxyanion hole. An arrow from O superscript minus points toward the C atom. An arrow from the dash bond between the C atom and O atom of serine residue points toward the H atom single bonded to the second N of histidine pentagonal ring. The pentagonal ring of histidine has a net positive charge.

Step 7:



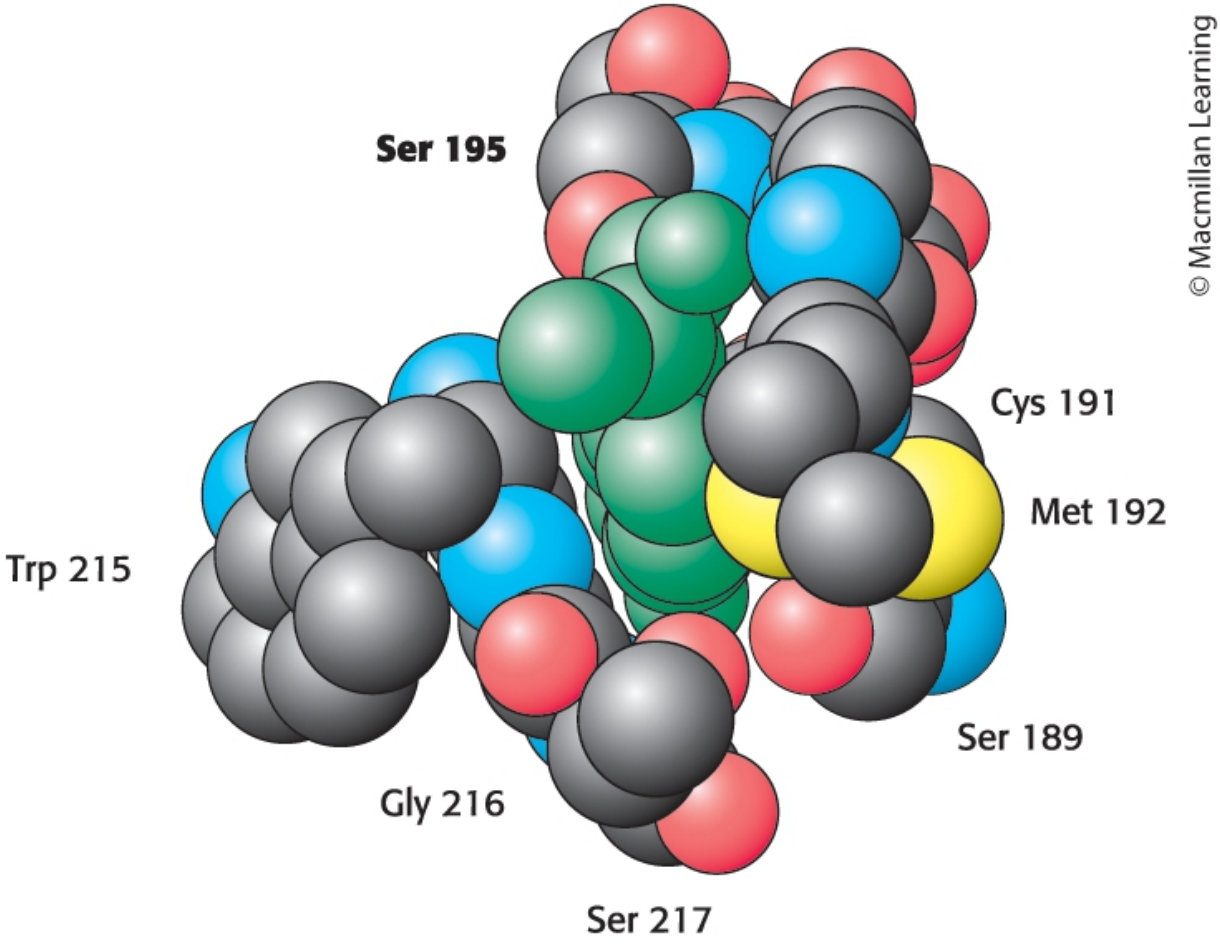
The catalytic triad re-attains its original bonding pattern. A molecule having the following structure is located above the active site: A central C atom is double bonded to O above, single bonded to O on the lower left, and single bonded to R 1 on the lower right. O atom is single bonded to H on the upper left.

Step 8:

The molecule in step 7 leaves the active site.

Return to FIGURE 6.8. Schematic illustration of the mechanism of peptide hydrolysis

Extended description for FIGURE 6.9. Schematic illustration of oxyanion hole-mediated stabilization of a tetrahedral intermediate formed during chymotrypsin catalysis



The oxyanion hole is depicted as a large bean-shaped structure with a cleft at the bottom center. The ball-and-stick model of the amino acid residues and the substrate are shown. They are composed of blue, black, red, and white spheres. G l y 193 is located at the center

of the hole. S e r 195 is located at the bottom right end of the hole. A white sphere connected to the S e r 195 residue depicting the oxygen atom is hydrogen-bonded to the red sphere of the tetrahedral intermediate located below the hole. This red sphere has a negative charge and is hydrogen-bonded on the upper left to a white sphere connected to an amino acid residue at the bottom left end of the hole.

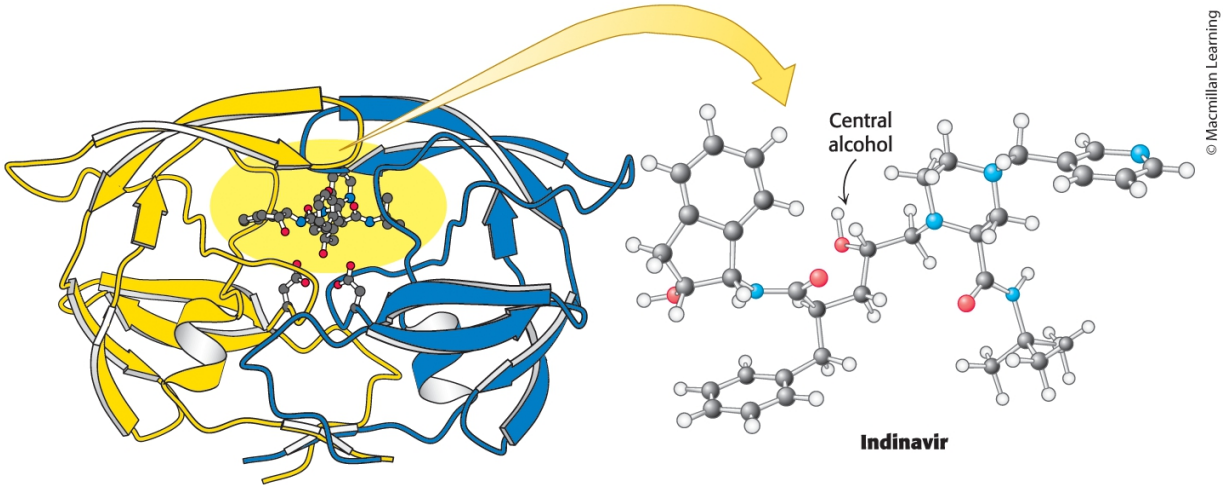
Extended description for FIGURE 6.16. Schematic illustration of the different catalytic strategies of (A) cysteine proteases, (B) aspartyl proteases, and (C) metalloproteases



(A) Cysteine proteases: The enzyme is depicted as a horizontal concave surface with a yellow highlight. A five-membered heterocyclic pentagonal ring consisting of 2 N and 3 C atoms is in a vertical orientation with C 1 occupying the topmost vertex. The first N atom occupies the first position, which is the top-left vertex. The second N atom occupies the third position, which is the top-right vertex. A double bond is present between C 1 and second N, and C 2 and C 3. The first N is single bonded to H on the upper left. C 3 is single bonded to C H 2 on the lower left in the form of a line. C H 2 is single bonded to the enzyme. The second N is connected to a dashed line to an H atom. A black arrow moves from the second N to H. This H atom is single bonded to S. This S is single bonded to C H 2 on the lower right in the form of a line. C H 2 is single bonded to the enzyme. A red arrow from H, single bond, S points toward a central C atom. The C atom is double bonded to O on the upper right, single bonded to R on the lower right, and single bonded to X on the lower left. A black arrow moves from the central C atom to O.

(B) Aspartyl proteases: The enzyme is depicted as a horizontal concave surface with a yellow highlight. A central C atom is partially double bonded to O on the upper left and upper right. The C O O group has a net negative charge. The central C atom is single bonded to C H 2 on the lower left in the form of a line. C H 2 is single bonded to the enzyme. The O atom on the upper right is hydrogen-bonded to a water molecule. The structure of the water molecule is as follows: O is single bonded to H on the upper left and H on the lower left. A red arrow from O, single bond, H points toward a central C atom of another molecule. The central C atom is double bonded to O on the upper right, single bonded to X on the lower left, and single bonded to R on the upper left. O is hydrogen-bonded to H on the lower right. H is single bonded to O on the lower right. O is single bonded to a central C atom. C is double bonded to O on the lower left and single bonded to C H 2 on the lower right in the form of a line. C H 2 is single bonded to the enzyme.

(C) Metalloproteases: The enzyme is depicted as a horizontal concave surface with a yellow highlight. A central Z n superscript 2 ion is associated with the enzyme through a single bond, wedge, bond, and dash bond. The Z n ion is single bonded to O above. This O atom is single bonded to H on the upper left and lower left. A red arrow from O, single bond, H points toward a central C atom of another molecule. The central C atom is double bonded to O on the upper right, single bonded to R on the lower right, and single bonded to X on the right. An atom B is single bonded to the enzyme. B has a single lone pair of electrons. A black arrow moves from B to H atom on the upper left.

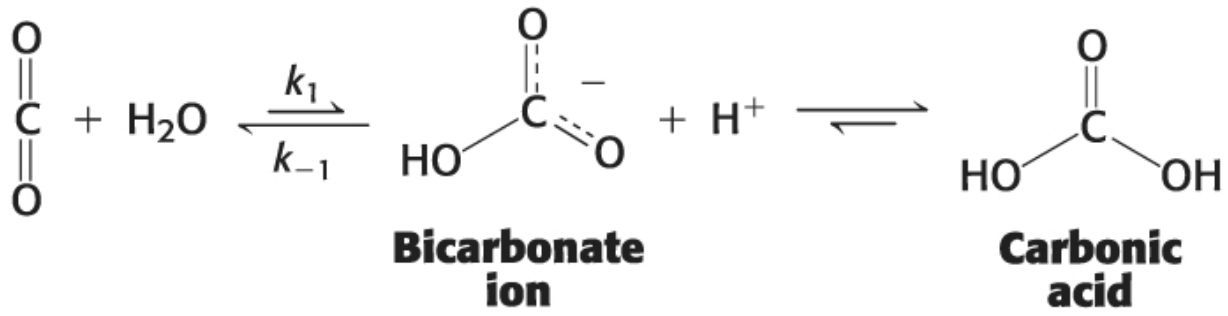
Extended description for FIGURE 6.17. Ribbon diagram and ball-and-stick model of H I V protease with inhibitor indinavir



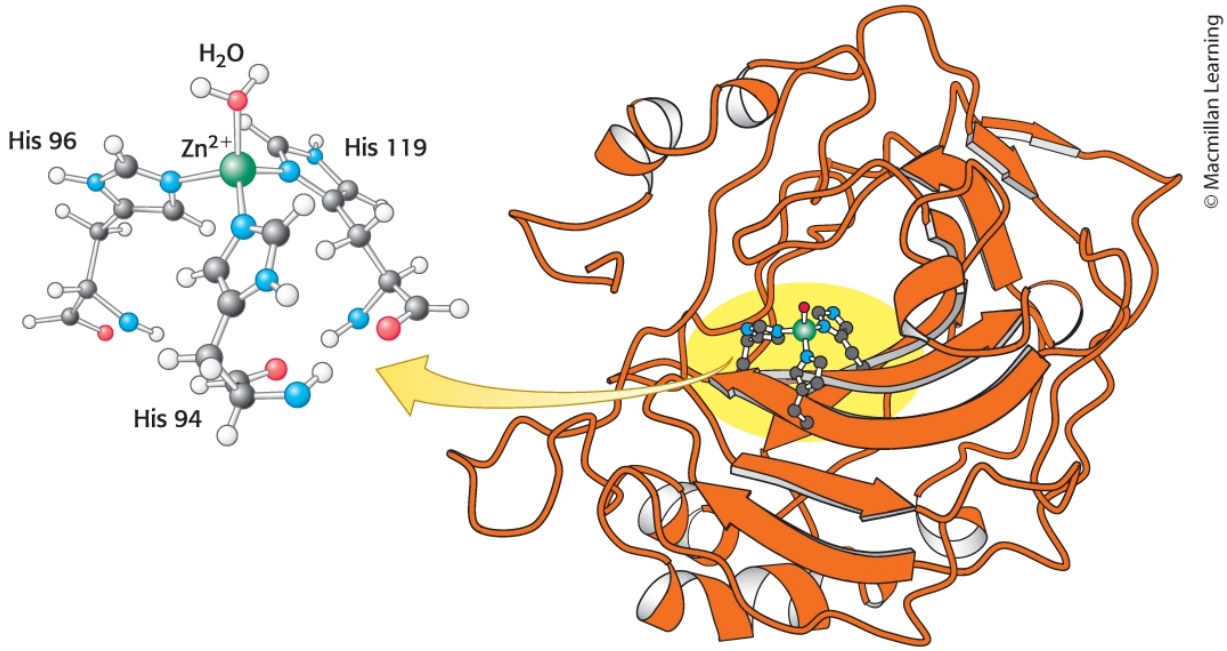
The ribbon diagram of H I V protease consists of yellow and blue colored beta-strands connected by thread-like loops. The protease shows two-fold symmetry. The inhibitor indinavir is bound to the active site.

The ball-and-stick model of indinavir consists of several interconnected red, blue, white, and black spheres. The model highlights the central alcohol molecule.

Return to FIGURE 6.17. Ribbon diagram and ball-and-stick model of H I V protease with inhibitor indinavir

Extended description for Reversible chemical reactions depicting the formation of carbonic acid

The first reversible reaction consists of two reactants and one product. The structure of the first reactant is as follows: A central C atom is double bonded to O above and O below. The second reactant is a H 2 O molecule. A reversible reaction arrow is labeled k subscript 1 above and k subscript minus 1 below.



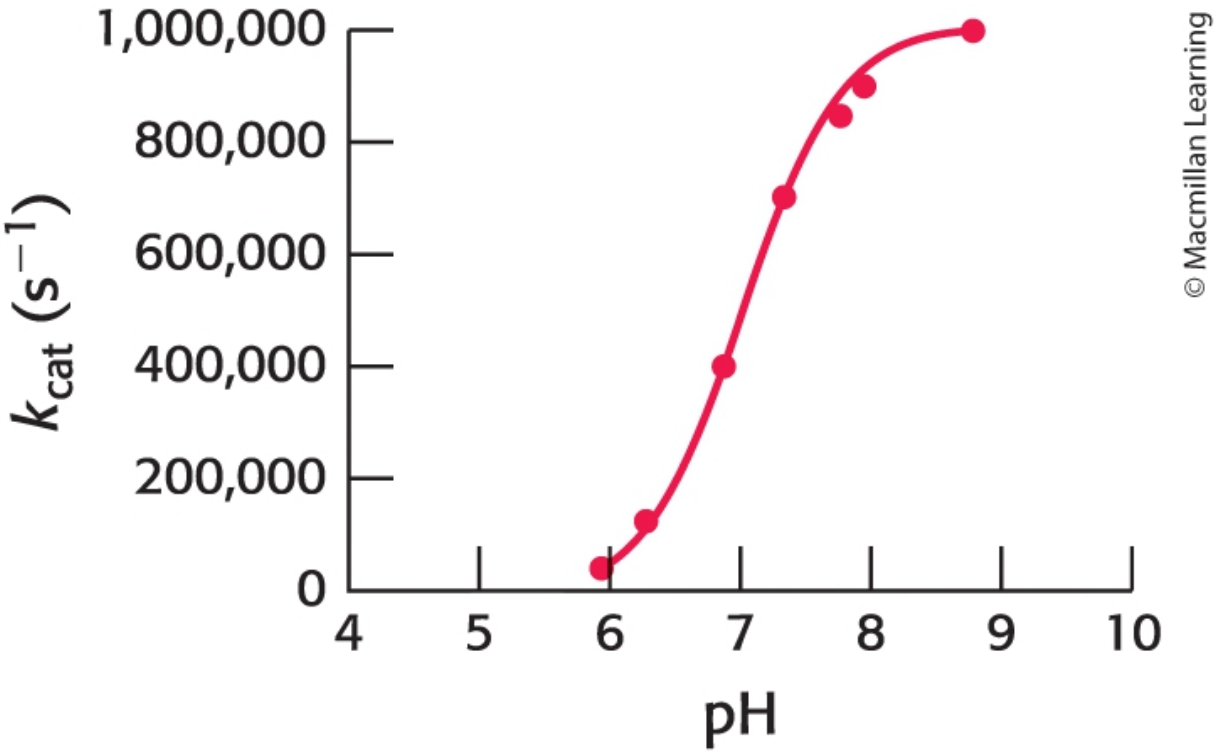
The first product is a bicarbonate ion whose structure is as follows: A central C atom is partially double bonded to O above, partially double bonded to O on the lower right, and single bonded to O H on the lower left. The second product is H superscript plus ion. A reversible reaction arrow is shown.

The forward reaction arrow is longer than the backward reaction arrow. The products of the first reversible reaction are the reactants of the second reversible reaction.

The product is carbonic acid whose structure is as follows: A central C atom is double bonded to O above, single bonded to O H on the lower right, and O H on the lower left.

Return to Reversible chemical reactions depicting the formation of carbonic acid

Extended description for FIGURE 6.18. Ribbon diagram of carbonic anhydrase roman number 2 and the ball-and-stick model of its active site

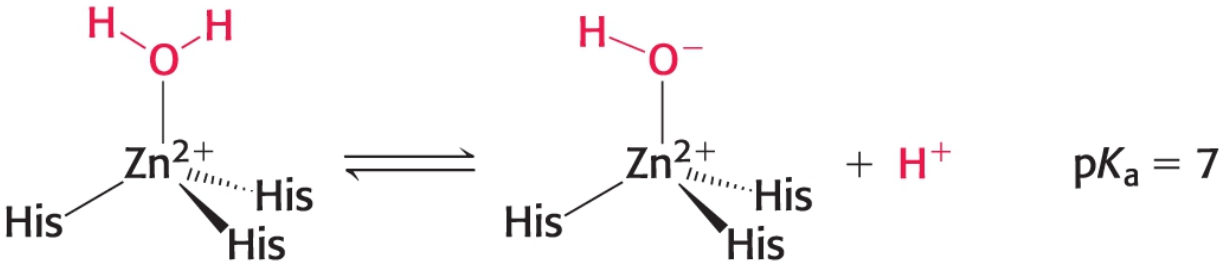


The ribbon diagram of human carbonic anhydrase roman number 2 is composed of anti-parallel beta-strands and a few alpha-helices connected by thread-like loops. The core of the enzyme is composed of beta-strands. The active site of the enzyme is present between the beta-strands and thread-like loops. It contains a zinc ion bound to the active site residues.

The ball-and-stick model shows a central Z n superscript ion connected to the imidazole rings of three histidine residues. Z n ion is depicted as a green sphere and is connected above to a H 2 O molecule. The histidine residues are composed of black, blue, white, and red spheres. The model highlights the residues H i s 96, H i s 119, and H i s 94.

Return to FIGURE 6.18. Ribbon diagram of carbonic anhydrase roman number 2 and the ball-and-stick model of its active site

Extended description for FIGURE 6.19. Graphical representation of the dependence of carbonic anhydrase activity on p H

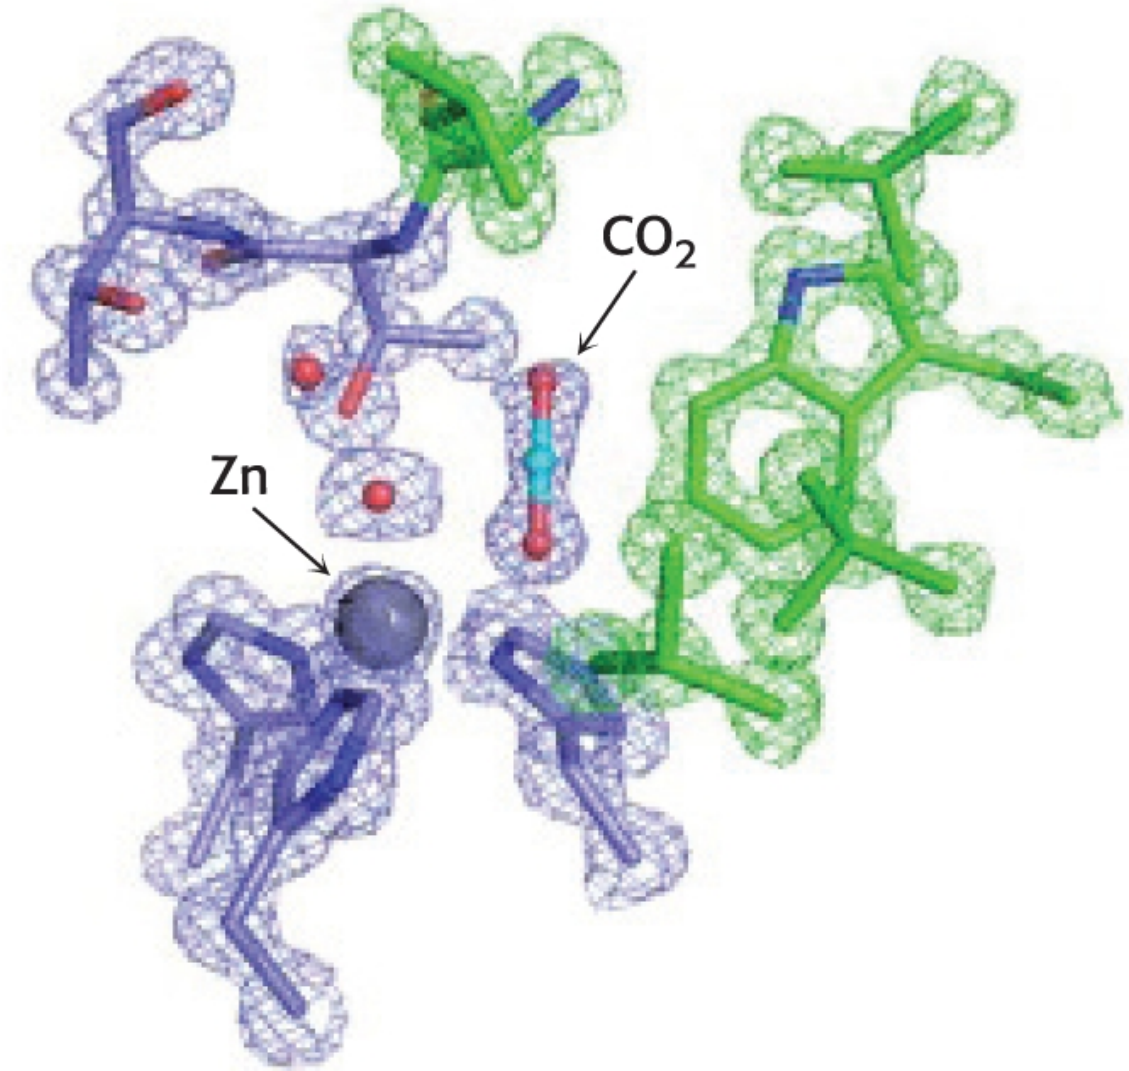


The horizontal axis is labeled p H. It has markings ranging from 4 to 10 in increments of 1 unit. The vertical axis is labeled k subscript cat in s superscript minus 1. It has markings ranging from 200,000 to 1,000,000 in increments of 200,000 units. A red curve rises from (6, 0) and moves steeply toward upper right to reach (9, 1,000,000). The data points marked on the curve are: (6, 0), (6.2,100,000), (7, 400,000), (7.2,700,000), (8, 900,000), (8, 950,000), and (9, 1,000,000).

All numerical values are estimated.

Return to FIGURE 6.19. Graphical representation of the dependence of carbonic anhydrase activity on p H

Extended description for FIGURE 6.20. Reversible reaction consisting of one reactant and two products is shown



The reversible reaction consists of one reactant and two products.

The structure of the first reactant is as follows: A central Z n superscript 2 plus ion is single bonded to O above, which is again single bonded to H on the upper left and H on the upper right. The central Z n superscript 2 plus ion is dash bonded to His on the right, wedge bonded to His on the lower right, and single bonded to His on the lower left. The structure of the first product is as follows: The central Z n superscript 2 plus ion is single bonded to O superscript minus above, which is again single bonded to H on the upper left. The central Z n superscript 2 plus ion is dash bonded to His on the right, wedge bonded to His on the lower right, and single bonded to His on the lower left. The second product is H superscript plus ion. Note: p K subscript a is equal to 7.

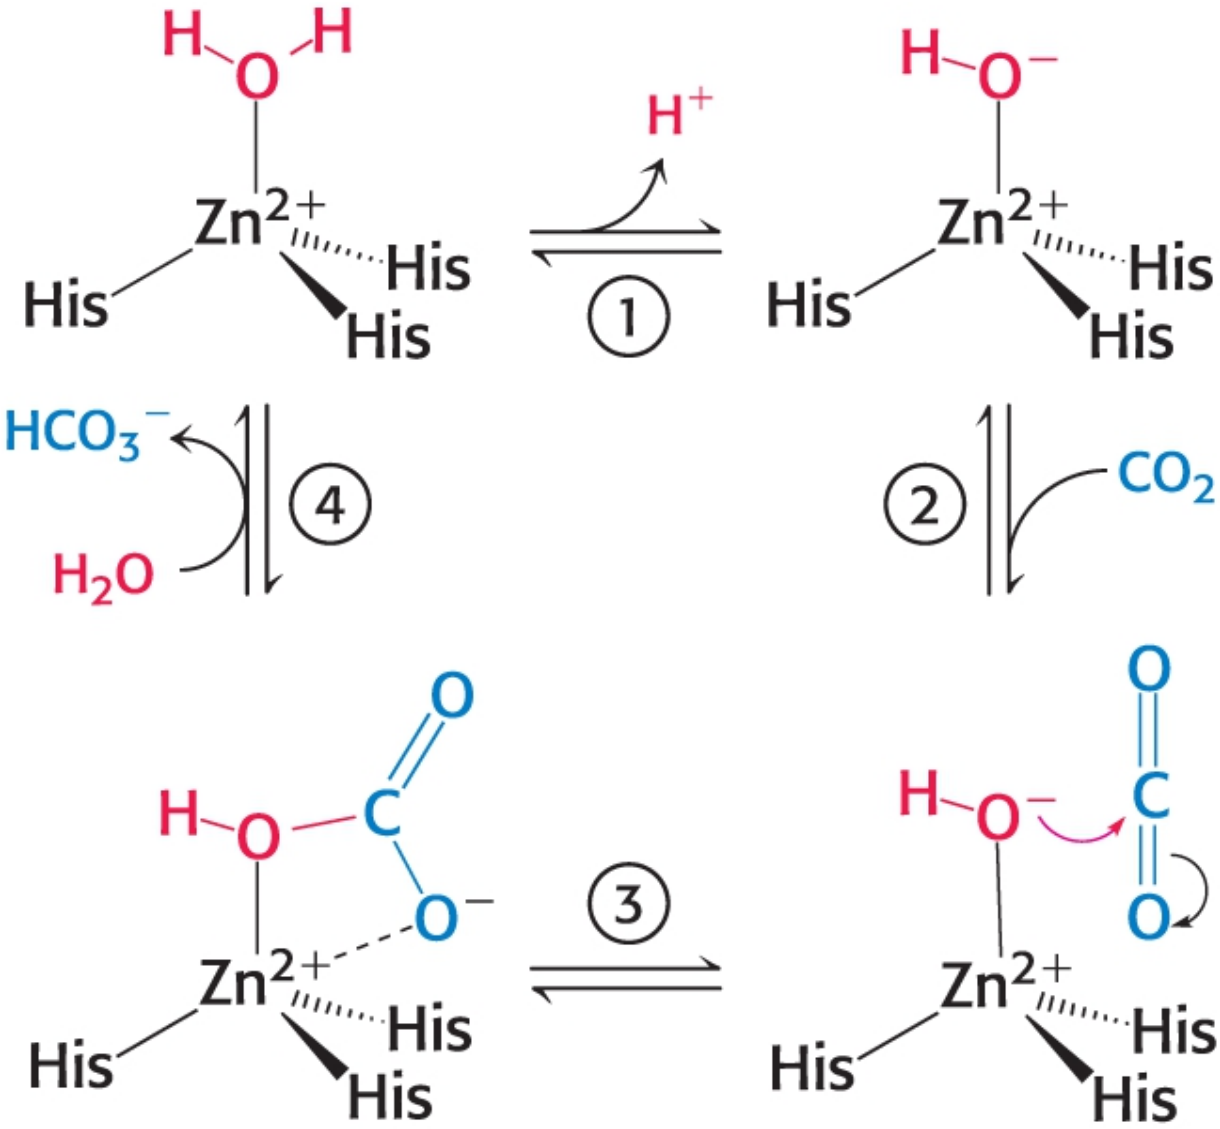
Extended description for FIGURE 6.21.Electron density map of carbonic anhydrase active site and C O 2 binding site



© Macmillan Learning

The electron density map is depicted as a cage-like structure outlining the shapes of the residues and molecules in the active site and C O 2 binding site. The hydrophobic amino acids are shown in green and hydrophilic amino acids are shown in purple. A vertically

oriented straight C O 2 molecule is located above the purple and green residues. Z n atom is depicted as a medium-sized sphere bound to cyclic rings shown in purple. Z n is located on the lower left of the C O 2 molecule.

Return to FIGURE 6.21.Electron density map of carbonic anhydrase active site and C O 2 binding site

Extended description for FIGURE 6.22. Mechanism for the hydration of carbon dioxide by carbonic anhydrase

The hydration of carbon dioxide takes place in four steps.

Step 1: The reversible reaction consists of one reactant and one product.

The structure of the reactant is as follows: A central Z n superscript 2 plus ion is single bonded to O above. This O atom is single bonded to H on the upper left and H on the upper right. The O and H atoms are highlighted in red. The Z n ion is dash bonded to His on the right, wedge bonded to His on the lower right, and single bonded to His on the lower left.

A reversible reaction arrow is shown. H superscript plus ion leaves the reaction.

The structure of the product is as follows: A central Z n superscript 2 plus ion is single bonded to O superscript minus above, which is single bonded to H on the upper left. The O and H atoms are highlighted in red. The Z n ion is dash bonded to His on the right, wedge bonded to His on the lower right, and single bonded to His on the lower left.

A reversible reaction arrow is shown. C O 2 enters the reaction.

Step 2: The reversible reaction consists of one reactant and one product.

The reactant of step 2 is the product of step 1.

The structure of the product is as follows: A central Z n superscript 2 plus ion is single bonded to O superscript minus above, which is single bonded to H on the upper left. The O and H atoms are highlighted in red. The Z n ion is dash bonded to His on the right, wedge bonded to His on the lower right, and single bonded to His on the lower left. A red arrow from O superscript minus atom points toward the central C atom of a C O 2 molecule. C is double bonded to O above and O below. The C O 2 molecule is highlighted in blue.

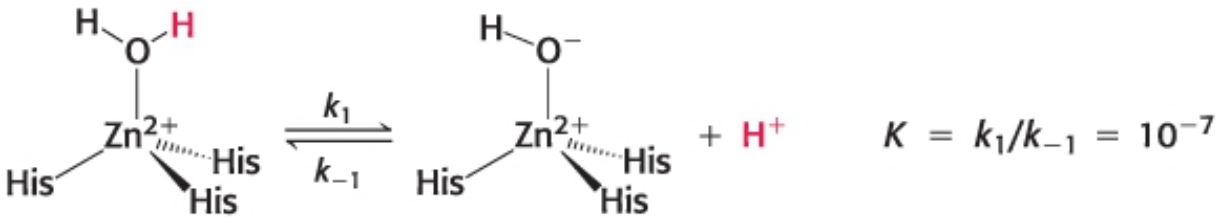
A reversible reaction arrow is shown.

Step 3: The reversible reaction consists of one reactant and one product.

The reactant of step 3 is the product of step 2.

The structure of the product is as follows: A central Z n superscript 2 plus ion is single bonded to O above, which is single bonded to H on the upper left. The O and H atoms are highlighted in red. The O atom is single bonded to C on the upper right. C is double bonded to O on the upper right and single bonded to O superscript minus on the lower right. A dashed blue line connects O superscript minus to the Z n ion. The Z n ion is dash bonded to His on the right, wedge bonded to His on the lower right, and single bonded to His on the lower left.

A reversible reaction arrow is shown. H 2 O enters and H C O 3 superscript minus leaves the reaction.



Step 4: The reversible reaction consists of one reactant and one product.

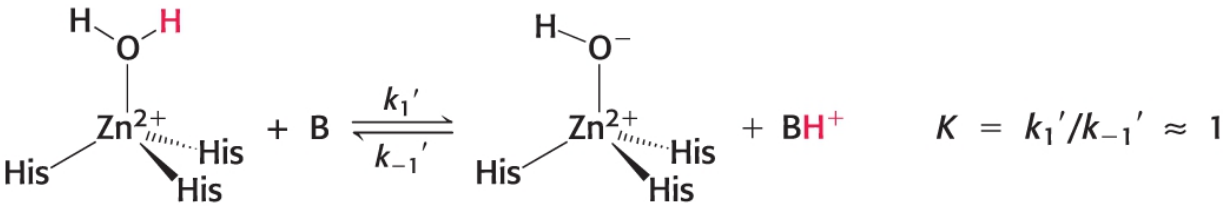
The reactant of step 4 is the product of step 3.

The structure of the product is as follows: A central Z n superscript 2 plus ion is single bonded to O above. The O atom is single bonded to H on the upper left and H on the upper right. The O and H atoms is highlighted in red. The Z n ion is dash bonded to His on the right, wedge bonded to His on the lower right, and single bonded to His on the lower left.

Return to FIGURE 6.22. Mechanism for the hydration of carbon dioxide by carbonic anhydrase

Extended description for FIGURE 6.23. Chemical reaction shows the reversible deprotonation of water molecule bound to carbonic anhydrase active site and the ratio of rate constants for protonation and deprotonation

The reversible reaction consists of one reactant and two products. The structure of the first reactant is as follows: A central Z n superscript 2 plus ion is single bonded to O above. O is single bonded to H on the upper left and H on the upper right. The H atom on the upper right is highlighted in red. The central Z n superscript 2 plus ion is dash bonded to H i s on the lower right, wedge bonded to H i s on the lower right, and single bonded to H i s on the lower left.



The forward reaction arrow is labeled k subscript 1. The reverse reaction arrow is labeled k subscript negative 1.

The structure of the first product is as follows: A central Z n superscript 2 plus ion is single bonded to O superscript minus above, which is single bonded to H on the upper left. The Z n superscript 2 plus ion is dash bonded to H i s on the lower right, wedge bonded to H i s on the lower right, and single bonded to H i s on the lower left. The second product is the H superscript plus ion which is highlighted in red.

Note: K equals StartFraction k subscript 1 over k subscript negative 1 EndFraction equals 10 raised to the negative 7th power.

Return to FIGURE 6.23. Chemical reaction shows the reversible deprotonation of water molecule bound to carbonic anhydrase active site and the ratio of rate constants for protonation and deprotonation

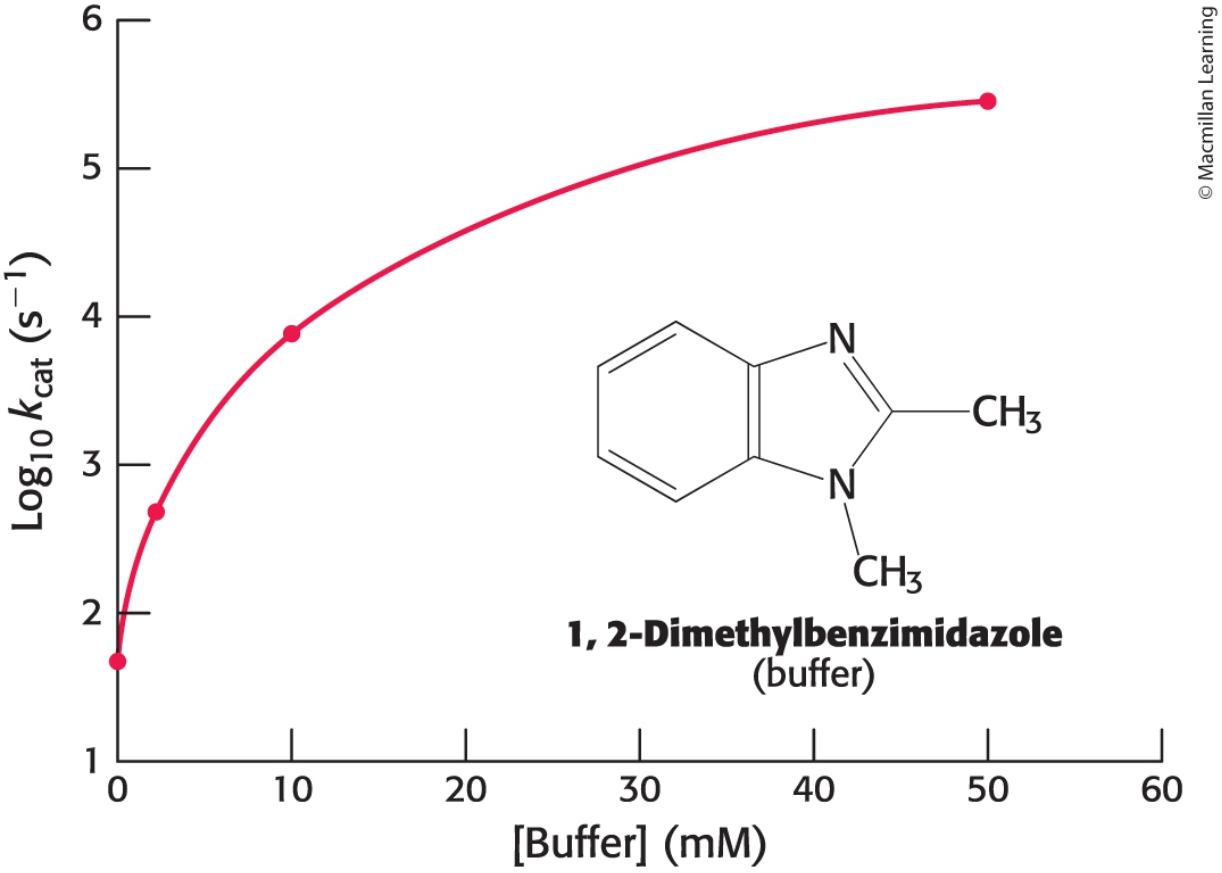
Extended description for FIGURE 6.24. Reversible reaction shows the deprotonation of the zinc-bound water molecule in carbonic anhydrase aided by buffer

The reversible reaction contains two reactants and two products.

The structure of first reactant is as follows: A central Z n superscript 2 plus ion is single bonded to O above. This O atom is single bonded to H on the upper left and H on the upper right. The H atom on the upper right is highlighted in red. The central Z n ion is dash bonded to His on the right, wedge bonded to His on the lower right, and single bonded to His on the lower left.

The second reactant is B.

A reversible reaction arrow is shown. The top forward reaction arrow is labeled k prime subscript 1. The bottom backward reaction arrow is labeled k prime subscript minus 1.



The structure of first product is as follows: A central Z n superscript 2 plus ion is single bonded to O superscript minus above. This O superscript minus atom is single bonded to H on the upper left. The central Z n ion is dash bonded to His on the right, wedge bonded to His on the lower right, and single bonded to His on the lower left.

The second product is B H superscript plus molecule. H superscript plus is highlighted in red.

Note: K equals StartFraction k prime subscript 1 over k prime subscript minus 1 EndFraction which is approximately equal to 1.

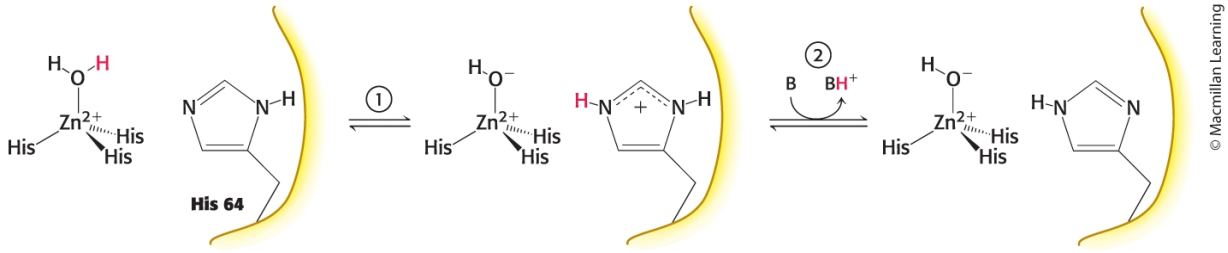
Return to FIGURE 6.24. Reversible reaction shows the deprotonation of the zinc-bound water molecule in carbonic anhydrase aided by buffer

Extended description for FIGURE 6.25. Graphical representation of the rate of carbon dioxide hydration by carbonic anhydrase as a function of buffer concentration

© Macmillan Learning

The horizontal axis is labeled the concentration of buffer in millimolar. It has markings ranging from 1 to 6 in increments of 1 unit. The vertical axis is labeled log base 10 k subscript cat close (s superscript minus 1).

A red concave down curve starts from (0, 1.8) and ends at (50, 5.4).



The data points on the curve are (0, 1.8), (2, 2.8), (10, 3.9), and (50, 5.4).

All numerical values are estimated.

The structure of 1, 2-Dimethylbenzimidazole (buffer) is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. The benzene ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 2 N and 3 C atoms such that C 2 and C 3 of the benzene ring are C 3 and C 2 respectively of the pentagonal ring. In the pentagonal ring, the first N atom occupies the first position, which is the topmost vertex. The second N atom occupies the third position, which is the bottom right vertex. A double bond is present between the first N and C 1. C 1 is single bonded to C H 3 on the right. The second N atom is single bonded to C H 3 on the lower right.

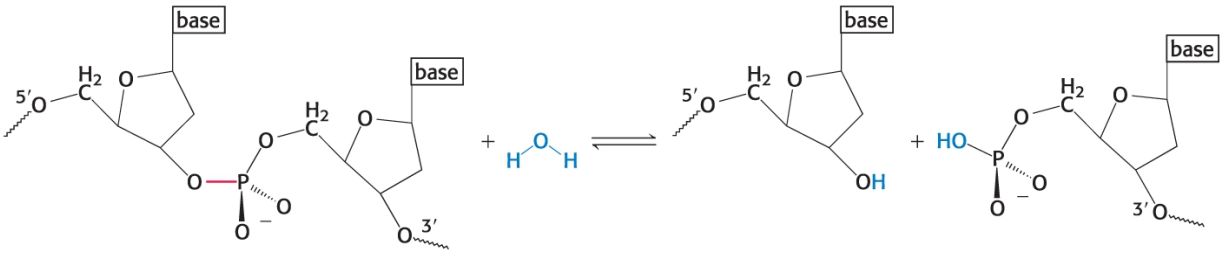
Return to FIGURE 6.25. Graphical representation of the rate of carbon dioxide hydration by carbonic anhydrase as a function of buffer concentration

Extended description for FIGURE 6.26. Schematic illustration of histidine 64 residue of carbonic anhydrase roman number 2 acting as a proton shuttle

The carbonic anhydrase roman number 2 enzyme is depicted as a vertical concave surface with a yellow highlight.

The structure of the first reactant is as follows: A central Z n superscript 2 plus ion is single bonded to O above. The O atom is single bonded to H on the upper left and H on the upper right. The H atom on the upper right is highlighted in red. The Z n ion is dash bonded to His on the right, wedge bonded to His on the lower right and single bonded to His on the lower left.

The structure of the second reactant is as follows: A five membered heterocyclic pentagonal ring consisting of 2 N and 3 C atoms is in a vertical orientation with C 1 occupying the topmost vertex. The first N atom occupies the first position, which is the top left vertex. The second N atom occupies the third position, which is the top right vertex. A double bond is present between C 2 and C 3, and the first N atom and C 1. The second N atom is single bonded to H on the upper right. C 2 of the pentagonal ring is single bonded to C H 2 on the lower right in the form of a line. C H 2 is single bonded to the enzyme. The pentagonal ring single bonded to the enzyme is labeled His 64.



Step 1: After the removal of a proton from the zinc-bound water molecule a new structure formed is as follows: A central Z n superscript 2 plus ion is single bonded to O superscript minus above. The O atom is single bonded to H on the upper left. The Z n ion is dash bonded to His on the right, wedge bonded to His on the lower right, and single bonded to His on the lower left. A five membered heterocyclic pentagonal ring consisting of 2 N and 3 C atoms is in a vertical orientation with C 1 occupying the topmost vertex. The first N atom occupies the first position, which is the top left vertex. The second N atom occupies the third position, which is the top right vertex. A double bond is present between C 2 and C 3. A resonance bond is shared between the first N, C 1, and the second N. A net positive charge is present in the ring. The first N atom is single bonded to H on the upper left. This H atom is highlighted in red. The second N atom is single bonded to H on the upper right. C 2 of the pentagonal ring is single bonded to C H 2 on the lower right in the form of a line. C H 2 is single bonded to the enzyme. The pentagonal ring single bonded to the enzyme is labeled His 64.

Step 2: The proton single bonded to the first N is transferred to the buffer molecules in the solution. A reversible reaction arrow is shown. B enters the reaction and leaves as B H superscript plus. H superscript plus is highlighted in red. The structure of the first products is as follows: A central Z n superscript 2 plus ion is single bonded to O superscript minus above. This O superscript minus atom is single bonded to H on the upper left. The Z n ion is dash bonded to His on the right, wedge bonded to His on the lower right, and single bonded to His on the lower left. The structure of the second product is as follows: A five membered heterocyclic pentagonal ring consisting of 2 N and 3 C atoms is in a vertical orientation with C 1 occupying the topmost vertex. The first N atom occupies the first position, which is the top left vertex. The second N occupies the third position, which is the top right vertex. A double bond is present between C 2 and C 3, and C 1 and second N atom. C 2

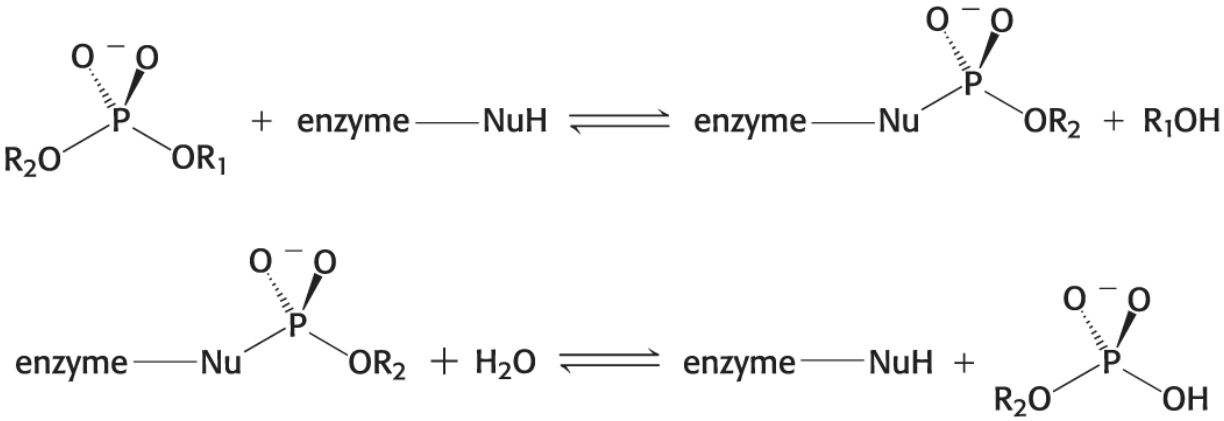
of the pentagonal ring is single bonded to C H 2 on the lower right in the form of line. C H 2 is single bonded to the enzyme.

Return to FIGURE 6.26. Schematic illustration of histidine 64 residue of carbonic anhydrase roman number 2 acting as a proton shuttle

Extended description for FIGURE 6.27. Chemical reaction shows the restriction enzyme-mediated hydrolysis of phosphodiester bond

The reversible reaction consists of two reactants and two products.

The structure of the first reactant is as follows: A five-membered heterocyclic pentagonal ring consisting of 1 O and 4 C atoms is in a vertical orientation. O occupies the first position, which is the top-left vertex. C 1 occupies the topmost vertex and is single bonded to the base enclosed in a box above. C 4 is single bonded to C bound to H 2 on the upper left. C H 2 is single bonded to O on the lower left. The O atom has an open single bond and is labeled 5 prime. C 3 is single bonded to O on the lower right. This O is single-bonded to a central P atom through a red line. The P atom is wedge bonded to O superscript minus below, dash bonded to O on the lower right, and single bonded to O on the upper right. The O atom on the upper right is single bonded to C H 2 above. C H 2 is single bonded to C 4 of another heterocyclic pentagonal ring in a vertical orientation. The ring consists of 1 O and 4 C atoms. O occupies the top-left vertex. C 1 of the pentagonal ring is single bonded to the base enclosed in a box above. C 3 of the pentagonal ring is single bonded to O on the lower right. This O atom has an open single bond and is labeled 3 prime.



The structure of the second reactant is as follows: A central O atom is single-bonded to H on the lower left and H on the lower right. The entire molecule is highlighted in blue.

The structure of the first product is as follows: A five-membered heterocyclic pentagonal ring consisting of 1 O and 4 C atoms is in a vertical orientation. O occupies the first position, which is the top-left vertex. C 1 is single bonded to the base enclosed in a box above. C 3 is single bonded to O H on the lower right. H atom is highlighted in blue. C 4 is single bonded to C H 2 on the upper left. C H 2 is single bonded to O on the lower left. The O atom has an open single bond on the lower left and is labeled 5 prime.

The structure of the second reactant is as follows: A five-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the first position, which is the top-left vertex. C 1 is single bonded to the base enclosed in a box above. C 3 is single bonded to O on the lower right. This O atom has an open single bond and is labeled 3 prime. C 4 is single bonded to C H 2 on the upper left. C H 2 is single bonded to O on the lower left. O is single bonded to a central P atom below. P is single bonded to O H on the upper left, dash bonded to O on the lower right, and wedge bonded to O superscript minus below. The O H group is highlighted in blue.

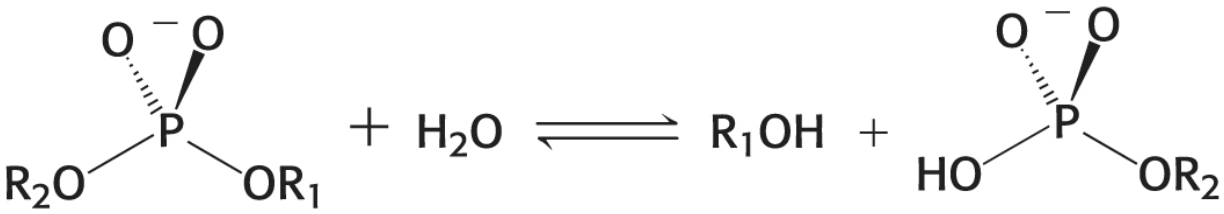
Return to FIGURE 6.27. Chemical reaction shows the restriction enzyme-mediated hydrolysis of phosphodiester bond

Extended description for Two reversible reactions consisting of two reactants and two products are shown

The first reversible reaction consists of two reactants and two products.

The structure of the first reactant is as follows: A central P atom is dash bonded to O superscript minus on the upper left, wedge bonded to O on the upper right, single bonded to R subscript 2 O on the lower left, and O R subscript 1 on the lower right. The structure of the second reactant is as follows: Enzyme, single bond, N u H.

The first product has the following structure: The central P atom is dash bonded to O superscript minus on the upper left, wedge bonded to O on the upper right, single bonded to O R subscript 2 on the lower right, and N u on the lower left, which is again single bonded to the enzyme on the left. The second product is R subscript 1 O H.



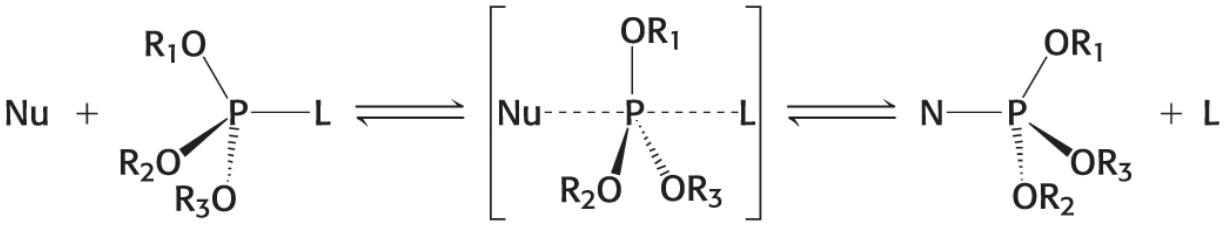
The second reversible reaction consists of two reactants and two products.

The structure of the first reactant is as follows: A central P atom is dash bonded to O superscript minus on the upper left, wedge bonded to O on the upper right, single bonded to O R subscript 2 on the lower right, and single bonded to N u on the lower left, which is again single bonded to the enzyme on the left. The second reactant is H 2 O molecule.

The first product is enzyme, single bond, N u H. The second product has the following structure: The central P atom is dash bonded to O superscript minus on the upper left, wedge bonded to O on the upper right, single bonded to R subscript 2 O on the lower left, and single O H on the lower right.

Return to Two reversible reactions consisting of two reactants and two products are shown

Extended description for Chemical reaction for the direct hydrolysis of D N A

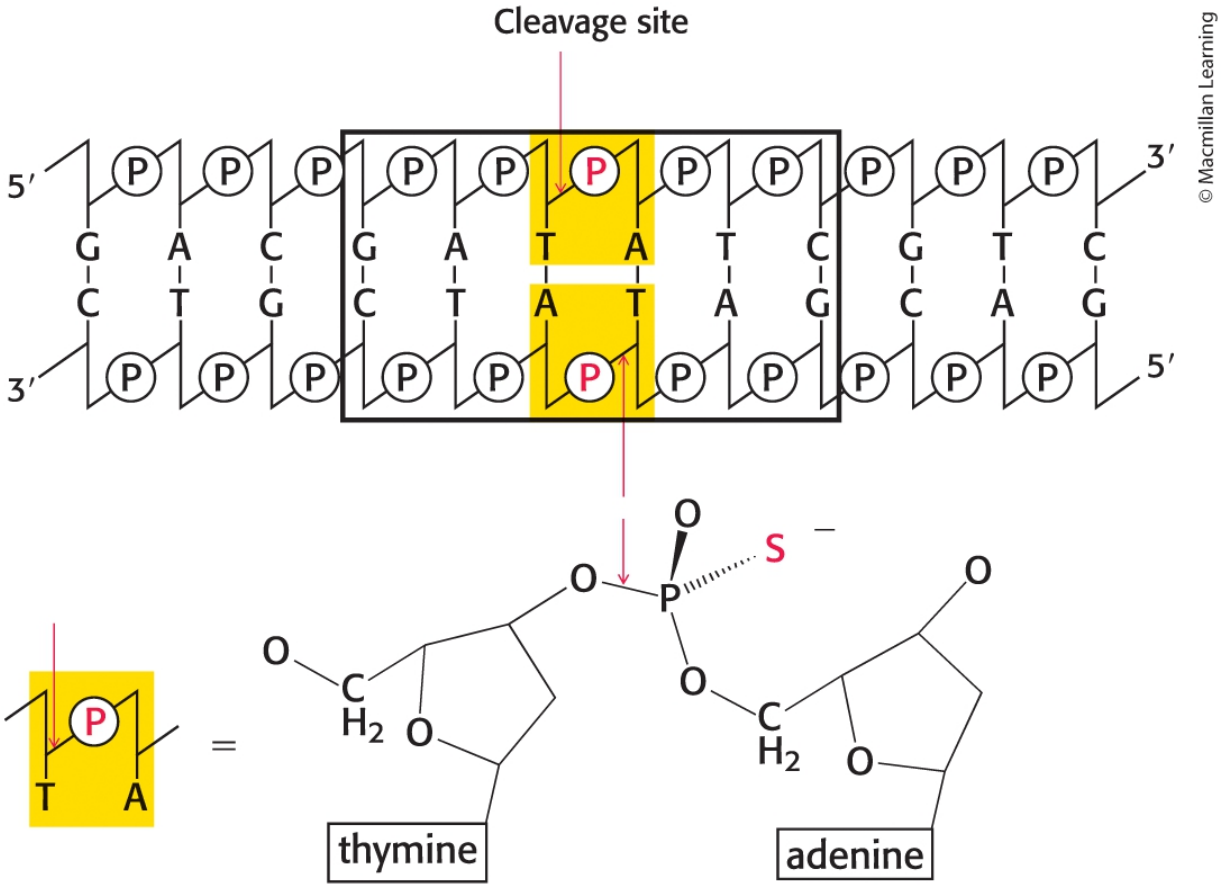


The reversible chemical reaction consists of two reactants and two products. The first reactant has the following structure: A central P atom is dash bonded to O superscript minus on the upper left, wedge bonded to O on the upper right, single bonded to R subscript 2 O on the lower left, and single bonded to O R subscript 1 on the lower right. The second reactant is H 2 O.

The first product has the following structure: R subscript 1 O H. The second product has the following structure: A central P atom is dash bonded to O superscript minus on the upper left, wedge bonded to O on the upper right, single bonded to O H on the lower left, and single bonded to O R subscript 2 on the lower right.

Return to Chemical reaction for the direct hydrolysis of D N A

Extended description for Series of reversible reactions consisting of two reactants, two products, and an intermediate product are shown



The first reactant is N u. The structure of the second reactant is as follows: P is single bonded to R subscript 1 O on the upper left, single bonded to L on the right, dash bonded to R subscript 3 O below, and wedge bonded to R subscript 2 O on the lower left.

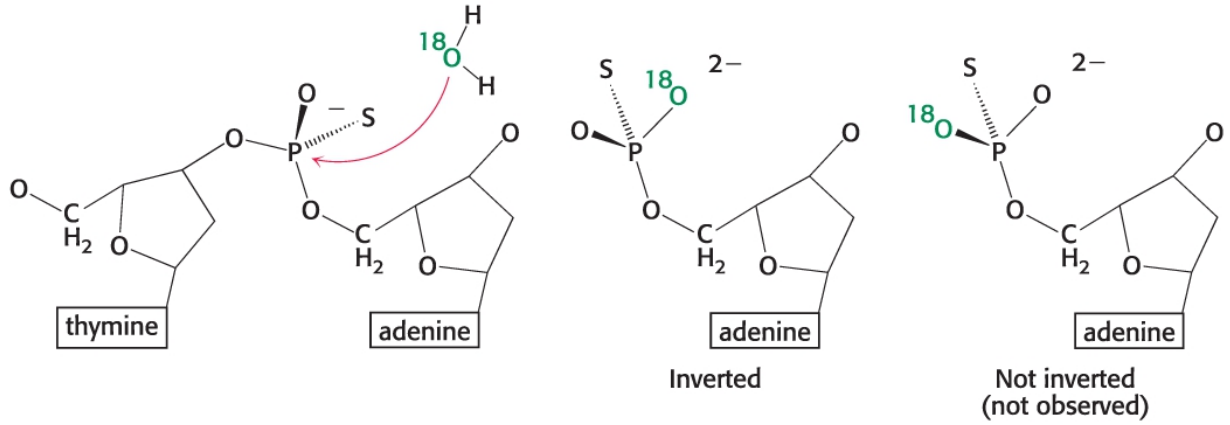
The structure of the intermediate is as follows: A central P atom is single bonded to O R subscript 1 above, L on the right, and N u on the left. P is dash bonded to O R subscript 3 on the lower right and wedge bonded to R subscript 2 O on the lower left.

The structure of the first product is as follows: A central P atom is single bonded to O R subscript 1 on the upper right, wedge bonded to O R subscript 3 on the lower right, dash bonded to O R subscript 2 below, and single bonded to N on the left. The second product is L.

Return to Series of reversible reactions consisting of two reactants, two products, and an intermediate product are shown

Extended description for FIGURE 6.28. Schematic representation of Eco R V cleavage site in a D N A sequences

© Macmillan Learning



The two DNA strands are present in 5 prime to 3 prime and 3 prime to 5 prime orientation. The first sequence is G A C G A T A T C G T C. The second sequence is C T G C T A T A G C A G. The cleavage site is enclosed in a rectangular box. The sequence enclosed in the box is G A T A T C and C T A T A G. The sequences T A and A T are enclosed in yellow color.

The T A sequence is enlarged to show the structure of thymine connected to adenine through a phosphodiester bond. C 2 of the

pentagonal ring of thymine residue is single bonded to O. This O is single bonded to a central P atom. An arrow points toward this single bond. P is wedge bonded to O above and dash bonded to S superscript minus on the upper right. P is single bonded to O below. This O is single bonded to adenine residue.

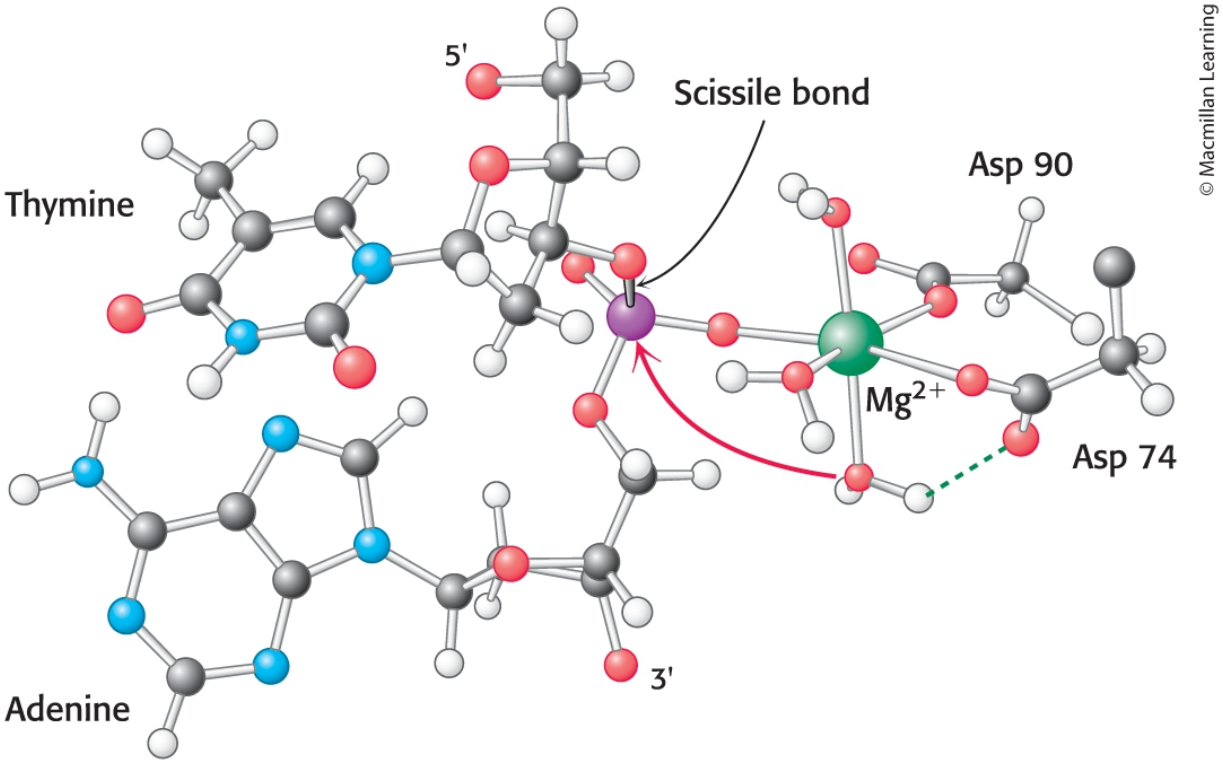
Return to FIGURE 6.28. Schematic representation of Eco R V cleavage site in a D N A sequences

Extended description for FIGURE 6.29. Schematic illustration of the inversion of the stereochemical configuration of phosphorus atom after cleavage of D N A by Eco R V

A chemical structure of a dinucleotide composed of thymine and adenine is shown.

The structure of the dinucleotide is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top left vertex. It consists of 1 O and 4 C atoms. O occupies the first position, which is the bottom left vertex. C 1 is single bonded to C H 2. C H 2 is single bonded to O on the upper left. C 4 is single bonded to thymine on the lower left. C 2 is single bonded to O on the upper right. This O is single bonded to a central P atom. This P is wedge bonded to O superscript minus above, dash bonded to S on the upper right, and single bonded to O below. This O atom is single bonded to C H 2 on the lower right. C H 2 is single bonded to C 1 of a 5-membered heterocyclic pentagonal ring in a vertical orientation. It consists of 1 O and 4 C atoms. O occupies the first position which is the bottom left vertex. C 2 is single bonded to

O on the upper right. C 4 is single bonded to adenine on the lower left.



H 2 O molecule has the following structure: A central O superscript 18 atoms highlighted in green is single bonded to H on the upper right and lower right. A red arrow moves from the O superscript 18 atom toward the central P atom. This attack of water on the P atom leads to the formation of two products.

The first product is inverted and has the following structure: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top left vertex. It consists of 1 O and 4 C atoms. O occupies the first position, which is the bottom left vertex. C 1 is single bonded to C H 2 on the left. C H 2 is single bonded to O on the upper left. This O atom is single bonded to a central P atom above. This P is wedge bonded to O on the upper left, dash bonded to S above, and single bonded to O superscript 18 with a negative charge of 2 minus on the upper right. C 2 is single bonded to O on the upper right. C 4 is single bonded to adenine on the lower left.

The second product is not inverted (not observed) and has the following structure: A 5-membered heterocyclic pentagonal ring in a vertical orientation. It consists of 1 O and 4 C atoms. O occupies the first position which is the bottom left vertex. C 1 is single bonded to C H 2 on the left. C H 2 is single bonded to O on the upper left. This O atom is single bonded to a central P atom above. This P is wedge bonded to O superscript 18 on the upper left, dash bonded to S above, and single bonded to O superscript 2 minus on the upper right. C 2 is single bonded to O on the upper right. C 4 is single bonded to adenine on the lower left.

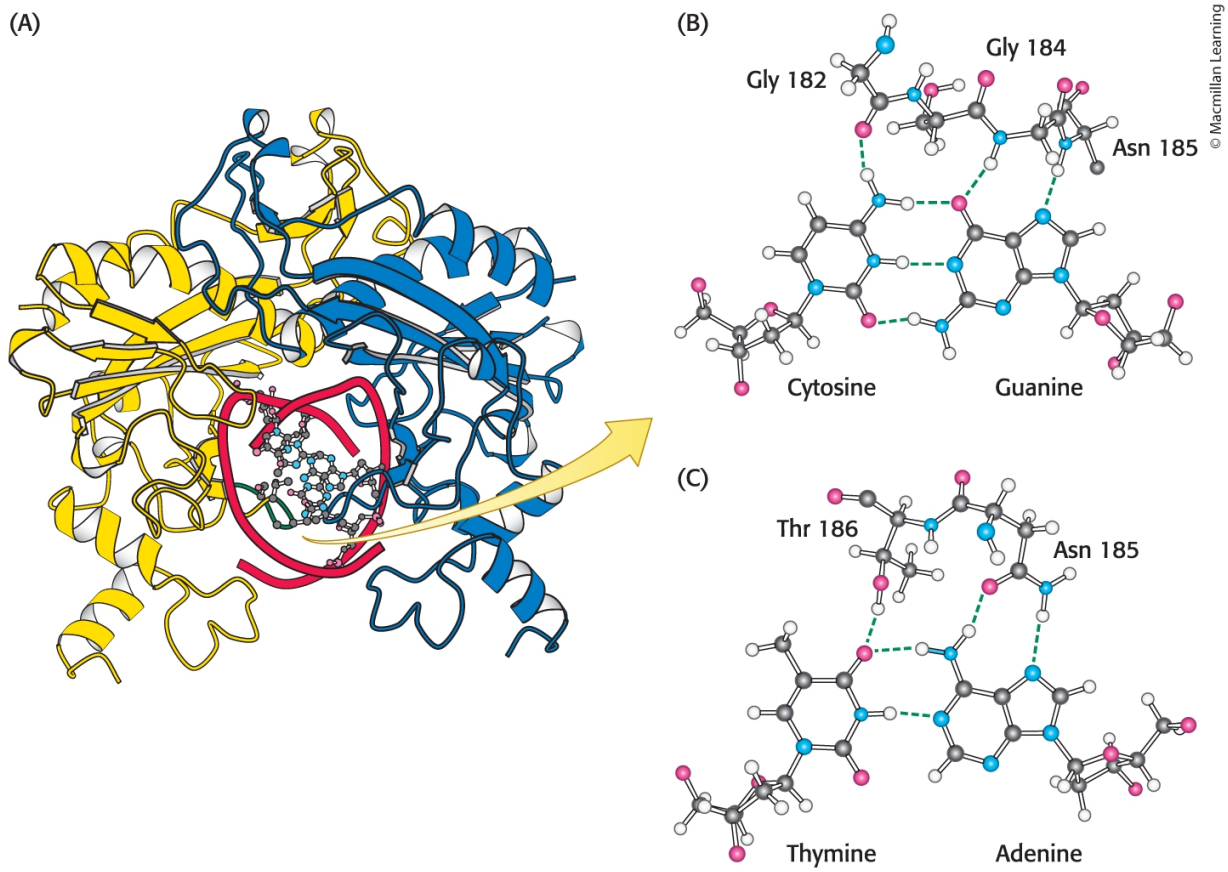
Extended description for FIGURE 6.31. Two fold rotational symmetry of recognition site for Eco R V



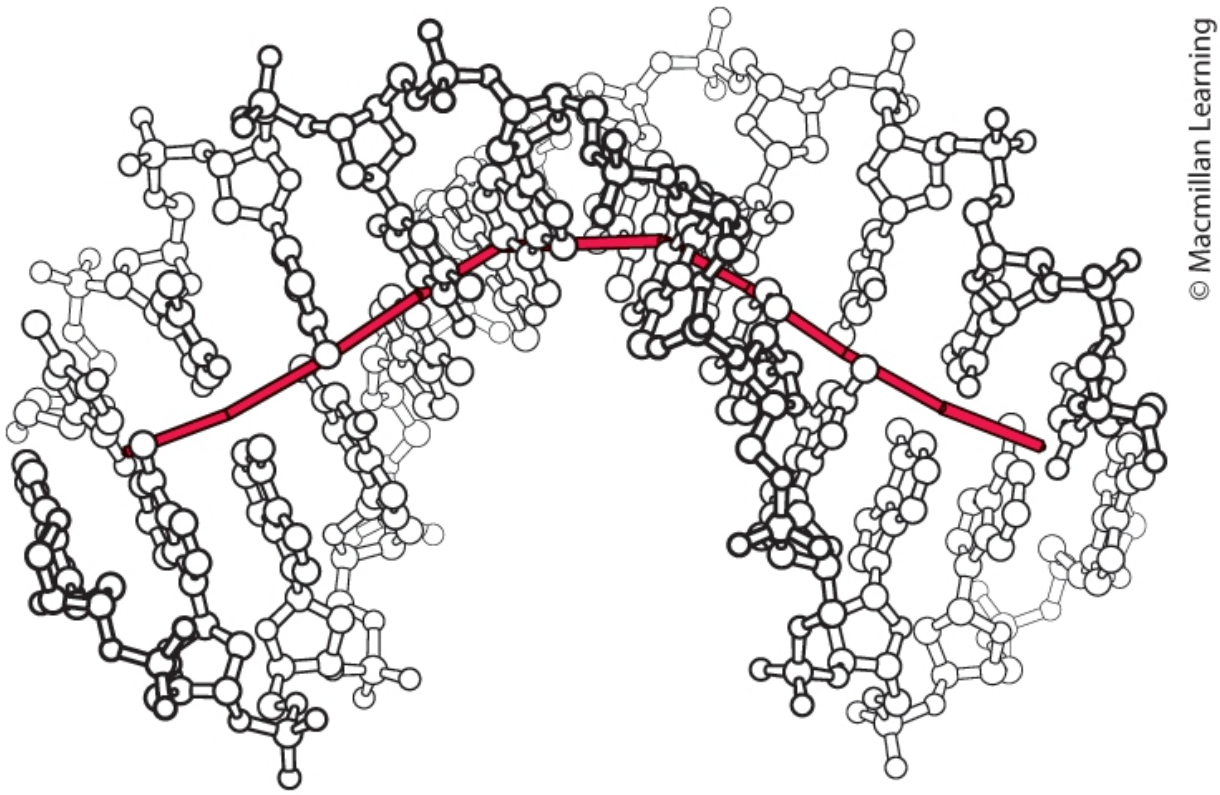
Part (A): The double stranded D N A sequence is 5 prime, zigzag line, G A T A T C, zigzag line, 3 prime. 3 prime, zigzag line, C T A T A G, zigzag line, 5 prime. A rightward arrow is given on the top and a leftward arrow is given on the bottom. The axis of rotation labeled symmetry axis is located between T A in the top sequence and A T in the bottom sequence.

Part (B): A section of a D N A double helix in a horizontal orientation composed of one complete turn is shown. The two D N A strands run in opposite directions that is 5 prime to 3 prime and 3 prime to 5 prime. The red and white spheres indicate different bases in the sequence. The sequences G A T A T C and C T A T A G are depicted as red spheres. The top strand in 3 prime to 5 prime orientation contains the sequence C T A in one half of the turn and T A G in the remaining half of the turn. The bottom strand in 5 prime to 3 prime orientation contains the sequence G A T in one half of the turn and

A T C n the remaining half of the turn. The two-fold symmetry is depicted as a vertical line with a clockwise arrow above the two halves of the D N A molecule. Two curved arrows at the bottom of the two halves of the D N A molecule point upward.

Return to FIGURE 6.31. Two fold rotational symmetry of recognition site for Eco R V

Extended description for FIGURE 6.32. The ribbon diagram of Eco R V bound to a cognate D N A and the ball-and-stick model of C G and A T base pair



Part (A): The two ribbon-shaped protein subunits are represented in yellow and blue colors. They consist of beta-strands and alpha-helices connected by thread-like loops. The D N A backbone is represented as the red hollow circular structure at the center of the protein subunits.

Part (B): The ball-and-stick model highlights G l y 182, G l y 184, and A s n 185 residues. These residues are hydrogen-bonded to the C G base pair.

Part (C): The ball-and-stick model highlights T h r 186 and A s n 185 residues. These residues are hydrogen-bonded to T A base pair.

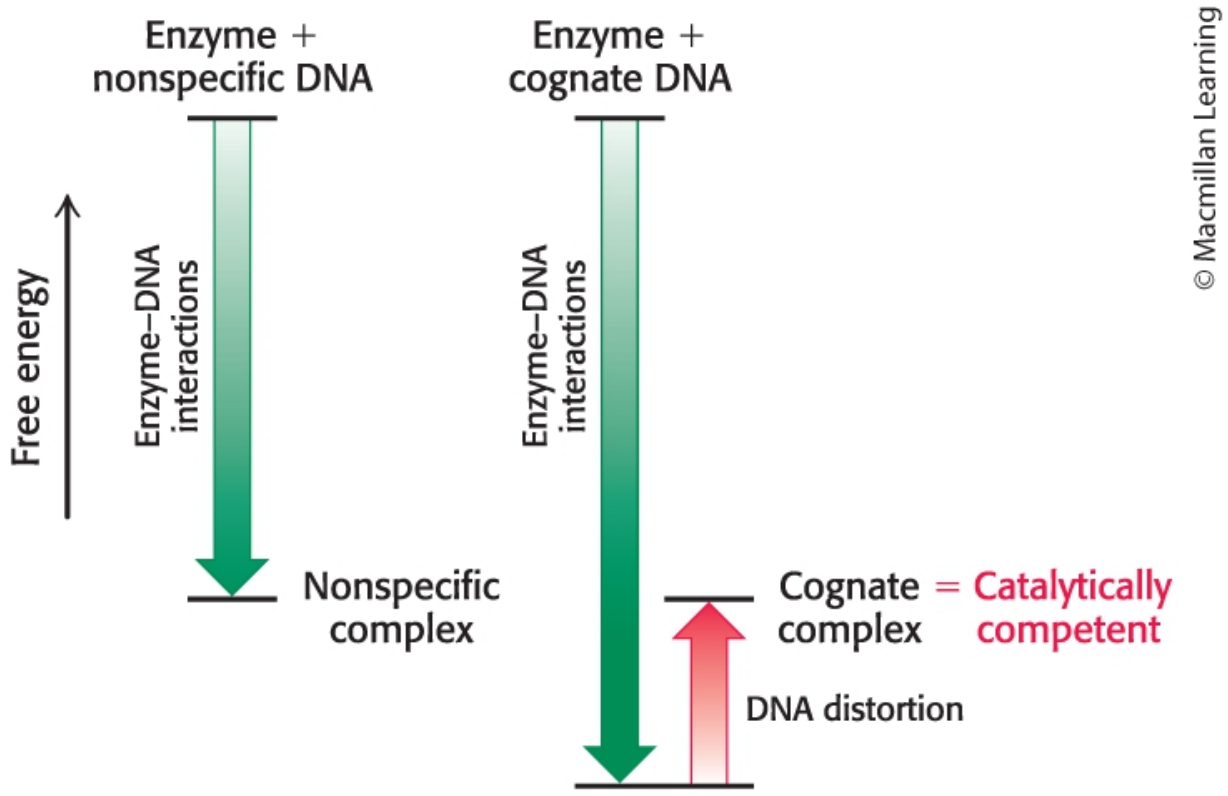
Extended description for Ball-and-stick model of cognate D N A from Eco R V complex

The D N A molecule is represented as a ball-and-stick model. The structure of D N A is distorted and bent downward at either end. A red downward curved line represents the path of the D N A helical axis.

Return to Ball-and-stick model of cognate D N A from Eco R V complex

Extended description for FIGURE 6.34.Ribbon diagram illustrates the positions of the nonspecific and the cognate D N A within Eco R V



The nonspecific and specific complexes are shown as overlapping structures. The D N A backbone in the nonspecific complex is depicted as a circular coiled orange-colored structure. The D N A backbone in the specific complex is depicted as a circular coiled red-

colored structure. These D N A backbones are surrounded by the Eco R V protein. Eco R V is composed of two monomers flanking the D N A backbones. Each monomer is composed of alpha-helices and beta-strands connected by short loops. An M g superscript 2 plus binding site is present in each monomer. The D N A backbone in the nonspecific complex is far away from these sites. The D N A backbone in the specific complex has distortions at the top left and top right that allows it to reach the M g binding sites.

Return to FIGURE 6.34.Ribbon diagram illustrates the positions of the nonspecific and the cognate D N A within Eco R V

Extended description for FIGURE 6.35. Energy level diagram showing D N A distortions due to an increase in binding energy

An upward-pointing arrow is labeled free energy which increases from the bottom to the top. A thick green downward pointing arrow is shown adjacent to the free energy arrow. The tail of the green arrow labeled enzyme plus nonspecific D N A extends much above the head of the free energy arrow. The head of the green arrow labeled nonspecific complex extends much below the tail of the free energy arrow. The middle of the green arrow is labeled enzyme-D N A interactions.

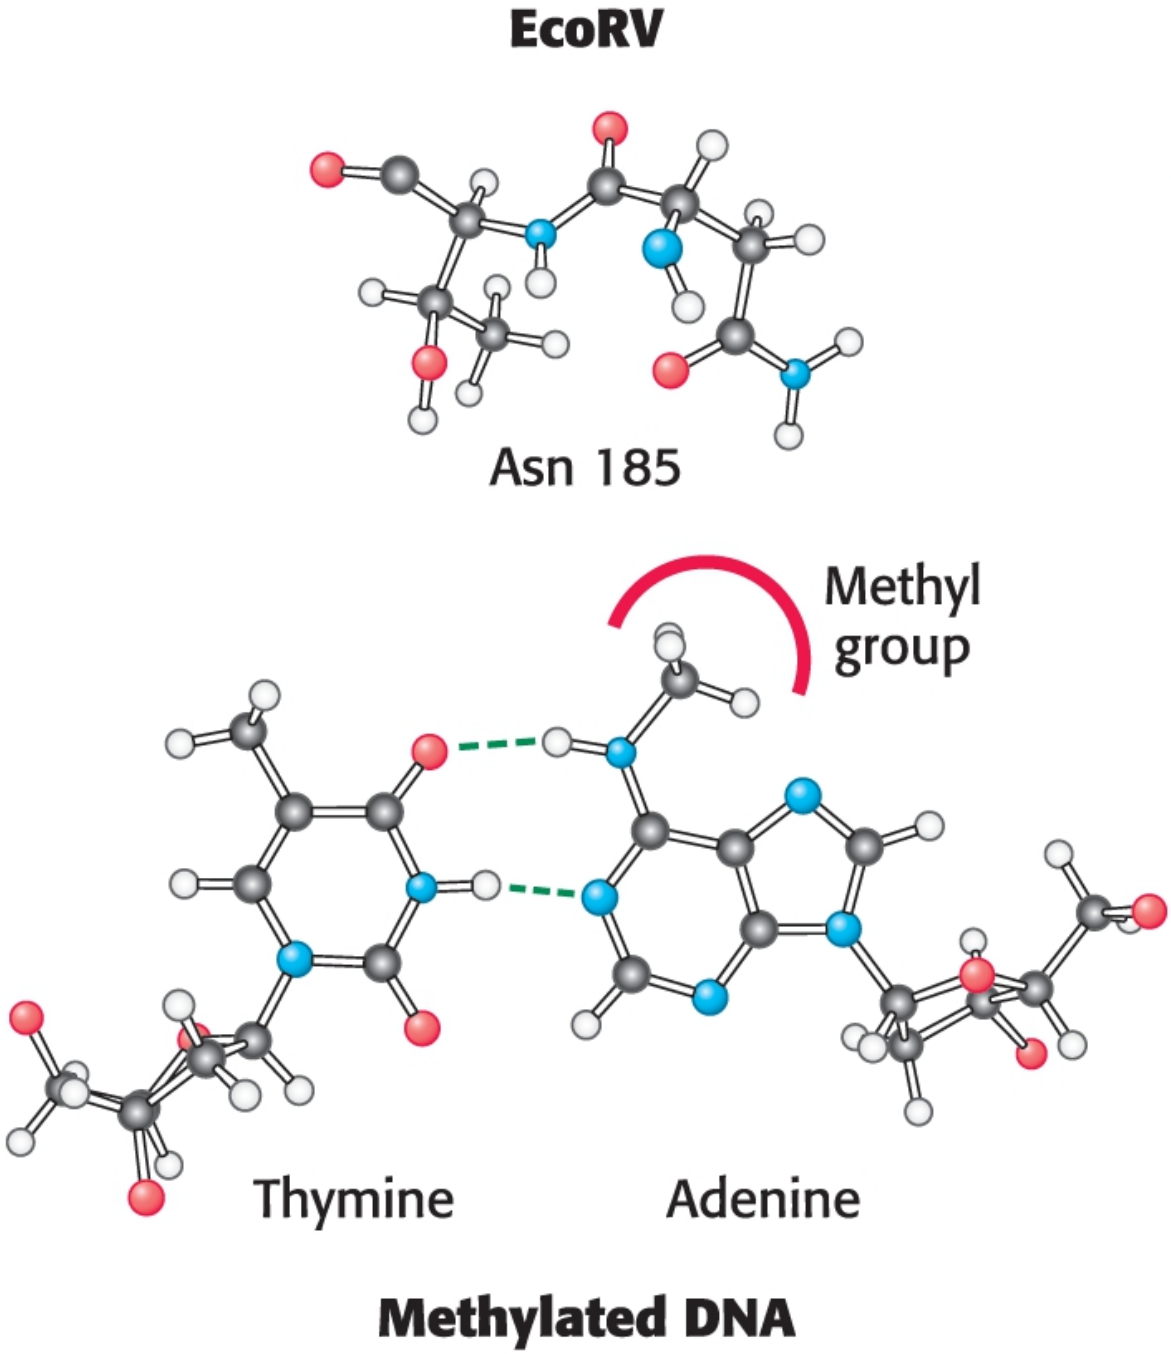
A second green downward pointing arrow, much longer than the first green arrow, is shown on its right. The tail of the second arrow

is labeled enzyme plus cognate D N A. Its middle portion is labeled enzyme-D N A interactions. The head of the second green arrow extends much below the head of the first green arrow. A short red upward-pointing arrow is present between the heads of the two green arrows. It is labeled D N A distortion. The head of the red arrow is labeled cognate complex equals catalytically competent.

Return to FIGURE 6.35. Energy level diagram showing D N A distortions due to an increase in binding energy

Extended description for FIGURE 6.36. Schematic illustration of the methylation of the recognition sequence of Eco R V

The structure of cleaved D N A is as follows: 5 prime, zigzag line, G A T A T C, zigzag line, 3 prime. A red vertical line is present between first A and first T. 3 prime, a zigzag line, C T A T A G, a zigzag line, 5 prime. A red vertical line is present between second T and second A.



The structure of not cleaved D N A is as follows: 5 prime, zigzag line, G A T A T C, zigzag line, 3 prime. The first A is marked with an asterisk. 3 prime, zigzag line, C T A T A G, zigzag line, 5 prime. The second A is marked with an asterisk.

A residue marked with an asterisk is methylated adenosine whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. The first N occupies the first position, which is the bottom-most vertex. The second N occupies the third position, which is the top-left vertex. A double bond is present between C 3 and C 4, first N and C 1, and second N and C 2. C 1 is single bonded to H on the lower left. C 2 is single bonded to N above. This N atom is single bonded to C H 3 on

the upper right and H on the upper left. C H 3 is labeled added methyl group. The hexagonal ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation such that C 3 and C 4 of the hexagonal ring are C 3 and C 2 respectively of the pentagonal ring. The pentagonal ring consists of 2 N and 3 C atoms. The first N occupies the first position, which is the topmost vertex. The second N occupies the third position, which is the bottom-most vertex. C 1 is single bonded to H on the right. A double bond is present between the first N and C 1. The second N atom is single bonded to deoxyribose.

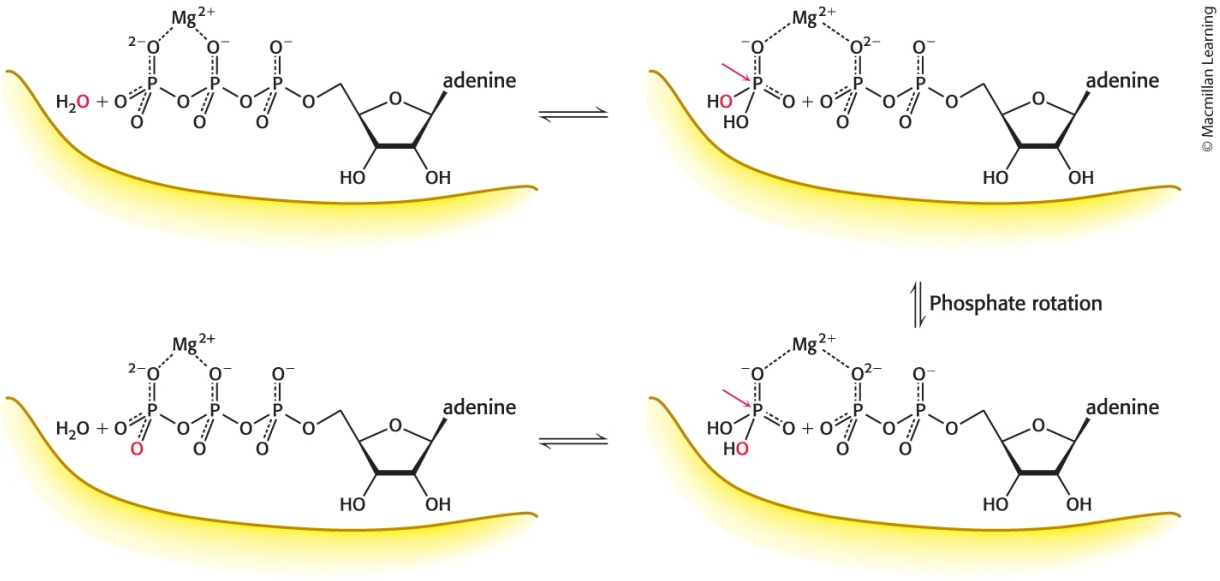
Extended description for Chemical equation of A T P hydrolysis in the presence of with O superscript 18 labeled water

The irreversible reaction consists of two reactants and two products.

The first reactant is H 2 O superscript 18 highlighted in red.

The second reactant is A T P whose structure is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 1 is single bonded to adenine on the upper right. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single bonded to O on the lower left. O is single bonded to P on the upper left. P is partially double bonded to O superscript minus above, partially double bonded to O on the lower left, and single bonded to O on the lower left. This O atom is single bonded to another P on the upper left. This P is partially double bonded to O superscript minus above, partially double bonded to O on the lower left, and single bonded to O on the lower left. This O atom is single bonded to another P on the upper left. This P is partially double bonded to O superscript 2 minus above, partially double bonded to O on the lower left, and partially double bonded to O below.



The structure of the first product is as follows: A central P atom is partially double bonded to O superscript minus above, partially

double bonded to O on the lower right P is single bonded to O H on the lower left, and H O superscript 18 on the lower left.

The structure of the second product is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 1 is single bonded to adenine on the upper right. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single bonded to O on the lower left. O is single bonded to P on the upper left. P is partially double bonded to O superscript minus above, partially double bonded to O on the lower left, and single bonded to O on the lower left. This O atom is single bonded to another P on the upper left. This P is partially double bonded to O superscript 2 minus above, partially double bonded to O below, and partially double bonded to O on the lower left.

Return to Chemical equation of A T P hydrolysis in the presence of with O superscript 18 labeled water

Extended description for FIGURE 6.43. Schematic illustration of the reversible hydrolysis of A T P within the active site of myosin

© Macmillan Learning

The hydrolysis of A T P is shown in 3 reversible steps. The A T P molecule is shown inside the active site of the myosin depicted as a concave surface with a yellow highlight.

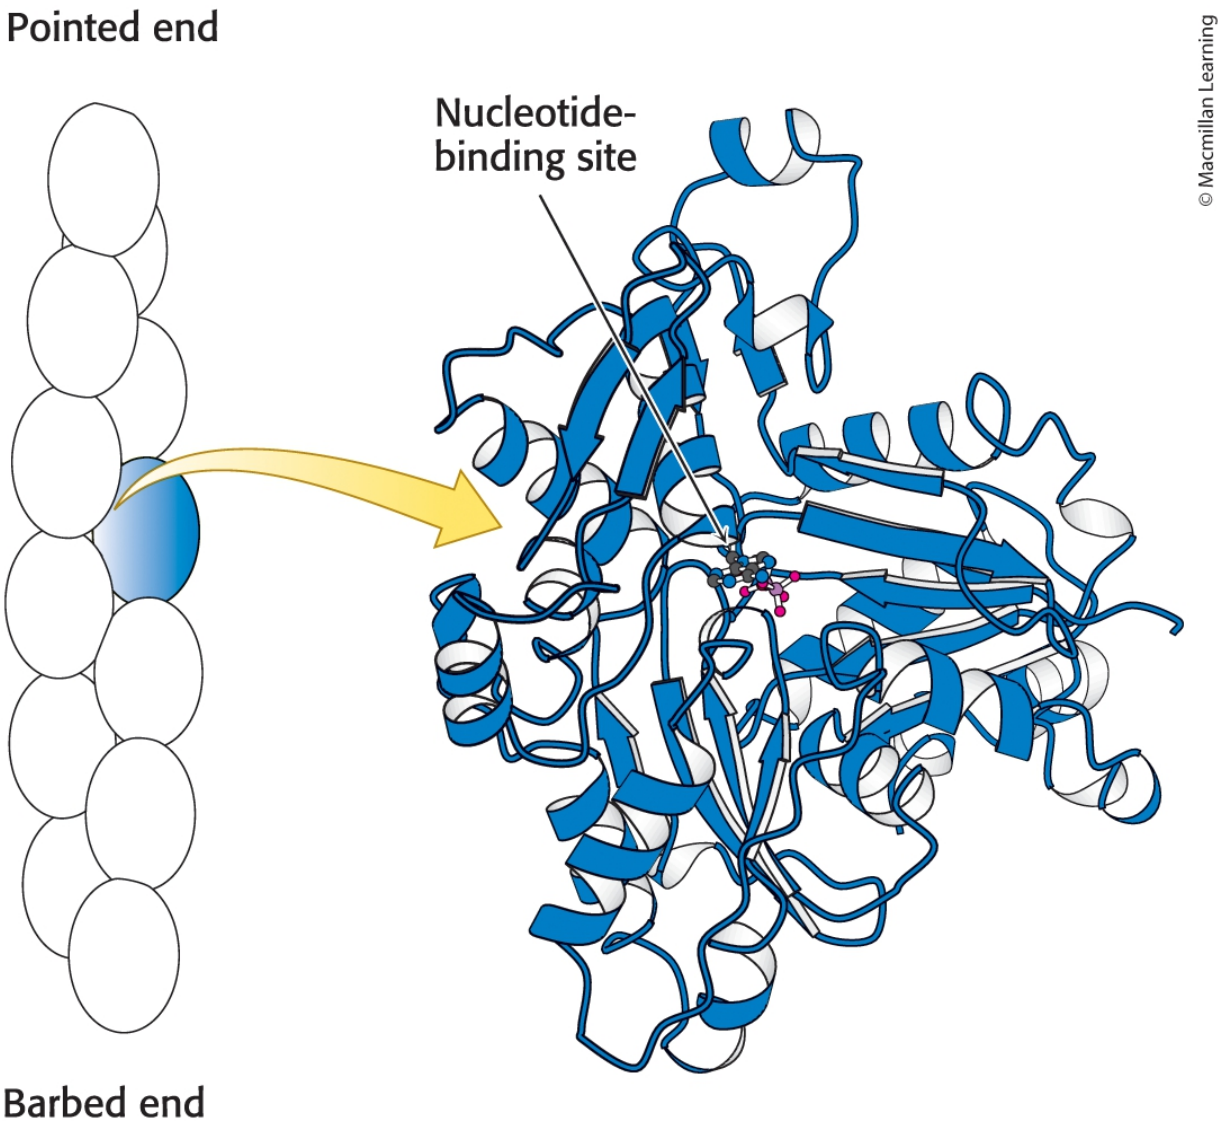
First reversible step:

The structure of the reactant is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 1 is wedge bonded to adenine on the upper right. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single bonded to O on the lower left. O is single bonded to P on the upper left. P is partially double bonded to O superscript minus above, partially double bonded to O on the lower left, and single

bonded to O on the lower left. This O atom is single-bonded to another P on the upper left. This P is partially double bonded to O superscript minus above, partially double bonded to O on the lower left, and single bonded to O on the lower left. This O atom is single-bonded to another P on the upper left. This P is partially double bonded to O superscript 2 minus above, partially double bonded to O on the lower left, and partially double bonded to O below. M g superscript 2 plus ion is connected to two O above through a dashed line. A water molecule having the formula H 2 O is present inside the active site. O atom is highlighted in red.

The structure of the first product is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 1 is wedge bonded to adenine on the upper right. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single bonded to O on the lower left. O is single bonded to P on the upper left. P is partially double bonded to O superscript minus above, partially double bonded to O on the lower left, and single bonded to O on the lower left. This O atom is single-bonded to another P on the upper left. This P is partially double bonded to O superscript 2 minus above, partially double bonded to O on the lower left, and partially bonded to O on the lower left.

The second product is the phosphate group whose structure is as follows: A central P atom is partially double bonded to O superscript minus above, partially double bonded to O on the lower right, single bonded to O H on the lower left and left. The O atom of the O H group on the left is highlighted in red. P has an open single bond on the upper left. M g superscript 2 plus ion is connected to O atom double-bonded to the free phosphate group and terminal P atom through a dashed line.



The second reversible step is labeled phosphate rotation. The structure of the product is the same as the product of the first step except that the O atom of the O H group on the lower left is highlighted in red. An arrow points toward the P atom.

Third reversible step:

The structure of the product is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 1 is wedge bonded to adenine on the upper right. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single bonded to O on the lower left. O is single bonded to P on the upper left. P is partially double bonded to O superscript minus above, partially double bonded to O on the lower left, and single bonded to O on the lower left. This O atom is single-bonded to another P on the upper left. This P is partially double bonded to O superscript minus above, partially double bonded to O on the lower left, and single bonded to O on the lower left. This O atom is single-bonded to another P on the upper left. This P is partially double bonded to O superscript 2 minus above, partially double bonded to O on the lower left, and partially double bonded to O below. The O atom below is highlighted in red. M g superscript 2 plus ion is connected to two O above through a dashed line. A water molecule having the formula H 2 O is present.

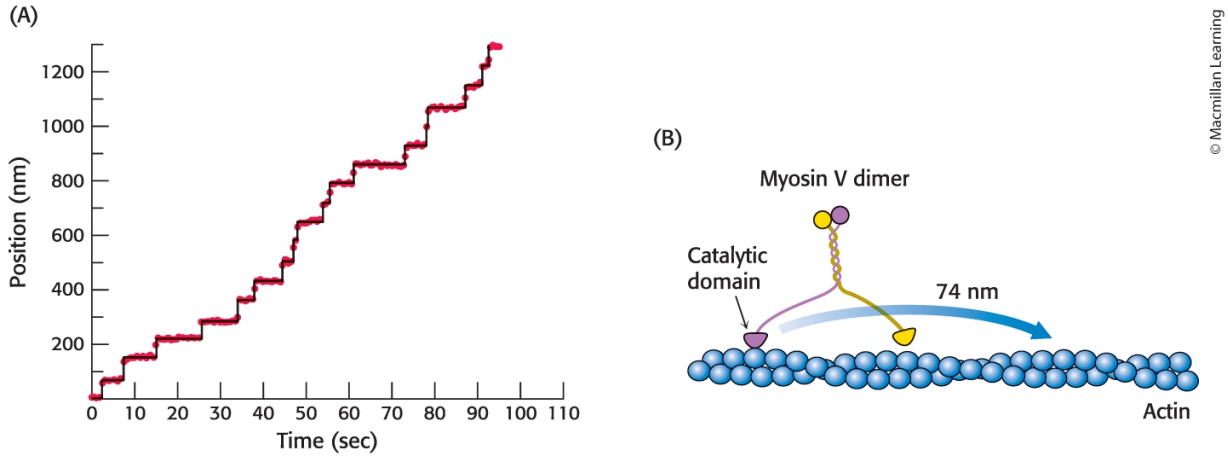
Extended description for FIGURE 6.44. Ribbon diagram and schematic illustration of actin filament



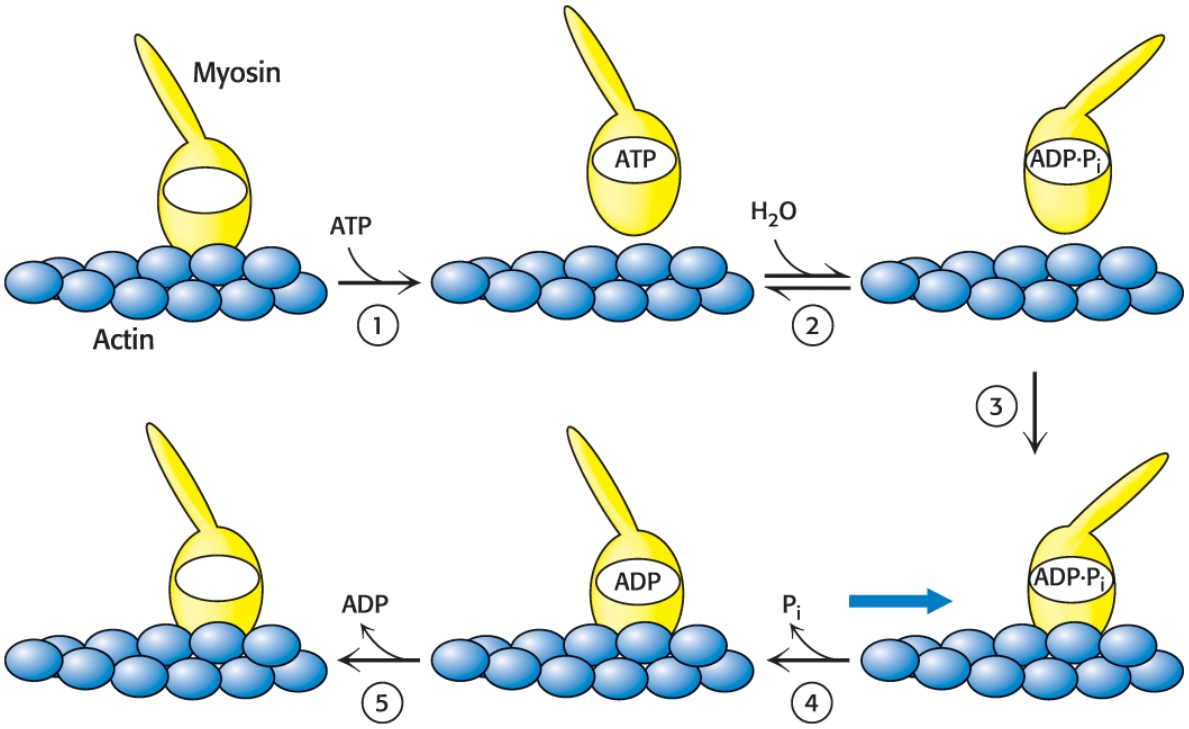
© Macmillan Learning

The schematic illustration of actin is composed of a vertical linear array of monomers. The monomers are depicted as oval-shaped structures. The top and bottom ends of the actin molecule are labeled pointed and barbed ends respectively. The ribbon diagram of an actin monomer is represented in blue color. It is composed of

beta-strands and alpha-helices connected by short thread-like loops. The nucleotide-binding site is located at the center.

Return to FIGURE 6.44. Ribbon diagram and schematic illustration of actin filament

Extended description for FIGURE 6.45. Graphical representation of the position of a single dimeric myosin roman number 5 molecule and a model of the movement of the dimeric molecule



Part (A): The horizontal axis is labeled time in seconds. It has markings ranging from 0 to 110 in increments of 10 units. The vertical axis is labeled position nanometers. It has markings ranging from 200 to 1200 in increments of 200 units. A red-black plot rises from the origin (0,0) and moves toward the upper right in a zigzag ladder-like pattern.

Part (B): The actin filament is represented as a pair of horizontal structure twisted around each other. Each structure is composed of a linear array of tiny blue spheres. Myosin V dimer is represented as a coiled structure having two spheres (yellow and purple) at the top and two cone-shaped structures (yellow and purple) at the bottom. The purple cone-shaped structure is attached to the actin molecule and is labeled catalytic domain. An arrow from the catalytic domain moves toward the right end of actin and is labeled 74 nanometers.

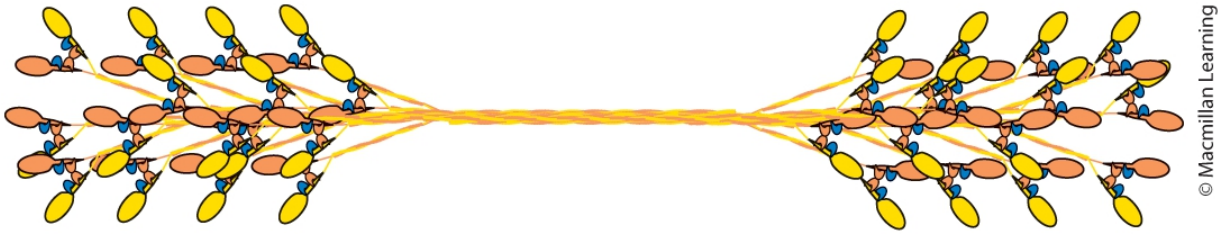
Return to FIGURE 6.45. Graphical representation of the position of a single dimeric myosin roman number 5 molecule and a model of the movement of the dimeric molecule

Extended description for FIGURE 6.46. Schematic illustration of the steps involved in the movement of myosin along an actin filament

Myosin is represented as a yellow sphere with a horizontal oval-shaped groove at the center and a short tubular projection at the top. The actin filament is represented as a horizontal linear structure composed of an array of blue spheres. Myosin is attached to the surface of the actin filament. The groove is empty and the tubular projection is oriented toward the upper left.

Step 1: ATP enters and binds to the groove of myosin protein. The myosin protein is detached from the actin surface. This step is irreversible.

Step 2: H 2 O molecule enters. An A D P-P subscript i complex is formed in the groove. The tubular projection is oriented toward the upper right. The myosin protein remains detached from the actin surface. This step is reversible.

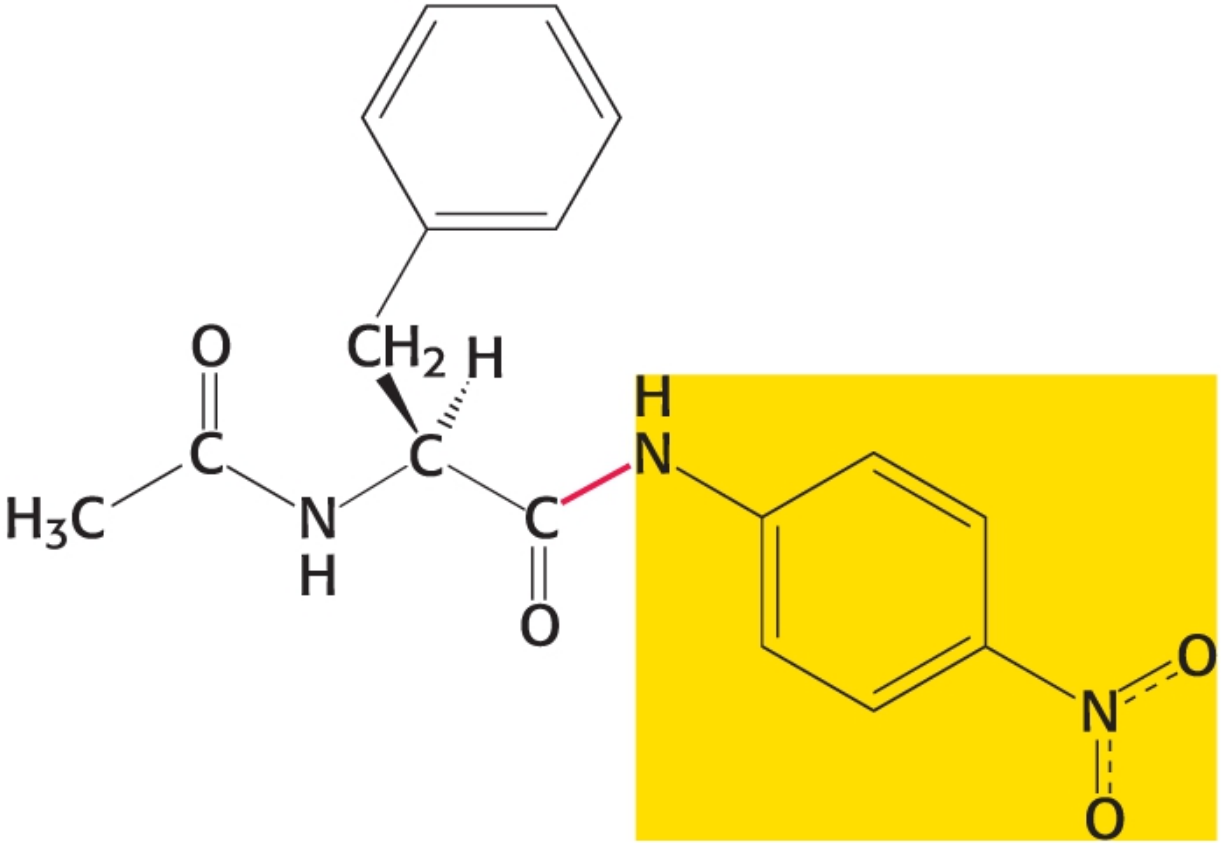


Step 3: The myosin protein with A D P-P subscript i complex in the groove attaches to the actin surface. The tubular projection is oriented toward the upper right. A rightward pointing blue arrow is shown adjacent to the myosin protein. This step is irreversible.

Step 4: P subscript i atom leaves the groove. The myosin protein with A D P in the groove is attached to the actin surface. The tubular projection is oriented toward the upper left. This step is irreversible.

Step 5: A D P is released from the groove. The myosin protein with an empty groove is attached to the actin surface. This step is irreversible.

Return to FIGURE 6.46. Schematic illustration of the steps involved in the movement of myosin along an actin filament



Extended description for FIGURE 6.47. Schematic illustration of the structure of myosin assembly in muscle

The dimeric myosin filaments are represented in yellow and orange colors. Multiple myosin dimers join together to form a thick filament. The globular heads protrude above and below from the left and right ends of a central thick filament.

Extended description for Enzyme catalyzed reaction

The chemical reaction consists of two reactants and two products. The ball-and-stick model for each is shown. The enzyme is catalyzed by A T C ase. The first product is shown to produce C T P through a multistep pathway. C T P is shown to inhibit A T C ase in turn.

[Return to Enzyme catalyzed reaction]

Extended description for A chemical reaction representing the committed step of pyrimidine synthesis

A reversible reaction consists of two reactants and two products.

The first reactant is carbamoyl phosphate, which has the following structure: A central C atom is double bonded to O on the left, single bonded to N H 2 on the upper right, and single bonded to O P O 3 superscript 2 minus on the lower right.

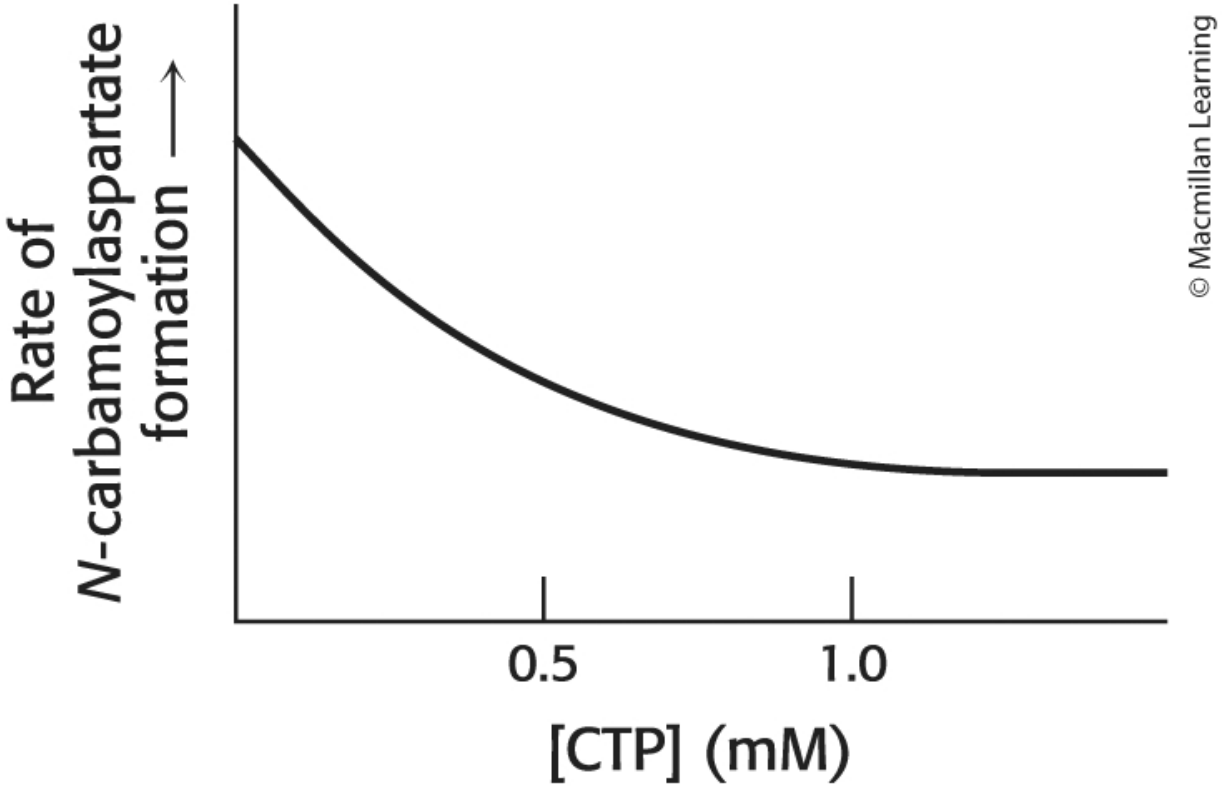
The second reactant is aspartate, which has the following structure: A central C atom is single bonded to C O O superscript minus on the lower right, single bonded to N H 3 superscript plus on the lower

left, dash bonded to H on the upper left, and wedge bonded to C H 2 on the upper right. C H 2 is single bonded to C on the upper left. This C is partially double bonded to O on the left and partially double bonded to O on the upper right. This C O O group carries a negative charge.

A reversible reaction arrow is labeled A T C ase. The forward reaction arrow is longer than the backward reaction arrow.

The first product is N-carbamoylaspartate, which has the following structure: A central C atom is single bonded to C O O superscript minus on the lower right, single bonded to N H on the lower left, dash bonded to H on the upper left, and wedge bonded to C H 2 on the upper right. N H is single bonded to C on the upper left which is single bonded to N H 2 on the upper right and double bonded to O on the lower left. The C atom of C H 2, wedge bonded to the central C atom, is partially double bonded to O on the left and partially double bonded to O on the upper right. This C O O group carries a negative charge.

The second product is P subscript i.



Three parallel arrows from the products indicate subsequent steps.

The final product is cytidine triphosphate (C T P), which has the following structure: A 5-membered heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. O occupies the first position, which is the topmost vertex. C 2 and C 3 are each single bonded to O H below. C 1 is wedge bonded to the first N of a 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 2 N and 4 C atoms. The first N atom occupies the first position which is the bottom left vertex and the second N atom occupies the third position which is the top-left vertex. C 1 occupies

the leftmost vertex and is double bonded to O on the left. A double bond is present between the second N and C 2, and C 3 and C 4. C 2 is single bonded to N H 2 on the upper right. C 4 of the pentagonal ring is single bonded to C H 2 in the form of a line. C H 2 is single bonded to O of a triphosphate group on the left. Each phosphate group has a central P atom single bonded to O on the lower right, single bonded to O on the lower left, partially double bonded to O above, and partially double bonded to O below. The single bond to O atoms is shared between two adjacent phosphate groups. The terminal phosphate group is partially double bonded to O on the lower left and carries a negative charge of 2 minus. The other two phosphate groups each carry a negative charge.

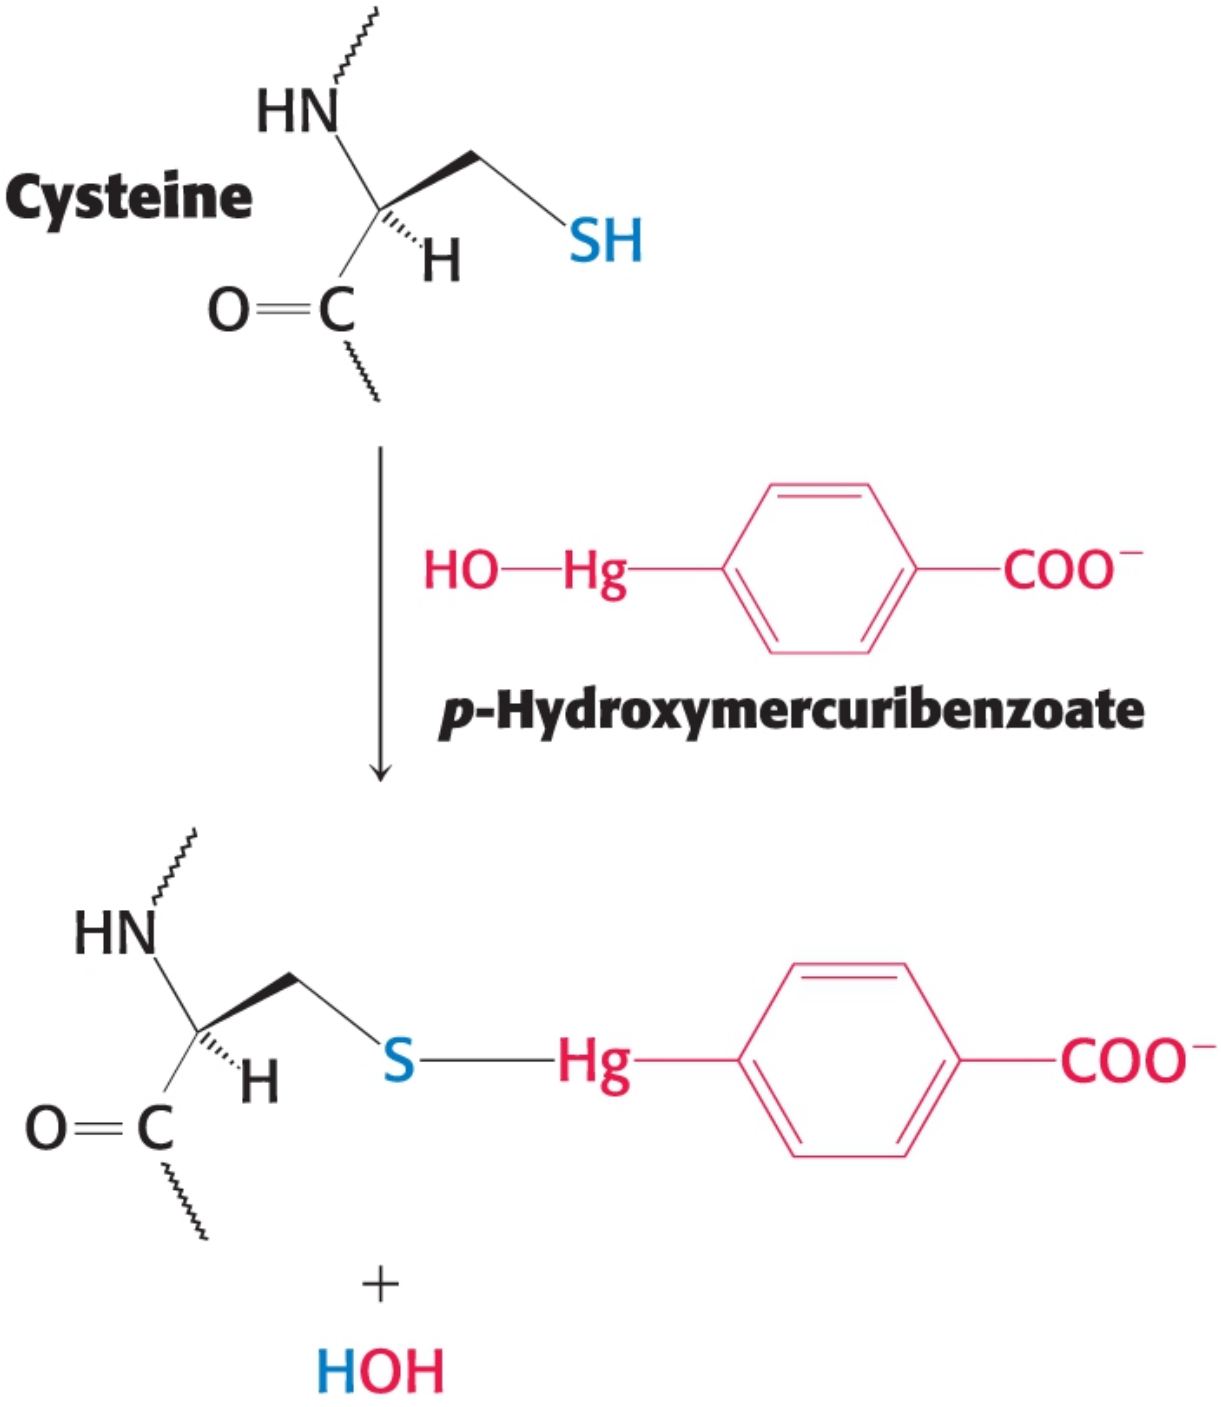
Extended description for Graphical representation of the inhibition of A T C ase by C T P

The horizontal axis is labeled C T P concentration in millimolar and ranges from 0.5 to 1.0 in increments of 0.5 units. The vertical axis is labeled the rate of N-carbamoylaspartate formation. The curve starts near the upper end of the vertical axis and then gradually falls below the midpoint of the vertical axis at a C T P concentration of 1 and then it remains constant beyond this point.

Return to Graphical representation of the inhibition of A T C ase by C T P



Extended description for Graph of the rate of formation of N-carbamoylaspartate as a function of aspartate concentration

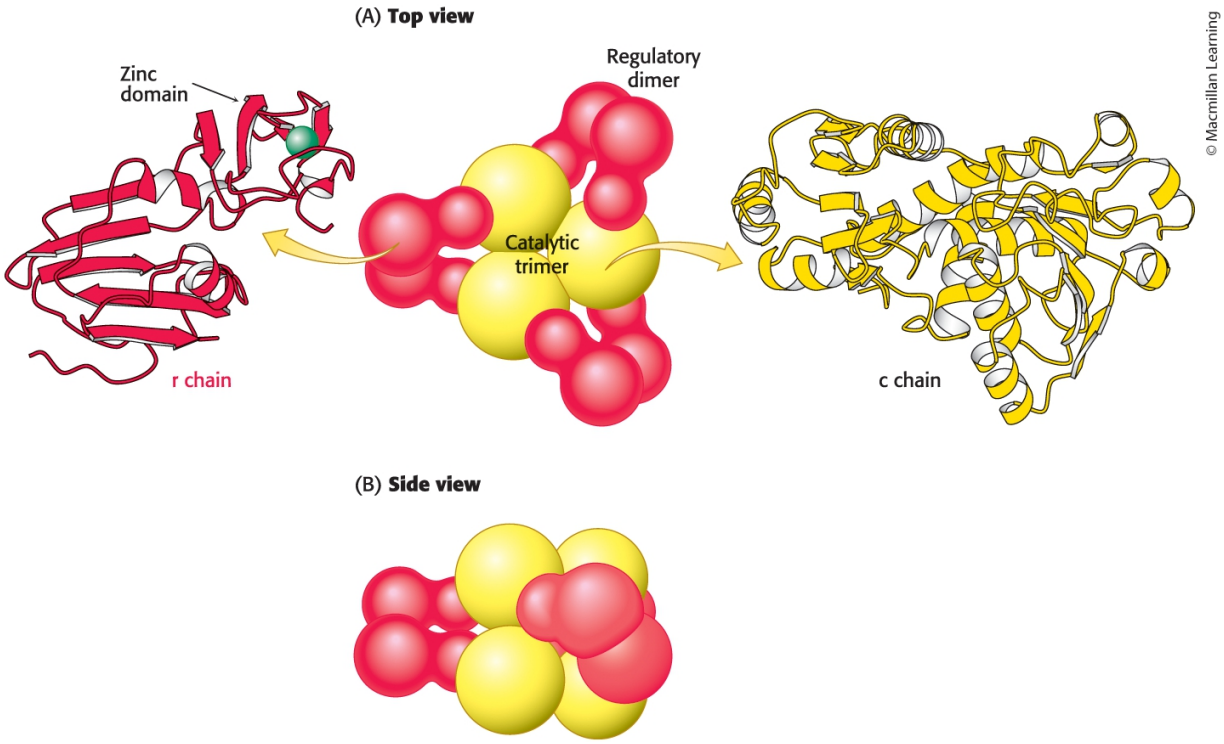
The horizontal axis is labeled aspartate concentration in millimolar. It has markings ranging from 0 to 40 in increments of 10 units. The vertical axis is labeled the rate of formation of N-carbamoylaspartate formation. The curve starts at the origin and steeply rises to a point corresponding to 20 milli moles aspartate at the top of the vertical axis. This is followed by a gradual plateau formation. The curve has a sigmoidal shape.

Return to Graph of the rate of formation of N-carbamoylaspartate as a function of aspartate concentration

Extended description for Chemical reaction of p-Hydroxymercuribenzoate with a crucial cysteine residue of aspartate transcarbamoylase

The reaction consists of two reactants and two products.

The first reactant is the cysteine residue of aspartate transcarbamoylase, which has the following structure: A central C atom is single bonded to C on the lower left, single bonded to N H on the upper left, wedge bonded to C H 2 on the upper right, and dash bonded to H on the lower right. N H has an open single bond on the upper right. C on the lower left is double bonded to O on the left and has an open single bond on the lower right. C H 2 on the upper right is single bonded to S H on the lower right. S H is highlighted in blue.



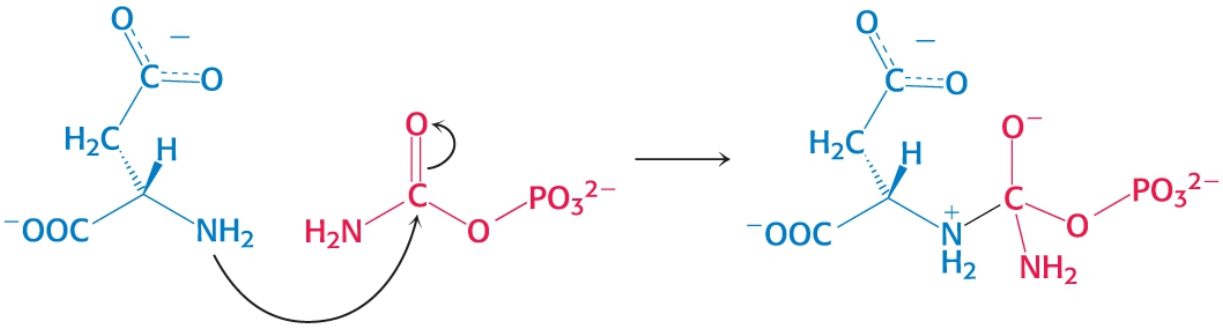
The reaction arrow is labeled p-Hydroxymercuribenzoate, which is the second reactant having the following structure: A benzene ring is in a horizontal orientation. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 1 is single bonded to C O O superscript minus on the right. C 4 is single bonded to H g, single bond, O H on the left.

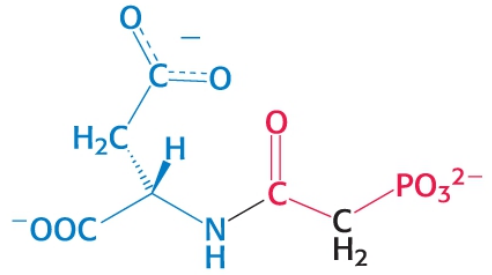
The first product has the following structure: A central C atom is single bonded to C on the lower left, single bonded to N H on the upper left, wedge bonded to C H 2 on the upper right, and dash bonded to H on the lower right. N H has an open single bond on the upper right. C on the lower left is double bonded to O on the left and has an open single bond on the lower right. C H 2 on the upper right is single bonded to S on the lower right, which is highlighted in blue. S is single bonded to H g on the right. H g is single bonded to C 4 of a benzene ring in a horizontal orientation. The benzene ring consists of alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 1 is single bonded to C O O superscript minus.

The second product is H O H. The left H atom is highlighted in blue.

Return to Chemical reaction of p-Hydroxymercuribenzoate with a crucial cysteine residue of aspartate transcarbamoylase

Extended description for Schematic illustration of the top and side views of the catalytic subunit trimer of A T C ase





Part (A): Top view. One catalytic subunit is shown to have a central yellow spherical structure with two arms at upward inclined angles. Each arm is made up of a pair of fused red spheres. The yellow structure is labeled c chain and the ribbon diagram shows it to comprise alpha helices and some beta strands connected by short loops. The red arms are labeled r chain and are shown to primarily consist of antiparallel beta-strands and an alpha helix joined by short loops. One small green sphere is associated with the top part of the r chain and is labeled zinc domain. The three subunits are arranged around a central axis with the yellow spheres at the center and the red arms toward the periphery. Adjacent arms are accommodated by positioning one above the other.

Part (B): Side view. A catalytic trimer is shown above another similar trimer. Two yellow spheres of each trimer are visible to the observer.

Return to Schematic illustration of the top and side views of the catalytic subunit trimer of A T C ase

Extended description for Chemical equation for the formation of an intermediate compound in the A T C ase catalytic pathway and the structure of its analog P A L A

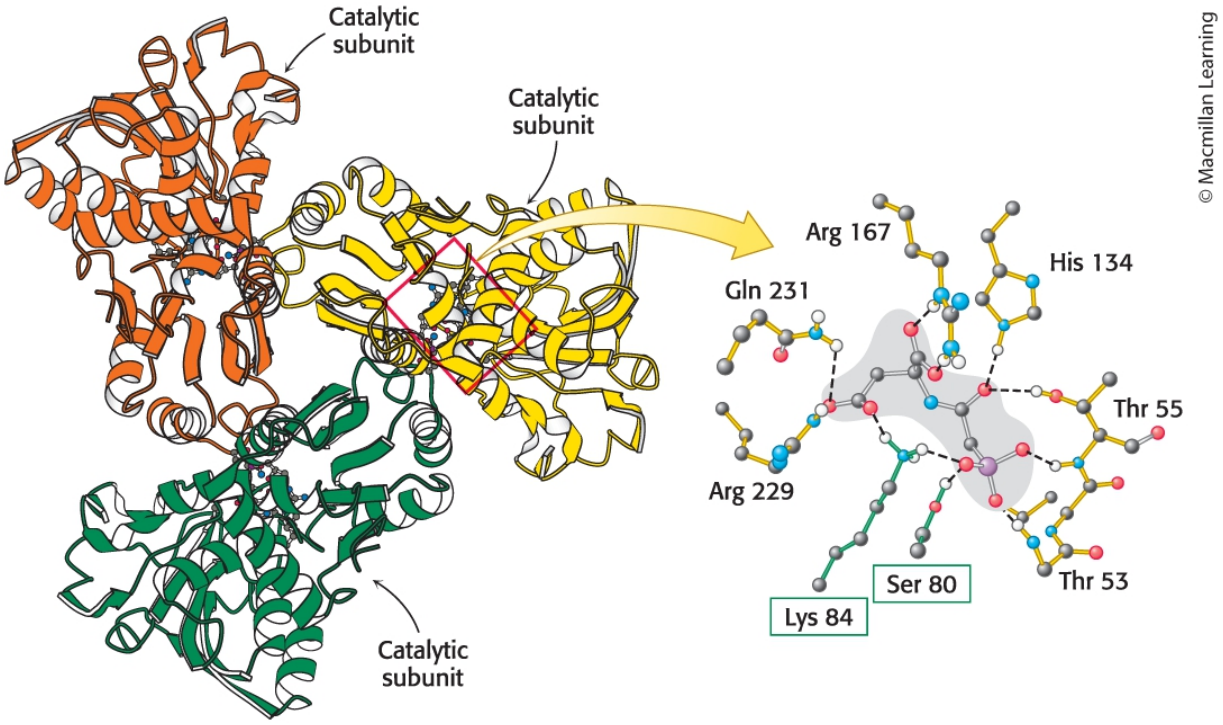
The reaction consists of two reactants and one product.

The first reactant has the following structure: A central C atom is single bonded to C O O superscript minus on the lower right, single bonded to N H 2 on the lower left, wedge bonded to H on the upper right, and dash bonded to C H 2 on the upper left. C H 2 is single bonded to C on the upper right. This C is partially double bonded to O on the right and partially double bonded to O on the upper left. This C O O group carries a negative charge.

The second reactant has the following structure: A central C atom is double bonded to O above, single bonded to N H 2 on the lower left, and single bonded to O on the lower right. O atom on the lower right is single bonded to P O 3 superscript 2 minus on the upper right.

A curved arrow is pointed from the N H 2 group of the first reactant to the central C atom of the second reactant. Another curved arrow is pointed from the central C atom of the second reactant to the double-bonded O above.

The reactants are labeled bound substrates.

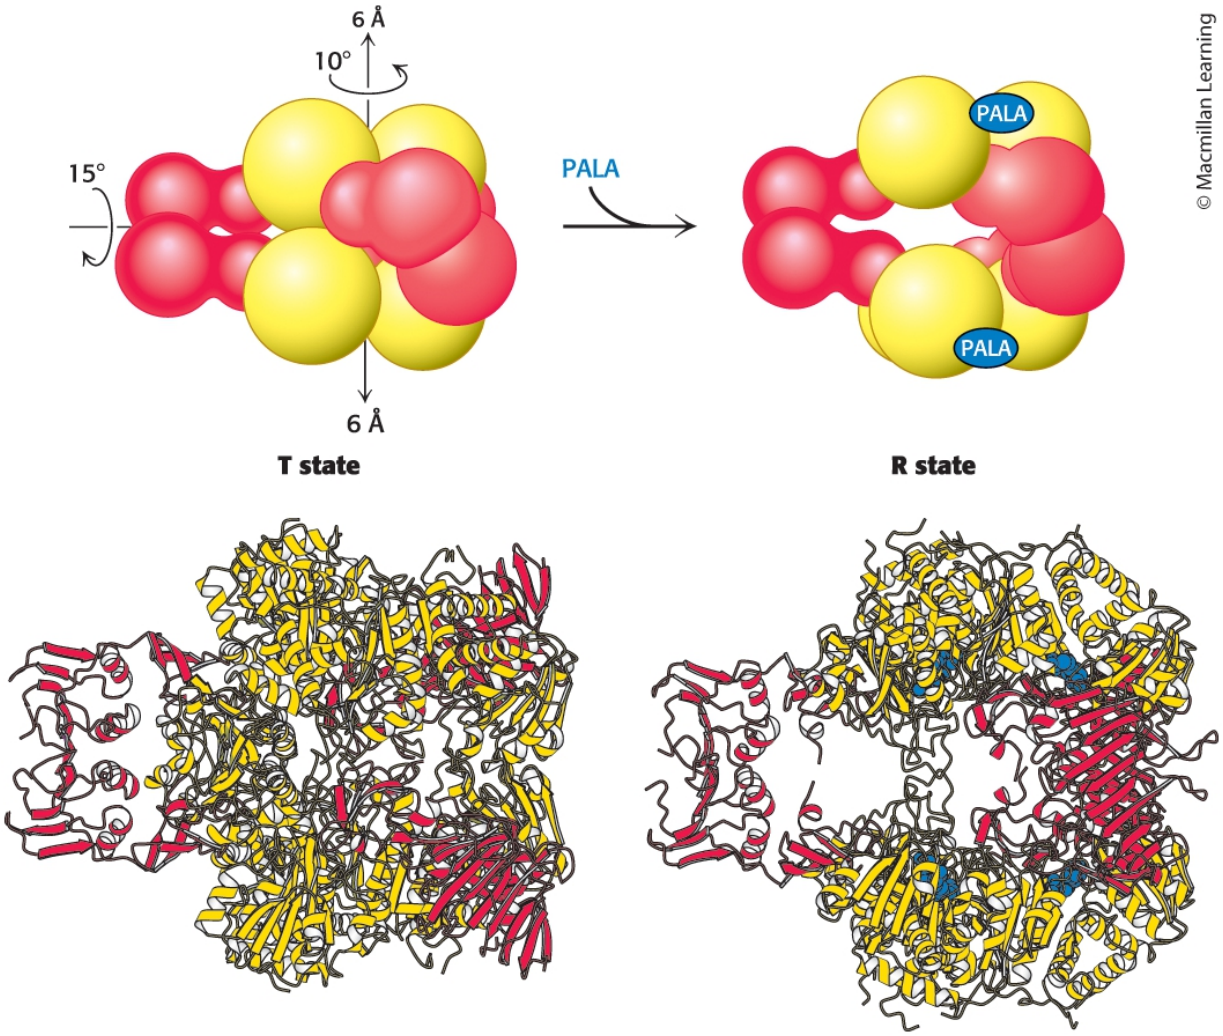


The product is labeled reaction intermediate, which has the following structure: A central C atom is single bonded to C O O superscript minus on the lower right, single bonded to N H 2 superscript plus on the lower left, wedge bonded to H on the upper right and dash bonded to C H 2 on the upper left. C H 2 is single bonded to C on the upper right. This C is partially double bonded to O on the right and partially double bonded to O on the upper left. This C O O group carries a negative charge. N H 2 superscript plus is single bonded to a C atom on the upper right. This C atom is single bonded to O superscript minus above, single bonded to N H 2 below, and single bonded to O on the lower right. The O atom on the lower right is single bonded to P O 3 superscript 2 minus on the upper right.

The structure of N-(Phosphonacetyl)-L-aspartate (P A L A) is as follows: A central C atom is single bonded to C O O superscript minus on the lower right, single bonded to N H on the lower left, wedge bonded to H on the upper right and dash bonded to C H 2 on the upper left. C H 2 is single bonded to C on the upper right. This C is partially double bonded to O on the right and partially double bonded to O on the upper left. This C O O group carries a negative charge. N H is single bonded to a C atom on the upper right. This C

atom is double bonded to O above, single bonded to C H 2 on the lower right which is single bonded to P O 3 superscript 2 minus on the upper right.

Return to Chemical equation for the formation of an intermediate compound in the A T C ase catalytic pathway and the structure of its analog P A L A

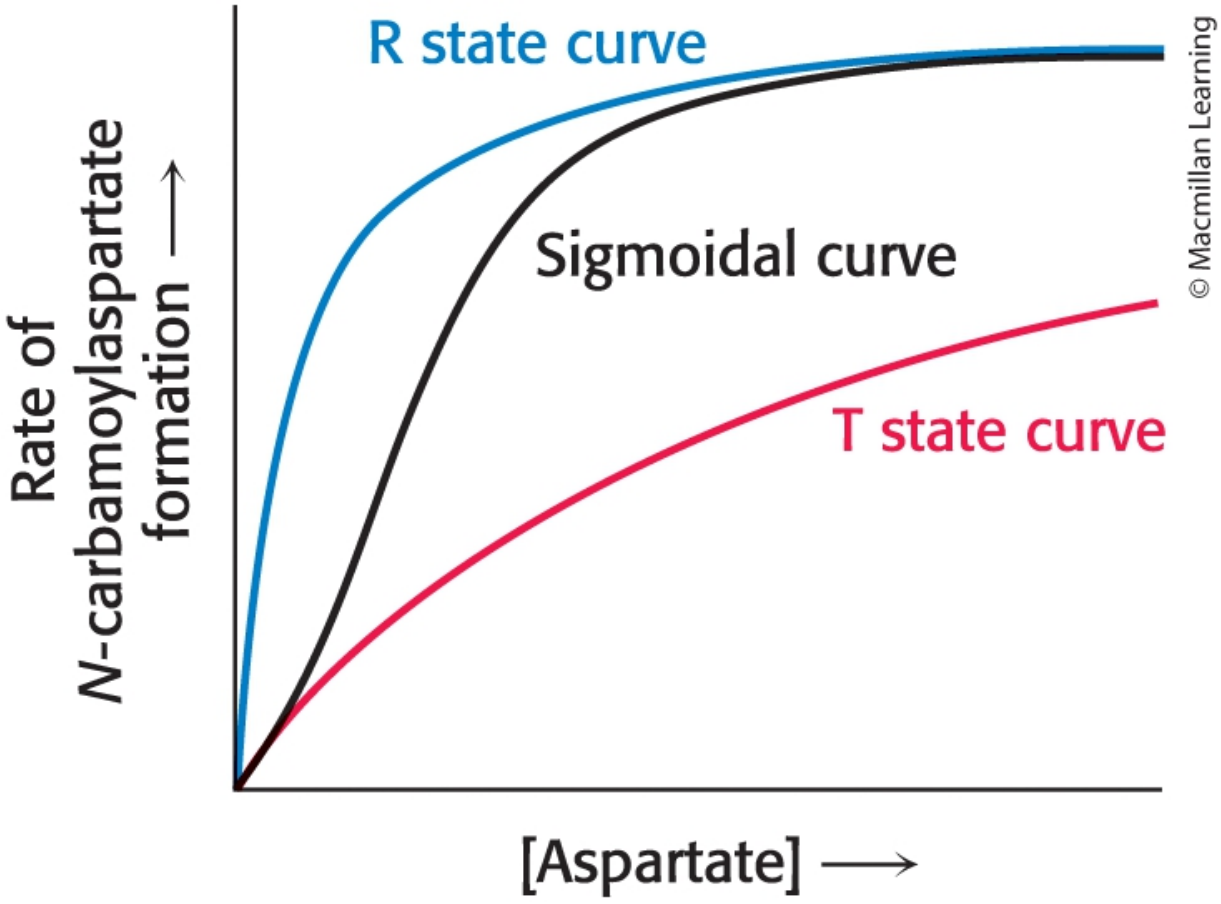


Extended description for The ribbon structure of the catalytic trimer of A T C ase and the active site residues of one of the catalytic subunits bound to P A L A

The catalytic trimer is shown to consist of three catalytic subunits colored orange, yellow, and green, respectively. Each subunit consists of alpha helices and beta strands joined by short loops. The catalytic subunits are connected around a central axis. The active site residues of the yellow subunit are shown in magnification. A central elongated gray shaded region highlights the ball-and-stick model of P A L A. It is surrounded by the following residues of the yellow subunit at the top: A r g 229, G l n 231, A r g 167, H i s 134, T h r 55, and T h r 53. The following residues of the green subunits are present at the bottom of P A L A: L y s 84 and S e r 80.

Return to The ribbon structure of the catalytic trimer of A T C ase and the active site residues of one of the catalytic subunits bound to P A L A

Extended description for Schematic illustration of the tense and relaxed states of A T C ase



Tense state (T). One catalytic subunit is shown to have a central yellow spherical structure with two arms at upward inclined angles. Each arm is made up of a pair of fused red spheres. The side view of the trimer shows the three subunits arranged around a central vertical axis with the yellow spheres at the center and the red arms to the periphery. Adjacent arms are accommodated by positioning one above the other. One trimer is positioned above the other and

there is no gap in between. An upward arrow along the vertical axis is labeled 6 Angstrom and a counter-clockwise arrow around the axis is labeled 10 degrees. A downward arrow along the vertical axis is labeled 6 Angstrom. A clockwise arrow around the horizontal axis is labeled 15 degrees. The ribbon structure shows the two catalytic trimers forming a vase-shaped structure tilted 90 degrees to the left. There is a minimal gap in between.

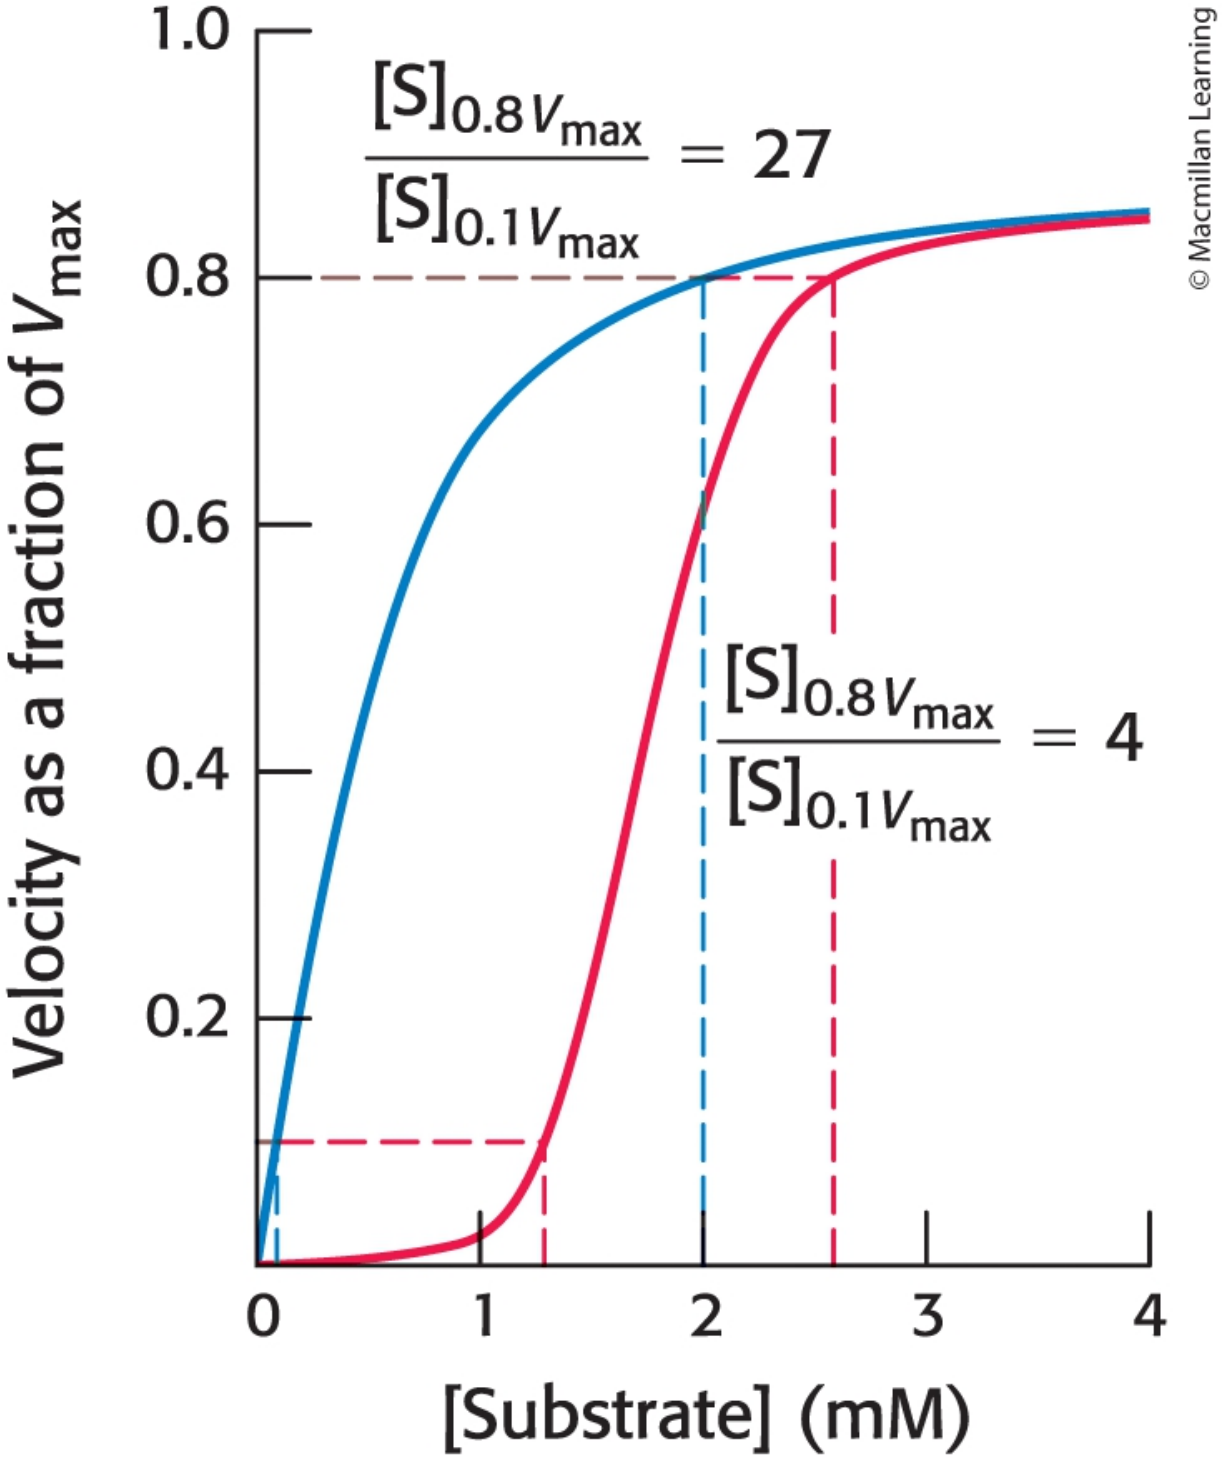
Relaxed state: Binding of P A L A to the catalytic trimer produces a relaxed state. The arrangement is almost identical to the tense state but there is more gap between the top and bottom trimers. The ribbon structure shows the two catalytic trimers forming a vase-shaped structure tilted 90 degrees to the left. There are enlarged gaps near the neck.

Return to Schematic illustration of the tense and relaxed states of A T C ase

Extended description for Graphical representation of the change of state in a cooperative enzyme as a function of substrate concentration

The horizontal axis is labeled aspartate concentration. The vertical axis is labeled the rate of N-carbamoylaspartate formation. The following three curves are shown:

T state curve (shown in red): It starts at the origin and rises almost linearly to a point corresponding to the midpoint of the vertical axis. It has a slight downward curve.



Sigmoidal curve (shown in black): It starts from the origin and rises steeply toward the top of the vertical axis and then plateaus. It has a slight S-shape.

R state curve (shown in blue): It starts from the origin and rises parallel to the sigmoidal curve but has a steeper slope. It then plateaus to meet the sigmoidal curve. It is a hyperbolic curve.

Return to Graphical representation of the change of state in a cooperative enzyme as a function of substrate concentration

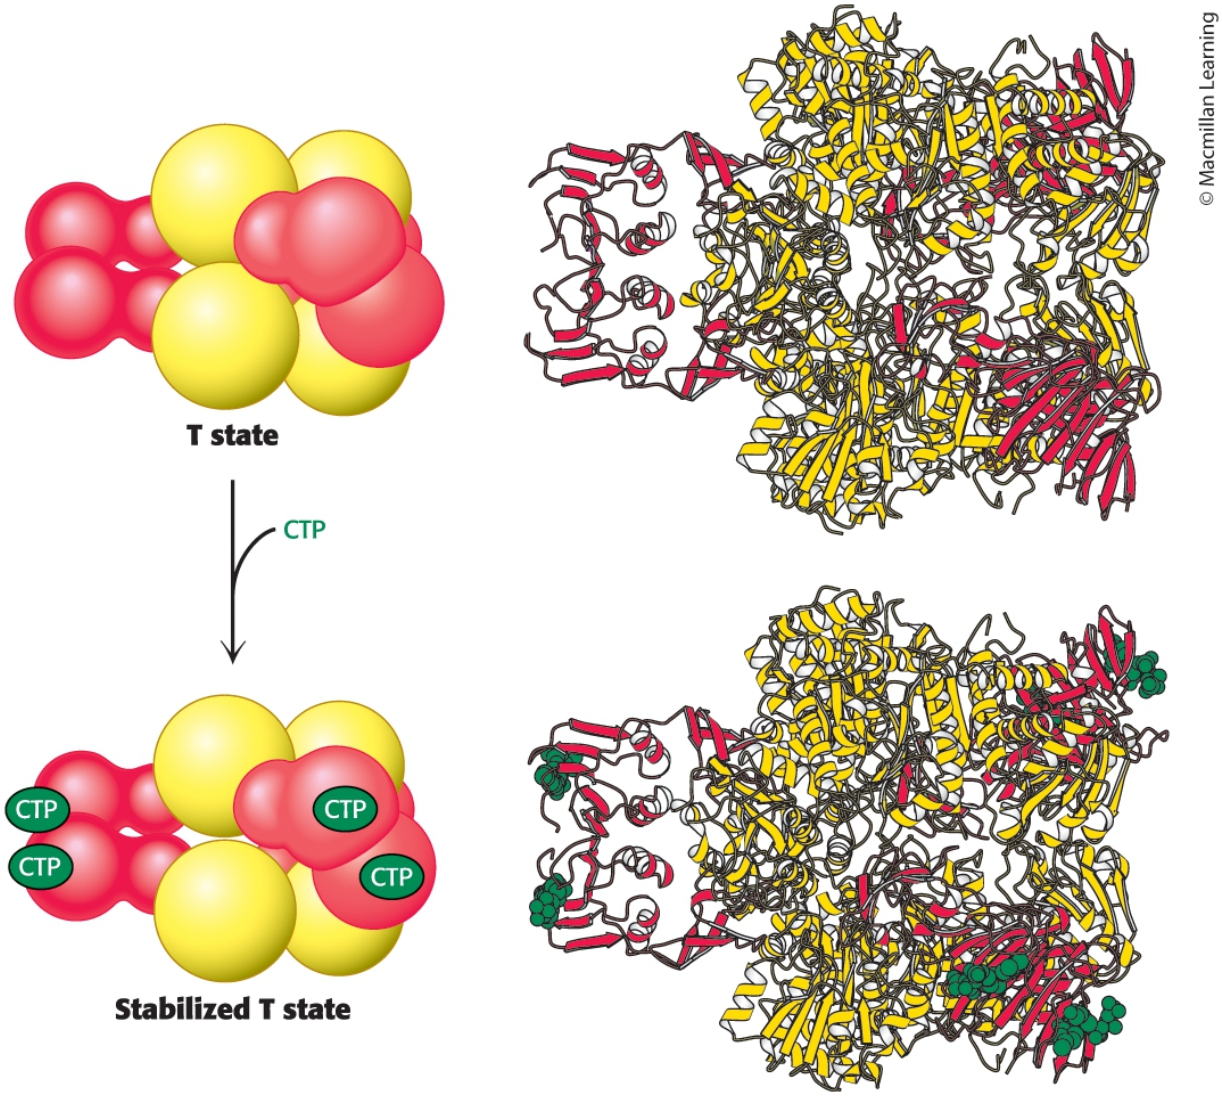
Extended description for Graphical representation of the velocity of reaction as a function of substrate

concentration for allosteric and Michaelis-Menten enzymes

The horizontal axis is labeled substrate concentration in millimolar. It has markings ranging from 0 to 4 in increments of 1 unit. The vertical axis is labeled velocity as a fraction of V max. It has markings ranging from 0 to 1.0 in increments of 0.2 units.

Two curves are shown as follows:

Red curve: It is a sigmoidal curve that starts at the origin, slowly rises to (1, 0.05), followed by a steep rise to nearly (2.6, 0.8) and it gradually plateaus. An equation next to the curve reads that the ratio of substrate concentration subscript 0.8 V max to substrate concentration subscript 0.1 V max equals 4.



Blue curve: It starts at the origin, steeply rises to (2, 0.8), and then gradually plateaus to meet the red curve. An equation next to the curve reads that the ratio of substrate concentration subscript 0.8 V max to substrate concentration subscript 0.1 V max equals 27.

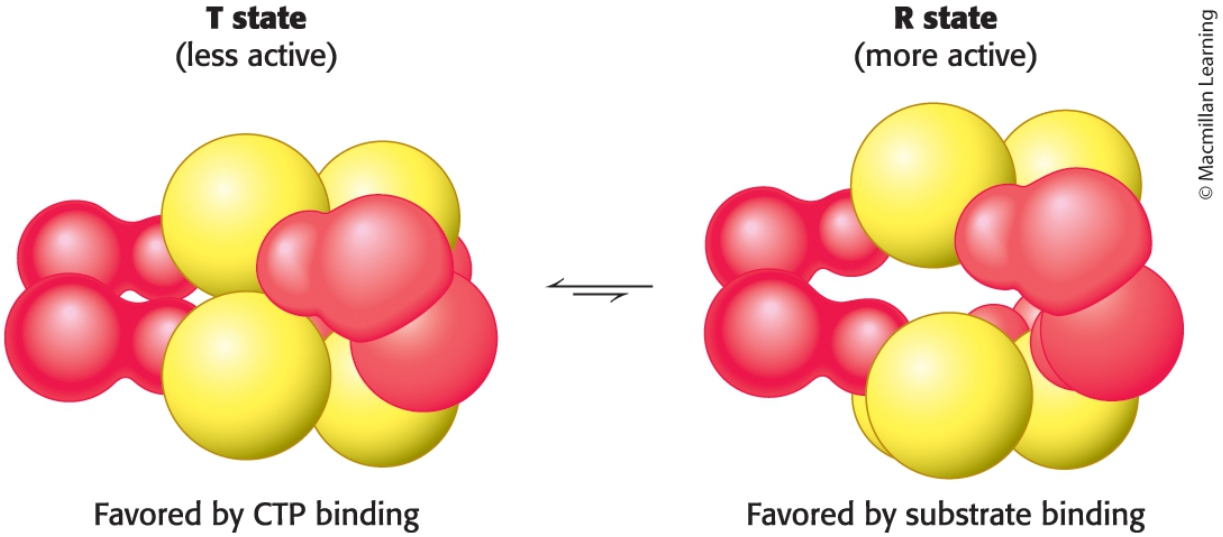
A vertical red dotted line is drawn up from 1.3 on the horizontal axis to meet the red curve at a point. A horizontal red dotted line is drawn from this point to the vertical axis at 0.1. Another vertical red line is drawn from 2.6 on the horizontal axis to meet the red curve at a point. A horizontal red dotted line is drawn from this point to the vertical axis at 0.8. A vertical blue line is drawn from 2 on the horizontal axis to meet the blue curve at a point. A horizontal blue dotted line is drawn from this point to the vertical axis at 0.8, which is overlapping the horizontal red dotted line.

All the numerical values are estimated.

Return to Graphical representation of the velocity of reaction as a function of substrate concentration for allosteric and Michaelis-Menten enzymes

Extended description for Schematic illustration of the stabilization of T state of A T C ase by C T P

© Macmillan Learning



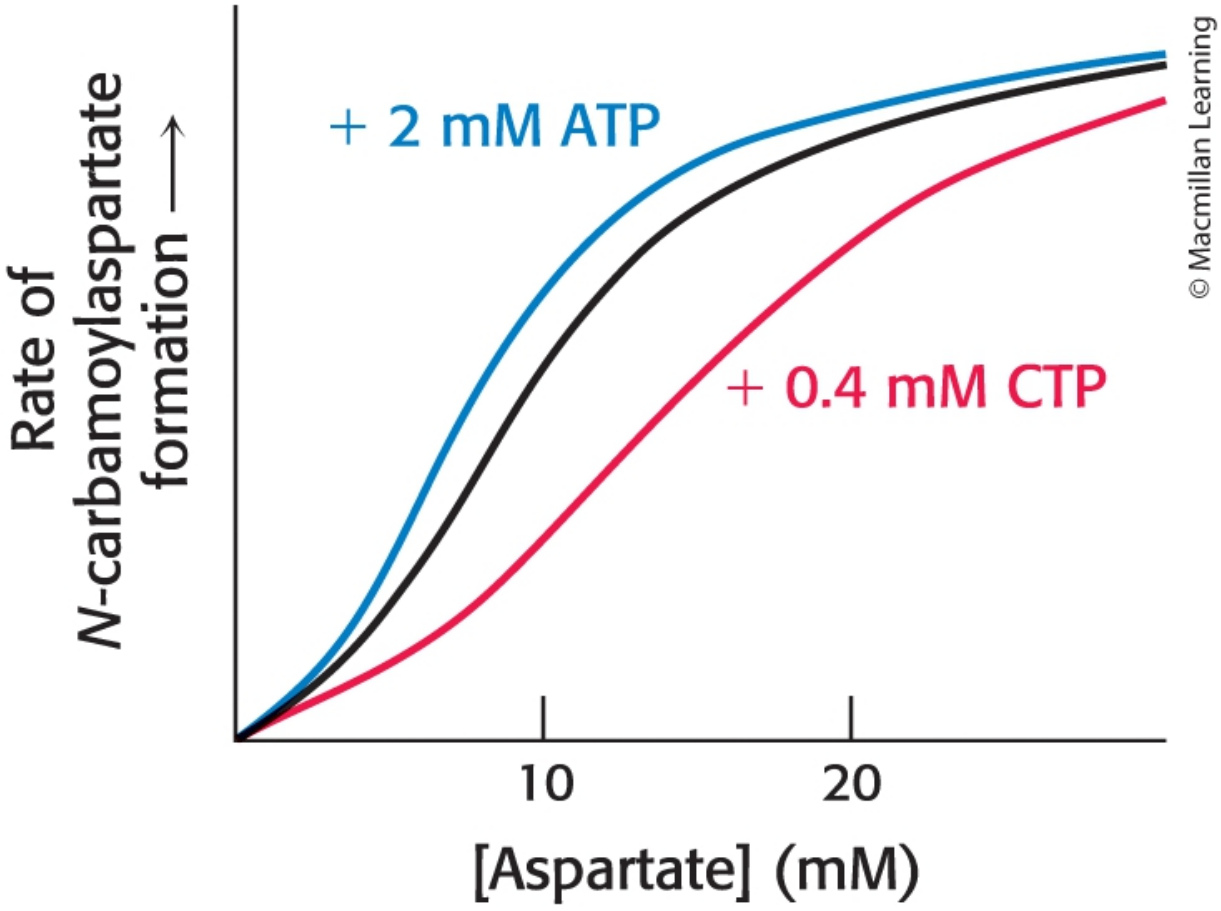
Tense state (T). One catalytic subunit is shown to have a central yellow spherical structure with two arms at upward inclined angles. Each arm is made up of a pair of fused red spheres. The side view of the trimer shows the three subunits arranged around a central vertical axis with the yellow spheres at the center and the red arms toward the periphery. Adjacent arms are accommodated by

positioning one above the other. One trimer is positioned above the other and there is no gap in between. The ribbon structure shows the two catalytic trimers forming a vase-shaped structure tilted 90 degrees to the left. There is a minimal gap in between.

Stabilized T state: C T P binds to the r chains of the catalytic trimers thereby stabilizing the T state. The arrangement is almost identical to the tense state. The ribbon structure shows the two catalytic trimers forming a vase-shaped structure tilted 90 degrees to the left. The structure is more compact.

Return to Schematic illustration of the stabilization of T state of A T C ase by C T P

Extended description for A schematic illustration of the equilibrium between the R and T states of A T C ase



T state (less active): It is favored by C T P binding. One catalytic subunit is shown to have a central yellow spherical structure with two arms at upward inclined angles. Each arm is made up of a pair of fused red spheres. The side view of the trimer shows the three subunits arranged around a central vertical axis with the yellow spheres at the center and the red arms to the periphery. Adjacent arms are accommodated by positioning one above the other. One trimer is positioned above the other and there is no gap in between.

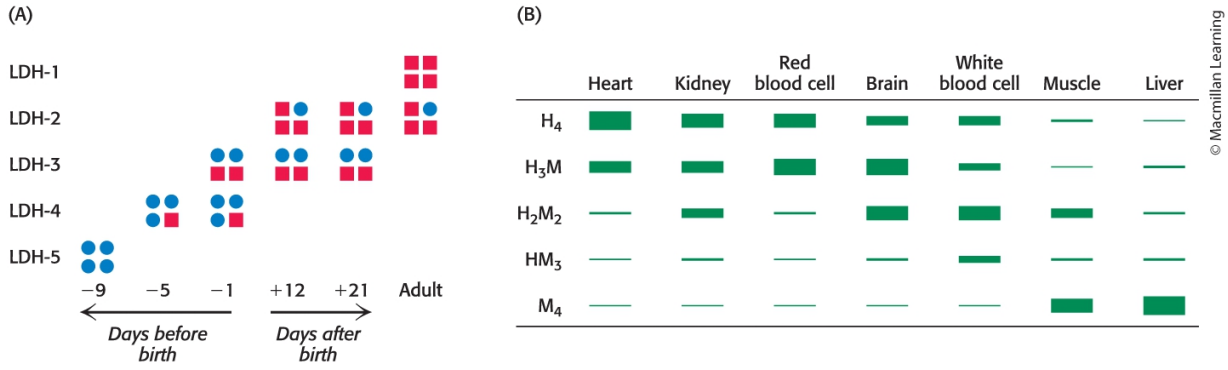
R state (more active): It is favored by substrate binding. The arrangement is almost identical to the tense state but there is more gap between the top and bottom trimers.

Return to A schematic illustration of the equilibrium between the R and T states of A T C ase

Extended description for Graphical representation of the different effects of A T P and C T P on A T C ase kinetics

The horizontal axis is labeled aspartate concentration in millimolar. It has markings ranging from 0 to 20 in increments of 10 units. The vertical axis is labeled the rate of N-carbamoylaspartate formation. The following three curves are shown:

Red curve: It starts at the origin and rises almost linearly to a point corresponding to the midpoint of the vertical axis. It has a slight S-shape. It is labeled plus 0.4 millimolar C T P.



Black curve: It starts from the origin and rises steeply toward the top of the vertical axis and then plateaus. It is located on the left of the red curve and has a slight S-shape.

Blue curve: It starts from the origin and rises parallel to the left of the black curve but has a steeper slope. It then plateaus to meet the black curve. It is labeled plus 2 millimolar A T P.

The black curve is closer to the blue curve.

Return to Graphical representation of the different effects of A T P and C T P on A T C ase kinetics

Extended description for Schematic illustration of the timing of expression of isozymes of lactate dehydrogenase and their tissue specific concentrations respectively

Part (A): Along the vertical axis, the following are marked from left to right: negative 9, negative 5, negative 1, positive 12, positive 21, Adult. A leftward arrow from negative 1 to negative 9 is labeled days before birth. A rightward arrow from positive 12 to positive 21 is labeled days after birth. The L D H profile is represented to consist of four quadrants. The H isozyme is represented by squares and the M isozyme by circles. The profiles for the following five isozymes are shown:

L D H 1: All the four quadrants are red squares. Expressed in Adults.

L D H 2: The top right quadrant is a blue circle and the other three quadrants are red squares. They are expressed at positive 12 and positive 21 days, and in adults.

L D H 3: The top left and top right quadrants are blue circles and the rest two quadrants are red squares. They are expressed at positive 12, positive 21, and negative 1 days.

L D H 4: The top left, top right, and bottom left quadrants are blue circles and the last quadrant is a red square. They are expressed at negative 1 and negative 5 days.

L D H 5: All the four quadrants are blue circles. They are expressed at negative 9 day.

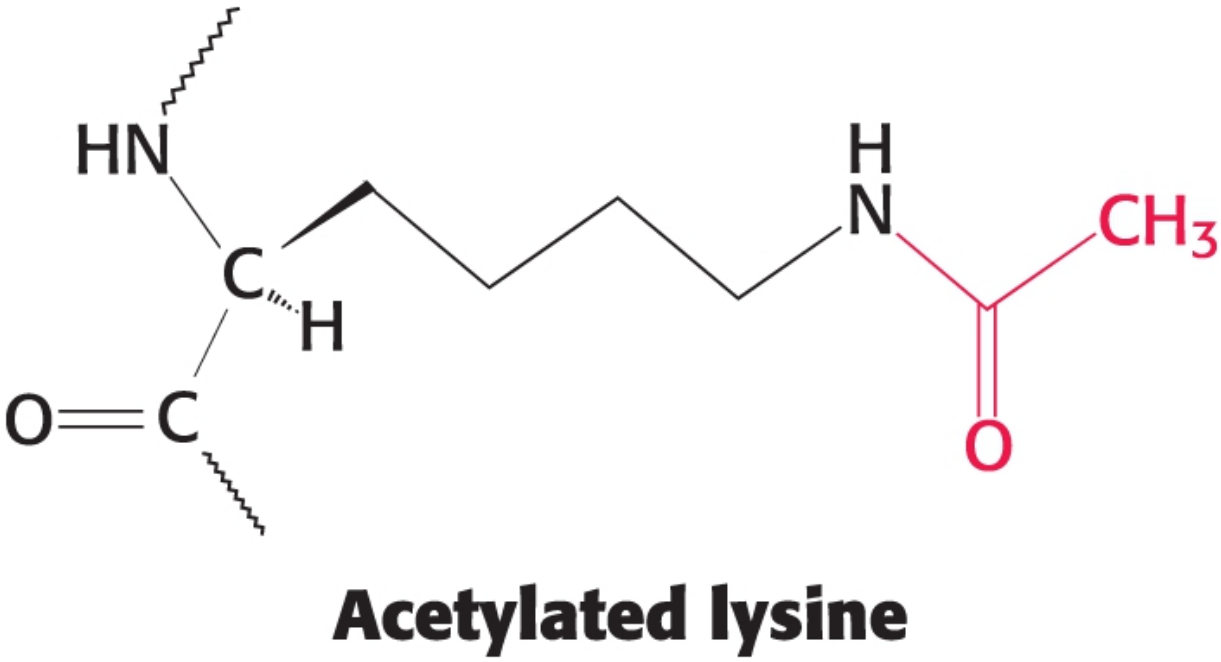
Part (B): Green bars represent the concentration of L D H isozymes in the following tissues:

Heart: Thickest bar for H subscript 4, thinner bar for H subscript 3 M, and thin lines for H subscript 2 M subscript 2, H M subscript 3, and M subscript 4.

Kidney: Thickest bar for H subscript 4, slightly thinner bar for H subscript 3 M subscript, relatively more thinner bar for H subscript 2 M 2, and thin lines for H M subscript 3 and M subscript 4.

Red blood cell: Thickest bar for H subscript 3 M, slightly thinner bar for H subscript 4, and thin lines for H subscript 2 M subscript 2, H M subscript 3, and M subscript 4.

Brain: Thickest bar for H subscript 3 M, slightly thinner bar for H subscript 2 M subscript 2, thinner bar for H subscript 4, and thin lines for H M subscript 3 and M subscript 4.



White blood cell: Thickest bar for H subscript 2 M subscript 2, thinner bar for H subscript 4, slightly thinner bars for H subscript 3 and H M subscript 3, and a thin line for M subscript 4.

Muscle: Thickest bar for M subscript 4, thinner bar for H subscript 2 M subscript 2, and thin lines for H subscript 4, H subscript 3 M, and H M subscript 3.

Liver: Thickest bar for M subscript 4 and thin lines for H subscript 4, H subscript 3 M, H subscript 2 M subscript 2, and H M subscript 3.

Extended description for Chemical structure of acetylated lysine

A central C atom is single bonded to N H on the upper left, single bonded to C on the lower left, dash bonded to H on the lower right, and wedge bonded to C 1 of a 4-carbon alkane chain on the upper right. N H has an open bond on the upper right. C on the lower left is double bonded to O on the left and has an open bond on the lower right. The 4 carbon alkane chain is depicted as a line structure using 3 zigzag lines. C 4 of the alkane chain is single bonded to N H on the upper right. N H is single bonded to C on the lower right which is double bonded to O below and single bonded to C H 3 on the upper right.

Return to Chemical structure of acetylated lysine

Extended description for Chemical reaction of the phosphorylation of an amino acid residue catalyzed by a protein kinase enzyme is shown

The reversible reaction consists of two reactants and three products.

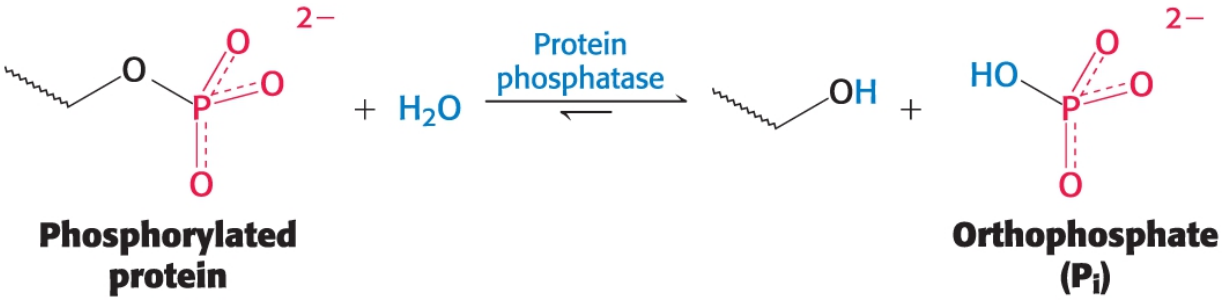
The first reactant is serine, threonine, or tyrosine residue, which has the following structure: A central C H 2 group is single bonded to O H on the upper right and has an open bond on the upper left.

The second reactant is A T P, which has the following structure: A 5-membered heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. The O atom occupies the first position which is the topmost vertex. C 2 and C 3 are each single bonded to O H. C 1 is wedge bonded to the first N of a 5-membered heterocyclic pentagonal ring in a vertical orientation consisting of 2 N and 3 C atoms. The first N atom occupies the first position which is the bottom left vertex and the second N atom occupies the third position which is the topmost vertex. A double bond is present between the second N and C 1, and C 2 and C 3. This ring is fused to a

heterocyclic hexagonal ring is a vertical orientation consisting of 2 N and 4 C atoms. The first N occupies the first position which is the top-right vertex and the second N occupies the third position which is the bottom-most vertex. A double bond is present between C 4 and the first N and C 1 and the second N. C 4 is single bonded to N H 2 above. The rings are fused such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 of the hexagonal ring, respectively. C 4 of the heterocyclic pentagonal ring, composed of 1 O and 4 C atoms, is single bonded to C H 2 in the form of a line. C H 2 is single bonded to O of a triphosphate group. Each phosphate group has a central P atom single bonded to O on the lower right, single bonded to O on the lower left, partially double bonded to O above, and partially double bonded to O below. The single bond to O atoms is shared between two adjacent phosphate groups. The terminal phosphate group is partially double bonded to O on the lower left and carries a negative charge of 2 minus. The other two phosphate groups each carry a negative charge. Starting from the terminal phosphate group, the phosphate groups are labeled gamma, beta, and alpha.

The reversible reaction arrow is labeled protein kinase. The forward reaction arrow is longer than the backward reaction arrow.

The first product is phosphorylated protein, which has the following structure: A central C H 2 group is single bonded to O on the upper right and has an open single bond on the upper left. O is single bonded to P on the lower right. P is partially double bonded to O on the upper right, partially double bonded to O on the right, and partially double bonded to O below. The P O 3 group carries a negative charge of 2 minus.



The second product is A D P, which has the following structure: A 5-membered heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. The O atom occupies the first position which is the topmost vertex. C 2 and C 3 are each single bonded to O

H below. C 1 is wedge bonded to the first N of a 5-membered heterocyclic pentagonal ring in a vertical orientation consisting of 2 N and 3 C atoms. The first N atom occupies the first position which is the bottom left vertex and the second N atom occupies the third position which is the topmost vertex. A double bond is present between the second N and C 1 and C 2 and C 3. This ring is fused to a heterocyclic hexagonal is a vertical orientation consisting of 2 N and 4 C atoms. The first N occupies the first position which is the top-right vertex and the second N occupies the third position which is the bottom-most vertex. A double bond is present between C 4 and the first N and C 1 and the second N. C 4 is single bonded to N H 2 above. The rings are fused such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 of the hexagonal ring, respectively. C 4 of the heterocyclic pentagonal ring, composed of 1 O and 4 C atoms, is single bonded to C H 2 which is single bonded to O of a diphosphate group. Each phosphate group has a central P atom single bonded to O on the lower right, single bonded to O on the lower left, partially double bonded to O above, and partially double bonded to O below. The single bond to O atoms is shared between two adjacent phosphate groups. The terminal phosphate group carries a negative charge of 2 minus and the other phosphate group carries a negative charge.

The third product is H superscript plus ion.

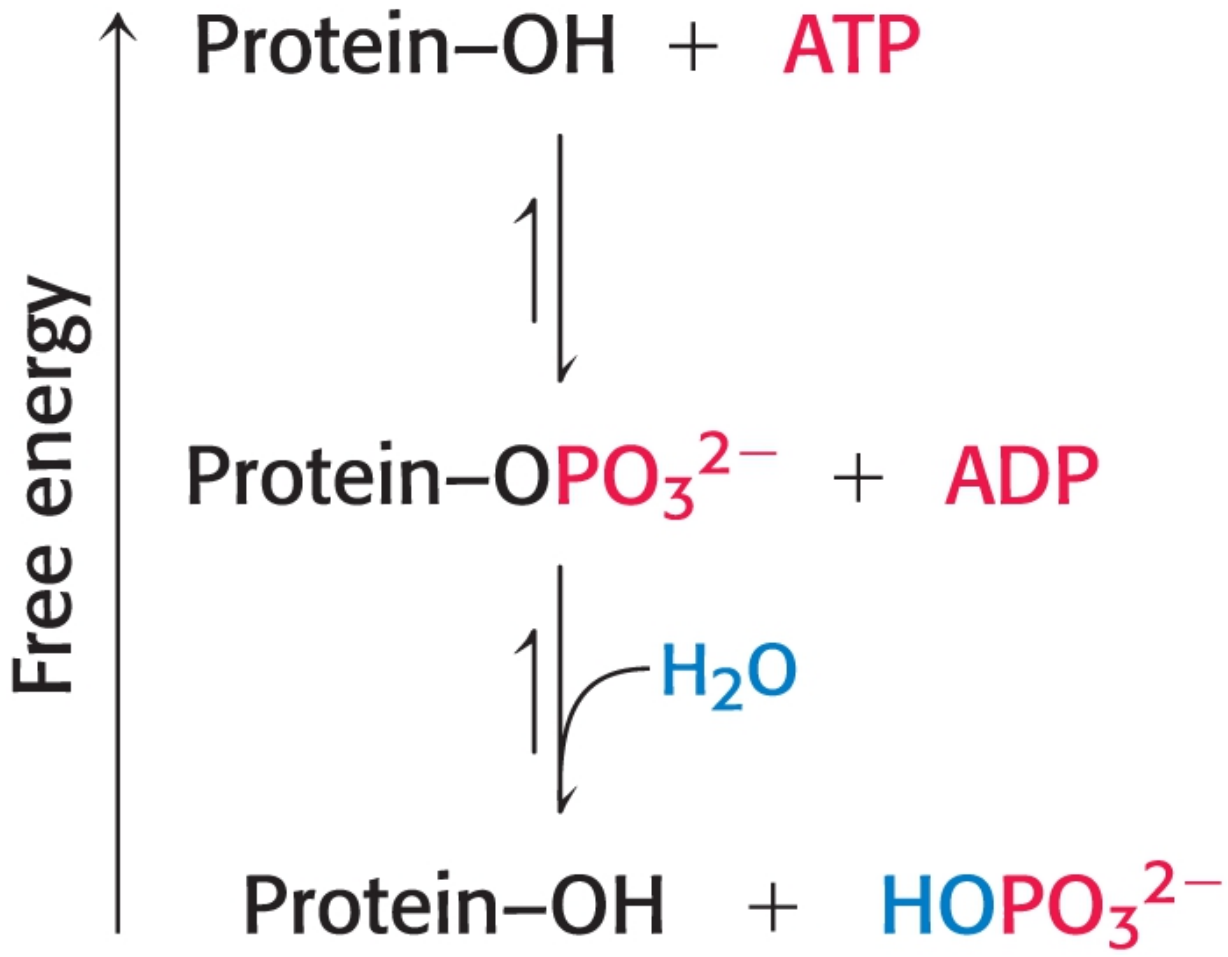
Return to Chemical reaction of the phosphorylation of an amino acid residue catalyzed by a protein kinase enzyme is shown

Extended description for Chemical reaction of dephosphorylation of a phosphorylated protein catalyzed by a protein phosphatase enzyme

The reversible reaction consists of two reactants and two products.

The first reactant is phosphorylated protein, which has the following structure: A central C H 2 group is single bonded to O on the upper right and has an open single bond on the upper left. O is single bonded to P on the lower right. P is partially double bonded to O on the upper right, partially double bonded to O on the right, and partially double bonded to O below. The P O 3 group carries a negative charge of 2 minus.

The second reactant is H 2 O.



The reversible reaction arrow is labeled protein phosphatase. The forward reaction arrow is longer than the backward reaction arrow.

The first product has the following structure: A central C H 2 group is single bonded to O H on the upper right and has an open bond on the upper left.

The second product is orthophosphate (P subscript i), which has the following structure: A central P atom is single bonded to O H on the upper left, partially double bonded to O on the upper right, partially double bonded to O on the right, and partially double bonded to O below. The P O 3 group carries a negative charge of 2 minus.

Return to Chemical reaction of dephosphorylation of a phosphorylated protein catalyzed by a protein phosphatase enzyme

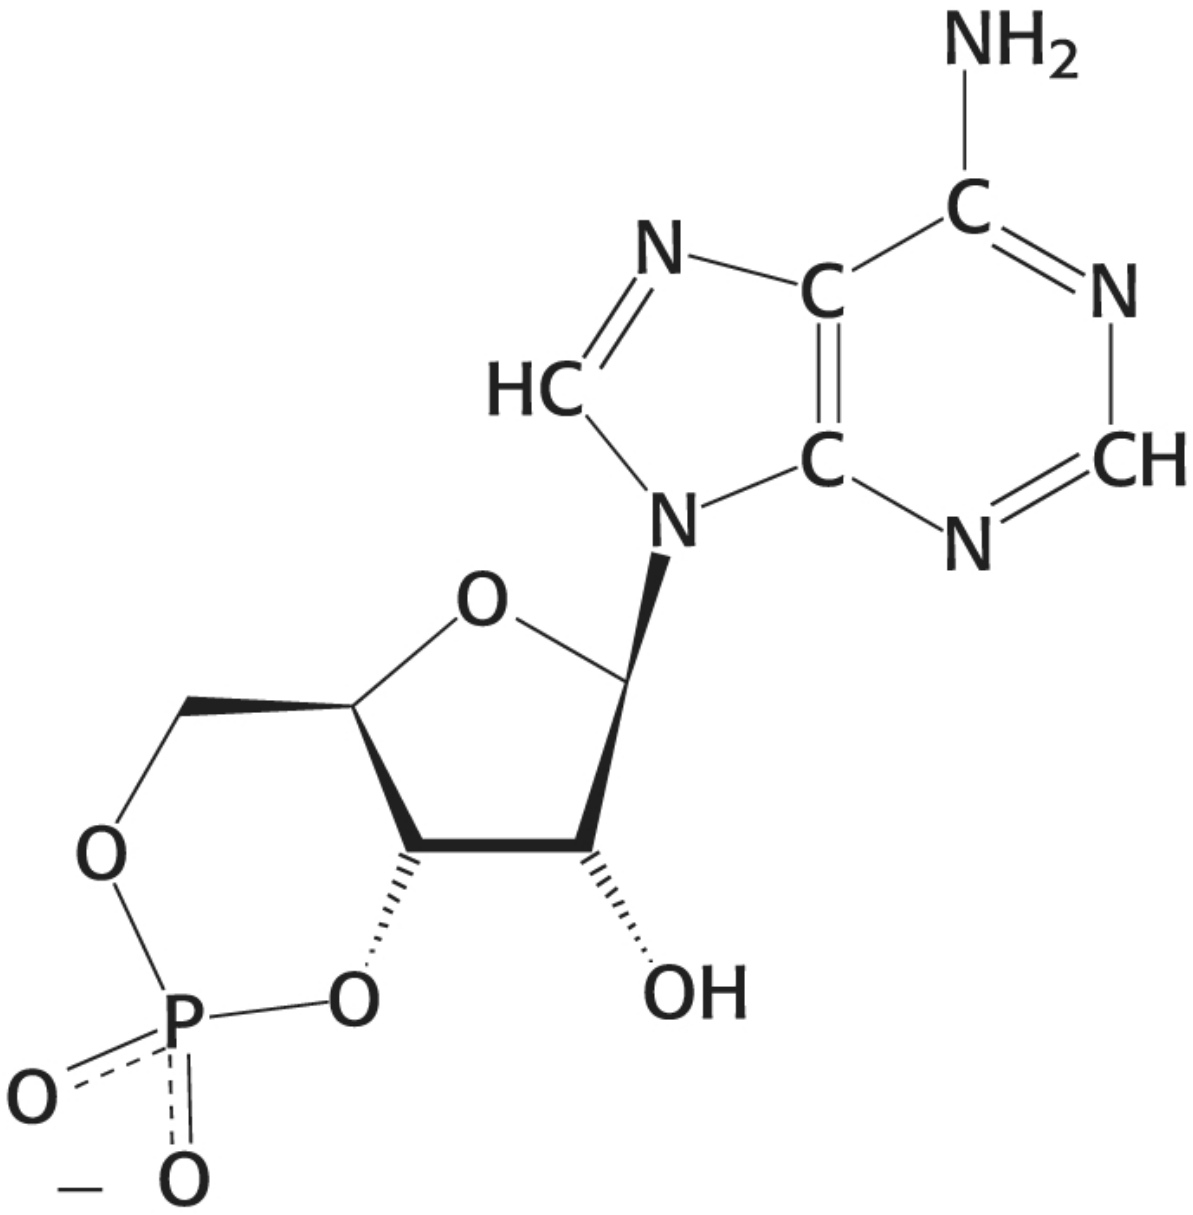
Extended description for Schematic illustration of the range of free energy between phosphorylated and dephosphorylated proteins

Two reversible reactions are shown. The first reaction shows the dephosphorylation of a protein. The products of this reaction are the reactants of the next dephosphorylation reaction.

The first reactant has the following structure: Protein, single bond, O H. The second reactant is A T P.

The forward reaction arrow is longer than the backward reaction arrow.

The first product has the following structure: Protein, single bond, O P O 3 superscript 2 minus. The second product is A D P. These products are the reactants of the next reaction.



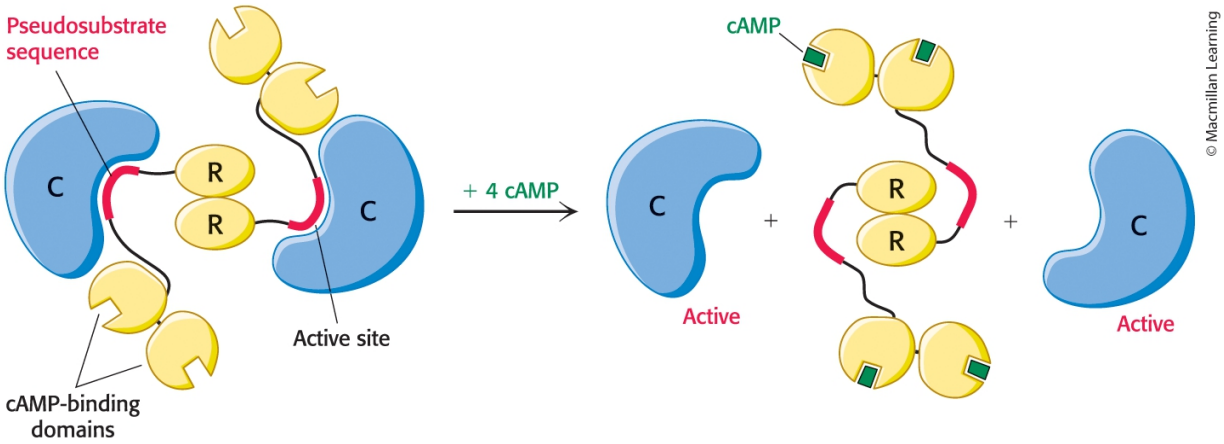
The forward reaction arrow is longer than the backward reaction arrow. H 2 O reacts with the phosphorylated protein.

The first product has the following structure: Protein, single bond, O H. The second product is H O P O 3 superscript 2 minus.

The free energy is shown to increase from the dephosphorylated protein at the bottom to the original protein at the top. The phosphorylated protein lies in the middle.

Return to Schematic illustration of the range of free energy between phosphorylated and dephosphorylated proteins

Extended description for Chemical structure of cyclic adenosine monophosphate



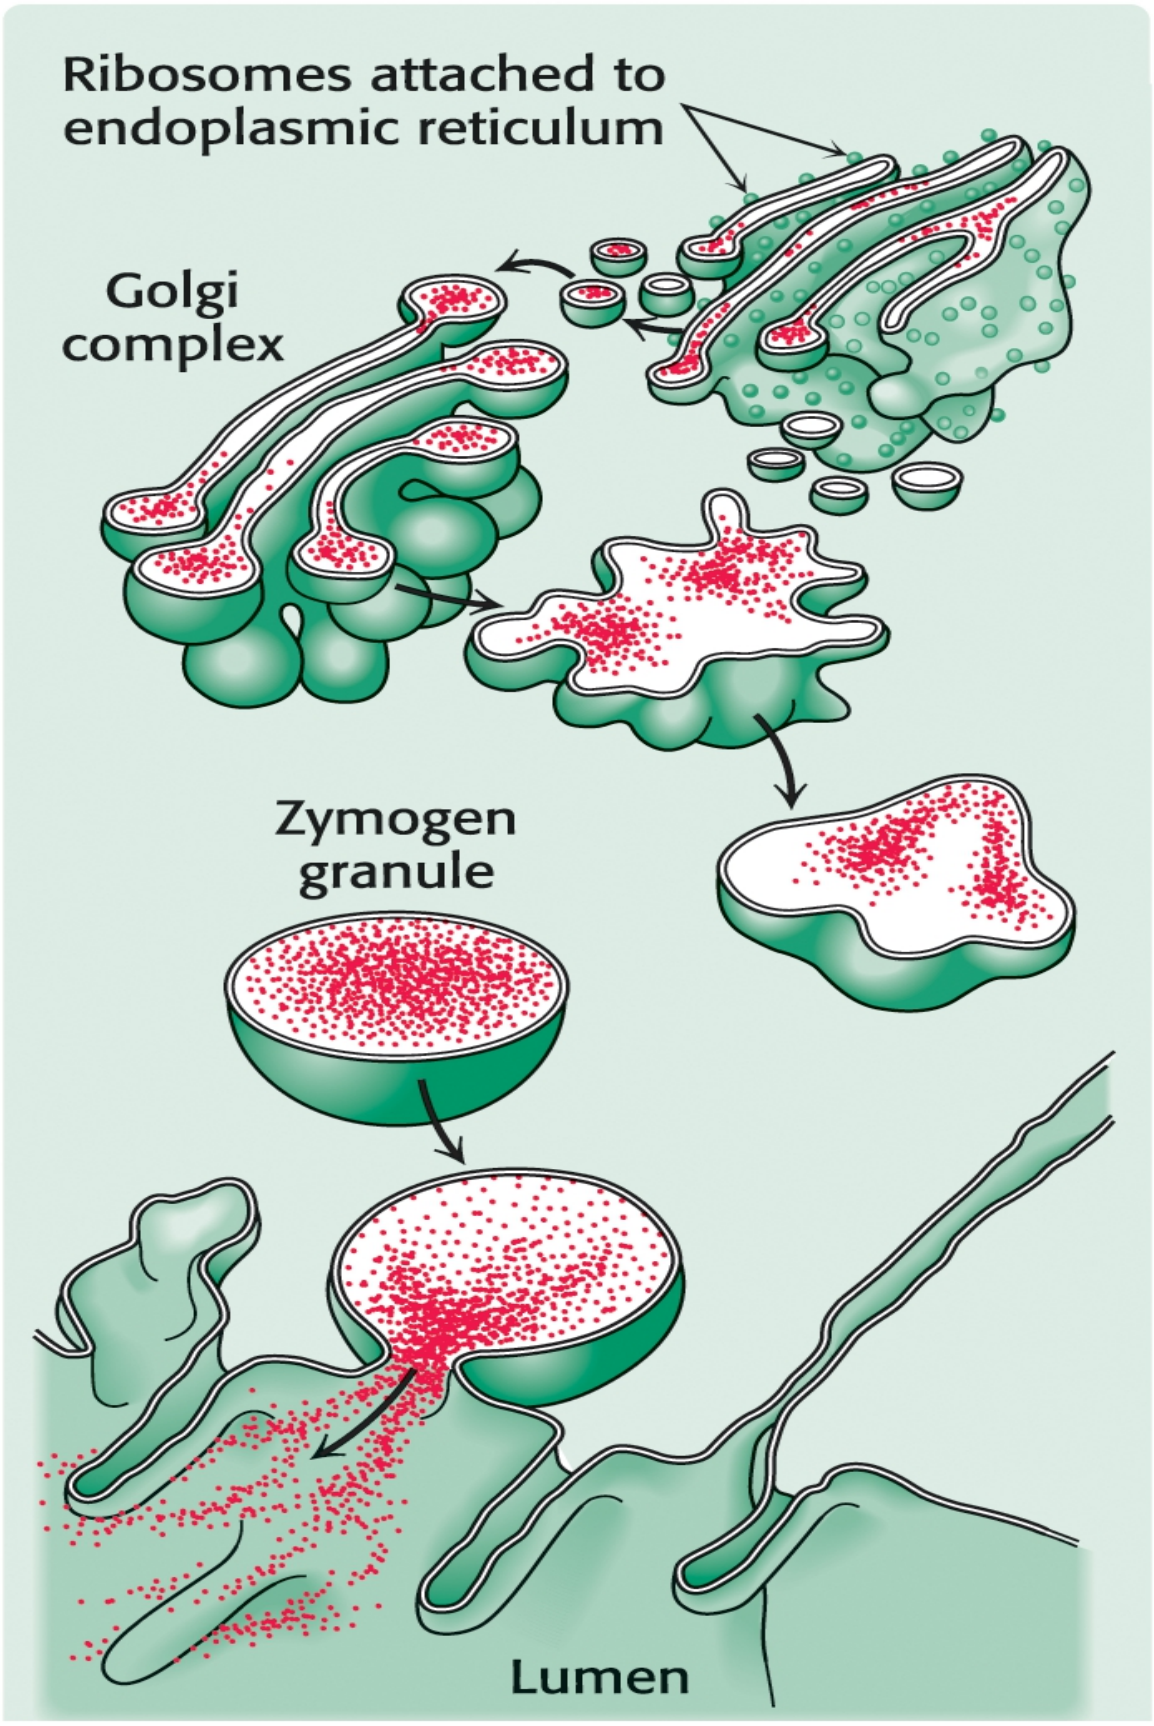
Cyclic adenosine monophosphate (cAMP)

A heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. The O atom occupies the first position which is the topmost vertex. C 2 is dash bonded to O H. C 3 is dash bonded to O and C 4 is wedge bonded to C H 2 which is single bonded to O on the lower left. These two O atoms are single bonded to a central P atom on the lower left. This P atom is partially double bonded to O on the lower left and partially double bonded to O below. The P O 2 group carries a negative charge. C 1 of the pentagonal ring is wedge bonded to the first N of a heterocyclic pentagonal ring in a horizontal orientation consisting of 2 N and 3 C atoms. The first N occupies the first position which is the bottom left vertex, the second N occupies the third position which is the top-left vertex, and C atoms occupy the remaining positions. C 1 is bound to H and is double bonded to the second N. This pentagonal ring is fused to a 6-membered heterocyclic ring in a vertical orientation which consists of 2 N and 4 C atoms. The first N atom occupies the first position which is the top-right vertex, the second N atom occupies the third position which is the bottom-most vertex, and C atoms occupy the remaining positions. C 1 is bound to H and C 4 is single bonded to N H 2. Alternating double bonds are present between C 1 and the second N, C 2 and C 3, and C 4 and the first N. The ring are fused such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 of the hexagonal ring, respectively.

Return to Chemical structure of cyclic adenosine monophosphate

Extended description for A schematic illustration of the binding of c A M P to the regulatory subunits of P K A

The holoenzyme is shown to have the following structure: Two kidney-shaped catalytic subunits labeled C are shown to face each other. Two ovoid regulatory subunits, labeled R, are placed one on top of the other and are present in the space between the two catalytic subunits. The top regulatory unit is connected by a chain to a pair of spherical structures with clefts. These clefts are labeled c A M P binding domains. A short region in the chain near the groove of the catalytic subunit is shown in red and labeled pseudosubstrate sequence. Another such chain is bound to the bottom regulatory subunit with the c A M P binding domains facing down.



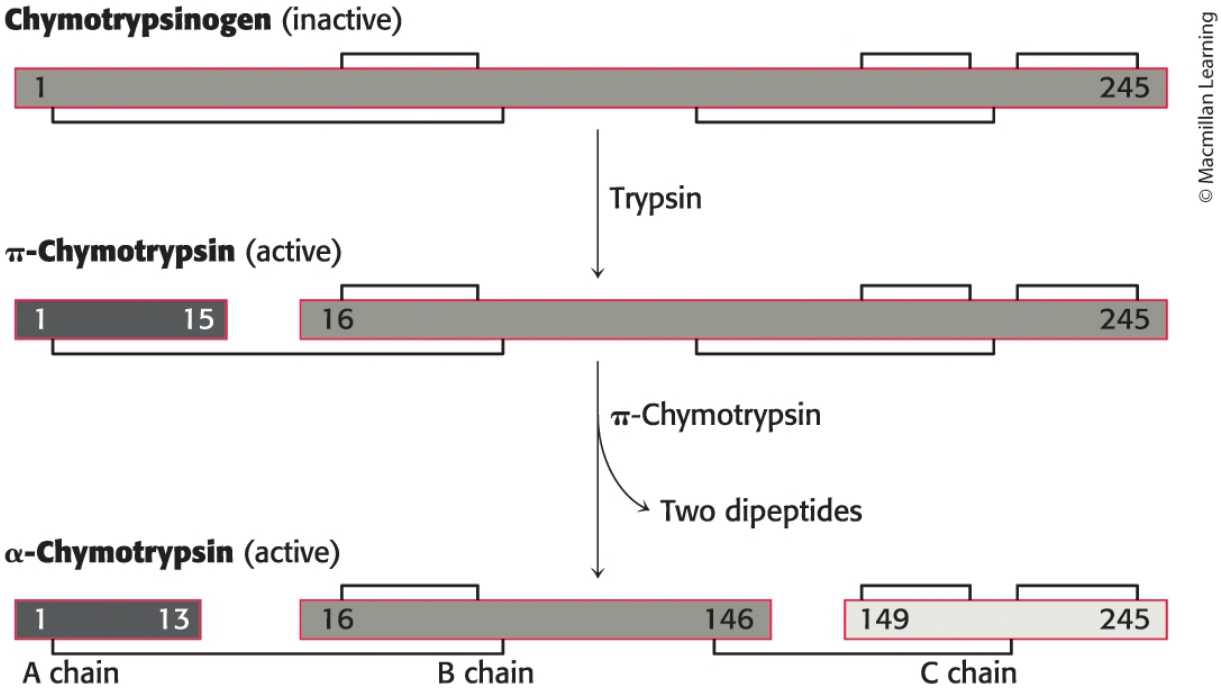
An arrow labeled plus 4 c A M P points from the holoenzyme to the activated enzyme.

In the activated enzyme, the c A M P molecules are shown to bind to the c A M P binding domains of the regulatory subunits. The kidney-shaped catalytic subunits are shown to separate from the regulatory subunits and become activated.

Return to A schematic illustration of the binding of c A M P to the regulatory subunits of P K A

Extended description for Schematic illustration of the

secretion of zymogens by acinar cells of the pancreas



© Macmillan Learning

The following steps are shown to take place in the cytoplasm of the acinar cells: The endoplasmic reticulum is shown as folded membranous structures with granules on their surface which are ribosomes. Cup-shaped vesicles filled with zymogen are shown to bud from the endoplasmic reticulum and fuse with the stacked flattened pouch-shaped Golgi complex. Irregular-shaped structures packed with zymogen are shown to exit the Golgi apparatus and gradually become large cup-shaped zymogen granules. These zymogen granules are shown to fuse with the folded plasma membrane of the cell and secrete their contents into the lumen outside the cell.

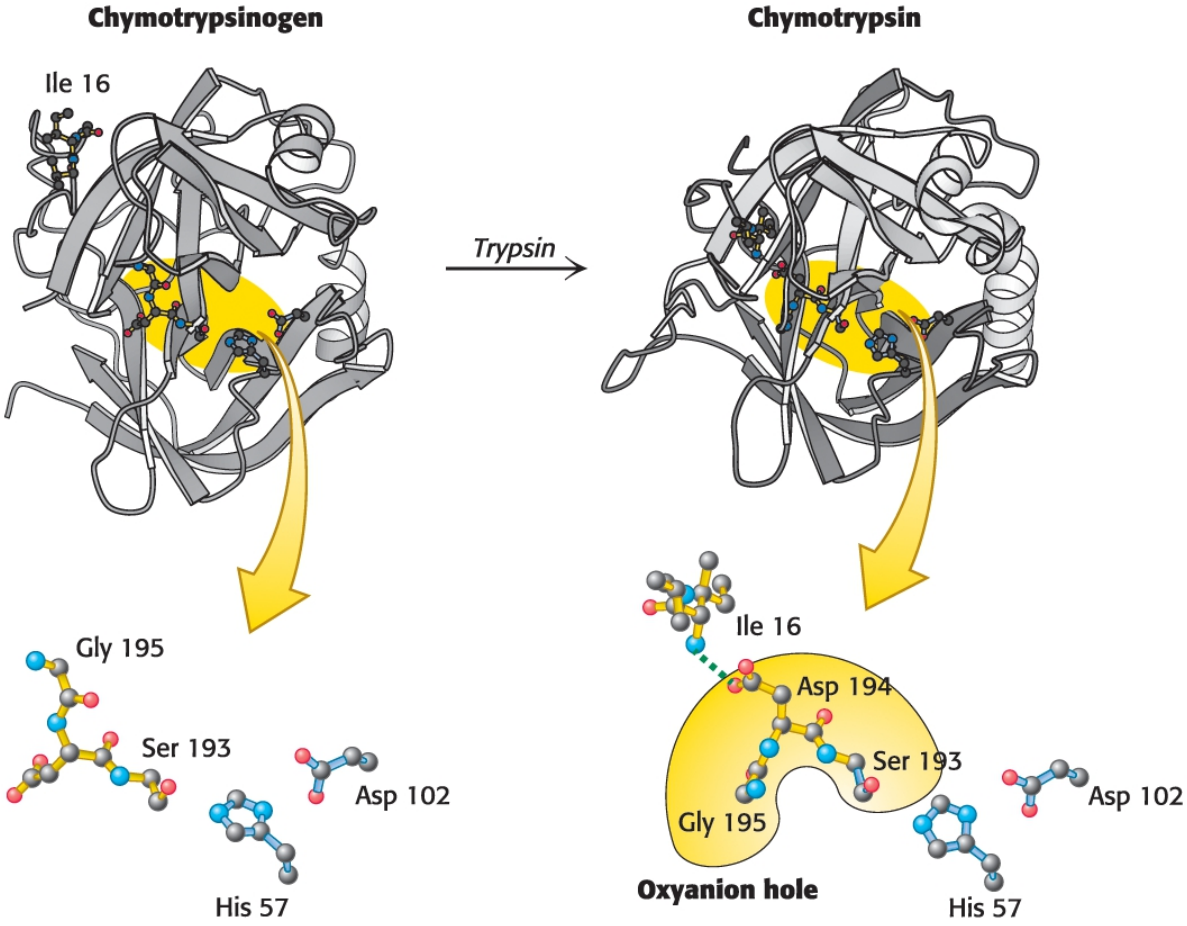
Return to Schematic illustration of the secretion of zymogens by acinar cells of the pancreas

Extended description for Schematic illustration of the activation of chymotrypsinogen by proteolysis

© Macmillan Learning

Chymotrypsinogen (inactive): It is shown as a long ribbon made up of 245 amino acids. Five intrachain disulfide bonds are shown, two in the left half and three in the right half.

Trypsin cleaves the chymotrypsinogen to give pi-Chymotrypsin.



pi-Chymotrypsin (active): This is created by cleavage of the peptide bond joining the amino acids at positions 15 and 16. An interchain disulfide bond is shown to link the two peptide chains. Four intrachain disulfide bonds are shown in the longer peptide chain.

pi-Chymotrypsin cleaves another pi-Chymotrypsin to give an alpha-Chymotrypsin and two dipeptides are released in the process.

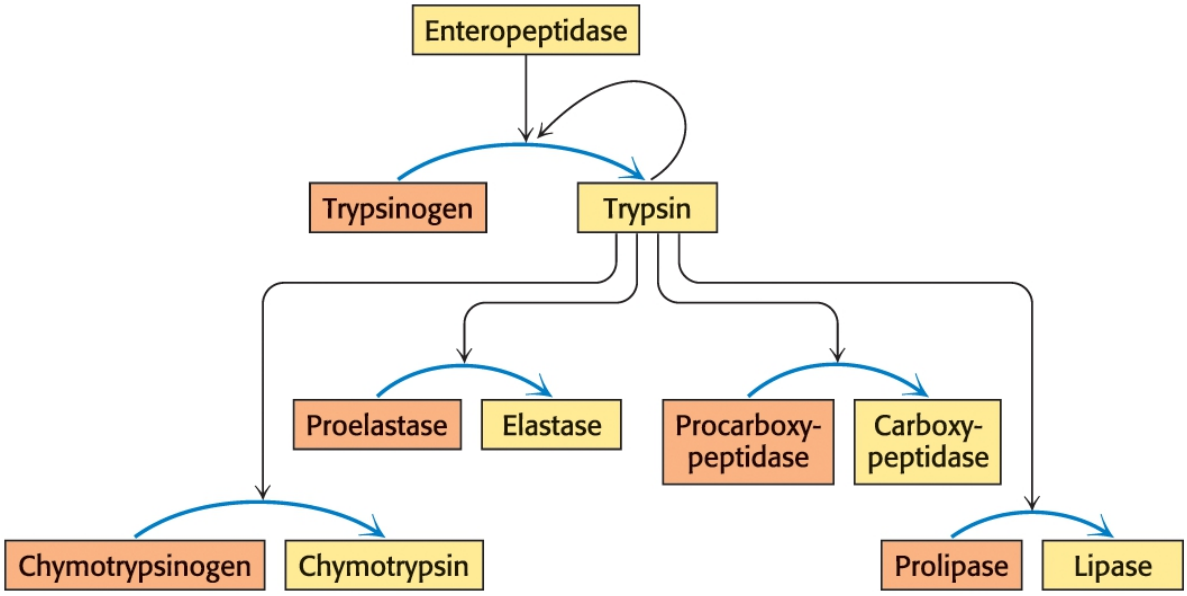
Alpha-Chymotrypsin (active): This is created by cleavage of the peptide bonds in bond the short and long peptide chains of pi-Chymotrypsin. The following three chains are formed: A chain consisting of amino acids 1 to 13, B chain consisting of amino acids 16 to 146, and C chain consisting of amino acids 149 to 245. An interchain disulfide bond is present between chain A and chain B, and chain B and chain C, respectively. One intrachain disulfide bond is present in chain B and two intrachain disulfide bonds are present in chain C.

Return to Schematic illustration of the activation of chymotrypsinogen by proteolysis

Extended description for Schematic illustration of the conversion of chymotrypsinogen into chymotrypsin

© Macmillan Learning

The ribbon structures of the enzymes are shown.



Chymotrypsinogen is shown to have a globular structure made up of several beta-strands and a few alpha helices connected by short loops. Isoleucine 16 residue is shown to be positioned away from the central active site. A magnified view of the amino acid residues at the catalytic site shows Glycine 195 and Serine 193 residues together at the top left, Histidine 57 below, and Aspartate 102 on the right.

Trypsin is shown to act on chymotrypsinogen to produce chymotrypsin.

Chymotrypsin is shown to have a more compact globular structure compared to chymotrypsinogen. A magnified view of the catalytic site shows the inverted U-shaped oxyanion hole comprising Glycine 195, Aspartate 194, and Serine 193 residues. The Isoleucine 16 residue is present on the top left of the oxyanion hole. Histidine 57 is present to the lower right and Aspartate 102 is present to the right of the oxyanion hole.

Return to Schematic illustration of the conversion of chymotrypsinogen into chymotrypsin

Extended description for A flow chart of the cascade of activation of zymogens initiated by the activation of trypsin

© Macmillan Learning

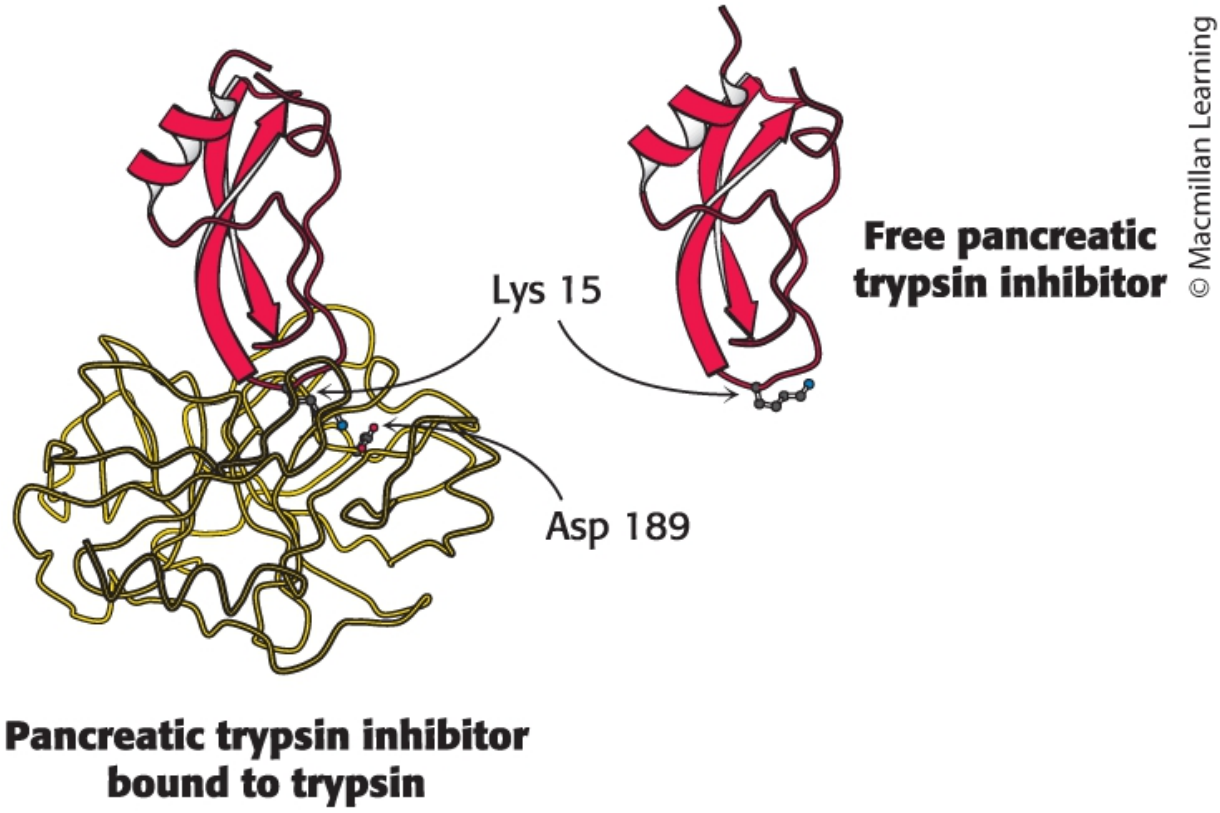
Enteropeptidase (yellow) is shown to aid the conversion of trypsinogen (orange) to trypsin (yellow).

Trypsin is shown to aid in the following conversions:

Trypsinogen to trypsin

Chymotrypsinogen (orange) to chymotrypsin (yellow)

Proelastase (orange) to elastase (yellow)



Procarboxypeptidase (orange) to carboxypeptidase (yellow)

Prolipase (orange) to lipase (yellow)

Active enzymes are shown in yellow and zymogens are shown in orange.

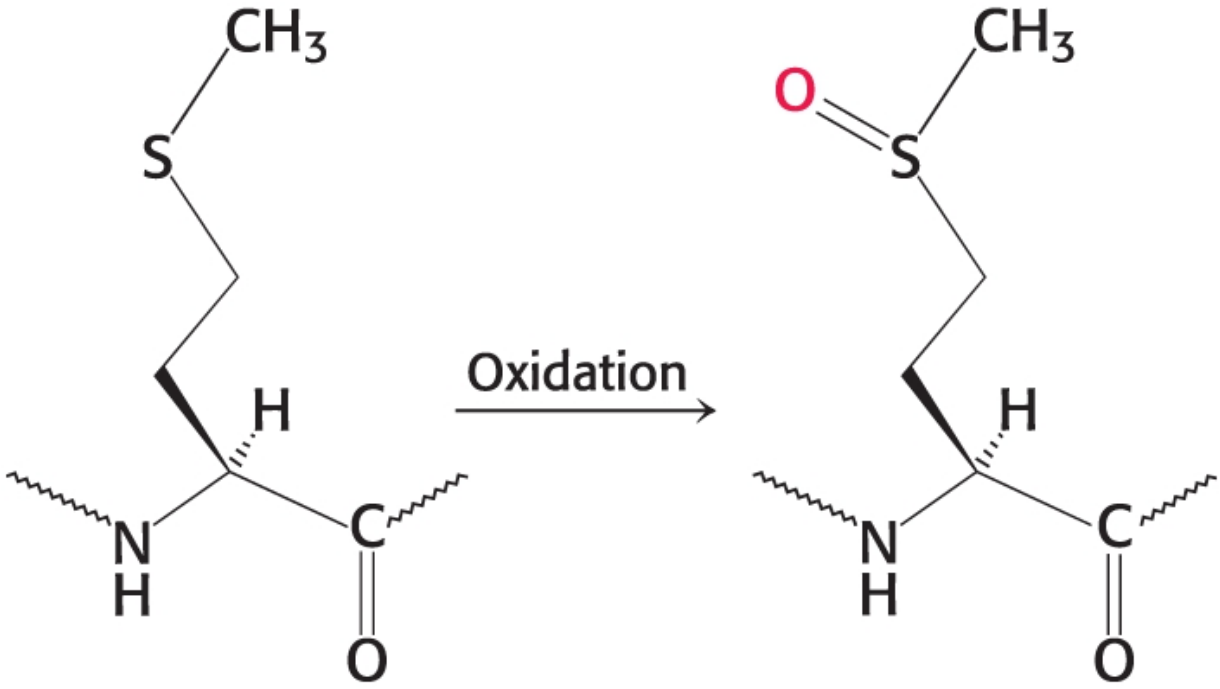
Extended description for The ribbon structures of free pancreatic trypsin inhibitor and the pancreatic trypsin inhibitor bound to trypsin



Free pancreatic trypsin inhibitor: It is shown to consist of two antiparallel beta strands and an alpha helix connected by short loops. A lysine 15 residue is present at the bottom.

Pancreatic trypsin inhibitor bound to trypsin: The pancreatic trypsin inhibitor is connected to trypsin below which is shown to be a globular structure made up of intertwined peptide chains. The lysine 15 residue of the pancreatic trypsin inhibitor is shown to protrude into the catalytic site of trypsin. Lysine 15 forms an ionic bond with aspartate 189 of trypsin.

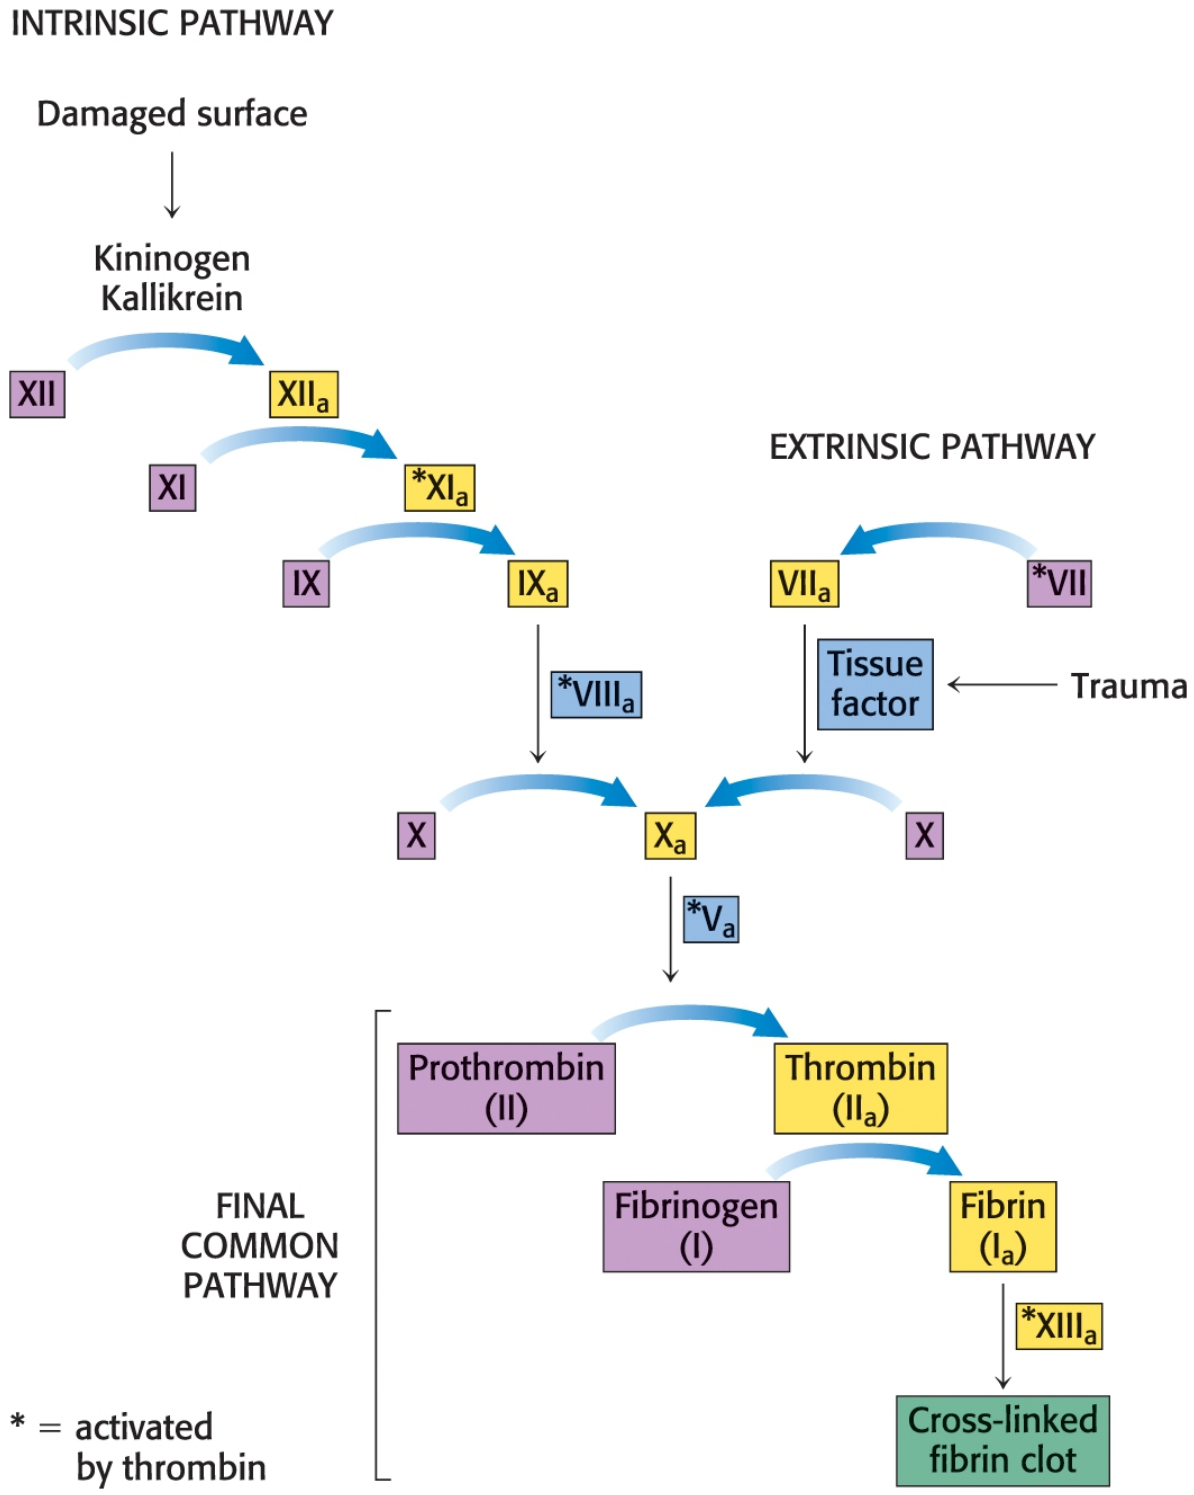
Extended description for Chemical reaction of the oxidation of methionine to methionine sulphoxide

The reaction consists of one reactant and one product.

The reactant has the following structure: A central C atom is dash bonded to H on the upper right, single bonded to C on the lower right, single bonded to N H on the lower left, and wedge bonded to C 1 of a heteronuclear alkane chain on the upper left. The C on the lower right is double bonded to O below and has an open single bond on the upper right. The N H on the lower left has an open single bond on the upper left. The heteronuclear alkane chain is depicted as a line structure using two zigzag lines and consists of 1 S and 2 C atoms. The S atom occupies the third position and is single bonded to C H 3 on the upper right.



The forward reaction arrow is labeled oxidation.

The product has the following structure: A central C atom is dash bonded to H on the upper right, single bonded to C on the lower right, single bonded to N H on the lower left, and wedge bonded to C 1 of a heteronuclear alkane chain on the upper left. The C on the lower right is double bonded to O below and has an open single bond on the upper right. The N H on the lower left has an open single bond on the upper left. The heteronuclear alkane chain is depicted as a line structure using two zigzag lines and consists of 1 S and 2 C atoms. The S atom occupies the third position and is double bonded to O on the upper left and single bonded to C H 3 on the upper right.

Extended description for Schematic illustration of an

enzymatic cascade leading to the clotting of blood

Two pathways are shown as follows:

Intrinsic pathway:

Damaged surface leads to Kininogen Kallikrein catalyzing the conversion of Factor 12 (purple) to Factor 12 subscript a (yellow).

Factor 12 subscript a catalyzes the conversion of Factor 11 (purple) to asterisk Factor 11 subscript a (yellow).

Asterisk factor 11 subscript a catalyzes the conversion of Factor 9 (purple) to Factor 9 subscript a (yellow).

Factor 9 subscript a forms a complex with asterisk Factor 8 subscript a (blue). This complex catalyzes the conversion of Factor 10 (purple) to factor 10 subscript a.

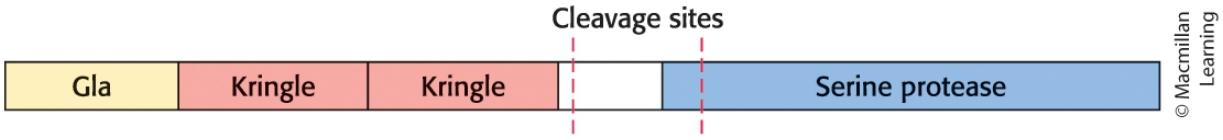
Extrinsic pathway:

Asterisk Factor 7 (purple) is converted to Factor 7 subscript a (yellow).

Trauma leads to the release of tissue factor (blue) which forms a complex with Factor 7 subscript a. This complex catalyzes the conversion of Factor 10 (purple) to factor 10 subscript a (yellow).

Factor 10 subscript a forms a complex with asterisk Factor 5 subscript a (blue). This complex catalyzes the conversion of Prothrombin 2 (purple) to Thrombin roman number 2 subscript a (yellow) and initiates the final common pathway.

Thrombin 2 subscript a catalyzes the conversion of Fibrinogen 1 (purple) to Fibrin 1 subscript a (yellow). Fibrin 1 subscript a forms a complex with asterisk Factor 13 subscript a (yellow). This complex leads to the formation of the cross-linked fibrin clot.



Inactive forms of clotting factors are shown in purple and their activated counterparts are shown in yellow.

Stimulatory proteins that are not themselves enzymes are shown in blue. All the numbers are given as roman numbers.

Note: Asterisk denotes activated by thrombin.

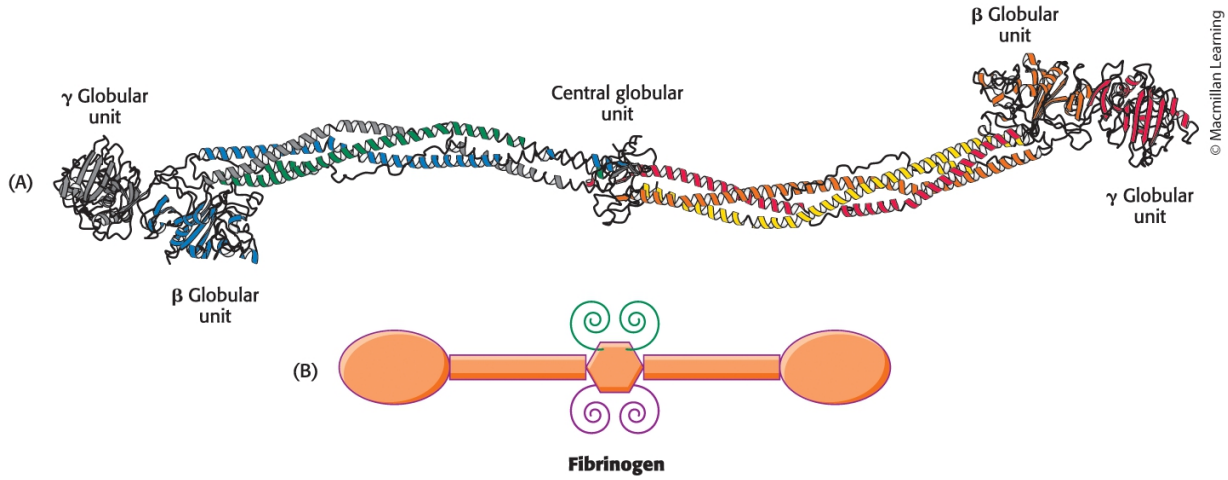
Extended description for Schematic illustration of the binding of calcium ions to the g l a domain of

prothrombin

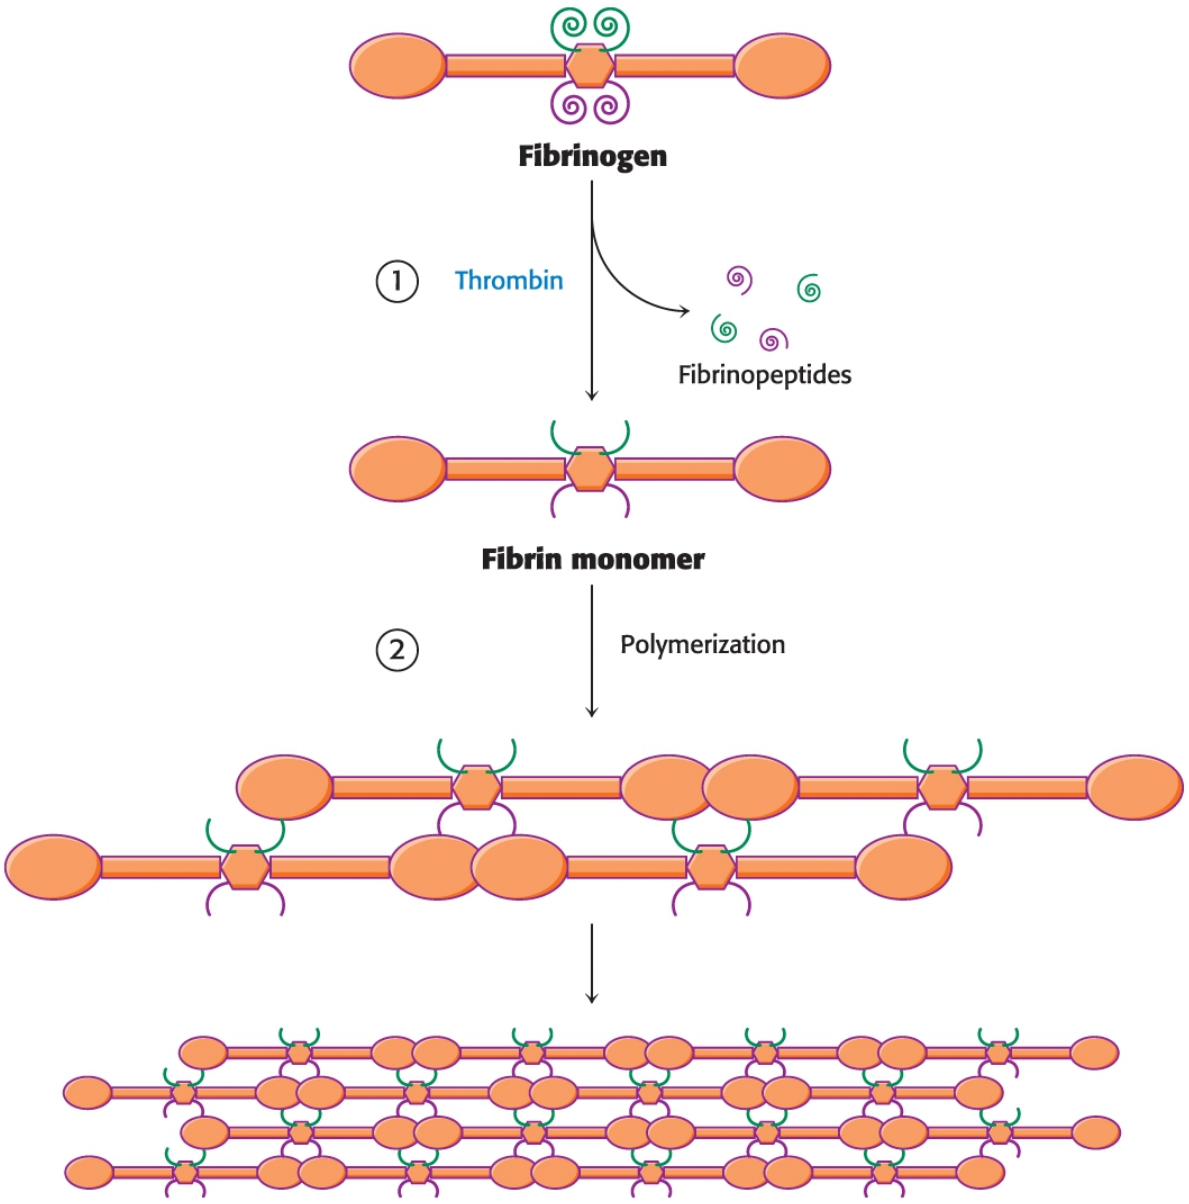


© Macmillan Learning

The ribbon structure of the protein is shown to have three alpha helices connected by short loops. The bottom terminus has a long peptide chain consisting of gamma-carboxyglutamate residues, shown in red. Several spherical calcium ions are shown to bind to these gamma-carboxyglutamate residues.

Return to Schematic illustration of the binding of calcium ions to the g l a domain of prothrombin

Extended description for Schematic illustration of the structure of fibrinogen



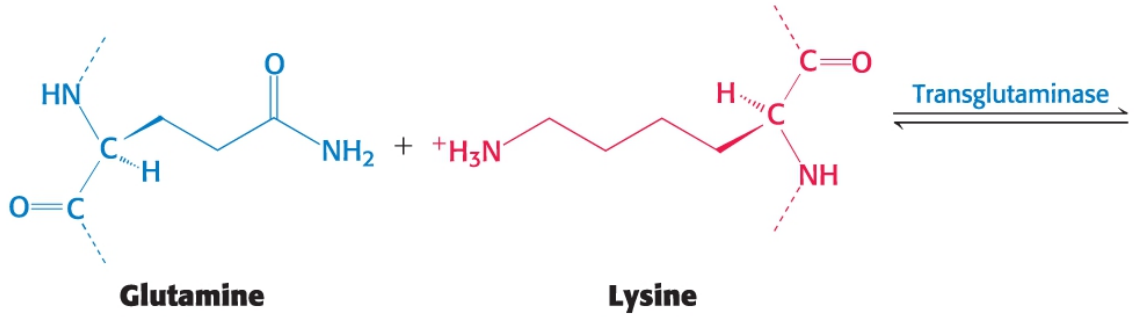
Part (A): The ribbon structure of fibrinogen consists of two long rod-shaped regions made up of alpha-helical coiled-coil structures. The two rods are connected in the middle by central globular units. The terminals of each rod consist of two globular units labeled gamma and beta globular units. The relative position of the identical terminal globular units is trans.

Part (B): A central hexagon is connected to two oval structures on the left and right by long rods, respectively. A pair of green comma-shaped fibrinopeptides facing each other are present at the top of the hexagonal unit. Similarly, a pair of red fibrinopeptides are present at the bottom of the hexagonal unit.

Return to Schematic illustration of the structure of fibrinogen

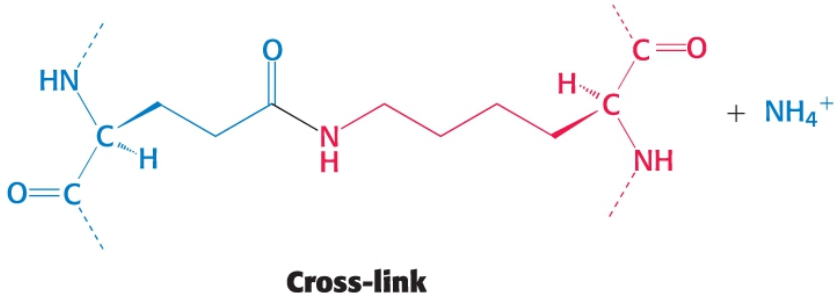
Extended description for Schematic illustration of the cleavage of fibrinogen by thrombin to initiate fibrin clot formation

© Macmillan Learning



Step 1: A fibrinogen unit is shown. A central hexagon is connected to two oval structures on the left and right by long rods, respectively. A pair of green comma-shaped fibrinopeptides facing each other are

present at the top of the hexagonal unit. Similarly, a pair of red fibrinopeptides are present at the bottom of the hexagonal unit. Thrombin is shown to remove the comma-shaped heads of the fibrinopeptides leaving behind short bent arms. This unit is labeled fibrin monomer.



Step 2: Several fibrin monomers are shown to polymerize. The adjacent oval structures of two monomers are shown to overlap. The short bent arms of one monomer are shown to attach to the overlapping oval structures of fibrin chains below. This is shown to grow in size to form an extended mesh.

Extended description for Cross-linking reaction between glutamine and lysine residue

Glutamine **Lysine**

Cross-link

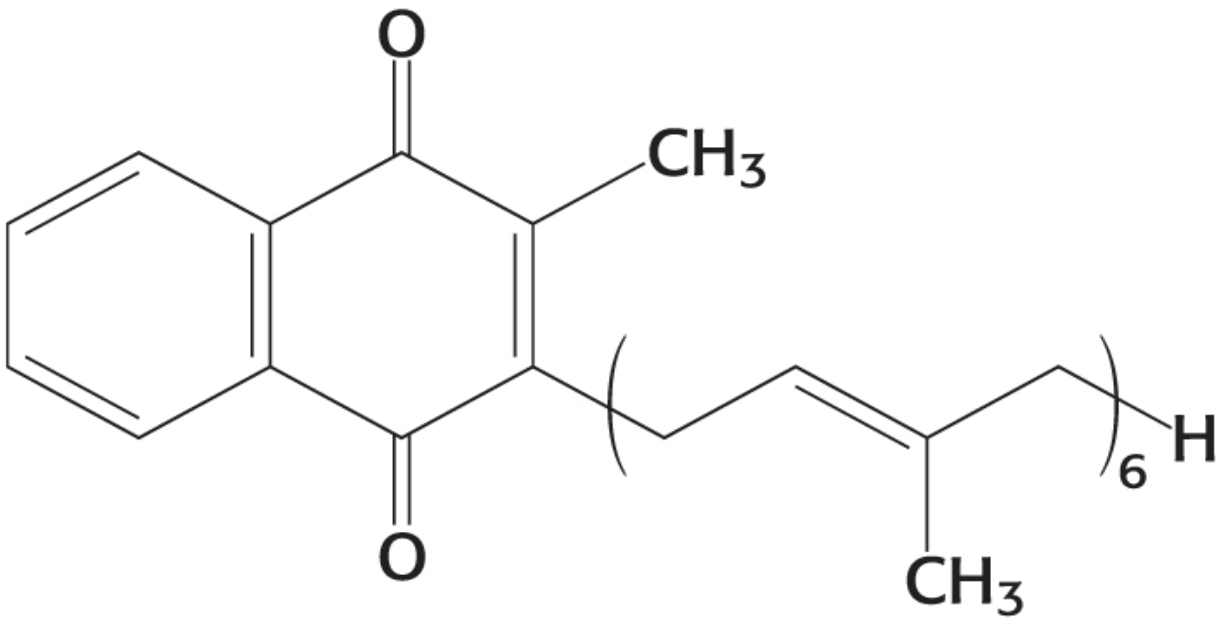
The reaction consists of two reactants and two products.

The first reactant is glutamine, which has the following structure: A central C atom is single bonded to N H on the upper left, single bonded to C on the lower left, dash bonded to H on the lower right, and wedge bonded to C 1 of a 3-carbon alkane chain on the upper right. N H has an open single bond on the upper right. C on the lower left is double bonded to O on the left and has an open single bond on the lower right. The alkane chain is depicted as a line structure using 2 zigzag lines. C 3 of the alkane chain is double bonded to O above and single bonded to N H 2 on the lower right.

The second reactant is lysine, which has the following structure: A central C atom is single bonded to N H on the lower right, single

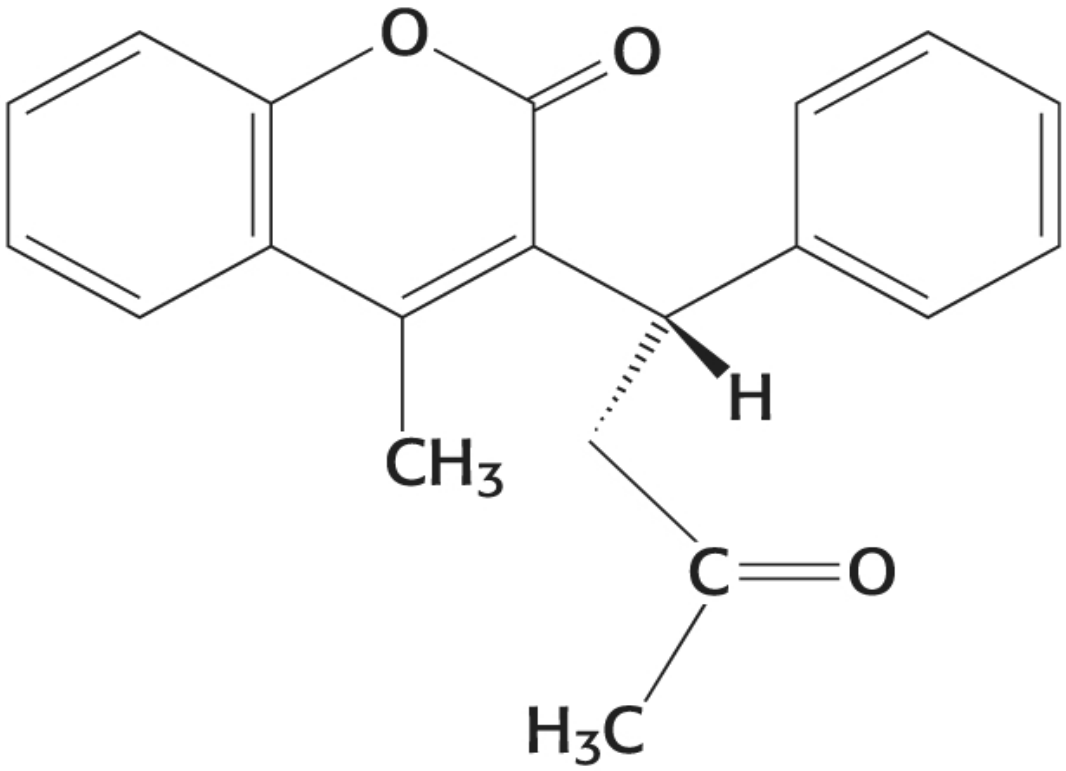
bonded to C on the upper right, dash bonded to H on the upper left, and wedge bonded to C 1 of a 4-carbon alkane chain on the lower left. N H has an open single bond on the lower left. C on the upper right is double bonded to O on the right and has an open single bond on the upper left. The alkane chain is depicted as a line structure using 3 zigzag lines. C 4 of the alkane chain is single bonded to N H 3 superscript plus on the lower left.

The reversible reaction arrow is labeled transglutaminase.



The first product is labeled cross-link and has the following structure: A central C atom is single bonded to N H on the upper left, single bonded to C on the lower left, dash bonded to H on the lower right, and wedge bonded to C 1 of an 8-membered heteronuclear alkane chain on the upper right. N H has an open single bond on the upper right. C on the lower left is double bonded to O on the left and has an open single bond on the lower right. The heteronuclear alkane chain is depicted as a line structure using 7 zigzag lines and consists of 1 N and 7 C atoms. The N atom occupies the fourth position and is bound to H. C 3 of the alkane chain is double bonded to O above. C 7 is wedge bonded to a central C atom on the upper right. The central C atom is single bonded to N H on the lower right, single bonded to C on the upper right, and dash bonded to H on the upper left. N H has an open single bond on the lower left. C on the upper right is double bonded to O on the right and has an open single bond on the upper left.

The second product is N H 4 superscript plus.

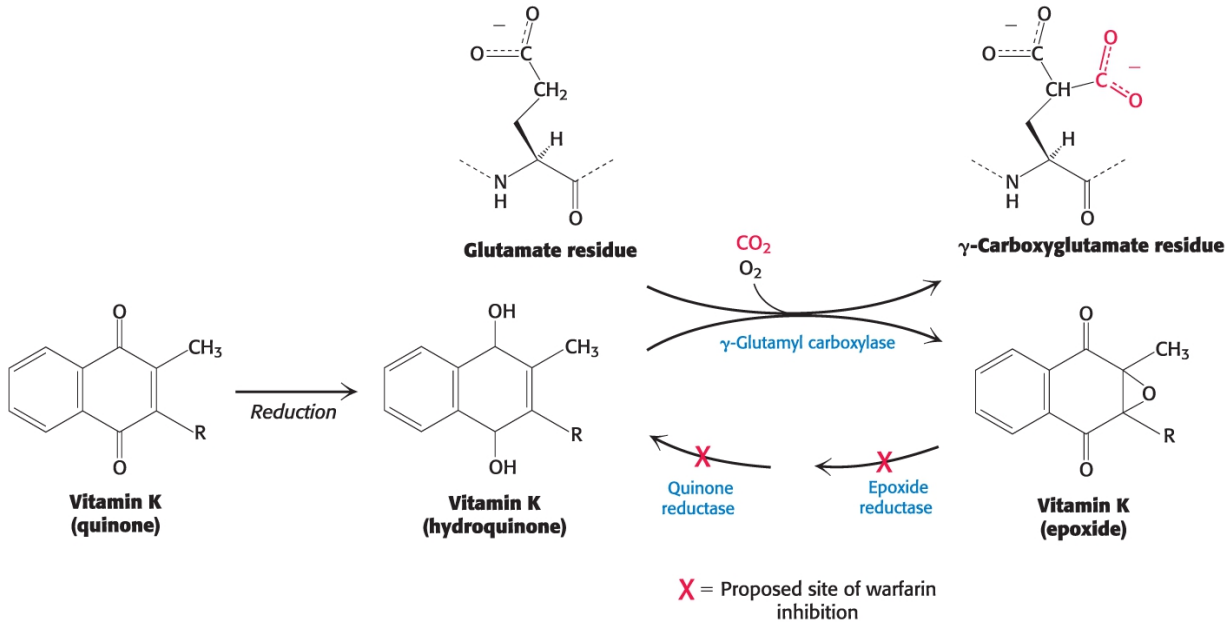


Return to Cross-linking reaction between glutamine and lysine residue

Extended description for Chemical structure of vitamin

K and warfarin

Vitamin K



Warfarin

Vitamin K has the following structure: A benzene ring in a vertical orientation consists of alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. The benzene ring is fused to a 6-carbon hexagonal ring in a vertical orientation. C 2 is double bonded to C 3. C 1 is double bonded to O above. C 2 is single bonded to C H 3 on the upper right. C 3 is single bonded to C 1 of a polymeric chain consisting of 6 monomeric units. C 4 is double bonded to O below. The two rings are fused such that C 2 and C 3 of the benzene ring are C 6 and C 5 of the hexagonal ring, respectively. The monomeric unit is a 4-carbon alkene chain depicted as a line structure using 3 zigzag lines. A double bond is present between C 2 and C 3. C 3 is single bonded to C H 3 below. C 4 of the terminal monomer is single bonded to H on the lower right.

Warfarin has the following structure: A benzene ring in a vertical orientation consists of alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. The benzene ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation. The ring consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the topmost vertex. C 2 is double bonded to C 3. C 1 is double bonded to O on the upper right. C 2 is single bonded to a central C atom. C 3 is single bonded to C H 3 below. The two rings are fused such that C 2 and C 3 of the benzene ring are C 5 and C 4 of the hexagonal ring, respectively. The central C atom is single bonded to C 5 a benzene ring in a vertical orientation on the upper right. The ring consists of alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. The central C atom is wedge bonded to H on the lower right and dash bonded to C H 2 on the lower left. C H 2 is single bonded to C on the lower right. This C atom is double bonded to O on the right and single bonded to C H 3 on the lower left.

Return to Chemical structure of vitamin K and warfarin

Extended description for Chemical reactions showing the synthesis of gamma-carboxyglutamate

Reduction of vitamin K (quinone) to vitamin K (hydroquinone):

The reactant vitamin K (quinone) has the following structure: A benzene ring in a vertical orientation consists of three alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. The benzene ring is fused to a 6-carbon hexagonal ring in a vertical orientation. C 2 is double bonded to C 3. C 1 is double bonded to O. C 2 is single bonded to C H 3. C 3 is single bonded to R. C 4 is double bonded to O. The two rings are fused such that C 2 and C 3 of the benzene ring are C 6 and C 5 of the hexagonal ring, respectively.

The product is vitamin K (hydroquinone), which has the following structure: A benzene ring in a vertical orientation consists of three alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. The benzene ring is fused to a 6-carbon hexagonal ring in a

vertical orientation. C 2 is double bonded to C 3. C 1 is single bonded to O H. C 2 is single bonded to C H 3. C 3 is single bonded to R. C 4 is single bonded to O H. The two rings are fused such that C 2 and C 3 of the benzene ring are C 6 and C 5 of the hexagonal ring, respectively.

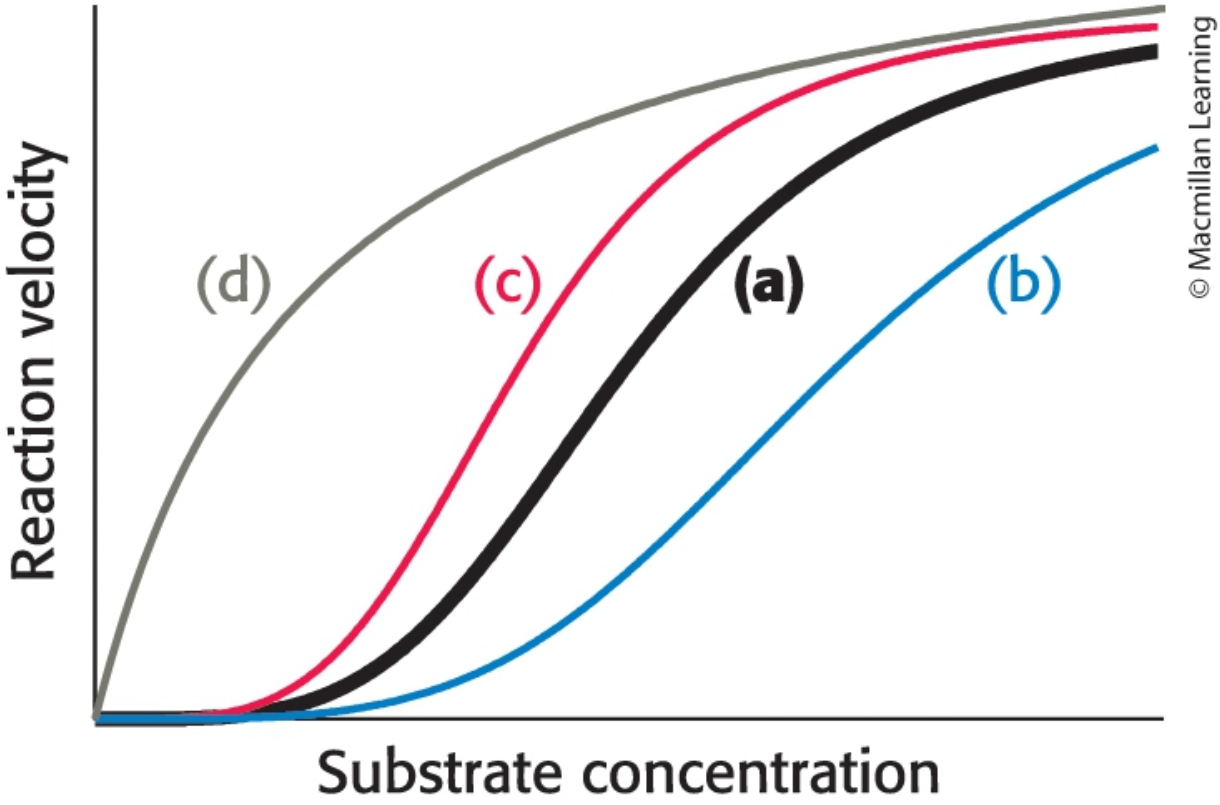
Conversion of vitamin K (hydroquinone) to vitamin K (epoxide):

The reaction arrow is labeled gamma-glutamyl carboxylase.

Vitamin K (epoxide) has the following structure: A benzene ring in a vertical orientation consists of three alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. The benzene ring is fused to a 6-carbon hexagonal ring in a vertical orientation. C 1 is double bonded to O. C 2 is single bonded to C H 3 on the upper right and single bonded to O on the lower right. C 3 is single bonded to R on the lower right and single bonded on the upper right to the same O atom which is single bonded to C 2. C 4 is double bonded to O below. The two rings are fused such that C 2 and C 3 of the benzene ring are C 6 and C 5 of the hexagonal ring, respectively.

The conversion of glutamate residue to gamma-carboxyglutamate residue takes place simultaneously and C O 2 and O 2 are consumed.

The structure of glutamate residue is as follows: A central C atom is dash bonded to H on the upper right, single bonded to C on the lower right, single bonded to N H on the lower left, and wedge bonded to C H 2 on the upper left. The C on the lower right is double bonded to O below and has an open bond on the upper right. The N H group on the lower left has an open bond on the upper left. C H 2 on the upper left is single bonded to C H 2 on the upper right which is single bonded to C on the upper left. This C is partially double



bonded to O above and partially double bonded to O on the left, and this C O O group carries a negative charge.

The structure of gamma-Carboxyglutamate residue is as follows: A central C atom is dash bonded to H on the upper right, single bonded to C on the lower right, single bonded to N H on the lower left, and wedge bonded to C H 2 on the upper left. The C on the lower right is double bonded to O below and has an open bond on the upper right. The N H on the lower left has an open single bond on the upper left. C H 2 on the upper left is single bonded to C H on the upper right which is single bonded to C on the upper left and single bonded to C on the upper right. The C on the upper left is partially double bonded to O above and partially double bonded to O on the left, and this C O O group carries a negative charge. The C on the upper right is partially double bonded to O above and partially double bonded to O on the lower right, and this C O O group carries a negative charge.

Two reaction arrows from vitamin K (epoxide) to vitamin K (hydroquinone) are crossed out indicating the proposed site of warfarin inhibition. The first reaction arrow is labeled epoxide reductase. The second reaction arrow is labeled quinone reductase.

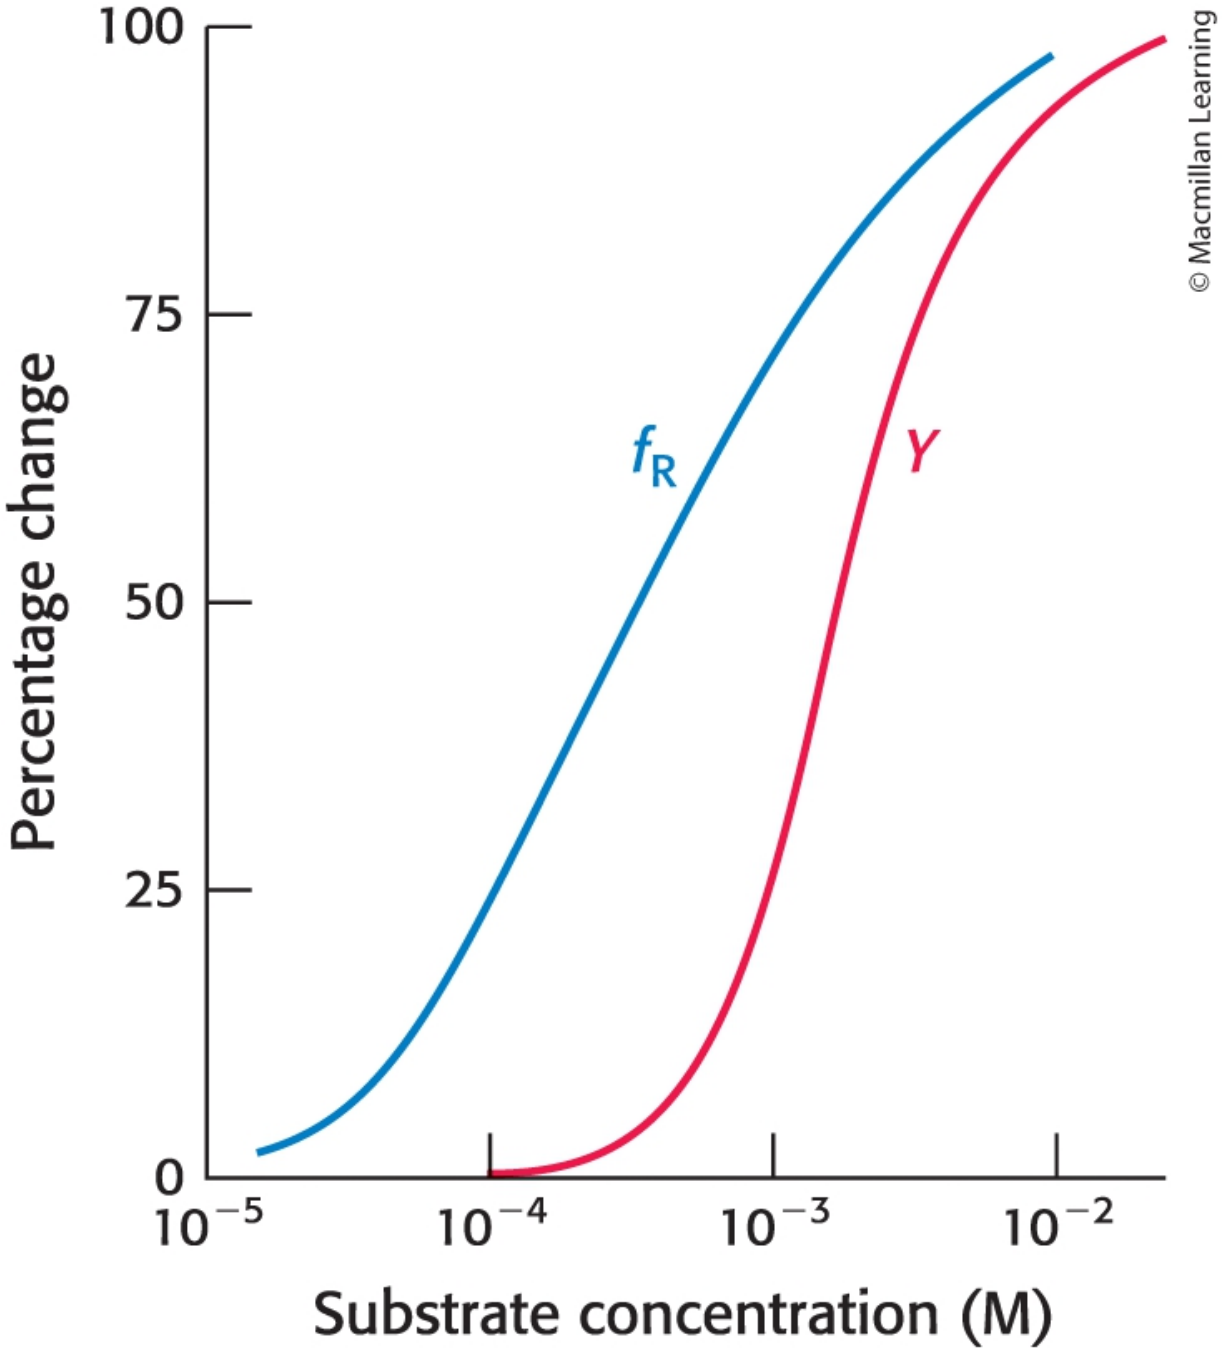
Return to Chemical reactions showing the synthesis of gamma-carboxyglutamate

Extended description for Graph depicts the velocity curve of an allosteric enzyme and the effect of negative modifier

The horizontal axis is labeled substrate concentration. The vertical axis is labeled reaction velocity. The following four curves are shown:

Curve (a), solid black: It starts from the origin and runs along the horizontal axis before rising steeply to a point near the top end of the vertical axis, followed by a short plateau. It has a sigmoidal shape.

Curve (b), blue: It starts from the origin and runs along the horizontal axis before rising linearly to a point near the top end of the vertical axis. The slope of this curve is less steep than the curve (a). This curve is located toward the right of the curve (a).



Curve (c), red: It starts from the origin and runs along the horizontal axis, and rises steeply before curve (a) to reach a point near the top end of the vertical axis, followed by a plateau. It has a sigmoidal shape and its slope is steeper than curve (a).

Curve (d), gray: It starts from the origin and rises steeply to a point near the top end of the vertical axis and then gradually plateaus. It is a hyperbolic curve.

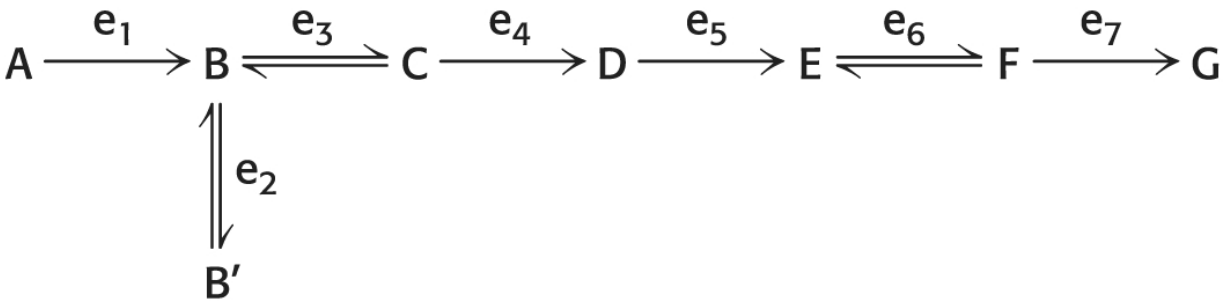
Return to Graph depicts the velocity curve of an allosteric enzyme and the effect of negative modifier

Extended description for Graphical representation of the fraction of enzyme in the R state and the fraction of

substrate-bound active sites as a function of substrate concentration.

The horizontal axis is labeled substrate concentration in molar. It has markings ranging from 10 raised to the power negative 5 to 10

raised to the power negative 2 in geometric increments of 10 units. The vertical axis is labeled percentage change. It has markings ranging from 0 to 100 in increments of 25 units.



Curve Y (red): It starts from (10 raised to the power negative 4, 0) and moves slightly horizontally toward the right. It then rises steeply to nearly (10 raised to the power negative 2, 95). It has a sigmoidal shape.

Curve f subscript R (blue): It starts near the origin and linearly rises to nearly (10 raised to the power negative 2, 100). It has a slightly sigmoidal shape but the slope is less steep than the red curve.

All the numerical values are estimated.

Return to Graphical representation of the fraction of enzyme in the R state and the fraction of substrate-bound active sites as a function of substrate concentration

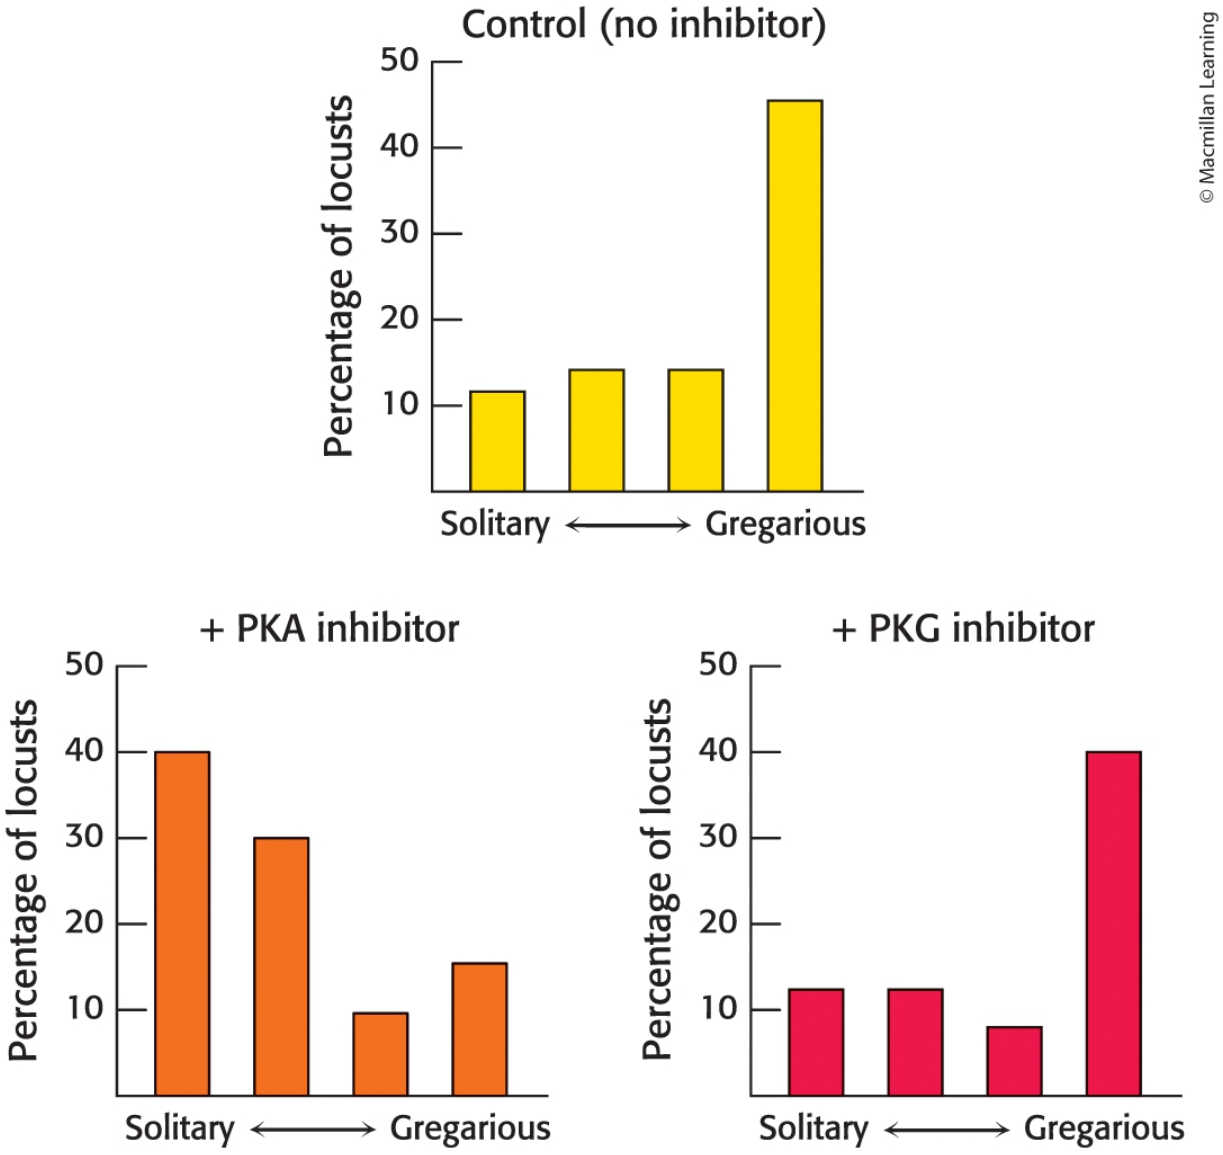
Extended description for Schematic illustration of a metabolic pathway

Reactant A forms product B. The forward reaction arrow is labeled e subscript 1.

B forms product B dash. The reversible reaction arrow is labeled e subscript 2.

B forms product C. The reversible reaction arrow is labeled e subscript 3.

C forms product D. The forward reaction arrow is labeled e subscript 4.



D forms product E. The forward reaction arrow is labeled e subscript 5.

E forms products F. The reversible reaction arrow is labeled e subscript 6.

F forms product G. The forward reaction arrow is labeled e subscript 7.

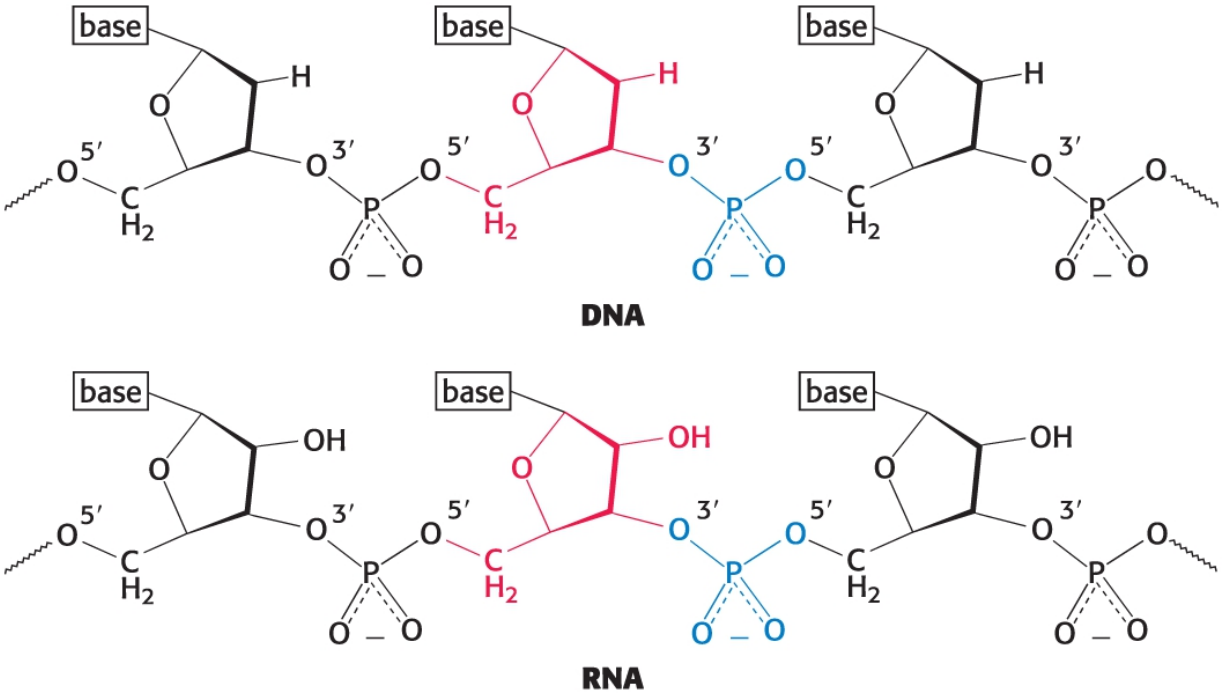
Extended description for FIGURE 8.1. Schematic representation of the structure of nucleic acids

A nucleic acid chain is shown to have a linear backbone linked to bases. The backbone is made up of sugars interspersed by phosphates. Vertical bars on top of each sugar are labeled Base. There are four such units shown labeled Base subscript i through Base subscript i plus 4.

Return to FIGURE 8.1. Schematic representation of the structure of nucleic acids

Extended description for FIGURE 8.2. Chemical structures of ribose and deoxyribose found in R N A and D N A respectively



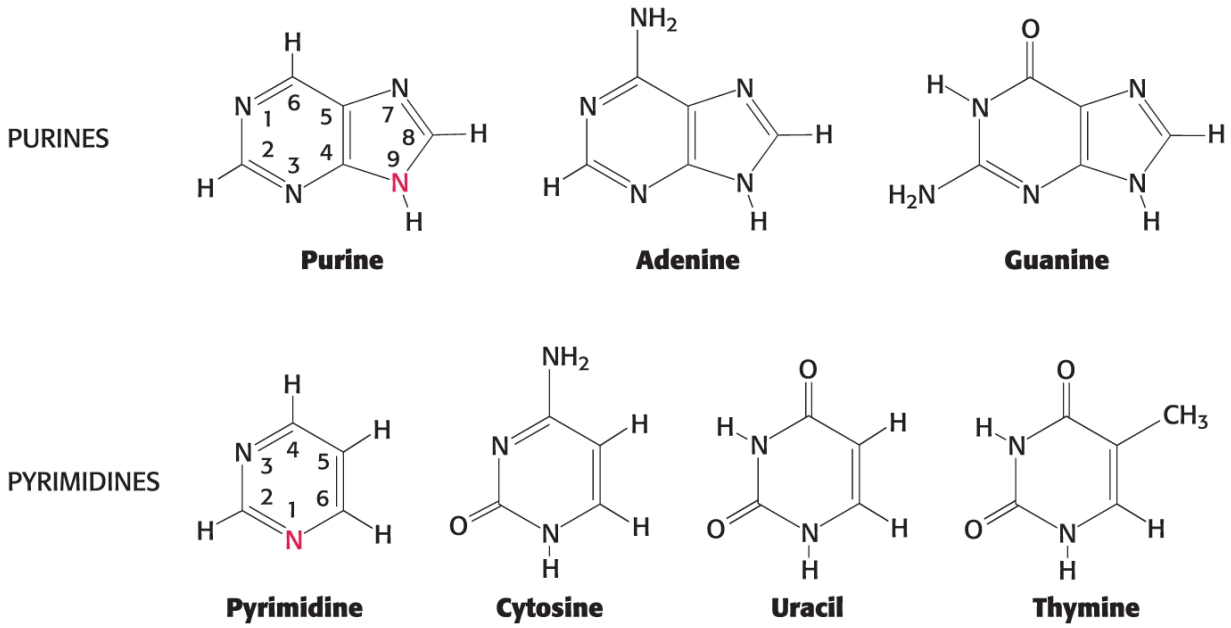
Ribose: A 5-membered heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. The O atom occupies the first position which is the topmost vertex. C 1, labeled 1 prime, is single bonded to an O H on the upper right and single bonded to H on the lower right. C 2, labeled 2 prime, is single bonded to H above and single bonded to O H on the lower right, which is highlighted in red. C 3, labeled 3 prime, is single bonded to O H on the lower left and single bonded to H above. C 4, labeled 4 prime, is single bonded to H on the lower left and single bonded to C on the upper left which is labeled 5 prime. This 5 prime C is single bonded to H on the upper right, single bonded to H above, and single bonded to O H on the lower left.

Deoxyribose: A 5-membered heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. The O atom occupies the first position which is the topmost vertex. C 1, labeled 1

prime, is single bonded to an O H on the upper right and single bonded to H on the lower right. C 2, labeled 2 prime, is single bonded to H above and single bonded to H on the lower right, which is highlighted in red. C 3, labeled 3 prime, is single bonded to O H on the lower left and single bonded to H above. C 4, labeled 4 prime, is single bonded to H on the lower left and single bonded to C on the upper left which is labeled 5 prime. This 5 prime C is single bonded to H on the upper right, single bonded to H above, and single bonded to O H on the lower left.

Return to FIGURE 8.2. Chemical structures of ribose and deoxyribose found in R N A and D N A respectively

Extended description for FIGURE 8.3. The chemical structure of D N A and R N A



D N A: Three nucleotide units are joined in a linear horizontal fashion. Each nucleotide unit has the following structure: A 5-membered heterocyclic pentagonal ring in a horizontal orientation consists of 1 O and 4 C atoms. The O atom occupies the first position which is the leftmost vertex. C 1 is single bonded to a base. C 2 is single bonded to H. C 3 is single bonded to O which is labeled 3 prime. This O atom is single-bonded to P on the lower right. P is single bonded to O on the upper right which is labeled 5 prime, partially double bonded to O on the lower right, and partially double bonded to O on the lower left. These partially double-bonded O atoms carry a negative charge. C 4 is single bonded to C H 2 which is single bonded to O on the upper left which is labeled 5 prime. Two adjacent nucleotides are linked by a phosphodiester bond formed between the 3 prime end of the left nucleotide and the 5 prime end

of the right nucleotide. The pentagonal ring of the second nucleotide is highlighted in red and the P O 4 group carrying a negative charge is highlighted in blue.

R N A: Three ribonucleotide units are joined in a linear horizontal fashion. Each ribonucleotide unit has the following structure: A 5-membered heterocyclic pentagonal ring in a horizontal orientation consists of 1 O and 4 C atoms. The O atom occupies the first position which is the leftmost vertex. C 1 is single bonded to a base. C 2 is single bonded to O H. C 3 is single bonded to O which is labeled 3 prime. O is single bonded to P on the lower right. P is single bonded to O on the upper right which is labeled 5 prime, partially double bonded to O on the lower right, and partially double bonded to O on the lower left. These partially double-bonded O atoms carry a negative charge. C 4 is single bonded to C H 2 which is single bonded to O on the upper left which is labeled 5 prime. Two adjacent ribonucleotides are linked by a phosphodiester bond formed between the 3 prime end of the left nucleotide and the 5 prime end of the right nucleotide. The pentagonal ring of the second ribonucleotide is highlighted in red and the P O 4 group carrying a negative charge is highlighted in blue.

Return to FIGURE 8.3. The chemical structure of D N A and R N A

Extended description for FIGURE 8.4. Chemical structures of different purines are pyrimidines

Purines:

The general structure of purine: A 6-membered heterocyclic hexagonal ring in a vertical orientation consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the bottom-most vertex. The second N atom occupies the third position, which is the top-left vertex. C 1 and C 2 are each single bonded to H. Double bonds are present between the first N and C 1 and the second N and C 2. This ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation. The pentagonal ring consists of 2 N and 3 C atoms. The first N atom occupies the first position which is the top-right vertex and the second N atom occupies the third position which is the bottom-right vertex which is highlighted in red. C 1 and the second N atom are each single bonded to H. Double bonds are present between the first N and C 1

and C 2 and C 3. The rings are fused such that C 3 and C 4 of the hexagonal ring are C 3 and C 2 of the pentagonal ring, respectively. The atoms of the hexagonal ring are numbered 1 to 6 in an anticlockwise direction starting from the top-left vertex. In the pentagonal ring, the first N atom is labeled 7, C 1 is labeled 8, and the second N atom is labeled 9.

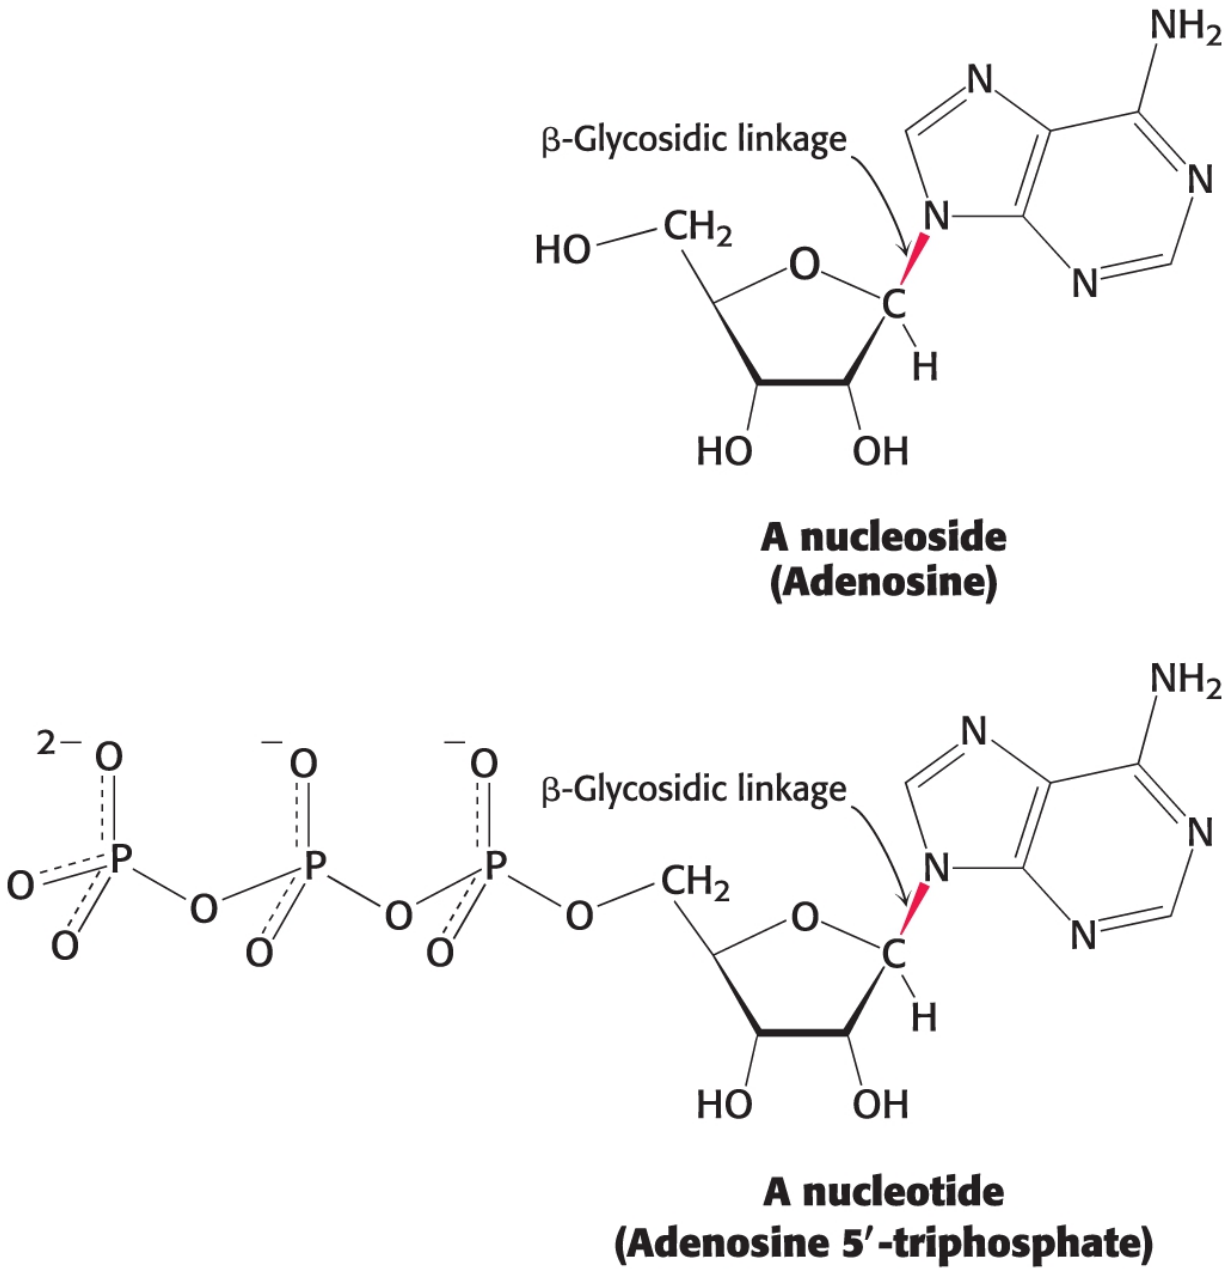
Adenine: A 6-membered heterocyclic hexagonal ring in a vertical orientation consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the bottom-most vertex. The second N atom occupies the third position, which is the top-left vertex. C 1 is single bonded to H and C 2 is single bonded to N H 2 above. Double bonds are present between the first N and C 1 and the second N and C 2. This ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation. The pentagonal ring consists of 2 N and 3 C atoms. The first N atom occupies the first position which is the top-right vertex and the second N atom occupies the third position which is the bottom-right vertex. C 1 and the second N atom are each single bonded to H. Double bonds are present between the first N and C 1 and C 2 and C 3. The rings are fused such that C 3 and C 4 of the hexagonal ring are C 3 and C 2 of the pentagonal ring, respectively.

Guanine: A 6-membered heterocyclic hexagonal ring in a vertical orientation consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the bottom-most vertex. The second N atom occupies the third position, which is the top-left vertex. The second N atom is single bonded to H. C 1 is single bonded to N H 2 on the lower left. C 2 is single bonded to O above. A double bond is present between the first N and C 1. This ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation. The pentagonal ring consists of 2 N and 3 C atoms. The first N atom occupies the first position which is the top right vertex and the second N atom occupies the third position which is the bottom right

vertex. C 1 and the second N atom are each single bonded to H. Double bonds are present between the first N and C 1 and C 2 and C 3. The rings are fused such that C 3 and C 4 of the hexagonal ring are C 3 and C 2 of the pentagonal ring, respectively.

Pyrimidines:

The general structure of pyrimidine is as follows: A 6-membered heterocyclic hexagonal ring in a vertical orientation consists of 2 N and 4 C atoms. The first N atom occupies the first position which is the bottom-most vertex and the second N atom occupies the third position which is the top-left vertex. Three alternating double bonds are present between the first N and C 1, the second N and C 2, and C 3 and C 4. C 1, C 2, C 3, and C 4 are each single bonded to H. The atoms of the hexagonal ring are numbered 1 to 6 in a clockwise direction starting from the bottom-most vertex.



Cytosine: A 6-membered heterocyclic hexagonal ring in a vertical orientation consists of 2 N and 4 C atoms. The first N atom occupies the first position which is the bottom-most vertex and the second N atom occupies the third position which is the top-left vertex. Double bonds are present between the second N and C 2 and C 3 and C 4. C 1 is double bonded to O on the lower left. The first N atom is single-bonded to H below. C 2 is single bonded to N H 2 above. C 3 and C 4 are each single bonded to H.

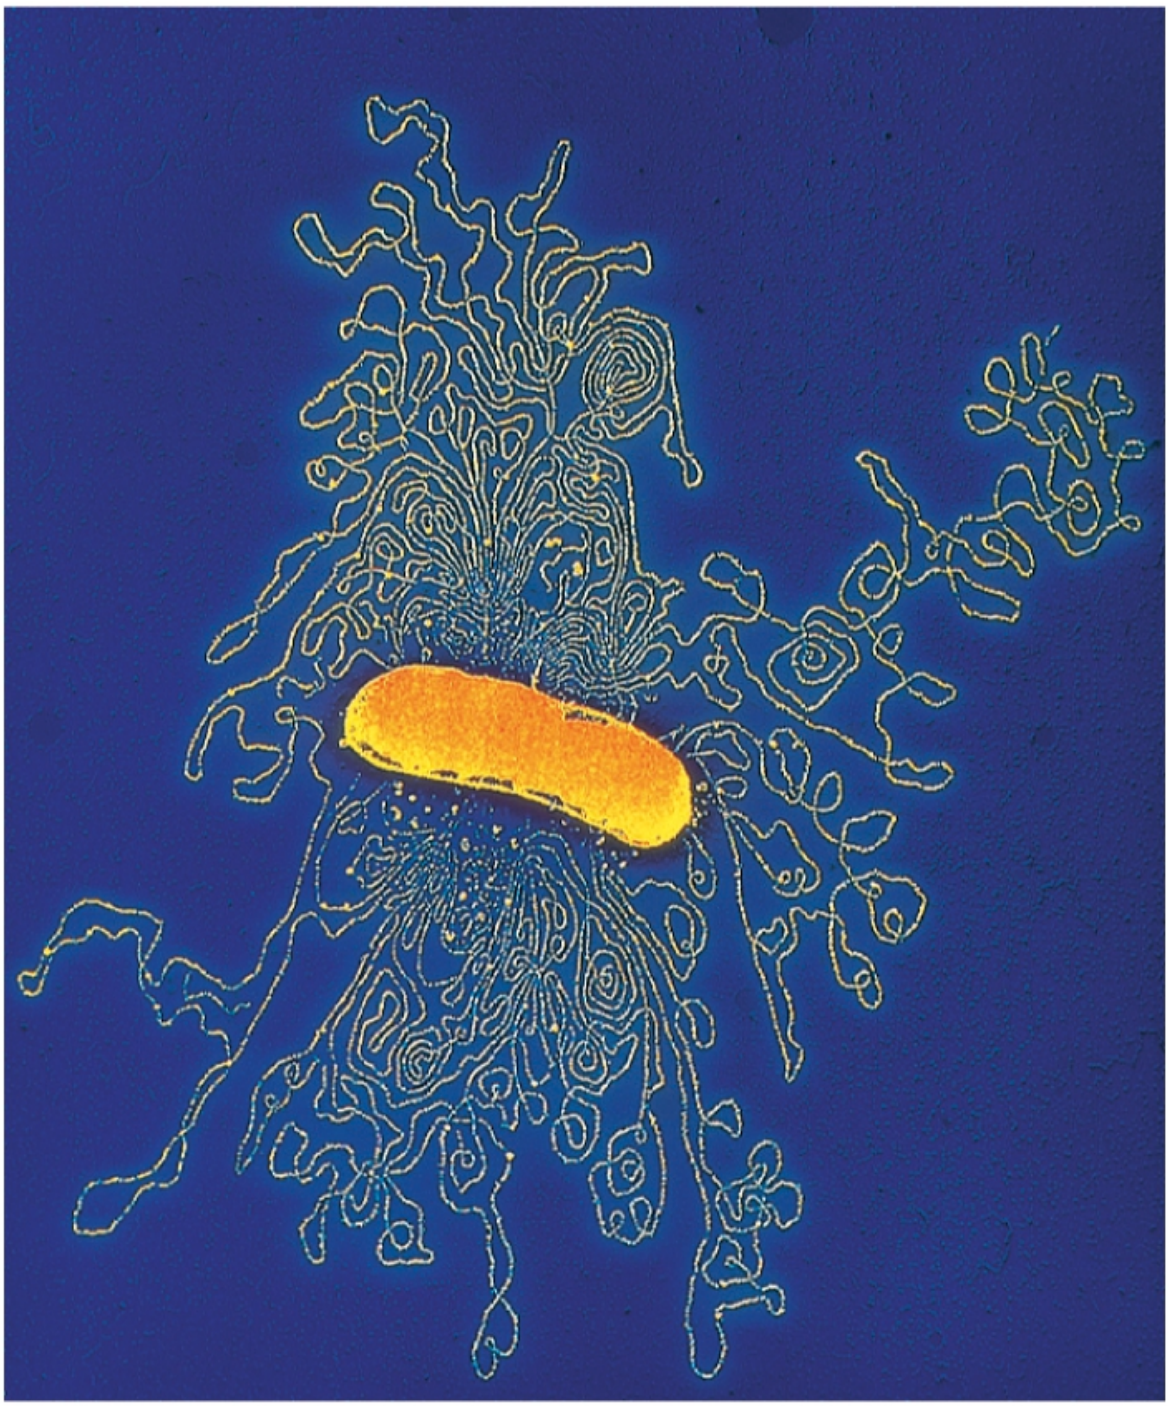
Uracil: A 6-membered heterocyclic hexagonal ring in a vertical orientation consists of 2 N and 4 C atoms. The first N atom occupies the first position which is the bottom-most vertex and the second N atom occupies the third position which is the top-left vertex. A double bond is present between C 3 and C 4. C 1 is double bonded to O on the lower left. The first N atom is single-bonded to H below. The second N atom is single-bonded to H on the upper left. C 2 is double bonded to O above. C 3 and C 4 are each single bonded to H.

Thymine: A 6-membered heterocyclic hexagonal ring in a vertical orientation consists of 2 N and 4 C atoms. The first N atom occupies the first position which is the bottom-most vertex and the second N atom occupies the third position which is the top-left vertex. A double bond is present between C 3 and C 4. C 1 is double bonded to O on the lower left. The first N atom is single-bonded to H below. The second N atom is single-bonded to H on the upper left. C 2 is double bonded to O above. C 3 is single bonded to C H 3 on the upper right. C 4 is single bonded to H on the lower right.

Return to FIGURE 8.4. Chemical structures of different purines are pyrimidines

Extended description for FIGURE 8.5. Chemical structures of a nucleoside and a nucleotide

A nucleoside (Adenosine): A 5-membered heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 2



and C 3 are each single bonded to O H. C 1 is single bonded to H on the lower right and wedge bonded to the first N of a 5-membered heterocyclic pentagonal ring in a horizontal orientation on the upper right. The wedge bond is highlighted in red and labeled beta-Glycosidic linkage. The pentagonal ring consists of 2 N and 3 C atoms. The first N atom occupies the first position which is the bottom left vertex and the second N atom occupies the third position which is the topmost vertex. A double bond is present between the second N and C 1 and C 2 and C 3. This ring is fused to a heterocyclic hexagonal in a vertical orientation consisting of 2 N and 4 C atoms. The first N atom occupies the first position which is the top right vertex and the second N atom occupies the third position which is the bottom-most vertex. A double bond is present between C 4 and the first N and C 1 and the second N. C 4 is single bonded to N H 2 above. The rings are fused such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 of the hexagonal ring, respectively. C 4 of the pentagonal ring consisting of 1 O and 4 C atoms is single bonded to C H 2 which is single bonded to O H on the lower left.

A nucleotide (Adenosine 5 prime-triphosphate): A 5-membered heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 2 and C 3 are each single bonded to O H. C 1 is single bonded to H on the lower right and wedge bonded to the first N of a 5-membered heterocyclic pentagonal ring in a horizontal orientation on the upper right. The wedge bond is highlighted in red and labeled beta-Glycosidic linkage. The pentagonal ring consists of 2 N and 3 C atoms. The first N atom occupies the first position which is the bottom left vertex and the second N atom occupies the third position which is the topmost vertex. A double bond is present between the second N and C 1 and C 2 and C 3. This ring is fused to a heterocyclic hexagonal in a vertical orientation consisting of 2 N and 4 C atoms. The first N atom occupies the first position which is the top right vertex and the second N atom occupies the third position

which is the bottom-most vertex. A double bond is present between C 4 and the first N and C 1 and the second N. C 4 is single bonded to N H 2 above. The rings are fused such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 of the hexagonal ring, respectively. C 4 of the pentagonal ring consisting of 1 O and 4 C atoms is single bonded to C H 2 which is single bonded to O atom of a triphosphate group. Each phosphate group has a central P atom single bonded to O on the lower right, single bonded to O on the lower left, partially double bonded to O above, and partially double bonded to O below. The single bonded O atoms are shared between two adjacent phosphate groups. The terminal phosphate group carries a negative charge of 2 minus as it is partially double bonded to O above, left, and on the lower left. The other two phosphate groups each carry a negative charge.

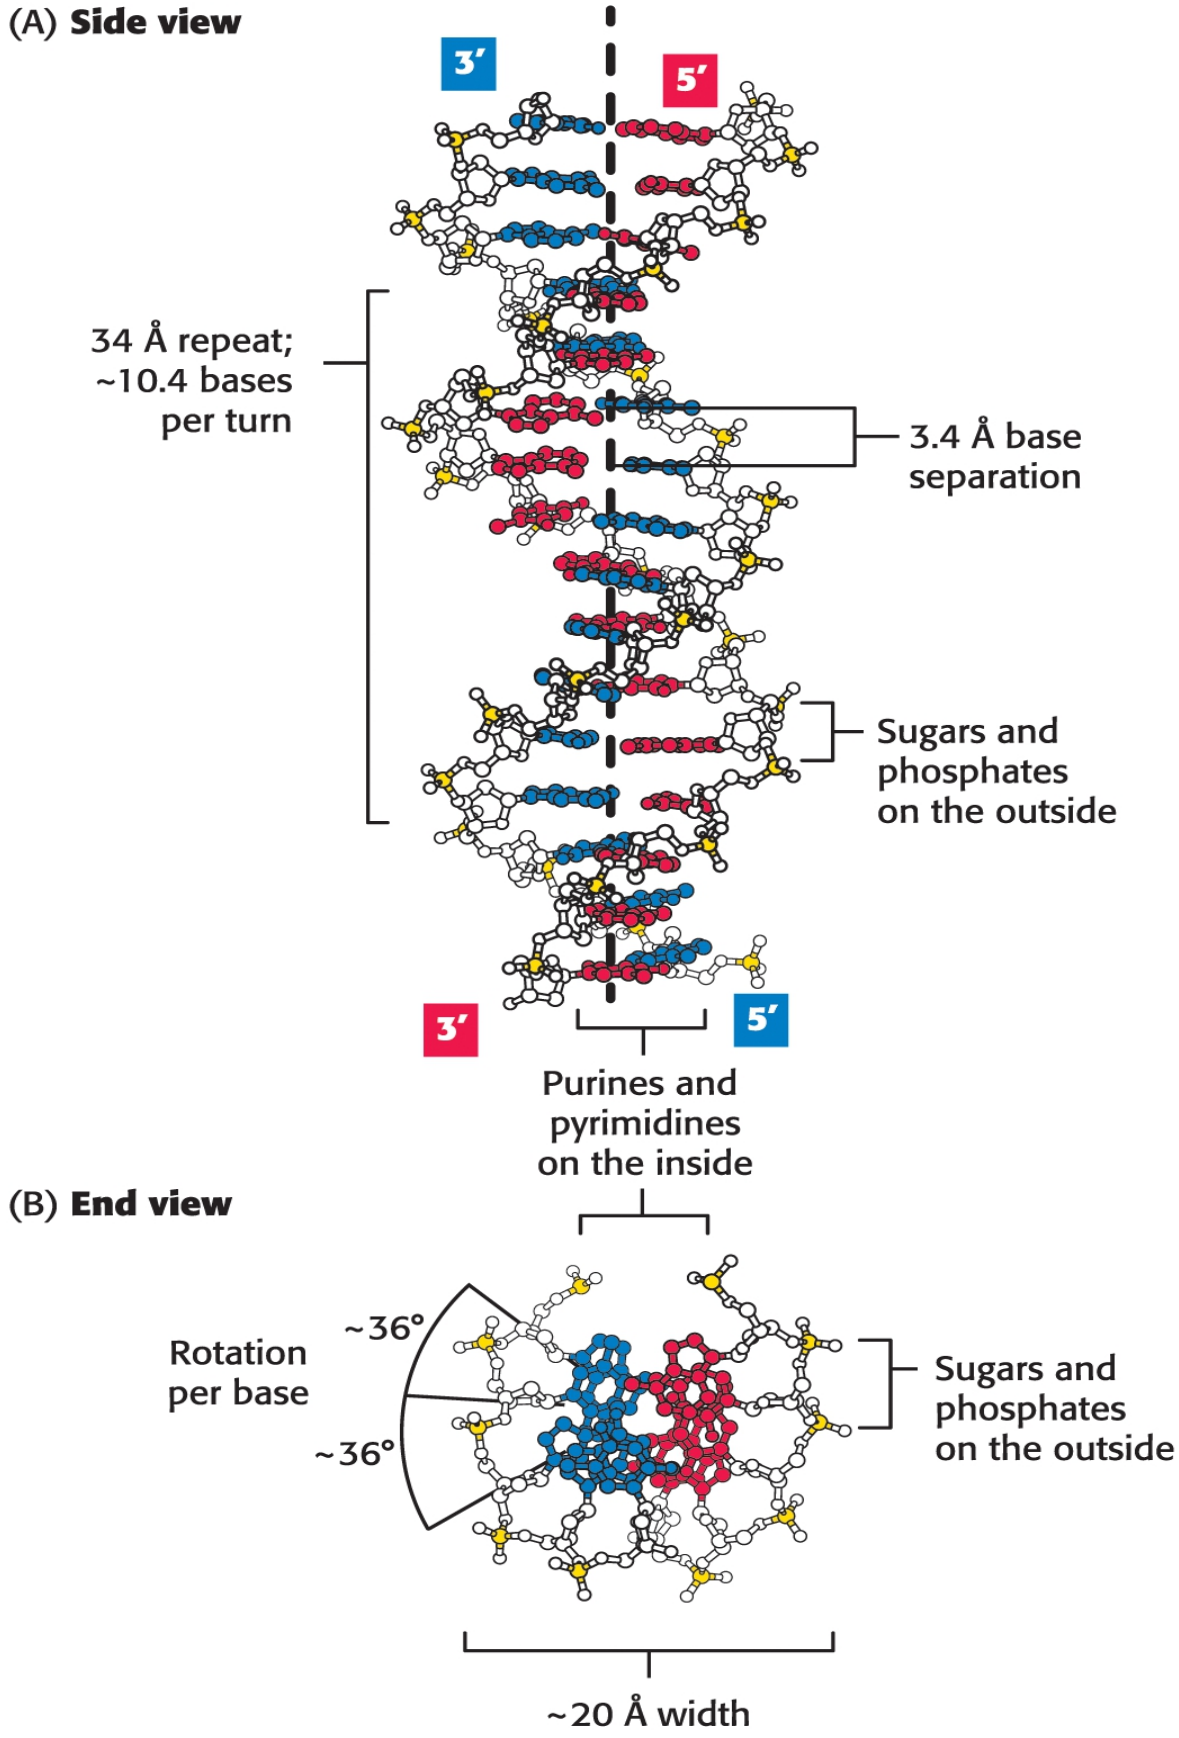
The photomicrograph shows three pairs of long X-shaped chromosomes stained orange. Two pairs of human chromosomes are also seen in green which are much smaller and appears like large blots.

[Return to FIGURE 8.7. Photomicrograph of the stained chromosomes of female Indian muntjac]

Extended description for FIGURE 8.8. Simplified schematic representation of a nucleic acid strand



A nucleic acid sequence is shown: A C A T T T G C T T C T C G A C A G A C A A C T G T G T T C A C T A G A C G. The last three bases are A C G, which are shown in magnification. The magnified portion shows three equally spaced vertical lines. The top of lines are labeled A, C, and G, from the left to right. The top end of each vertical line is labeled 3 prime and the bottom end is labeled 5 prime. A phosphoryl group represented by P in a yellow circle is bonded to 3 prime of the left vertical line and 5 prime of the right vertical line. The 3 prime end of the terminal G base is single bonded to O H. This entire arrangement of the strand resembles a saw tooth structure.

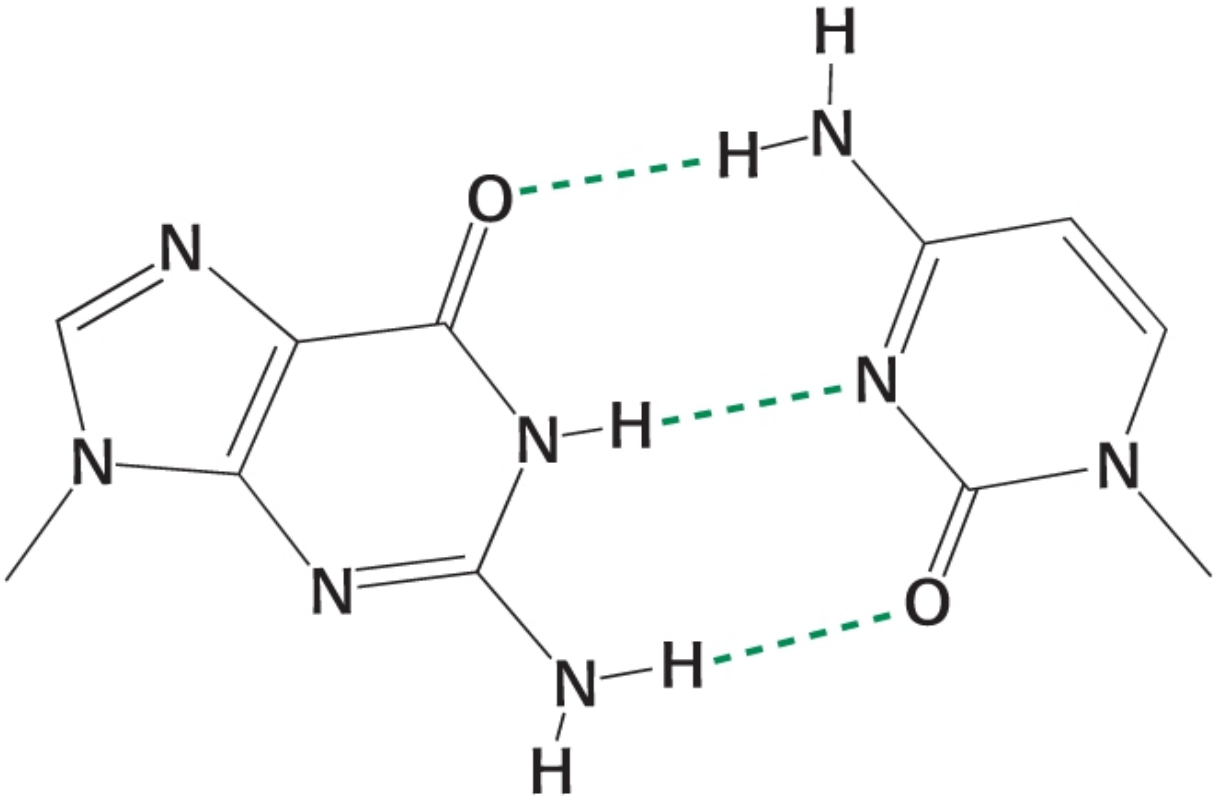
Extended description for FIGURE 8.10. The Watson–

Crick model of double-helical D N A

© Macmillan Learning



Part (A): Side view. The double helix is left-handed. The purine and pyrimidine bases are inside and pointed toward the central vertical axis of the double helix, and the sugar-phosphate backbone is located outside toward the periphery. The bases of one strand are shown in red and the bases of the other strand are shown in blue. The orientation of the red strand is 3 prime to 5 prime from the bottom to top. The orientation of the blue strand is 5 prime to 3 prime from the bottom to top. One turn is labeled 34 Angstrom repeat; approximately 10.4 bases per turn. Base separation is 3.4 Angstrom.

Part (B): End view. The purine and pyrimidine bases are buried inside the helix. The blue bases are shown on the left and the red bases is shown on the right. The two bases resemble C-shapes facing each other. The sugar-phosphate backbone forms an incomplete circle around the bases. Rotation per base is approximately 36 degrees. The width of the helix is approximately 20 Angstrom.

nucleotide bases

Guanine **Cytosine**

Adenine **Thymine**

Guanine and Cytosine: Three hydrogen bonds are formed between these two bases.

Cytosine has the following structure: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the bottom right vertex, and the second N atom occupies the third position, which is the leftmost vertex. Double bonds are present between the second N and C 2 and C 3 and C 4. C 1 is double bonded to O on the lower left. C 2 is single bonded to N on the upper left which is single bonded to H above and single bonded to H on the left. The second N has an open single bond on the lower right.

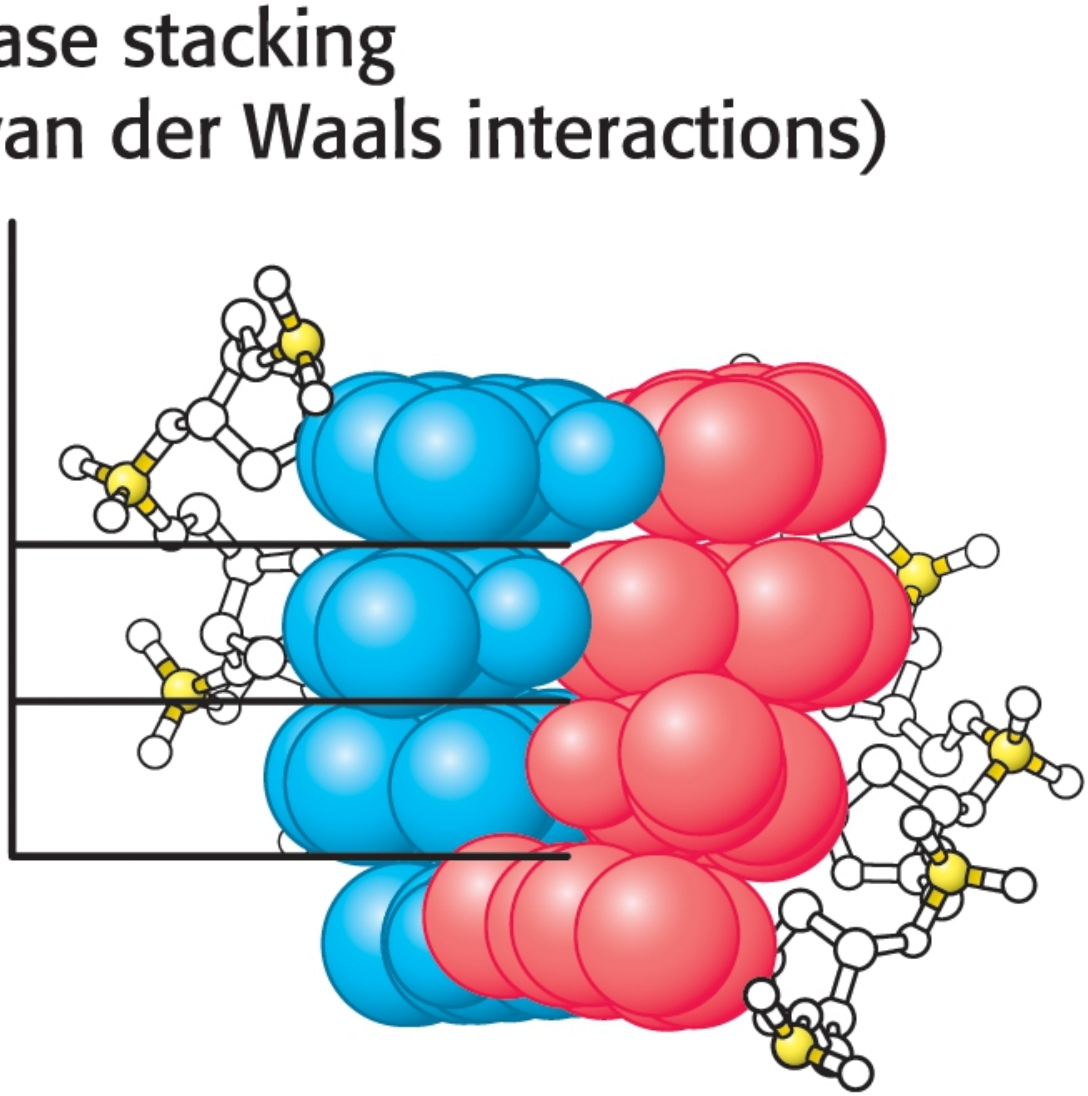
Guanine has the following structure: A 6-membered heterocyclic hexagonal ring and a 5-membered pentagonal ring are fused. The six-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the top-left vertex and the second N atom single bonded to H occupies the third position, which is the bottom-most vertex. A double bond is present between the second N and C 1. C 1 is single bonded to N on the lower right which is single bonded to H below and single bonded to H on the right. C 4 is double bonded to O above. The 6-membered hexagonal ring is fused to a 5-membered heterocyclic ring in a vertical orientation which consists of 2 N and 3 C atoms. The first N atom occupies the first position, which is the bottom left vertex and the second N atom occupies the third position, which is the topmost vertex. A double bond is present between the second N and C 1 and C 2 and C 3. The first N has an open single bond on the lower left. The rings are fused such that C 2 and C 3 of the hexagonal ring are the C 3 and C 2 of the pentagonal ring, respectively.

The first hydrogen bond is present between N H single bonded to C 2 of cytosine and O double bonded to C 4 of the hexagonal ring of

guanine. The second hydrogen bond is present between the second N of cytosine and the first N bound to H of the hexagonal ring of guanine. The third hydrogen bond is present between the O atom double-bonded to C 1 of cytosine and N H single-bonded to C 1 of the hexagonal ring of guanine.

Adenine and Thymine: Two hydrogen bonds are formed between these two bases.

Thymine has the following structure: A 6-membered heterocyclic hexagonal ring in a horizontal orientation consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the bottom right vertex. The second N atom bound to H occupies the third position, which is the leftmost vertex. A double bond is present between C 3 and C 4. C 3 is single bonded to C H 3 on the upper right. C 1 is double bonded to O on the lower left. C 2 is double bonded to O on the upper left. The first N atom has an open single bond on the lower right.



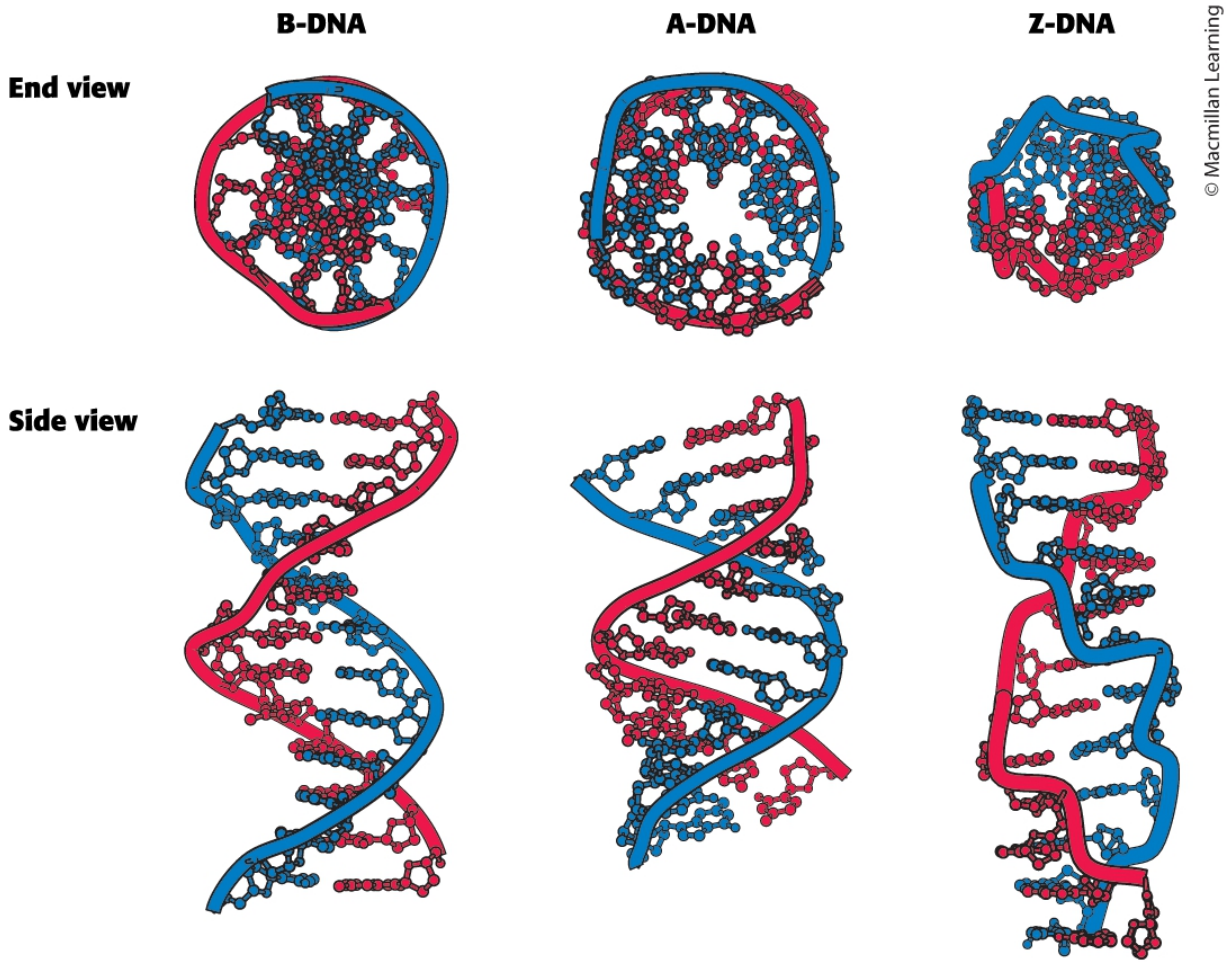
Adenine has the following structure: A 6-membered heterocyclic hexagonal ring and a 5-membered pentagonal ring are fused. The six-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the top-right vertex, and the second N atom occupies the third position, which is the bottom-most vertex. Double bonds are present between the first N and C 4 and the second N and C 1. C 4 is single bonded to N which is single bonded to H on the upper left and single bonded to H on the upper right. The 6-membered ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation which consists of 2 N and 3 C atoms. The first N atom occupies the first position, which is the bottom left vertex, and the second N atom occupies the third position, which is the topmost vertex. A double bond is present between the second N and C 1 and C 2 and C 3. The first N has an

open single bond on the lower left. The rings are fused such that C 2 and C 3 of the hexagonal ring are the C 3 and C 2 of the pentagonal ring, respectively.

The first hydrogen bond is present between the H bound to the second N of thymine and the first N atom of the hexagonal ring of adenine. The second hydrogen bond is present between the O atom double-bonded to C 2 of thymine and N H single bonded to C 4 of the hexagonal ring of adenine.

Return to FIGURE 8.11. Base-pairing of nucleotide bases

Extended description for FIGURE 8.12. Schematic representation of the side view of D N A reveals the stacking of base pairs within the double helix



© Macmillan Learning

A D N A double helix is diagrammatically represented. The space-filling model of the bases is shown. The bases of the left strand are shown as blue spheres and those of the right strand are shown as red spheres. They coil around each other along the vertical axis. The bases of each strand are stacked almost perfectly one above the

other. The ball-and-stick model of the sugar-phosphate backbone is shown on the outside. Base stacking is shown to be via van der Waals interactions.

Return to FIGURE 8.12. Schematic representation of the side view of D N A reveals the stacking of base pairs within the double helix

Extended description for FIGURE 8.13. Schematic representation of the different structural forms of D N A

B-D N A:

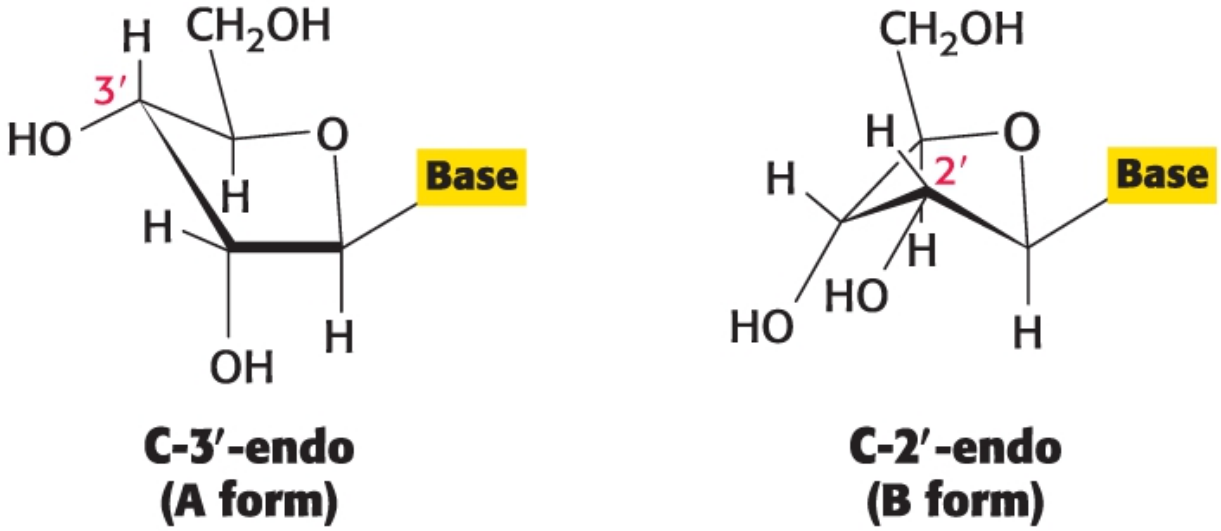
End view: It resembles a wheel. Half of the circumference is red and the other half is blue, and this represents the sugar-phosphate backbone. The bases are arranged such that they resemble the spokes of the wheel and form a central donut shape around the central axis.

Side view: The double helix is left-handed. The purine and pyrimidine bases are inside and point toward the central vertical axis of the double helix, and the sugar-phosphate backbone is outside toward the periphery. The bases and the backbone of one strand are shown in red and the bases and the backbone of the other strand are shown in blue.

A-D N A:

End view: It is shaped like a large donut. Half of the circumference is red and the other half is blue, and this represents the sugar-phosphate backbone. The bases are oriented toward the central axis. The central hole is much larger compared to that of B-D N A.

Side view: The width of the double helix is greater than that of B-D N A.



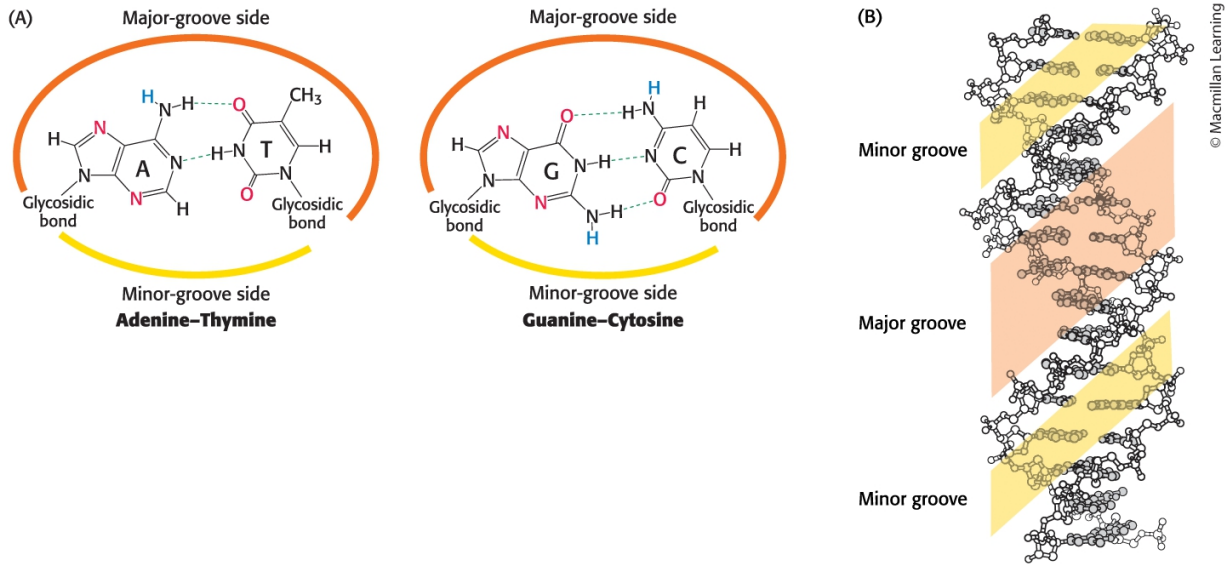
Z-D N A:

End view: It is shaped like a small donut. Half of the circumference is red and the other half is blue, and this represents the sugar-phosphate backbone. The backbone is wrinkled. The bases are oriented toward the central axis and are much more staggered compared to the other two forms.

Side view: The width of the double helix is smaller than that of B-D N A. The sugar-phosphate backbone is zigzag along the vertical axis.

Return to FIGURE 8.13. Schematic representation of the different structural forms of D N A

Extended description for FIGURE 8.14. The structures of the sugars in the A and B forms of D N A



C-3 prime-endo (A form): The puckered sugar is a 5-membered ring consisting of 1 O and 4 C atoms. The O atom occupies the first position which is the top right vertex. O is single bonded to C 1 below. C 1 is single bonded to Base on the upper right, single bonded to H below, and single bonded to C 2 on the left. C 1 and C 2 are toward the observer. C 2 is single bonded to O H below, single bonded to H on the upper left, and wedge bonded to C 3 on the upper left. C 3 is labeled 3 prime and is single bonded to H above, single bonded to O H on the lower left, and single bonded to C 4 on the lower right. C 4 is single bonded to H below, single bonded to C H 2 O H on the upper left, and single bonded to O at the first position on the right.

C-2 prime-endo (B form): The puckered sugar is a 5-membered ring consisting of 1 O and 4 C atoms. The O atom occupies the first position which is the top right vertex. O is single bonded to C 1 below. C 1 is single bonded to Base on the upper right, single bonded

to H below, and wedge bonded to C 2 on the upper left. C 2 is labeled 2 prime and is single bonded to O H on the lower left, single bonded to H on the upper left, and wedge bonded to C 3 on the lower left. C 3 is single bonded to O H on the lower left, single bonded to H on the upper left, and single bonded to C 4 on the upper right. C 4 is single bonded to C H 2 O H on the upper left, single bonded to H below, and single bonded to O at the first position on the right.

Return to FIGURE 8.14. The structures of the sugars in the A and B forms of D N A

Extended description for FIGURE 8.15. The major and minor grooves of a D N A double helix

Part (A): The major and minor grooves in an adenine-thymine and guanine-cytosine base pair are shown.

Adenine-thymine base pair:

Thymine has the following structure: A 6-membered heterocyclic hexagonal ring in a horizontal orientation consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the bottom right vertex. The second N atom bound to H occupies the third position, which is the left-most vertex. A double bond is present between C 3 and C 4. C 3 is single bonded to C H 3. C 1 is double bonded to O (red) on the lower left. C 2 is double bonded to O (red) on the upper left. The first N has a glycosidic bond on the lower right. C 4 is single bonded to H.

Adenine has the following structure: A 6-membered heterocyclic hexagonal ring and a 5-membered pentagonal ring are fused. The six-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the top-right vertex. The second N atom (red) occupies the third position, which is the bottom-most vertex. Double bonds are present between the first N and C 4 and the second N and C 1. C 4 is single bonded to N which is single bonded to H (blue) on the upper left and single bonded to H on the upper right. C 1 is single bonded to H. The 6-membered ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation which consists of 2 N and 3 C atoms. The first N atom occupies the first position, which is the bottom left vertex. The second N atom (red) occupies the third position, which is the topmost vertex. A double bond is present between the second N and C 1 and C 2 and C 3. The first N has a glycosidic bond on the lower left. The rings are fused such that C 2 and C 3 of the hexagonal ring are the C 3 and C 2 of the pentagonal ring, respectively.

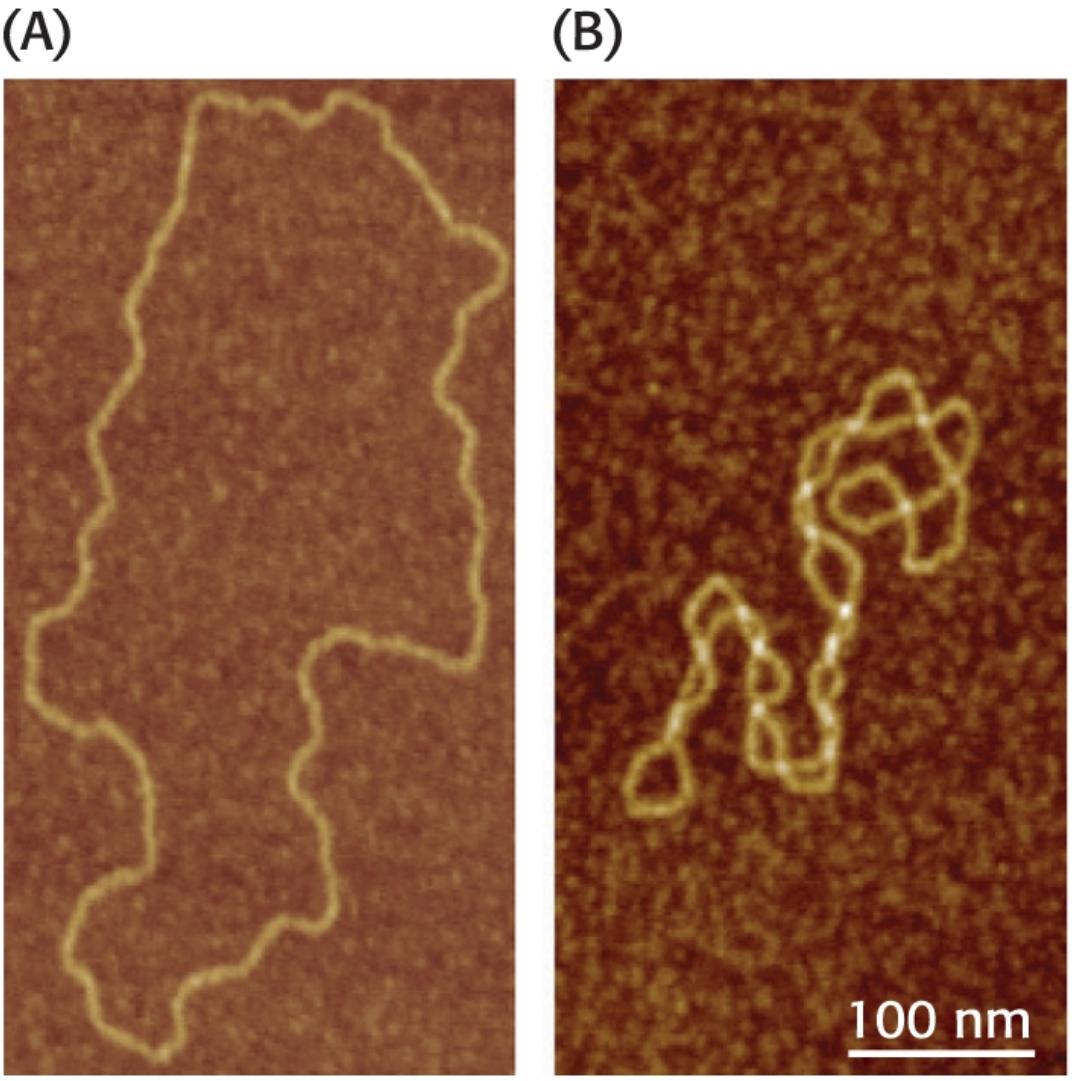
The first hydrogen bond is present between the H bound to the second N of thymine and the first N of the hexagonal ring of adenine. The second hydrogen bond is present between the O atom double-bonded to C 2 of thymine and N H single bonded to C 4 of the hexagonal ring of adenine. A large arc joining the glycosidic bond of adenine and thymine, over the base pair, is labeled the major-groove side. A smaller arc joining the glycosidic bond of adenine and thymine, below the base pair, is labeled minor-groove side.

Guanine-Cytosine base pairing:

Cytosine has the following structure: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the bottom right vertex. The second N atom occupies the third position,

which is the left-most vertex. Double bonds are present between C 3 and C 4 and the second N and C 2. C 1 is double bonded to O (red) on the lower left. C 2 is single bonded to N on the upper left which is single bonded to H (blue) above and single bonded to H on the left. The first N has a glycosidic bond on the lower right. 3 and C 4 are each single bonded to H.

Guanine has the following structure: A 6-membered heterocyclic hexagonal ring and a 5-membered pentagonal ring are fused. The six-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. The first N atom single bonded to H occupies the first position, which is the top vertex. The second N atom (red) occupies the third position, which is the bottom-most vertex. A double bond is present between the second N and C 1. C 1 is single bonded to N on the lower right which is single bonded to H (blue) below and single bonded to H on the upper right. C 4 is double bonded to O (red) above. The 6-membered hexagonal ring is fused to a 5-membered heterocyclic ring in a horizontal orientation which consists of 2 N and 3 C atoms. The first N atom occupies the first position, which is the bottom left vertex. The second N atom (red) occupies the third position, which is the topmost vertex. A double bond is present between the second N and C 1 and C 2 and C 3. C 1 is single bonded to H. The first N has a glycosidic bond on the lower left. The rings are fused such that C 2 and C 3 of the hexagonal ring are the C 3 and C 2 of the pentagonal ring, respectively.



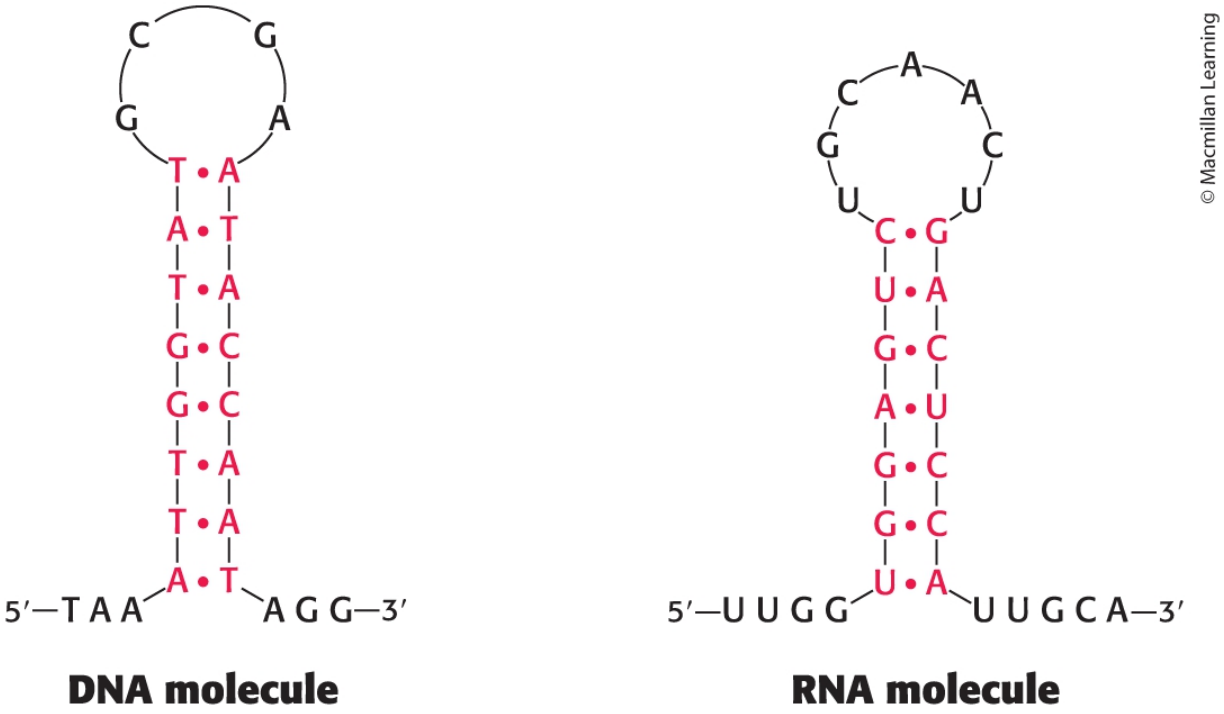
The first hydrogen bond is present between N H single bonded to C 2 of cytosine and O double bonded to C 4 of the hexagonal ring of guanine. The second hydrogen bond is present between the second N of cytosine and H single bonded to the first N of the hexagonal ring of guanine. The third hydrogen bond is present between the O atom double-bonded to C 1 of cytosine and N H single-bonded C 1 of the hexagonal ring of guanine. A large arc joining the glycosidic

bond of guanine and cytosine, over the base pair, is labeled the major-groove side. A smaller arc joining the glycosidic bond of guanine and cytosine, below the base pair, is labeled minor-groove side.

Part (B): A side view of the D N A double helix is illustrated. A thick wedge across the middle turn (turning toward the top left) is labeled major groove. A thinner wedge is shown across the regions (turning toward the top right) above and below the thick wedge, respectively. The thinner wedges are labeled minor groove.

Return to FIGURE 8.15. The major and minor grooves of a D N A double helix

Extended description for FIGURE 8.16. Two photomicrographs show the relaxed and supercoiled forms of circular bacterial D N A



Credit: Republished with permission of Oxford University Press, from Witz, Guillaume; Stasiak, Andrzej, "DNA supercoiling and its role in DNA decatenation and unknotting," (2010) *Nuc. Acids Res.* 38(7) 2119-2133, Figure 1. Permission conveyed through Copyright Clearance Center, Inc.

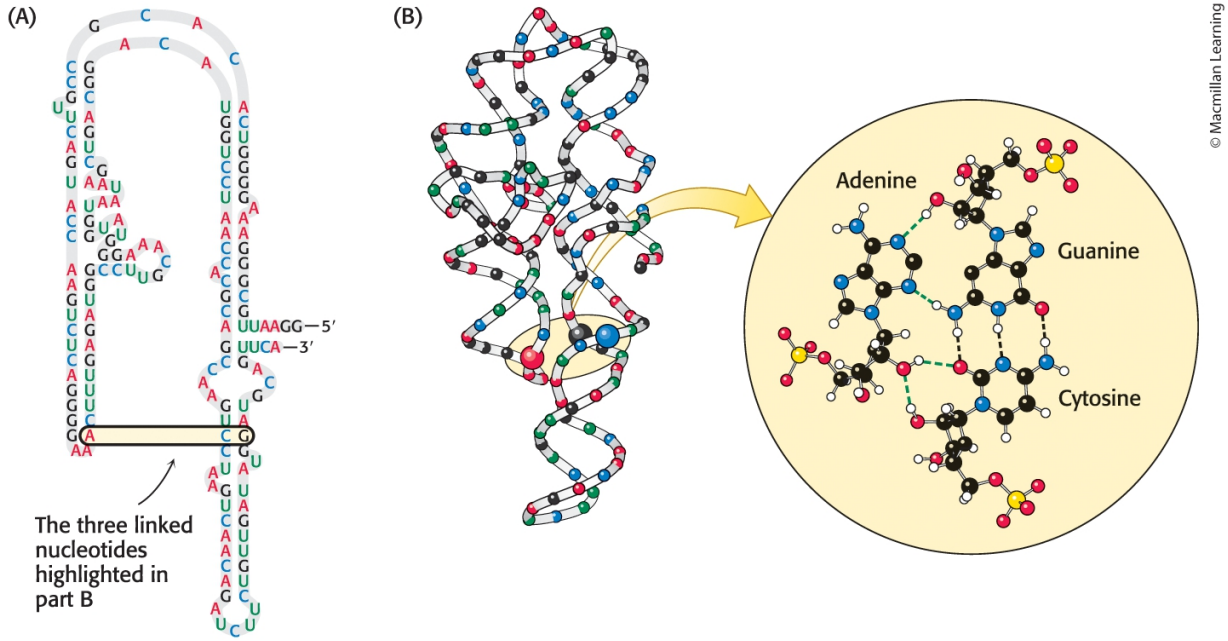
Part (A): Relaxed form: The circular D N A is a single thread-like structure that forms an irregular closed loop.

Part (B): The circular D N A is a single thread-like structure that forms a tightly coiled shape. The scale is 100 nanometers.

Return to FIGURE 8.16. Two photomicrographs show the relaxed and supercoiled forms of circular bacterial D N A

Extended description for FIGURE 8.17. Stem-loop structures formed in single-stranded D N A and R N A molecules

© Macmillan Learning



Single-stranded D N A: The stem-loop structure has a 5 prime trail end to the left and a 3 prime trail end to the right. The nucleotides of the stem are shown in red. Base pairing between A and T and G and C are shown by red dots. The loop has 4 nucleotides G, C, G, and A in a clockwise direction starting from the bottom left. They are shown in black.

Single-stranded R N A: The stem-loop structure has a 5 prime trail end to the left and a 3 prime trail end to the right. The nucleotides of the stem are shown in red. Base pairing between A and U and G and C are shown by red dots. The loop has 7 nucleotides U, G, C, A, A, C,

and U in a clockwise direction starting from the bottom left. They are shown in black.

Return to FIGURE 8.17. Stem-loop structures formed in single-stranded D N A and R N A molecules

Extended description for FIGURE 8.18. Schematic representation of complex structure adopted by R N A molecule

Part (A): Stem-loop structure. A single-stranded R N A molecule is shown to fold back on itself to form a structure resembling a double-stranded structure. This further is shown to fold to form an inverted U-shape, with the left arm longer than the right arm. A nucleotide (A) of the left arm is linked horizontally to two adjacent nucleotides (C and G) on the inner and outer region of the right arm.

Part (B): Three-dimensional stem-loop structure. The stem-loop structure is represented as a twisted rope made up of a series of colored spheres. The linkage of the nucleotides in the two arms is also highlighted. A magnified view of this linkage is shown. The ball-and-stick models of the nucleotides are shown. Guanine at the top is shown to be linked to cytosine at the bottom by three hydrogen bonds shown as black dashed lines. Cytosine is linked to adenine on

the top left by two hydrogen bonds shown as green dashed lines. Adenine is also linked to guanine on the right by two hydrogen bonds shown as green dashed lines.

Extended description for FIGURE 8.22 Single-stranded DNA absorbs light more effectively than does double-helical DNA

Part (A): The horizontal axis is labeled Wavelength (n m) and ranges from 220 to 300 in increments of 40 units. The vertical axis is labeled Absorbance. The following two curves are shown:

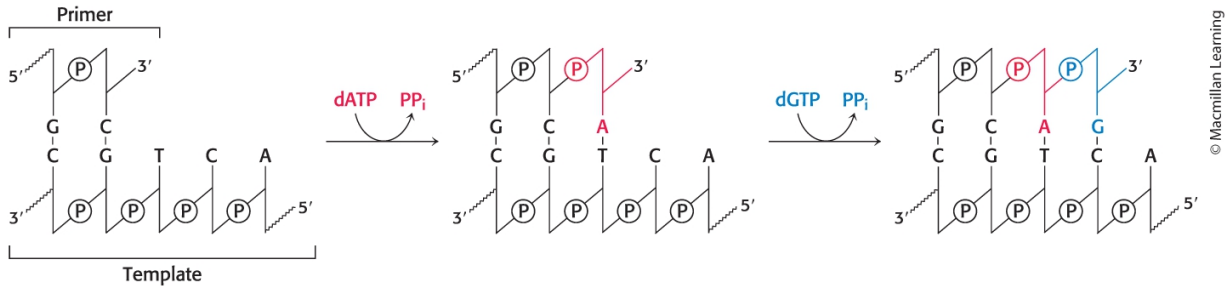
Single-stranded (blue): It starts near the mid-point of the vertical axis and drops slightly at 220 n m, and rises to a high peak at 260 n m before dropping to a minimum at 300 n m.

Double-helical (red): It starts slightly below the blue curve and follows nearly the same trajectory as that of the blue curve but lies below it. The curve intersects the blue curve near the end before terminating at a point slightly higher than that of the blue curve at 300 n m.

Part (B): The horizontal axis is labeled temperature in degrees Celsius and ranges from 60 to 80 in increments of 10 units. The left vertical axis is labeled Relative absorbance (260 n m) and ranges from 1 to 1.4 in increments of 0.1 units. The right vertical axis is labeled Percentage single-stranded and ranges from 0 to 100 percent. The curve has a rainbow color gradient starting as blue and ending as red. The curve has a sigmoid shape. It starts just above (60, 1), rises slightly followed by a steep rise to (77, 1.35), then it gradually plateaus. The curve rises from 0 percent to 100 percent along the right vertical axis. A vertical arrow is drawn from the mid-point of the slope of the curve to the horizontal axis at nearly 71 degrees Celsius and is labeled Melting temperature (T subscript m).

All numerical values are estimated.

Return to FIGURE 8.22 Single-stranded DNA absorbs light more effectively than does double-helical DNA



Extended description for Reaction catalyzed by D N A polymerase

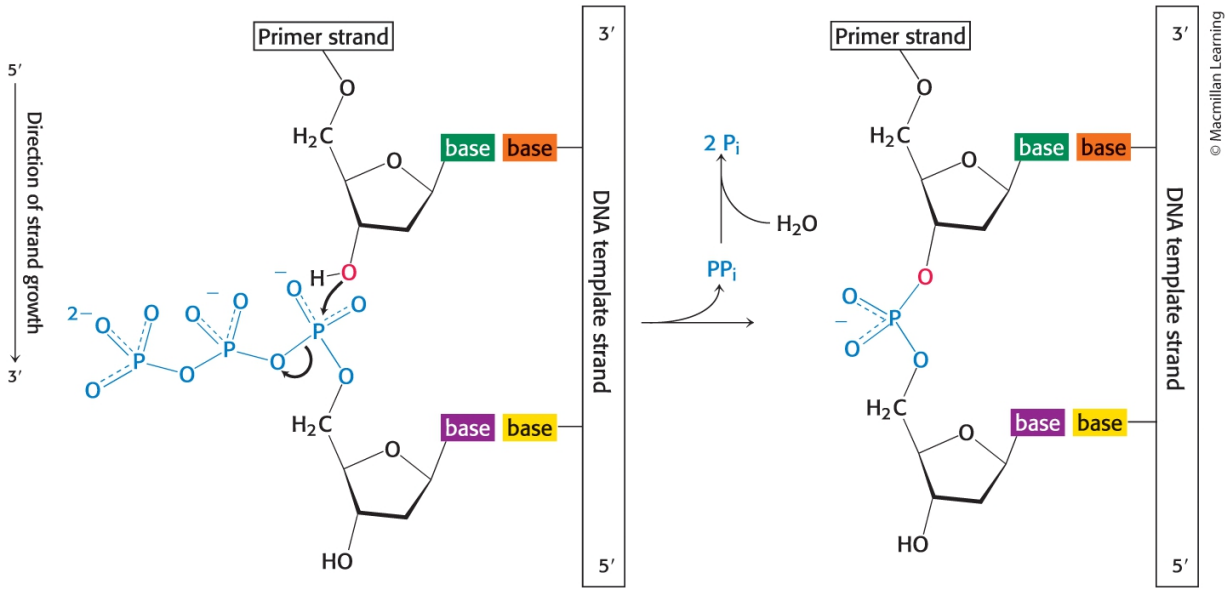
The reaction consists of two reactants and two products. The first reactant is open parenthesis D N A close parenthesis with subscript n. The second reactant is d N T P. A reversible reaction arrow leads to the products. The first product is open parenthesis D N A close parenthesis with subscript n plus 1. The second product is P P subscript i.

Return to Reaction catalyzed by D N A polymerase

Extended description for FIGURE 8.23. Schematic illustration of D N A polymerization using the saw-tooth schematic

The template is shown to have the following sequence: 3 prime, C, G, T, C, A, 5 prime. The primer is bound to the template at the top near the 3 prime end and has the following sequence: 5 prime, G, C, 3 prime.

The reaction arrow shows the consumption of d A T P (red) and release of P P subscript i.



The product shows the growing primer with the following sequence: 5 prime, G, C, A (red), 3 prime.

The reaction arrow shows the consumption of d G T P (blue) and release of P P subscript i.

The product shows the growing primer with the following sequence: 5 prime, G, C, A (red), G (blue) 3 prime.

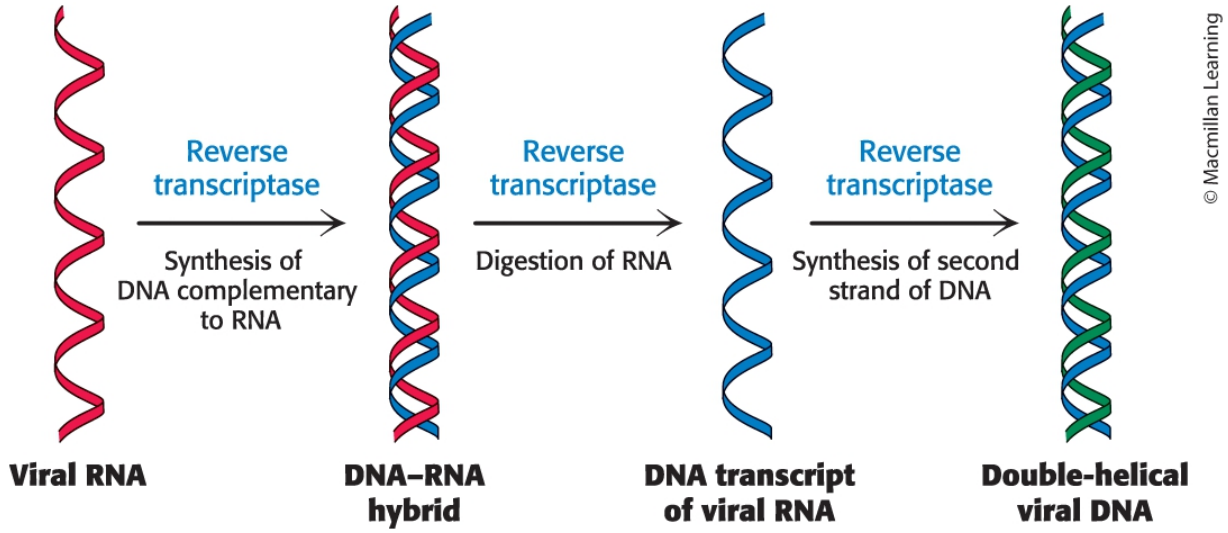
Return to FIGURE 8.23. Schematic illustration of D N A polymerization using the saw-tooth schematic

Extended description for FIGURE 8.24 DNA polymerases catalyze the strand-elongation reaction in the 5'-to-3' direction

The direction of polymerization is from the 5 prime to the 3 prime end. A vertical strip represents the D N A template strand with the top end labeled 3 prime and the bottom end labeled 5 prime. Two bases are highlighted in orange and yellow along the length of the template strand, from top to bottom. The primer strand is shown to the left of the template strand and is anti-parallel to the template strand. The 3 prime terminal nucleotide of the primer strand is base-paired with the orange base of the template strand.

The terminal primer nucleotide has the following structure: A 5-membered heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. The O atom occupies the first position which is the topmost vertex. C 1 is single bonded to the base (green). C 3 is single bonded to O (red) which is single bonded to H on the lower left. C 4 is single bonded to C H 2 which is single bonded to O

on the upper right which is single bonded to the primer strand on the upper left.



A nucleotide triphosphate is shown to react with the terminal primer nucleotide. The nucleotide triphosphate has the following structure: A 5-membered heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 1 is single bonded to the base (purple). The base is aligned with the bottom base of the template strand. C 3 is single bonded to O H on the lower left. C 4 is single bonded to C H 2 which is single bonded to O of a triphosphate group on the upper right. Each phosphate group has a central P atom single bonded to O on the lower right, single bonded to O on the lower left, partially double bonded to O on the upper left, and partially double bonded to O on the upper right. The single bonded O atoms are shared between two adjacent phosphate groups. The terminal phosphate group carries a negative charge of 2 minus and the other two phosphate groups each carries a negative charge. An arrow points from the O of the O H group of the terminal primer nucleotide to the alpha P of the triphosphate. Another arrow points from this P to the single-bonded O on the lower left.

The reaction arrow shows the release of P P subscript i. P P subscript i reacts with H 2 O to give 2 P subscript i.

The product shows the formation of a 3 prime to 5 prime phosphodiester bond between the two nucleotides in the growing primer strand. The purple base of the primer strand is paired with the yellow base of the template strand.

Return to FIGURE 8.24 DNA polymerases catalyze the strand-elongation reaction in the 5'-to-3' direction

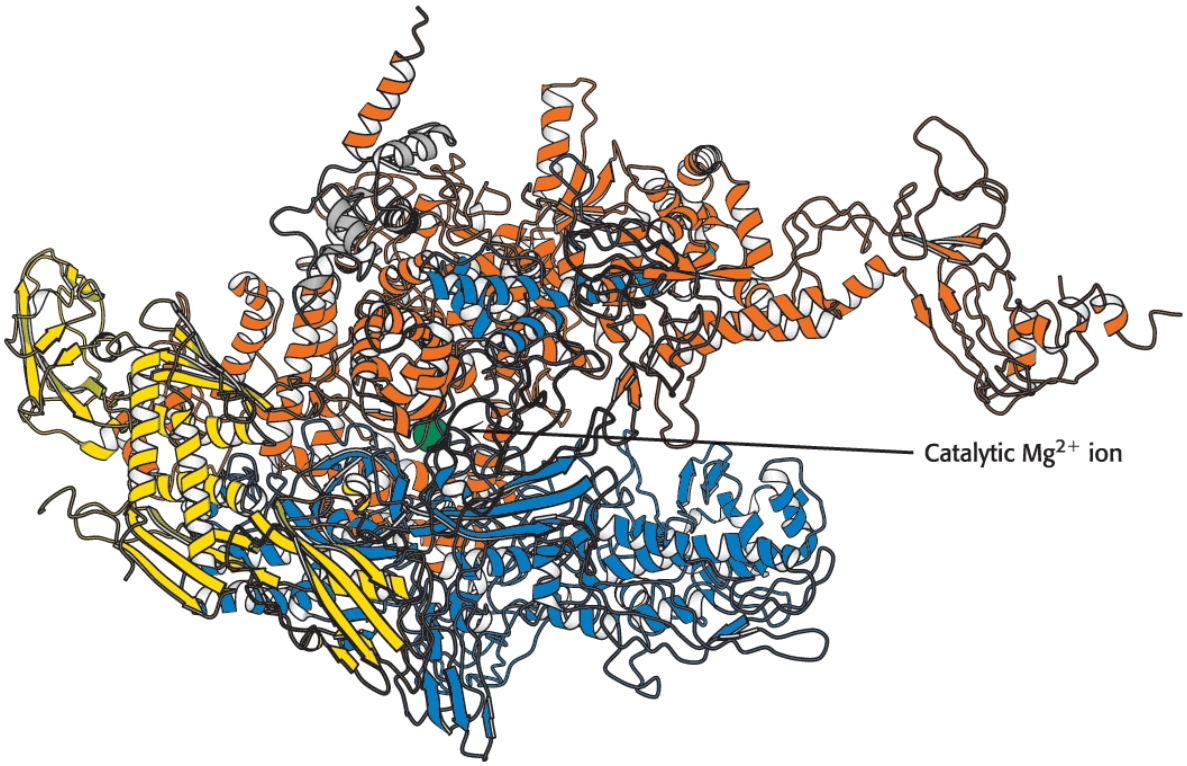
Extended description for FIGURE 8.25. Schematic representation of D N A synthesis from R N A template in retroviruses

Synthesis of D N A complementary to R N A. The viral R N A is represented by a red single helix. An arrow from the viral R N A to the D N A-R N A hybrid is labeled Reverse transcriptase. The D N A-R N A hybrid is represented by a double helix with one red and one blue strand.

Digestion of R N A: An arrow from the D N A-R N A hybrid to the D N A transcript of viral R N A is labeled Reverse transcriptase. The D N A transcript of viral R N A is represented by a blue single helix.

Synthesis of second strand of D N A: An arrow from the D N A transcript of viral R N A to double-helical viral D N A is labeled Reverse transcriptase. The double-helical viral D N A is represented by a double helix with one blue and one green strand.

Return to FIGURE 8.25. Schematic representation of D N A synthesis from R N A template in retroviruses



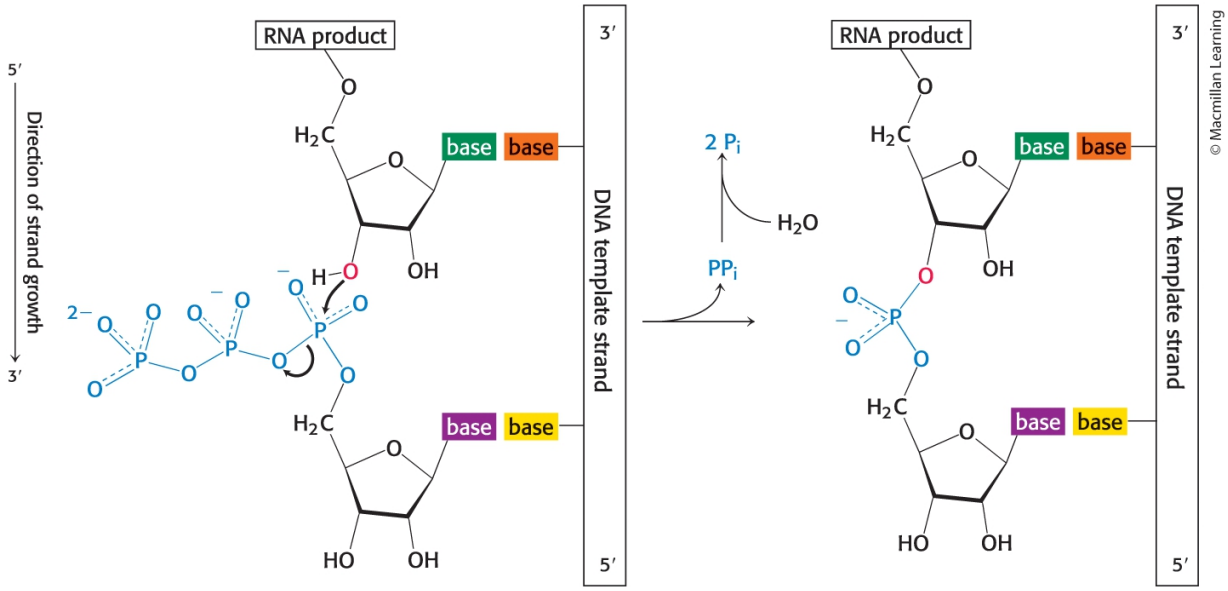
Extended description for Reaction catalyzed by R N A polymerase

$$(\mathrm{RNA})_{n\ \mathrm{residues}} + \mathrm{ribonucleoside\ triphosphate} \rightleftharpoons (\mathrm{RNA})_{n+1\ \mathrm{residues}} + \mathrm{PP_i}$$

The reaction consists of two reactants and two products. The first reactant is open parenthesis R N A close parenthesis with subscript n residues. The second reactant is ribonucleoside triphosphate. A reversible reaction arrow leads to the products. The first product is open parenthesis R N A close parenthesis with subscript n plus 1 residues. The second product is P P subscript i.

Return to Reaction catalyzed by R N A polymerase

Extended description for FIGURE 8.26. Ribbon structure of R N A polymerase



© Macmillan Learning

The multisubunit R N A polymerase enzyme consists of yellow, orange, and blue subunits. The overall shape of the enzyme resembles a crab claw. A green sphere embedded in the center of the enzyme is labeled catalytic M g superscript 2 plus ion.

Return to FIGURE 8.26. Ribbon structure of R N A polymerase

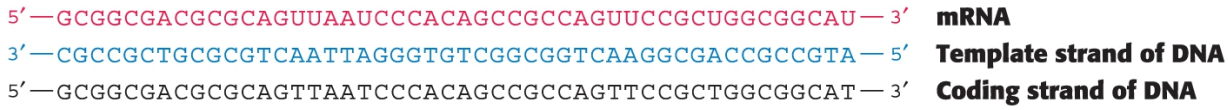
Extended description for FIGURE 8.27. Schematic representation of the elongation of the R N A strand catalyzed by R N A polymerase using D N A as a template

The direction of R N A strand growth is from the 5 prime to the 3 prime end. A vertical strip represents the D N A template strand with the top end labeled 3 prime and the bottom end labeled 5 prime. Two bases are highlighted in orange and yellow along the length of the template strand, from top to bottom. The R N A product strand is shown to the left of the template strand and is anti-parallel to the template strand. The 3 prime terminal nucleotide of the R N A product strand is base-paired with the orange base of the template strand.

The terminal primer nucleotide has the following structure: A 5-membered heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. The O atom occupies the first

position, which is the topmost vertex. C 1 is single bonded to the base (green). C 2 is single bonded to O H. C 3 is single bonded to O (red) which is single bonded to H on the lower left. C 4 is single bonded to C H 2 which is single bonded to O on the upper right which is single bonded to the R N A product strand on the upper left. A nucleotide triphosphate is shown to react with the terminal R N A product nucleotide.

The nucleotide triphosphate has the following structure: A 5-membered heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 1 is single bonded to the base (purple). C 2 and C 3 are each single bonded to O H. C 4 is single bonded to C H 2 which is single bonded to O of a triphosphate group on the upper right. Each phosphate group has a central P atom single bonded to O on the lower right, single bonded to O on the lower left, partially double bonded to O on the upper left, and partially double bonded to O on the upper right. The single bonded O atoms are shared between two adjacent phosphate groups. The terminal phosphate group carries a negative charge of 2 minus and the other two phosphate groups each carry a negative charge.



An arrow points from the O atom of the O H group bound to C 3 of the R N A product nucleotide to the alpha P of the triphosphate. Another arrow points from this P to the single-bonded O on the lower left.

The reaction arrow shows the release of P P subscript i. P P subscript i reacts with H 2 O to give 2 P subscript i.

The product shows the formation of a 3 prime to 5 prime phosphodiester bond between the two nucleotides in the growing R N A product strand. The purple base of the R N A product strand is paired with the yellow base of the D N A template strand.

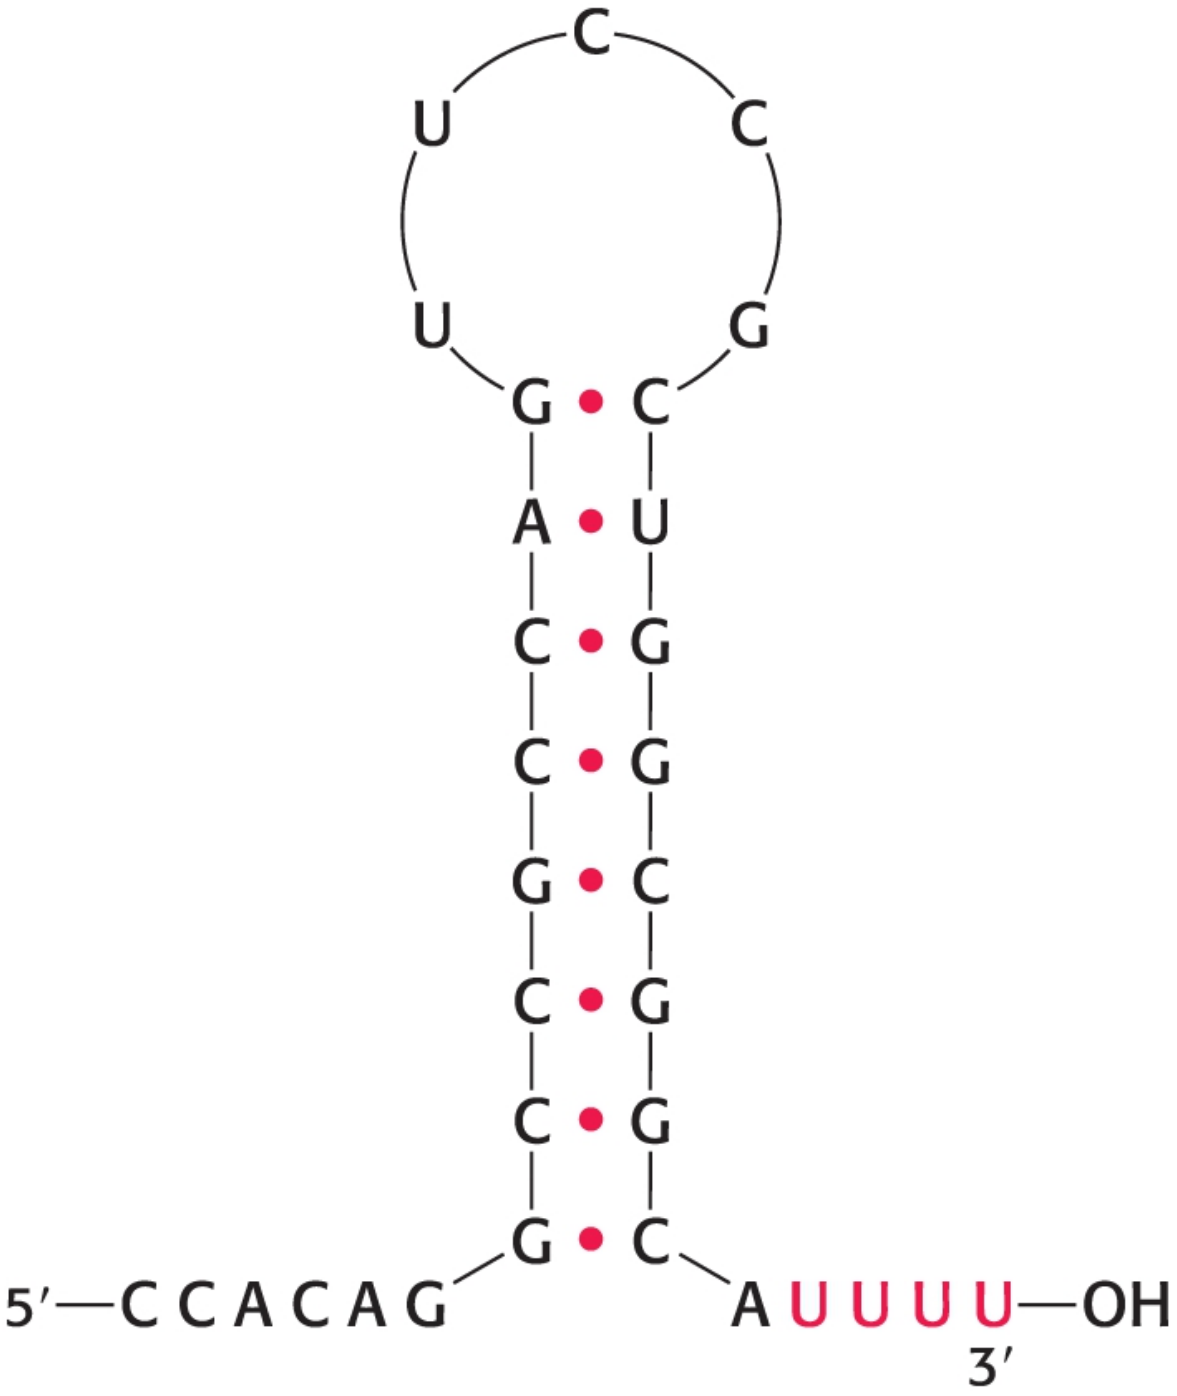
Extended description for FIGURE 8.28. Sequences of m R N A strand, template D N A strand, and coding D N A strand

The orientation of the m R N A strand is 5 prime to 3 prime, from the left to right. It is composed of G, C, A, and U bases. The orientation of the template D N A strand is 3 prime to 5 prime, from the left to right. It is composed of G, C, A, and T bases. The orientation of the coding D N A strand is 5 prime to 3 prime, from the left to right. It is composed of G, C, A, and T bases. The m R N A strand is complementary to the template strand. In the m R N A strand, G is present opposite to C in the template D N A strand, U is present opposite to A in the template D N A strand, and T is present opposite to A in the template D N A strand. The m R N A is identical to the coding D N A strand except for the U replaced with T in the D N A strand. The template strand is complementary to the coding strand.

Return to FIGURE 8.28. Sequences of m R N A strand, template D N A strand, and coding D N A strand

Extended description for FIGURE 8.29. Schematic representation of the prokaryotic and eukaryotic promoter sites

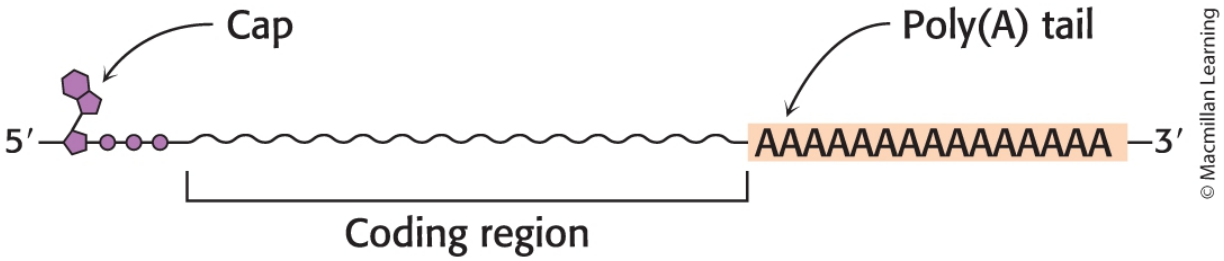


Part (A): Prokaryotic promoter sites. The D N A template is shown to extend to a minus 35 region (blue) with the sequence T T G A C A. This is followed by the Pribnow box (orange) at minus 10 with the sequence T A T A A T. This is followed by a green box labeled plus 1 at the start. The plus 1 mark denotes the start of R N A synthesis.

Part (B): Eukaryotic promoter sites. The D N A template is shown to extend to the C A A T box region (blue) which is sometimes present at minus 75 and has the sequence G G N C A A T C T. This is followed by the TATA box (orange) at minus 25 with the sequence T A T A A A. This is followed by a green box labeled plus 1 at the start. The plus 1 mark denotes the start of R N A synthesis.

Return to FIGURE 8.29. Schematic representation of the prokaryotic and eukaryotic promoter sites

Extended description for FIGURE 8.30. Stem-loop structure at the 3 prime end of an *E.coli* m R N A transcript

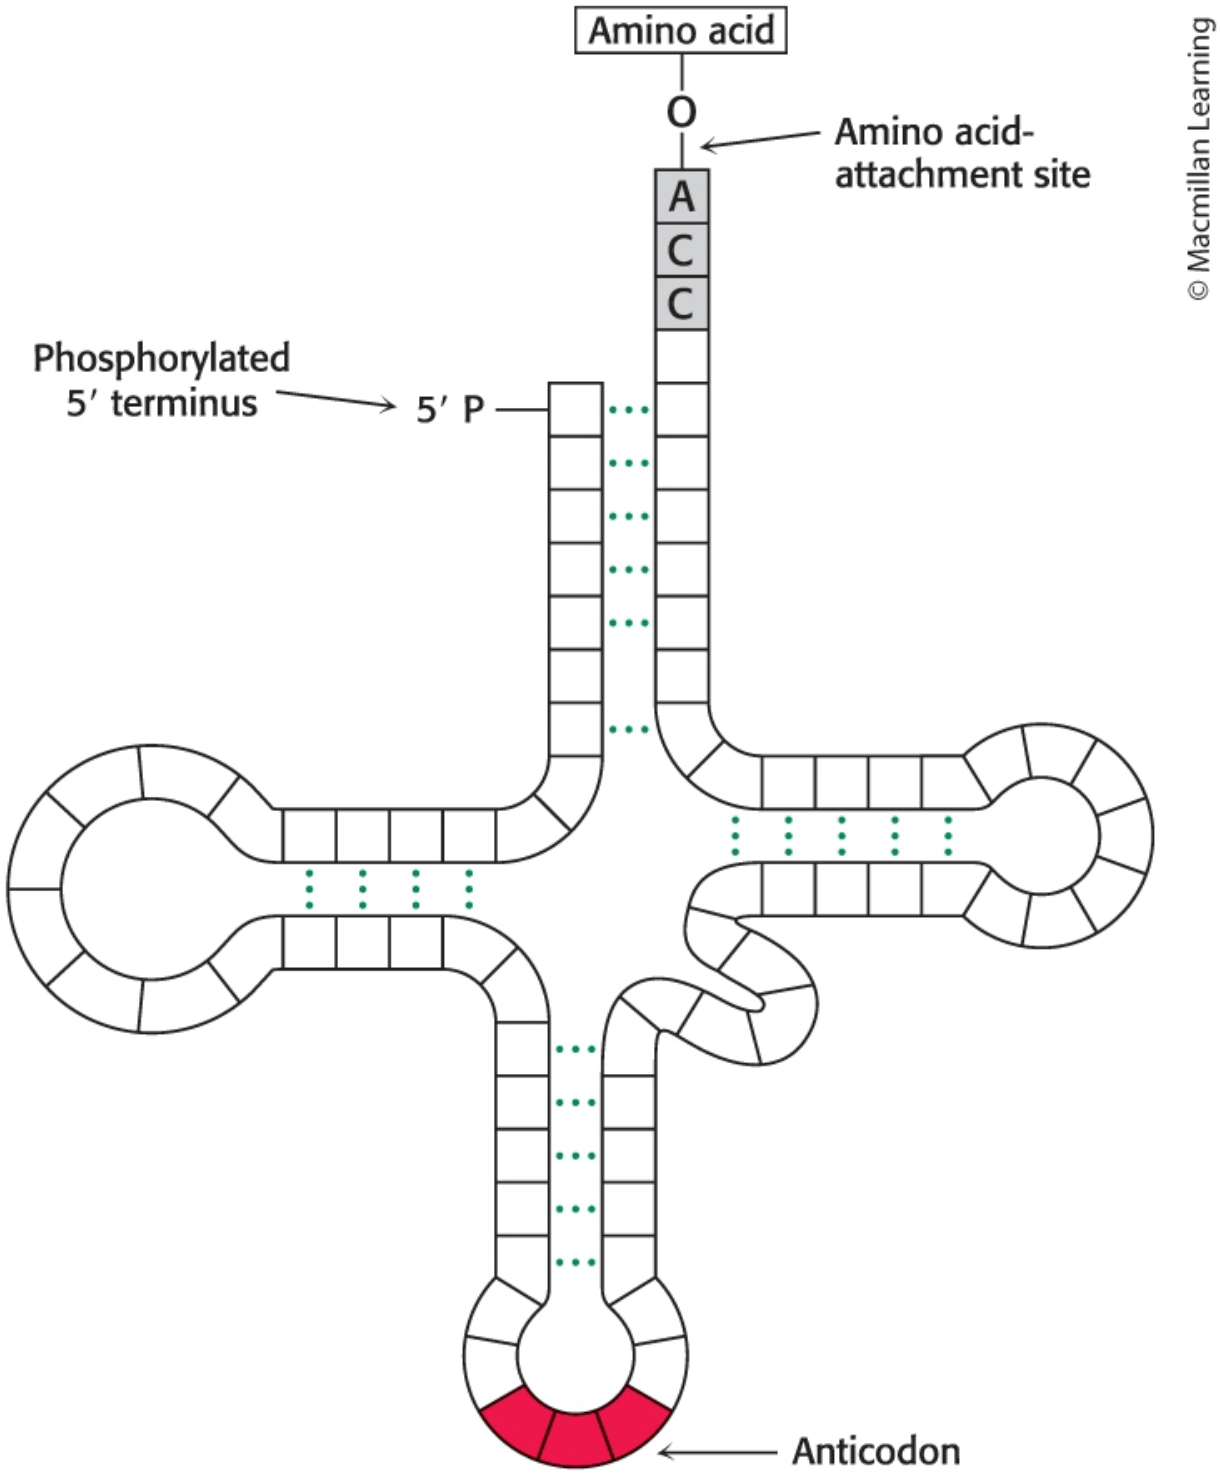


© Macmillan Learning

The stem-loop structure has a 5 prime trail end to the left and a 3 prime trail end to the right. Base pairing between A and U and G and C are shown by red dots along the stem. The loop has 5 nucleotides, U, U, C, C, and G in a clockwise direction starting from the bottom left. The 3 prime end of the stem-loop has a repeating U sequence with an O H terminal. The sequence at the 5 prime end is C C A C A G.

Return to FIGURE 8.30. Stem-loop structure at the 3 prime end of an *E.coli* m R N A transcript

Extended description for FIGURE 8.31. Schematic representation of mRNA in eukaryotes modified after transcription

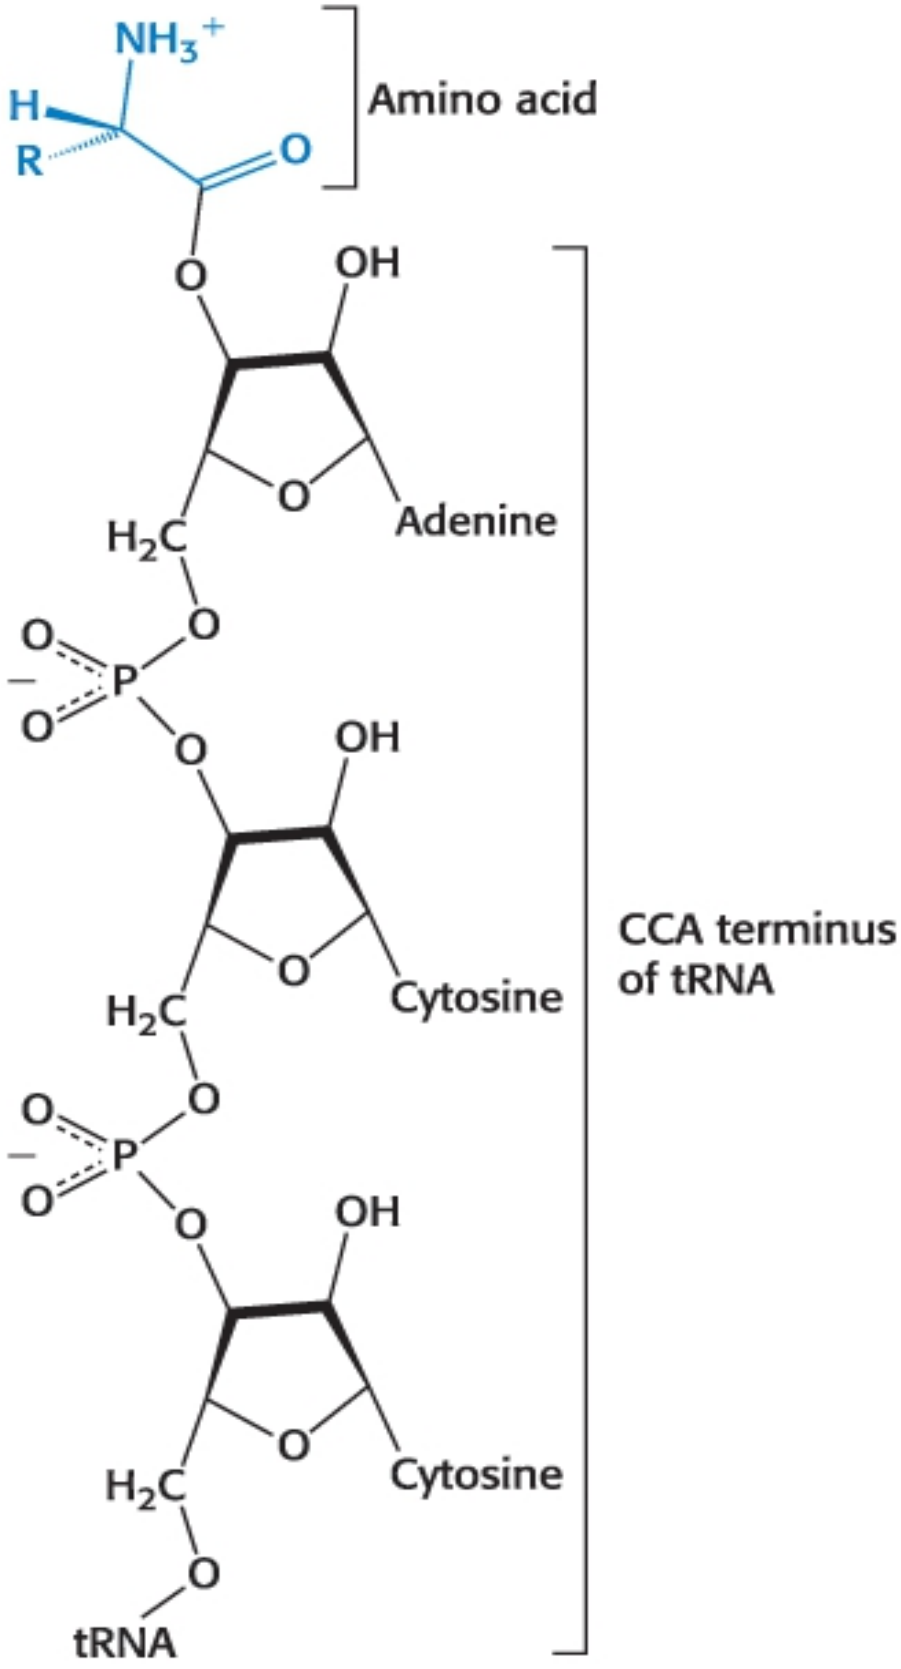


The coding region in the middle is flanked by a cap at the 5 prime end (left) and a Poly (A) tail at the 3 prime end (right). The cap is shown as a purine nucleotide. The poly (A) tail is shown as a repeating A sequence.

Return to FIGURE 8.31. Schematic representation of mRNA in eukaryotes modified after transcription

Extended description for FIGURE 8.32. Structure of a t

R N A molecule



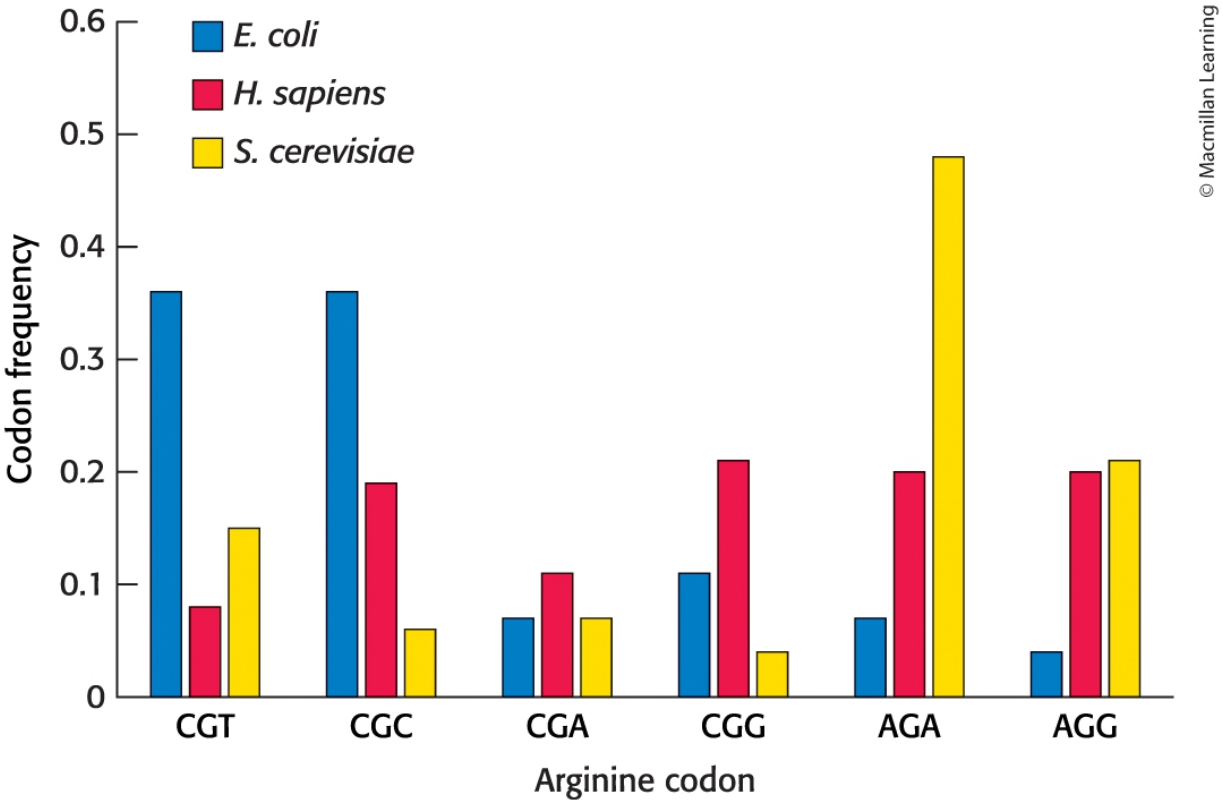
The t R N A molecule is shown to comprise several stem-loop structures formed by a single-strand of R N A via intramolecular hydrogen bonding. The three-dimensional structure resembles a clover leaf structure with 4 arms- 3 long and 1 short arm. The terminal of the left segments of the extended top portion is labeled phosphorylated 5 prime terminus. The left segment has a terminal C C A sequence. An amino acid is single bonded to O which is single bonded to the terminal base A. This site is labeled amino-acid attachment site. The three bases at the bottom loop are highlighted in red and labeled anticodon. A short loop is present between the right and bottom loops.

Return to FIGURE 8.32. Structure of a t R N A molecule

Extended description for FIGURE 8.33. The structure of

amino acyl-t R N A

Aminoacyl-tRNA



Amino acyl-t R N A:

The amino acid (blue) has the following structure: A central C atom is single bonded to N H 3 superscript plus above, wedge bonded to H on the left, dash bonded to R on the lower left, and single bonded to a central C atom on the lower right. This C atom is double bonded to O on the upper right and single bonded to O of a nucleotide of the C C A terminus of t R N A below.

The nucleotide has the following structure: A 5-membered heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. The O atom occupies the first position which is the bottom-most vertex. C 1 is single bonded to C H 2. C 2 is single bonded to O which is single bonded to the amino acid. C 3 is single bonded to O H. C 4 is single bonded to Adenine on the lower right. C H 2 bonded to C 1 is single bonded to O on the lower right which is single bonded to P on the lower left. P is partially double bonded to O on the upper left, partially double bonded to O on the lower left, and single bonded to O on the lower right. The partially double-bonded O atoms carry a negative charge. The O on the lower right is single bonded to C 2 of the pentagonal ring of the next nucleotide, cytosine. This is further linked to another cytosine below.

Return to FIGURE 8.33. The structure of amino acyl-t R N A

Extended description for FIGURE 8.34. Graphical representation of arginine codon usage preference in different species

Extended description for FIGURE 8.38. Schematic representation of the location of splice sites in an m R N A

The order of sequences from the 5 prime to the 3 prime end in the left to right direction are as follows: Exon 1 (blue), 5 prime splice site, G U (red), m R N A stretch, pyrimidine tract (yellow), A G (green), 3 prime splice site, exon 2 (blue). The region of m R N A between the 5 prime and the 3 prime splice site is labeled intron.

Return to FIGURE 8.38. Schematic representation of the location of splice sites in an m R N A

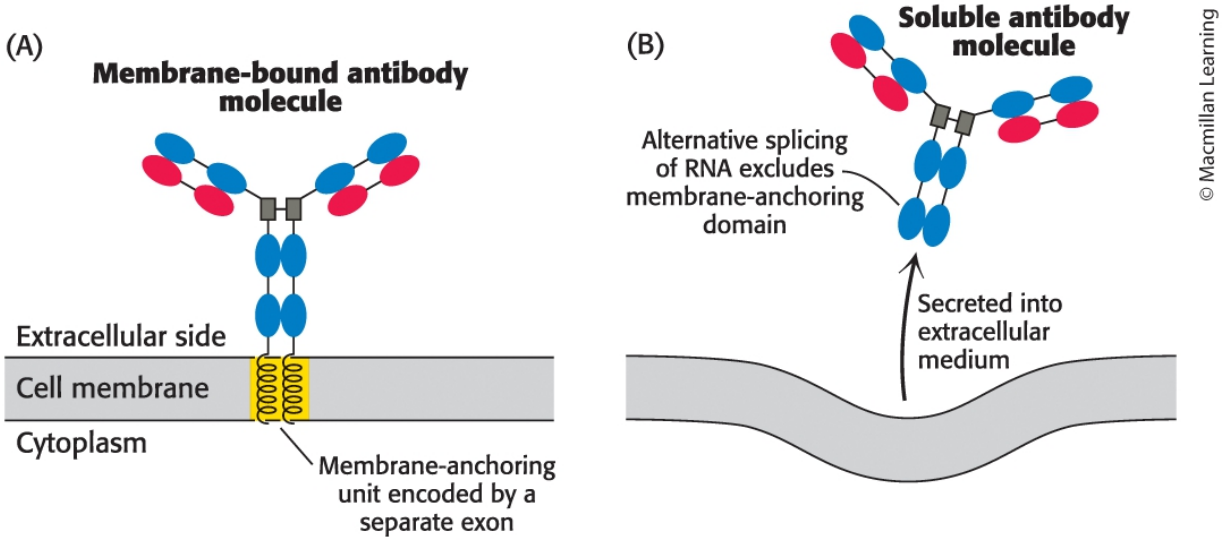
Extended description for FIGURE 8.39 The tissue plasminogen activator (TPA) gene was generated by exon shuffling

Portions of ancestral genes:

Epidermal growth factor gene with multiple E G F exons: A stretch of a gene is shown with E G F exons (green) interspersed with short introns.

Epidermal growth factor gene with multiple "finger" exons: A stretch of a gene is shown with short F exons (pink) interspersed with introns.

Plasminogen gene with a "kringle" exon: A gene is shown with one K exon (purple) flanked by two introns on either side.



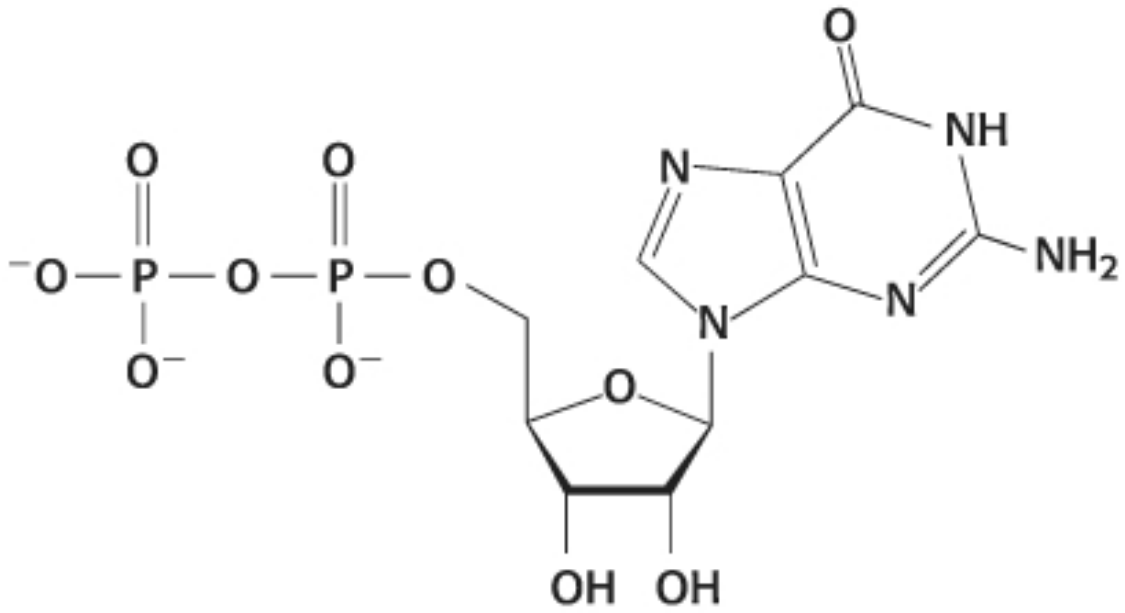
T P A gene as it exists today:

An arrow each from the E G F exon, F exon, and K exon to the T P A gene is labeled Exon shuffling.

The sequence of the T P A gene is as follows: Intron, F exon, intron, E G F exon, intron, K exon, intron, K exon, intron. An arrow from the first K exon to the next K exon in the T P A gene is labeled Exon duplication.

Return to FIGURE 8.39 The tissue plasminogen activator (TPA) gene was generated by exon shuffling

Extended description for FIGURE 8.40. Schematic illustration of membrane-bound and soluble antibody molecules generated by alternative splicing

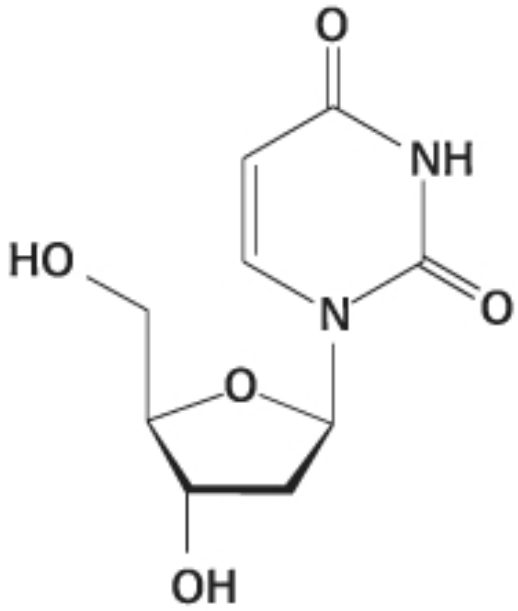


Part (A): Membrane-bound antibody molecule. A horizontal strip is labeled Cell membrane which separates the extracellular side above from the Cytoplasm below. A pair of vertical yellow coils are shown embedded in the cell membrane and labeled Membrane-anchoring unit encoded by a separate exon. A Y-shaped antibody molecule is shown adhered to the membrane-anchoring units. The antibody has two blue heavy chains forming the Y-shape. A short red light chain is linked in parallel to each top arm of the heavy chain.

Part (B): Soluble antibody molecule. The cell membrane is shown to curve slightly inward forming a bowl shape. The Y-shaped antibody molecule is shown to be secreted into the extracellular medium. An arrow directed to the bottom of the antibody is labeled Alternative splicing of R N A excludes membrane-anchoring domain.

Return to FIGURE 8.40. Schematic illustration of membrane-bound and soluble antibody molecules generated by alternative splicing

Extended description for Chemical structure



The structure is as follows: A 5-membered heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 above in the form of a line that is further single bonded to O on the upper left. O is single bonded to P, single bond, O, single bond, P, single bond, O superscript minus. Each P is double bonded to O above and single bonded to O superscript minus below. C 1 is single bonded to the first N of a 5-membered heterocyclic pentagonal ring in a horizontal orientation. The ring consists of 2 N and 3 C atoms. The first N occupies the first position which is the bottom left vertex and the second N occupies the third position which is the top left vertex. C 1 occupies the leftmost vertex. A double bond is present between C 1 and the second N. The pentagonal ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 of the hexagonal ring respectively. The hexagonal ring consists of 2 N and 4

C atoms. The first N atom bound to H occupies the first position, which is the top right vertex and the second N atom occupies the third position, which is the bottom-most vertex. C 1 occupies the bottom right vertex. A double bond is present between C 1 and the second N and C 2 and C 3. C 1 is single bonded to N H 2 on the lower right. C 4 is double bonded to O above.

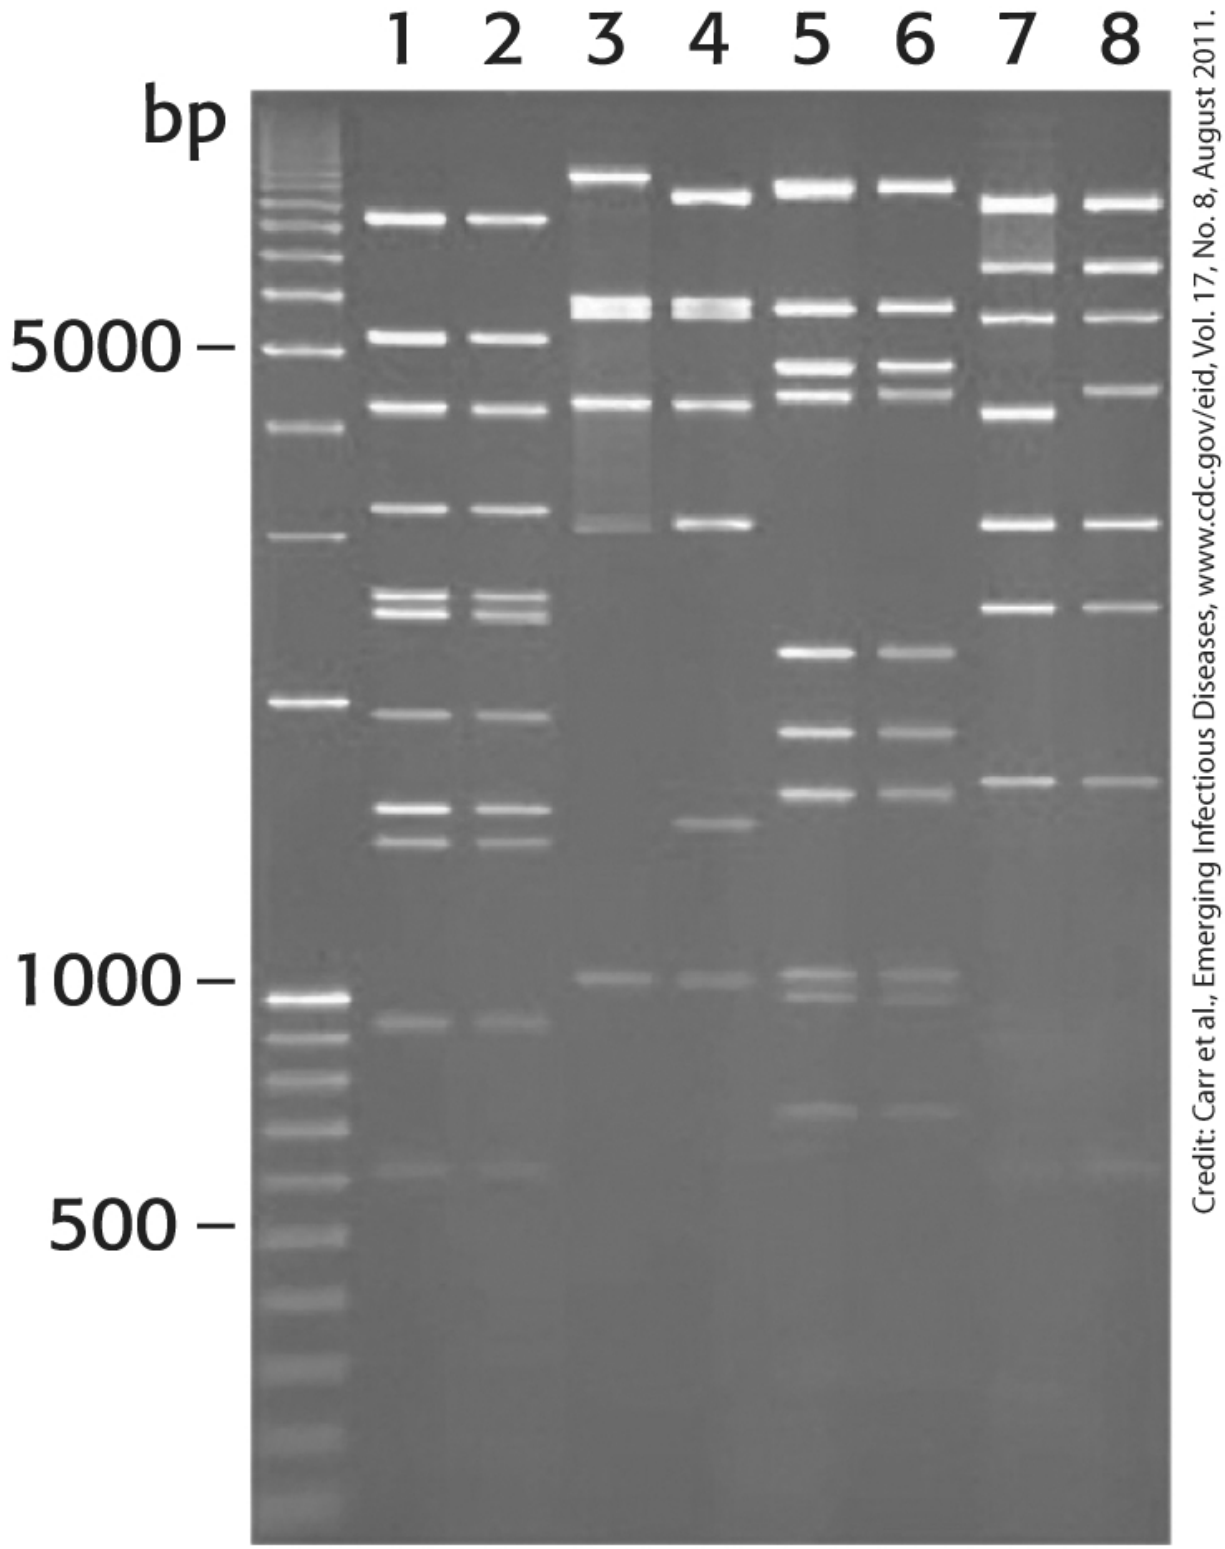
Double stranded palindromic D N A sequences are shown along with the corresponding cleavage sites of the following enzymes:

Bam H roman number 1: The D N A sequence in the 3 prime to 5 prime direction is C, C, T, A, G, G. The symmetry axis is indicated to be between T and A at the third and fourth positions, respectively, from the 3 prime end. The cleavage site on each strand is between G and G at the first and second positions, respectively, from the 5 prime end.

Eco R roman number 1: The D N A sequence in the 3 prime to 5 prime direction is C, T, T, A, A, G. The symmetry axis is indicated to be between T and A at the third and fourth positions, respectively, from the 3 prime end. The cleavage site on each strand is between G and A at the first and second positions, respectively, from the 5 prime end.

H a e roman number 3: The D N A sequence in the 3 prime 5 prime direction is C, C, G, G. The symmetry axis is indicated to be between C and G at the second and third positions, respectively, from the 3 prime end. The cleavage site on each strand is between C and G at the second and third positions, respectively, from the 3 prime end.

H h a roman 1: The D N A sequence in the 3 prime to 5 prime direction is C, G, C, G. The symmetry axis is indicated to be between G and C at the second and third positions, respectively, from the 3 prime end. The cleavage site on each strand is between C and G at the first and second positions, respectively, from the 3 prime end.



X h o 1: The D N A sequence in the 3 prime to 5 prime direction is G, A, G, C, T, C. The symmetry axis is indicated to be between G and C at the third and fourth positions, respectively, from the 3 prime end.

The cleavage site on each strand is between T and C at the fifth and sixth positions, respectively, from the 3 prime end.

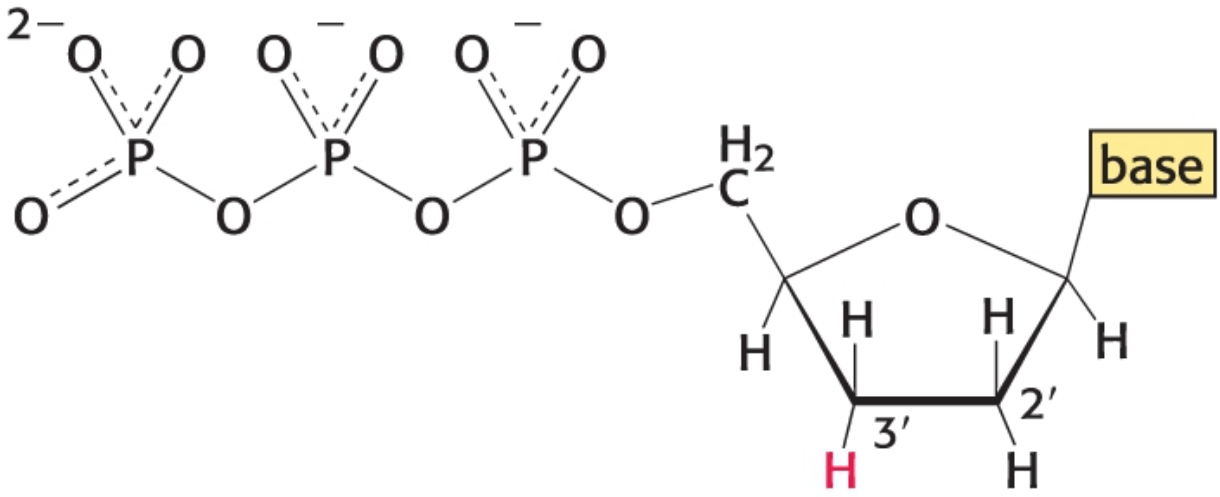
Step 1: The template strand has the following sequence in the 3 prime to 5 prime direction, from left to right: G, A, A, T, T, A, T, C, A, C, A, G, T, G. The complementary primer has the following sequence in the 5 prime to 3 prime direction, from left to right: C, T, T, A, A. D N A Polymerase roman number 1 is added along with excess unlabeled nucleotides (d A T P, d C T P. d G T P, T T P). Fluorescently labeled dideoxy analogs are also added and color coded as follows: d d A T P (green), d d C T P (blue), d d G T P(orange), and d d T T P (red).

Step 2: Strand separation.



Step 3: The template strand is illustrated at the top. This is followed by the newly synthesized strands in increasing order of length, from top to bottom, such that the successive strands terminate at a base one position further down the preceding strand along the 5 prime to 3 prime direction. For each new strand, the terminal nucleotide is labeled with a dideoxy analog.

Step 4: Capillary electrophoresis.

Step 5: A graph depicts the sequence of the newly synthesized strand as the primer is extended. The horizontal axis is labeled elution time from capillary. The vertical axis is labeled fluorescence intensity. Peaks of varying height are observed whose colors correspond to the respective terminating dideoxy analog. The order of the peaks represents the sequence of the complement, which is as follows: T, A, G, T, G, T, C, A, C.

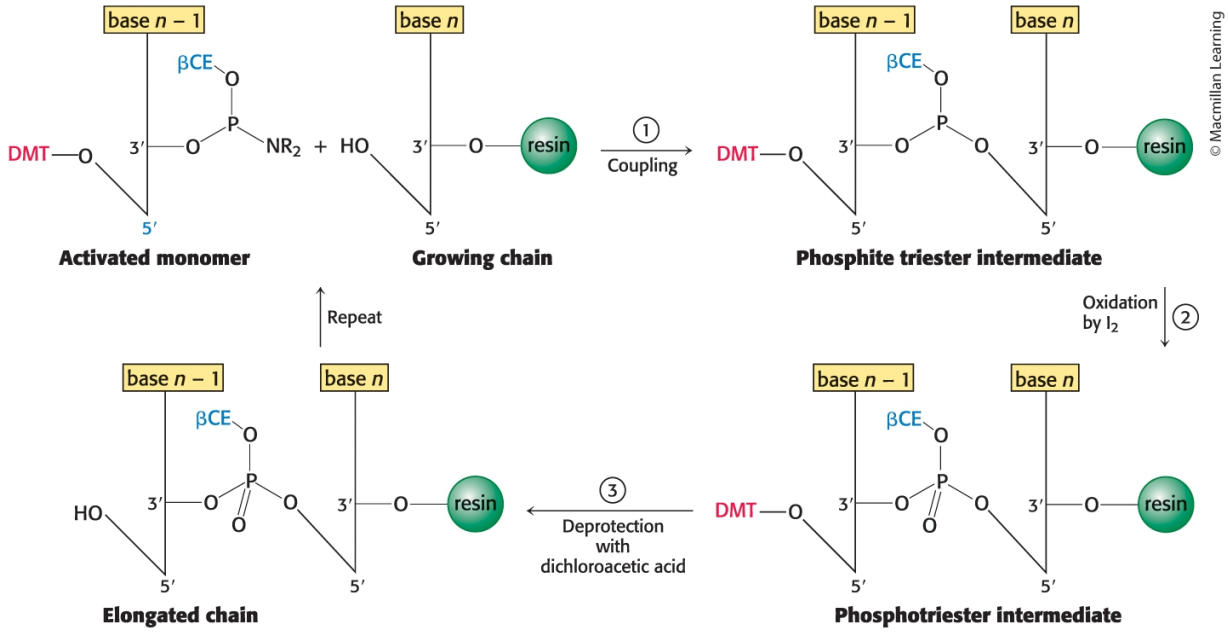
Extended description for Chemical Structure of 2 prime, 3 prime-dideoxy analog



2′, 3′-Dideoxy analog

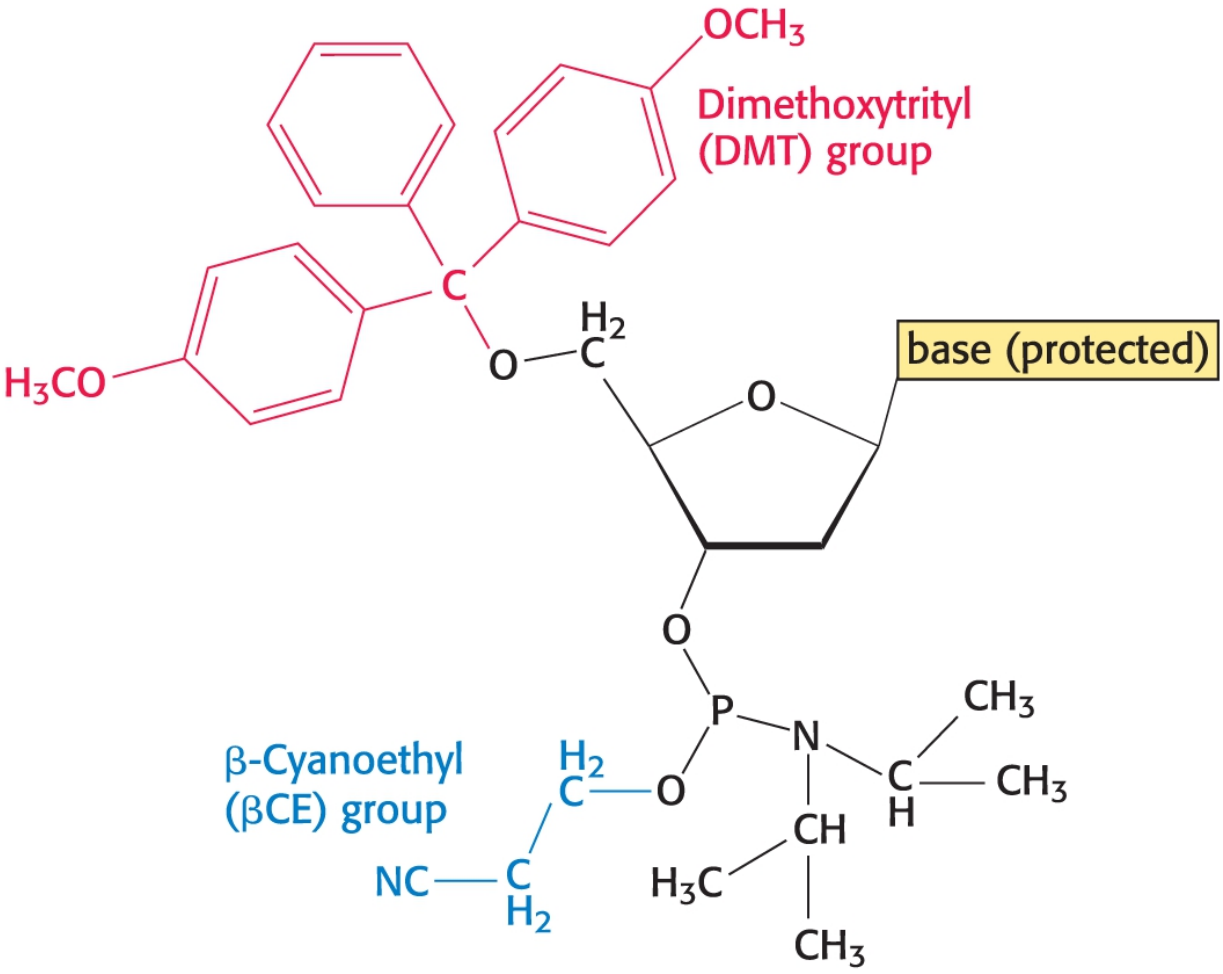
The structure is as follows: A 5-membered heterocyclic pentagonal ring in a vertical orientation consists of 1 and 4 C atoms. The O atom occupies the first position which is the topmost vertex. C 1 is single bonded to a base at the top right and single bonded to H on the bottom right. C 2 is labeled 2 prime and is single bonded to H above and single bonded to H on the lower right. C 3 is labeled 3 prime and is single bonded to H above and single bonded to H on the lower left which is colored red. C 4 is single bonded to H on the lower left and single bonded to C H 2 on the upper left. C H 2 is single bonded to O of a triphosphate group. The terminal phosphate group carries 2 minus charge and has a central P atom that is partially double bonded to O on the upper left, partially double bonded to O on the upper right, partially double bonded to O on the lower left, and single bonded to O on the lower right. Each of the other two phosphate groups has a central P atom single bonded to O on the lower right, single bonded to O on the lower left, partially double

bonded to O on the upper left, and partially double bonded to O on the upper right. The single bonded O atoms are shared between two adjacent phosphate groups. These two phosphate groups each carry a negative charge.

Return to Chemical Structure of 2 prime, 3 prime-dideoxy analog

Extended description for Stepwise illustration of the Phosphite triester method of oligonucleotide synthesis

Step 1: Coupling. The reaction consists of two reactants and one product. The first reactant is labeled Activated monomer and has the following structure: The sugar is represented by a vertical line with the top labeled 3 prime and the bottom labeled 5 prime. The 3 prime carbon is single bonded to base n minus 1 above and single bonded to O on the right. O is single bonded to P on the upper right. P is single bonded to N R 2 on the lower right and single bonded to O above which is single bonded to beta C E (blue) on the upper left. The 5 prime carbon is single bonded to O on the upper left which is single bonded to D M T (red) on the left. The second reactant is labeled growing chain and has the following structure: The sugar is represented by a vertical line with the top labeled 3 prime and the bottom labeled 5 prime. The 3 prime carbon is single bonded to base n above and single bonded to O on the right. O is single bonded to resin represented by a green circle on the right. The 5 prime carbon



is single bonded to O H on the upper left. The product is labeled phosphite triester intermediate and has the following structure: It is represented by the formation of a link between the two reactants. The P of the activated monomer is single bonded to O on the lower right which is single bonded to the 5 prime carbon of the growing chain.

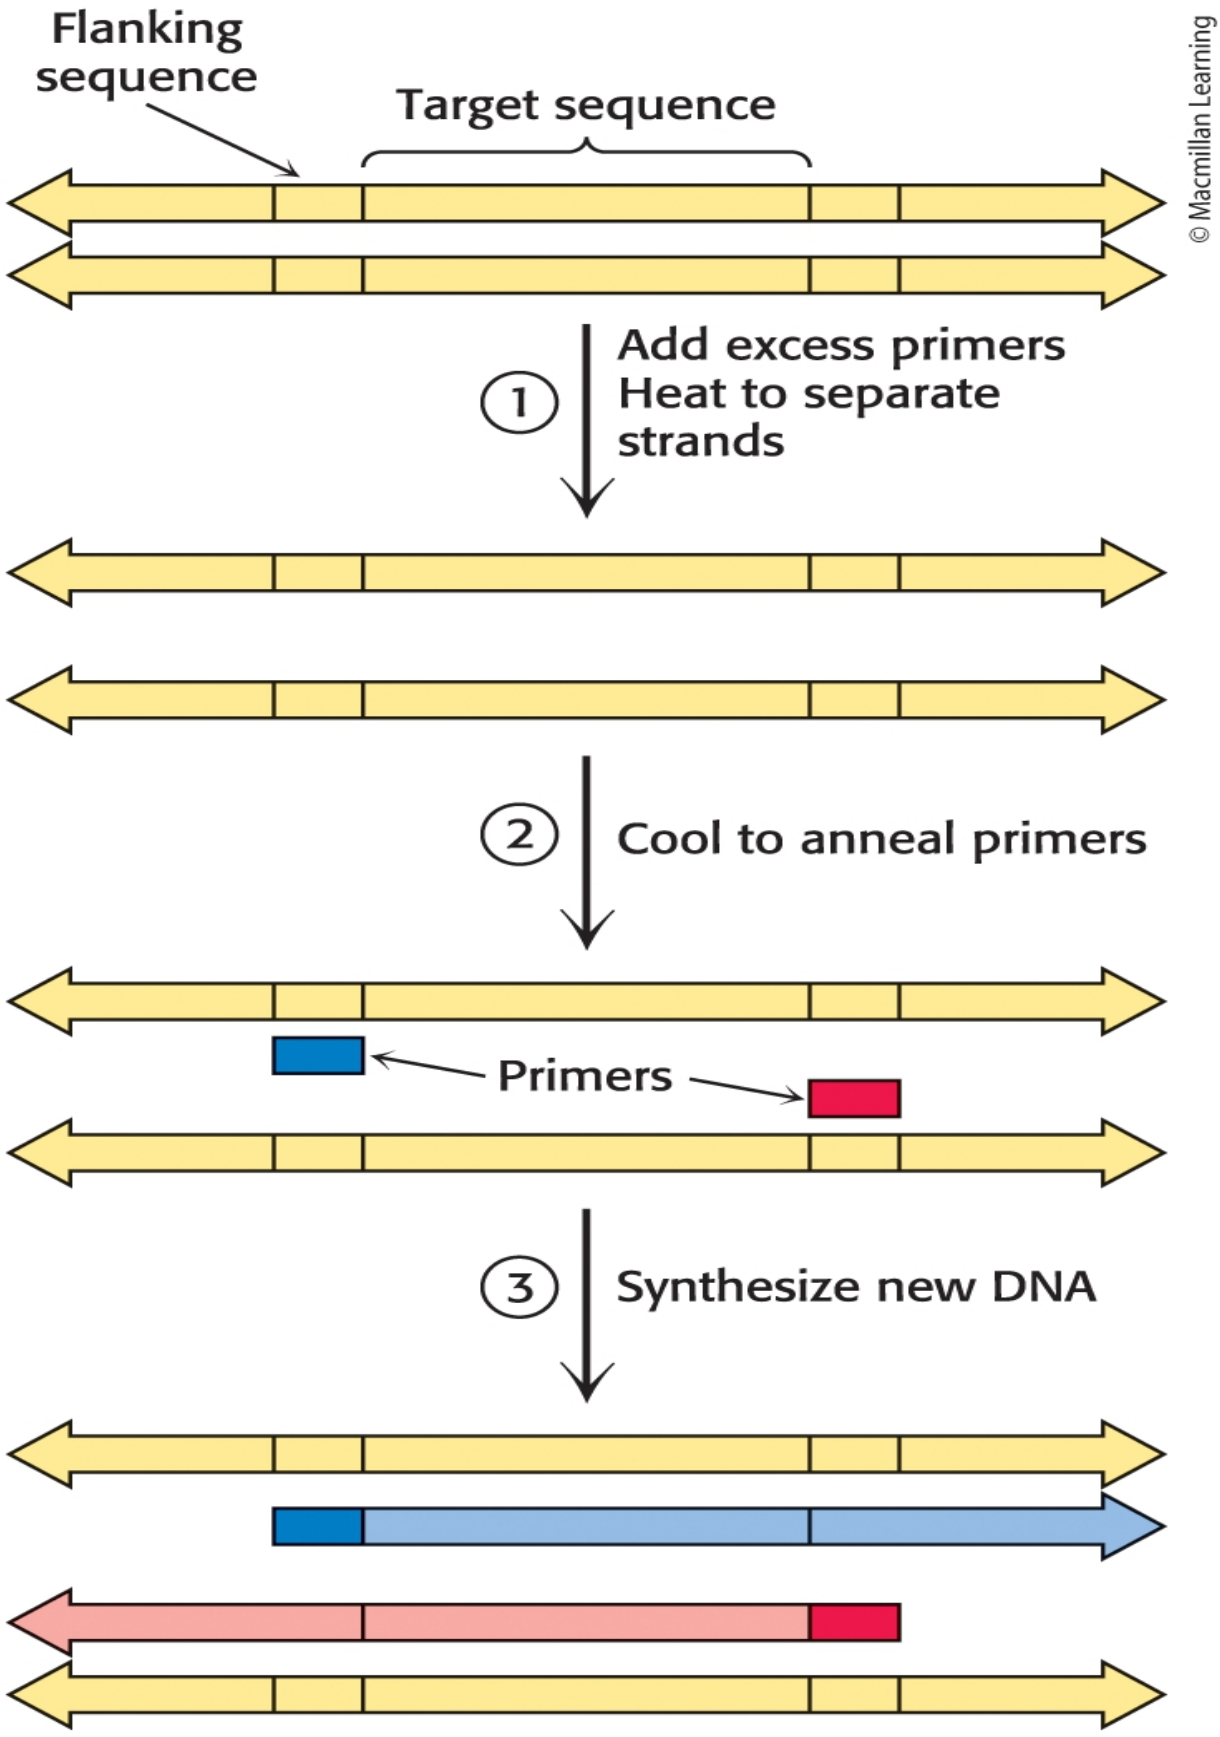
Step 2: Oxidation by I 2. Phosphite triester intermediate is converted into phosphotriester intermediate, which has a similar structure to the former except that P is also double bonded to O on the lower left.

Step 3: Deprotection with dichloroacetic acid. Phosphotriester intermediate forms the product, elongated chain, which has a similar structure to the former except the O atom single bonded to the 5 prime carbon of the n minus 1 nucleotide is bound to H instead of D M T. An arrow from this product points at the reactants of step 1 and is labeled Repeat.

Return to Stepwise illustration of the Phosphite triester method of oligonucleotide synthesis

Extended description for Structure of a deoxyribonucleoside 3 prime phosphoramidite with D M T and beta C E attached

A deoxyribonucleoside 3′-phosphoramidite with DMT and βCE attached



A 5 carbon heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 1 is single bonded to a protected base on the upper right. C 3 is single bonded to O which is single bonded to P on the lower right. P is single bonded to O on the

lower left and single bonded to N on the lower right. The O on the lower left is single bonded to C H 2 on the left which is single bonded to C H 2 on the lower left which again is single bonded to C N on the left. The C H 2, single bond, C H 2, single bond, C N group is highlighted in blue and labeled beta-Cyanoethyl group or beta C E group. The N atom single bonded to P is single bonded to C H on the lower right and single bonded to C H below. The C H on the lower right is single bonded to C H 3 on the upper right and single bonded to C H 3 on the right. The C H below is single bonded to C H 3 below and single bonded to C H 3 on the lower left. C 4 of the pentagonal ring is single bonded to C H 2 which is single bonded to O on the lower left. O is bonded to a dimethoxytrityl group or D M T group highlighted in red. O is single bonded to a central C atom. C is single bonded to C 4 of a benzene ring in a horizontal orientation on the upper right. The benzene ring has three alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 1 of the benzene ring is single bonded to O C H 3. The central C atom is single bonded to C 4 of another benzene ring in a horizontal orientation on the left. This benzene ring has three alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 1 is single bonded to O C H 3 on the left. The central C atom is single bonded to C 4 of another benzene ring in a vertical orientation. This benzene ring has three alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6.

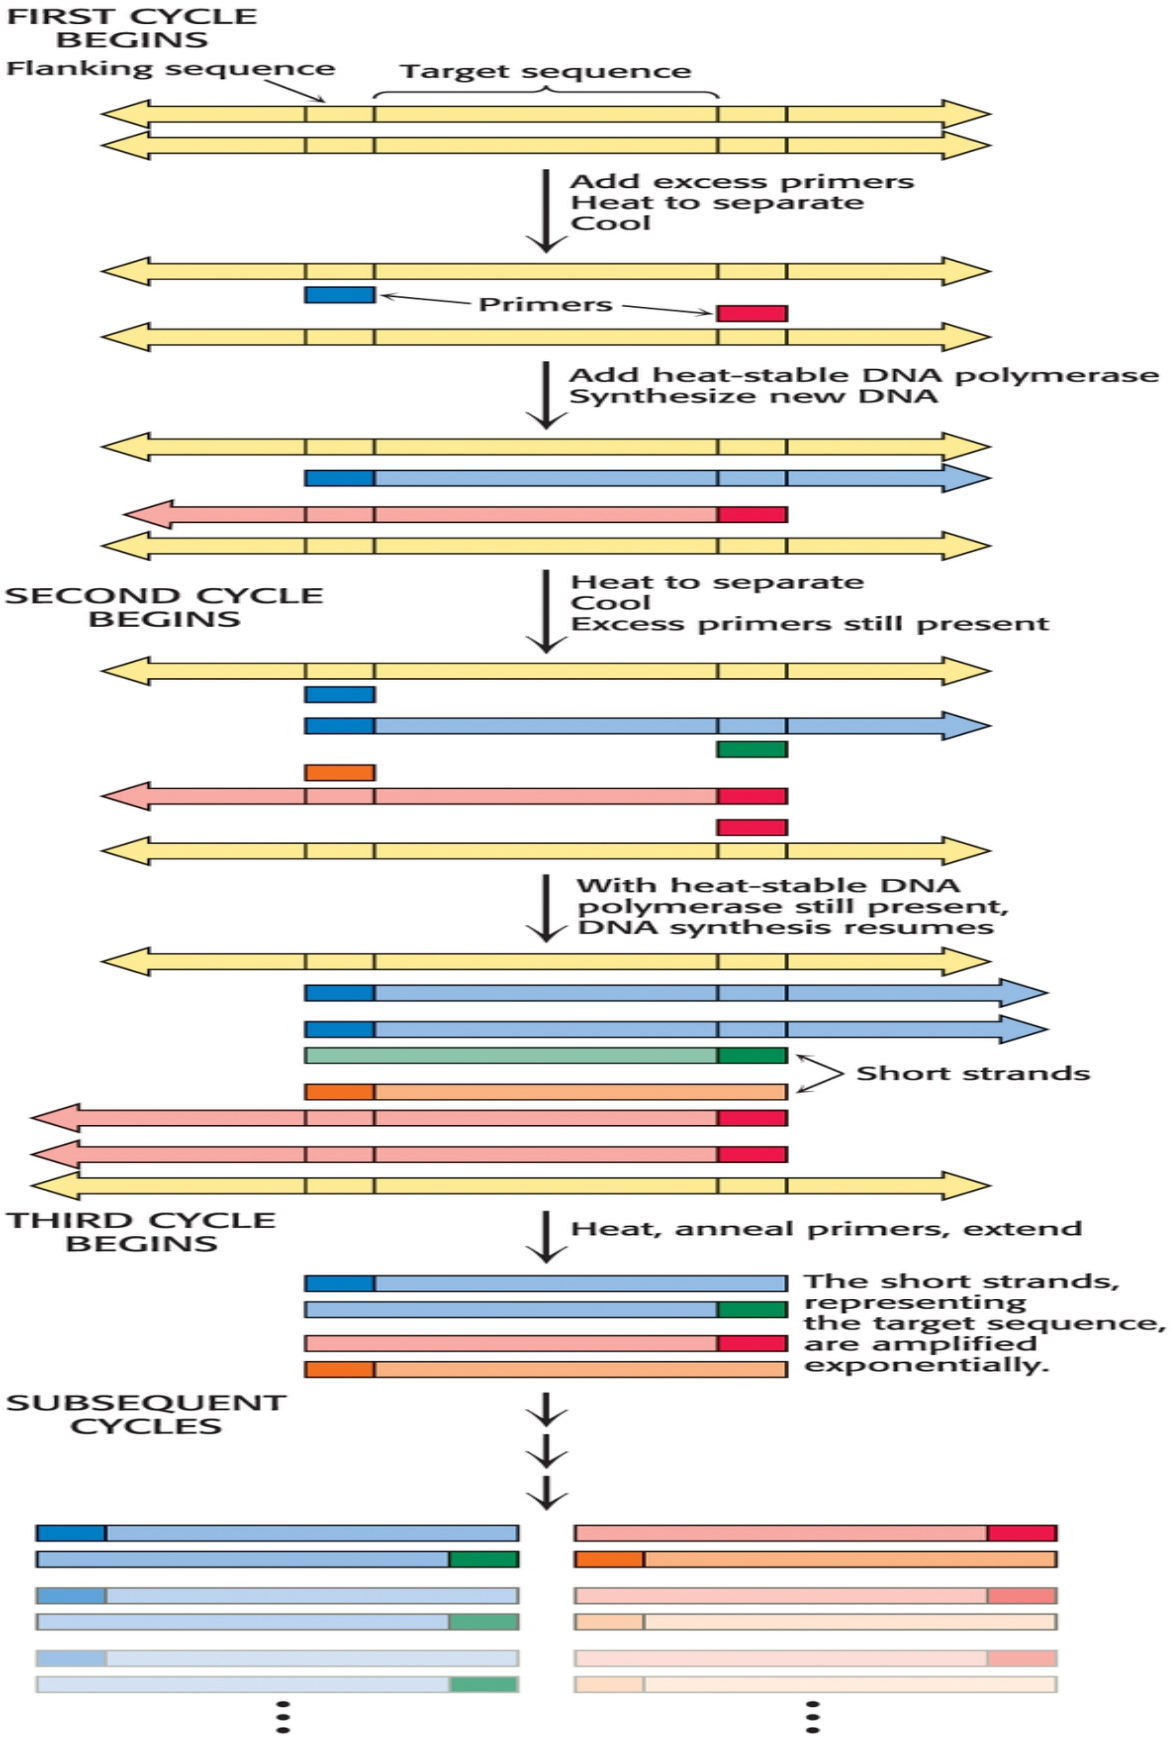
Extended description for Schematic illustration of the

steps of the first cycle of Polymerase Chain Reaction

© Macmillan Learning

Step 1: Add excess primers. Heat to separate strands. Two parallel double headed arrows represent a double-stranded D N A molecule. A region in the middle of both the strands is labeled Target sequence. Each target sequence is flanked on both sides by short sequences labeled Flanking sequence. The strands are shown to separate upon heating.



Step 2: Cool to anneal primers. A short primer colored blue is shown to anneal to the left flanking sequence of the top strand. A short primer colored red is shown to anneal to the right flanking sequence of the bottom strand.

Step 3: Synthesize new D N A. The blue primer annealed to the top strand is shown to extend in the rightward direction. The red primer annealed to the bottom strand is shown to extend in the leftward direction. This gives two D N A molecules.

multiple cycles of Polymerase Chain Reaction

FIRST CYCLE BEGINS
Flanking sequence
Target sequence
Add excess primers
Heat to separate
Cool
Primers
Add heat-stable DNA polymerase
Synthesize new DNA
SECOND CYCLE BEGINS
Heat to separate
Cool
Excess primers still present
With heat-stable DNA polymerase still present, DNA synthesis resumes
Short strands
THIRD CYCLE BEGINS
Heat, anneal primers, extend
The short strands, representing the target sequence, are amplified exponentially.
SUBSEQUENT CYCLES
© Macmillan Learning

First cycle begins:

Step 1: Add excess primers. Heat to separate strands. Cool. Two parallel double headed arrows represent a double-stranded D N A molecule. A region in the middle of both the strands is labeled Target sequence. Each target sequence is flanked on both sides by short sequences labeled Flanking sequence. The strands are shown to separate upon heating. A short primer colored blue is shown to anneal to the left flanking sequence of the top strand. A short primer colored red is shown to anneal to the right flanking sequence of the bottom strand.

Step 2: Add heat-stable D N A polymerase. Synthesize new D NA. The blue primer annealed to the top strand is shown to extend in the rightward direction. The red primer annealed to the bottom strand is shown to extend in the leftward direction. This gives two D N A molecules.

Second cycle begins:

Step 3: Heat to separate. Cool. Excess primers are still present. The newly synthesized strands are shown to separate. A blue primer is shown to anneal to the left flanking sequence of the top strand. A green primer is shown to anneal to the right flanking sequence of the newly synthesized blue strand. An orange primer is shown to anneal to the left flanking sequence of the newly synthesized red strand. A red primer is shown to anneal to the right flanking sequence of the bottom strand. With heat-stable D N A polymerase still present, D N A synthesis resumes. The blue primer is shown to extend in the rightward direction and the red primer is shown to extend in the leftward direction. The green primer extends leftward until the left flanking sequence and the orange primer extends rightward until the right flanking sequence. The green and orange

strands are labeled short strands which include the target sequence and the flanking sequences.

Third cycle begins:

Step 4: Heat, anneal primers, extend. The short strands representing the target sequence are shown to be amplified exponentially. Two short double stranded D N A molecules are shown.

Subsequent cycles:

Several short double stranded D N A molecules representing the target and flanking sequence are shown.

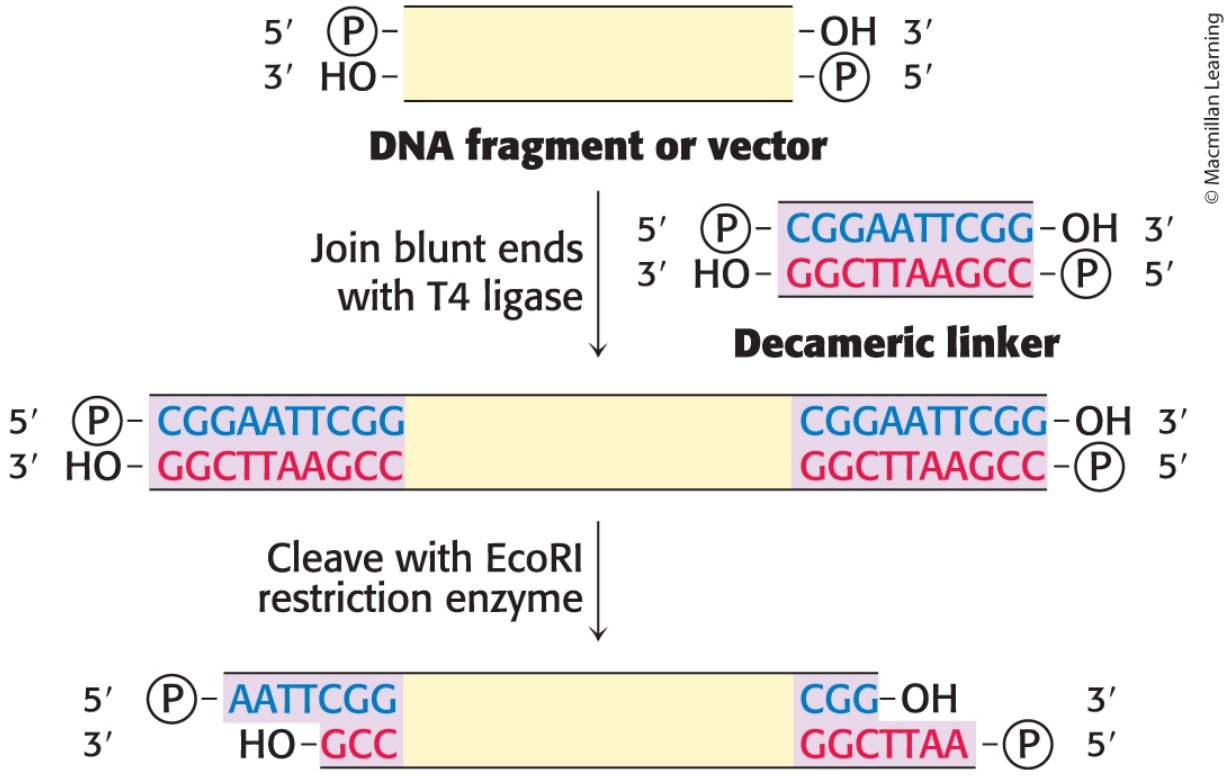
Extended description for Schematic illustration of cohesive-end method of D N A ligation



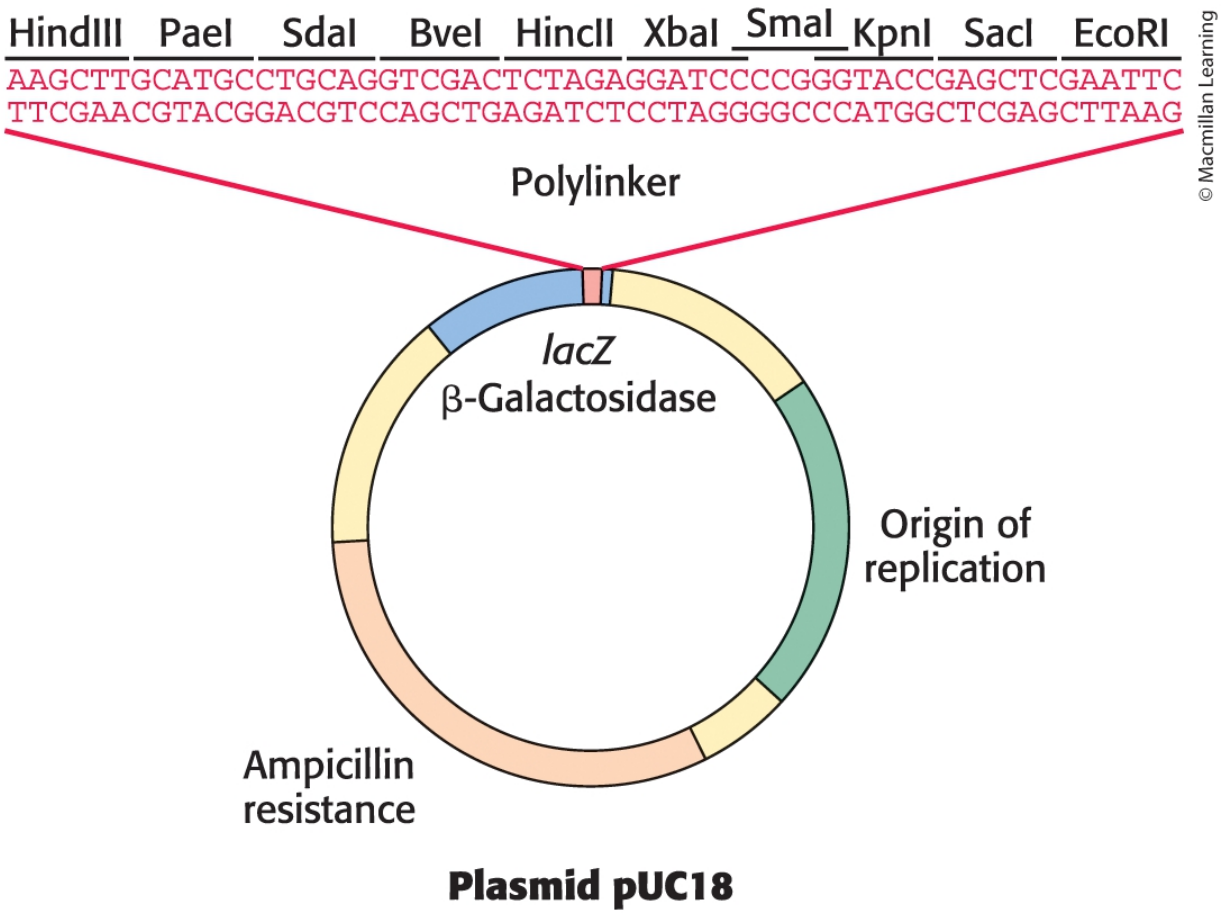
© Macmillan Learning

Step 1: Cleave with Eco R roman number 1 restriction enzyme. A circular plasmid labeled p S C 1 0 1 is shown in blue. The palindromic recognition sequence, in the clockwise direction, in the outer strand is G A A T T C. The cleavage is shown to take place between G and A leaving complementary cohesive ends on both the inner and outer strands. A straight D N A fragment is shown in red. It has the same recognition sequence as that of the plasmid. The D N A fragment has two of the recognition sequence spaced by a short D N A segment. It is cleaved with Eco R roman number 1. The cleavage is shown to take place between G and A leaving complementary cohesive ends on both the upper and lower strands.

Step 2: Anneal D N A fragment and rejoin with D N A ligase. The cleaved D N A fragment has cohesive ends that are complementary to those of the cleaved plasmid. The D N A fragment is shown to ligate with the plasmid at the restriction site. The ligated plasmid is labeled p S C 1 0 1 plasmid with D N A insert.

Return to Schematic illustration of cohesive-end method of D N A ligation

Extended description for Schematic illustration of addition of cohesive ends to a D N A fragment



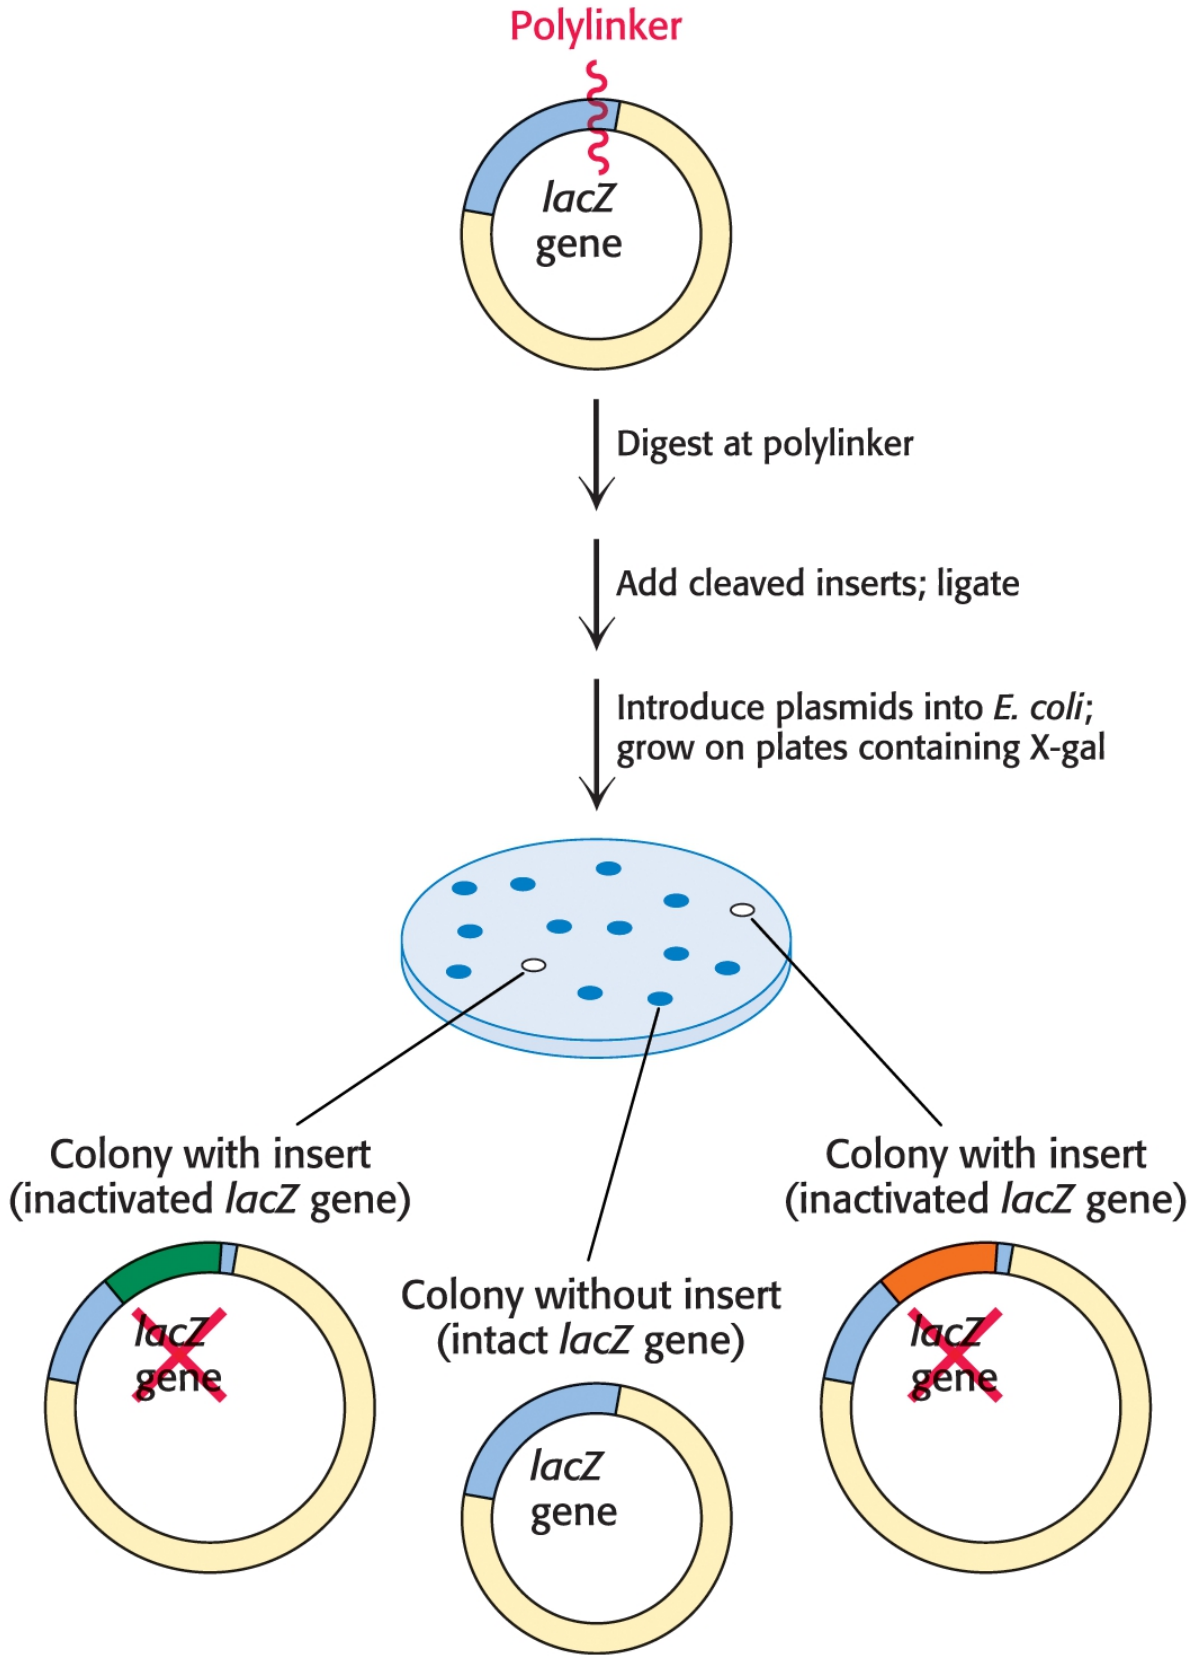
© Macmillan Learning

Step 1: Join blunt ends with T 4 ligase. A D N A fragment or vector is shown as a double stranded molecule with blunt ends. In both strands, the 5 prime terminal has a phosphate group and the 3 prime terminal has an O H group. A decameric linker is shown as another short D N A fragment having a palindromic sequence. The sequence, in the 5 prime to 3 prime direction, is as follows: C G G A A T T C G G. In both strands, the 5 prime terminal has a phosphate group and the 3 prime terminal has an O H group. The top strand is shown in blue and the bottom strand is shown in red. Two decameric linkers are shown to ligate to the D N A fragment in such a way that they flank the fragment.

Step 2: Cleave with Eco R 1 restriction enzyme. Eco R 1 is shown to cleave between G and A in both the flanking linker sequences thereby leaving cohesive ends. The sequence at the 5 prime terminal is phosphate group, single bond, A A T T C G G. The sequence at the 3 prime terminal O H, single bond, G C C.

Return to Schematic illustration of addition of cohesive ends to a D N A fragment

Extended description for Schematic illustration of unique restriction sites in a polylinker sequence of a plasmid



The plasmid labeled p U C 18 is shown to have the following highlighted sequences: Origin of replication, lac Z beta galactosidase, and ampicillin resistance. A short sequence within the lac Z gene is labeled polylinker. The polylinker sequence is magnified to indicate the following unique restriction sites: Hind roman number 3, P a e Roman number 1, S d a Roman number 1, B v e Roman number 1, H i n c Roman number 2, X b a Roman

number 1, S m a Roman number 1, K p n roman number 1, S a c Roman number 1, and Eco R Roman number 1.

Return to Schematic illustration of unique restriction sites in a polylinker sequence of a plasmid

Extended description for Schematic illustration of the steps of insertional inactivation of genes for

identification of colonies

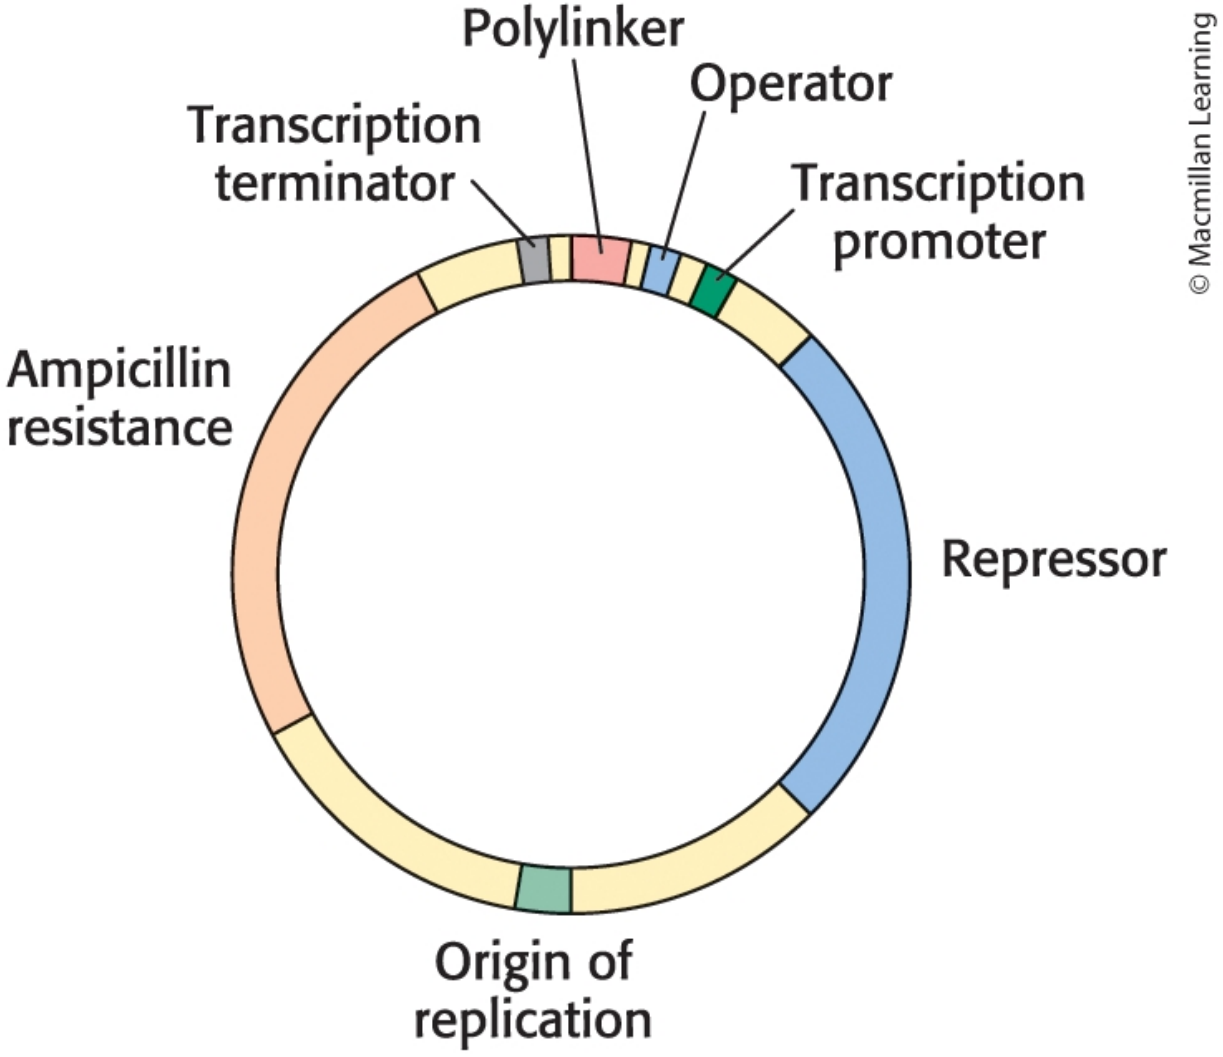
© Macmillan Learning

A plasmid is shown with the lac Z gene highlighted. Cleavage at the polylinker site within the lac Z gene is highlighted in red.

Digest at polylinker.

Add cleaved inserts; ligate.

Introduce plasmids into E. coli; grow on plates containing X-gal.



A culture plate is shown with several colonies. Two colonies are shown in white and the rest are shown in blue.

The plasmid of one of the white colonies is shown to have a short green D N A insert within the lac Z gene thereby inactivating the gene. The plasmid of the other white colony is shown to have an orange insert within the lac Z gene thereby inactivating the gene.

The plasmid of the blue colonies is shown to have an intact lac Z gene with no D N A inserts.

Return to Schematic illustration of the steps of insertional inactivation of genes for identification of colonies

Extended description for Structure of an expression vector

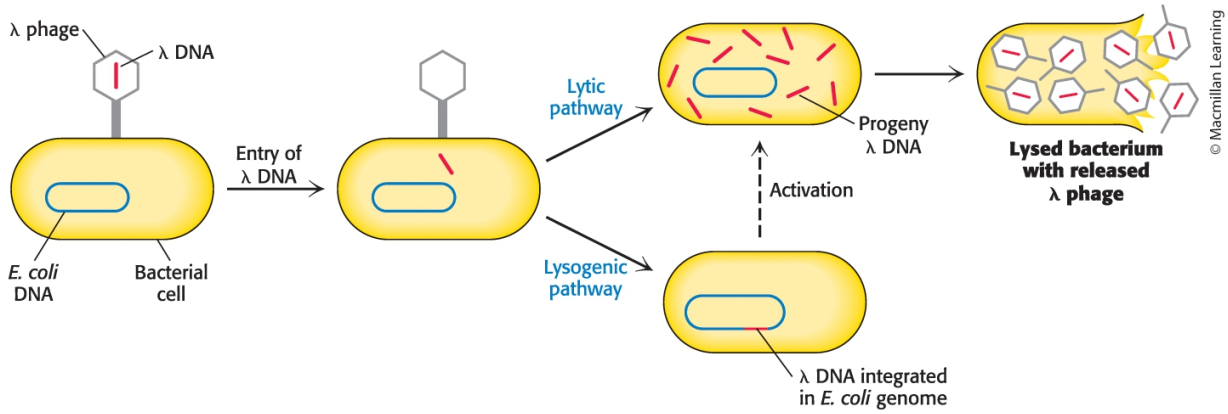
The following sequences of varying sizes are highlighted in the expression vector in a clockwise direction starting from the bottom:

Origin of replication

Ampicillin resistance

Transcription terminator

Polylinker



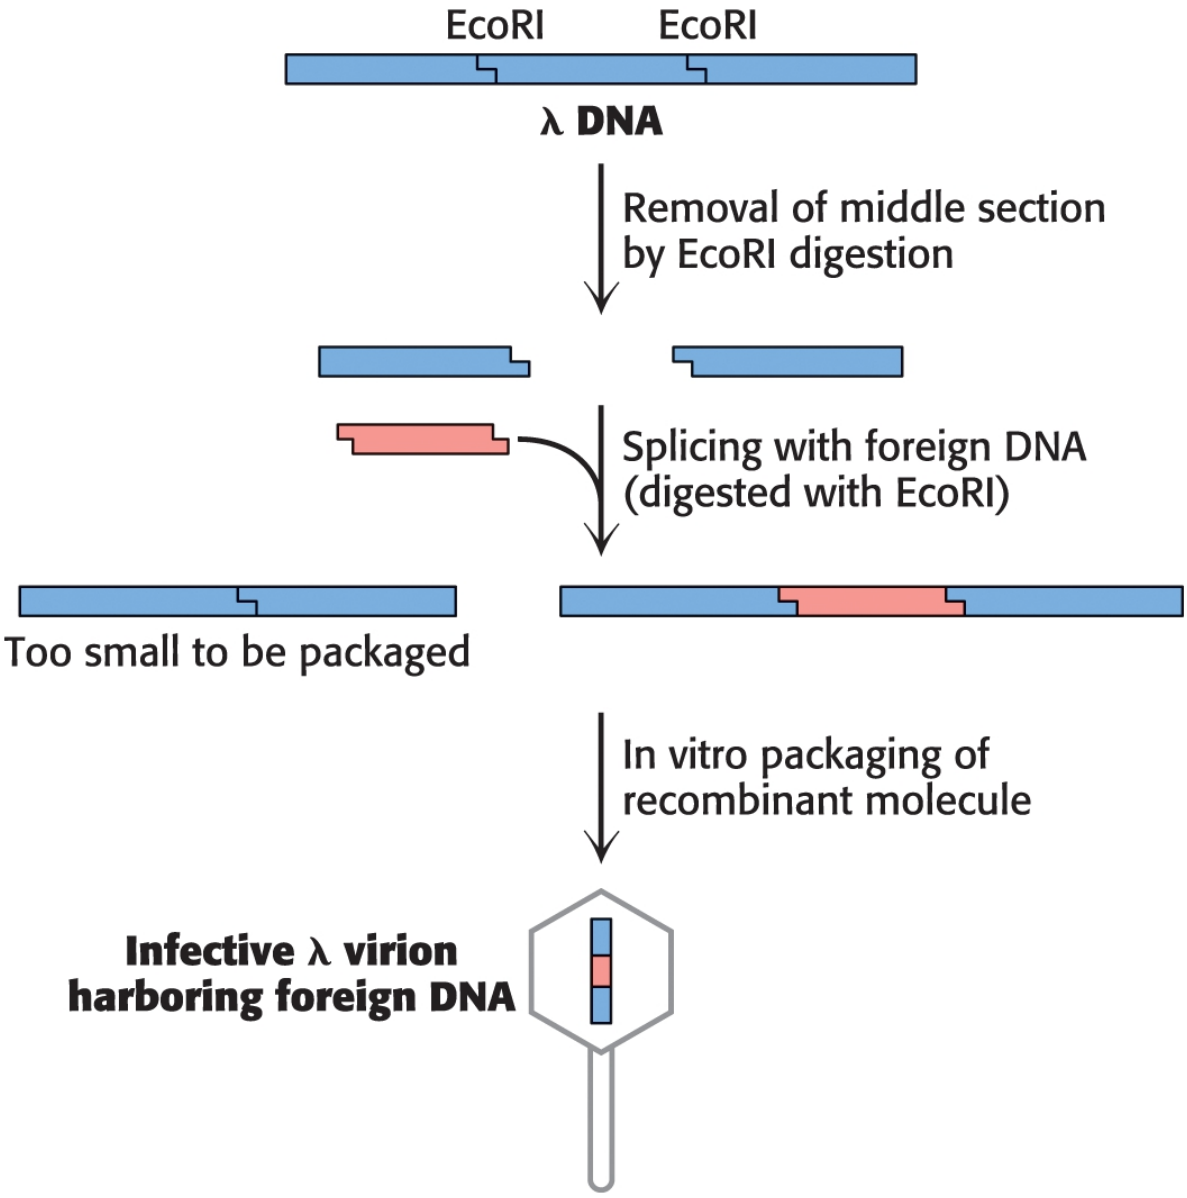
Operator

Transcription promoter

Repressor

Return to Structure of an expression vector

Extended description for Schematic illustration of the lytic and lysogenic pathways of infection in lambda phage



A rod-shaped bacterial cell (E. coli) is shown. The E. coli D N A is depicted as a small blue oval ring. A lambda phage is shown to adhere to the bacterial cell. The phage has a hexagonal head on top of a cylindrical tail which attaches to the bacterial cell. The phage head is shown to contain a short red D N A labeled lambda D N A. The lambda D N A is shown to be injected into bacterial cell by the phage.

Lytic pathway: The injected lambda D N A is shown to amplify within the bacterial cell. The new lambda D N A molecules are labeled progeny lambda D N A. New phage particles are shown to assemble within the bacterial cell which are eventually released from the lysed bacterium.

Lysogenic pathway: The lambda D N A is shown to be integrated into the E. coli D N A.

Return to Schematic illustration of the lytic and lysogenic pathways of infection in lambda phage

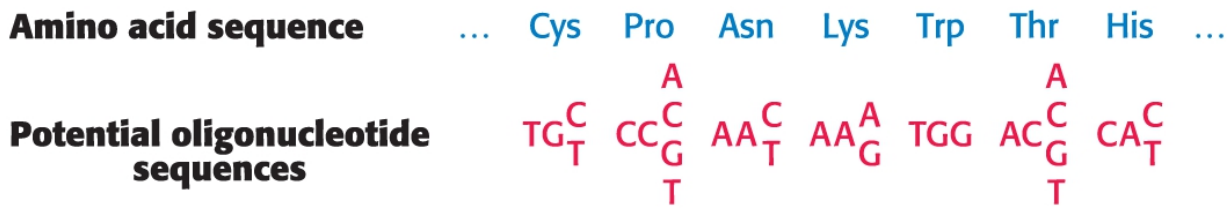
Extended description for Steps of development of mutant lambda phage to be used as cloning vector

© Macmillan Learning

Step 1: Removal of the middle section by Eco R 1 digestion. A lambda D N A is shown to have three sections interspaced by two Eco R 1 restriction sites. After Eco R 1 digestion, the left and right segments are shown to have cohesive ends. The right end is cohesive

for the left segment and the left end is cohesive for the right segment.

Step 2: Splicing with foreign D N A (digested with Eco R 1). A foreign D N A segment is shown with cohesive ends on both terminals. The following two modified lambda D N A are shown:



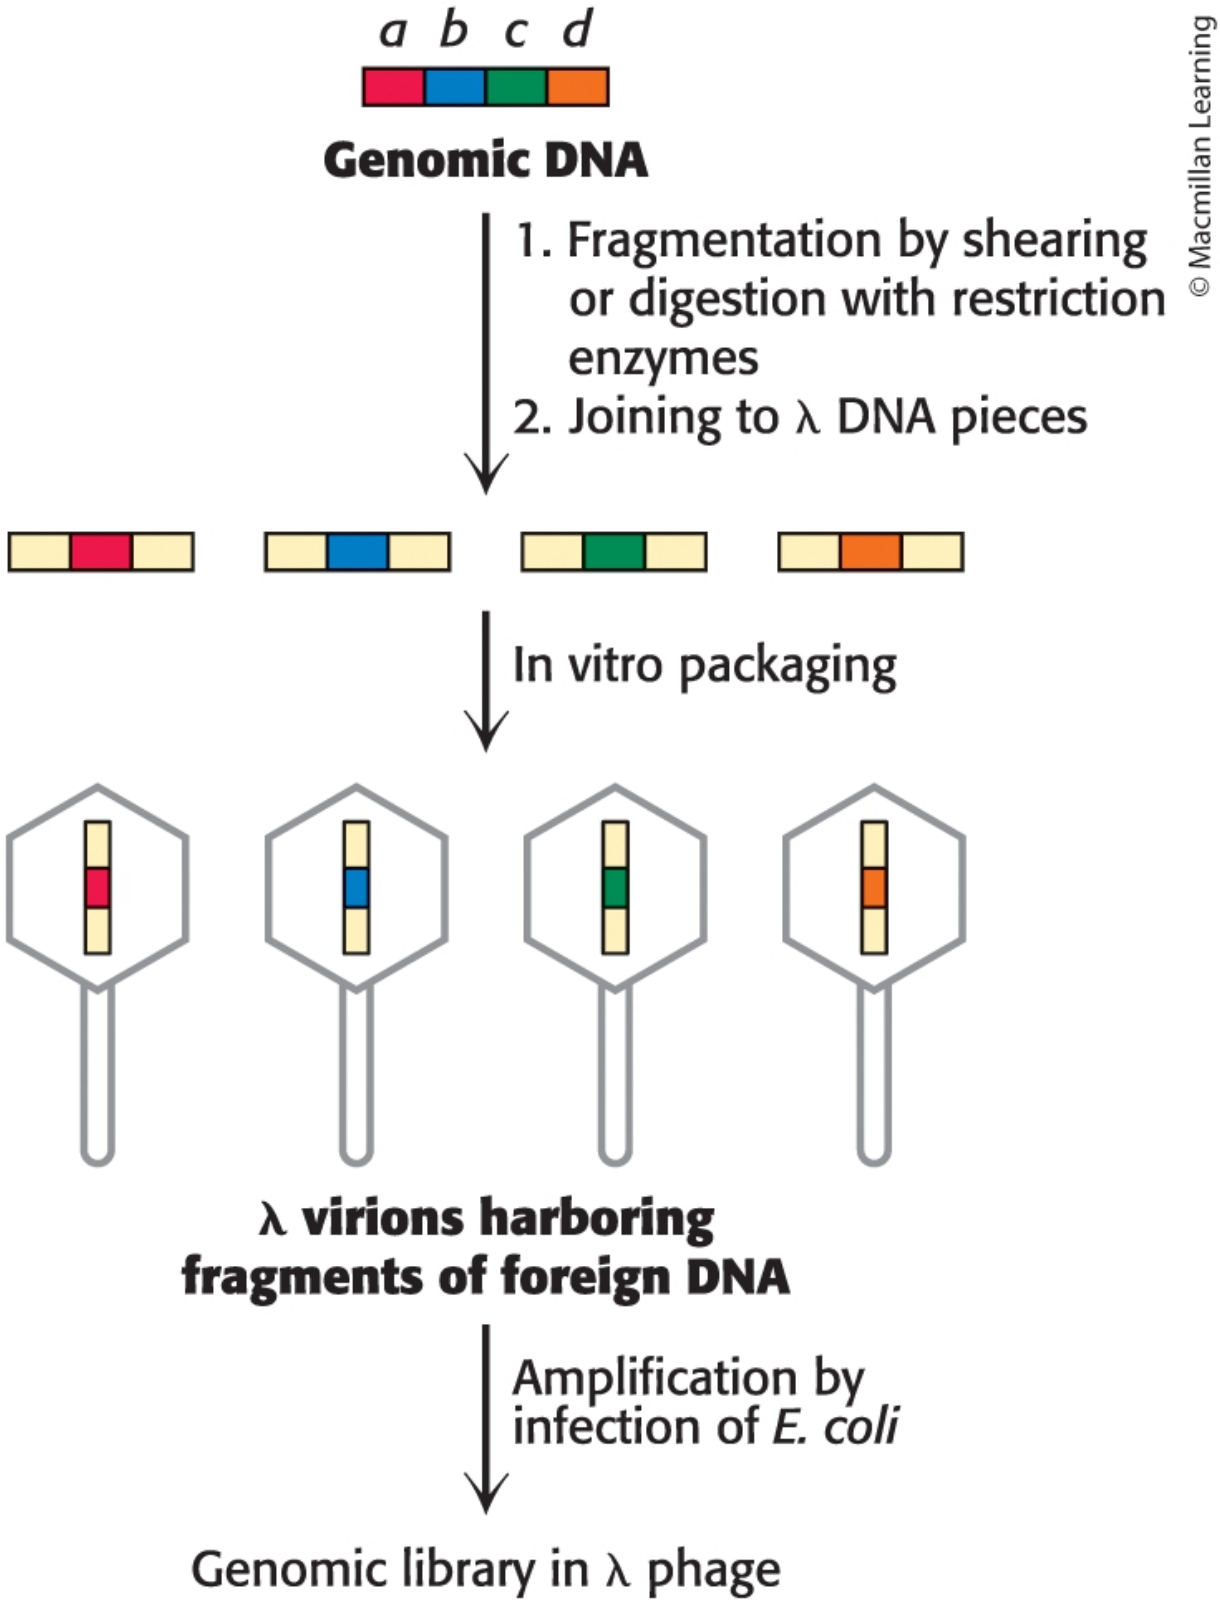
The two sections of lambda D N A after Eco R 1 digestion are shown to be ligated. This ligated D N A is too small to be packaged into a virion.

The foreign D N A is inserted in between the two sections of Eco R 1 digested lambda D N A. This gives a recombinant D N A of favorable size.

Step 3: In vitro packaging of the recombinant molecule. The lambda D N A with the foreign insert is shown to be packed into the head of an infective lambda virion.

Return to Steps of development of mutant lambda phage to be used as cloning vector

Extended description for Oligonucleotide probe designed from a target sequence



The amino acid sequence is as follows: Cysteine, Praline, Asparagine, Lysine, Tryptophan, Threonine, and Histidine.

The potential oligonucleotide sequences are as follows: T G, C or T, C C, A or C or G or T, A A, C or T, A A, A or G, T G G A C, A or C or G or T, C A, C or T.

Return to Oligonucleotide probe designed from a target sequence

Extended description for Schematic illustration of the creation of genomic library from a whole genome

digest

© Macmillan Learning

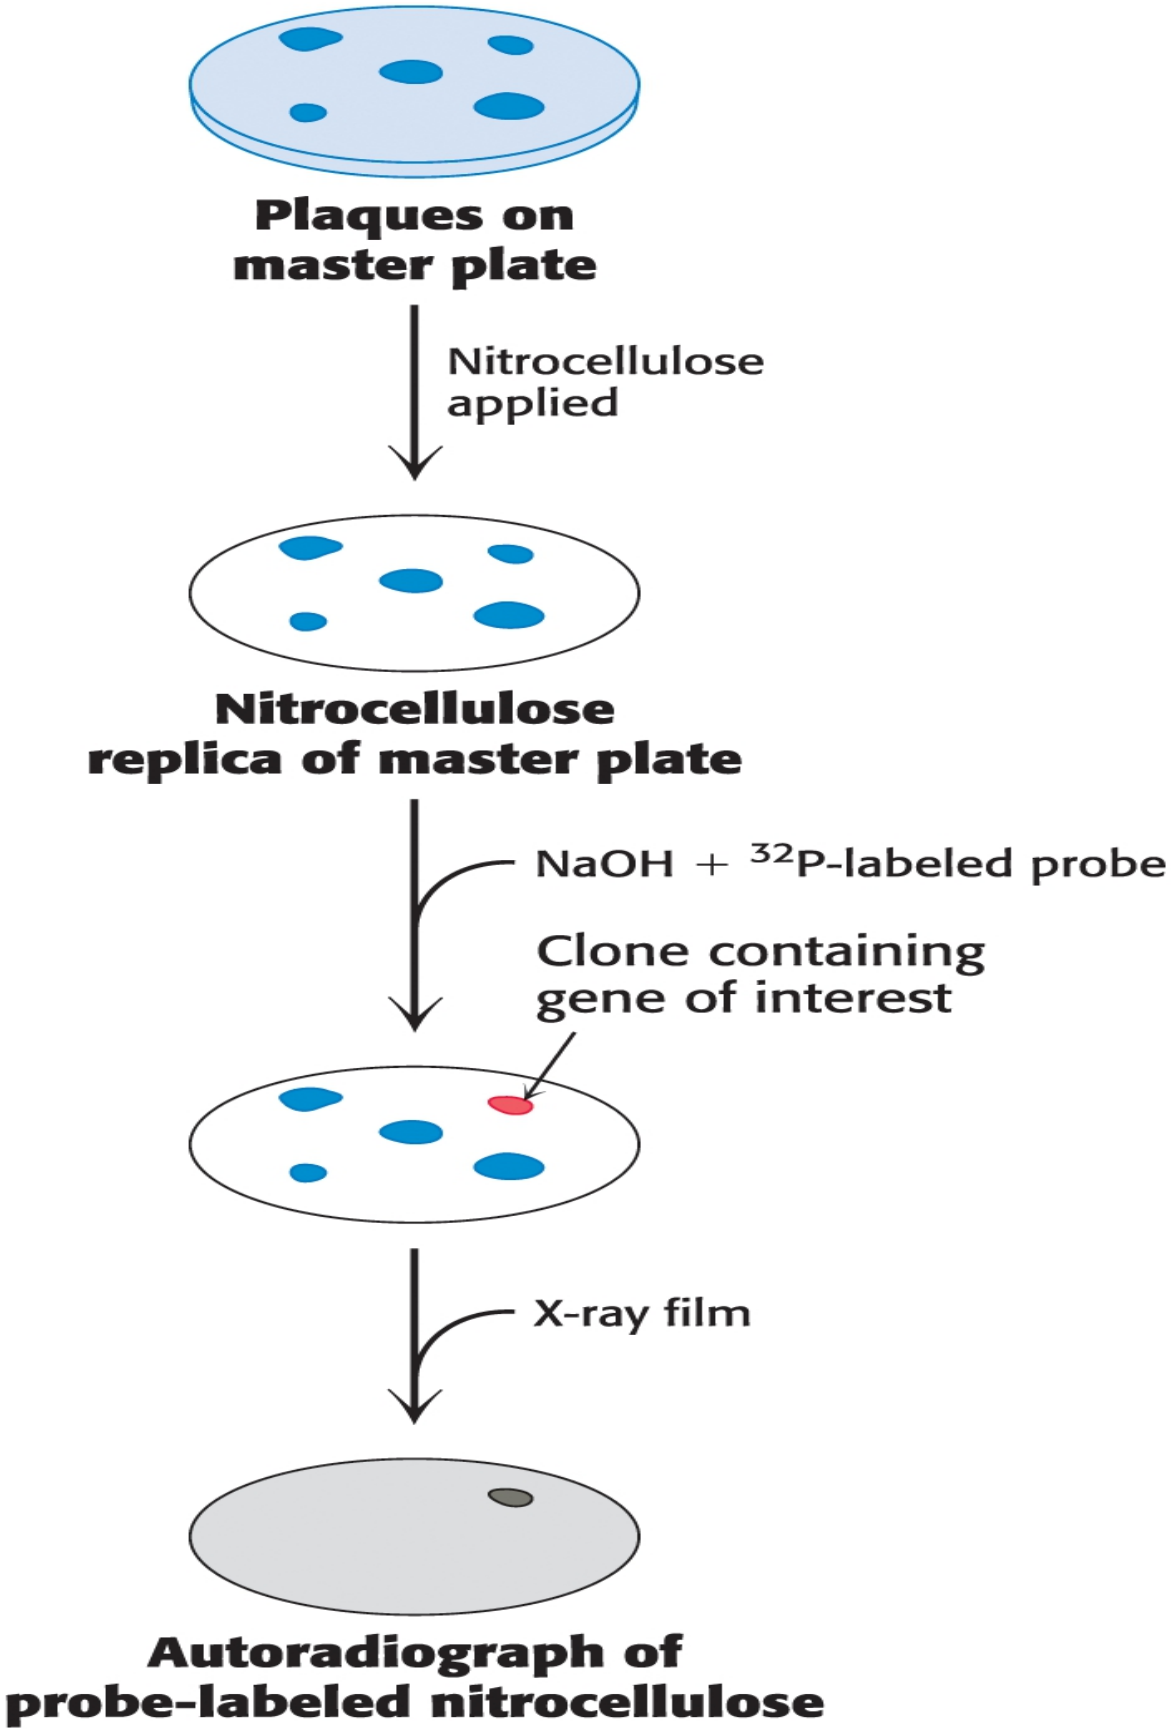
A genomic D N A is shown to have the following overlapping sequences: a (red), b (blue), c (green), and d (orange).

Step 1: Fragmentation by shearing or digestion with restriction enzymes.

Step 2: Joining lambda D N A pieces.

Four recombinant lambda D N A are shown with inserts corresponding to a, b, c, and d segments of the genomic D N A, respectively.

Step 3: In vitro packaging.



The recombinant lambda D N A is shown to be packed into the hexagonal heads of lambda virions, respectively.

Step 4: Amplification by infection of E. coli. This gives a genomic library in lambda phage.

Return to Schematic illustration of the creation of genomic library from a whole genome digest

Extended description for Schematic illustration of the

screening of a genomic library for a specific gene

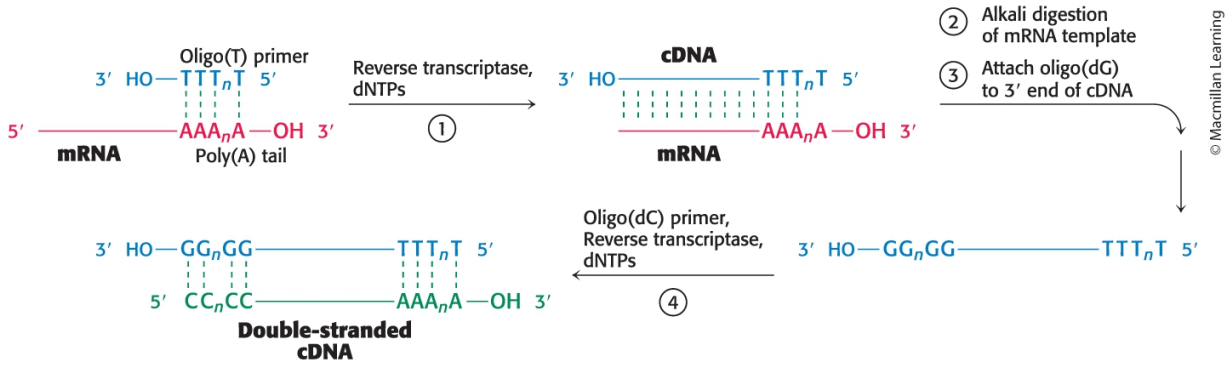
© Macmillan Learning

A master culture plate is shown with five blue plaques of varying sizes.

Step 1: Nitrocellulose applied.

The nitrocellulose replica of the master plate is shown to have the same pattern of plaques as the master plate.

Step 2: Treatment with N a O H and P superscript 32 labeled probe.



A plaque in the nitrocellulose replica is shown in red. This plaque is labeled clone containing gene of interest.

Step 3: Development of X-ray film.

The autoradiograph of the probe-labeled nitrocellulose shows only one spot at a position corresponding to the red labeled plaque.

Return to Schematic illustration of the screening of a genomic library for a specific gene

Extended description for Schematic illustration of double-stranded c D N A preparation from m R N A using reverse transcriptase

A single stranded red m R N A is shown. The 3 prime end of the m R N A has a poly A tail (repeating sequence of adenine) terminating in an O H group. An oligo T primer is shown to bind to the poly A tail of the m R N A. The primer has a repeating sequence of thymine terminating in an O H group at the 3 prime end. Hydrogen bonding between T and A is shown by dotted green lines.

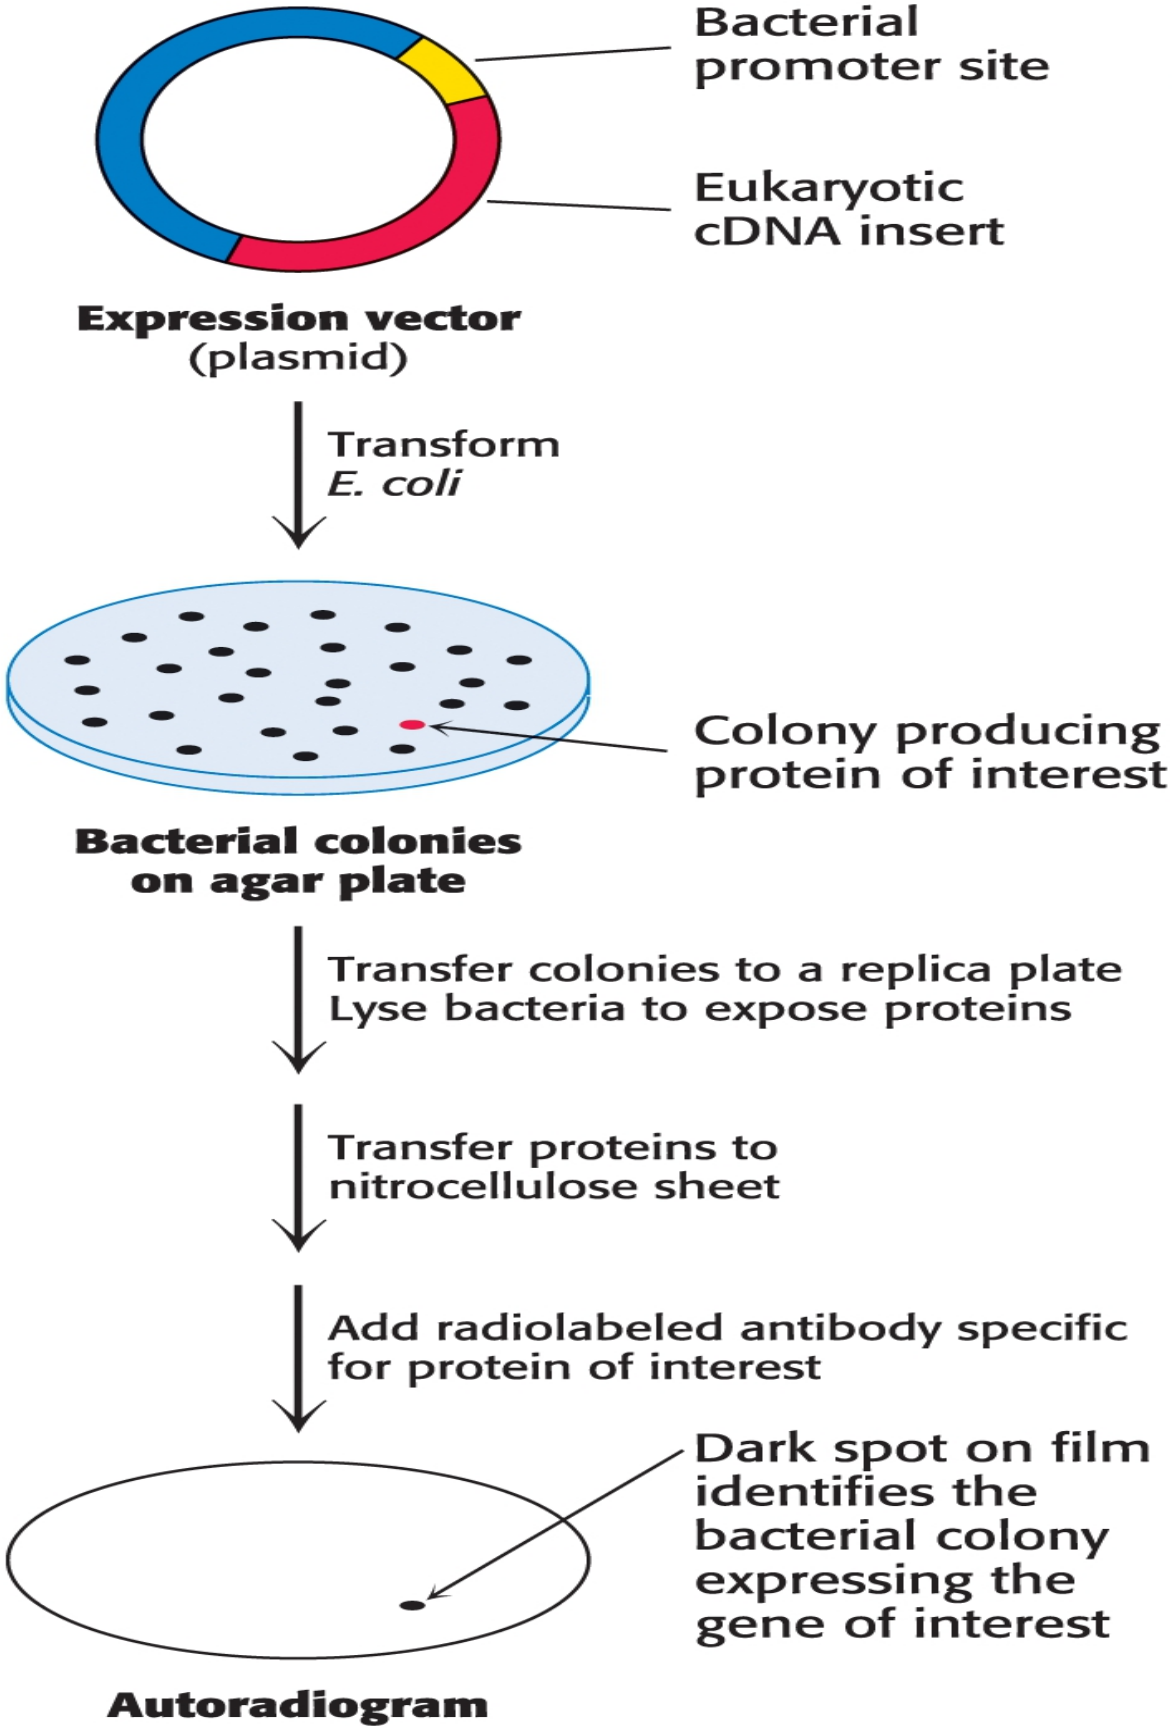
Step 1: Addition of reverse transcriptase and d N T Ps.

The oligo T primer is shown to be extended in the 5 prime to 3 prime direction giving c D N A which is hydrogen bonded to the m R N A.

Step 2: Alkali digestion of m R N A template.

Step 3: Attach oligo d G to 3 prime end of c D N A.

The c D N A is shown to have a repeating sequence of guanine residues terminating in O H at the 3 prime end and a repeating sequence of thymine residues at the 5 prime end.



Step 4: Addition of Oligo d C primer, reverse transcriptase, and d N T Ps.

A double-stranded c D N A is shown. The c D N A strand from the previous step is hydrogen bonded to a new strand below. The new strand has a repeating sequence of adenine residues terminating in O H at the 3 prime end and a repeating sequence of cytosine residues at the 5 prime end.

Return to Schematic illustration of double-stranded c D N A preparation from m R N A using reverse transcriptase

Extended description for Schematic illustration of the screening of colonies in a c D N A library that express a

protein of interest

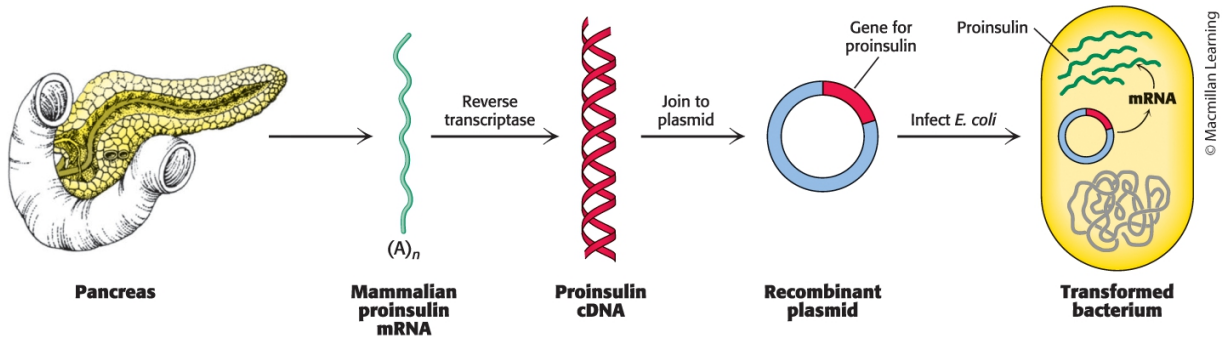
© Macmillan Learning

An expression vector (plasmid) is shown to have a circular D N A with a short sequence labeled bacterial promoter site followed by another longer sequence labeled eukaryotic c D N A insert.

Step 1: Transform E. coli.

An agar culture plate is shown with several bacterial colonies. One of the colonies is shown in red and labeled colony producing protein of interest.

Step 2: Transfer colonies to a replica plate. Lyse bacteria to expose proteins.



Step 3: Transfer proteins to nitrocellulose sheet.

Step 4: Add radiolabeled antibody specific to the protein of interest.

An autoradiogram is shown with a single spot corresponding to the labeled red colony in the agar plate. This dark spot on the film identifies the bacterial colony expressing the gene of interest.

Return to Schematic illustration of the screening of colonies in a c D N A library that express a protein of interest

Extended description for Schematic illustration of designing a bacteria to express proinsulin by infection with proinsulin c D N A

A human pancreas is illustrated.

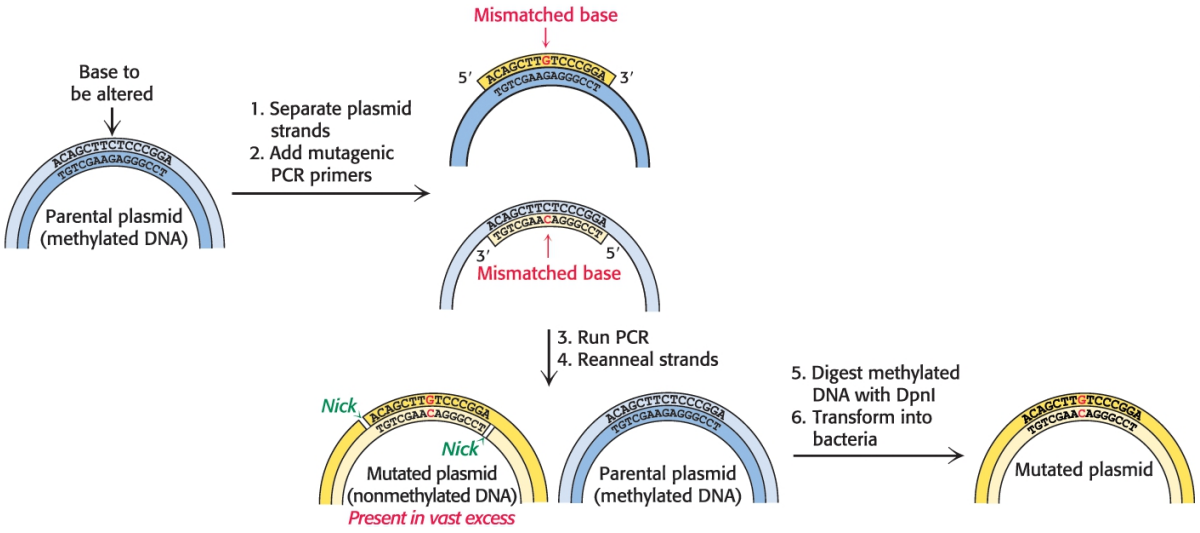
A single-stranded mammalian proinsulin m R N A with a poly A tail is illustrated.

It is treated with reverse transcriptase.

A double-stranded helical proinsulin c D N A is produced by reverse transcriptase activity.

It is joined to a plasmid.

A circular recombinant plasmid with the inserted gene for proinsulin is illustrated.



E. coli is infected with this recombinant plasmid.

Arod-shaped transformed bacterium with the recombinant plasmid is illustrated. Proinsulin m R N A is shown to be synthesized within

the cytoplasm of the bacterium.

Return to Schematic illustration of designing a bacteria to express proinsulin by infection with proinsulin c D N A

Extended description for Schematic illustration of site-directed mutagenesis in P C R

A parental plasmid (methylated D N A) is shown. The eighth base in the highlighted 15 bases long D N A segment is to be altered which is C in the outer strand and G in the inner strand.

Step 1: Separate plasmid strands.

Step 2: Add mutagenic P C R primers.

A complementary primer sequence with G (mismatched base) at the eighth position is shown to anneal to the inner strand.

A complementary primer sequence with C (mismatched base) at the eighth position is shown to anneal to the outer strand.

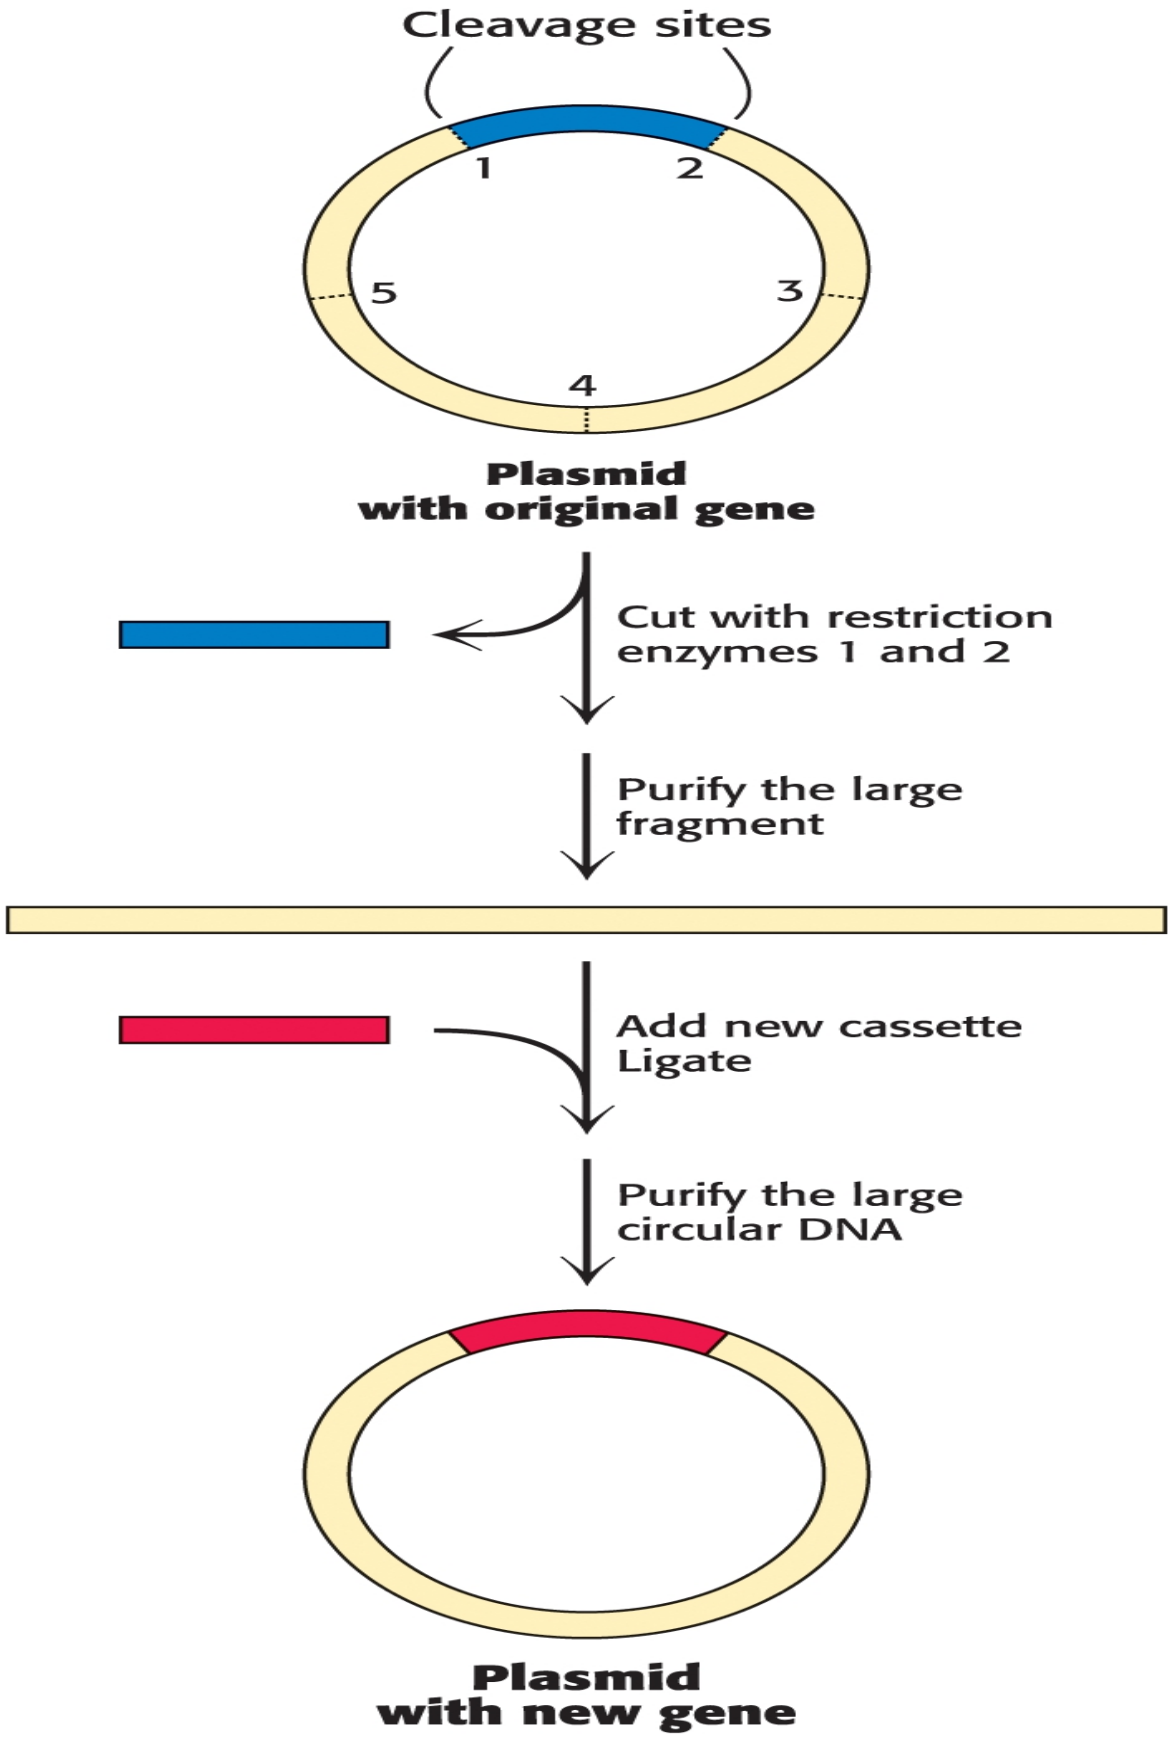
Step 3: Run P C R.

Step 4: Reanneal strands.

Mutated plasmid (nonmethylated D N A) is present in vast excess in the P C R product. The plasmid has G in the outer strand and C in the inner strand at the eighth position. A nick is present in both strands where the 5 prime end of the primer was present.

Parental plasmid (methylated D N A) has the original sequence.

Step 5: Digest methylated D N A with D p n roman number 1.



Step 6: Transform bacteria.

The final result is shown to be the mutated plasmid.

Return to Schematic illustration of site-directed mutagenesis in P C R

Extended description for Schematic illustration of

cassette mutagenesis

© Macmillan Learning

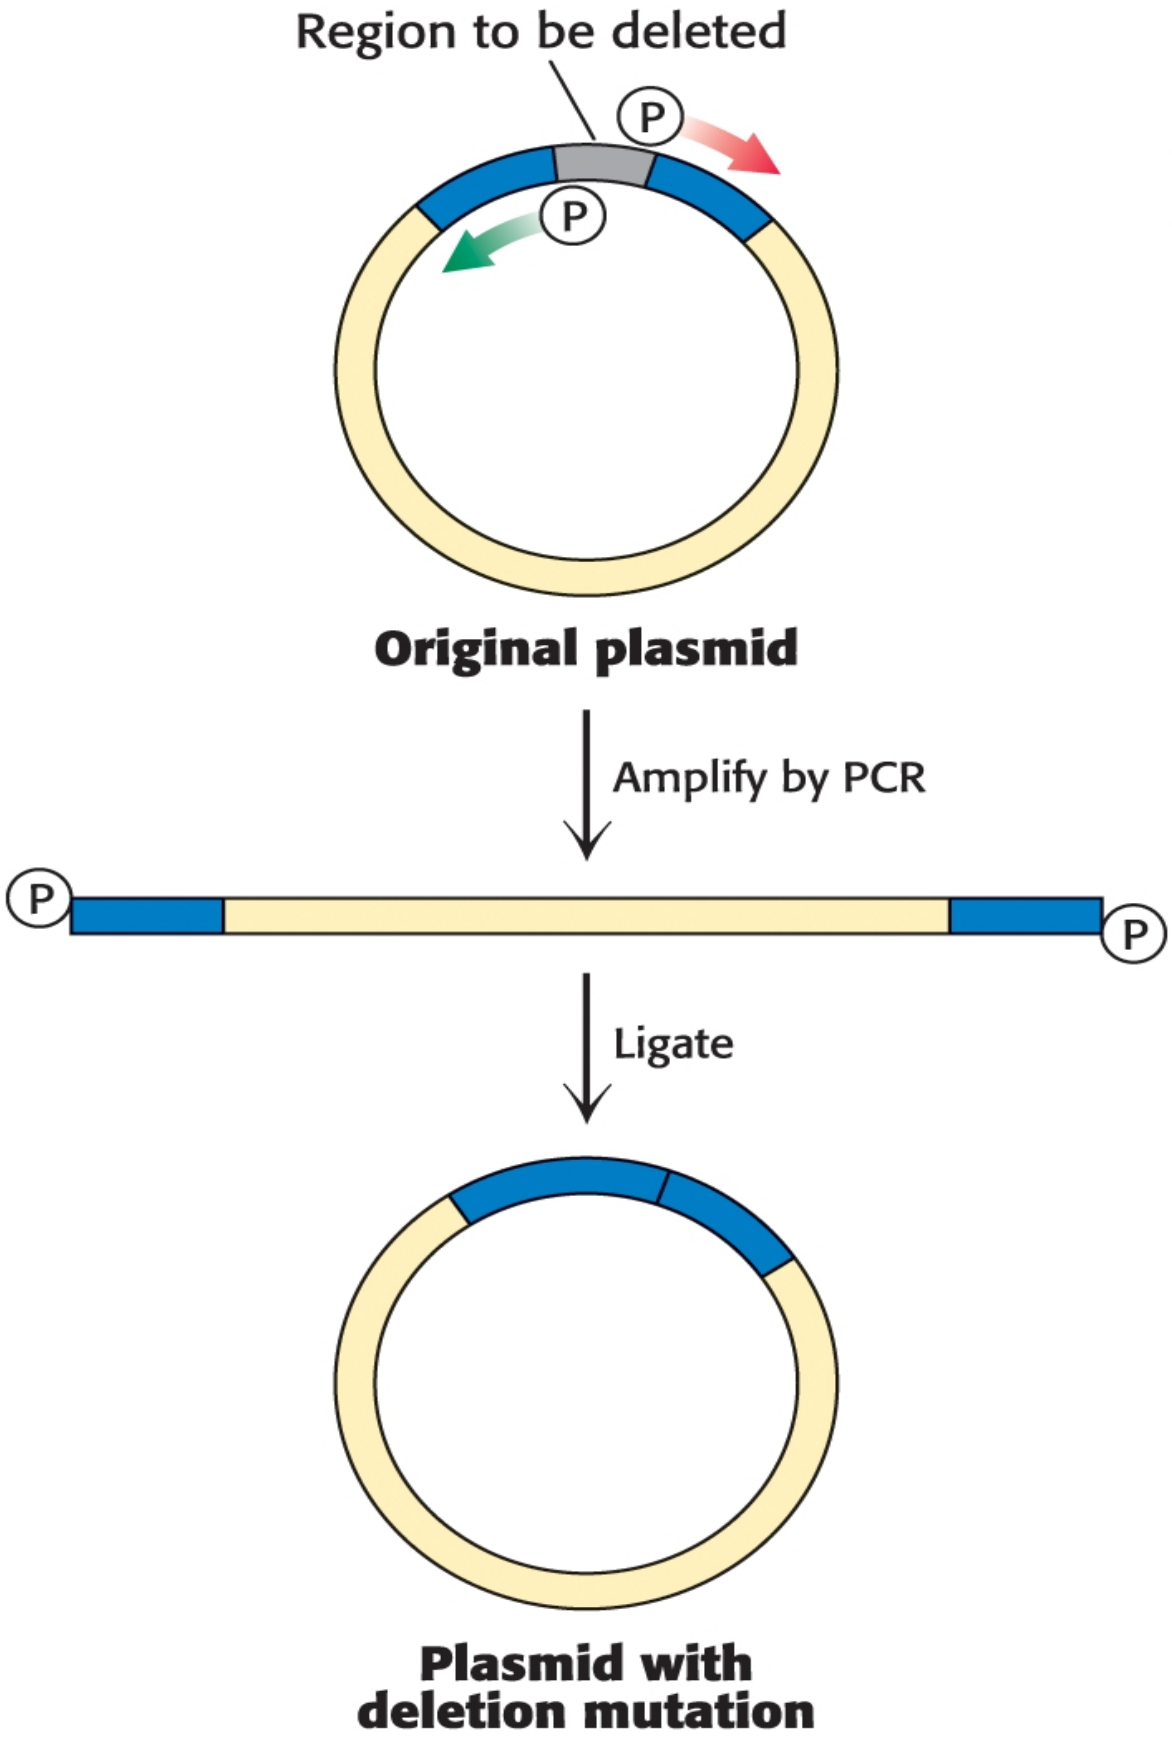
A plasmid with the original gene is shown. Five unique restriction sites numbered 1 to 5 are indicated in the plasmid. The segment between sites 1 and 2 is highlighted in blue to indicate the gene to be replaced.

Step 1: Cut with restriction enzymes 1 and 2.

Step 2: Purify large fragment.

The blue gene is shown to be removed. The remaining plasmid is shown as a linear D N A molecule.

Step 3: Add new cassette ligate.



Step 4: Purify the large circular D N A.

The circular plasmid with the new gene is shown with a red D N A cassette inserted in the place of the original blue gene.

Return to Schematic illustration of cassette mutagenesis

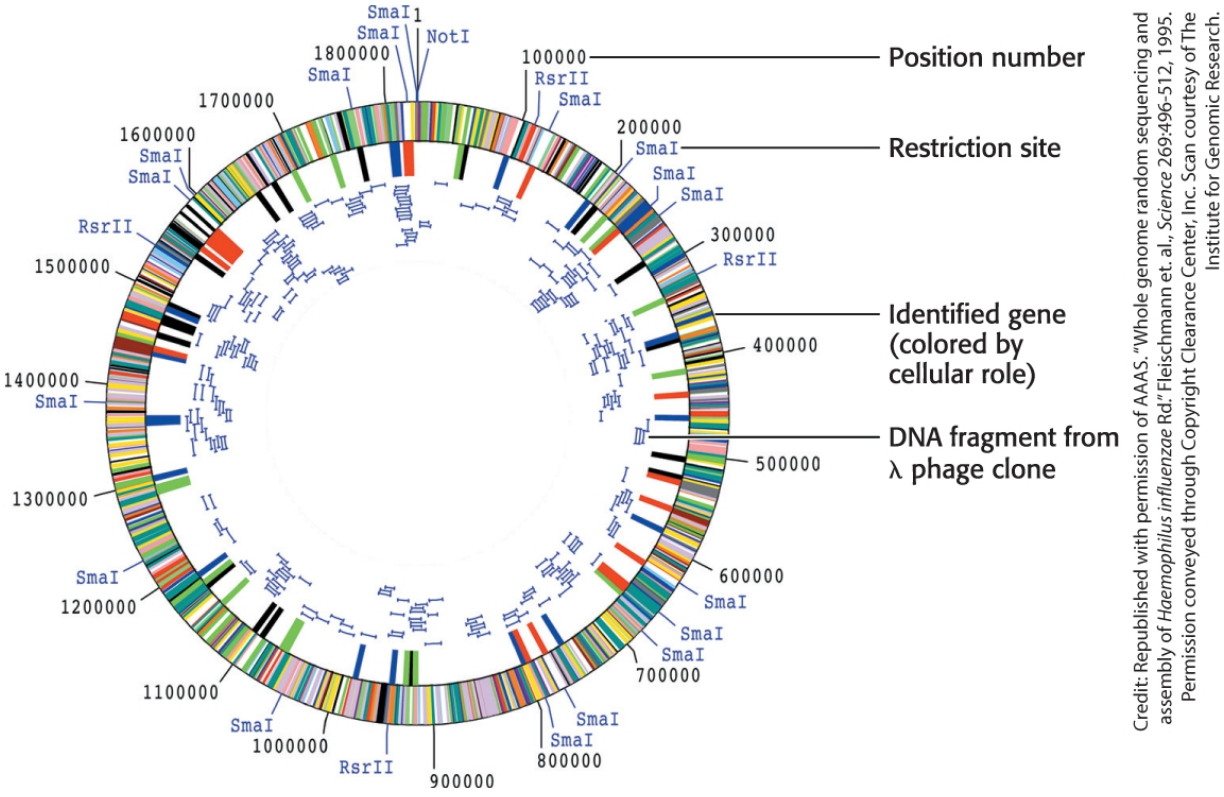
Extended description for Schematic illustration of the

application of P C R to generate mutations

© Macmillan Learning

An original circular plasmid is shown. The region in the plasmid to be deleted is shown in grey. This region is flanked by two blue segments on both sides. Primers containing a phosphate group are shown to anneal to the flanking segments.

Step 1: Amplify by P C R.



A linear D N A is shown with the blue flanking segments. Both the segments have a phosphate group at the free end.

Step 2: Ligate.

The product is a circular plasmid with deletion mutation. The ends of the blue flanking segments are ligated and grey region is removed.

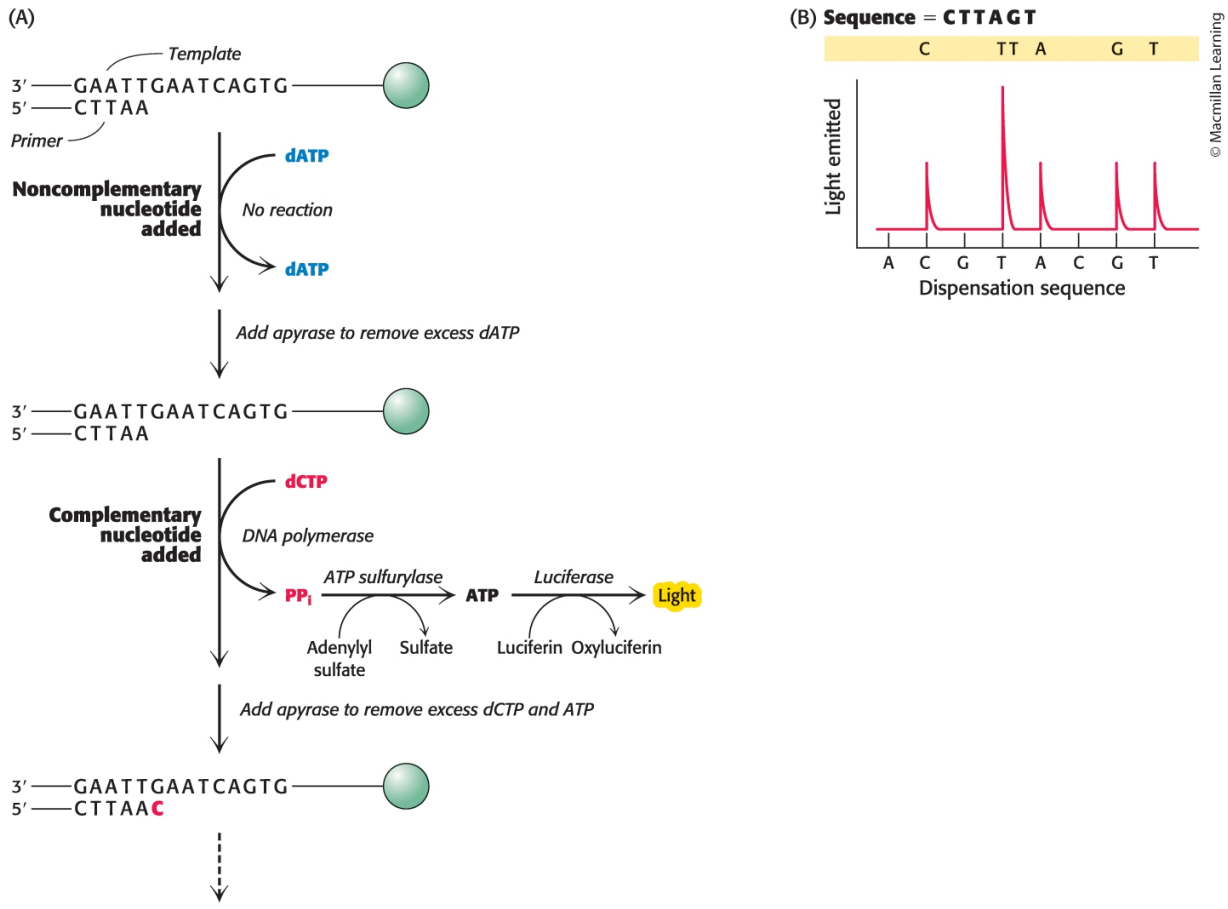
Extended description for The set of human chromosomes with the location of genes associated with important biochemical pathways marked

Each chromosome is shown to have a long and a short arm joined at the centromere. The chromosomes vary in size. The following genes are highlighted:

3-Hydroxy-3-methylglutaryl-coenzyme A reductase (Chapters 27 and 32): On the long arm near the centromere of Chromosome 5.



Glyceraldehyde-3-phosphate dehydrogenase (Chapter 16): On the tip of the short arm of Chromosome 12.

Glycogen phosphate (liver) (Chapter 21): On the long arm near the centromere of Chromosome 14.

Hypoxanthine phosphoribosyl transferase (Chapter 26): On the tip of the long arm of the X Chromosome.

Return to The set of human chromosomes with the location of genes associated with important biochemical pathways marked

Extended description for Schematic illustration of pyrosequencing

Part (A): Steps of pyrosequencing.

The template D N A sequence in the 3 prime to 5 prime direction is as follows: G A A T T G A A T C A G T G. The D N A template is tethered to a solid spherical support at the 5 prime end. The primer sequence annealed to the template is as follows: 5 prime C T T A A.

Noncomplementary nucleotide added: d A T P is added but no reaction takes place and d A T P leaves. Apyrase is added to remove excess d A T P. The primer is not extended in this case.

Complementary nucleotide added: d C T P is added in the presence of D N A polymerase. C is added to the primer. P P subscript i is released which is converted to A T P by A T P sulfurylase and in the process adenyl sulfate is converted to sulfate. A T P is then converted into light by luciferase and in the process luciferin is converted into oxyluciferin.

Apyrase is again added to remove excess d C T P and A T P.

The primer extends by the addition of a complementary C nucleotide base.

Part (B): A graph shows the determination of the sequence by pyrosequencing. The vertical axis is labeled Light emitted. The horizontal axis is labeled Dispensation sequence and has the following markings:

A: No peak

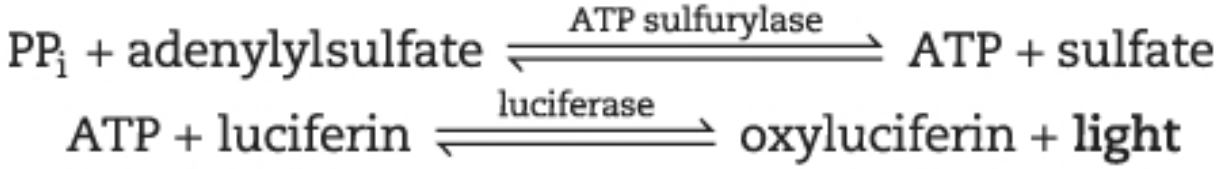
C: Short peak

G: No peak

T: A tall peak

A: Short peak

C: No peak



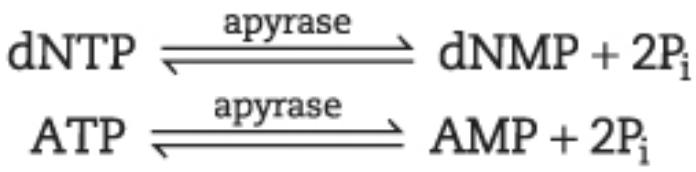
G: Short peak

T: Short peak

Sequence equals C T T A G T.

Return to Schematic illustration of pyrosequencing

Extended description for Light generation during the pyrosequencing process



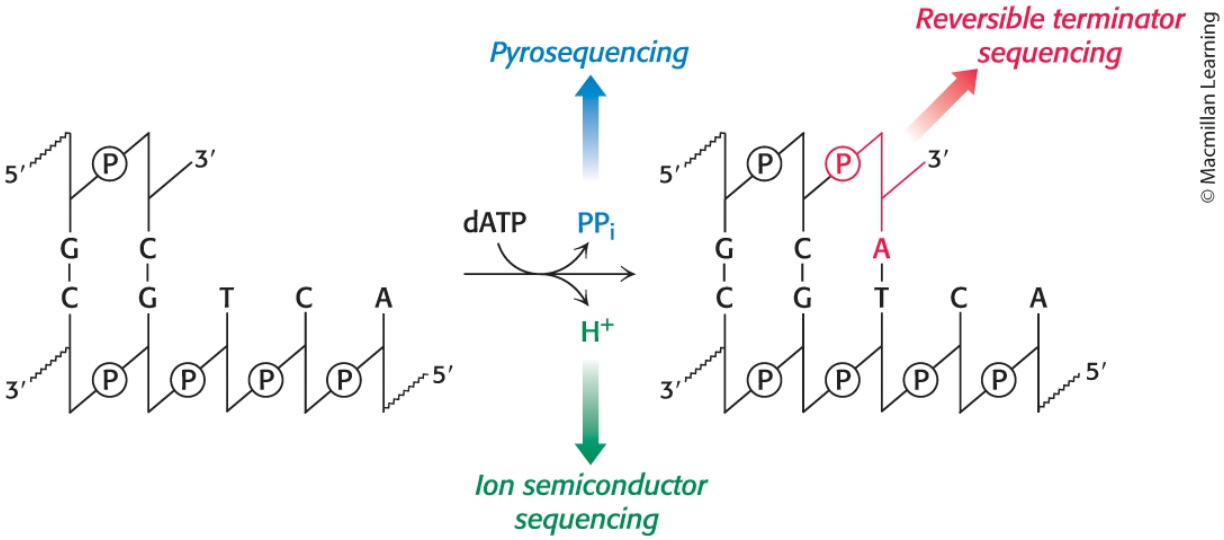
The first chemical reaction consists of two reactants and two products. The first reactant is P P subscript i. The second reactant is adenylylsulfate. A reversible reaction arrow labeled "A T P sulfurylase" leads to the products. The first product is A T P. The second product is sulfate.

The second chemical reaction consists of two reactants and two products. The first reactant is A T P. The second reactant is luciferin. A reversible reaction arrow labeled "luciferase" leads to the products. The first product is oxyluciferin. The second product is light.

Return to Light generation during the pyrosequencing process

Extended description for Chemical reactions catalyzed by apyrase

Reaction 1: The reversible reaction consists of 1 reactant and 2 products.

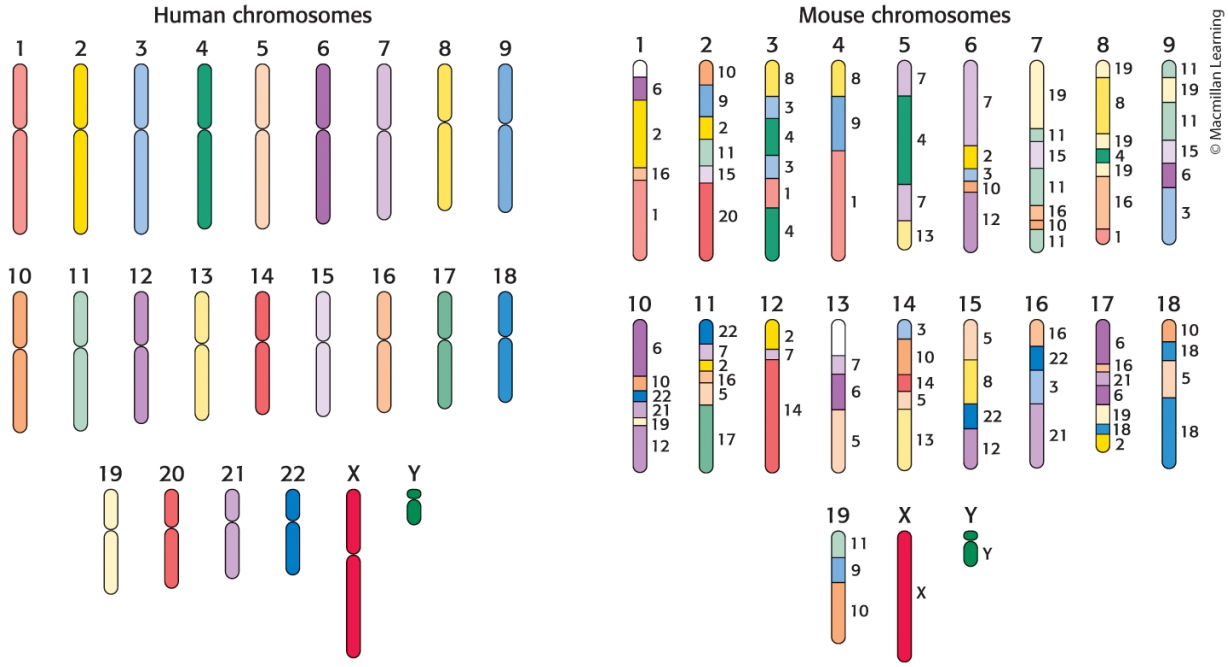


The reactant is d N T P. The first product is d N M P. The second product is 2 P subscript i. The reversible reaction arrow is labeled apyrase.

Reaction 2: The reversible reaction consists of 1 reactant and 2 products.

The first reactant is A T P. The first product is A M P. The second product is 2 P subscript i. The reversible reaction arrow is labeled apyrase.

Return to Chemical reactions catalyzed by apyrase



Extended description for Different approaches used in next-generation sequencing methods

The template D N A has the following sequence in the 3 prime to 5 prime direction: C G T C A. The primer has the following sequence in the 5 prime to 3 prime direction: G C. d A T P is added to extend the primer by adding A to the 3 prime end. This approach is used in reversible terminator sequencing. During this addition, P P subscript i and H superscript ions are released. P P subscript i is utilized in pyrosequencing. H superscript plus is utilized in ion semiconductor sequencing.

Return to Different approaches used in next-generation sequencing methods

Extended description for Comparison of human and mouse genomes

The human autosomes and the X and Y chromosomes are shown.

The mouse chromosomes are shown to indicate each region closely related to that of humans, from top to bottom, as follows:

Chromosome 1: Human chromosomes 6, 2, 16, and 1.

Chromosome 2: Human chromosomes 10, 9, 2, 11, 15, and 20.

Chromosome 3: Human chromosomes 8, 3, 4, 3, 1, and 4.

Chromosome 4: Human chromosomes 8, 9, and 1.

Chromosome 5: Human chromosomes 7, 4, 7, and 13.

Chromosome 6: Human chromosomes 7, 2, 3, 10, and 12.

Chromosome 7: Human chromosomes 19, 11, 15, 11, 16, 10, and 11.

Chromosome 8: Human chromosomes 19, 8, 19, 4, 19, 16, and 1.

Chromosome 9: Human chromosomes 11, 19, 11, 15, 6, and 3.

Chromosome 10: Human chromosomes 6, 10, 22, 21, 19, and 12.

Chromosome 11: Human chromosomes 22, 7, 2, 16, 5, and 17.

Chromosome 12: Human chromosomes 2, 7, and 14.

Chromosome 13: Human chromosomes 7, 6, and 5.

Chromosome 14: Human chromosomes 3, 10, 14, 5, and 13.

Chromosome 15: Human chromosomes 5, 8, 22, and 12.

Chromosome 16: Human chromosomes 16, 22, 3, and 21.

Chromosome 17: Human chromosomes 6, 16, 21, 6, 19, 18, and 2.

Chromosome 18: Human chromosomes 10, 18, 5, and 18.

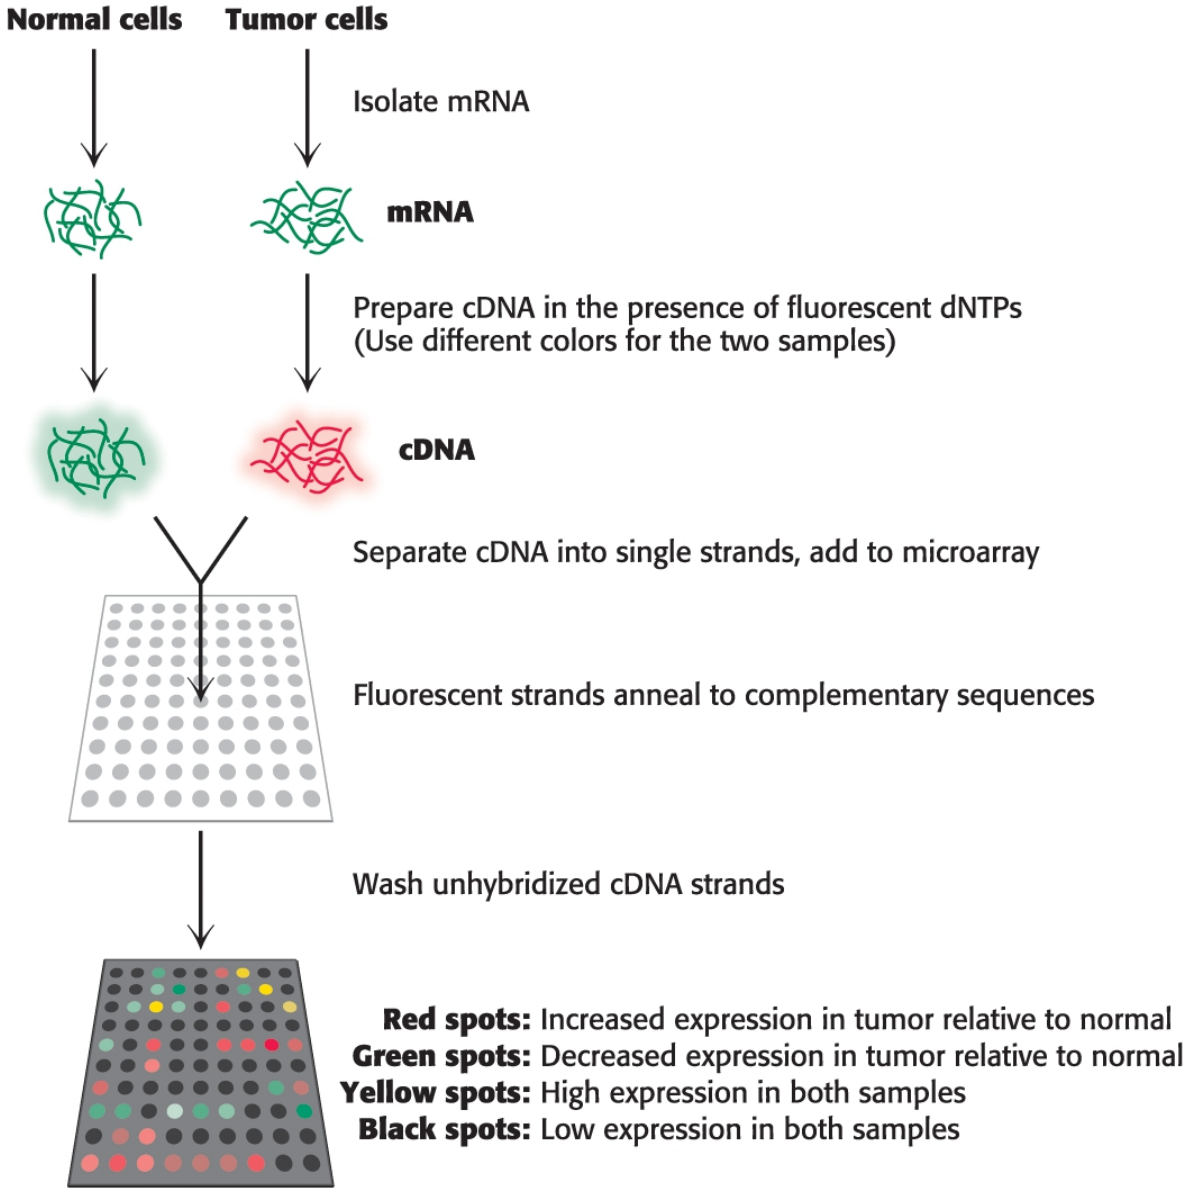
Extended description for Graphs depicting results of a

quantitative P C R



© Macmillan Learning

Graph (A): The horizontal axis is labeled cycle and ranges from 2 to 50 in increments of 4 units. The vertical axis is labeled fluorescence and ranges from 10 raised to the power minus 2 to 10 raised to the power in geometric increments of 10 units. A horizontal line labeled threshold passes through a point just above 10 raised to the power minus 2. Seven color coded curves corresponding to different samples are shown to have an S-shape and plateau to the same point. The points at which the curves cross the threshold is labeled C subscript T value. The arrangement of curves in the increasing order of C subscript T values is as follows: Red, turquoise, yellow, purple, pink, blue, and green.

Part (B): The horizontal axis is labeled Starting quantity and ranges from 10 raised to the power 0 to 10 raised to the power 6 in geometric increments of 10 units. The vertical axis is labeled C subscript T and ranges from 10 to 35 in increments of 5 units. A straight trendline starts at (0, 35) and ends at (10 raised to the power 6, 0). The color coded points lie on the trendline corresponding to their C subscript T values as mentioned above.

© Macmillan Learning

Step 1: Isolate m R N A from normal and tumor cells.

Step 2: Prepare c D N A in the presence of fluorescent d N TPs (use different colors for two samples). Normal cell c D N A is shown in

green. Tumor cell c D N A is shown in red.

Step 4: Separate c D N A into single strands and add to microarray. Fluorescent strands anneal to complementary sequences.

The microarray plate is shown to have several wells arranged in a row-wise pattern.

Step 5: Wash unhybridized c D N A strands.

The resultant microarray plate is shown to show the following spots:

Red spots: Increased expression in tumor relative to normal.

Green spots: Decreased expression in tumor relative to normal.

Yellow spots: High expression in both samples.

Black spots: Low expression in both samples.

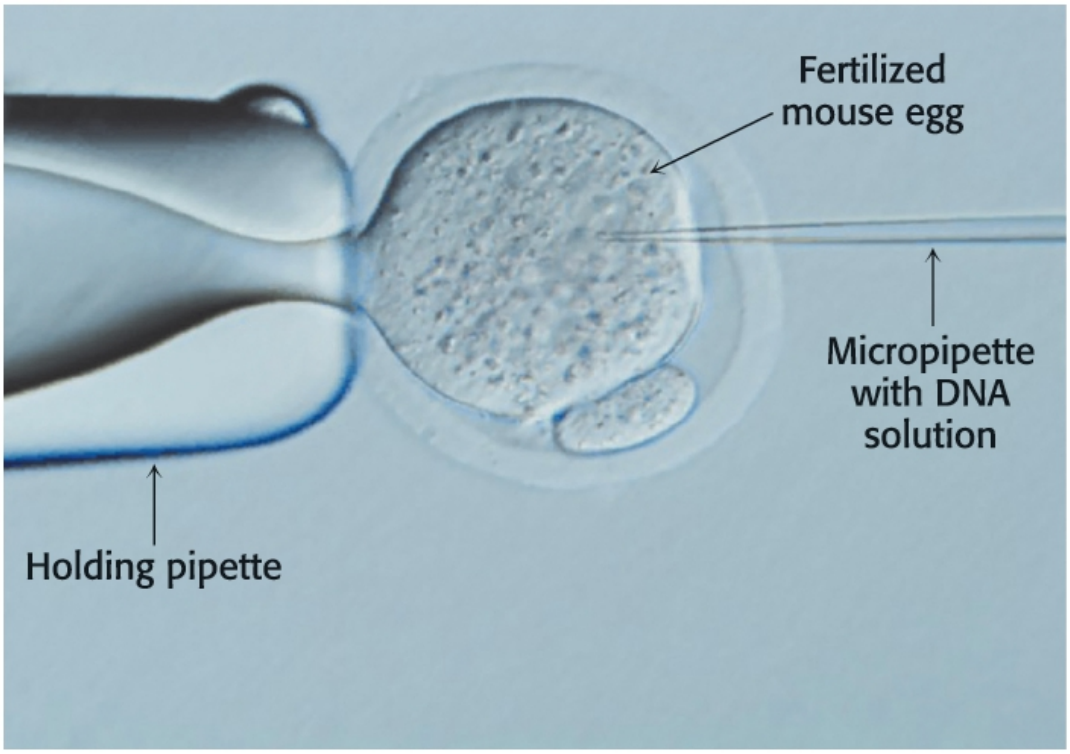
Extended description for Heat map of a microarray



analysis of tumors

Credit: Kao J, Salari K, Bocanegra M, Choi YL, Girard L, Gandhi J, Kwei KA, Hernandez-Boussard T, Wang P, Gazdar AF, Minna JD, Pollack JR. Molecular profiling of breast cancer cell lines defines relevant tumor models and provides a resource for cancer gene discovery. February 2009. *PLoS One* 4(7):e6146, Figure 1B. DOI:10.1371/journal.pone.0006146.

The horizontal axis is labeled different tumors. The vertical axis is labeled different genes. Seven horizontal rectangles of varying thickness are shown one below the other. Each rectangle contains a cluster of red and green spots in a random arrangement. The red spots are clustered toward the left in the first, second, and third rectangles from the top. From the fourth to seventh rectangles, the cluster of red spots moves from the middle region toward the right. The green spots are clustered toward the right in the first, second, and third rectangles. From the fourth to seventh rectangles, the cluster of green spots moves from the right end toward the left.

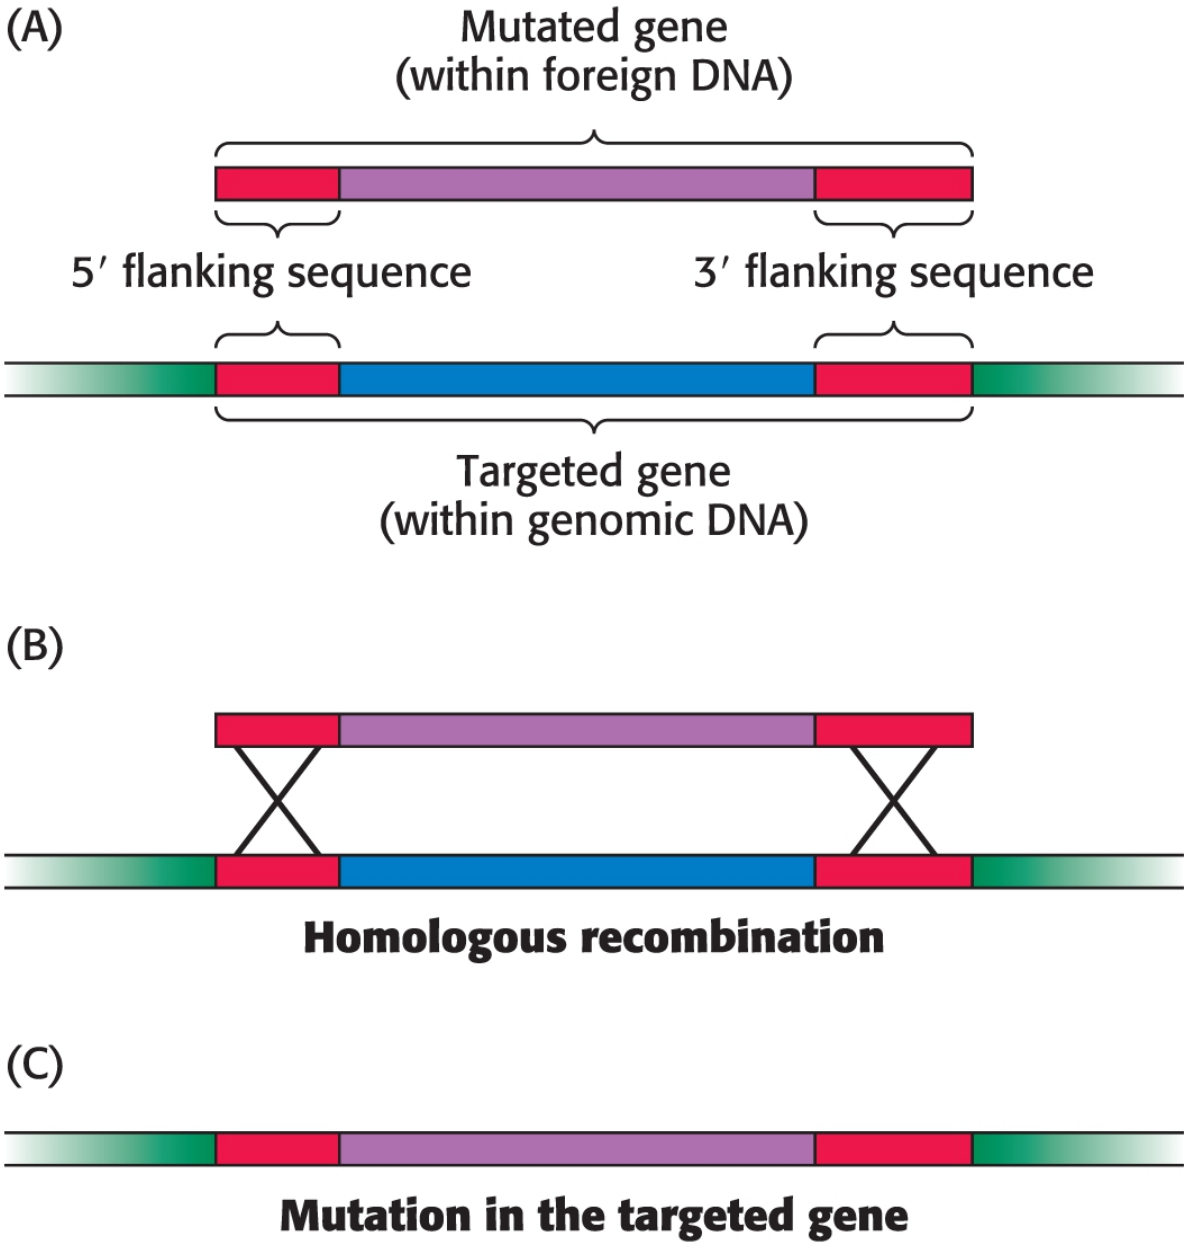
Extended description for Micrograph of a cloned plasmid D N A being injected into a fertilized mouse egg



Credit: Marh et al, Hyperactive self-inactivating piggyBac for transposase-enhanced pronuclear microinjection transgenesis, PNAS, Vol 109, no. 47, pp. 19184–19189. Copyright 2012 National Academy of Sciences.

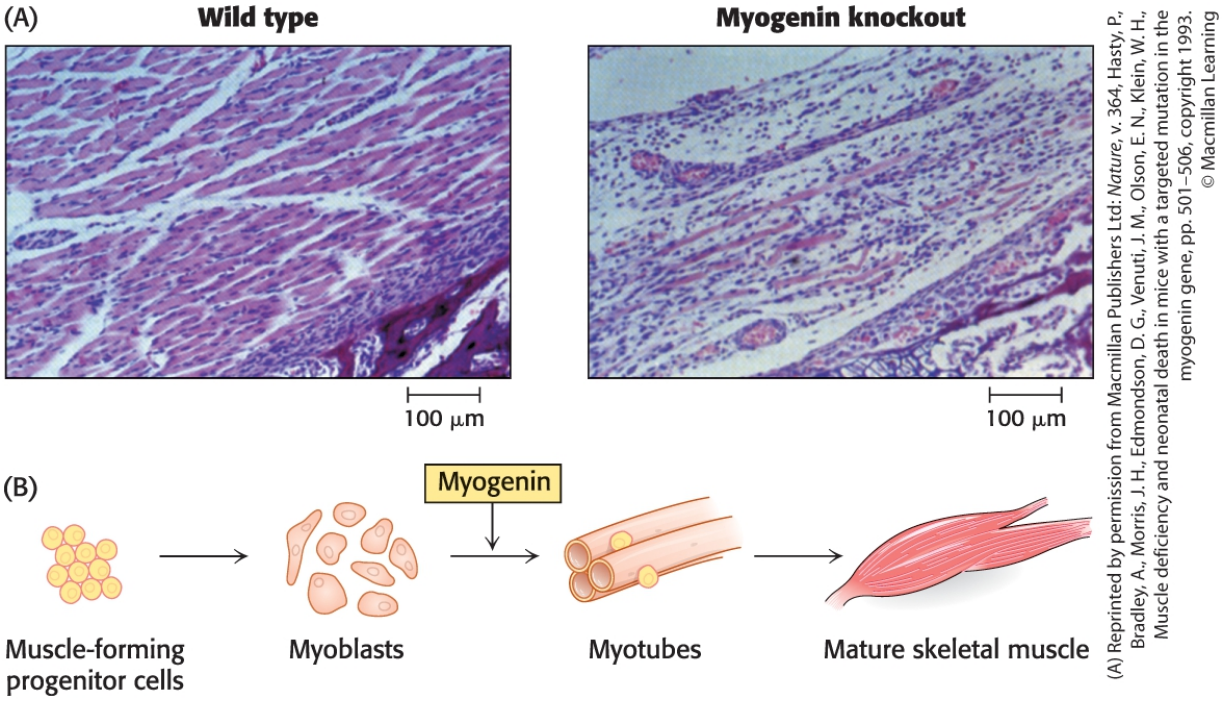
The fertilized mouse egg is shown to be held in place by a holding pipette. A thin micropipette is shown to inject the D N A solution into the egg.

Return to Micrograph of a cloned plasmid D N A being injected into a fertilized mouse egg

Extended description for Schematic illustration of foreign D N A insertion by homologous recombination

© Macmillan Learning

Part (A): A mutated gene within foreign D N A is shown in purple and is flanked by a 5 prime and 3 prime flanking sequence on either ends. The targeted gene within genomic D N A is shown in blue. The



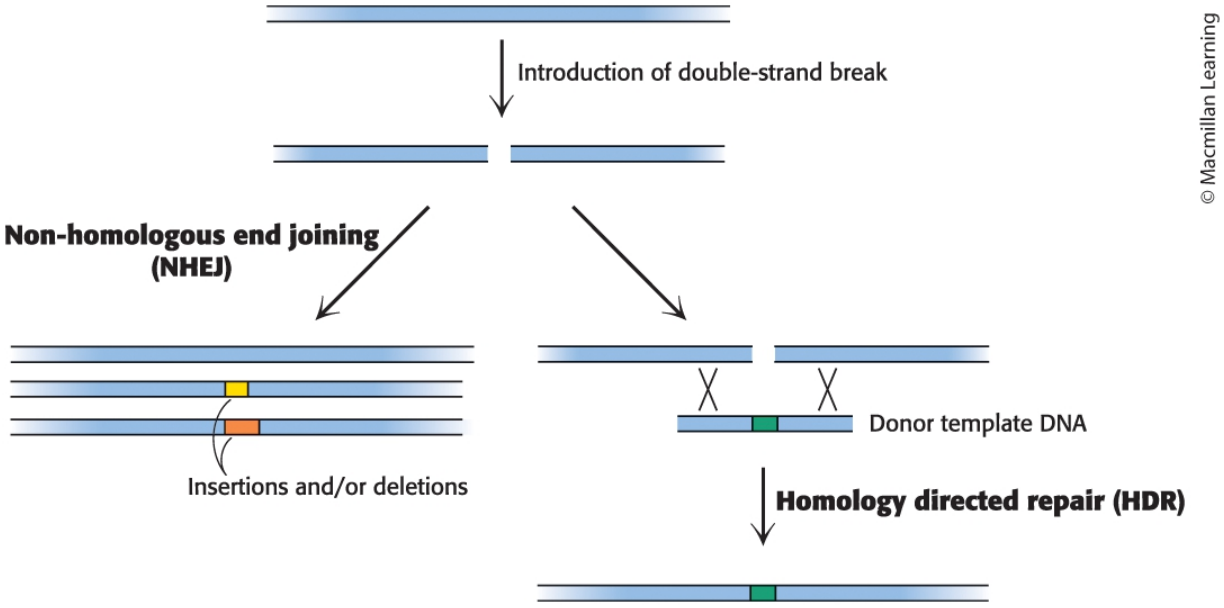
target sequence is also flanked by a 5 prime and 3 prime flanking sequence on either ends. The flanking sequences are shown in red. The genomic D N A is shown in green.

Part (B): A cross-joining of the corresponding flanking sequences of the mutated gene and the target gene shows homologous recombination.

Part (C): The purple mutated gene is shown to replace the target gene within the genomic D N A and is flanked by the 5 prime and 3 prime flanking sequences on either ends.

Return to Schematic illustration of foreign D N A insertion by homologous recombination

Extended description for Consequences of myogenin knockout in mice

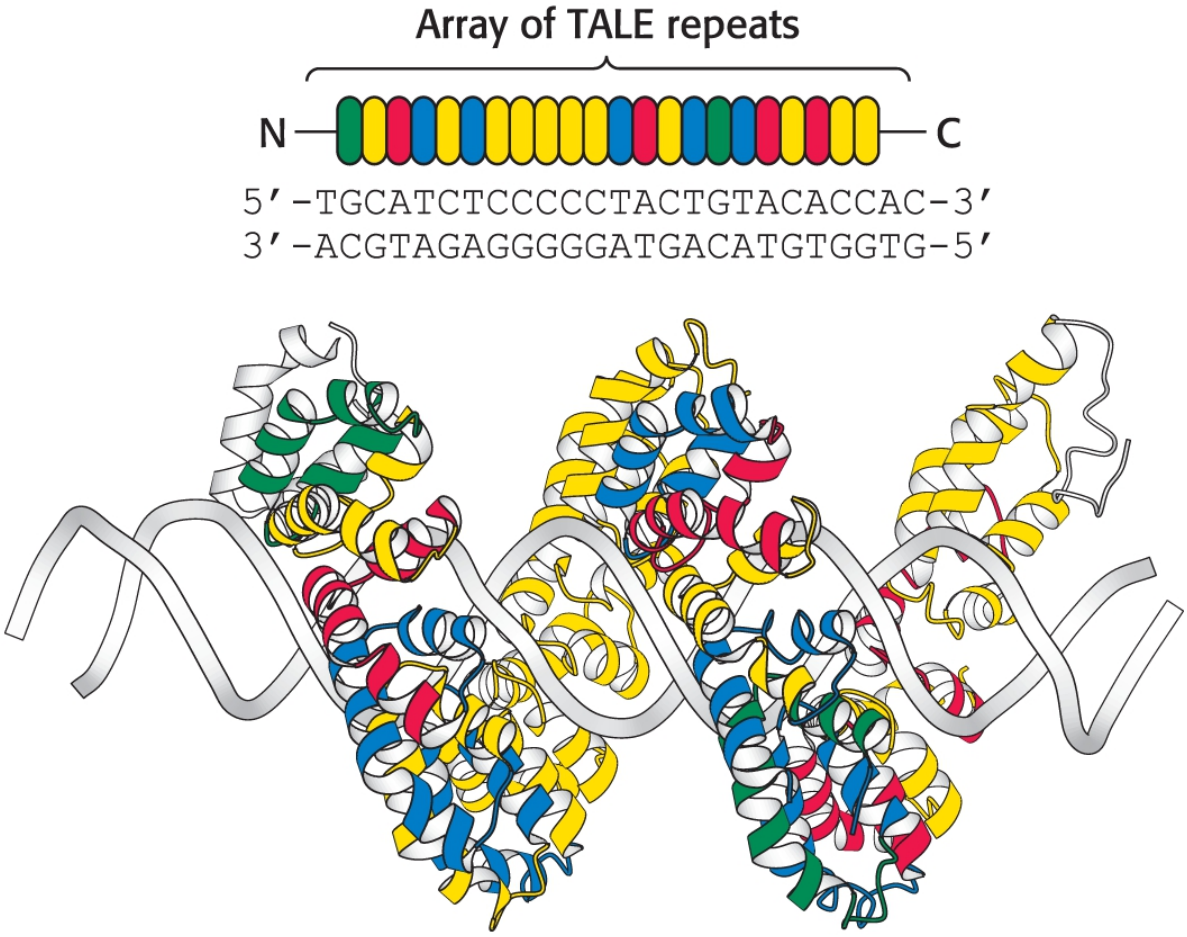


Part (A): A micrograph of muscle in wild type mice shows properly formed muscle tissue. A micrograph of muscle in myogenin knockout mice shows underdeveloped muscle tissue. The scale bar is 100 micrometers.

Part (B): A cluster of yellow spherical cells are labeled muscle-forming progenitor cells. These give rise to irregularly shaped myoblasts. Myogenin stimulates myoblasts to form tubular-shaped myotubules. These aggregate to form mature skeletal muscle.

Return to Consequences of myogenin knockout in mice

Extended description for Schematic illustration of non-homologous end joining and homology directed repair of D N A



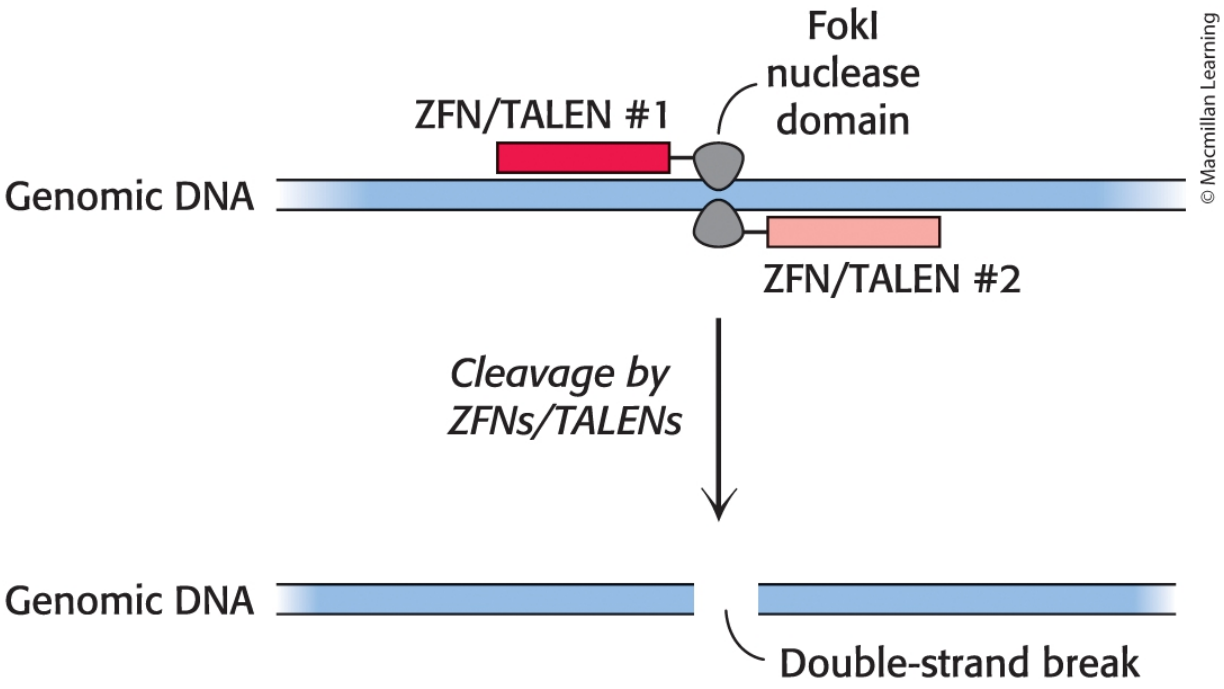
A linear double-stranded D N A is shown. A double-stranded break is introduced into the linear D N A.

Non-homologous end joining (N H E J): The repaired D N A can be of three types: identical to the original strand, joined with insertions, and slash or deletions in the strand.

Homology directed repair (H D R): A donor template D N A with a short green sequence in middle is shown to undergo homologous recombination with the original strand having a break. The resultant strand is shown to have the short green sequence incorporated into the repaired strand.

Return to Schematic illustration of non-homologous end joining and homology directed repair of D N A

Extended description for Recognition of individual bases in D N A by TALE repeats

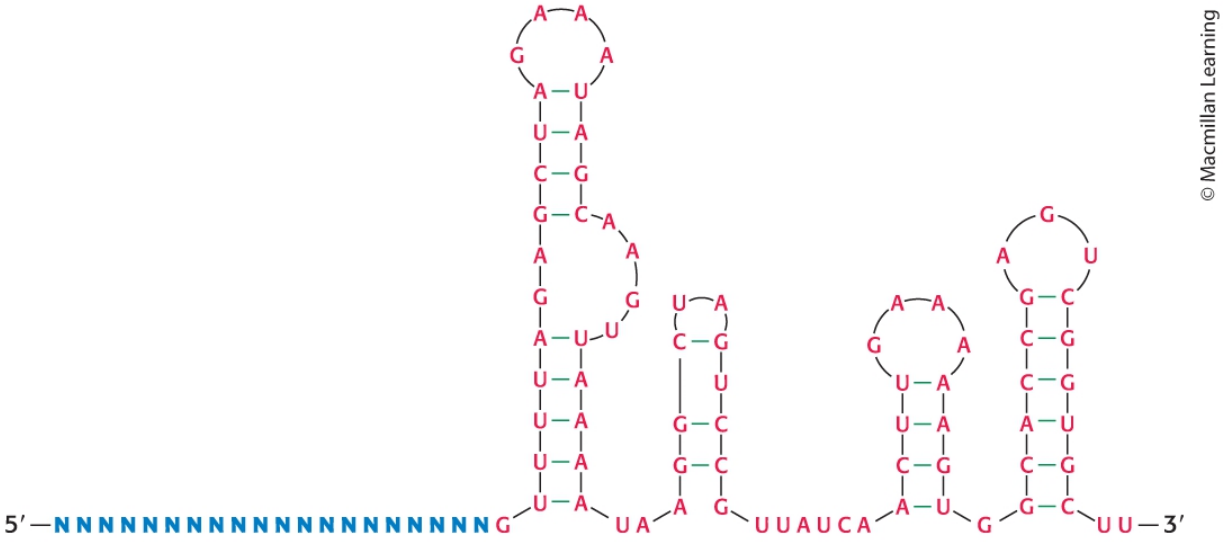


© Macmillan Learning

The D N A sequence in the 3 prime to 5 prime direction is T G C A T C T C C C C C T A C T G T A C A C C A C. The array of TALE repeats is a protein sequence aligned to the D N A sequence. The amino acid residues are color coded for each base as follows: G is green, C is yellow, A is red, and T is blue.

A double stranded D N A is shown to be bound by a TALE protein consisting of alpha helices connected by short loops.

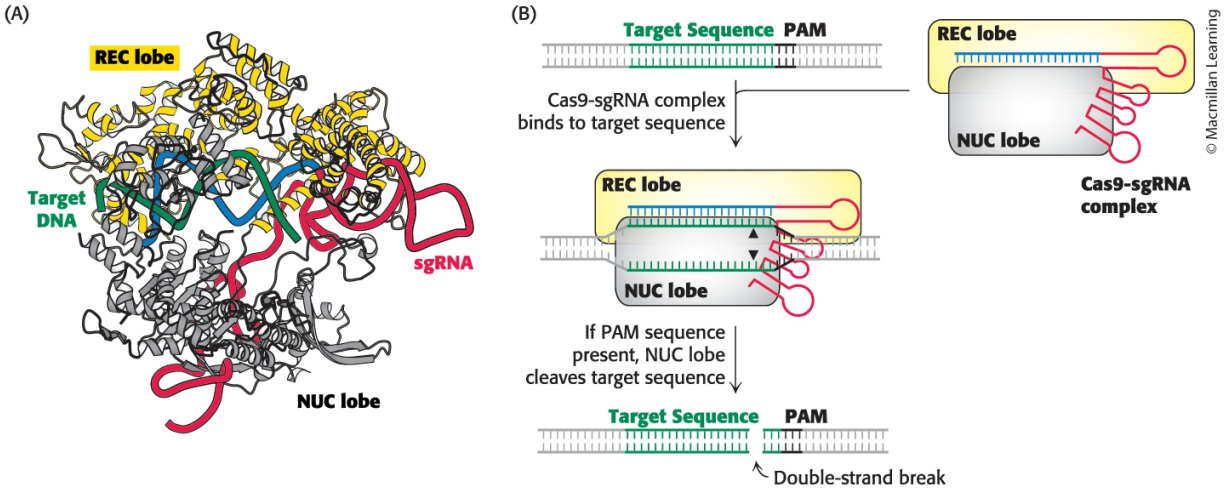
Return to Recognition of individual bases in D N A by TALE repeats



Extended description for Schematic illustration of the introduction of double-stranded break into D N A by Z F N or TALEN

A linear double-stranded genomic D N A is shown. Two triangular F o k roman number 1 nuclease domains are shown attached to the top and bottom strand on the D N A, respectively. A red bar labeled Z F N slash TALEN number 1 is linked to the left of the F o k 1 nuclease domain attached to the top strand. Similarly, a pink bar labeled Z F N slash TALEN number 2 is linked to the right of the F o k roman number 1 nuclease domain attached to the bottom strand. This introduces a double-stranded break at the D N A site.

Return to Schematic illustration of the introduction of double-stranded break into D N A by Z F N or TALEN



Extended description for Structure of single guide R N A

Twenty nucleotide residues (N) are present at the 5 prime end of the R N A. This is followed by four loops-stem structures toward the 3 prime end.

[Return to Structure of single guide R N A]

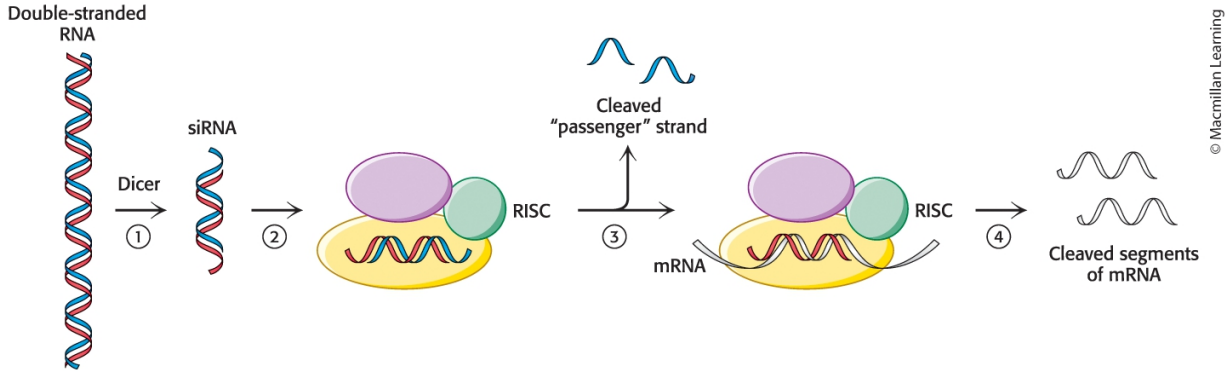
Extended description for Schematic illustration of D N A cleavage by CRISPR-Cas system

Part (A): Cas 9- s g R N A complex: The target D N A is shown as a green and blue double helix. The s g R N A shown in red is bound to one end of the target D N A. Some of the loops of the s g R N A are bound to the N U C lobe below. The N U C lobe shown in grey encircles the D N A. The R E C lobe shown in yellow covers the D N A from the top.

Part (B): D N A cleavage by CRISPR-Cas system:

The target sequence in a D N A segment in highlighted in green. A short PAM sequence to the right of the target sequence is highlighted in black.

The Cas 9- s g R N A complex is shown to have a rectangular R E C lobe. A short rectangular N U C lobe overlaps the R E C lobe above. The 20 nucleotide sequence (blue) of the s g R N A is shown linearly above the N U C lobe and within the R E C lobe. The first loop



connected to the 20 nucleotides is shown to be horizontal and the other three loops bend into the N U C lobe.

The Cas 9- s g R N A complex binds to the target sequence. The strands at the target sequence and PAM are shown to separate. The blue 20 nucleotide sequence of the Cas 9- s g R N A complex is shown to bind to the top strand.

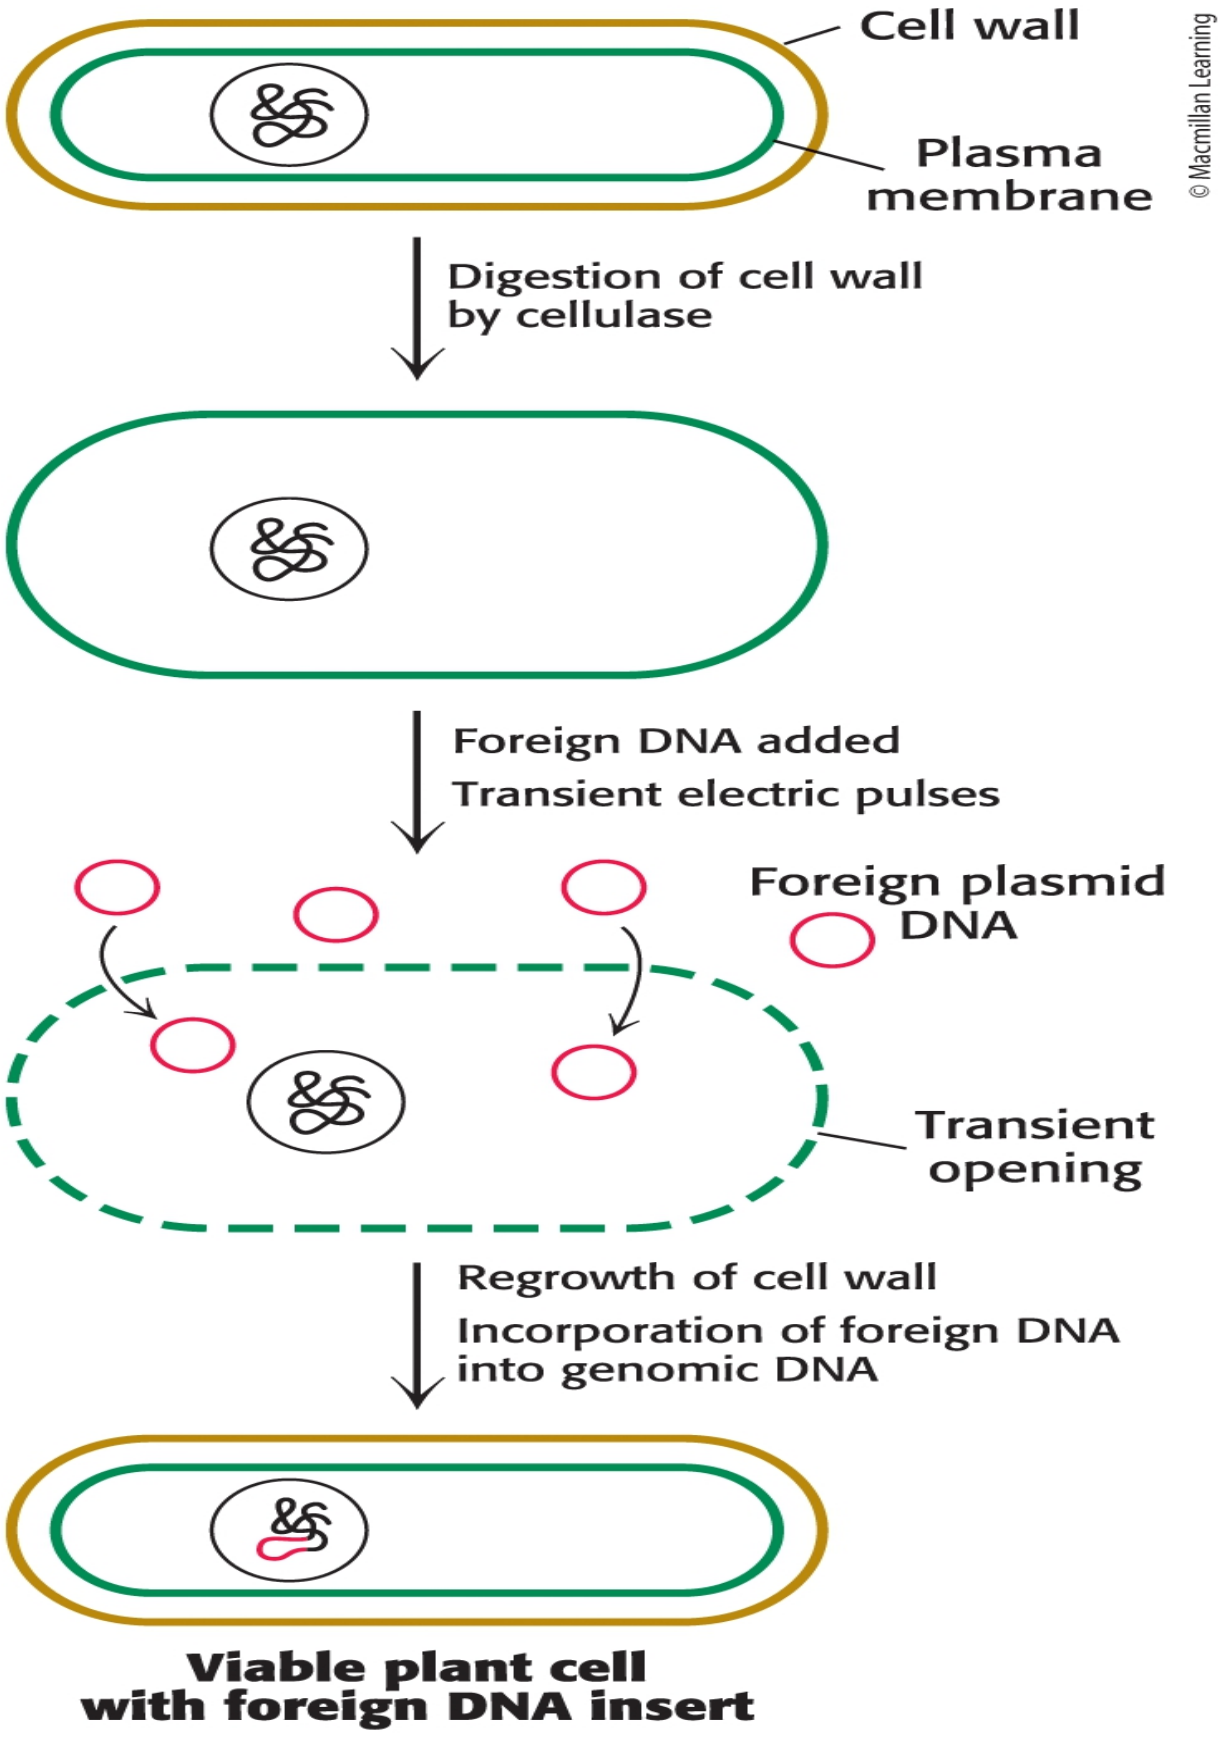
If PAM sequence is present, N U C lobe cleaves the target sequence. Two black triangles indicate the cleavage site in both strands. A double-stranded break in the target sequence is shown at a few bases upstream of the PAM sequence.

Return to Schematic illustration of D N A cleavage by CRISPR-Cas system

Extended description for Mechanism of R N A interference

Step 1: It is catalyzed by dicer. A long double-stranded R N A is shown to consist of a red and a blue strand. This long stretch on R N A is shown to be diced into a much smaller section labeled s i R N A.

Step 2: The fragmented s i R N A is shown to be incorporated into the R I S C. R I S C consists of three globular subunits and the s i R N A.



Step 3: The passenger strand (blue) of the s i R N A is cleaved and the red strand binds to an m R N A molecule.

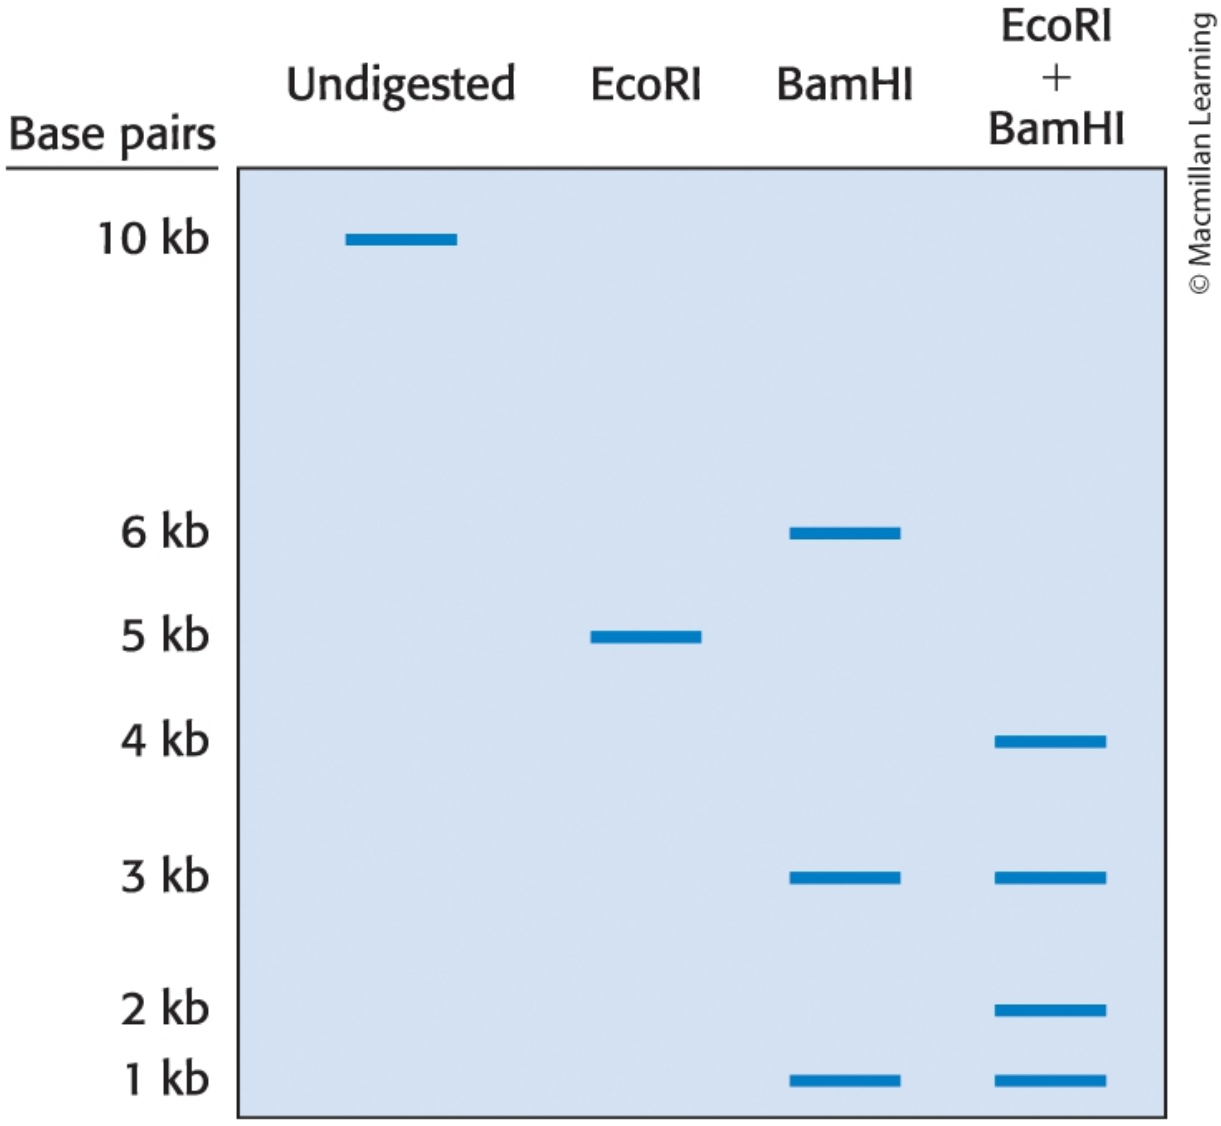
Step 4: The m R N A molecule is cleaved by the R I S C into short segments.

[Return to Mechanism of R N A interference]

Extended description for Schematic illustration of the steps of introduction of foreign D N A into plant cell by

electroporation

© Macmillan Learning



Step 1: Digestion of cell wall by cellulase. A plant cell is illustrated to have a plasma membrane enveloped by a cell wall. The nucleus containing the genome is present within the cell. The cell wall is shown to be digested leaving the plasma membrane exposed.

Step 2: Foreign D N A added and transient electric pulses are given to the plant cell. Foreign plasmid D N A molecules are shown as red rings. Electric pulses are shown to create transient openings in the cell membrane allowing the plasmids to enter the cell.

Step 3: Regrowth of cell wall. Incorporation of foreign D N A into genomic D N A. A viable plant cell with an intact cell wall and plasma membrane is shown to have the foreign D N A incorporated into its genomic D N A in the nucleus.

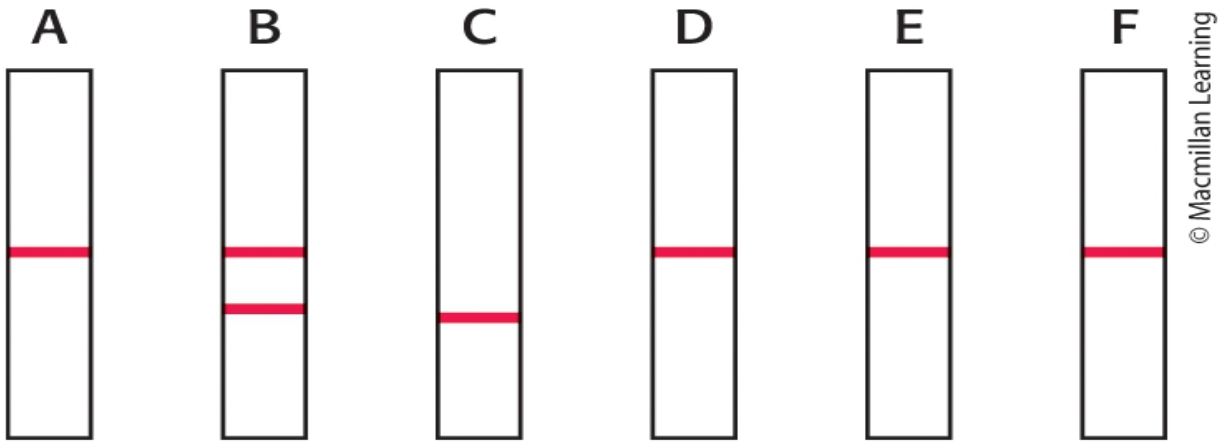
Return to Schematic illustration of the steps of introduction of foreign D N A into plant cell by electroporation

Extended description for Electrophoresis gel slab

The gel slab has four lanes with bands of varying sizes as follows:

Undigested: One band at 10 k b.

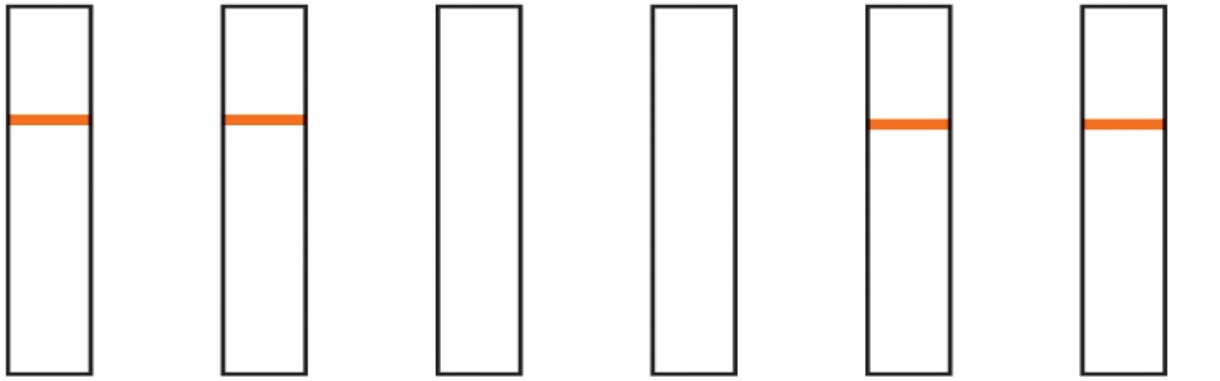
Eco R Roman number 1: One band at 5 k b.



Bam H Roman number 1: Three bands at 6 k b, 3 k b, and 1 k b respectively.

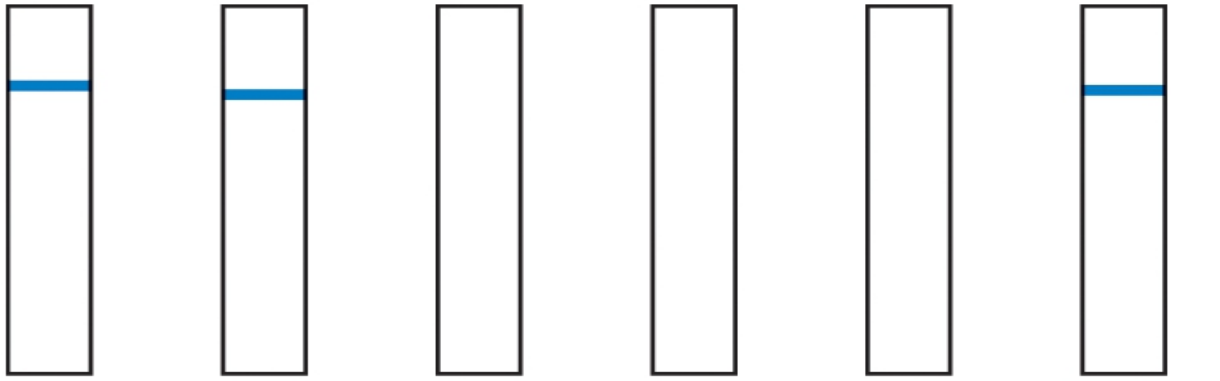
Eco R Roman number 1 plus Bam H Roman number 1: Four bands at 4 k b, 3 k b, 2 k b, and 1 k b.

Return to Electrophoresis gel slab



Extended description for Banding pattern in southern,

northern, and western blots



© Macmillan Learning

Southern blots

Northern blots

Western blots

The blot patterns for six individuals labeled A through F are given as follows:

Southern blot:

A: One red band in the middle.

B: One red band at the same level as A and one below.

C: One red band at the same level as the lower band of B.

D: One red band at the same level as A

E: One red band at the same level as A

F: One red band at the same level as A

Northern blot:

A: One orange band slightly above the midpoint.

B: One orange band at the same level as A.

C: No band.

D: No band.

E: One orange band at the same level as A.

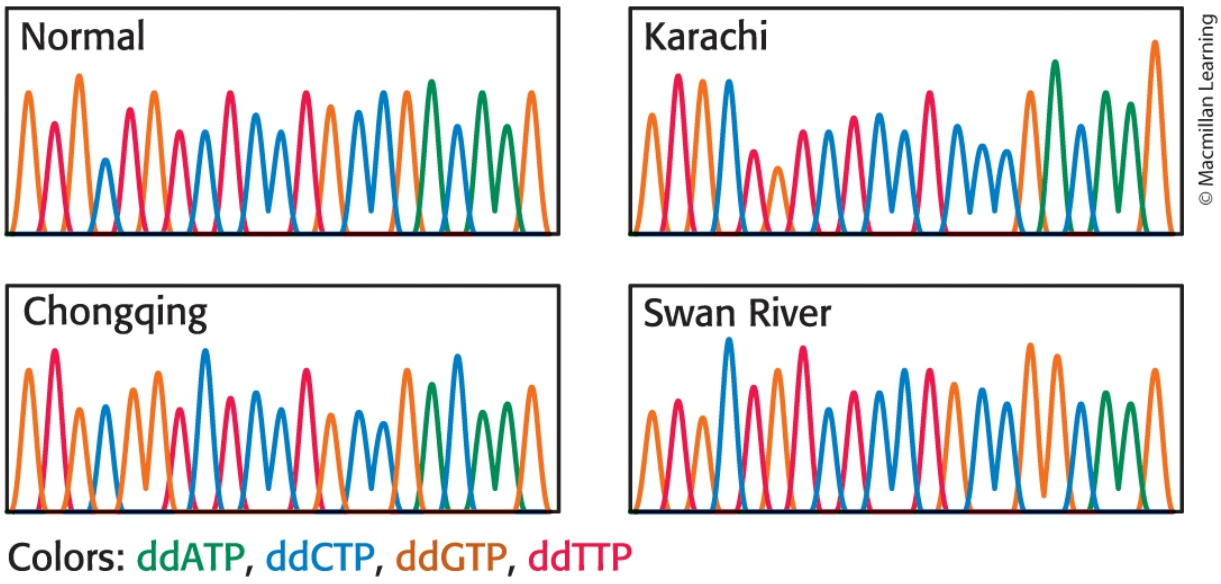
F: One orange band at the same level as A.

Western blot:

A: One blue band below the top end.

B: One blue band at the same level as A.

C: No band.



D: No band.

E: No band.

F: One blue band at the same level as A.

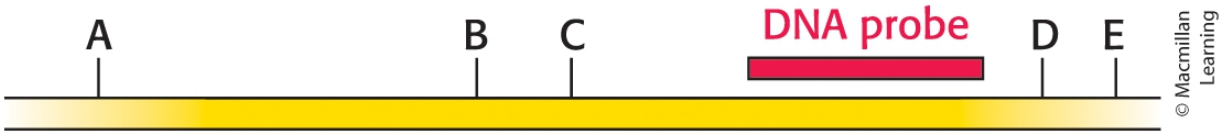
Extended description for A time versus temperature plot

© Macmillan Learning



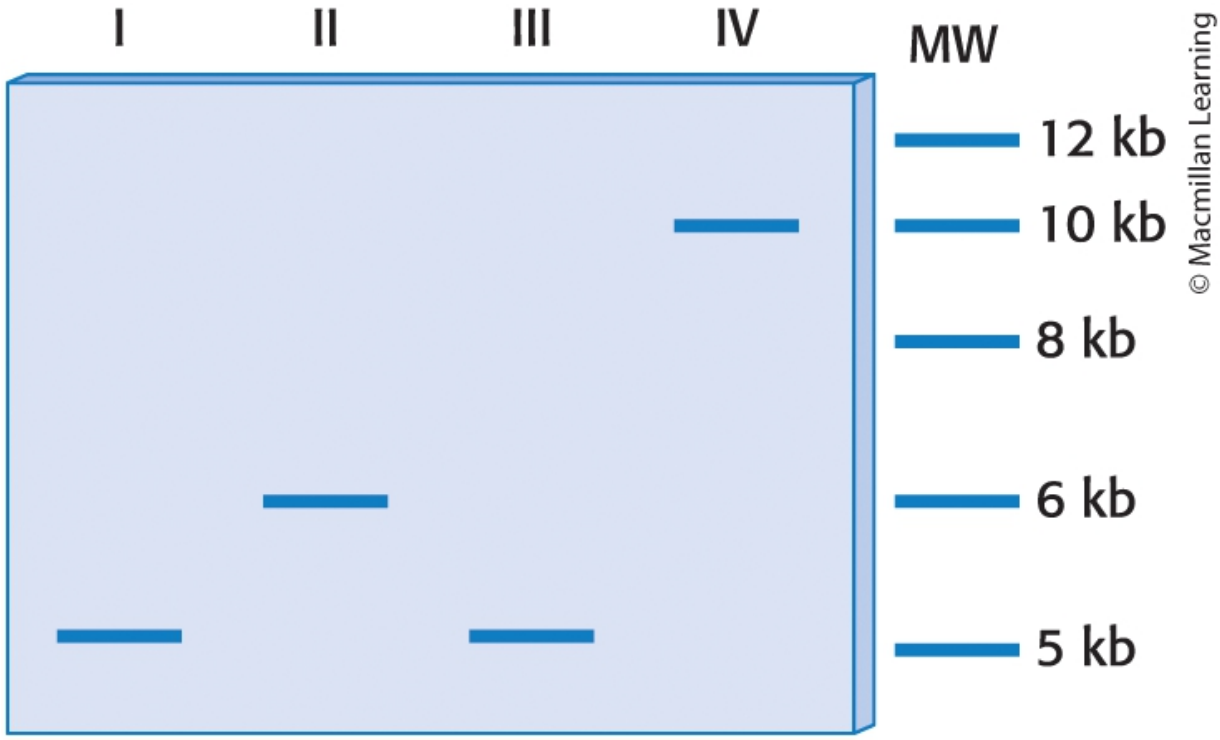
The horizontal axis is labeled time. The vertical axis is labeled temperature (degree Celsius) and ranges from 50 to 90 in increments of 20 units.

A red plot line starts from nearly 75 on the vertical axis and rises steeply to a plateau above 90. The plateau is labeled 1. The plot then falls sharply to another plateau below 60. The plateau is labeled 2.

The plot then rises sharply to another plateau just above 70. The plateau is labeled 3.

Return to A time versus temperature plot

Extended description for Cleavage sites in a D N A segment



The D N A segment from the left to right is labeled Athrough E. The distance between A and B is large. The distance between B and C is one-fourth of that between A and B. The distance between C and D is greater than that between A and B. The distance between D and E is slightly less than that between B and C.

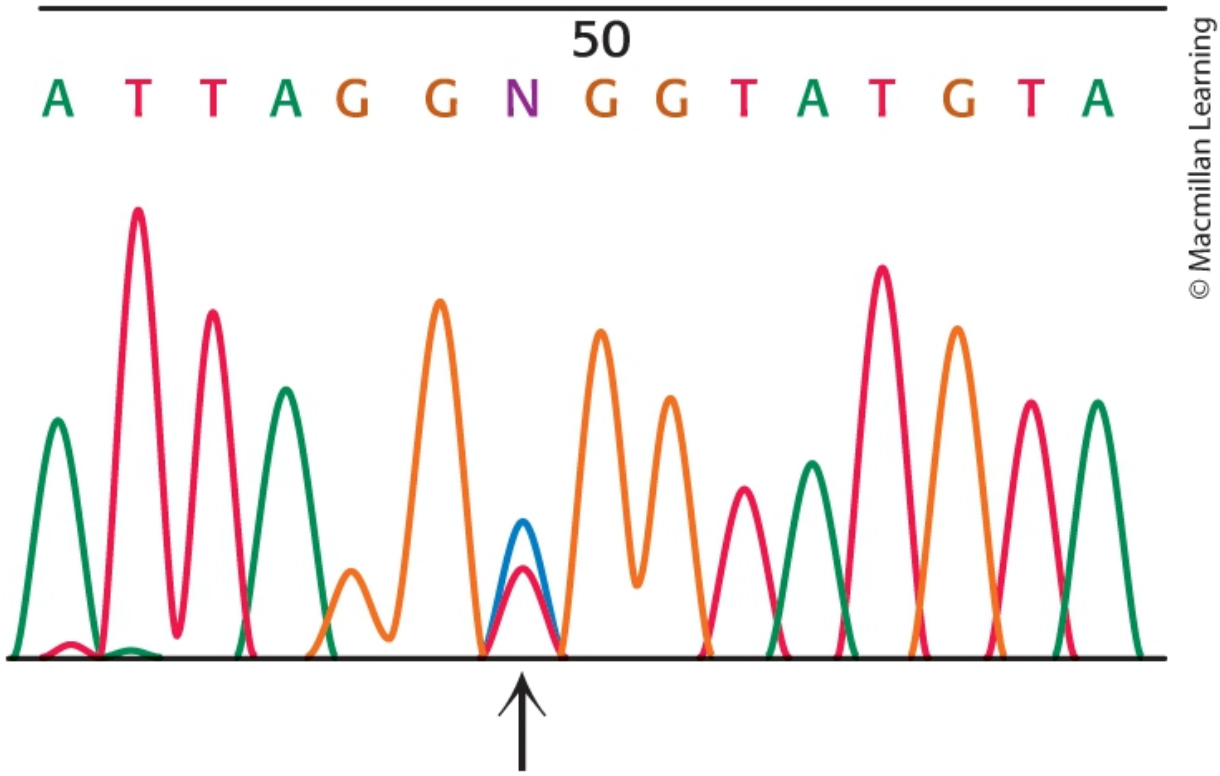
A D N A probe is complementary to a region between C and D and is closer to D.

Return to Cleavage sites in a D N A segment

Extended description for Electrophoresis gel slab

The gel slab has four lanes with bands of varying sizes as follows:

Lane 1: One band at 5 k b.



Lane 2: One band at 6 k b.

Lane 3: One band at 5 k b.

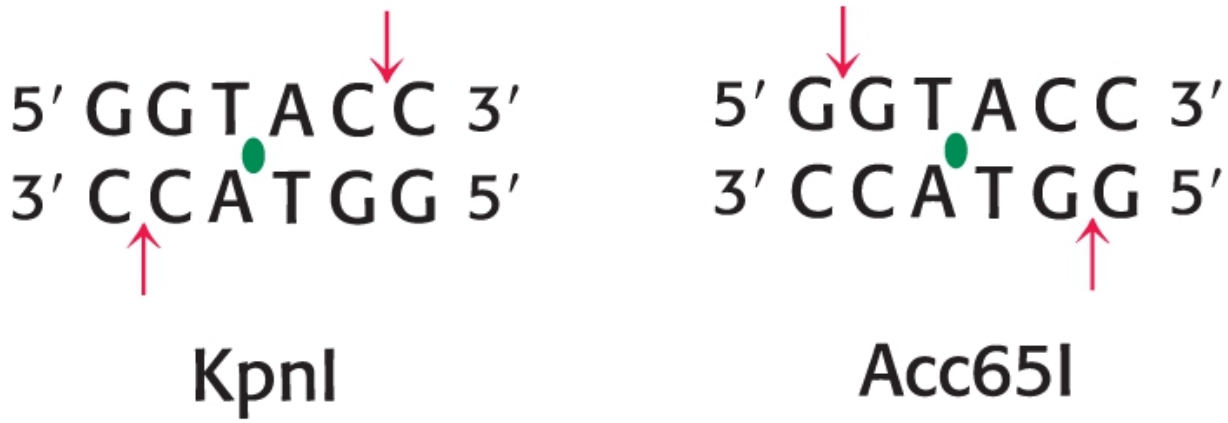
Lane 4: One band at 10 k b.

Return to Electrophoresis gel slab

Extended description for Sequencing chromatogram

The nucleotides are color coded as follows:

A: green



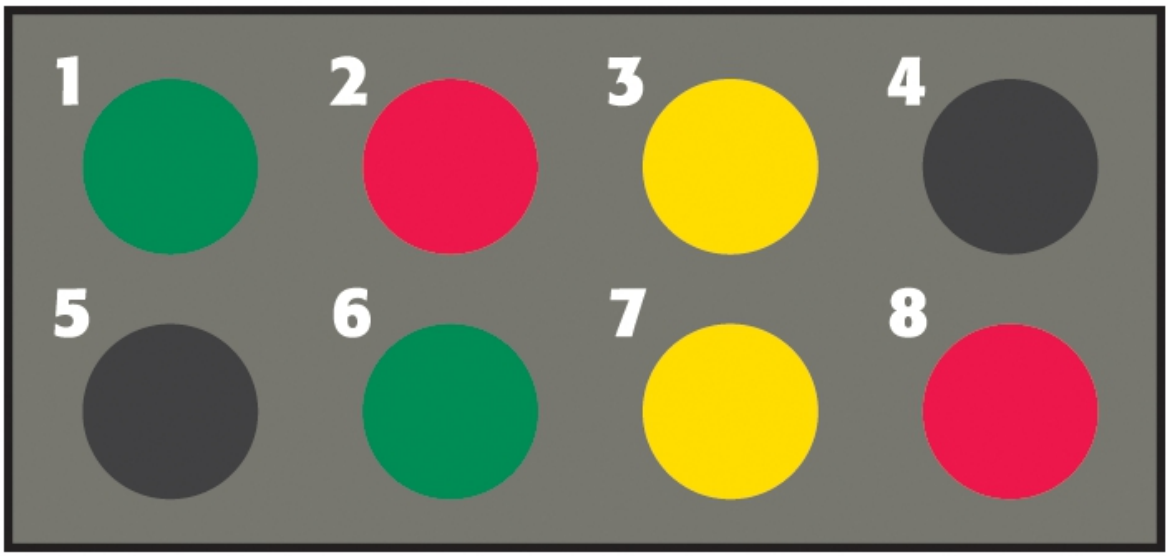
T: red

G: orange

At position 49 two overlapping peaks are observed. A short red peak and a slightly higher blue peak. The corresponding nucleotide is labeled N in purple.

Return to Sequencing chromatogram

Extended description for Cleavage sites of K p n roman number 1 and A c c 6 5 roman number 1.



Two double-stranded palindromic D N A sequences are shown along with the corresponding cleavage sites of the following enzymes:

K p n Roman number 1: The D N A sequence in the 5 prime to 3 prime direction is G G T A C C. The symmetry axis is indicated to be between T and A at the third and fourth positions, respectively, from the 5 prime end. The cleavage site on each strand is between C and C at the first and second positions, respectively, from the 3 prime end.

A c c 6 5 Roman number 1: The D N A sequence in the 5 prime to 3 prime direction is G G T A C C. The symmetry axis is indicated to be between T and A at the third and fourth positions, respectively, from the 5 prime end. The cleavage site on each strand is between G and G at the first and second positions, respectively, from the 5 prime end.

Return to Cleavage sites of K p n roman number 1 and A c c 6 5 roman number 1.

Extended description for FIGURE 10.1 Homologs can be divided into two classes

Bovine ribonuclease (digestive enzyme) has a cup shaped structure and consists of both beta sheets and alpha helices connected by short loops. It is followed by a double headed arrow labeled orthologs that points toward human ribonuclease (digestive enzyme). Human ribonuclease has a very similar structure to that of bovine ribonuclease but is slightly more compact. It is again followed by a double headed arrow labeled paralogs that points toward human angiogenin (stimulates blood-vessel growth). It has a similar structure to that of human ribonuclease.

Return to FIGURE 10.1 Homologs can be divided into two classes

Extended description for FIGURE 10.2 The amino acid sequences of human hemoglobin (chain) and human myoglobin will be used to demonstrate sequence alignments

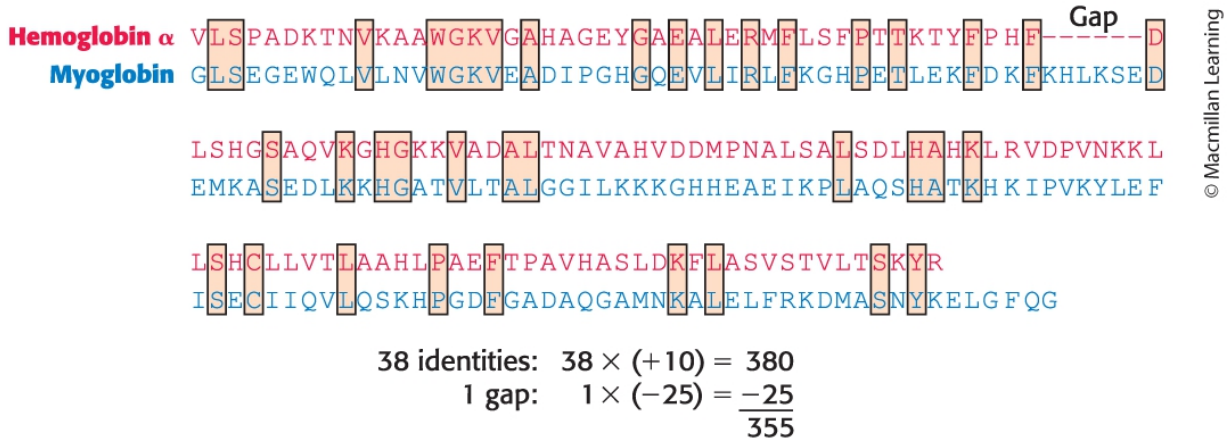
Return to FIGURE 10.2 The amino acid sequences of human hemoglobin (chain) and human myoglobin will be used to demonstrate sequence alignments

Extended description for FIGURE 10.3 Amino acid sequences are compared by sliding one sequence past the other, one amino acid at a time



Part (A): The hemoglobin sequence is aligned above the myoglobin sequence. The hemoglobin sequence is placed slightly to the left and is only partially overlapped with the myoglobin sequence. After sliding sequences past each other, the hemoglobin sequence is

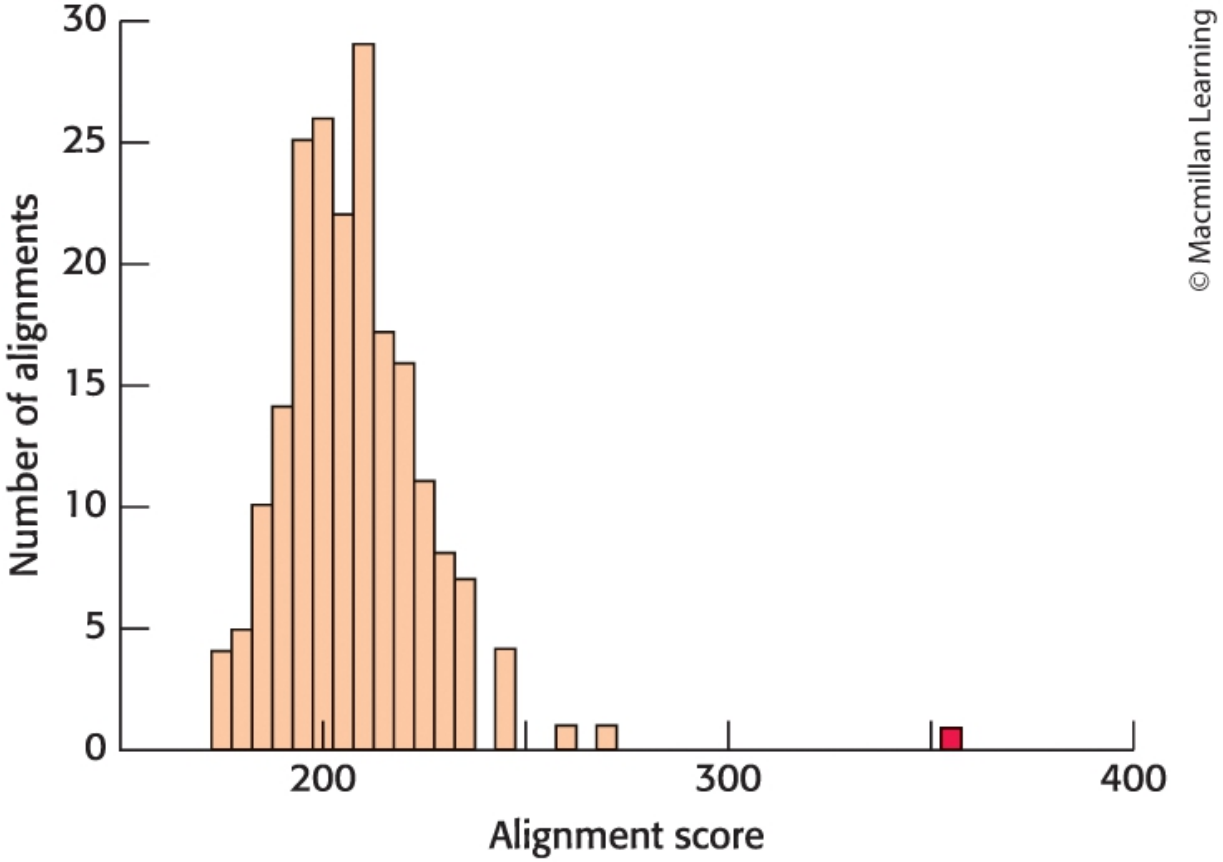
placed slightly to the right and is only partially overlapped with the myoglobin sequence.

Part (B): A histogram is shown. The horizontal axis is labeled Alignment. The vertical axis is labeled Number of matches and ranges from 0 to 25 in increments of 5 units. The histogram has a mountain shape with two tall peaks in the center. The first peak corresponds to 22 matches when hemoglobin is to the left of myoglobin. The second peak corresponds to 23 matches when hemoglobin is to the right of myoglobin after sliding. The matching amino acid residues are shown within boxes in both alignments. There is a short gap in the hemoglobin sequence when aligned with myoglobin.

Return to FIGURE 10.3 Amino acid sequences are compared by sliding one sequence past the other, one amino acid at a time

Extended description for FIGURE 10.4 Scoring method

The amino acid sequences of hemoglobin alpha and myoglobin are aligned. Several identical amino acids are identified across the aligned sequences and enclosed in rectangular boxes. The identical amino acids either occur singly or in a cluster of 2 to 3. A gap is shown in the hemoglobin alpha sequence. It is flanked by F and D amino acids and occurs between amino acid positions 47 and 52 in the myoglobin sequence. A calculation is shown as follows:



Line 1: 38 identities: 38 times positive 10 equals 380

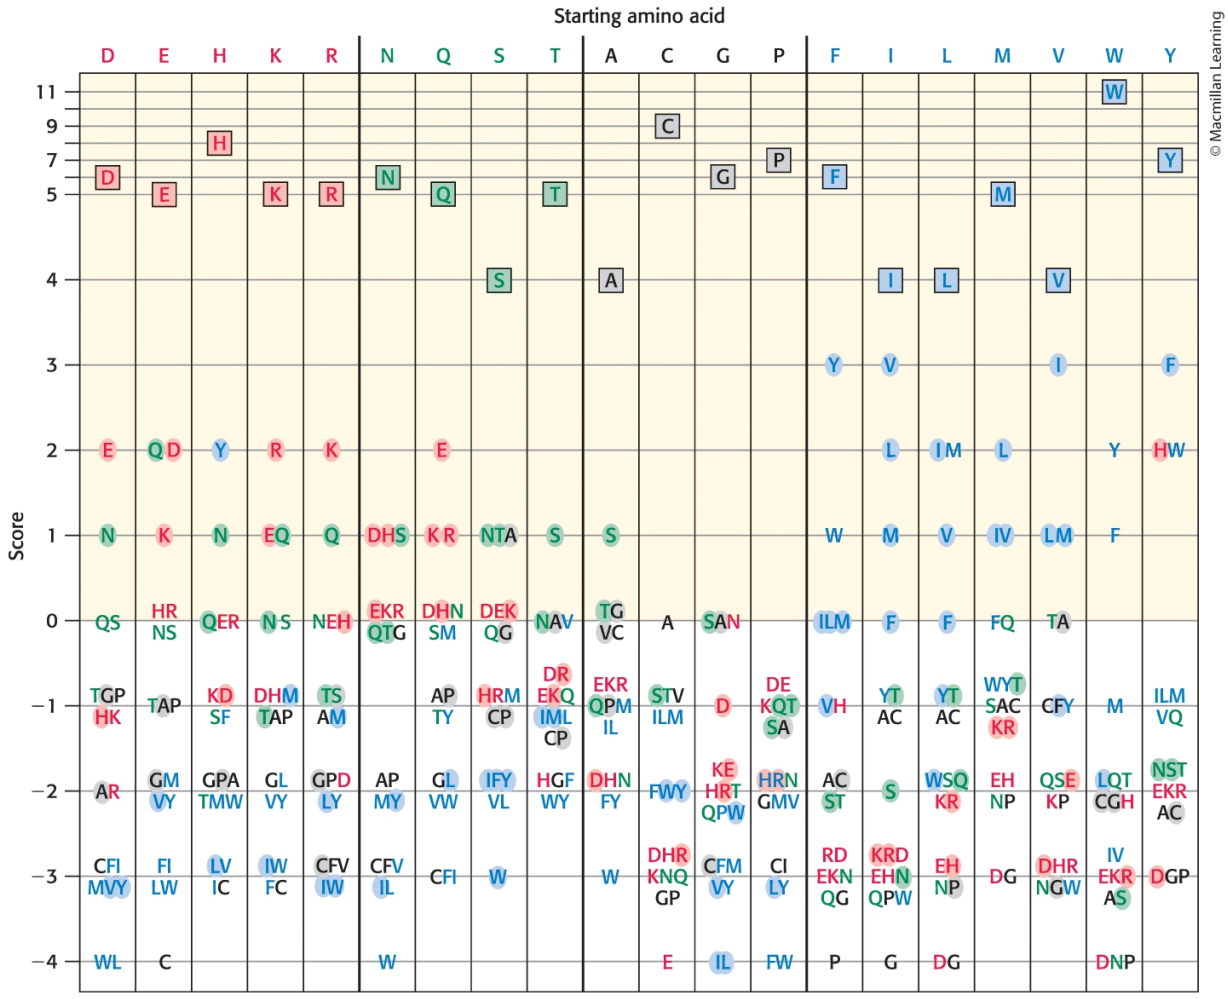
Line 2: 1 gap: 1 times negative 25 equals negative 25

The sum of 380 and negative 25 is 355.

Return to FIGURE 10.4 Scoring method

Extended description for FIGURE 10.6 Comparison of alignment scores reveals the statistical significance of an unshuffled alignment

© Macmillan Learning



The horizontal axis is labeled Alignment score and ranges from 0 to 400 in increments of 100 units. The vertical axis is labeled Number of alignments and ranges from 0 to 30 in increments of 5 units.

Shuffled sequence: The histogram starts at nearly (100, 4), peaks at nearly (215, 29), and falls to (270, 2).

Unshuffled sequence: A single bar at almost (355, 2). All values are estimated.

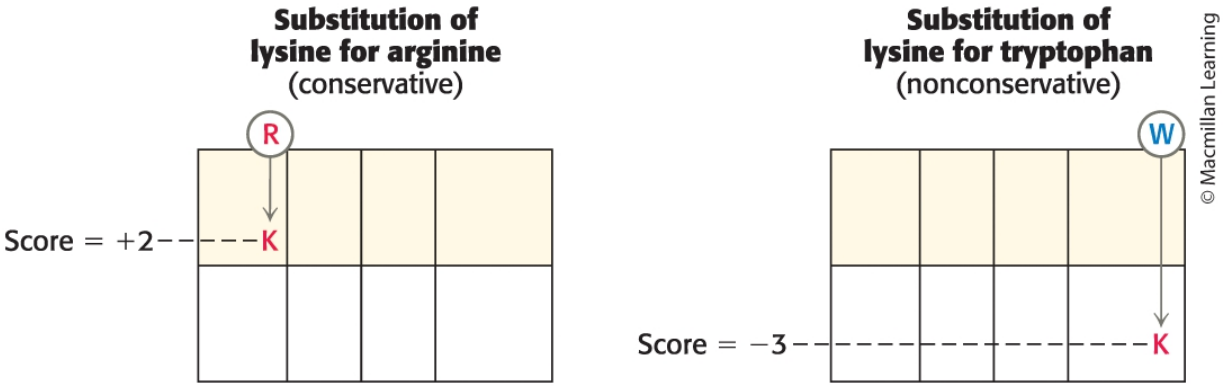
Return to FIGURE 10.6 Comparison of alignment scores reveals the statistical significance of an unshuffled alignment

Extended description for FIGURE 10.7 The Blosum-62 substitution matrix enables scoring based on amino acid similarity

The columns are labeled Starting amino acid. There are 20 columns, from left to right as follows: D, E, H, K, R, N, Q, S, T, A, C, G, P, F, I, L, M, V, W, and Y. D, E, H, K, and R are labeled in red. N, Q, S, and T are labeled in green. A, C, G, and P are labeled in black. F, I, L, M, V, W, and Y are labeled in blue.

The rows are labeled Score and range from 11, 9, 7 5,4, 3, 2, 1, 0,-1, -2, -3 and -4, from top to bottom.

Substitutions scores are as follows:



The rows entries for column D are as follows:

D shaded within a box is 6, E shaded is 2, N shaded is 1, Q S is 0, T G (shaded) P H (shaded) K is negative 1, A (shaded) R is negative 2, C F I M V (shaded) Y (shaded) is negative 3, W L is negative 4.

Similarly, the scores are given for the rest of the 19 amino acids.

Return to FIGURE 10.7 The Blosum-62 substitution matrix enables scoring based on amino acid similarity

Extended description for FIGURE 10.8 Conservative and nonconservative substitutions yield very different scores in the Blosum-62 matrix

Substitution of lysine for arginine (conservative): A matrix of 2 rows and 4 columns is shown. R (red) is substituted by K (red) in row 1 and column 1. The score is positive 2.

Substitution of lysine for tryptophan (nonconservative): A matrix of 4 rows and 2 columns is shown. W (blue) is substituted by K (red) in row 1 column 4. The score is negative 3.

© Macmillan Learning

Both are three-dimensional structures that form an inverted U-shape. They consist of alpha helices and beta sheets connected by short loops. H s p 70 has a narrower groove as compared to actin.

Return to FIGURE 10.14 The structures of actin and a large fragment of heat shock protein 70 (Hsp70) reveal an unexpected relationship

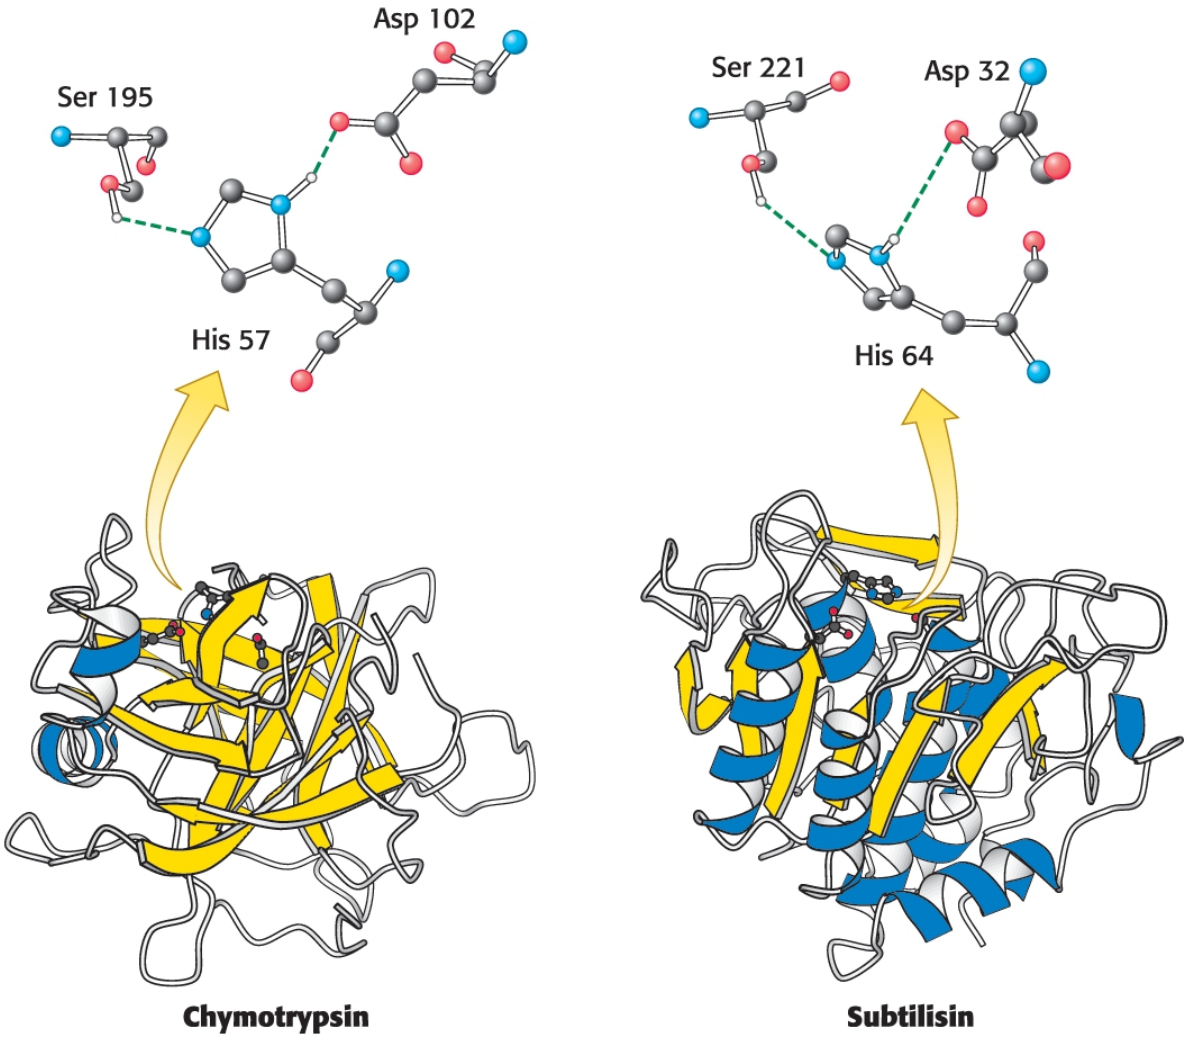
Extended description for FIGURE 10.15 Internal repeats can be identified using a self-alignment

Part (A): The sequence of TATA-box-binding protein is sliding over the same sequence. When the top sequence is shifted to the left and

partially overlaps the sequence below, there is 40 percent identity. When the top sequence completely overlaps the bottom sequence, 100 percent identity is observed. When the top sequence is positioned to the right and partially overlaps the sequence below, 40 percent identity is observed.

Part (B): Sequence alignment within the internal region of similarity

Amino acid residues 25 to 88 (red) are placed above residues 115 to 179 (blue).



Conservative substitutions are indicated by yellow shading. The count is 12, which are as follows: L I, T S, L V, L I, K E, I L, A S, K E, V L, I M, R K, and M I.

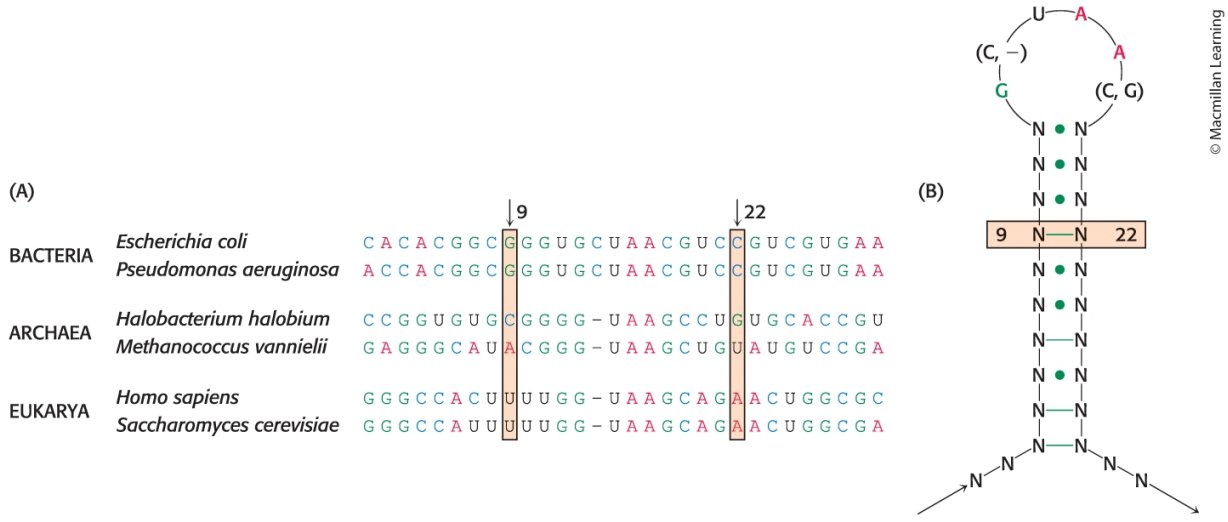
Identities are indicated by orange boxes. The count is 26. They are as follows: Q Q, N N, I I, V V, L L, A A, A A, Y Y, P P, F F, I I, R R, P P, K K, L L, I I, F F, S S, G G, K K, V V, T T, G G, A A, K K, and D D.

Part (C): Structure of TATA-box-binding protein. The N-terminal repeat is shown, which has a similar three-dimensional ribbon structure as the C-terminal repeat. Each terminal consists of alpha helices and beta sheets connected by short loops.

Return to FIGURE 10.15 Internal repeats can be identified using a self-alignment

Extended description for FIGURE 10.16 Mammalian chymotrypsin and bacterial subtilisin are examples of convergent evolution

© Macmillan Learning



Both chymotrypsin and subtilisin have globular structures.

Chymotrypsin: The catalytic residues are Serine 195, Aspartate 102, and Histidine 57. Histidine below is hydrogen bonded to Serine on the upper left and Aspartate on the upper right.

Subtilisin: The catalytic residues are Serine 221, Aspartate 32, and Histidine 64. Histidine below is hydrogen bonded to Serine on the upper left and Aspartate on the upper right.

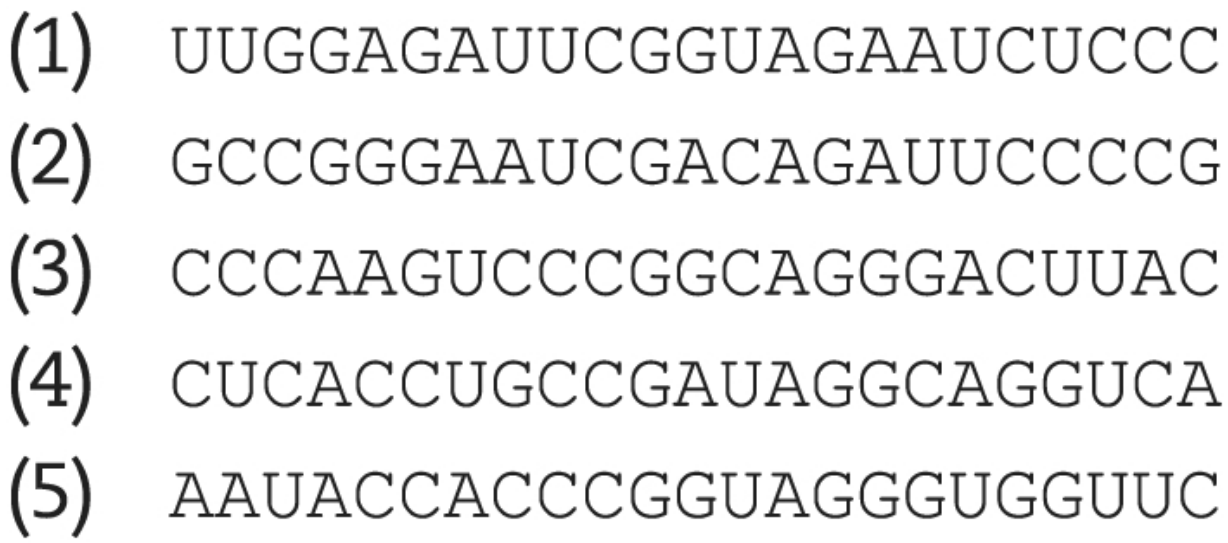
Extended description for FIGURE 10.17 RNA sequence alignments provide insights into structure based on conservation of base-pairing. (A) A comparison of sequences in a part of ribosomal RNA taken from a variety of species

Part (A):

Bacteria: Eschericia coli and Pseudomonas aeruginosa.

Archaea: Halobacterium halobium and Methanococcus vannielii.



Eukarya: Homo sapiens and Saccharomyces cerevisiae.

The nucleotides at the ninth and twenty-second positions in all the organisms are identities that are indicated by orange boxes. The identities at the ninth position are: G G, C A, and U U. The identities at the twenty-second are: C C, G U, and A A.

Part (B): The secondary structure is a stem-loop structure. The Watson-Crick base pairing between the bases at the ninth and the twenty-second positions is shown to be conserved.

Extended description for Stem loop structure of R N A

A stem-loop structure is shown. It contains a trail of N residues at the left and right ends. The stem is composed of a pair of 5 N residues and a G C pair hydrogen bonded to each other from bottom to top. The loop part contains the residues G, N, N, and A arranged in a clockwise direction from bottom left to bottom right.

Return to Stem loop structure of R N A

Extended description for FIGURE 10.18 Sequence alignments enable the construction of an evolutionary tree

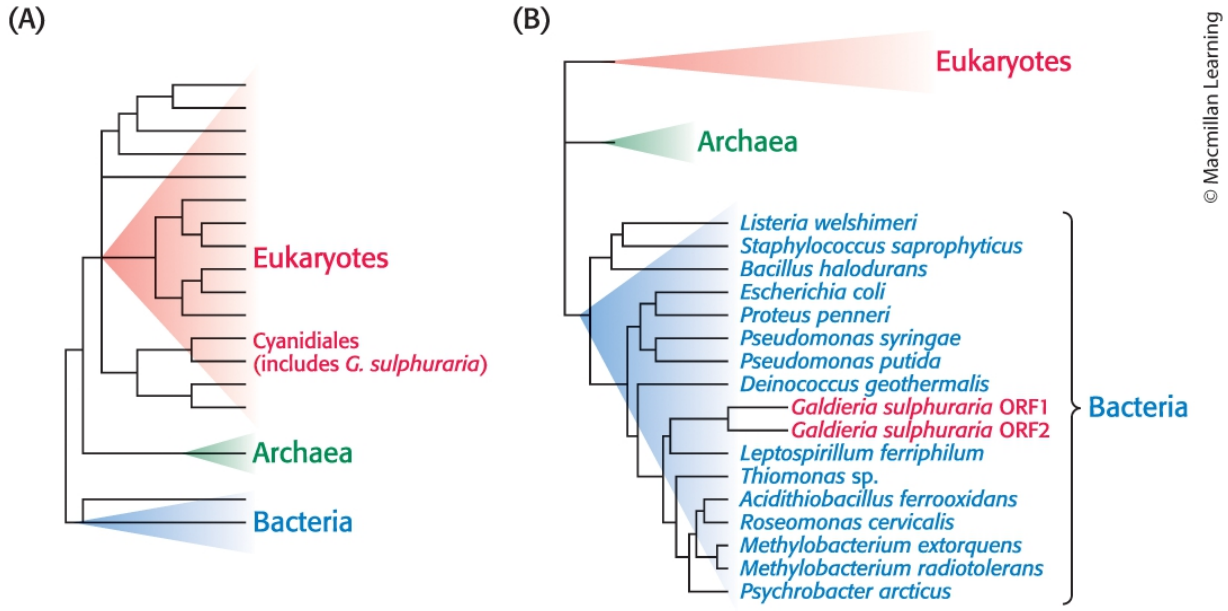
The vertical evolutionary tree is shown next to a vertical axis labeled Time (millions of years ago) and ranges from 800 to 0 in decrements of 200 units.

The root of the evolutionary tree is at 900 and it splits into two level-1 branches just before 800.

The first level-1 branch terminates in Leghemoglobin at 0.

The second level-1 branch splits into two level-2 branches just after 600.

The first level-2 branch terminates in myoglobin at 0.



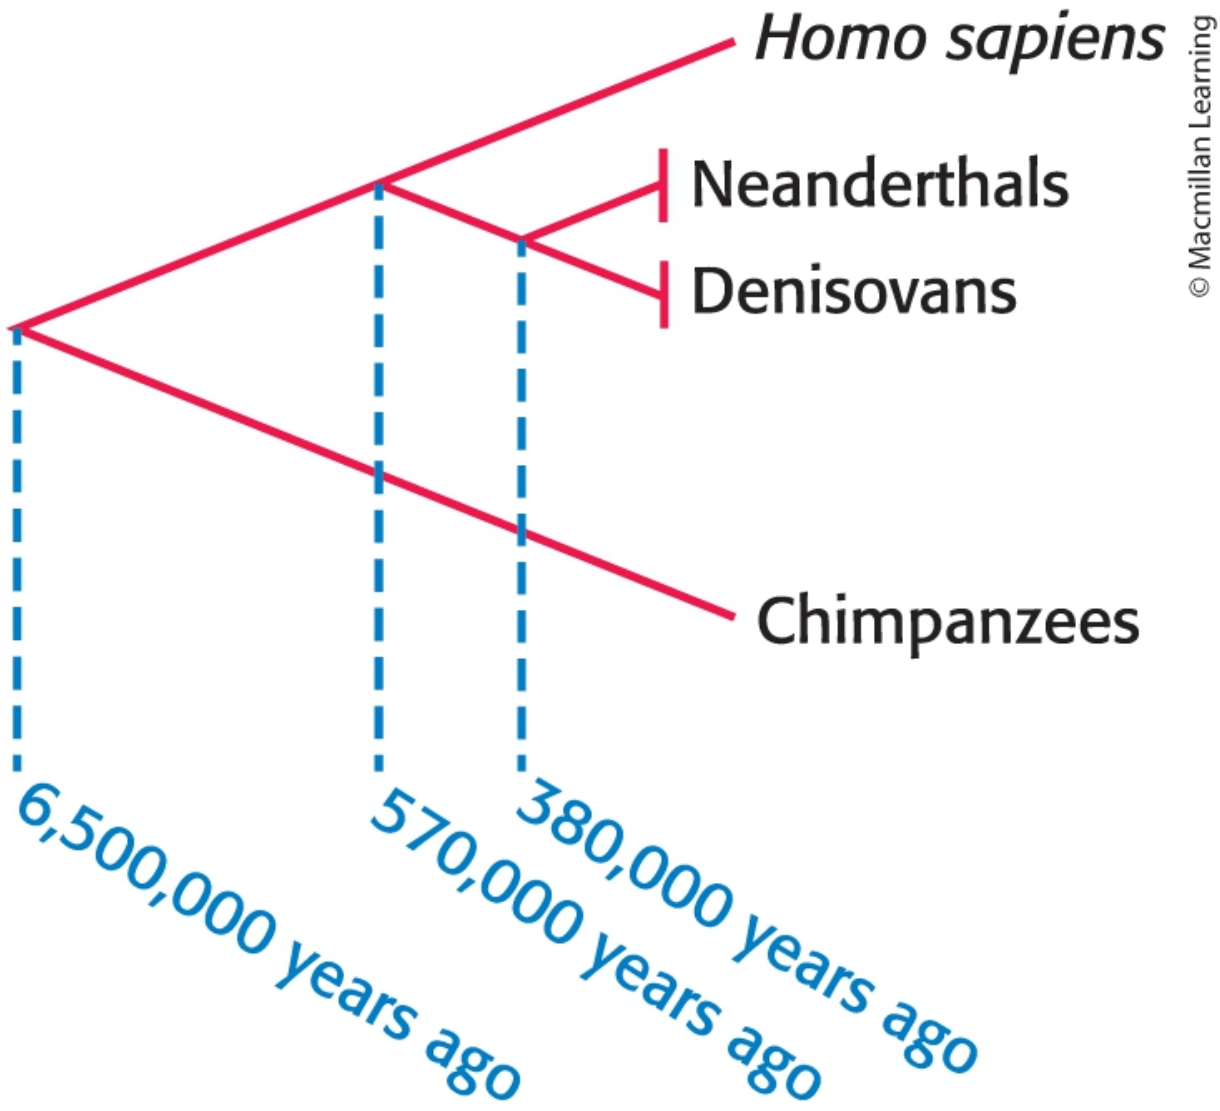
The second level-2 branch splits into two level-3 branches just after 400.

The first level-3 branch terminates in hemoglobin alpha at 0.

The second level-3 branch terminates in hemoglobin beta at 0.

Return to FIGURE 10.18 Sequence alignments enable the construction of an evolutionary tree

Extended description for FIGURE 10.21 Proteins encoded within the G. sulphuraria genome with high homology to prokaryotic sequences are suggestive of horizontal gene transfer



Part (A): A common ancestor gives rise to two level-1 branches. From bottom to top, the first level-1 branch splits into two level-2 branches that represent bacteria. The second level-1 branch splits into two level-2 branches. The first level-2 branch represents Archaea. The second level-2 branch splits into three level-3 branches. The first and second level-3 branches subsequently split into multiple branches that represent eukaryotes. The third level-3 branch subsequently splits into multiple branches that represent Cyanidiales (includes G. suphuraria).

Part (B): There are three level-1 branches. From top to bottom, the first level-1 branch represents eukaryotes. The second level-1 branch represents Archaea. The third level-3 branch subsequently splits

into multiple branches that represent bacteria named: *Listeria welshimeri, Staphylococcus saprophyticus, Bacillus halodurans, Escherichia coli, Proteus penneri, Pseudomonas syringae, Pseudomonas putida, Deinococcus geothermalis, Leptospirillum ferriphilum, Thiomonas sp., Acidithiobacillus ferrooxidans, Roseomonas cervicalis, Methylobacterium extorquens, Methylobacterium radiotolerans, Psychrobacter arcticus*. Two terminal branches in between represent *Galdieria sulphuraria* O R F 1 and *Galdieria sulphuraria* O R F 2.

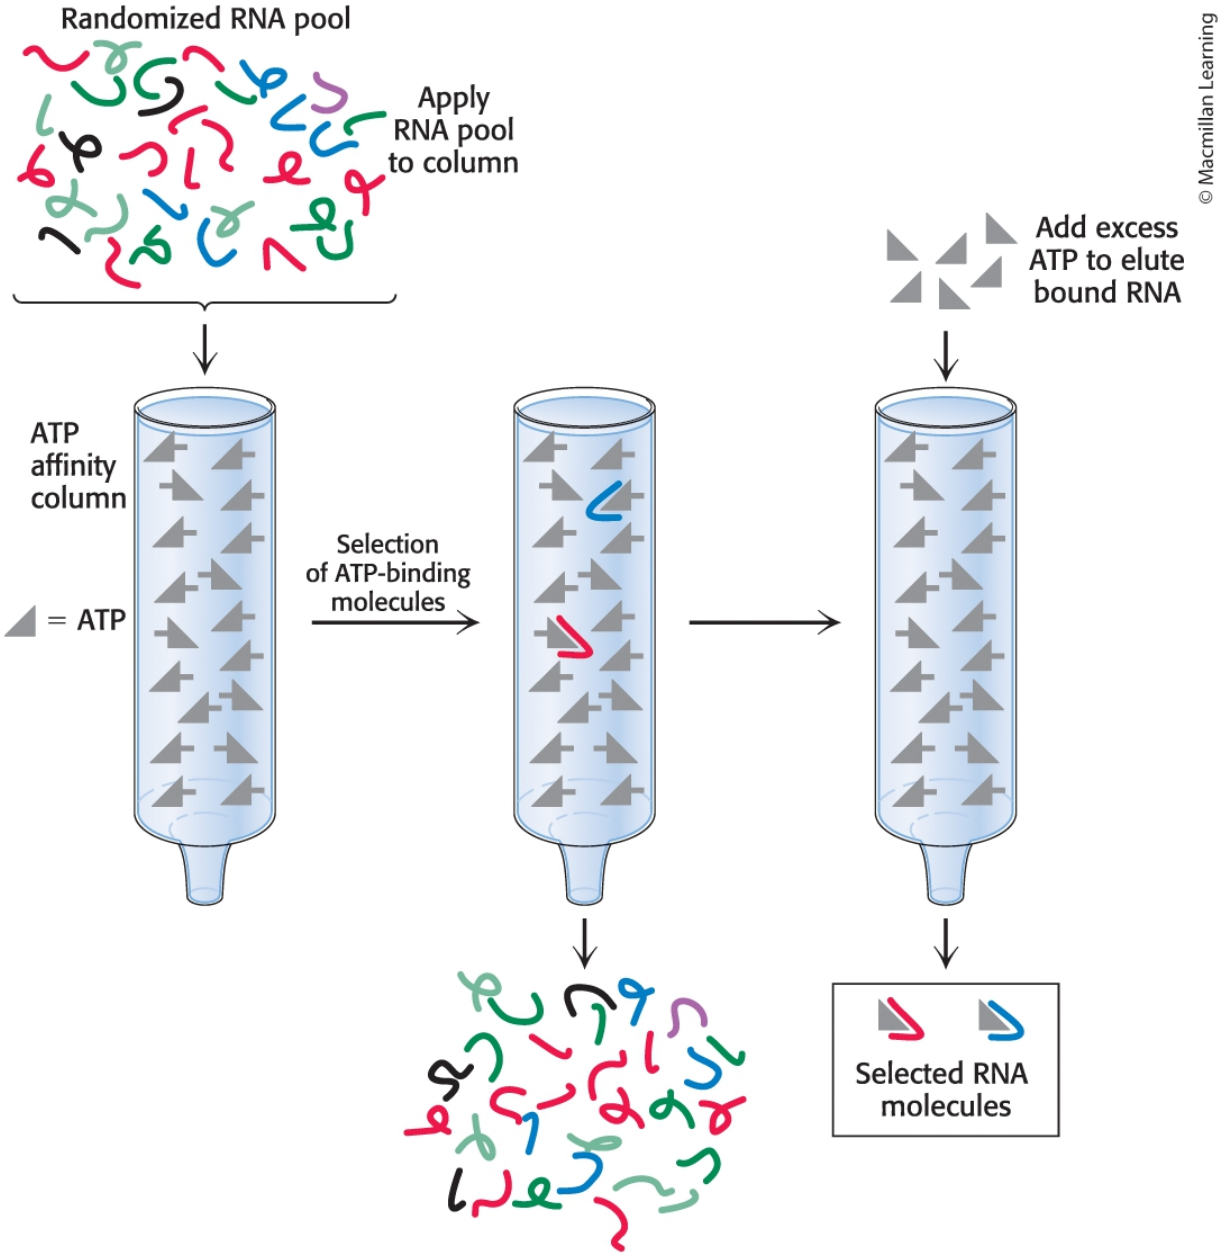
Extended description for FIGURE 10.22 DNA sequence comparisons enable the placement of Neanderthals and Denisovans on an evolutionary tree

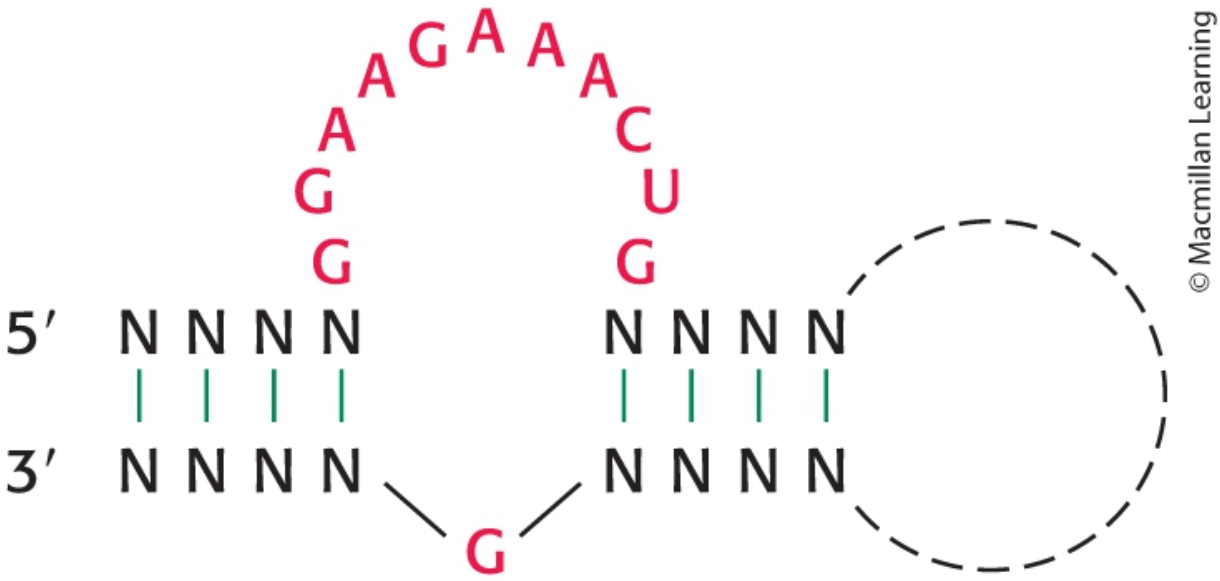


The common ancestor existed 6,500,000 years ago. This splits into two level-1 branches. The first level-1 branch is Chimpanzees. The second level-1 branch split into two level-2 branches 570,000 years ago. The first level-2 branch is Homo sapiens. The second level-2 branch split into two level-3 branches 380,000 years ago. The first

level-3 branch is the Neanderthals. The second level-3 branch is Denisovans.

Return to FIGURE 10.22 DNA sequence comparisons enable the placement of Neanderthals and Denisovans on an evolutionary tree

Extended description for FIGURE 10.23 Evolution can be studied in the laboratory setting



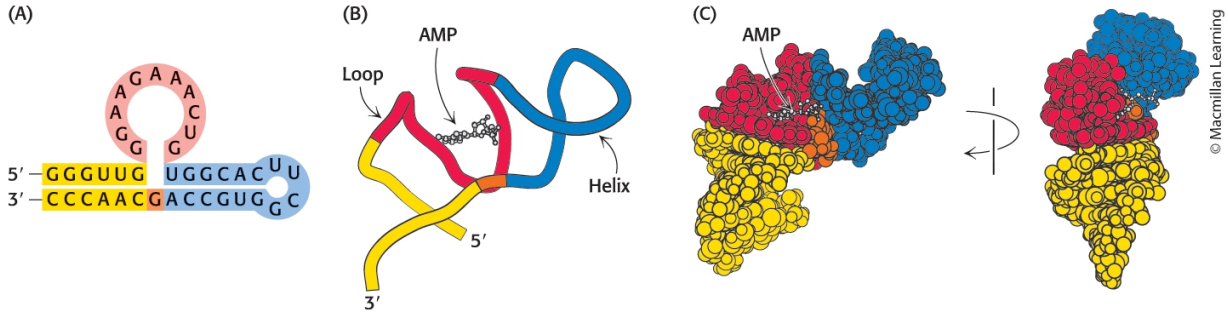
A randomized R N A pool with several R N A molecules is shown. A vertical column labeled A T P affinity column is shown. The column is layered with A T P molecules. The R N A pool is applied to the A T

P affinity column. The selection of A T P binding molecules is done by selecting the R N A molecules that bind to the A T P in the column. The unbound R N A molecules are released from the column.

Excess A T P is added to the column to elute out the selected R N A molecules.

Return to FIGURE 10.23 Evolution can be studied in the laboratory setting

Extended description for FIGURE 10.24 A conserved secondary structure is common to RNA molecules selected for ATP binding



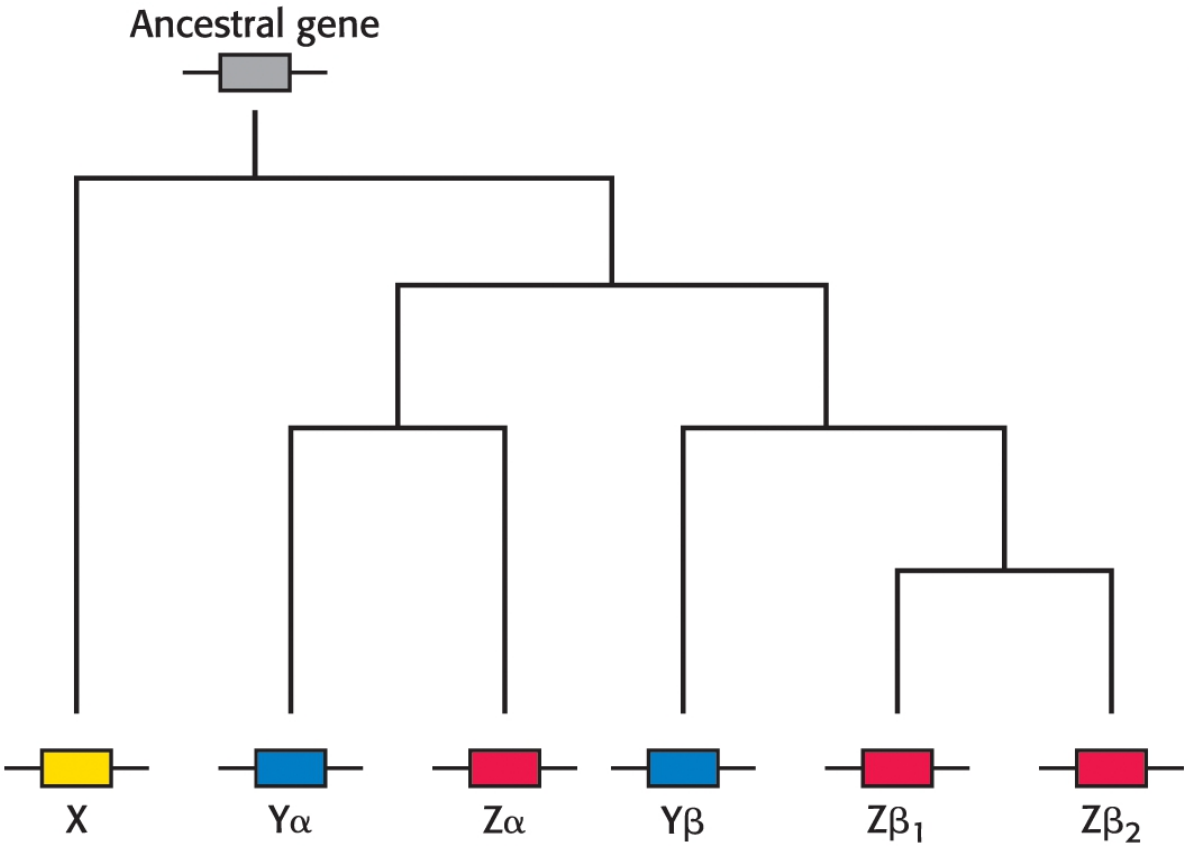
© Macmillan Learning

The sequence from the 3 prime end to loop is as follows: N N N N G G A A G A A A C U G N N N N loop.

The bases that are not conserved following the loop are paired with the top stem and have the following structure: N N N N G N N N N. The conserved bases are base paired.

Return to FIGURE 10.24 A conserved secondary structure is common to RNA molecules selected for ATP binding

Extended description for FIGURE 10.25 Experimental molecular evolution yields an ATP-binding RNA molecule



Part (A): The primary structure shows a horizontal stem loop structure. The left end of the stem is colored yellow containing the sequences C C C A A C at the 3 prime end and G G G U U G at the 5 prime end. The terminal loop at the right end is colored blue and contains the sequence U G G C A C U U C G G U G C C A G. A central loop of the upper strand is colored red and contains the sequence G G A A G A A A C U G.

Part (B): The N M R-structure reveals the blue region to be a helix. An A M P molecule is shown to be wedged within the red loop.

Part (C): The three-dimensional space-filling model shows a tightly bound helical structure with the distinct A M P binding region.

Return to FIGURE 10.25 Experimental molecular evolution yields an ATP-binding RNA molecule

Extended description for Evolutionary tree of similar genes

© Macmillan Learning

The ancestral gene is shown in gray, and it splits into two level-1 branches.

The first level-1 branch represents gene X shown in yellow.

The second level-1 branch splits into two level-2 branches.

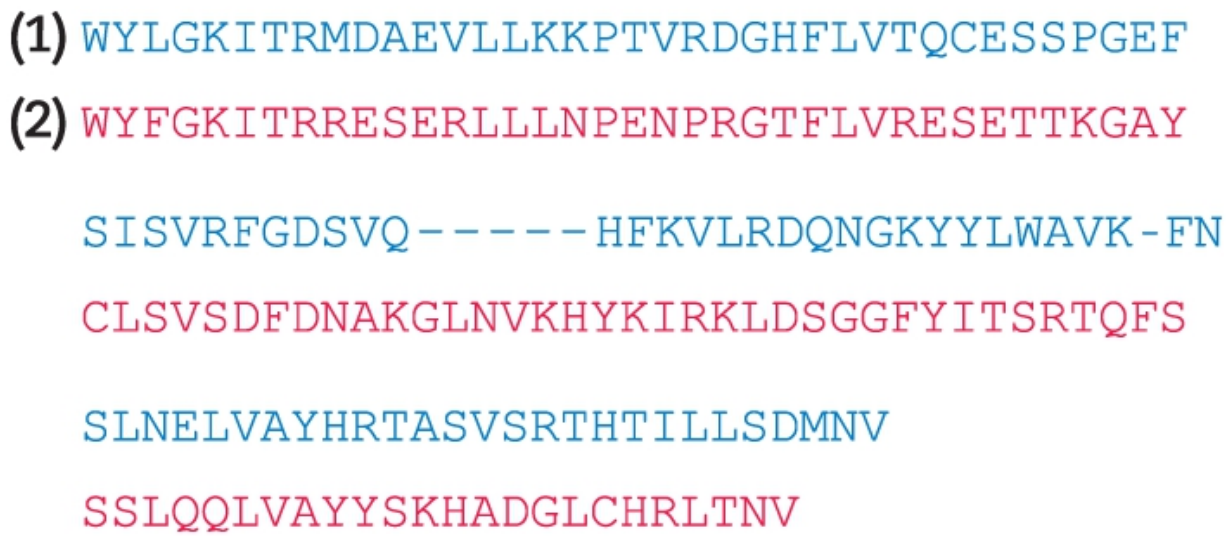
The first level-2 branch splits into two level-3 branches.

The first level-3 branch represents gene Y alpha, shown in blue.

The second level-3 branch represents gene Z alpha, shown in red.

The second level-2 branch splits into two level-3 branches.

The first level-3 branch represents gene Y beta, shown in blue.



The second level-3 branch splits into two level-4 branches.

The first level-4 branch represents gene Z beta 1, shown in red.

The second level-4 branch represents gene Z beta 2, shown in red.

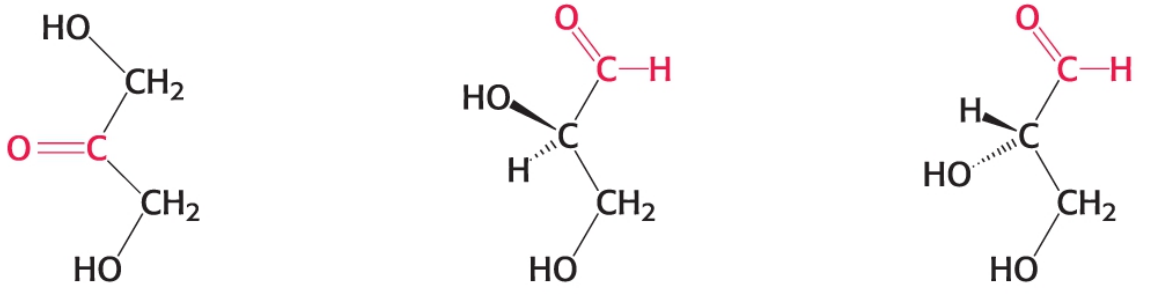
Extended description for An evolutionary tree



The vertical axis labeled Time (millions of years ago) is shown alongside the evolutionary tree and ranges from 900 to 0 in decrements of 100 units.

The root of the tree lies at 900 and splits into two level-1 branches. The first level-1 branch splits into two level-2 branches at 300. The first level-2 branch is labeled 1. The second level-2 branch is labeled 2. The second level-1 branch splits into two level-2 branches just after 550. The first level-2 branch is labeled 3. The second level-2 branch splits into two level-3 branches at 100. The first level-3 branch is labeled 4. The second level-3 branch represents Solvin E.

Return to An evolutionary tree

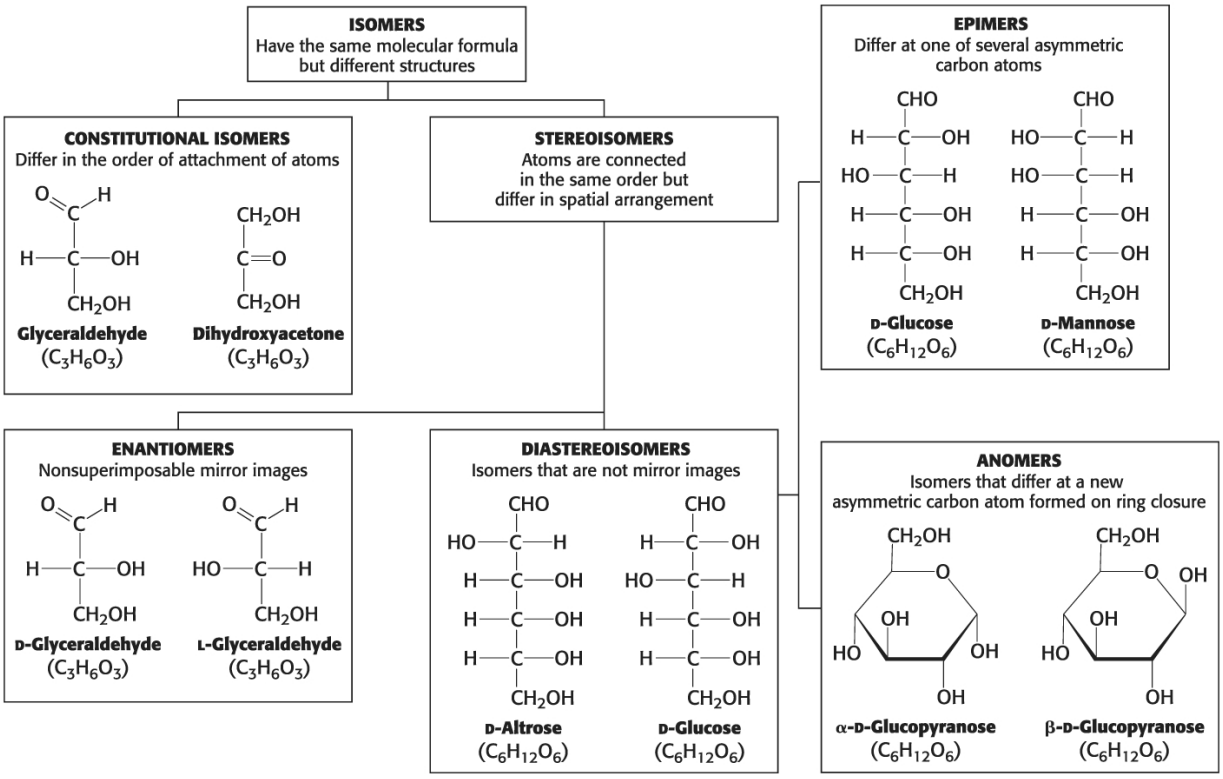
Extended description for Structures of dihydroxyacetone, D-glyceraldehyde, and L-Glyceraldehyde

Dihydroxyacetone
(a ketose)

D-Glyceraldehyde
(an aldose)

L-Glyceraldehyde
(an aldose)

The structure of dihydroxyacetone (a ketose) is as follows: A 3-carbon alkane chain is depicted as a vertical line structure using 2 zigzag lines. C 1 and C 3 are bound to H 2. C 1 is single bonded to O H on the upper left. C 2 is double bonded to O on the left. C 2 and O are highlighted in red. C 3 is single bonded to O H on the lower left.



The structure of D-Glyceraldehyde (an aldose) is as follows: A 3-carbon alkane chain is depicted as a vertical line structure using 2 zigzag lines. C 3 is bound to H 2. C 1 is single bonded to H on the right and double bonded to O on the upper left. C 1 and the bonded H and O atoms are highlighted in red. C 2 is wedge bonded to H on the upper left and dash bonded to H on the lower left. C 3 is single bonded to O H on the lower left.

The structure of L-Glyceraldehyde (an aldose) is as follows: A 3-carbon alkane chain is depicted as a vertical line structure using 2 zigzag lines. C 3 is bound to H 2. C 1 is single bonded to H on the right and double bonded to O on the upper left. C 1 and the bonded

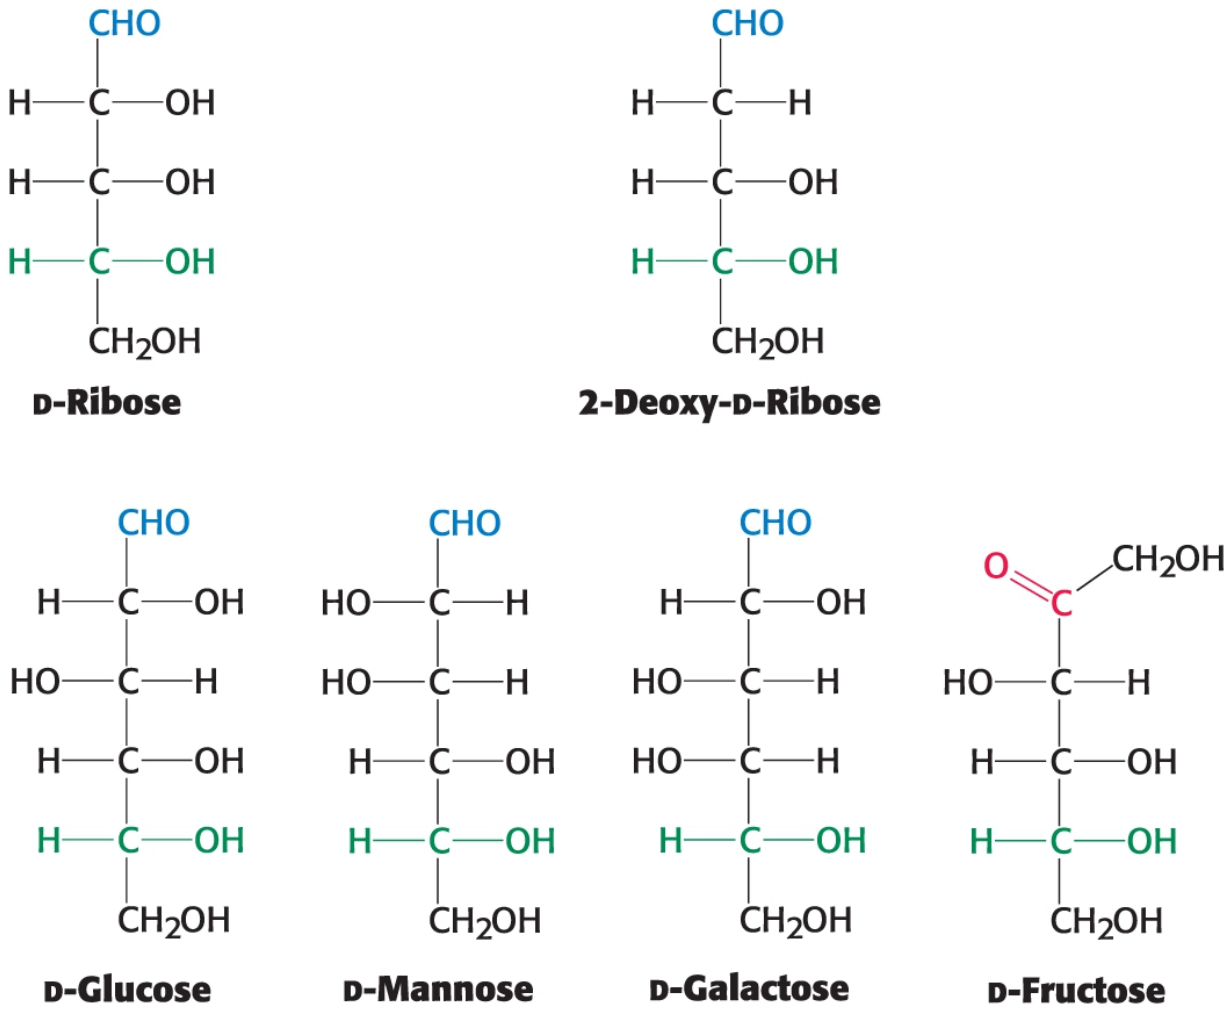
H and O atoms are highlighted in red. C 2 is wedge bonded to H on the upper left and dash bonded to O H on the lower left. C 3 is single bonded to O H on the lower left.

Return to Structures of dihydroxyacetone, D-glyceraldehyde, and L-Glyceraldehyde

Extended description for Classification of isomers

A flowchart starts with isomers that have the same molecular formula but different structures. These isomers are constitutional isomers that differ in the order of attachment of atoms and stereoisomers in which atoms are connected in the same order but differ in spatial arrangement. Constitutional isomers have two structures labeled glyceraldehyde (C 3 H 6 O 3) and dihydroxyacetone (C 3 H 6 O 3). The structure of glyceraldehyde is as follows: A central C atom is single bonded to H on the left, O H on the right, C H 2 O H below, and C above. The C atom above is double bonded to O on the upper left and single bonded to H on the upper right. The structure of dihydroxyacetone is as follows: A central C atom is single bonded to C H 2 O H above, C H 2 O H below, and double bonded to O on the right.

Stereoisomers are divided into enantiomers which are non-superimposable mirror images and diastereoisomers are isomers that are not mirror images. Enantiomers have two structures labeled D-Glyceraldehyde (C 3 H 6 O 3) and L-glyceraldehyde (C 3 H 6 O 3). The structure of D-Glyceraldehyde is as follows: A central C atom is single bonded to H on the left, O H on the right, C H 2 O H below, and C above. The C atom above is double bonded to O on the upper left and single bonded to H on the upper right. The structure of L-Glyceraldehyde is as follows: A central C atom is single bonded to O H on the left, H on the right, C H 2 O H below, and C above. The C atom above is double bonded to O on the upper left and single bonded to H on the upper right.



Diastereoisomers have two structures labeled D-Altrose (C 6 H 12 O 6) and D-Glucose (C 6 H 12 O 6). The structure of D-Altrose is as follows: The Fischer projection consists of a vertical line with C H O above and C H 2 O H below. The projection contains four C atoms placed one below the other on the vertical line. The C atoms are numbered from top to bottom. C 2 is single bonded to O H on the left and H on the right. C 3, C 4, and C 5 are each single bonded H on the left and O H on the right. The structure of D-Glucose is as follows: The Fischer projection consists of a vertical line with C H O above and C H 2 O H below. The projection contains four C atoms placed one below the other on the vertical line. The C atoms are numbered from top to bottom. C 2, C 4, and C 5 are each single bonded to H on the left and O H on the right. C 3 is single bonded to O H on the left and H on the right.

Diastereoisomers are classified into epimers that differ at one of several asymmetric carbon atoms and anomers are isomers that differ at a new asymmetric carbon atom formed on ring closure. Epimers have two structures labeled D-Glucose (C 6 H 12 O 6) and D-Mannose (C 6 H 12 O 6). The structure of D-Glucose is as follows: The Fischer projection consists of a vertical line with C H O above and C

H 2 O H below. The projection contains four C atoms placed one below the other on the vertical line. The C atoms are numbered from top to bottom. C 2, C 4, and C 5 are each single bonded to H on the left and O H on the right. C 3 is single bonded to O H on the left and H on the right. The structure of D-Mannose is as follows: The Fischer projection consists of a vertical line with C H O above and C H 2 O H below. The projection contains four C atoms placed one below the other on the vertical chain. The C atoms are numbered from top to bottom. C 2 and C 3 are each single bonded to O H on the left and H on the right. C 4 and C 5 are each single bonded to H on the left and O H on the right. Anomers have two structures labeled alpha-D-Glucopyranose (C 6 H 12 O 6) and beta-D-Glucopyranose (C 6 H 12 O 6). The structure of alpha-D-Glucopyranose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1, C 2, and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above. The structure of beta-D-Glucopyranose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 and C 3 are each single bonded to O H above. C 2 and C 4 are each single bonded to O H below. C 5 is single bonded to C H 2 O H above.

Return to Classification of isomers

Extended description for Molecular structures of common monosaccharides

The structure of D-Ribose is as follows: The Fischer projection consists of a vertical line with C H O above and C H 2 O H below. The projection contains three C atoms placed one below the other on the vertical line. The C atoms are numbered from top to bottom. C 2, C 3, and C 4 are each single bonded to H on the left and O H on the right. C H O is highlighted in blue. C 4 and the H atom and O H group bonded to it are highlighted in green.

The structure of 2-Deoxy-D-Ribose is as follows: The Fischer projection consists of a vertical line with C H O above and C H 2 O H below. The projection contains three C atoms placed one below the other on the vertical line. The C atoms are numbered from top to bottom. C 2 is single bonded to H on the left and H on the right. C 3 and C 4 are each single bonded to H on the left and O H on the right. C H O is highlighted in blue. C 4 and the H atom and O H group bonded to it are highlighted in green.

The structure of D-Glucose is as follows: The Fischer projection consists of a vertical line with C H O above and C H 2 O H below. The projection contains four C atoms placed one below the other on the vertical line. The C atoms are numbered from top to bottom. C 2, C 4, and C 5 are single bonded to H on the left and O H on the right. C 3 is single bonded to O H on the left and H on the right. C H O is highlighted in blue. C 5 and the H atom and O H group bonded to it are highlighted in green.

The structure of D-Mannose is as follows: The Fischer projection consists of a vertical line with C H O above and C H 2 O H below. The projection contains four C atoms placed one below the other on the vertical line. The C atoms are numbered from top to bottom. C 2 and C 3 are single bonded to O H on the left and H on the right. C 4 and C 5 are each single bonded to H on the left and O H on the right. C H O is highlighted in blue. C 5 and the H atom and O H group bonded to it are highlighted in green.

The structure of D-Galactose is as follows: The Fischer projection consists of a vertical line with C H O above and C H 2 O H below. The projection contains four C atoms placed one below the other on the vertical line. The C atoms are numbered from top to bottom. C 2 and C 5 are single bonded to H on the left and O H on the right. C 3 and C 4 are each single bonded to O H on the left and H on the right. C H O

is highlighted in blue. C 5 and the H atom and O H group bonded to it are highlighted in green.

The structure of D-Fructose is as follows: The Fischer projection consists of a vertical line with C above and C H 2 O H below. The projection contains three C atoms placed one below the other on the vertical line. The C atoms are numbered from top to bottom. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 and C 4 are each single bonded to H on the left and O H on the right. C 1 double bonded to O is highlighted in red. C 4 and the H atom and O H group bonded to it are highlighted in green.

Extended description for Chemical structure of pyran

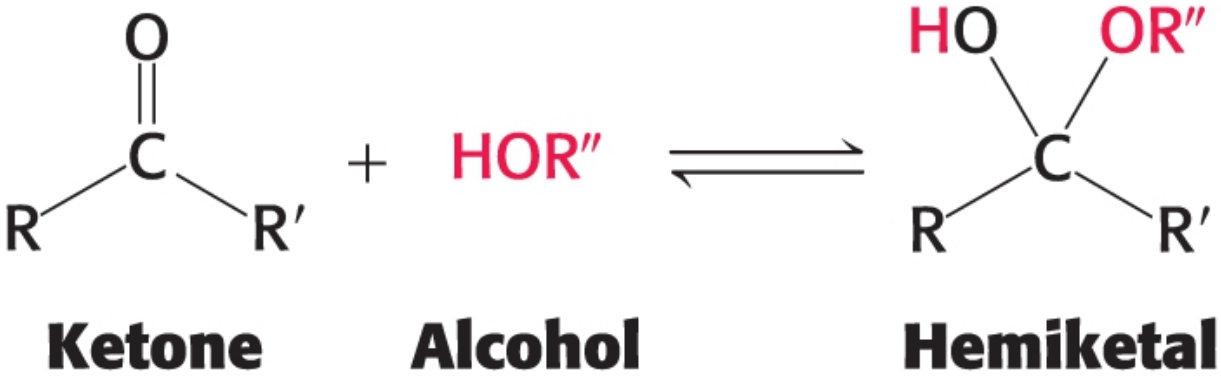
The structure is as follows: A 6-membered heterocyclic hexagonal ring labeled pyran is in a vertical orientation and consists of 1 O and 5 C atoms. O occupies the first position, which is the topmost vertex. A double bond is present between C 1 and C 2, and, C 4 and C 5.

Return to Chemical structure of pyran

Extended description for Formation of alpha-D-Glucopyranose and beta-D-Glucopyranose from D-Glucose

The structure of the open-chain form of D-Glucose is as follows: The Fischer projection consists of a vertical line with C above and C H 2 O H below. The projection contains four C atoms placed one below the other on the vertical line. The C atoms are numbered from top to bottom. C 1 is double bonded to O on the upper left and single bonded to H on the upper right. C 2, C 4, and C 5 are single bonded to H on the left and O H on the right. C 3 is single bonded to O H on the left and H on the right. C 1 and its bonded O and H atoms are highlighted in blue. The O H group bonded to C 5 is highlighted in red.

An equal symbol on the right of D-glucose shows the formation of a ring-like structure as follows: C 1 to C 5 atoms of the open-chain form fold to produce an open ring-like structure. C 1 to C 5 atoms are located in a clockwise direction starting from the right. The red highlighted O H group bonded to C 5 attacks C 1. C 6 is located above the open ring-like structure.

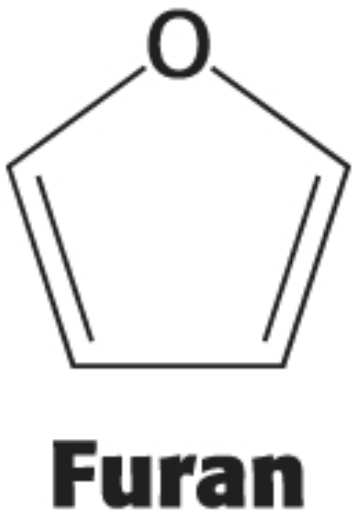


Two reversible reaction arrows show the formation of alpha-D-Glucopyranose and beta-D-glucopyranose.

The structure of alpha-D-Glucopyranose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. It is highlighted in red. C 1, C 2, C 4 are each single bonded to H above and O H below. C 3 is single bonded to O H above and H below. C 5 is single bonded to C H 2 O H above and H below. The H atom above and O atom of O H group bonded to C 1 are highlighted in blue. The H atom of O H group is highlighted in red.

The structure of beta-D-glucopyranose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. It is highlighted in red. C 1 and C 3 are each single bonded to O H above and H below. C 2 and C 4 are each single bonded to H above and O H below. C 5 is single bonded to C H 2 O H above and H below. The H atom below and the O atom of O H group bonded to C 1 are highlighted in blue. The H atom of the O H group is highlighted in red.

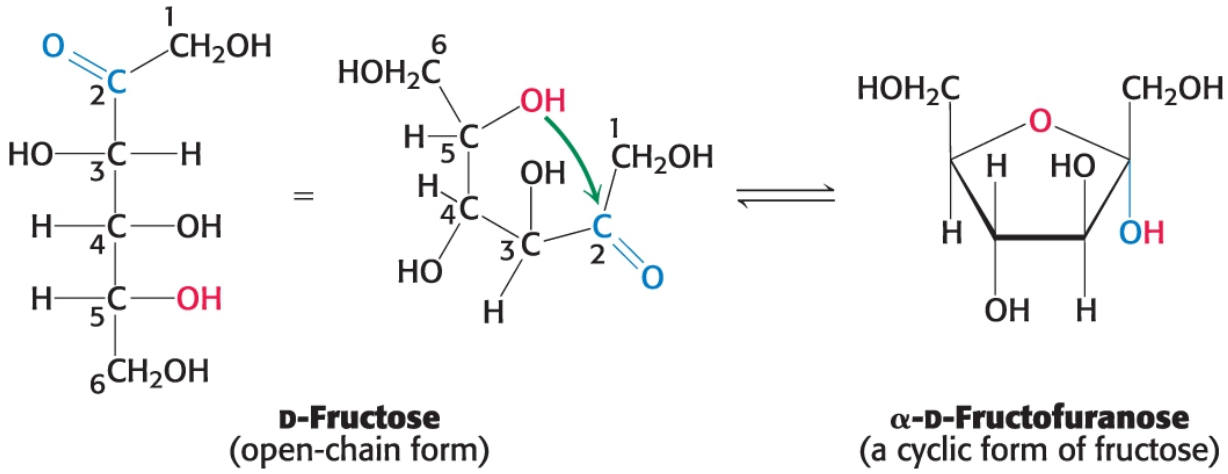
Return to Formation of alpha-D-Glucopyranose and beta-D-Glucopyranose from D-Glucose



Extended description for Formation of hemiketal from ketone and alcohol

The chemical reaction consists of two reactants and one product. The first reactant is ketone whose structure is as follows: A central C atom is single bonded to R on the lower left, R dash on the lower right, and double bonded to O above. The second reactant is alcohol whose formula is H O R double dash highlighted in red. The product is hemiketal whose structure is as follows: A central C atom is single bonded to O H on the upper left, O R double dash on the upper right, R on the lower left, and R dash on the lower right. The H atom of the O H group is highlighted in red. The O R double dash group is highlighted in red.

Return to Formation of hemiketal from ketone and alcohol



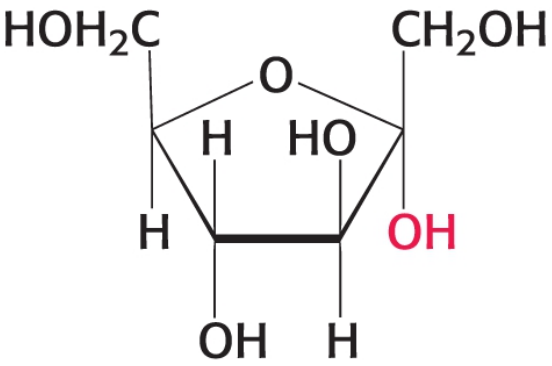
Extended description for Chemical structure of furan

The structure is as follows: A 5-membered heterocyclic pentagonal ring labeled furan is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the first position, which is the topmost vertex. A double bond is present between C 1 and C 2, and, C 3 and C 4.

Return to Chemical structure of furan

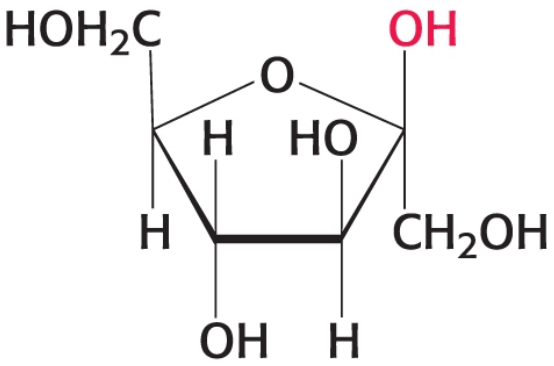
Extended description for Formation of alpha-D-Fructofuranose from D-Fructose

The structure of open-chain form of D-Fructose is as follows: The Fischer projection consists of a vertical line with C above and C H 2 O H below. The projection contains four C atoms placed one below the other on the vertical line. The C atoms are numbered from 2 to 6 from the top to bottom. C 2 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. The C atom of C H 2 O H group is numbered 1. C 3 is single bonded to O H on the left and H on the right. C 4 and C 5 are each single bonded to H on the left and O H on the right. The O H group bonded to C 5 is highlighted in red.



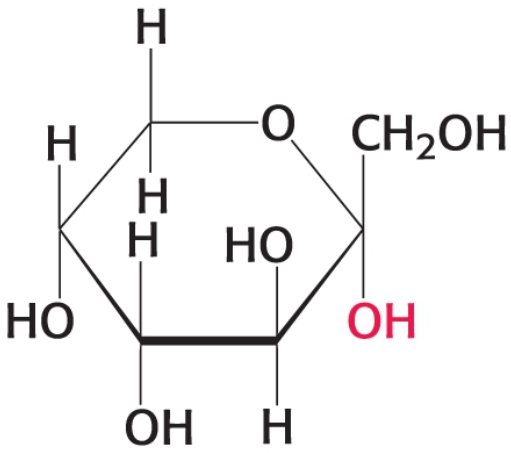
An equal symbol on the right of D-fructose shows the formation of a ring-like structure as follows: C 2 to C 5 atoms of the open-chain form fold to produce an open pentagonal ring-like structure. C 2 to C 5 atoms are located in a clockwise direction starting from the bottom right. The red highlighted O H group bonded to C 5 attacks C 2. C 6 is located above the open ring-like structure. C 1 is located above C 2, outside the ring-like structure.

A reversible reaction arrow is shown.

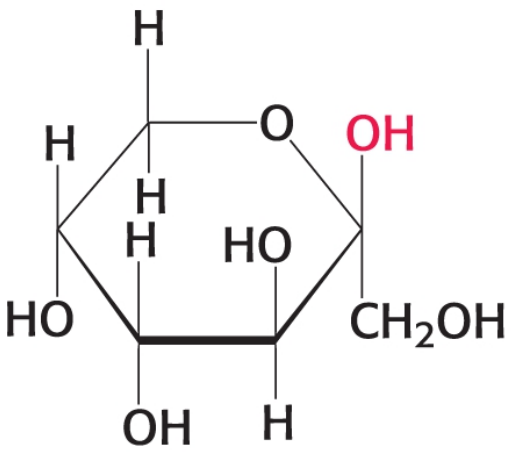


The structure of alpha D-Fructofuranose (a cyclic form of fructose) is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. C 1 occupies the top right vertex. The O atom highlighted in red occupies the first position, which is the topmost vertex. C 1 is single bonded to C H 2 O H above and O H below. The O and H atoms of O H group are highlighted in blue and red respectively. C 2 is single bonded to O H above and H below. C 3 is single bonded to H above and O H below. C 4 is single bonded to C H 2 O H above and H below.

Return to Formation of alpha-D-Fructofuranose from D-Fructose



Extended description for Four distinct ring structures adopted by D-fructose in solution



α-D-Fructofuranose

β-D-Fructofuranose

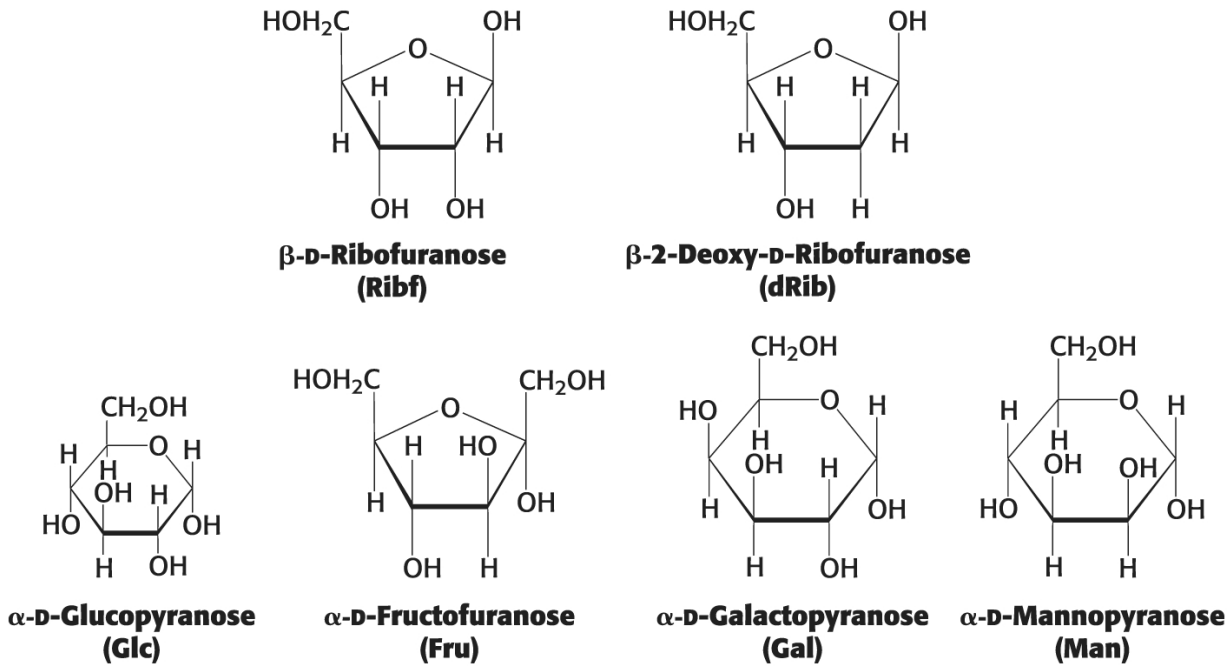
α-D-Fructopyranose

β-D-Fructopyranose

The four ring structures are alpha-D-Fructofuranose, beta-D-Fructofuranose, alpha-D-Fructopyranose, beta-D-Fructopyranose.

The structure of alpha-D-Fructofuranose is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first

position, which is the topmost vertex. C 1 is single bonded to C H 2 O H above and O H below. C 2 is single bonded to O H above and H below. C 3 is single bonded to H above and O H below. C 4 is single bonded to C H 2 O H above and H below.



The structure of beta-D-Fructofuranose is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 1 is single bonded to O H above and C H 2 O H below. O H is highlighted in red. C 2 is single bonded to O H above and H below. C 3 is single bonded to H above and O H below. C 4 is single bonded to C H 2 O H above and H below.

The structure of alpha-D-Fructopyranose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to C H 2 O H above and O H below. O H is highlighted in red. C 2 is single bonded to O H above and H below. C 3 and C 4 are each single bonded to H above and O H below. C 5 is single bonded to H above and H below.

The structure of beta-D-Fructopyranose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to O H above and C H 2 O H below. O H is highlighted in red. C 2 is single bonded to O H above and H below. C 3 and C 4 are each single bonded to H above and O H below. C 5 is single bonded to H above and H below.

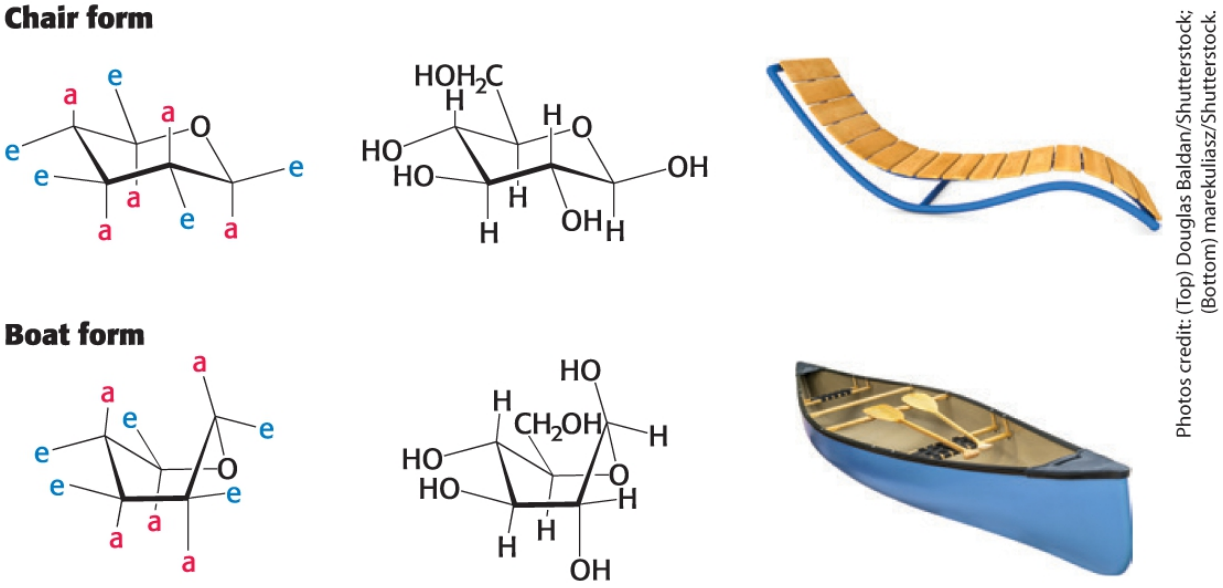
Extended description for The ring structures of common monosaccharides

The structure of beta-D-Ribofuranose (R i b f) is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 1 is single bonded to O H above and H below. C 2 and C 3 are each single bonded to H above and O H below. C 4 is single bonded to C H 2 O H above and H below.

The structure of beta-2-Deoxy-D-Ribofuranose (d R i b) is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 1 is single bonded to O H above and H below. C 2 is single bonded to H above and H below. C 3 is single bonded to H above and O H below. C 4 is single bonded to C H 2 O H above and H below.

The structure of alpha-D-Glucopyranose (G l c) is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1, C 2, and C 4 are each single bonded to H above and O H below. C 3 is single bonded to O H above and H below. C 5 is single bonded to C H 2 O H above and H below.



The structure of alpha-D-Fructofuranose (F r u) is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 1 is single bonded to C H 2 O H above and H below. C 2 is single bonded to O H above and H below. C 3 is single bonded to H above and O H below. C 4 is single bonded to C H 2 O H above and H below.

The structure of alpha-D-Galactopyranose (G a l) is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 and C 2 are each single bonded to H above and O H below. C 3 are C 4 are each single bonded to O H above and H below. C 5 is single bonded to C H 2 O H above and H below.

The structure of alpha-D-Mannopyranose (M a n) is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 and C 4 are each single bonded to H above and O H below. C 2 are C 3 are each single bonded to O H above and H below. C 5 is single bonded to C H 2 O H above and H below.

Extended description for Structure of the chair and boat forms of beta-D-glucopyranose

Photos credit: (Top) Douglas Baldan/Shutterstock; (Bottom) marekuliasz/Shutterstock.

The chair form of beta-D-glucopyranose:

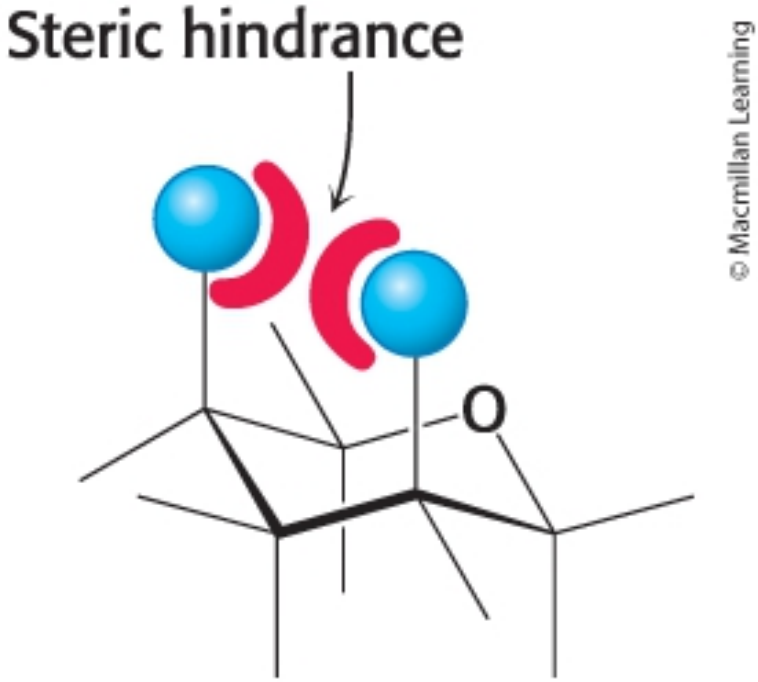
The structure of the first ring is as follows: A 6-membered heterocyclic ring is in a chair conformation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 2 and C 5 are close to each other. C 4 occupies the top left vertex. C 1 is single bonded to e on the upper right and a below. C 2 is single bonded to a above and e on the lower right. C 3 is single bonded to e on the left and a below. C 4 is single bonded to e on the lower left and a above. C 5 is single bonded to e on the upper left and a below. a is highlighted in red and e is highlighted in blue.

The structure of the second ring is as follows: A 6-membered heterocyclic ring is in a chair conformation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 2 and C 5 are close to each other. C 4 occupies the top

left vertex. C 1 is single bonded to O H on the upper right and H below. C 2 is single bonded to H above and O H on the lower right. C 3 is single bonded to O H on the left and H below. C 4 is single bonded to O H on the lower left and H above. C 5 is single bonded to C H 2 O H on the upper left and H below.

A photograph of a pool lounge chair is shown alongside the rings.

The boat form of beta-D-glucopyranose:

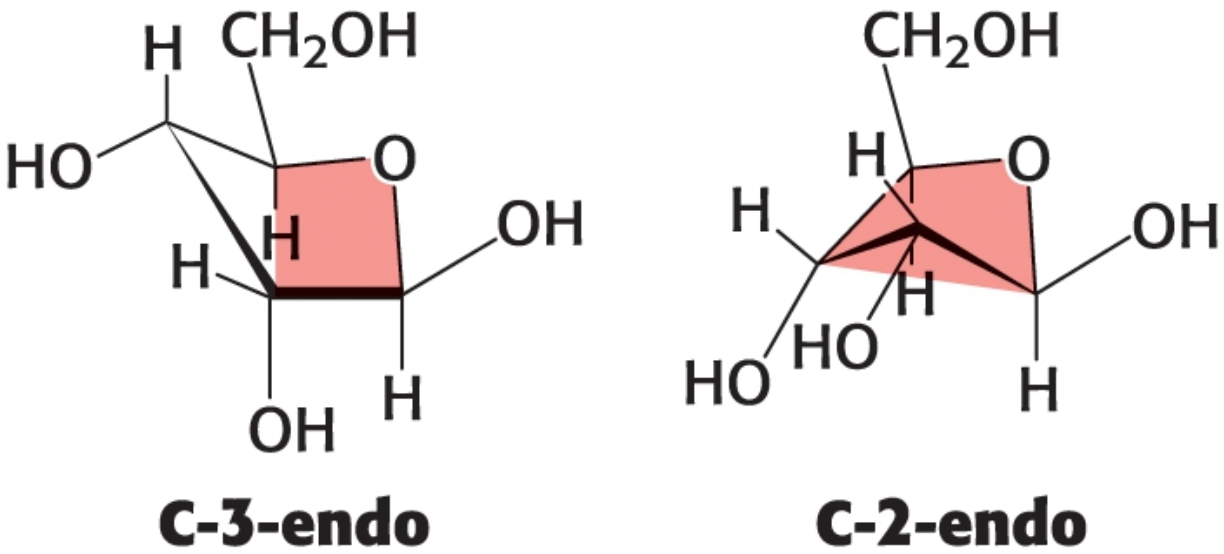


The structure of the first ring is as follows: A 6-membered heterocyclic hexagonal ring is in a boat conformation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 2 and C 3 are close to each other. O and C 5 are located in the same plane. C 1, C 2, C 3, and C 4 are located in the same plane above the plane of O and C 5. C 1 is single bonded to e on the right and a above. C 2 is single bonded to a below and e on the right. C 3 is single bonded to a below and e on the upper left. C 4 is single bonded to a above and e on the right. C 5 is single bonded to e on the upper left and a below.

The structure of the second ring is as follows: A 6-membered heterocyclic hexagonal ring is in a boat conformation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 2 and C 3 are close to each other. O and C 5 are located in the same plane. C 1, C 2, C 3, and C 4 are located in the same plane above the plane of O and C 5. C 1 is single bonded to O H above and H on the lower right. C 2 is single bonded to H on the right and O H below. C 3 is single bonded to O H on the upper left and H below. C 4 is single bonded to O H on the left and H above. C 5 is single bonded to C H 2 O H above and H on the lower right.

A photograph of a boat is shown alongside the rings.

Return to Structure of the chair and boat forms of beta-D-glucopyranose

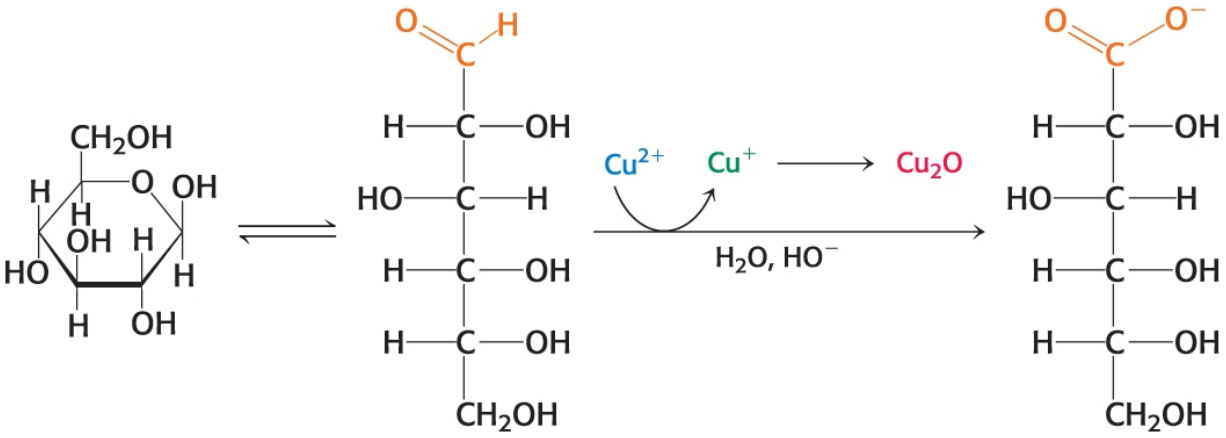


Extended description for Chair form of beta-D glucopyranose with steric hinderance

The structure of the chain form of beta-D glucopyranose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the bottom right vertex. It consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1 has an open single bond on the right and below. C 2 is single bonded to a blue sphere above and has an open single bond below. C 3 has an open single bond on the left and below. C 4 is single bonded to a blue sphere above and has an open single bond on the lower left. C 5 has an open single bond above and below. The blue spheres are located above the plane of the ring. A curved bean-shaped structure covers the sides of the blue spheres facing each other. A small gap is present between these curved structures and is labeled steric hindrance.

Return to Chair form of beta-D glucopyranose with steric hinderance

Extended description for Structures of C-3 endo and C-2 endo forms of a puckered furanose ring



C-3 endo: The ring consists of 1 O and 4 C atoms. O is single bonded to C 1 below. C 1 is single bonded to C 2 on the left. C 2 is wedge bonded to C 3 on the upper left. C 3 is single bonded to C 4 on the lower right. C 4 is single bonded to O on the right. O, C 1, C 2, and C 4 are located in the same plane. C 3 is located above the plane. C 1 is single bonded to O H on the upper right and H below. C 2 is single bonded to H on the upper left and O H below. C 3 is single bonded to H above and O H on the lower left. C 4 is single bonded to C H 2 O H above and H below.

C-2 endo: The ring consists of 1 O and 4 C atoms. O is single bonded to C 1 below. C 1 is wedge bonded to C 2 on the upper left. C 2 is wedge bonded to C 3 on the lower left. C 3 is single bonded to C 4 on the upper right. C 4 is single bonded to O on the right. O, C 1, C 3, and C 4 are located in the same plane. C 2 is located above the plane of the ring. C 1 is single bonded to O H on the upper right and H below. C 2 is single bonded to H on the upper left and O H on the

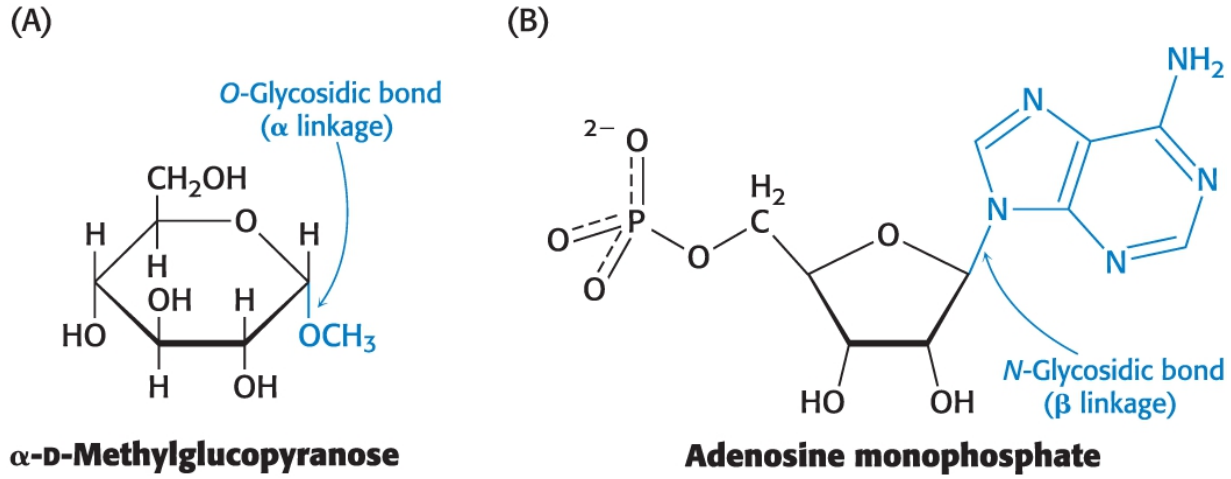
lower left. C 3 is single bonded to H on the upper left and O H on the lower left. C 4 is single bonded to C H 2 O H above and H below.

Return to Structures of C-3 endo and C-2 endo forms of a puckered furanose ring

Extended description for Oxidation of glucose

The ring form of glucose is reversibly converted into open-chain form. The structure of the ring form of glucose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 and C 3 are each single bonded to O H above and H below. C 2 and C 4 are each single bonded to H above and O H below. C 5 is single bonded to C H 2 O H above and H below.

The structure of the open-chain form is as follows: The Fischer projection consists of a vertical line with C above and C H 2 O H below. The projection contains four C atoms placed one below the other on the vertical line. The C atoms are numbered from top to bottom. C 1 is double bonded to O on the upper left and single bonded to H on the upper right. C 2, C 4, and C 5 are each single bonded to H on the left and O H on the right. C 3 is single bonded to O H on the left and H on the right.



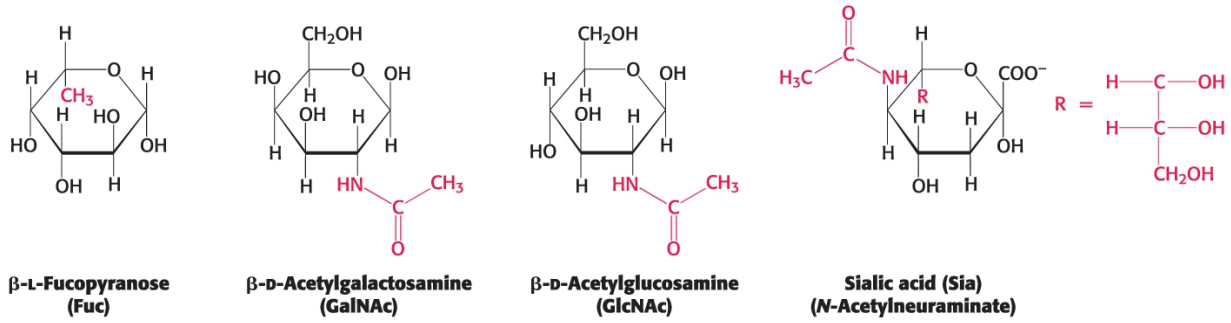
A forward reaction arrow is labeled H 2 O, H O superscript minus below. C u superscript 2 plus ion highlighted in blue enters the

reaction and C u superscript plus highlighted in green leaves the reaction. C u superscript plus is later converted into C u 2 O.

The structure of the oxidized product is as follows: The Fischer projection consists of a vertical line with C above and C H 2 O H below. The projection contains four C atoms placed one below the other on the vertical line. The C atoms are numbered from top to bottom. C 1 is double bonded to O on the upper left and single bonded to O superscript minus on the upper right. C 2, C 4, and C 5 are each single bonded to H on the left and O H on the right. C 3 is single bonded to O H on the left and H on the right.

Return to Oxidation of glucose

Extended description for Chemical structures of alpha-D-Methylglucopyranose and adenosine monophosphate



(A) The structure of alpha-D-Methylglucopyranose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to H above and O C H 3 below. The single bond between C 1 and O C H 3 is labeled O-Glycosidic bond (alpha linkage). C 2 and C 4 are each single bonded to H above and O H below. C 3 is single bonded to O H above and H below. C 5 is single bonded to C H 2 O H above and H below.

(B) The structure of adenosine monophosphate is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 1 is single bonded to N 1 of a 5-membered pentagonal ring in a horizontal orientation on the top right. The single bond between C 1 and N 1 is labeled the N-glycosidic bond (beta linkage). C 2 and C 3 are single bonded to O H

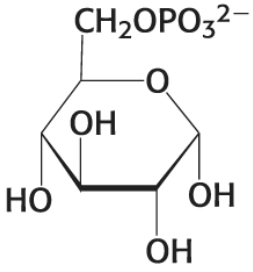
below. C 4 is single bonded to C H 2, single bond, O, single bond, P on the top left. The P atom is partially double bonded to O above, O on the left, and O on the lower left. The 5-membered pentagonal ring on the top right has two N atoms. First N occupies the first position, which is the bottom left vertex. Second N occupies the third position, which is the topmost vertex. A double bond is present between C 1 and N 2 and C 2 and C 3. This ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. The hexagonal ring consists of 2 N and 4 C atoms. C 1 occupies the bottom right vertex. First N occupies the top right vertex. Second N occupies the bottom-most vertex. C 4 is single bonded to N H 2 above. A double bond is present between C 1 and N 2 and C 4 and N 1.

Return to Chemical structures of alpha-D-Methylglucopyranose and adenosine monophosphate

Extended description for Chemical structures of beta-L-Fucopyranose, beta-D-Acetylgalactosamine, beta-D-Acetylglucosamine, and sialic acid

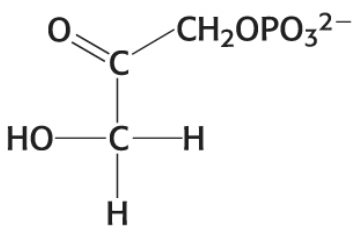
The structure of beta-L-Fucopyranose (F u c) is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1, C 3, and C 4 are each single bonded to H above and O H below. C 2 is single bonded to O H above and H below. C 5 is single bonded to H above and C H 3 below.

The structure of beta-D-Acetylgalactosamine (G a l N A c) is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1, C 3, and C 4 are each single bonded to O H above and H below. C 2 is single bonded to H above and N H below. C 5 is single bonded to C H 2 O H above and H below. The N H bonded to C 2 is single bonded to C on the lower right. This C is single bonded to C H 3 on the upper right and double bonded to O below.



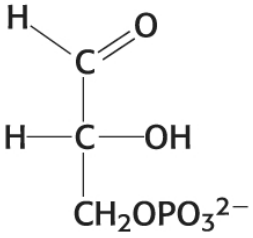
The structure of beta-D-Acetylglycosamine (G l c N A c) is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies

the first position, which is the top right vertex. C 1 and C 3 are each single bonded to O H above and H below. C 2 is single bonded to H above and N H below. C 4 is single bonded to H above and O H below. C 5 is single bonded to C H 2 O H above and H below. The N H group bonded to C 2 is single bonded to C on the lower right. This C is single bonded to C H 3 on the upper right and double bonded to O below.



The structure of sialic acid (S i a) (N-Acetylneuraminate) is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to C O O minus above and O H below. C 2 is single bonded to H above and H below. C 3 is single bonded to H above and O H below. C 4 is single bonded to N H above and H below. C 5 is single bonded to H above and R below. N H bonded to C 4 is single bonded to C on the top left. This C is single bonded to C H 3 on the bottom left and double bonded to O above. On the right, the structure of R is depicted. The structure of R is as follows: C, single bond, C, single bond, C H 2 O H. C 1 and C 2 are single bonded to H on the left and O H right.

Return to Chemical structures of beta-L-Fucopyranose, beta-D-Acetylgalactosamine, beta-D-Acetylglucosamine, and sialic acid



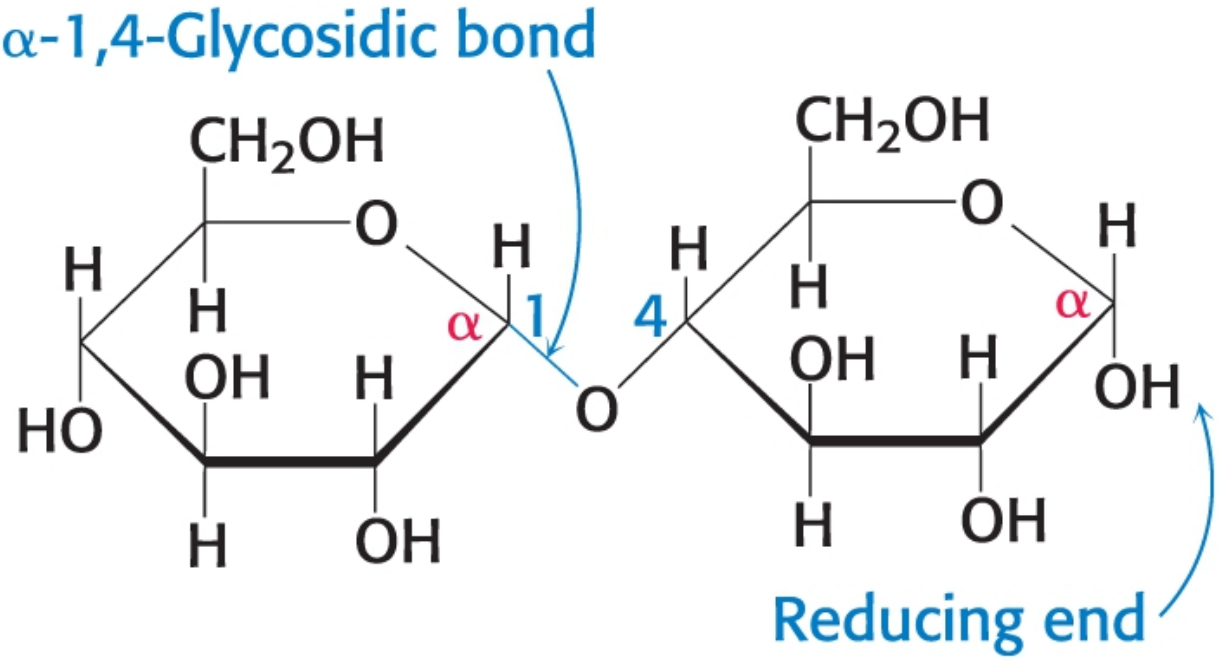
Extended description for Chemical structures of glucose 6-phosphate (G-6 P), dihydroxyacetone phosphate (D H A P), glyceraldehyde 3-phosphate (G A P)

Glucose 6-phosphate (G-6P)

Dihydroxyacetone phosphate (DHAP)

Glyceraldehyde 3-phosphate (GAP)

The structure of glucose 6-phosphate is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1, C 2, and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O P O 3 superscript 2 minus above.



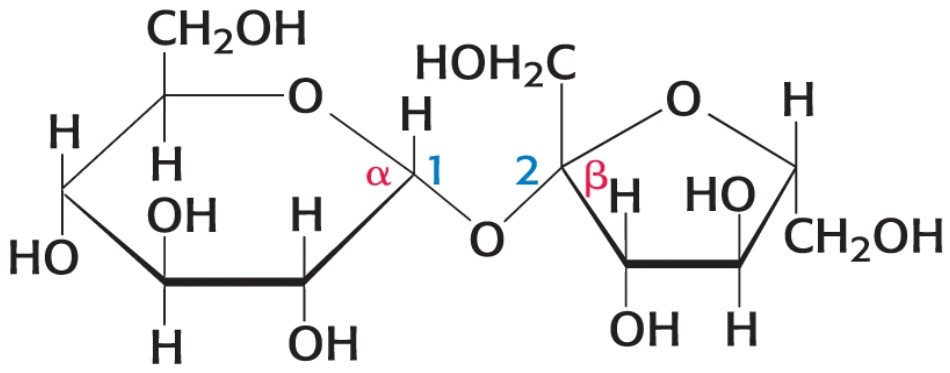
The structure of dihydroxyacetone phosphate is as follows: A central carbon atom is single-bonded to O H on the left, H on the right, H below, and C above. The C atom above is double bonded to O on the upper left and single bonded to C H 2 O P O 3 superscript 2 minus on the upper right.

The structure of glyceraldehyde 3-phosphate is as follows: A central carbon atom is single bonded to C H 2 O P O 3 superscript 2 minus below, O H on the right, H on the left, and C above. The C atom

above is double bonded to O on the upper right and single bonded to H on the upper left.

Return to Chemical structures of glucose 6-phosphate (G-6 P), dihydroxyacetone phosphate (D H A P), glyceraldehyde 3-phosphate (G A P)

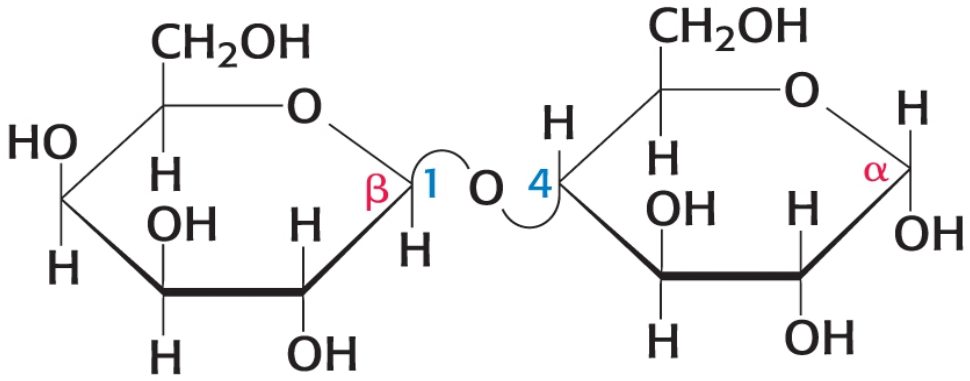
Extended description for Chemical structure of maltose



The structure of maltose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to H above. C 2 and C 4 are each single bonded to H above. C 3 is single bonded to O H above and H below. C 5 is single bonded to C H 2 O H above and H below. C 1 labeled alpha is single bonded to O below and the bond is labeled alpha 1, 4-Glycosidic bond. O is single bonded to C 4 of a 6-membered heterocyclic ring in a horizontal orientation consisting of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 and C 2 are each single bonded to H above and O H below. C 1 is labeled alpha. C 3 is single bonded to O H above and H below. C 4 is single bonded to H above. C 5 is single bonded to C H 2 O H above and H below. C 1 end of this ring is

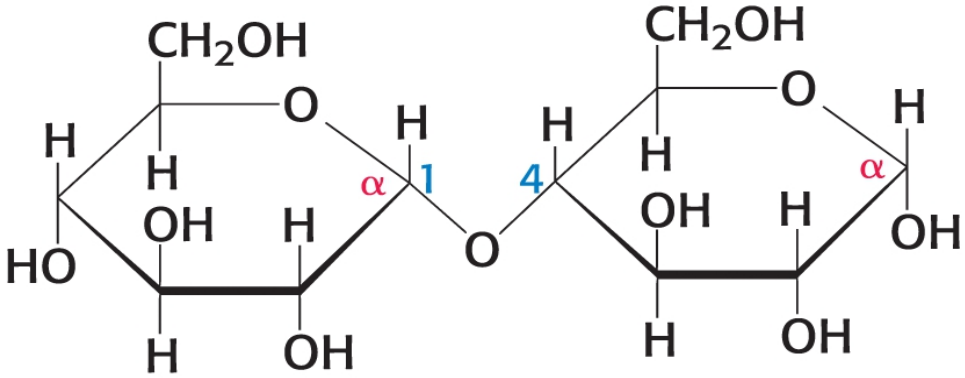
labeled reducing end. The single bond between C 1 and O is labeled 1. The single bond between C 4 and O is labeled 4.

Return to Chemical structure of maltose



Extended description for Chemical structures of

sucrose, alpha-Lactose, and alpha-maltose



Sucrose

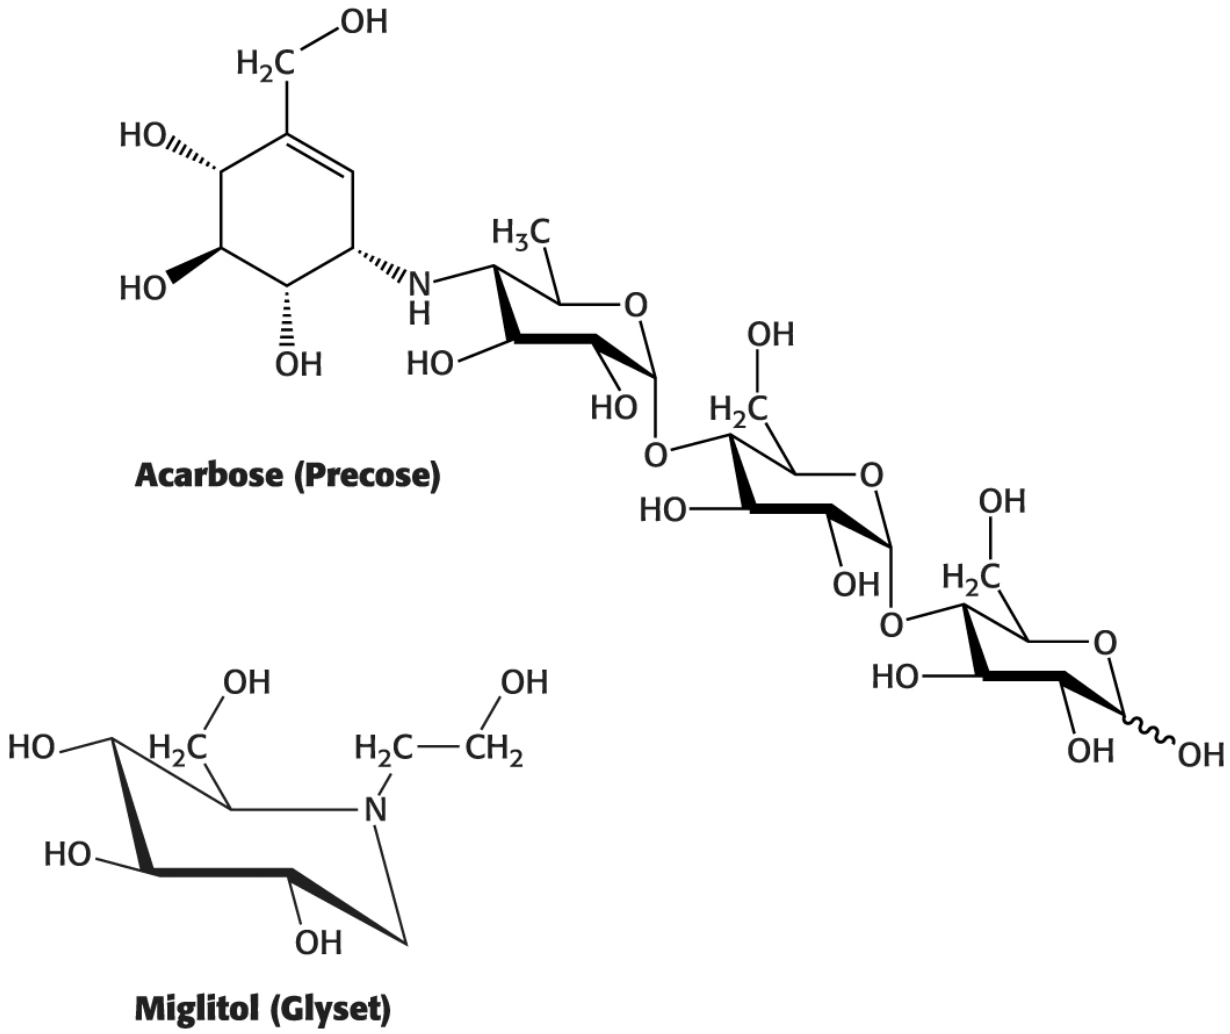
(α-D-Glucopyranosyl-(1→2)-β-D-Fructofuranose)

α-Lactose

(β-D-Galactopyranosyl-(1→4)-α-D-Glucopyranose)

α-Maltose

(α-D-Glucopyranosyl-(1→4)-α-D-Glucopyranose)



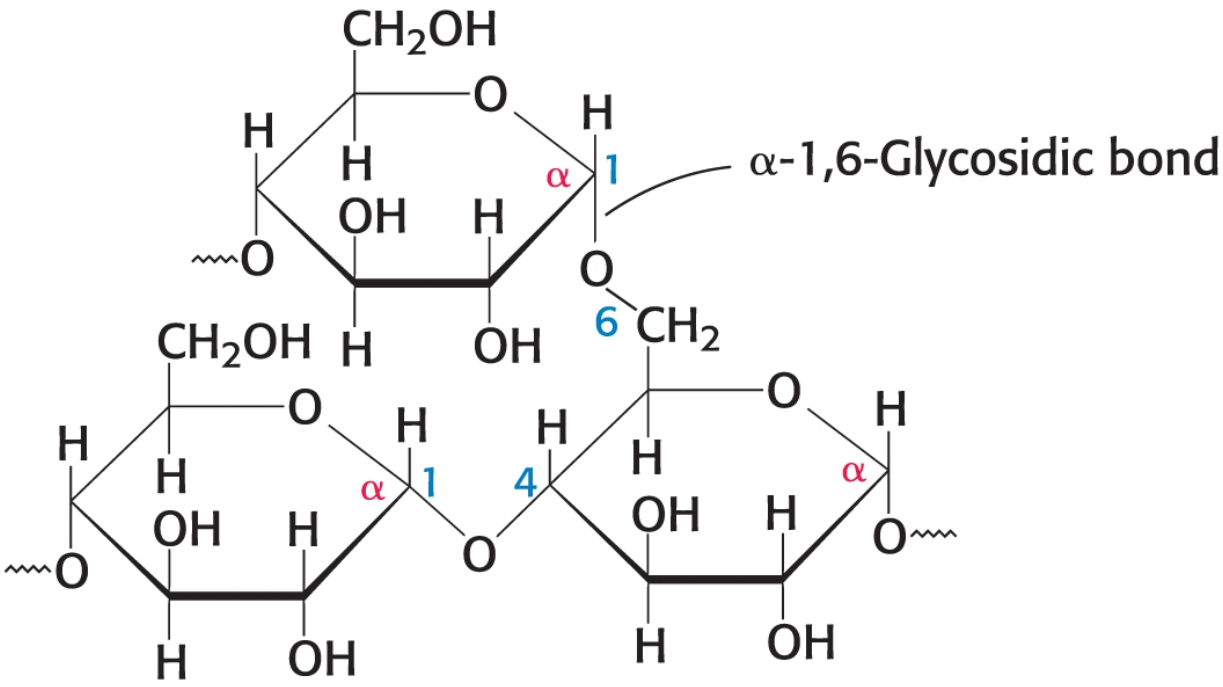
The structure of sucrose (alpha-D-Glucopyranosyl-(1 to 2)-beta-D-Fructofuranose) is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to H above and labeled alpha. C 2 and C 4 are each single bonded to H above and O H below. C 3 is single bonded to O H above and H below. C 5 is single bonded to C H 2 O H above and H below. C 1 is single bonded to O on the lower right. This O is single bonded to C 4 of a 5-membered heterocyclic pentagonal ring in a vertical orientation consisting of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 1 is single bonded to H above and C H 2 O H below. C 2 is single bonded to O H above and H below. C 3 is single bonded to H above and O H below. C 4 is single bonded to C H 2 O H above and labeled beta. The single bond between C 1 and O is labeled 1. The single bond between C 4 and O is labeled 2.

The structure of alpha-Lactose (beta-D-Galactopyranosyl-(1 to 4)-alpha-Glucopyranose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to H below and labeled beta. C 2 is single bonded to H above and O H below. C 3 and C 4 are each single bonded to O H above and H below. C 5 is single bonded to C H 2 O H above and H below. C 1 is single bonded to O on the right. This O is single bonded to C 4 of a 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 and C 2 are each single bonded to H above and O H below. C 1 is labeled alpha. C 3 is single bonded to O H above and H below. C 5 is single bonded to C H 2 O H above and H below. C 4 is single bonded to H above. The single bond between C 1 and O is labeled 1. The single bond between C 4 and O is labeled 4.

The structure of alpha-Maltose (D-Glucopyranosyl-(1 to 4)-alpha-D-Glucopyranose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 labeled alpha is single bonded to H above. C 2 and C 4 are each single bonded to H above and O H below. C 3 is single bonded to O H above and H below. C 5 is single bonded to C H 2 O H above and H below. C 1 is single bonded to O below. This O is single bonded to C 4 of a 6-membered heterocyclic ring in a horizontal orientation consisting of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 and C 2 are each single bonded to H above and O H below. C 1 is labeled alpha. C 3 is single bonded to O H above and H below. C 4 is single bonded to H above. C 5 is single bonded to C H 2 O H above and H below. The single bond between C 1 and O is labeled 1. The single bond between C 4 and O is labeled 4.

Return to Chemical structures of sucrose, alpha-Lactose, and alpha-maltose

Extended description for Chemical structures of acarbose (Precose) and miglitol (Glyset)



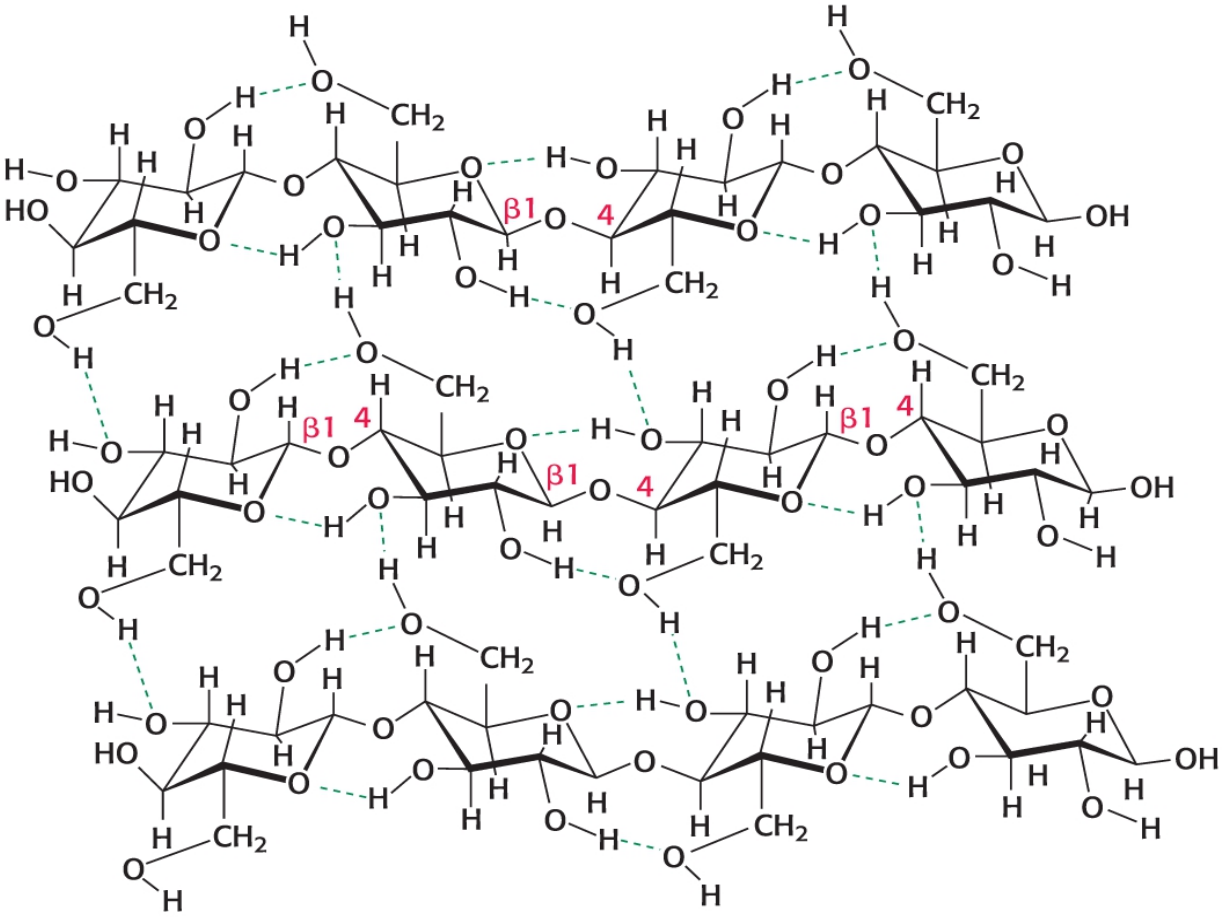
The structure acarbose (Precose) is as follows: A 6-carbon homocyclic ring in a vertical orientation has C 1 on the topmost vertex. A double bond is present between C 1 and C 2. C 1 is single bonded to C H 2 above and this C H 2 is single bonded to O H on the upper right. C 4 and C 6 are each dash bonded to O H. C 5 is wedge bonded to O H on the lower left. C 3 is dash bonded to N H on the bottom right. This N H is single bonded to C 4 of the first 6-

membered heterocyclic ring in a chair conformation that consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 occupies the bottom right vertex. C 2 and C 5 are close to each other. C 4 occupies the top left vertex. C 1 is single bonded to O below. C 2 is single bonded to O H on the lower right. C 3 is single bonded to O H on the lower left. C 5 is single bonded to C H 3 on the upper left. The O atom bonded to C 1 is single bonded to the C 4 atom of a second 6-membered heterocyclic ring in a chair conformation that consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 occupies the bottom-right vertex. C 2 and C 5 are close to each other. C 4 occupies the top left vertex. C 1 is single bonded to O below. C 2 is single bonded to O H on the lower right. C 3 is single bonded to O H on the left. C 5 is single bonded to C H 2 above and this C H 2 is single bonded to O H above. The O atom bonded to C 1 is single bonded to C 4 of a third 6-membered heterocyclic ring in a chair conformation that consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 2 and C 5 are close to each other. C 4 occupies the top left vertex. C 1 is single bonded to O H on the lower right. C 2 is single bonded to O H on the lower right. C 3 is single bonded to O H on the left. C 5 is single bonded to C H 2 above and this C H 2 is single bonded to O H above.

The structure miglitol (Glyset) is as follows: A 6-membered heterocyclic hexagonal ring is in a chair conformation and consists of 1 N and 5 C atoms. The N atom occupies the first position, which is the top right vertex. C 1 occupies the bottom right vertex. N is single bonded to C H 2 on the upper right. This C H 2 is single bonded to another C H 2 on the right. This C H 2 is single bonded to O H on the upper right. C 2 and C 5 are close to each other. C 4 occupies the top left vertex. C 2 is single bonded to O H below. C 3 and C 4 are single bonded to O H on the left. C 5 is single bonded to C H 2 above and this C H 2 is single bonded to O H on the upper right.

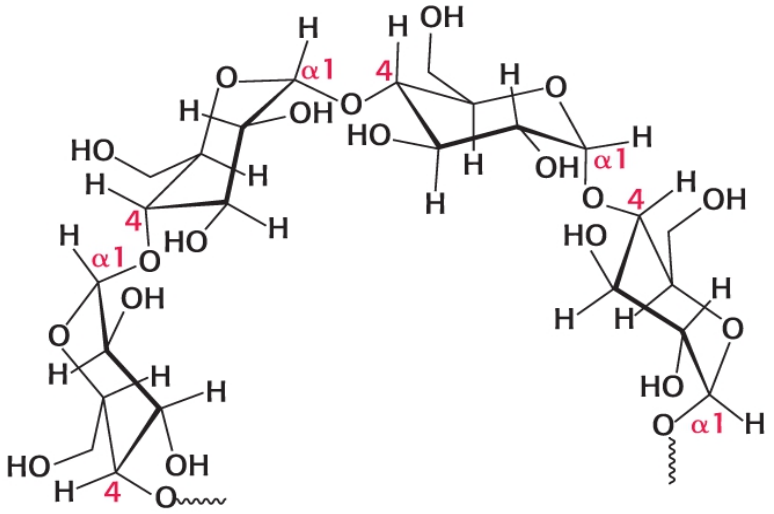
Return to Chemical structures of acarbose (Precose) and miglitol (Glyset)

Extended description for Chemical structure of glycogen



The structure of glycogen is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to H above. C 2 is single bonded to H above and O H below. C 3 is single bonded to O H above and H below. C 4 is single bonded to H above and O below. This O has an open single bond on the left. C 5 is single bonded to C H 2 O H above and H below. C 1 is single bonded to O below. This O is single bonded to C 4 of a 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to H above and O below. This O has an open single bond on the right. C 2 is single bonded to H above and O H below. C 3 is single bonded to O H above and H. C 4 is single bonded to H above.

C 5 is single bonded to C H 2 above and H below. C H 2 is single bonded to O on the upper left. This O is single bonded to C 1 of another 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 1 O and 5 C atoms. The single bond between O and C 1 is labeled alpha 1, 6-Glycosidic bond. The O atom occupies the first position which is the top right vertex. C 1 is single bonded to H above. C 2 is single bonded to H above and O H below. C 3 is single bonded to O H above and H below. C 4 is single bonded to H above and O below. This O has an open single bond on the left. C 5 is single bonded to C H 2 O H above and H below.

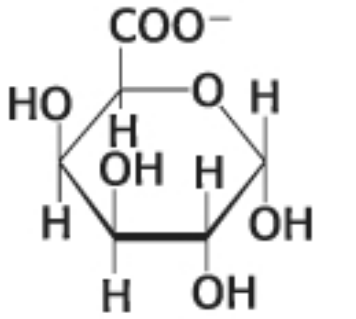


Return to Chemical structure of glycogen

Extended description for Straight chain of cellulose

and bent structure of starch and glycogen

Cellulose
(β-1,4 linkages)



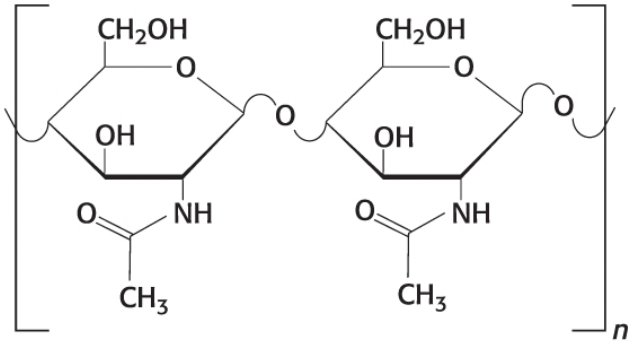
Starch and glycogen
(α-1,4 linkages)

Cellulose (beta-1, 4 linkages): Three straight chains of glucose molecules in a chair conformation connected by beta 1 to 4 glycosidic bonds are shown. The O atom of glucose residues in each chain alternatively occupies the bottom right and top right vertices. In the beta 1 to 4 glycosidic bond, C 1 and C 4 of adjacent glucose residues are single-bonded to a common O atom. The O atom is located above the plane of C 1 and C 4 atoms. Hydrogen bonds are present between O and H atoms of adjacent glucose residues within the same chain and between the adjacent chains. They are depicted as dashed lines.

Starch and glycogen (alpha-1, 4 linkages): A downward curved chain composed of glucose molecules in a chair conformation is shown. The O atom of each glucose residue occupies the top right vertex. The adjacent glucose residues are connected by alpha-1, 4 glycosidic bonds. In this bond, C 1 and C 4 of adjacent glucose residues are single-bonded to a common O atom. The O atom is located below the plane of C 1 and C 4 atoms.

Return to Straight chain of cellulose and bent structure of starch and glycogen

Extended description for Chemical structure of galacturonic acid

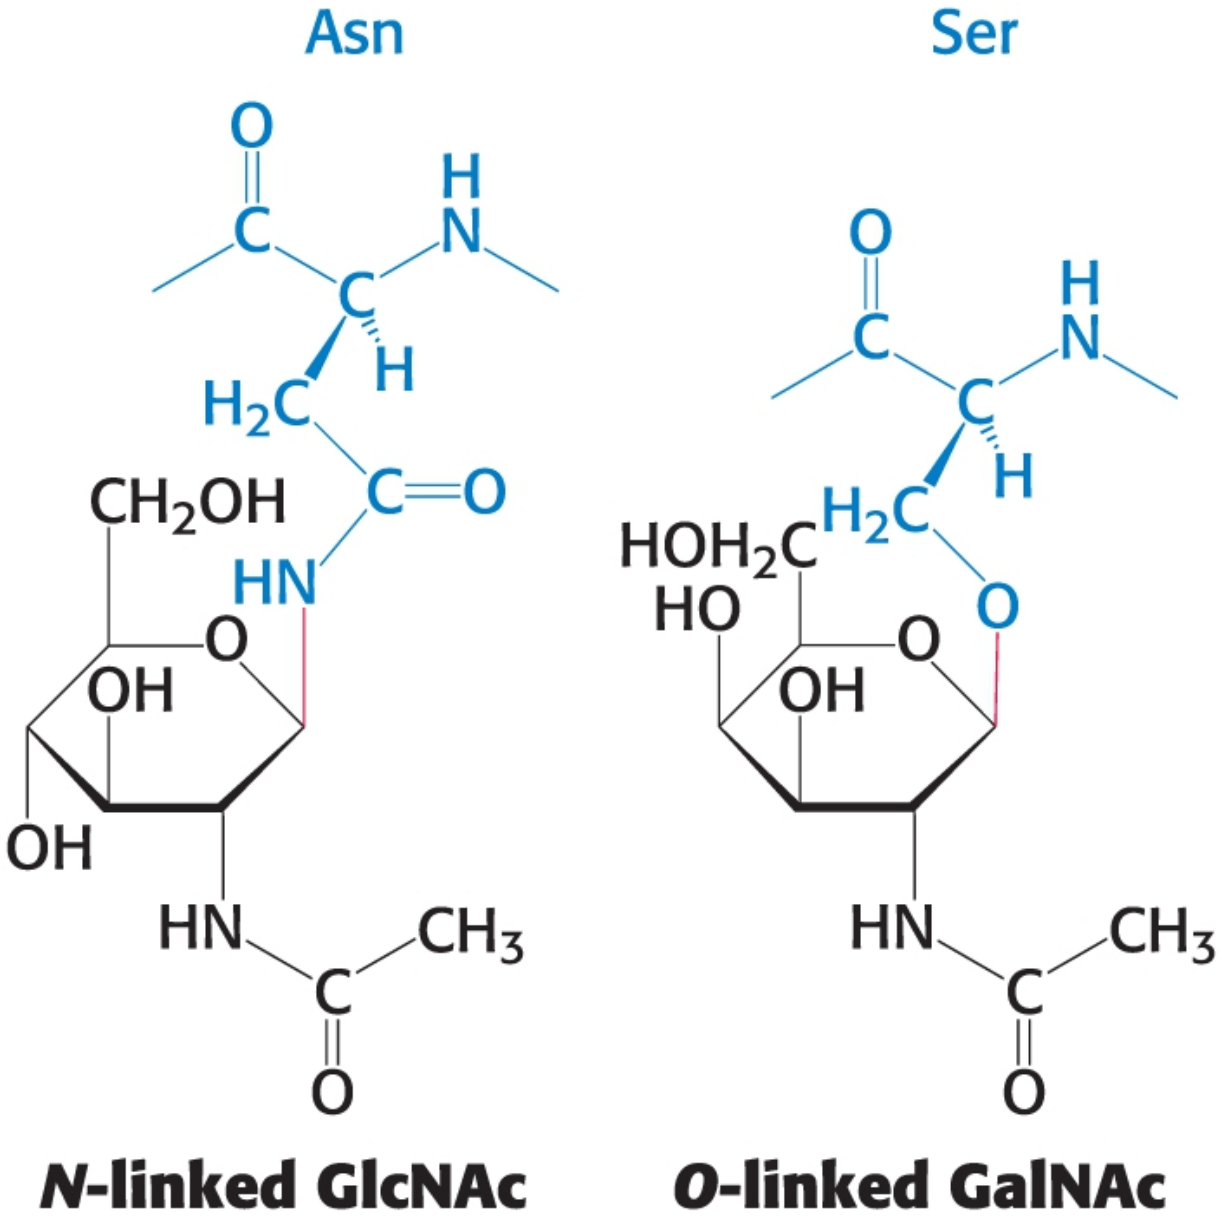


Galacturonic acid

The structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. The ring is in a plane perpendicular to the plane of the paper such that C 5 and O are away from the observer and C 2 and C 3 are toward the observer. C 1 and C 2 are each single bonded to H above and O H below. C 3 and C 4 are each single bonded to O H above and H below. C 5 is single bonded to C O O superscript minus above and H below.

Return to Chemical structure of galacturonic acid

Extended description for Chemical structure of chitin repeating unit



Charles Curtis/Shutterstock

The structure of the repeating unit is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 2 is single bonded to N H below. This N H is single bonded to C on the lower left. This C is double bonded to O on the upper left and single bonded to C H 3 below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above. C 4 has an open single bond on the left. C 1 is single bonded to O on the right which is further single bonded to C 4 of a 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 1 O and 5 C atoms. The O atom occupies the first position, which is the topmost vertex. C 1 is single bonded to O on the right. This O has an open single bond on the right. C 2 is single bonded to N H below. This N H is single bonded to C on the lower left. This C is double bonded to O on the upper left and single bonded to C H 3 below. C 3 is single bonded to O H above. C 5 is

single bonded to C H 2 O H above. The repeating unit is enclosed within brackets with subscript n.

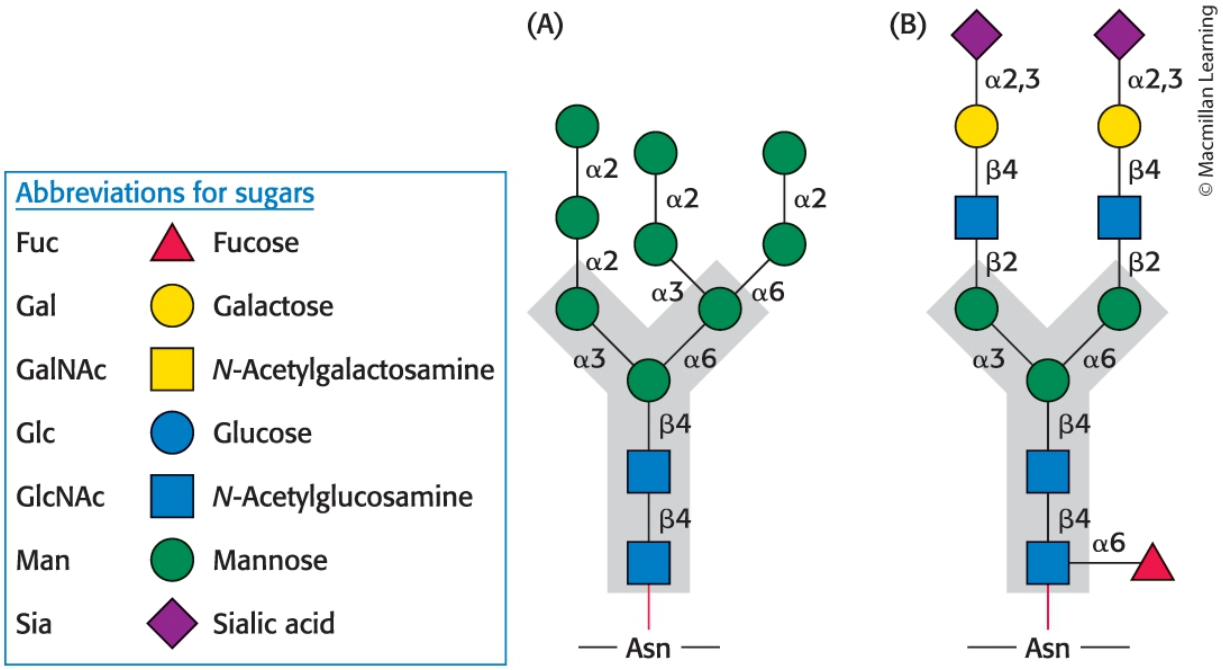
Extended description for Chemical structures of N-linked G l c N A c and O-linked G a l N A c

The structure of N-linked G l c N A c is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to N H on



the top. C 2 is single bonded to N H below. C 3 is single bonded to O H above. C 4 is single bonded to O H below. C 5 is single bonded to C H 2 O H above. N H bonded to C 1 is further single bonded to C on the upper right. This C is double bonded to O on the right and single bonded to C H 2 on the upper left. C H 2 is wedge bonded to C on the upper right. This C is dash bonded to H on the lower right, single bonded to N H on the upper right, and single bonded to C on the upper left. This C is double bonded to O on the top and has an open single bond on the lower left. N H has an open single bond on the lower right. This group connected to C 1 of the ring through N H is labeled A s n.

N H bonded to C 2 is further single bonded to C on the lower right. This C is single bonded to C H 3 on the upper right and double bonded to O below.

The structure of O-linked G a l N A c is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to O on the top. C 2 is single bonded to N H below. C 3 and C 4 are each single bonded to O H above. C 5 is single bonded to C H 2 O H above. O bonded to C 1 is further single bonded to C H 2 on the upper left. This C H 2 is wedge bonded to C on the upper right. This C atom is single bonded to N H on the upper right, single bonded to C on the upper left, and dash bonded to H on the lower right. The C atom on the upper left is double bonded to O on the top and has an open single bond on the lower left. N H has an open single bond on the lower right. This group connected to C 1 of the ring through O is labeled S e r. The N H group bonded to C 2 is further single bonded to C on the lower right. This C is single bonded to C H 3 on the upper right and double bonded to O below.

Extended description for Schematic illustrations of N-linked oligosaccharides

(A) The structure of the first N-linked oligosaccharide from bottom to top is as follows: A s n, single bond, blue square, single bond labeled beta 4, blue square, single bond labeled beta 4, green circle. A s n has an open single bond on the left and right. The green circle is single bonded to a green circle on the upper left and upper right. The single bond on the upper left and upper right are labeled alpha 3 and alpha 6 respectively. The green circle on the upper left is single bonded to a green circle above. The single bond is labeled alpha. The green circle above is further single bonded to a green circle. The single bond is labeled alpha 2.

The green circle on the upper right is single bonded to a green circle on the upper left and upper right. The single bond on the upper left and upper right are labeled alpha 3 and alpha 6 respectively. Each of

the green circles is single bonded to a green circle above. The single bond is labeled alpha 2.

A grey-colored Y-shape covers the blue squares and the three green circles from bottom to top.

(b) The structure of the second N-linked oligosaccharide from bottom to top is as follows: A s n, single bond, blue square, single bond labeled beta 4, blue square, single bond labeled beta 4, green circle. A s n has an open single bond on the left and right. The first blue square is single bonded to a red triangle on the right. The single bond is labeled alpha 6. The green circle is single bonded to a green circle on the upper left and upper right. The single bond on the upper left and upper right are labeled alpha 3 and alpha 6 respectively. Each of these green circles is single bonded above to blue square, single bond, yellow circle, single bond, purple rhombus. The single bond between the green circle and blue square is labeled beta 2. The single bond between blue square and yellow circle is labeled beta 4. The single bond between the yellow circle and purple rhombus is labeled alpha 2, 3.

A grey-colored Y-shape covers the blue squares and the three green circles from bottom to top.

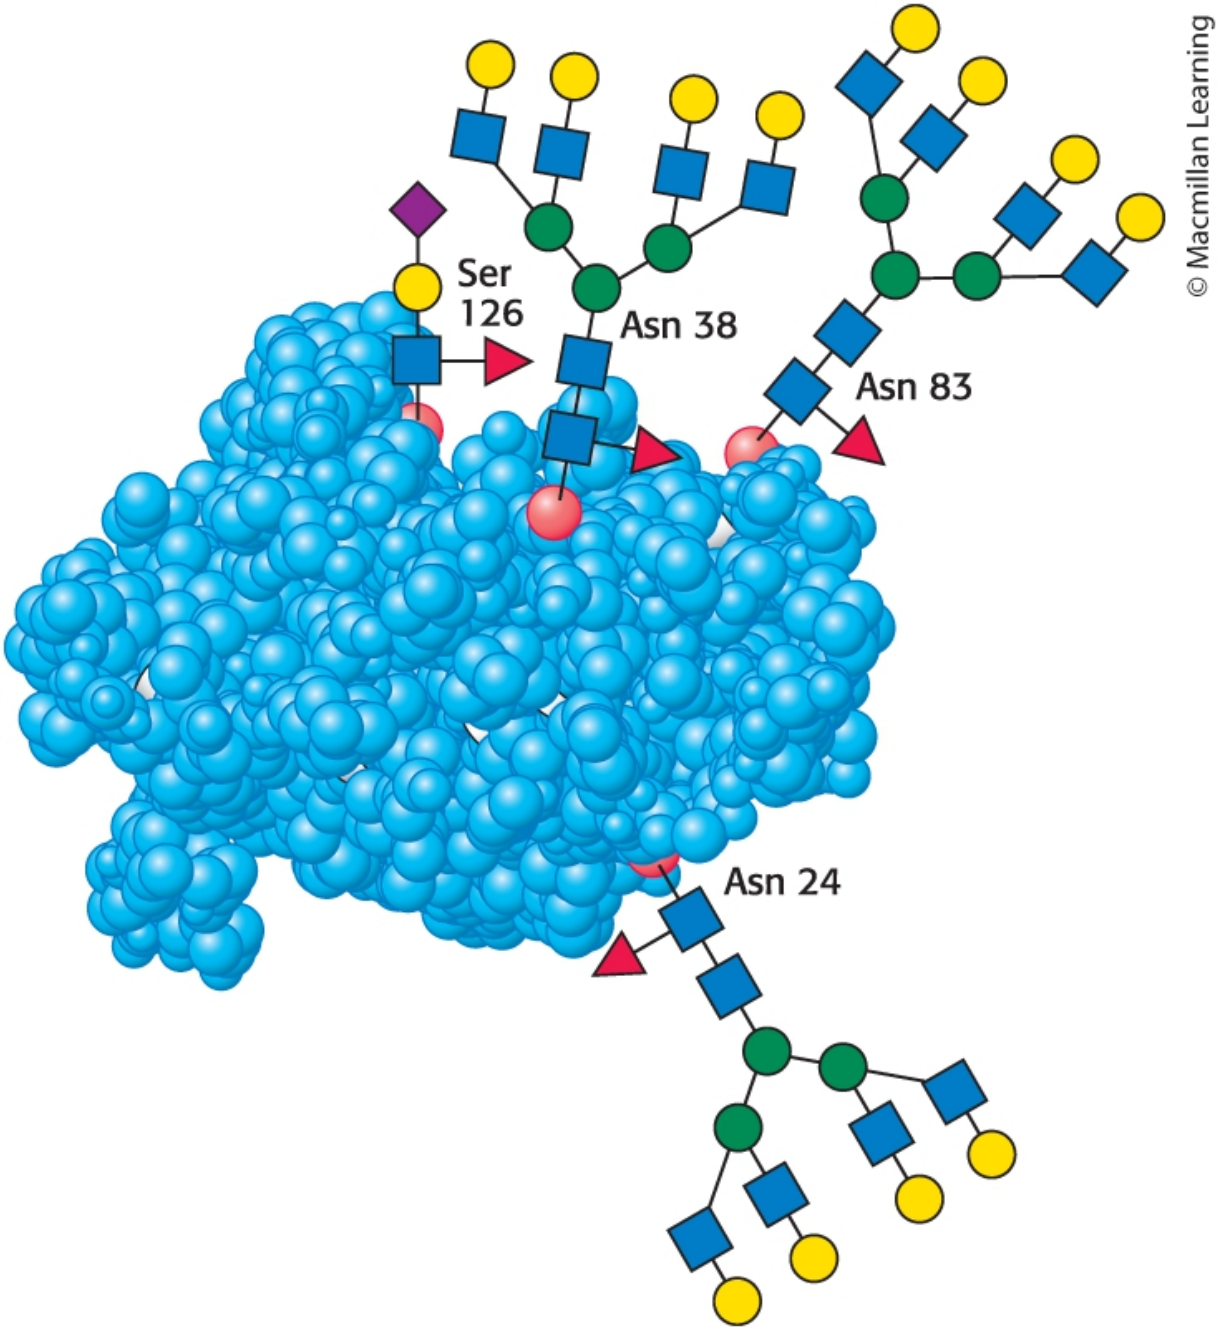
The chart for abbreviations for sugars on the left is as follows:

F u c - Red triangle - Fucose

G a l - Yellow circle - Galactose

G a l N A c - Yellow square - N-Acetylgalactosamine

G l c - Blue circle - Glucose



G l c N A c - Blue square - N-Acetylglucosamine

M a n - Green circle - Mannose

S i a - Purple rhombus - Sialic acid.

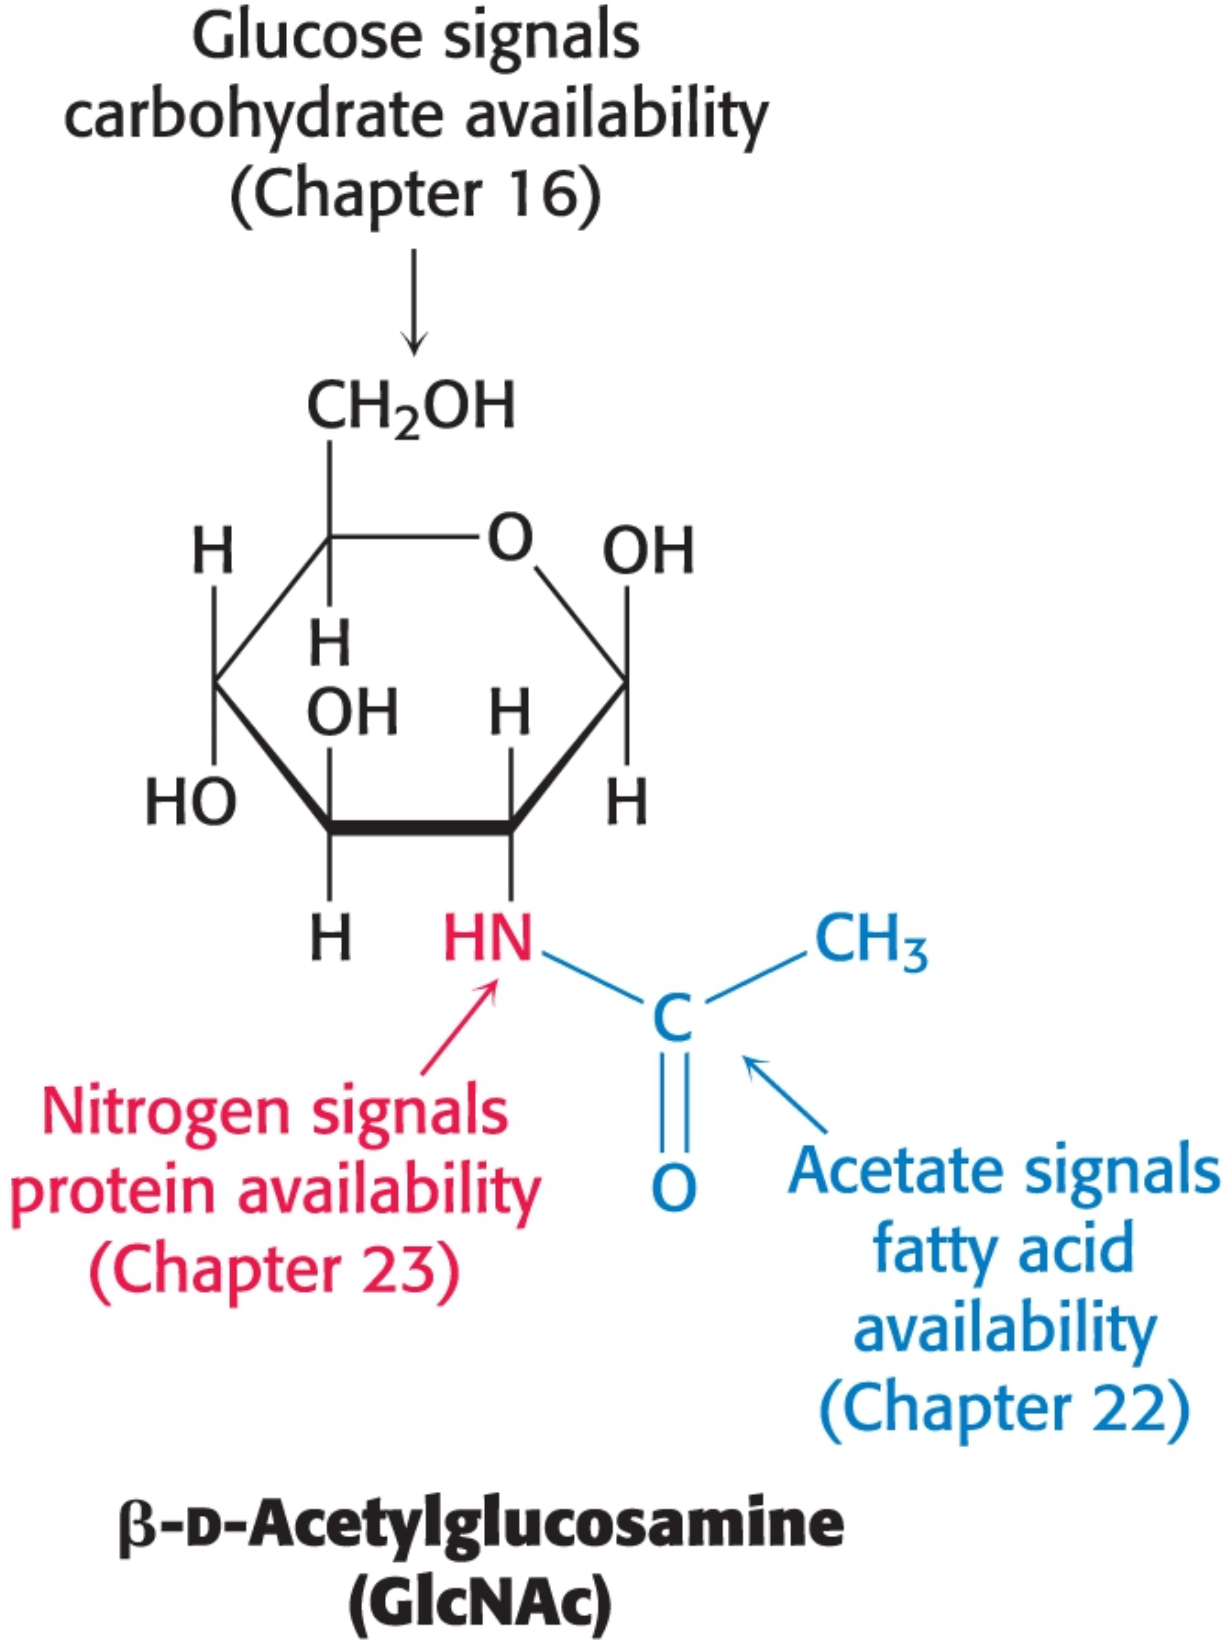
Extended description for Schematic illustration of erythropoietin with oligosaccharides linked to amino acid residues



Erythropoietin is depicted as a compact cluster of blue spheres. Each of the amino acid residues; S e r 126, A s n 38, A s n 83, and A s n 24; is depicted as red sphere at the surface of erythropoietin. S e r 126, A s n 38, and A s n 83 are located at the top surface. A s n 24 is located at the bottom surface. Each of these amino acid residues are bound to oligosaccharides. The structure of oligosaccharide bound to S e r 126 is as follows: Red sphere, single bond, blue square, single bond, yellow circle, single bond, purple rhombus. The blue square is single bonded to a red triangle on the right.

The structure of oligosaccharide bound to A s n 38, A s n 83, and A s n 24 is as follows: Red sphere, single bond, blue square, single bond, blue square, single bond, green circle. The first blue square is single bonded to a red triangle. The green circle is single bonded to two green circles. Each green circle is single bonded to two blue squares. Each blue square is single bonded to a yellow circle.

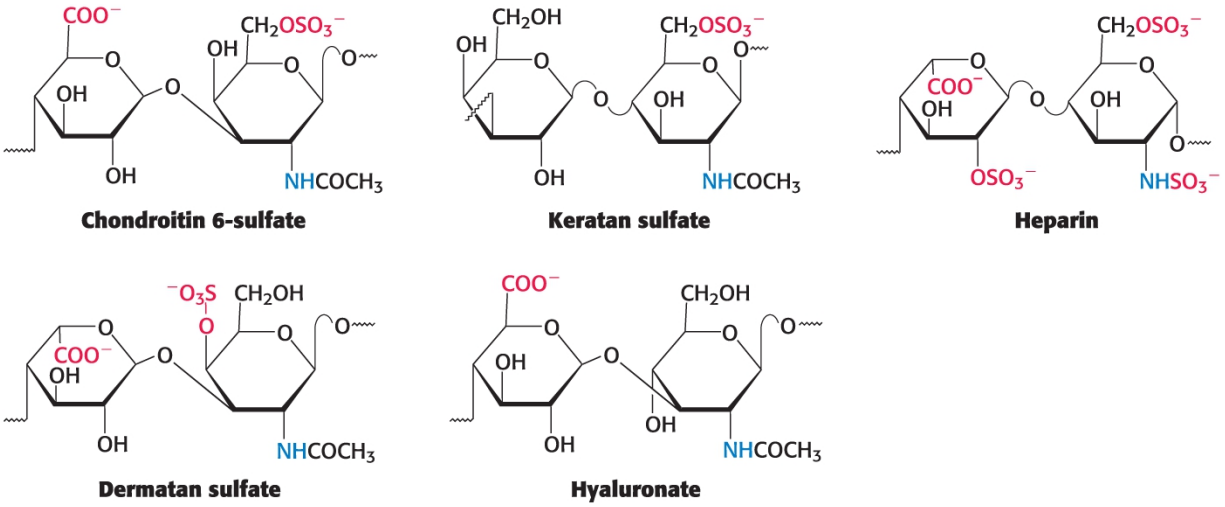
Extended description for Structure of beta-D-

acetylglucosamine



β-D-Acetylglucosamine (GlcNAc)

The structure of beta-D-acetylglucosamine (G l c N A c) is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 and C 3 are each single bonded to O H above and H below. C 2 is single bonded to H above and N H below. N H is highlighted in red. C 4 is single bonded to H above and O H below. C 5 is single bonded to C H 2 O H above and H below. The ring is labeled "glucose signals carbohydrate availability (Chapter 16)". N H bonded to C 2 is further single bonded to C on the lower right and is labeled "nitrogen signals protein availability (chapter 23)". The C atom on the lower right is single bonded to C H 3 on the upper right and double bonded to O below. The C atom, O atom, C H 3 group, and their associated bonds are highlighted in blue. They are labeled "acetate signals fatty acid availability (Chapter 22)".

Return to Structure of beta-D-acetylglucosamine

Extended description for Structures of chondroitin 6-sulfate, keratan sulfate, heparin, dermatan sulfate, and hyaluronate

The structure of chondroitin 6-sulfate is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 2 is single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C O O superscript minus above. C 4 has an open single bond below. C 1 is single bonded to O on the upper right. This O is single bonded to C 3 of a 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to O above. O has an open single bond on the right. C 2 is single bonded to N H C O C H 3 below. C 4 is single bonded to O H above. C 5 is single bonded to C H 2 O S O 3 superscript minus above. C O O superscript minus and O S O 3 superscript minus are highlighted in red. N H group of N H C O C H 3 is highlighted in blue.

The structure of keratan sulfate is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 2 is single bonded to O H below. C 3 is single bonded to C H 2 above in the form of a line. This C H 2 group has an open single bond on the lower left. C 4 is single bonded to O H above. C 5 is single bonded to C H 2 O H above. C 1 is single bonded to O on the right. This O is single bonded to C 4 of a 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to O above. O has an open single bond on the right. C 2 is single bonded to N H C O C H 3 below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O S O 3 superscript minus above. O S O 3 superscript minus is highlighted in red. N H group of N H C OC H 3 is highlighted in blue.

The structure of heparin is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 2 is single bonded to O S O 3 superscript minus below. C 3 is single bonded to O H above. C 4 is single bonded to C H 2 below in the form of a line. This C H 2 has an open single bond on the left. C 5 is single bonded to C O O superscript minus below. C 1 is single bonded to O on the upper right. This O is single bonded to C 4 of a 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to O below. O has an open single bond on the right. C 2 is single bonded to N H S O 3 superscript minus below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O S O 3 superscript minus above. C O O superscript minus, O S O 3 superscript minus and S O 3 superscript minus are highlighted in red. N H group of N H S O 3 superscript minus is highlighted in blue.

The structure of dermatan sulfate is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 2 is single bonded to O H below. C 3 is single bonded to O H above. C 4 is single bonded to C H 2 below in the form of a line. This C H 2 group has an open single bond on the left. C 5 is single bonded to C O O superscript minus below. C 1 is single bonded to O on the upper right. This O is single bonded to C 3 of a 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to O above. O has an open single bond on the right. C 2 is single bonded to N H C O C H 3 below. C 4 is single bonded to O above. This O is single bonded to S O 3 superscript minus above. C 5 is single bonded to C H 2 O H above. C O O superscript minus and O, single bond, S O 3 superscript minus are highlighted in red. N H group of N H C OC H 3 is highlighted in blue.

The structure of hyaluronate is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 2 is single bonded to O H below. C 3 is single bonded to O H above. C 4 is single bonded to C H 2 below. This C H 2 has an open single bond on the right. C 5 is single bonded to C O O superscript minus below. C 1 is single bonded to O on the upper right. This O is single bonded to C 3 of a 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to O above. O has an open single bond on the right. C 2 is single bonded to N H C O C H 3 below. C 4 is single bonded to O H below. C 5 is single bonded to C H 2 O H above. C O O superscript minus is highlighted in red. N H group of N H C OC H 3 is highlighted in blue.

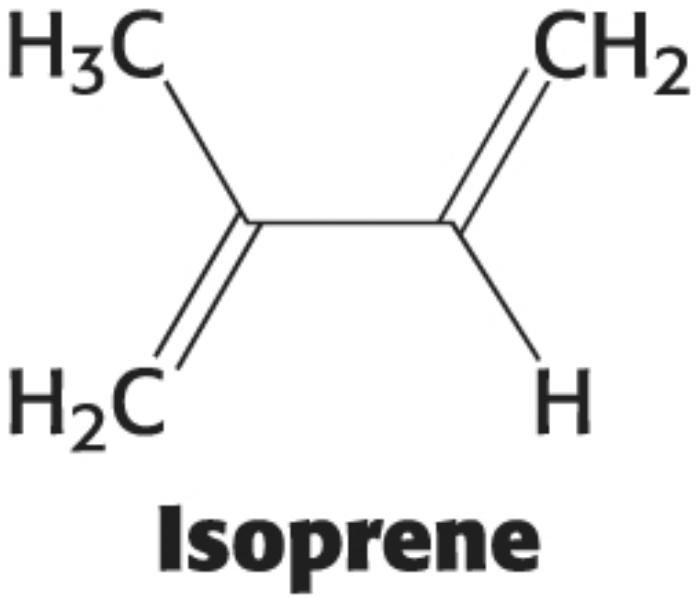
Extended description for Structure of dolichol phosphate



n = 15–19

Dolichol phosphate

The structure of dolichol phosphate is as follows: An 11-carbon alkene chain is depicted as a line structure using 10 zigzag lines. The alkene chain contains double bonds between C 1 and C 2 and C 5 and C 6. C 1 is single bonded to C H 3 on the upper left and C H 3 on the lower left. C 5 is single bonded to C H 3 on the lower left. C 4 to C 7 is enclosed in parentheses with subscript n. C 9 is single bonded to H on the lower left and C H 3 on the lower right. C 11 is single bonded to O on the right. O is single bonded to P on the lower right. P is partially double-bonded to O on the upper right, lower right, and lower left. This group has an overall negative charge of 2 minus.

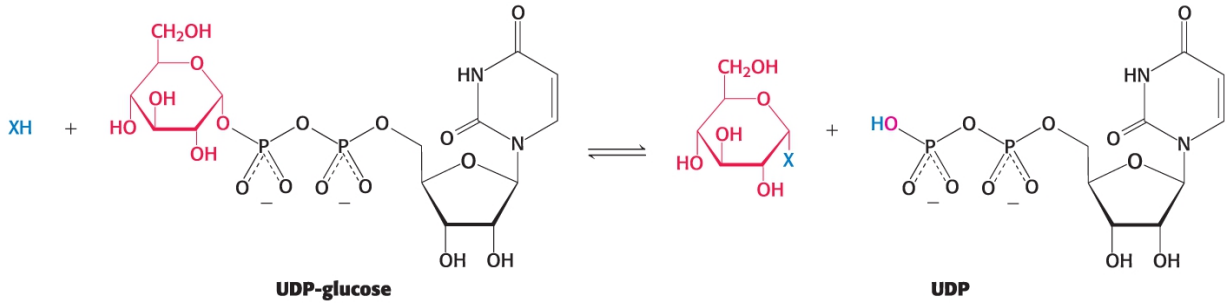
Extended description for Schematic illustration of protein sorting in the Golgi complex



© Macmillan Learning

The endoplasmic reticulum is depicted as a tubular flat structure lined by thick black dots on the bottom surface. Round vesicles protrude from the top surface of endoplasmic reticulum and move toward the Cis Golgi compartment. The Golgi complex consists of 5 flat tubular sacs located one above the other. The size of these sacs decreases from bottom to top. The topmost face of the Golgi complex is labeled trans. Tiny vesicles emerge from each sac of Golgi complex and move to the next sac located above. The interior

of a vesicle emerging from the trans face of Golgi is lined with green dots that represent proteins. This vesicle fuses with the surface of the cell leading to the insertion of the protein (green dots) in plasma membrane. A tiny vesicle emerging from the second sac of the trans face moves toward a pre-lysosome. Another large vesicle emerging from this sac is labeled secretory granule. It is filled with tiny red colored granules. It fuses with the cell surface to release the granules into the exterior.

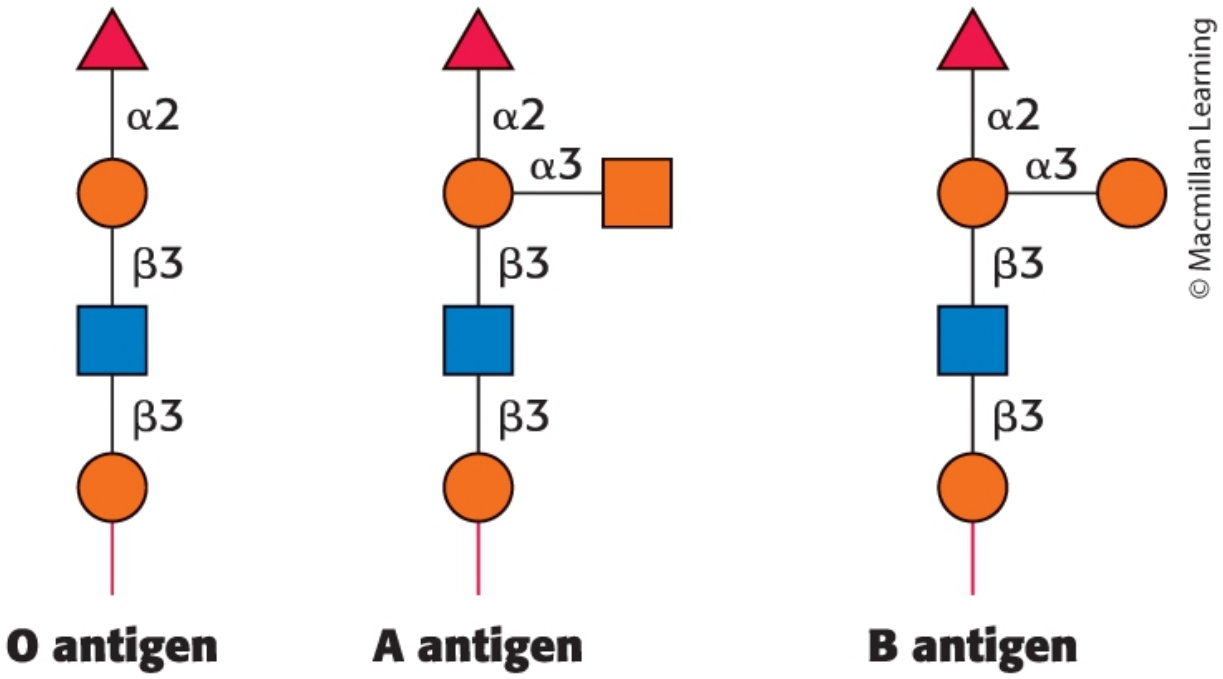
Extended description for Glycosyltransferase reaction

The reaction consists of two reactants and two products. The first reactant is X H. The second reactant is U D P glucose whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to O below. C 2 and C 4 are each single bonded to O H below. C 3 is single bonded O H above. C 5 is single bonded to C H 2 O H above. The O bonded to C 1 is further single bonded to P, single bond, O, single bond, P, single bond, O, single bond, C H 2 in the form of a line. P 1 and P 2 are each partially double bonded to O on the lower left and lower right. The O atoms bonded to P have an overall negative charge. C H 2 is single bonded to C 4 of a 5-membered pentagonal ring in a vertical orientation. The heterocyclic pentagonal ring has 1 O and 5 C atoms with O occupying the topmost vertex. C 2 and C 3 are each single bonded to O H below. C 1 is single bonded to N 1 of a 6 membered heterocyclic hexagonal ring in a vertical orientation. It consists of 2 N and 4 C atoms. C 1 occupies the bottom left vertex and is double bonded to O on the lower left. First N occupies the first position, which is the bottom-most vertex. Second N bound to H occupies the second position, which is the top left vertex. C 2 is double bonded to O above. A double bond is present between C 3 and C 4.



A reversible reaction arrow is shown.

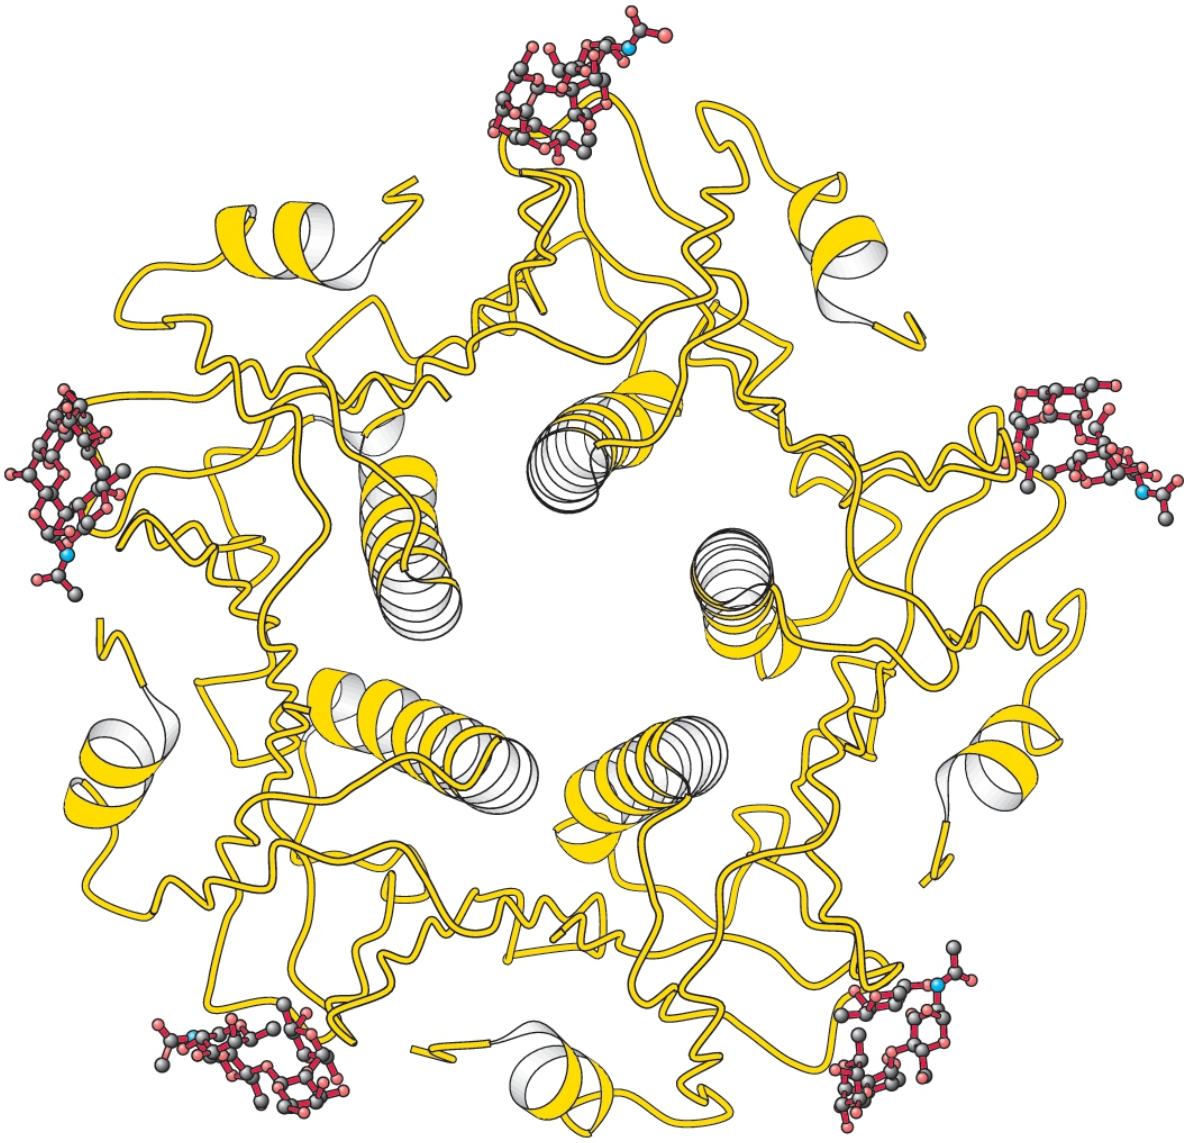
The structure of the first product is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to X below. C 2 and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above.

The second product is U D P whose structure is as follows: A 5-membered heterocyclic pentagonal ring in vertical orientation has 1 O and 4 C atoms with C 1 occupying the top right vertex. O occupies the topmost vertex. C 2 and C 3 are each single bonded to O H below. C 4 is single bonded to C H 2 above in the form of a line. C H 2 is single bonded to O, single bond, P, single bond, O, single bond, P, single bond, O H. P 1 and P 2 are each partially double bonded to O on the lower left and lower right. C 1 is single bonded to N 1 of a 6 membered heterocyclic hexagonal ring in a vertical orientation. It consists of 2 N and 4 C atoms. C 1 occupies the bottom left vertex and is double bonded to O on the lower left. First N occupies the first position, which is the bottom-most vertex. Second N bound to H occupies the second position, which is the top left vertex. C 2 is double bonded to O above. A double bond is present between C 3 and C 4.

Return to Glycosyltransferase reaction

Extended description for Schematic illustration of the structures of O antigen, A antigen, and B-antigen

The structure of O antigen is as follows: A red triangle is single bonded below to an orange circle by alpha 2. The orange circle is single bonded to below blue square by beta 3. The blue square is single bonded to orange circle by beta 3.



The structure of A antigen is as follows: A red triangle is single bonded below to an orange circle by alpha 2. The orange circle is single bonded below to blue square by beta 3. The blue square is single bonded below to an orange circle by beta 3. The first orange circle is single bonded to an orange square on the right by alpha 3.

The structure of B antigen is as follows: A red triangle is single bonded below to an orange circle by alpha 2. The orange circle is single bonded below to a blue square by beta 3. The blue square is

single bonded below to an orange circle by beta 3. The first orange circle is single bonded to an orange circle by alpha 3.

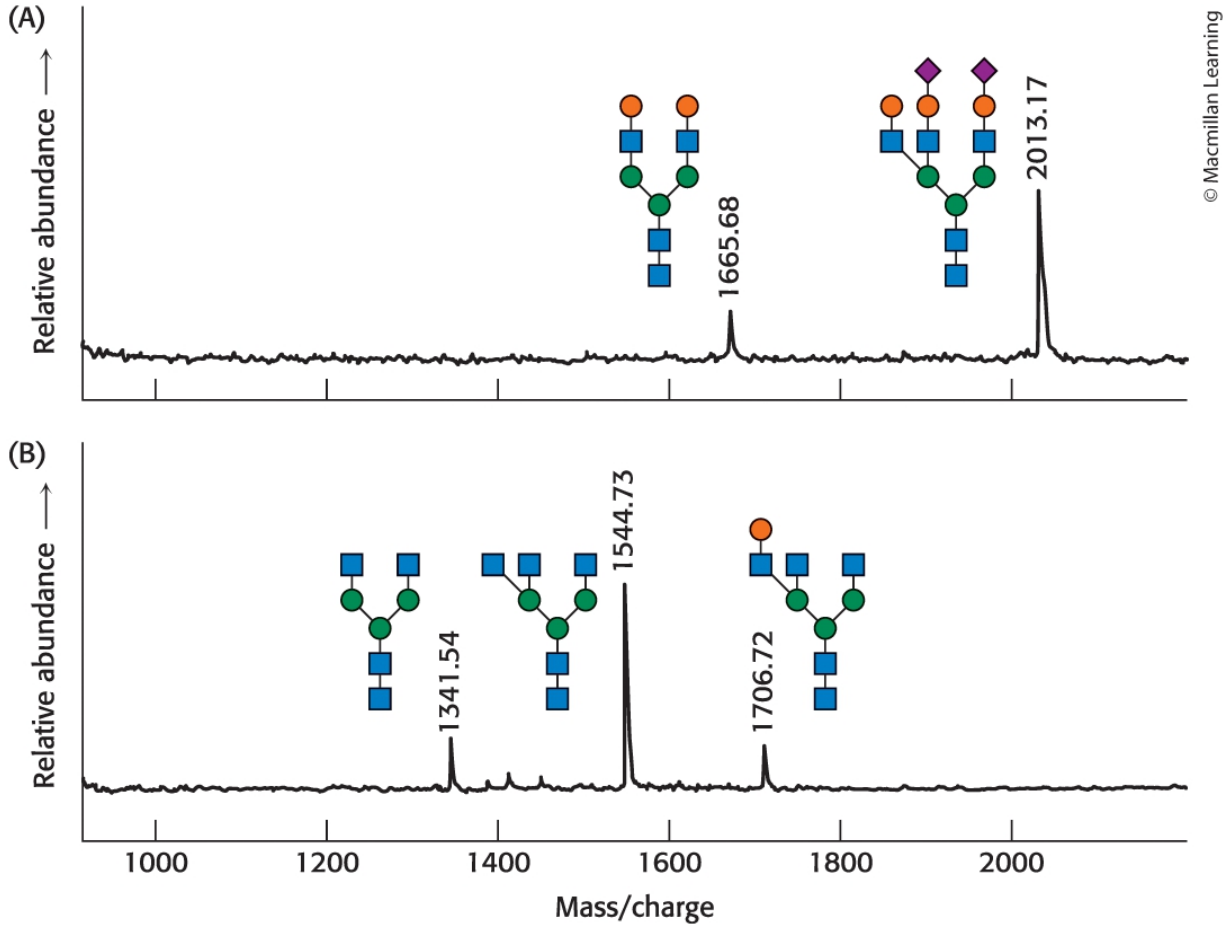
Mannose 6-phosphate residue

Step 1: It is catalyzed by phosphotransferase. The reactant is mannose residue whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to O R below. C 2 and C 3 are each single bonded to O H above. C 4 is single bonded to O H below. C 5 is single bonded to C H 2, single bond, O H above.

A forward reaction arrow shows the conversion of U D P-G l c N A c to U M P and the product.

The structure of the product is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1 is single bonded to O R below. C 2 and C 3 are each single bonded to O H above. C 4 is single bonded to O H below. C 5 is single bonded to C H 2 above. This C H 2 is single bonded on the upper left to O, single bond, P, single bond, O, single bond, G l c N A c. The P atom is partially double bonded to O on the lower left and lower right. The O atom have an overall negative charge.



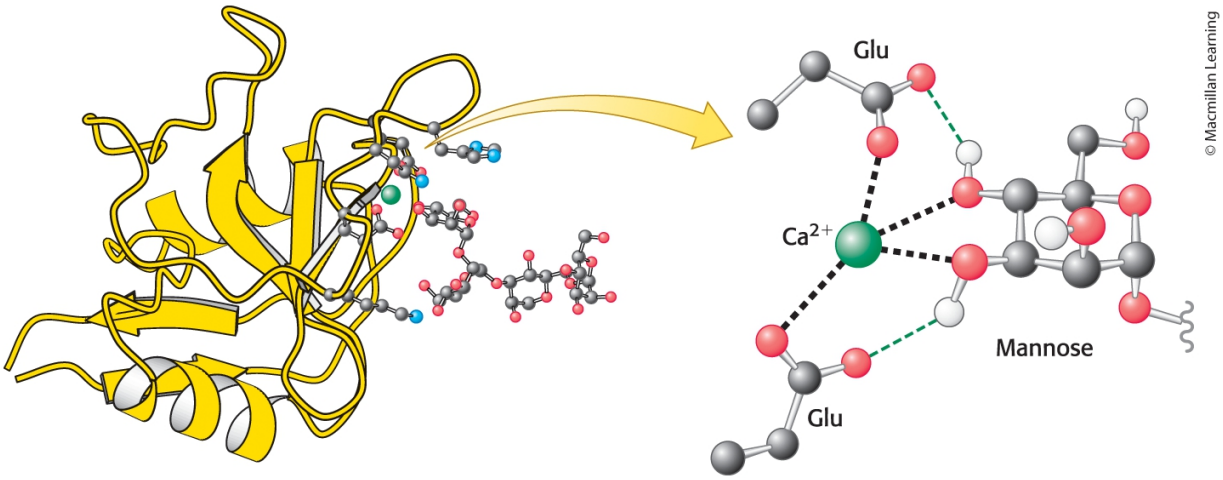
Step 2: The product formed in step 1 is converted into mannose 6-phosphate residue. It is catalyzed by N-acetylglucosaminidase. A forward reaction arrow is shown below the first product. It shows the entry of H 2 O and exit of G l c N A c.

The structure of mannose 6-phosphate residue is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the upper right vertex. C 1 is single bonded to O R below. C 2 and C 3 are each single bonded to O H above. C 4 is single bonded to O H below. C 5 is single bonded to C H 2 above. This C H 2

is single bonded on the upper left to O, single bond, P, partial double bond, O. The P atom is partially double bonded to O on the lower left and lower right. This group has an overall negative charge of 2 minus.

Return to Stepwise formation of mannose 6-phosphate residue

Extended description for Mass spectrums for the characterization of oligosaccharides



(A) The vertical axis is labeled relative abundance which increases from the bottom to the top. The horizontal axis has a series of evenly spaced markings. A line starts from the lowest relative abundance and moves horizontally toward the right. A tiny peak labeled 1665.68 is formed between the fourth and fifth marking on the horizontal axis. An oligosaccharide composed of four blue squares, three green circles, and two orange circles is shown along this peak. A relatively longer peak labeled 2013.17 is formed after the sixth marking on the horizontal axis. An oligosaccharide composed of five blue squares,

three green circles, three orange circles, and two purple rhombi is shown along the peak.

(B) The vertical axis is labeled relative abundance which increases from the bottom to the top. The horizontal axis is labeled mass over charge. It has markings ranging from 1000 to 2000 in increments of 200 units. A line starts from the lowest relative abundance and moves horizontally toward the right. A first tiny peak labeled 1341.54 is formed between 1200 and 1400 on the horizontal axis. An oligosaccharide composed of four blue squares and three green circles is shown along this peak. A relatively longer peak labeled 1544.73 is formed between 1400 and 1600 on the horizontal axis. An oligosaccharide composed of five blue squares and three green circles is shown along the peak. A third tiny peak slightly smaller than the first tiny peak is formed between 1600 and 1800. It is labeled 1706.72. An oligosaccharide composed of five blue squares, three green circles, and one orange circle is shown along the peak.

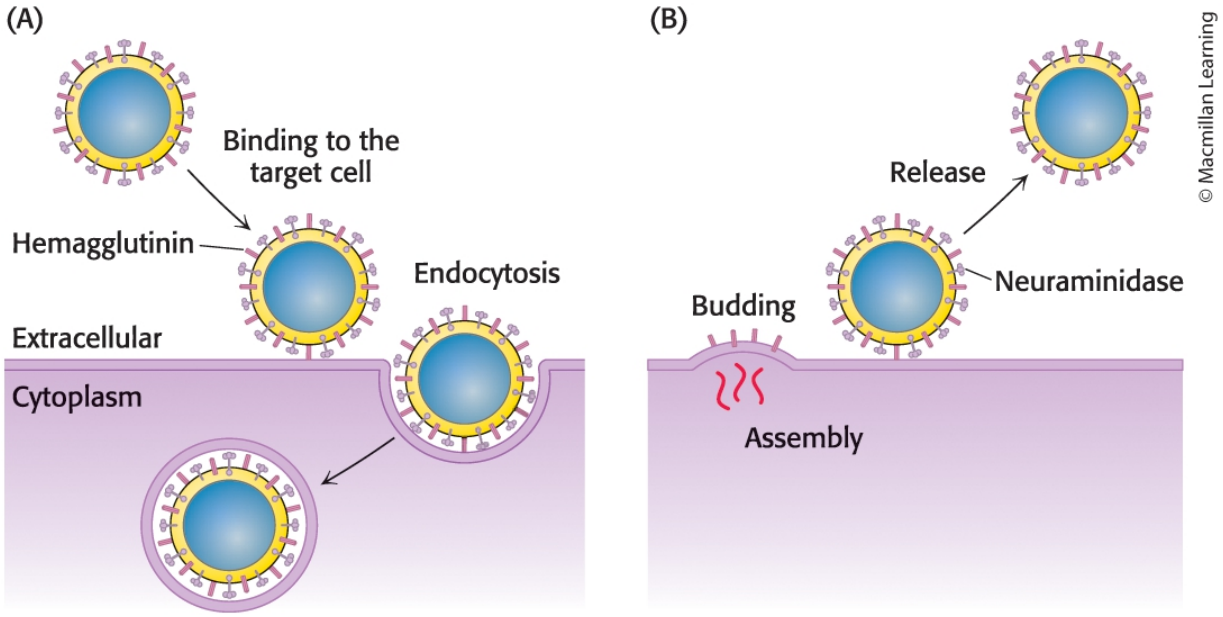
Extended description for Ribbon diagram and ball and stick model depict the calcium ion mediated binding of C-type lectin to carbohydrates



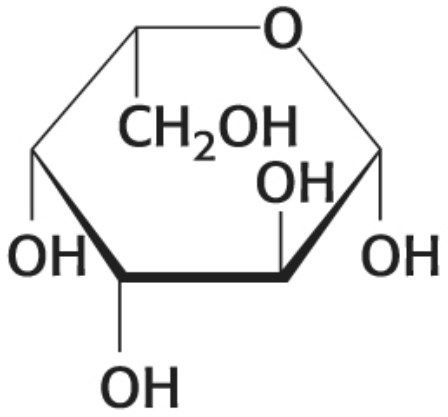
The ribbon diagram of C-type lectin consists of several beta-strands at the top and an alpha-helix at the bottom. These secondary structures are interconnected by long thread-like loops. A cluster of long thread-like loops at the right is connected to the ball-and-stick models of amino acid side chains, carbohydrates, and a green sphere.

These ball and stick models are enlarged on the right. A central green sphere is labeled C a superscript 2 plus. The side chains of G l u are shown above and below the green sphere. They are composed of 3 black and two red spheres. A red sphere of each side chain above and below is connected to the central grey sphere through a dashed line. A ball and stick model of mannose is shown on the right of the central green sphere. It is composed of a ring of one red and 5 black spheres. The black spheres of the ring are connected to black spheres or red spheres. The top left and bottom left black spheres of the ring are each connected to a red sphere on the left.

Each of these red spheres is connected to the central green sphere through a dashed line. A white sphere connected to each of these red spheres is further connected to the corresponding red sphere of G l u side chain above and below respectively through a dashed line.

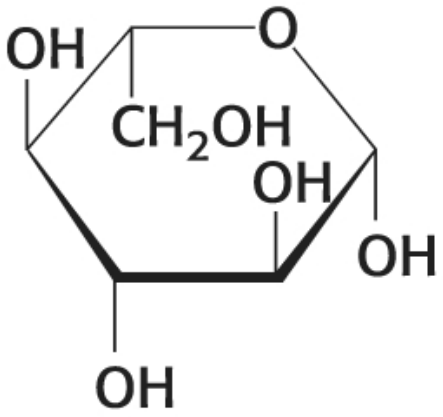
Return to Ribbon diagram and ball and stick model depict the calcium ion mediated binding of C-type lectin to carbohydrates

Extended description for Schematic illustrations depict the entry and exit of influenza virus from host cell



(a) The virus particle is depicted as a blue circle with a thick yellow border. It is located in the extracellular space. A series of surface proteins protrude from the yellow border, above the surface of the virus particle. The virus particle binds to the surface of the target cell through a surface protein labeled hemagglutinin. A semicircular invagination is formed on the surface of the target cell. The virus particle then fits inside this invagination. This process is labeled endocytosis. The virus particle enters inside the cytoplasm and is enclosed inside a circular portion of the target cell membrane.

(b) A slightly raised surface is shown on the target cell membrane. A series of viral surface proteins protrude outside from this raised surface. Three short irregular lines are located below this surface. The red lines depict the process of assembly. The raised surface



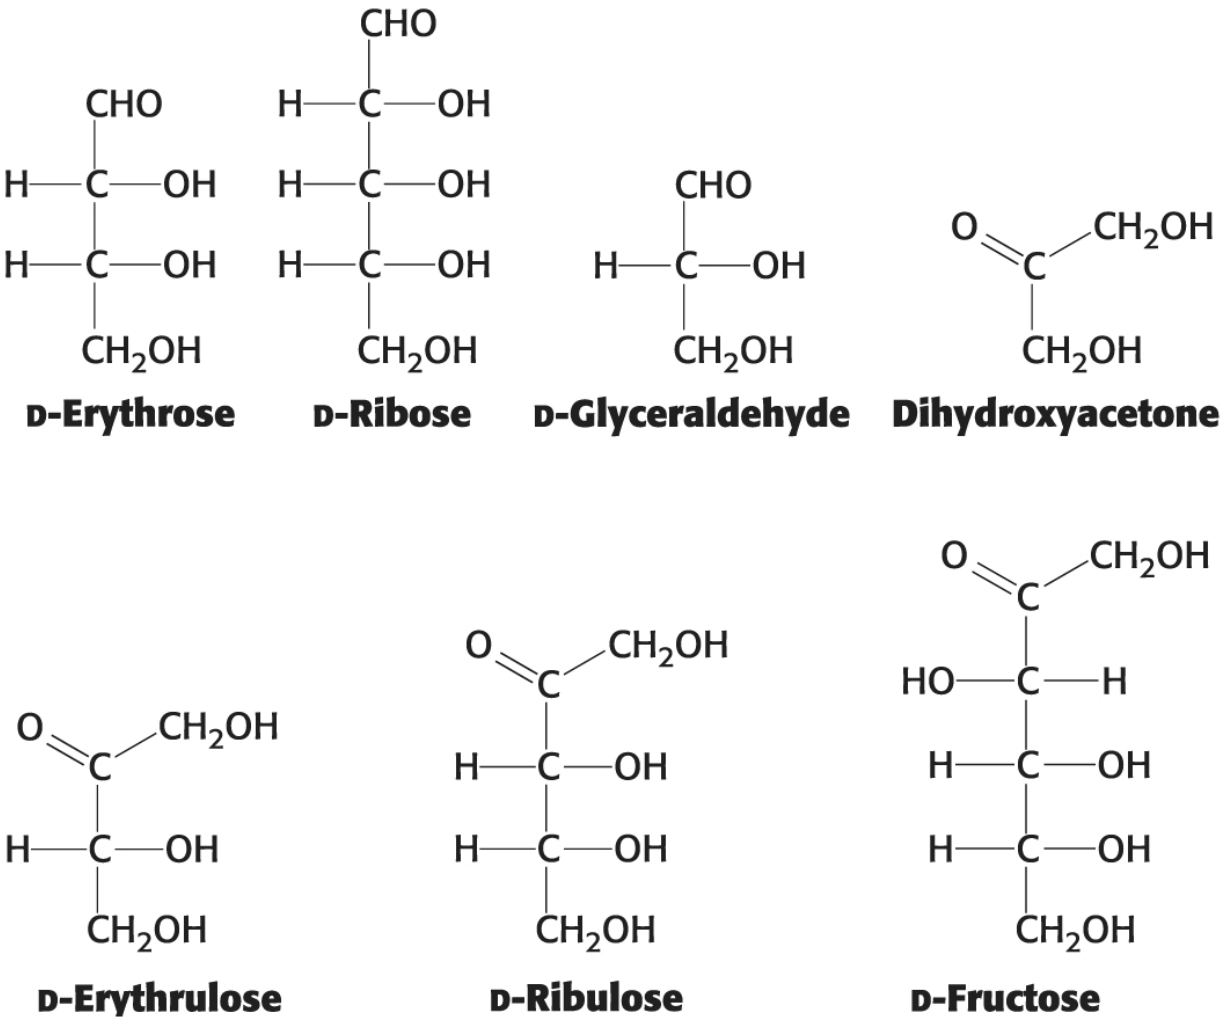
depicts the process of budding. A mature virus particle produced by budding is shown attached to the target cell membrane through hemagglutinin. The action of neuraminidase, a second set of viral surface proteins, causes the release of the virus.

Return to Schematic illustrations depict the entry and exit of influenza virus from host cell

Extended description for Chemical structures of beta L-Galactopyranose and beta L-Glucopyranose

β–L–Galactopyranose

β–L–Glucopyranose



The structure of beta L-Galactopyranose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. C 1 occupies the rightmost vertex. The O atom occupies the first position, which is the top right vertex. The ring is in a plane perpendicular to the plane of the paper such that C 5 and O are away from the observer and C 2 and C 3 are toward the observer. C 1, C 3, and C 4 are each single bonded to O H below. C 2 is single bonded to O H above. C 5 is single bonded to C H 2 O H below.

The structure of beta L-Glucopyranose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. C 1 occupies the rightmost vertex. The O atom occupies the first position, which is the top right vertex. The ring is in a plane perpendicular to the plane of the paper such that C 5 and O are away from the observer and C 2 and C 3 are toward the observer. C 1 and C 3 are each single bonded to O H below. C 2 and C

4 are each single bonded to O H above. C 5 is single bonded to C H 2 O H below.

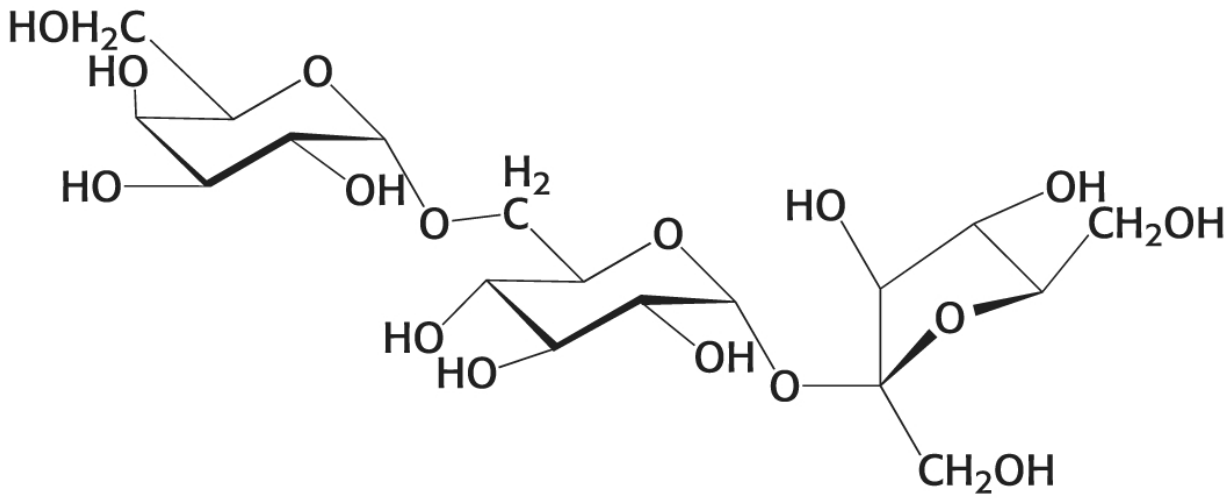
Extended description for Chemical structures of D-Erythrose, D-Ribose, D-Glyceraldehyde, Dihydroxyacetone, D-Erythrulose, D-Ribulose, and D-Fructose

The structure of D-Erythrose is as follows: The Fischer projection consists of a vertical line with C H O above and C H 2 O H below. The projection contains two C atoms placed one below the other on the vertical line. The C atoms are numbered from top to bottom. C 2 and C 3 each are single bonded to O H on the right and H on the left.

The structure of D-Ribose is as follows: The Fischer projection consists of a vertical line with C H O above and C H 2 O H below. The projection contains three C atoms placed one below the other on the vertical line. The C atoms are numbered from top to bottom. C 2, C 3, and C 4 each are single bonded to H on the left and O H on the right.

The structure of D-Glyceraldehyde is as follows: The Fischer projection consists of a vertical line with C H O above and C H 2 O H below. The projection contains a C atom at the center of the vertical line. The C atom is single-bonded to H on the left and O H on the right.

The structure of Dihydroxyacetone is as follows: A central carbon atom is double bonded to O on the upper left, single bonded to C H 2 O H on the upper right, and single bonded to C H 2 O H below.



The structure of D-Erythrulose is as follows: The Fischer projection consists of a vertical chain with C above and C H 2 O H below. The projection contains a C at the center of the vertical line. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 is single bonded to H on the left and O H on the right.

The structure of D-Ribulose is as follows: The Fischer projection consists of a vertical chain with C above and C H 2 O H below. The projection contains two C atoms placed one below the other on the vertical chain. The C atoms are numbered from top to bottom. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 and C 3 are each single bonded to H on the left and O H on the right.

The structure of D-Fructose is as follows: The Fischer projection consists of a vertical chain with C above and C H 2 O H below. The projection contains three C atoms placed one below the other on the vertical chain. The C atoms are numbered from top to bottom. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 and C 4 are each single bonded to H on the left and O H on the right.

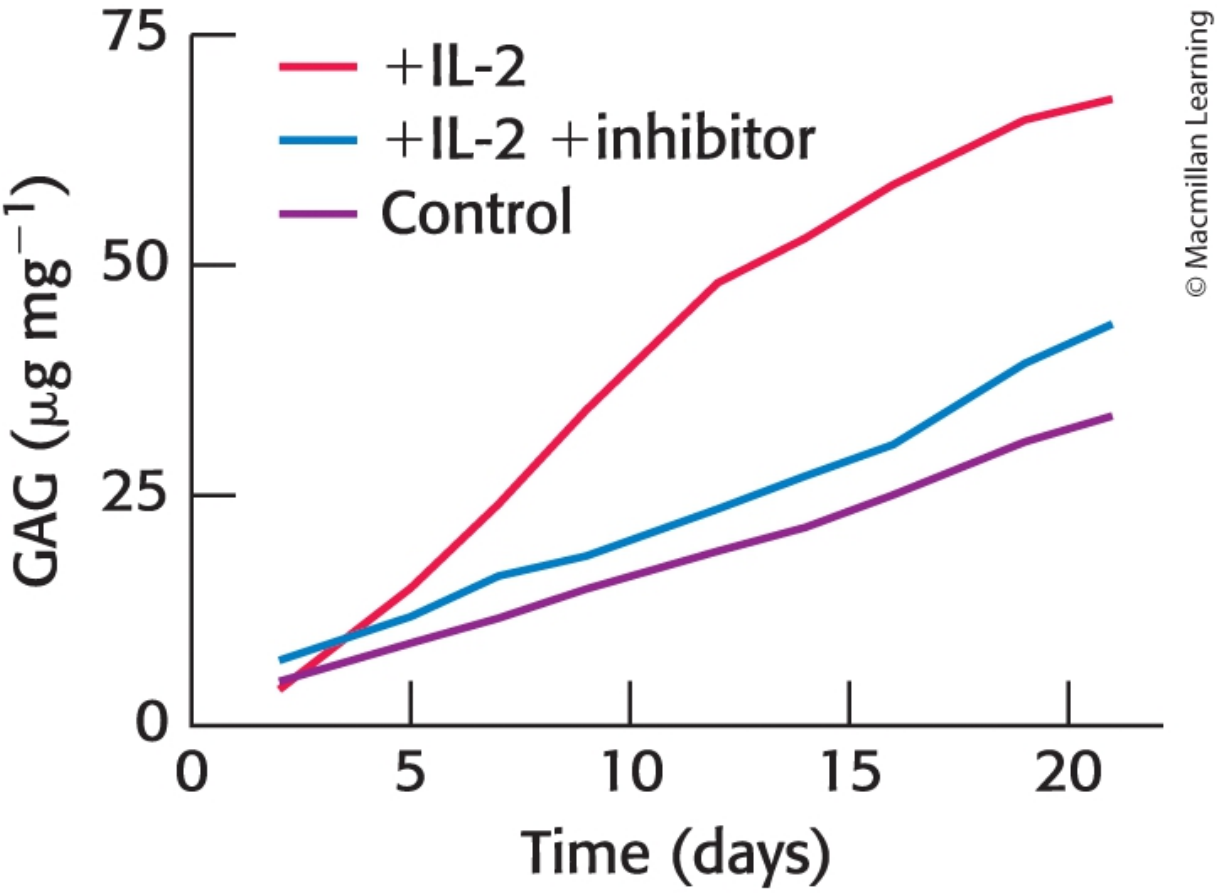
Extended description for Chemical structure of raffinose



Raffinose

The structure of raffinose is as follows: A 6-membered heterocyclic hexagonal ring is in a chair conformation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 2 and C 5 are close to each other. C 4 occupies the top left vertex. C 1 is single bonded to O, single bond, C H 2 on the lower right. C 2 is single bonded to O H on the lower right. C 3 is single bonded to O H on the left. C 4 is single bonded to O H above. C 5 is single bonded to C H 2 O H on the upper left. The C H 2 group bonded to C 1 through O is single bonded to C 5 of another 6-membered heterocyclic hexagonal ring in a chair conformation that consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 2 and C 5 are close to each other. C 4 occupies the top left vertex. C 1 is single bonded to O on the lower right. C 2 is single bonded to O H on the lower right. C 3 is single bonded to O H on the left. C 4 is single bonded to O H on the lower left. The O atom bonded to C 1 is single bonded to C 1 of a 5-membered heterocyclic pentagonal ring that consists of 1 O and 4 C

atoms. C 1 occupies the bottom left vertex. O occupies the bottom-most vertex. C 1 and C 4 are wedge bonded to O atom. C 2 is single bonded to O H above. C 3 is single bonded to O H on the right. C 4 is single bonded to C H 2 O H on the upper right.

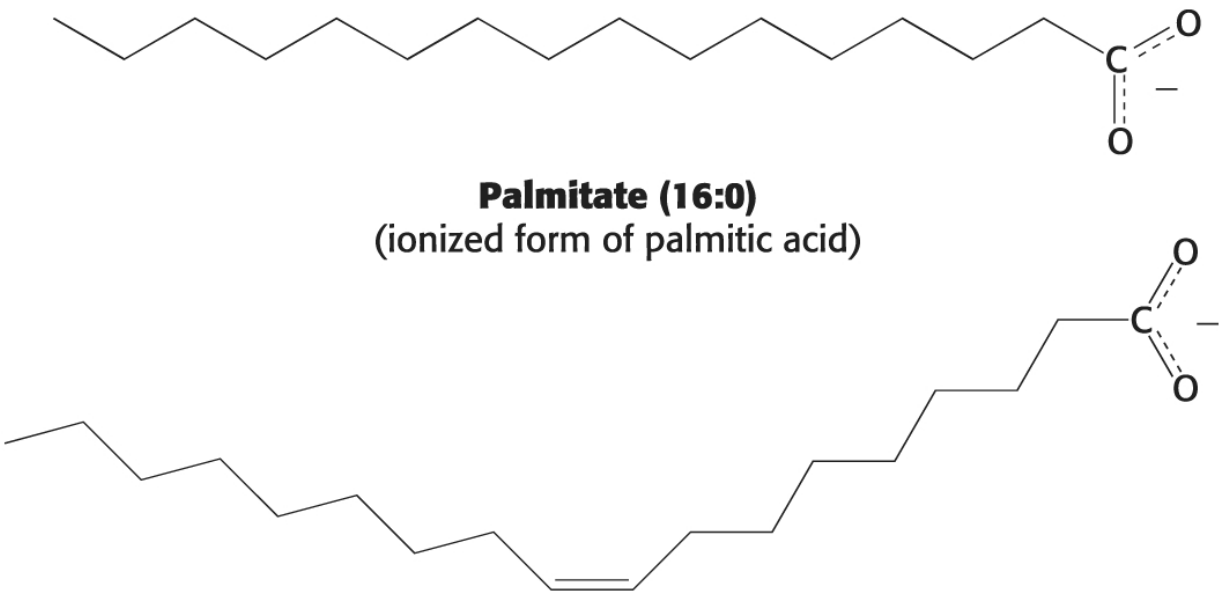
Extended description for Graphical representation of G A G concentration versus time in days

The horizontal axis is labeled time in days. It has markings ranging from 0 to 20 in increments of 5 units. The vertical axis is labeled G A G microgram m g superscript minus 1. It has markings ranging from 0 to 75 in increments of 25 units. The graph shows three increasing lines for plus I L 2, plus I L 2 plus inhibitor, and control. The line for plus I L 2 starts from (2.5, 5) and terminates at (20, 70). The line for plus I L 2 plus inhibitor starts from (2.5, 6) and terminates at (20, 35). The line for control starts from (2.5, 5) and terminates at (20, 30). All values are approximated.

Return to Graphical representation of G A G concentration versus time in days

Extended description for Space-filling model of sphingomyelin and scanning electron micrograph of the myelin sheath

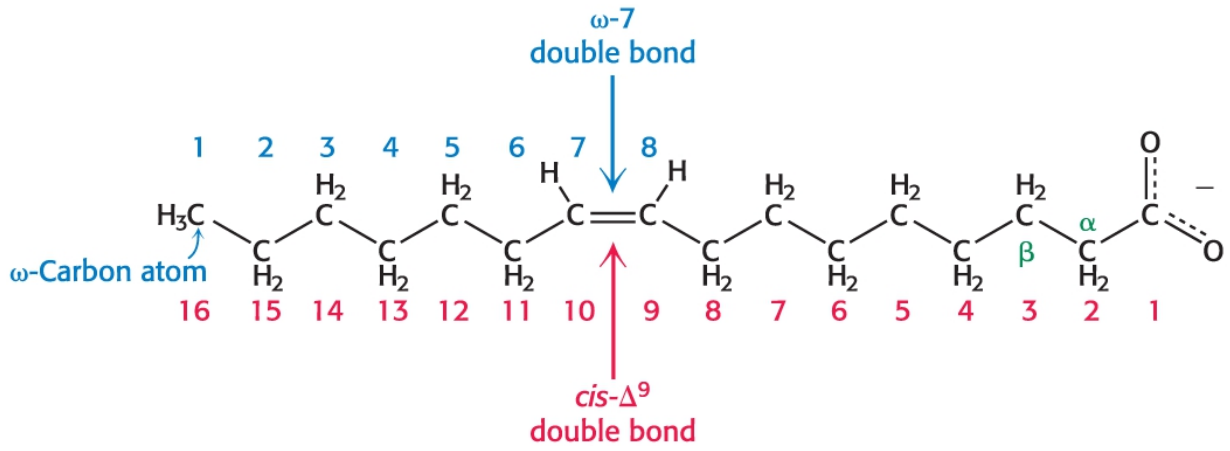


The space-filling model consists of two chains of black spheres fused side by side. Each black sphere is fused with three small white spheres. The white spheres cover the entire surface. The chains continue into a cluster composed of red spheres, a blue sphere, and a purple sphere. This cluster of red spheres is fused to a small cluster of black spheres on the right which is further fused to white spheres. The white spheres cover the entire surface of this cluster.

In the scanning electron micrograph, the cross-section of the myelin sheath is depicted as a cylindrical structure with a thick pink layer and a sponge-like interior.

Return to Space-filling model of sphingomyelin and scanning electron micrograph of the myelin sheath

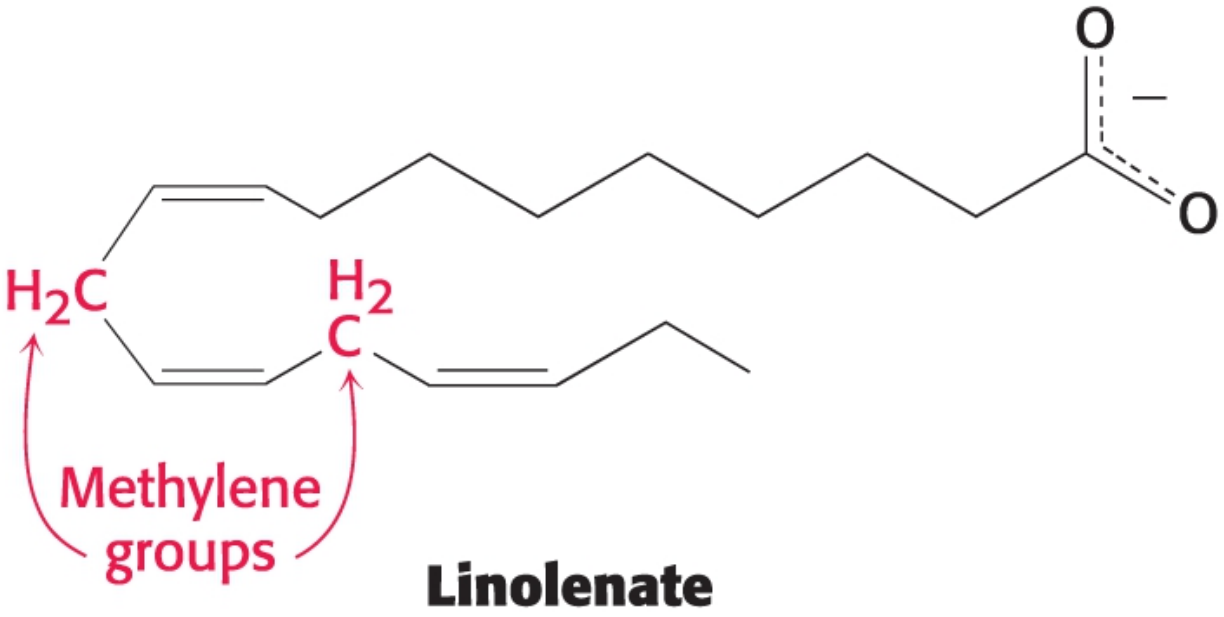
Extended description for Chemical structures of palmitate and oleate



Palmitate is ionized form of palmitic acid. Its structure is as follows: A 16-carbon alkane chain is depicted as a line structure using 15 zigzag lines. C 16 is partially double bonded to O below and O on the upper right. The O atoms have an overall negative charge.

Oleate is the ionized form of oleic acid. Its structure is as follows: An 18-carbon alkene chain is depicted as a line structure using 17 zigzag lines. A double bond is present between C 9 and C 10. C 18 is partially double bonded to O on the upper right and lower right. The O atoms have an overall negative charge.

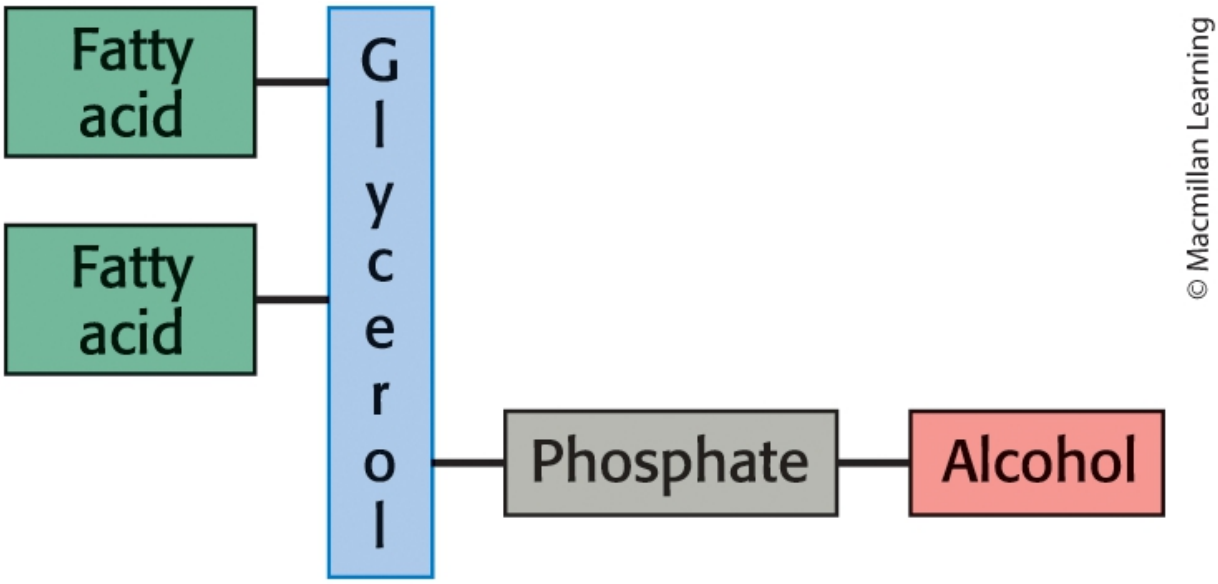
Return to Chemical structures of palmitate and oleate



Extended description for Numbering of carbon atoms in a fatty acid chain

A 16 C alkene chain is depicted as a line structure using 15 zigzag lines. A double bond is present between C 7 and C 8. C 2, C 3, C 4, C 5, C 6, C 9, C 10, C 11, C 12, C 13, C 14 and C 15 are bound to H 2. C 1 is bound to H 3. C 7 and C 8 are each single bonded to H on the upper left and upper right respectively. C 16 is partially double bonded to O above and O on the lower right. The C O O group has an overall negative charge. C 1 is labeled omega-carbon atom. The double bond between C 7 and C 8 is labeled "omega-7 double bond". C 16 to C 1 are numbered 1 to 16 from right to left. These numbers are highlighted in red. C 2 and C 3 in this order are labeled alpha are labeled alpha and beta respectively. The double bond between C 9 and C 10 in this order is labeled "cis-delta superscript 9 double bond"

Return to Numbering of carbon atoms in a fatty acid chain



Extended description for Structure of linolenate

The structure of linolenate is as follows: An 18 C homonuclear alkene chain is depicted as a line structure using 17 zigzag lines. C 11 and C 14 are bound to H 2 and labeled methylene groups. A double bond is present between C 9 and C 10, C 12 and C 13, and C 15 and C 16. C 1 is partially double bonded to O above and O on the lower right. This C O O group has an overall negative charge. The chain folds at C 11.

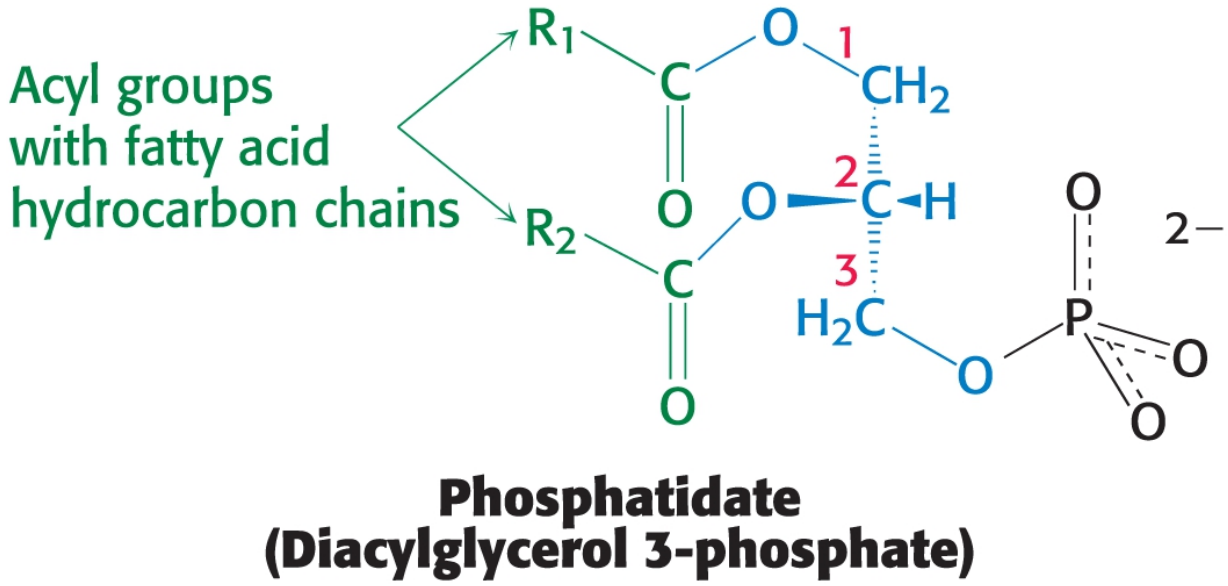
Extended description for Schematic representation of a phospholipid molecule



© Macmillan Learning

The glycerol molecule is depicted as a blue vertical bar. It is connected to a green square labeled fatty acid on the top left and middle left. It is connected to a grey rectangle labeled phosphate on the bottom right. The grey rectangle is further connected to a red rectangle on the right labeled alcohol.

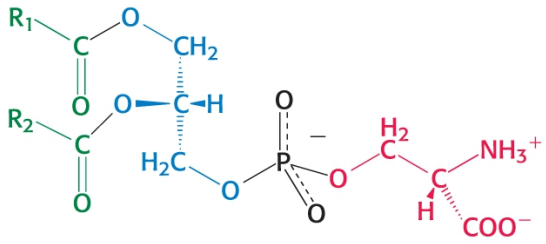
Return to Schematic representation of a phospholipid molecule

Extended description for Chemical structure of phosphatidate

Phosphatidate
(Diacylglycerol 3-phosphate)

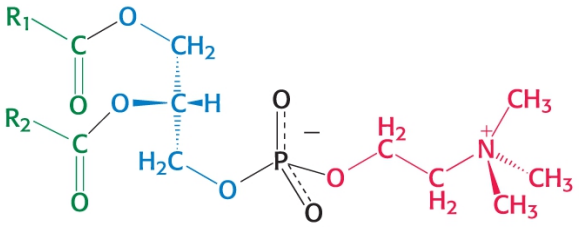
Phosphatidate is also called diacylglycerol 3-phosphate. Its structure is as follows: A central C atom is dash bonded to C H 2 above and C H 2 below. These C atoms are numbered 1 to 3 from top to bottom with the central C atom labeled 2. C 1 is single bonded to O on the upper left. This O atom is single bonded to C on the lower left. The C atom is double bonded to O below and single bonded to R 1 on the upper left.

C 2 is wedge bonded to H on the right and wedge bonded to O on the left. The O atom is single bonded to C on the lower left. This C atom is double bonded to O below and single bonded to R 2 on the upper left.



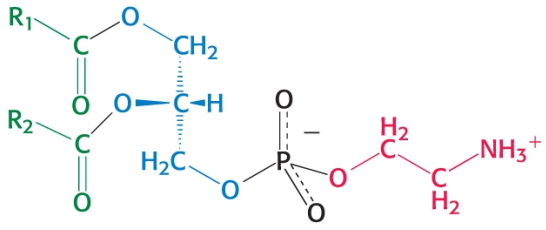
R 1 and R 2 are labeled “acyl groups with fatty acid hydrocarbon chains ”.

C 3 is single bonded to O on the lower right. This O atom is single bonded to P on the upper right. The P atom is partially double bonded to O above, O on the right, and O on the lower right. The P O 3 group has an overall negative charge of 2 minus.

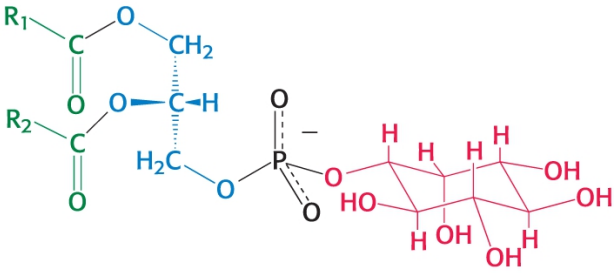


C 1 to C 3 and the O atoms bonded to them are highlighted in blue. The C O groups bonded to R 1 and these O atoms are highlighted in green. The P O 3 group is highlighted in black.

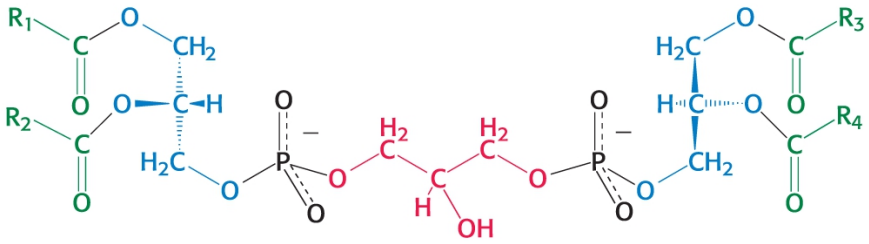
Return to Chemical structure of phosphatidate



Extended description for Chemical structures of common phosphoglycerides located in the membrane



Phosphatidylserine



Phosphatidylcholine

Phosphatidylethanolamine

Phosphatidylinositol

Diphosphatidylglycerol (cardiolipin)

The common phosphoglycerides in the membrane are phosphatidylserine, phosphatidylcholine, phosphatidylethanolamine, phosphatidylinositol, and diphosphatidylglycerol (cardiolipin).

The structure of phosphatidylserine is as follows: A central C atom is dash bonded to C H 2 above, dash bonded to C H 2 below, wedge bonded to O on the left, and wedge bonded to H on the right. This O

atom is single bonded to C on the lower left. The C atom is double bonded to O below and single bonded to R 2 on the upper left.

The C H 2 group above is single bonded to O on the upper left. The O atom is single bonded to C on the lower left. This C atom is double bonded to O below and single bonded to R 1 on the upper left.

C H 2 group below is single bonded to O on the lower right. This O atom is single bonded to P on the upper right. The P atom is partially double bonded to O above, partially double bonded to O on the lower right, and single bonded to O on the right. The partially double bonded O atoms have an overall negative charge. The O atom on the right is single bonded to a 2-carbon alkane chain depicted as C H 2, single bond, C. C 2 of this chain is single bonded to N H 3 superscript plus on the upper right, dash bonded to C O O superscript minus on the lower right, and wedge bonded to H below.

The structure of phosphatidylcholine is as follows: A central C atom is dash bonded to C H 2 above, dash bonded to C H 2 below, wedge bonded to O on the left, and wedge bonded to H on the right. This O atom is single bonded to C on the lower left. The C atom is double bonded to O below and single bonded to R 2 on the upper left.

The C H 2 group above is single bonded to O on the upper left. The O atom is single bonded to C on the lower left. This C atom is double bonded to O below and single bonded to R 1 on the upper left.

C H 2 group below is single bonded to O on the lower right. This O atom is single bonded to P on the upper right. The P atom is partially double bonded to O above, partially double bonded to O on the lower right, and single bonded to O on the right. The partially double bonded O atoms have an overall negative charge. The O atom on the right is single bonded to a 2-carbon alkane chain depicted as

C H 2, single bond, C H 2. C 2 of this chain is single bonded to N superscript plus on the upper right. The N superscript plus atom is single bonded to C H 3 on the upper right, dash bonded to C H 3 on the lower right, and wedge bonded to C H 3 below.

The structure of phosphatidylethanolamine is as follows: A central C atom is dash bonded to C H 2 above, dash bonded to C H 2 below, wedge bonded to O on the left, and wedge bonded to H on the right. This O atom is single bonded to C on the lower left. The C atom is double bonded to O below and single bonded to R 2 on the upper left.

The C H 2 group above is single bonded to O on the upper left. The O atom is single bonded to C on the lower left. This C atom is double bonded to O below and single bonded to R 1 on the upper left.

C H 2 group below is single bonded to O on the lower right. This O atom is single bonded to P on the upper right. The P atom is partially double bonded to O above, partially double bonded to O on the lower right, and single bonded to O on the right. The partially double bonded O atoms have an overall negative charge. The O atom on the right is single bonded to a 2-carbon alkane chain depicted as C H 2, single bond, C H 2. C 2 of this chain is single bonded to N H 3 superscript plus on the upper right.

The structure of phosphatidylinositol is as follows: A central C atom is dash bonded to C H 2 above, dash bonded to C H 2 below, wedge bonded to O on the left, and wedge bonded to H on the right. This O atom is single bonded to C on the lower left. The C atom is double bonded to O below and single bonded to R 2 on the upper left.

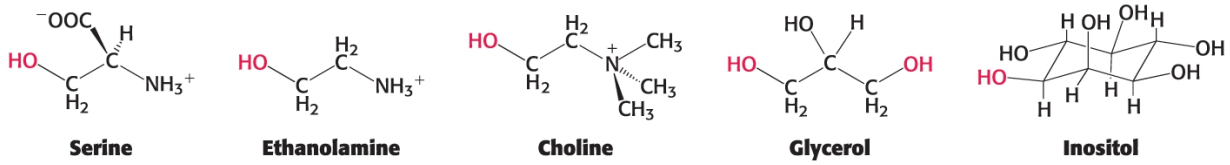
The C H 2 group above is single bonded to O on the upper left. The O atom is single bonded to C on the lower left. This C atom is double

bonded to O below and single bonded to R 1 on the upper left.

C H 2 group below is single bonded to O on the lower right. This O atom is single bonded to P on the upper right. The P atom is partially double bonded to O above, partially double bonded to O on the lower right, and single bonded to O on the right. The partially double bonded O atoms have an overall negative charge. The O atom on the right is single bonded to C 5 of a 6-carbon homocyclic hexagonal ring in a chair conformation. In the ring, C 3 and C 6 are located closer. C 1 occupies the top right vertex. C 1 is single bonded to H above and O H on the right. C 2 is single bonded to O H on the right and H below. C 3 is single bonded to H above and O H on the lower right. C 4 is single bonded to O H on the left and H below. C 5 is single bonded to H above. C 6 is single bonded to H on the upper left and O H below.

The structure of diphosphatidylglycerol (cardiolipin) is as follows: A central C atom is dash bonded to C H 2 above, dash bonded to C H 2 below, wedge bonded to O on the left, and wedge bonded to H on the right. This O atom is single bonded to C on the lower left. The C atom is double bonded to O below and single bonded to R 2 on the upper left.

The C H 2 group above is single bonded to O on the upper left. The O atom is single bonded to C on the lower left. This C atom is double bonded to O below and single bonded to R 1 on the upper left.



C H 2 group below is single bonded to O on the lower right. This O atom is single bonded to P on the upper right. The P atom is partially double bonded to O above, partially double bonded to O on the lower right, and single bonded to O on the right. The partially double bonded O atoms have an overall negative charge. The O atom on the right is single bonded to a 3-carbon alkane chain depicted as C H 2, single bond, C, single bond, C H 2. C 2 of this chain is single

bonded to H on the lower left and O H on the lower right. C 3 is single bonded to O on the lower right. This O atom is single bonded to P on the upper right. The P atom is partially double bonded to O above, partially double bonded to O below, and single bonded to O on the lower right. The O atom on the lower right is single bonded to C H 2 on the upper right.

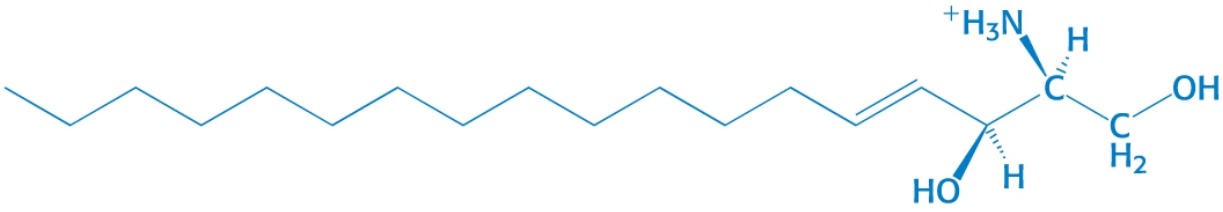
C H 2 is wedge bonded above to C, wedge bond, C H 2. C 1 of this chain is dash bonded to H on the right and dash bonded to O on the right. The O atom is single bonded to C on the lower right. This C atom is double bonded to O below and single bonded to R 4 on the upper right. C 2 of the chain is single bonded to O on the upper right. The O atom is further single bonded to C on the lower right. The C atom is double bonded to O below and single bonded to R 3 on the upper right.

Return to Chemical structures of common phosphoglycerides located in the membrane

Extended description for Structures of serine, ethanolamine, choline, glycerol, and inositol

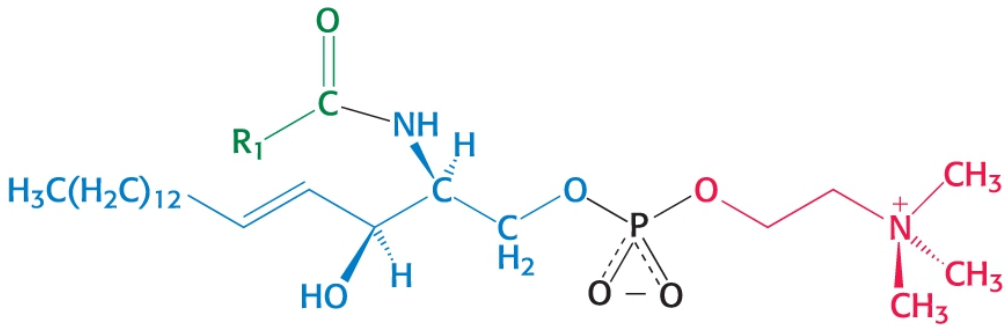
The structure of serine is as follows: A central C atom is wedge bonded to C O O superscript minus on the upper left, dash bonded to H on the upper right, single bonded to N H 3 superscript plus on the lower right, and single bonded to C H 2 on the lower left. The C H 2 group is single bonded to O H on the upper left.

The structure of ethanolamine is as follows: A central C atom bound to H 2 is single bonded to N H 3 superscript plus on the lower right and single bonded to C H 2 on the lower left. The C H 2 group is single bonded to O H on the upper left.



The structure of choline is as follows: A central C atom bound to H 2 is single bonded to N superscript plus on the lower right and single bonded to C H 2 on the lower left. The C H 2 group is single bonded to O H on the upper left. The N superscript plus atom is single bonded to C H 3 on the upper right, dash bonded to C H 3 on the lower right, and wedge bonded to C H 3 below.

The structure of glycerol is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 and C 3 are each bound to H 2. C 1 is single bonded to O H on the upper left. C 2 is single bonded to O H on the upper left and single bonded to H on the upper right. C 3 is single bonded to O H on the upper right.



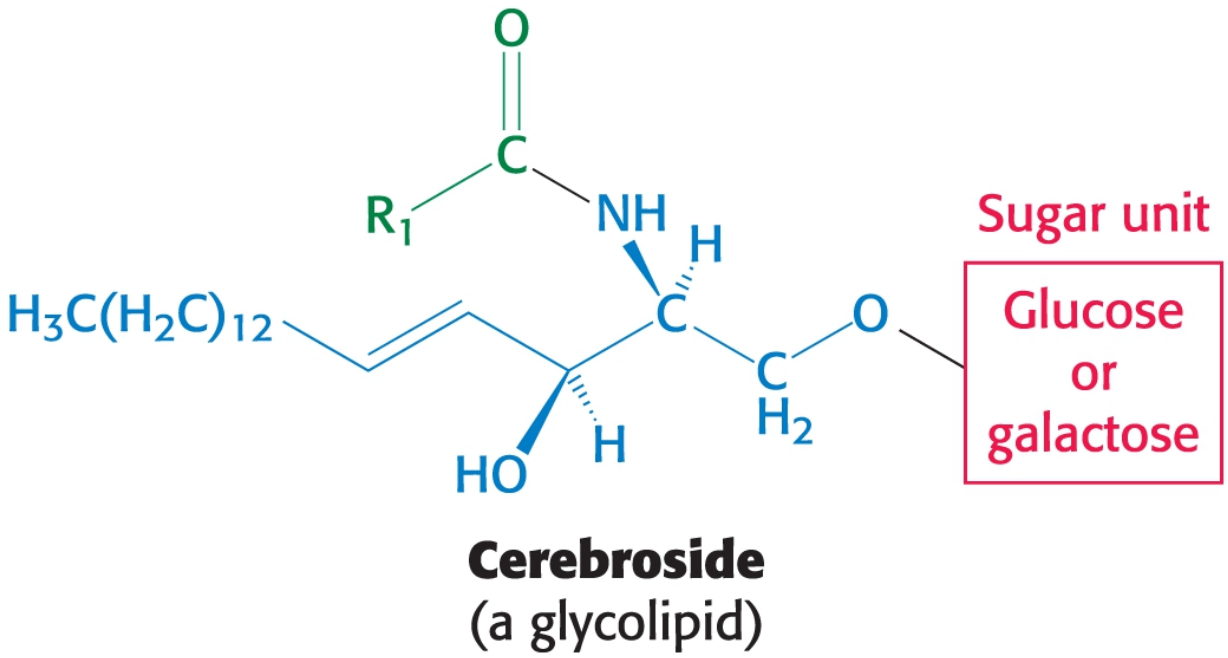
The structure of inositol is as follows: A 6-carbon homocyclic hexagonal ring is in a chair conformation. C 3 and C 6 are located close to each other. C 2, C 3, and C 4 are located toward the observer. C 1, C 5, and C 6 are located away from the observer. C 1 is single bonded to H above and O H on the lower right. C 2 is single bonded to O H on the upper right and H below. C 3 is single bonded to O H above and H below. C 4 is single bonded to O H on the upper left and H below. C 5 is single bonded to H above and O H on the lower right. C 6 is single bonded to O H on the upper right and H below.

Return to Structures of serine, ethanolamine, choline, glycerol, and inositol

Extended description for Structures of sphingosine and sphingomyelin

Sphingosine

Sphingomyelin

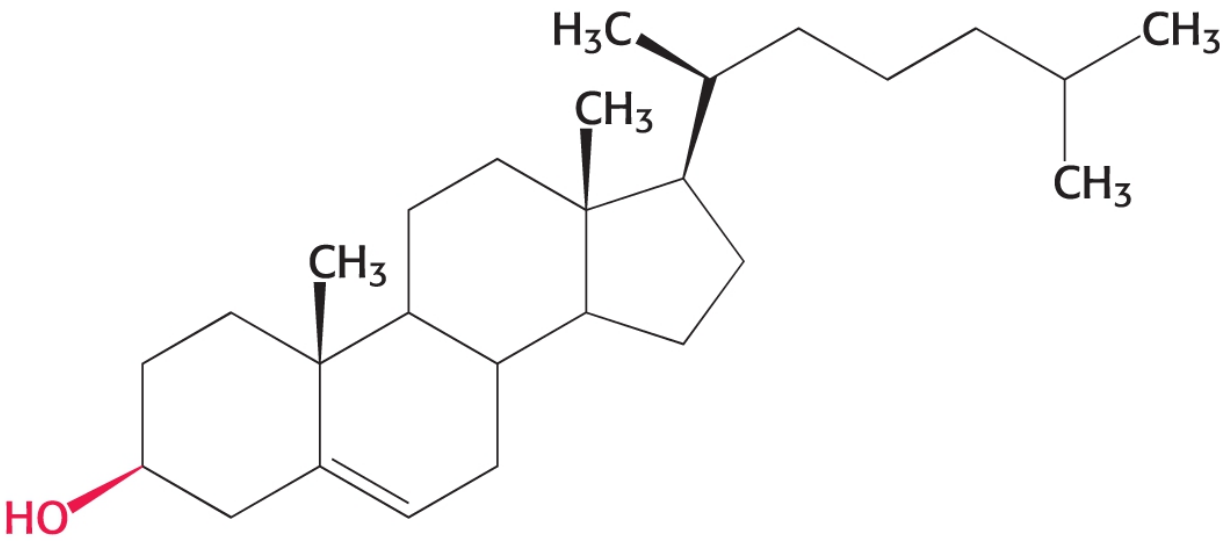


Sphingosine: A 17 Carbon homonuclear alkene chain is depicted as a line structure using 16 zigzag lines. A double bond is present between C 14 and C 15. C 16 is wedge bonded to O H on the lower left and dash bonded to H on the lower right. C 17 is wedge bonded to N H 3 superscript plus on the upper left and dash bonded to H on the upper right. C 17 is also single bonded to C H 2 on the lower right. C H 2 is single bonded to O H on the upper right.

Sphingomyelin: A 1 N, 1 P, 2 O, and 7 C heteronuclear alkene chain is depicted as a line structure using 10 zigzag lines. A double bond is present between C 1 and C 2. C 1 is single bonded to open bracket C H 2 close bracket with subscript 12 C H 3 on the upper left. The O atoms occupy the sixth and eighth positions. P occupies the seventh position. The N atom has an overall positive charge and occupies the

eleventh position. It is single bonded to C H 3 on the upper right, dash bonded to C H 3 on the lower right, and wedge bonded to C H 3 below. C 3 is wedge bonded to O H on the lower left and dash bonded to H on the lower right. C 4 is dash bonded to H on the upper right and wedge bonded to N H on the upper left. N H is single bonded to a central C atom that is double bonded to O above and single bonded to R 1 on the lower left. P is partially double bonded to O on the lower left and O on the lower right. The P O O group has an overall negative charge.

Return to Structures of sphingosine and sphingomyelin

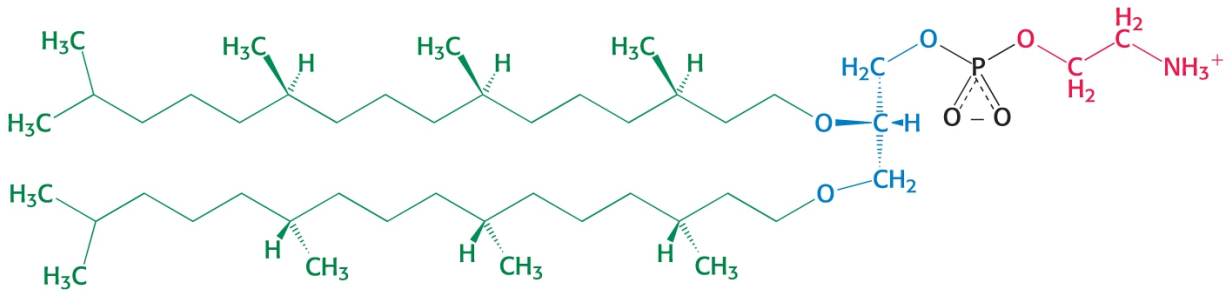


Extended description for Chemical structure of cerebroside

The structure of cerebroside is as follows: A 1 O and 5 C heteronuclear alkene chain is depicted as a line structure using 5 zigzag lines. O occupies the sixth position. A double bond is present between C 1 and C 2. C 1 is single bonded to open bracket C H 2 close bracket with subscript 12 C H 3 on the upper right. C 3 is wedge bonded to O H on the lower left and dash bonded to H on the lower right. C 4 is wedge bonded to N H on the upper left and dash bonded to H on the upper right. C 5 is bound to H 2. O is single bonded to a glucose or galactose molecule on the lower right. The glucose or galactose molecule is labeled sugar unit. The N H group on the upper left is single bonded to C on the upper left. This C atom is double bonded to O above and single bonded to R 1 on the lower right.

Return to Chemical structure of cerebroside

Extended description for Chemical structure of cholesterol



Cholesterol

The structure of cholesterol is as follows: A 6-carbon homocyclic hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. C 5 is wedge bonded to O H on the lower left. O H and its wedge bond are highlighted in red. It is fused to a second 6-carbon homocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. In the second ring, C 6 is wedge bonded to C H 3 above. A double bond is present between C 4 and C 5. The second ring is fused to a third 6-carbon homocyclic hexagonal ring in a vertical orientation such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. The third ring is fused to a 5-carbon homocyclic pentagonal ring in a horizontal orientation such that C 2 and C 3 of the third ring are C 4 and C 3 respectively of the pentagonal ring. C 4 is wedge bonded to C H 3 above. C 5 is wedge bonded to C 1 of a 5 carbon alkane chain depicted as a line structure

using 4 zigzag lines. C 1 is wedge bonded to C H 3 on the upper left. C 5 is single bonded to C H 3 on the upper right and C H 3 below.

Return to Chemical structure of cholesterol

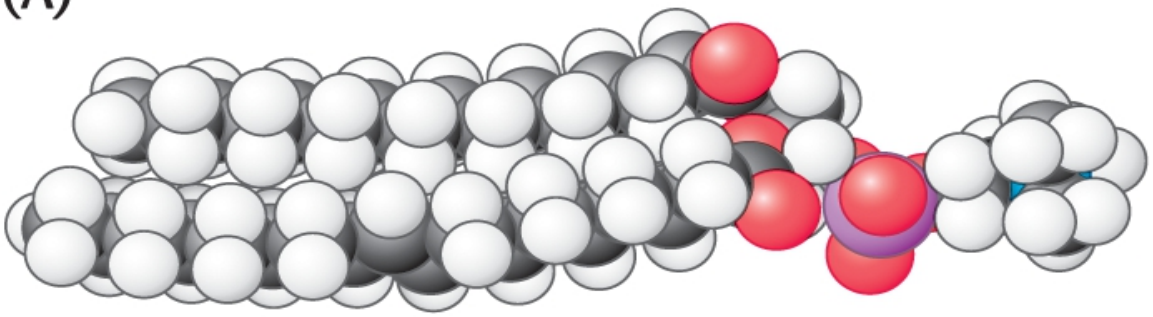
Extended description for Structure of membrane lipid of the archaeon *Methanococcus jannaschii*

Membrane lipid from the archaeon *Methanococcus jannaschii*

The structure of the membrane lipid is as follows: A vertical chain consists of C H 2, dash bond, C, dash bond, C H 2. C 1 of this chain is single bonded to O 1 of a 1 P, 2 O, and 2 C alkane chain depicted as a line structure using 4 zigzag lines. The first O occupies the first position. The second O occupies the third position. P occupies the second position. C 4 and C 5 are each bound to H 2. P is partially double bonded to O on the lower right and lower left. The P O O group has an overall negative charge. C 5 is single bonded to N H 3 superscript plus on the lower right.

C 2 of the vertical chain is wedge bonded to H on the right and wedge bonded to O on the left. The O atom is single bonded to C 16 of a 16 carbon alkane chain depicted as a line structure using 15 zigzag lines. C 1 is single bonded to C H 3 on the lower left and C H 3 above. C 5, C 9, and C 13 are each wedge bonded to C H 3 on the upper left and dash bonded to H on the upper right.

C 3 of the vertical chain is single bonded to O of an 1 O and 15 C alkane chain depicted as a line structure using 15 zigzag lines. C 1 is single bonded to C H 3 on the upper left and C H 3 below. C 5, C 9, C



13 are each wedge bonded to H on the lower left and dash bonded to C H 3 on the lower right.

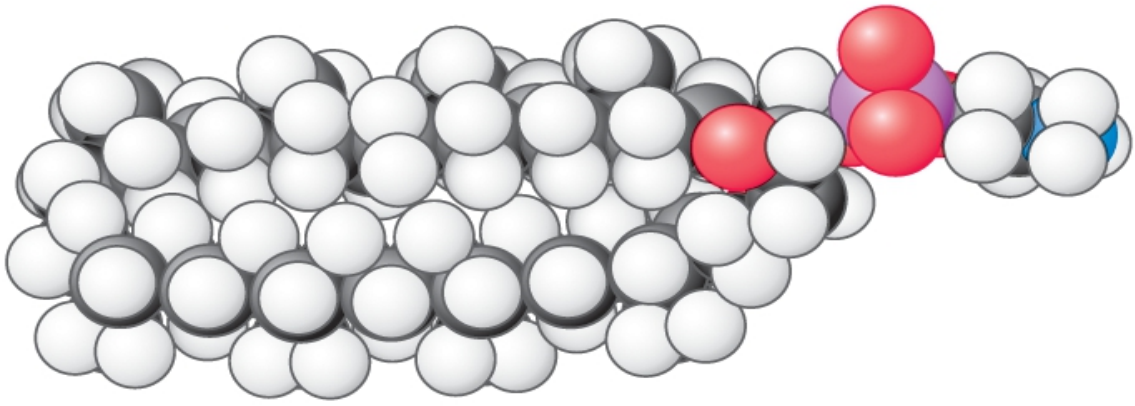
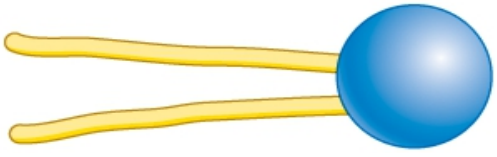
Extended description for Space filling models of phosphoglyceride, sphingomyelin, and an archaeal

lipid; and shorthand depiction of membrane lipid labeled (A) and (B) respectively



(A)

Phosphoglyceride

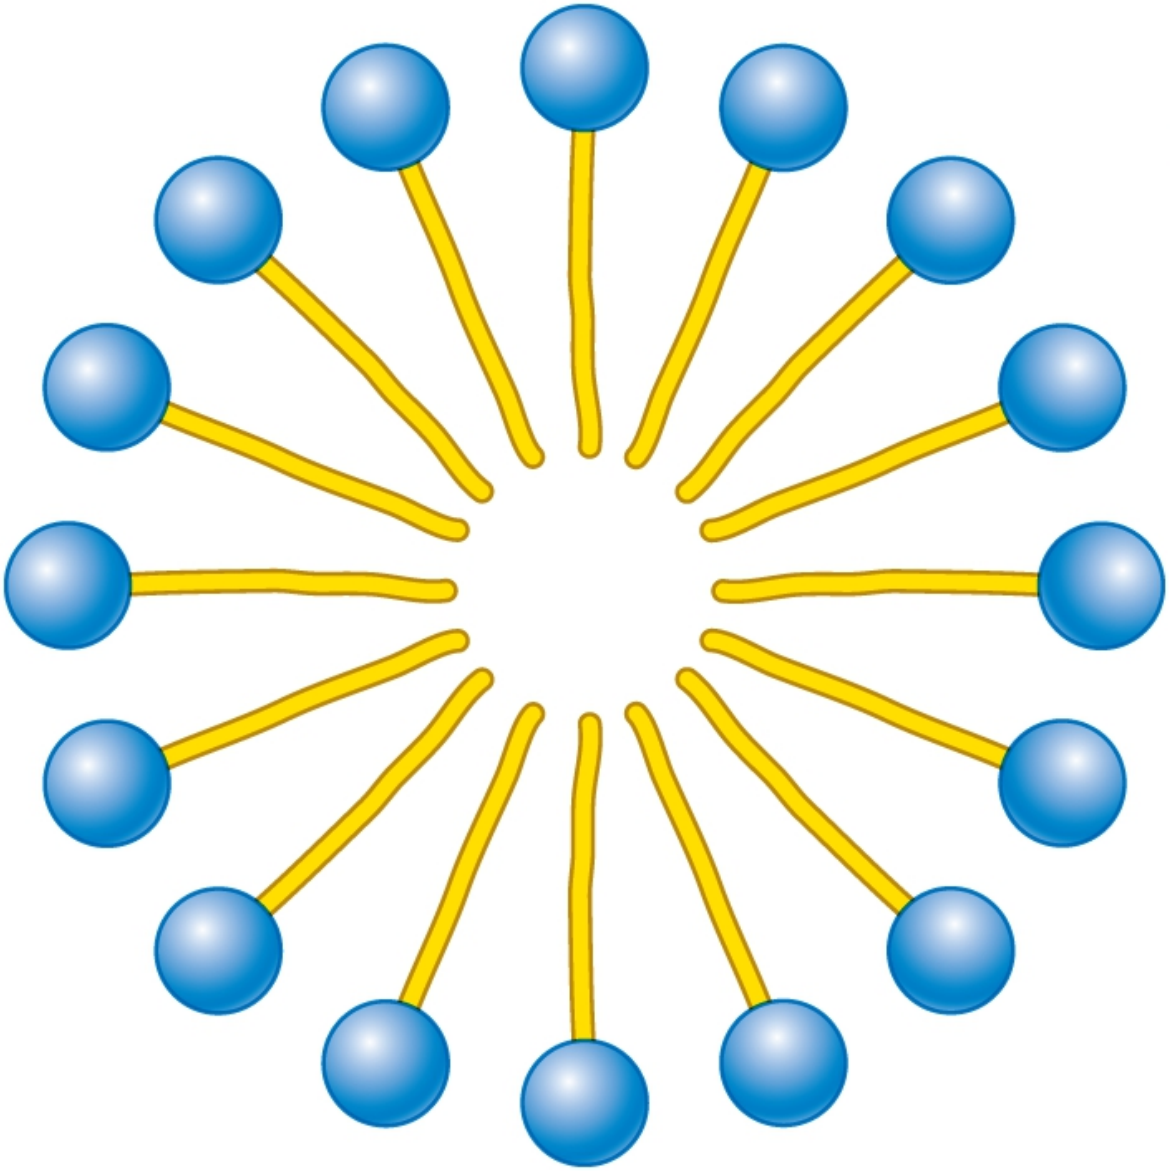


Sphingomyelin

Archaeal lipid

(B)

© Macmillan Learning



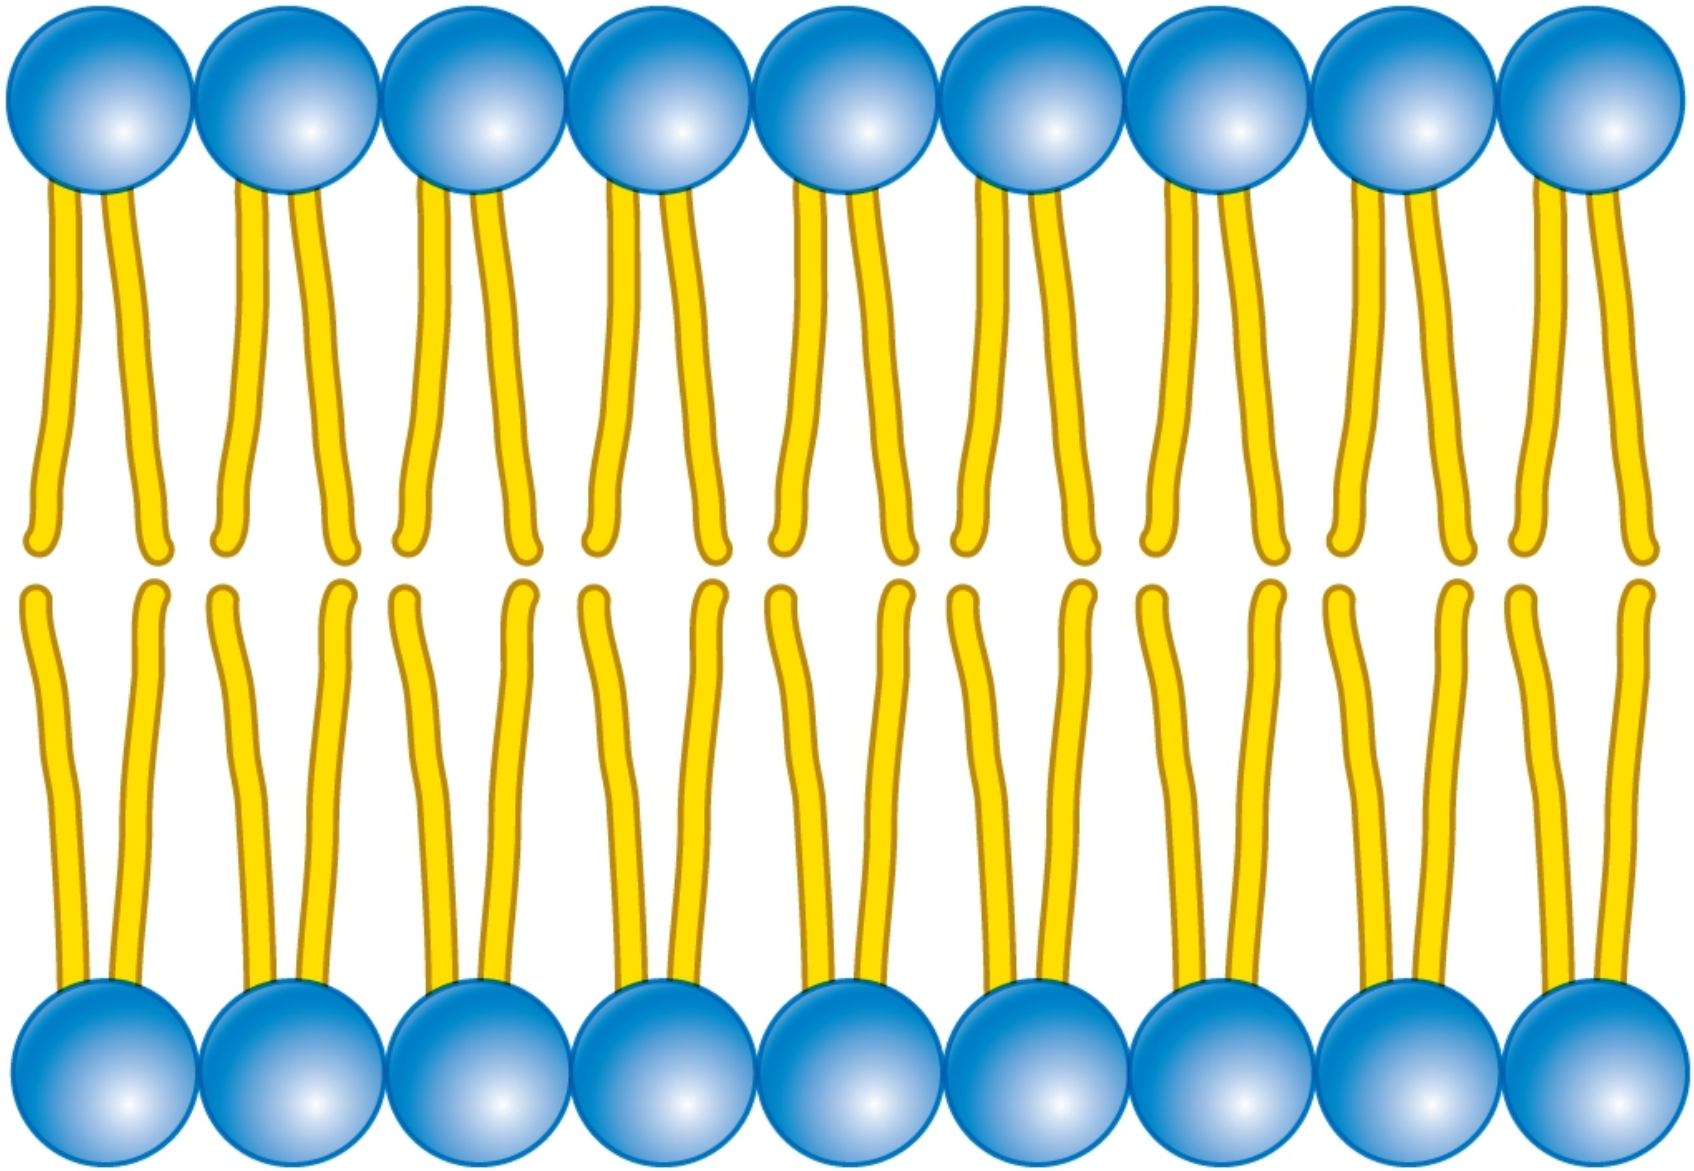
Part (A): The space-filling model consists of two chains of black spheres fused side by side. Each black sphere is fused with three small white spheres. The white spheres cover the entire surface. These chains of black spheres in phosphoglyceride are fused to a cluster of red spheres with a purple sphere in the center. This cluster of red spheres is fused to a small cluster of black spheres which are further fused to white spheres. The white spheres cover the entire surface of the cluster. In sphingomyelin, the chains continue into a cluster composed of red spheres, a blue sphere, and a purple sphere. This cluster of red spheres is fused to a small cluster of black spheres which is further fused to white spheres. The white spheres cover the entire surface of the cluster.

In archaeal lipid, the chains of black sphere continue into a cluster of four red spheres containing a purple sphere in the center. This cluster of red spheres is fused to a small cluster of black spheres which are further fused to white spheres. The white spheres cover the entire surface of the cluster.

Part (B): A blue sphere is connected to two horizontal and anti-parallel yellow extensions.

Return to Space filling models of phosphoglyceride, sphingomyelin, and an archaeal lipid; and shorthand depiction of membrane lipid labeled (A) and (B) respectively

Extended description for Schematic illustration of micelles



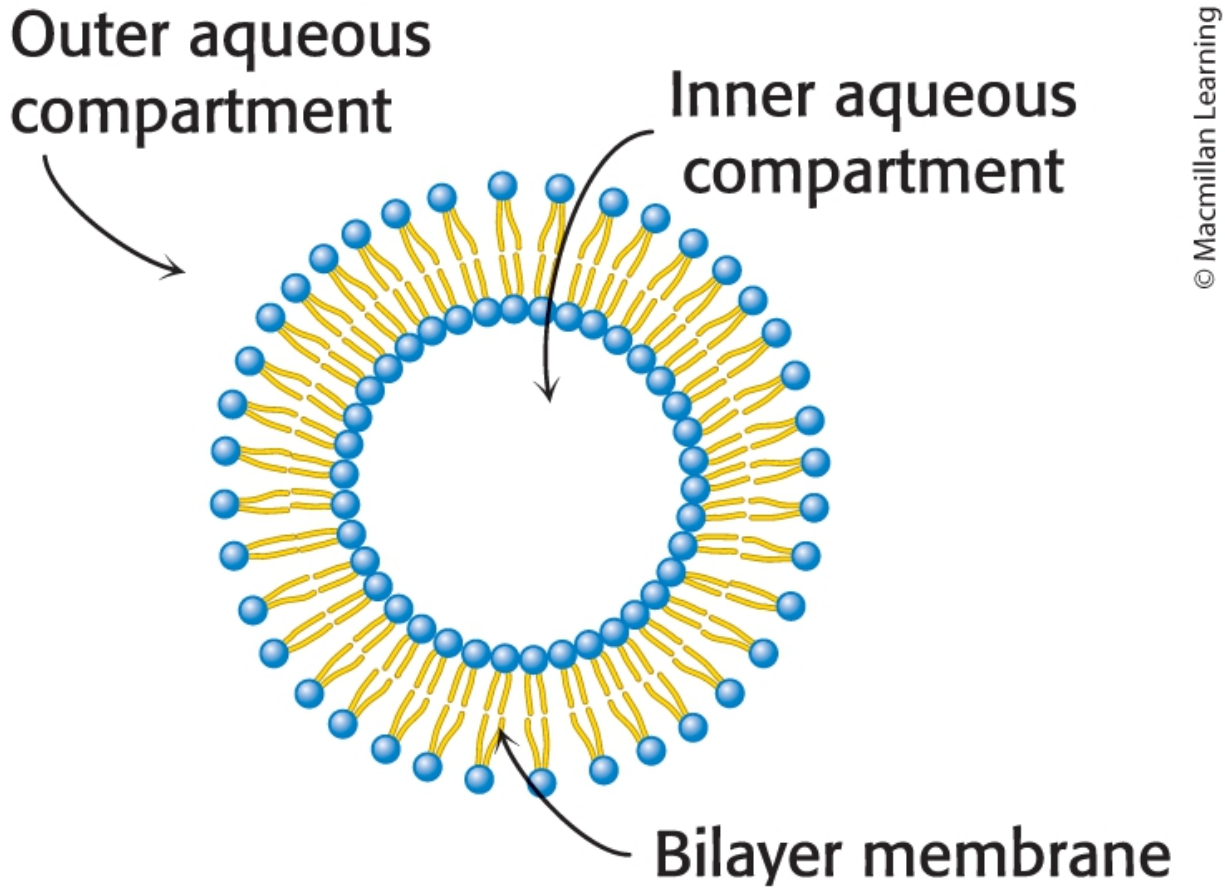
The micelle is depicted as a circular structure composed of 16 ionized fatty acids with single tails. Each ionized fatty acids with single tail is depicted as a blue sphere connected to a long and narrow yellow extension. They are radially arranged such that blue

spheres form the border of the circular structure and yellow extensions form the core.

Return to Schematic illustration of micelles

Extended description for Schematic illustration of lipid

bilayer

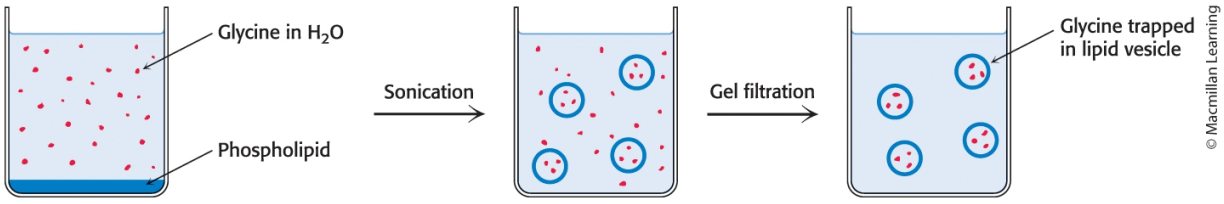


© Macmillan Learning

The lipid bilayer consists of two parallel layers of lipids. Each layer consists of 9 lipid molecules vertically stacked together. The lipid molecules are shown in a shorthand depiction. The yellow extensions of the shorthand depiction from the two layers are aligned together and form the core of the bilayer. The blue spheres of the two layers are located away from each other such that they form the left and right borders of the bilayer.

Return to Schematic illustration of lipid bilayer

Extended description for Schematic illustration of liposome



© Macmillan Learning

The liposome is depicted as a circular structure having a lipid bilayer outline and an empty core. The empty core is labeled the inner aqueous compartment. The lipid bilayer is labeled as a bilayer membrane. The space outside the bilayer is labeled the outer aqueous compartment. The blue spheres of the bilayer line the inner and outer surface of the liposome.

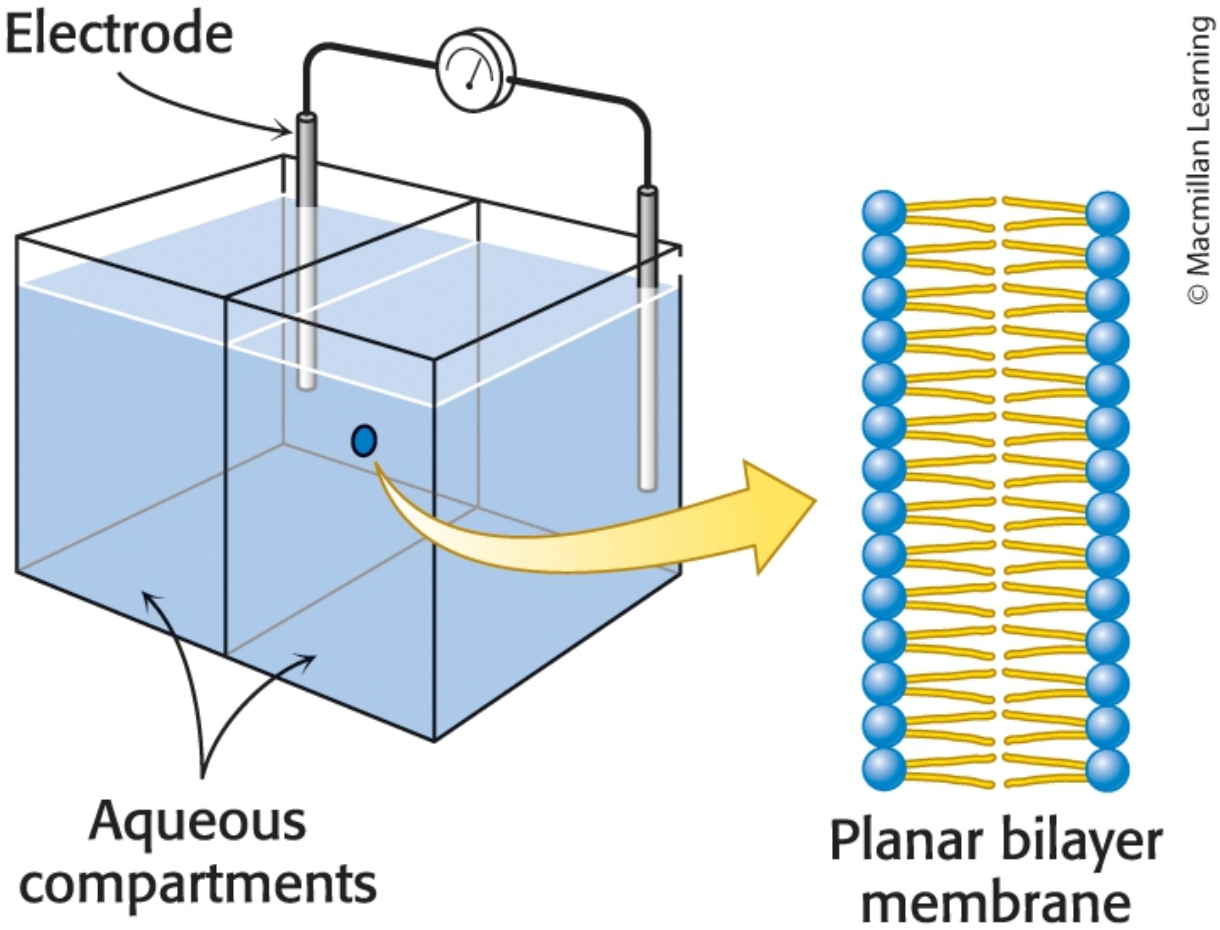
Extended description for Production of liposomes containing glycine

A square-shaped vessel is shown to contain water and a layer of phospholipid settled at the bottom. Glycine molecules are suspended in water and are depicted as tiny red particles. Phospholipid is depicted as a thick blue layer.

The procedure is divided into two steps:

Step 1: Sonication.



The vessel contains 4 circles with a thick blue border. Each of these circles contain three tiny red particles. Some red particles are suspended in the water outside.

Step 2: Gel filtration

The water in the vessel becomes clear and devoid of any red particles. The glycine trapped in lipid vesicles depicted as circles with thick blue border is highlighted by an arrow.

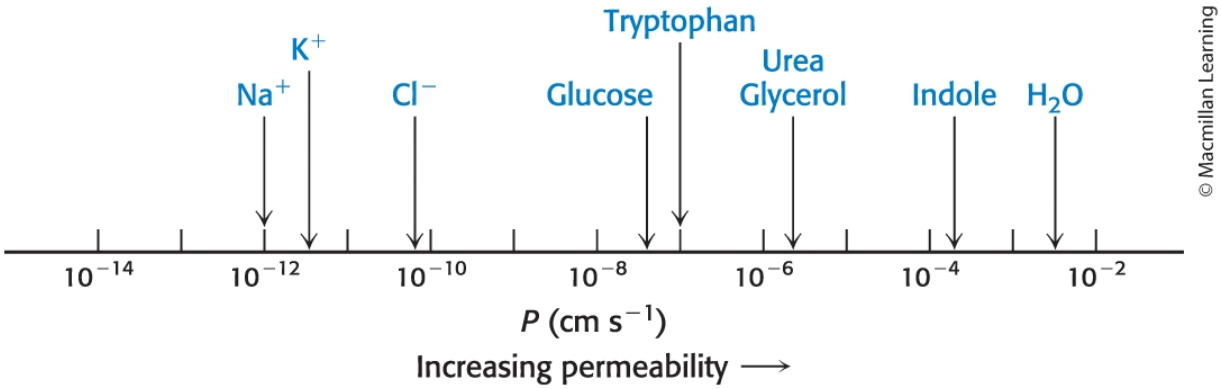
Extended description for Experimental study of the properties of planar bilayer membranes



The figure has two parts. The first part shows an experimental setup consisting of a large tank. The tank is separated into two compartments with the help of a septum. Both the compartments are filled equally with water and are labeled aqueous compartments. An electrode is dipped inside each compartment. The electrodes are connected to each other through a meter. The center of the septum contains a tiny blue circle representing the hole. An arrow from hole points toward a planar bilayer membrane. The planar bilayer membrane consists of two vertically parallel layers of lipids. Each

layer consists of 14 lipid molecules stacked together. Each lipid molecule is shown in a shorthand depiction. The yellow extensions of the shorthand depiction are aligned together and form the core of the bilayer. The blue spheres are located away from each other.

Return to Experimental study of the properties of planar bilayer membranes

Extended description for The permeability coefficients (P) of ions and molecules in a lipid bilayer

© Macmillan Learning

The figure shows a horizontal scale labeled “permeability (centimeter second superscript negative 1)”. It increases from left to right. The scale has markings ranging from 10 superscript negative 14 to 10 superscript negative 2 in multiples of 10 superscript 2. The permeability of different ions and molecules is represented with the help of downward arrows on this scale. The permeability of different ions and molecules are as follows:

N a superscript plus: 10 superscript negative 12.

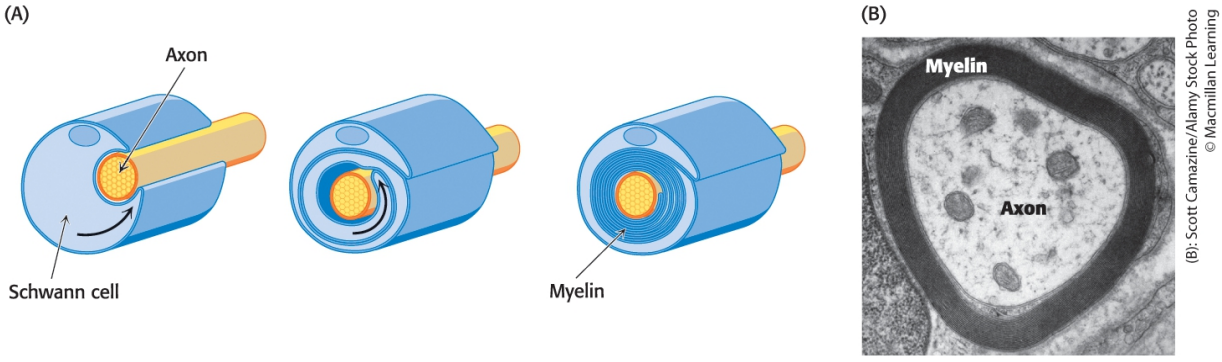
K superscript plus: 5 times 10 superscript negative 12.

C l superscript minus: 9 times 10 superscript negative 11.

Glucose: 6 times 10 superscript negative 8.

Tryptophan: 10 superscript negative 7.

Urea Glycerol: 3 times 10 superscript negative 6.



Indole: 3 times 10 superscript negative 4.

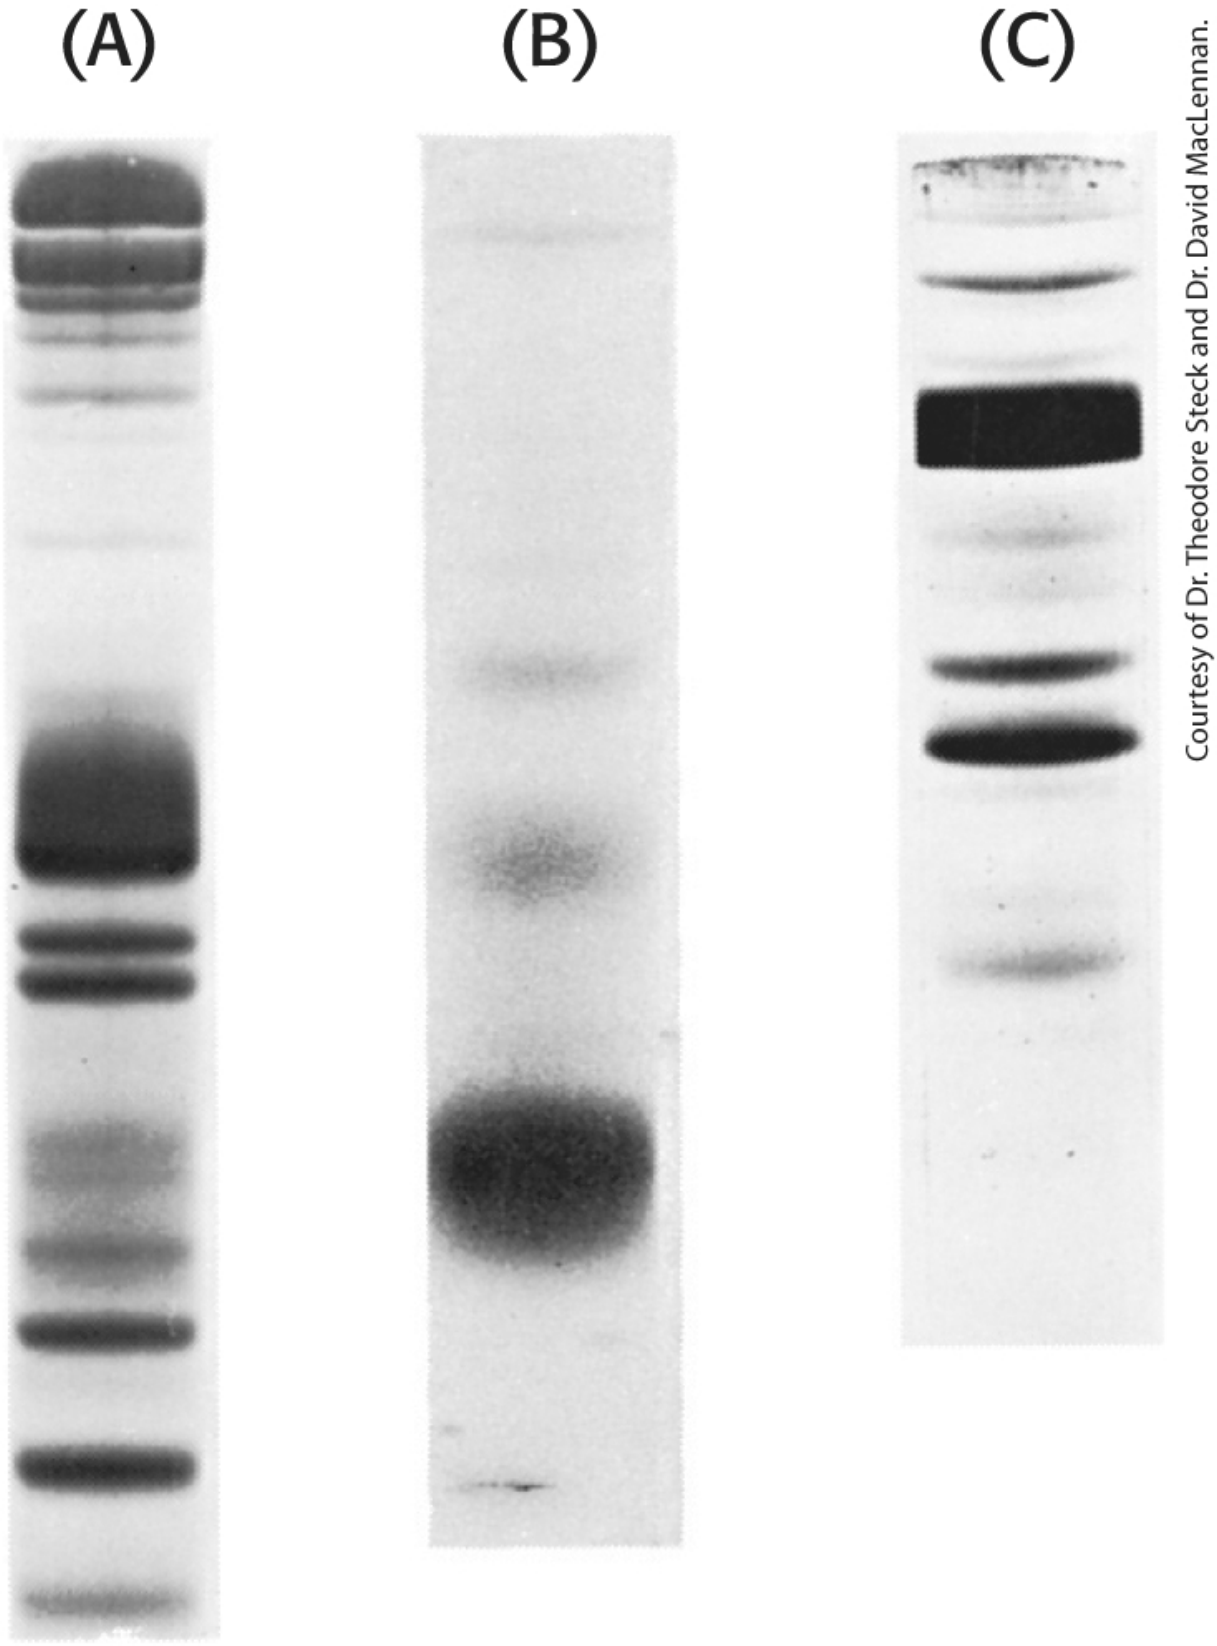
Extended description for Schematic illustration of the wrapping of Schwann cell membrane around an axon and an electron micrograph of myelin sheath around the axon

Part (A): It shows the wrapping of Schwann cell membrane around an axon in three steps.

Step 1: A cross-section of tubular axon is wrapped by a thick Schwann cell half-way through. A curved upward arrow shows the direction of wrapping of the Schwann cell membrane.

Step 2: The tubular axon is surrounded by 2 layers of the cell membrane as the wrapping continues in the inward direction.



Step 3: The axon cross-section is surrounded by multiple layers of Schwann cell membrane. This thick layer of membrane is labeled myelin.

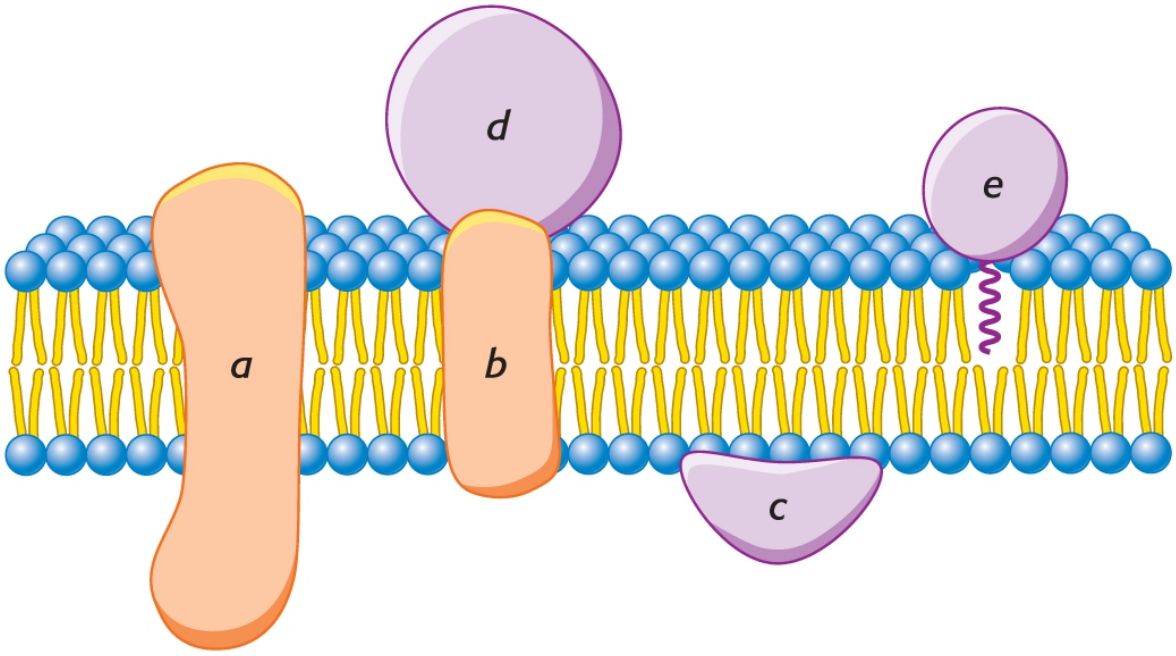
Part (B): A cross-section of axon is surrounded by a thick and dark layer of myelin.

Return to Schematic illustration of the wrapping of Schwann cell membrane around an axon and an electron micrograph of myelin sheath around the axon

Extended description for S D S gel patterns of

membrane proteins from different cell types

Courtesy of Dr. Theodore Steck and Dr. David MacLennan.



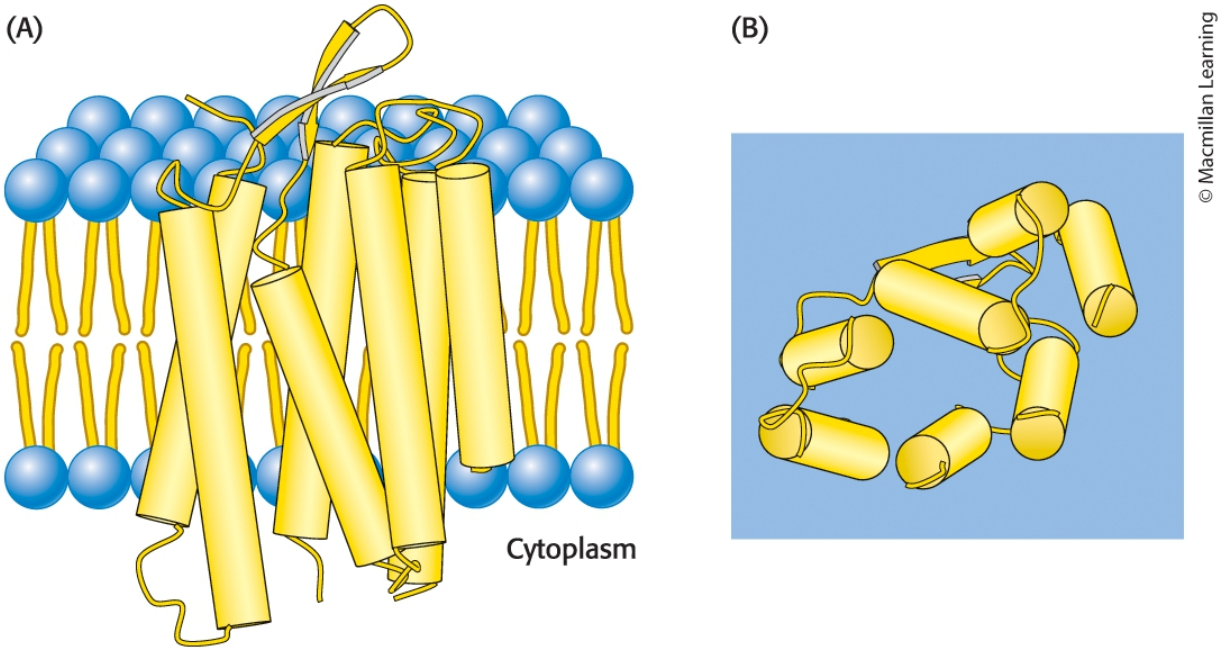
(A): The S D S gel pattern consists of a series of dark and light bands having narrow to medium thickness.

(B): The S D S gel pattern consists of a thick dark band near the bottom and two faint bands above it.

(C): The S D S gel pattern consists of a thick dark and rectangular band near the top. Two dark bands of medium thickness are seen below it. Two narrow and faint bands are seen above it. A narrow faint band is located below the medium thickness bands.

Return to S D S gel patterns of membrane proteins from different cell types

Extended description for Membrane proteins interact with lipid bilayers in different ways



© Macmillan Learning

The lipid bilayer consists of two horizontally parallel layers of lipids. The upper layer consists of three rows of lipid molecules packed together compactly. Each lipid molecule is shown in a shorthand depiction. The yellow extensions of the shorthand depiction are aligned together and form the core of the bilayer. The blue spheres are located away from each other. The lipid bilayer shows five membrane proteins. The first membrane protein labeled "a" resembles a sausage. It traverses the lipid bilayer and extends above and below the bilayer. The second protein labeled "b" also resembles a sausage. Its size is relatively short than "a" and it also traverses the bilayer but does not extend above and below the bilayer. The third protein labeled "c" resembles an inverted triangle. This protein is attached to the lower surface of the lipid bilayer. The fourth oval-shaped protein labeled "d" is attached to the blue spheres of the outer leaflet of the lipid bilayer and protein b. The fifth oval-shaped

protein labeled "e" is attached to the top surface of the lipid bilayer through a zigzag anchor that penetrates the core of the bilayer halfway through.

Extended description for Schematic illustration of the view of bacteriorhodopsin through the membrane and cytoplasmic side

Part (A): The membrane is depicted as a lipid bilayer. It is composed of shorthand depictions of lipids. The bacteriorhodopsin is composed of seven vertical cylindrical structures and a pair of anti-parallel beta-strands interconnected by thread-like loops. The cylindrical structures pass vertically through the membrane and the beta-strands project into the external space above the membrane surface.

Part (B): The bacteriorhodopsin is composed of a cluster of 5 short cylindrical structures interconnected to each other and the remaining two cylinders and a pair of beta-strands through thread-like loops. The 5 cylinders form a circular shape with a hollow space in the center.

Return to Schematic illustration of the view of bacteriorhodopsin through the membrane and cytoplasmic side

Extended description for Amino acid sequence of the membrane spanning helices of bacteriorhodopsin

The amino acid sequence is as follows:

First line: A Q I T G R P E W I W L A L G T A L M G L G T L Y F L V K G M G V S D P D A K K F Y A I T T L V P A. The sequences R P E W I W L A L G T A L M G L G T L Y F L V K and D P D A K K F Y A I T T L V P A are highlighted. In the first sequence R, E, and K are highlighted in red. In the second sequence, 2 D and 2 K are highlighted in red.

Second line: I A F T M Y L S M L L G Y G L T M V P F G G E Q N P I Y W A R Y A D W L F T T P L L L L D L A L L V. The sequences I A F T M Y L S M L and W A R Y A D W L F T T P L L L L D L A L are highlighted. An E residue between the two sequences is highlighted in red. Extended description for Schematic illustration of the side view and periplasmic view of porin protein from *Rhodopseudomonas blastica*

Part (A): The membrane is depicted as a lipid bilayer. It is composed of shorthand depictions of lipids. The porin protein has a barrel-shaped structure that is open at the top and bottom. It is composed of diagonally orientated anti-parallel beta strands interconnected by thread-like loops. The loops extend above and below the external and periplasmic surface respectively.

Part (B): The porin protein is depicted as a circular structure with a border composed of beta-strands. Some thread-like loops extend into the hollow interior of the protein.

Return to Schematic illustration of the side view and periplasmic view of porin protein from *Rhodopseudomonas blastica*

Extended description for Secondary structure of porin protein from *Rhodopseudomonas blastica*

The secondary structure of porin contains 16 vertical chains arranged side by side. Each of these chains has a different sequence. Their sequence from top to bottom is as follows:

Sequence 1: E I S L N G Y G R F G L Q Y V E.

Sequence 2: T T G V I N I R L R S S I I T D.

Sequence 3: T F G A K L R M Q W D D.

Sequence 4: Y S T W F Q A.

Sequence 5: V T V S V G N.

Sequence 6: I S Y T V A I G N.

Sequence 7: G V N L Y L S Y V D.

Sequence 8: N S W D A A I G F E.

Sequence 9: M I S L A A A Y T T.

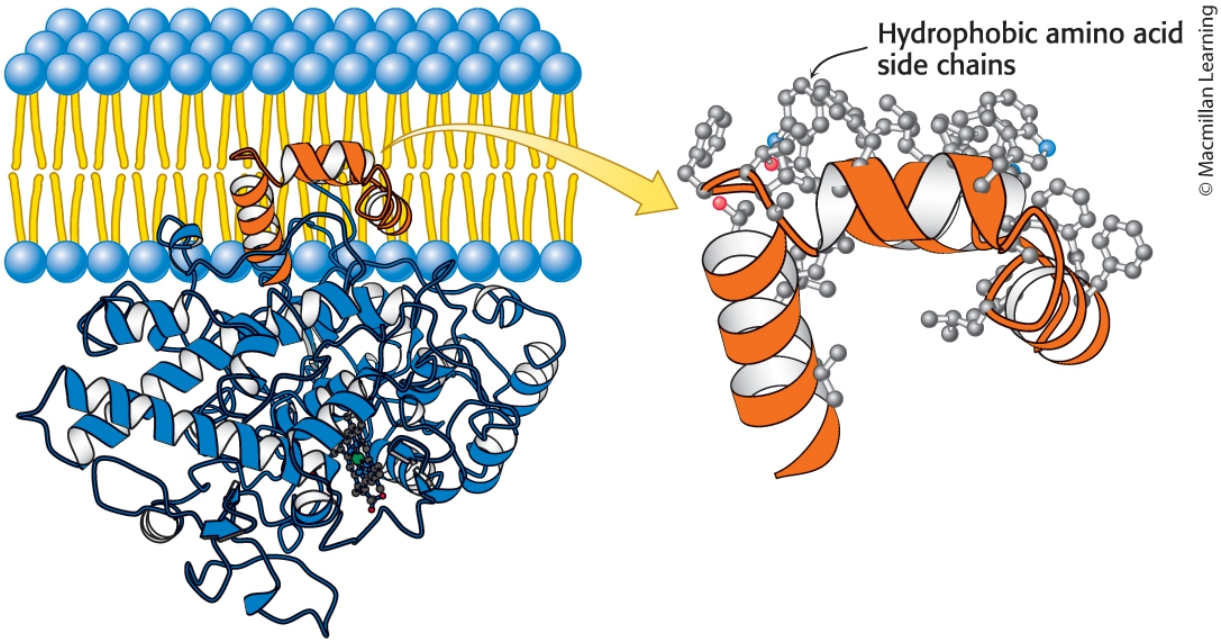
Sequence 10: K Y A A G V F A I.

Sequence 11: A G T V G L N W Y D.

Sequence 12: F A Y N G Y L T V Q D.

Sequence 13: A T T V R A Y V S D I D.

Sequence 14: F Q Y D A G I G Y A.



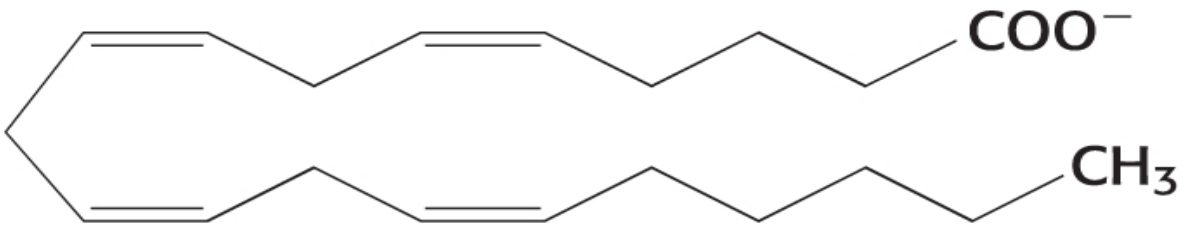
Sequence 15: G V K V S G S V Q S G.

Sequence 16: F D F R V G V D A V T E.

The first E residue of sequence 1 is single bonded to N H 3 superscript plus and the first F residue of sequence 16 is single bonded to C O O superscript minus. The wavy lines connect the adjacent chains from top and bottom in an alternating manner. Diagonal lines are drawn across the chains indicating hydrogen bonding. The hydrophobic residues F I L M V W and Y are highlighted in yellow.

Return to Secondary structure of porin protein from *Rhodopseudomonas blastica*

Extended description for Ribbon structure of prostaglandin H 2 synthase-1 attached to the membrane surface



The membrane is depicted as a lipid bilayer. It is composed of shorthand depictions of lipids. The prostaglandin H 2 synthase-1 is composed of several alpha helices and a few beta-strands interconnected by thread-like loops. It is connected to the membrane through three alpha-helices at the top shown in orange. These alpha-helices are integrated into the yellow extensions of the lipid molecules. An arrow shows the enlarged view of the three orange alpha-helices interacting with ball-and-stick models of hydrophobic amino acid side chains. The ball-and-stick models are composed of grey spheres.

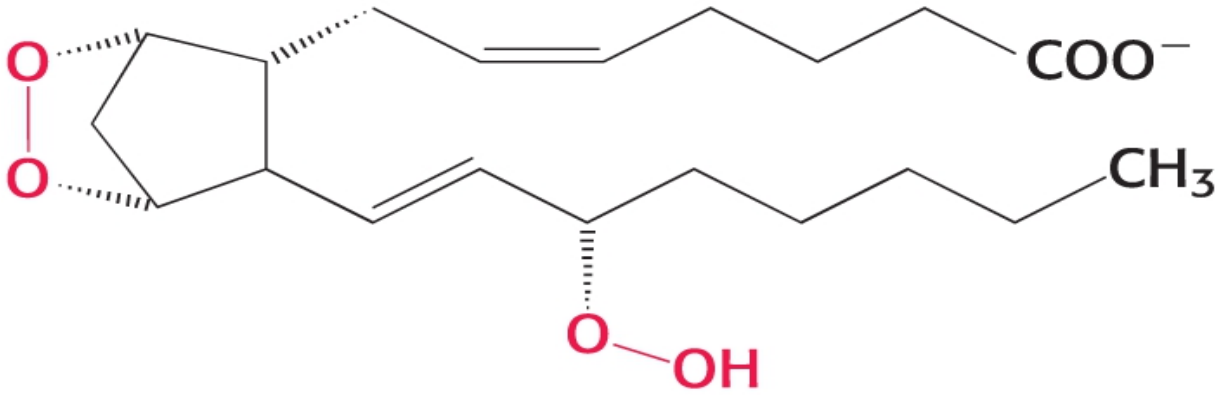
Extended description for Step-wise formation of

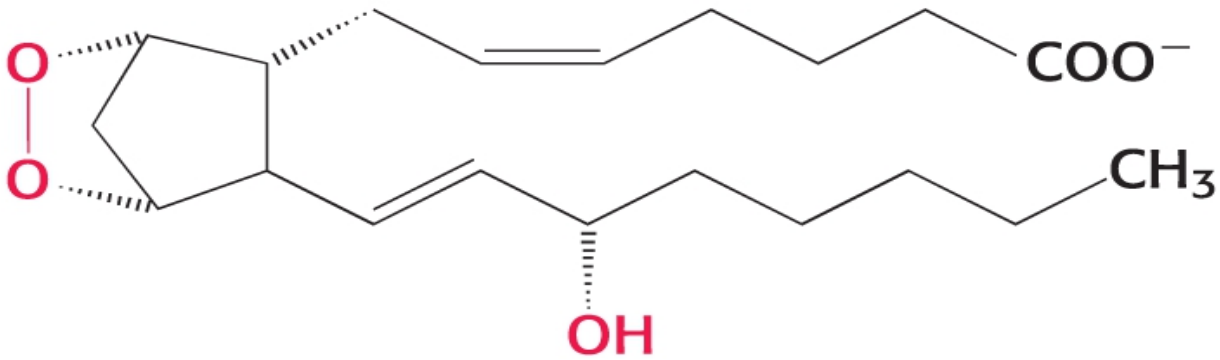


prostaglandin H 2 from arachidonate

Arachidonate

Cyclooxygenase

2 O_2



Prostaglandin G_2

Peroxidase

2 H^+ + 2 e^-

H_2O

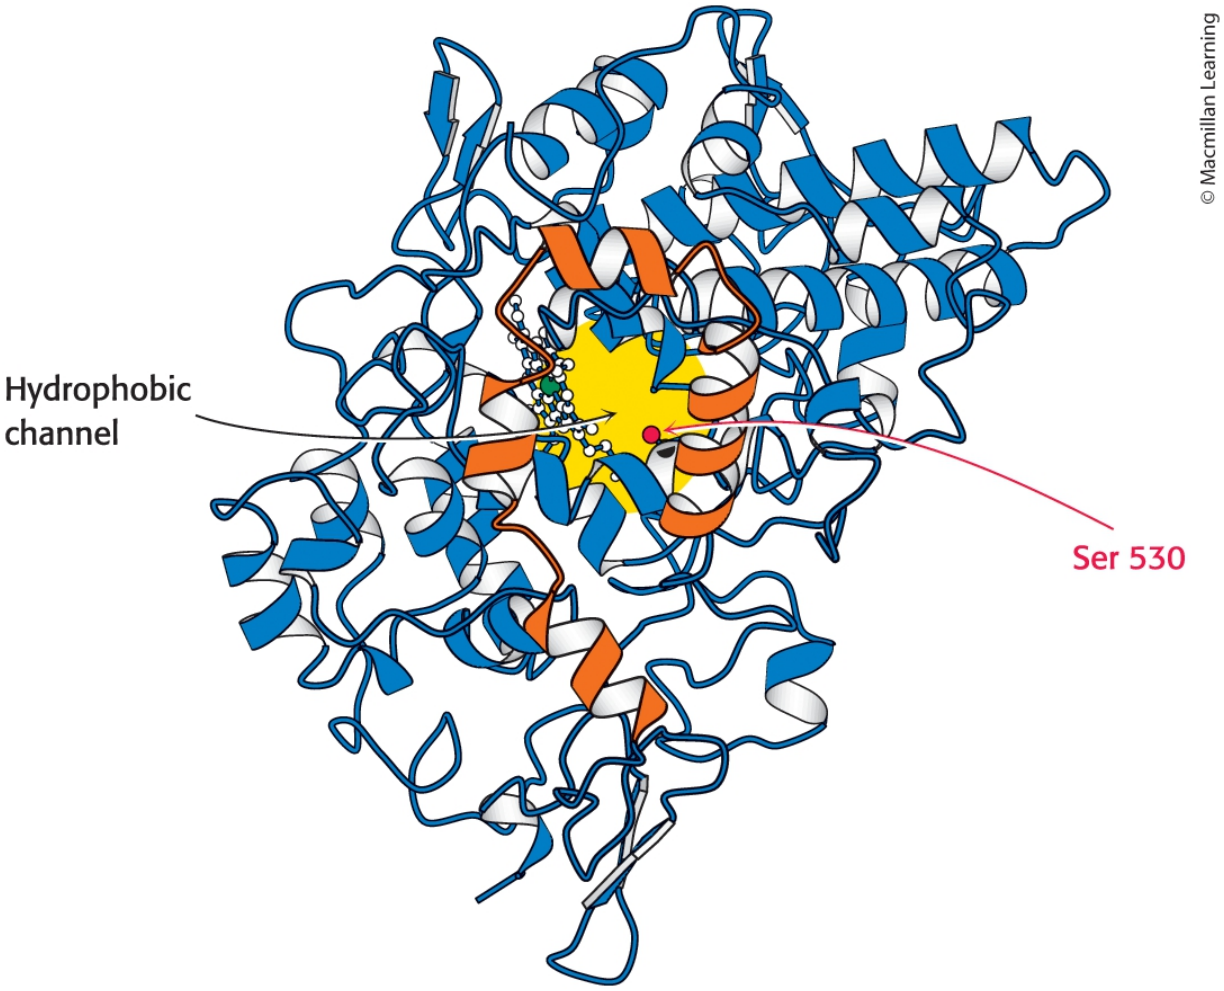
Prostaglandin H_2

The conversion of arachidonate to prostaglandin H 2 occurs in two steps.

First step: The conversion of arachidonate to prostaglandin G 2 is catalyzed by cyclooxygenase and involves the addition of 2 O 2.

The structure of arachidonate is as follows: An 18-carbon alkene chain is depicted as a line structure using 17 zigzag lines. A double bond is present between C 4 and C 5, C 7 and C 8, C 10 and C 11, and C 13 and C 14. C 1 is single bonded to C O O superscript minus on the upper right. C 18 is single bonded to C H 3 on the upper right. The alkene chain is folded at C 9.

The structure of prostaglandin G 2 is as follows: A 5 carbon homocyclic pentagonal ring is in a horizontal orientation with C 1 occupying the leftmost vertex. C 2 is dash bonded to O on the lower left. C 5 is dash bonded to O on the upper left. The O's are single bonded to each other. C 3 is dash bonded to C 6 of a 6 carbon alkene chain depicted as a line structure using 5 zigzag lines. A double bond is present between C 4 and C 5. C 1 is single bonded to C O O superscript minus on the lower right. C 4 of the pentagonal ring is single bonded to C 7 of a 7 carbon alkene chain depicted as a line structure using 6 zigzag lines. A double bond is present between C 6 and C 7. C 5 is dash bonded to O below. This O is single bonded to O H on the lower right. C 1 is single bonded to C H 3 on the upper right.



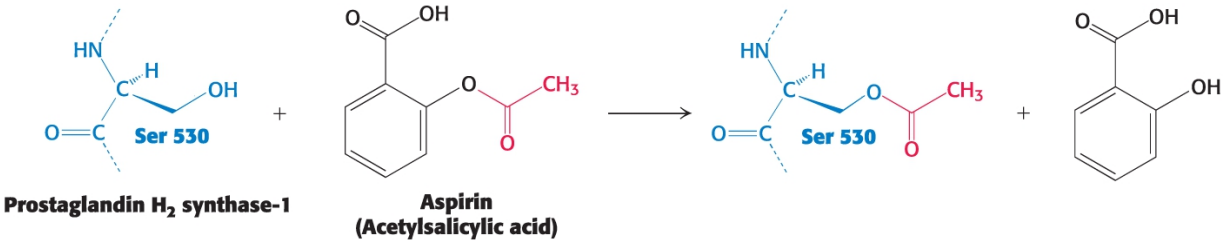
Second step: The conversion of prostaglandin G 2 to prostaglandin H 2 is catalyzed by peroxidase. It also involves the formation of H 2 O from 2 H superscript plus and 2 electrons.

The structure of prostaglandin H 2 is as follows: A 5 carbon homocyclic pentagonal ring is in a horizontal orientation with C 1

occupying the leftmost vertex. C 2 is dash bonded to O on the lower left. C 5 is dash bonded to O on the upper left. The O's are single bonded to each other. C 3 is dash bonded to C 6 of a 6 carbon alkene chain depicted as a line structure using 5 zigzag lines. A double bond is present between C 4 and C 5. C 1 is single bonded to C O O superscript minus on the lower right. C 4 of the pentagonal ring is single bonded to C 7 of a 7 carbon alkene chain depicted as a line structure using 6 zigzag lines. A double bond is present between C 6 and C 7. C 5 is dash bonded to O H below. C 1 is single bonded to C H 3 on the upper right.

Return to Step-wise formation of prostaglandin H 2 from arachidonate

Extended description for Ribbon structure of prostaglandin H 2 synthase-1 containing a hydrophobic channel



© Macmillan Learning

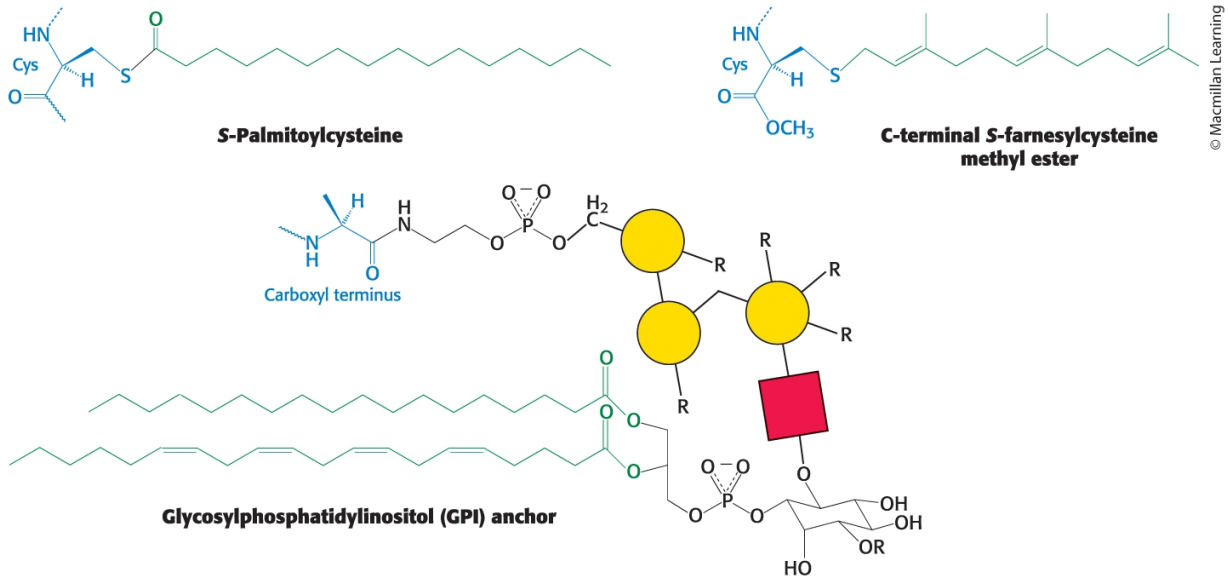
The ribbon structure shows the membrane-facing side of prostaglandin H 2 synthase-1. It is composed of several alpha-helices and a few beta-strands interconnected by thread-like loops. A central hollow space lined by the helices is highlighted in yellow and labeled hydrophobic channel. A set of three orange alpha-helices are located around the hydrophobic channel. A serine 530 residue attached to one of the alpha-helix around the channel is

depicted as a tiny red circle. A ball-and-stick model consisting of a green sphere and a several white spheres is connected to a few alpha-helices around the channel.

Return to Ribbon structure of prostaglandin H 2 synthase-1 containing a hydrophobic channel

Extended description for Acetyl group transfer to serine residue of prostaglandin H 2 synthase 1 by aspirin

The reaction consists of two reactants and two products. The first reactant is prostaglandin H 2 synthase-1 and its structure is as follows: A central carbon atom is single bonded to N H on the upper left. N H has an open single bond on the top right. The central C atom is dash bonded to H on the upper right, wedge bonded to C H 2 on the lower right, and single bonded to C on the lower left. The C atom on the lower left is double bonded to O on the left and has an open single bond on the lower right. C H 2 group is single bonded to O H on the upper right. The entire structure is labeled S e r 530.



The second reactant is aspirin and its structure is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. A double bond is present between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to a central C atom above in the form of a line. The central C atom is double bonded to O on the upper left and single bonded to OH on the upper right. C 2 is single bonded to O atom of an 1 O and 1 C heteronuclear alkane chain depicted as a line structure using 1 line. O occupies the first position. C atom of this alkane chain is double bonded to O below and single bonded to C H 3 on the upper right. The C O C H 3 group is highlighted in red.

The structure of the first product is as follows: A central carbon atom is single bonded to N H on the upper left. N H has an open single bond on the top right. The central C atom is dash bonded to H on the upper right, wedge bonded to C H 2 on the lower right, and single bonded to C on the lower left. The C atom on the lower left is double bonded to O on the left and has an open single bond on the lower right. C H 2 group is single bonded to the O atom of a 1 O and 1 C heteronuclear alkane chain depicted as a line structure using 1 line. O occupies the first position. C 1 of this alkane chain is double bonded to O below and single bonded to C H 3 on the upper right. The C O C H 3 group is highlighted in red.

The structure of the second product is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. Alternating double bonds are present between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to a central C atom above in the form of a line. The central C atom is double bonded to O on the upper left and single bonded to O H on the upper right. C 2 is single bonded to O H on the upper right.

Return to Acetyl group transfer to serine residue of prostaglandin H 2 synthase 1 by aspirin

Extended description for Structures of S-Palmitoyl cysteine, C-terminal S-farnesyl cysteine methyl ester, and Glycosylphosphatidylinositol (G P I) anchor

The structure of S- Palmitoyl cysteine is as follows: A 16-carbon alkane chain is depicted as a line structure using 15 zigzag lines. C 1 is single bonded to S on the lower left and double bonded to O above. S is single bonded to C on the upper left. This C atom is wedge bonded on the lower left to a central C atom of cysteine residue. The central C atom is dash bonded to H on the lower left, single bonded to N H on the upper left, and single bonded to another C atom on the lower left in the form of a line. N H has an open single bond on the top right. The C atom on the lower left is double bonded to O on the left and single bonded to C H 3 on the lower right in the form of a line.

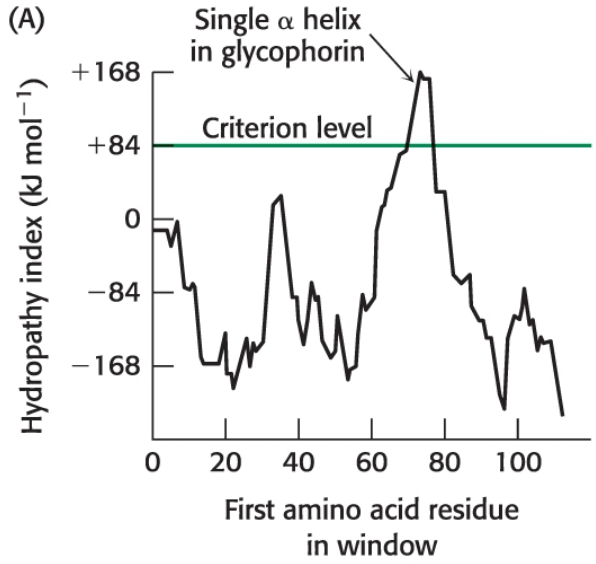
The structure of C-terminal S-farnesyl cysteine methyl ester is as follows: A 13-carbon alkene chain is depicted as a line structure using 12 zigzag lines. A double bond is present between C 2 and C 3,

C 6 and C 7, C 10 and C 11. C 1 is single bonded to S on the lower left. C 3, C 7 and C 11 are each single bonded to C H 3 above in the form of a line. S is single bonded C on the upper left. This C is wedge bonded to a central C atom of cysteine residue on the lower left. The central C is dash bonded to H on the lower left, single bonded to N H on the upper left, and single bonded to another C atom on the lower left in the form of a line. N H has an open single bond on the top right. The C atom on the lower left is double bonded to O on the left and single bonded to O C H 3 on the lower right.

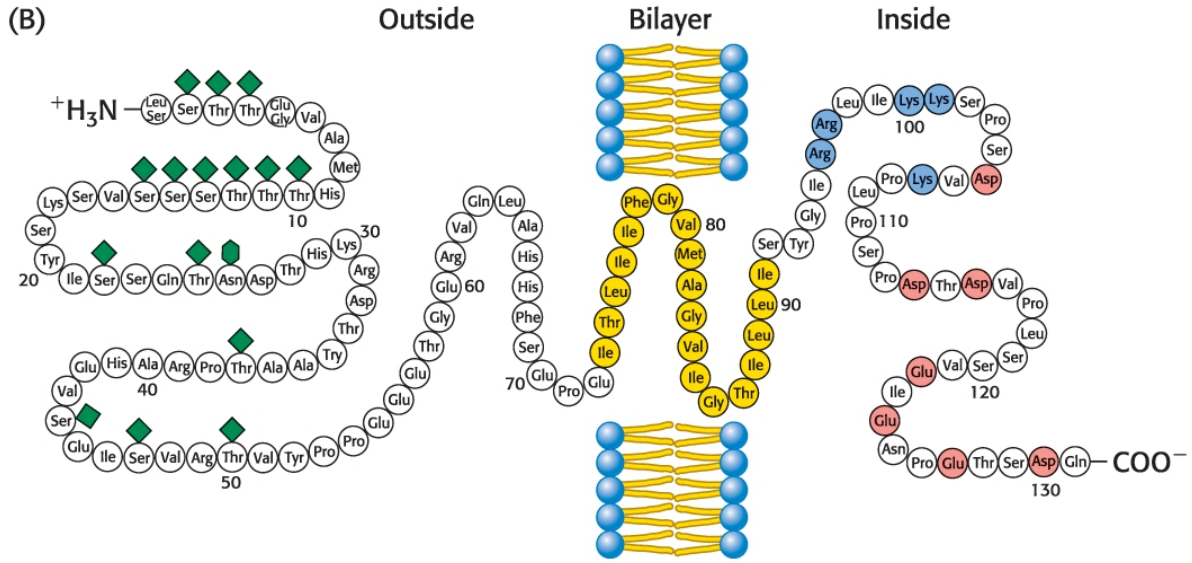
The structure of glycosylphosphatidylinositol (G P I) anchor is as follows: A 1 P, 2 O, 2 N, and 5 C alkane chain depicted as a line structure using 9 zigzag lines. O atoms occupy the seventh and ninth positions. P occupies the eighth position. N occupies the first and fourth positions and are bound to H atoms. N 1 has an open single bond on the upper left. P is partially double bonded to O on the upper left and O on the upper right. The P O O group has an overall negative charge. C 2 is dash bonded to H on the upper right and wedge bonded to C H 3 on the upper left in the form of a line. C 3 is double bonded to O below. C 10 is bound to H 2 and is single bonded to a yellow circle on the right.

This yellow circle is single bonded to another yellow circle below. Both the yellow circles are single bonded to R. The yellow circle below is single bonded to C H 2 on the upper right in the form of a line. This C H 2 group is single bonded to a third yellow circle on the lower right. The third yellow circle is single bonded to R above, R on the upper right, and R on the lower right. It is single bonded to a red square below.

The red square is single bonded to O below. This O atom is single bonded to C 6 of a 6-carbon homocyclic ring in a chair conformation. In this ring, C 3 and C 6 are located closer. C 1 and C 2 are each single bonded to O H on the right. C 3 is single bonded to O



R on the lower right. C 4 is single bonded to O H below. C 5 is single bonded to O on the lower left. This O atom is single bonded to a P atom on the upper left. This P atom is partially double bonded to O on the upper left and O on the upper right The P O O group has an overall negative charge. The P atom is single bonded to O on the lower left. This O atom is single bonded to C 3 of a 3-carbon vertical chain.



C 2 of the vertical chain is single bonded to O atom of a 1 O and 20 C heteronuclear alkene chain depicted as a line structure using 20 zigzag lines. A double bond is present between C 6 and C 7, C 9 and C 10, C 12 and C 13, C 15 and C 16. O occupies the twenty-first position. C 20 is double bonded to O above.

C 1 of the vertical chain is single bonded to O atom of an 1 O and 18 C heteronuclear alkane chain depicted as a line structure using 18 zigzag lines. C 1 8 is double bonded to O above.

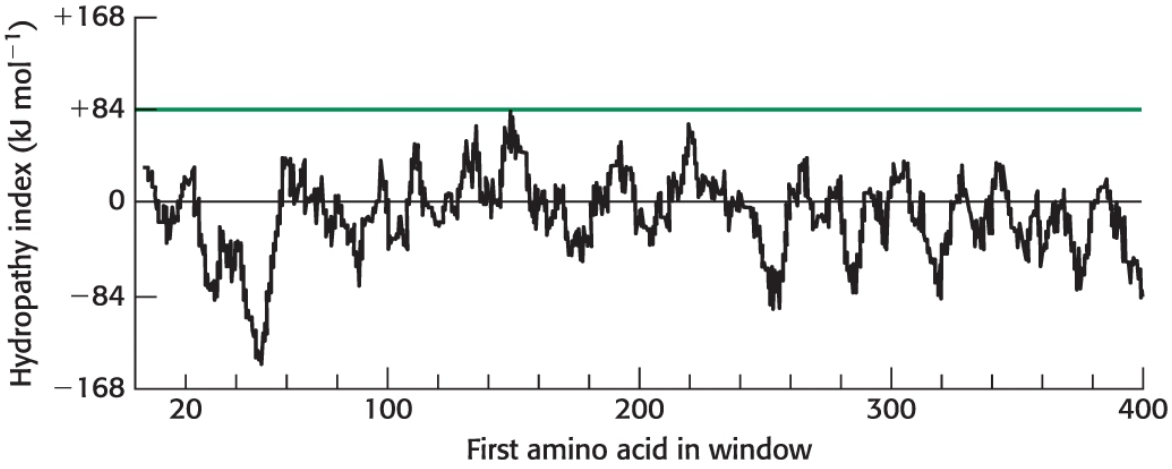
Extended description for Hydropathy plot for glycophorin A and the amino acid sequence and disposition of glycophorin A

© Macmillan Learning



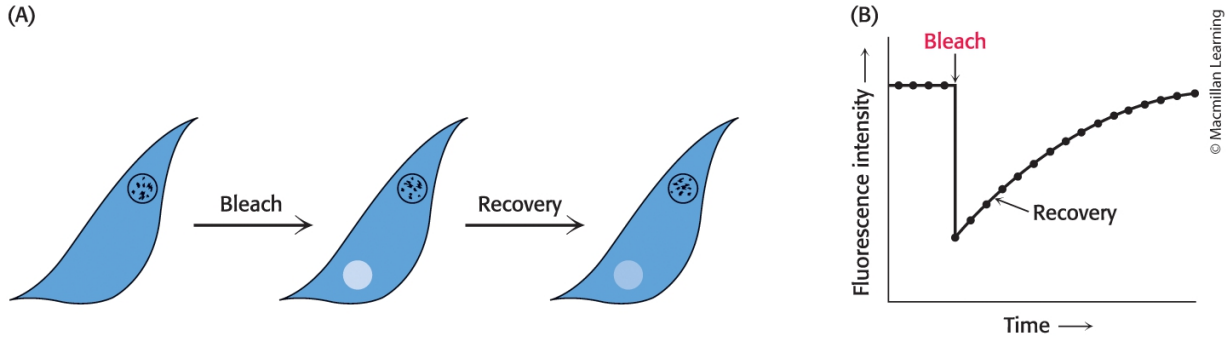
Part (A): The horizontal axis is labeled “First amino acid residue in window”. It has markings ranging from 0 to 100 in increments of 20 units. The vertical axis is labeled hydropathy index (k J mole

superscript minus 1). It has markings ranging from negative 168 to plus 168 in increments of 84 units. A green horizontal line parallel to the horizontal axis is drawn from the marking plus 84 on the vertical axis. A line curve starts from (0, negative 10) on the vertical axis and moves horizontally toward the right till (5, negative 10). It then forms a series of short and long peaks. The longest peak is seen at (80, plus 150) and is labeled single alpha helix in glycophorin.

Part (B): The amino acid sequence of glycophorin is divided into three regions: outside, bilayer, and inside. The outside region is composed of the first 73 amino acid residues from the N H 3 superscript plus terminal. It contains amino acids like leucine, serine, threonine, glutamic acid, glycine, valine, alanine, methionine, histidine, lysine, isoleucine, tyrosine, glutamine, asparagine, arginine, proline, and phenylalanine. Serine 2, threonine 3, threonine 4, threonine 10 to 12, serine 13 to 15, serine 22, threonine 25, threonine 37, serine 44, serine 47, and threonine 50 residues are labeled with a small green rhombus. The asparagine 26 residue is labeled with a small green hexagon. The amino acid residues from 74 to 91 pass through the lipid bilayer. It includes isoleucine, threonine, leucine, glycine, valine, methionine, and alanine. The inside region includes the C O O superscript minus terminal consisting of the amino acid residues from 92 to 131. These residues are serine, tyrosine, glycine, isoleucine, arginine, leucine, proline, aspartic acid, valine, lysine, threonine, glutamic acid, asparagine, and glutamine. Two arginine and three lysine residues are highlighted in blue. Four aspartic acid and three glutamic acid residues are highlighted in red.

Return to Hydropathy plot for glycophorin A and the amino acid sequence and disposition of glycophorin A

Extended description for Hydropathy plot for porin

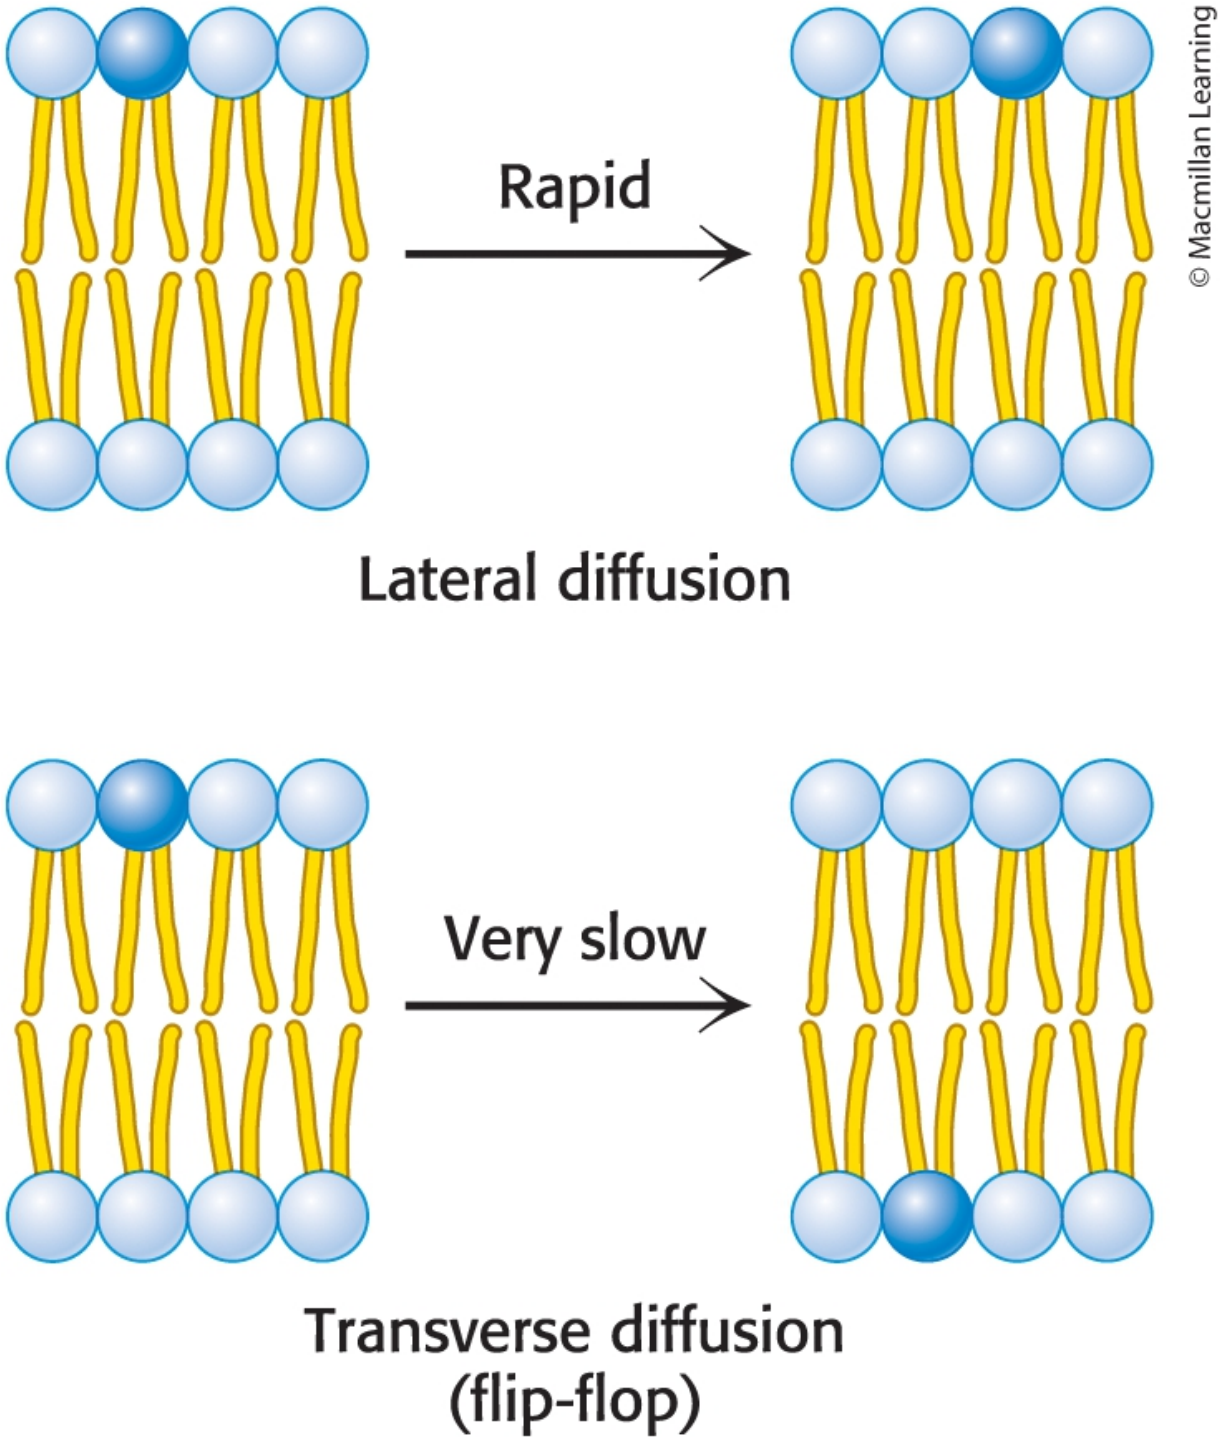


© Macmillan Learning

The horizontal axis is labeled first amino acid in window. It has markings 20, 100, 200, 300, and 400. The vertical axis is labeled hydropathy index in K J per mol. It has markings ranging from negative 168 to positive 168 in increments of 84 units. The graph shows two horizontal lines parallel to the horizontal axis starting from 0 and positive 84 on the vertical axis. The graph shows a line forming series of peaks and depressions without any strong peaks. It starts from (0, 40) shows a gradual downward fall to reach (50, negative 158) and raises upward to (60, 42). It then moves toward the right and forms several peaks and depressions. Several sharp falls are seen at (260, negative 90), (290, negative 84), (320, negative 84), (380, negative 70). The line terminates at (400, negative 80). All values are approximated.

Return to Hydropathy plot for porin

Extended description for Schematic representation of fluorescence bleaching and recovery and a graphical representation of fluorescence intensity versus time

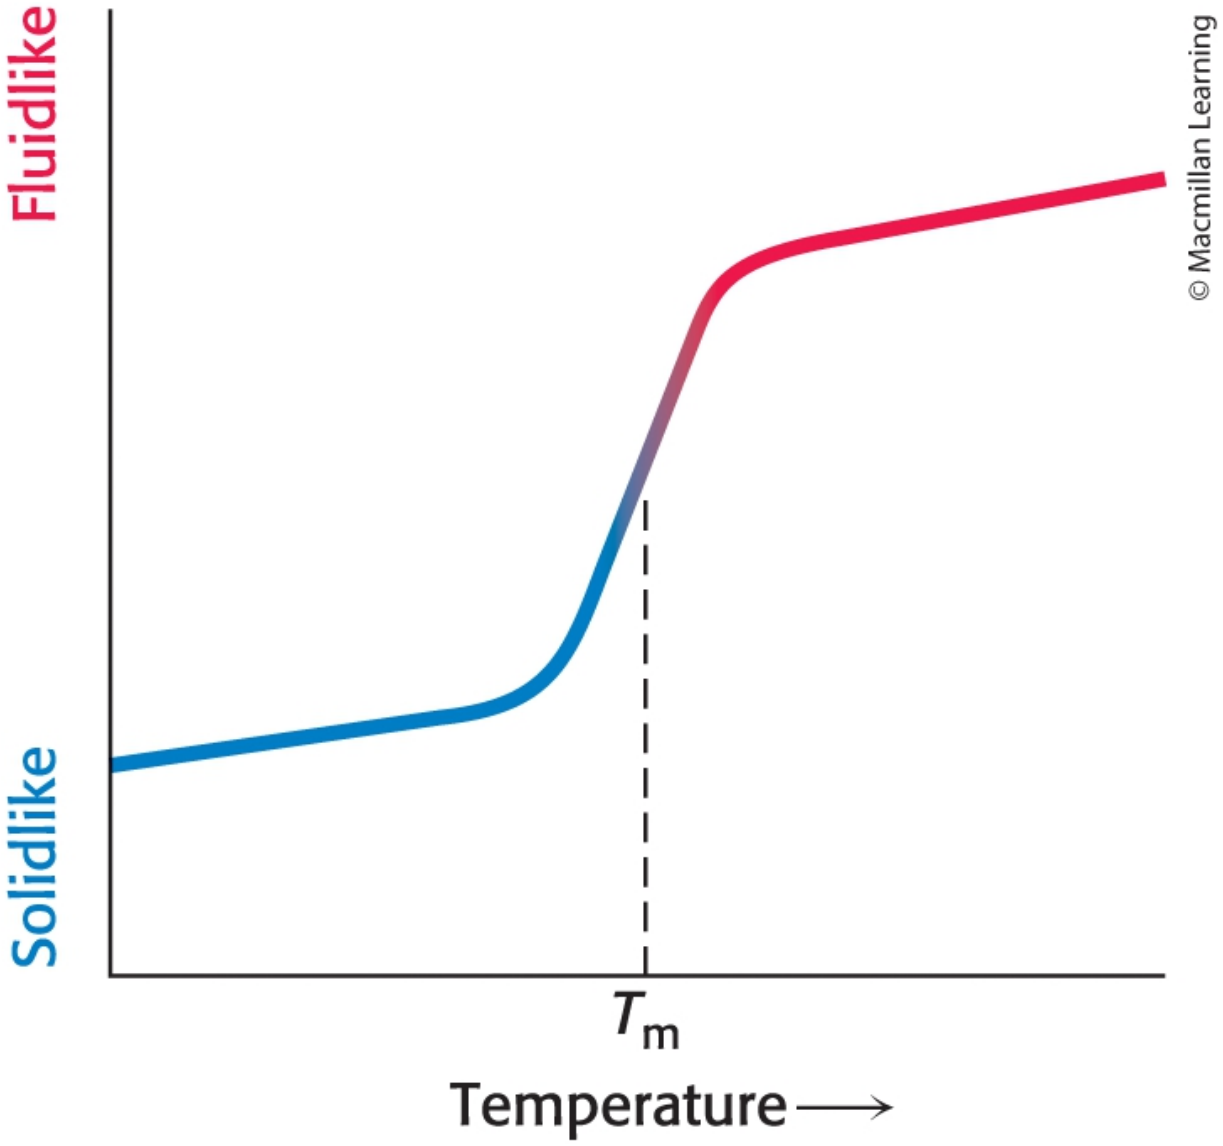


Part (A): It shows a spindle-shaped cell. The cell has a small circular structure containing a cluster of black dots in it. The cell undergoes bleaching leading to the formation of a circular white patch on the cell. The cell undergoes recovery and the bleached part starts to disappear slowly.

Part (B): The horizontal axis is labeled time and the vertical axis is labeled fluorescence intensity. The graph shows a line that starts from a point well above the middle of the vertical axis. It moves horizontally toward the right and is labeled bleach. The line then moves vertically downward up to a point much below the middle of the vertical axis. It again rises upward in a concave down fashion and this curve is labeled recovery.

Return to Schematic representation of fluorescence bleaching and recovery and a graphical representation of fluorescence intensity versus time

Extended description for Schematic illustration of lateral and transverse diffusion in lipid bilayer



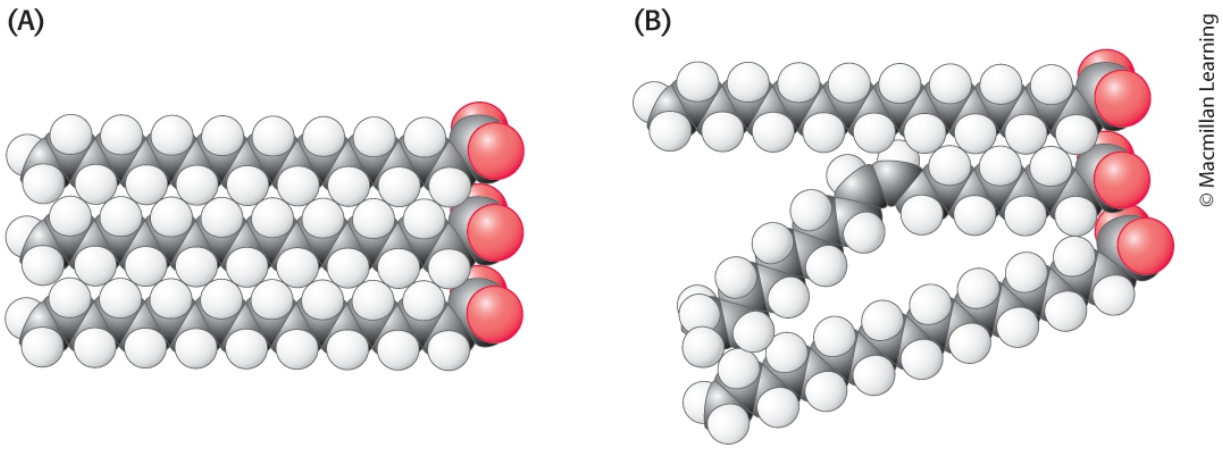
The lipid bilayer before diffusion consists of two layers of lipid molecules shown in shorthand depiction. Each layer consists of 4 lipid molecules. The spherical groups of all lipid molecules are light blue except for one lipid located at the second position of the top layer. The spherical group of this lipid is dark blue colored.

Lateral diffusion: It occurs very rapidly. The position of the lipid molecule having blue spherical group changes from second to third in the top layer.

Transverse diffusion (flip-flop): It occurs very slowly, The position of the lipid molecule having blue spherical group changes from second in the top layer to second in the bottom layer.

Return to Schematic illustration of lateral and transverse diffusion in lipid bilayer

Extended description for Graph showing the melting temperature of a phospholipid membrane

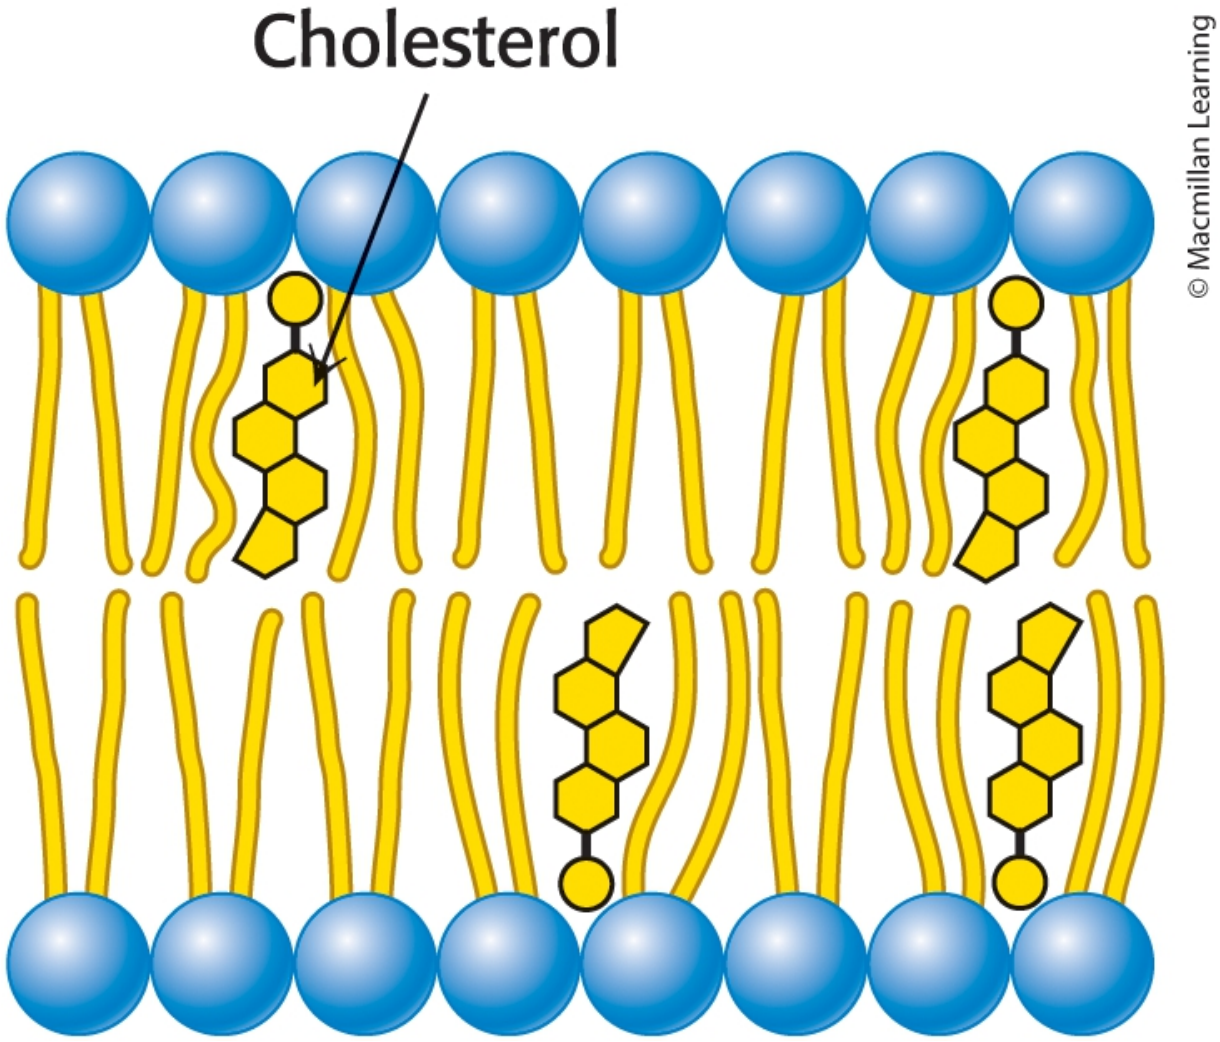


The horizontal axis is labeled temperature. The vertical axis is labeled solidlike at the bottom and fluidlike at the top. The sigmoidal curve starts from solidlike region and moves toward the right and suddenly rises upward near the mid point of the horizontal axis. It then terminates on the right near the fluidlike region. The midpoint

along the upward transition of the curve has a dashed vertical line touching the mid point of the horizontal axis and is labeled T subscript m.

Return to Graph showing the melting temperature of a phospholipid membrane

Extended description for Space-filling models labeled (A) and (B)



Space-filling model (A): It shows three horizontally oriented models stacked one above the other. Each model is composed of a linear chain of 18 fused black spheres. The second to seventeenth black spheres are fused to a white sphere, all located toward the observer. These white spheres are oriented upward or downward in an alternating manner. The first black sphere is fused with two white spheres. One white sphere is located away from the observer and another one is located toward the observer. The eighteenth black sphere is fused with two red spheres. One red sphere is located toward the observer and another one is located away from the observer.

Space filling model (B): It shows three models. The topmost model is in a horizontal orientation. The middle model has a kink at the tenth black sphere. The bottom-most model has a diagonal orientation. The eighteenth black spheres of all the three models are stacked one above the other. Each model is composed of a chain of 18 fused black spheres. The second to seventeenth black spheres are fused to a white sphere, all located toward the observer. These white spheres

are oriented upward or downward in an alternating manner. The first black sphere is fused with two white spheres. The eighteenth black sphere is fused with two red spheres. One red sphere is located toward the observer and another one is located away from the observer.

Return to Space-filling models labeled (A) and (B)

Extended description for Schematic illustration of cholesterol inserted in lipid bilayer

A lipid bilayer composed of lipid molecules in a shorthand depiction is shown. The cholesterol molecules are inserted between the yellow extensions of adjacent lipid molecules. A cholesterol molecule is depicted as a yellow circle connected to three fused hexagons. The insertion of a cholesterol molecule introduces a kink in the yellow extensions.

Extended description for Lipid raft and human monocytic cell stained with a fluorescent dye

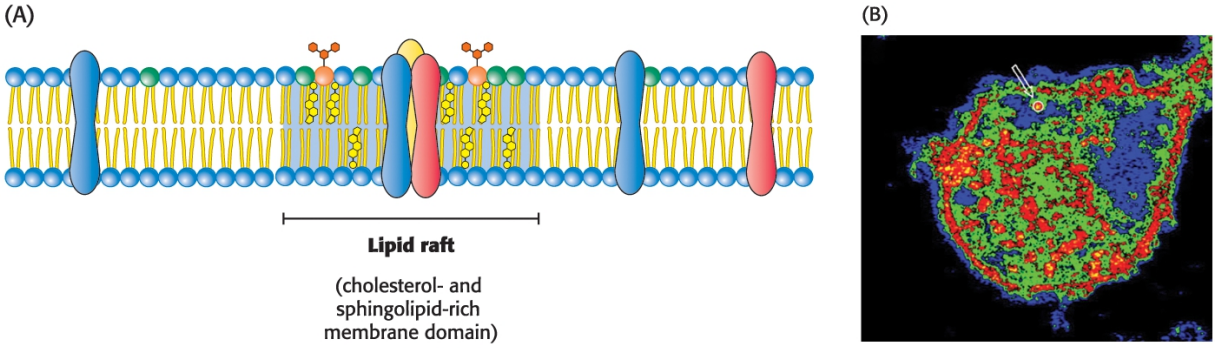

Photo credit: Katharina Gaus, Enrico Gratton, Eleanor P. W. Kable, et al., "Visualizing lipid structure and raft domains in living cells with two-photon microscopy." PNAS December 23, 2003 100 (26) 15554–15559; https://doi.org/10.1073/pnas.2534386100, Figure 1B. Copyright (2003) National Academy of Sciences, U.S.A.
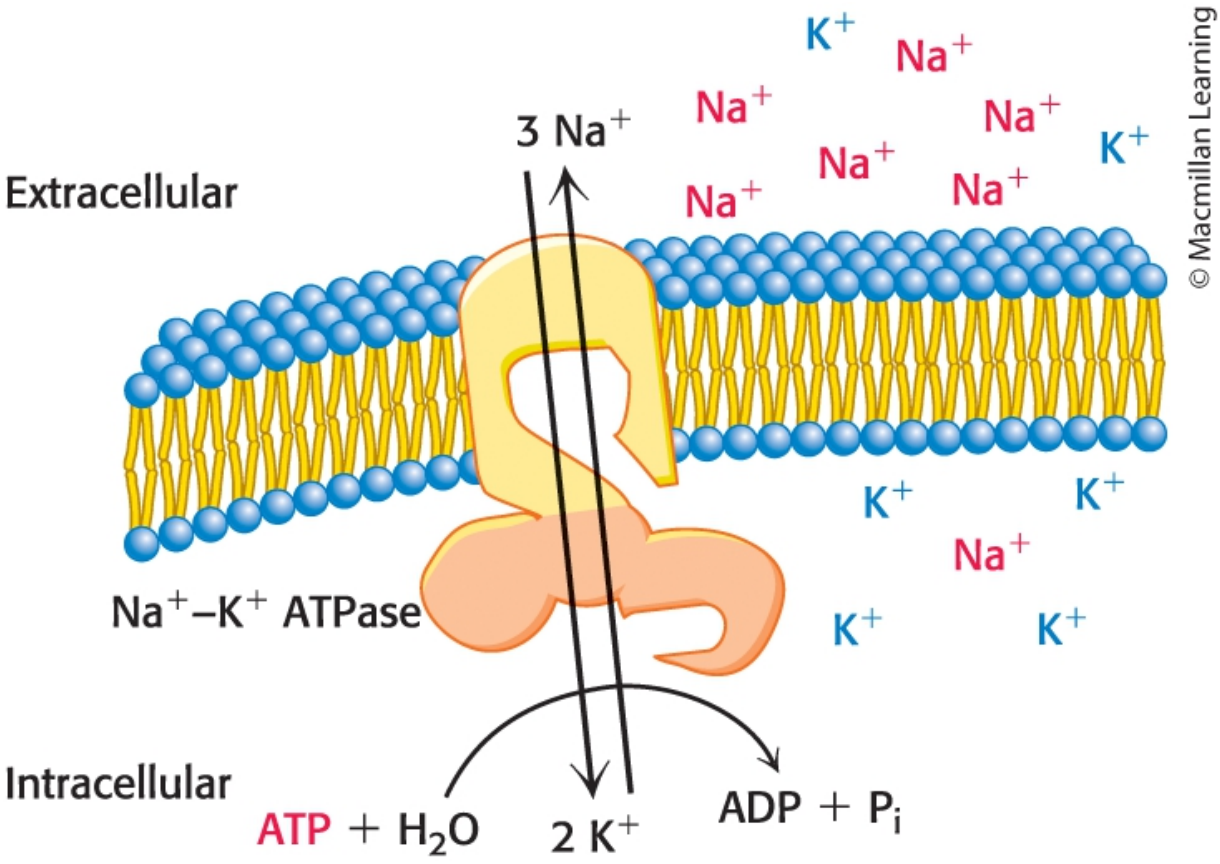
© Macmillan Learning



Part (A): It shows a lipid bilayer consisting of two horizontally parallel layers of lipids arranged compactly. Each lipid molecule is shown in a shorthand depiction. The yellow extensions of the shorthand depiction are aligned together and form the core of the bilayer. The spherical groups are blue, green, and orange colored. The lipid raft is a cholesterol-sphingolipid rich membrane domain. The orange and green spherical groups are concentrated in the outer leaflet of the lipid bilayer in the lipid raft. Cholesterol molecules depicted as fused hexagons are inserted between the yellow extensions of the lipid bilayer in the raft. The orange spherical groups are connected to a cluster of three orange hexagons. The bilayer also consists of 3 blue and 2 red dumble-shaped membrane proteins that traverse the bilayer. The lipid raft contains a cluster of yellow, blue, and red dumble-shaped membrane proteins.

Part (b): It shows a micrograph of circular human monocytic cell stained with fluorescent dye that is sensitive to the level of disorder. The cell shows small irregular-shaped red patches across a green

background. It shows a blue outline and a few large and small irregular-shaped blue patches. Some of the red patches contain a tiny yellow spot at center. An arrow points at a red patch surrounded by a medium-sized blue patch. The red patch contains a tiny yellow spot.

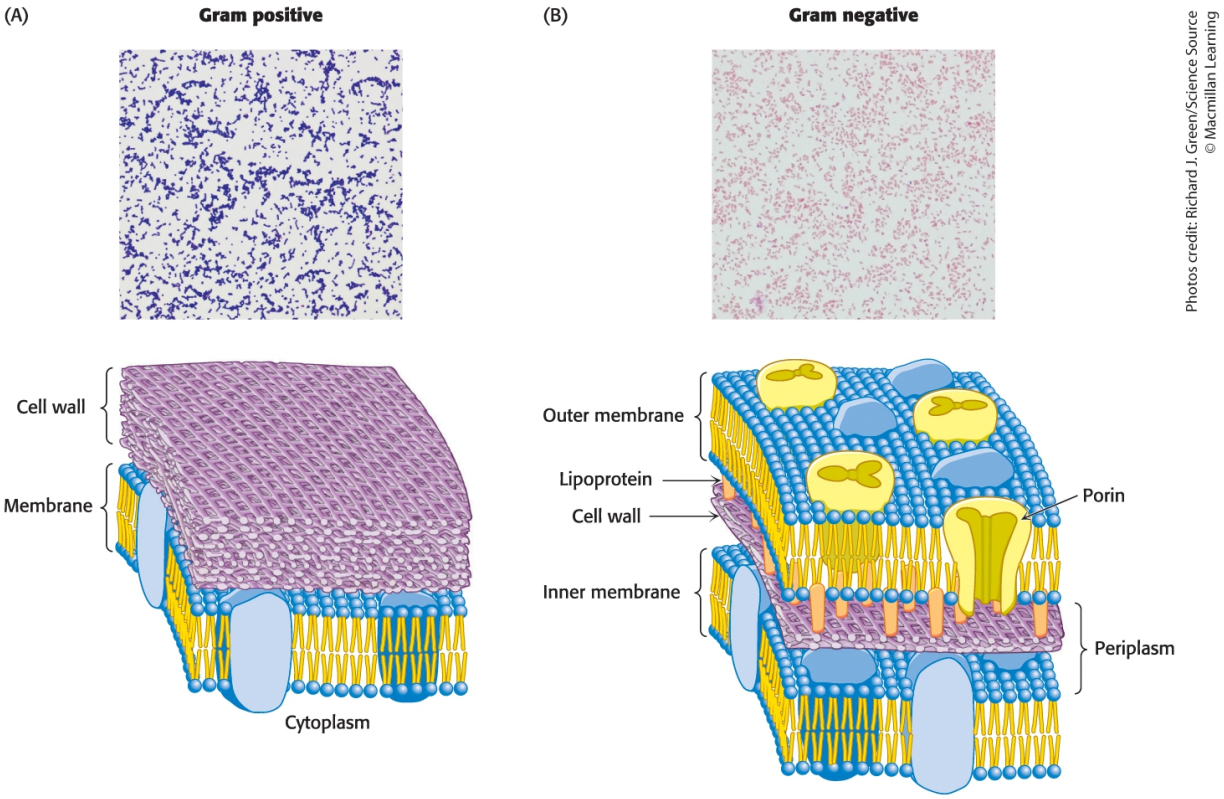
Extended description for Transport of ions by N a superscript plus-K superscript plus transport system in the lipid bilayer

The lipid bilayer consists of two horizontally parallel layers of lipids. The outer leaflet consists of three rows of lipid molecules packed together compactly. Each lipid molecule is shown in a shorthand depiction. The yellow extensions of the shorthand depiction are aligned together and form the core of the bilayer. The blue spheres are located away from each other. The lipid bilayer consists of a transport system that extends from the extracellular region above the bilayer to the intracellular region below the bilayer. This transport system is labeled N a superscript plus-K superscript plus A



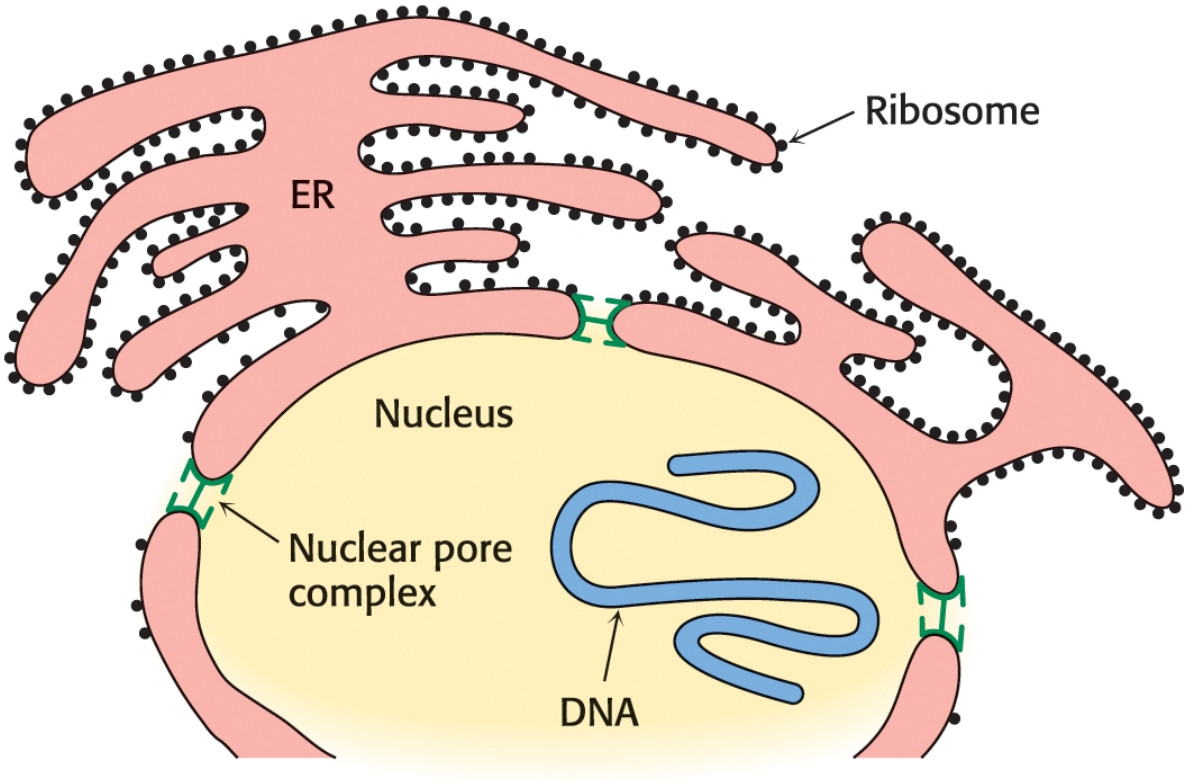
T P ase. The number of N a superscript plus ions in the extracellular region is much higher than the intracellular region. The number of K superscript plus ions in the intracellular region is much higher than the extracellular region.

A downward arrow across the A T P ase shows the movement of 2 K superscript plus ions into the intracellular region. An upward arrow across the A T P ase shows the movement of 3 N a superscript plus ions into the extracellular region.

The intracellular space below the A T P ase shows the conversion of A T P and H 2 O to A D P and P subscript i as the transport of ions occurs.

Return to Transport of ions by N a superscript plus-K superscript plus transport system in the lipid bilayer

Extended description for Structure of the plasma membrane of gram positive and gram negative bacteria and their photomicrographs



Part (A): It shows a photomicrograph of purple-stained gram-positive bacteria. The 3-D structure of the plasma membrane of the gram-positive bacteria is shown below the photomicrograph. The plasma membrane consists of two parallel layers of lipids. Both the layers consist of several rows of lipid molecules packed together compactly. Each lipid molecule is shown in a shorthand depiction. The yellow extensions of the shorthand depiction are aligned together and form the core of the bilayer. The blue spheres are located away from each other. The bilayer consists of two membrane proteins. A thick mesh-like purple-colored cell wall is present above the bilayer.

Part (B): It shows a photomicrograph of pink-stained gram-negative bacteria. The 3-D structure of the plasma membrane of the gram-negative bacteria is shown below the photomicrograph. These bacteria have two separate lipid bilayers. Each lipid bilayer consists of several rows of lipid molecules packed together compactly. Each lipid molecule is shown in a shorthand depiction. The yellow extensions of the shorthand depiction are aligned together and form the core of the bilayer. The blue spheres are located away from each other. The upper bilayer is labeled outer membrane and the bilayer at the bottom is labeled inner membrane. A thin mesh-like cell wall is present between the outer and inner membrane. Several short tube-like structures connecting the outer and inner membrane are labeled lipoproteins. The space between the two membranes is labeled periplasm. The outer membrane consists of channel-like structures labeled porin.

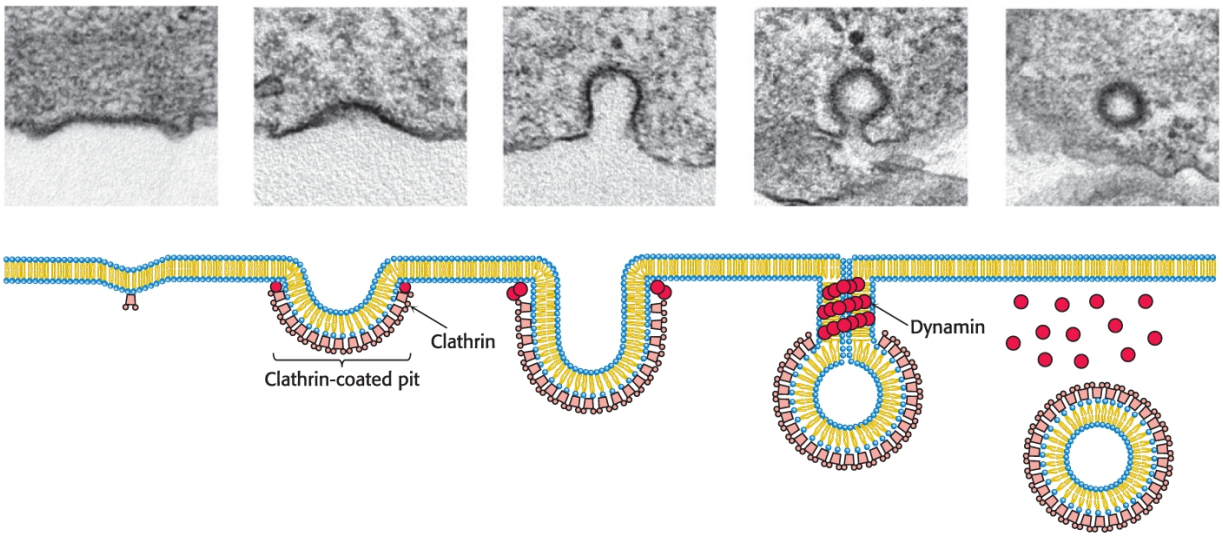
Extended description for Schematic illustration of nuclear and surrounding E R



© Macmillan Learning

The nucleus is a circular structure containing a D N A molecule. The D N A molecule is depicted as a zigzag blue strand. The nucleus is surrounded by a double membrane nuclear envelope having a narrow lumen between them. A nuclear pore complex depicted as a narrow channel is present in the double membrane. At these complexes, the outer and inner membrane of the envelope becomes continuous. The outer membrane of the nuclear envelope continues into a network of membranes in the cytoplasm labeled E R. The surface of E R is lined by tiny black dots labeled ribosomes. The E R encloses a lumen that is continuous with the lumen of nuclear envelope.

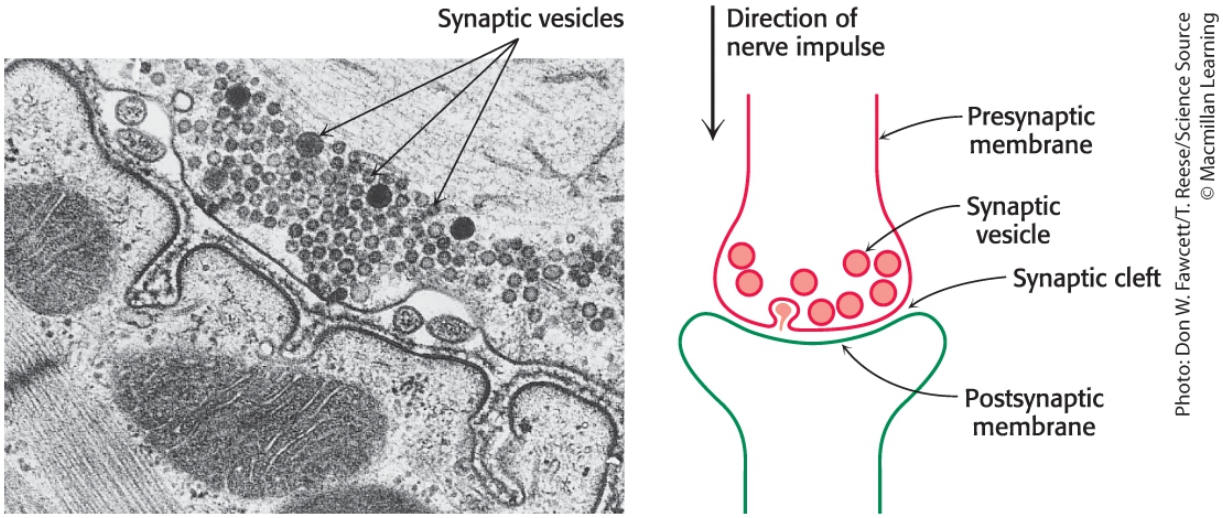
Extended description for Schematic representation and photomicrographs of the steps of receptor-mediated endocytosis

Credit: *Top*: Republished with permission of Company of Biologists, from Membrane remodeling in clathrin-mediated endocytosis. Volker Haucke, Michael M. Kozlov, J Cell Sci (2018) 131 (17): jcs216812. Figure 1. Permission conveyed through Copyright Clearance Center, Inc.; *Bottom*: Schmid SL. Reciprocal regulation of signaling and endocytosis: Implications for the evolving cancer cell. J Cell Biol. 2017 Sep 4;216(9):2623-2632. doi: 10.1083/jcb.201705017. Epub 2017 Jul 3. PMID: 28674108; PMCID: PMC5584184. Copyright © 2017 Schmid. Illustration by Marcel Mettlen. Used with permission.

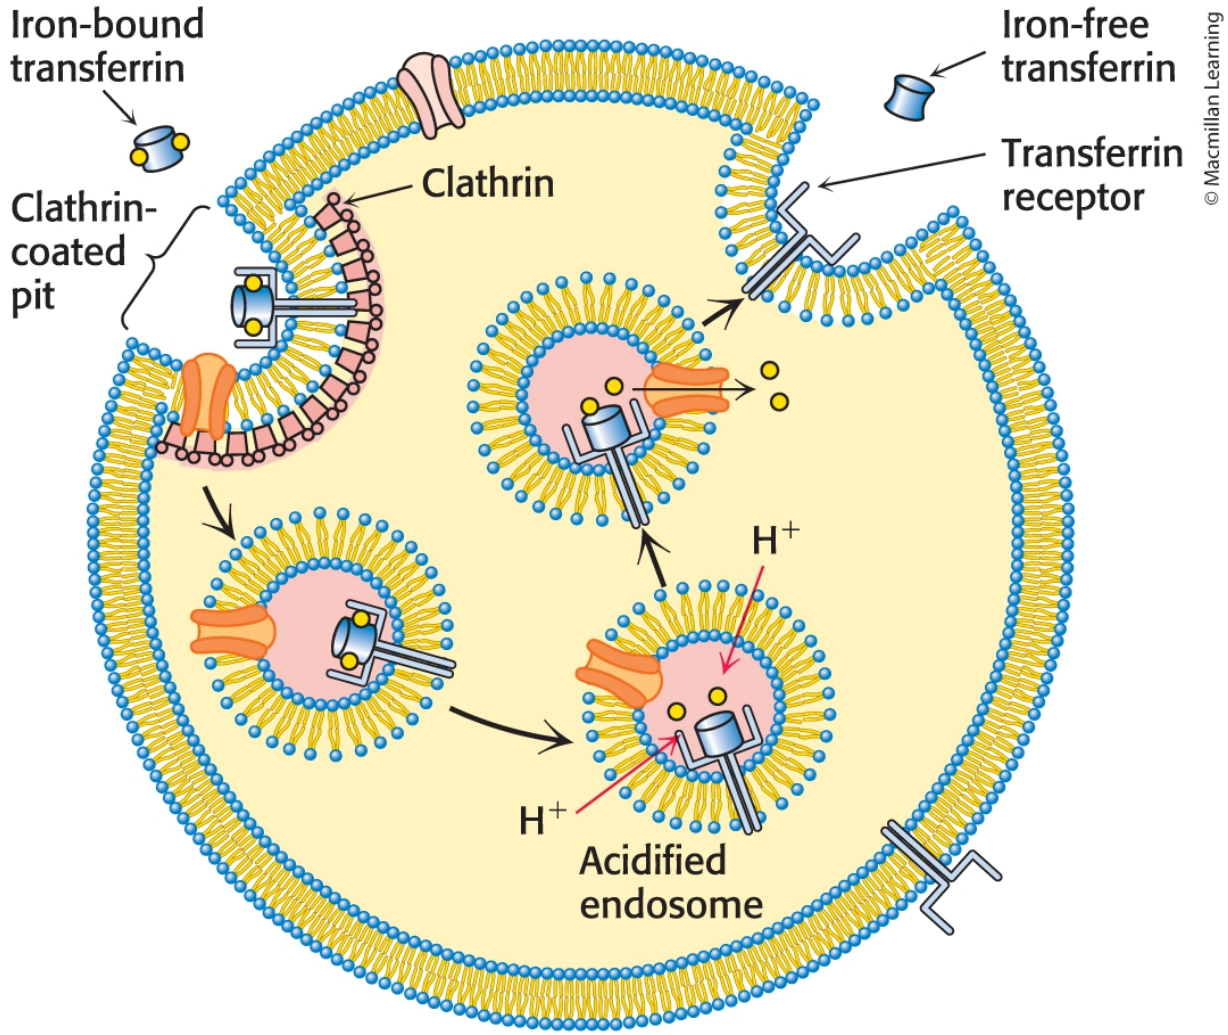


The figure shows photomicrographs of endocytosis on the top and corresponding steps of endocytosis below. The first photomicrograph shows the surface of the cell. In the second photomicrograph, the surface begins to invaginate slightly. In the third photomicrograph, the invagination becomes prominent. In the fourth photomicrograph, the neck of the invagination starts to get closer. In the fifth photomicrograph, the completely invaginated membrane appears as a sphere inside the cell.

The schematic illustration of the corresponding steps of endocytosis is shown below the photomicrographs. The lipid bilayer of the membrane consists of two parallel layers of lipids. Each lipid molecule is shown in a shorthand depiction. The yellow extensions of the shorthand depiction are aligned together and form the core of

the bilayer. The blue spheres are located away from each other. In the first step, the plasma membrane forms a slight invagination. A clathrin molecule attaches to the inner surface of the invagination. In the second step, the invagination becomes slightly deeper and the inner surface of the invagination is lined by a series of clathrin molecules. This invagination is labeled clathrin-coated pit. The clathrin molecule is depicted as a box-like structure fused to a sphere on the bottom left and bottom right. In the third step, the invagination becomes prominent. In the fourth step, the invagination becomes spherical and its neck is continuous with the membrane. Several spherical bead-like structures called dynamin zip the neck of the spherical invagination. In the fifth step, the dynamin spheres are released and a spherical structure surrounded by a lipid bilayer is released into the intracellular space.

Return to Schematic representation and photomicrographs of the steps of receptor-mediated endocytosis



Extended description for Fusion of vesicles to the plasma membrane to release neurotransmitter

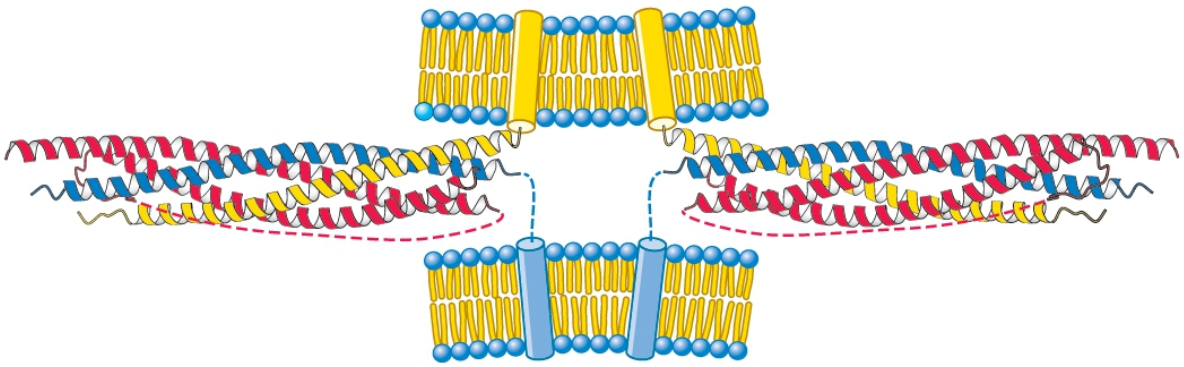
The figure has two parts. The first part shows the photomicrograph of two closely apposed cell membranes. Several spherical structures labeled synaptic vesicles are located close to the top membrane. The second part shows an elongated structure with a broad top having an inwardly curved surface. Its outline is labeled postsynaptic membrane. A bulb-like structure with an outline labeled presynaptic membrane sits in the depression of the postsynaptic membrane. The space between the presynaptic and postsynaptic membrane is labeled synaptic cleft. A downward arrow above the presynaptic membrane depicts the direction of nerve impulse. The presynaptic membrane contains several spheres labeled synaptic vesicles. A small invagination is present on the presynaptic membrane opposite the postsynaptic membrane to show the release of neurotransmitters into the synaptic cleft.

[Return to Fusion of vesicles to the plasma membrane to release neurotransmitter]

Extended description for Schematic illustration of receptor-mediated endocytosis of transferrin receptor and iron

A large circular cell surrounded by a lipid bilayer is shown. The bilayer contains a transferrin receptor and a protein channel. A clathrin-coated pit is created on the top left of the cell. In this pit, the lipid bilayer invaginates and the inner surface of the invagination is lined by a series of identical molecules. The protein channel is inserted into a portion of the invaginated bilayer. A short

cylindrical structure bound to a yellow sphere on either side is labeled “iron-bound transferrin”. The yellow spheres depict iron atoms. The iron-bound transferrin associated with the transferrin receptor in the clathrin-coated pit.



The pit forms a lipid vesicle having the protein channel and iron-bound transferrin associated with the transferrin receptor.

The lipid vesicle matures into an acidified endosome containing H superscript plus ions. This leads to the dissociation of yellow spheres from the transferrin protein.

The dissociated yellow spheres move into the cytoplasm through the protein channel in the endosomal membrane. The endosome then fuses with the lipid bilayer leading to the release of iron-free transferrin into the exterior and insertion of the transferrin receptor in the lipid bilayer.

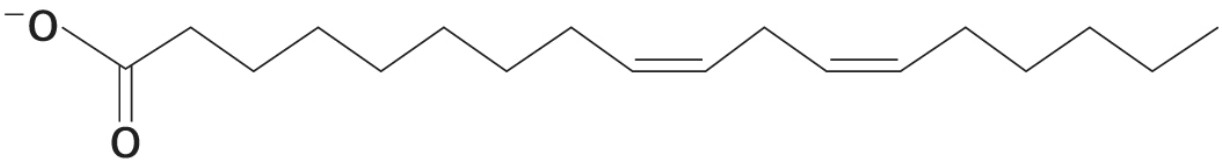
Extended description for Schematic illustration of the initiation of membrane fusion



© Macmillan Learning

Two sections of lipid bilayers are shown one above the other. They are separated by a gap. Two yellow vertical cylindrical structures separated by a small space are inserted in the top bilayer. The bottom surface of each of these cylindrical structures are connected to a long yellow alpha-helix. Two blue vertical cylindrical structures separated by a small space are inserted in the bottom bilayer. The top surface of each of these cylindrical structures are connected to a long blue alpha-helix. The blue cylinders in the bottom bilayer are aligned with the yellow cylinders in the top bilayer. The blue and yellow helices form two tight bundles with two red alpha-helices.

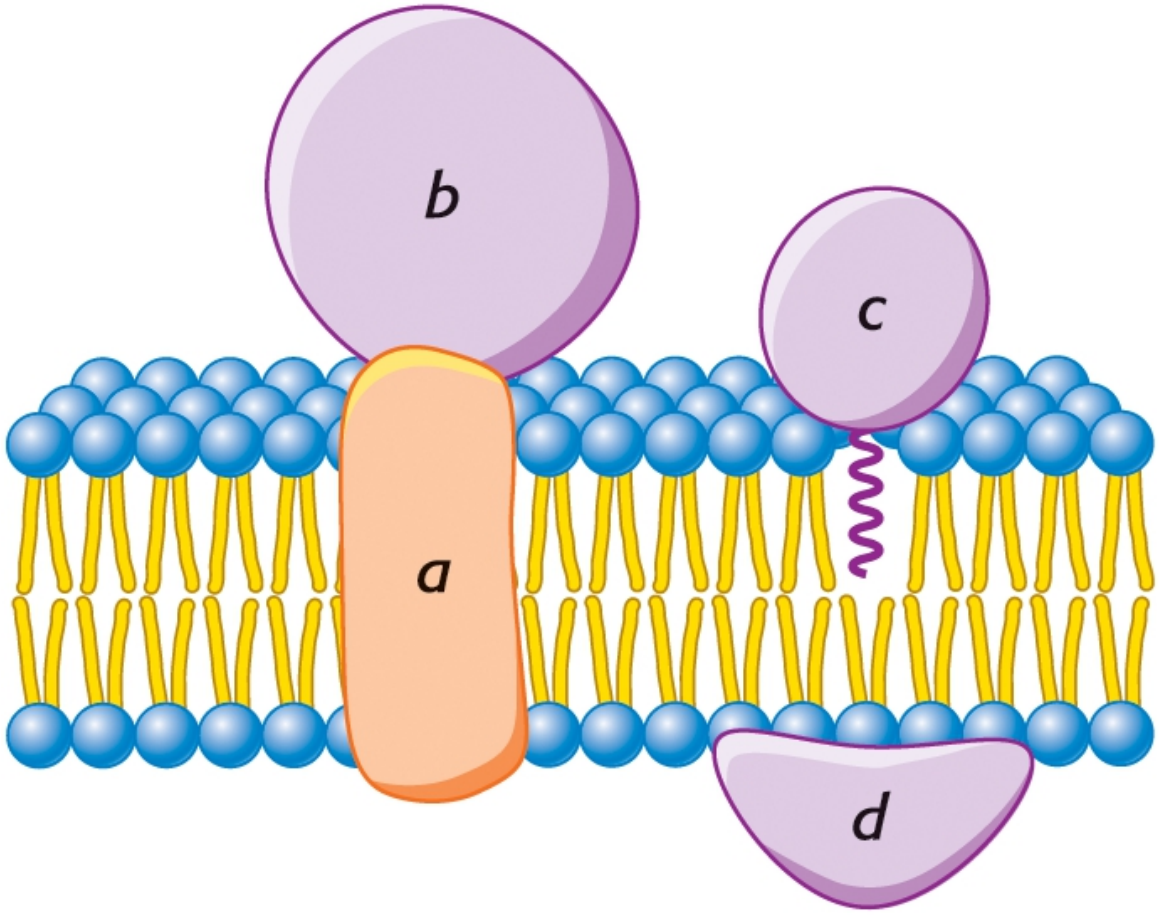
Extended description for Chemical structure of a fatty acid

The structure of the fatty acid is as follows: A 18-carbon alkene chain is depicted as a line structure using 17 zigzag lines. A double bond is present between C 9 and C 10, C 12 and C 13. C 1 is single bonded to O superscript minus on the upper left and double bonded to O below.

Return to Chemical structure of a fatty acid

Extended description for Chemical structure of platelet-activating factor (P A F)

Platelet-activating factor (PAF)



The structure of the platelet-activating factor is as follows: A central P atom is partially double bonded to O on the upper left, partially double bonded to O on the upper right, single bonded to O on the lower left, and single bonded to O on the lower right. Both the partially double-bonded O atoms have an overall negative charge. The O atom on the lower left is single-bonded to C H 2 in the form of a line on the left. This C H 2 is single bonded to C on the upper left. This C atom is wedge bonded to H on the lower left, dash bonded to O on the upper left, and single bonded to C H 2 above in the form of a line. The C H 2 group is single-bonded to O on the upper left. This O atom is single bonded to open bracket C H 2 close bracket with subscript 15 C H 3 on the left. The dash bonded O atom is single bonded to C on the lower left. This C atom is single bonded to C H 3 on the upper left and double bonded to O below.

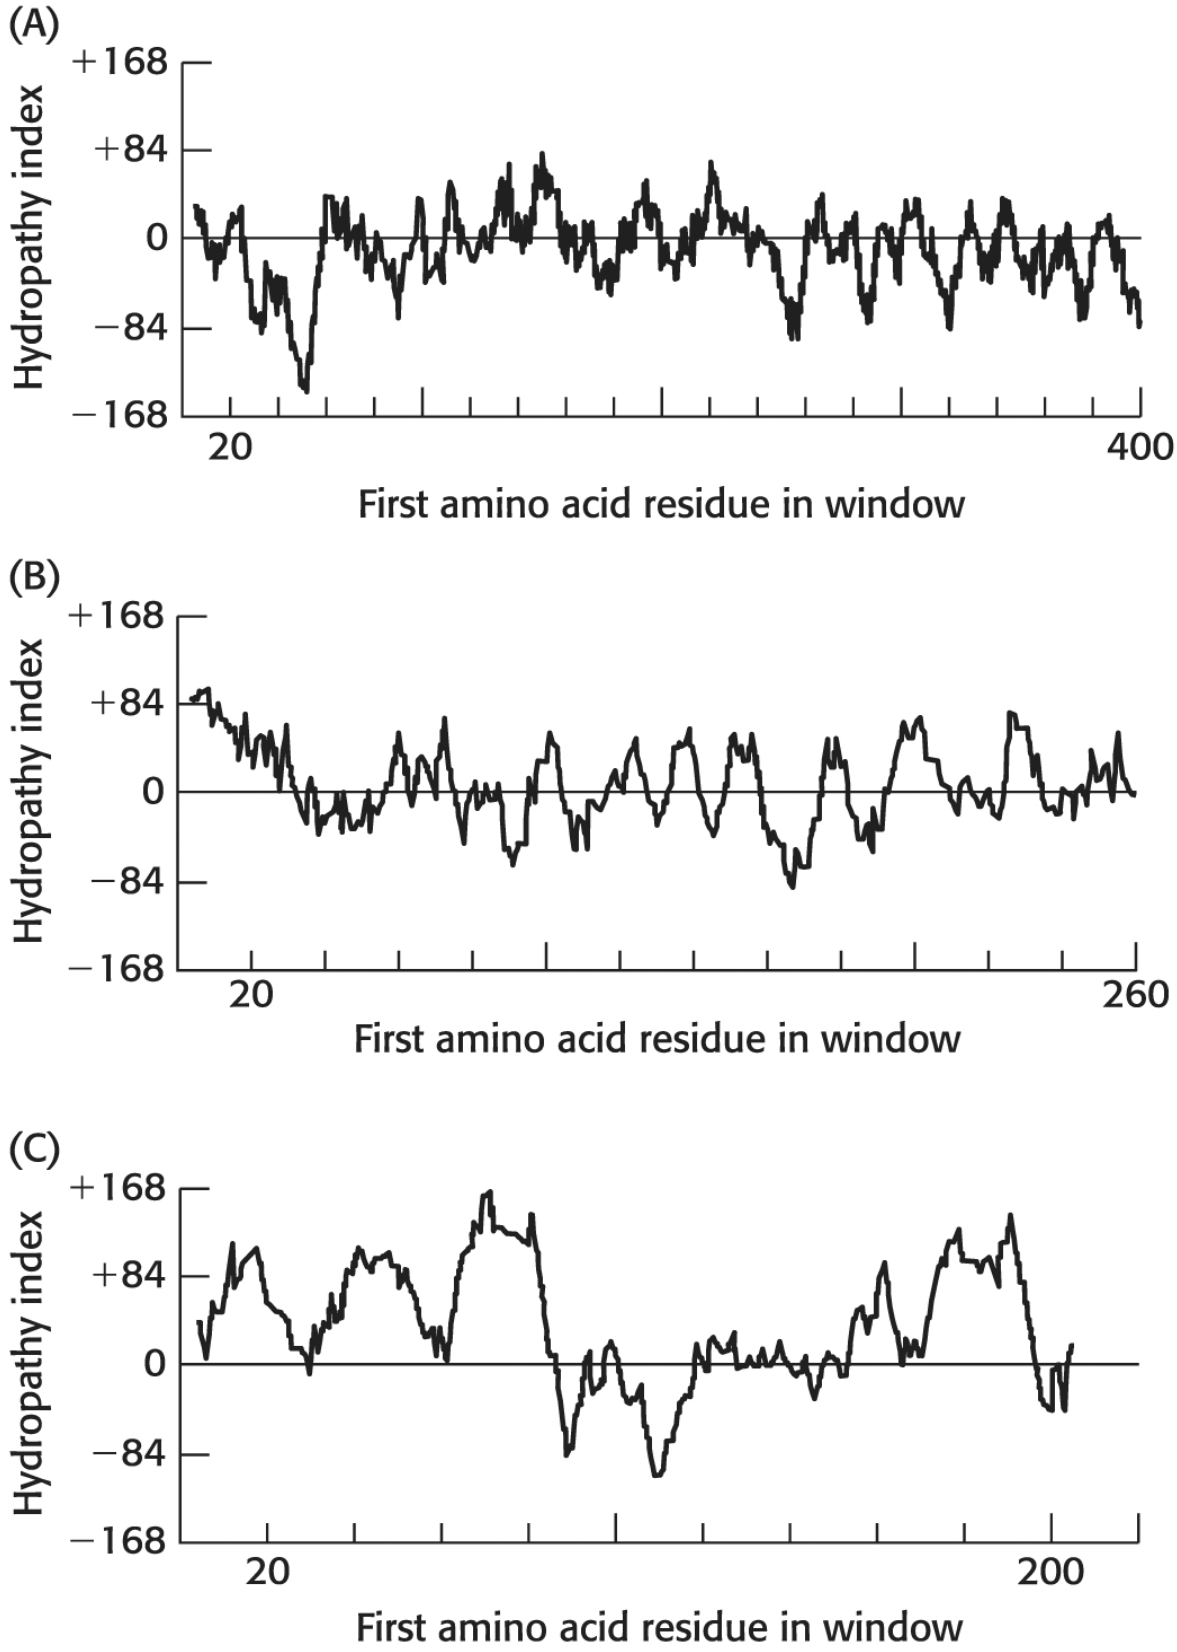
The O atom on the lower that is right single bonded to P is further single bonded to a 2 carbon alkane chain depicted as a line structure

using a line. C 2 of this chain is single bonded to N superscript plus open bracket C H 3 close bracket with subscript 3 on the upper right.

Return to Chemical structure of platelet-activating factor (P A F)

Extended description for Different ways in which membrane proteins interact with lipid bilayers

© Macmillan Learning



The lipid bilayer consists of two horizontally parallel layers of lipids. The upper layer consists of three rows of lipid molecules packed together compactly. Each lipid molecule is shown in a shorthand depiction. The yellow extensions of the shorthand depiction are aligned together and form the core of the bilayer. The blue spheres are located away from each other. The lipid bilayer shows four membrane proteins. The first membrane protein labeled "a" resembles a sausage and traverses the bilayer but does not extend above and below the bilayer. The second spherical protein labeled

"b" is attached to the blue spheres of the outer leaflet of the lipid bilayer and protein a. The third protein labeled "c" s attached to the top surface of the lipid bilayer through a zigzag anchor that penetrates the core of the bilayer halfway through. The fourth protein labeled "d" has an inverted triangular shape. It is attached to the lower surface of the lipid bilayer.

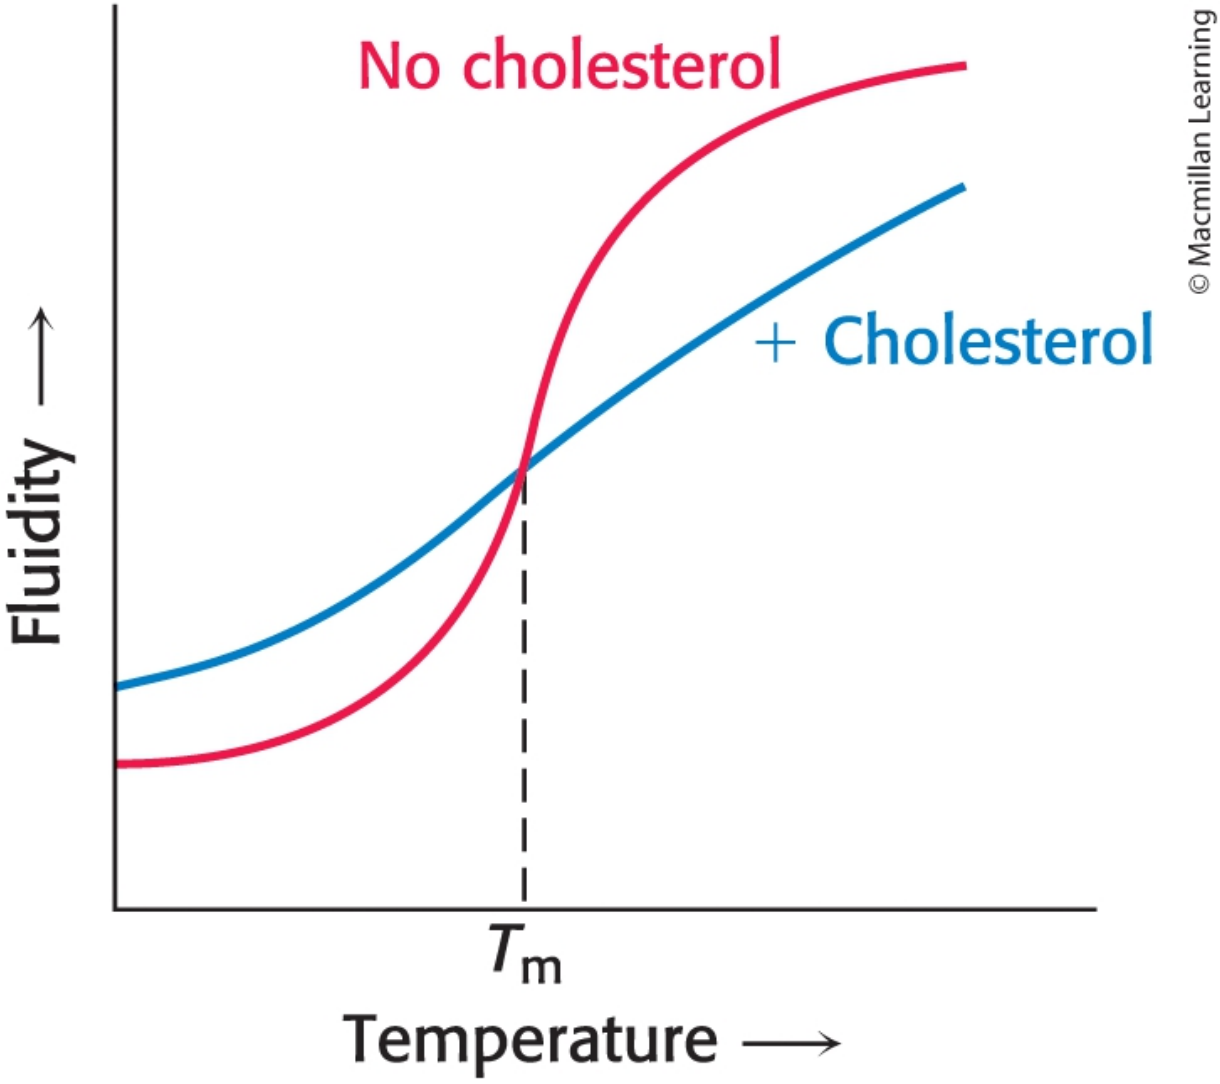
Extended description for Hydropathy plots of different

proteins A, B, and C

© Macmillan Learning

Hydropathy plot for protein A: The horizontal axis is labeled first amino acid in window. It has markings 20 and 400. 20 is on the extreme left and 400 is on the extreme right. The vertical axis is labeled hydropathy index. It has markings ranging from negative 168 to positive 168 in increments of 84 units. The graph shows a horizontal line parallel to the horizontal axis starting from 0 on the vertical axis. The graph shows a line forming series of peaks and depressions without any strong peaks. It starts at (0, 40) and shows a gradual downward fall to reach (50, negative 158) and again rises upward to (60, 20). It then moves toward the right and forms several peaks and depressions. Several sharp falls are seen at (260, negative 90), (290, negative 84), (320, negative 84), (380, negative 70). The line terminates at (400, minus 80). All values are approximated.



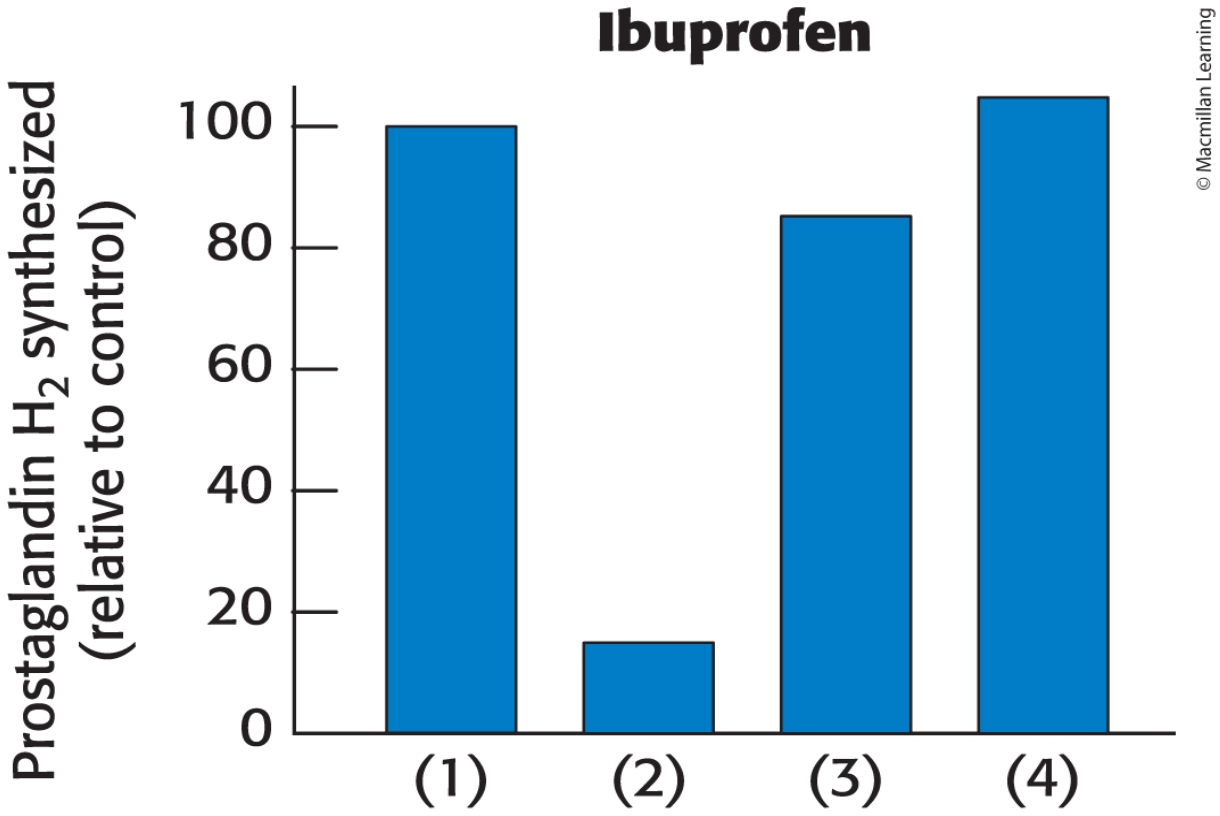
Hydropathy plot for protein B: The horizontal axis is labeled first amino acid in window. It has markings 20 and 400. 20 is on the extreme left and 260 is on the extreme right. The vertical axis is labeled hydropathy index. It has markings ranging from negative 168 to positive 168 in increments of 84 units. The graph shows a horizontal line parallel to the horizontal axis starting from 0 on the vertical axis. The graph shows a line forming series of peaks and depressions without any strong peaks. It starts from (0, 84) shows a gradual downward fall to reach (40, negative 40). It again rises upward to (75, 70) and then moves toward the right. It forms several peaks and depressions and terminates at (260, 0). All values are approximated.

Hydropathy plot for protein C: The horizontal axis is labeled first amino acid in window. It has markings 20 and 200. 20 is on the extreme left and 200 is on the extreme right. The vertical axis is labeled hydropathy index. It has markings ranging from negative 168 to positive 168 in increments of 84 units. The graph shows a horizontal line parallel to the horizontal axis starting from 0 on the vertical axis. The graph shows a line forming series of peaks and

depressions without any strong peaks. It starts from (10, 0) and shows an upward rise to (20, positive 90). It again falls downward to (30, 0). It then moves toward the right and forms several peaks and depressions. Sharp falls are seen at (90, negative 84), (110, negative 84), and terminates at (200, minus 0). All values are approximated.

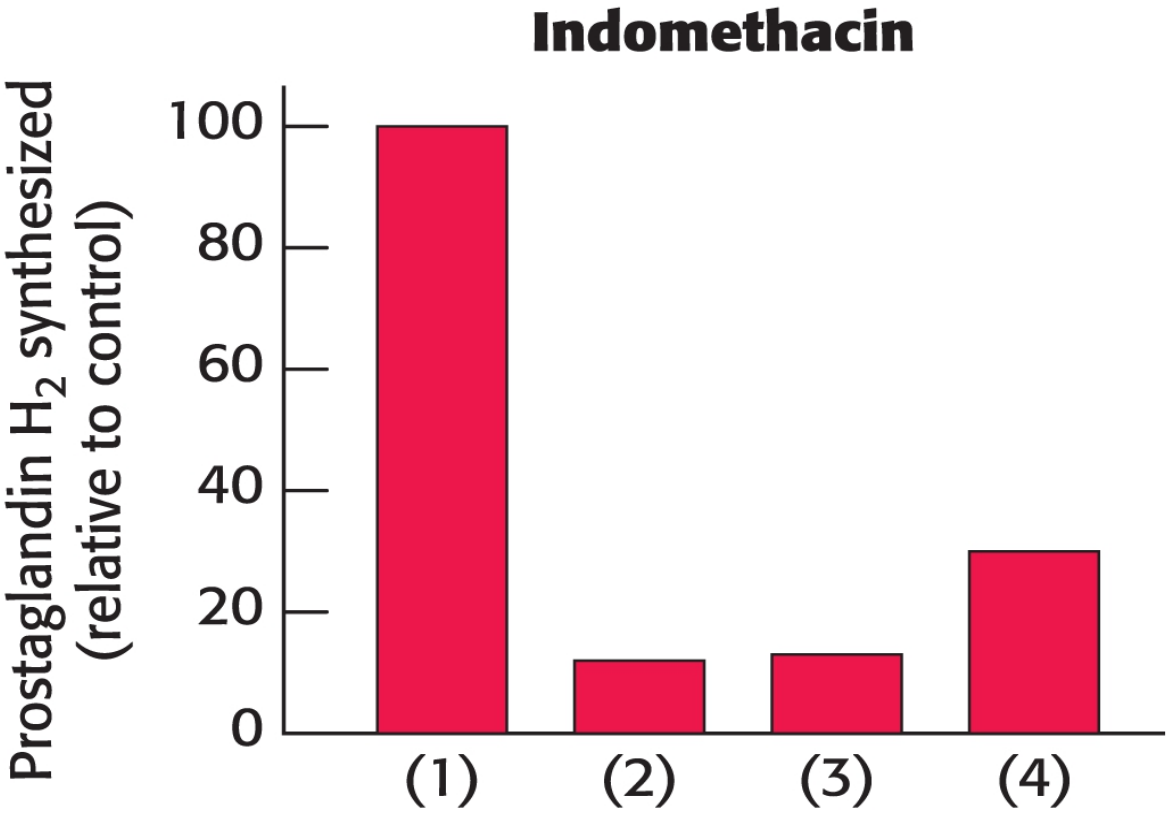
Return to Hydropathy plots of different proteins A, B, and C

Extended description for Graphical representation of the fluidity of fatty acids in a phospholipid bilayer as a function of temperature



The horizontal axis is labeled temperature which increases from left to right. The vertical axis is labeled fluidity which increases from bottom to top. An increasing blue line curve labeled plus cholesterol starts at a fluidity value below the mid point of the vertical axis. It gradually moves toward the upper right. A red S-shaped curve is

labeled no cholesterol. It start below the blue line and terminates above the blue line at the highest fluidity. A vertical dashed line is drawn from the point of intersection of the blue line curve and the red curve to the mid point of the vertical axis. This dashed line is labeled T subscript m.



Return to Graphical representation of the fluidity of fatty acids in a phospholipid bilayer as a function of temperature

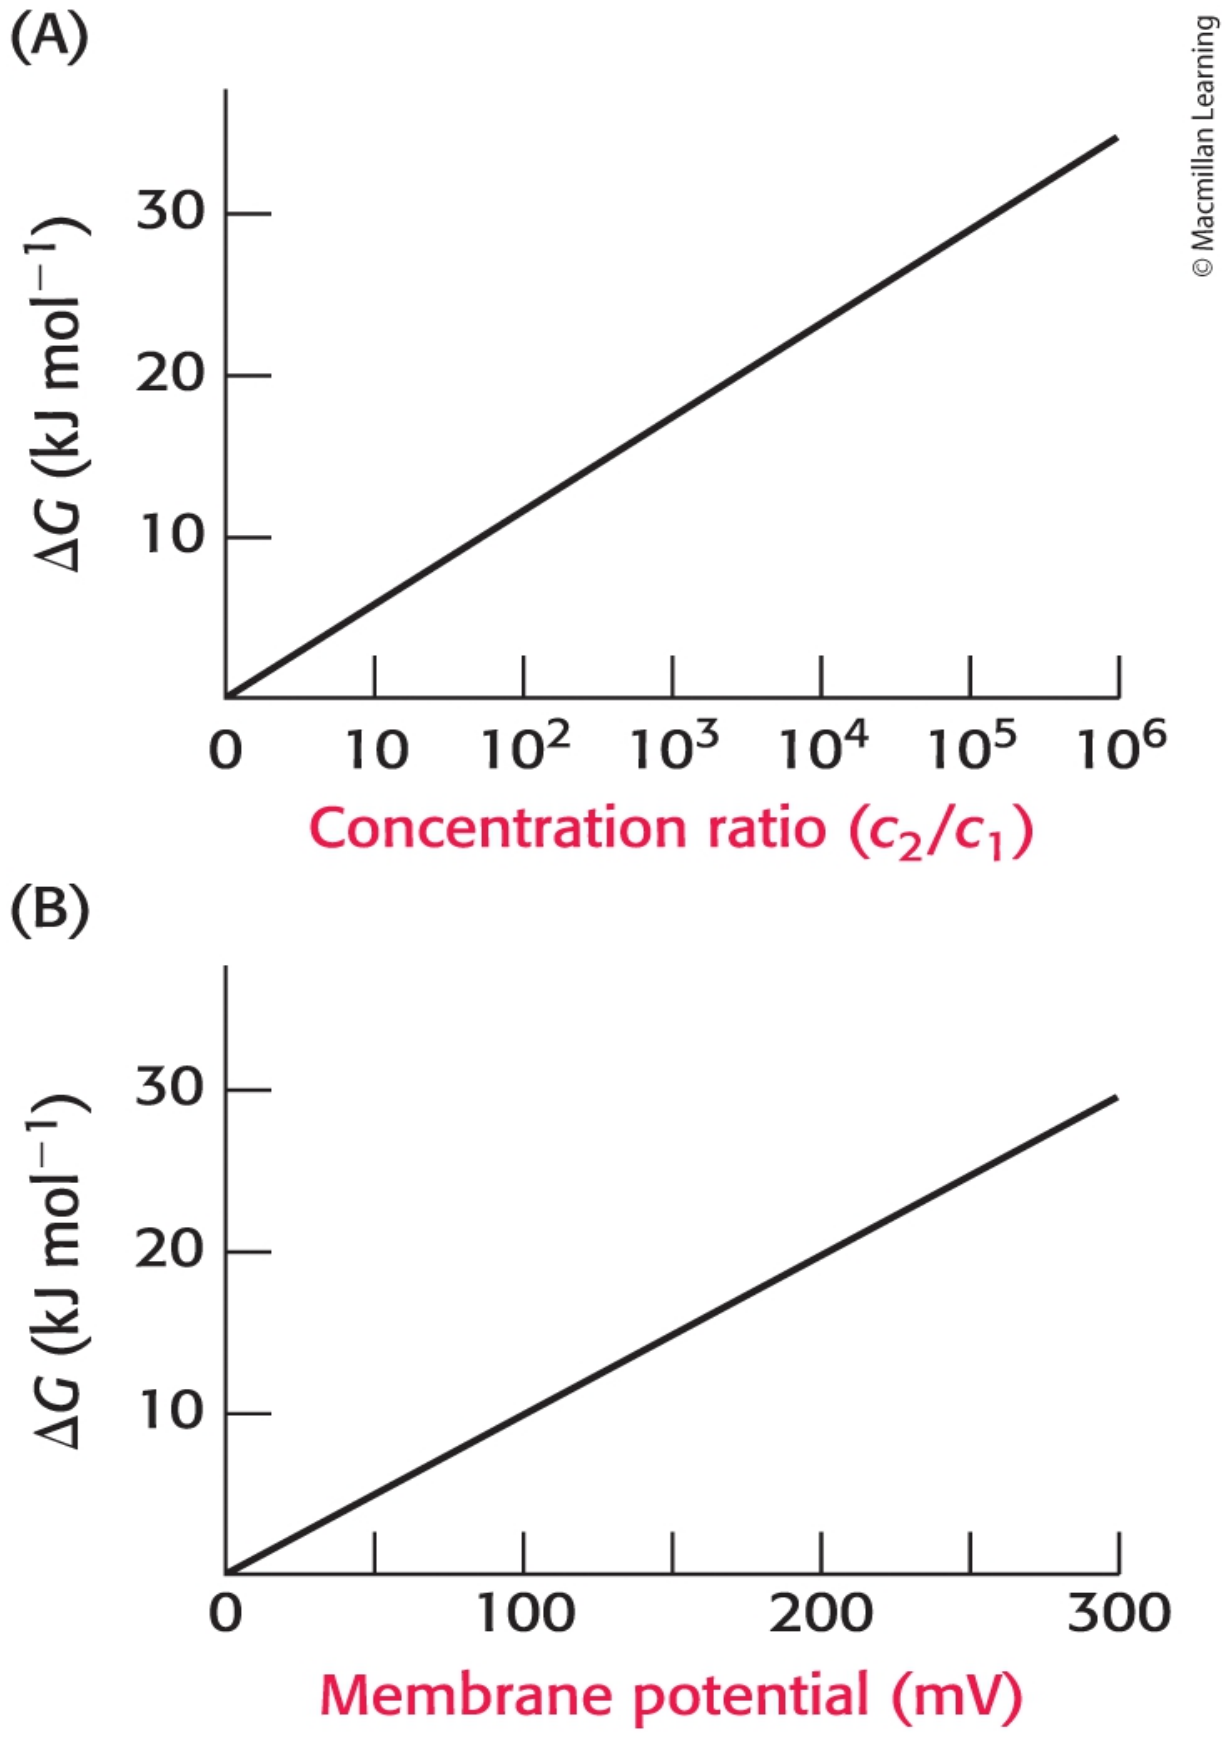
Extended description for Bar graphs depict the effect of ibuprofen and indomethacin on prostaglandin H 2

synthesis

© Macmillan Learning

The first bar graph is labeled as Ibuprofen. The horizontal axis has the markings (1), (2), (3), and (4). The vertical axis is labeled prostaglandin H 2 synthesized (relative to control). It has markings ranging from 0 to 100 in increments of 20 units. Four vertical bars are shown at (1),(2), (3), and (4). The coordinates of the vertical bars are as follows:

First bar: (1), 100; Second bar: (2), 18; Third bar: (3), 82; Fourth bar: (4), 120.



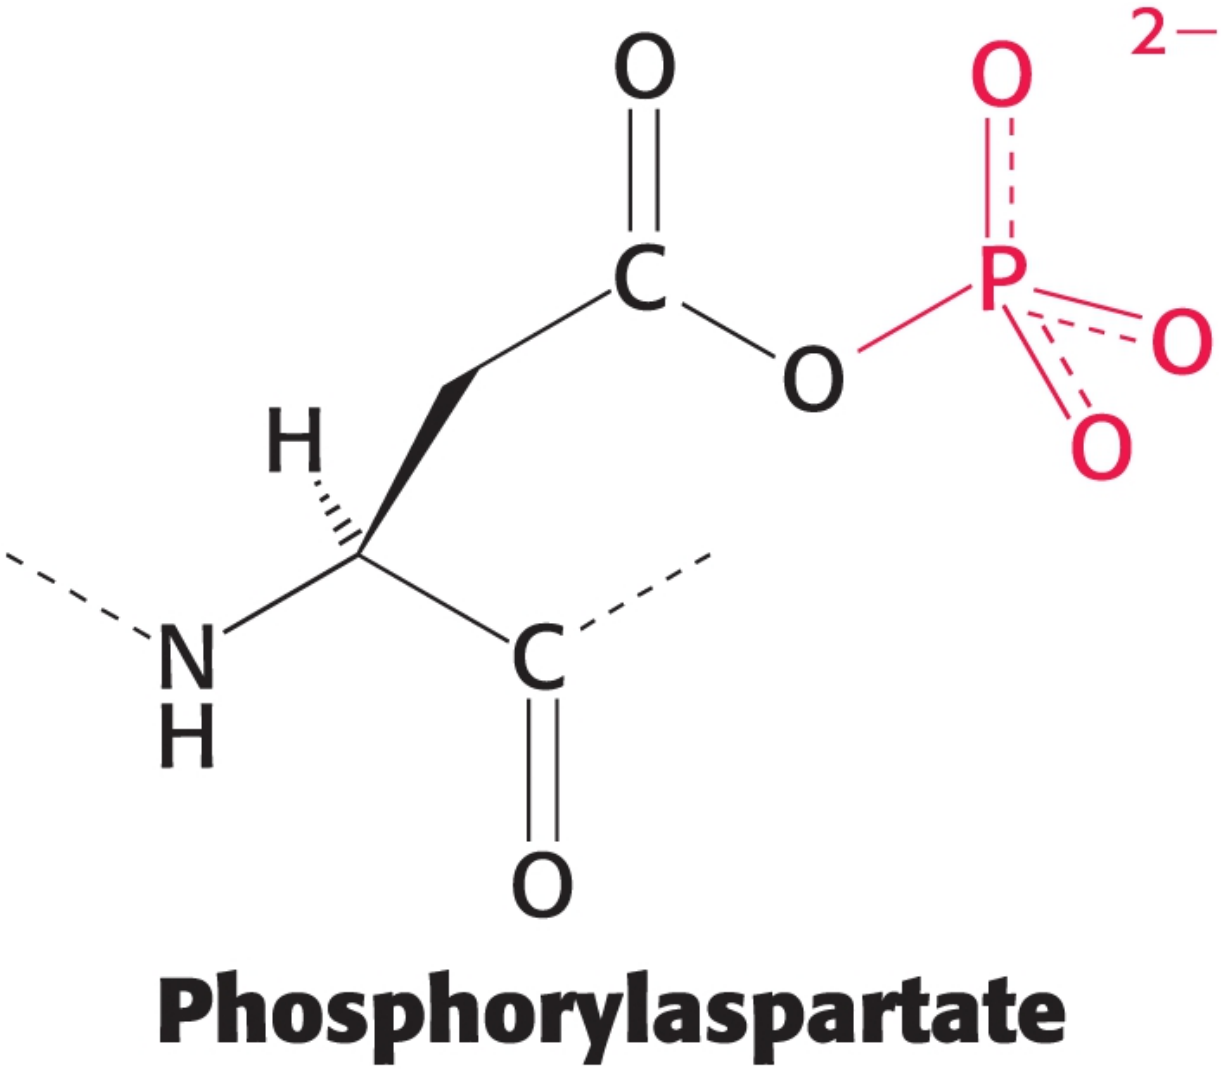
The second bar graph is labeled as Indomethacin. The horizontal axis has the markings (1), (2), (3), and (4). The vertical axis is labeled prostaglandin H 2 synthesized (relative to control). It has markings ranging from 0 to 100 in increments of 20 units. Four vertical bars are shown at (1), (2), (3), and (4). The coordinates of the vertical bars are as follows:

First bar: (1), 100; Second bar: (2), 10; Third bar: (3), 12; Fourth bar: (4), 30.

Return to Bar graphs depict the effect of ibuprofen and indomethacin on prostaglandin H 2 synthesis

Extended description for Two graphs depict the variation of free energy as a function of concentration

ratio and membrane potential respectively



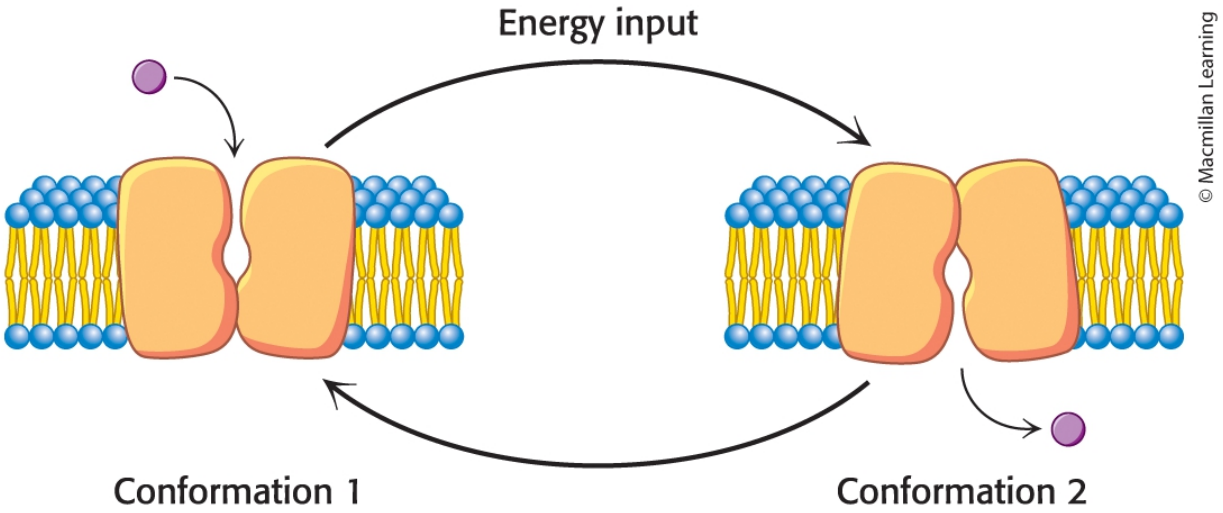
© Macmillan Learning

Graph (A): The horizontal axis is labeled concentration ratio (C 2 over C 1). It has markings ranging from 0 to 10 superscript 6 in multiples of 10 units. The vertical axis is labeled delta G (k J per mole). It has markings ranging from 10 to 30 in increments of 10 units. An increasing straight line starts from (0, 0) and ends (10 superscript 6, 40).

Graph (B): The horizontal axis is labeled membrane potential (m V). It has markings ranging from 0 to 300 in increments of 100 units. The vertical axis is labeled delta G (k J per mole). It has markings ranging from 10 to 30 in increments of 10 units. An increasing straight line starts from (0, 0) and ends at (300, 30).

Return to Two graphs depict the variation of free energy as a function of concentration ratio and membrane potential respectively

Extended description for Chemical structure of phoshorylaspartate



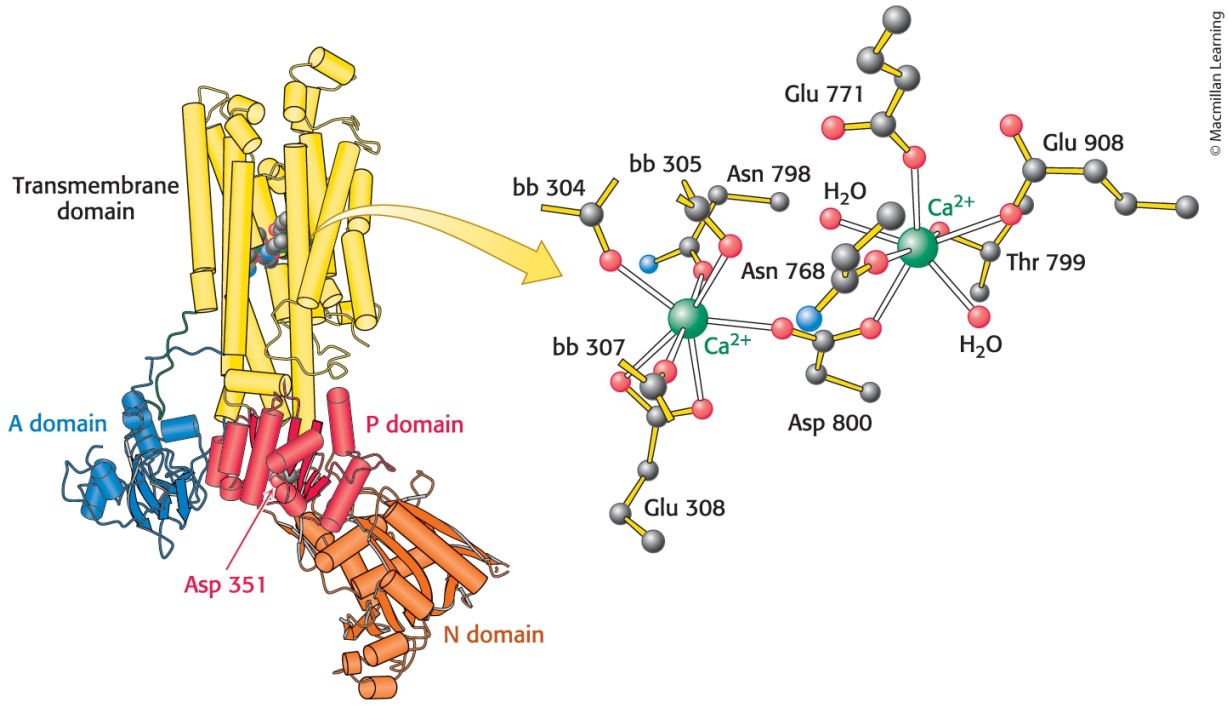
The structure of phosphorylaspartate is as follows: A 1 O, 1 C, and 1 P heteronuclear alkane chain is depicted as a line structure using 2 zigzag lines. O occupies the second position. P occupies the third position. C 1 is double bonded to O above. P is partially double bonded to O above, O on the lower right, and O below. The P O O group carries an overall negative charge of 2 minus. C 1 is single

bonded to C H 2 on the lower left. The C H 2 group is wedge bonded to a central C atom. This C atom is dash bonded to H on the upper left, single bonded to N H on the lower left, and single bonded to C on the lower right. This C atom is double bonded to O below and has an open single bond on the upper right. The N atom also has an open single bond on the upper left.

Return to Chemical structure of phoshorylaspartate

Extended description for Schematic representation of a conformational change of pump proteins during transport of a molecule

Conformation 1: A pair of integral membrane proteins are shown to span across a lipid bilayer. A groove is located at the center of the proteins that can accommodate a tiny circular molecule. A narrow channel is created between the top portion of the proteins to allow the entry of the molecule into the groove. The bottom portions of the proteins are attached tightly together.



An energy input causes a conformational change to conformation 2

Conformation 2: The molecule is released into another side of the lipid bilayer. The top portion of the proteins is attached tightly together. A narrow channel is created between the bottom portion of the proteins to allow the release of the molecule from the groove.

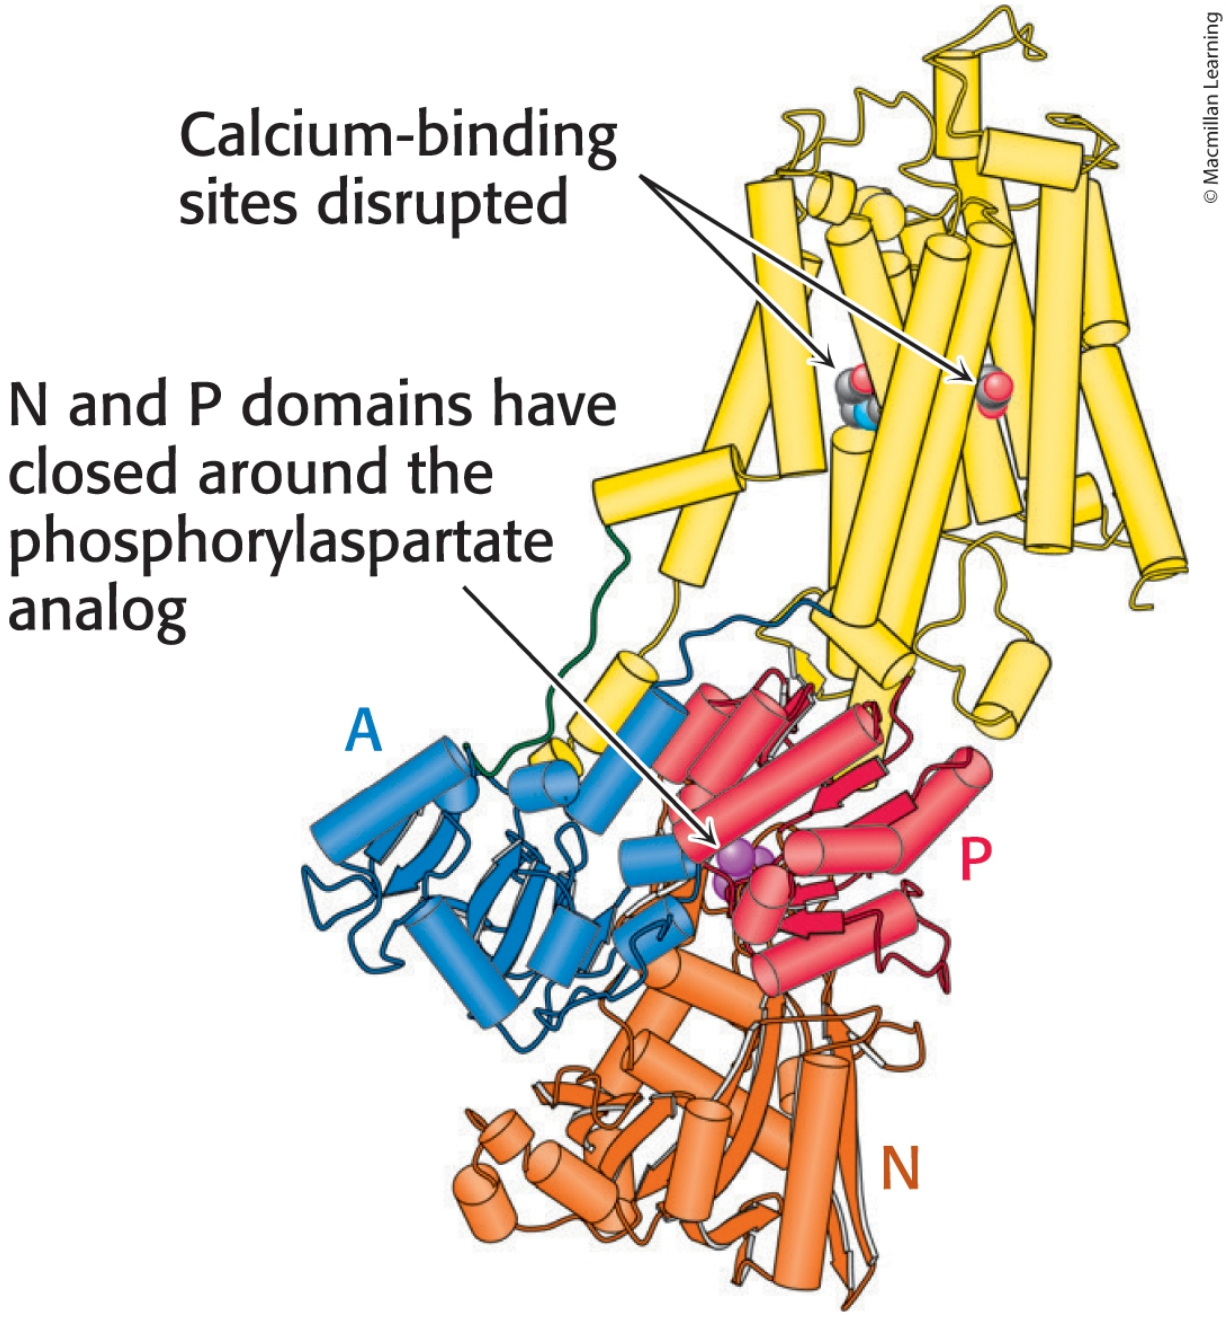
The proteins again under a conformational change to conformation 1.

Return to Schematic representation of a conformational change of pump proteins during transport of a molecule

Extended description for Schematic structure of S E R C A P-type A T P ase and the ball-and-stick model of amino acid residues in the transmembrane domain bound to calcium

The S E R C A P-type A T P ase is composed of 4 domains from top to bottom. These domains are the transmembrane domain, A domain, P domain, and N domain. A and P domains are located in the middle. The transmembrane domain consists of long and short cylindrical structures interconnected by thread-like loops. A cluster of spheres is shown in the center of the transmembrane domain. The A domain consists of short cylindrical structures and beta-strands interconnected by thread-like loops. The P domain consists of medium to short cylindrical structures and beta-strands interconnected by thread-like loops. A cluster of spheres located in the center of the P domain is labeled A s p 531. The N domain has

long, medium, and short cylindrical structures and a few beta-strands interconnected by thread-like loops. It is oriented toward the bottom right.



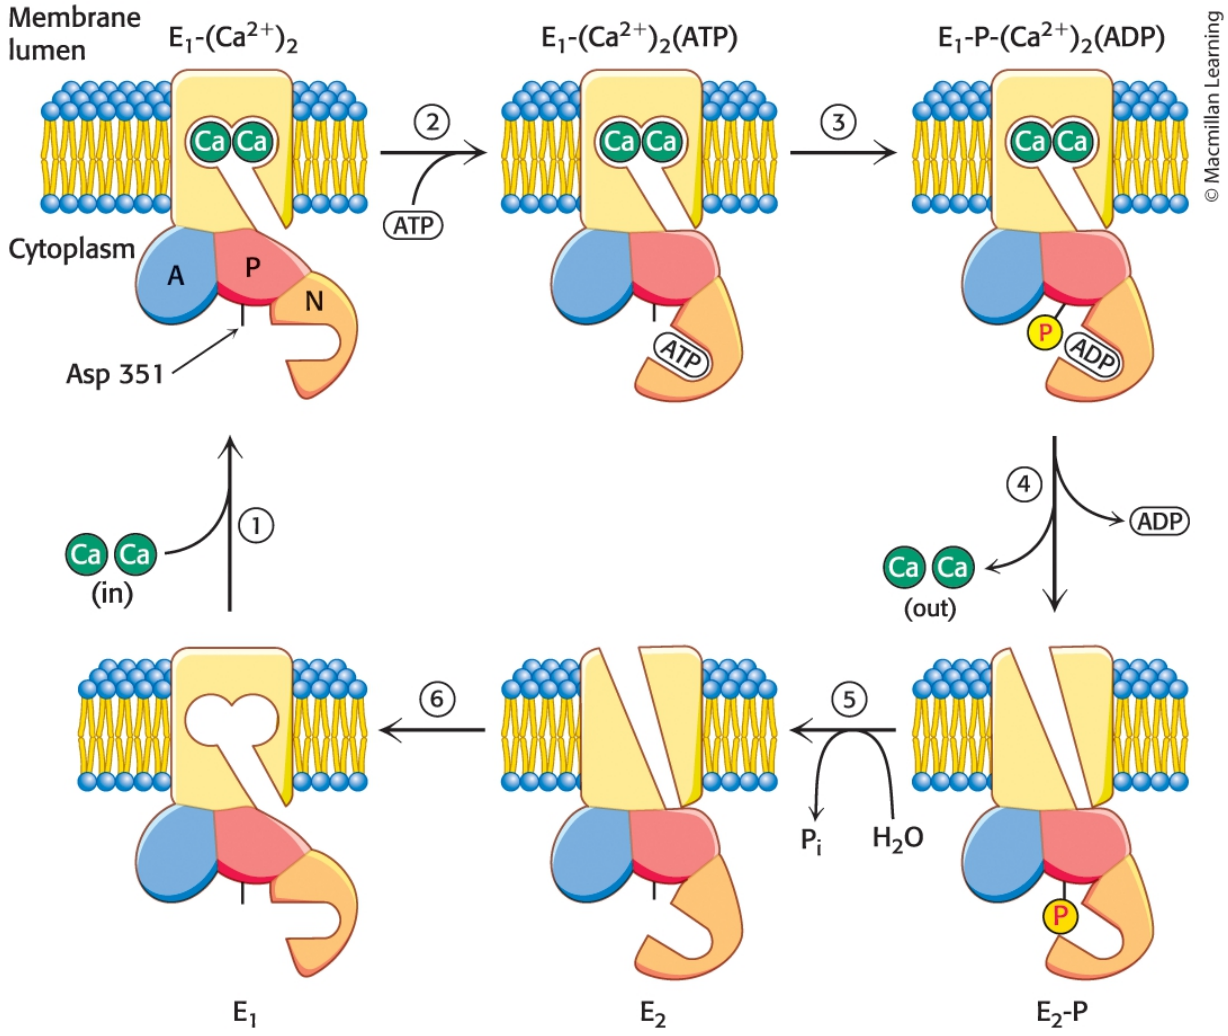
An arrow from the cluster of spheres in the center of the transmembrane points toward a ball-and-stick model. The model shows two C a superscript 2 plus ions connected to H 2 O, side chains of amino acid residues, and backbone carbonyl groups written as b b.

The first C a superscript 2 plus ion depicted as a green sphere is connected to a red sphere of G l u 771, G l u 908, T h r 799, H 2 O, A s p 800, A s n 768, and H 2 O in a clockwise direction starting from the top.

The second C a superscript 2 plus ion depicted as a green sphere is connected to a red sphere of A s n 798, a red sphere of b b 305, a red sphere of A s p 800, two red spheres of G l u 308, a red sphere of b b 307, and a red sphere of b b 304 in a clockwise direction starting from the top. A s n 798 and bb 305 are both oriented toward the upper right. G l u 308 and b b 307 are both oriented toward the lower left.

Return to Schematic structure of S E R C A P-type A T P ase and the ball-and-stick model of amino acid residues in the transmembrane domain bound to calcium

Extended description for Conformational change in the structure of S E R C A P-type A T P ase



The structure of the A T P ase is altered such that the calcium-binding sites in the transmembrane domain are disrupted. The

orientation of cylindrical structures in the transmembrane domain is altered. Two clusters of spheres are shown in the center of the domain. The clusters are separated by two diagonally oriented long cylinders. The A and P domains have become closer and surround a phosphorylaspartate analog in the center of P domain. The orientation of N domain is shifted toward the bottom from bottom right.

Return to Conformational change in the structure of S E R C A P-type A T P ase

Extended description for Conformational change of S E R C A during a catalytic cycle

S E R C A is inserted into a membrane through a square-shaped domain having a pair of circular grooves in the center and a narrow channel connected to it. The circular groove allows C a ion binding and the channel opens into the cytoplasm. The square-shaped domain is fused below to the A and P domains located in the cytoplasm. The A and P domains are fused sideways. The P domain

is fused to the N domain. The N domain has a wide groove to allow the binding of A T P.

The catalytic cycle is divided into 6 steps.

Step 1:

E 1-open parenthesis C a superscript 2 plus close parenthesis with subscript 2: Two C a ions enter and bind to the circular grooves in the transmembrane domain of S E R C A. The A s p 351 residue of the P domain is depicted as a short thick line.

Step 2:

E 1-open parenthesis C a superscript 2 plus close parenthesis with subscript 2 A T P: The circular grooves in the transmembrane domain of S E R C A are bound to two C a ions. The wide groove in the N domain is bound to an A T P molecule. This causes a conformational change in the N domain and shifts the side bound to A T P toward the A s p 351 residue.

Step 3:

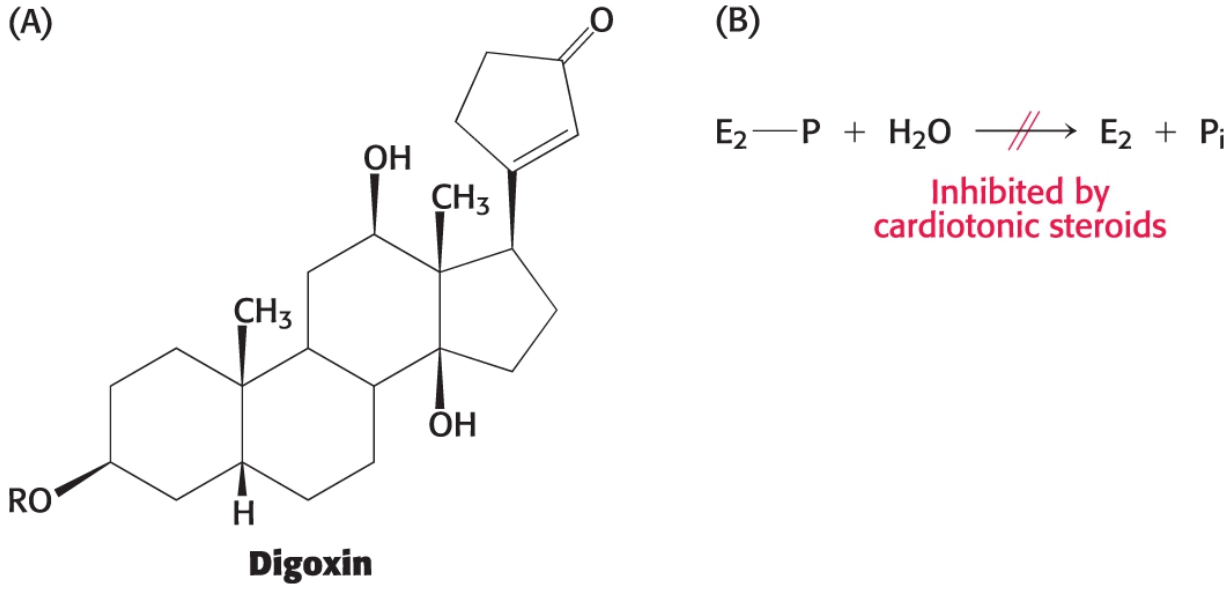
E 1-P-open parenthesis C a superscript 2 plus close parenthesis with subscript 2 A D P: The circular grooves in the transmembrane domain of S E R C A are bound to two C a ions. The wide groove in the N domain is bound to an A D Pmolecule. The A s p 351 residue of the P domain is phosphorylated.

Step 4:

E 2-P: The circular grooves of the transmembrane domain disappear as the two Ca ions are released. A diagonal channel is created in this

domain. The groove of the N domain also becomes empty as the A D P molecule is released. The N domain becomes attached to the phosphorylated A s p 351 residue.

Step 5:



E 2: H 2 O enters and P subscript i is released. The A s p 351 residue is dephosphorylated.

Step 6:

E 1: The pair of circular grooves connected to a narrow channel is created again in the transmembrane domain. The N domain shifts away from the P domain.

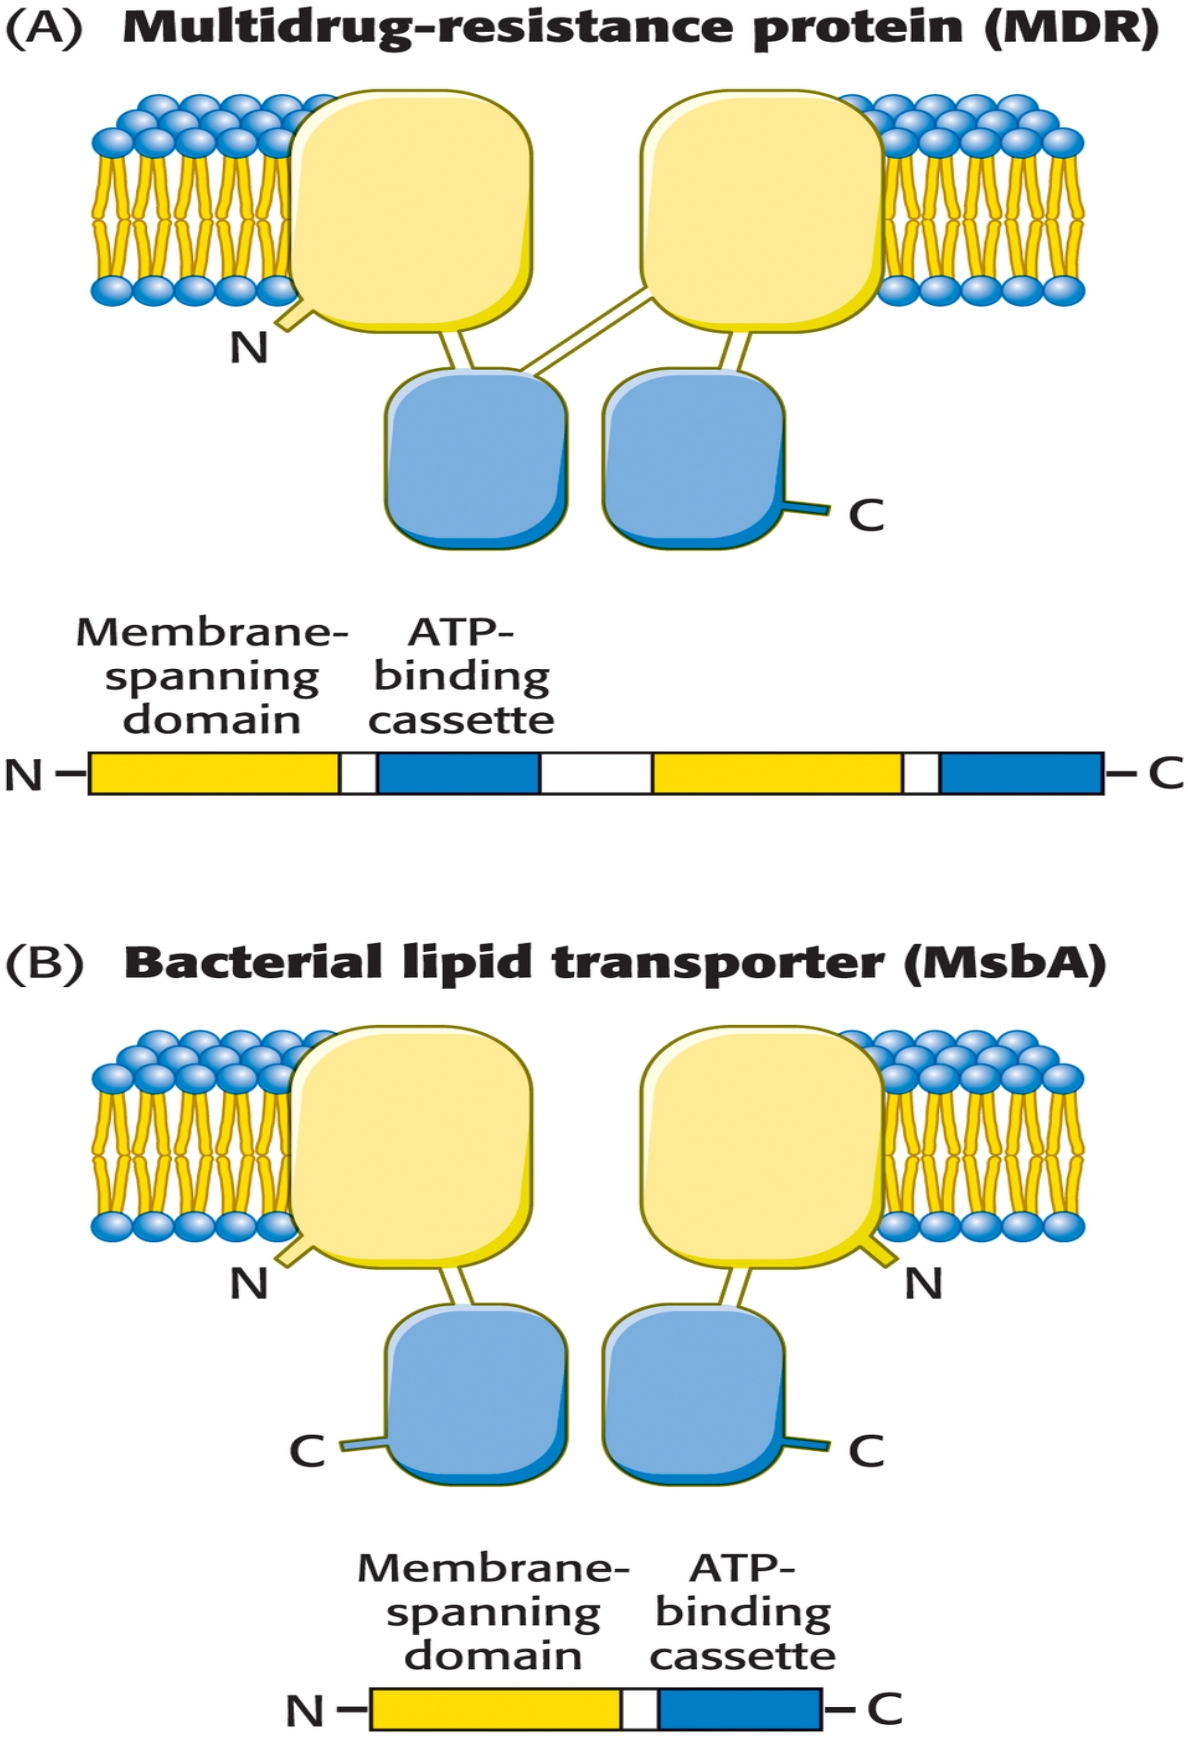
Return to Conformational change of S E R C A during a catalytic cycle

Extended description for Chemical structure of digoxin and chemical reaction inhibited by cardiotonic steroids

Part (A):

The structure of digoxin is as follows: A 6-carbon homocyclic hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. C 5 is wedge bonded to O R on the lower left. It is fused to a second 6-carbon homocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. In the second ring, C 5 is wedge bonded to H below and C 6 is wedge bonded to C H 3 above. The second ring is fused to a third 6-carbon homocyclic hexagonal ring in a vertical orientation such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. In the third ring, C 1 is wedge bonded to O H above. The third ring is fused to a 5-carbon homocyclic pentagonal ring in a horizontal orientation such that C 2 and C 3 of the third ring are C 4 and C 3 respectively of the pentagonal ring. C 3 is wedge bonded to O H below and C 4 is wedge

bonded to C H 3 above. C 5 is wedge bonded to C 3 of a 5-carbon homocyclic pentagonal ring in a vertical orientation. In the pentagonal ring, C 1 is double bonded to O on the upper right. A double bond is present between C 2 and C 3.



Part (B): The chemical reaction consists of two reactants and two products. The first reactant is E 2, single bond, P. The second reactant is H 2 O. A forward reaction arrow has two short and parallel red lines drawn across it. The red lines are labeled “Inhibited by cardiotonic steroids”. The first product is E 2. The second product is P subscript i.

Return to Chemical structure of digoxin and chemical reaction inhibited by cardiotonic steroids

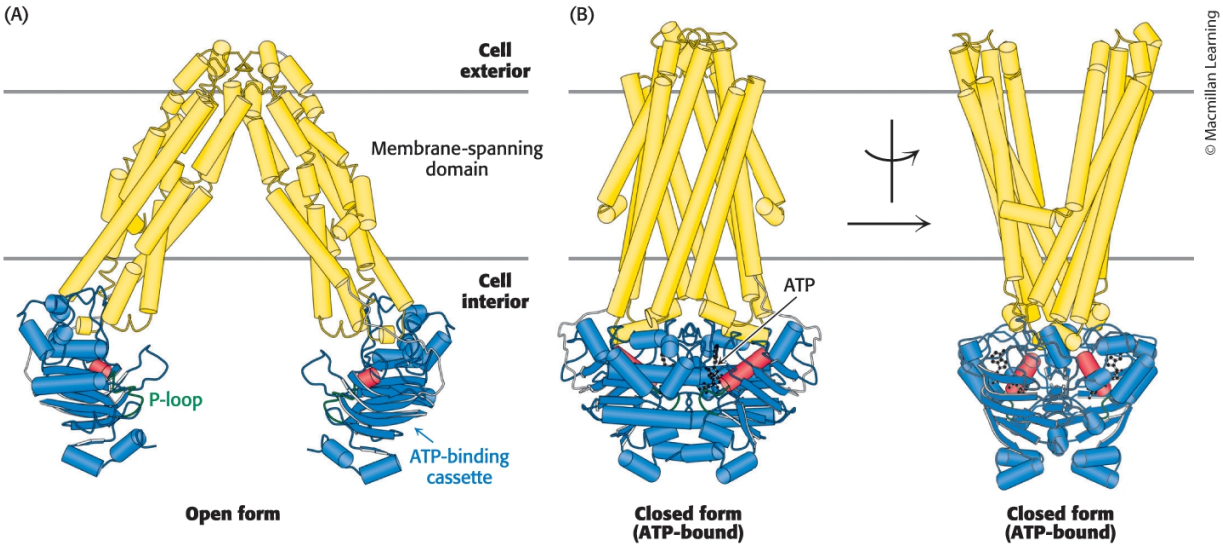
Extended description for Schematic structure of multidrug-resistance protein and bacterial lipid

transport protein

© Macmillan Learning

Part (A): Multidrug-resistance protein (M D R). M D R consists of two large square-shaped transmembrane domains. A tiny extension on the bottom left of the left transmembrane domain is labeled N. An extension from the bottom right of the left transmembrane domain and the bottom left of the right transmembrane domain are connected to a small blue square-shaped domain in the cytoplasm. An extension at the bottom of the right transmembrane domain connects it to another small blue square-shaped domain in the cytoplasm. This square-shaped domain has an extension on the bottom right labeled C.

A long and narrow horizontal rectangular structure is shown. Its left end is labeled N and the right end is labeled C. From N to C, the domains are colored as follows: yellow, white, blue, white, yellow, white, and blue. The yellow domains are longer than the blue domains. The white domains are the shortest. The yellow domain is labeled the membrane-spanning domain. The blue domain is labeled A T P-binding cassette.



Part (B): Bacterial lipid transporter (M s b A). M s b A consists of two large square-shaped transmembrane domains. A tiny extension on the bottom left of the left transmembrane domain is labeled N. An extension from the bottom right of the left transmembrane domain is connected to a small blue square-shaped domain in the cytoplasm. An extension at the bottom of the right transmembrane domain connects it to another small blue square-shaped domain in the cytoplasm. Both of these small square-shaped domains have an extension at the bottom labeled C.

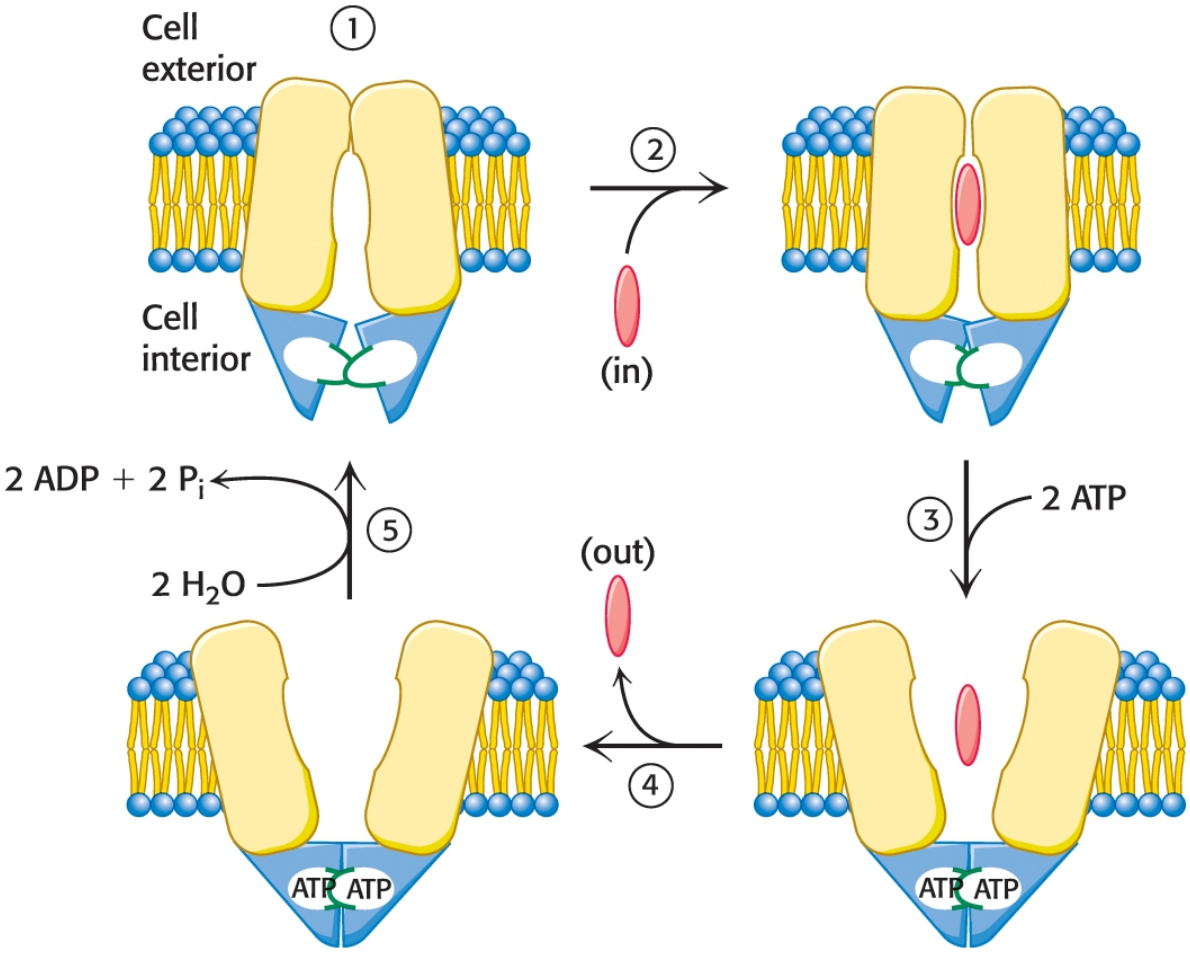
A long and narrow horizontal rectangular structure is shown. The left end is labeled N and the right end is labeled C. From N to C, the domains are colored as follows: Yellow, white, and blue.

The yellow domain is longer than the blue domain. The white domain is the shortest. The yellow domain is labeled the membrane-spanning domain. The blue domain is labeled A T P-binding cassette.

Return to Schematic structure of multidrug-resistance protein and bacterial lipid transport protein

Extended description for Open and closed forms of bacterial lipid transporter M s b A

Part (A) open form: Two horizontal lines separated by a large gap are shown. The region above the top line is labeled cell exterior. The region below the bottom line is labeled cell interior. An inverted V-shaped structure composed of short, medium, and long cylindrical structures pass the two horizontal lines. It extends into the cell exterior and interior. The region of this structure enclosed between the two lines is labeled membrane-spanning domain. In the cell interior, the extensions of the inverted structure are each bound to a small cluster of short and medium cylindrical structures and beta-strands interconnected by thread-like loops. A small loop from the left cluster is labeled P-loop. An arrow points toward an A T P-binding cassette in the right cluster.



Part (B): It shows two views of the closed-form of M s b A protein bound to A T P. In the first view, a cluster of diagonally orientated long and a few short cylindrical structures pass through the two horizontal lines. They extend in the cell exterior and interior. The

extension into the cell interior is bound to a large cluster of short and medium cylindrical structures and beta-strands interconnected by thread-like loops. An A T P molecule is bound to the center of this cluster.

The first view is rotated by 90 degrees to get the second view. In the second view, an erect V-shaped structure composed of long cylindrical structures passes the two horizontal lines. It extends into the cell exterior and interior. The extension into the cell interior is bound to a large cluster of short and medium cylindrical structures and beta-strands interconnected by thread-like loops.

Return to Open and closed forms of bacterial lipid transporter M s b A

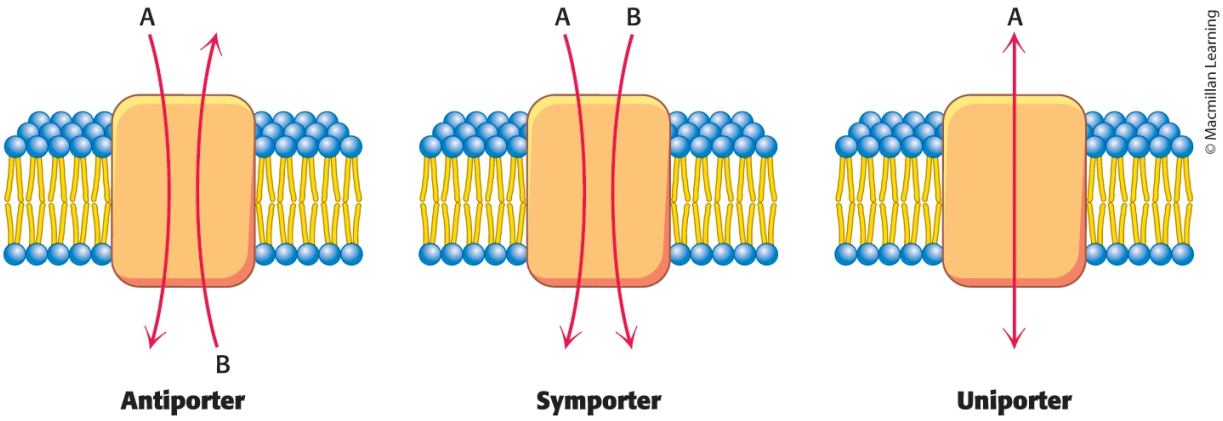
Extended description for Mechanism of transport of molecules by A B C transporters

© Macmillan Learning

The mechanism is divided into five steps as follows:

Step 1: A pair of large transmembrane domains are open toward the cell interior and closed toward the cell exterior. Each of the transmembrane domains is attached to a cytoplasmic domain having a wide empty groove. The grooves of the two cytoplasmic domains face each other.

Step 2: An oval-shaped molecule binds to a central groove formed between the transmembrane domains. This causes a conformational change as the transmembrane domains become closed at their intracellular region. The cytoplasmic domains also come closer.



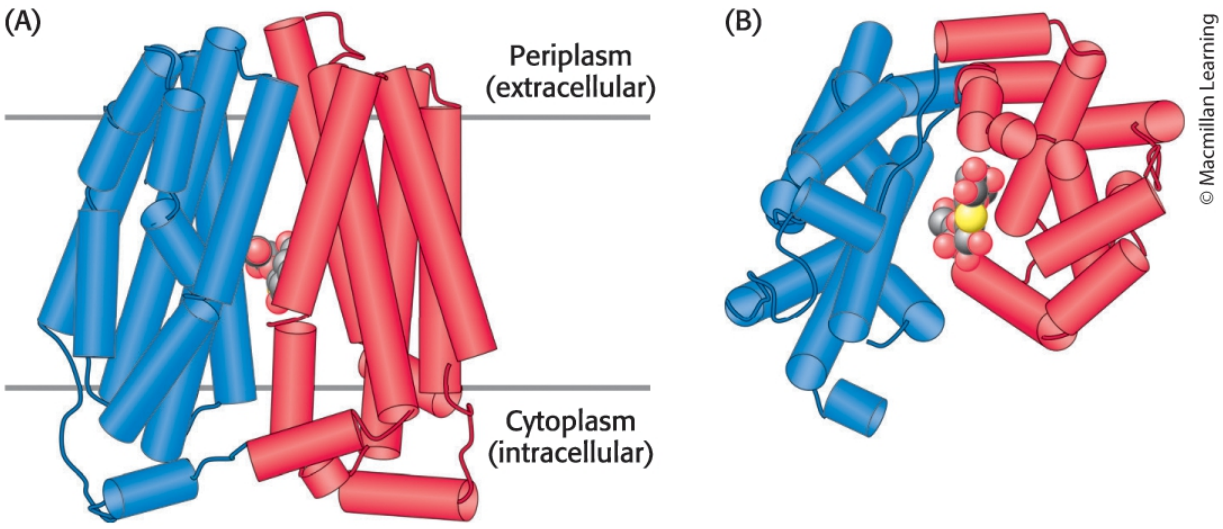
Step 3: 2 A T P molecules enter and bind to the grooves of the cytoplasmic domains. This causes a conformational change in the structure of the transmembrane domain such that it opens toward the cell exterior.

Step 4: The oval-shaped molecule is released from the central groove of the transmembrane domain. The A T P molecules are still bound to the groove of the cytoplasmic domains.

Step 5: 2 H 2 O molecules enter and 2 A D P plus 2 P subscript i are released.

Return to Mechanism of transport of molecules by A B C transporters

Extended description for Schematic representation of antiporter, symporter, and uniporter



Antiporter: A large rectangular transmembrane protein is shown. It passes through a lipid bilayer. A downward arrow across the protein shows the inward movement of “A”. An upward arrow across the protein shows the outward movement of “B”.

Symporter: A large rectangular transmembrane protein is shown. It passes through a lipid bilayer. Two downward arrows across the protein show the inward movement of “A” and “B”.

Uniporter: A large rectangular transmembrane protein is shown. It passes through a lipid bilayer. A double-headed vertical arrow passing across the protein shows the inward and outward movement of A.

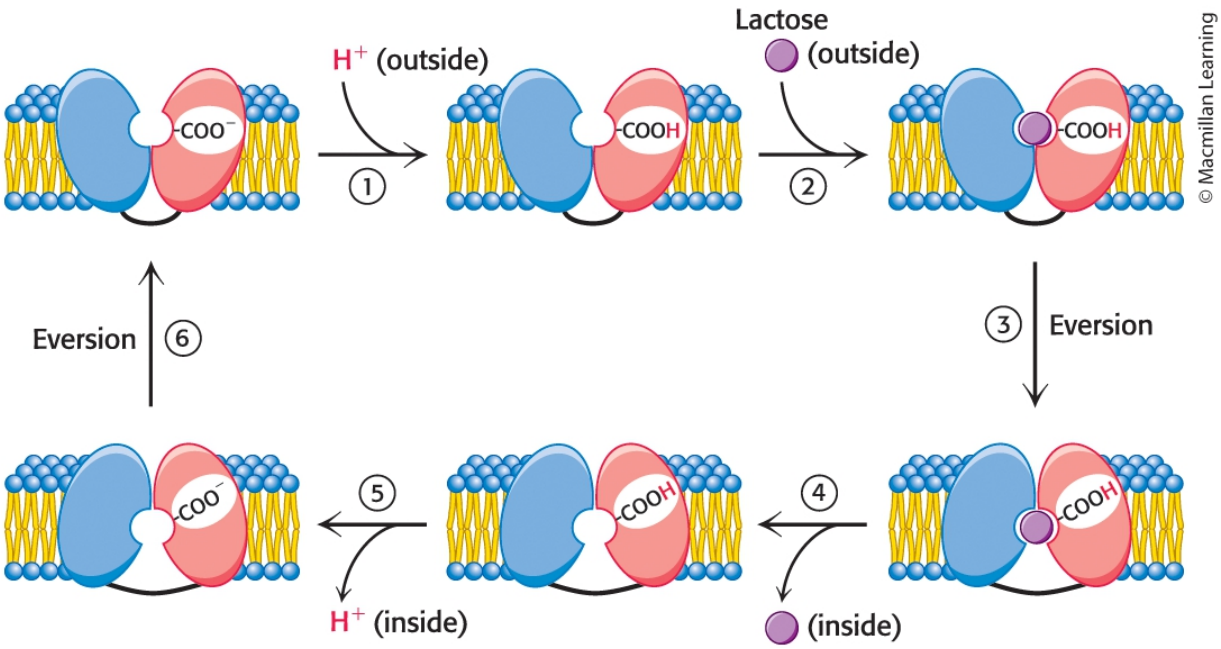
Extended description for Side view and bottom view of *E.coli* lactose permease



Part (A): Two horizontal lines separated by a large gap are shown. The region above the top line is labeled periplasm (extracellular). The region below the bottom line is labeled cytoplasm (intracellular). The lactose permease consists of a cluster of medium and long cylindrical structures passing through the gap between the two lines. They extend into the periplasm and cytoplasm. The cylindrical structures are connected by thread-like loops and a few medium cylindrical structures are located in the cytoplasm. The left half of the permease is colored blue and the right half is colored red.

Part (B): The bottom view shows a cluster of blue short and long cylindrical structures on the left and a cluster of red short and long cylindrical structures on the right. They surround a cluster of yellow, black, red, and grey spheres in the center.

Return to Side view and bottom view of *E.coli* lactose permease

Extended description for Mechanism of transport of lactose by lactose permease

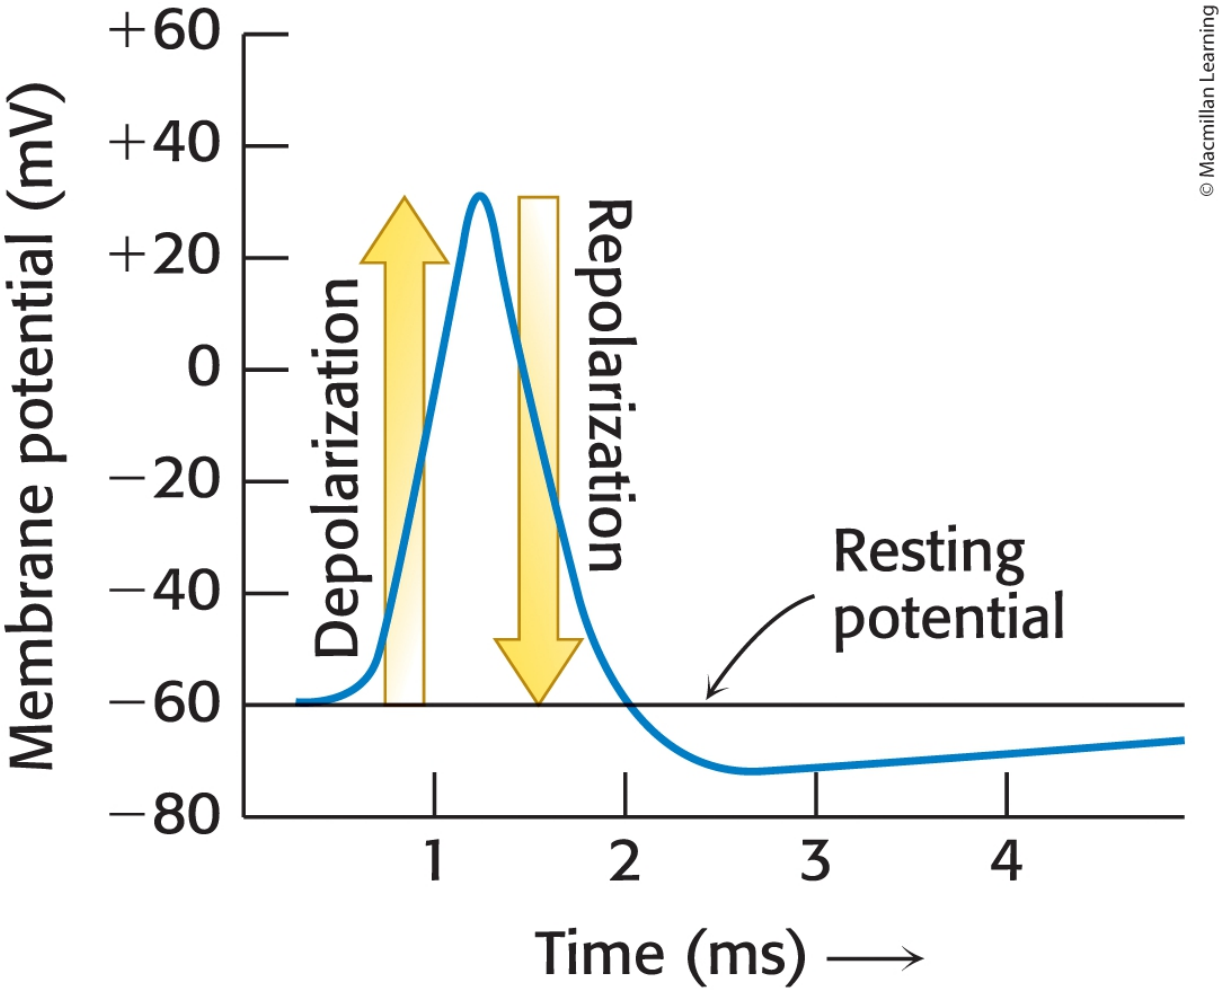
The mechanism is divided into six steps as follows:

Step 1: A pair of oval-shaped transmembrane proteins are embedded in a lipid bilayer. A central groove located between the two proteins forms a circular shape. The groove of the right transmembrane protein is single bonded to C O O superscript minus inside the protein. The paired transmembrane proteins form an open face at the external surface. An H superscript plus ion enters and binds to C O O superscript minus to form a C O O H group.

Step 2: A purple circle labeled lactose binds to the circular central groove.

Step 3: This step is labeled eversion. It shows a conformational change in the transmembrane proteins as they form an open face at

the cytoplasmic surface.



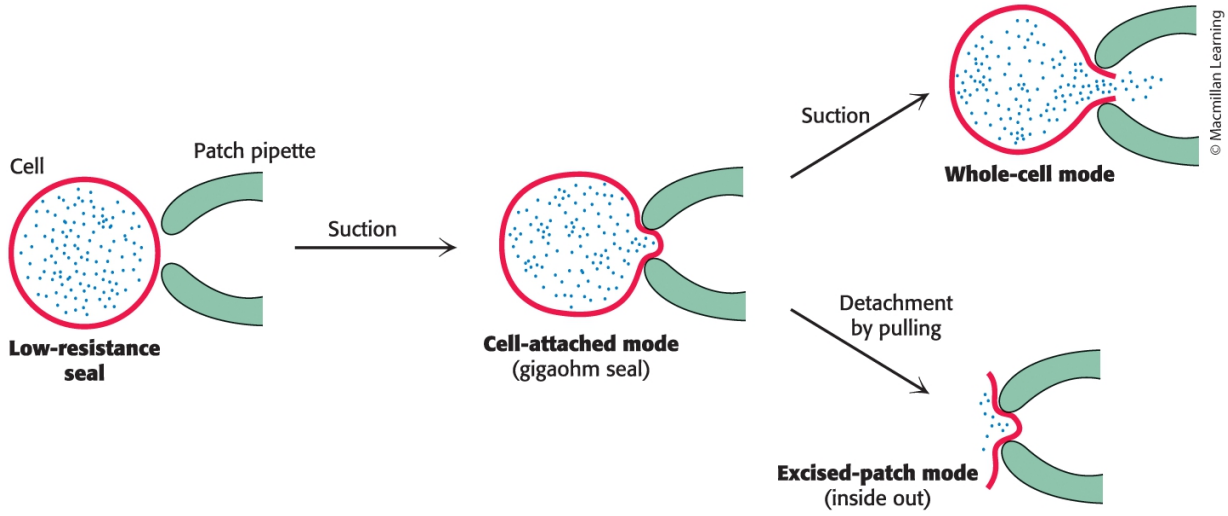
Step 4: The lactose molecule leaves the circular groove and moves inside.

Step 5: The H superscript plus ion leaves and a carboxylate group C O O superscript minus is formed again.

Step 6: This step is labeled eversion. It shows a conformational change in the transmembrane proteins as they form an open face at the external surface.

Return to Mechanism of transport of lactose by lactose permease

Extended description for Graphical representation of action potential



© Macmillan Learning

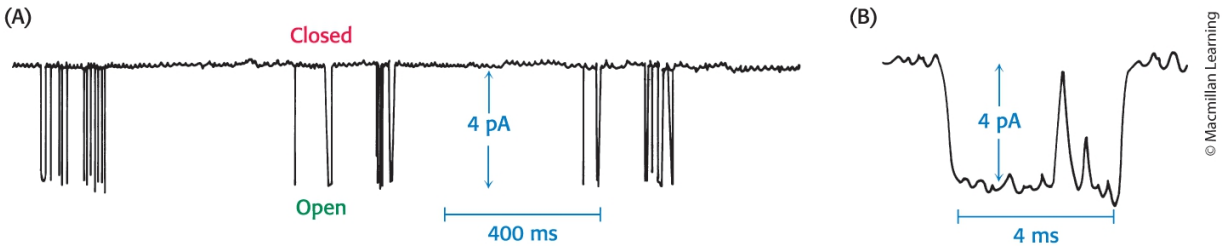
The horizontal axis is labeled time in milliseconds. It has markings ranging from 1 to 4 in increments of 1 unit. The vertical axis is labeled membrane potential in m V. It has markings ranging from negative 80 to positive 60 in increments of 20 units. A horizontal line parallel to the horizontal axis starts from negative 60 on the vertical axis. This line is labeled resting potential. A line curve starts at (0.4, negative 60) and shows upward movement to reach (1.3, positive 35). It then falls steeply to reach (2.5, negative 70) and continues moving

almost horizontally toward the right. An upward arrow labeled depolarization is shown along the upward slope of the curve. A downward arrow labeled repolarization is shown along the downward slope of the curve.

Return to Graphical representation of action potential

Extended description for Patch-clamp technique

A circular cell with a red outline contains tiny scattered dots. The red outline depicts the membrane. A patch pipette is located close to the red outline of the cell to form a low-resistance seal.



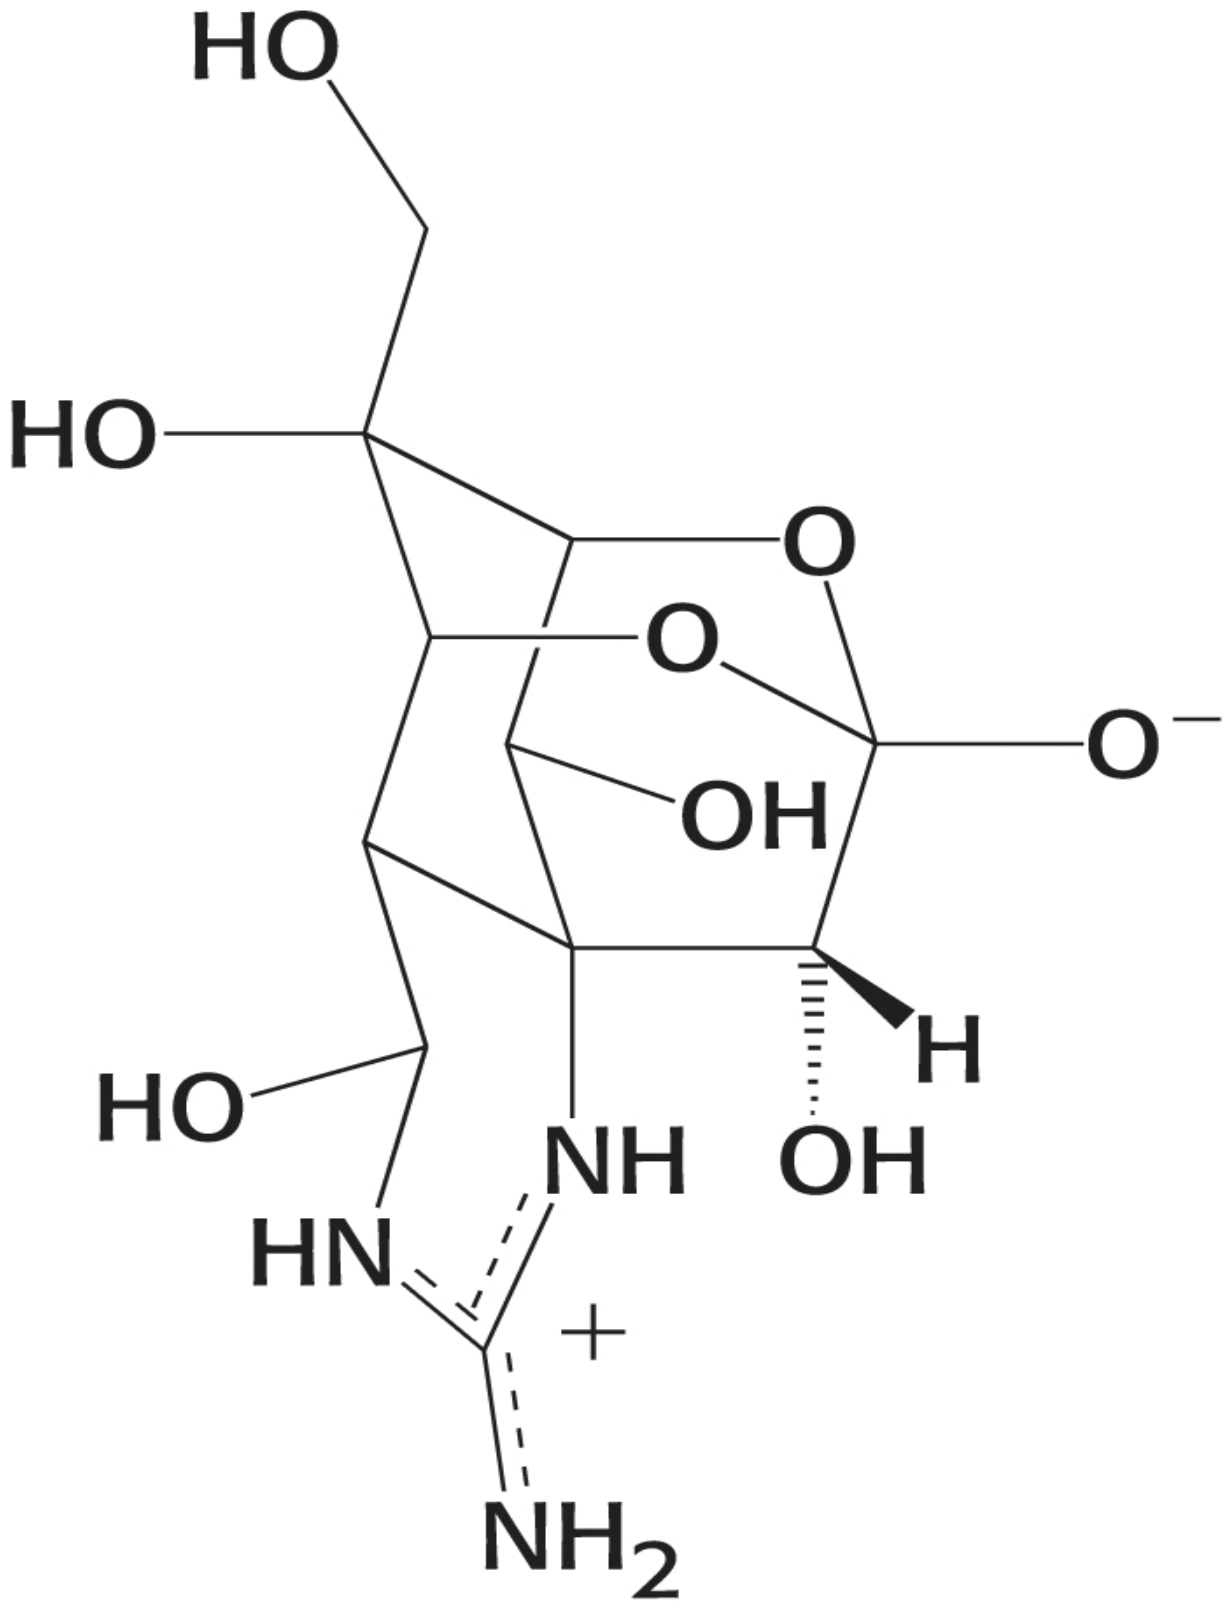
The pipette sucks a small portion of the cell in a cell-attached mode configuration. This produces a gigaohm seal.

The further suction of the cell portion causes it to burst open and release blue dots into the pipette. This configuration is the whole-cell mode.

However, pipette pulling leads to the detachment of a small section of the cell membrane and its cytoplasmic content. This configuration is an excised-patch mode (inside out).

[Return to Patch-clamp technique]

Extended description for Result of patch-clamp experiment

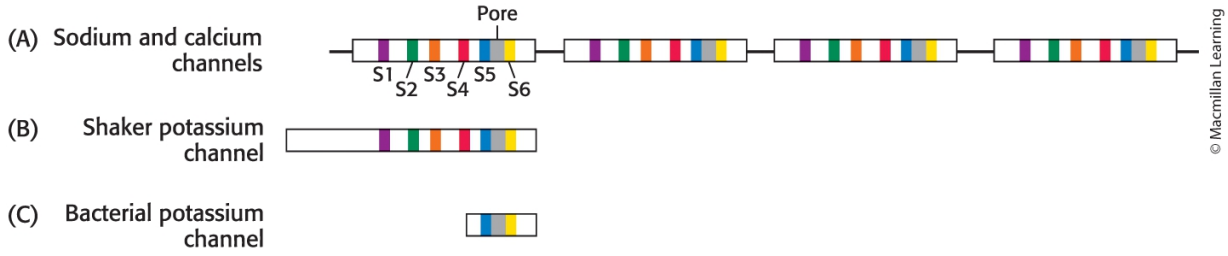


(A) A graph from patch-clamp experiment shows downward spikes with few gaps in between. The downward spikes indicate transitions between closed and open states of single ion channels. The length of a spike depicts 4 picoamperes and the time length between two spikes is 400 milliseconds.

(B) A zoomed-in view of one of the spikes is shown. It shows a series of small peaks and a single long peak. The time length from left to right for these peaks is 4 milliseconds.

Return to Result of patch-clamp experiment

Extended description for Sructure of Tetrodotoxin



Tetrodotoxin

A 5-carbon vertical alkane chain is depicted as a line structure using 4 zigzag lines. C 1 is single bonded to O H on the upper left. C 2 is single bonded to O H on the left. C 5 is single bonded to O H on the lower left and N H on the lower left. C 2 is single bonded on the lower right to C 5 of a 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 1 O and 5 C atoms. In the ring, O occupies the first position, which is the top right vertex. C 3 of the alkane chain is single bonded to O on the right. O is single bonded on the lower right to C 1 of the ring. C 4 of the alkane chain is single bonded on the lower right to C 3 of the ring. C 1 of the ring is single bonded to O superscript minus on the right. C 2 of the ring is wedge bonded to H on the lower right and dash bonded to O H below. C 4 of the ring is single bonded to O H on the lower right. C 3 of the ring is single bonded to a second N H group below. The first and the second N H groups are each partially double bonded to a common central C H group, on the lower right, and on the lower left, respectively, each in the form of a line. A positive charge is indicated near the second N H group. The central C H group is partially double bonded to N H 2 on the lower right.

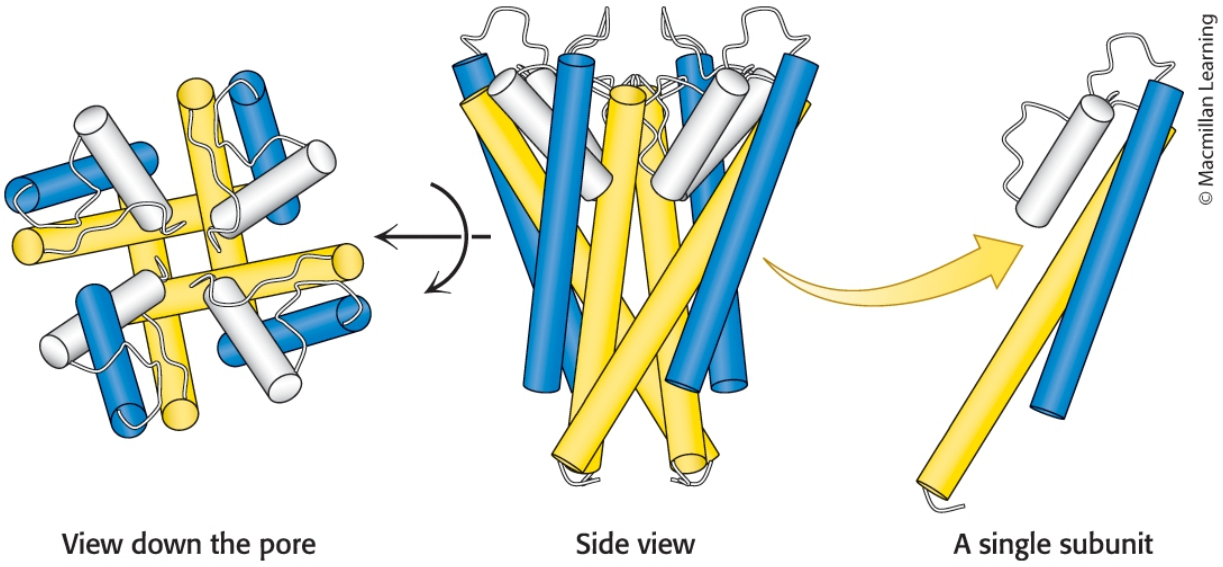
Extended description for Structural features of sodium and calcium channels, shaker potassium channel, and bacterial potassium channel



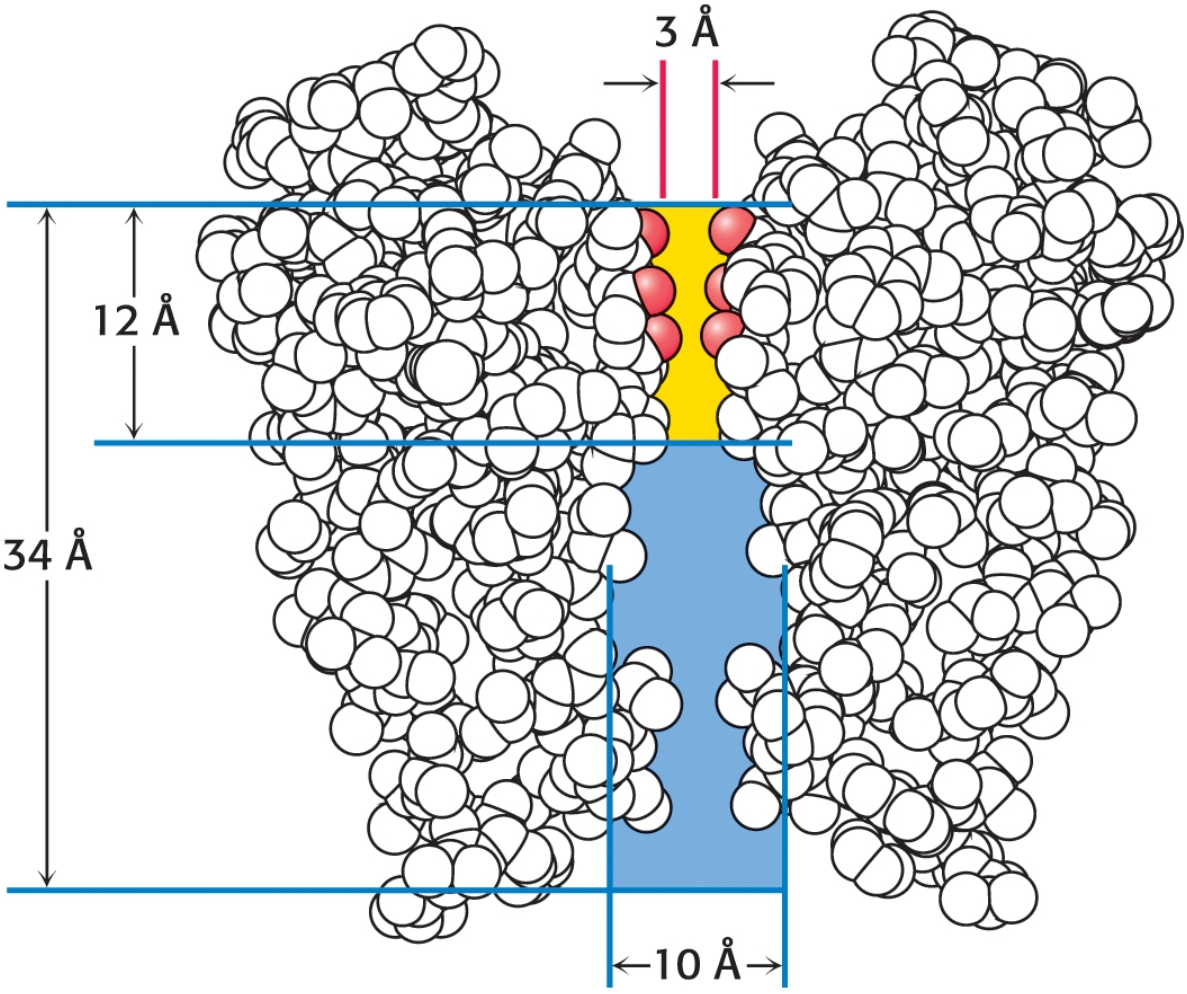
(A) The structure of sodium and calcium channels is as follows: The channel shows four interconnected horizontal bars. Each bar has a series of colored bands. From left to right the colors are violet, green, orange, red, blue, grey, and yellow. The bands with colors blue, grey, and yellow do not have spacing between them. The other bands are separated by spaces. The bands are labeled S 1, S 2, S 3, S 4, S 5, pore, and S 6 from left to right.

(B) The structure of the shaker potassium channel is as follows: The channel shows a horizontal bar. The bar has a series of colored bands. From left to right the colors are violet, green, orange, red, blue, grey, and yellow. The bands with colors blue, grey, and yellow do not have spacing between them. The other bands are separated by gaps.

(C) The structure of the bacterial potassium channel is as follows: The channel shows a horizontal bar. The bar has a series of colored bands. From left to right the colors are blue, grey, and yellow. These bands are not separated by a gap.

Return to Structural features of sodium and calcium channels, shaker potassium channel, and bacterial potassium channel

Extended description for Different views of the bacterial potassium ion channel



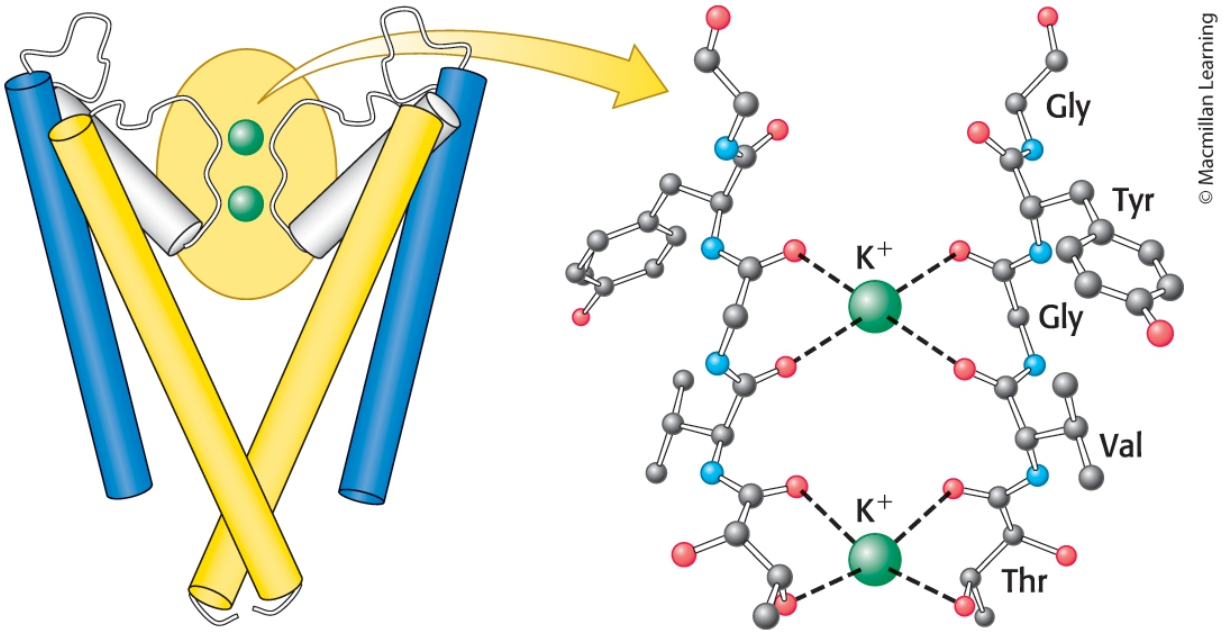
The structure of view down the pore is as follows: It shows four identical subunits. Each subunit consists of white, blue, and yellow elongated cylinders attached by threads. The four subunits are arranged such that they form a square with a pore in the center. The rotation of this view gives the side view.

The structure of the side view is as follows: It shows four identical subunits. Each subunit consists of white, blue, and yellow elongated cylinders attached by threads. The four subunits are arranged vertically.

The structure of a single subunit is as follows: It shows a single subunit with white, blue, and yellow elongated cylinders attached by threads.

Return to Different views of the bacterial potassium ion channel

Extended description for Space-filling model of a potassium ion channel

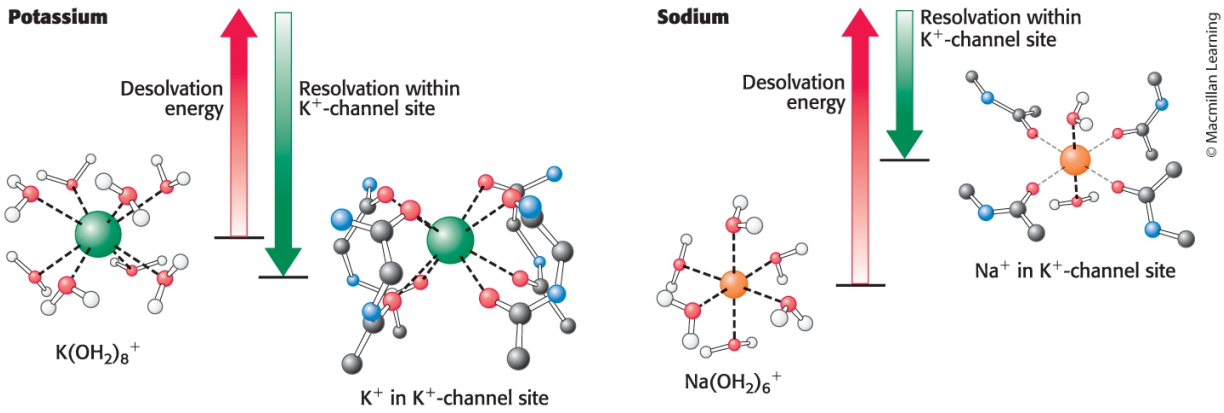


© Macmillan Learning

The figure shows two clusters of white spheres that are vertically separated by a gap. These clusters represent the potassium channel. The inner surface of the upper region of the clusters is separated by a gap of 3 angstroms. This gap is depicted by a yellow background and is lined by red spheres. The inner surface of the lower region of the clusters is separated by a 10-angstrom gap depicted by a blue background. The vertical length of the 3-angstrom gap is 12

angstrom. The vertical length of the entire gap from top to bottom is 34 angstrom.

Return to Space-filling model of a potassium ion channel



Extended description for Selectivity filter of potassium ion channel

The figure has two parts. The first part shows two identical subunits. Each subunit consists of white, blue, and yellow elongated cylinders attached by thread-like loops. The subunits form a V-shaped structure. The pore on the upper surface of the subunit is depicted as an oval with two green spheres. An arrow from this part point toward the next part on the right. In the second part, a ball and stick model of amino acid residues connected to two K superscript plus ions is shown. The first K superscript plus ion depicted as a green sphere is connected to a red sphere of different amino acid residues like tyrosine and glycine on either side. Tyrosine is connected to glycine above and glycine below. This glycine is connected to valine. Valine is further connected to threonine below. The second K superscript ion is connected to the red spheres of valine and threonine on either side. The amino acids are symmetrical and are attached in the same manner on the other side.

Return to Selectivity filter of potassium ion channel

Extended description for Desolvation and resolvation energy of potassium and sodium ions

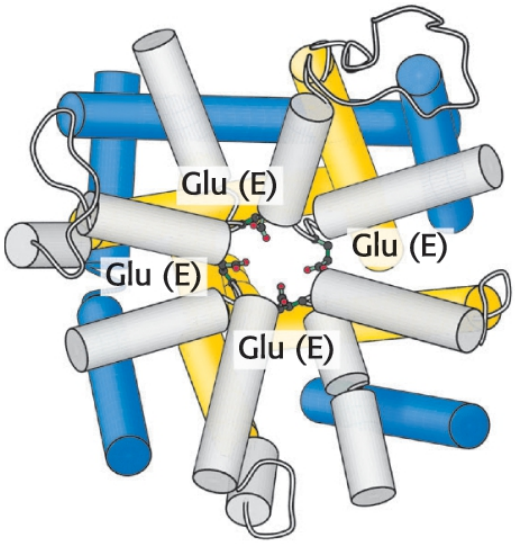
The figure shows four structures.

The ball and stick model for K (O H 2) subscript 8 superscript plus is as follows: A central green sphere depicting potassium ion is connected to 8 red spheres. The 8 spheres represent the oxygen atoms of water molecules. Each red sphere is connected to two white spheres that represent hydrogen atoms oriented away from the green sphere.

The ball and stick model for K superscript plus ion in K superscript plus ion channel site is as follows: A central green K sphere is connected to 8 red spheres. The 8 red spheres are part of the side chains of amino acid residues oriented away from the central green sphere.

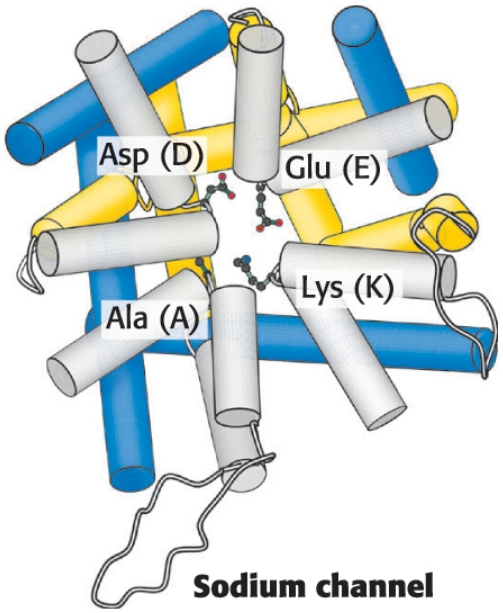
A red arrow from the right side of the K (O H 2) subscript 8 superscript plus points upward and is labeled desolvation energy. A downward green arrow beside the red arrow extends slightly below

the tail of the red arrow and is labeled resolvation within K superscript plus ion channel site.



The ball and stick model for N a (O H 2) subscript 6 superscript plus is as follows: A central orange sphere depicting sodium ion is connected to 6 red spheres. The red spheres depict O atoms of water molecules. Each red sphere is connected to two white spheres that represent hydrogen atoms oriented away from the sodium ion.

The ball and stick model for N a superscript plus ion in K superscript plus ion channel site is as follows: A central orange sphere is connected to 6 red spheres. The red spheres above and below depict the O atom of water molecules and are further connected to 2 white spheres representing H atoms. The red spheres on the top left, top right, bottom left, and bottom right are part of the side chains of amino acid resides.



A red upward arrow from the right side of N a (O H 2) subscript 6 superscript plus is labeled desolvation energy. A downward green arrow beside the red arrow stops halfway near the middle of the first red arrow. The green arrow is labeled resolvation within K superscript plus ion channel site.

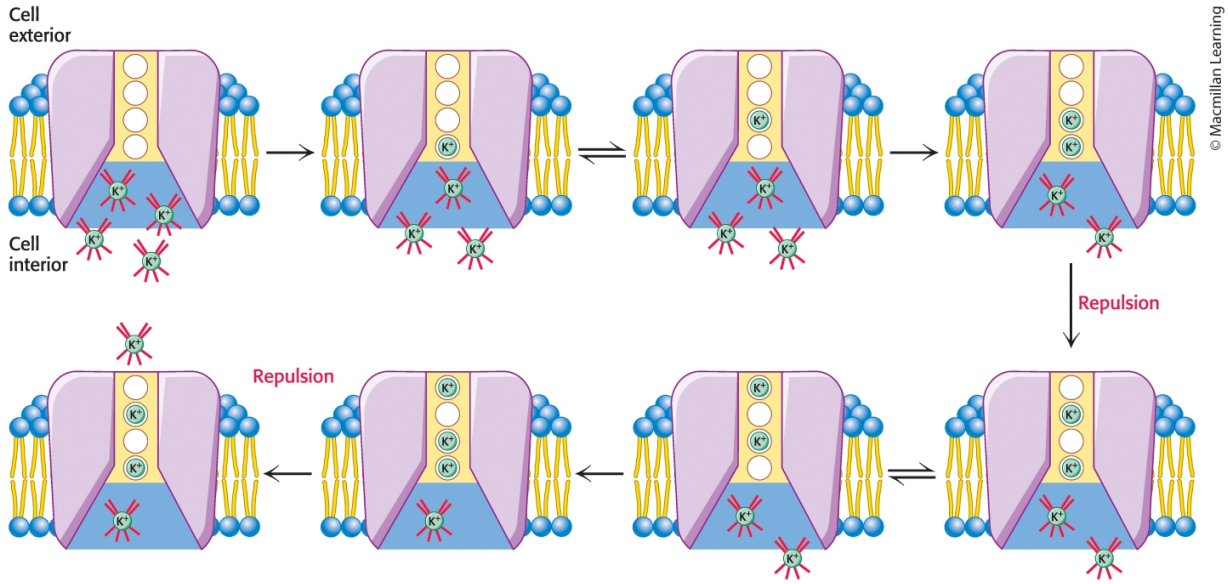
Return to Desolvation and resolvation energy of potassium and sodium ions

Extended description for Calcium channel and sodium channel

Calcium channel

Sodium channel

© Macmillan Learning



The structure of the calcium channel is as follows: The channel consists of 8 radially oriented white cylindrical structures surrounding a central pore. A similar orientation of yellow cylindrical structures is shown behind it, away from the observer. A few blue cylindrical structures are shown behind the yellow structures. These cylindrical structures are interconnected by thread-like loops. Four glutamate (E) residues line the central pore of the calcium channel.

The structure of the sodium channel is as follows: The channel consists of 8 radially oriented white cylindrical structures surrounding a central pore. A similar orientation of yellow cylindrical structures is shown behind it, away from the observer. A few blue cylindrical structures are shown behind the yellow structures. These cylindrical structures are interconnected by

thread-like loops. Aspartic acid (D), glutamic acid (E), alanine (A), and lysine (K) residues line the central pore of the sodium channel.

Return to Calcium channel and sodium channel

Extended description for Model of K superscript plus channel ion transport

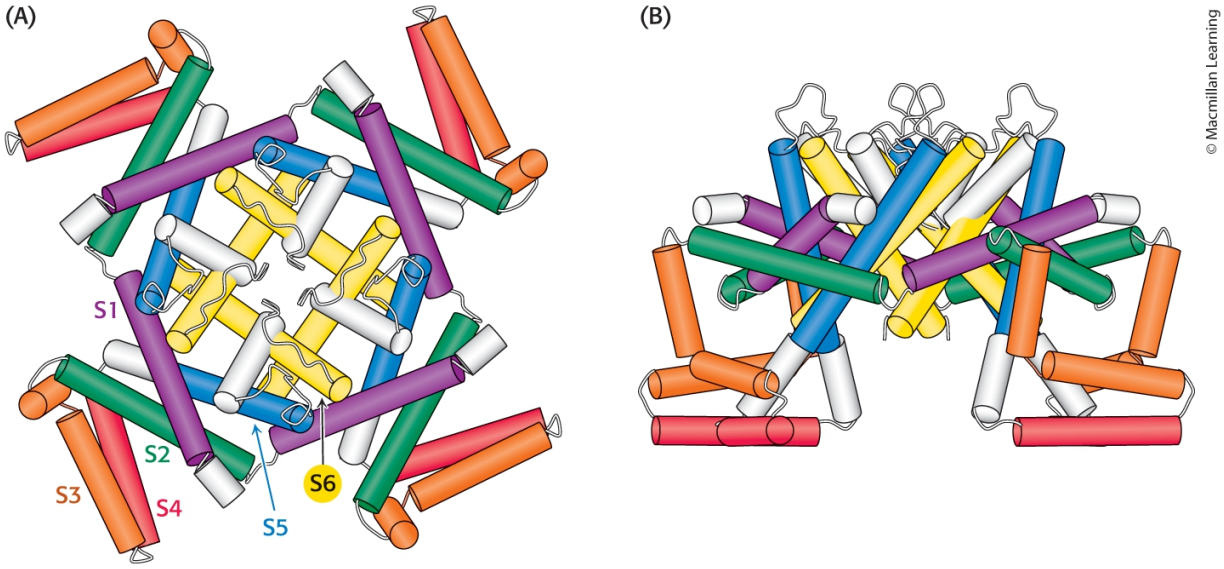
The mechanism occurs in eight steps. In the first step, an inverted Y-shaped membrane channel is embedded in a lipid bilayer. The upper portion is labeled cell exterior and the inner portion is labeled cell interior. The interior of the cell contains four K superscript plus ions bound by water molecules depicted as red sticks. A forward arrow from this step points toward the second step.

In the second step, one of the K superscript plus ions enters the channel. Once it enters the channel, the water molecules are lost. A reversible reaction arrow points to the third step.

In the third step, the K superscript plus ion moves through the ion channel. Aforward arrow points toward the fourth step.

In the fourth step, two K superscript plus ions are depicted inside the ion channel. The K superscript plus ions lose their bound water molecules. An arrow from the fourth step points toward the fifth step and is labeled repulsion.

In the fifth step, the two K superscript plus ions in the channel repel one another and are present away from each other. A reversible reaction arrow points to the sixth step.



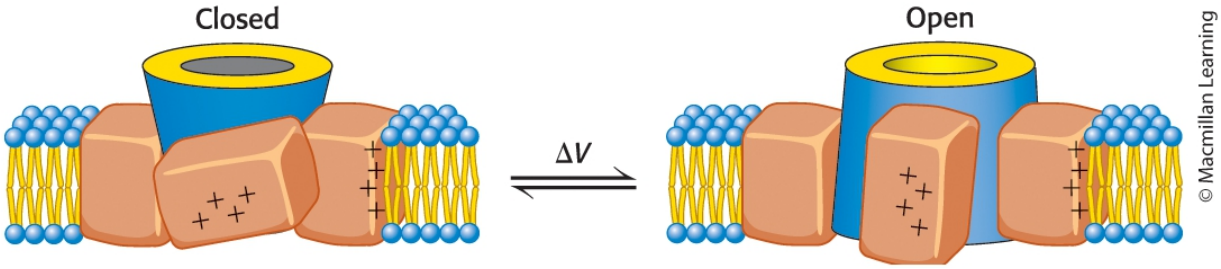
In the sixth step, out of the two K superscript plus ions in the channel one ion reaches the upper portion of the channel. An arrow from the sixth step points toward the seventh step.

In the seventh step, 3 K superscript plus ions without water molecules are seen inside the ion channel. An arrow from the seventh step points toward the eighth step.

In the eighth step, one of the K superscript plus ion bound to water molecules depicted as red sticks is seen in the cell exterior. 2 K plus ions without water molecules are seen inside the channel, and 1 K superscript plus ion bound to water molecules is seen in the cell interior.

Return to Model of K superscript plus channel ion transport

Extended description for View through the pore and side view of the voltage-gated potassium channel

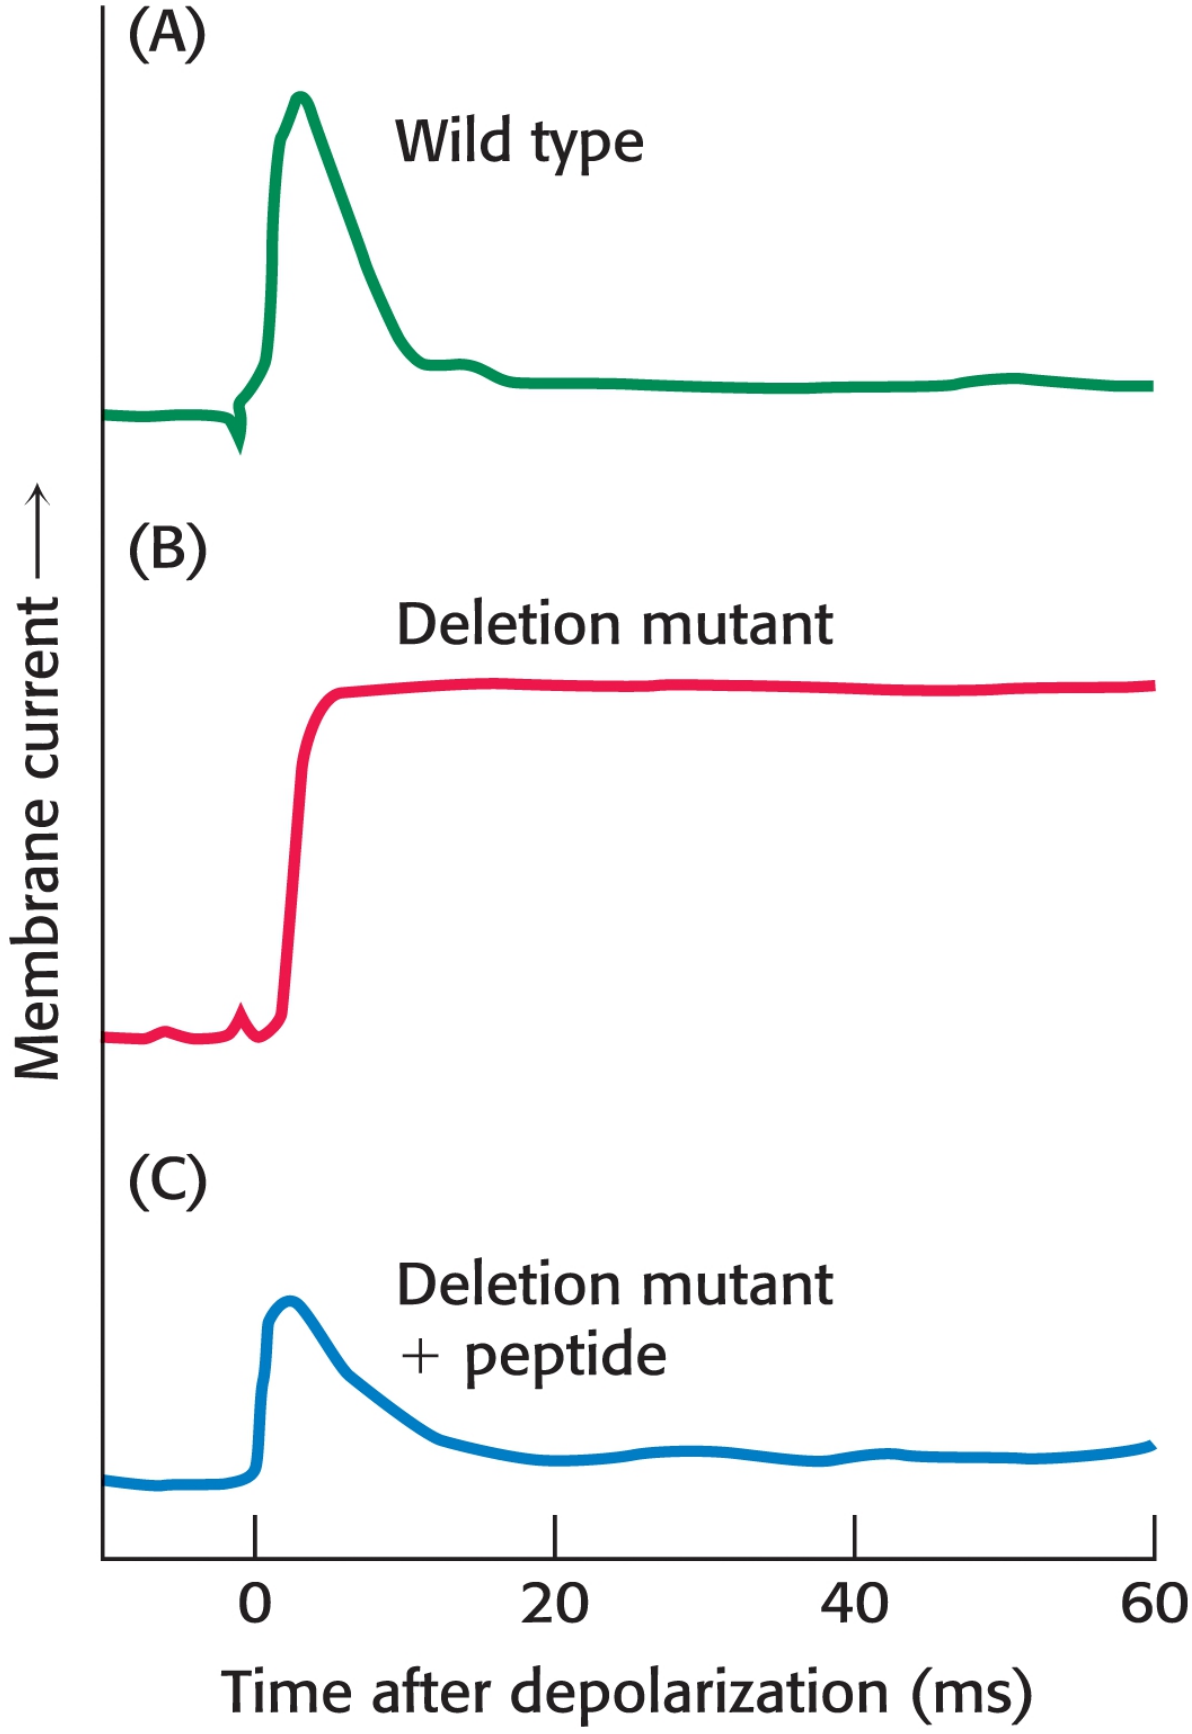


Part (A): The view looking down through the pore of the voltage-gated potassium channel is as follows: The channel consists of 6 identical subunits of S 1, S 2, S 3, S 4, S 5, and S 6 depicted as cylindrical structures. S 1 is purple, S 2 is green, S 3 is orange, S 4 is pink, S 5 is blue, and S 6 is yellow. Each subunit is arranged in such a way that a central square-shaped pore is formed. The subunits are attached by thread-like loops.

Part (B): The side view of the voltage-gated potassium channel is as follows: The channel consists of 6 identical subunits of S 1, S 2, S 3, S 4, S 5, and S 6 depicted as cylindrical structures. S 1 is purple, S 2 is green, S 3 is orange, S 4 is pink, S 5 is blue, and S 6 is yellow. The subunits form an arch-like structure.

Return to View through the pore and side view of the voltage-gated potassium channel

Extended description for Closed and open voltage-gated potassium channel



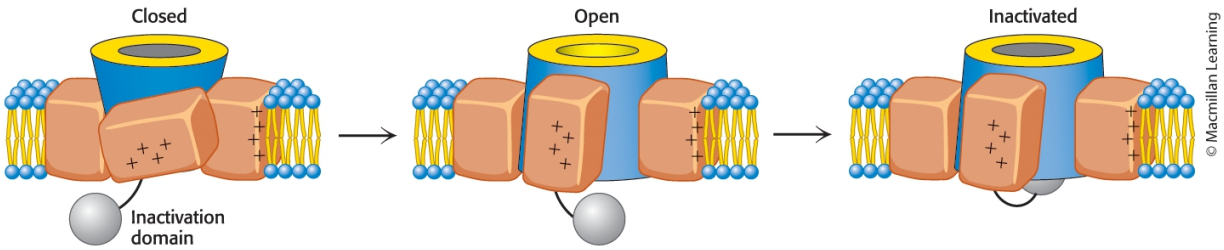
The structure of the closed voltage-gated potassium channel is as follows: The closed voltage-gated channel consists of a closed cylindrical channel that is surrounded by three rectangular block-like voltage sensing paddles with a positive charge. The voltage sensing paddles are embedded in a lipid bilayer. The structure of the open voltage-gated potassium channel is as follows: The open voltage-gated channel consists of an open cylindrical channel that is surrounded by vertical block-like voltage sensing paddles with a positive charge. The voltage sensing paddles are embedded in a lipid bilayer. The closed and open forms are separated by a reversible reaction arrow labeled delta V.

Return to Closed and open voltage-gated potassium channel

Extended description for Graph of membrane current

versus time after depolarization

© Macmillan Learning



The horizontal axis is labeled time after depolarization in milliseconds. It has markings ranging from 0 to 60 in increments of 20 units. The vertical axis is labeled membrane current which increases from bottom to top. Three line curves labeled (A), (B), and (C) are shown in green, red, and blue colors. The green curve located at the top is labeled wild type. The red curve located in the middle is labeled deletion mutant. The blue curve located at the bottom is labeled deletion mutation plus peptide. The green curve starts at a membrane current above the midpoint of the vertical axis and moves almost horizontally till 0 milliseconds. It shows a slight dip before 0 milliseconds and then rises vertically upward to peak at the highest membrane current. It falls to a value of membrane current slightly above the initial value at 16 milliseconds. The line then moves horizontally toward the right.

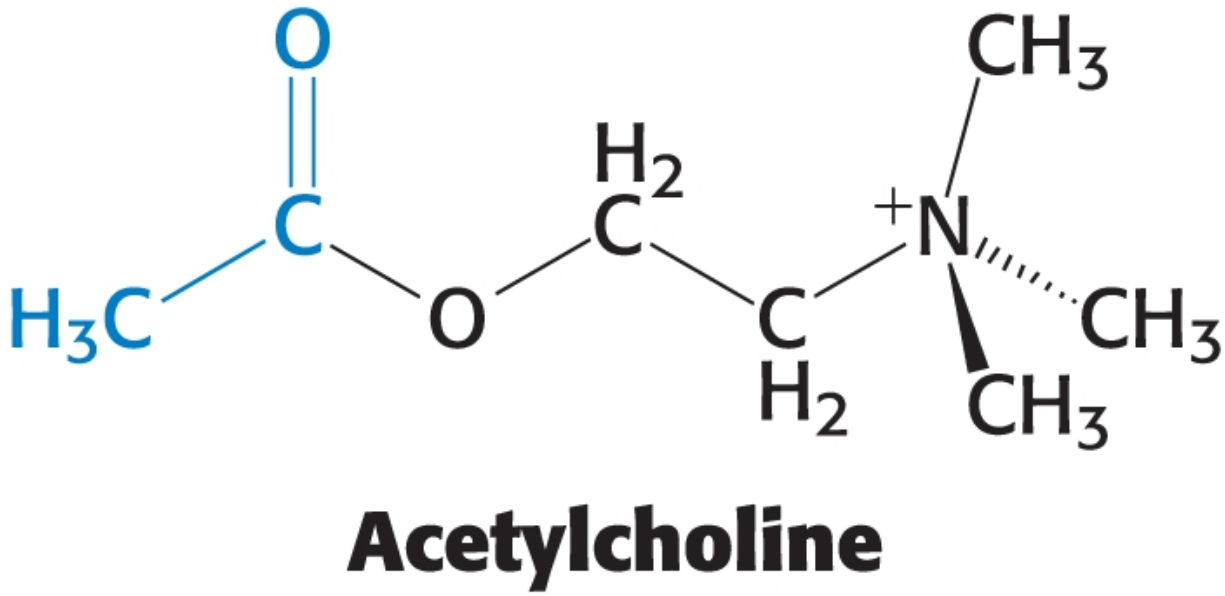
The red curve starts at a value of membrane current just below the midpoint of the vertical axis and moves horizontally toward the right till 0 milliseconds. It shows a very tiny peak before 0 milliseconds and then rises vertically upward to a membrane current value above the midpoint of the vertical axis. The curve then continues moving horizontally toward the right.

The blue curve starts at the lowest membrane current and moves horizontally toward the right till 0 milliseconds. It then rises vertically upward to a point much below the midpoint of the vertical axis at 0 milliseconds. It then falls gradually downward to reach a membrane current value slightly higher than the initial value at 17 milliseconds. The line then moves horizontally toward the right.

Return to Graph of membrane current versus time after depolarization

Extended description for Mechanism of channel inactivation

The ball-and-chain model shows a channel in closed, open, and inactivated forms.

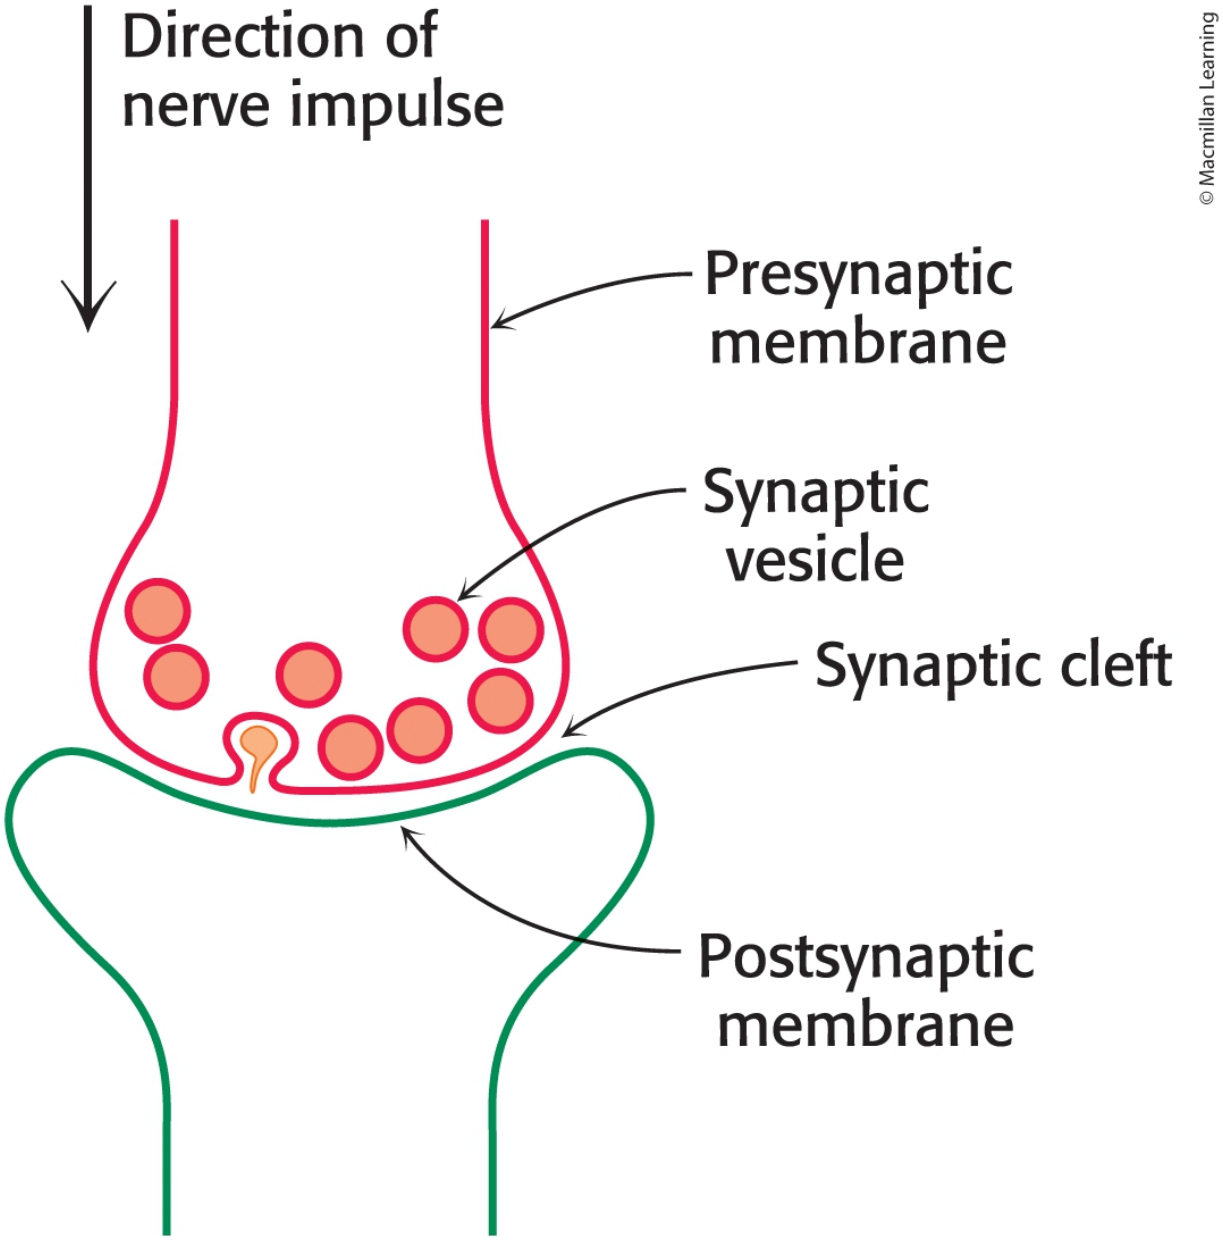


Closed form: The channel is embedded in a membrane with the broad side facing upward. It is surrounded by three rectangular blocks. Two vertical rectangular blocks are attached to the sides of the channel. The third rectangular block is located in front of the channel in a diagonal orientation. It is connected to a flexible chain which is further attached to a grey sphere labeled “inactivation domain”. The sphere is located away from the channel. The front and right rectangular blocks are positively charged.

Open form: The broad side of the channel faces downward. The orientation of the front rectangular block becomes vertical. The grey sphere is located toward the channel.

Inactivated: The grey sphere moves into the pore of the channel thereby blocking it.

Return to Mechanism of channel inactivation

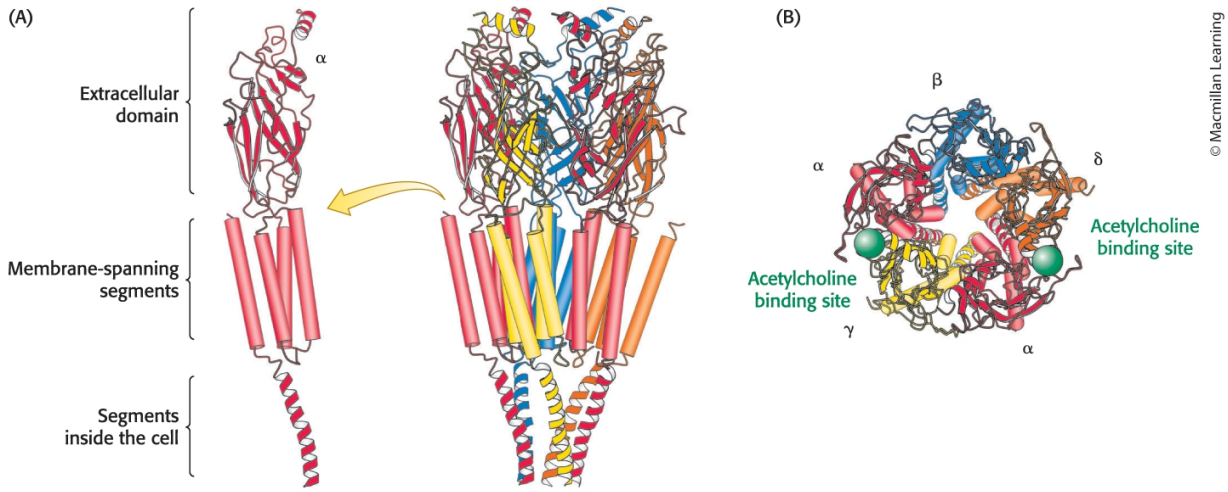


Extended description for Structure of acetylcholine

The structure of acetylcholine is as follows: A 1 O, 1 N, and 3 C heteronuclear alkane chain is depicted as a line structure using 4 zigzag lines. O occupies the second position. N occupies the fifth position and has an overall positive charge. C 1 is double bonded to O above and single bonded to C H 3 on the lower left. C 3 and C 4 are each bound to H 2. N is single bonded to C H 3 on the upper right, dash bonded to C H 3 on the lower right, and wedge bonded to C H 3 below.

Return to Structure of acetylcholine

Extended description for Schematic representation of synapse



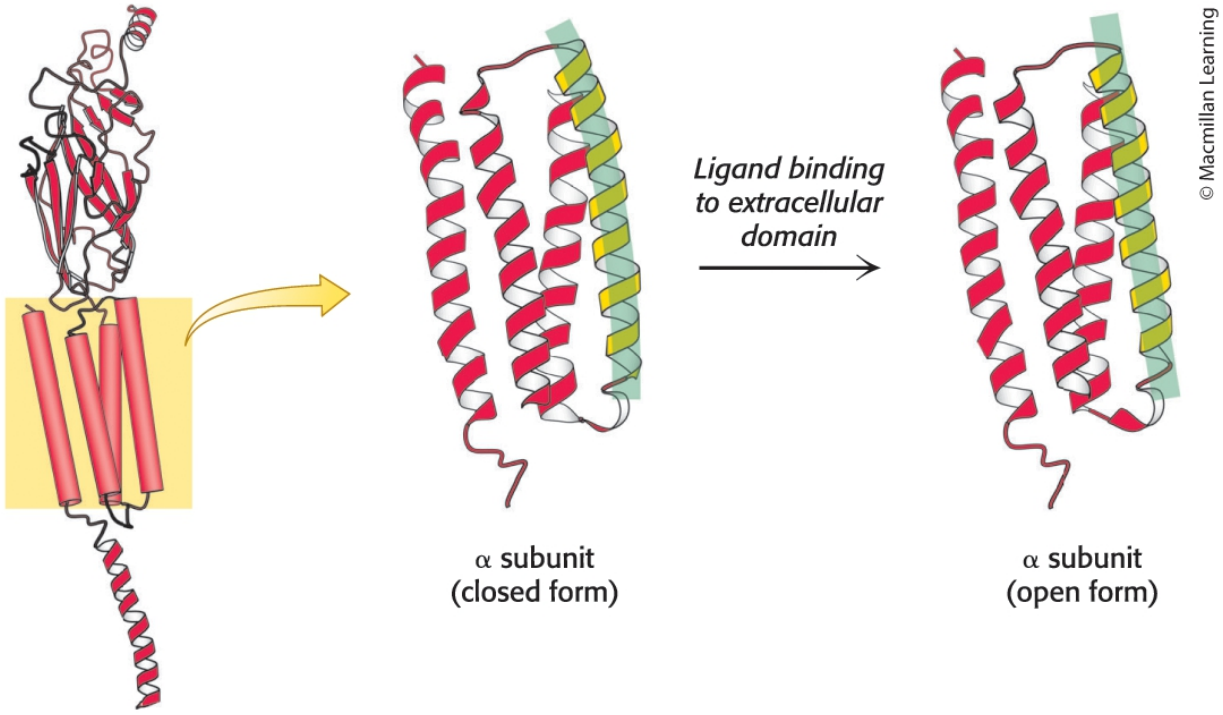
© Macmillan Learning

An elongated structure with a broad top having an inwardly curved surface is shown. Its outline is labeled postsynaptic membrane. A bulb-like structure with an outline labeled presynaptic membrane

sits in the depression of the postsynaptic membrane. The space between the presynaptic and postsynaptic membrane is labeled synaptic cleft. A downward arrow above the presynaptic membrane depicts the direction of nerve impulse. The presynaptic membrane encloses several spheres labeled synaptic vesicles. A small invagination is present on the presynaptic membrane opposite the postsynaptic membrane to show the release of neurotransmitters into the synaptic cleft.

Return to Schematic representation of synapse

Extended description for Model of acetylcholine receptor and a view of the receptor from outside the cell

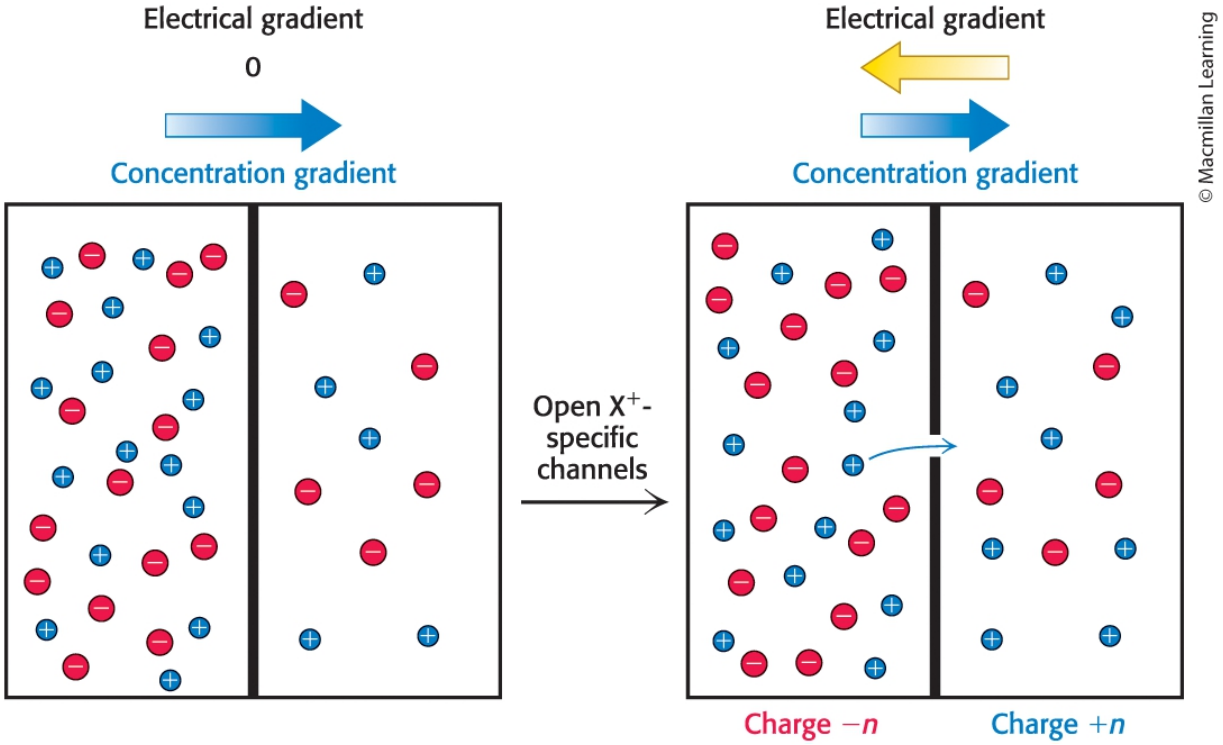


Part (A): The acetylcholine receptor consists of three parts from top to bottom: extracellular domain, membrane-spanning segments, and segments inside the cell. The extracellular domain consists of several beta-strands and a few alpha-helices. The membrane-spanning segments are depicted as vertically oriented long cylindrical structures shown in red, yellow, orange, and blue colors. These cylindrical structures are interconnected by short thread-like loops. Some of them are connected below to a few vertically oriented alpha-helices that are 5 in total. An arrow from the model of acetylcholine receptor points toward the model of its alpha subunit. In the alpha subunit, the extracellular domain consists of several beta-strands and one alpha-helix at the top interconnected by thread-like loops. The membrane-spanning segment consists of four long vertical cylindrical structures. One such structure is connected below to a vertical alpha helix.

Part (B): It shows two alpha, one beta, one gamma, and one delta subunit arranged in a circular cluster with a hollow core. The alpha subunit occupies the top left and bottom right region. The delta and gamma subunits occupy the top right and bottom left regions respectively. The beta subunit occupies the topmost region. A green sphere labeled “acetylcholine binding site” is bound to the gamma subunit and the alpha subunit at the bottom right. Each of the subunits consists of a few beta-strands and alpha-helices and randomly oriented cylindrical structures.

Return to Model of acetylcholine receptor and a view of the receptor from outside the cell

Extended description for Opening of the acetylcholine receptor due to ligand binding



The alpha-subunit of the acetylcholine receptor is shown. An arrow from the alpha-subunit shows the enlarged view of the alpha subunit in close form. The close form consists of four vertical orientated long alpha-helices interconnected by short thread-like loops. The rightmost alpha-helix is shown in green. A vertical light green bar across this helix shows that the helix is slightly curved.

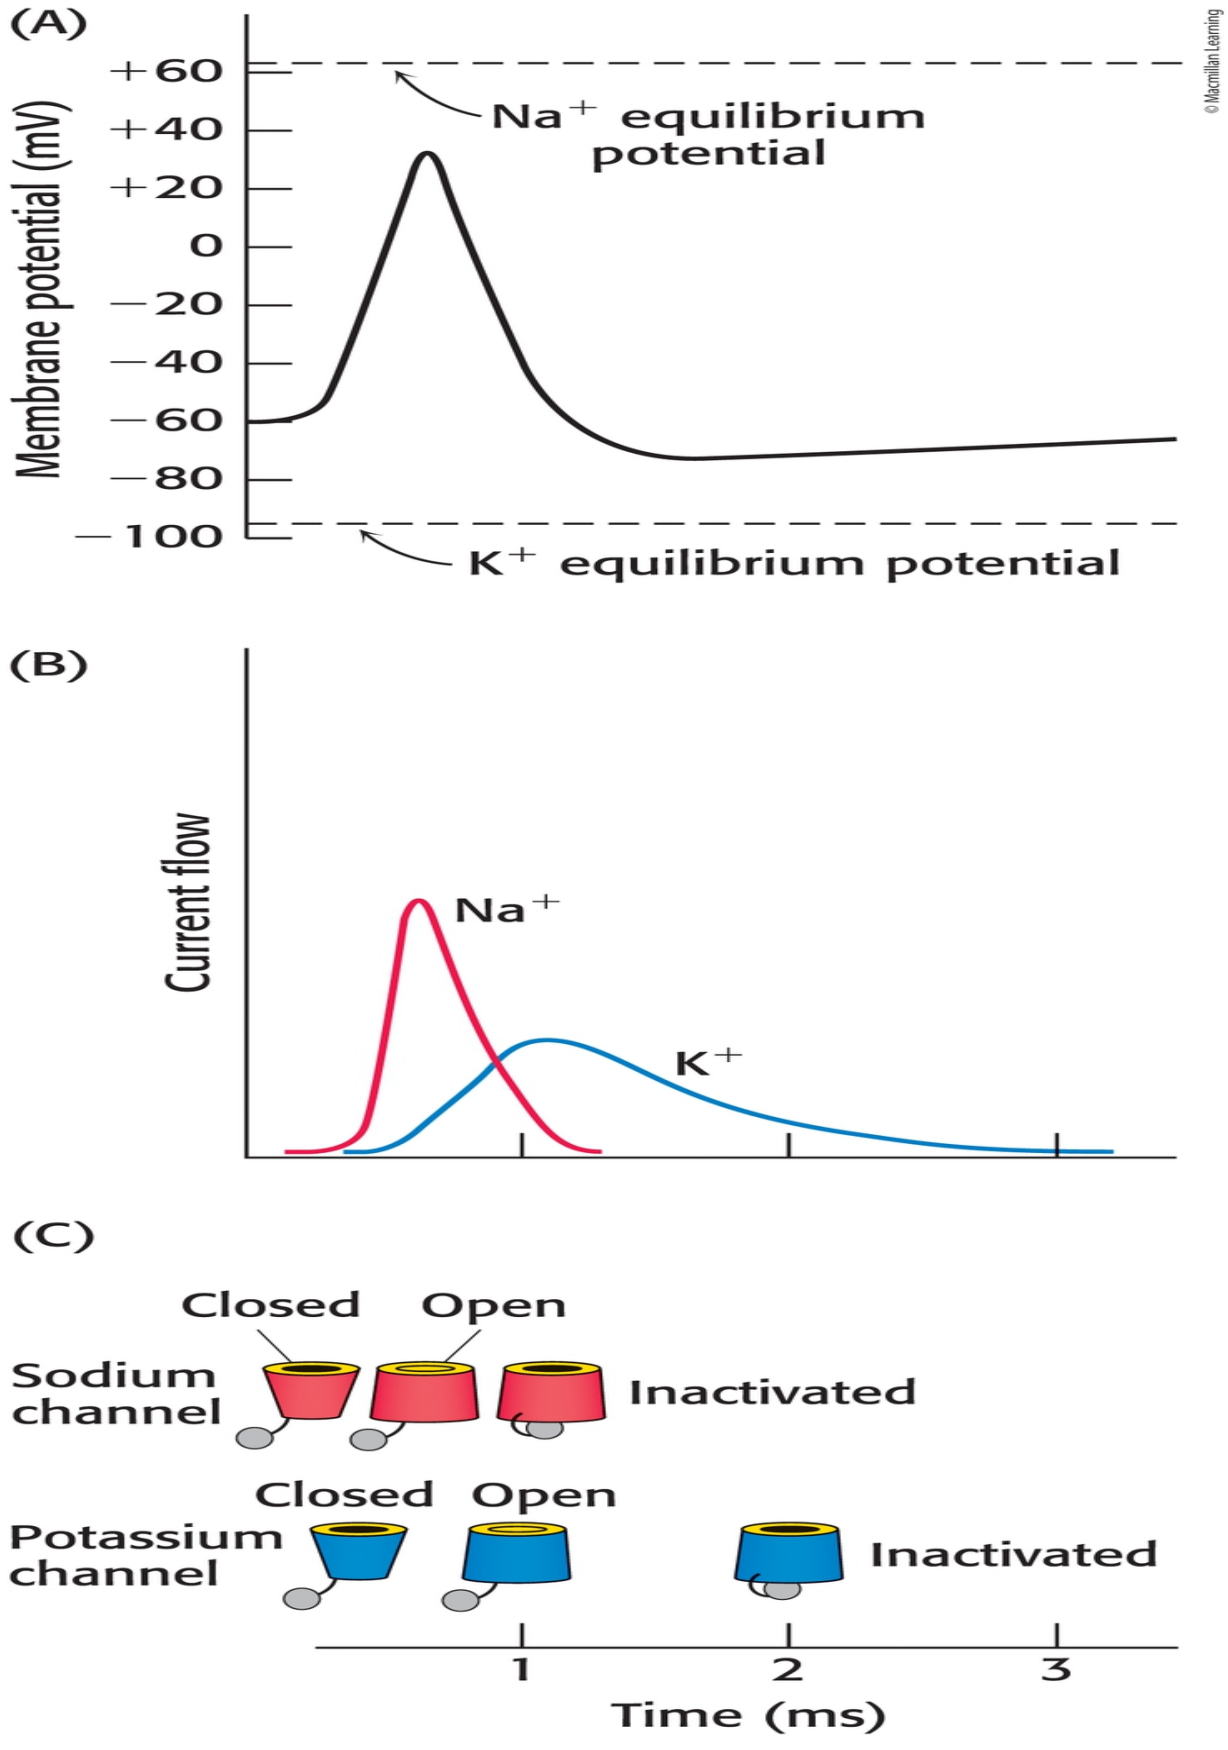
A forward arrow labeled "ligand binding to extracellular domain leads to the open form of alpha-subunit. In the open form, a vertical light green bar across the rightmost helix shows that the helix has straightened.

Return to Opening of the acetylcholine receptor due to ligand binding

Extended description for Schematic representation of equilibrium potential

© Macmillan Learning

A square box is separated into two compartments. The left compartment contains several red and blue circles. The red circles are negatively charged. The blue circles are positively charged. The size of the blue circles is smaller than the red circles. The right compartment contains five red and five blue randomly scattered circles. An arrow at the top of the square box is labeled concentration gradient. It moves from the left compartment toward the right compartment. The electrical gradient is zero at this point.



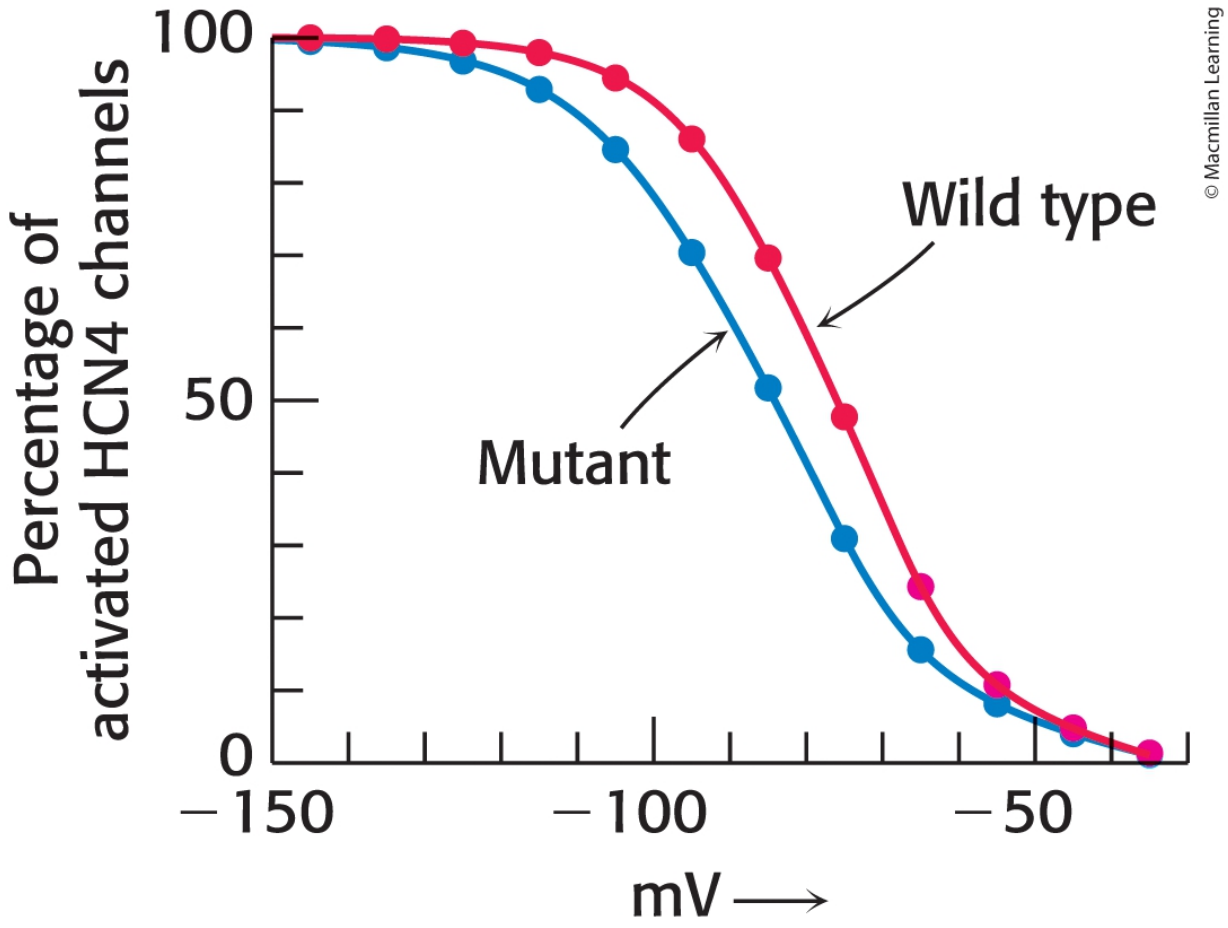
An arrow labeled “open X superscript plus specific channels” leads to another compartmentalized square box.

A narrow slit is shown in the center of the septum that separates the two compartments. The left compartment is labeled charge negative n. The right compartment is labeled charge positive n. An arrow from the left compartment moves toward the right compartment through the slit. An arrow at the top of the square is labeled concentration gradient. It moves from the left compartment toward the right compartment. Another arrow above it is labeled electrical gradient. This arrow moves from the right compartment toward the left compartment.

Return to Schematic representation of equilibrium potential

Extended description for Graphs for membrane potential and current flow and schematic

representation of the states of ion channels during an action potential



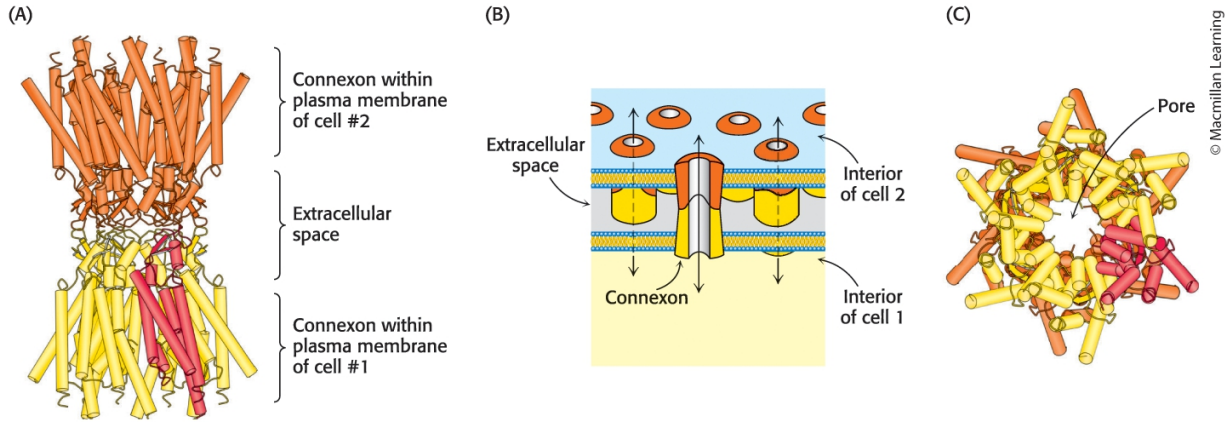
© Macmillan Learning

Graph (A): The vertical axis is labeled membrane potential (m V). It has markings ranging from negative 100 to positive 60 in increments of 20 units. A dashed horizontal line originates from approximately positive 62 m V on the vertical axis. This line is labeled N a superscript plus equilibrium potential. A dashed horizontal line originates from approximately negative 96 on the vertical axis. This line is labeled K superscript plus equilibrium potential. A line curve starts at negative 60 on the vertical axis. It moves horizontally for a short while and then moves gradually upward to peak at approximately 37 m V. It then falls gradually downward to reach approximately negative 70 m V and later moves almost horizontally toward the right. Graph (B): The vertical axis is labeled current flow. The horizontal axis has three equally spaced markings. The graph shows two lines curves in red and blue color. The red line curve starts near (0, 0) and moves horizontally for a short while. It shows steep upward movement to form a peak at a point above the midpoint of the vertical axis. It then falls vertically downward to reach a point on the right of the first marking on the horizontal axis. The blue line curve starts just toward the right of the red curve. It gradually moves upward to peak around the first marking on the horizontal axis at a point on the vertical axis much below its midpoint. The curve then moves gradually down to reach the lowest current flow at the third marking on the horizontal axis. Part (C): The sodium and potassium channels are depicted as rubber stopper-like structures shown in red and blue respectively. A scale for the time in milliseconds is shown. It has markings ranging from 1 to 3 in increments of 1 unit. The sodium channels in three orientations are shown from 0 to 1.2 milliseconds. A closed sodium channel is shown at 0 milliseconds with the broad side facing upward. A grey sphere is connected to the bottom of the channel through a curved line. An open sodium channel is shown at 0.5 milliseconds. It is relatively wider than the closed channel. An inactivated sodium channel is shown at 1.2 milliseconds. The grey sphere is attached to the bottom surface of the channel. The potassium channels in three

orientations are shown from 0 to 2 milliseconds. A closed potassium channel is shown at 0 milliseconds with the broad side facing upward. A grey sphere is connected to the bottom of the channel through a curved line. An open potassium channel is shown at 1 millisecond. It is relatively wider than the closed channel. An inactivated potassium channel is shown at 2 milliseconds. The grey sphere is attached to the bottom surface of the channel.

Return to Graphs for membrane potential and current flow and schematic representation of the states of ion channels during an action potential

Extended description for Graph depicts the percentage of activated H C N 4 channels as function of potential



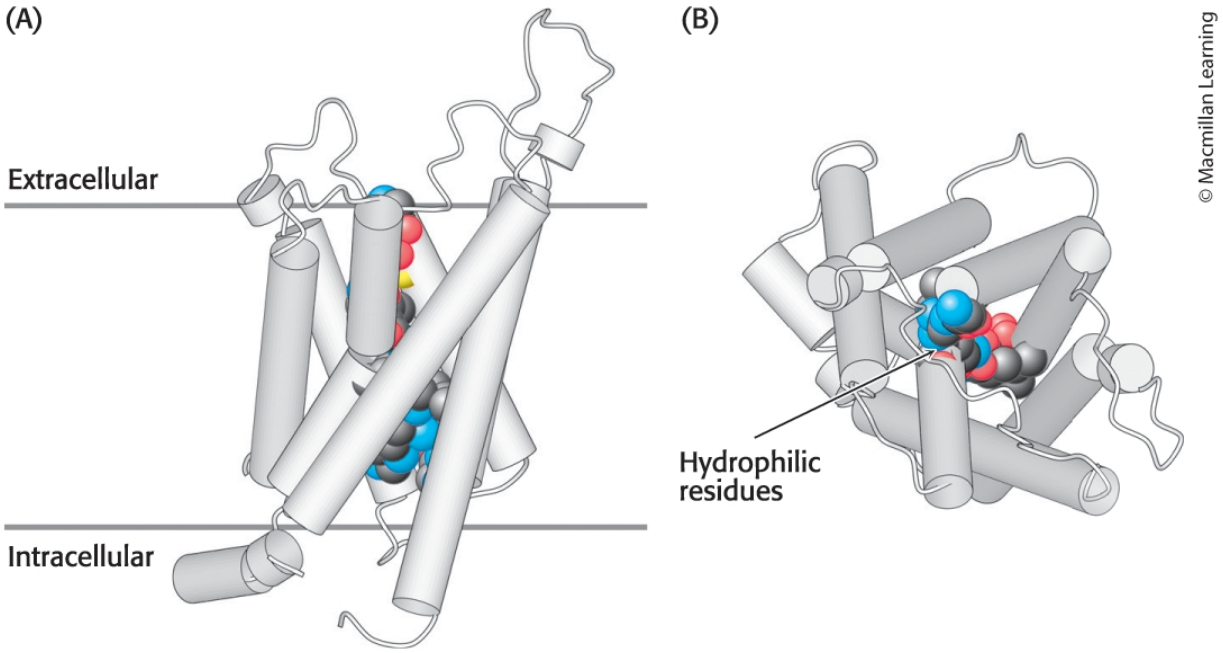
The horizontal axis labeled “m V” has markings ranging from negative 150 to negative 50 in increments of 50 units. The vertical axis labeled “percentage of activated H C N 4 channels” has markings ranging from 0 to 100 in increments of 50 units. The graph shows two decreasing curves. The blue curve is labeled mutant and the red curve is labeled wild type. The mutant curve starts from (negative 150, 100) moves toward the right to (negative 110, 100), and slopes downward passing through coordinates (negative 95, 70), (negative 75, 30), and terminates at (negative 40, 0). The wild-type curve starts from (negative 150, 100) moves toward the right to

(negative 120, 95), and slopes downward passing through coordinates (negative 90, 70), (negative 75, 30), and terminates at (negative 40, 0). All values are approximated.

Return to Graph depicts the percentage of activated H C N 4 channels as function of potential

Extended description for Structure and orientation of connexon

Part (A): The connexon is divided into three parts from top to bottom as follows: connexon within plasma membrane of cell number 2, extracellular space, and connexon within plasma membrane of cell number 1. The top and bottom parts consist of a cluster of vertically oriented long cylindrical structures connected by short thread-like loops. The middle part that resides in the extracellular space consists of a cluster of short cylindrical structures at the top and bottom connected by short thread-like loops located in the center.



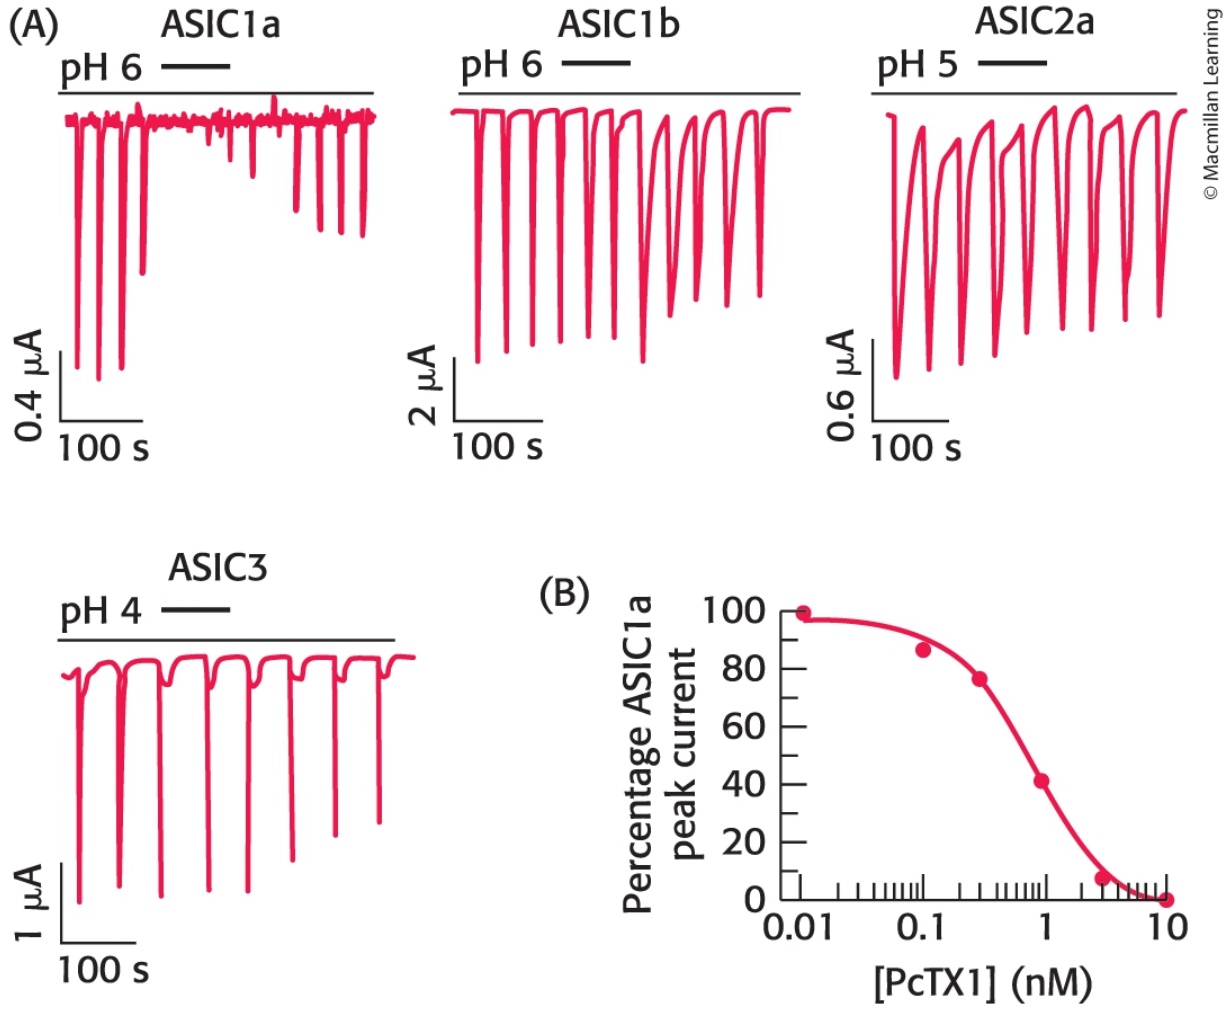
Part (B): Several connexons are depicted as long and hollow cylindrical structures spanning from one membrane to another membrane. The middle portion of the connexons is located in the extracellular space between the two membranes. The top surface of the upper membrane is labeled interior of cell 2. The bottom surface of the lower membrane is labeled interior of cell 1.

Part (C): It shows the bottom view of a connexon. The connexon is depicted as a star-shaped structure outlined by a cluster of short

cylindrical structures. A central pore is located in the connexon.

Return to Structure and orientation of connexon

Extended description for Side and bottom view of aquaporin



Part (A): The aquaporin consists of a few short, medium, and long cylindrical structures in a diagonal orientation interconnected by thread-like loops. Most of the portion of aquaporin is embedded within the plasma membrane depicted as two horizontal grey lines separated by a gap. The thread-like loops and a few short cylindrical structures extend into the extracellular region above. The bottom portion of aquaporin extends into the intracellular region below. The transmembrane portion of aquaporin contains a cluster of black, blue, red, and yellow spheres.

Part (B): It shows the top view of aquaporin. The top view consists of several cylindrical structures interconnected by thread-like loops. A cluster of black, blue, and red spheres is shown in the center of the aquaporin. The cluster is labeled hydrophilic residues.

Return to Side and bottom view of aquaporin

Extended description for Electrophysiological recordings of cells

Part (A):

First electrophysiological recording: It is labeled A S I C 1 a, p H 6. A series of downward spikes are shown on the left and right. The middle region does not contain any downward spike. The size of the spike on the extreme right is much smaller than the extreme left spikes. The length of time for 4 spikes is 100 seconds and the current is 0.4 microamperes.

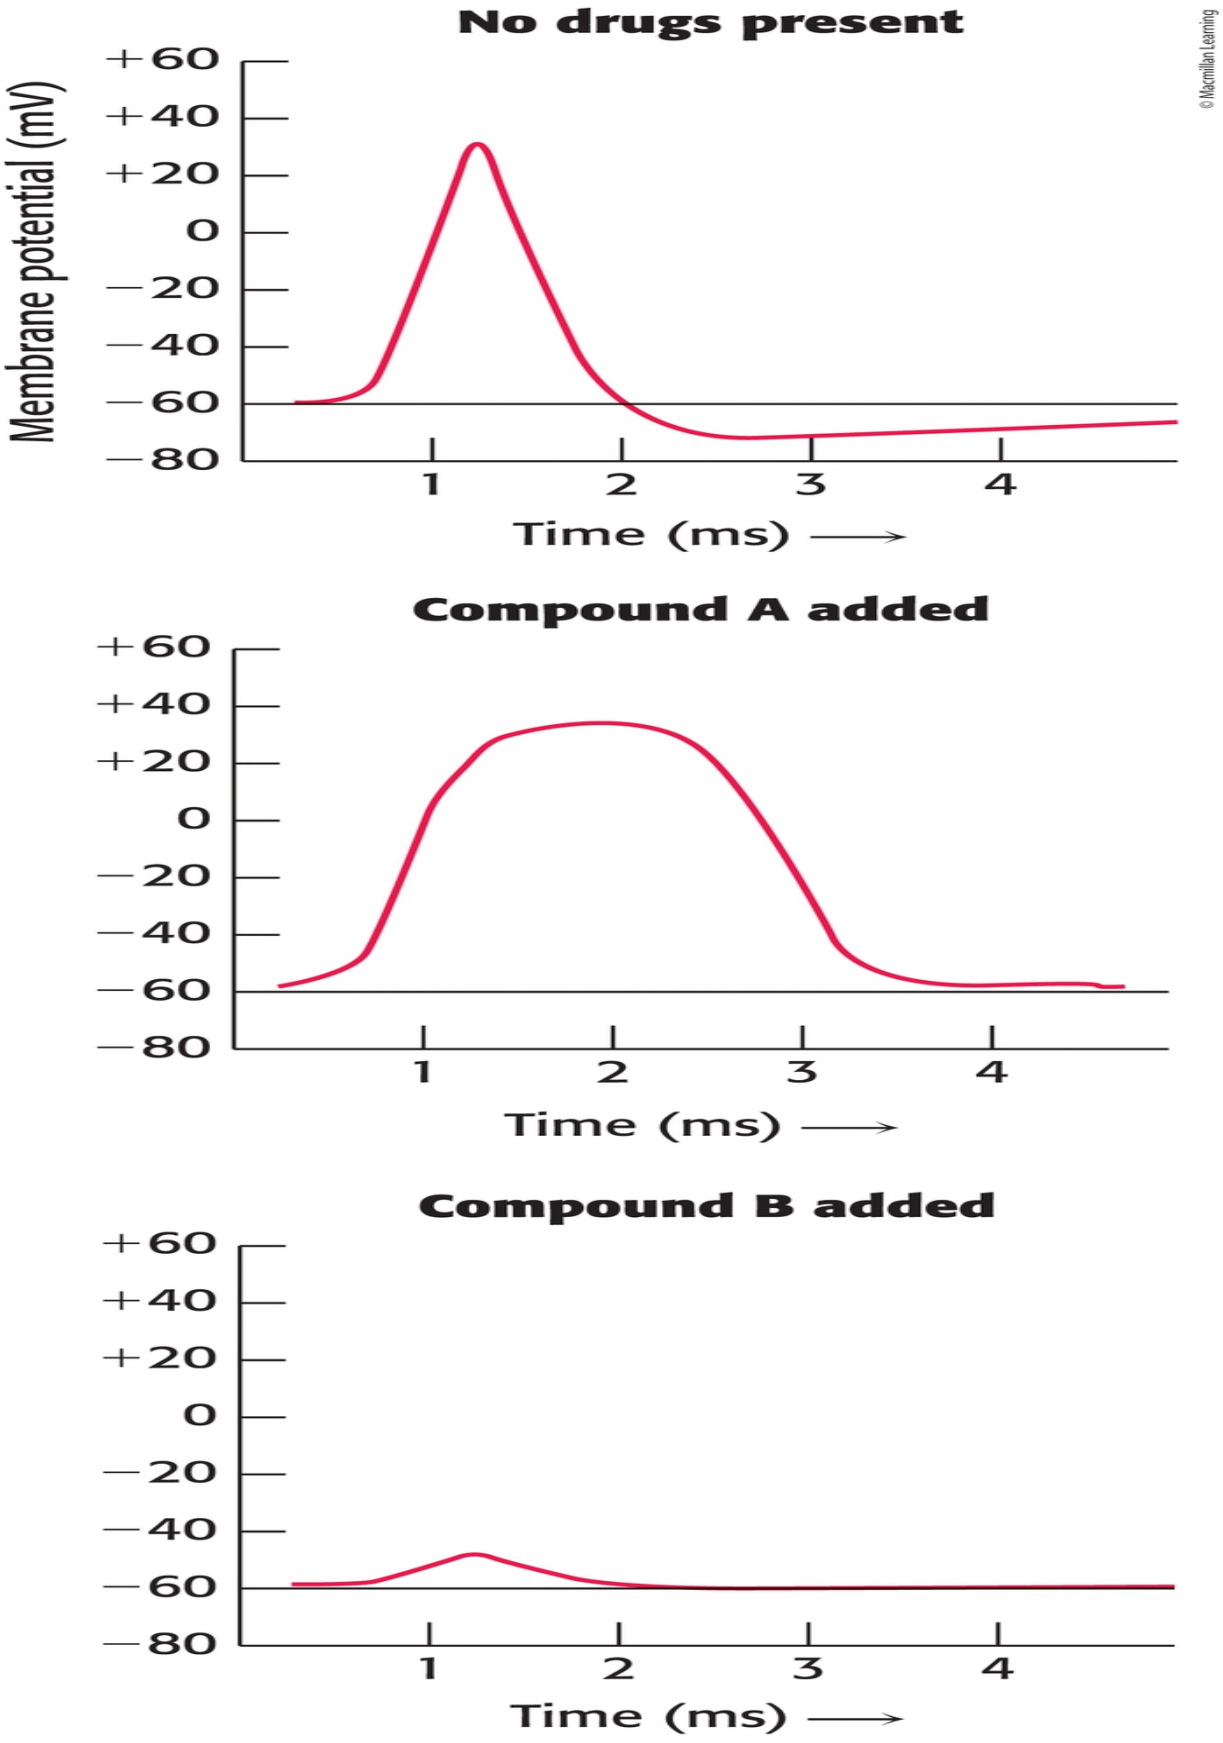
Second electrophysiological recording:

It is labeled A S I C 1 b, p H 6. A series of downward spikes are shown from left to right. They have almost equal lengths. The length of time for 3 spikes is 100 seconds and the current is 2 microamperes.

Third electrophysiological recording:

It is labeled A S I C 2 a, p H 5. A series of downward spikes are shown from left to right. Their length decreases from left to right. The length of time for 2 spikes is 100 seconds and the current is 0.6 microamperes.

Fourth electrophysiological recording:



It is labeled A S I C 3, p H 4. A series of widely spaced downward spikes are shown from left to right. Their length decreases from left to right. The length of time for 2 spikes is 100 seconds and the current is 1 microampere.

Part (B): A graph is shown. The horizontal axis is labeled concentration of P c T X 1 in nanomolar. It has the markings 0.01, 0.1, 1, and 10. The vertical axis is labeled percentage A S I C 1 a peak current. It has markings ranging from 0 to 100 in increments of 10 units. A decreasing line curve begins at (0.01, 100) and moves almost horizontally till (0.1, 90). It then falls gradually downward through the points (0.3, 80), (0.9, 40), and (3, 10). It ultimately terminates at (10, 0). All values are estimated.

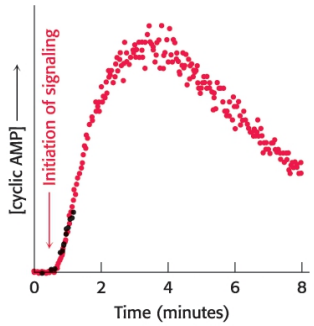
Return to Electrophysiological recordings of cells

Extended description for Graphs depicting membrane potential in the presence or absence of a drug or

compound

© Macmillan Learning

Graph 1: It is labeled “No drugs present”. The horizontal axis is labeled time in milliseconds. It has markings ranging from 1 to 4 in increments of 1 unit. The vertical axis is labeled membrane potential (m V). It has markings ranging from negative 80 to positive 60 in increments of 20 units. A horizontal line starts from negative 60 on the vertical axis. A line curve starts at (0.4, negative 60) and shows upward movement to reach (1.3, positive 35). It then falls steeply to reach (2.5, negative 70) and continues moving almost horizontally toward the right.



Graph 2: It is labeled “Compound A added”. It has markings ranging from 1 to 4 in increments of 1 unit. The vertical axis is labeled membrane potential (m V). It has markings ranging from negative 80 to positive 60 in increments of 20 units. A horizontal line starts from negative 60 on the vertical axis. A line curve starts at (0.2, negative 60) and rises upward to form a broad peak at positive 35 m V from 1.5 to 2.2 milliseconds. The curve then falls to reach (3.8, negative 61) and continues moving horizontally toward the right.

Graph 3: It is labeled “Compound B added”. It has markings ranging from 1 to 4 in increments of 1 unit. The vertical axis is labeled membrane potential (m V). It has markings ranging from negative 80 to positive 60 in increments of 20 units. A horizontal line starts from negative 60 on the vertical axis. A line curve starts at (0.2, negative 60) and moves horizontally toward the right for a while. It then gradually rises upward to peak at (1.2, negative 52) and then moves gradually downward to (2, negative 60). The curve then continues moving horizontally toward the right along the horizontal line.

All values are estimated.

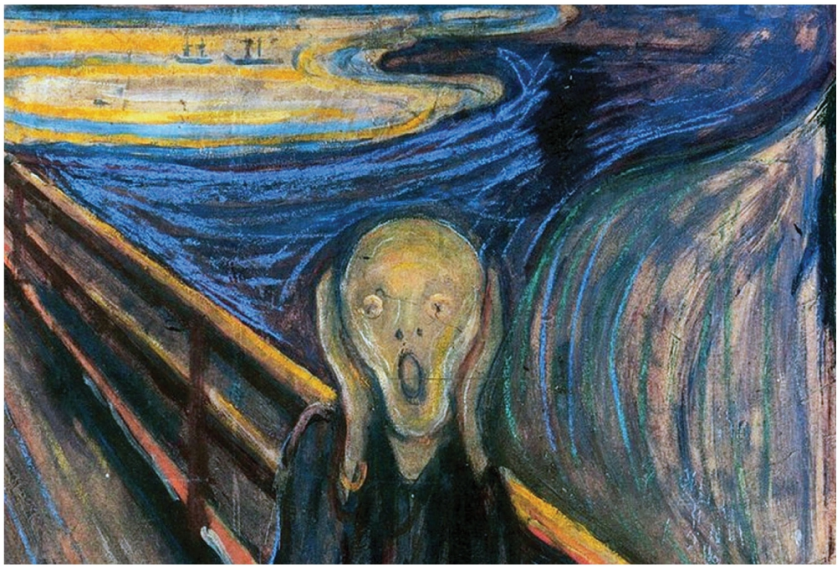
Extended description for A graph and a photograph



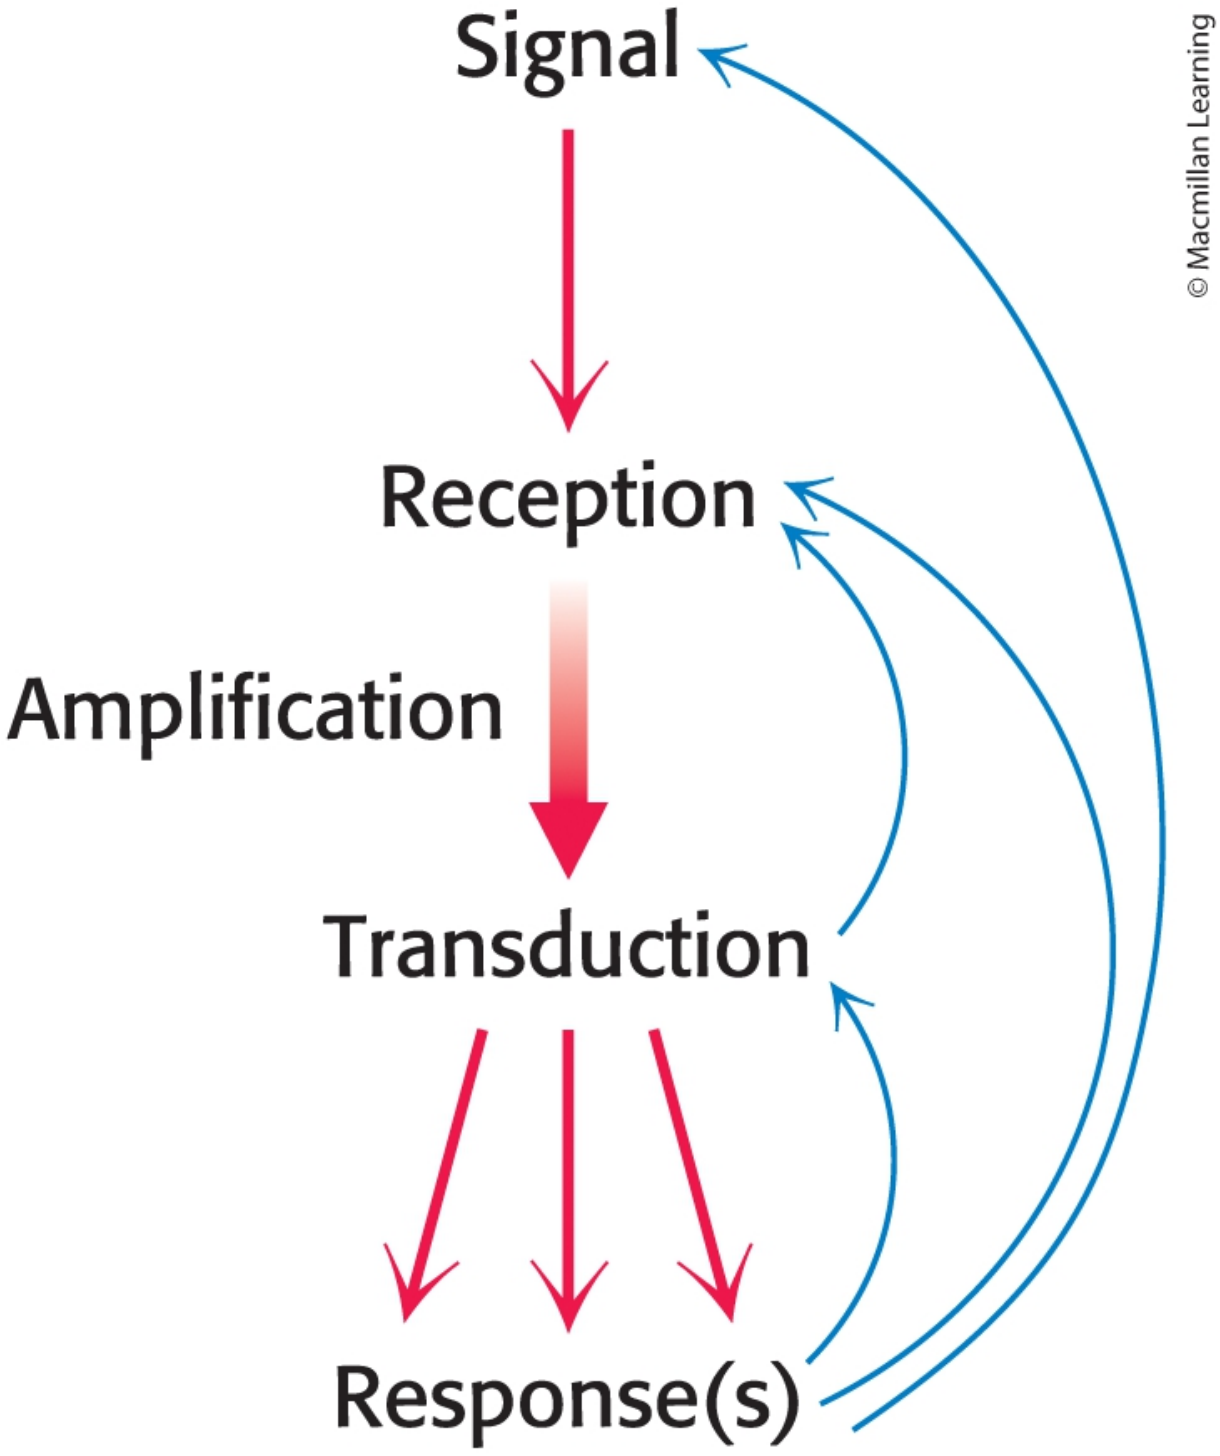


Photo12/Universal Images Group/Getty Images
© Macmillan Learning

The figure has two parts. The first part is a graph illustrating time in minutes on the horizontal axis. It has markings ranging from 0 to 8 in increments of 2 units. The vertical axis shows the concentration of cyclic A M P enclosed which increases from bottom to top. The data points depicted as red dots form a red curve. The curve starts at 0 on the horizontal axis and moves horizontally toward the right till it reaches 1 on the horizontal axis. The curve then rises steeply till it reaches a maximum point at 4 on the horizontal axis and then it starts decreasing gradually till at a point of 8 on the horizontal axis and the middle of the vertical axis. The curve is bell-shaped and the starting horizontal portion of the curve is marked with an arrow and labeled "Initiation of signaling." The second part shows an artistic painting.

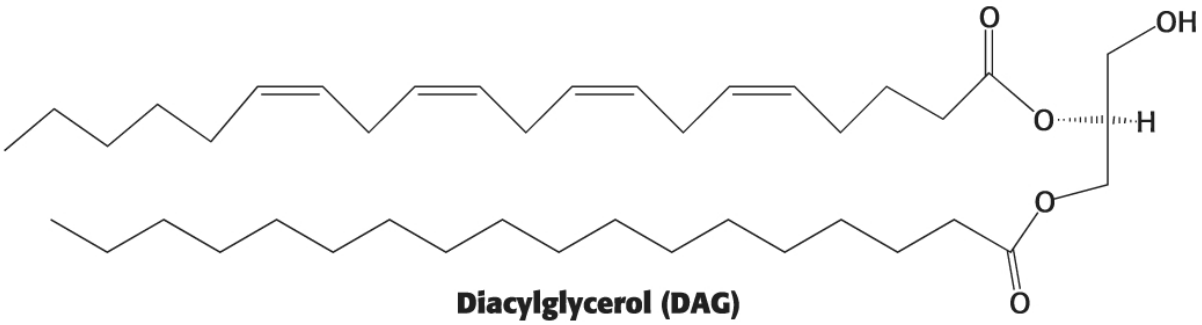
Extended description for Chemical structure of different secondary messengers



cAMP, cGMP

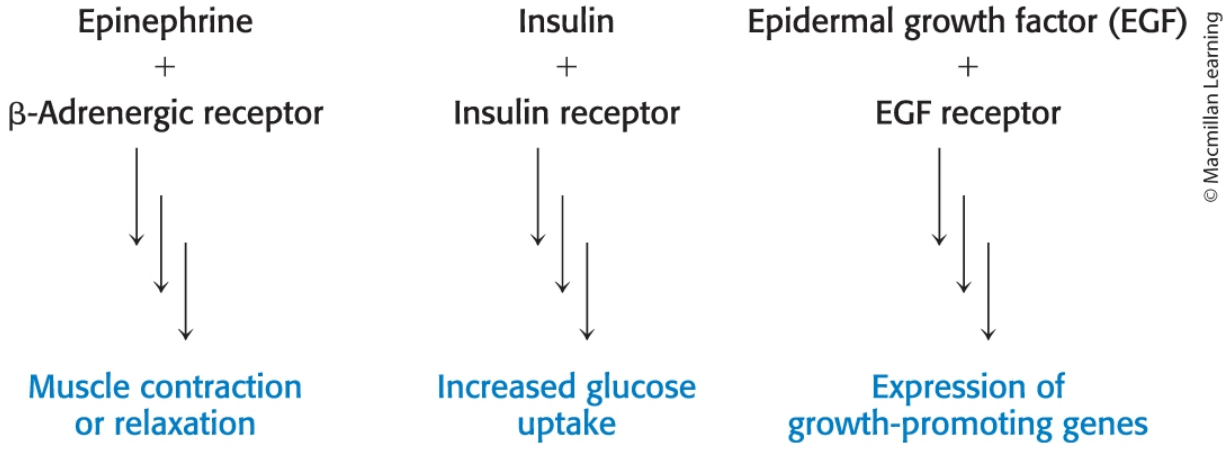
Calcium ion

Inositol 1,4,5-trisphosphate (IP_3)

Diacylglycerol (DAG)

The structure of c A M P or c G M P is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 occupies the top right vertex and is wedge bonded to A or G on the upper right. C 2 is dash bonded to O H on the lower right. C 3 is dash bonded to O on the lower left. C 4 is wedge bonded to C H 2 on the left. This C H 2 is single bonded to O on the lower left. The O atoms of the C 3 and C H 2 group are single-bonded to a common P atom. This P atom is partially double bonded to O on the lower left and below. The P O O group has an overall negative charge.

The structure of calcium ion bound to water is as follows: A central C a atom is single bonded to O H 2 above, O H 2 below, H 2 O on the left, dash bonded to O H 2 on the upper right, dash bonded to H 2 O



on the upper left, wedge bonded to O H 2 on the lower right, and wedge bonded to H 2 O on the lower right. This structure has an overall positive charge of 2 plus.

The structure of inositol 1,4,5-triphosphate (I P 3) is as follows: A 6-membered homocyclic hexagonal ring is in a chair conformation. The ring is in a plane perpendicular to the plane of paper such that C 2 and C 4 are located toward the observer and C 1 and C 5 are located away from the observer. C 3 and C 6 are located close to each other. C 1 is single bonded to O P O 3 superscript 2 minus. C 2 is single bonded to O H on the right. C 3 is single bonded to O H above. C 4 is single bonded to O P O 3 superscript 2 minus on the upper left. C 5 is single bonded to O H on the left. C 6 is single bonded to O P O 3 superscript 2 minus on the upper right.

The structure of diacylglycerol (D A G) is as follows: A vertical chain consists of three C atoms. C 1 is single bonded to O H on the upper right. C 2 is dash bonded to O on the left and H on the right. C 3 is single bonded to O on the lower left. The O atom bonded to C 2 is single bonded to a 20 carbon alkene chain depicted as a line structure using 19 zigzag lines. In this alkane chain, C 1 atom closer to the O atom is double bonded to O above. A double bond is present between C 5 and C 6, C 8 and C 9, C 11 and C 12, C 14 and C 15. The O atom bonded to C 3 of the vertical chain is single bonded to an 18-carbon alkane chain depicted as a line structure using 17 zigzag lines. C 1 closer to the O atom is double bonded to O below.

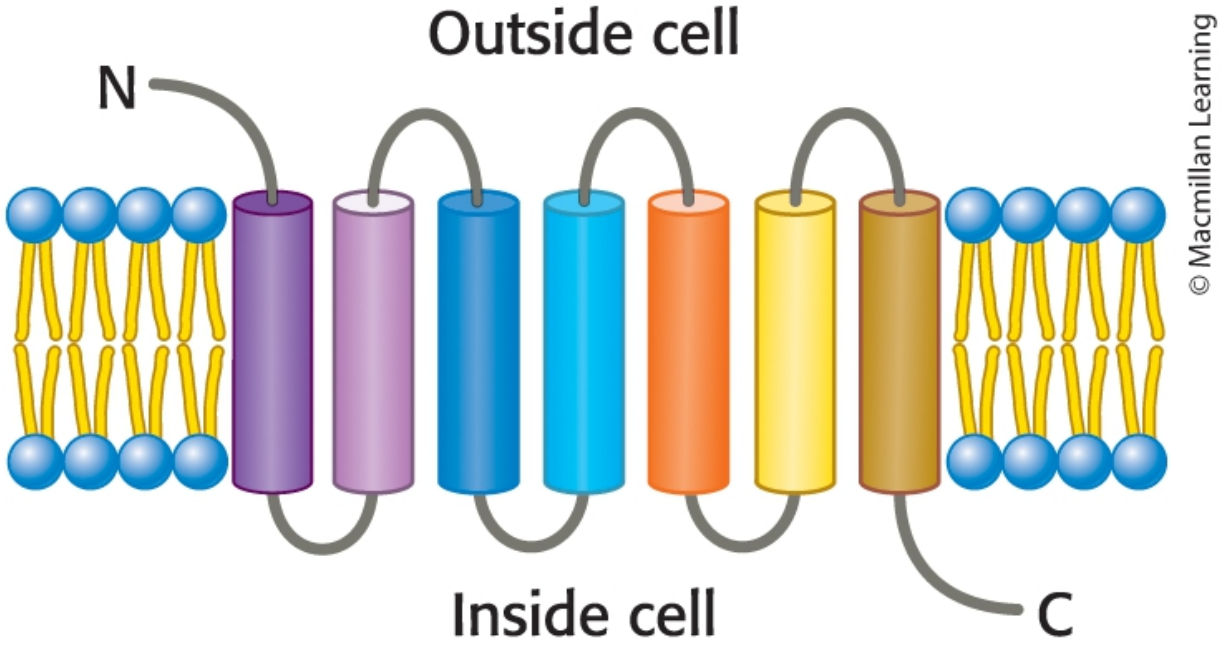
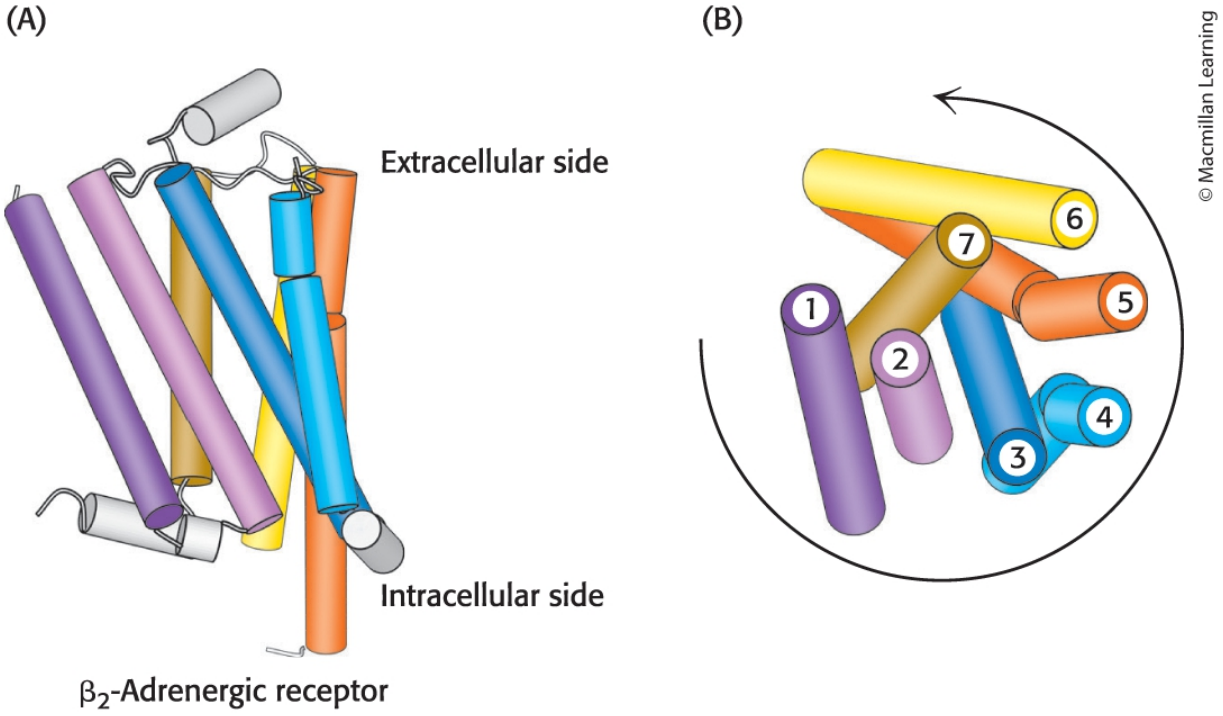
Extended description for Chemical structure of epinephrine



The structure of epinephrine or adrenaline is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to C 1 of a 1 N and 2 C heteronuclear alkane chain depicted as a line structure using 2 zigzag lines. N bound to H occupies the third position. C 1 is wedge bonded to O H on the upper left and dash bonded to H on the upper right. N is single bonded to C H 3 on the lower right.

C 5 of the benzene ring is single bonded to O H on the lower left. C 6 is single bonded to O H on the upper left.

Return to Chemical structure of epinephrine



Extended description for Schematic representation of 7 T M helix receptor

The 7 T M helix receptor consists of 7 vertically oriented cylindrical structures that span through a lipid bilayer. The cylindrical structures are placed adjacent to each other in a tandem arrangement. The leftmost cylindrical structure has a short thread-like extension at the top labeled "N" which is located outside the cell. The rightmost cylindrical structure has a short thread-like extension at the bottom labeled "C" which is located inside the cell. The adjacent cylindrical structures are connected by curved thread-like loops at the bottom or top in an alternating manner.

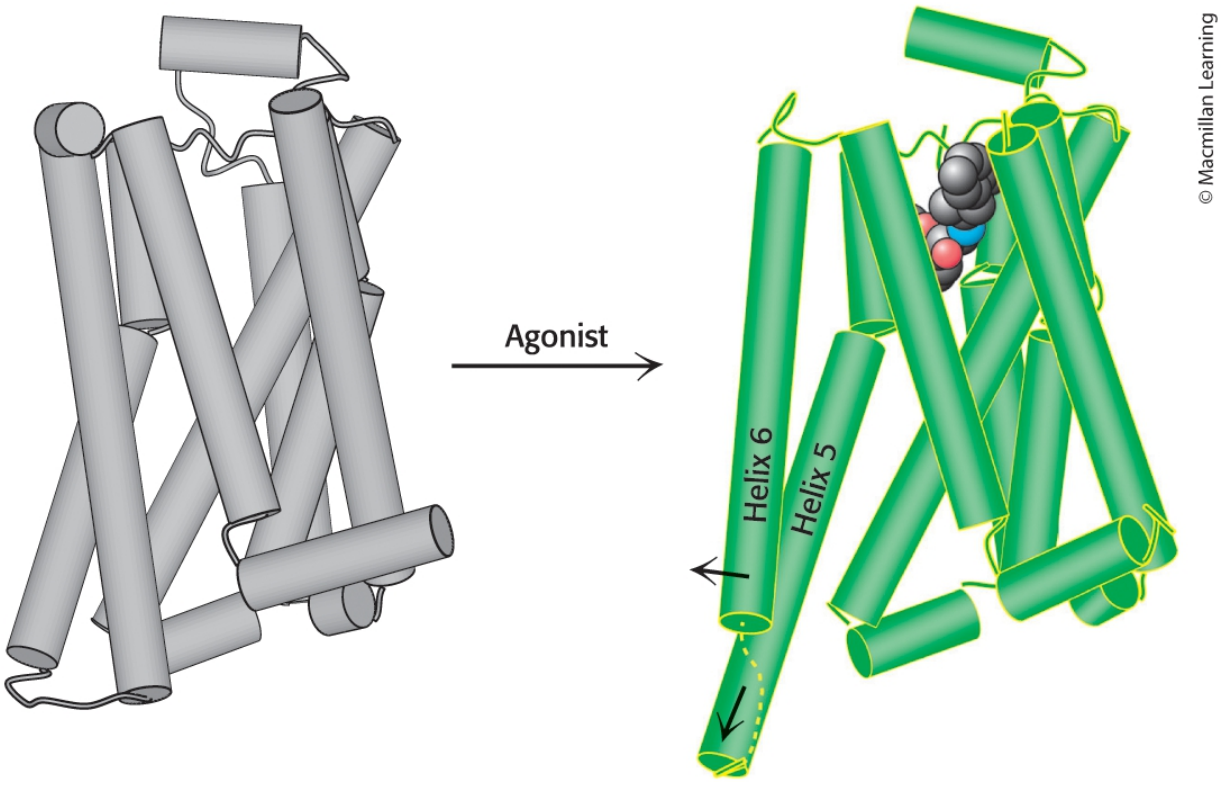
Extended description for Schematic representation of the side view and top view of the beta-2 adrenergic receptor



Part (A): The side view of the beta 2-adrenergic receptor shows a cluster of slightly diagonally oriented or vertically oriented long cylindrical structures. Their top is labeled extracellular side and the bottom is labeled intracellular side. They are interconnected by short thread-like loops. An irregular thread at the top of this cluster is connected to a short cylindrical structure at the extracellular side. A few short cylindrical structures are located on the intracellular side.

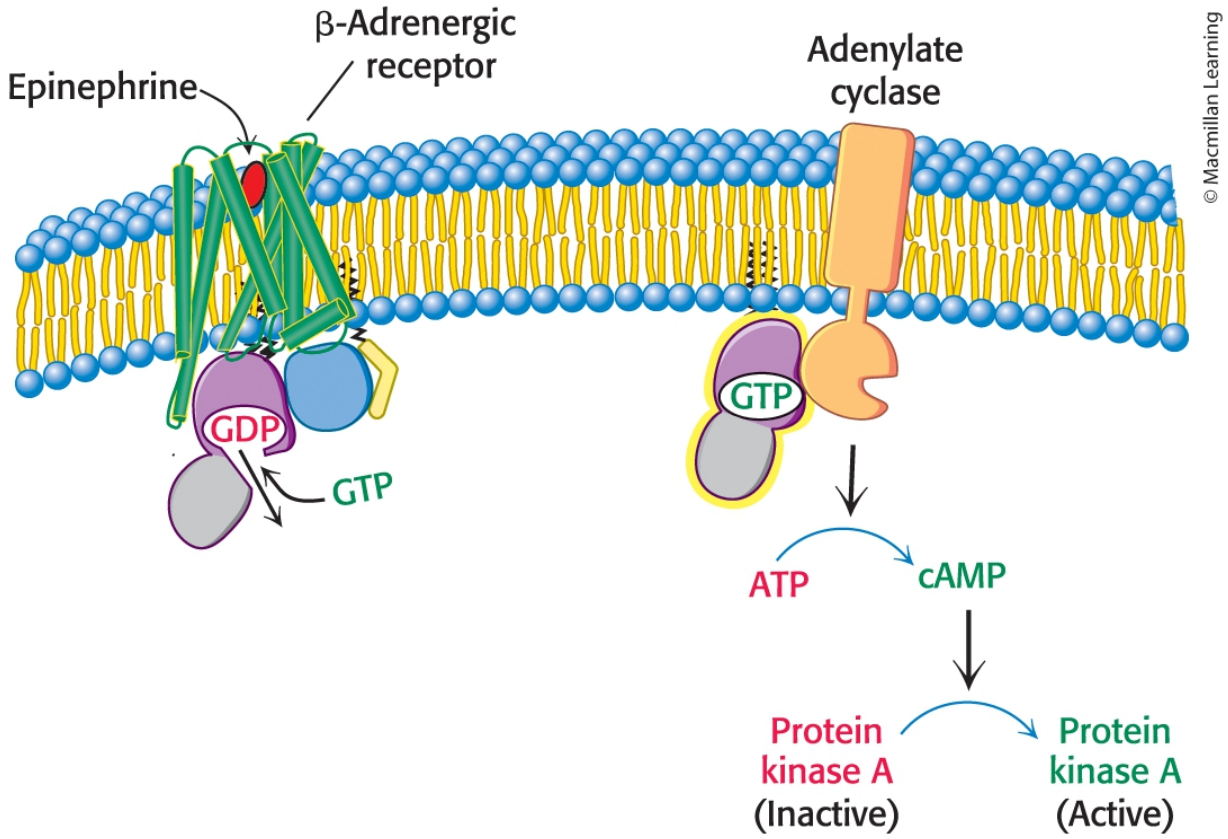
Part (B): The top view shows a cluster of randomly oriented seven long or short cylindrical structures labeled 1 to 7. These structures are arranged in an anticlockwise direction starting from the left.

Return to Schematic representation of the side view and top view of the beta-2 adrenergic receptor

Extended description for Stabilization of the active conformation of beta-adrenergic receptor

© Macmillan Learning

The beta 2-adrenergic receptor consists of a cluster of slightly diagonally oriented or vertically oriented long cylindrical structures. They are interconnected by short thread-like loops. An irregular thread at the top of this cluster is connected to a short cylindrical structure. A few short cylindrical structures are located at bottom of the receptor.



A forward arrow labeled agonist leads to the stabilized activated form of the receptor.

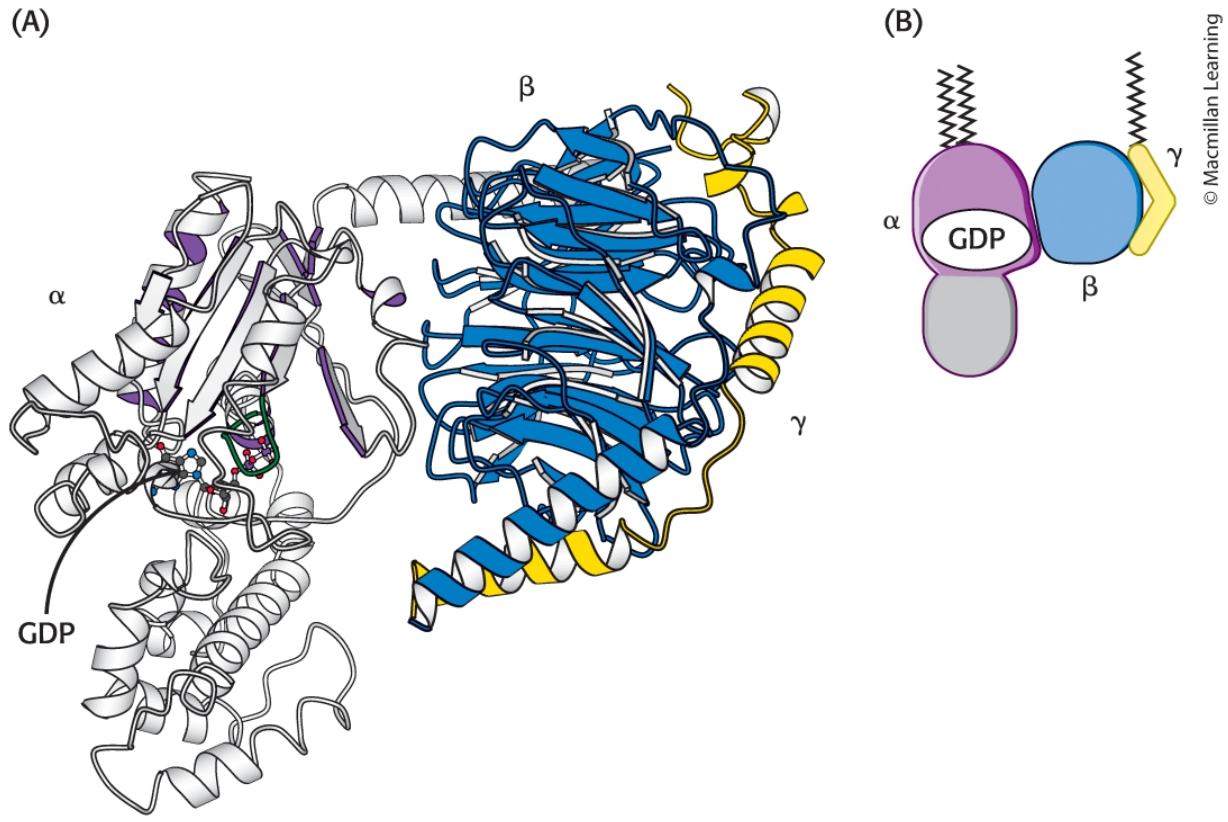
The orientation of some cylindrical structures on the left has altered as they are separated by a gap. A space-filling model composed of

black, red, and blue spheres is bound to the top groove of the receptor. The leftmost cylindrical structure is labeled helix 6 and its adjacent cylindrical structure is labeled helix 5. A leftward arrow is shown at the bottom of helix 6. A downward arrow is shown at the bottom of helix 5. These arrows depict the movement of helix 6 away from the receptor and the downward extension of helix 5 into the cell.

Return to Stabilization of the active conformation of beta-adrenergic receptor

Extended description for Signaling pathway initiated by epinephrine

A section of a horizontally oriented lipid bilayer is shown. The beta-adrenergic receptor is embedded in the lipid bilayer. It is composed of long and a few short cylindrical structures interconnected by thread-like loops. Epinephrine depicted as a red oval-shaped structure is bound to the top groove of the receptor. The cytoplasmic side of the receptor is bound to a trimeric structure. This structure is composed of a blue rounded-square-shaped structure associated with a purple round structure having a wide groove at the bottom labeled G D P. The purple round structure is further connected to a round and relatively smaller grey structure. The grey structure is located at the lower left of the purple structure such that a small



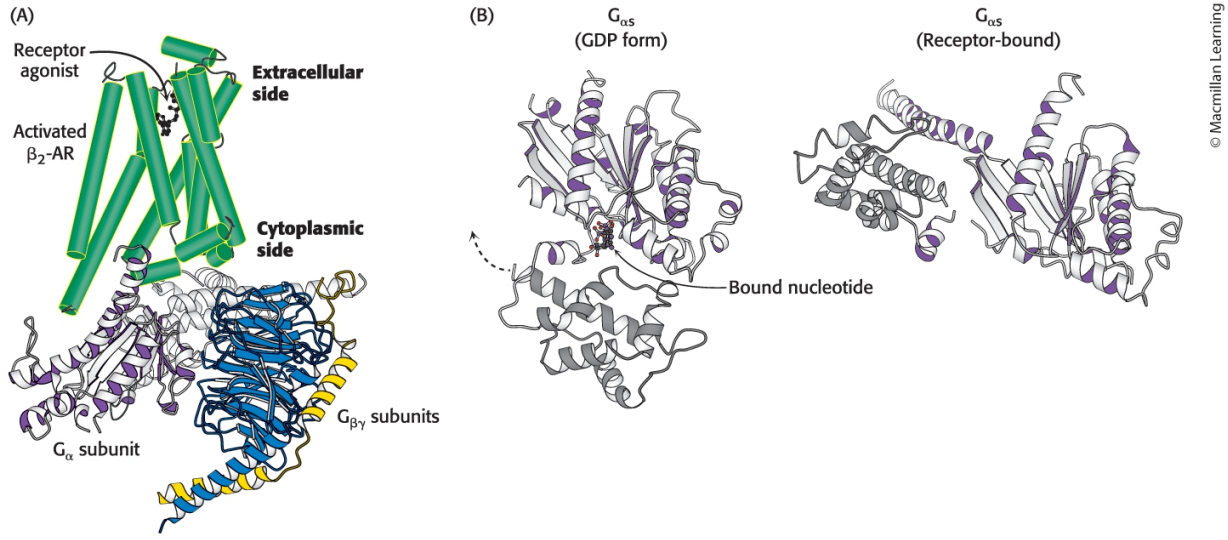
passage is created for the exit of G D P and entry of G T P into the groove of the purple structure. The blue rounded square is associated with a short yellow kinked structure that is attached to the inner leaflet of the bilayer through a zigzag line embedded in the bilayer. Likewise, the purple structure is attached to the inner leaflet of the bilayer through a zigzag line embedded within the bilayer.

On the right side, adenylate cyclase is shown embedded in the same bilayer. It is composed of a rectangular membrane-spanning region and a cytoplasmic round region having a tiny groove. The complex of purple and grey structure is bound to the cytoplasmic round region of adenylate cyclase. The purple structure is bound to G T P and its groove is closed by the grey sphere located below it.

A downward arrow below the cytoplasmic region of adenylate cyclase shows the conversion of A T P to c A M P. c A M P further helps in the conversion of inactive protein kinase A to active protein kinase A.

Return to Signaling pathway initiated by epinephrine

Extended description for Ribbon diagram and schematic representation of the G protein subunits



Part (A): The G protein is composed of alpha, beta, and gamma subunits. The beta and gamma subunits are closely associated to form a dimer. The beta subunit is composed of several horizontal beta-strands stacked together and a long alpha helix at the bottom. The gamma subunit consists of three alpha-helices out of which two are long and are associated with the bottom and right periphery of the beta subunit. The alpha subunit is located at a certain gap from the beta-gamma dimer. The beta-subunit of the dimer faces the alpha subunit. The alpha subunit is composed of several alpha-helices and few-beta strands. The beta-strands form the core of the top portion of the alpha subunit. The ball-and-stick model of G D P

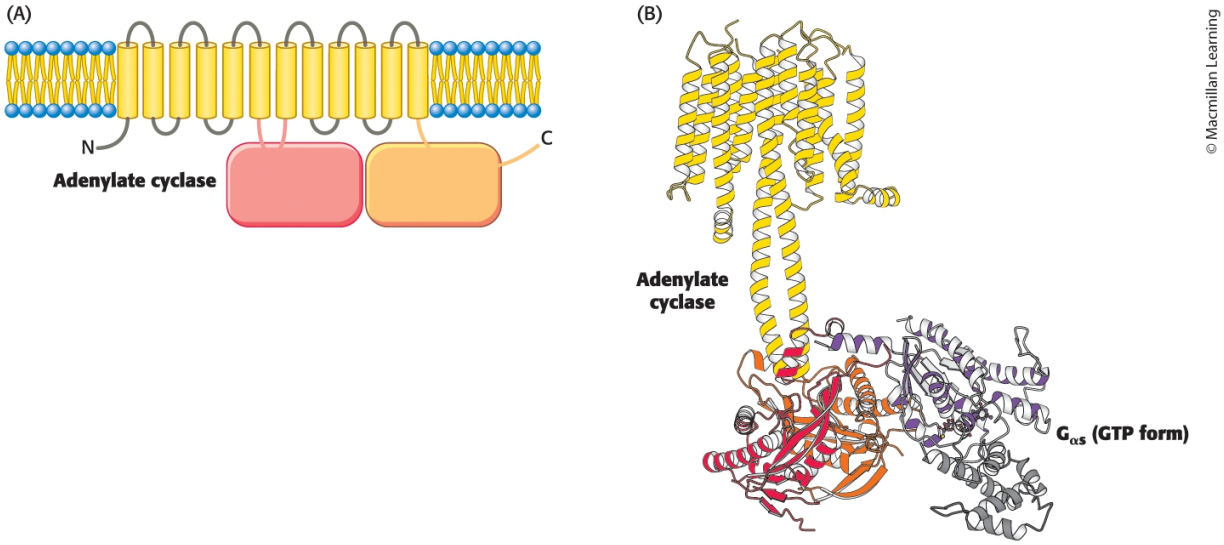
is bound to a groove in the top region of the alpha subunit. An alpha-helix from the top region extends horizontally into the beta-subunit.

Part (B): The G protein is composed of a blue rounded-square-shaped structure labeled beta associated with a complex of purple round and grey round structures on the left labeled alpha and a yellow structure on the right labeled gamma. The purple structure has a wide groove at the bottom labeled G D P. The purple round structure is further connected to a round and relatively smaller grey structure below such that its groove is closed. The blue rounded square is associated with a short yellow kinked structure having a vertical zigzag line at the top. The purple structure of the alpha subunit has two vertical zigzag lines at the top.

Return to Ribbon diagram and schematic representation of the G protein subunits

Extended description for Beta-2 A R bound to G protein and G D P and receptor bound forms of alpha subunit

Part (A): A receptor agonist is bound to the top groove of the activated beta-2 A R. The top and bottom of the receptor are labeled extracellular side and cytoplasmic side respectively. The cytoplasmic side is associated with the ribbon diagram of G protein. The G protein is composed of G subscript alpha subunit and G subscript beta gamma subunits. The alpha-helices of the G subscript alpha subunit directly interact with the cytoplasmic side of activated beta-2 A R. The G subscript beta gamma subunits are associated with the G subscript alpha subunit.



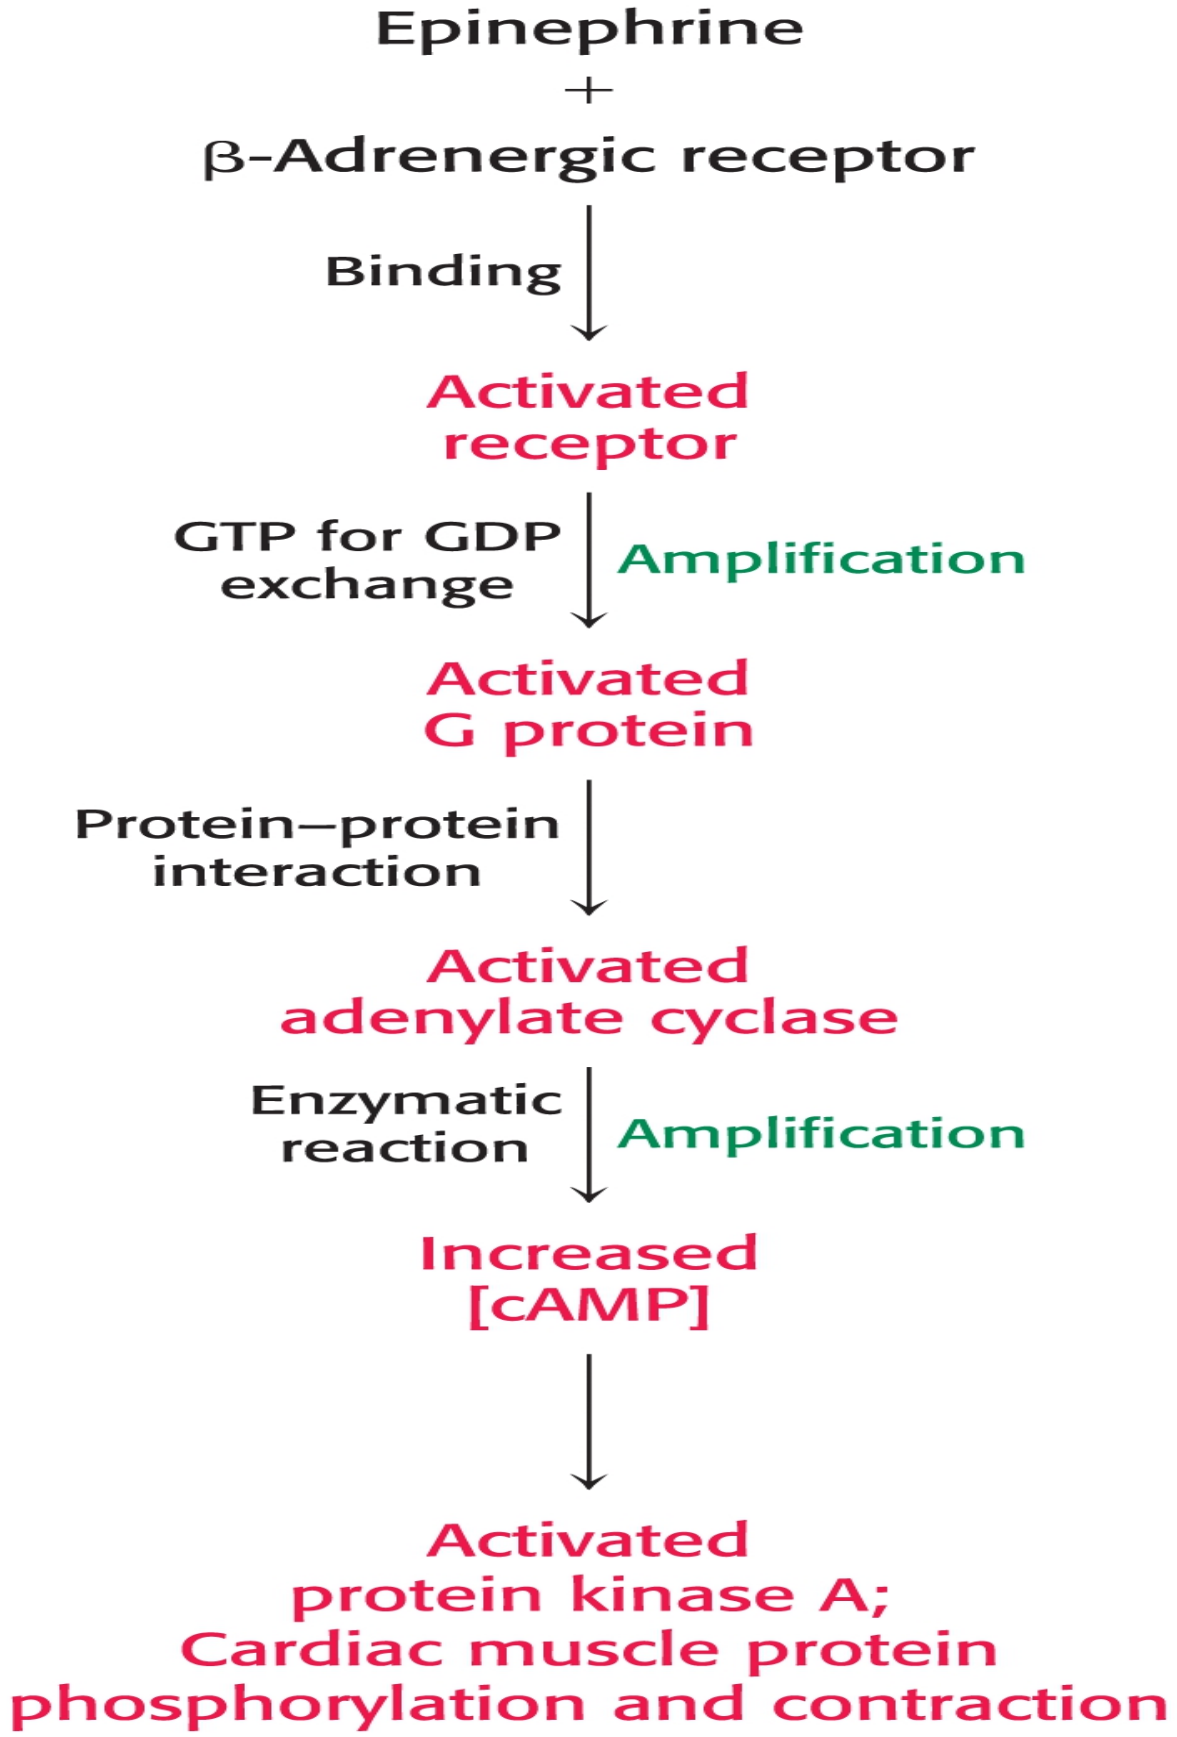
Part (B): The G alpha S (G D P form) is composed of top and bottom portions. The top portion contains three crisscrossing beta-strands circularly surrounded by alpha-helices. The secondary structures are interconnected by thread-like loops. The bottom portion is composed of a few loosely arranged alpha-helices interconnected by long threads. The ball-and-stick model of nucleotide is bound to alpha-helices at the bottom side of the top portion. An upward

curved dashed arrow is shown above a diagonally oriented central alpha-helix of the bottom portion.

The G subscript alpha S (receptor-bound) subunit shows that the bottom portion of the G D P form has moved to the left side of the top portion. This exposes the bottom side of the top portion.

Return to Beta-2 A R bound to G protein and G D P and receptor bound forms of alpha subunit

Extended description for Schematic representation of adenylate cyclase and ribbon diagram of adenylate cyclase bound to G subscript alpha S subunit



Part (A): A section of a horizontal lipid bilayer is shown. The adenylate cyclase protein consists of 12 vertically oriented cylindrical structures that span through the lipid bilayer. The cylindrical structures are placed adjacent to each other in a tandem arrangement. The leftmost cylindrical structure has a short thread-like extension in the cytoplasm labeled “N.” The rightmost cylindrical structure has a short thread-like extension in the cytoplasm labeled “C.” The adjacent cylindrical structures are connected by curved thread-like loops at the top or bottom in an alternating manner. The third bottom loop connecting the sixth and seventh structure is associated with a red rounded rectangle and the extension “C” is associated with an orange rounded rectangle. The red and orange rectangles are located side by side in the cytoplasm, below the lipid bilayer.

Part (B): The adenylate cyclase protein is depicted as a cluster of vertically oriented yellow alpha-helices. Two long yellow alpha-helices at the center of the cluster extend below into a small cluster composed of several alpha-helices and beta-strands shown in red or orange color. The ribbon diagram of G subscript alpha S (G T P form) is bound to the orange alpha-helices of the cluster. An alpha-helix at the top of the G subscript alpha S subunit is attached to the long yellow vertical alpha-helix extending below.

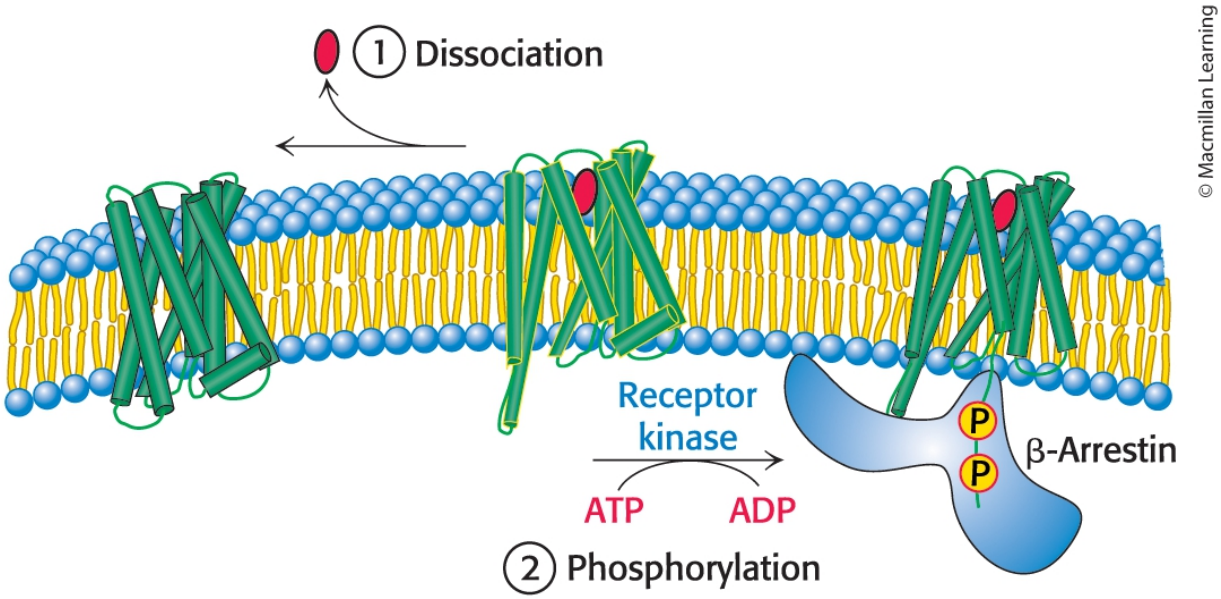
Extended description for G protein resetting

© Macmillan Learning



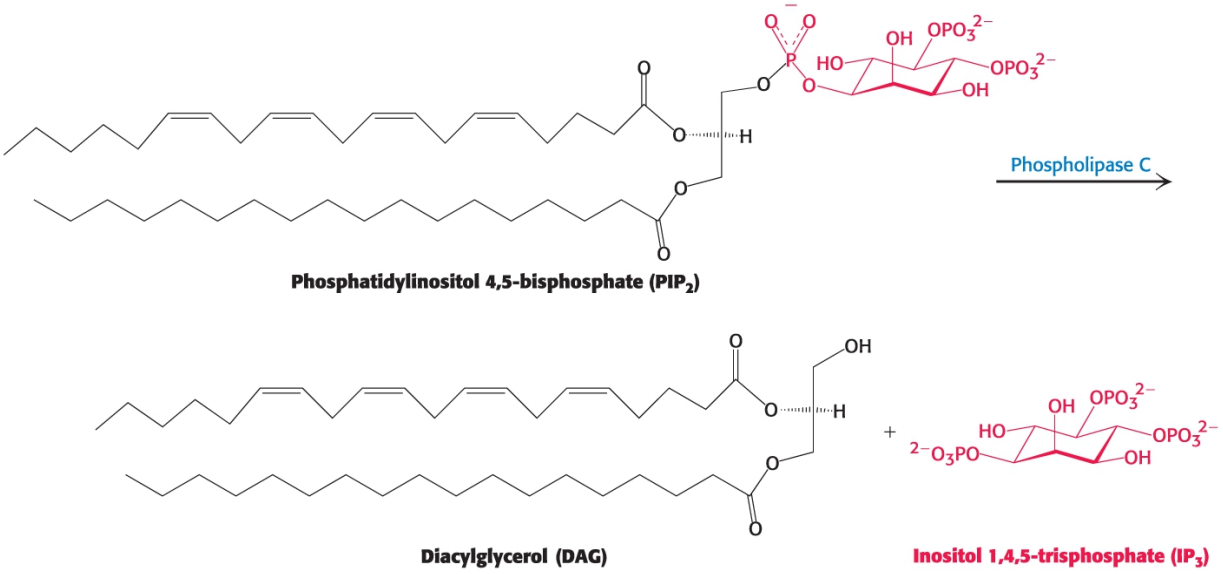
A section of a lipid bilayer is shown. The adenylate cyclase protein is shown embedded in the same bilayer. It is composed of a rectangular membrane-spanning region and a cytoplasmic round region having a tiny groove. A complex of purple and grey round structures is bound to the cytoplasmic round region of adenylate cyclase. The purple structure directly interacts with the cytoplasmic region of adenylate cyclase. The purple structure has a groove bound to G T P. This groove is closed by the grey sphere located below. Two zigzag lines at the top of the purple structure are embedded in the lipid bilayer.

A forward arrow leads to the purple structure bound to G D P and a grey structure below. It also shows the entry of H 2 O and exit of P subscript i. The complex of purple structure bound to G D P and a grey structure below is detached from the cytoplasmic region of adenylate cyclase. It is still attached to the inner leaflet of the lipid bilayer through two zigzag lines at the top.

A forward arrow leads to the trimeric G protein complex composed of G D P bound purple structure and its associated grey structure bound to a blue oval structure on the right. The blue structure is bound to a short yellow kinked structure on the right. The yellow structure is attached to the inner leaflet of the lipid bilayer through a zigzag line at the top embedded in the bilayer. The unbounded adenylate cyclase is shown embedded in the lipid bilayer on the right of the trimeric complex.

Return to G protein resetting

Extended description for Termination of beta-adrenergic receptor signaling



© Macmillan Learning

A section of a lipid bilayer is shown. The beta-adrenergic receptor is shown embedded in the center of the lipid bilayer. Its top groove is bound to a red tiny oval-shaped structure. A leftward arrow shows (1) dissociation of the red oval-shaped structure from the receptor to show an unbound receptor on the left.

A rightward arrow below the centrally located receptor shows (2) phosphorylation catalyzed by receptor kinase. During phosphorylation, A T P is converted into A D P. This arrow leads to the receptor bound to beta-arrestin at the cytoplasmic side. The beta-arrestin molecule contains two P atoms.

Return to Termination of beta-adrenergic receptor signaling

Extended description for Cleavage of phosphatidylinositol 4,5-bisphosphate

The chemical reaction consists of one reactant and two products. The reactant phosphatidylinositol 4,5-bisphosphate (P I P 2) has the following structure: A vertical chain consists of 3 C atoms. C 1 is single bonded to O on the right. This O atom is single-bonded to P on the upper right. P is further single bonded to O on the lower right and partially double bonded to O on the upper left and upper right. The partially double-bonded O atoms have an overall negative charge. The O atom on the lower right is single bonded to C 4 of a 6-membered homocyclic hexagonal ring in a chair conformation. The ring is in a plane perpendicular to the plane of paper such that C 1 and C 5 are located away from the observer and C 2 and C 4 are located toward the observer. C 3 and C 6 are located close to each other. C 1 is single bonded to O P O 3 superscript 2 minus on the lower right. C 2 is single bonded to O H on the upper right. C 3 is single bonded to O H above. C 5 is single bonded to O H on the lower

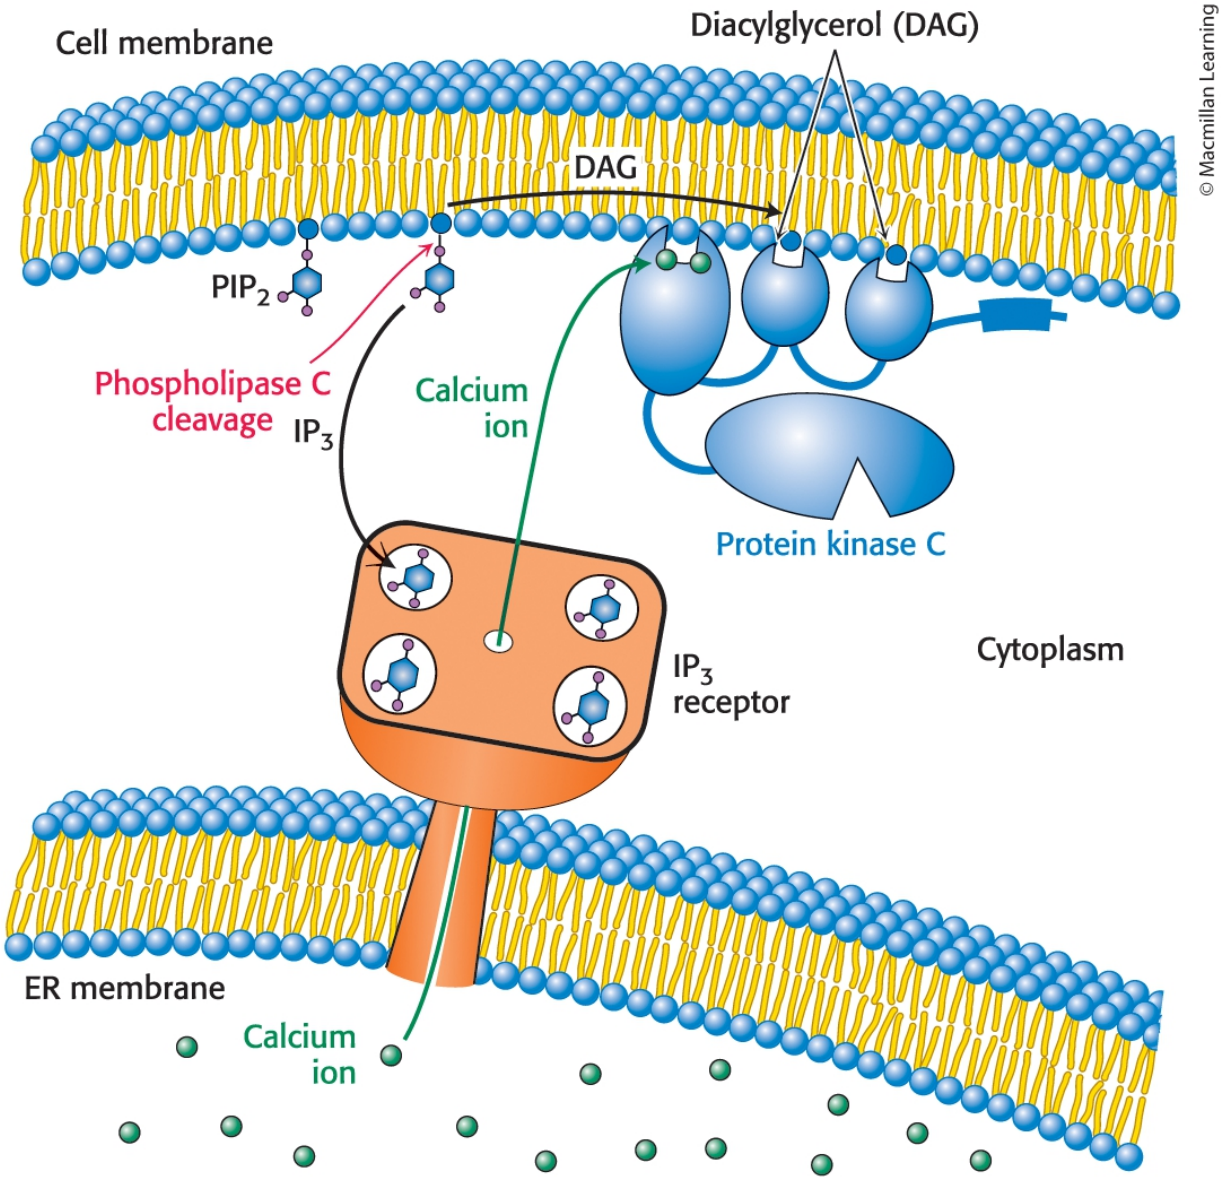
left. C 6 is single bonded to O P O 3 superscript 2 minus on the upper right.

C 2 of the vertical chain is dash bonded to H on the right and dash bonded to O on the left. This O atom is single bonded to C 1 of a 20-carbon alkene chain depicted as a line structure using 19 zigzag lines. C 1 of the chain is double bonded to O above. A double bond is present between C 5 and C 6, C 8 and C 9, C 11 and C 12, and C 14 and C 15.

C 3 of the vertical chain is single bonded to O on the lower left. This O is single bonded to C 1 of an 18-carbon alkane chain depicted as a line structure using 17 zigzag lines. C 1 of the chain is double bonded to O below.

A forward arrow labeled phospholipase C shows the products.

The first product is diacylglycerol (D A G) whose structure is as follows: A vertical chain consists of 3 C atoms. C 1 is single bonded to O H on the upper right. C 2 of the vertical chain is dash bonded to H on the right and dash bonded to O on the left. This O atom is single bonded to C 1 of a 20-carbon alkene chain depicted as a line structure using 19 zigzag lines. C 1 of the chain is double bonded to O above. A double bond is present between C 5 and C 6, C 8 and C 9, C 11 and C 12, and C 14 and C 15.



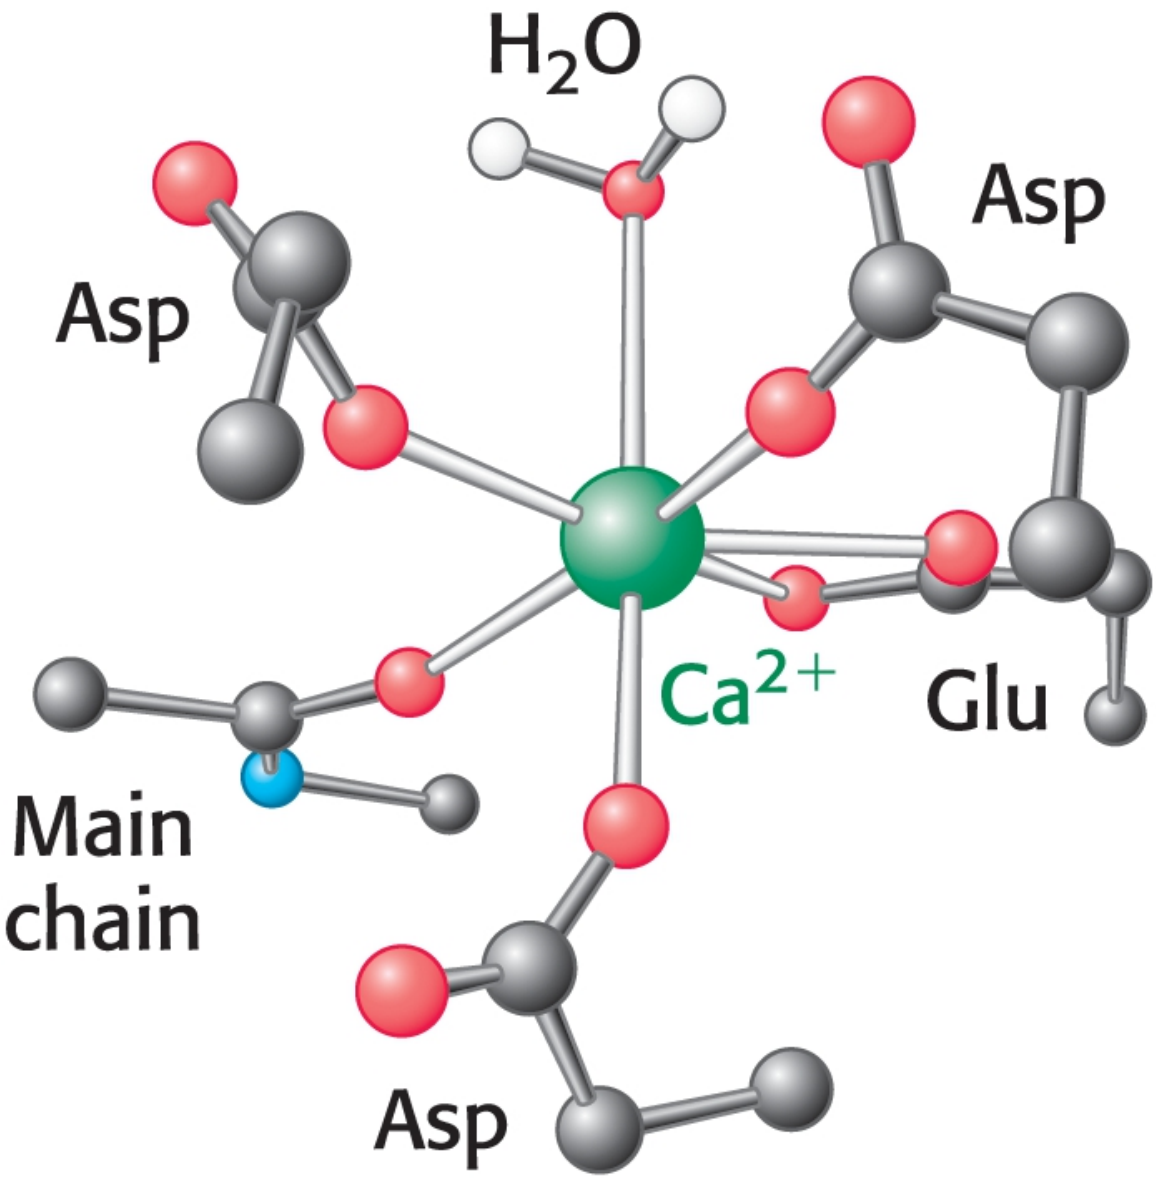
C 3 of the vertical chain is single bonded to O on the lower left. This O is single bonded to C 1 of an 18-carbon alkane chain depicted as a line structure using 17 zigzag lines. C 1 of the chain is double bonded to O below.

The second product is inositol 1,4,5-triphosphate (I P 3) whose structure is as follows: A 6-membered homocyclic hexagonal ring in

a chair conformation. The ring is in a plane perpendicular to the plane of paper such that C 1 and C 5 are located away from the observer and C 2 and C 4 are located toward the observer. C 3 and C 6 are located close to each other. C 1 is single bonded to O P O 3 superscript 2 minus on the lower right. C 2 is single bonded to O H on the upper right. C 3 is single bonded to O H above. C 4 is single bonded to O P O 3 superscript 2 minus on the upper left. C 5 is single bonded to O H on the lower left. C 6 is single bonded to O P O 3 superscript 2 minus on the upper right.

Return to Cleavage of phosphatidylinositol 4,5-bisphosphate

Extended description for Protein kinase C activation



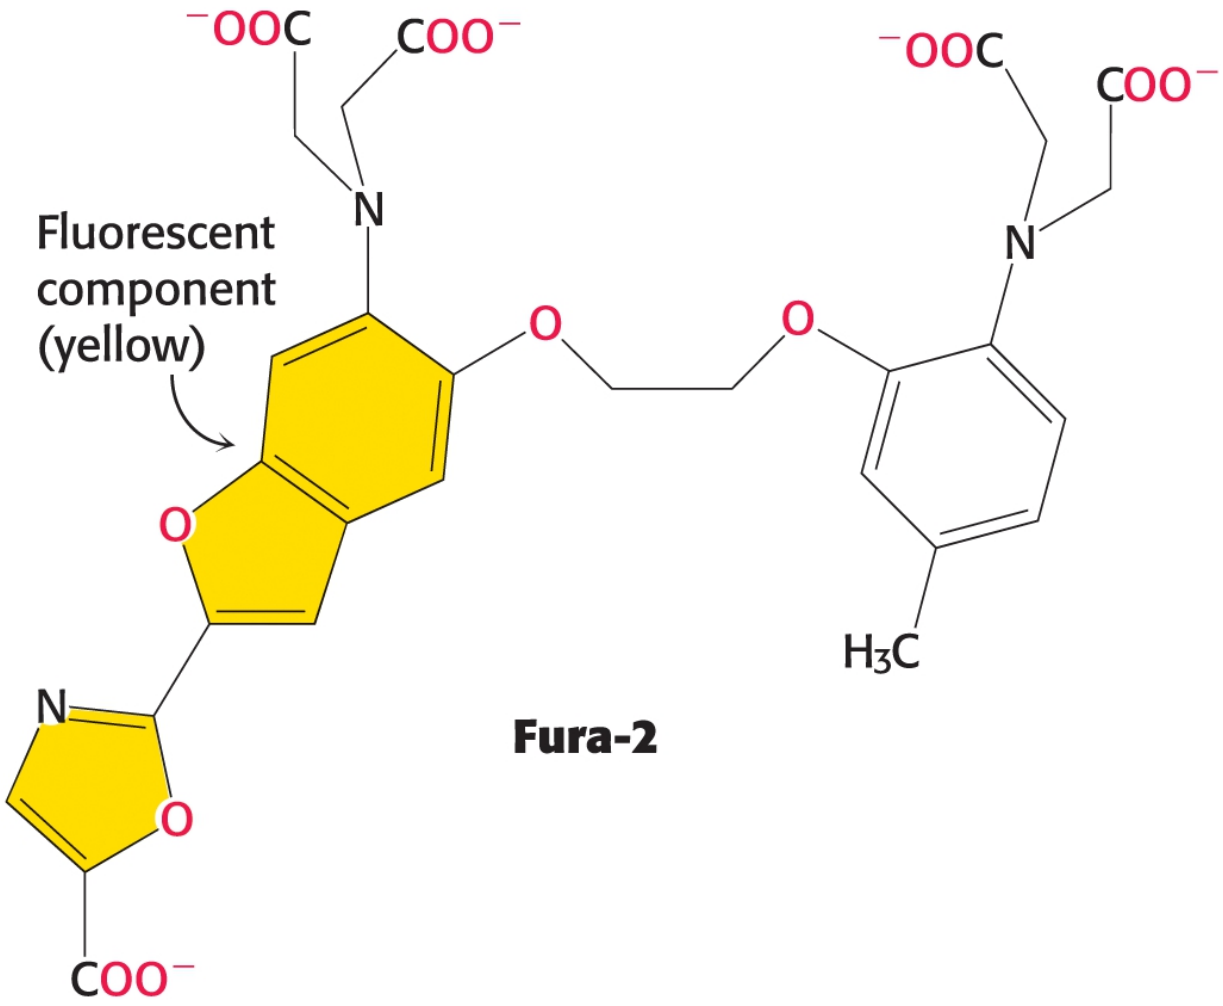
Two lipid bilayers separated by a large gap labeled cytoplasm are shown. The top bilayer is labeled cell membrane. The bottom bilayer is labeled E R membrane. P I P 2 in the inner leaflet of the cell membrane is cleaved into D A G and I P 3 by phospholipase C. P I P 2 is represented as a hexagon with its bottom-most vertex,

bottom left vertex, and topmost vertex connected to a tiny circle. The top tiny circle is connected to a circle in the inner leaflet. In P I P 2, phospholipase C breaks the linkage between the topmost tiny circle and the circle located in the inner leaflet.

I P 3 is depicted as a hexagon with its bottom-most vertex, bottom-left vertex, and topmost vertex connected to a tiny circle. It binds to four circular grooves of the I P 3 receptor embedded in the E R membrane. Several tiny green spheres depicting calcium ions are scattered below the E R membrane. One calcium ion passes through the transmembrane domain of the I P 3 receptor and enters the cytoplasm. The protein kinase is composed of four domains each containing a single groove connected by threads. A thread extending from the last domain of protein kinase C has a tiny rectangular domain. The three domains are attached to the inner leaflet of the cell membrane and the fourth domain is located in the cytoplasm. The shapes of the three domains are oval and round. Two calcium ions bind to the groove of the oval domain of protein kinase C attached to the inner leaflet. The grooves of the remaining two round domains bind to diacylglycerol.

Return to Protein kinase C activation

Extended description for Ball-and-stick model of calcium ion bound to oxygen atoms



© Macmillan Learning

A central green sphere representing C a superscript 2 plus ion is connected to a red sphere above, on the upper right, right, lower right, below, on the lower left, and upper left. The red spheres represent O atoms. The red sphere above is connected to a white

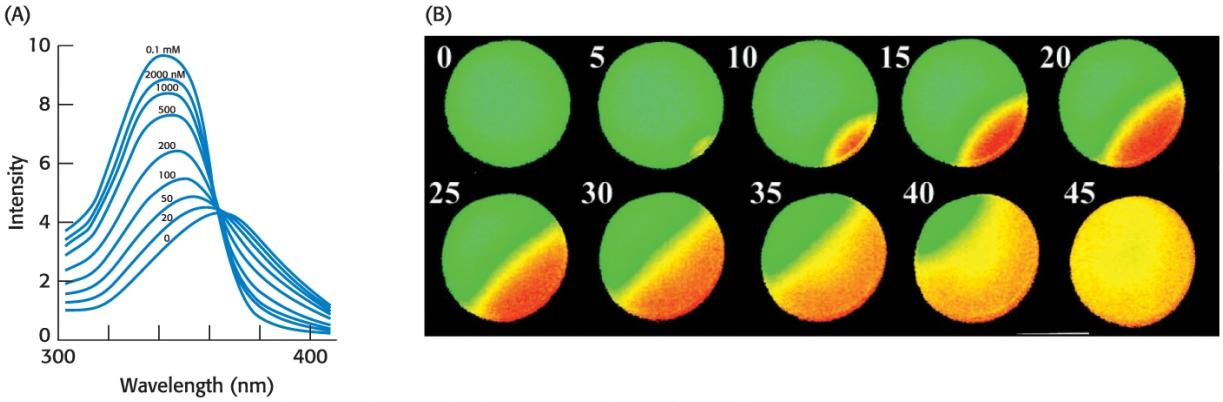
sphere on the upper left and upper right that are part of H 2 O. The red spheres on the upper right and lower right are connected to a chain of dark grey spheres which are part of aspartic acid and glutamic acid residues respectively. The red sphere below is connected to a dark grey sphere on the lower left which is further connected to a red sphere on the left and a dark grey sphere on the lower right. The dark grey sphere on the lower right is further connected to another dark grey sphere on the right. These dark grey and red spheres located below are part of the aspartic acid residue. The red sphere on the lower right is connected to a chain of dark grey spheres. The first dark grey sphere is connected to a chain of blue and dark grey spheres below that are part of the main chain. The red sphere on the upper left is connected to a cluster of three dark grey spheres and one red sphere that is part of the aspartic acid residue.

Return to Ball-and-stick model of calcium ion bound to oxygen atoms

Extended description for Structure of Fura-2

Fura-2

The structure of Fura-2 is as follows: A 5-membered heterocyclic pentagonal ring shown in yellow is in a vertical orientation and consists of 1 N, 1 O, and 3 C atoms. C 1 occupies the top right vertex. N occupies the topmost vertex. O occupies the bottom right vertex. A double bond is present between N and C 1, and C 2 and C 3. C 2 is single bonded to C O O superscript minus below. C 1 is single bonded to C 4 of another 5-membered heterocyclic pentagonal ring in a vertical orientation consisting of 1 O and 4 C atoms. O occupies the top left vertex. A double bond is present between C 3 and C 4.



This pentagonal ring is fused to a benzene ring in a vertical orientation such that C 1 and C 2 of the pentagonal ring are C 5 and C 4, respectively, of the benzene ring. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1.

C 1 is single bonded to N above. N is further single bonded to two different C H 2 groups on the upper left in the form of a line. Each C H 2 group is single bonded to C O O superscript minus above. The fused pentagonal ring and benzene ring are shown in yellow and labeled “Fluorescent component (yellow).”

C 2 of the benzene ring is single bonded to O 1 of a 2 O and 2 C heteronuclear alkane chain depicted as a line structure using 3 lines. O 2 occupies the fourth position of the alkane chain and is single bonded to C 6 of another benzene ring on the right. This benzene ring is in a vertical orientation and contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 1 is single bonded to N above. N is further single bonded to C H 2 above and C H 2 on the upper right in the form of a line. Each C H 2 group is single bonded to C O O superscript minus above. C 4 is single bonded to C H 3 below.

Part (A): It shows a graph with different curves. The horizontal axis is labeled wavelength in nanometers. It has markings ranging from 300 to 400 in increments of 100 units. The vertical axis is labeled intensity. It has markings ranging from 0 to 10 in increments of 2 units. The graph shows a series of bell-shaped curves arranged in ascending order of peak size from the bottom to the top. The topmost curve has a peak size of 10 at 350 nanometers. From bottom to top, the curves shift gradually shift toward the left. The bottommost curve has a peak size of 4.2 at 370 nanometers. From bottom to top, the curves are labeled 0, 20, 50, 100, 200, 500, 1000, 2000 nanomolar, and 0.1 millimolar.

Part (B): It shows 10 circular views of C a superscript 2 plus ion spreading across an egg cell at 0, 5, 10, 15, 20, 25, 30, 35, 40, and 45 seconds. At 0 seconds, the entire view is green-colored. At 5 seconds, a tiny yellow-orange patch is seen at the bottom right. From 10 to 40 seconds, the yellow-orange patch becomes

progressively larger and ultimately covers the entire view at 45 seconds.

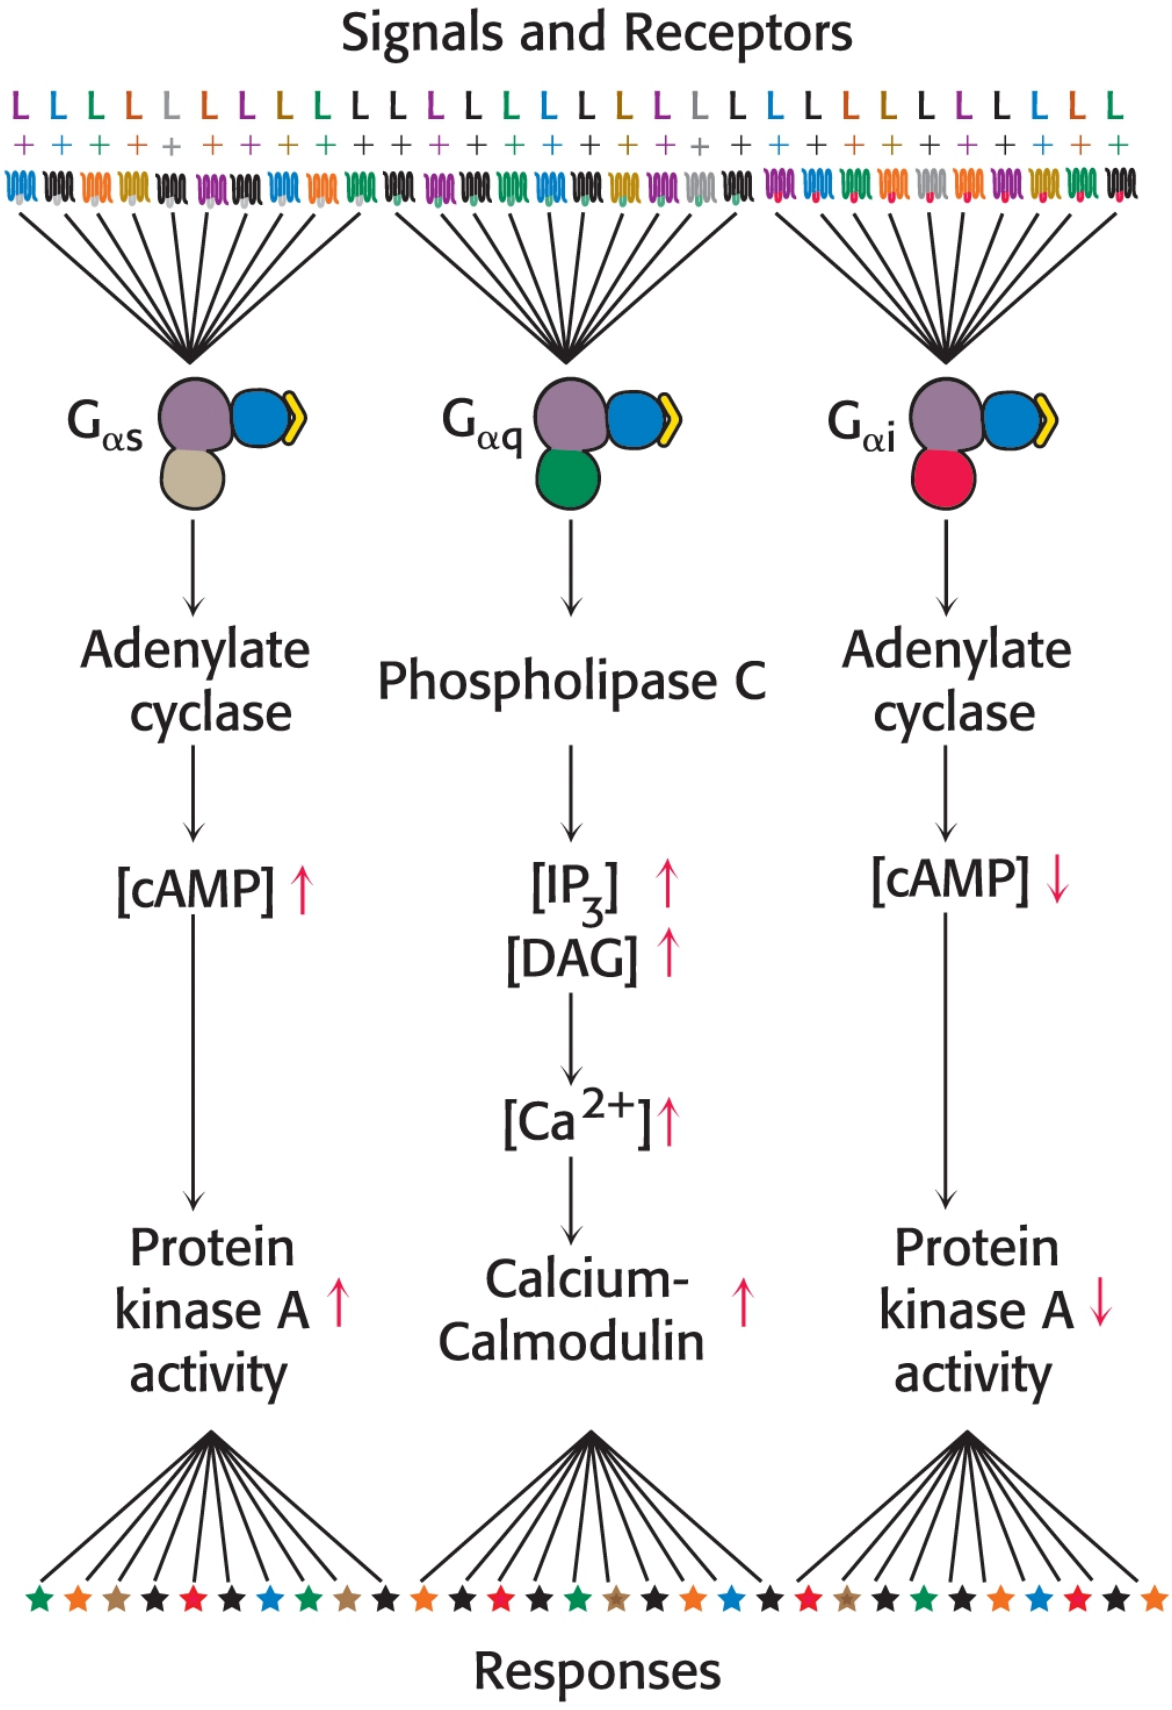
Extended description for Signal transduction by G protein beta gamma dimer



A horizontal section of a lipid bilayer is shown. The beta-adrenergic receptor bound to a red oval-shaped structure at the top is shown embedded in the bilayer. The cytoplasmic side of the receptor is bound to the trimeric G protein. The grey structure associated with the purple round structure is displaced toward the lower left to allow the exit of G D P and entry of G T P into the groove of the purple round structure. An arrow shows the G subscript beta gamma subunit associated with the cytoplasmic region of a cork-shaped structure embedded on the right of the same bilayer. G subscript beta gamma subunit consists of a blue rounded square and a short yellow kinked structure having a zigzag line at the top embedded in the lipid bilayer. The blue structure is directly associated with the cork-shaped structure. A downward arrow across the central channel of the cork-shaped structure shows the inward movement of C a superscript 2 plus.

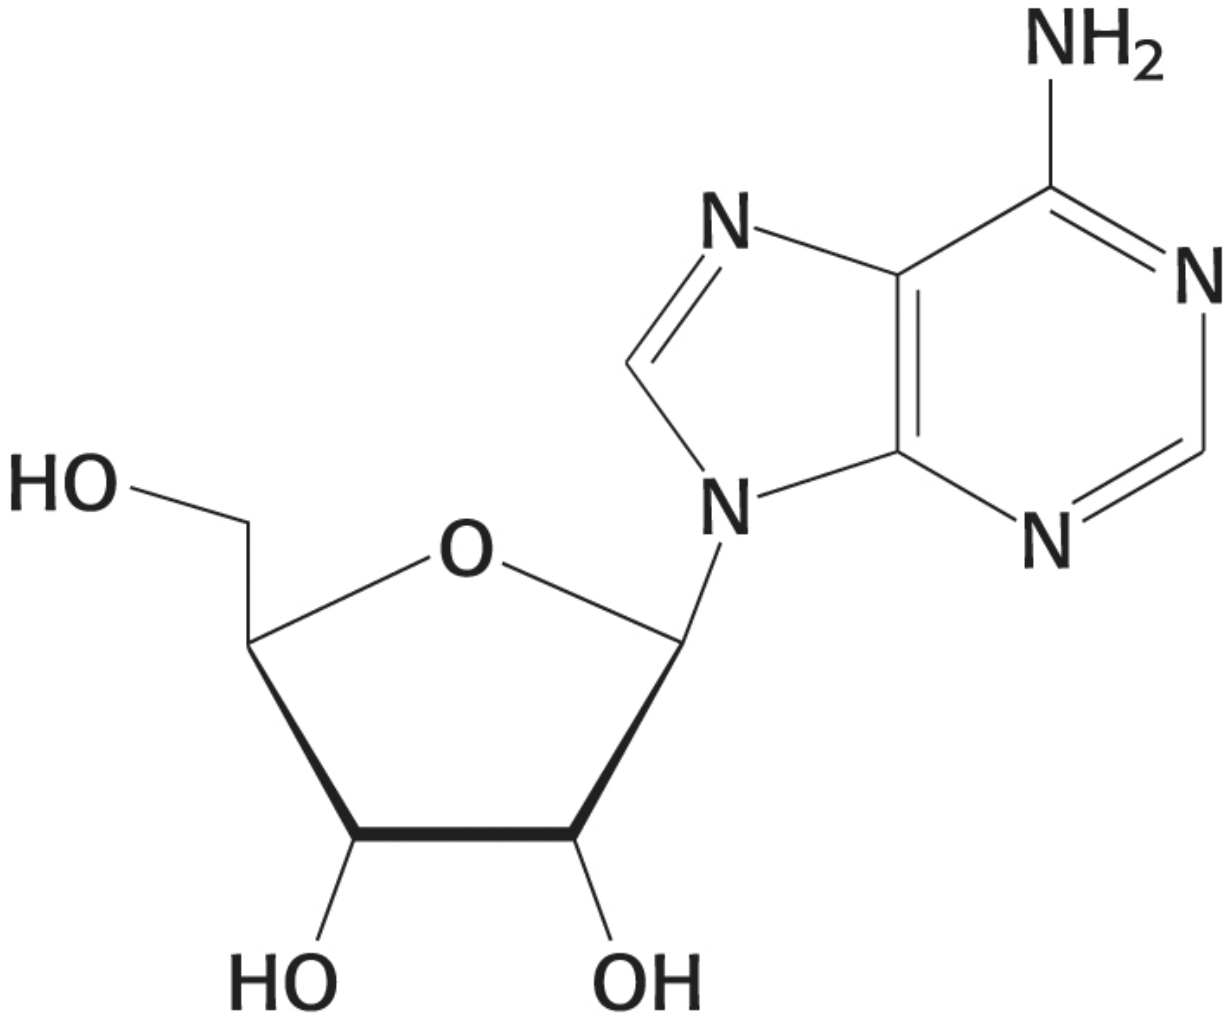
Return to Signal transduction by G protein beta gamma dimer

Extended description for Generalized signaling pathway involving the three classes of G protein alpha

subunits

© Macmillan Learning

Three classes of the G protein alpha subunits are G subscript alpha S, G subscript alpha q, and G subscript alpha i. Ten different “7 T M” receptors bound to a ligand L are shown above each type of subunit to show signals and receptors. The 7 T M receptor is depicted as a tiny structure with zigzag turns. Lines from each of the receptor-ligand complex converge together and point below to a particular type of G protein alpha subunit.



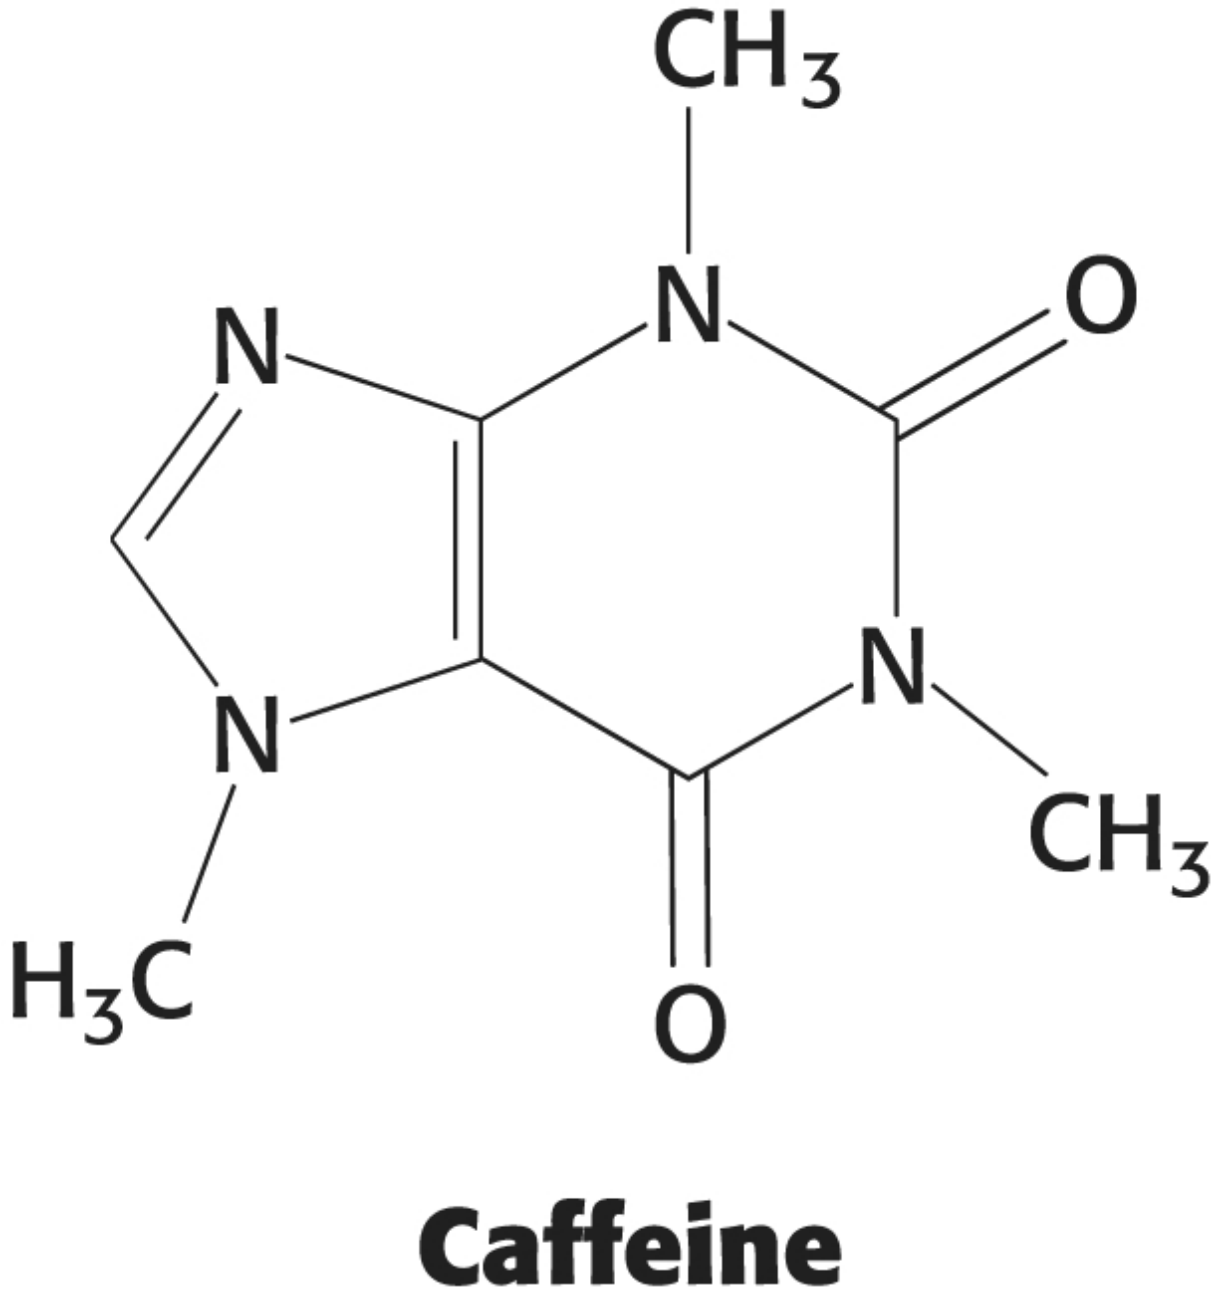
The signaling pathway initiated by the G subscript alpha S subunit is as follows: adenylate cyclase, concentration of c A M P increases, downward arrow, protein kinase A activity increases, 10 downward lines each pointing toward a differently colored star symbol to show the different responses.

The signaling pathway initiated by the G subscript alpha q subunit is as follows: Phospholipase C, downward arrow, concentration of I P 3 and D A G increases, downward arrow, concentration of C a superscript 2 plus ion increases, downward arrow, calcium-calmodulin increases, 10 downward lines each pointing toward a differently colored star symbol to show the different responses.

The signaling pathway initiated by the G subscript alpha i subunit is as follows: Adenylate cyclase, downward arrow, concentration of c A M P increases, downward arrow, protein kinase A activity decreases, 10 downward lines each pointing toward a differently colored star symbol to show the different responses.

Return to Generalized signaling pathway involving the three classes of G protein alpha subunits

Extended description for Structure of adenosine



Adenosine

The structure of adenosine is as follows: A 5-membered heterocyclic pentagonal is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single bonded to N 1 of a 5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 2 N and 3 C atoms. The first N atom occupies the first position, which is the bottom left vertex. The second N atom occupies the third position, which is the top left

vertex. C 1 occupies the rightmost vertex. A double bond is present between C 1 and N 2. This pentagonal ring is fused to a 6-membered heterocyclic hexagonal such that C 2 and C 3 of the pentagonal are C 3 and C 2 respectively of the hexagonal ring. The first N occupies the first position, which is the top right vertex. The second N occupies the third position, which is the bottom-most vertex. A double bond is present between C 1 and N 2, C 2 and C 3, C 4 and N 1. C 4 is single bonded to N H 2 above. C 2 and C 3 of the first pentagonal ring are each single bonded to O H below. C 4 is single bonded to C H 2 above in the form of a line. C H 2 is further single bonded to O H on the upper left.

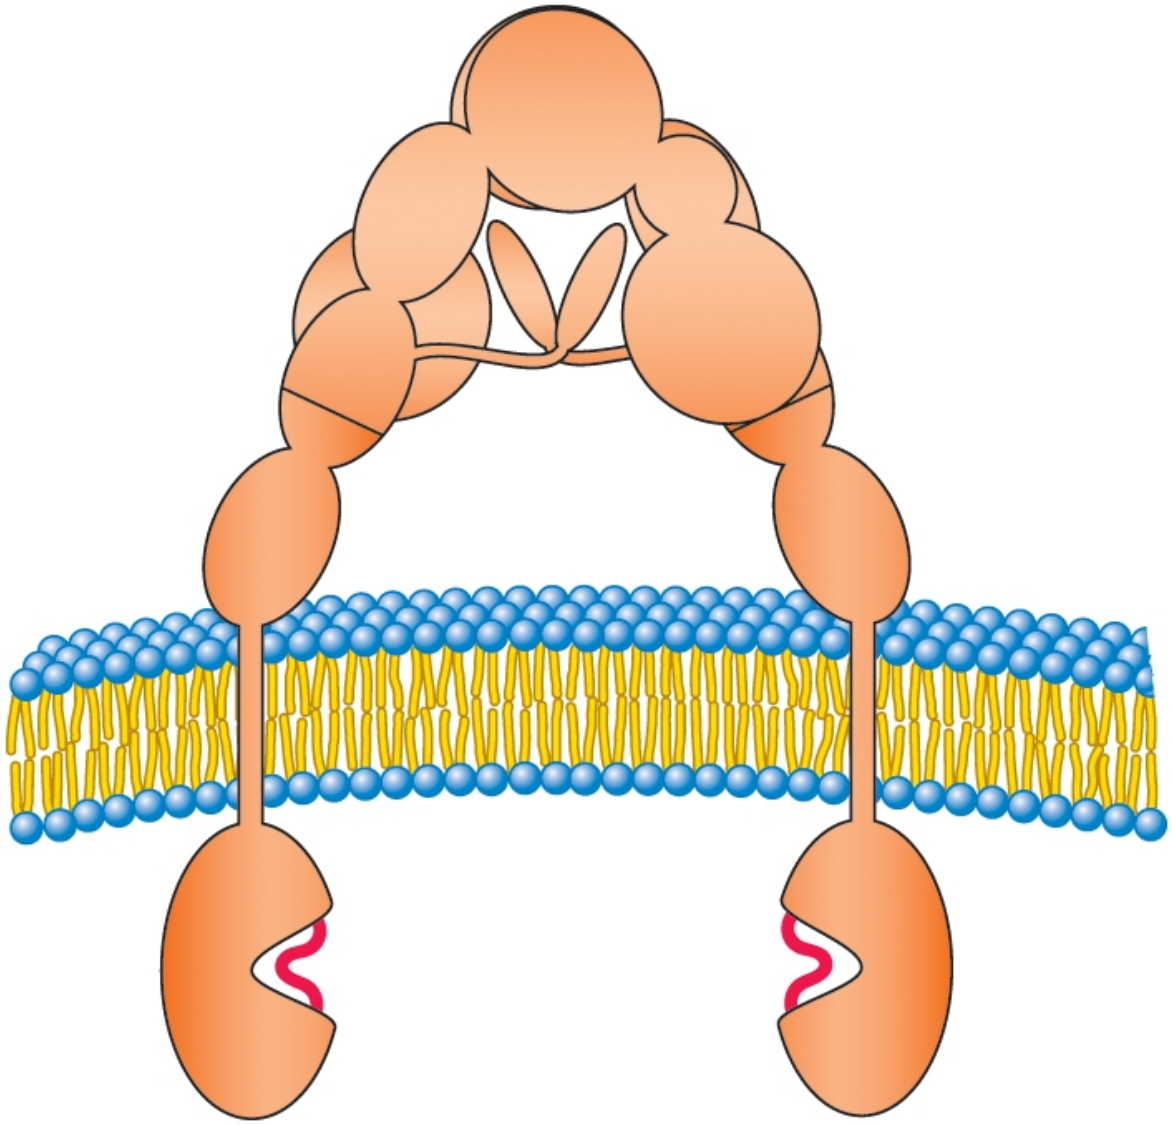
Extended description for Insulin ribbon structure



© Macmillan Learning

A vertical yellow alpha-helix is shown on the left. Long threads originate from the top and bottom portions of the alpha-helix. Two

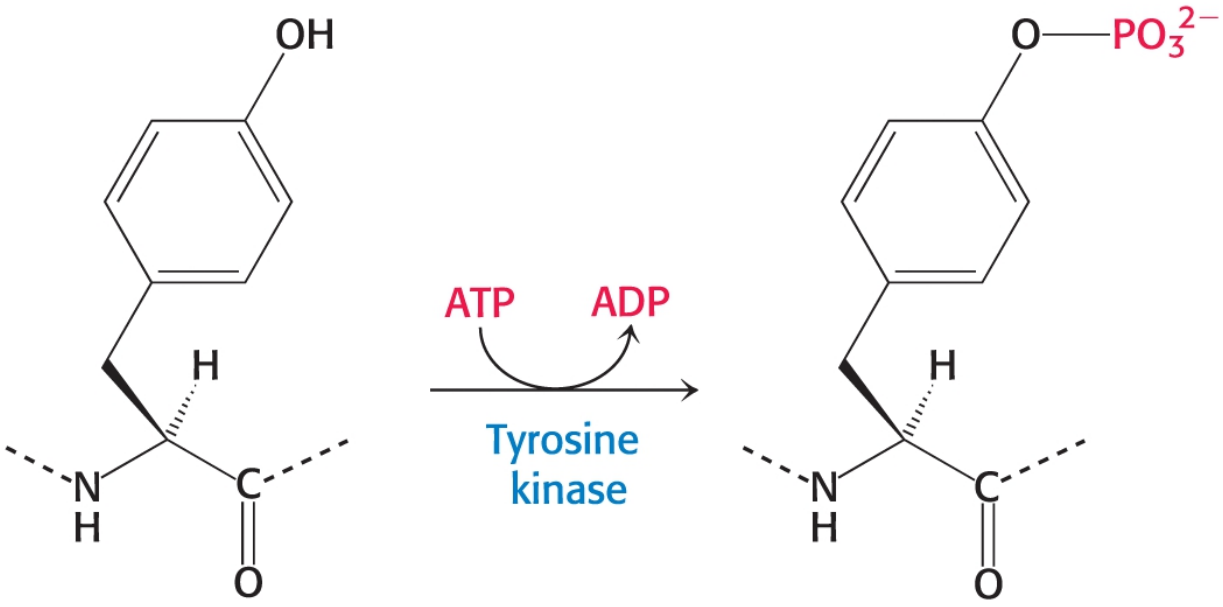
short blue alpha-helices interconnected by a long blue thread are shown on the right. The long yellow thread of the left helix extends toward the upper right. Two ball-and-stick models connect the top portion of the yellow alpha-helix with the blue thread and bottom portion of the yellow alpha-helix with the second short blue alpha-helix. A third ball-and-stick model connects the different sections of the blue thread. The ball-and-stick model is composed of a chain of two black spheres connected to a yellow sphere. The yellow sphere is connected to another yellow sphere which is further connected to a chain of two black spheres.

Return to Insulin ribbon structure

Extended description for Insulin receptor

© Macmillan Learning

A section of a horizontal lipid bilayer is shown. The insulin receptor consists of two subunits each consisting of two different chains shown in dark orange and light orange colors. The dark orange chain consists of an oval-shaped domain located above the bilayer, a thin tubular domain spanning the bilayer, and a large oval-shaped



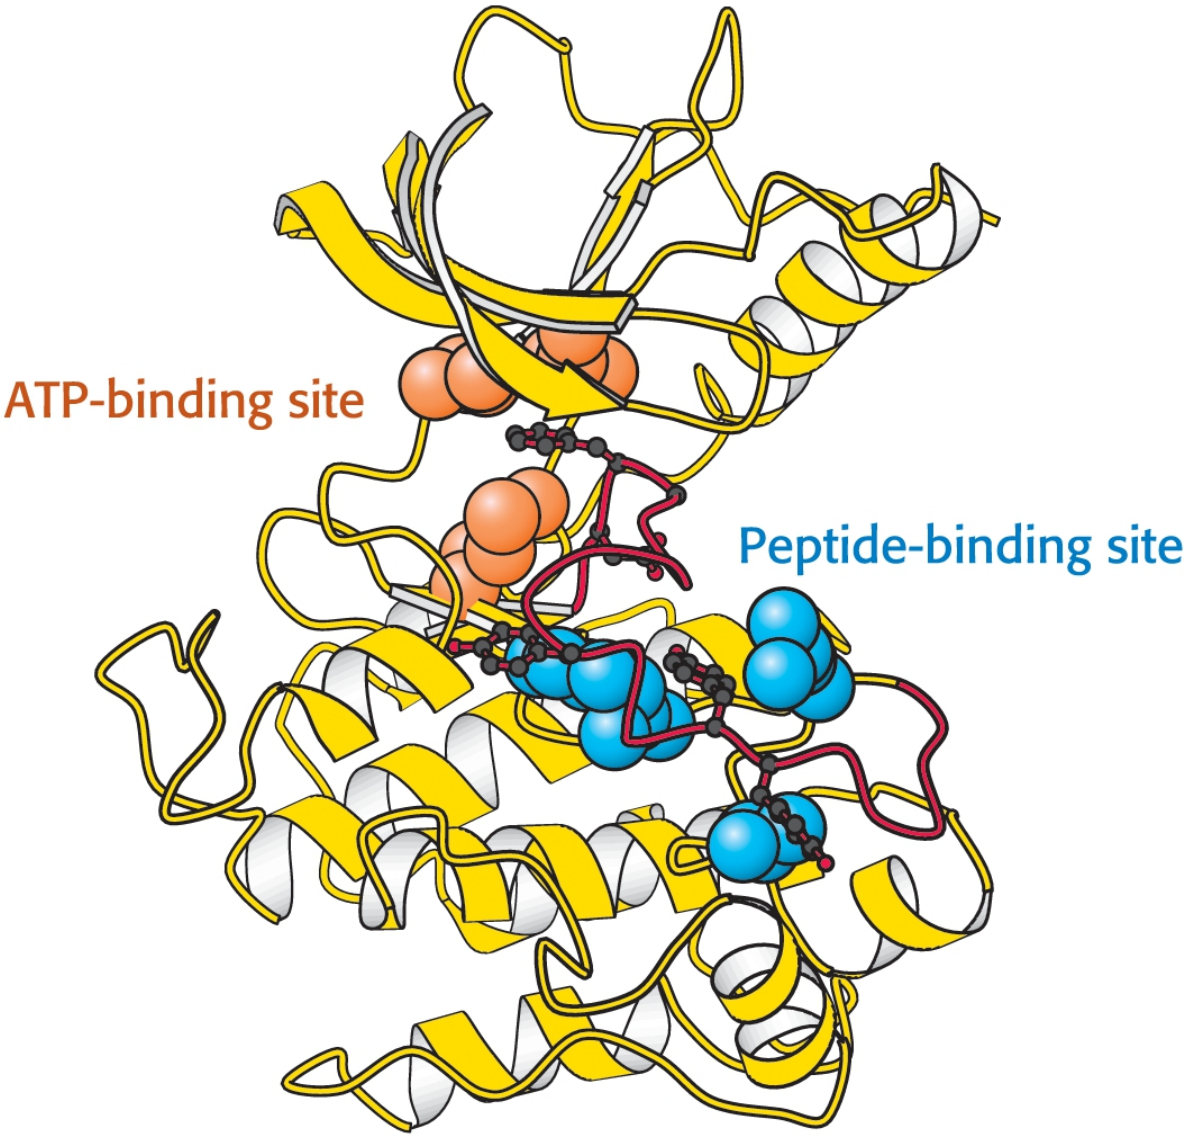
domain below the bilayer. The oval-shaped domain above the bilayer is connected to a half oval domain above. The large oval-shaped domain has a triangular groove. A wavy red line within the groove connects the ends of the groove.

The light orange chain consists of four globular domains and a half-globular domain at the bottom that is connected to the half oval domain of the dark orange chain located above the bilayer.

The light orange chains of the two subunits fold over one another to form an arch-shaped structure. A short extension having a leaf-shaped structure at the end originates from the half globular domain of each of the light orange chain. These leaf-shaped structures cross each other just below the arch formed by light orange chains.

Return to Insulin receptor

Extended description for Chemical reaction catalyzed by tyrosine kinase



The chemical reaction consists of one reactant and one product. The reactant has the following structure: A benzene ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 6 is single bonded to O H on the upper right. C 3 is single bonded to C H 2 in the form of a line on the lower left. This C H 2 is wedge bonded to C 1 of a 1 N and 2 C heteronuclear alkane chain depicted as a line structure using 2 zigzag lines. In the alkane chain, N bound to H occupies the first position and has a dashed line on the upper left. C 1 is dash bonded to H on the upper right. C 2 is double bonded to O below and has a dashed line on the upper right.

A forward arrow labeled tyrosine kinase shows the product. A curved arrow above the forward arrow shows the simultaneous conversion of A T P into A D P.

The structure of the product is as follows: A benzene ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 6 is single bonded to O, single bond, P O 3 superscript 2 minus on the upper right. C 3 is single bonded to C H 2 in the form of a line on the lower left. This C H 2 is wedge bonded to C 1 of a 1 N and 2 C heteronuclear alkane chain depicted as a line structure using 2 zigzag lines. In the alkane chain, N bound to H occupies the first position and has a dashed line on the upper left. C 1 is dash bonded to H on the upper right. C 2 is double bonded to O below and has a dashed line on the upper right.

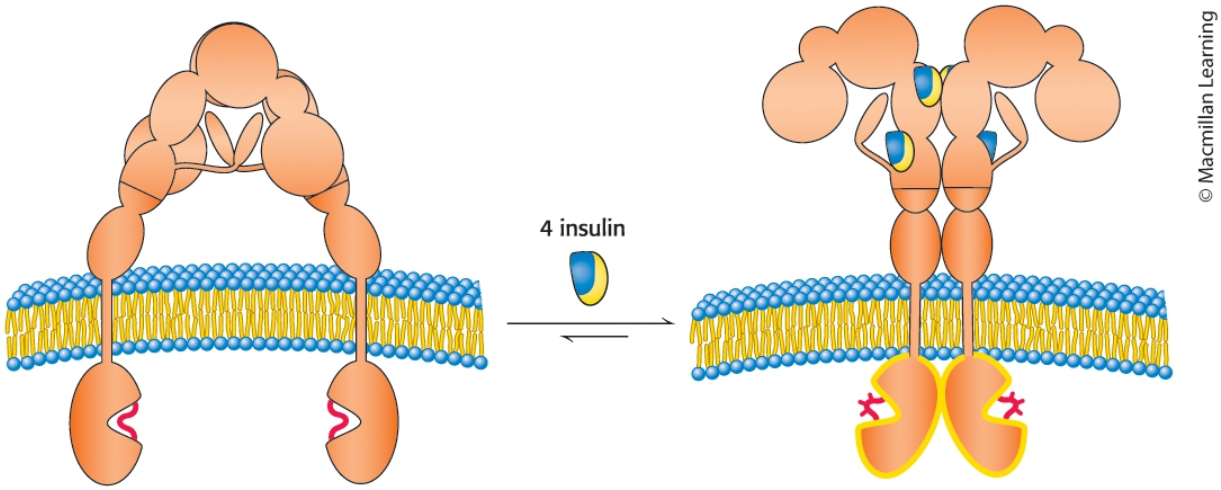
Extended description for Unactivated form of insulin receptor kinase



© Macmillan Learning

The unactivated insulin receptor kinase consists of several alpha-helices in the bottom portion and a few beta-strands and an alpha helix in the top portion. Several threads are located between the top and bottom portions. A cluster of orange spheres is located inside the beta-strands of the top portion and the top surface of the bottom

portion. These orange spheres depict residues from the A T P-binding site. Three clusters of blue spheres are shown around the top right of the bottom portion of the kinase. These blue spheres represent the peptide binding site. A long and wavy loop highlighted in red spans from the bottom portion to the junction between the top and bottom portion. The red loop passes across the blue and orange clusters and contains 5 ball-and-stick models of amino acid side chains.

Return to Unactivated form of insulin receptor kinase

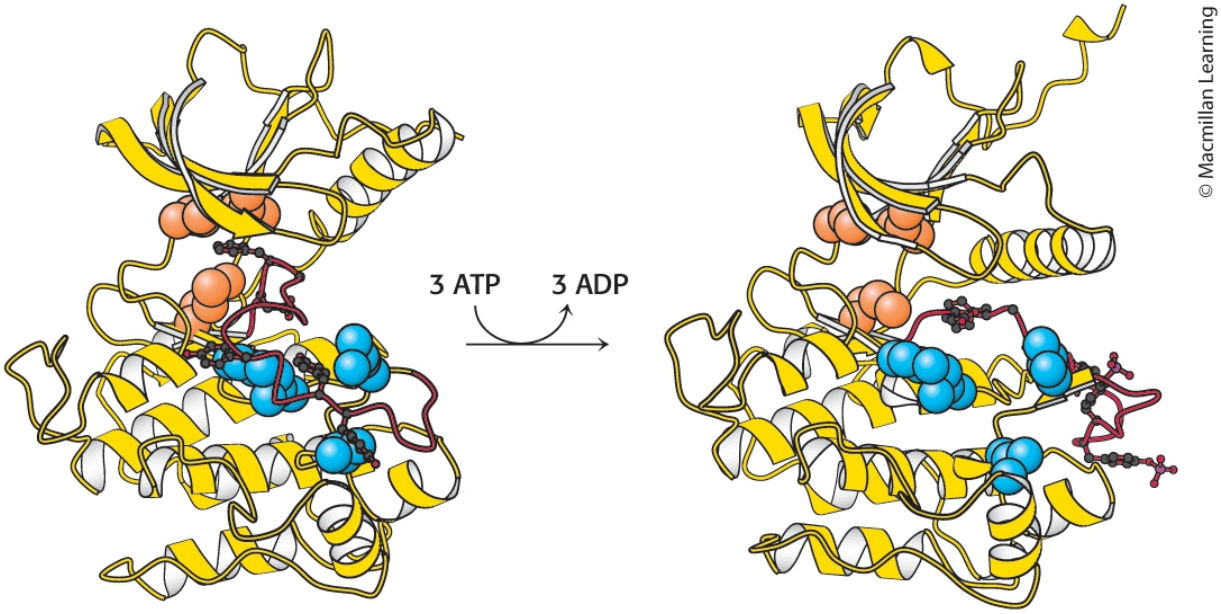
Extended description for Conformational change in insulin receptor

© Macmillan Learning

A section of a horizontal lipid bilayer is shown. The insulin receptor consists of two subunits each consisting of two different chains shown in dark orange and light orange colors. The dark orange chain consists of an oval-shaped domain located above the bilayer, a thin tubular domain spanning the bilayer, and a large oval-shaped domain below the bilayer. The oval-shaped domain above the bilayer is connected to a half oval domain above. The large oval-shaped domain has a triangular groove. A wavy red line within the groove connects the ends of the groove.

The light orange chain consists of four globular domains and a half-globular domain at the bottom that is connected to the half oval domain of the dark orange chain located above the bilayer.

The light orange chains of the two subunits fold over one another to form an arch-shaped structure. The dark orange chains of the two subunits are located at a gap. A short extension having a leaf-shaped structure at the end originates from the half globular domain of



each of the light orange chains. These leaf-shaped structures cross each other just below the arch formed by light orange chains.

A reversible arrow labeled 4 insulin is shown and it leads to an altered conformation of the insulin receptor.

The insulin molecule is bound to the globular domains of the light orange chain located closer to the dark orange chain. The dark orange chains have come close together. The grooves of the large oval-shaped domains of the dark orange chain face away from each other and these domains contact each other. Before insulin binding, the grooves were facing each other and these domains were located at a large gap. Except for the three terminal globular domains of the light orange chain, the remaining domains, and the dark orange chain are located close together. The terminal globular domains of the left subunit hang toward the lower left and that of the right subunit hang toward the lower right.

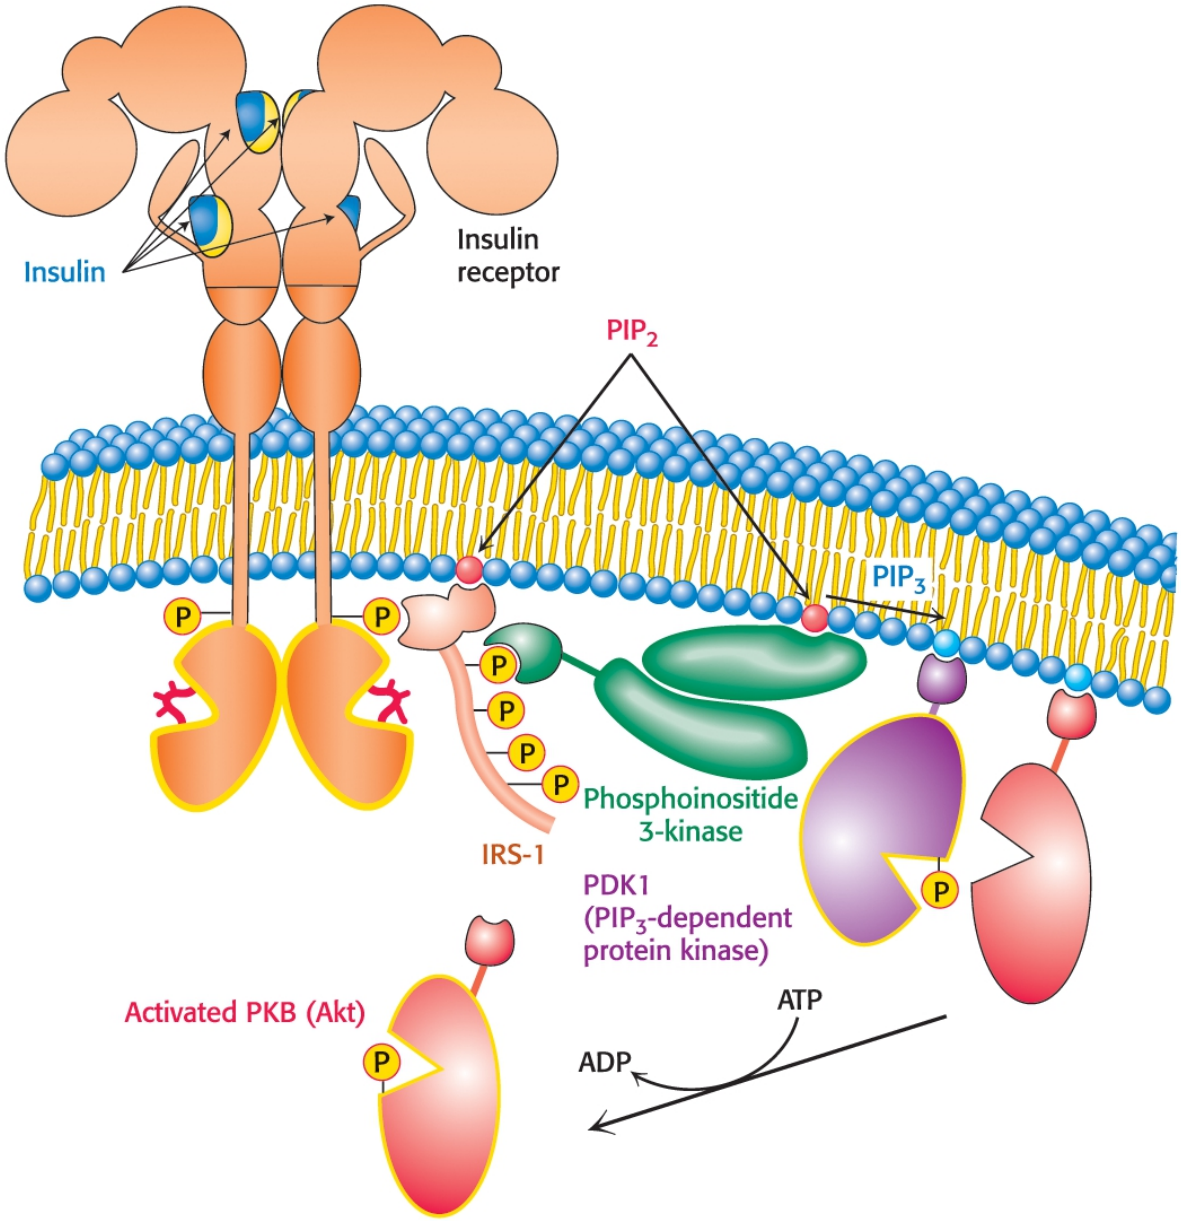
Extended description for Formation of phosphatidyl 3,4,5-trisphosphate

The chemical reaction consists of one reactant and one product.

The reactant is phosphatidylinositol 4, 5-bisphosphate (P I P 2) whose structure is as follows: A vertical chain consists of 3 C atoms. C 1 is single bonded to O on the right. This O atom is single-bonded to P on the upper right. P is further single bonded to O on the lower right and partially double bonded to O on the upper left and upper right. The partially double-bonded O atoms have an overall negative charge. The O atom on the lower right is single bonded to C 4 of a 6-membered homocyclic hexagonal ring in a chair conformation. The ring is in a plane perpendicular to the plane of paper such that C 1 and C 5 are located away from the observer and C 2 and C 4 are located toward the observer. C 3 and C 6 are located close to each other. C 1 is single bonded to O P O 3 superscript 2 minus on the lower right. C 2 is single bonded to O H on the upper right. C 3 is single bonded to O H above. C 5 is single bonded to O H on the lower left. C 6 is single bonded to O P O 3 superscript 2 minus on the upper right.

C 2 of the vertical chain is dash bonded to O R on the left and H on the right. C 3 of the vertical chain is single bonded to O R prime on the lower left.



A forward arrow labeled phosphoinositide 3-kinase shows the product. A curved arrow above the forward arrow shows the simultaneous conversion of A T P to A D P.

The product is phosphatidylinositol 3,4,5-triphosphate (P I P 3) whose structure is as follows: A vertical chain consists of 3 C atoms. C 1 is single bonded to O on the right. This O atom is single-bonded to P on the upper right. P is further single bonded to O on the lower right and partially double bonded to O on the upper left and upper right. The partially double-bonded O atoms have an overall negative charge. The O atom on the lower right is single bonded to C 4 of a 6-membered homocyclic hexagonal ring in a chair conformation. The ring is in a plane perpendicular to the plane of paper such that C 1 and C 5 are located away from the observer and C 2 and C 4 are located toward the observer. C 3 and C 6 are located close to each other. C 1 is single bonded to O P O 3 superscript 2 minus on the lower right. C 2 is single bonded to O P O 3 superscript 2 minus on the upper right. C 3 is single bonded to O H above. C 5 is single bonded to O H on the lower left. C 6 is single bonded to O P O 3 superscript 2 minus on the upper right.

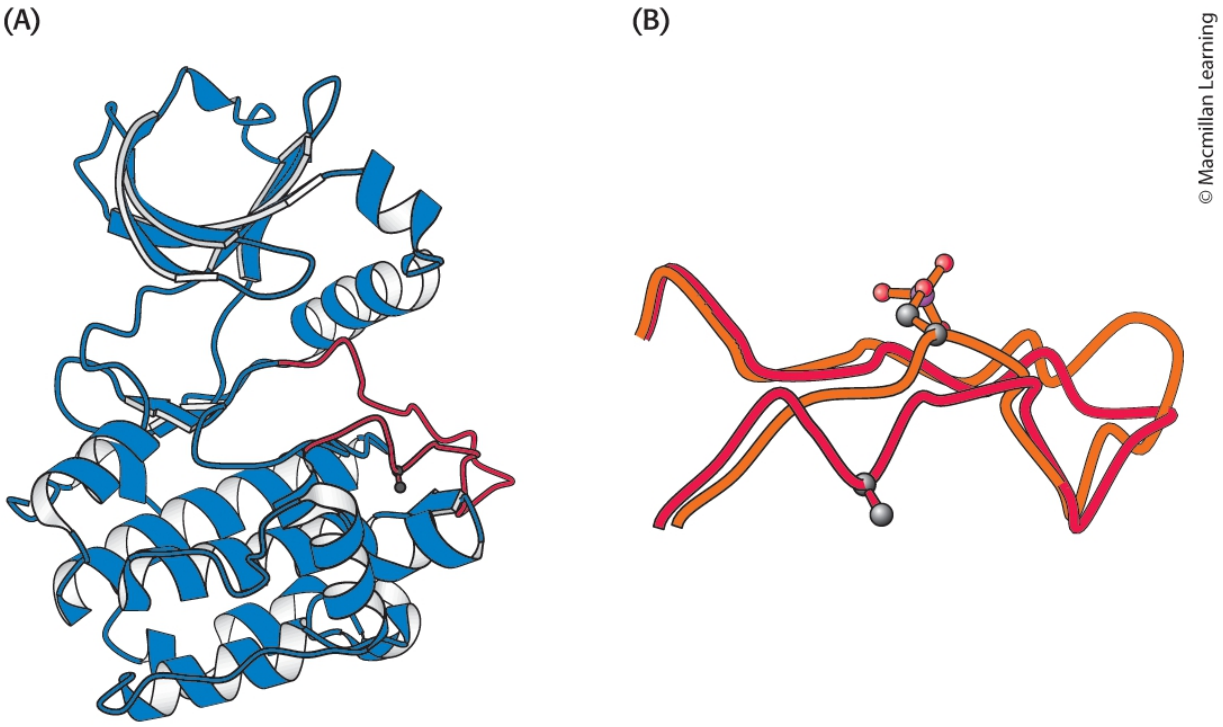
C 2 of the vertical chain is dash bonded to O R on the left and H on the right. C 3 of the vertical chain is single bonded to O R prime on the lower left.

Return to Formation of phosphatidyl 3,4,5-trisphosphate

Extended description for Insulin signaling pathway

© Macmillan Learning

An activated insulin receptor bound to 3 insulin molecules is shown spanning through a lipid bilayer. The cytoplasmic portion of the thin transmembrane domain of the dark orange chain is single-bonded to the P atom, just above the large oval-shaped domains in the cytoplasm.



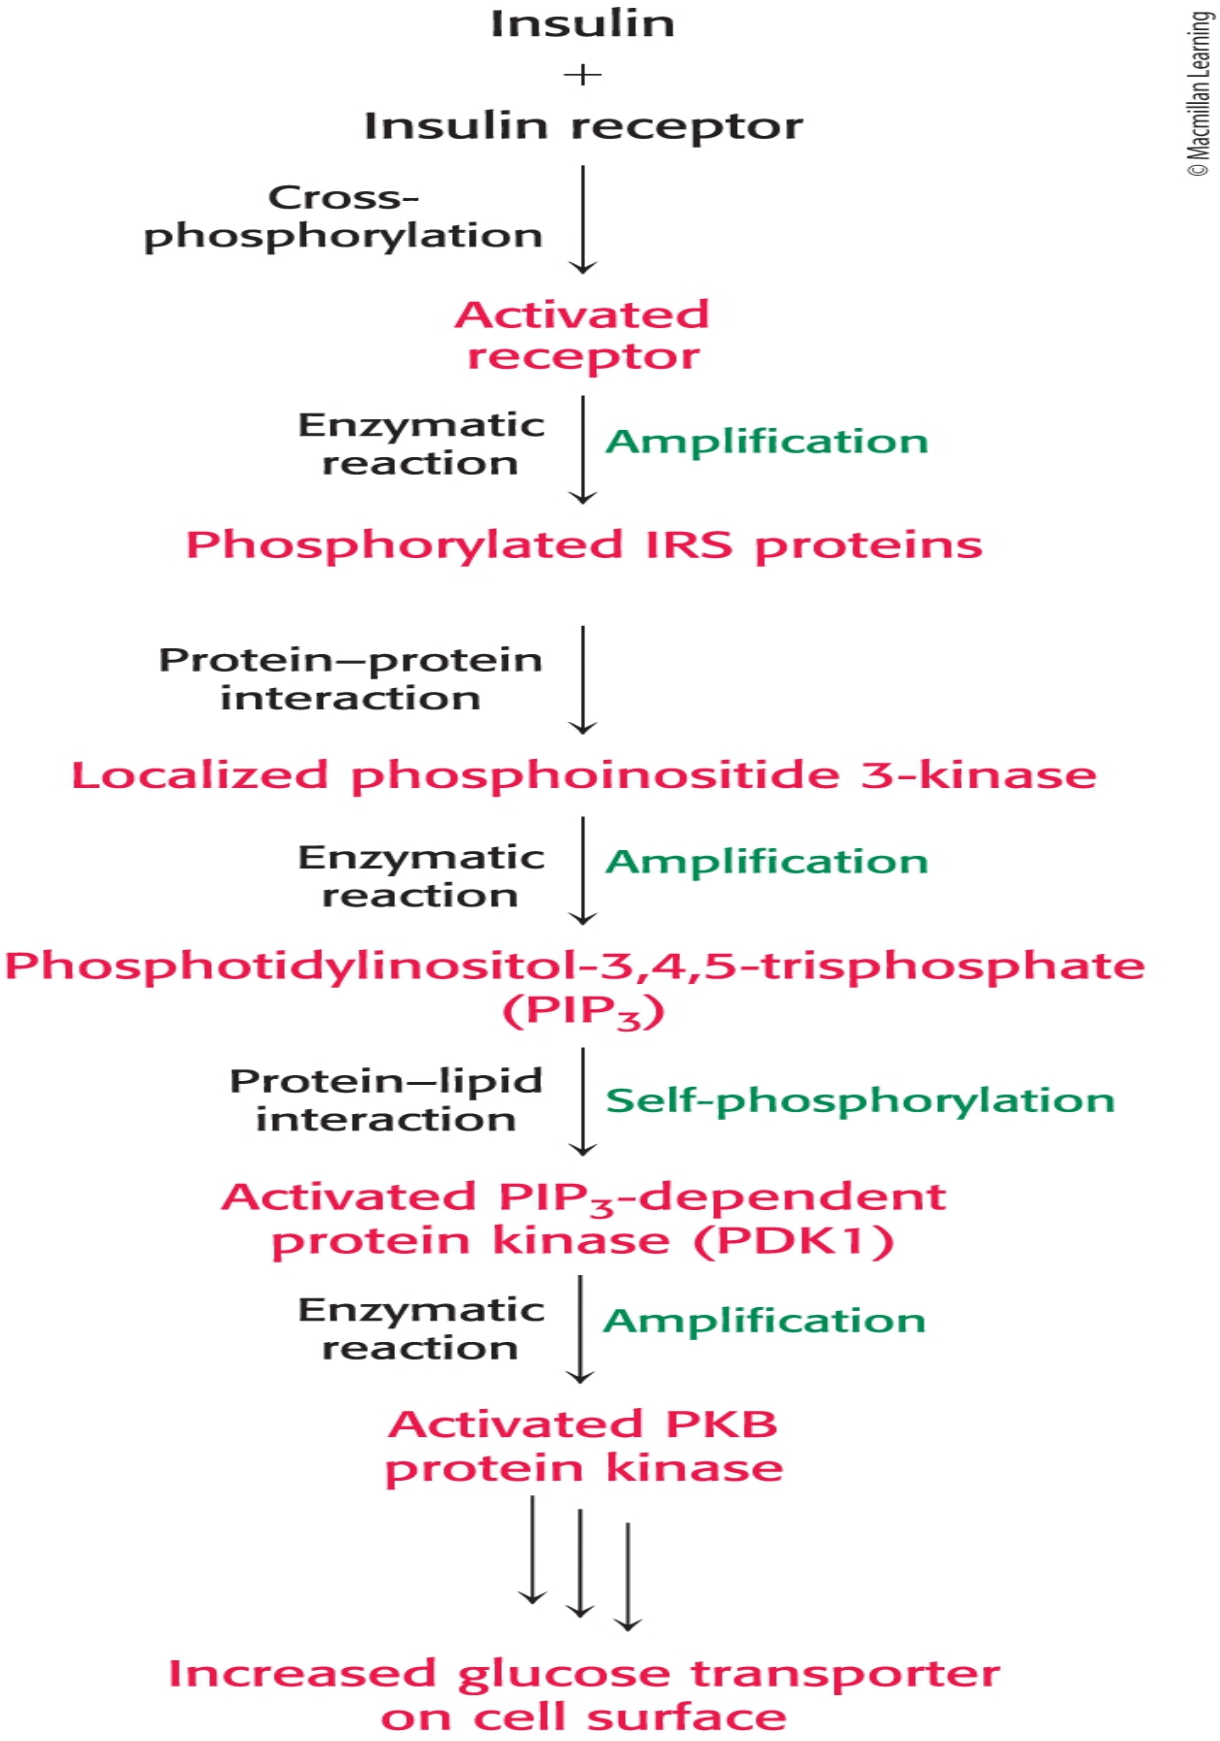
A small irregular-shaped protein with a long tail single bonded to 4 different P atoms is labeled I R S-1. It is shown in close proximity to the cytoplasmic region of the activated insulin receptor. The P atom single bonded to one of the dark orange chains fits inside the groove of I R S -1. Another groove on the top of I R S-1 surrounds a red sphere, labeled P I P 2, in the inner leaflet of the bilayer.

The phosphoinositide 3-kinase consists of a dimer. One subunit of this dimer has a globular domain with a groove surrounding the topmost P atom single bonded to the tail of I R S-1, and a long elongated domain connected to the globular domain by a thin thread. Another subunit is elongated and located above the first subunit. It has a tiny groove that surrounded P I P 2 in the inner leaflet of the bilayer.

P I P 2 is converted into P I P 3 depicted as a light blue sphere in the inner leaflet. A tiny globular domain of P D K 1 (P I P 3-dependent protein kinase) is bound to P I P 3. This domain is connected to a large oval-shaped domain of P D K 1. A triangular groove in P D K 1 is single-bonded to the P atom. An inactivated P K B (A k t) is located in close proximity to P D K 1. A tiny globular domain of P K B is bound to P I P 3 and its large oval-shaped domain has an empty triangular groove facing P D K 1. An arrow from inactivated P K B points toward activated P K B (A k t). A curved arrow above this arrow shows the simultaneous conversion of A T P to A D P. The triangular groove of the activated P K B is single bonded to P and detaches from P I P 3 in the inner leaflet.

Return to Insulin signaling pathway

Extended description for Ribbon diagram of the inactive conformation of P D K 1 and comparison of the activation loops of inactive and active forms



Part (A): The ribbon diagram of P D K 1 consists of top and bottom portions. The top portion consists of a few beta strands forming a concave groove and free short alpha-helices. The bottom portion consists of several alpha-helices and a few beta strands. The top and bottom portions are interconnected by long threads. A wavy red highlighted folded loop is shown near the top portion. It is located toward the top right of the bottom portion.

Part (B): Two superimposed activation loops of the active and inactive forms of P D K 1 are shown. The activation loop of the inactive form is shown in red and that of the active form is shown in orange. The right ends of the loops are entangled together. The

orange loop shows a small upward raised region near the middle of the bottom arm. The red loop shows a downward depression having a triangular shape in the bottom arm, toward the left of the raised region.

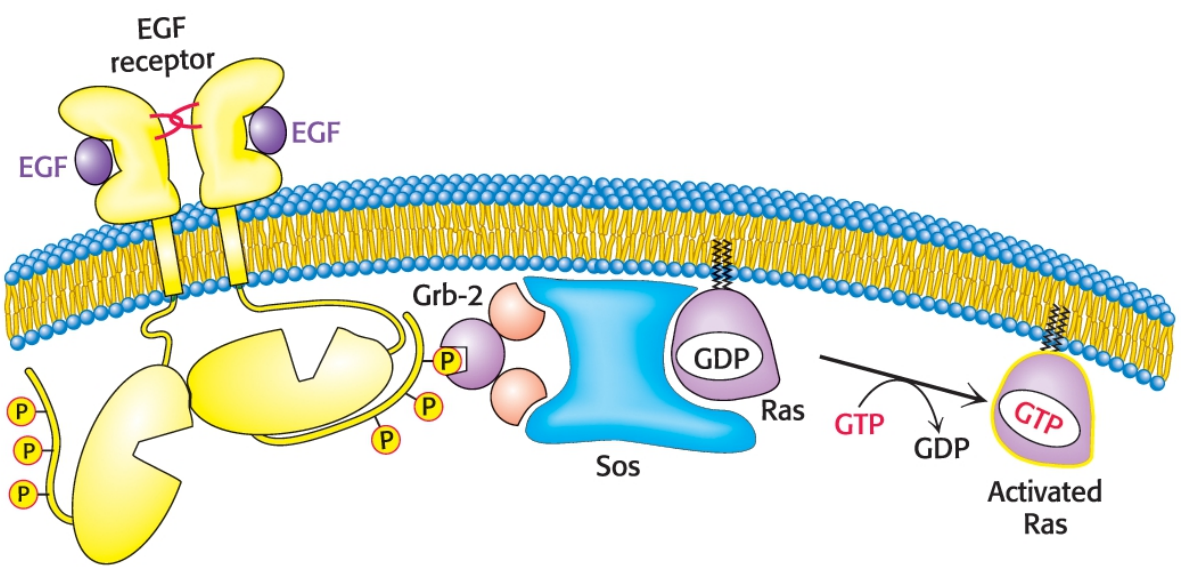
Extended description for Ribbon diagram of epidermal growth factor

The ribbon diagram consists of a few long and short beta-strands interconnected by long thread-like loops. Two long antiparallel beta strands are shown in the center. A short upward pointing beta-strand is located on the lower left of the central strands. A cluster of three short beta-strands is located at the top right of the central strands. The three disulfide bonds are depicted through three ball-and-stick models composed of a chain of two black spheres connected to a yellow sphere. The yellow sphere is connected to another yellow sphere which is further connected to a chain of two black spheres.

Return to Ribbon diagram of epidermal growth factor

Extended description for Extracellular domain of the E G F receptor and its dimerization upon E G F binding

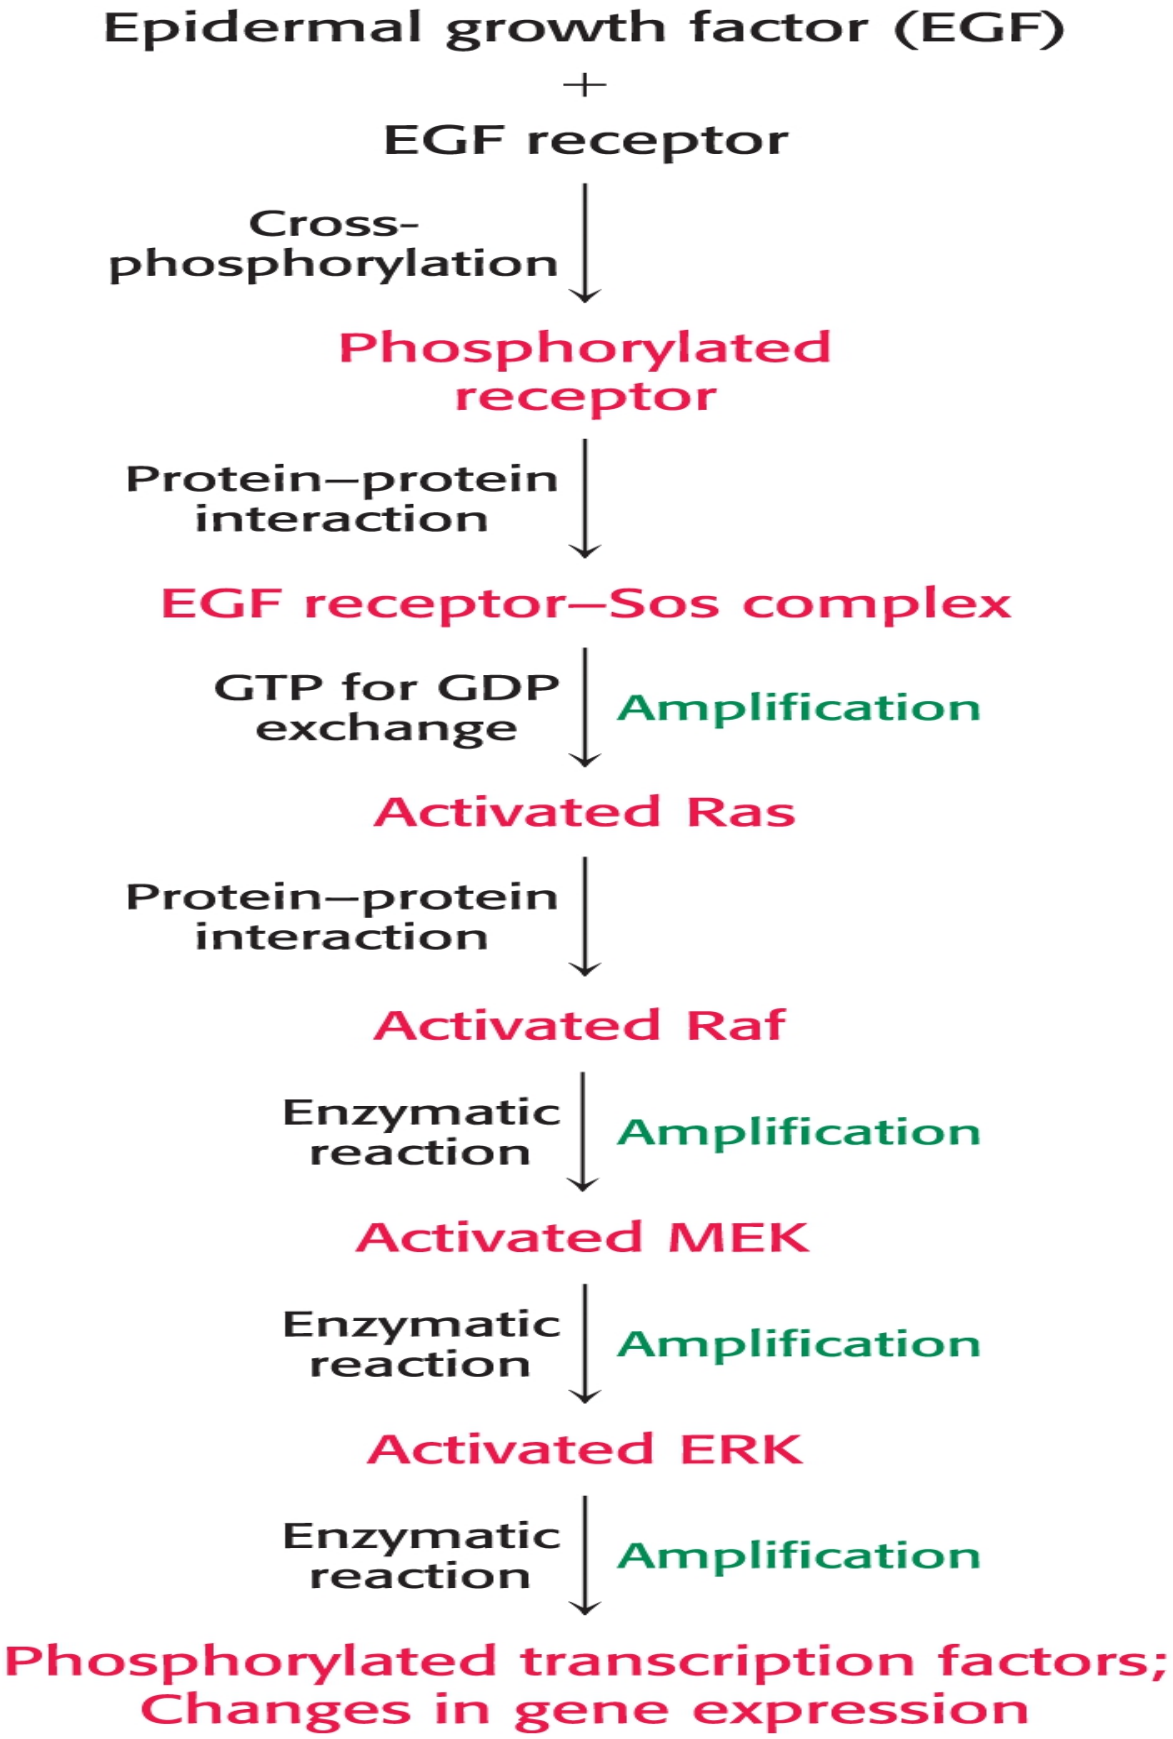


Part (A): The ribbon diagram of the extracellular domain consists of a top portion and a bottom portion. The top portion contains beta-strands and a few alpha-helices interconnected by long thread-like loops. The bottom portion has a roughly circular shape with a large hollow gap in the center. It is lined by several beta-strands and a few alpha-helices interconnected by long threads. A dimerization arm composed of two short antiparallel beta-strands is located inside the top opening of the bottom portion.

Part (B): Two extracellular domains have dimerized. The dimerization arm has extended outward into the center of the junction between the extracellular domains. An E G F molecule is bound to the outer periphery of the junction between the top and bottom portions of each domain. The E G F molecule consists of two antiparallel beta-strands surrounded by long thread-like loops.

Return to Extracellular domain of the E G F receptor and its dimerization upon E G F binding

Extended description for E G F receptor signaling



© Macmillan Learning

A horizontal section of a lipid bilayer is shown. An E G F receptor dimer is shown as a transmembrane protein. Each subunit of the dimer consists of an extracellular domain located above the bilayer and bound to a purple oval structure labeled E G F. The extracellular domains are linked by red curved lines. It is followed by a thin transmembrane domain connected below to a long thread which is further connected to a large oval-shaped domain located below the bilayer. Each domain has a wide groove and a tail single bonded to three P atoms.

One of the P atoms bonded to the tail is bound to the groove of a subunit of the trimeric G r b-2 protein. The remaining two subunits of G r b-2 have a groove that is bound to S o s. A large groove on the right side of S o s protein accommodates Ras protein bound to G D P and attached to the inner leaflet of the bilayer through two zigzag lines at the top. A forward arrow shows an activated Ras bound to G T P as G T P enters and G D P leaves.

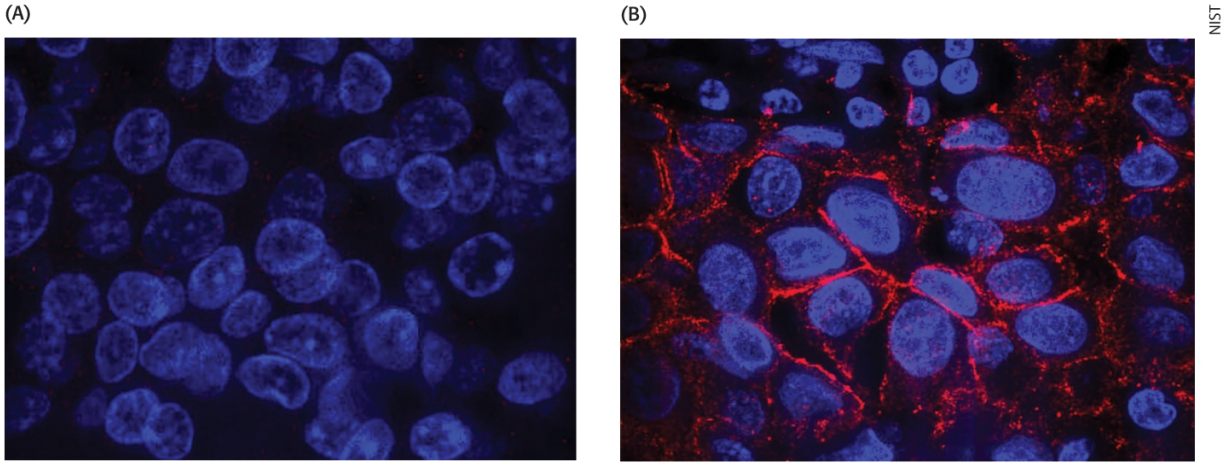
Return to E G F signaling pathway

Extended description for E G F receptor bound to

cetuximab



© Macmillan Learning

The ribbon diagram of the E G F receptor consists of a top portion and a bottom portion. The top portion contains several beta-strands and the bottom portion contains several beta-strands and a few helices. They are connected by long thread-like loops. The top and bottom portions are widely spaced. Long ribbons interconnecting these portions have a few beta-strands in the middle. Cetuximab is a paired cluster in which each cluster is composed of several randomly oriented beta-strands. There is a small gap between the clusters and one cluster of the pair interacts with the top portion of the E G F receptor.

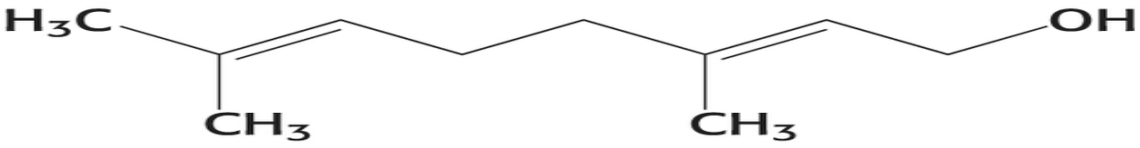
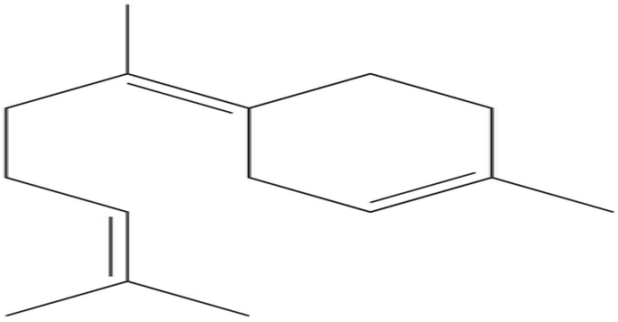
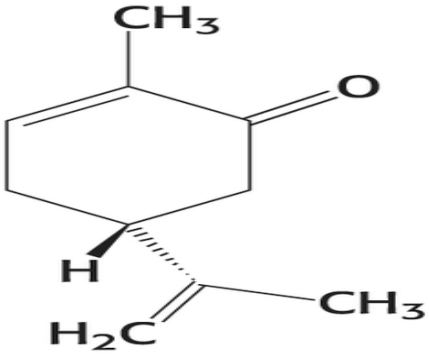
Extended description for Structures of benzaldehyde, 3-methylbutane-1-thiol, geraniol, zingiberene, R-



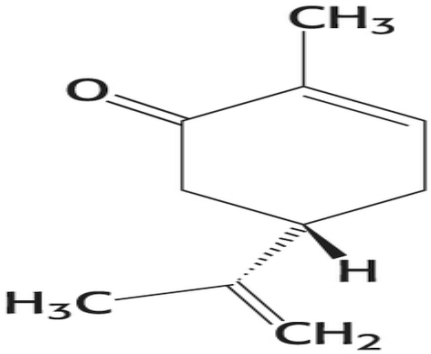
Carvone, and S-Carvone



Benzaldehyde
(Almond)



3-Methylbutane-1-thiol
(Skunk)



Geraniol
(Rose)

Zingiberene
(Ginger)

***R*-Carvone**
(Spearmint)

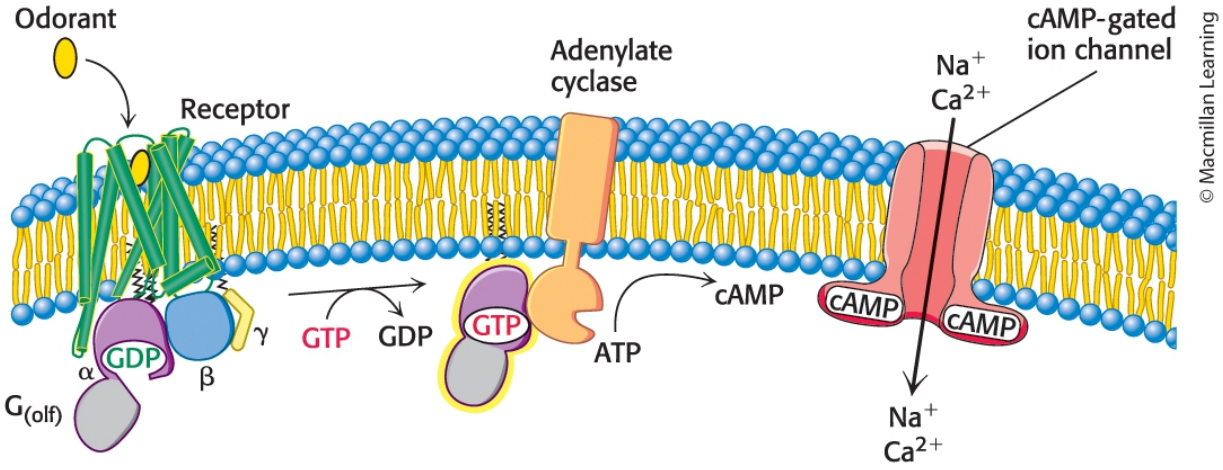
***S*-Carvone**
(Caraway)

The structure of benzaldehyde (Almond) is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. Alternating double bonds are present between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to a central C atom above in the form of a line. The central C atom is double bonded to O on the upper left and single bonded to H on the upper right.

The structure of 3-Methylbutane-1-thiol (Skunk) is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C H 3 above and C H 3 on the lower left. C 3 is single bonded to S H on the lower right.

The structure geraniol (Rose) is as follows: A 7-carbon alkene chain is depicted as a line structure using 6 zigzag lines. A double bond is present between C 1 and C 2 and C 5 and C 6. C 1 and C 5 are each single bonded to C H 3 below. C 1 is single bonded to H 3 C on the upper left. C 7 is single bonded to O H on the upper right.

The structure of zingiberene (Ginger) is as follows: A 6-carbon homocyclic hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. A double bond is present between C 3 and C 4. C 3 is single bonded to C H 3 on the lower right in the form of a line. C 6 is double bonded to C 1 of a 4-carbon alkane side chain depicted as a line structure using 3 lines that resemble the left half of a vertical hexagon. C 1 of the side chain is single bonded to C H 3 above in the form of a line. C 4 is double bonded to C 2 of a second 3-carbon alkane side chain below, depicted as a line structure using 2 zigzag lines.



The structure of R-Carvone (spearmint) is as follows: A 6-carbon homocyclic hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. A double bond is present between C 6 and C 1. C 1 is single bonded to C H 3 above. C 2 is double bonded to O on the upper right. C 4 is wedge bonded to H on the lower left and

dash bonded to a C atom in the form of a line on the lower right. The C atom is double bonded to C H 2 on the lower left and single bonded to C H 3 on the lower right.

The structure of S-Carvone (Caraway) is as follows: A 6-carbon hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. A double bond is present between C 1 and C 2. C 1 is single bonded to C H 3 above. C 6 is double bonded to O on the upper left. C 4 is wedge bonded to H on the lower right and dash bonded to a C atom in the form of a line on the lower left. The C atom is double bonded to C H 2 on the lower right and single bonded to C H 3 on the lower left.

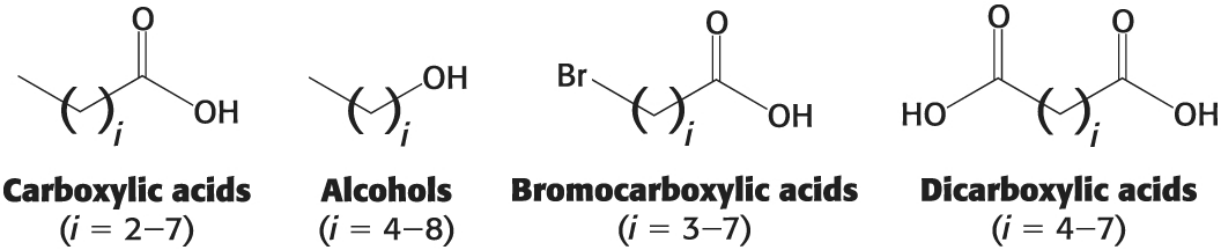
Extended description for Olfactory signal-transduction cascade



A section of a lipid bilayer is shown. The receptor bound to a yellow oval-shaped odorant at the top is shown embedded in the bilayer. The cytoplasmic side of the receptor is bound to the trimeric G subscript o l f protein composed of alpha, beta, and gamma subunits. In the alpha subunit, the grey structure associated with the purple round structure is displaced toward the lower left to allow the exit of G D P and entry of G T P into the groove of the purple round structure. The adenylate cyclase protein is shown embedded in the same bilayer. It is composed of a rectangular membrane-spanning region and a cytoplasmic round region having a tiny groove. The alpha subunit bound to G T P is associated with the cytoplasmic round region of adenylate cyclase. The purple structure directly interacts with the cytoplasmic region of adenylate cyclase. The purple structure has a groove bound to G T P. This groove is closed by the grey sphere located below. A curved arrow across the groove of adenylate cyclase shows the conversion of A T P to c A M P. Two zigzag lines at the top of the purple structure is embedded in the lipid bilayer. c A M P - gated ion channel is embedded in the lipid bilayer. It has a long transmembrane channel and two rectangular

grooves on the cytoplasmic side. Both grooves are bound to c A M P. A long downward vertical arrow passes through the transmembrane channel to show the inward movement of N a superscript plus and C a superscript 2 plus ions.

A horizontal line is labeled wavelength in meters and has 13 short vertical markings. The first marking from the left is labeled 10 superscript negative 10. The fourth, fifth, and thirteenth markings are labeled 10 superscript negative 7, 10 superscript negative 6, and 10 superscript 2 respectively. The left end of the line is labeled X-rays. The right end of the line is labeled radiowaves. The markings 10 superscript negative 7 and 10 superscript negative 6 are labeled visible light. The region between the fourth and fifth marking is enlarged to show a horizontal bar having colors violet, indigo, blue, green, yellow, orange, and red from left to right.

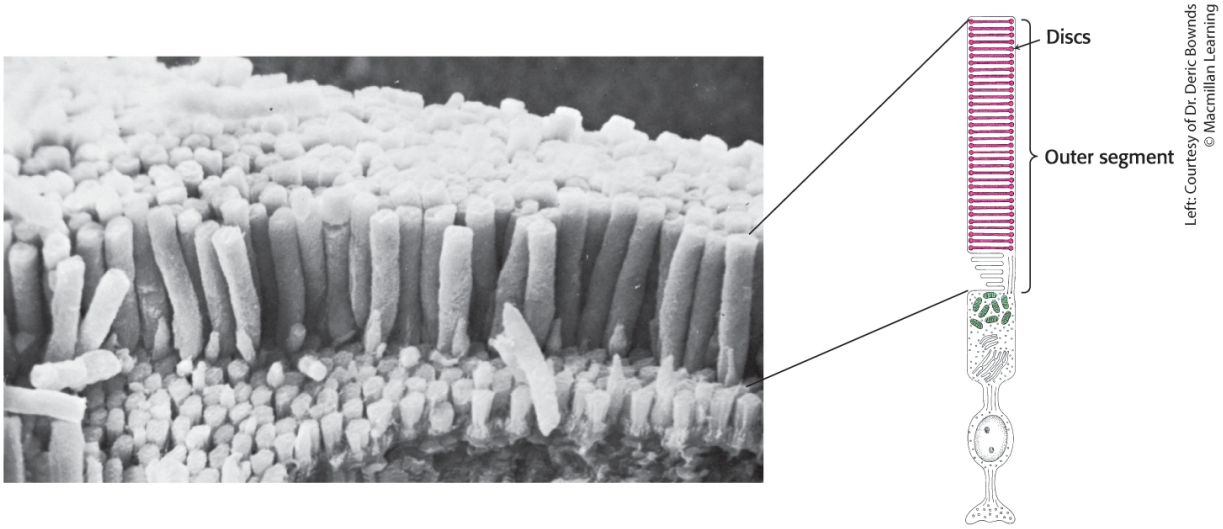
Extended description for Structures of 11-cis-Retinal and 11-cis-Retinal connected to lysine through Schiff base



The structure of 11-cis-Retinal is as follows: A 6-carbon homocyclic hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. A double bond is present between C 2 and C 3. C 1 is wedge bonded to C H 3 on the upper left in the form of a wedged line and dash bonded to C H 3 on the upper right in the form of a dashed line. C 3 is single bonded to C H 3 on the lower right in the form of a line. C 2 is single bonded to a 6-carbon alkene side chain depicted as a line structure using 5 zigzag lines. A double bond is present between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 3 of an alkene chain is single bonded to C H 3 above in the form of a line. C 6 of the alkene side chain is single bonded to C 2 of a second 3-carbon alkene side chain below. The second 3-carbon alkene side chain is depicted as a line structure using 2 zigzag lines. A double bond is present between C 2 and C 3. C 3 of the second alkene side chain is single bonded C below. This C atom located below is single-bonded to H on the lower left and double-bonded to O on the lower right.

The structure of 11-cis-Retinal connected to lysine through Schiff base is as follows: A 6-carbon homocyclic hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. A double

bond is present between C 2 and C 3. C 1 is wedge bonded to C H 3 on the upper left in the form of a wedged line and dash bonded to C H 3 on the upper right in the form of a dashed line. C 3 is single bonded to C H 3 on the lower right in the form of a line. C 2 is single bonded to a 6-carbon alkene chain depicted as a line structure using 5 zigzag lines. A double bond is present between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 3 of an alkene chain is single bonded to C H 3 above in the form of a line. C 6 of the alkene side chain is single bonded to C 2 of the second 3-carbon alkene side chain below. The second 3-carbon alkene side chain is depicted as a line structure using 2 zigzag lines. A double bond is present between C 2 and C 3. C 3 of the second alkene side chain is single bonded to C below. This C atom located below is further single bonded to H on the lower left and double bonded to N on the lower right. N is single bonded to C 1 of a third 5-carbon alkane side chain depicted as a line structure using 4 zigzag lines. The third alkane side chain along with N is colored blue and labeled Lysine.

Extended description for Scanning electron micrograph and schematic representation of retinal rod cells

The scanning electron micrograph of retinol rod cells depicts white-long slender tubes densely arranged next to each other. The micrograph also shows some of the broken tubes of very small lengths. A schematic representation of the retinal rod cell shows a slender and elongated structure composed of a stack of several discs at the top. These discs are pink colored and labeled outer segment. The bottom part of the rod cell has a short cylinder filled with capsules and tube-like structures. The cylinder then has a white circular shape below it with a white colored circle enclosing two small black colored balls. The bottom cylindrical shape is filled with small black colored dots. An extension below the cylindrical shape has a broad base.

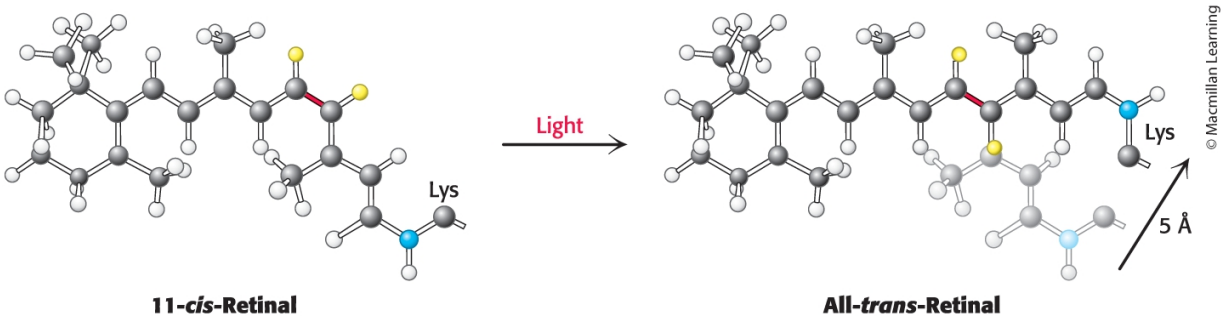
Extended description for Graphical representation of light absorption by rhodopsin



© Macmillan Learning

The horizontal axis is labeled wavelength in nanometers. It has markings ranging from 300 to 700 in increments of 100 units. The vertical axis is labeled extinction coefficient in molar inverse centimeter inverse. It has markings ranging from 0 to 40,000 in increments of 10,000 units. A bell-shaped structure is shown in the graph. It starts at (300, 12,000), moves to (340, 10,000), and then rises vertically upward to peak at (500, 40,000). It then falls vertically downward to reach (680, 0). All the values are estimated.

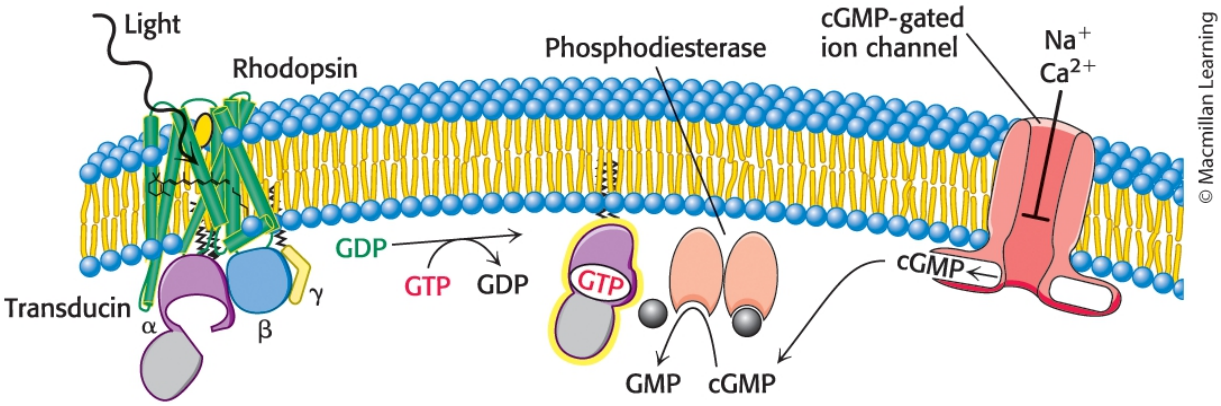
Extended description for Isomerization of 11-cis-retinal in presence of light

The reaction contains one reactant and one product. The reactant labeled 11-cis-retinal has the following structure: In the ball and stick model the C atoms are depicted as large black spheres and H atoms are depicted as small grey spheres. Six black spheres are connected in the form of a hexagonal ring in a vertical orientation with the first black sphere occupying the topmost position. The black sphere at the bottom right vertex is connected to another black sphere on the lower right. This black sphere is connected to two white spheres on the upper right, one away and one toward the observer, and a white sphere below. The black sphere at the bottom-most vertex is connected to a white sphere below and a second white sphere on the lower left and away from the observer. The black sphere at the bottom right is connected to the white sphere on the lower left and connected to the second white sphere above. The black sphere at the top left vertex is connected to the white sphere on the upper left and connected to the white sphere on the lower right and away from the observer. The black sphere at the topmost vertex is connected to the first black sphere on the upper left and toward the observer and connected to the second black sphere on the upper right and away from the observer. The first black sphere is connected to a white sphere on the upper left and connected to a white sphere on the upper right. The second black sphere is

connected to three white spheres on the upper left, upper right, and lower right. The black sphere at the top right vertex is connected to the first black sphere of a chain composed of 6 black spheres arranged in a zigzag manner. The first black sphere of the side chain is connected to a white sphere above. The second black sphere is connected to a white sphere below. The third black sphere is connected to another black sphere above which is further connected to three white spheres. The fourth black sphere is connected to a white sphere below. The fifth black sphere is single-bonded to a small yellow sphere above. The sixth black sphere is connected to a small yellow sphere on the upper right and connected to another black sphere below. The bond between the fifth and sixth black sphere is shown in red. The black sphere located below is connected to two black spheres on the lower left and lower right. The lower right black sphere is connected to a black sphere below. The black sphere below is connected to the white sphere on the lower left and connected to the blue sphere on the lower right. The blue-colored small sphere is connected to the black sphere on the upper right and a white sphere below. The black sphere on the upper right is labeled L y s.

A forward arrow labeled light leads to the product.



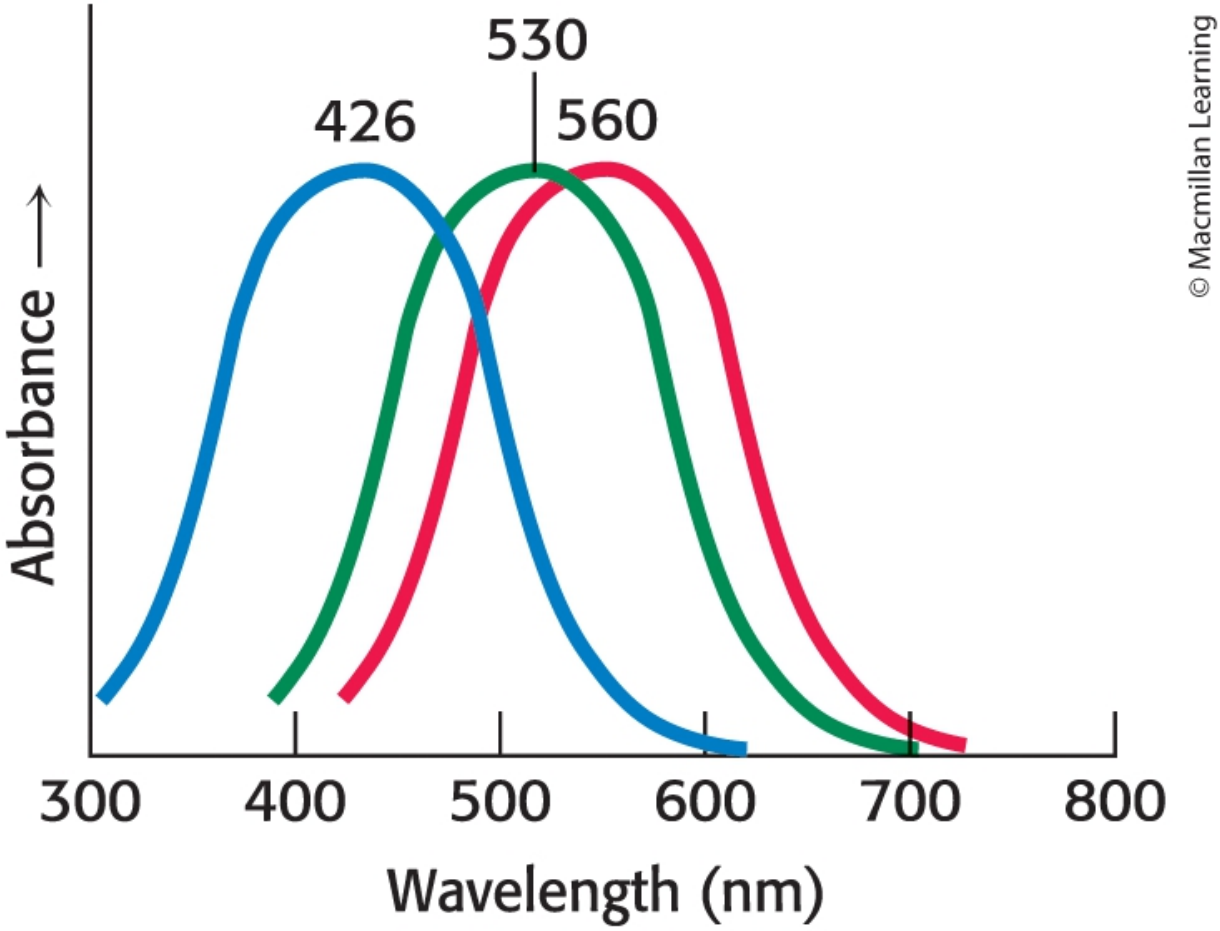
The product labeled All-trans-Retinal has the following structure: In the ball and stick model the C atoms are depicted as large black spheres and H atoms are depicted as small grey spheres. Six black spheres are connected in the form of a hexagonal ring in a vertical orientation with the first black sphere occupying the topmost position. The bottom right black sphere is connected to another black sphere on the lower right. This black sphere is connected to two white spheres on the upper right, one located away and another located toward the observer, and a white sphere below. The bottom-most black sphere is connected to a white sphere below and a second white sphere on the lower left and away from the observer.

The bottom left black sphere is connected to the white sphere on the lower left and connected to the second white sphere above. The top left is connected to the white sphere on the upper left and connected to the white sphere on the lower right and away from the observer. The topmost black sphere is connected to the first black sphere on the upper left and toward the observer and connected to the second black sphere on the upper right and away from the observer. The first black sphere is connected to three white spheres. The second black sphere is connected to three white spheres. The top right black sphere is connected to the first black sphere of a chain composed of 9 black spheres arranged in a zigzag manner. The first black sphere of the side chain is connected to a white sphere above. The second black sphere is connected to a white sphere below. The third black sphere is connected to another black sphere above which is further connected to three white spheres. The fourth black sphere is connected to a white sphere below. The fifth black sphere is single-bonded to a small yellow sphere above. The sixth black sphere is connected to a small yellow sphere below. The seventh black sphere is connected to a black sphere above. The black sphere above is connected to three white spheres. The eighth black sphere is connected to the white sphere below. The ninth black sphere is connected to a white sphere above and connected to a small blue sphere on the lower right. The blue sphere is connected to a white sphere on the upper right and connected to another black sphere below.

The rotation of Lys is marked with an arrow labeled 5 angstroms.

Return to Isomerization of 11-cis-retinal in presence of light

Extended description for Visual signal transduction



A section of a lipid bilayer is shown. Rhodopsin bound to a yellow oval-shaped structure at the top is shown embedded in the bilayer. The cytoplasmic side of the rhodopsin is bound to the trimeric G protein composed of alpha, beta, and gamma subunits. A wavy line labeled light strikes rhodopsin. In the alpha subunit, the grey structure associated with the purple round structure is displaced toward the lower left to allow the exit of G D P and entry of G T P into the groove of the purple round structure. Two zigzag lines at the top of the purple structure are embedded in the lipid bilayer.

c A M P - gated ion channel is embedded in same the lipid bilayer, toward the right. It has a long transmembrane channel and two rectangular grooves on the cytoplasmic side. A long vertical line with a minus symbol is shown inside the channel to depict the blockage of the entry of N a superscript plus and C a superscript 2 plus ions into the cell. The right groove of the channel is empty and the left groove contains c G M P. An arrow shows the displacement of this c G M P. The c G M P molecule moves toward the empty groove of phosphodiesterase.

The independent alpha subunit of G protein bound to G T P is shown attached to the inner leaflet through two zigzag lines at the top of the purple structure. A pair of oval-shaped structures labeled phosphodiesterase having a circular groove at the bottom surface are associated with the alpha subunit. The groove of the right oval is bound to a black sphere. The black sphere is displaced from the groove of the right oval structure. An arrow shows the conversion of c G M P, displaced from the left groove of c G M P-gated ion channel, to G M P in this groove.

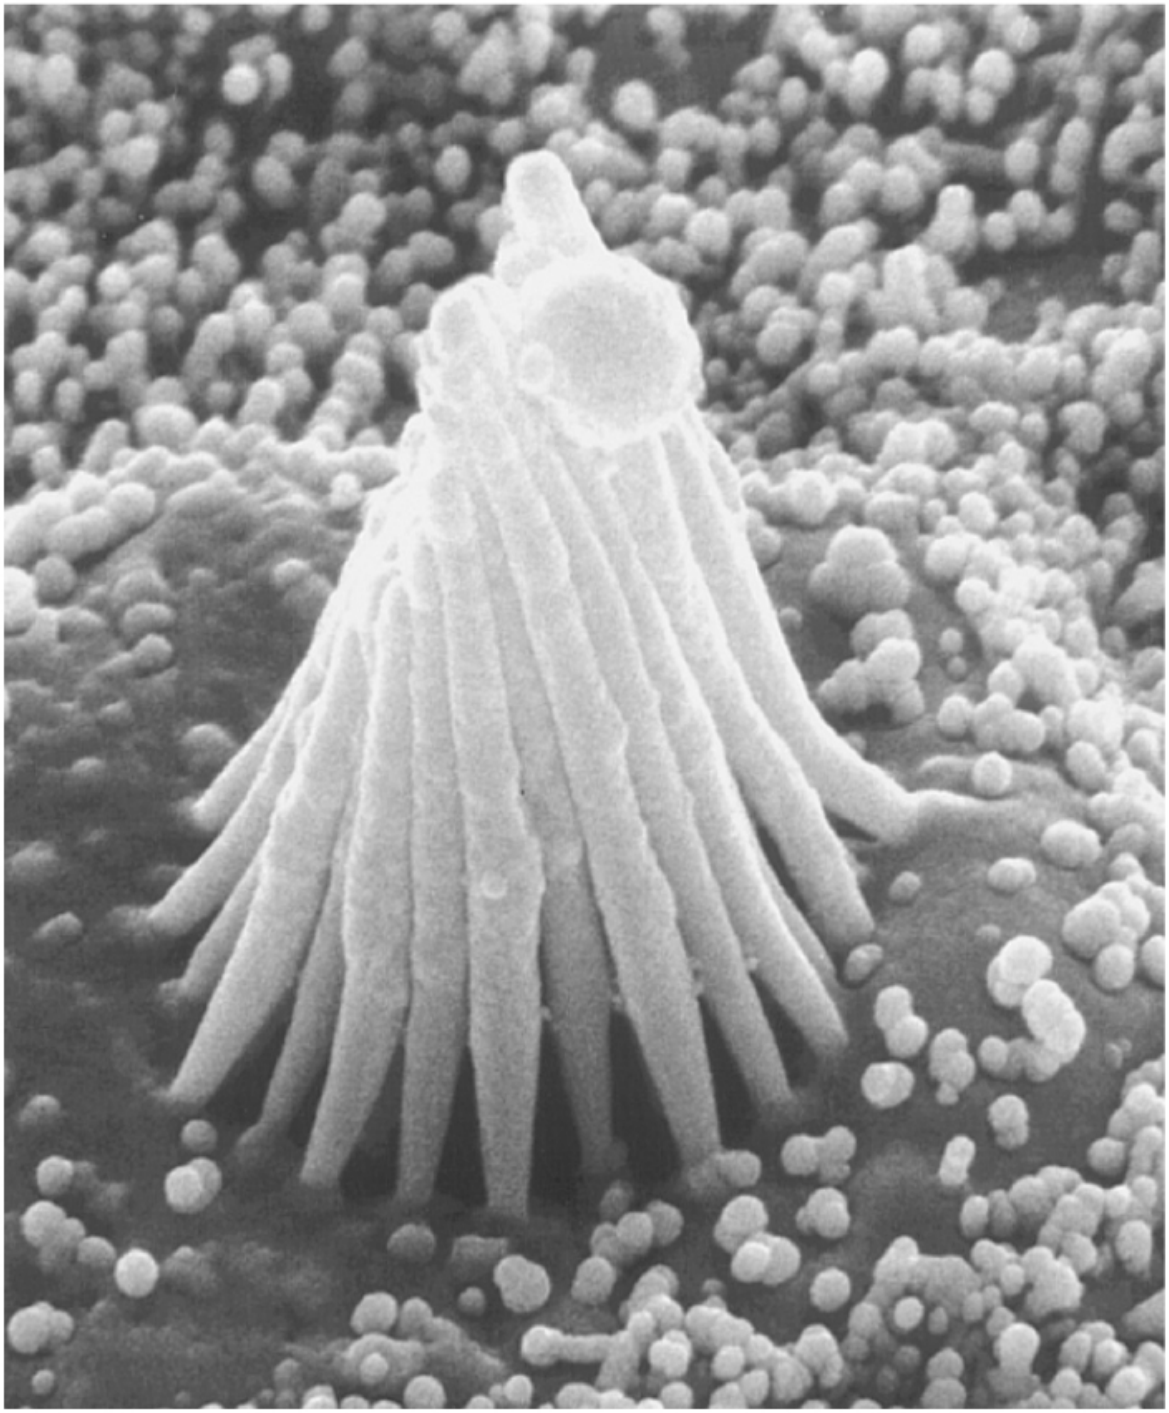
Extended description for Absorption spectra of different light receptors from human cone cells



© Macmillan Learning

The horizontal axis is labeled wavelength in nanometers. It has markings ranging from 300 to 800 in increments of 100 units. The vertical axis is labeled absorbance. It increases from the bottom to the top. The graph contains three bell-shaped curves shown in blue, green, and red colors. The blue curve starts near the origin, forms a peak at 426 nanometers, and then falls vertically downward to reach the lowest absorbance at 610 nanometers. The green curve starts just above the lowest absorbance at 390 nanometers, forms a peak at 530 nanometers, and then falls vertically downward to reach the

lowest absorbance at 700 nanometers. The red curve starts just above the lowest absorbance at 410 nanometers, forms a peak at 560 nanometers, and then falls vertically downward to reach the lowest absorbance at 710 nanometers.

Extended description for Scanning electron micrograph of stereocilia bundle on hair cells

Courtesy of R. Jacobs and A.J. Hudspeth

The scanning electron micrograph depicts stereocilia as a bundle of white-colored tubes in vertical orientation arranged around each other to form a conical shape. The base of the conical shape is located inside a depression on the surface. The conical arrangement has a large white-colored sphere on the top. Small white-colored spherical balls are scattered on the surface.

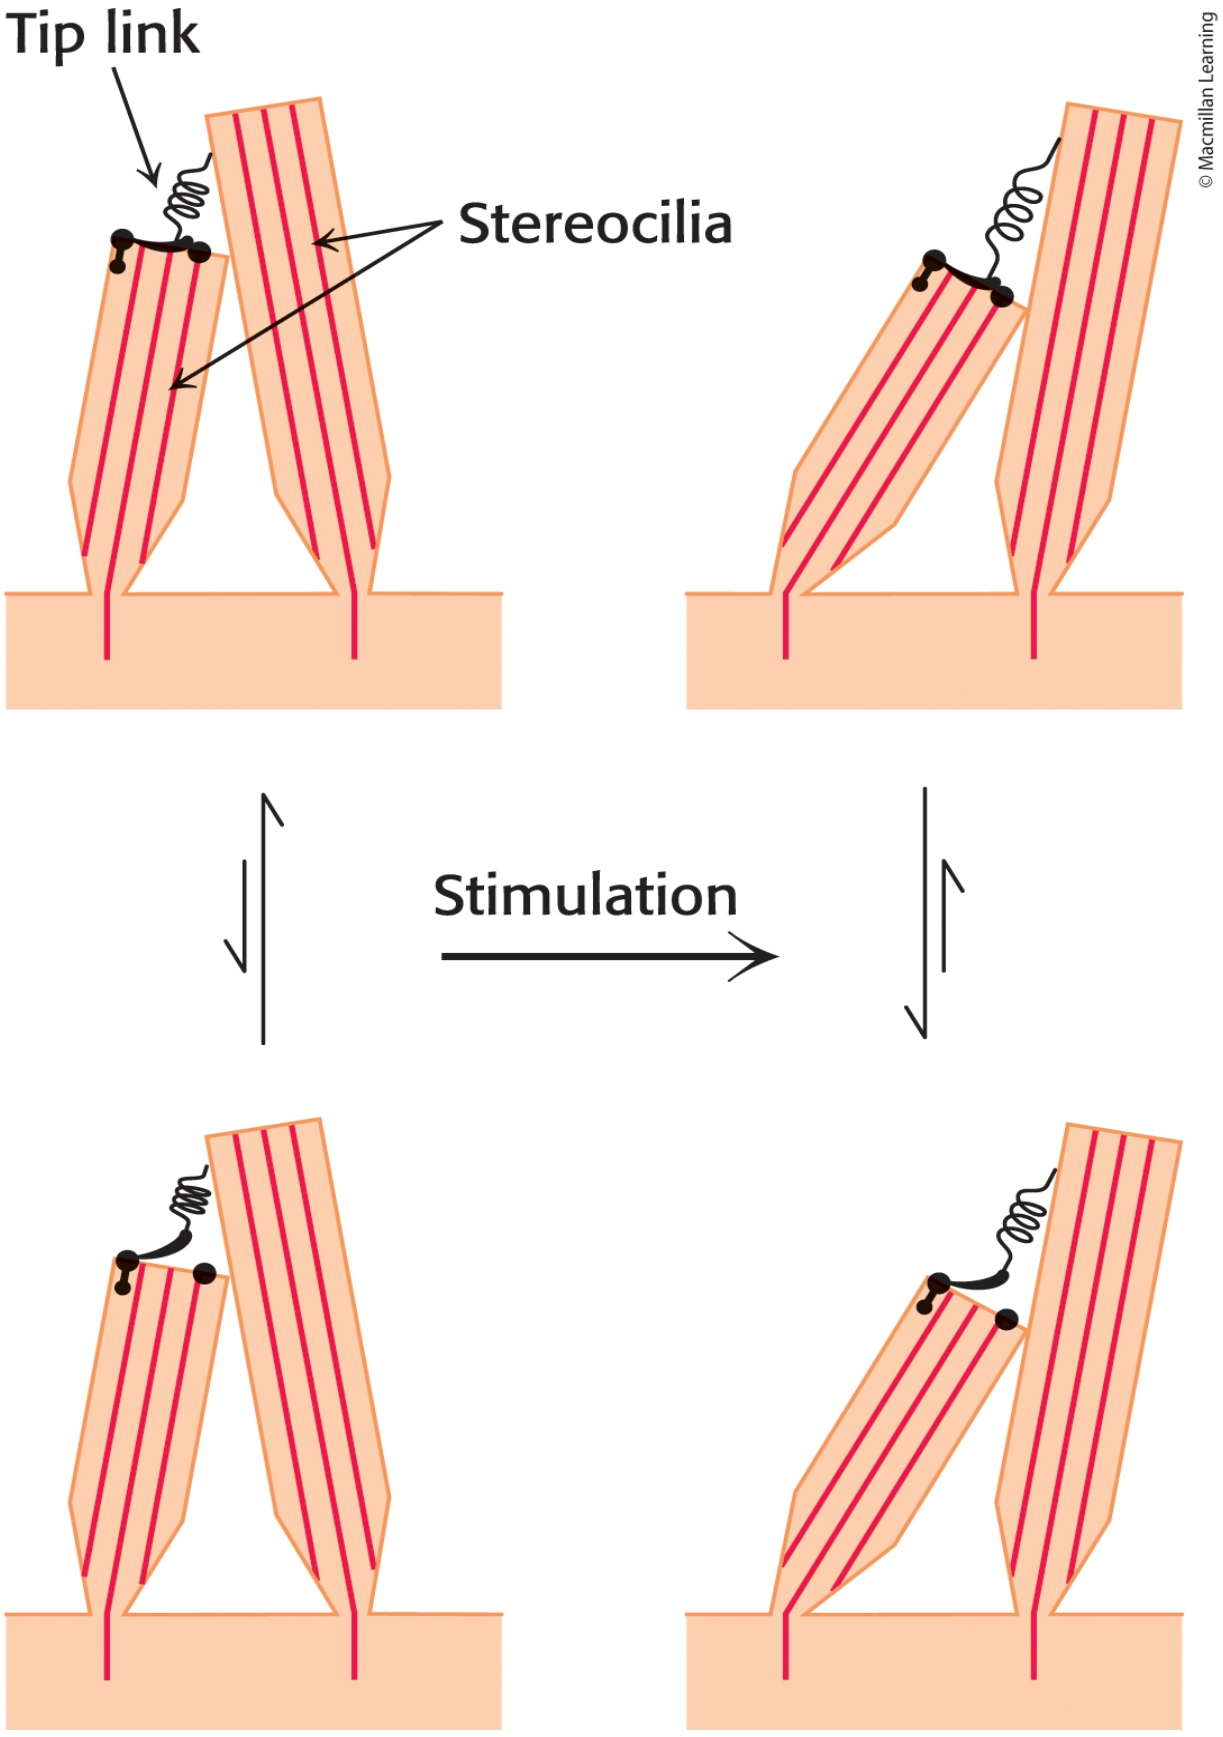
Extended description for Micrograph of tips of two stereocilia

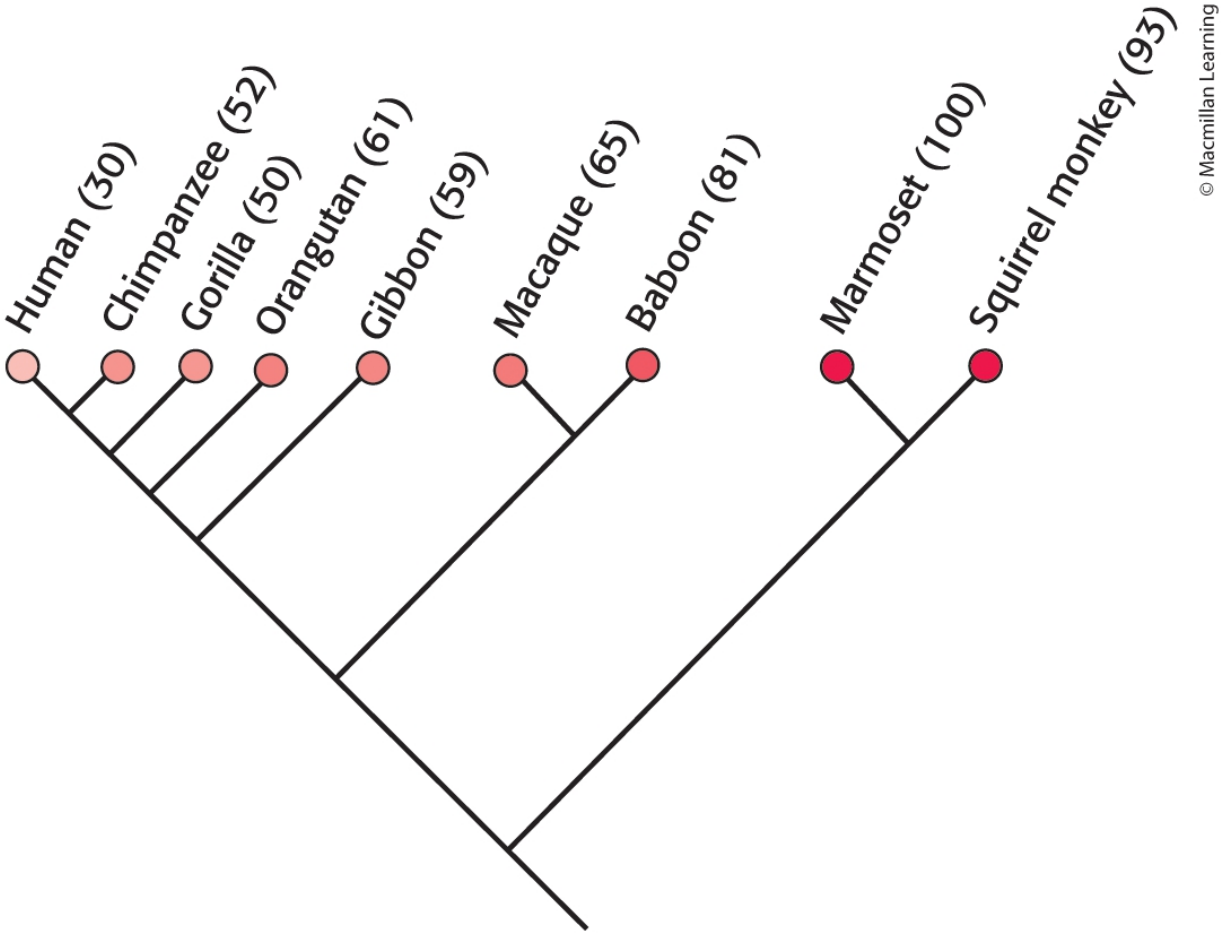


Courtesy of R. Jacobs and A.J. Hudspeth

The scanning electron micrograph shows the tips of two stereocilia. Stereocilia are depicted as grey-colored tubes. The tip of one tube is linked to another tube through a very thin thread. The thread is marked with an arrow.

Return to Micrograph of tips of two stereocilia

Extended description for Hair cell signal detection



© Macmillan Learning

The stereocilia are depicted as two pencil-shaped structures with their tips embedded in the surface. One of the stereocilia is taller than the other. Their tips are linked through a spring-like structure. The spring-like structure is connected to an ion channel at the tip of the shorter stereocilia. In the first arrangement on the top left, the two stereocilia are inclined toward each other in the middle and the spring is in a compressed form and the gates of the ion channel are closed. In the second arrangement on the bottom left, the short stereocilia are inclined toward the right and the tall stereocilia are inclined toward the left such that the compressed spring pulls open the ion channel. In the third arrangement on the top right, the tall stereocilia are inclined toward the left and the smaller stereocilia are inclined toward the tall stereocilia. The spring connecting them is stretched and the ion channel is closed. In the fourth arrangement on the bottom right, both the stereocilia are inclined toward the right but the inclination of the smaller stereocilia is more than the inclination of the taller stereocilia, and the spring is stretched to open the ion channel. The first and second arrangements and the third and fourth arrangements are interconvertible as depicted by reversible reaction arrows. A forward arrow from the left reversible arrow to the right reversible arrow is labeled stimulation.

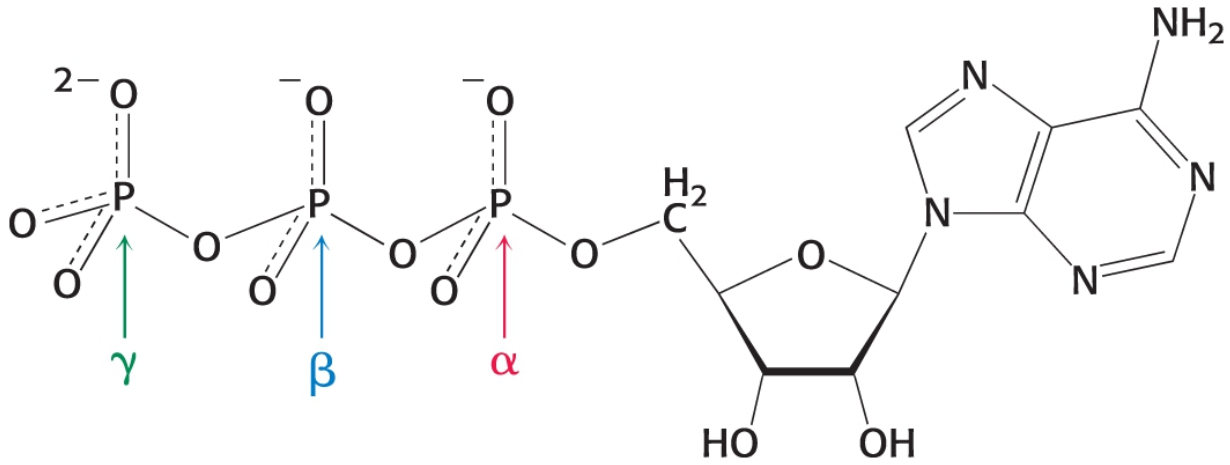
Extended description for Flow Chart for the cleavage of membrane lipid



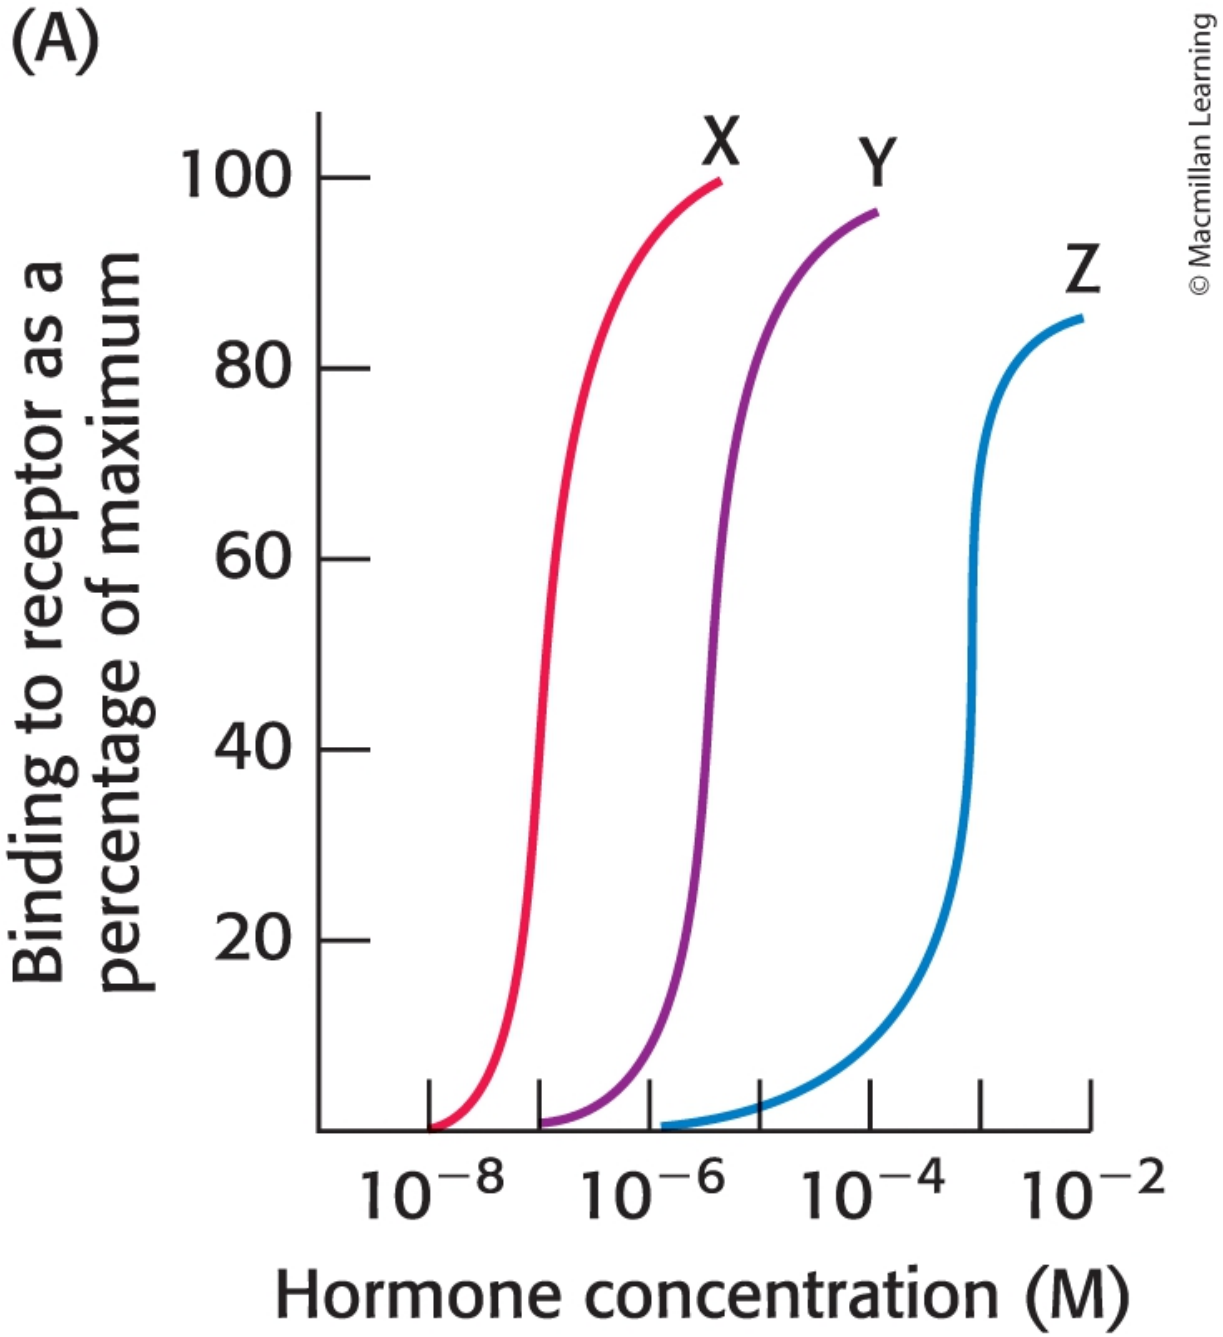
© Macmillan Learning

The flow chart has a yellow-colored rectangular box on the top middle with a vertical line below divided into two downward-facing

arrows with the first arrow on the left and the second arrow on the right. The vertical line is labeled “is hydrolyzed by P L C to produce,” on the right. The left arrow and right arrow each have an empty yellow-colored rectangular box below. The empty yellow-colored rectangular box on the right has a downward-facing arrow labeled “which diffuses to the E R, where it causes the release of.” The arrow leads to a second yellow-colored rectangular box on the right. The vertical lines from both the left and right rectangle meet together in the middle and merge with a downward-facing arrow leading to a second yellow-colored rectangular box in the middle. The downward-facing arrow is labeled “which activates.” A downward-facing arrow from the second yellow-colored rectangular box points to a third yellow-colored rectangular box in the middle. The downward facing arrow between the second and third boxes is labeled “which phosphorylates.”

Return to Flow Chart for the cleavage of membrane lipid

Extended description for Structure of A T P



The structure of A T P is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 Oand 4 C atoms. O occupies the first position, which is the topmost vertex. The ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are toward the observer and O is away from the observer. C 1 is single bonded to above the first N atom of a second 5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 2 N and 3 C atoms. In the second pentagonal ring, the first N atom occupies the first position, which is the bottom left vertex, and the second N atom occupies the third position, which is the top left vertex. A double bond is present between C 1 and the second N atom and C 2 and C 3. The second pentagonal ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 2 N and 4 C atoms. In the hexagonal ring, the first N atom occupies the first position, which is the top right vertex, and the second N atom occupies the third position, which is the bottommost vertex. The two rings are fused to each other such that C 2 and C 3 of the second pentagonal ring are the C 3 and C 2 of the hexagonal ring, respectively. In the hexagonal ring, a double bond is present between C 1 and the second N atom,

C 2 and C 3, and C 4 and first N. In the hexagonal ring, C 4 is single bonded to N H 2 above.

C 3 and C 4 of the first pentagonal ring are each single bonded to O H below. C 4 of the first pentagonal ring is single bonded to C H 2 above. C H 2 is single bonded to the first O atom of the following zigzag chain: O, single bond, P, single bond, O, single bond, P, single bond, O, single bond, P, partial double bond, O. P 1 and P 2 are each partially double bonded to O superscript minus above and partially double bonded to O on the lower left. P 3 is partially double bonded to O superscript minus above and partially double bonded to O on the lower left. The first P atom is labeled alpha, the second P atom is labeled beta and the third P atom is labeled gamma.

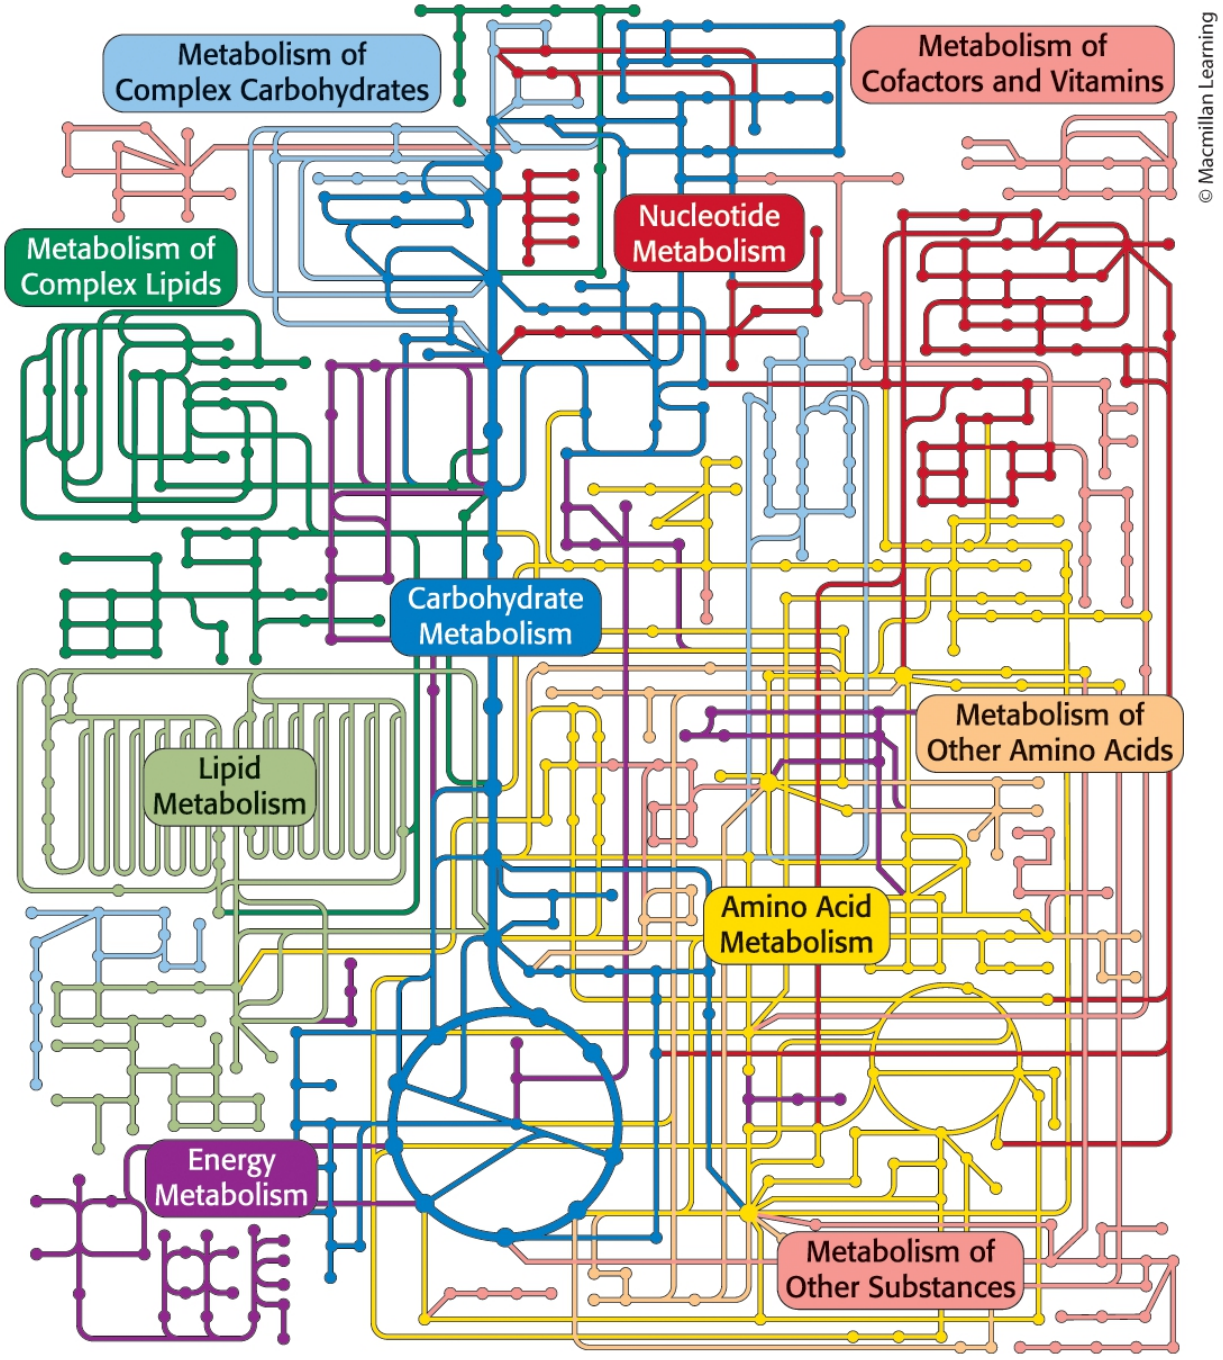
Extended description for Flow chart depicting the

transformation of glucose to pyruvate



© Macmillan Learning

The flow chart has two steps. Glucose undergoes transformation to form pyruvate. Three step-like downward arrows labeled “10 steps” from glucose point to pyruvate. The structure of glucose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1, C 2, and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above.

The structure of pyruvate is as follows: A 2-carbon alkane chain is depicted as a line structure using one line. C 1 is single bonded to C H 3 on the lower left and double bonded to O above. C 2 is partially double bonded to O on the upper right and partially double bonded to O below and has a negative sign as a counter sign.

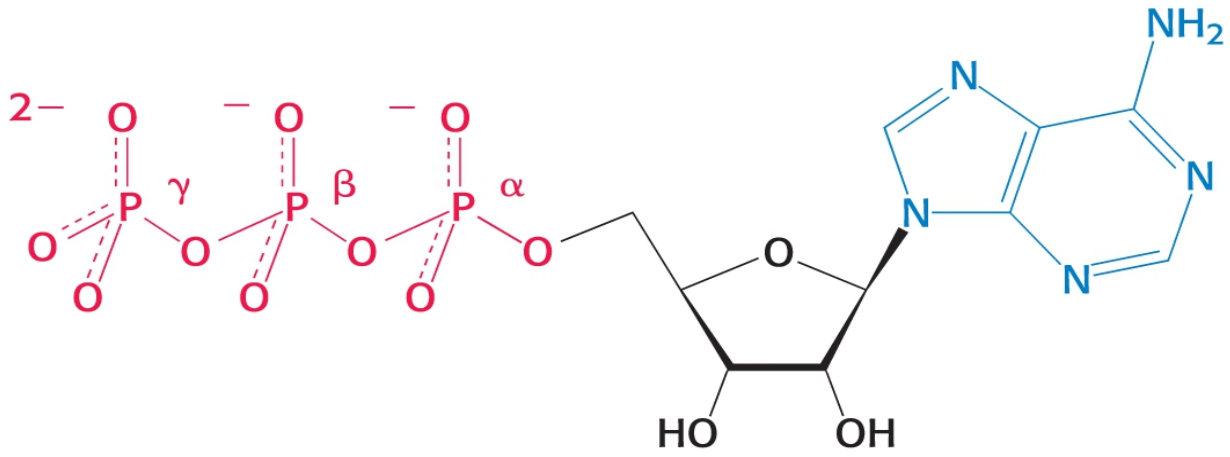
Extended description for Chemical reactions and their respective standard free energy changes



$A \rightleftharpoons B + C$	$\Delta G^{\circ\prime} = +21\ kJ\ mol^{-1}\ (+5\ kcal\ mol^{-1})$
$B \rightleftharpoons D$	$\Delta G^{\circ\prime} = -34\ kJ\ mol^{-1}\ (-8\ kcal\ mol^{-1})$
$A \rightleftharpoons C + D$	$\Delta G^{\circ\prime} = -13\ kJ\ mol^{-1}\ (-3\ kcal\ mol^{-1})$

The first reaction consists of one reactant and two products. The reactant is A. A reversible reaction arrow leads to products B and C. The value of delta G nought prime is positive 21 kilojoules per mole or positive 5 kilocalories per mole. The second reaction consists of one reactant and one product. The reactant is B. A reversible reaction arrow leads to product D. The value of delta G nought prime is negative 34 kilojoules per mole or negative 8 kilocalories per mole. The summation reaction consists of one reactant and two products. The reactant is A. A reversible reaction arrow leads to the products C and D. The value of delta G nought prime is 13 kilojoules per mole or negative 3 kilocalories per mole.

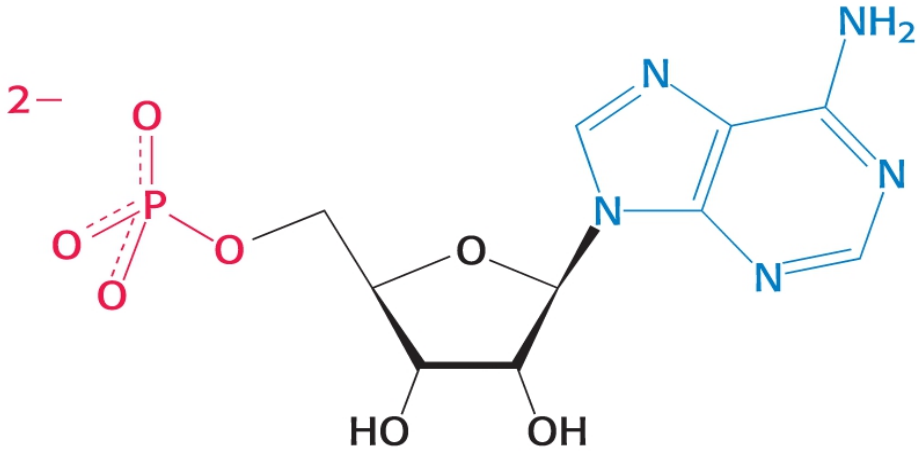
Extended description for Structures of A T P, A D P, and



AMP

Adenosine triphosphate (ATP)

Adenosine diphosphate (ADP)

Adenosine monophosphate (AMP)

Adenosine triphosphate (A T P) has the following structure: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. The ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are toward the observer and O is away from the observer. C 2 is single bonded to O H on the lower right. C 3 is single bonded to O H on the lower left. C 1 is single bonded to the first N atom of a second 5-membered heterocyclic pentagonal ring in a vertical orientation and consisting of 2 N and 3 C atoms. In the second 5-membered ring, the first N atom occupies the first position which is the bottom left vertex and the second N atom occupies the third position which is the topmost vertex. In the second 5-membered ring, a double bond is present between C 1 and the second N atom and C 2 and C 3. The second pentagonal ring is fused to a 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 2 N and 4 C atoms. In the 6-membered ring, the first N atom occupies the first position which is the rightmost vertex and the second N atom occupies the third position which is the bottom left vertex. The two rings are fused to each other such that C 2 and C 3 of the second pentagonal ring are the C 3 and C 2 of the hexagonal ring, respectively. In the hexagonal ring, a double bond is present between C 1 and the second N atom and C 4 and the first N atom. C 4 of the hexagonal ring is single bonded to N H 2. C 4 of the first pentagonal ring is single bonded to C H 2 on the upper left in the form of a line, which is again single bonded on the lower left to the fourth O atom of the following zigzag horizontal chain: O, partial double bond, P, single bond, O, single bond, P, single bond, O, single bond, P, single bond, O. In the zigzag horizontal chain, the first P atom is partially double bonded to O superscript 2 minus above and an O atom on the lower left. In the zigzag horizontal chain, the second and third P atoms are each partially double bonded to O superscript minus above and an O atom on the lower left. The zigzag

horizontal chain is highlighted in pink and the second pentagonal ring and hexagonal ring are highlighted in blue.

Adenosine diphosphate (A D P) has the following structure: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. The ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are toward the observer and O is away from the observer. C 2 is single bonded to O H on the lower right. C 3 is single bonded to O H on the lower left. C 1 is single bonded to the first N atom of a second 5-membered heterocyclic pentagonal ring in a vertical orientation and consisting of 2 N and 3 C atoms. In the second 5-membered ring, the first N atom occupies the first position which is the bottom left vertex and the second N atom occupies the third position which is the topmost vertex. In the second 5-membered ring, a double bond is present between C 1 and the second N atom and C 2 and C 3. The second pentagonal ring is fused to a 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 2 N and 4 C atoms. In the 6-membered ring, the first N atom occupies the first position which is the rightmost vertex and the second N atom occupies the third position which is the bottom left vertex. The two rings are fused to each other such that C 2 and C 3 of the second pentagonal ring are the C 3 and C 2 of the hexagonal ring, respectively. In the hexagonal ring, a double bond is present between C 1 and the second N atom and C 4 and the first N atom. C 4 of the hexagonal ring is single bonded to N H 2. C 4 of the first pentagonal ring is single bonded to C H 2 on the upper left in the form of a line, which is again single bonded on the lower left to the third O atom of the following zigzag horizontal chain: O, partial double bond, P, single bond, O, single bond, P, single bond, O. In the zigzag horizontal chain, the first P atom is partially double bonded to O superscript 2 minus above and an O atom on the lower left. In the zigzag horizontal chain, the second P atom is partially double

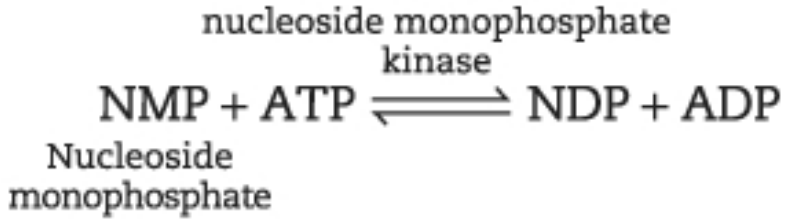
bonded to O superscript minus above and an O atom on the lower left. The zigzag horizontal chain is highlighted in pink and the second pentagonal ring and hexagonal ring are highlighted in blue.

Adenosine monophosphate (A T P) has the following structure: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. The ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are toward the observer and O is away from the observer. C 2 is single bonded to O H on the lower right. C 3 is single bonded to O H on the lower left. C 1 is single bonded to the first N atom of a second 5-membered heterocyclic pentagonal ring in a vertical orientation and consisting of 2 N and 3 C atoms. In the second 5-membered ring, the first N atom occupies the first position which is the bottom left vertex and the second N atom occupies the third position which is the topmost vertex. In the second 5-membered ring, a double bond is present between C 1 and the second N atom and C 2 and C 3. The second pentagonal ring is fused to a 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 2 N and 4 C atoms. In the 6-membered ring, the first N atom occupies the first position which is the rightmost vertex and the second N atom occupies the third position which is the bottom left vertex. The two rings are fused to each other such that C 2 and C 3 of the second pentagonal ring are the C 3 and C 2 of the hexagonal ring, respectively. In the hexagonal ring, a double bond is present between C 1 and the second N atom and C 4 and the first N atom. C 4 of the hexagonal ring is single bonded to N H 2. C 4 of the first pentagonal ring is single bonded to C H 2 on the upper left in the form of a line, which is again single bonded on the lower left to the second O atom of the following zigzag horizontal chain: O, partial double bond, P, single bond, O. In the zigzag horizontal chain, P is partially double bonded to O superscript 2 minus above and an O atom on the lower left. The zigzag horizontal chain is highlighted in

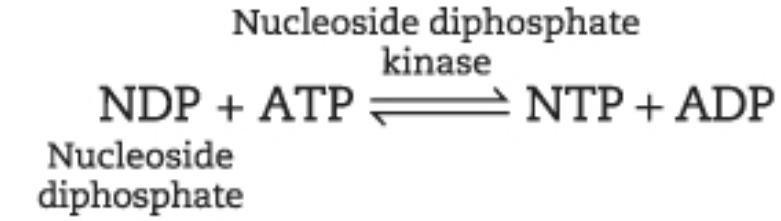
pink and the second pentagonal ring and hexagonal ring are highlighted in blue.

Return to Structures of A T P, A D P, and A M P

Extended description for A T P hydrolysis and standard free energy changes



$$ATP + H_2O \rightleftharpoons ADP + P_i$$
$$\Delta G^{\circ\prime} = -30.5 \text{ kJ mol}^{-1} (-7.3 \text{ kcal mol}^{-1})$$



$$ATP + H_2O \rightleftharpoons AMP + PP_i$$
$$\Delta G^{\circ\prime} = -45.6 \text{ kJ mol}^{-1} (-10.9 \text{ kcal mol}^{-1})$$

The first reversible reaction consists of two reactants and two products. The reactants are A T P and H 2 O. The products are A D P and P subscript i. The value of delta G nought prime is negative 30.5 kilojoules per mole or negative 7.3 kilocalories per mole. The second reversible reaction consists of two reactants and two products. The reactants are A T P and H 2 O. The products are A M P and P P subscript i. The value of delta G nought prime is negative 45.6 kilojoules per mole or negative 10.9 kilocalories per mole.

Return to A T P hydrolysis and standard free energy changes

Extended description for Reversible reactions catalyzed by nucleoside monophosphate kinase and nucleoside diphosphate kinase

The reaction catalyzed by nucleoside monophosphate kinase consists of two reactants and two products. The reactants are N M P (nucleoside monophosphate) and A T P. The products are N D P and A D P. The reaction catalyzed by nucleoside diphosphate kinase consists of two reactants and two products. The reactants are N D P (nucleoside diphosphate) and A T P. The products are N T P and A D P.

Return to Reversible reactions catalyzed by nucleoside monophosphate kinase and nucleoside diphosphate kinase

Extended description for Reaction with its standard free energy change

$$A + ATP + H_2O \rightleftharpoons B + ADP + P_i$$

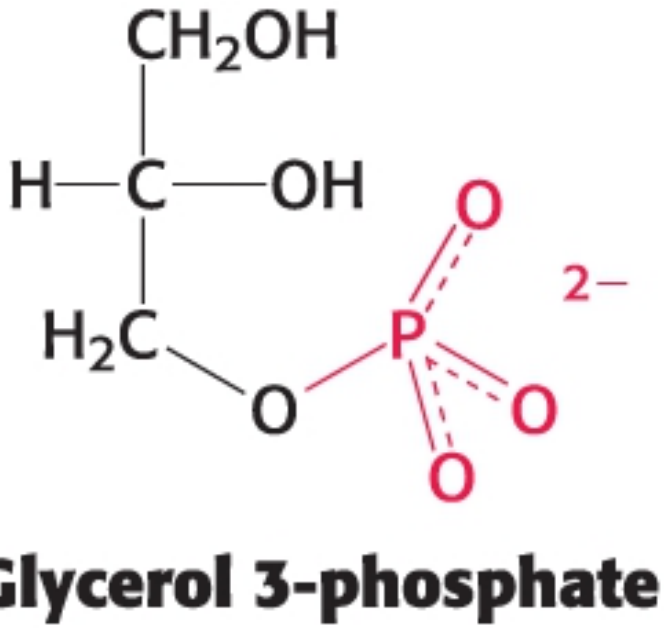
$$\Delta G^{\circ\prime} = -13.8 \text{ kJ mol}^{-1} (-3.3 \text{ kcal mol}^{-1})$$

The reaction consists of three reactants and three products. The reactants are A, A T P, and H 2 O. The products are B, A D P, and P subscript i. The value of delta G nought prime is negative 13.8 kilojoules per mole or negative 3.3 kilocalories per mole.

Return to Reaction with its standard free energy change

Extended description for Standard free energy changes of A T P and glycerol-3-phosphate hydrolysis

$$ATP + H_2O \rightleftharpoons ADP + P_i$$
$$\Delta G^{\circ\prime} = -30.5 \text{ kJ mol}^{-1} (-7.3 \text{ kcal mol}^{-1})$$



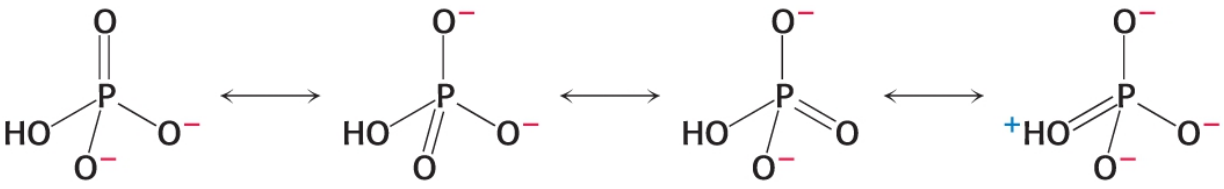
$$\text{Glycerol 3-phosphate} + H_2O \rightleftharpoons \text{glycerol} + P_i$$
$$\Delta G^{\circ\prime} = -9.2 \text{ kJ mol}^{-1} (-2.2 \text{ kcal mol}^{-1})$$

A T P hydrolysis reaction consists of two reactants and two products. The reactants are A T P and H 2 O. The products are A D P and P subscript i. The value of delta G nought prime is negative 30.5 kilojoules per mole or negative 7.3 kilocalories per mole.

Glycerol 3-phosphate reaction consists of two reactants and two products. The reactants are glycerol-3-phosphate and H 2 O. The products are glycerol and P subscript i. The value of delta G nought prime is negative 9.2 kilojoules per mole or negative 2.2 kilocalories per mole.

Return to Standard free energy changes of A T P and glycerol-3-phosphate hydrolysis

Extended description for Structure of Glycerol 3-phosphate



Glycerol 3-phosphate

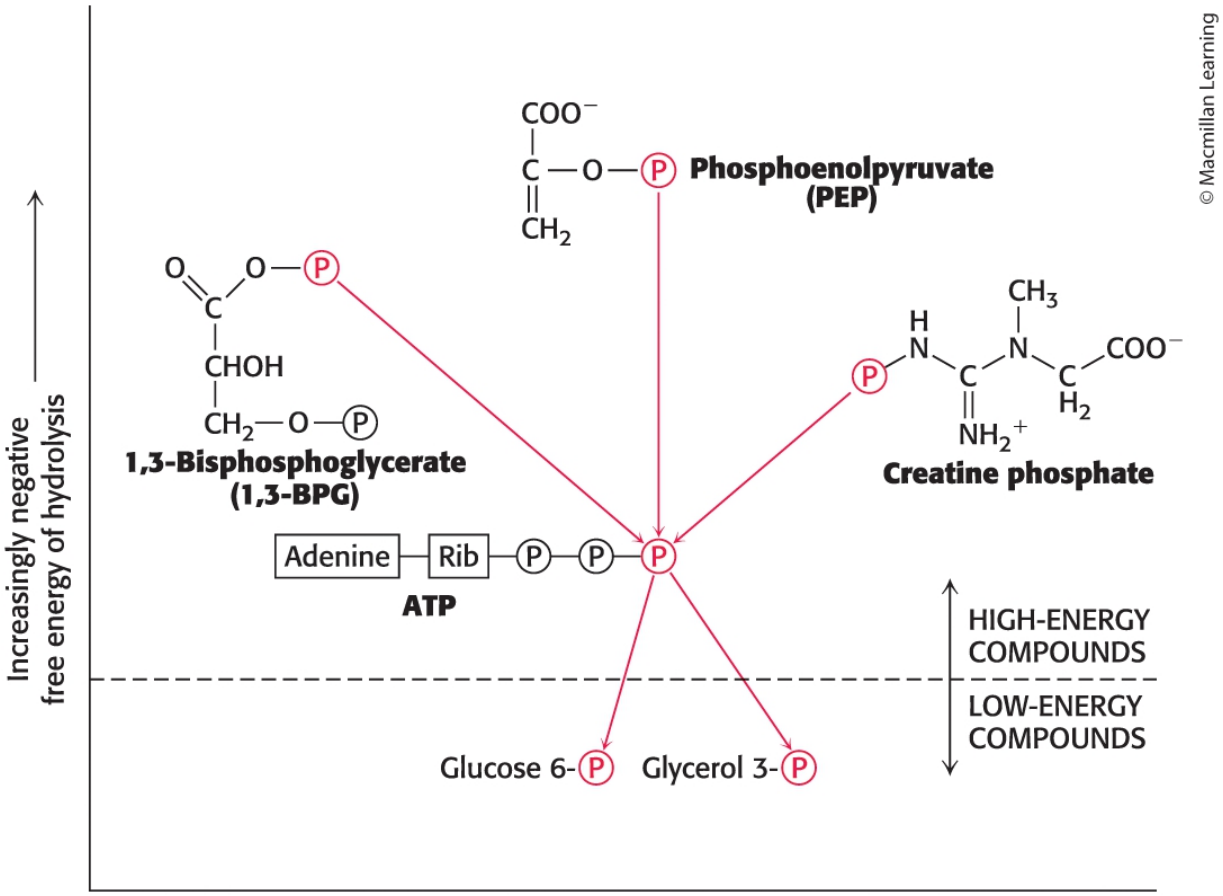
The structure of glycerol 3-phosphate is as follows: A central C atom is single bonded to C H 2 O H above, H on the left, O H on the right, and C H 2 below. C H 2 is further single bonded to O on the lower right. This O is single bonded to P on the upper right. This P is partially double bonded to O on the upper right, O on the right, and O on the lower right. It has a counter 2 superscript minus on the right. The P atom and 3 O atoms are highlighted in red.

Return to Structure of Glycerol 3-phosphate

Extended description for Four resonance structures of orthophosphate separated by two-way arrows

The structure of the first resonance orthophosphate is as follows: A central P atom is double bonded to O above, single bonded to O H on the lower left, O superscript minus below, and O superscript minus on the lower right.

The structure of the second resonance orthophosphate is as follows: A central P atom is single bonded to O superscript minus above, single bonded to O H on the lower left, double bonded to O below, and single bonded to O superscript minus on the lower right.



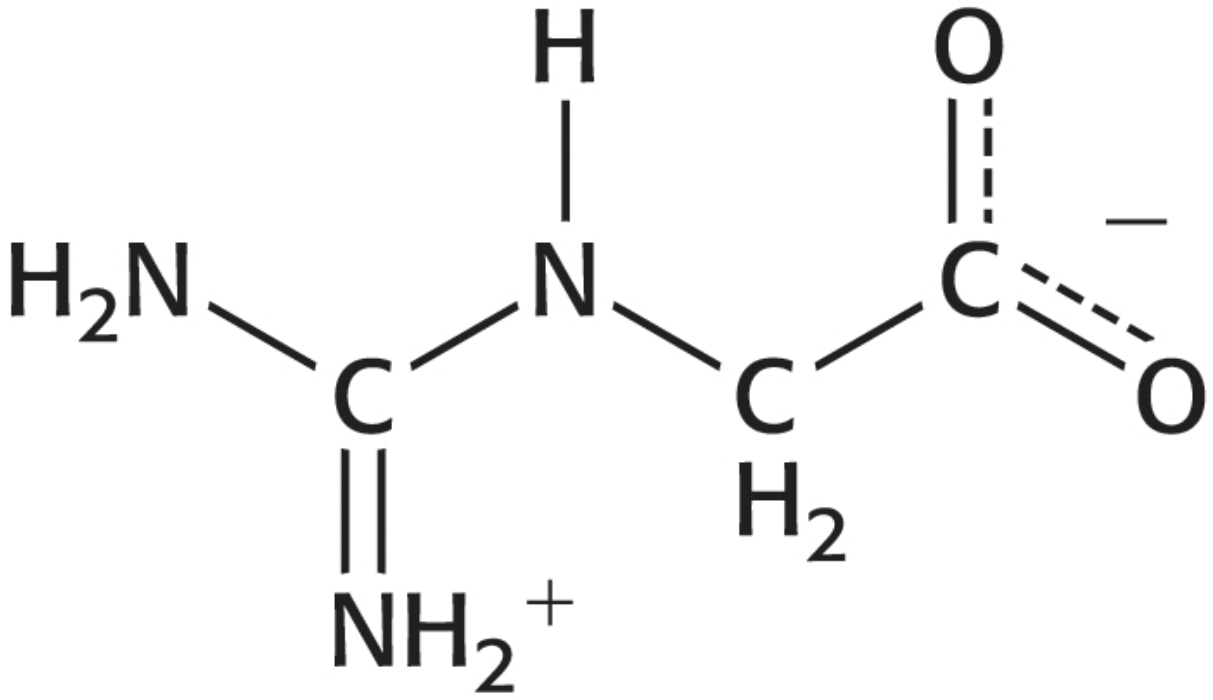
The structure of the third resonance orthophosphate is as follows: A central P atom is single bonded to O superscript minus above, single bonded to O H on the lower left, single bonded to O superscript minus below, and double bonded to O on the lower right.

The structure of the fourth resonance orthophosphate is as follows: A central P atom is single bonded to O superscript minus above, double bonded to O H superscript plus on the lower left, single bonded to O superscript minus below, and single bonded to O superscript minus on the lower right. Minus is highlighted in red and plus is highlighted in blue.

Three double headed arrows are placed between these four structures.

Return to Four resonance structures of orthophosphate separated by two-way arrows

Extended description for Graphical representation of the compounds with high phosphoryl-transfer potential that can be used to make A T P from A D P



The vertical axis of the graph is labeled increasingly negative free energy of hydrolysis. The graph shows a horizontal dotted line well above the origin. A double-headed vertical arrow across the dotted line reads low-energy compounds below and high-energy compounds above. A compound above the dotted line labeled A T P has the following structure: adenine, single bond, R i b, single bond P, single bond, P, single bond, P. The compound 1, 3-Bisphosphoglycerate (1,3-B P G) above A T P has the following structure: A vertical chain is illustrated by C, single bond, C H O H,

single bond, C H 2. C 1 is double bonded to O on the upper left and single bonded to a second O atom on the upper right. The second O atom is single bonded to P on the right. C 3 is single bonded to a third O atom on the right which is single bonded to a second P atom on the right. The compound creatine phosphate on the right side of 1,3-Bisphosphoglycerate (1,3- B P G) has the following structure: A zigzag horizontal chain is illustrated by P, single bond, N H, single bond, C, single bond, N, single bond, C H 2, single bond, C O O superscript minus. C1 is double bonded to N H 2 below. The second N atom is single bonded to C H 3 above. The structure between 1,3-B P G, and creatine phosphate is labeled Phosphoenolpyruvate (P E P) and has the following structure: A vertical chain is illustrated by C O O superscript minus, single bond, C, double bond, C H 2. C 2 is single bonded to O on the right which is single bonded to P on the right. Two structures below the dotted lines read glucose 6, single bond, P and Glycerol 3, single bond, P. Arrows each from the first P atom of 1,3 B P G, and the P atoms from P E P, and creatinine phosphate point to the third P atom in A T P. Arrows each from the third P atom of A T P point to the P atoms of glucose 6, single bond, P and Glycerol 3, single bond, P. All the 6 P atoms that are connected by arrows are circled and highlighted in red.

Extended description for Graphical representation of the sources of A T P change as exercise duration increases

The horizontal axis has markings from left to right labeled second, minutes, and hours. The vertical axis is labeled energy. The graph shows four curves. The first curve is an S-shaped orange curve labeled anaerobic metabolism (Chapter 16) that starts from the origin and ends at hours and mid energy. The second curve is an S-shaped black curve labeled aerobic metabolism (chapters 17 and 18) that starts between seconds and minutes on the horizontal axis and moves toward the upper right at hours and high energy. The third curve is blue and labeled creatinine phosphate. The curve starts from origin, rises to a peak at seconds on the horizontal axis, and falls steeply between seconds and minutes on the horizontal axis. The fourth pink curve starts at high energy on the vertical axis and exponentially decreases to seconds on the horizontal axis.

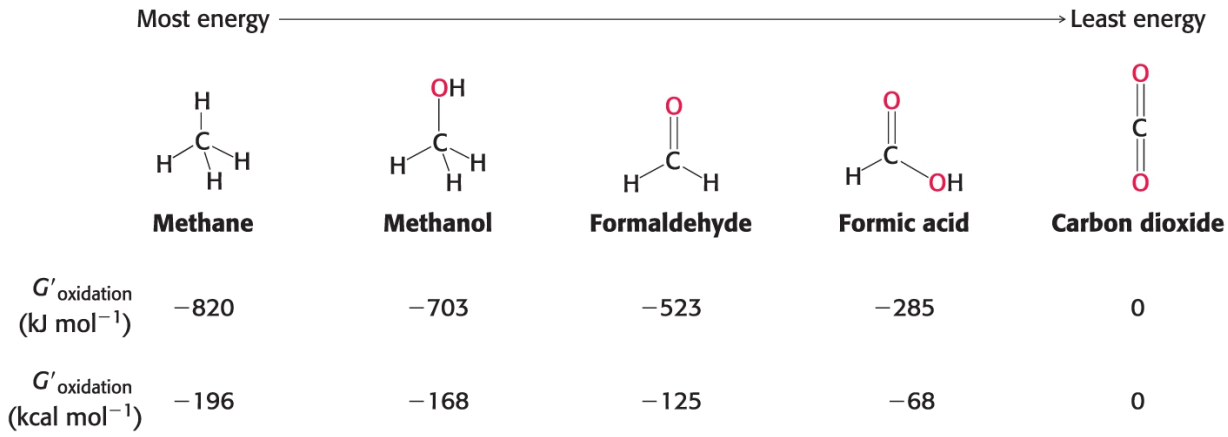
Extended description for A T P and A D P cycle



© Macmillan Learning

The figure reads A T P on the left and A D P on the right. A red curvy arrow from A T P points to A D P. A blue curvy arrow from A D P points to A T P. The text placed in a box above the red arrow reads: “Motion active transport biosynthesis signal amplification.” The text

placed in a box below the blue arrow reads: “Oxidation of fuel molecules or photosynthesis.”

Return to A T P and A D P cycle

Extended description for Free energy of oxidation of single-carbon compounds increases with the degree of hydrogen saturation from most energy on the left to least energy on the right

The compounds from left to right include methane, methanol, formaldehyde, formic acid, and carbon dioxide.

The structure of methane is as follows: A central C atom is single bonded to H above, H on the lower left, H below, and H on the lower right.

The structure of methanol is as follows: A central C atom is single bonded to O H above, H on the lower left, H below, and H on the lower right. The O atom from O H is highlighted in red.

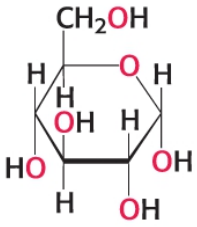
The structure of formaldehyde is as follows: A central C atom is double bonded to O above, single bonded to H on the lower left, and single bonded to H on the lower right. O atom above is highlighted in red.

The structure of formic acid is as follows: A central C atom is double bonded to O above, single bonded to H on the lower left, and single bonded to O H on the lower right. The O atom above and O from O H on the lower right are highlighted in red.

The structure of carbon dioxide is as follows: A central C atom is double bonded to O above and double bonded to O below. Both the O atoms are highlighted in red.

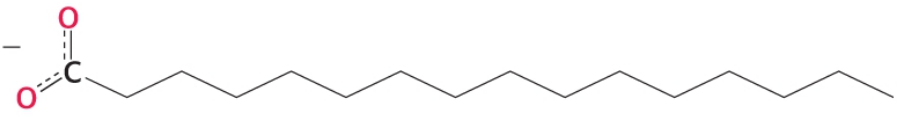
The G dash oxidation in K J mol superscript minus 1 for methane is negative 820 and G dash oxidation in k c a l mol superscript minus 1 for methane is negative 196.

The G dash oxidation in K J mol superscript minus 1 for methanol is negative 703 and G dash oxidation in k c a l mol superscript minus 1 for methanol is negative 168.



The G dash oxidation in K J mol superscript minus 1 for formaldehyde is negative 523 and G dash oxidation in k c a l mol superscript minus 1 for formaldehyde is negative 125.

The G dash oxidation in K J mol superscript minus 1 for formic acid is negative 285 and G dash oxidation in k c a l mol superscript minus 1 for formic acid is negative 68.



The G dash oxidation in K J mol superscript minus 1 for carbon dioxide is 0 and G dash oxidation in k c a l mol superscript minus 1 for carbon dioxide is 0.

Return to Free energy of oxidation of single-carbon compounds increases with the degree of hydrogen saturation from most energy on the left to least energy on the right

Extended description for Structures of glucose and saturated fatty acids

Glucose

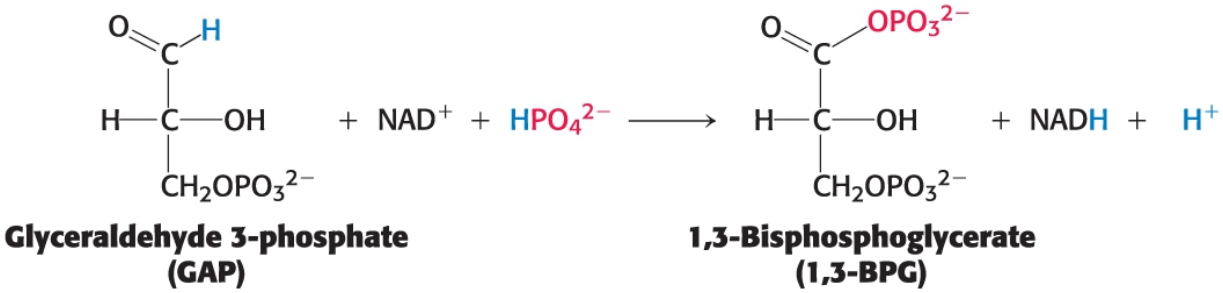
Saturated fatty acid

The structure of glucose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1, C 2, and C 4 are each single bonded to H above and O H below. C 3 is single bonded to O H above and H below. C 5 is single bonded to C H 2 O H above and H below. All the O atoms in the heterocyclic ring are highlighted in red.

The structure of saturated fatty acid is as follows: A 16-carbon alkane chain is depicted as a line structure using 15 zigzag lines. C 1 is partially double bonded to the O atom above and partially double bonded to another O atom on the lower left. O atoms are highlighted in red.

Return to Structures of glucose and saturated fatty acids

Extended description for Reaction for oxidation of glyceraldehyde 3-phosphate to 3-Phosphoglyceric acid



Glyceraldehyde 3-phosphate **3-Phosphoglyceric acid**

The structure of Glyceraldehyde 3-phosphate is as follows: The Fischer projection consists of a vertical chain with C above and C H 2 O P O 3 superscript 2 minus below. The projection contains a C atom at the center of the vertical line. The C atoms are numbered from top to bottom. C 1 is highlighted in red. C 1 is double bonded to O on the upper left and single bonded to H on the upper right. C 2 is single bonded to H on the left and O H on the right.

The structure of 3-Phosphoglyceric acid is as follows: The Fischer projection consists of a vertical chain with C above and C H 2 O P O 3 superscript 2 minus below. The projection contains a C atom at the center of the vertical line. The C atoms are numbered from top to bottom. C 1 is highlighted in red. C 1 is double bonded to O on the upper left and single bonded to H on the upper right. C 2 is single bonded to H on the left and O H on the right.

Return to Reaction for oxidation of glyceraldehyde 3-phosphate to 3-Phosphoglyceric acid

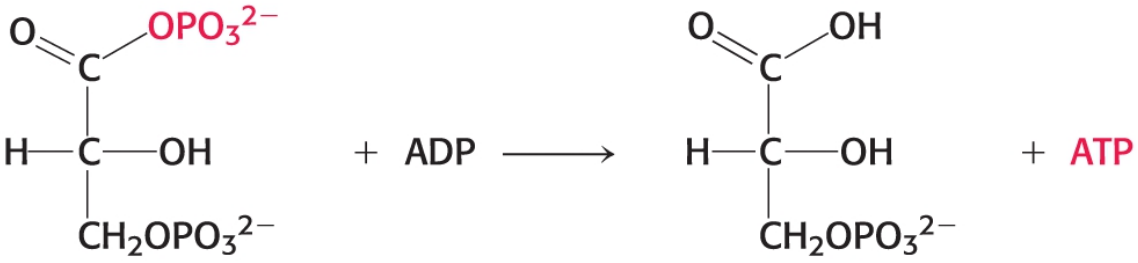
Extended description for Reaction for the formation of 1,3-Bisphosphoglycerate

Glyceraldehyde 3-phosphate reacts with N A D superscript plus and H P O 4 superscript 2 minus to give rise to 1,3-Bisphosphoglycerate plus N A D H plus H superscript plus.

The structure of glyceraldehyde 3-phosphate (G A P) is as follows: The Fischer projection consists of a vertical chain with C above and C H 2 O P O 3 superscript 2 minus below. The projection contains a C atom at the center of the vertical line. The C atoms are numbered from top to bottom. C 1 is double bonded to O on the upper left and single bonded to H on the upper right. The H on the upper right is highlighted in blue. C 2 is single bonded to H on the left and O H on the right.

In the third reactant H P O 4 superscript 2 minus, H is highlighted in blue and P O 4 superscript 2 minus is highlighted in red.

The structure of 1,3-Bisphosphoglycerate (1,3-B P G) is as follows: The Fischer projection consists of a vertical chain with C above and C H 2 O P O 3 superscript 2 minus below. The projection contains a C atom at the center of the vertical line. The C atoms are numbered from top to bottom. C 1 is double bonded to O on the upper left. C 1 is single bonded to O P O 3 superscript 2 minus on the upper right



and highlighted in red. C 2 is single bonded to H on the left and O H on the right.

In the second product N A D H, H is highlighted in blue.

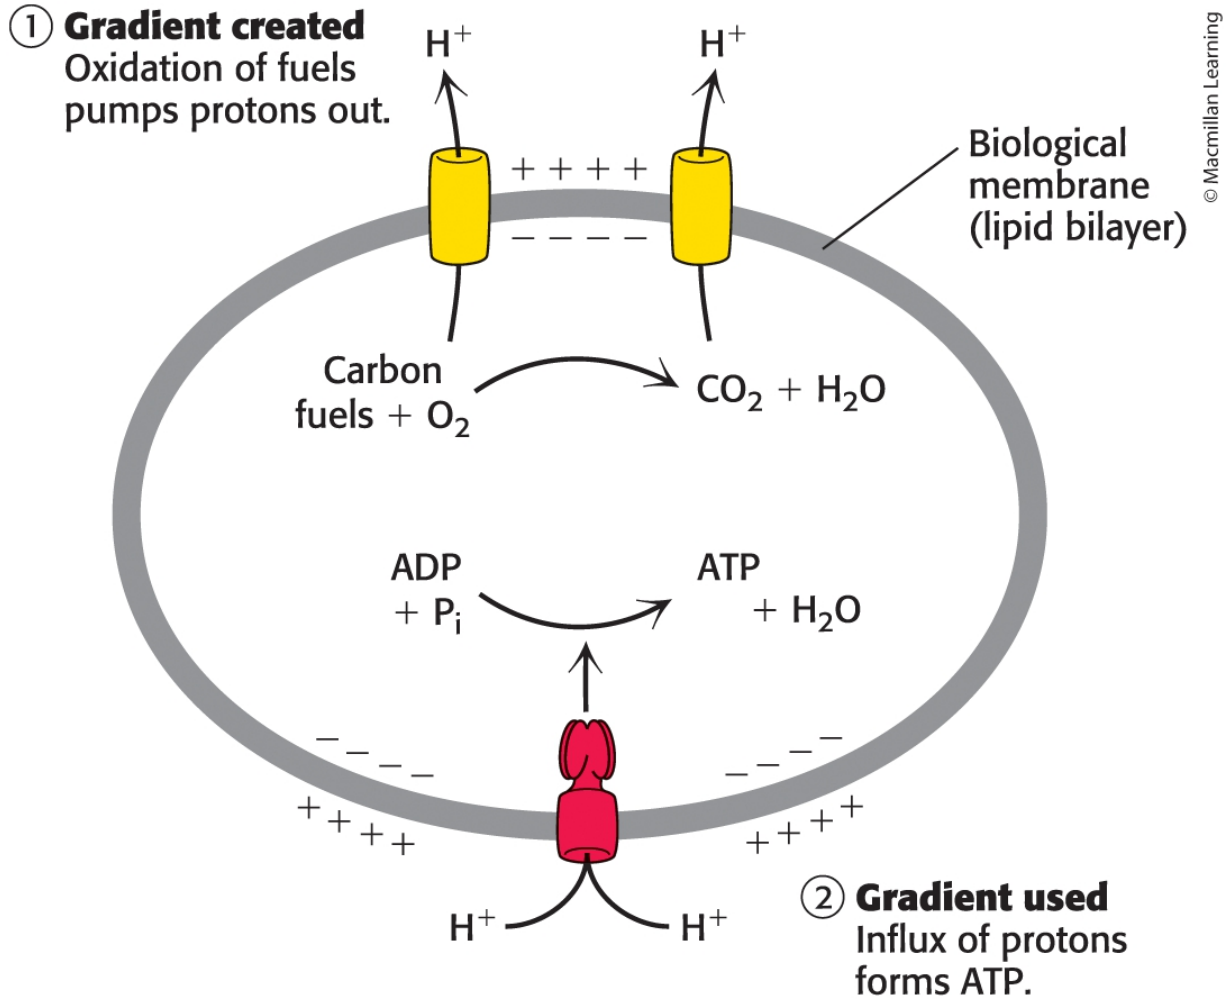
In the third product H superscript plus is highlighted in blue.

Return to Reaction for the formation of 1,3-Bisphosphoglycerate

Extended description for Reaction for the formation of 3-phosphoglyceric acid

1,3-Bisphosphoglycerate **3-Phosphoglyceric acid**

1,3-Bisphosphoglycerate reacts with A D P to form 3-phosphoglyceric acid and A T P.



The structure of 1,3-Bisphosphoglycerate is as follows: The Fischer projection consists of a vertical chain with C above and C H 2 O P O 3 superscript 2 minus below. The projection contains a C atom at the center of the vertical line. The C atoms are numbered from top to bottom. C 1 is double bonded to O on the upper left. C 1 is single bonded to O P O 3 superscript 2 minus on the upper right and highlighted in red. C 2 is single bonded to H on the left and O H on the right.

The structure of 3-Phosphoglyceric acid is as follows: The Fischer projection consists of a vertical chain with C above and C H 2 O P O 3 superscript 2 minus below. The projection contains a C atom at the center of the vertical line. The C atoms are numbered from top to bottom. C 1 is double bonded to O on the upper left and O H on the upper right. C 2 is single bonded to H on the left and O H on the right.

The second product A T P is highlighted in red.

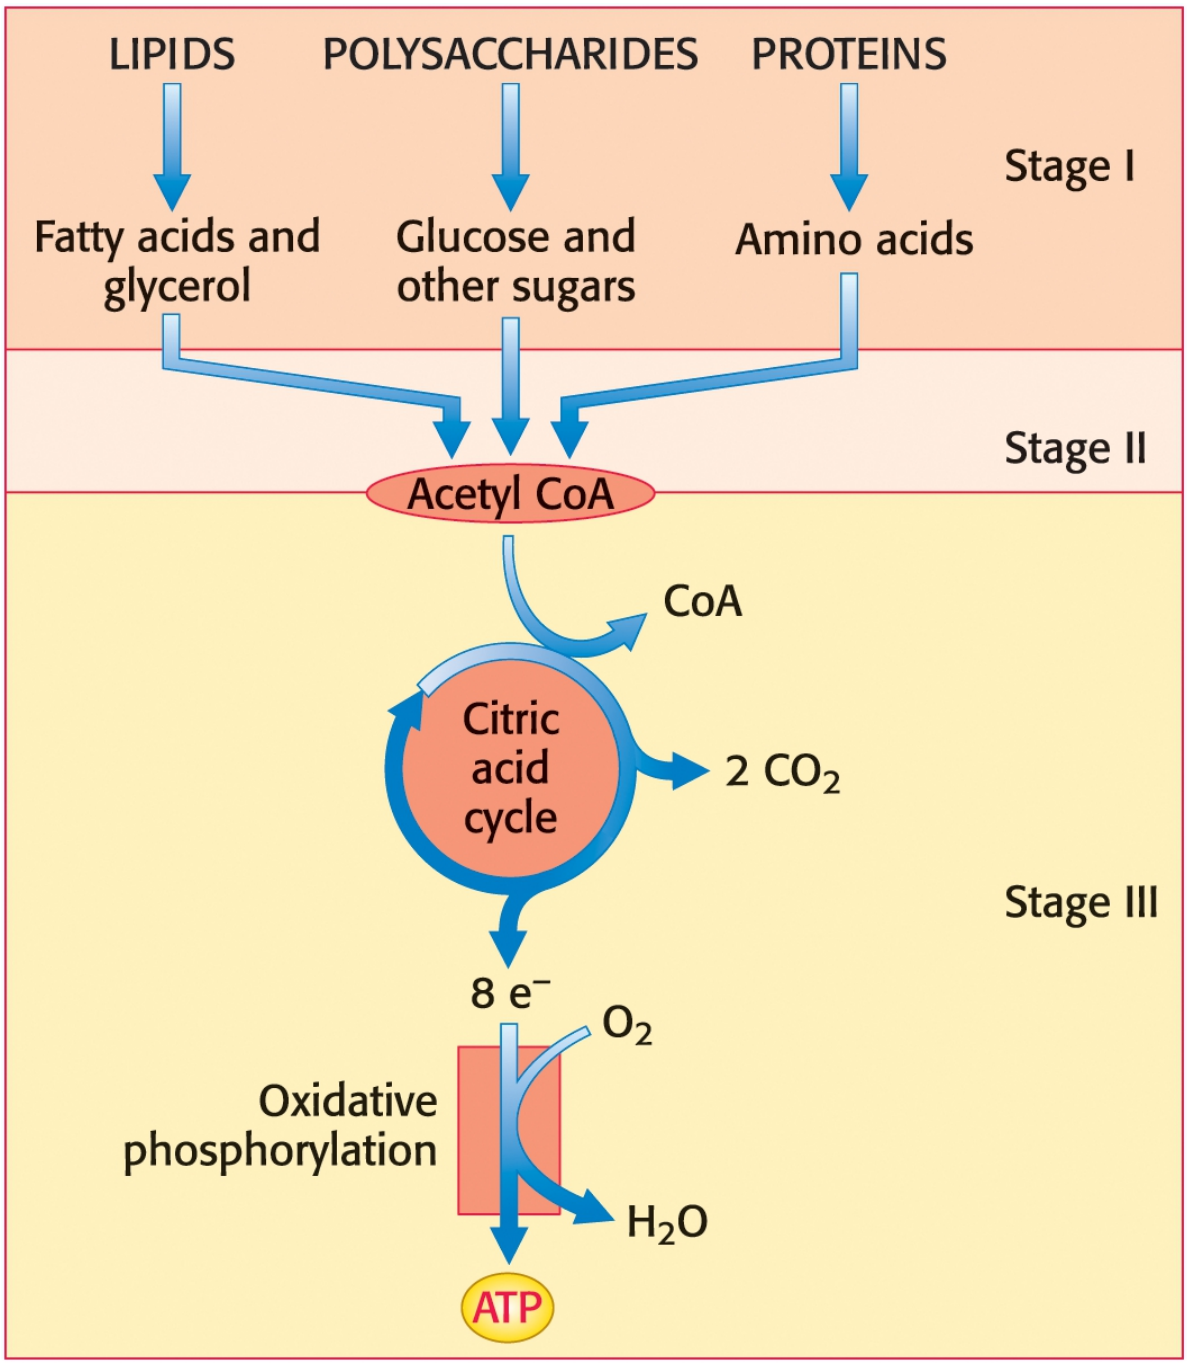
Extended description for Proton gradients formed in the biological membrane using energy from either sunlight or chemical oxidation can power A T P synthesis

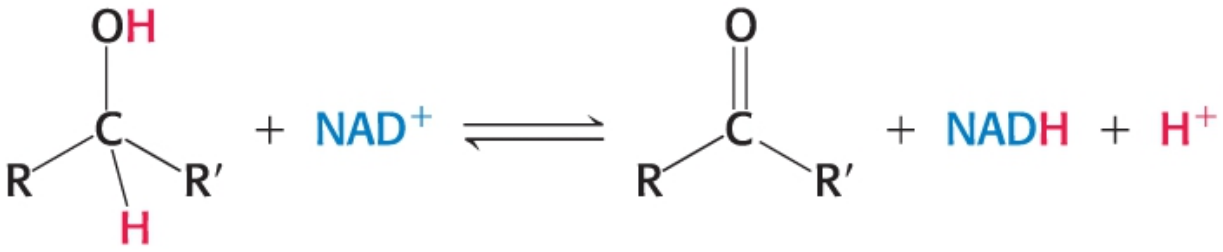


The figure shows a thick oval structure labeled biological membrane (lipid bilayer). The upper portion of the oval has two yellow cylindrical structures that depict proton pumps. The lower portion has a red cylindrical structure that depicts A T P synthesizing enzyme complex. Arrows from two yellow cylinders emerge outside.

The head of the arrow reads H superscript plus. The upper outer surface of the oval has four positive charges aligned in a row and the inner surface of the oval has four negative charges aligned in a row. An equation inside the oval close to the yellow cylinders reads Carbon fuels plus O 2 gives C O 2 plus H 2 O. Two H superscript plus ions from the lower region of the biological membrane enter the membrane through the red cylinder and point to an equation inside the oval that reads A D P plus P i gives A T P plus H 2 O. A text on the top left reads gradient created oxidation of fuels pumps protons out. A text on the bottom right reads gradient used influx of protons forms A T P.

Return to Proton gradients formed in the biological membrane using energy from either sunlight or chemical oxidation can power A T P synthesis

Extended description for Three stages of extraction of energy from food to form A T P in aerobic organisms



© Macmillan Learning

The flow chart starts with stage 1. In stage 1, lipids are hydrolyzed to fatty acids and glycerol, polysaccharides are hydrolyzed to glucose and other sugars, and proteins are hydrolyzed to amino acids. These products are converted to Acetyl C o A in stage 2. The acetyl C o A then enters the citric acid cycle in stage 3 where C o A, 2 C O 2, and 8 electrons are liberated. The 8 electrons undergo oxidative phosphorylation to produce A T P by converting O 2 to H 2 O.

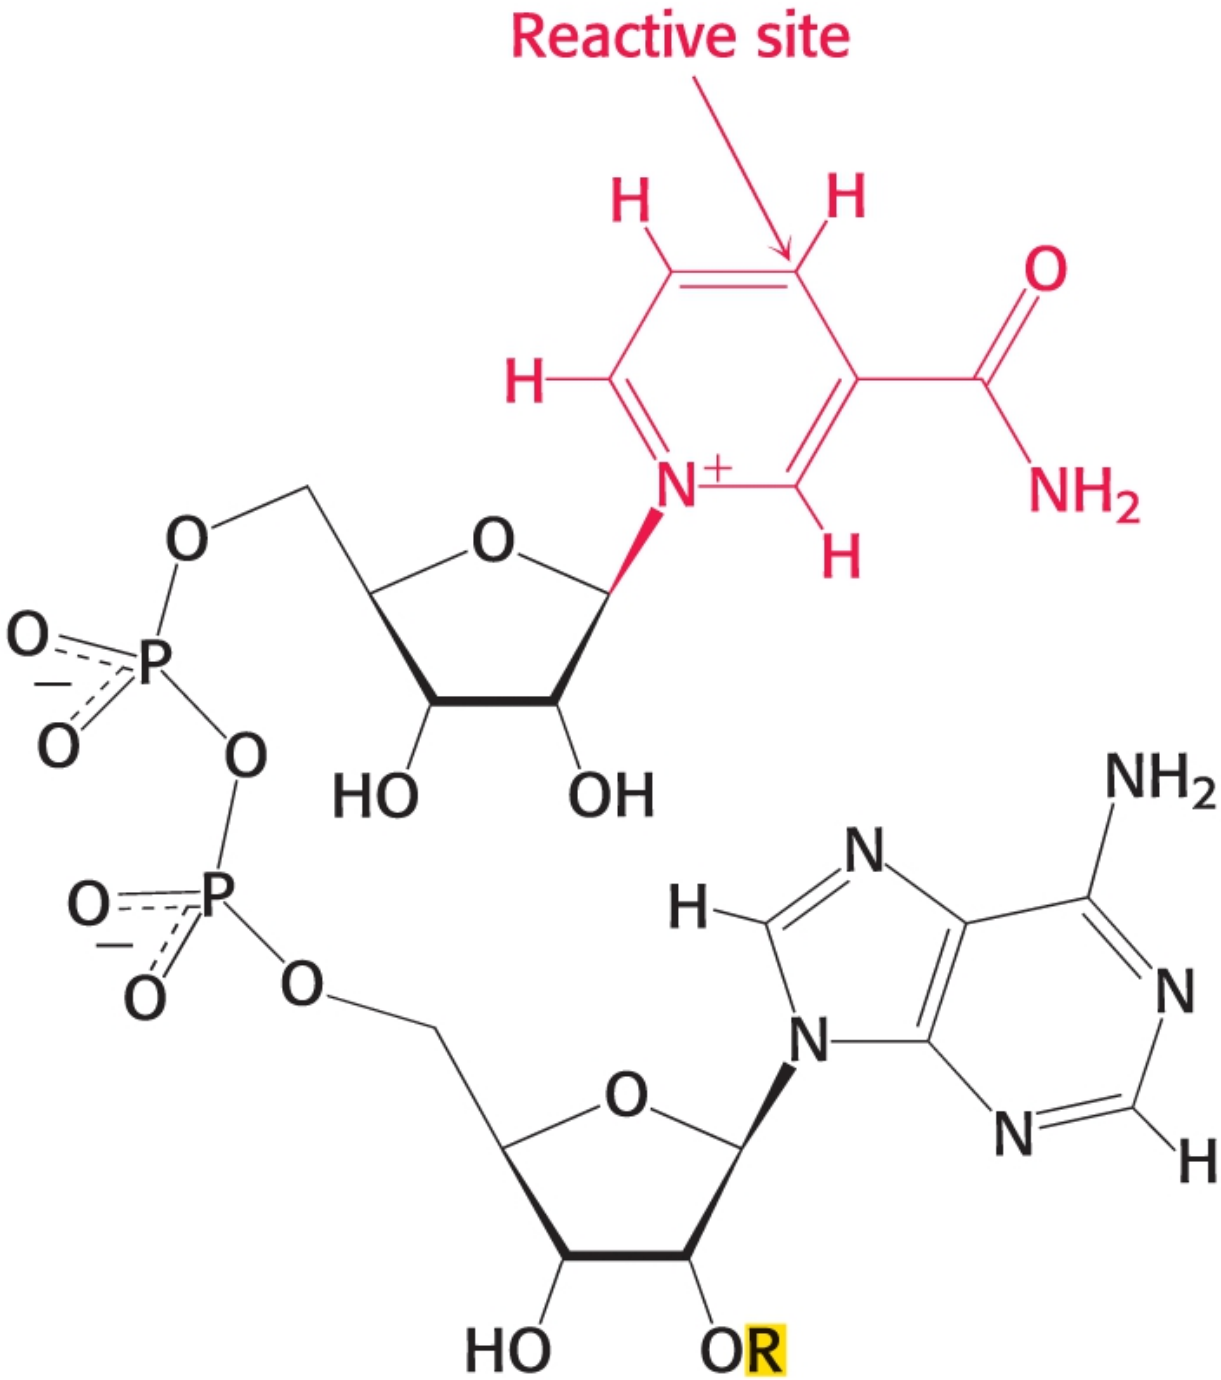
Return to Three stages of extraction of energy from food to form A T P in aerobic organisms

Extended description for Reaction for the formation of N A D H

The two reactants combine by equilibrium reaction to form three products.

The structure of the first reactant is as follows: A central C atom is single bonded to O H above, R on the lower left, H below, and R dash on the lower right. H from O H above and H below are highlighted in red.

The second reactant N A D superscript plus is highlighted in blue.



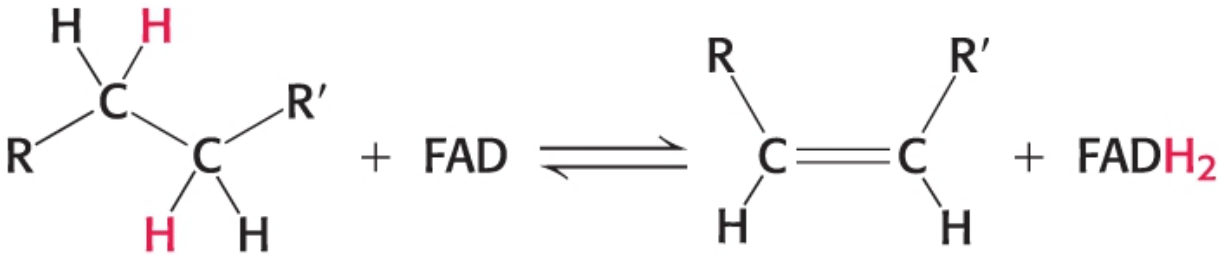
The structure of the first product is as follows: A central C atom is double bonded to O above, single bonded to R on the lower left, and R dash on the lower right.

In the second product, N A D H, N A D is highlighted in blue and H is highlighted in red.

The third product H superscript plus is highlighted in red.

Return to Reaction for the formation of N A D H

Extended description for Structure of oxidized forms of N A D superscript plus and N A D P superscript plus



A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 N and 5 C atoms with N superscript plus occupying the first position which is the bottom left vertex. Double bonds are present between N superscript plus and C 1, C 2 and C 3, and C 4 and C 5 atoms. C 1, C 2, C 3, and C 5 are each single bonded to H. C 3 is labeled reactive site. C 4 is single bonded to C on the right in the form of a line. This C is double bonded to O on the top right and single bonded to N H 2 on the bottom right. The 6-membered ring is highlighted in red. N superscript plus is wedge bonded to C 1 of a 5-membered heterocyclic pentagonal ring in a vertical orientation consisting of 1 O and 4 C atoms. O occupies the first position, which is the topmost vertex. The 5-membered ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are toward the observer and O is away from the observer. C 2 and C 3 are single bonded to O H. C 4 is single bonded to C H 2 on the top left in the form of a line. This C H 2 is single bonded to O on the bottom left. The O atom is single bonded to P on the lower left. P atom is partially double bonded to O superscript minus on the upper left and O on the lower left. P is also single bonded to O in the lower right. This O is single bonded to P below. This P atom is partially double bonded to O on the left and O superscript minus on the bottom left. P is also single bonded to O on the lower right. This O is single bonded to C H 2 in the form of a line which in turn is single bonded to C 4 of a second 5-membered heterocyclic pentagonal ring in a vertical orientation consisting of 1 O and 4 C atoms. O occupies the first position, which is the topmost vertex. The 5-membered ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are toward the observer and O is away from the observer. C 2 is single bonded to O R and C 3 is single bonded to O H. C 1 is wedge bonded to the first N atom of a third 5-membered heterocyclic pentagonal ring in a vertical orientation consisting of 2 N and 3 C atoms. The first N atom occupies the first position which is the bottom left vertex and the second N atom occupies the third position which is the topmost vertex. Double bonds are present between C 1

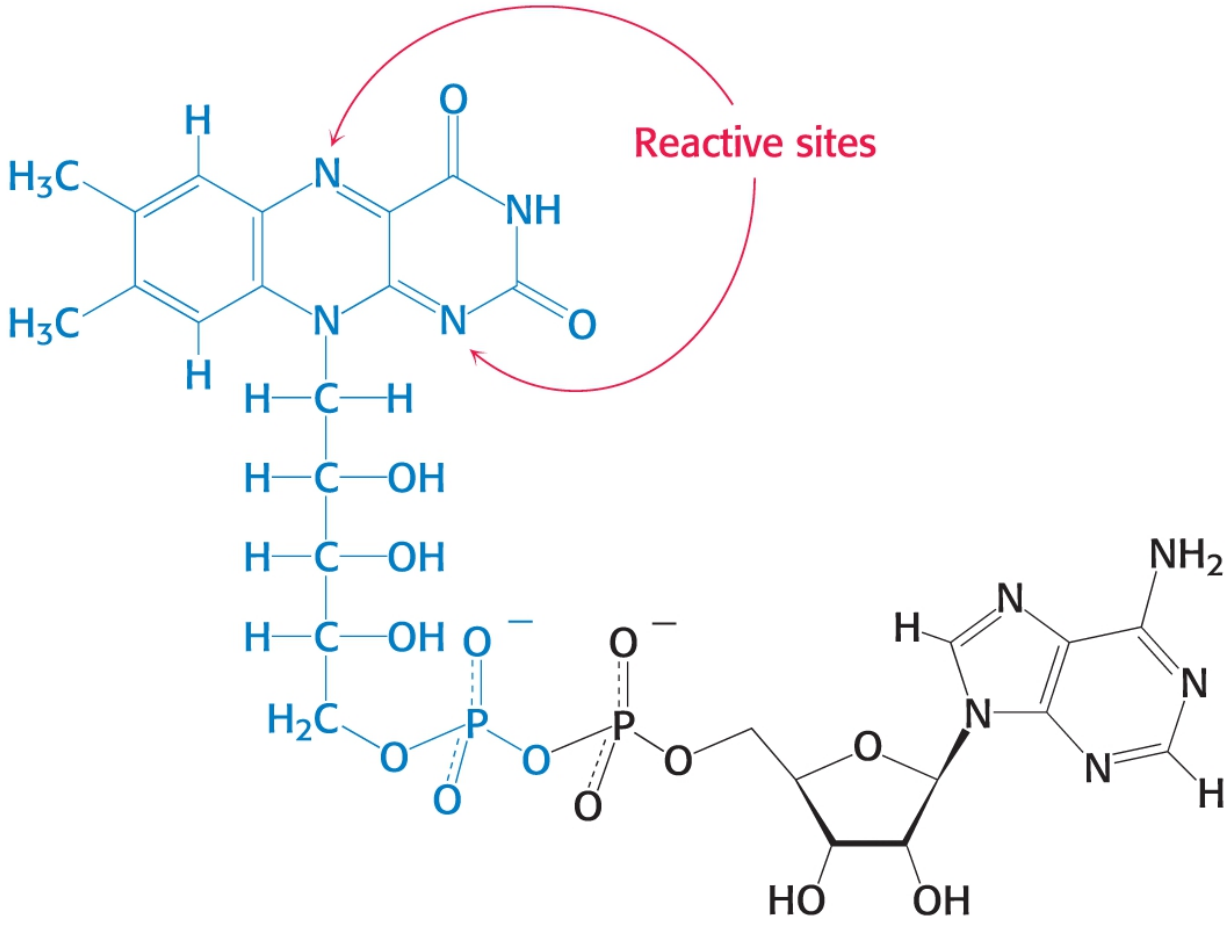
and the second N atom, and C 2 and C 3. C 1 is single bonded to H. The 5-membered ring is fused to a second 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 2 N and 4 C atoms. The first N atom occupies the first position which is the top right vertex and the second N atom occupies the third position which is the bottommost vertex. Double bonds are present between C 1 and the second N atom and C 4 and the first N atom. C 1 is single bonded to H and C 4 is single bonded to N H 2. The two rings are fused such that C 1 and C 2 of the third 5-membered ring are C 3 and C 2 of the second 6-membered ring, respectively.

Return to Structure of oxidized forms of N A D superscript plus and N A D P superscript plus

Extended description for Reaction for the formation of F A D H 2

The two reactants combine by equilibrium reaction to form two products.

The structure of the first product is as follows: A 2-carbon alkane chain is depicted as a line structure using one line. C 1 is single bonded to R on the lower left, H on the upper left, and H on the upper right. H on the upper right is highlighted in red. C 2 is single bonded to R dash on the upper right, H on the lower right, and H on the lower left. H on the lower left is highlighted in red.



The second reactant is F A D.

The structure of the first product is as follows: C, double bond, C. C 1 is single bonded to R on the upper left and H on the lower left. C 2 is single bonded to R dash on the upper right and H on the lower right.

In the second product F A D H 2, H 2 is highlighted in red.

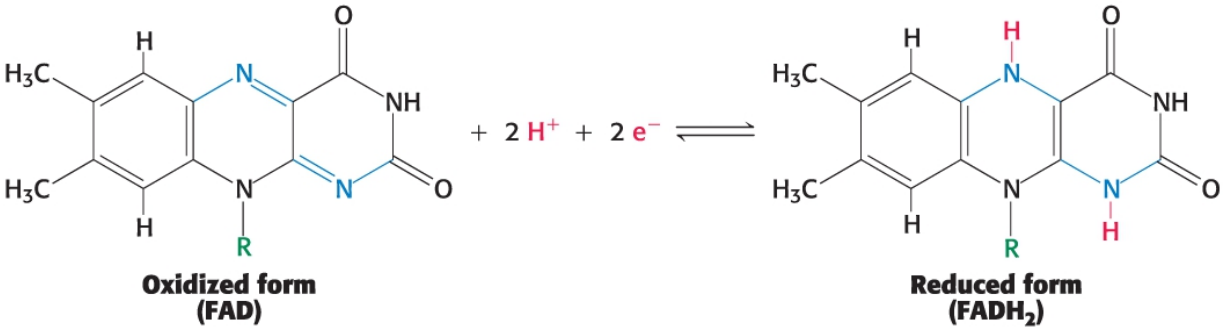
Extended description for Structure of flavin adenine dinucleotide



A benzene ring in a vertical orientation with C 1 occupying the topmost vertex is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 2 N and 4 C atoms. The first N atom occupies the first position, which is the topmost vertex and the second N atom occupies the fourth position which is the bottommost vertex. The two rings are fused to each other such that C 2 and C 3 of the benzene ring are the C 4 and C 3 of the 6-membered ring, respectively. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1

and C 4 are each single bonded to H. C 5 and C 6 are each single bonded to C H 3. In the 6-membered ring, a double bond is present between the first N atom and C 1. The heterocyclic hexagonal ring is fused to a second 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 2 N and 4 C atoms. The first N atom bound to H occupies the first position which is the top right vertex. The second N atom occupies the third position which is the bottommost vertex. The two rings are fused to each other such that C 1 and C 2 of the first heterocyclic ring are C 3 and C 2 of the second heterocyclic ring, respectively. A double bond is present between the second N atom and C 2. C 1 and C 4 are each double bonded to O. The first N atom of the first heterocyclic ring and the second N atom of the second heterocyclic ring are labeled reactive sites. The second N atom of the first heterocyclic ring is single bonded below to C 1 of a vertical chain consisting of 5 C atoms placed vertically. C 1 is single bonded to H on the left and H on the right. C 2, C 3, and C 4 are each single bonded to H on the left and O H on the right. C 5 bound to H 2 is single bonded to O on the lower right. O is single bonded to a P atom on the upper right. The P atom is partially double bonded to O superscript minus above and O on the lower left. P is also single bonded to O on the lower right. The structures until this point are highlighted in blue. The structures beyond this are highlighted in black. The O atom is single bonded to P on the upper right. The P atom is partially double bonded to O superscript minus above and O on the lower left. P is also single bonded to O on the lower right. The O atom is single bonded to C H 2 on the upper right in the form of a line. This C H 2 is single bonded to C 4 of a 5-membered pentagonal ring in a vertical orientation with O occupying the topmost vertex. The pentagonal ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are toward the observer and O is away from the observer. C 2 and C 3 are each single bonded to O H. C 1 is wedge bonded to N of a second 5-membered pentagonal heterocyclic ring in a vertical orientation consisting of 2 N and 3 C atoms such that the first N atom occupies the first position which is

the bottom left vertex and the second N atom occupies the third position which is the topmost vertex. C 1 is single bonded to H. Double bonds are present between C 1 and the second N atom, and C 2 and C 3. This 5-membered ring is fused to a third 6-membered heterocyclic hexagonal ring consisting of 2 N and 4 C atoms. The first N atom occupies the first position which is the top right vertex. The second N atom occupies the third position which is the bottommost vertex. A double bond is present between C 4 and the first N atom and C 1 and the second N atom. C 1 is single bonded to H. C 4 is single bonded to N H 2. The two rings are fused to each other such that C 2 and C 3 of the second pentagonal ring are C 3 and C 2 of the third 6-membered heterocyclic ring.

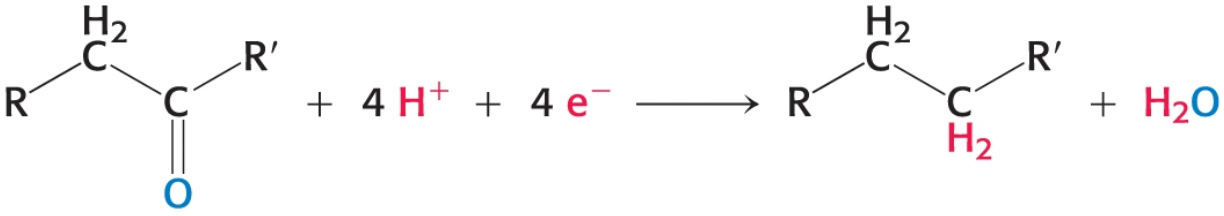
Extended description for Reaction for the formation of reduced form (F A D H 2) from oxidized form (F A D)

The reaction shows that oxidized form (F A D) reacts with 2 H superscript plus and 2 electrons to produce the reduced form (F A D H 2).



The structure of oxidized form (F A D) is as follows: A benzene ring in a vertical orientation with C 1 occupying the topmost vertex is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 2 N and 4 C atoms. The first N atom occupies the first position, which is the topmost vertex and the second N atom occupies the fourth position which is the bottommost vertex. The second N atom is single bonded to R. The first N atom, C 1, and C 4 are highlighted in blue. The two rings are fused to each other such that C 2 and C 3 of the benzene ring are the C 4 and C 3 of the 6-membered ring, respectively. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 and C 4 are each single bonded to H. C 5 and C 6 are each single bonded to C H 3. In the 6-membered ring, a double bond is present between the first N atom and C 1. The heterocyclic hexagonal ring is fused to a second 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 2 N and 4 C atoms. The first N atom bound to H occupies the first position which

is the top right vertex. The second N atom occupies the third position which is the bottommost vertex. The two rings are fused to each other such that C 1 and C 2 of the first heterocyclic ring are C 3 and C 2 of the second heterocyclic ring. C 1, the second N atom, and C 2 are highlighted in blue. A double bond is present between the second N atom and C 2. C 1 and C 4 are each double bonded to O.

The structure of reduced form (F A D H 2) is as follows: A benzene ring in a vertical orientation with C 1 occupying the topmost vertex is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 2 N and 4 C atoms. The first N atom occupies the first position, which is the topmost vertex and the second N atom occupies the fourth position which is the bottommost vertex. The first N atom is single bonded to H highlighted in red. The second N atom is single bonded to R. The first N atom and C 4 are highlighted in blue. The two rings are fused to each other such that C 2 and C 3 of the benzene ring are the C 4 and C 3 of the 6-membered ring, respectively. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 and C 4 are each single bonded to H. C 5 and C 6 are each single bonded to C H 3. The heterocyclic hexagonal ring is fused to a second 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 2 N and 4 C atoms. The first N atom bound to H occupies the first position which is the top right vertex. The second N atom occupies the third position which is the bottommost vertex. The two rings are fused to each other such that C 1 and C 2 of the first heterocyclic ring are C 3 and C 2 of the second heterocyclic ring. C 1, the second N atom, and C 2 are highlighted in blue. C 1 and C 4 are each double bonded to O. The second N atom is single bonded to H highlighted in red.

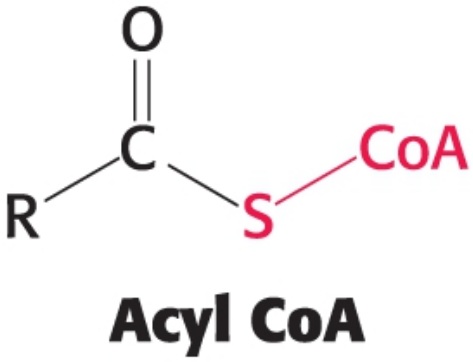
Return to Reaction for the formation of reduced form (F A D H 2) from oxidized form (F A D)

Extended description for Reaction for the biosynthesis of fatty acids

The three reactants combine to form two products.

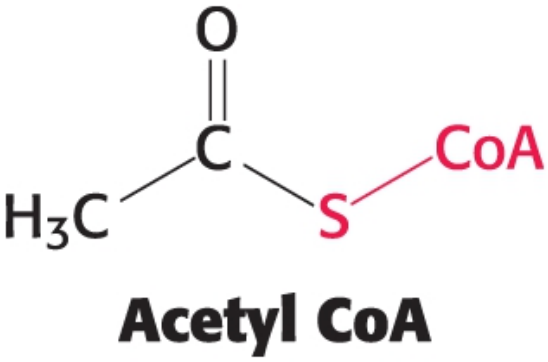
The structure of the first product is as follows: A 2-carbon alkane chain is depicted as a line structure using one line. C 1 bound to H 2 is single bonded to R on the lower left. C 2 is single bonded to R dash on the upper right and double bonded to O below. O is highlighted in blue.

The second reactant is 4 H superscript plus. H superscript plus is highlighted in red.



The third reactant 4 e superscript minus. e superscript minus is highlighted in red.

The structure of the first product is as follows: A 2-carbon alkane chain is depicted as a line structure using one line. C 1 bound to H 2 is single bonded to R on the lower left. C 2 bound to H 2 is single bonded to R dash on the upper right. H 2 bound to C 2 is highlighted in red.

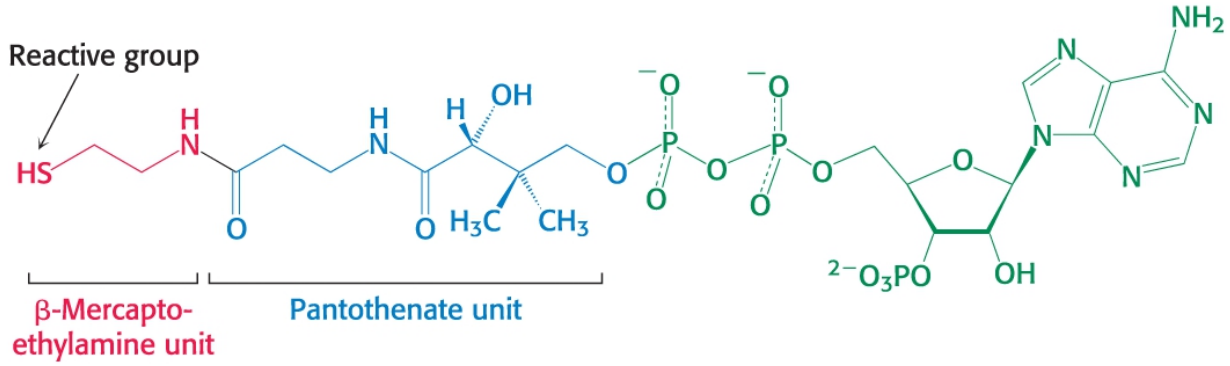


In the second product H 2 O, H 2 is highlighted in red and O is highlighted in blue.

Return to Reaction for the biosynthesis of fatty acids

Extended description for Structure of Acyl C o A and Acetyl C o A

Acyl CoA



Acetyl CoA

The structure of Acyl C o A is as follows: A central C atom is double bonded to O above. C is single bonded to R on the lower left and S on the lower right. S is further single bonded to C o A on the upper right. S and C o A are highlighted in red.

The structure of Acetyl C o A is as follows: A central C atom is double bonded to O above. C is single bonded to C H 3 on the lower left and S on the lower right. S is further single bonded to C o A on the upper right. S and C o A are highlighted in red.

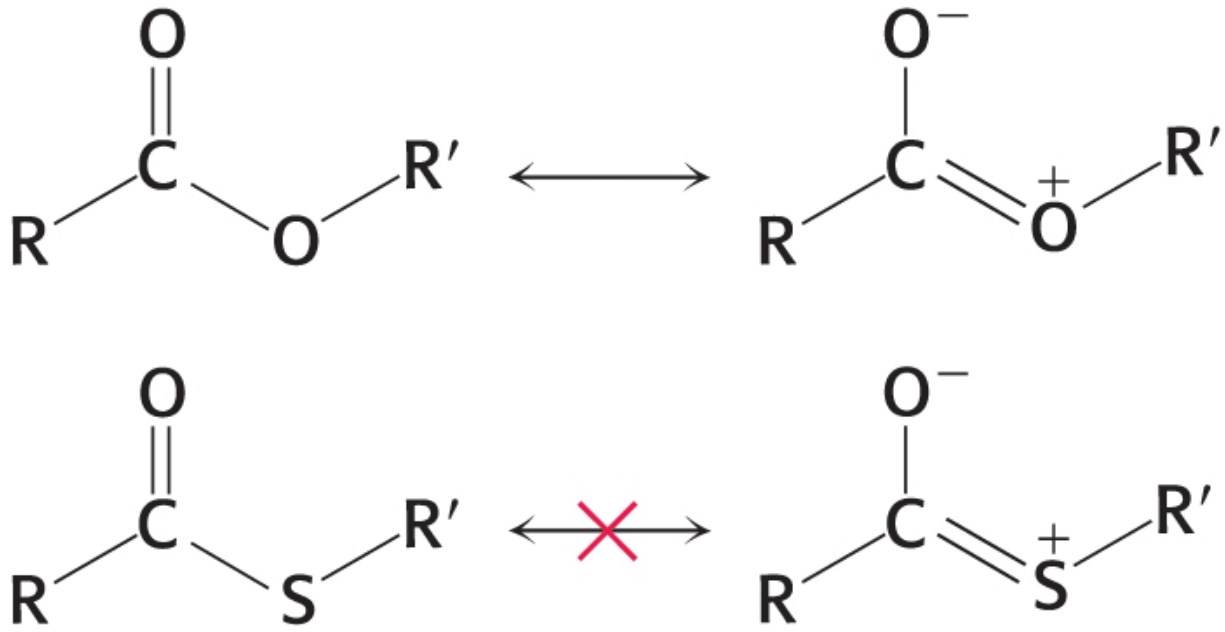
Return to Structure of Acyl C o A and Acetyl C o A

Extended description for Structure of coenzyme A

A 2-carbon alkane chain is depicted as a line structure using one line. C 1 is single bonded to S H on the lower left and C 2 is single bonded to N H 2 on the upper right. This is labeled beta-mercaptoethylamine unit and highlighted in red. S H is labeled reactive group. N H is single bonded to a 1 N and 7 C alkane chain depicted as a line structure using 7 zigzag lines. N occupies the fourth position and is bound to N H. C 1 and C 4 are each double bonded to O below. C 5 is wedge bonded to H on the upper left and dash bonded to O H on the upper right. C 6 is wedge bonded to C H 3 on the lower left and dash bonded to C H 3 on the lower right. C 7 is single bonded to O on the lower right. This structure is labeled panthothenate unit and is highlighted in blue. The O atom is single bonded to P on the upper right, single bond, O, single bond, P, single bond O in the form of a zigzag line. P 1 and P 2 are each partially double bonded to O superscript minus above and O on the lower left. The second O atom in the zigzag line is single bonded to C. This C atom is single bonded to C 4 of a 5-membered heterocyclic pentagonal ring in vertical orientation consisting of 1 O and 4 C atoms with O occupying the topmost vertex. C 2 is single bonded to O H and C 3 is single bonded to O 3 superscript 2 minus P O. C 1 is wedge bonded to N 2 of a 5-membered heterocyclic pentagonal ring consisting of 2 N and 3 C atoms. N 1 occupies the first position which

is the topmost vertex and N 2 occupies the fourth position which is the bottom left vertex. Double bonds are present between C 1 and C 2, and C 3 and N 1. The 5-membered ring is fused with a 6-membered heterocyclic hexagonal ring in a vertical orientation such that it contains 2 N and 4 C atoms. N 1 occupies the first position which is the top right vertex and N 2 occupies the third position which is the bottommost vertex. Double bonds are present between C 1 and N 2 and C 4 and N 1. C 1 is single bonded to N H 2. The two rings are fused such that C 1 and C 2 of the 5-membered ring are C 3 and C 2 of the 6-membered ring respectively. The structure beyond panthothenate is highlighted in green.

Return to Structure of coenzyme A



Extended description for Reversible reaction depicts the formation of acetate from acetyl C o A and its standard free energy change

$$\text{Acetyl CoA} + H_2O \rightleftharpoons \text{acetate} + \text{CoA} + H^+$$
$$\Delta G^{\circ\prime} = -31.4 \text{ kJ mol}^{-1} \ (-7.5 \text{ kcal mol}^{-1})$$

The reaction consists of two reactants and three products. The reactants are acetyl C o A and H 2 O. The products are acetate, C o A, and H superscript plus. The value of delta G nought prime is negative 31.4 kilojoules per mole or negative 7.5 kilocalories per mole.

Return to Reversible reaction depicts the formation of acetate from acetyl C o A and its standard free energy change

Extended description for Structures of oxygen esters and thioesters

Oxygen esters are stabilized by resonance structures not available to thioesters.

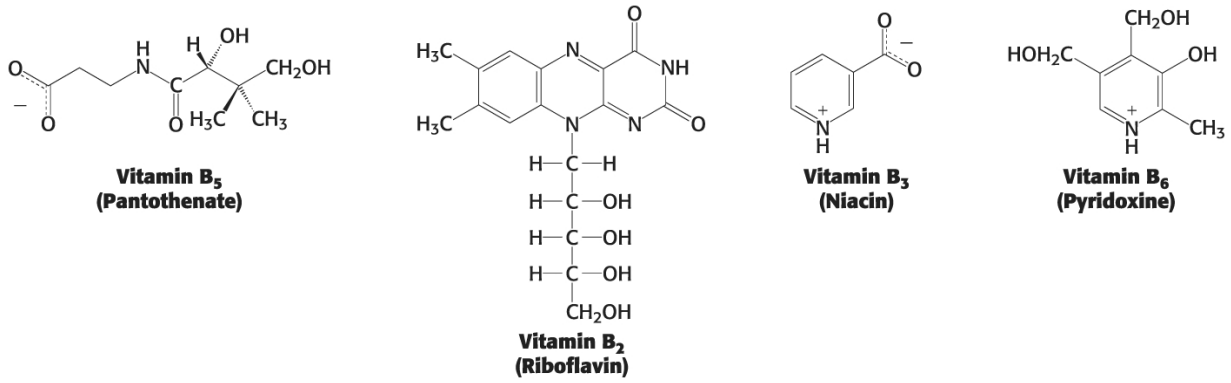
On the top, the figure shows two resonance structures of oxygen esters that are separated by double headed arrows.

The structure of the first oxygen ester on the left is as follows: A central C atom is double bonded to O above, single bonded to R on the lower left and single bonded to O on the lower right. This O is single bonded to R dash on the upper right.

The structure of the second oxygen ester on the left is as follows: A central C atom is single bonded to O superscript minus above, single

bonded to R on the lower left, and double bonded to O superscript plus on the lower right. This O superscript plus is single bonded to R dash on the upper right.

At the bottom, the figure shows two resonance structures of thioesters that are separated by double headed arrows and a cross is placed above this arrow.



The structure of the first thioester on the left is as follows: A central C atom is double bonded to O above, single bonded to R on the lower left, and single bonded to S on the lower right. This S is single bonded to R dash on the upper right.

The structure of the second thioester on the left is as follows: A central C atom is single bonded to O superscript minus above, single bonded to R on the lower left and double bonded to S superscript plus on the lower right. This S superscript plus is single bonded to R dash on the upper right.

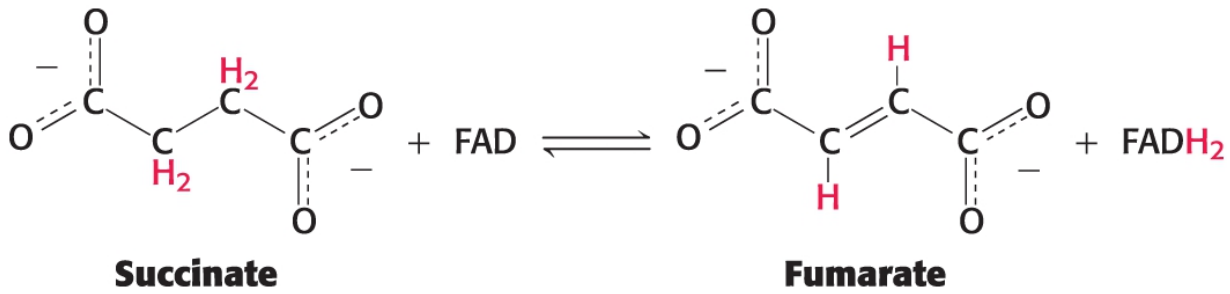
A text below reads: “Oxygen esters are stabilized by resonance structures not available to thioesters.”

Return to Structures of oxygen esters and thioesters

Extended description for Structures of water-soluble B vitamins

The structure of Vitamin B 5 (Panthotenate) is as follows: A 1 N and 6 C heteronuclear alkane chain is depicted as a line structure using 7 zigzag lines. N occupies the fourth position and is bound to H. C 1 is partially double bonded to O on the upper right and partially double bonded to O superscript minus below. C 4 is double bonded to O below. C 5 is wedge bonded to H on the upper left and dash bonded to O H on the upper right. C 6 is wedge bonded to C H 3 on the lower left and dash bonded to C H 3 on the lower right. C 6 is also single bonded to C H 2 O H on the upper right.

The structure of Vitamin B 2 (Riboflavin) is as follows: A benzene ring in a vertical orientation with C 1 occupying the topmost vertex is fused to another 6-membered heterocyclic hexagonal ring in vertical orientation consisting of 2 N and 4 C atoms. N 1 occupies the first position, which is the topmost vertex and N 2 occupies the fourth position which is the bottommost vertex. The two rings are fused to each other such that C 2 and C 3 of the benzene ring are the C 4 and C 3 of the 6-membered ring, respectively. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 5 and C 6 are each single bonded to C H 3. In the



6-membered ring, a double bond is present between N 1 and C 1. The heterocyclic hexagonal ring is fused to another hexagonal ring in vertical orientation consisting of 2 N and 4 C atoms. The two rings are fused to each other such that C 1 and C 2 of the first heterocyclic ring are C 3 and C 2 of the second heterocyclic ring. N 1 bound to H occupies the first position which is the top right vertex. N 2 occupies the third position which is the bottommost vertex. A double bond is present between N 2 and C 2. C 1 and C 4 are each double bonded to O. N 2 of the first heterocyclic ring is attached to a Fischer projection consisting of a vertical line with 4 C atoms placed vertically with C H 2 O H at the bottom. The C atoms are numbered from top to bottom. C 1 is single bonded to H on the left and H on the right. C 2, C 3, and C 4 are each single bonded to H on the left and O H on the right.

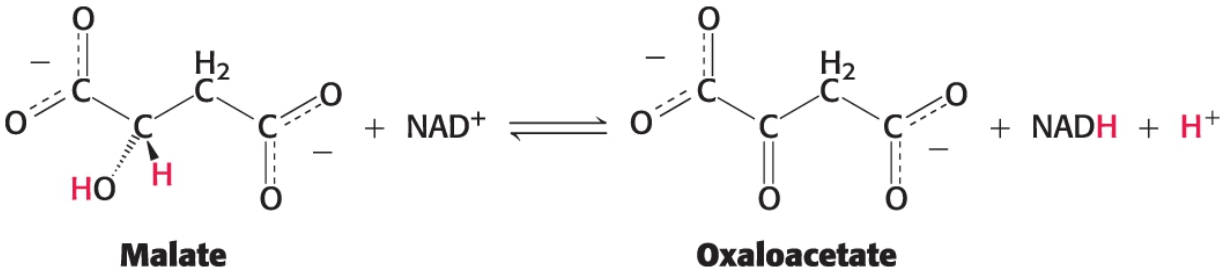
The structure of Vitamin B 3 (Niacin) is as follows: A 6-membered hexagonal heterocyclic ring is in a vertical orientation consisting of 1 N and 5 C atoms with N H superscript plus occupying the first position which is the bottommost vertex. Double bonds are present between N H superscript plus and C 1, C 2 and C 3, and C 4 and C 5. C 4 is single bonded to a central C atom on the top right. The central C atom is partially double bonded to O above and O on the lower right and has a counter negative sign.

The structure of Vitamin B 6 (Pyridoxine) is as follows: A 6-membered hexagonal heterocyclic ring is in a vertical orientation consisting of 1 N and 5 C atoms. N atom bound to H superscript plus occupies the first position which is the bottommost vertex. Double bonds are present between N H superscript plus and C 1, C 2 and C 3, and C 4 and C 5. C 2 and C 3 are each single bonded to C H 2 O H. C 4 is single bonded to O H on the top right. C 5 is single bonded to C H 3 on the bottom right.

Return to Structures of water-soluble B vitamins

Extended description for Formation of Fumarate from Succinate

Succinate reacts with F A D through equilibrium reaction to produce Fumarate and F A D H 2.



The structure of Succinate is as follows: A 4-carbon alkane chain is depicted as a line structure using 3 zigzag lines. C 1 is partially double bonded to O above and O on the lower left and has a counter negative sign. C 2 and C 3 are each bound to H 2 and these H 2 are highlighted in red. C 4 is partially double bonded to O on the upper right and O below and has a counter negative sign.

The structure of Fumarate is as follows: A 4-carbon alkene chain is depicted as a line structure using 3 zigzag lines. A double bond is present between C 2 and C 3. C 1 is partially double bonded to O above and O on the lower left and has a counter negative sign. C 2 is single bonded to H below and highlighted in red. C 3 is single bonded to H above and highlighted in red. C 4 is partially double bonded to O on the upper right and O below and has a counter negative sign.

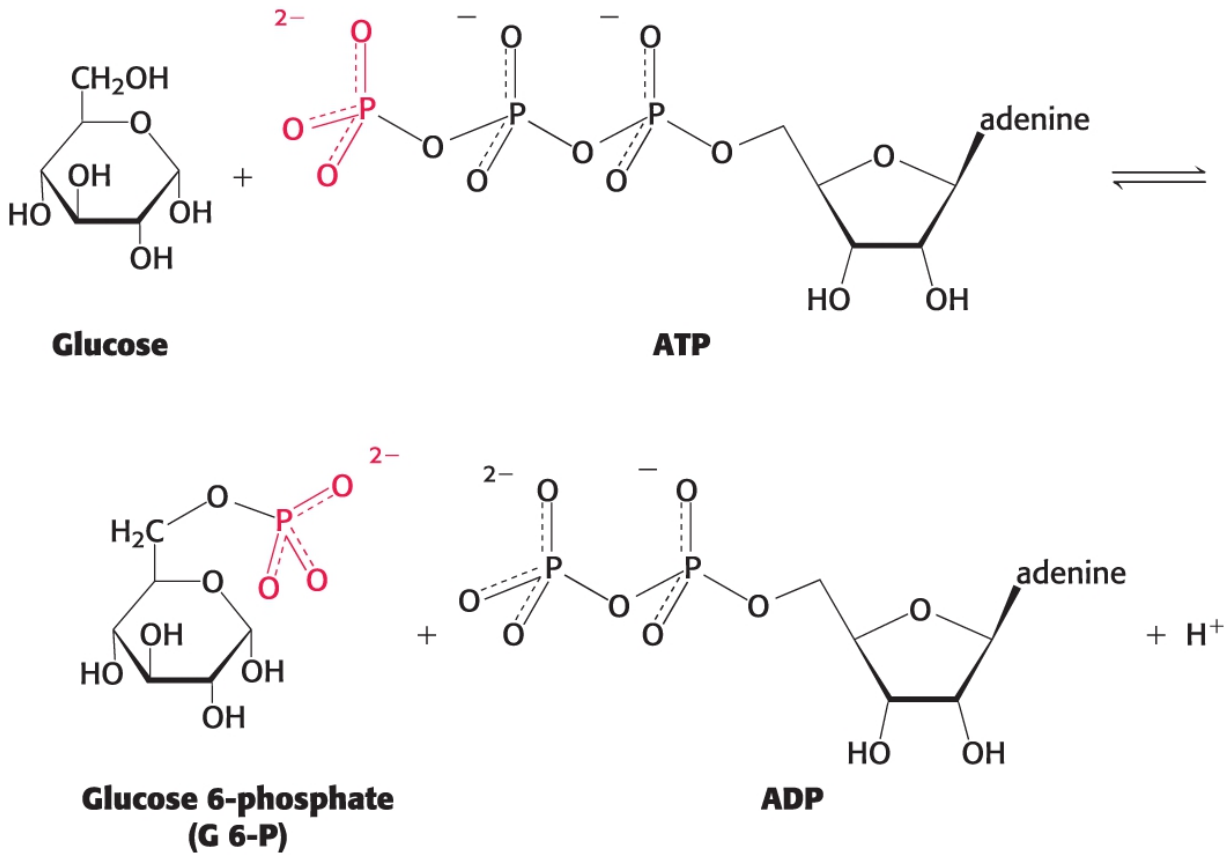
In the product F A D H 2, H 2 is highlighted in red.

Return to Formation of Fumarate from Succinate

Extended description for Formation of oxaloacetate from malate

Malate reacts with N A D superscript plus through equilibrium reaction to produce oxaloacetate, N A D H and H superscript plus.

The structure of Malate is as follows: A 4-carbon alkane chain is depicted as a line structure using 3 zigzag lines. C 1 is partially double bonded to O above and O on the lower left and has a counter negative sign. C 2 is dash bonded to O H on the lower left and wedge bonded to H on the lower right. The H from O H on the lower left and H on the lower right are highlighted in red. C 3 is bound to H 2. C 4 is partially double bonded to O on the upper right and O below and has a counter negative sign.



The structure of Oxaloacetate is as follows: A 4-carbon alkane chain is depicted as a line structure using 3 zigzag lines. C 1 is partially double bonded to O above and O on the lower left and has a counter negative sign. C 2 is double bonded to O below. C 3 is bound to H 2. C 4 is partially double bonded to O on the upper right and O below and has a counter negative sign.

In the second product N A D H, H is highlighted in red.

The third product H superscript plus is highlighted in red.

Return to Formation of oxaloacetate from malate

Extended description for Formation of glucose 6-phosphate and A D P

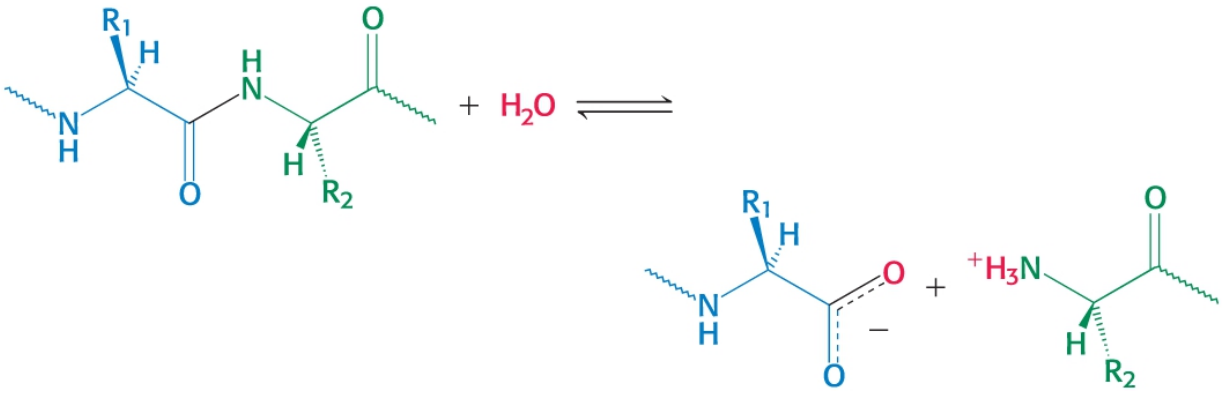
The reaction between glucose and A T P leads to the formation of glucose 6-phosphate, ADP, and hydrogen ion.

The reversible reaction consists of two reactants and three products.

The first reactant is glucose whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1, C 2, and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above.

The second reactant is A T P whose structure is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 1 is single bonded to adenine on the upper right. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single bonded to O on the lower left. O is single bonded to P on the upper left. P is partially double bonded to O superscript minus above, partially double bonded to O on the lower left, and single bonded to O on the lower left. This O atom is single bonded to another P on the upper left. This P is partially double bonded to O superscript minus above, partially double bonded to O on the lower left, and single bonded to O on the lower left. This O atom is single bonded to another P on the upper left. This P is partially double bonded to O superscript 2 minus above, partially double bonded to O on the lower left, and partially double bonded to O below.

The first product is glucose 6-phosphate. The structure of glucose 6-phosphate is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. C 1, C 2, and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 above. The C atom of C H 2 is further single bonded to O atom on the upper right. The O atom is further single bonded to P atom on the lower right. This P is partially double bonded to O superscript 2 minus on the upper right, partially double bonded to O below, and partially double bonded to O on the lower right.



The structure of the second product, that is A D P is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. C 1 is single bonded to adenine on the upper right. C 2 and C 3 are single bonded to O H

below. C 4 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single bonded to O on the lower left. O is single bonded to P on the upper left. P is partially double bonded to O superscript minus above, partially double bonded to O on the lower left, and single bonded to O on the lower left. This O atom is single bonded to another P on the upper left. This P is partially double bonded to O superscript 2 minus above, partially double bonded to O below, and partially double bonded to O on the lower left.

The third product is H superscript positive ion.

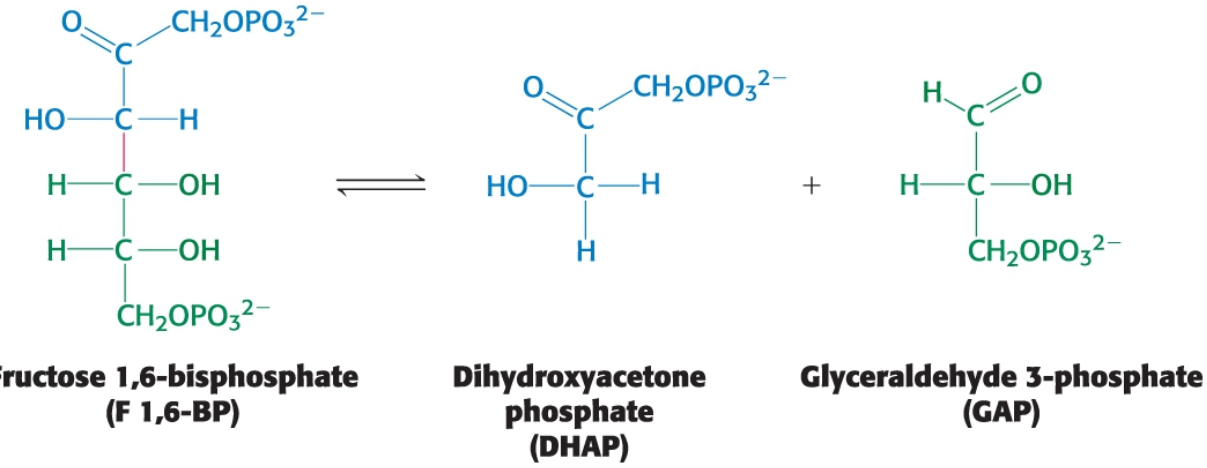
Return to Formation of glucose 6-phosphate and A D P

Extended description for Hydrolytic reaction

The two reactants combine by equilibrium reaction to form two products.

The structure of the first reactant is as follows: A 2 N and 4 C heteronuclear alkane chain is depicted as a line structure using 5 zigzag lines. N 1 occupies the first position and N 2 occupies the fourth position. N 1 and N 2 are each bound to H. N 1 has an open wavy bond. C 1 is wedge bonded to R 1 on the upper left and dash bonded to H on the upper right. C 2 is double bonded to O below. The structures upto this point are highlighted in blue. C 3 is wedge bonded to H on the lower left and dash bonded to R 2 on the lower right. C 4 is double bonded to O above and has an open wavy bond on the right. The structures from N 2 are highlighted in green.

The second reactant H 2 O is highlighted in red.



The structure of the first product is as follows: A 1 N and 2 C heteronuclear alkane chain is depicted as a line structure using 2 zigzag lines. N bound to H occupies the first position. C 1 is wedge bonded to R 1 on the upper left and dash bonded to H on the upper right. C 2 is partially double bonded to O on the upper right and O

below and has a counter negative sign. N has an open wavy bond on the left. The O atom single bonded to C 2 on the top right is highlighted in red and the rest of the structure is highlighted in blue.

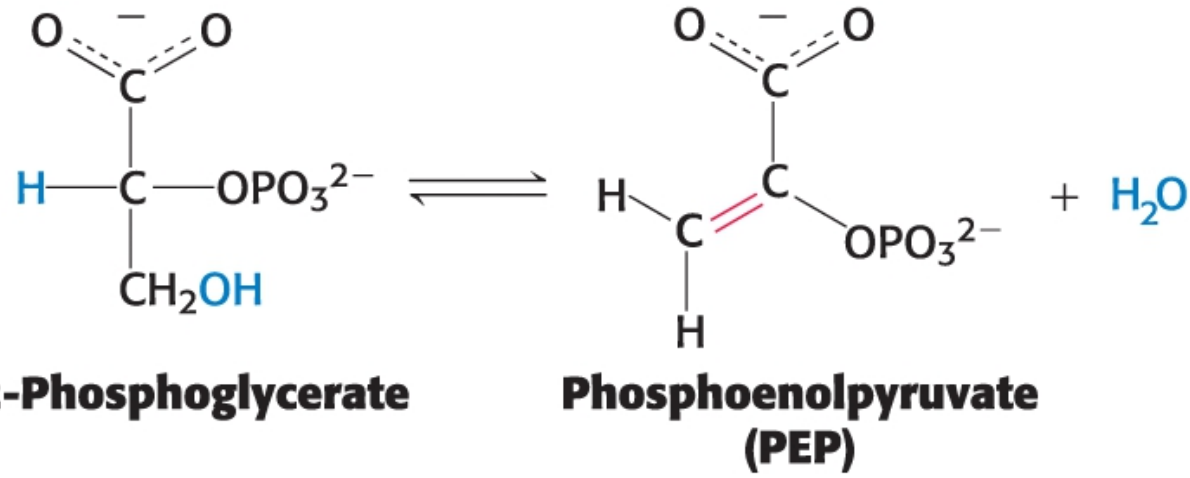
The structure of the second product is as follows: A 1 N and 2 C heteronuclear alkane chain is depicted as a line structure using 2 zigzag lines. N bound to H 3 superscript plus occupies the first position. H 3 superscript plus is highlighted in red. C 1 is wedge bonded to H on the lower left and dash bonded to R 2 on the lower right. C 2 is double bonded to O above and has an open wavy bond on the left. The entire structure is highlighted in green.

Return to Hydrolytic reaction

Extended description for Formation of Glyceraldehyde 3-phosphate from Fructose 1, 6-Bisphosphate

The reaction reads fructose 1, 6-bisphosphate (F 1, 6-B P) equilibrium reaction arrow dihydroxyacetone phosphate (D H A P) and Glyceraldehyde 3-phosphate (G A P).

The structure of Fructose 1, 6-bisphosphate (F 1, 6-B P) is as follows: The Fischer projection consists of a vertical chain with C above and C H 2 O P O 3 superscript 2 minus below. The projection contains four C atoms placed one below the other on the vertical chain. The C atoms are numbered from top to bottom. C 1 is double bonded to O on the upper left and single bonded to C H 2 O P O 3 superscript 2 minus on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 and C 4 are each single bonded to H on the left and O H on the right. C 1 and C 2 are highlighted in blue and structures below this are highlighted in green. The vertical line between C 2 and C 3 is highlighted in red.



The structure of Dihydroxyacetone phosphate (D H A P) is as follows: The Fischer projection consists of a vertical chain with C

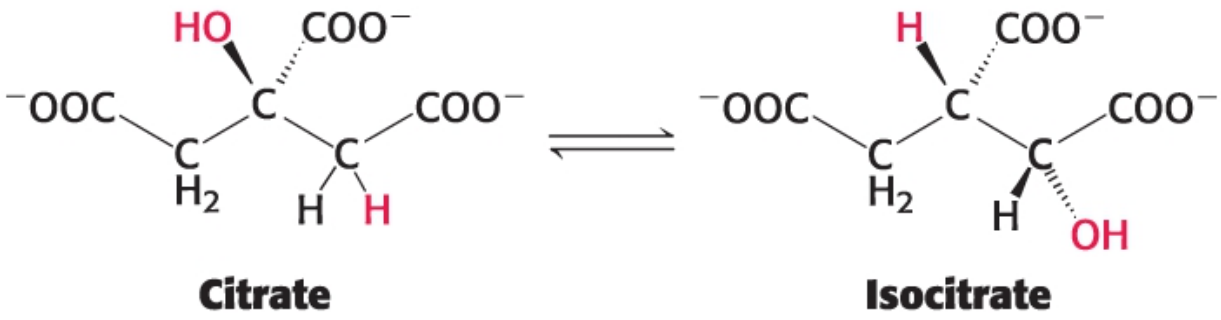
above and H below. The projection contains 1 C atom at the center. C 1 is double bonded to O on the left and single bonded to C H 2 O P O 3 superscript 2 minus on the right. C 2 is single bonded to O H on the left and H on the right. The entire structure is highlighted in blue.

The structure of Glyceraldehyde 3-phosphate (G A P) is as follows: The Fischer projection consists of a vertical chain with C above and C H 2 O P 3 superscript 2 minus below. The projection contains 1 C atom at the center. C 1 is single bonded to H on the left and double bonded to O on the right. C 2 is single bonded to H on the left and O H on the right. The entire structure is highlighted in green.

Return to Formation of Glyceraldehyde 3-phosphate from Fructose 1, 6-Bisphosphate

Extended description for Formation of Phosphoenolpyruvate (P E P) from 2-Phosphoglycerate

The reaction reads 2-Phosphoglycerate equilibrium arrow phosphoenolpyruvate (P E P) plus H 2 O.



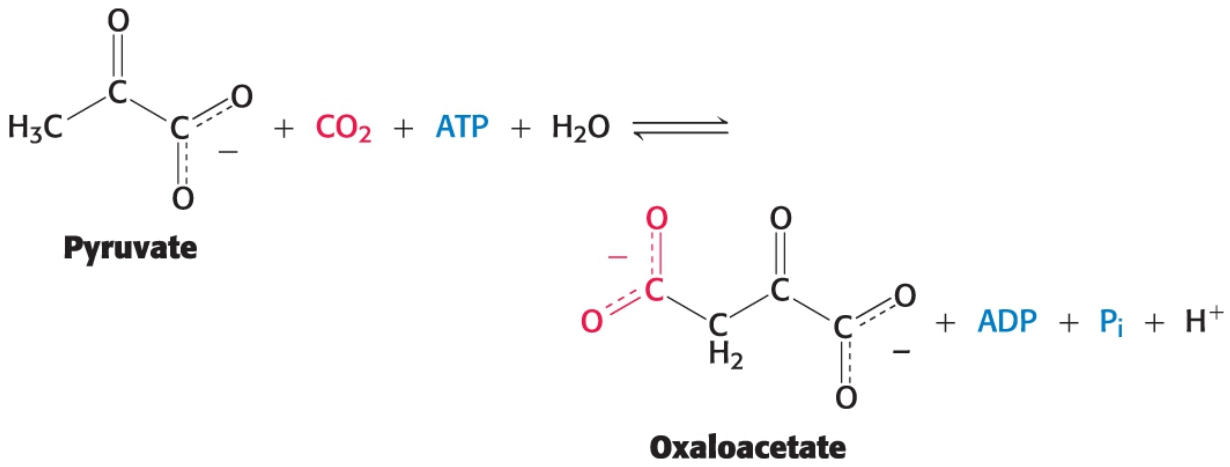
The structure of 2-Phosphoglycerate is as follows: The Fischer projection consists of a vertical chain with C above and C H 2 O H below. The projection contains 1 C atom at the center. C 1 is partially double bonded to O on the upper left and O on the upper right and has a counter negative sign. C 2 is single bonded to H on the left and O P O 3 superscript 2 minus on the right. H on the left side of C 1 and O H from C H 2 O H below are highlighted in blue.

The structure of phosphoenolpyruvate (P E P) is as follows: The Fischer projection consists of a vertical chain with C above and C below. C 1 is partially double bonded to O on the upper left and O on the upper right and has a counter negative sign. C 2 is single bonded to O P 3 superscript 2 minus on the lower right and double bonded to C on the lower left. The C atom is single bonded to H on the upper left and H below. The double bond is highlighted in red.

The second product H 2 O is highlighted in blue.

Return to Formation of Phosphoenolpyruvate (P E P) from 2-Phosphoglycerate

Extended description for Equilibrium reaction depicts the formation of isocitrate from citrate



The structure of citrate is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 bound to H 2 is single bonded to C O O superscript minus on the upper left. C 2 is wedge bonded to O H on the upper left and dash bonded to C O O superscript minus on the upper right. O H on the upper left is highlighted in red. C 3 is single bonded to C O O superscript minus on the upper right, H on the lower left, and H on the lower right. H on the lower right is highlighted in red.

The structure of isocitrate is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 bound to H 2 is single bonded to C O O superscript minus on the upper left. C 2 is wedge bonded to H on the upper left and dash bonded to C O O superscript minus on the upper right. H on the upper left is highlighted in red. C 3 is single bonded to C O O superscript minus on the upper right. C 3 is wedge bonded to H on the lower left, and dash bonded to O H on the lower right. O H on the lower right is highlighted in red.

Return to Equilibrium reaction depicts the formation of isocitrate from citrate

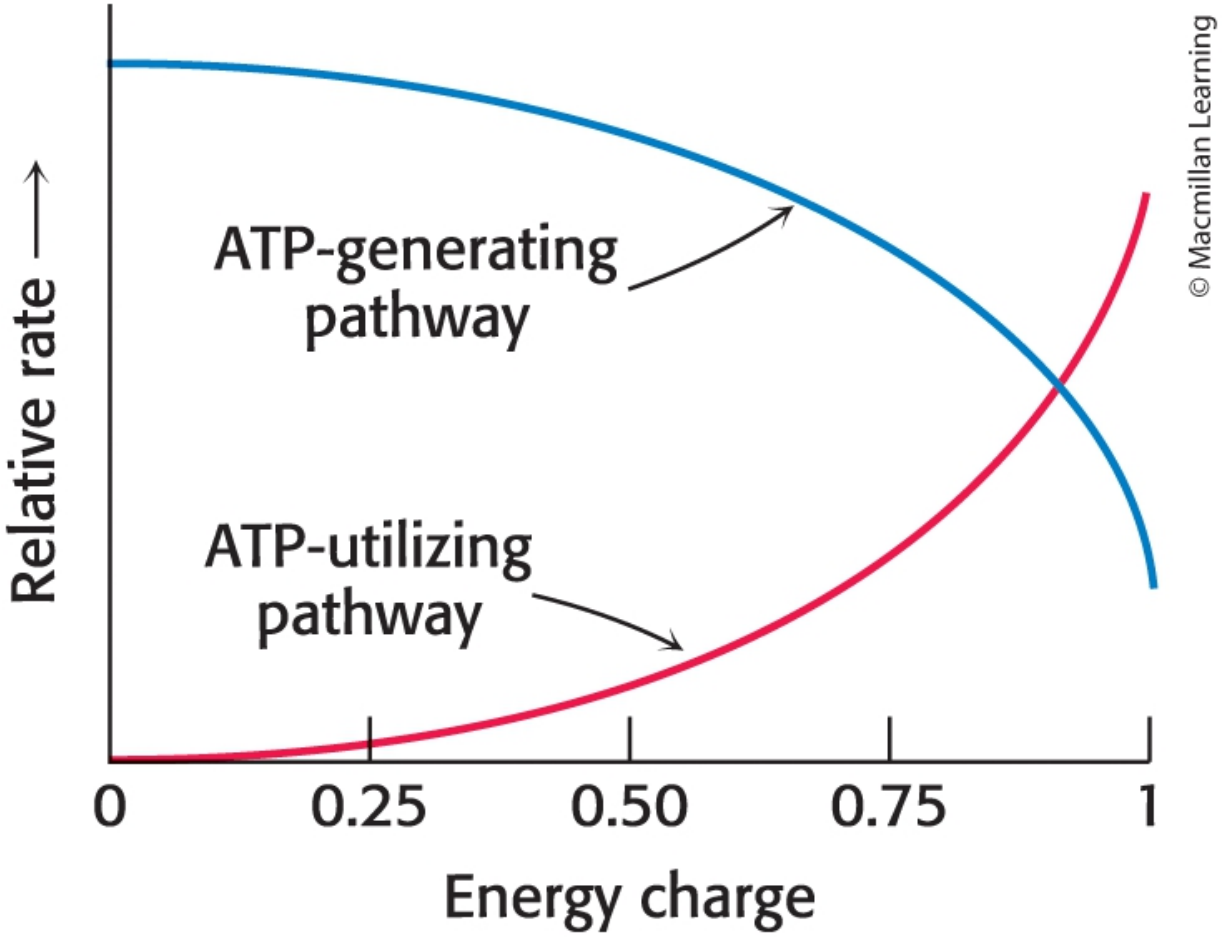
Extended description for Equilibrium reaction depicts the formation of oxaloacetate from pyruvate

The reaction reads pyruvate plus C O 2 plus A T P plus H 2 O equilibrium reaction arrow oxaloacetate plus A D P plus P i plus H superscript plus.

The structure of Pyruvate is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is bound to H 3. C 2 is double bonded to O above. C 3 is partially double bonded to O on the upper right and O below and has a counter negative sign.

The second reactant C O 2 is highlighted in red.

The third reactant A T P is highlighted in blue.



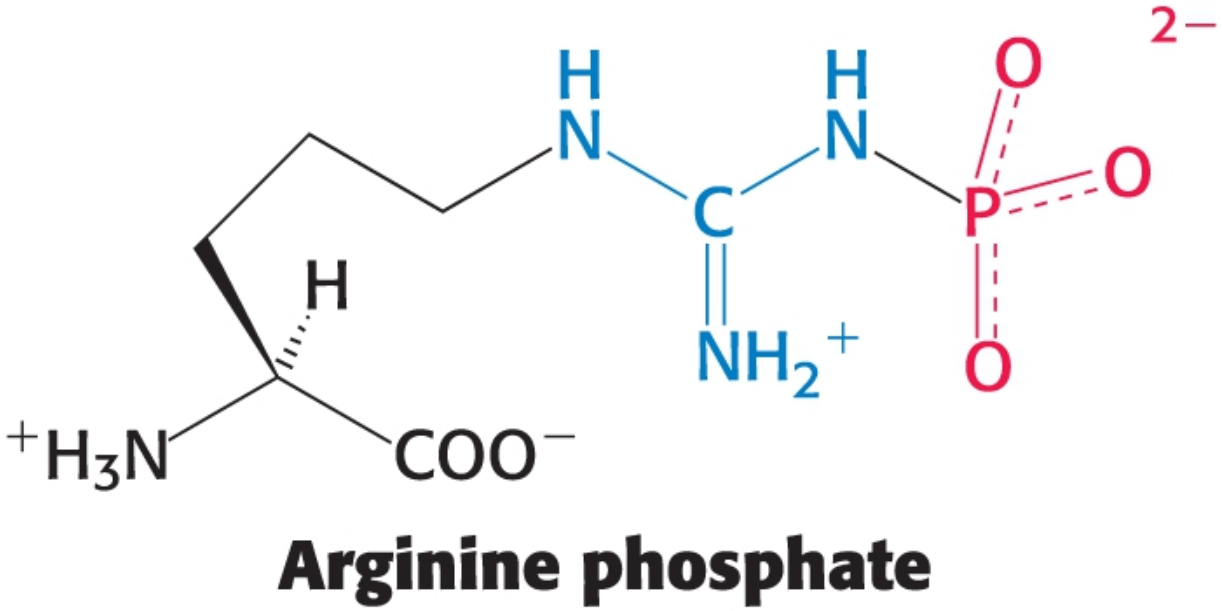
The structure of Oxaloacetate is as follows: A 4-carbon alkane chain is depicted as a line structure using 3 zigzag lines. C 1 is partially double bonded to O above and O on the lower left and has a counter negative sign. C 2 is bound to H 2. C 3 is double bonded to O above. C 4 is partially double bonded to O on the upper right and O below and

has a counter negative sign. C 1 and the O atoms attached to it are highlighted in red.

The second and third products A D P and P i are highlighted in blue.

Return to Equilibrium reaction depicts the formation of oxaloacetate from pyruvate

Extended description for Graphical representation of energy charge versus relative rate of A T P synthesis



The horizontal axis of the graph labeled "energy charge" has markings ranging from 0 to 1 in increments of 0.25. The vertical axis is labeled "relative rate." The graph shows an increasing curve labeled A T P utilizing pathway that starts from the origin, takes a curve between 0.50 and 0.75 on the horizontal axis, and terminates well above the middle of the graph at marking 1 on the horizontal axis. The graph shows a decreasing curve labeled A T P generating pathway that starts well above the middle of the graph, slopes down

between 0.50 and 0.75, intersects with the first curve, and terminates well above the horizontal axis at marking 1.

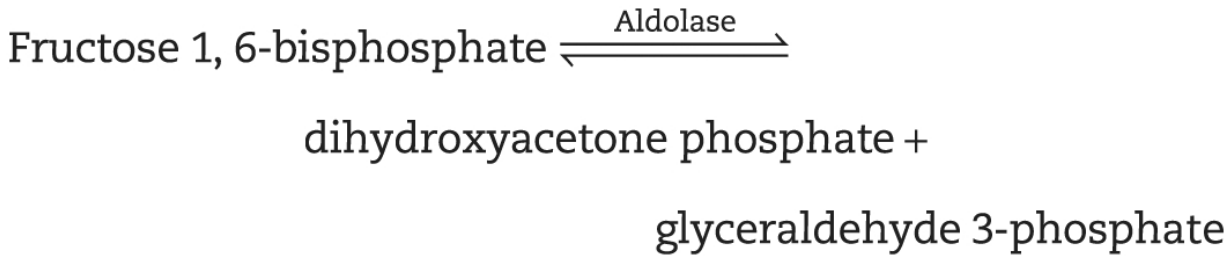
Extended description for Structure of Arginine phosphate



Arginine phosphate

The structure of Arginine phosphate is as follows: A 2 N and 4 C heteronuclear alkane chain is depicted as a line structure using 5 zigzag lines. N 1 occupies the fourth position and N 2 occupies the sixth position. N 1 and N 2 are each bound to H above. C 1 is wedge bonded on the lower right to a central C atom in the form of a line. The central C atom is dash bonded to H on the upper right, single bonded to N H 3 superscript plus on the lower left and C O O superscript minus on the lower right. C 4 is double bonded to N H 2 superscript plus below. N 2 is single bonded to P on the lower right. This P is partially double bonded to O above, O below, and O on the upper right and has a counter 2 negative sign. The structures from N 1 to N 2 are highlighted in blue. P and O atoms attached to it are highlighted in red.

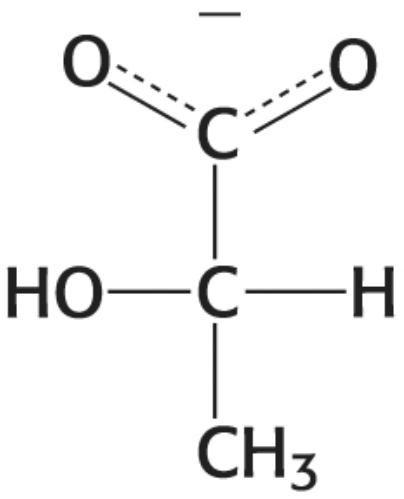
Return to Structure of Arginine phosphate

Extended description for Reaction catalyzed by aldolase

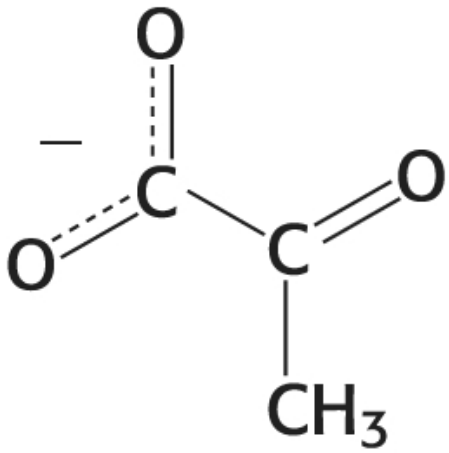
The reaction consists of one reactant and two products. The reactant is fructose-1, 6-bisphosphate. The products are dihydroxyacetone phosphate and glyceraldehyde 3-phosphate.

Return to Reaction catalyzed by aldolase

Extended description for Structures of Ethanol and Acetaldehyde



On the left, the structure of Ethanol is as follows: A central C atom is single bonded to O H on the upper right, H on the upper left, H on the lower left, and C H 3 below.

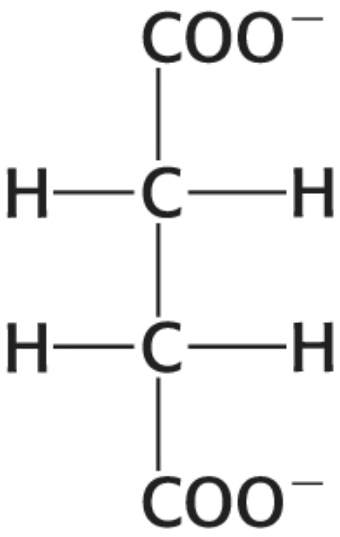


On the left, the structure of Acetaldehyde is as follows: A central C atom is single bonded to H on the upper left, double bonded to O on the upper right, and single bonded to C H 3 below.

Return to Structures of Ethanol and Acetaldehyde

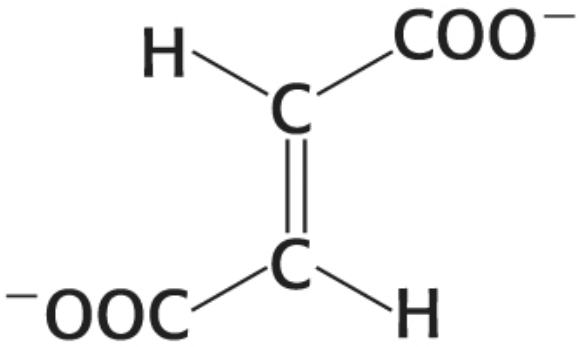
Extended description for Structures of Lactate and Pyruvate

Lactate



Pyruvate

The structure of Lactate is as follows: The Fischer projection of Lactate consists of a vertical chain with C above and C H 3 below. The projection contains 1 C atom at the center. C 1 is partially double bonded to O on the upper left and O on the upper right and has a counter negative sign. C 2 is single bonded to O H on the left and H on the right.

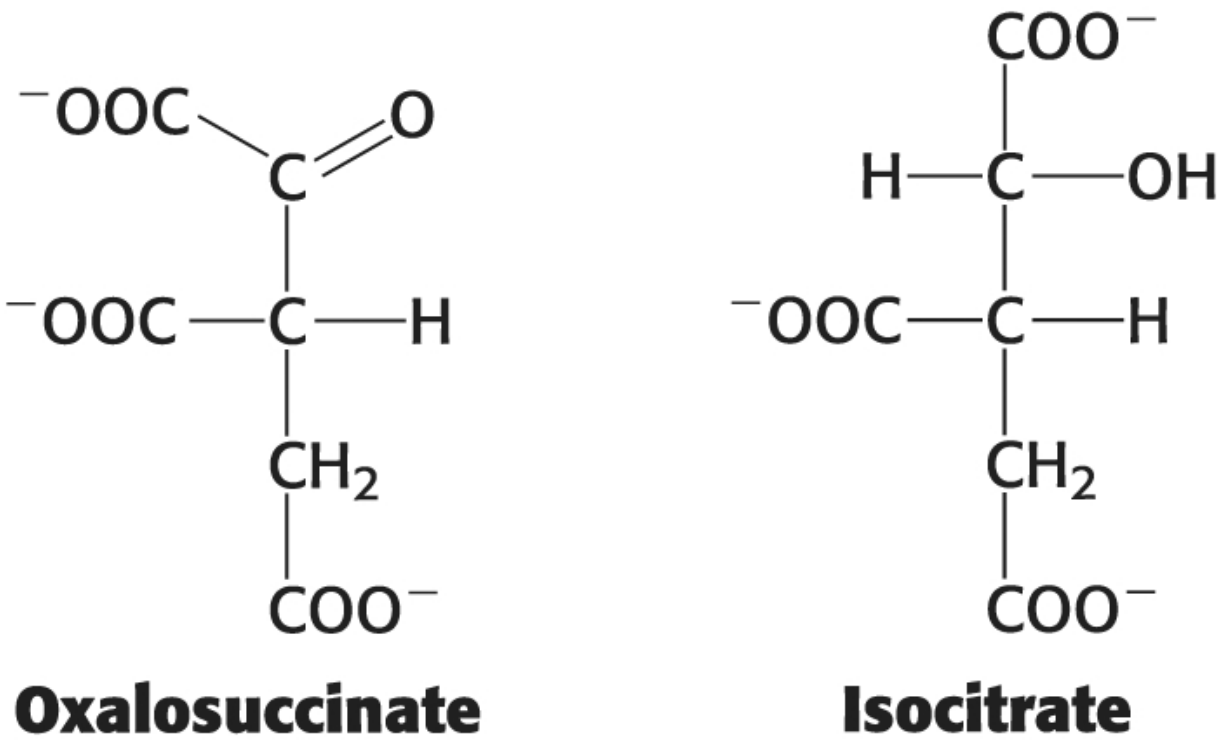


The structure of Pyruvate is as follows: A 2-carbon alkane chain is depicted as a line structure using a line. C 1 is partially double bonded to O above and O on the lower left and has a counter negative sign. C 2 is single bonded to C H 3 below and double bonded to O on the upper right.

Return to Structures of Lactate and Pyruvate

Extended description for Structure of Succinate and Fumarate

Succinate



Fumarate

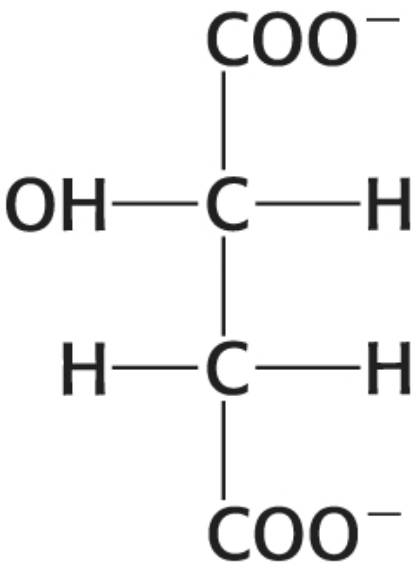
The structure of Succinate is as follows: The Fischer projection of Succinate consists of a vertical chain with C O O superscript minus above and C O O superscript minus below. The projection contains two C atoms placed one below the other on the vertical chain. The C atoms are numbered from top to bottom. C 1 and C 2 are each single bonded to H on the left and right.

The structure of Fumarate is as follows: Two C atoms are vertically double bonded. The C atoms are numbered from top to bottom. C 1 is single bonded to H on the upper left and C O O superscript minus on the upper right. C 2 is single bonded to C O O superscript minus on the lower left and H on the lower right.

Return to Structure of Succinate and Fumarate

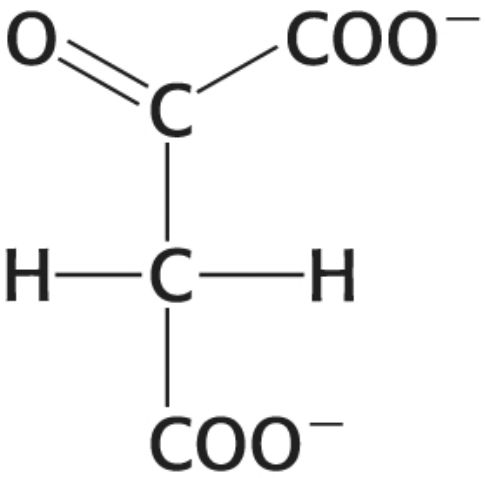
Extended description for Structure of Oxalosuccinate and Isocitrate

Oxalosuccinate **Isocitrate**



The structure of Oxalosuccinate is as follows: The Fischer projection of Oxalosuccinate consists of a vertical chain with C above and C O O superscript minus below. The projection contains two C atoms placed one below the other on the vertical chain. The C atoms are numbered from top to bottom. C 1 is single bonded to C O O superscript minus on the upper left and double bonded to O on the upper right. C 2 is single bonded to C O O superscript minus on the left and H on the right. C 3 is bound to H 2.

The structure of Isocitrate is as follows: The Fischer projection of Isocitrate consists of a vertical chain with C O O superscript minus above and C O O superscript minus below. The projection contains three C atoms placed one below the other on the vertical chain. The



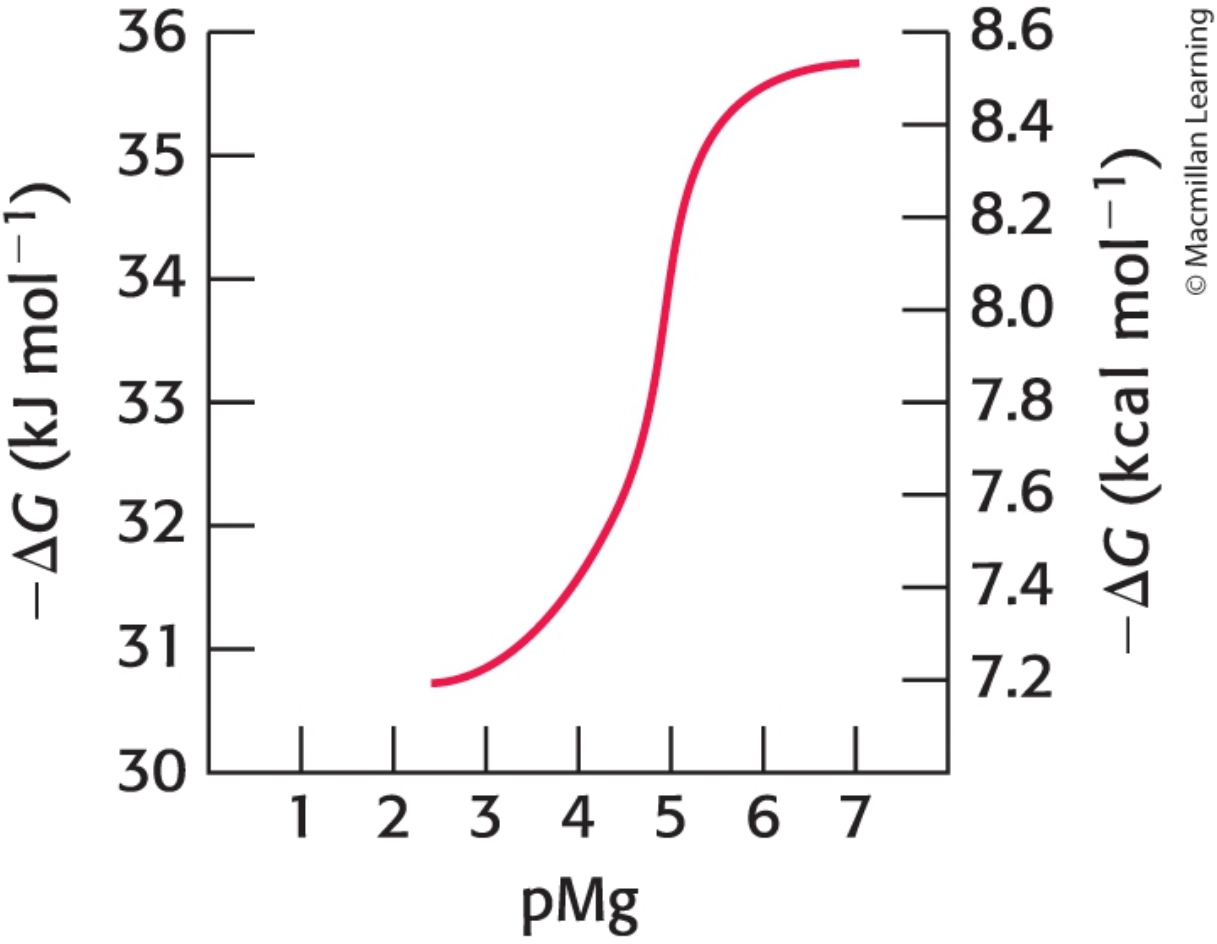
C atoms are numbered from top to bottom. C 1 is single bonded to H on the left and O H on the right. C 2 is single bonded to C O O superscript minus on the left and H on the right. C 3 is bound to H 2.

Return to Structure of Oxalosuccinate and Isocitrate

Extended description for Structure of Malate and Oxaloacetate

Malate

Oxaloacetate



The structure of Malate is as follows: The Fischer projection of Malate consists of a vertical chain with C O O superscript minus above and C O O superscript minus below. The projection contains two C atoms placed one below the other on the vertical chain. The C atoms are numbered from top to bottom. C 1 is single bonded to O H on the left and H on the right. C 2 is single bonded to H on the left and H on the right.

The structure of Oxaloacetate is as follows: The Fischer projection of Oxaloacetate consists of a vertical chain with C above and C O O superscript minus below. The projection contains a C atom at the center. The C atoms are numbered from top to bottom. C 1 is double bonded to O on the upper left and single bonded to C O O

superscript minus on the upper right. C 2 is single bonded to H on the left and H on the right.

Return to Structure of Malate and Oxaloacetate

Extended description for Graphical representation of delta G for the hydrolysis of A T P varies as a function of the M g superscript 2 plus concentration

The horizontal axis of the graph labeled “p M g” has markings ranging from 1 to 7 in increments of 1 unit. The vertical axis on the left labeled “negative delta G in Kilojoule per mol” has markings ranging from 30 to 36 in increments of 1 unit. The vertical axis on the right labeled “negative delta G in Kilocalorie per mol” has markings ranging from 7.2 to 8.6 in increments of 0.2 units. The graph shows an S-shaped curve that starts roughly between 2 and 3 on the horizontal axis and between 30 and 31 on the left vertical

axis. The graph rises upwards and shows a curve at 5 on the horizontal axis and 33 on the left vertical axis. The graph terminates at 7 on the horizontal axis and at 36 on the left vertical axis. All values are approximated.

Extended description for Schematic illustration of sources of A T P for muscle contraction

In the schematic illustration, glucose is converted into pyruvate via glycolysis in the cytoplasm. The A T P generated during glycolysis moves toward the muscle fiber. The muscle fiber consists of a series of thick horizontal lines in the middle interdigitated with thin horizontal and parallel lines on either side. There are two fates of pyruvate that is A and B. In fate A, pyruvate is converted into lactate in the cytoplasm. In fate B, pyruvate moves inside the mitochondrion and is converted into C O 2 plus H 2 O and A T P. This A T P moves from the mitochondrion toward the muscle fiber.

Return to Schematic illustration of sources of A T P for muscle contraction

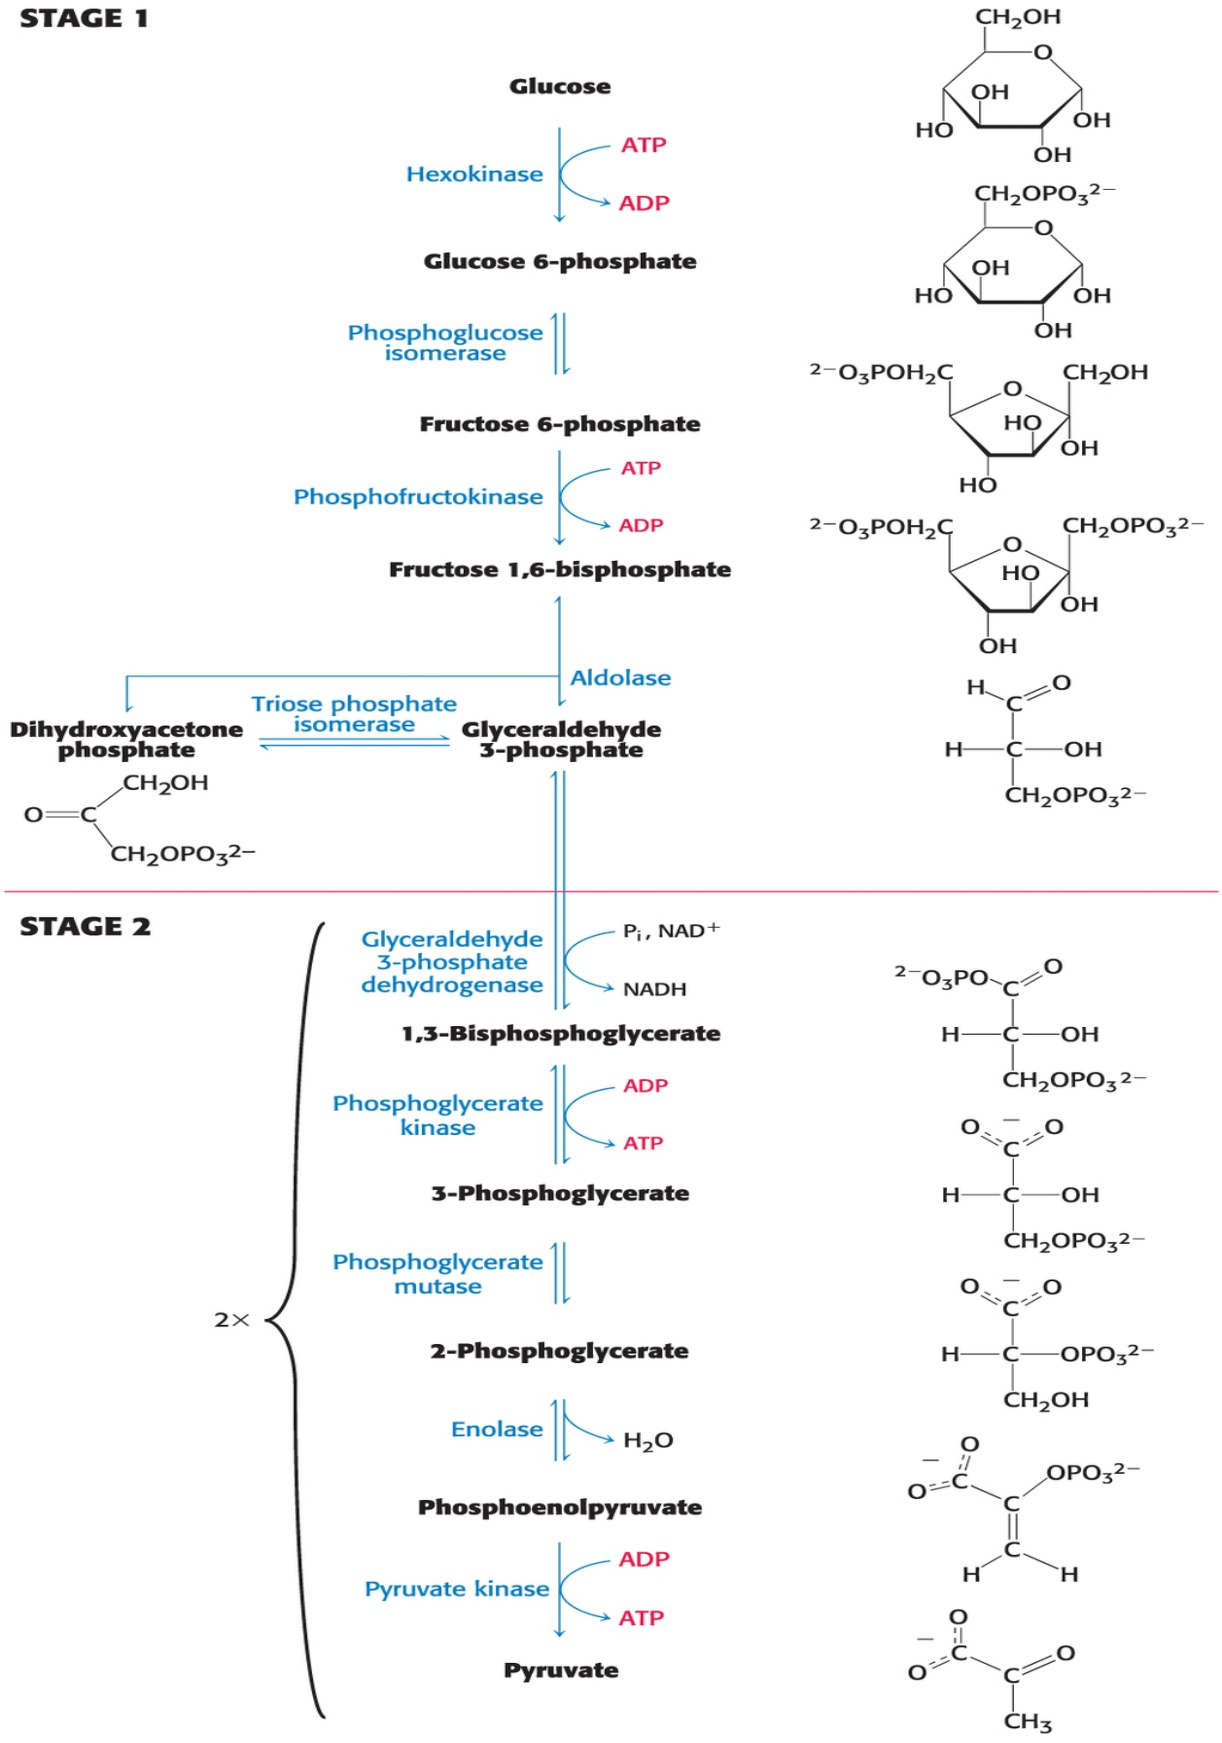
Extended description for Schematic representation of glucose metabolism

Glucose C 6 H 12 O 6 is converted into pyruvate via glycolysis. The structure of pyruvate is as follows: A central C atom is double bonded to O on the upper right, single bonded to C H 3 below, and single bonded to C on the upper left. This C atom is partially double bonded to O above and O on the lower left. This C O O group has an overall negative charge.

Pyruvate has three fates as follows:

It can be converted into ethanol via fermentation. The structure of ethanol is C H 3, single bond, C H 2 O H.

It can be converted into C O 2 plus H 2 O via complete oxidation in presence of O 2.



It can be converted into lactate. The structure of lactate is as follows: C, single bond, C, single bond, C H 3. C 1 is partially double bonded to O on the upper left and O on the upper right. This C O O group has

an overall negative charge. C 2 is single bonded to O H on the left and H on the right.

ATP
Pyruvate

The glycolytic pathway is divided into stage 1 and stage 2.

Stage 1 is depicted as follows:

Glucose is irreversibly converted into glucose 6-phosphate by hexokinase. This conversion requires the breakdown of A T P to A D P.

The structure of glucose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1 occupies the rightmost vertex and is single bonded to O H below. C 2 is single bonded to O H below. C 3 is single bonded to O H above. C 4 is single bonded to O H below. C 5 is single bonded to C H 2 O H above.

The structure of glucose 6-phosphate is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1 occupies the rightmost vertex and is single bonded to O H below. C 2 is single bonded to O H below. C 3 is single bonded to O H above. C 4 is single bonded to O H below. C 5 is single bonded to C H 2 O P O 3 superscript 2 minus above.

Glucose 6-phosphate is reversibly converted into fructose 6-phosphate by phosphoglucose isomerase.

The structure of fructose 6-phosphate is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 occupies the rightmost vertex and is single bonded to C H 2 O H above and O H below. C 2 is single bonded to O H above. C 3 is single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 superscript 2 minus above.

Fructose 6-phosphate is irreversibly converted into fructose 1, 6-bisphosphate by phosphofructokinase. This conversion requires the breakdown of A T P to A D P.

The structure of fructose 1, 6-bisphosphate is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 occupies the rightmost vertex and is single bonded to C H 2 O P O 3 superscript 2 minus above and O H below. C 2 is single bonded to O H above. C 3 is single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 superscript 2 minus above.

Fructose 1, 6-bisphosphate is irreversibly converted into glyceraldehyde 3-phosphate or dihydroxyacetone phosphate by aldolase.

The structure of glyceraldehyde 3-phosphate is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is single bonded to H on the upper left and double bonded to O on the upper right. C 2 is single bonded to H on the left and O H on the right.

The structure of dihydroxyacetone phosphate is as follows: A central C atom is single bonded to C H 2 O H on the upper right, double bonded to O on the left, and single bonded to C H 2 O P O 3 superscript 2 minus on the lower right.

Glyceraldehyde 3-phosphate is reversibly converted into dihydroxyacetone phosphate by triose phosphate isomerase.

Stage 2 is depicted as follows:

Glyceraldehyde 3-phosphate is reversibly converted into 1,3-bisphosphoglycerate by glyceraldehyde 3-phosphate dehydrogenase.

This conversion requires the reduction of N A D superscript plus to N A D H and entry of P subscript i.

The structure of 1,3-bisphosphoglycerate is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is single bonded to O P O 3 superscript 2 minus on the upper left and double bonded to O on the upper right. C 2 is single bonded to H on the left and O H on the right.

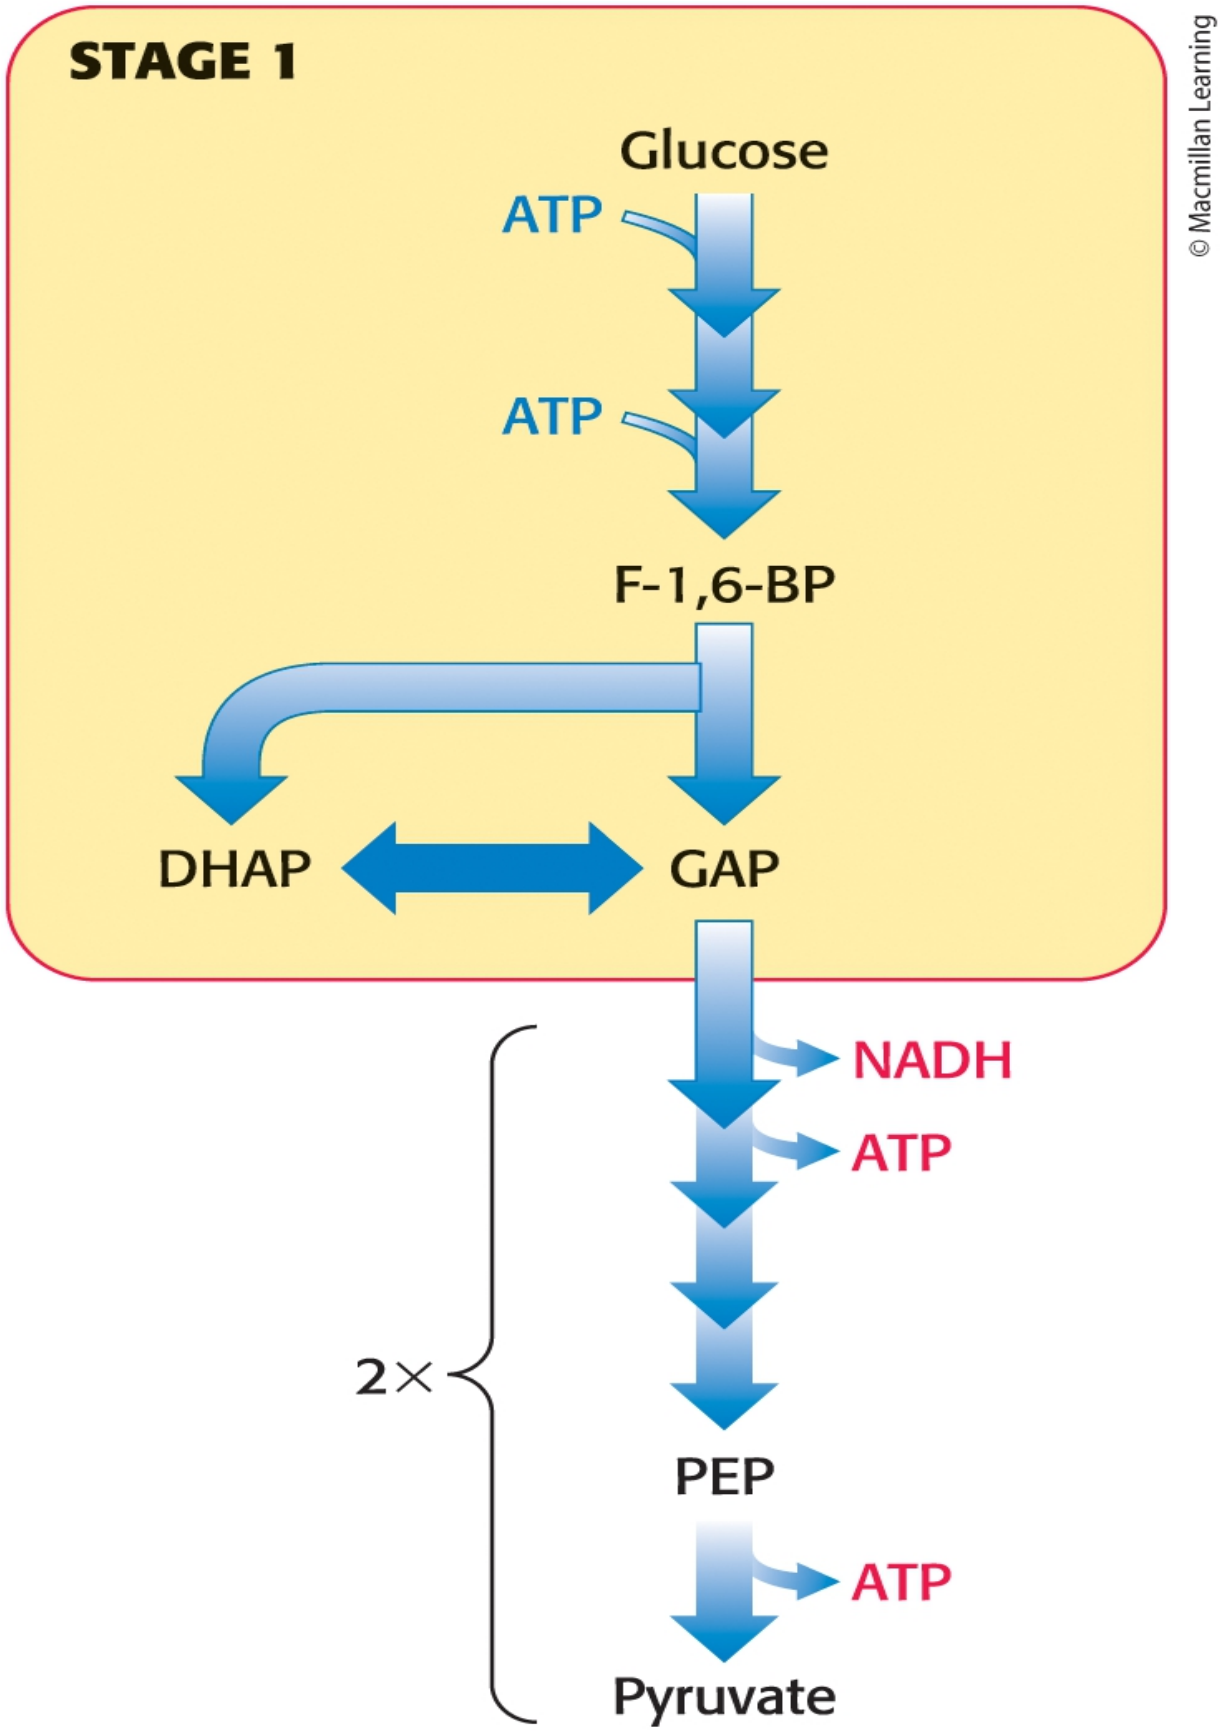
1,3-bisphosphoglycerate is reversibly converted into 3-phosphoglycerate by phosphoglycerate kinase. This conversion involves the formation of A T P from A D P.

The structure of 3-phosphoglycerate is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is partially double bonded to O on the upper left and O on the upper right. This C O O group has an overall negative charge. C 2 is single bonded to H on the left and O H on the right.

3-phosphoglycerate is reversibly converted into 2-phosphoglycerate by phosphoglycerate mutase.

The structure of 2-phosphoglycerate is as follows: C, single bond, C, single bond, C H 2 O H. C 1 is partially double bonded to O on the upper left and O on the upper right. This C O O group has an overall negative charge. C 2 is single bonded to H on the left and O P O 3 superscript 2 minus on the right.

2-phosphoglycerate is reversibly converted into phosphoenolpyruvate by enolase. An H 2 O molecule is released during this conversion.



The structure of phosphoenolpyruvate is as follows: A central C atom is double bonded to C below, single bonded to O P O 3 superscript 2 minus on the upper right, and single bonded to C on the upper left. The C atom below is single-bonded to H on the lower left and H on the lower right. The C atom on the upper left is partially double bonded to O above and O on the lower left. This C O O group has an overall negative charge.

Phosphoenolpyruvate is irreversibly converted into pyruvate by pyruvate kinase. A D P is converted into A T P simultaneously.

The structure of pyruvate is as follows: A central C atom is double bonded to O on the upper right, single bonded to C H 3 below, and single bonded to C on the upper left. This C atom is partially double bonded to O above and O on the lower left. This C O O group has an overall negative charge.

Return to Two stages of glycolytic pathway

Extended description for Stage 1 of glycolytic pathway

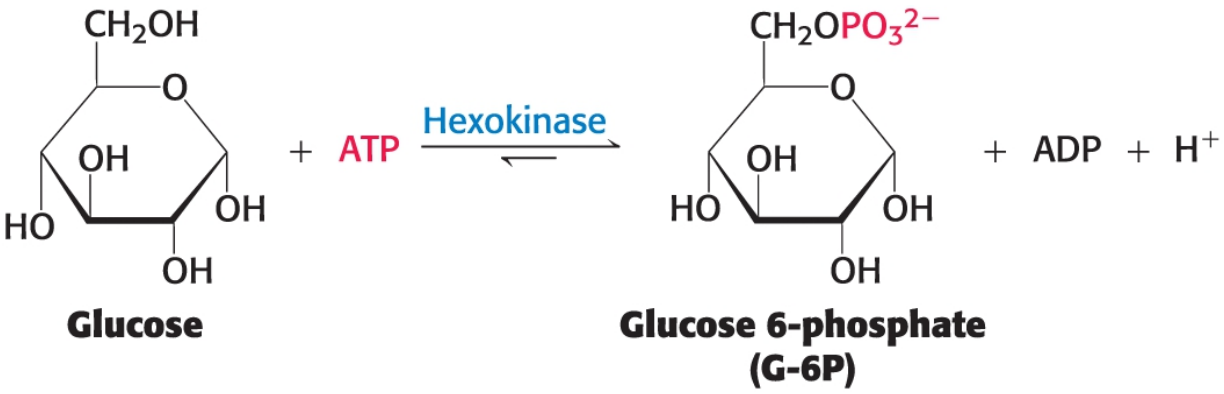
© Macmillan Learning

The flowchart is depicted as follows:

Glucose, three downward arrows, F-1, 6-B P. The first and third downward arrows show the entry of A T P.

F-1, 6-B P, one downward arrow and one curved leftward arrow.

The downward arrow leads to G A P. The curved leftward arrow leads to D H A P. A double-headed arrow is shown between G A P and D H A P.



G A P, four downward arrows, P E P. The first and second downward arrow show the release of N A D H and A T P respectively.

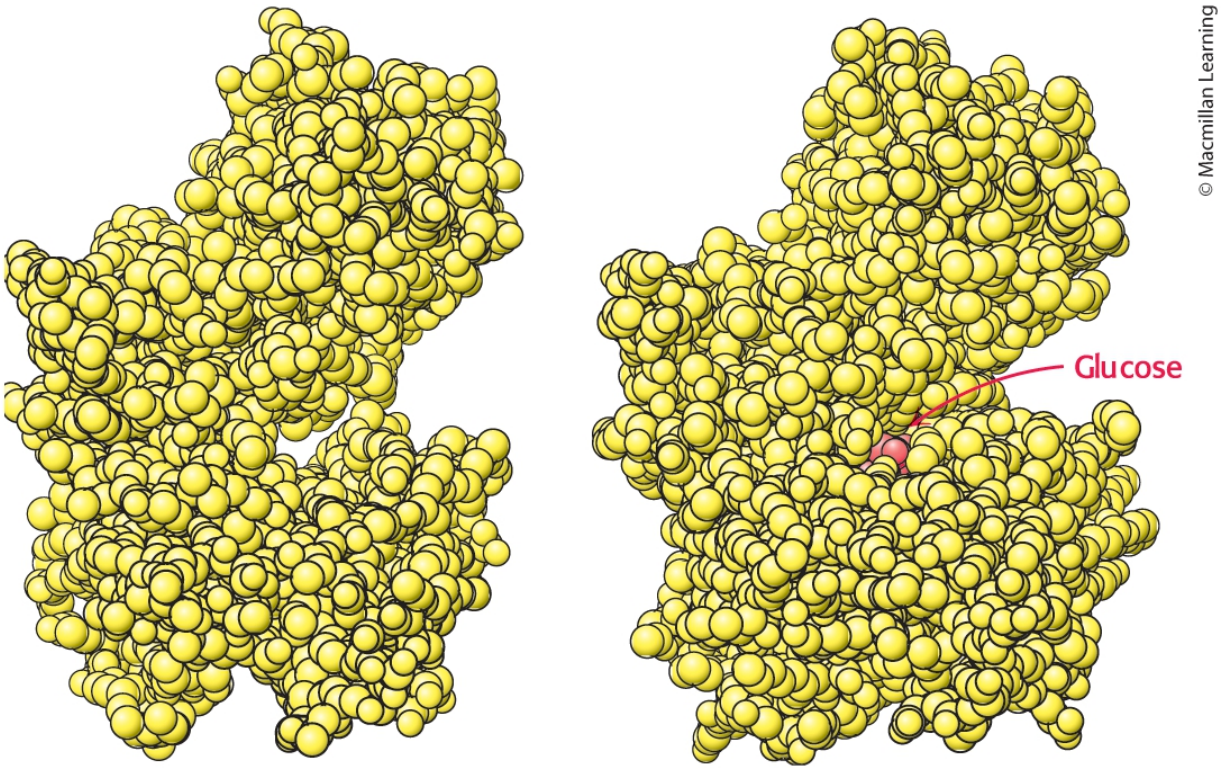
P E P, one downward arrow, pyruvate. The downward arrow shows the release of A T P. The steps from the first downward arrow below G A P to the final pyruvate molecule are enclosed by left curly bracket labeled 2 times.

Note: The steps involving the conversion of glucose to D H A P and G A P are enclosed in a yellow rectangle labeled stage 1.

Return to Stage 1 of glycolytic pathway

Extended description for Reversible conversion of glucose to glucose 6-phosphate

The chemical reaction consists of two reactants and three products. The first reactant is glucose whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. The ring is in a plane perpendicular to the plane of paper such that O and C 5 are located away from the observer and C 2 and C 3 are located toward the observer. C 1, C 2, and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H. The second reactant is A T P.



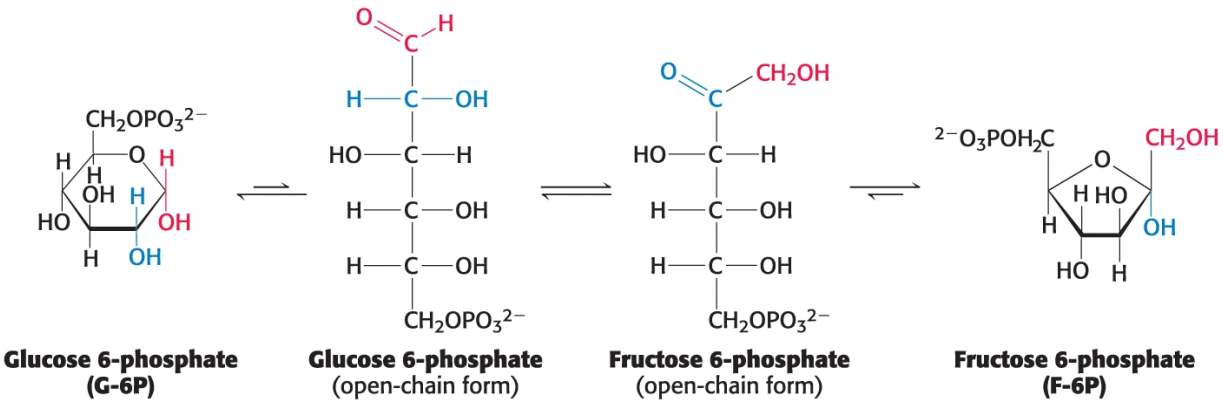
A reversible reaction arrow labeled hexokinase leads to the products.

The first product is glucose 6-phosphate (G-6 P) whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. The ring is in a plane perpendicular to the plane of paper such that O and C 5 are located away from the observer and C 2 and C 3 are located toward the observer. C 1, C 2, and C 4 are each single bonded to O H below. C 3 is single bonded to O H above.

C 5 is single bonded to C H 2 O P O 3 superscript 2 minus above. The second product is A D P. The third product is H superscript plus.

Return to Reversible conversion of glucose to glucose 6-phosphate

Extended description for Conformational change in hexokinase upon glucose binding



© Macmillan Learning

The hexokinase enzyme is depicted as a space-filling model composed of a large cluster of yellow spheres. The free hexokinase has two lobes with a tiny groove in the center. The groove is later occupied by a glucose molecule depicted as a cluster of red spheres. In the glucose-bound hexokinase, the two lobes are located close together.

Return to Conformational change in hexokinase upon glucose binding

Extended description for Conversion of glucose 6-phosphate to fructose 6-phosphate

The conversion of glucose 6-phosphate to fructose 6-phosphate takes place in 3 reversible steps.

The first step involves the reversible conversion of the cyclic form of glucose 6-phosphate (G-6 P) to its open-chain form.

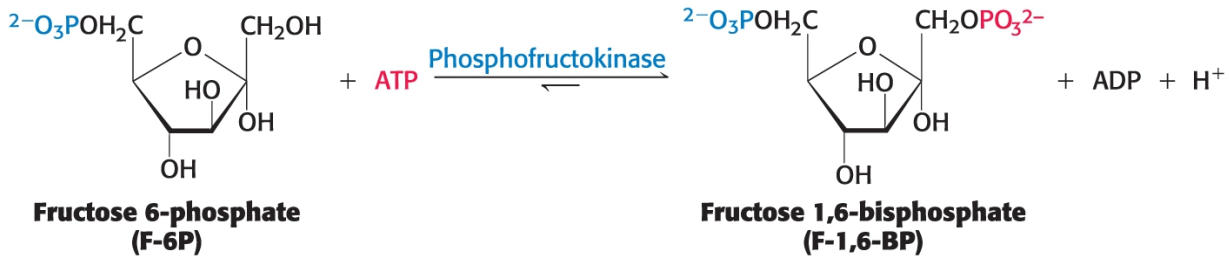
The structure of the cyclic form of glucose 6-phosphate is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. The ring is in a plane perpendicular to the plane of paper such that O and C 5 are located away from the observer and C 2 and C 3 are located toward the observer. C 1, C 2, and C 4 are each single bonded to H above and O H below. The H atom and O H group bonded to C 1 are highlighted in red. The H atom and O H group bonded to C 2 are highlighted in blue. C 3 is single bonded to O H above and H below. C 5 is single bonded to C H 2 O P O 3 superscript 2 minus above and H below.

The structure of glucose 6-phosphate (open-chain form) is as follows: C, single bond, C, single bond, C, single bond, C, single

bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 highlighted in red is double bonded to O on the upper left and single bonded to H on the upper right, both highlighted in red. C 2 highlighted in blue is single bonded to H on the left and O H on the right, both highlighted in blue. C 3 is single bonded to O H on the left and H on the right. C 4 and C 5 are each single bonded to H on the left and O H on the right.

In the second step, the open-chain form of glucose 6-phosphate is reversibly converted into the open-chain form of fructose 6-phosphate.

The structure of fructose 6-phosphate (open-chain form) is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 highlighted in blue is double bonded to O on the upper left and C H 2 O H on the upper right. The O atom is highlighted in blue and the C H 2 O H group is highlighted in red. C 2 is single bonded to O H on the left and H on the right. C 3 and C 4 are each single bonded to H on the left and O H on the right.



In the third step, the open-chain form of fructose 6-phosphate is reversibly converted into the cyclic form of fructose 6-phosphate (F-6 P).

The structure of the cyclic form of fructose 6-phosphate (F-6 P) is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The ring is in a plane perpendicular to the plane of the paper such that O is located away from the observer and C 2 and C 3 are located toward the observer. C 1 is single bonded to C H 2 O H above and O H below. C H 2 O H is highlighted in red. O H is highlighted in blue. C 2 is single bonded to O H above and H below. C 3 is single bonded to H above and O H

below. C 4 is single bonded to C H 2 O P O 3 superscript 2 minus above and H below.

Return to Conversion of glucose 6-phosphate to fructose 6-phosphate

Extended description for Reversible conversion of fructose 6-phosphate to fructose 1, 6-bisphosphate

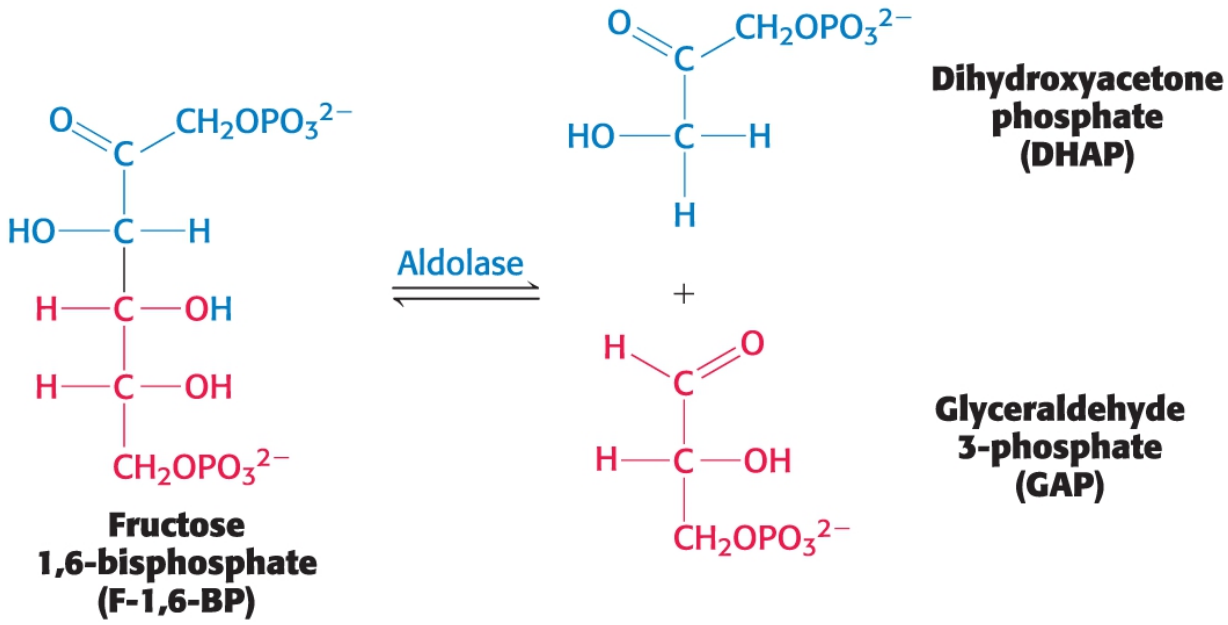
Fructose 6-phosphate (F-6P)

Fructose 1,6-bisphosphate (F-1,6-BP)

The chemical reaction consists of two reactants and three products. The first reactant is fructose 6-phosphate (F-6 P) whose structure is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The ring is in a plane perpendicular to the plane of the paper such that O is located away from the observer and C 2 and C 3 are located toward the observer. C 1 is single bonded to C H 2 O H above and O H below. C 2 is single bonded to O H above. C 3 is single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 superscript 2 minus above. P O 3 superscript 2 minus group is highlighted in blue.

The second reactant is A T P highlighted in red.

A reversible reaction arrow labeled phosphofructokinase shows the products.



The first product is fructose 1, 6-bisphosphate (F-1, 6-B P) whose structure is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The ring is in a plane perpendicular to the plane of the paper such that O is located away from the observer and C 2 and C 3 are located toward the observer. C 1 is single bonded to C H 2 O P O 3 superscript 2

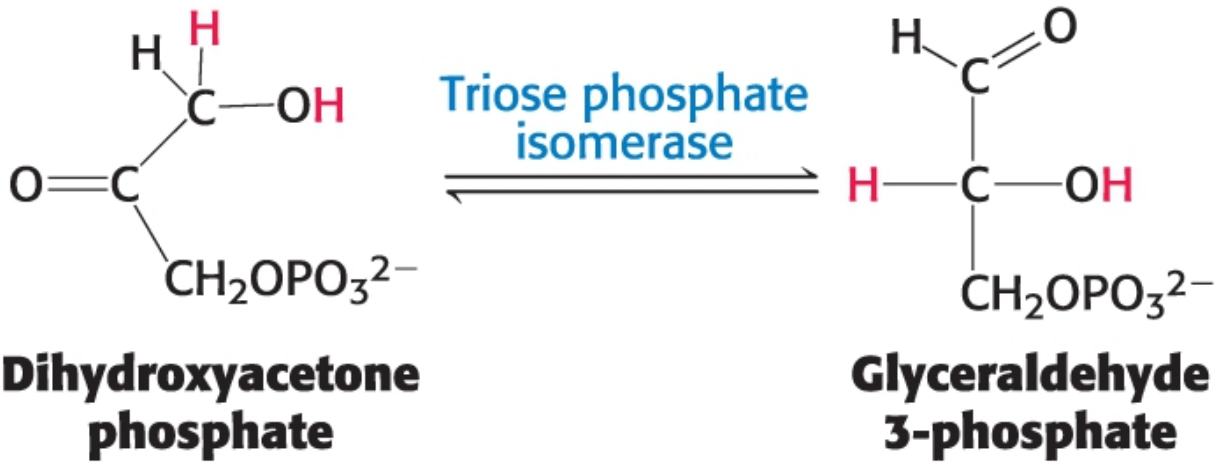
minus above and O H below. The P O 3 superscript 2 minus is highlighted in red. C 2 is single bonded to O H above. C 3 is single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 superscript 2 minus above. P O 3 superscript 2 minus group is highlighted in blue.

The second product is A D P. The third reactant is H superscript plus.

Return to Reversible conversion of fructose 6-phosphate to fructose 1, 6-bisphosphate

Extended description for Reversible conversion of fructose 1, 6-bisphosphate to dihydroxyacetone phosphate and glyceraldehyde 3-phosphate

The structure of fructose 1, 6-bisphosphate (F-1,6 B P) is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 highlighted in blue is double bonded to O on the upper left and single bonded to C H 2 O P O 3 superscript 2 minus on the upper right, both highlighted in blue. C 2 highlighted in blue is single bonded to O H on the left and H on the right, both highlighted in blue. C 3 highlighted in red is single bonded to H on the left and O H on the right. The H atom is highlighted in red. The O atom of the O H group is highlighted in red and the H atom is highlighted in blue. C 4 highlighted in red is single bonded to H on the left and O H on the right, both highlighted in red. C H 2 O P O 3 superscript 2 minus group is also highlighted in red.



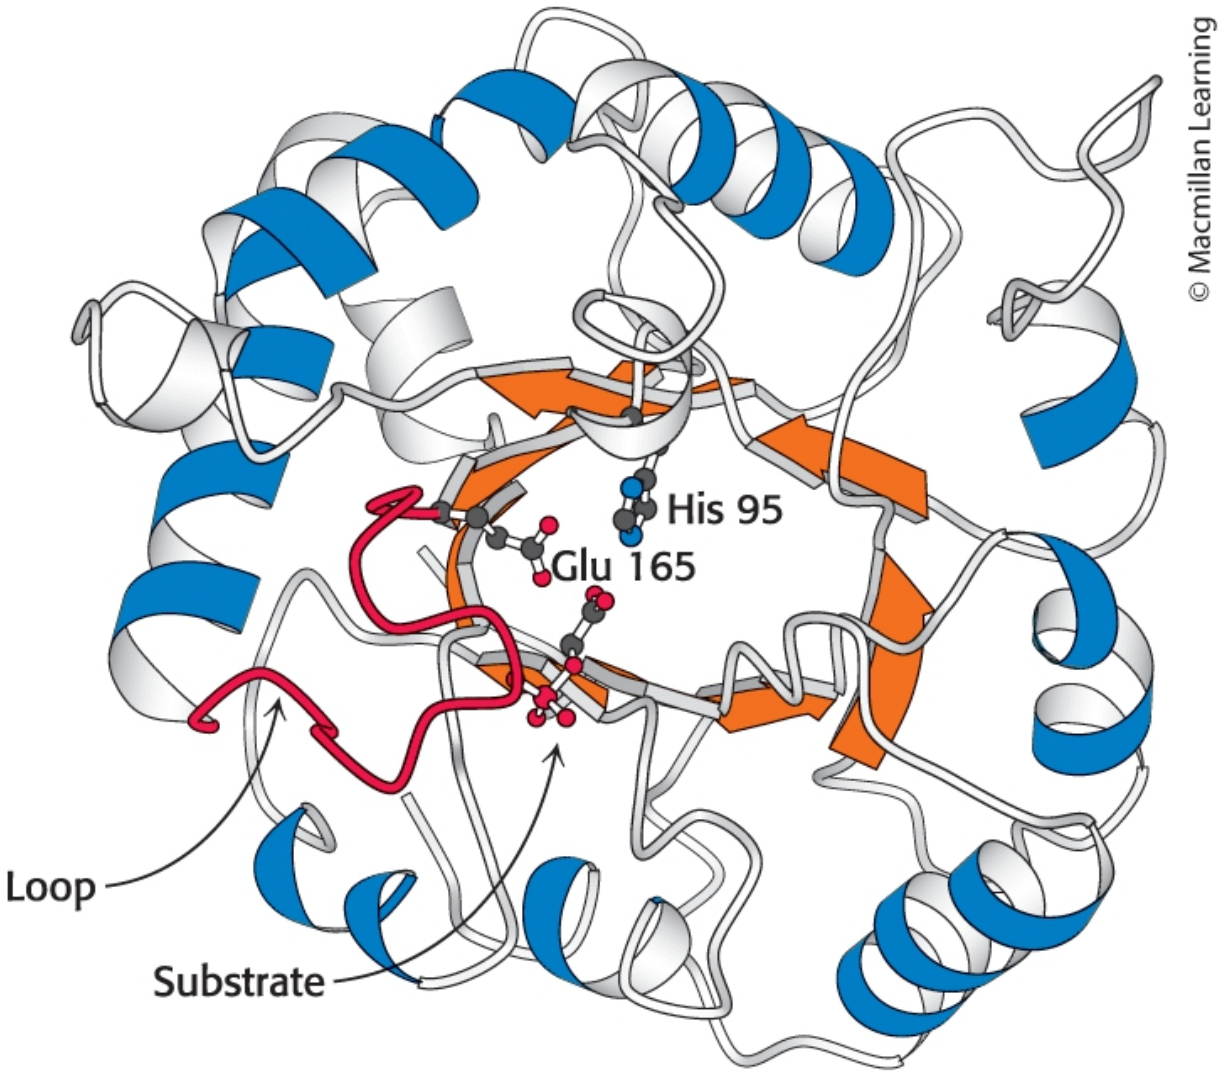
A reversible reaction arrow labeled aldolase leads to dihydroxyacetone phosphate and glyceraldehyde 3-phosphate.

The structure of dihydroxyacetone phosphate (D H A P) is as follows: C, single bond, C, single bond, H. C 1 is double bonded to O on the upper left and single bonded to C H 2 O P O 3 superscript 2 minus on the upper right. C 2 is single bonded to O H on the left and H on the right. The entire molecule is highlighted in blue.

The structure of glyceraldehyde 3-phosphate is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is single bonded to H on the upper left and double bonded to O on the upper right. C 2 is single bonded to H on the left and O H on the right. The entire molecule is highlighted in red.

Return to Reversible conversion of fructose 1, 6-bisphosphate to dihydroxyacetone phosphate and glyceraldehyde 3-phosphate

Extended description for Reversible conversion of dihydroxyacetone phosphate to glyceraldehyde 3-phosphate



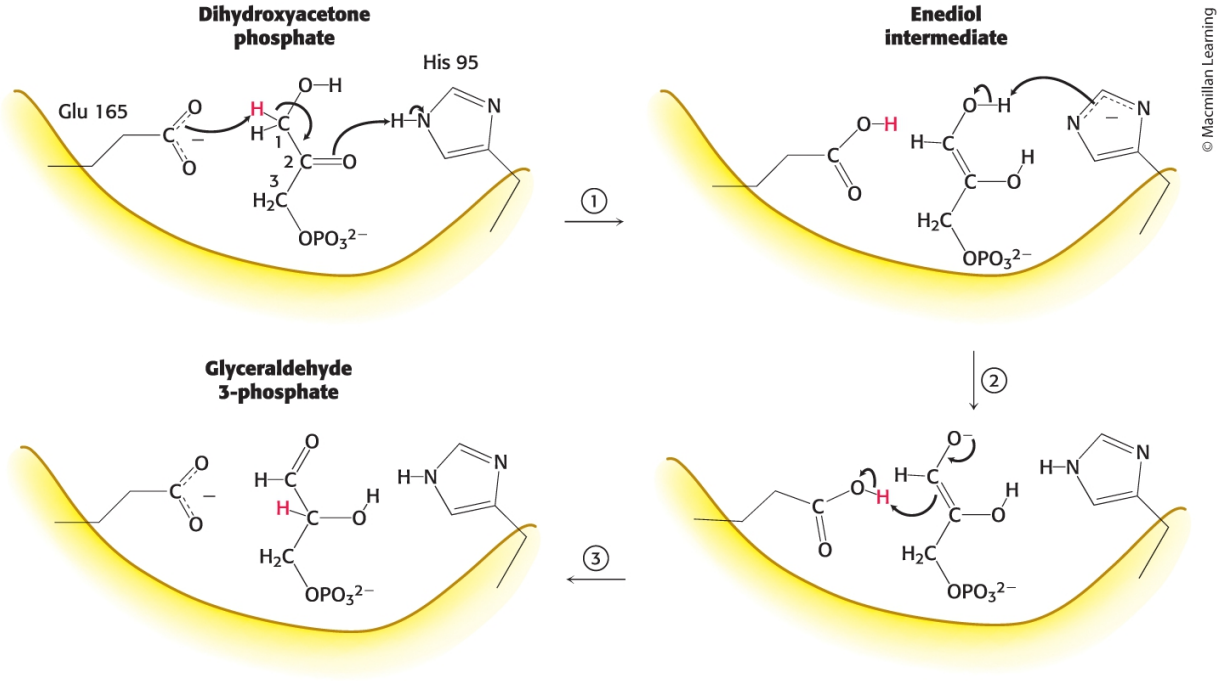
The structure of dihydroxyacetone phosphate is as follows: A central C atom is single bonded to C on the upper right, double bonded to O on the left, and single bonded to C H 2 O P O 3 superscript 2 minus on the lower right. The C atom on the upper right is single bonded to H on the upper left, single bonded to H above highlighted in red, and single bonded to O H on the right. The H atom of the O H group is highlighted in red.

A reversible reaction arrow labeled triose phosphate isomerase leads to glyceraldehyde 3-phosphate.

The structure of glyceraldehyde 3-phosphate is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is single bonded to H on the upper left and double bonded to O on the upper right. C 2 is single bonded to H on the left highlighted in red and single bonded to O H on the right. The H atom of the O H group is highlighted in red.

Return to Reversible conversion of dihydroxyacetone phosphate to glyceraldehyde 3-phosphate

Extended description for Ribbon diagram of triose phosphate isomerase



The ribbon diagram consists of a central core of 8 parallel beta-strands arranged in a circular fashion. These beta-strands are surrounded by a similar circular arrangement of eight alpha-helices. They are interconnected by long thread-like loops that extend into the space between the beta-strands and alpha-helices. The ball-and-stick model of H i s 95 and G l u 165 are located inside the hollow

center enclosed by the beta-strands. A wavy red loop connected to G l u 95 moves toward the lower left.

Return to Ribbon diagram of triose phosphate isomerase

Extended description for Catalytic mechanism of triose phosphate isomerase

The enzyme active site is depicted as a concave depression outlined by an orange line with a yellow highlight. The active site contains the side chains of G l u 165 on the upper left and H i s 95 on the upper right. The side chain of G l u 165 is as follows: A 2-carbon alkane chain is depicted as a line structure using 1 line. C 2 is single bonded to C which is further partially double bonded to O on the upper right and lower right. This C O O group has an overall negative charge. The side chain of H i s 95 is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 2 N and 3 C atoms. First N occupies the top left vertex. Second N occupies the top right vertex. N 1 is single bonded to H on the left. A double bond is present between C 1 and N 2, and C 2 and C 3.

A dihydroxyacetone phosphate molecule is shown between G l u 165 and H i s 95 side chain. The structure of dihydroxyacetone phosphate is as follows: C, single bond, C, single bond, C H 2, single bond, O P O 3 superscript 2 minus. C 1 is single bonded to O, single bond, H on the upper right, H on the upper left, and H on the lower right. C 2 is double bonded to O on the right.

A black curved arrow moves from the C atom of the C O O group of G l u 165 toward the upper left H atom bonded to C 1 of dihydroxyacetone phosphate. Another black downward curved arrow moves the single bond between C 1 and the upper left H atom of dihydroxyacetone phosphate toward the single bond between C 1 and C 2. Another black arrow moves from the double bond between C 2 and O of the dihydroxyacetone phosphate molecule toward the H atom bonded to N 1 of H i s 95 side chain.

A forward arrow labeled 1 shows the enediol intermediate inside the active site of the enzyme.

The side chain of G l u 165 is as follows: A 2-carbon alkane chain is depicted as a line structure using 1 line. C 2 is single bonded to C which is further single bonded to O, single bond, H on the upper right, and double bonded to O lower right. The side chain of H i s 95 is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 2 N and 3 C atoms. First N occupies the top left vertex. Second N occupies the top right vertex. A double bond is present between C 2 and C 3. A partial double bond is present between C 1 and N 1 and C 1 and N 1 thereby imparting a negative charge.

The structure of the intermediate is as follows: C, double bond, C, single bond, C H 2, single bond, O P O 3 superscript 2 minus. C 1 is single bonded to H on the left and single bonded to O, single bond,

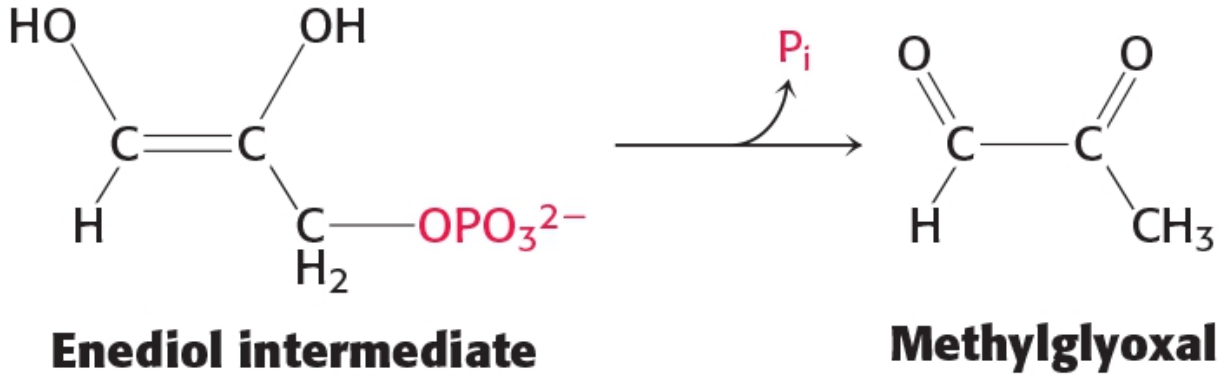
H on the upper right. C 2 is single bonded to O, single bond, H on the right.

A black arrow moves from the partial double bond between C 1 and N 1 of H i s 95 toward the H atom of the O H group bonded to C 1 of the intermediate. Another arrow moves from the single bond between the O and H atom of the O H group toward the O atom.

A forward arrow labeled 2 shows the next intermediate inside the active site.

The side chain of G l u 165 is as follows: A 2-carbon alkane chain is depicted as a line structure using 1 line. C 2 is single bonded to C which is further single bonded to O, single bond, H on the upper right, and double bonded to O below. The side chain of H i s 95 is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 2 N and 3 C atoms. First N occupies the top left vertex. Second N occupies the top right vertex. N 1 is single bonded to H. A double bond is present between C 1 and N 2, and C 2 and C 3.

The structure of the intermediate is as follows: C, double bond, C, single bond, C H 2, single bond, O P O 3 superscript 2 minus. C 1 is single bonded to H on the left and single bonded to O superscript minus on the upper right. C 2 is single bonded to O, single bond, H on the right.



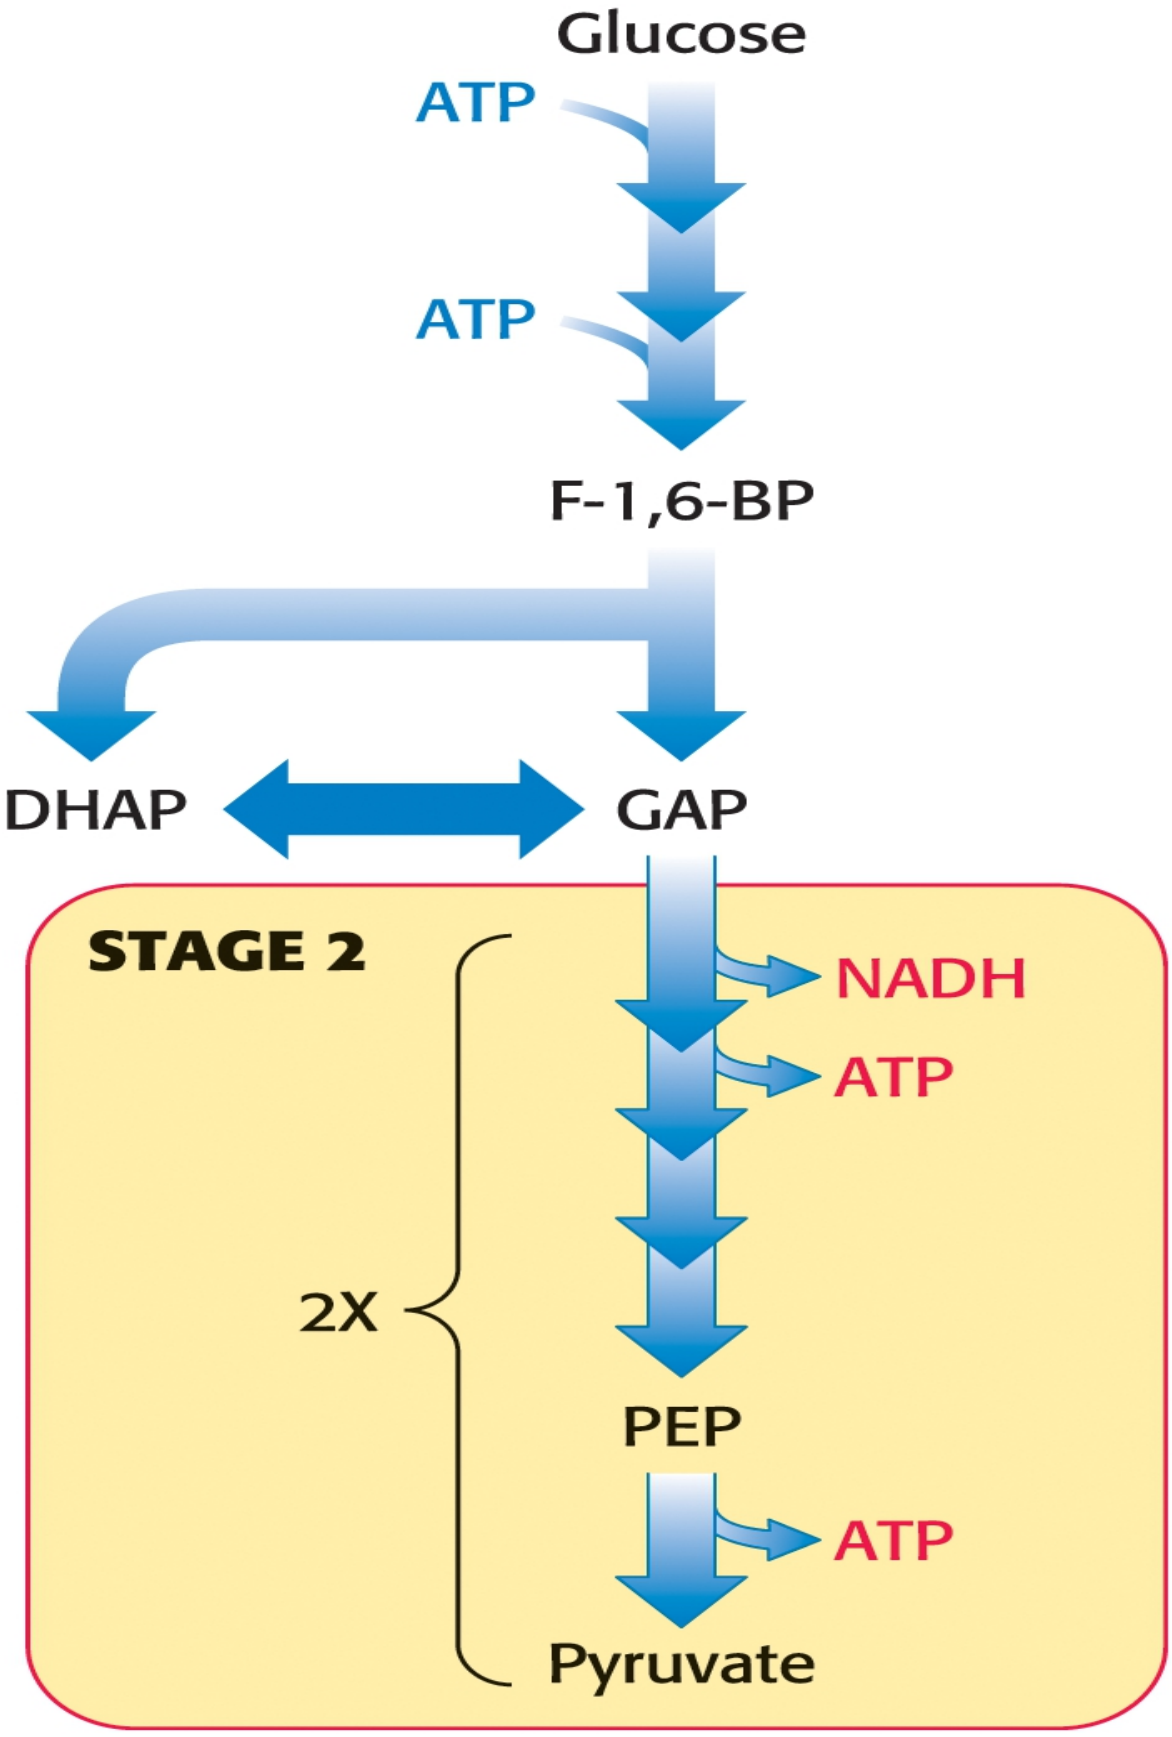
A curved arrow moves from O superscript minus toward its single bond with C 1 of the intermediate. Another arrow moves from the double bond between C 1 and C 2 moves toward the H atom of the O H group of G l u 165. Another arrow moves from the single bond between the O and H atom of the O H group toward the O atom.

A forward arrow labeled 3 shows the product glyceraldehyde 3-phosphate between the side chains of G l u 165 and H i s 95.

The structure of the product is as follows: C, single bond, C, single bond, C H 2, single bond, O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper right and single bonded to H on the left. C 2 is single bonded to O, single bond, H on the right and H on the upper left.

Return to Catalytic mechanism of triose phosphate isomerase

Extended description for Conversion of enediol intermediate into methylglyoxal



The chemical reaction consists of one reactant and one product. The reactant is enediol intermediate whose structure is as follows: C, double bond, C. C 1 is single bonded to O H on the upper left and H on the lower right. C 2 is single bonded to O H on the upper right and C H 2, single bond, O P O 3 superscript 2 minus on the lower right.

A forward reaction arrow leads to the product and shows the simultaneous release of P subscript i.

The product is methylglyoxal whose structure is as follows: C, single bond, C. C 1 is double bonded to O on the upper left and single bonded to H on the lower left. C 2 is double bonded to O on the upper right and single bonded to C H 3 on the lower right.

Extended description for Stage 2 of glycolytic pathway

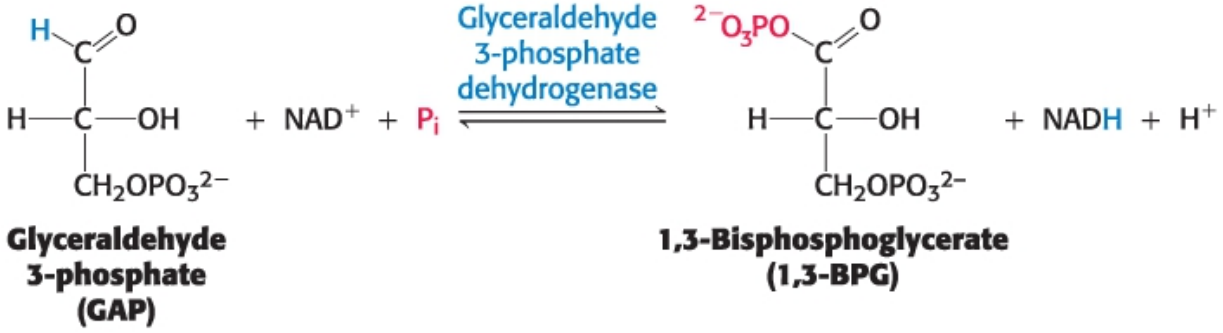
© Macmillan Learning

The flowchart is depicted as follows:

Glucose, three downward arrows, F-1, 6-B P. The first and third downward arrows show the entry of A T P.

F-1, 6-B P, one downward arrow and one curved leftward arrow.

The downward arrow leads to G A P. The curved leftward arrow leads to D H A P. A double-headed arrow is shown between G A P and D H A P.



G A P, four downward arrows, P E P. The first and second downward arrow show the release of N A D H and A T P respectively.

P E P, one downward arrow, pyruvate. The downward arrow shows the release of A T P. The steps from the first downward arrow below G A P to the final pyruvate molecule are enclosed by left curly bracket labeled 2 times.

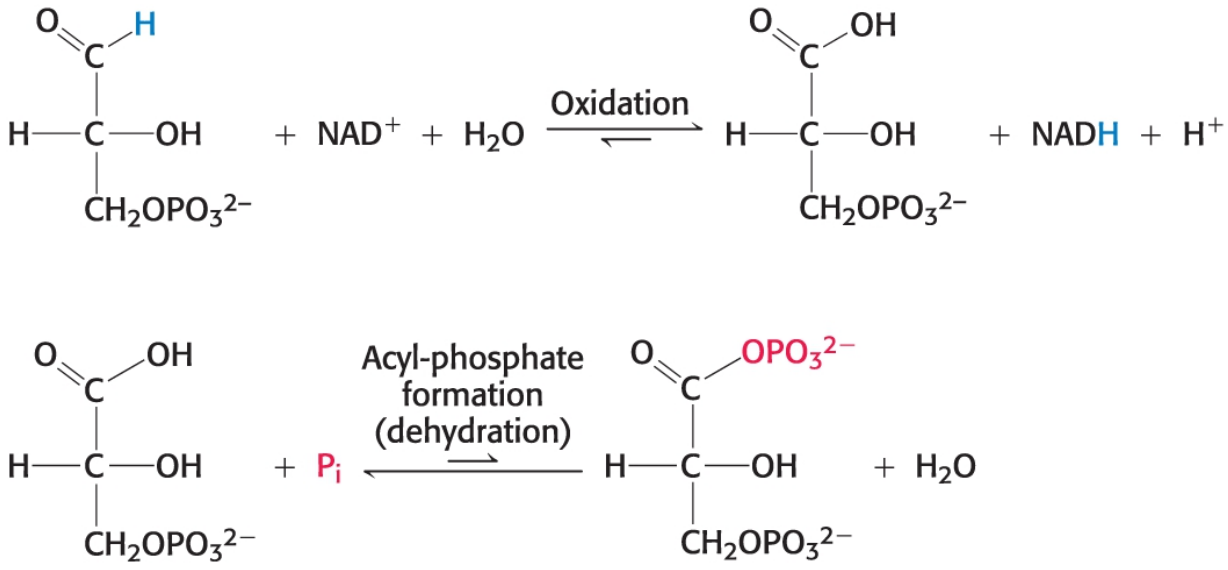
Note: The steps involving the conversion of G A P to pyruvate are enclosed in a yellow rectangle labeled stage 2.

Return to Stage 2 of glycolytic pathway

Extended description for Reversible conversion of glyceraldehyde 3-phosphate to 1,3-bisphosphoglycerate

The chemical reaction consists of three reactants and three products. The first reactant is glyceraldehyde 3-phosphate (G A P) whose structure is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is single bonded to H on the upper left highlighted in blue and double bonded to O on the upper right. C 2 is single bonded to H on the left and O H on the right.

The second reactant is N A D superscript plus. The third reactant is P subscript i.



A reversible reaction arrow labeled glyceraldehyde 3-phosphate dehydrogenase leads to the products.

The first product is 1,3-bisphosphoglycerate (1,3-B P G) whose structure is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is single bonded to O P O 3 superscript 2 minus on the upper left highlighted in red and double bonded to O on the upper right. C 2 is single bonded to H on the left and O H on the right.

The second product is N A D H with H highlighted in blue. The third product is H superscript plus.

Return to Reversible conversion of glyceraldehyde 3-phosphate to 1,3-bisphosphoglycerate

Extended description for Chemical reactions depict the oxidation of an aldehyde and formation of acyl-phosphate production

The first chemical reaction consists of three reactants and three products. The structure of the first reactant is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to H on the upper right highlighted in blue. C 2 is single bonded to H on the left and O H on the right.

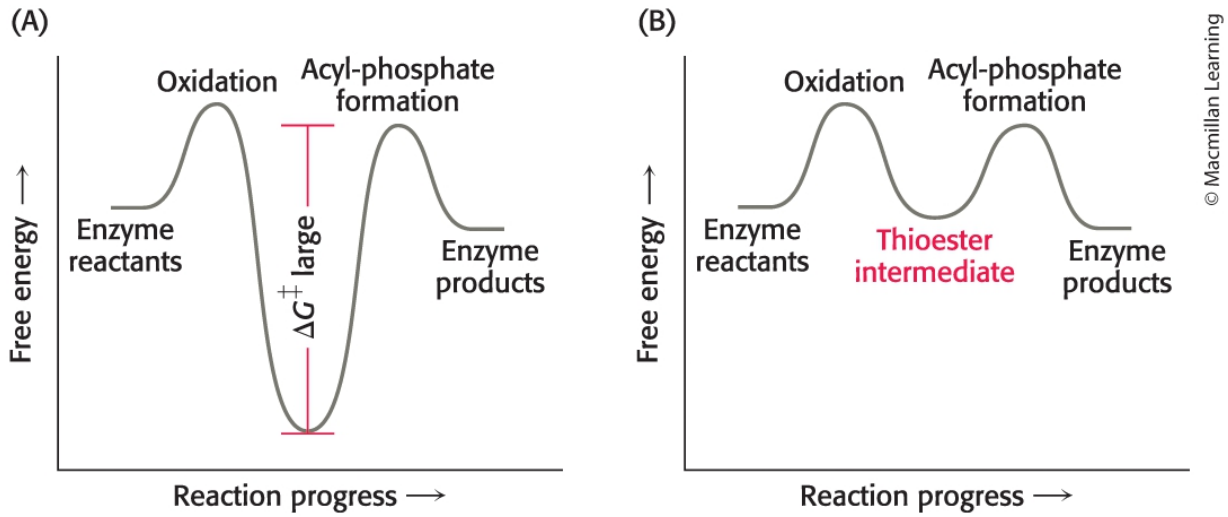
The second reactant is N A D superscript plus. The third reactant is H 2 O.

A reversible reaction arrow labeled oxidation leads to the products.

The structure of the first product is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded

to O on the upper left and single bonded to O H on the upper right. C 2 is single bonded to H on the left and O H on the right.

The second product is N A D H with H highlighted in blue. The third product is H superscript plus.



The second chemical reaction consists of two reactants and two products. The structure of the first reactant is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to O H on the upper right. C 2 is single bonded to H on the left and O H on the right. The second reactant is P subscript i highlighted in red.

A reversible reaction arrow labeled acyl-phosphate formation (dehydration) leads to the products.

The structure of the first product is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to O P O 3 superscript 2 minus on the upper right highlighted in red. C 2 is single bonded to H on the left and O H on the right. The second product is H 2 O.

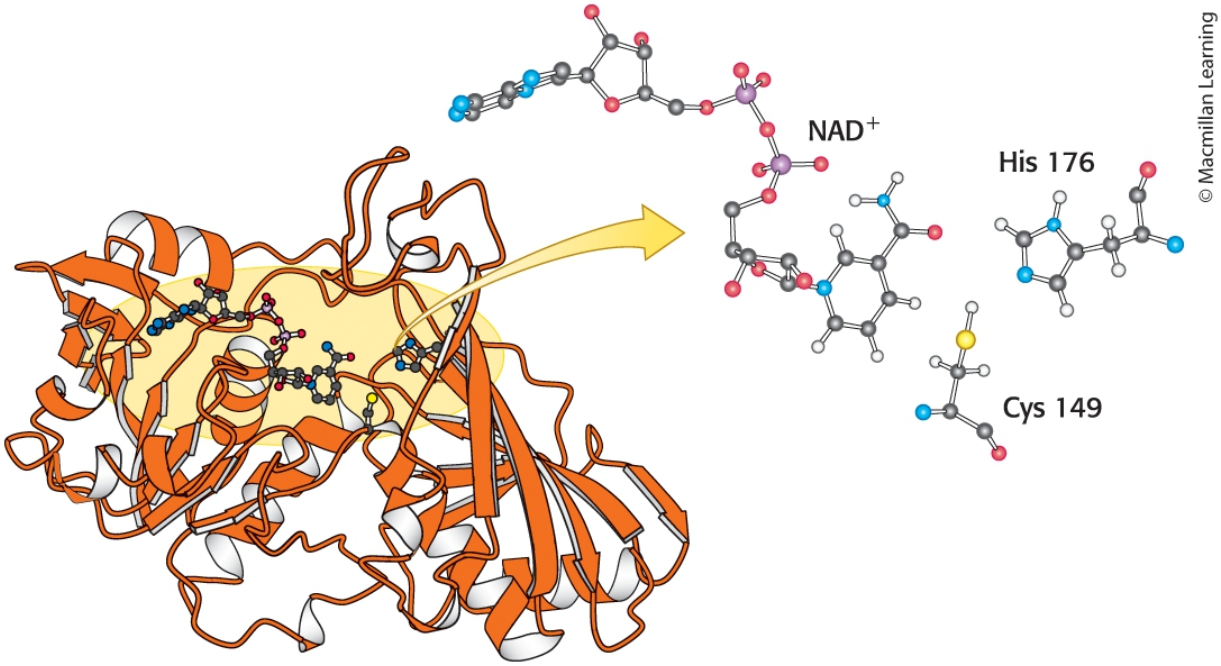
Extended description for Graphs depicting free energy profiles



Graph (A): The horizontal axis is labeled reaction progress. The vertical axis is labeled free energy which increases from the bottom to the top. The curve begins at a point above the midpoint of the vertical axis and then moves horizontally for a short duration. This section of the curve is labeled “enzyme reactants.” It then rises steeply to form the first peak labeled “oxidation” at the highest free energy and then falls steeply to form a depression at the lowest free energy in the middle of the horizontal axis. It again rises vertically upward to form a second peak labeled “acyl-phosphate formation” just below the first peak. It then falls down to reach the same level as enzyme reactants and starts moving horizontally toward the right. This horizontal section is labeled “enzyme products.” The vertical length of the depression in the curve is labeled delta G superscript plus plus large.

Graph (B): The horizontal axis is labeled reaction progress. The vertical axis is labeled free energy which increases from the bottom

to the top. The curve begins at a point above the midpoint of the vertical axis and then moves horizontally for a short duration. This section of the curve is labeled “enzyme reactants.” It then rises steeply to form the first peak labeled “oxidation” at the highest free energy and then falls steeply to form a depression labeled “thioester intermediate” at the same free energy as the enzyme reactants, in the middle of the horizontal axis. It again rises vertically upward to form a second peak labeled “acyl-phosphate formation” just below the first peak. It then falls down to reach the same level as enzyme reactants and starts moving horizontally toward the right. This horizontal section is labeled “enzyme products.”

Extended description for Ribbon diagram of G A P D H

The ribbon diagram consists of several beta-strands and alpha-helices interconnected by thread-like loops. A groove is located at the top of the diagram. A loose cluster of long and curved threads like loops are located at the top of the groove. A few ball-and-stick models are located inside the groove. An arrow shows the magnified view of the ball-and-stick models of H i s 176, C y s 149, and N A D superscript plus located in the groove. N A D superscript plus is located on the left and H i s 176 and C y s 149 are located on the right and lower right respectively.

Return to Ribbon diagram of G A P D H

Extended description for Catalytic mechanism of G A P D H

The enzyme active site is depicted as a concave depression outlined by an orange line with a yellow highlight. The active site has side chains of two unlabeled amino acids located at the bottom and top right.

The side chain of the first amino acid residue is as follows: C H 2, single bond, S, single bond, H.

The side chain of the second amino acid residue is as follows: C H 2 is single bonded to C 2 of a 5-membered heterocyclic pentagonal ring in a horizontal orientation. First N occupies the bottom left vertex. The second N bound to H occupies the topmost vertex. C 1 occupies the leftmost vertex. A double bond is present between N 1 and C 1, and C 2 and C 3.

The active site is bound to N A D superscript plus and glyceraldehyde 3-phosphate. For simplification, only the aldehyde group of glyceraldehyde 3-phosphate is shown. The structure of the aldehyde group is as follows: A central C atom is double bonded to O above, single bonded to H on the lower left, and single bonded to R on the lower right.

The structure of N A D superscript plus is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 N and 5 C atoms. N occupies the leftmost vertex and is single bonded to R prime on the left. A double bond is present between N 1 and C 1, C 2 and C 3, C 4 and C 5. C 1, C 3, C 4, and C 5 are each single bonded to H. C 2 is single bonded to C O N H 2. A plus symbol is shown at the center of the ring.

An arrow from the single bond between S and H atoms of one of the amino acid residues points toward the central C atom of the aldehyde group.

A forward reaction arrow labeled 1 shows the formation of hemithioacetal.

The S atom of the amino acid residue becomes single-bonded to the central C atom of the aldehyde group. This C atom is single bonded to O, single bond, H above, and single bonded to H on the lower left and R on the lower right.

A curved arrow points from N 1 atom of the pentagonal ring of an amino acid residue toward the H atom of the O H group of the aldehyde group. Another arrow points from the single bond between the O and H atoms of this group toward the single bond between the O and C atoms.

Another arrow points from the central C atom toward the H atom bonded to C 3 of N A D superscript plus.

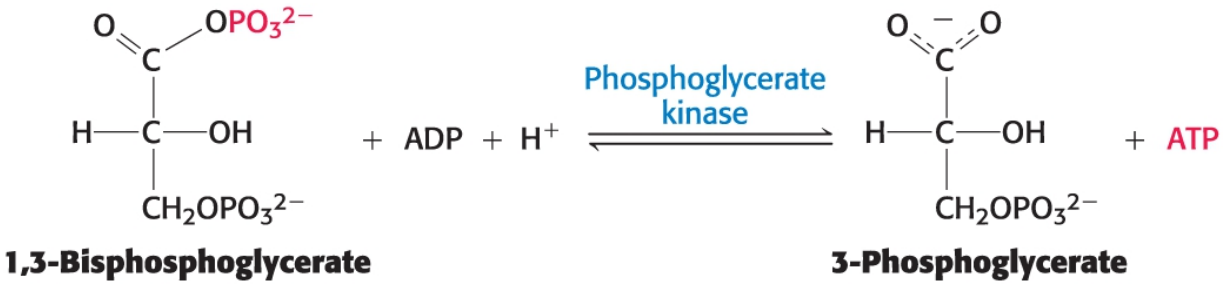
A forward arrow labeled 2 and oxidation shows the thioester intermediate.

N A D superscript plus bound to the active site is converted into N A D H. C 3 of N A D H is single bonded to two different H atoms.

The thioester intermediate consists of an S atom of one of the amino acid residues single bonded to C on the upper right. This C atom is double bonded to O above and single bonded to R on the lower right.

The pentagonal ring of the second amino acid residue attains a positive charge. C 1 is partially double bonded to N 1 and N 2. Both N 1 and N 2 are single-bonded to the H atom.

A forward arrow labeled 3 shows the thioester intermediate bound to the active site. N A D superscript plus molecule enters and N A D H is released.



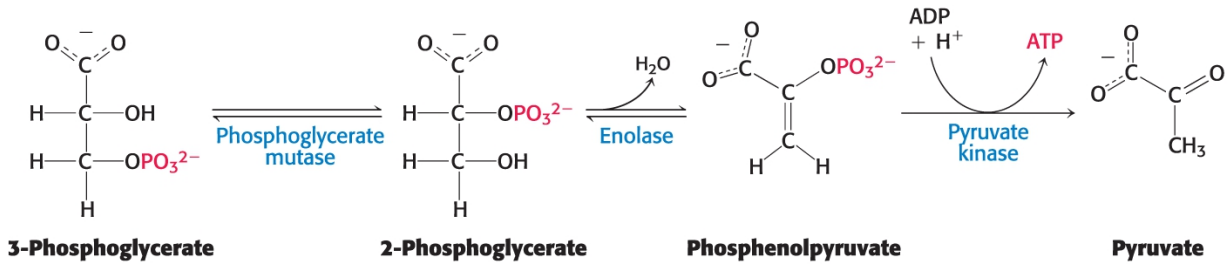
A forward arrow labeled 4 and phosphorylation shows the formation of 1,3-B P G. It also involves the entry of P subscript i.

The structure of 1, 3-B P G is depicted as follows: A central C atom is double bonded to O above, single bonded to O P O 3 superscript 2 minus on the lower left, and single bonded to R on the lower right.

The S atom of one of the amino acid residues is bound to H. The pentagonal ring of the second amino acid residue becomes neutral.

Return to Catalytic mechanism of G A P D H

Extended description for Chemical reaction shows the conversion of 1,3-bisphosphoglycerate to 3-phosphoglycerate



The chemical reaction consists of three reactants and two products. The first reactant is 1,3-bisphosphoglycerate whose structure is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to O P O 3 superscript 2 minus on the upper right. C 2 is single bonded to H on the left and O H on the right. The second reactant is A D P. The third reactant is H superscript plus.

A reversible reaction arrow labeled phosphoglycerate kinase leads to the products.

The first product is 3-phosphoglycerate whose structure is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is partially double bonded to O on the upper left and O on the upper right. This C O O group has an overall negative charge. C 2 is single bonded to H on the left and O H on the right. The second product is A T P.

Return to Chemical reaction shows the conversion of 1,3-bisphosphoglycerate to 3-phosphoglycerate

Extended description for Conversion of 3-phosphoglycerate to pyruvate

The conversion of 3-phosphoglycerate to pyruvate takes place in three steps.

The first step involves the reversible conversion of 3-phosphoglycerate to 2-phosphoglycerate.

The structure of 3-phosphoglycerate is as follows: C, single bond, C, single bond, C, single bond, H. C 1 is partially double bonded to O on the upper left and O on the upper right. This C O O group has an overall negative charge. C 2 is single bonded to H on the left and O H on the right. C 3 is single bonded to H on the left and O P O 3 superscript 2 minus on the right. The P O 3 superscript 2 minus group is highlighted in red.

A reversible reaction arrow labeled phosphoglycerate mutase leads to the product 2-phosphoglycerate.

The structure of 2-phosphoglycerate is as follows: C, single bond, C, single bond, C, single bond, H. C 1 is partially double bonded to O on the upper left and O on the upper right. This C O O group has an overall negative charge. C 2 is single bonded to H on the left and O P O 3 superscript 2 minus on the right. The P O 3 superscript 2 minus

group is highlighted in red. C 3 is single bonded to H on the left and O H on the right.

The second step involves the reversible conversion of 2-phosphoglycerate to phosphoenolpyruvate.

A reversible reaction arrow labeled enolase leads to phosphoenolpyruvate from 2-phosphoglycerate. A curved upward pointing arrow above it shows the release of H 2 O.

The structure of phosphoenolpyruvate is as follows: A central C atom is double bonded to C below, single bonded to O P O 3 superscript 2 minus on the upper right, and single bonded to C on the upper left. The P O 3 superscript 2 minus group is highlighted in red. The C atom below is single-bonded to H on the lower left and H on the lower right. The C atom on the upper left is partially double bonded to O above and O on the lower left. This C O O group has an overall negative charge.

The third step involves the irreversible conversion of phosphoenolpyruvate to pyruvate.

A forward reaction arrow labeled pyruvate leads to pyruvate from phosphoenolpyruvate. A curved arrow above it shows the simultaneous conversion of A D P plus H superscript plus to A T P highlighted in red.

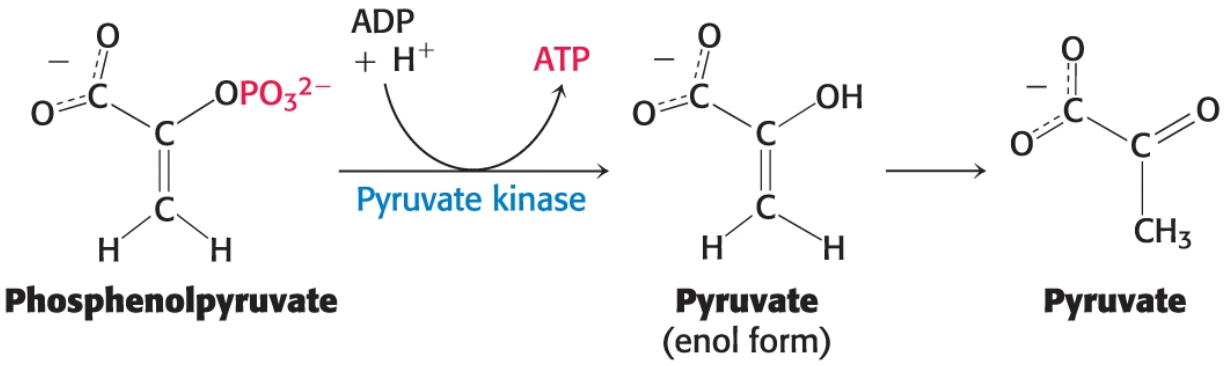
The structure of pyruvate is as follows: A central C atom is double bonded to O on the upper right, single bonded to C H 3 below, and single bonded to C on the upper left. This C atom is partially double bonded to O above and O on the lower left. This C O O group has an overall negative charge.

Return to Conversion of 3-phosphoglycerate to pyruvate

Extended description for Transfer of phosphoryl group from histidine residues of an enzyme to 3-phosphoglycerate

The reaction consists of two reactants and two products. The reactants are enzyme, single bond, histidine, single bond, phosphate, and 3-phosphoglycerate. The products are enzyme, single bond, histidine, and 2,3-bisphosphoglycerate.

Return to Transfer of phosphoryl group from histidine residues of an enzyme to 3-phosphoglycerate



Extended description for Removal of phosphoryl group from 2,3-bisphosphoglycerate

The reaction consists of two reactants and two products. The reactants are enzyme, single bond, histidine, and 2,3-bisphosphoglycerate. The products are enzyme, single bond, histidine, single bond, phosphate, and 2-phosphoglycerate.

Return to Removal of phosphoryl group from 2,3-bisphosphoglycerate

Extended description for Conversion of phosphoenolpyruvate to pyruvate

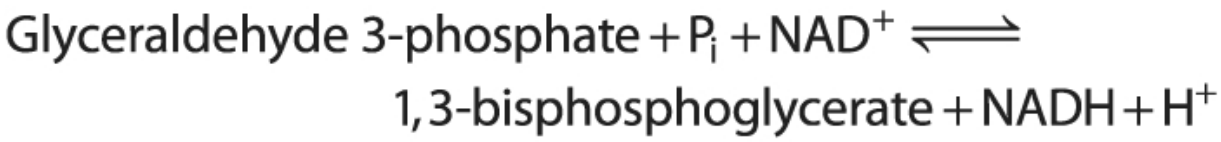
The conversion of phosphoenolpyruvate to pyruvate takes place in three irreversible steps.

The first step involves the conversion of phosphoenolpyruvate to pyruvate (enol form).

The structure of phosphoenolpyruvate is as follows: A central C atom is double bonded to C below, single bonded to O P O 3 superscript 2 minus on the upper right, and single bonded to C on the upper left. The P O 3 superscript 2 minus group is highlighted in red. The C atom below is single-bonded to H on the lower left and H on the lower right. The C atom on the upper left is partially double bonded to O above and O on the lower left. This C O O group has an overall negative charge.

A forward reaction arrow labeled pyruvate kinase leads to pyruvate. A curved arrow above it shows the simultaneous conversion of A D P plus H superscript plus to A T P highlighted in red.

The structure of pyruvate (enol form) is as follows: A central C atom is double bonded to C below, single bonded to O H on the upper right, and single bonded to C on the upper left. The C atom below is single-bonded to H on the lower left and H on the lower right. The C atom on the upper left is partially double bonded to O above and O on the lower left. This C O O group has an overall negative charge.

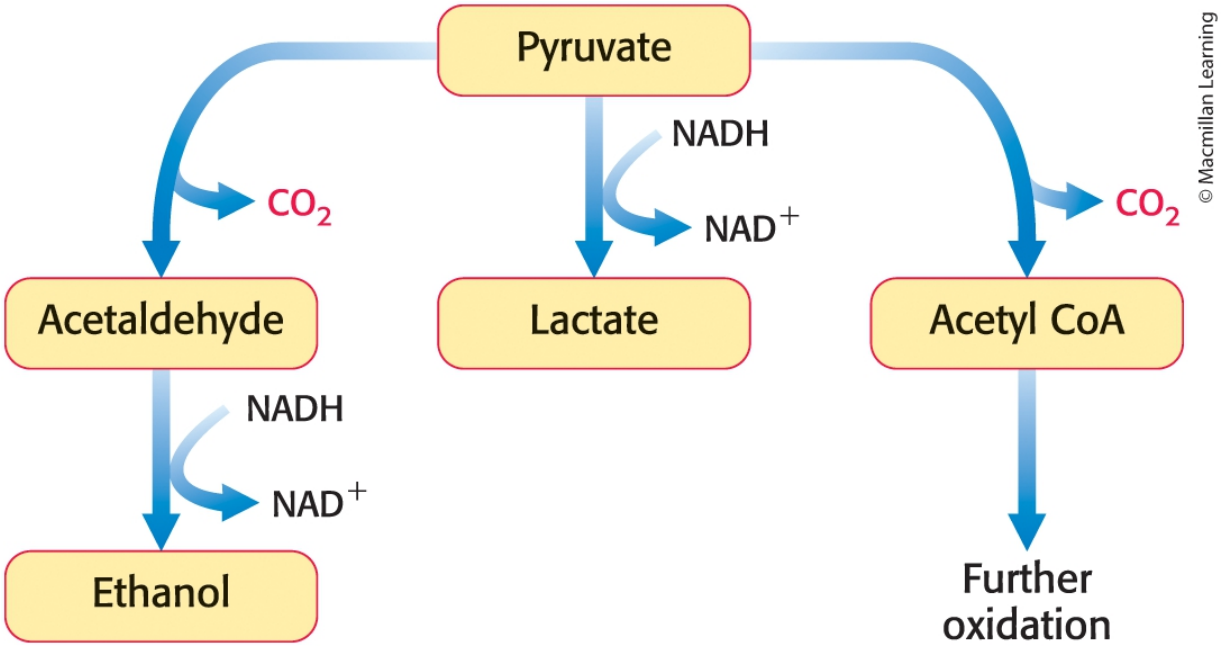


The second step involves the conversion of the enol form of pyruvate to pyruvate.

A forward reaction arrow leads to pyruvate from the enol form of pyruvate.

The structure of pyruvate is as follows: A central C atom is double bonded to O on the upper right, single bonded to C H 3 below, and single bonded to C on the upper left. This C atom is partially double bonded to O above and O on the lower left. This C O O group has an overall negative charge.

Return to Conversion of phosphoenolpyruvate to pyruvate



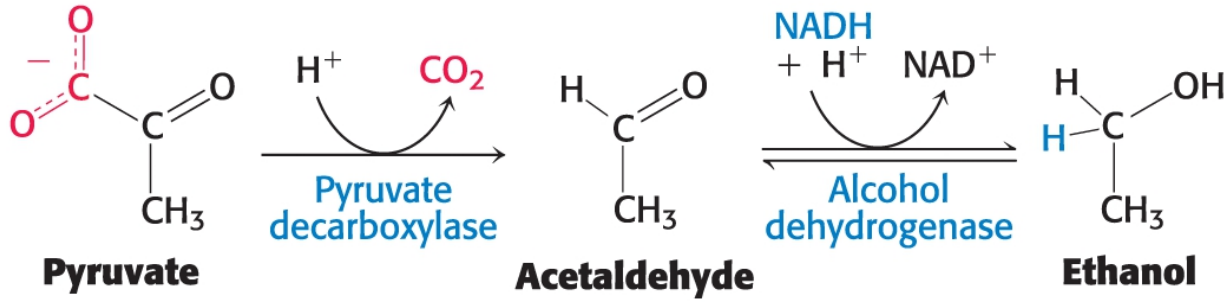
Extended description for Step 6 of glycolysis

The reaction consists of 3 reactants and 3 products. The reactants are glyceraldehyde 3-phosphate, P subscript i, and N A D superscript plus. The products are 1,3-bisphosphoglycerate, N A D H, and H superscript plus.

Return to Step 6 of glycolysis

Extended description for Different fates of pyruvate molecule

The flowchart is depicted as follows:



Pyruvate is shown at the top center. A leftward curved below pyruvate leads to acetaldehyde and shows the release of C O 2. A rightward curved arrow below pyruvate leads to acetyl-C o A and shows the release of C O 2. A downward arrow below pyruvate leads to lactate and shows the oxidation of N A D H to N A D superscript plus.

A downward arrow below acetaldehyde leads to ethanol. It also shows the oxidation of N A D H to N A D superscript plus.

A downward arrow below acetyl C o A leads to further oxidation.

Return to Different fates of pyruvate molecule

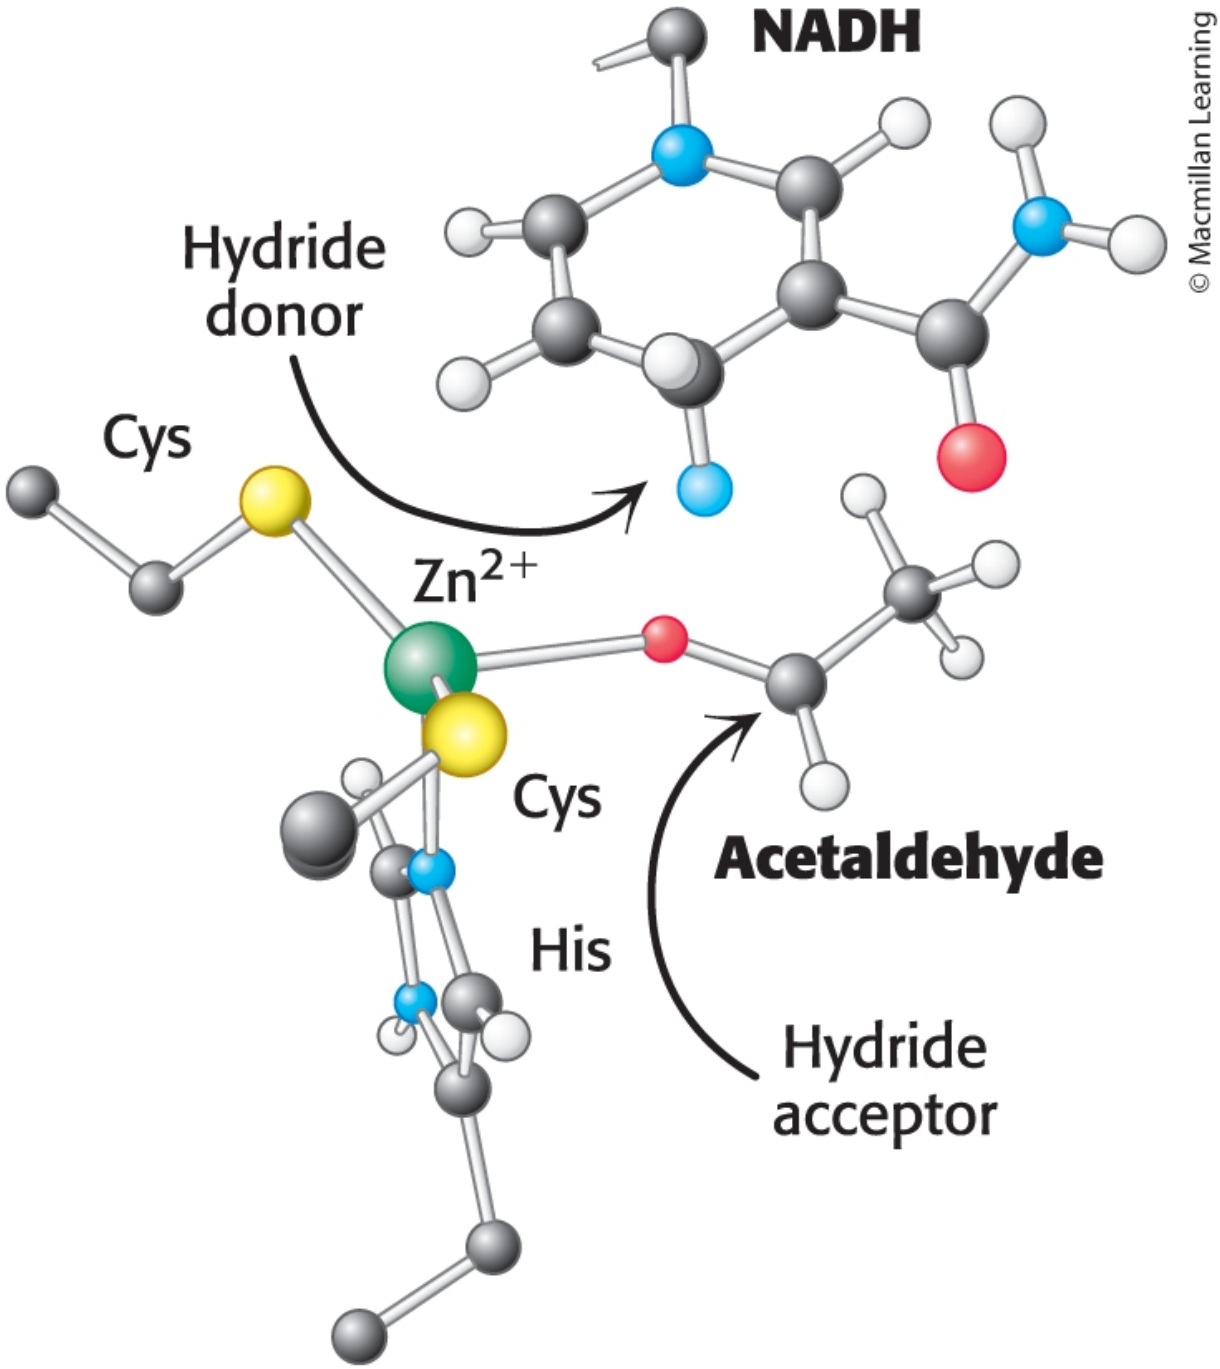
Extended description for Conversion of pyruvate to ethanol

In the first chemical reaction, pyruvate is converted into acetaldehyde. The structure of pyruvate is as follows: A central C atom is double bonded to O on the upper right, single bonded to C H 3 below, and single bonded to C on the upper left. This C atom is partially double bonded to O above and O on the lower left. This C O O group has an overall negative charge.

A forward reaction arrow labeled pyruvate decarboxylase leads to acetaldehyde. A curved arrow above it shows the simultaneous entry of H superscript plus and exit of C O 2.

The structure of acetaldehyde is as follows: A central C atom is single bonded to H on the upper left, double bonded to O on the upper right, and single bonded to C H 3 below.

In the second chemical reaction, acetaldehyde is further converted into ethanol.



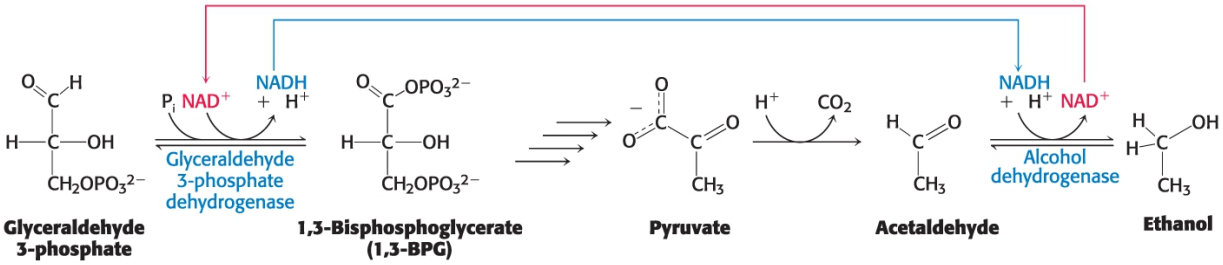
A reversible reaction arrow labeled alcohol dehydrogenase leads to ethanol from acetaldehyde. A curved arrow above it shows the

simultaneous oxidation of N A D H plus H superscript plus to N A D superscript plus.

The structure of ethanol is as follows: A central C atom is single bonded to H highlighted in blue on the left, single bonded to H on the upper left, single bonded to O H on the upper right, and single bonded to C H 3 below.

Return to Conversion of pyruvate to ethanol

Extended description for Ball-and-stick model of zinc ion in the alcohol dehydrogenase active site and its binding partners



The Z n superscript 2 plus ion is depicted as a green sphere. It is connected to a yellow sphere of a cysteine residue located on the upper left and in the front, toward the observer. The yellow sphere of each cysteine residue is further connected to a chain of two black spheres. The Z n superscript 2 plus ion is connected to the blue sphere of the pentagonal ring of a histidine residue below. The ring consists of 2 blue and 3 black spheres. The bottom-most black sphere is connected to a chain of two black spheres below. The remaining spheres are connected to a white sphere. The Z n superscript 2 plus ion is also connected to a small red sphere of an acetaldehyde molecule labeled hydride acceptor. The red sphere is further connected to a chain of two black spheres. The first black sphere is connected to a white sphere below. The second black sphere is connected to three white spheres.

N A D H molecule labeled hydride donor is located above the acetaldehyde molecule. The ball-and-stick model of N A D H consists of a hexagonal ring composed of 1 blue and 5 black spheres. The blue sphere occupies the topmost vertex and is connected to a black sphere above. The bottom-most black sphere is connected to a blue sphere below. The top right and top left black spheres are connected to a white sphere. The bottom left black sphere is connected to a white sphere on the left and lower right. The bottom right black sphere is connected to a chain composed of a black sphere and a blue sphere. The black sphere of this chain is connected to a red sphere below. The blue sphere is connected to a white sphere above and a white sphere on the lower right.

Return to Ball-and-stick model of zinc ion in the alcohol dehydrogenase active site and its binding partners

Extended description for Reoxidation of N A D H

The figure shows a series of reactions. The first reaction consists of one reactant and one product. The reactant is glyceraldehyde 3-phosphate whose structure is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper right and single bonded to H on the upper left. C 2 is single bonded to H on the left and O H on the right.

A reversible reaction arrow labeled glyceraldehyde 3-phosphate dehydrogenase leads to the product 1,3-bisphosphoglycerate (1,3-B P G). It shows the entry of P subscript i and a curved arrow above it shows the simultaneous reduction of N A D superscript plus to N A D H plus H superscript plus.

The structure of the product 1,3-bisphosphoglycerate (1,3-B P G) is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper right and single bonded to O P O 3 superscript 2 minus on the upper right. C 2 is single bonded to H on the left and O H on the right.

Four parallel forward arrows are shown next to the product.

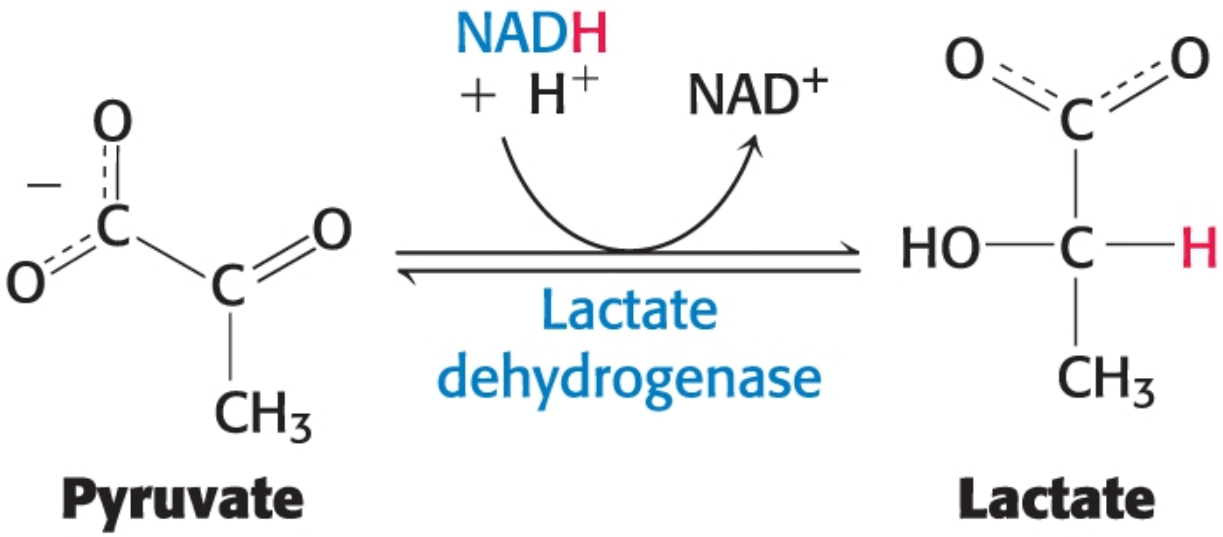
The second reaction consists of one reactant and one product. The reactant is pyruvate whose structure is as follows: A central C atom

is double bonded to O on the upper right, single bonded to C H 3 below, and single bonded to C on the upper left. This C atom is partially double bonded to O above and O on the lower left. This C O O group has an overall negative charge.

A forward reaction arrow leads to the product acetaldehyde. A curved arrow above it shows the simultaneous entry of H superscript plus and exit of C O 2.

The structure of the product acetaldehyde is as follows: A central C atom is single bonded to H on the upper left, double bonded to O on the upper right, and single bonded to C H 3 below.

The third reaction consists of one reactant and one product. The reactant is acetaldehyde. A reversible arrow labeled alcohol dehydrogenase leads to the product ethanol. A curved arrow above it shows the simultaneous reoxidation of N A D H plus H superscript plus to N A D superscript plus.



The structure of the product ethanol is as follows: A central C atom is single bonded to H on the lower left, H on the upper left, O H on the upper right, and C H 3 below.

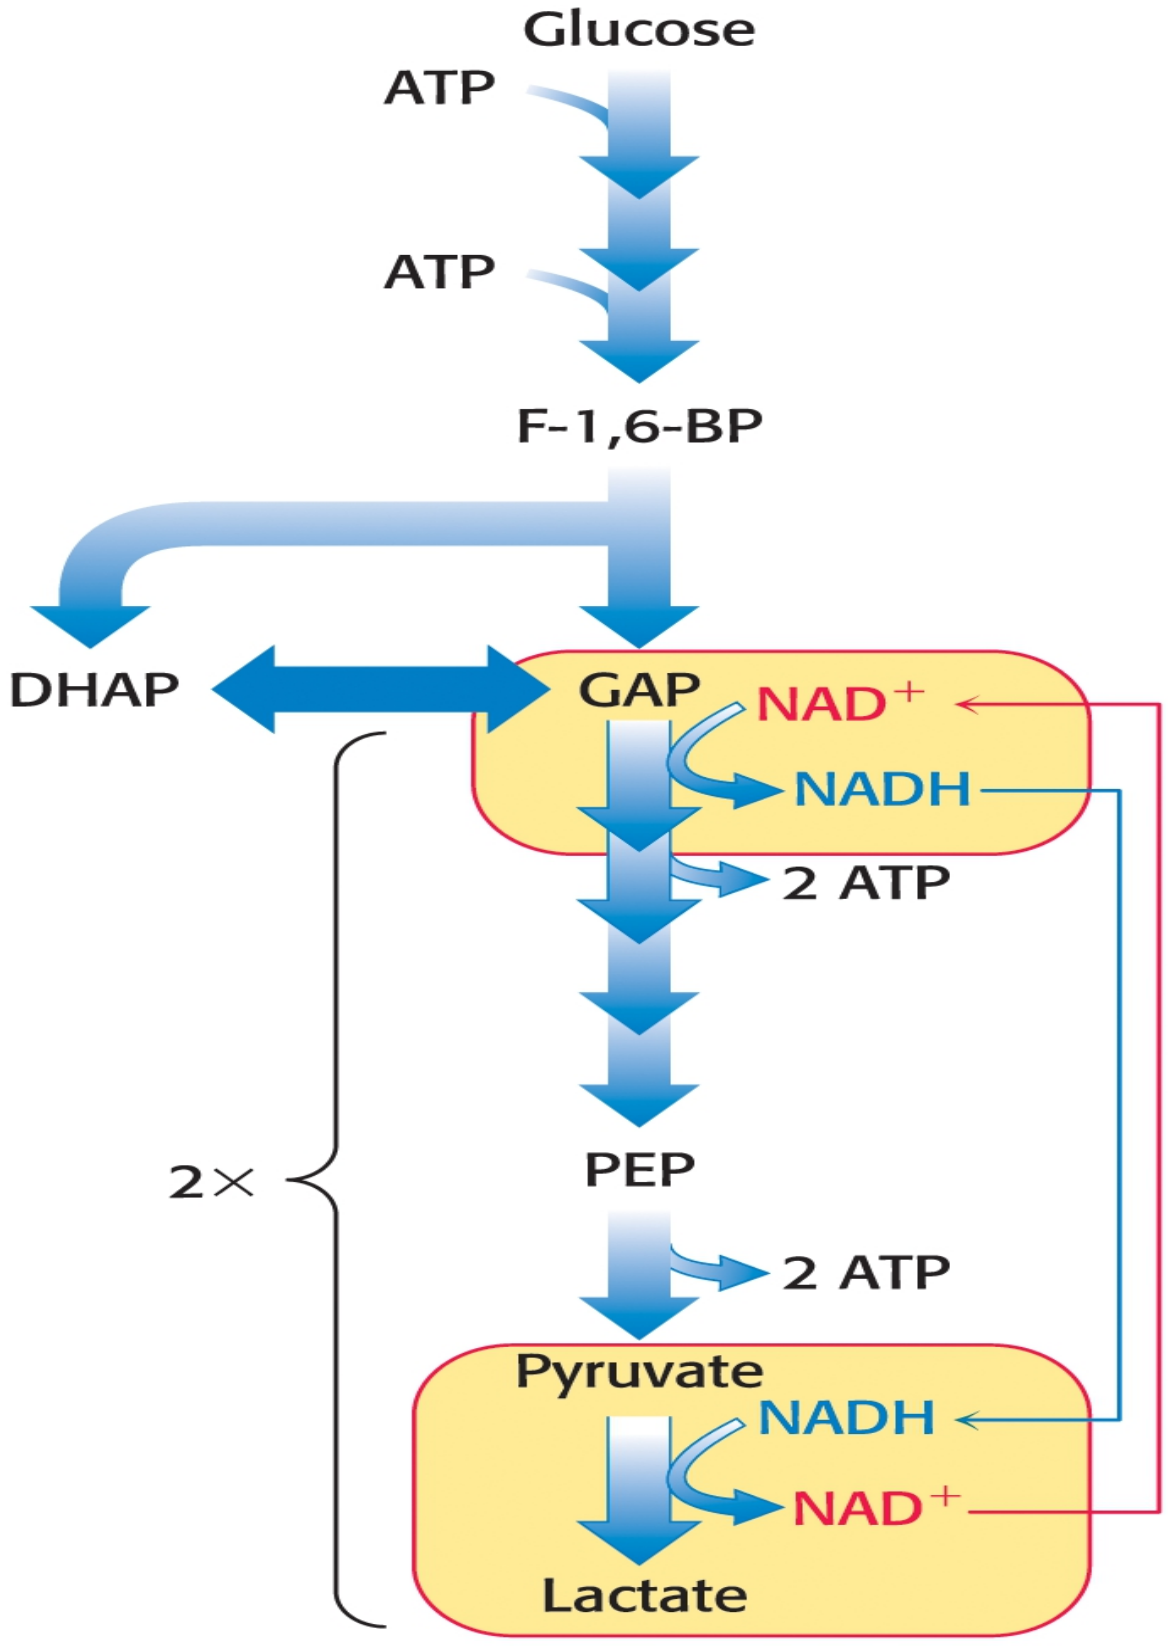
An arrow moves from N A D H plus H superscript plus in the first reaction toward N A D H plus H superscript plus in the third reaction.

Another arrow moves from N A D superscript plus in the third reaction toward N A D superscript plus in the first reaction.

Return to Reoxidation of N A D H

Extended description for Chemical reaction shows the conversion of pyruvate to lactate

The chemical reaction consists of one reactant and one product. The reactant is pyruvate whose structure is as follows: A central C atom is double bonded to O on the upper right, single bonded to C H 3 below, and single bonded to C on the upper left. This C atom is partially double bonded to O above and O on the lower left. This C O O group has an overall negative charge.



A reversible reaction arrow labeled lactate dehydrogenase leads to the product. A curved arrow above it shows the simultaneous oxidation of N A D H plus H superscript plus to N A D superscript plus. The H atom of N A D H is highlighted in red.

The product is lactate whose structure is as follows: C, single bond, C, single bond, C H 3. C 1 is partially double bonded to O on the upper left and O on the upper right. C 2 is single bonded to O H on the left and single bonded to H on the right highlighted in red.

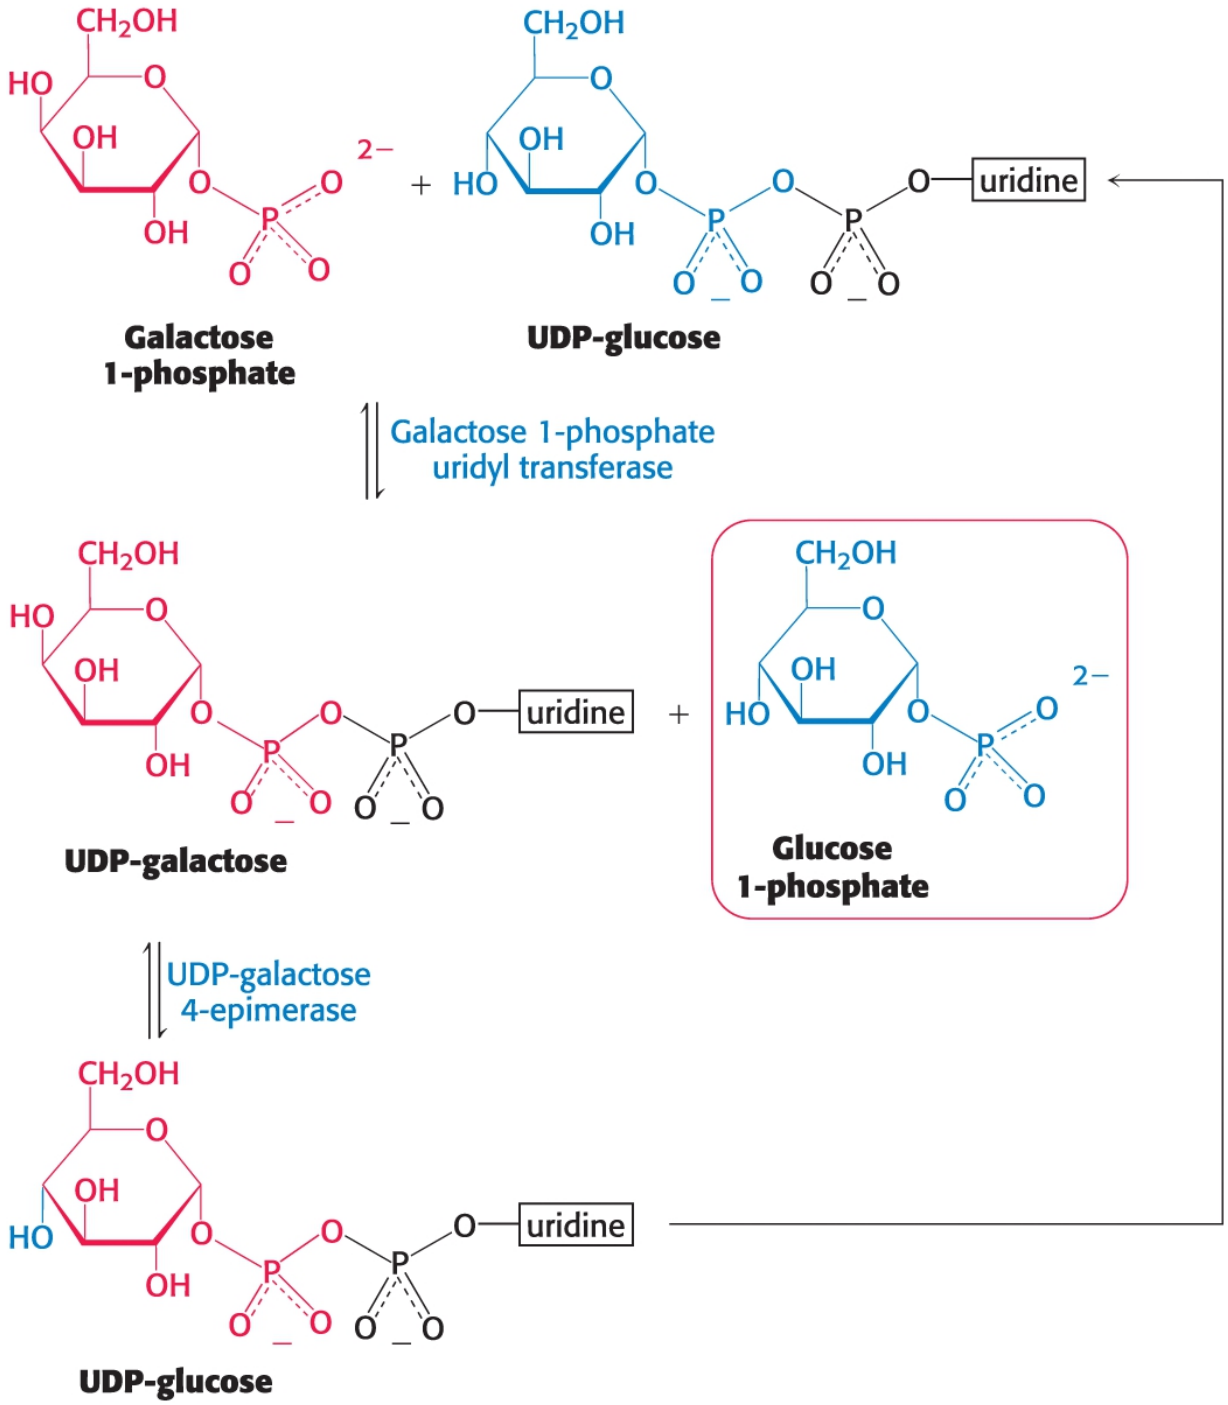
Extended description for Irreversible conversion of galactose to galactose 1-phosphate

Galactose **Galactose 1-phosphate**

The structure of galactose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. The ring is in a plane perpendicular to the plane of the paper such that O and C 5 are located away from the observer and C 2 and C 3 are located toward the observer. C 1 and C 2 are each single bonded to O H below. C 3 and C 4 are each single bonded to O H above. C 5 is single bonded to C H 2 O H above.



A forward reaction arrow labeled galactokinase leads to galactose 1-phosphate. A curved arrow above it shows the simultaneous breakdown of A T P highlighted in red to A D P plus H superscript plus.

The structure of galactose 1-phosphate is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. The ring is in a plane perpendicular to the plane of the paper such that O

and C 5 are located away from the observer and C 2 and C 3 are located toward the observer. C 1 is single bonded to O below. This O is single-bonded to a central P atom highlighted in red. The P atom is partially double bonded to O on the upper right, O on the lower right, and O on the lower left. The O atoms have an overall negative charge of 2 minus. C 2 is single bonded to O H below. C 3 and C 4 are each single bonded to O H above. C 5 is single bonded to C H 2 O H above.

Return to Irreversible conversion of galactose to galactose 1-phosphate

Extended description for Formation of U D P-glucose from galactose 1-phosphate and U D P-glucose

The formation of U D P-glucose takes place in two steps. The first step involves the formation of U D P-galactose and glucose 1-phosphate from galactose 1-phosphate and U D P-glucose.

The structure of galactose 1-phosphate is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. The ring is in a plane perpendicular to the plane of the paper such that O and C 5 are located away from the observer and C 2 and C 3 are located toward the observer. C 1 is single bonded to O below. This O is single-bonded to a central P atom. The P atom is partially double bonded to O on the upper right, O on the lower right, and O on the lower left. The O atoms have an overall negative charge of 2 minus. C 2 is single bonded to O H below. C 3 and C 4 are each single bonded to O H above. C 5 is single bonded to C H 2 O H above.

The structure of U D P-glucose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. The ring is in a plane perpendicular to the plane of the paper such that O and C 5 are located away from the observer and C 2 and C 3 are located toward the observer. C 1 is single bonded to O below. This O is single-bonded to a zigzag chain composed of P, single bond, O, single bond, P, single bond, O, single bond, uridine. Each P atom is partially double bonded to O on the lower left and lower left. These O atoms have an overall negative charge. C 2 and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above.

A reversible reaction arrow labeled galactose 1-phosphate uridyl transferase leads to U D P-galactose and glucose 1-phosphate.

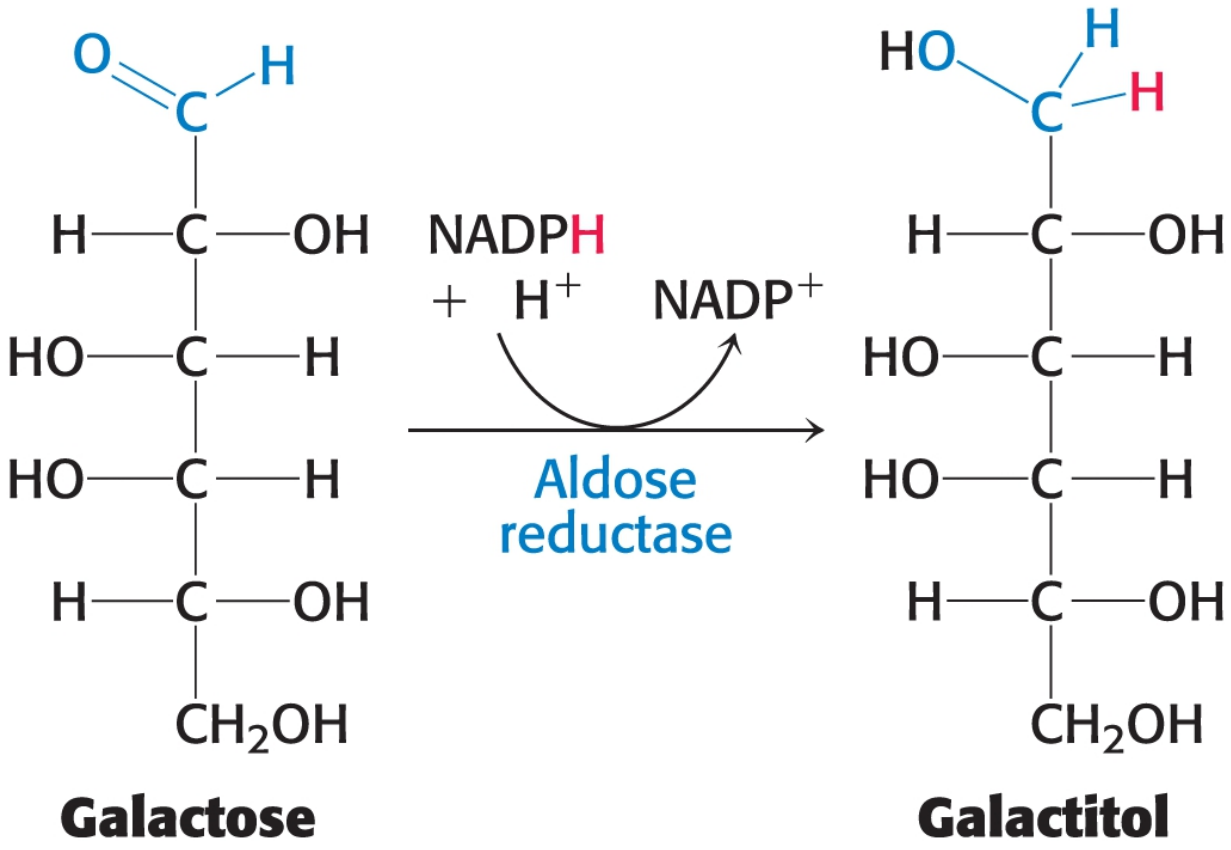
The structure of U D P-galactose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and

consists of 1 O and 5 C atoms. O occupies the top right vertex. The ring is in a plane perpendicular to the plane of the paper such that O and C 5 are located away from the observer and C 2 and C 3 are located toward the observer. C 1 is single bonded to O below. This O is single-bonded to a zigzag chain composed of P, single bond, O, single bond, P, single bond, O, single bond, uridine. Each P atom is partially double bonded to O on the lower left and lower left. These O atoms have an overall negative charge. C 2 is single bonded to O H below. C 3 and C 4 are single bonded to O H above. C 5 is single bonded to C H 2 O H above.

The structure of glucose 1-phosphate is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. The ring is in a plane perpendicular to the plane of the paper such that O and C 5 are located away from the observer and C 2 and C 3 are located toward the observer. C 1 is single bonded to O below. This O is single-bonded to a central P atom. The P atom is partially double bonded to O on the upper right, O on the lower right, and O on the lower left. The O atoms have an overall negative charge of 2 minus. C 2 and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above.

The second step involves the formation of U D P-glucose from U D P-galactose and glucose 1-phosphate.

A reversible reaction arrow below U D P-galactose and glucose 1-phosphate lead to U D P-glucose. The arrow is labeled U D P-galactose 4-epimerase.



The structure of U D P-glucose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. The ring is in a plane perpendicular to the plane of the paper such that O

and C 5 are located away from the observer and C 2 and C 3 are located toward the observer. C 1 is single bonded to O below. This O is single-bonded to a zigzag chain composed of P, single bond, O, single bond, P, single bond, O, single bond, uridine. Each P atom is partially double bonded to O on the lower left and lower left. These O atoms have an overall negative charge. C 2 and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above.

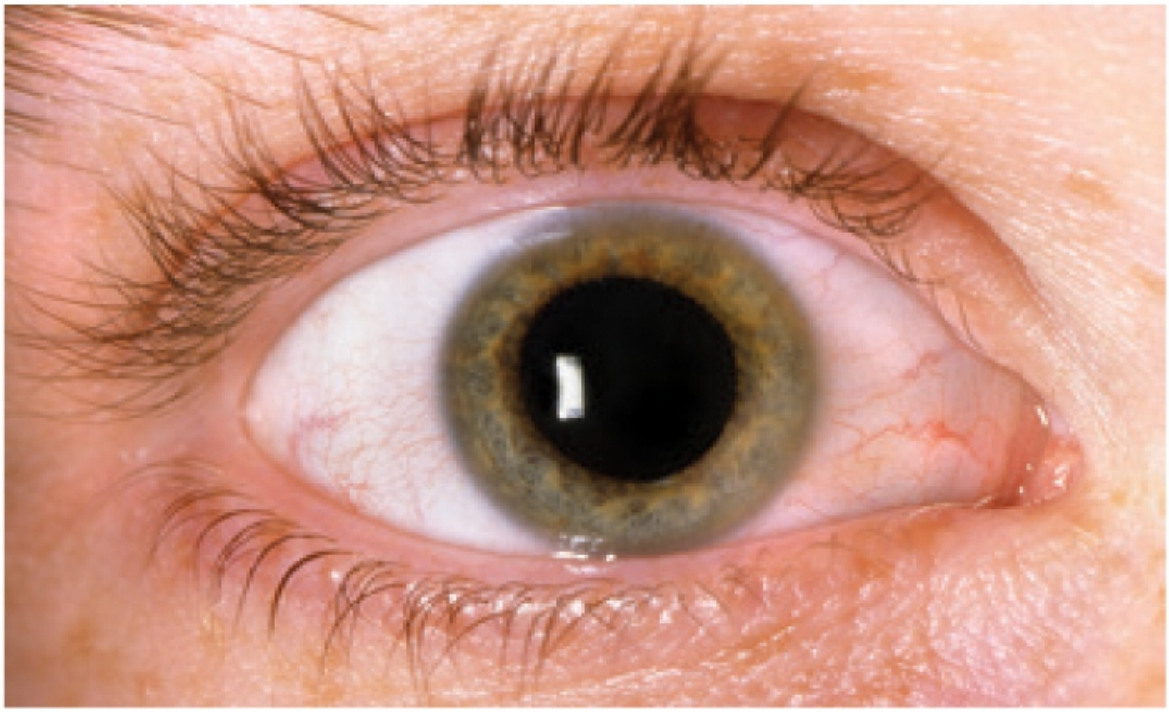
An arrow from U D P-glucose points toward galactose 1-phosphate and U D P-glucose at the top.

Return to Formation of U D P-glucose from galactose 1-phosphate and U D P-glucose

Extended description for Chemical reaction shows the conversion of galactose to galactitol

The chemical reaction consists of one reactant and one product. The reactant is galactose whose structure is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O H. C 1 is double bond to O on the upper left and single bonded to H on the upper right. C 1, O, and H are highlighted in blue.

A forward reaction arrow labeled aldose reductase leads to the product. A curved arrow above it shows the simultaneous oxidation of N A D P H plus H superscript plus to N A D P superscript plus. The H atom of N A D P H is highlighted in red.



The product is galactitol whose structure is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O H. C 1 is single bonded to O H on the upper left, H on the upper right, and H on the right. The H atom on right is highlighted in red. C 1, H on the upper right, and the O atom of the O H group is highlighted in blue.

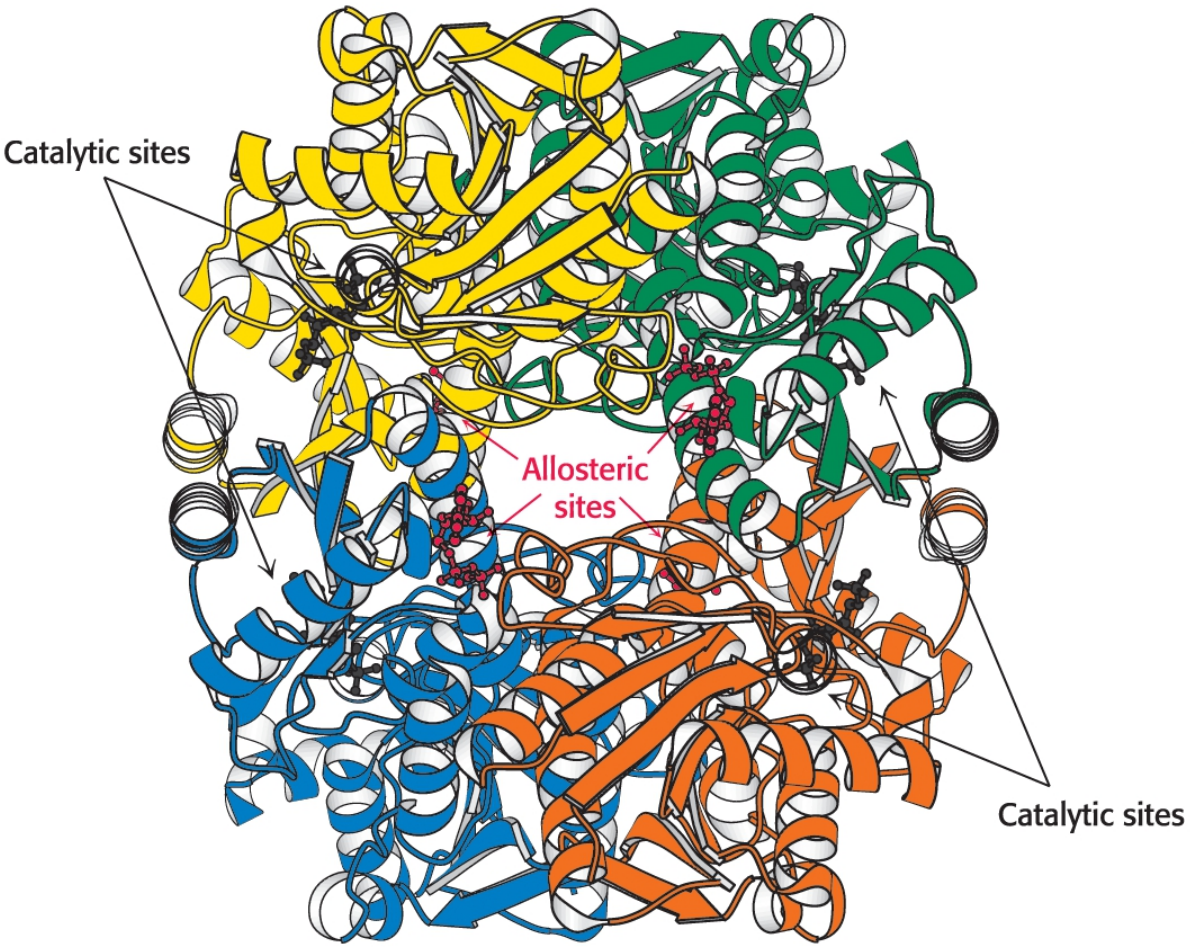
Extended description for Breakdown of lactose into galactose and glucose

The chemical reaction consists of two reactants and two products. The first reactant is lactose whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1 occupies the rightmost vertex. C 2 is single bonded to O H below. C 3 and C 4 are each single bonded to O H above. C 5 is single bonded to C H 2 O H above. C 1 is single bonded to O through a curved line. This O is further single bonded to C 4 of another 6-membered heterocyclic hexagonal ring in a horizontal orientation. This ring consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1 and C 2 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above.

The second reactant is H 2 O.

A reversible reaction arrow labeled lactase leads to the products.



The first product is galactose whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1 occupies the rightmost vertex and is single bonded to O H above. C

2 is single bonded to O H below. C 3 and C 4 are each single bonded to O H above. C 5 is single bonded to C H 2 O H above.

The second product is glucose whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1 and C 2 are each single bonded to O H below. C 3 is single bonded to O H above. C 4 is single bonded to O H below. C 5 is single bonded to C H 2 O H above.

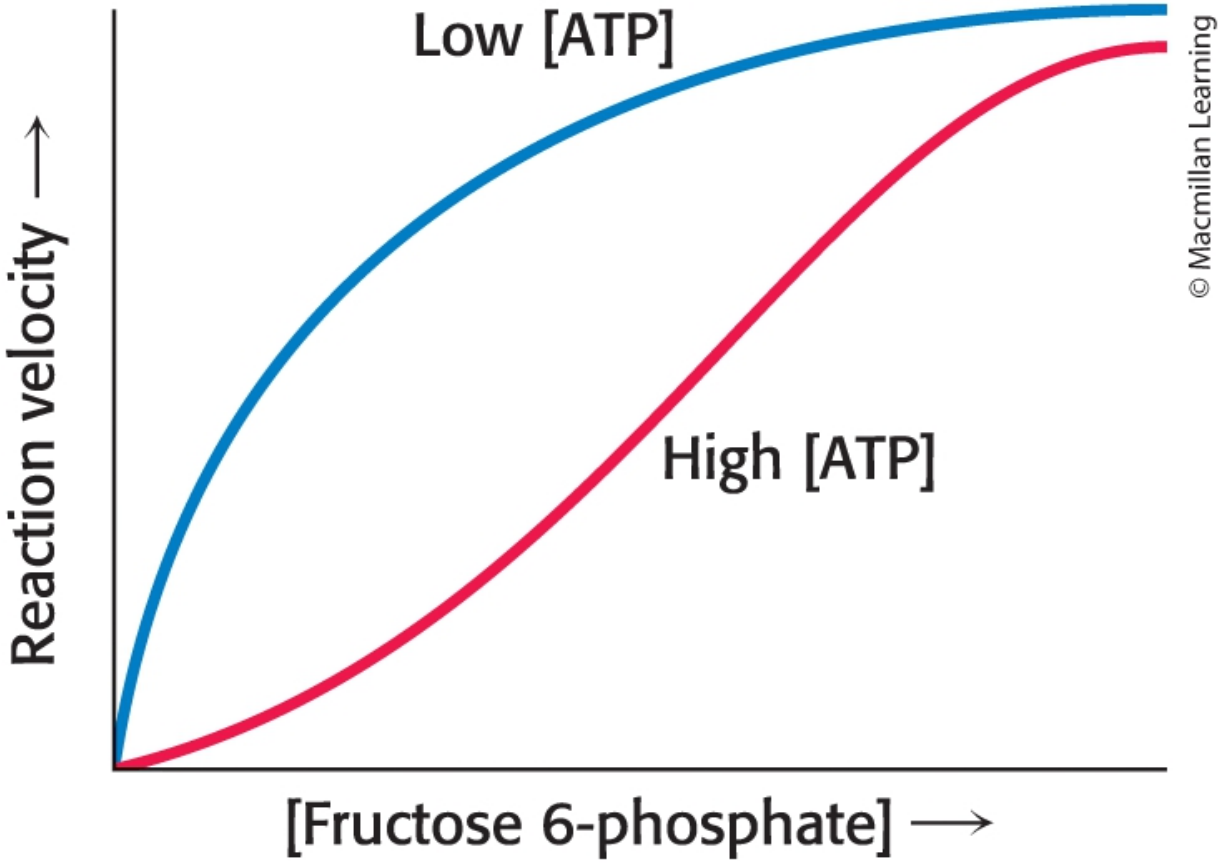
Extended description for Ribbon diagram of *E.coli* phosphofructokinase



© Macmillan Learning

The ribbon diagram has a circular shape with a hollow core. It consists of four identical subunits shown in yellow, green, orange, and blue color. Each subunit is composed of alpha-helices and beta-strands. Each subunit has a tiny groove labeled catalytic site. A thread from the top left and bottom left subunit move toward each other and independently undergo coiling on the left periphery of the enzyme. Similarly, a thread from the top right and bottom right subunit moves toward each other and independently undergoes

coiling on the right periphery of the enzyme. An allosteric site is present in each subunit toward the hollow core.

Extended description for Graphical representation of the inhibition of phosphofructokinase activity

The horizontal axis is labeled concentration of fructose 6-phosphate which increases from left to right. The vertical axis is labeled reaction velocity which increases from the bottom to the top. The graph shows two curves. The blue curve labeled “low A T P concentration” starts from the origin and moves gradually toward the upper right in a concave-down manner. It then forms a plateau at the highest reaction velocity. The red curve labeled “high A T P concentration” starts at the origin and moves almost linearly toward the upper right. It then forms a small plateau at the highest reaction velocity, near the extreme right end of the horizontal axis.

Return to Graphical representation of the inhibition of phosphofructokinase activity

Extended description for Flowcharts depict glycolysis regulation

The first flowchart is labeled “At rest (glycolysis inhibited)” and is depicted as follows.

Glucose, downward arrow labeled hexokinase, glucose 6-phosphate, downward arrow, fructose 6-phosphate, downward arrow labeled P F K, fructose 1, 6-bisphosphate, five downward arrows, phosphoenolpyruvate, downward arrow labeled pyruvate kinase, pyruvate.

A leftward arrow from glucose 6-phosphate leads to glycogen. The third downward arrow between fructose 1, 6-bisphosphate and phosphoenolpyruvate shows the release of A T P.

The downward arrow labeled pyruvate kinase shows the release of A T P.

A curved red arrow with a minus symbol is labeled “negative feedback” and it points from glucose 6-phosphate to hexokinase.

A double-headed red arrow with a minus symbol is labeled “A T P over A M P high energy charge” and it points toward P F K and pyruvate kinase.

A schematic illustration of the relaxed muscle fiber is shown alongside the flow chart. It shows elongated muscle fibers.

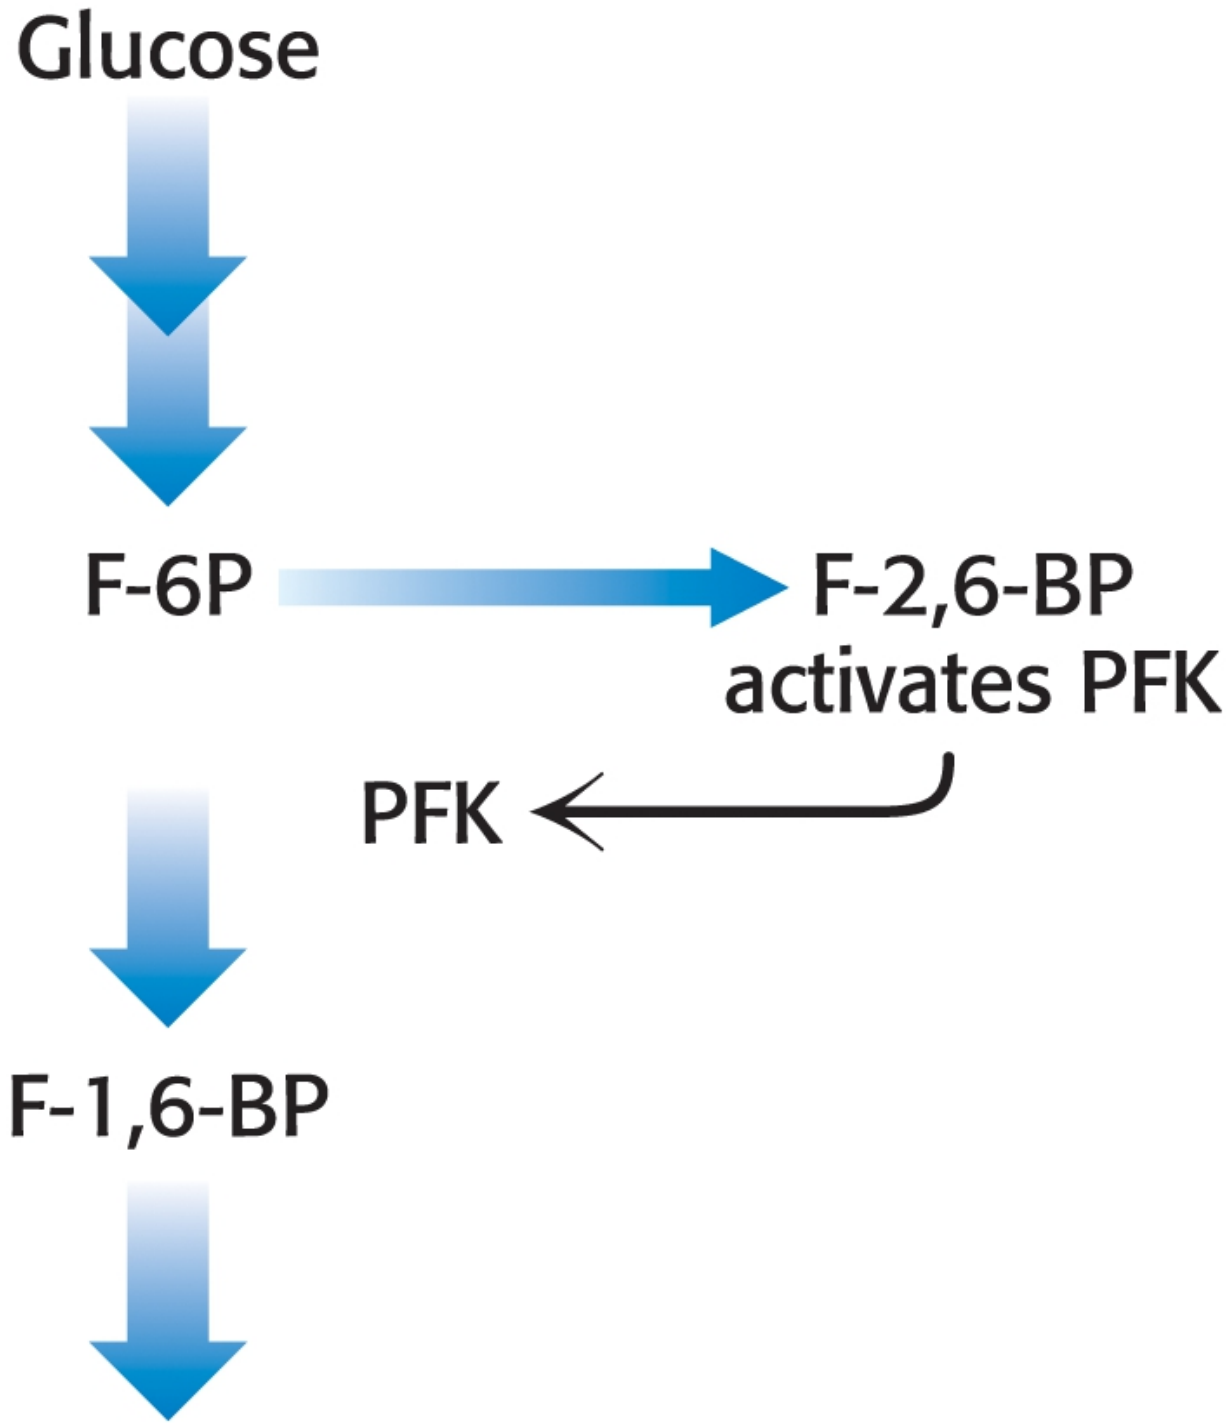
The second flowchart is labeled “During exercise (glycolysis stimulated)” and is depicted as follows:

Glucose, downward arrow labeled hexokinase, glucose 6-phosphate, downward arrow, fructose 6-phosphate, downward arrow labeled P F K, fructose 1, 6-bisphosphate, five downward arrows, phosphoenolpyruvate, downward arrow labeled pyruvate kinase, pyruvate, two downward arrows. The lower left downward arrow leads to C O 2 plus H 2 O (long, slow run). The lower right downward arrow leads to lactate (sprint).

A rightward arrow from glycogen leads to glucose 6-phosphate. The third downward arrow between fructose 1, 6-bisphosphate and phosphoenolpyruvate shows the release of A T P.

The downward arrow labeled pyruvate kinase shows the release of A T P.

A green arrow with a minus symbol is labeled “A T P over A M P low energy charge” and it points toward P F K.



A curved green arrow with a plus symbol is labeled “feedforward stimulation” and it points from fructose 1, 6-bisphosphate toward pyruvate kinase.

A schematic illustration of the muscle-fiber contraction is shown alongside the flow chart. It shows shortened muscle fibers.

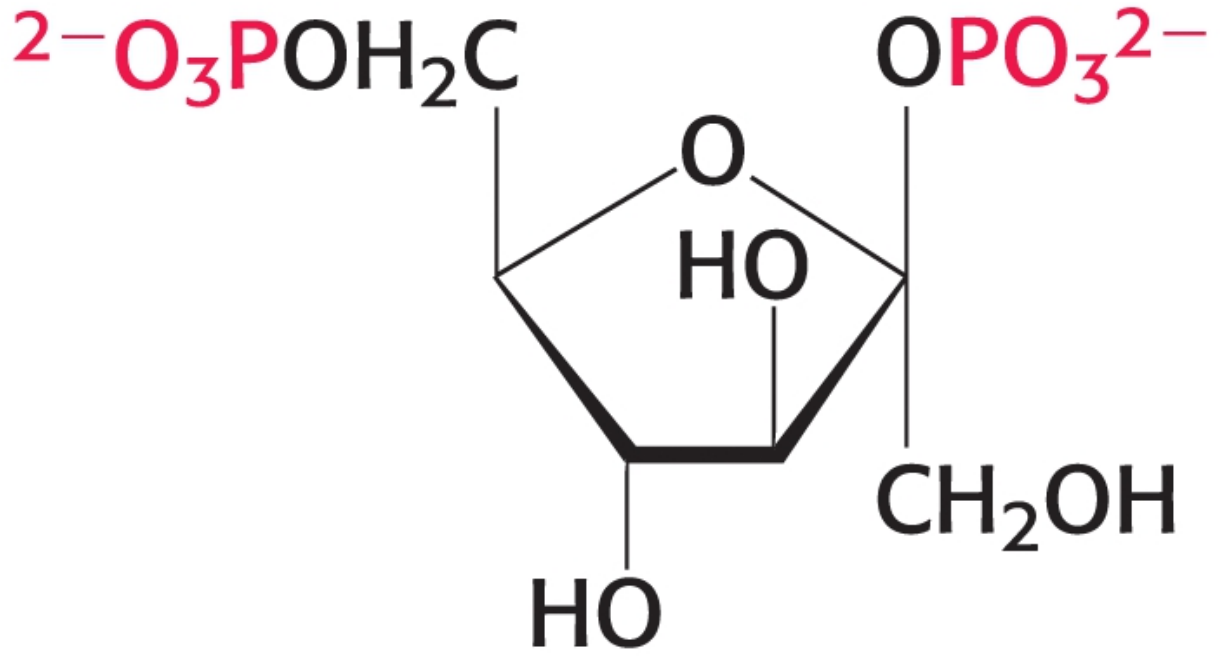
Extended description for Chemical structure of fructose 2, 6-bisphosphate and flow chart depicting

allosteric activation of phosphofructokinase

The structure of fructose 2, 6-bisphosphate (F-2, 6-B P) is as follows: A 5membered heterocyclic pentagonal ring is in a vertical



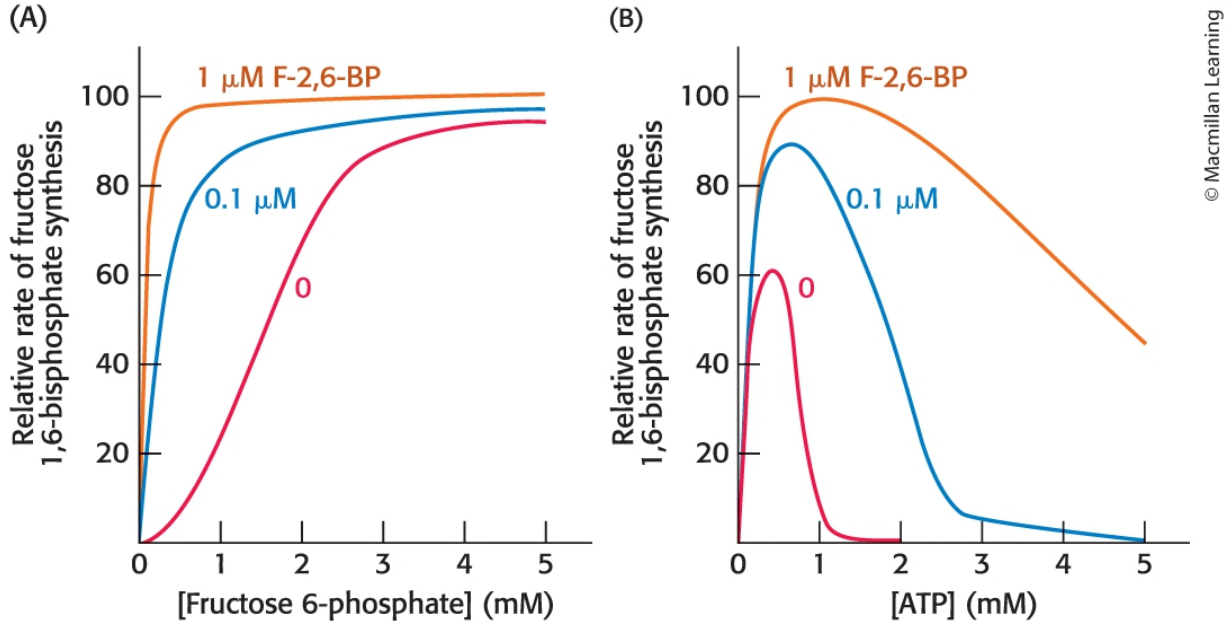
orientation and consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single bonded to O P O 3 superscript 2 minus above and single bonded to C H 2 O H below. C 2 is single bonded to O H above. C 3 is single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 superscript 2 minus above.

The flow chart is depicted as follows:

Glucose, two downward arrows, F-6 P, downward arrow, F-1, 6-B P, downward arrow. A rightward arrow from F-6 P leads to F-2, 6-B P activates P F K. A curved black arrow from F-2, 6-B P activates P F K leads to P F K.

Return to Chemical structure of fructose 2, 6-bisphosphate and flow chart depicting allosteric activation of phosphofructokinase

Extended description for Structure of fructose 2, 6-bisphosphate

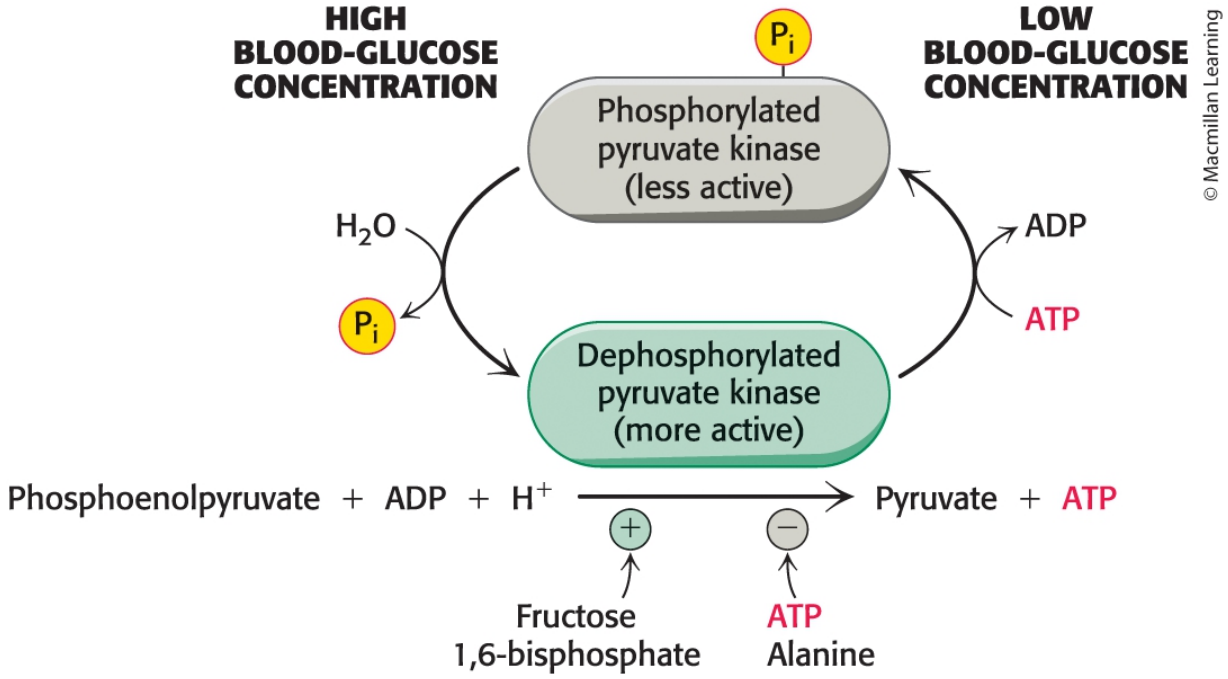


Fructose 2,6-bisphosphate (F-2,6-BP)

The structure is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 1 O and 4 C atoms. The ring is perpendicular to the plane of paper such that O is located away from the observer and C 2 and C 3 are located toward the observer. O occupies the topmost vertex. C 1 is single bonded to O P O 3 superscript 2 minus above and C H 2 O H below. C 2 is single bonded to O H above. C 3 is single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 superscript 2 minus.

Return to Structure of fructose 2, 6-bisphosphate

Extended description for Graphs depict fructose 1, 6-bisphosphate synthesis with respect to fructose 6-phosphate concentration

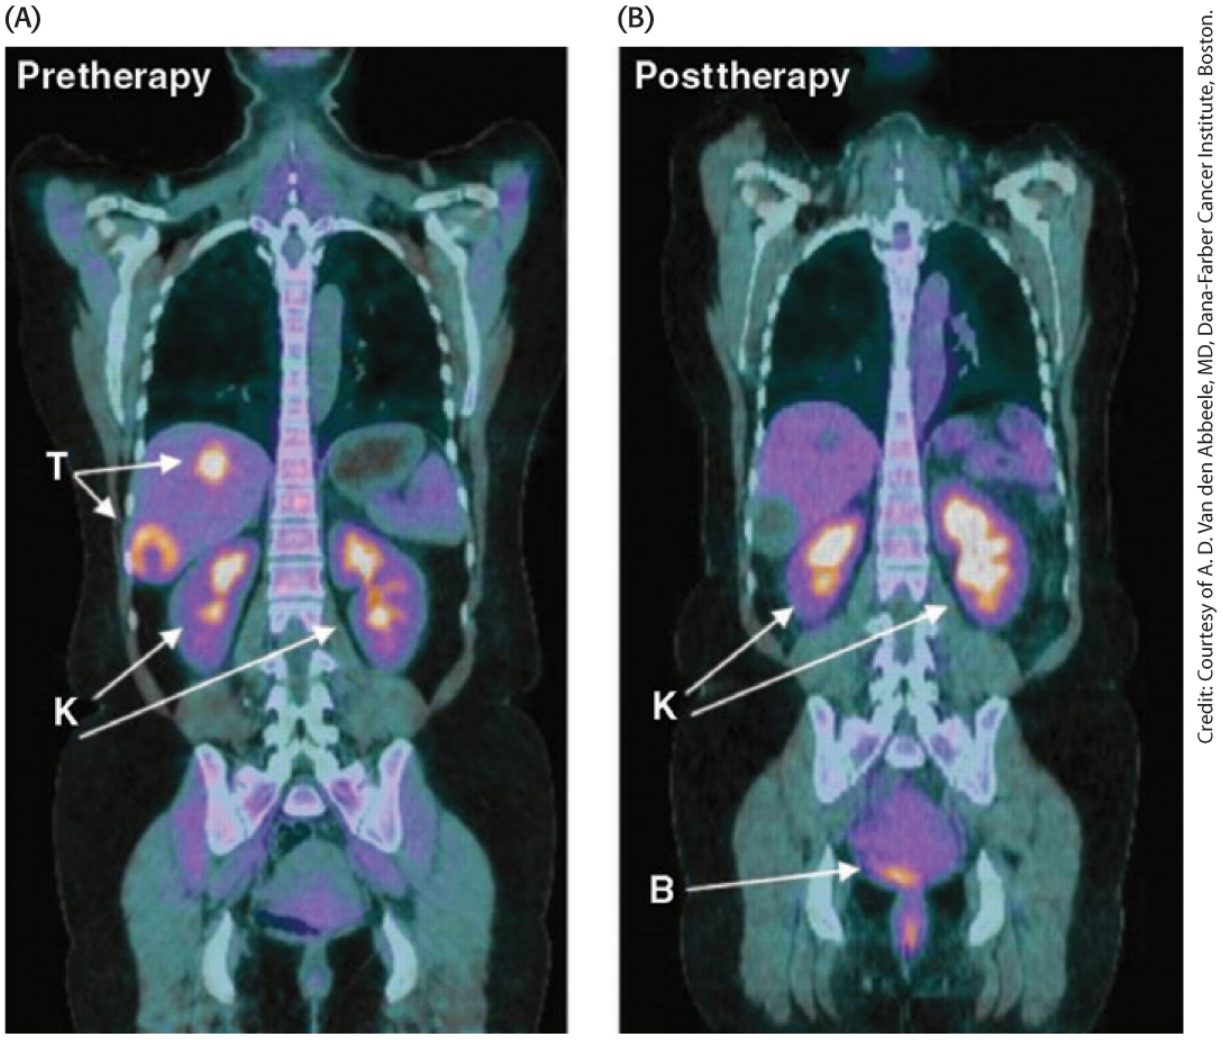


Part (A): The horizontal axis is labeled concentration of fructose 6-phosphate in millimolar. It has markings ranging from 0 to 5 in increments of 1 unit. The vertical axis is labeled the relative rate of fructose 1, 6-bisphosphate synthesis. It has markings ranging from 0 to 100 in increments of 20 units. The graph contains three curves shown in orange, blue, and red colors. The orange curve is labeled 1 micromolar F-2, 6-B P. It starts from the origin, rises steeply to reach the point (0.5, 99), and then starts moving horizontally toward the right. The blue curve is labeled 0.1 micromolar. It starts from the origin, rises steeply to reach the point (1, 90), and then moves gradually to reach (2, 95). The curve then starts moving horizontally toward the right. The red curve is labeled 0. It also begins from the origin, rises linearly toward the upper right to reach (3, 93), and then starts moving horizontally toward the right.

Part (B): The horizontal axis is labeled concentration of A T P in millimolar. It has markings ranging from 0 to 5 in increments of 1 unit. The vertical axis is labeled relative rate of fructose 1, 6-bisphosphate synthesis. It has markings ranging from 0 to 100 in increments of 20 units. The graph contains three curves shown in orange, blue, and red colors. The orange curve is labeled 1 micromolar F-2, 6-B P. It starts at the origin, moves vertically upward, forms a peak at (1.5, 100), and then starts declining toward the lower right to terminate at (5, 45). The blue curve is labeled 0.1 micromolar. It begins at the origin, moves vertically upward, forms a peak at (1, 88), and then starts declining toward the lower right to reach (2.8, 8). It then gradually declines to reach (5, 0). The red curve is labeled 0. It starts from the origin, moves vertically upward, forms a peak at (0.5, 60), and then starts declining toward the lower right to reach (1.4, 0). It then moves horizontally toward the right to reach (2, 0). All values are estimated.

Return to Graphs depict fructose 1, 6-bisphosphate synthesis with respect to fructose 6-phosphate concentration

Extended description for Regulation of pyruvate kinase activity



A grey rounded rectangle is labeled “phosphorylated pyruvate kinase (less active)” and it is single bonded to P subscript i above. A green rounded rectangle labeled “dephosphorylated pyruvate kinase (more active)” is located below it. The region toward the top left of the grey rectangle shows “high blood-glucose concentration”. The region toward the top right of the grey rectangle shows “Low blood-glucose concentration”. A curved downward arrow on the left moves from the grey rectangle to the green rectangle. Another curved arrow adjacent to it shows the simultaneous entry of H 2 O and the release of P subscript i. A curved upward arrow on the right moves from a green rectangle to a grey rectangle. Another curved arrow adjacent to it shows the conversion of A T P to A D P.

A reaction is shown below. It consists of 3 reactants and 2 products. The first reactant is phosphoenolpyruvate. The second reactant is A D P. The third reactant is H superscript plus. A forward arrow leads to the products. It has a plus and minus symbol. An arrow labeled “fructose 1, 6-bisphosphate” points toward the plus symbol. An arrow labeled “A T P alanine” points toward the minus symbol. The products are pyruvate and A T P.

The pathway is depicted as follows from the bottom to the top:

Pyruvate is irreversibly converted into oxaloacetate by pyruvate carboxylase. This conversion requires the entry of A T P, H C O 3 superscript, and release of A D P plus P subscript i.

An arrow from a yellow rectangle labeled “lactate some amino acids” points toward pyruvate. An arrow from a yellow rectangle labeled “some amino acids” points toward oxaloacetate.

The structure of pyruvate is as follows: A central C atom is double bonded to O on the upper right, single bonded to C H 3 below, and single bonded to C on the upper left. This C atom is partially double bonded to O above and O on the lower left. This C O O group has an overall negative charge.

The structure of oxaloacetate is as follows: A 4-carbon alkane chain is depicted as a line structure using 3 zigzag lines. C 3 is bound to H 2. C 1 is partially double bonded to O above and O on the lower right. This C O O group has an overall negative charge. C 2 is double bonded to O below. C 4 is partially double bonded to O on the upper right and O below. This C O O group has an overall negative charge.

Oxaloacetate is reversibly converted into phosphoenolpyruvate by phosphoenolpyruvate carboxykinase. This conversion requires the breakdown of GT P to G D P and the release of C O 2.

The structure of phosphoenolpyruvate is as follows: A central C atom is double bonded to C below, single bonded to O P O 3 superscript 2 minus on the upper right, and single bonded to C on the upper left. The C atom below is single-bonded to H on the lower left and H on the lower right. The C atom on the upper left is

partially double bonded to O above and O on the lower left. This C O O group has an overall negative charge.

Phosphoenolpyruvate is reversibly converted into 2-phosphoglycerate by enolase. This conversion requires the entry of H 2 O.

The structure of 2-phosphoglycerate is as follows: C, single bond, C, single bond, C H 2 O H. C 1 is partially double bonded to O on the upper left and O on the upper right. This C O O group has an overall negative charge. C 2 is single bonded to H on the left and O P O 3 superscript 2 minus on the right.

2-phosphoglycerate is reversibly converted into 3-phosphoglycerate by phosphoglycerate mutase.

The structure of 3-phosphoglycerate is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is partially double bonded to O on the upper left and O on the upper right. This C O O group has an overall negative charge. C 2 is single bonded to H on the left and O H on the right.

3-phosphoglycerate is reversibly converted into 1,3-bisphosphoglycerate by phosphoglycerate kinase. This conversion requires the breakdown of A T P to A D P.

The structure of 1,3-bisphosphoglycerate is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is single bonded to O P O 3 superscript 2 minus on the upper left and double bonded to O on the upper right. C 2 is single bonded to H on the left and O H on the right.

1,3-bisphosphoglycerate is reversibly converted into glyceraldehyde 3-phosphate by glyceraldehyde 3-phosphate dehydrogenase. This conversion requires the oxidation of N A D H to N A D superscript plus and release of P subscript i.

The structure of glyceraldehyde 3-phosphate is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is single bonded to H on the upper left and double bonded to O on the upper right. C 2 is single bonded to H on the left and O H on the right.

Glyceraldehyde 3-phosphate is reversibly converted into dihydroxyacetone phosphate by triose phosphate isomerase. A yellow rectangle labeled glycerol points toward dihydroxyacetone phosphate.

The structure of dihydroxyacetone phosphate is as follows: A central C atom is single bonded to C H 2 O H on the upper right, double bonded to O on the left, and single bonded to C H 2 O P O 3 superscript 2 minus on the lower right.

Glyceraldehyde 3-phosphate and dihydroxyacetone phosphate are reversibly converted into fructose 1, 6-bisphosphate.

The structure of fructose 1, 6-bisphosphate is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 occupies the rightmost vertex and is single bonded to C H 2 O P O 3 superscript 2 minus above and O H below. C 2 is single bonded to O H above. C 3 is single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 superscript 2 minus above.

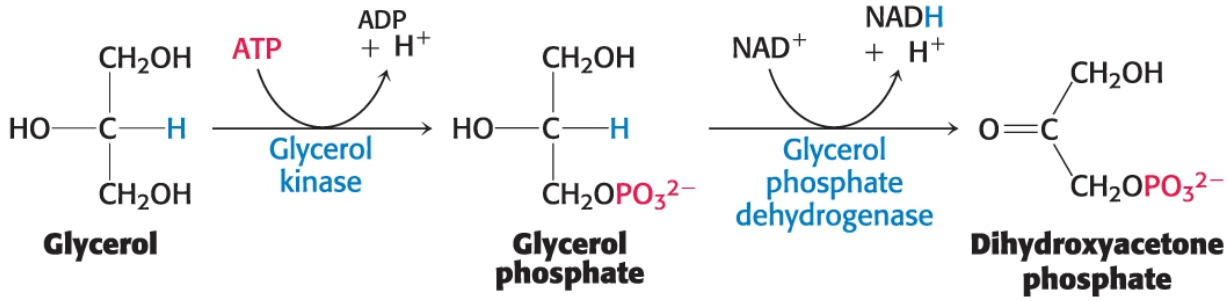
Fructose 1, 6-bisphosphate is irreversibly converted into fructose 6-phosphate by fructose 1, 6-bisphosphatase. This conversion requires

the entry of H 2 O and exit of P subscript i.

The structure of fructose 6-phosphate is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 occupies the rightmost vertex and is single bonded to C H 2 O H above and O H below. C 2 is single bonded to O H above. C 3 is single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 superscript 2 minus above.

Fructose 6-phosphate is reversibly converted into glucose 6-phosphate by phosphoglucose isomerase.

The structure of glucose 6-phosphate is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1 occupies the rightmost vertex and is single bonded to O H below. C 2 is single bonded to O H below. C 3 is single bonded to O H above. C 4 is single bonded to O H below. C 5 is single bonded to C H 2 O P O 3 superscript 2 minus above.



Glucose 6-phosphate is irreversibly converted into glucose by glucose 6-phosphatase. This conversion requires the entry of H 2 O and the release of P subscript i.

The structure of glucose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1 occupies the rightmost vertex and is single bonded to O H below. C 2 is single bonded to O H below. C 3 is single bonded to O H above. C 4 is single bonded to O H below. C 5 is single bonded to C H 2 O H above.

The steps from pyruvate to glyceraldehyde 3-phosphate are enclosed by a left curly bracket labeled 2 times.

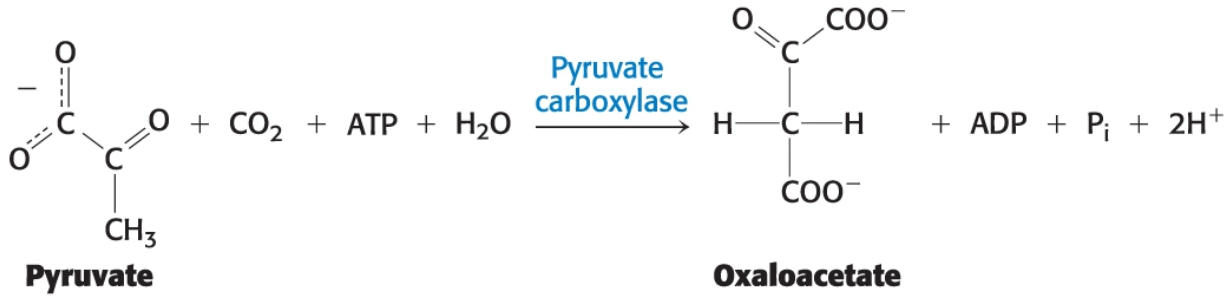
Return to Gluconeogenesis pathway

Extended description for Formation of dihydroxyacetone phosphate from glycerol

The formation of dihydroxyacetone phosphate from glycerol takes place in two irreversible steps.

In the first step, glycerol is converted into glycerol phosphate. The structure of glycerol is as follows: C H 2 O H, single bond, C, single bond, C H 2 O H. C 2 is single bonded to O H on the left and H on the right.

A forward reaction arrow labeled glycerol kinase leads to glycerol phosphate. A curved arrow above it shows the simultaneous breakdown of A T P into A D P plus H superscript plus.



The structure of glycerol phosphate is as follows: C H 2 O H, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 2 is single bonded to O H on the left and H on the right. In the second step, glycerol phosphate is converted into dihydroxyacetone phosphate.

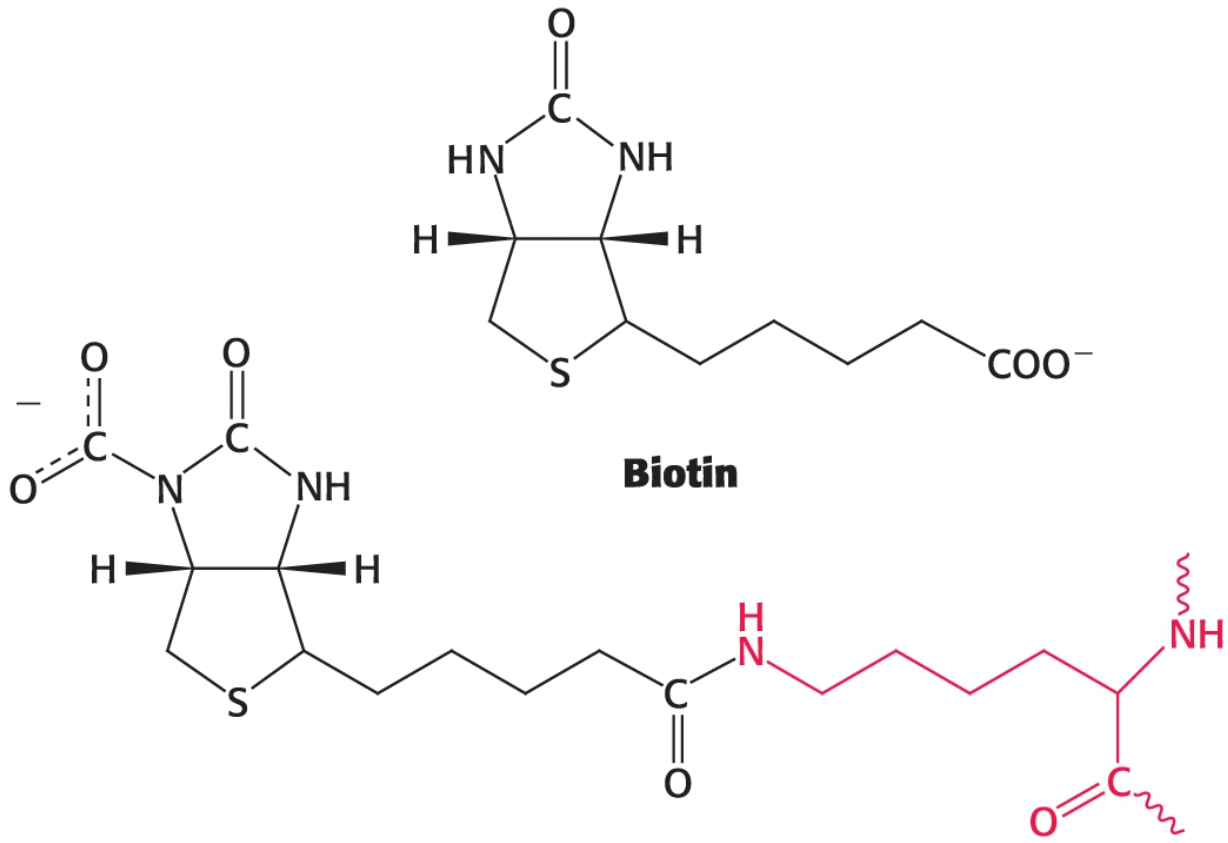
A forward reaction arrow labeled glycerol phosphate dehydrogenase leads to dihydroxyacetone phosphate from glycerol phosphate. A curved arrow above it shows the simultaneous reduction of N A D superscript plus to N A D H plus H superscript plus.

The structure of dihydroxyacetone phosphate is as follows: A central C atom is single bonded to C H 2 O H on the upper right, double bonded to O on the left, and single bonded to C H 2 O P O 3 superscript 2 minus on the lower right.

Return to Formation of dihydroxyacetone phosphate from glycerol

Extended description for Formation of oxaloacetate from pyruvate

The chemical reaction consists of four reactants and four products. The first reactant is pyruvate whose structure is as follows: A central C atom is double bonded to O on the upper right, single bonded to C H 3 below, and single bonded to C on the upper left. This C atom is partially double bonded to O above and O on the lower left. This C O O group has an overall negative charge. The second reactant is C O 2. The third reactant is A T P. The fourth reactant is H 2 O.



A forward reaction arrow labeled pyruvate carboxylase leads to the products.

The first product is oxaloacetate whose structure is as follows: C, single bond, C, single bond, C O O superscript minus. C 1 is double bonded to O on the upper left and single bonded to C O O superscript minus on the upper right. C 2 is single bonded to H on the left and H on the right.

The second product is A D P. The third product is P subscript i. The fourth product is 2 H superscript plus.

Return to Formation of oxaloacetate from pyruvate

Extended description for Structures of biotin and carboxybiotin covalently bound to the epsilon-amino group of a lysine

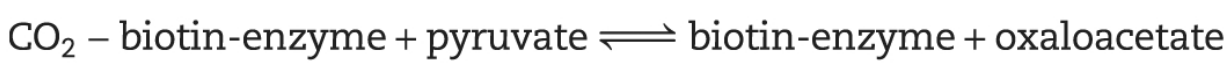
Carboxybiotin covalently bound to ε-amino group of a lysine

The structure of biotin is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 2 N and 3 C atoms. First N bound to H occupies the first position, which is the top left vertex. The second N bound to H occupies the third position, which is the top right vertex. C 1 occupies the topmost vertex and is double bonded to O above. This ring is fused to another 5-membered heterocyclic pentagonal ring in a vertical orientation such that C 2

and C 3 of the first pentagonal ring are C 3 and C 2 respectively of the second ring. The second pentagonal ring consists of 1 S and 4 C atoms. S occupies the first position, which is the bottom-most vertex. C 2 is wedge bonded to H on the left. C 3 is wedge bonded to H on the right. C 4 is single bonded to a 4-carbon alkane chain depicted as a line structure using 3 zigzag lines. C 4 is single bonded to C O O superscript minus on the lower right.

The structure of carboxybiotin covalently bound to the epsilon-amino group of lysine is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 2 N and 3 C atoms. The first N bound occupies the first position, which is the top left vertex. The second N bound to H occupies the third position, which is the top right vertex. C 1 occupies the topmost vertex and is double bonded to O above. N 1 is single bonded to C on the upper left. This C atom is partially double bonded to O above and O on the lower left. This C O O group has an overall negative charge. This pentagonal ring is fused to another 5-membered heterocyclic pentagonal ring in a vertical orientation such that C 2 and C 3 of the first pentagonal ring are C 3 and C 2 respectively of the second ring. The second pentagonal ring consists of 1 S and 4 C atoms. S occupies the first position, which is the bottom-most vertex. C 2 is wedge bonded to H on the left. C 3 is wedge bonded to H on the right. C 4 is single bonded to a 1 N and 10 C alkane chain depicted as a line structure using 10 zigzag lines. The N atom occupies the sixth position and is bound to H. C 5 is double bonded to O below. C 11 is single bonded to N H on the upper right with a wavy line at the top and single bonded to C below. This C atom is double bonded to O on the lower left and has a wavy line on the lower right. N 6 to C 11 and their substituent groups are shown in red.

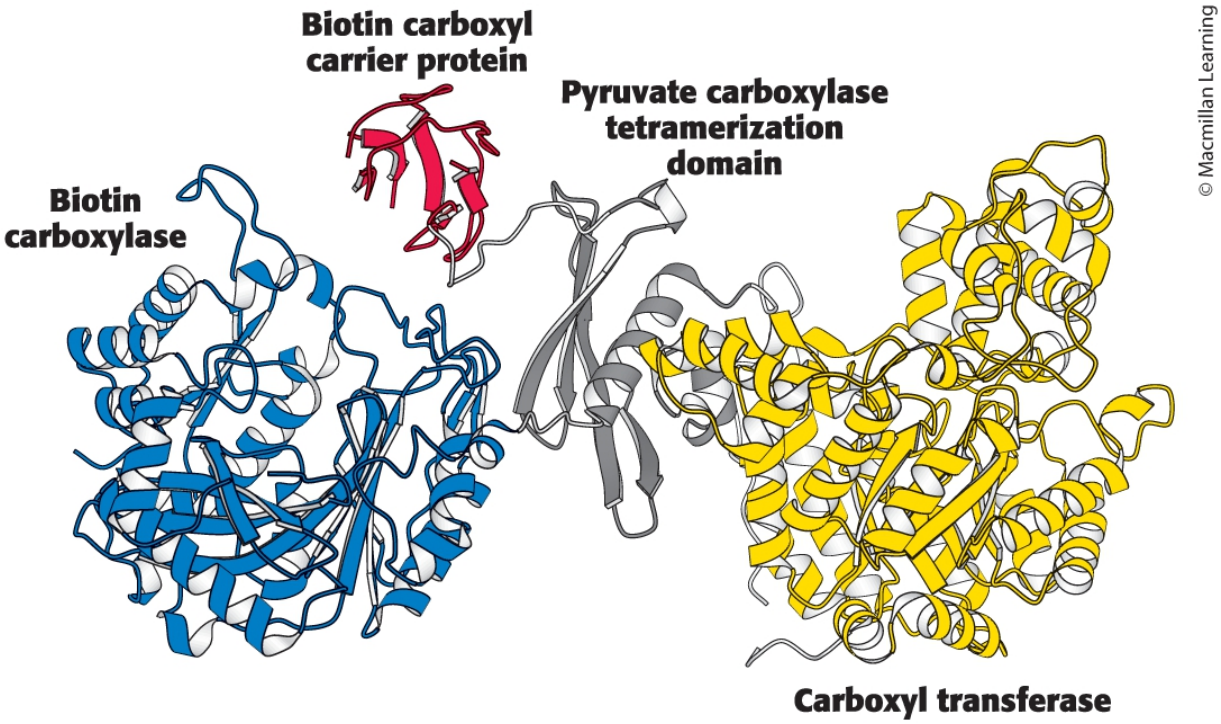
Return to Structures of biotin and carboxybiotin covalently bound to the epsilon-amino group of a lysine



Extended description for First stage of pyruvate carboxylation

The reaction consists of two reactants and two products. The first reactant is H C O 3 superscript minus. The second reactant is A T P. The first product is H O C O 2, single bond, P O 3 superscript 2 minus. The second product is A D P.

Return to First stage of pyruvate carboxylation



Extended description for Final stage of pyruvate carboxylation

The reaction consists of two reactants and two products. The first reactant is C O 2, single bond, Biotin-enzyme. The second reactant is pyruvate. The first product is biotin-enzyme. The second product is oxaloacetate.

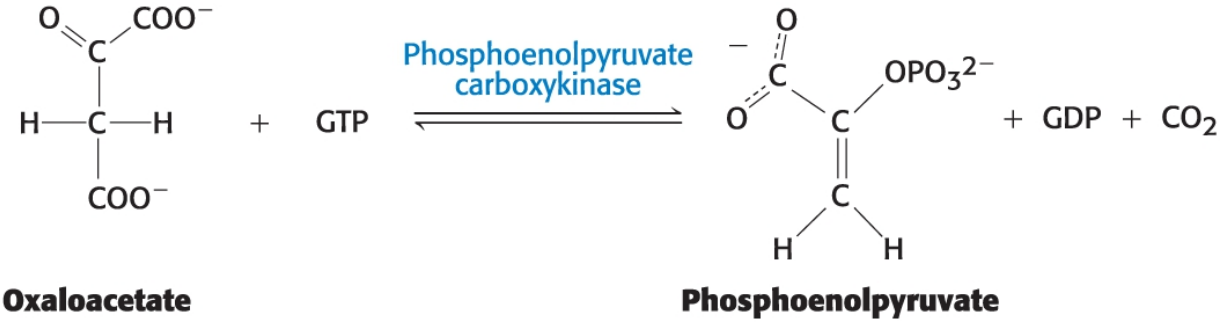
Return to Final stage of pyruvate carboxylation

Extended description for Ribbon diagrams of pyruvate carboxylase subunits

The four subunits of pyruvate carboxylase are biotin carboxylase, biotin carboxyl carrier protein, pyruvate carboxylase tetramerization domain, and carboxyl transferase. The biotin carboxylase subunit consists of a compact and large cluster of several alpha-helices and beta strands. They are interconnected by long threads.

The biotin carboxyl carrier protein is a small structure composed of 5 beta-strands interconnected by long thread-like loops.

The pyruvate carboxylase tetramerization domain is located between the biotin carboxylase and carboxyl transferase subunits. It



consists of four long and vertical beta-strands and two alpha-helices interconnected by thread-like loops.

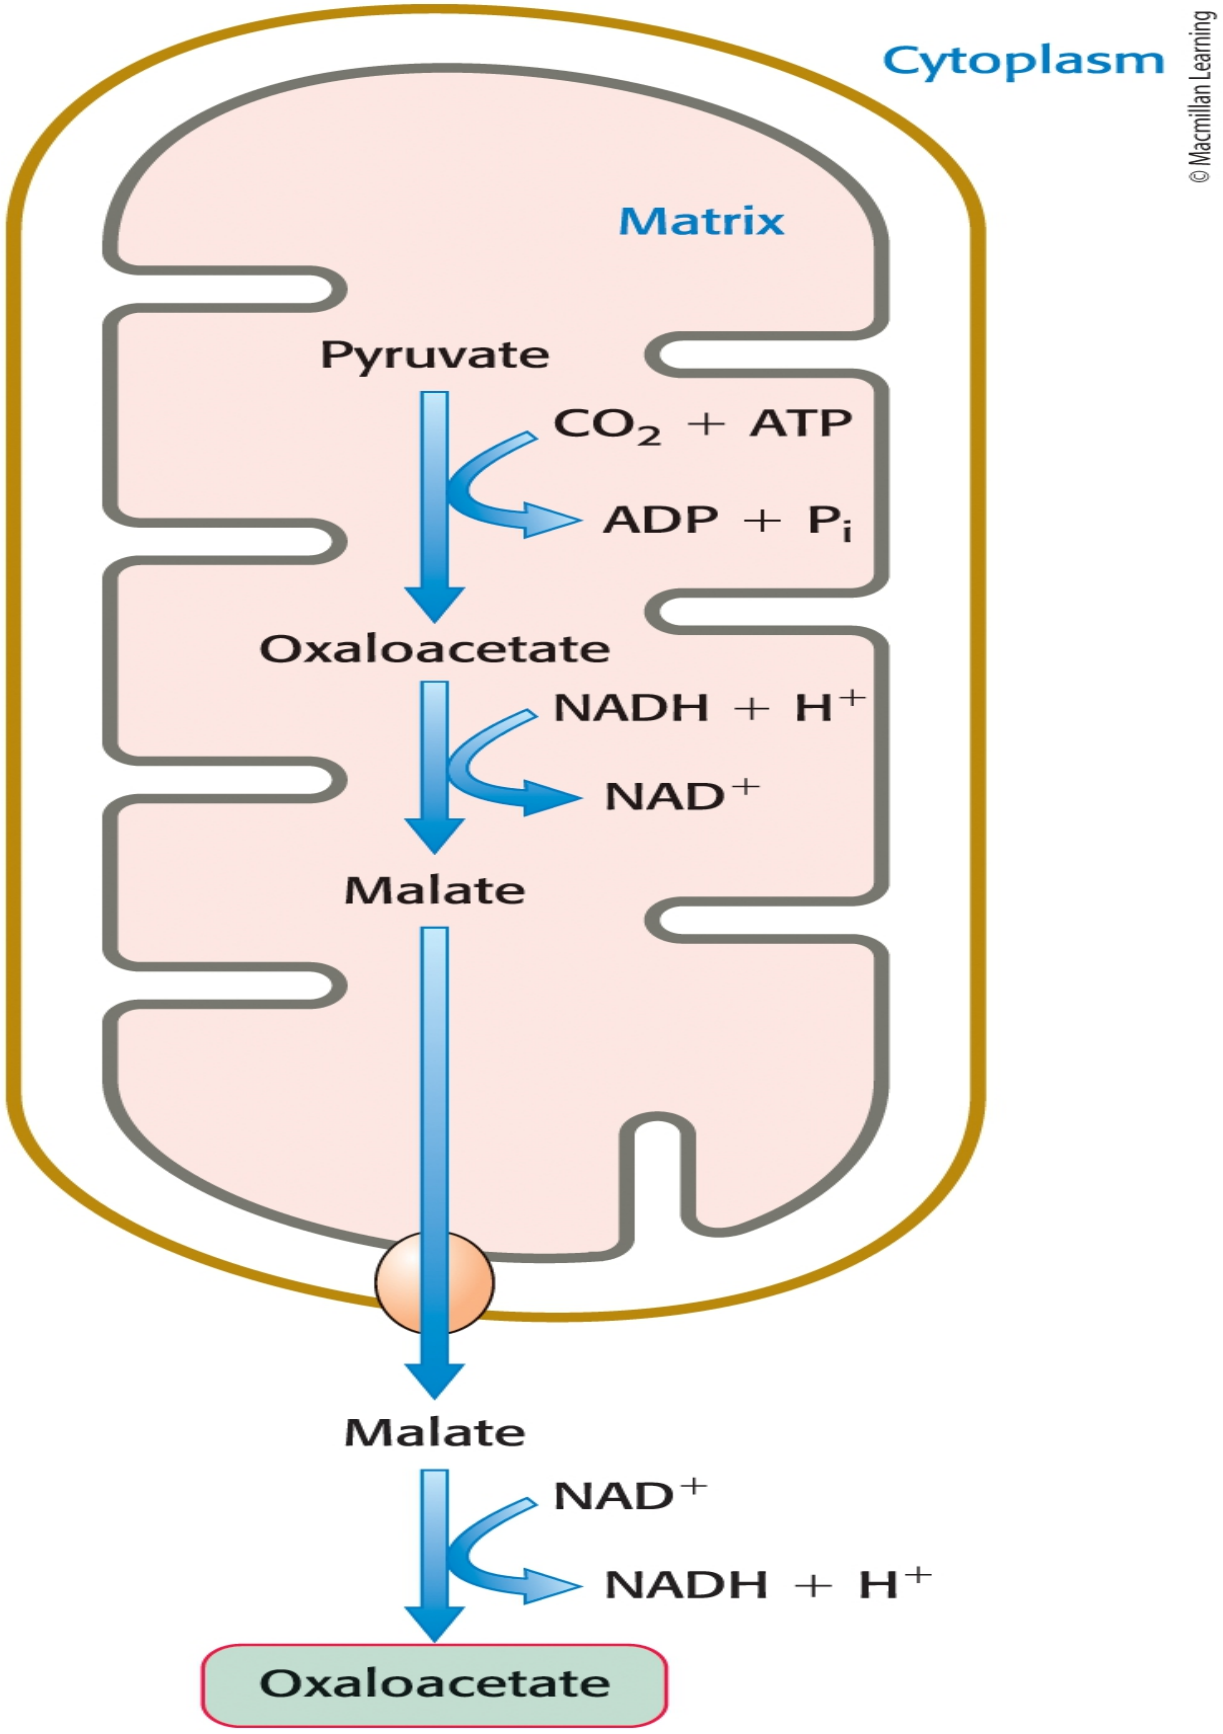
The carboxyl transferase subunit consists of a large cluster of several alpha-helices and few beta-strands interconnected by thread-like loops.

The biotin carboxyl carrier protein subunit is located at the top of the junction between biotin carboxylase and pyruvate carboxylase tetramerization domain.

Return to Ribbon diagrams of pyruvate carboxylase subunits

Extended description for Formation of phosphoenolpyruvate from oxaloacetate

The chemical reaction consists of two reactants and three products. The first reactant is oxaloacetate whose structure is as follows: C, single bond, C, single bond, C O O superscript minus. C 1 is double bonded to O on the upper left and single bonded to C O O superscript minus on the upper right. C 2 is single bonded to H on the left and H on the right. The second reactant is G T P.



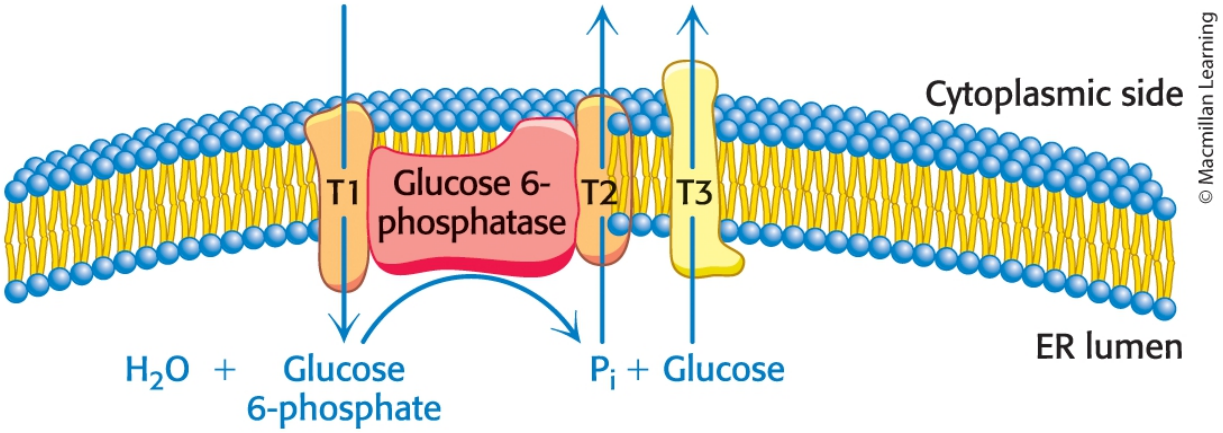
A reversible reaction arrow labeled phosphoenolpyruvate carboxykinase leads to the products.

The first product is phosphoenolpyruvate whose structure is as follows: A central C atom is double bonded to C below, single bonded to O P O 3 superscript 2 minus on the upper right, and single bonded to C on the upper left. The C atom below is single-bonded to H on the lower left and H on the lower right. The C atom on the upper left is partially double bonded to O above and O on the lower left. This C O O group has an overall negative charge. The second product is G D P. The third product is C O 2.

Return to Formation of phosphoenolpyruvate from oxaloacetate

Extended description for Transport of malate produced in the mitochondrial matrix to the cytoplasm and its

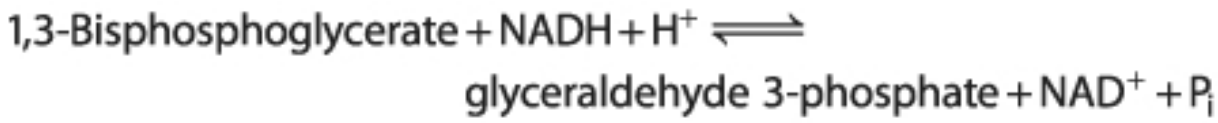
conversion to oxaloacetate



© Macmillan Learning

The mitochondrion is depicted as a big rounded rectangular structure in a vertical orientation. Its inner membrane has invaginations and encloses the matrix. The space outside the mitochondria is labeled cytoplasm. In the matrix, pyruvate is converted into oxaloacetate with the simultaneous breakdown of A T P into A D P plus P subscript i and the incorporation of C O 2. Oxaloacetate is further converted into malate with the simultaneous oxidation of N A D H plus H superscript into N A D superscript plus. The malate molecule moves into the cytoplasm through a transporter depicted as an orange circle between the inner and outer membrane of the mitochondria. In the cytoplasm, malate is converted into oxaloacetate with the simultaneous reduction of N A D superscript plus to N A D H plus H superscript plus.

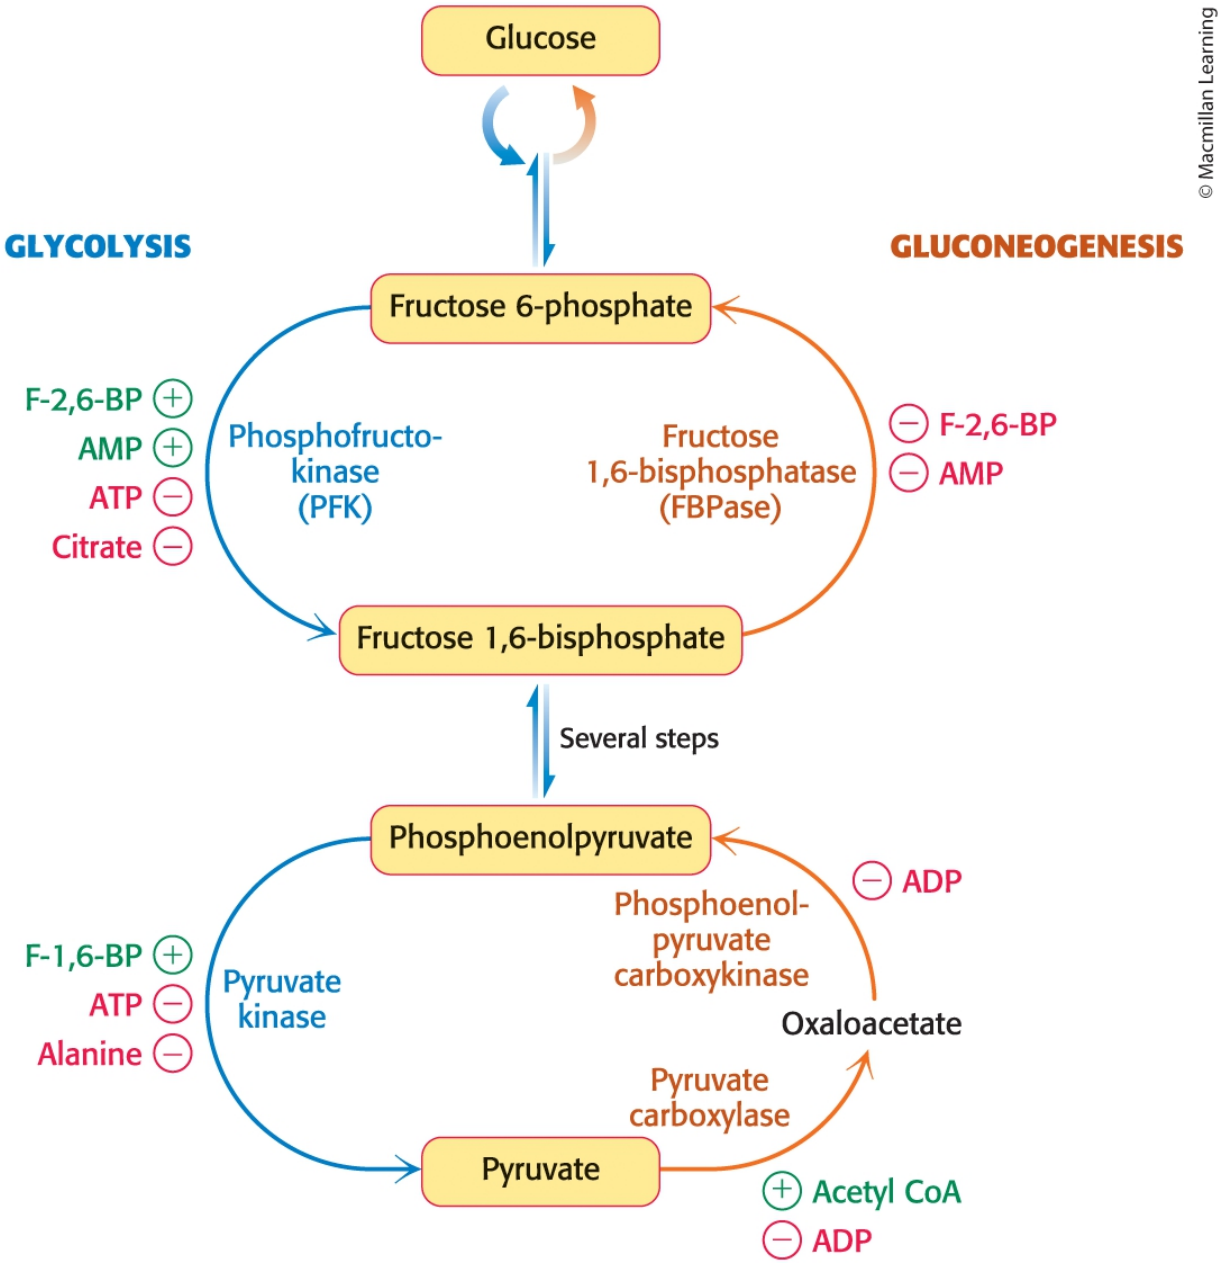
Return to Transport of malate produced in the mitochondrial matrix to the cytoplasm and its conversion to oxaloacetate



Extended description for Formation of free glucose in E R lumen

A section of the lipid bilayer is shown. The region above the bilayer is labeled the cytoplasmic side. The region below the lipid bilayer is labeled E R lumen. A square-shaped glucose 6-phosphatase enzyme with a groove at the top left is shown embedded in the bilayer. It is flanked by two tubular structures embedded in the bilayer and labeled T 1 and T 2. Another long and tubular transmembrane structure labeled T 3 is shown on the right of T 2 with a gap between them. A downward arrow across T 1 shows the entry of glucose 6-phosphate into the E R lumen. In the E R lumen, glucose plus H 2 O are converted into P subscript i plus glucose by glucose 6-phosphatase. Upward arrows across T 2 and T 3 show the exit of P subscript i and glucose respectively into the cytoplasmic side.

Return to Formation of free glucose in E R lumen



Extended description for Step 6 of gluconeogenesis

The reaction consists of 3 reactants and 3 products. The reactants are 1,3-bisphosphoglycerate, N A D H, and H superscript plus. The products are glyceraldehyde 3-phosphate, N A D superscript plus, and P subscript i.

Return to Step 6 of gluconeogenesis

Extended description for Reciprocal regulation of glycolysis and gluconeogenesis

The flowchart is depicted as follows from top to bottom:

A yellow rectangle is labeled glucose. A downward curved below and an upward curved orange arrow is shown below glucose. A blue reversible arrow is shown below the curved arrow and leads to a yellow rectangle labeled fructose 6-phosphate.

A downward curved blue arrow below fructose 6-phosphate is labeled phosphofructokinase (P F K) and leads to fructose 1, 6-bisphosphate.

An upward curved orange arrow above fructose 1, 6-bisphosphate is labeled fructose 1, 6-bisphosphatase (F B P ase) and leads to fructose 6-phosphate.

A reversible reaction arrow below fructose 1, 6-bisphosphate is labeled several steps and leads to phosphoenolpyruvate.

A downward curved blue arrow below phosphoenolpyruvate is labeled pyruvate kinase and leads to pyruvate.

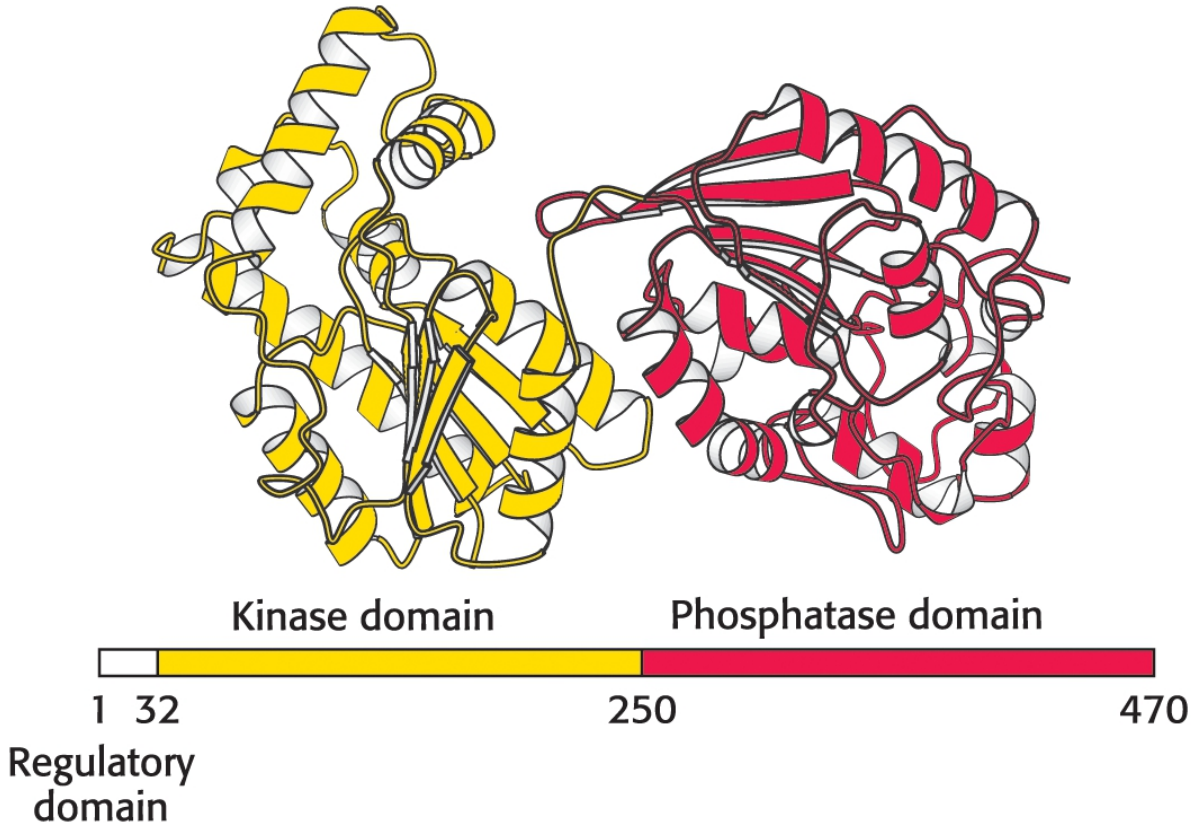
An upward curved orange arrow above pyruvate is labeled pyruvate carboxylase and leads to oxaloacetate.

An upward curved orange arrow above oxaloacetate is labeled phosphoenol pyruvate carboxykinase and leads to phosphoenolpyruvate.

The left side of the flowchart shown by blue arrows depicts glycolysis and the right side shown by orange arrows depicts gluconeogenesis.

The activators of phosphofructokinase are F-2, 6-B P and A M P and its inhibitors are A T P and citrate.

The activator of pyruvate kinase is F-1, 6-B P and its inhibitors are A T P and alanine.



The activator of pyruvate carboxylase is acetyl C o A and its inhibitor is A D P.

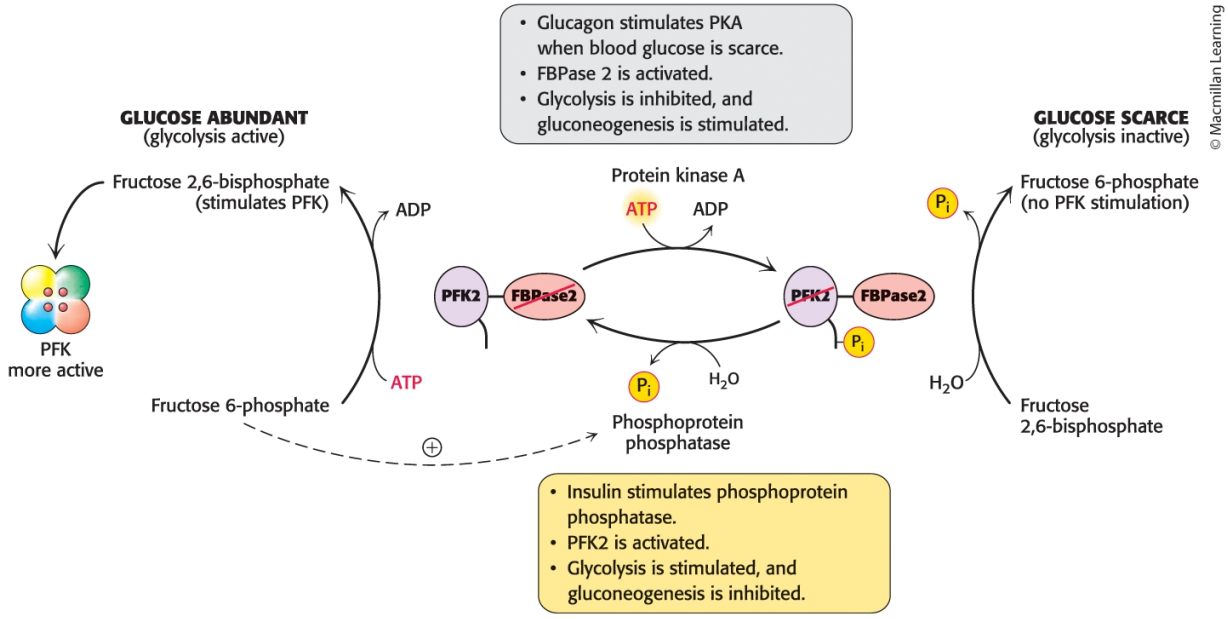
The inhibitor of phosphoenolpyruvate carboxykinase is A D P.

The inhibitors of fructose 1, 6-bisphosphatase are F-2, 6-B P and A M P.

Return to Reciprocal regulation of glycolysis and gluconeogenesis

Extended description for Schematic representation and ribbon diagram of the domains of P F K 2 slash F B P ase 2

© Macmillan Learning



The schematic representation shows a narrow rectangular bar. Its left and right ends are labeled 1 and 470 respectively. A marking near the left end is labeled 32 and another marking in the middle is labeled 250. The region between 1 to 32 is shown in the white and labeled regulatory domain. The region between 32 and 250 is shown in the yellow and labeled kinase domain. The region between 250 and 470 is shown in red and labeled phosphatase domain.

The ribbon diagram of the kinase domain consists of several alpha-helices and a few beta-strand in the center interconnected by

thread-like loops. It is connected to a ribbon diagram of the phosphate domain composed of a few alpha-helices and beta-strands at the top interconnected by long loops.

Return to Schematic representation and ribbon diagram of the domains of P F K 2 slash F B P ase 2

Extended description for Hormonal regulation of synthesis and degradation of fructose 2, 6-bisphosphate

P F K 2 slash F B P ase 2 is depicted as a purple circle connected to a pink oval. In the initial state, F B P ase 2 has a red diagonal line. Protein kinase A carries out the phosphorylation of P F K 2 with the simultaneous breakdown of A T P to A D P. In the phosphorylated state, a red diagonal line is drawn across P F K 2 and an overhang originating from it is single bonded to P subscript i. Phosphoprotein phosphatase carries out the removal of P subscript i from P F K 2 with the simultaneous entry of H 2 O and release of P subscript i.

A text box above protein kinase A mentions the following points:

Glucagon stimulates P K A when blood glucose is scarce.

F B P ase 2 is activated.

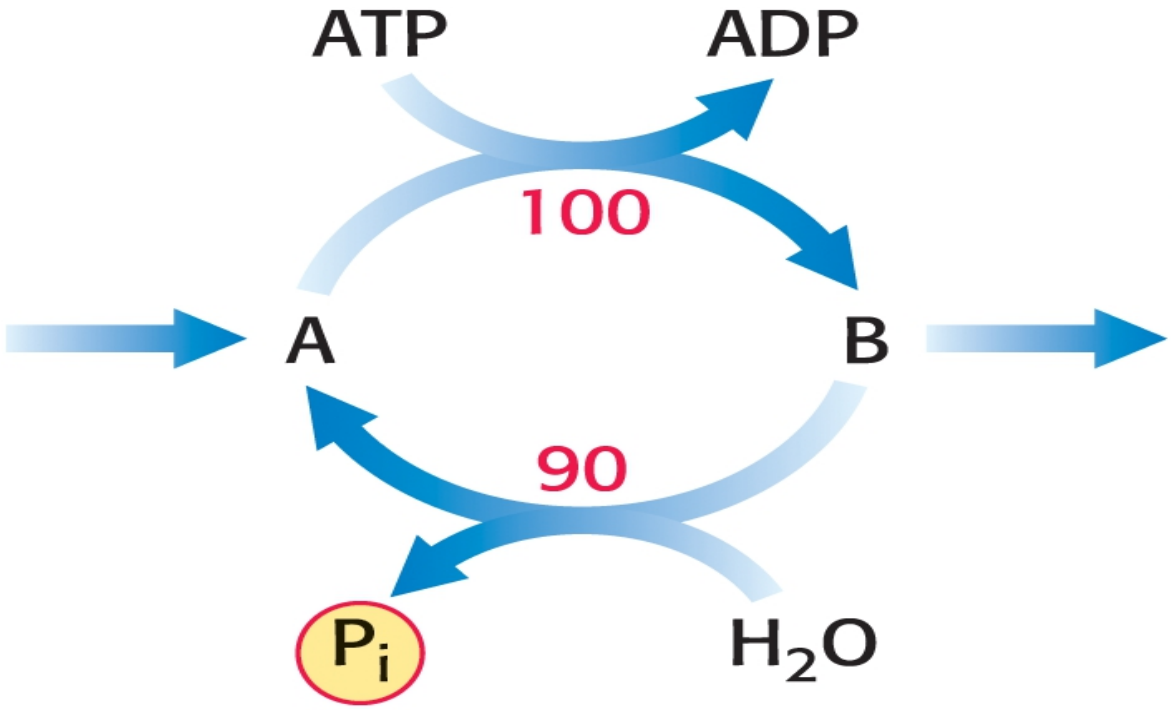
Glycolysis is inhibited, and gluconeogenesis is stimulated.

A text box below phosphoprotein phosphatase mentions the following points:

Insulin stimulates phosphoprotein phosphatase.

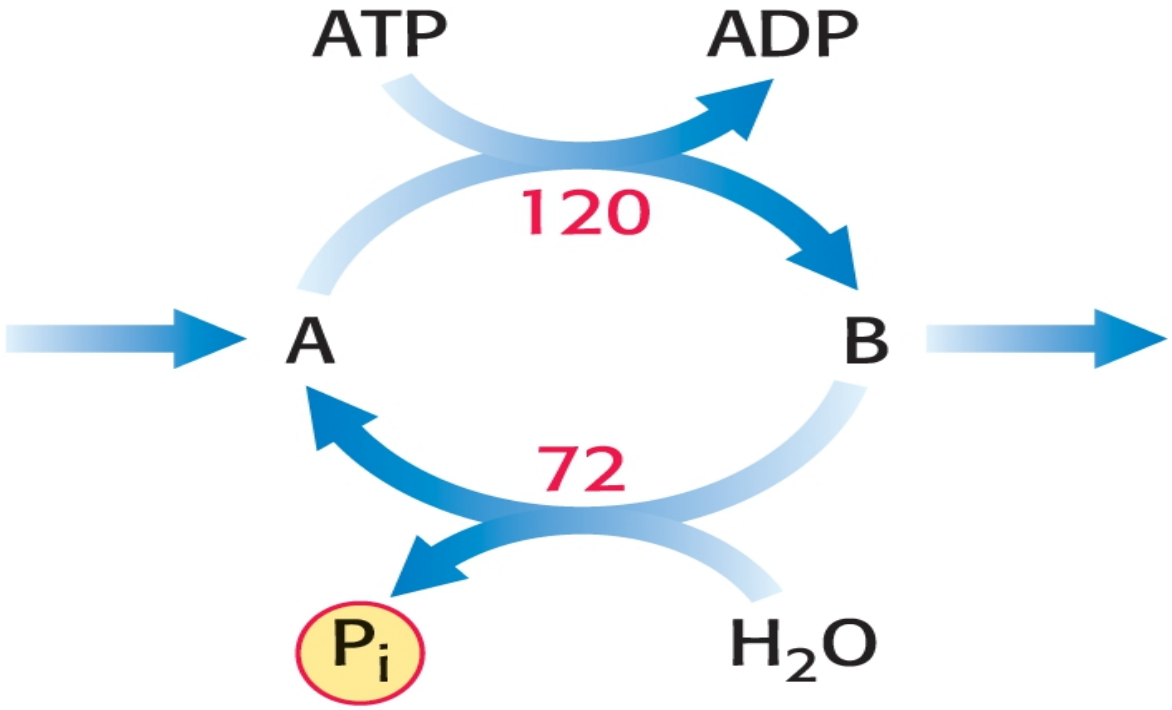
P F K 2 is activated.

Glycolysis is stimulated, and gluconeogenesis is inhibited.



In the case of abundant glucose (glycolysis active), fructose 6-phosphate is phosphorylated to fructose 2, 6-bisphosphate with the simultaneous breakdown of A T P to A D P. Fructose 2, 6-bisphosphate stimulates P F K. It binds to P F K to make it more active. A dashed arrow from fructose 6-phosphate points toward phosphoprotein phosphatase and is labeled with a plus symbol.

In case of scarce glucose (glycolysis inactive), fructose 2, 6-bisphosphate is converted into fructose 6-phosphate with simultaneous uptake of H 2 O and release of P subscript i. Fructose 6-phosphate does not cause P F K stimulation.



Return to Hormonal regulation of synthesis and degradation of fructose 2, 6-bisphosphate

Extended description for Different rates of operation of

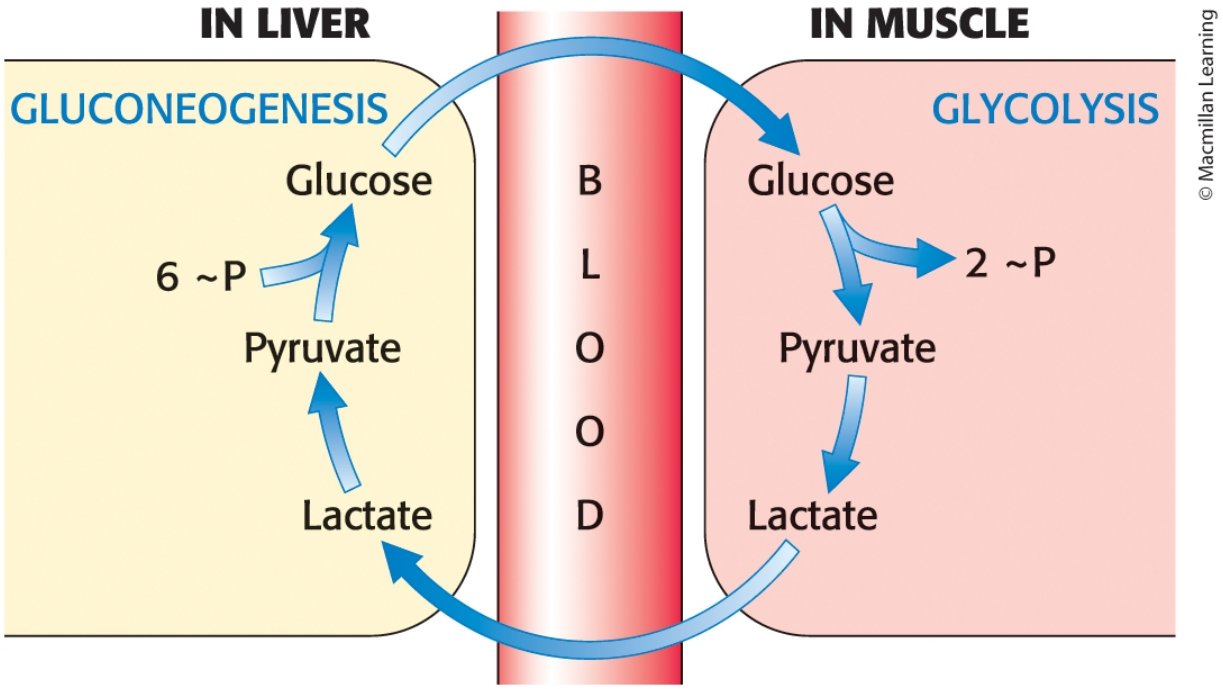
a A T P-driven cycle

Net flux of B = 10

Net flux of B = 48

© Macmillan Learning

The first cycle is depicted as follows:

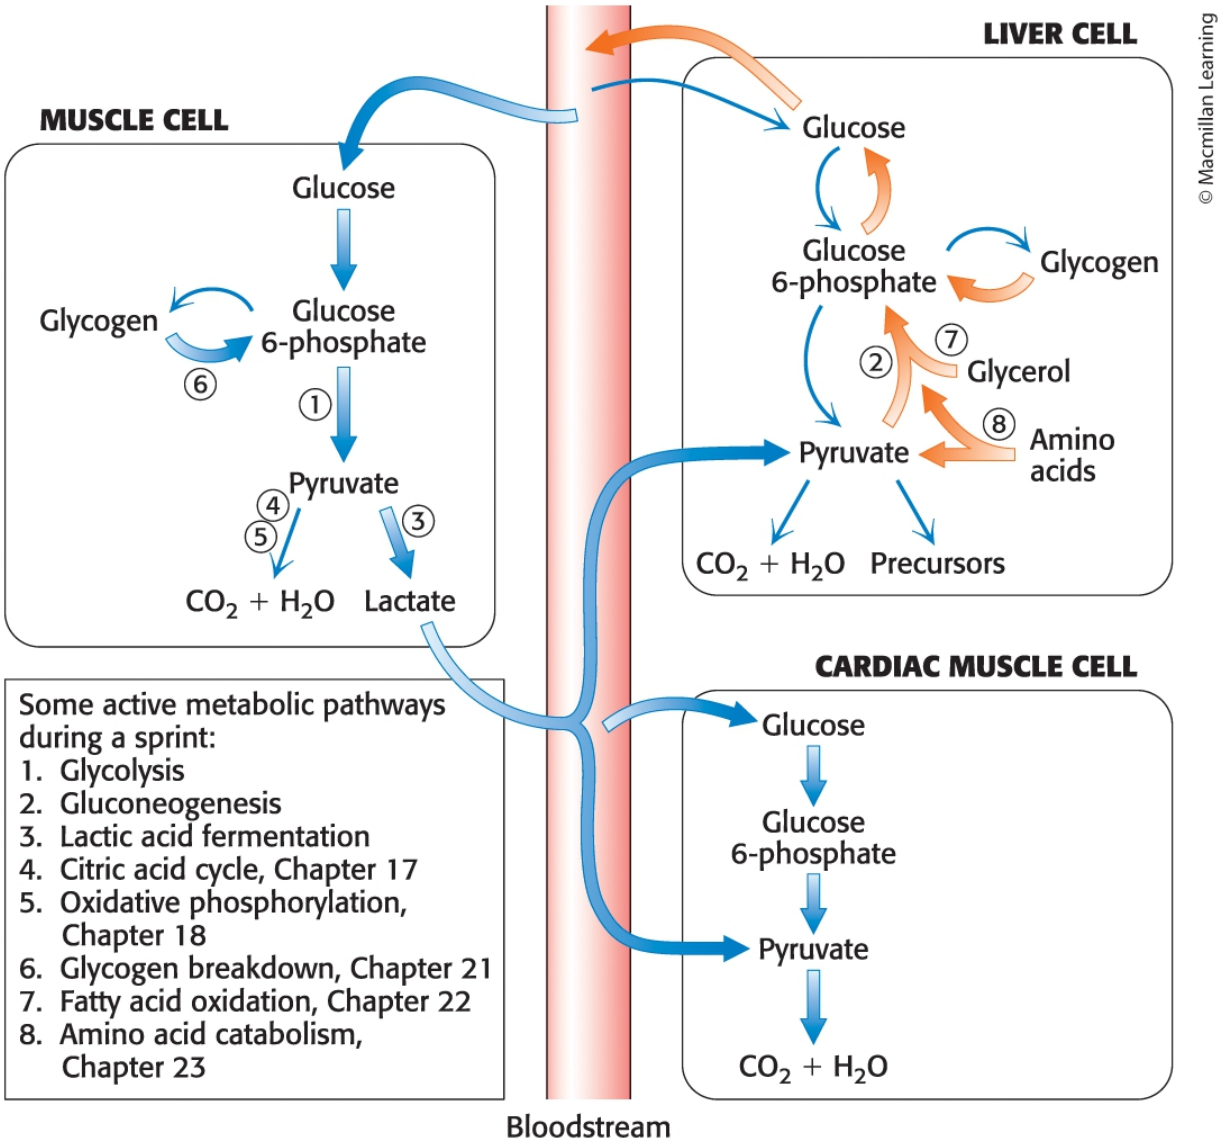


A forward arrow shows the entry of A. A curved arrow at the top of A is labeled 100 and leads to B. Another curved arrow above it shows the simultaneous breakdown of A T P into A D P. A forward arrow shows the exit of B. A curved arrow below B is labeled 90 and leads back to A. Another curved arrow below it shows the entry of H 2 O and the release of P subscript i. The net flux of B equals 10.

The second cycle is depicted as follows:

A forward arrow shows the entry of A. A curved arrow at the top of A is labeled 120 and leads to B. Another curved arrow above it shows the simultaneous breakdown of A T P into A D P. A forward arrow shows the exit of B. A curved arrow below B is labeled 72 and leads back to A. Another curved arrow below it shows the entry of H 2 O and the release of P subscript i. The net flux of B equals 48.

Return to Different rates of operation of a A T P-driven cycle



Extended description for Cori cycle

The illustration shows three different compartments. The central compartment is labeled blood and is long and cylindrical. The left compartment is a half-rectangle labeled "In liver." The right compartment is also a half-rectangle labeled "In muscle." In muscle, glycolysis is depicted as follows: Glucose is converted into pyruvate with the release of 2 wavy line P which presents 2 nucleoside triphosphates. Pyruvate is further converted into lactate. This lactate travels to the liver compartment through the blood compartment. In the liver, gluconeogenesis is depicted as follows: Lactate is converted into pyruvate. Pyruvate is further converted into glucose with the use of 6 wavy line P which represents 6 nucleoside triphosphates. The glucose molecule travels back to the muscle compartment through the blood compartment.

Return to Cori cycle

Extended description for Cooperation between glycolysis and gluconeogenesis during a sprint

© Macmillan Learning

Three rectangular compartments are shown separated by a bloodstream depicted as a long vertical cylindrical structure. These rectangular compartments are labeled muscle cell, liver cell, and cardiac muscle cell. The muscle cell is shown on the left of the

bloodstream and the liver cell and cardiac muscle cell are shown on the right of the bloodstream.

Inside the muscle cell, glucose is converted into glucose 6-phosphate. A curved arrow labeled 6 points from glycogen toward glucose 6-phosphate. Another curved arrow above it points back to glycogen. A downward arrow labeled 1 point from glucose 6-phosphate to pyruvate.

A downward arrow labeled 4 and 5 points from pyruvate to C O 2 plus H 2 O. Another downward arrow labeled 3 points from pyruvate to lactate.

Lactate moves into the liver cell and cardiac muscle cell via the bloodstream.

Glucose enters and exits the liver cell via the bloodstream. Two curved arrows pointing upward and downward are shown below glucose and they lead to glucose 6-phosphate. Two curved arrows pointing rightward and leftward are shown adjacent to glucose 6-phosphate and they lead to glycogen.

A two-way arrow labeled 8 points from amino acids in the liver cell toward pyruvate and in the upward direction. Two arrows labeled 2 and 7 from pyruvate and glycerol respectively, merge together, above the upward pointing head of arrow 8, and point toward glucose 6-phosphate. A downward curved arrow from glucose 6-phosphate point toward pyruvate below. Pyruvate is converted into C O 2 plus H 2 O or precursors.

Glucose enters the cardiac muscle cell through the bloodstream. It is converted into glucose 6-phosphate which is further converted into pyruvate. Pyruvate is ultimately converted into C O 2 plus H 2 O.

A key below the muscle cell compartment lists the following points below the heading "Some active metabolic pathways during a sprint:"

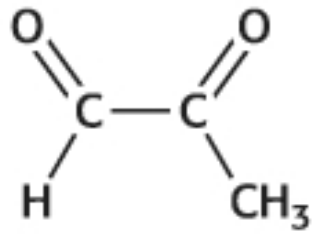
1. Glycolysis

2. Gluconeogenesis

3. Lactic acid fermentation

4. Citric acid cycle, Chapter 17

5. Oxidative phosphorylation, Chapter 18



6. Glycogen breakdown, Chapter 21

7. Fatty acid oxidation, Chapter 22

8. Amino acid catabolism, Chapter 23

Extended description for Activity of P F K and F B P ase in different bumblebee species

The horizontal axis has markings for different bumblebee species from left to right. These are *B. terrestris, B. affinis, B. bimaculatus, B. impatiens, B. vagans, B. perplexus, B. rufocinctus, B. griseocollis, P. citrinus*. The vertical axis is labeled enzyme activity in units per gram. It has markings ranging from 0 to 140 in increments of 20 units. Two vertical bars in blue and red colors are shown for each bumblebee species. The height of these vertical bars is as follows:

B. terrestris: Blue bar: 75 units per gram, Red bar: 40 units per gram.

B. affinis: Blue bar: 50 units per gram, Red bar: 5 units per gram.

B. bimaculatus: Blue bar: 92 units per gram, Red bar: 8 units per gram.

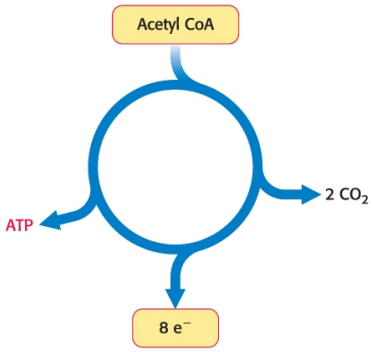
B. impatiens: Blue bar: 100 units per gram, Red bar: 0.5 units per gram.

B. vagans: Blue bar: 120 units per gram, Red bar: 20 units per gram.

B. perplexus: Blue bar: 90 units per gram, Red bar: 21 units per gram.

B. rufocinctus: Blue bar: 100 units per gram, Red bar: 50 units per gram.

B. griseocollis: Blue bar: 91 units per gram, Red bar: 5 units per gram.



P. citrinus: Blue bar: 60 units per gram, Red bar: 0 units per gram.

All values are estimated.

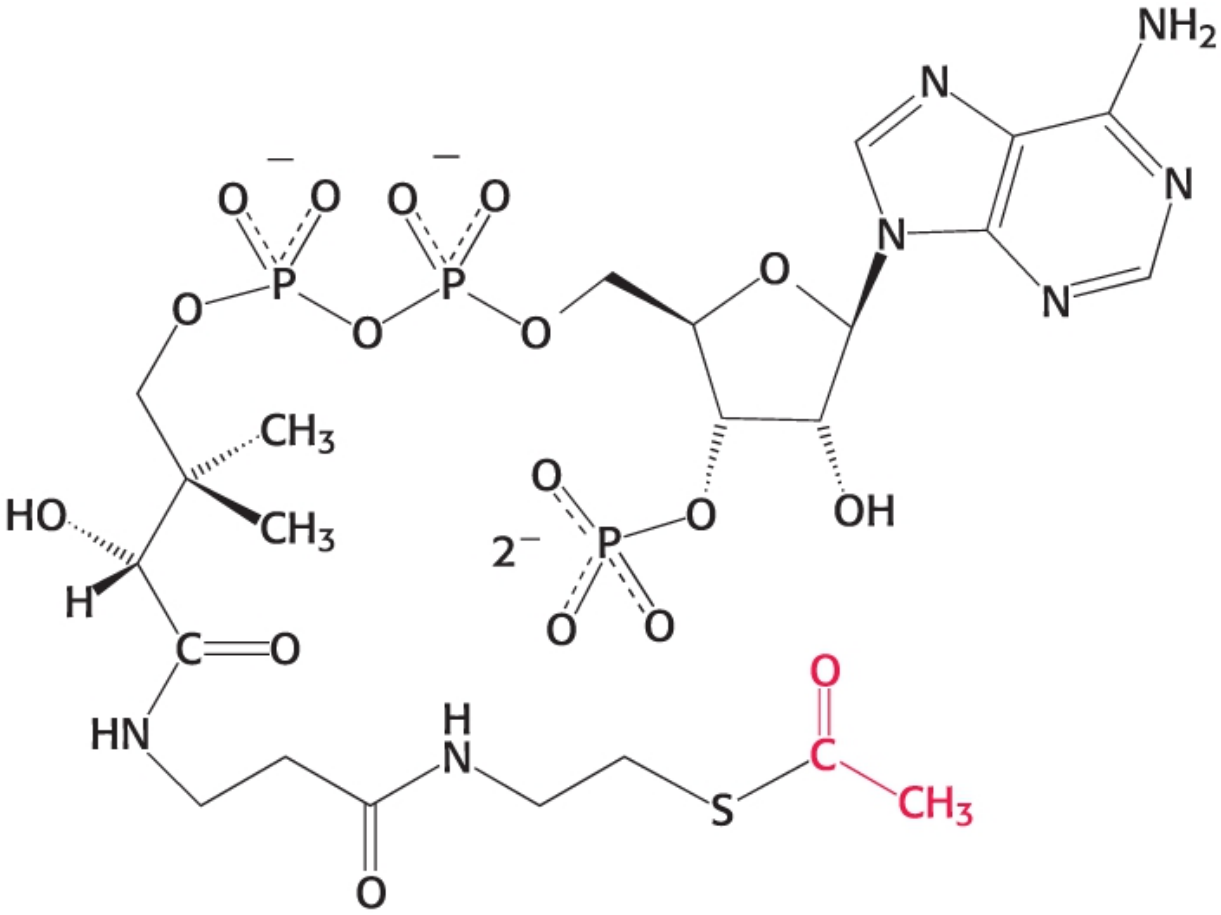
Extended description for Schematic representation of the citric acid cycle



Chalermkiat Seedokmai/Getty Images
© Macmillan Learning

The citric acid cycle is depicted as a large circle with a thick blue outline. A line from a rectangle labeled acetyl C o A merges with the top of the large circle. An outward arrow from the right side of the large circle shows the exit of 2 C O 2. A downward arrow from the bottom of the large circle shows the exit of 8 electrons. An outward arrow from the bottom right of the large circle shows the exit of A T P.

Return to Schematic representation of the citric acid cycle

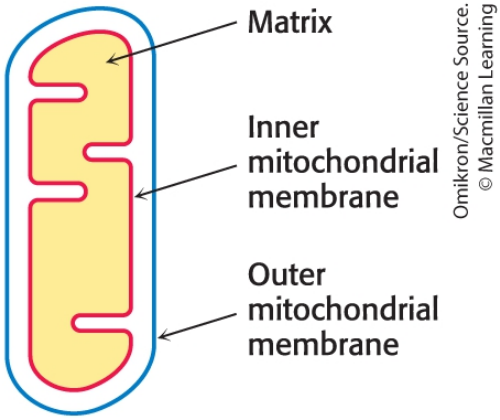
Extended description for Structure of acetyl coenzyme A or acetyl C o A

Acetyl coenzyme A (Acetyl CoA)

The structure of acetyl coenzyme A is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 occupies the top right vertex and is wedge bonded to N 1 of another 5-membered heterocyclic pentagonal ring in a horizontal orientation. This pentagonal ring consists of 2 N and 3 C atoms. The first N occupies the first position, which is the bottom left vertex. The second N occupies the third position, which is the topmost vertex. C

1 occupies the leftmost vertex. A double bond is present between C 1 and N 2. This pentagonal ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively, of the hexagonal ring. The hexagonal ring consists of 2 N and 4 C atoms. The first N occupies the first position, which is the top-right vertex. The second N occupies the third position, which is the bottommost vertex. C 1 occupies the bottom right vertex. A double bond is present between C 1 and N 2, C 2 and C 3, and C 4 and N 1. C 4 is single bonded to N H 2 above.

In the first pentagonal ring, C 2 is dash bonded to O H on the lower right, and C 3 is dashed bonded to O on the lower left. This O is single bonded to a central P atom which is further partially double bonded to O on the upper left, O on the lower left, and O on the lower right. These O atoms have an overall negative charge of 2 minus. C 4 is wedge bonded to C H 2 on the upper left in the form of a wedged line. This C H 2 is single bonded to a zigzag chain composed of O, single bond, P, single bond, O, single bond, P, single bond, O. Each P atom of this chain is partially double bonded to O on the upper left and O on the upper right. These O atoms have an overall negative charge.



O 3 of the zigzag chain is single bonded to C 1 of a 1 S, 2 N, and 10 C alkane chain depicted as a line structure using 12 zigzag lines. The first and second N atoms occupy the fifth and ninth positions and both are bound to H. S occupies the twelfth position. C 2 is dash bonded to C H 3 on the upper right and wedge bonded to C H 3 on the lower right. C 3 is dash bonded to O H on the upper left and wedge bonded to H on the lower right. C 4 is double bonded to O on the right. C 7 is double bonded to O below. C 10 highlighted in red is double bonded to O above and single bonded to C H 3 on the lower right, both highlighted in red. The alkane chain is in a vertical

orientation from C 1 to N 1 and a horizontal orientation from C 5 to C 10.

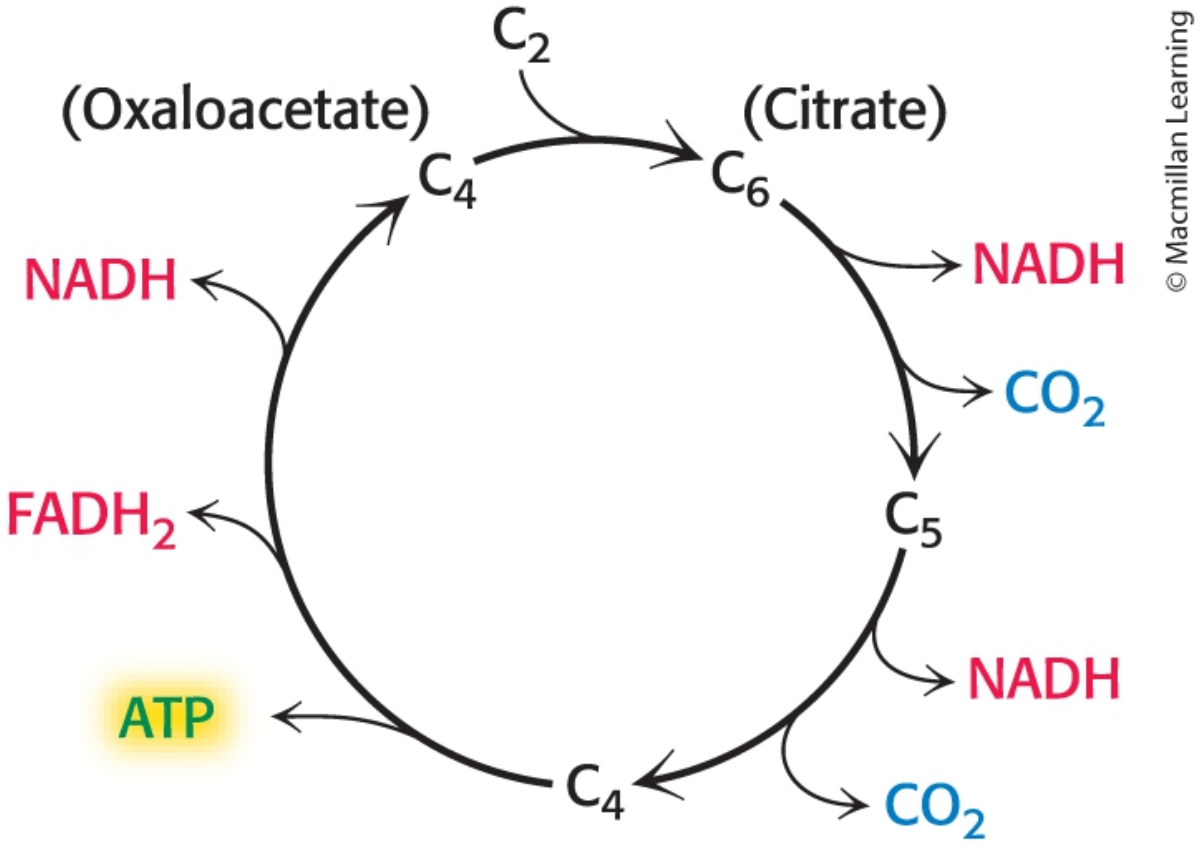
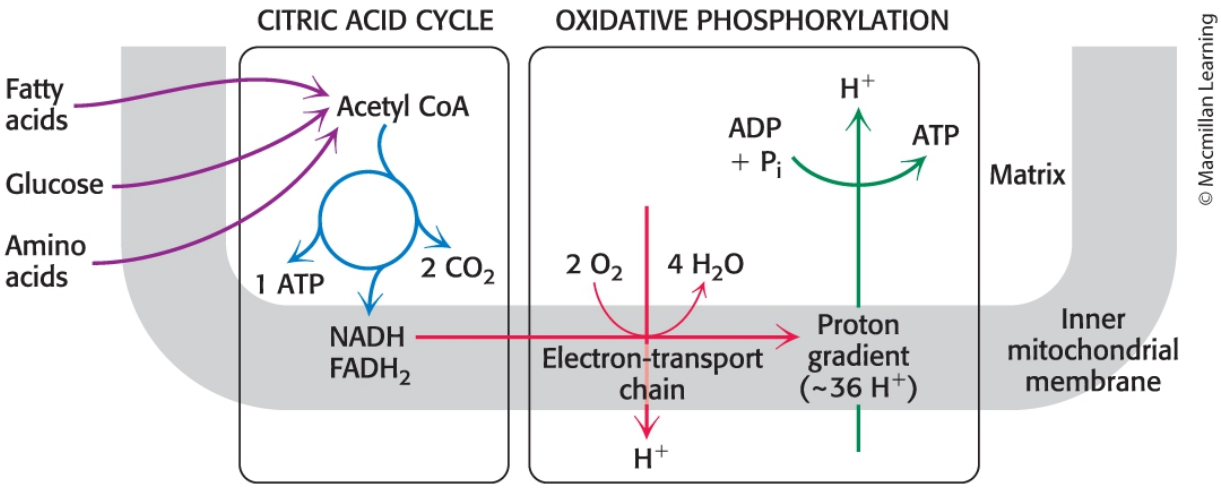
Extended description for Electron micrograph and schematic illustration of a mitochondrion



The electron micrograph shows an elongated mitochondrion with invaginations of membrane extending into the matrix. The schematic illustration shows a vertically elongated rod-shaped structure with a blue outline labeled outer mitochondrial membrane. The inner mitochondrial membrane inside the outer membrane is shown in red. It is invaginated several times to form short rectangular grooves. The space inside the inner mitochondrial membrane is labeled matrix.

Return to Electron micrograph and schematic illustration of a mitochondrion



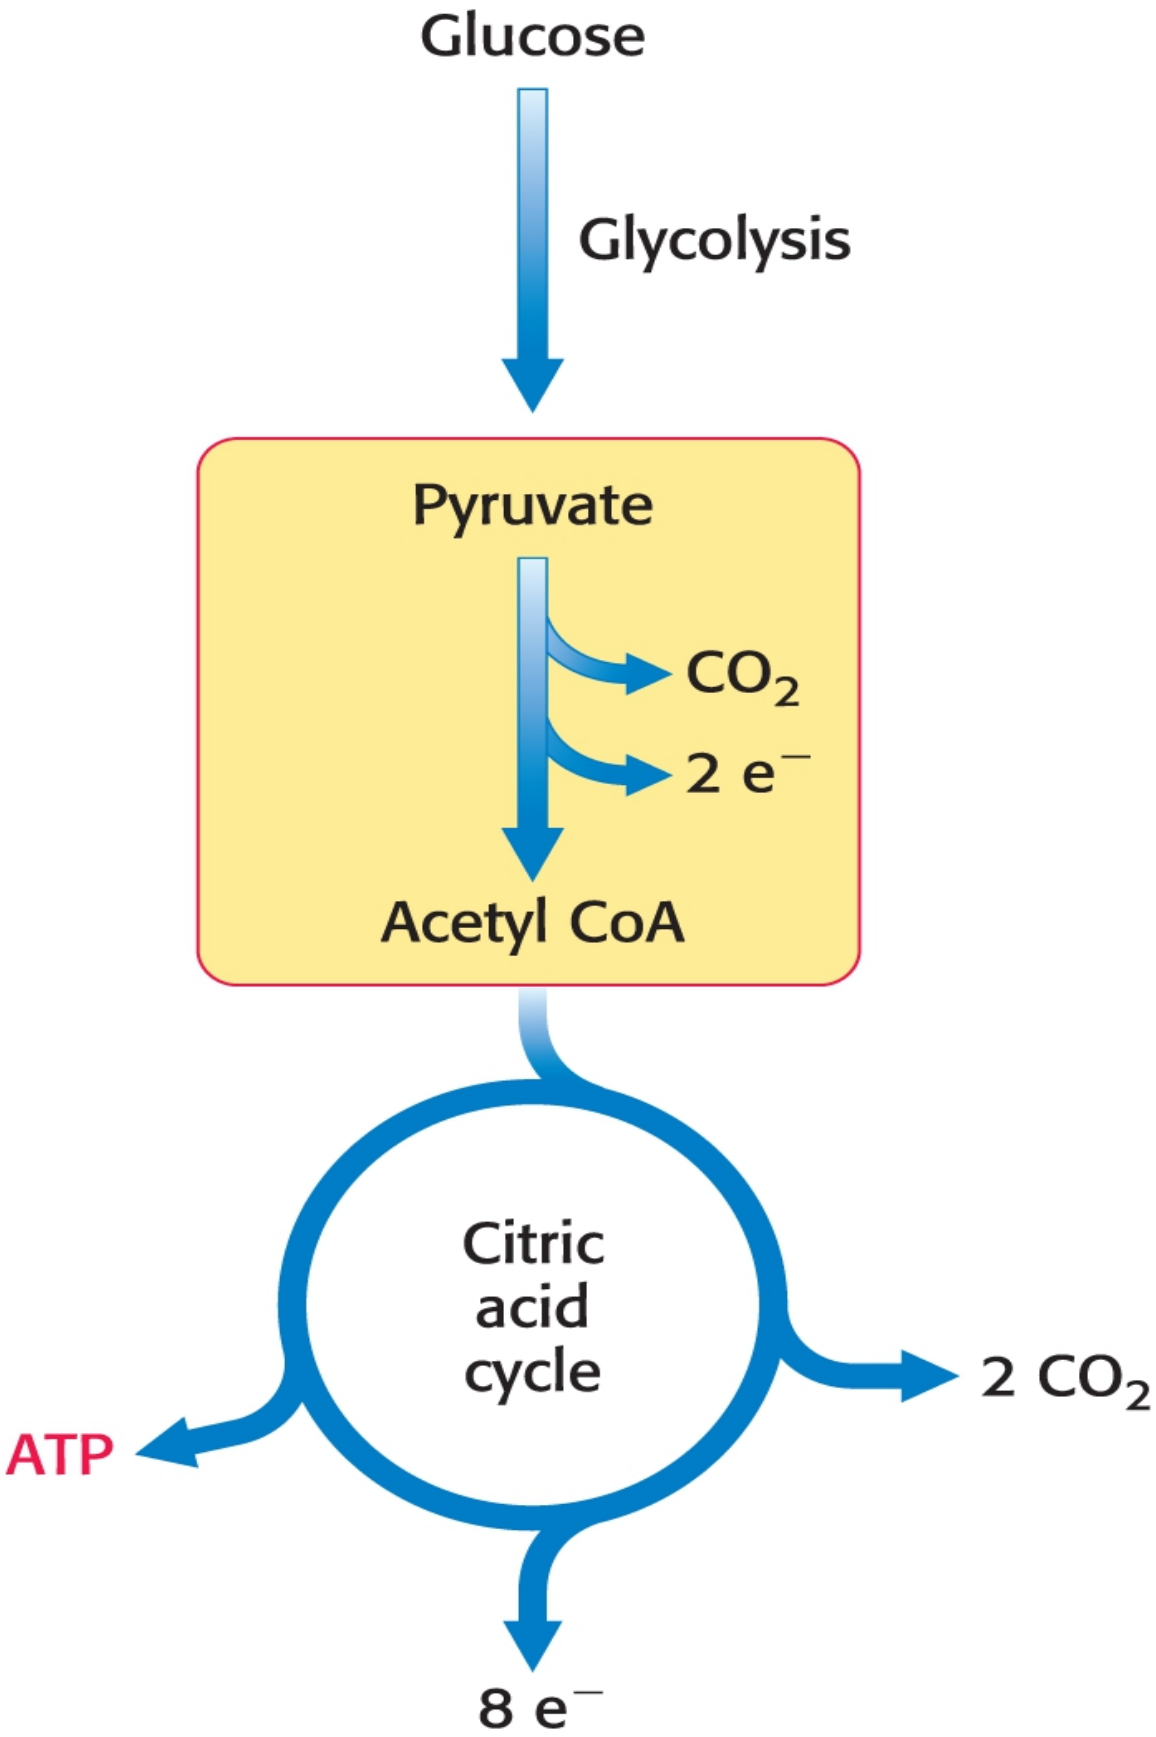
Extended description for Citric acid cycle

The citric acid cycle is depicted as follows: It begins with C 4 (oxaloacetate) and C 2 that combine to form C 6 (citrate). C 6 is converted into C 5 with the simultaneous release of N A D H and C O 2 in the same sequence. C 5 is further converted into C 4 with the simultaneous release of N A D H and C O 2 in the same sequence. C 4 is converted back to C 4 with the simultaneous release of A T P, F A D H 2, and N A D H in the same sequence.

Return to Citric acid cycle

Extended description for Citric acid cycle and oxidative phosphorylation in a mitochondrion

A long rectangular structure open at the top is shown. It has a thick grey border labeled inner mitochondrial membrane. The space enclosed by the grey border is labeled matrix. A rectangle labeled citric acid cycle is shown inside the open rectangle. Three purple arrows labeled fatty acids, glucose, and amino acids respectively, depict the movement of these molecules from external space to the matrix through the inner mitochondrial membrane. All the purple arrows point toward acetyl-C o A which enters the citric acid cycle. The cycle is depicted as a circle with a blue outline. An outward arrow is shown at the right, bottom, and bottom left of the circle to show the release of 2 C O 2; N A D H, F A D H 2; and 1 A T P respectively. N A D H and F A D H 2 are shown inside the inner mitochondrial membrane. A rectangle labeled oxidative phosphorylation is shown adjacent to the first rectangle labeled citric acid cycle. A red forward arrow from N A D H and F A D H 2 produced in the citric acid cycle is labeled electron-transport chain and its points toward proton gradient (approximately 36 H superscript). A downward arrow across it shows the movement of H



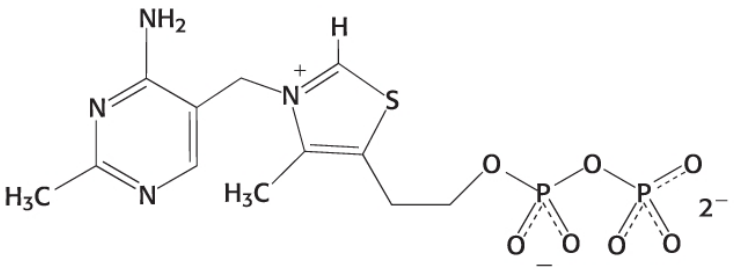
superscript plus ion from the matrix to the space outside the inner mitochondrial membrane. Another curved arrow above the forward arrow and across the downward arrow shows the simultaneous conversion of 2 O 2 to 4 H 2 O.

An upward green arrow across the proton gradient in the membrane shows the entry of H superscript plus into the matrix from a space outside the membrane. A curved arrow across it shows the simultaneous conversion of A D P plus P subscript i into A T P in the matrix.

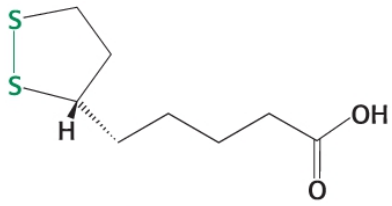
Return to Citric acid cycle and oxidative phosphorylation in a mitochondrion

Extended description for Connection between

glycolysis and citric acid cycle



© Macmillan Learning



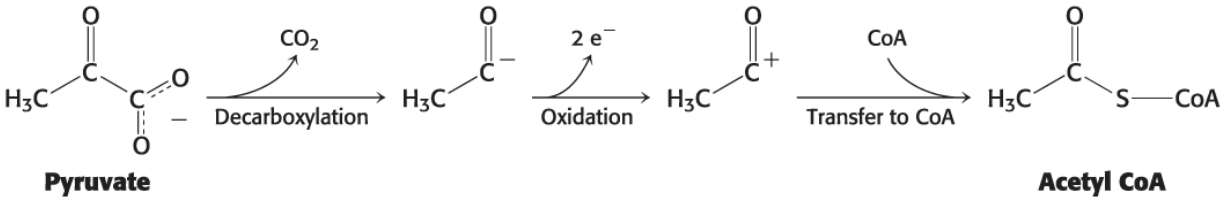
Glucose is converted into pyruvate via glycolysis. Pyruvate is further converted into acetyl C o A with the simultaneous release of C O 2 and 2 electrons. Acetyl C o A enters the citric acid cycle which is depicted as a circle with a thick blue outline. An outward arrow is shown on the right, bottom, and bottom left of the circle. These arrows represent the release of 2 C O 2, 8 electrons, and A T P respectively.

Return to Connection between glycolysis and citric acid cycle

Extended description for Structure of thiamine pyrophosphate (T P P) and lipoic acid

Thiamine pyrophosphate (TPP)

Lipoic acid



The structure of thiamine pyrophosphate (T P P) is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. The first N occupies the first position, which is the bottommost vertex. The second N occupies the third position, which is the top left vertex. C 1 occupies the bottom left vertex. A double bond is present between N 1 and C 1, N 2 and C 2, and C 3 and C 4. C 1 is single bonded to C H 3 on the lower left. C 2 is single bonded to N H 2 above. C 3 is single bonded to C H 2 on the upper right in the form of a line. This C H 2 group is single-bonded to the N atom of a 5-membered heterocyclic pentagonal ring in a vertical orientation. The pentagonal ring consists of 1 N, 1 S, and 3 C atoms. N with a positive charge occupies the first position, which is the top left vertex. S occupies the third position, which is the top right vertex. C 1 occupies the topmost vertex. A double bond is present between N and C 1, and C 2 and C 3. C 1 is single bonded to H above. C 3 is single bonded to C H 3 on the lower left. C 2 is single bonded to a 2-carbon alkane chain depicted as a single line. C 2 of this alkane chain is single bonded to a zigzag chain composed of O, single bond, P, single bond, O, single bond, P. P 1 is partially double bonded to O on the lower left and O on the lower right. The O atoms have a negative charge. P 2 is partially double bonded to O on

the upper right, O on the lower left, O on the lower right. The O atoms have an overall negative charge of 2 minus.

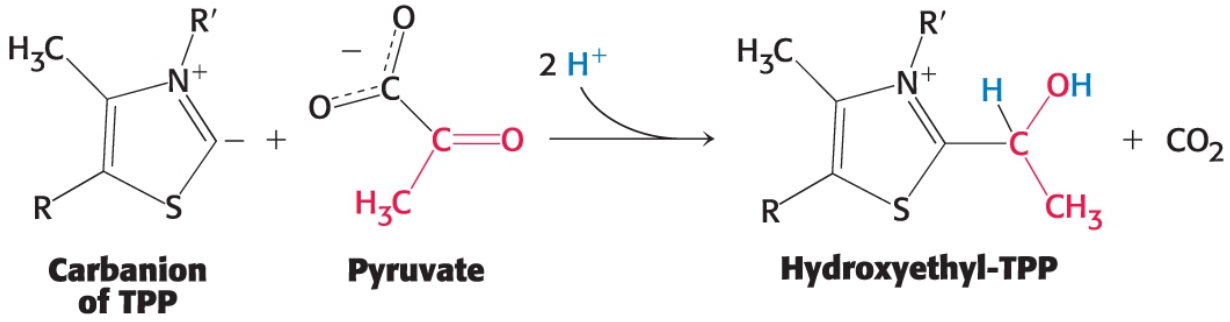
The structure of lipoic acid is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 2 S and 3 C atoms. First S occupies the first position, which is the bottom left vertex. Second S occupies the second position, which is the top left vertex. C 1 occupies the top right vertex. C 3 is wedge bonded to H on the lower left and dash bonded to C 1 of a 5-carbon alkane chain depicted as a line structure using 4 zigzag lines. C 5 is double bonded to O below and single bonded to O H on the upper right.

Return to Structure of thiamine pyrophosphate (T P P) and lipoic acid

Extended description for Stepwise conversion pyruvate to acetyl C o A

The reaction consists of 3 steps labeled decarboxylation, oxidation, and transfer to C o A.

In the decarboxylation step, pyruvate is converted into the first intermediate with the simultaneous release of C O 2. The structure of pyruvate is as follows: A central C atom is single bonded to C H 3 on the lower left, double bonded to O above, and single bonded to C on the lower right. The lower right C atom is partially double bonded to O on the upper right and O below. These O atoms have an overall negative charge. The structure of the first intermediate is as follows: A central C atom with a negative charge is double bonded to O above and single bonded to C H 3 on the lower left.



In the oxidation step, the first intermediate is converted into the second intermediate with the simultaneous release of 2 electrons.

The structure of the second intermediate is as follows: A central C atom with a positive charge is double bonded to O above and single bonded to C H 3 on the lower left. In the transfer to C o A step, the second intermediate is converted into acetyl C o A with the simultaneous entry of C o A.

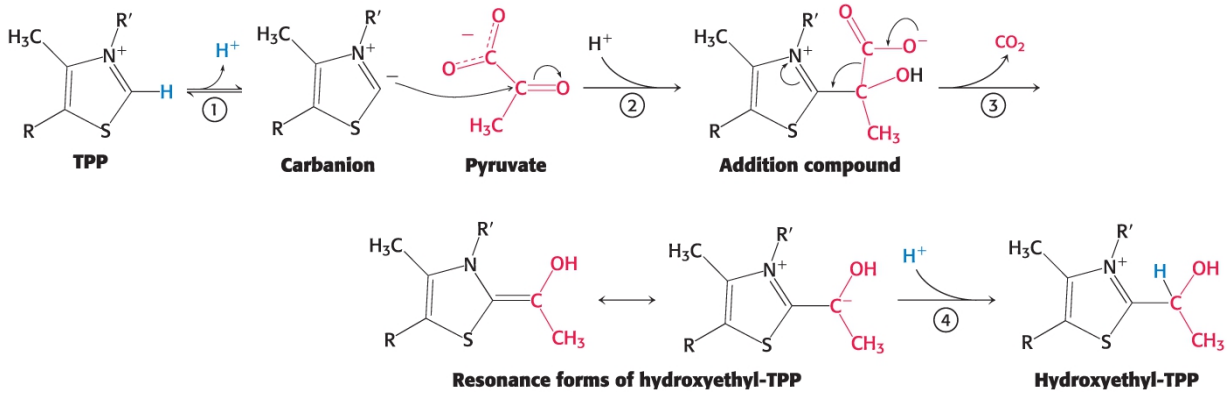
The structure of acetyl C o A is as follows: A central C atom is double bonded to O above, single bonded to C H 3 on the lower left, and single bonded to S, single bond, C o A on the lower right.

Return to Stepwise conversion pyruvate to acetyl C o A

Extended description for Formation of hydroxyethyl-T P P

The chemical reaction consists of two reactants and two products. The reactants are carbanion of T P P and pyruvate. The products are hydroxyethyl-T P P and C O 2.

The structure of the carbanion of T P P is as follows: A 5-membered heterocyclic pentagonal ring is in the horizontal orientation and contains 1 N, 1 S, and 3 C atoms. N atom has a positive charge and occupies the first position, which is the top right vertex. S occupies the third position, which is the bottom right vertex. C 1 has a negative charge and occupies the rightmost vertex. A double bond is present between N and C 1 and C 2 and C 3. N is single bonded to R dash above. C 2 is single bonded to R on the lower left. C 3 is single bonded to C H 3 on the upper left.



The structure of pyruvate is as follows: A central C atom is single bonded to C on the upper left, double bonded to O on the right, and single bonded to C H 3 on the lower right. The upper left C atom is partially double bonded to O on the upper right and lower left. The O atoms have an overall negative charge.

A forward arrow leads to the products. 2 H superscript plus ions enter the reaction.

The structure of hydroxyethyl-T P P is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 1 N, 1 S, and 3 C atoms. The N atom has a positive charge and occupies the first position, which is the top right vertex. S occupies the third position, which is the bottom right vertex. C 1 occupies the rightmost vertex. A double bond is present between N and C 1 and C 2 and C 3. N is single bonded to R dash above. C 1 is single bonded to C on the right. This C is single bonded to O H on the upper right, H on the upper left, and C H 3 on the lower right. C 2 is single bonded to R on the lower left. C 3 is single bonded to C H 3 on the upper left.

Return to Formation of hydroxyethyl-T P P

Extended description for Mechanism of E 1 decarboxylation reaction

The mechanism is divided into 4 main steps. The first step is reversible and the remaining steps are irreversible.

The structure of T P P is as follows: A 5-membered heterocyclic pentagonal ring is in the horizontal orientation and contains 1 N, 1 S, and 3 C atoms. N atom has a positive charge and occupies the first position, which is the top right vertex. S occupies the third position, which is the bottom right vertex. C 1 occupies the rightmost vertex. It is single bonded to H on the right. A double bond is present between N and C 1 and C 2 and C 3. N is single bonded to R dash above. C 2 is single bonded to R on the lower left. C 3 is single bonded to C H 3 on the upper left.

A reversible reaction arrow labeled 1 shows the carbanion. An upward pointing arrow above it shows the release of H superscript plus ion.

The structure of the carbanion is as follows: A 5-membered heterocyclic pentagonal ring is in the horizontal orientation and contains 1 N, 1 S, and 3 C atoms. N atom has a positive charge and

occupies the first position, which is the top right vertex. S occupies the third position, which is the bottom right vertex. C 1 has a negative charge and occupies the rightmost vertex. A double bond is present between N and C 1 and C 2 and C 3. N is single bonded to R dash above. C 2 is single bonded to R on the lower left. C 3 is single bonded to C H 3 on the upper left.

A pyruvate molecule is shown adjacent to the carbanion.

The structure of the pyruvate molecule is as follows: A central C atom is single bonded to C on the upper left, double bonded to O on the right, and single bonded to C H 3 on the lower right. The upper left C atom is partially double bonded to O on the upper right and lower left. These O atoms have an overall negative charge.

An arrow points from negatively charged C 1 of carbanion to the central C atom of pyruvate.

Another arrow points from the double bond between the central C and O of the pyruvate molecule toward the O atom.

A forward reaction arrow labeled 2 shows the addition compound. An H superscript plus ion also enters the reaction.

The structure of the addition compound is as follows: A 5-membered heterocyclic pentagonal ring is in the horizontal orientation and contains 1 N, 1 S, and 3 C atoms. N atom has a positive charge and occupies the first position, which is the top right vertex. S occupies the third position, which is the bottom right vertex. C 1 occupies the rightmost vertex. A double bond is present between N and C 1 and C 2 and C 3. N is single bonded to R dash above. C 2 is single bonded to R on the lower left. C 3 is single bonded to C H 3 on the upper left. C 1 is single bonded to C on the

right. This C atom is single bonded to C above, O H on the upper right, and C H 3 below. The C atom above is double bonded to O on the upper right and single bonded to O superscript minus on the right.

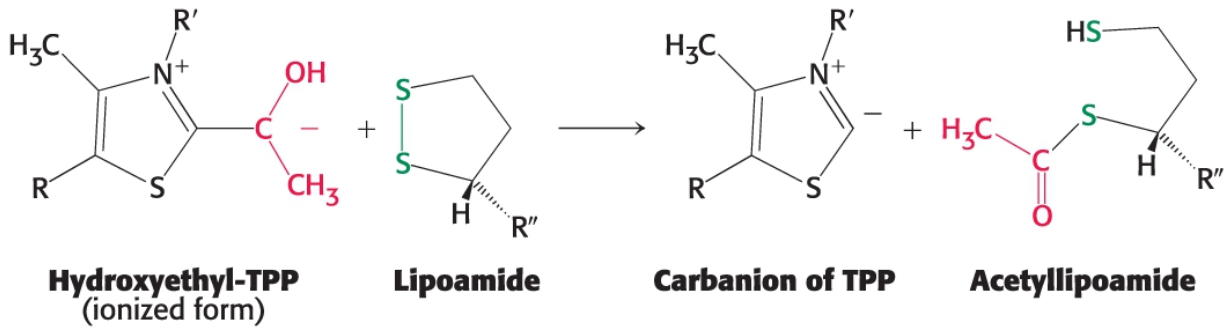
An arrow points from O superscript minus toward its single bond with the C atom located above. A second arrow points from the single bond between the C atom above and the right C atom bonded to C 1 toward the single bond between C 1 and the right C atom. A third arrow points from the double bond between the C 1 and N atom of the ring toward the N atom.

A forward arrow labeled 3 shows the resonance forms of hydroxyethyl-T P P. An upward arrow above it shows the release of C O 2.

The structures of the resonance forms are as follows:

First form: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 1 N, 1 S, and 3 C atoms. The N atom occupies the first position, which is the top right vertex. S occupies the third position, which is the bottom right vertex. C 1 occupies the rightmost vertex. A double bond is present between C 2 and C 3. N is single bonded to R dash above. C 1 is double bonded to C on the right. This C is single bonded to O H on the upper right and C H 3 on the lower right. C 2 is single bonded to R on the lower left. C 3 is single bonded to C H 3 on the upper left.

Second form: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 1 N, 1 S, and 3 C atoms. The N atom has a positive charge and occupies the first position, which is the top right vertex. S occupies the third position, which is the bottom right vertex. C 1 occupies the rightmost vertex. A double



bond is present between N and C 1 and C 2 and C 3. N is single bonded to R dash above. C 1 is single bonded to C having a negative charge on the right. This C is single bonded to O H on the upper right and C H 3 on the lower right. C 2 is single bonded to R on the lower left. C 3 is single bonded to C H 3 on the upper left.

A forward reaction arrow labeled 4 shows the hydroxyethyl-T P P. An H superscript plus ion also enters the reaction.

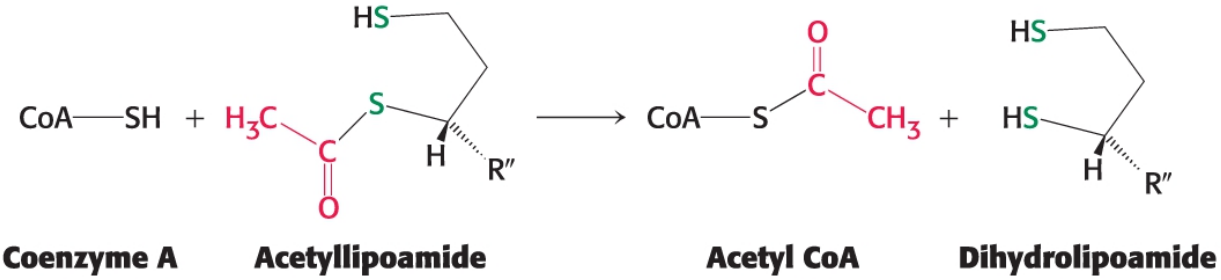
The structure of hydroxyethyl-T P P is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 1 N, 1 S, and 3 C atoms. The N atom has a positive charge and occupies the first position, which is the top right vertex. S occupies the third position, which is the bottom right vertex. C 1 occupies the rightmost vertex. A double bond is present between N and C 1 and C 2 and C 3. N is single bonded to R dash above. C 1 is single bonded to C on the right. This C is single bonded to O H on the upper right, H on the upper left, and C H 3 on the lower right. C 2 is single bonded to R on the lower left. C 3 is single bonded to C H 3 on the upper left.

Return to Mechanism of E 1 decarboxylation reaction

Extended description for Oxidation of hydroxyethyl-T P P

The hydroxyethyl T P P (ionized form) reacts with lipoamide to give rise to the carbanion of T P P and acetyllipoamide.

The structure of hydroxyethyl T P P (ionized form) is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 1 N, 1 S, and 3 C atoms. The N atom has a positive charge and occupies the first position, which is the top right vertex. S occupies the third position, which is the bottom right vertex. C 1 occupies the rightmost vertex. A double bond is present between N and C 1 and C 2 and C 3. N is single bonded to R dash above. C 1 is single bonded to C on the right. This C is single bonded to O H on the upper right and C H 3 on the lower right. C 2 is single bonded to R on the lower left. C 3 is single bonded to C H 3 on the upper left.



The structure of lipoamide is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 2 S and 3 C atoms. S 1 occupies the first position, which is the bottom left vertex. S 2 occupies the second position, which is the top right vertex. C 3 is wedge bonded to H on the lower left and dash bonded to R double dash on the lower right.

The structure of the carbanion of T P P is as follows: A 5-membered heterocyclic pentagonal ring is in the horizontal orientation and contains 1 N, 1 S, and 3 C atoms. N atom has a positive charge and occupies the first position, which is the top right vertex. S occupies the third position, which is the bottom right vertex. C 1 has a negative charge and occupies the rightmost vertex. A double bond is present between N and C 1 and C 2 and C 3. N is single bonded to R dash above. C 2 is single bonded to R on the lower left. C 3 is single bonded to C H 3 on the upper left.

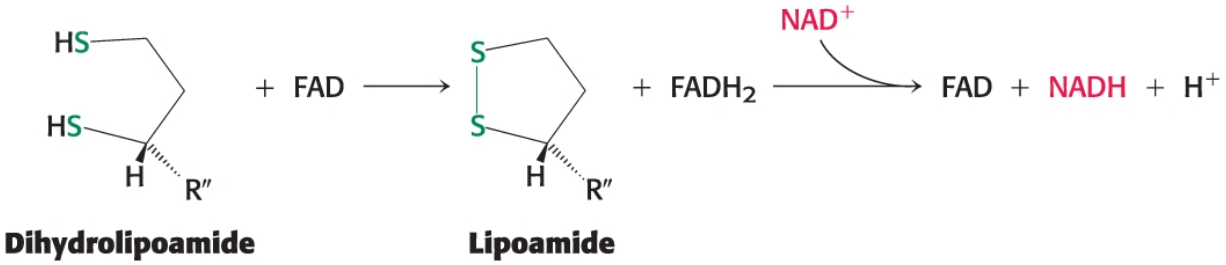
The structure of acetyllipoamide is as follows: A 3-carbon alkane chain is depicted as a vertical line structure using 2 zigzag lines. C 1 is single bonded to S H on the left. C 3 is single bonded to S on the left. C 3 is also wedge bonded to H on the lower left and dash bonded to R double dash on the lower right. The S atom on left is single-bonded to C on the lower left. This C is single bonded to C H 3 on the upper left and double bonded to O below.

Return to Oxidation of hydroxyethyl-T P P

Extended description for Formation of acetyl C o A

The reaction consists of two reactants and two products. The reactants are coenzyme A and acetyllipoamide. The products are acetyl C o A and dihydrolipoamide.

The structure of coenzyme A is as follows: C o A, single bond, S H.



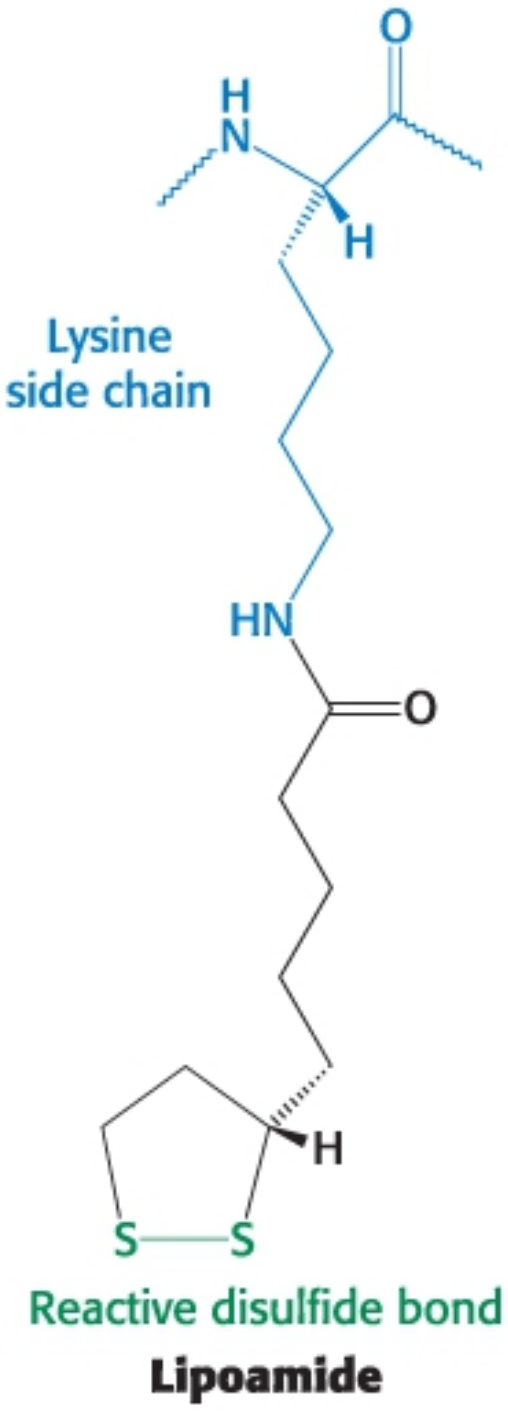
The structure of acetyllipoamide is as follows: A 3-carbon alkane chain is depicted as a vertical line structure using 2 zigzag lines. C 1 is single bonded to S H on the left. C 3 is single bonded to S on the left. C 3 is also wedge bonded to H on the lower left and dash bonded to R double dash on the lower right. The S atom is single bonded to C on the lower left. This C is single bonded to C H 3 on the upper left and double bonded to O below.

The structure of acetyl C o A is as follows: A central C atom is single bonded to C H 3 on the lower left, double bonded to O above, and single bonded to S, single bond, C o A on the lower left.

The structure of dihydrolipoamide is as follows: A 3-carbon alkane chain is depicted as a vertical line structure using 2 zigzag lines. C 1 and C 3 are each single bonded to S H on the left. C 3 is wedge bonded to H on the lower left and dash bonded to R double dash on the lower right.

Return to Formation of acetyl C o A

Extended description for Regeneration of oxidized lipoamide

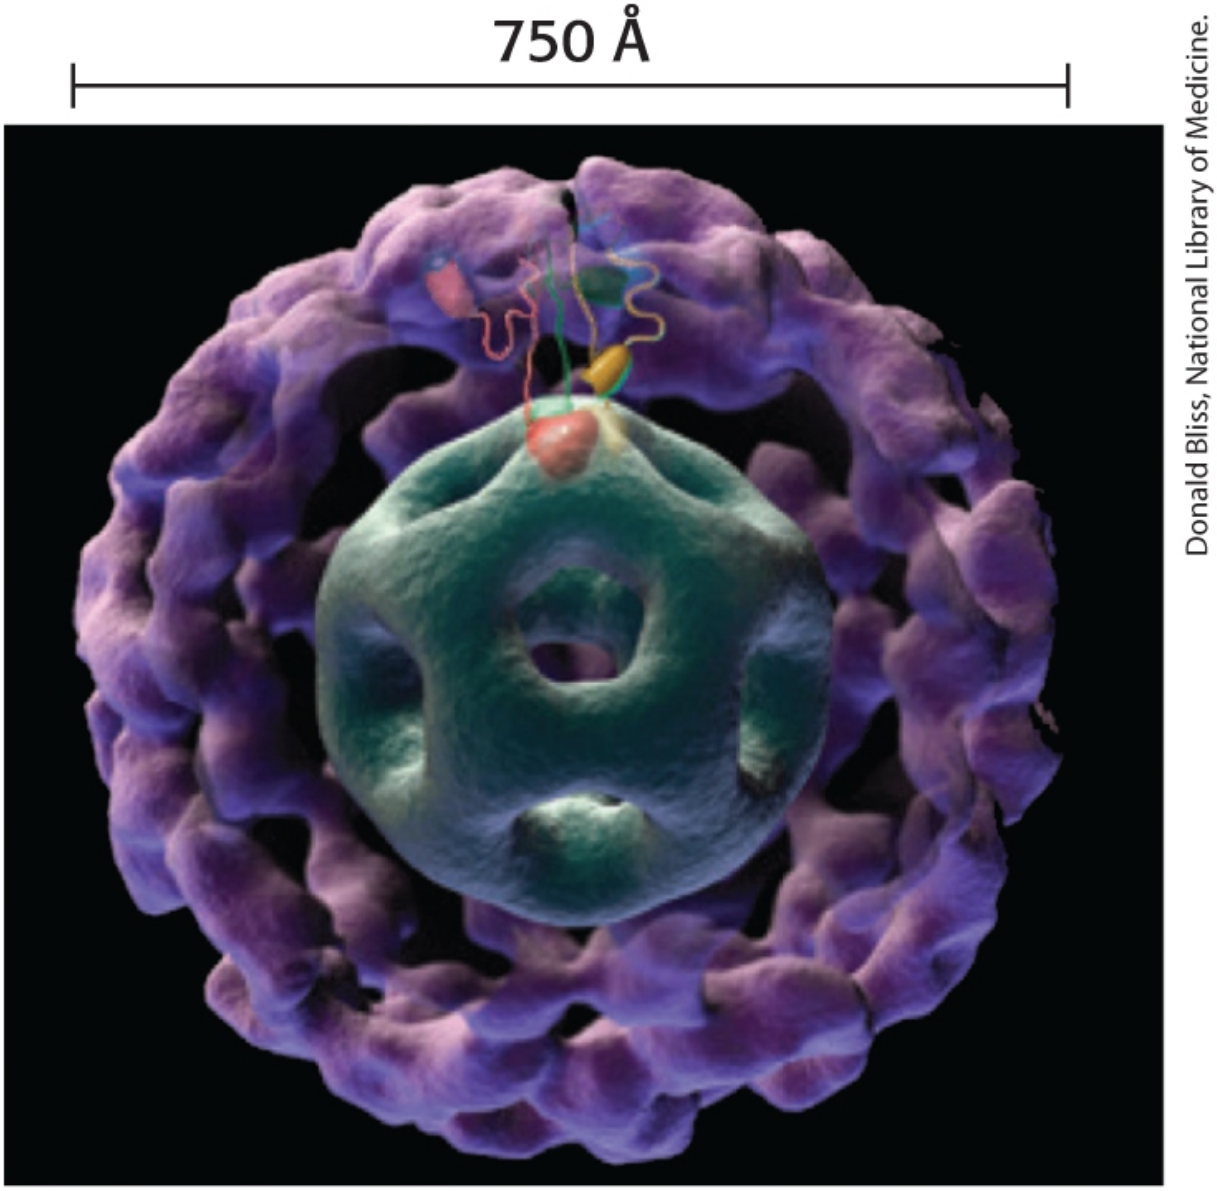


Dihydrolipoamide reacts with F A D to give rise to lipoamide. Lipoamide reacts with F A D H 2 in the presence of N A D superscript plus to give rise to F A D plus N A D H plus H superscript plus.

The structure of dihydrolipoamide is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines vertically. C 1 and C 3 are each single bonded to S H on the left. C 3 is wedge bonded to H on the lower left and dash bonded to R double dash on the lower right.

The structure of lipoamide is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 2 S and 3 C atoms. S 1 occupies the first position, which is the bottom left vertex. S 2 occupies the second position, which is the top left vertex. C 1 occupies the top right vertex. C 3 is wedge bonded to H on the lower left and dash bonded to R double dash on the lower right.

Return to Regeneration of oxidized lipoamide



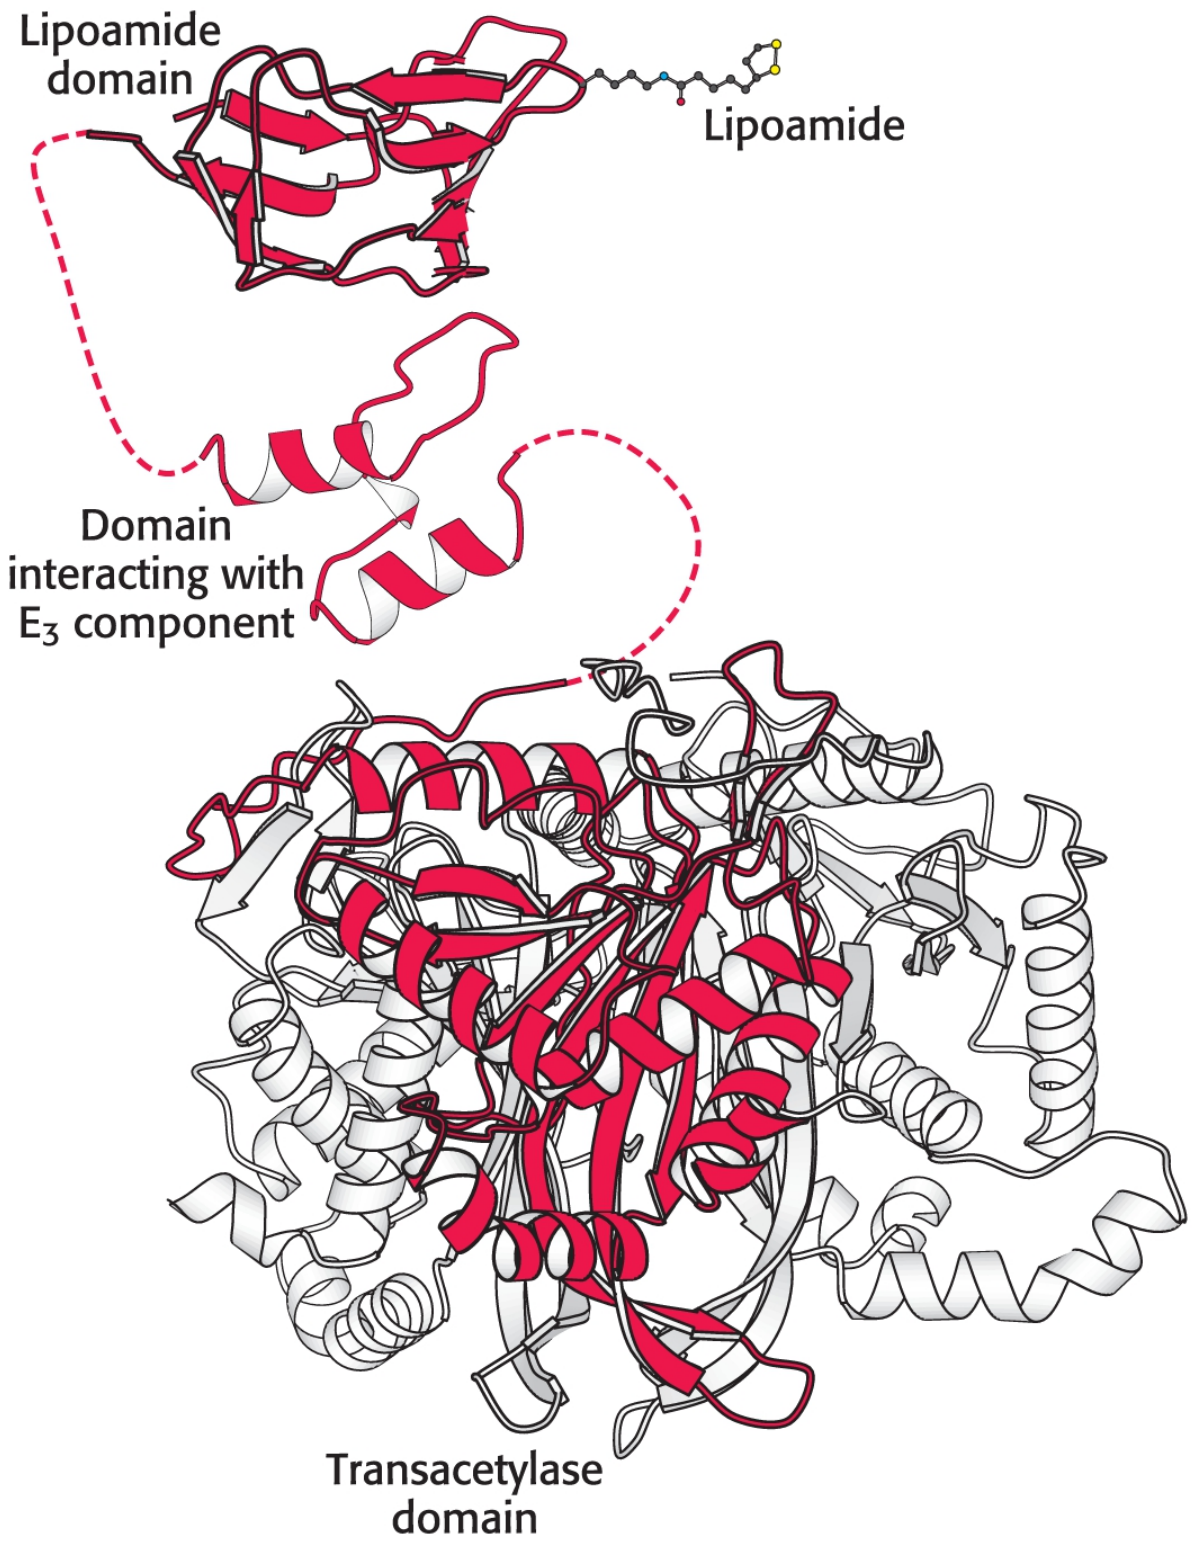
Extended description for Structure of lipoamide

The structure of lipoamide is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 2 S and 3 C atoms. First S occupies the first position, which is the bottom right vertex. Second S occupies the second position, which is the bottom left vertex. C 1 occupies the top left vertex. C 3 is wedge bonded to H on the lower right and dash bonded to C 1 of a 1 N and 9 C heteronuclear alkane chain depicted as a vertical line structure using 9 zigzag lines. N bound to H occupies the sixth position. C 5 is double bonded to O on the right. C 9 is dash bonded to C 2 of a 1 N and 4 C heteronuclear alkane chain depicted as a horizontal line structure using 4 zigzag lines. N bound to H occupies the second position. C 2 is wedge bonded to H on the lower right. C 3 is double bonded to O above.

Return to Structure of lipoamide

Extended description for Photograph of bacterial pyruvate dehydrogenase complex

Donald Bliss, National Library of Medicine.



The pyruvate dehydrogenase complex consists of an inner core having several large-sized pores. The inner core is made up of the E 2 enzyme. It is surrounded by a shell composed of E 1 and E 3 enzymes. The diameter of the entire complex is 750 angstrom. Two

lipoamide arms are shown in red and yellow extending from the inner core to the shell.

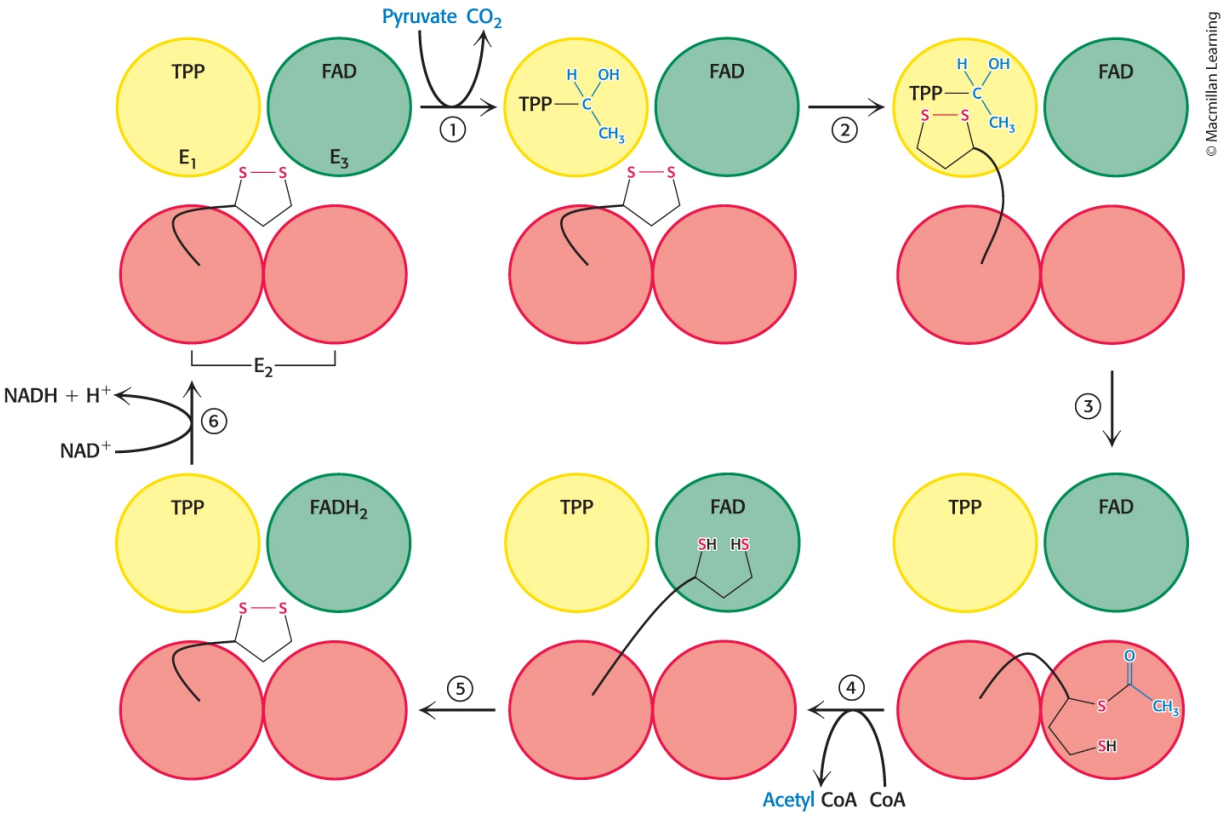
Extended description for Ribbon diagram of a subunit

of the transacetylase trimer



© Macmillan Learning

The ribbon diagram is composed of three domains labeled lipoamide domain, domain interacting with E 3 component, and transacetylase domain from top to bottom. The lipoamide domain is a very small cluster composed of beta-strands interconnected by long thread-like loops. A loop extending on the right is connected to a ball-and-stick model of lipoamide. A thread emerging from the left end of this domain is connected to the domain interacting with the E 3 component in the middle through a dashed-red line. This middle domain is composed of two short alpha-helices interconnected by long loops. A short thread emerging from the right end of the middle domain is connected to the transacetylase domain at the bottom through a dashed red line. The transacetylase domain is a large cluster composed of several randomly oriented alpha helices and beta-strands interconnected by thread-like loops.

Return to Ribbon diagram of a subunit of the transacetylase trimer

Extended description for Activity of pyruvate dehydrogenase complex

The activity of the pyruvate dehydrogenase complex is divided into 6 steps. The complex consists of two joined red circles labeled E 2. A yellow circle and green circle are located above the joined circles on the top left and top right respectively. The yellow circle is labeled E 1 and is bound to T P P. The green circle is labeled E 3 and is bound to F A D. A curved line from the left red sphere is connected to C 3 of a 5-membered heterocyclic pentagonal ring located in the center of the complex. The ring contains 2 S and 3 C atoms. First S occupies the first position, which is the top left vertex. Second S occupies the second position, which is the top right vertex.

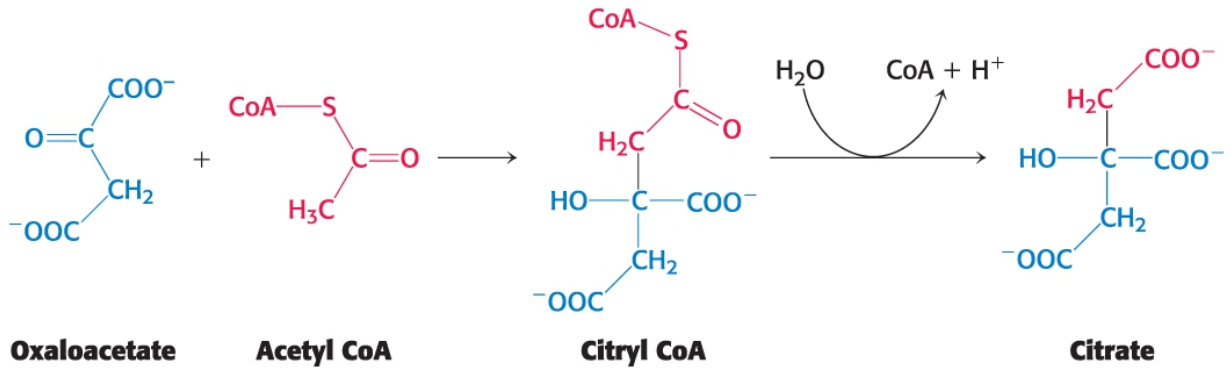
A forward arrow labeled 1 lead to the complex bound to pyruvate. A curved arrow above it shows the entry of pyruvate and the release of C O 2.

T P P of E 1 subunit is single bonded to a central C atom. This C atom is single bonded to H on the upper left, O H on the upper right, C H 3 on the lower right.

A forward arrow labeled 2 leads to the next configuration of the complex. The pentagonal ring bound the E 2 subunit is located inside E 1 subunit.

A forward arrow labeled 3 shows the next configuration of the complex. The E 1 and E 3 subunits are bound to T P P and F A D respectively. The partially open pentagonal ring of E 2 is located inside the right red circle. The single bond between the S atoms is broken. S 1 is single bonded to C on the upper right. This C is double bonded to O above and single bonded to C H 3 on the lower right. S 2 is bound to H.

A forward arrow labeled 4 shows the next configuration of the complex. A curved arrow below it shows the conversion of C o A to acetyl C o A.



The partially open ring of the right red circle is located inside E 3 subunit. Both the S atoms are bound to H and are located at the top left and top right.

A forward arrow labeled 5 leads to the next configuration of the complex. The pentagonal ring is closed as the single bond between the S atoms is reformed. It is located in the center of the complex.

A forward arrow labeled 6 leads to the initial configuration of the complex. A curved arrow on its left shows the simultaneous reduction of N A D superscript plus to N A D H plus H superscript plus.

Return to Activity of pyruvate dehydrogenase complex

Extended description for Formation of citrate from oxaloacetate

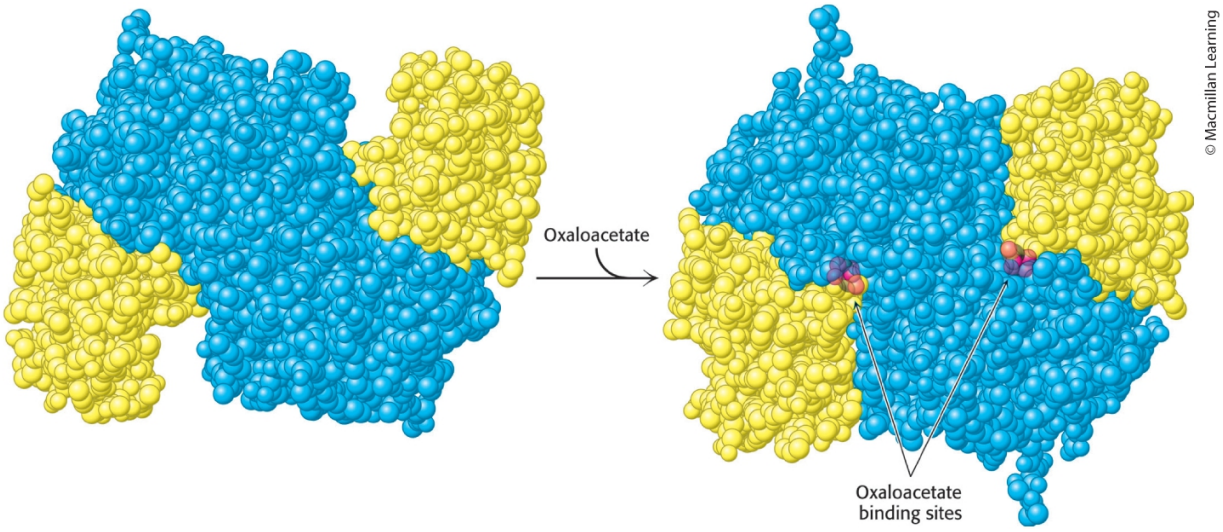
The reaction consists of two reactants, one intermediate, and one product.

The first reactant is oxaloacetate whose structure is as follows: A central C atom is single bonded to C O O superscript minus on the upper right, double bonded to O on the left, single bonded to C H 2 on the lower right. This C H 2 is further single bonded to C O O superscript minus on the lower left.

The second reactant is acetyl C o A whose structure is as follows: A central C atom is single bonded to S, single bond, C o A on the upper left, double bonded to O on the right, and single bonded C H 3 on the lower left.

A forward reaction arrow leads to the intermediate citryl C o A.

The structure of citryl C o A is as follows: C H 2, single bond, C, single bond, C H 2. C 1 is single bonded to C, single bond, S on the upper right. The S atom is single bonded to C o A on the upper left. The C atom is double bonded to O on the lower right. C 2 of the main



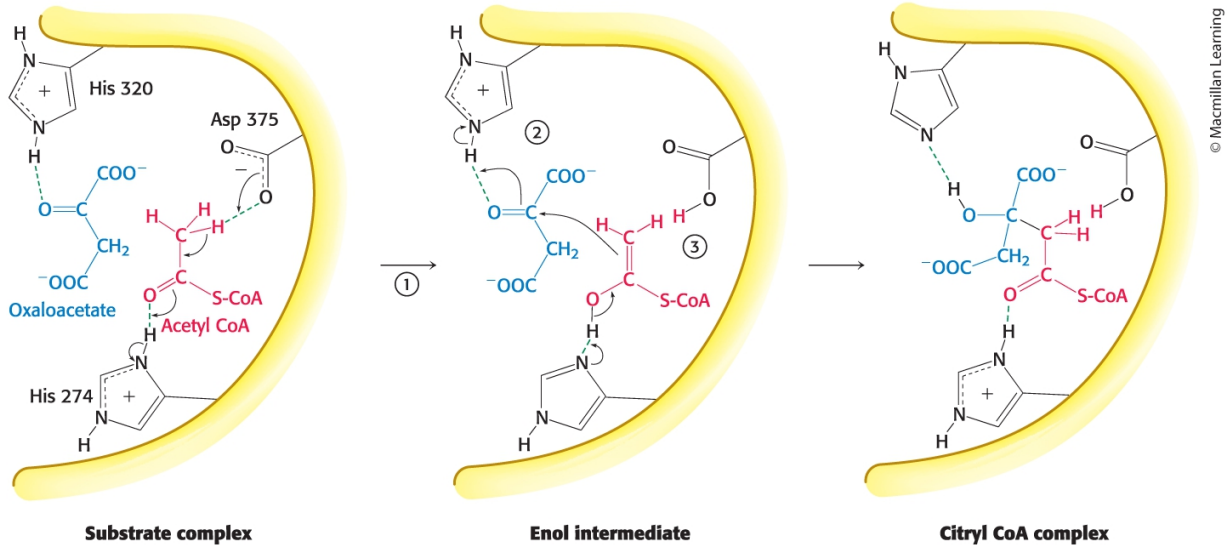
chain is single bonded to O H on the left and C O O superscript minus on the right. C 3 is single bonded to C O O superscript minus on the lower left.

A forward arrow leads to the product citrate. A curved arrow above it shows the simultaneous entry of H 2 O and exit of C o A plus H superscript plus.

The structure of citrate is as follows: C H 2, single bond, C, single bond, C H 2. C 1 is single bonded to C O O superscript minus on the upper right. C 2 is single bonded to O H on the left and single bonded to C O O superscript minus on the right. C 3 is single bonded to C O O superscript minus on the lower left.

Return to Formation of citrate from oxaloacetate

Extended description for Space filling model shows the binding of oxaloacetate to citrate synthesis



The space-filling model of citrate synthase consists of two domains. The small domain is shown as a cluster of yellow spheres. The large domain is shown as a cluster of blue spheres. The large domain is shown in the middle in a diagonal orientation. Its top left and bottom right regions are bound the small domain.

A forward arrow shows the enzyme bound to oxaloacetate. The large domain in diagonal orientation has a deep indentation on the mid left and mid right ends. These indented grooves are bound to small domains. The oxaloacetate binding sites are located in these grooves of large domain where it joins with the small domains. A few blue spheres extend upward and downward from the top and bottom ends of the large domain.

Return to Space filling model shows the binding of oxaloacetate to citrate synthesis

Extended description for Citrate synthase mechanism

The enzyme active site is depicted as a curved groove outlined with an orange line having a yellow highlight. The groove is open on the left. Its active site contains a side chain of H i s 320, A s p 375, and H i s 274 from top to bottom.

The side chain of H i s 320 and H i s 274 are as follows: A 5-membered heterocyclic pentagonal ring consists of 2 N and 3 C atoms. The first N occupies the first position, which is the bottom left vertex. The second N occupies the third position, which is the topmost vertex. Both N atoms are single-bonded to H. A partial double bond is present between C 1 and N 1 and C 1 and N 2. A double bond is present between C 2 and C 3. The ring has a plus symbol in the middle.

The side chain of A s p 375 is as follows: A central C is partially double bonded to O on the upper left and O on the lower left. The O atom has an overall negative charge.

The mechanism shows three complexes labeled substrate complex, enol intermediate, and citryl C o A complex.

The substrate complex is depicted as follows:

The oxaloacetate and acetyl-C o A molecule are shown inside the active site.

The structure of oxaloacetate is as follows: A central C atom is single bonded to C O O superscript minus on the upper right, double bonded to O on the left, and single bonded to C H 2 on the lower right. This C H 2 group is single bonded to C O O superscript minus on the lower left.

The O atom double bonded to the central C is further hydrogen bonded to the H atom bonded to N 1 of H i s 320 ring.

The structure of acetyl-C o A is as follows: C, single bond, C. C 1 is single bonded to H on the upper left, upper right, and right. C 2 is double bonded to O on the lower left and S, single bond, C o A on the lower right.

An arrow from the partial double bond between C and the lower left O atom of A s p 375 points toward the hydrogen bond between right H bonded to C 1 of acetyl C o A and the lower left O atom of the A s p 375 side chain.

A second arrow points from the single bond between this H and C 1 toward the single bond between C 1 and C 2 of acetyl C o A.

A third arrow points from the double bond between C 2 and O of acetyl C o A toward the hydrogen bond between this O and H atom bonded to N 2 of H i s 274 ring.

A forward arrow labeled 1 shows the enol intermediate which is depicted as follows:

The lower left O of A s p 375 is single bonded to H.

The structure of the intermediate product is as follows: C, double bond, C. C 1 is single bonded to H on the upper left and H on the upper right. C 2 is single bonded to O on the lower left and single bonded to S, single bond, C o A on the lower right. The lower left O is single bonded to H below.

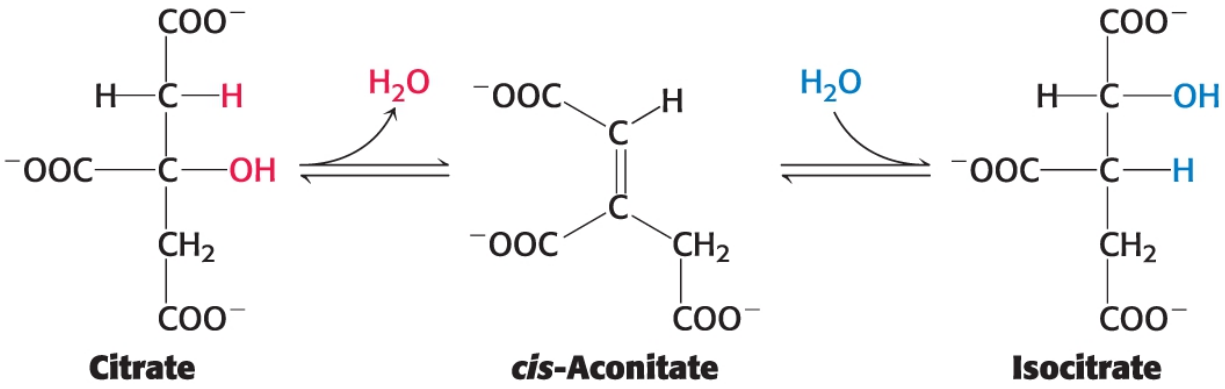
N 2 of the H i s 274 ring is hydrogen bonded to H which is single bonded to the lower left O of the intermediate.

An arrow from N 2 points toward the hydrogen-bonded H atom.

A second arrow from the single bond between this H and lower left O of the intermediate points toward the single bond between this O and C 2 of the intermediate.

A third arrow points from the double bond between C 1 and C 2 of the intermediate toward the central C atom of oxaloacetate.

A fourth arrow points from this central C atom toward the hydrogen bond between H bonded to N 1 of H i s 320 ring and O double bonded to the central C.



A fifth arrow points from the single bond between this H and N 1 toward N 1 of H i s 320 ring.

A forward arrow leads to the citryl C o A complex.

The central C atom of oxaloacetate and C 1 of the intermediate become single-bonded to each other. The central C is single bonded to O, single bond, H on the left. This H is hydrogen bonded to N 1 of H i s 320 ring.

Return to Citrate synthase mechanism

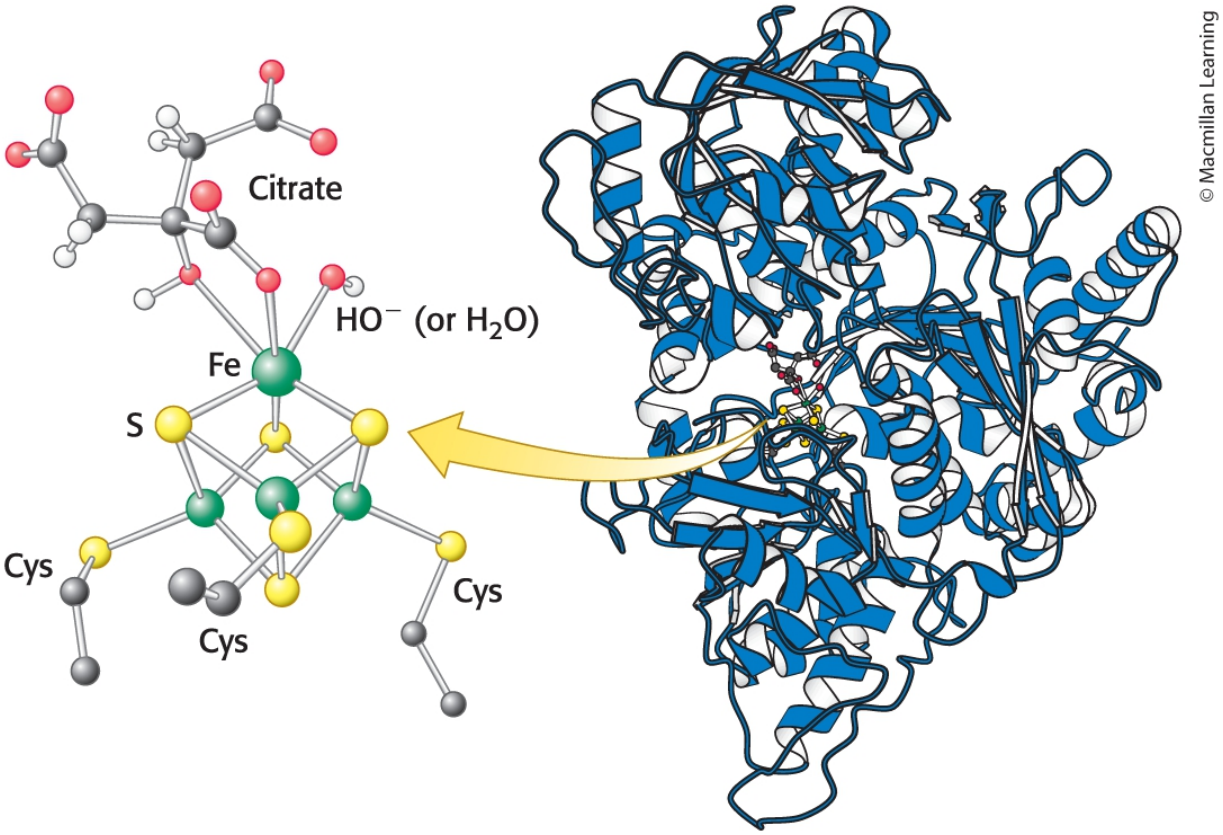
Extended description for Conversion of citrate to isocitrate

The conversion of citrate to isocitrate takes place in two reversible steps.

In the first step, citrate is reversibly converted into cis-aconitate. The structure of citrate is as follows: C O O superscript minus, single bond, C, single bond, C, single bond, C H 2, single bond, C O O superscript minus. C 2 is single bonded to H on the left and H on the right highlighted in red. C 3 is single bonded to C O O superscript minus on the left and O H on the right highlighted in red.

A reversible reaction arrow leads to cis-aconitate. An upward arrow above it shows the release of H 2 O highlighted in red.

The structure of cis-aconitate is as follows: A central C atom is double bonded to C above, single bonded to C O O superscript minus on the lower left, and single bonded to C H 2 on the lower right. This C H 2 group is single bonded to C O O superscript minus below. The C atom above is single bonded to C O O superscript minus on the upper right and single bonded to H on the upper right.



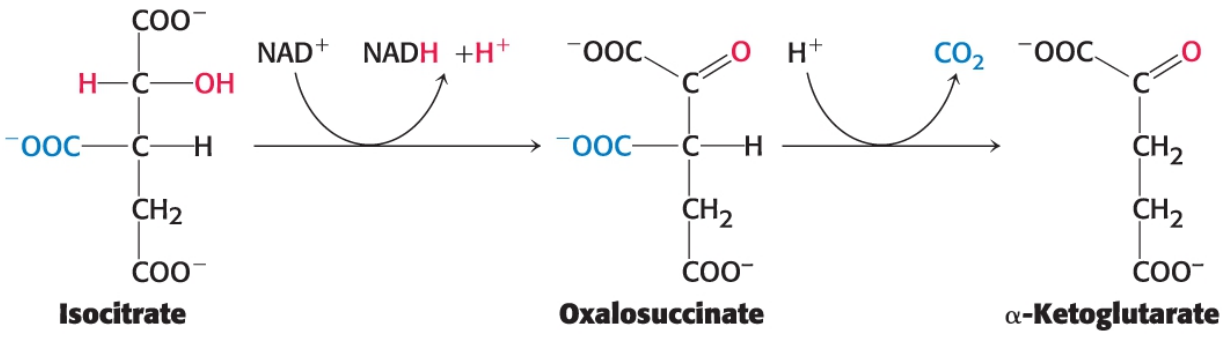
In the second step, cis-aconitate is reversibly converted into isocitrate.

A reversible reaction arrow from cis-aconitate leads to isocitrate. A line labeled H 2 O highlighted in blue is located above the arrow and shows the entry of H 2 O.

The structure of isocitrate is as follows: C O O superscript minus, single bond, C, single bond, C, single bond, C H 2, single bond, C O O superscript minus. C 2 is single bonded to H on the left and O H on the right highlighted in blue. C 3 is single bonded to C O O superscript minus on the left and single bonded to H on the right highlighted in blue.

Return to Conversion of citrate to isocitrate

Extended description for Ribbon diagram of citrate synthase and ball-and-stick model of its iron-sulfur cluster connected to citrate and side chains of amino acids



The ribbon diagram consists of several alpha-helices and a few beta-strands interconnected by thread-like loops. A narrow groove in the center is bound to a ball-and-stick model. A magnified view of the ball-and-stick model is shown on the left. It consists of a 4 F e-4 S iron-sulfur cluster connected to citrate above, O H superscript minus or H 2 O on the upper right, and the side chains of cysteine residues located on the lower left, below, and lower right. The 4 F e-4 S cluster consists of a cubical shape in which the vertices are occupied by 4 green and 4 yellow spheres. The green sphere

represents the F e atom. The yellow sphere represents the S atom. 2 green and 2 yellow spheres occupy each face of the cube.

The side chain of cysteine is depicted as a chain of two black spheres and a yellow sphere. The yellow sphere of each cysteine side chain is connected to a separate green sphere of the iron-sulfur cluster. The green sphere located at the top face of the cube, away from the observer, is connected to two red spheres of a citrate molecule and one red sphere of O H superscript minus or H 2 O molecule. The O H superscript minus molecule consists of a red sphere connected to a white sphere. The citrate molecule consists of a chain of 4 black spheres. The first black sphere is connected to two red spheres. The second black sphere is connected to two white spheres. The third black sphere is connected to a red sphere below which is further connected to a white sphere on the left and the green sphere of the iron-sulfur cluster below. The fourth black sphere is connected to a red sphere above and a red sphere below. The red sphere located below is further connected to the same green sphere of the iron-sulfur cluster. The third black sphere is connected to a chain of two black spheres above. In this chain, the first black sphere is connected to two white spheres and the second black sphere is connected to two red spheres.

Return to Ribbon diagram of citrate synthase and ball-and-stick model of its iron-sulfur cluster connected to citrate and side chains of amino acids

Extended description for Conversion of isocitrate to alpha-ketoglutarate

The conversion of isocitrate to alpha-ketoglutarate takes place in two irreversible steps.

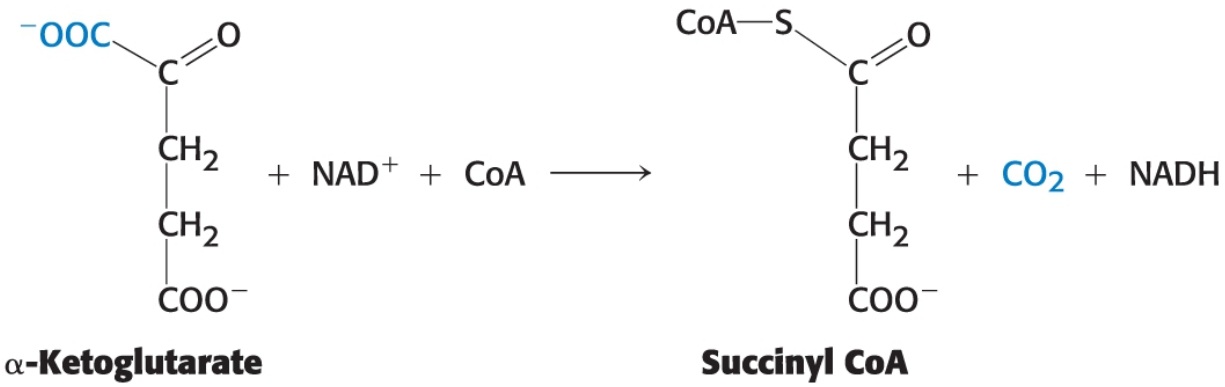
In the first step, isocitrate is converted into oxalosuccinate.

The structure of isocitrate is as follows: C O O superscript minus, single bond, C, single bond, C, single bond, C H 2, single bond, C O O superscript minus. C 2 is single bonded to H on the left and O H on the right, both highlighted in red. C 3 is single bonded to C O O superscript minus highlighted in blue on the left and single bonded to H on the right.

A forward arrow leads to oxalosuccinate. A curved arrow above it shows the simultaneous reduction of N A D superscript plus to N A D H plus H superscript plus. H atom of N A D H and H superscript plus are highlighted in red.

The structure of oxalosuccinate is as follows: C, single bond, C, single bond, C H 2, single bond, C O O superscript minus. C 1 is single bonded to C O O superscript minus on the upper left and double bonded to O on the upper right highlighted in red. C 2 is

single bonded to C O O superscript minus on the left highlighted in blue and single bonded to H on the right.



In the second step, oxalosuccinate is converted into alpha-ketoglutarate.

A forward arrow from oxalosuccinate leads to alpha-ketoglutarate. A curved arrow above it shows the entry of H superscript plus and exit of C O 2 highlighted in blue.

The structure of alpha-ketoglutarate is as follows: C, single bond, C H 2, single bond, C H 2, single bond, C O O superscript minus. C 1 is single bonded to C O O superscript minus on the upper left and double bonded to O on the upper right highlighted in red.

Return to Conversion of isocitrate to alpha-ketoglutarate

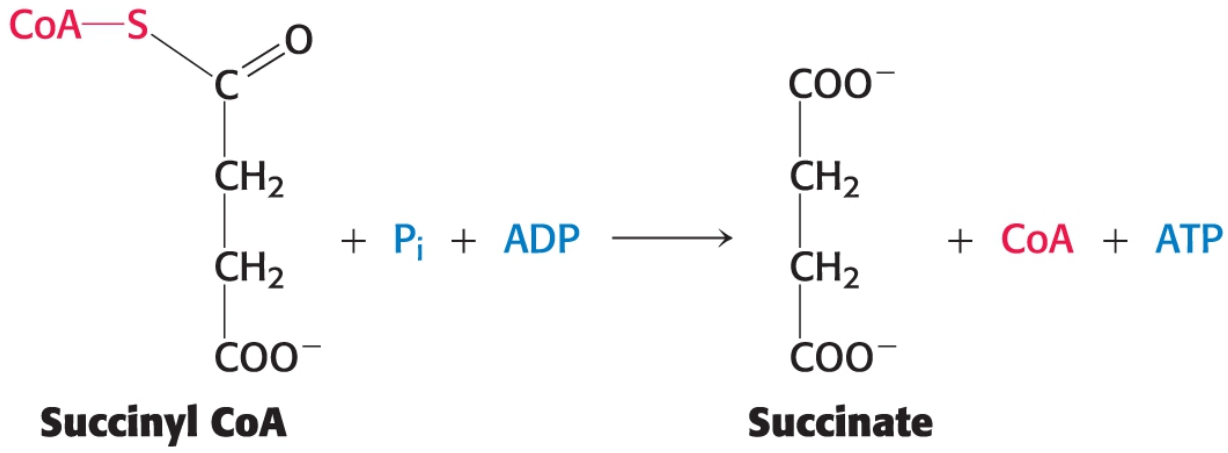
Extended description for Oxidative decarboxylation of alpha-ketoglutarate

The reaction has 3 reactants and 3 products.

The structure of the first reactant "alpha-ketoglutarate" consists of a vertical chain depicted as follows: C, single bond, C H 2, single bond, C H 2, single bond, C O O superscript minus. C 1 is double-bonded to O on the upper right and single-bonded to C O O superscript minus on the upper left highlighted in blue.

The second reactant is N A D superscript plus.

The third reactant is C o A.



A forward arrow leads to the following three products. The first product "succinyl Co A" has the following vertical chain: C, single bond, C H 2, single bond, C H 2, single bond, C O O superscript minus. C 1 is single bonded to S, single bond, C o A on the upper left, and double bonded to O on the upper right.

The second product is C O 2 highlighted in blue.

The third product is N A D H.

Return to Oxidative decarboxylation of alpha-ketoglutarate

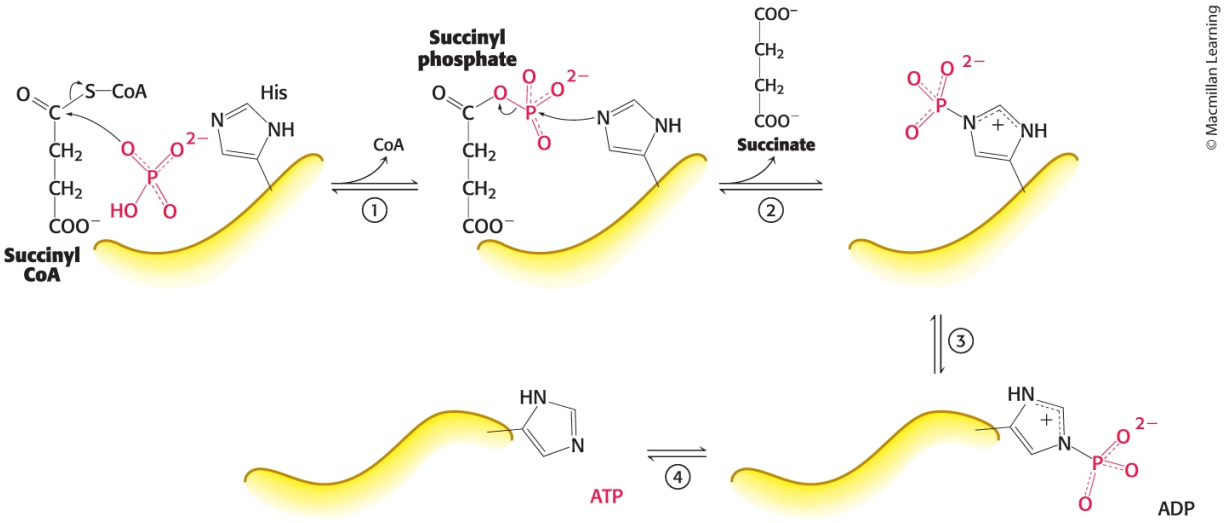
Extended description for Conversion of succinyl C o A into succinate

The reaction has 3 reactants and 3 products.

The first reactant "succinyl C o A" has the following vertical chain: C, single bond, C H 2, single bond, C H 2, single bond, C O O superscript minus. C 1 is single bonded to S, single bond, C o A on the upper left. C 1 is double bonded to O on the upper right.

The second reactant is P subscript i.

The third reactant is A D P.



A forward arrow leads to the following three products. The first product "succinate" has the following vertical chain: C O O superscript minus, single bond, C H 2, single bond, C H 2, single bond, C O O superscript minus.

The second product is C o A.

The third product is A T P.

Return to Conversion of succinyl C o A into succinate

Extended description for Mechanism of action of succinyl C o A synthetase

The enzyme active site is depicted as a shallow groove outlined by an orange line with a yellow highlight. The active site contains an H i s side chain whose structure is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 2 N and 3 C atoms. The first N occupies the first position, which is the top left vertex. The second N bound to H occupies the third position, which is the top right vertex. A double bond is present between N 1 and C 1, and C 2 and C 3.

A succinyl C o A molecule is also present in the active site. An H P O 4 superscript 2 minus molecule is present between succinyl C o A and the side chain of H i s.

The structure of succinyl C o A is as follows: C, single bond, C H 2, single bond, C H 2, single bond, C O O superscript minus. C 1 is double bonded to O on the upper left and single bonded to S, single bond, C o A on the upper right.

The structure of H P O 4 superscript 2 minus is as follows: A central P atom is partially double bonded to O on the upper left, O superscript 2 minus on the upper right, O on the lower right, and single bonded to O H on the lower left.

An arrow from the upper left O atom of H P O 4 superscript 2 minus molecule points toward C 1 of succinyl C o A. Another arrow points from the single bond between C 1 and S toward the S atom of the succinyl C o A molecule.

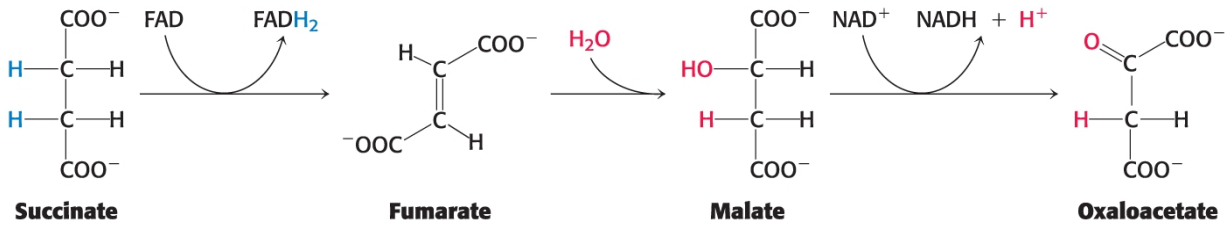
A reversible reaction arrow labeled 1 shows the succinyl phosphate molecule in the active site. An upward pointing arrow above it shows the release of C o A.

The structure of succinyl phosphate is as follows: C, single bond, C H 2, single bond, C H 2, single bond, C O O superscript minus. C 1 is double bonded to O on the upper left and single bonded to O on the upper right. This O is single-bonded to a central P atom. The P atom is partially double bonded to O above, O superscript 2 minus on the upper right, and O on the lower right.

An arrow from N 1 of H i s pentagonal ring points toward the central P atom. Another arrow points from the single bond between O and central P atom points toward the O atom directly bonded to C 1 of succinyl phosphate.

A reversible reaction arrow labeled 2 shows the phosphorylated H i s ring. An upward pointing arrow above it shows the release of succinate.

The structure of succinate is as follows: C O O superscript minus, single bond, C H 2, single bond, C H 2, single bond, C O O superscript minus.



In the active site, N 1 of the H i s pentagonal ring is single bonded to a central P atom. This P is partially double bonded to O on the upper left, O superscript 2 minus above, and O on the lower left. C 1 has an overall positive charge. A partial double bond is present between C 1 and N 1, and C 1 and N 2.

A reversible reaction arrow labeled 3 shows the phosphorylated H i s pentagonal ring oriented toward A D P located in the space outside the active site.

A reversible reaction arrow labeled 4 shows the final product. The A D P molecule outside the active site is converted into A T P. The pentagonal ring of H i s loses the phosphoryl group but it is still oriented toward the outside space.

Return to Mechanism of action of succinyl C o A synthetase

Extended description for Sequential reaction showing conversion of succinate to oxaloacetate

The sequential reaction has one reactant, two intermediates, and one final product.

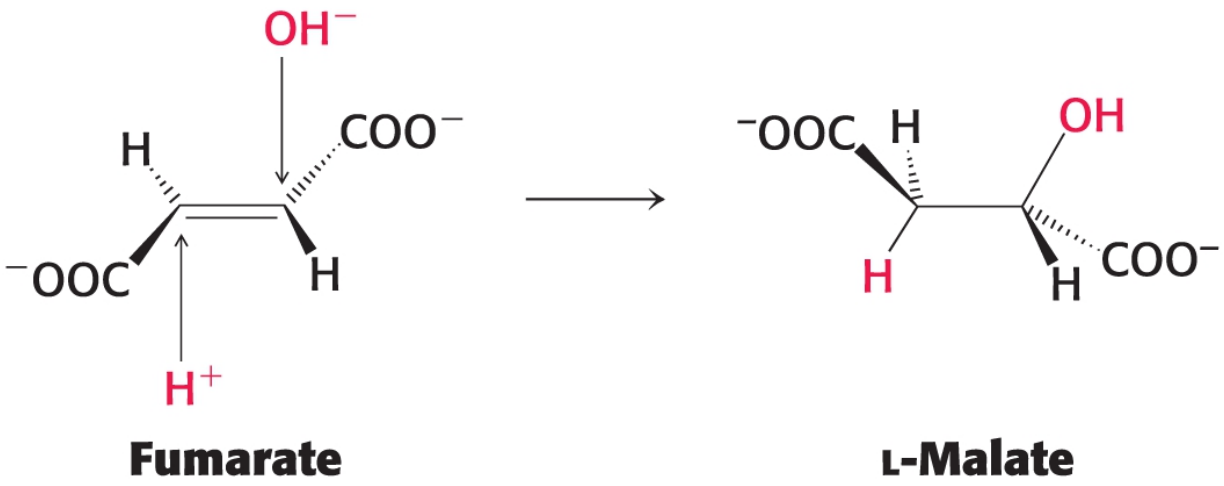
The structure of the reactant "Succinate" has the following vertical chain: C O O superscript minus, single bond, C, single bond, C, single bond, C O O superscript minus. C 2 and C 3 are each single bonded to H on the left and H on the right. The H atoms on the left are highlighted in blue.

A forward arrow shows the coupled conversion of F A D to F A D H 2 by the curved arrow and leads to the intermediate. H 2 of F A D H 2 is highlighted in blue.

The first intermediate "Fumarate" has the following vertical chain: C, double bond, C. C 1 is single bonded to C O O superscript minus on the upper right and H on the upper left. C 2 is single bonded to C O O superscript minus on the lower left and H on the lower right.

A forward arrow shows the entry of the H 2 O molecule highlighted in red.

The second intermediate "Malate" has the following vertical chain: C O O superscript minus, single bond, C, single bond, C, single bond,



C O O superscript minus. C 2 and C 3 are each single bonded to H on the right. C 2 is single bonded to O H on the left and C 3 is single bonded to H on the left. The O H and H on the left are highlighted in red.

A forward arrow has a curved arrow above that shows coupled conversion of N A D superscript plus into N A D H and H superscript plus highlighted in red.

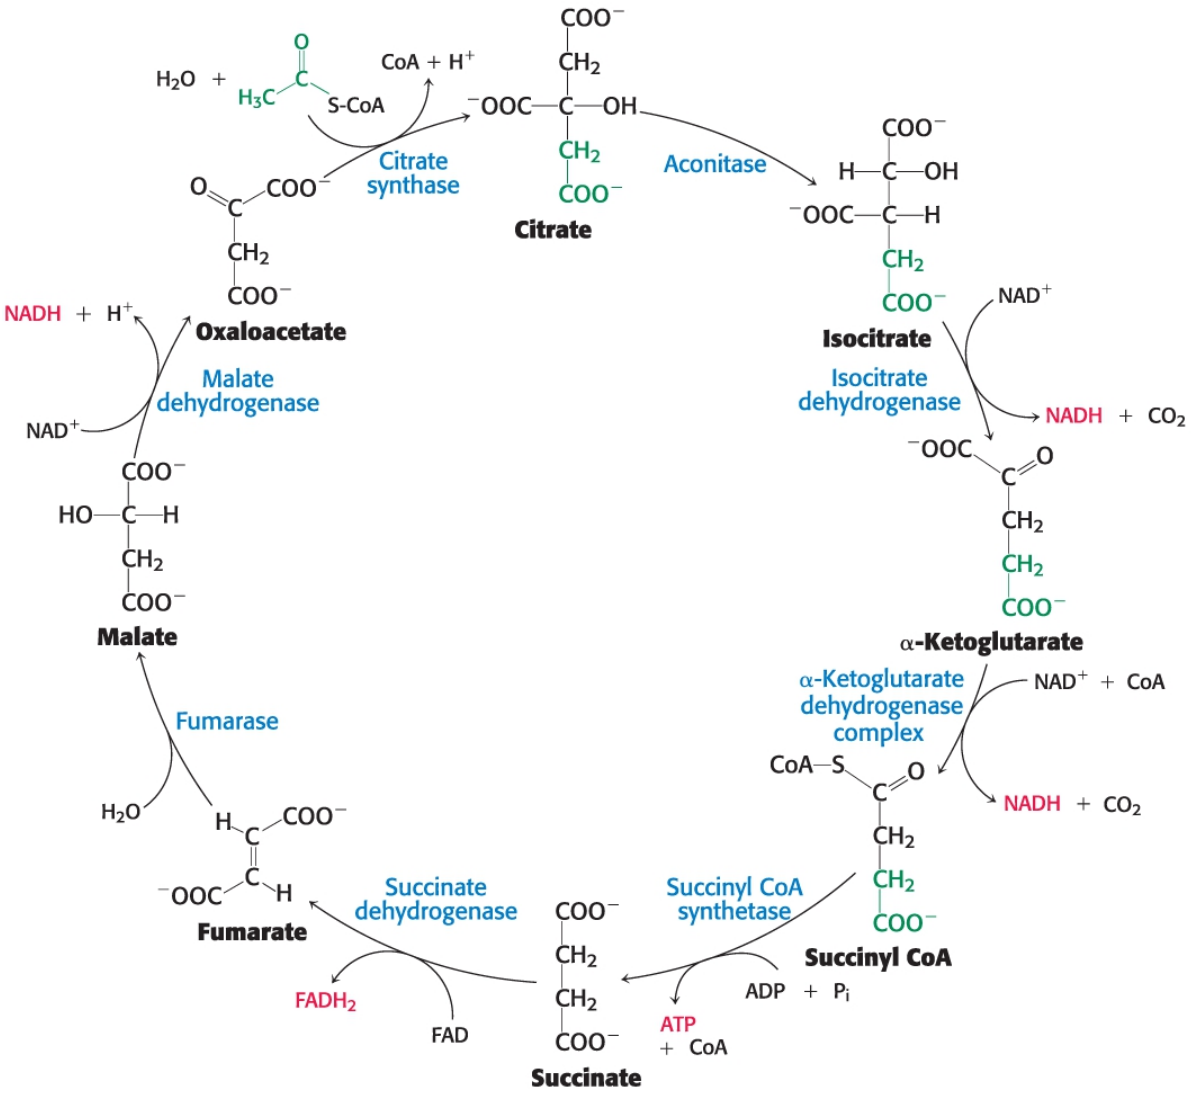
The final product "Oxaloacetate" has the following vertical chain: C, single bond, C, single bond, C O O superscript minus. C 1 is single bonded to C O O superscript minus on the upper right and double bonded to O on the upper left. C 2 is single bonded to H on the left and H on the right. The H atom on the left is highlighted in red.

Return to Sequential reaction showing conversion of succinate to oxaloacetate

Extended description for Conversion of fumarate into L-malate

The structure Fumarate is depicted as follows: C, double bond, C. C 1 is dash bonded to H on the upper left, and wedge bonded to C O O superscript minus on the lower left. C 2 is dash bonded to C O O superscript minus on the upper right and wedge bonded to H on the lower right.

A downward arrow points from the O H superscript minus to the dash bond between C 2 and C O O superscript minus on the upper right. An upward arrow points from the H superscript plus to the wedge bond between C 1 and C O O superscript minus on the lower left.



A forward arrow leads to the product.

The structure of L-Malate is depicted as follows: C, double bond, C. C 1 is dash bonded to H above, wedge bonded to C O O superscript minus on the upper left, and single bonded to H on the lower left. C 2 is dash bonded to C O O superscript minus on the lower right,

wedge bonded to H on the lower right, and single bonded to O H on the upper right.

Return to Conversion of fumarate into L-malate

Extended description for Citric acid cycle

The citric acid cycle includes 8 enzyme-catalyzed reactions depicted as follows:

1) Citrate is converted into isocitrate by the aconitase enzyme. The structure of citrate is as follows: C O O superscript minus, single bond, C H 2, single bond, C, single bond, C H 2, single bond, C O O superscript minus. C 3 is single bonded to C O O superscript minus

on the left and single bonded to O H on the right. The structure of isocitrate is as follows: C O O superscript minus, single bond, C, single bond, C, single bond, C H 2, single bond, C O O superscript minus. C 2 is single bonded to H on the left and O H on the right. C 3 is single bonded to C O O superscript minus on the left and single bonded to H.

2) Isocitrate is converted into alpha-ketoglutarate by the isocitrate dehydrogenase enzyme. It involves the reduction of N A D superscript plus to N A D H and the release of C O 2. The structure of alpha-ketoglutarate is as follows: C, single bond, C H 2, single bond, C H 2, single bond, C O O superscript minus. C 1 is single bonded to C O O superscript minus on the upper left and double bonded to O on the upper right.

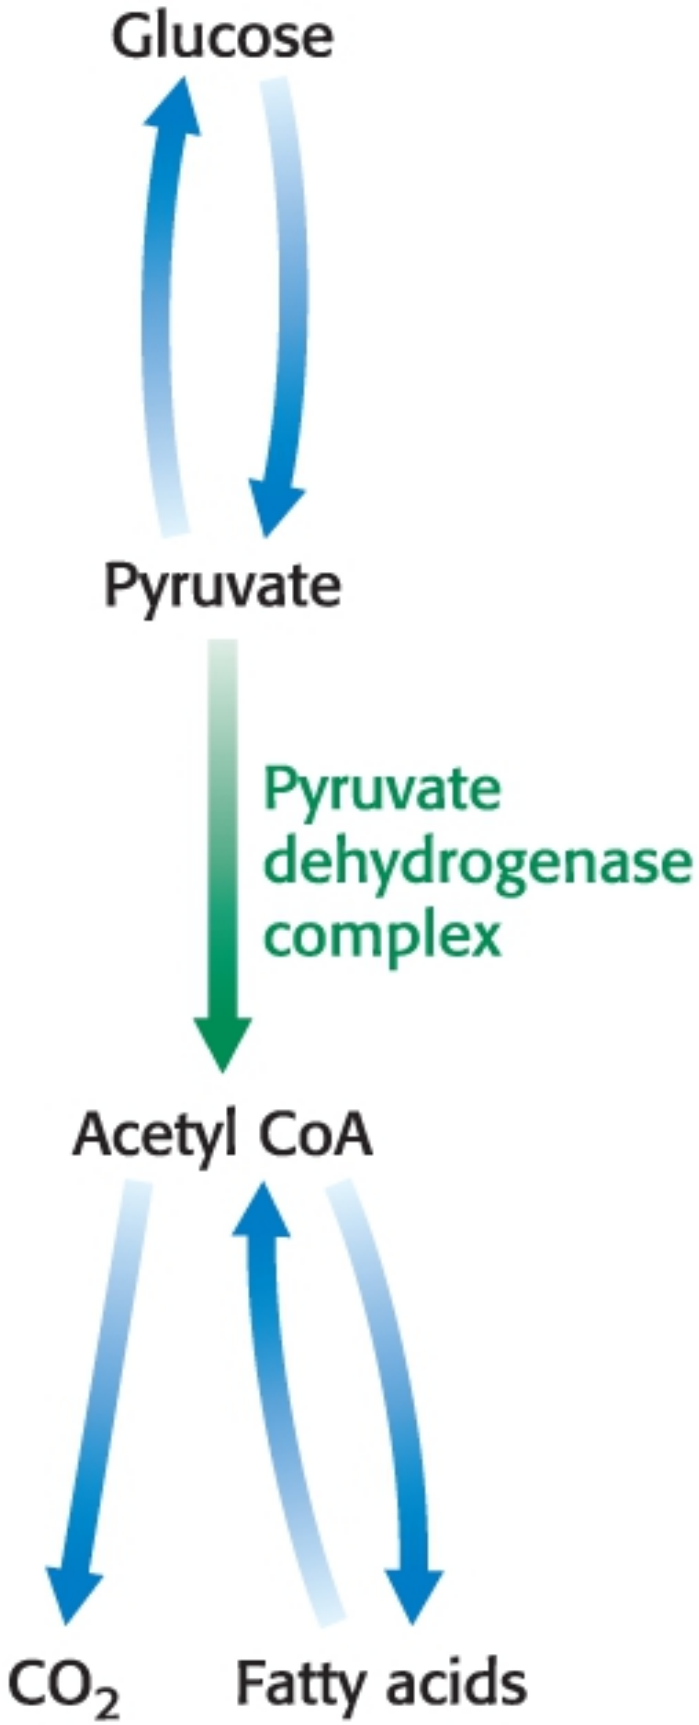
3) Alpha-ketoglutarate is converted into succinyl-C o A by alpha-ketoglutarate dehydrogenase complex. It involves the reduction of N A D superscript plus to N A D H, entry of C o A, and exit of C O 2. The structure of succinyl-C o A is as follows: C, single bond, C H 2, single bond, C H 2, single bond, C O O superscript minus. C 1 is single bonded to S, single bond, C o A on the upper left, and double bonded to O on the upper right.

4) Succinyl-C o A is converted into succinate by succinyl C o A synthetase. It involves the conversion of A D P plus P subscript i to A T P and the release of C o A. The structure of succinate is as follows: C O O superscript minus, single bond, C H 2, single bond, C H 2, single bond, C O O superscript minus.

5) Succinate is converted into fumarate by succinate dehydrogenase. It involves the reduction of F A D to F A D H 2. The structure of fumarate is as follows: A central C is single bonded to H on the upper left, single bonded to C O O superscript minus on the upper right, and double bonded to C below. The C atom below is single

bonded to C O O superscript minus on the lower left and single bonded to H on the lower right.

6) Fumarate is converted into malate by fumarase. An H 2 O molecule also enters the reaction. The structure of malate is as follows: C O O superscript minus, single bond, C, single bond, C H 2, single bond, C O O superscript minus. C 2 is single bonded to O H on the left and H on the right.



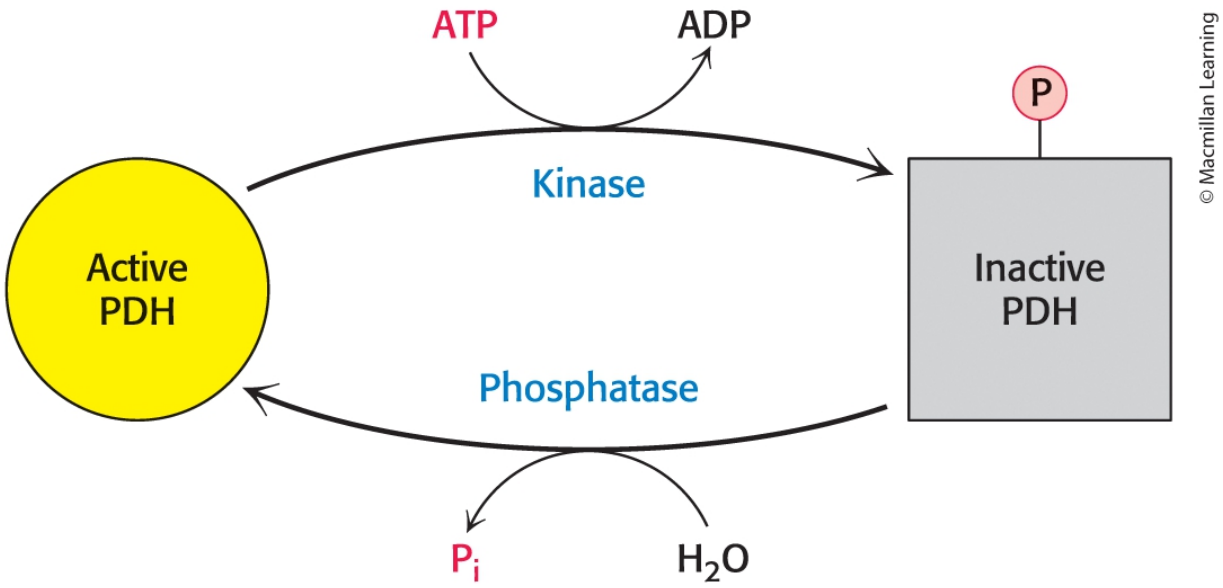
7) Malate is converted into oxaloacetate by malate dehydrogenase. It also involves the reduction of N A D superscript plus to N A D H plus H superscript plus. The structure of oxaloacetate is as follows: C, single bond, C H 2, single bond, C O O superscript minus. C 1 is double bonded to O on the upper left and single bonded to C O O superscript minus on the upper right.

8) Oxaloacetate is converted back to citrate by citrate synthase. It involves the entry of H 2 O plus a molecule whose structure is as follows: A central C atom is double bonded to O above, single bonded to C H 3 on the lower left, and single bonded to S, single bond, C o A on the lower right. C o A and H superscript plus are released during this reaction.

Return to Citric acid cycle

Extended description for Conversion of glucose to C O

2 and fatty acids



© Macmillan Learning

The flowchart is depicted as follows: Glucose, a pair of downward and upward arrows, pyruvate, a single downward arrow labeled pyruvate dehydrogenase complex, acetyl C o A, lower left arrow, and a pair of downward and upward arrows. The lower left arrow leads to C O 2 and the pair of arrows lead to fatty acids.

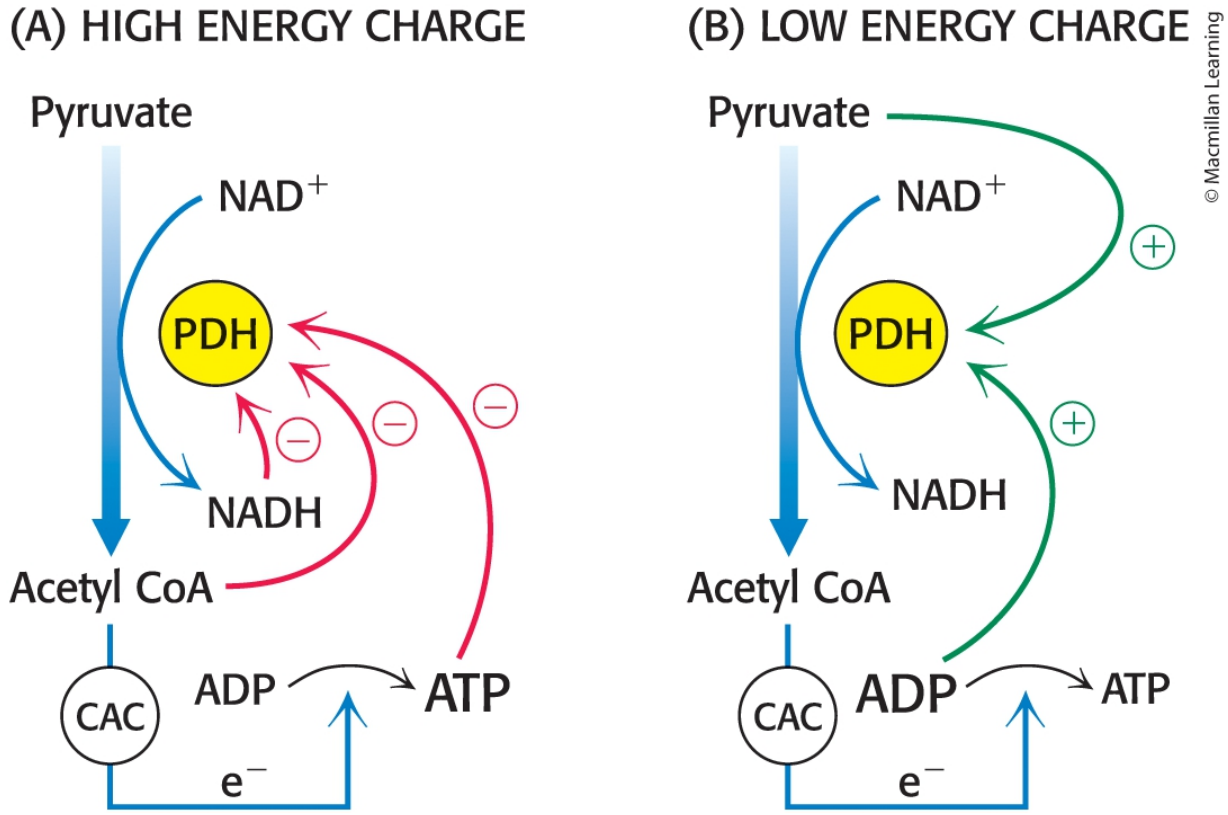
Extended description for Regulation of pyruvate dehydrogenase complex activity

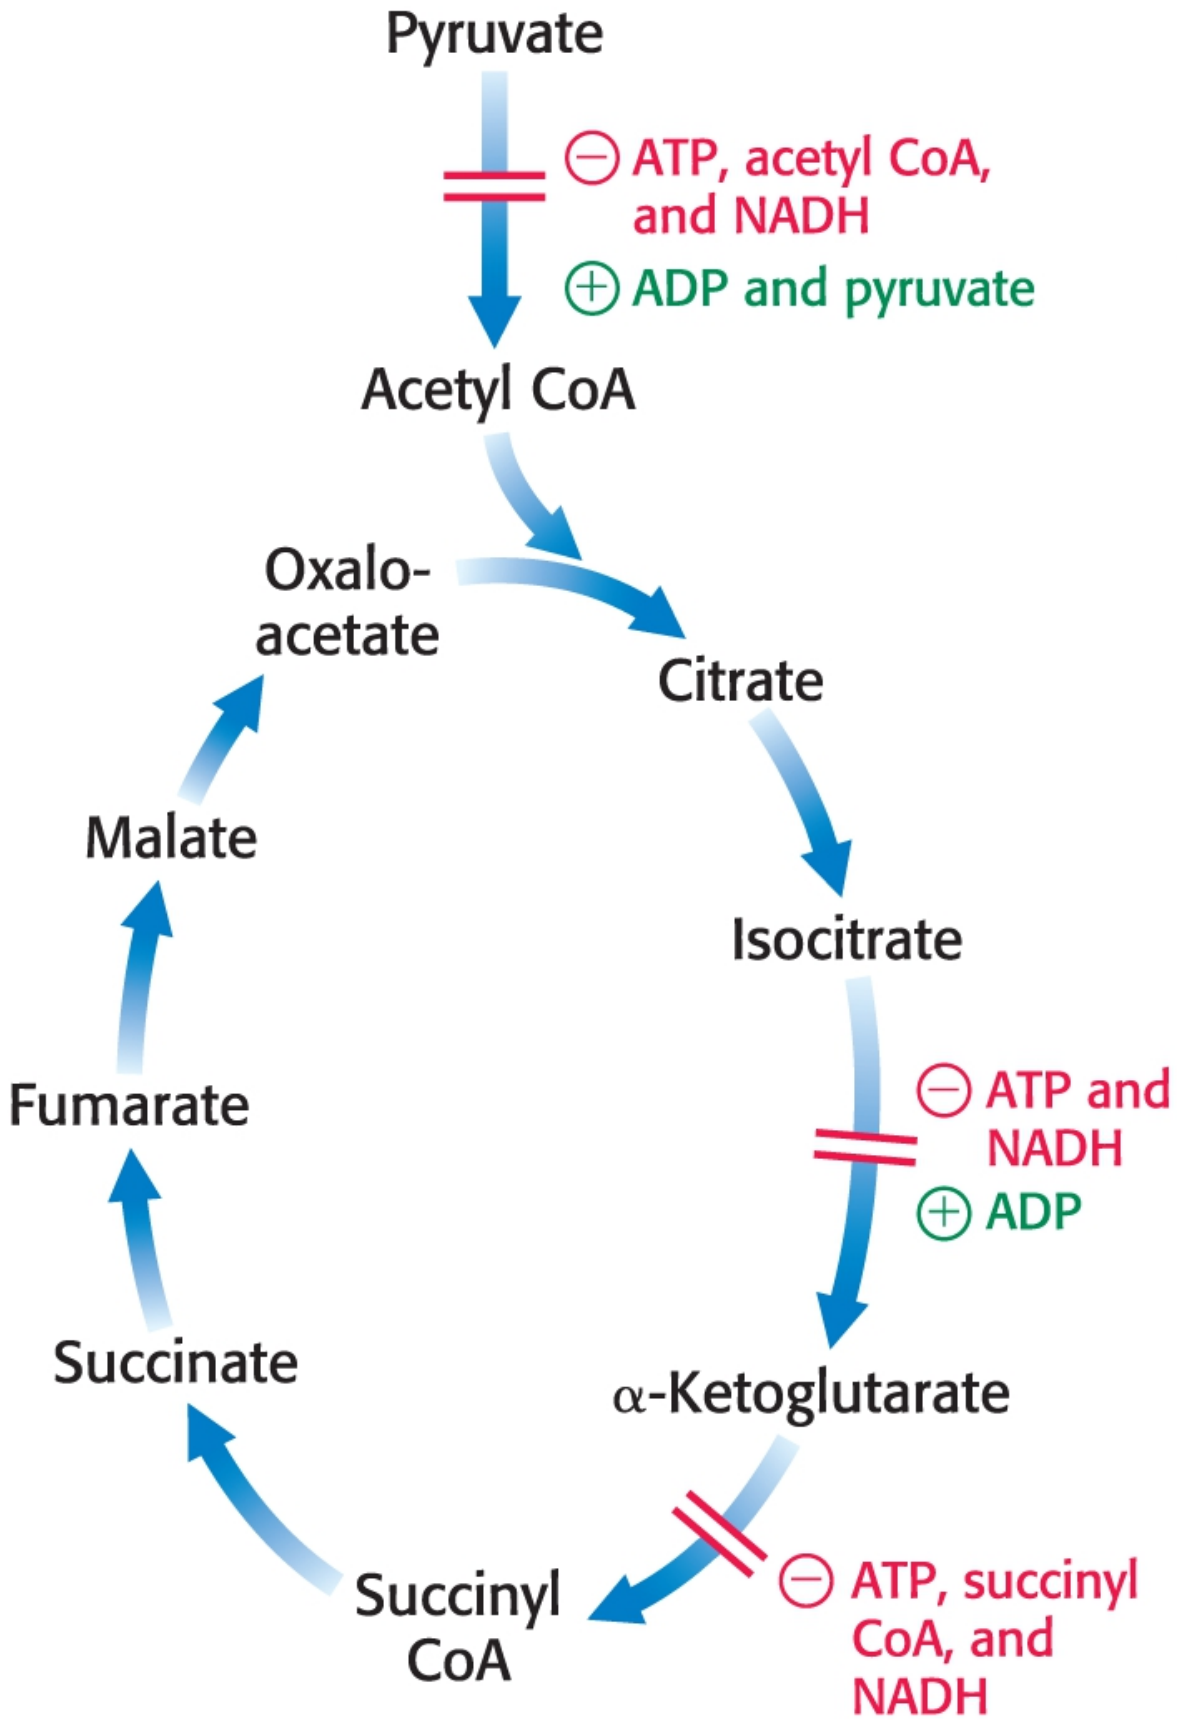


A yellow circle labeled active P D H is shown on the left. A forward arrow labeled kinase points from this circle toward a grey rectangle on the right labeled inactive P D H. A curved arrow above the forward arrow shows the simultaneous breakdown of A T P to A D P. The grey rectangle is single bonded to P above.

A backward arrow labeled phosphatase points from the grey rectangle toward the circle. A curved arrow below the backward arrow shows the simultaneous entry of H 2 O and the release of P subscript i.

Return to Regulation of pyruvate dehydrogenase complex activity

Extended description for Response of pyruvate dehydrogenase complex to changes in the energy of the cell



(A) High energy charge: Pyruvate, a downward arrow labeled P D H, acetyl C o A. A curved arrow on the right of the downward arrow shows the simultaneous reduction of N A D superscript plus to N A D H. An arrow from acetyl C o A passes through a circle labeled C A C. The arrow transfers electron to carry out the conversion of A D P to A T P. A red arrow with a minus symbol points from acetyl C o A to P D H, A T P to P D H, and N A D H to P D H.

(B) Low energy charge: Pyruvate, a downward arrow labeled P D H, acetyl C o A. A curved arrow on the right of the downward arrow

shows the simultaneous reduction of N A D superscript plus to N A D H. An arrow from acetyl C o A passes through a circle labeled C A C. The arrow transfers electron to carry out the conversion of A D P to A T P. A green arrow with a plus symbol points from A D P to P D H, and pyruvate to P D H.

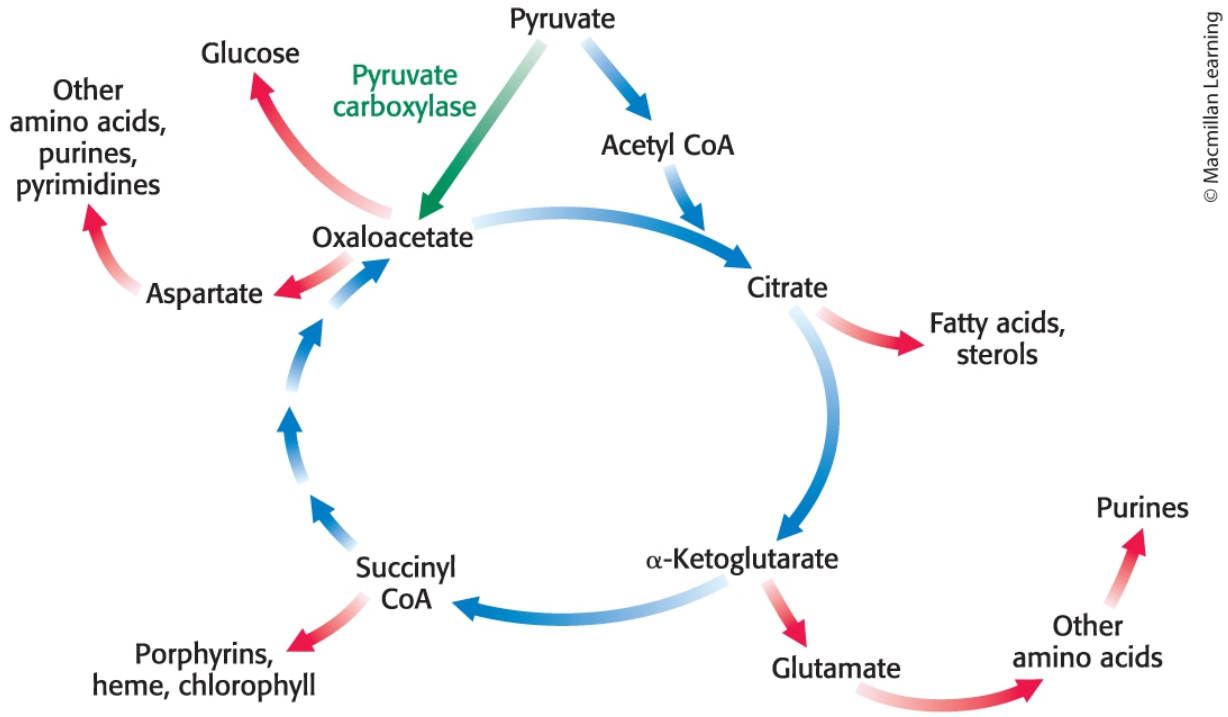
Extended description for Regulation of citric acid cycle

© Macmillan Learning



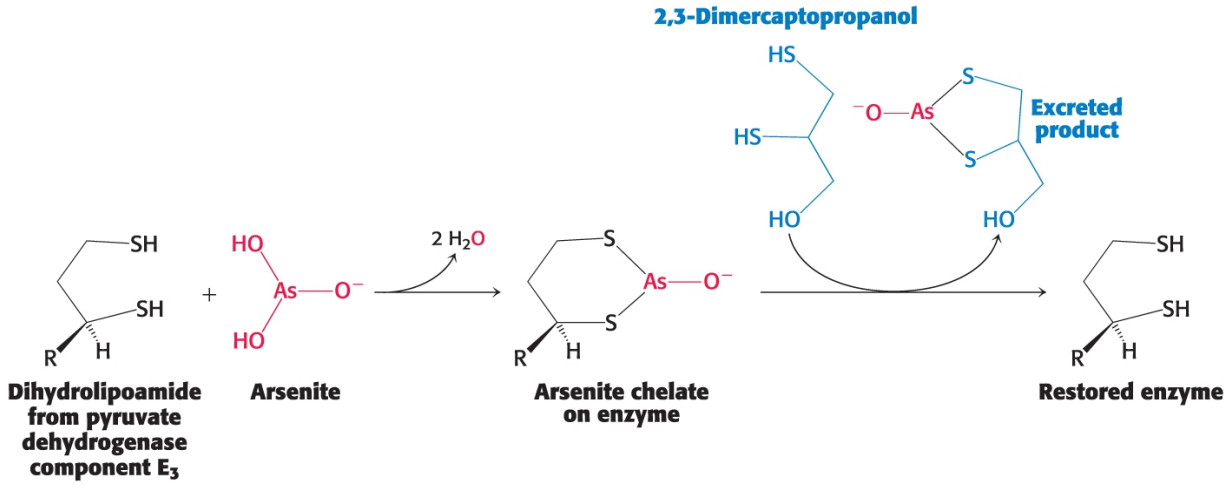
The citric acid cycle is depicted as follows: Pyruvate, downward arrow, acetyl C o A. A downward arrow from acetyl C o A leads to a forward arrow pointing from oxaloacetate to citrate. Citrate, downward arrow, isocitrate, downward arrow, alpha-ketoglutarate, lower left arrow, succinyl C o A, upper left arrow, succinate, upward arrow, fumarate, upward arrow, malate, upper right arrow, oxaloacetate. Two parallel red lines are shown over the downward arrow between pyruvate and acetyl C o A. This conversion is inhibited by A T P, acetyl C o A, and N A D H and activated by A D P and pyruvate.

Two parallel red lines are shown over the downward arrow between isocitrate and alpha-ketoglutarate. This conversion is inhibited by A T P and N A D H and activated by A D P.

Two parallel red lines are shown over the lower left arrow between alpha-ketoglutarate and succinyl C o A. This conversion is inhibited by A T P, succinyl C o A, and N A D H.

Return to Regulation of citric acid cycle

Extended description for Fates of the intermediates of citric acid cycle



A green lower left arrow labeled pyruvate carboxylase leads from pyruvate to oxaloacetate. A lower right blue arrow leads from pyruvate to acetyl C o A. A lower right blue arrow leads from acetyl C o A toward the blue forward arrow pointing from oxaloacetate to citrate. A blue downward from citrate points toward alpha-ketoglutarate and a red arrow from citrate points toward fatty acid, sterols located outside the cycle. A blue arrow from alpha-ketoglutarate leads to succinyl C o A and a red lower right arrow from alpha-ketoglutarate points toward glutamate located outside the cycle. A red arrow from glutamate points toward other amino acids. A red arrow from other amino acids points toward purines. A red lower left arrow from succinyl C o A points toward porphyrins, heme, and chlorophyll located outside the cycle. Four blue upward arrows point from succinyl C o A points toward oxaloacetate. A red

lower left arrow from oxaloacetate points toward aspartate outside the cycle. Another arrow from aspartate points toward other amino acids, purines, and pyrimidines. A red upper left arrow from oxaloacetate points toward glucose outside the cycle.

Extended description for Inhibition of pyruvate dehydrogenase by arsenite and its reversal by 2,3-dimercaptopropanol

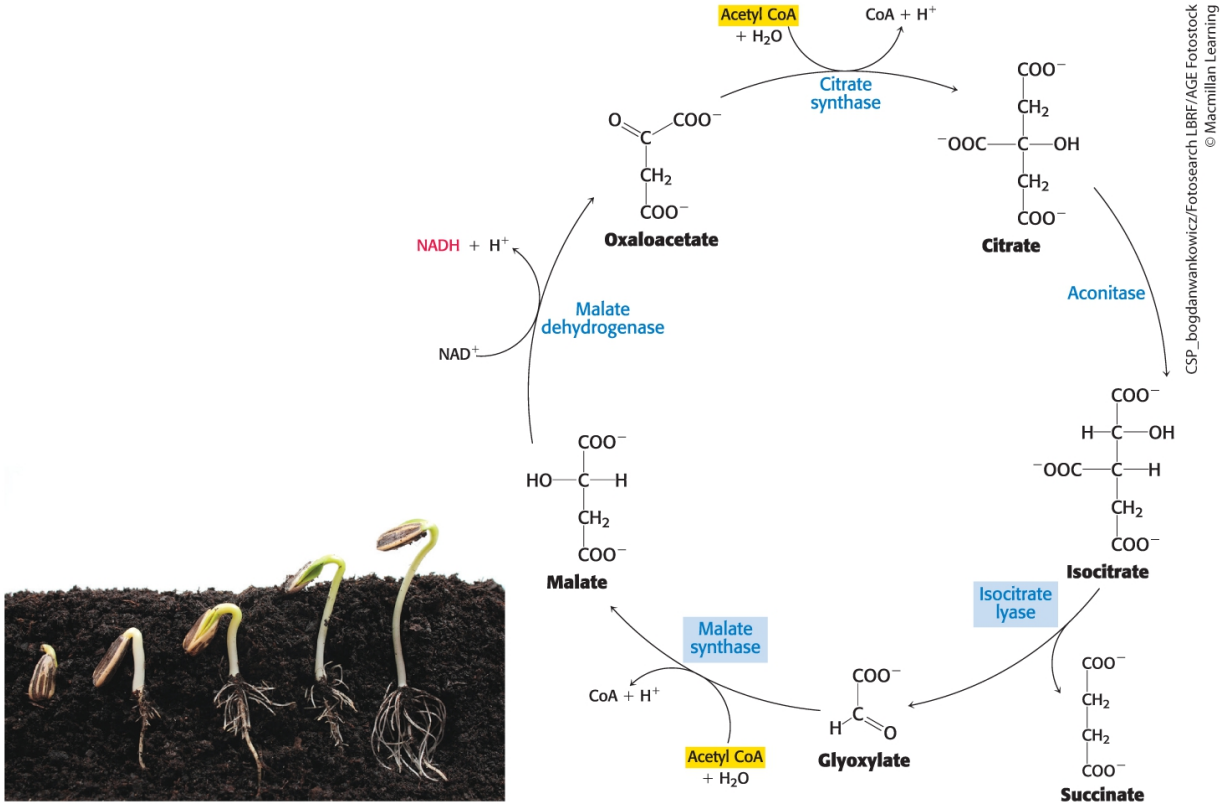
The reaction is divided into two steps. In the first step, the arsenite chelate on enzyme is formed. Dihydrolipoamide from pyruvate dehydrogenase component E 3 reacts with arsenite to produce arsenite chelate on enzyme. This step is coupled with the release of 2 H 2 O. In the second step, the restored enzyme is formed. The arsenite chelate on enzyme is converted into the restored enzyme in the presence of 2, 3-Dimercaptopropanol which itself is converted into an excreted product.

The structure of dihydrolipoamide from pyruvate dehydrogenase component E 3 is as follows: A 3-carbon alkane chain is depicted as a vertical line structure using 2 zigzag lines. C 1 and C 3 are each single bonded to S H on the right. C 3 is wedge bonded to R on the lower left and dash bonded to H on the lower right.

The structure of arsenite is as follows: A central A s atom is single bonded to O superscript minus on the right, single bonded to O H on

the upper left, and single bonded to O H on the lower left.

The structure of arsenite chelate on enzyme is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 A s, 2 S, and 3 C atoms. S 1 occupies the first position, which is the top right vertex. A s occupies the second position, which is the rightmost vertex. A s is single bonded to O superscript minus on the right. S 2 occupies the third position, which is the bottom right vertex. C 1 occupies the bottom left vertex and is wedge bonded to R on the lower left and dash bonded to H on the lower right.



The structure of 2,3-Dimercaptopropanol is as follows: A 3-carbon alkane chain is depicted as a vertical line structure using 2 zigzag lines. C 1 is single bonded to S H on the upper left. C 2 is single bonded to S H on the left. C 3 is single bonded to O H on the lower left.

The structure of the excreted product is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation with 1 A s, 2 S, and 2 C atoms. S 1 occupies the first position, which is the bottom-most vertex. A s occupies the second position, which is the leftmost vertex. A s is single bonded to O superscript minus on the right. S 2 occupies the third position, which is the top right vertex. C 2 is single bonded to C H 2 on the lower right in the form of a line. This C H 2 is single bonded to O H on the lower left.

The structure of the restored enzyme is as follows: A 3-carbon alkane chain is depicted as a vertical line structure using 2 zigzag lines vertically. C 1 and C 3 are each single bonded to S H on the right. C 3 is wedge bonded to R on the lower left and dash bonded to H on the lower right.

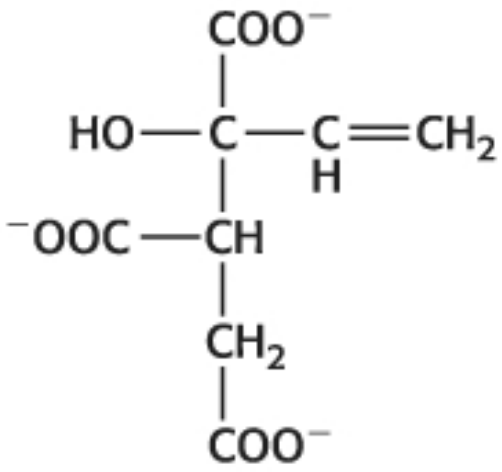
Return to Inhibition of pyruvate dehydrogenase by arsenite and its reversal by 2,3-dimercaptopropanol

Extended description for Glyoxylate cycle

The glyoxylate cycle consists of 5 enzyme-catalyzed reactions depicted as follows:

1) Oxaloacetate is converted into citrate by citrate synthase. It involves the simultaneous entry of acetyl C o A and H 2 O and release of C o A plus H superscript plus. The structure of oxaloacetate is as follows: C, single bond, C H 2, single bond, C O O superscript minus. C 1 is double bonded to O on the upper left and single bonded to C O O superscript minus on the upper right. The structure of citrate is as follows: C O O superscript minus, single bond, C H 2, single bond, C, single bond, C H 2, single bond, C O O superscript minus. C 3 is single bonded to C O O superscript minus on the left and O H on the right.

2) Citrate is converted into isocitrate by aconitase. The structure of isocitrate is as follows: C O O superscript minus, single bond, C, single bond, C, single bond, C H 2, single bond, C O O superscript minus. C 2 is single bonded to H on the left and O H on the right. C 3 is single bonded to C O O superscript minus on the left and H on the right.



3) Isocitrate is broken down into succinate and glyoxylate by isocitrate lyase. Succinate leaves the cycle and its structure is as follows: C O O superscript minus, single bond, C H 2, single bond, C H 2, single bond, C O O superscript minus. The structure of glyoxylate is as follows: A central C atom is single bonded to H on the lower left, single bonded to C O O superscript minus above, and double bonded to O on the lower right.

4) Glyoxylate is converted into malate by malate synthase. It involves the simultaneous entry of acetyl C o A plus H 2 O and release of C o A plus H superscript plus. The structure of malate is as follows: C O O superscript minus, single bond, C, single bond, C H 2, single bond, C O O superscript minus. C 2 is single bonded to O H on the left and H on the right.

5) Malate is converted into oxaloacetate by malate dehydrogenase. It involves the simultaneous reduction of N A D superscript plus to N A D H plus H superscript plus. Oxaloacetate reenters the first reaction catalyzed by citrate synthase.

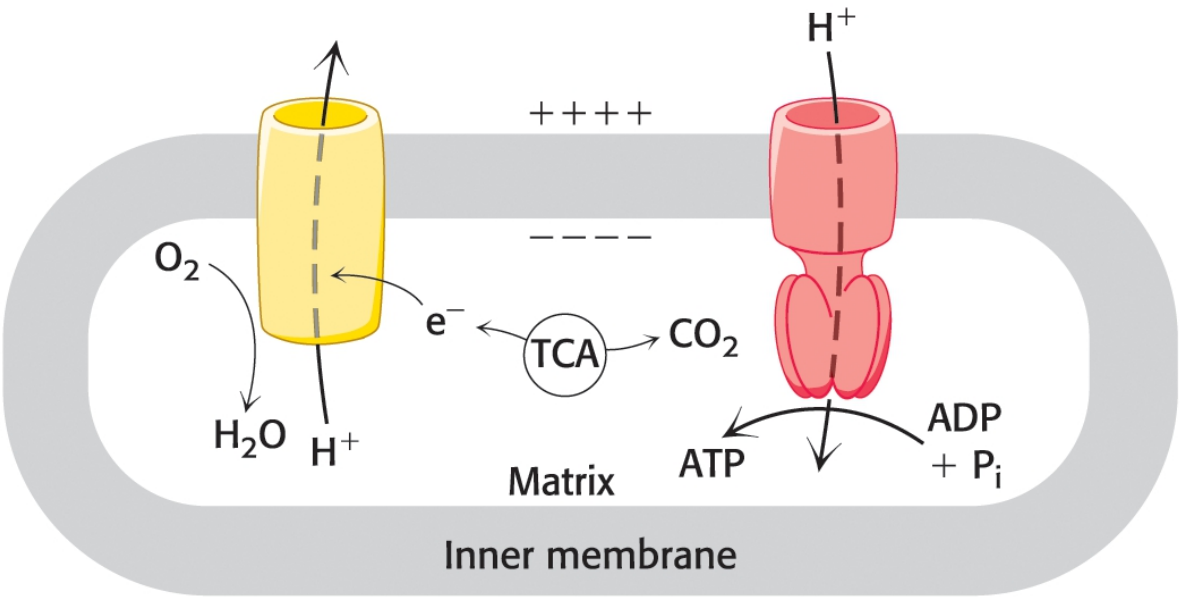
Extended description for Schematic representation of proton flow across A T P synthase



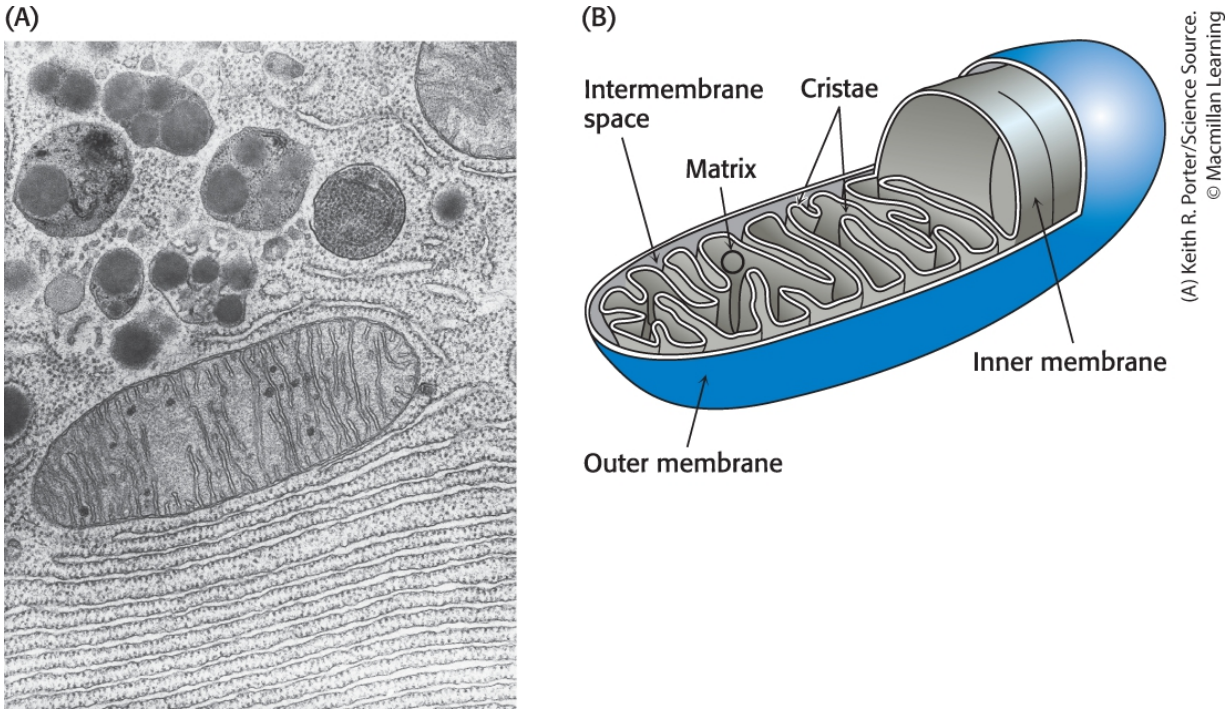
Melvyn Longhurst/Corbis Documentary/Getty Images
© Macmillan Learning

The c ring of A T P synthase is depicted as a cylindrical structure composed of 10 elongated vertical subunits. These subunits are bound to H. The region above the ring is labeled intermembrane space and the region below is labeled matrix. The front surface of the ring is enclosed by subunit a. An H superscript plus ion from the intermembrane space enters the intermembrane half-channel of subunit a. A curved circular arrow from the intermembrane half-channel moves in a clockwise direction around the c ring and returns back to the matrix half-channel of the subunit a. A downward arrow from the matrix half channel depicts the release of the H superscript plus ion into the matrix after its complete rotation around the c ring.

Return to Schematic representation of proton flow across A T P synthase

Extended description for Oxidative phosphorylation

© Macmillan Learning



A capsule-shaped structure with a thick grey border is shown. The border is labeled inner membrane. The interior is labeled matrix. A hollow cylindrical structure spans through the inner membrane. Another hollow cylindrical structure connected to a tetramer composed of oval-shaped structures also spans through the membrane. The tetramer is located in the matrix and the hollow cylindrical portion spans through the membrane. Four plus symbols are present above the membrane and four minus symbols are present below the membrane. Inside the matrix, a circle labeled T C A is shown in the center. An arrow from this circle shows the release of C O 2 and electrons.

An upward arrow across the first hollow cylindrical structure depicts the movement of H superscript plus ion from the matrix to the outside space. The electrons from the T C A cycle are simultaneously used to convert O 2 into H 2 O by the cylindrical structure. A downward arrow across the second hollow cylindrical

structure shows the movement of the H superscript ion from outside space into the matrix. This movement is accompanied by the conversion of A D P plus P subscript i to A T P.

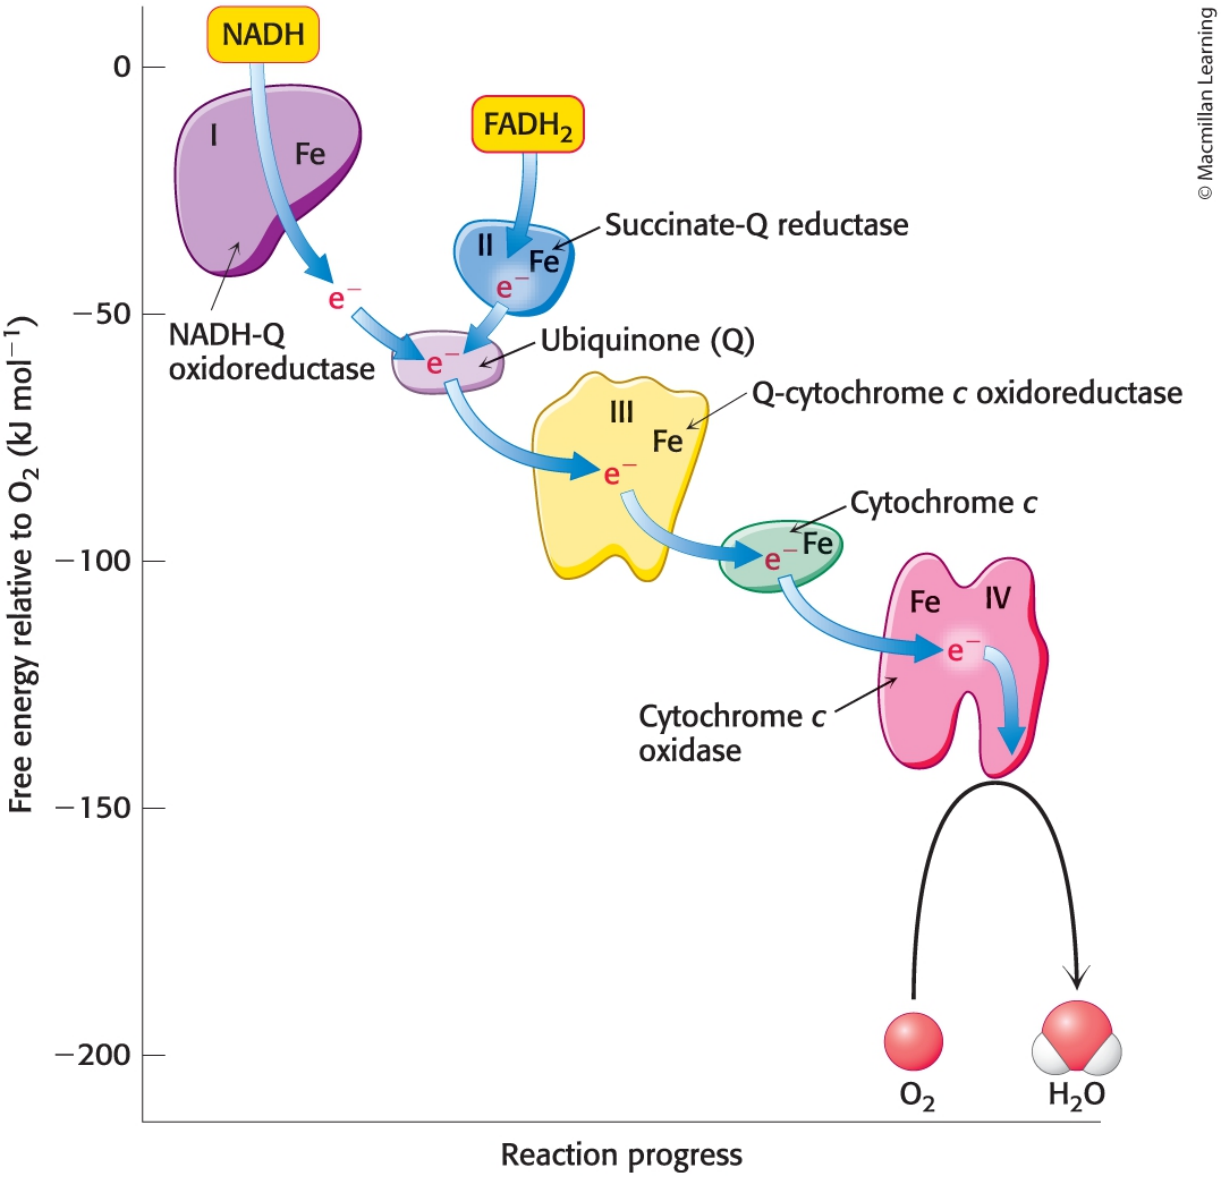
Extended description for FIGURE 18.3 Redox potential can be precisely measured

© Macmillan Learning

The schematic illustration shows the apparatus composed of two glass containers joined externally and horizontally by a tubular agar bridge at the center.



The left container has a solution of 1 Molar X and 1 molar X superscript minus. The right container has 1 molar H superscript

plus in equilibrium with 1 atmosphere H 2 gas.

Each container has a rectangular strip dipped in the solution. The strips are connected by wires to a common voltmeter at the top center.

Return to FIGURE 18.3 Redox potential can be precisely measured

Extended description for FIGURE 18.4 Components of the electron-transport chain

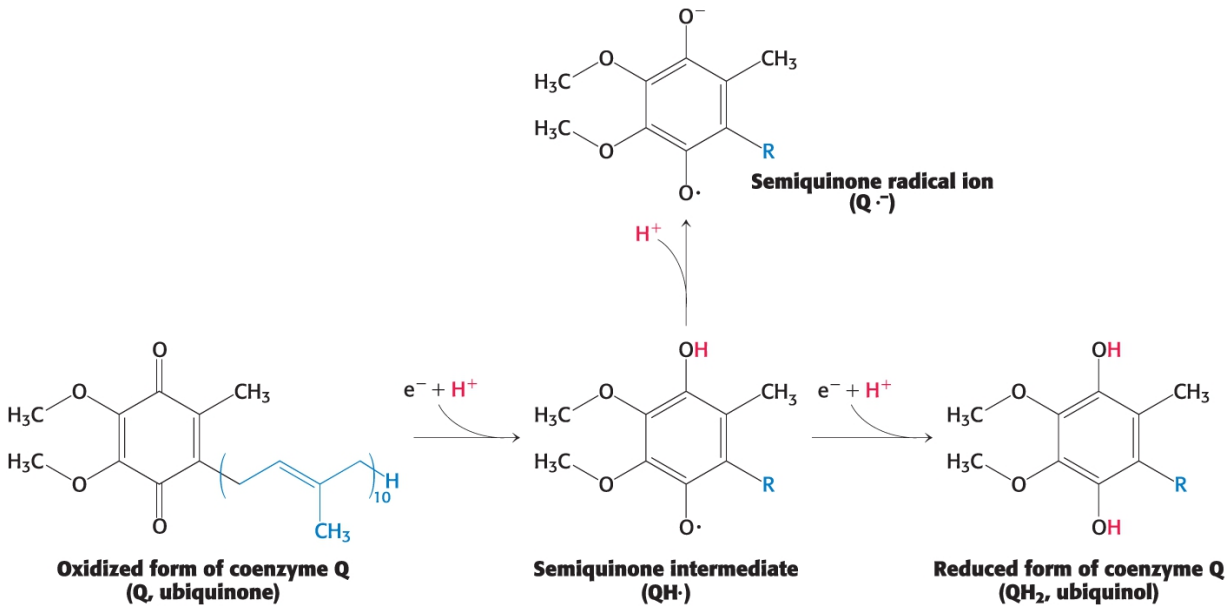
The schematic shows a graphical representation. The horizontal axis has label reaction progress and the vertical axis indicates free energy relative to O 2 in kilojoules per mole ranging from negative 200 to 0 in increments of 50 kilojoules per mole.

Step 1: A triangular complex I (F e) labeled N A D H- Q oxidoreductase at the top left corner of the graph is shown between negative 50 to 0 kilojoules per mole. An arrow is drawn through this complex from N A D H to an electron. Another arrow leads this electron to oval labeled ubiquinone (Q) shown in the range below negative 50 kilojoules per mole.

Step 2: An oval complex II (F e) labeled Succinate Q reductase is shown in the range of negative 50 to negative 35 kilojoules per mole. An arrow is drawn from F A D H 2 to succinate-Q reductase complex. Another arrow is drawn from an electron in the succinate Q reductase complex to an electron in ubiquinone (Q).

Step 3: A distorted polygon with a wavy border depicts complex III (F e) labeled Q- cytochrome c oxidoreductase shown in the range between negative 100 to negative 60 Kilojoules per mole. A curved arrow is drawn from an electron in ubiquinone (Q) to an electron in the Q-cytochrome c oxidoreductase complex.

Step 4: An oval labeled cytochrome c is shown at negative 100 Kilojoules per mole. An arrow is drawn from an electron in Q-cytochrome c oxidoreductase complex to the electron in cytochrome c.



Step 5: A distorted H-shaped complex IV (F e) labeled Cytochrome c oxidase is shown in the range between negative 150 to negative 100 Kilojoules per mole. An arrow is drawn from an electron in cytochrome c to an electron in the cytochrome c oxidase complex.

Step 6: An arrow is drawn from an electron in the cytochrome c oxidase complex pointing to the coupled conversion of O 2 to H 2 O. O 2 and H 2 O is shown at negative 200 kilojoules per mole.

The coupled conversion is depicted by a curved arrow touching the lower right corner of complex IV from a sphere labeled O 2 to a triatomic space-filling model of H 2 O.

Return to FIGURE 18.4 Components of the electron-transport chain

Extended description for FIGURE 18.5 Quinones can have three different oxidation states, two of which are stable

The schematic reaction shows the following conversions.

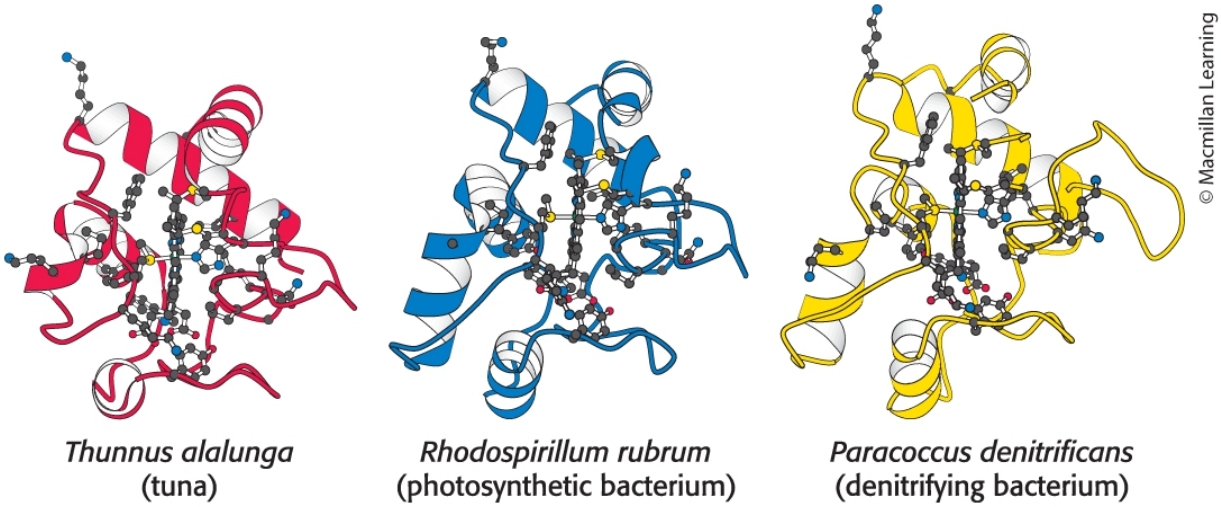
Structure 1: An oxidized form of coenzyme Q (Q, ubiquinone) has the following structure: A 6-carbon hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains double bonds between C 2 and C 3, and C 5 and C 6. C 1 and C 4 are each double bonded to O and C 2 is single bonded to C H 3. C 3 is single bonded to a 4-carbon alkene chain depicted as a line structure using 3 zigzag lines. C 1 to C 4 of the alkene chain is enclosed by brackets with subscript 10. C 2 of the alkene chain is double bonded to C 3. C 3 is single bonded to C H 3 below. C 4 is single bonded to H on the lower right. C 5 and C 6 are each single bonded to O on the lower left and upper left respectively. Each O is single-bonded to C H 3. The alkene chain is blue-highlighted.

A forward arrow coupled with electron and H superscript plus ions (red highlighted) leads to the next structure.

Structure 2: Semiquinone intermediate (Q H with dot) has the following structure: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to O H (H red highlighted) above and C 2 is single bonded to C H 3. C 3 is single bonded to R (blue highlighted). C 4 is single-bonded to O with an unpaired electron below. C 5 and C 6 are each single bonded to O on the lower left and upper left respectively. Each O is single-bonded to C H 3.

A forward arrow coupled with electron and H superscript plus ions (red highlighted) leads to the next structure.

Structure 3: The reduced form of coenzyme Q (Q H 2, ubiquinol) has the following structure: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 and C 4 are each single bonded to O H (H red highlighted) and C 2 is single bonded to C H 3. C 3 is single bonded to R (blue highlighted). C 5 and C 6 are each single bonded to O on the lower left and upper left respectively. Each O is single-bonded to C H 3.



An upward arrow coupled with H superscript plus ion (red highlighted) is drawn from structure 2 leading to the next structure above.

Structure 4: Semiquinone radical ion (Q superscript minus with an unpaired electron) has the following structure: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains double bonds between C 2 and C 3, C 4 and C 5, and C 6

and C 1. C 1 is single bonded to O superscript minus. C 4 is single-bonded to O with an unpaired electron. C 2 is single bonded to C H 3. C 3 is single bonded to R (blue highlighted). C 5 and C 6 are each single bonded to O on the lower left and upper left respectively. Each O is single-bonded to C H 3.

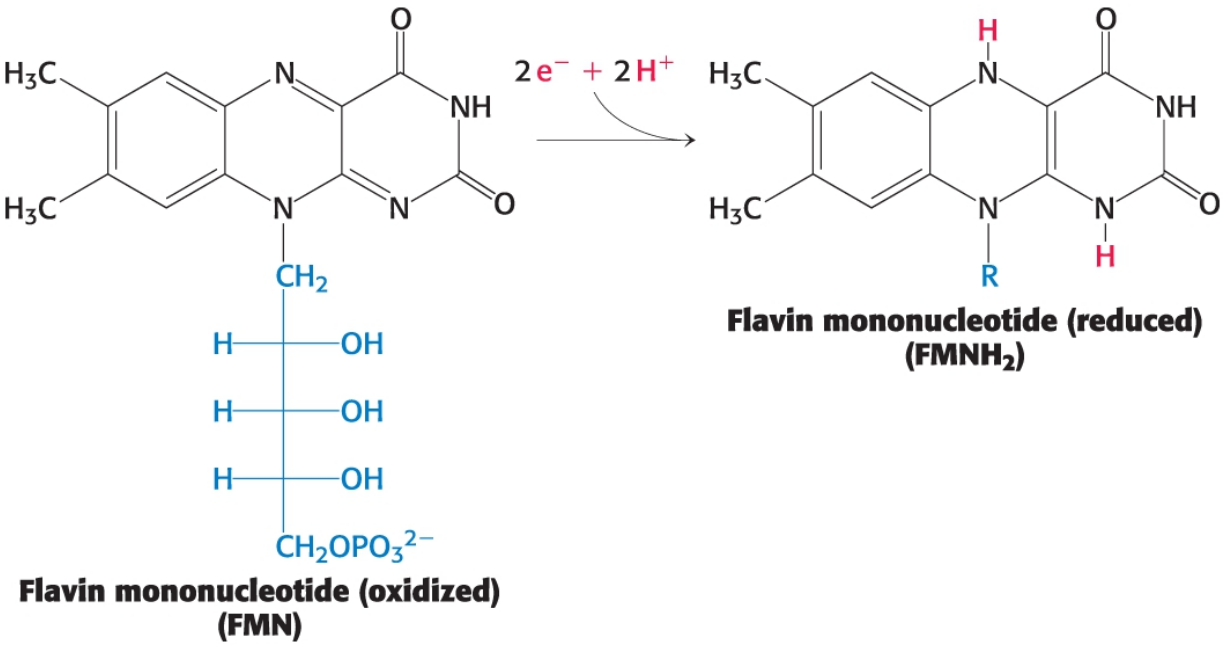
Extended description for FIGURE 18.6. The three-dimensional structure of cytochrome c is remarkably conserved among distantly related species

The ribbon diagrams of cytochrome c from Thunnus alalunga (tuna), Rhodospirillum rubrum (photosynthetic bacterium), and Paracoccus denitrificans (denitrifying bacterium) are shown. They consist of a few alpha-helices connected by long thread-like loops. Each ribbon diagram has a ball-and-stick model of the heme group in the center. The ball-and-stick models of side chain of different amino acids is shown along each ribbon diagram.

Return to FIGURE 18.6. The three-dimensional structure of cytochrome c is remarkably conserved among distantly related species

Extended description for FIGURE 18.7 Three different types of iron–sulfur clusters are commonly found in biological systems

(A): It shows a single central F e atom depicted as a green sphere connected to four cysteine resides. Each cysteine residue is composed of a yellow and a black sphere. The green sphere is connected to a yellow sphere on the upper left, upper right, lower left, and lower right. The upper right and lower left yellow spheres are located toward the observer. Each yellow sphere is connected to a black sphere.



(B): It shows the 2 F e 2 S cluster. Two central green spheres depicting F e atoms are shown adjacent to each other and are separated by a short distance. They are connected to a common yellow sphere at the top center and bottom center. The yellow spheres depict S atoms. The left green sphere is further connected to a yellow sphere on the upper left and lower left. Each yellow sphere is connected to a black sphere. The right green sphere is connected to a yellow sphere on the upper right and lower right. Each yellow

sphere is connected to a black sphere. The yellow sphere connected to a black sphere depicts cysteine residue.

(C): It shows the 4 F e 4 S cluster. It is depicted as 3-D trapezium-shaped structure with four vertices at the top and bottom. Each of the vertices of the top and bottom faces are occupied by yellow and green spheres in an alternating fashion. The yellow sphere depicts the S atom and the green spheres depict the F e atom. Each green sphere is connected to a yellow sphere which is further connected to a black sphere. The yellow sphere connected to a black sphere depicts cysteine residue.

Return to FIGURE 18.7 Three different types of iron–sulfur clusters are commonly found in biological systems

Extended description for FIGURE 18.8 Flavins have two oxidation states

The reaction shows one reactant and one product.

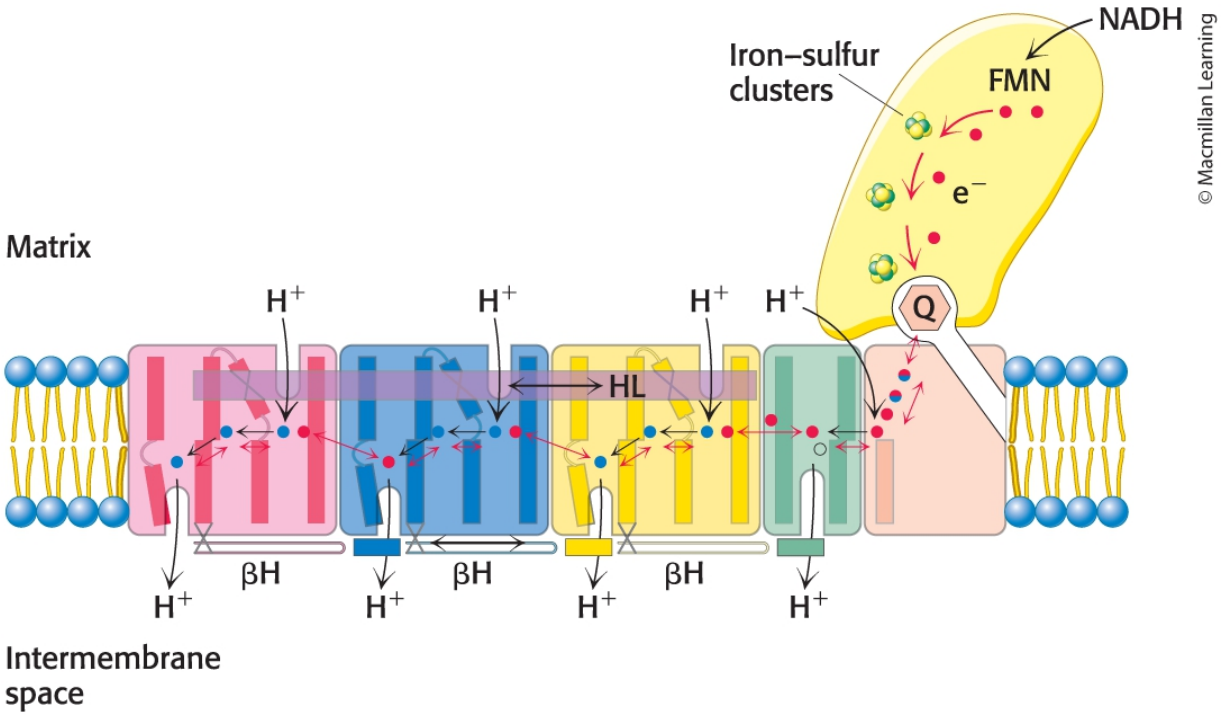
The reactant labeled “Flavin mononucleotide (oxidized) (F M N)” has the following structure: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex and is fused to a 6-membered heterocyclic hexagonal ring consisting of 2 N and 4 C atoms in a vertical orientation with N occupying the topmost vertex. The two rings are fused such that C 2 and C 3 of the benzene ring are the C 4 and C 3 of the 6-membered hexagonal ring, respectively. The benzene ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 5 and C 6 are each single bonded to C H 3. In the 6-membered heterocyclic hexagonal ring, a double bond is present between N 1 and C 1. N 2 occupies the fourth position, which is the bottom-most vertex. N 2 is single bonded to the C H 2 of the Fischer projection below.

The Fischer projection consists of a vertical line with C H 2 above and C H 2 O P O 3 superscript 2 minus below. The projection contains three C atoms placed one below the other on the vertical line. The C atoms are numbered from top to bottom. C 2, C 3, and C 4 each have a horizontal line drawn across them with H on the left and O H on the right.

The 6-membered heterocyclic hexagonal ring is fused to a second 6-membered heterocyclic hexagonal ring consisting of 2 N and 4 C atoms in a vertical orientation. In the second ring, C 1 occupies the bottom-right vertex. The two rings are fused such that C 1 and C 2 of the first hexagonal ring are the C 3 and C 2 of the second hexagonal ring, respectively.

In the second hexagonal ring, N 1 bound to H and N 2 are positioned at the top right and bottom vertices respectively. C 1 and C 4 are each double bonded to O. N 2 is double bonded to C 2.

A forward arrow is coupled with 2 electrons and 2 H superscript plus ions.



The product labeled flavin mononucleotide (reduced) (F M N H2) has the following structure: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It is fused to a 6-membered heterocyclic hexagonal ring consisting of 2 N and 4 C atoms in a vertical orientation with Noccupying the topmost vertex. The two rings are fused such that C 2 and C 3 of the benzene ring are the C 4 and C 3 of the 6-membered hexagonal ring, respectively. The benzene ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 5 and C 6 are each single bonded to CH 3. In the 6-membered heterocyclic, N 1 occupies the topmost vertex and N 2 occupies the bottom-most vertex. N 1 is single bonded to H above and N 2 is single bonded to R below.

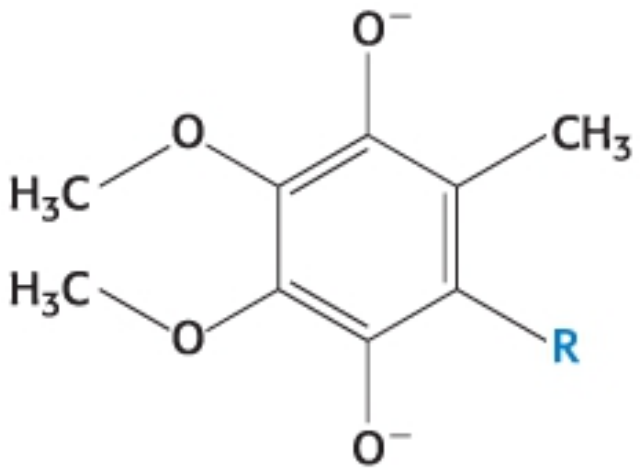
The 6-membered heterocyclic hexagonal ring is fused to a second 6-membered heterocyclic hexagonal ring consisting of 2 N and 4 C atoms in a vertical orientation. In the second ring, C 1 occupies the bottom-right vertex. The two rings are fused such that C 1 and C 2 of the first hexagonal ring are the C 3 and C 2 of the second hexagonal ring, respectively.

In the second hexagonal ring, N 1 bound to H and N 2 are positioned at the top right and bottom vertices respectively. C 1 and C 4 are each double bonded to O. N 2 is single bonded to H below. A double bond is present between C 2 and C 3.

Return to FIGURE 18.8 Flavins have two oxidation states

Extended description for FIGURE 18.9 Electron transfer through NADH-Q oxidoreductase is coupled to proton transfer reactions

Five different complexes are shown embedded in a lipid bilayer. The region above the bilayer is labeled matrix and the region below the bilayer is labeled intermembrane space. From the left end, three adjacent complexes are depicted as rectangles with a U-shaped groove in the top right and bottom left surface. A long horizontal and rectangular H L component spans across these three complexes. Each of the complexes contains a thin elongated and horizontal beta H complex in the intermembrane space. The next complex contains a U-shaped groove at the bottom surface. The final square-shaped complex contains a diagonal channel near the top right end. Complex 1 is depicted as a wide elongated structure in the matrix, above the square-shaped complex. N A D H enters complex 1



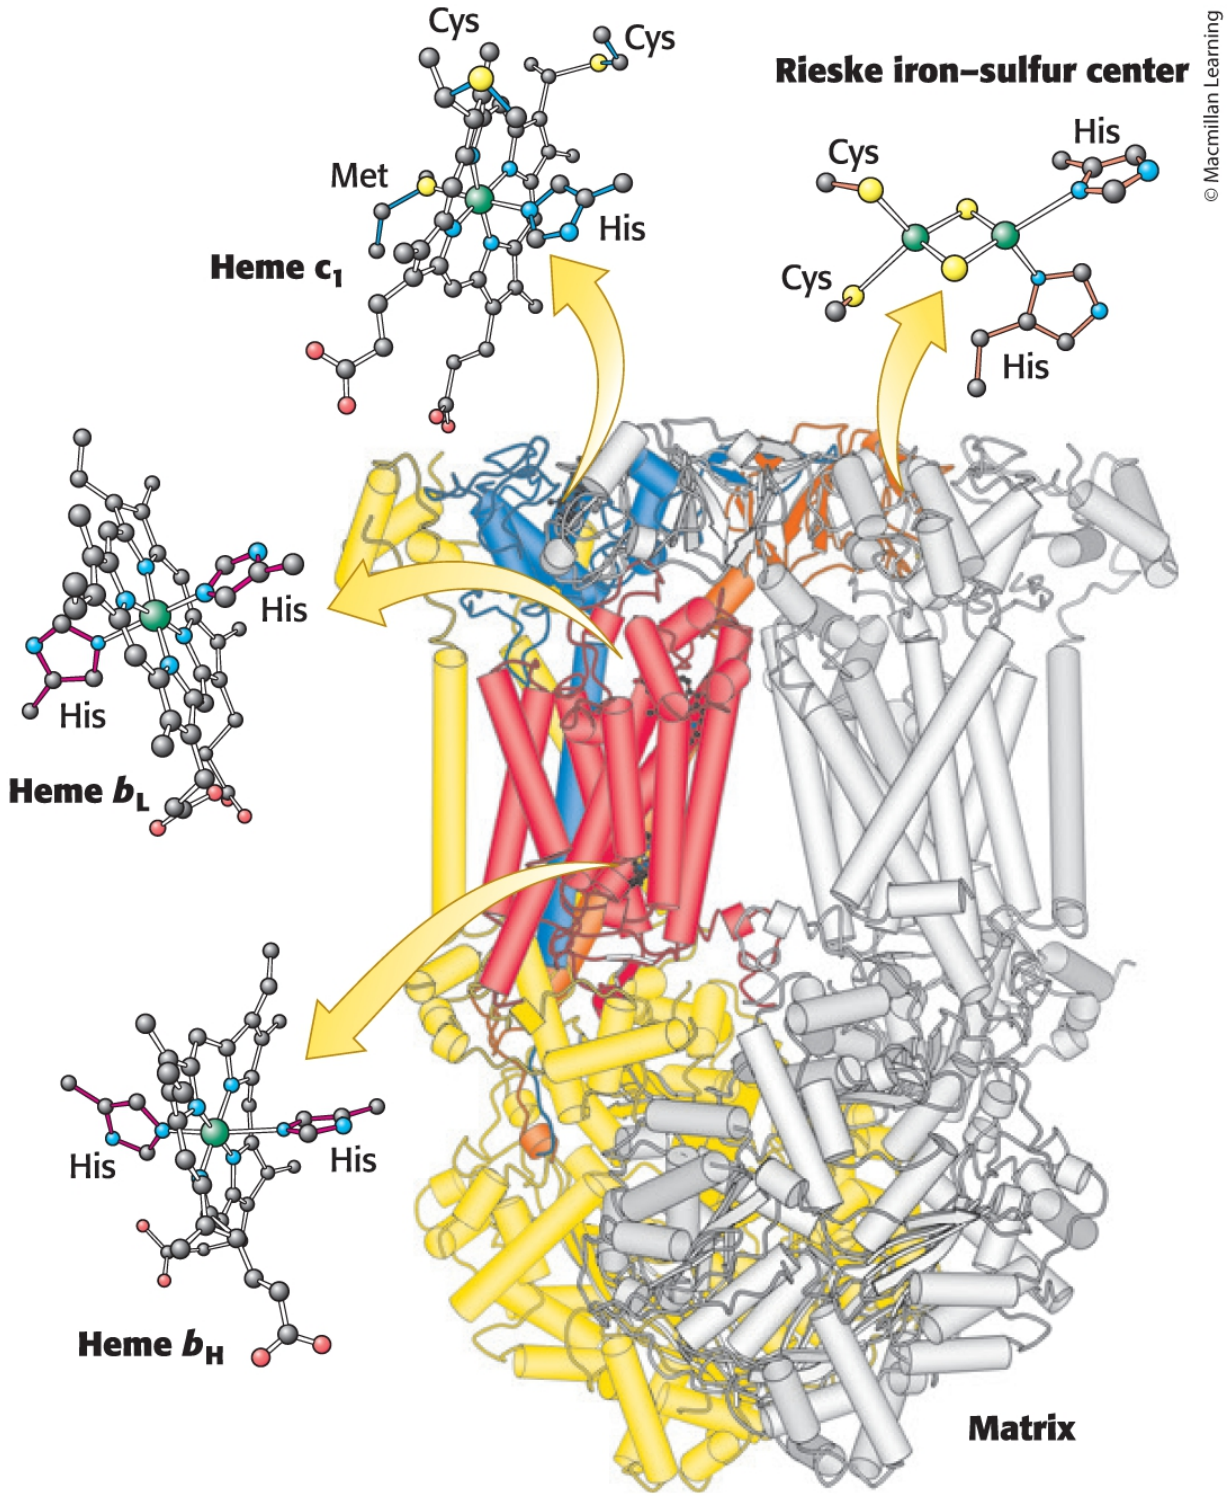
and donates electron to F M N. The electrons from F M N depicted as red dots pass through three different iron-sulfur clusters in complex 1. They travel to ubiquinone depicted as a horizontal hexagon labeled Q inside a circular groove between the junction of complex 1 and the square-shaped complex. This circular groove is continuous with the diagonal channel.

A two-way arrow depicts the movement of electrons through red and blue balls in the square-shaped complex. The electron then combines with an H superscript plus ion from the matrix. It then enters the adjacent complex and passes across it into the next adjacent complex. This movement of electrons is coupled with the release of H superscript plus ion into the intermembrane space through the bottom U-shaped groove.

The electron moves through red and blue balls leading to the alteration of the conformation of a central transmembrane helix. As a result, an H superscript plus ion enters into the top right U-shaped groove and exits through the bottom left groove into the intermembrane space. Similarly, the electrons pass through the remaining complexes with the simultaneous passage of H superscript ions from the matrix into the intermembrane space.

Return to FIGURE 18.9 Electron transfer through NADH-Q oxidoreductase is coupled to proton transfer reactions

Extended description for Structure of reduced ubiquinone



Reduced ubiquinone
(Q^{2-})

The structure of reduced ubiquinone is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 and C 4 are single bonded to O superscript minus above and below respectively. C 2 is single bonded to C H 3 on the upper right. C 3 is single bonded to R on the lower right. C 5 is single bonded to O on the lower left, which is further single bonded to C H 3 on the upper left. C 6 is single bonded to O on the upper left, which is further single bonded to C H 3 on the lower left.

Return to Structure of reduced ubiquinone

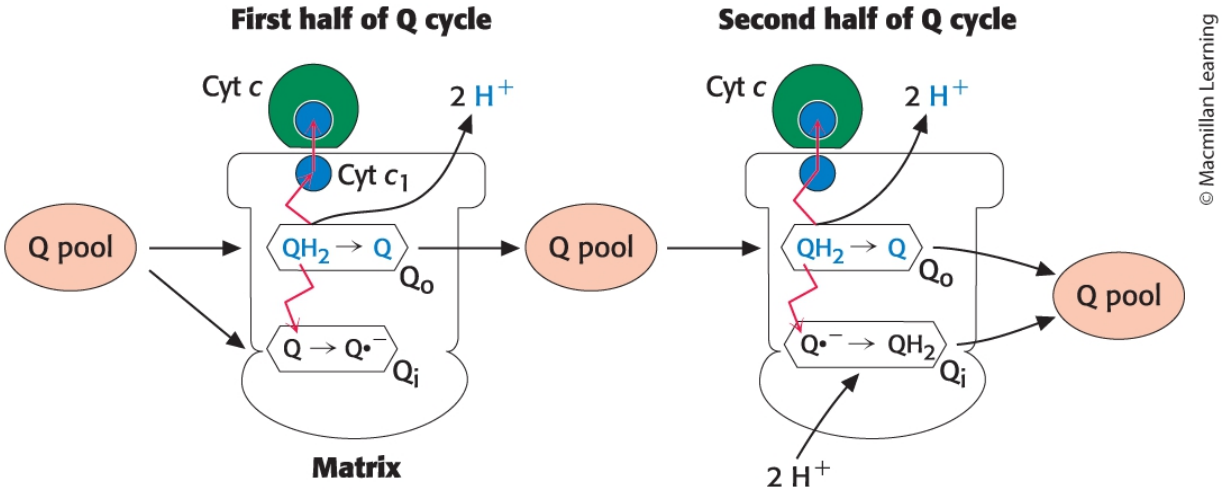
Extended description for FIGURE 18.10 Q-cytochrome c oxidoreductase is a homodimer, with each monomer

consisting of 11 distinct polypeptide chains

Q-cytochrome c oxidoreductase is a homodimer. The left half is shown in color and the right half is shown in grey. The right half shows a cluster of medium cylindrical structures at the top connected by thread-like loops. The bottom portion consists of a mixture of short and medium cylindrical structures connected by thread-like loops. A cluster of long vertical cylindrical structures is located in the middle. An arrow from the top portion points toward a Rieske iron-sulfur center. It consists of two green spheres connected to a common yellow sphere in the top center and bottom center. The left green sphere is connected to a cysteine side chain on the upper left and lower left. The right green sphere is connected to the nitrogen atom of the pentagonal ring of the histidine side chain on the upper right and lower right.

The left half shows a cluster of short and medium cylindrical structures at the top. These cylindrical structures are shown in yellow, blue, and grey colors. The bottom portion contains a cluster of short and medium yellow cylindrical structures. A cluster of long vertical cylindrical structures shown in red, blue, and yellow is located in the middle.

An arrow from the top portion of the left half points toward a ball-and-stick model of Heme c 1. It shows a central green sphere connected to blue spheres in a radial fashion. The blue spheres are further connected to black spheres that form a cage-like structure. One blue sphere is connected to the pentagonal ring of the histidine side chain and methionine side chain. The side chains of cysteine residues are connected to the black spheres on the top right and top left. An arrow from the junction between the top and middle portion of the left half points toward the ball and stick model of heme b subscript L. It consists of a central green sphere connected to blue spheres in a radial manner. The blue spheres are further connected to black spheres that form a cage-like structure. One blue sphere on



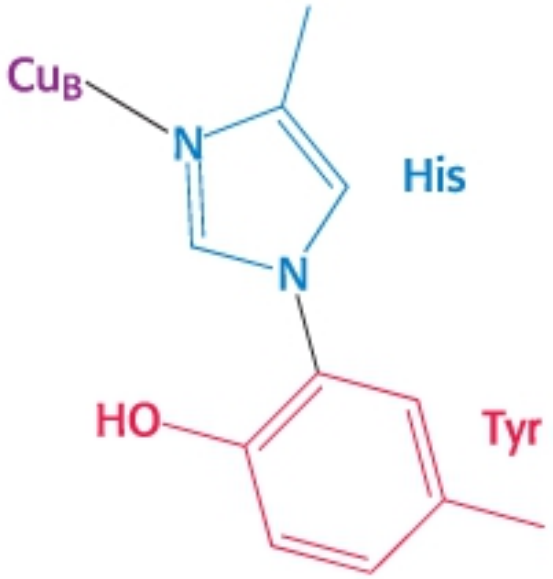
either end is connected to the pentagonal ring of the histidine side chain.

An arrow from the bottom end of the middle portion shows the ball-and-stick model of heme b subscript H. It consists of a central green sphere connected to blue spheres in a radial manner. The blue spheres are further connected to black spheres that form a cage-like structure. One blue sphere on either end is connected to the pentagonal ring of the histidine side chain.

The entire bottom portion of the oxidoreductase is in the matrix.

Return to FIGURE 18.10 Q-cytochrome c oxidoreductase is a homodimer, with each monomer consisting of 11 distinct polypeptide chains

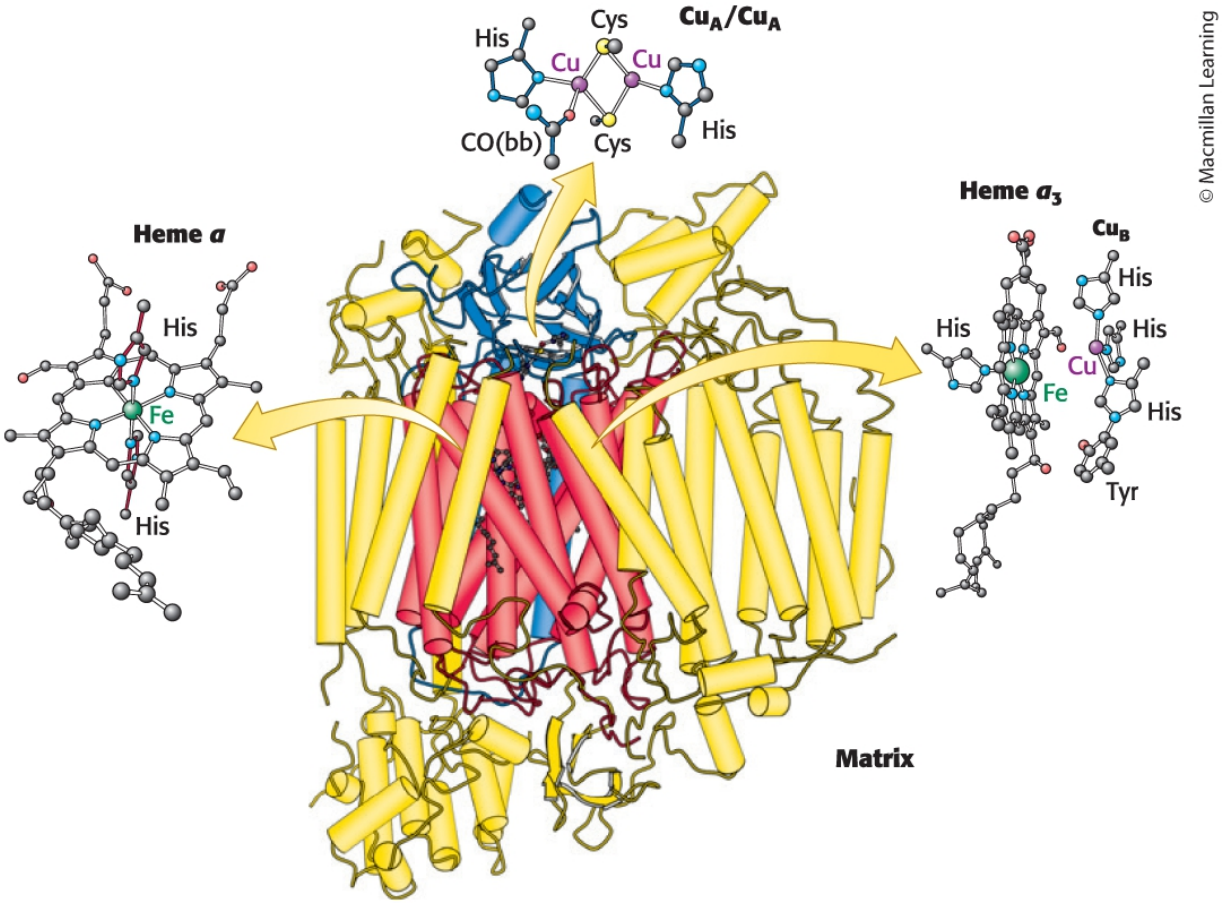
Extended description for FIGURE 18.11 The Q cycle allows the safe transfer of electrons from Q H 2 to cytochrome c



First half of Q cycle: An outline form of complex 3 is shown. Its top surface is bound to cytochrome c depicted as a medium-sized green sphere. The bottom surface is located in the matrix. Two arrows from a circle labeled Q pool point toward the inside of complex 3. The first arrow points toward the conversion of Q H 2 to Q inside a box. The box is labeled Q subscript 0. The second arrow points to the conversion of Q to semiquinone radical anion inside a box labeled Q subscript i. The semiquinone radical anion is depicted as Q superscript minus with an electron. A zigzag arrow from Q subscript 0 moves to cytochrome c 1 depicted as a small blue circle. Cytochrome c 1 then transfers the electron to cytochrome c. A black arrow from Q subscript 0 points toward 2 H superscript plus outside the complex 3. Another zigzag arrow from Q subscript 0 moves toward Q in Q subscript i. An arrow from Q subscript 0 points to a circle labeled Q pool located outside complex 3.

Second half of Q cycle: An outline form of complex 3 is shown. Its top surface is bound to cytochrome c depicted as a medium-sized green sphere. An arrow from the Q pool points toward Q subscript 0 inside complex 3. A zigzag arrow from Q subscript 0 moves to cytochrome c 1 depicted as a small blue circle. Cytochrome c 1 then transfers the electron to cytochrome c. A black arrow from Q subscript 0 points toward 2 H superscript plus outside the complex 3. Another zigzag arrow from Q subscript 0 moves toward semiquinone radical anion in Q subscript i. The box labeled Q subscript i shows the conversion of semiquinone radical anion to Q H 2. During this conversion, 2 H superscript plus ions from the matrix are used up. An arrow from Q subscript 0 and Q subscript i points toward a Q pool outside complex 3.

Return to FIGURE 18.11 The Q cycle allows the safe transfer of electrons from Q H 2 to cytochrome c



Extended description for Chemical structure of copper ion bonded to histidine residue covalently linked to a tyrosine residue

The histidine residue is depicted as a 5-membered heterocyclic pentagonal ring in a vertical orientation consisting of 2 N and 3 C atoms. First N occupies the bottom-most vertex and the second N occupies the top left vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. N 2 is single bonded to C u subscript B on the upper left. C 2 has an open single bond on the upper right. N 1 is single bonded to C 5 of the tyrosine residue. The tyrosine residue is depicted as a benzene ring in a horizontal orientation with C 1 occupying the rightmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 has an open single bond on the right. C 4 is single-bonded to O H on the left.

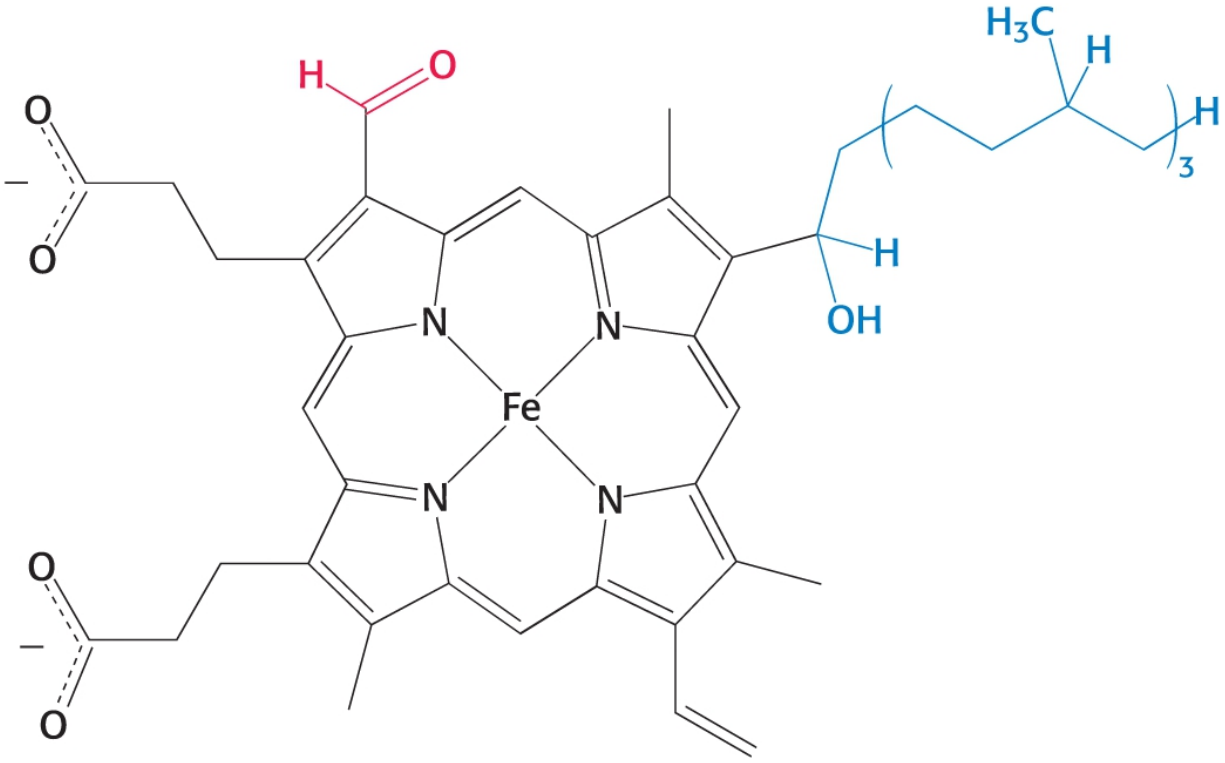
Extended description for FIGURE 18.12 The structure of bovine cytochrome c oxidase reveals 13 polypeptide chains and numerous electron carriers

© Macmillan Learning

The bovine cytochrome c consists of a central cluster of long vertical red cylindrical structures. These are flanked by long vertical yellow cylindrical structures. A blue cylindrical structure is shown in the center of the cluster of red cylindrical structures. A few short and medium cylindrical structures are shown above them. Several short threads extend from these cylindrical structures. Just above the blue cylindrical structure, a few beta-strands are located. The bottom portion oriented toward the bottom left consists of a cluster of short and medium yellow cylindrical structures. Several short

threads are extending from the cylindrical structure. An arrow from the hollow center of the beta-strands in the top points toward C u subscript A slash C u subscript A. It shows two C u atoms depicted as purple spheres connected to a yellow sphere of a common cysteine side chain in the top center and bottom center. The left purple sphere is connected to a blue sphere of the pentagonal ring of the histidine side chain and a tiny red sphere of C O

open parenthesis b b close parenthesis. The red sphere is further connected to a black sphere. The black sphere is further connected to a blue sphere on the upper left and a black sphere below. The right purple sphere is connected to a blue sphere of the pentagonal ring of the histidine side chain.



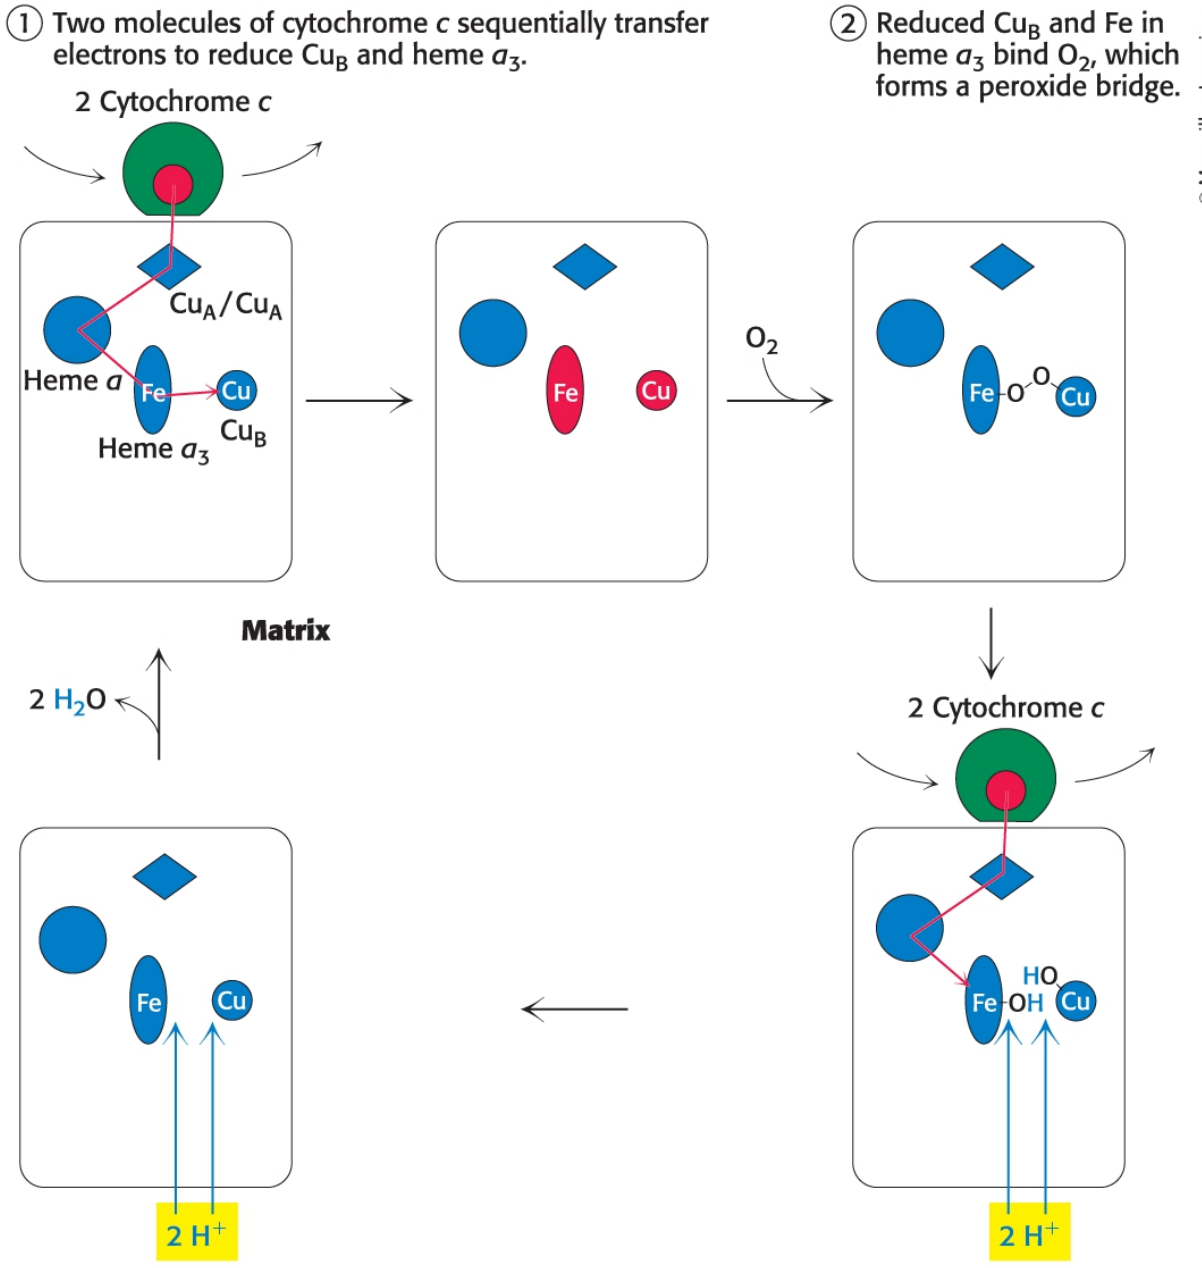
An arrow from the left end of the central cluster of red cylindrical structures point toward heme a. It consists of a central F e atom depicted as a green sphere connected to 5 blue and one black sphere in a radial manner. These blue and black spheres are further connected to black spheres to form a cage-like network. Heme a is connected to two histidine side chains.

An arrow from the right end of the central cluster of red cylindrical structures point toward heme a subscript 3 and C u subscript B. Heme a subscript 3 consists of a central green sphere connected to blue spheres that are further connected to black spheres to form a cage-like network. The heme ring is connected to the pentagonal ring of the histidine side chain. C u subscript B consists of a central purple sphere depicting C u atom connected to a blue sphere of the pentagonal ring of the histidine side chain above, on the right, and below. The second blue sphere of the pentagonal ring of the bottom histidine side chain is further connected to the tyrosine side chain.

Return to FIGURE 18.12 The structure of bovine cytochrome c oxidase reveals 13 polypeptide chains and numerous electron

carriers

Extended description for Structure of heme A



Heme A

The structure consists of a central F e atom single bonded to the N atom of a 5-membered heterocyclic pentagonal ring on the upper left, upper right, lower left, and lower right. Each ring consists of 1 N and 4 C atoms. All rings except the upper left ring contain two double bonds between any two of the following atoms: C 2 and C 3, N and C 1, C 1 and C 2, C 3 and C 4, or C 4 and N. The upper left ring contains a double bond between C 2 and C 3. C 1 and C 4 atoms of adjacent rings are connected by methylene bridges. In the upper left ring, C 2 is single bonded to a 3-carbon alkane chain depicted as a line structure using 2 lines. C 3 is partially double bonded to O on the upper left and lower left. This group has an overall negative charge. C 3 is single bonded to C above, which is further single bonded to H on the upper left and double bonded to O on the upper

right. In the upper right ring, C 2 is single-bonded to C H 3 above in the form of a line. C 3 is single-bonded to a 6-carbon alkane chain depicted as a line structure using 5 zigzag lines. C 1 is single bonded to O H on the lower right and H on the right. C 3 to C 6 are enclosed in parenthesis with subscript 3. C 6 is single bonded to H on the upper right. C 5 is single bonded to C H 3 on the upper left and H on the upper right. In the lower right ring, C 2 is single-bonded to C H 3 in the form of a line on the right. C 3 is single-bonded to a 2-carbon alkene chain depicted as two parallel lines. In the lower-left ring, C 2 is single-bonded to C H 3 below in the form of a line. C 3 is single bonded to a 3-carbon alkane chain depicted using 2 lines. C 3 is partially double-bonded to O on the upper left and O on the lower right. This group has an overall negative charge.

Return to Structure of heme A

Extended description for FIGURE 18.13 The mechanism of cytochrome c oxidase prevents early oxygen release

© Macmillan Learning

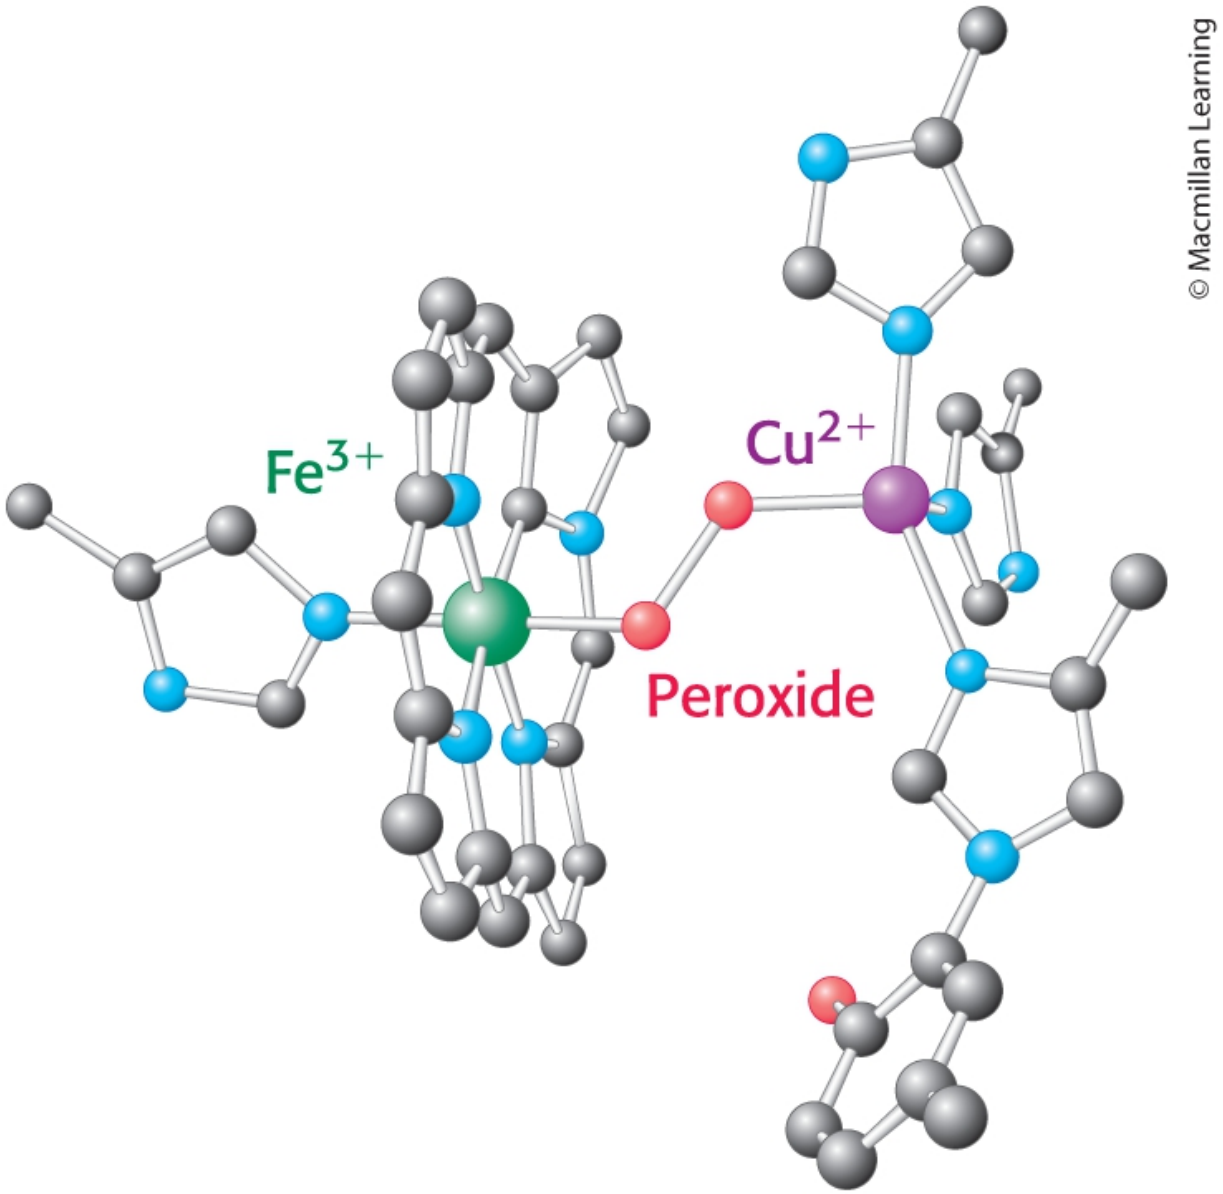
The mechanism is divided into 4 steps as follows:

Step 1: A square is shown and the region below its bottom surface is labeled matrix. The square contains the following components: A blue diamond labeled C u subscript A slash C u subscript A, a medium blue circle labeled heme a, a blue oval containing F e labeled heme a subscript 3, and a tiny blue circle containing C u labeled C u subscript B. A medium green circle with a red core is located above the top surface of the square and is labeled 2 cytochrome c. An arrow points toward cytochrome c and another arrow points away from it. A zigzag arrow starts from the red core of cytochrome c and passes through C u subscript A slash C u subscript A, heme a, and heme a subscript 3, to ultimately reach C u subscript B. The text above reads “Two molecules of cytochrome c sequentially transfer electrons to reduce C u subscript B and heme a subscript 3.

An arrow from the first square leads to the second square. The components of the second square are a blue diamond, a medium blue circle, a red oval containing F e, and a tiny red circle containing C u. It lacks cytochrome c at the top surface.

Step 2: O 2 enters and cross-links the blue oval containing Fe with the tiny blue circle containing C u through O, single bond, O. The square lacks cytochrome c at the top surface. The text above reads “Reduced C u subscript B and F e in heme a subscript 3 bind O 2, which forms a peroxide bridge.

Step 3: 2 cytochrome c binds to the surface of the square again. A zigzag arrow from the red core of cytochrome c passes through the blue diamond and medium blue circle to ultimately reach a blue oval containing Fe. The blue oval is single-bonded to O H. The tiny blue circle containing C u is also single bonded to O H. This happens as 2 H superscript plus from the matrix and electrons from



cytochrome c travel toward the peroxide bridge. The text below reads “The addition of two more electrons and two more protons cleaves the peroxide bridge.

Step 4: The square contains a blue diamond, a medium blue circle, a blue oval containing F e, and a tiny blue circle containing C u. Two arrows from 2 H superscript plus in the matrix point toward the oval and the tiny circle. The text below reads “The addition of two more protons leads to the release of water.”

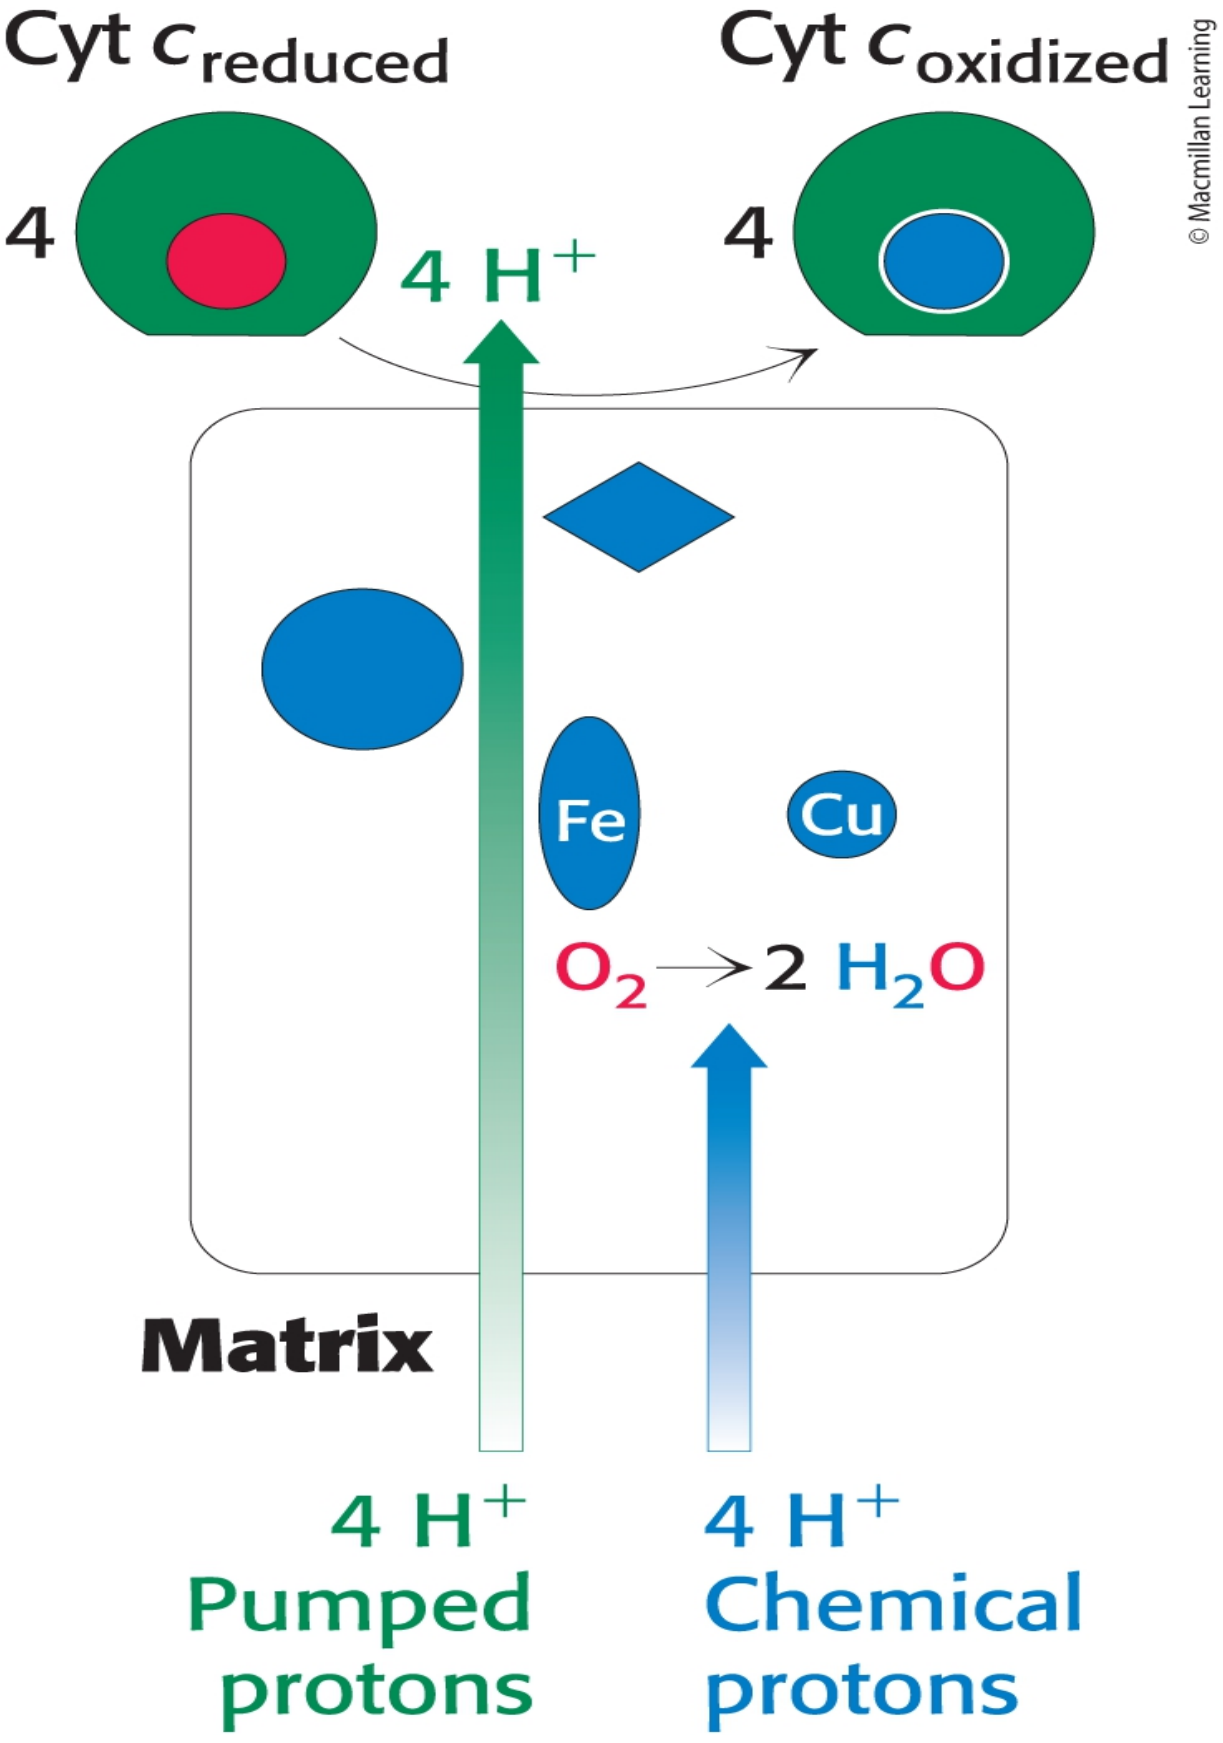
2 H 2 O molecules are released and the cycle begins again.

Return to FIGURE 18.13 The mechanism of cytochrome c oxidase prevents early oxygen release

Extended description for FIGURE 18.14 Two metals form a peroxide bridge in cytochrome c oxidase

© Macmillan Learning

The ball-and-stick model of heme a subscript 3 is shown on the left and C u subscript B is shown on the right. The heme a subscript 3 molecule consists of a central green sphere depicting F e superscript 3 plus. It is connected to 4 blue spheres, one red sphere, and one



black sphere in a radial fashion. Three blue spheres and one black sphere are further connected to more black spheres to form a cage-like structure. One blue sphere is part of a pentagonal ring composed of 2 blue and 3 black spheres. The ring is located toward the left, away from the plane of the cage-like structure. The red sphere is further connected to a second red sphere. The second red sphere is in turn connected to a purple sphere depicting C u superscript 2 plus metal atom of C u subscript B. The chain of two red spheres depicts peroxide.

In C u subscript B, the central purple sphere is connected to a blue sphere of a pentagonal ring at the top, right, and bottom. The pentagonal rings consist of 2 blue and 3 black spheres. One black sphere is further connected to a black sphere. The second blue sphere of the bottom pentagonal ring is connected to a hexagonal ring composed of 6 black spheres. In the hexagonal ring, one black sphere is connected to a red sphere and another black sphere is connected to a black sphere.

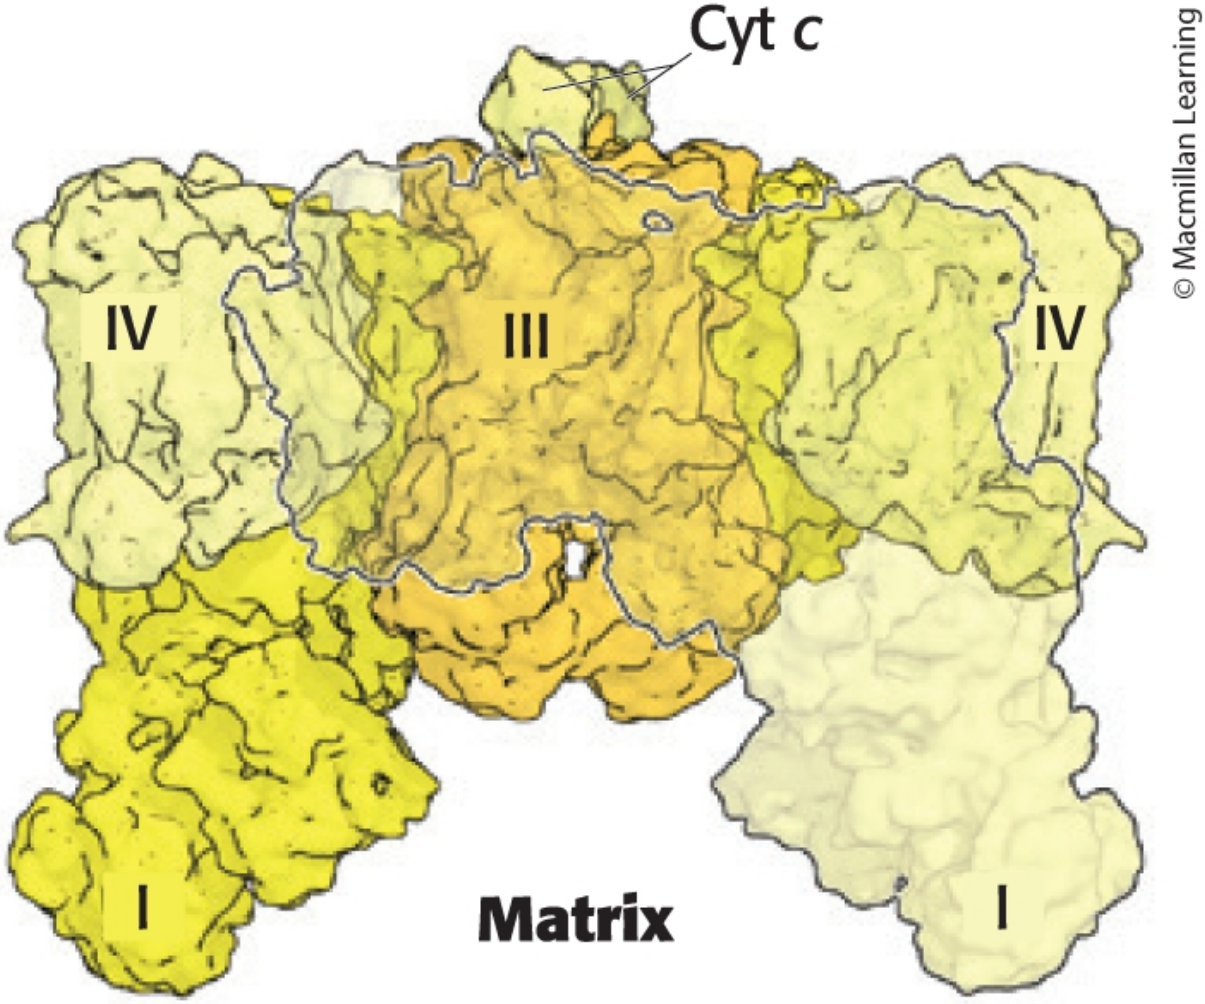
A square contains a blue diamond, a medium blue circle, a blue oval containing F e, and a tiny circle containing C u. A green upward arrow passes across the square from bottom to the top surface to depict 4 H superscript plus ions or protons being pumped from the matrix into the intermembrane space. An arrow across the head of the green arrow, above the top surface of the square, depicts the conversion of 4 cytochrome c reduced to 4 cytochrome c oxidized. The reduced form is depicted as a medium-green circle with a red core. The oxidized form is depicted as a medium-green circle with a blue core. A blue upward arrow depicts the transport of 4 H superscript plus ions or chemical protons from the matrix into the square. The arrowhead points toward an irreversible reaction showing the conversion of O 2 to 2 H 2 O inside the square.

Return to FIGURE 18.15 Proton transport by cytochrome c oxidase has two components

Extended description for FIGURE 18.16 Electrons flow via two pathways through the electron-transport chain



Three complexes labeled roman numbers 1, 2, and 3 are shown embedded in the lipid bilayer from left to right. The fourth complex labeled roman number 4 is attached to the inner leaflet of the bilayer. A small purple structure is embedded in the membrane between complex 2 and 3 and is labeled Q pool. Q pool alternates between Q and Q H 2 during electron transport. A small orange structure labeled cytochrome c is embedded in the membrane between complex 3 and 4. The region above the bilayer is labeled intermembrane space and the region below is labeled matrix. A very simplified citric acid cycle is shown to operate in the matrix. Its products include acetyl C o A, F A D H 2, and N A D H. Electrons from N A D H travel through complex 1, 2, Q pool, complex 3, cytochrome c, and then complex 4. Electrons from F A D H 2 travel

through complex 2, Q pool, complex 3, cytochrome c, and complex 4. An upward arrow across complex 1, 3, and 4 shows the transport of H superscript ion from the matrix to the intermembrane space. A curved arrow below complex 4 denotes the simultaneous conversion of O 2 to H 2 O.

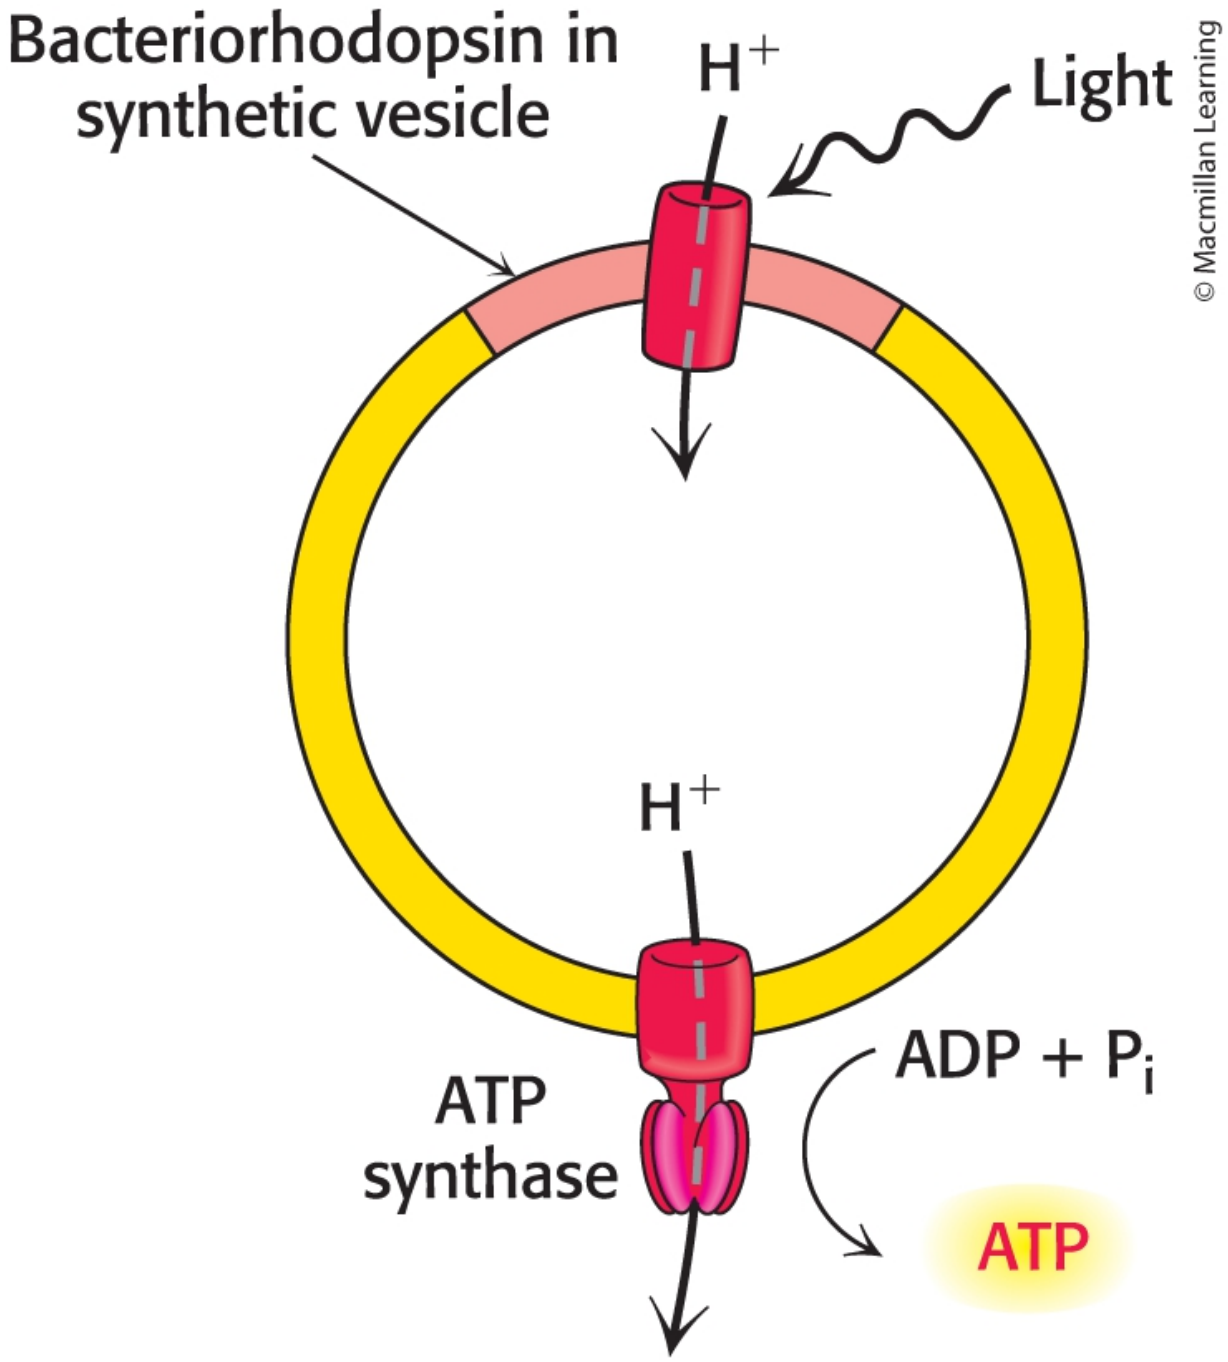
Extended description for FIGURE 18.20 The chemiosmotic hypothesis states that electron-driven proton transport and ATP synthesis are coupled

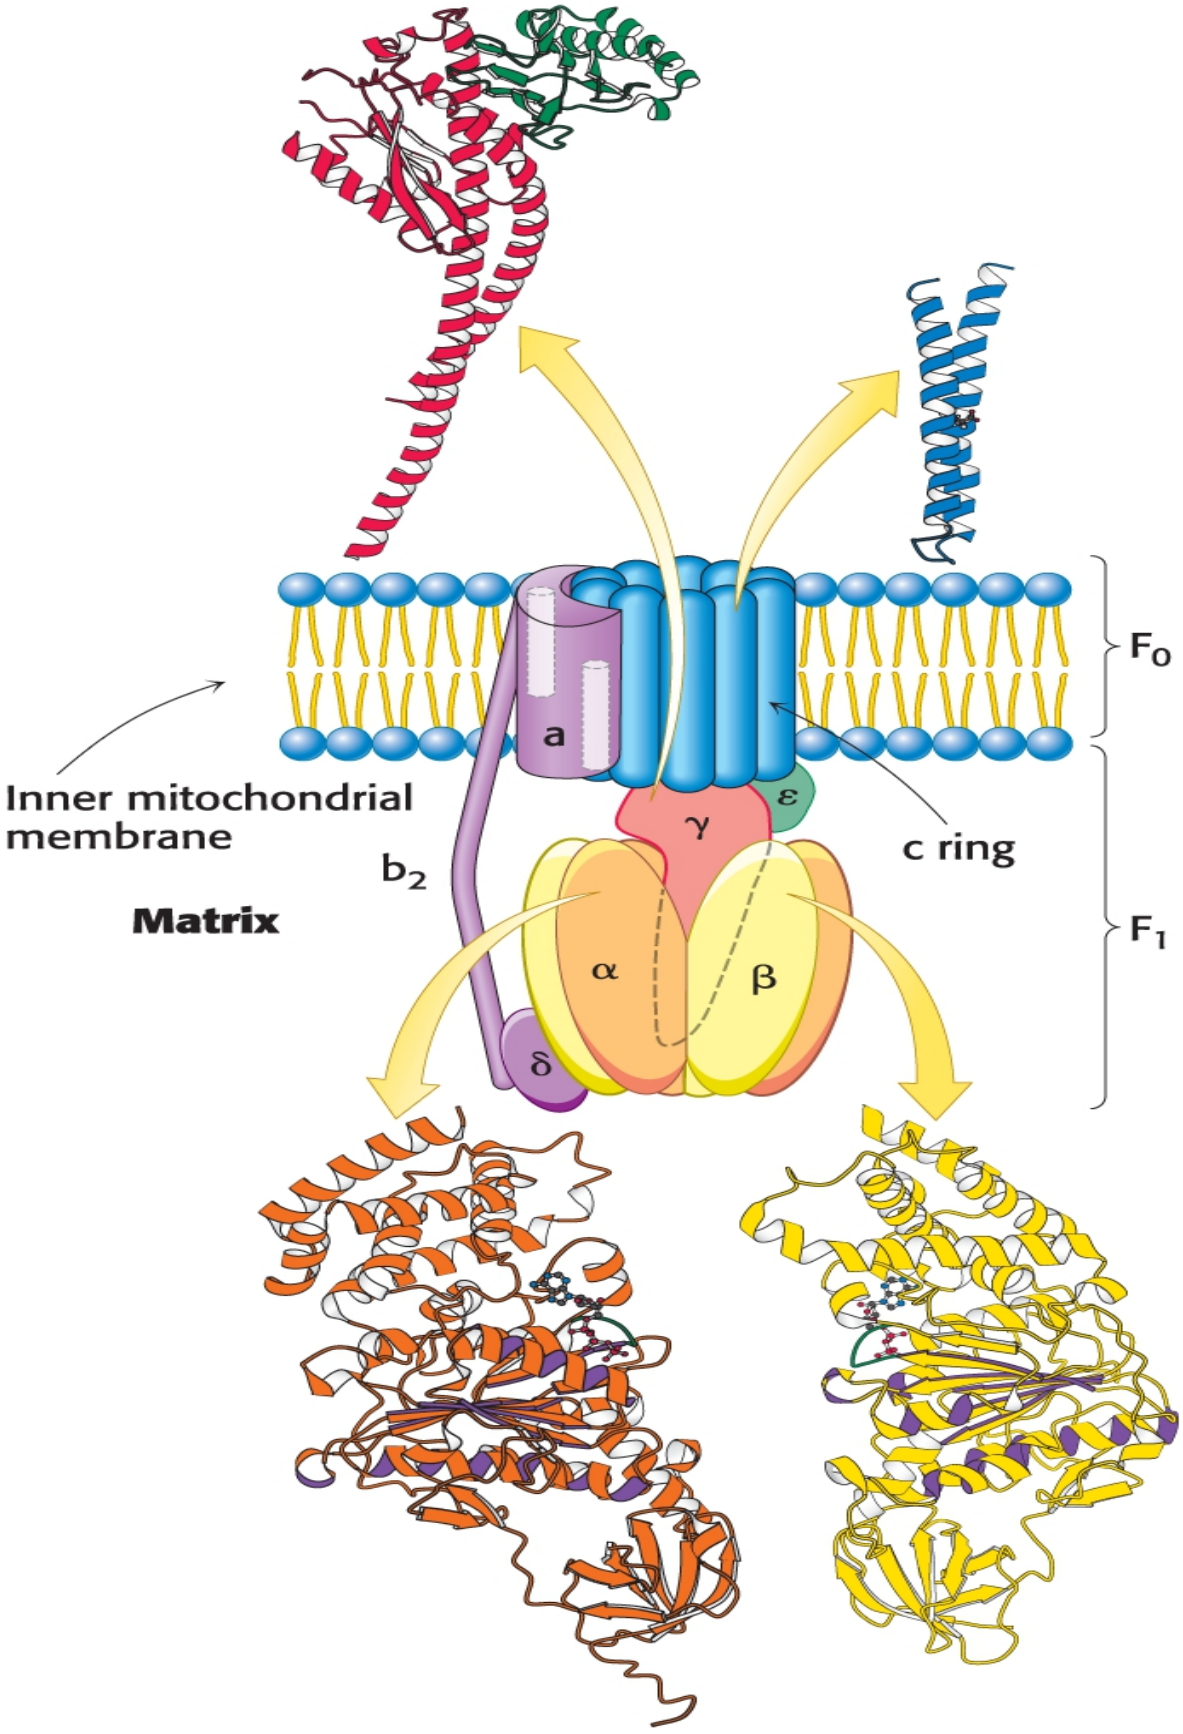


© Macmillan Learning

The mitochondrion is depicted as a large capsule-shaped structure with a solid blue outline labeled outer mitochondrial membrane. The inner mitochondrial membrane is shown as a solid grey line forming several invaginations into the matrix. The space between the inner and outer mitochondrial membrane is labeled intermembrane space. Discrete clusters of negative and positive charge are shown along the inner mitochondrial membrane. The inner surface of the inner membrane is negatively charged and the outer surface is positively charged. An arrow from the matrix points toward the intermembrane space to show the movement of the H superscript plus ion. The intermembrane space has a high H superscript plus ion concentration and the matrix has a low H superscript plus ion concentration. The text alongside an arrow pointing toward the inner mitochondrial membrane reads "Protons are pumped across this membrane as electrons flow through the respiratory chain."

Return to FIGURE 18.20 The chemiosmotic hypothesis states that electron-driven proton transport and ATP synthesis are coupled

Extended description for FIGURE 18.21 The chemiosmotic hypothesis is supported by experiments using bacterial proton pumps

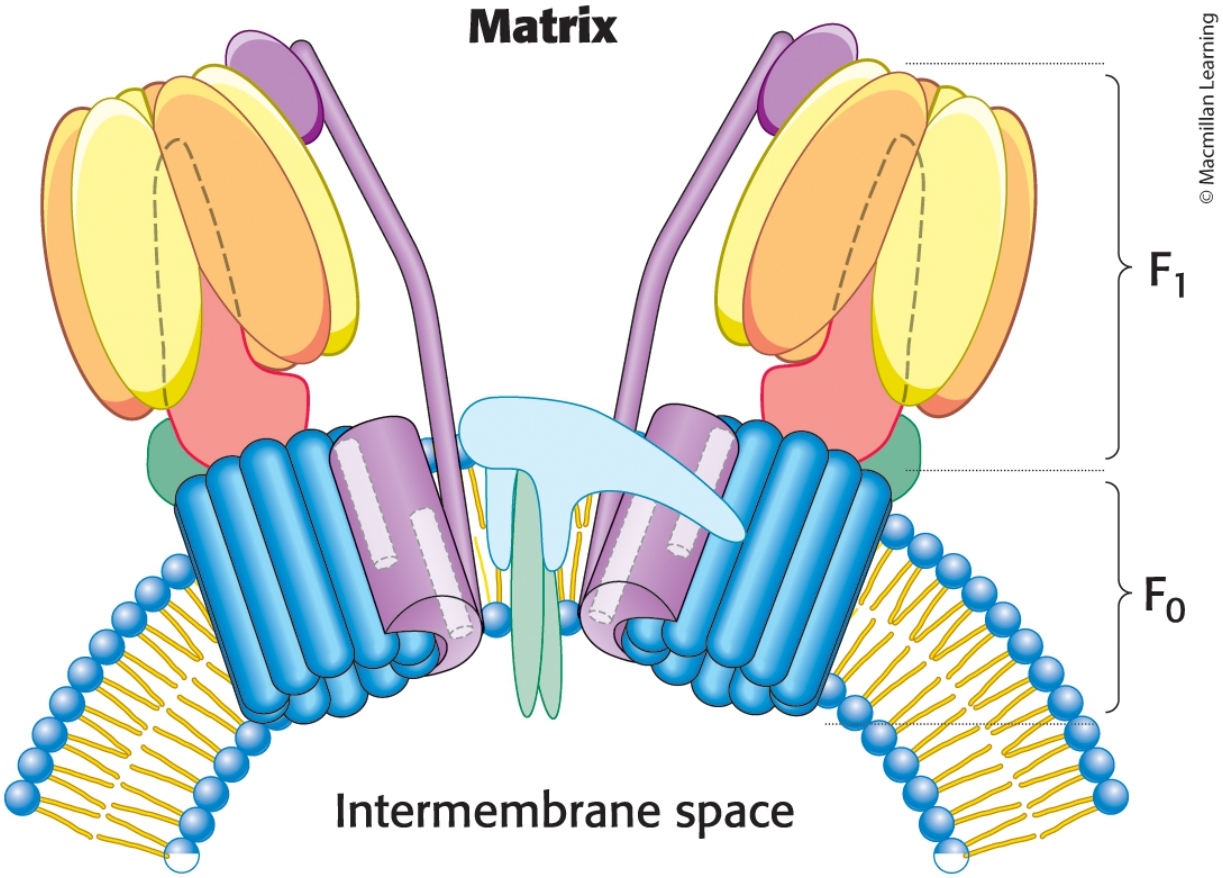


The membrane vesicle is depicted as a hollow circle with a thick yellow outline. The topmost area of the membrane vesicle has a stretch of pink area containing a hollow cylindrical structure. This region is labeled "Bacteriorhodopsin in synthetic vesicle." A wavy line labeled light points toward the hollow cylindrical structure. An inward arrow across the cylindrical structure shows the entry of H superscript plus ion. The bottom area of the membrane vesicle contains an A T P synthase. An outward arrow across it depicts the exit of the H superscript plus ion from the membrane vesicle. This movement powers the synthesis of A T P from A D P and P subscript i by the A T P synthase.

Return to FIGURE 18.21 The chemiosmotic hypothesis is supported by experiments using bacterial proton pumps

Extended description for FIGURE 18.22 The structure of ATP synthase reveals a complex molecular rotational

motor



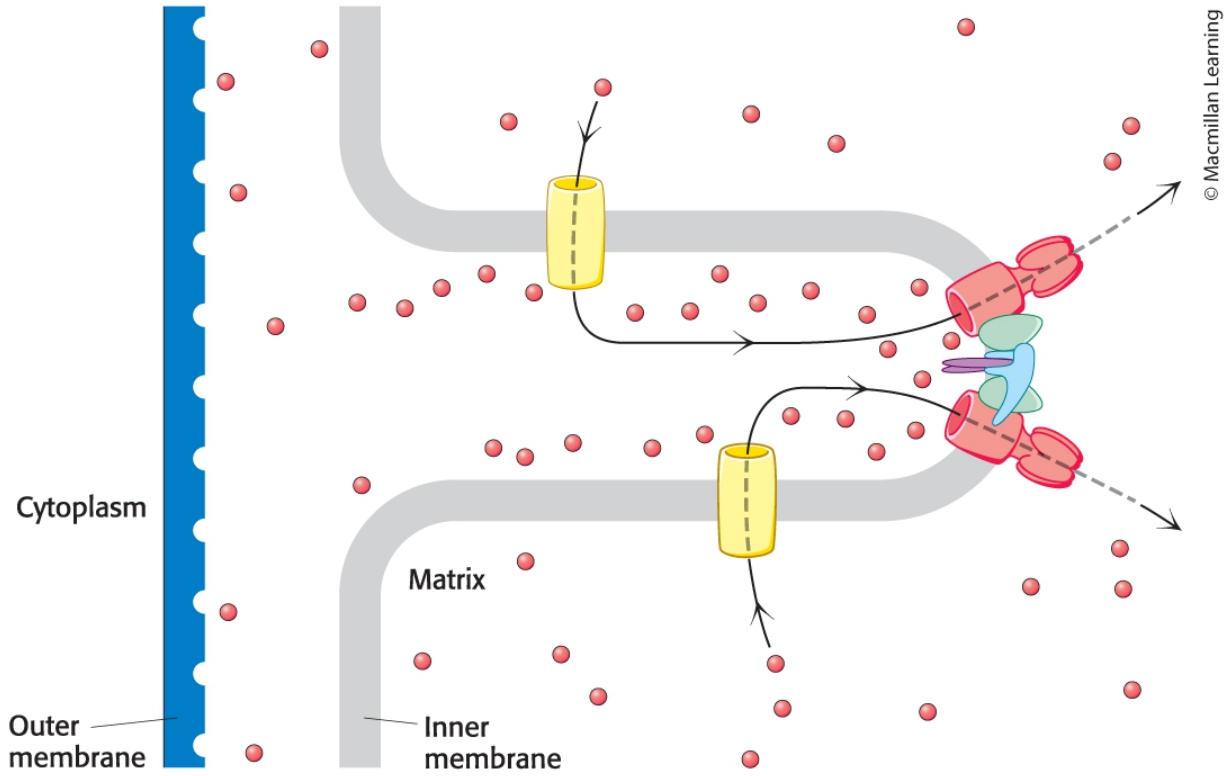
© Macmillan Learning

The A T P synthase consists of a hollow cylindrical structure embedded in the inner mitochondrial membrane. The cylindrical structure is labeled “c ring” and is lined by 10 elongated subunits. Three of these subunits are enclosed in a long cylindrical groove of a half-cut vertical cylindrical structure labeled “a.” The structure a is also embedded in the membrane. A tubular extension with a bend is labeled b 2 and its connects structure “a” with structure “delta” in the matrix. The structure delta is small oval-shaped and is part of a large complex in the matrix composed of alpha, beta, gamma, and epsilon subunits. The alpha and beta subunits are long oval-shaped structures that form a unit. The gamma subunit has a broad top and a tapered bottom. The bottom extends into the space between the alpha and beta subunits. The broad top is attached to the bottom surface of the “c ring.” The epsilon subunit is small and located on the right of the gamma subunit, just below the bottom surface of the c ring. The A T P synthase is divided into two regions, namely F 0 and F 1. F 0 includes membrane-embedded components like c-ring and structure a. F 1 includes matrix components like a portion of b 2, alpha, beta, gamma, delta, and epsilon subunits.

The elongated subunits of the c ring consist of a pair of long and vertical alpha-helices. The gamma subunit is composed of a long and slightly curved alpha-helix. Its top portion has three short and medium-sized alpha helices and a few beta-strands. One of the helices extends downward, halfway through the length of the long alpha-helix. The top right portion of the gamma subunit is attached to a small green cluster composed of two alpha-helices and a few beta-strands. The alpha subunit is composed of several alpha-helices interconnected by thread-like loops and a cluster of beta-strands at the bottom. The beta subunit is composed of several alpha-helices interconnected by thread-like loops and a cluster of beta-strands at the bottom.

Return to FIGURE 18.22 The structure of ATP synthase reveals a complex molecular rotational motor

Extended description for FIGURE 18.23 Mitochondrial ATP synthase forms homodimers

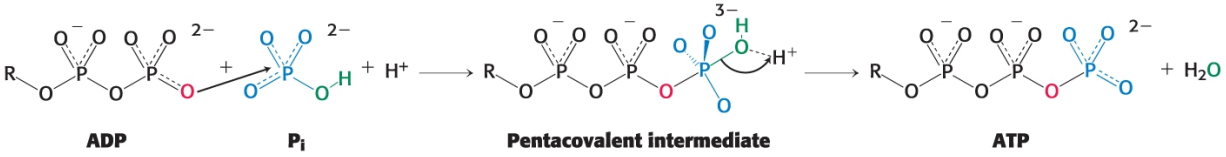


Two mitochondrial A T P synthases are shown embedded into the inner mitochondrial membrane. The membrane is curved outward and the region above it is labeled matrix and the region below is labeled intermembrane space. The F 0 component including the c ring, structure a, and portion of b 2 is embedded in the membrane. The F 1 component including alpha, beta, gamma, delta, epsilon subunits, and a portion of b 2 are located in the matrix. The dimer of A T P synthase is joined by a complex of proteins. The complex is composed of a pair of elongated oval proteins spanning the membrane. The pair has an irregularly shaped protein at the top

that extends between the b 2 subunit of one A T P synthase and the c-ring subunits of the second A T P synthase.

Return to FIGURE 18.23 Mitochondrial ATP synthase forms homodimers

Extended description for FIGURE 18.24 ATP synthase assists in the formation of cristae



A long and vertical blue strip depicting the outer membrane contains uniformly spaced tiny semicircular grooves along its right edge. The region on its left is labeled cytoplasm. The crista is shown as a horizontal U-shaped structure formed by the inner membrane. The inner membrane is depicted as a continuous grey strip. The outer and inner membranes have a gap between them. A dimer of mitochondrial A T P synthase is shown embedded in the crista. The dimer is joined by a protein complex. Several red balls are scattered across the space between the inner and outer membrane. They are more concentrated in the U-shaped groove formed by the crista. A few red balls are also shown in the matrix, depicted as the space on the right of the inner membrane. Two yellow-colored hollow

cylindrical structures are also embedded in the inner membrane forming the side walls of the crista. A continuous arrow shows the movement of the red balls in the matrix across the cylindrical structure into the U-shaped groove and then back into the matrix through the A T P synthase.

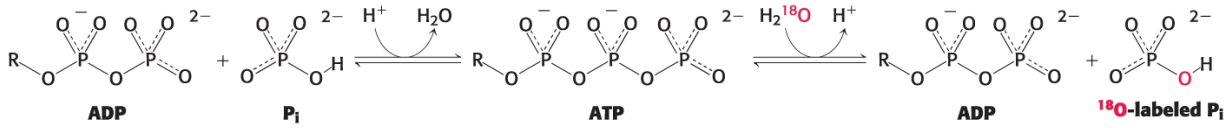
Return to FIGURE 18.24 ATP synthase assists in the formation of cristae

Extended description for FIGURE 18.25 ATP-synthesis is catalyzed by ATP synthase

The reaction consists of three reactants, one intermediate, and two products. The first reactant is A D P whose structure is as follows: A zigzag chain is composed of 2 P and 3 O atoms. P atoms occupy the second and fourth positions and the remaining positions are occupied by O atoms. A partial double bond is present between P 2 and O 3. O 1 is single-bonded to R on the upper left. Both P atoms are partially double-bonded to O on the upper left and O on the upper right. The O atoms bonded to P 1 have an overall negative charge. The O atoms bonded to P 2 have an overall negative charge of 2 minus.

The second reactant is P subscript i whose structure is as follows: A central P atom is partially double bonded to O on the upper left, upper right, and lower left. The O atoms on the upper left and upper right have an overall negative charge of 2 minus. P atom is also single-bonded to O on the lower right which is further single-bonded to H on the upper right. The third reactant is H superscript plus ion.

A solid black arrow points from O 3 of A D P to the central P atom of P subscript i.



The intermediate is a pentacovalent intermediate whose structure is as follows: A zigzag chain is composed of 3 P and 3 O atoms. P atoms

occupy the second, fourth, and sixth positions, and the remaining positions are occupied by O atoms. O 1 is single-bonded to R on the upper left. P 1 and P 2 are partially double-bonded to O on the upper left and O on the upper right. The O atoms bonded to P 1 and P 2 have an overall negative charge. P 3 is dash bonded to O on the upper left, wedge bonded to O above, single bonded to O on the upper right, and single bonded to O on the lower right. The upper right O is further single bonded to H above and connected through a dashed line to H superscript minus on the lower right. The O atoms bonded to P 3 have an overall negative charge of 3 minus. A solid curved arrow from the single bond between P 3 and O on the upper right points toward the dashed line connecting the O atom and H superscript plus ion.

The first product is A T P whose structure is as follows: A zigzag chain is composed of 3 P and 4 O atoms. P atoms occupy the second, fourth, and sixth positions, and the remaining positions are occupied by O atoms. A partial double bond is present between P 3 and O 4. O 1 is single-bonded to R on the upper left. P 1, P 2, and P 3 are partially double bonded to O on the upper left and O on the upper right. The O atoms bonded to P 1 and P 2 have an overall negative charge. The O atoms bonded to P 3 have an overall charge of 2 minus. The second product is H 2 O.

Return to FIGURE 18.25 ATP-synthesis is catalyzed by ATP synthase

Extended description for FIGURE 18.26 ATP forms without a proton-motive force but is not released

The reaction consists of two reactants, one intermediate product, and two final products.

The first reactant is A D P whose structure is as follows: A zigzag chain is composed of 2 P and 3 O atoms. P atoms occupy the second and fourth positions and the remaining positions are occupied by O atoms. A partial double bond is present between P 2 and O 3. O 1 is single-bonded to R on the upper left. Both P atoms are partially double-bonded to O on the upper left and O on the upper right. The O atoms bonded to P 1 have an overall negative charge. The O atoms bonded to P 2 have an overall negative charge of 2 minus.

The second reactant is P subscript i whose structure is as follows: A central P atom is partially double bonded to O on the upper left, upper right, and lower left. The O atoms on the upper left and upper right have an overall negative charge of 2 minus. P atom is also single-bonded to O on the lower right which is further single-bonded to H on the upper right.

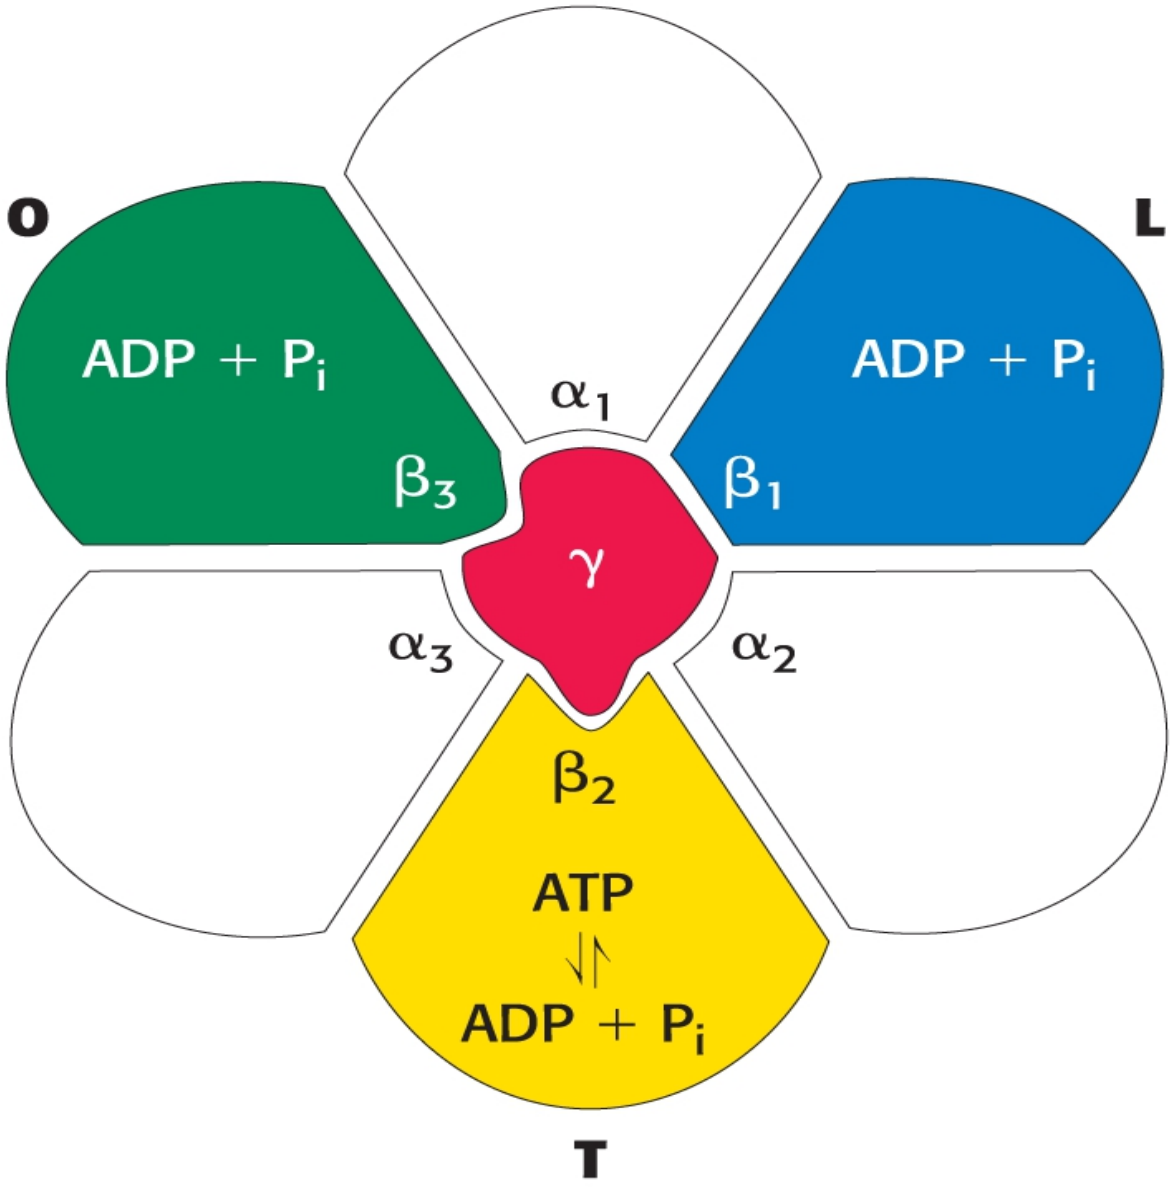
A reversible reaction arrow leads to the intermediate. A curved arrow above it shows the simultaneous conversion of the H superscript plus ion to H 2 O.

The intermediate product is A T P whose structure is as follows: A zigzag chain is composed of 3 P and 4 O atoms. P atoms occupy the

second, fourth, and sixth positions, and the remaining positions are occupied by O atoms. A partial double bond is present between P 3 and O 4. O 1 is single-bonded to R on the upper left. P 1, P 2, and P 3 are partially double bonded to O on the upper left and O on the upper right. The O atoms bonded to P 1 and P 2 have an overall negative charge. The O atoms bonded to P 3 have an overall charge of 2 minus.

A reversible reaction arrow leads to the final products. A curved arrow above it shows the simultaneous conversion of H 2 O superscript 18 to H superscript plus ion. O superscript 18 atom is highlighted in red.

The first final product is A D P whose structure is as follows: A zigzag chain is composed of 2 P and 3 O atoms. P atoms occupy the second and fourth positions and the remaining positions are occupied by O atoms. A partial double bond is present between P 2 and O 3. O 1 is single-bonded to R on the upper left. Both P atoms are partially double-bonded to O on the upper left and O on the upper right. The O atoms bonded to P 1 have an overall negative charge. The O atoms bonded to P 2 have an overall negative charge of 2 minus.



The second final product is O superscript 18-labeled P subscript i whose structure is as follows: A central P atom is partially double bonded to O on the upper left, upper right, and lower left. The O atoms on the upper left and upper right have an overall negative charge of 2 minus. P atom is also single-bonded to O on the lower right which is further single-bonded to H on the upper right. The lower right O is highlighted in red.

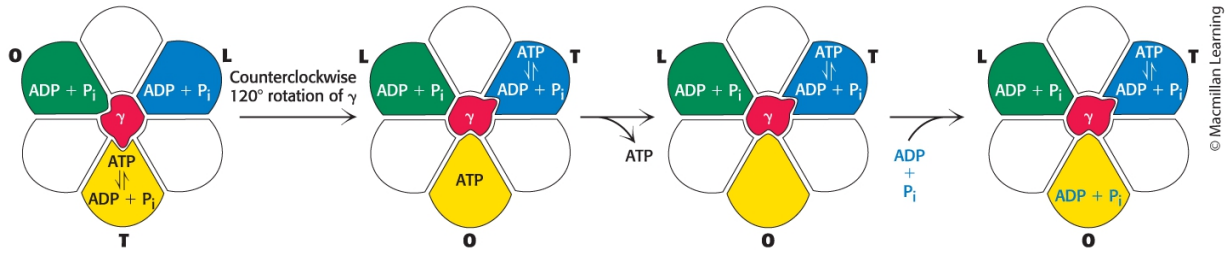
(B)

β subunit 1	L → T → O → L → T → O...
β subunit 2	O → L → T → O → L → T...
β subunit 3	T → O → L → T → O → L...

Part (A): The alpha and beta subunits of the A T P synthase are arranged radially around a central gamma subunit. This arrangement resembles the petals of a flower. The alpha 1, alpha 2, and alpha 3 subunits occupy the top, bottom left, and bottom right positions respectively. Beta 1, beta 2, and beta 3 subunits occupy the top right, bottom, and top left positions respectively. The beta 1 subunit in the conformational state “L” is bound to A D P plus P subscript i. The beta 2 subunit in the conformational state “T” carries out reversible hydrolysis of A T P to A D P plus P subscript i. The beta 3 subunit in the conformational state “O” is bound to A D P plus P subscript i.

Part (B): It shows the different conformational states adopted by A T P synthase.



Beta subunit 1: L, forward arrow, T, forward arrow, O, forward arrow, L, forward arrow, T, forward arrow, O, dot dot dot.

Beta subunit 2: O, forward arrow, L, forward arrow, T, forward arrow, O, forward arrow, L, forward arrow, T, dot dot dot.

Beta subunit 3: T, forward arrow, O, forward arrow, L, forward arrow, T, forward arrow, O, forward arrow, L, dot dot dot.

Return to FIGURE 18.27 ATP synthase nucleotide-binding sites cycle through distinct conformational states

Extended description for FIGURE 18.28 The binding-change mechanism involves the cycling of all three β subunits through three conformations

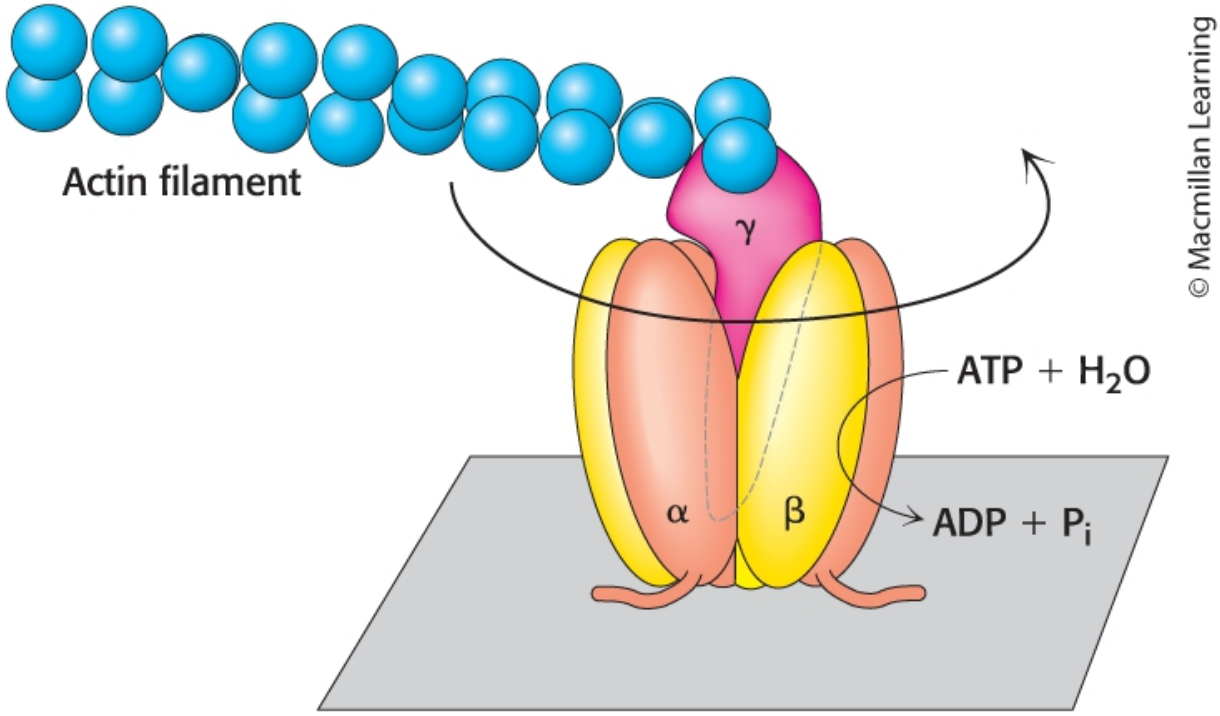
The mechanism shows four views of the petal-like arrangement of the alpha and beta subunit around a central gamma subunit.

In the first view, the top left, top right, and bottom subunits are in O, L, and T conformational states respectively. The conformational states O and L are bound to A D P plus P subscript i. The conformational state T carries out the reversible hydrolysis of A T P to A D P plus P subscript i. The counterclockwise 120-degree rotation of gamma leads to the second view.

In the second view, the top left, top right, and bottom subunits are in the L, T, and O conformational states respectively. The conformational state L is bound to A D P plus P subscript i. The conformational state T carries out the reversible hydrolysis of A T P to A D P plus P subscript i. The conformational state O is bound to A T P.

A T P is released and leads to the third view.

In the third view, the top left, top right, and bottom subunits are in the L, T, and O conformational states respectively. The



conformational state L is bound to A D P plus P subscript i. The conformational state T carries out the reversible hydrolysis of A T P to A D P plus P subscript i. The conformational state O is empty.

A D P plus P subscript i enters and leads to the fourth view.

In the fourth view, the top left, top right, and bottom subunits are in the L, T, and O conformational states respectively. The conformational state L is bound to A D P plus P subscript i. The conformational state T carries out the reversible hydrolysis of A T P to A D P plus P subscript i. The conformational state O is bound to A D P plus P subscript i.

Extended description for FIGURE 18.30 Components of the proton-conducting unit of ATP synthase include

two half channels and a critical charged residue

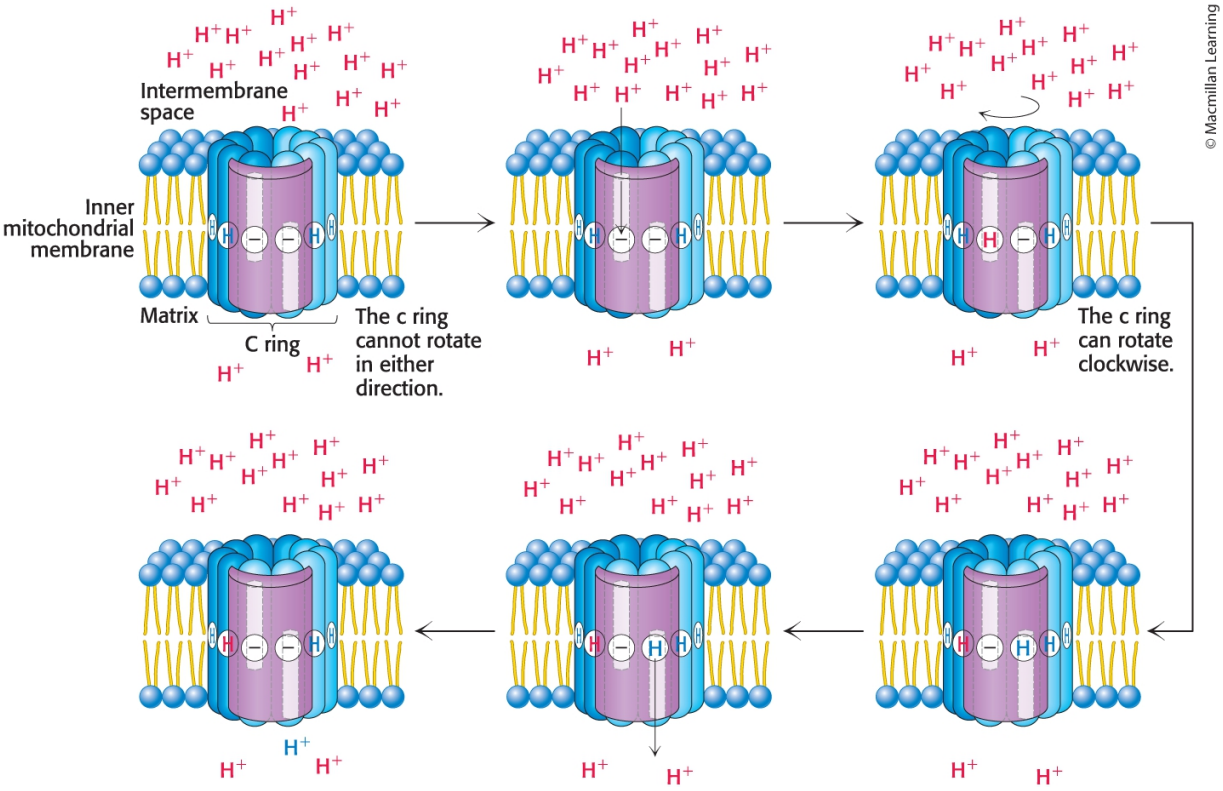
Aspartic acid or glutamic acid

Subunit **c**

Intermembrane half-channel

Matrix half-channel

Subunit **a**



© Macmillan Learning

The ribbon diagram of subunit c consists of a pair of long and vertical alpha-helices connected by a short thread-like loop at the bottom. An aspartic acid or glutamic acid residue is shown in the center of the pair of alpha-helices.

The schematic structure of subunit a shows a thick cylindrical structure having a long and vertical cylindrical groove along its entire length. There are two half-channels inside subunit a. The intermembrane half-channel is depicted as a thin cylinder that extends from the top to a little below the center. The matrix half-channel starts a little above the center and extends to the bottom.

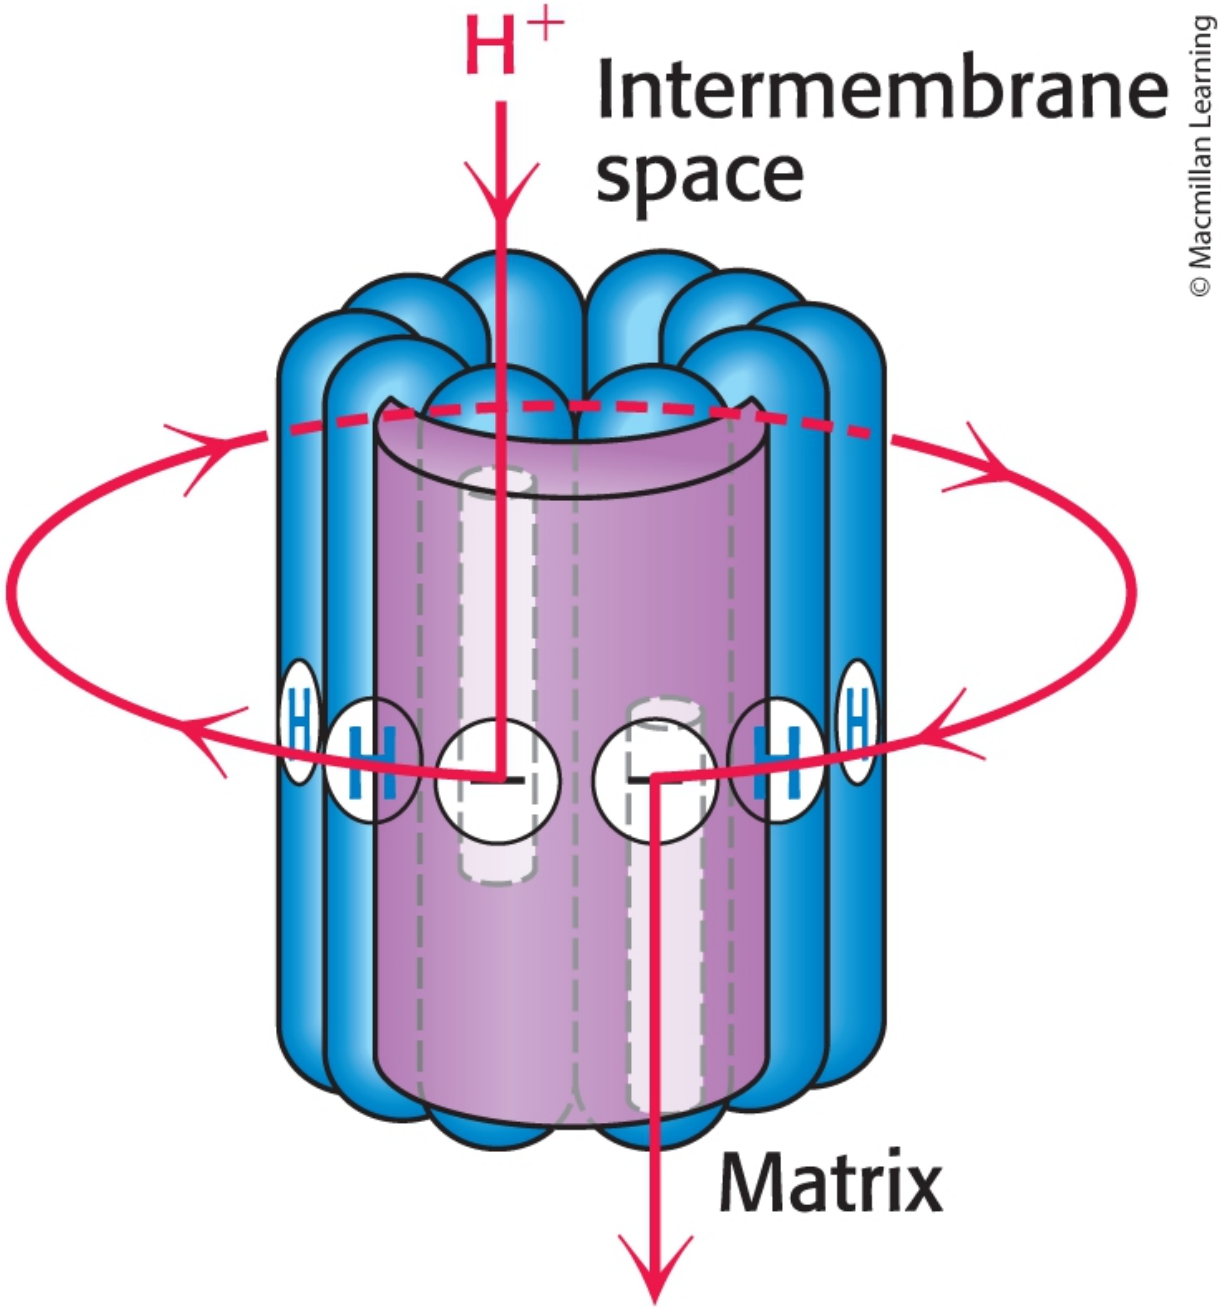
Return to FIGURE 18.30 Components of the proton-conducting unit of ATP synthase include two half channels and a critical charged residue

Extended description for FIGURE 18.31 Proton motion across the membrane drives rotation of the c ring

Step 1: The c ring embedded in a section of the inner mitochondrial membrane is shown. Its front surface is enclosed by subunit a. The region above the membrane is labeled intermembrane space and the region below is labeled matrix. The concentration of H superscript plus ions in the intermembrane space is much higher than in the matrix. The subunits of the c ring are bound to H. The half-channels of the subunit a have a negative charge. The text alongside reads “The c ring cannot rotate in either direction.”

Step 2: An arrow from an H superscript plus ion in the intermembrane space points toward the negative charge in the intermembrane half-channel of subunit a.

Step 3: The negative charge in the intermembrane half-channel is replaced by H transported from the intermembrane. A curved clockwise arrow is shown above the c ring. The text alongside reads “The c ring can rotate clockwise.”



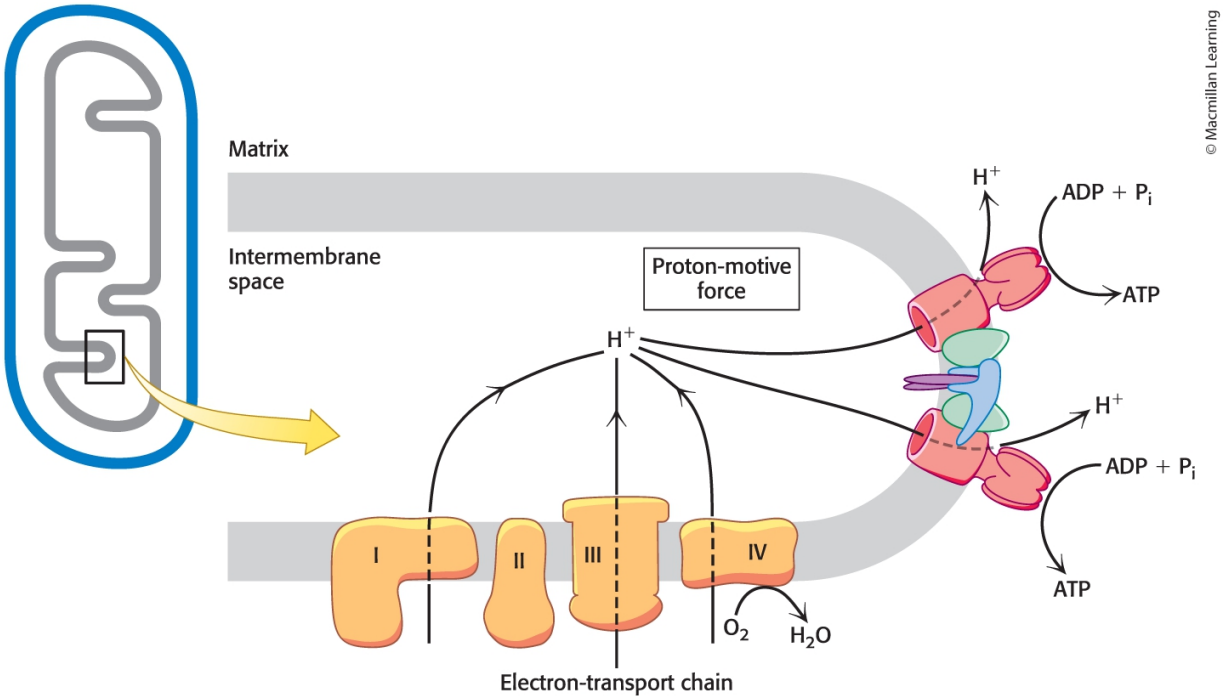
Step 4: Due to rotation of the c ring, the intermembrane half-channel again attains a negative charge and the matrix half-channel becomes bound to H. The H in the intermembrane half-channel is transferred to the rotated subunit of the c ring. The H in the matrix half-channel is transferred from the adjacent subunit of c ring.

Step 5: A downward arrow from H in the matrix half-channel points toward the matrix.

Step 6: The H atom from the matrix half-channel is released into the matrix and is depicted as H superscript plus. Both the half-channel attain the negative charge again.

Return to FIGURE 18.31 Proton motion across the membrane drives rotation of the c ring

Extended description for FIGURE 18.32 Protons must travel around the c ring to cross the membrane



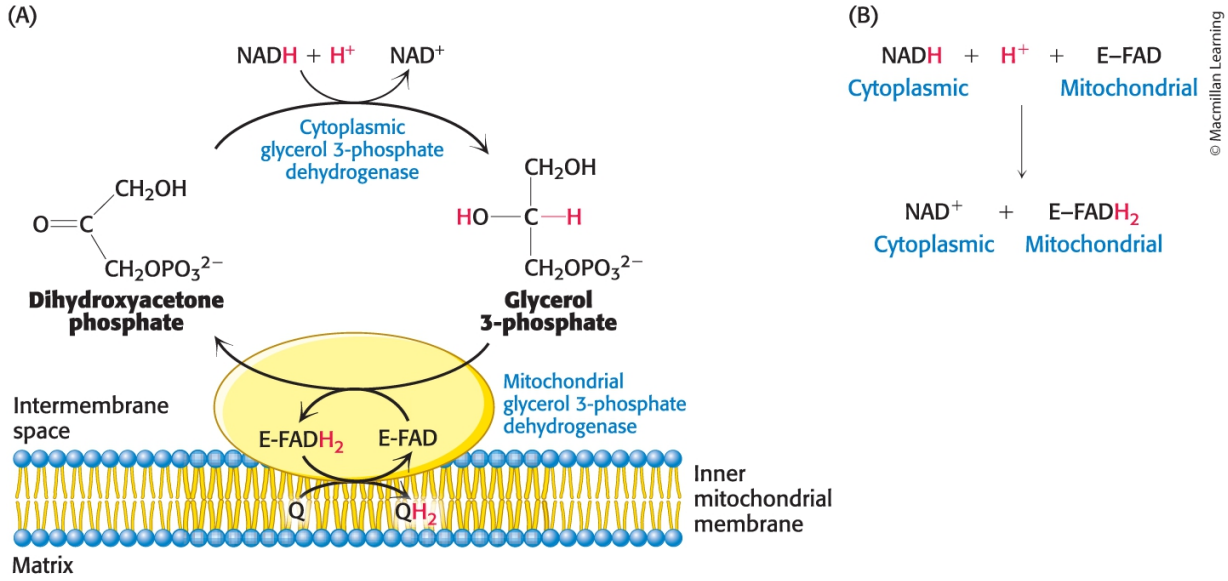
© Macmillan Learning

The c ring is depicted as a cylindrical structure composed of 10 elongated vertical subunits. These subunits are bound to H. The

region above the ring is labeled intermembrane space and the region below is labeled matrix. The front surface of the ring is enclosed by subunit a. An H superscript plus ion from the intermembrane space enters the intermembrane half-channel of subunit a. A curved circular arrow from the intermembrane half-channel moves in a clockwise direction around the c ring and returns back to the matrix half-channel of the subunit a. A downward arrow from the matrix half channel depicts the release of the H superscript plus ion into the matrix after its complete rotation around the c ring.

Return to FIGURE 18.32 Protons must travel around the c ring to cross the membrane

Extended description for FIGURE 18.33 An overview of oxidative phosphorylation shows the spatial relationship of the components



© Macmillan Learning

A schematic structure of a mitochondrion is shown. A section of the cristae formed by the inner mitochondrial membrane shows an enlarged view of a horizontal U-shaped crista. The region above the inner membrane is labeled matrix and the region inside the U-shaped structure is labeled intermembrane space. Complex 1 to 4 are shown embedded in the inner membrane. They are part of the electron transport chain. Arrows across complex 1, 3, and 4 point toward a common H superscript ion in the intermembrane space. A curved arrow below complex 4 depicts the conversion of O 2 to H 2 O in the matrix. The H superscript plus ion depicts proton motive force. Two arrows from this H superscript ion pass through a dimer of A T P synthase embedded in the inner membrane and enter the matrix. A curved arrow across the component of A T P synthase in

the matrix depicts the phosphorylation of A D P plus P subscript i to A T P.

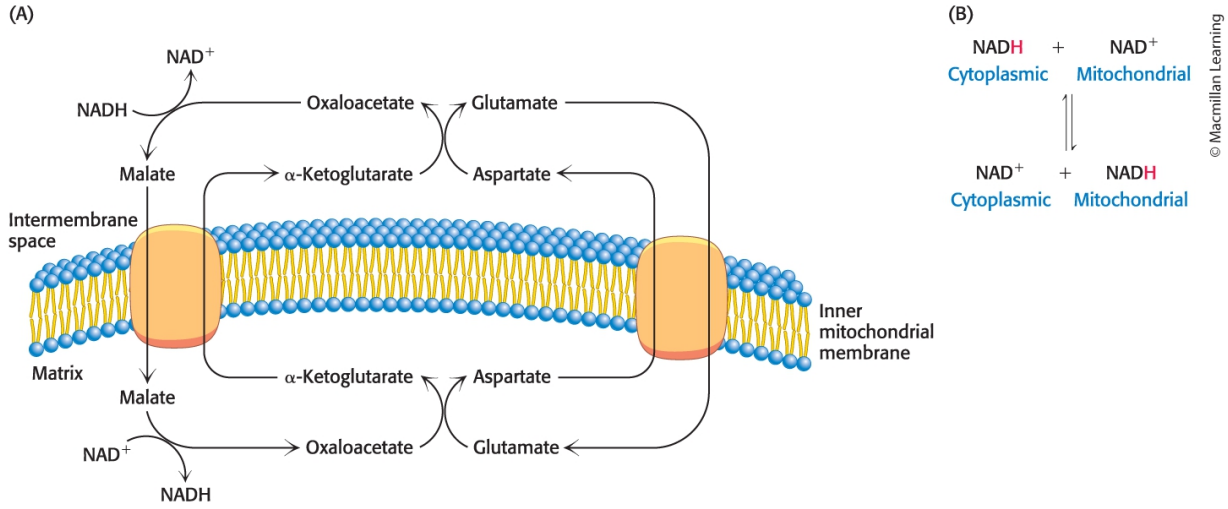
Return to FIGURE 18.33 An overview of oxidative phosphorylation shows the spatial relationship of the components

Extended description for FIGURE 18.34 The glycerol 3-phosphate shuttle allows for rapid rates of oxidative phosphorylation at the cost of energetic efficiency

Part (A): The outer leaflet of the inner mitochondrial membrane is attached to a mitochondrial glycerol 3-phosphate dehydrogenase depicted as a large oval. The region above the membrane is labeled intermembrane space and the region below is labeled matrix. The glycerol 3-phosphate dehydrogenase catalyzes the conversion of glycerol 3-phosphate to dihydroxyacetone phosphate and the simultaneous reduction of enzyme-bound F A D to F A D H 2. F A D H 2 is again oxidized as it transfers electrons to Q in the membrane and converts them into Q H 2.

The structure of glycerol 3-phosphate is as follows: C H 2 O H, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 2 is single bonded to O H on the left and H on the right.

The structure of dihydroxyacetone phosphate is as follows: Acentral C atom is single bonded to C H 2 O H on the upper right, single bonded to C H 2 O P O 3 superscript 2 minus on the lower right, and double bonded to O on the left.



A cytoplasmic glycerol 3-phosphate dehydrogenase catalyzes the conversion of dihydroxyacetone phosphate back to glycerol 3-phosphate. It is coupled with the oxidation of N A D H plus H superscript plus to N A D superscript plus.

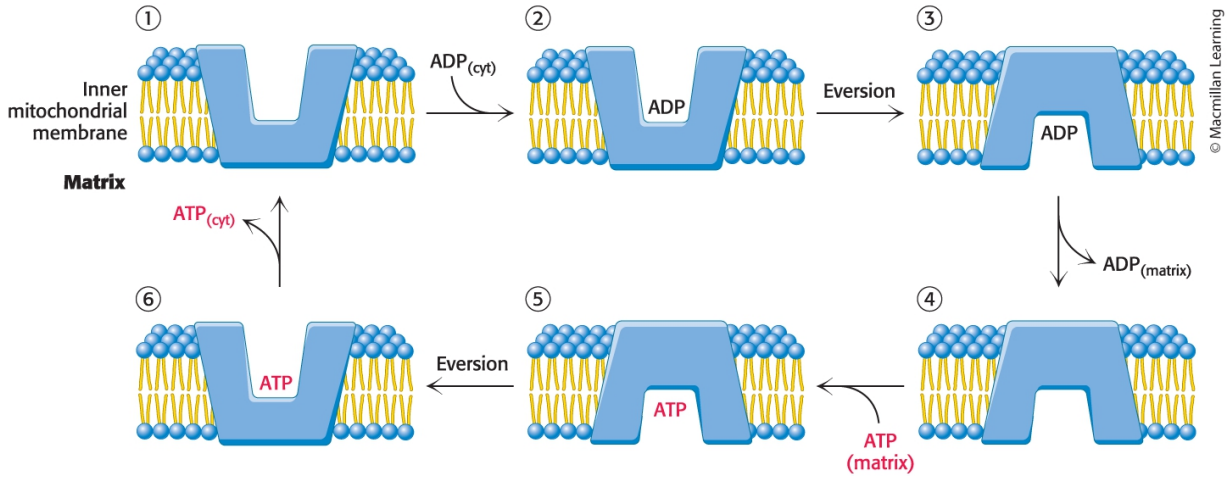
Part (B): It shows an equation depicted as follows:

N A D H cytoplasmic plus H superscript plus and E-F A D mitochondrial are irreversibly converted into N A D superscript plus cytoplasmic and E-F A D H 2 mitochondrial.

Return to FIGURE 18.34 The glycerol 3-phosphate shuttle allows for rapid rates of oxidative phosphorylation at the cost of energetic efficiency

Extended description for FIGURE 18.35 The malate–aspartate shuttle preserves all the chemical potential energy of cytoplasmically generated NADH

Part (A): Two cuboidal structures are embedded in the inner mitochondrial membrane on the left and right ends. The region above the membrane is labeled intermembrane space and the region below is labeled matrix. Malate from the intermembrane space enters the matrix through the left cuboidal structure. It is converted into oxaloacetate inside the matrix with the simultaneous reduction of N A D superscript plus to N A D H. The oxaloacetate is converted into alpha-ketoglutarate with the simultaneous conversion of glutamate to aspartate in the matrix. The alpha-ketoglutarate molecule moves back into the intermembrane space through the left cuboidal structure. The aspartate molecule exits the matrix and enters the intermembrane space through the right cuboidal structure. In the intermembrane space, aspartate is converted back to glutamate with the simultaneous conversion of alpha-ketoglutarate into oxaloacetate. Glutamate moves back into the matrix through the right cuboidal structure. Oxaloacetate is



converted into malate in the intermembrane space with the simultaneous reduction of N A D superscript plus to N A D H.

Part (B): It shows an equation depicted as follows:

N A D H cytoplasmic plus N A D superscript plus mitochondrial is reversibly converted into N A D superscript plus cytoplasmic and N A D H mitochondrial.

Return to FIGURE 18.35 The malate–aspartate shuttle preserves all the chemical potential energy of cytoplasmically generated NADH

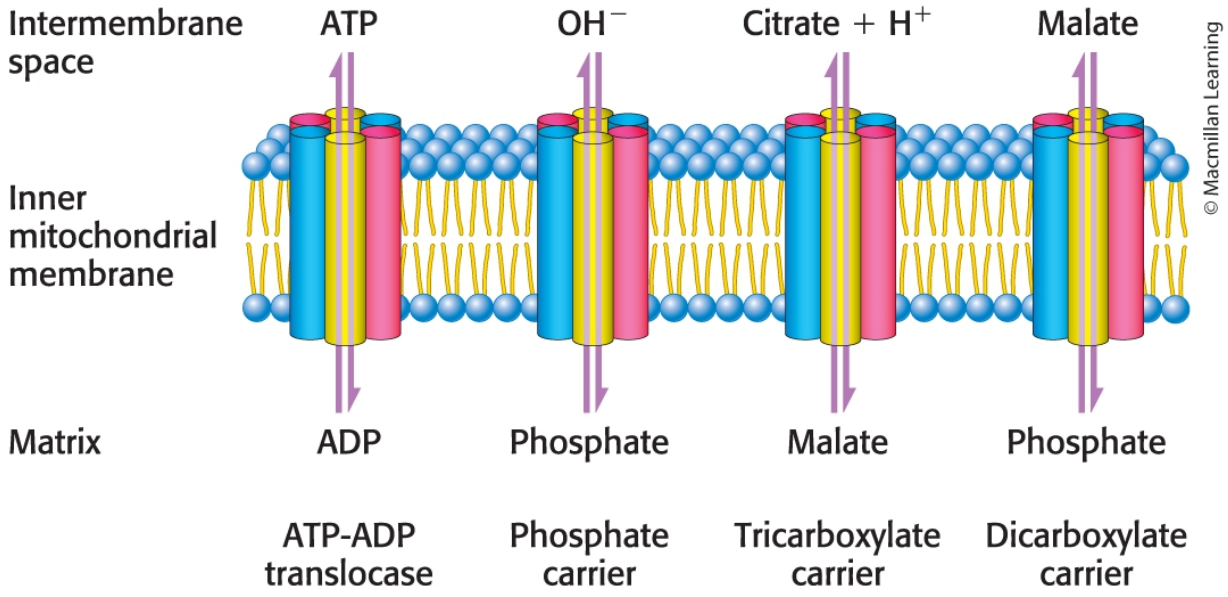
Extended description for FIGURE 18.36 The ATP-ADP translocase catalyzes the exchange of entry of ADP and ATP

The action of A T P-A D P translocase is divided into 6 steps as follows:

Step 1: An inverted V-shaped structure is shown embedded in the inner mitochondrial membrane. The region below the membrane is labeled matrix.

Step 2: A D P from the cytoplasm enters and binds to the central elongated groove in the structure.

Step 3: Eversion takes place and the groove containing A D P is now oriented toward the matrix. The A D P molecule is released into the matrix.



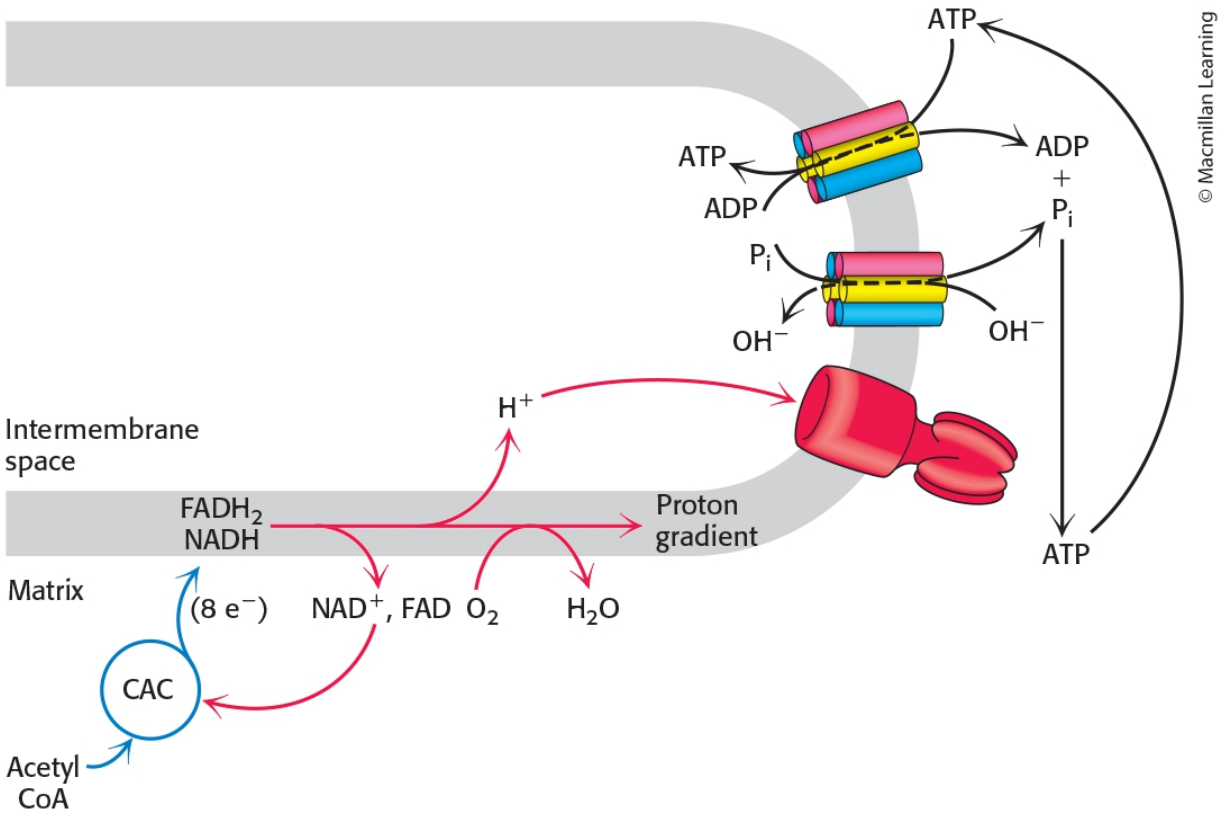
Step 4: The groove becomes empty.

Step 5: A T P from the matrix enters the groove.

Step 6: Eversion occurs again and the groove now faces upward. The A T P molecule is released into the cytoplasm.

Return to FIGURE 18.36 The ATP-ADP translocase catalyzes the exchange of entry of ADP and ATP

Extended description for FIGURE 18.37 Structurally homologous mitochondrial transporters

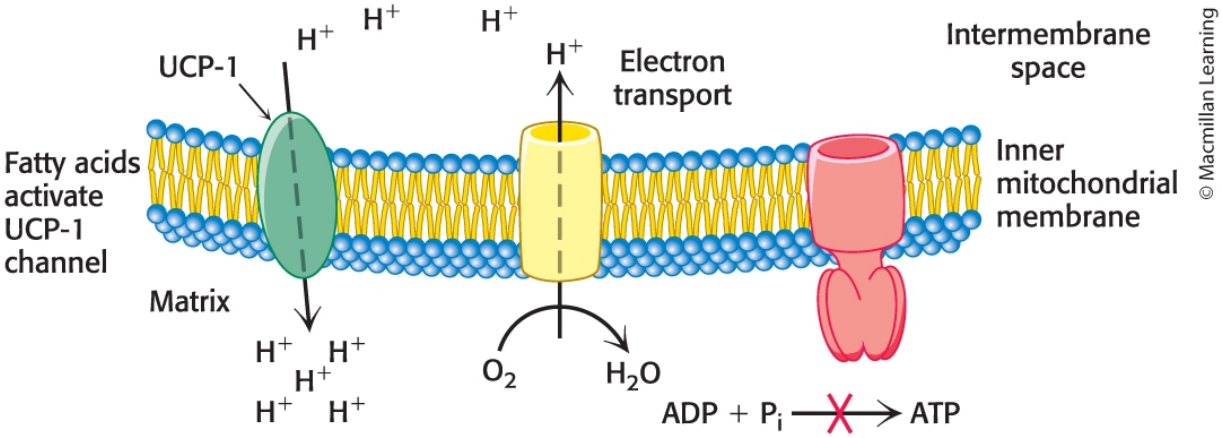


Four different transporters are shown embedded in the inner mitochondrial membrane. The region above the membrane is labeled intermembrane space and the region below is labeled matrix. From left to right, the transporters are labeled as follows: A T P-A D P translocase, phosphate carrier, tricarboxylate carrier, and dicarboxylate carrier. They are depicted as hollow structures composed of 6 thin cylindrical structures. The A T P-A D P translocase carries out the transport of A T P (intermembrane space) and A D P (matrix) across the inner mitochondrial membrane. The phosphate carrier performs the transport of O H superscript minus (intermembrane space) and phosphate (matrix) across the inner mitochondrial membrane. The tricarboxylate carrier performs the transport of citrate plus H superscript plus (intermembrane space) and malate (matrix) across the inner mitochondrial membrane. The dicarboxylate carrier performs the transport of malate

(intermembrane space) and phosphate (matrix) across the inner mitochondrial membrane.

Return to FIGURE 18.37 Structurally homologous mitochondrial transporters

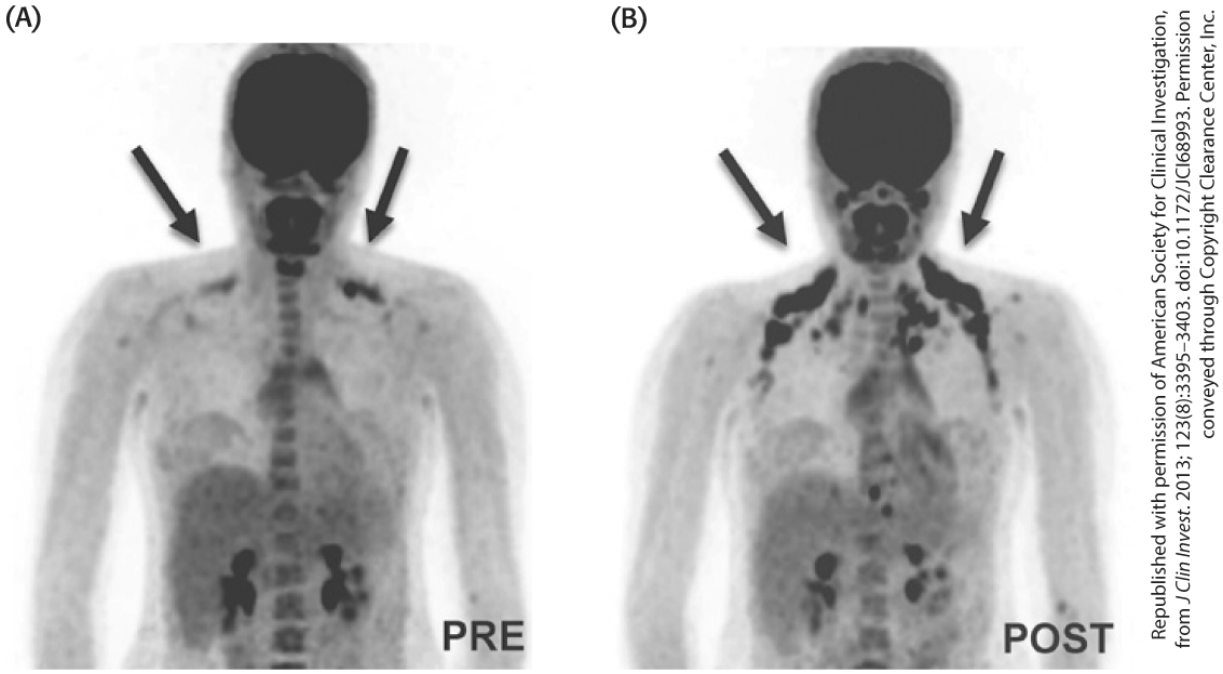
Extended description for FIGURE 18.38 ATP synthase depends upon the rest of the ATP synthesome, as well as the ETC and CAC



A section of crista is shown as a horizontal U-shaped structure. The region inside the crista is labeled intermembrane space and the region outside is labeled matrix. A circle labeled C A C is shown in the matrix. An arrow labeled acetyl C o A points toward the circle. An arrow labeled 8 electrons points from the circle to F A D H 2 and N A D H in the inner mitochondrial membrane lining the crista. A long arrow from F A D H 2 and N A D H points toward the proton gradient in the inner membrane. A downward arrow from the long arrow depicts the exit of N A D superscript plus and F A D into the matrix. The N A D superscript plus and F A D molecules enter into

the circle labeled C A C. A curved arrow below the long arrow depicts the conversion of O 2 to H 2 O in the matrix. An upward arrow arising from the long arrow depicts the entry of the H superscript plus ion into the intermembrane space. This H superscript plus ion enters into the A T P synthase embedded into the membrane. An A T P-A D P translocase and phosphate carrier are shown embedded into the inner membrane, adjacent to the A T P synthase. An inward arrow across the translocase depicts the entry of A T P from the matrix and the release of A D P into the intermembrane space. An outward arrow depicts the entry of P subscript i from the intermembrane space and release of A D P into the matrix. The phosphate carrier also picks the P subscript i in the intermembrane space and transfers it to the matrix. Simultaneously, it also transports the O H superscript minus from the matrix into the intermembrane space. The A D P and P subscript i in the matrix are phosphorylated by the A T P synthase to produce A T P. This A T P molecule is recycled by the A T P-A D P translocase.

Return to FIGURE 18.38 ATP synthase depends upon the rest of the ATP synthesome, as well as the ETC and CAC



Extended description for FIGURE 18.39 Mechanism of heat generation by U C P-1

A section of the inner mitochondrial membrane is shown. The region above the membrane is labeled intermembrane space and the region below is labeled matrix. An oval-shaped protein embedded into the membrane is labeled U C P-1. A hollow cylindrical protein is shown embedded in the middle of the membrane. An A T P synthase is shown embedded in the membrane, near the right end. A few H superscript plus ions are shown in the intermembrane space, above the U C P-1 protein. A downward arrow across U C P-1 depicts the entry of H superscript plus ions from intermembrane space into the matrix. The text alongside U C P-1 reads "Fatty acids activate U C P-1 channel." The hollow cylindrical structure depicts the electron transport and shows the movement of the H superscript plus ion from the matrix into the intermembrane space. The cylindrical structure simultaneously converts O 2 into H 2 O in the matrix. The A T P synthase does not carry out the phosphorylation of A D P and P subscript i to produce A T P.

Return to FIGURE 18.39 Mechanism of heat generation by U C P-1

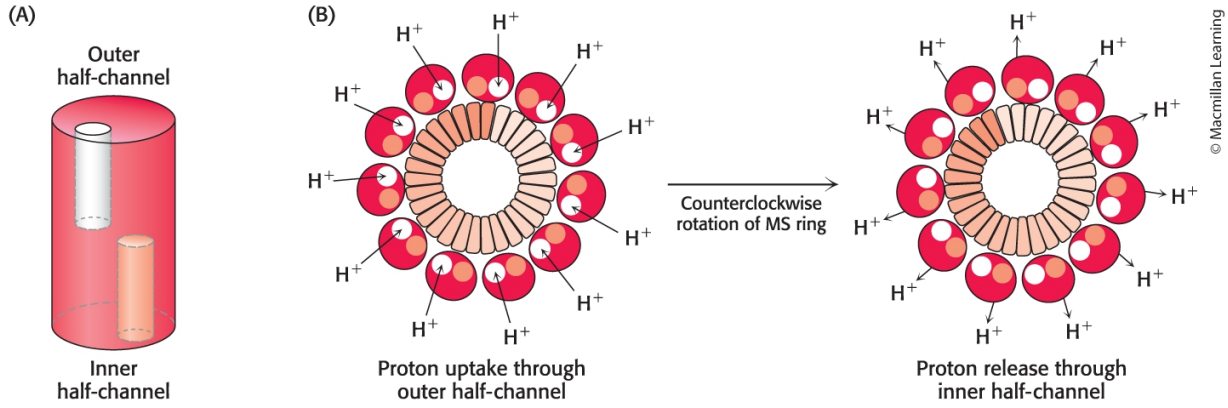
Extended description for FIGURE 18.43 The flagellar motor is a complex structure containing as many as 40 distinct types of proteins



Two lipid bilayers are shown with a large gap between them. The top bilayer is labeled the outer membrane. A long rectangular strip in the gap is labeled peptidoglycan. The peptidoglycan is located closer to the outer membrane. The space between the peptidoglycan and the bottom bilayer is labeled periplasm. The region below the bottom bilayer is labeled cytoplasm. M S ring composed of several

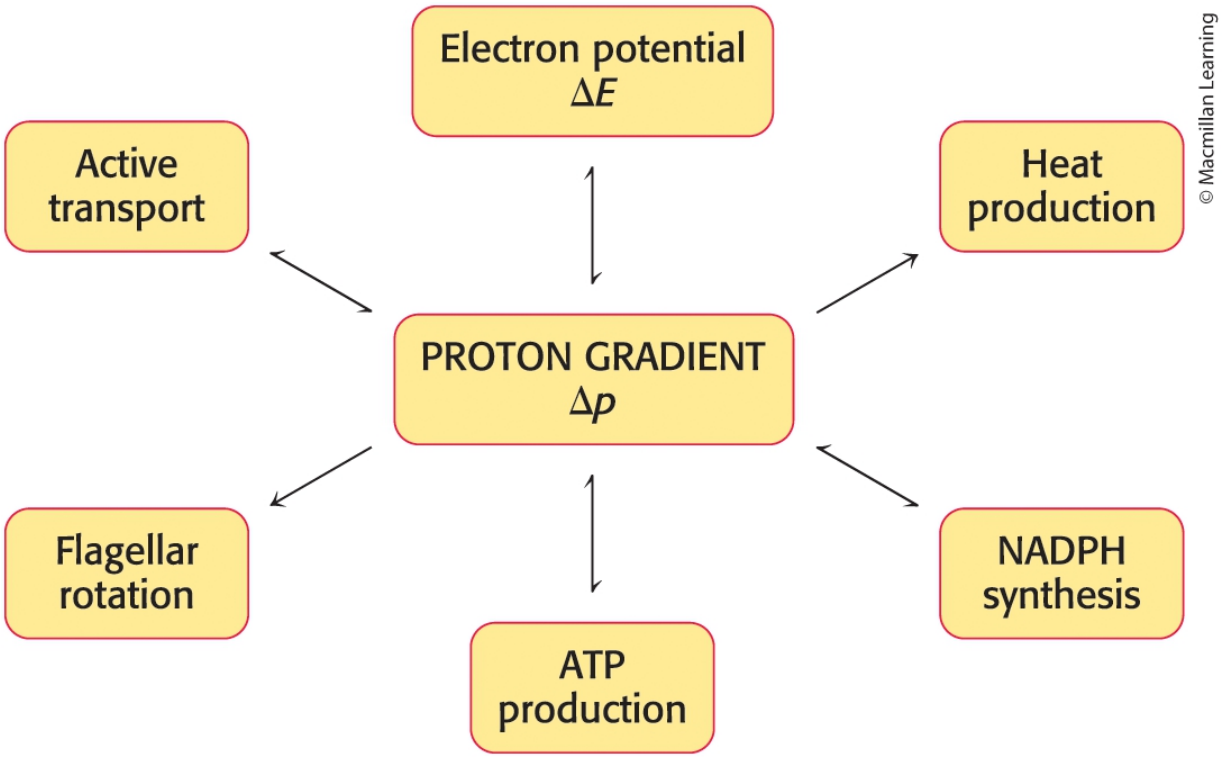
adjacently placed orange oval-shaped structures is embedded in the bottom bilayer. The orange oval-shaped structure is labeled F l i G. A layer of yellow circles connected to a layer of green oval-shaped structures is attached to the bottom surface of the M S ring and extends into the cytoplasm. The green oval-shaped structures are labeled F l i M. A budding yeast-like structure is embedded in the bottom bilayer and flanks the M S ring. It is labeled Mot A. A circular hand-mirror-like structure labeled Mot B is embedded in the bottom bilayer and flanks the entire complex composed of the M S ring and Mot A. A cylindrical rod extends from the center of the M S ring and passes across the peptidoglycan layer and outer membrane. It protrudes above the outer membrane and is labeled flagellum. It curves toward the right, above the outer membrane and this portion is labeled hook. The right end of the flagellum is surrounded by a layer of hexagonal structures labeled filament. A rightward pointing arrow is shown next to the filament. The rod-like structure in the peptidoglycan and the outer membrane is surrounded by a P ring and L ring respectively.

Return to FIGURE 18.43 The flagellar motor is a complex structure containing as many as 40 distinct types of proteins

Extended description for FIGURE 18.44 Rotation of the flagellum involves proton half-channels like ATP synthase

Part (A): A solid cylindrical structure is shown. It contains two half-channels. The outer half-channel is depicted as a thin cylinder that extends from the top to the center. The inner half-channel starts just where the outer channel terminates and extends to the bottom.

Part (B): A hollow ring is outlined by elongated structures. The outer surface of the ring is lined by medium-sized circular structures. Each circle contains a pair of tiny circles. In each pair, one circle is white and another one is orange. Arrows labeled H superscript plus ion point toward the tiny white circle inside each medium circle. The text below the entire structure reads “Proton uptake through outer half-channel.”

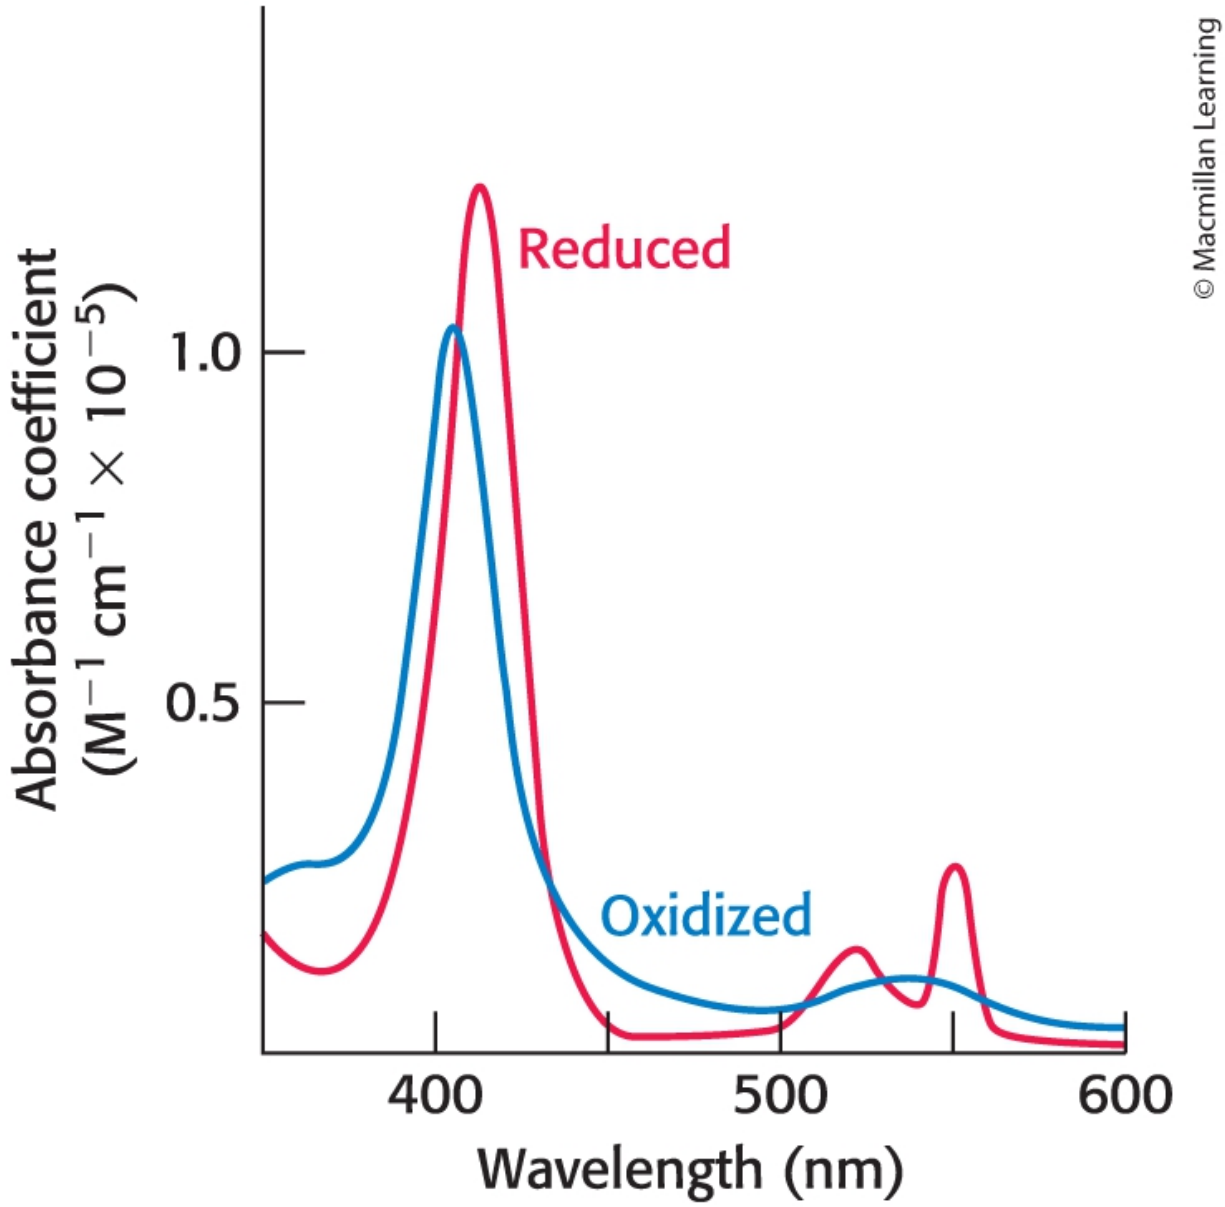


An arrow labeled “Counterclockwise rotation of M S ring” is shown.

It shows the anticlockwise rotation of the circular ring. An outward arrow from each medium circle points toward the H superscript

plus ion. The text below the entire structure reads “Proton release through inner half-channel.”

Return to FIGURE 18.44 Rotation of the flagellum involves proton half-channels like ATP synthase



Extended description for FIGURE 18.45 Proton gradient as an interconvertible form of free energy

A rectangular box labeled proton gradient delta P is shown at the center. A two-way arrow with half arrow heads is shown above, below, on the top left, and bottom right. The arrows above, below, on the top left, and bottom right point toward different boxes labeled electron potential delta E, A T P production, active transport, and N A D P H synthesis respectively. An arrow with a complete arrowhead is shown on the top right and bottom left and points toward boxes labeled heat production and flagellar rotation.

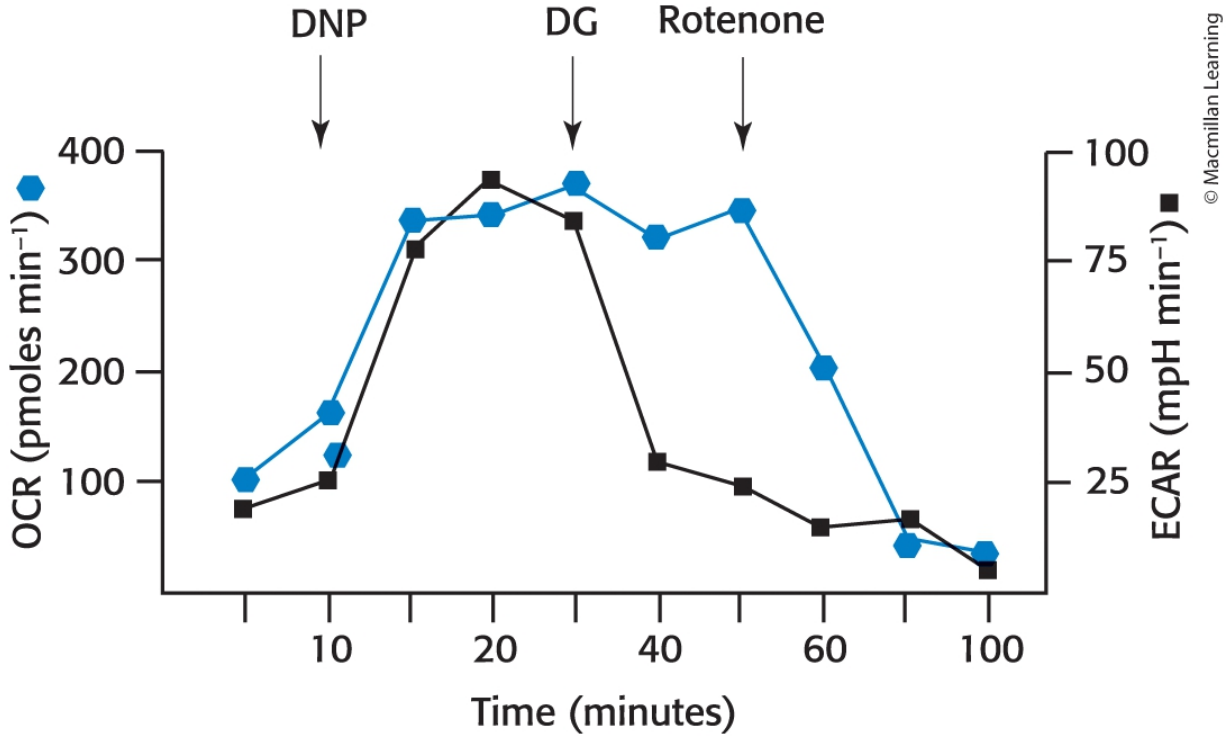
Extended description for Absorption spectra of the reduced and oxidized forms of cytochrome c



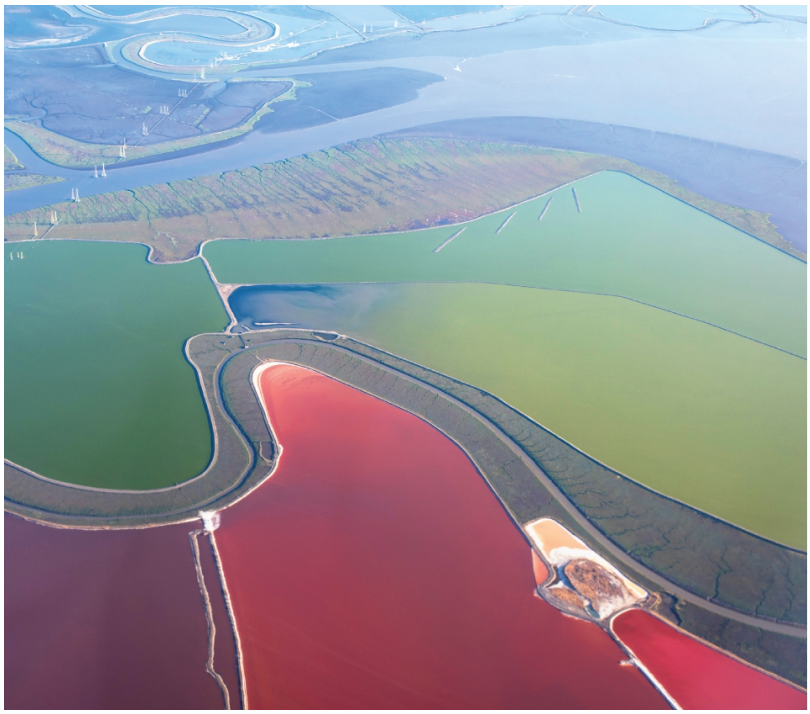
© Macmillan Learning

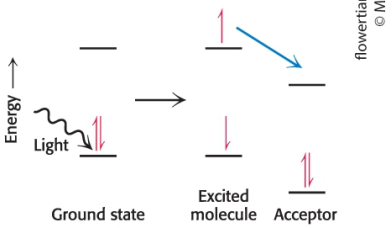
The horizontal axis is labeled wavelength in nanometers. It has markings ranging from 400 to 600 in increments of 100 units. The vertical axis is labeled absorbance coefficient in molar inverse centimeter inverse into 10 to the power negative 5. It has markings

ranging from 0 to 1.0 in increments of 0.5 units. The graph contains two curves. The blue curve labeled oxidized starts at 0.25 on the vertical axis and moves toward the right. It rises steeply to reach (400, 1.0), falls steeply toward the lower right to reach (430, 0.25), and then moves toward the right to reach (600, 0.2). The red curve labeled reduced starts below the red curve at 0.15 and forms a slight depression before steeply rising to (410, 1.25). It then steeply falls to (450, 0.05) and moves toward the right. During its path toward the right, it forms two tiny peaks at (520, 0.1) and (550, 0.25) and then moves along the horizontal axis. All values are estimated.

Return to Absorption spectra of the reduced and oxidized forms of cytochrome c

Extended description for Results of an experiment using the X F technology





The horizontal axis is labeled time in minutes. It has markings 10, 20, 40, 60, and 100 from left to right. The left vertical axis is labeled O C R in picomoles per minute. It has markings ranging from 100 to 400 in increments of 100 units. The right vertical axis is labeled E C A R in Milli p H per minute. It has markings ranging from 25 to 100 in increments of 25 units. A blue curve with solid blue hexagonal data points represents O C R. A black curve with solid black square data points represents E C A R. The data points of the blue curve are as follows: (5, 100), (10, 180), (15, 350), (20, 351), (30, 380), (40, 320), (50, 350), (60, 210), (80, 30), and (100, 30). The data points of the blue curve are as follows: (5, 90), (10, 100), (15, 310), (20, 380), (30, 350), (40, 110), (50, 100), (60, 40), (80, 45), and (100, 10). D N P is added at

10 minutes, D G is added at 30 minutes, and rotenone is added at 50 minutes. All values are estimated.

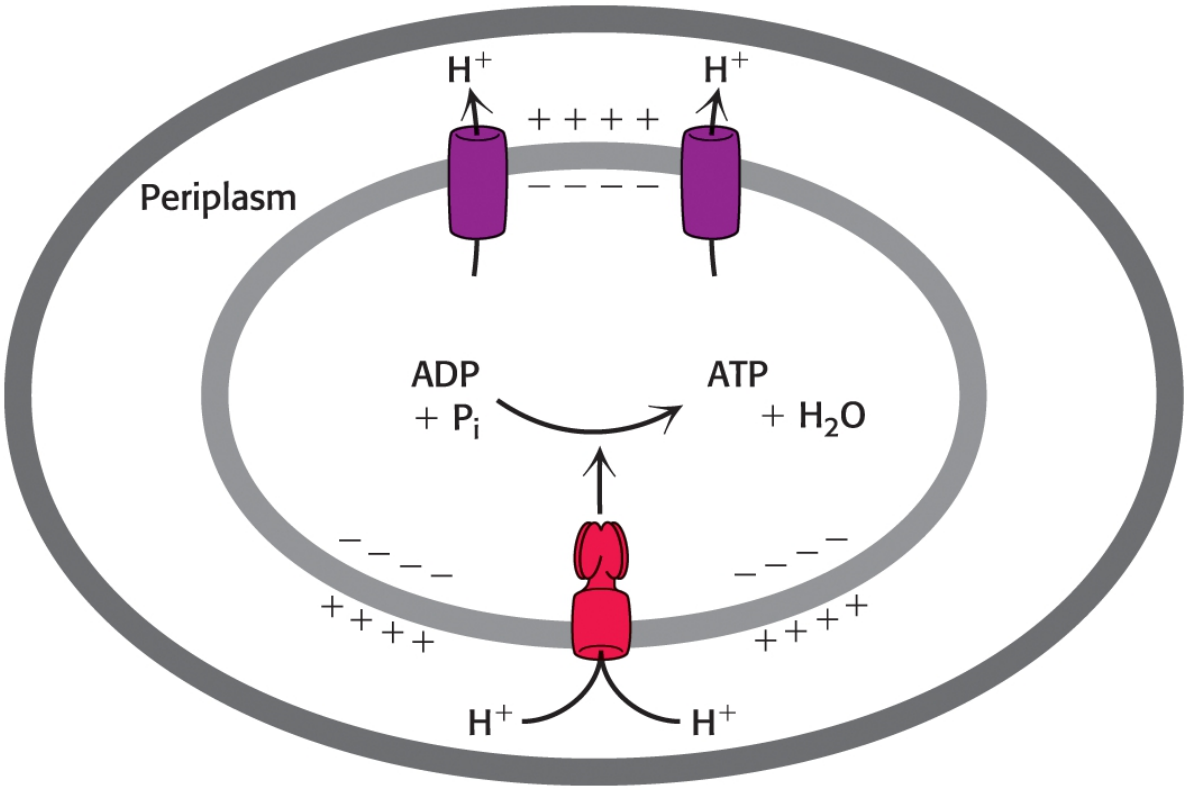
Extended description for Phototrophic halobacteria are visible from the air in salt ponds near the San Francisco Bay and a schematic shows electron excitation and its transfer to acceptor



flowertiare/Deposit Photos
© Macmillan Learning

The aerial view of the salt ponds near San Francisco Bay shows the red color of the water due to the phototrophic halobacteria. The halobacteria produce distinct red and purple colors in the pond. On the right, the schematic shows the excitation of electrons. It shows a molecule in the ground state on the left and an excited molecule on the right. An upward arrow on the left side is labeled energy. On the left, an upward and downward arrow is present in the ground state. A blank is shown above the ground state at a higher energy level. An arrow from the ground state points to the excited state on the right. A downward arrow is present at the bottom excited state and an upward arrow is present in the top excited state. An arrow from the

top excited state points to the excited state of the acceptor. The excited state is blank in the acceptor. Upward and downward arrow is present in the ground state of the acceptor.

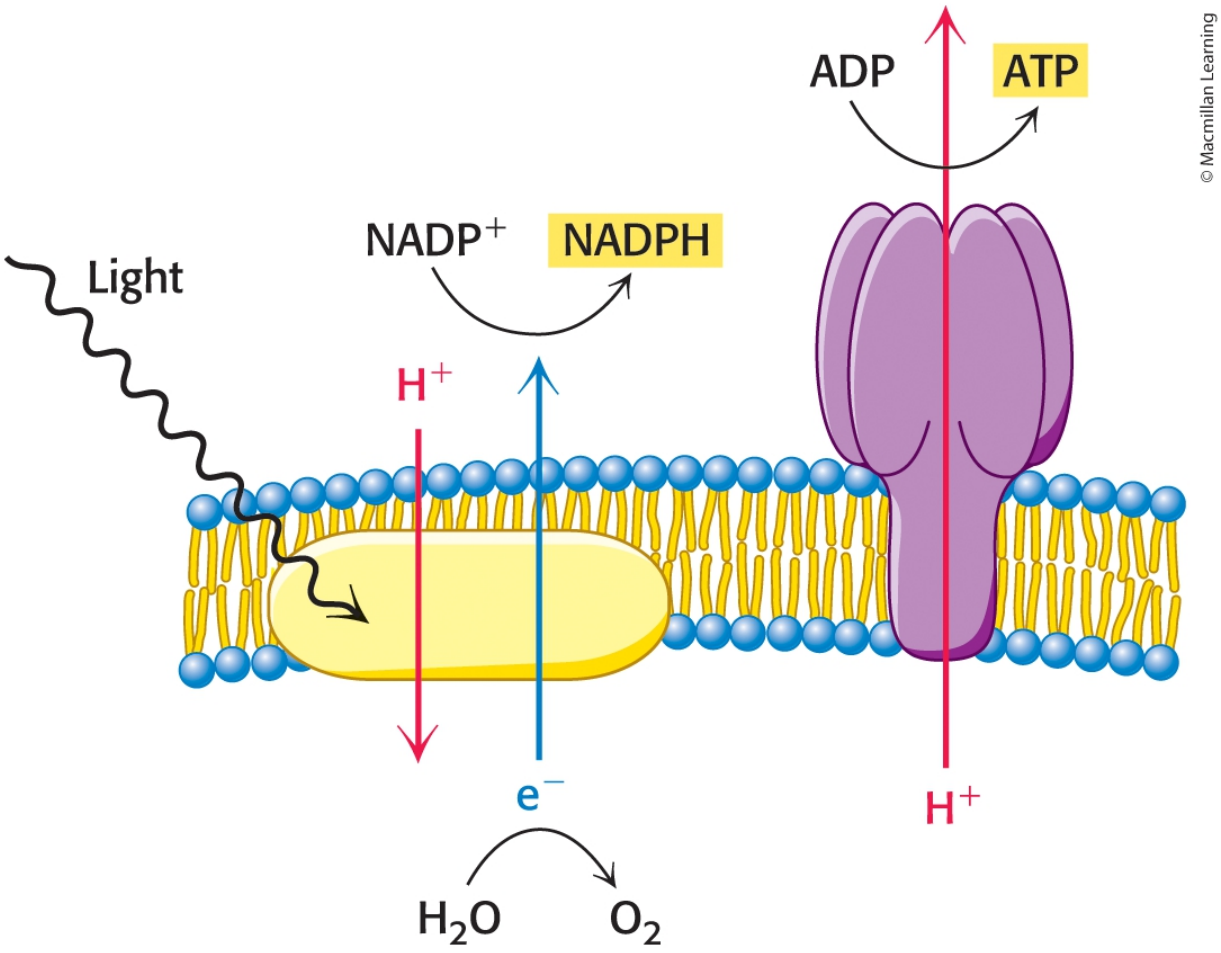
Extended description for FIGURE 19.1 Phototrophy can be accomplished by the cooperation of just two proteins



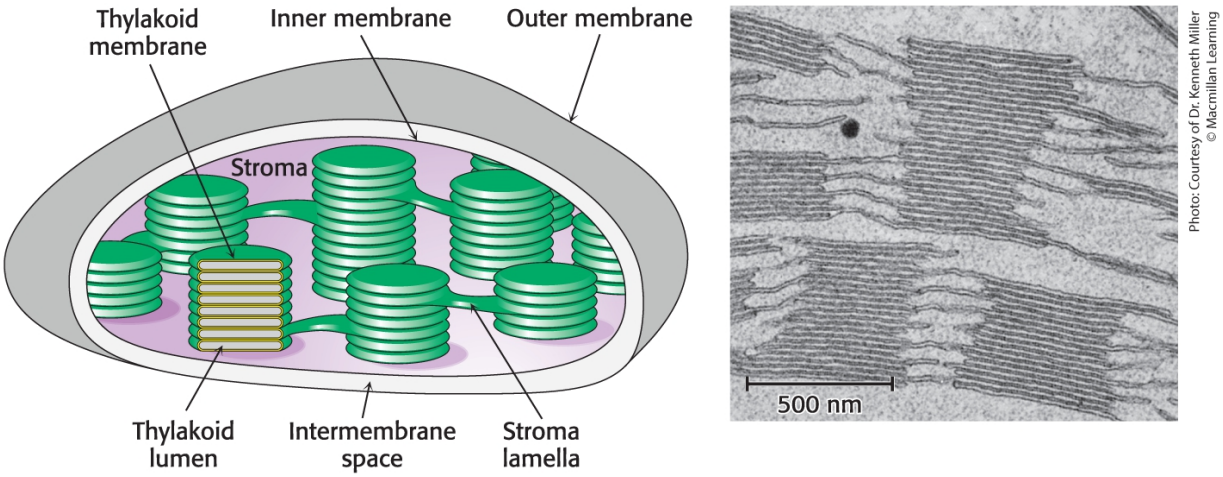
© Macmillan Learning

The cell wall is made up of two concentric circles that are separated by a space. The space between the two concentric circles is labeled periplasm. In the inner circle, a red-colored cylindrical membrane protein is present on the lower surface. 2 H plus ions enter into the inner circle through the membrane protein from the periplasm. The outer surface of the circle has a positive charge while the inner surface has a negative charge. Once the H superscript plus ions enter the circle they are used up for converting A D P and P subscript i to A T P and H 2 O. The H superscript plus ions later move into the periplasm through two purple-colored cylindered

located on the upper surface of the inner circle. Arrows indicate the outward movement of the H plus ions.

Return to FIGURE 19.1 Phototrophy can be accomplished by the cooperation of just two proteins

Extended description for FIGURE 19.2 The light reactions of oxygenic photosynthesis generate both A T P and reducing power



© Macmillan Learning

A capsule-shaped protein and a protein complex are embedded in a lipid bilayer. A wavy arrow labeled light strikes the capsule-shaped protein. A downward arrow across the capsule-shaped protein depicts the entry of H superscript plus into the region below the bilayer. An upward arrow across the capsule-shaped protein depicts the exit of electrons into the region above the bilayer. This movement of electrons is coupled with the conversion of H 2 O to O 2 in the region below the membrane. The electron is used to reduce

N A D P superscript plus to N A D P H above the bilayer. An upward arrow across the protein complex depicts the transfer of the H superscript plus ion from the region below the bilayer to the region above. This movement is coupled with the conversion of A D P to A T P.

Extended description for FIGURE 19.3 The anatomy of a chloroplast reveals complex membrane-enclosed structures

The chloroplast is an oval-shaped, hollow sac-like structure that consists of two membranes labeled the outer membrane and the inner membrane. The space between the outer membrane and inner membrane is labeled intermembrane space. The hollow interior of the chloroplast is labeled stroma. The stroma of the chloroplast consists of numerous stacked discs. These discs are surrounded by thylakoid membranes. The bridges connecting the stacked discs with the neighboring stacked discs are labeled stroma lamella. One of the thylakoid membranes is cut open to expose the thylakoid lumen. An electron micrograph of a chloroplast on the right depicts the stacked grana interconnected by stroma lamella. A scale on the bottom left of the electron micrograph reads 500 nanometers.

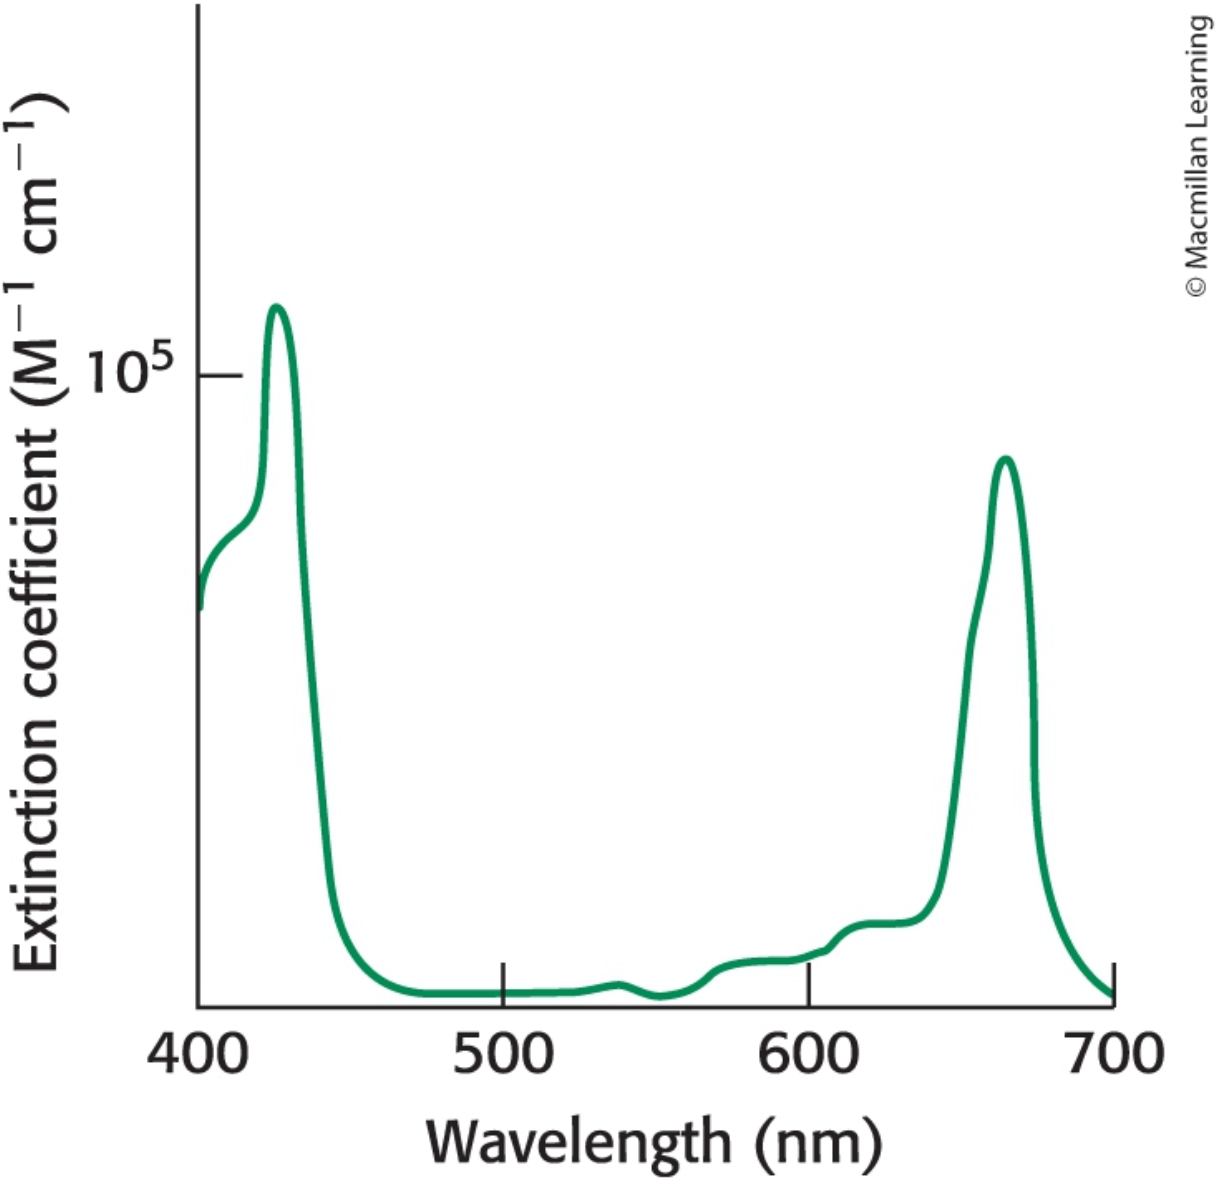
Extended description for FIGURE 19.5: Structure of Chlorophyll alpha

Four 5-membered heterocyclic pentagonal rings, four 6-membered heterocyclic hexagonal rings, and one 5-carbon hexagonal ring are fused together. The first 5-membered heterocyclic pentagonal ring is in a vertical orientation consisting of 1 N and 4 C atoms. In the first 5-membered heterocyclic pentagonal ring, N occupies the first position which is the bottom right vertex. In the first 5-membered heterocyclic pentagonal ring, a double bond is present between C 2 and C 3. C 2 of the first 5-membered heterocyclic pentagonal ring is single bonded to C H 3. C 3 of the first 5-membered heterocyclic pentagonal ring is single bonded to a central C H group in the form of a line. The central C H group is double bonded to C H 2 on the upper left. The first 5-membered heterocyclic pentagonal ring is fused to the first 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 1 M g, 2 N, and 3 C atoms. In the first hexagonal ring, the first N atom occupies the first position which is the bottom right vertex, M g occupies the second position which is the bottommost vertex, and the second N atom occupies the third position which is the bottom left vertex. The two rings are fused to each other such that C 4 and N of the first 5-membered heterocyclic pentagonal ring are the C 1 and the second N atom of the first hexagonal ring, respectively. In the first hexagonal ring, a double bond is present between C 1 and C 2. The first hexagonal ring is fused to the second 5-membered pentagonal ring in a vertical orientation consisting of 1 N and 4 C atoms. In the second 5-membered heterocyclic pentagonal ring, N occupies the first position which is the bottom left vertex. The two rings are fused to each other such that C 3 and the first N atom of the first hexagonal ring are the C 1 and N of the second 5-membered heterocyclic pentagonal ring, respectively. In the second 5-membered heterocyclic pentagonal ring, a double bond is present between N and C 1, and C 2 and C 3. C 2 of the second 5-membered heterocyclic pentagonal ring is single bonded to C H 3. C 3 of the second 5-membered heterocyclic pentagonal ring is single bonded to a central C H 2 group in the form of a line. The central C H 2 group is



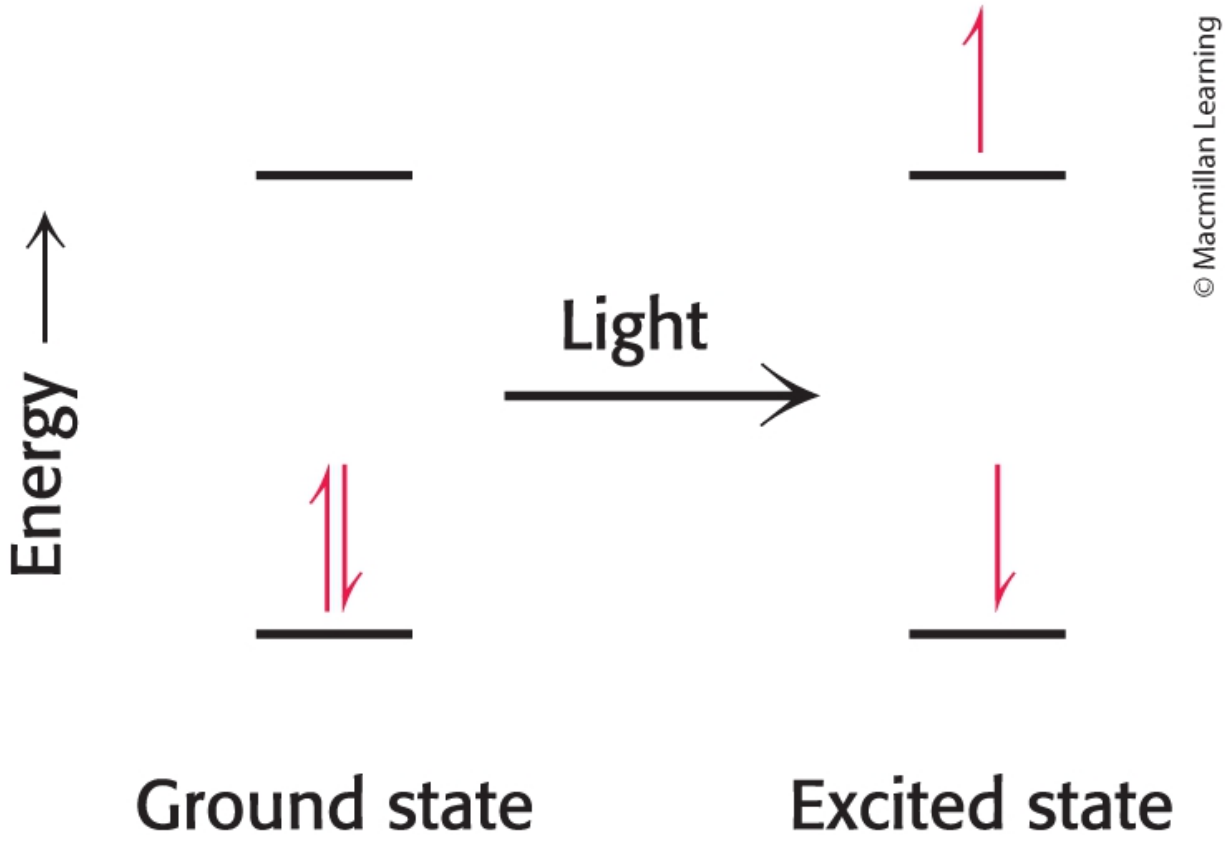
single bonded to C H 3 on the upper right. The first hexagonal ring and the second 5-membered heterocyclic pentagonal ring are fused to a second 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 1 M g, 2 N, and 3 C atoms. In the second hexagonal ring, the first N atom occupies the first position which is the bottom left vertex, M g occupies the second position which is the leftmost vertex, and the second N atom occupies the third position which is the top left vertex. The three rings are fused to each other as follows: The first N atom and M g of the first hexagonal ring are the second N atom and M g of the second hexagonal ring, respectively. N and C 4 of the second 5-membered heterocyclic pentagonal ring are the second N atom and C 1 of the second hexagonal ring, respectively. In the second hexagonal ring, a double bond is present between C 1 and C 2. The second hexagonal ring is fused to the third 5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 1 N and 4 C atoms. In the third 5-membered heterocyclic pentagonal ring, N occupies the first position which is the top left vertex. The two rings are fused to each other such that the first N atom and C 3 of the second hexagonal ring are N and C 1 of the third 5-membered heterocyclic pentagonal ring, respectively. In the third 5-membered heterocyclic pentagonal ring, a double bond is present between C 1 and C 2, and C 3 and C 4. C 2 of the third 5-membered heterocyclic pentagonal ring is single bonded to C H 3. The second hexagonal ring and the third 5-membered heterocyclic pentagonal ring are fused to the third 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 1 M g, 2 N and 3 C atoms. In the third hexagonal ring, the first N atom occupies the first position which is the top left vertex, M g occupies the second position which is the topmost vertex, and the second N atom occupies the third position which is the top right vertex. The three rings are fused to each other as follows: M g and the first N atom of the second hexagonal ring are the M g and the second N atom of the third hexagonal ring, respectively. N and C 4 of the third 5-membered heterocyclic pentagonal ring are the second N atom

and C 1 of the third hexagonal ring, respectively. In the third hexagonal ring, a double bond is present between C 2 and C 3. The third 5-membered heterocyclic pentagonal ring and the third hexagonal ring are fused to the 5-carbon pentagonal ring in a vertical orientation highlighted in blue with C 1 occupying the topmost vertex. The three rings are fused to each other as follows: C 3 and C 4 of the third 5-membered heterocyclic pentagonal ring are the C 2 and C 1 of the 5-carbon pentagonal ring, respectively. C 1 and C 2 of the third hexagonal ring are the C 1 and C 5 of the 5-carbon pentagonal ring, respectively. C 3 of the 5-carbon pentagonal ring is double bonded to O. C 4 of the 5-carbon pentagonal ring is wedge bonded to H on the lower left and dash bonded to a central C atom on the lower left in the form of a dashed line. The central C atom is double bonded to a second O atom on the lower left and single bonded to O C H 3 on the lower right. The third hexagonal ring is fused to the fourth 5-membered heterocyclic pentagonal ring in a horizontal orientation highlighted in red consisting of 1 N and 4 C atoms. In the fourth 5-membered heterocyclic pentagonal ring, N occupies the first position which is the top right vertex. The two rings are fused to each other such that the first N atom and C 3 of the third hexagonal ring are the N and C 1 of the fourth 5-membered heterocyclic pentagonal ring, respectively. In the fourth 5-membered heterocyclic pentagonal ring, a double bond is present between C 4 and N. C 2 of the fourth 5-membered heterocyclic pentagonal ring is single bonded to H on the lower right and wedge bonded to C 1 of a 2-carbon alkane chain depicted as a line structure using 1 line. C 3 of the fourth 5-membered heterocyclic pentagonal ring is wedge bonded to H on the lower left and dash bonded to C H 3 on the upper left. The groups attached to C 1 and C 2 of the fourth 5-membered heterocyclic pentagonal ring are highlighted in red. C 2 of the 2-carbon alkane chain is double bonded to a third O atom on the lower right and single bonded to a fourth O atom on the lower left. The fourth O atom is single bonded to R below which is highlighted in green. The third hexagonal ring and the fourth 5-

membered heterocyclic pentagonal ring are fused to the fourth 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 1 M g, 2 N, and 3 C atoms. In the fourth hexagonal ring, the first N atom occupies the first position which is the top right vertex, M g occupies the second position which is the rightmost vertex, and the second N atom occupies the third position which is the bottom right vertex. The three rings are fused to each other as follows: The first N atom and M g of the third hexagonal ring are the second N atom and M g of the fourth hexagonal ring, respectively. C 4 and N of the fourth 5-membered heterocyclic pentagonal ring are the C 1 and the second N atom of the fourth hexagonal ring, respectively. The fourth hexagonal ring, the first 5-membered heterocyclic pentagonal ring, and the first hexagonal ring are also fused to each other as follows: C 3 and the first N atom of the fourth hexagonal ring are the C 1 and N of the first 5-membered heterocyclic pentagonal ring, respectively. The first N atom and M g of the fourth hexagonal ring are the second N atom and M g of the first hexagonal ring, respectively. R has the following structure highlighted in green: A 15-carbon alkene chain is depicted as a line structure using 10 zigzag lines in which the three zigzag lines between C 4 and C 13 are enclosed within parentheses with subscript 2. A double bond is present between C 2 and C 3. C 3, C 7, and C 11 are each single bonded to C H 3 above. C 15 is single bonded to C H 3 above and C H 3 on the lower right.

Return to FIGURE 19.5: Structure of Chlorophyll alpha

Extended description for FIGURE 19.6 Chlorophyll a has a distinct absorbance spectrum in the visible range



The horizontal axis, labeled wavelength in nanometers, has markings ranging from 400 to 700 in increments of 100 units. The vertical axis, labeled extinction coefficient in M inverse centimeter inverse, has the marking 10 to the power 5 much above the midpoint

of the vertical axis. The graph shows a green curve that starts from a point below 10 to power 5, peaks at 420 just above 10 to power 5, and steeply falls to 450 on the horizontal axis. It then continues moving along the horizontal axis to reach 600. The curve rises upward and peaks again at 670 nanometer and below 10 to the power 5 on the vertical axis. It then steeply falls again to terminate at 700 on the horizontal axis. All values are approximated.

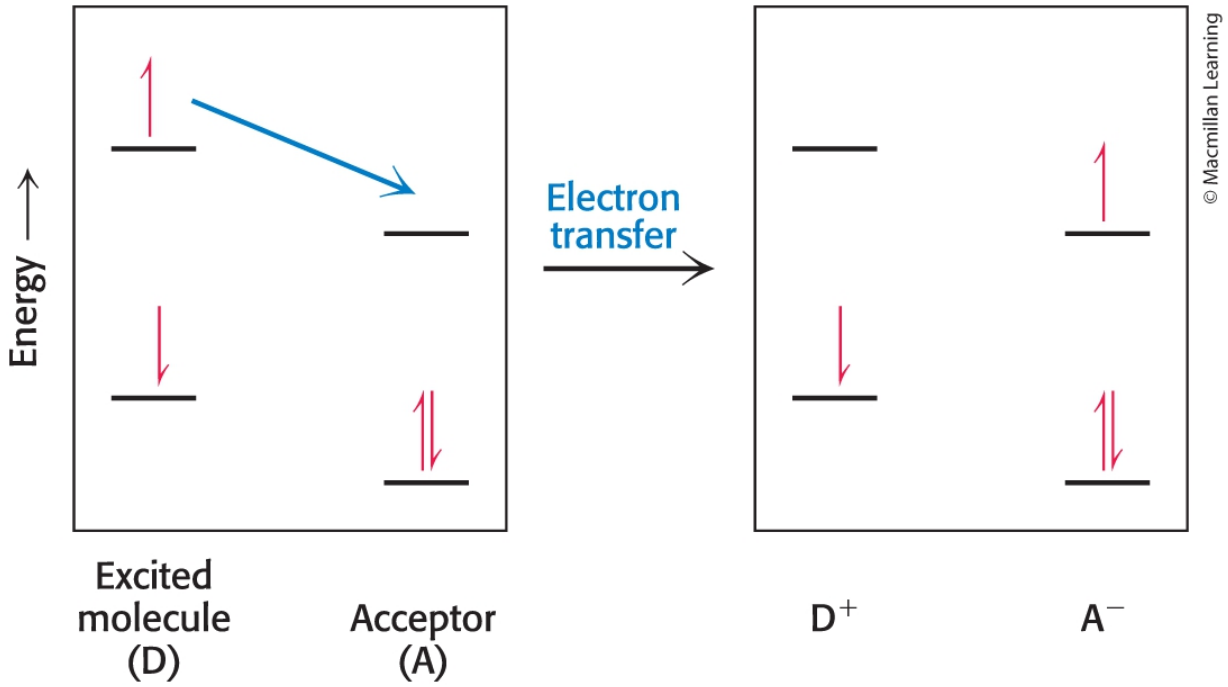
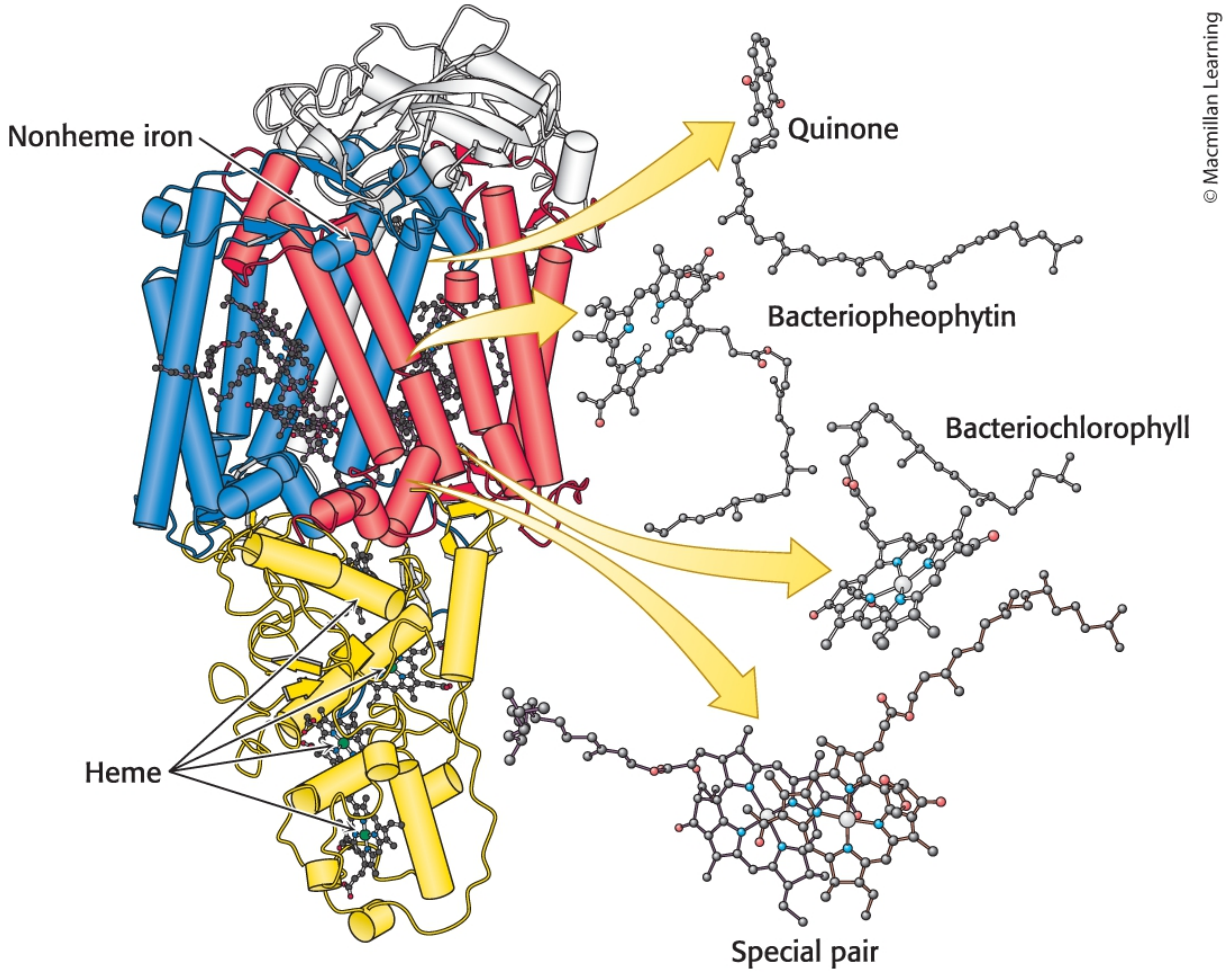
Extended description for FIGURE 19.7 The absorption of light leads to the excitation of an electron from its ground state to a higher energy level



© Macmillan Learning

The figure shows the ground state of the electron on the left and the excited state of the electron on the right. An upward arrow on the left side of the figure is labeled energy. On the left, an upward and downward arrow is present in the ground state. A blank is shown above the ground state at a higher energy level. An arrow from the ground state points to the excited state on the right. The arrow is labeled light. A downward arrow is present at the bottom excited state and an upward arrow is present in the top excited state.

Return to FIGURE 19.7 The absorption of light leads to the excitation of an electron from its ground state to a higher energy level

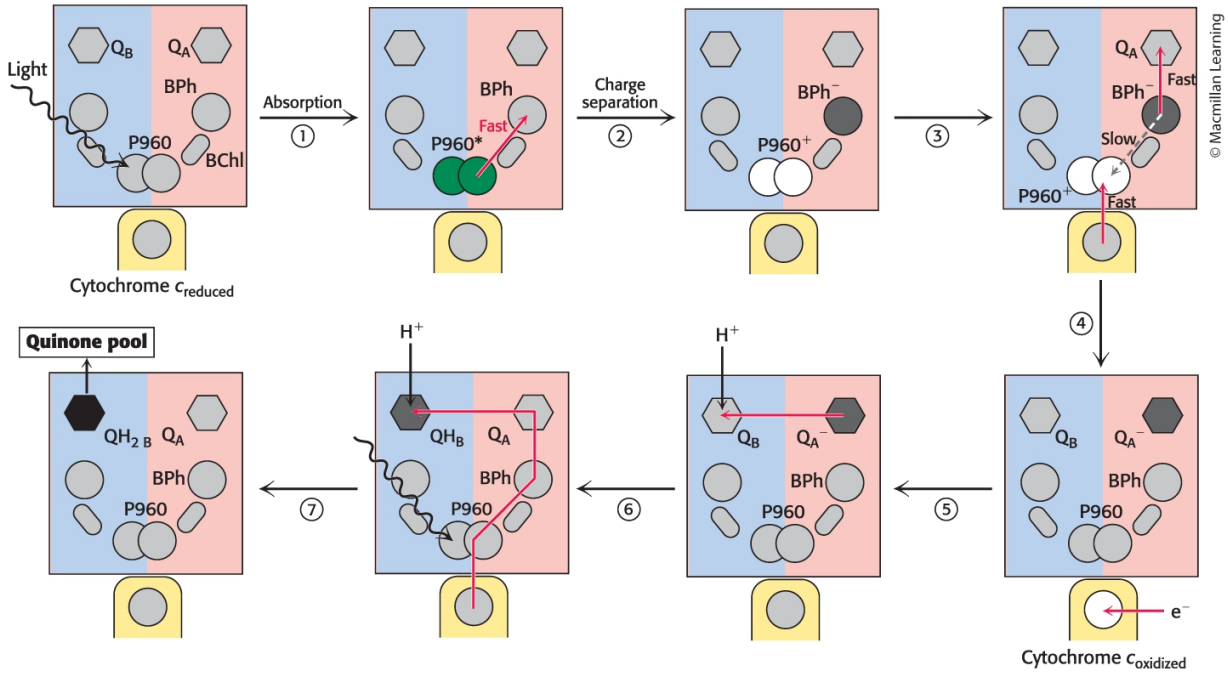


Extended description for FIGURE 19.8 The key to photosynthesis is photoinduced charge separation

The figure shows two panels. The first panel shows an excited molecule D on the left. A downward arrow is present in the bottom ground state and an upward arrow is present in the top excited state. An arrow from the excited molecule is directed toward the excited state of the acceptor A. In the ground state of acceptor A, an upward and downward arrow is present. An arrow from the first panel points to the second panel on the right and the arrow is labeled electron transfer. The second panel shows an excited molecule D superscript plus on the left. A downward arrow is present in the ground state and the top excited state is blank. In the acceptor A superscript minus, an upward arrow is present in the top excited state, and upward and downward arrow is present in the bottom ground state.

Return to FIGURE 19.8 The key to photosynthesis is photoinduced charge separation

Extended description for FIGURE 19.9 The photosynthetic reaction center in a nonsulfur purple bacterium is a large complex with many electron-carrying groups and one special pair



The core of the reaction center from *Rhodopseudomonas viridis* has red, blue, white, and yellow cylinders. The red cylinders represent the L chain, the blue cylinders represent the M chain, and the white chain represents the H chain. The yellow cylinders represent cytochrome subunits. The L, M, H, and cytochrome subunits are composed largely of alpha helices that span the membrane. The H

chain consists of beta sheets. A chain of electron-carrying prosthetic groups runs from the bottom to the top. It includes a special pair of bacteriochlorophylls, bacteriopheophytin, and quinone. Nonheme iron is bound to an M chain. The cytochrome subunits are bound to heme groups.

Return to FIGURE 19.9 The photosynthetic reaction center in a nonsulfur purple bacterium is a large complex with many electron-carrying groups and one special pair

Extended description for FIGURE 19.10 In the reaction center of nonsulfur purple bacteria, electrons flow from the special pair to a quinone

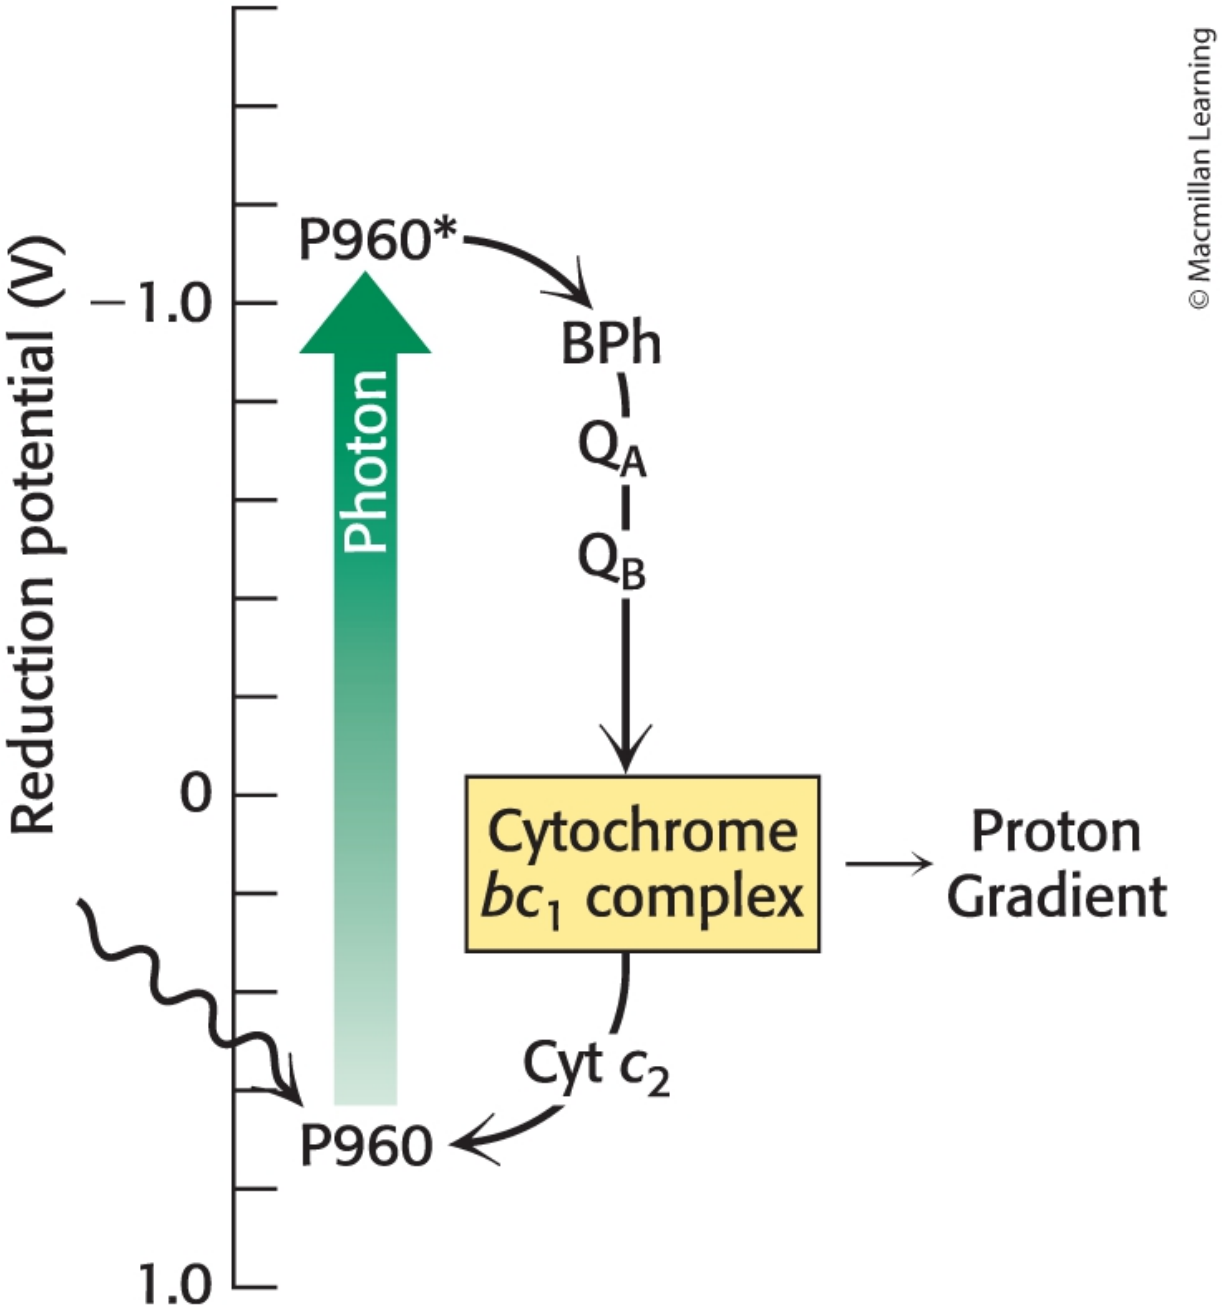
The figure depicts the electron flow in the reaction center in seven steps. It starts with the excitation of a pair of P 960 depicted as two overlapping circles. P 960 is present at the bottom. A wavy arrow representing light strikes P 960. Cytochrome c reduced is present below P 960. An arrow from this points to the first step and is labeled absorption and numbered 1.

In the first step, P 960 is converted to P 960 asterisk. The electron is transferred from P 960 to B P h through B C h l. The arrow is labeled fast. An arrow from the first step points toward the second step and is labeled charge separation and numbered 2.

In the second step, P 960 gives up an electron to B P h and becomes positively charged. B P h now acquires a negative charge. An arrow from the second step points to the third step and is numbered 3.

In the third step, cytochrome+ c reduced gives an electron to P 960 superscript plus. The arrow is labeled fast. A dotted arrow from B P h superscript minus points to P 960 superscript plus and is labeled slow. An arrow from B P h superscript minus points upward to Q subscript A and is labeled fast. An arrow from the third step points to the fourth step and is numbered 4.

In the fourth step, Q subscript A acquires a negative charge. An electron enters cytochrome c oxidized and converts it to cytochrome c reduced. An arrow from the fourth step points toward the fifth step and is numbered 5.



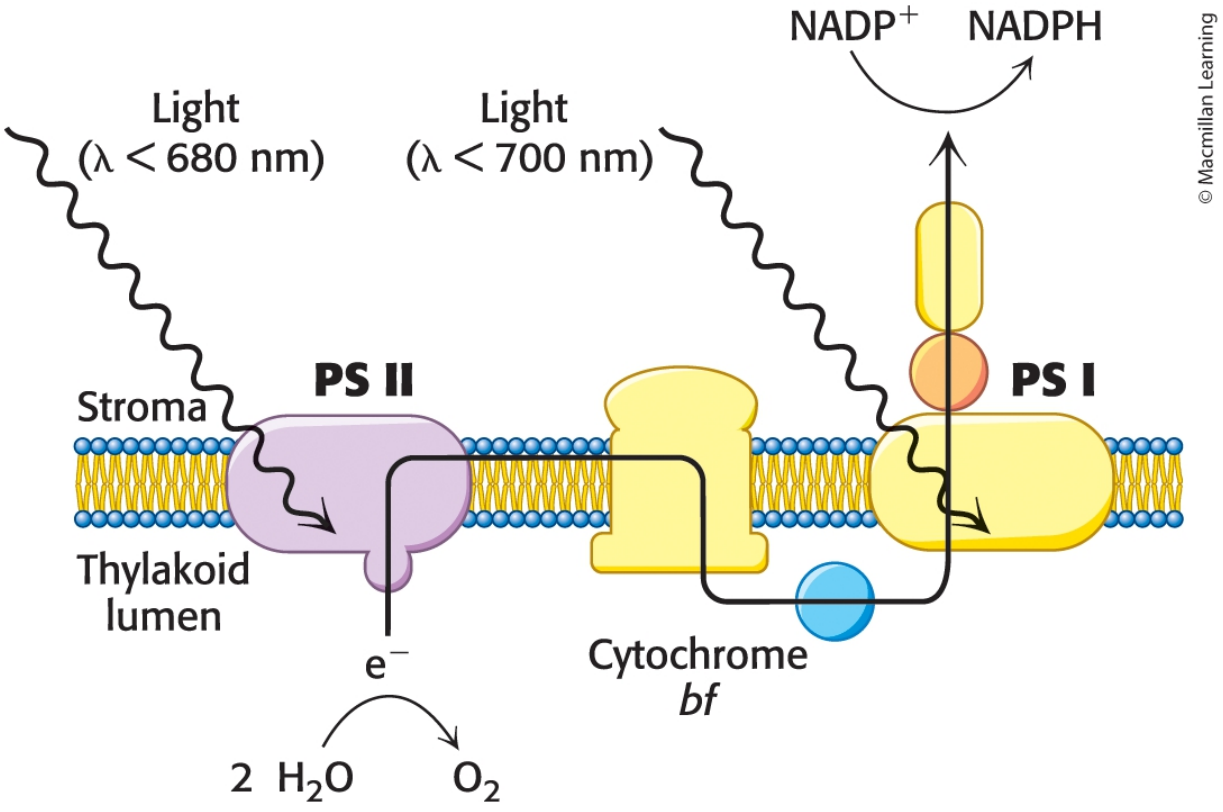
In the fifth step, Q subscript A superscript minus transfers an electron to Q subscript B. An H superscript plus ion also enters the Q subscript B. An arrow from the fifth step points to the sixth step and is numbered 6.

In the sixth step, an electron from cytochrome C reduced goes to Q H subscript B in the site Q subscript B through P 960, B P h, and Q subscript A. An H superscript plus ion also enters Q H subscript B. An arrow from the sixth step points to the seventh step and is numbered 7.

In the seventh step, Q H 2 moves into the quinone pool outside the reaction center.

Return to FIGURE 19.10 In the reaction center of nonsulfur purple bacteria, electrons flow from the special pair to a quinone

Extended description for FIGURE 19.11 Cyclic electron flow in the bacterial reaction center allows the generation of A T P but not reducing power



© Macmillan Learning

The vertical axis is labeled reduction potential V. It has the markings 1.0, 0, and negative 1.0 from the bottom to the top. A wavy arrow strikes P 960 corresponding to 0.8 on the vertical axis. P 960 points to the P 960 asterisk corresponding to negative 1.0. The arrow is labeled photon. P 960 asterisk leads to B P h. B P h leads to cytochrome b c subscript 1 complex through Q subscript A and Q subscript B. Cytochrome b c subscript 1 complex generates proton gradient and leads to cytochrome c subscript 2. Cytochrome c subscript 2 leads back to P 960.

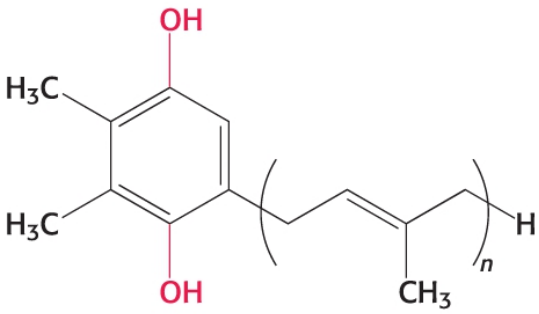
The figure depicts a lipid bilayer. The lipid bilayer consists of two horizontally parallel layers of lipids. The upper and lower layer consists of lipid molecules packed together compactly. Each lipid molecule is shown in a shorthand depiction. The yellow extensions of the shorthand depiction are aligned together and form the core of the bilayer. The blue spheres are located away from each other. The region above the lipid bilayer is labeled stroma and the region below the lipid bilayer is labeled thylakoid lumen. The lipid bilayer shows three membrane proteins. The first membrane protein labeled P S 2 is capsule-like and penetrates the entire lipid bilayer. The second membrane protein is rectangular with a bulb-like upper portion labeled cytochrome b f. The third membrane protein resembles a



capsule and is labeled P S 1. The third membrane protein has two other structures attached to it at the upper end in the stroma. A wavy arrow labeled light lambda less than 680 nanometer strikes the P S 2. This converts 2 H 2 O to O 2. An electron in the thylakoid lumen near P S 2 moves into the P S 2 membrane protein. From P S 2 it goes to cytochrome b f. From cytochrome b f complex, it moves to a blue-colored sphere in the thylakoid lumen. It then moves into the P S 1. A wavy arrow labeled lambda less than 700 nanometers strikes P S 1. The electron exits the P S 1 and is used up for the reduction of N A D P superscript plus to N A D P H.

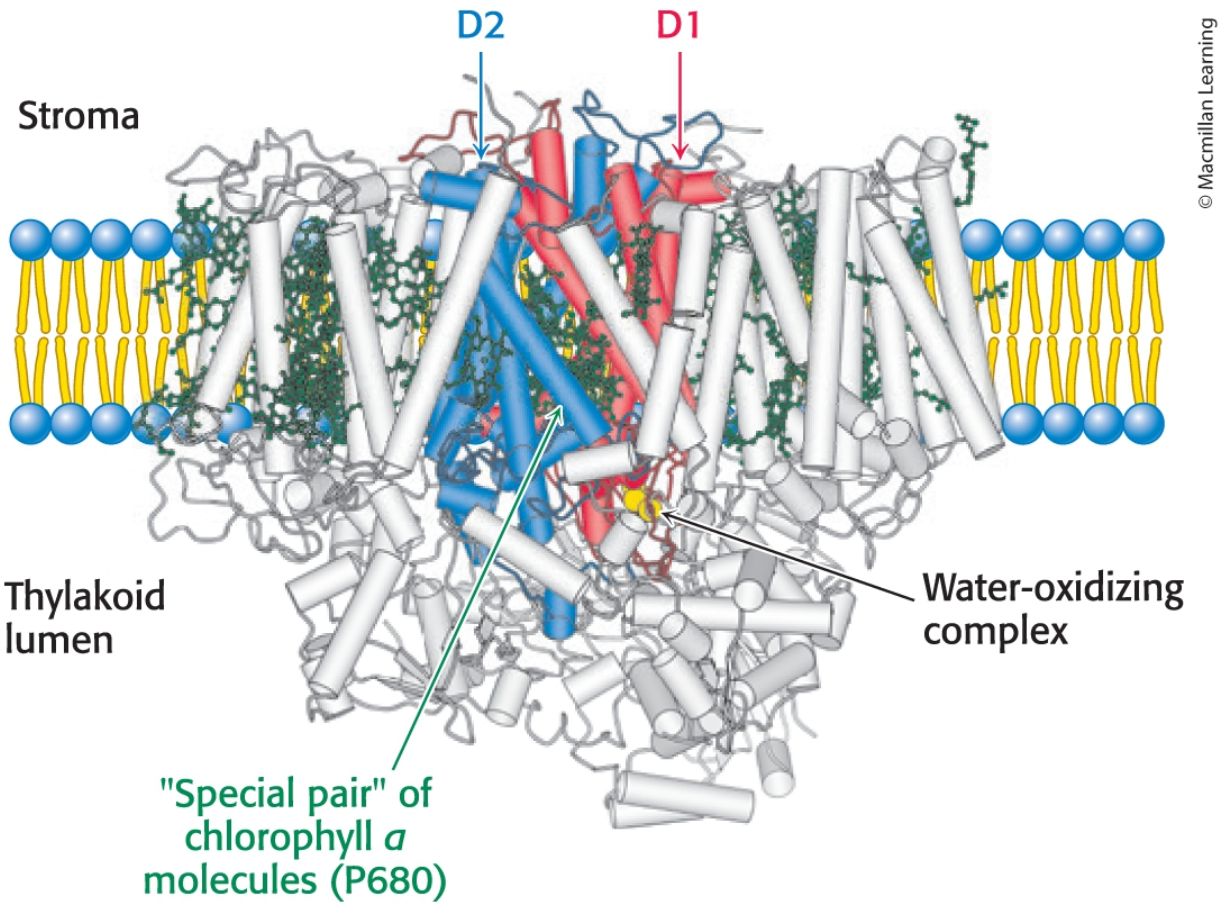
Extended description for Structures of Plastoquinone and Plastoquinol

Plastoquinone
(oxidized form, Q)



Plastoquinol
(reduced form, QH_2)

The structure of plastoquinone (oxidized form, Q) is as follows: A 6-carbon hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. A double bond is present between C 2 and C 3 and C 5 and C 6. C 1 and C 4 are each double bonded to O highlighted in red. C 5 and C 6 are each single bonded to C H 3. C 3 is single bonded to C 1 of a 4-carbon alkene chain depicted as a line structure using 3 zigzag lines. In the alkene chain, a double bond is present between C 2 and C 3. C 3 of the alkene chain is single bonded to C H 3 below. C 4 of the alkene chain is single bonded to H on the lower right. The alkene chain is enclosed within parenthesis with subscript n. The text below reads n equals 6 to 10. The structure of plastoquinol (reduced form, Q H 2) is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 and C 4 are each single bonded to O H highlighted in red. C 5 and C 6 are each single bonded to C H 3. C 3 is single bonded to C 1 of a 4-carbon alkene chain depicted as a line structure using 3 zigzag lines. In the alkene chain, a double bond is present between C 2 and C 3. C 3 of the alkene chain is single bonded to C H 3 below. C 4 of the alkene chain is single bonded to H

on the lower right. The alkene chain is enclosed within parenthesis followed by subscript n.

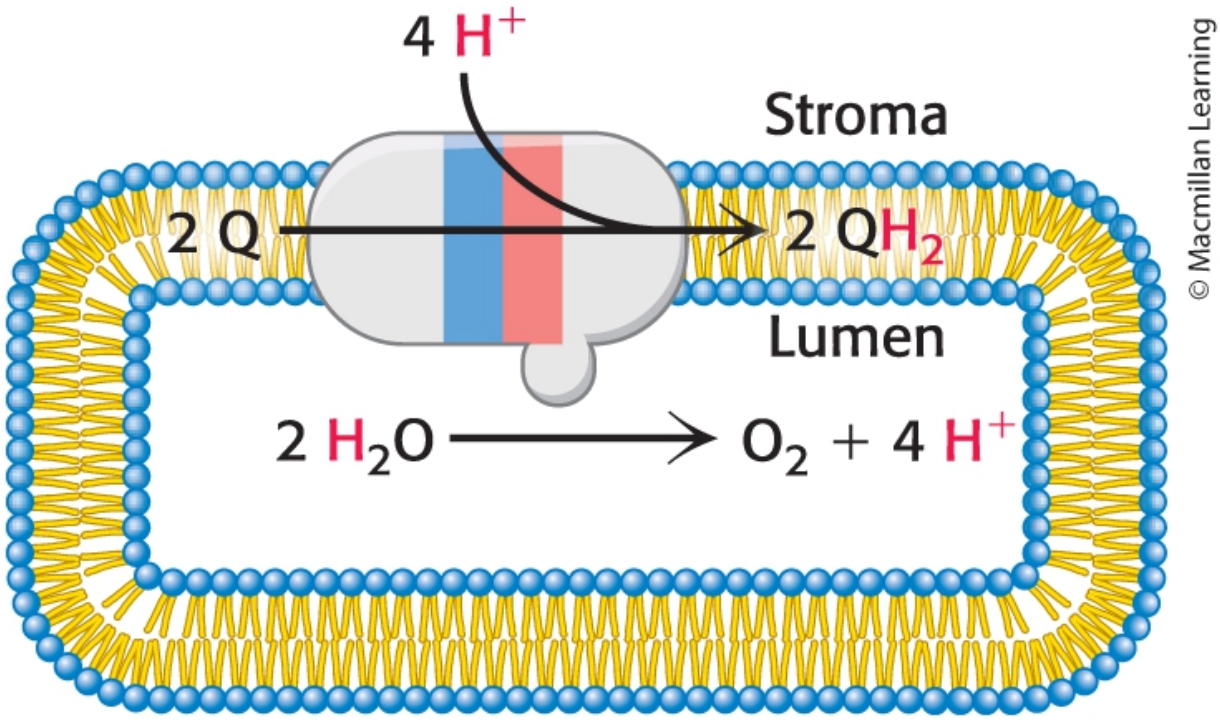
Extended description for FIGURE 19.16 Four photons are required to generate one oxygen molecule after the first cycle

The horizontal axis, labeled flash number, has markings ranging from 0 to 12 in increments of 1 unit. The vertical axis is labeled O 2 evolved per flash. The graph starts from 1 on the horizontal axis, moves toward the right to 2, shows a sharp peak at 3, slopes down to 6 slightly above the origin, peaks again at 7 much lower than the first peak, slopes down through 8, 9, and 10, and then rises upward at 11 to the midpoint of the vertical axis and terminates on the right at 12.

Return to FIGURE 19.16 Four photons are required to generate one oxygen molecule after the first cycle

Extended description for FIGURE 19.17 The model for the water-oxidizing complex explains the light-flash experiments



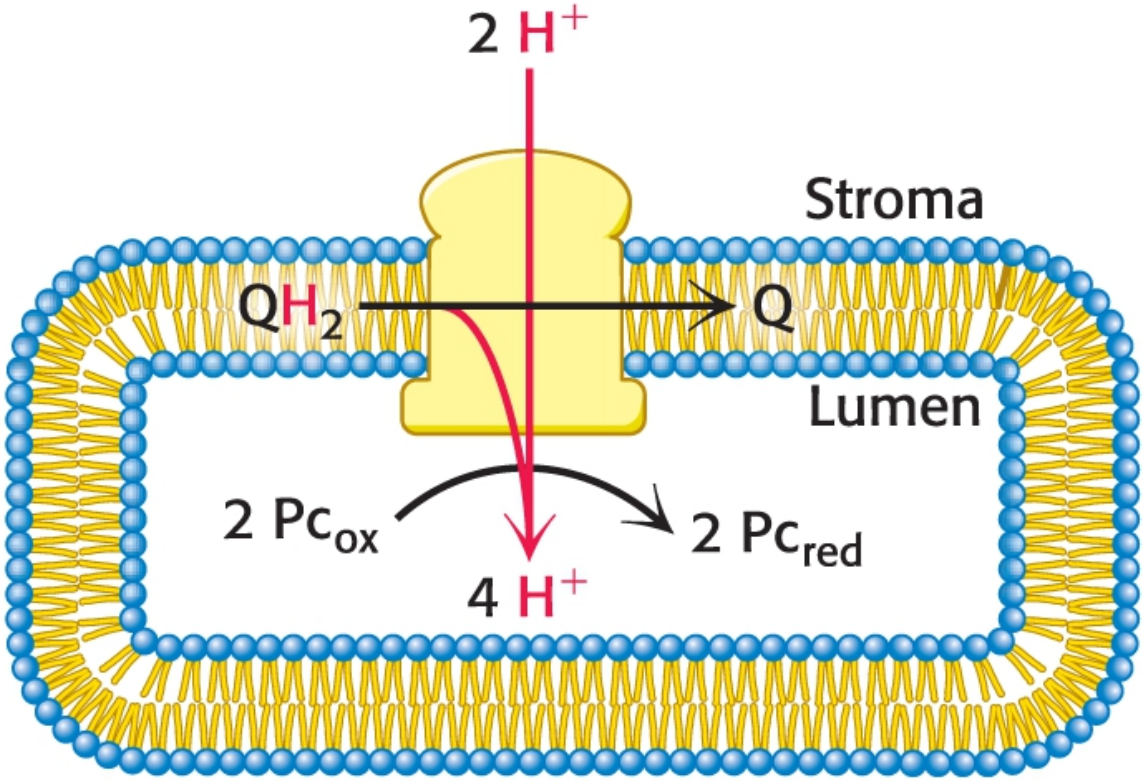
The figure has two parts labeled (A) and (B). Part (A) shows a coupled reaction of a water-oxidizing complex. The main reactant contains one reactant and one product. The reactant has the following structure: An 8-membered cuboid is shown consisting of 3 M n superscript roman numeral I V ions, 4 O atoms, and 1 C a atom. The cube is shown with its front left and front right faces toward the observer and its back left and back right faces away from the observer. Each M n superscript roman numeral I V ion occupies the front top vertex, the left bottom vertex, and the right bottom vertex, respectively. Each O atom occupies the front bottom vertex, the left top vertex, the right top vertex, and the back bottom vertex, respectively. The C a atom occupies the back top vertex. The C a atom is wedge bonded to O H 2 on the upper right and O H on the upper left. The O atom at the left top vertex is wedge bonded to M n superscript roman numeral V ion on the left which is wedge bonded to a fifth O atom below which is wedge bonded to the M n

superscript roman numeral I V ion at the left bottom vertex of the cuboid. The M n superscript roman numeral V ion is triple bonded to a sixth O atom above and is wedge bonded to O H 2 on the lower left. A curved arrow from the O H wedge bonded to C a points to the sixth O atom. The main reaction is coupled with the conversion of 2 molecules of H 2 O to O 2 shaded yellow and H superscript plus. The product has the following structure: An 8-membered cuboid is shown consisting of 2 M n superscript roman numeral I I I ions, 4 O atoms, 1 C a atom, and 1 M n superscript roman numeral I V atom. The cube is shown with its front left and front right faces toward the observer and its back left and back right faces away from the observer. Each M n superscript roman numeral I I I ion occupies the front top vertex and the left bottom vertex, respectively. Each O atom occupies the front bottom vertex, the left top vertex, the right top vertex, and the back bottom vertex, respectively. The C a atom occupies the back top vertex. The M n superscript roman numeral I V ion occupies the right bottom vertex. The C a atom is wedge bonded to O H 2 on the upper right and O H on the upper left. The O atom at the left top vertex is wedge bonded to a third M n superscript roman numeral I I I ion on the left which is wedge bonded to a fifth O atom below which is wedge bonded to the M n superscript roman numeral I I I ion at the left bottom vertex of the cuboid. The third M n superscript roman numeral I I I ion is wedge bonded to O H 2 on the upper right and is wedge bonded to O H 2 on the lower left. All the M n ions are highlighted in purple, the C a atom is highlighted in blue, and all O atoms are highlighted in red. The reactant is labeled S 4 and the product is labeled S 0. A rightward arrow from S 4 points to S 0. A downward arrow from S 0 points to S 1. The arrow is labeled 30 microseconds and depicts the release of an electron and H superscript plus ion. S 1 is labeled dark-adapted state. A leftward arrow from S 1 points to S 2 on the left. The arrow is labeled 100 microseconds and depicts the release of an electron. A leftward arrow from S 2 points to S 3 on the left. The arrow is labeled 350 microseconds and depicts the release of an

electron and H superscript plus ion. An upward arrow from S 3 points to S 4. The arrow depicts the release of an electron and H superscript plus ion. A dotted arrow from S 3 points to S 0 and is labeled 1 millisecond. The second part of the figure depicts oxygen generation by elodea plants immersed in water. The plants generate bubbles which depict the production of oxygen.

Return to FIGURE 19.17 The model for the water-oxidizing complex explains the light-flash experiments

Extended description for FIGURE 19.18 Photosystem II releases protons into the thylakoid lumen and takes them up from the stroma



© Macmillan Learning

The figure depicts a lipid bilayer forming a rectangular loop. The lipid bilayer consists of two horizontally parallel layers of lipids. The upper and lower layer consists of lipid molecules packed together compactly. Each lipid molecule is shown in a shorthand depiction. The yellow extensions of the shorthand depiction are aligned together and form the core of the bilayer. The blue spheres are located away from each other. The region outside the lipid bilayer is labeled stroma and the region enclosed by the lipid bilayer is labeled thylakoid lumen. The lipid bilayer consists of a capsule-like membrane protein that converts 2 Q to 2 Q H 2 in the bilayer by the addition of 4 H superscript plus from the stroma. In the lumen, 2 H 2 O is converted to O 2 and 4 H superscript plus.

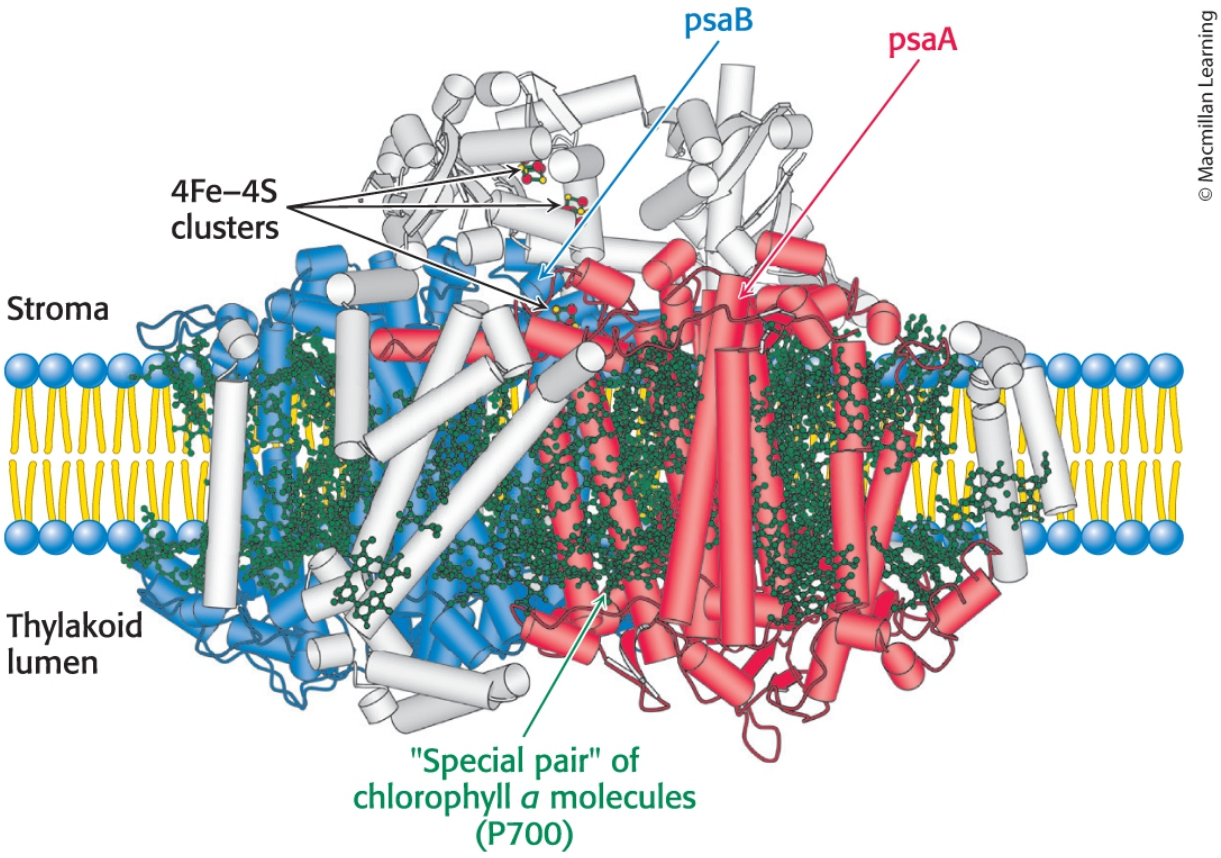
Extended description for FIGURE 19.19 Electron flow through cytochrome bf contributes to the proton gradient



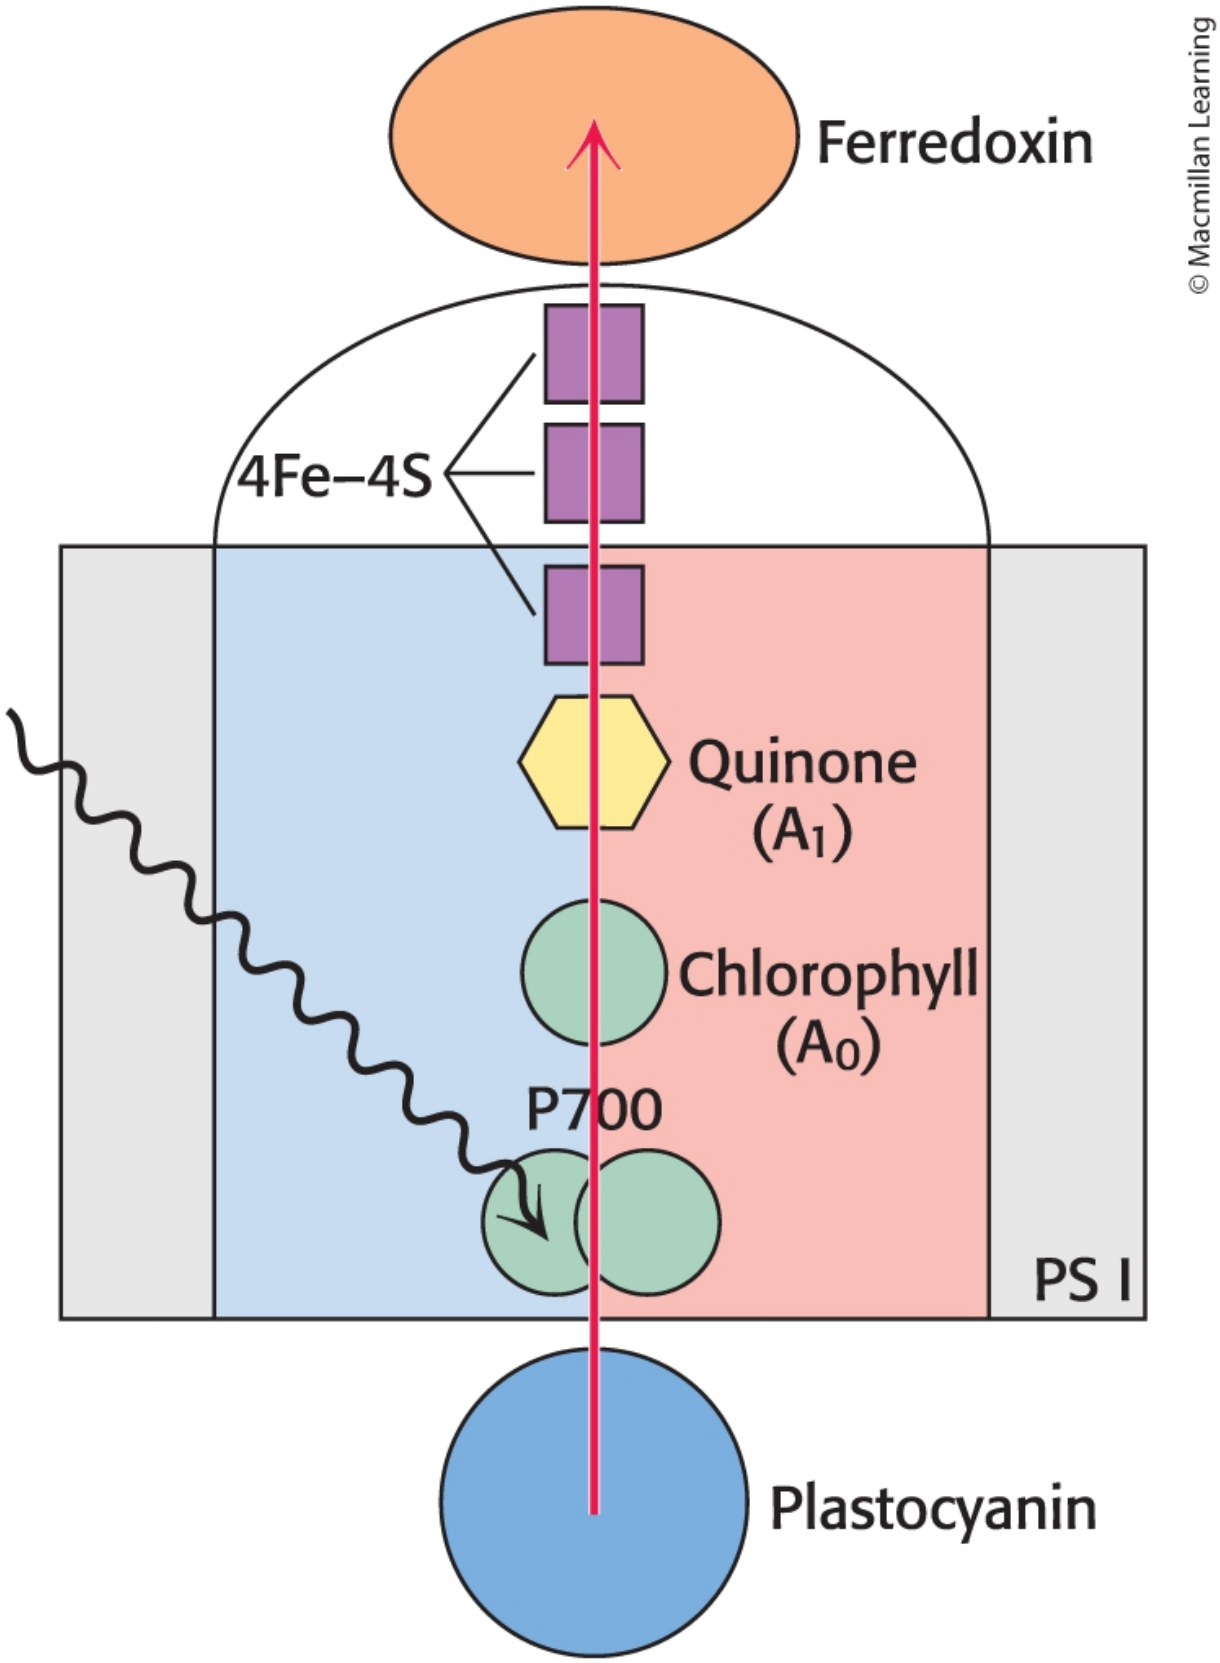
© Macmillan Learning

The figure depicts a lipid bilayer forming a rectangular loop. The lipid bilayer consists of two horizontally parallel layers of lipids. The upper and lower layer consists of lipid molecules packed together compactly. Each lipid molecule is shown in a shorthand depiction. The yellow extensions of the shorthand depiction are aligned together and form the core of the bilayer. The blue spheres are located away from each other. The region outside the lipid bilayer is labeled stroma and the region enclosed within the lipid bilayer is labeled lumen. A rectangular membrane protein is embedded in the bilayer that converts Q H 2 to Q. Q H 2 from the bilayer and 2 H superscript plus ions from the stroma enter the lumen through the

membrane protein to release 4 H superscript plus ions in the lumen. This movement is coupled with the conversion of 2 P c oxidized is converted to 2 P c reduced.

Return to FIGURE 19.19 Electron flow through cytochrome bf contributes to the proton gradient

Extended description for FIGURE 19.20 Photosystem I is a protein complex with numerous chlorophyll molecules and one special pair.



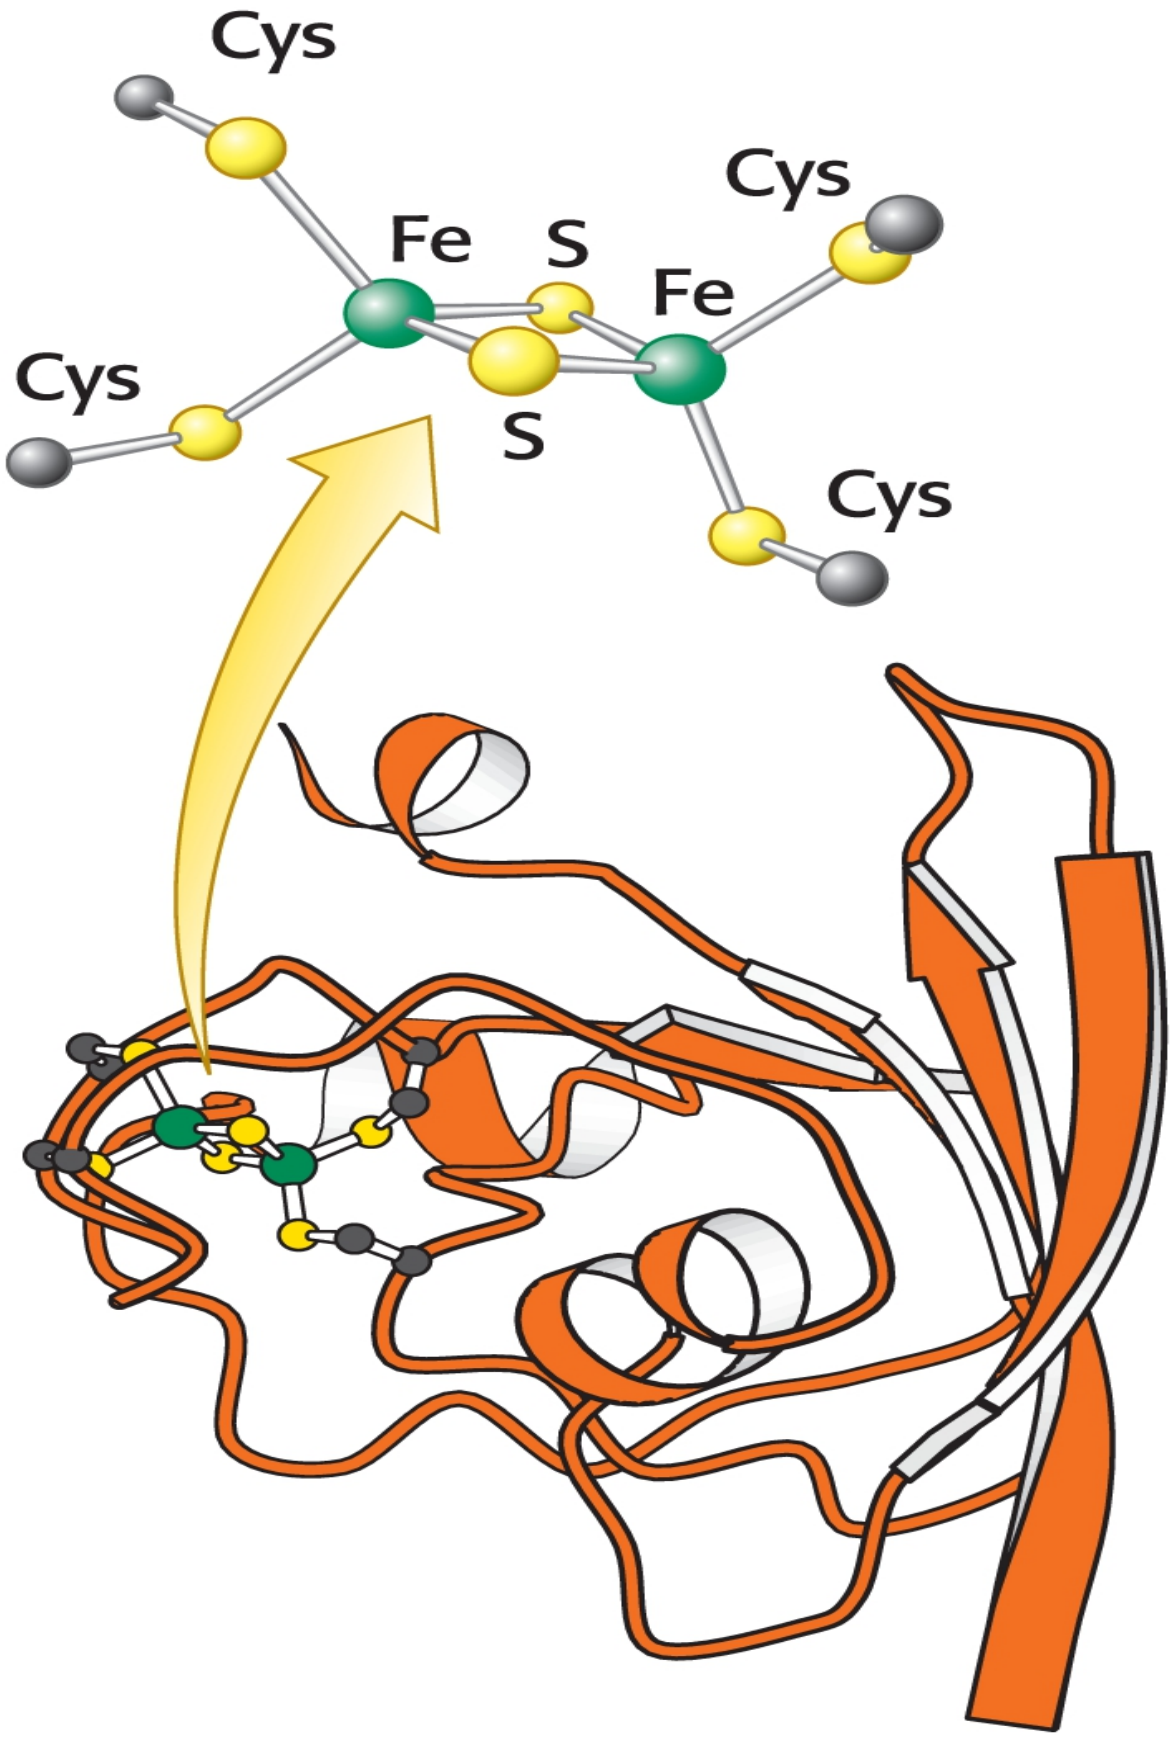
The figure depicts a lipid bilayer. The lipid bilayer consists of two horizontally parallel layers of lipids. The upper and lower layer consists of lipid molecules packed together compactly. Each lipid molecule is shown in a shorthand depiction. The yellow extensions of the shorthand depiction are aligned together and form the core of the bilayer. The blue spheres are located away from each other. The region above the lipid bilayer is labeled stroma and the region below the lipid bilayer is labeled thylakoid lumen. A cluster of red, white, and blue cylinders bound to alpha helices is embedded in the bilayer. A cluster of short white cylinders protrudes from the surface

of this complex into the stroma. The red and blue cylinders are labeled p s a A and p s a B, respectively. Interconnected red and yellow spheres labeled 4 F e 4 S clusters are buried between the cluster of white cylinders and the cluster of blue cylinders in the stroma. Green-colored molecules labeled special pair of chlorophyll a molecules P 700 are bound to the long blue and red cylinders embedded in the lipid bilayer.

Return to FIGURE 19.20 Photosystem I is a protein complex with numerous chlorophyll molecules and one special pair.

Extended description for FIGURE 19.21 In photosystem

I, electrons flow to ferredoxin



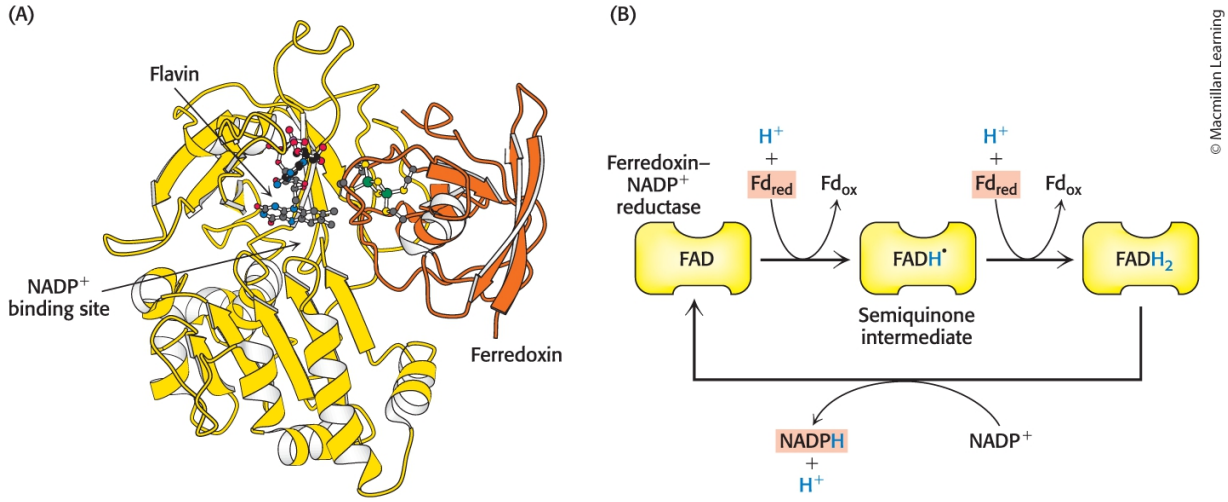
© Macmillan Learning

The electron flow in photosystem 1 starts with the excitation of a pair of chlorophyll molecules in P 700 depicted as two overlapping circles. P 700 is present at the bottom. A wavy arrow representing light strikes P 700. P 700 transfers an electron from plastocyanin to chlorophyll A subscript 0. From chlorophyll A subscript 0, the electron is transferred to Quinone A subscript 1. From quinone, it is transferred to 4 F e 4 S. From 4 F e 4 S it is finally transferred to ferredoxin.

Return to FIGURE 19.21 In photosystem I, electrons flow to ferredoxin

Extended description for FIGURE 19.22 Ferredoxin is an

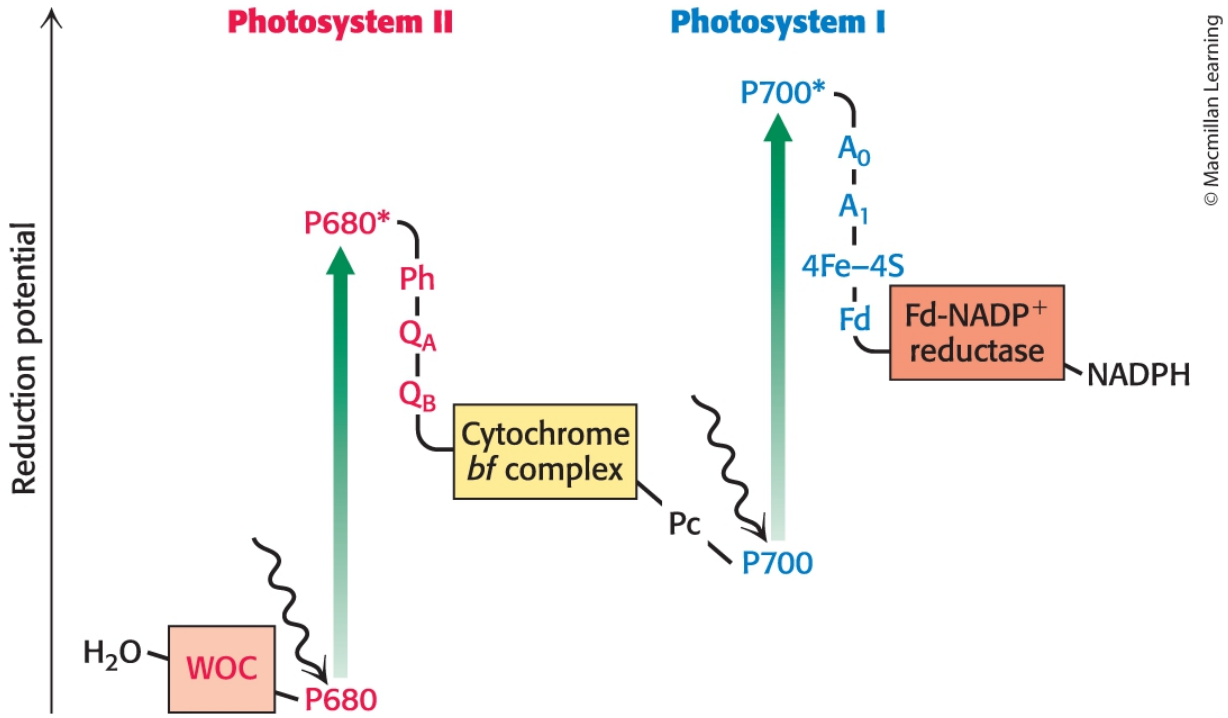
electron-carrying, iron-sulfur protein



© Macmillan Learning

Ferredoxin protein is composed of four vertical beta-strands and three short alpha-helices interconnected by thread-like loops. It contains an iron and sulfur cluster attached to the thread-like loops on the left. A zoomed-in view of the ball and stick model of the iron and sulfur cluster is shown. The iron-sulfur cluster consists of green and yellow spheres. Yellows spheres represent sulfur and green sphere represents iron. Two sulfur atoms, at the top and bottom, are single-bonded to a common iron atom on the left and right. Each of the iron atoms is further single-bonded to one sulfur atom. Each sulfur atom is attached to a grey sphere labeled cysteine.

Return to FIGURE 19.22 Ferredoxin is an electron-carrying, iron-sulfur protein

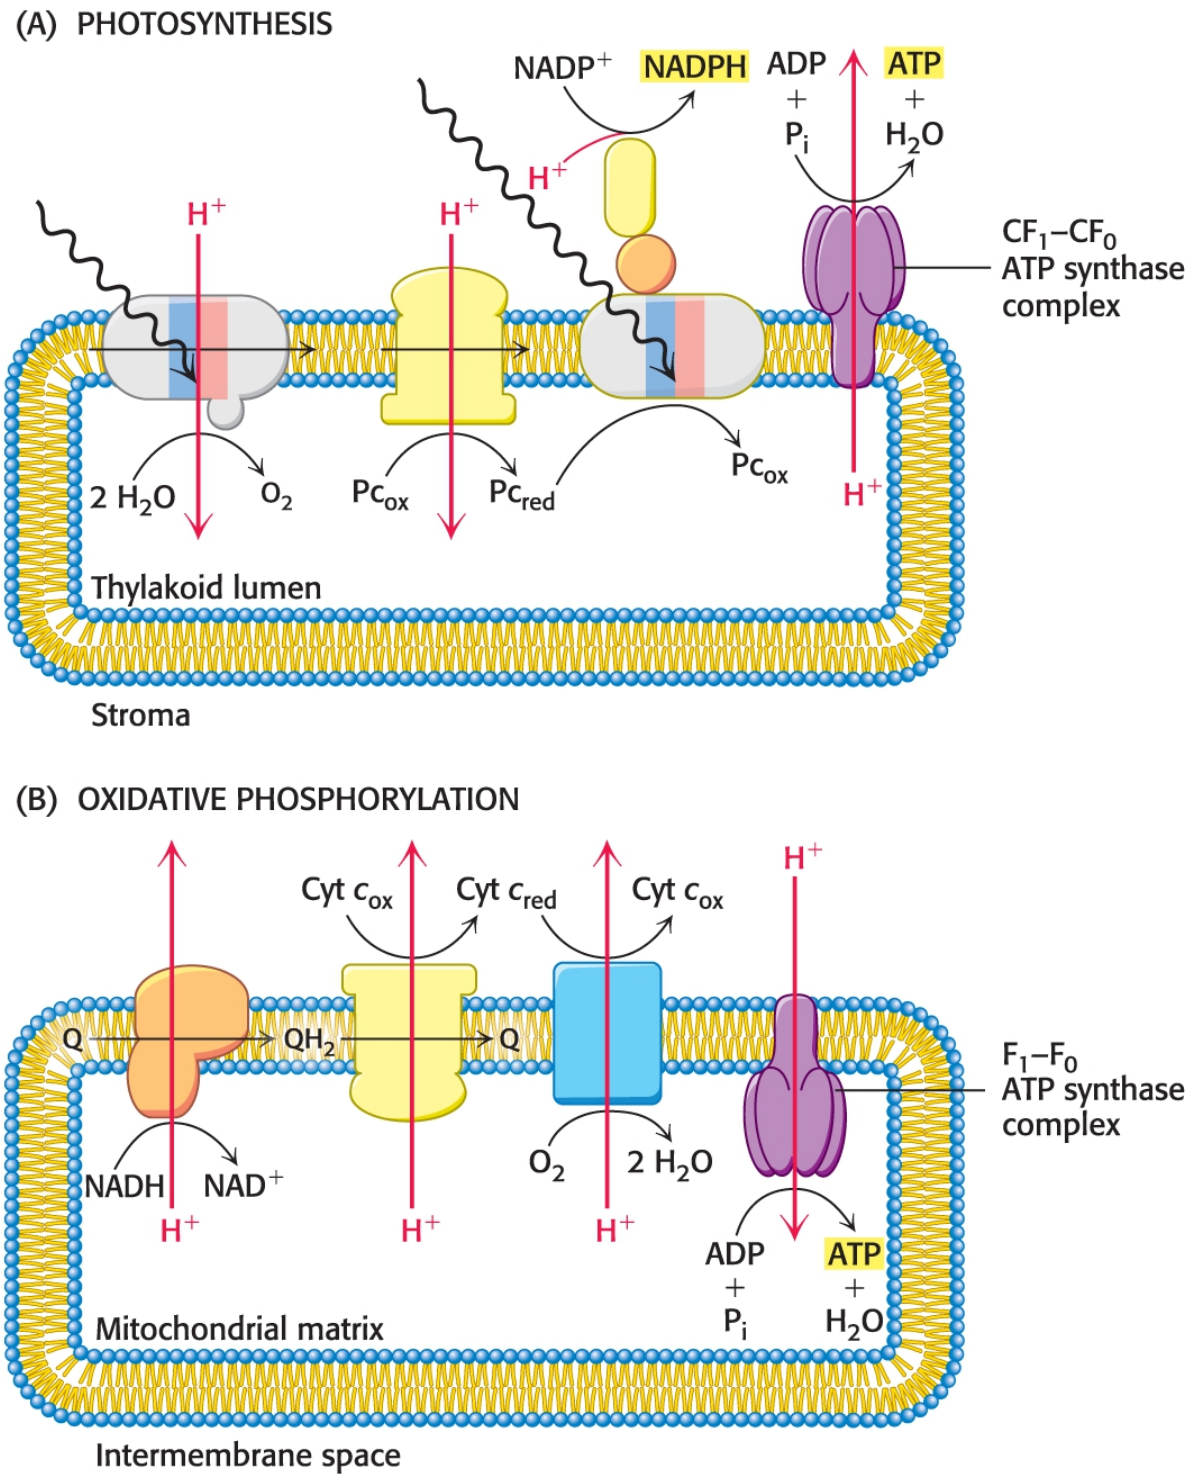


Extended description for FIGURE 19.23 Ferredoxin–N A D P + reductase transfers electrons from the protein ferredoxin to N A D P +

The figure has two parts. The first part labeled (A) shows the ribbon diagram of ferredoxin–N A D P superscript plus reductase consisting of yellow and orange alpha helices and beta strands. The orange alpha helices and beta strands are labeled ferredoxin. It is bound to an iron-sulfur cluster. The yellow alpha helices and beta strands are bound to flavin and an empty N A D P superscript plus binding site is located below it. The second part labeled (B) depicts a flowchart for the formation of N A D P H plus H superscript plus. In the first step, F A D bound to ferredoxin-N A D P superscript plus reductase is converted to F A D H coupled with the simultaneous conversion of F d reduced plus H superscript plus to F d oxidized. F A D H bound reductase is labeled semiquinone intermediate. F A D H is converted to F A D H 2 with the coupled conversion of F d reduced plus H superscript plus to F d oxidized. F A D H 2 is converted back to F A D and is used to reduce N A D P superscript plus to N A D P H and H superscript plus and cycle continues.

Return to FIGURE 19.23 Ferredoxin–N A D P + reductase transfers electrons from the protein ferredoxin to N A D P +

Extended description for FIGURE 19.24 The “Z” scheme of photosynthesis is the linear path of electrons from H 2 O to N A D P +



An upward arrow on the left side of the figure is labeled reduction potential. The figure is labeled photosystem 2 on the left and photosystem 1 on the right. Photosystem 2 consists of P 680 while photosystem 1 consists of P 700. In photosystem 2, P 680 is present at the bottom. A wavy arrow representing light strikes P 680 along with H 2 O through W O C. An upward arrow from P 680 points to the P 680 asterisk at the top. P 680 then leads to cytochrome b f complex on the lower right through the components namely P h, Q subscript A, and Q subscript B. Cytochrome b f complex leads to P 700 through P subscript c. A wavy arrow representing light strikes P 700. An upward arrow from P 700 points to the P 700 asterisk at the top in photosystem 1. P 700 asterisk leads to F d-N A D P superscript

plus reductase through components namely A subscript 0, A subscript 1, 4 F e 4 S, and F d. F d-N A D P superscript plus reductase leads to N A D P H.

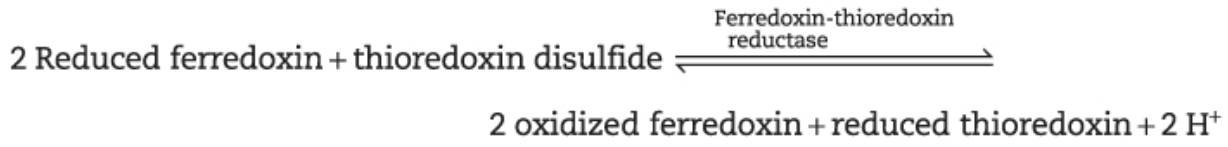
Extended description for FIGURE 19.25 Photosynthesis and oxidative phosphorylation have a similar layout

but differ in a number of ways

© Macmillan Learning



(A) Photosynthesis: The figure depicts a lipid bilayer forming a rectangular loop. The lipid bilayer consists of two horizontally parallel layers of lipids. The upper and lower layer consists of lipid molecules packed together compactly. Each lipid molecule is shown in a shorthand depiction. The yellow extensions of the shorthand depiction are aligned together and form the core of the bilayer. The blue spheres are located away from each other. The region outside the lipid bilayer is labeled stroma and the region enclosed within the lipid bilayer is labeled thylakoid lumen. Four membrane proteins are embedded in the bilayer. A wavy arrow representing light strikes the first membrane protein. H superscript plus ion from the stroma is transferred into the thylakoid lumen through the first membrane protein. This movement is coupled with the conversion of 2 H 2 O to O 2 in the thylakoid lumen. An arrow from the first membrane protein points to the second membrane protein. H plus ion from the stroma is transferred into the thylakoid lumen through the second membrane protein. This is coupled with the conversion of P c oxidized to P c reduced in the thylakoid lumen. An arrow from the second membrane protein points to the third membrane protein. A wavy arrow representing light strikes the third membrane protein. This converts P c reduced to P c oxidized in the thylakoid lumen and N A D P superscript plus and H superscript plus to N A D P H in the stroma. H superscript plus ion exits the thylakoid lumen through the fourth membrane protein. This movement is coupled with the conversion of A D P plus P subscript i to A T P and H 2 O. The fourth membrane protein is labeled C F 1-c F 0 A T P synthase complex.

(B) Oxidative phosphorylation: The figure depicts a lipid bilayer forming a rectangular loop. The lipid bilayer consists of two horizontally parallel layers of lipids. The upper and lower layer consists of lipid molecules packed together compactly. Each lipid molecule is shown in a shorthand depiction. The yellow extensions of the shorthand depiction are aligned together and form the core of the bilayer. The blue spheres are located away from each other. The

region outside the lipid bilayer is labeled intermembrane space and the region enclosed within the lipid bilayer is labeled mitochondrial matrix. Four membrane proteins are embedded in the lipid bilayer. H superscript plus ion exits the mitochondrial matrix through the first membrane protein. This is coupled with the oxidation of N A D H to N A D superscript plus in the mitochondrial matrix. Q is simultaneously converted to Q H 2 in the lipid bilayer by the first membrane protein. H superscript plus ion exits the mitochondrial matrix through the second membrane protein. It also converts cytochrome c oxidized to cytochrome c reduced. Q H 2 is simultaneously converted to Q in the lipid bilayer by the second membrane protein. H superscript plus exits the mitochondrial matrix through the third membrane protein. It converts O 2 to 2 H 2 O in the mitochondrial matrix and Cytochrome c redox to Cytochrome c oxidized in the intermembrane space. H superscript plus enters the mitochondrial matrix through the fourth membrane protein. This is coupled with the conversion of A D P and P i to A T P and H 2 O in the mitochondrial matrix. The fourth membrane protein is labeled F 1 F 0 A T P synthase complex.

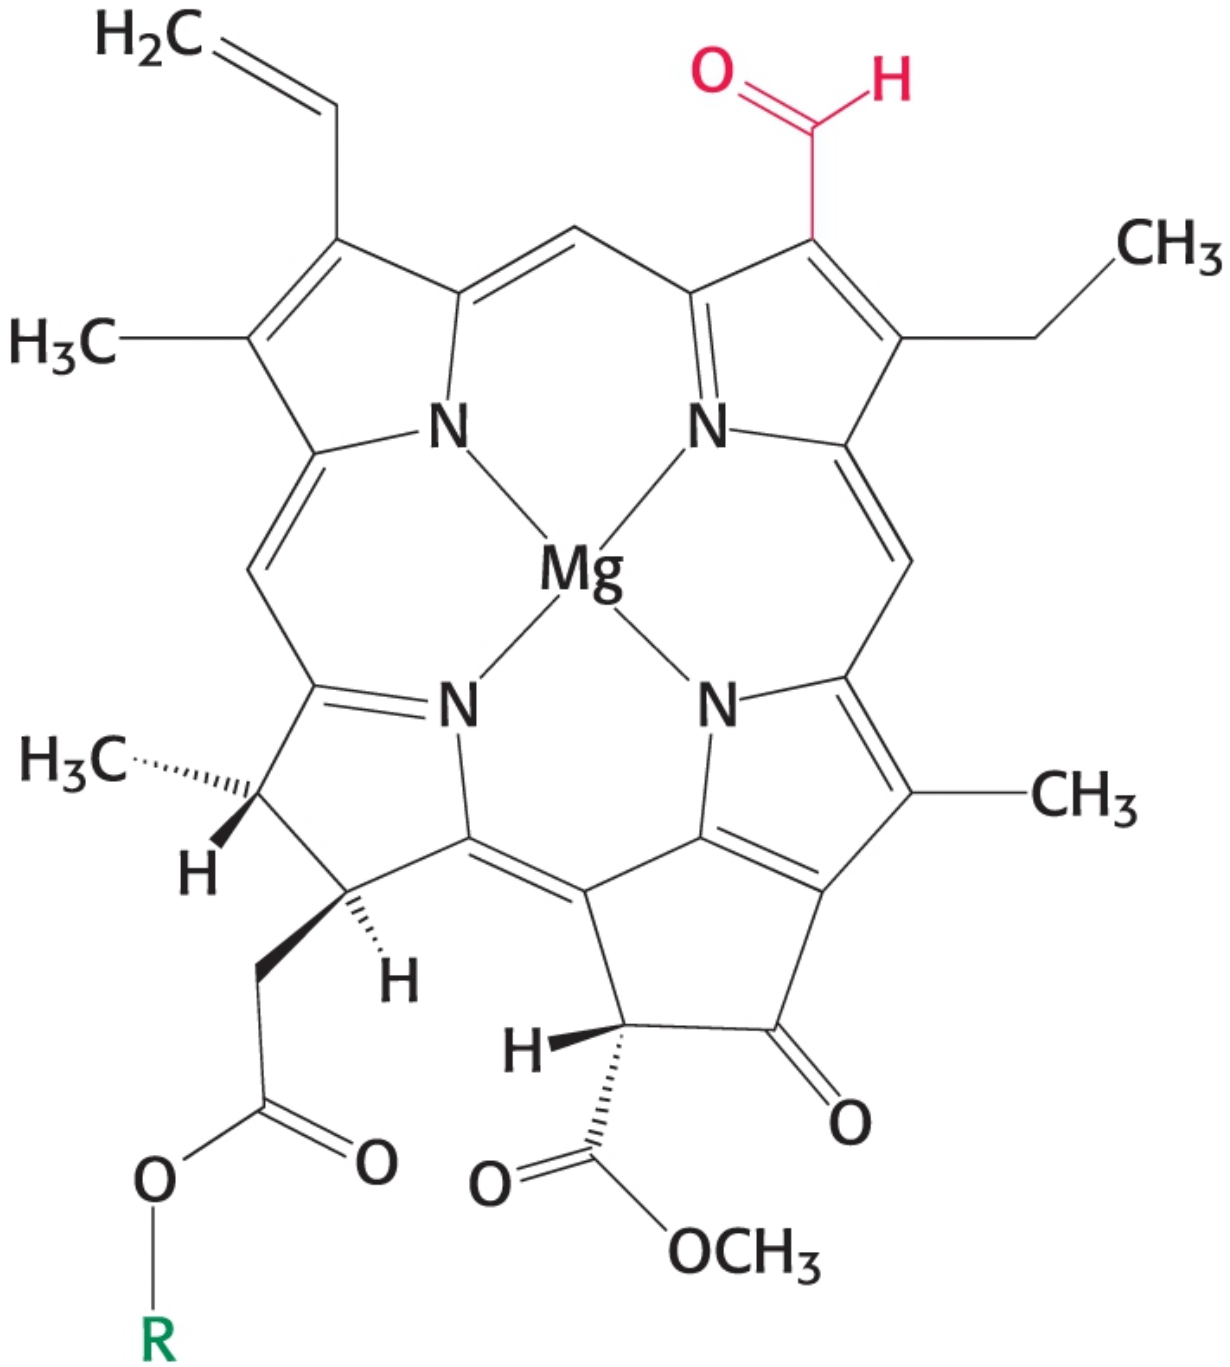
Extended description for Reversible reaction catalyzed by ferredoxin-thioredoxin reductase

2 reduced ferredoxin reacts with thioredoxin disulfide in a reversible reaction catalyzed by ferredoxin-thioredoxin reductase to form 2 oxidized ferredoxin, reduced thioredoxin, and 2 H superscript plus.

Return to Reversible reaction catalyzed by ferredoxin-thioredoxin reductase

Extended description for FIGURE 19.26 Cyclic photophosphorylation allows A T P production without a need for an electron source



The figure has two parts. The first part depicts a lipid bilayer forming a rectangular loop. The lipid bilayer consists of two horizontally parallel layers of lipids. The upper and lower layer consists of lipid molecules packed together compactly. Each lipid molecule is shown in a shorthand depiction. The yellow extensions of the shorthand depiction are aligned together and form the core of the bilayer. The blue spheres are located away from each other. The region outside the lipid bilayer is labeled stroma and the region enclosed within the lipid bilayer is labeled lumen. The lipid bilayer has three membrane proteins. H superscript plus ion from the stroma enters the lumen through the first membrane protein. A wavy arrow representing light strikes the second membrane protein. This leads to the reversible conversion of P c reduced to P c oxidized in the lumen. In the stroma, this leads to the reversible

conversion of F d oxidized to F d reduced in photosystem 1. F d reduced is converted back to F d oxidized by cytochrome b f. H superscript plus exits the lumen through the third membrane protein. This leads to the conversion of A D P plus P subscript i to A T P and H 2 O in the stroma.

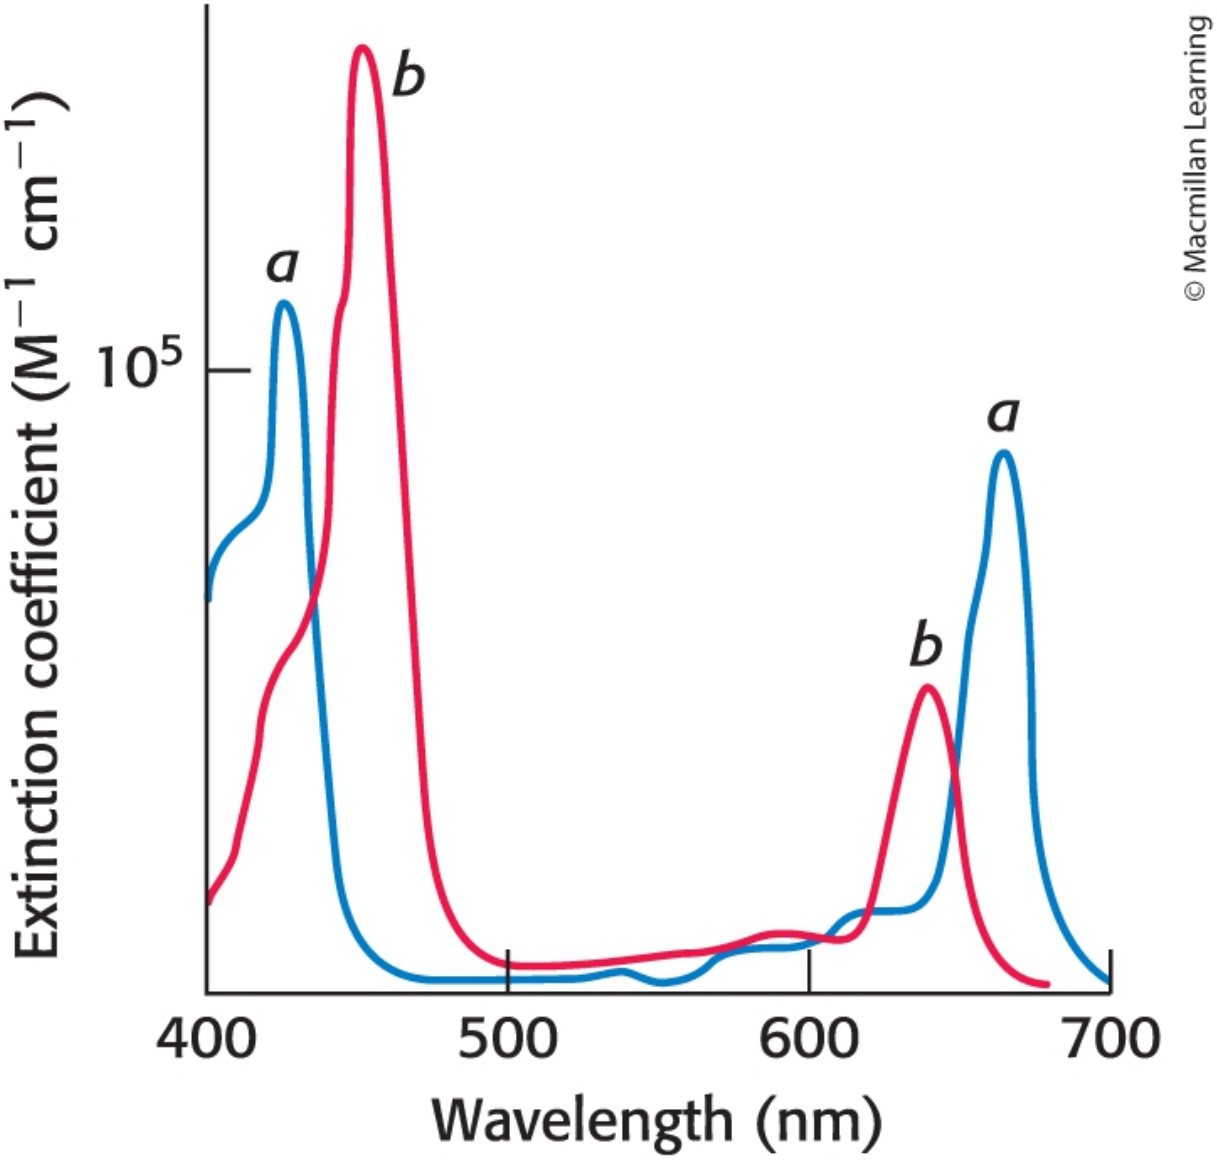
The second part shows a vertical axis labeled reduction potential V. It has markings ranging from positive 0.4 to negative 1.2 in decrements of 0.4 units. P 700 is present corresponding to positive 0.4 on the vertical axis. P 700 points to P 700 asterisk corresponding to negative 1.2. The arrow is labeled photon. P 700 asterisk transfers the electron to ferredoxin. Ferredoxin transfers the electron to cytochrome b f complex. Cytochrome b f complex then transfers the electron to plastocyanin and also produces a proton gradient. Plastocyanin leads back to P 700.

Return to FIGURE 19.26 Cyclic photophosphorylation allows A T P production without a need for an electron source

Extended description for Structure of chlorophyll b

Chlorophyll *b*

Four 5-membered heterocyclic pentagonal rings, four 6-membered heterocyclic hexagonal rings, and one 5-carbon hexagonal ring are fused together. The first 5-membered heterocyclic pentagonal ring is in a vertical orientation consisting of 1 N and 4 C atoms. In the first 5-membered heterocyclic pentagonal ring, N occupies the first position which is the bottom right vertex. In the first 5-membered heterocyclic pentagonal ring, a double bond is present between C 2 and C 3. C 2 of the first 5-membered heterocyclic pentagonal ring is single bonded to C H 3. C 3 of the first 5-membered heterocyclic pentagonal ring is single bonded to a central C H group in the form of a line. The central C H group is double bonded to C H 2 on the upper left. The first 5-membered heterocyclic pentagonal ring is fused to the first 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 1 M g, 2 N, and 3 C atoms. In the first hexagonal ring, the first N atom occupies the first position which is the bottom right vertex, M g occupies the second position which is the bottommost vertex, and the second N atom occupies the third position which is the bottom left vertex. The two rings are fused to each other such that C 4 and N of the first 5-membered heterocyclic pentagonal ring are the C 1 and the second N atom of the first hexagonal ring, respectively. In the first hexagonal ring, a double bond is present between C 1 and C 2. The first hexagonal ring is fused to the second 5-membered pentagonal ring in a vertical orientation consisting of 1 N and 4 C atoms. In the second 5-membered heterocyclic pentagonal ring, N occupies the first position which is the bottom left vertex. The two rings are fused to each other such that C 3 and the first N atom of the first hexagonal ring are the C 1 and N of the second 5-membered heterocyclic pentagonal ring, respectively. In the second 5-membered heterocyclic pentagonal ring, a double bond is present between N and C 1, and C 2 and C 3. C 2 of the second 5-membered heterocyclic pentagonal ring is single bonded to a central C atom in the form of a line. The central C atom is double bonded to O on the upper left and single bonded to H on the upper right. C 3 of the second 5-



membered heterocyclic pentagonal ring is single bonded to a central C H 2 group in the form of a line. The central C H 2 group is single bonded to C H 3 on the upper right. The first hexagonal ring and the second 5-membered heterocyclic pentagonal ring are fused to a second 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 1 M g, 2 N, and 3 C atoms. In the second hexagonal ring, the first N atom occupies the first position which is the bottom left vertex, M g occupies the second position which is the leftmost vertex, and the second N atom occupies the third position which is the top left vertex. The three rings are fused to each other as follows: The first N atom and M g of the first hexagonal ring are the second N atom and M g of the second hexagonal ring, respectively. N and C 4 of the second 5-membered heterocyclic pentagonal ring are the second N atom and C 1 of the second hexagonal ring, respectively. In the second hexagonal ring, a double bond is present between C 1 and C 2. The second hexagonal ring is fused to the third 5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 1 N and 4 C atoms. In the third 5-membered heterocyclic pentagonal ring, N occupies the first position which is the top left vertex. The two rings are fused to each other such that the first N atom and C 3 of the second hexagonal ring are N and C 1 of the third 5-membered heterocyclic pentagonal ring, respectively. In the third 5-membered heterocyclic pentagonal ring, a double bond is present between C 1 and C 2, and C 3 and C 4. C 2 of the third 5-membered heterocyclic pentagonal ring is single bonded to C H 3. The second hexagonal ring and the third 5-membered heterocyclic pentagonal ring are fused to the third 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 1 M g, 2 N and 3 C atoms. In the third hexagonal ring, the first N atom occupies the first position which is the top left vertex, M g occupies the second position which is the topmost vertex, and the second N atom occupies the third position which is the top right vertex. The three rings are fused to each other as follows: M g and the first N atom of the second hexagonal ring are the M g and the second N

atom of the third hexagonal ring, respectively. N and C 4 of the third 5-membered heterocyclic pentagonal ring are the second N atom and C 1 of the third hexagonal ring, respectively. In the third hexagonal ring, a double bond is present between C 2 and C 3. The third 5-membered heterocyclic pentagonal ring and the third hexagonal ring are fused to the 5-carbon pentagonal ring in a vertical orientation with C 1 occupying the topmost vertex. The three rings are fused to each other as follows: C 3 and C 4 of the third 5-membered heterocyclic pentagonal ring are the C 2 and C 1 of the 5-carbon pentagonal ring, respectively. C 1 and C 2 of the third hexagonal ring are the C 1 and C 5 of the 5-carbon pentagonal ring, respectively. C 3 of the 5-carbon pentagonal ring is double bonded to a second O atom. C 4 of the 5-carbon pentagonal ring is wedge bonded to H on the lower left and dash bonded to a central C atom on the lower left in the form of a dashed line. The central C atom is double bonded to a third O atom on the lower left and single bonded to O C H 3 on the lower right. The third hexagonal ring is fused to the fourth 5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 1 N and 4 C atoms. In the fourth 5-membered heterocyclic pentagonal ring, N occupies the first position which is the top right vertex. The two rings are fused to each other such that the first N atom and C 3 of the third hexagonal ring are the N and C 1 of the fourth 5-membered heterocyclic pentagonal ring, respectively. In the fourth 5-membered heterocyclic pentagonal ring, a double bond is present between C 4 and N. C 2 of the fourth 5-membered heterocyclic pentagonal ring is single bonded to H on the lower right and wedge bonded to C 1 of a 2-carbon alkane chain depicted as a line structure using 1 line. C 3 of the fourth 5-membered heterocyclic pentagonal ring is wedge bonded to H on the lower left and dash bonded to C H 3 on the upper left. C 2 of the 2-carbon alkane chain is double bonded to a fourth O atom on the lower right and single bonded to a fifth O atom on the lower left. The fifth O atom is single bonded to R below which is highlighted in green. The third hexagonal ring and the fourth 5-

membered heterocyclic pentagonal ring are fused to the fourth 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 1 M g, 2 N, and 3 C atoms. In the fourth hexagonal ring, the first N atom occupies the first position which is the top right vertex, M g occupies the second position which is the rightmost vertex, and the second N atom occupies the third position which is the bottom right vertex. The three rings are fused to each other as follows: The first N atom and M g of the third hexagonal ring are the second N atom and M g of the fourth hexagonal ring, respectively. C 4 and N of the fourth 5-membered heterocyclic pentagonal ring are the C 1 and the second N atom of the fourth hexagonal ring, respectively. The fourth hexagonal ring, the first 5-membered heterocyclic pentagonal ring, and the first hexagonal ring are also fused to each other as follows: C 3 and the first N atom of the fourth hexagonal ring are the C 1 and N of the first 5-membered heterocyclic pentagonal ring, respectively. The first N atom and M g of the fourth hexagonal ring are the second N atom and M g of the first hexagonal ring, respectively.

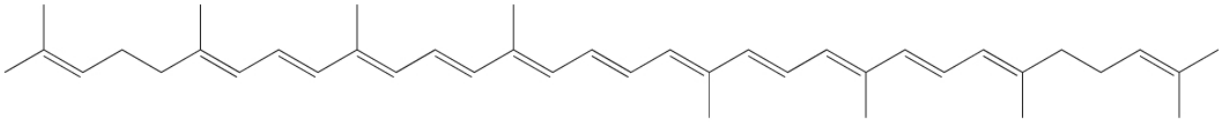
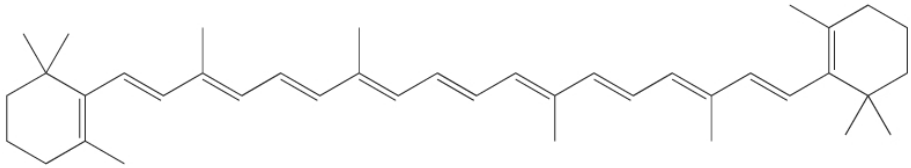
Extended description for FIGURE 19.27 Chlorophylls a and b absorb light maximally at different wavelengths



© Macmillan Learning

The horizontal axis labeled wavelength in nanometers has markings ranging from 400 to 700 in increments of 100 units. The vertical axis labeled extinction coefficient in M inverse 1-centimeter inverse has the marking 10 to the power 5 much above the midpoint. The graph shows two curves. The first blue curve labeled a starts from the



midpoint of the vertical axis and peaks at 420 on the horizontal axis slightly above 10 to the power 5 on the vertical axis, it slopes down to the lowest extinction coefficient at 470, moves toward the right to reach 600, rises upward and peaks slightly below 10 to the power 5 on the vertical axis. The second red curve labeled b starts just above the origin on the vertical axis, peaks at 470 much above the first peak of the blue curve, slopes down to 500 on the horizontal axis, moves toward the right to reach 600, peaks at 650 much below the second peak of the blue curve.

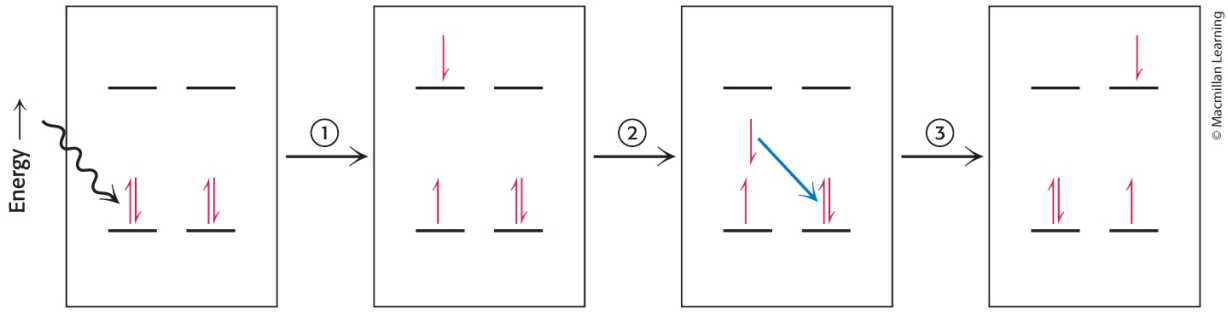
Extended description for Structure of Lycopene and beta carotene

Lycopene



β-Carotene

The structure of lycopene is as follows: A 32-carbon alkene chain is depicted as a line structure using 31 zigzag lines. A double bond is present between C 2 and C 3, C 6 and C 7, C 8 and C 9, C 10 and C 11, C 12 and C 13, C 14 and C 15, C 16 and C 17, C 18 and C 19, C 20 and C 21, C 22 and C 23, C 24 and C 25, C 26 and C 27, and C 30 and C 31. C 2, C 6, C 10, and C 14 are each single bonded to C H 3 above in the form of a line. C 19, C 23, C 27, and C 31 are each single bonded to C H 3 below in the form of a line. The structure of beta-carotene is as follows: A 6-carbon hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. A double bond is present between C 2 and C 3. C 1 is single bonded to C H 3 on the upper right and C H 3 on the upper left, each in the form of a line. C 3 is single bonded to C H 3 in the form of a line. C 2 is single-bonded to C 1 of an 18-carbon alkene chain depicted as a line structure using 17 zigzag lines. In the alkene chain, a double bond is present between C 1 and C 2, C 3 and C 4, C 5 and C 6, C 7 and C 8, C 9 and C 10, C 11 and C 12, C 13 and C 14, C 15 and C 16, and C 17 and C 18. In the alkene chain, C 3 and C 7 are each single bonded to C H 3 above in the form of a line. In the alkene chain, C 12 and C 16 are each single bonded to C H 3 below in the form of a line. C 18 of the alkene chain is single bonded to C 5 of

a second 6-carbon hexagonal ring in a vertical orientation with C 1 occupying the topmost vertex. In the second ring, a double bond is present between C 5 and C 6. C 4 of the second ring is single bonded to C H 3 on the lower right and C H 3 on the lower left, each in the form of a line. C 6 of the second ring is single bonded to C H 3 in the form of a line.

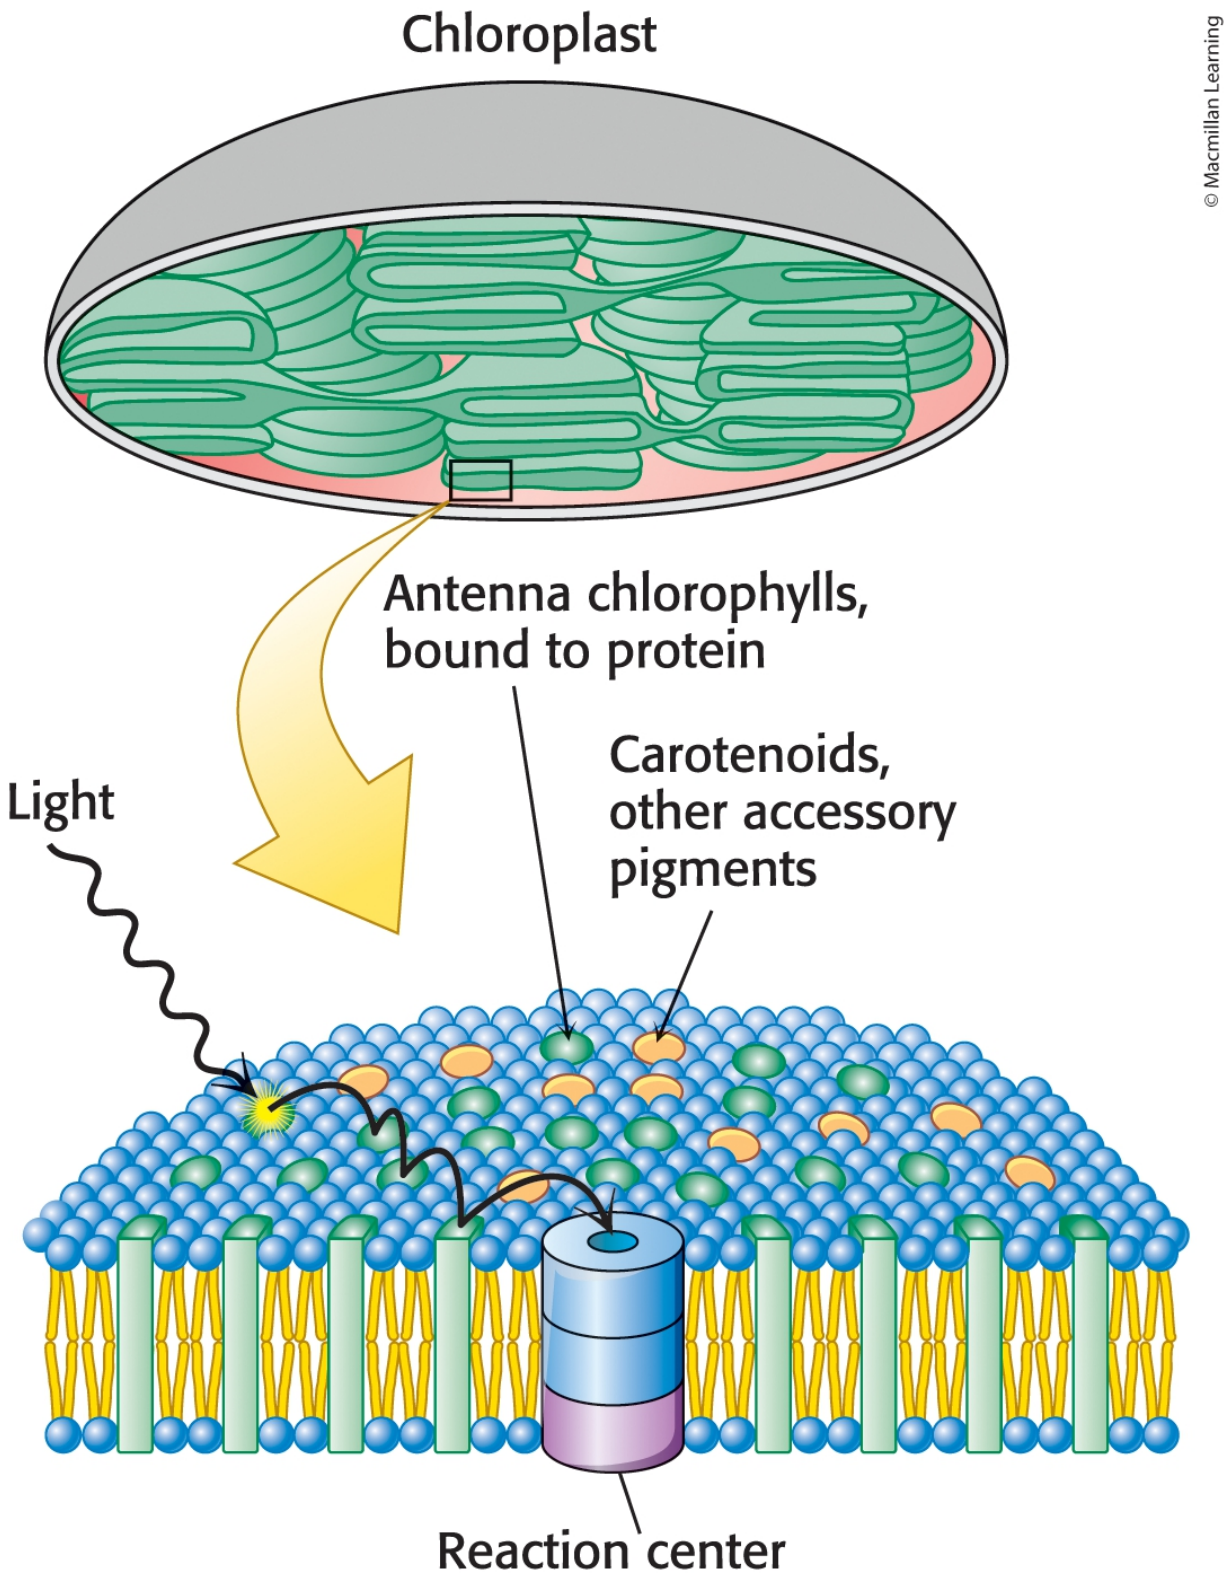
Extended description for FIGURE 19.28 Resonance energy transfer allows electrons to transfer energy over a distance



The figure has four panels. In the first panel, two pairs of upward and downward arrows are present in the ground state. The upward and downward arrows represent electrons. The excited states at the top are blank. A wavy arrow representing light strikes the first pair of upward and downward arrows. An arrow from the first panel leads to the second panel and is numbered 1. In the second panel, the first downward arrow from the first pair moves to the excited state and the upward arrow remains in the ground state. The second pair of upward and downward arrows remain in the ground state and the excited state is blank. An arrow from the second panel points to the third panel and is numbered 2. The downward arrow in the excited state is directed toward the second pair of arrows in the ground state. An arrow from the third panel points to the fourth panel and is numbered 3. In the fourth panel, the first pair of arrows are present in the ground state and the excited state is blank. The second ground state has one upward arrow and the excited state has one downward arrow.

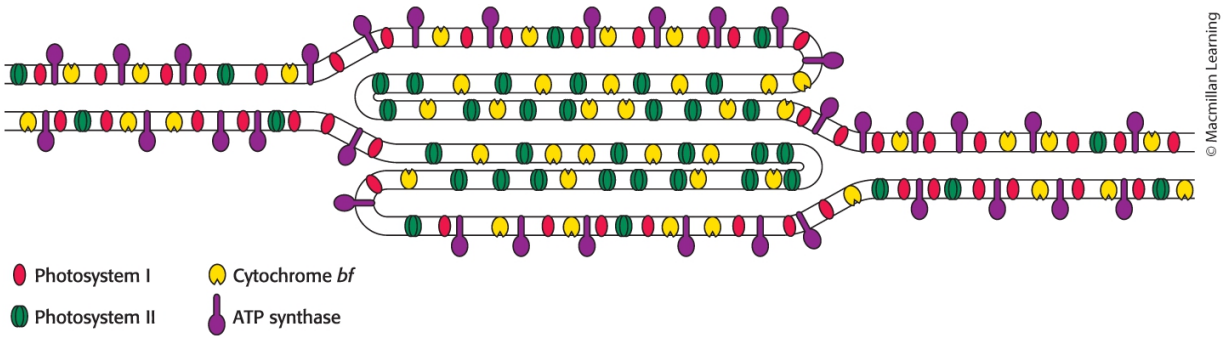
Extended description for FIGURE 19.29 Energy is transferred from accessory pigments to reaction

centers



© Macmillan Learning

The figure shows a chloroplast. The chloroplast is an oval-shaped, hollow sac-like structure that consists of two membranes. The hollow interior of the chloroplast is called the stroma. The stroma of the chloroplast consists of numerous stacked discs. These discs are called thylakoids. A zoomed-in view from one of the thylakoids shows a lipid bilayer. The lipid bilayer consists of horizontally parallel layers of lipids. The upper and lower layer consists of lipid molecules packed together compactly. Each lipid molecule is shown in a shorthand depiction. The yellow extensions of the shorthand depiction are aligned together and form the core of the bilayer. The blue spheres are located away from each other. The upper layer of the lipid bilayer consists of orange and green spheres embedded in between. The orange spheres are labeled carotenoids, other accessory pigments. The green spheres are labeled antenna chlorophylls, bound to protein. Three stacked disc-like structures are embedded in the center of the lipid bilayer and labeled reaction center. A wavy arrow representing light strikes the upper layer of the lipid bilayer and is directed toward the reaction center.

Extended description for FIGURE 19.30 Photosynthetic assemblies are differentially distributed in the stacked and unstacked regions of thylakoid membranes

The figure depicts two horizontal thick walled Y-shaped structures coinciding with one another to form a continuous bridge. The walls of these Y-shaped structures have a linear assembly of photosystem 1, photosystem 2, cytochrome b f, and A T P synthase. In the region of overlap or stacking between the two Y-shaped structures, the assembly follows an alternative pattern of photosystem 2 and cytochrome b f. In the region where there is direct contact with the stroma or there is no stacking, the assembly pattern consists of photosystem 2, photosystem 1, A T P synthase, and cytochrome b f.

Extended description for Graph depicts atmospheric C O 2 measured at Mauna Loa, Hawaii

The horizontal axis is labeled year. It has markings ranging from 1960 to 2020 in increments of 10 units. The vertical axis is labeled C O 2 concentration (p p m v). It has markings ranging from 320 to 420 in increments of 20 units. An increasing straight line moving toward the upper right is shown. A red zigzag line overlaps with a straight line and resembles a sawtooth. An inset graph shows the markings: January, April, July, October, and January on the horizontal axis. The inset graph is titled "Annual cycle." It contains a curve that starts at the midpoint of the vertical axis and rises gradually to peak in April and then slopes down in October and then starts rising again.

Extended description for FIGURE 20.1 The Calvin–Benson cycle consists of three stages

The Calvin Benson cycle is divided into three stages as follows:

Stage 1: Fixation, Stage 2: Reduction, and Stage 3: Regeneration.

Stage 1: It involves the addition of C O 2 to ribulose 1,5-bisphosphate to produce 3-phosphoglycerate.

The structure of ribulose 1,5-bisphosphate is as follows: C H 2 O P O 3 superscript 2 minus, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 2 is double bonded to O on the right. C 3 and C 4 are each single bonded to H on the left and O H on the right.

The structure of 3-phosphoglycerate is as follows: C H 2 O P O 3 superscript 2 minus, single bond, C, single bond, C O 2 superscript minus. C 2 is single bonded to 2 H on the left and O H on the right.

Later 2 A T P molecules enter and convert 3-phosphoglycerate to 1,3-bisphosphoglycerate (1,3-B P G).

The structure of 1,3-bisphosphoglycerate is as follows: C H 2 O P O 3 superscript 2 minus, single bond, C, single bond, C. C 2 is single bonded to 2 H on the left and O H on the right. C 3 is single bonded to O P O 3 superscript 2 minus on the lower left and double bonded to O on the lower right.

Stage 2: It involves the reduction of 1,3-bisphosphoglycerate by 2 N A D P H to produce glyceraldehyde 3-phosphate.

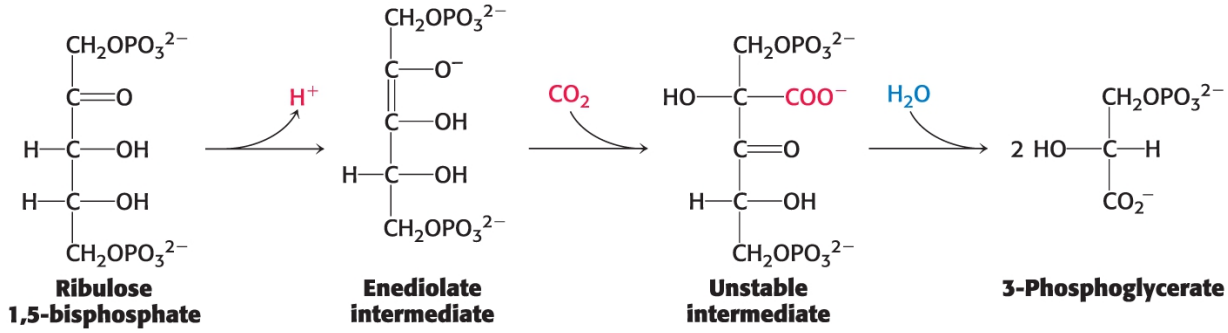
The structure of glyceraldehyde 3-phosphate is as follows: C H 2 O P O 3 superscript 2 minus, single bond, C, single bond, C. C 2 is single bonded to 2 H on the left and O H on the right. C 3 is single-bonded to H on the lower left and double-bonded to O on the lower right.

Glyceraldehyde 3-phosphate can be further converted into fructose 6-phosphate (F-6 P) or enter stage 3.

The structure of fructose 6-phosphate is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and

single bonded to C H 2 O H on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 and C 4 are each single bonded to H on the left and O H on the right.

Fructose 6-phosphate is further converted into hexose sugars.



Stage 3: It involves the conversion of glyceraldehyde 3-phosphate to ribulose 5-phosphate.

The structure of ribulose 5-phosphate is as follows: C H 2 O H, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 3 and C 4 are each single bonded to H on the left and O H on the right.

Ribulose 5-phosphate is further converted into ribulose 1,5-bisphosphate by the addition of A T P.

Return to FIGURE 20.1 The Calvin–Benson cycle consists of three stages

Extended description for Sequential conversion of ribulose 1,5-bisphosphate to 3-phosphoglycerate

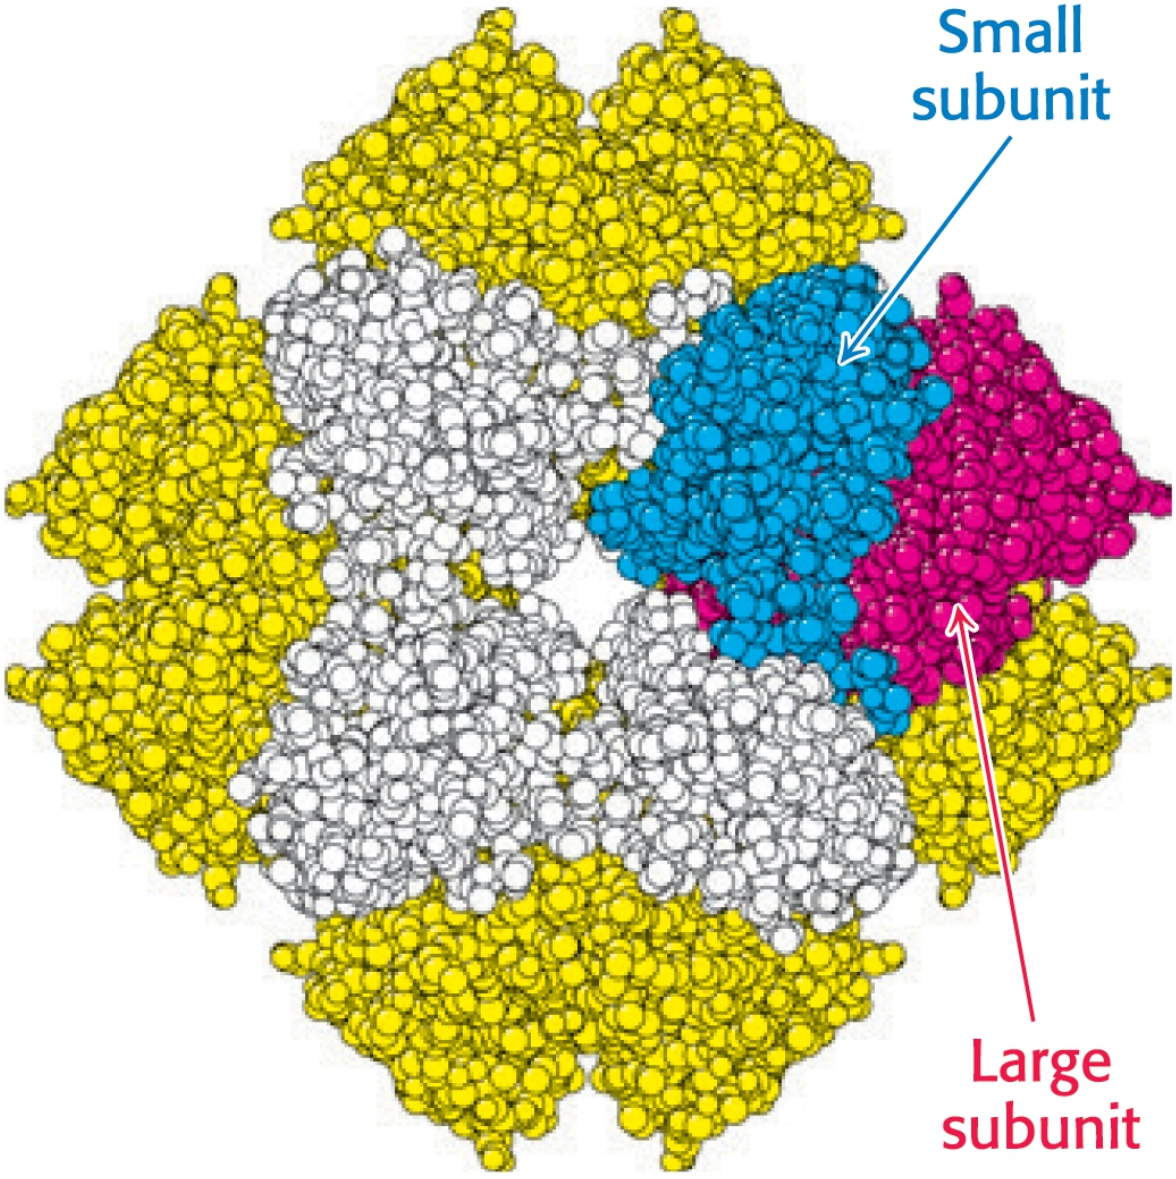
In the first step, ribulose 1,5-bisphosphate is irreversibly converted into enediolate intermediate with the simultaneous release of H superscript plus ion.

The structure of ribulose 1,5-bisphosphate is as follows: C H 2 O P O 3 superscript 2 minus, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 2 is double bonded to O on the right. C 3 and C 4 are each single bonded to H on the left and O H on the right.

The structure of enediolate intermediate is as follows: C H 2 O P O 3 superscript 2 minus, single bond, C, double bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 2 is single bonded to O superscript minus on the right. C 3 is single bonded to O H on the right. C 4 is single bonded to H on the left and O H on the right.

In the second step, the enediolate intermediate is converted into an unstable intermediate by the addition of C O 2.

The structure of the unstable intermediate is as follows: C H 2 O P O 3 superscript 2 minus, single bond, C, single bond, C, single bond, C,



single bond, C H 2 O P O 3 superscript 2 minus. C 2 is single bonded to O H on the left C O O superscript minus on the right. C 3 is double bonded to O on the right. C 4 is single bonded to H on the left and O H on the right.

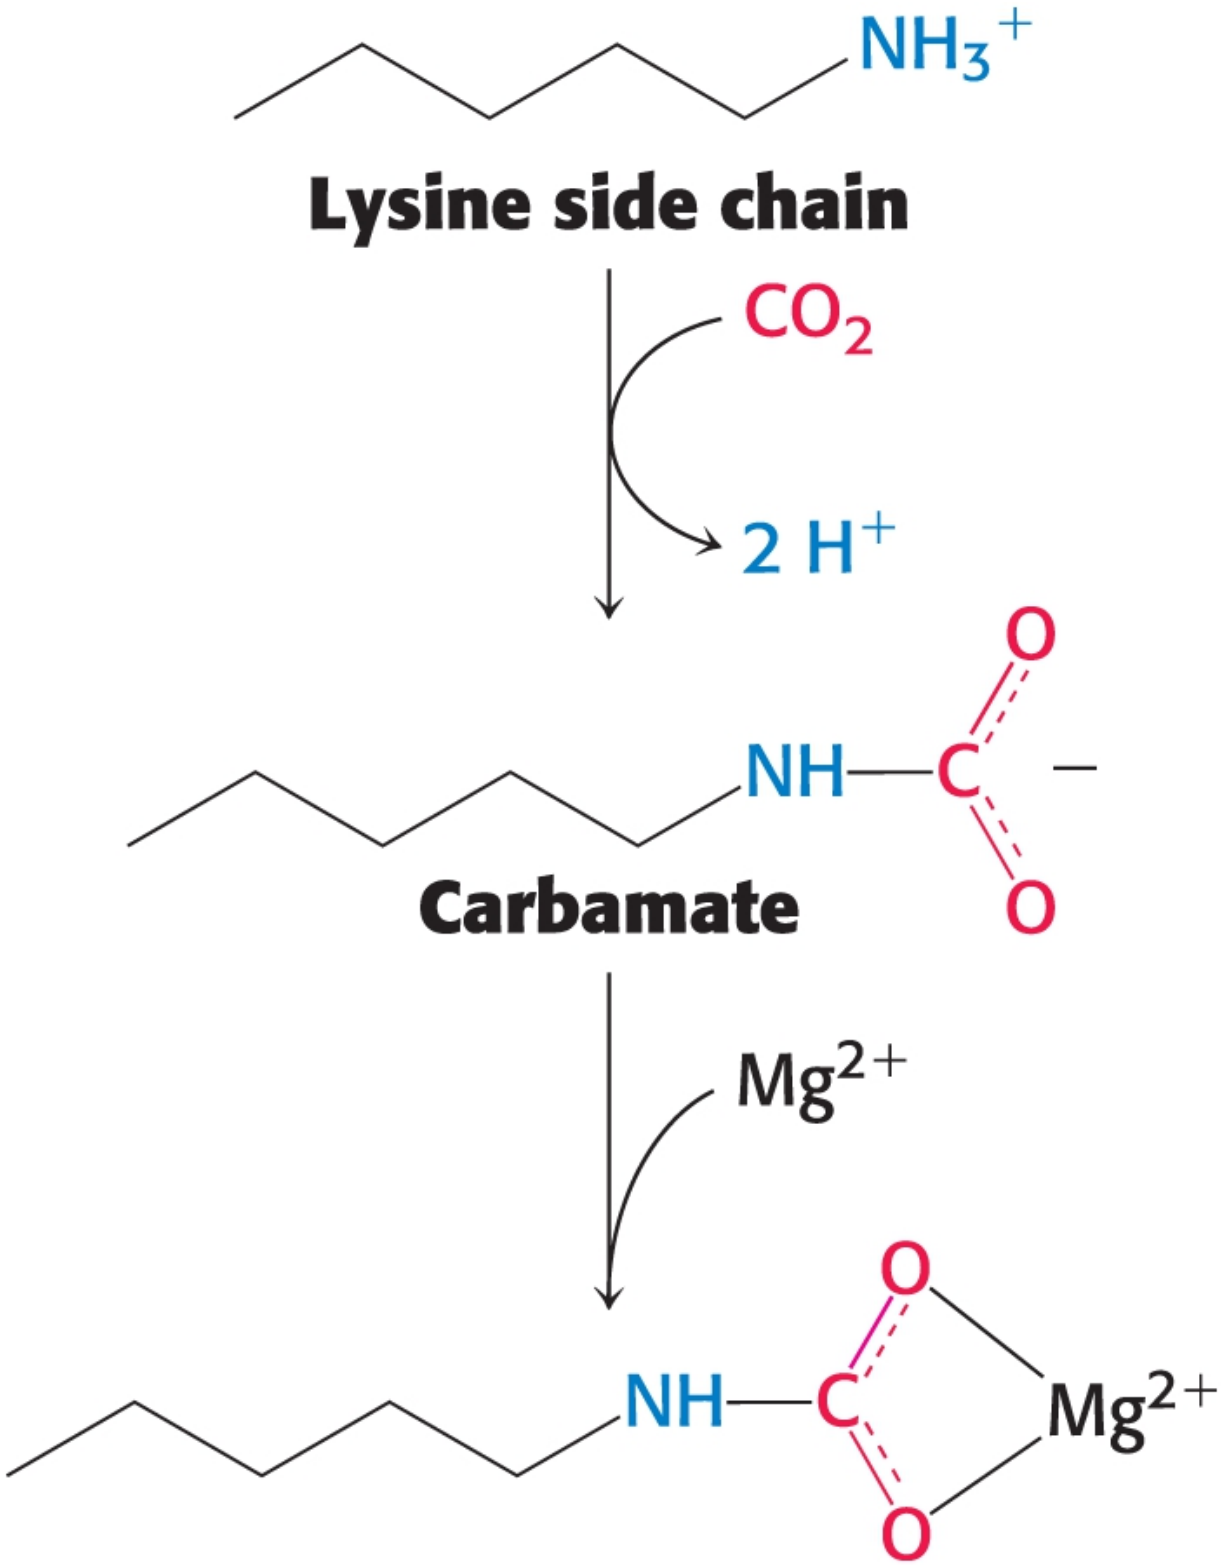
In the third step, the unstable intermediate is converted into 3-phosphoglycerate by the addition of H 2 O.

The structure of 3-phosphoglycerate is as follows: C H 2 O P O 3 superscript 2 minus, single bond, C, single bond, C O 2 superscript minus. C 2 is single bonded to 2 O H on the left and H on the right.

Return to Sequential conversion of ribulose 1,5-bisphosphate to 3-phosphoglycerate

Extended description for FIGURE 20.2 The enzyme ribulose 1,5-bisphosphate carboxylase slash oxygenase (Rubisco) comprises 16 subunits

© Macmillan Learning



The figure shows the subunits of the enzyme ribulose 1,5-bisphosphate. Out of the sixteen subunits, 12 subunits are visible. These subunits are formed by clusters of differently colored

spheres. The figure shows four subunits in the front. The subunit on the top right is blue and is labeled small subunit. The other three subunits are white. Two subunits each are attached to the top, bottom, left, and right face of the cluster of four subunits. All these subunits are yellow except for the subunit on the top right. This subunit is pink and is labeled a large subunit.

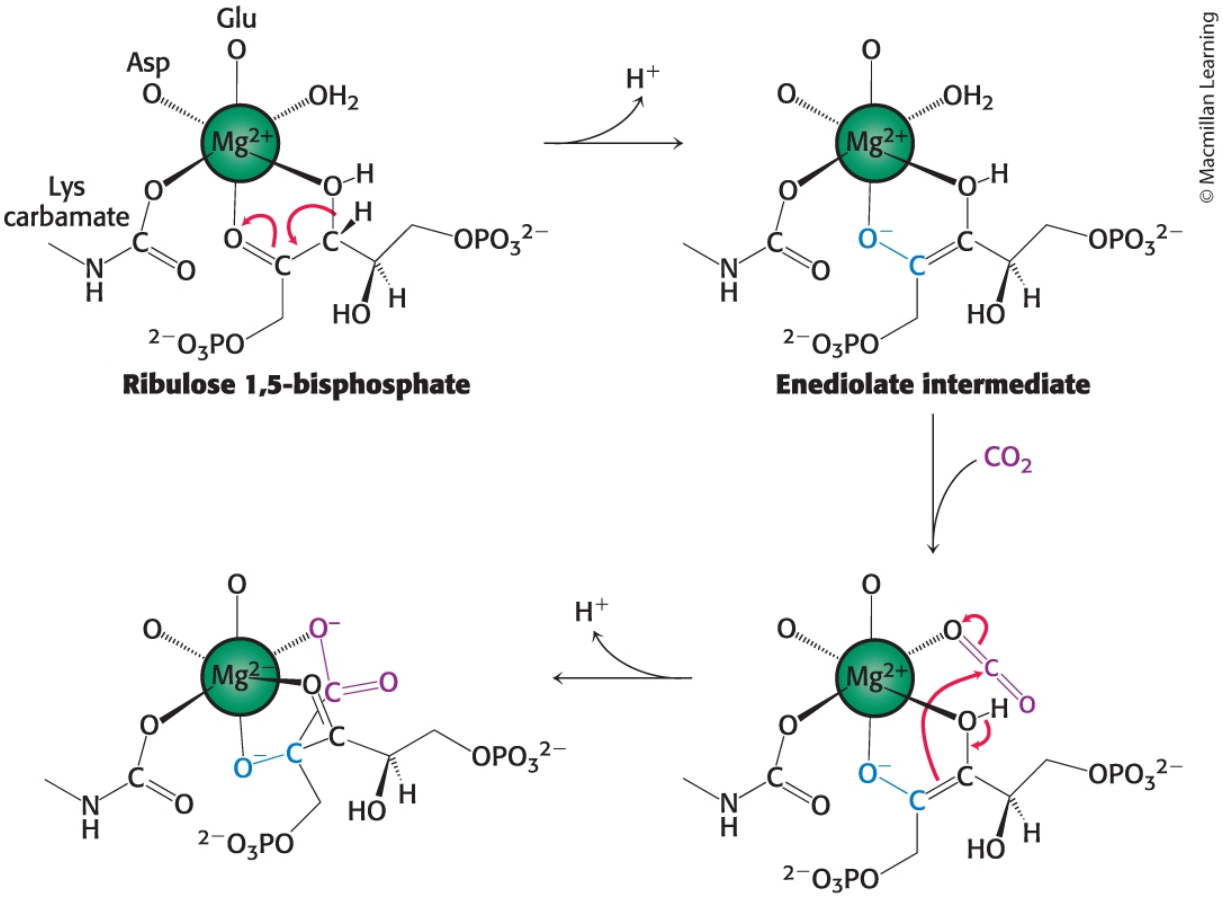
Return to FIGURE 20.2 The enzyme ribulose 1,5-bisphosphate carboxylase slash oxygenase (Rubisco) comprises 16 subunits

Extended description for Formation of carbamate from the lysine side chain and its binding to a magnesium

ion

The lysine side chain is depicted as a 5-carbon alkane chain using 4 zigzag lines. C 5 is single bonded to N H 3 superscript plus highlighted in blue on the upper right.

A downward arrow from the lysine chain points to carbamate. It is coupled with the entry of C O 2 and the release of 2 H superscript plus.



The carbamate molecule is depicted as a 5-carbon alkane chain using 4 zigzag lines. C 5 is single bonded to N H on the upper right. N H is single bonded to C on the right. This C is partially double-bonded to O on the upper right and lower right. This C O O group has a negative charge.

A downward arrow from carbamate shows the entry of M g superscript 2 plus ion.

The partially double-bonded O atoms of carbamate are single-bonded to a common M g superscript 2 plus ion.

Return to Formation of carbamate from the lysine side chain and its binding to a magnesium ion

Extended description for FIGURE 20.3 C O 2 fixation by magnesium-coordinated ribulose 1,5- bisphosphate

The process of C O 2 fixation is divided into 3 steps.

In the first step, ribulose 1,5-bisphosphate is converted to an enediolate intermediate with the simultaneous release of H superscript plus ion.

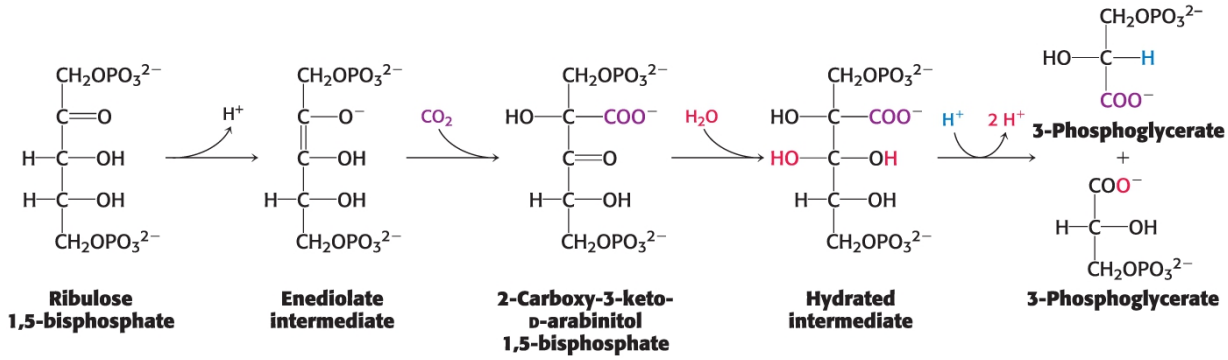
M g superscript 2 plus ion is depicted as a central green sphere. It single bonded to the O atom of glutamate above, dash bonded to O H 2 on the upper right, wedge bonded to O atom of O H group that is single bonded to C 2 of ribulose 1,5-bisphosphate, single bonded to

O atom that is double bonded to C 1 of ribulose-1,5-bisphosphate, wedge bonded to O atom of lysine carbamate, and dash bonded to O atom of aspartic acid.

Lysine carbamate consists of N, single bond, C. N bound to H has an open single bond on the upper left. C is single-bonded to O on the upper right and double-bonded to O on the lower right.

The structure of ribulose-1,5-bisphosphate is depicted as follows: C, single bond, C. C 1 is single bonded to C H 2 on the lower right in the form of a line. C H 2 is further single bonded to O P O 3 superscript 2 minus on the lower left. C 1 is also double bonded to O on the upper left. C 2 is single bonded to O, single bond, H above, and wedge bonded to H on the upper right. C 2 is also single bonded to a 2-carbon alkane chain depicted using a line. C 1 of this chain is wedge bonded to O H on the lower left and dash bonded to H on the lower right. C 2 is single bonded to O P O 3 superscript 2 minus on the right. A red curved arrow from C 1 points toward the O atom double bonded to it. A red curved arrow points from the single bond between C 2 and O points toward the single bond between C 1 and C 2.

The product of this step is the enediolate intermediate. In this intermediate, the M g superscript 2 plus ion becomes single bonded to O superscript minus below which is further single bonded to C 1 of the substrate. C 1 of the substrate becomes double bonded to C 2. The wedge bond between C 2 and H is broken down.



In the second step, C O 2 binds to the enediolate intermediate. In the product of this step, Mg superscript 2 plus ion becomes dash-bonded to O on the upper right. This O is double bonded to C, double bond, O on the lower right.

A red curved arrow points from the double bond between C and O bound to M g superscript 2 plus toward the O atom. A second curved arrow points from the double bond between C 1 and C 2 of the substrate toward the C atom of the C O 2 molecule bound to M g superscript 2 plus ion through the O atom. A third curved arrow points form the single bond between the O and H atom of the O H group bound to C 2 to the single bond between C 2 and O.

In the third step, the H superscript plus ion is released. The M g superscript 2 plus ion becomes dash bonded to O superscript minus on the upper right. This O superscript minus ion is further single bonded to C below. This C atom is single-bonded to C 1 of the substrate and double-bonded to O on the right. The M g superscript 2 plus ion is also wedge bonded to O on the right. This O is further double bonded to C 2 of the substrate.

Return to FIGURE 20.3 C O 2 fixation by magnesium-coordinated ribulose 1,5- bisphosphate

Extended description for FIGURE 20.4 In stage 1 of the Calvin–Benson cycle, 3-phosphoglycerate is formed

In the first step, ribulose 1,5-bisphosphate is converted into enediolate intermediate with the simultaneous release of H superscript plus ion.

The structure of ribulose 1,5-bisphosphate is as follows: C H 2 O P O 3 superscript 2 minus, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 2 is double bonded to O on the right. C 3 and C 4 are each single bonded to H on the left and O H on the right.

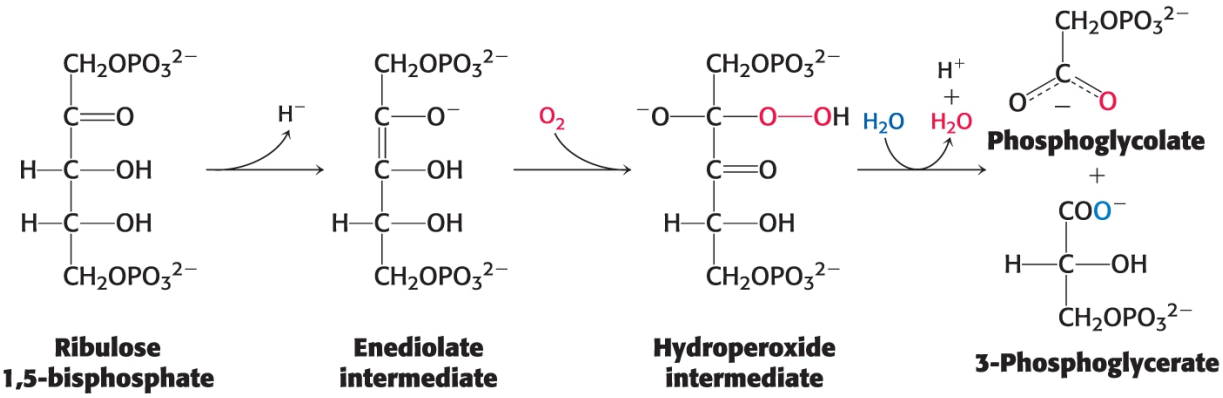
The structure of enediolate intermediate is as follows: C H 2 O P O 3 superscript 2 minus, single bond, C, double bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 2 is single bonded to O superscript minus on the right. C 3 is single bonded to O H on the right. C 4 is single bonded to H on the left and O H on the right.

In the second step, the enediolate intermediate is converted into 2-carboxy-3-keto-D-arabinitol 1,5-bisphosphate by the addition of C O 2.

The structure of 2-carboxy-3-keto-D-arabinitol 1,5-bisphosphate is as follows: C H 2 O P O 3 superscript 2 minus, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 2 is single bonded to O H on the left and C O O superscript minus on the right. C 3 is double bonded to O on the right. C 4 is single bonded to H on the left and O H on the right.

In the third step, 2-carboxy-3-keto-D-arabinitol 1,5-bisphosphate is converted into hydrate intermediate by the addition of H 2 O.

The structure of the hydrate intermediate is as follows: C H 2 O P O 3 superscript 2 minus, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 2 is single bonded to O H on the left and C O O superscript minus on the right. C 3 is single bonded to O H on the right and left. C 4 is single bonded to H on the left and O H on the right.



In the fourth step, the hydrated intermediate is converted into two molecules of 3-phosphoglycerate with the simultaneous entry of one H superscript plus ion and release of 2 H superscript plus ions.

The structure of the first 3-phosphoglycerate molecule is as follows: C H 2 O P O 3 superscript 2 minus, single bond, C, single bond, C O O superscript minus. C 2 is single bonded to O H on the left and H on the right.

The structure of the second 3-phosphoglycerate molecule is as follows: C O O superscript minus, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 2 is single bonded to H on the left and O H on the right.

Return to FIGURE 20.4 In stage 1 of the Calvin–Benson cycle, 3-phosphoglycerate is formed

Extended description for FIGURE 20.5 The enediolate on Rubisco can react with oxygen in a wasteful side reaction

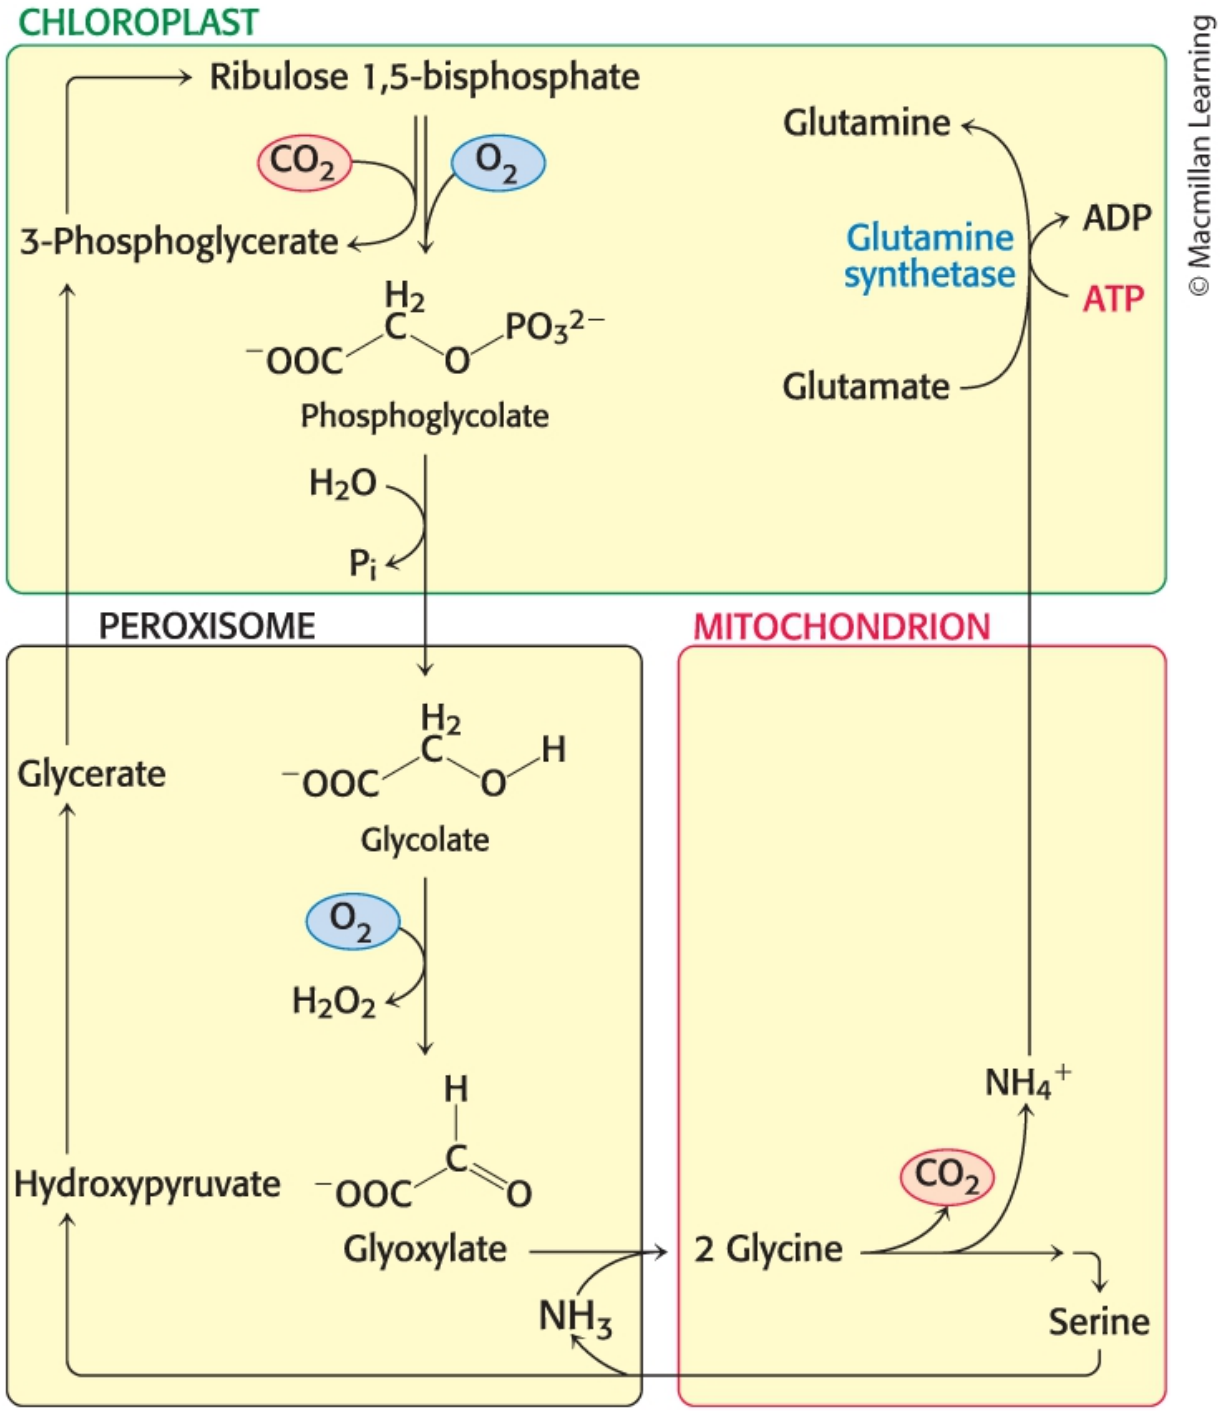
In the first step, ribulose 1,5-bisphosphate is converted into enediolate intermediate with the simultaneous release of H superscript plus ion.

The structure of ribulose 1,5-bisphosphate is as follows: C H 2 O P O 3 superscript 2 minus, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 2 is double bonded to O on the right. C 3 and C 4 are each single bonded to H on the left and O H on the right.

The structure of enediolate intermediate is as follows: C H 2 O P O 3 superscript 2 minus, single bond, C, double bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 2 is single bonded to O superscript minus on the right. C 3 is single bonded to O H on the right. C 4 is single bonded to H on the left and O H on the right.

In the second step, the enediolate intermediate is converted into a hydroperoxide intermediate by the addition of O 2.

The structure of the hydroperoxide intermediate is as follows: C H 2 O P O 3 superscript 2 minus, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 2 is single bonded to O superscript minus on the right and single bonded to O, single bond, O H on the right. C 3 is double bonded to O on the right. C 4 is single bonded to H on the left and O H on the right.



In the third step, the hydroperoxide intermediate is converted into phosphoglycolate and 3-phosphoglycerate with the simultaneous entry of H 2 O and release of H 2 O and H superscript plus ion.

The structure of phosphoglycolate is as follows: A central C atom is single bonded to C H 2 O P O 3 superscript 2 minus above and partially double bonded to O on the lower left and lower right. This C O O group has an overall negative charge.

The structure of 3-phosphoglycerate is as follows: C O O superscript minus, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 2 is single bonded to H on the left and O H on the right.

Return to FIGURE 20.5 The enediolate on Rubisco can react with oxygen in a wasteful side reaction

Extended description for FIGURE 20.6 Photorespiration consumes O 2 and produces C O 2

Three rectangular compartments labeled chloroplast, mitochondrion, and peroxisome are shown. In the chloroplast, ribulose 1,5-bisphosphate is irreversibly converted into phosphoglycerate by the addition of O 2. The structure of phosphoglycerate is as follows: C H 2 is single bonded to C O O superscript minus on the lower left and O on the lower right. This O is single bonded to P O 3 superscript 2 minus on the upper right. An arrow points from phosphoglycolate in the chloroplast to glycolate in the peroxisome. This arrow is coupled with another arrow showing the entry of H 2 O and the release of P subscript i in the chloroplast.

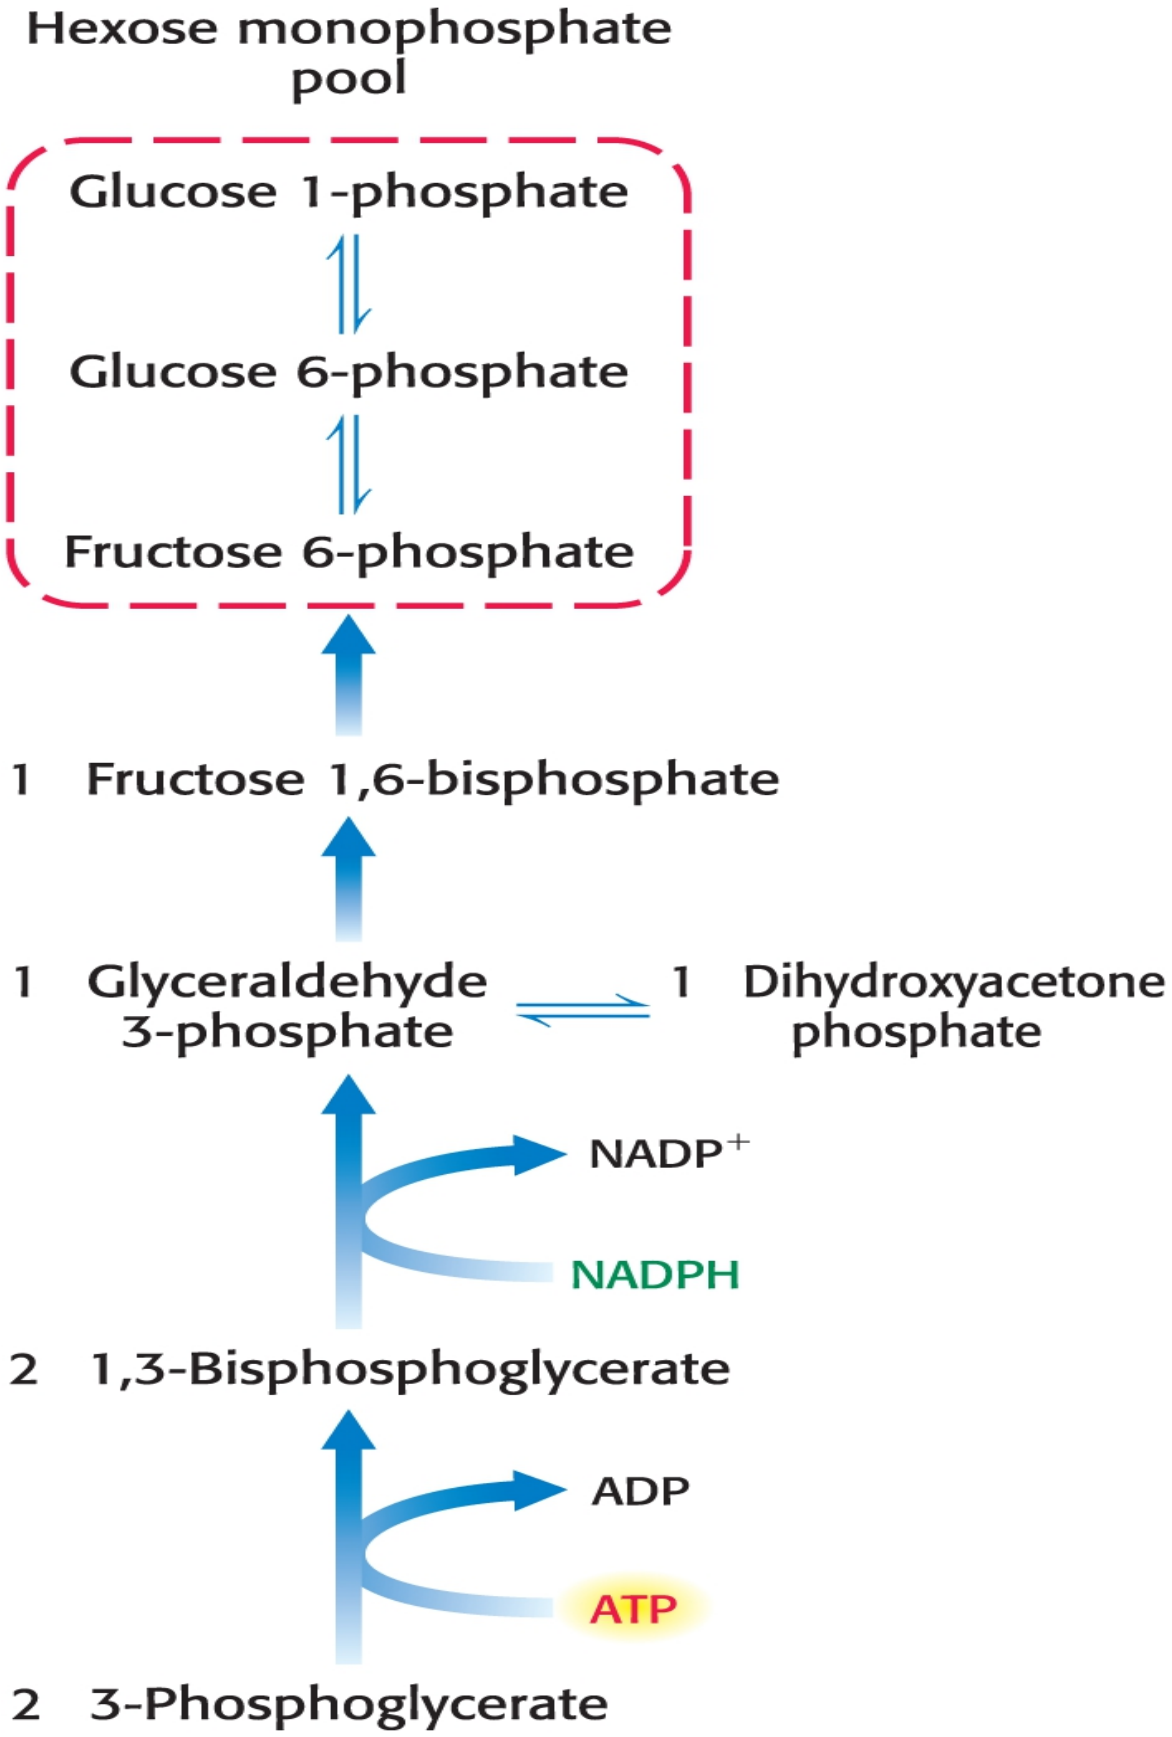
The structure of glycolate is as follows: C H 2 is single bonded to C O O superscript minus on the lower left and O on the lower right. This O is single-bonded to H on the upper right.

In the peroxisome, glycolate is irreversibly converted into glyoxylate with the simultaneous conversion of O 2 to H 2 O 2.

The structure of glyoxylate is as follows: A central C atom is single bonded to H above, single bonded to C O O superscript minus on the lower left, and double bonded to O on the lower right.

An arrow points from glyoxylate in peroxisome to 2 glycine in the mitochondrion. This arrow is coupled with the entry of N H 3.

In the mitochondrion, 2 glycine is converted into serine in two steps. The first step involves the release of C O 2 and N H 4 superscript plus. The N H 4 superscript plus molecule in the mitochondrion enters the chloroplast. In the chloroplast, it is used to convert glutamate into glutamine by glutamine synthetase with the simultaneous hydrolysis of A T P to A D P.



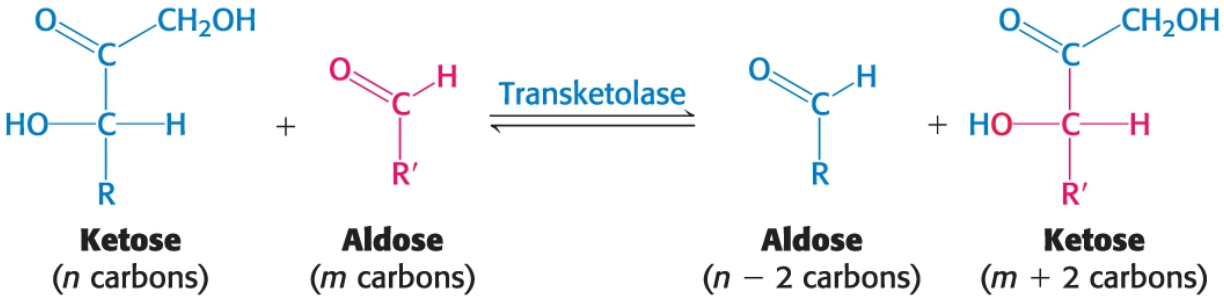
The serine molecule in the mitochondrion is transported back to the peroxisome. N H 3 molecule is released from serine to produce hydroxypyruvate. N H 3 molecule is used up to convert glyoxylate to glycine.

The hydroxypyruvate molecule is converted into glycerate in the peroxisome. The glycerate molecule enters the chloroplast where it is converted into 3-phosphoglycerate. The 3-phosphoglycerate molecule is further converted back to ribulose 1, 5-bisphosphate. The ribulose 1,5-bisphosphate molecule is converted back to 3-phosphoglycerate by the addition of C O 2.

Return to FIGURE 20.6 Photorespiration consumes O 2 and produces C O 2

Extended description for FIGURE 20.8 In stage 2 of the

Calvin–Benson cycle, hexose phosphate is formed



© Macmillan Learning

The cycle is depicted as a flowchart starting from the bottom to the top. In the first step, two 3-phosphoglycerate molecules are converted to two 1,3-Bisphosphoglycerate molecules with the simultaneous hydrolysis of A T P to A D P. In the second step, one glyceraldehyde 3-phosphate is formed from 1,3-Bisphosphoglycerate with the simultaneous oxidation of N A D P H to N A D P superscript plus. Alternatively, glyceraldehyde 3-phosphate produced in the second step can be reversibly converted to 1 dihydroxyacetone phosphate. In the third step, fructose 1, 6-bisphosphate is formed from glyceraldehyde 3-phosphate. Fructose 1, 6-bisphosphate is converted to fructose 6-phosphate in the fourth step. Fructose 6-phosphate is reversibly converted to glucose 6-phosphate in the fifth step. Glucose 6-phosphate is reversibly converted to glucose 1-phosphate in the sixth step. The sugar molecules fructose 6-phosphate, glucose 6-phosphate, and glucose 1-phosphate are labeled hexose monophosphate pool.

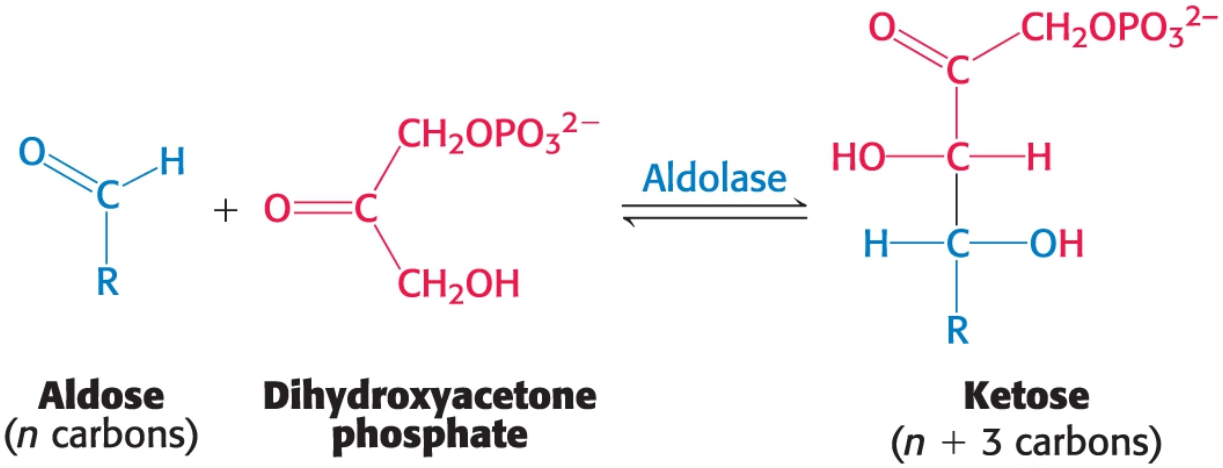
Return to FIGURE 20.8 In stage 2 of the Calvin–Benson cycle, hexose phosphate is formed

Extended description for Aldose and ketose formation

The reaction has 2 reactants and 2 products. Ketose (n carbons) reacts with aldose (m carbons) in the presence of transketolase to reversibly form aldose (n minus 2 carbons) and ketose (m plus 2 carbons).

The structure of ketose (n carbons) is as follows: The Fischer projection consists of a vertical line with C above and R below. The projection contains one C atom placed on a vertical line. The C atoms are numbered from top to bottom. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 is single bonded to O H on the left and H on the right.

The structure of aldose (m carbons) is as follows: A central C atom is double bonded to O on the top left, single bonded to H on the top right, and single bonded to R dash below.



The structure of aldose (n minus 2 carbons) is as follows: A central C atom is double bonded to O on the top left, single bonded to H on the top right, and single bonded to R below.

The structure of ketose (m plus 2 carbons) is as follows: The Fischer projection consists of a vertical line with C above and R dash below. The projection contains one C atom on a vertical line. The C atoms

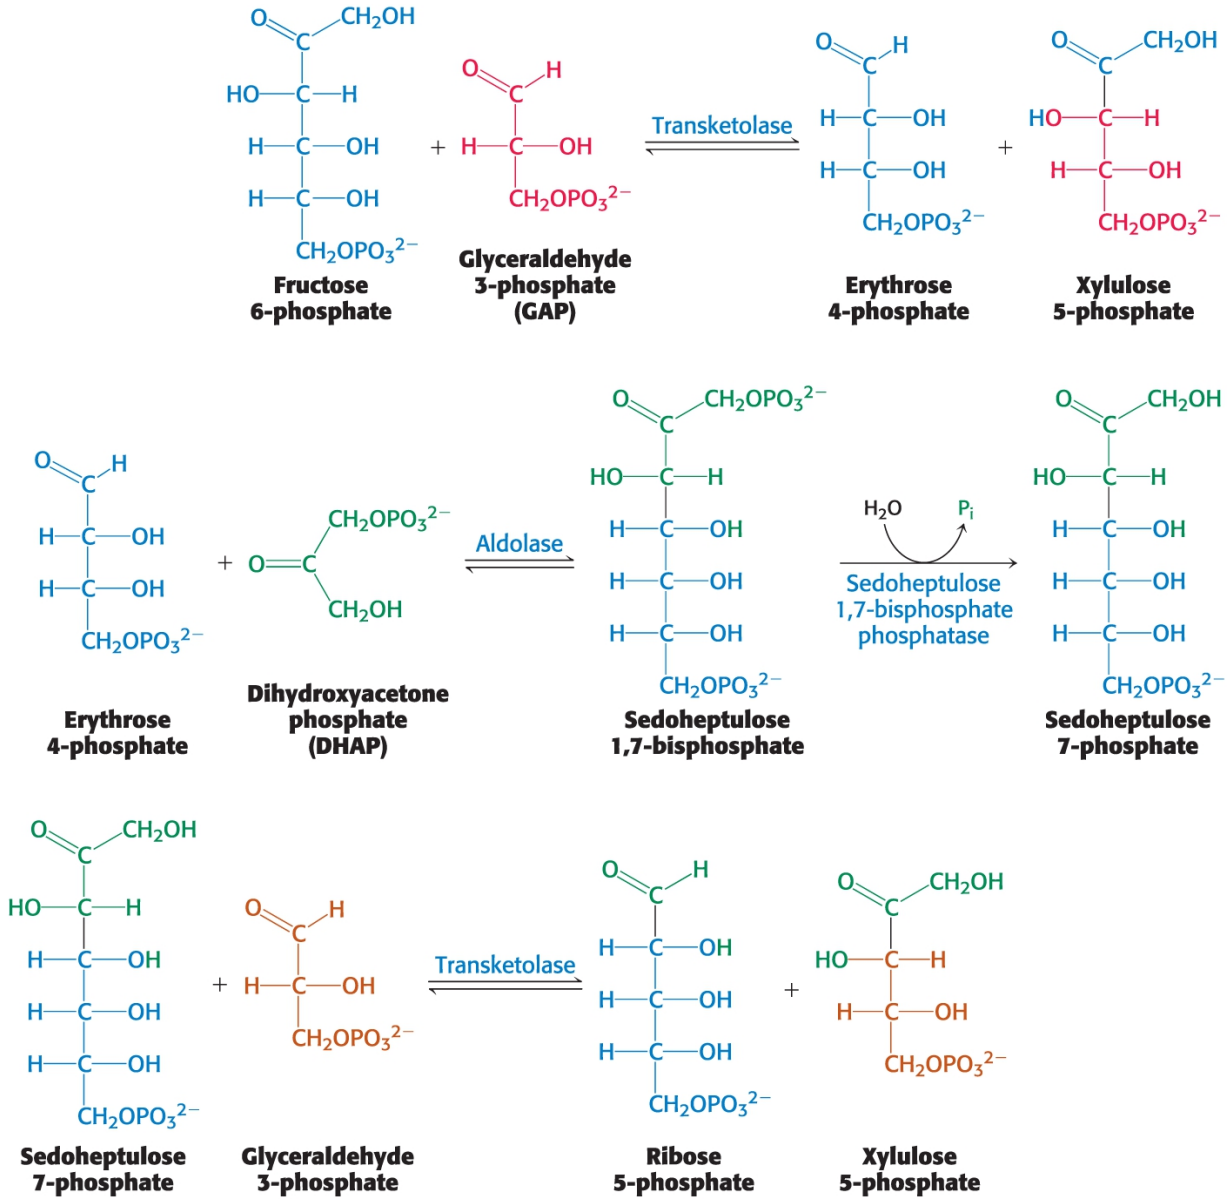
are numbered from top to bottom. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 is single bonded to O H on the left and H on the right.

Return to Aldose and ketose formation

Extended description for Ketose formation

The reaction has 2 reactants and 1 product. Aldose reacts with dihydroxyacetone phosphate in the presence of aldolase to reversibly form ketose.

The structure of aldose (n carbons) is as follows: A central C atom is double bonded to O on the top left, single bonded to H on the top right, and single bonded to R below.



The structure of dihydroxyacetone phosphate is as follows: A central C atom is double bonded to O on the left, single bonded to C H 2 O P O 3 superscript 2 minus on the top right, and C H 2 O H on the lower right.

The structure of ketose (n plus 3 carbons) is as follows: The Fischer projection consists of a vertical line with C above and R below. The projection contains two C atoms placed one below the other on the vertical line. The C atoms are numbered from top to bottom. C 1 is double bonded to O on the upper left and single bonded to C H 2 O P O 3 superscript 2 minus on the upper right. C 2 is single bonded to O

H on the left and H on the right. C 3 is single bonded to H on the left and O H on the right.

Return to Ketose formation

Extended description for FIGURE 20.9 Five-carbon sugars are formed from six-carbon and three-carbon sugars

The first reversible chemical reaction catalyzed by transketolase depicts the formation of erythrose 4-phosphate and xylulose 5-

phosphate from fructose 6-phosphate and glyceraldehyde 3-phosphate.

The structure of fructose 6-phosphate is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 and C 4 are each single bonded to H on the left and O H.

The structure of glyceraldehyde 3-phosphate (G A P) is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double-bonded to O on the upper left and single-bonded to H on the upper right. C 2 is single-bonded to H on the left and O H on the right.

The structure of xylulose 5-phosphate is as follows: C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 is single bonded to H on the left and O H on the right.

The second reversible chemical reaction catalyzed by aldolase depicts the formation of sedoheptulose 7-phosphate from erythrose 4-phosphate and dihydroxyacetone phosphate. Sedoheptulose 1,7-bisphosphate is formed as an intermediate.

The structure of erythrose 4-phosphate is as follows: C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double-bonded to O on the upper left and single-bonded to H on the upper right. C 2 and C 3 are each single bonded to H on the left and O H on the right.

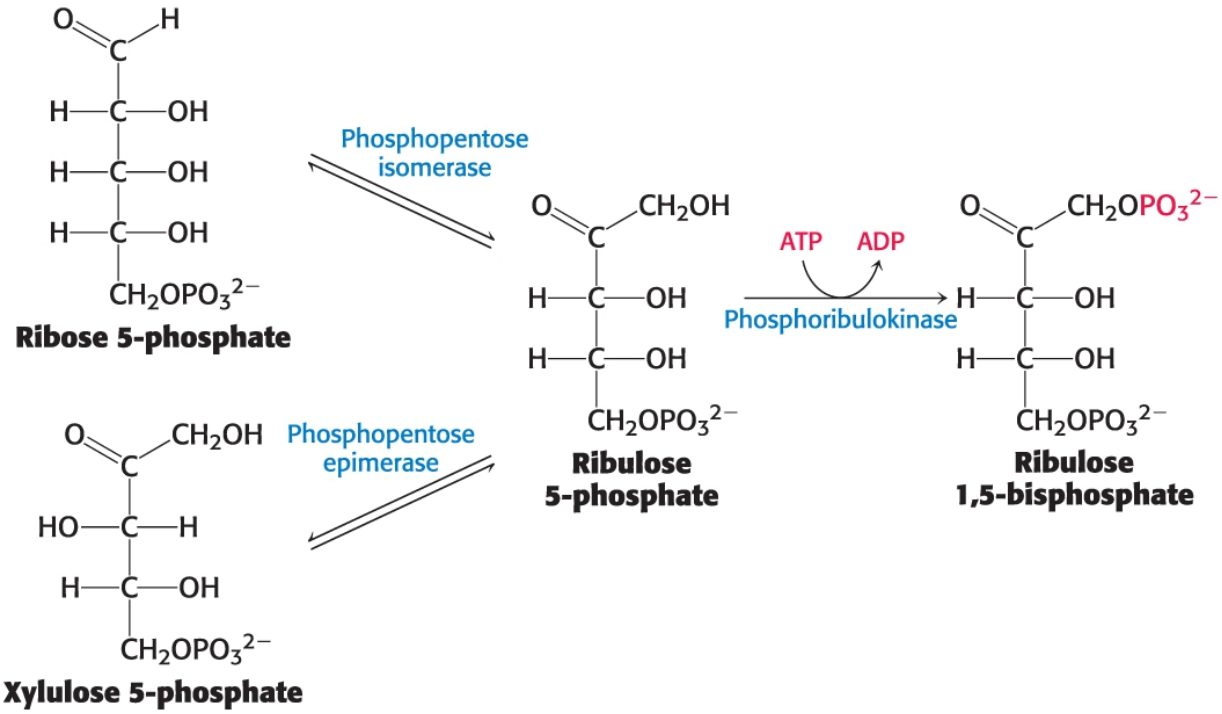
The structure of dihydroxyacetone phosphate (D H A P) is as follows: A central C atom is single bonded to C H 2 O P O 3 superscript 2 minus on the upper right, double bonded to O on the left, and single bonded to C H 2 O H on the lower right.

The structure of sedoheptulose 1,7-bisphosphate is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2 O P O 3 superscript minus on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 to C 5 are single-bonded to H on the left and O H on the right.

Sedoheptulose 1,7-bisphosphate is irreversibly converted into sedoheptulose 7-phosphate in a reaction catalyzed by sedoheptulose 1,7-bisphosphate phosphatase coupled with the entry of H 2 O and release of P subscript i.

The structure of sedoheptulose 7-phosphate is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 to C 5 are single-bonded to H on the left and O H on the right.

The third reversible chemical reaction catalyzed by transketolase depicts the formation of ribose 5-phosphate and xylulose 5-phosphate from sedoheptulose 7-phosphate and glyceraldehyde 3-phosphate.



The structure of ribose 5-phosphate is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double-bonded to O on the upper left and

single-bonded to H on the upper right. C 2 to C 4 are each single bonded to H on the left and O H on the right.

The structure of xylulose 5-phosphate is as follows: C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 is single bonded to H on the left and O H on the right.

Return to FIGURE 20.9 Five-carbon sugars are formed from six-carbon and three-carbon sugars

Extended description for FIGURE 20.10 In stage 3 of the Calvin–Benson cycle, ribulose 1,5-bisphosphate is regenerated

In the first step, ribose 5-phosphate and xylulose 5-phosphate produce ribulose 5-phosphate that is further converted into ribulose 1,5-bisphosphate.

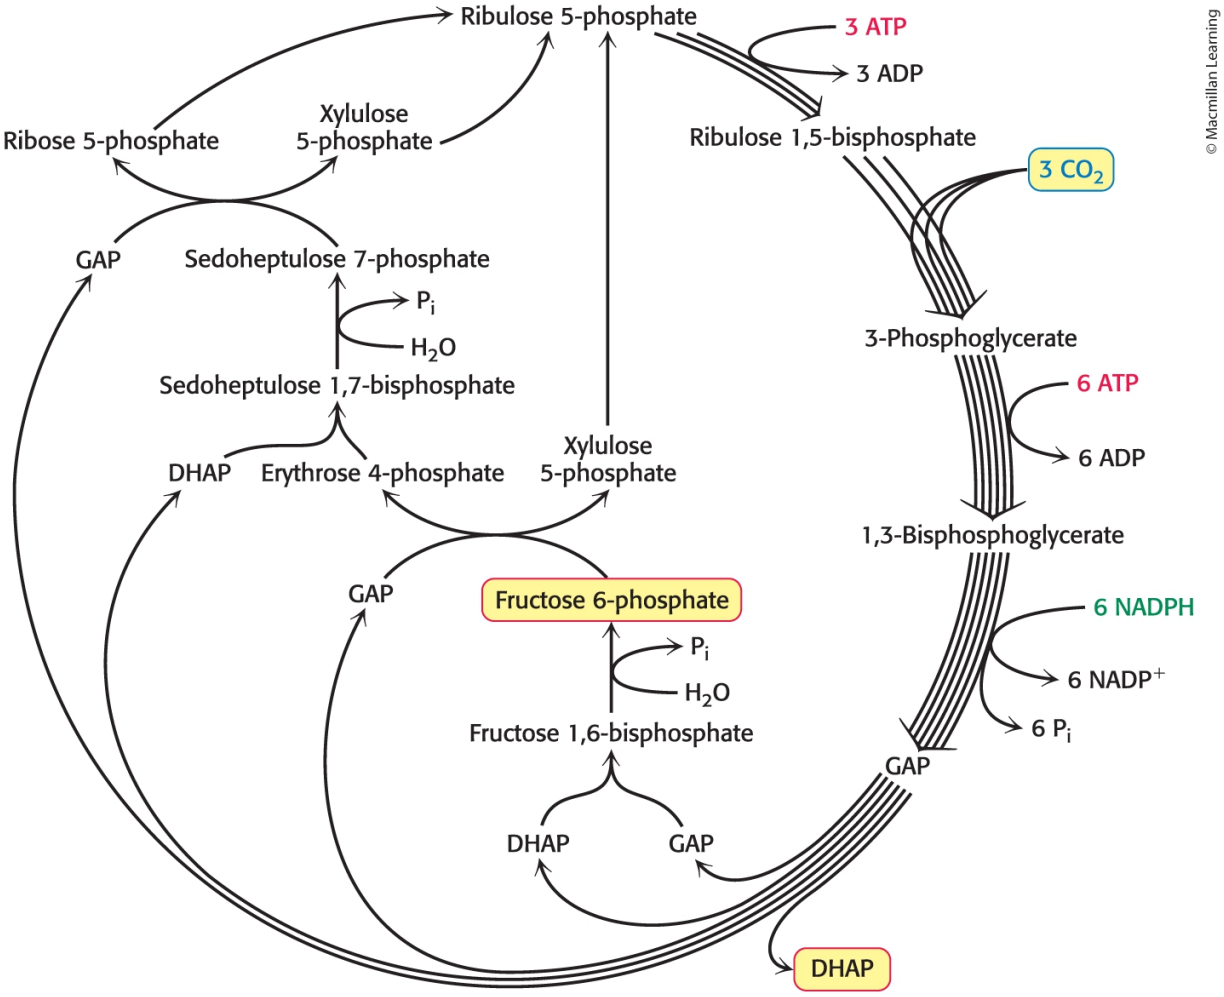
Ribose 5-phosphate is reversibly converted into ribulose 5-phosphate by the enzyme phosphopentose isomerase.

Xylulose 5-phosphate is reversibly converted into ribulose 5-phosphate by the enzyme phosphopentose epimerase.

The structure of ribose 5-phosphate is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3

superscript 2 minus. C 1 is double-bonded to O on the upper left and single-bonded to H on the upper right. C 2 to C 4 are each single bonded to H on the left and O H on the right.

The structure of xylulose 5-phosphate is as follows: C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 is single bonded to H on the left and O H on the right.



The structure of ribulose 5-phosphate is as follows: C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 and C 3 are each single bonded to H on the left and O H on the right.

In the second step, ribulose 5-phosphate is irreversibly converted into ribulose 1,5-bisphosphate by the enzyme phosphoribulokinase coupled with the hydrolysis of A T P to A D P.

The structure of ribulose 1,5-bisphosphate is as follows: C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2 OP O 3 superscript 2 minus on the upper right. C 2 and C 3 are each single bonded to H on the left and O H on the right.

Return to FIGURE 20.10 In stage 3 of the Calvin–Benson cycle, ribulose 1,5-bisphosphate is regenerated

Extended description for FIGURE 20.11 The full Calvin–Benson cycle process for converting three molecules of C O 2 to dihydroxyacetone phosphate is complex

The cycle starts with ribulose 5-phosphate at the top center. An arrow with three tails leads from ribulose 5-phosphate to ribulose 1,5-bisphosphate. A coupled curved arrow depicts the hydrolysis of 3 A T P to 3 A D P. An arrow with three tails leads from ribulose 1,5-bisphosphate to 3-phosphoglycerate. 3 C O 2 also enter during this step. An arrow with 6 tails leads from 3-phosphoglycerate to 1,3-bisphosphoglycerate. A coupled curved arrow depicts the hydrolysis

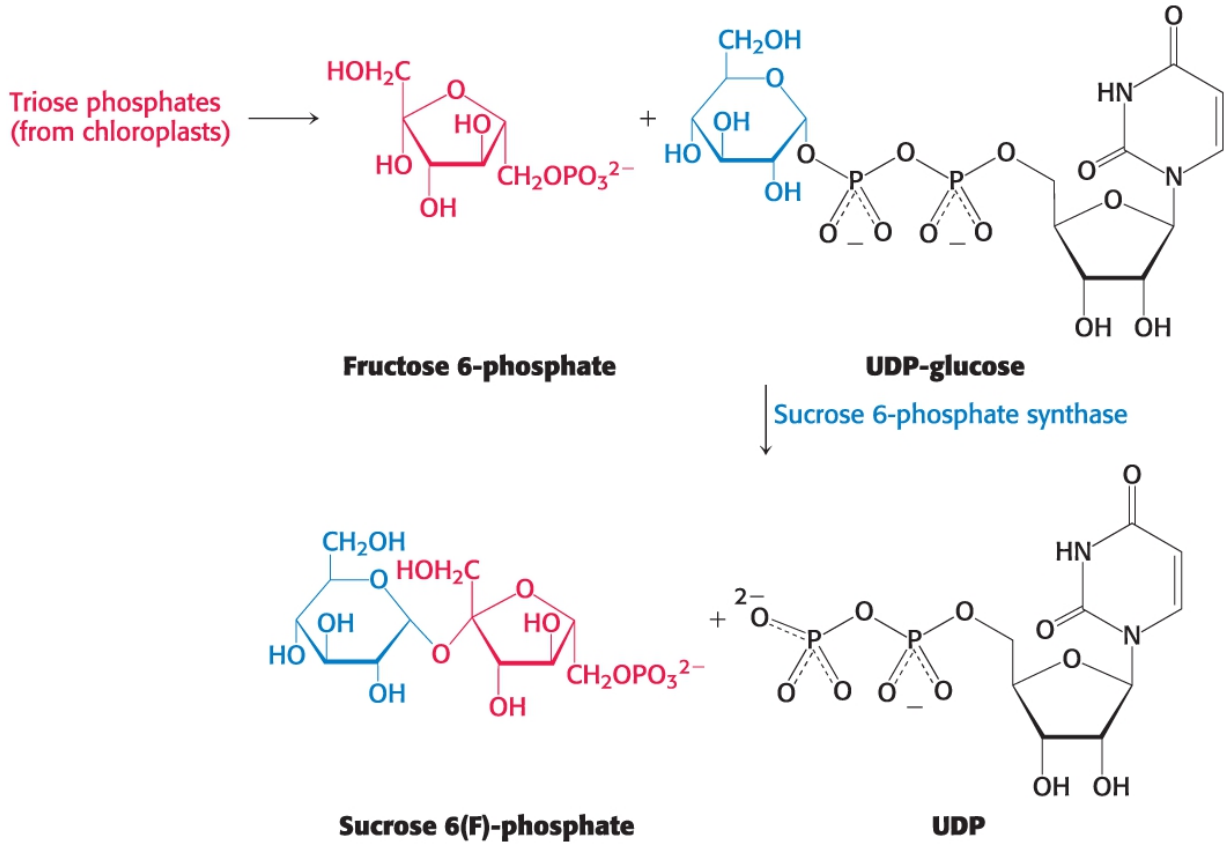
of 6 A T P to 6 A D P. An arrow with 6 tails leads from 1,3-bisphosphoglycerate to G A P. A coupled curved arrow depicts the oxidation of 6 N A D P H to 6 N A D P superscript plus and release of 6 P subscript i.

Two arrows from G A P leads to G A P and D A P. One arrow leads to D H A P and the remaining three arrows lead to G A P, D H A P, and G A P. One D A P molecule exits the cycle.

The first G A P and D H A P combine to produce fructose 1, 6-bisphosphate which is further irreversibly converted to fructose 6-phosphate. This irreversible conversion is coupled with the entry of H 2 O and the release of P subscript i.

Fructose 6-phosphate and second G A P are converted into erythrose 4-phosphate and xylulose 5-phosphate which are interconvertible.

Xylulose 5-phosphate is irreversibly converted to ribulose 5-phosphate.



Erythrose 4-phosphate and second D H A P combine to form sedoheptulose-1,7-bisphosphate. Sedoheptulose 1,7-bisphosphate is irreversibly converted into sedoheptulose 7-phosphate coupled with the entry of H 2 O and release of P subscript i.

Sedoheptulose 7-phosphate and third G A P are converted into ribose 5-phosphate and xylulose 5-phosphate which are interconvertible.

Xylulose 5-phosphate and ribose 5-phosphate are converted to ribulose 5-phosphate.

Return to FIGURE 20.11 The full Calvin–Benson cycle process for converting three molecules of C O 2 to dihydroxyacetone phosphate is complex

Extended description for FIGURE 20.12 Carbohydrates are stored as sucrose

Triose phosphates from chloroplasts are irreversibly converted into fructose 6-phosphate.

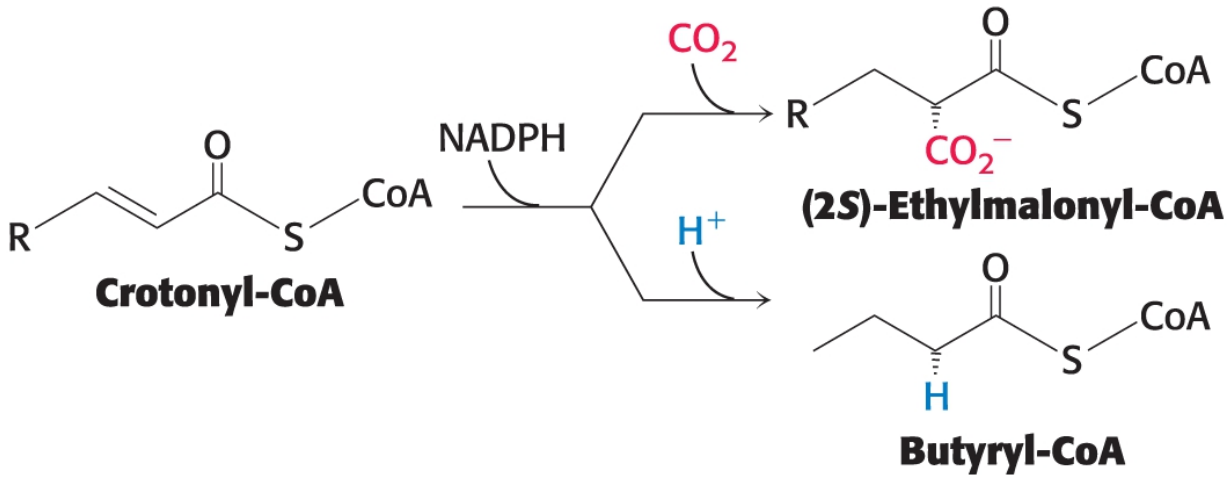
Fructose 6-phosphate and U D P-glucose are converted into sucrose 6-phosphate and U D P by the enzyme sucrose 6-phosphate synthase.

The structure of fructose 6-phosphate is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single bonded to C H 2 O P O 3

superscript 2 minus below. C 2 is single bonded to O H above. C 3 is single bonded to O H below. C 4 is single bonded to C H 2 O H above and O H below.

The structure of U D P-glucose is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 2 and C 3 are single bonded to O H below. C 1 is single-bonded to N 1 of a 6-membered heterocyclic hexagonal ring in a vertical orientation with C 1 occupying the bottom left vertex. It consists of 2 N and 4 C atoms. First N occupies the bottom-most vertex. The second N bound to H occupies the top left vertex. C 1 and C 2 are double bonded to O. A double bond is present between C 3 and C 4.

C 4 of the pentagonal ring is single-bonded to C H 2 above in the form of a line. C H 2 is single bonded to O, single bond, P, single bond, O, single bond, P in a zigzag conformation. Both P atoms are partially double-bonded to O on the lower left and lower right. The O atoms have an overall negative charge. The terminal P atom of the zigzag chain is single-bonded to the O atom which in turn is single-bonded to C 1 of a 6-membered heterocyclic hexagonal ring in a horizontal orientation. It consists of 1 O and 5 C atoms. O occupies the top right vertex. C 2 and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above.



The structure of sucrose 6 (F)-phosphate is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single bonded to C H 2 O P O 3 superscript 2 minus below. C 2 is single bonded to O H above. C 3 is single bonded to O H below. C 4 is single bonded to C H 2 O H above and O on the lower left. This O atom is single-bonded to

C 1 of a 6-membered heterocyclic hexagonal ring in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 O and 5 C atoms. O occupies the top right vertex. C 2 and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above.

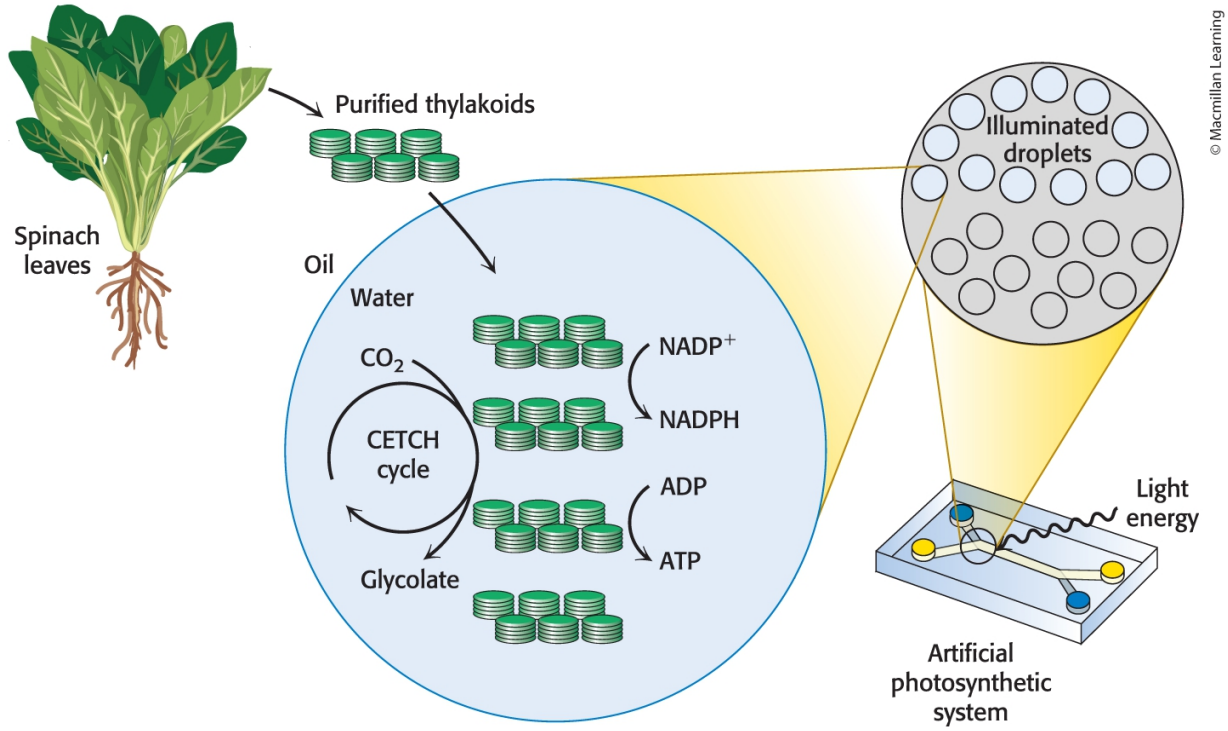
The structure of U D P is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 2 and C 3 are single bonded to O H below. C 1 is single-bonded to N 1 of a 6-membered heterocyclic hexagonal ring in a vertical orientation with C 1 occupying the bottom left vertex. It consists of 2 N and 4 C atoms. First N occupies the bottom-most vertex. The second N bound to H occupies the top left vertex. C 1 and C 2 are double bonded to O. A double bond is present between C 3 and C 4. C 4 of the pentagonal ring is single-bonded to C H 2 above in the form of a line. C H 2 is single bonded to O, single bond, P, single bond, O, single bond, P in a zigzag conformation. The first P atom is partially double-bonded to O on the lower left and lower right. The O atoms have an overall negative charge. The terminal P atom is partially double-bonded to O on the upper left, lower left, and lower right. The O atoms have an overall negative charge of 2 minus.

Return to FIGURE 20.12 Carbohydrates are stored as sucrose

Extended description for Conversion of crotonyl-C o A to ethylmalonyl-C o A and butyryl-C o A

The structure of crotonyl-C o A is as follows: A 1 S and 3 C heteronuclear alkene chain is depicted as a line structure using 3 zigzag lines. S occupies the fourth position and is single-bonded to C o A on the upper right. C 1 is single bonded to R on the lower left. C 3 is double bonded to O above. A double bond is present between C 1 and C 2.

A bifurcated forward arrow is shown. It shows the entry of N A D P H. The top branch of the arrow shows the entry of C O 2 and leads to open parenthesis 2 S close parenthesis-Ethylmalonyl-C o A.



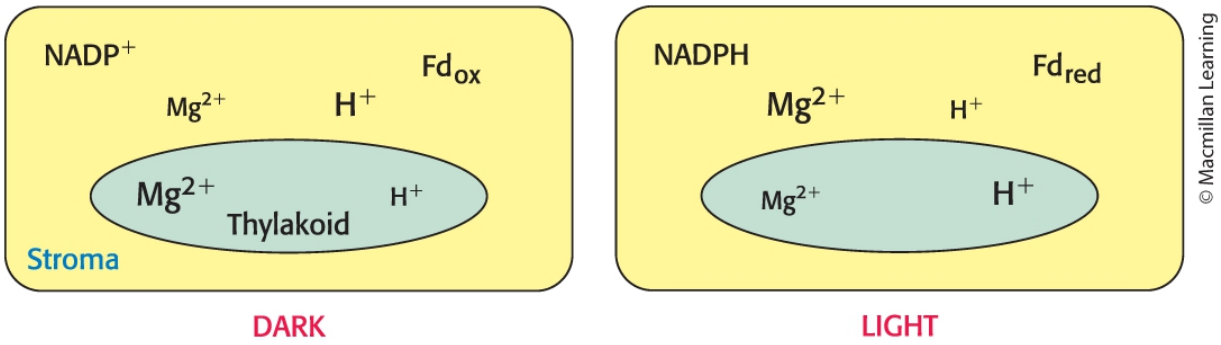
The structure of open parenthesis 2 S close parenthesis-Ethylmalonyl-C o A is as follows: A 1 S and 3 C heteronuclear alkene chain is depicted as a line structure using 3 zigzag lines. S occupies the fourth position and is single-bonded to C o A on the upper right. C 1 is single bonded to R on the lower left. C 2 is dash bonded to C O 2 superscript minus below. C 3 is double bonded to O above.

The bottom branch of the arrow shows the entry of the H superscript plus ion and leads to butyryl-C o A.

The structure of butyryl-C o A is as follows: A 1 S and 4 C heteronuclear alkene chain is depicted as a line structure using 4 zigzag lines. S occupies the fifth position and is single-bonded to C o A on the upper right. C 3 is dash bonded to H below. C 4 is double bonded to O above.

Return to Conversion of crotonyl-C o A to ethylmalonyl-C o A and butyryl-C o A

Extended description for FIGURE 20.13 Scientists have engineered artificial photosynthesis using alternative C O 2 fixation pathways

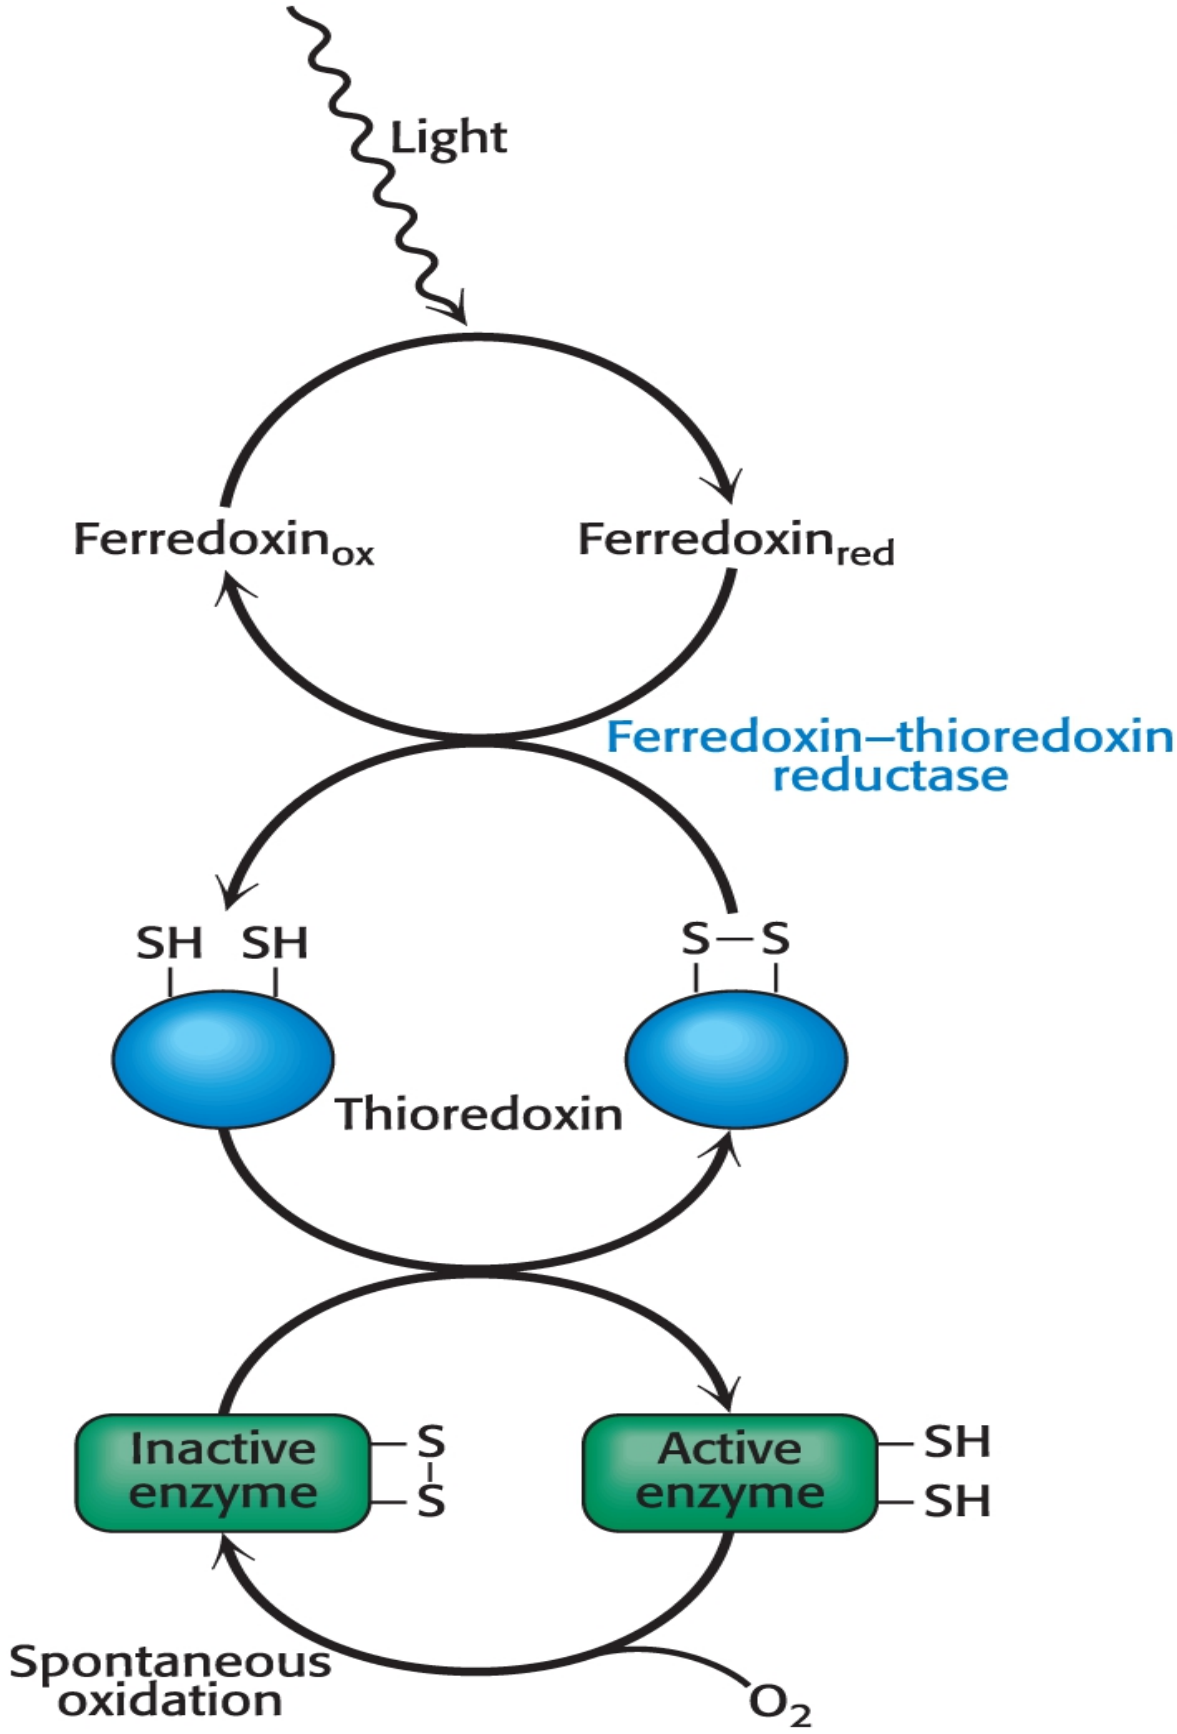


The artificial photosynthetic system is shown. A wavy arrow labeled light energy is falling on the system. An enlarged view of the part illuminated by light shows a large circle with several tiny circles. The circles at the top are shown in blue and labeled illuminated droplets. One of the blue circles is enlarged. It contains 4 sets of stacked discs of thylakoids arranged in two rows from top to the bottom. The interior of the circle is labeled water and the space outside it is labeled oil. Arrows depict the reduction of N A D P superscript plus to N A D P H and hydrolysis of A D P to A T P by the thylakoids. A curved arrow next to the thylakoid disc is labeled "CETCH cycle". C O 2 enters this cycle and glycolate is released. A bundle of spinach leaves is shown outside the circle. An arrow from

the leaves depict the purified thylakoid discs and another arrow from the purified thylakoid points toward the thylakoid discs inside the blue circle.

Return to FIGURE 20.13 Scientists have engineered artificial photosynthesis using alternative C O 2 fixation pathways

Extended description for FIGURE 20.14 Light regulates the Calvin–Benson cycle

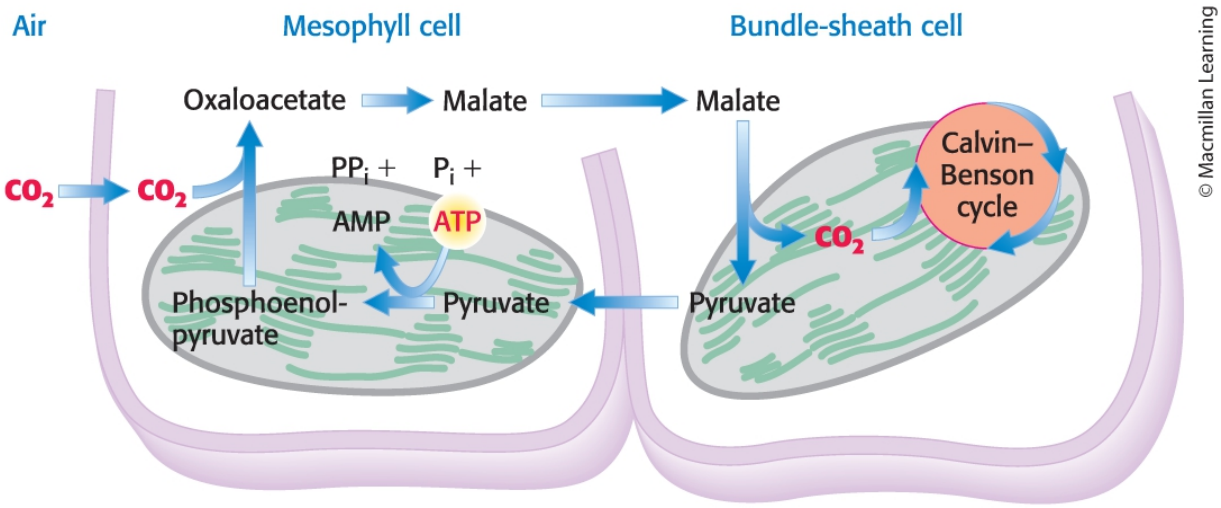


The figure has two panels. The first panel on the left is labeled dark. It consists of an oval region labeled thylakoid. The region outside the thylakoid is labeled stroma. M g superscript 2 plus and H superscript plus ions are present in the thylakoid. N A D P superscript plus, F d oxidized, M g superscript 2 plus, and H superscript plus ions are present in the stroma. The second panel on the right is labeled light. It consists of an oval region labeled thylakoid. The region outside the thylakoid is labeled stroma. M g superscript 2 plus and H superscript plus ions are present in the thylakoid. N A D P H, F d reduced, M g superscript 2 plus, and H superscript plus ions are present in the stroma.

Return to FIGURE 20.14 Light regulates the Calvin–Benson cycle

Extended description for FIGURE 20.16 Thioredoxin

can activate enzymes by reducing them

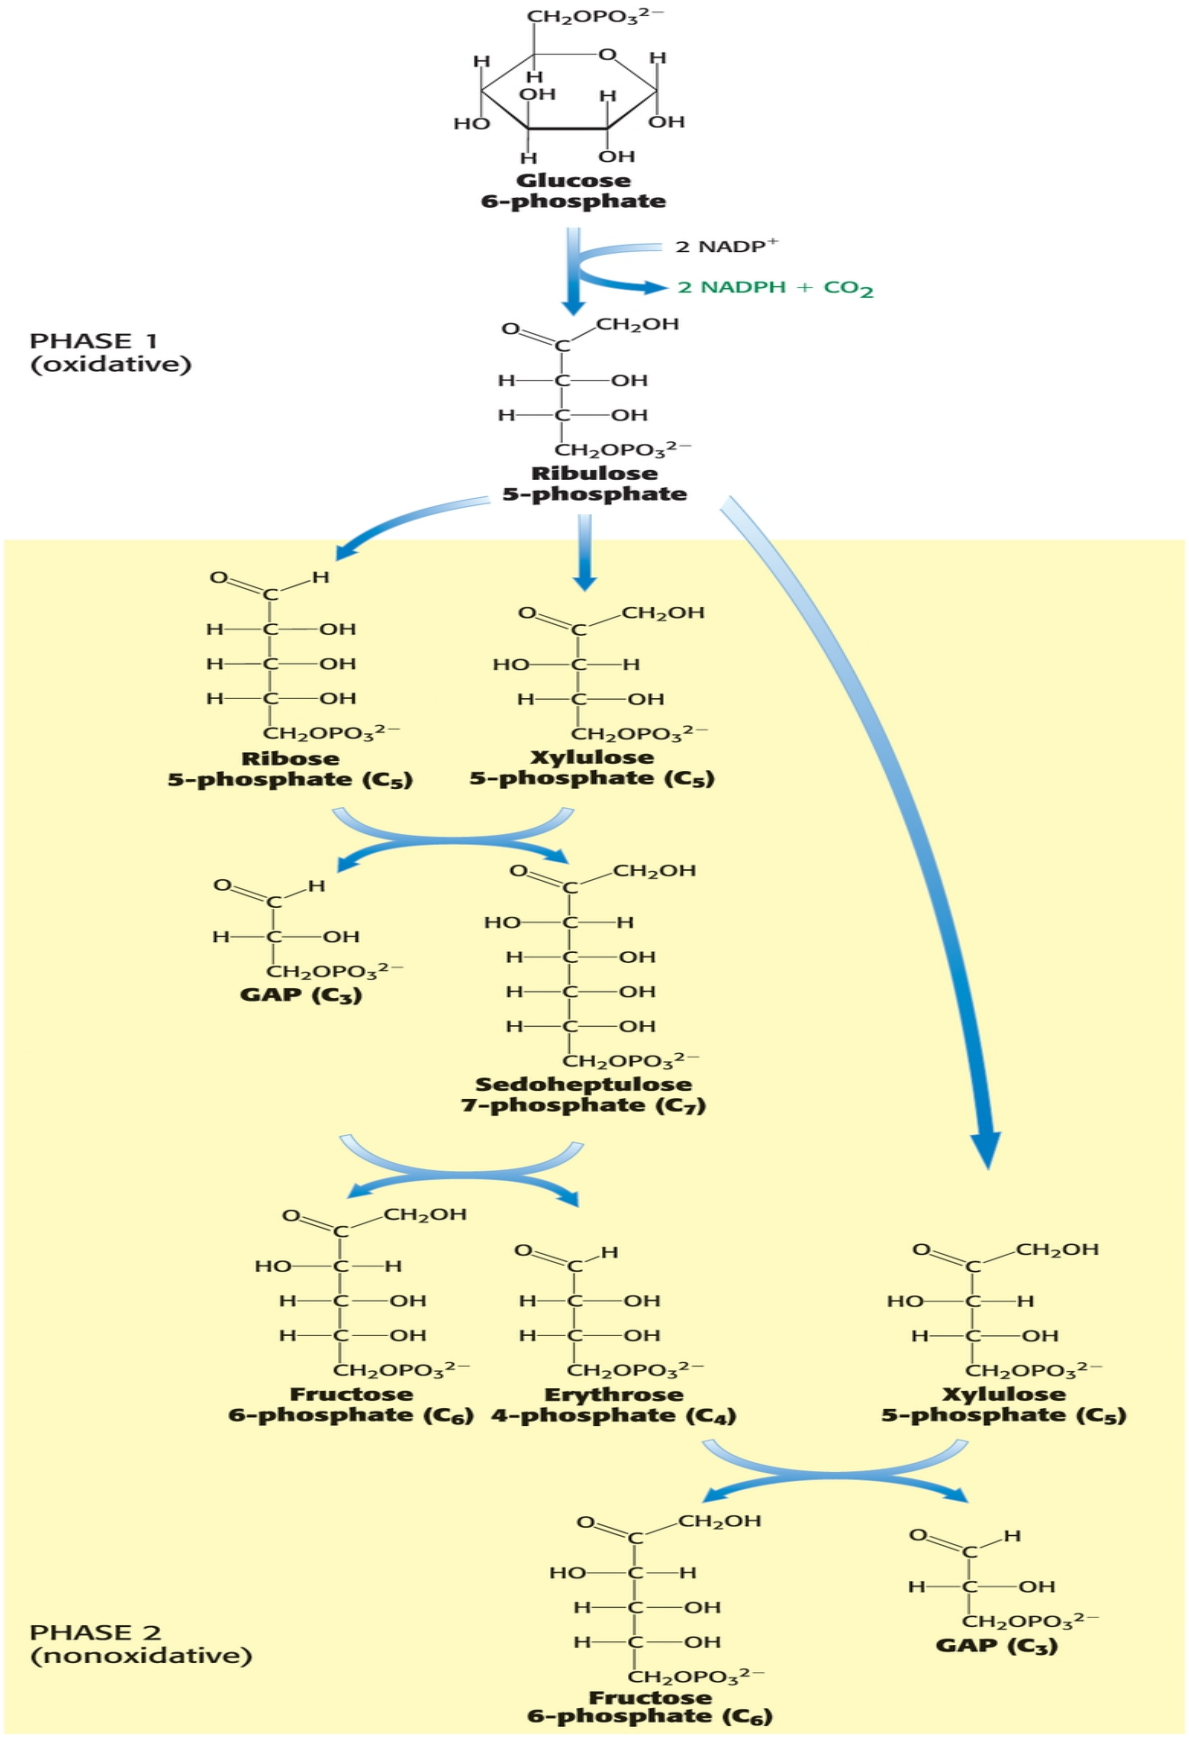


© Macmillan Learning

Light depicted as a wavy arrow stimulates the conversion of the ferredoxin oxidized form to the ferredoxin reduced form. The reduced form transfers electrons to oxidized thioredoxin in a reaction catalyzed by ferredoxin-thioredoxin reductase. The oxidized thioredoxin is depicted as a blue circle single bonded to two S atoms. These S atoms are also single-bonded. The reduced thioredoxin is depicted as a blue circle single bonded to two S H groups above. The reduced thioredoxin converts an inactive enzyme to an active enzyme. The inactive enzyme is depicted as a green rectangle single-bonded to two S atoms. These S atoms are also single-bonded to each other. The active enzyme is depicted as a green rectangle single bonded to two S H groups. Spontaneous oxidation that involves the addition of O 2 can convert the active enzyme back to its inactive form.

Return to FIGURE 20.16 Thioredoxin can activate enzymes by reducing them

Extended description for FIGURE 20.17 The C 4 pathway can concentrate C O 2



An open section of mesophyll cell attached laterally to a bundle-sheath cell is shown. The region outside the cells is labeled air. Both cells contain chloroplast with stacked thylakoids. C O 2 from the air enters the mesophyll cell. This C O 2 is combined with phosphoenolpyruvate from chloroplast to produce oxaloacetate in the cytoplasm. Oxaloacetate is converted to malate which is transported to the bundle-sheath cell. The malate molecule is converted into pyruvate and C O 2 inside the chloroplast of the bundle-sheath cell. C O 2 enters the Calvin-Benson cycle operating inside the chloroplast of the bundle-sheath cell. Pyruvate is transported back to the mesophyll cell. Inside the chloroplast of the mesophyll cell, pyruvate is converted back to phosphoenolpyruvate with the simultaneous hydrolysis of A T P to A M P.

Return to FIGURE 20.17 The C 4 pathway can concentrate C O 2

Extended description for FIGURE 20.21 The pentose phosphate pathway consists of an oxidative and a

nonoxidative phase

© Macmillan Learning

The events of phase 1 (oxidative) are as follows:

In the first step, glucose 6-phosphate is converted to ribulose 5-phosphate with the simultaneous reduction of 2 N A D P superscript plus to 2 N A D P H and release of C O 2.

The structure of glucose 6-phosphate is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1, C 2, and C 4 are single bonded to H above and O H below. C 3 is single bonded to O H above and H below. C 5 is single bonded to C H 2 O P O 3 superscript 2 minus above and H below.

The structure of ribulose 5-phosphate is as follows: C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 and C 3 are each single bonded to H on the left and O H on the right.

The events of phase 2 (non-oxidative) are as follows:

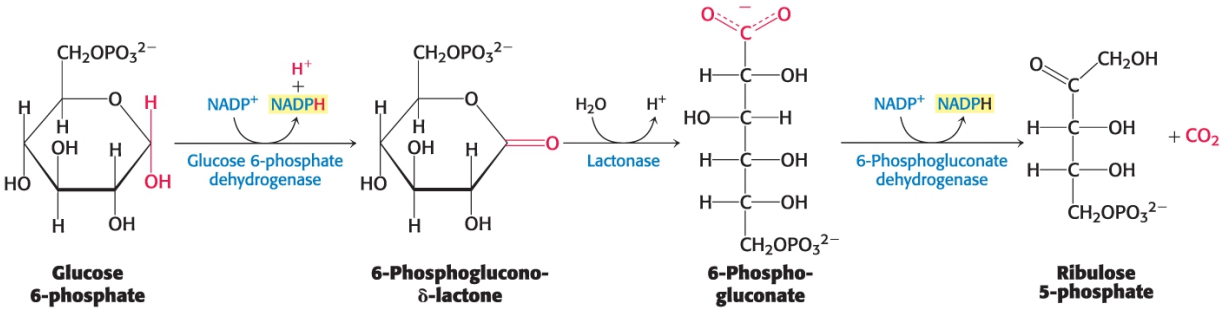
In the first step, ribulose 5-phosphate is converted into ribose 5-phosphate (C 5) and xylulose 5-phosphate (C 5). Ribulose 5-phosphate can also be directly converted into xylulose 5-phosphate. The structure of ribose 5-phosphate is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double-bonded to O on the upper left and single-bonded to H on the upper right. C 2 to C 4 are each single bonded to H on the left and O H on the right.

The structure of xylulose 5-phosphate is as follows: C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2

O H on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 is single bonded to H on the left and O H on the right. Ribose 5-phosphate and xylulose 5-phosphate are further converted into G A P (C 3) and sedoheptulose 7-phosphate (C 7).

The structure of glyceraldehyde 3-phosphate (G A P) is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double-bonded to O on the upper left and single-bonded to H on the upper right. C 2 is single-bonded to H on the left and O H on the right. The structure of sedoheptulose 7-phosphate is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 to C 5 are single-bonded to H on the left and O H on the right.

Sedoheptulose 7-phosphate and G A P are further converted to fructose 6-phosphate (C 6) and erythrose 4-phosphate (C 4).



The structure of fructose 6-phosphate is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 and C 4 are each single bonded to H on the left and O H.

The structure of erythrose 4-phosphate is as follows: C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double-bonded to O on the upper left and single-bonded to H on the upper right. C 2 and C 3 are each single bonded to H on the left and O H on the right.

Erythrose 4-phosphate and xylulose 5-phosphate (C 5) are converted into fructose 6-phosphate (C 6) and G A P.

Return to FIGURE 20.21 The pentose phosphate pathway consists of an oxidative and a nonoxidative phase

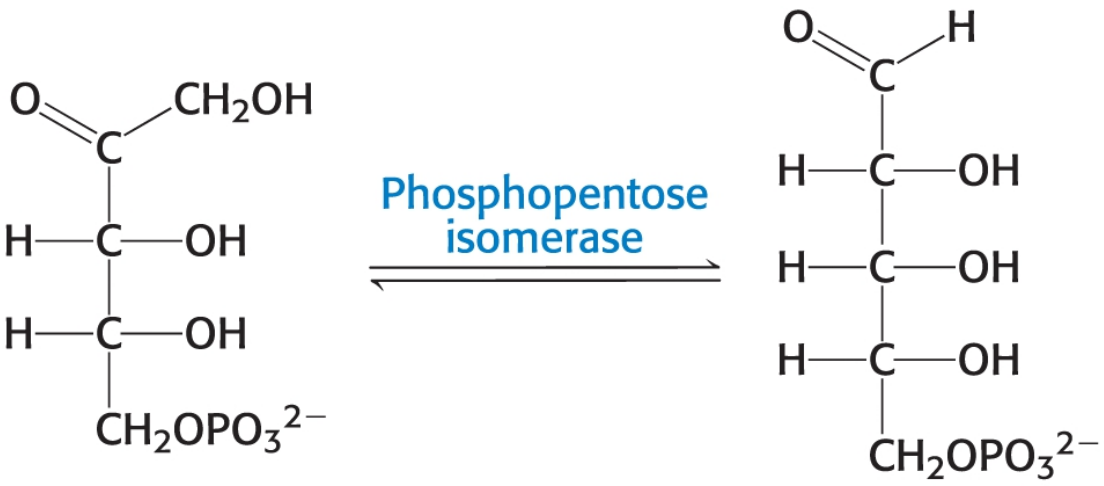
Extended description for FIGURE 20.22 The oxidative phase of the pentose phosphate pathway yields two molecules of NADPH

In the first step, glucose 6-phosphate is irreversibly converted into 6-phosphoglucono-delta-lactone by glucose 6-phosphate dehydrogenase. It is coupled with the reduction of N A D P superscript plus to N A D P H plus H superscript plus.

The structure of glucose 6-phosphate is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1, C 2, and C 4 are single bonded to H above and O H below. C 3 is single bonded to O H above and H below. C 5 is single bonded to C H 2 O P O 3 superscript 2 minus above and H below.

The structure of 6-phosphoglucono-delta-lactone is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1 is double bonded to O on the right. C 2 and C 4 are each single bonded to H above and O H below. C 3 is single bonded to O H above and H below. C 5 is single bonded to C H 2 O P O 3 superscript 2 minus above and H below.

In the second step, 6-phosphoglucono-delta-lactone is irreversibly converted into 6-phosphogluconate by lactonase. It is coupled with the entry of H 2 O and the release of H superscript plus ion.



The structure of 6-phosphogluconate is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is partially double bonded to O on the upper left and upper right. This C O O group has an overall negative charge. C 2, C 4, and C 5 are each single bonded to H on the left and O H on the right. C 3 is single bonded to O H on the left and H on the right.

In the third step, 6-phosphogluconate is irreversibly converted into ribulose 5-phosphate by 6-phosphogluconate dehydrogenase and C O 2. It is coupled with the reduction of N A D P superscript plus to N A D P H.

The structure of ribulose 5-phosphate is as follows: C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 and C 3 are each single bonded to H on the left and O H on the right.

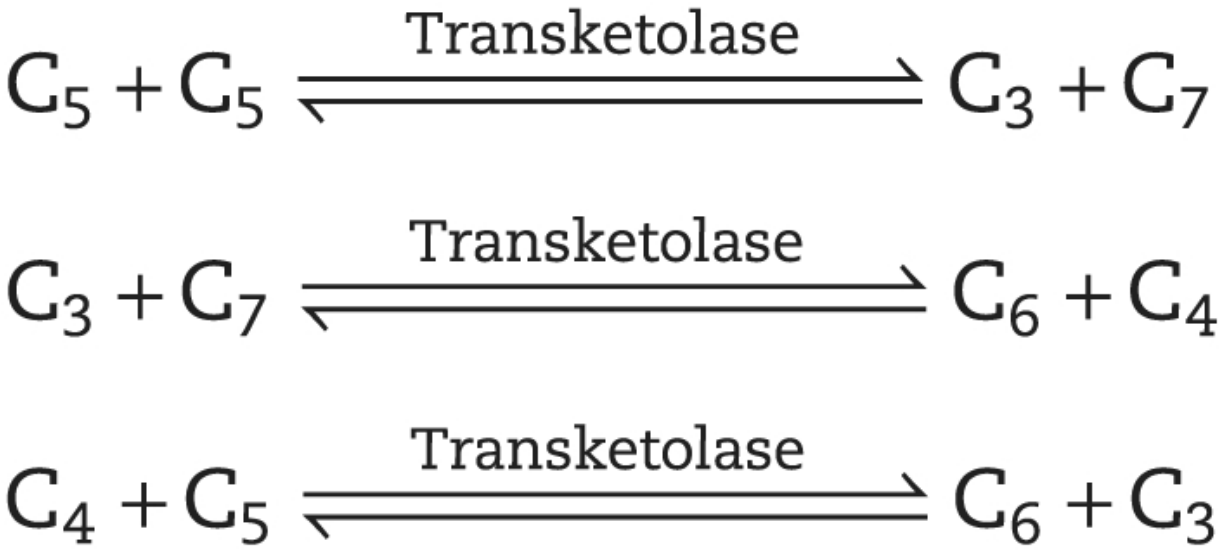
Extended description for Formation of ribose 5-phosphate

Ribulose 5-phosphate **Ribose 5-phosphate**

Ribulose 5-phosphate is reversibly converted to ribose 5-phosphate in the presence of phosphopentose isomerase.



The structure of ribulose 5-phosphate is as follows: The Fischer projection consists of a vertical line with C above and C H 2 O P O 3 superscript 2 minus below. The projection contains 2 C atoms placed one below the other on a vertical line. The C atoms are numbered from top to bottom. C 1 is double bonded to O on the top left and single bonded to C H 2 O H on the top right. C 2 and C 3 are each single bonded to H on the left and O H on the right.

The structure of ribose 5-phosphate is as follows: The Fischer projection consists of a vertical line with C above and C H 2 O P O 3 superscript 2 minus below. The projection contains 3 C atoms placed one below the other on a vertical line. The C atoms are numbered from top to bottom. C 1 is double bonded to O on the top left and

single bonded to H on the top right. C 2, C 3, and C 4 are each single bonded to H on the left and O H on the right.

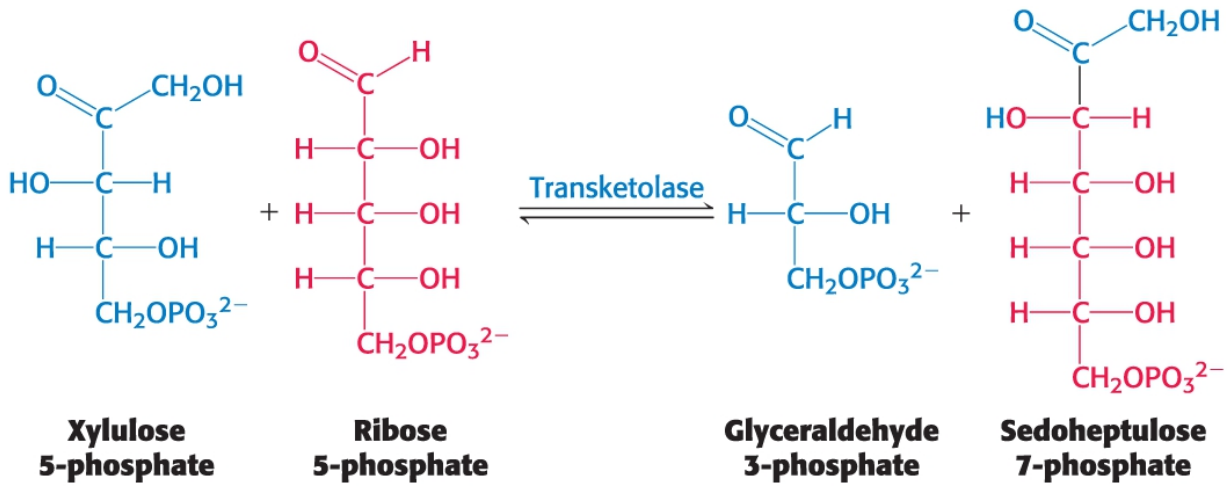
Extended description for Reactions catalyzed by transketolase



The first reaction consists of two reactants and two products. The reactants are C 5 and C 5. The products are C 3 and C 7.

The second reaction consists of two reactants and two products. The reactants are C 3 and C 7. The products are C 6 and C 4.

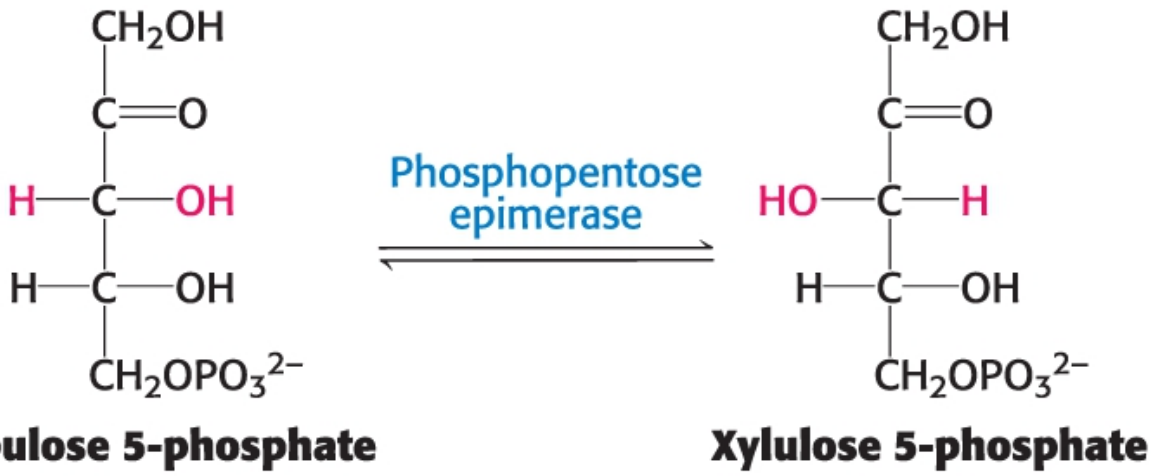
The third reaction consists of two reactants and two products. The reactants are C 4 and C 5. The products are C 6 and C 3.

Return to Reactions catalyzed by transketolase

Extended description for Reaction catalyzed by transketolase

Transketolase catalyzes a reversible reaction that involves the conversion of xylulose 5-phosphate and ribose 5-phosphate to glyceraldehyde 3-phosphate and sedoheptulose 7-phosphate.

The structure of xylulose 5-phosphate is as follows: C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 is single bonded to H on the left and O H on the right.



The structure of ribose 5-phosphate is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double-bonded to O on the upper left and single-bonded to H on the upper right. C 2 to C 4 are each single bonded to H on the left and O H on the right.

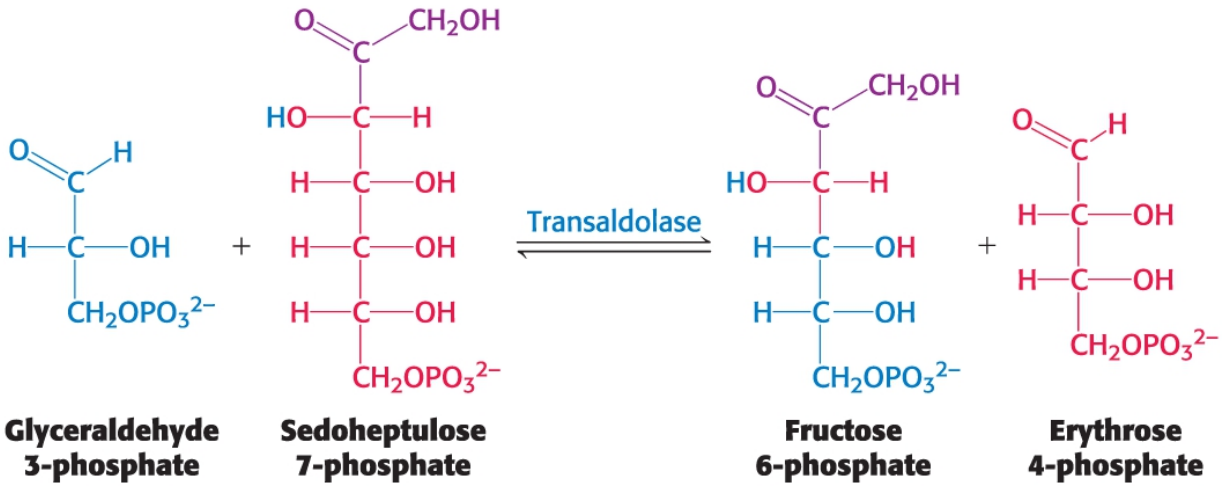
The structure of glyceraldehyde 3-phosphate is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double-bonded to O on the upper left and single-bonded to H on the upper right. C 2 is single-bonded to H on the left and O H on the right.

The structure of sedoheptulose 7-phosphate is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 to C 5 are single-bonded to H on the left and O H on the right.

Return to Reaction catalyzed by transketolase

Extended description for Formation of xylulose 5-phosphate

Ribulose 5-phosphate **Xylulose 5-phosphate**



Ribulose 5-phosphate is reversibly converted to xylulose 5-phosphate in the presence of phosphopentose epimerase.

The structure of ribulose 5-phosphate is as follows: The Fischer projection consists of a vertical line with C H 2 O H above and C H 2 O P O 3 superscript 2 minus below. The projection contains 3 C atoms placed one below the other on a vertical line. The C atoms are numbered from top to bottom. C 2 is double bonded to O on the right. Return to Formation of xylulose 5-phosphate

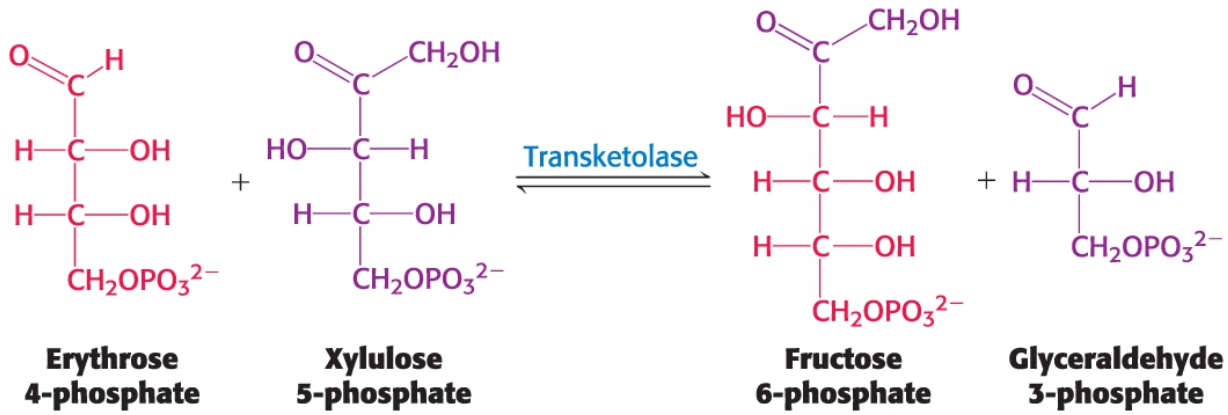
Extended description for Reaction catalyzed by transaldolase

Transaldolase catalyzes a reversible reaction that produces fructose 6-phosphate and erythrose 4-phosphate from glyceraldehyde 3-phosphate and sedoheptulose 7-phosphate.

The structure of glyceraldehyde 3-phosphate is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double-bonded to O on the upper left and single-bonded to H on the upper right. C 2 is single-bonded to H on the left and O H on the right.



The structure of sedoheptulose 7-phosphate is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 to C 5 are single-bonded to H on the left and O H on the right.

The structure of fructose 6-phosphate is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 and C 4 are each single bonded to H on the left and O H.

The structure of erythrose 4-phosphate is as follows: C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double-bonded to O on the upper left and single-bonded to H on the upper right. C 2 and C 3 are each single bonded to H on the left and O H on the right.

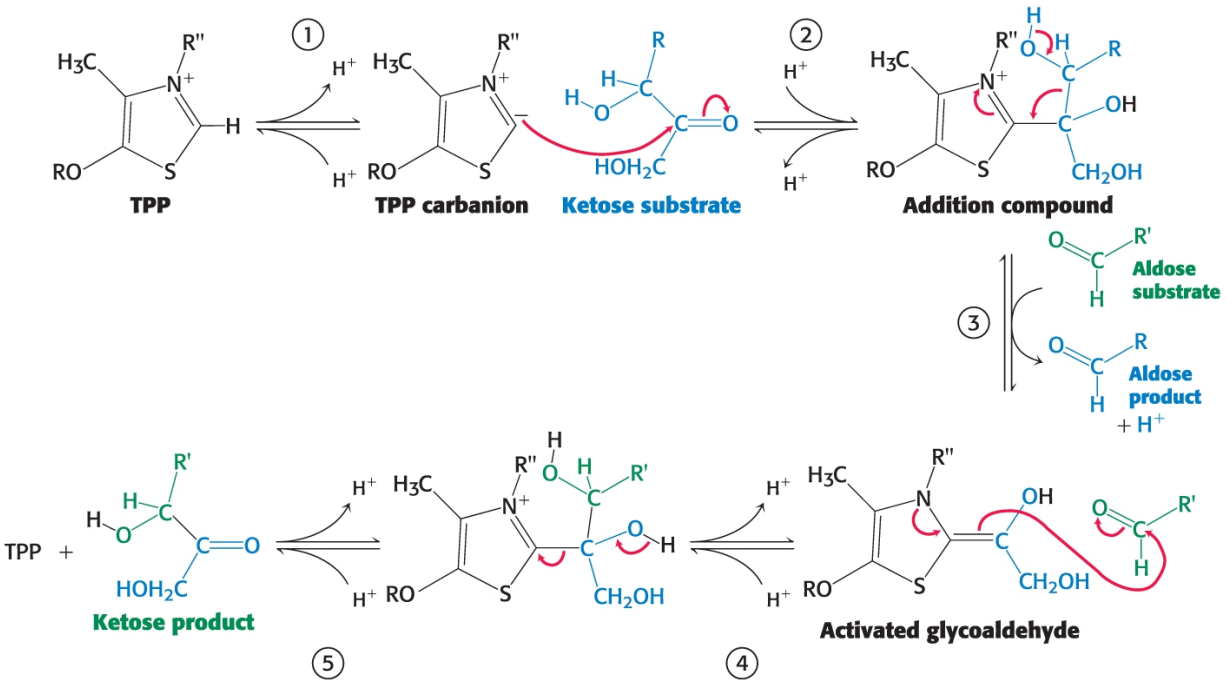
Return to Reaction catalyzed by transaldolase

Extended description for Reaction catalyzed by transketolase

Transketolase catalyzes a reversible reaction that involves the conversion of erythrose 4-phosphate and xylulose 5-phosphate to fructose 6-phosphate and glyceraldehyde 3-phosphate.

The structure of erythrose 4-phosphate is as follows: C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double-bonded to O on the upper left and single-bonded to H on the upper right. C 2 and C 3 are each single bonded to H on the left and O H on the right.

The structure of xylulose 5-phosphate is as follows: C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 is single bonded to H on the left and O H on the right.



The structure of fructose 6-phosphate is as follows: C, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3

superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C H 2 O H on the upper right. C 2 is single bonded to O H on the left and H on the right. C 3 and C 4 are each single bonded to H on the left and O H.

The structure of glyceraldehyde 3-phosphate is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double-bonded to O on the upper left and single-bonded to H on the upper right. C 2 is single-bonded to H on the left and O H on the right.

Return to Reaction catalyzed by transketolase

Extended description for FIGURE 20.23 The transketolase reaction takes place on thiamine pyrophosphate

The conversion of ketose substrate to ketose product takes place in five sequential steps.

In the first step, T P P is converted into a T P P carbanion.

The structure of T P P is as follows: A 5-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 N, 1 S, and 3 C atoms. N with a positive charge occupies the top right vertex. S occupies the bottom right vertex. A double bond is present between N and C 1, and C 2 and C 3. N is single bonded to R double dash on the upper right. C 1 is single bonded to H on the right. C 2 is single bonded to O R on the lower left. C 3 is single bonded to C H 3 on the upper left.

A reversible reaction arrow shows the release of the H superscript plus ion as the reaction proceeds forward and the entry of the H superscript plus as the reaction proceeds backward.

The structure of the T P P carbanion is as follows: A 5-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 N, 1 S, and 3 C atoms. N with a positive charge occupies the top right vertex. S occupies the bottom right vertex. A double bond is present between N and C 1, and C 2 and C 3. N is single bonded to R double dash on the upper right. C 2 is single bonded to O R on the lower left. C 3 is single bonded to C H 3 on the upper left. C 1 has a negative charge.

In the second step, the ketose substrate reacts with T P P carbanion to form an addition compound.

The structure of the ketose substrate is as follows: C, single bond, C. C 1 is single bonded to H on the left, R on the upper right, and O on the lower left. O atom is single-bonded to H on the upper left. C 2 is double bonded to O on the right and single bonded to C H 2 O H on the lower left.

A red curved arrow points from C 1 of T P P carbanion to C 2 of ketose substrate. Another red curved arrow points from the double bond between C 2 and O of the ketose substrate toward the O atom.

A reversible reaction arrow shows the entry of the H superscript plus ion as the reaction proceeds forward and the release of the H superscript plus as the reaction proceeds backward.

The structure of the addition compound is as follows: A 5-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 N, 1 S, and 3

C atoms. N with a positive charge occupies the top right vertex. S occupies the bottom right vertex. A double bond is present between N and C 1, and C 2 and C 3. N is single bonded to R double dash on the upper right. C 2 is single bonded to O R on the lower left. C 3 is single bonded to C H 3 on the upper left. C 1 is single bonded to C, single bond, O H on the right. This C atom is single-bonded to C above and C H 2 O H below. The C atom above is further single bonded to O, single bond, H on the upper left, H above, and R on the upper right.

A red curved arrow points from the single bond between O and H on the upper left toward the single bond between O and the C atom located above. A second red curved arrow points from the single bond between the C atom on the right and C above toward the single bond between C 1 of the ring and the C atom on the right. A third red-curved arrow points from the double bond between N and C 1 toward the N atom of the ring.

In the third step, the addition compound is converted into activated glycoaldehyde with the simultaneous conversion of aldose substrate to aldose product.

A reversible reaction arrow leads to the activated glycoaldehyde.

The structure of the aldose substrate is as follows: A central C atom is double bonded to O on the upper left, single bonded to R dash on the upper right, and H below.

The structure of the aldose product is as follows: A central C atom is double bonded to O on the upper left, single bonded to R on the upper right, and single bonded to H below.

An H superscript plus ion is also produced during this coupled conversion.

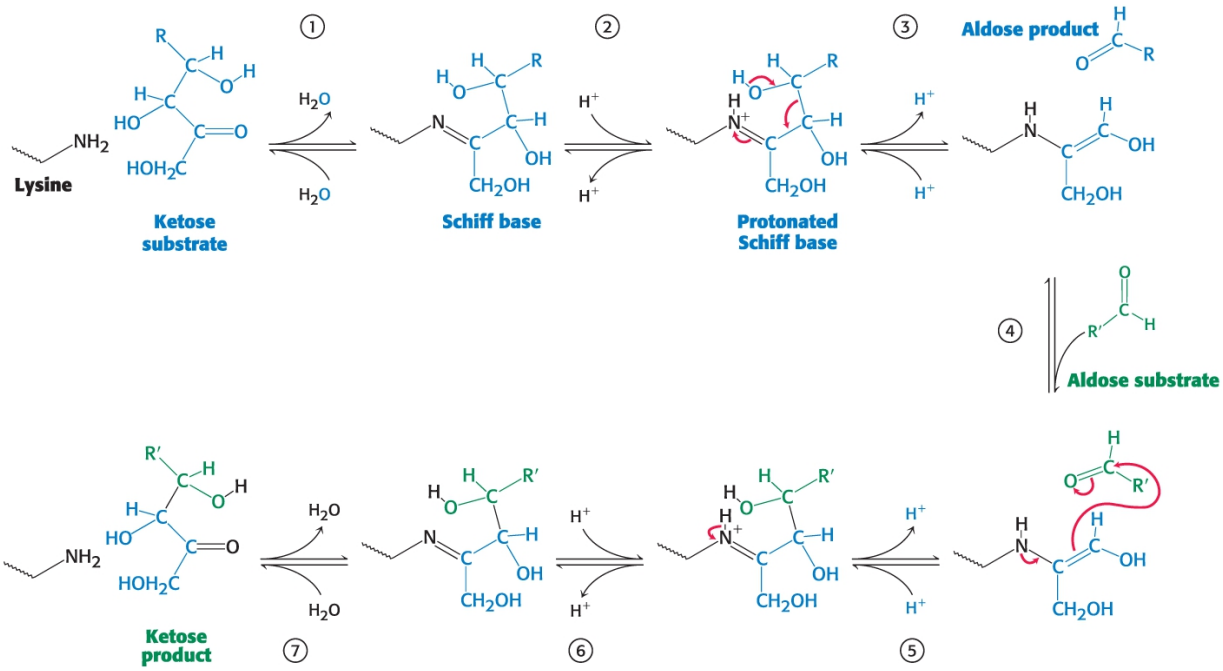
The structure of the activated glycoaldehyde is as follows: A 5-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 N, 1 S, and 3 C atoms. N occupies the top right vertex. S occupies the bottom right vertex. A double bond is present between C 2 and C 3. N is single bonded to R double dash on the upper right. C 2 is single bonded to O R on the lower left. C 3 is single bonded to C H 3 on the upper left. C 1 is double bonded to C on the right. This C atom is single-bonded to O H on the upper right and C H 2 O H on the lower right.

A red curved arrow points from the N atom to the C 1 atom of the pentagonal ring. A second red curved arrow points from the double bond between C 1 and C on the right toward the central C atom of the aldose substrate. A third red-curved arrow points from the double bond between the central C atom and O toward the O atom. In the fourth step, activated glycoaldehyde is converted into another intermediate.

A reversible reaction arrow shows the entry of the H superscript plus ion as the reaction proceeds forward and the release of the H superscript plus as the reaction proceeds backward.

The structure of the intermediate is as follows: A 5-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 N, 1 S, and 3 C atoms. N with a positive charge occupies the top right vertex. S occupies the bottom right vertex. A double bond is present between N and C 1, and C 2 and C 3. N is single bonded to R double dash on the upper right. C 2 is single bonded to O R on the lower left. C 3 is single bonded to C H 3 on the upper left. C 1 is single bonded to C, single bond, O, single bond, H on the right. This C atom is single-bonded to

C above and C H 2 O H below. The C atom above is further single bonded to O, single bond, H on the upper left, H above, and R on the upper right.



A red curved arrow points from the single bond between O and H on the right toward the single bond between the O and the C atom on the right. A second red curved arrow points from the single bond between the C atom on the right and C 1 toward the C 1 atom of the ring.

In the fifth step, the intermediate is converted into a ketose product. A reversible reaction arrow shows the entry of the H superscript plus ion as the reaction proceeds forward and the release of the H superscript plus as the reaction proceeds backward.

The structure of the ketose product is as follows: A central C atom is single-bonded to C on the upper left, C H 2 O H on the lower right, and double-bonded to O on the right. The C atom on the upper left is single bonded to O, single bond, H on the lower left, H on the upper left, and R dash on the upper right.

Return to FIGURE 20.23 The transketolase reaction takes place on thiamine pyrophosphate

Extended description for FIGURE 20.24 The transaldolase reaction involves a Schiff base intermediate

The conversion of ketose substrate into ketose product takes place in 7 steps.

In the first step, the ketose substrate and lysine side chain form a Schiff base.

The structure of the ketose substrate is as follows: A 3-carbon alkane chain is shown in a zigzag vertical orientation. From top to bottom, C 1 is single bonded to R on the upper left, H on the upper right, and O, single bond, H on the lower right. C 2 is single bonded to H on the left and O H on the lower right. C 3 is double bonded to O on the right and single bonded to C H 2 O H on the lower left.

The lysine side chain is depicted as a C atom single bonded to N H 2 on the upper right. It has a wiggly line on the upper left.

A reversible reaction arrow shows the release of H 2 O as the reaction proceeds forward and the entry of H 2 O as the reaction proceeds backward.

The structure of the Schiff base is as follows: The C 3 atom of the ketose substrate becomes double bonded to the N atom of the lysine side chain. The N atom loses 2 H and the C 3 loses the O atom.

A reversible reaction arrow shows the entry of H superscript plus ion as the reaction proceeds forward and the release of H superscript plus ion as the reaction proceeds backward.

In the second step, the Schiff base is converted into protonated Schiff base.

The structure of the protonated Schiff base is as follows: The N atom of the lysine side chain is single-bonded to H above and becomes positively charged. A curved arrow from the single bond between the O and H atoms points toward the single bond between the O atom and C 1. A second curved arrow points from the single bond between C 1 and C 2 toward the single bond between C 2 and C 3. A third curved arrow points from the double bond between C 3 and N with a positive charge toward the N atom.

A reversible reaction arrow shows the exit of the H superscript plus ion as the reaction proceeds forward and the entry of the H superscript plus ion as the reaction proceeds backward.

In the third step, the protonated Schiff base is converted into another compound and aldose product.

The structure of the compound is as follows: 1 N and 2 C alkane chains are depicted as a zigzag structure. N single-bonded to H occupies the first position. The remaining positions are occupied by C atoms. C 1 is single bonded to C H 2 O H below. A double bond is present between C 1 and C 2. C 2 is single bonded to H above and O H on the lower right. The N atom is single-bonded to C on the lower right. This C has a wiggly line on the upper left.

The structure of the aldose product is as follows: A central C atom is single bonded to H above, double bonded to O on the lower left, and single bonded to R on the lower right.

In the fourth reversible step, the aldose substrate enters.

The structure of the aldose substrate is as follows: A central C atom is double bonded to O above, single bonded to R dash on the lower left, and single bonded to H on the lower right.

The product side shows rearrangement between the compound formed in step 3 and the aldose substrate.

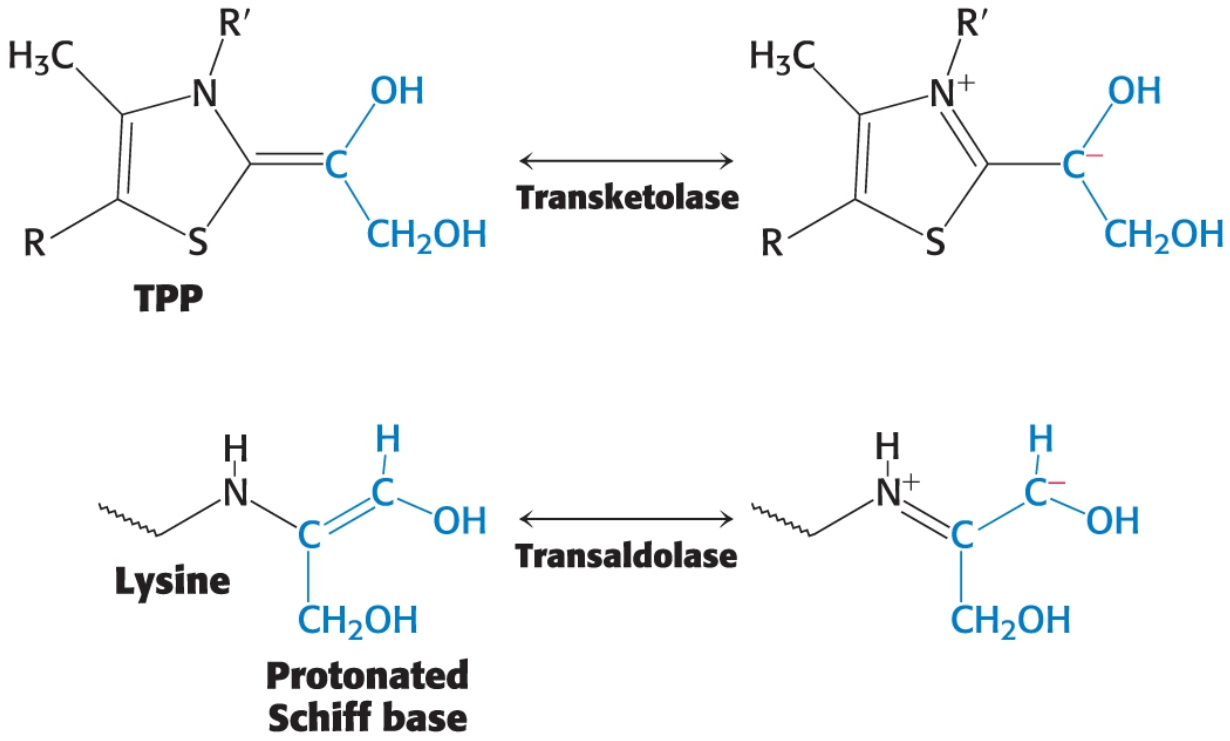
A curved arrow from the N atom of the substrate points toward its single bond with C 1. A second curved arrow points from the double bond between C 1 and C 2 toward the central C atom of the aldose substrate. A third curved arrow points from the double bond between the central C atom and O atom of the aldose substrate toward the O atom.

A reversible reaction arrow shows the entry of H superscript plus ion as the reaction proceeds forward and the exit of H superscript plus ion as the reaction proceeds backward.

In the fifth reversible step, the central C atom of the aldose substrate becomes single-bonded to C 2 of the compound formed in step 3. The central C atom is single bonded to O, single bond, H on the left, H above, and R dash on the upper right. The N atom of the lysine side chain becomes double bonded to C 1 and acquires a positive charge. A curved arrow from the single bond between N and H atoms points to the N atom.

A reversible reaction arrow shows the exit of the H superscript plus ion as the reaction proceeds forward and the entry of the H superscript plus ion as the reaction proceeds backward.

In the sixth step, an intermediate compound is formed.



The structure of the intermediate compound is the same as the compound formed in step 5, except the N atom of the lysine side chain does not have a positive charge as the H atom is released. A reversible reaction arrow shows the entry of H 2 O as the reaction proceeds forward and the exit of H 2 O as the reaction proceeds backward.

In the seventh step, the ketose product is formed.

In the ketose product, the double bond between the N atom of the lysine side chain and C 1 is broken. The N atom binds to two H atoms to form N H 2 group. C 1 becomes double bonded to O and the remaining structure is the same as the product in step 6.

Return to FIGURE 20.24 The transaldolase reaction involves a Schiff base intermediate

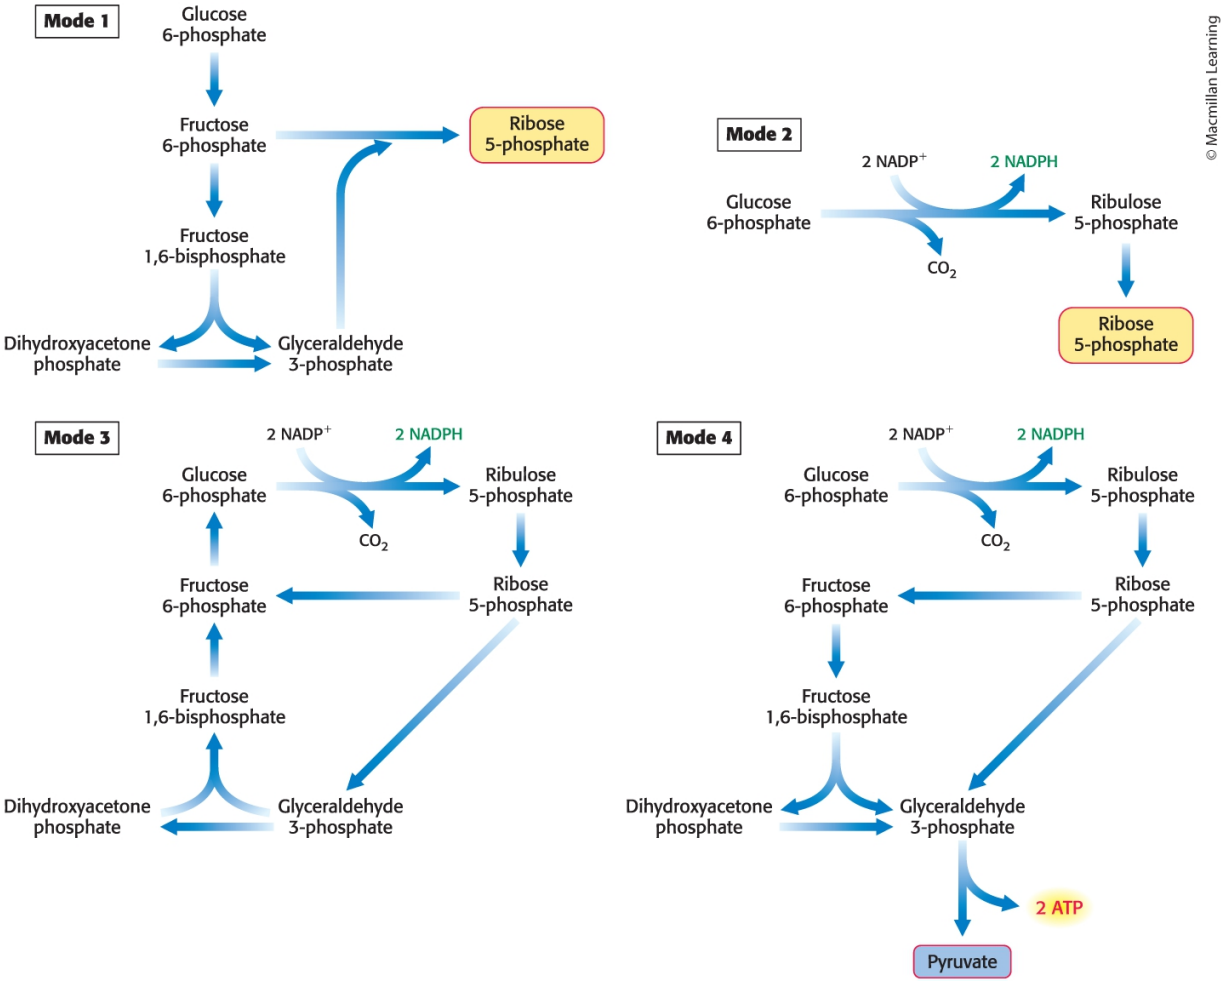
Extended description for FIGURE 20.25 For transketolase and transaldolase, a carbanion intermediate is stabilized by resonance

The resonance structures of T P P bound to a compound are separated by a double-headed horizontal arrow labeled transketolase.

The left structure is as follows: A 5-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 N, 1 S, and 3 C atoms. N occupies the top right vertex. S occupies the bottom right vertex. A double bond is present between C 2 and C 3. N is single-bonded to the R dash on the upper right. C 1 is double bonded to C on the right. This C is further single bonded to O H on the upper right and C H 2 O H

on the lower right. C 2 is single bonded to R on the lower left. C 3 is single bonded to C H 3 on the upper left.

The right structure is as follows: A 5-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 N, 1 S, and 3 C atoms. N with a positive charge occupies the top right vertex. S occupies the bottom right vertex. A double bond is present between N and C 1, and C 2 and C 3. N is single-bonded to the R dash on the upper right. C 1 is single bonded to C superscript minus on the right. C superscript minus is further single bonded to O H on the upper right and C H 2 O H on the lower right. C 2 is single bonded to R on the lower left. C 3 is single bonded to C H 3 on the upper left.



The resonance structures of protonated Schiff base bound to the lysine side chain are separated by a double-headed arrow labeled transaldolase.

The left structure is as follows: The lysine side chain consists of C single bonded to N, single bond, H on the upper right. The C atom has a wiggly line on the upper left. The N atom is single-bonded to C, double bond, C in a zigzag manner. C 1 is single bonded to C H 2 O H below. C 2 is single bonded to H above and O H on the lower right.

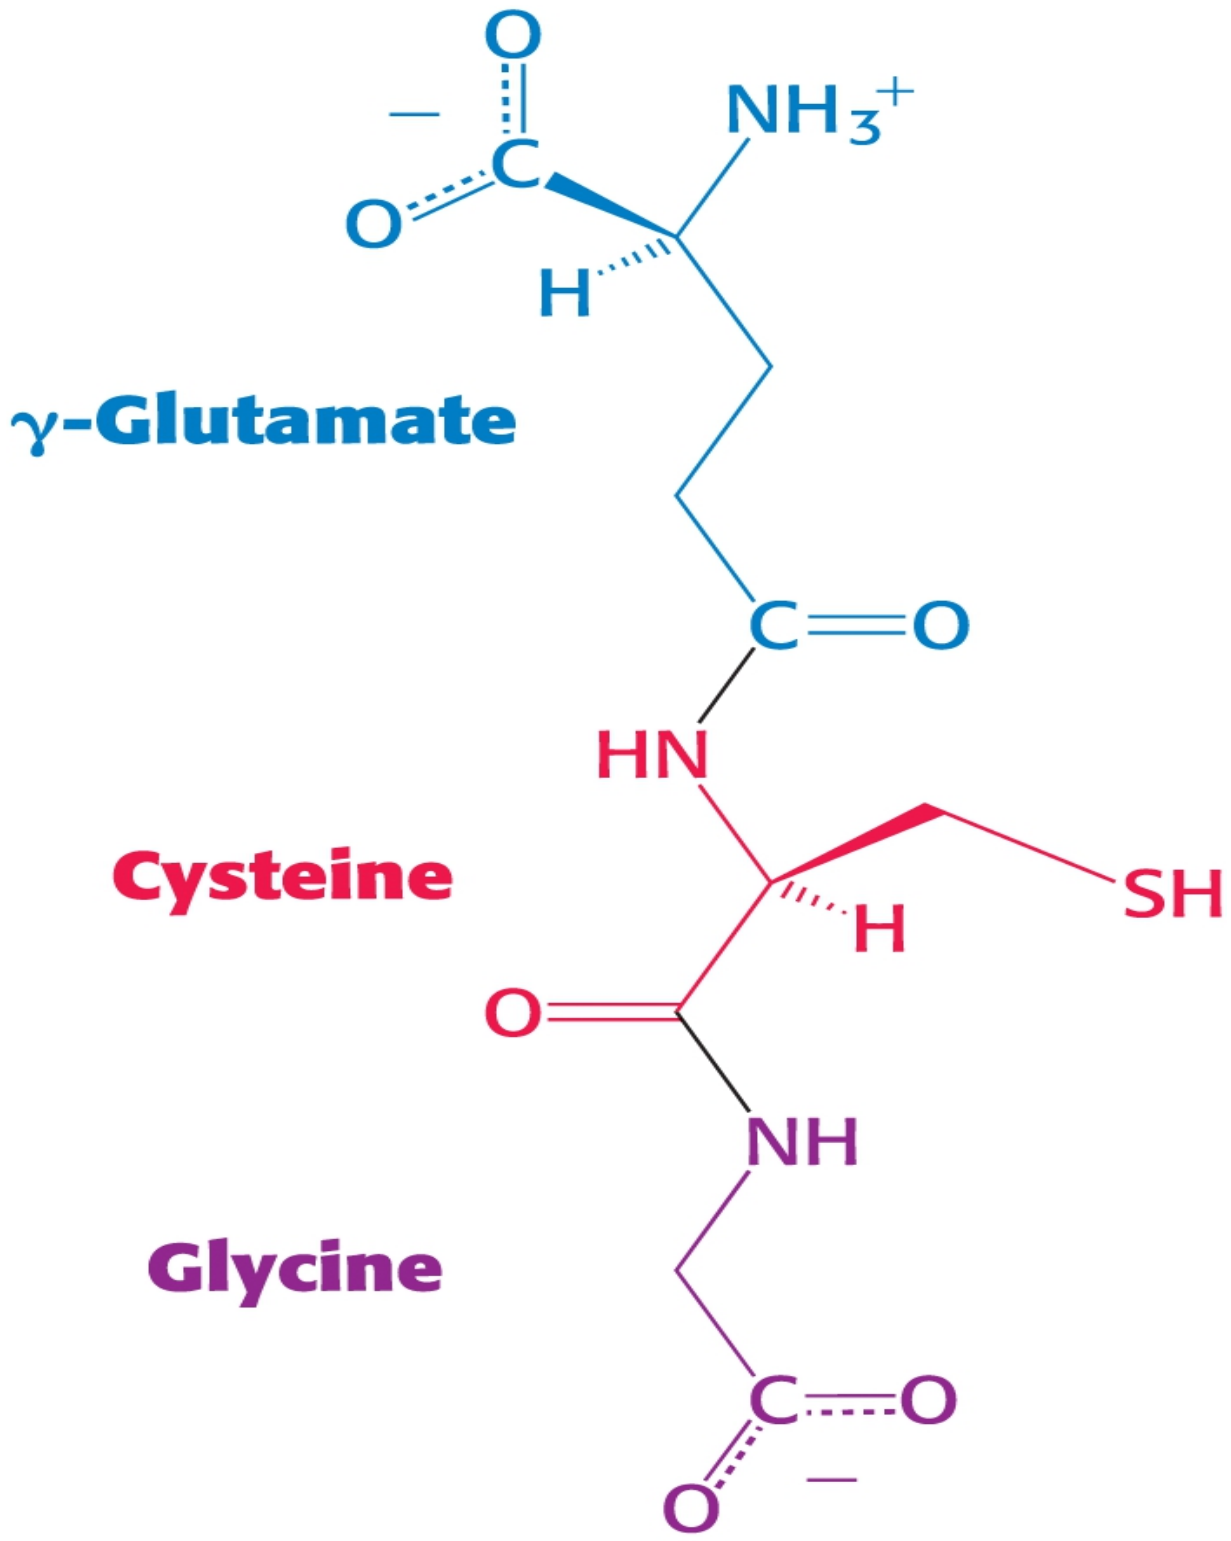
The right structure is as follows: The lysine side chain consists of C single bonded to N superscript plus, single bond, H on the upper right. The C atom has a wiggly line on the upper left. The N atom is single bonded to C, single bond, C superscript minus in a zigzag manner. C 1 is single bonded to C H 2 O H below. C 2 is single bonded to H above and O H on the lower right.

Return to FIGURE 20.25 For transketolase and transaldolase, a carbanion intermediate is stabilized by resonance

Extended description for FIGURE 20.26 The pentose phosphate pathway can operate in four modes

Mode 1 is depicted as follows: Glucose 6-phosphate is converted into fructose 6-phosphate. Fructose 6-phosphate is converted into fructose 1, 6-bisphosphate. Fructose 1, 6-bisphosphate is cleaved into dihydroxyacetone phosphate and glyceraldehyde 3-phosphate which are interconvertible. The glyceraldehyde 3-phosphate molecule and fructose 6-phosphate are converted into ribose 5-phosphate.

Mode 2 is depicted as follows: Glucose 6-phosphate is converted into ribulose 5-phosphate coupled with the release of C O 2 and the reduction of 2 N A D P superscript plus to 2 N A D P H. Ribulose 5-phosphate is converted into ribose 5-phosphate.



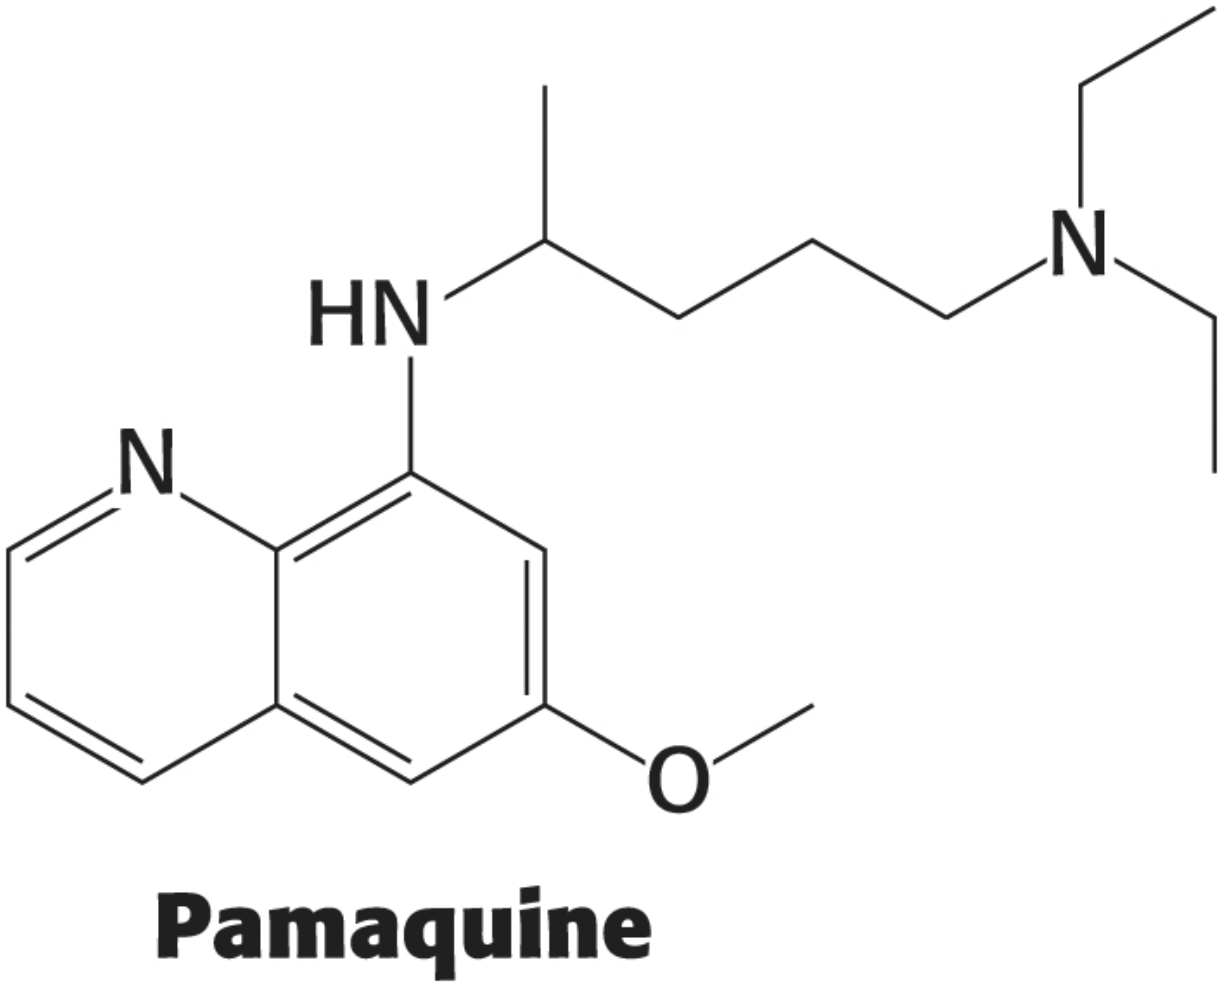
Mode 3 is depicted as follows: Glucose 6-phosphate is converted into ribulose 5-phosphate coupled with the release of C O 2 and the reduction of 2 N A D P superscript plus to 2 N A D P H. Ribulose 5-phosphate is converted into ribose 5-phosphate. Ribose 5-phosphate is further converted into fructose 6-phosphate or glyceraldehyde 3-phosphate. Glyceraldehyde 3-phosphate can be converted into dihydroxyacetone phosphate. The glyceraldehyde 3-phosphate and dihydroxyacetone phosphate molecules combine to form fructose 1, 6-bisphosphate. The fructose 1, 6-bisphosphate molecule is converted into fructose 6-phosphate which is further converted back to glucose 6-phosphate.

Mode 4 is depicted as follows: Glucose 6-phosphate is converted into ribulose 5-phosphate coupled with the release of C O 2 and the reduction of 2 N A D P superscript plus to 2 N A D P H. Ribulose 5-phosphate is converted into ribose 5-phosphate. Ribose 5-phosphate is further converted into fructose 6-phosphate or glyceraldehyde 3-phosphate. Glyceraldehyde 3-phosphate is converted into pyruvate coupled with the release of 2 A T P. The fructose 6-phosphate molecule is converted into fructose 1, 6-bisphosphate which is further broken down into dihydroxyacetone phosphate and glyceraldehyde 3-phosphate. The dihydroxyacetone phosphate molecule can be converted into glyceraldehyde 3-phosphate.

Return to FIGURE 20.26 The pentose phosphate pathway can operate in four modes

Extended description for Structure of reduced

glutathione

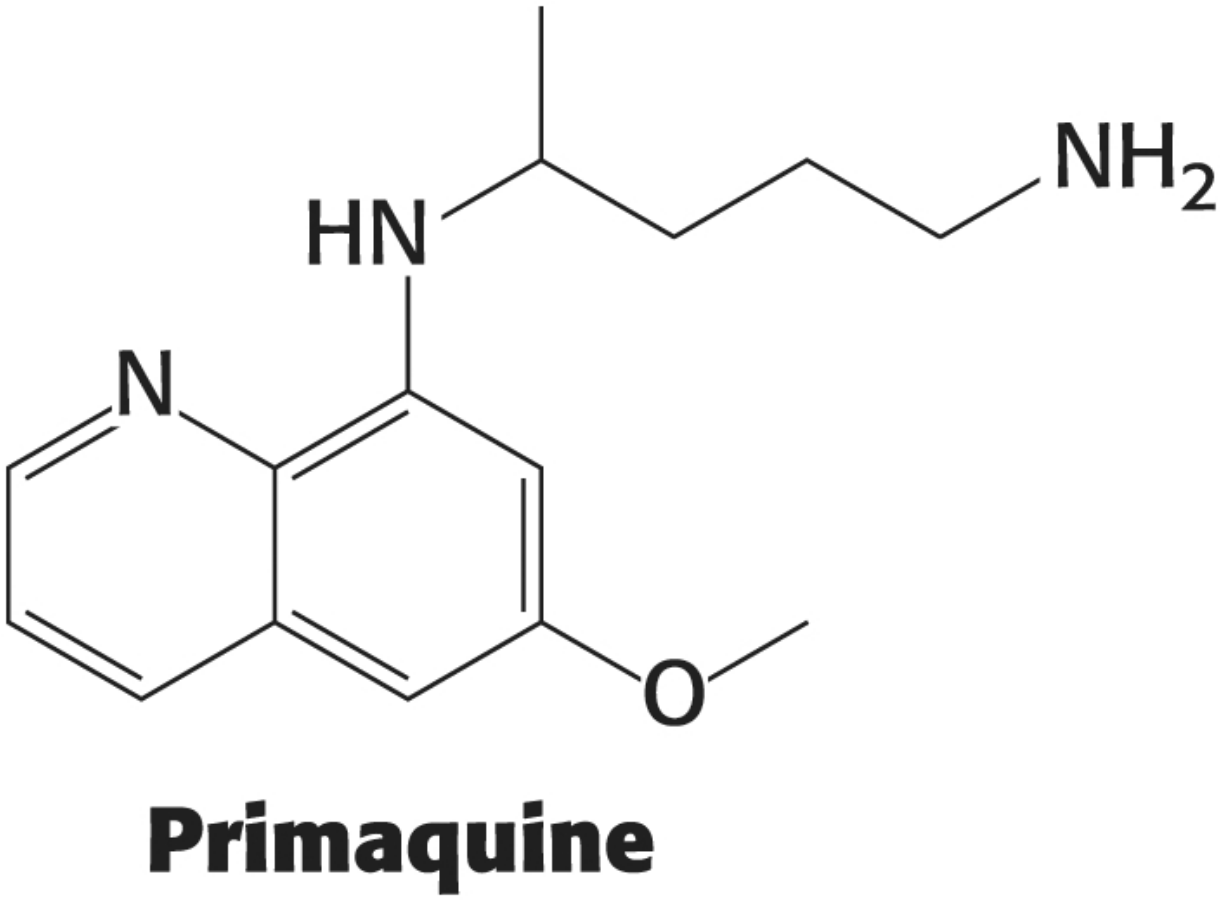


Glutathione (reduced)
(γ-Glutamylcysteinylglycine)

The structure of reduced glutathione is as follows: A 2 N and 7 C heteronuclear alkane chain is depicted as a vertical line structure using 8 zigzag lines. N atoms bound to H occupy the fifth and eighth positions. C 1 is wedge bonded to C on the upper left. This C is partially double bonded to O above and O on the lower left. This C O O group has an overall negative charge. C 1 is also single bonded to N H 3 superscript plus on the upper right and dash bonded to H on the lower left. C 4 is double bonded to O on the right. C 5 is wedge bonded to C H 2 on the upper right, which is further single bonded to S H on the lower right. C 5 is also dash bonded to H on the lower right. C 6 is double bonded to O on the left. C 7 is single bonded to C on the lower right, which is further partially double bonded to O on the right and O on the lower left. This C O O group has an overall negative charge. C 1 to C 4 and their substituents are labeled gamma-glutamate. N 1 to C 6 and their substituents are labeled cysteine. N 2 to C 7 and their substituents are labeled glycine.

Return to Structure of reduced glutathione

Extended description for Structure of pamaquine

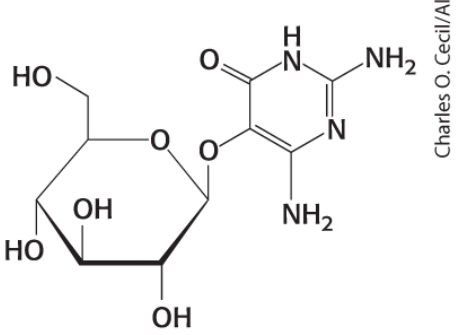


The structure of pamaquine is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation. It consists of 1 N and 5 C atoms. The N atom occupies the topmost vertex. C 1 occupies the top right vertex. Double bonds are present between C 3 and C 4 and C 5 and N. This ring is fused with a benzene ring in a vertical orientation such that C 1 and C 2 of the hexagonal ring are C 6 and C 5 of the benzene ring respectively. In the benzene ring, double bonds are present between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to N H on the top. N H is single bonded

to a 6-membered alkane chain depicted as a line structure using 5 zigzag lines. It consists of 1 N and 5 C atoms. N occupies the fifth position. C 1 is single bonded to C H 3 above in the form of a line. N is single bonded to C H 2 above in the form of a line. C H 2 is further single bonded to C H 3 on the upper right in the form of a line. C 5 is single bonded to C H 3 below in the form of a line. C 3 is single bonded to O on the lower right, which is further single-bonded to C H 3 on the upper right.

Return to Structure of pamaquine

Extended description for Structure of primaquine



The structure of primaquine is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation. It consists of 1 N and 5 C atoms. The N atom occupies the topmost vertex. C 1 occupies the top right vertex. Double bonds are present between C 3 and C 4 and C 5 and N. This ring is fused with a benzene ring in a vertical orientation such that C 1 and C 2 of the hexagonal ring are C 6 and C 5 of the benzene ring respectively. In the benzene ring, double bonds are present between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to N H on the top. N H is single bonded to a 4-carbon alkane chain depicted as a line structure using 3 zigzag lines. C 4 is single bonded to N H 2 on the top right. C 1 is single

bonded to C H 3 above in the formation of a line. C 3 of the benzene ring is single bonded to O on the lower right. O is further single bonded to C H 3 on the upper right.

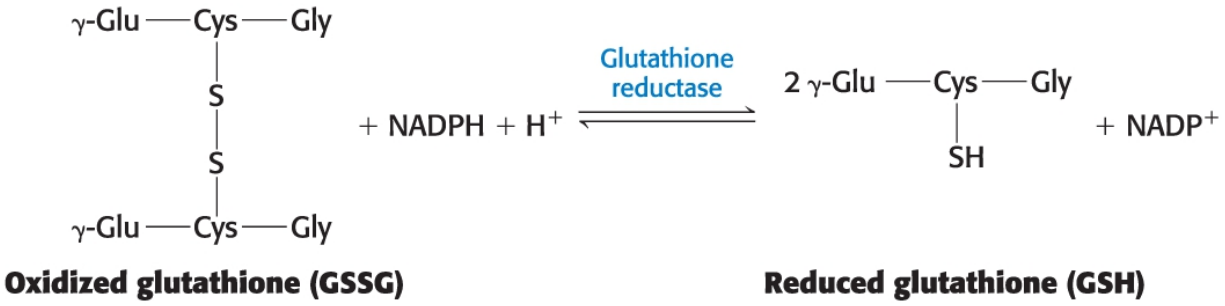
Extended description for FIGURE 20.27 Fava beans produce a pyrimidine glycoside

Vicine



Charles O. Cecil/Alamy

The photograph shows a heap of fava beans in a marketplace.

The structure of the vicine is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 O and 5 C atoms. The ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are toward the observer and C 5 and O are away from the observer. C 2 and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 above in the form of a line. This C H 2 group is single-bonded to O H on the upper left. C 1 is single bonded to O above. This O atom is single-bonded to C 3 of a 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 2 N and 4 C atoms. N occupies the first and third positions. First N is bound to H. Double bonds are present between C 1 and N 2 and C 2 and C 3. C 1 is single bonded to N H 2 on the upper right. C 2 is single bonded to N H 2 below. C 4 is double bonded to O on the upper left.

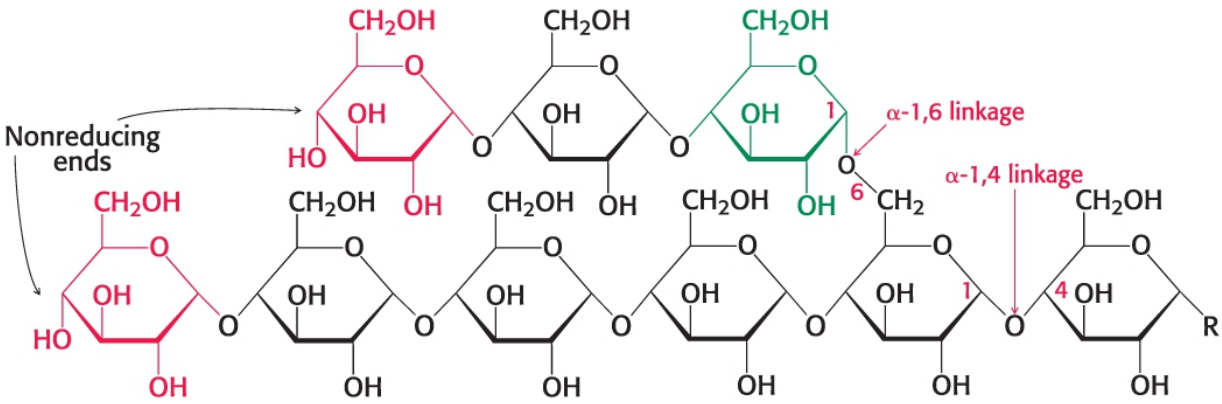
Extended description for Conversion of oxidized glutathione to reduced glutathione catalyzed by glutathione reductase

The reaction consists of two reactants and two products.

The first reactant is oxidized glutathione (G S S G) whose structure is as follows: gamma glutamic acid, single bond, cysteine, single bond, glycine. Cysteine is single bonded to S, single bond, S below. The second S atom is single-bonded to cysteine below. This cysteine is further single-bonded to gamma glutamic acid on the left and glycine on the right.

The second reactant is N A D P H plus H superscript plus.



A reversible reaction arrow labeled glutathione reductase leads to the products.

The first product is reduced glutathione (G S H) whose structure is as follows: 2 gamma glutamic acid, single bond, cysteine, single bond, glycine. Cysteine is single bonded to S H below.

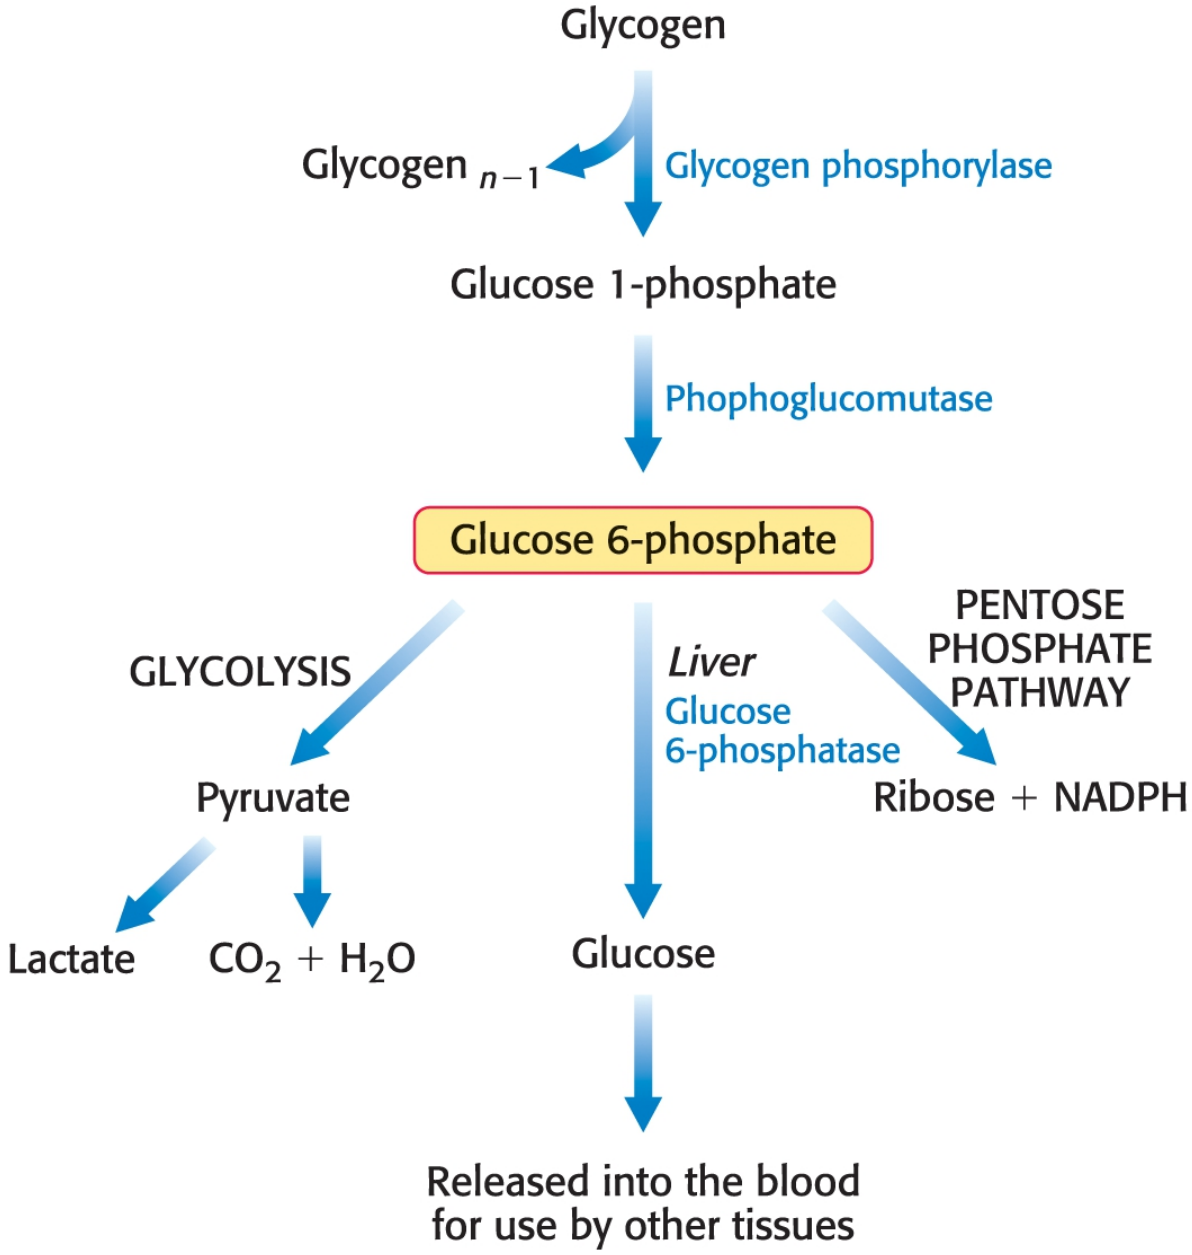
The second product is N A D P superscript plus.

Return to Conversion of oxidized glutathione to reduced glutathione catalyzed by glutathione reductase

Extended description for FIGURE 21.3 The fundamental structure of glycogen is a linear polymer with occasional branches

Glycogen consists of two linear chains of glucose molecules linked by alpha-1,4 linkage. The bottom chain contains 6 glucose molecules. The top chain contains 3 glucose molecules. The top chain is connected to the bottom chain through an alpha-1,6 linkage between the third and fifth glucose residues respectively.

The structure of a glucose residue is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 O and 5 C atoms. O occupies the top right vertex. C 2 and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above. The adjacent glucose residues are connected by a common O atom single bonded to C 1 and C 4 of the adjacent residues.



The free C 4 ends of the glucose residues of the top and bottom chains are labeled nonreducing ends. In the alpha-1,6 linkage, C 1 of the third glucose residue of the top chain is single-bonded to O

below. This O is further single-bonded to the C H 2 group bonded to the C 5 atom of the fifth glucose residue of the bottom chain.

The C 1 atom of the sixth glucose residue of the bottom chain is single-bonded to R on the lower right.

Return to FIGURE 21.3 The fundamental structure of glycogen is a linear polymer with occasional branches

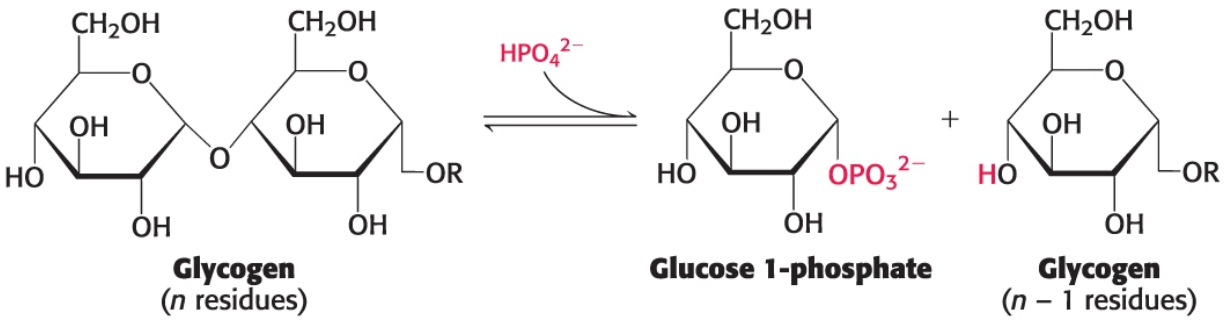
Extended description for FIGURE 21.4 Glucose 6-phosphate can have many metabolic fates

© Macmillan Learning

The flowchart is described from top to bottom as follows:

Glycogen is broken down to release glucose 1-phosphate by the action of glycogen phosphorylase. This is accompanied by the release of glycogen n minus 1.

Glucose 1-phosphate is converted into glucose 6-phosphate by phosphoglucomutase.



Glucose 6-phosphate has three fates: glycolysis, conversion to glucose in the liver, and pentose phosphate pathway.

In glycolysis, glucose 6-phosphate is converted to pyruvate, which is further broken down into lactate, and C O 2 plus H 2 O.

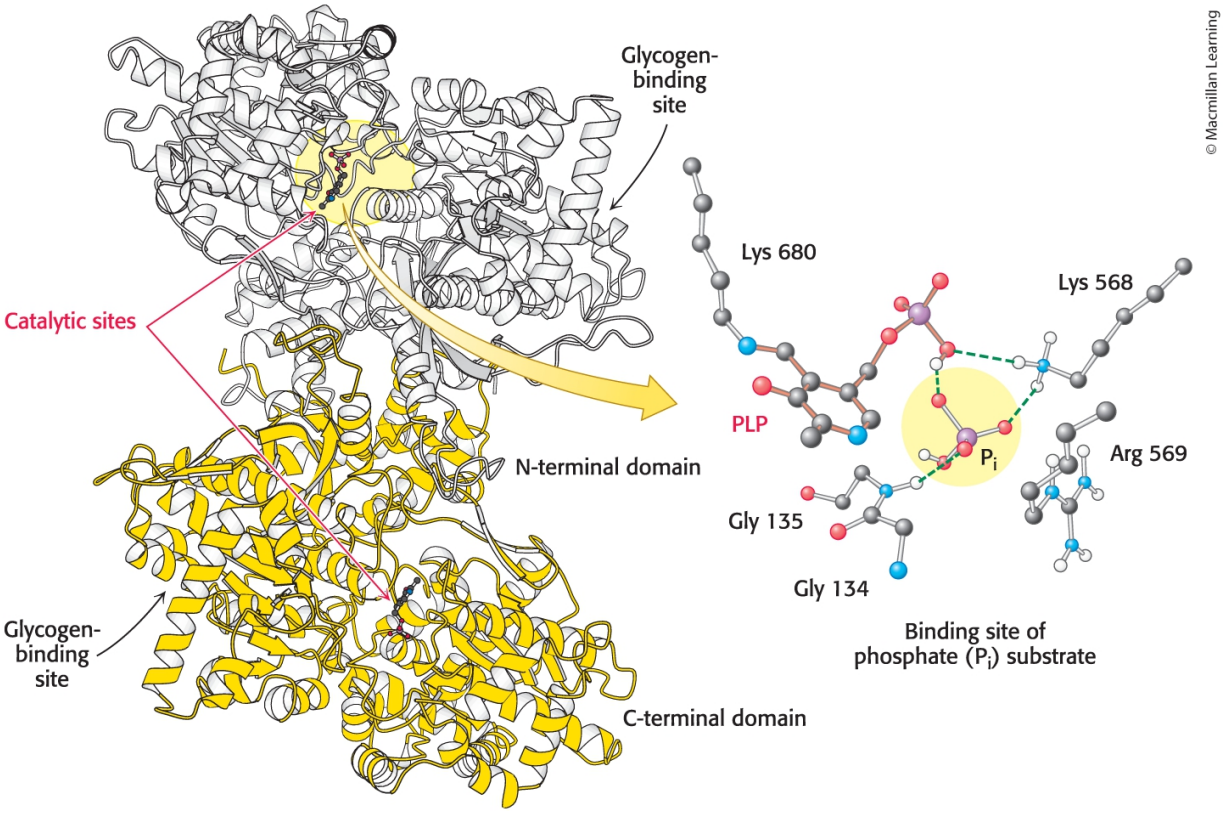
In the liver, the enzyme glucose 6-phosphatase converts glucose 6-phosphate into glucose. The glucose molecule is then released into the blood for use by other tissues. In the pentose phosphate pathway, glucose 6-phosphate is converted into ribose plus N A D P H.

Return to FIGURE 21.4 Glucose 6-phosphate can have many metabolic fates

Extended description for Cleavage of glucose 1-phosphate residue from glycogen with n residues

The reaction consists of one reactant and two products. The first reactant is glycogen with n residues.

The structure of glycogen is depicted as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1 is single bonded to O on the lower right. C 2 and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above. The lower right O is single-bonded to C 4 of a second 6-membered heterocyclic hexagonal ring in a horizontal orientation. In this ring, O occupies the top right vertex. C 1 is single bonded to O R below. C 2 is single bonded to O H below. C 3 is single bonded to O H above and C 5 is single bonded to C H 2 O H above. A reversible reaction arrow shows the entry of H P O 4 superscript 2 minus.



The first product is glucose 1-phosphate whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1 is single bonded to O P O 3 superscript 2 minus below. C 2 and C 4 are

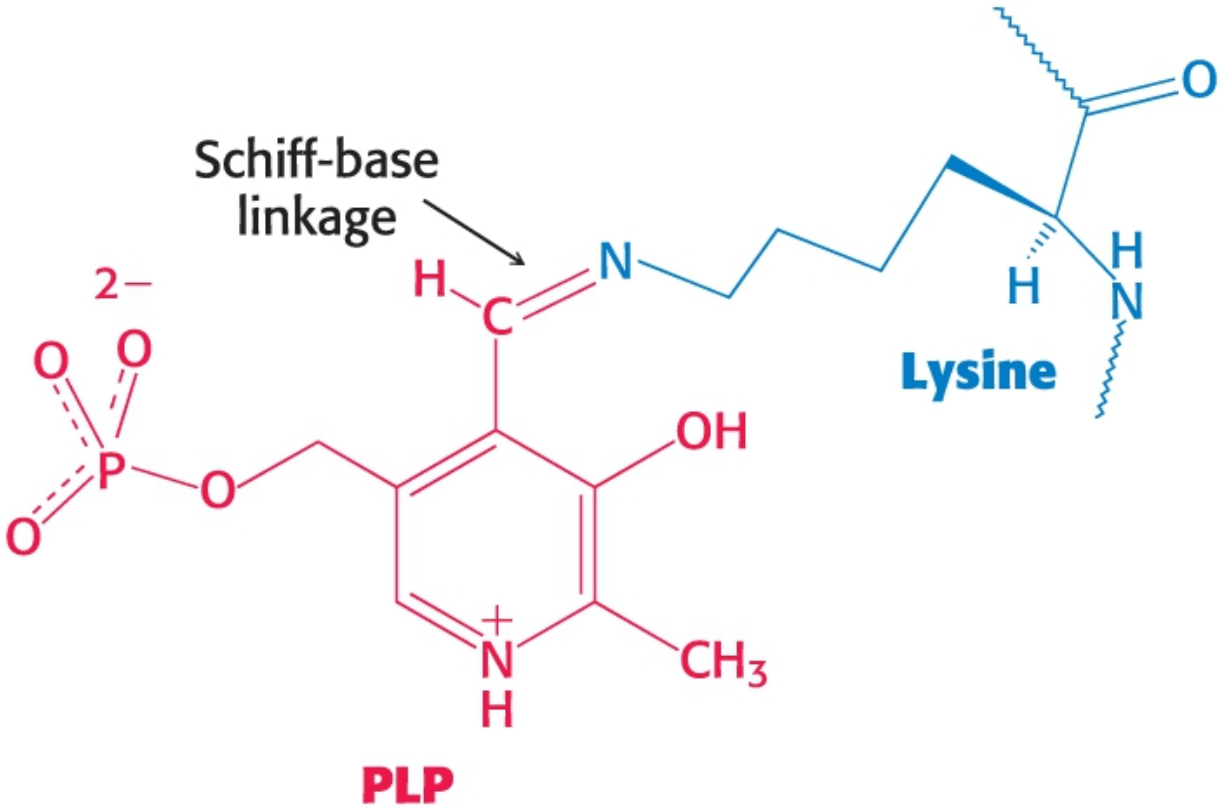
each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above.

The second product is glycogen with n minus 1 residues whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1 is single bonded to O R below. C 2 and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above.

Return to Cleavage of glucose 1-phosphate residue from glycogen with n residues

Extended description for FIGURE 21.5 Glycogen phosphorylase forms a homodimer with a pyridoxal phosphate (P L P) group in each active site

Glycogen phosphorylase is a homodimer consisting of top and bottom subunits shown in white and yellow color respectively. The individual subunits contain several alpha-helices and some beta-strands interconnected by thread-like loops. A catalytic site is located in the center of each subunit. A glycogen binding site is shown at the top right and bottom left ends of the top and bottom subunits respectively. Each catalytic site is bound to pyridoxal phosphate. An arrow from the catalytic site of the top subunit points toward a ball-and-stick model depicted as follows:



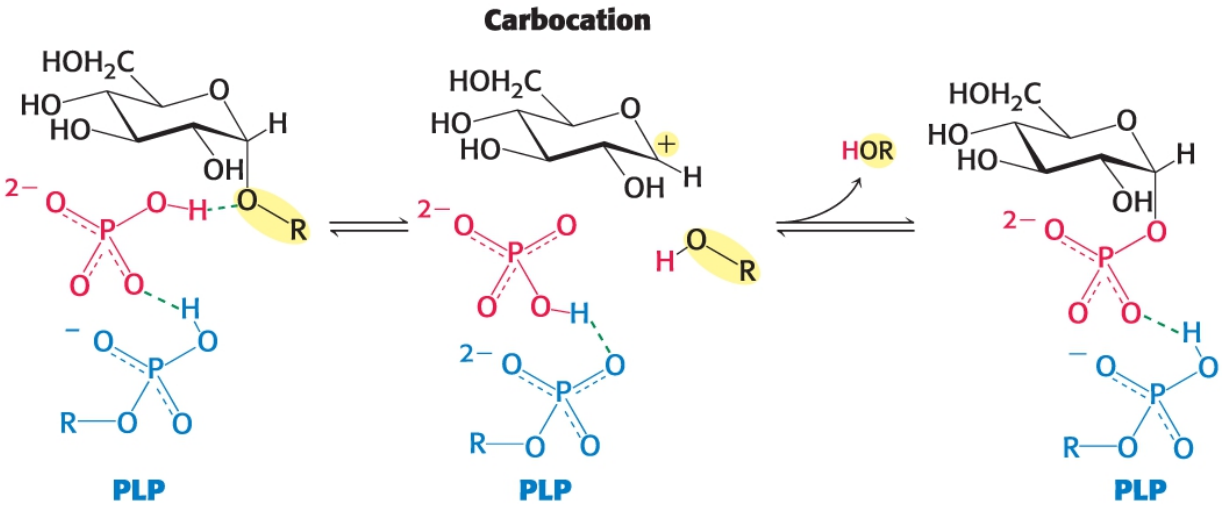
A central yellow circle depicting the catalytic site contains P subscript i or phosphate substrate. It is labeled the "Binding site of phosphate (P subscript i) substrate." It consists of a central purple sphere connected to a red sphere on the upper left, right, lower left, and front. The lower left red sphere is further connected to a white sphere.

Pyridoxal phosphate or P L P is bound to the side chain of lysine 680. P L P contains a hexagonal ring composed of 1 blue and 5 black spheres. One of the black spheres of the ring is connected to a red sphere which is further connected to a central purple sphere. The purple sphere is connected to 3 red spheres. One of the red spheres is connected to a white sphere.

The red spheres of the phosphate are connected to a white sphere of P L P, a white sphere of lysine 568, and a white sphere of glycine 135 through a dashed line. A ball and stick model of arginine 569 is shown on the bottom left of the catalytic site. A glycine 134 residue bonded to glycine 135 is also shown. A dashed line connects one white sphere of lysine 568 with the red sphere of P L P, which is connected to a white sphere.

Return to FIGURE 21.5 Glycogen phosphorylase forms a homodimer with a pyridoxal phosphate (P L P) group in each active site

Extended description for FIGURE 21.6 P L P forms a Schiff-base linkage with lysine



The structure of P L P is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the bottom left vertex. It consists of 1 N and 5 C atoms. N with a positive charge bound to H occupies the bottom-most vertex. A double bond is present between N and C 1, C 2 and C 3, and C 4 and C 5. C 4 is single bonded to O H. C 5 is single bonded to C H 3. C 2 is single bonded to C H 2 on the upper left in the form of a line. This C H 2 is further single-bonded to O on the lower left. This O is single-bonded to a central P atom, which is further partially double-bonded to three O atoms. The O atoms have an overall negative charge of 2 minus. C 3 is single bonded to C above, which is further single bonded to H on the upper left and double bonded to N on the upper

right. The double bond between C and N is labeled "Schiff-base linkage." This N is part of the lysine residue.

The structure of lysine residue is depicted as follows: N atom of the Schiff-base linkage is single bonded to a 4-carbon alkane chain depicted as a line structure using 3 zigzag lines. C 4 is wedge bonded to C on the lower right. This C is single-bonded to another C atom on the upper right. The upper right C is double bonded to O on the right and has a wiggly line on the upper left. The lower right C is dash bonded to H on the lower left and single bonded to N H on the lower right. N has a wiggly line below.

Return to FIGURE 21.6 P L P forms a Schiff-base linkage with lysine

Extended description for FIGURE 21.7 The mechanism of phosphorylase involves P L P and the formation of a carbocation

The mechanism involves the formation of a carbocation intermediate.

The first structure shows a central phosphate molecule connected to a glycosidic bond above and P L P below. The structure of phosphate molecule is depicted as follows: A central P atom is partially double-bonded to O on the upper left, lower left, and lower right. These O atoms have an overall negative charge of 2 minus. The P atom is single bonded to O, single bond, H on the upper right.

The structure of P L P is depicted as follows: A central P atom is partially double bonded to O on the upper left, partially double bonded O on the lower right, single bonded to O, single bond, R on the lower left, and single bonded to O, single bond, H on the upper right. A dashed line connects the lower right O atom of the central

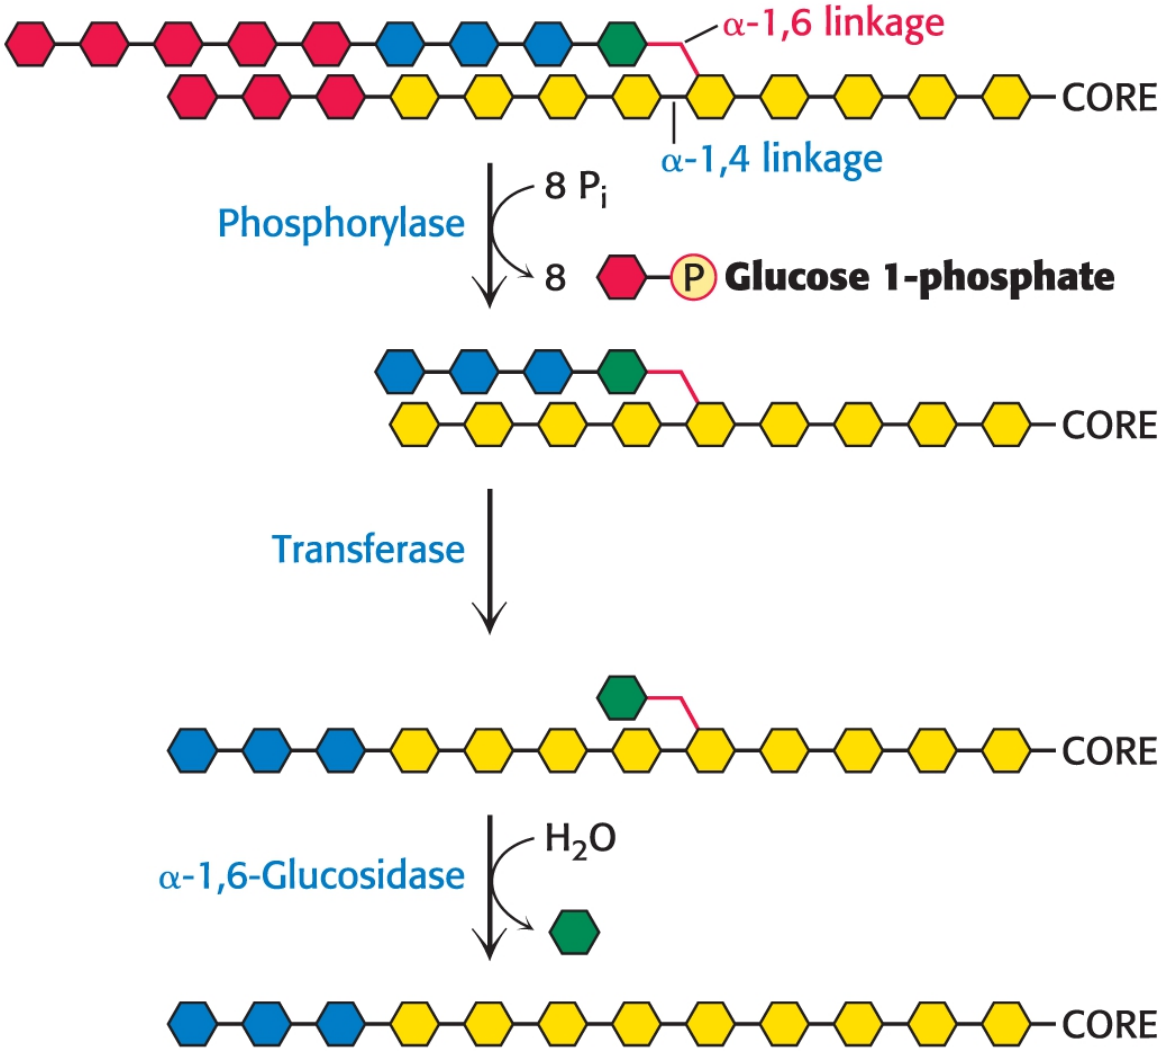
phosphate molecule with the upper right H atom of the P L P molecule.

The structure of the sugar molecule with the glycosidic bond is depicted as follows: A 6-membered heterocyclic hexagonal ring is in a chair conformation. It consists of 1 O and 5 C atoms. C 2 and C 5 are located close to each other. C 1 is single bonded to H on the upper right and single bonded to O, single bond, R on the lower right. C 2 is single bonded to O H below. C 3 is single bonded to O H on the upper left. C 4 is single bonded to O H on the lower left. C 5 is single bonded to C H 2 O H above.

A dashed line connects the O atom of the O R group to the upper right H atom of the central phosphate molecule.

A reversible reaction arrow leads to the carbocation intermediate.

The cleaved glycosidic bond produces three products as follows: The first molecule is a 6-membered heterocyclic hexagonal ring in a chair conformation. It consists of 1 O and 5 C atoms. C 2 and C 5 are located close to each other. C 1 is single bonded to H on the lower right and it has a positive charge. C 2 is single bonded to O H on the lower right. C 3 is single bonded to H on the upper left. C 4 is single bonded to O H on the lower left. C 5 is single bonded to C H 2 O H above. The second molecule consists of a central O atom single bonded to H on the lower left and R on the lower right.



The third product consists of the central phosphate molecule single-bonded to the P L P molecule below. The central phosphate molecule has lost the upper right H atom. The lower right H atom of the central phosphate molecule is single-bonded to the upper right H atom of P L P. The H atom is further connected to the upper right O atom of P L P through a dashed line.

A reversible reaction arrow shows the release of H O R.

In the final product, the C 1 atom of the heterocyclic ring becomes single-bonded to the upper right O atom of the central phosphate. This O atom becomes single bonded to the central P atom. The lower right O atom of the phosphate molecule is connected to the upper right H atom of the P L P molecule through a dashed line. This H atom becomes single-bonded to the upper right O atom of the P L P molecule.

Return to FIGURE 21.7 The mechanism of phosphorylase involves P L P and the formation of a carbocation

Extended description for FIGURE 21.8 Glycogen remodeling requires three distinct catalytic activities

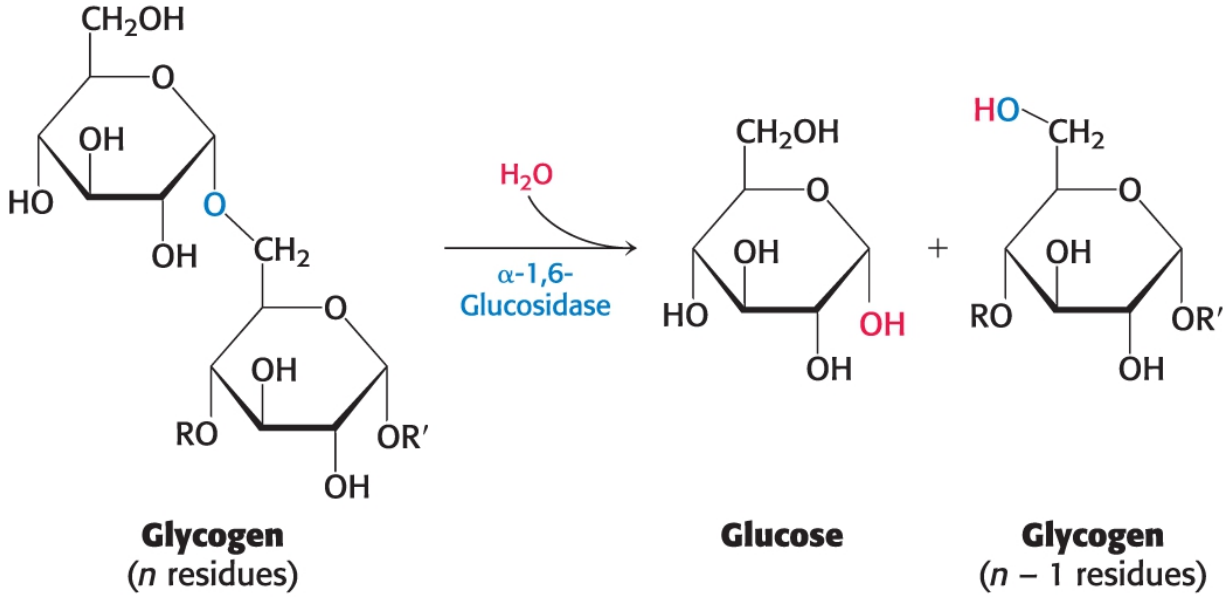
© Macmillan Learning

A linear chain is composed of three red hexagons and nine yellow hexagons connected to the core. The red hexagons are located at the left end. The fifth yellow hexagon from the left is connected to the left green hexagon of the top linear chain through an alpha-1,6 linkage. The top linear chain is composed of five red hexagons on the left, three blue hexagons in the middle, and one green hexagon on the right.

A downward arrow labeled phosphorylase is shown. A curved arrow alongside it shows the entry of 8 P subscript i and the release of 8 glucose 1-phosphate molecules. The glucose 1-phosphate molecule is depicted as a red hexagon single bonded to P on the right.

The product consists of a bottom linear chain of 9 yellow hexagons connected to the core. The fifth yellow hexagon is connected to the green hexagon of the top linear chain composed of three blue hexagons on the left and a green hexagon on the right.

A downward arrow labeled transferase leads the second product.



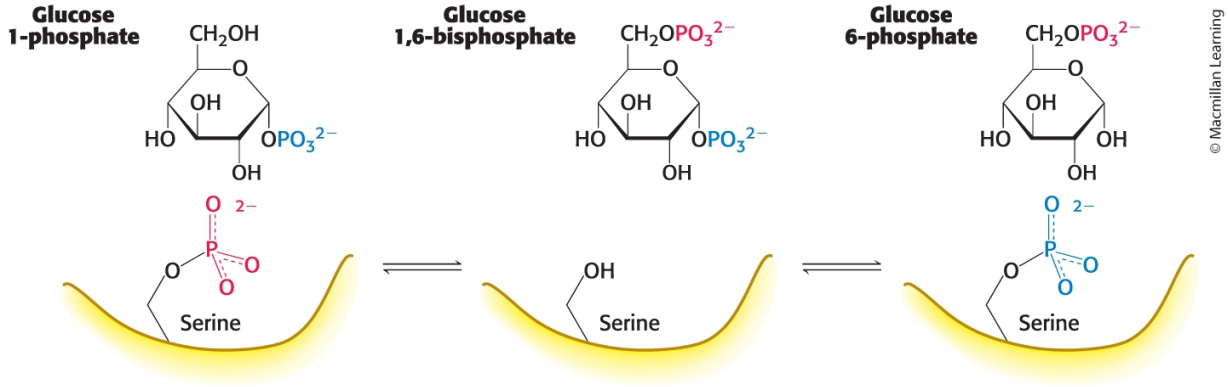
The second product consists of a linear chain composed of three blue hexagons on the left and nine yellow hexagons on the right. The rightmost yellow hexagon is connected to the core. The fifth yellow hexagon from the left is connected to a green hexagon above.

A downward arrow labeled alpha-1, 6-glucosidase leads to the product. A curved arrow alongside it shows the entry of H 2 O and the release of a green hexagon.

The third product consists of a linear chain composed of three blue hexagons on the left and nine yellow hexagons on the right. The rightmost yellow hexagon is connected to the core.

Return to FIGURE 21.8 Glycogen remodeling requires three distinct catalytic activities

Extended description for Action of alpha-1, 6-glucosidase



The reaction consists of one reactant and two products. The reactant is glycogen with n residues whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 O and 5 C atoms. O occupies the top right vertex. C 2 and C 4 are single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above. C 1 is single bonded to O below, which is further single bonded to C H 2 below. This C H 2 group is single-bonded to the C 5 atom of a second 6-membered heterocyclic hexagonal ring in a horizontal orientation. It consists of 1 O and 5 C atoms. C 1 is single bonded to O R dash below. C 2 is single bonded to O H below. C 3 is single bonded to O H above. C 4 is single bonded to O R below. A forward arrow labeled alpha-1, 6-glucosidase depicts the entry of H 2 O and leads to the products.

The first product is glucose whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1, C 2, and C 4 are single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above.

The second product is glycogen with n minus 1 residues whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1 is single bonded to O R dash below. C 2 is single bonded to O H below. C 3 is single bonded to O H above. C 4 is single bonded to O R below. C 5 is single bonded to C H 2, single bond, O H below.

Return to Action of alpha-1, 6-glucosidase

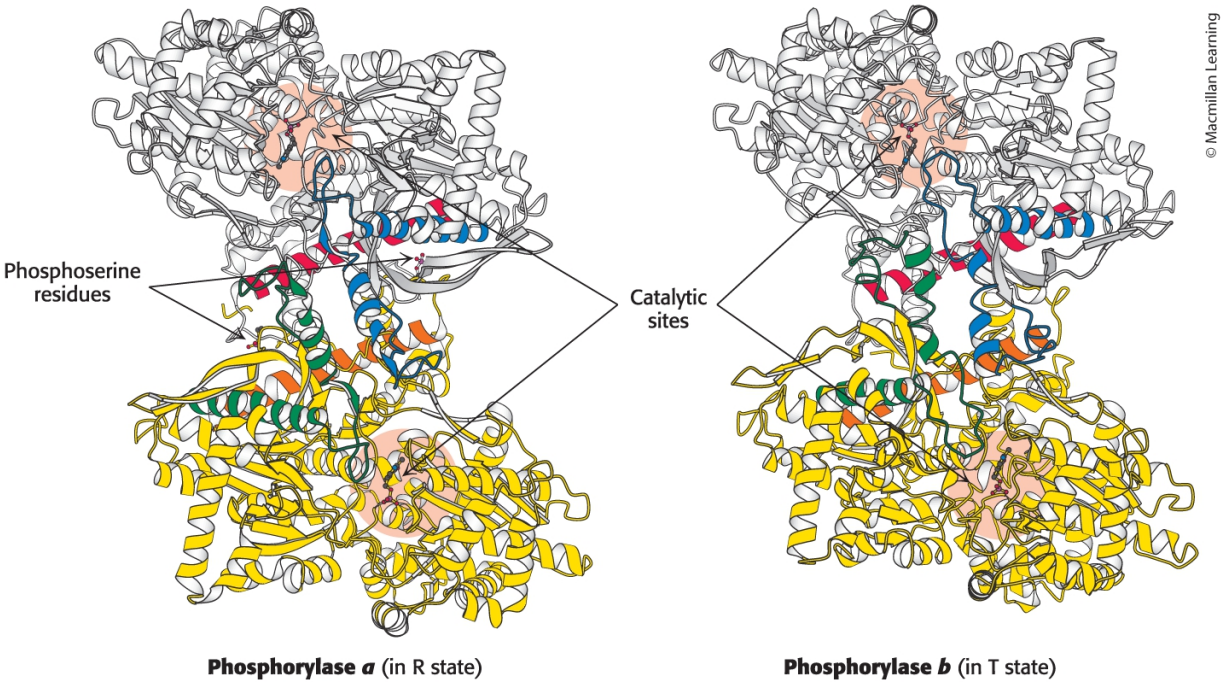
Extended description for FIGURE 21.9 Phosphoglucomutase transfers a phosphoryl group to the substrate

The active site of the enzyme is depicted as a U-shaped depression with an orange outline. The side chain of the serine residue consists of C H 2 depicted as a line. This C H 2 group is single-bonded to O on the upper right. This O atom is single-bonded to a central P atom. This P atom is partially double-bonded to O above, O below, and O on the lower right. The partially double-bonded O atoms have an overall charge of 2 minus.

The glucose 1-phosphate molecule is shown above the phosphate group, outside the active site. The structure of glucose 1-phosphate is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1 is single bonded to O P O 3 superscript 2 minus below. C 2 is single bonded to O H below. C 3 is single bonded to O H above. C 4 is single bonded to O H below. C 5 is single bonded to C H 2 O H above.

A reversible reaction arrow shows the side chain of the active site serine residue. It consists of C H 2 depicted as a line single bonded

to O H on the upper right.



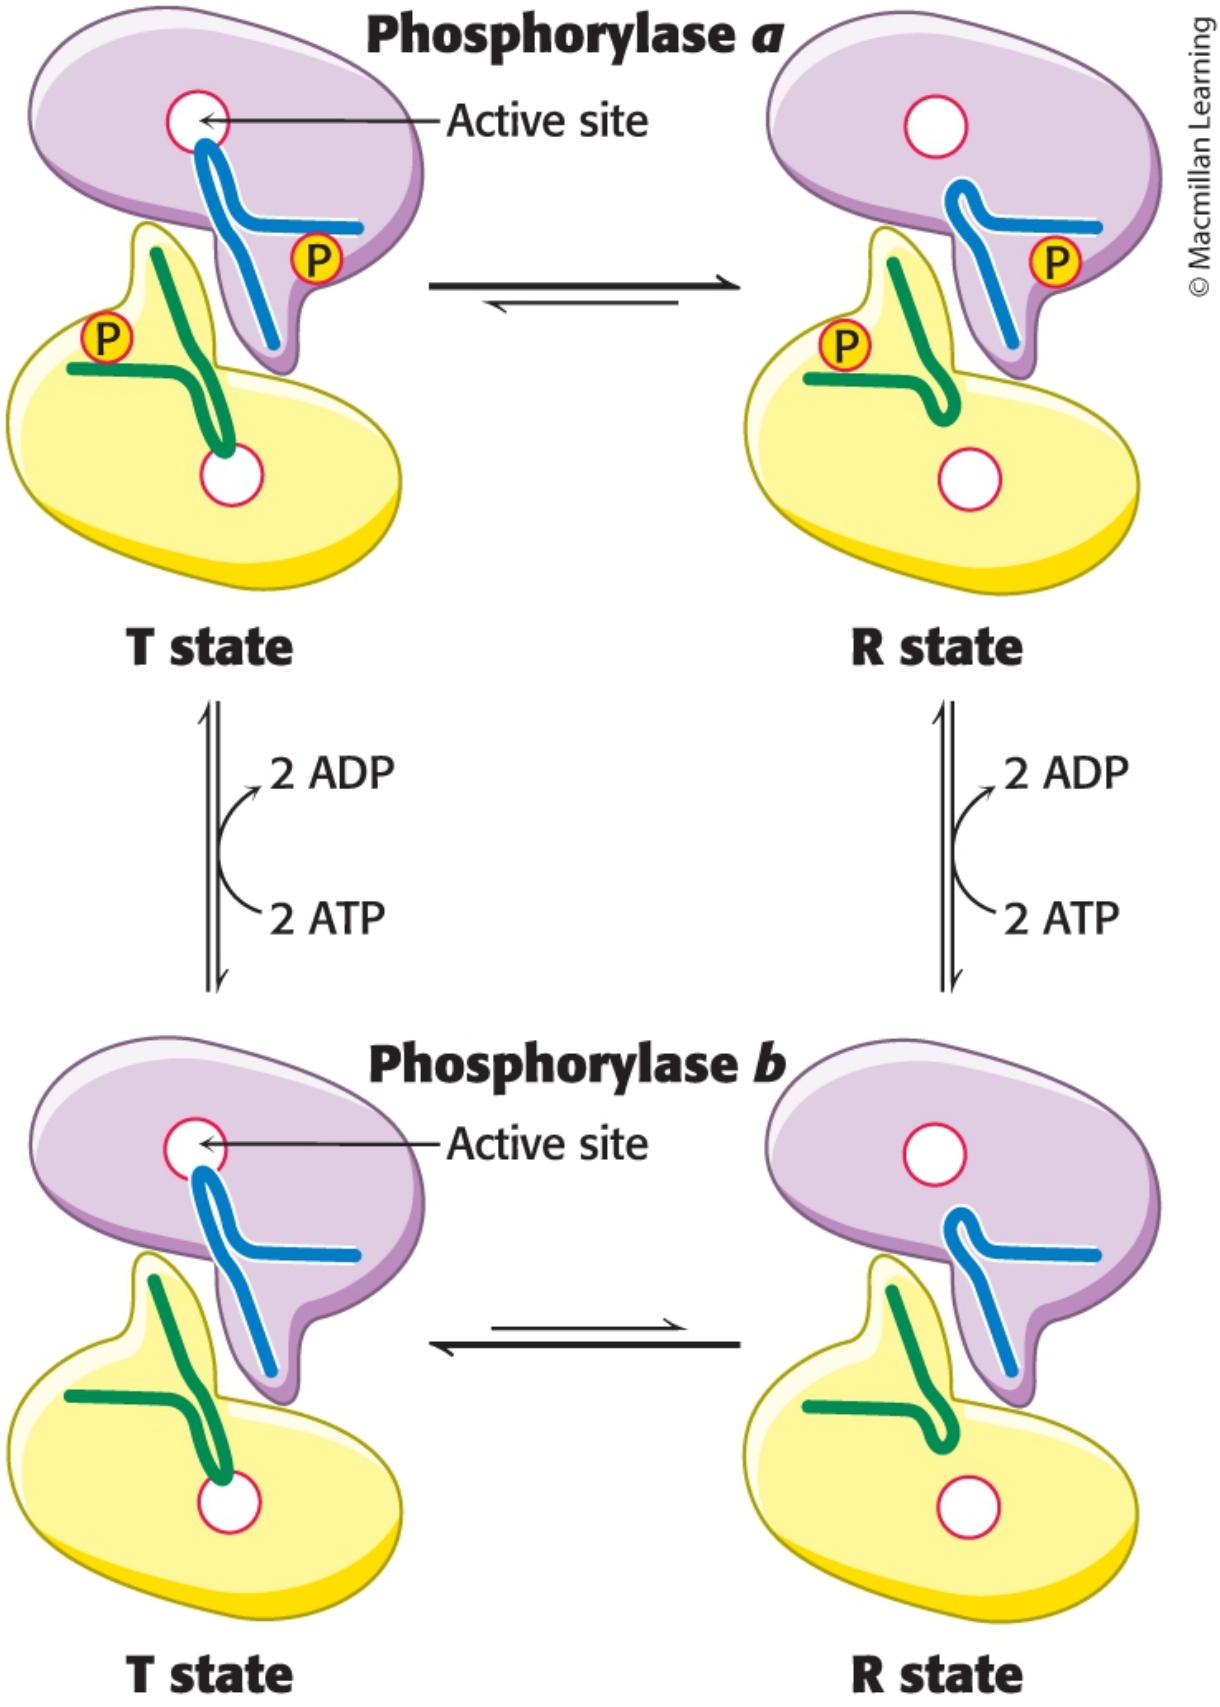
A glucose 1, 6-bisphosphate molecule is shown above the active site. Its structure is depicted as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1 is single bonded to O P O 3 superscript 2 minus below. C 2 is single bonded to O H below. C 3 is single bonded to O H above. C 4 is single bonded to O H below. C 5 is single bonded to C H 2 O P O 3 superscript 2 minus above.

A reversible reaction leads to the next structure. It shows the O atom of the O H group of active site serine side chain single-bonded to a central P atom. This P atom is partially double bonded to O above, O on the lower right, and O below. The O atoms have an overall negative charge of 2 minus.

A glucose 6-phosphate molecule is shown above the active site. Its structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1 is single bonded to O H below. C 2 is single bonded to O H below. C 3 is single bonded to O H above. C 4 is single bonded to O H below. C 5 is single bonded to C H 2 O P O 3 superscript 2 minus above.

Return to FIGURE 21.9 Phosphoglucomutase transfers a phosphoryl group to the substrate

Extended description for FIGURE 21.10 Phosphorylase exists in two distinct quaternary states



Phosphorylase a exists in the R state and phosphorylase b exists in the T state. They consist of two subunits, one at the top and the other at the bottom. The top subunit is shown in white and the bottom subunit is shown in yellow. Each subunit has a central catalytic site and is composed of several alpha-helices and beta-strands interconnected by thread-like loops. The bottom side of the top subunit contains two blue alpha-helices, one red horizontal alpha-helix, one blue beta-strand, and two blue thread-like loops. The top side of the bottom subunit contains one orange alpha-helix, two green alpha-helices, a green beta-strand, and two green thread-like loops. In phosphorylase a, a phosphoserine residue is located on the bottom right and top left sides of the top and bottom subunits respectively. The phosphorylase b lacks any phosphoserine residue.

Return to FIGURE 21.10 Phosphorylase exists in two distinct quaternary states

Extended description for FIGURE 21.11 Phosphorylase

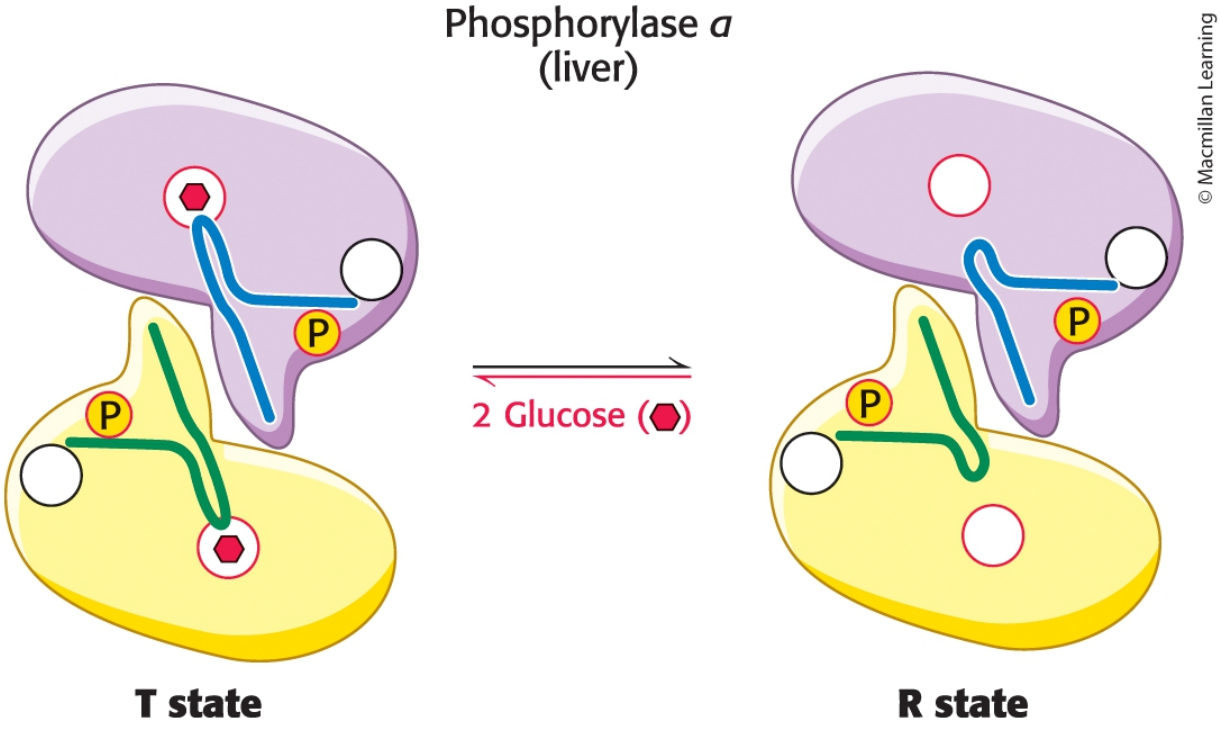
is regulated by phosphorylation

© Macmillan Learning

The phosphorylase consists of a top purple subunit and a bottom yellow subunit. A pointed protrusion from the bottom right end of the top subunit extends toward the bottom subunit. A pointed protrusion from the top left end of the bottom subunit extends toward the top subunit. Each subunit contains an active site depicted as a small circle with a red outline.

The phosphorylase a can be reversibly converted from the T to the R state. The R state is preferred. In both states, each subunit contains a phosphate molecule depicted as a tiny circle labeled P. In the T state, a thick blue loop extends into the active site of the top subunit and a thick green loop extends into the active site of the bottom subunit. In the R state, the loops are located away from the active site.

The T state of phosphorylase a can be reversibly converted into the T state of phosphorylase b with the simultaneous hydrolysis of 2 A T P to 2 A D P.



In the T state of phosphorylase b, phosphate is absent in both subunits. The respective loops, however, extend into the active site of each subunit.

The T state of phosphorylase b is preferred. It can be reversibly converted into the R state. In the R state, the loops are located away from the active site.

The R state of phosphorylase b can be reversibly converted into the R state of phosphorylase a with the simultaneous hydrolysis of 2 A T P to 2 A D P.

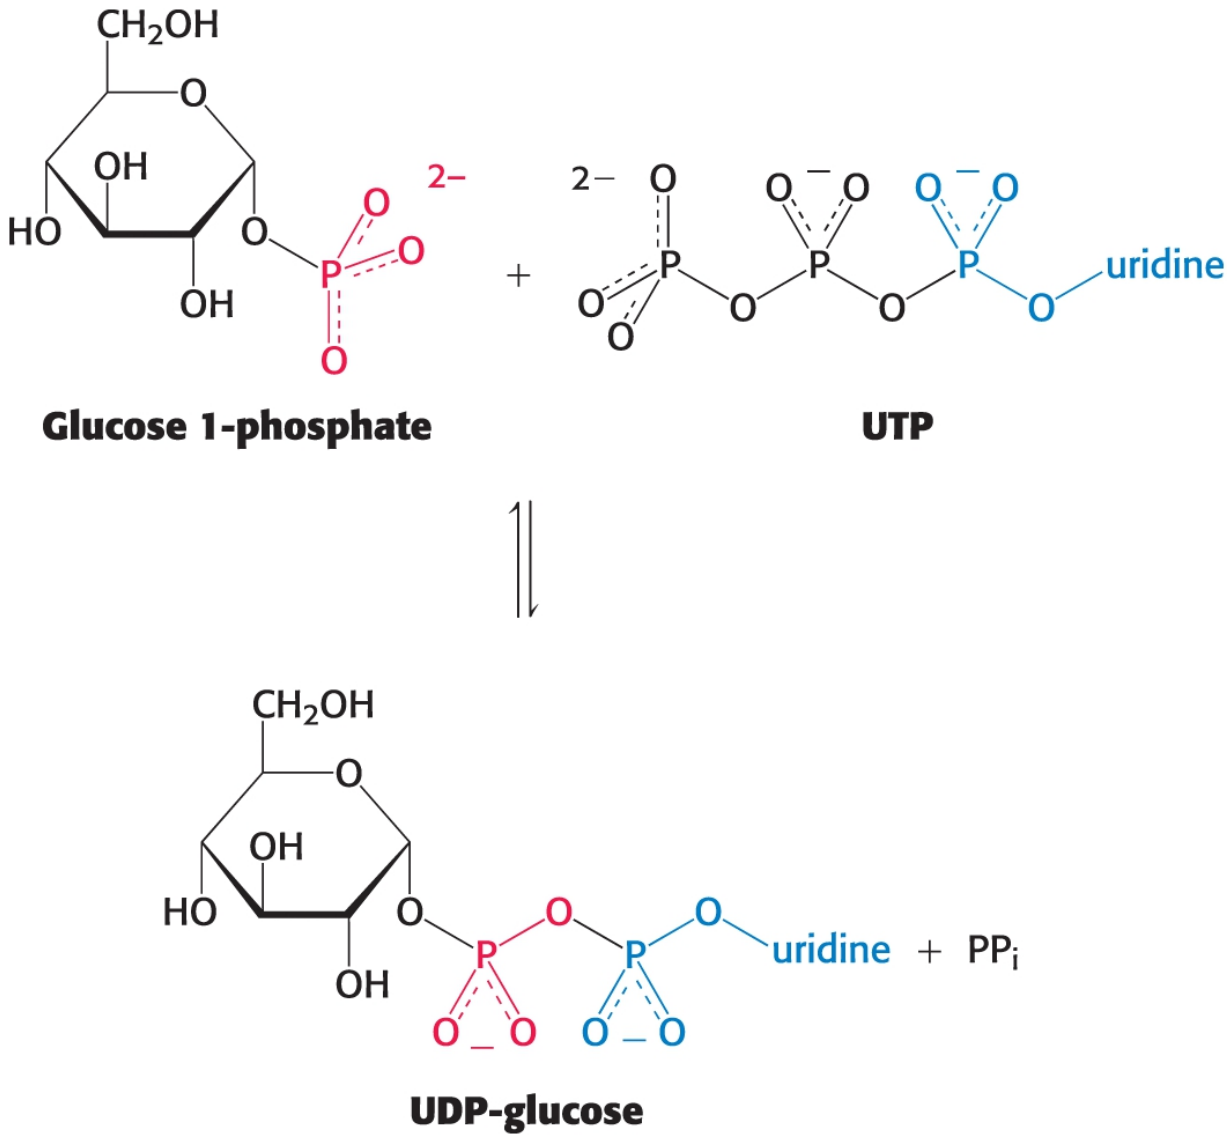
Extended description for Structure of uridine

diphosphate glucose (U D P-glucose)



Uridine diphosphate glucose (UDP-glucose)

The structure of U D P-glucose is depicted as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is wedge bonded to N 2 of a 6-membered heterocyclic hexagonal ring in a vertical orientation. The hexagonal ring consists of 2 N and 4 C atoms. The first N bound to H occupies the top right vertex. The second N occupies the bottom-most vertex. C 1 occupies the bottom right vertex. C 1 and C 4 are double bonded to O. A double bond is present between C 2 and C 3. C 2 and C 3 of the pentagonal ring are single-bonded to O H below. C 4 is single-bonded to C H 2 on the upper left in the form of a line. The C H 2 group is further single bonded to a vertical zigzag chain depicted as follows: O, single bond, P, single bond, O, single bond, P. Both P atoms are partially double-bonded to two O atoms. The O atoms have an overall negative charge. The terminal P atom is single-bonded to an O atom, which is further single-bonded to C 1 of a 6-membered heterocyclic hexagonal ring in a horizontal orientation. This ring consists of 1 O and 5 C atoms. O occupies the top right vertex. C 1 occupies the rightmost vertex. C 2 and C 4 are single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above.

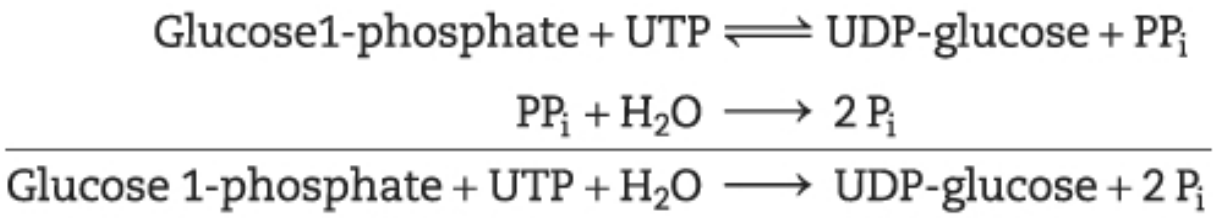
Return to Structure of uridine diphosphate glucose (U D P-glucose)

Extended description for Formation of U D P-glucose from glucose 1-phosphate and U T P

The reactant consists of two reactants and two products.

The first reactant is glucose 1-phosphate whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It

consists of 1 O and 5 C atoms. C 1 is single bonded to O below. This O atom is single-bonded to a central P atom. This P atom is partially double bonded to O above, O on the upper right, and O below. The O atoms have an overall charge of 2 minus. C 2 and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above.



The second reactant is U T P whose structure is as follows: A horizontal zigzag chain consists of P, single bond, O, single bond, P, single bond, O, single bond, P, single bond, O. The first P atom is partially double bonded to O above, O on the lower left, and O below. These O atoms have an overall charge of 2 minus. The second and third P atoms are partially double-bonded to O on the upper left and upper right. These O atoms have an overall negative charge. O 3 atom is single-bonded to uridine on the upper right.

The first product is U D P-glucose whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 O and 5 C atoms. C 2 and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above. C 1 is single bonded to O below, which is further single bonded to a zigzag chain composed of P, single bond, O, single bond, P, single bond, O. Each P atom is partially double bonded to O on the lower left and lower right. The O atoms have an overall negative charge. O 2 of the chain is single-bonded to uridine on the lower right.

The second product is P P subscript i.

Extended description for Synthesis of U D P-glucose and the hydrolysis of pyrophosphate and the resulting reaction

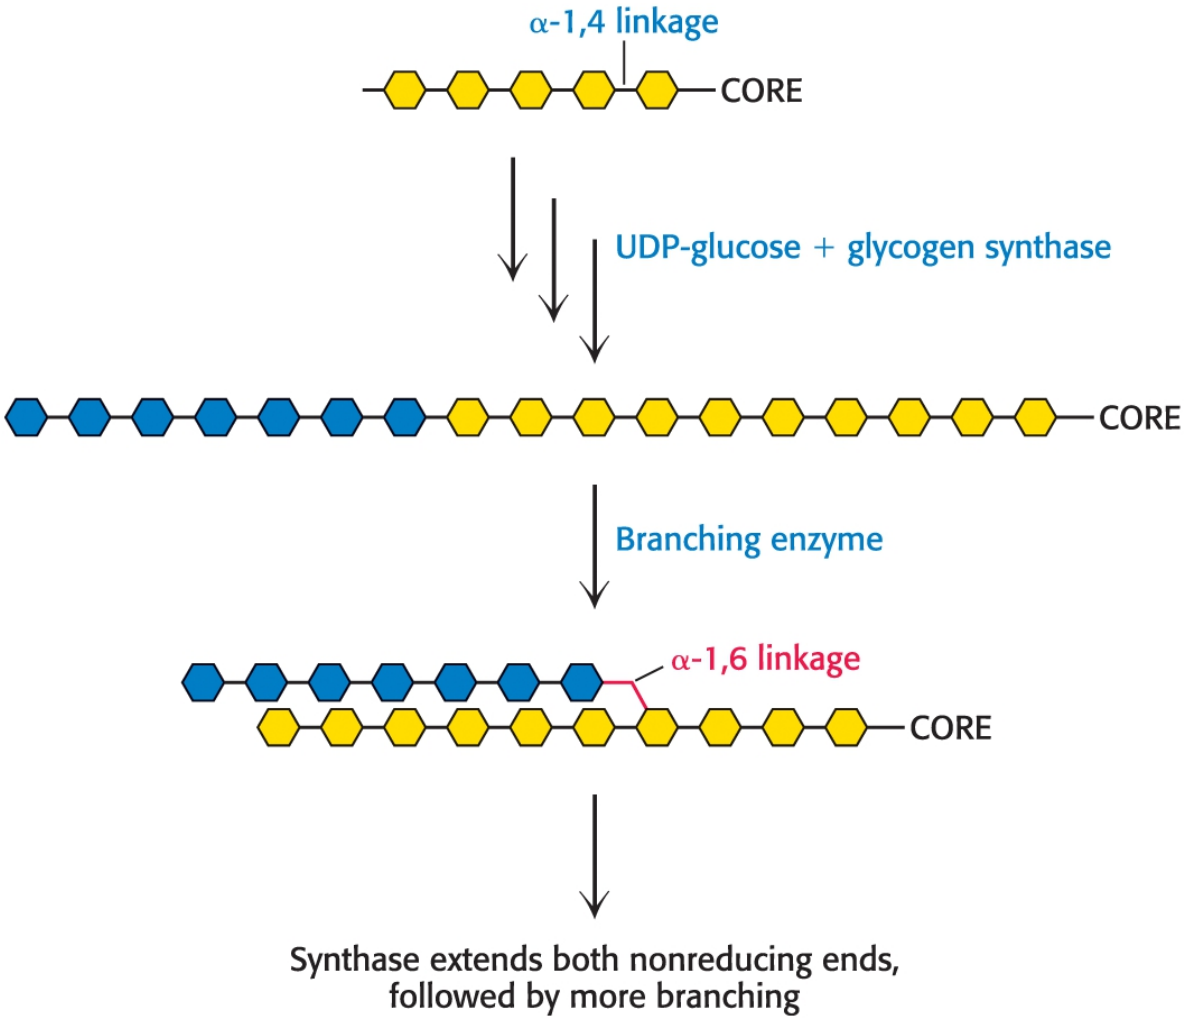
Synthesis of U D P-Glucose: Glucose 1-phosphate, plus, U T P, reversible arrows, U D P-glucose, plus, P P i. Hydrolysis of Pyrophosphate: P P i, plus, H 2 O, right arrow, 2 molecules of P i. The two reactions are added to give the third reaction as follows: Glucose 1-phosphate, plus, U T P, plus, H 2 O, right arrow, U D P-glucose, plus, 2 molecules of P i.

Return to Synthesis of U D P-glucose and the hydrolysis of pyrophosphate and the resulting reaction

Extended description for Elongation of glycogen molecule by 1 glucose residue

The reactant consists of two reactants and two products.

The first reactant is glucose 1-phosphate whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 O and 5 C atoms. C 1 is single bonded to O below. This O atom is single-bonded to a central P atom. This P atom is partially double bonded to O above, O on the upper right, and O below. The O atoms have an overall charge of 2 minus. C 2 and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above.



The second reactant is U T P whose structure is as follows: A horizontal zigzag chain consists of P, single bond, O, single bond, P, single bond, O, single bond, P, single bond, O. The first P atom is partially double bonded to O above, O on the lower left, and O below. These O atoms have an overall charge of 2 minus. The second and third P atoms are partially double-bonded to O on the upper left and upper right. These O atoms have an overall negative charge. O 3 atom is single-bonded to uridine on the upper right.

The first product is U D P-glucose whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 1 O and 5 C atoms. C 2 and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C H 2 O H above. C 1 is single bonded to O below, which is further single bonded to a zigzag chain composed of P, single bond, O, single bond, P, single bond, O. Each P atom is partially double bonded to O on the lower left and lower right. The O atoms have an overall negative charge. O 2 of the chain is single-bonded to uridine on the lower right.

The second product is P P subscript i.

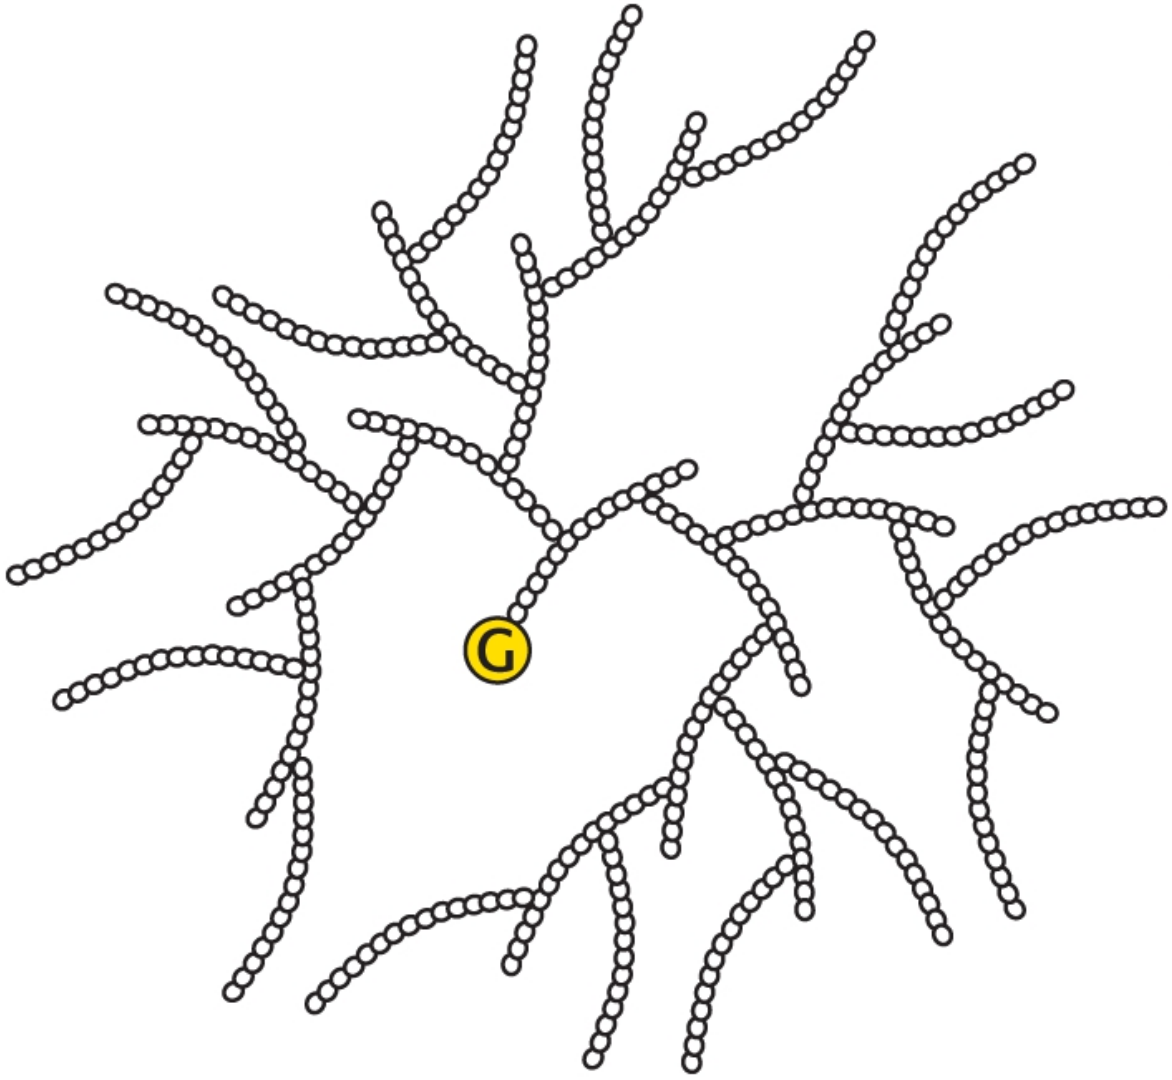
Extended description for FIGURE 21.17 Action of a branching enzyme



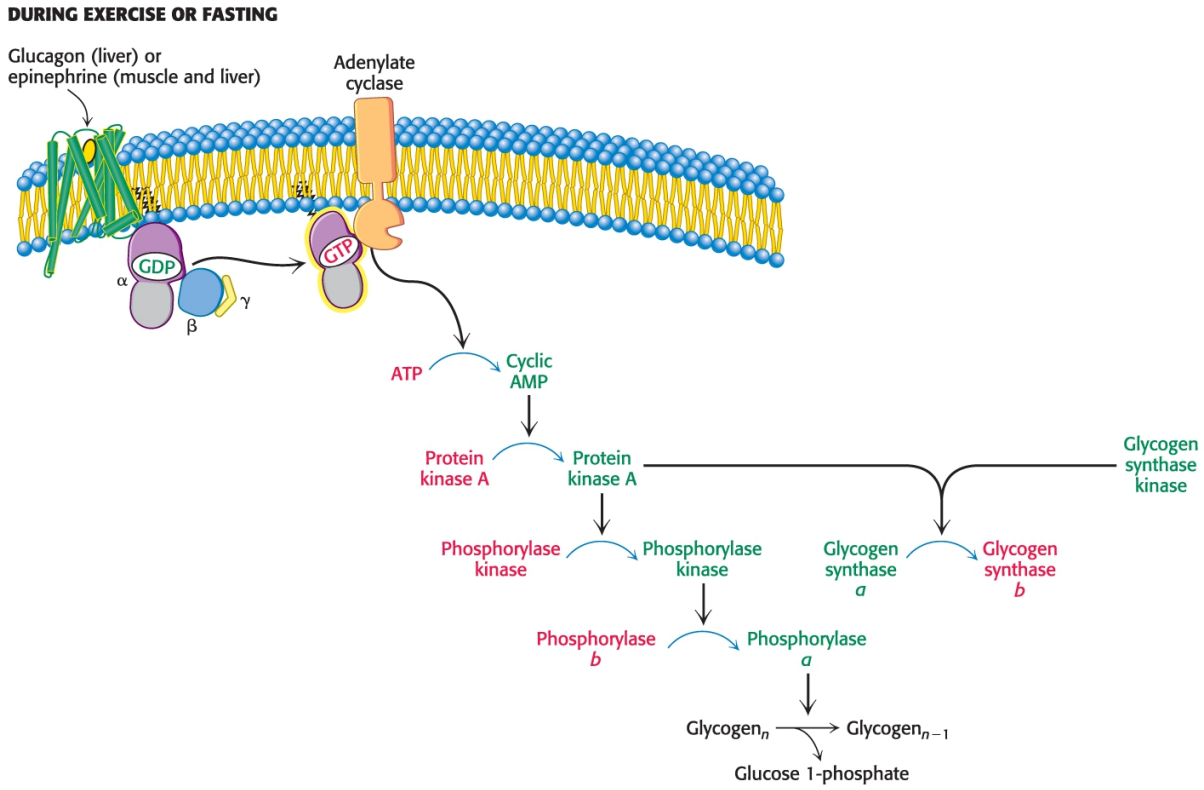
© Macmillan Learning

A linear chain composed of 5 yellow hexagons is connected to the core. The hexagons are connected by alpha-1,4 linkage. Three successive downward arrows are labeled “U D P-glucose plus glycogen synthase.” A linear chain composed of seven blue hexagons on the right and ten yellow hexagons on the right is shown below the arrows. The rightmost yellow hexagon is connected to the core. A downward arrow is labeled branching enzyme. It leads to a branched glycogen molecule below. The branched molecule consists

of a linear chain composed of ten yellow hexagons connected to another linear chain at the top composed of seven blue hexagons through an alpha-1,6 linkage. The leftmost yellow hexagon of the bottom chain is connected to the core. A downward arrow points below a text that read “Synthase extends both nonreducing ends, followed by more branching.”

Return to FIGURE 21.17 Action of a branching enzyme

Extended description for FIGURE 21.18 A cross section of a glycogen molecule reveals the basic branching structure

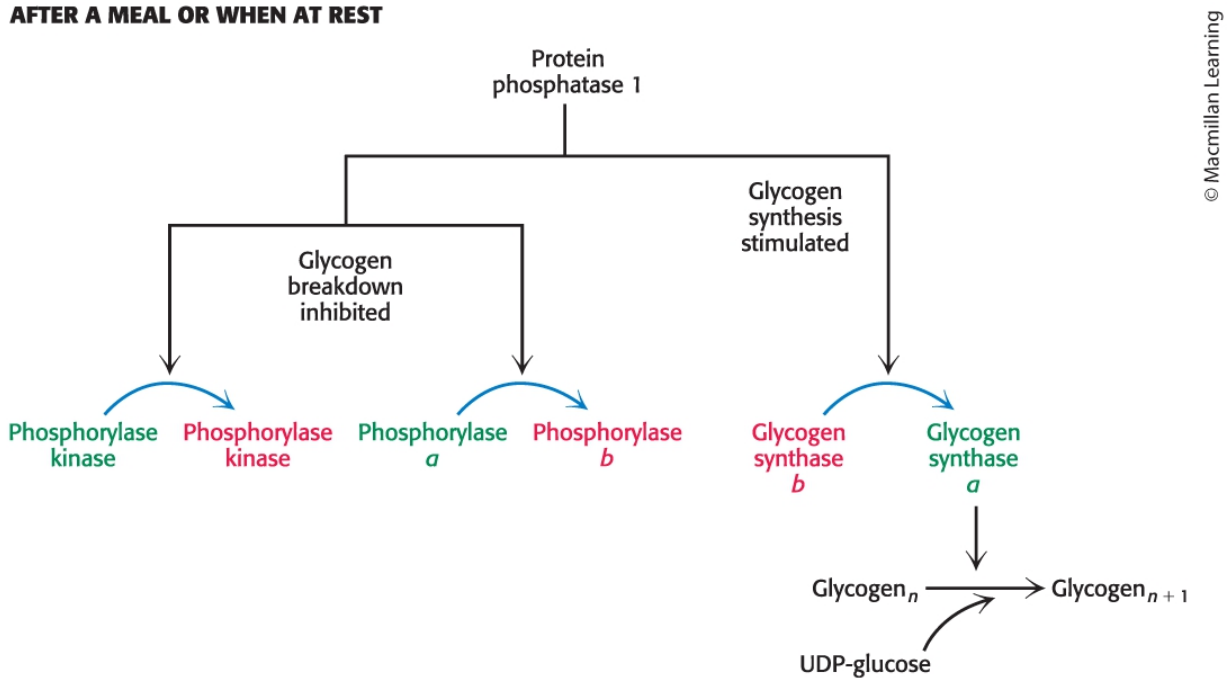


© Macmillan Learning

The cross-section contains a tiny circle labeled G at the center. It is connected to a linear chain of tiny circles oriented toward the upper right. The linear chain further undergoes extensive branching and sub-branching to form a network.

Return to FIGURE 21.18 A cross section of a glycogen molecule reveals the basic branching structure

Extended description for FIGURE 21.19 Glycogen metabolism is regulated in part by hormone-triggered cyclic A M P cascades



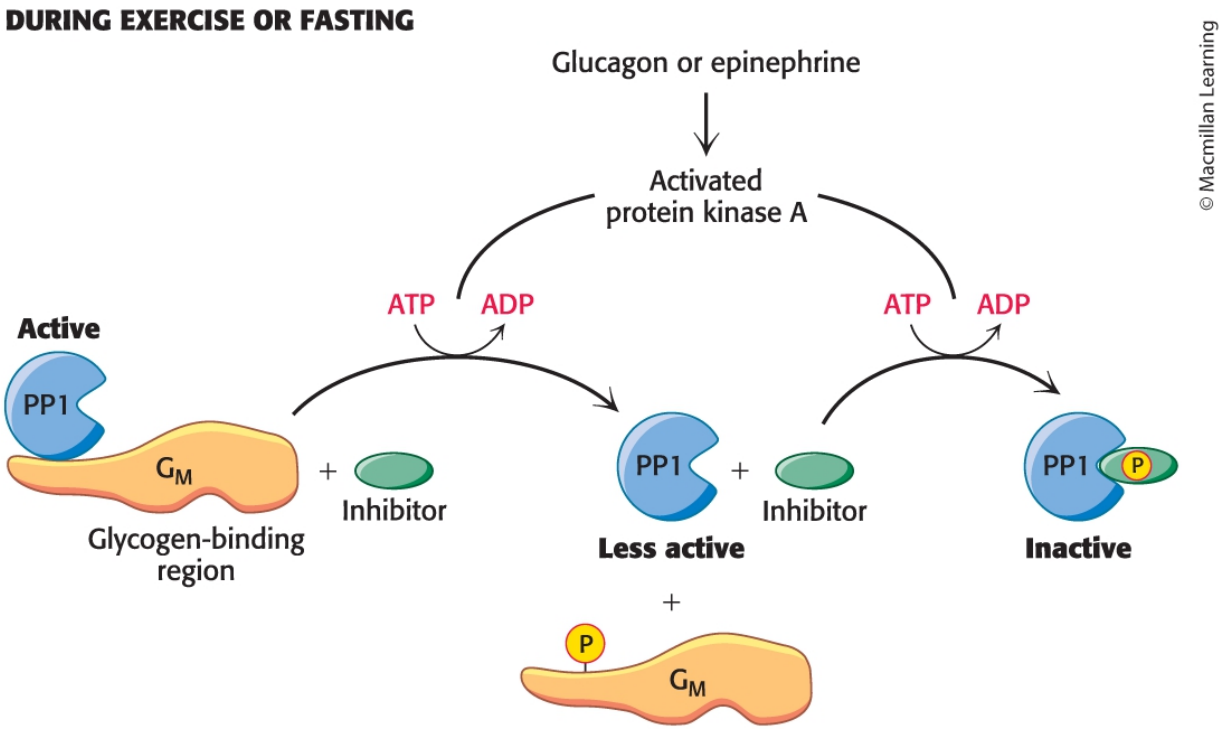
© Macmillan Learning

A “7 T M receptor” and adenylate cyclase are embedded in a membrane. The receptor binds to glucagon in the liver and epinephrine in the muscle and liver during exercise or fasting. The epinephrine or glucagon molecule is depicted as a tiny yellow oval. The cytoplasmic region of the receptor is bound to a trimeric G-protein consisting of alpha, beta, and gamma subunits. The alpha subunit is bound to G D P. An arrow from the G protein points toward the alpha subunit bound to G T P and associated with the cytoplasmic region of the adenylate cyclase. A downward arrow from adenylate cyclase points to the conversion of A T P highlighted in red to cyclic A M P highlighted in green. A downward arrow from

cyclic A M P points to the conversion of protein kinase A highlighted in red to protein kinase A highlighted in green. A downward arrow from green highlighted protein kinase A points to the conversion of phosphorylase kinase highlighted in red to phosphorylase kinase highlighted in green. A downward arrow from green highlighted phosphorylase kinase points to the conversion of phosphorylase b highlighted in red to phosphorylase a highlighted in green. The green highlighted phosphorylase a points toward a reaction depicting the conversion of glycogen subscript n into glycogen subscript n minus 1 and the release of glucose 1-phosphate. The green-highlighted protein kinase and green-highlighted glycogen synthase kinase together carry out the conversion of glycogen synthase a highlighted in green to glycogen synthase b highlighted in red.

Return to FIGURE 21.19 Glycogen metabolism is regulated in part by hormone-triggered cyclic A M P cascades

Extended description for FIGURE 21.20 Glycogen synthesis is regulated by protein phosphatase 1 (P P 1)

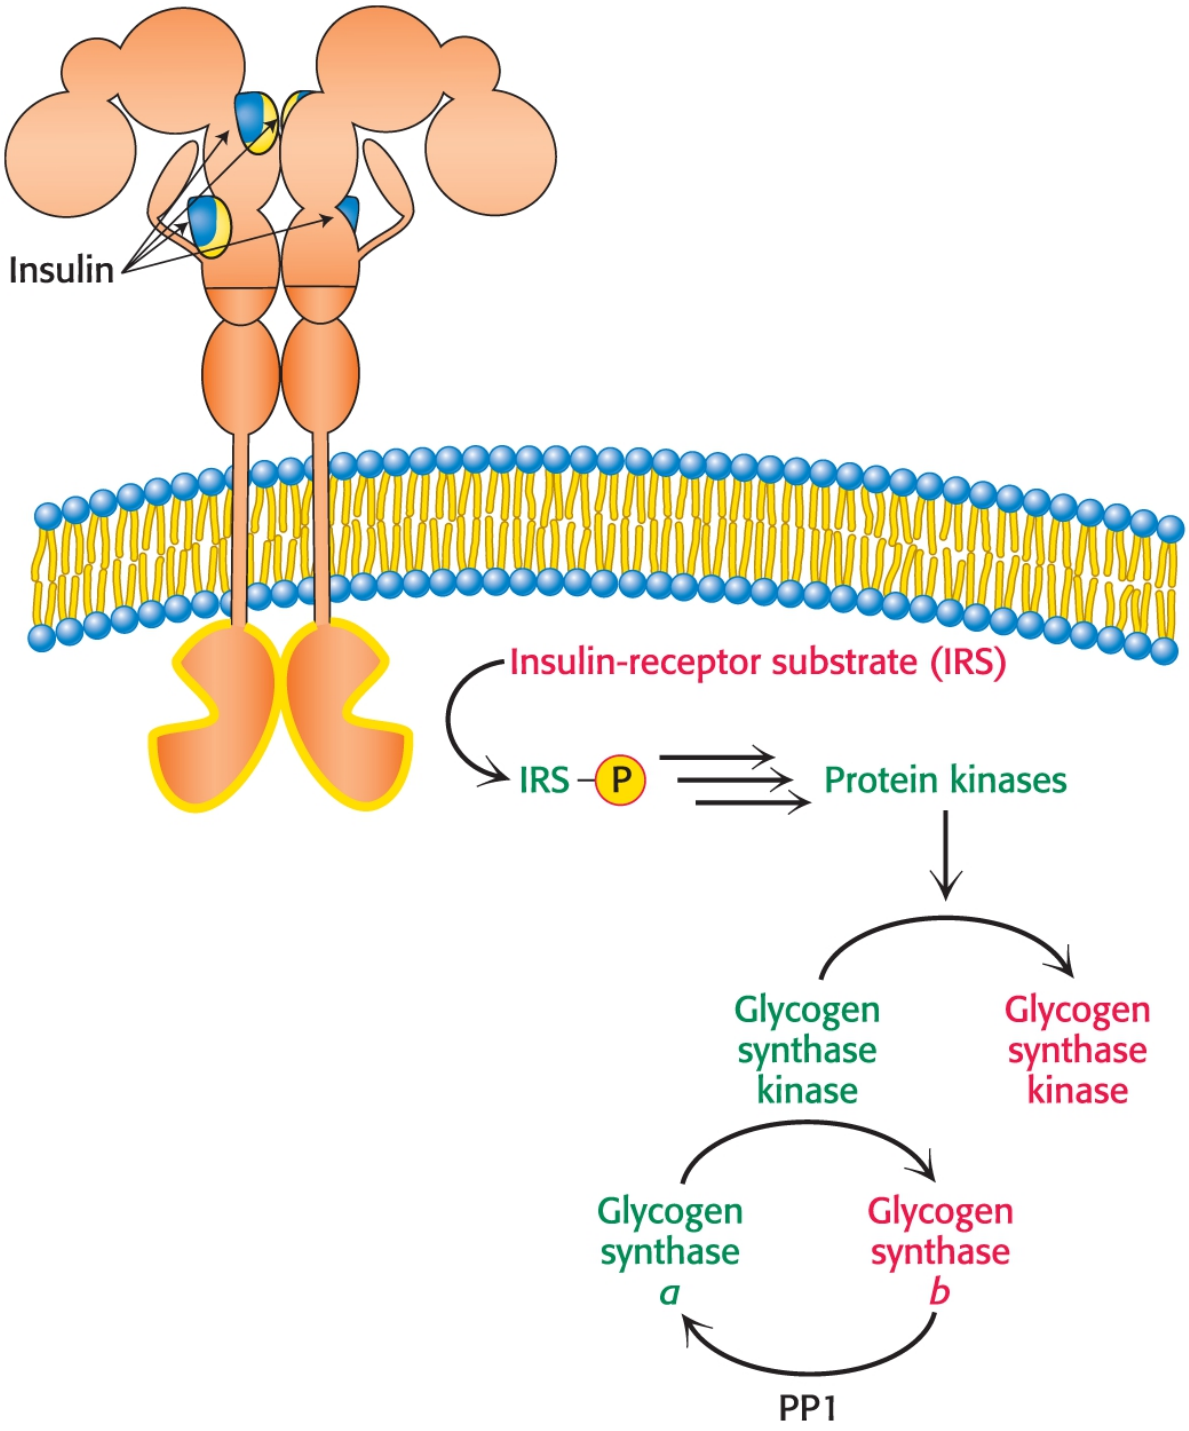


The flowchart shows the regulation of glycogen synthesis after a meal or when at rest. A line below protein phosphatase 1 splits into two branches. The right branch is labeled glycogen synthesis stimulated. It points toward the conversion of glycogen synthase b highlighted in red to glycogen synthase a highlighted in green. A downward arrow below the green-highlighted "glycogen synthase a" points toward a reaction depicting the conversion of glycogen subscript n into glycogen subscript n plus 1. A "U D P-glucose" molecule is used up during this conversion. The left branch further splits into two sub-branches and is labeled glycogen breakdown inhibited. The left sub-branch points to the conversion of phosphorylase kinase highlighted in green to phosphorylase kinase highlighted in red. The right sub-branch points to the conversion of

phosphorylase a highlighted in green to phosphorylase b highlighted in red.

Return to FIGURE 21.20 Glycogen synthesis is regulated by protein phosphatase 1 (P P 1)

Extended description for FIGURE 21.21 P P 1 is regulated by hormonally controlled cascades

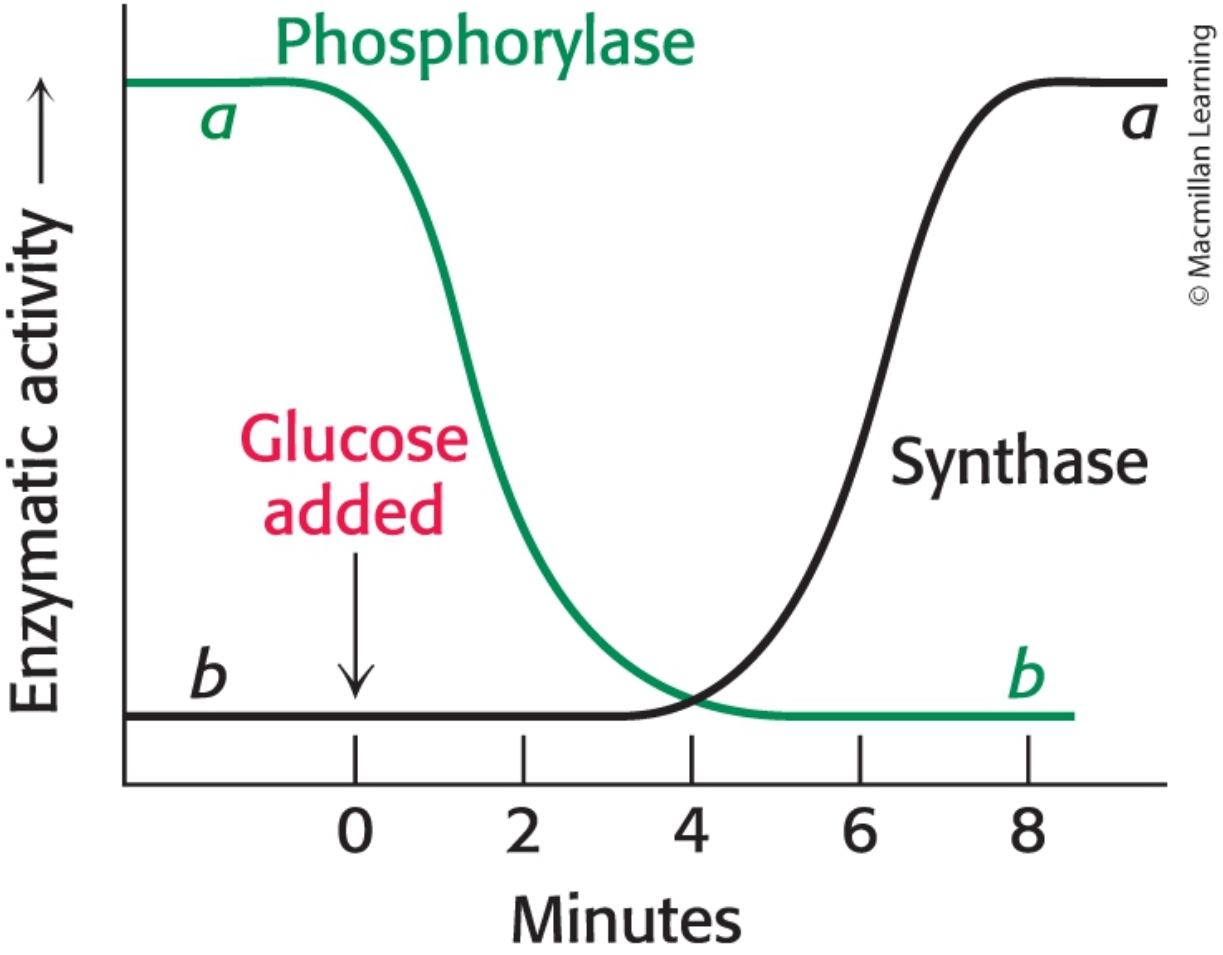


The regulation of P P 1 is depicted during exercise or fasting. A downward arrow below glucagon or epinephrine points to activated protein kinase A. The activated protein kinase A carries out the conversion of the active form of P P 1 to a less active form with the simultaneous hydrolysis of A T P to A D P. The active P P 1 is depicted as a blue circle with a triangular groove. It is bound to an elongated structure labeled G subscript M. The bottom free surface of G subscript M is labeled "Glycogen-binding region." An inhibitor depicted as a green oval is shown alongside. The less active P P 1 dissociates from the G subscript M. This occurs due to the addition of the phosphate group to G subscript M by the activated protein kinase A. The activated protein kinase A stimulates the binding of P P 1 to the inhibitor with the simultaneous hydrolysis of A T P to A D

P. The phosphorylated inhibitor binds to the triangular groove of P P 1.

Return to FIGURE 21.21 P P 1 is regulated by hormonally controlled cascades

Extended description for FIGURE 21.22 Insulin inactivates glycogen synthase kinase

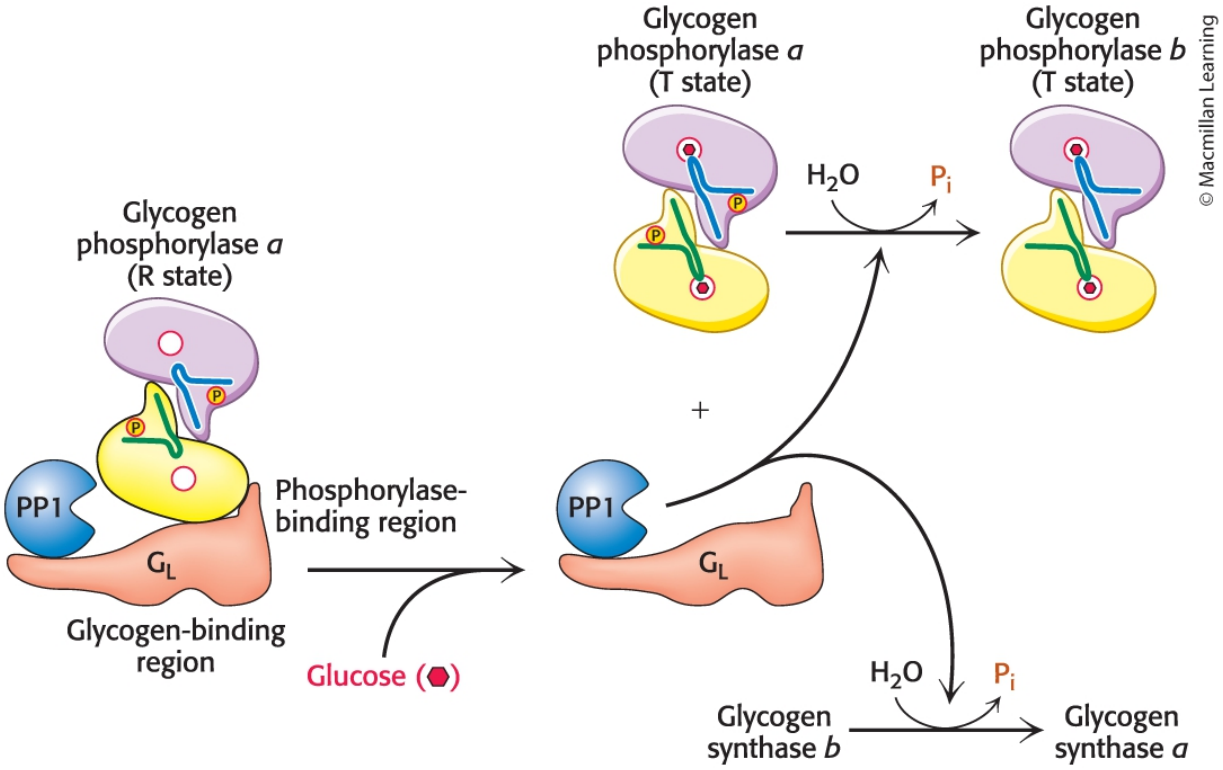


© Macmillan Learning

A transmembrane insulin receptor is embedded in the membrane. It is bound to three insulin molecules. The cytoplasmic domain of the receptor carries out the phosphorylation of insulin receptor substrate (I R S) to I R S, single, bond, P. Three successive forward arrows from phosphorylated I R S point toward protein kinases highlighted in green. A downward arrow below protein kinases shows the conversion of glycogen synthase kinase highlighted in green to glycogen synthase kinase highlighted in red. The green-highlighted glycogen synthase kinase stimulates the conversion of glycogen synthase a highlighted in green to glycogen synthase b highlighted in red. An arrow labeled P P 1 depicts the conversion of glycogen synthase b back to glycogen synthase a.

Return to FIGURE 21.22 Insulin inactivates glycogen synthase kinase

Extended description for FIGURE 21.23 Blood glucose regulates liver-glycogen metabolism

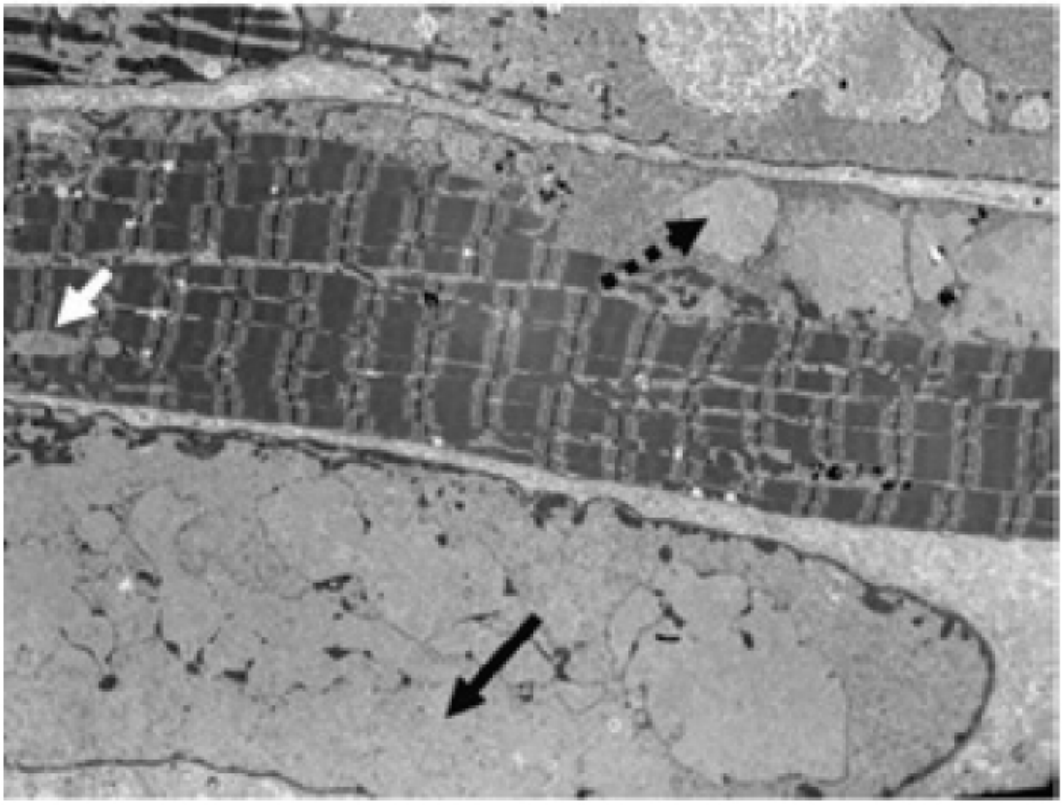


The horizontal axis is labeled minutes. It has markings ranging from 0 to 8 in increments of 2 units. The vertical axis is labeled enzymatic activity that increases from the bottom to the top. Glucose is added at 0 minutes. A green line curve labeled phosphorylase starts at the highest enzymatic activity. It moves horizontally toward the right and starts moving downward after 0 minutes. It reaches the lowest enzymatic activity at 4 minutes and then continues moving horizontally toward the right till 8 minutes. The starting point of the curve is labeled a and the endpoint is labeled b. A black line curve

starts at the lowest enzymatic activity. It moves horizontally toward the right till 4 minutes and then starts rising to reach the highest enzymatic activity at 8 minutes. The curve then moves horizontally toward the right. The starting point of the curve is labeled b and the endpoint is labeled a.

Return to FIGURE 21.23 Blood glucose regulates liver-glycogen metabolism

Extended description for FIGURE 21.24 Glucose regulates liver-glycogen metabolism



The phosphorylated R state of "glycogen phosphorylase a" is bound to an elongated protein labeled G subscript L. The top surface of G subscript L that is bound to the glycogen phosphorylase a is labeled "Phosphorylase-binding region" and the bottom free surface is labeled "Glycogen-binding region." The G subscript L protein is bound to P P 1 on the top left surface. A forward arrow shows the entry of glucose depicted as a red hexagon. The entry of glucose leads to the dissociation of glycogen phosphorylase a from G subscript L. The P P 1 protein is still attached to G subscript L. The active site of both subunits of glycogen phosphorylase a are bound to glucose and labeled T state. An arrow from P P 1 bound to G subscript L points toward a forward arrow depicting the conversion

of glycogen phosphorylase a (T state) to glycogen phosphorylase b (T state). This conversion is coupled with the entry of H 2 O and the release of P subscript i. The active site of glycogen phosphorylase b is still bound to the glucose molecule. However, both the subunits have lost the phosphate group. An arrow from P P 1 bound to G subscript L points toward a forward arrow depicting the conversion of glycogen synthase b to glycogen synthase a coupled with the entry of H 2 O and release of P subscript i.

Extended description for Western blot photograph shows the separation of samples of glycogen isolated from a cell line

The left side of the blot has molecular weight in kilodalton markings from the bottom to the top. These are 37, 43, 56, 66, 97, 116, 158, and 212. Two sets of lanes of samples 1 to 4 are shown. The first set of lanes for each sample is labeled minus to show no treatment with alpha-amylase. The second set of lanes for each sample is labeled plus to show treatment with alpha-amylase. The banding pattern is as follows:

Sample 1, minus lane: A distinct dark band is visible at 66 kilodaltons. A faint band is present above and below 56 kilodaltons. A smear of bands is visible between 66 and 116 kilodaltons.

Sample 2, minus lane: A distinct dark band is visible at 66 kilodaltons. A faint band is present above and below 56 kilodaltons. The band below is more noticeable. A smear of bands is visible above 66 kilodaltons.

Sample 3, minus lane: A distinct dark band is visible at 66 kilodaltons. A faint band is present above and below 56 kilodaltons. A smear of bands is present between 66 and 116 kilodaltons.

Sample 4, minus lane: A distinct dark band is visible at 66 kilodaltons. A faint band is present below 56 kilodaltons. A smear of bands is present between 66 and 116 kilodaltons.

Sample 1, plus lane: A thick dark band is visible at 66 kilodaltons. A thin dark band is present above and below 56 kilodaltons.

Sample 2, plus lane: A thick dark band is visible at 66 kilodaltons. A thin dark band is present below 56 kilodaltons.

Sample 3, plus lane: A thick dark band is visible at 66 kilodaltons. A thin dark band is present below 56 kilodaltons.

Sample 4, plus lane: A thick dark band is visible at 66 kilodaltons. A thin dark band is present below 56 kilodaltons.

Return to Western blot photograph shows the separation of samples of glycogen isolated from a cell line

Extended description for Synthesis and degradation of fatty acids

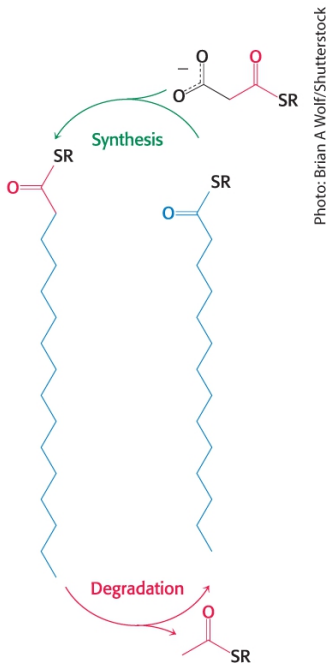

Photo: Brian A Wolf/Shutterstock

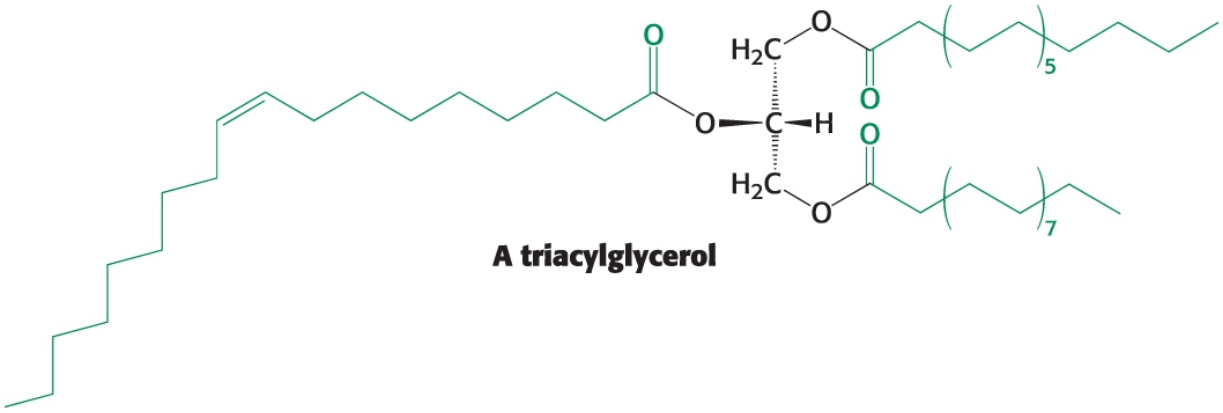
A curved arrow labeled synthesis shows the entry of a molecule and points toward a fatty acid.

The structure of the molecule is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is partially double bonded to O above and O on the lower left. The O atoms have an overall negative charge. C 3 is double bonded to O above and single bonded to S R on the lower right.

The structure of the fatty acid is as follows: A 16-carbon alkane chain is depicted as a vertical line structure using 15 zigzag lines. C 1 is double bonded to O on the left and single bonded to S R on the upper right.

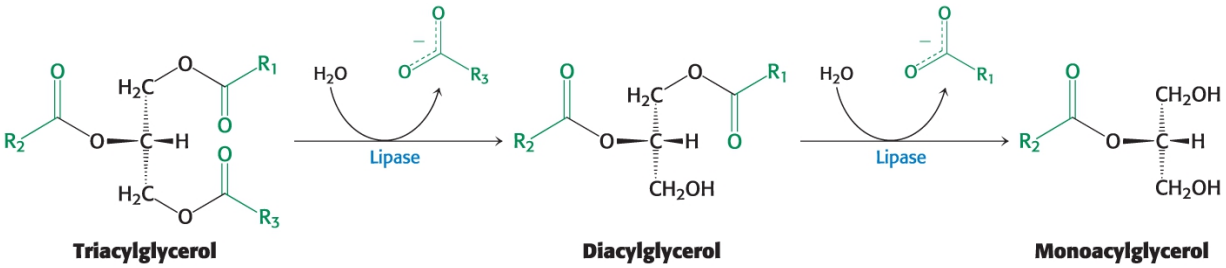


A curved arrow labeled degradation points from the fatty acid to two products.

The structure of the first product is as follows: A central C atom is double bonded to O above, single bonded to S R on the lower right, and single bonded to C H 3 on the lower left in the form of a line.

The structure of the second product is as follows: A 14-carbon alkane chain is depicted as a vertical line structure using 13 zigzag lines. C 1 is double bonded to O on the left and single bonded to S R on the upper right.

Return to Synthesis and degradation of fatty acids



Extended description for Structure of triacylglycerol

The structure of triacylglycerol is as follows: A central C atom is dash-bonded to C H 2 above, dash-bonded to C H 2, wedge bonded to O on the left, and wedge bonded to H on the right. The C H 2 groups, located above and below, are single-bonded to an O atom. The O atom above is single-bonded to an 8-carbon alkane chain depicted as a line structure using 7 zigzag lines. C 1 is double bonded to O below. C 3 and C 4 are enclosed in parenthesis with subscript 5. The O atom below is single-bonded to a 6-carbon alkane chain depicted as a line structure using 5 zigzag lines. C 1 is double bonded to O above and C 3 and C 4 are enclosed in parenthesis with subscript 7. The left O atom, wedge bonded to the central C atom, is further single bonded to an 18-carbon alkene chain depicted as a line structure using 17 zigzag lines. A double bond is present between C 9 and C 10. C 1 is double bonded to O above. The alkene chain is bent at C 10.

Return to Structure of triacylglycerol

Extended description for FIGURE 22.2 Breakdown of triacylglycerol into monoacylglycerol and fatty acids by lipase

The first step involves the breakdown of triacylglycerol into fatty acid and diacylglycerol by lipase.

The structure of triacylglycerol is as follows: A central C atom is dash-bonded to C H 2 above, dash-bonded to C H 2 below, wedge bonded to O on the left, and wedge bonded to H on the right. The C H 2 groups, located above and below, are single-bonded to an O atom. The O atom above is single-bonded to C on the lower right. This C is double bonded to O below and single bonded to R 1 on the upper right. The O atom below is single-bonded to C on the upper right. This C is double bonded to O above and single bonded to R 3 on the lower right. The O atom, wedge bonded to the central C atom, is further single bonded to C on the upper left. This C is double bonded to O above and single bonded to R 2 on the lower left.

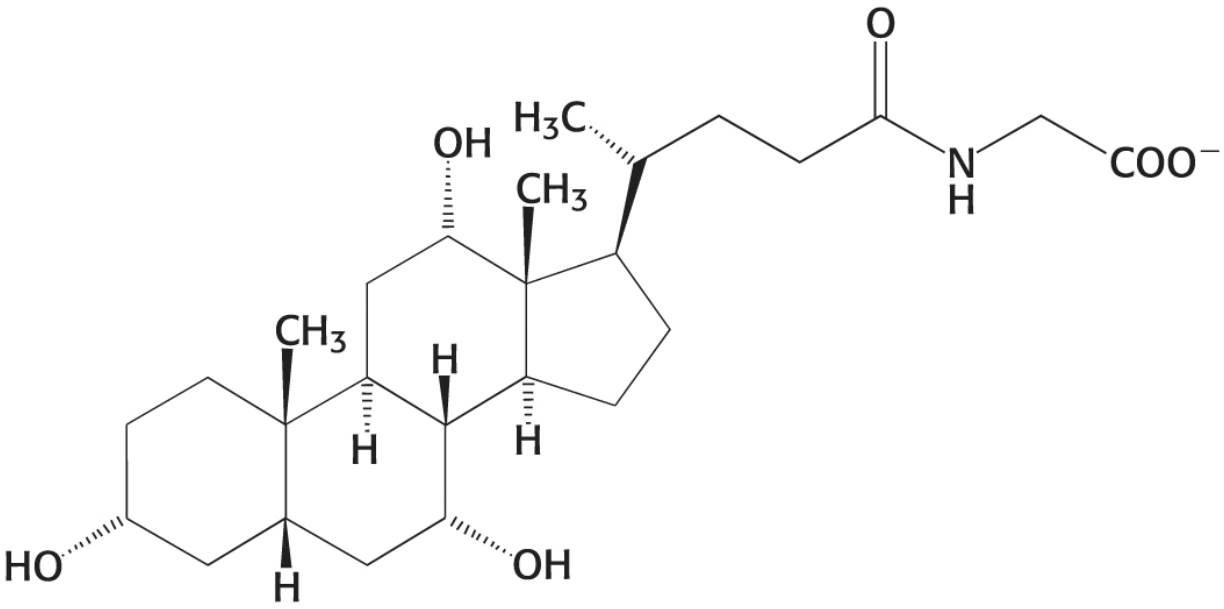
A forward arrow labeled lipase leads to diacylglycerol. A curved arrow above it shows the simultaneous entry of H 2 O and the release of a fatty acid.

The structure of this fatty acid is as follows: A central C atom is partially double-bonded to O above, partially double-bonded to O on

the lower left, and single-bonded to R 3 on the lower right. The O atoms have an overall negative charge.

The structure of diacylglycerol is as follows: A central C atom is dash-bonded to C H 2 above, dash bonded to C H 2 O H below, wedge bonded to O on the left, and wedge bonded to H on the right. The C H 2 group located above is single-bonded to an O atom. This O atom is single-bonded to C on the lower right. This C is double bonded to O below and single bonded to R 1 on the upper right. The O atom, wedge bonded to the central C atom, is further single bonded to C on the upper left. This C is double bonded to O above and single bonded to R 2 on the lower left.

The second step involves the breakdown of diacylglycerol into fatty acid and monoacylglycerol by lipase.



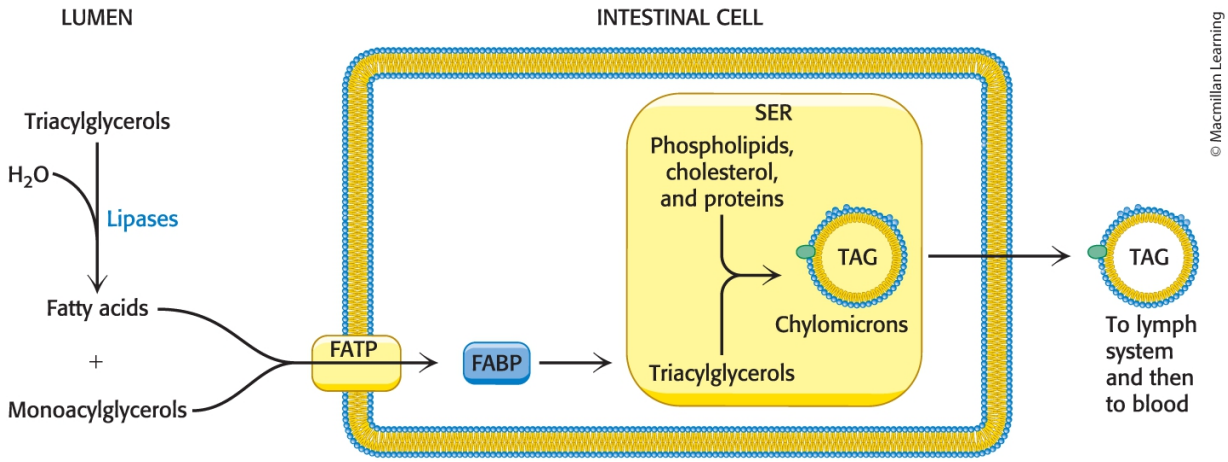
A forward arrow labeled lipase leads to monoacylglycerol. A curved arrow above it shows the simultaneous entry of H 2 O and the release of a fatty acid.

The structure of this fatty acid is as follows: A central C atom is partially double-bonded to O above, partially double-bonded to O on the lower left, and single-bonded to R 1 on the lower right. The O atoms have an overall negative charge.

The structure of monoacylglycerol is as follows: A central C atom is dash-bonded to C H 2 O H above, dash bonded to C H 2 O H below, wedge bonded to O on the left, and wedge bonded to H on the right. The O atom, wedge bonded to the central C atom, is further single bonded to C on the upper left. This C is double bonded to O above and single bonded to R 2 on the lower left.

Return to FIGURE 22.2 Breakdown of triacylglycerol into monoacylglycerol and fatty acids by lipase

Extended description for Structure of glycocholate



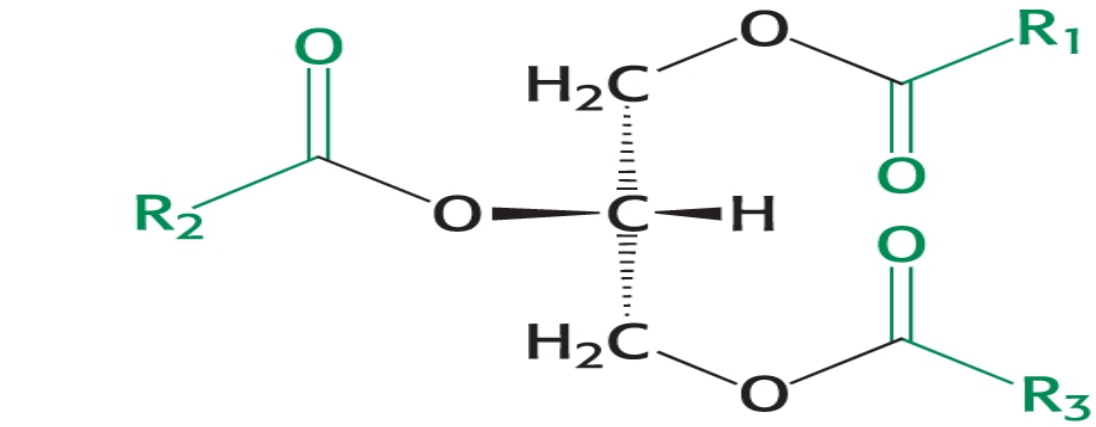
Glycocholate

The structure of glycocholate is as follows: A 6-carbon homocyclic hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. C 5 is dash bonded to O H on the lower left. It is fused to a second 6-carbon homocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. In the second ring, C 1 is dash bonded to H below. C 2 is wedge bonded to H above. C 3 is dash-bonded to O H on the lower right. C 5 is wedge bonded to H below. C 6 is wedge bonded to C H 3 above. The second ring is fused to a third 6-carbon homocyclic hexagonal ring in a vertical orientation such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. In the third ring, C 1 is dash bonded to O H above. The third ring is fused to a 5-carbon homocyclic pentagonal ring in a horizontal orientation such that C 2 and C 3 of the third ring are C 4 and C 3 respectively of the pentagonal ring. In the pentagonal ring,

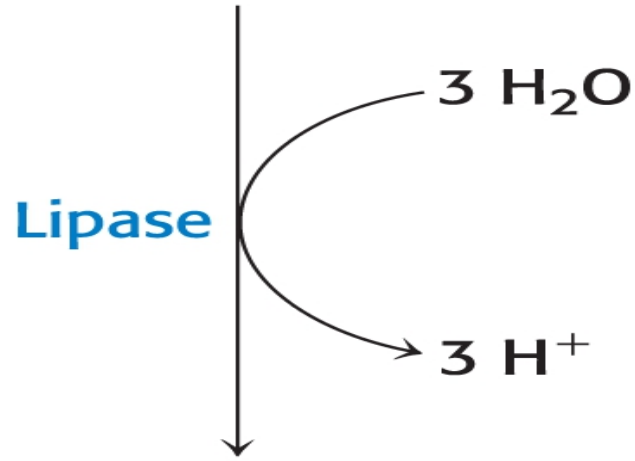
C 3 is dash bonded to H below. C 4 is wedge bonded to C H 3 above. C 5 is wedge bonded to C 1 of a 1 N and 5 C alkane chain depicted as a line structure using 5 zigzag lines. N bound to H occupies the fifth position. C 1 is dash bonded to C H 3 on the upper left. C 4 is double bonded to O above. C 5 is single bonded to C O O superscript minus on the lower right.

Return to Structure of glycocholate

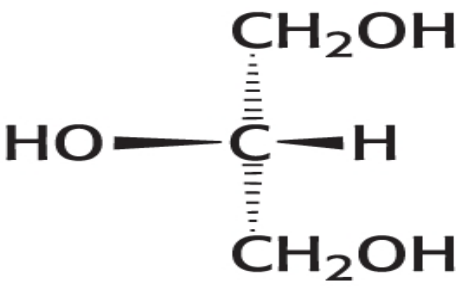
Extended description for FIGURE 22.4 Fat absorption and transport is a complex process involving multiple proteins



A rectangular intestine cell is shown in the center. It is surrounded by a lipid bilayer. The region on the left of the cell is labeled lumen. In the lumen, triacylglycerols are converted into fatty acids and monoacylglycerols by the action of lipases. This conversion requires the use of H 2 O. The fatty acids and monoacylglycerols in the lumen are transported to the intestinal cell through a transmembrane protein labeled F A T P. Inside the intestinal cell, the F A B P depicted as a small blue rectangle transports the fatty acids and monoacylglycerols to S E R, where they are converted back to triacylglycerols. The S E R is depicted as a large yellow rectangle inside the cell. Inside the S E R, the phospholipids, cholesterol, and proteins combine with triacylglycerol to produce chylomicrons. The chylomicron is depicted as a circular structure surrounded by a lipid monolayer. The core of the chylomicrons contains triacylglycerol abbreviated as T A G. The chylomicrons are transported out of the intestinal cell to the lymph system and then to blood.

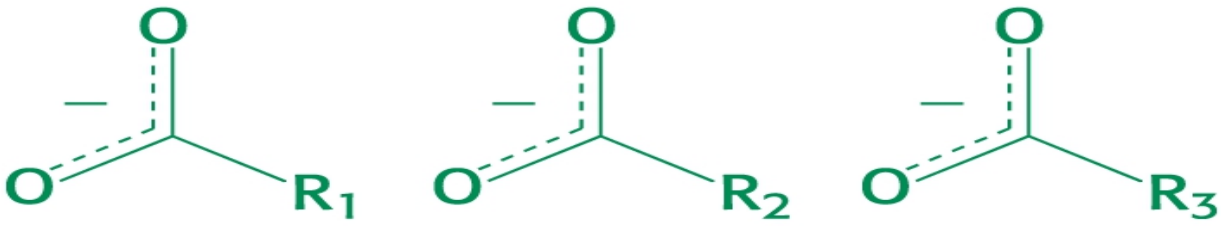


Return to FIGURE 22.4 Fat absorption and transport is a complex process involving multiple proteins



Extended description for Hydrolyzation of

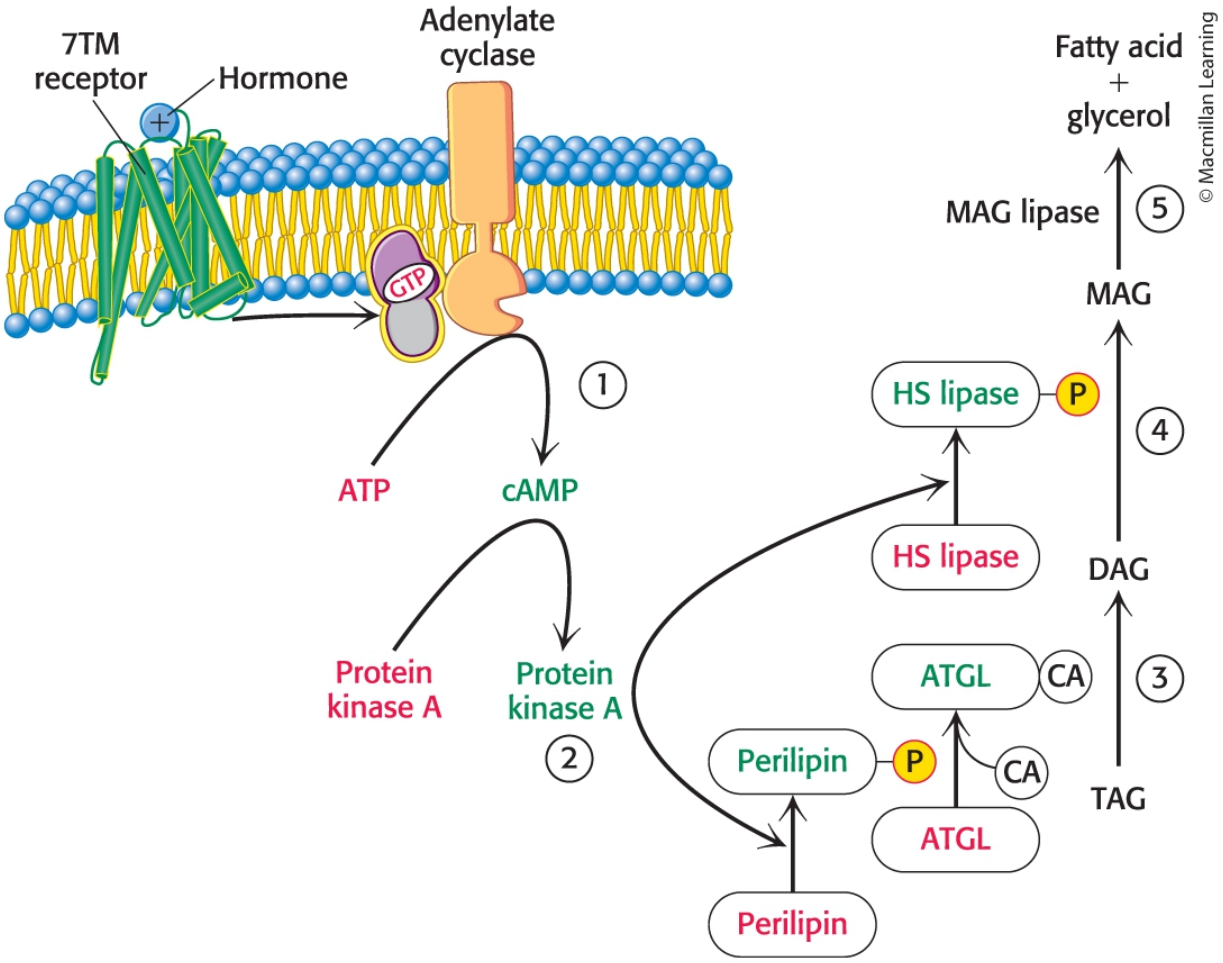
triacylglycerol to yield glycerol and isolated fatty acids



Triacylglycerol

Glycerol

+



Fatty acids

The coupled reaction contains one reactant and four products. The reactant labeled Triacylglycerol has the following structure: A central C atom is dash bonded to C H 2 above, a second C H 2 group below and is wedge bonded to H on the right and O on the left. The first C H 2 group is single bonded to a second O atom on the upper right. The second O atom is single bonded to a second central C atom on the lower right in the form of a line. The second central C atom is double bonded to a third O atom below and is single bonded to R 1 on the upper right. The second central C atom and the groups attached to it are highlighted in green. The first O atom is single bonded to a third central C atom on the upper left in the form of a line. The third central C atom is double bonded to a fourth O atom above and is single bonded to R 2 on the lower left. The third central C atom and the groups attached to it are highlighted in green. The second C H 2 group is single bonded to a fifth O atom on the lower right. The fifth O atom is single bonded to a fourth central C atom on the upper right in the form of a line. The fourth central C atom is double bonded to a sixth O atom above and is single bonded to R 3 on the lower right. The fourth central C atom and the groups attached to it are highlighted in green. The reaction takes place in the presence of lipase and is coupled with the conversion of 3 H 2 O to 3 H superscript plus. The first product labeled Glycerol has the following structure: A central C atom is dash bonded to C H 2 above, a second C H 2 group below and is wedge bonded to H on the right and O H on the left. The second to the fourth products are highlighted in green and collectively labeled fatty acids. The second product has the following structure: A central C atom is partially double bonded to O above, a second O atom on the lower left and is single bonded to R 1 on the lower right. The structure carries a negative charge. The third product has the following structure: A central C atom is partially double bonded to O above, a second O atom on the lower left and is single bonded to R 2 on the lower right. The structure carries a negative charge. The fourth product has the following structure: A central C atom is partially double bonded to O

above, a second O atom on the lower left and is single bonded to R 3 on the lower right. The structure carries a negative charge.

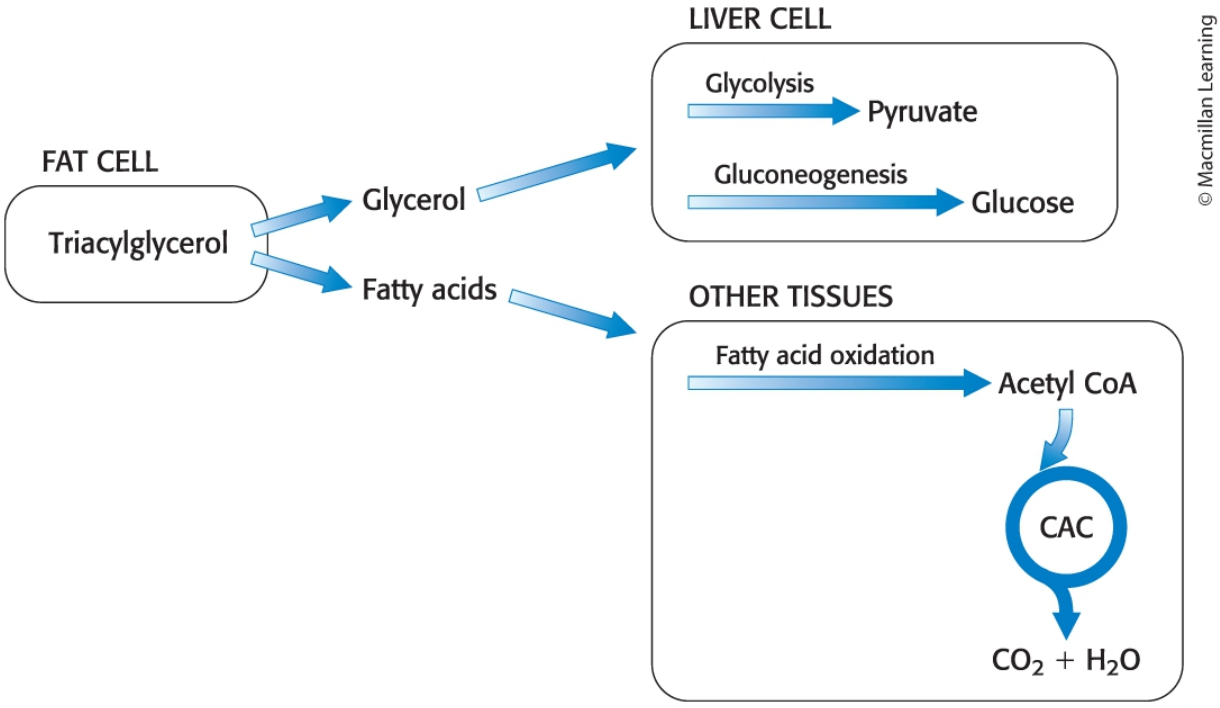
Return to Hydrolyzation of triacylglycerol to yield glycerol and isolated fatty acids

Extended description for FIGURE 22.5 Triacylglycerols in adipose tissue are converted into free fatty acids in response to hormonal signals

A "7 T M receptor" and adenylate cyclase are embedded in a lipid bilayer. A hormone depicted as a tiny blue circle with a plus symbol is bound to the outer surface of the receptor. An arrow from the cytoplasmic surface of the receptor points toward the alpha subunit of G protein bound to G T P. The G protein is associated with the cytoplasmic region of adenylate cyclase. A curved arrow labeled 1 shows the conversion of A T P highlighted in red to c A M P

highlighted in green by adenylate cyclase. Another curved arrow depicts the conversion of protein kinase A highlighted in red to protein kinase A highlighted in green after c A M P binding. The green highlighted protein kinase A is labeled 2. It carries out the phosphorylation of perilipin to perilipin, single bond, P and H S lipase to H S lipase, single bond, P.

The phosphorylated perilipin and binding of C A cause the conversion of A T G L highlighted in red to A T G L highlighted in green.

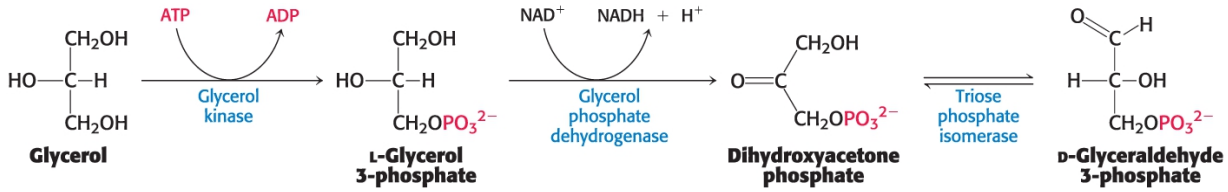


The activated A T G L bound to C A carries out the conversion of T A G to D A G depicted by an upward arrow labeled 3.

The phosphorylated H S lipase carries out the conversion of D A G to M A G depicted by an upward arrow labeled 4.

M A G is broken down by M A G lipase to produce fatty acid plus glycerol. This is depicted by an upward arrow labeled 5.

Return to FIGURE 22.5 Triacylglycerols in adipose tissue are converted into free fatty acids in response to hormonal signals



Extended description for FIGURE 22.6 Lipolysis generates fatty acids and glycerol

The fat cell is depicted as a small rectangle containing triacylglycerol. The triacylglycerol is broken down in the fat cell to release glycerol and fatty acids. The glycerol molecule travels to the liver cell depicted as a relatively larger rectangle. Inside the liver cell, glycerol is either converted into pyruvate via glycolysis or converted into glucose via gluconeogenesis. The fatty acids travel to other tissues depicted as a large square. Inside other tissues, fatty acids undergo oxidation to produce acetyl C o A. The acetyl C o A molecule enters the citric acid cycle depicted as a small circle labeled C A C. The products of the citric acid cycle are C O 2 plus H 2 O.

Return to FIGURE 22.6 Lipolysis generates fatty acids and glycerol

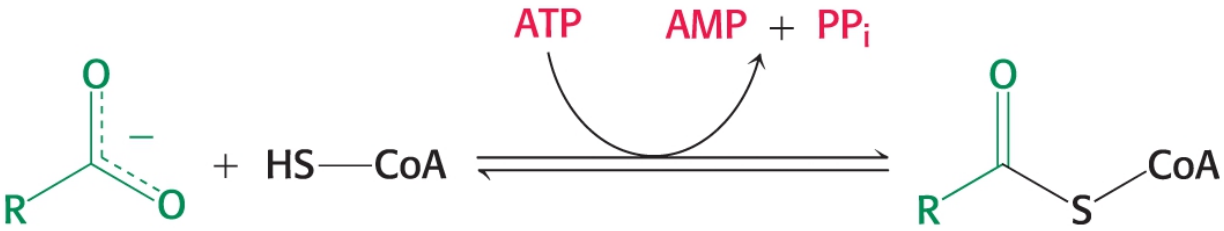
Extended description for Stepwise conversion of glycerol to D-Glyceraldehyde 3-phosphate

In the first step, glycerol is irreversibly converted into L-Glycerol 3-phosphate by the enzyme glycerol kinase with the simultaneous hydrolysis of A T P to A D P.

The structure of glycerol is as follows: C H 2 O H, single bond, C, single bond, C H 2 O H. C 2 is single bonded to O H on the left and H on the right.

The structure of L-Glycerol 3-phosphate is as follows: C H 2 O H, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 2 is single bonded to O H on the left and H on the right.

In the second step, L-Glycerol 3-phosphate is irreversibly converted into dihydroxyacetone phosphate by glycerol phosphate dehydrogenase with the simultaneous reduction of N A D superscript plus to N A D H plus H superscript plus.



The structure of dihydroxyacetone phosphate is as follows: A central C atom is single bonded to C H 2 O H on the upper right, double bonded to O on the left, and single bonded to C H 2 O P O 3 superscript 2 minus.

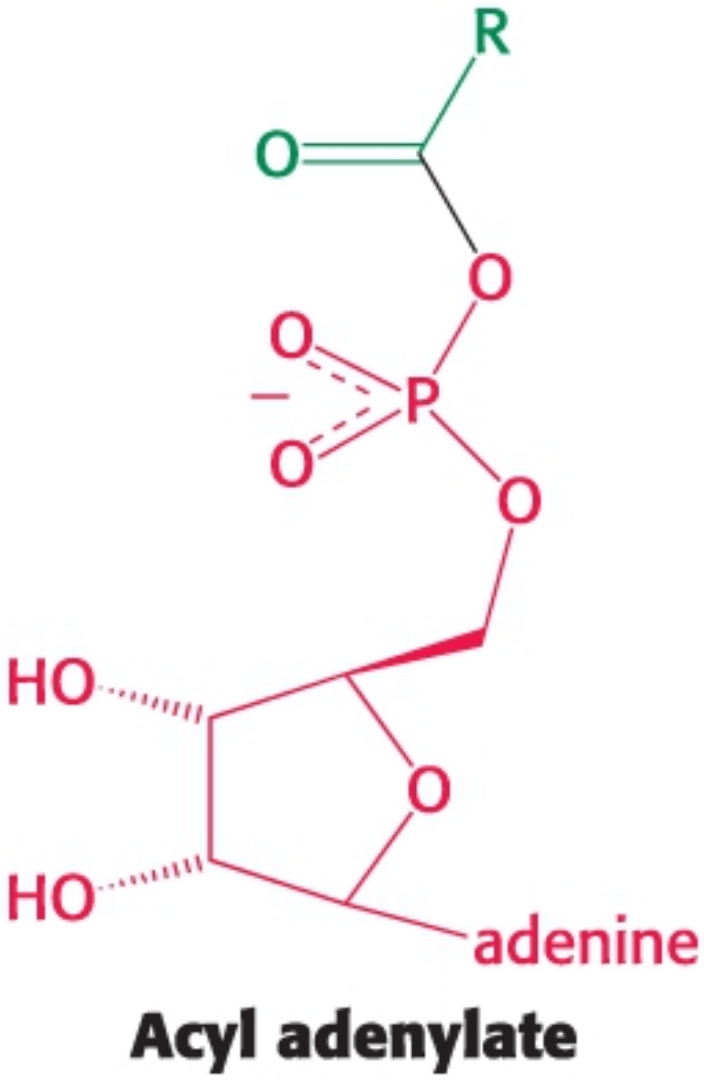
the third step, dihydroxyacetone phosphate is reversibly converted into D-Glyceraldehyde 3-phosphate by triose phosphate isomerase.

The structure of D-Glyceraldehyde 3-phosphate is as follows: C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to H on the upper right. C 2 is single bonded to H on the left and O H on the right.

Return to Stepwise conversion of glycerol to D-Glyceraldehyde 3-phosphate

Extended description for Thioester linkage formation between fatty acid and coenzyme A

The reaction consists of two reactants and one product. The structure of the first reactant is as follows: A central C atom is partially double-bonded to O above, partially double-bonded to O on the lower right, and single-bonded to R on the lower left. The O atoms have an overall negative charge.



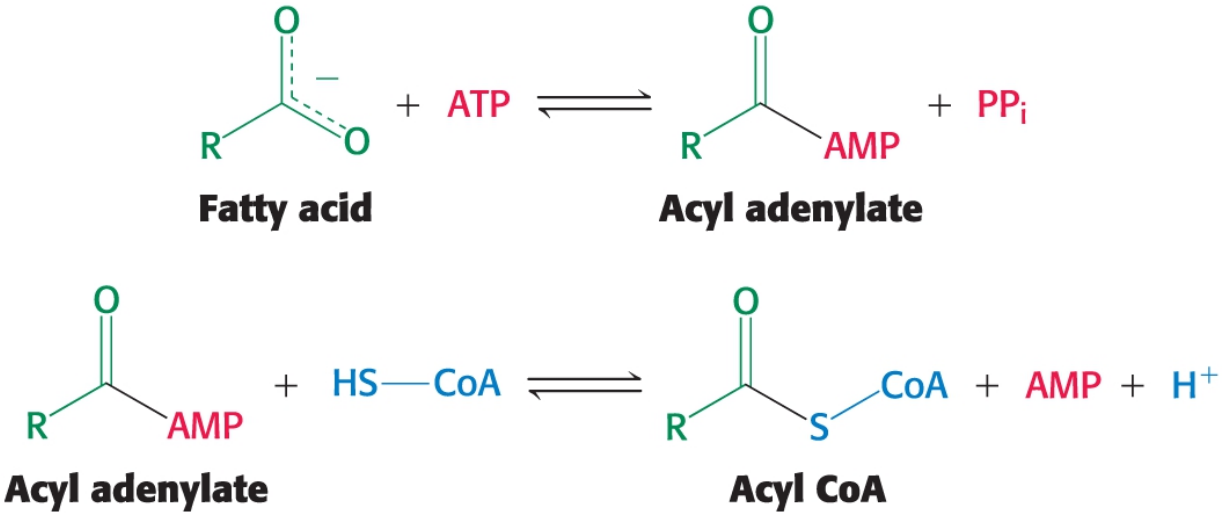
The second reactant is H S, single bond, C o A.

A reversible reaction arrow leads to the product. A curved arrow above it shows the simultaneous hydrolysis of A T P to A M P plus P P subscript i.

The structure of the product is as follows: A central C atom is double bonded to O above, single bonded to R on the lower left, and single bonded to S on the lower right. The S atom is single bonded to C o A on the upper right.

Return to Thioester linkage formation between fatty acid and coenzyme A

Extended description for Structure of acyl adenylate



Acyl adenylate

The structure of acyl adenylate is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation with C 1 occupying the bottom-right vertex. It consists of 1 O and 4 C atoms. O occupies the rightmost vertex. C 1 is single bonded to adenine on the lower right. C 2 and C 3 are dash bonded to O H on the left. C 4 is wedge bonded to C H 2 on the upper right. C H 2 is single bonded to O 1 atom of a zigzag vertical chain composed of O, single bond, P,

single bond, O. P is partially double bonded to O on the upper left and lower left. The O atoms bonded to P have an overall negative charge. O 2 of the chain is single-bonded to C on the upper left. This C atom is double-bonded to O on the left and single-bonded to R on the upper right.

Extended description for Conversion of fatty acid to acyl adenylate and acyl adenylate to acyl C o A

The first reversible reaction consists of two reactants and two products. The first reactant is fatty acid whose structure is as follows: A central C atom is partially double bonded to O above, partially double bonded to O on the lower right, and single bonded to R on the lower left. The O atoms have an overall negative charge.

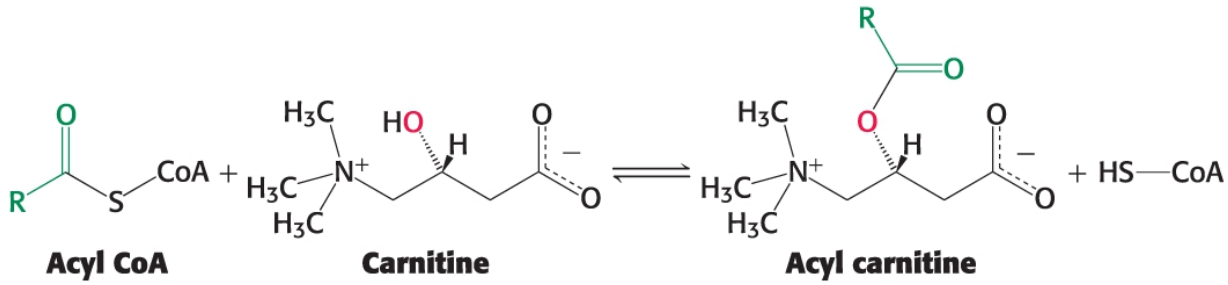
The second reactant is A T P.

The first product is acyl adenylate whose structure is as follows: A central C atom is double bonded to O above, single bonded to R on the lower left, and single bonded to A M P on the lower right.

The second product is P P subscript i.

The second reversible reaction consists of two reactants and three products.

The first reactant is acyl adenylate whose structure is as follows: A central C atom is double bonded to O above, single bonded to R on the lower left, and single bonded to A M P on the lower right.



The second reactant is H S, single bond, C o A.

The first product is acyl C o A whose structure is as follows: A central C atom is single bonded to R on the lower left, double bonded to O above, and single bonded to S on the lower right. The S atom is single bonded to C o A on the upper right.

The second product is A M P. The third product is H superscript plus ion.

Return to Conversion of fatty acid to acyl adenylate and acyl adenylate to acyl C o A

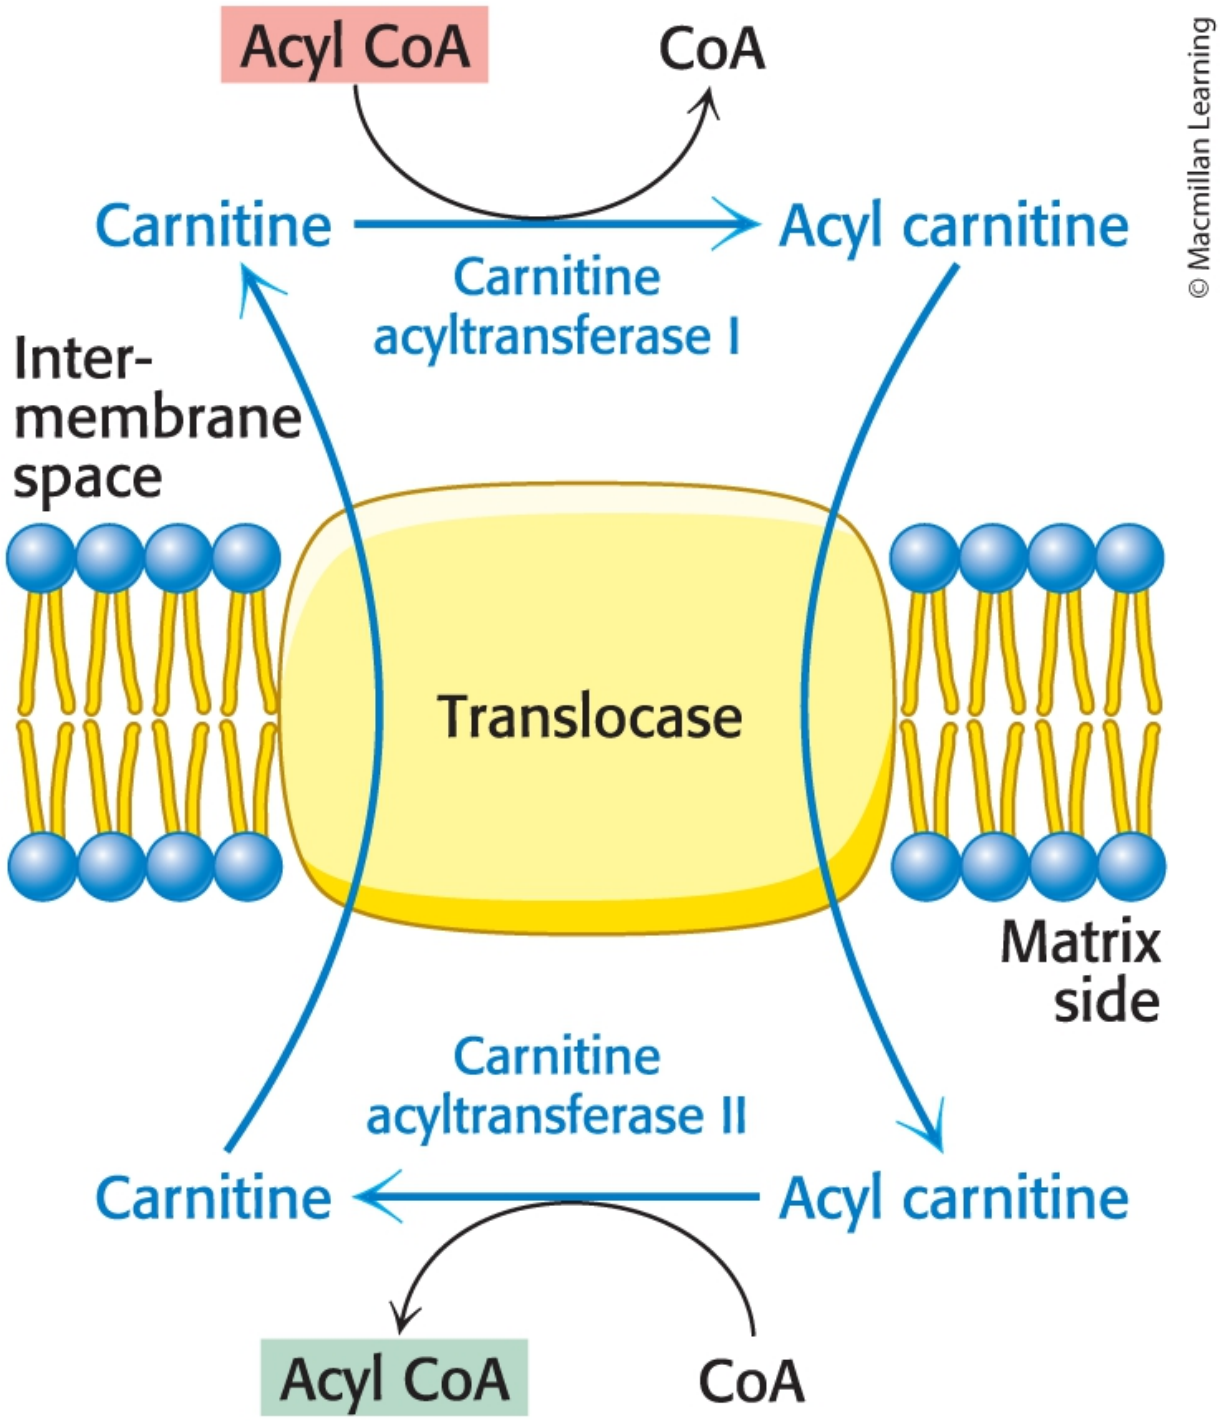
Extended description for Formation of acyl carnitine from acyl C o A and carnitine

The reaction consists of two reactants and two products. The first reactant is acyl C o A whose structure is as follows: A central C atom is single bonded to R on the lower left, double bonded to O above, and single bonded to S on the lower right. The S atom is single-bonded to C o A on the upper right.

The second reactant is carnitine whose structure is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to N superscript plus on the upper left. N superscript plus is single bonded to C H 3 above, on the left, and lower left. C 2 is dash bonded to O H on the upper left and wedge bonded to H on the upper right. C 3 is single-bonded to C on the upper right. This C atom is partially double-bonded to O above and O on the lower right. The O atoms have an overall negative charge.

A reversible reaction arrow leads to the products.

The first product is acyl-carnitine whose structure is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to N superscript plus on the upper left. N superscript plus is single bonded to C H 3 above, on the left, and lower left. C 2 is dash bonded to O on the upper left and wedge



bonded to H on the upper right. The O atom is single-bonded to C on the upper right. This C is single-bonded to R on the upper left and double-bonded to O on the right. C 3 is single-bonded to C on the upper right. This C atom is partially double-bonded to O above and O on the lower right. The O atoms have an overall negative charge.

The second product is H S, single bond, C o A.

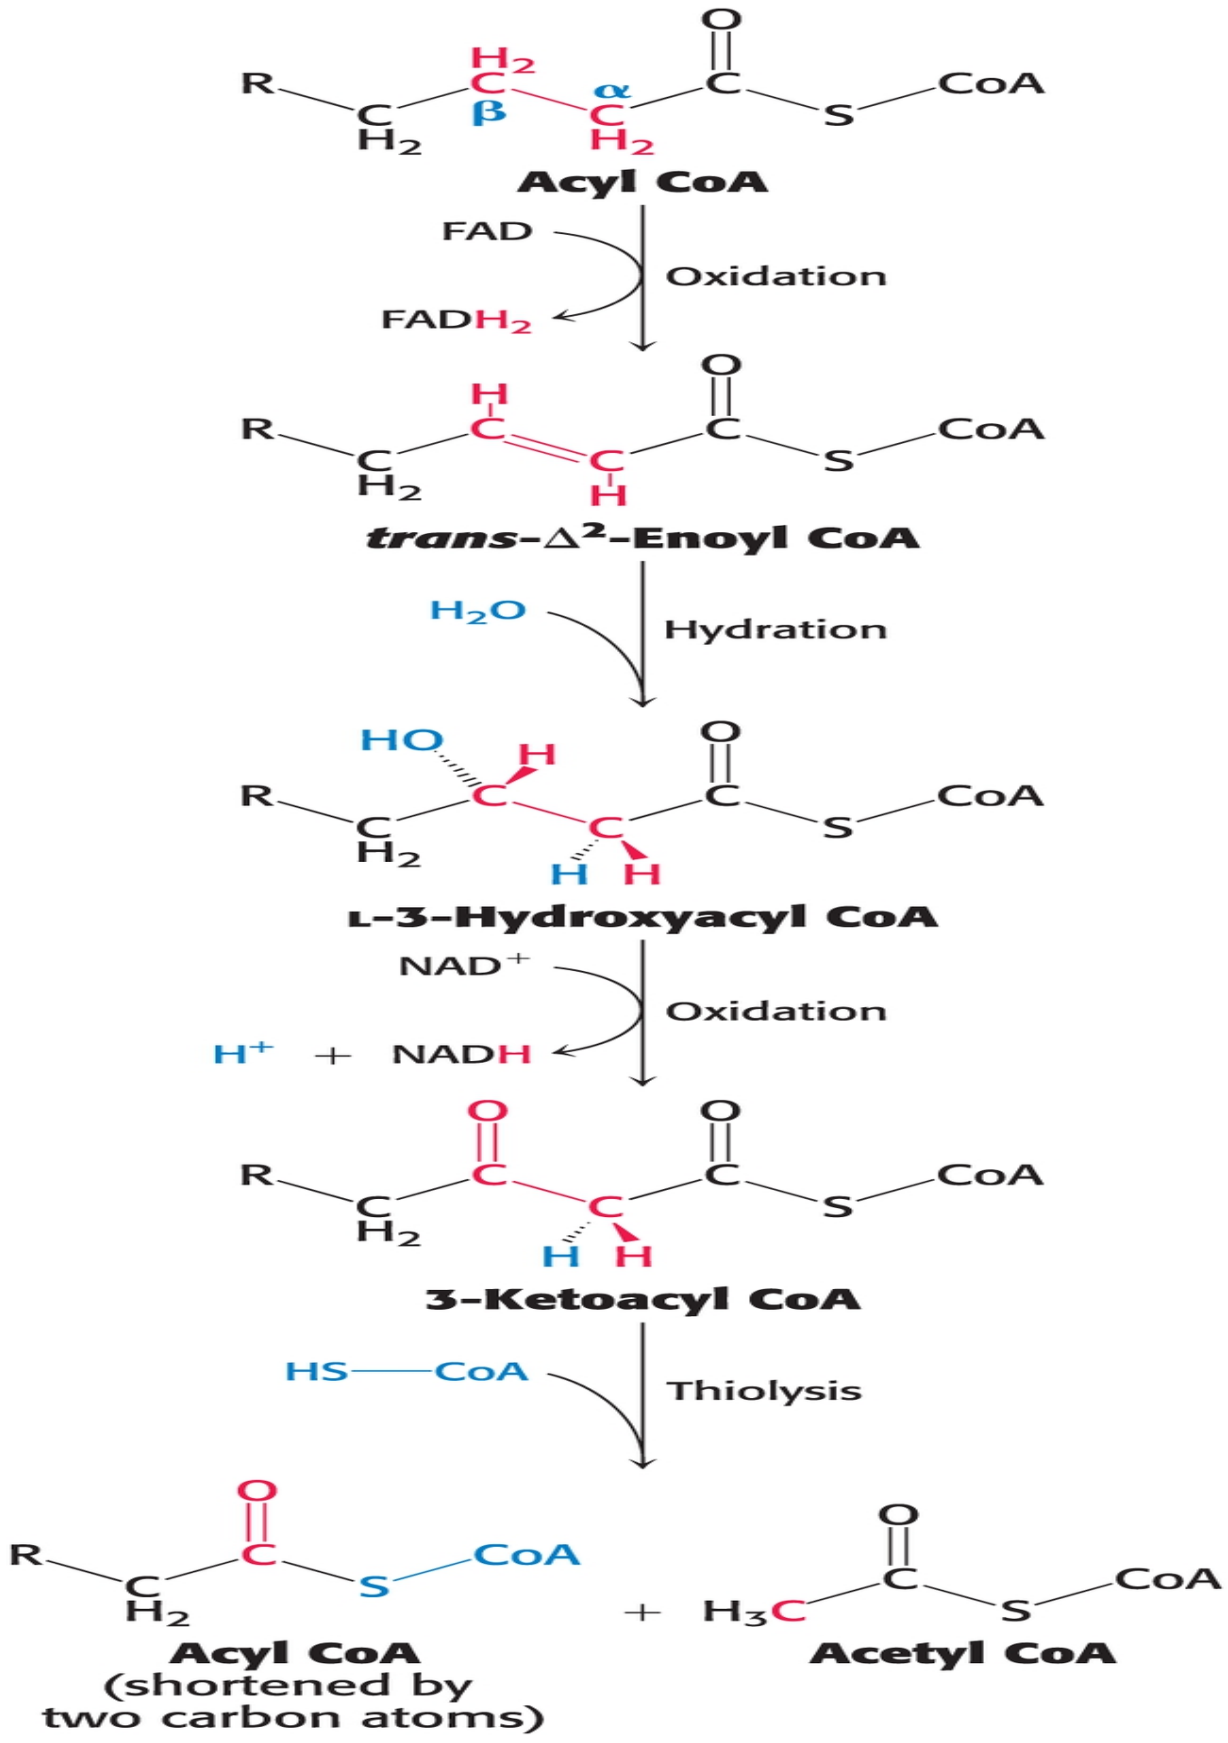
Extended description for FIGURE 22.7 Acyl carnitine translocase mediates the entry of acyl carnitine into

the mitochondrial matrix



A lipid bilayer contains an oblong transport protein labeled translocase embedded in the membrane. The region above the

membrane is labeled intermembrane space and the region below is labeled matrix side. On the matrix side, acyl carnitine is irreversibly converted into carnitine by carnitine acyltransferase 2 with the simultaneous conversion of C o A to acyl C o A. The carnitine produced in the matrix side is transported into the intermembrane space by the translocase. In the intermembrane space, carnitine is irreversibly converted into acyl carnitine by carnitine acyltransferase 1 with the simultaneous conversion of acyl C o A to C o A. The acyl carnitine is then transported into the matrix site by the translocase.

In the first step, acyl C o A undergoes irreversible oxidation to produce trans-delta superscript 2-Enoyl C o A. It is coupled with the reduction of F A D to F A D H 2.

The structure of acyl C o A is as follows: A zigzag chain is composed of R, single bond, C H 2, single bond, C H 2, single bond, C H 2, single bond, C, single bond, S. The second C H 2 group is labeled beta and the third C H 2 group is labeled alpha. C 4 is double bonded to O above. S is single-bonded to C o A on the upper right.

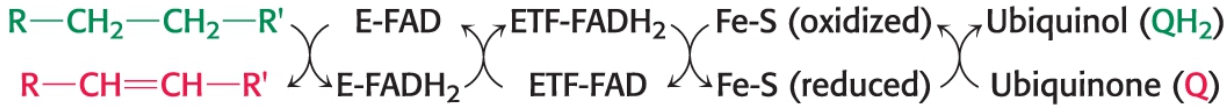
The structure of trans-delta superscript 2-Enoyl C o A is as follows: A zigzag chain is composed of R, single bond, C H 2, single bond, C, double bond, C, single bond, C, single bond, S. C 2 and C 3 are each single bonded to H. C 4 is double bonded to O above. S is single-bonded to C o A on the upper right.

In the second step, trans-delta superscript 2-Enoyl C o A undergoes hydration to produce L-3-Hydroxyacyl C o A. It is coupled with the entry of H 2 O.

The structure of L-3-Hydroxyacyl C o A is as follows: A zigzag chain is composed of R, single bond, C H 2, single bond, C, single bond, C, single bond, C, single bond, S. C 2 is dash bonded to O H on the upper left and wedge bonded to H on the upper right. C 3 is dash bonded to H on the lower left and wedge bonded to H on the lower right. C 4 is double bonded to O above. S is single-bonded to C o A on the upper right.

In the third step, L-3-Hydroxyacyl C o A undergoes oxidation to produce 3-ketoacyl C o A. It is coupled with the reduction of N A D superscript plus to N A D H plus H superscript plus.

The structure of 3-ketoacyl C o A is as follows: A zigzag chain is composed of R, single bond, C H 2, single bond, C, single bond, C, single bond, C, single bond, S. C 2 is double bonded to O above. C 3 is dash bonded to H on the lower left and wedge bonded to H on the lower right. C 4 is double bonded to O above. S is single-bonded to C o A on the upper right.



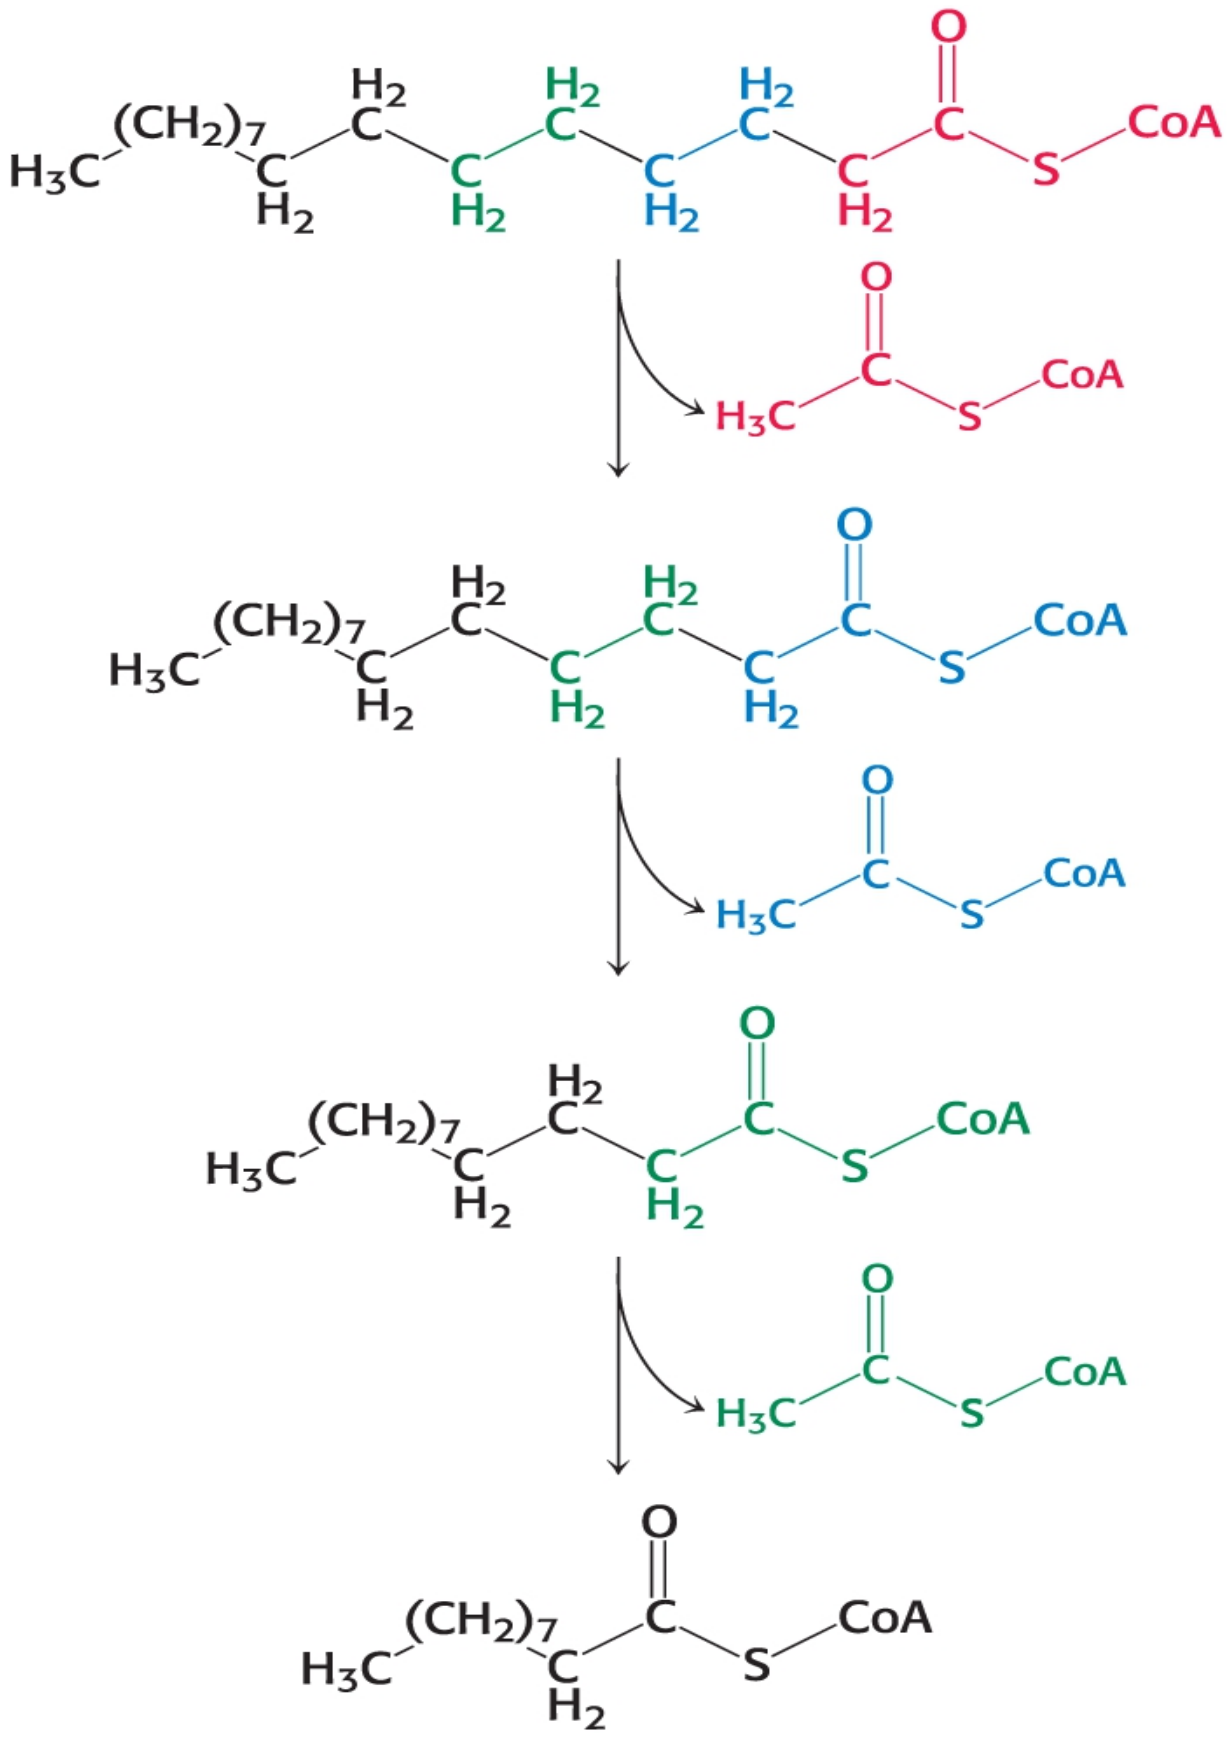
In the fourth step, 3-ketoacyl C o A undergoes thiolysis to produce acyl C o A and acetyl C o A with the simultaneous entry of H S, single bond, C o A.

The structure of acyl C o A is as follows: A zigzag chain is composed of R, single bond, C H 2, single bond, C, single bond, S. C 2 is double bonded to O above. S is single-bonded to C o A on the upper right. The acyl C o A is shortened by two carbon atoms.

The structure of acetyl C o A is as follows: A zigzag chain is composed of C H 3, single bond, C, single bond, S. C 2 is double bonded to O above. S is single-bonded to C o A on the upper right.

Return to FIGURE 22.8 The reaction sequence for the degradation of fatty acids has four sequential steps

Extended description for Sequential transfer of electrons from substrate to ubiquinone



The transfer of electrons is depicted as follows: R, single bond, C H 2, single bond, C H 2, single bond, R dash is oxidized to R, single bond, C H, double bond, C H, single bond, R dash. The oxidation is coupled with the reduction of E, single bond, F A D to E, single bond, F A D H 2. E, single bond, F A D H 2 then transfers electrons to E T F, single bond, F A D to produce E T F, single bond, F A D H 2. The electrons from E T F-F A D H 2 are used to convert F e, single bond, S (oxidized) to F e, single bond, S (reduced). The reduced Fe, single bond, S donates electrons to ubiquinone (Q) to convert it into ubiquinol (Q H 2).

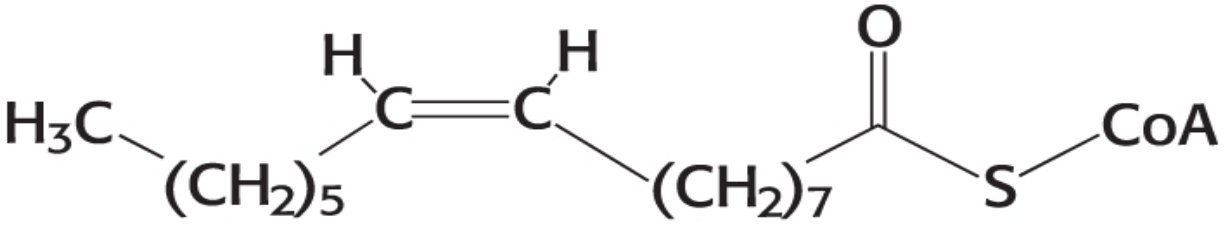
The initial substrate has the following structure: A zigzag chain is composed of C H 3, single bond, open parenthesis C H 2 close parenthesis with subscript 7, single bond, C H 2, single bond, C H 2, single bond, C H 2, single bond, C H 2, single bond, C H 2, single bond, C H 2, single bond, C, single bond, S. C 10 is double bonded to O above. S is single-bonded to C o A on the upper right.

A downward arrow points to the product of the first round of degradation.

The leaving 2-carbon unit has the following structure: A zigzag chain is composed of C H 3, single bond, C, single bond, S. C 2 is double bonded to O above. S is single-bonded to C o A on the upper right.

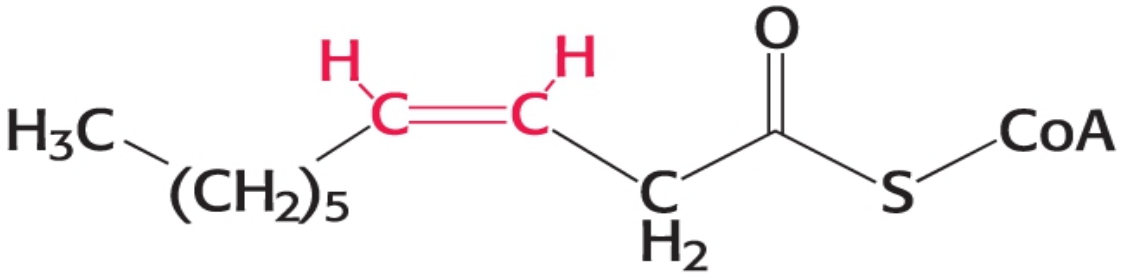
The structure of the product of the first round of degradation is as follows: A zigzag chain is composed of C H 3, single bond, open parenthesis C H 2 close parenthesis with subscript 7, single bond, C H 2, single bond, C H 2, single bond, C H 2, single bond, C H 2, single bond, C H 2, single bond, C, single bond, S. C 8 is double bonded to O above. S is single-bonded to C o A on the upper right.

In the second round of degradation, another 2-carbon unit leaves from the right end of the first product. The structure of the product of the second round of degradation is as follows: A zigzag chain is composed of C H 3, single bond, open parenthesis C H 2 close parenthesis with subscript 7, single bond, C H 2, single bond, C H 2, single bond, C H 2, single bond, C H 2, single bond, C, single bond, S. C 6 is double bonded to O above. S is single-bonded to C o A on the upper right.



In the third round of degradation, another 2-carbon unit leaves from the right end of the second product. The structure of the product of the third round of degradation is as follows: A zigzag chain is

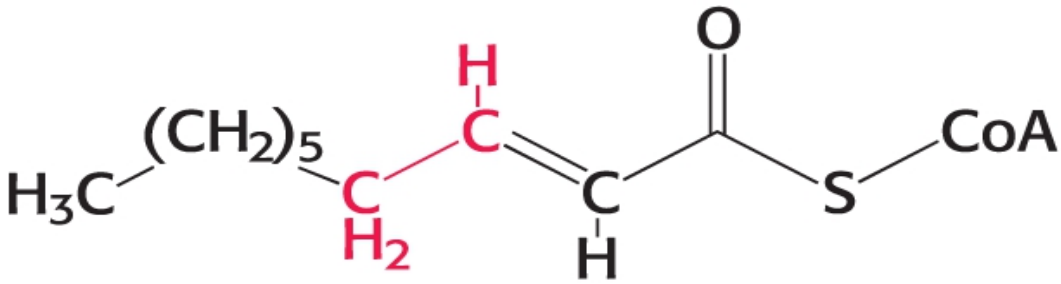
composed of C H 3, single bond, open parenthesis C H 2 close parenthesis with subscript 7, single bond, C H 2, single bond, C, single bond, S. C 4 is double bonded to O above. S is single-bonded to C o A on the upper right.



Return to FIGURE 22.9 Each round of fatty acid degradation removes two carbons

Extended description for FIGURE 22.10 The degradation of a monounsaturated fatty acid involves

an additional enzymatic step



Palmitoleoyl CoA

4 3 2 1

***cis*-Δ^3-Enoyl CoA**

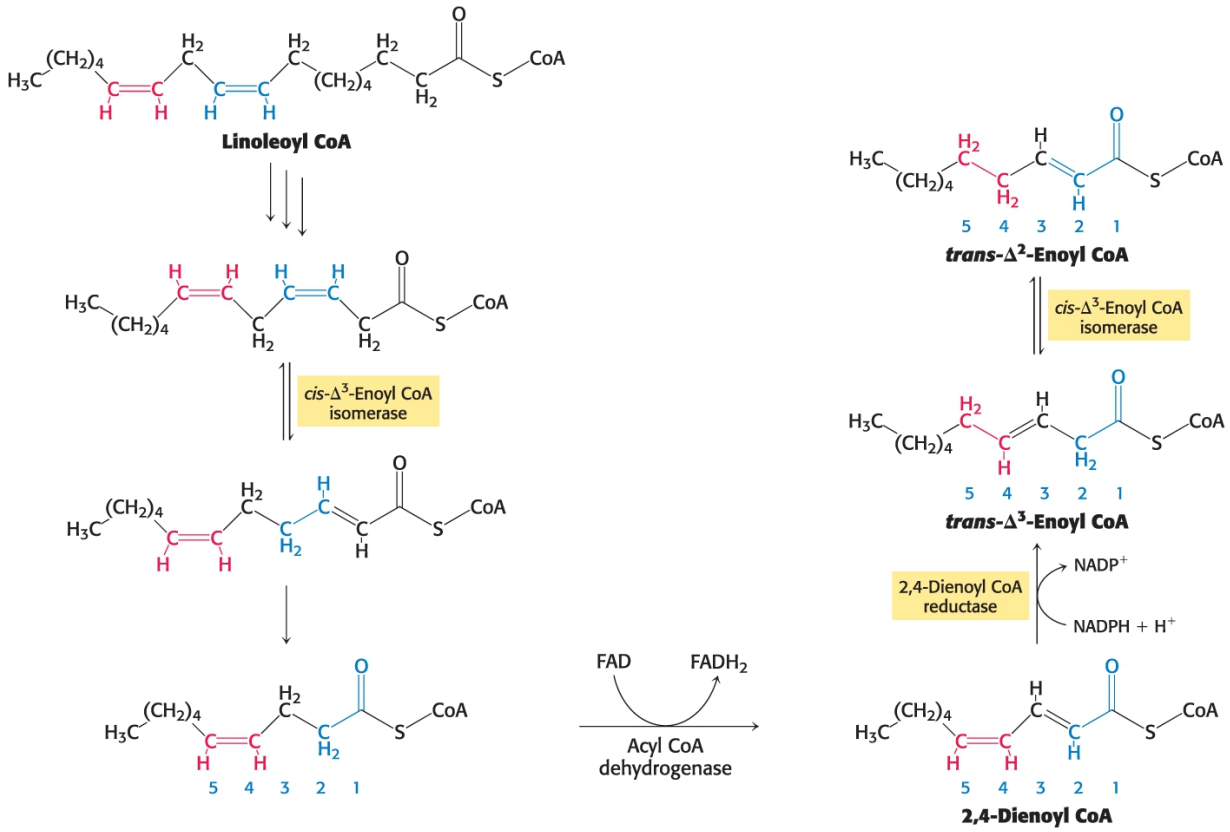
cis-Δ^3-Enoyl CoA isomerase

4 3 2 1

***trans*-Δ^2-Enoyl CoA**

In the first step, palmitoleoyl C o A is converted into cis-delta superscript 3-Enoyl C o A. Three successive downward arrows from palmitoleoyl C o A point to cis-delta superscript 3-Enoyl C o A.

The structure of palmitoleoyl C o A is as follows: C, double bond, C. C 1 and C 2 are single bonded to H. C 1 is single bonded to open parenthesis C H 2 close parenthesis with subscript 5, which is further single bonded to C H 3 on the upper left. C 2 is single bonded to open parenthesis C H 2 close parenthesis with subscript 7, which is further single bonded to a zigzag chain composed of C, single bond, S, single bond, C o A. C 1 of this chain is double bonded to O above.



The structure of cis-delta superscript 3-Enoyl C o A is as follows: C, double bond, C. The first C is numbered 4 and the second C is numbered 3. C 3 and C 4 are single bonded to H. C 4 is single bonded to open parenthesis C H 2 close parenthesis with subscript 5, which is further single bonded to C H 3 on the upper left. C 3 is single bonded to a zigzag chain composed of C H 2, single bond, C, single bond, S, single bond, C o A. C 2 of this chain is double bonded to O above. The C atom of the C H 2 group is numbered 2 and the C atom is numbered 1.

In the second step, cis-delta superscript 3-Enoyl C o A is reversibly converted into trans-delta superscript 2-Enoyl C o A by the enzyme cis-delta superscript 3-Enoyl C o A isomerase.
