The structure of trans-delta superscript 2-Enoyl C o A is as follows: A zigzag chain is composed of C H 3, single bond, open parenthesis C H 2 close parenthesis with subscript 5, single bond, C H 2, single bond, C, double bond, C, single bond, C, single bond, S, single bond, C o A. The C atoms starting with the third carbon atom from the left end are numbered 4 to 1. C 3 is single bonded to H above. C 2 is single bonded to H below. C 1 is double bonded to O above.

Return to FIGURE 22.10 The degradation of a monounsaturated fatty acid involves an additional enzymatic step

Extended description for FIGURE 22.11 Multiple additional enzymes are necessary to oxidize polyunsaturated fatty acids

The structure of linoleoyl C o A is as follows: A zigzag chain is composed of C H 3, single bond, open parenthesis C H 2 close parenthesis with subscript 4, single bond, C, double bond, C, single bond, C H 2, single bond, C, double bond, C, single bond, C H 2, single bond, open parenthesis C H 2 close parenthesis with subscript 4, single bond, C H 2, single bond, C H 2, single bond, C, single bond, S, single bond, C o A. Starting from the left end, C 3, C 4, C 6, and C 7 are single bonded to H below. C 12 is double bonded to O above.

Three successive downward arrows lead to the product.

The structure of the product is as follows: A zigzag chain is composed of C H 3, single bond, open parenthesis C H 2 close parenthesis with subscript 4, single bond, C, double bond, C, single bond, C H 2, single bond, C, double bond, C, single bond, C H 2, single bond, C, single bond, S, single bond, C o A. C 3, C 4, C 6, and C 7 are single bonded to H above. C 9 is double bonded to O above.

The enzyme cis-delta superscript 3-Enoyl C o A isomerase reversibly converts this product into a second product.

The structure of the second product is as follows: A zigzag chain is composed of C H 3, single bond, open parenthesis C H 2 close parenthesis with subscript 4, single bond, C, double bond, C, single bond, C H 2, single bond, C H 2, single bond, C, double bond, C, single bond, C, single bond, S, single bond, C o A. C 3 and C 4 are single bonded to H below. C 7 is single bonded to H above and C 8 is single bonded to H below.

The second product is irreversibly converted into a third product.

The structure of the third product is as follows: A zigzag chain is composed of C H 3, single bond, open parenthesis C H 2 close parenthesis with subscript 4, single bond, C, double bond, C, single bond, C H 2, single bond, C H 2, single bond, C, single bond, S, single bond, C o A. The carbon atoms starting with the C single bonded to S are numbered 1 to 5. C 4 and C 5 are single bonded to H below. C 1 is double bonded to O above.

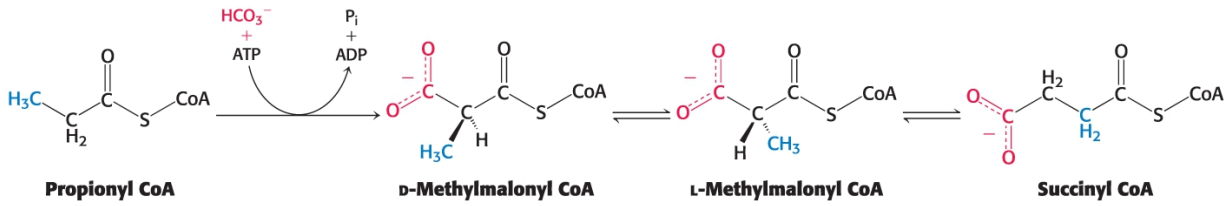
A forward arrow labeled acyl C o A dehydrogenase leads to 2,4-Dienoyl C o A, which is produced by the oxidation of the third

product. This step is coupled with the reduction of F A D to F A D H 2.

The structure of 2,4-Dienoyl C o A is as follows: A zigzag chain is composed of C H 3, single bond, open parenthesis C H 2 close parenthesis with subscript 4, single bond, C, double bond, C, single bond, C, double bond, C, single bond, C, single bond, S, single bond, C o A. The carbon atoms starting with the C single bonded to S are numbered 1 to 5. C 4 and C 5 are single bonded to H below. C 2 is single bonded to H below and C 3 is single bonded to H above. C 1 is double bonded to O above.

An upward arrow labeled 2-4 dienoyl C o A reductase leads to trans-delta superscript 3-Enoyl C o A, which is produced by the reduction of 2,4-Dienoyl C o A. This step is coupled with the oxidation of N A D P H plus H superscript plus to N A D P superscript plus.

The structure of trans-delta superscript 3-Enoyl C o A is as follows: A zigzag chain is composed of C H 3, single bond, open parenthesis C H 2 close parenthesis with subscript 4, single bond, C H 2, single bond, C, double bond, C, single bond, C H 2, single bond, C, single bond, S, single bond, C o A. The carbon atoms starting with the C single bonded to S are numbered 1 to 5. C 4 is single bonded to H below. C 3 is single bonded to H above and C 1 is double bonded to O above.



A reversible reaction arrow labeled cis-delta superscript 3-Enoyl C o A isomerase leads to trans-delta superscript 2-Enoyl C o A.

The structure of trans-delta superscript 2-Enoyl C o A is as follows: A zigzag chain is composed of C H 3, single bond, open parenthesis C H 2 close parenthesis with subscript 4, single bond, C H 2, single bond, C H 2, single bond, C, double bond, C, single bond, C, single

bond, S, single bond, C o A. The carbon atoms starting with the C single bonded to S are numbered 1 to 5. C 2 and C 3 are single bonded to H below and above respectively. C 1 is double bonded to O above.

Return to FIGURE 22.11 Multiple additional enzymes are necessary to oxidize polyunsaturated fatty acids

Extended description for FIGURE 22.12 The final product of odd-numbered fatty acid degradation is converted into a C A C intermediate

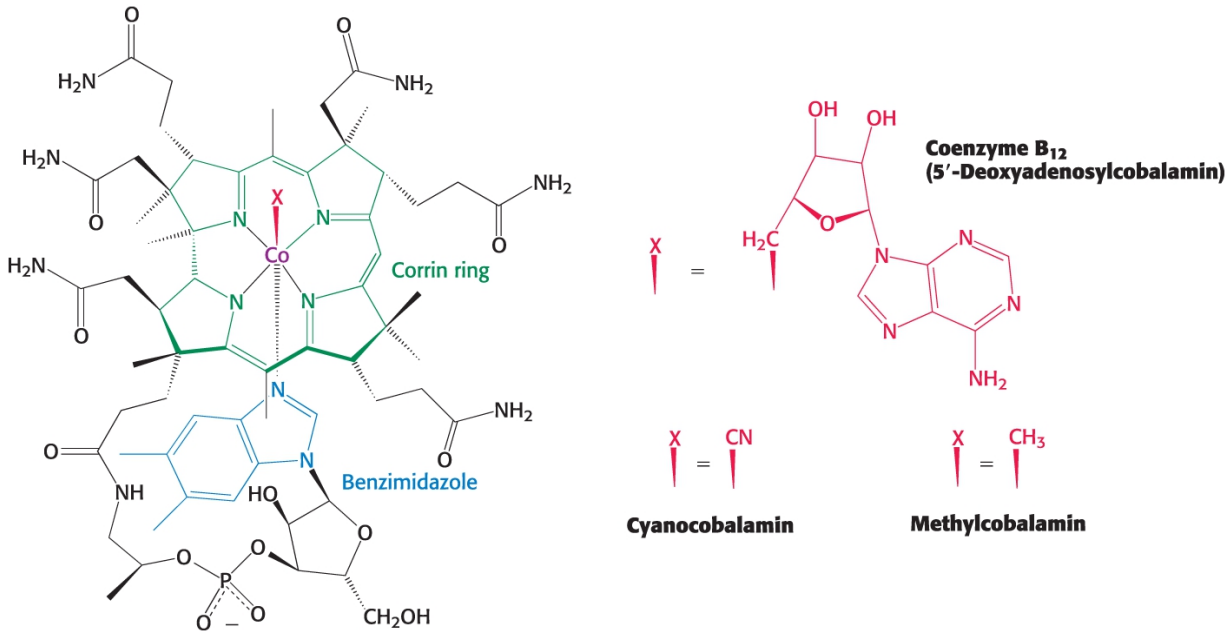
In the first irreversible step, propionyl C o A is converted into D-methylmalonyl C o A with the simultaneous entry of H C O 3 superscript minus, release of P subscript i, and the hydrolysis of A T P to A D P.

The structure of propionyl C o A is as follows: A zigzag chain is composed of C H 3, single bond, C H 2, single bond, C, single bond, S, single bond, C o A. C 3 is double bonded to O above.

The structure of D-methylmalonyl C o A is as follows: A zigzag chain is composed of C, single bond, C, single bond, C, single bond, S, single bond, C o A. C 1 is partially double bonded to O above and O on the lower left. The O atoms have an overall negative charge. C 2 is wedge bonded to C H 3 on the lower left and dash bonded to H on the lower right. C 3 is double bonded to O above.

In the second reversible step, D-methylmalonyl C o A is converted to L-Methylmalonyl C o A.

The structure of L-Methylmalonyl C o A is as follows: A zigzag chain is composed of C, single bond, C, single bond, C, single bond, S, single bond, C o A. C 1 is partially double bonded to O above and O



on the lower left. The O atoms have an overall negative charge. C 2 is wedge bonded to H on the lower left and dash bonded to C H 3 on the lower right. C 3 is double bonded to O above.

In the third reversible step, L-Methylmalonyl C o A is converted to succinyl C o A.

The structure of succinyl C o A is as follows: A zigzag chain is composed of C, single bond, C H 2, single bond, C H 2, single bond, C, single bond, S, single bond, C o A. C 1 is partially double bonded to O below and O on the upper left. The O atoms have an overall negative charge. C 4 is double bonded to O above.

Return to FIGURE 22.12 The final product of odd-numbered fatty acid degradation is converted into a C A C intermediate

Extended description for FIGURE 22.13 Coenzyme B 12 (cobalamin) is a class of molecules with a complex structure

The generalized structure of coenzyme B 12 is as follows: A central C o atom is single-bonded to an N atom of four different pyrrole rings located on the upper left, upper right, lower left, and lower right. The C o atom is wedge bonded to X above. The pyrrole rings are described as 5-membered heterocyclic pentagonal rings consisting of 1 N and 4 C atoms. The adjacent rings are connected by a methylene bridge between C 4 and C 1 except for two rings. The upper left and lower left rings are directly connected by a dash-bond between C 4 and C 1. The methylene bridge connecting the upper left and upper right, and the lower left and the lower right ring is single bonded to C H 3 in the form of a line.

C 2 of the upper left and upper right rings have an open dash-bond and are wedge bonded to C H 2. This C H 2 group is single-bonded to

C. The C atom is double bonded to O and single bonded to N H 2. C 3 of the upper left and upper right rings are dash bonded to C H 2 which is further single bonded to C H 2 in the form of a line. The C H 2 is single-bonded to C. This C is double bonded to O and single bonded to N H 2. C 1 of the upper left ring has an open dash bond.

C 2 of the lower right ring is dash bonded to C H 3 and wedge bonded to C H 3. C 3 is dash bonded to C H 2 which is further single bonded to C H 2 in the form of a line. The C H 2 is single-bonded to C. This C is double bonded to O and single bonded to N H 2.

C 2 of the lower left ring is wedge bonded to C H 3 and dash bonded to a 1 N and 5 C heteronuclear alkane chain depicted as a line structure using 5 zigzag lines. N occupies the fourth position and is bound to H. C 3 is double bonded to O. C 5 is wedge bonded to C H 3 and single bonded to the upper left O atom of a phosphate group. C 3 of the lower left ring is wedge bonded to C H 2, which is further single bonded to C. This C is double bonded to O and single bonded to N H 2.

The central C o atom is dash bonded below to N 1 of a 5-membered heterocyclic pentagonal ring consisting of 2 N and 3 C atoms. It contains a double bond between N 1 and C 1. This ring is fused to a benzene ring such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively, of the benzene ring. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 5 and C 6 are single-bonded to C H 3 in the form of a line. These fused rings are labeled benzimidazole.

N 2 of the pentagonal ring is wedge bonded to C 4 of another 5-membered heterocyclic pentagonal ring consisting of 1 O and 4 C atoms. C 1 is dash bonded to C H 2 O H. C 2 is wedge bonded to the upper right O atom of the phosphate group. C 3 is wedge bonded to O H.

In coenzyme B 12 (5 prime-deoxyadenosylcobalamin), the structure of the X group is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 2 N and 3 C atoms. A double bond is present between N 1 and C 1. The pentagonal ring is fused to a 6-membered heterocyclic hexagonal ring such that C 2 and C 3 of the pentagonal ring are C 4 and C 3 respectively of the hexagonal ring. In the hexagonal ring, N 1 occupies the topmost vertex and N 2 occupies the bottom right vertex. A double bond is present between N 1 and C 1, and N 2 and C 2. C 2 is single bonded to N H 2 below. N 2 of the pentagonal ring is single-bonded to C 4 of a 5-membered heterocyclic pentagonal ring in a vertical orientation. This pentagonal ring consists of 1 O and 4 C atoms. O occupies the bottom-most vertex. A wedge bond is present between O and C 1, and O and C 4. C 1 is single bonded to C H 2 below. This C H 2 group is wedge bonded to the central C o atom of the coenzyme B 12. C 2 and C 3 are each single bonded to O H above. In cyanocobalamin, the X group is C N. In methylcobalamin, the X group is C H 3.

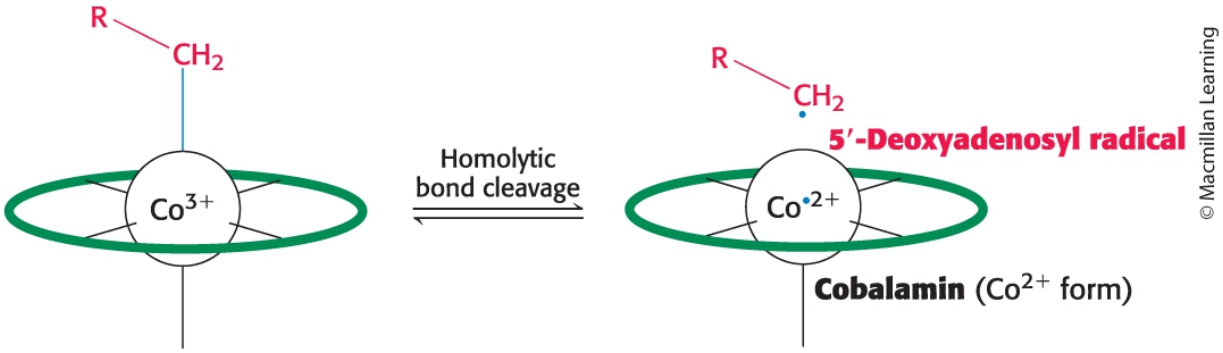
Extended description for FIGURE 22.14 Cobalamin enzymes catalyze specific rearrangement reactions

The reaction consists of one reactant and one product.



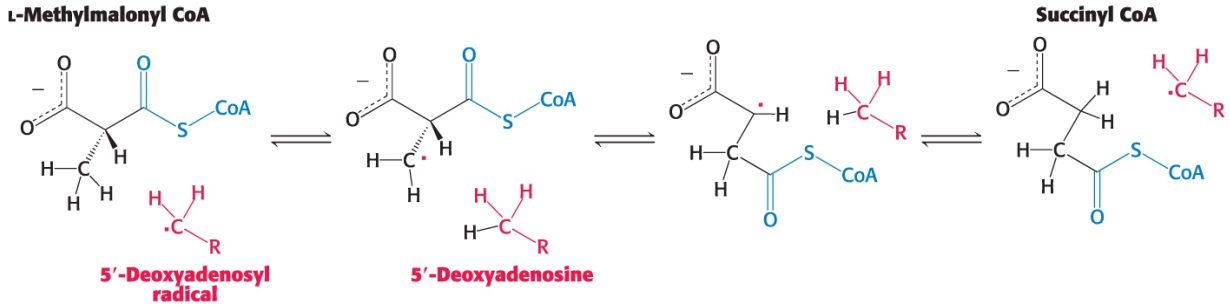
The structure of the reactant is as follows: C, single bond, C. C 1 has an open single bond above, an open single bond on the left, and is single bonded to H below. C 2 is single bonded to R above and has an open single bond on the right and below.

A reversible reaction arrow points to the product.

The structure of the product is as follows: C, single bond, C. C 1 has an open single bond above, an open single bond on the left, and is single bonded to R below. C 2 is single bonded to H above and has an open single bond on the right and below.

Return to FIGURE 22.14 Cobalamin enzymes catalyze specific rearrangement reactions

Extended description for FIGURE 22.15 Cobalamin enzymes accomplish homolytic bond cleavage to form a radical



A structure on the left consists of a central white sphere depicting C o superscript 3 plus ion. It is surrounded by a green ring. The C o superscript 3 plus ion is connected to the ring through a single bond on the upper left, upper right, lower left, and lower right. It has an open single bond below and is single bonded to C H 2 above. The C H 2 group is single-bonded to R on the upper left.

A reversible reaction arrow labeled homolytic bond cleavage leads to a structure on the right.

The structure on the right is labeled cobalamin C o superscript 2 plus form. It consists of a central white sphere depicting C o superscript 2 plus with a blue dot. It is surrounded by a green ring. The C o superscript 2 plus ion is connected to the ring through a single bond on the upper left, upper right, lower left, and lower right. It has an open single bond below. An isolated C H 2 group is single-bonded to R on the upper left. The C atom of the C H 2 group has a blue dot. This structure composed of C H 2, single bond, R is labeled 5 prime-deoxyadenosyl radical.

Return to FIGURE 22.15 Cobalamin enzymes accomplish homolytic bond cleavage to form a radical

Extended description for FIGURE 22.16 Succinyl C o A is formed from methylmalonyl C o A by a rearrangement reaction

L-methylmalonyl C o A reacts with 5 prime-deoxyadenosyl radical to form two intermediate products.

The structure of L-methylmalonyl C o A is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is partially double bonded to O above and O on the lower left. The O atoms have an overall negative charge. C 2 is wedge bonded to H on the lower right and dash-bonded to C on the lower left. This C atom is single-bonded to H on the left, lower left, and lower right. C 3 is double bonded to O above and single bonded to S on the lower right. The S atom is single-bonded to C o A on the upper right.

The structure of 5 prime-deoxyadenosyl radical is as follows: A central C atom with an unpaired electron is single-bonded to H on the upper left, H on the upper right, and R on the lower right.

A reversible reaction arrow leads to the intermediate products.

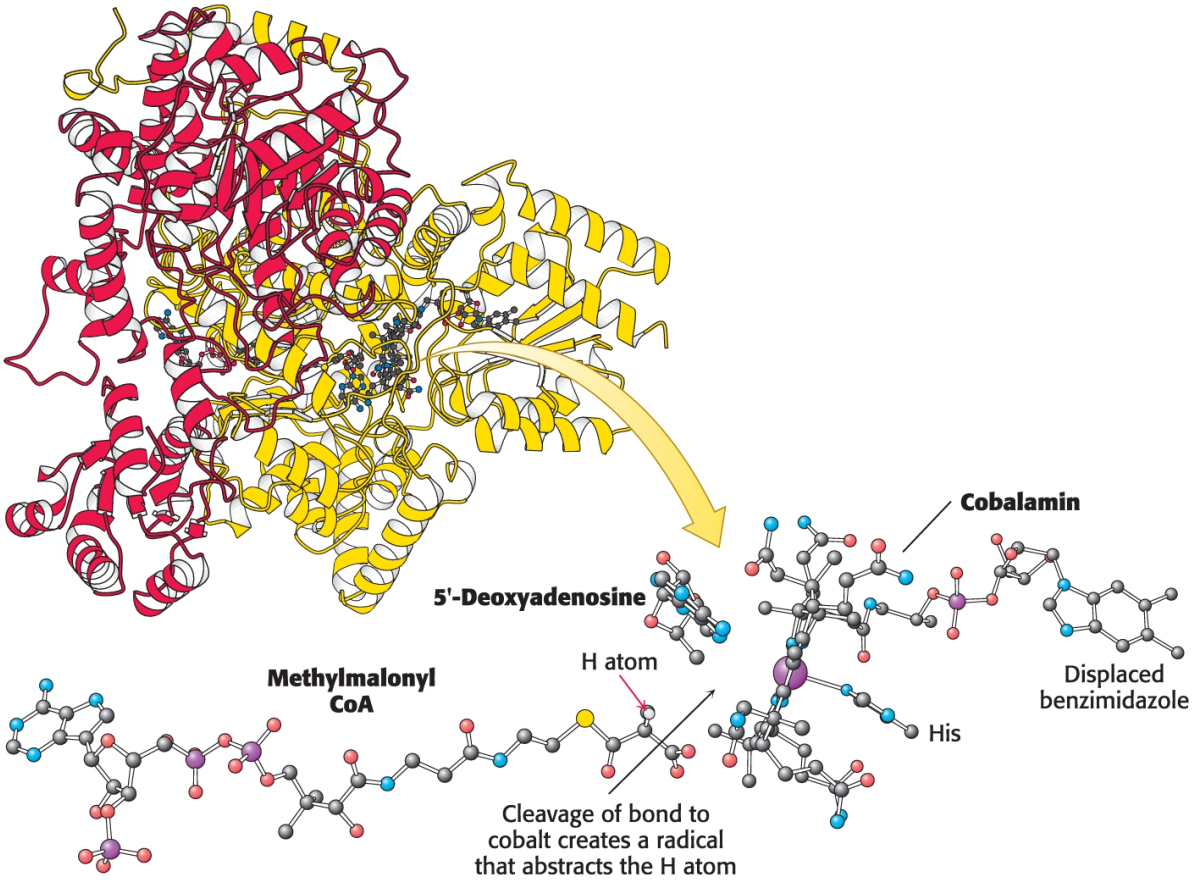
The first intermediate product is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is partially

double bonded to O above and O on the lower left. The O atoms have an overall negative charge. C 2 is wedge bonded to H on the lower right and dash-bonded to C with an unpaired electron on the lower left. This C atom is single-bonded to H on the left and below. C 3 is double bonded to O above and single bonded to S on the lower right. The S atom is single-bonded to C o A on the upper right.

The second intermediate product is 5 prime-deoxyadenosine whose structure is as follows: A central C atom is single bonded to H on the left, H on the upper left, H on the upper right, and R on the lower right.

A reversible reaction arrow leads to the intermediate products.

The first intermediate product is as follows: A 2-carbon alkane chain is depicted as a line structure using a line. C 1 is partially double bonded to O above and O on the lower left. The O atoms have an overall negative charge. C 2 with an unpaired electron is single bonded to H on the right and C below. The C atom is single-bonded to H on the left and H on the lower left, and single-bonded to C on the lower right. The lower right C atom is double bonded to O below and single bonded to S on the upper right, which is further single bonded to C o A on the lower right.



The second intermediate product is as follows: A central C atom is single-bonded to H on the left, H on the upper left, H on the upper right, and R on the lower right. A reversible reaction arrow leads to the final products. The first product is succinyl C o A whose structure is as follows: A 2-carbon alkane chain is depicted as a line structure using a line. C 1 is partially double bonded to O above and O on the lower left. The O atoms have an overall negative charge. C 2 is single bonded to H on the upper right, H on the lower right, and C below. The C atom is single-bonded to H on the left and H on the lower left, and single-bonded to C on the lower right. The C atom is

double bonded to O below and single bonded to S on the upper right, which is further single bonded to C o A on the lower right.

The second product is as follows: A central C atom with an unpaired electron is single-bonded to H on the upper left, H on the upper right, and R on the lower right.

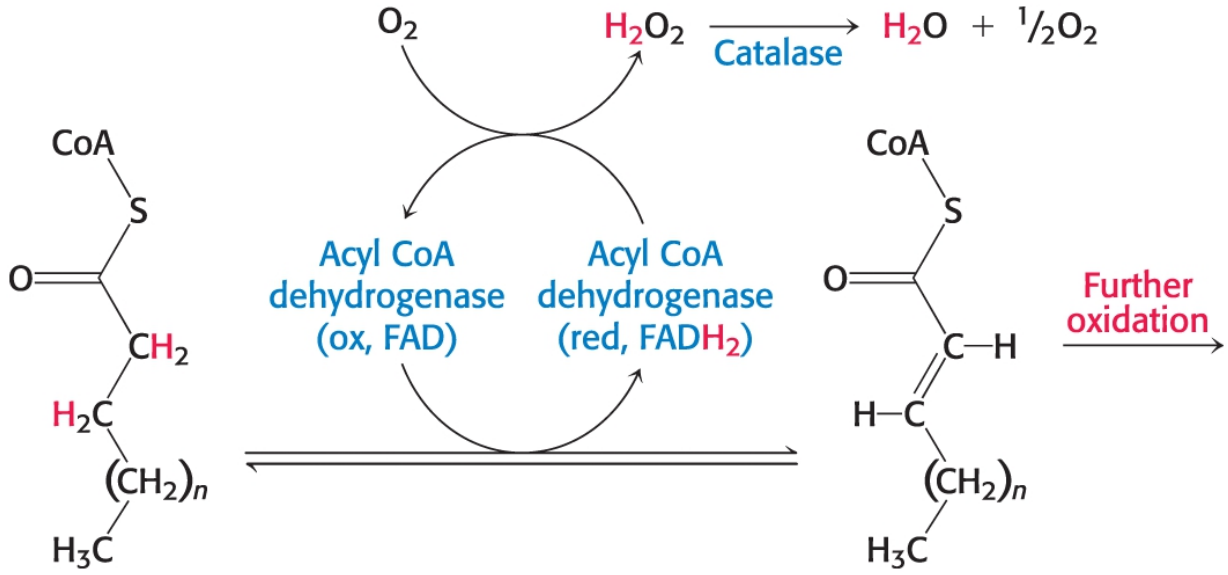
Extended description for FIGURE 22.17 The active site of methylmalonyl C o A mutase reveals how radical formation is accomplished

© Macmillan Learning



The ribbon diagram consists of two interconnected clusters. One cluster is composed of red alpha-helices and red beta-strands and the other cluster is composed of yellow alpha-helices and yellow beta-strands. The center of the enzyme contains an active site with several molecules depicted as ball-and-stick models. An arrow from the active site shows the enlarged view of the arrangement of the ball-and-stick models of the substrate, coenzymes, and amino acid residues.

A ball-and-stick model of methylmalonyl C o A is shown on the left. A white sphere connected to the second black sphere from the right end is labeled the H atom. The rightmost black sphere is connected to two red spheres. An arrow passes through the bond connecting these two black spheres. The text alongside this arrow reads "Cleavage of bond to cobalt creates a radical that abstracts the H atom."

A ball-and-stick model of cobalamin is shown on the right. Its four pyrrole rings connected to a central cobalt atom are oriented toward the right end of methylmalonyl C o A. The cobalt atom depicted as a purple sphere is connected to the histidine side chain on the lower right. The benzimidazole ring of cobalamin is displaced. A ball-and-stick model of 5 prime-deoxyadenosine is located above the right terminal of methylmalonyl C o A and the tetrapyrrole ring of cobalamin.

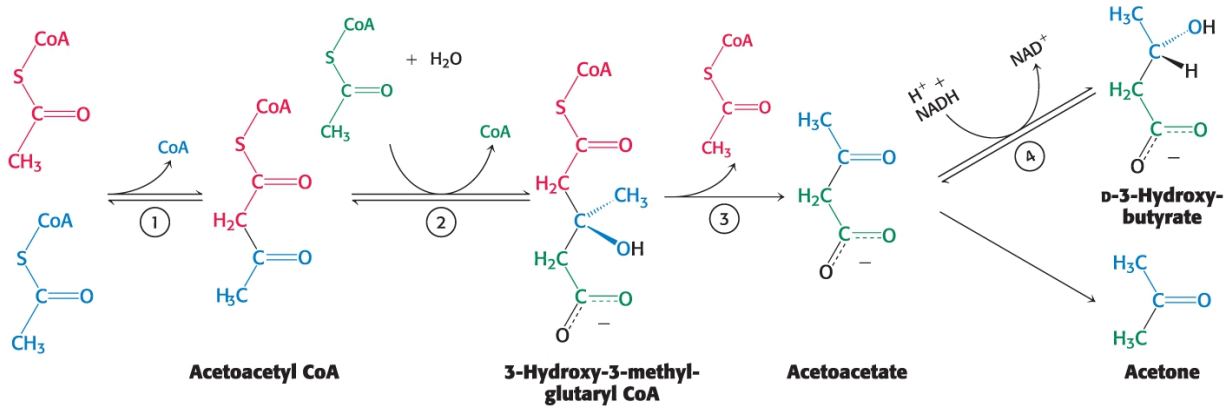
Extended description for FIGURE 22.18 Initiation of peroxisomal fatty acid degradation requires a flavoprotein

The reaction consists of one reactant and one product. The structure of the reactant is as follows: A vertical zigzag chain is composed of C o A, single bond, S, single bond, C, single bond, C H 2, single bond, C H 2, single bond, open parenthesis C H 2 close parenthesis with subscript n, single bond, C H 3. C 1 is double bonded to O on the left.

A reversible reaction arrow leads to the product. A curved arrow above it depicts the simultaneous conversion of acyl C o A dehydrogenase (oxidized, F A D) to acyl C o A dehydrogenase (reduced, F A D H 2).



The structure of the product is as follows: A vertical zigzag chain is composed of C o A, single bond, S, single bond, C, single bond, C, double bond, C, single bond, open parenthesis C H 2 close parenthesis with subscript n, single bond, C H 3. C 1 is double

bonded to O on the left. C 2 is single bonded to H on the right. C 3 is single-bonded to H on the left. A forward arrow on the right of the product is labeled further oxidation.

The acyl C o A dehydrogenase (reduced, F A D H 2) is converted back to acyl C o A dehydrogenase (oxidized, F A D) with the simultaneous conversion of O 2 to H 2 O 2. H 2 O 2 is further converted into H 2 O and a half O 2 by the enzyme catalase.

Return to FIGURE 22.18 Initiation of peroxisomal fatty acid degradation requires a flavoprotein

Extended description for FIGURE 22.19 Ketone bodies are formed from acetyl C o A primarily in the liver

The formation of ketone bodies is divided into 4 steps.

In the first reversible step, acetoacetyl C o A is formed from two acetyl C o A molecules.

The structure of acetyl C o A is as follows: A central C atom is single bonded to C H 3 on the lower left, double bonded to O on the right, and single bonded to S, single bond, C o A on the upper left. C o A leaves the reaction.

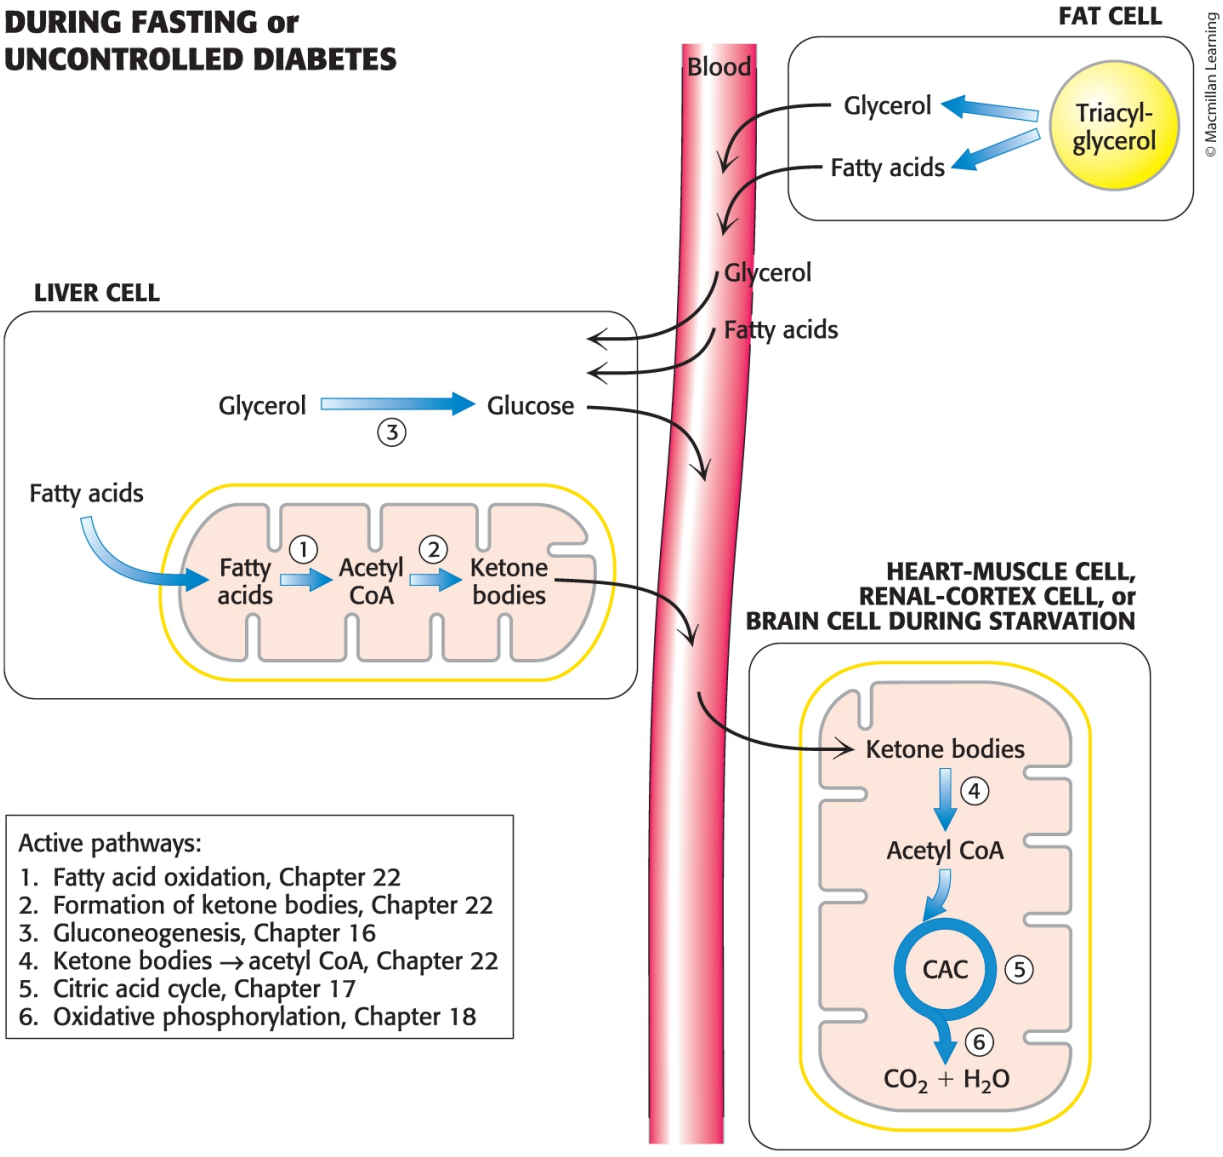
The structure of acetoacetyl C o A is as follows: A vertical zigzag chain is composed of C o A, single bond, S, single bond, C, single bond, C H 2, single bond, C, single bond, C H 3. C 1 and C 3 are each double bonded to O on the right.

In the second reversible step, acetoacetyl C o A is converted into 3-hydroxy-3-methylglutaryl C o A. An acetyl C o A plus H 2 O molecule enters and C o A leaves the reaction.

The structure of 3-hydroxy-3-methylglutaryl C o A is as follows: A vertical zigzag chain is composed of C o A, single bond, S, single bond, C, single bond, C H 2, single bond, C, single bond, C H 2, single bond, C. C 1 is double bonded to O on the right. C 3 is dash-bonded to C H 3 on the upper right and wedge bonded to O H on the lower right. C 5 is partially double bonded to O on the right and O on the lower left. The O atoms have an overall negative charge.

In the third irreversible step, 3-hydroxy-3-methylglutaryl C o A is converted into acetoacetate. An acetyl-C o A group leaves the reaction.

The structure of acetoacetate is as follows: A vertical zigzag chain is composed of C H 3, single bond, C, single bond, C H 2, single bond, C. C 2 is double bonded to O on the right. C 4 is partially double bonded to O on the right and O on the lower left. The O atoms have an overall negative charge.



In the fourth step, D-3-hydroxy-butyrate is formed reversibly from acetoacetate with the simultaneous oxidation of N A D H plus H superscript plus to N A D superscript plus. Acetone is formed irreversibly from acetoacetate.

The structure of D-3-hydroxy-butyrate is as follows: A vertical zigzag chain is composed of C H 3, single bond, C, single bond, C H 2, single bond, C. C 2 is dash bonded to O H on the upper right and wedge bonded to H on the lower right. C 4 is partially double bonded to O on the right and O on the lower left. The O atoms have an overall negative charge.

The structure of acetone is as follows: A central C atom is single-bonded to C H 3 on the upper left, C H 3 on the lower left, and double-bonded to O on the right.

Return to FIGURE 22.19 Ketone bodies are formed from acetyl C o A primarily in the liver

Extended description for FIGURE 22.20 Pathway Integration: The liver supplies ketone bodies to the peripheral tissues

A long and tubular structure shown in the center depicts a blood vessel containing blood. A fat cell is depicted on the right as a rectangular structure. It contains a large yellow circle labeled triacylglycerol. The triacylglycerol is broken down into glycerol and

fatty acids. The glycerol and fatty acids are released into the bloodstream. They travel through the bloodstream to reach the liver cell depicted as a large rectangle. Inside the liver cell, fatty acids are transported into mitochondria. Inside the liver mitochondria, fatty acids are converted into acetyl C o A. This step is depicted as a forward arrow labeled 1. Acetyl C o A is converted into ketone bodies. This step is depicted as a forward arrow labeled 2. In the liver cell cytoplasm, glycerol is converted into glucose. This step is depicted as a forward arrow labeled 3. Glucose and ketone bodies are released into the bloodstream from the liver cell. The ketone bodies enter the heart-muscle cell, renal-cortex cell, or brain cell during starvation. Inside the mitochondria of these cells, ketone bodies are converted into acetyl C o A. This step is depicted as a forward arrow labeled 4. Acetyl C o A enters the citric acid cycle depicted as a tiny circle with a blue outline labeled C A C in the center. C A C step is numbered 5. An arrow labeled 6 from the C A C shows the release of C O 2 plus H 2 O in the mitochondria.

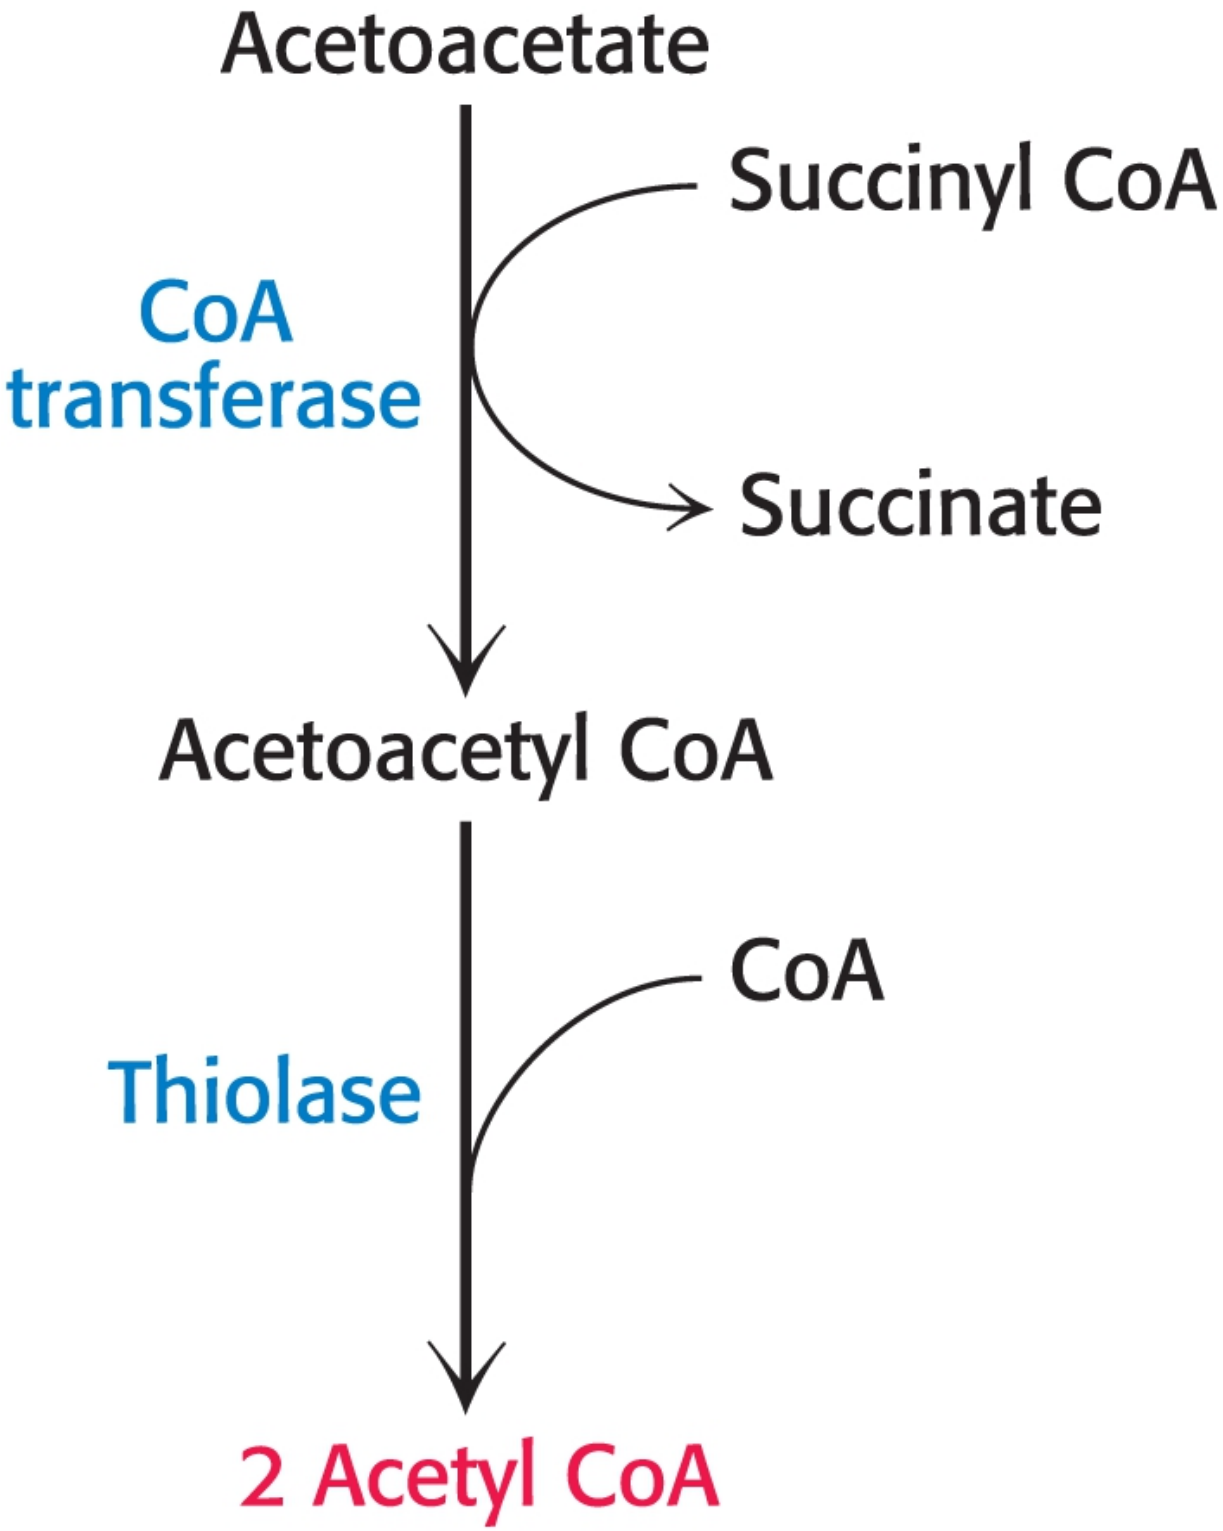
A key titled "active pathways" lists the following points:

1. Fatty acid oxidation, Chapter 22.

2. Formation of ketone bodies, Chapter 22.

3. Gluconeogenesis, Chapter 16.

4. Ketone bodies, forward arrow, acetyl C o A, Chapter 22.



5. Citric acid cycle, Chapter 17.

6. Oxidative phosphorylation, Chapter 18.

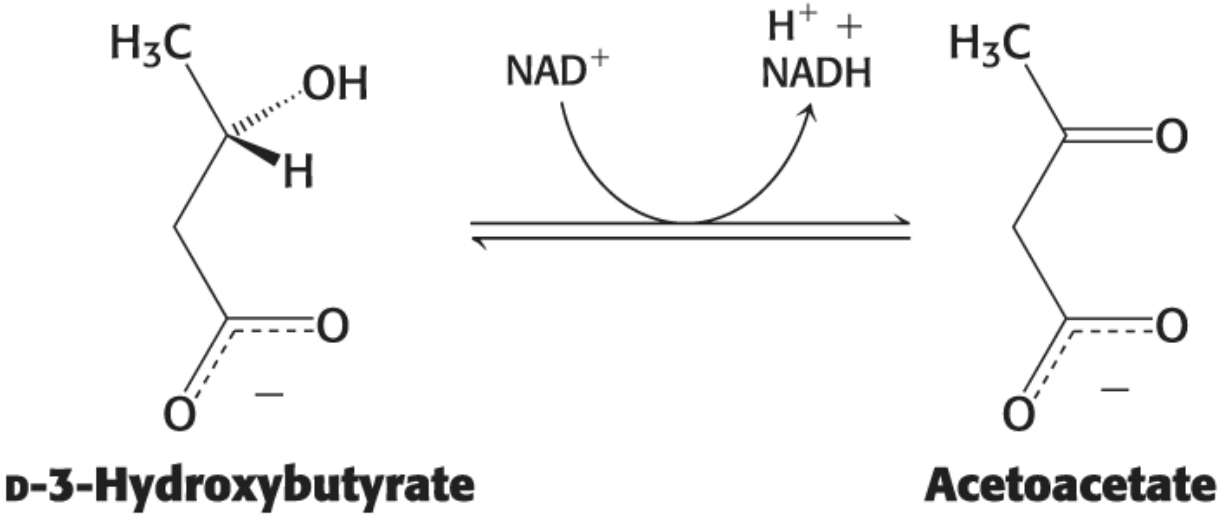
Extended description for FIGURE 22.21 Acetoacetate



can be used as a fuel to drive A T P formation

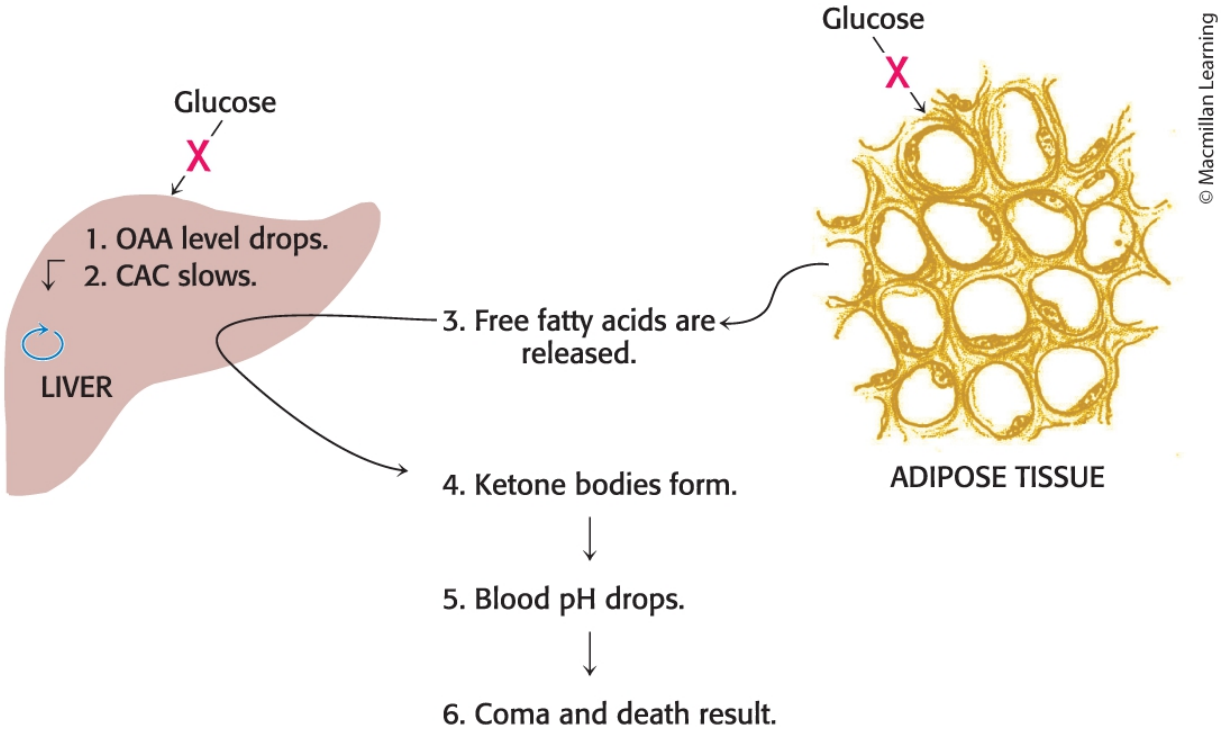
Acetoacetate is converted into acetoacetyl C o A by C o A transferase with the simultaneous conversion of succinyl C o A to succinate. The acetoacetyl C o A is converted into 2 acetyl C o A by thiolase with the simultaneous entry of C o A.

Return to FIGURE 22.21 Acetoacetate can be used as a fuel to drive A T P formation

Extended description for Formation of acetoacetate from D-3-hydroxybutyrate

The reaction consists of one reactant and one product.

The reactant is D-3-hydroxybutyrate whose structure is as follows: A 3-carbon alkane chain is depicted as a vertical line structure using 2 zigzag lines. C 1 is single bonded to C H 3 on the upper left, dash bonded to O H on the upper right, and wedge bonded to H on the lower right. C 3 is partially double bonded to O on the lower left and right. The O atoms have an overall negative charge.



A reversible reaction arrow leads to the product. A curved arrow above it depicts the simultaneous reduction of N A D superscript plus to N A D H plus H superscript plus.

The product is acetoacetate whose structure is as follows: A 3-carbon alkane chain is depicted as a vertical line structure using 2 zigzag lines. C 1 is single bonded to C H 3 on the upper left and double bonded to O on the right. C 3 is partially double bonded to O

on the lower left and right. The O atoms have an overall negative charge.

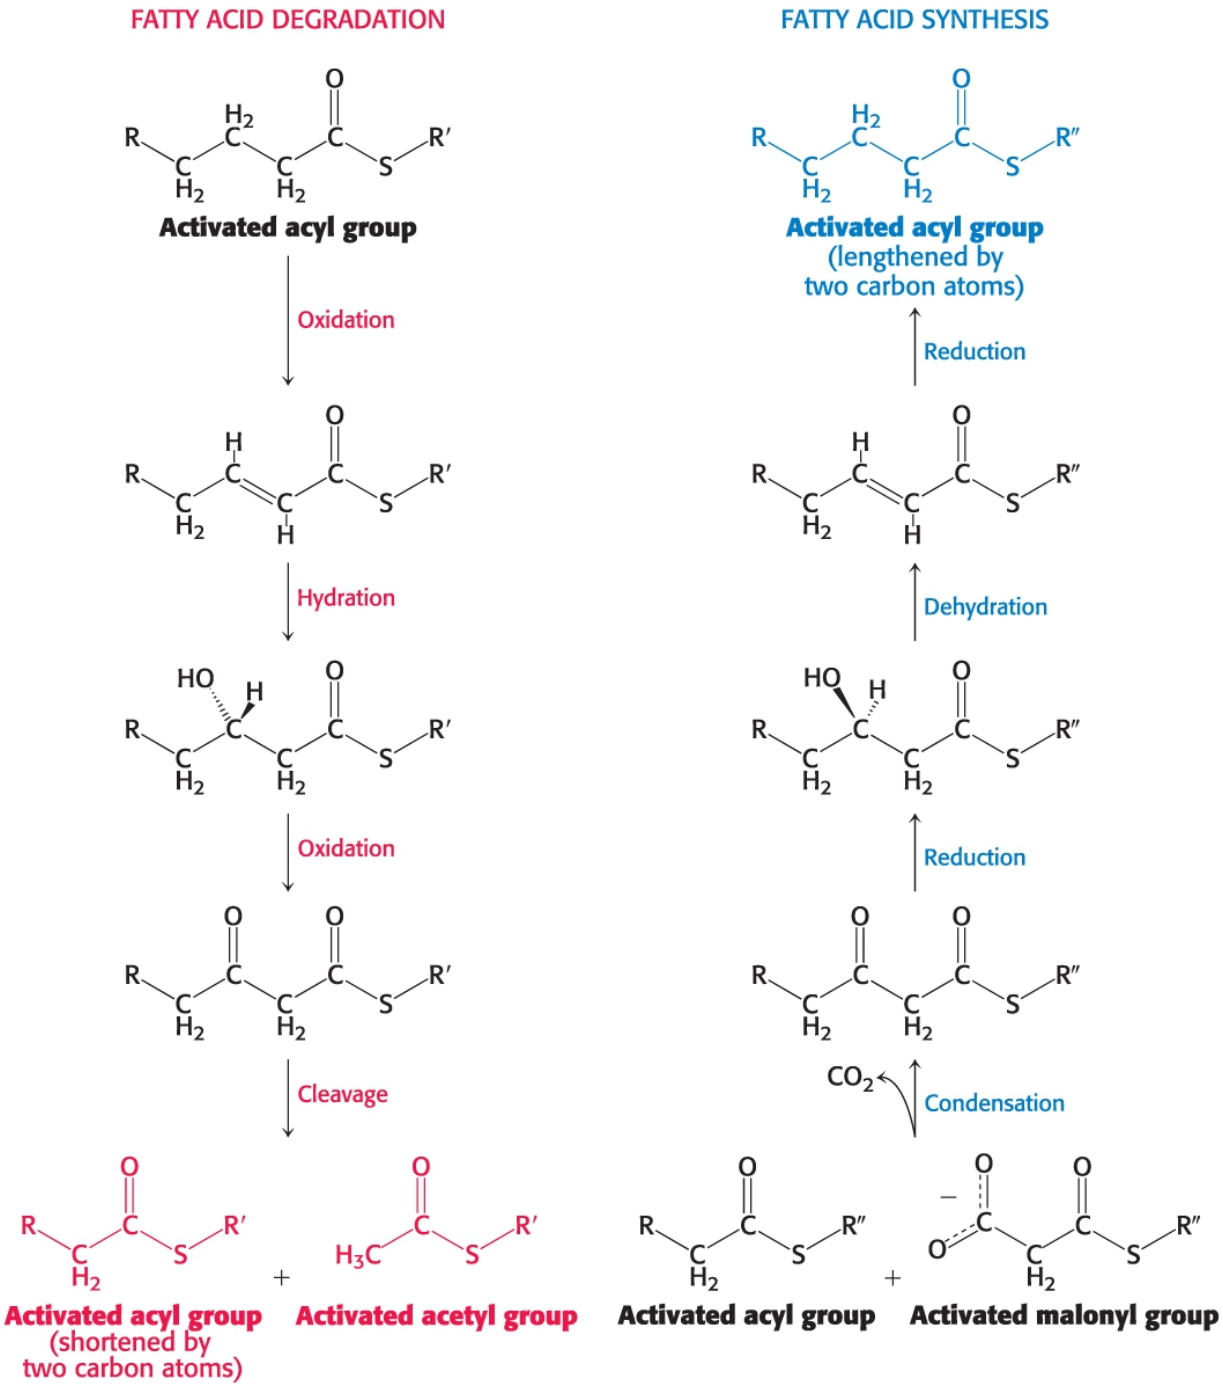
Extended description for FIGURE 22.22 Diabetic ketosis results when insulin signaling is impaired

The liver is shown on the left and the adipose tissue is shown on the right. The adipose tissue is depicted as a cluster of cells containing large lipid droplets. A dashed arrow labeled glucose points to the liver and the adipose tissue. Both the arrows have a cross symbol. Inside the liver, the two points are listed:

1. O A A level drops.



2. C A C slows.

An arrow points toward a curved clockwise arrow inside the liver.

An arrow from adipose tissue points toward point 3 with the text "Free fatty acids are released." A curved arrow from point 3 moves to the liver and then moves to point 4 with the text "Ketone bodies form." Point 4 leads to point 5 with the text "Blood p H drops." Point 5 leads to point 6 with the text "Coma and death result."

Return to FIGURE 22.22 Diabetic ketosis results when insulin signaling is impaired

Extended description for FIGURE 22.23 The steps in fatty acid degradation and synthesis are chemically similar

The reaction sequence of fatty acid degradation is depicted as follows:

In the first step, the activated acyl group undergoes irreversible oxidation.

The structure of the activated acyl group is as follows: A zigzag chain is composed of R, single bond, C H 2, single bond, C H 2, single bond, C H 2, single bond, C, single bond, S, single bond, R dash. C 4 is double bonded to O above.

The product of oxidation is as follows: A zigzag chain is composed of R, single bond, C H 2, single bond, C, double bond, C, single bond, C, single bond, S, single bond, R dash. C 2 and C 3 are single bonded to H above and H below respectively. C 4 is double bonded to O above.

In the second step, the product formed in step 1 undergoes irreversible hydration.

The product of hydration is as follows: A zigzag chain is composed of R, single bond, C H 2, single bond, C, single bond, C H 2, single bond, C, single bond, S, single bond, R dash. C 2 is dash bonded to O H on the upper left and wedge bonded to H on the upper right. C 4 is double bonded to O above.

In the third step, the product formed in step 2 undergoes irreversible oxidation.

The product of oxidation is as follows: A zigzag chain is composed of R, single bond, C H 2, single bond, C, single bond, C H 2, single bond, C, single bond, S, single bond, R dash. C 2 and C 4 are each double bonded to O above.

In the fourth step, the product formed in step 3 undergoes irreversible cleavage.

The first product of cleavage is the activated acyl group depicted as follows: A zigzag chain is composed of R, single bond, C H 2, single bond, C, single bond, S, single bond, R dash. C 2 is double bonded to O above. The activated acyl group is shortened by two carbon atoms.

The second product of cleavage is the activated acetyl group depicted as follows: A zigzag chain is composed of C H 3, single bond, C, single bond, S, single bond, R dash. C 2 is double bonded to O above.

The reaction sequence of fatty acid synthesis is depicted as follows from bottom to the top:

In the first step, the activated acyl group and activated malonyl group undergo irreversible condensation with the simultaneous release of C O 2.

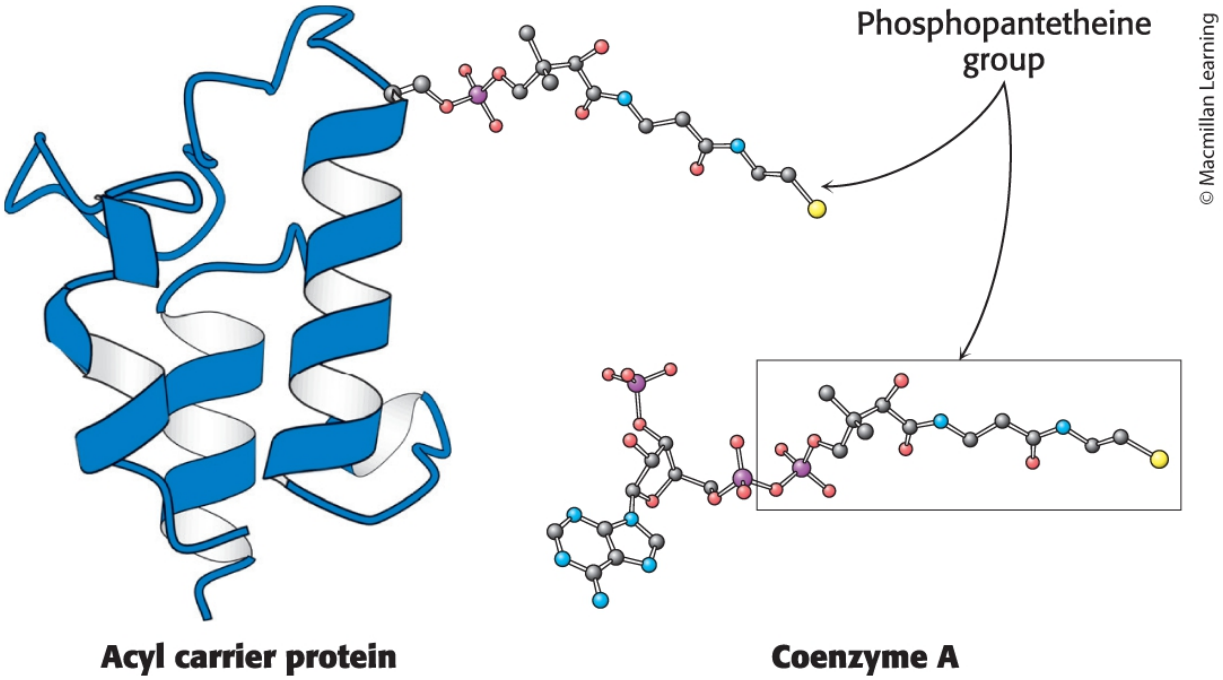
The structure of the activated malonyl group is as follows: A zigzag chain is composed of C, single bond, C H 2, single bond, C, single bond, S, single bond, R double dash. C 1 is partially double bonded to O above and O on the lower left. The O atoms have an overall negative charge. C 3 is double bonded to O above.

The product of condensation is depicted as follows: A zigzag chain is composed of R, single bond, C H 2, single bond, C, single bond, C H 2, single bond, C, single bond, S, single bond, R double dash. C 2 and C 4 are each double bonded to O above.

In the second step, the product of condensation undergoes irreversible reduction.

The product of reduction is depicted as follows: A zigzag chain is composed of R, single bond, C H 2, single bond, C, single bond, C H 2, single bond, C, single bond, S, single bond, R double dash. C 2 is wedge bonded to O H on the upper left and dash bonded to H on the upper right. C 4 is double bonded to O above.

In the third step, the production of reduction undergoes irreversible dehydration.



The product of dehydration is depicted as follows: A zigzag chain is composed of R, single bond, C H 2, single bond, C, double bond, C, single bond, C, single bond, S, single bond, R double dash. C 2 and C 3 are single bonded to H above and H below respectively. C 4 is double bonded to O above.

In the fourth step, the product of dehydration undergoes irreversible reduction to produce an activated acyl group.

The structure of the activated acyl group is as follows: A zigzag chain is composed of R, single bond, C H 2, single bond, C H 2, single bond, C H 2, single bond, C, single bond, S, single bond, R double dash. C 4 is double bonded to O above. The activated acyl group is lengthened by two carbon atoms.

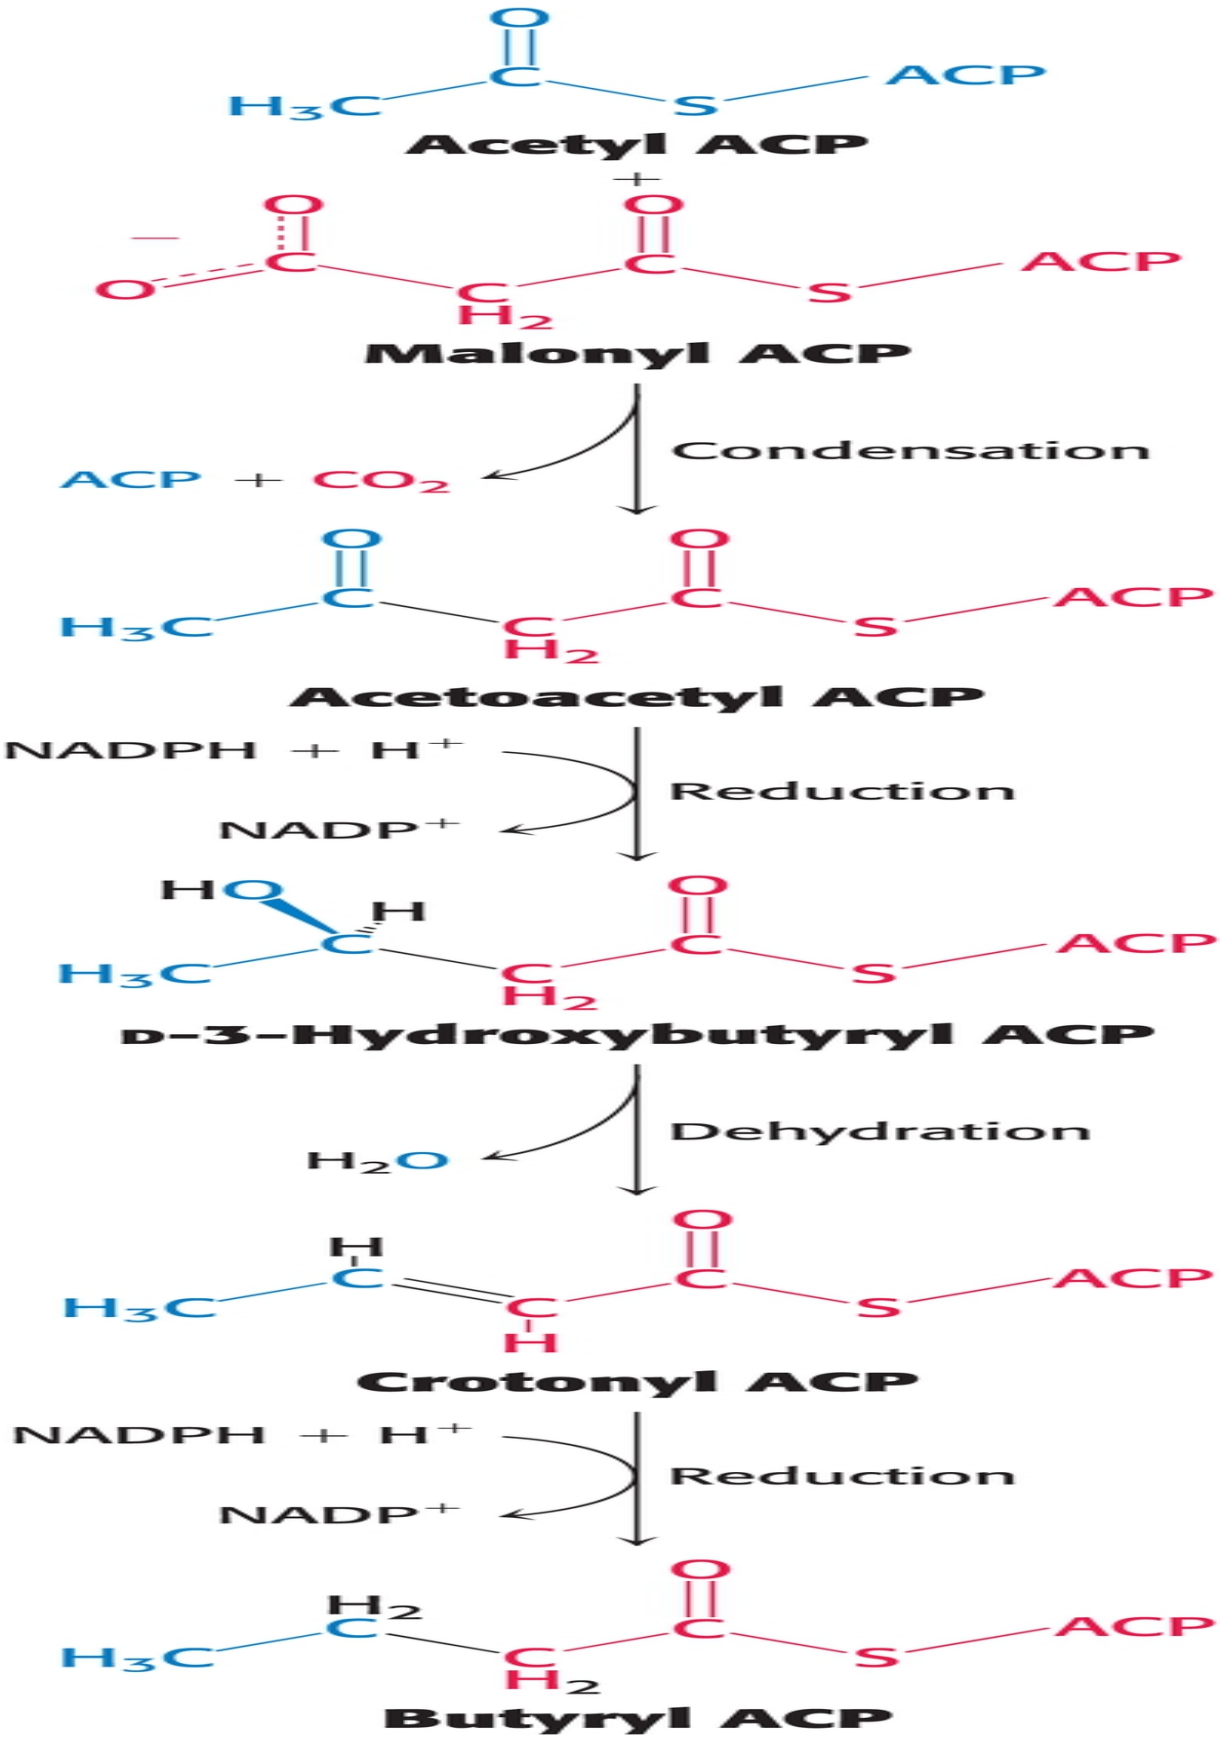
Extended description for FIGURE 22.24 Phosphopantetheine group in acyl carrier protein and coenzyme A

© Macmillan Learning

The acyl carrier protein consists of two medium-sized and one short alpha-helices in vertical orientation interconnected by thread-like loops. The loop at the top is connected to a ball-and-stick model composed of a zigzag chain of 1 purple sphere, 1 yellow sphere, 2 blue spheres, 2 red spheres, and 11 black spheres. The purple sphere is located at the fourth position, the red spheres are located at the third and fifth positions, the blue spheres occupy the tenth and fourteenth positions, and the yellow sphere occupies the right terminal or seventeenth position.



The ball-and-stick model of coenzyme A also contains an identical zigzag chain starting from the purple sphere. This region of the zigzag chain from the purple sphere to the right terminal yellow

sphere is labeled the phosphopantetheine group in both acyl carrier protein and coenzyme.

In the first step, acetyl A C P and malonyl A C P undergo irreversible condensation to produce acetoacetyl A C P with the simultaneous release of A C P plus C O 2.

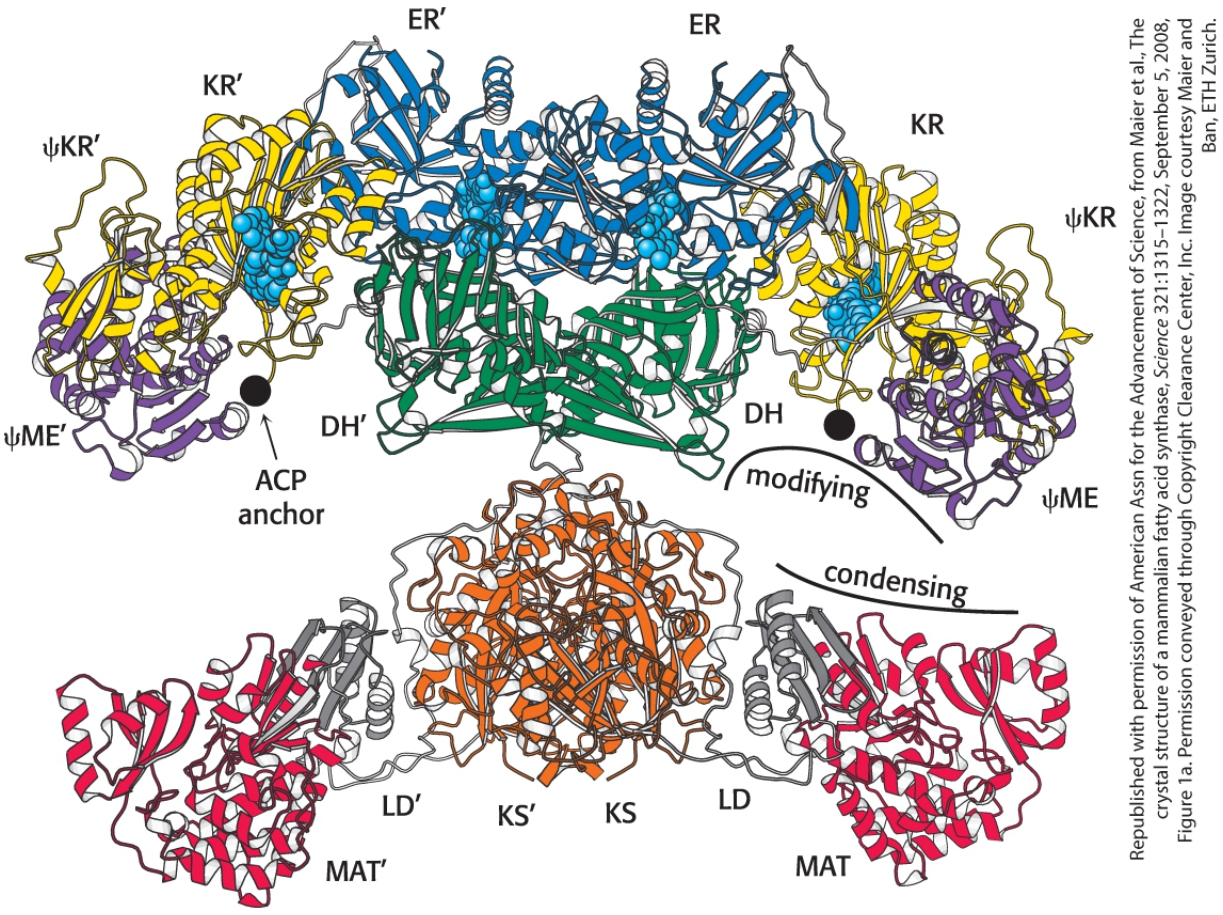
The structure of acetyl A C P is as follows: A zigzag chain is composed of C H 3, single bond, C, single bond, S, single bond, A C P. C 2 is double bonded to O above. The structure of malonyl A C P is as follows: A zigzag chain is composed of C, single bond, C H 2, single bond, C, single bond, S, single bond, A C P. C 1 is partially double bonded to O above and O on the lower left. The O atoms have an overall negative charge. C 3 is double bonded to O above.

The structure of acetoacetyl A C P is as follows: A zigzag chain is composed of C H 3, single bond, C, single bond, C H 2, single bond, C, single bond, S, single bond, A C P. C 2 and C 4 are each double bonded to O above.

In the second step, acetoacetyl A C P undergoes irreversible reduction to D-3-hydroxybutyryl A C P with the simultaneous oxidation of N A D P H plus H superscript plus to N A D P superscript plus.

The structure of D-3-hydroxybutyryl A C P is as follows: A zigzag chain is composed of C H 3, single bond, C, single bond, C H 2, single bond, C, single bond, S, single bond, A C P. C 2 is wedge bonded to O H on the upper left and dash bonded to H on the upper right. C 4 is double bonded to O above.

In the third step, D-3-hydroxybutyryl A C P undergoes irreversible dehydration to produce crotonyl A C P with the simultaneous release of H 2 O.



The structure of crotonyl A C P is as follows: A zigzag chain is composed of C H 3, single bond, C, double bond, C, single bond, C, single bond, S, single bond, A C P. C 2 and C 3 are single bonded to H above and below respectively. C 4 is double bonded to O above.

In the fourth step, crotonyl A C P undergoes irreversible reduction to produce butyryl A C P with the simultaneous oxidation of N A D P H plus H superscript plus to N A D P superscript plus.

The structure of butyryl A C P is as follows: A zigzag chain is composed of C H 3, single bond, C H 2, single bond, C H 2, single bond, C, single bond, S, single bond, A C P. C 4 is double bonded to O above.

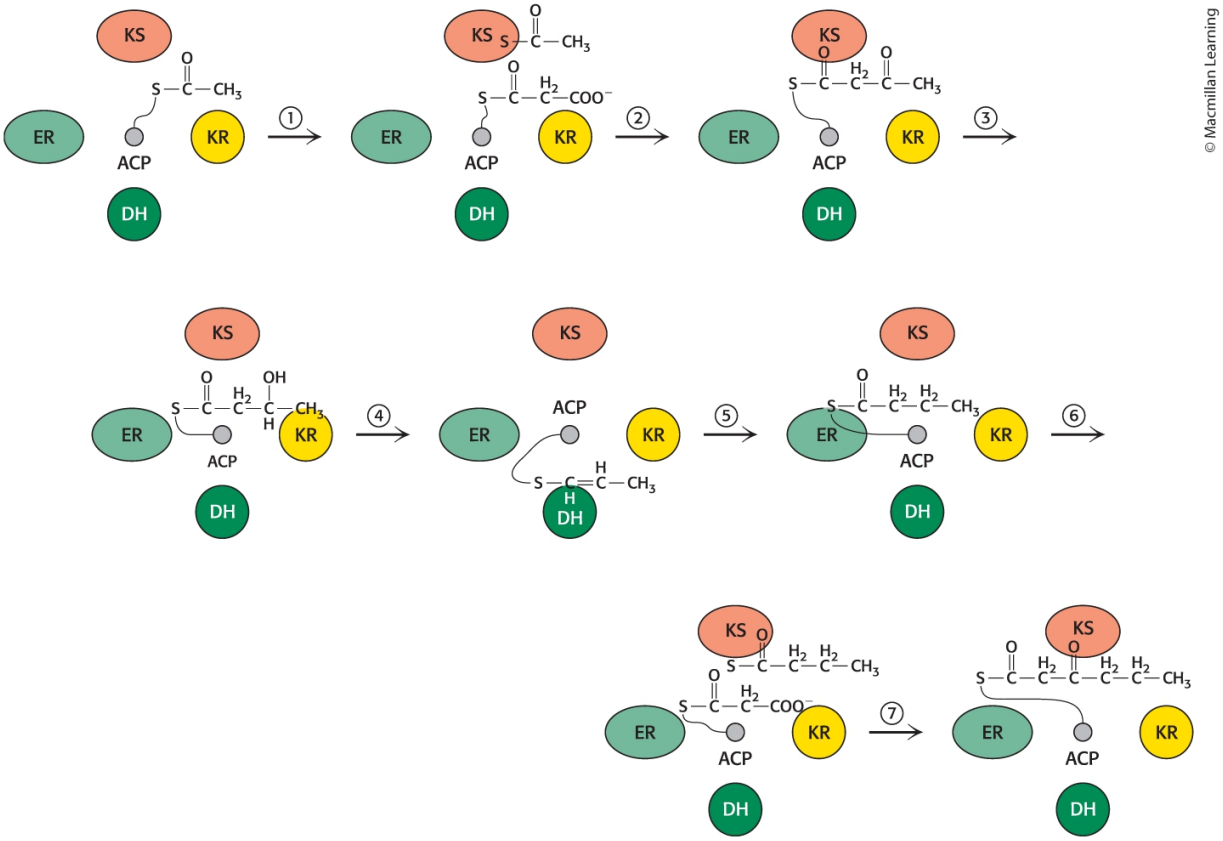
Extended description for FIGURE 22.26 Mammalian fatty acid synthase is a large, dimeric, multidomain protein complex

Republished with permission of American Assn for the Advancement of Science, from Maier et al., The crystal structure of a mammalian fatty acid synthase, *Science* 321:1315–1322, September 5, 2008, Figure 1a. Permission conveyed through Copyright Clearance Center, Inc. Image courtesy Maier and Ban, ETH Zurich.



The ribbon diagram consists of two multisubunit monomers. The bottom monomer contains a central circular cluster composed of alpha-helices and beta-strands. Its left half is labeled K S prime and the right half is labeled K S. The central cluster is connected to M A T prime domain on the lower left and M A T domain on the lower right through an L D prime domain and L D domain respectively. The L D and L D prime domains are linker domains consisting of

long loops, a few alpha-helices, and beta-strands. The top surface of L D and M A T domains is together labeled condensing.

The central part of the top monomer contains a V-shaped domain composed of several beta-strands. The left half is labeled D H prime and the right half is labeled D H. A U-shaped domain is located above it. It consists of beta-strands in the center surrounded by alpha-helices which are further flanked by beta-strands on either end. The left half is labeled E R prime and the right half is labeled E R. Each half contains a cluster of blue spheres. K R prime domain and a K R domain are located on the left and right side of the central part composed of V-shaped and U-shaped domains. Both the K R prime and K R domains contain a cluster of blue spheres. The left side of the K R prime domain is attached to a psi K R prime domain and a psi M E prime domain. The right side of the K R domain is attached to a psi K R domain and psi M E domain. The black sphere depicting the A C P anchor is attached to the bottom loop of the K R prime domain and K R domain. The bottom surface of the K R and psi M E domain is labeled modifying.

A C P depicted as a central tiny grey circle is connected to the S atom which is further single bonded to C, single bond, C H 3. The C atom is double bonded to O above. It is surrounded by the K S domain at the top, the K R domain on the right, the D H domain below, and the E R domain on the left.

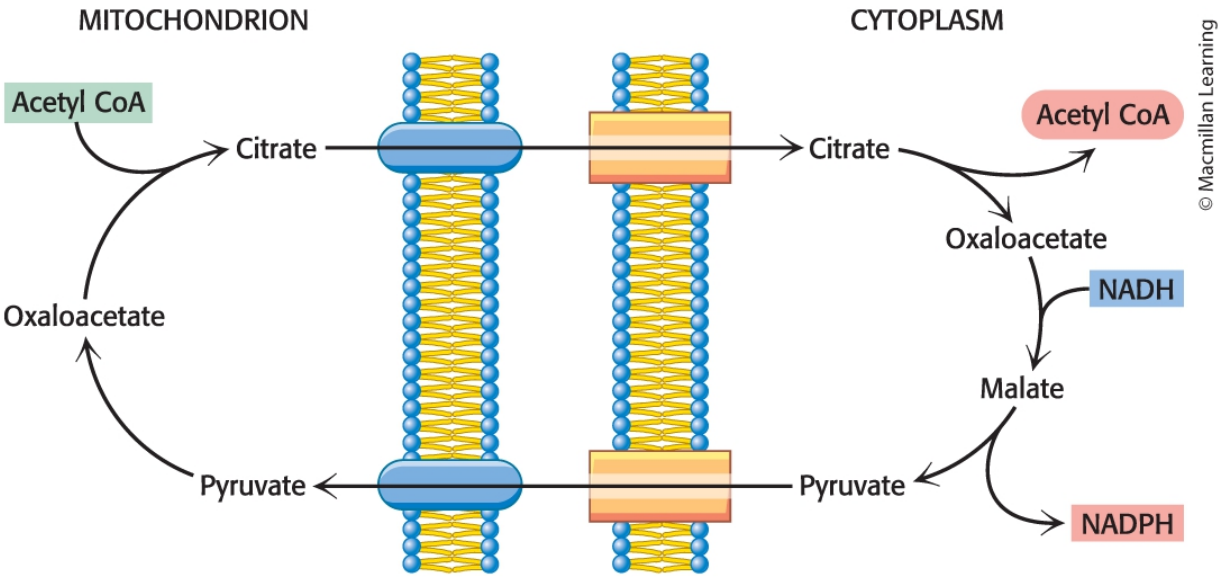
A forward arrow labeled 1 lead to the next structure. This structure consists of the tiny grey circle connected to S, single bond, C, single bond, C H 2, single bond, C O O superscript minus. C 1 is double bonded to O above. The K S domain at the top is bound to the S atom

of S, single bond, C, single bond, C H 3. The central C atom is double bonded to O above.

A forward arrow labeled 2 leads to the next structure. This structure consists of the tiny grey circle connected to S, single bond, C, single bond, C H 2, single bond, C, single bond, C H 3. C 1 and C 3 are each double bonded to O above. The O atom of C 1 is bound to the K S domain.

A forward arrow labeled 3 leads to the next structure. This structure consists of a tiny grey circle connected to S, single bond, C, single bond, C H 2, single bond, C H, single bond, C H 3. C 1 is single bonded to O above. C 3 is single bonded to O H above. C H 3 group is bound to K R domain.

A forward arrow labeled 4 leads to the next structure. This structure consists of a tiny grey circle connected to S, single bond, C H, double bond, C H, single bond, C H 3. H atom of C 1 is bound to D H.



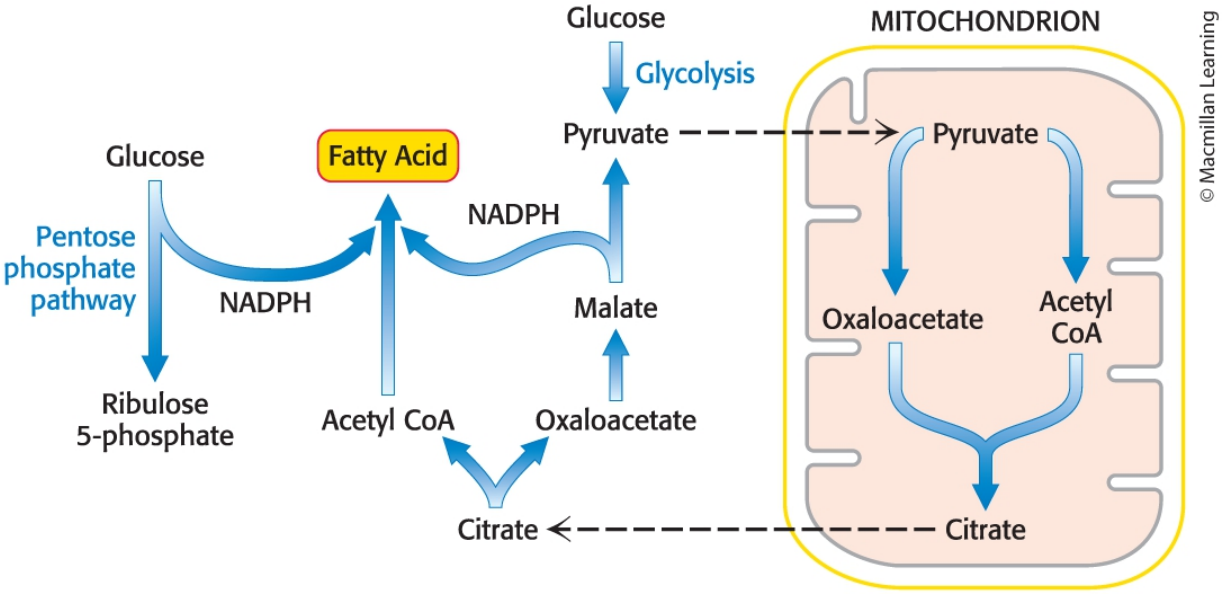
A forward arrow labeled 5 leads to the next structure. The tiny grey circle is connected to S, single bond, C, single bond, C H 2, single bond, C H 2, single bond, C H 3. C 1 is double bonded to O above. The S atom is bound to the E R domain.

A forward arrow labeled 6 leads to the next structure. A tiny grey circle is connected to S, single bond, C, single bond, C H 2, single bond, C O O superscript minus. C 1 is double bonded to O above. The S atom is located close to the E R domain and the C O O superscript minus group is located close to the K R domain. A structure composed of S, single bond, C, single bond, C H 2, single bond, C H 2, single bond, C H 3 is bound to the K S domain. C 1 is double bonded to O above which is bound to K S.

A forward arrow labeled 7 leads to the next structure. The tiny grey circle is connected to S, single bond, C, single bond, C H 2, single bond, C, single bond, C H 2, single bond, C H 2, single bond, C H 3. C 1 and C 3 are double bonded to O above. The O atom bonded to C 3 is bound to the K S domain.

Return to FIGURE 22.27 One catalytic cycle of mammalian fatty acid synthase consists of seven steps

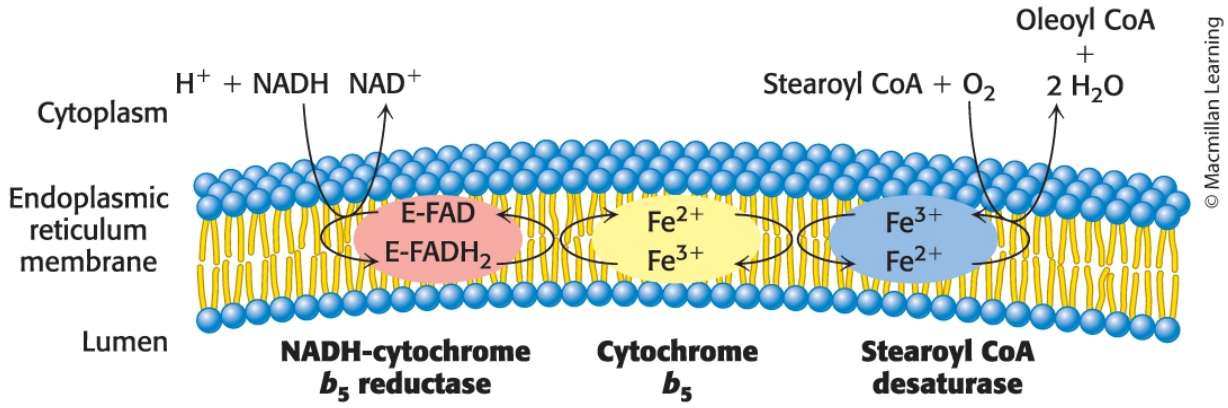
Extended description for FIGURE 22.28 Acetyl C o A can be transferred from the mitochondrial matrix to the cytoplasm



Two lipid bilayers separated by a small gap are shown in the vertical orientation. The left bilayer contains a blue oblong transport protein embedded in the membrane at the top and bottom. The right bilayer contains an orange rectangular channel at the top and bottom. The region on the left of the left bilayer is labeled mitochondrion. The region on the right of the right bilayer is labeled cytoplasm. Oxaloacetate in the mitochondrion combines with acetyl C o A to form citrate. The citrate molecule passes through the oblong transport protein in the left bilayer and then the rectangular channel in the right bilayer to enter the cytoplasm. Inside the cytoplasm, citrate breaks down into oxaloacetate and acetyl C o A. The oxaloacetate is converted into malate with the simultaneous use of N A D H. The malate molecule is converted into pyruvate with the simultaneous release of N A D P H. The pyruvate molecule passes through the bottom rectangular channel in the right bilayer and

then the bottom oblong channel in the left bilayer to reach the mitochondrion and the cycle continues.

Return to FIGURE 22.28 Acetyl C o A can be transferred from the mitochondrial matrix to the cytoplasm

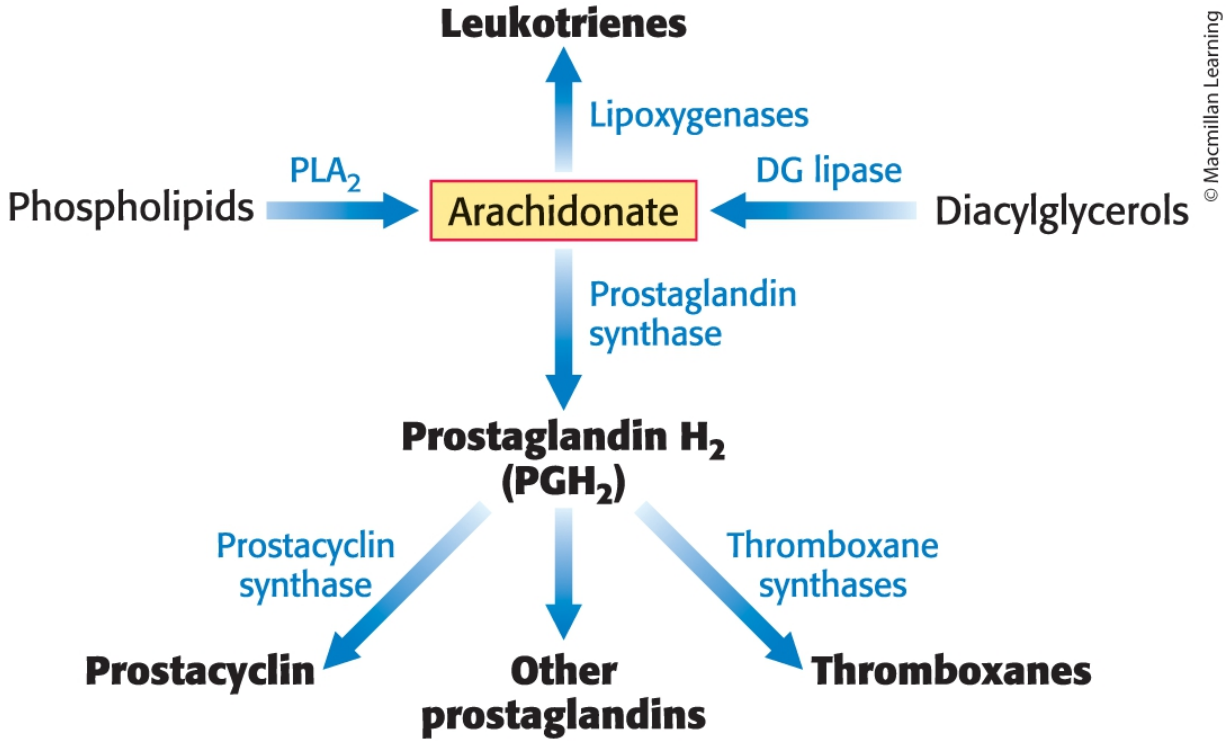


Extended description for FIGURE 22.29 Pathway Integration: Fatty acid synthesis requires the cooperation of various pathways in different cellular compartments

A mitochondrion is shown in a vertical orientation. Outside the mitochondrion, glucose is converted into pyruvate via glycolysis. Simultaneously, another glucose molecule is converted into ribulose 5-phosphate via the pentose phosphate pathway with the simultaneous release of N A D P H. Inside the mitochondrion, pyruvate is converted into oxaloacetate or acetyl C o A, both of which combine to form citrate. The citrate molecule leaves the mitochondrion and breaks down into acetyl C o A and oxaloacetate. The oxaloacetate molecule is converted into malate, which is further converted into pyruvate with the simultaneous release of N A D P H. This N A D P H and the N A D P H molecule produced by pentose phosphate pathway is used during the conversion of acetyl C o A into fatty acid.

Return to FIGURE 22.29 Pathway Integration: Fatty acid synthesis requires the cooperation of various pathways in different cellular compartments

Extended description for FIGURE 22.30 Desaturation of fatty acids by an electron transport chain in the E R membrane



A lipid bilayer is labeled endoplasmic reticulum membrane. The region above the membrane is labeled cytoplasm and the region below is the lumen. Three proteins are embedded in the membrane from left to right. These membrane proteins are labeled N A D H-cytochrome b 5 reductase, cytochrome b 5, and stearoyl C o A desaturase. N A D H-cytochrome b 5 reductase is depicted as a pink oval. It undergoes reduction from E-F A D to E-F A D H 2 with the simultaneous oxidation of N A D H plus H superscript to N A D superscript plus in the cytoplasm. It later undergoes re-oxidation from E-F A D H 2 to E-F A D with the simultaneous reduction of F e superscript 3 plus in cytochrome b 5 to F e superscript 2 plus.

The cytochrome b 5 transfers its electrons to stearoyl C o A desaturase with the simultaneous conversion of F e superscript 2 plus to F e superscript 3 plus. The F e superscript 3 plus bound to the desaturase is reduced to F e superscript 2 plus. The desaturase transfers electrons to Stearoyl C o A plus O 2 in the cytoplasm to

produce oleoyl C o A plus 2 H 2 O. The F e superscript 2 plus in the desaturase is converted back to F e superscript 3 plus.

Extended description for FIGURE 22.31 Several eicosanoid hormones are produced from arachidonate by distinct enzymatic pathways

A rectangle labeled arachidonate is shown at the top center. An upward arrow labeled lipoxygenases points from arachidonate to leukotrienes. An arrow labeled P L A 2 points from phospholipids on the left to arachidonate. An arrow labeled D G lipase points from diacylglycerols on the right to arachidonate. A downward arrow labeled prostaglandin synthase points from arachidonate to prostaglandin H 2 (P G H 2). An arrow labeled prostacyclin synthase points from P G H 2 to prostacyclin. A downward arrow from P G H 2 points to other prostaglandins. An arrow labeled thromboxane synthases points from P G H 2 to thromboxanes.

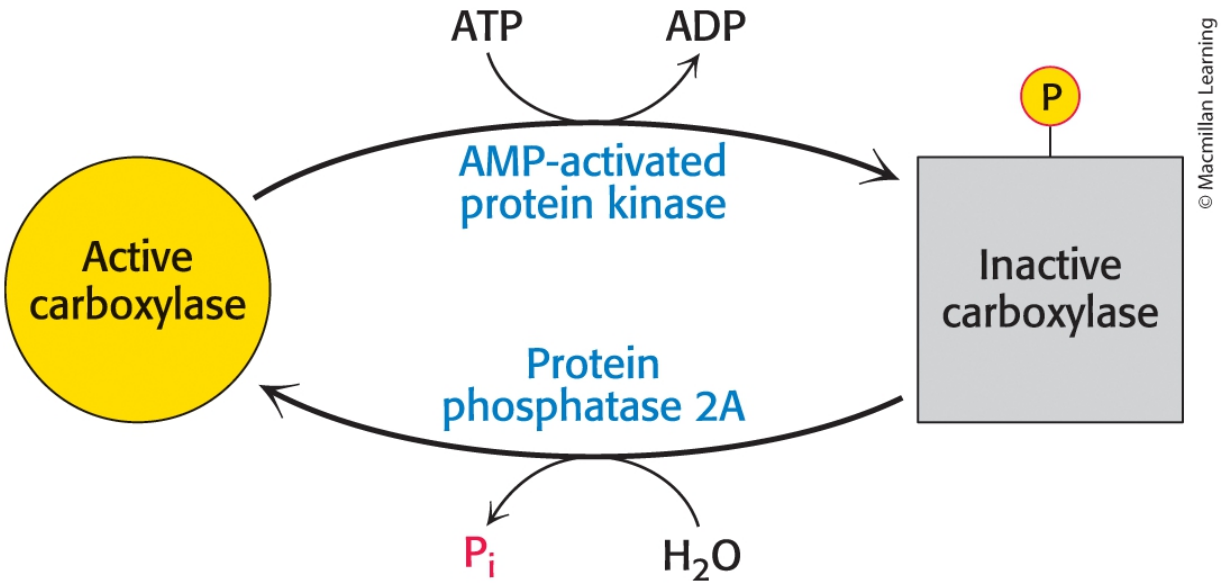
Return to FIGURE 22.31 Several eicosanoid hormones are produced from arachidonate by distinct enzymatic pathways

Extended description for FIGURE 22.32 Structures of different eicosanoids

Prostaglandin E 2 which induces labor has the following structure: A 5-carbon homocyclic pentagonal ring is in a horizontal orientation with C 1 occupying the leftmost vertex. C 2 is double bonded to O on the upper left. C 5 is dash bonded to O H on the lower left. C 3 is dash bonded to C 1 of a 6-carbon alkene chain depicted as a line structure using 5 zigzag lines. A double bond is present between C 2 and C 3. C 6 is single bonded to C O O superscript minus on the lower right. C 4 of the ring is single bonded to C 1 of a 7-carbon alkene chain depicted as a line structure using 6 zigzag lines. A double bond is present between C 1 and C 2. C 3 is dash bonded to O H below. C 7 is single bonded to C H 3 on the upper right.

Thromboxane A 2 (T X A 2) which enhances platelet aggregation has the following structure: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the bottom-left vertex.

It contains 1 O and 5 C atoms. O occupies the bottom-most vertex. C 1 and C 3 are dash bonded to an O atom located outside the ring. A wedge bond is present between C 1 and C 2 and C 2 and C 3. C 4 is dash bonded to C 1 of a 6-carbon alkene chain depicted as a line structure using 5 zigzag lines. A double bond is present between C 2 and C 3. C 6 is single bonded to C O O superscript minus on the lower right. C 5 of the ring is single bonded to C 1 of a 7-carbon alkene chain depicted as a line structure using 6 zigzag lines. A double bond is present between C 1 and C 2. C 3 is dash bonded to O H below. C 7 is single bonded to C H 3 on the upper right.



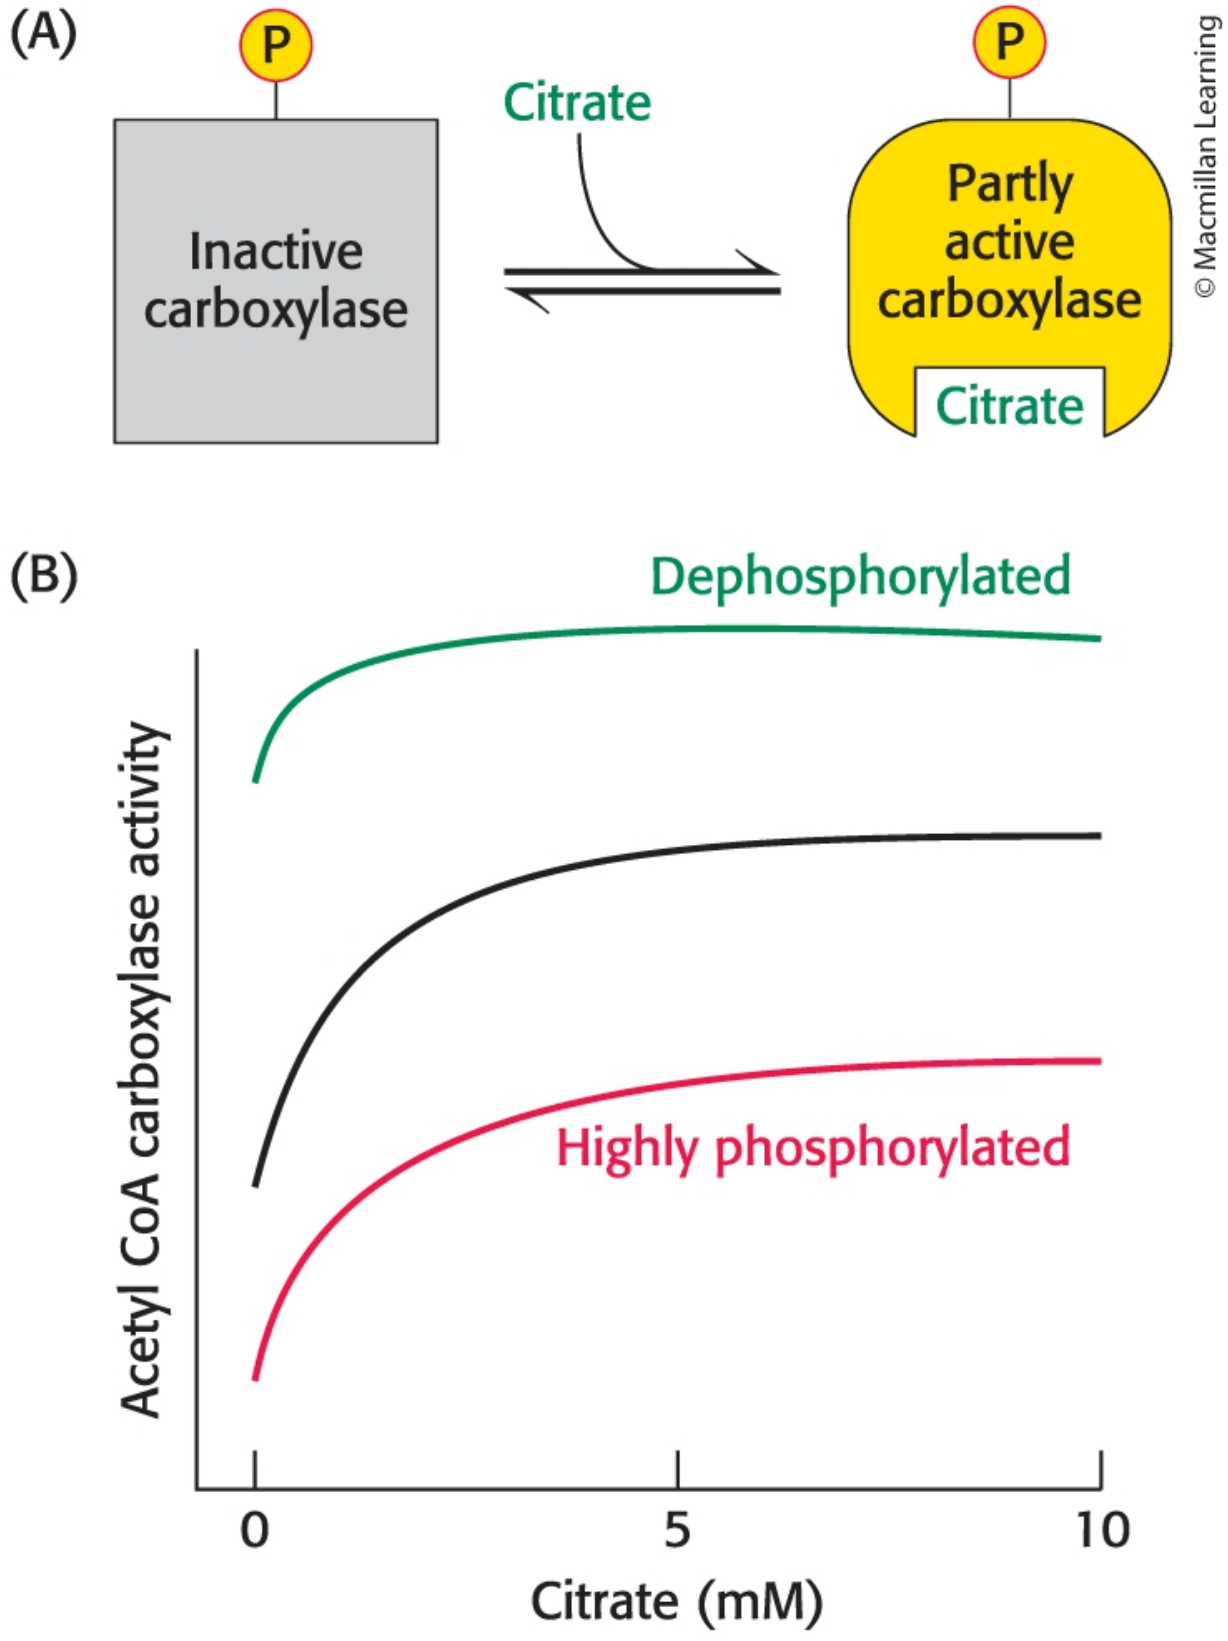
Prostacyclin (P G I 2) which is a vasodilator has the following structure: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the top left vertex. C 1 occupies the topmost vertex. C 1 is double bonded to a 4-carbon alkane chain depicted as a line structure using 3 zigzag lines. C 4 of the alkane chain is single bonded to C O O superscript minus on the lower left. The heterocyclic ring is fused to a 5-carbon homocyclic pentagonal ring in a vertical orientation such that C 3 and C 4 of the heterocyclic ring are C 4 and C 3 respectively of the homocyclic ring. In the heterocyclic pentagonal ring, C 1 occupies the bottom-most vertex and is dash-bonded to O H below. C 5 is single bonded to a 7-carbon alkene chain depicted as a line structure using 6 zigzag lines. A double bond is present between C 1 and C 2. C 3 is dash bonded to O H below. C 7 is single bonded to C H 3 on the upper right.

(d) Leukotriene B 4 which is responsible for the proinflammatory signal has the following structure: A 18-carbon alkene chain is depicted as a line structure using 17 zigzag lines. C 1 is single bonded on the upper right to C O O superscript minus. C 4 and C 11 are wedge-bonded to O H above. A double bond is present between C 5 and C 6, C 7 and C 8, C 9 and C 10, and C 13 and C 14. The alkene

chain is folded at C 12. C 18 is single bonded to C H 3 on the upper right.

Return to FIGURE 22.32 Structures of different eicosanoids

Extended description for FIGURE 22.33 Inhibition and activation of acetyl C o A carboxylase

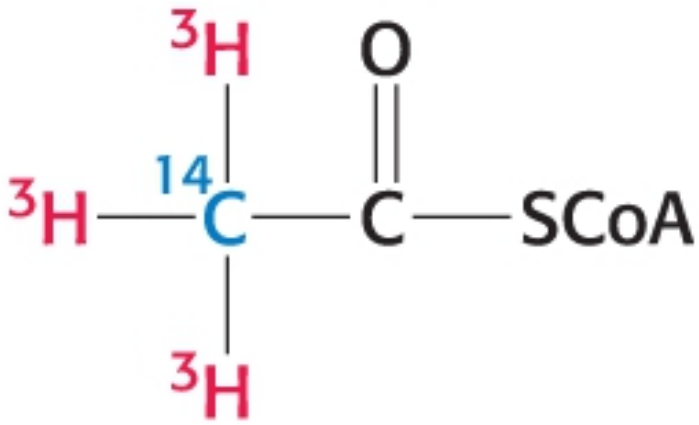


A yellow circle is labeled active carboxylase and a grey square is labeled inactive carboxylase. The inactive carboxylase is phosphorylated which is depicted as a tiny yellow circle labeled P connected to the square. A forward arrow labeled A M P-activated protein kinase points from active carboxylase to inactive carboxylase with the simultaneous hydrolysis of A T P to A D P. A backward arrow labeled protein phosphatase 2 A points from inactive carboxylase to active carboxylase with the simultaneous entry of H 2 O and release of P subscript i.

Return to FIGURE 22.33 Inhibition and activation of acetyl C o A carboxylase

Extended description for FIGURE 22.35 The catalytic activity of acetyl C o A carboxylase depends upon the

concentration of citrate



© Macmillan Learning

Part (A): It shows an inactive carboxylase as a grey square single bonded to a phosphate group. A reversible reaction arrow shows the entry of citrate and leads to a rounded yellow square labeled partly active carboxylase. The partly active carboxylase is bound to citrate and single-bonded to the phosphate group.

Part (B): It shows a graph. The horizontal axis is labeled citrate in millimolar. It has markings ranging from 0 to 10 in increments of 5 units. The vertical axis is labeled acetyl C o A carboxylase activity. It contains three curves from top to bottom. A green horizontal curve is labeled dephosphorylated. It starts at a carboxylase activity slightly less than the maximum at 0 millimolar of citrate. It rises to the highest activity and then moves horizontally toward the right. The middle black curve starts at a carboxylase activity much below the average value. It then rises gradually to a carboxylase activity much above the average value till 2.5 millimolar of citrate and then continues moving horizontally toward the right. The bottom red curve is labeled highly phosphorylated. It starts at the lowest carboxylase activity at 0 millimolar of citrate. It then rises in a concave down fashion to reach a below-average carboxylase activity at 5 millimolar and then moves horizontally toward the right. All values are estimated.

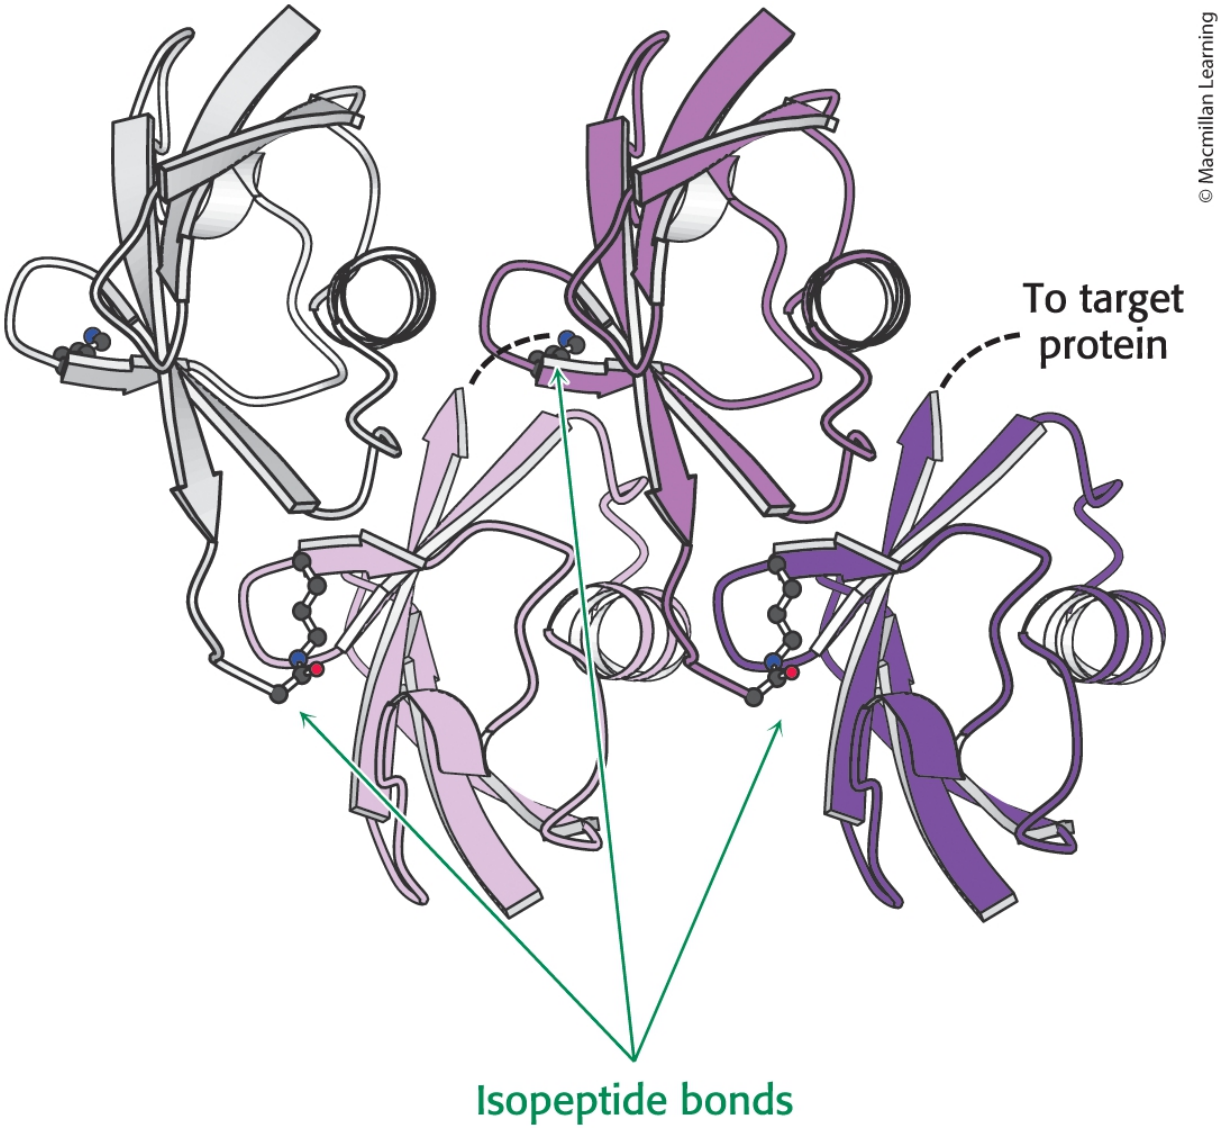
Extended description for FIGURE 23.3 Ubiquitin conjugation requires three enzymes

In the first reversible step catalyzed by E 1, a ubiquitin-protein depicted as a small red oval connected to a short tube below is single bonded to C below. The C atom is partially double-bonded to O on the lower left and lower right. The O atoms have an overall negative charge. The ubiquitin protein reacts with A T P. The product of the first step consists of ubiquitin single bonded to C below. This C atom is double-bonded to O on the lower left and single-bonded to A M P on the lower right. P P subscript i is released during this step.

In the second reversible step, E 1 enters, and A M P is released. The ubiquitin is single-bonded to C below. This C is double-bonded to O on the lower left and single-bonded to S on the lower right. This S atom is single-bonded to E 1 which is depicted as a blue curved structure.



In the third irreversible step, E 2 enters and E 1 is released. The orientation of ubiquitin is reversed such that it is single-bonded to C above. This C is double-bonded to O on the upper right and single-bonded to S on the upper left. This S atom is single-bonded to E 2 which is depicted as a green crescent-shaped structure.

In the irreversible step 4 a, E 3 enters. E 3 is an elongated L-shaped protein that accommodates ubiquitin connected to E 2 and a target protein depicted as a yellow oval connected to a 4-carbon alkane chain. The alkane chain is depicted as a line structure using 3 zigzag lines. C 4 is single bonded to N H 3 superscript plus.

In irreversible step 4 b, E 2 and E 3 are released. The ubiquitin is single-bonded to C. This C is double bonded to O on the upper left and single bonded to the N H group connected to the target through a 4-carbon alkane chain.

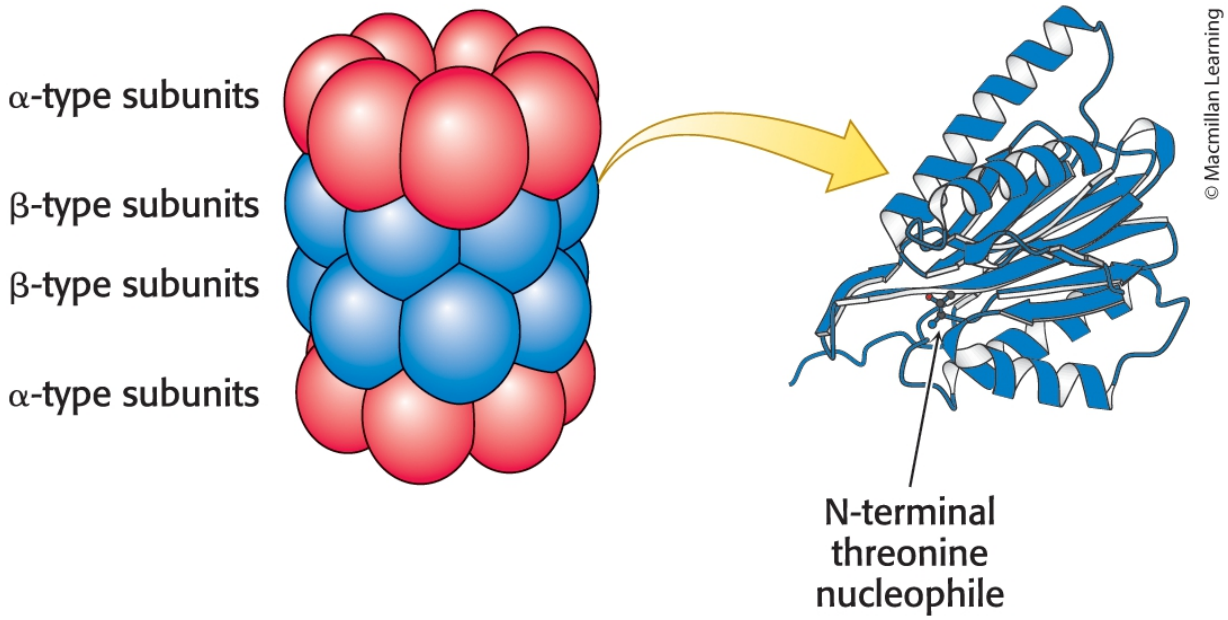
Extended description for FIGURE 23.4 In a tetraubiquitin chain, four ubiquitin molecules are linked by isopeptide bonds



© Macmillan Learning

The ribbon diagram of four ubiquitin molecules is shown. Each molecule consists of a few beta-strands and one alpha-helix interconnected by long thread-like loops. The adjacent ubiquitin molecules are connected by isopeptide bonds. The isopeptide bond

is formed by the linkage of the carboxylate group at the end of the extended C terminus with the epsilon-amino group of a lysine residue 48. The extended C terminus of the second ubiquitin molecule is depicted as a dashed line. In the rightmost ubiquitin, a dashed line connected to one of the beta-strands is labeled "To target protein."

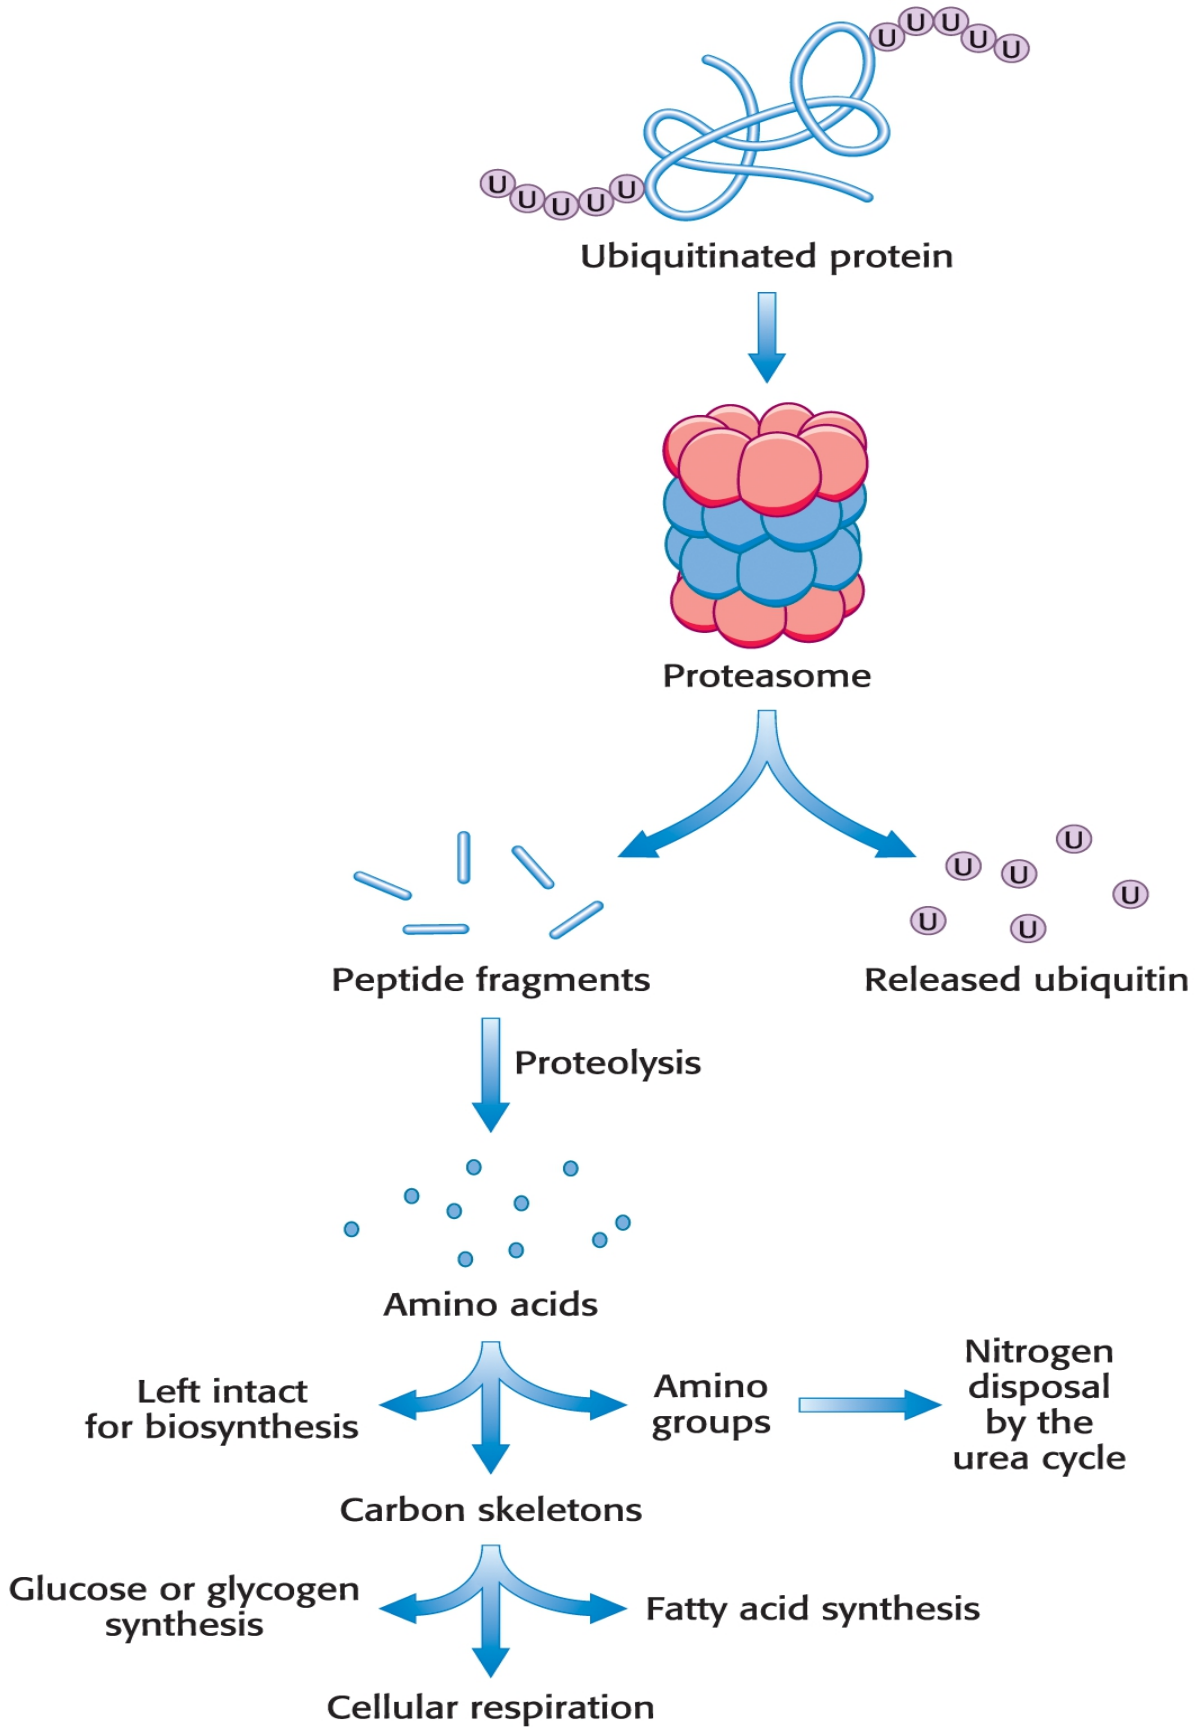
Extended description for FIGURE 23.5 The 20 S proteasome is barrel-shaped and made up of 28 homologous subunits

The 20 S proteasome is composed of 4 rings of alpha-type and beta-type subunits. Each ring is composed of 7 subunits. The alpha-type subunit is depicted as a red oval and the beta-type subunit is depicted as a blue oval. The top and bottom rings are composed of alpha-type subunits. The two rings in the middle are composed of beta-type subunits. An arrow from the beta-type subunit shows a ribbon diagram consisting of beta-strands in the middle flanked by alpha-helices at the top and bottom. An N-terminal threonine nucleophile is shown in a thread connected to one of the beta-strands.

Return to FIGURE 23.5 The 20 S proteasome is barrel-shaped and made up of 28 homologous subunits

Extended description for FIGURE 23.6 The 26 S proteasome consists of one 20 S and two 19 S subunits



The 26 S proteasome is an elongated structure that consists of a 20 S catalytic core and a 19 S regulatory unit at the top and bottom. The 20 S catalytic core consists of thick blue subunit in the middle connected to a thin pink subunit at the top and bottom. The pink

subunits are further connected to a large white subunit having an uneven surface.

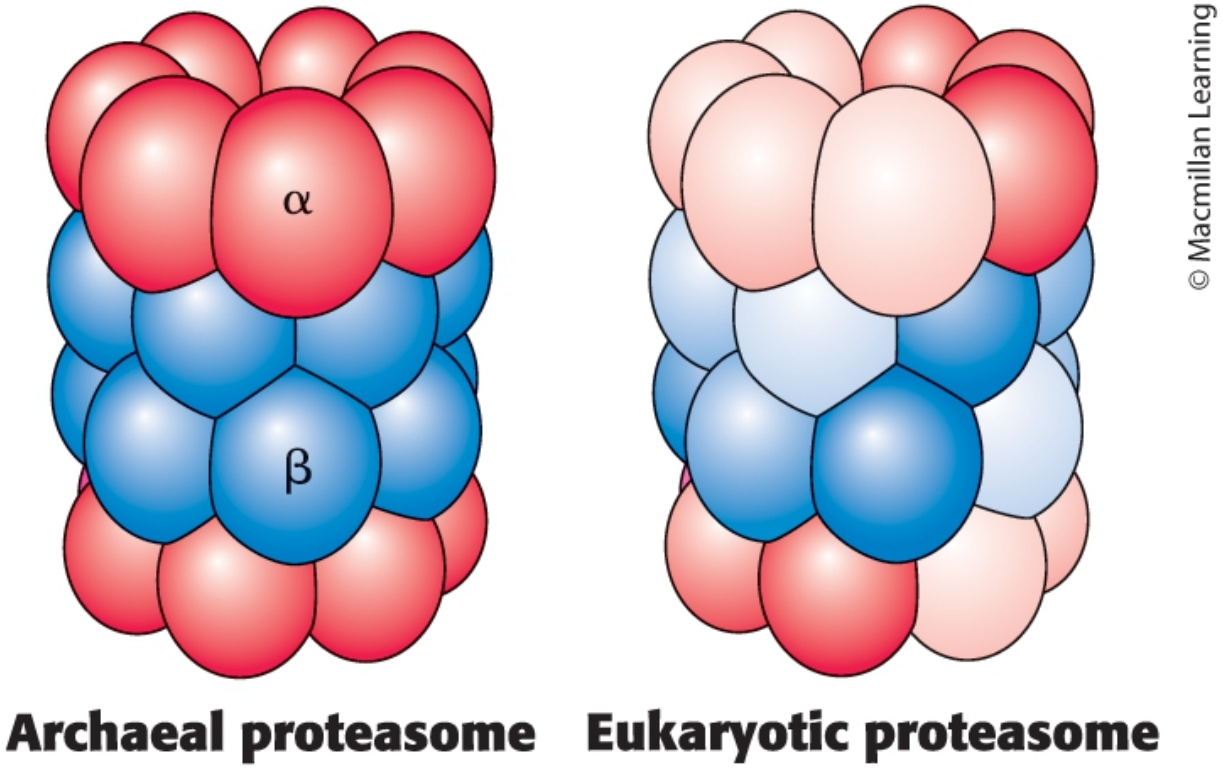
Extended description for FIGURE 23.7 The proteasome

and other proteases generate free amino acids

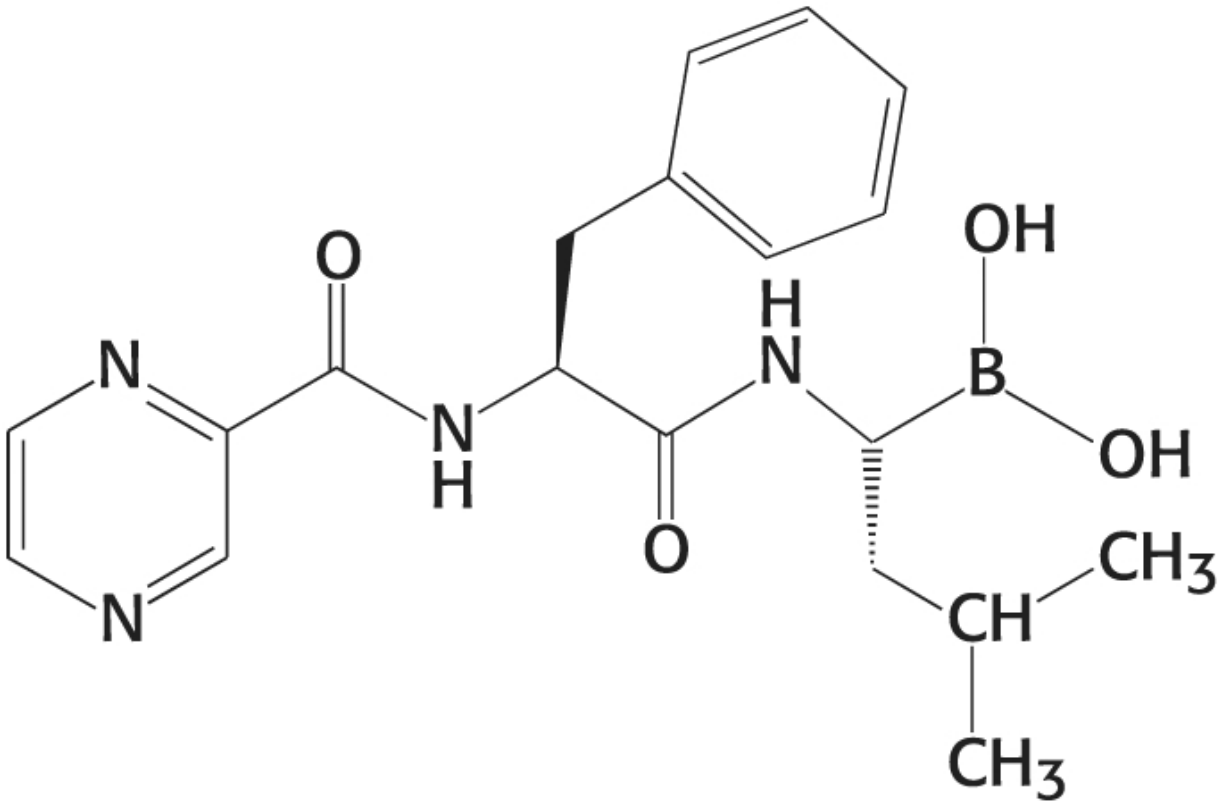


© Macmillan Learning

The ubiquitinated protein is depicted as an entangled filament. It is connected to a chain of U on the left and right. A downward arrow from ubiquitinated protein points to proteasome. Two arrows from the proteasome point toward peptide fragments and released ubiquitin. The peptide fragments are depicted as short filaments. The released ubiquitin is depicted as several isolated tiny circles labeled U. A downward arrow from peptide fragments point toward tiny blue circles depicting amino acids. Arrows from the amino acids point toward carbon skeletons, left intact for biosynthesis, and amino groups. An arrow from amino groups points toward nitrogen disposal by the urea cycle. An arrow from carbon skeletons points toward glucose or glycogen synthesis, cellular respiration, and fatty acid synthesis.

Return to FIGURE 23.7 The proteasome and other proteases generate free amino acids

Extended description for FIGURE 23.8 Proteasomes have become more complex in eukaryotes



© Macmillan Learning

The archaeal proteasome is composed of 4 rings. The top and bottom rings are composed of identical alpha subunits depicted as a red oval. The two rings in the middle are composed of identical beta subunits depicted as a blue oval. The eukaryotic proteasome is composed of 4 rings. The top and bottom rings are composed of 7 distinct types of alpha subunits. The different alpha subunits are shown in red color of varying intensity. The two rings in the middle are composed of 7 distinct types of beta-subunits. The different beta subunits are shown in blue color of varying intensity.

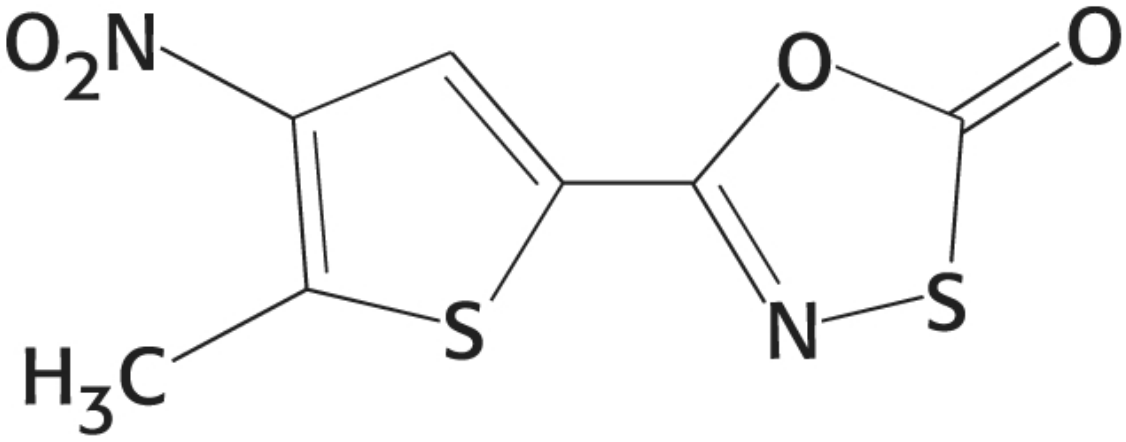
Extended description for Structure of bortezomib



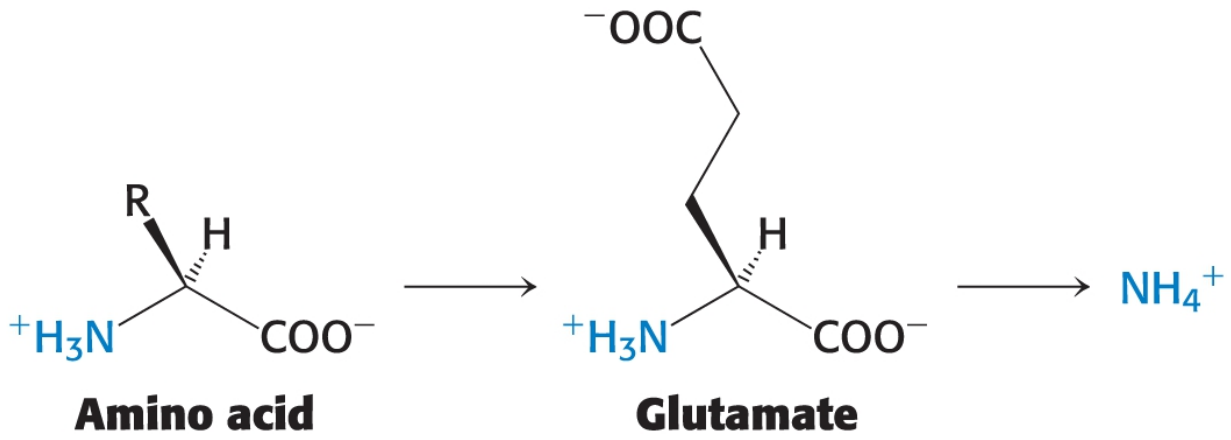
Bortezomib
(a dipeptidyl boronic acid)

The structure of bortezomib is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation. It consists of 2 N and 4 C atoms. C 1 occupies the top right vertex. The first N occupies the topmost vertex and the second N occupies the bottom-most vertex. A double bond is present between N 1 and C 1, C 2 and N 2, and C 3 and C 4. C 1 is single bonded to a 2 N and 3 C heteronuclear alkane chain depicted as a line structure using 4 zigzag lines. The first N bound to H occupies the second position and the second N bound to H occupies the fifth position. C 1 is double bonded to O above. C 2 is wedge bonded to C H 2 on the

upper right. This C H 2 group is single-bonded to C 1 of a benzene ring. In the benzene ring, alternating double bonds are present between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 3 of the alkane chain is double bonded to O below. N 2 of the alkane chain is single-bonded to C H 2 on the lower right. This C H 2 group is dash bonded to C H 2 below and single bonded to B on the upper right. The B atom is single-bonded to O H above and O H on the lower right. The C H 2 group below is single-bonded to C H on the lower right. The C H group is single bonded to C H 3 on the upper right and C H 3 below.

Return to Structure of bortezomib

Extended description for Structure of H T 1171



HT1171

5-(2-methyl-3-nitrothiophen-2-yl)-1,3,4-oxathiazol-2-one

The structure of H T 1171 is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 S and 4 C atoms. S occupies the bottom-right vertex. C 1 occupies the bottom-left vertex. A double bond is present between C 1 and C 2, and C 3 and C 4. C 1 is single bonded to C H 3 on the lower left. C 2 is single bonded to N O 2 on the upper left. C 4 is single-bonded to C 2 of another 5-membered heterocyclic pentagonal ring in a vertical orientation. This ring consists of 1 O, 1 N, 1 S, and 2 C atoms. N occupies the bottom left vertex and S occupies the bottom right vertex. O occupies the topmost vertex. C 1 occupies the top right vertex. A double bond is present between N and C 2. C 1 is double bonded to O on the upper right.

Return to Structure of H T 1171

Extended description for Oxidative deamination in the liver

In oxidative deamination, the amino acid is first irreversibly converted into glutamate.

The structure of amino acid is depicted as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to R on the upper left, and dash bonded to H on the upper right.

The structure of glutamate is depicted as follows: A 2-carbon alkane chain is depicted using a single line. C 1 is single bonded to C O O superscript minus on the upper left. C 2 is wedge bonded to C on the lower right. This C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, and dash bonded to H on the upper right.

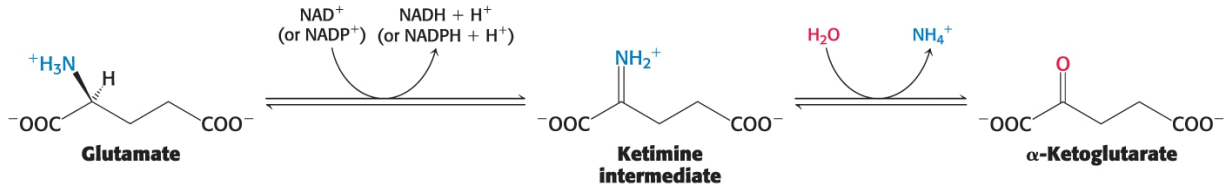
In the next irreversible step, glutamate gives an ammonium ion depicted as N H 4 superscript plus.

Return to Oxidative deamination in the liver

Extended description for Transfer of the alpha-amino group from an alpha-amino acid to an alpha-ketoacid

The reversible reaction catalyzed by aminotransferase consists of two reactants and two products.

The structure of the first reactant is as follows: A central C atom is single bonded to C O O superscript minus on the lower left, single bonded to R 1 on the lower right, wedge bonded to N H 3 superscript plus on the upper left, and dash bonded to H on the upper right.



The structure of the second reactant is as follows: A central C atom is single bonded to C O O superscript minus on the lower left, single bonded to R 2 on the lower right, and double bonded to O above.

The structure of first product is as follows: A central C atom is single bonded to C O O superscript minus on the lower left, single bonded to R 1 on the lower right, and double bonded to O above.

The structure of the second product is as follows: A central C atom is single bonded to C O O superscript minus on the lower left, single bonded to R 2 on the lower right, wedge bonded to N H 3 superscript plus on the upper left, and dash bonded to H on the upper right.

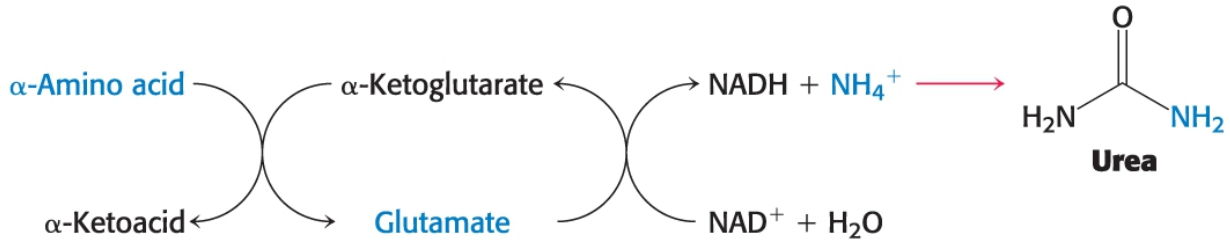
Return to Transfer of the alpha-amino group from an alpha-amino acid to an alpha-ketoacid

Extended description for Formation of alpha-ketoglutarate from glutamate

The reaction consists of one reactant, one intermediate, and one product.

The reactant is glutamate whose structure is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the lower left, wedge bonded to N H 3 superscript plus on the upper left, and dash bonded to H on the upper right. C 3 is single bonded to C O O superscript minus on the lower right.

A reversible reaction arrow leads to the ketimine intermediate. A curved arrow above it depicts the coupled reduction of N A D superscript plus or N A D P superscript plus to N A D H plus H superscript plus or N A D P H plus H superscript plus respectively.

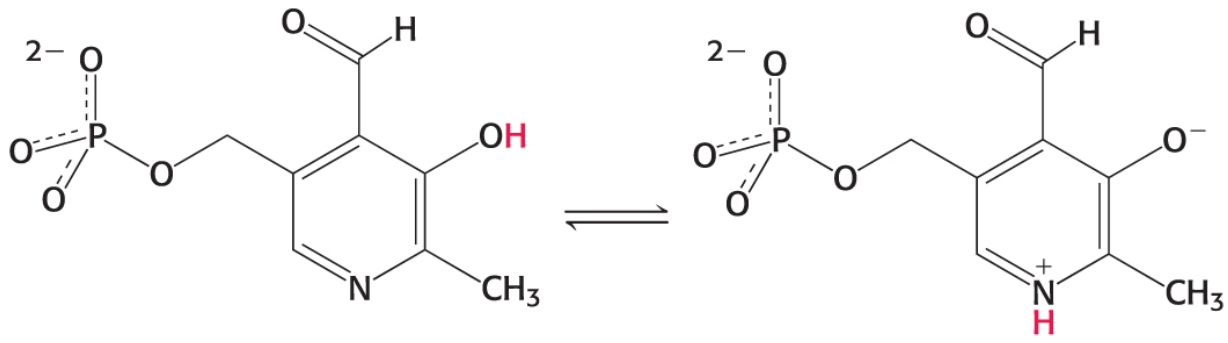


The structure of the ketimine intermediate is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the lower left and double bonded to N H 2 superscript plus above. C 3 is single bonded to C O O superscript minus on the lower right.

A reversible reaction arrow leads to the product. A curved arrow above it shows the entry of H 2 O and the release of N H 4 superscript plus ion.

The product is alpha-ketoglutarate whose structure is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the lower left and double bonded to O above. C 3 is single bonded to C O O superscript minus on the lower right.

Return to Formation of alpha-ketoglutarate from glutamate



Extended description for Conversion of an ammonium ion into urea in terrestrial vertebrates

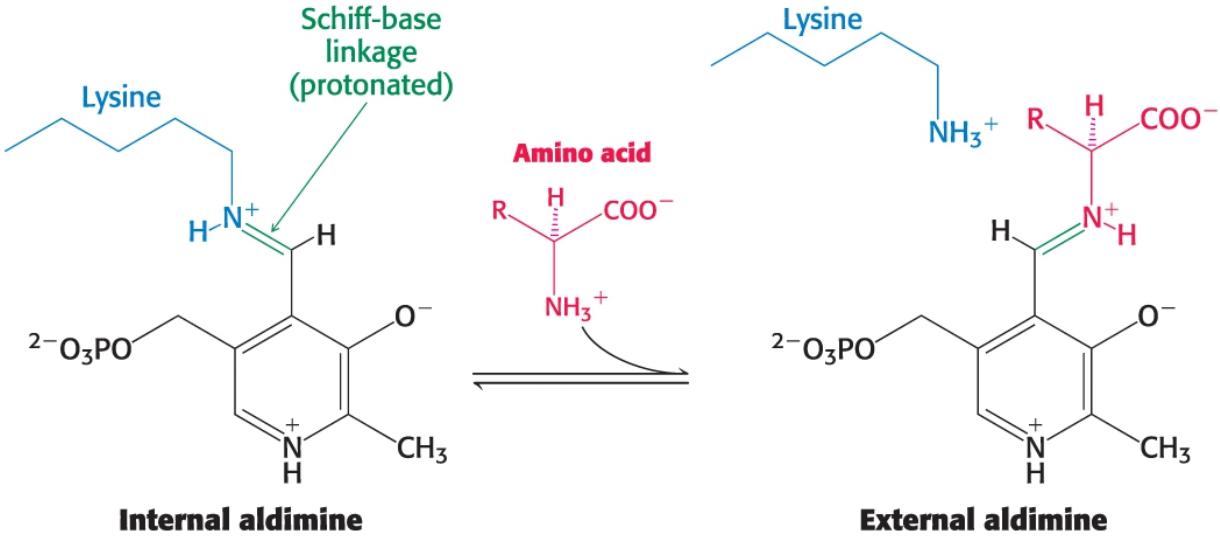
Alpha-amino acid transfers the amino group to alpha-ketoglutarate. The alpha-amino acid forms alpha-ketoacid and alpha-ketoglutarate is converted into glutamate. The glutamate molecule is converted back to alpha-ketoglutarate with the simultaneous reduction of N A D superscript plus to N A D H. H 2 O is also used up during this conversion and the N H 4 superscript plus group is also released. The N H 4 superscript plus is irreversibly converted into urea. The structure of urea consists of a central C atom single bonded to N H 2 on the lower left, N H 2 on the lower right, and double bonded to O above.

Return to Conversion of an ammonium ion into urea in terrestrial vertebrates

Extended description for Reversible conversion of P L P (phenol) to P L P (phenolate)

PLP (phenol) **PLP (phenolate)**

The structure of P L P (phenol) is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 1 N and 5 C atoms. N occupies the bottom-most vertex. C 1 occupies the bottom-left vertex. A double bond is present between N and C 1, C 2 and C 3, and C 4 and C 5. C 2 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single-bonded to O on the lower left. This O is single-bonded to a P atom. The P atom is partially double-bonded to O above, O on the left, and O on the lower left. The O atoms have an overall negative charge of 2 minus. C 3 is single bonded to C above. This C is double-bonded to O on the upper left and single-bonded to H on the upper right. C 4 is single bonded to O H on the upper right. The H atom of the O H group is highlighted in red. C 5 is single bonded to C H 3 on the lower right.



A reversible reaction arrow leads to P L P (phenolate).

The structure of P L P (phenolate) is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 1 N and 5 C atoms. N with a positive charge occupies the bottom-most vertex. It is bound to H highlighted in red. C 1 occupies the

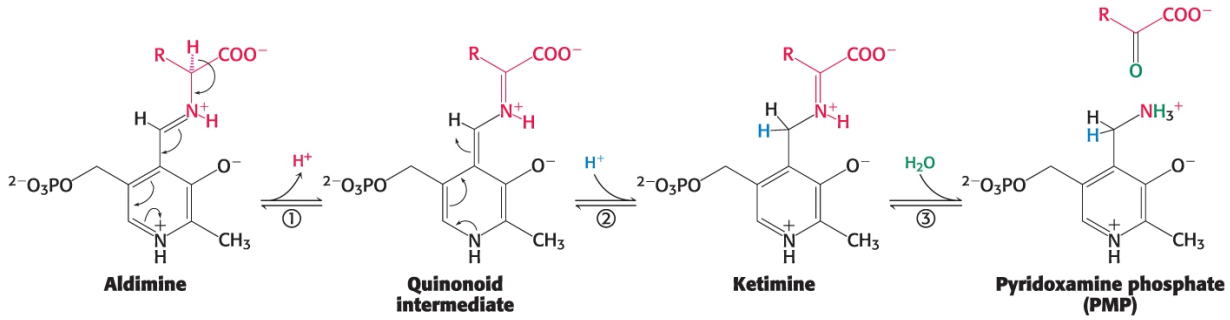
bottom-left vertex. A double bond is present between N and C 1, C 2 and C 3, and C 4 and C 5. C 2 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single-bonded to O on the lower left. This O is single-bonded to a P atom. The P atom is partially double-bonded to O above, O on the left, and O on the lower left. The O atoms have an overall negative charge of 2 minus. C 3 is single bonded to C above. This C is double-bonded to O on the upper left and single-bonded to H on the upper right. C 4 is single bonded to O superscript minus on the upper right. C 5 is single bonded to C H 3 on the lower right.

Return to Reversible conversion of P L P (phenol) to P L P (phenolate)

Extended description for Formation of external aldimine from internal aldimine

The structure of internal aldimine is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 1 N and 5 C atoms. N with a positive charge occupies the bottom-most vertex. It is bound to H. C 1 occupies the bottom-left vertex. A double bond is present between N and C 1, C 2 and C 3, and C 4 and C 5. C 2 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single-bonded to O P O 3 superscript 2 minus on the lower left. C 3 is single bonded to C above. This C is double-bonded to N superscript plus on the upper left and single-bonded to H on the upper right. The double bond between the N superscript plus and the C atom is labeled "Schiff-base linkage (protonated)." The N superscript plus is single-bonded to H on the left and single-bonded to a 5-carbon alkane chain depicted as a line structure using 4 zigzag lines. The alkane chain is labeled lysine. C 4 of the ring is single bonded to O superscript minus on the upper right. C 5 is single bonded to C H 3 on the lower right.

A reversible reaction arrow leads to the external aldimine.



An amino acid enters the reaction. The amino acid consists of a central C atom single bonded to R on the upper left, single bonded to C O O superscript minus on the upper right, single bonded to N H 3 superscript plus, and dash bonded to H above.

The structure of external aldimine is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 1 N and 5 C atoms. N with a positive charge occupies the bottom-most vertex. It is bound to H. C 1 occupies the bottom-left vertex. A double bond is present between N and C 1, C 2 and C 3, and C 4 and C 5. C 2 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single-bonded to O P O 3 superscript 2 minus on the lower left. C 3 is single bonded to C above. This C is double-bonded to N superscript plus on the upper left and single-bonded to H on the upper right. The N superscript plus atom is single-bonded to H on the lower right and single-bonded to a central C atom above. This C is single bonded to R on the upper left, single bonded to C O O superscript minus on the upper right, and dash bonded to H above.

A 5-carbon alkane chain is depicted as a line structure using 4 zigzag lines. The alkane chain is labeled lysine. C 5 is single bonded to N H 3 superscript plus below.

Return to Formation of external aldimine from internal aldimine

Extended description for FIGURE 23.9 Transaminations proceed through three steps to form P M P

In the first reversible step, aldimine is reversibly converted into a quinonoid intermediate with the concomitant release of H superscript plus.

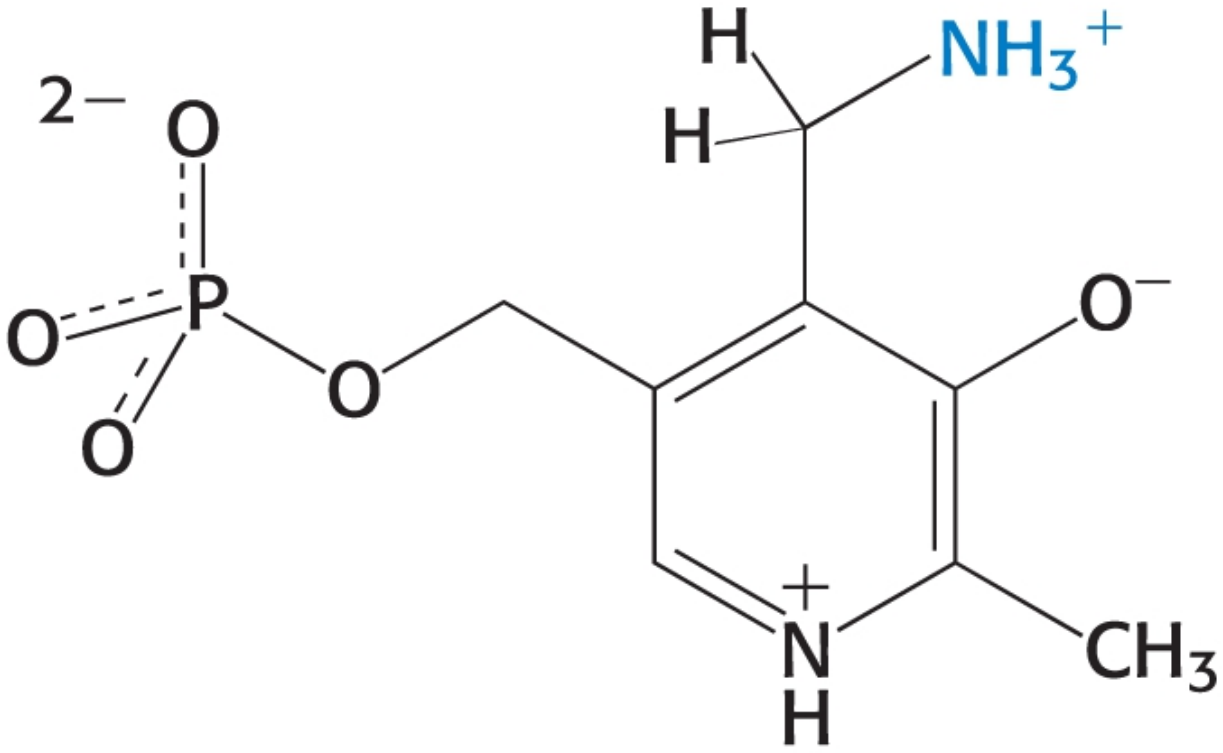
The structure of aldimine is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 1 N and 5 C atoms. N with a positive charge occupies the bottom-most vertex. It is bound to H. C 1 occupies the bottom-left vertex. A double bond is present between N and C 1, C 2 and C 3, and C 4 and C 5. C 2 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single-bonded to O P O 3 superscript 2 minus on the lower left. C 3 is single bonded to C above. This C is double-bonded to N superscript plus on the upper right and single-bonded to H on the upper left. The N superscript plus is single-bonded to H on the right and single-bonded to C above. The C atom is single bonded to R on the upper left, single bonded to C O O superscript minus on the upper right, and dash bonded to H above. An arrow from this H atom points toward the single bond between C and N superscript plus. A second arrow points from the double bond between the N superscript plus and C atom toward the single bond between this C atom and C 3 of the ring. Inside the ring, a third arrow points from the double bond

between C 2 and C 3 toward the single bond between C 1 and C 2. A fourth arrow points from the double bond between N superscript plus and C 1 of the ring toward N superscript plus.

The structure of the quinonoid intermediate is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 1 N and 5 C atoms. N bound to H occupies the bottom-most vertex. C 1 occupies the bottom-left vertex. A double bond is present between C 1 and C 2, and C 4 and C 5. C 2 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single-bonded to O P O 3 superscript 2 minus on the lower left. C 3 is double bonded to C above. This C is single-bonded to N superscript plus on the upper right and single-bonded to H on the upper left. The N superscript plus is single-bonded to H on the right and double-bonded to C above. The C atom is single bonded to R on the upper left and single bonded to C O O superscript minus on the upper right. An arrow from the N atom of the ring points toward the single bond between N and C 1. A second arrow points from the double bond between C 1 and C 2 toward the single bond between C 2 and C 3. A third arrow points from the double bond between C 3 of the ring and C toward the H atom bonded to C.

In the second step, the quinonoid intermediate is reversibly converted into ketimine with the concomitant entry of H superscript plus.

The structure of ketimine is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 1 N and 5 C atoms. N superscript plus bound to H occupies the bottom-most vertex. C 1 occupies the bottom-left vertex. A double bond is present between N and C 1, C 2 and C 3, and C 4 and C 5. C 2 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single-bonded to O P O 3 superscript 2 minus on the lower left. C 3 is single bonded to C above. This C is single-bonded to N superscript plus on



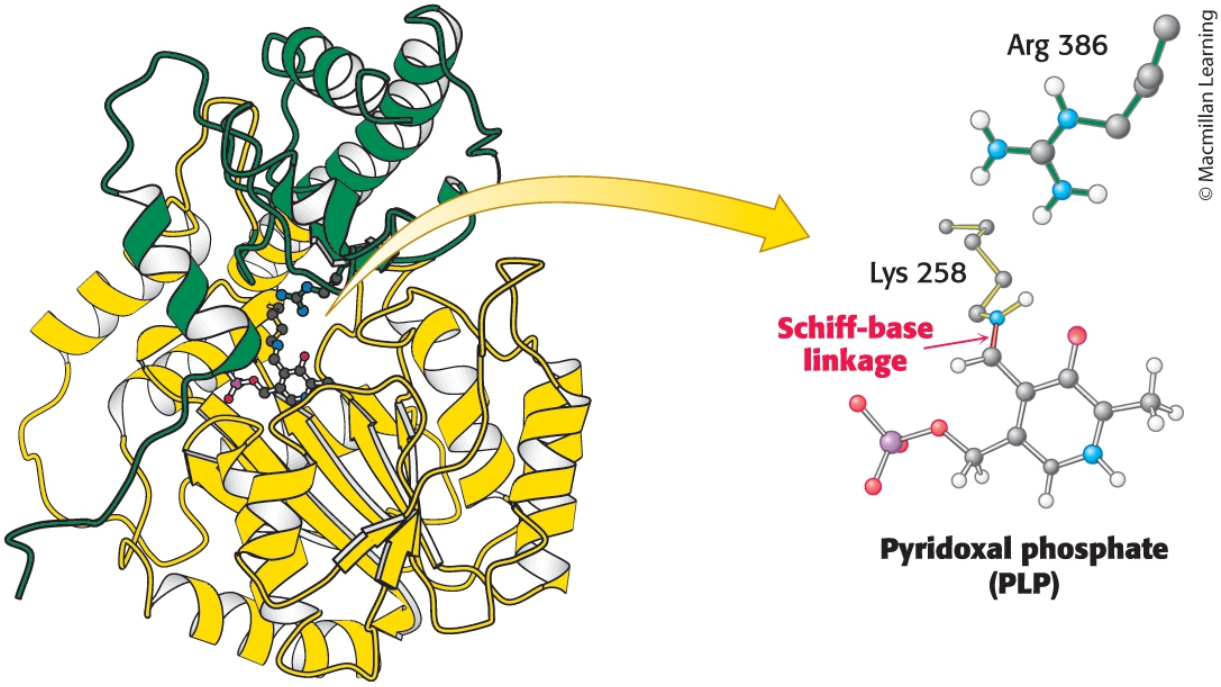
the upper right, single-bonded to H on the upper left, and single-bonded to H on the left. The N superscript plus is single-bonded to H on the right and double-bonded to C above. The C atom is single bonded to R on the upper left and single bonded to C O O superscript minus on the upper right. C 4 of the ring is single bonded to O superscript minus on the upper right. C 5 is single bonded to C H 3 on the lower right.

In the third step, ketimine is reversibly converted into pyridoxamine phosphate (P M P) and another unlabeled compound with the concomitant addition of H 2 O.

The structure of pyridoxamine phosphate (P M P) is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 1 N and 5 C atoms. N superscript plus bound to H occupies the bottom-most vertex. C 1 occupies the bottom-left vertex. A double bond is present between N and C 1, C 2 and C 3, and C 4 and C 5. C 2 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single-bonded to O P O 3 superscript 2 minus on the lower left. C 3 is single bonded to C above. This C is single-bonded to N H 3 superscript plus on the upper right, single-bonded to H on the upper left, and single-bonded to H on the left. C 4 is single bonded to O superscript minus on the upper right. C 5 is single bonded to C H 3 on the lower right. The structure of the second unlabeled product is as follows: A central C atom is single bonded to R on the upper left, single bonded to C O O superscript minus on the upper right, and double bonded to O below.

Return to FIGURE 23.9 Transaminations proceed through three steps to form P M P

Extended description for Structure of pyridoxamine phosphate



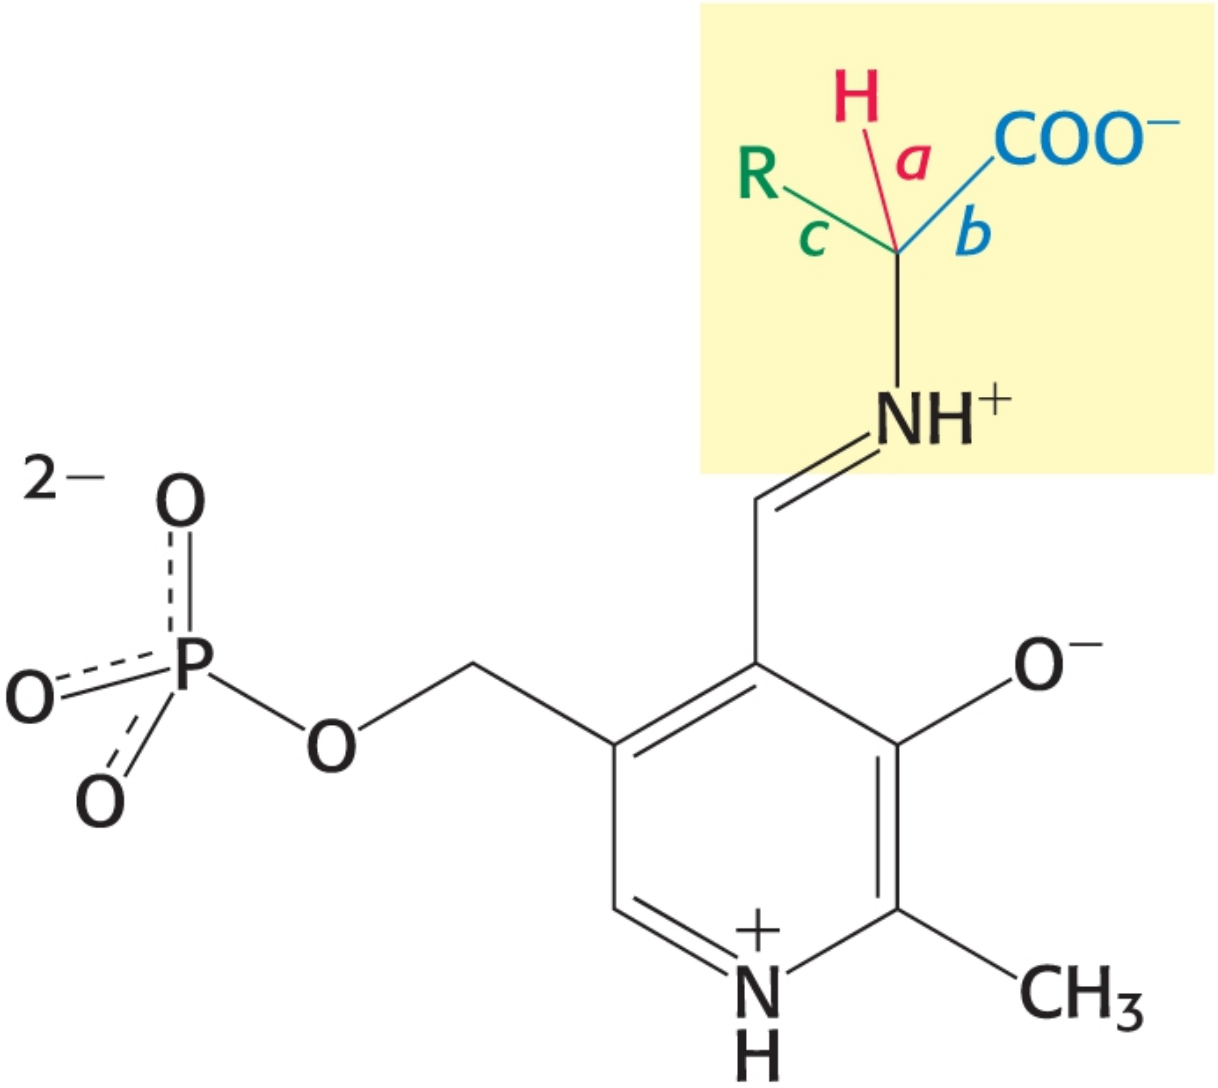
Pyridoxamine phosphate (PMP)

The structure of pyridoxamine phosphate is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 1 N and 5 C atoms. N occupies the bottom-most vertex. It has a positive charge and is bound to H. C 1 occupies the bottom-left vertex. A double bond is present between N and C 1, C 2 and C 3, and C 4 and C 5. C 2 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single-bonded to O on the lower left. This O is single-bonded to a P atom. The P atom is partially

double-bonded to O above, O on the left, and O on the lower left. The O atoms have an overall negative charge of 2 minus. C 3 is single bonded to C above. This C is single bonded to H on the left, H on the upper left, and N H 3 superscript plus on the upper right. C 4 is single bonded to O superscript minus on the upper right. C 5 is single bonded to C H 3 on the lower right.

Return to Structure of pyridoxamine phosphate

Extended description for FIGURE 23.10 The active site of aspartate aminotransferase reveals P L P bound to a lysine through a Schiff-base linkage

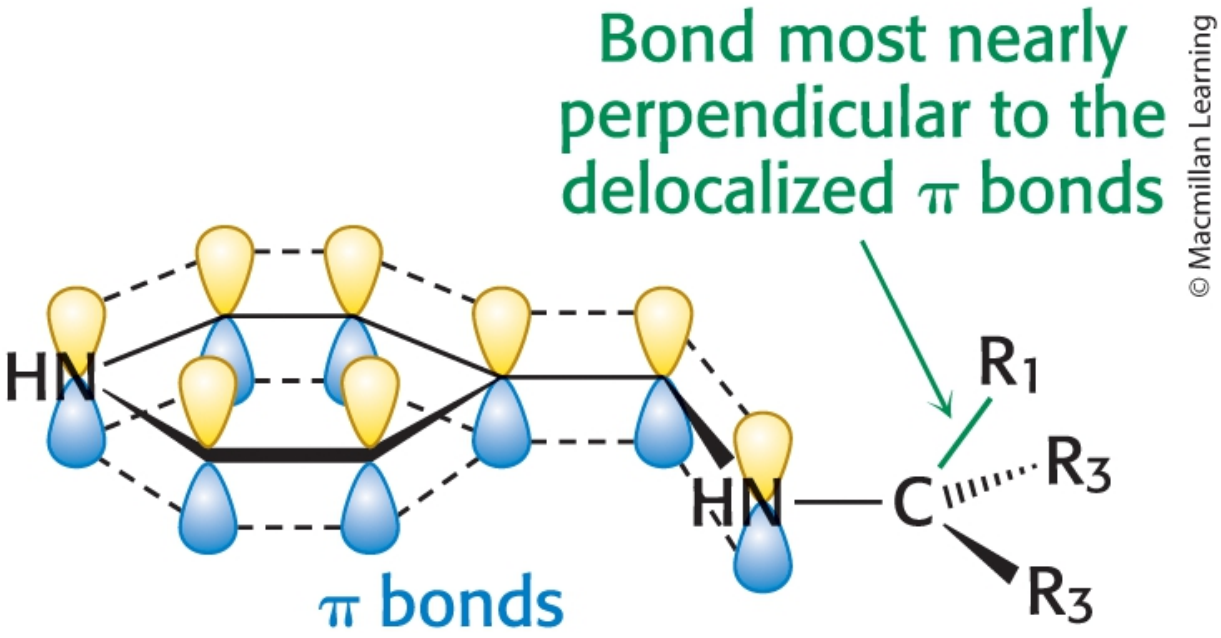


The ribbon diagram consists of a few green alpha-helices at the top interconnected by thread-like loops. A large cluster of yellow alpha-helices and beta-strands at the bottom are associated with the green helices. The center of the subunit contains a ball-and-stick model. An arrow from the center of the enzyme subunit shows an enlarged view of the Schiff-base linkage between pyridoxal phosphate (P L P) and lysine 258 residues of the active site. The ball-and-stick model of P L P consists of a hexagon composed of 1 blue and 5 black spheres. The bottom left black sphere is connected to a chain of one black, one red, and one purple sphere in the same order. The black sphere is connected to two white spheres. The terminal purple sphere is connected to three red spheres. The blue sphere is located at the bottom right vertex of the hexagon. It is connected to a white sphere

on the lower right. The bottom-most black sphere is connected to a white sphere. The top right black sphere is connected to a black sphere, which is further connected to three white spheres. The topmost black sphere is connected to a red sphere above. The top left black sphere is connected to a chain of one black and one white sphere in the same order. The black sphere of this chain is connected to the blue sphere of the lysine 258 side chain through a Schiff-base linkage. The side chain of lysine 258 is composed of a chain of 5 black spheres and 1 blue sphere. A ball-and-stick model of arginine 386 residues is composed of a chain of 2 blue and 5 black spheres. It is shown on the top right of the lysine side chain. The blue spheres occupy the first and third positions. The first blue sphere is connected to two white spheres. The first black sphere is connected to a blue sphere, which is further connected to two white spheres. The second blue sphere is connected to a white sphere above.

Return to FIGURE 23.10 The active site of aspartate aminotransferase reveals P L P bound to a lysine through a Schiff-base linkage

Extended description for FIGURE 23.11 P L P enzymes labilize one of three bonds at the alpha-carbon atom of an amino acid substrate

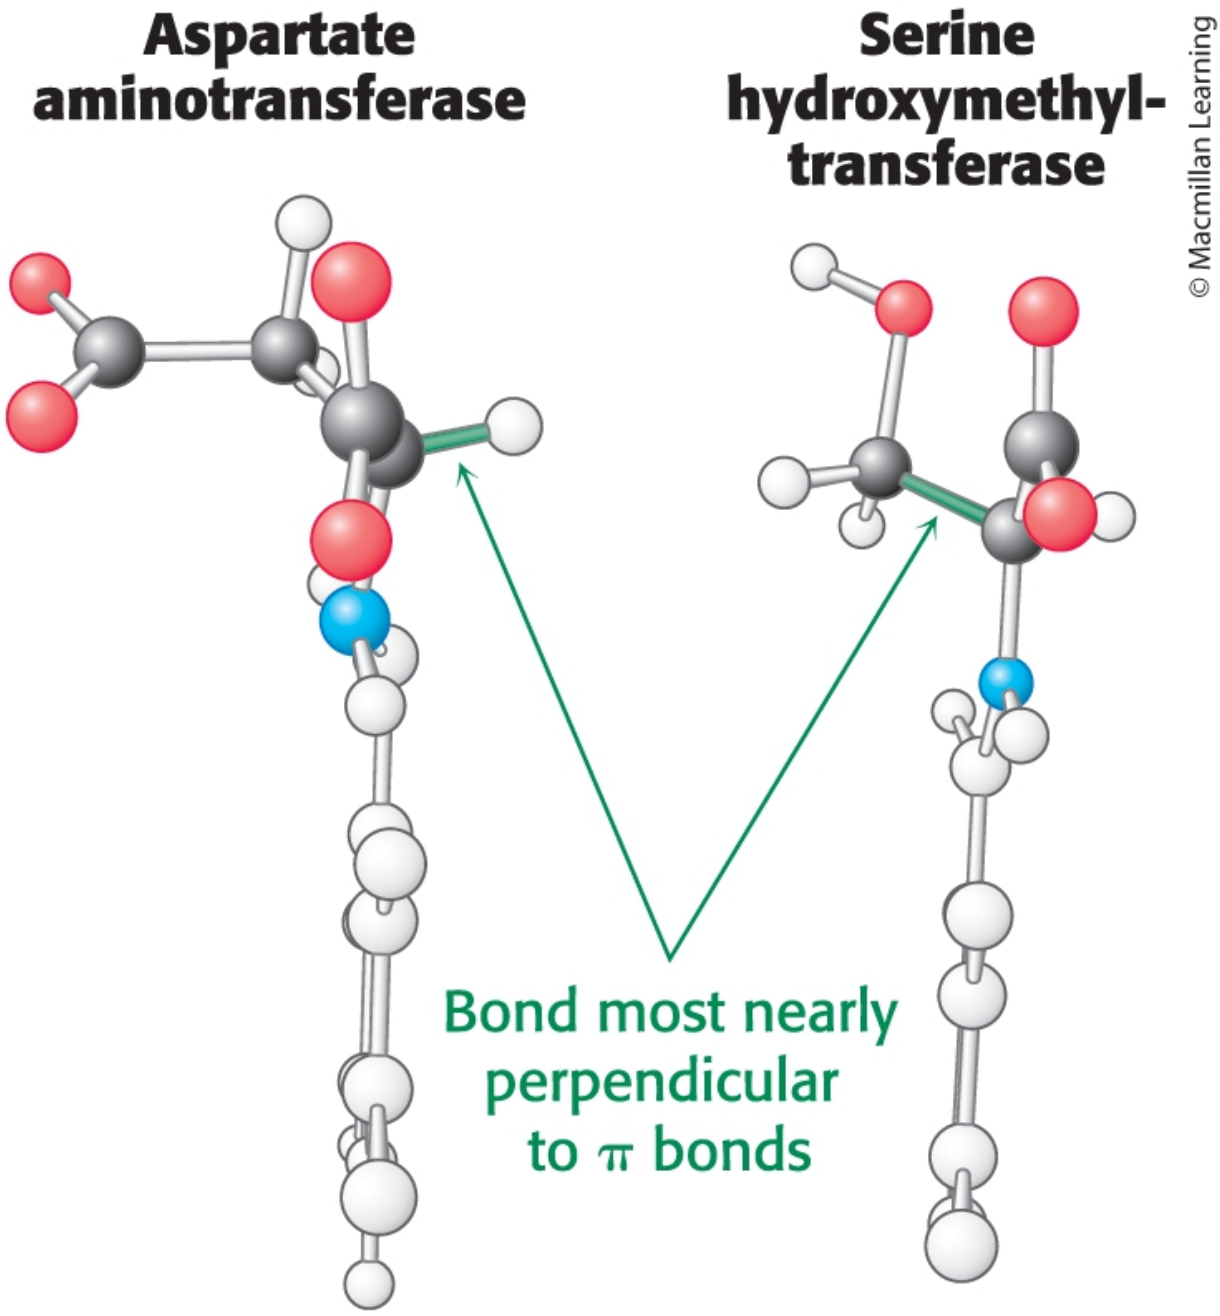


The structure is depicted as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 1 N and 5 C atoms. N occupies the bottom-most vertex. It has a positive charge and is bound to H. C 1 occupies the bottom-left vertex. A double bond is present between N and C 1, C 2 and C 3, and C 4 and C 5. C 2

is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single-bonded to O on the lower left. This O is single-bonded to a P atom. The P atom is partially double-bonded to O above, O on the left, and O on the lower left. The O atoms have an overall negative charge of 2 minus. C 3 is single bonded to C above. This C is double-bonded to N H superscript plus on the upper left. The N H superscript plus group is single-bonded to C above. This C is single bonded to R on the upper left, H above, and C O O superscript minus. The single bond between C and R is labeled c, the single bond between C and H is labeled a, and the single bond between C and C O O superscript minus is labeled b. The N H superscript plus group and its substituents are highlighted in the yellow box.

Return to FIGURE 23.11 P L P enzymes labilize one of three bonds at the alpha-carbon atom of an amino acid substrate

Extended description for FIGURE 23.12 Stereoelectronic effects determine specific bond cleavage

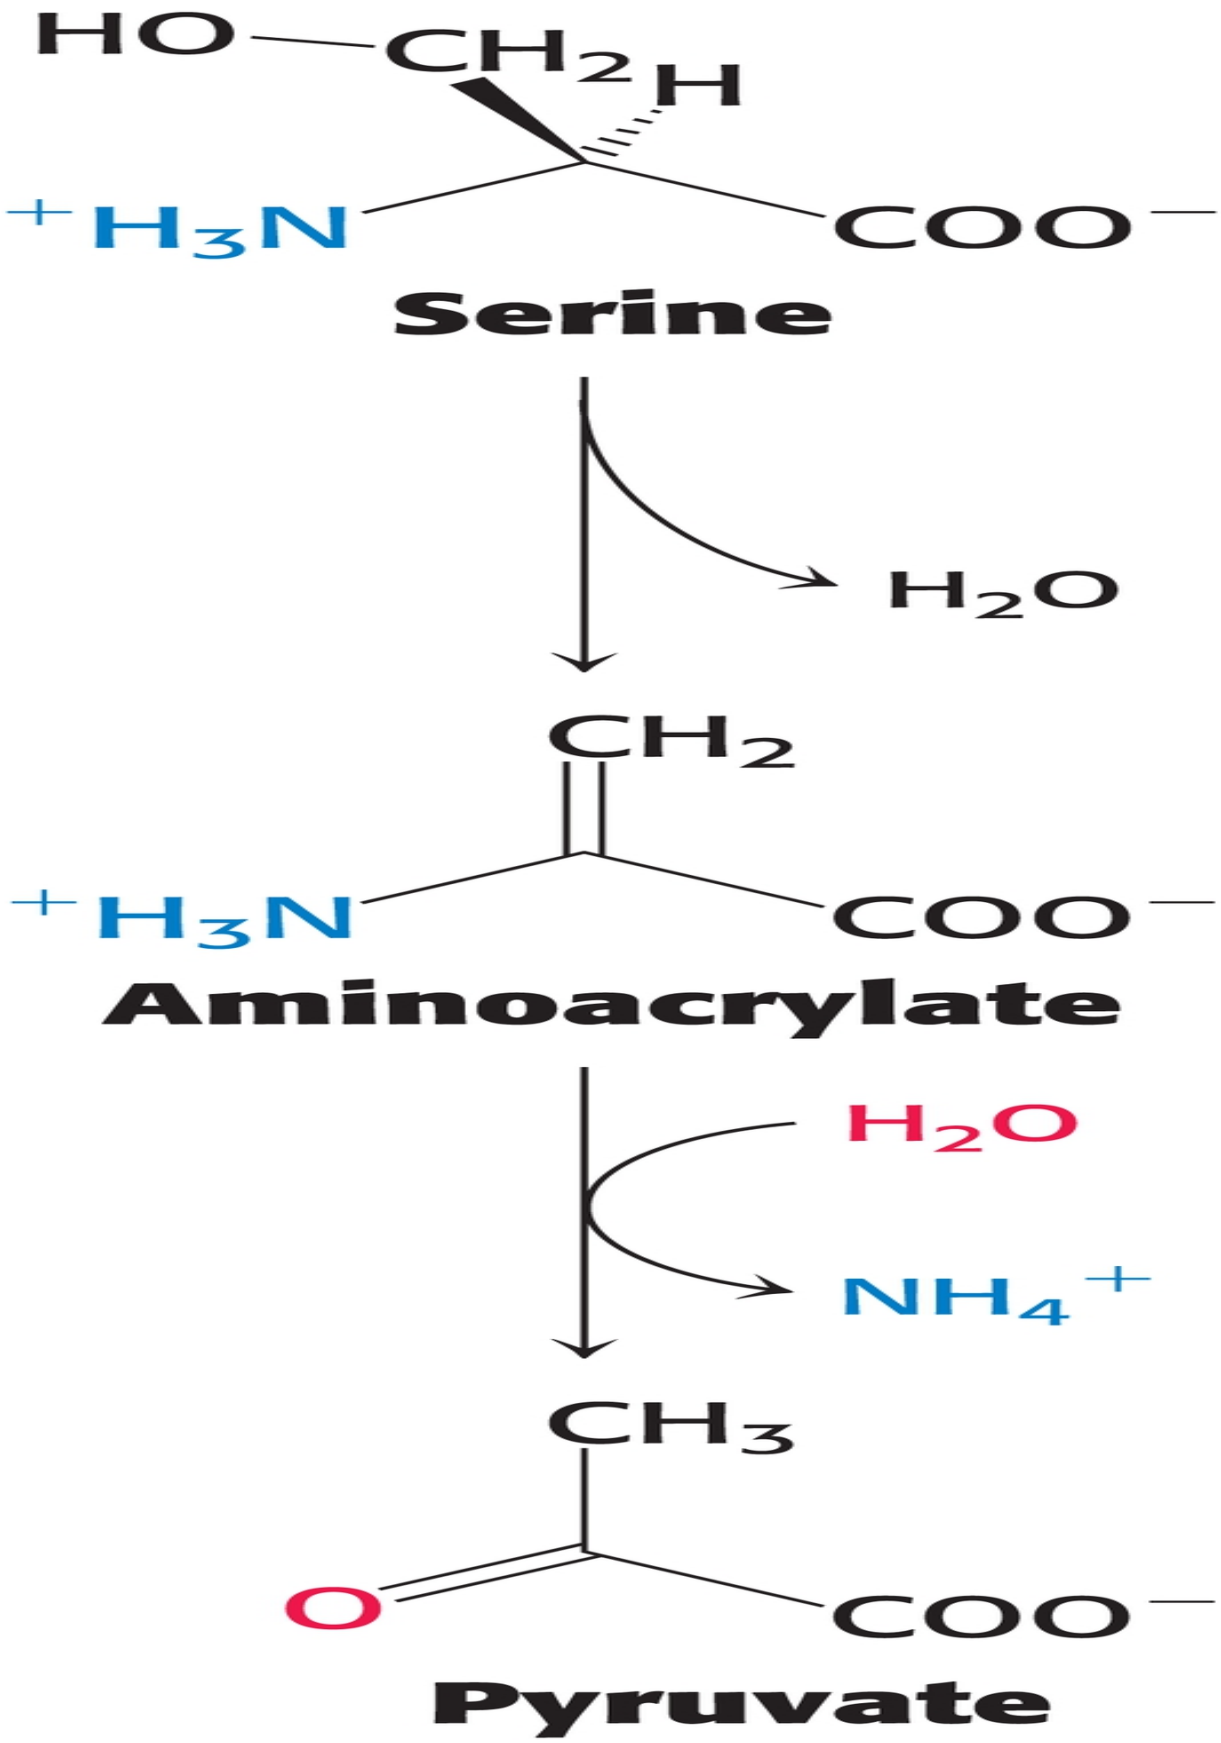


A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. The ring is laying flat such that C 2 and C 3 are located toward the observer. The ring consists of 1 N and 5 C atoms. N occupies the rightmost vertex and is bound to H. C 1 is single-bonded to C H 2 on the right in the form of a line. C H 2 is further wedge bonded to N H on the lower right. N H is single bonded to C on the right. This C is single bonded to R 1 on the upper right, dash bonded to R 3 on right, and wedge bonded to R 3 on the lower right. The single bond between C 1 and R 1 is labeled with the text that reads "Bond most nearly perpendicular to the delocalized pi bonds." Each vertex of the hexagon and the positions occupied by C H 2 and N H contain dumbbell-shaped orbitals in a vertical orientation. The orbitals are composed of a tear-shaped structure located above and below the plane of the ring.

The top tear-shaped structure is shown in yellow and the bottom tear-shaped structure is shown in blue. A dashed line connects the blue tear-shaped structure below the plane of the ring. A dashed line connects the yellow tear-shaped structures, located above the plane of the ring, of all orbitals except the orbitals at C 2 and C 3.

Return to FIGURE 23.12 Stereoelectronic effects determine specific bond cleavage

Extended description for FIGURE 23.13 Bond orientation in the active site determines bond cleavage in different P L P enzymes



Two ball-and-stick models are shown. The left model is labeled aspartate aminotransferase and the right model is labeled serine hydroxymethyltransferase. The left model consists of several white spheres in vertical orientation connected to a blue, red, white, and two black spheres at the top. The black sphere located toward the observer is connected to a red sphere above and below. The black sphere away from the observer is connected to a white sphere on the upper right and a black sphere on the upper left. The connection between the black sphere and the upper right white sphere is labeled with a text that reads "Bond most nearly perpendicular to pi bonds." The upper left black sphere is connected to a black sphere on the left and two white spheres. The left black sphere is connected to two red spheres.

The right model consists of several white spheres in vertical orientation connected to a chain of one blue and two black spheres in the same order. The second black sphere at the top is connected to two red spheres. The first black sphere is connected to a white sphere on the upper right and a black sphere on the left. The connection between the two black spheres is labeled with a text that reads "Bond most nearly perpendicular to pi bonds." The left black sphere is connected to a red sphere above and two white spheres in the same plane. The red sphere is connected to a white sphere.

Extended description for FIGURE 23.14 PATHWAY INTEGRATION: The glucose–alanine cycle allows muscle cells to use amino acids as fuel

A central tubular structure depicts a blood vessel containing blood. A rectangular compartment on the left of the blood vessel is labeled liver and a rectangular compartment on the right is labeled muscle.

Glycogen in the muscle is converted into glucose. This step is depicted by a forward arrow labeled 1. Glucose is converted into pyruvate. This step is depicted by an arrow labeled 2.

Simultaneously, branched-chain amino acids take part in the addition of amino group to alpha-ketoglutarate to produce glutamate. Alternatively, the branched-chain amino acids also give rise to carbon skeletons for cellular respiration. This step is depicted by an arrow labeled 3 and 4. Glutamate transfers the amino group to pyruvate leading to the formation of alanine. Glutamate is itself converted back to alpha-ketoglutarate. The alanine molecule

produced in the muscle travels through the bloodstream into the liver.

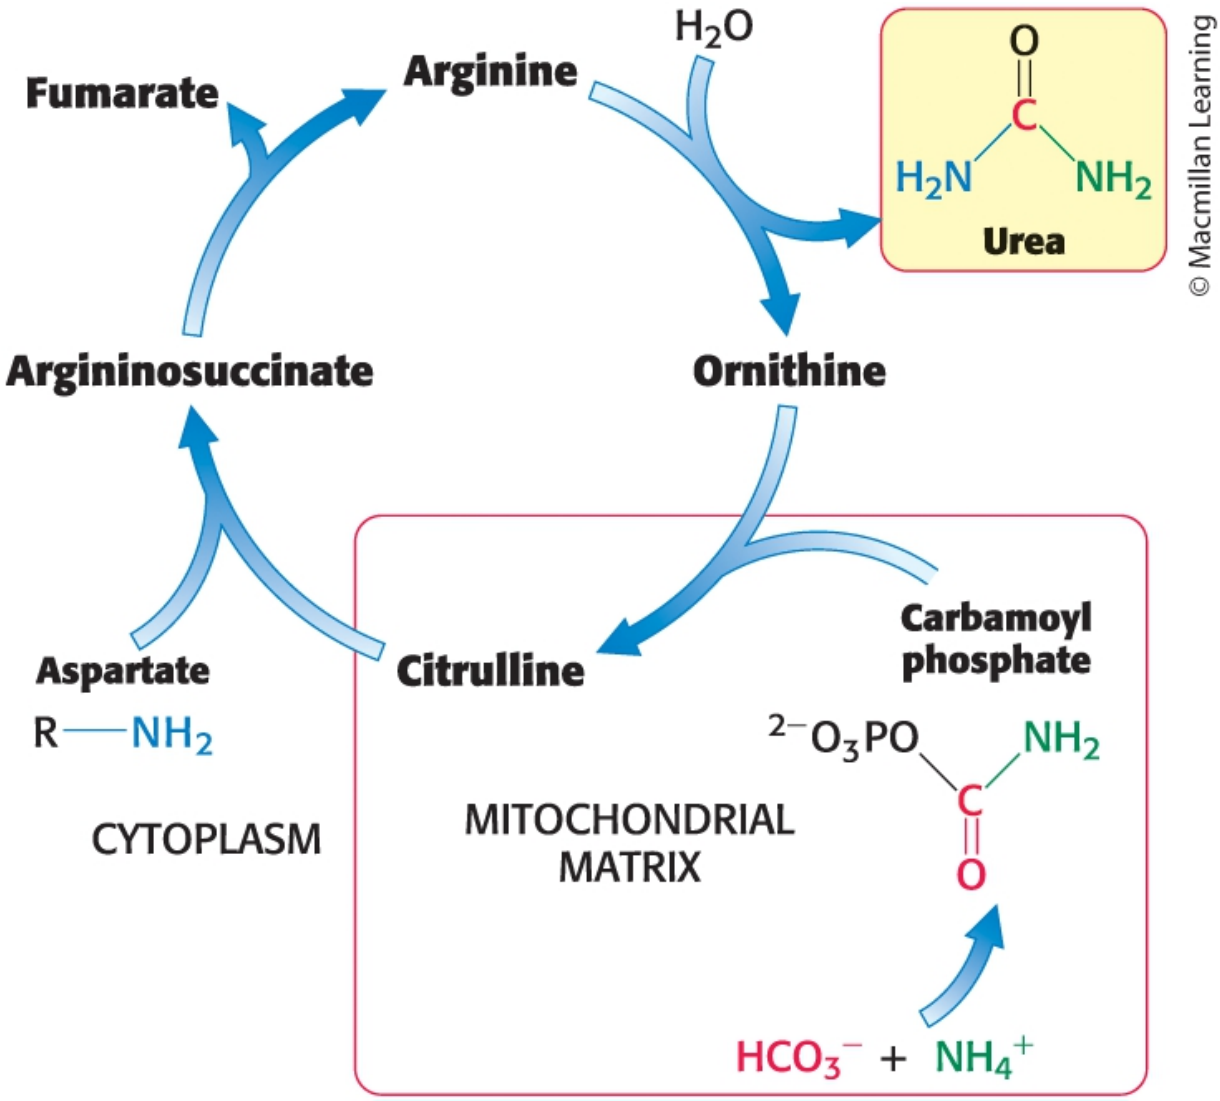
Inside the liver, alanine is deaminated to produce pyruvate or convert alpha-ketoglutarate into glutamate. The pyruvate molecule is converted back into glucose. This step is depicted by an arrow labeled 5. The glucose molecule is released from the liver and travels through the bloodstream to enter the muscle and continue the cycle. The glutamate molecule further undergoes deamination to release N H 4 superscript plus and form alpha-ketoglutarate. The N H 4 superscript plus molecule is converted into urea. This step is depicted by an arrow labeled 6.

A key titled "Active pathways" lists the following points:

1. Glycogen breakdown, Chapter 21.

2. Glycolysis, Chapter 16.

3. Citric acid cycle, Chapter 17.



4. Oxidative phosphorylation, Chapter 18.

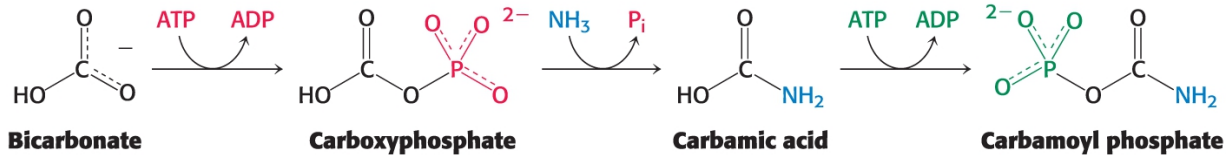
5. Gluconeogenesis, Chapter 16.

6. Urea cycle, Chapter 23.

Return to FIGURE 23.14 PATHWAY INTEGRATION: The glucose–alanine cycle allows muscle cells to use amino acids as fuel

Extended description for FIGURE 23.15 The urea cycle eliminates both nitrogen and carbon waste products

The urea cycle begins with arginine at the top. It is converted into ornithine with the simultaneous entry of H 2 O and release of urea. The structure of urea consists of a central C atom single-bonded to N H 2 on the lower left, single-bonded to N H 2 on the lower right, and double-bonded to O above.



Ornithine is converted into citrulline in the mitochondrial matrix by the addition of carbamoyl phosphate. The carbamoyl phosphate is produced from H C O 3 superscript minus plus N H 4 superscript plus in the mitochondrial matrix. The structure of carbamoyl phosphate consists of a central C atom single bonded to O P O 3 superscript 2 minus on the upper left, single bonded to N H 2 on the upper right, and double bonded to O below.

Citrulline is converted into argininosuccinate in the cytoplasm by the addition of aspartate. The aspartate molecule is depicted as R, single bond, N H 2.

Argininosuccinate is converted into arginine with the release of fumarate. All reaction of the urea cycle take place in the cytoplasm except the formation of citrulline.

Return to FIGURE 23.15 The urea cycle eliminates both nitrogen and carbon waste products

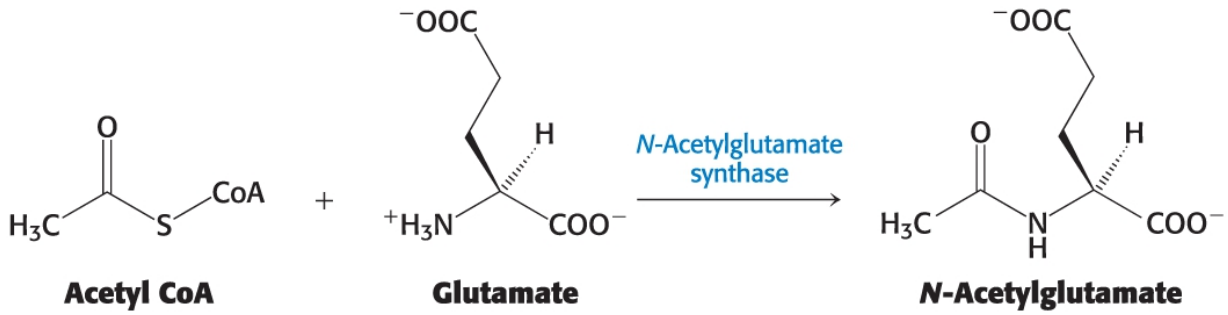
Extended description for Formation of carbamoyl phosphate from bicarbonate

In the first irreversible step, bicarbonate is converted into carboxyphosphate with the simultaneous hydrolysis of A T P to A D P.

The structure of bicarbonate is as follows: A central C atom is single-bonded to O H on the lower left, partially double-bonded to O above, and partially double-bonded to O on the lower right. The O atoms have an overall negative charge.

The structure of carboxyphosphate is as follows: A central C atom is double-bonded to O above, single-bonded to O H on the lower left, and single-bonded to O on the lower right. The lower right O is single-bonded to a central P atom on the upper right. The P atom is partially double bonded to O on the upper left, O on the upper right, and O on the lower left. The O atoms have an overall negative charge of 2 minus.

In the second irreversible step, carboxyphosphate is converted into carbamic acid with the simultaneous entry of N H 3 and release of P subscript i.



The structure of carbamic acid is as follows: A central C atom is single-bonded to O H on the lower left, single-bonded to N H 2 on the lower right, and double-bonded to O above.

In the third irreversible step, carbamic acid is converted into carbamoyl phosphate with the simultaneous hydrolysis of A T P to A D P.

The structure of carbamoyl phosphate is as follows: A central P atom is partially double-bonded to O on the upper left, O on the upper right, and O on the lower left. The O atoms have an overall negative charge of 2 minus. It is single-bonded to O on the lower right. This O atom is single-bonded to C on the upper right. This C atom is double bonded to O above and single bonded to N H 2 on the lower right.

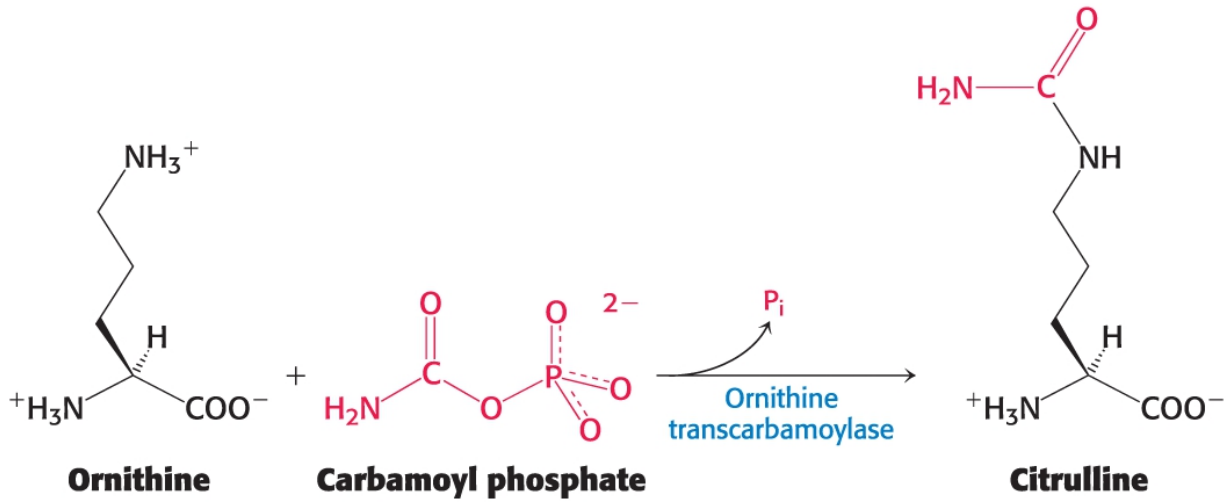
Return to Formation of carbamoyl phosphate from bicarbonate

Extended description for Reaction catalyzed by N-acetylglutamate synthase

The reaction consists of two reactants and one product.

The first reactant is acetyl C o A whose structure is as follows: A central C atom is single bonded to C H 3 on the lower left, single bonded to S on the lower right, and double bonded to O above. S atom is single bonded to C o A on the upper right.

The second reactant is glutamate whose structure is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to another C H 2 group on the upper right in the form of a line. This C H 2 is single bonded to C O O superscript minus on the upper left.



A forward arrow labeled N-acetylglutamate synthase leads to the product.

The product is N-acetylglutamate whose structure is as follows: A 1 N and 2 C heteronuclear alkane chain is depicted as a line structure using 2 zigzag lines. N bound to H occupies the second position. C 1

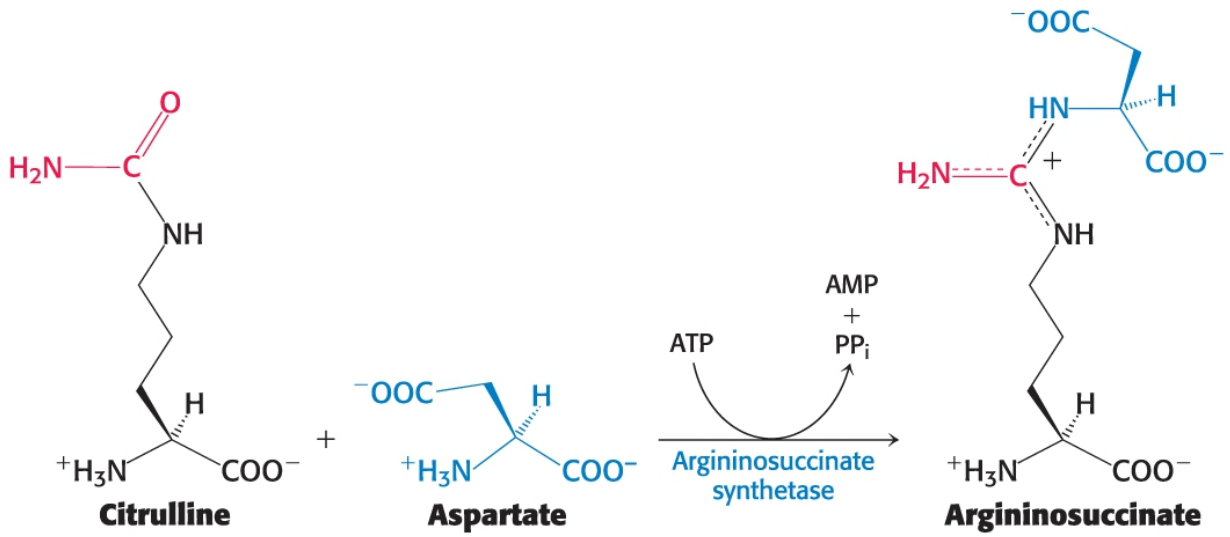
is double bonded to O above and single bonded to C H 3 on the lower left. C 2 is single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to another C H 2 group on the upper right in the form of a line. This C H 2 is single bonded to C O O superscript minus on the upper left.

Return to Reaction catalyzed by N-acetylglutamate synthase

Extended description for Reaction catalyzed by ornithine transcarbamoylase

The reaction consists of two reactants and one product.

The first reactant is ornithine whose structure is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to a 2-carbon alkane chain depicted using a single line. C 2 of this alkane chain is single bonded to N H 3 superscript plus on the upper right.



The second reactant is carbamoyl phosphate whose structure is as follows: A central C atom is double bonded to O above, single bonded to N H 2 on the lower right, and single bonded to O on the lower right. This O atom is single-bonded to a central P atom. The P atom is partially double-bonded to O above, O on the right, and O on the lower right. The O atoms have an overall negative charge of 2 minus.

A forward arrow labeled ornithine transcarbamoylase leads to the product. It also shows the release of P subscript i.

The product is citrulline whose structure is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to a 1 N and 2 C alkane chain depicted as a vertical line structure using 2 zigzag lines. N bound to H occupies the third position. N is single-bonded to C on the upper right. This C is single bonded to N H 2 on the left and double bonded to O on the upper right.

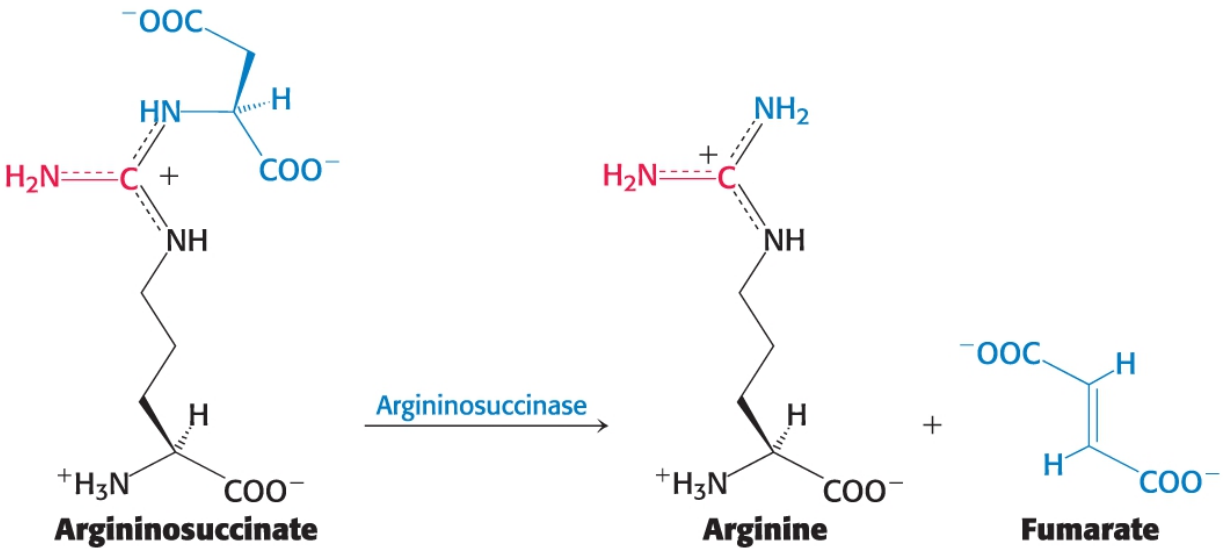
Return to Reaction catalyzed by ornithine transcarbamoylase

Extended description for Reaction catalyzed by argininosuccinate synthetase

The reaction consists of two reactants and one product.

The first reactant is citrulline whose structure is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to a 1 N and 2 C alkane chain depicted as a vertical line structure using 2 zigzag lines. N bound to H occupies the third position. N is single-bonded to C on the upper right. This C is single bonded to N H 2 on the left and double bonded to O on the upper right.

The second reactant is aspartate whose structure is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to



H on the upper right. The C H 2 group is single-bonded to C O O superscript minus on the left.

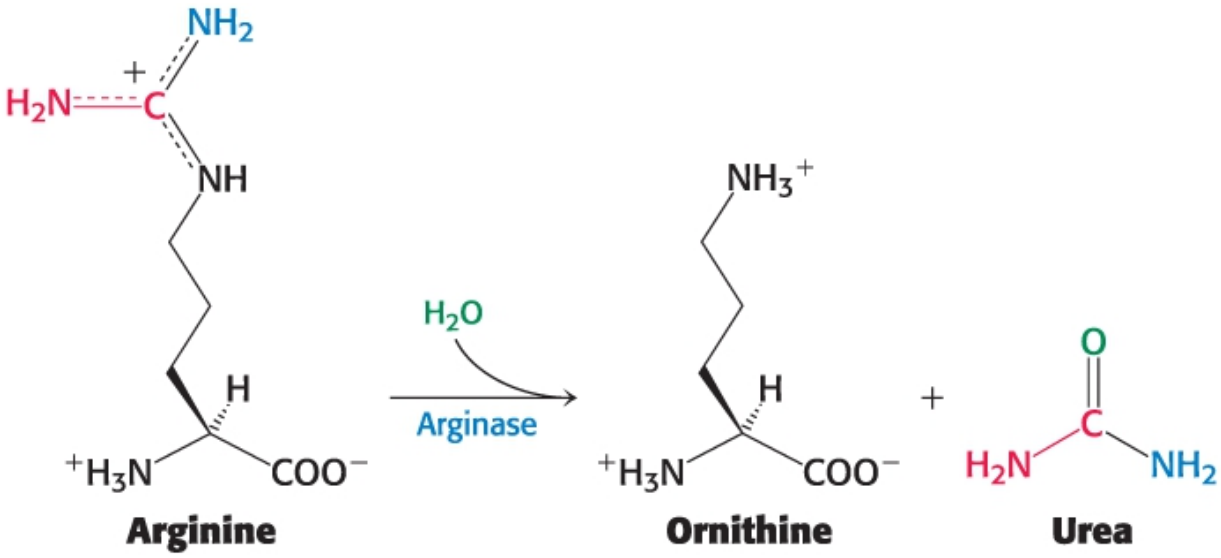
A forward arrow labeled argininosuccinate synthetase leads to the product. A curved arrow above it shows the coupled hydrolysis of A T P to A M P plus P P subscript i.

The product is argininosuccinate whose structure is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to a 1 N and 2 C alkane chain depicted as a vertical line structure using 2 zigzag lines. N bound to H occupies the third position. N is partially double-bonded to C on the upper right. This C atom has a positive charge and is partially double-bonded to N H 2 on the left and partially double-bonded to N H on the upper right. The N H group on the upper right is single-bonded to C on the right. This C is wedge bonded to C H 2 on the upper right, dash bonded to H on the right, and single bonded to C O O superscript minus on the lower right. The C H 2 group is single-bonded to C O O superscript minus on the upper left.

Return to Reaction catalyzed by argininosuccinate synthetase

Extended description for Reaction catalyzed by argininosuccinase

The reaction consists of one reactant and two products. The reactant is argininosuccinate whose structure is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to a 1 N and 2 C alkane chain depicted as a vertical line structure using 2 zigzag lines. N bound to H occupies the third position. N is partially double-bonded to C on the upper right. This C atom has a positive charge and is partially double-bonded to N H 2 on the left and partially double-bonded to N H on the upper right. The N H group on the upper right is single-bonded to C on the right. This C is wedge bonded to C H 2 on the upper right, dash bonded to H on the right, and single bonded to C O O superscript minus on the lower right. The C H 2 group is single-bonded to C O O superscript minus on the upper left.



A forward arrow labeled argininosuccinase leads to the products.

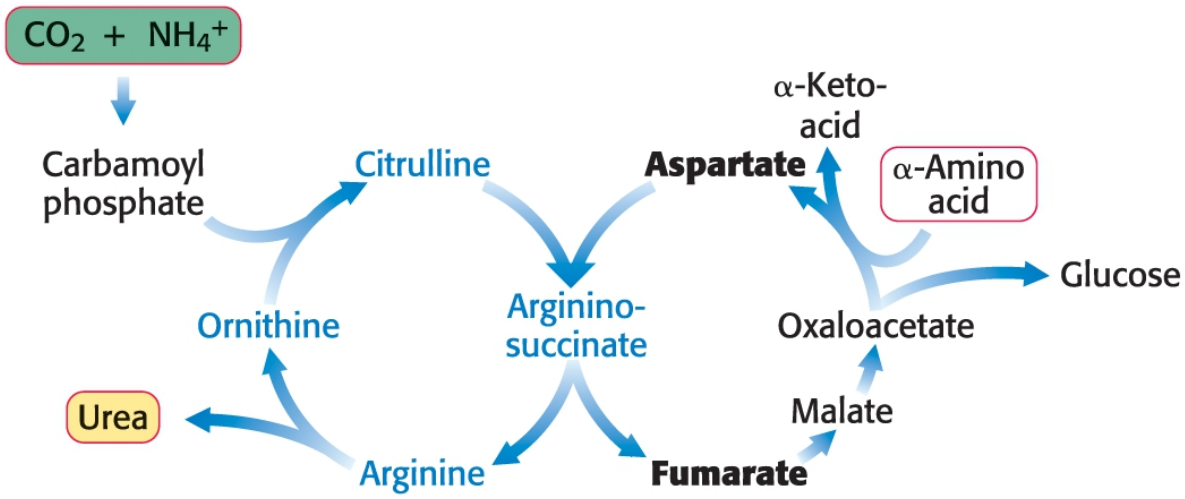
The first product is arginine whose structure is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to a 1 N and 2 C alkane chain depicted as a vertical line structure using 2 zigzag lines. N bound to H occupies the third position. N is partially double-bonded to C on the upper right. This C atom has a positive charge and is partially double-bonded to N H 2 on the left and partially double-bonded to N H 2 on the upper right.

The second product is fumarate whose structure is as follows: A central C atom is single-bonded to H on the lower left, single-bonded to C O O superscript minus on the lower right, and double-bonded to C above. This C atom is single bonded to C O O superscript minus on the upper left and single bonded to H on the upper right.

Return to Reaction catalyzed by argininosuccinase

Extended description for Reaction catalyzed by arginase

The reaction consists of one reactant and two products. The reactant is arginine whose structure is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to a 1 N and 2 C alkane chain depicted as a vertical line structure using 2 zigzag lines. N bound to H occupies the third position. N is partially double-bonded to C on the upper right. This C atom has a positive charge and is partially double-bonded to N H 2 on the left and partially double-bonded to N H 2 on the upper right.



A forward arrow labeled arginase leads to the products. It also shows the entry of H 2 O.

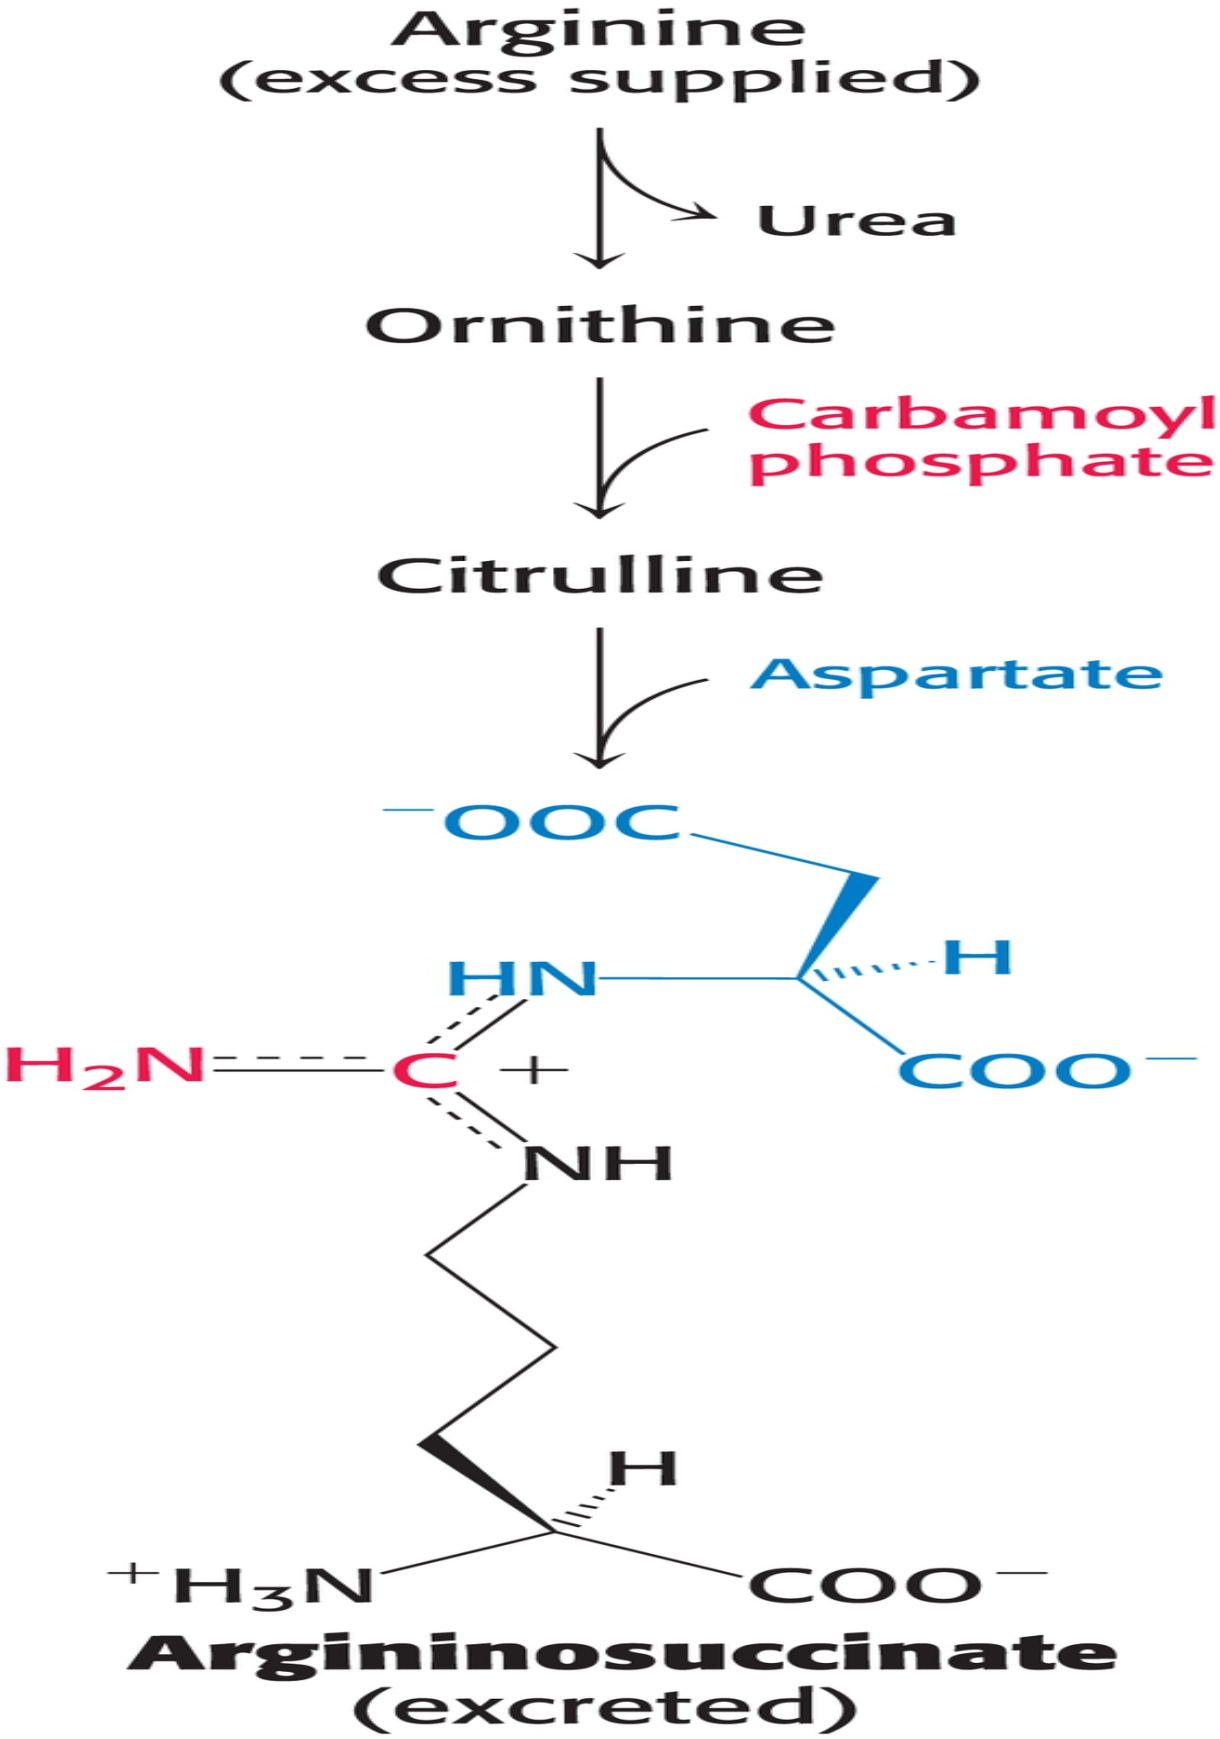
The first product is ornithine whose structure is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to a 2-carbon alkane chain depicted using a single line. C 2 of this alkane chain is single bonded to N H 3 superscript plus on the upper right.

The second product is urea whose structure is as follows: A central C atom is single-bonded to N H 2 on the lower left, single-bonded to N H 2 on the lower right, and double-bonded to O above.

Return to Reaction catalyzed by arginase

Extended description for FIGURE 23.16 Nitrogen metabolism is integrated with other pathways

© Macmillan Learning



Two cyclical pathways are shown to integrate by forming a common compound named argininosuccinate. Citrulline and aspartate from the left and right cyclical pathways respectively produce argininosuccinate. The argininosuccinate molecule breaks down to produce fumarate which is channeled into the right cyclical pathway and arginine which is channeled into the left cyclical pathway.

In the right pathway, fumarate is converted into malate, which is further converted into oxaloacetate. The oxaloacetate molecule is converted back to aspartate or glucose. Glucose molecule leaves the cycle. The conversion of oxaloacetate to aspartate is coupled with the conversion of alpha-amino acid to alpha-ketoacid. In the left cyclical pathway, arginine is converted into ornithine with the simultaneous release of urea. Ornithine is converted into citrulline by the addition of carbamoyl phosphate. Carbamoyl phosphate is itself produced from C O 2 plus N H 4 superscript plus.

The pathway begins with arginine (excess supplied). This arginine is converted into ornithine with the simultaneous release of urea. Ornithine is converted into citrulline by the addition of carbamoyl phosphate. The addition of aspartate leads to the conversion of citrulline to argininosuccinate, which is excreted from the body.

The structure of argininosuccinate is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to a 1 N and 2 C alkane chain depicted as a vertical line structure using 2 zigzag lines. N bound to H occupies the third position. N is partially double-bonded to C on the upper right. This C atom has a positive charge and is partially double-bonded to N H 2 on the left and partially double-bonded to N H on the upper right. The N H group on the upper right is single-bonded to C on the right. This C is wedge bonded to C H 2 on the upper right, dash bonded to H on the right, and single bonded to C O O superscript minus on the lower right. The C H 2 group is single-bonded to C O O superscript minus on the upper left.

Return to FIGURE 23.17 Argininosuccinase deficiency can be managed by supplementing the diet with arginine

Extended description for FIGURE 23.18 Both carbamoyl phosphate synthetase and ornithine transcarbamoylase deficiencies can be treated the same way

The benzoate (excess supplied) is converted into hippurate through a benzoyl C o A intermediate. Hippurate is excreted from the body.

The irreversible conversion of benzoate to benzoyl C o A is coupled with the hydrolysis of A T P to A M P plus P P subscript i and entry of C o A.

The structure of benzoate is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 2 is single-bonded to C on the upper right. This C

is partially double bonded to O above and O on the lower right. These O atoms have an overall negative charge.

The structure of benzoyl C o A is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 2 is single-bonded to C on the upper right. This C atom is double bonded to O above and single bonded to S on the lower right. The S atom is single-bonded to C o A on the upper right.

The benzoyl C o A is irreversibly converted into hippurate with the simultaneous entry of glycine and release of C o A. Glycine is depicted as a central C atom single bonded to N H 3 superscript plus on the lower left and single bonded to C O O superscript minus on the lower right.

The structure of hippurate is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 2 is single-bonded to C on the upper right. This C atom is double bonded to O above and single bonded to N H on the lower right. The N H atom is single-bonded to C H 2 on the upper right in the form of a line. The C H 2 group is further single bonded to the C O O superscript minus on the lower right.

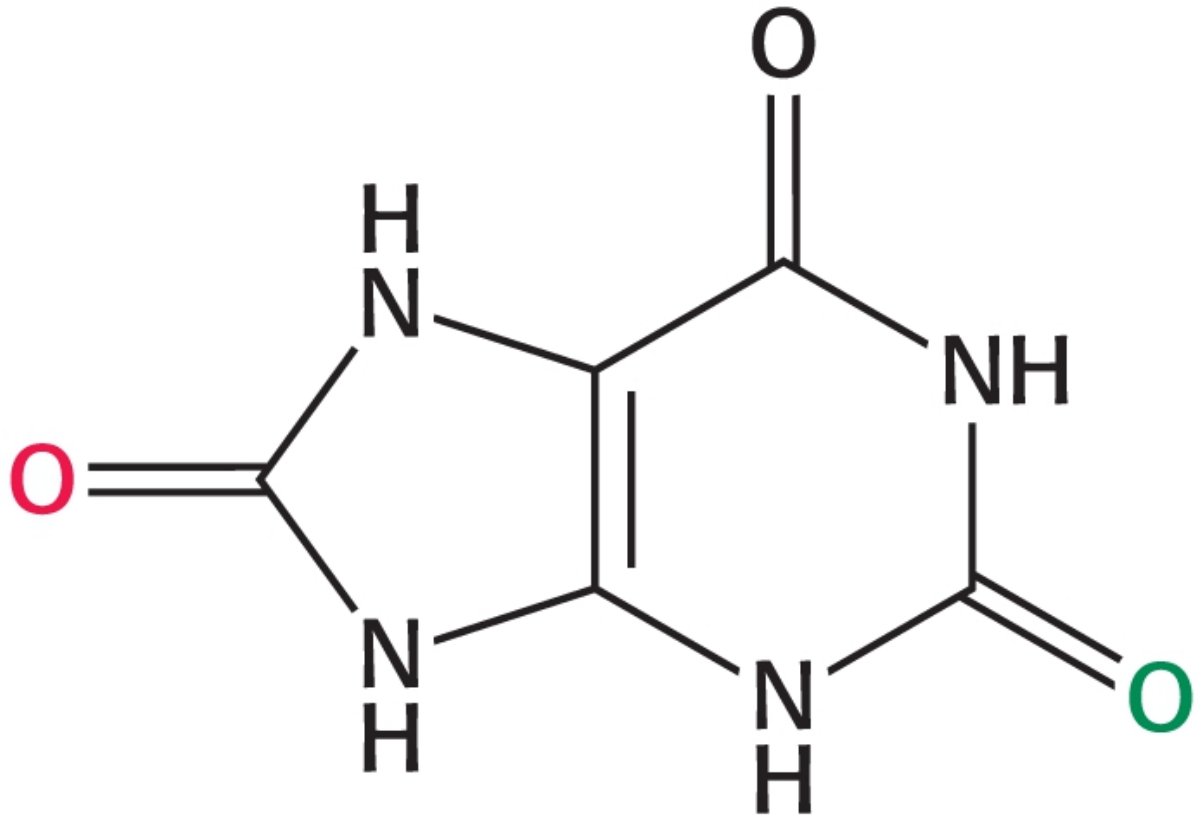
The phenylacetate (excess supplied) is converted into phenylacetylglutamine through a phenylacetyl C o A intermediate. Phenylacetylglutamine is excreted from the body.

The irreversible conversion of phenylacetate to phenylacetyl C o A is coupled with the hydrolysis of A T P to A M P plus P P subscript i and entry of C o A.

The structure of phenylacetate is as follows: A benzene ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 5 is single bonded to C H 2 on the upper left in the form of a line. The C H 2 group is further single-bonded to C. The C atom is partially double-bonded to O on the upper left and O on the right. The O atoms have an overall negative charge.

The structure of phenylacetyl C o A is as follows: A benzene ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 5 is single bonded to C H 2 on the upper left in the form of a line. The C H 2 group is further single-bonded to C on the upper right. The C atom is double bonded to O on the right and single bonded to S, single bond, C o A on the upper left.

Phenylacetyl C o A is irreversibly converted into phenylacetylglutamine with the simultaneous entry of glutamine and release of C o A.



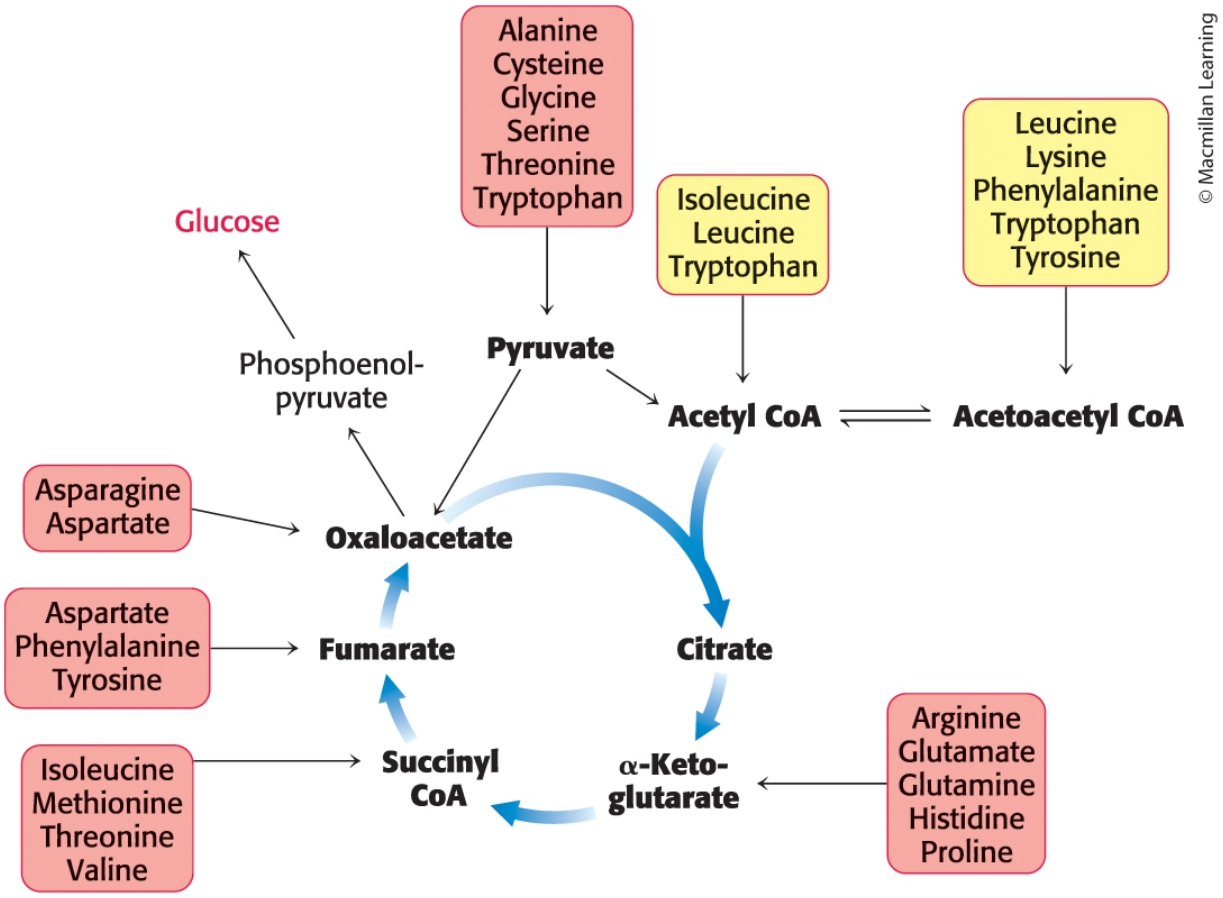
Glutamine consists of a 3-carbon alkane chain depicted as a line structure using 2 zigzag lines. C 1 is dash bonded to C on the upper left. This C atom is single bonded to C O O superscript minus on the upper left, single bonded to N H 3 superscript plus on the lower left, and wedge bonded to H on the upper right. C 3 is single bonded to N H 2 below and double bonded to O on the upper right.

The structure of phenylacetylglutamine is as follows: A benzene ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 5 is single bonded to C H 2 on the upper left in the form of a line. The C H 2 group is further single-bonded to C on the upper right. The C atom is double-bonded to O on the right and single-bonded to N H on the upper left. The N H group is single-

bonded to a C atom. This C atom is single bonded to C O O superscript plus on the upper left, wedge bonded to H on the upper right, and dash bonded to a 3-carbon alkane chain depicted as a line structure using 2 zigzag lines. C 3 is double bonded to O on the upper right and single bonded to N H 2 below.

Return to FIGURE 23.18 Both carbamoyl phosphate synthetase and ornithine transcarbamoylase deficiencies can be treated the same way

Extended description for Structure of uric acid



The structure of uric acid is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation with C 1 occupying the leftmost vertex. It consists of 2 N and 3 C atoms. The N atoms are bound to H and occupy the bottom left and top left vertices. C 1 is double bonded to O on the left. The pentagonal ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. The hexagonal ring consists of 2 N and 4 C atoms. The first N bound to H occupies the top right vertex and the second N bound to H occupies the bottom-most vertex. C 1 occupies

the bottom left vertex. C 1 is double bonded to O on the lower right. C 4 is double bonded to O above. A double bond is present between C 2 and C 3.

Return to Structure of uric acid

Extended description for FIGURE 23.19 The carbon skeletons of all 20 proteogenic amino acids enter central metabolism as just seven different molecules

A simplified citric acid cycle is shown in the center. Acetyl C o A and oxaloacetate combine to form citrate. Acetyl C o A and oxaloacetate are produced from pyruvate. Citrate is converted into alpha-ketoglutarate. Alpha-ketoglutarate is converted into succinyl C o A. The succinyl C o A molecule is converted into fumarate, which is further converted into oxaloacetate. The acetyl C o A entering the citric acid cycle can be alternatively converted into acetoacetyl C o A in a reversible reaction. The oxaloacetate molecule from the citric

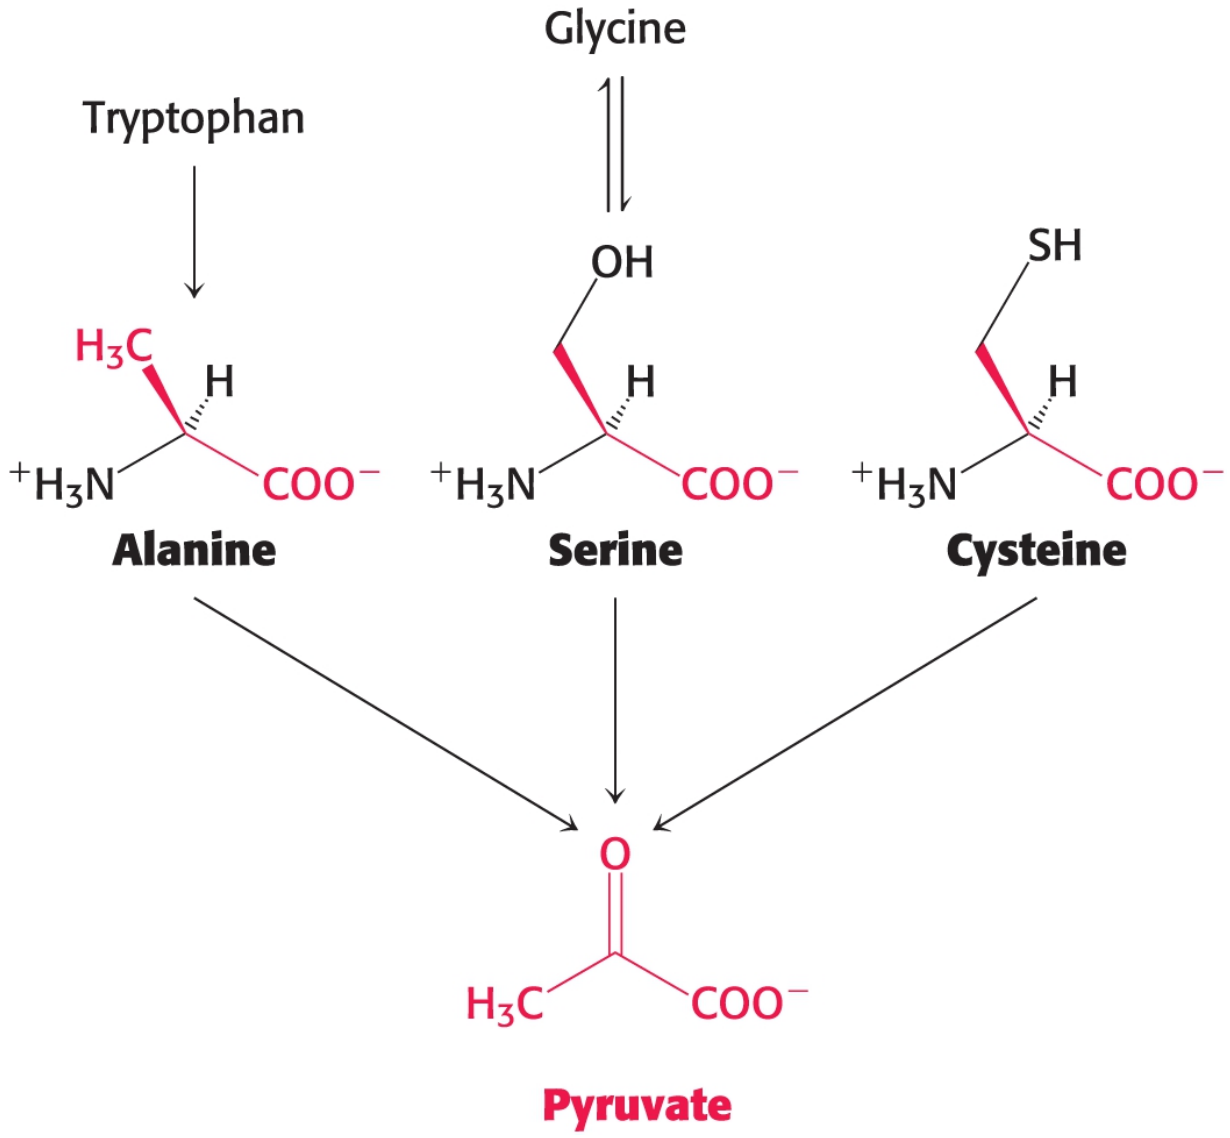
acid cycle can form phosphoenolpyruvate, which is further converted into glucose highlighted in red.

A red box containing arginine, glutamate, glutamine, histidine, and proline points toward alpha-ketoglutarate.

A red box containing isoleucine, methionine, threonine, and valine points toward succinyl C o A.

A red box containing aspartate, phenylalanine, and tyrosine points toward fumarate.

A red box containing asparagine and aspartate points toward oxaloacetate.



A red box containing alanine, cysteine, glycine, serine, threonine, and tryptophan points toward pyruvate.

A yellow box containing isoleucine, leucine, and tryptophan points toward acetyl C o A.

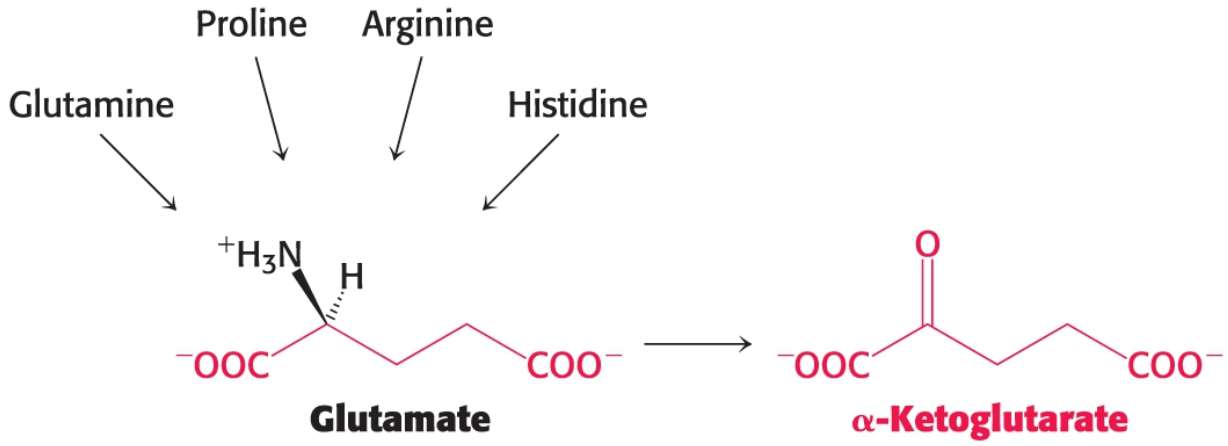
A yellow box containing leucine, lysine, phenylalanine, tryptophan, and tyrosine points toward acetoacetyl C o A.

Return to FIGURE 23.19 The carbon skeletons of all 20 proteogenic amino acids enter central metabolism as just seven different molecules

Extended description for FIGURE 23.20 Pyruvate is the metabolic entry point for the carbon skeletons from three-carbon amino acids

An arrow from alanine, serine, and cysteine points toward a common pyruvate molecule below. Alanine is produced irreversibly from tryptophan and serine is produced reversibly from glycine.

The structure of alanine is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, wedge bonded to C H 3 on the upper left, dash bonded to H on the upper right, and single bonded to C O O superscript minus on the lower right.



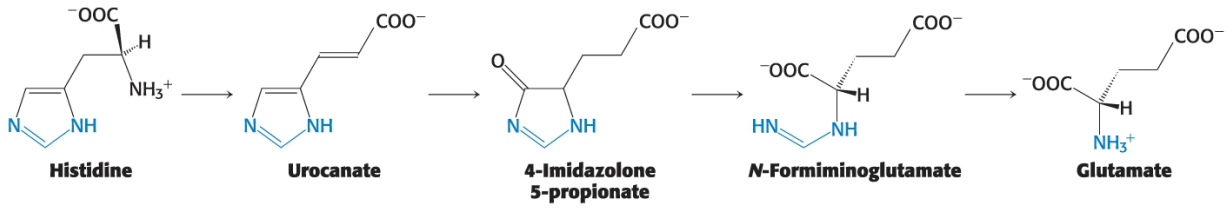
The structure of serine is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, wedge bonded to C H 2 on the upper left, dash bonded to H on the upper right, and single bonded to C O O superscript minus on the lower right. The C H 2 group is single-bonded to O H on the upper right.

The structure of cysteine is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, wedge bonded to C H 2 on the upper left, dash bonded to H on the upper right, and single bonded to C O O superscript minus on the lower right. The C H 2 group is single-bonded to S H on the upper right.

The structure of pyruvate is as follows: A central C atom is single bonded to C H 3 on the lower left, single bonded to C O O superscript minus on the lower right, and double bonded to O above.

Return to FIGURE 23.20 Pyruvate is the metabolic entry point for the carbon skeletons from three-carbon amino acids

Extended description for FIGURE 23.21 Four amino acids produce carbon skeletons that enter central metabolism as alpha-ketoglutarate



An arrow from glutamine, proline, arginine, and histidine points toward a common glutamate molecule. Glutamate is further irreversibly converted into alpha-ketoglutarate.

The structure of glutamate is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the lower left, wedge bonded to N H 3 superscript plus on the upper left, and dash bonded to H on the upper right. C 3 is single bonded to C O O superscript minus on the lower right.

The structure of alpha-ketoglutarate is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the lower left and double bonded to O above. C 3 is single bonded to C O O superscript minus on the lower right.

Return to FIGURE 23.21 Four amino acids produce carbon skeletons that enter central metabolism as alpha-ketoglutarate

Extended description for FIGURE 23.22 Stepwise conversion of histidine to glutamate

The conversion of histidine to glutamate takes place in four successive steps.

In the first step, histidine is irreversibly converted into urocanate.

The structure of histidine is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the bottom-most vertex. It consists of 2 N and 3 C atoms. The first N bound to H occupies the bottom-right vertex and the second N occupies the bottom-left vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 3 is single bonded to C H 2 on the upper right in the form of a line. The C H 2 group is further single-bonded to C on the right. The C atom is wedge bonded to C O O superscript minus above, dash bonded to H on the upper right, and single bonded to N H 3 superscript plus on the lower right.

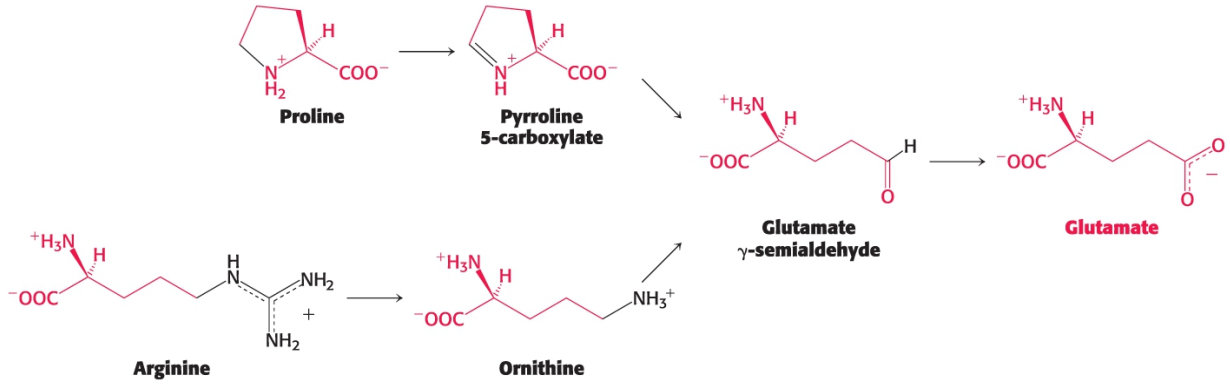
The structure of urocanate is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the bottom-most vertex. It consists of 2 N and 3 C atoms. The first N bound to H occupies the bottom-right vertex and the second N occupies the bottom-left vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 3 is single bonded to C H on the upper right in the form of a line. The C H group is further double bonded

to C H on the right. The C H group is single-bonded to C O O superscript minus on the upper right.

In the second step, urocanate is irreversibly converted into 4-imidazolone 5-propionate.

The structure of 4-imidazolone 5-propionate is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the bottom-most vertex. It consists of 2 N and 3 C atoms. The first N bound to H occupies the bottom-right vertex and the second N occupies the bottom-left vertex. A double bond is present between C 1 and N 2. C 2 is double bonded to O on the upper left. C 3 is single bonded to C H 2 on the upper right in the form of a line. The C H 2 group is further single-bonded to another C H 2 on the right in the form of a line. This C H 2 group is single bonded to C O O superscript minus on the upper right.

In the third step, 4-imidazolone 5-propionate is irreversibly converted into N-Formiminoglutamate.



The structure of N-Formiminoglutamate is as follows: A central C atom is single bonded to C O O superscript minus on the upper left, dash bonded to C H 2 on the upper right, wedge bonded to H on the right, single bonded to N H below. The N H group is single-bonded to the C H group on the lower left. The C H group is double bonded to N H on the upper left. The upper right C H 2 group is single-bonded to C H 2 on the right in the form of a line. This C H 2 group is single bonded to C O O superscript minus on the upper right.

In the fourth step, N-Formiminoglutamate is irreversibly converted into glutamate.

The structure of glutamate is as follows: A central C atom is single bonded to C O O superscript minus on the upper left, dash bonded to C H 2 on the upper right, wedge bonded to H on the right, single bonded to N H 3 superscript plus below. The upper right C H 2 group is single-bonded to C H 2 on the right in the form of a line. The C H 2 group is single-bonded to C O O superscript minus on the upper right.

Return to FIGURE 23.22 Stepwise conversion of histidine to glutamate

Extended description for FIGURE 23.23 The degradation pathways for proline and arginine converge on a common intermediate

The degradation pathways for proline and arginine produce a common intermediate called glutamate gamma-semialdehyde. This intermediate is converted into glutamate.

Proline is first irreversibly converted into pyrroline 5-carboxylate. Simultaneously, arginine is irreversibly converted into ornithine.

The structure of proline is as follows: A central C atom is wedge bonded to C H 2 on the upper left, single bonded to N H 2 with a positive charge on the lower left, dash bonded to H on the upper right, and single bonded to C O O superscript minus on the lower right. The upper left C H 2 group is single-bonded to a 2-carbon alkane chain depicted using a line. C 2 of this chain is single-bonded to the N H 2 group on the lower left such that a cyclic pentagonal-shaped ring structure is formed.

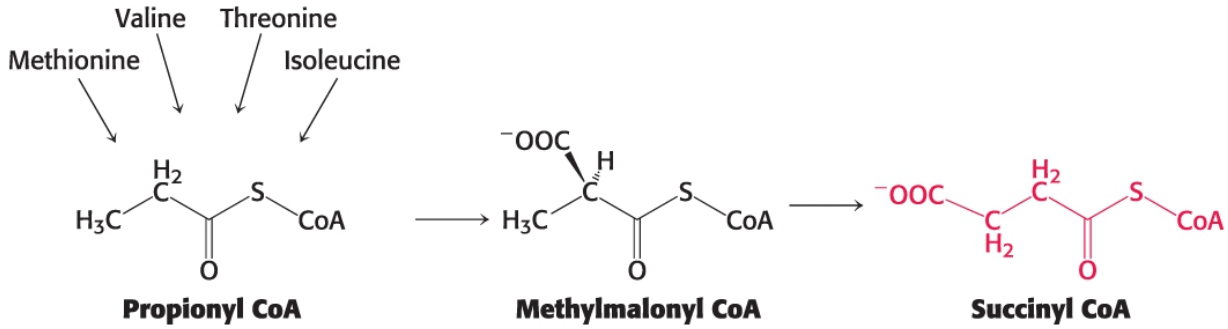
The structure of pyrroline 5-carboxylate is as follows: A central C atom is wedge bonded to C H 2 on the upper left, single bonded to N H with a positive charge on the lower left, dash bonded to H on the

upper right, and single bonded to C O O superscript minus on the lower right. The upper left C H 2 group is single-bonded to a 2-carbon alkane chain depicted using a line. C 2 of this chain is double bonded to the N H group on the lower left such that a cyclic pentagonal-shaped ring structure is formed.

The structure of arginine is as follows: A 4-carbon alkane chain is depicted as a line structure using 3 zigzag lines. C 1 is wedge bonded to N H 3 superscript plus on the upper left, dash bonded to H on the upper right, and single bonded to C O O superscript minus on the lower left. C 4 is single bonded to N H on the upper right. This N H group is partially double-bonded to a central C atom. This C atom is partially double bonded to N H 2 on the upper right and N H 2 below. This C atom has a positive charge.

The structure of ornithine is as follows: A 4-carbon alkane chain is depicted as a line structure using 3 zigzag lines. C 1 is wedge bonded to N H 3 superscript plus on the upper left, dash bonded to H on the upper right, and single bonded to C O O superscript minus on the lower left. C 4 is single bonded to N H 3 superscript plus on the upper right.

Both pyrroline 5-carboxylate and ornithine are irreversibly converted into glutamate gamma-semialdehyde.



The structure of glutamate gamma-semialdehyde is as follows: A 4-carbon alkane chain is depicted as a line structure using 3 zigzag lines. C 1 is wedge bonded to N H 3 superscript plus on the upper left, dash bonded to H on the upper right, and single bonded to C O O superscript minus on the lower left. C 4 is single bonded to H on the upper right and double bonded to O below.

The common intermediate glutamate gamma-semialdehyde is irreversibly converted into glutamate.

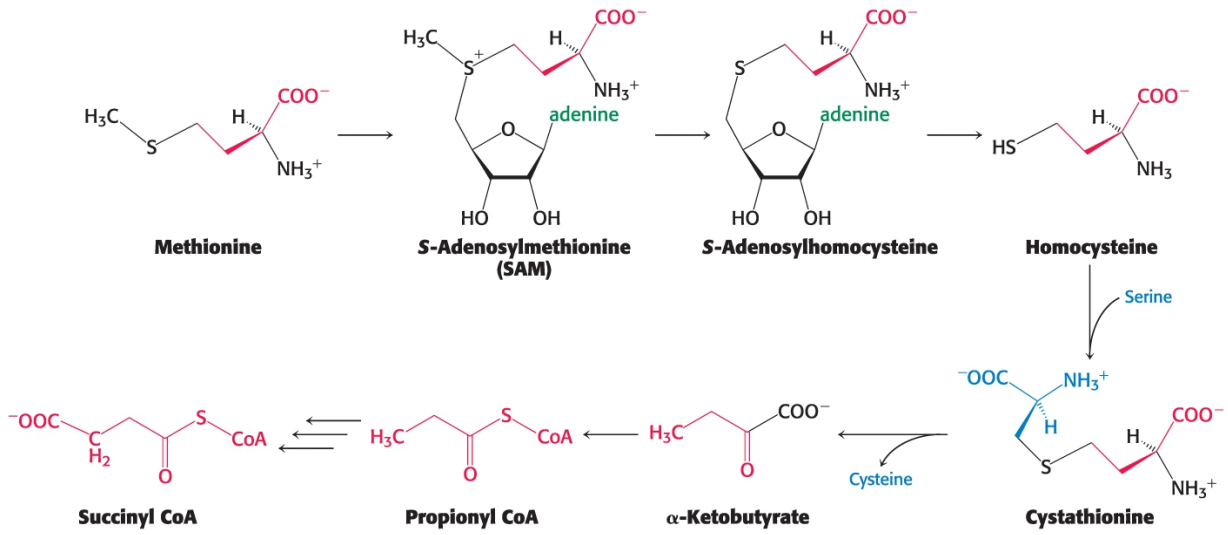
The structure of glutamate is as follows: A 4-carbon alkane chain is depicted as a line structure using 3 zigzag lines. C 1 is wedge bonded to N H 3 superscript plus on the upper left, dash bonded to H on the upper right, and single bonded to C O O superscript minus on the lower left. C 4 is partially double bonded to O on the upper right and O below. C 4 has an overall negative charge.

Return to FIGURE 23.23 The degradation pathways for proline and arginine converge on a common intermediate

Extended description for FIGURE 23.24 Succinyl C o A is formed from methionine, isoleucine, threonine, and valine

The amino acids methionine, valine, threonine, and isoleucine give rise to propionyl C o A. The propionyl C o A molecule is irreversibly converted into methylmalonyl C o A, which is further irreversibly converted into succinyl C o A.

The structure of propionyl C o A is as follows: A central C atom is single bonded to C H 2 on the upper left, double bonded to O below, and single bonded to S on the upper right. The C H 2 group is single-bonded to C H 3 on the lower left. The S atom is single-bonded to C o A on the lower right.



The structure of methylmalonyl C o A is as follows: A central C atom is single-bonded to C on the upper left, double-bonded to O below, and single-bonded to S on the upper right. The upper left C is single bonded to C H 3 on the lower left, wedge bonded to C O O superscript minus on the upper left, and dash bonded to H on the upper right. The S atom is single-bonded to C o A on the lower right.

The structure of succinyl C o A is as follows: A central C atom is single bonded to C H 2 on the upper left, double bonded to O below,

and single bonded to S on the upper right. The upper left C H 2 group is single bonded to C H 2 on the lower left, which is further single bonded to C O O superscript minus on the upper left. The S atom is single-bonded to C o A on the lower right.

Return to FIGURE 23.24 Succinyl C o A is formed from methionine, isoleucine, threonine, and valine

Extended description for FIGURE 23.25 Methionine catabolism proceeds through the formation of S A M

The catabolism of methionine produces succinyl C o A as the end product. It takes place in 9 irreversible steps.

In the first step, methionine is converted into S-adenosylmethionine (S A M).

The structure of methionine is as follows: A 2-carbon alkane chain is depicted using a line. C 1 is single bonded to S on the lower left. The S atom is single-bonded to C H 3 on the upper left. C 2 is wedge bonded to C on the upper right. The C atom is single bonded to C O O superscript minus on the upper right, single bonded to N H 3 superscript plus on the lower right, and dash bonded to H on the upper left.

The structure of S-adenosylmethionine is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. C 1 occupies the top right vertex and is single-

bonded to adenine on the upper right. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 above, which is further single bonded to the S atom of methionine. The S atom is positively charged.

In the second step, S-adenosylmethionine is converted into S-adenosylhomocysteine.

The structure of S-adenosylhomocysteine is as follows: The C H 3 group of the methionine amino acid is removed and the S atom loses its positive charge. The remaining structure is the same as S-adenosylmethionine.

In the third step, S-adenosylhomocysteine is converted into homocysteine.

The structure of homocysteine is as follows: A 2-carbon alkane chain is depicted using a single line. C 1 is single bonded to S H on the lower left. C 2 is wedge bonded to C on the upper right. The C atom is single bonded to C O O superscript minus on the upper right, single bonded to N H 3 on the lower right, and dash bonded to H on the upper left.

In the fourth step, homocysteine is converted into cystathionine by the addition of serine.

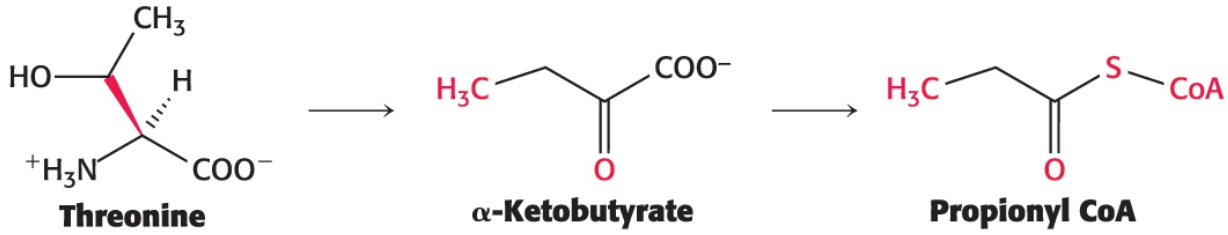
The structure of cystathionine is as follows: A 2-carbon alkane chain is depicted using a single line. C 1 is single bonded to S on the lower left. C 2 is wedge bonded to C on the upper right. The C atom is single bonded to C O O superscript minus on the upper right, single bonded to N H 3 superscript plus on the lower right, and dash bonded to H on the upper left. The S atom is single-bonded to C H 2 on the upper left in the form of a line. This C H 2 group is wedge

bonded to a central C atom on the upper right. This C is single bonded to C O O superscript minus on the upper left, single bonded to N H 3 superscript plus on the upper right, and dash bonded to H on the lower right.

In the fifth step, cystathionine is converted into alpha-ketobutyrate with the simultaneous release of cysteine.

The structure of alpha-ketobutyrate is as follows: A 2-carbon alkane chain is depicted using a single line. C 1 is single bonded to C H 3 on the lower left. C 2 is double bonded to O below and single bonded to C O O superscript minus on the upper right.

In the sixth step, alpha-ketobutyrate is converted into propionyl C o A.



The structure of propionyl C o A is as follows: A central C atom is single bonded to C H 2 on the upper left in the form of a line, double bonded to O below, and single bonded to S on the upper right. The C H 2 group is single-bonded to C H 3 on the lower left. The S atom is single-bonded to C o A on the lower right.

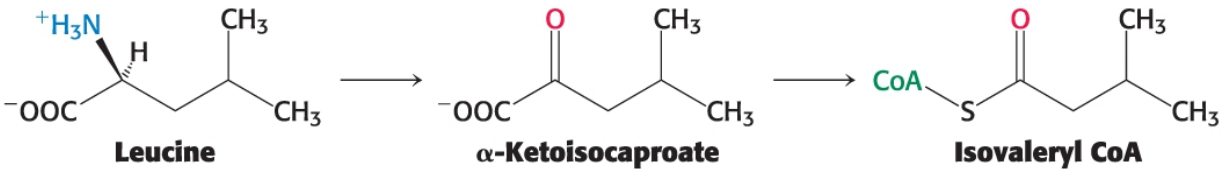
The seventh, eighth, and ninth steps cause the conversion of propionyl C o A to succinyl C o A. They are depicted as three forward arrows.

The structure of succinyl C o A is as follows: A central C atom is single bonded to C H 2 on the upper left in the form of a line, double bonded to O below, and single bonded to S on the upper right. The upper left C H 2 group is single bonded to C H 2 on the lower left, which is further single bonded to C O O superscript minus on the upper left. The S atom is single-bonded to C o A on the lower right.

Return to FIGURE 23.25 Methionine catabolism proceeds through the formation of S A M

Extended description for Conversion of threonine to propionyl C o A

Threonine is irreversibly converted into propionyl C o A through an alpha-ketobutyrate intermediate.



The structure of threonine is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C on the upper left, and dash bonded to H on the upper right. The upper left C atom is single-bonded to O H on the left and single-bonded to C H 3 on the upper right.

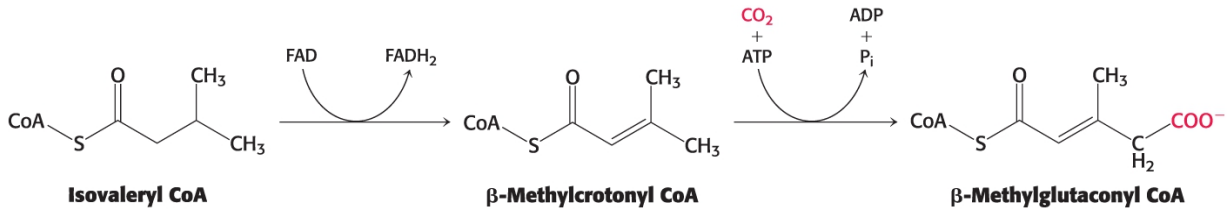
The structure of alpha-ketobutyrate is as follows: A central C atom is single bonded to C H 2 on the upper left in the form of a line, double bonded to O below, and single bonded to C O O superscript minus. The C H 2 group is single-bonded to C H 3 on the lower left.

The structure of propionyl C o A is as follows: A central C atom is single bonded to C H 2 on the upper left in the form of a line, double bonded to O below, and single bonded to S on the upper right. The C H 2 group is single-bonded to C H 3 on the lower left. The S atom is single-bonded to C o A on the lower right.

Return to Conversion of threonine to propionyl C o A

Extended description for Conversion of leucine to isovaleryl C o A

Leucine is irreversibly converted into isovaleryl C o A through an alpha-ketoisocaproate intermediate.



The structure of leucine is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the lower left, wedge bonded to N H 3 superscript plus on the upper left, and dash bonded to H on the upper right. C 3 is single bonded to C H 3 above and C H 3 on the lower right.

The structure of alpha-ketoisocaproate is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the lower left and double bonded to O above. C 3 is single bonded to C H 3 above and C H 3 on the lower right.

The structure of isovaleryl C o A is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to S on the lower left and double bonded to O above. S is single bonded to C o A on the upper left. C 3 is single-bonded to C H 3 above and C H 3 on the lower right.

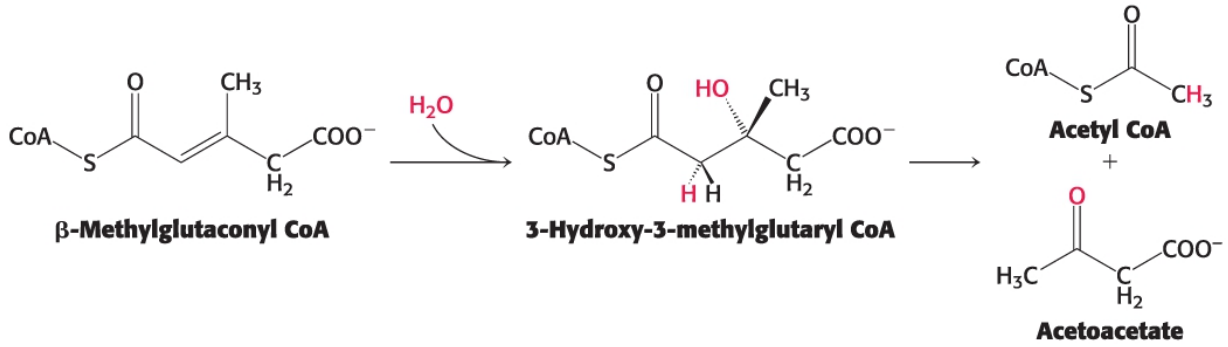
Return to Conversion of leucine to isovaleryl C o A

Extended description for Conversion of isovaleryl C o A to beta-methylglutaconyl C o A

Isovaleryl C o A is irreversibly converted into beta-methylglutaconyl C o A through a beta-methylcrotonyl C o A intermediate.

The structure of isovaleryl C o A is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to S on the lower left and double bonded to O above. S is single bonded to C o A on the upper left. C 3 is single-bonded to C H 3 above and C H 3 on the lower right.

Isovaleryl C o A is irreversibly converted into beta-methylcrotonyl C o A with the simultaneous reduction of F A D to F A D H 2.



The structure of beta-methylcrotonyl C o A is as follows: A 3-carbon alkene chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to S on the lower left and double bonded to O above. S is single bonded to C o A on the upper left. C 3 is single-bonded to C H 3 above and C H 3 on the lower right. A double bond is present between C 2 and C 3.

Beta-methylcrotonyl C o A is irreversibly converted into beta-methylglutaconyl C o A with the simultaneous hydrolysis of A T P to A D P and P subscript i and entry of C O 2.

The structure of beta-methylglutaconyl C o A is as follows: A 3-carbon alkene chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to S on the lower left and double bonded to O above. S is single-bonded to C o A on the upper left. C 3 is single-bonded to C H 3 above and C H 2 on the lower right. C H 2 is single bonded to C O O superscript minus on the upper right. A double bond is present between C 2 and C 3.

Return to Conversion of isovaleryl C o A to beta-methylglutaconyl C o A

Extended description for Conversion of beta-methylglutaconyl C o A to acetyl C o A and acetoacetate

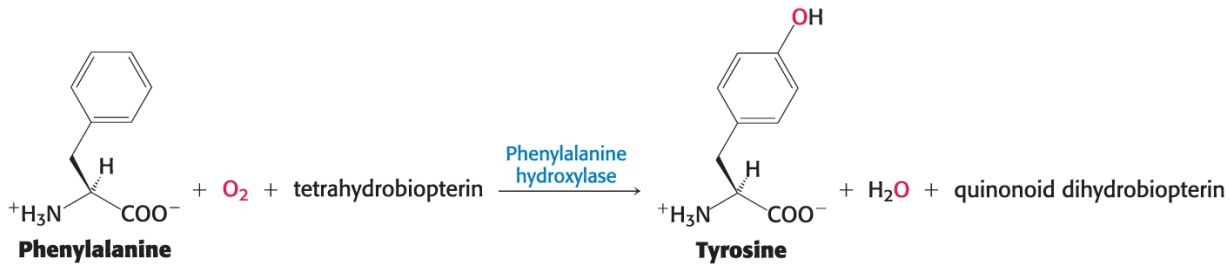
Beta-methylglutaconyl C o A is irreversibly converted to acetyl C o A and acetoacetate through a 3-hydroxy-3-methylglutaryl C o A intermediate.

In the first step, beta-methylglutaconyl C o A is converted into 3-hydroxy-3-methylglutaryl C o A by the addition of H 2 O.

The structure of beta-methylglutaconyl C o A is as follows: A 3-carbon alkene chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to S on the lower left and double bonded to O above. S is single-bonded to C o A on the upper left. C 3 is single-bonded to C H 3 above and C H 2 on the lower right. C H 2 is single bonded to C O O superscript minus on the upper right. A double bond is present between C 2 and C 3.

The structure of 3-hydroxy-3-methylglutaryl C o A is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to S on the lower left and double bonded to O above. S is single-bonded to C o A on the upper left. C 2 is dash bonded to H on the lower left and wedge bonded to H on the lower right. C 3 is dash bonded to O H on the upper left, wedge bonded to

C H 3 on the upper right, and single bonded to C H 2 on the lower right. The C H 2 group is single-bonded to C O O superscript minus on the upper right.



In the second step, 3-hydroxy-3-methylglutaryl C o A is converted into acetyl C o A and acetoacetate.

The structure of acetyl C o A is as follows: A central C atom is single-bonded to S on the lower left, single-bonded to C H 3 on the lower right, and double-bonded to O above. The S atom is single-bonded to C o A on the upper left.

The structure of acetoacetate is as follows: A central C atom is single-bonded to C H 3 on the lower left, single-bonded to C H 2 on the lower right, and double-bonded to O above. The lower right C H 2 group is single bonded to C O O superscript minus on the upper right.

Return to Conversion of beta-methylglutaconyl C o A to acetyl C o A and acetoacetate

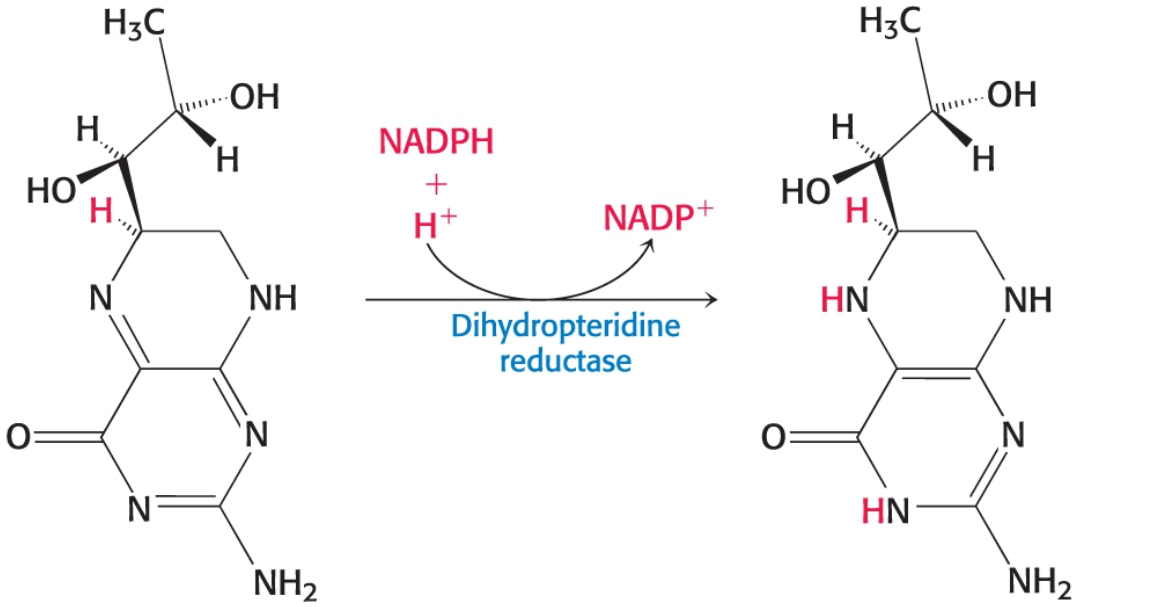
Extended description for Reaction catalyzed by phenylalanine hydroxylase

The reaction consists of three reactants and three products.

The first reactant is phenylalanine whose structure is as follows: A benzene ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 3 is single bonded to C H 2 on the lower left in the form of a line. The C H 2 group is wedge bonded to C on the lower right. This C atom is dash bonded to H on the upper right, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right.

The second reactant is O 2 and the third reactant is tetrahydrobiopterin.

A forward arrow labeled phenylalanine hydroxylase leads to the products.



The first product is tyrosine whose structure is as follows: A benzene ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 6 is single bonded to O H on the upper

right. C 3 is single bonded to C H 2 on the lower left in the form of a line. The C H 2 group is wedge bonded to C on the lower right. This C atom is dash bonded to H on the upper right, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right.

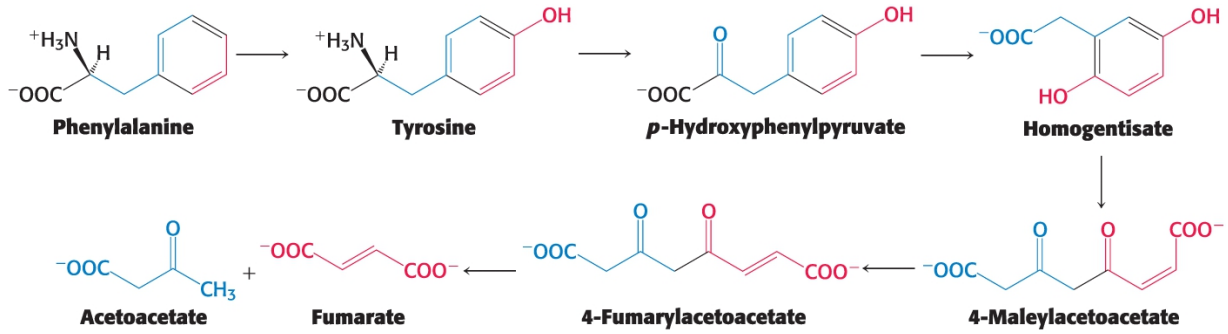
The second product is H 2 O and the third product is quinonoid dihydrobiopterin.

Return to Reaction catalyzed by phenylalanine hydroxylase

Extended description for Irreversible conversion of quinonoid dihydrobiopterin to tetrahydrobiopterin

Quinonoid dihydrobiopterin **Tetrahydrobiopterin**

The reaction consists of one reactant and one product. It is catalyzed by dihydropteridine reductase with the simultaneous oxidation of N A D P H plus H superscript plus to N A D P superscript plus.



The reactant is quinonoid dihydrobiopterin whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 2 N and 4 C atoms. C 1 occupies the bottom right vertex. The first N occupies the rightmost vertex and the second N occupies the bottom left vertex. A double bond is present between C 4 and N 1 and C 1 and N 2. C 1 is single bonded to N H 2 on the lower right. C 2 is double bonded to O on the left. This hexagonal ring is fused to a second 6-membered heterocyclic hexagonal ring in a horizontal orientation such that C 3 and C 4 of the first ring are C 2 and C 1 respectively of the second ring. The second ring consists of 2 N and 4 C atoms. The first N

bound to H occupies the rightmost vertex and the second N occupies the leftmost vertex. A double bond is present between C 2 and N 2. C 3 is wedge bonded to a C atom above and dash bonded to H on the upper left. The C atom is dash bonded to H on the upper left, wedge bonded to O H on the left, and single bonded to another C atom on the upper right. The upper right C atom is single bonded to C H 3 above, dash bonded to O H on the right, and wedge bonded to H on the lower right.

The product is tetrahydrobiopterin whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 2 N and 4 C atoms. C 1 occupies the bottom right vertex. The first N occupies the rightmost vertex and the second N bound to H occupies the bottom left vertex. A double bond is present between N 1 and C 1, and C 3 and C 4. C 1 is single bonded to N H 2 on the lower right. C 2 is double bonded to O on the left. This hexagonal ring is fused to a second 6-membered heterocyclic hexagonal ring in a horizontal orientation such that C 3 and C 4 of the first ring are C 2 and C 1 respectively of the second ring. The second ring consists of 2 N and 4 C atoms. The first N bound to H occupies the rightmost vertex and the second N bound to H occupies the leftmost vertex. C 3 is wedge bonded to a C atom above and dash bonded to H on the upper left. The C atom is dash bonded to H on the upper left, wedge bonded to O H on the left, and single bonded to another C atom on the upper right. The upper right C atom is single bonded to C H 3 above, dash bonded to O H on the right, and wedge bonded to H on the lower right.

Return to Irreversible conversion of quinonoid dihydrobiopterin to tetrahydrobiopterin

Extended description for FIGURE 23.26 Phenylalanine and tyrosine degradation produce both acetoacetate and fumarate

In the first step, phenylalanine is irreversibly converted into tyrosine. The structure of phenylalanine is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 5 is single bonded to C H 2 on the lower left in the form of a line. This C H 2 group is single-bonded to C on the upper left. The C atom is wedge bonded to N H 3 superscript plus on the upper left, single bonded to C O O superscript minus on the lower left, and dash bonded to H on the upper right.

The structure of tyrosine is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to O H on the upper right. C 5 is single bonded to C H 2 on the lower left in the form of a line. This C H 2 group is single-bonded to C on the upper left. The C atom is wedge bonded to N H 3 superscript plus on the upper left, single bonded to C O O superscript minus on the lower left, and dash bonded to H on the upper right.

In the second step, tyrosine is irreversibly converted into p-hydroxyphenylpyruvate.

The structure of p-hydroxyphenylpyruvate is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to O H on the upper right. C 5 is single bonded to C H 2 on the lower left in the form of a line. This C H 2 group is single-bonded to C on the upper left. The C atom is double-bonded to O above and single-bonded to C O O superscript minus on the lower left.

In the third step, p-hydroxyphenylpyruvate is irreversibly converted into homogentisate.

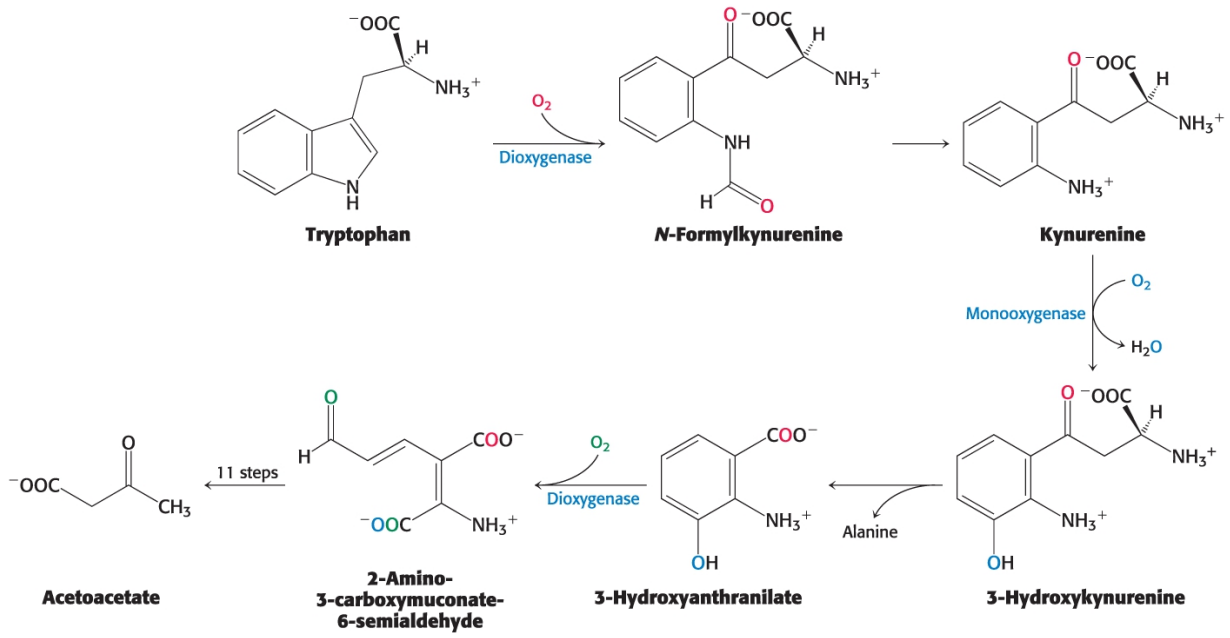
The structure of homogentisate is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to O H on the upper right. C 5 is single bonded to O H on the lower left. C 6 is single bonded to C H 2 on the upper left in the form of a line. This C H 2 group is single bonded to C O O superscript minus on the lower left.

In the fourth step, homogentisate is irreversibly converted into 4-Maleylacetoacetate.

The structure of 4-Maleylacetoacetate is as follows: A 6-carbon alkene chain is depicted as a line structure using 5 zigzag lines. A double bond is present between C 5 and C 6. C 1 is single bonded to C O O superscript minus on the upper left. C 2 and C 4 are double bonded to O above. C 6 is single bonded to C O O superscript minus above.

In the fifth step, 4-Maleylacetoacetate is irreversibly converted into 4-Fumarylacetoacetate.

The structure of 4-Fumarylacetoacetate is as follows: A 6-carbon alkene chain is depicted as a line structure using 5 zigzag lines. A double bond is present between C 5 and C 6. C 1 is single bonded to C O O superscript minus on the upper left. C 2 and C 4 are double bonded to O above. C 6 is single bonded to C O O superscript minus on the lower right.



In the sixth step, 4-Fumarylacetoacetate is irreversibly converted into fumarate and acetoacetate.

The structure of fumarate is as follows: A 2-carbon alkene chain is depicted using 2 parallel lines. C 1 is single bonded to C O O superscript minus on the upper left. C 2 is single bonded to C O O superscript minus on the lower right.

The structure of acetoacetate is as follows: A central C atom is double bonded to O above, single bonded to C H 3 on the lower right, and single bonded to C H 2 on the lower left in the form of a line. The C H 2 group is single-bonded to C O O superscript minus on the upper left.

Return to FIGURE 23.26 Phenylalanine and tyrosine degradation produce both acetoacetate and fumarate

Extended description for FIGURE 23.27 Tryptophan degradation requires multiple oxygenases and numerous steps

In the first step, tryptophan is irreversibly converted into N-formylkynurenine by dioxygenase. This step requires the addition of O 2.

The structure of tryptophan is as follows: A benzene ring is a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. The benzene ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation such that C 2 and C 3 of the benzene ring are C 2 and C 1 respectively of the pentagonal ring. It consists of 1 N and 4 C atoms. N bound to H occupies the bottom right vertex. C 1 occupies the bottom left vertex. A double bond is present between C 3 and C 4. C 3 is single bonded to C H 2 on the upper right in the form of a line. C H 2 is

single bonded to C on the right. This C atom is wedge bonded to C O O superscript minus on the upper left, dash bonded to H on the upper right, and single bonded to N H 3 superscript plus on the right.

The structure of N-formylkynurenine is as follows: A benzene ring is a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 2 is single bonded to a 3-carbon alkane chain depicted as a line structure using 2 zigzag lines. In the alkane chain, C 1 is double bonded to O above. C 3 is wedge bonded to C O O superscript minus on the upper left, dash bonded to H on the upper right, and single bonded to N H 3 superscript plus on the lower right. C 3 of the benzene ring is single bonded to N H on the lower right. This N H group is single bonded to C below. The C atom is single bonded to H on the lower left and double bonded to O on the lower right.

In the second step, N-formylkynurenine is irreversibly converted into kynurenine.

The structure of kynurenine is as follows: A benzene ring is a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 2 is single bonded to a 3-carbon alkane chain depicted as a line structure using 2 zigzag lines. In the alkane chain, C 1 is double bonded to O above. C 3 is wedge bonded to C O O superscript minus on the upper left, dash bonded to H on the upper right, and single bonded to N H 3 superscript plus on the lower right. C 3 of the benzene ring is single bonded to N H 3 superscript plus on the lower right.

In the third step, kynurenine is irreversibly converted into 3-hydroxykynurenine by monooxygenase with the simultaneous

conversion of O 2 to H 2 O.

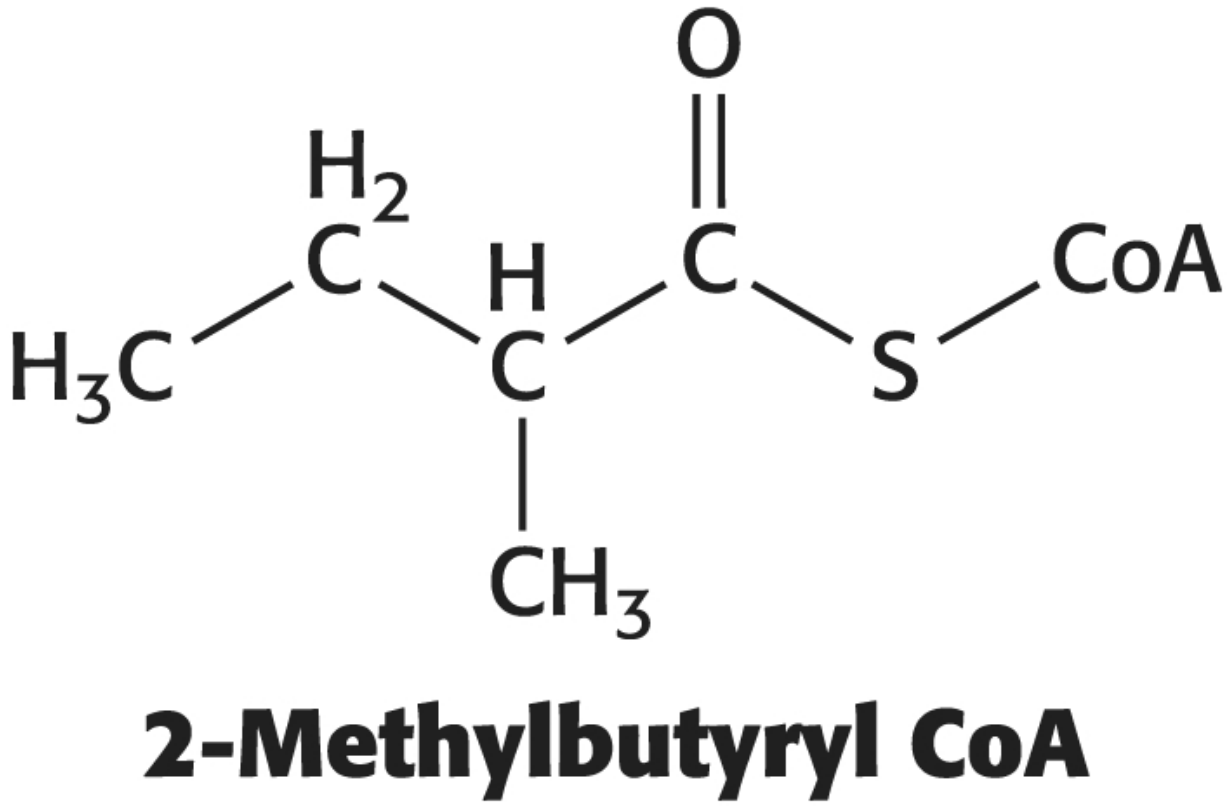
The structure of 3-hydroxykynurenine is as follows: A benzene ring is a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 2 is single bonded to a 3-carbon alkane chain depicted as a line structure using 2 zigzag lines. In the alkane chain, C 1 is double bonded to O above. C 3 is wedge bonded to C O O superscript minus on the upper left, dash bonded to H on the upper right, and single bonded to N H 3 superscript plus on the lower right. C 3 of the benzene ring is single bonded to N H 3 superscript plus on the lower right. C 4 is single bonded to O H below.

In the fourth step, 3-hydroxykynurenine is irreversibly converted into 3-hydroxyanthranilate with the simultaneous release of alanine.

The structure of 3-hydroxyanthranilate is as follows: A benzene ring is a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 2 is single bonded to C O O superscript minus on the upper right. C 3 is single bonded to N H 3 superscript plus on the lower right. C 4 is single bonded to O H below.

In the fifth step, 3-hydroxyanthranilate is irreversibly converted into 2-amino-3-carboxymuconate-6-semialdehyde by dioxygenase. This step requires the addition of O 2.

The structure of 2-amino-3-carboxymuconate-6-semialdehyde is as follows: A 4-carbon alkene chain is depicted as a line structure using 3 zigzag lines. A double bond is present between C 2 and C 3. C 1 is double bonded to O above and single bonded to H on the lower right. C 4 is single bonded to C O O superscript minus on the upper right and double bonded to C below. The C atom below is single



bonded to C O O superscript minus on the lower left and single bonded to N H 3 superscript plus on the lower right.

2-amino-3-carboxymuconate-6-semialdehyde is converted into acetoacetate in 11 irreversible steps.

The structure of acetoacetate is as follows: A central C atom is double bonded to O above, single bonded to C H 3 on the lower right, and single bonded to C H 2 on the lower left in the form of a line. The C H 2 group is single-bonded to C O O superscript minus on the upper left.

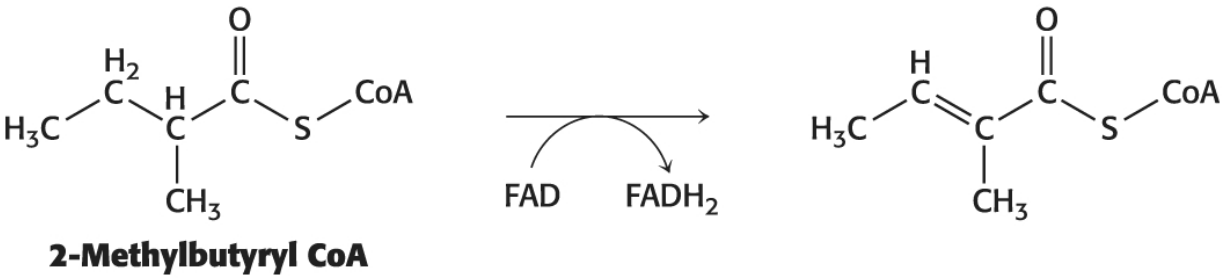
Extended description for Structure of 2-methylbutyryl C o A

The structure of 2-methylbutyryl C o A is as follows: A zigzag chain is composed of C H 3, single bond, C H 2, single bond, C H, single bond, C, single bond, S, single bond, C o A. C 3 is single bonded to C H 3 below. C 4 is double bonded to O above.

Return to Structure of 2-methylbutyryl C o A



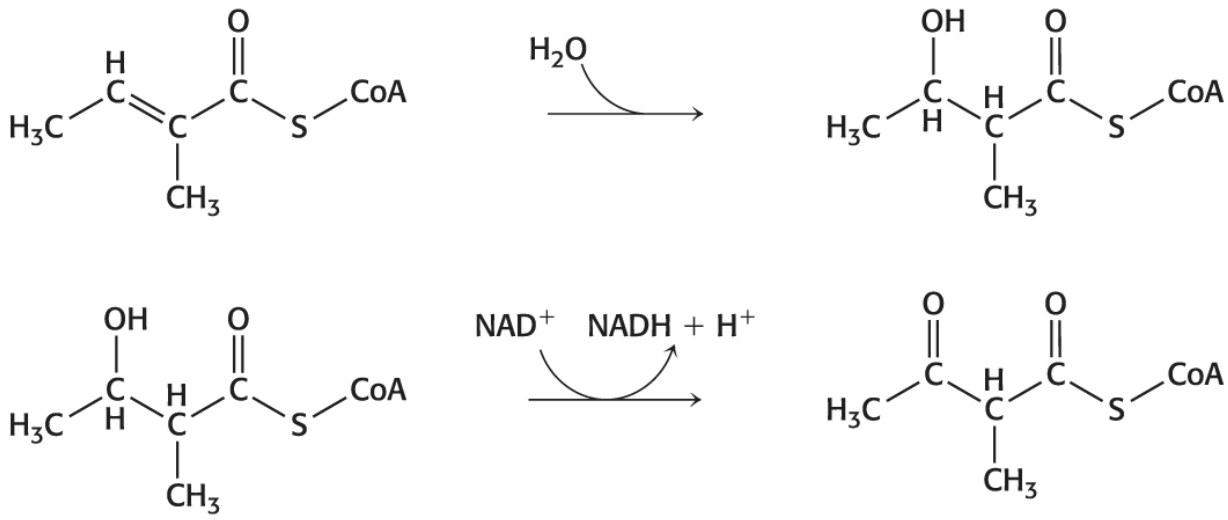
Extended description for Structure of butyryl C o A

The structure of butyryl C o A is as follows: A zigzag chain is composed of C H 3, single bond, C H 2, single bond, C H 2, single bond, C, single bond, S, single bond, C o A. C 4 is double bonded to O above.

Return to Structure of butyryl C o A

Extended description for Beta-oxidation of 2-methylbutyryl C o A

2-Methylbutyryl CoA



2-methylbutyryl C o A is irreversibly oxidized to another compound with the simultaneous reduction of F A D to F A D H 2.

The structure of 2-methylbutyryl C o A is as follows: A zigzag chain is composed of C H 3, single bond, C H 2, single bond, C H, single bond, C, single bond, S, single bond, C o A. C 3 is single bonded to C H 3 below. C 4 is double bonded to O above.

The structure of the compound produced after oxidation is as follows: A zigzag chain is composed of C H 3, single bond, C H, double bond, C, single bond, C, single bond, S, single bond, C o A. C 3 is single bonded to C H 3 below. C 4 is double bonded to O above.

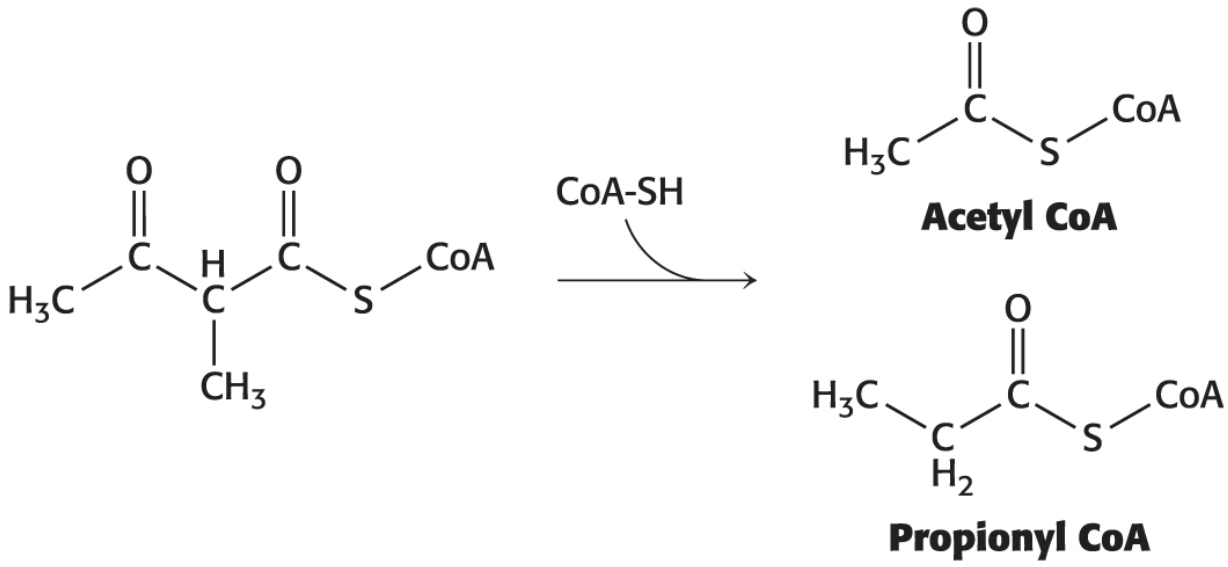
Return to Beta-oxidation of 2-methylbutyryl C o A

Extended description for Hydration and oxidation steps of beta-oxidation

The first reaction depicts hydration as it involves the addition of H 2 O. It consists of one reactant and one product.

The structure of the reactant is as follows: A zigzag chain is composed of C H 3, single bond, C H, double bond, C, single bond, C, single bond, S, single bond, C o A. C 3 is single bonded to C H 3 below. C 4 is double bonded to O above.

The structure of the product is as follows: A zigzag chain is composed of C H 3, single bond, C H, single bond, C H, single bond, C, single bond, S, single bond, C o A. C 2 is single bonded to O H above. C 3 is single bonded to C H 3 below. C 4 is double bonded to O above.



The second reaction depicts oxidation as it involves the concomitant reduction of N A D superscript plus to N A D H plus H superscript plus.

The structure of the reactant is as follows: A zigzag chain is composed of C H 3, single bond, C H, single bond, C H, single bond, C, single bond, S, single bond, C o A. C 2 is single bonded to O H above. C 3 is single bonded to C H 3 below. C 4 is double bonded to O above.

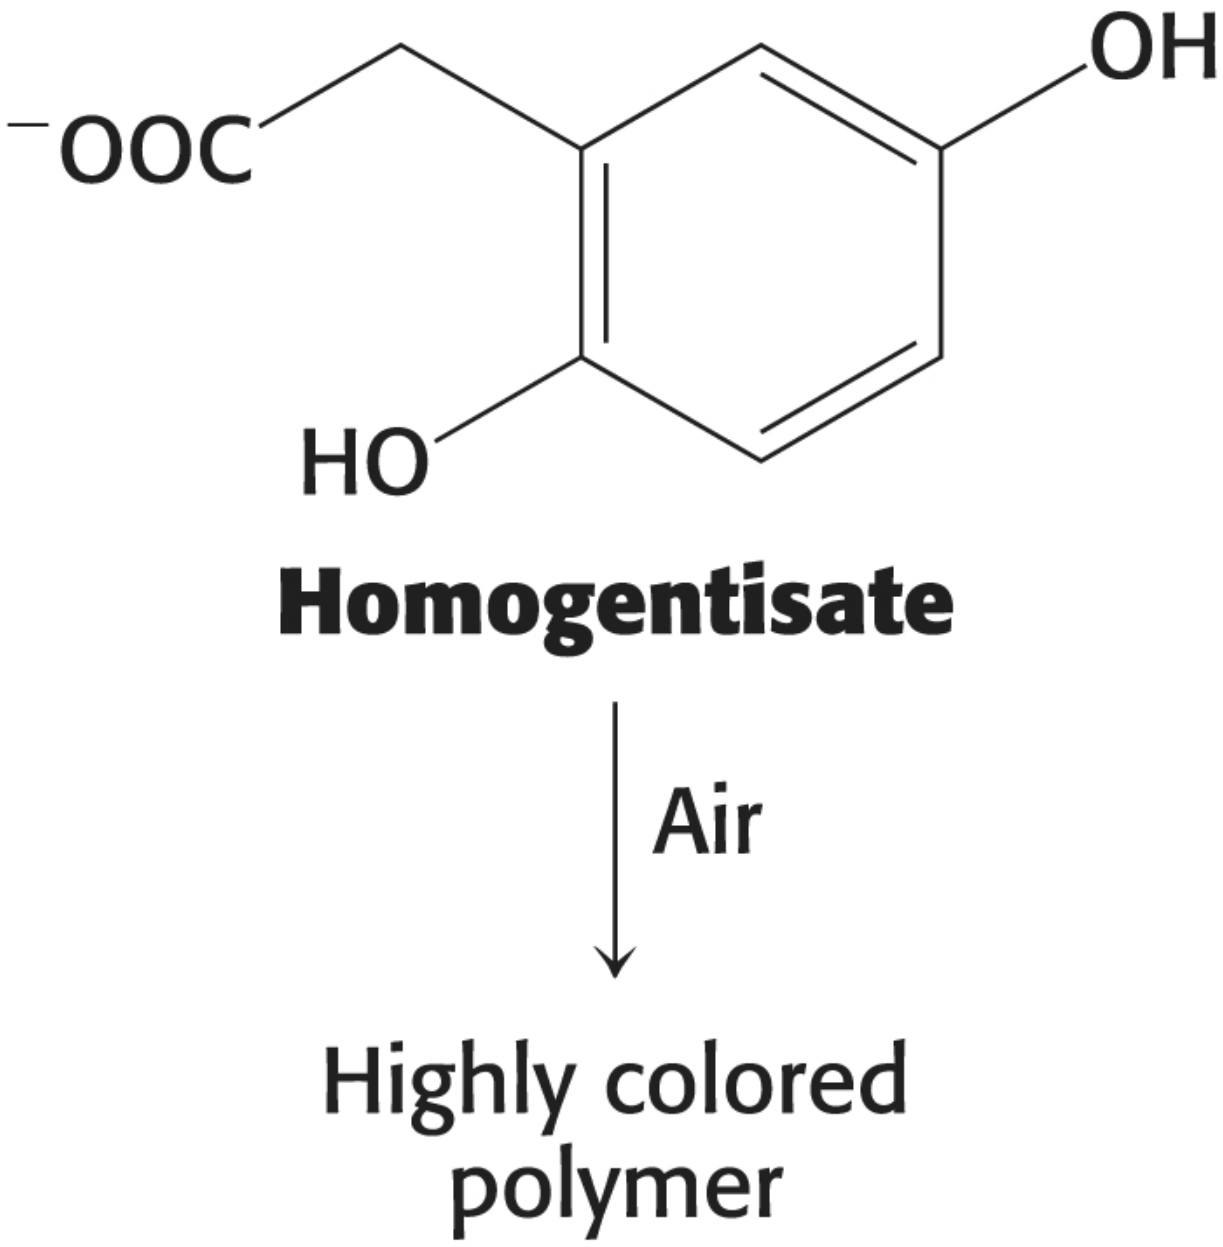
The structure of the product is as follows: A zigzag chain is composed of C H 3, single bond, C, single bond, C H, single bond, C, single bond, S, single bond, C o A. C 2 is double bonded to O above. C 3 is single bonded to C H 3 below. C 4 is double bonded to O above.

Return to Hydration and oxidation steps of beta-oxidation

Extended description for Thiolysis of the product of the oxidation step of beta-oxidation

The reaction consists of one reactant and two products. It requires the addition of C o A, single bond, S H.

The structure of the reactant is as follows: A zigzag chain is composed of C H 3, single bond, C, single bond, C H, single bond, C, single bond, S, single bond, C o A. C 2 is double bonded to O above. C 3 is single bonded to C H 3 below. C 4 is double bonded to O above.



The first product is acetyl C o A whose structure is as follows: A central C atom is single bonded to C H 3 on the lower left, double bonded to O above, and single bonded to S on the lower right. The S atom is single-bonded to C o A on the upper right.

The second product is propionyl C o A whose structure is as follows: A zigzag chain is composed of C H 3, single bond, C H 2, single

bond, C, single bond, S, single bond, C o A. C 3 is double bonded to O above.

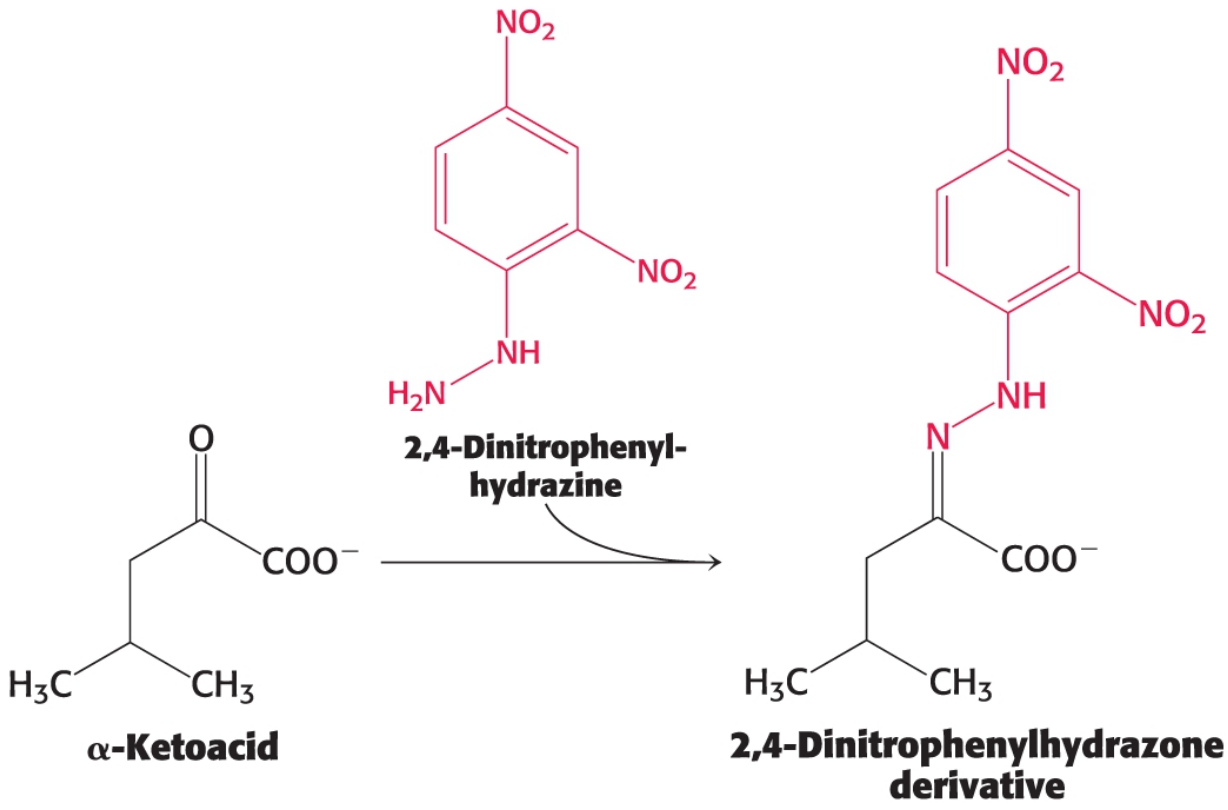
Extended description for FIGURE 23.28 Urine has long been used to diagnose diseases due to the excretion of unusual biochemical products



Ulrich Pinder. Epiphanie Medicorum. Speculum videndi urinas hominum. Clavis aperiendi portas pulsuum. Berillus discernendi causas & differentias febrium. Nuremberg: 1506. Rosenwald Collection. Rare Book and Special Collections Division, Library of Congress (128.2).

The center of the wheel shows a doctor sitting on a chair and inspecting a patient's urine. The patient is standing beside the doctor. The illustration of the doctor and the patient in the center is

surrounded by a radial arrangement of vials containing differently colored urine samples. A text in a foreign language is mentioned in a radial manner along the outer edge of the wheel corresponding to each vial.

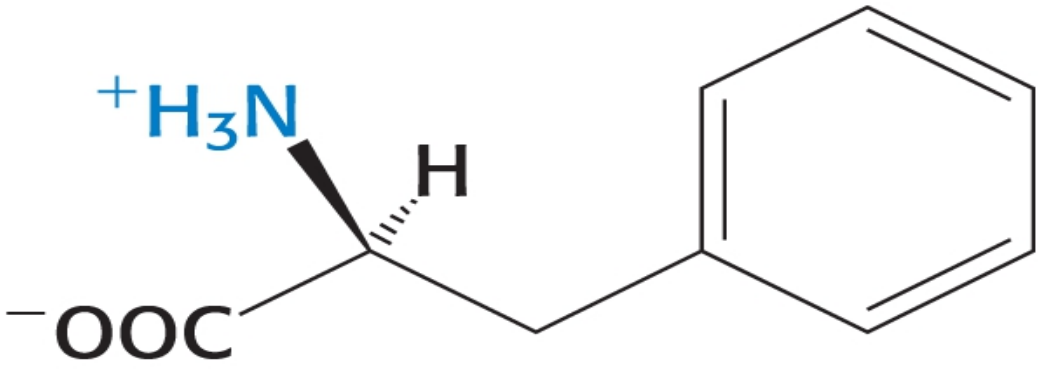
Return to FIGURE 23.28 Urine has long been used to diagnose diseases due to the excretion of unusual biochemical products

Extended description for Conversion of alpha-ketoacid to 2,4-dinitrophenylhydrazone derivative

The reaction consists of one reactant and one product. It involves the addition of 2,4-Dinitrophenyl-hydrazine.

The reactant is alpha-ketoacid whose structure is as follows: A 3-carbon alkane chain is depicted as a vertical line structure using 2 zigzag lines. C 1 is single bonded to C H 3 on the lower left and C H 3 on the lower right. C 3 is double bonded to O above and single bonded to C O O superscript minus on the lower right.

The structure of 2,4-Dinitrophenyl-hydrazine is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1



and C 2, C 3 and C 4, and C 5 and C 6. C 1 is single bonded to N O 2 above. C 3 is single bonded to N O 2 on the lower right. C 4 is single bonded to N H, single bond, N H 2 below.

The product is 2,4-dinitrophenylhydrazone derivative whose structure is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 1 is single bonded to N O 2 above. C 3 is single bonded to N O 2 on the lower right. C 4 is single bonded to N H, single bond, N below. The N atom is double bonded to C 3 of the alpha-ketoacid instead of the O atom.

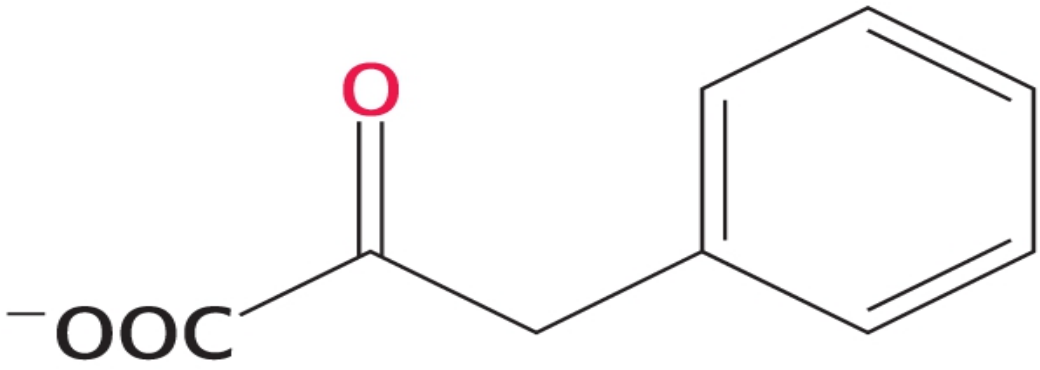
Extended description for Conversion of phenylalanine



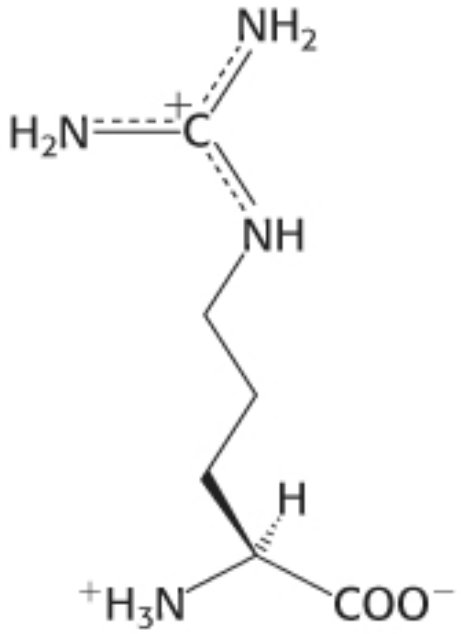
to phenylpyruvate

Phenylalanine

α-Ketoacid

α-Amino acid

Phenylpyruvate



The reaction consists of one reactant and one product. It is accompanied by the simultaneous conversion of alpha-ketoacid to alpha-amino acid.

The reactant is phenylalanine whose structure is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 5 is single bonded to C H 2 on the lower left in the form of a line. This C H 2 group is single-bonded to C on the upper left. The C atom is wedge bonded to N H 3 superscript plus on the upper left, single bonded to C O O superscript minus on the lower left, and dash bonded to H on the upper right.

The product is phenylpyruvate whose structure is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 5 is single bonded to C H 2 on the lower left in the form of a line. This C H 2 group is single-bonded to C on the upper left. The C atom is double bonded to O above and single bonded to C O O superscript minus on the lower left.

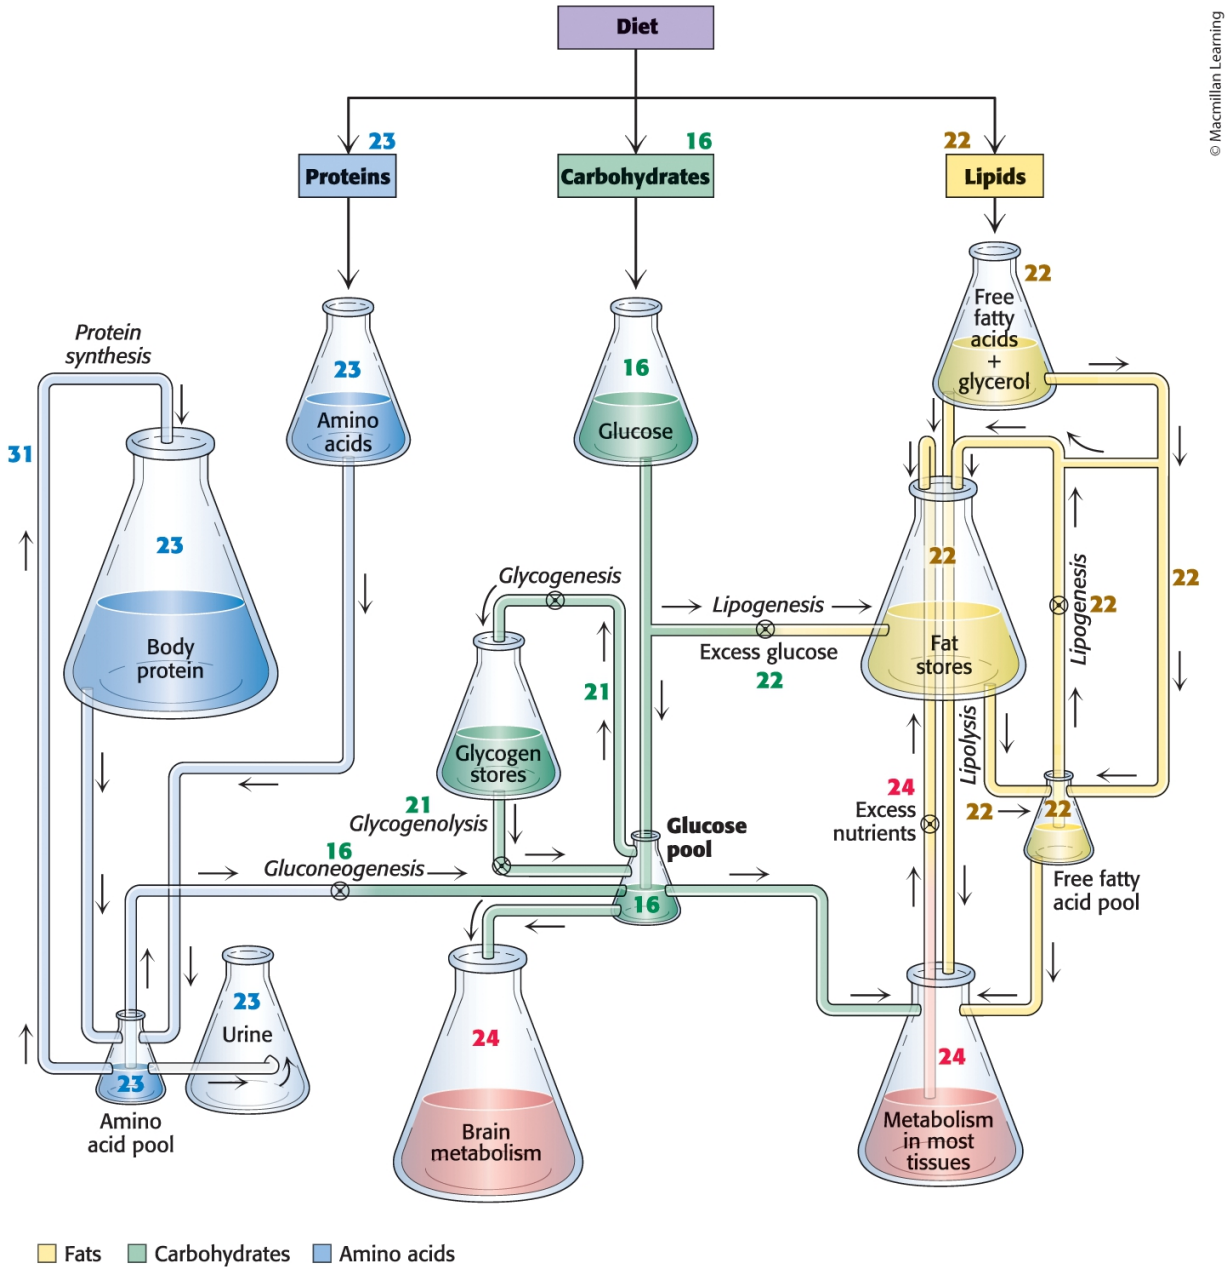
Extended description for Photograph of an event and schematic representation of integration of metabolic pathways for glucose homeostasis

Debbie Eckert/Alamy
© Macmillan Learning



The entrance in the photograph has an arch-shaped structure. The text written on the structure is "J D R F, One Walk, For a world without type 1 diabetes."

In the schematic representation, glucose is shown in the center. An upward arrow from glucose points toward the brain at the top. A red rightward arrow with a minus symbol points from the brain to eating. A downward arrow from eating leads to the intestine. An arrow from the intestine points back to glucose. An arrow on the lower right of glucose points toward muscle and an arrow on the lower left of glucose points toward fat depicted as a cluster of cells. An arrow from fat points toward leptin at the top. Another arrow from leptin points toward the brain. Insulin is shown at the bottom. An upper left green arrow with a plus symbol leads from insulin to fat and an upper right green arrow with a plus symbol leads from

insulin to muscle. A red arrow with a minus symbol points toward the liver. A lower right arrow from liver points toward glucose. An upward arrow from the pancreas points toward insulin.

Return to Photograph of an event and schematic representation of integration of metabolic pathways for glucose homeostasis

Extended description for Coordinated use of nutrient pools to maintain homeostasis

The illustration shows different nutrient pools as conical flasks containing a solution. The flasks are interconnected by tubular

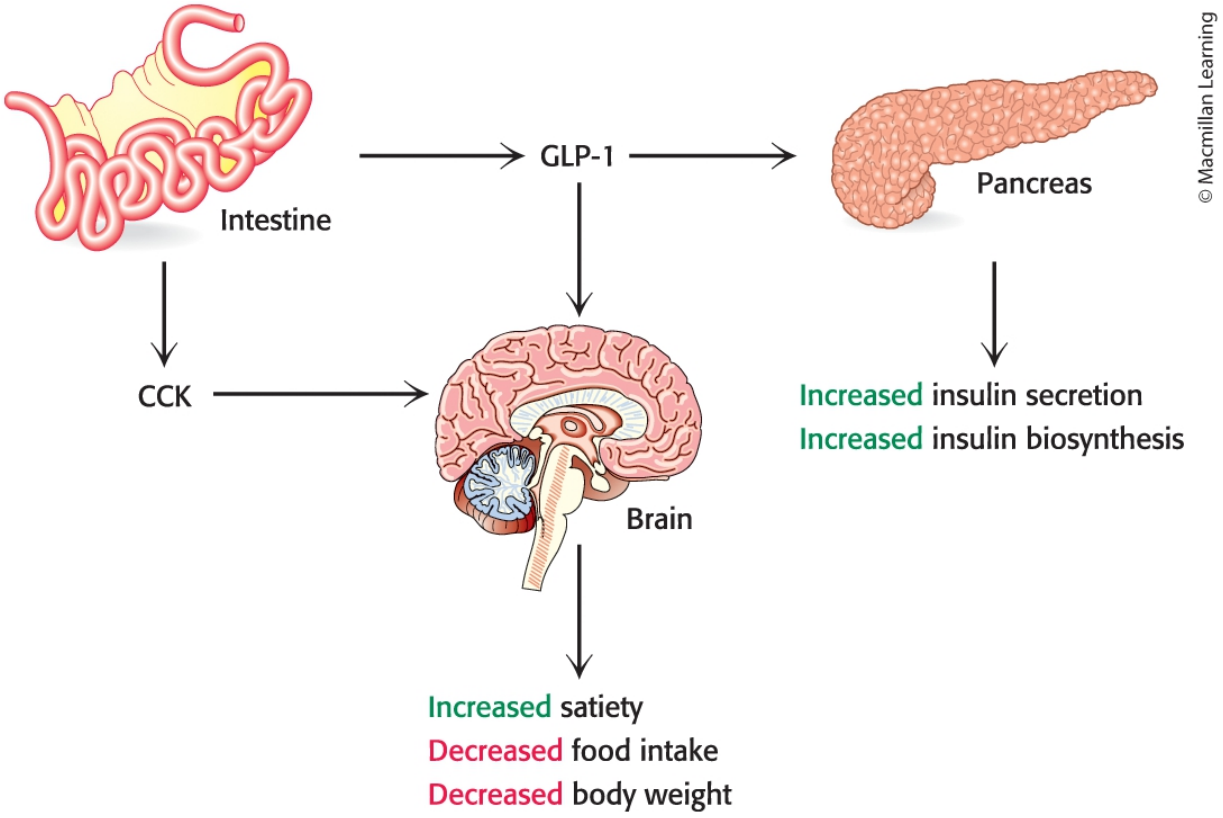
pipes. The flasks and pipes are differently numbered and each number indicates the chapters in which the topics are discussed.

A purple rectangle labeled diet is shown at the top. A line below it bifurcates into three downward arrows numbered 23, 16, and 22 from left to right. The arrow number 23 points toward a blue rectangle labeled protein. The arrow number 16 points toward a green rectangle labeled carbohydrates. The arrow number 22 points toward a yellow rectangle labeled lipids.

A downward arrow from proteins points toward flask number 23 containing amino acids. A tubular pipe containing blue solution travels toward a small flask, numbered 23, containing an amino acid pool. Three tubular pipes containing blue solution originate sideways from the small flask. A tubular pipe containing blue solution originates from the mouth of the small flask. The pipe from the right wall travels to a medium-sized flask number 23 containing urine. One of the pipes originating from the left wall is numbered 31 and labeled protein synthesis. It enters into the mouth of a large flask, numbered 23, containing body protein. A pipe from the body protein flask enters the amino acid pool flask. The pipe from the mouth of the amino acid pool flask is labeled gluconeogenesis and it travels to a small flask, numbered 16, containing a glucose pool. This pipe contains a half-blue and half-green solution. At the junction of the blue and green solution, a cross symbol is shown below the label gluconeogenesis.

A downward arrow from carbohydrates points toward a medium-sized flask, numbered 16, containing glucose. A tubular pipe from the base of this flask travels downward to the glucose pool flask. Halfway through a pipe labeled lipogenesis, excess glucose and numbered 22 branches off and travels to a large flask, numbered 22, containing fat stores. This branch of the pipe contains a half-green and half-yellow solution. At the junction of the green and yellow

solution, a cross symbol is shown below the label lipogenesis. A pipe numbered 21 and labeled glycogenesis travels from the glucose pool to a medium-sized flask containing glycogen stores. The end of the pipe closer to the mouth of the glycogen stores flask has a cross symbol below the label glycogenesis. Another pipe originates from the base of the glycogen stores flask and is labeled 21 glycogenesis. It travels back to the glucose pool flask. The end of this pipe closer to the glycogen stores flask has a cross symbol. A pipe from the glucose pool flask travels to a large flask, numbered 24 and labeled brain metabolism. Another pipe from the glucose pool flask travels to another large flask, numbered 24, and labeled metabolism in most tissues.



A downward arrow from lipids points toward a medium-sized flask, numbered 22, containing free fatty acids plus glycerol. A vertical pipe from the base of this flask travels through fat stores and enters into the mouth of the large flask numbered 24. Another pipe numbered 22 travels from flask number 22 to a small flask numbered 22 and labeled free fatty acid pool. A pipe originating from the mouth of the free fatty acid pool flask is numbered 22 and labeled lipogenesis. It travels to the mouth of fat stores. The pipe has a cross-symbol halfway through and it is connected above to pipe number 22 coming from the free fatty acids plus glycerol flask. Another pipe from the base of the free fatty acid pool flask travels to flask number 24 labeled metabolism in most tissues. A pipe from fat stores is numbered 22 and labeled lipolysis. It travels back to the free fatty acid pool flask.

A long pipe from flask number 24 labeled metabolism in most tissues travels to the fat stores flask and enters its mouth. This pipe is numbered 24 and labeled excess nutrients. It has a cross symbol on its end closer to the flask number 24.

Fats are depicted in yellow color, carbohydrates are depicted in green color, and amino acids are depicted in blue color.

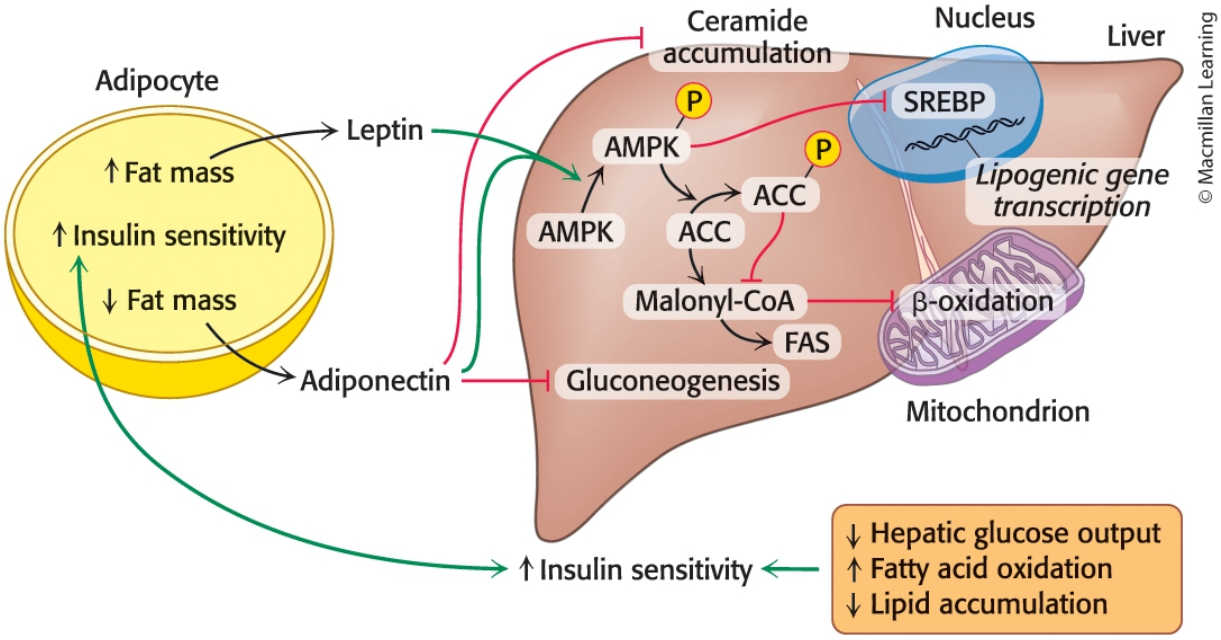
Extended description for FIGURE 24.3 Leptin suppresses appetite by affecting the brain

© Macmillan Learning

The flowchart is depicted as follows:



Increase in fat cell mass, downward arrow, Increased in leptin expression, downward arrow, Increase in leptin action in the hypothalamus. Two distinct paths are shown by two separate downward arrows below "Increase in leptin expression."

The left downward arrow points to the "Inhibition of N P Y and A g R P-producing neurons." A downward arrow below it points to "Decrease in N P Y and A g R P expression and release." A downward arrow below it points to "Decrease in food intake."

The right downward arrow points to the "Activation of P O M C-producing neurons." A downward arrow below it points to "Increase in M S H expression." A downward arrow below it points to "Decrease in food intake."

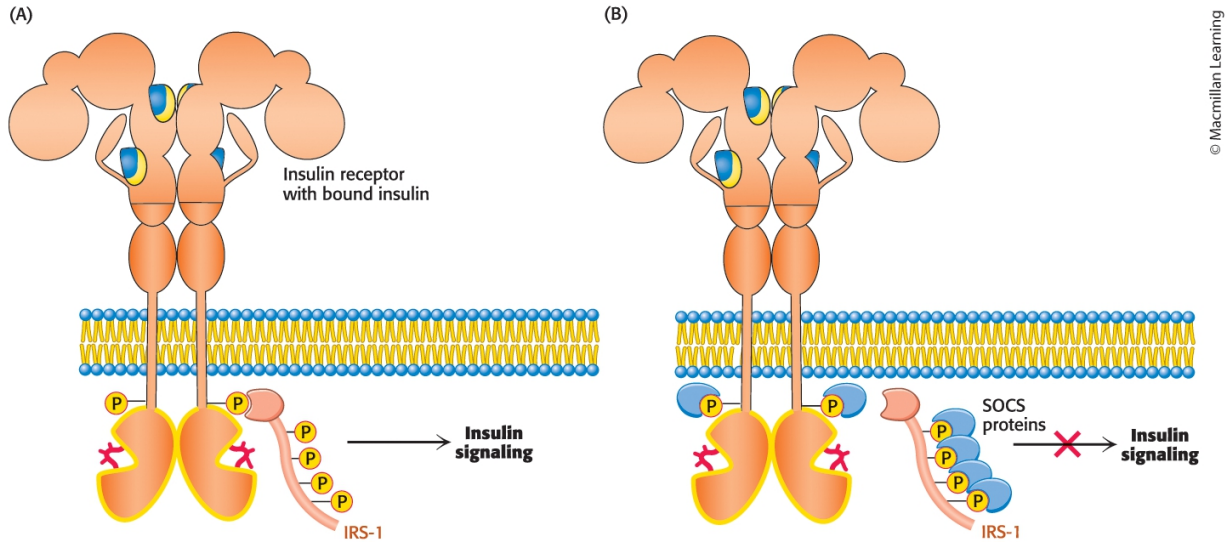
Return to FIGURE 24.3 Leptin suppresses appetite by affecting the brain

Extended description for FIGURE 24.4 Adipokines help to maintain systemic lipid and glucose homeostasis

The adipocyte is depicted as a half-cut sphere and the liver is depicted as a triangular organ. Increased fat mass in the adipocyte causes the release of leptin, whereas decreased fat mass cause the release of adiponectin. Leptin and adiponectin together cause the conversion of A M P K to phosphorylated A M P K in the liver. The adiponectin, independently, inhibits ceramide accumulation and gluconeogenesis in the liver. The phosphorylated A M P K in the liver inhibits S R E B P in the nucleus. S R E B P is essential for lipogenic gene transcription. The phosphorylated A M P K causes the conversion of A C C to phosphorylated A C C in the liver. A C C has an activating effect on malonyl-C o A in the liver and phosphorylated A C C has an inhibitory effect on malonyl-C o A. The malonyl-C o A inhibits beta-oxidation and activates F A S in the liver.

An orange rectangle lists the following points:

Decreased hepatic glucose output.



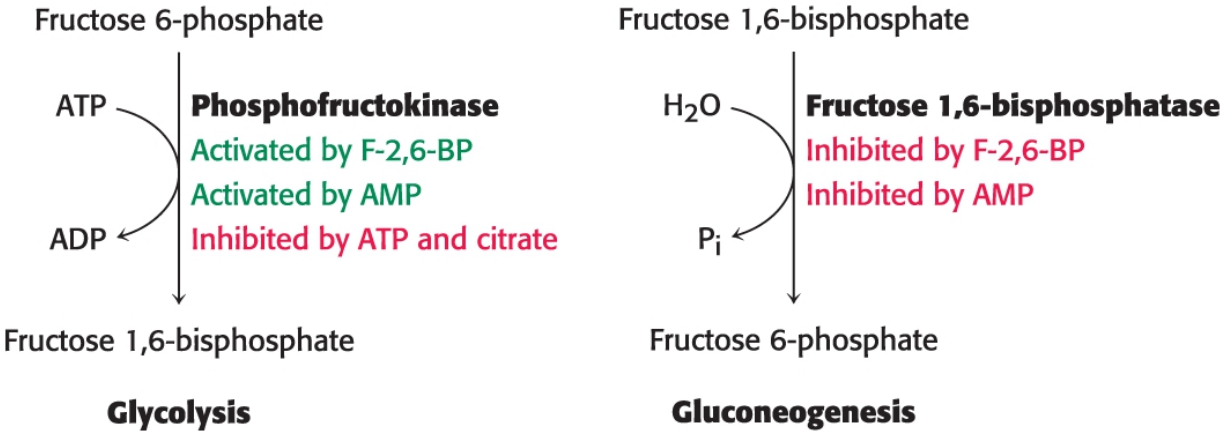
Increased fatty acid oxidation.

Decreased lipid accumulation.

An arrow from this rectangle points toward increased insulin sensitivity. A double-headed points from increased insulin sensitivity to increased insulin sensitivity inside the adipocyte.

Return to FIGURE 24.4 Adipokines help to maintain systemic lipid and glucose homeostasis

Extended description for FIGURE 24.5 Suppressors of cytokine signaling (S O C S) regulate insulin receptor function



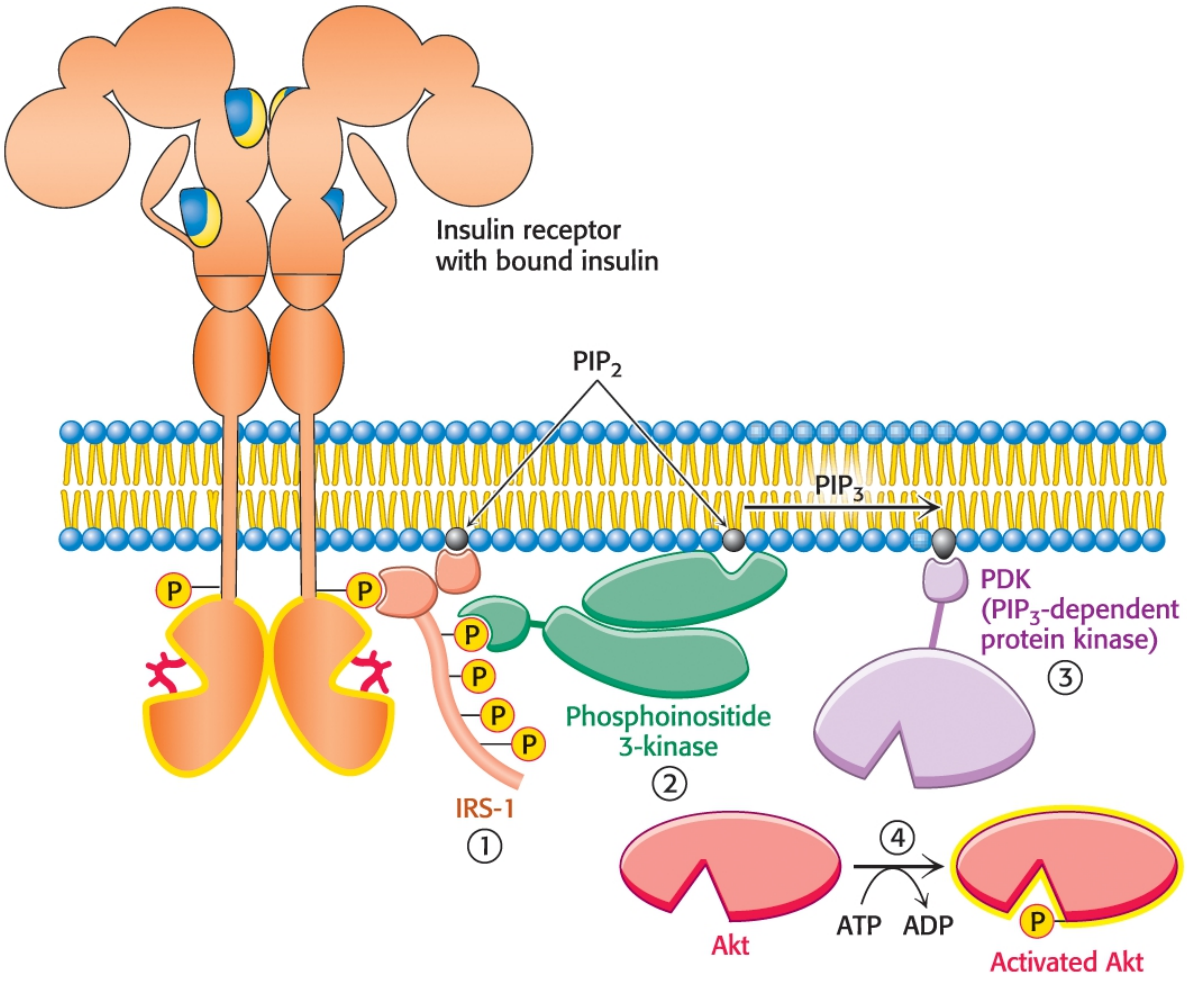
© Macmillan Learning

Part (A): An insulin receptor is embedded in the membrane. It consists of a pair of the transmembrane domain having one and a half oval above the membrane and a long tubular region passing through the membrane. Each tubular region is connected to an oval-shaped structure in the cytoplasm. The oval-shaped structure has a triangular groove. The half-oval of the transmembrane domain is connected to a region composed of one and a half oval and two spheres. The spheres are located at the terminal and oriented downward. The half-oval at the bottom is connected to a small elongated structure through a short tubular region. Insulin is bound to oval structures of the insulin receptor. The long tubular region extending into the cytoplasm is phosphorylated. The triangular groove has a thread-like structure connecting its walls. One of the phosphorylated groups is connected to a small sphere with a long tail labeled I R S-1. The tail contains 4 phosphoryl groups. A forward arrow adjacent to I R S-1 points toward insulin signaling.

Part (B): The insulin receptor is bound to insulin molecules. A blue sphere is bound to the phosphoryl group of the long tubular region in the cytoplasm. This hinders the binding of the small sphere of I R S-1. Four blue spheres are also bound to the phosphoryl groups in the tail of I R S-1. These blue spheres are labeled S C O C S proteins. The forward arrow pointing toward insulin signaling has a cross symbol over it.

Return to FIGURE 24.5 Suppressors of cytokine signaling (S O C S) regulate insulin receptor function

Extended description for FIGURE 24.6 Glycolysis and gluconeogenesis are reciprocally regulated

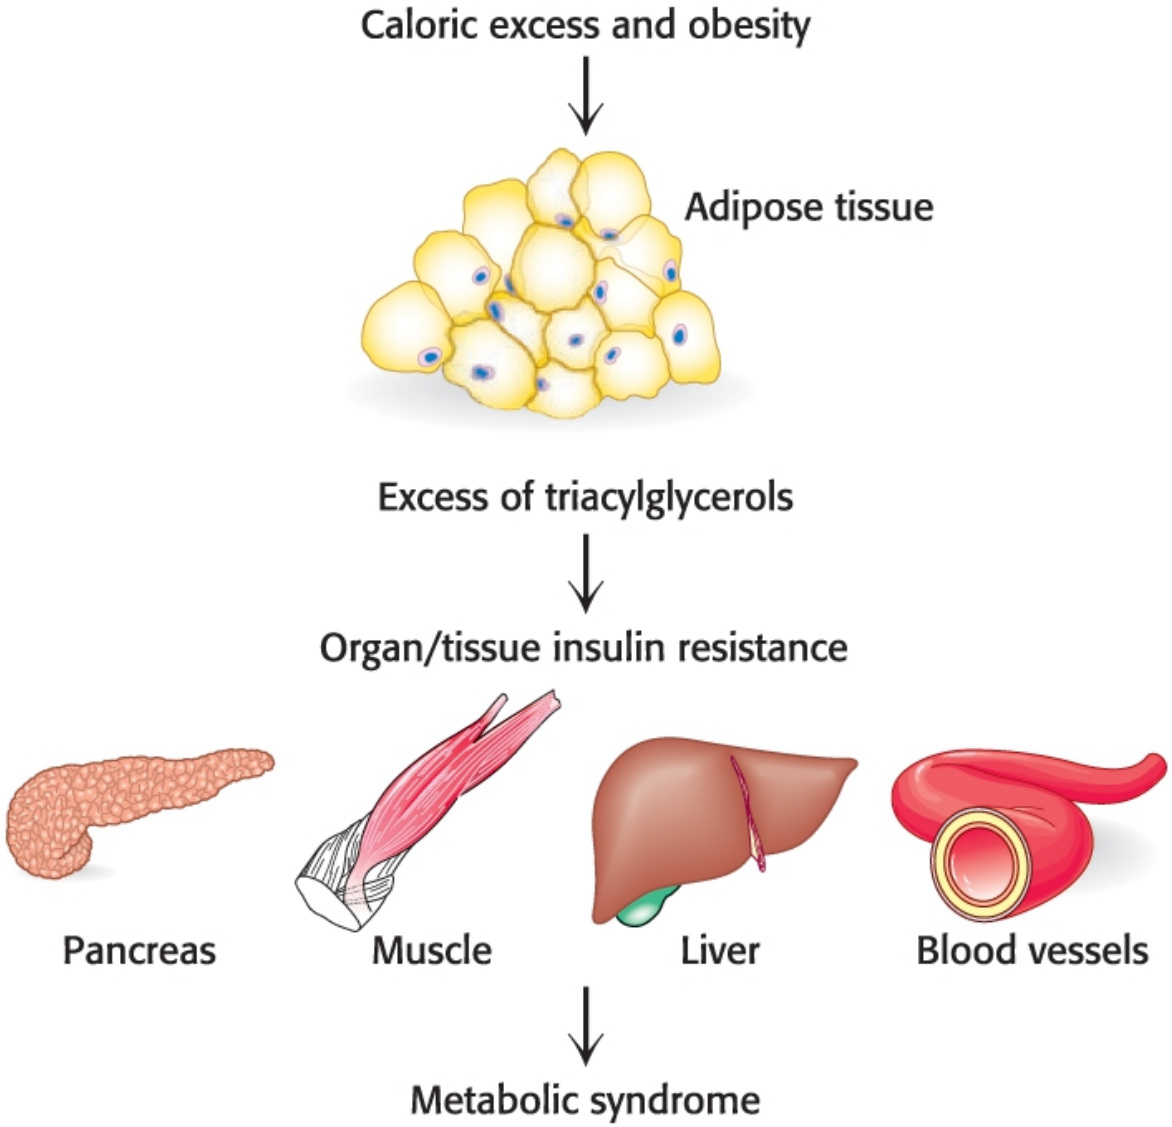


In glycolysis, fructose 6-phosphate is irreversibly converted into fructose 1, 6-bisphosphate with the concomitant hydrolysis of A T P to A D P. This step is catalyzed by phosphofructokinase. It is activated by F-2,6 B P and A M P and inhibited by A T P and citrate.

In gluconeogenesis, fructose 1, 6-bisphosphate is irreversibly converted into fructose 6-phosphate with the concomitant entry of H 2 O and release of P subscript i. This step is catalyzed by fructose 1, 6-bisphosphatase. It is inhibited by F-2, 6-B P and A M P.

Return to FIGURE 24.6 Glycolysis and gluconeogenesis are reciprocally regulated

Extended description for FIGURE 24.7 Insulin signaling activates A k t using the second messenger P I P 3



© Macmillan Learning

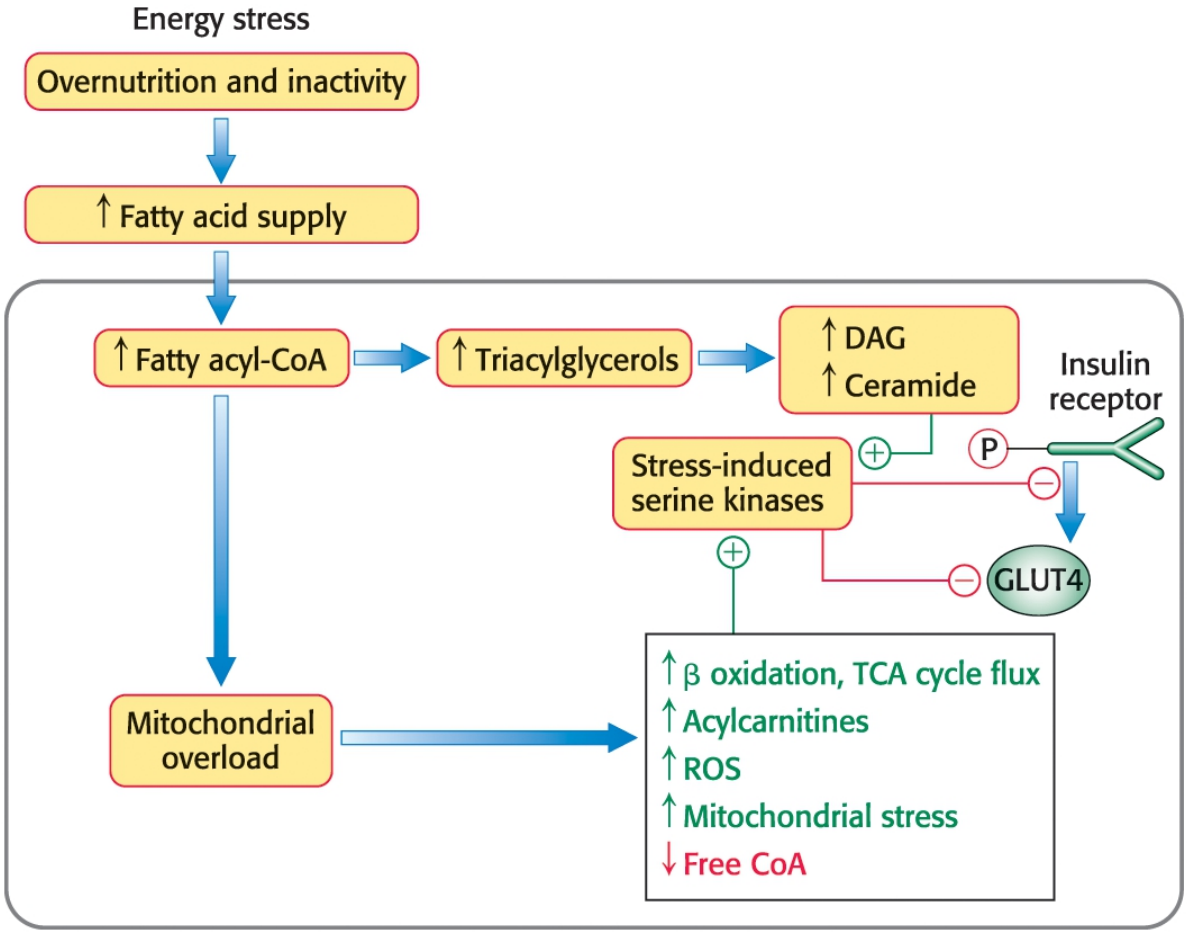
An insulin receptor bound to an insulin molecule is embedded in the membrane. The long tubular region of the receptor extending into the cytoplasm is phosphorylated. I R S-1 with a phosphorylated tail is bound to phosphoryl group on one of the tubular regions. The I R S-1 protein is labeled 1. The small spherical region of I R S-1 is associated with a small structure, which is further associated with P I P 2 in the inner leaflet of the membrane. One of the phosphoryl groups of the I R S-1 tail is bound by phosphoinositide 3-kinase

labeled 2. The phosphoinositide 3-kinase consists of three subunits. One small subunit is bound to the phosphoryl group on the tail of I R S-1. It is connected to a long subunit through a short and narrow bridge. The long subunit is associated with a long and horizontal oval subunit with a tiny triangular groove. The triangular groove is associated with P I P 2 in the inner leaflet of the membrane. The phosphoinositide 3-kinase converts P I P 2 into P I P 3. This P I P 3 in the inner leaflet is bound by P D K (P I P 3-dependent protein kinase) labeled 3. P D K is composed of a small subunit associated with P I P 3 and a large oval subunit connected to it through a short and narrow bridge. This oval-subunit of P D K causes the conversion of A k t to activated A k t by phosphorylation. A k t is depicted as a long oval having a triangular groove. A forward arrow labeled 4 leads to activated A k t in which the groove is bonded to a phosphoryl group. This conversion is coupled with the breakdown of A T P to A D P.

Return to FIGURE 24.7 Insulin signaling activates A k t using the second messenger P I P 3

Extended description for FIGURE 24.8 The storage capacity of fat tissue can be exceeded in obesity

© Macmillan Learning



The flowchart is depicted as follows:

A downward arrow from caloric excess and obesity leads to adipose tissue depicted as a cluster of cells with irregular borders. The adipose tissue has an excess of triacylglycerols. A downward arrow

from adipose tissue leads to organ slash tissue insulin resistance. Under organ slash tissue insulin resistance, four different organs like pancreas, muscle, liver, and blood vessels are shown. A downward arrow from these organs leads to metabolic syndrome.

Return to FIGURE 24.8 The storage capacity of fat tissue can be exceeded in obesity

Extended description for FIGURE 24.9 Excess fat can disrupt signal-transduction pathways and lead to insulin insensitivity

© Macmillan Learning

A yellow rectangle with the text "Overnutrition and inactivity" is labeled energy stress on the top. Overnutrition and inactivity lead to increased fatty acid supply. A downward arrow from increased fatty acid supply points to increased fatty acyl-C o A inside a large rectangle. The remaining pathway is shown inside the large rectangle. Increased fatty acyl-C o A leads to increased triacylglycerols and mitochondrial overload. Increased triacylglycerol leads to increased D A G and ceramide. The increased

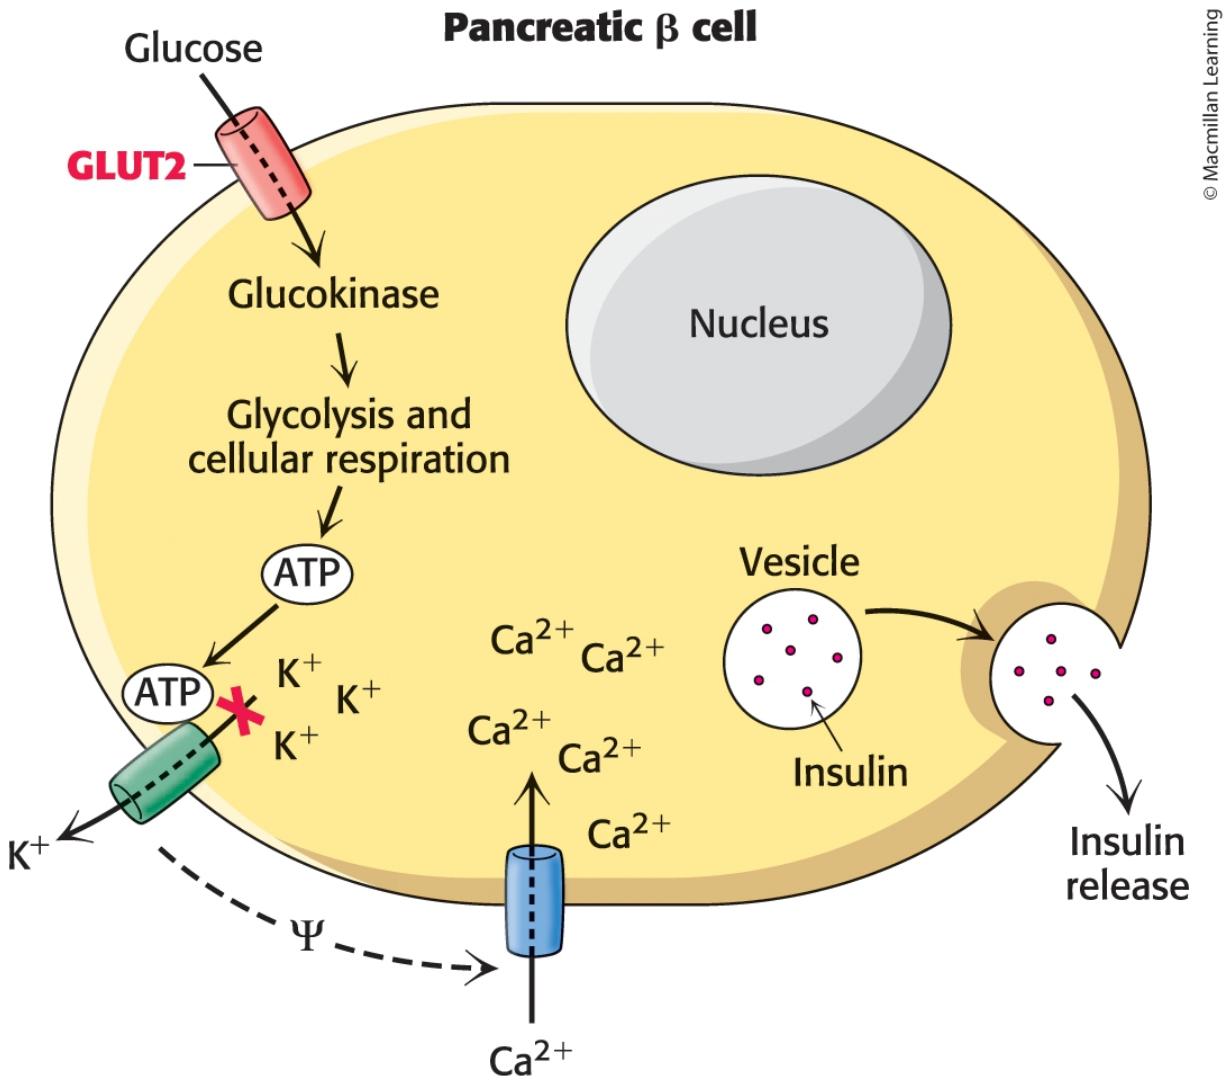
D A G and ceramide have a stimulatory effect on stress-induced serine kinases. The stimulatory effect is depicted by a plus symbol. The stress-induced serine kinases have an inhibitory effect on the action of phosphorylated insulin receptors, depicted as a Y-shaped structure bonded to P inside a circle, on G L U T 4 and G L U T 4 itself. The inhibitory effect is depicted by a minus symbol.

Mitochondrial overload leads to different effects listed below:

Increased beta-oxidation, T C A cycle flux.

Increased acylcarnitines.

Increased R O S.



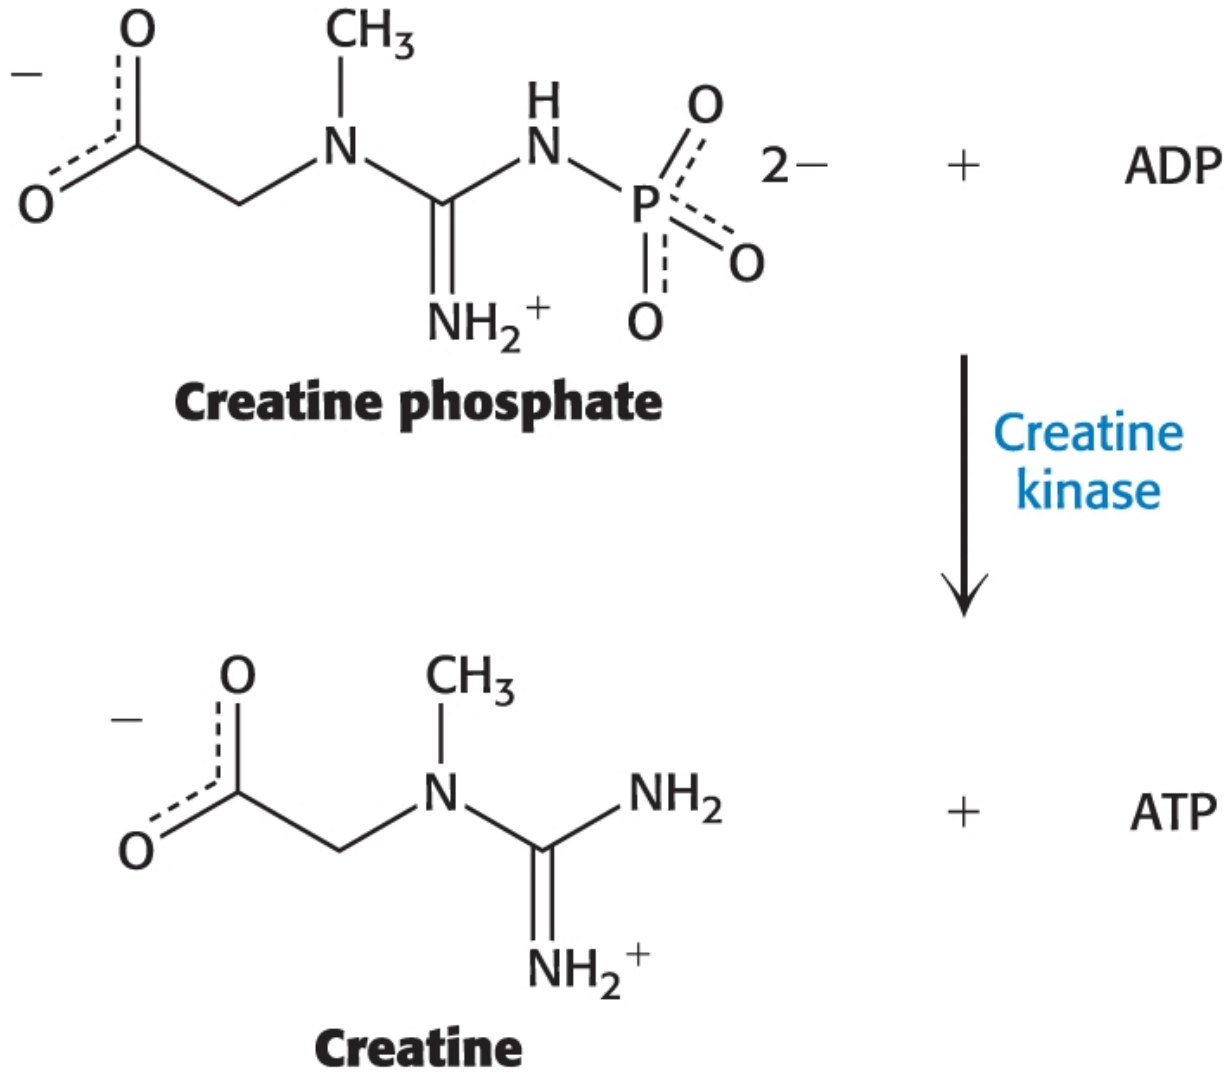
Increased mitochondrial stress.

Decrease free C o A.

All the effects listed above have a stimulatory effect on stress-induced serine kinases.

Return to FIGURE 24.9 Excess fat can disrupt signal-transduction pathways and lead to insulin insensitivity

Extended description for FIGURE 24.10 Insulin release by the pancreas is regulated by blood-glucose concentration, using A T P as a second messenger



The pancreatic beta cell is depicted as a large capsule-shaped structure containing a large nucleus. A cylindrical channel on the cell surface is labeled G L U T 2. Glucose enters the pancreatic beta cell through G L U T 2. It activates glucokinase which leads to glycolysis and cellular respiration and ultimately A T P production.

A T P binds to another cylindrical channel on the cell surface. This channel is normally responsible for the transport of K superscript ions outside the cell. However, A T P binding to this channel prevents K superscript plus ion transport. A dashed arrow labeled psi points toward another channel on the cell surface which begins transporting C a superscript 2 plus ion inside the cell. The number of C a superscript 2 plus ions inside the cell increases. A vesicle containing insulin depicted as tiny dots fuses with the cell surface to release insulin.

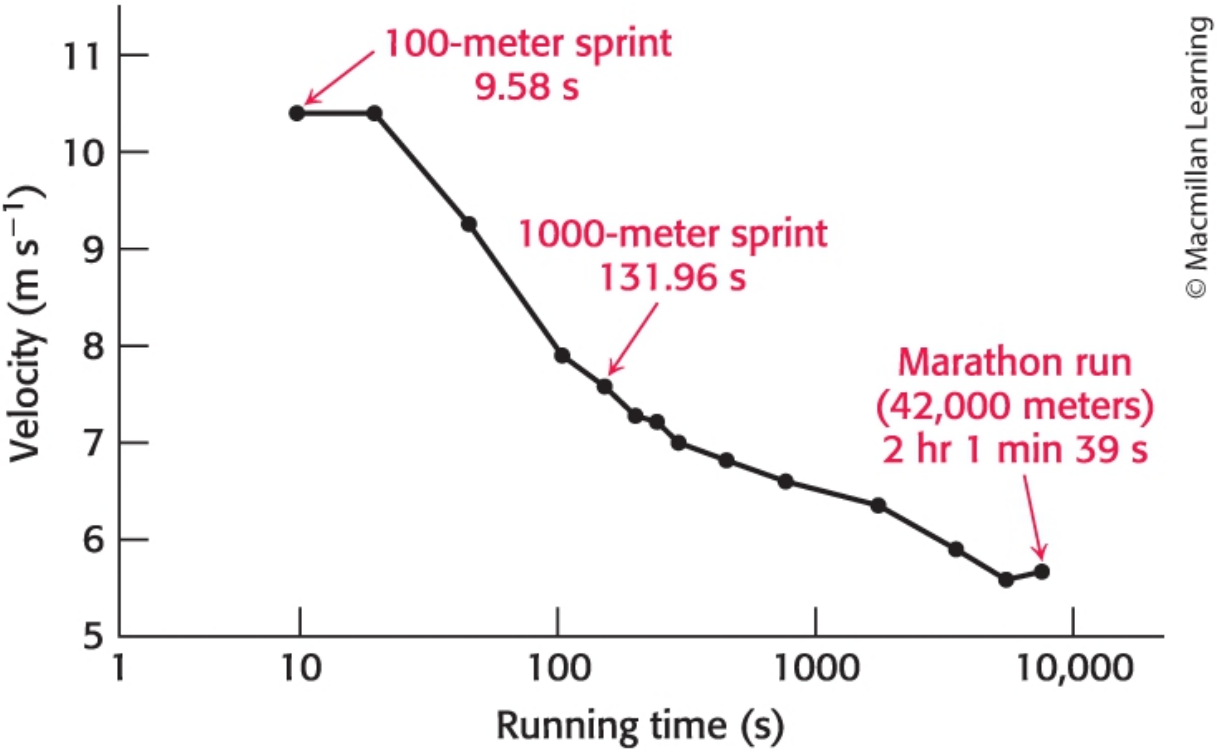
Return to FIGURE 24.10 Insulin release by the pancreas is regulated by blood-glucose concentration, using A T P as a second messenger

Extended description for Irreversible reaction catalyzed by creatine kinase

The reaction consists of two reactants and two products. It is catalyzed by creatine kinase.

The first reactant is creatine phosphate whose structure is as follows: A 2 N and 3 C heteronuclear alkane chain is depicted as a line structure using 4 zigzag lines. First N occupies the third position

and the second N bound to H occupies the fifth position. C 1 is partially double bonded to O above and O on the lower left. The O atoms have an overall negative charge. N 1 is single bonded to C H 3 above. C 3 is double bonded to N H 2 superscript plus below. N 2 is single bonded to P on the lower right. P is partially double bonded to O on the upper right, O on the lower right, and O below. The O atoms have an overall negative charge of 2 minus.



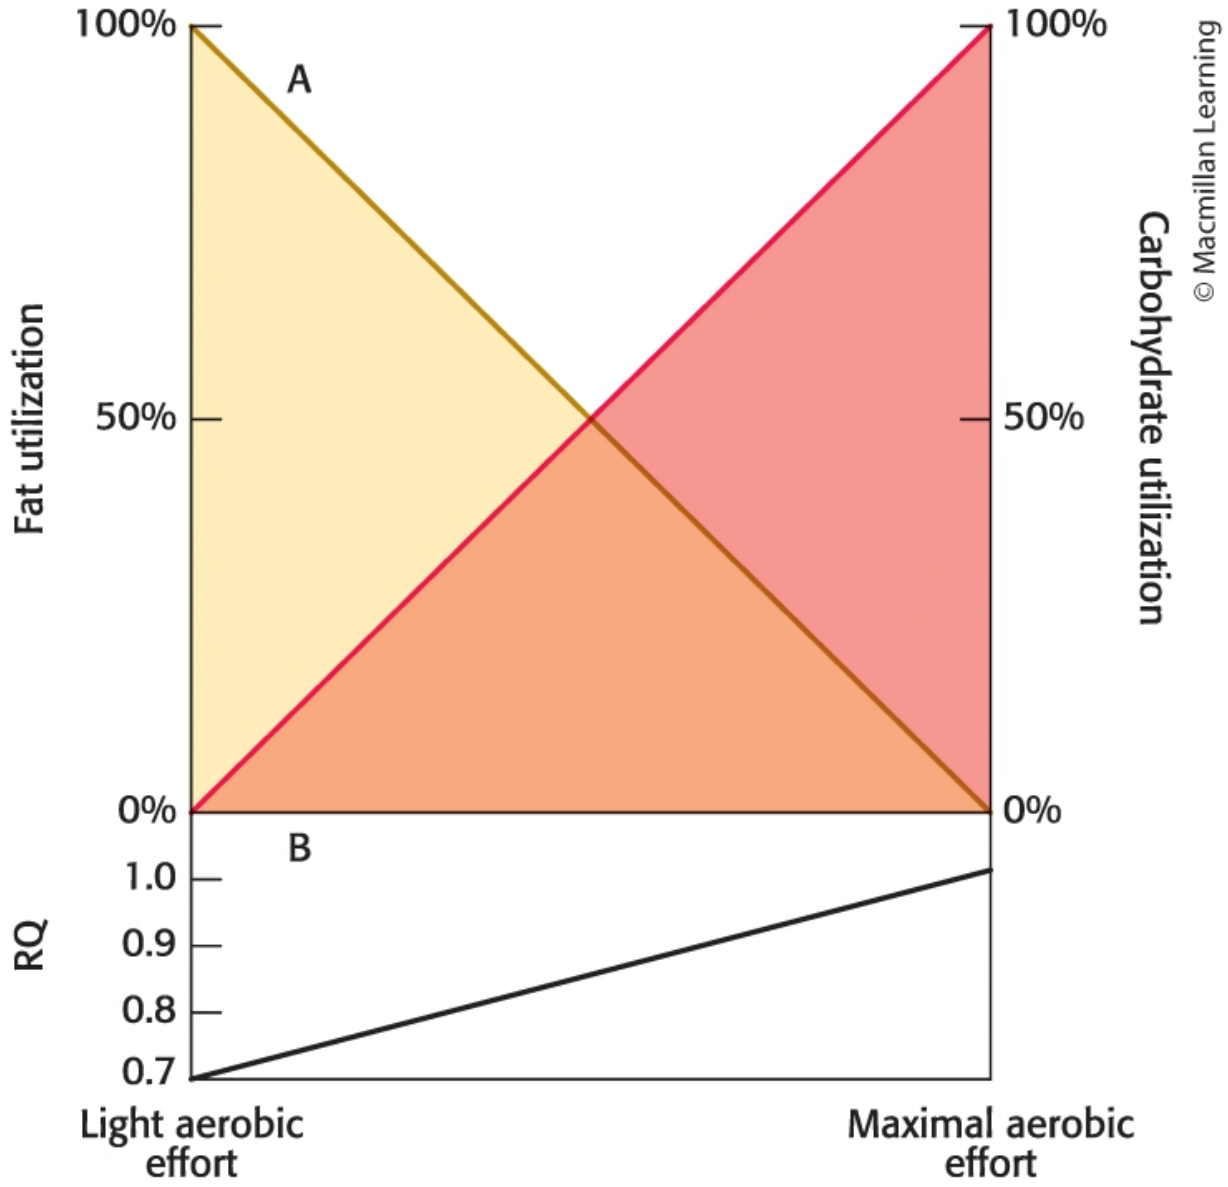
The second reactant is A D P.

The first product is creatine whose structure is as follows: A 1 N and 3 C heteronuclear alkane chain is depicted as a line structure using 3 zigzag lines. N occupies the third position. C 1 is partially double bonded to O above and O on the lower left. The O atoms have an overall negative charge. N is single bonded to C H 3 above. C 3 is double bonded to N H 2 superscript plus below and single bonded to N H 2 on the upper right.

The second product is A T P.

Return to Irreversible reaction catalyzed by creatine kinase

Extended description for FIGURE 24.11 Running velocity decreases dramatically as a function of the duration of the race

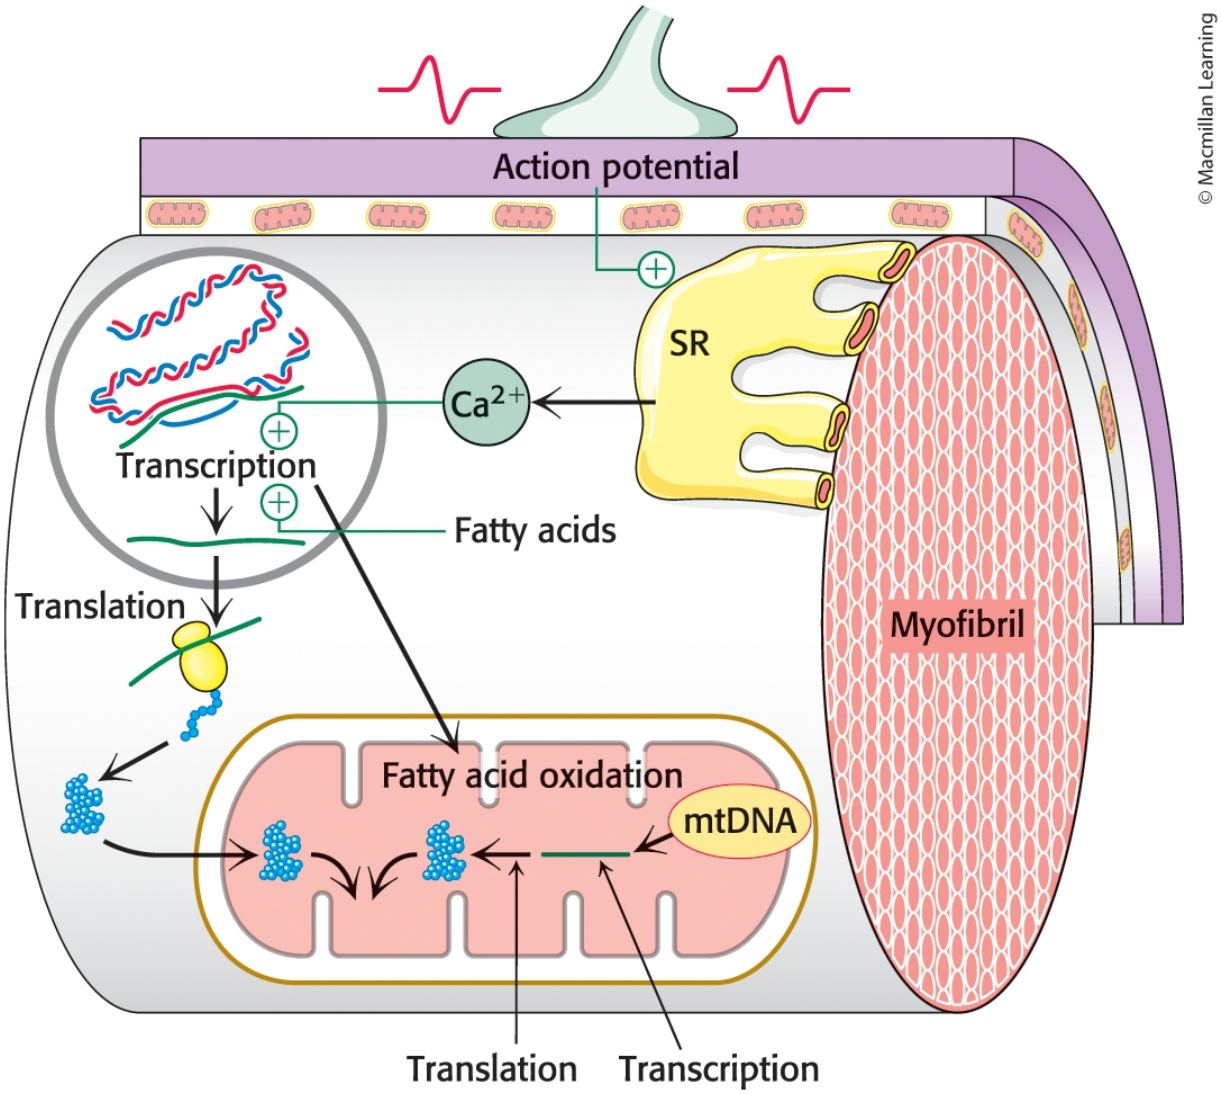


© Macmillan Learning

The horizontal axis is labeled running time in seconds. It has markings 1, 10, 100, 1000, and 10,000. The vertical axis is labeled velocity in meters per second. It has markings ranging from 5 to 11 in increments of 1 unit. The graph contains a black curve. The curve starts at (9.58, 10.5), moves horizontally toward (30, 10.5), and then falls to (7,299, 5.8). Several data points are shown on the curve and three of them are highlighted. The data point (9.58, 10.5) is labeled 100-meter sprint 9.58 seconds. The data point (131.96, 7.6) is labeled 100-meter sprint 131.96 seconds. The data point (7,299, 5.99) is labeled marathon run (42,000 meters) 2 hour 1 minute 39 seconds. All values are estimated.

Return to FIGURE 24.11 Running velocity decreases dramatically as a function of the duration of the race

Extended description for FIGURE 24.12 An idealized representation of fuel use and RQ illustrates major changes as a function of aerobic exercise intensity



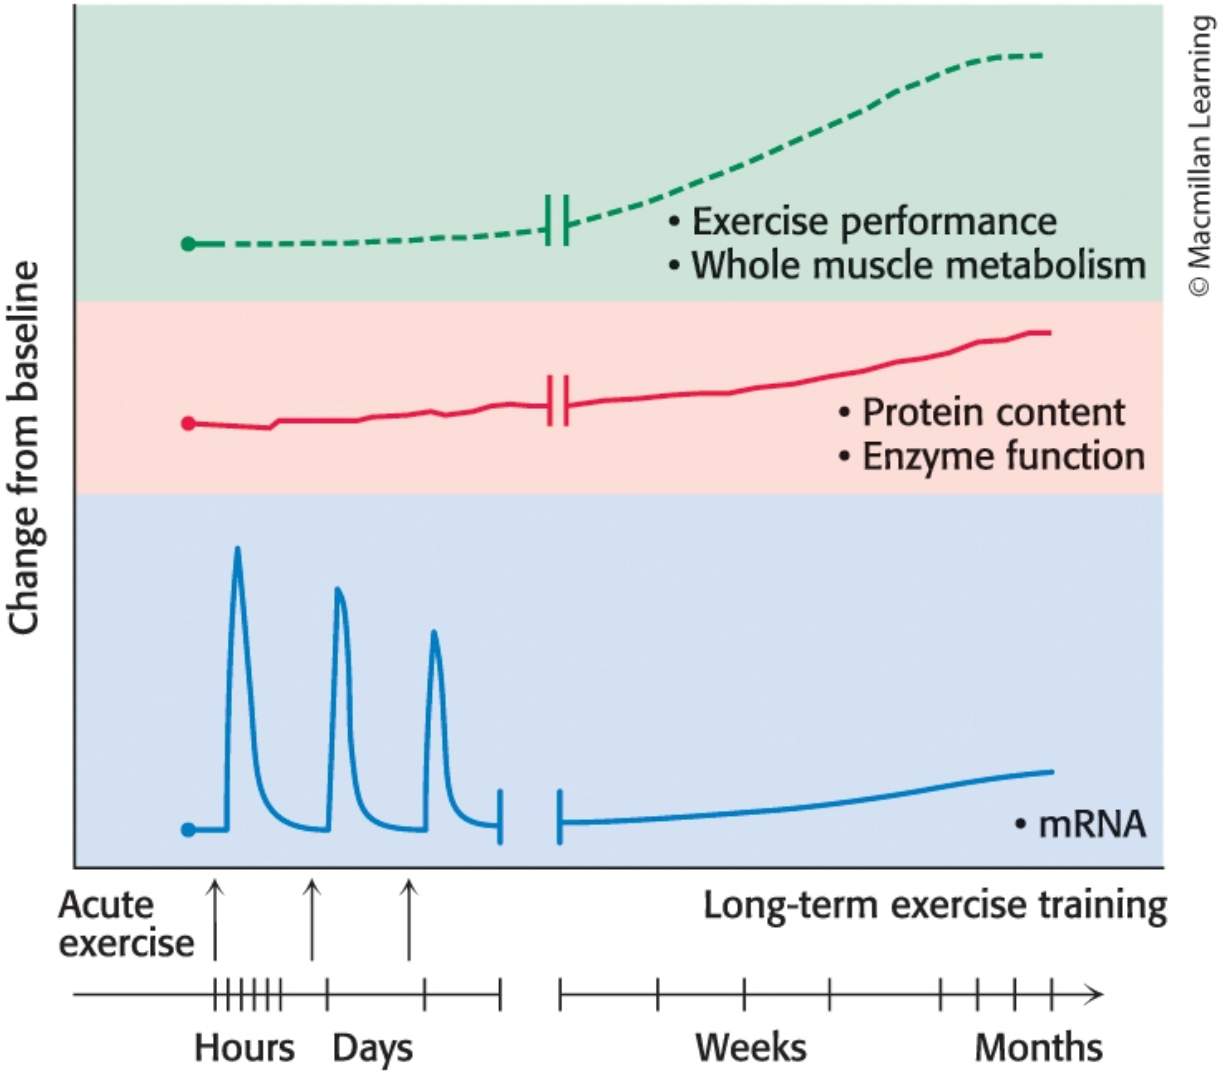
Part (A): The left vertical axis is labeled fat utilization. It has markings ranging from 0 percent to 100 percent in increments of 50 units. The right vertical axis is labeled carbohydrate utilization. It

has markings ranging from 0 to 100 percent in increments of 50 units. The horizontal axis has two markings on the extreme left and extreme right ends labeled light aerobic effort and maximal aerobic effort. A yellow decreasing line starts at 100 percent fat utilization in response to the light aerobic effort. It moves toward the lower right to reach 0 percent fat utilization in response to the maximal aerobic effort. A red decreasing line starts at 100 percent carbohydrate utilization in response to the maximal aerobic effort. It moves toward the lower left to reach 0 percent carbohydrate utilization in response to the light aerobic effort. The area under the yellow line is shown in yellow and the area under the red line is shown in red. The common triangular region below the intersection point of the two lines is shown in orange.

Part (B): The vertical axis for R Q has markings ranging from 0.7 to 1.0 in increments of 0.1 units. The horizontal axis has two markings on the extreme left and extreme right ends labeled light aerobic effort and maximal aerobic effort. An increasing straight line starts at 0. 7 R Q in response to the light aerobic effort. It moves toward the upper right to reach 1.1 R Q in response to the maximal aerobic effort.

Return to FIGURE 24.12 An idealized representation of fuel use and RQ illustrates major changes as a function of aerobic exercise intensity

Extended description for FIGURE 24.13 Exercise results in mitochondrial biogenesis and enhanced fat metabolism



© Macmillan Learning

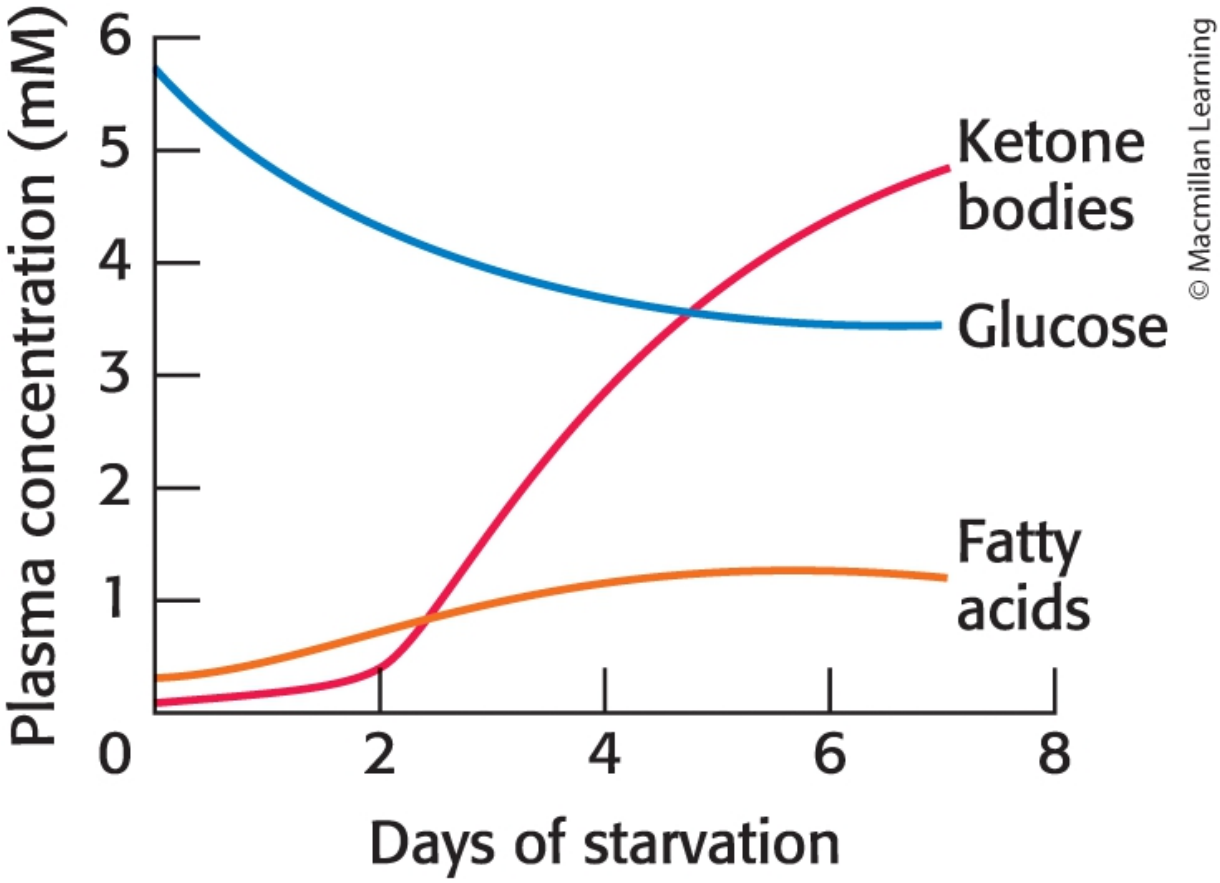
The myofibril is depicted as a thick horizontal cylindrical structure. Its cross-section on the right end shows vertical arrays of tiny circles. The myofibril is surrounded by a half-cut curved thick sheet containing several mitochondria. Another thick curved sheet is located above this sheet with an axon terminal attached to it for

transmission of the action potential. The action potential is also depicted as a zigzag curve. The action potential has a stimulatory effect on the sarcoplasmic reticulum (S R) depicted as a yellow irregular-shaped structure with tubular extensions. In response to stimulation, S R releases C a superscript 2 plus ions. The C a superscript 2 plus ion and fatty acids stimulate gene transcription in the nucleus containing double helical D N A. The transcribed m R N A moves to the sarcoplasm where it undergoes translation by ribosomes. The protein product of translation enters the mitochondria. Inside the mitochondria, the mitochondrial D N A also undergoes transcription followed by translation to produce proteins. The protein transported from outside and the protein produced in the mitochondria together promote mitochondrial biogenesis. Simultaneously, the genes stimulated by fatty acid in the nucleus promote fatty acid oxidation in the mitochondria.

Return to FIGURE 24.13 Exercise results in mitochondrial biogenesis and enhanced fat metabolism

Extended description for FIGURE 24.14 Biochemical adaptations to exercise vary over a range of time scales

The horizontal axis contains markings for hours, days, weeks, and months from left to right. There are 6 closely spaced markings for hours, 3 widely spaced markings for days, four widely spaced markings for weeks, and four closely spaced markings for months. The hours and days markings represent acute exercise. The weeks and months markings represent long-term exercise training. The



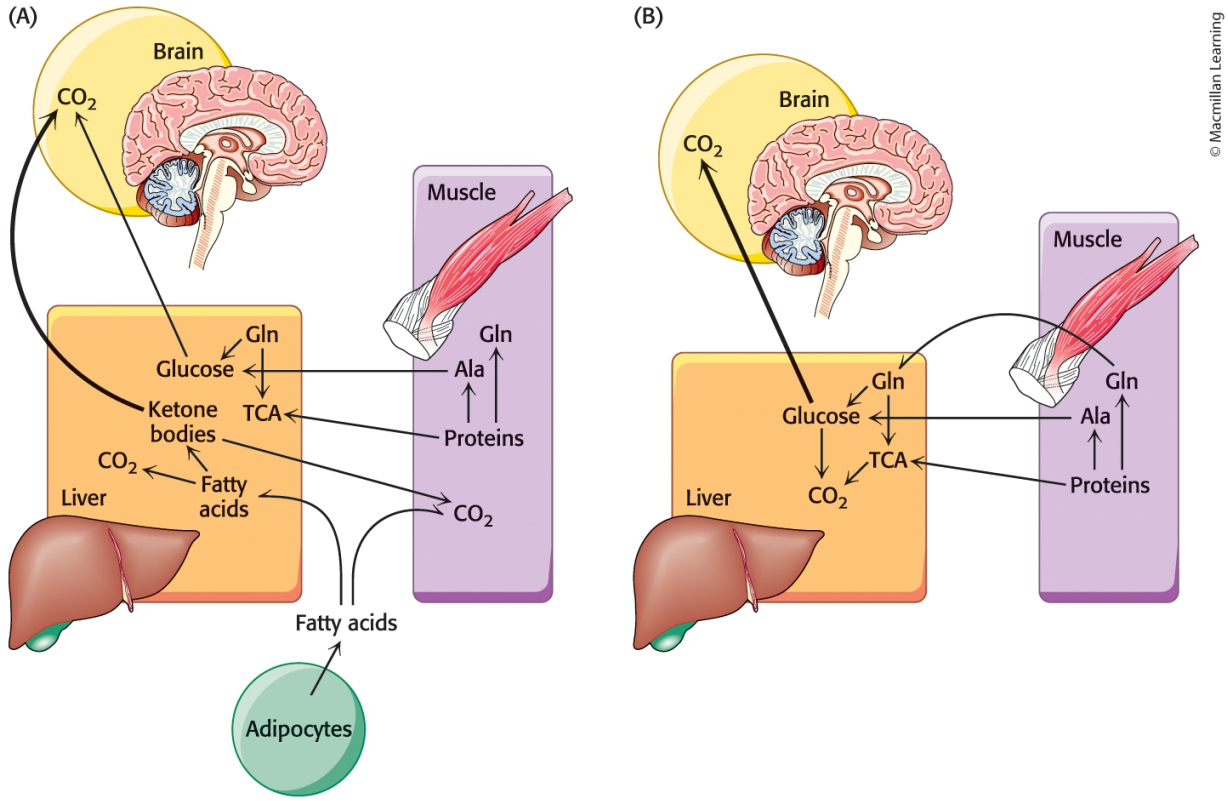
vertical axis is labeled change from baseline. The graph area is divided into three sections from top to bottom. The bottom section shown in blue depicts m R N A synthesis. During the acute exercise phase, a blue curve starts slightly above the baseline and moves horizontally till the second hour's markings. It then forms three peaks having a progressively shorter height from left to right. The peaks are separated by short baseline stretches. The first peak is formed between the second and fourth hours markings, the second peak is formed closer to the first-day marking, and the third peak is formed closer to the second-day marking. There is a break in the curve after the third-day marking. During long-term exercise training, a curve starts slightly above the baseline and slightly rises as it moves toward the right.

The middle section shown in red depicts protein content and enzyme function. It contains a red curve that starts much above the baseline during acute exercise. It moves toward the right almost horizontally. A break is shown in the curve between the third day marking and the first week marking. The curve rises gradually toward the upper right during long-term exercise training across weeks and months.

The top section shown in green depicts exercise performance and whole muscle metabolism. It contains a green dashed curve. It starts slightly above the baseline during acute exercise and moves horizontally toward the right. A break is shown in the curve between the third-day marking and the first-week marking. During the long-term exercise training, the curve rises linearly toward the upper right and then forms a plateau between second and fourth-months markings.

Return to FIGURE 24.14 Biochemical adaptations to exercise vary over a range of time scales

Extended description for FIGURE 24.15 The blood concentrations of ketone bodies glucose, and fatty acids during starvation

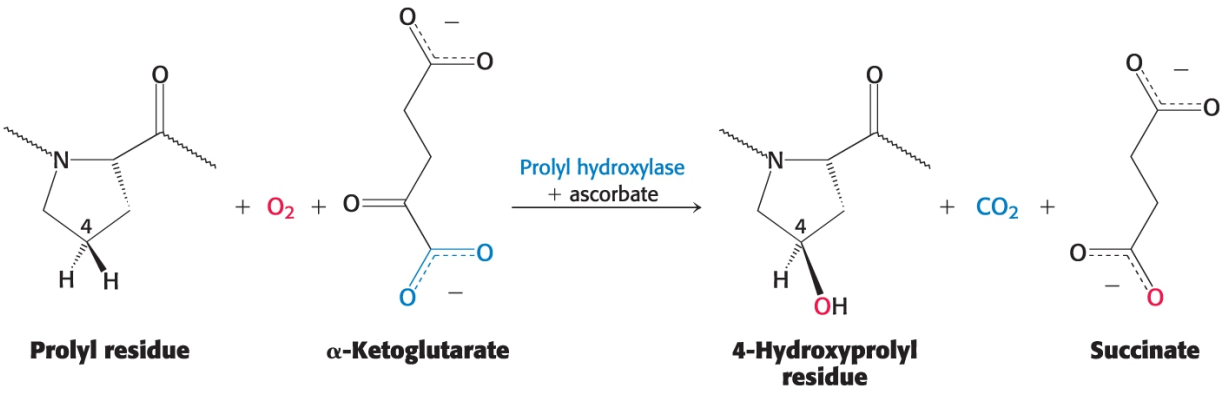


The horizontal axis is labeled days of starvation. It has markings ranging from 0 to 8 in increments of 2 units. The vertical axis is labeled plasma concentration in millimolar. It has markings ranging from 0 to 6 in increments of 1 unit. The graph contains three curves shown in orange, blue, and red. The orange curve depicts the concentration of fatty acids. It starts at (0, 0.2) and slightly rises to (7, 1.2) as it moves toward the right. The blue curve depicts glucose concentration. It starts at (0, 5.8) and falls down in a concave-up manner to reach (7, 3.6). The red curve depicts ketone bodies. It

starts at (0, 0), moves almost horizontally till (2, 0.1), and then starts rising toward the upper right in a concave-down manner to reach (7, 5). All values are estimated.

Return to FIGURE 24.15 The blood concentrations of ketone bodies glucose, and fatty acids during starvation

Extended description for FIGURE 24.16 Fuel use during prolonged starvation changes after fat mass is depleted



Part (A): A green circle labeled adipocytes releases fatty acids. The fatty acids are distributed to the muscle depicted as a long purple vertical rectangle and the liver depicted as an orange square. In the muscle, fatty acids are converted into C O 2. In the liver, fatty acids give rise to C O 2 and ketone bodies. The ketone bodies travel to the brain depicted as a yellow circle. Inside the brain, ketone bodies are broken down to generate C O 2. Simultaneously, in the muscle proteins are broken down to release amino acids like glutamine and alanine. These amino acids and proteins travel to the liver. In the liver, alanine gives rise to glucose and proteins enter the T C A. Glutamine can be converted into glucose or enter T C A. The glucose

produced in the liver also travels to the brain, where it is broken down to generate C O 2. A diagram of the organ is also shown alongside each depiction of the organ.

Part (B): In the muscle, proteins are broken down to release amino acids like glutamine and alanine. These amino acids and proteins travel to the liver. In the liver, alanine gives rise to glucose and proteins enter the T C A. Glutamine can be converted into glucose or enter T C A. The glucose produced in the liver also travels to the brain, where it is broken down to generate C O 2. The glucose is also broken down to generate C O 2 inside the liver. A diagram of the organ is also shown alongside each depiction of the organ.

Extended description for FIGURE 24.17 Formation of 4-hydroxyproline requires ascorbate

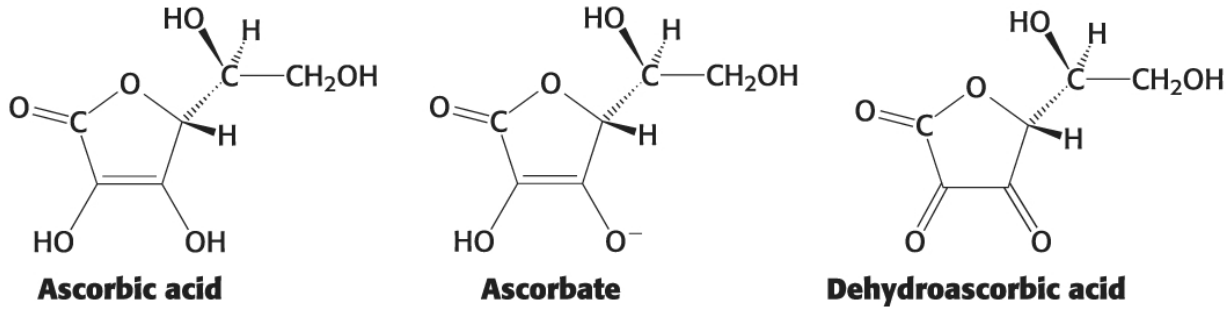
The reaction consists of three reactants and three products. It is catalyzed by prolyl hydroxylase plus ascorbate.

The first reactant is prolyl residue whose structure is as follows: A central C atom is double bonded to O above, single bonded to C H 2 on the lower left in the form of a line. It has a wiggly line on the lower right. C H 2 is single bonded to N on the left and dash bonded to C 3 of a 3-carbon alkane chain depicted as a line structure using 2 zigzag lines. N atom has a wiggly line on the upper left and is single-bonded to C 1 of the alkane chain. In the alkane chain, C 2 is numbered 4 and it is dash bonded to H on the lower left and wedge bonded to H on the lower right. The alkane chain, N atom, and C H 2 group form a pentagonal ring-like structure.

The second reactant is O 2.

The third reactant is alpha-ketoglutarate whose structure is as follows: A 5-carbon alkane chain is depicted as a vertical line structure using 4 zigzag lines. C 1 is partially double-bonded to O on the upper left and O on the right. The O atoms have an overall

negative charge. C 4 is double bonded to O on the left. C 5 is partially double bonded to O on the right and O on the lower left. The O atoms have an overall negative charge.



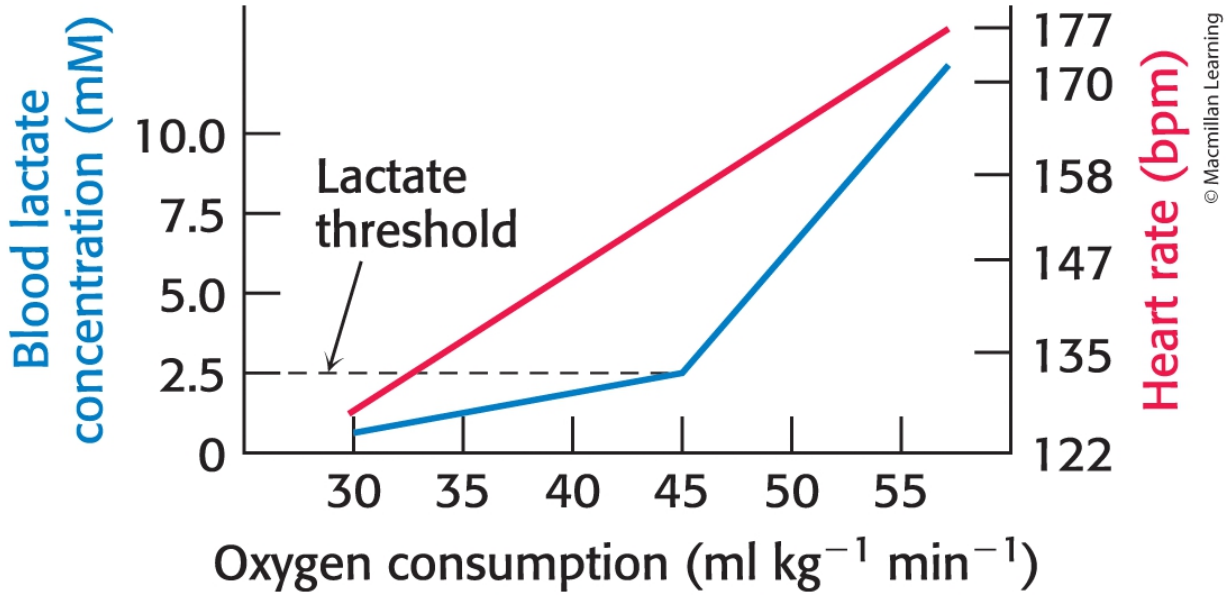
The first product is a 4-hydroxyprolyl residue whose structure is as follows: A central C atom is double bonded to O above, single bonded to C H 2 on the lower left in the form of a line. It has a wiggly line on the lower right. C H 2 is single bonded to N on the left and dash bonded to C 3 of a 3-carbon alkane chain depicted as a line structure using 2 zigzag lines. N atom has a wiggly line on the upper left and is single-bonded to C 1 of the alkane chain. In the alkane chain, C 2 is numbered 4 and it is dash bonded to H on the lower left and wedge bonded to O H on the lower right. The alkane chain, N atom, and C H 2 group form a pentagonal ring-like structure.

The second product is C O 2.

The third product is succinate whose structure is as follows: A 4-carbon alkane chain is depicted as a vertical line structure using 3 zigzag lines. C 1 is partially double-bonded to O on the upper left and O on the right. The O atoms have an overall negative charge. C 4 is partially double bonded to O on the left and O on the lower right. The O atoms have an overall negative charge.

Return to FIGURE 24.17 Formation of 4-hydroxyproline requires ascorbate

Extended description for Structure of ascorbic acid, ascorbate, and dehydroascorbic acid



The structure of ascorbic acid is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 occupies the top right vertex. A double bond is present between C 2 and C 3. C 1 is dash bonded to C on the upper right and wedge bonded to H on the lower right. The upper right C is wedge bonded to O H on the upper left, dash bonded to H on the upper right, and single bonded to C H 2 O H on the right. C 2 and C 3 are each single bonded to O H below. C 4 is double bonded to O on the upper left.

The structure of ascorbate is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 occupies the top right vertex. A double bond is present between C 2 and C 3. C 1 is dash bonded to C on the upper right and wedge bonded to H on the lower right. The upper right C is wedge bonded to O H on the upper left, dash bonded to H on the upper right, and single bonded to C H 2 O H on the right. C 2 is single bonded to O superscript minus below. C 3 is single bonded to O H below. C 4 is double bonded to O on the upper left.

The structure of dehydroascorbic acid is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 occupies the top right vertex. C 1 is dash bonded to C on the upper right and wedge bonded to H on the lower right. The upper right C is wedge bonded to O H on the upper left, dash bonded to H on the upper right, and single bonded to C H 2 O H on the right. C 2 and C 3 are each double bonded to O below. C 4 is double bonded to O on the upper left.

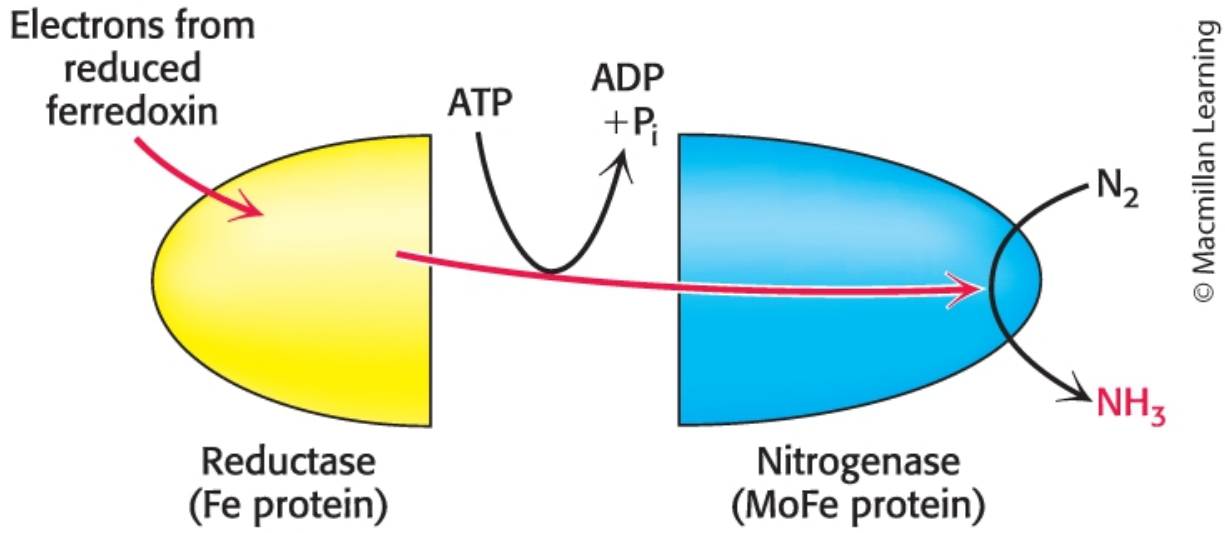
Extended description for Relation between blood-lactate levels, oxygen consumption, and heart rate during exercise of increasing intensity

The horizontal axis is labeled oxygen consumption in milliliters per kilogram per minute. It has markings ranging from 30 to 55 in increments of 5 units. The left vertical axis is labeled blood lactate concentration in millimolar. It has markings ranging from 0 to 10.0 in increments of 2.5 units. The right vertical axis is labeled heart rate in beats per minute. It has markings 122, 135, 147, 158, 170, and 177. The graph contains two curves shown in red and blue. The red curve is a straight increasing line that depicts the variation of heart rate with oxygen consumption. It starts at (30, 128) and moves toward the upper right to reach (56, 177). The blue curve depicts the variation of blood lactate concentration with oxygen consumption. It starts at (30, 0.5), moves toward (45, 2.5), and then rises upward to (56, 13). A horizontal dashed line starting from 2.5 on the left vertical axis touches the blue curve at (45, 2.5) and is labeled lactate threshold. All values are estimated.

Return to Relation between blood-lactate levels, oxygen consumption, and heart rate during exercise of increasing intensity

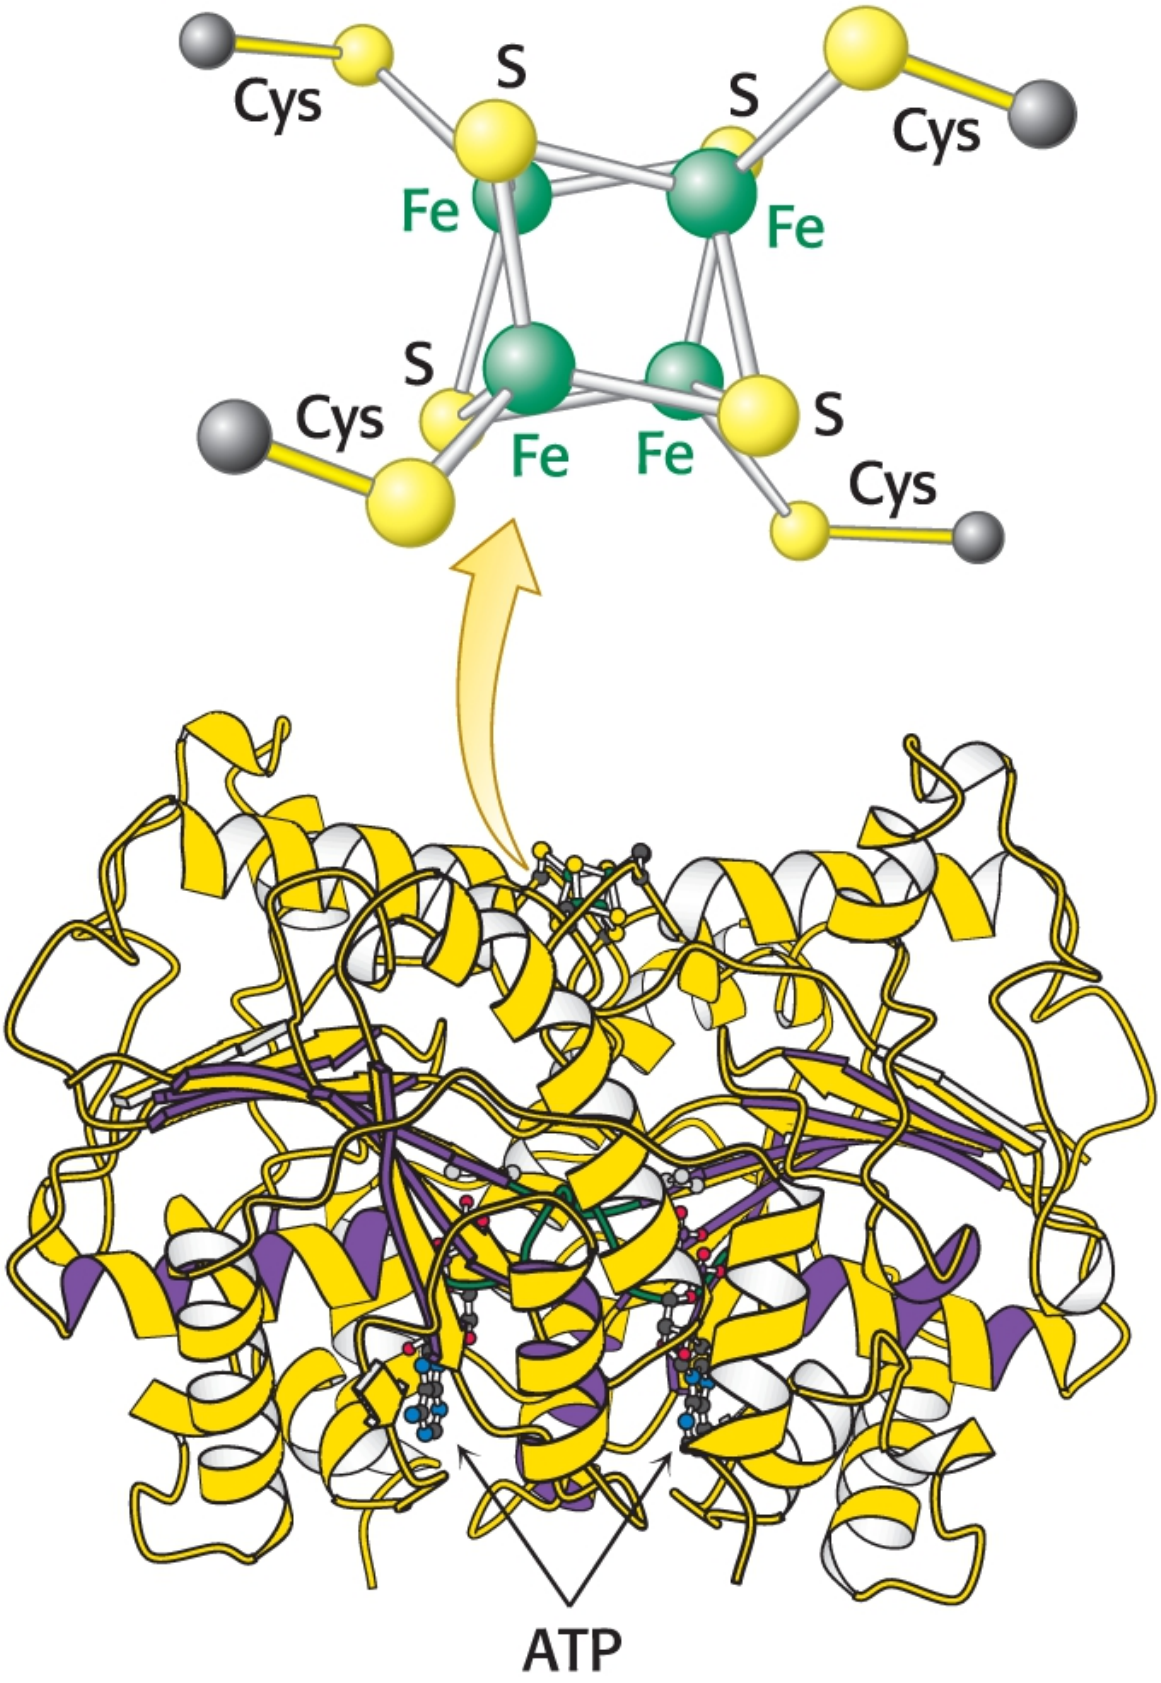


Extended description for Reaction sequence depicting the assimilation of N 2

The reaction sequence shows the conversion of N 2 to glutamate through an N H 3 intermediate. The N 2, N H 3, and glutamate molecules are depicted as ball-and-stick models. N 2 consists of two blue spheres connected by three parallel sticks. N H 3 consists of a central blue sphere connected to a white sphere on the left, upper right, and lower right. Glutamate consists of 5 grey spheres in a vertical zigzag orientation. The first grey sphere is connected to a red sphere on the left and upper right. The second and third grey sphere is connected to two white spheres. The fourth grey sphere is connected to a white sphere at the back and a blue sphere on the lower left. The blue sphere is connected to three white spheres. The fifth grey sphere is connected to two red spheres.

Return to Reaction sequence depicting the assimilation of N 2

Extended description for FIGURE 25.1 The nitrogenase complex fixes nitrogen to ammonia

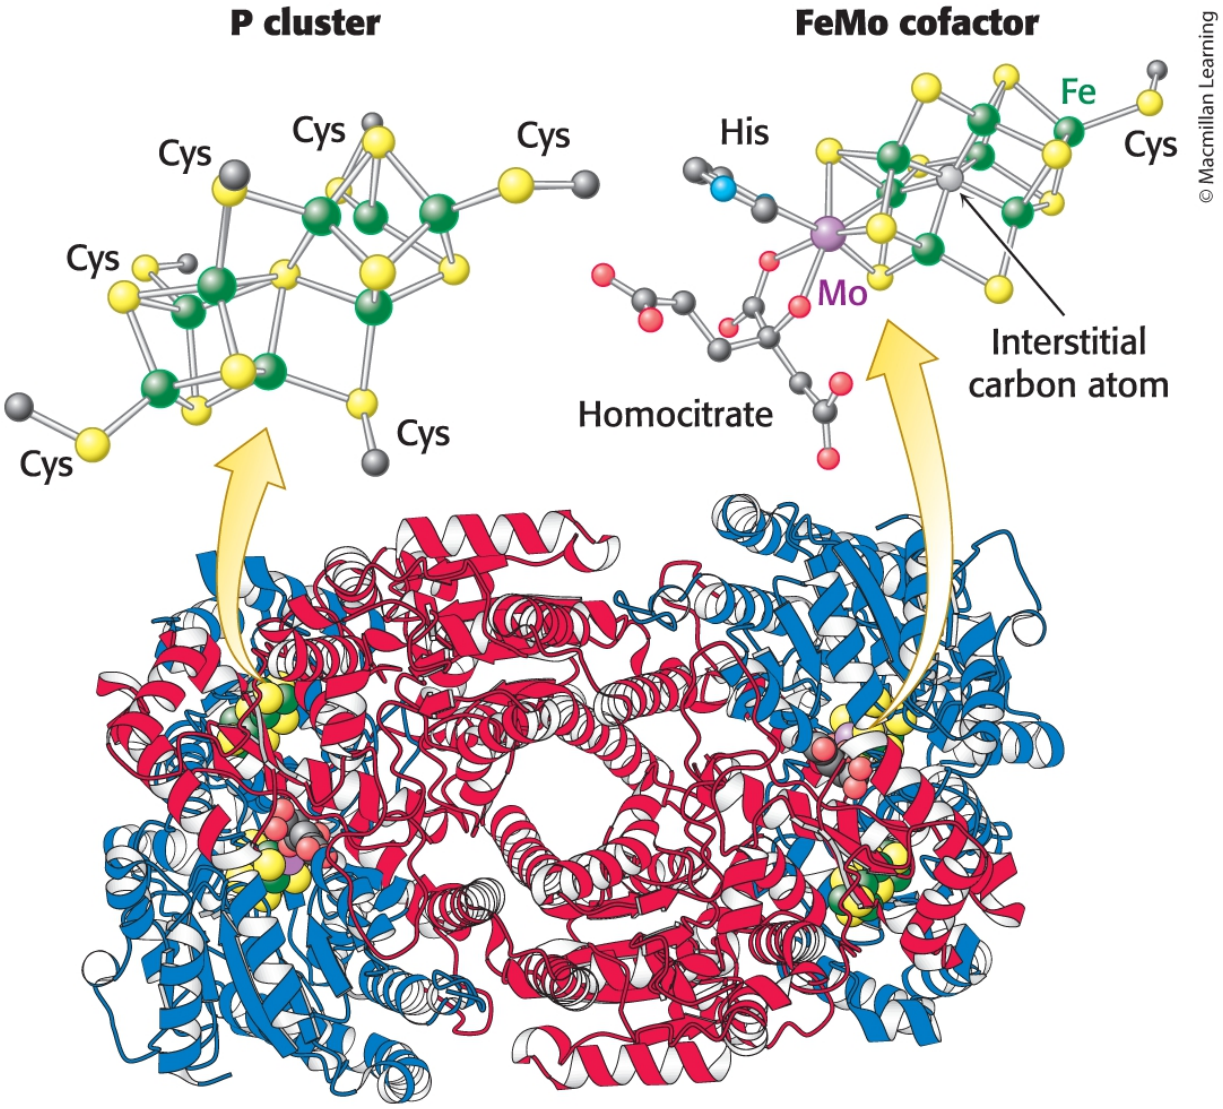


The reductase (F e protein) is depicted as a yellow-colored half-cut circle. The nitrogenase (M o F e protein) is depicted as a blue half-cut oval. Electrons from reduced ferredoxin are transferred to reductase. The reductase then transfers the electrons to nitrogenase, which uses them to convert N 2 to N H 3. The transfer of electrons from reductase to nitrogenase is coupled with the breakdown of A T P to A D P plus P subscript i.

Return to FIGURE 25.1 The nitrogenase complex fixes nitrogen to ammonia

Extended description for FIGURE 25.2 The F e protein, or reductase, transfers elections of high reducing

power



© Macmillan Learning

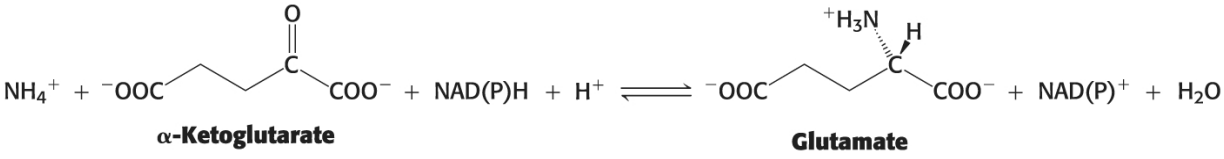
The ribbon diagram consists of two monomers, each composed of several alpha-helices and a few beta-strands in the center. Each monomer is bound to A T P. A ball-and-stick model of 4 F e-4 S cluster connects the two monomers at the top. An arrow shows the enlarged view of the ball-and-stick model of the 4 F e-4 S cluster. It consists of two square-shaped arrangements of F e and S atoms. The F e atoms are depicted as green spheres and the S atoms are depicted as yellow spheres. The front square arrangement consists of a yellow sphere at the top left and bottom right vertex. The green sphere occupies the top right and bottom left vertex. The rear square arrangement consists of a green sphere at the top left and bottom right vertex. The yellow sphere occupies the top right and bottom left vertex. The front and rear square arrangements are not perfectly aligned with each other. Each green sphere is connected to the side chain of cysteine residue depicted as a chain of 1 black and 1 yellow sphere.

Return to FIGURE 25.2 The F e protein, or reductase, transfers elections of high reducing power

Extended description for FIGURE 25.3 The M o F e protein, or nitrogenase, catalyzes the reduction of N 2 to N H 3

The ribbon diagram consists of the heterotetrameric nitrogenase consisting of two alpha-subunits and two beta-subunits. The alpha-subunits are depicted in red color and the beta-subunits are depicted in blue color. Each subunit is composed of several alpha-

helices and a few beta strands. The alpha subunit is located at the top left and bottom right. The beta subunit is located at the top right and bottom left. A few alpha-helices of alpha subunits form a hollow circular arrangement in the center. The alpha-subunit is bound to the P cluster and the beta-subunits are bound to the F e M o cofactor.



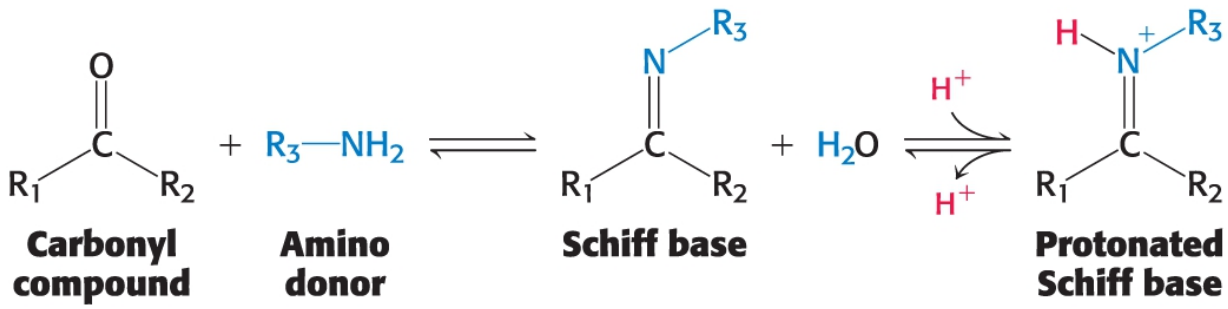
The enlarged views of the ball-and-stick model of the P cluster and F e M o are shown by arrows from the respective subunits.

Each P cluster contains eight F e atoms, depicted as green spheres, and seven S atoms, depicted as yellow spheres, interconnected to form 3 separate cage-like structures. The F e atoms are connected to 6 different cysteine residues of the protein subunit.

The F e M o cofactor contains one molybdenum atom depicted as a purple sphere, seven F e atoms depicted as a green sphere, nine S atoms depicted as yellow spheres, an interstitial carbon atom depicted as a grey sphere, and homocitrate composed of 7 black and 7 red spheres. The F e, S, and the interstitial carbon atom form a cage-like structure with the carbon atom in the center. One of the F e atoms is linked to the protein by a cysteine residue and the molybdenum atom is connected to the histidine residue. The molybdenum atom is connected to two red spheres of homocitrate.

Return to FIGURE 25.3 The M o F e protein, or nitrogenase, catalyzes the reduction of N 2 to N H 3

Extended description for Formation of glutamate



The reaction consists of four reactants and three products.

The first reactant is N H 4 superscript plus. The second reactant is alpha-ketoglutarate whose structure is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the lower left. C 3 is double bonded to O above and single bonded to C O O superscript minus on the lower right. The third reactant is N A D open parenthesis P close parenthesis H. The fourth reactant is H superscript plus.

The first product is glutamate whose structure is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the lower left. C 3 is dash bonded to N H 3 superscript plus on the upper left, wedge bonded to H on the upper right, and single bonded to C O O superscript minus on the lower right. The second product is N A D open parenthesis P close parenthesis with superscript plus. The third product is H 2 O.

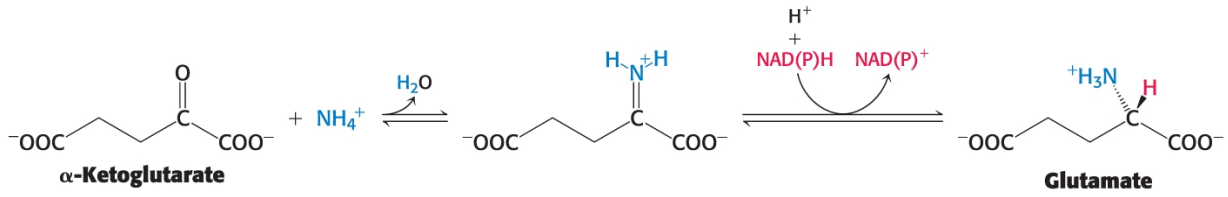
Return to Formation of glutamate

Extended description for Formation of protonated Schiff base

The reaction sequence consists of two reactants, two intermediates, and one product.

The first reactant is a carbonyl compound whose structure is as follows: A central C atom is double bonded to O above, single bonded to R 1 on the lower left, and single bonded to R 2 on the lower right.

The second reactant is an amino donor which consists of R 3, single bond, N H 2.



The first intermediate is Schiff base: A central C atom is single bonded to R 1 on the lower left, double bonded to N above, and single bonded to R 2 on the lower right. The N atom is single-bonded to R 3 on the upper right. The second intermediate is H 2 O.

The intermediate Schiff base is converted into protonated Schiff base after the entry of H superscript plus ion and the protonated Schiff base is converted back to the intermediate Schiff base by the removal of H superscript plus ion. The product is protonated Schiff base whose structure is as follows: A central C atom is single-bonded

to R 1 on the lower left, double-bonded to N superscript plus, and single-bonded to R 2 on the lower right. The N atom is single-bonded to R 3 on the upper right and single-bonded to H on the upper left.

Return to Formation of protonated Schiff base

Extended description for Formation of glutamate from alpha-ketoglutarate

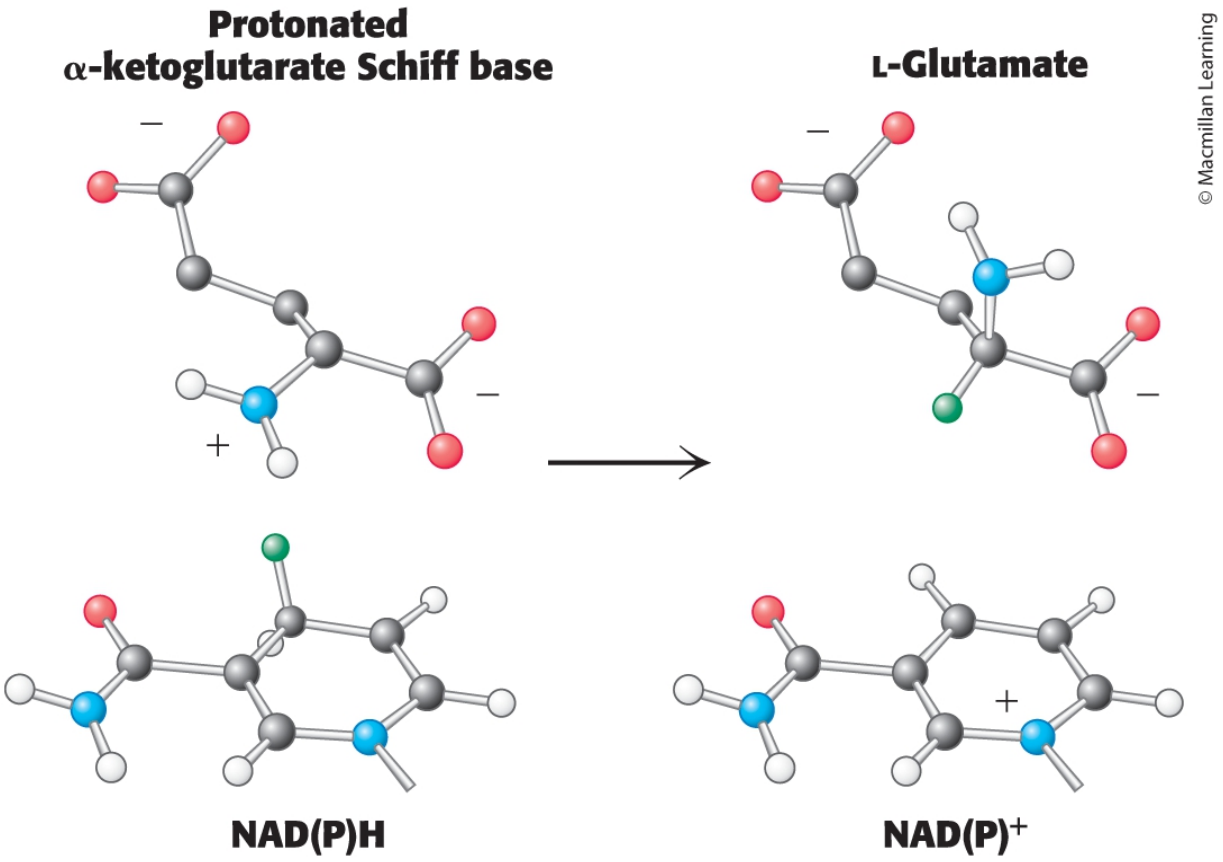
The reaction sequence consists of two reactants, one intermediate, and one product.

The first reactant is alpha-ketoglutarate whose structure is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the lower left. C 3 is double bonded to O above and single bonded to C O O superscript minus on the lower right.

The second reactant is N H 4 superscript plus.

The intermediate is reversibly produced from the reactants with concomitant release of H 2 O.

The structure of the intermediate is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the lower left. C 3 is double bonded to N superscript plus above and single bonded to C O O superscript minus on the lower right. The N superscript plus is single-bonded to H on the upper left and H on the upper right.



The intermediate is reversibly converted into glutamate with the concomitant oxidation of N A D open parenthesis P close

parenthesis H plus H superscript plus into N A D close parenthesis P close parenthesis with superscript plus.

The product is glutamate whose structure is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the lower left. C 3 is dash bonded to N H 3 superscript plus on the upper left, wedge bonded to H on the upper right, and single bonded to C O O superscript minus on the lower right.

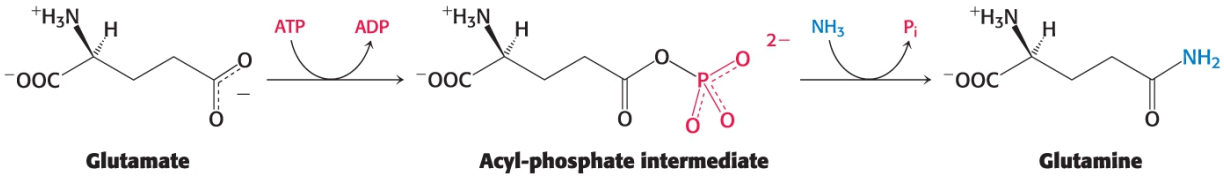
Return to Formation of glutamate from alpha-ketoglutarate

Extended description for FIGURE 25.4 Glutamate chirality is established by hydride transfer to the Schiff base

© Macmillan Learning

The irreversible reaction consists of two reactants and two products. The reactants and products are depicted as ball-and-stick models.

The first reactant is protonated alpha-ketoglutarate Schiff base. It consists of a chain of 5 black spheres. The first and the fifth black spheres are each connected to two red spheres and have an overall negative charge. The fourth black sphere is connected to a blue sphere on the lower left. This blue sphere is further connected to two white spheres and has an overall positive charge.



The second reactant is N A D open parenthesis P close parenthesis H. It consists of a horizontal hexagonal ring composed of 1 blue and 5 black spheres. The blue sphere occupies the bottom-right vertex. The leftmost black sphere is connected to another black sphere, which is further connected to a red sphere on the upper left and a blue sphere on the lower left. The blue sphere is connected to two white spheres. The top left black sphere is connected to a green sphere and a white sphere. The remaining black spheres are connected to a single white sphere.

The first product is L-Glutamate. It consists of a chain of 5 black spheres. The first and the fifth black spheres are each connected to two red spheres and have an overall negative charge. The fourth black sphere is connected to a blue sphere on the upper left and a green sphere on the lower left. The blue sphere is further connected to two white spheres.

The second product is N A D open parenthesis P close parenthesis with superscript plus. It consists of a horizontal hexagonal ring composed of 1 blue and 5 black spheres. The blue sphere with a positive charge occupies the bottom-right vertex. The leftmost black sphere is connected to another black sphere, which is further connected to a red sphere on the upper left and a blue sphere on the lower left. The blue sphere is connected to two white spheres. The remaining black spheres are connected to a single white sphere.

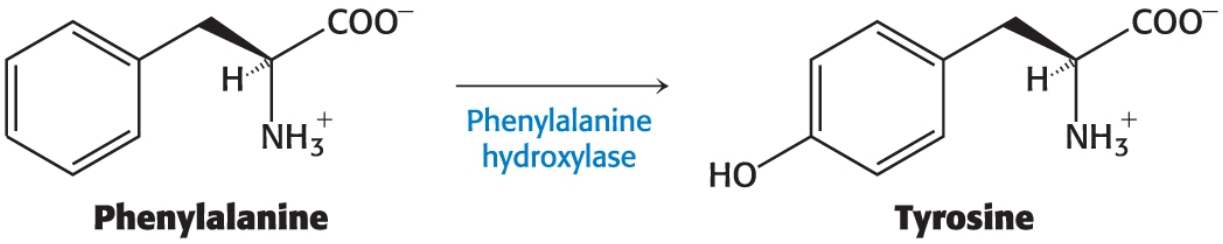
Return to FIGURE 25.4 Glutamate chirality is established by hydride transfer to the Schiff base

Extended description for Conversion of glutamate to glutamine

The reaction sequence consists of one reactant, one intermediate, and one product. The reactant is glutamate whose structure is as follows: A 4-carbon alkane chain is depicted as a line structure using 3 zigzag lines. C 1 is single bonded to C O O superscript minus on the lower left, wedge bonded to N H 3 superscript plus on the upper left, and dash bonded to H on the upper right. C 4 is partially double bonded to O on the upper right and O below. The O atoms have an overall negative charge.

Glutamate is irreversibly converted into acyl-phosphate intermediate with the simultaneous breakdown of A T P to A D P.

The structure of the acyl-phosphate intermediate is as follows: A 4-carbon alkane chain is depicted as a line structure using 3 zigzag lines. C 1 is single bonded to C O O superscript minus on the lower left, wedge bonded to N H 3 superscript plus on the upper left, and dash bonded to H on the upper right. C 4 is double bonded O below and single bonded to O on the upper right. The upper right O is further single-bonded to P on the lower right. The P atom is partially double-bonded to O on the upper right, O below, and O on the lower right. The O atoms have an overall negative charge of 2 minus.



Acyl-phosphate intermediate is irreversibly converted into glutamine with the simultaneous entry of N H 3 and exit of P

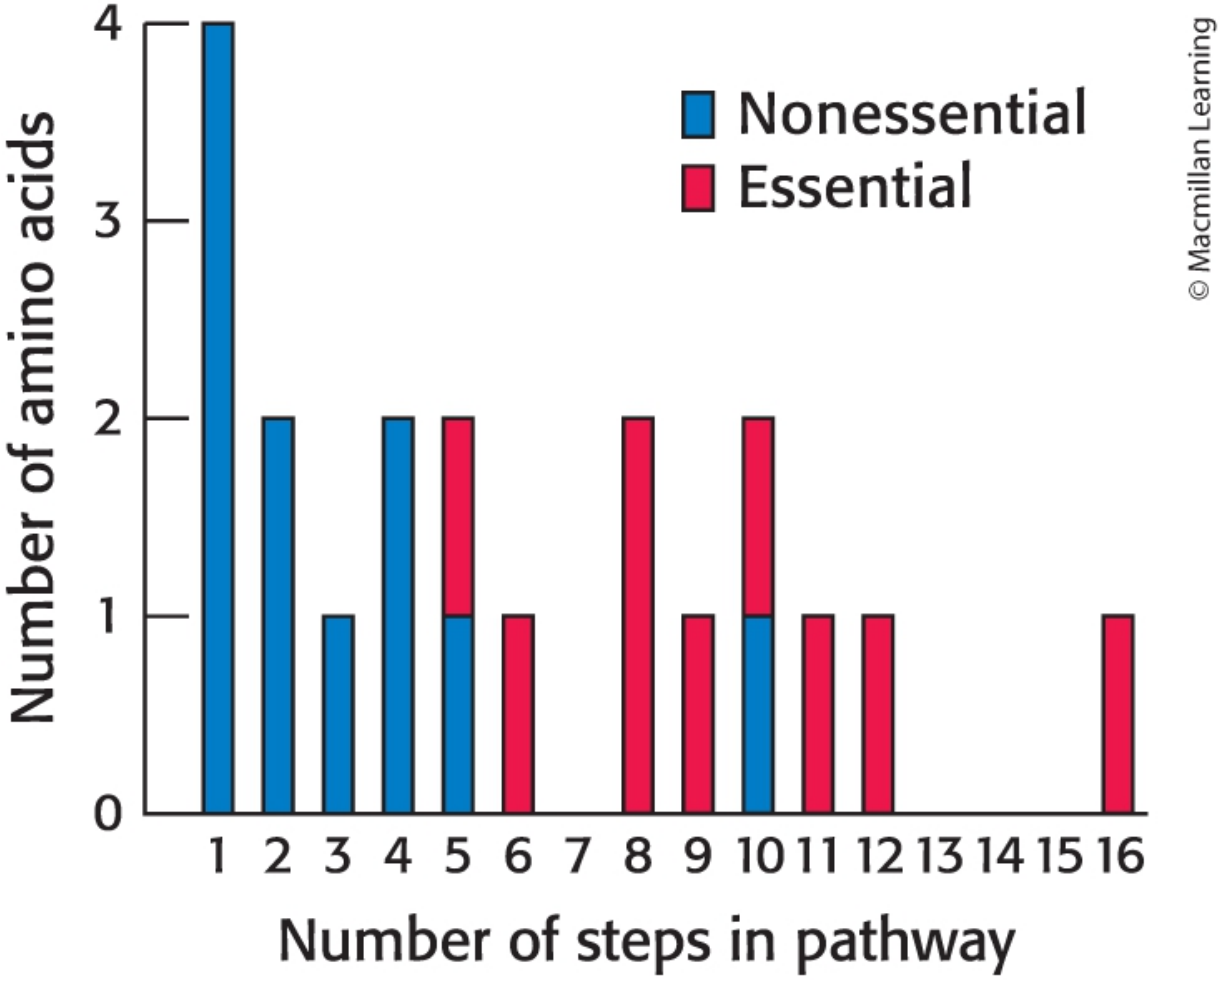
subscript i.

The product is glutamine whose structure is as follows: A 4-carbon alkane chain is depicted as a line structure using 3 zigzag lines. C 1 is single bonded to C O O superscript minus on the lower left, wedge bonded to N H 3 superscript plus on the upper left, and dash bonded to H on the upper right. C 4 is double bonded O below and single bonded to N H 2 on the upper right.

Return to Conversion of glutamate to glutamine

Extended description for Irreversible reaction catalyzed by phenylalanine hydroxylase

Phenylalanine **Tyrosine**



The reaction consists of one reactant and one product. It is catalyzed by phenylalanine hydroxylase.

The reactant is phenylalanine whose structure is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to C H 2 on the upper right in the form of a line. C H 2 is wedge bonded to C on the lower right. The C atom is single bonded to C O O superscript minus on the upper right, dash bonded to H on the lower left, and single bonded to N H 3 superscript plus below.

The product is tyrosine whose structure is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to C H 2 on the upper right in the form of a line. C H 2 is wedge bonded to C on the lower right. The C atom is single bonded to C O O superscript minus on the upper right, dash bonded to H on the lower left, and single bonded to N H 3 superscript plus below. C 5 of the ring is single-bonded to O H on the lower right.

Return to Irreversible reaction catalyzed by phenylalanine hydroxylase

Extended description for FIGURE 25.6 Essential and nonessential amino acids can be distinguished by the required number of biosynthetic steps

The horizontal axis is labeled "Number of steps in pathway." It has markings ranging from 1 to 16 in increments of 1 unit. The vertical axis is labeled "Number of amino acids." It has markings ranging from 0 to 4 in increments of 1 unit. Vertical bars are shown at the markings on the horizontal axis. The blue bars represent nonessential amino acids and red bars represent essential amino

acids. The values of the blue and red bars at the different markings are as follows:

15: No bar

16: Red bar: 1

Return to FIGURE 25.6 Essential and nonessential amino acids can be distinguished by the required number of biosynthetic steps

Extended description for FIGURE 25.7 Transamination is a critical step in the biosynthesis of most amino acids

In the first reversible step, internal aldimine is converted into pyridoxamine phosphate (P M P) with the simultaneous conversion of glutamic acid to alpha-ketoglutarate.

The structure of internal aldimine is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 1 N and 5 C atoms. N with a positive charge occupies the bottom-most vertex. It is bound to H. C 1 occupies the bottom-left vertex. A double bond is present between N and C 1, C 2 and C 3, and C 4 and C 5. C 2 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single-bonded to O P O 3 superscript 2 minus on the lower left. C 3 is single bonded to C above. This C is double-bonded

to N superscript plus on the upper left and single-bonded to H on the upper right. N superscript plus is single-bonded to H on the lower right and single-bonded to a 4-carbon alkane chain depicted as a line structure using 3 zigzag lines. The alkane chain is labeled lysine which is single-bonded to an enzyme. C 4 of the ring is single bonded to O superscript minus on the upper right. C 5 is single bonded to C H 3 on the lower right.

The structure of pyridoxamine phosphate is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 1 N and 5 C atoms. N occupies the bottom-most vertex. It has a positive charge and is bound to H. C 1 occupies the bottom-left vertex. A double bond is present between N and C 1, C 2 and C 3, and C 4 and C 5. C 2 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single-bonded to O P O 3 superscript 2 minus on the lower left. C 3 is single bonded to C above. This C is single bonded to H on the left, H on the upper left, and N H 3 superscript plus on the upper right. C 4 is single bonded to O superscript minus on the upper right. C 5 is single bonded to C H 3 on the lower right.

In the second step, pyridoxamine phosphate is reversibly converted into ketimine with the simultaneous entry of a compound and release of H 2 O.

The structure of this compound is as follows: A central C atom is single bonded to R on the upper left, double bonded to O below, and single bonded to C O O superscript minus on the upper right.

The structure of ketimine is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 1 N and 5 C atoms. N superscript plus bound to H occupies the bottom-most vertex. C 1 occupies the bottom-left vertex. A double bond is present between N and C 1, C 2 and C 3, and C 4 and C 5. C 2 is single bonded

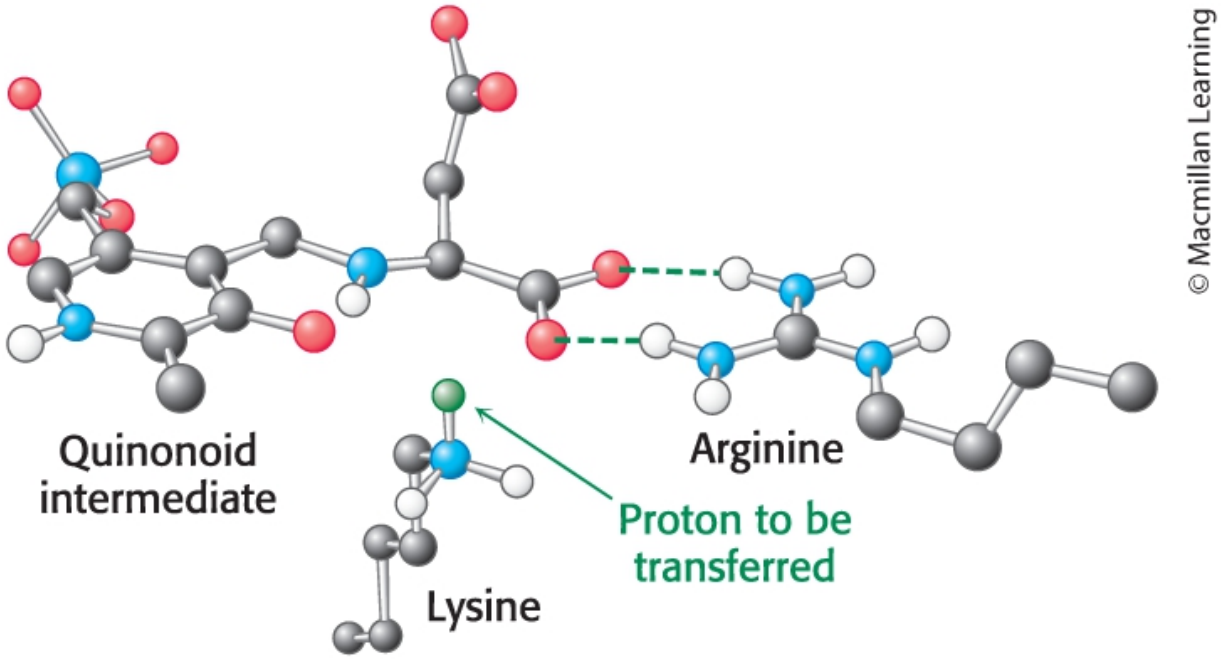
to C H 2 on the upper left in the form of a line. C H 2 is single-bonded to O P O 3 superscript 2 minus on the lower left. C 3 is single bonded to C above. This C is single-bonded to N superscript plus on the upper right, single-bonded to H on the upper left, and single-bonded to H on the lower right. The N superscript plus is single-bonded to H on the right and double-bonded to C above. The C atom is single bonded to R on the upper left and single bonded to C O O superscript minus on the upper right. C 4 of the ring is single bonded to O superscript minus on the upper right. C 5 is single bonded to C H 3 on the lower right. An arrow points from H single bonded to C above toward the single bond between this C and C 3 of the ring. A second arrow points from the double bond between C 2 and C 3 toward the single bond between C 1 and C 2. A third arrow points from the double bond between C 1 and N toward the N atom.

In the third reversible step, ketimine is converted into a quinonoid intermediate with the simultaneous release of H superscript plus ion.

The structure of the quinonoid intermediate is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 1 N and 5 C atoms. N bound to H occupies the bottom-most vertex. C 1 occupies the bottom-left vertex. A double bond is present between C 1 and C 2, and C 4 and C 5. C 2 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single-bonded to O P O 3 superscript 2 minus on the lower left. C 3 is double bonded to C above. This C is single-bonded to N superscript plus on the upper right and single-bonded to H on the upper left. The N superscript plus is single-bonded to H on the right and double-bonded to C above. The C atom is single bonded to R on the upper left and single bonded to C O O superscript minus on the upper right. C 4 of the ring is single bonded to O superscript minus on the upper right. C 5 is single bonded to C H 3 on the lower right. An arrow from the N atom of the ring points toward the single bond

between N and C 1. A second arrow points from the double bond between C 1 and C 2 toward the single bond between C 2 and C 3. A third arrow points from the double bond between C 3 of the ring and C toward the single bond between C and N superscript plus.

In the fourth reversible step, the quinonoid intermediate is converted into external aldimine with the simultaneous addition of H superscript plus.



The structure of external aldimine: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 1 N and 5 C atoms. N with a positive charge occupies the bottom-most vertex. It is bound to H. C 1 occupies the bottom-left vertex. A double bond is present between N and C 1, C 2 and C 3, and C 4 and C 5. C 2 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single-bonded to O P O 3 superscript 2 minus on the lower left. C 3 is single bonded to C above. This C is double-bonded to N superscript plus on the upper left and single-bonded to H on the upper right. The N superscript plus atom is single-bonded to H on the lower right and single-bonded to a central C atom above. This C is wedge bonded to R on the upper left, single bonded to C O O superscript minus on the upper right, and dash bonded to H above. C 4 of the ring is single bonded to O superscript minus on the upper right. C 5 is single bonded to C H 3 on the lower right.

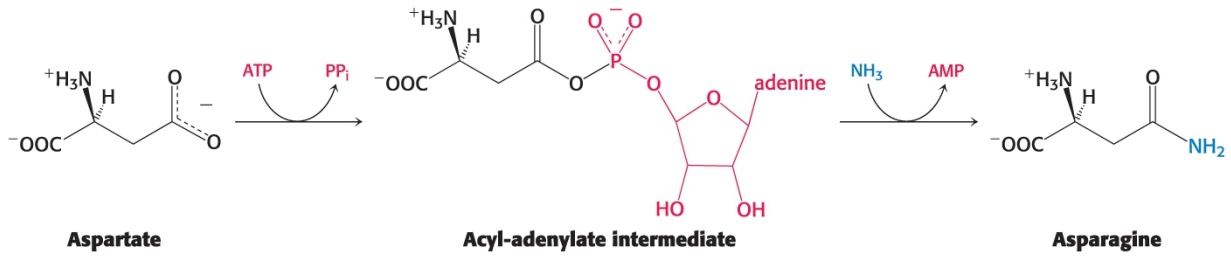
In the fifth reversible step, external aldimine is converted back to internal aldimine with the simultaneous release of L-amino acid.

The structure of L-amino acid is as follows: A central C atom is single bonded to N H 3 superscript plus below, wedge bonded to R on the upper left, dash bonded to H above, and single bonded to C O O superscript minus on the upper right.

Return to FIGURE 25.7 Transamination is a critical step in the biosynthesis of most amino acids

Extended description for FIGURE 25.8 Proton addition during transamination establishes amino acid stereochemistry

© Macmillan Learning



The ball-and-stick model of quinonoid intermediate, arginine, and lysine is shown. The quinonoid intermediate is laying flat. It consists of a hexagonal ring composed of 1 blue and 5 black spheres. The blue sphere is connected to a white sphere. All the black spheres except the top left sphere are connected to different substituent groups. The top right black sphere is connected to a horizontal chain composed of one blue and three black spheres. The blue sphere occupies the second position and is connected to a white sphere toward the observer. The second black sphere is connected to a vertical chain of 2 black spheres. The terminal black sphere of this chain is connected to two red spheres. The third black sphere of the horizontal chain is connected to two red spheres. A dashed line

connects these two red spheres to two different white spheres of arginine residue on the right.

The side chain of lysine residue is located below the horizontal chain connected to the top right black sphere of the ring. The side chain consists of 5 black spheres. The top black sphere is connected to a blue sphere on the right. This blue sphere is connected to a green sphere above, a white sphere on the lower left, and a white sphere on the lower right. An arrow pointing toward the green sphere is labeled "Proton to be transferred." The green sphere is aligned directly below the second black sphere of the horizontal chain.

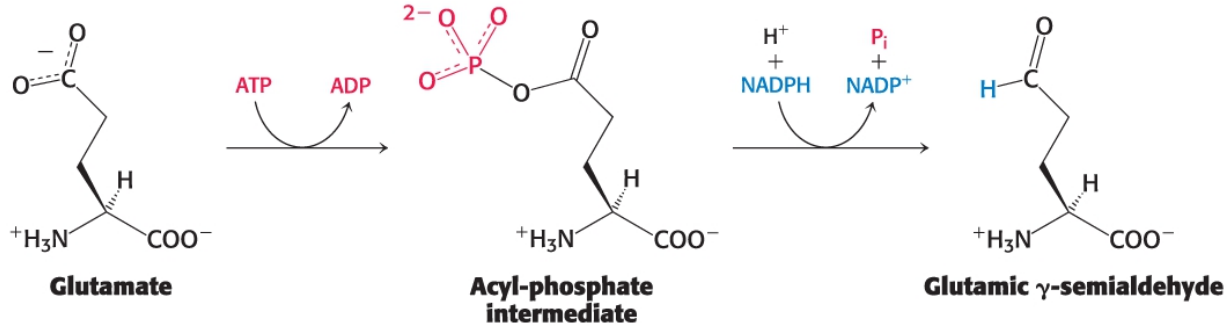
Return to FIGURE 25.8 Proton addition during transamination establishes amino acid stereochemistry

Extended description for Conversion of aspartate to asparagine

In the first step, aspartate is irreversibly converted into acyl-adenylate intermediate with the simultaneous breakdown of A T P to P P subscript i.

The structure of aspartate is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the lower left, wedge bonded to N H 3 superscript plus on the upper left, and dash bonded to H on the upper right. C 3 is partially double bonded to O above and O on the lower right. The O atoms have an overall negative charge.

The structure of the acyl-adenylate intermediate is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single bonded to adenine on the upper right. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to O above. The O atom is single-bonded to P on the upper left. This P atom is partially double-bonded to O on the upper left, partially double-bonded to O on the upper right, and single-bonded to O on the lower left. The O atoms on the upper left and upper right have an overall negative charge. The lower left O is single bonded to C 3 of a 3-carbon alkane chain depicted as a line structure using 2 zigzag lines. In the alkane chain, C 1 is single bonded to C O O superscript minus on the lower



left, wedge bonded to N H 3 superscript plus on the upper left, and dash bonded to H on the upper right. C 3 is double bonded to O above.

In the second step, the acyl-adenylate intermediate is irreversibly converted into asparagine with the simultaneous entry of N H 3 and release of A M P.

The structure of asparagine is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the lower left, wedge bonded to N H 3 superscript plus on the upper left, and dash bonded to H on the upper right. C 3 is double bonded to O above and single bonded to N H 2 on the lower right.

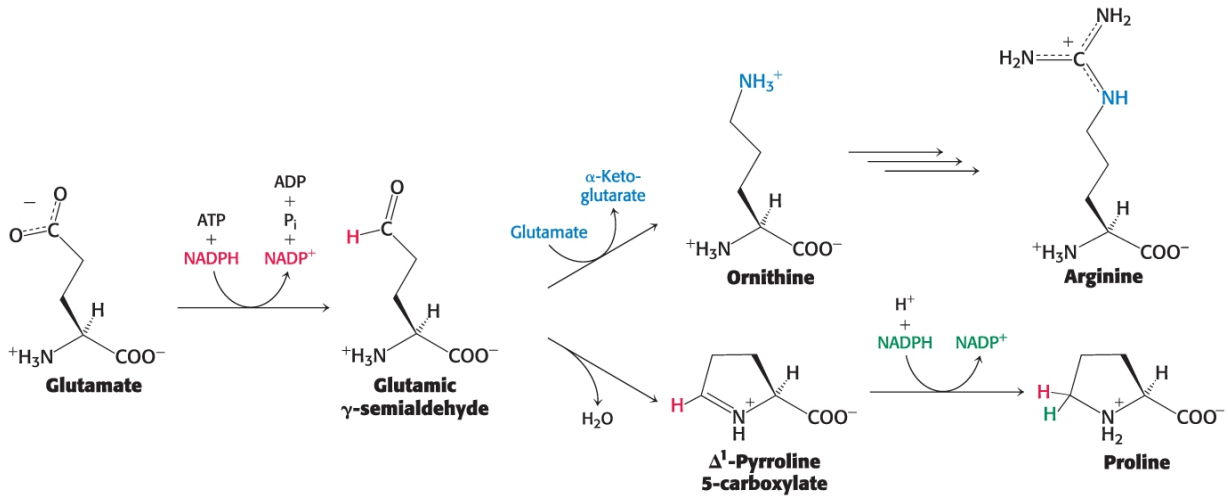
Return to Conversion of aspartate to asparagine

Extended description for Conversion of glutamate to glutamic gamma-semialdehyde

In the first irreversible step, glutamate is converted into an acyl-phosphate intermediate with the simultaneous breakdown of A T P to A D P.

The structure of glutamate is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to another C H 2 group on the upper right in the form of a line. This C H 2 is single-bonded to C on the upper left. This C is partially double bonded to O above and O on the lower left. The O atoms have an overall negative charge.

The structure of the acyl-phosphate intermediate is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to another C H 2 group on the upper right in the form of a line. This C H 2 is single-bonded to C on the upper left. This C is double bonded to O above and single bonded to O on the lower left. The lower left O



atom is single-bonded to P on the upper left. This P is partially double-bonded to O on the upper left, O on the upper right, and O on the lower left. The O atoms have an overall negative charge.

In the second irreversible step, the acyl-phosphate intermediate is converted into glutamic gamma-semialdehyde with the simultaneous oxidation of N A D P H plus H superscript plus to N A D P superscript plus and release of P subscript i.

The structure of glutamic gamma-semialdehyde is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to another C H 2 group on the upper right in the form of a line. This C H 2 is single-bonded to C on the upper left. This C is double bonded to O above and single bonded to H on the lower left.

Return to Conversion of glutamate to glutamic gamma-semialdehyde

Extended description for Formation of arginine and proline from glutamate

In the first irreversible step, glutamate is converted into glutamic gamma-semialdehyde with the simultaneous oxidation of N A D P H to N A D P superscript plus and breakdown of A T P to A D P plus P subscript i.

The structure of glutamate is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to another C H 2 group on the upper right in the form of a line. This C H 2 is single-bonded to C on the upper left. This C is partially double bonded to O above and O on the lower left. The O atoms have an overall negative charge.

The structure of glutamic gamma-semialdehyde is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to

H on the upper right. The C H 2 group is single-bonded to another C H 2 group on the upper right in the form of a line. This C H 2 is single-bonded to C on the upper left. This C is double bonded to O above and single bonded to H on the lower left.

Glutamic gamma-semialdehyde can be channeled into two distinct paths. The first path leads to the formation of arginine. The second path leads to the formation of proline.

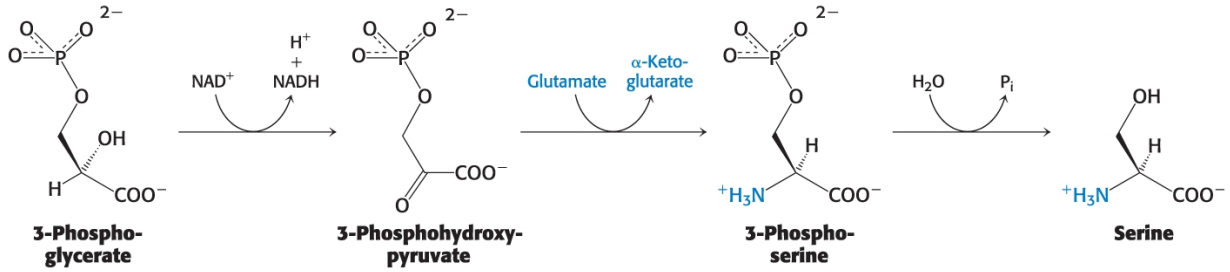
In the first path, glutamic gamma-semialdehyde is irreversibly converted into ornithine with the simultaneous conversion of glutamate into alpha-ketoglutarate.

The structure of ornithine is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to a 2-carbon alkane chain depicted using a single line. C 2 of this alkane chain is single bonded to N H 3 superscript plus on the upper right.

Three successive forward arrows from ornithine lead to arginine.

The structure of arginine is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to a 1 N and 2 C alkane chain depicted as a vertical line structure using 2 zigzag lines. N bound to H occupies the third position. N is partially double-bonded to C on the upper right. This C atom has a positive charge and is partially double-bonded to N H 2 on the left and partially double-bonded to N H 2 on the upper right.

In the second path, glutamic gamma-semialdehyde is irreversibly converted into delta superscript 1-pyrroline 5-carboxylate with the simultaneous release of H 2 O.



The structure of delta superscript 1-pyrroline 5-carboxylate is as follows: A central C atom is wedge bonded to C H 2 on the upper left, single bonded to N H with a positive charge on the lower left, dash bonded to H on the upper right, and single bonded to C O O superscript minus on the lower right. The upper left C H 2 group is single-bonded to a 2-carbon alkane chain depicted using a line. C 2 of this chain is double bonded to the N H group on the lower left such that a cyclic pentagonal-shaped ring structure is formed. C 2 is also single bonded to H on the lower left.

Later, delta superscript 1-pyrroline 5-carboxylate is irreversibly converted into proline with the simultaneous oxidation of N A D P H plus H superscript plus to N A D P superscript plus.

The structure of proline is as follows: A central C atom is wedge bonded to C H 2 on the upper left, single bonded to N H 2 with a positive charge on the lower left, dash bonded to H on the upper right, and single bonded to C O O superscript minus on the lower right. The upper left C H 2 group is single-bonded to a 2-carbon alkane chain depicted using a line. C 2 of this chain is single-bonded to the N H 2 group on the lower left such that a cyclic pentagonal-shaped ring structure is formed. C 2 is also single bonded to H on the upper left and lower left.

Return to Formation of arginine and proline from glutamate

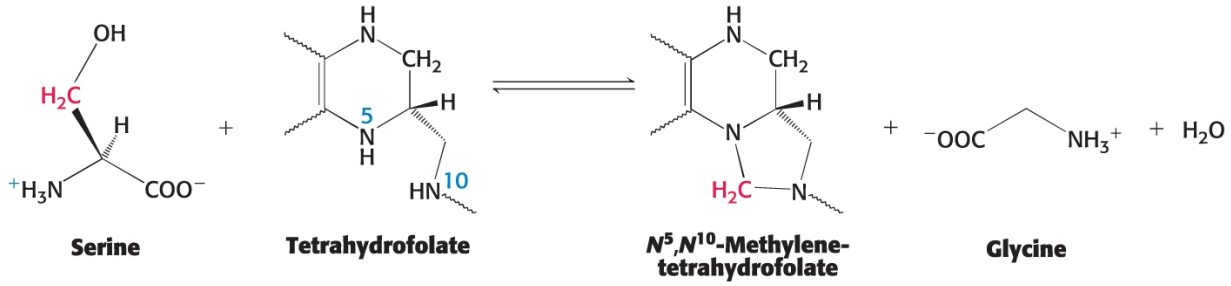
Extended description for Formation of serine from 3-phosphoglycerate

In the first irreversible step, 3-phosphoglycerate is converted into 3-phosphohydroxypyruvate with the simultaneous reduction of N A D superscript plus to N A D H plus H superscript plus.

The structure of 3-phosphoglycerate is as follows: A central C atom is single bonded to H on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to O H on the upper right. The C H 2 group is single-bonded to O on the upper right. This O is single-bonded to P on the upper left. This P is partially double-bonded to O on the left, O on the upper left, and O on the upper right. The O atoms have an overall negative charge of 2 minus.

The structure of 3-phosphohydroxypyruvate is as follows: A central C atom is double bonded to O on the lower left and single bonded to C O O superscript minus on the right, and single bonded to C H 2 on the upper left in the form of a line. The C H 2 group is single-bonded to O on the upper right. This O is single-bonded to P on the upper left. This P is partially double-bonded to O on the left, O on the upper left, and O on the upper right. The O atoms have an overall negative charge of 2 minus.

In the second irreversible step, 3-phosphohydroxypyruvate is converted into 3-phosphoserine with the simultaneous conversion of glutamate to alpha-ketoglutarate.



The structure of 3-phosphoserine is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to O on the upper right. This O is single-bonded to P on the upper left. This P is partially double-bonded to O on the left, O on the upper left, and O on the upper right. The O atoms have an overall negative charge of 2 minus.

In the third irreversible step, 3-phosphoserine is converted into serine with the simultaneous addition of H 2 O and release of P subscript i.

The structure of serine is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2, single bond, O H on the upper left, and dash bonded to H on the upper right.

Return to Formation of serine from 3-phosphoglycerate

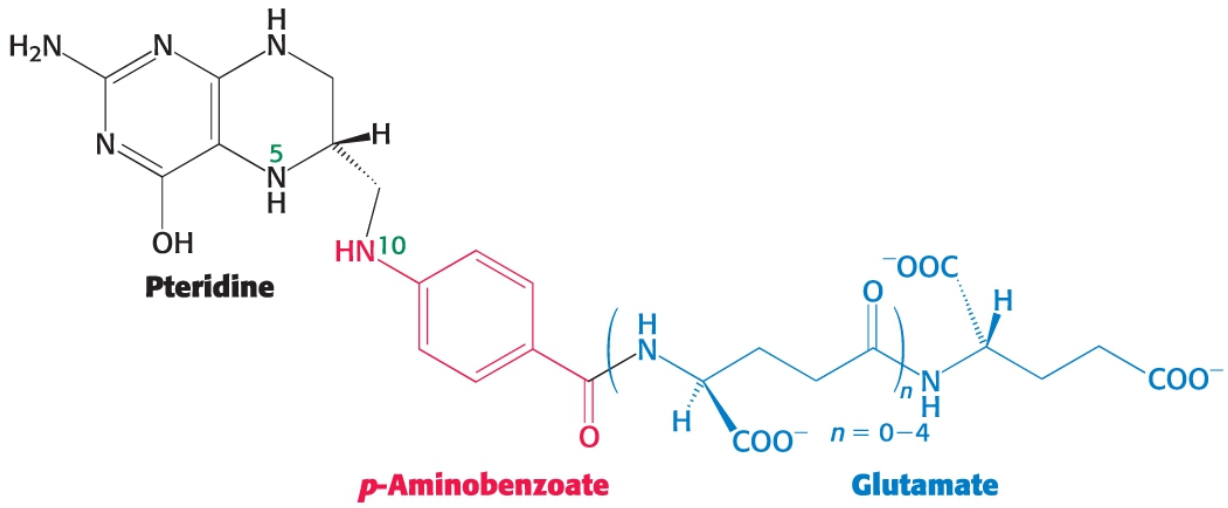
Extended description for Formation of glycine from serine

The reaction consists of two reactants and three products.

The first reactant is serine whose structure is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2, single bond, O H on the upper left, and dash bonded to H on the upper right.

The second reactant is tetrahydrofolate whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. First N occupies the topmost vertex and second occupies the bottom-most vertex. Both N atoms are bound to H. The second N is numbered 5. C 1 is bound to H 2. C 2 is wedge bonded to H on the upper right and dash bonded to C H 2 on the lower right. C H 2 is single bonded to N H below numbered 10. N H has a wiggly line on the lower right. C 3 and C 4 have a wiggly line and are double bonded to each other.

The first product is N superscript 5, N superscript 10-Methylene tetrahydrofolate whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. First N occupies the topmost vertex and the



second N occupies the bottom-most vertex. First N atom is bound to H. C 1 is bound to H 2. C 2 is wedge bonded to H on the upper right and dash bonded to C H 2 on the lower right. C H 2 is single bonded to N below. N has a wiggly line on the lower right and is single-bonded to C H 2 on the left. This C H 2 is single-bonded to N 2 of the ring to form a pentagonal ring-like structure. C 3 and C 4 have a wiggly line and are double bonded to each other.

The second product is glycine whose structure is as follows: C O O superscript minus is single bonded to C H 2 on the upper right in the form of a line. C H 2 is single bonded to N H 3 superscript plus on the lower right.

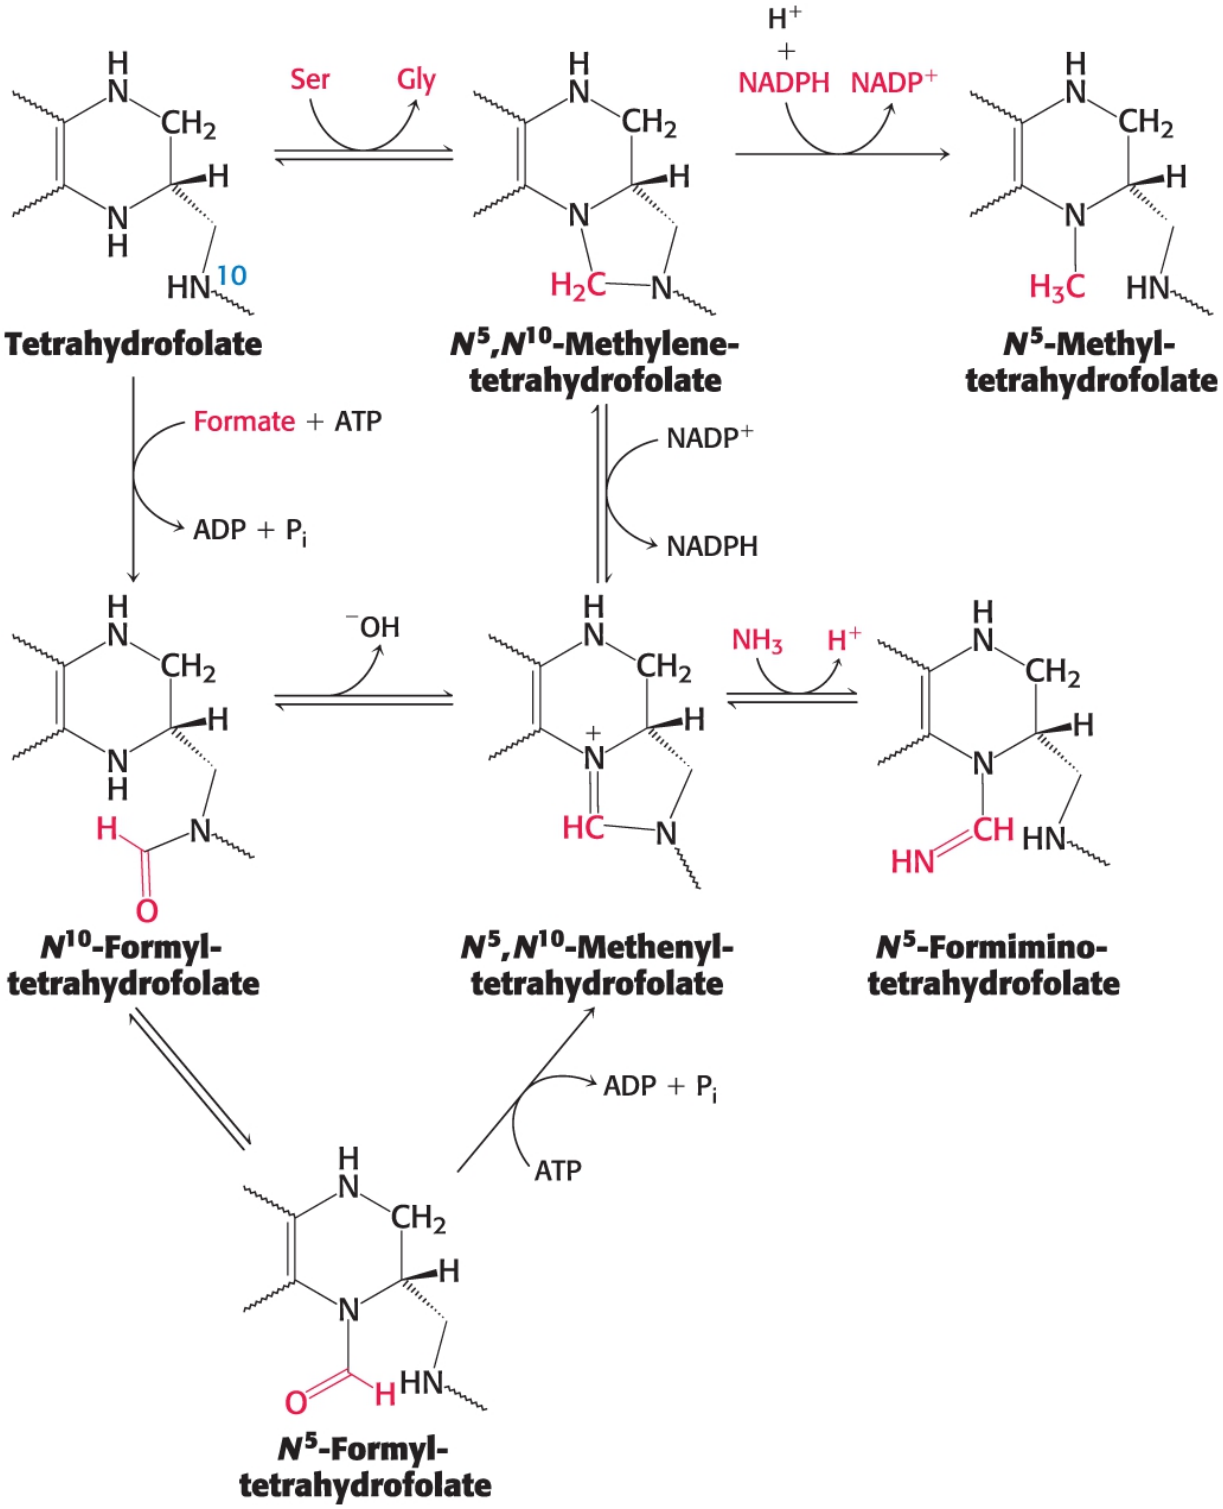
The third product is H 2 O.

Return to Formation of glycine from serine

Extended description for FIGURE 25.9 Tetrahydrofolate is an important carrier of activated one-carbon units

The structure is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. First N occupies the bottom left vertex and the second N occupies the topmost vertex. A double bond is present between C 1 and N 2, C 2 and C 3, and C 4 and N 1. C 1 is single bonded to N H 2 on the upper left. C 4 is single bonded to O H below. This ring is fused to a second 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the first ring are C 4 and C 3 respectively of the second ring. The second ring consists of 2 N and 4 C atoms. First N occupies the topmost vertex and the second N occupies the bottom-most vertex. Both N atoms are bound to H. The second N is numbered 5. C 2 is wedge bonded to H on the upper right and dash bonded to C H 2 on the lower right. The C H 2 group is single-bonded to the N H group of para-aminobenzoate. The fused rings are labeled pteridine.

The para-aminobenzoate consist of a benzene ring in a vertical orientation. The ring contains alternating double bonds between C 1



and C 2, C 3 and C 4, and C 5 and C 6. C 3 is single bonded to C on the lower right. This C is double bonded to O below and single bonded to the first N of glutamate. C 6 is single bonded to N H on the upper left numbered 10.

Glutamate consists of 2 N and 7 C heteronuclear alkane chain depicted as a line structure using 8 zigzag lines. First N bound to H occupies the first position. Second N bound to H occupies the sixth position. C 1 is dash bonded to H on the lower left and wedge bonded to C O O superscript minus on the lower right. C 4 is double bonded to O above. C 5 is dash bonded to C O O superscript minus on the upper left and wedge bonded to H on the upper right. C 7 is single bonded to C O O superscript minus on the lower right. First N to C 4 are enclosed in parenthesis with subscript n, where n equals 0 to 4.

Return to FIGURE 25.9 Tetrahydrofolate is an important carrier of activated one-carbon units

Extended description for FIGURE 25.10 Interconversion

of one carbon units attached to tetrahydrofolate

The figure shows four reaction sequences to depict the interconversion of one carbon units attached to tetrahydrofolate. The first reaction sequence shows the reversible conversion of tetrahydrofolate to N superscript 5, N superscript 10-Methylene tetrahydrofolate with the simultaneous conversion of serine to glycine. This is followed by irreversible conversion of N superscript 5, N superscript 10-Methylene tetrahydrofolate to N superscript 5-Methyl- tetrahydrofolate with the simultaneous oxidation of N A D P H plus H superscript plus to N A D P superscript plus.

The structure of tetrahydrofolate is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. First N occupies the topmost vertex and second occupies the bottom-most vertex. Both N atoms are bound to H. C 1 is bound to H 2. C 2 is wedge bonded to H on the upper right and dash bonded to C H 2 on the lower right. C H 2 is single bonded to N H below numbered 10. N H has a wiggly line on the lower right. C 3 and C 4 have a wiggly line and are double bonded to each other.

The structure of N superscript 5, N superscript 10-Methylene tetrahydrofolate whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. First N occupies the topmost vertex and the second N occupies the bottom-most vertex. First N atom is bound to H. C 1 is bound to H 2. C 2 is wedge bonded to H on the upper right and dash bonded to C H 2 on the lower right. C H 2 is single bonded to N below. N has a wiggly line on the lower right and is single-bonded to C H 2 on the left. This C H 2 is single-bonded to N 2 of the ring to form a pentagonal ring-like structure. C 3 and C 4 have a wiggly line and are double bonded to each other.

The structure of N superscript 5-Methyl tetrahydrofolate is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. First N occupies the

topmost vertex and the second N occupies the bottom-most vertex. First N atom is bound to H. C 1 is bound to H 2. C 2 is wedge bonded to H on the upper right and dash bonded to C H 2 on the lower right. C H 2 is single bonded to N H below. N H has a wiggly line on the lower right. N 2 of the ring is single bonded to C H 3 below. C 3 and C 4 have a wiggly line and are double bonded to each other.

In the second reaction sequence, tetrahydrofolate is irreversibly converted into N superscript 10-Formyl tetrahydrofolate with the simultaneous entry of formate and the breakdown of A T P to A D P plus P subscript i. N superscript 10-Formyl tetrahydrofolate is further reversibly converted into N superscript 5-Formyl tetrahydrofolate.

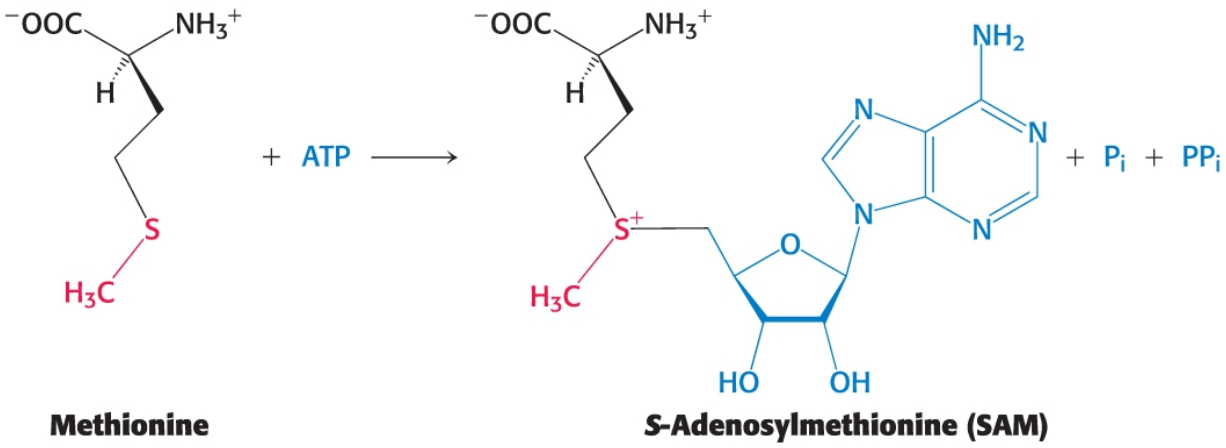
The structure of N superscript 10-Formyl tetrahydrofolate is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. First N occupies the topmost vertex and the second N occupies the bottom-most vertex. Both N atoms are bound to H. C 1 is bound to H 2. C 2 is wedge bonded to H on the upper right and dash bonded to C H 2 on the lower right. C H 2 is single bonded to N below. N has a wiggly line on the lower right and is single bonded to C on the lower right. This C is single bonded to H on the upper left and double bonded to O below. C 3 and C 4 have a wiggly line and are double bonded to each other.

The structure of N superscript 5-Formyl tetrahydrofolate is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. First N occupies the topmost vertex and the second N occupies the bottom-most vertex. First N is bound to H. C 1 is bound to H 2. C 2 is wedge bonded to H on the upper right and dash bonded to C H 2 on the lower right. C H 2 is single bonded to N H below. N H has a wiggly line on the lower right. The second N of the ring is single bonded to C below. This C is single bonded to H on the lower right and double bonded to O on the

lower left. C 3 and C 4 have a wiggly line and are double bonded to each other.

In the third reaction sequence, N superscript 5, N superscript 10-Methylene tetrahydrofolate is reversibly converted into N superscript 5, N superscript 10-Methenyl tetrahydrofolate with the simultaneous reduction of N A D P superscript plus to N A D P H. N superscript 5, N superscript 10-Methenyl tetrahydrofolate is further irreversibly converted into N superscript 5-Formyl tetrahydrofolate with the simultaneous breakdown of A T P to A D P plus P subscript i.

The structure of N superscript 5, N superscript 10-Methenyl tetrahydrofolate is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. First N occupies the topmost vertex and the second N occupies the bottom-most vertex. First N atom is bound to H. Second N has a positive charge. C 1 is bound to H 2. C 2 is wedge bonded to H on the upper right and dash bonded to C H 2 on the lower right. C H 2 is single bonded to N below. N has a wiggly line on the lower right and is single-bonded to C H on the left. This C H group is double-bonded to N 2 of the ring to form a pentagonal ring-like structure. C 3 and C 4 have a wiggly line and are double bonded to each other.



In the fourth reaction sequence, N superscript 10-Formyltetrahydrofolate is reversibly converted into N superscript 5, N superscript 10-Methenyl tetrahydrofolate with the simultaneous release of O H superscript minus. N superscript 5, N superscript 10-Methenyl tetrahydrofolate is further reversibly converted into N superscript 5-Formiminotetrahydrofolate with the simultaneous entry of N H 3 and release of H superscript plus.

The structure of N superscript 5-Formiminotetrahydrofolate is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical

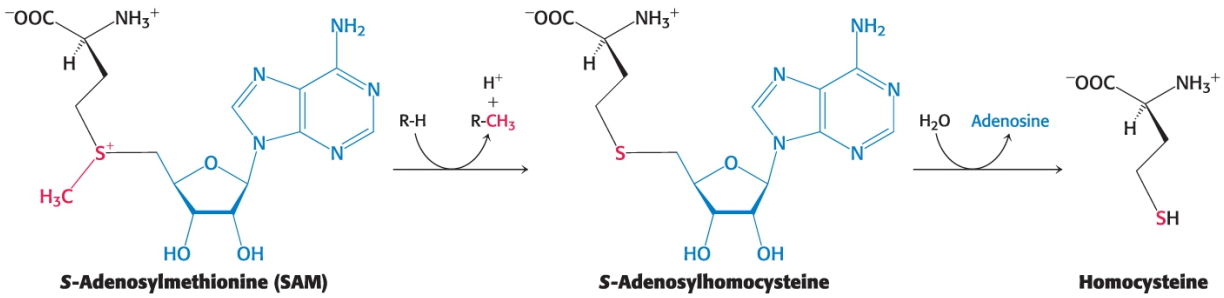
orientation and consists of 2 N and 4 C atoms. First N occupies the topmost vertex and the second N occupies the bottom-most vertex. The first N atom is bound to H. C 1 is bound to H 2. C 2 is wedge bonded to H on the upper right and dash bonded to C H 2 on the lower right. C H 2 is single bonded to N H below. N H has a wiggly line on the lower right. The second N is single bonded to C H below. This C H group is double-bonded to N H on the lower left. C 3 and C 4 have a wiggly line and are double bonded to each other.

Return to FIGURE 25.10 Interconversion of one carbon units attached to tetrahydrofolate

Extended description for Formation of S-adenosylmethionine from methionine

The reaction consists of two reactants and three products.

The first reactant is methionine whose structure is as follows: A central C atom is single bonded to C O O superscript minus on the upper left, single bonded to N H 3 superscript plus on the upper right, dash bonded to H on the lower left, and wedge bonded to C H 2 on the lower right. This C H 2 group is further single-bonded to C H 2 on the lower left in the form of a line. This C H 2 group is single-bonded to S on the lower right, which is further single-bonded to C H 3 on the lower left.



The second reactant is A T P.

The first product is S-adenosylmethionine (S A M) whose structure is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 occupies the top right vertex. C 2 and C 3 are single bonded to O H below. C 4 is single-bonded to C H 2 above in the form of a line, which is further single-bonded to the S atom of

methionine. The S atom is positively charged. C 1 is single-bonded to N 1 of a 5-membered heterocyclic pentagonal ring in a horizontal orientation with C 1 occupying the leftmost vertex. This ring consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the topmost vertex. A double bond is present between C 1 and N 2. The pentagonal ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 of the hexagonal ring respectively. The hexagonal ring consists of 2 N and 4 C atoms. First N occupies the top right vertex and the second N occupies the bottom-most vertex. A double bond is present between C 1 and N 2, C 2 and C 3, and C 4 and N 1. C 4 is single bonded to N H 2 above. The second product is P subscript i. The third product is P P subscript i.

Return to Formation of S-adenosylmethionine from methionine

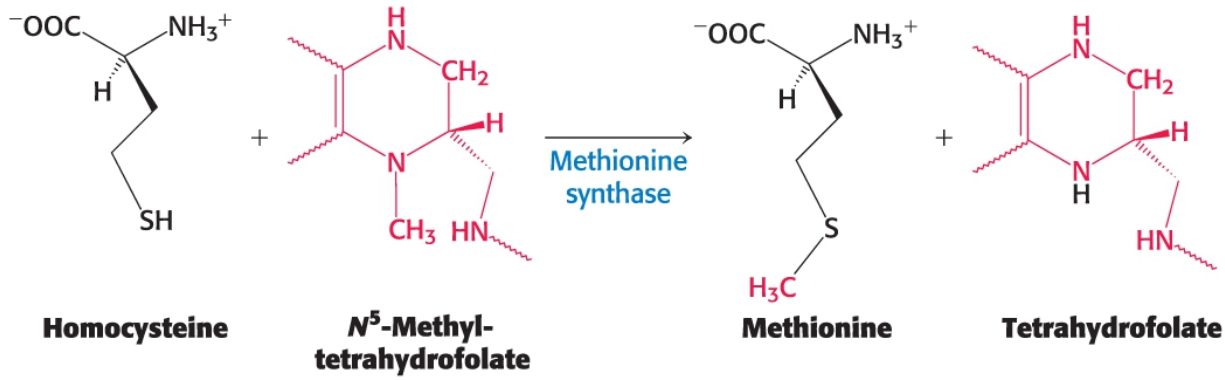
Extended description for Formation of homocysteine from S-adenosylmethionine

In the first step, S-adenosylmethionine (S A M) is irreversibly converted into S-adenosylhomocysteine with the simultaneous entry of R, single bond, H and release of R, single bond, C H 3 and H superscript plus.

The structure of S-adenosylmethionine (S A M) is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. C 1 occupies the top right vertex. C 2 and C 3 are single bonded to O H below. C 4 is single-bonded to C H 2 above in the form of a line, which is further single-bonded to the S atom of methionine amino acid. The S atom is positively charged. C 1 is single-bonded to N 1 of a 5-membered heterocyclic pentagonal ring in a horizontal orientation with C 1 occupying the leftmost vertex. This ring consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the topmost vertex. A double bond is present between C 1 and N 2. The pentagonal ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 of the hexagonal ring respectively. The hexagonal ring consists of 2 N and 4 C atoms. First N occupies the top right vertex and the second N occupies the bottom-most vertex. A double bond is

present between C 1 and N 2, C 2 and C 3, and C 4 and N 1. C 4 is single bonded to N H 2 above.

The structure of S-adenosylhomocysteine is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 occupies the top right vertex. C 2 and C 3 are single bonded to O H below. C 4 is single-bonded to C H 2 above in the form of a line, which is further single-bonded to the S atom on the left. S is single bonded to a 2-carbon alkane chain depicted using a single line. C 2 of this chain is wedge bonded to a C atom on the upper left. This C atom is single bonded to C O O superscript minus on the upper left, dash bonded to H on the lower left, and single bonded to N H 3 superscript plus on the upper right. C 1 of the pentagonal ring is single-bonded to N 1 of a 5-membered heterocyclic pentagonal ring in a horizontal orientation with C 1 occupying the leftmost vertex. This ring consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the topmost vertex. A double bond is present between C 1 and N 2. The pentagonal ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 of the hexagonal ring respectively. The hexagonal ring consists of 2 N and 4 C atoms. First N occupies the top right vertex and the second N occupies the bottom-most vertex. A double bond is present between C 1 and N 2, C 2 and C 3, and C 4 and N 1. C 4 is single bonded to N H 2 above.



In the second step, S-adenosylhomocysteine is irreversibly converted into homocysteine with the simultaneous entry of H 2 O and release of adenosine.

The structure of homocysteine is as follows: A central C atom is single bonded to C O O superscript minus on the upper left, dash bonded to H on the lower left, single bonded to N H 3 superscript

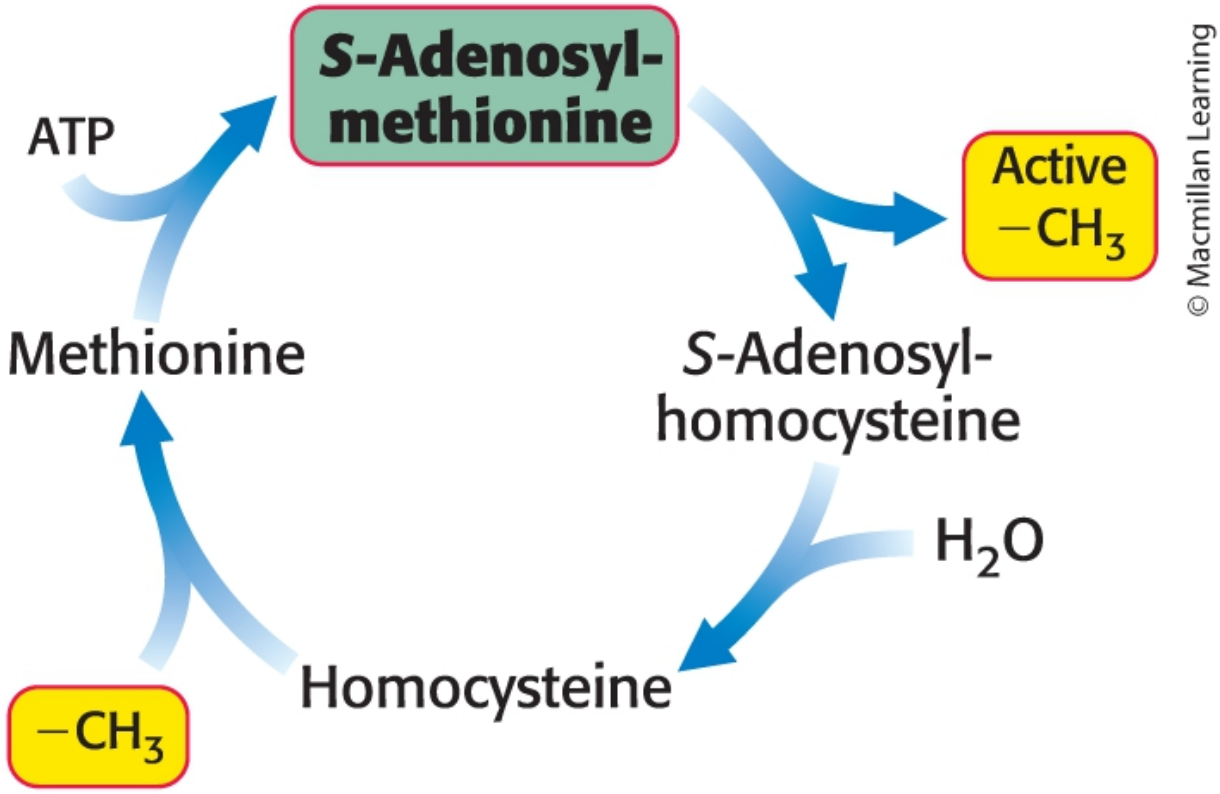
plus on the upper right, and wedge bonded to a 2-carbon alkane chain depicted using a line. C 2 of this chain is single-bonded to S H on the lower right.

Return to Formation of homocysteine from S-adenosylmethionine

Extended description for Reaction catalyzed by methionine synthase

The reaction consists of two reactants and two products. It is catalyzed by methionine synthase.

The first reactant is homocysteine whose structure is as follows: A central C atom is single bonded to C O O superscript minus on the upper left, dash bonded to H on the lower left, single bonded to N H 3 superscript plus on the upper right, and wedge bonded to a 2-carbon alkane chain depicted using a line. C 2 of this chain is single-bonded to S H on the lower right.

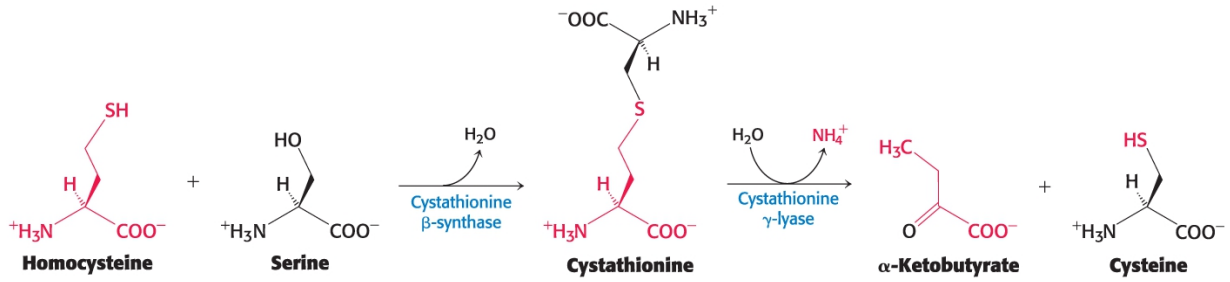


The second reactant is N superscript 5-Methyl tetrahydrofolate whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. First N occupies the topmost vertex and the second N occupies the bottom-most vertex. First N atom is bound to H. C 1 is bound to H 2. C 2 is wedge bonded to H on the upper right and dash bonded to C H 2 on the lower right. C H 2 is single bonded to N H below. N H has a wiggly line on the lower right. N 2 of the ring is single bonded to C H 3 below. C 3 and C 4 have a wiggly line and are double bonded to each other.

The first product is methionine whose structure is as follows: A central C atom is single bonded to C O O superscript minus on the upper left, single bonded to N H 3 superscript plus on the upper right, dash bonded to H on the lower left, and wedge bonded to C H 2 on the lower right. This C H 2 group is further single-bonded to C H 2 on the lower left in the form of a line. This C H 2 group is single-bonded to S on the lower right, which is further single-bonded to C H 3 on the lower left.

The second product is tetrahydrofolate whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. First N occupies the topmost vertex and second occupies the bottom-most vertex. Both N atoms are bound to H. C 1 is bound to H 2. C 2 is wedge bonded to H on the upper right and dash bonded to C H 2 on the lower right. C H 2 is single bonded to N H. N H has a wiggly line on the lower right. C 3 and C 4 have a wiggly line and are double bonded to each other.

Return to Reaction catalyzed by methionine synthase



Extended description for FIGURE 25.11 The activated methyl cycle enables regeneration of methionine

The cycle is depicted as follows: S-adenosylmethionine is converted into S-adenosylhomocysteine with the simultaneous release of active C H 3. S-adenosylhomocysteine is converted into homocysteine with the concomitant entry of H 2 O. Homocysteine is further converted into methionine with the concomitant entry of C H 3. Methionine is converted back to S-adenosylmethionine with the concomitant entry of A T P.

Return to FIGURE 25.11 The activated methyl cycle enables regeneration of methionine

Extended description for Formation of alpha-ketobutyrate and cysteine

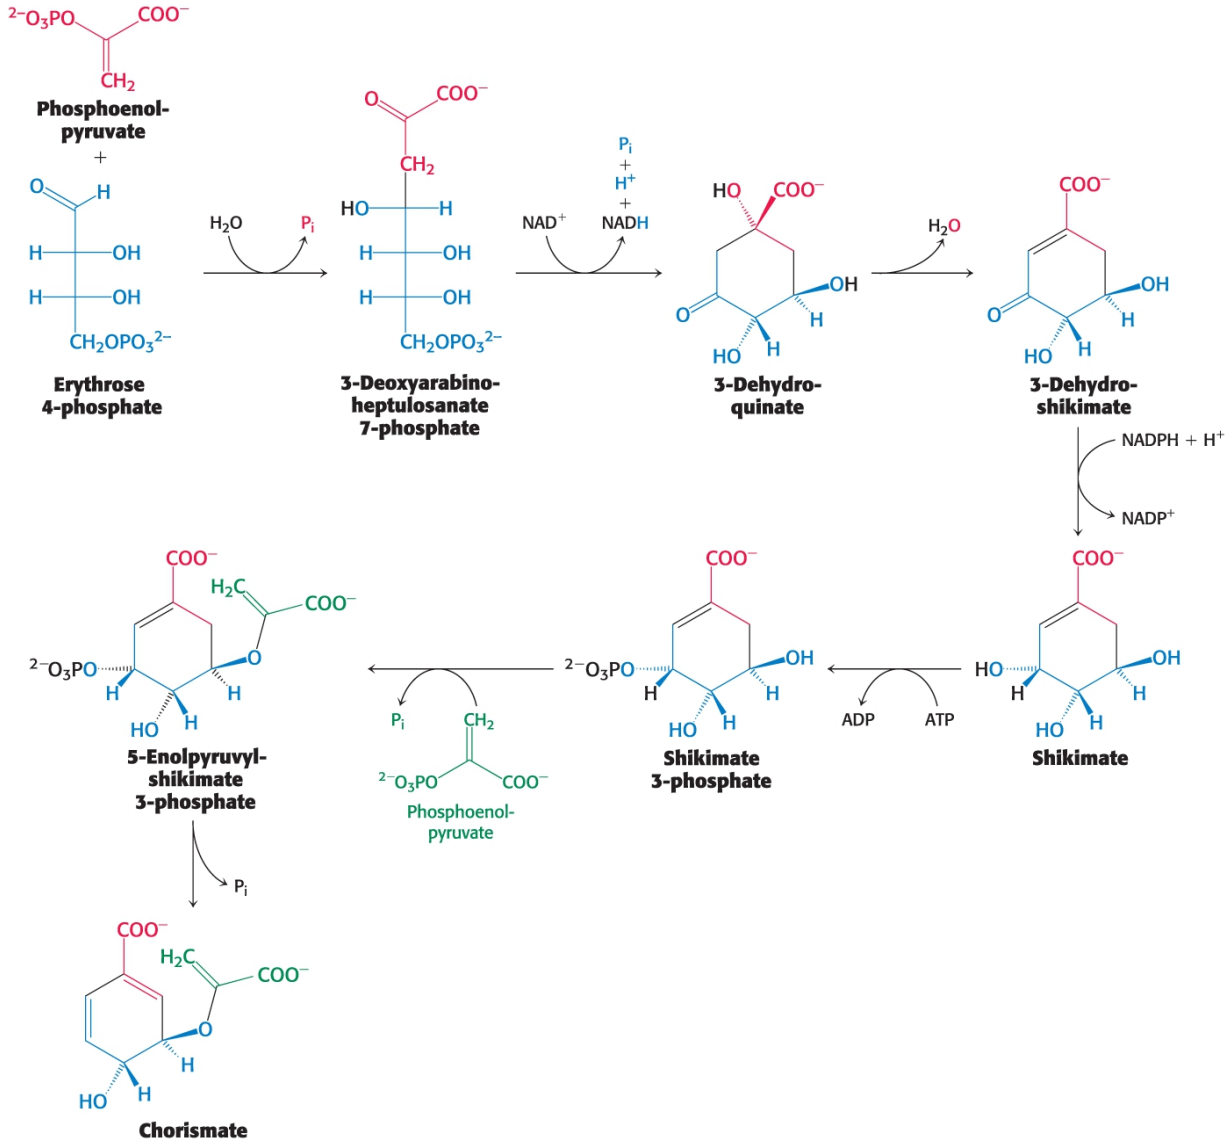
The reaction sequence consists of two reactants, one intermediate, and two products.

In the first irreversible step, homocysteine and serine are irreversibly converted into the intermediate called cystathionine by cystathionine beta-synthase. An H 2 O molecule is also released during this step.

The first reactant is homocysteine whose structure is as follows: A central C atom is single bonded to C O O superscript minus on the lower right, dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left, and wedge bonded on the upper right to a 2-carbon alkane chain depicted using a line. C 2 of this chain is single-bonded to S H on the upper right.

The second reactant is serine whose structure is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2, single bond, O H on the upper right, and dash bonded to H on the upper left.

The intermediate is cystathione whose structure is as follows: A central C atom is single bonded to C O O superscript minus on the lower right, dash bonded to H on the upper left, single bonded to N H 3 superscript plus on the lower left, and wedge bonded on the upper right to a 2-carbon alkane chain depicted using a line. C 2 of this chain is single-bonded to S on the upper right. S is single bonded to C H 2 on the upper left. This C H 2 is wedge bonded to a C atom on the upper right. This C atom is single bonded to C O O superscript minus on the upper left, single bonded to N H 3 superscript plus on the upper right, and dash bonded to H on the lower right.



In the second irreversible step, cystathionine is converted into alpha-ketobutyrate and cysteine by cystathionine gamma-lyase. This step is coupled with the entry of H 2 O and release of N H 4 superscript plus.

The first product is alpha-ketobutyrate whose structure is as follows: A central C atom is double bonded to O on the lower left, single bonded to C O O superscript minus on the lower right, and single bonded to C H 2 above in the form of a line. This C H 2 is single bonded to C H 3 on the upper left.

The second product is cysteine whose structure is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, wedge bonded to C H 2 on the upper right, dash bonded to H on the upper left, and single bonded to C O O superscript minus on the lower right. The C H 2 group is single-bonded to S H on the upper right.

Return to Formation of alpha-ketobutyrate and cysteine

Extended description for FIGURE 25.12 Chorismate is formed from phosphoenolpyruvate and erythrose 4-phosphate

In the first irreversible step, phosphoenolpyruvate and erythrose 4-phosphate are converted into 3-deoxyarabino-heptulosanate 7-phosphate. It is coupled with the entry of H 2 O and release of P subscript i.

The structure of phosphoenolpyruvate is as follows: A central C atom is single bonded to O P O 3 superscript 2 minus on the upper left, single bonded to C O O superscript minus on the upper right, and double bonded to C H 2 below.

The structure of erythrose 4-phosphate is as follows: C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double-bonded to O on the upper left and single-bonded to H on the upper right. C 2 and C 3 are each single bonded to H on the left and O H on the right.

The structure of 3-deoxyarabino-heptulosanate 7-phosphate is as follows: C, single bond, C H 2, single bond, C, single bond, C, single bond, C, single bond, C H 2 O P O 3 superscript 2 minus. C 1 is double bonded to O on the upper left and single bonded to C O O superscript minus on the upper right. C 3 is single bonded to O H on the left and single bonded to H on the right. C 4 and C 5 are each single bonded to H on the left and O H on the right.

In the second irreversible step, 3-deoxyarabino-heptulosanate 7-phosphate is converted into 3-dehydroquinate. It is coupled with the reduction of N A D superscript plus to N A D H plus H superscript plus and the release of P subscript i.

The structure of 3-dehydroquinate is as follows: A 6-carbon homocyclic hexagonal ring is in a vertical orientation. C 1 occupies the topmost vertex. It is dash bonded to O H on the upper left and wedge bonded to C O O superscript minus on the upper right. C 3 is dash bonded to H on the lower right and wedge bonded to O H on the upper right. C 4 is dash bonded to O H on the lower left and wedge bonded to H on the lower right. C 5 is double bonded to O on the lower left.

In the third irreversible step, 3-dehydroquinate is converted into 3-dehydro-shikimate. It is coupled with the release of H 2 O.

The structure of 3-dehydro-shikimate is as follows: A 6-carbon homocyclic hexagonal ring is in a vertical orientation. C 1 occupies the topmost vertex. It is single bonded to C O O superscript minus above. C 3 is dash bonded to H on the lower right and wedge bonded to O H on the upper right. C 4 is dash bonded to O H on the lower left and wedge bonded to H on the lower right. C 5 is double bonded to O on the lower left. A double bond is present between C 6 and C 1.

In the fourth irreversible step, 3-dehydro-shikimate is converted into shikimate. It is coupled with the oxidation of N A D P H plus H superscript plus to N A D P superscript plus.

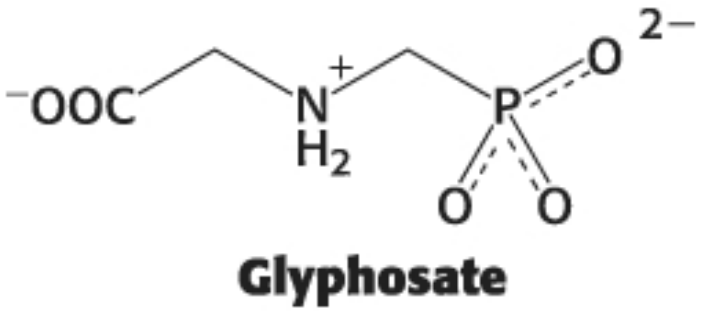
The structure of shikimate is as follows: A 6-carbon homocyclic hexagonal ring is in a vertical orientation. C 1 occupies the topmost vertex. It is single bonded to C O O superscript minus above. C 3 is dash bonded to H on the lower right and wedge bonded to O H on the upper right. C 4 is dash bonded to O H on the lower left and wedge bonded to H on the lower right. C 5 is dash bonded to O H on the left and wedge bonded to H on the lower left. A double bond is present between C 6 and C 1.

In the fifth irreversible step, shikimate is converted into shikimate 3-phosphate. This step is coupled with the hydrolysis of A T P to A D P.

The structure of shikimate 3-phosphate is as follows: A 6-carbon homocyclic hexagonal ring is in a vertical orientation. C 1 occupies the topmost vertex. It is single bonded to C O O superscript minus above. C 3 is dash bonded to H on the lower right and wedge bonded to O H on the upper right. C 4 is dash bonded to O H on the lower left and wedge bonded to H on the lower right. C 5 is dash bonded to

O P O 3 superscript 2 minus on the left and wedge bonded to H on the lower left. A double bond is present between C 6 and C 1.

In the sixth irreversible step, shikimate 3-phosphate is converted into 5-enolpyruvyl-shikimate 3-phosphate. This step is coupled with the entry of another molecule of phosphoenolpyruvate and the release of P subscript i.



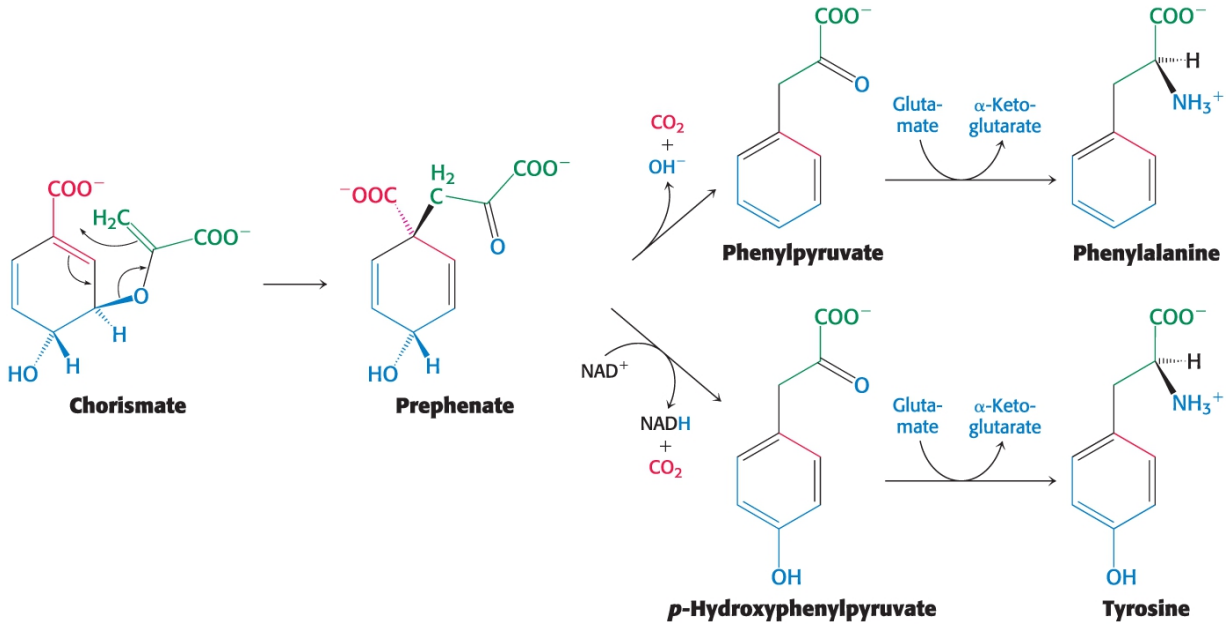
The structure of 5-enolpyruvyl-shikimate 3-phosphate is as follows: A 6-carbon homocyclic hexagonal ring is in a vertical orientation. C 1 occupies the topmost vertex. It is single bonded to C O O superscript minus above. C 3 is dash bonded to H on the lower right and wedge bonded to O on the upper right. This O is single-bonded to C on the upper right. This C is double bonded to C H 2 on the upper left and single bonded to C O O superscript minus on the upper right. C 4 is dash bonded to O H on the lower left and wedge bonded to H on the lower right. C 5 is dash bonded to O P O 3 superscript 2 minus on the left and wedge bonded to H on the lower left. A double bond is present between C 6 and C 1.

In the seventh irreversible step, 5-enolpyruvyl-shikimate 3-phosphate is converted into chorismate with the simultaneous release of P subscript i.

The structure of chorismate is as follows: A 6-carbon homocyclic hexagonal ring is in a vertical orientation. C 1 occupies the topmost vertex. It is single bonded to C O O superscript minus above. C 3 is dash bonded to H on the lower right and wedge bonded to O on the upper right. This O is single-bonded to C on the upper right. This C is double bonded to C H 2 on the upper left and single bonded to C O O superscript minus on the upper right. C 4 is dash bonded to O H on the lower left and wedge bonded to H on the lower right. A double bond is present between C 1 and C 2 and C 5 and C 6.

Return to FIGURE 25.12 Chorismate is formed from phosphoenolpyruvate and erythrose 4-phosphate

Extended description for Structure of glyphosate



Glyphosate

The structure of glyphosate is as follows: A 1 N and 2 C heteronuclear alkane is depicted as a line structure using 2 zigzag lines. N with a positive charge occupies the second position. C 1 is single bonded to C O O superscript minus on the lower left. N with a positive charge is bound to H 2. C 2 is single bonded to P on the lower right. The P atom is partially double-bonded to O on the upper right, O on the lower left, and O on the lower right. The O atoms have an overall negative charge of 2 minus.

Return to Structure of glyphosate

Extended description for FIGURE 25.13 Phenylalanine and tyrosine are formed in the prephenate branch

In the first irreversible step, chorismate is converted into prephenate.

The structure of chorismate is as follows: A 6-carbon homocyclic hexagonal ring is in a vertical orientation. C 1 occupies the topmost vertex. It is single bonded to C O O superscript minus above. C 3 is dash bonded to H on the lower right and wedge bonded to O on the upper right. This O is single-bonded to C on the upper right. This C is double bonded to C H 2 on the upper left and single bonded to C O O superscript minus on the upper right. C 4 is dash bonded to O H on the lower left and wedge bonded to H on the lower right. A double bond is present between C 1 and C 2 and C 5 and C 6. An arrow from the double bond between C 1 and C 2 of the ring points toward the single bond between C 2 and C 3. A second arrow points from the wedge bond between C 3 and O toward the single bond

between O and upper right C. A third arrow points from the double bond between this C and C H 2 toward the single bond between C 1 and C O O superscript minus.

The structure of prephenate is as follows: A 6-carbon homocyclic hexagonal ring is in a vertical orientation. C 1 occupies the topmost vertex. It dash bonded to C O O superscript minus on the upper left, wedge bonded to C H 2 on the upper right. C H 2 is single bonded to C on the right. This C is single bonded to C O O superscript minus on the upper right and double bonded to O on the lower right. C 4 is dash bonded to O H on the lower left and wedge bonded to H on the lower right. A double bond is present between C 2 and C 3, and C 5 and C 6.

Prephenate follows two different paths. In the first path, prephenate is converted into phenylalanine. In the second path, prephenate is converted into tyrosine.

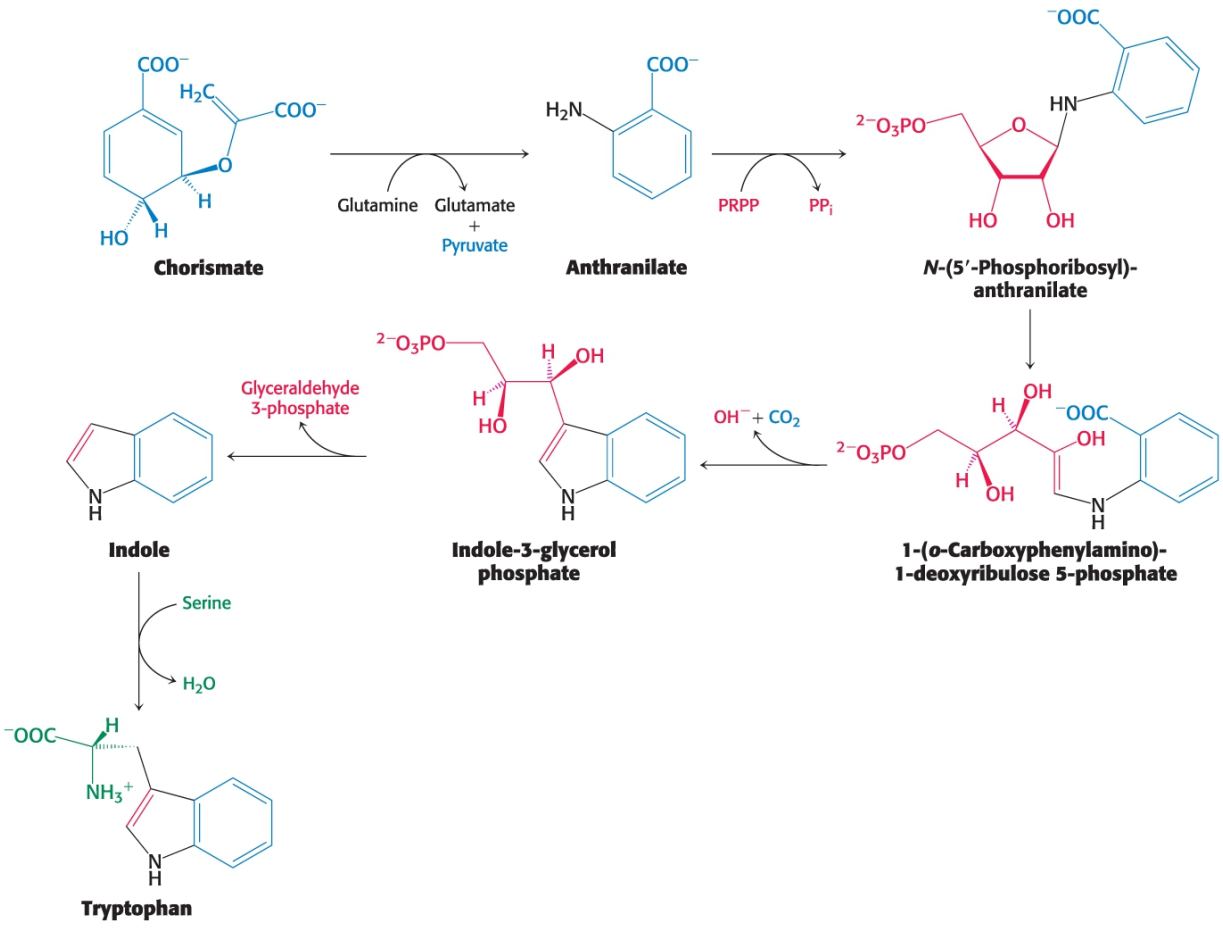
In the first path, prephenate is irreversibly converted into phenylpyruvate with the simultaneous release of C O 2 plus O H superscript minus.

The structure of phenylpyruvate is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to C H 2 above in the form of a line. This C H 2 is single-bonded to C on the upper right. C is single bonded to C O O superscript minus above and double bonded to O on the lower right.

Later, phenylpyruvate is irreversibly converted into phenylalanine. This step is coupled with the entry of glutamate and the release of alpha-ketoglutarate.

The structure of phenylalanine is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to C H 2 above in the form of a line. This C H 2 is single-bonded to C on the upper right. C is single bonded to C O O superscript minus above, dash bonded to H on the right, and wedge bonded to N H 3 superscript plus on the lower right.

In the second path, prephenate is irreversibly converted into para-hydroxyphenylpyruvate. This step is coupled with the reduction of N A D superscript plus to N A D H and the release of C O 2.



The structure of para-hydroxyphenylpyruvate is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to C H 2 above in the form of a line. This C H 2 is single-bonded to C on the upper right. C is single bonded to C O O superscript minus above and double bonded to O on the lower right. C 4 of the ring is single bonded to O H below.

Later, para-hydroxyphenylpyruvate is irreversibly converted into tyrosine. This step is coupled with the entry of glutamate and the release of alpha-ketoglutarate.

The structure of tyrosine is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to C H 2 above in the form of a line. This C H 2 is single-bonded to C on the upper right. C is single bonded to C O O superscript minus above, dash bonded to H on the right, and wedge bonded to N H 3 superscript plus on the lower right. C 4 of the ring is single bonded to O H below.

Return to FIGURE 25.13 Phenylalanine and tyrosine are formed in the prephenate branch

Extended description for FIGURE 25.14 Tryptophan is formed in the anthranilate branch

In the first irreversible step, chorismate is converted into anthranilate. It is coupled with the entry of glutamine and the release of glutamate plus pyruvate.

The structure of chorismate is as follows: A 6-carbon homocyclic hexagonal ring is in a vertical orientation. C 1 occupies the topmost vertex. It is single bonded to C O O superscript minus above. C 3 is dash bonded to H on the lower right and wedge bonded to O on the upper right. This O is single-bonded to C on the upper right. This C

is double bonded to C H 2 on the upper left and single bonded to C O O superscript minus on the upper right. C 4 is dash bonded to O H on the lower left and wedge bonded to H on the lower right. A double bond is present between C 1 and C 2 and C 5 and C 6.

The structure of anthranilate is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to C O O superscript minus above. C 5 is single bonded to N H 2 on the upper left.

In the second irreversible step, anthranilate is converted into N-open parenthesis 5 prime-Phosphoribosyl close parenthesis-anthranilate. This step is coupled with the entry of P R P P and release of P P subscript i.

The structure of N-open parenthesis 5 prime-Phosphoribosyl close parenthesis-anthranilate is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single bonded to N H. N H is further single bonded to C 5 of a benzene ring in a vertical orientation. The benzene ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 6 is single bonded to C O O superscript minus on the upper left. C 2 and C 3 of the pentagonal ring are each single bonded to O H below. C 4 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single bonded to O P O 3 superscript 2 minus on the left.

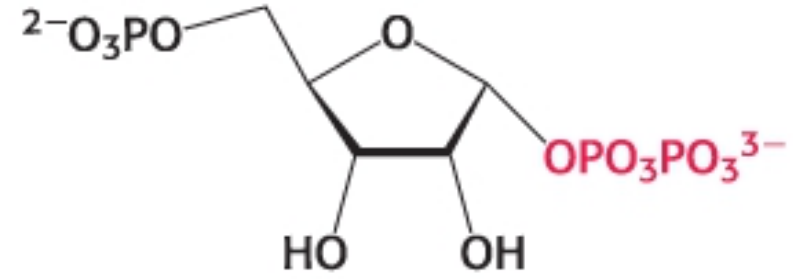
In the third irreversible step, N-open parenthesis 5 prime-Phosphoribosyl close parenthesis-anthranilate is converted into 1-open parenthesis ortho-carboxyphenylamino close parenthesis-1-deoxyribulose 5-phosphate.

The structure of 1-open parenthesis ortho-carboxyphenylamino close parenthesis-1-deoxyribulose 5-phosphate is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 6 is single bonded to C O O superscript minus on the upper left. C 5 is single bonded to N H on the lower left. N H is single bonded to C H on the left in the form of a line. C H is double bonded to C above. This C is single bonded to O H on the upper right and single bonded to C 3 of a 3-carbon alkane chain, depicted using 2 zigzag lines, on the upper left. In the alkane chain, C 1 is single bonded to O P O 3 superscript 2 minus on the lower left. C 2 is dash bonded to H on the lower left and wedge bonded to O H on the lower right. C 3 is dash bonded to H on the upper left and wedge bonded to O H on the upper right.

In the fourth irreversible step, 1-open parenthesis ortho-carboxyphenylamino close parenthesis-1-deoxyribulose 5-phosphate is converted into indole-3-glycerol phosphate. This step is coupled with the release of C O 2 plus O H superscript minus.

The structure of indole-3-glycerol phosphate is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation. It consists of 1 N and 4 C atoms. N bound to H occupies the bottom left vertex. A double bond is present between C 1 and C 2. It is fused to a benzene ring in a vertical orientation such that C 3 and C 4 of the pentagonal ring are C 6 and C 5 respectively of the benzene ring. The benzene ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 of the pentagonal ring is single bonded to C 3 of a 3-carbon alkane chain depicted using 2 zigzag lines. In the alkane chain, C 1 is single bonded to O P O 3 superscript 2 minus on the left. C 2 is dash bonded to H on the lower left and wedge bonded to O H below. C 3 is dash bonded to H above and wedge bonded to O H on the upper right.

In the fifth irreversible step, indole-3-glycerol phosphate is converted into indole. It is coupled with the release of glyceraldehyde 3-phosphate.



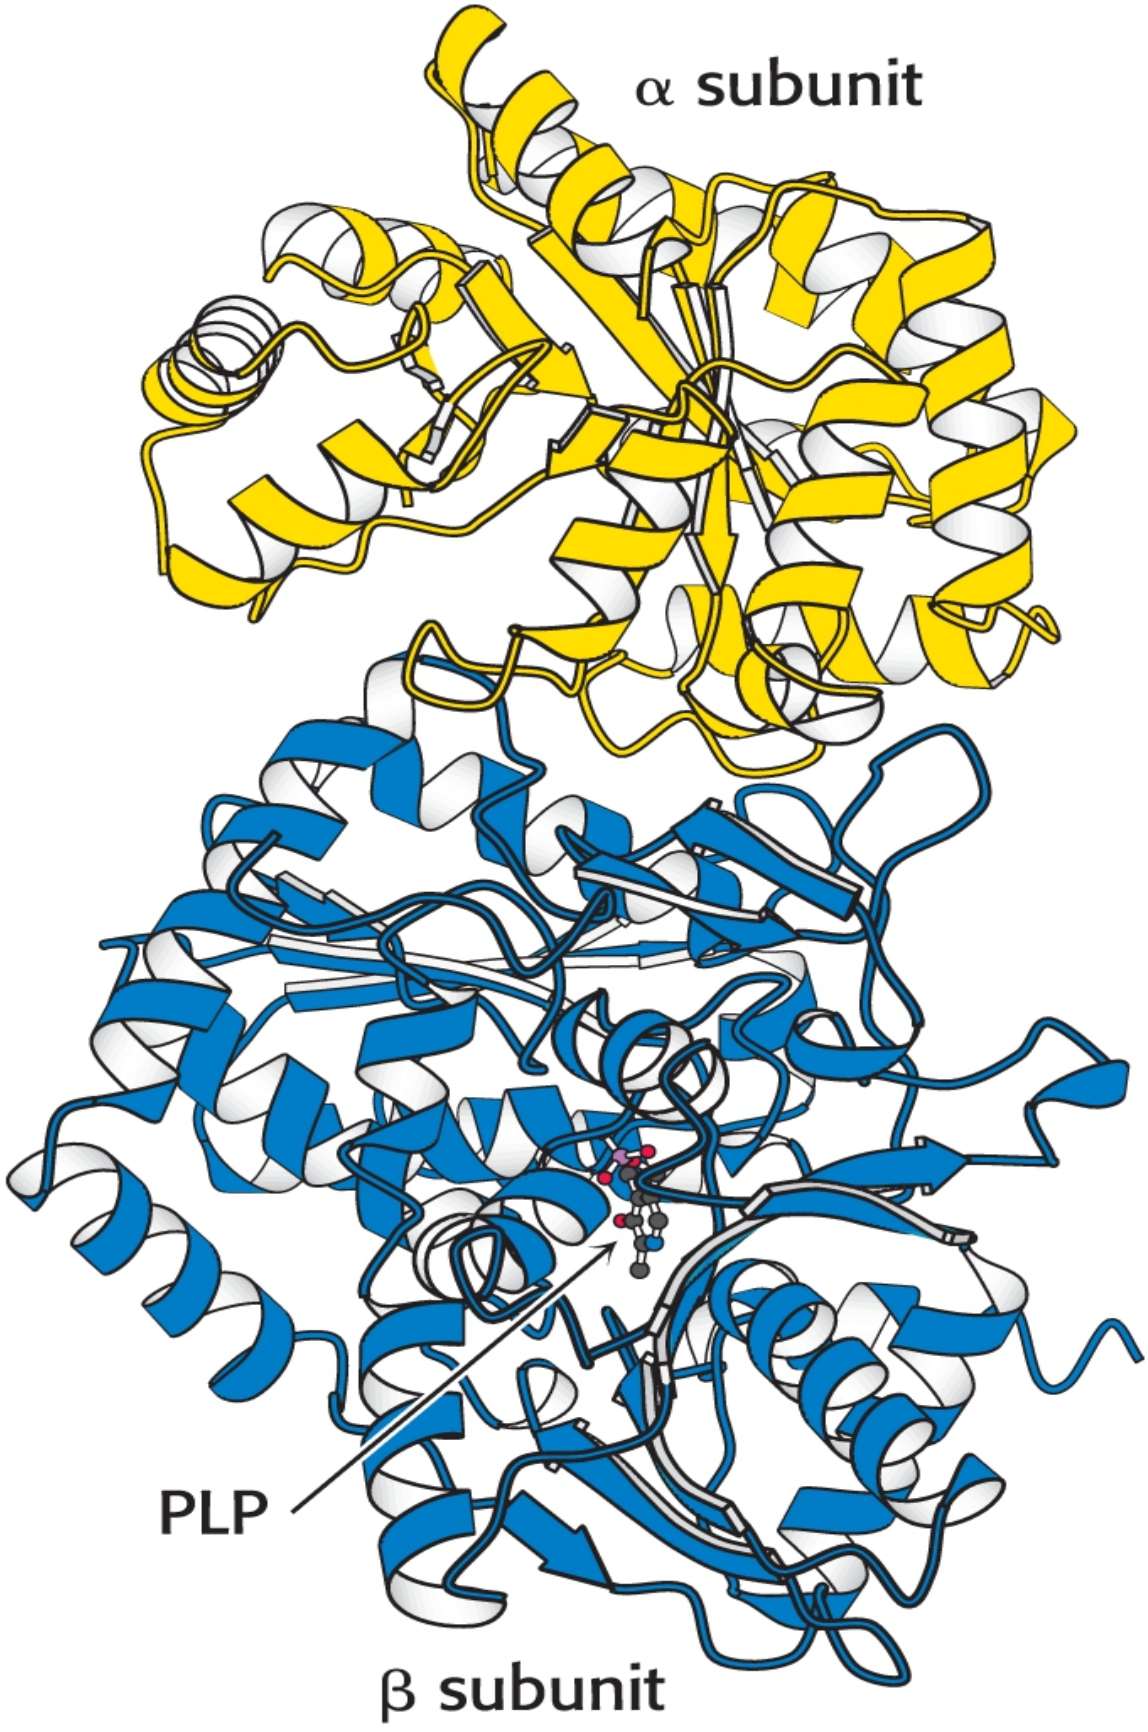
The structure of indole is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation. It consists of 1 N and 4 C atoms. N bound to H occupies the bottom left vertex. A double bond is present between C 1 and C 2. It is fused to a benzene ring in a vertical orientation such that C 3 and C 4 of the pentagonal ring are C 6 and C 5 respectively of the benzene ring. The benzene ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6.

In the sixth irreversible step, indole is converted into tryptophan with the simultaneous entry of serine and release of H 2 O.

The structure of tryptophan is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation. It consists of 1 N and 4 C atoms. N bound to H occupies the bottom left vertex. A double bond is present between C 1 and C 2. It is fused to a benzene ring in a vertical orientation such that C 3 and C 4 of the pentagonal ring are C 6 and C 5 respectively of the benzene ring. The benzene ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 of the pentagonal ring is single-bonded to C H 2 on the upper left in the form of a line. C H 2 is dash bonded to C on the left. This C is single bonded to C O O superscript minus on the left, wedge bonded to H on the upper right, and single bonded to N H 3 superscript plus below.

Return to FIGURE 25.14 Tryptophan is formed in the anthranilate branch

Extended description for Structure of 5-phosphoribosyl-1-pyrophosphate



5-Phosphoribosyl-1-pyrophosphate (PRPP)

The structure of 5-phosphoribosyl-1-pyrophosphate (P R P P) is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. The ring is in a plane perpendicular to the plane of paper such that C 2 and C 3 are located toward the observer and O is located away from the observer. C 1 is single bonded to O P O 3 P O 3 superscript 3 minus below. C 2 and C 3 are each single bonded to O H below. C 4 is single bonded to C H 2 above in the form of a line. The C H 2 group is single bonded to O P O 3 superscript 2 minus on the left.

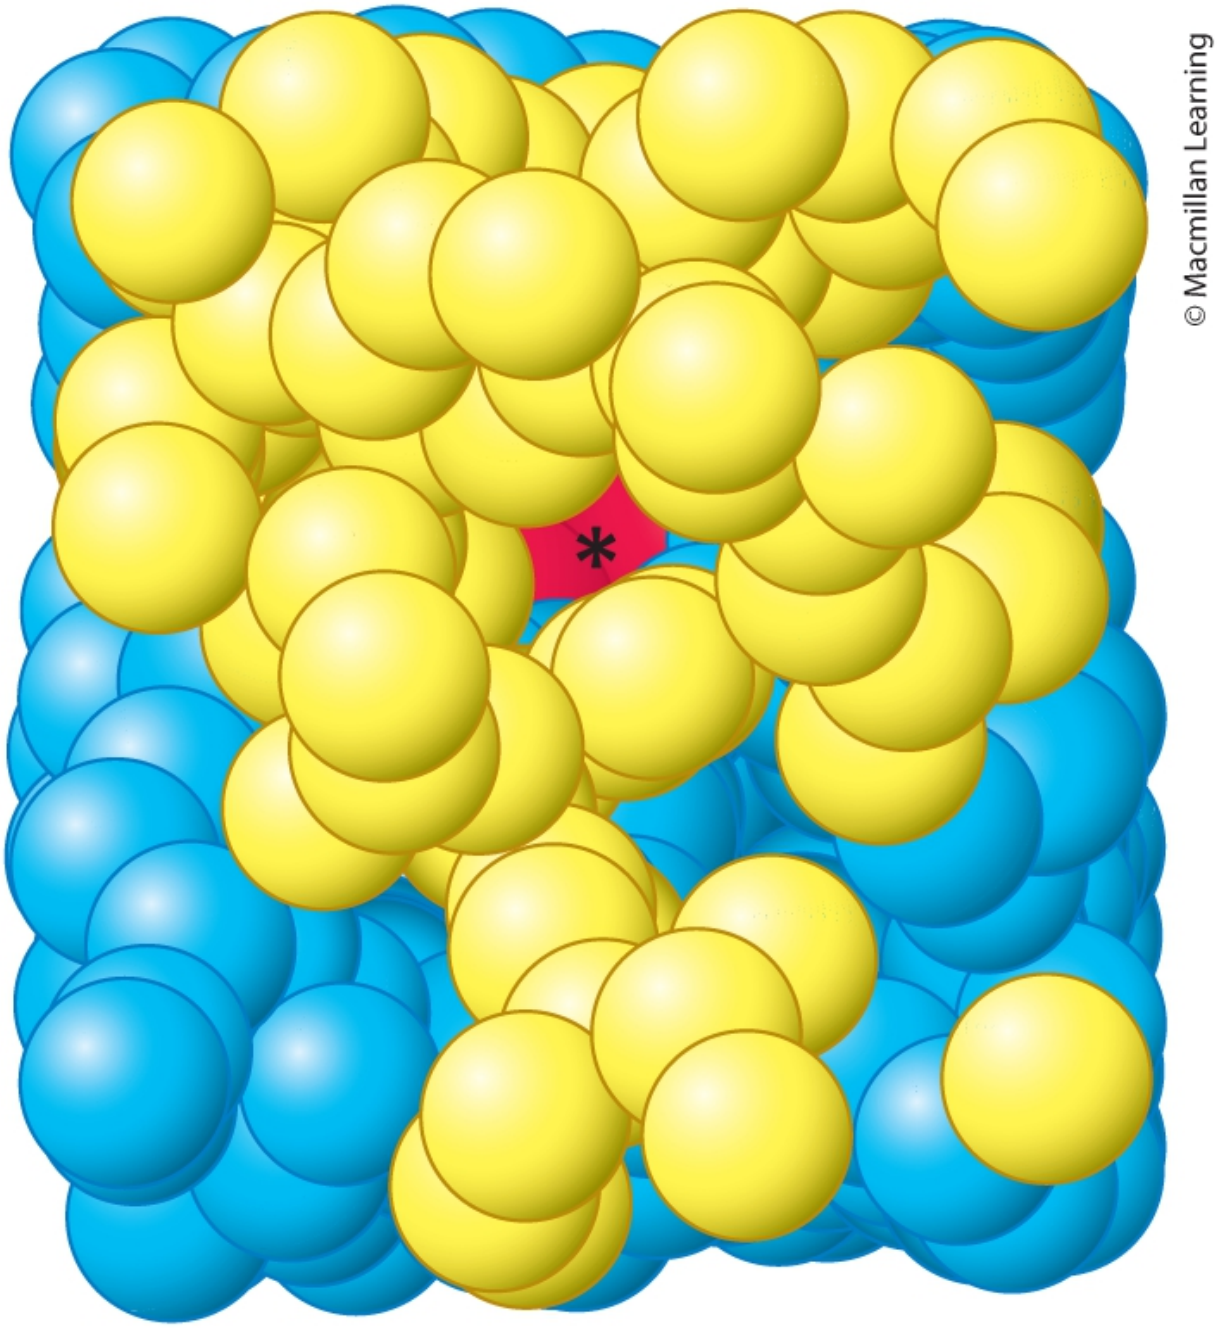
Extended description for Reaction between Schiff base

of aminoacrylate and indole

Schiff base of aminoacrylate
(derived from serine)

The structure of indole is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 1 N and 4 C atoms. N bound to H occupies the bottom left vertex. A double bond is present between C 3 and C 4. It is fused to a benzene ring in a horizontal orientation such that C 1 and C 2 of the pentagonal ring are C 3 and C 2 respectively of the benzene ring. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1.



The structure of the Schiff base of aminoacrylate, derived from serine, is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation. It consists of 1 N and 5 C atoms. N with a positive charge bound to H occupies the bottom-most vertex. A double bond is present between N and C 1, C 2 and C 3, and C 4 and C 5. C 2 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single bonded to O P O 3 superscript 2 minus on the lower left. C 3 is single bonded to C above. This C is single bonded to H on the upper left and double bonded to N superscript plus on the upper right. This N superscript plus atom is single-bonded to H on the lower right and single-bonded to C above. This C is double bonded to C H 2 on the upper left and single bonded to C O O superscript minus on the upper right. C 4 is single bonded to O superscript minus on the upper right. C 5 is single bonded to C H 3 on the lower right.

An arrow from the N H group of indole points toward the single bond between the N H group and C 4 of the pentagonal ring. A second arrow points from the double bond between C 3 and C 4 points toward the C H 2 group of Schiff base of aminoacrylate. A third arrow from the double bond between this C H 2 group and C points toward the single bond between this C and N superscript plus atom. A fourth arrow points from the double bond between the N superscript plus atom and C toward the single bond between this C and C 3 of the ring. Inside the ring of the Schiff base, a fifth arrow

points from the double bond between C 2 and C 3 toward the single bond between C 1 and C 2. A sixth arrow points from the double bond between C 1 and N superscript plus atom toward the N superscript plus atom.

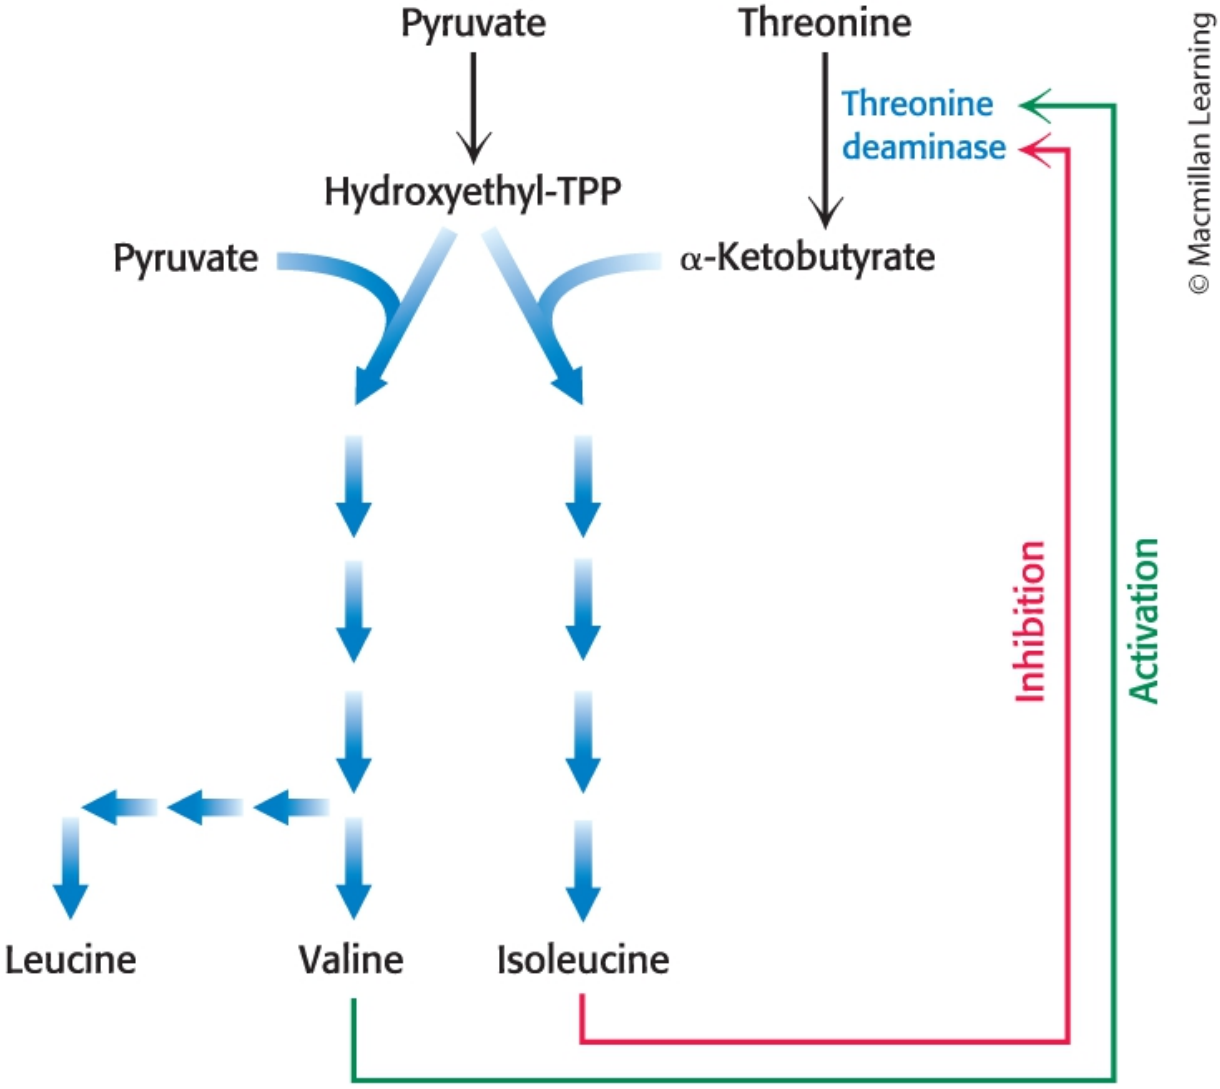
Extended description for FIGURE 25.17 3-

Phosphoglycerate dehydrogenase is a homotetramer



© Macmillan Learning

The ribbon diagram of phosphoglycerate dehydrogenase is depicted as a hollow oval-shaped structure. It consists of two catalytic domains, one on each side. The catalytic domain is narrow, elongated, and composed of several beta-strands and a few alpha-helices. Each of the catalytic domains is bound to N A D P H. The dimeric regulatory domain is located at the top and bottom. The regulatory domain is small and composed of beta-strands at the bottom and alpha-helices forming the top. Two adjacent hollow regions are present in each domain. These hollow regions are bound to serine amino acids. The bottom regulatory domain is inverted such that beta-strands form the top and alpha-helices constitute the bottom.

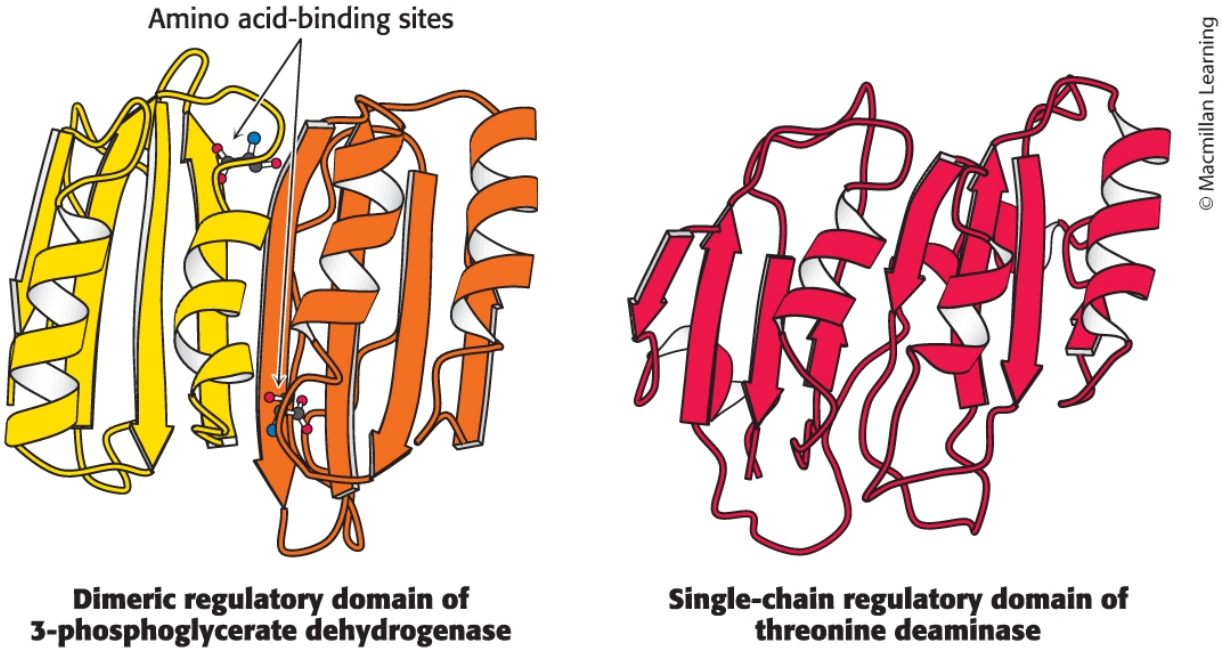
Extended description for FIGURE 25.18 Threonine deaminase is regulated by feedback inhibition and activation



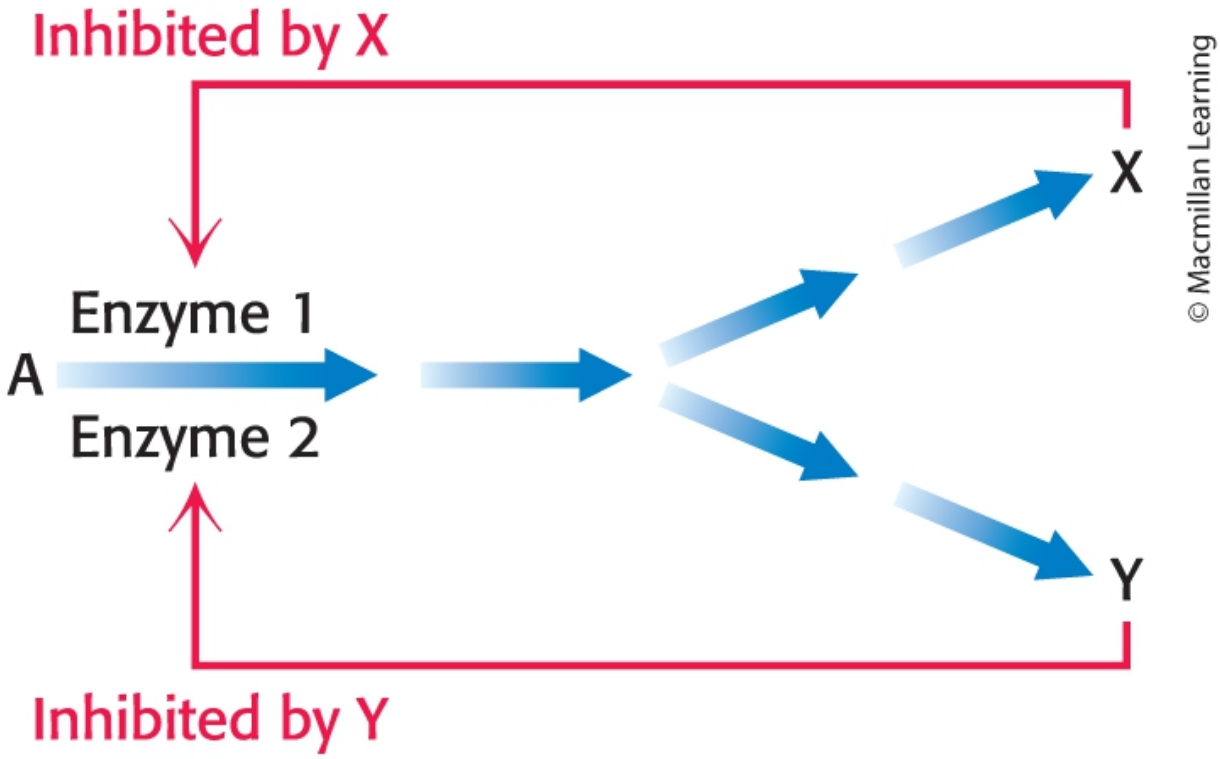
A biosynthetic pathway leading to the formation of amino acids leucine, valine, and isoleucine from pyruvate is shown. An adjacent, single-step conversion of threonine to alpha-ketobutyrate is shown. It is catalyzed by threonine deaminase. In the biosynthetic pathway, pyruvate is first irreversibly converted into hydroxyethyl-T P P,

which has two fates. It can either combine with pyruvate to form valine and leucine or combine with alpha-ketobutyrate from the single-step conversion to form isoleucine. In the first fate, four downward arrows lead to valine. Four successive arrows originating from the middle of the third and fourth downward arrows lead to leucine. In the second fate, four downward arrows lead to isoleucine. A red arrow labeled inhibition points from isoleucine to threonine deaminase. A green arrow labeled activation points from valine to threonine deaminase.

Return to FIGURE 25.18 Threonine deaminase is regulated by feedback inhibition and activation

Extended description for FIGURE 25.19 The regulatory domains of 3-phosphoglycerate dehydrogenase and threonine deaminase are related structurally

© Macmillan Learning



The dimeric regulatory domain of 3-phosphoglycerate dehydrogenase consists of two subunits shown in yellow and orange. The left yellow subunit consists of two vertical alpha-helices and four vertical beta-strands interconnected by thread-like loops. The right orange subunit consists of two vertical alpha-helices and four vertical beta-strands interconnected by thread-like loops. The amino acid-binding site is located on the top right and bottom left of the left and right subunits respectively. Each of these sites is bound to a ball-and-stick model of amino acid.

The single-chain regulatory domain of threonine deaminase consists of vertical and adjacently placed alpha-helices and beta-

strands interconnected by thread-like loops. It contains four alpha-helices and eight beta-strands.

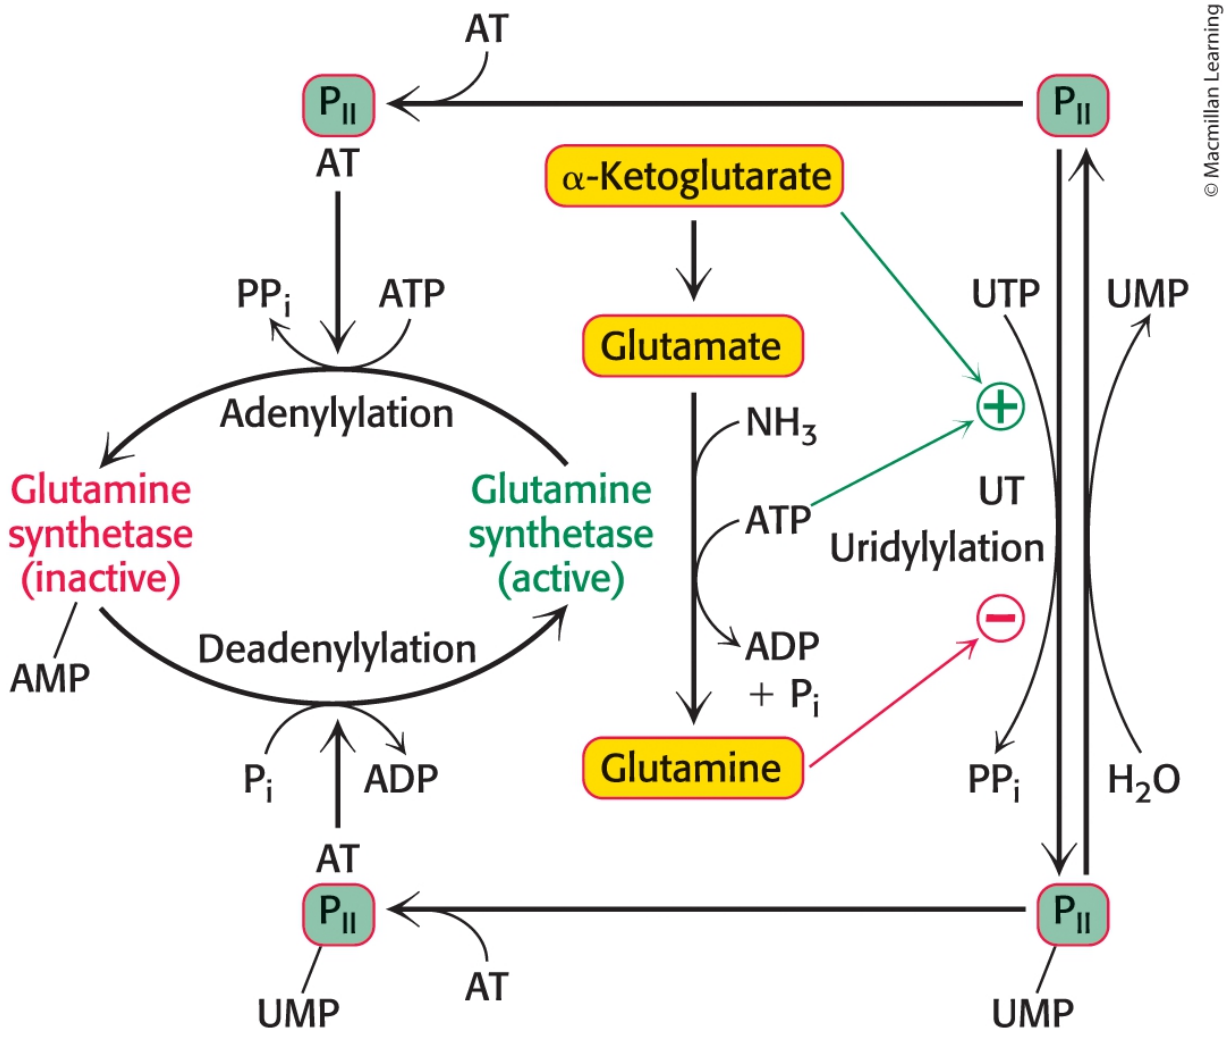
Extended description for Structure of tyrosine residue modified by adenylylation

Tyrosine residue modified by adenylylation

The tyrosine residue modified by adenylylation consists of tyrosine residue connected to A M P.

The structure of tyrosine is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains

alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to C H 2 above in the form of a line. This C H 2 is dash-bonded to C on the upper left. C is single bonded to C on the upper right, wedge bonded to H on the lower left, and single bonded to N H on the upper left. The upper right C is double bonded to O above and has a wiggly line on the lower right. N H has a wiggly line on the lower left. C 4 of the ring is single bonded to O below. This O is single-bonded to the P atom of A M P.



The structure of A M P is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. C 1 occupies the top right vertex. C 2 and C 3 are single bonded to O H below. C 4 is single-bonded to C H 2 above in the form of a line, which is further single-bonded to the S atom of methionine amino acid. The S atom is positively charged. C 1 is single-bonded to N 1 of a 5-membered heterocyclic pentagonal ring in a horizontal orientation with C 1 occupying the leftmost vertex. This ring consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the topmost vertex. A double bond is present between C 1 and N 2. The pentagonal ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 of the hexagonal ring respectively. The hexagonal ring consists of 2 N and 4 C atoms. First N occupies the top right vertex and the second N occupies the bottom-most vertex. A double bond is present between C 1 and N 2, C 2 and C 3, and C 4 and N 1. C 4 is single bonded to N H 2 above.

The structure of A M P is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 occupies the top right vertex. C 2 and C 3 are single bonded to O H below. C 4 is single-bonded to C H 2 above in the form of a line, which is further single-bonded to the O atom on the left. O is single-bonded to P. This P is

partially double-bonded to O on the lower left, partially double-bonded to O on the lower right, and single-bonded to the O atom of tyrosine residues. The partially double-bonded O atoms have an overall negative charge. C 1 of the pentagonal ring is single-bonded to N 1 of a 5-membered heterocyclic pentagonal ring in a horizontal orientation with C 1 occupying the leftmost vertex. This ring consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the topmost vertex. A double bond is present between C 1 and N 2. The pentagonal ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 4 and C 3 of the hexagonal ring respectively. The hexagonal ring consists of 2 N and 4 C atoms. First N occupies the topmost vertex and the second N occupies the bottom-right vertex. A double bond is present between C 1 and N 1, N 2 and C 2, and C 3 and C 4. C 1 is single bonded to N H 2 on the upper right.

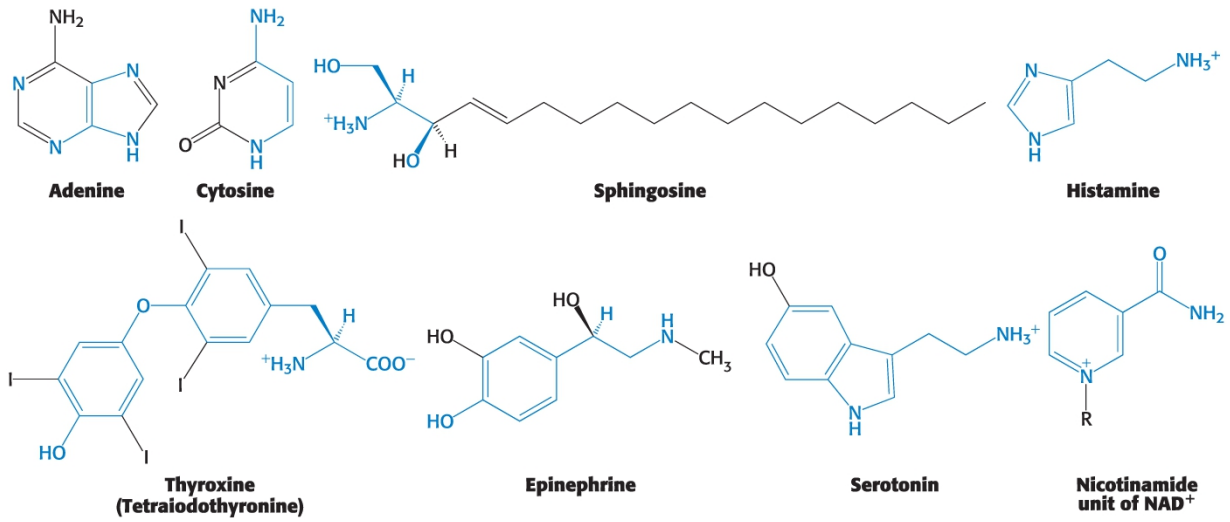
Return to Structure of tyrosine residue modified by adenylylation

Extended description for FIGURE 25.21 Glutamine synthetase is regulated by covalent modification

A pathway is shown in the center. It shows the irreversible conversion of alpha-ketoglutarate to glutamate. Glutamate is then irreversibly converted into glutamine by glutamine synthetase (active) with the simultaneous entry of N H 3 and breakdown of A T P to A D P plus P subscript i. A T associated with P subscript roman number 2 is shown at the top left, P subscript roman number 2 is shown at the top right, P subscript roman number 2 linked to U M P

is shown at the bottom right, A T associated with P subscript roman number 2 linked to U M P is shown at the bottom left.

P subscript roman number 2 is irreversibly converted into A T associated with P subscript roman number 2 by the addition of A T. P subscript roman number 2 undergoes reversible uridylylation to P subscript roman number 2 linked to U M P. This conversion is catalyzed by U T with the simultaneous entry of U T P and release of P P subscript i. P subscript roman number 2 linked to U M P is converted back to P subscript roman number 2 with the simultaneous entry of H 2 O and release of U M P. U T enzyme is activated by alpha-ketoglutarate, A T P and inhibited by glutamine from the pathway. Activation is depicted by a plus symbol and inhibition is depicted by a minus symbol.



P subscript roman number 2 linked to U M P is also irreversibly converted into A T associated with P subscript roman number 2 linked to U M P by the addition of A T.

The A T associated with P subscript roman number 2 linked to U M P carries out the deadenylylation of A M P bound-glutamine synthetase (inactive) to the active form. This conversion is coupled with the entry of P subscript i and the release of A D P.

The A T associated with P subscript roman number 2 carries out the adenylylation of glutamine synthetase (active) to inactive form bound to A M P. This conversion is coupled with the entry of A T P and release of P P subscript i.

Return to FIGURE 25.21 Glutamine synthetase is regulated by covalent modification

Extended description for FIGURE 25.22 A diverse array of biomolecules are derived from amino acids

The structure of adenine is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. First N occupies the bottom-most vertex and the second N occupies the top left vertex. A double bond is present between N 1 and C 1, N 2 and C 2, and C 3 and C 4. C 2 is single bonded to N H 2 above. It is fused to a 5-membered heterocyclic pentagonal ring such that C 3 and C 4 of the hexagonal ring are C 3 and C 2 respectively of the pentagonal ring. The pentagonal ring consists of 2 N and 3 C atoms. First N occupies the topmost vertex and the second N bound to H occupies the bottom right vertex. A double bond is present between N 1 and C 1. The N atoms of both rings, the H atom bound to the N atom, and the fused part of the rings are highlighted in blue.

The structure of cytosine is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. The first N bound to H occupies the bottom-most vertex and

the second N occupies the top left vertex. A double bond is present between N 2 and C 2, and C 3 and C 4. C 1 is double bonded to O on the lower left. C 2 is single bonded to N H 2 above. The first N bound to H, N H 2 group, C 3, and C 4 are highlighted in blue.

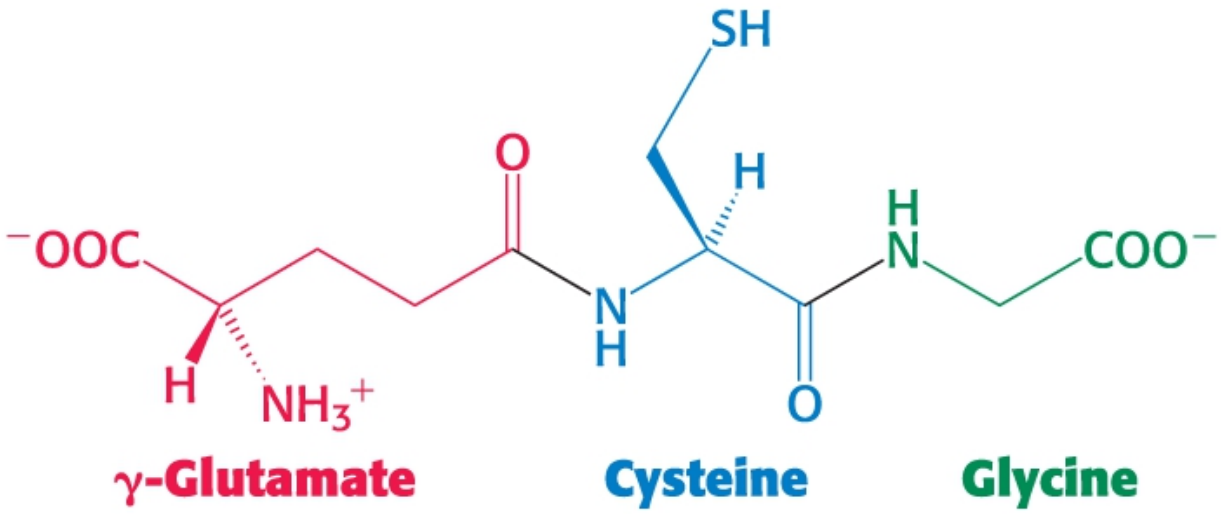
The structure of sphingosine is as follows: A 2-carbon alkane chain is depicted using a single line. C 1 is wedge bonded to C H 2 on the upper left, dash bonded to H on the upper right, and single bonded to N H 3 superscript plus on the lower left. C H 2 is single-bonded to O H on the left. C 2 is wedge bonded to O H, dash bonded to H on the lower right, and single bonded to a 15-carbon alkene chain depicted using a line structure. A double bond is present between C 1 and C 2. The 2-carbon alkane chain and its substituent groups except for the 15-carbon alkene chain, lower right H, and the H atom of the lower left O H group are highlighted in blue.

The structure of histamine is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 2 N and 3 C atoms. First N bound to H occupies the bottom left vertex. Second N occupies the topmost vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 2 is single bonded to a 2-carbon alkane chain depicted using a line. C 2 of this chain is single bonded to N H 3 superscript plus on the upper right. The entire structure is highlighted in blue.

The structure of thyroxine (tetraiodothyronine) is as follows: A benzene ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 1 and C 4 are single-bonded to I. C 3 is single bonded to O H on the lower left. C 6 is single bonded to O on the upper right. This O is single bonded to C 4 of another benzene ring in horizontal orientation. In the second ring, C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 3 and C 5 are each single bonded to I. C 1 occupies the rightmost vertex and is single-bonded

to C H 2 on the right in the form of a line. C H 2 is wedge bonded to C on the lower right. This C is dash bonded to H on the upper right, single bonded to C O O superscript minus on the lower right, and single bonded to N H 3 superscript plus on the lower left. The entire structure except I atoms is highlighted in blue.

The structure of epinephrine is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to C 1 of a 1 N and 2 C heteronuclear alkane chain depicted as a line structure using 2 zigzag lines. N bound to H occupies the third position. C 1 is wedge bonded to O H on the upper left and dash bonded to H on the upper right. N is single bonded to C H 3 on the lower right. C 5 of the benzene ring is single-bonded to O H on the lower left. C 6 is single bonded to O H on the upper left. The entire benzene ring, alkane chain, H atom dashed bonded to C 1 of the alkane chain, and O H group bonded to C 5 are highlighted in blue.



The structure of serotonin is as follows: A benzene ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 5 is single bonded to O H. The benzene ring is fused to a 5-membered heterocyclic pentagonal ring in a vertical orientation such that C 1 and C 2 of the benzene ring are C 2 and C 1 respectively of the pentagonal ring. The pentagonal ring consists of 1 N and 4 C atoms. N bound to H occupies the bottom-most vertex. A double bond is present between C 3 and C 4. C 3 is single bonded to a 2-carbon alkane chain depicted using a line. C 2 of this chain is single bonded to N H 3 superscript plus on the upper right. The entire structure except the O H group is highlighted in blue.

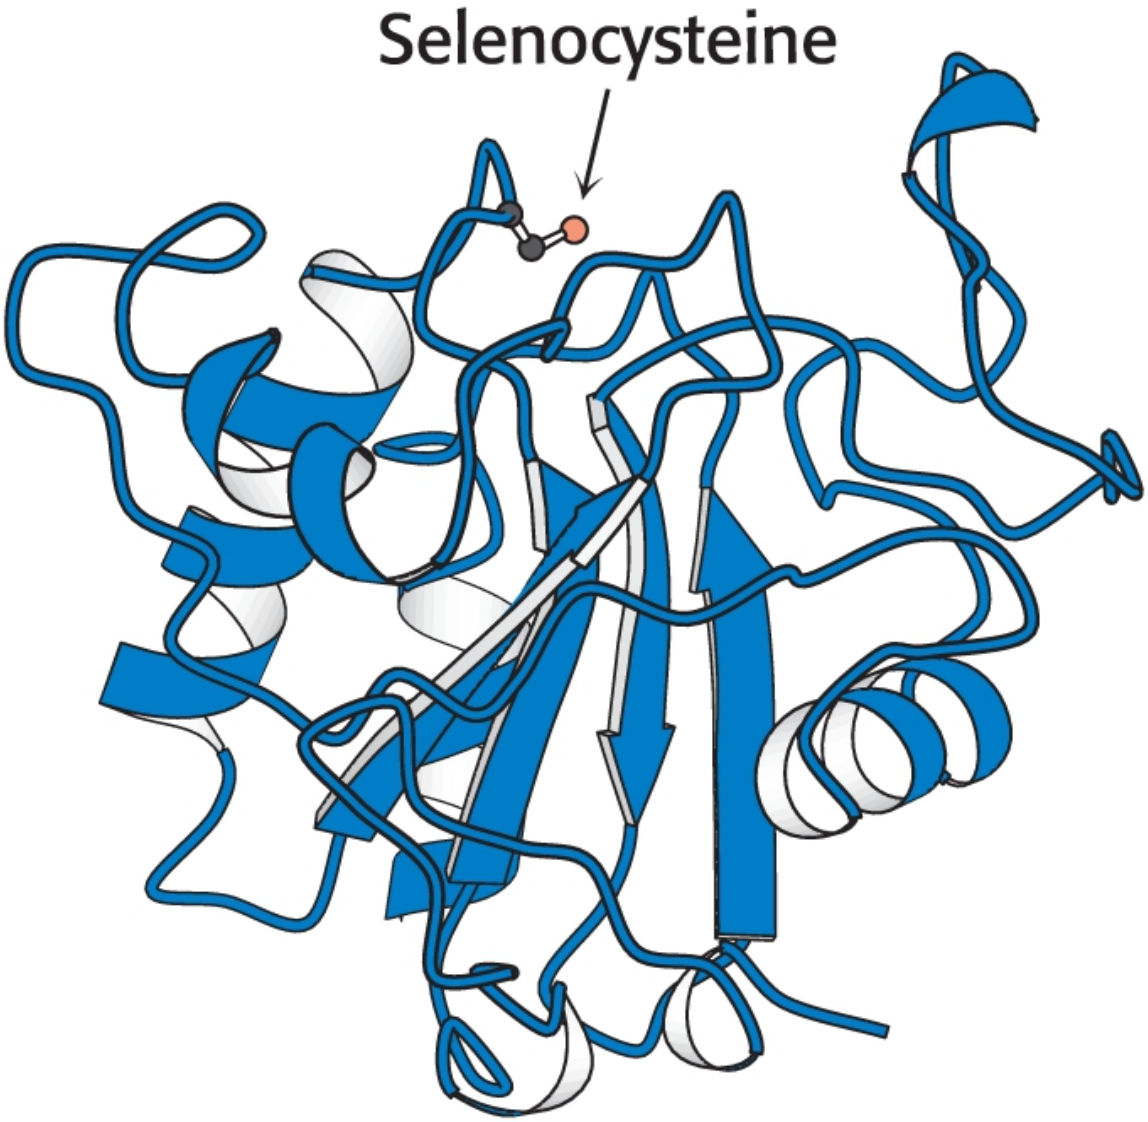
The structure of the nicotinamide unit of N A D superscript plus is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical

orientation. It consists of 1 N and 5 C atoms. N with a positive charge occupies the bottom-most vertex. N is single bonded to R below. A double bond is present between N and C 1, C 2 and C 3, and C 4 and C 5. C 4 is single bonded to C on the upper right. This C is double bonded to O above and single bonded to N H 2 on the lower right. The entire structure except the R group is highlighted in blue.

Return to FIGURE 25.22 A diverse array of biomolecules are derived from amino acids

Extended description for FIGURE 25.23 Glutathione structure

Glutathione is composed of 3 amino acids namely gamma-glutamate, cysteine, and glycine from left to right.



Gamma-glutamate consists of 4 carbon alkane chain depicted as a line structure using 3 zigzag lines. C 1 is single bonded to C O O superscript minus on the upper left, wedge bonded to H on the lower left, and dash bonded to N H 3 superscript plus on the lower right. C 4 is double bonded to O above and single bonded to N H of a cysteine residue.

Cysteine consists of a central C atom single bonded to N H on the lower left, wedge bonded to C H 2 on the upper left, dash bonded to H on the upper right, and single bonded to C on the lower right. This C atom is double bonded to O below and single bonded to N H of glycine on the upper right. The upper left C H 2 is single-bonded to S H on the upper right.

Glycine consists of N H single bonded to C H 2 on the lower right in the form of a line. C H 2 is single bonded to C O O superscript minus on the upper right.

The cycle is depicted as follows: E, single bond, S e superscript minus labeled selenolate is converted into selenenic acid depicted as E, single bond, S e O H. This conversion is coupled with the entry of R O O H plus H superscript plus and release of R O H. Selenenic acid is further converted into selenosulfide depicted as E, single bond, S e, single bond, S, single bond, G. This conversion is coupled with the entry of G S H and release of H 2 O. The selenosulfide is converted back to selenolate with the simultaneous entry of G S H and release of G S S G plus H superscript plus.

Return to FIGURE 25.25 Regeneration of selenolate active site after peroxide cleavage

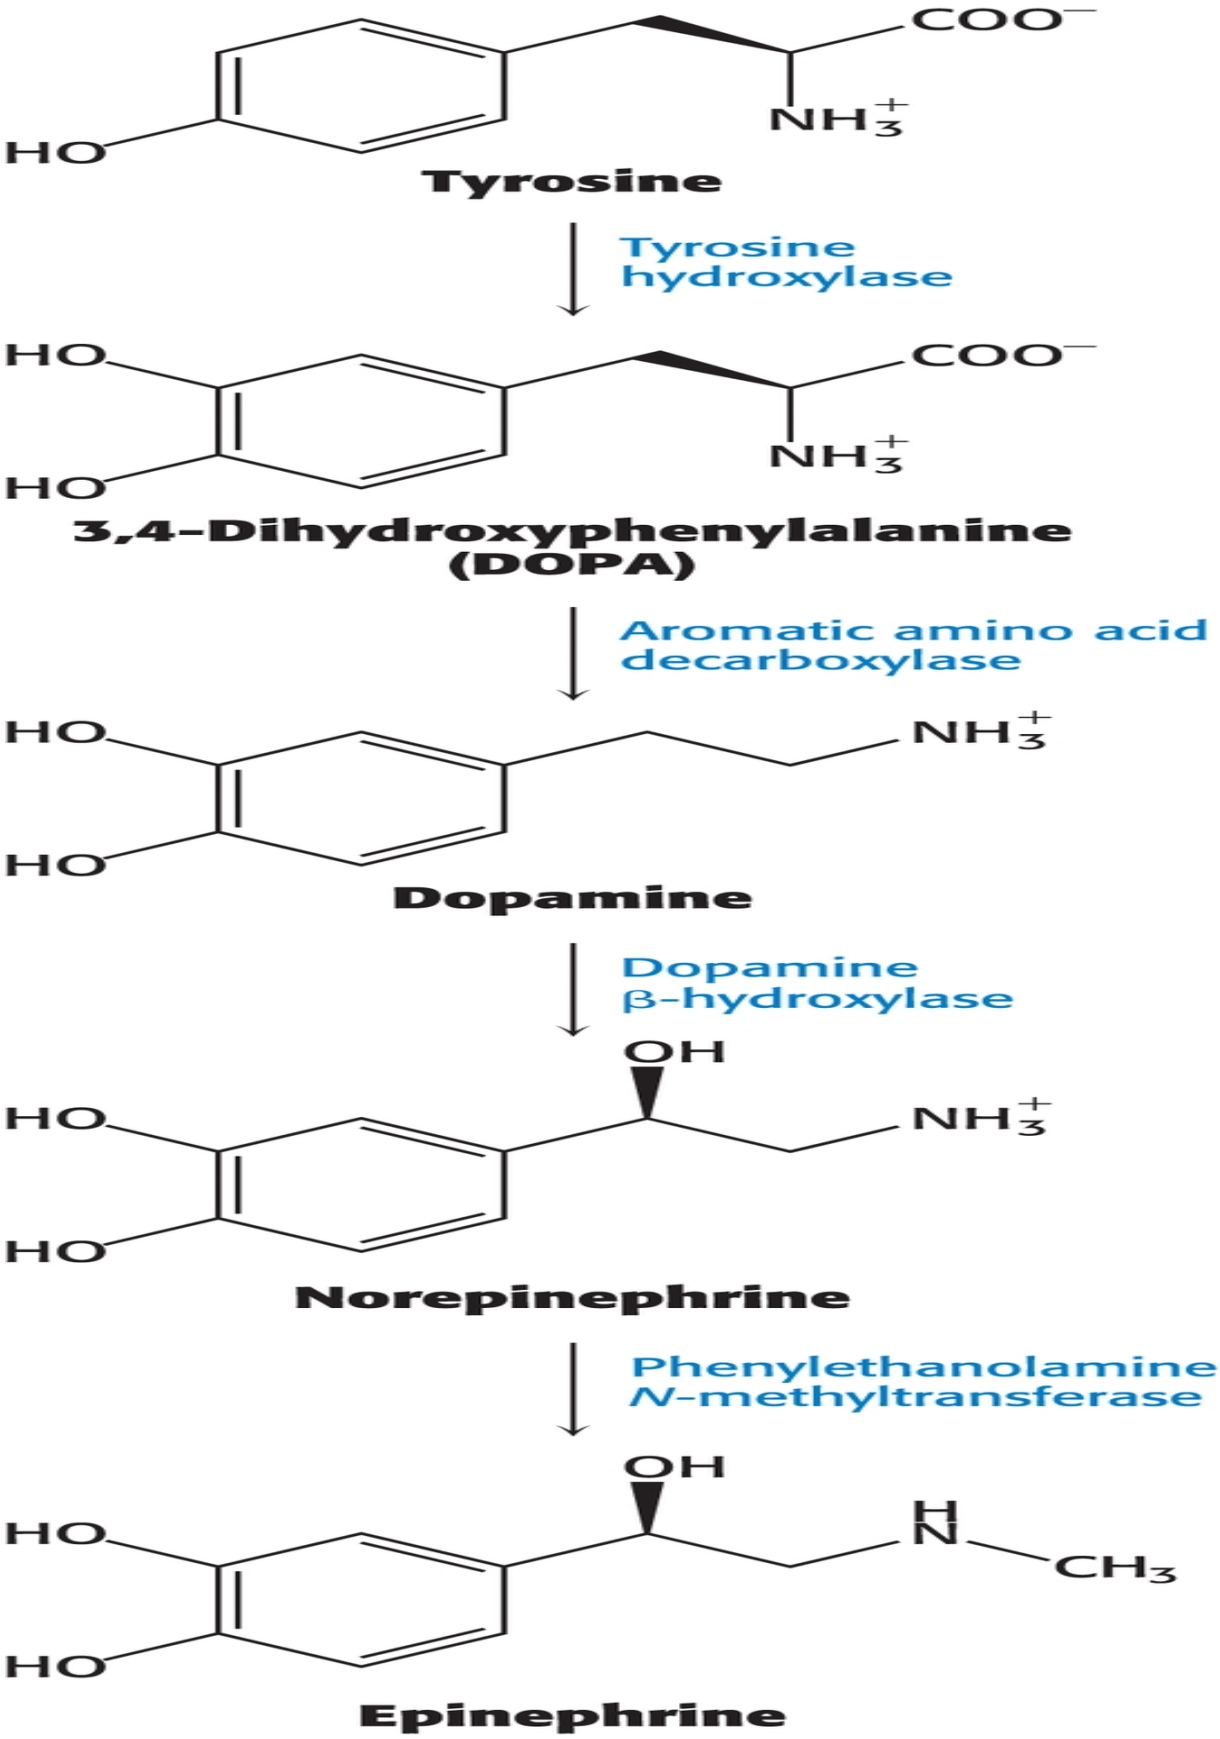
Extended description for FIGURE 25.26 Generation of nitric oxide from arginine

In the first irreversible step, arginine is converted into N-omega-hydroxy-arginine. This step is coupled with the entry of H superscript plus and O 2, the release of H 2 O, and the oxidation of N A D P H to N A D P superscript plus.

The structure of arginine is as follows: A central C is wedge bonded to C H 2 on the upper left, dash bonded to H on the upper right, single bonded to C O O superscript minus on the lower right, and single bonded to N H 3 superscript plus on the lower left. C H 2 is single bonded to 1 N and 2 C heteronuclear alkane chain depicted as vertical line structure using 2 zigzag lines. N bound to H occupies the third position. This N H group is partially double-bonded to a central C atom on the upper left. This C atom is partially double-bonded to N H 2 on the upper right and N H 2 on the lower left. The N H 2 groups have an overall positive charge.

The structure of N-omega-hydroxy-arginine is as follows: A central C is wedge bonded to C H 2 on the upper left, dash bonded to H on the upper right, single bonded to C O O superscript minus on the lower

right, and single bonded to N H 3 superscript plus on the lower left. C H 2 is single bonded to 1 N and 2 C heteronuclear alkane chain depicted as vertical line structure using 2 zigzag lines. N bound to H occupies the third position. This N H group is single-bonded to a central C atom on the upper left. This C atom is double bonded to N superscript plus on the upper right and single bonded to N H 2 on the lower left. The N atom is single-bonded to H on the upper right and single-bonded to the O H group on the upper left.



In the second irreversible step, N-omega-hydroxy-arginine is converted into citrulline and nitric oxide. This step is coupled with the entry of O 2, the release of H 2 O, and the oxidation of N A D P H to N A D P superscript plus.

The structure of citrulline is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to a 1 N and 2 C alkane chain depicted as a vertical line structure using 2 zigzag lines. N bound to H occupies the third position. N is single-bonded to C on the upper right. This C is single bonded to N H 2 on the left and double bonded to O on the upper right. The formula of nitric oxide is N O. N atom has an unpaired electron.

In the first irreversible step catalyzed by tyrosine hydroxylase, tyrosine is converted into 3,4-Dihydroxyphenylalanine (D O P A).

The structure of tyrosine is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to C H 2 on the upper right in the form of a line. C H 2 is wedge bonded to C on the lower right. The C atom is single bonded to C O O superscript minus on the upper right and single bonded to N H 3 superscript plus below. C 5 of the ring is single-bonded to O H on the lower right.

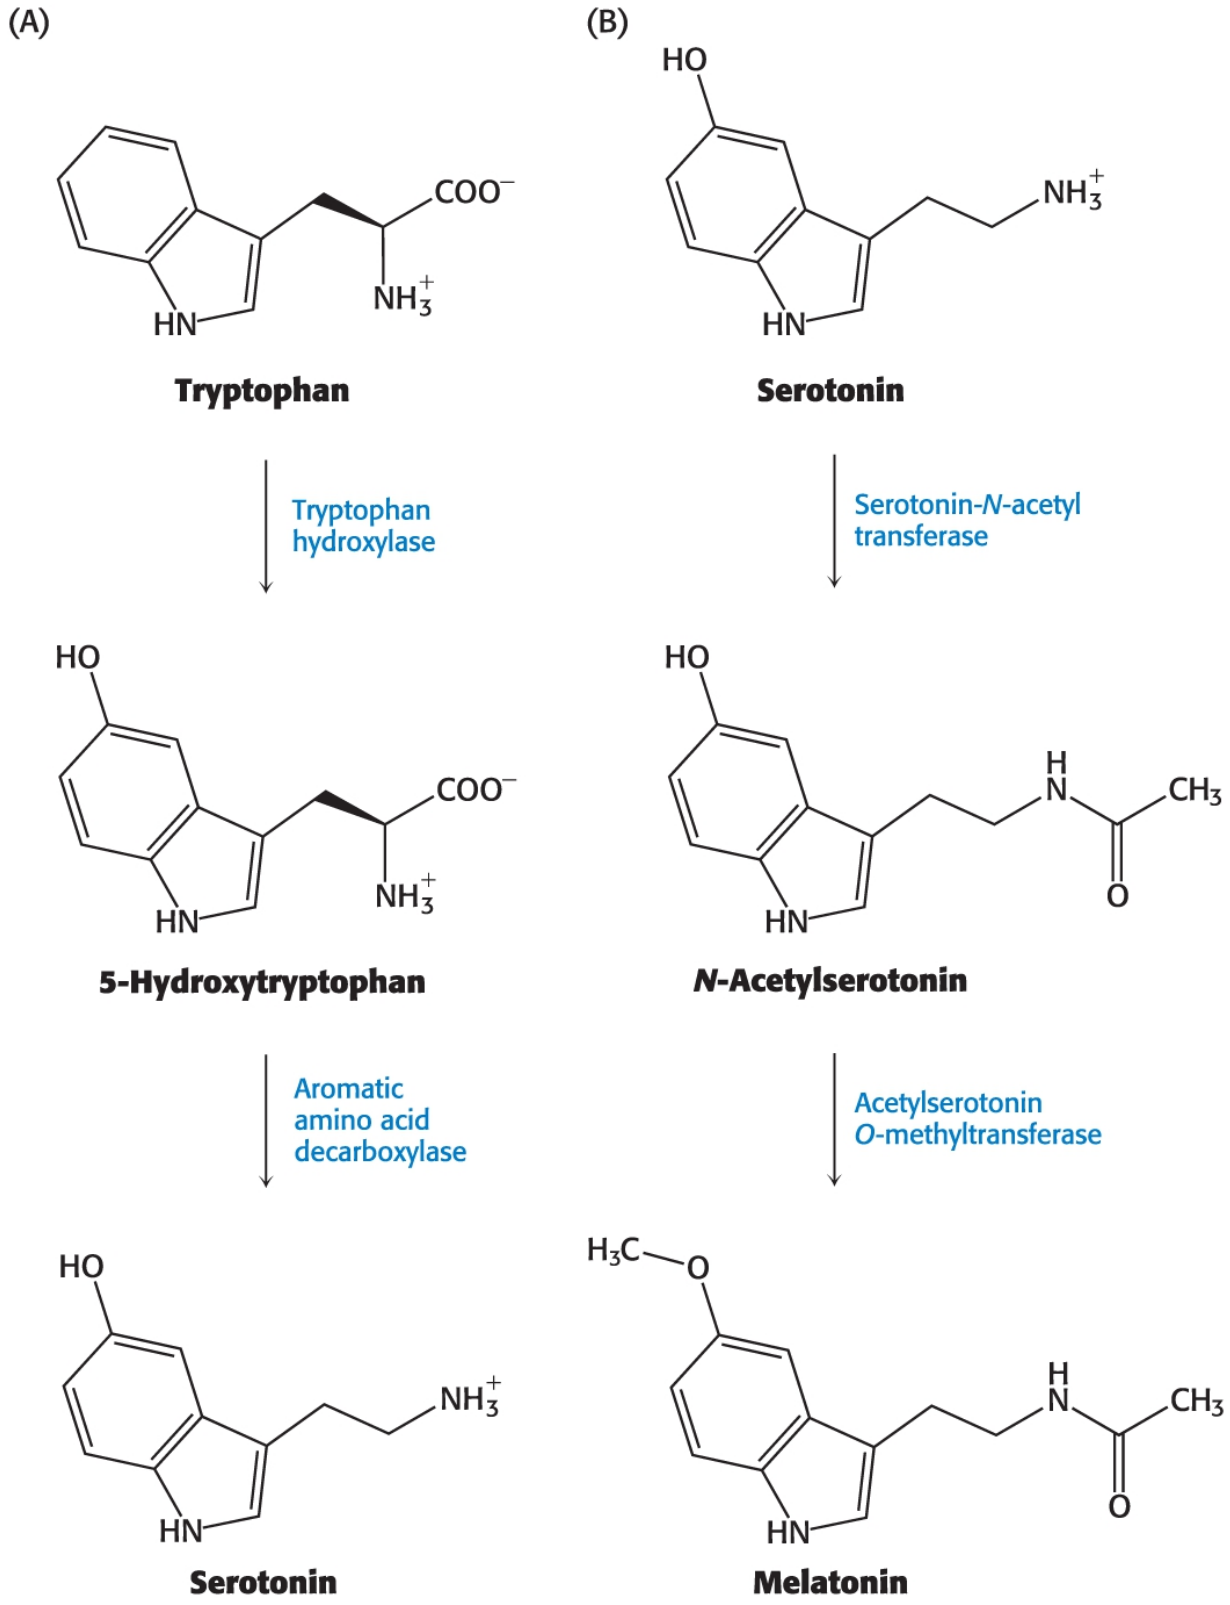
The structure of 3,4-Dihydroxyphenylalanine is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to C H 2 on the upper right in the form of a line. C H 2 is wedge bonded to C on the lower right. The C atom is single bonded to C O O superscript minus on the upper right and single bonded to N H 3 superscript plus below. C 5 and C 6 of the ring are each single-bonded to O H.

In the second irreversible step catalyzed by aromatic amino acid decarboxylase, 3,4-Dihydroxyphenylalanine is converted into dopamine.

The structure of dopamine is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to a 2-carbon alkane chain depicted using a line. C 2 of this chain is single bonded to N H 3 superscript plus on the upper right. C 5 and C 6 of the ring are each single-bonded to O H.

In the third irreversible step catalyzed by dopamine beta-hydroxylase, dopamine is converted into norepinephrine.

The structure of norepinephrine is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to a 2-carbon alkane chain depicted using a line. C 1 of this chain is wedge bonded to O H above. C 2 of this chain is single bonded to N H 3 superscript plus on the upper right. C 5 and C 6 of the ring are each single-bonded to O H.



In the fourth irreversible step catalyzed by phenylethanolamine N-methyltransferase, norepinephrine is converted into epinephrine.

The structure of epinephrine is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to C 1 of a 1 N and 2 C alkane chain depicted using 2 zigzag lines. N bound to H occupies the third position. C 1 of this chain is wedge bonded to O H above. N H is single bonded to C H 3 on the lower right. C 5 and C 6 of the ring are each single-bonded to O H.

Return to FIGURE 25.27 Tyrosine is a precursor for the catecholamines

Extended description for FIGURE 25.28 The neurotransmitters serotonin and melatonin are

synthesized from tryptophan

Reaction sequence (A): In the first irreversible step catalyzed by tryptophan hydroxylase, tryptophan is converted into 5-hydroxytryptophan.

The structure of tryptophan is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 1 N and 4 C atoms. N bound to H occupies the bottom-most vertex. A double bond is present between C 3 and C 4. It is fused to a benzene ring in a vertical orientation such that C 1 and C 2 of the pentagonal ring are C 3 and C 2 respectively of the benzene ring. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 3 of the pentagonal ring is single-bonded to C H 2 on the upper right in the form of a line. C H 2 is wedge bonded to C on the right. This C is single bonded to C O O superscript minus on the upper right and single bonded to N H 3 superscript plus below.

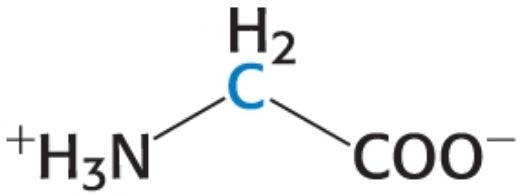
The structure of 5-hydroxytryptophan is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 1 N and 4 C atoms. N bound to H occupies the bottom-most vertex. A double bond is present between C 3 and C 4. It is fused to a benzene ring in a vertical orientation such that C 1 and C 2 of the pentagonal ring are C 3 and C 2 respectively of the benzene ring. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 6 of the benzene ring is single-bonded to O H. C 3 of the pentagonal ring is single-bonded to C H 2 on the upper right in the form of a line. C H 2 is wedge bonded to C on the right. This C is single bonded to C O O superscript minus on the upper right and single bonded to N H 3 superscript plus below.

In the second irreversible step catalyzed by aromatic amino acid decarboxylase, 5-hydroxytryptophan is converted into serotonin.

The structure of serotonin is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 1 N and 4 C atoms. N bound to H occupies the bottom-most vertex. A double bond is present between C 3 and C 4. It is fused to a benzene ring in a vertical orientation such that C 1 and C 2 of the pentagonal ring are C 3 and C 2 respectively of the benzene ring. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 6 of the benzene ring is single-bonded to O H. C 3 of the pentagonal ring is single-bonded to a 2-carbon alkane chain on the upper right depicted using a line. C 2 is single bonded to N H 3 superscript plus on the upper right.

Reaction sequence (B): In the first irreversible step catalyzed by serotonin-N-acetyl transferase, serotonin is converted into N-acetylserotonin.

The structure of N-acetylserotonin is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 1 N and 4 C atoms. N bound to H occupies the bottom-most vertex. A double bond is present between C 3 and C 4. It is fused to a benzene ring in a vertical orientation such that C 1 and C 2 of the pentagonal ring are C 3 and C 2 respectively of the benzene ring. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 6 of the benzene ring is single-bonded to O H. C 3 of the pentagonal ring is single-bonded to C 1 of a 1 N and 2 C alkane chain on the upper right depicted as line structure using 2 zigzag lines. N bound to H occupies the third position. N is further single-bonded to C on the lower right. This C is single bonded to C H 3 on the upper right and double bonded to O below.



In the second irreversible step catalyzed by acetylserotonin O-methyltransferase, N-acetylserotonin is converted into melatonin.

The structure of melatonin is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 1 N and 4 C atoms. N bound to H occupies the bottom-most vertex. A double bond is present between C 3 and C 4. It is fused to a benzene ring in a vertical orientation such that C 1 and C 2 of the pentagonal ring are C 3 and C 2 respectively of the benzene ring. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 6 of the benzene ring is single bonded to O, single bond, C H 3. C 3 of the pentagonal ring is single-bonded to C 1 of a 1 N and 2 C alkane chain on the upper right depicted as a line structure using 2 zigzag lines. N bound to H occupies the third position. N is further single-bonded to C on the lower right. This C is single bonded to C H 3 on the upper right and double bonded to O below.

studies

Glycine

Acetate

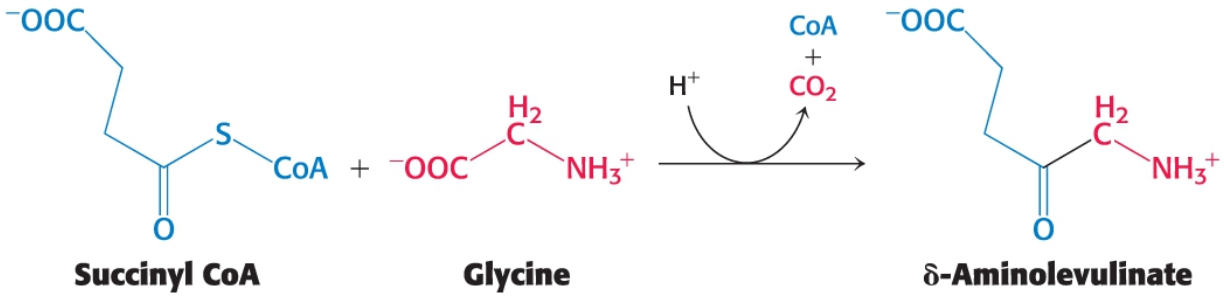
Heme

A structure of glycine and acetate is shown above the heme ring. Glycine consists of C H 2 single bonded to N H 3 superscript plus on the lower left and single bonded to C O O superscript minus on the lower right. The C atom of the C H 2 group is highlighted in blue.

Acetate is composed of C H 3, single bond, C O O superscript minus. C O O is highlighted in green and the C atom of C H 3 is highlighted in red.

Heme consists of a central C atom single bonded to the N atom of a pentagonal ring on the upper left, upper right, lower left, and lower right. Each pentagonal ring consists of 1 N and 4 C atoms. C 1 and C 4 of adjacent rings are connected by a methylene bridge composed of C 1, single bond, C H, double bond, C 4 or C 4, single bond, C H, double bond, C 1. The C atom of the C H group in the bridge is highlighted in blue. In the upper left ring, C 1, C 2, and C 3 are highlighted in red. C 4 is highlighted in blue. A double bond is present between C 2 and C 3. C 2 is single bonded to C H 3. The C atom of C H 3 is highlighted in red. C 3 is single bonded to C H 2, single bond, C H 2, single bond, C O O superscript minus. The C atom of C H 2 groups are highlighted in red. C O O group is highlighted in green.

In the upper right ring, C 2, C 3, and C 4 are highlighted in red. C 1 is highlighted in blue. A double bond is present between C 2 and C 3. C 2 is single bonded to C H 2, single bond, C H 2, single bond, C O O superscript minus. The C atom of C H 2 groups are highlighted in red. C O O group is highlighted in green. C 3 is single bonded to C H 3. The C atom of C H 3 is highlighted in red.



In the lower right ring, C 1, C 2, and C 3 are highlighted in red. C 4 is highlighted in blue. A double bond is present between N and C 1, and C 2 and C 3. C 2 is single bonded to C H 3. The C atom of C H 3 is

highlighted in red. C 3 is single bonded to C H, double bond, C H 2. The C atom of C H 2 and C H groups are highlighted in red.

In the lower-left ring, C 1, C 2, and C 3 are highlighted in red. C 4 is highlighted in blue. A double bond is present between C 1 and C 2, and C 3 and C 4. C 2 is single bonded to C H 3. The C atom of C H 3 is highlighted in red. C 3 is single bonded to C H, double bond, C H 2. The C atom of C H 2 and C H groups are highlighted in red.

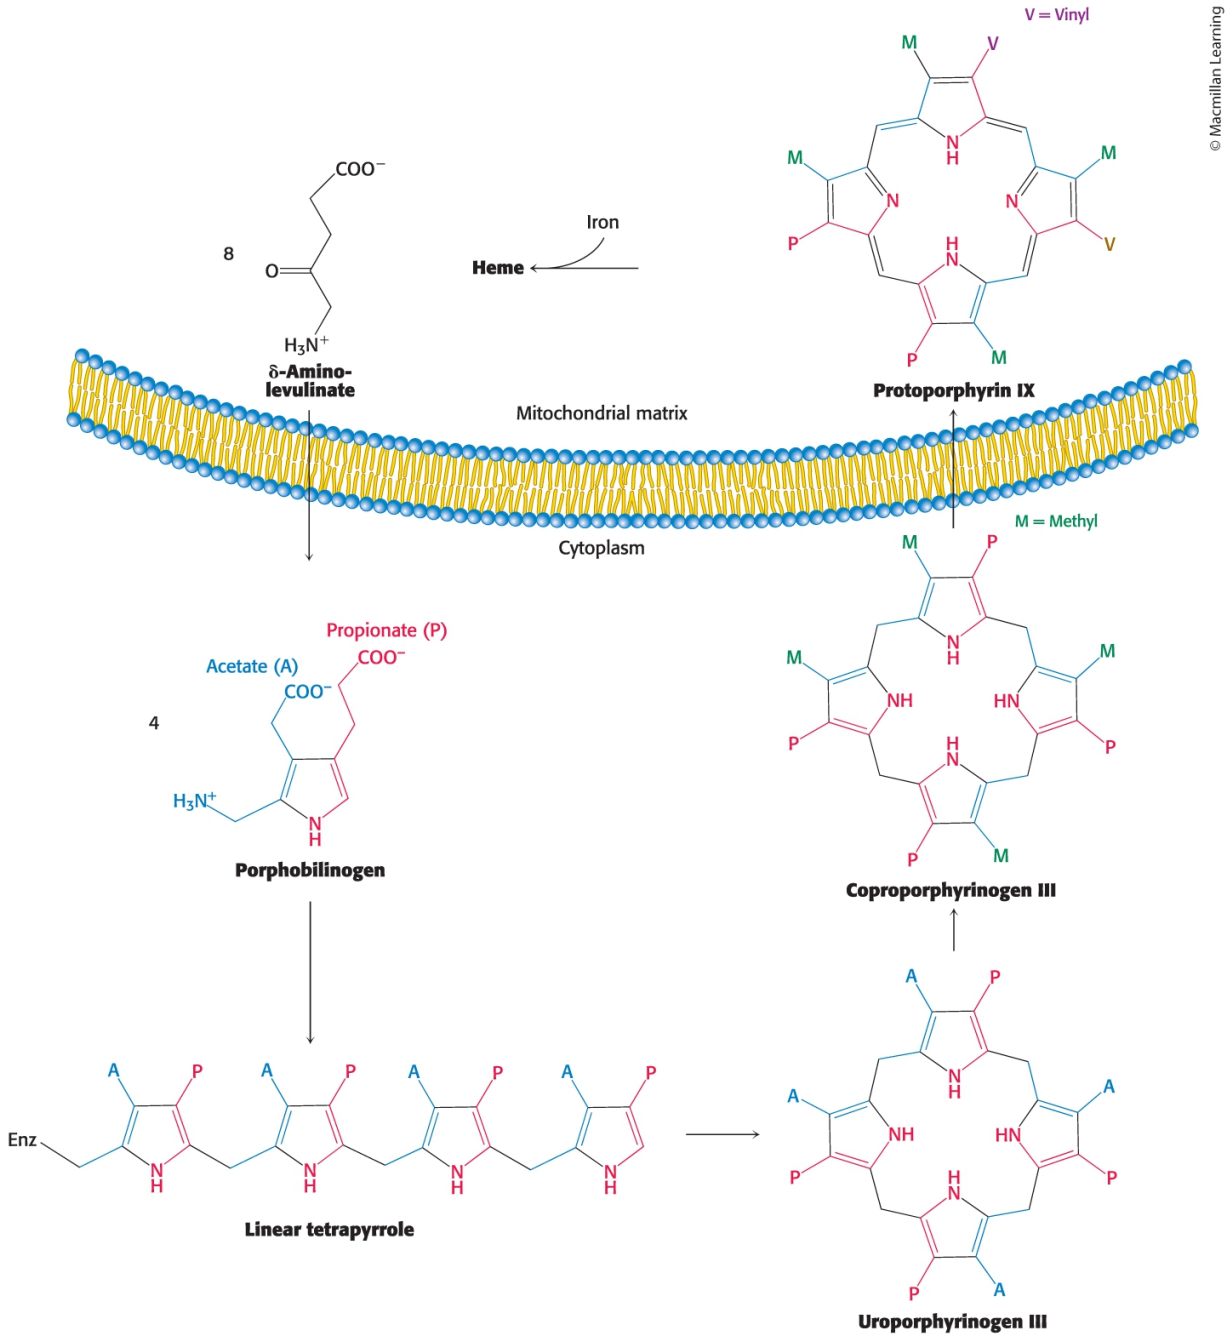
Extended description for Formation of delta-aminolevulinate

The reaction consists of two reactants and one product. It is coupled with the entry of H superscript plus and release of C o A plus C O 2.

The first reactant is succinyl C o A whose structure is as follows: A central C atom is single bonded to C H 2 on the upper left in the form of a line, double bonded to O below, and single bonded to S on the upper right. S is single bonded to C o A on the lower right. C H 2 is single bonded to C H 2 above in the form of a line. This C H 2 group is further single bonded to C O O superscript minus on the upper left.



The second reactant is glycine whose structure is as follows: A central C atom bound to H 2 is single bonded to C O O superscript minus on the lower left and single bonded to N H 3 superscript plus on the lower right.

The product is delta-aminolevulinate whose structure is as follows: A central C atom is single bonded to C H 2 on the upper left in the form of a line, double bonded to O below, and single bonded to C H 2 on the upper right. The upper right C H 2 is single bonded to N H 3 superscript plus on the lower right. The upper left C H 2 is further single bonded to C H 2 above in the form of a line. This C H 2 group

is further single bonded to C O O superscript minus on the upper left.

Return to Formation of delta-aminolevulinate

Extended description for FIGURE 25.30 Heme is synthesized from eight molecules of delta-aminolevulinate

© Macmillan Learning

A lipid bilayer is shown. The region above the bilayer is labeled mitochondrial matrix and the region below is labeled cytoplasm. Eight delta-aminolevulinate molecules from the matrix enter the cytoplasm.

The structure of delta-aminolevulinate is as follows: A 4-carbon alkane chain is depicted as a vertical line structure using 3 zigzag lines. C 1 is single bonded to C O O superscript minus on the upper right. C 3 is double bonded to O on the left. C 4 is single bonded to N H 3 superscript plus on the lower left.

Inside the cytoplasm, delta-aminolevulinate molecules are converted into 4 porphobilinogen molecules.

The structure of 4 porphobilinogen is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 1 N and 4 C atoms. N bound to H occupies the bottom-most vertex. C 1 is single bonded to C H 2, single bond, N H 3 superscript plus on the left. C 2 is single bonded to C H 2, single bond, C O O superscript minus. C 3 is single bonded to C H 2, single bond, C H 2, single bond, C O O superscript minus above. A double bond is present between C 1 and C 2, and C 3 and C 4. C 1, C 2, and their substituent groups are highlighted in blue and labeled acetate (A). N H, C 3, C 4, and their substituent groups are highlighted in red and labeled propionate (P).

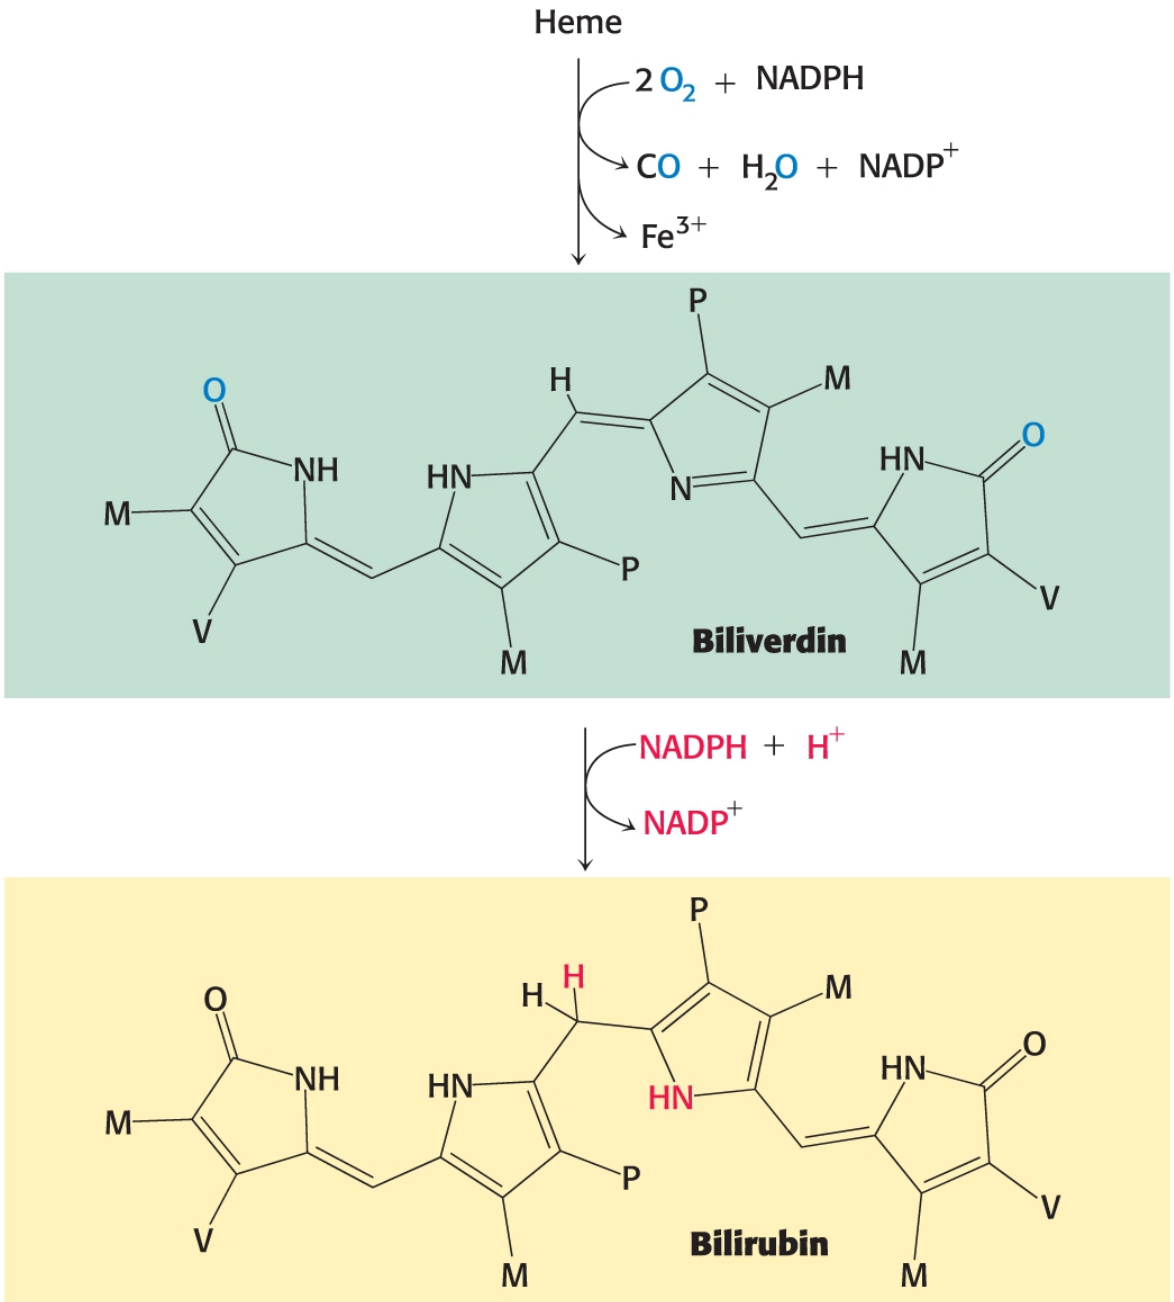
Porphobilinogen is converted into linear tetrapyrrole inside the cytoplasm.

The linear tetrapyrrole consists of four 5-membered heterocyclic pentagonal rings composed of 1 N and 4 C atoms. N bound to H occupies the bottom-most vertex. A double bond is present between C 1 and C 2, and C 3 and C 4. C 2 is single-bonded to A and C 3 is

single-bonded to P. The adjacent rings are connected by C 4, single bond, C H 2, single bond, C 1. C 1 of the leftmost ring is single-bonded to C H 2, which is further single-bonded to an enzyme.

Linear tetrapyrrole is converted into uroporphyrinogen 3 inside the cytoplasm.

Uroporphyrinogen 3 consists of a ring-like arrangement of tetrapyrrole. The N H groups of the individual rings face the interior and A and P substituents are located toward the exterior.



Uroporphyrinogen 3 is converted into coproporphyrinogen 3 inside the cytoplasm. In coproporphyrinogen 3, A is replaced with M. M depicts the methyl group.

Coproporphyrinogen 3 crosses the bilayer to enter the mitochondrial matrix. In the matrix, protoporphyrin 9 is formed. In protoporphyrin 9, P bonded to C 3 of the topmost and right pyrrole rings is replaced with V. V depicts the vinyl group. In addition, the adjacent rings are connected by C 4, double bond, C H, single bond, C 1 or C 4, single bond, C H, double bond, C 1. The topmost ring contains only one double bond between C 2 and C 3. The position of double bonds is altered in the left and right rings.

In the matrix, iron is added to protoporphyrin 9 to produce heme.

Return to FIGURE 25.30 Heme is synthesized from eight molecules of delta-aminolevulinate

Extended description for FIGURE 25.31 Heme is degraded into biliverdin and bilirubin

© Macmillan Learning

In the first irreversible step, heme is converted into biliverdin. This step is coupled with the entry of 2 O 2, the release of C O 2 plus H 2 O

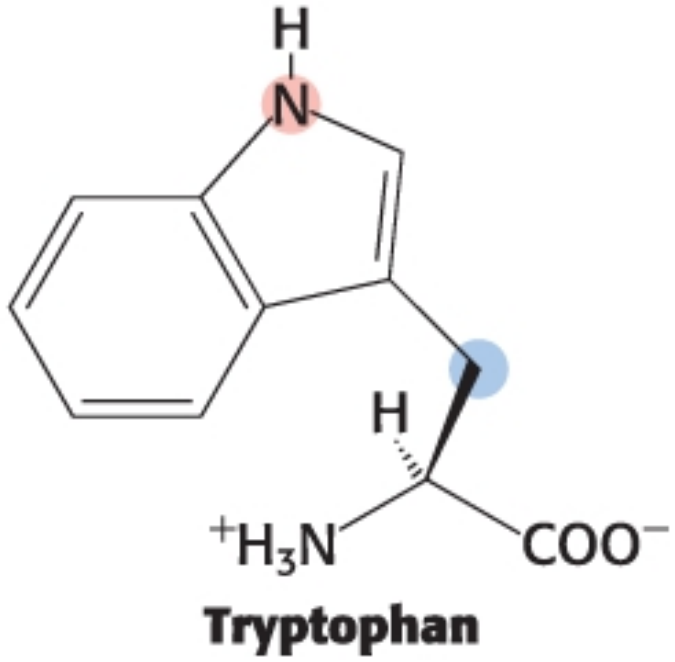
and F e superscript 3 plus, and the oxidation of N A D P H to N A D P superscript plus.

The structure of the biliverdin is shown inside a green rectangle. It is composed of four 5-membered heterocyclic pentagonal rings. The adjacent rings are connected by a methylene bridge. In the methylene bridge, the adjacent rings are connected by a double bond, C H, single bond or single bond, C H, double bond.

Each ring consists of 1 N and 4 C atoms. In the first ring from left, C 2 is single bonded to V, C 3 is single bonded to M, and C 4 is double bonded to O above. A double bond is present between C 2 and C 3.

In the second ring, a double bond is present between C 1 and C 2, and C 3 and C 4. C 2 is single-bonded to P and C 3 is single-bonded to M.

In the third ring, a double bond is present between C 2 and C 3, and C 4 and N. C 2 is single bonded to P, and C 3 is single bonded to M.

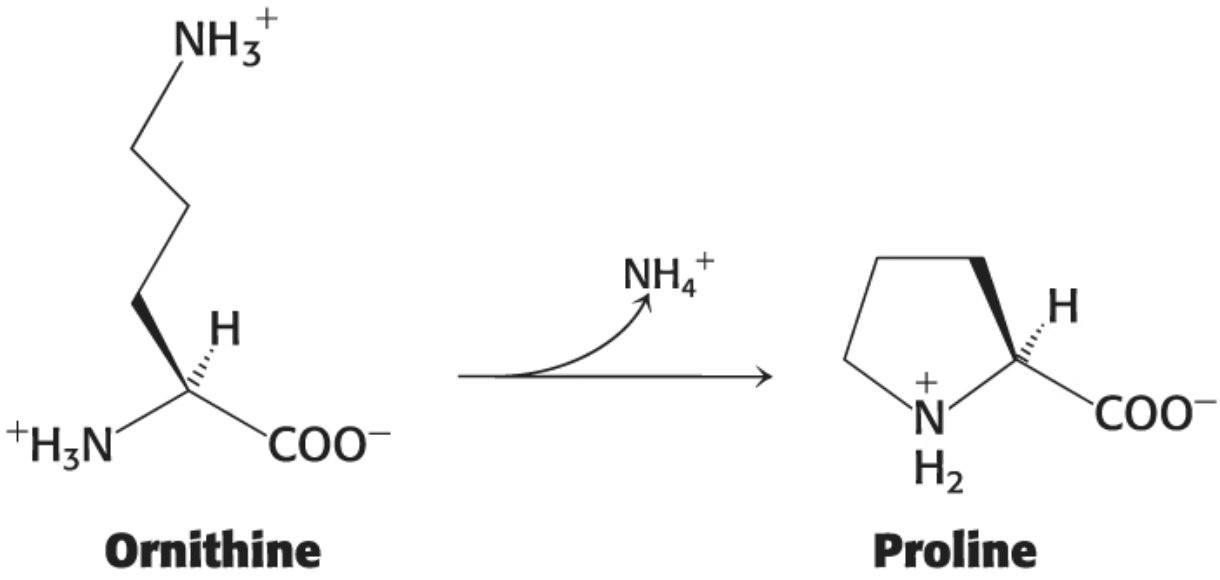


In the fourth ring, C 2 is single bonded to V, C 3 is single bonded to M, and C 1 is double bonded to O above. A double bond is present between C 2 and C 3.

In the second irreversible step, biliverdin is converted into bilirubin with the simultaneous oxidation of N A D P H plus H superscript plus into N A D P superscript plus. The structure of bilirubin is shown inside a yellow rectangle.

Bilirubin is similar to biliverdin except the methylene bridge connecting the second and third ring is altered to single bond, C H 2, single bond. In addition, N of the third ring is bound to H and the position of double bonds is altered in the third ring.

Return to FIGURE 25.31 Heme is degraded into biliverdin and bilirubin



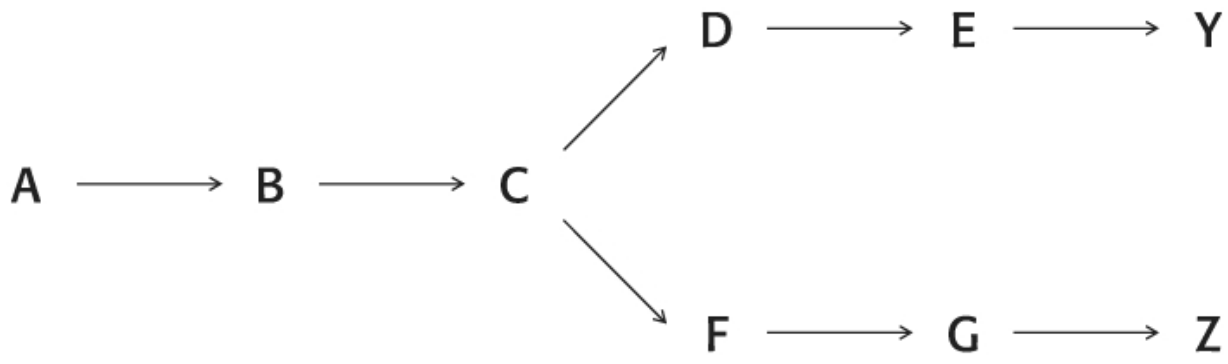
Extended description for Structure of tryptophan

The structure of tryptophan is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 1 N and 4 C atoms. N single bonded to H occupies the topmost vertex and is highlighted inside a pink circle. A double bond is present between C 1 and C 2. It is fused to a benzene ring in a horizontal orientation such that C 3 and C 4 of the pentagonal ring are C 1 and C 6 respectively of the benzene ring. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 2 of the pentagonal ring is single-bonded to C H 2 on the lower right in the form of a line. C H 2 is highlighted inside a blue circle. It is wedge bonded to C on the lower left. This C is single bonded to C O O superscript minus on the lower right, dash bonded to H on the upper left, and single bonded to N H 3 superscript plus on the lower left.

Return to Structure of tryptophan

Extended description for Formation of proline from ornithine

The reaction consists of one reactant and one product. It is coupled with the release of N H 4 superscript plus molecule. The reactant is ornithine and the product is proline.



The structure of ornithine is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left, single bonded to C O O superscript minus on the lower right, wedge bonded to C H 2 on the upper left, and dash bonded to H on the upper right. The C H 2 group is single-bonded to a 2-carbon alkane chain depicted using a single line. C 2 of this alkane chain is single bonded to N H 3 superscript plus on the upper right.

The structure of proline is as follows: A central C atom is wedge bonded to C H 2 on the upper left, single bonded to N H 2 with a positive charge on the lower left, dash bonded to H on the upper right, and single bonded to C O O superscript minus on the lower

right. The upper left C H 2 group is single-bonded to a 2-carbon alkane chain depicted using a line. C 2 of this chain is single-bonded to the N H 2 group on the lower left such that a cyclic pentagonal-shaped ring structure is formed.

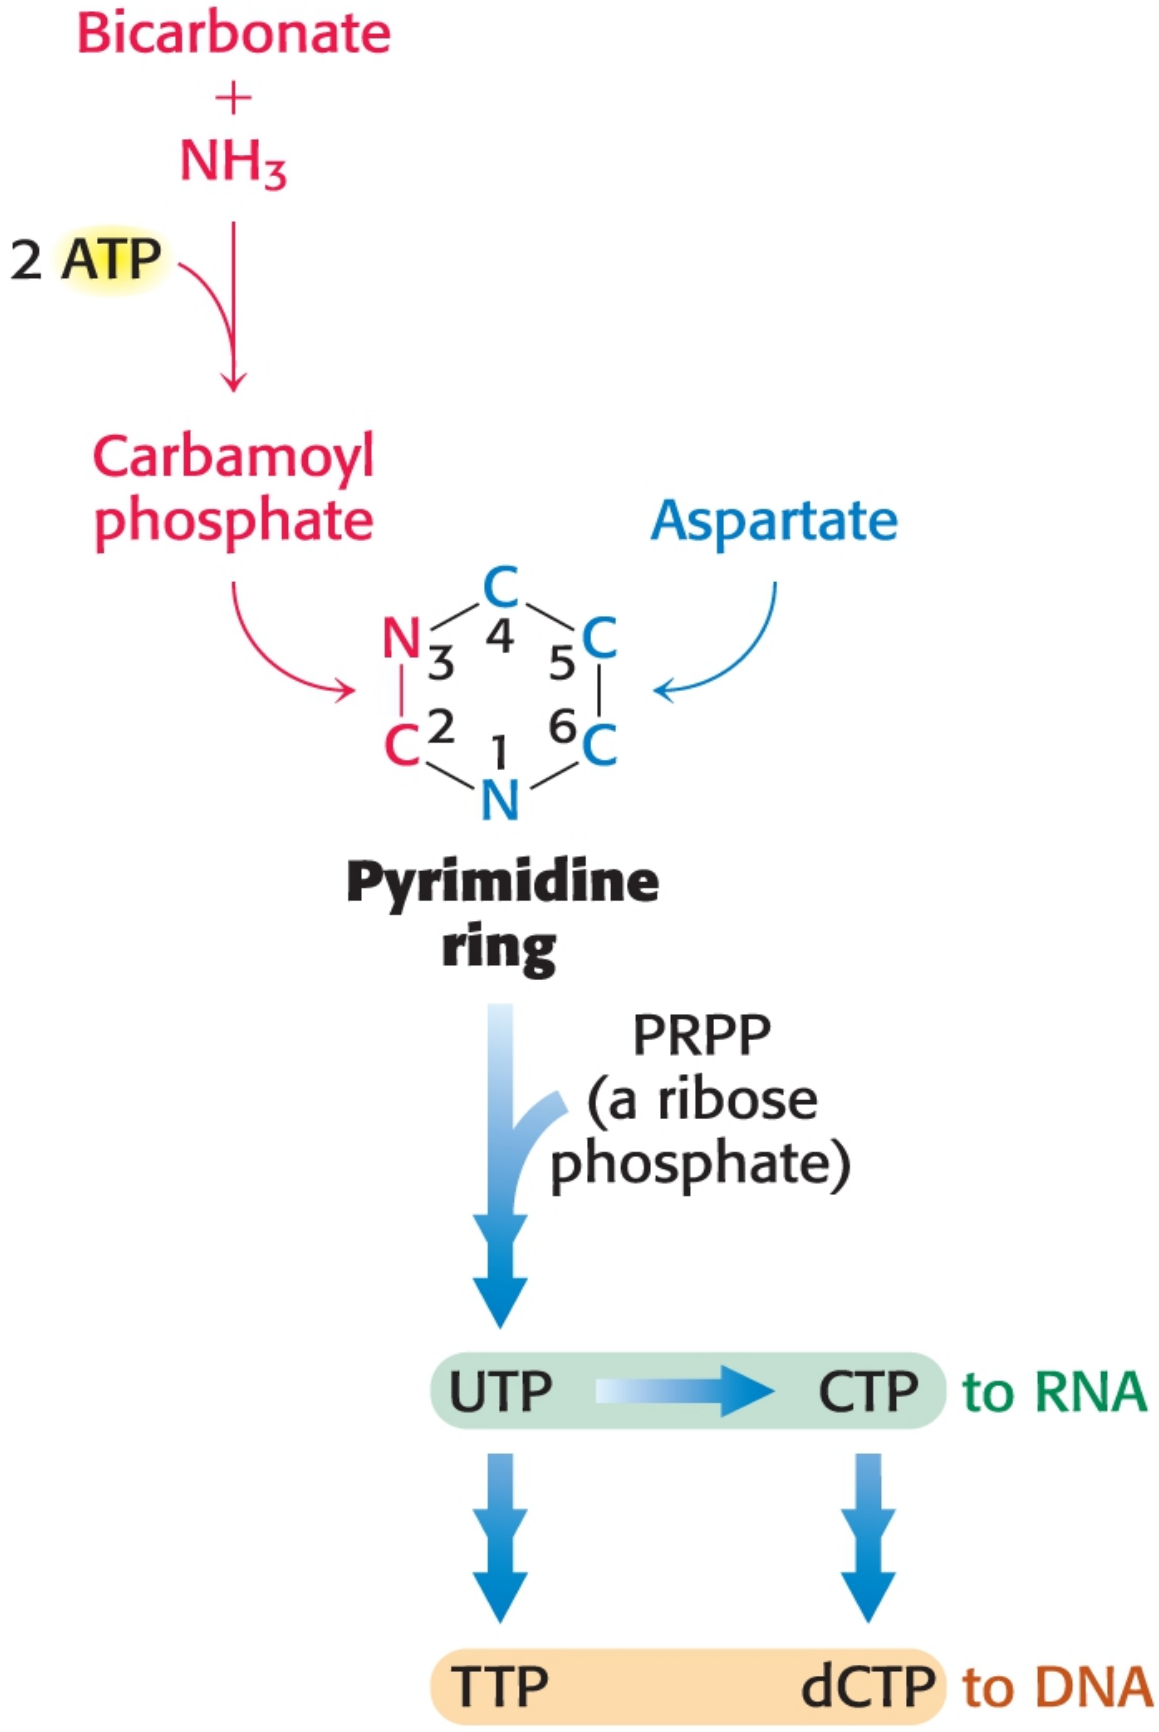
Extended description for FIGURE 26.1 Nucleotides can be synthesized by de novo and salvage pathways



The first pathway for nucleotide biosynthesis is the de novo pathway. The precursor materials for this pathway are depicted as follows: Activated ribose (P R P P) plus amino acids plus A T P plus C O 2 plus dot dot. A downward arrow from these precursors leads to the nucleotide.

The second pathway for nucleotide biosynthesis is the salvage pathway. The precursor materials for this pathway are depicted as follows: Activated ribose (P R P P) plus base. A downward arrow from these precursors leads to the nucleotide.

Return to FIGURE 26.1 Nucleotides can be synthesized by de novo and salvage pathways

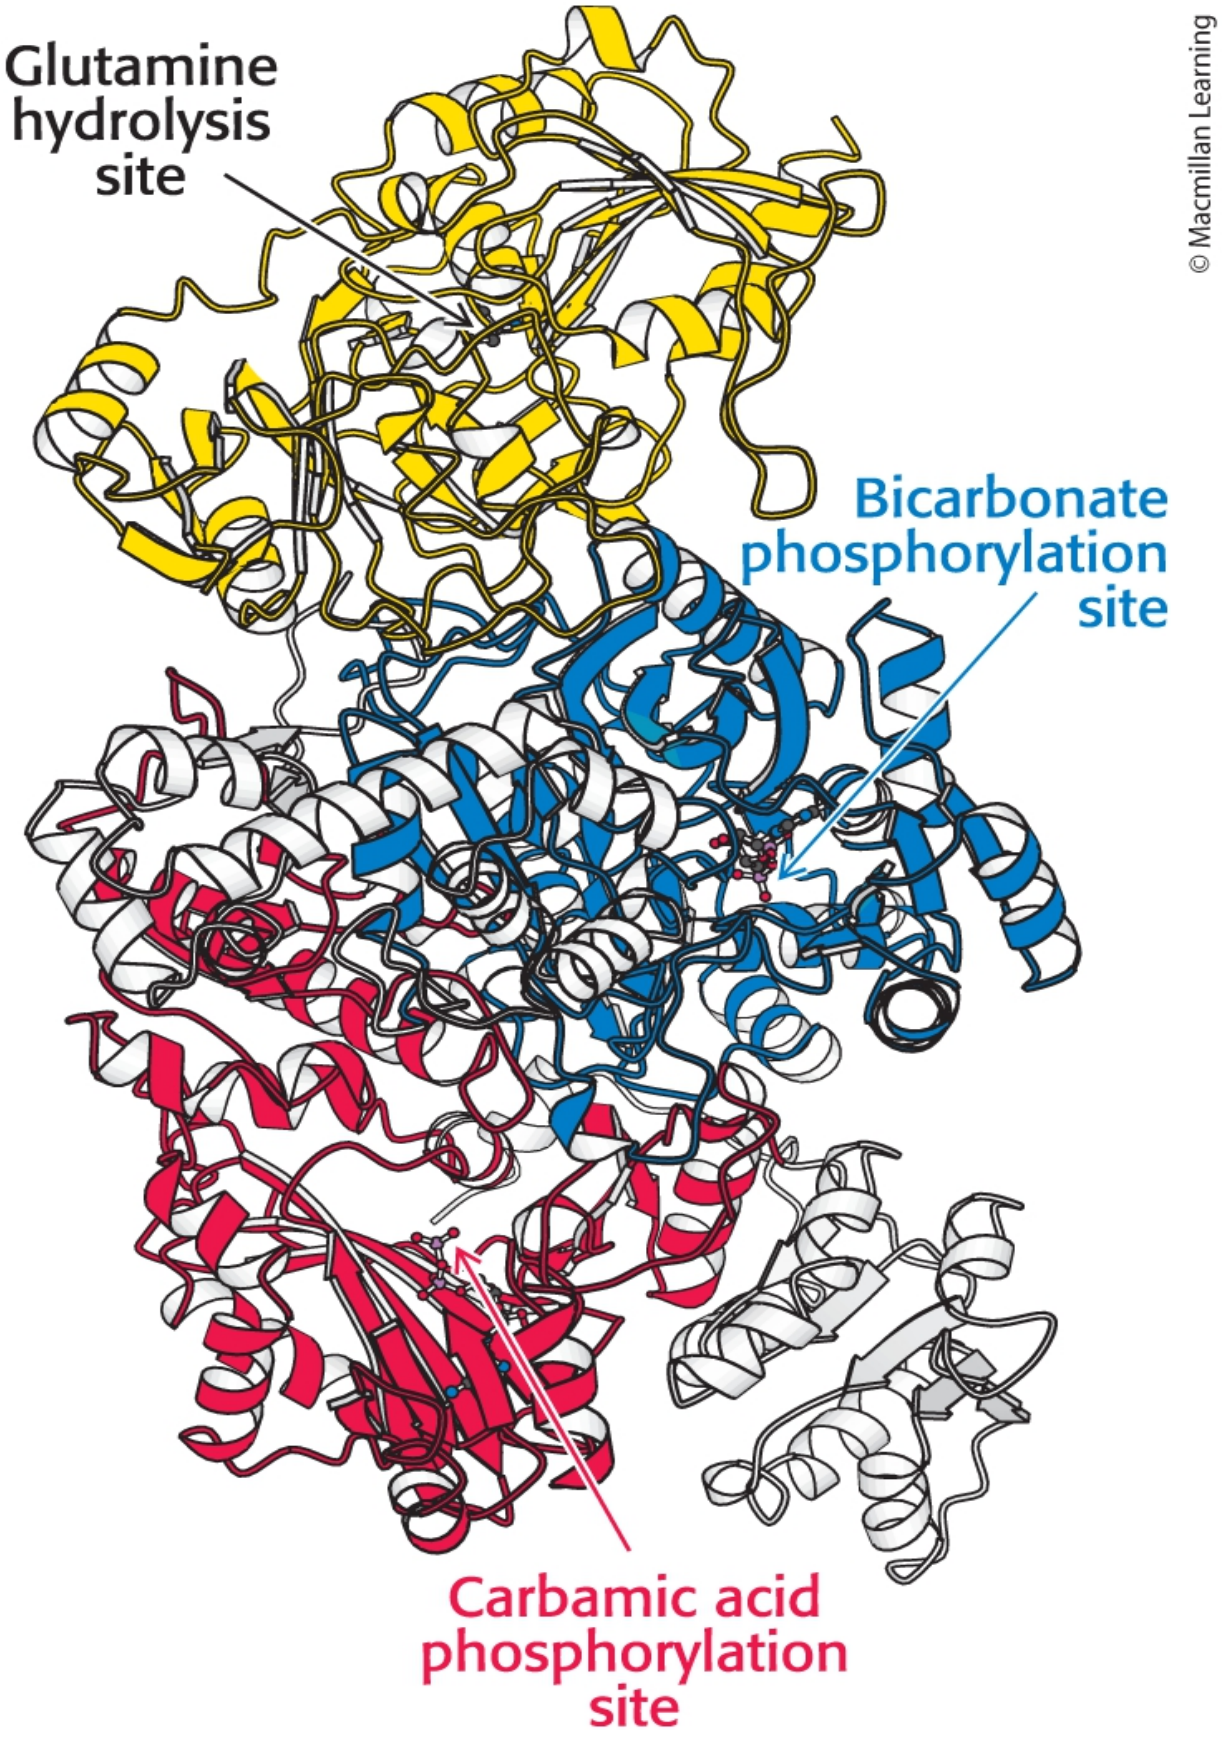
Extended description for FIGURE 26.2 Pyrimidine

nucleotides can be synthesized de novo

© Macmillan Learning

The de novo synthesis of pyrimidine nucleotides is depicted as follows:

Bicarbonate plus N H 3 are irreversibly converted into carbamoyl phosphate with the addition of 2 A T P.



A 6-membered heterocyclic hexagonal ring in vertical orientation is shown below. The ring is labeled pyrimidine ring. It consists of 2 N and 4 C atoms. First N occupies the bottom-most vertex and the second N occupies the top left vertex. The remaining positions are occupied by C atoms. The atoms of the ring are numbered 1 to 6 in a clockwise manner starting from the bottom-most N atom. C 2 occupying the bottom left vertex and N 3 occupying the top left vertex are highlighted in red. The remaining atoms are highlighted in blue. The red highlighted atoms are derived from carbamoyl phosphate and the blue highlighted atoms are derived from aspartate.

A downward arrow from the pyrimidine ring leads to U T P with the simultaneous addition of P R P P (a ribose phosphate). A single forward arrow from U T P leads to C T P. U T P and C T P are labeled "to R N A." Two successive downward arrows below U T P and C T P lead to T P P and d C T P respectively. T T P and d C T P are labeled "to D N A."

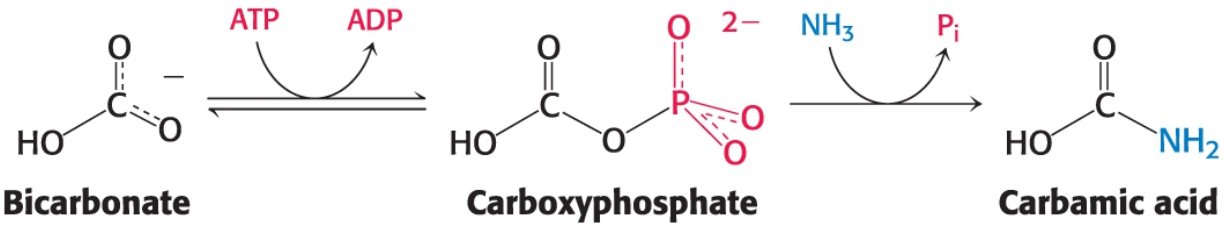
Extended description for FIGURE 26.3 Carbamoyl phosphate synthetase 2 includes sites for three

reactions



© Macmillan Learning

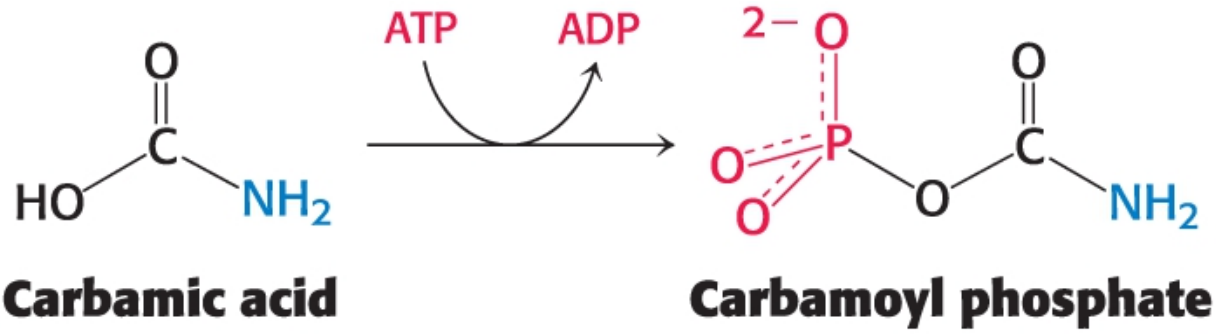
The carbamoyl phosphate synthetase 2 consists of a small domain at the top, a large domain in the middle, and a tiny domain at the bottom right. The top domain is shown in yellow. A glutamine hydrolysis site is located in the center of this domain. The middle large domain is composed of two A T P-grasp domains shown in blue and red. The blue domain is located above the red domain and contains a bicarbonate phosphorylation site. The red domain contains a carbamic acid phosphorylation site. The tiny bottom right domain is shown in white. It consists of a few alpha-helices and short beta-strands.

Return to FIGURE 26.3 Carbamoyl phosphate synthetase 2 includes sites for three reactions

Extended description for Formation of carbamic acid from bicarbonate

In the first reversible step, bicarbonate is converted into carboxyphosphate. It is coupled with the breakdown of A T P to A D P.

The structure of bicarbonate is as follows: A central C atom is partially double-bonded to O above, partially double-bonded to O on the lower right, and single-bonded to O H on the lower left. The partially double-bonded O atoms have an overall negative charge.



The structure of carboxyphosphate is as follows: A central C atom is double bonded to O above, single bonded to O H on the lower left, and single bonded to O on the lower right. The lower right O is single-bonded to P on the upper right. P is partially double bonded to O above, O on the right, and O on the lower right. The partially double bonded O atoms have an overall negative charge of 2 minus.

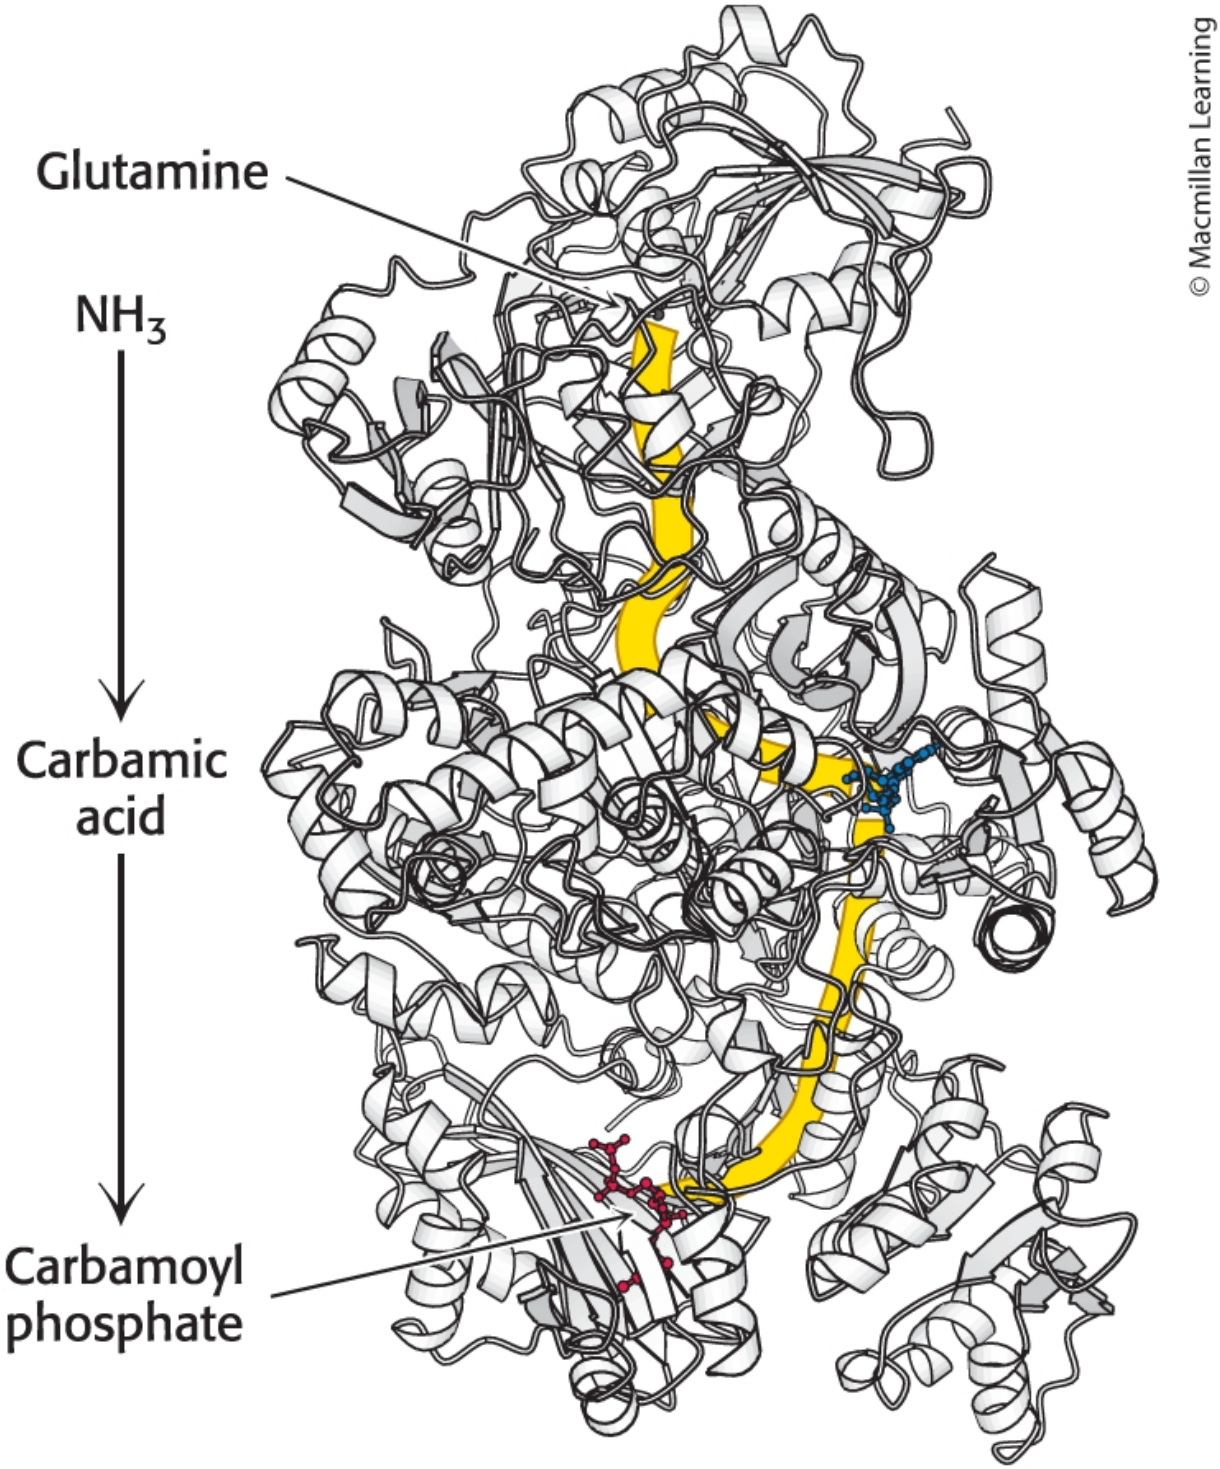
In the second irreversible step, carboxyphosphate is converted into carbamic acid. It is coupled with the entry of N H 3 and the release of P subscript i.

The structure of carbamic acid is as follows: A central C atom is double bonded to O above, single bonded to O H on the lower left, and single bonded to N H 2 on the lower right.

Return to Formation of carbamic acid from bicarbonate

Extended description for Formation of carbamoyl phosphate from carbamic acid

The reaction consists of one reactant and one product. It is coupled with the breakdown of A T P to A D P. The reactant is carbamic acid and the product is carbamoyl phosphate.



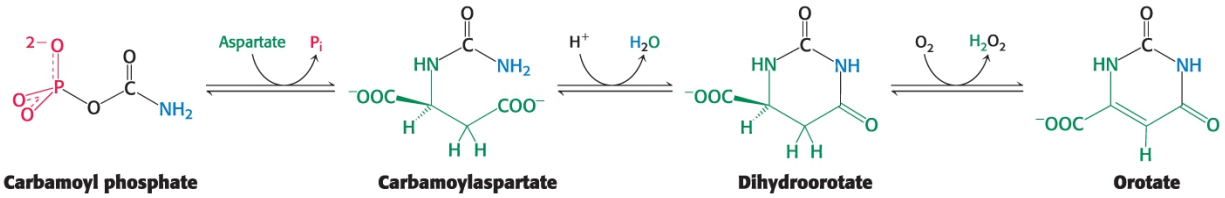
The structure of carbamic acid is as follows: A central C atom is double bonded to O above, single bonded to O H on the lower left, and single bonded to N H 2 on the lower right.

The structure of carbamoyl phosphate is as follows: A central C atom is double bonded to O above, single bonded to O on the lower left, and single bonded to N H 2 on the lower right. The lower left O is single-bonded to P on the upper left. P is partially double bonded to O above, O on the left, and O on the lower left. The partially double bonded O atoms have an overall negative charge of 2 minus.

Return to Formation of carbamoyl phosphate from carbamic acid

Extended description for FIGURE 26.4 The three active sites of carbamoyl phosphate synthetase 2 are linked

by a channel through which intermediates pass



© Macmillan Learning

The ribbon diagram shows an elongated structure composed of several alpha helices and a few-beta strands interconnected by thread-like loops. A yellow tubular channel moves vertically down from top to the bottom in a slightly wavy manner. It passes through the three active sites. An arrow pointing toward the top mouth of the channel is labeled glutamine. An arrow pointing toward the bottom end of the channel is labeled carbamoyl phosphate. An irreversible conversion of N H 3 to carbamoyl phosphate is shown outside the ribbon diagram, along the channel. N H 3 near the top mouth of the channel is irreversibly converted into carbamic acid, corresponding to the middle of the channel. Carbamic acid is later irreversibly converted into carbamoyl phosphate.

Return to FIGURE 26.4 The three active sites of carbamoyl phosphate synthetase 2 are linked by a channel through which intermediates pass

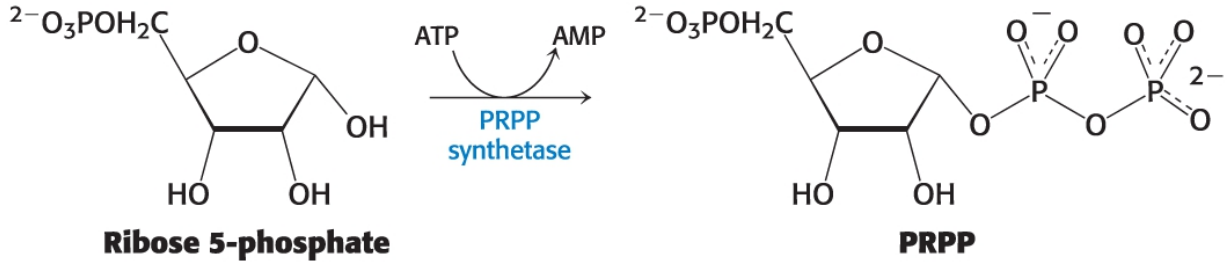
Extended description for Formation of orotate from carbamoyl phosphate

In the first irreversible step, carbamoyl phosphate is converted into carbamoylaspartate. It is coupled with the entry of aspartate and release of P subscript i.

The structure of carbamoyl phosphate is as follows: A central C atom is double bonded to O above, single bonded to O on the lower left, and single bonded to N H 2 on the lower right. The lower left O is single-bonded to P on the upper left. P is partially double bonded to O above, O on the left, and O on the lower left. The partially double-bonded O atoms have an overall negative charge of 2 minus.

The structure of carbamoylaspartate is as follows: A central C atom is double bonded to O above, single bonded to N H on the lower left, and single bonded to N H 2 on the lower right. The lower left N H is single-bonded to C 1 of a 2-carbon alkane chain depicted using a line. C 1 is wedge bonded to C O O superscript minus on the upper left, dash bonded to H on the lower left. C 2 is single bonded to C O O superscript minus on the upper right, single bonded to H on the lower left and lower right.

In the second reversible step, carbamoylaspartate is converted into dihydroorotate. It is coupled with the entry of H superscript plus ion and release of H 2 O.



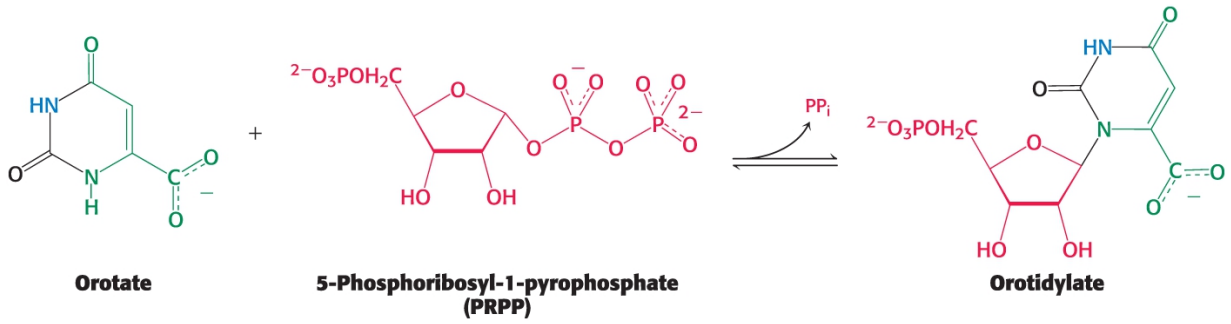
The structure of dihydroorotate is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation. It consists of 2 N and 4 C atoms. The first N bound to H occupies the top left vertex and the second N bound to H occupies the top right vertex. C 1 occupies the topmost vertex and is double bonded to O above. C 2 is double bonded to O on the lower right. C 3 is single bonded to H on the lower left and H on the lower right. C 4 is wedge bonded to C O O superscript minus on the left and dash bonded to H on the lower left.

In the third reversible step, dihydroorotate is converted into orotate. It is coupled with the entry of O 2 and the release of H 2 O 2.

The structure of orotate is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation. It consists of 2 N and 4 C atoms. The first N bound to H occupies the top left vertex and the second N bound to H occupies the top right vertex. C 1 occupies the topmost vertex and is double bonded to O above. A double bond is present between C 3 and C 4. C 2 is double bonded to O on the lower right. C 3 is single bonded to H below. C 4 is single bonded to C O O superscript minus on the lower left.

Return to Formation of orotate from carbamoyl phosphate

Extended description for Reaction catalyzed by P R P P synthetase



The reaction consists of one reactant and one product. It is catalyzed by P R P P synthetase and is coupled with the breakdown of A T P to A M P.

The reactant is ribose 5-phosphate whose structure is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1, C 2, and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 superscript 2 minus on the upper left.

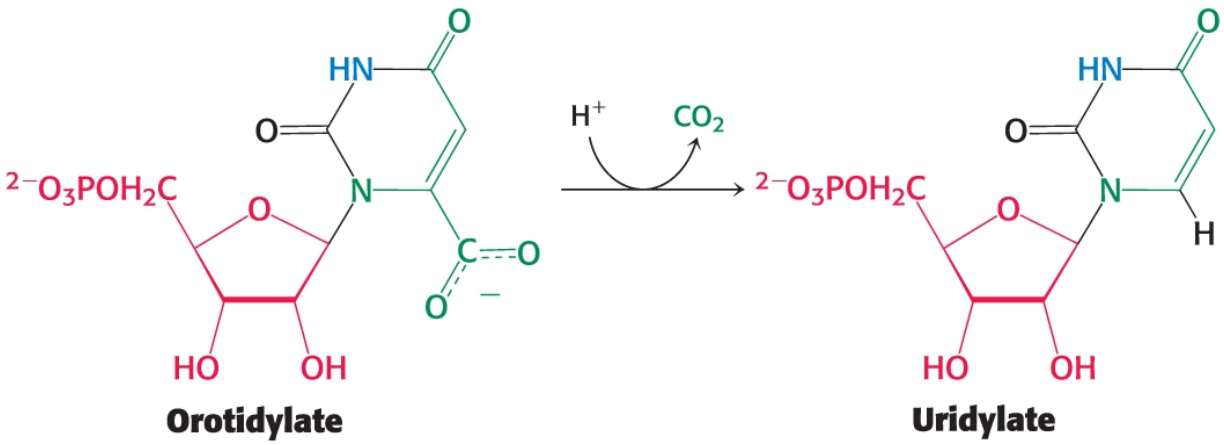
The product is P R P P whose structure is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single bonded to a zigzag chain composed of O, single bond, P, single bond, O, single bond, P. P 1 is partially double bonded to O on the upper left and O on the upper right. The O atoms have an overall negative charge. P 2 is partially double bonded to O on the upper left, upper right, and lower right. The O atoms have an overall negative charge of 2 minus. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 superscript 2 minus on the upper left.

Return to Reaction catalyzed by P R P P synthetase

Extended description for Formation of orotidylate

The reaction consists of two reactants and one product. It is coupled with the release of P P subscript i.

The first reactant is orotate whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation. It consists of 2 N and 4 C atoms. The first N single bonded to H occupies the bottom-most vertex and the second N bound to H occupies the top left vertex. A double bond is present between C 3 and C 4. C 1 occupies the bottom left vertex and is double bonded to O on the lower left. C 2 is double bonded to O above. C 4 is single bonded to C on the lower left. This C is partially double bonded on the upper right and O below. The O atoms have an overall negative charge.



The second reactant is 5-phosphoribosyl1-pyrophosphate (P R P P) whose structure is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single bonded to a zigzag chain composed of O, single bond, P, single bond, O, single bond, P. P 1 is partially double bonded to O on the upper left and O on the upper right. The O atoms have an overall negative charge. P 2 is partially double

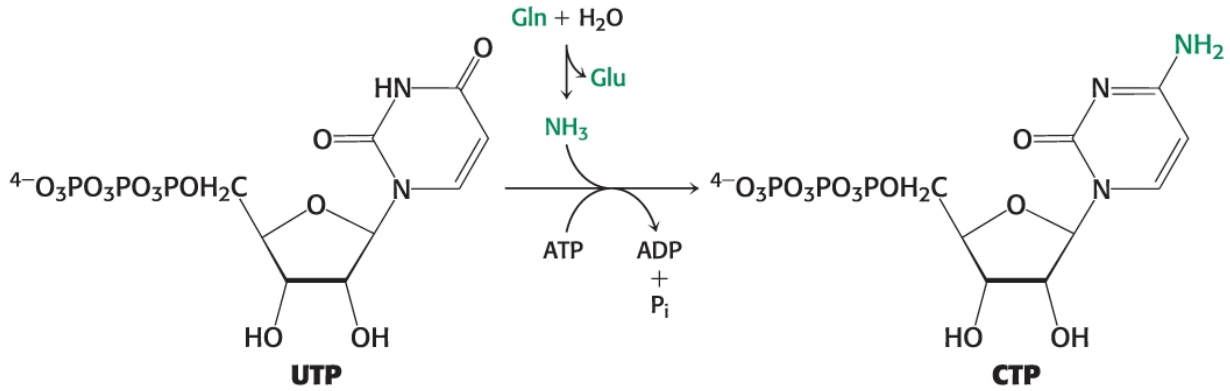
bonded to O on the upper left, upper right, and lower right. The O atoms have an overall negative charge of 2 minus. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 superscript 2 minus on the upper left.

The product is orotidylate whose structure is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single bonded to N 1 of orotate in horizontal orientation. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 superscript 2 minus on the upper left.

Return to Formation of orotidylate

Extended description for Formation of uridylate from orotidylate

The reaction consists of one reactant and one product. It is coupled with the entry of H superscript plus ion and release of C O 2.



The reactant is orotidylate whose structure is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single-bonded to N 1 of a 6-membered heterocyclic hexagonal ring in a horizontal orientation. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 superscript 2 minus on the upper left. The hexagonal ring consists of 2 N and 4 C atoms. First N occupies the bottom left vertex and second N bound to H occupies the top left vertex. A double bond is present between C 3 and C 4. C 1 is double bonded to O on the left. C 2 is double bonded to O on the upper right. C 4 is single bonded to C on the lower right. This C is partially double-bonded to O on the right and O on the lower left.

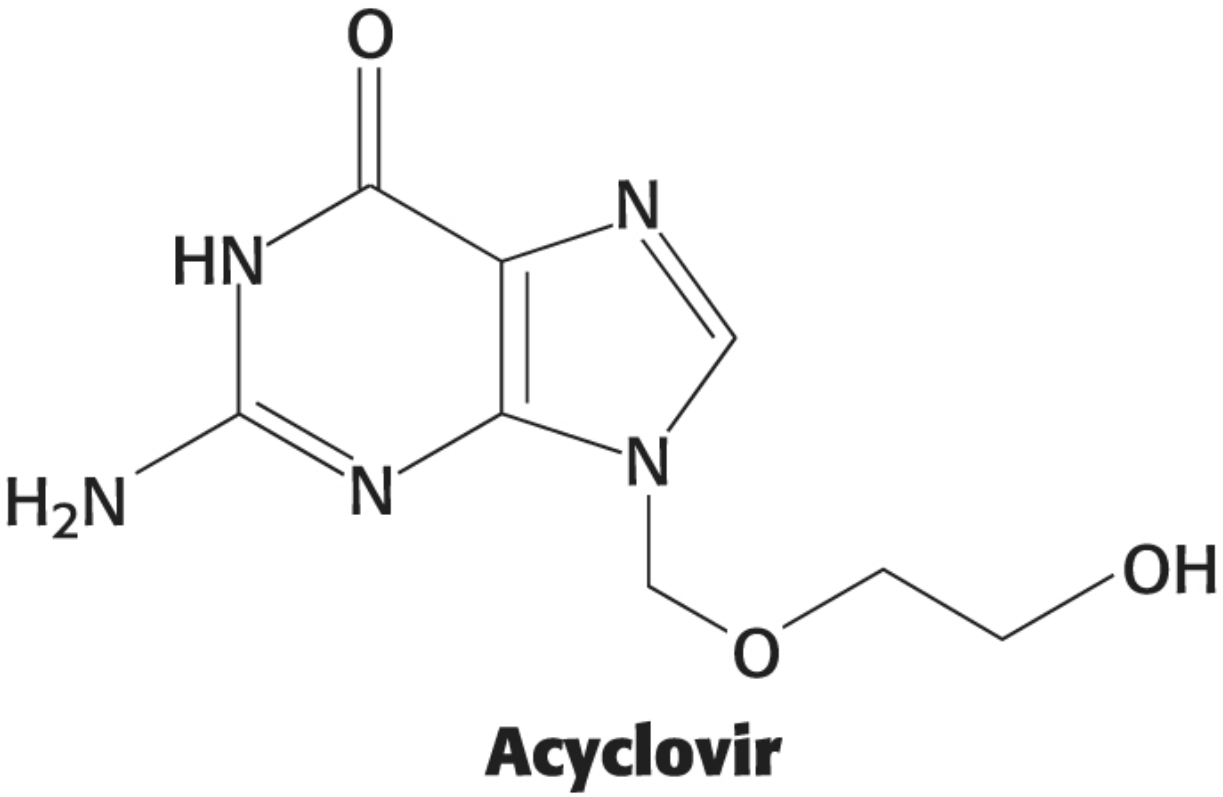
The product is uridylate whose structure is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation

with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single-bonded to N 1 of a 6-membered heterocyclic hexagonal ring in a horizontal orientation. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 superscript 2 minus on the upper left. The hexagonal ring consists of 2 N and 4 C atoms. First N occupies the bottom left vertex and second N bound to H occupies the top left vertex. A double bond is present between C 3 and C 4. C 1 is double bonded to O on the left. C 2 is double bonded to O on the upper right. C 4 is single bonded to H on the lower right.

Return to Formation of uridylate from orotidylate

Extended description for Formation of C T P from U T P

The reaction consists of one reactant and one product. The reactant is U T P and the product is C T P. This reaction is coupled with the entry of N H 3 and breakdown of A T P to A D P plus P subscript i. N H 3 is derived from glutamine. Glutamine reacts with H 2 O to form N H 3 and releases glutamic acid.



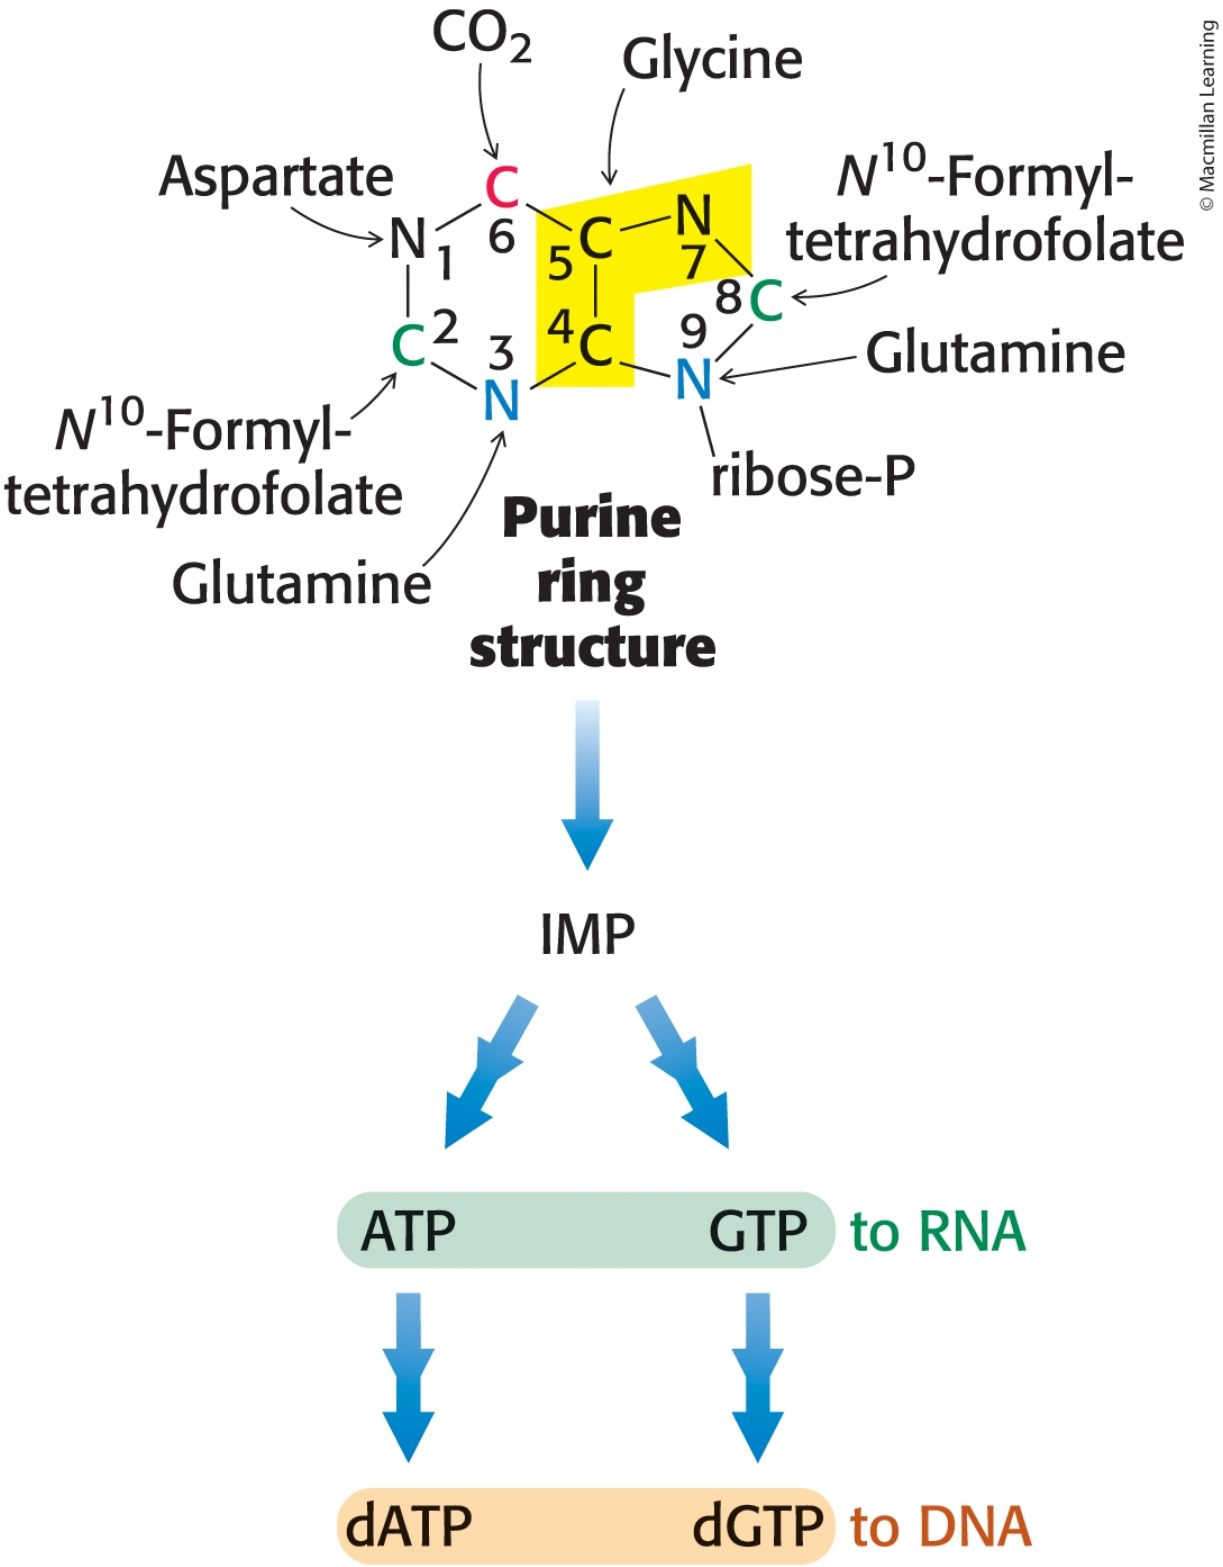
The structure of U T P is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single-bonded to N 1 of a 6-membered heterocyclic hexagonal ring in a horizontal orientation. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 P O 3 P O 3 superscript 4 minus on the upper left. The hexagonal ring consists of 2 N and 4 C atoms. First N occupies the bottom left vertex and second N bound to H occupies the top left vertex. A double bond is present between C 3 and C 4. C 1 is double bonded to O on the left. C 2 is double bonded to O on the upper right.

The structure of C T P is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the

topmost vertex. C 1 is single-bonded to N 1 of a 6-membered heterocyclic hexagonal ring in a horizontal orientation. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 P O 3 P O 3 superscript 4 minus on the upper left. The hexagonal ring consists of 2 N and 4 C atoms. First N occupies the bottom left vertex and the second N occupies the top left vertex. A double bond is present between N 2 and C 2, and C 3 and C 4. C 1 is double bonded to O on the left. C 2 is single bonded to N H 2 on the upper right.

Return to Formation of C T P from U T P

Extended description for Structure of acyclovir



The structure of acyclovir is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the bottom left vertex. It consists of 2 N and 4 C atoms. First N occupies the bottom-most vertex. The second N bound to H occupies the top left vertex. A double bond is present between N 1 and C 1. C 1 is single bonded to N H 2 on the lower left. C 2 is double bonded to O above. The hexagonal ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation such that C 3 and C 4 of the hexagonal ring are C 3 and C 2 respectively of the pentagonal ring. The pentagonal ring consists of 2 N and 3 C atoms. First N occupies the topmost vertex and the second N occupies the bottom right vertex. A double bond is present between N 1 and C 1, and C 2 and C 3. N 2 is single bonded to a 1 O and 3 C heteronuclear alkane

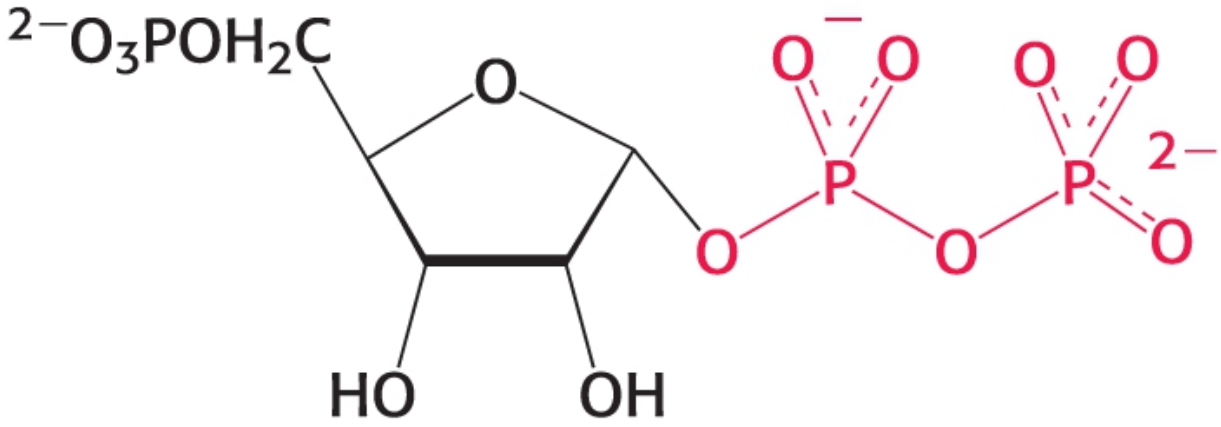
chain depicted as a line structure using 3 zigzag lines. O occupies the second position. C 3 is single bonded to O H on the upper right.

Return to Structure of acyclovir

Extended description for FIGURE 26.5 Purine

nucleotides can be synthesized de novo

© Macmillan Learning



The purine ring structure is shown at the top. It consists of a 6-membered heterocyclic hexagonal ring in a vertical orientation. The ring consists of 2 N and 4 C atoms. First N occupies the bottom-most vertex and the second N occupies the top left vertex. The remaining positions are occupied by C atoms. The atoms of the ring are numbered 1 to 6 in an anticlockwise manner starting from the top-left N atom. N 1 occupying the top left vertex is derived from aspartate. C 2 occupying the bottom left vertex, highlighted in green, is derived from N superscript 10-Formyl-tetrahydrofolate. N 3 occupying the bottom-most vertex, highlighted in blue, is derived from glutamine. C 6 occupying the topmost vertex, highlighted in red, is derived from C O 2. The hexagonal ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation such the C 4 and C 5 atoms are shared between them. The pentagonal ring consists of 2 N and 3 C atoms. First N occupies the topmost vertex. Second N occupies the bottom right vertex. First N, C 1, and second N are numbered 7, 8, and 9 respectively. N 7, C 4, and C 5, highlighted in yellow, are derived from glycine. C 8, highlighted in green, is derived from N superscript 10-Formyl-tetrahydrofolate. N 9, highlighted in blue, is derived from glutamine. N 9 is single bonded to ribose, single bond, P.

A downward arrow from the purine ring structure leads to I M P. I M P has two fates. It can either produce A T P or G T P. A T P and G T P are highlighted in a green bar labeled "to R N A." Two successive downward arrows from A T P lead to d A T P. Two successive downward arrows from G T P lead to d G T P. d A T P and d G T P are highlighted in an orange bar labeled "to D N A."

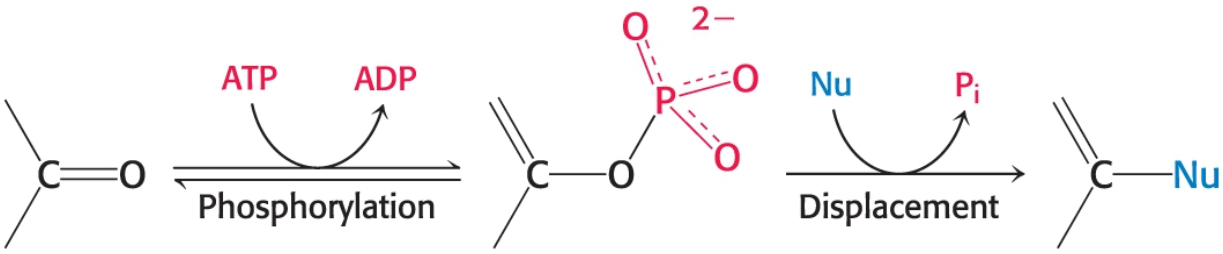
Extended description for Formation of 5-

phosphoribosyl-1-amine from P R P P

PRPP

5-Phosphoribosyl-1-amine



The reaction consists of one reactant and one product. The reactant is P R P P and the product is 5-phosphoribosyl-1-amine. It is coupled with the entry of glutamic acid plus N H 3 and the release of P P subscript i. Glutamic acid plus N H 3 is produced from glutamine plus H 2 O.

The structure of P R P P is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single bonded to a zigzag chain composed of O, single bond, P, single bond, O, single bond, P. P 1 is partially double bonded to O on the upper left and O on the upper right. The O atoms have an overall negative charge. P 2 is partially double bonded to O on the upper left, upper right, and lower right. The O atoms have an overall negative charge of 2 minus. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 superscript 2 minus on the upper left.

The structure of 5-phosphoribosyl-1-amine is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single bonded to N H 2 on the upper right. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 superscript 2 minus on the upper left.

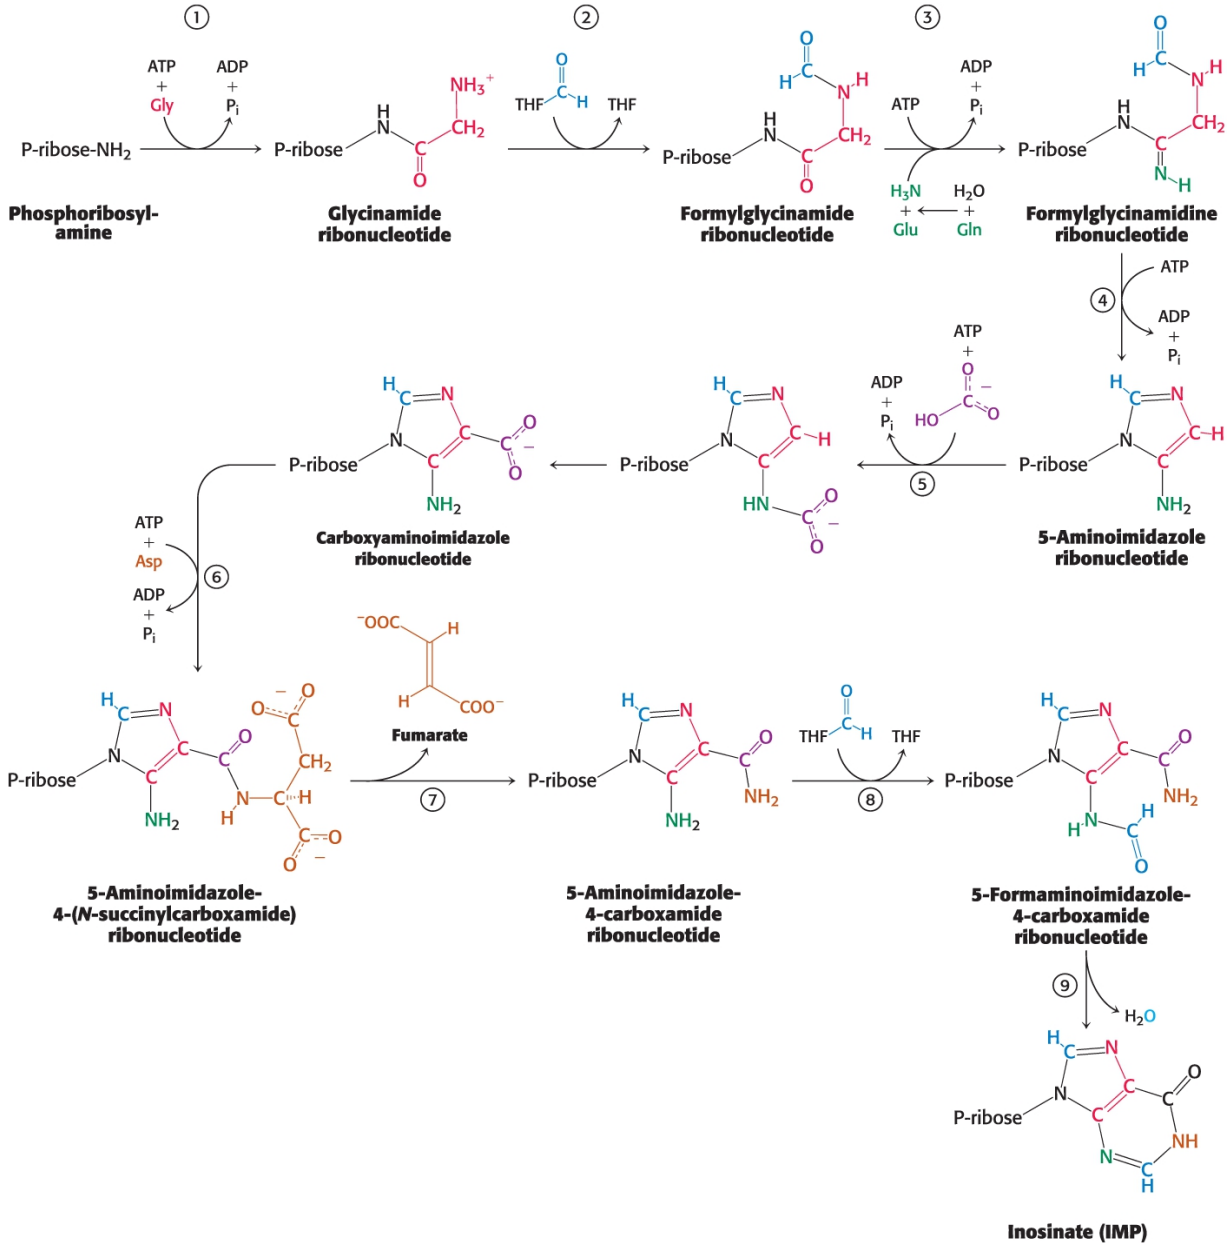
Extended description for Activation of the carbonyl oxygen atom followed by the displacement of the phosphoryl group by a nucleophile

In the first reversible step, a carbonyl oxygen atom is phosphorylated. It is coupled with the breakdown of A T P to A D P.

The structure of the reactant is as follows: A central C atom is double-bonded to O on the right and has an open single bond on the upper left and lower left.



The structure of the product is as follows: A central C atom is single-bonded to O on the right and has an open double bond on the upper left and an open single bond on the lower left. The right O atom is single-bonded to P on the upper right. P is partially double bonded to O above, O on the upper right, and O on the lower right. The O atoms have an overall negative charge of 2 minus.

In the second irreversible step, the phosphoryl group or P subscript i in the product of the first step is displaced by a nucleophile depicted as N u.

The structure of the product of displacement is as follows: A central C is single bonded to N u on the right and has an open double bond on the upper left and an open single bond on the lower left.

Return to Activation of the carbonyl oxygen atom followed by the displacement of the phosphoryl group by a nucleophile

Extended description for FIGURE 26.6 The de novo purine biosynthesis pathway involves nine steps

In the first irreversible step, phosphoribosyl-amine is converted into glycinamide ribonucleotide. It is coupled with the entry of A T P plus glycine and the release of A D P plus P subscript i.

Phosphoribosyl-amine consists of P, single bond, ribose, single bond, N H 2.

Glycinamide ribonucleotide consists of P, single bond, ribose, single bond, N H, single bond, C, single bond, C H 2. C 1 is double bonded to O below. C H 2 is single bonded to N H 3 superscript plus above.

In the second irreversible step, glycinamide ribonucleotide is converted into formylglycinamide ribonucleotide. It is coupled with the entry of the formyl group bonded to T H F and release of T H F. The structure of formylglycinamide ribonucleotide is as follows: P, single bond, ribose, single bond, N H, single bond, C, single bond, C H 2. C 1 is double bonded to O below. C H 2 is single bonded to N above. N is single-bonded to H on the upper right and C on the upper left. C is double bonded to O above and single bonded to H on the lower left.

In the third irreversible step, formylglycinamide ribonucleotide is converted into formylglycinamidine ribonucleotide. It is coupled with the entry of N H 3 and the breakdown of A T P to A D P plus P subscript i. N H 3 and glutamic acid are derived from a reaction between glutamine and H 2 O.

The structure of formylglycinamidine ribonucleotide is as follows: P, single bond, ribose, single bond, N H, single bond, C, single bond, C H 2. C 1 is double bonded to N, single bond, H below. C H 2 is single bonded to N above. N is single-bonded to H on the upper right and C on the upper left. C is double bonded to O above and single bonded to H on the lower left.

In the fourth irreversible step, formylglycinamidine ribonucleotide is converted into 5-aminoimidazole ribonucleotide. It is coupled with the breakdown of A T P to A D P plus P subscript i.

The structure of 5-aminoimidazole ribonucleotide is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the top right vertex. The remaining positions are occupied by C atoms. C 1 occupies the top left vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. N 1 is single bonded to ribose, single bond, P on the lower left. C 1 and C 2 are each single bonded to H. C 3 is single bonded to N H 2 below.

In the fifth irreversible step, 5-aminoimidazole ribonucleotide is converted into another unlabeled compound with the simultaneous entry of bicarbonate and breakdown of A T P to A D P plus P subscript i. The bicarbonate ion is composed of a central C partially double-bonded to O above, partially double-bonded to O on the lower right, and single-bonded to O H on the lower left. The partially double-bonded O atoms have an overall negative charge.

The structure of the unlabeled compound is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the top right vertex. The remaining positions are occupied by C atoms. C 1 occupies the top left vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. N 1 is single bonded to ribose, single bond, P on the lower left. C 1 and C 2 are each single bonded to H. C 3 is single bonded to N H. N H is single bonded to C on the right. This C is partially double-bonded to O on the upper right and lower right. The O atoms have an overall negative charge.

This unlabeled compound is irreversibly converted into carboxyaminoimidazole ribonucleotide.

The structure of carboxyaminoimidazole ribonucleotide is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the top right vertex. The remaining positions are occupied by C atoms. C 1 occupies the top left vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. N 1 is single bonded to ribose, single bond, P on the lower left. C 1 is single bonded to H. C 2 is single bonded to C on the lower right, which is further partially double bonded to O on the upper right and O on the lower right. The O atoms have an overall negative charge. C 3 is single bonded to N H 2 below.

In the sixth irreversible step, carboxyaminoimidazole ribonucleotide is irreversibly converted into 5-aminoimidazole-4-open parenthesis N-succinylcarboxamide close parenthesis ribonucleotide. It is coupled with the simultaneous entry of aspartic acid and breakdown of A T P to A D P plus P subscript i.

The structure of 5-aminoimidazole-4-open parenthesis N-succinylcarboxamide close parenthesis ribonucleotide is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the top right vertex. The remaining positions are occupied by C atoms. C 1 occupies the top left vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. N 1 is single bonded to ribose, single bond, P on the lower left. C 1 is single bonded to H. C 2 is single bonded to C on the right. This C is single-bonded to N on the lower right and double-bonded to O on the upper right. N is single-bonded to H on the lower left and single-bonded to C 2 of a 2-carbon alkane chain in a vertical orientation. C 1 of this chain is single bonded to C above, which is further partially double bonded to O on the upper left and O on the upper right. The O atoms have an overall negative charge. C 2 is single-bonded to H on the right and single-bonded to C on the lower

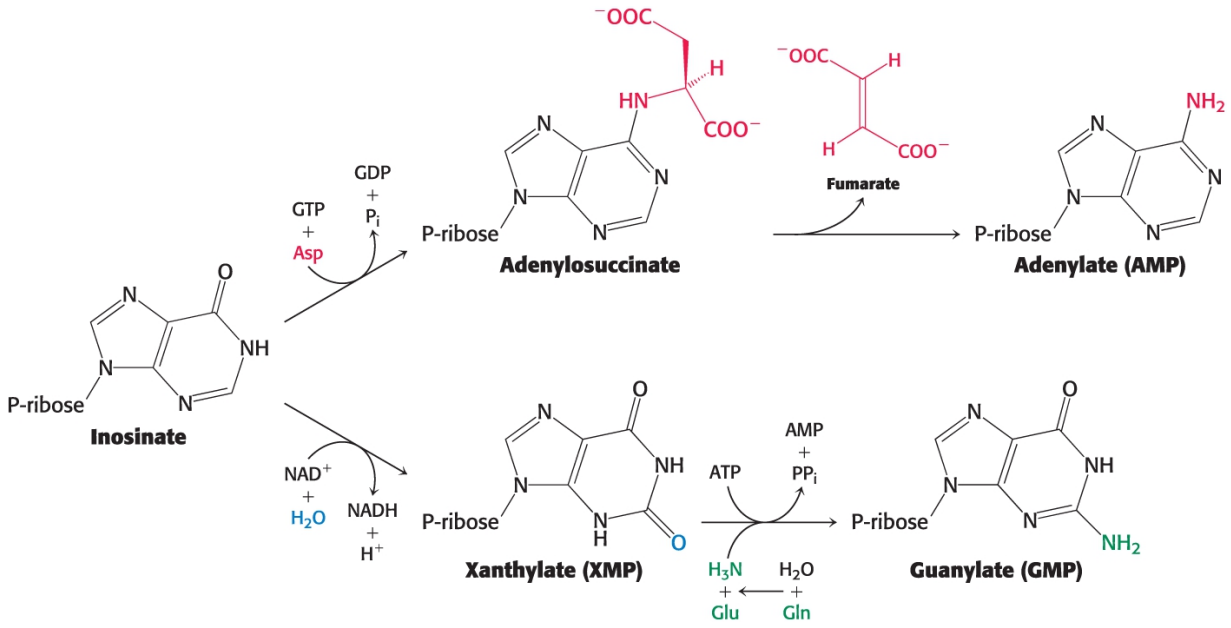
right. This C is partially double-bonded to O on the right and lower left. The O atoms have an overall negative charge. C 3 of the ring is single bonded to N H 2 below.

In the seventh irreversible step, 5-aminoimidazole-4-open parenthesis N-succinylcarboxamide close parenthesis ribonucleotide is converted into 5-aminoimidazole-4-carboxamide ribonucleotide. It is coupled with the release of fumarate.

The structure of fumarate is as follows: A central C atom is single-bonded to H on the lower left, single-bonded to C O O superscript minus on the lower right, and double-bonded to C above. The C atom above is single bonded to C O O superscript minus on the upper left and single bonded to H on the upper right.

The structure of 5-aminoimidazole-4-carboxamide ribonucleotide is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the top right vertex. The remaining positions are occupied by C atoms. C 1 occupies the top left vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. N 1 is single bonded to ribose, single bond, P on the lower left. C 1 is single bonded to H. C 2 is single bonded to C on the right. This C is single-bonded to N H 2 on the lower right and double-bonded to O on the upper right. C 3 is single bonded to N H 2 below.

In the eighth irreversible step, 5-aminoimidazole-4-carboxamide ribonucleotide is converted into 5-formaminoimidazole-4-carboxamide ribonucleotide. It is coupled with the entry of T H F bonded to the formyl group and the release of T H F.



The structure of 5-formaminoimidazole-4-carboxamide ribonucleotide is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the top right vertex. The remaining positions are occupied by C atoms. C 1 occupies the top left vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. N 1 is single bonded to ribose, single bond, P on the lower left. C 1 is single bonded to H. C 2 is single bonded to C on the right. This C is single-bonded to N H 2 on the lower right and double-bonded to O on the upper right. C 3 is single bonded to N H below. N H is single bonded to C on the lower right. This C is single bonded to H on the upper right and double bonded to O below.

In the ninth step, 5-formaminoimidazole-4-carboxamide ribonucleotide is converted into inosinate (I M P). It is coupled with the release of H 2 O.

The structure of inosinate is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the top right vertex. The remaining positions are occupied by C atoms. C 1 occupies the top left vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. N 1 is single bonded to ribose, single bond, P on the lower left. C 1 is single bonded to H. It is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. The hexagonal ring is composed of 2 N and 4 C atoms. The first N bound to H occupies the bottom right vertex and the second N occupies the bottom left vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 1 is bound to H. C 4 is double bonded to O on the upper right.

Return to FIGURE 26.6 The de novo purine biosynthesis pathway involves nine steps

Extended description for FIGURE 26.7 Inosinate can be converted to A M P and G M P

The formation of adenylate (A M P) from inosinate is depicted as follows:

In the first irreversible step, inosinate is converted into adenylosuccinate. It is coupled with the entry of G T P plus aspartic acid and the release of G D P plus P subscript i.

The structure of inosinate is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the bottom right vertex. It consists of 2 N and 4 C atoms. First N bound to H occupies the top right vertex. The second N occupies the bottom-most vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 4 is double bonded to O above. The hexagonal ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation such that C 2 and C 3 of the hexagonal ring

are C 3 and C 2 respectively of the pentagonal ring. The pentagonal ring consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the topmost vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. N 1 is single bonded to ribose, single bond, P on the lower left.

The structure of adenylosuccinate is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the bottom right vertex. It consists of 2 N and 4 C atoms. The first N bound occupies the top right vertex. The second N occupies the bottom-most vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 4 is double bonded to N H above. This N H is single-bonded to a central C atom on the upper right. This C is wedge bonded to C H 2, single bond, C O O superscript minus above, dash bonded to H on the upper right, and single bonded to C O O superscript minus on the lower right. The hexagonal ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation such that C 2 and C 3 of the hexagonal ring are C 3 and C 2 respectively of the pentagonal ring. The pentagonal ring consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the topmost vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. N 1 is single bonded to ribose, single bond, P on the lower left.

In the second irreversible step, adenylosuccinate is converted into adenylate (A M P). It is coupled with the release of fumarate.

The structure of fumarate is as follows: A central C atom is single-bonded to H on the lower left, single-bonded to C O O superscript minus on the lower right, and double-bonded to C above. The C atom above is single bonded to C O O superscript minus on the upper left and single bonded to H on the upper right.

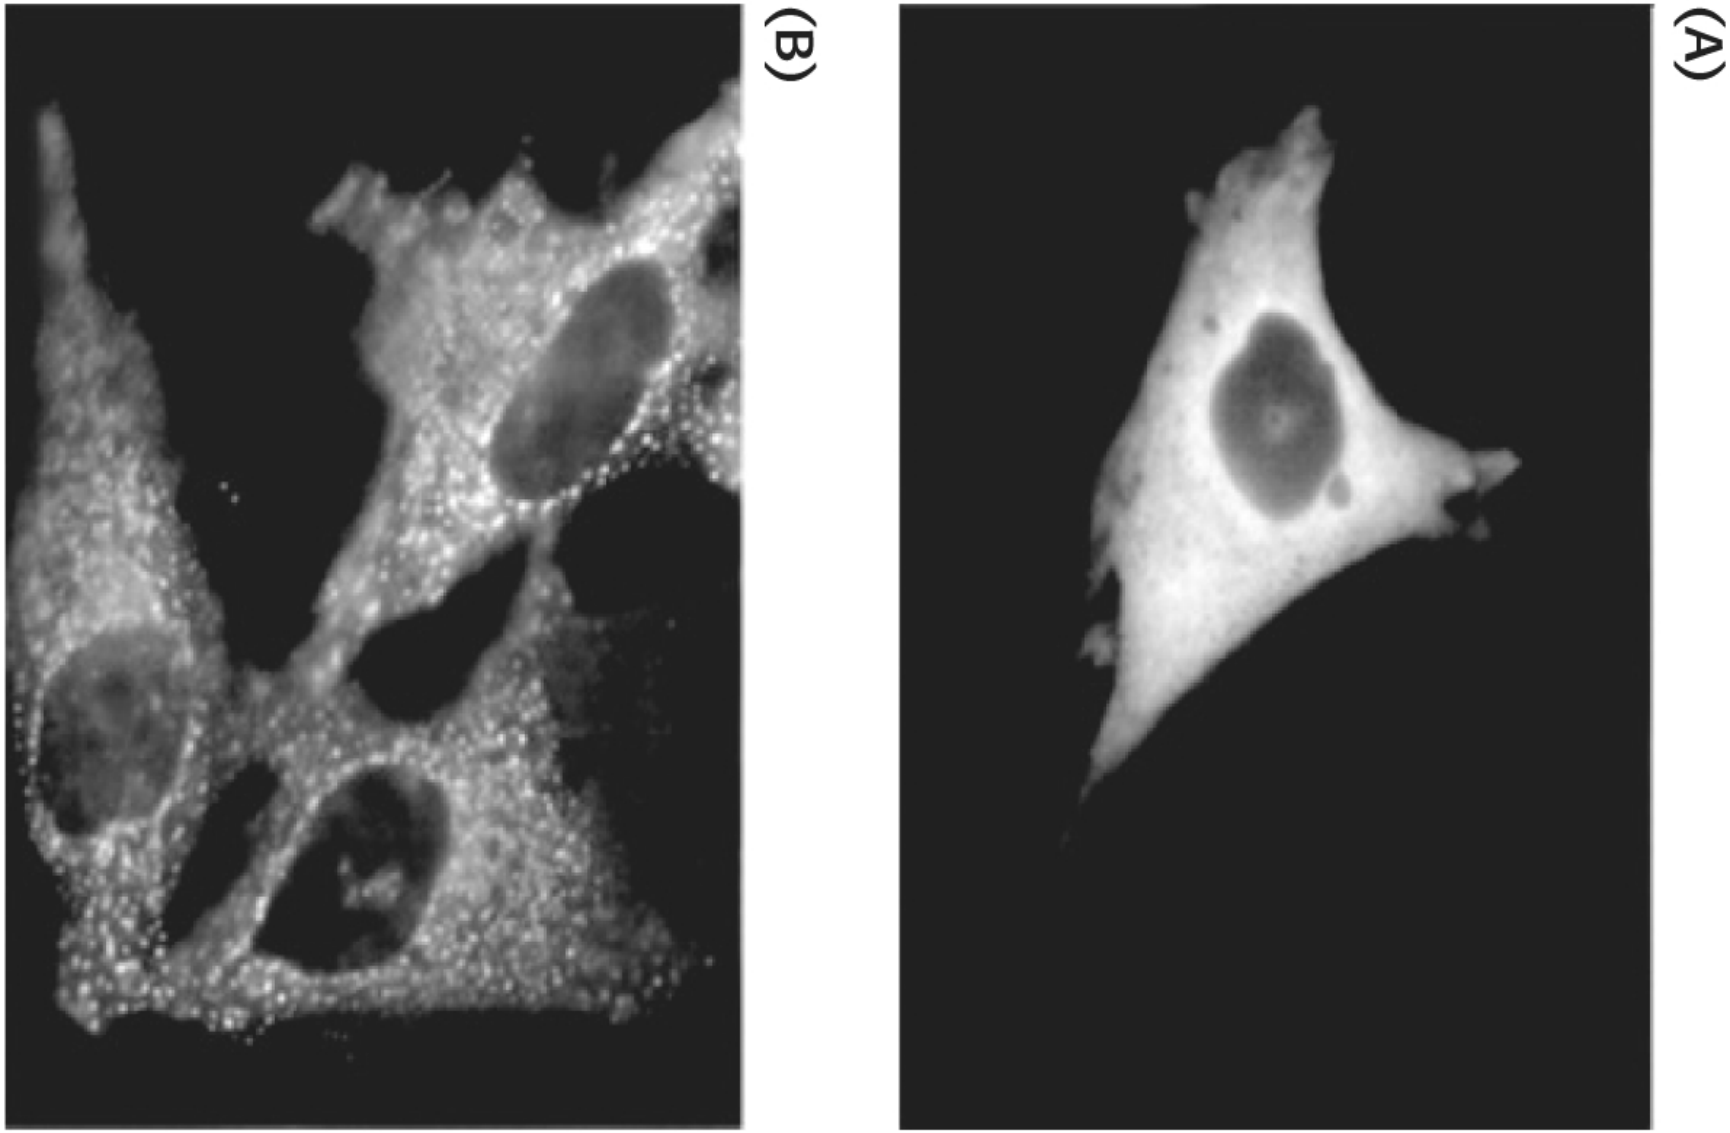
The structure of adenylate (A M P) is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the bottom right vertex. It consists of 2 N and 4 C atoms. First N occupies the top right vertex. The second N occupies the bottom-most vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 4 is single bonded to N H 2 above. The hexagonal ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation such that C 2 and C 3 of the hexagonal ring are C 3 and C 2 respectively of the pentagonal ring. The pentagonal ring consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the topmost vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. N 1 is single bonded to ribose, single bond, P on the lower left.

The formation of guanylate (G M P) from inosinate is depicted as follows:

In the first irreversible step, inosinate is converted into xanthylate (X M P). It is coupled with the reduction of N A D superscript plus to N A D H plus H superscript plus and the entry of H 2 O.

The structure of xanthylate (X M P) is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the bottom right vertex. It consists of 2 N and 4 C atoms. First N bound to H occupies the top right vertex. The second N bound to H occupies the bottom-most vertex. A double bond is present between C 2 and C 3. C 1 and C 4 are double bonded to O. The hexagonal ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation such that C 2 and C 3 of the hexagonal ring are C 3 and C 2 respectively of the pentagonal ring. The pentagonal ring consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the topmost vertex. A double bond is present between C 1 and N 2, and

C 2 and C 3. N 1 is single bonded to ribose, single bond, P on the lower left.



In the second irreversible step, xanthylate (X M P) is converted into guanylate (G M P). It is coupled with the breakdown of A T P to A M P plus P P subscript i and entry of N H 3. N H 3 and glutamic acid are derived from the reaction of glutamine with H 2 O.

The structure of guanylate (G M P) is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the bottom right vertex. It consists of 2 N and 4 C atoms. First N bound to H occupies the top right vertex. The second N occupies the bottom-most vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 1 is single bonded to N H 2. C 4 is double bonded to O above. The hexagonal ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation such that C 2 and C 3 of the hexagonal ring are C 3 and C 2 respectively of the pentagonal ring. The pentagonal ring consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the topmost vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. N 1 is single bonded to ribose, single bond, P on the lower left.

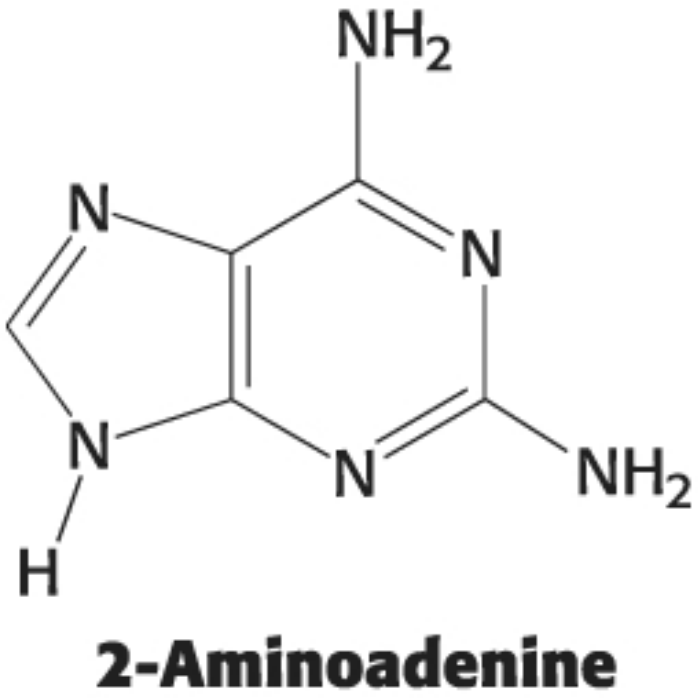
Extended description for Structure of inosinate

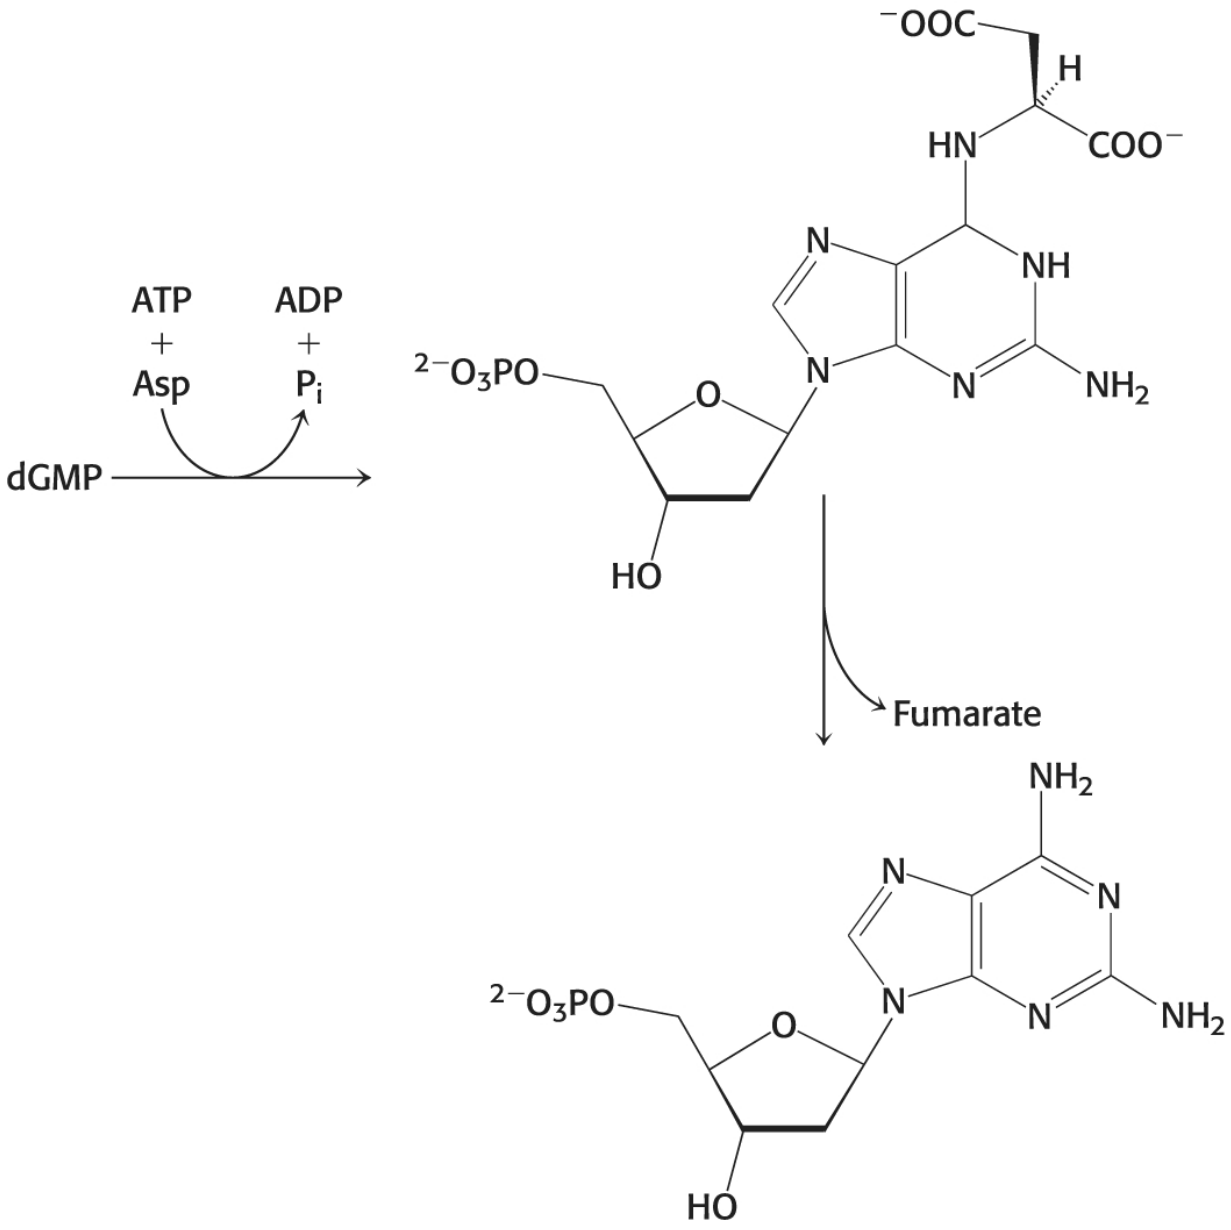


The structure of inosinate is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 O P O 3 superscript 2 minus on the upper left. C 1 is single bonded to N 1 of the pentagonal ring of hypoxanthine.

The structure of hypoxanthine is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation. It consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the topmost vertex. C 1 occupies the leftmost vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. It is fused to a 6-membered heterocyclic hexagonal ring

in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. The hexagonal ring is composed of 2 N and 4 C atoms. The first N bound to H occupies the top right vertex and the second N occupies the bottom-most vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 4 is double bonded to O above.

Return to Structure of inosinate



Extended description for Structure of 2-aminoadenine

The structure of 2-aminoadenine is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation. It consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the top left vertex. C 1 occupies the leftmost vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. N 1 is single bonded to H. It is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. The hexagonal ring is composed of 2 N and 4 C atoms. The first N occupies the top right vertex and the second N occupies the bottom-most vertex. A double bond is present between C 1 and N 2, C 2 and C 3, and C 4 and N 1. C 1 and C 4 are each single bonded to N H 2.

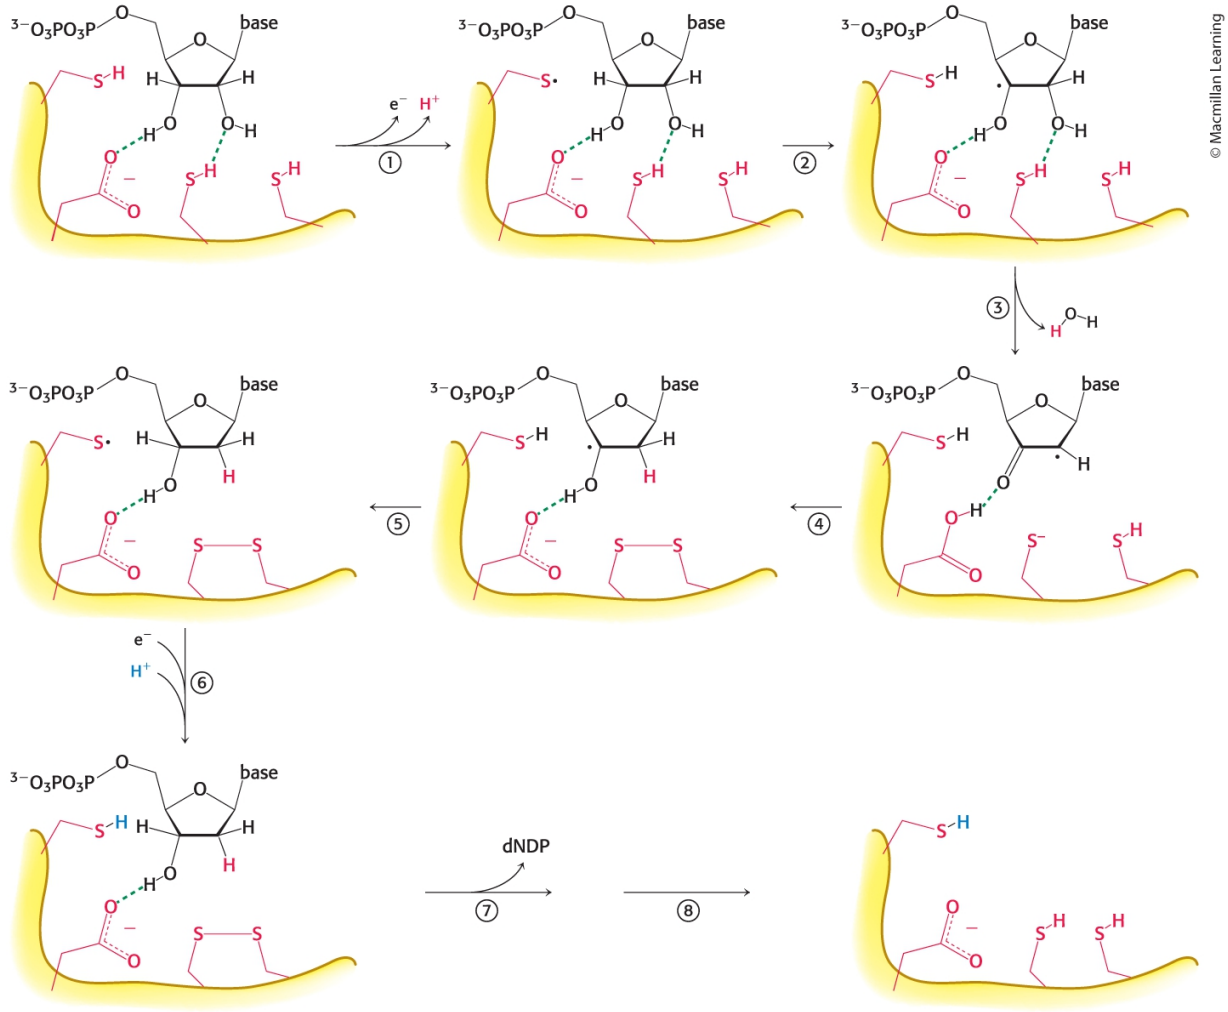
Return to Structure of 2-aminoadenine

Extended description for FIGURE 26.9 The nucleotide containing 2-aminoadenine is synthesized from deoxyguanylate

In the first irreversible step, d G M P is converted into an unlabeled compound. It is coupled with the entry of aspartic acid and the

breakdown of A T P to A D P plus P subscript i.

The structure of the unlabeled compound is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 3 is single bonded to O H below. C 4 is single bonded to C H 2 on the upper left in the form of a line. C H 2 in single bonded to O P O 3 superscript 2 minus on the left. C 1 is single-bonded to N 1 of a 5-membered heterocyclic pentagonal ring in a horizontal orientation. The pentagonal ring consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the top left vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. It is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. The hexagonal ring consists of 2 N and 4 C atoms. First N bound to H occupies the top right vertex. The second N occupies the bottom-most vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 4 is single bonded to N H above. N H is single bonded to C on the upper right. This C is wedge bonded to C H 2, single bond, C O O superscript minus above, dash bonded to H on the upper right, and single bonded to C O O superscript minus on the lower right.



In the second irreversible step, fumarate is released leading to the formation of the final product.

The structure of the final product is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 3 is single bonded to O H below. C 4 is single bonded to C H 2 on the upper left in the form of a line. C H 2 in single bonded to O P O 3 superscript 2 minus on the left. C 1 is single-bonded to N 1 of a 5-membered heterocyclic pentagonal ring in a horizontal orientation. The pentagonal ring consists of 2 N and 3 C atoms. First N occupies the

bottom left vertex and the second N occupies the top left vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. It is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. The hexagonal ring consists of 2 N and 4 C atoms. First N occupies the top right vertex. The second N occupies the bottom-most vertex. A double bond is present between C 1 and N 2, C 2 and C 3, and C 4 and N 1. C 1 and C 4 are each single bonded to N H 2.

Return to FIGURE 26.9 The nucleotide containing 2-aminoadenine is synthesized from deoxyguanylate

Extended description for FIGURE 26.10 Ribonucleotide reductase uses a radical mechanism to produce deoxyribonucleotides

© Macmillan Learning

The active site of the ribonucleotide reductase is depicted as a cleft with an orange outline. The outline has a yellow highlight. It contains side chains of three cysteine residues and one tyrosine residue.

The side chain of cysteine is depicted as C H 2, single bond, S, single bond, H. The side chain of tyrosine is depicted as C H 2, single bond, C. C is partially double bonded to O above and O on the lower right. The O atoms have an overall negative charge.

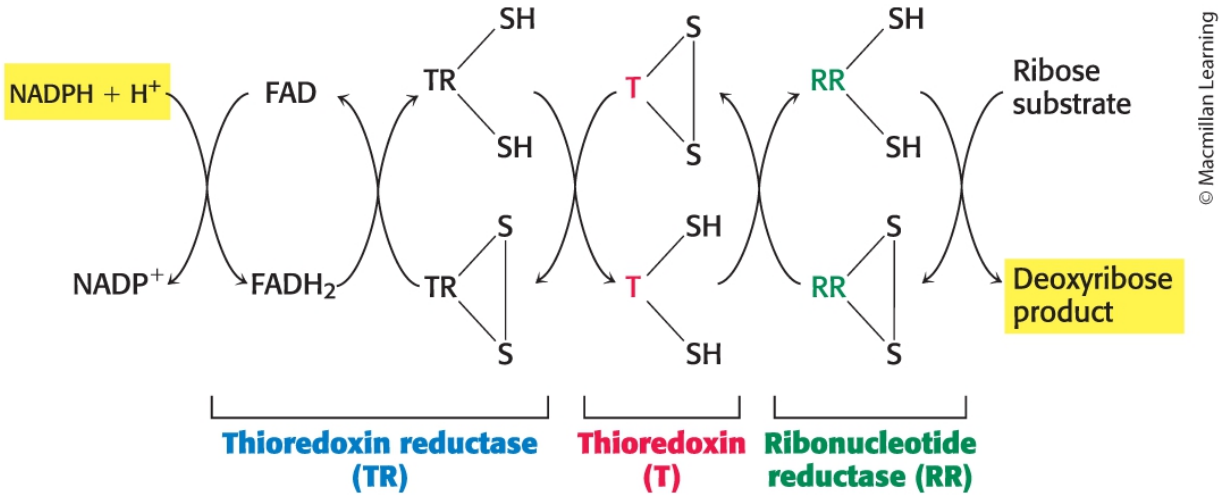
A pentagonal ring is shown in the active site of the enzyme. The structure of the ring is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single-bonded to base. C 2 is single bonded to H and O, single bond, H. C 3 is single bonded to H and O, single bond, H. C 4 is single bonded to C H 2, single bond, O, single bond, P O 3 P O 3 superscript 3 minus. A dashed line connects the H atom of O H groups bonded to C 2 and C 3 with the H atom of one cysteine side chain and the O atom of the tyrosine side chain.

In step 1, an electron and H superscript plus ion are released. This electron and H atom are released from the side chain of one of the cysteine side chains. As a result, the S atom of the cysteine side chain contains an unpaired electron.

In step 2, the H atom bonded to C 3 of the ring is transferred to the S atom with an unpaired electron of the cysteine side chain. As a result, C 3 contains an unpaired electron.

In step 3, H, single bond, O, single bond, H is released from the active site. C 3 of the ring becomes double bonded to O, which is further connected to H through a dashed line. This H becomes single-bonded to the O atom of the tyrosine side chain. This O becomes single-bonded to C of the tyrosine side chain and the other O becomes double-bonded to the C atom. C 2 of the ring loses its O H group. As a result, C 2 contains an unpaired electron and the S atom of the cysteine side chain with which it was previously bonded becomes negatively charged.

In step 4, a single bond forms between the negatively charged S atom of one cysteine side chain and the S atom of the adjacent side chain. This happens as the H atom of one cysteine side chain is transferred to C 2. As a result, C 2 is single-bonded to two H atoms. C 3 contains an unpaired electron and it is single bonded to O, single bond, H below. H is connected to the O atom of the tyrosine side chain through a dashed line. The double bonds between C and O atoms of the tyrosine side chain again start resonating.



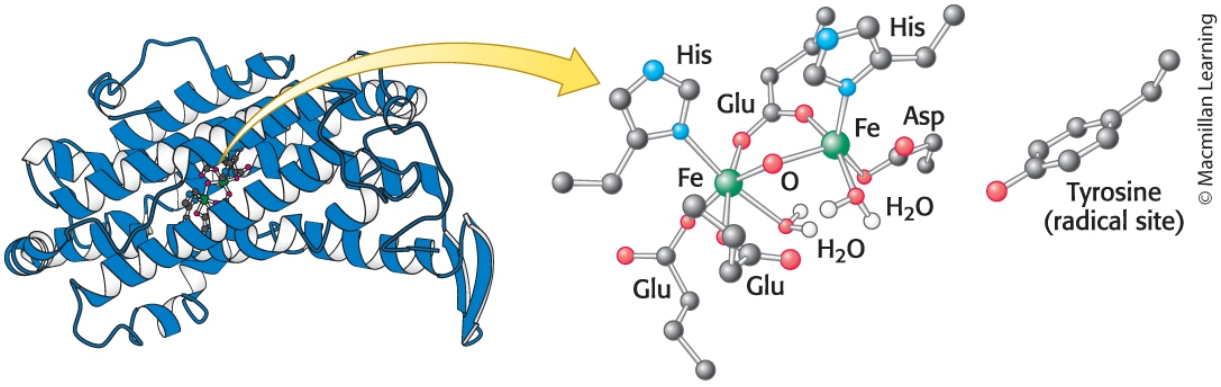
In step 5, the H atom from the S H group of the same cysteine side chain is transferred to C 3. This S atom contains an unpaired electron similar to step 1.

In step 6, H superscript plus ion and electron enter the active site. The S atom with an unpaired electron becomes single-bonded to this H.

In step 7, d N D P is released. It is followed by step 8, which leads to an empty active site. The empty active site contains the side chains of three cysteine residues and one tyrosine residue in their native configuration.

Return to FIGURE 26.10 Ribonucleotide reductase uses a radical mechanism to produce deoxyribonucleotides

Extended description for Oxidation of N A D P H coupled with the reduction of ribose substrate



© Macmillan Learning

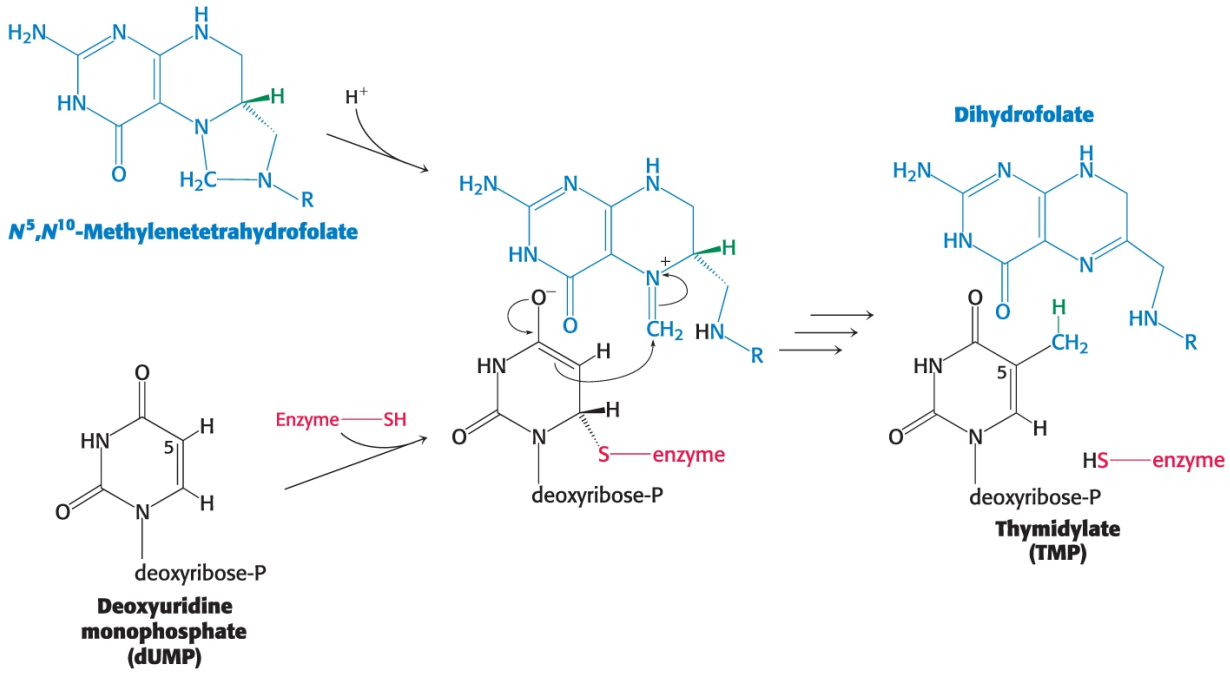
N A D P H plus H superscript plus highlighted in yellow transfers electron to F A D bound to thioredoxin reductase (T R). As a result, it is converted into N A D P superscript plus, and F A D is converted to F A D H 2. F A D H 2 of T R transfer electrons to the disulfide linkage of T R. The disulfide linkage is depicted as T R single bonded to S on the upper right and S on the lower right. Both S atoms are single-bonded to each other. After electron transfer, the disulfide linkage is broken and T R is single-bonded to S H on the upper right and S H on the lower right. Electrons from the S H groups are transferred to the disulfide linkage of thioredoxin (T). The disulfide linkage is depicted as T single bonded to S on the upper right and S on the lower right. Both S atoms are single-bonded to each other. After electron transfer, the disulfide linkage is broken and T is single-bonded to S H on the upper right and S H on the lower right. Electrons from the S H group are transferred to the disulfide linkage of ribonucleotide reductase (R R). The disulfide linkage is depicted as R R single bonded to S on the upper right and S on the lower right. Both S atoms are single-bonded to each other. After electron

transfer, the disulfide linkage is broken and R R is single-bonded to S H on the upper right and S H on the lower right. Electrons from the S H group are transferred to the ribose substrate to produce the deoxyribose product highlighted in yellow.

Return to Oxidation of N A D P H coupled with the reduction of ribose substrate

Extended description for FIGURE 26.11 The ribonucleotide reductase R 2 subunit contains a stable free radical on a tyrosine residue

The ribonucleotide reductase R 2 subunit is composed of several horizontally oriented alpha-helices and 2 vertical beta-strands on the bottom right interconnected by thread-like loops. An arrow from the center of the R 2 subunit points toward a ball-and-stick on the right. The model shows a central O atom connected to F e on the lower left and O on the upper right. O is depicted as a red sphere and F e is depicted as a green sphere. The lower left F e is connected to a histidine residue on the top, glutamic acid on the lower left and below, H 2 O on the lower right, and glutamic acid on the upper right. The upper right F e is connected to the upper left glutamic acid, which is also connected to the lower left F e. It is also connected to a histidine residue on the upper right, aspartic acid on the lower right, and H 2 O below.



The histidine residue contains a pentagonal ring composed of 2 blue and 3 black spheres. The F e atom is connected to one of the blue spheres. One of the black spheres is further connected to a chain of two black spheres. The glutamic acid residue is composed of a chain of 4 black spheres. One of the black spheres is connected to two red

spheres. The F e atom is connected to the red sphere. The H 2 O molecule is composed of a red sphere connected to a white sphere on either side. The F e atom is connected to the red sphere of H 2 O. The aspartic acid residue is composed of 3 black spheres. One of the black spheres is connected to a red sphere.

A tyrosine (radical site) is located on the right side of the ball-and-stick model. The side view of the radical site is shown. Tyrosine consists of a hexagonal ring composed of 6 black spheres. One of the black spheres is connected to a chain of two black spheres on the upper right and another black sphere, opposite to it, is connected to a red sphere on the lower left.

Return to FIGURE 26.11 The ribonucleotide reductase R 2 subunit contains a stable free radical on a tyrosine residue

Extended description for FIGURE 26.12 Thymidylate synthase catalyzes the addition of a methyl group to d U M P to form T M P

In the first irreversible step, deoxyuridine monophosphate (d U M P) binds to an enzyme with an S H group. Simultaneously, N superscript 5, N superscript 10-Methylenetetrahydrofolate gains an H superscript plus ion.

The structure of deoxyuridine monophosphate (d U M P) is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the bottom left vertex. It consists of 2 N and 4 C atoms. First N occupies the bottom-most vertex. The second N bound to H occupies the top left vertex. C 1 and C 2 are double bonded to O. C 3 is numbered 5. C 3 and C 4 are single-bonded to H and double-bonded to each other. N 1 is single bonded to deoxyribose, single bond, P.

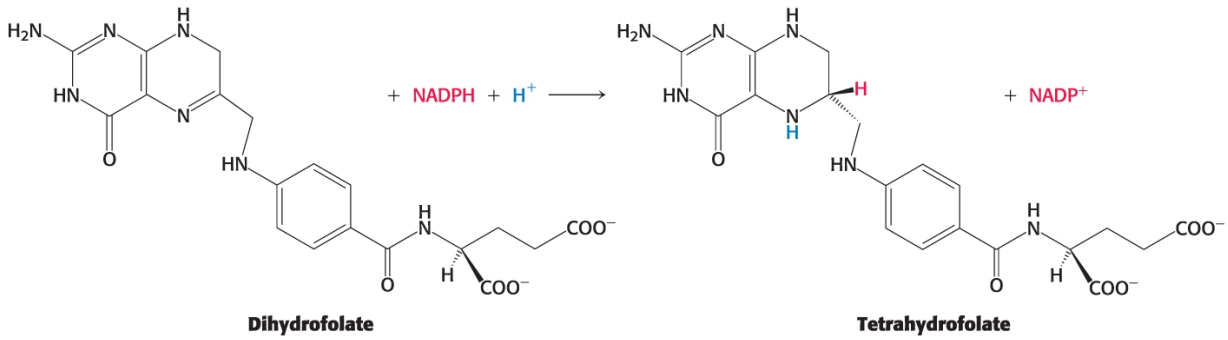
The structure of N superscript 5, N superscript 10-Methylenetetrahydrofolate is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. First N occupies the topmost vertex and the second N occupies the bottom-most vertex. First N atom is bound to H. C 2 is wedge bonded to H on the upper right and dash bonded to C H 2 on the lower right. C H 2 is single bonded to N below. N is single-bonded to R on the lower right and single-bonded to C H 2 on the left. This C H 2 is single-bonded to N 2 of the ring to form a pentagonal ring-like structure. The ring is fused to a second 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 3 and C 4 of the first hexagonal ring are C 3 and C 2 respectively of the second hexagonal ring. The second ring consists of 2 N and 4 C atoms. First N bound to H occupies the bottom left vertex. Second N occupies the topmost vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 1 is single bonded to N H 2. C 4 is double bonded to O below.

After enzyme addition, the S atom of the enzyme forms a dash bond with C 4 of d U M P. C 4 also forms a wedge bond with H. The double bond between C 3 and C 4 is broken. A double bond is formed between C 2 and C 3. C 2 is single bonded to O superscript minus above. The remaining structure is the same.

In N superscript 5, N superscript 10-Methylenetetrahydrofolate, H superscript plus ion binds to N below, which is single bonded to C H 2. As a result, the single bond between this N and C H 2 on the left is broken and the C H 2 group forms a double bond with N 2 of the first ring. N2 acquires a positive charge.

An arrow points from O superscript minus toward its single bond with C 2 of d U M P. An arrow from the double bond between C 2 and C 3 points toward the C H 2 of protonated N superscript 5, N superscript 10-Methylenetetrahydrofolate. An arrow from the

double bond between this C H 2 group and the second N with positive charge points toward the second N atom.



Three forward arrows lead to the products that are thymidylate (T M P) and dihydrofolate. The enzyme bound to S H is released.

The structure of thymidylate (T M P) is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the bottom left vertex. It consists of 2 N and 4 C atoms. First N occupies the bottom-most vertex. The second N bound to H occupies the top left vertex. C 1 and C 2 are double bonded to O. C 3 is numbered 5. C 3 is single bonded to CH 2, single bond, H on the upper right. C 4 is single bonded to H on the lower right. A double bond is present between C 3 and C 4. N 1 is single bonded to deoxyribose, single bond, P.

The structure of dihydrofolate is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. First N occupies the topmost vertex and the second N occupies the bottom-most vertex. First N atom is bound to H. C 2 is single-bonded to C H 2 on the lower right in the form of a line. C H 2 is single bonded to N H below. N H is single bonded to R on the lower right. The ring is fused to a second 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 3 and C 4 of the first hexagonal ring are C 3 and C 2 respectively of the second hexagonal ring. The second ring consists of 2 N and 4 C atoms. First N bound to H occupies the bottom left vertex. Second N occupies the topmost vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 1 is single bonded to N H 2. C 4 is double bonded to O below.

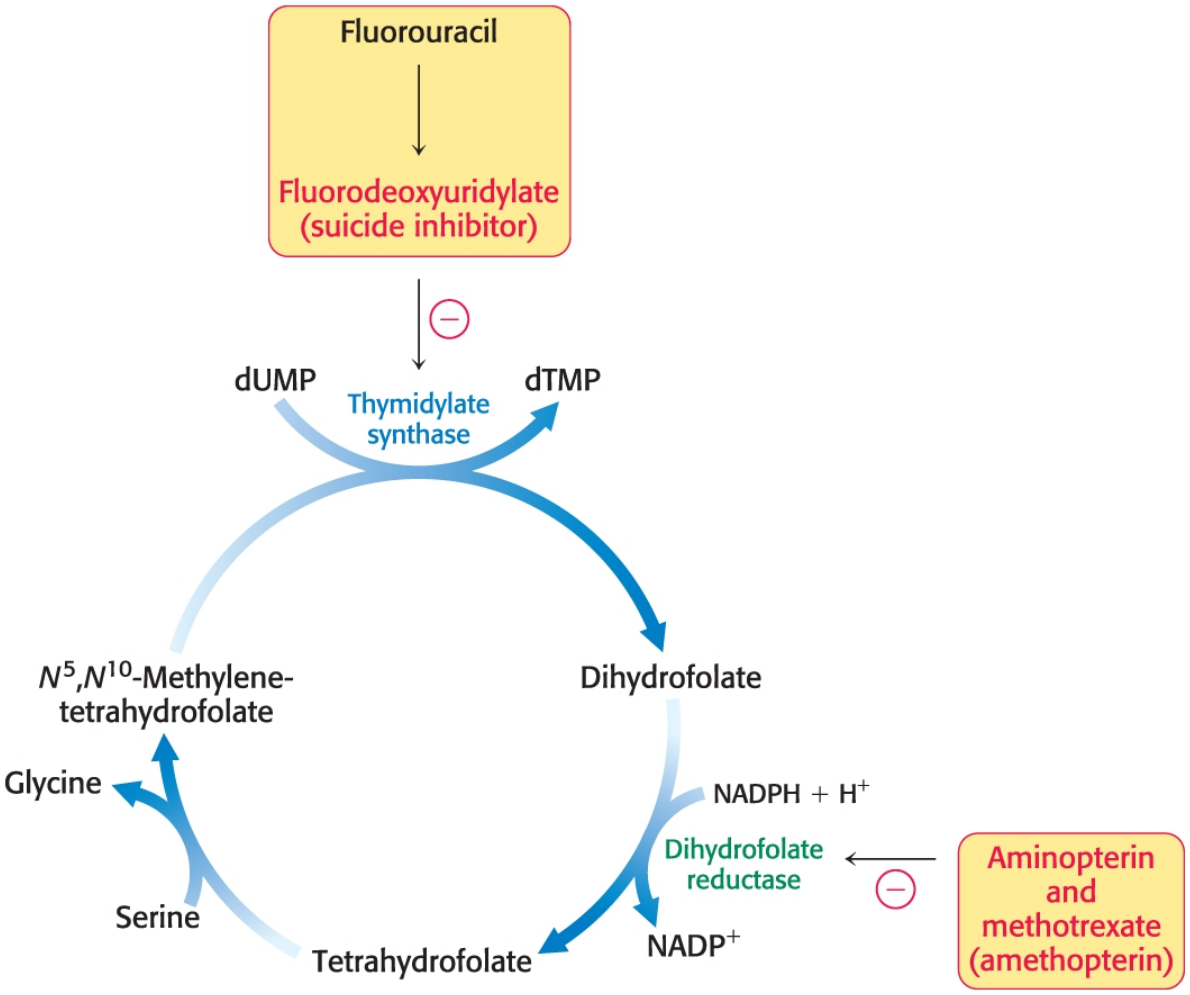
Return to FIGURE 26.12 Thymidylate synthase catalyzes the addition of a methyl group to d U M P to form T M P

Extended description for Reduction of dihydrofolate to tetrahydrofolate

The reaction consists of two reactants and two products.

The first reactant is dihydrofolate whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. First N occupies the topmost vertex and the second N occupies the bottom-most vertex. The first N atom is bound to H. A double bond is present between C 2 and N 2. C 2 is single-bonded to C H 2 on the lower right in the form of a line. C H 2 is single bonded to N H below. The ring is fused to a second 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 3 and C 4 of the first hexagonal ring are C 3 and C 2 respectively of the second hexagonal ring. The second ring consists of 2 N and 4 C atoms. First N bound to H occupies the bottom left vertex. Second N occupies the topmost vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 1 is single bonded to N H 2. C 4 is double bonded to O below. N H group connected to the first ring is single bonded to C 6 of a benzene ring in a vertical orientation on the lower right. The benzene ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 3 is single bonded to C 1 of a 1 N and 4 C heteronuclear alkane chain depicted as a line structure using 4

zigzag lines. N bound to H occupies the second position. C 1 is double bonded to O below. C 2 is dash bonded to H on the lower left and single bonded to C O O superscript minus on the lower right. C 4 is single bonded to C O O superscript minus on the upper right.



The second reactant is N A D P H plus H superscript plus.

The first product is tetrahydrofolate whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. The first N occupies the topmost vertex and the second N occupies the bottom-most vertex. Both N atoms are bound to H. C 2 is dash bonded to C H 2 on the lower right and wedge bonded to H on the right. C H 2 is single bonded to N H below. The ring is fused to a second 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 3 and C 4 of the first hexagonal ring are C 3 and C 2 respectively of the second hexagonal ring. The second ring consists of 2 N and 4 C atoms. First N bound to H occupies the bottom left vertex. Second N occupies the topmost vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 1 is single bonded to N H 2. C 4 is double bonded to O below. N H group connected to the first ring is single bonded to C 6 of a benzene ring in a vertical orientation on the lower right. The benzene ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 3 is single bonded to C 1 of a 1 N and 4 C heteronuclear alkane chain depicted as a line structure using 4 zigzag lines. N bound to H occupies the second position. C 1 is double bonded to O below. C 2 is dash bonded to H on the lower left and wedge bonded to C O O superscript minus on the lower right. C 4 is single bonded to C O O superscript minus on the upper right.

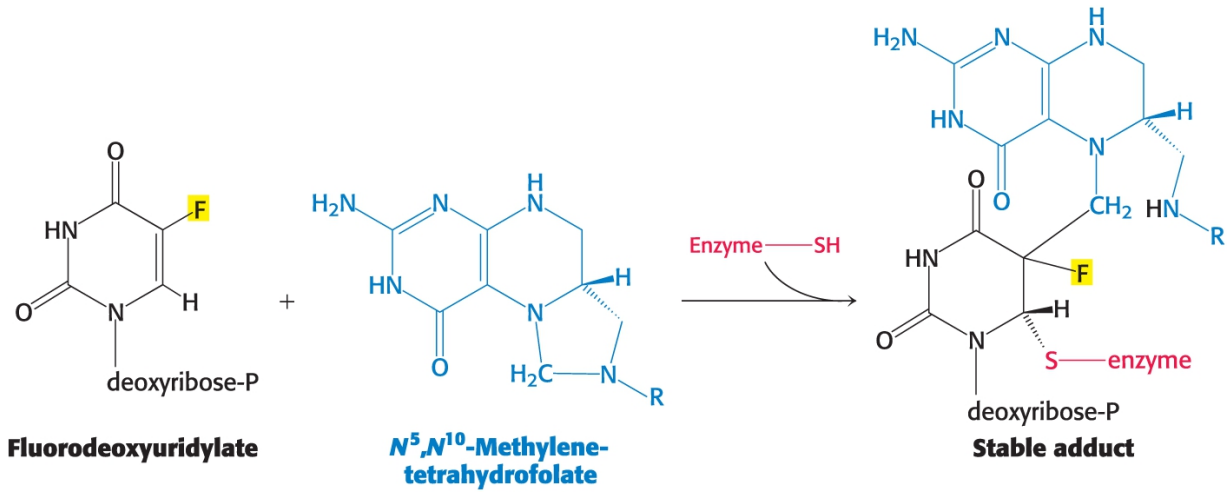
The second product is N A D P superscript plus.

Return to Reduction of dihydrofolate to tetrahydrofolate

Extended description for FIGURE 26.13 Enzymes crucial for nucleotide synthesis are anticancer drug targets

© Macmillan Learning

A cycle shows the site of action of thymidylate synthase and dihydrofolate reductase.



N superscript 5, N superscript 10-Methylene tetrahydrofolate is converted into dihydrofolate by thymidylate synthase. It is coupled with the conversion of d U M P to d T M P. Dihydrofolate is converted into tetrahydrofolate by dihydrofolate reductase. It is

coupled with the oxidation of N A D P H plus H superscript plus to N A D P superscript plus.

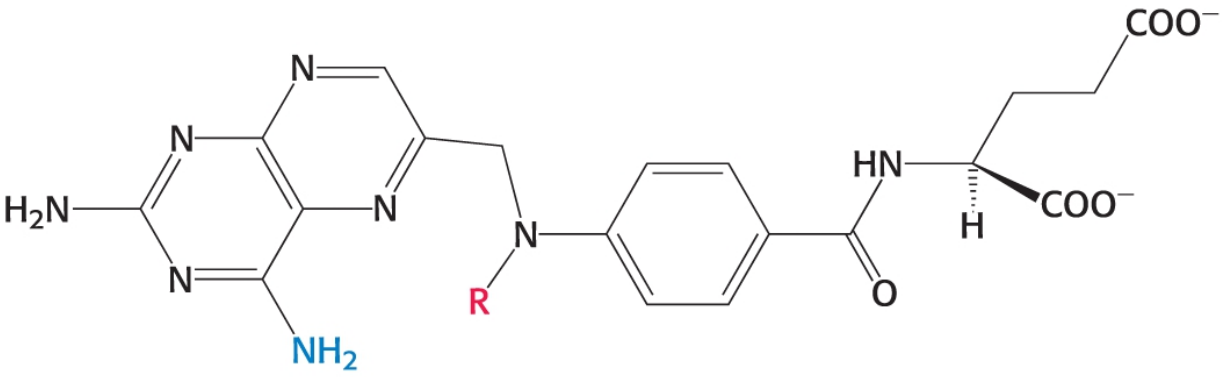
Tetrahydrofolate is converted back to N superscript 5, N superscript 10-Methylene tetrahydrofolate. It is coupled with the entry of serine and the release of glycine. The cycle continues in this manner. A yellow square shows the conversion of fluorouracil to fluorodeoxyuridylate (suicide inhibitor) highlighted in red. A downward arrow with a minus symbol points from this yellow square toward thymidylate synthase. Another yellow square contains aminopterin and methotrexate (amethopterin). An arrow with a minus symbol points from this square to dihydrofolate reductase.

Return to FIGURE 26.13 Enzymes crucial for nucleotide synthesis are anticancer drug targets

Extended description for FIGURE 26.14 Fluoruracil acts by suicide inhibition

The reaction consists of two reactants and one product.

The first reactant is fluorodeoxyuridylate whose structure is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the bottom left vertex. It consists of 2 N and 4 C atoms. First N occupies the bottom-most vertex. The second N bound to H occupies the top left vertex. C 1 and C 2 are double bonded to O. C 3 is single bonded to F on the upper right. C 4 is single-bonded to H on the lower right. A double bond is present between C 3 and C 4. N 1 is single bonded to deoxyribose, single bond, P.



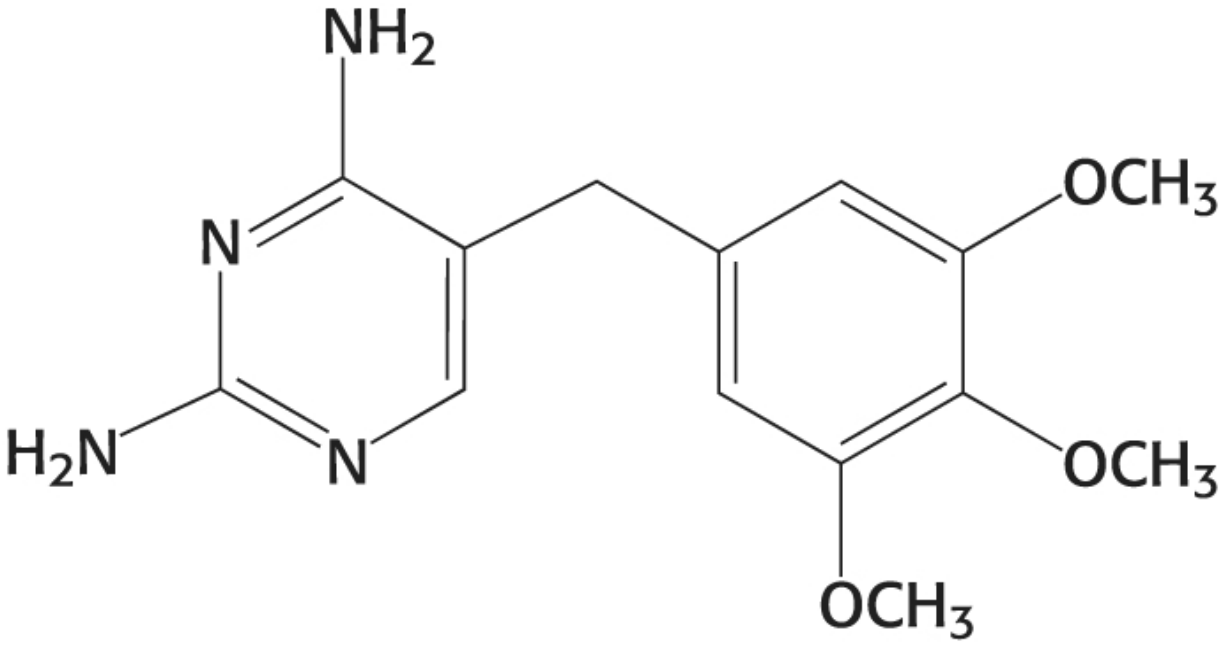
The structure of N superscript 5, N superscript 10-Methylene tetrahydrofolate is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. First N occupies the topmost vertex and the second N occupies the bottom-most vertex. First N atom is bound to H. C 2 is wedge bonded to H on the upper right and dash bonded to C H 2 on the

lower right. C H 2 is single bonded to N below. N is single-bonded to R on the lower right and single-bonded to C H 2 on the left. This C H 2 is single-bonded to N 2 of the ring to form a pentagonal ring-like structure. The ring is fused to a second 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 3 and C 4 of the first hexagonal ring are C 3 and C 2 respectively of the second hexagonal ring. The second ring consists of 2 N and 4 C atoms. First N bound to H occupies the bottom left vertex. Second N occupies the topmost vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 1 is single bonded to N H 2. C 4 is double bonded to O below.

An enzyme bound to the S H group enters the reaction. The product is a stable adduct between fluorodeoxyuridylate, N superscript 5, N superscript 10-Methylene tetrahydrofolate, and the enzyme. The C 4 of fluorodeoxyuridylate is dash bonded to S, single bond, enzyme. It becomes wedge bonded to H. C 3 of fluorodeoxyuridylate is single bonded to C H 2 group of the pentagonal ring-like structure of N superscript 5, N superscript 10-Methylene tetrahydrofolate. The single bond between N and this C H 2 group breaks. As a result, N becomes bound to H.

Return to FIGURE 26.14 Fluoruracil acts by suicide inhibition

Extended description for Generalized structure of aminopterin and methotrexate



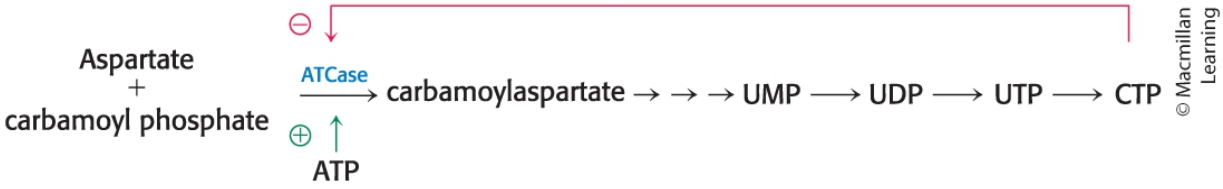
Aminopterin (R = H) or methotrexate (R = CH_3)

The generalized structure is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the rightmost vertex. It consists of 2 N and 4 C atoms. First N occupies the bottom-left vertex and the second N occupies the top-left vertex. A double bond is present between C 1 and N 2, C 2 and C 3, and C 4 and N 1. C 1 is single bonded to N H 2 on the left. C 4 is single bonded to N H 2 on the lower right. It is fused to another 6-membered heterocyclic hexagonal ring in a horizontal orientation such that C 2 and C 3 of the first ring are C 4 and C 3 respectively of the second ring. The second hexagonal ring consists of 2 N and 4 C atoms. First N occupies the top left vertex and the second N occupies the bottom right vertex. A double bond is present between N 1 and C 1, and C 2 and N 2. C 2 is single bonded to C H 2 on the lower right in the form of a line. This C H 2 is single bonded to N below. N is single bonded to R on the lower right and single bonded to C 4 of a benzene ring in horizontal orientation. The benzene ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 1 is single-bonded to C on the right. This C is single-bonded to N H on the upper right and double-bonded to O on

the lower right. N H is single bonded to C on the right. This C is dash bonded to H below, wedge bonded to C O O superscript minus on the lower right, and single bonded to a 2-carbon alkane chain depicted using a line on the upper right. C 2 of this chain is single bonded to C O O superscript minus on the upper right. In aminopterin, R equals H, and in methotrexate, R equals C H 3.

Return to Generalized structure of aminopterin and methotrexate

Extended description for Structure of trimethoprim



Trimethoprim

The structure of trimethoprim is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the bottom left vertex. First N occupies the bottom-most vertex and the second N occupies the top left vertex. A double bond is present between N 1 and C 1, N 2 and C 2, and C 2 and C 3. C 1 and C 2 are each single bonded to N H 2. C 3 is single bonded to C H 2 on the upper right in the form of a line. This C H 2 is single bonded to C 6 of a benzene ring in a vertical orientation. The benzene ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2, C 3, and C 4 are each single bonded to O C H 3.

Extended description for Regulation of aspartate transcarbamoylase

A horizontal sequence shows the formation of C T P from aspartate and carbamoyl phosphate. Aspartate plus carbamoyl phosphate combine to form carbamoylaspartate. This step is catalyzed by A T C ase (aspartate transcarbamoylase). Carbamoylaspartate is converted into U M P in three irreversible steps depicted as three successive forward arrows. The remaining steps consist of U M P, forward arrow, U D P, forward arrow, U T P, forward arrow, C T P. A red arrow with a minus symbol points from C T P to A T C ase. A green arrow labeled A T P has a plus symbol and it points toward A C T ase.

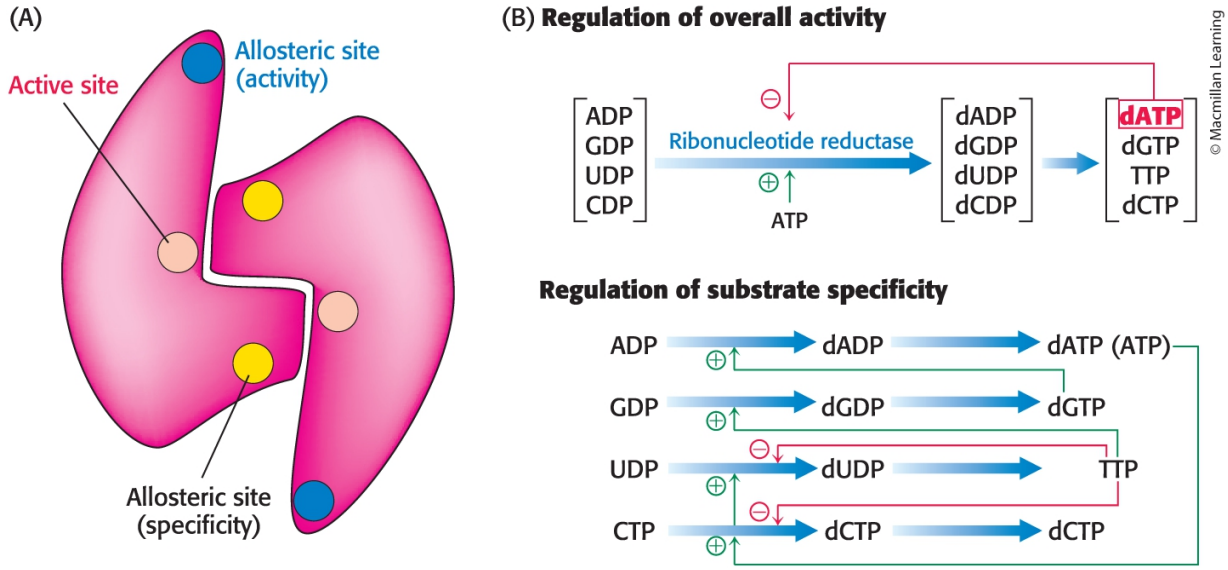
Extended description for FIGURE 26.15 Purine biosynthesis is regulated at many steps



A horizontal sequence shows the conversion of ribose 5-phosphate to I M P. It is depicted as follows: Ribose 5-phosphate, forward arrow, P R P P, forward arrow, phosphoribosyl amine, forward arrow, I M P. The first and second forward arrows have two red parallel lines. These parallel lines depict inhibition by I M P, A M P, and G M P. An upper left arrow points from P R P P toward histidine. An upper right arrow points from P R P P toward pyrimidine nucleotides.

I M P has two fates. An upper left arrow from I M P points toward adenylosuccinate. A forward arrow from adenylosuccinate leads to A M P. A lower left arrow from I M P points toward xanthylate. A forward arrow from xanthylate leads to G M P. Two parallel red lines are shown over the upper left and lower left arrows. The parallel lines over the upper left arrow depict inhibition by A M P. The parallel lines over the lower left arrow depict inhibition by G M P.

Extended description for FIGURE 26.16 Ribonucleotide reductase is highly regulated to balance the pool of deoxyribonucleotides

Part (A): The ribonucleotide reductase R 1 dimer consists of two subunits. The subunits are elongated and hooked to each other at the center. Each subunit contains an active site, an allosteric site (specificity), and an allosteric site (activity). The left subunit protrudes upward and the right subunit protrudes downward.

Part (B): A horizontal sequence labeled "Regulation of overall activity" is depicted as follows: left square bracket, A D P, G D P, U D P, C D P, right square bracket; forward arrow labeled ribonucleotide reductase; left square bracket, d A D P, d G D P, d U D P, and d C T P, right square bracket; forward arrow, left square bracket, d A T P, d G T P, T T P, d C T P. d A T P is highlighted in red. A red arrow with a minus symbol points from d A T P to ribonucleotide reductase. A green upward arrow labeled A T P with a plus symbol points toward ribonucleotide reductase.

Four horizontal sequences labeled "Regulation of substrate specificity" are depicted as follows:

First sequence: A D P, forward arrow, d A D P, forward arrow, d A T P open parenthesis A T P close parenthesis.

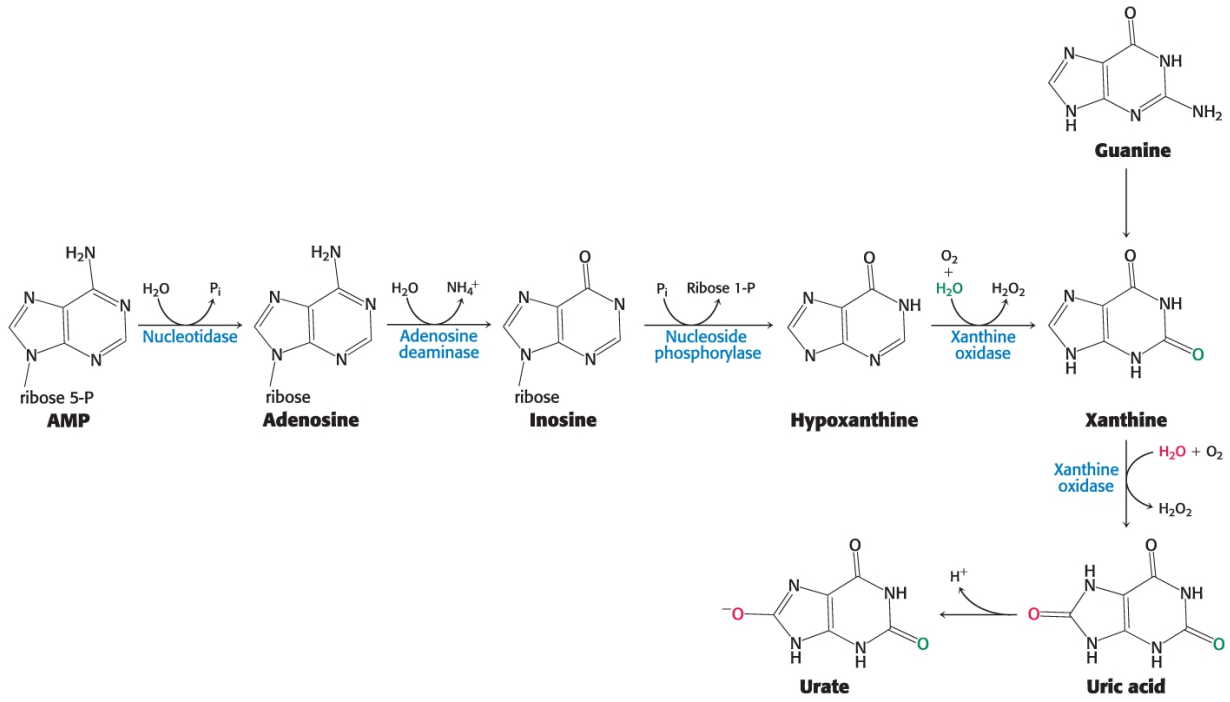
Second sequence: G D P, forward arrow, d G D P, forward arrow, d G T P.

Third sequence: U D P, forward arrow, d U D P, forward arrow, T T P.

Fourth sequence: C T P, forward arrow, d C T P, forward arrow, d C T P.

A green arrow with a plus symbol points from d G T P to the first forward arrow of the first sequence.

A green arrow with a plus symbol points from T T P to the first forward arrow of the second sequence.



A green upward arrow with a plus symbol points from the first forward arrow of the fourth sequence to the first forward arrow of the third sequence.

A green arrow with a plus symbol points from d A T P open parenthesis A T P close parenthesis points toward the first forward arrow of the fourth sequence.

A red arrow with a minus symbol points from T T P to the first forward arrow of the third sequence. Another red arrow with a minus symbol points from T T P toward the first forward arrow of the fourth sequence.

Return to FIGURE 26.16 Ribonucleotide reductase is highly regulated to balance the pool of deoxyribonucleotides

Extended description for FIGURE 26.17 Purines are catabolized for excretion

In the first irreversible step catalyzed by nucleotidase, A M P is converted into adenosine. It is coupled with the addition of H 2 O and the release of P subscript i.

The structure of A M P is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation. It consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the top left vertex. C 1 occupies the leftmost vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. N 1 is single-bonded to ribose 5-phosphate. It is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. The hexagonal ring is composed of 2 N and 4 C atoms. The first N occupies the top right vertex and the second N

occupies the bottom-most vertex. A double bond is present between C 1 and N 2, C 2 and C 3, and C 4 and N 1. C 4 is single bonded to N H 2.

The structure of adenosine is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation. It consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the top left vertex. C 1 occupies the leftmost vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. N 1 is single-bonded to ribose below. It is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. The hexagonal ring is composed of 2 N and 4 C atoms. The first N occupies the top right vertex and the second N occupies the bottom-most vertex. A double bond is present between C 1 and N 2, C 2 and C 3, and C 4 and N 1. C 4 is single bonded to N H 2.

In the second irreversible step, adenosine is converted into inosine by adenosine deaminase. It is coupled with the entry of H 2 O and release of N H 4 superscript plus.

The structure of inosine is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation. It consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the top left vertex. C 1 occupies the leftmost vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. N 1 is single-bonded to ribose below. It is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. The hexagonal ring is composed of 2 N and 4 C atoms. The first N occupies the top right vertex and the second N occupies the bottom-most vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 4 is double bonded to O above.

In the third irreversible step, inosine is converted into hypoxanthine by nucleoside phosphorylase. It is coupled with the entry of P subscript i and the release of ribose 1-phosphate.

The structure of hypoxanthine is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation. It consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the top left vertex. C 1 occupies the leftmost vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. It is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. The hexagonal ring is composed of 2 N and 4 C atoms. The first N bound to H occupies the top right vertex and the second N occupies the bottom-most vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 4 is double bonded to O above.

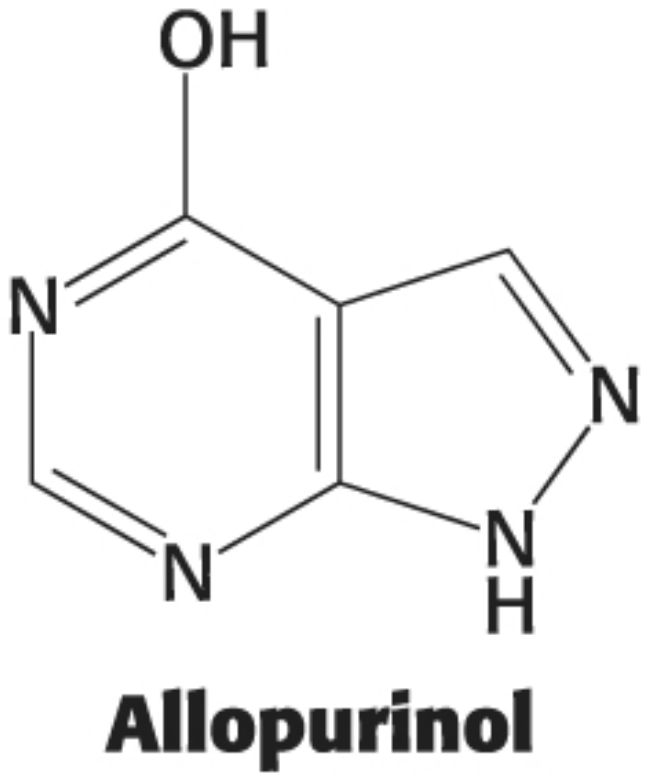
In the fourth irreversible step, hypoxanthine is converted into xanthine by xanthine oxidase. It is coupled with the entry of H 2 O plus O 2 and the release of H 2 O 2.

The structure of xanthine is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation. It consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the top left vertex. C 1 occupies the leftmost vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. It is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. The hexagonal ring is composed of 2 N and 4 C atoms. The first N bound to H occupies the top right vertex and the second N bound to H occupies the bottom-most vertex. A double bond is present between C 2 and C 3. C 1 and C 4 are each double bonded to O.

A downward arrow from guanine leads to xanthine below.

The structure of guanine is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation. It consists of 2 N and 3 C atoms. The first N bound to H occupies the bottom left vertex and the second N occupies the top left vertex. C 1 occupies the leftmost vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. It is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. The hexagonal ring is composed of 2 N and 4 C atoms. The first N bound to H occupies the top right vertex and the second N occupies the bottom-most vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 1 is single bonded to N H 2. C 4 is double bonded to O above.

In the fifth irreversible step, xanthine is converted into uric acid by xanthine oxidase. It is coupled with the entry of H 2 O plus O 2 and the release of H 2 O 2.

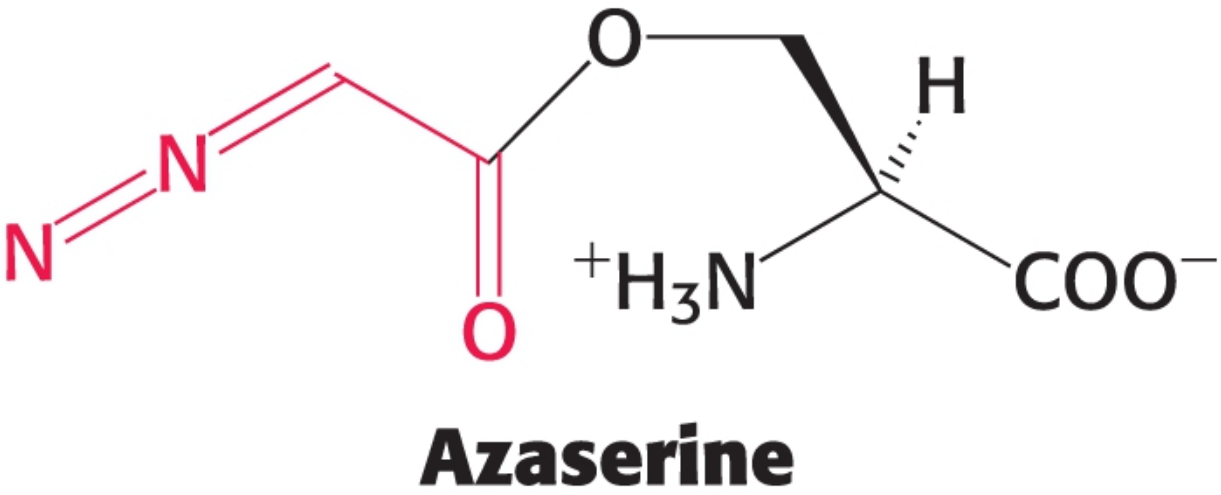


The structure of uric acid is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation. It consists of 2 N and 3 C atoms. The first N bound to H occupies the bottom left vertex and the second N bound to H occupies the top left vertex. C 1 occupies the leftmost vertex. A double bond is present between C 2 and C 3. C 1 is double bonded to O on the left. It is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. The hexagonal ring is composed of 2 N and 4 C atoms. The first N bound to H occupies the top right vertex and the second N bound to H occupies the bottom-most vertex. A double bond is present between C 2 and C 3. C 1 and C 4 are each double bonded to O.

In the sixth irreversible step, uric acid is converted into urate. It is coupled with the release of urate.

The structure of the urate is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation. It consists of 2 N and 3 C atoms. The first N bound to H occupies the bottom left vertex and the second N occupies the top left vertex. C 1 occupies the leftmost vertex. A double bond is present between C 1 and N 2. C 1 is single bonded to O superscript minus on the left. It is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. The hexagonal ring is composed of 2 N and 4 C atoms. The first N bound to H occupies the top right vertex and the second N bound to H occupies the bottom-most vertex. A double bond is present between C 2 and C 3. C 1 and C 4 are each double bonded to O.

Return to FIGURE 26.17 Purines are catabolized for excretion



Extended description for Structure of allopurinol

The structure of allopurinol is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the bottom left vertex. First N occupies the bottom-most vertex and the second N occupies the top left vertex. A double bond is present between N 1 and C 1, N 2 and C 2, and C 3 and C 4. C 2 is single bonded to O H above. The ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation such that C 3 and C 4 of the hexagonal ring are C 2 and C 1 respectively of the pentagonal ring. The pentagonal ring consists of 2 N and 3 C atoms. First N occupies the rightmost vertex. The second N bound to H occupies the bottom right vertex. A double bond is present between C 3 and N 1.

Return to Structure of allopurinol

Extended description for Structure of azaserine

The structure of azaserine is as follows: A central C atom is single-bonded to C H on the upper left in the form of a line, double-bonded to O below, and single-bonded to O on the upper right. C H is double bonded to N, double bond, N on the lower left. The upper right O is single-bonded to C H 2 on the right in the form of a line. C H 2 is wedge bonded to a central C atom on the lower right. This C is dash bonded to H on the upper right, single bonded to N H 3 superscript plus on the lower left, and single bonded to C O O superscript minus on the lower right.

Extended description for Action of statins on cholesterol level and photograph of medicines targeting lipid biosynthesis

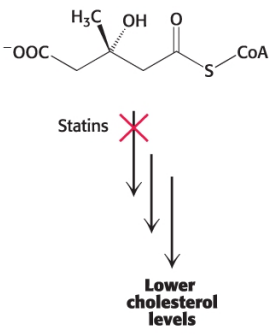

Photo: Kumar Sriskandan/Alamy

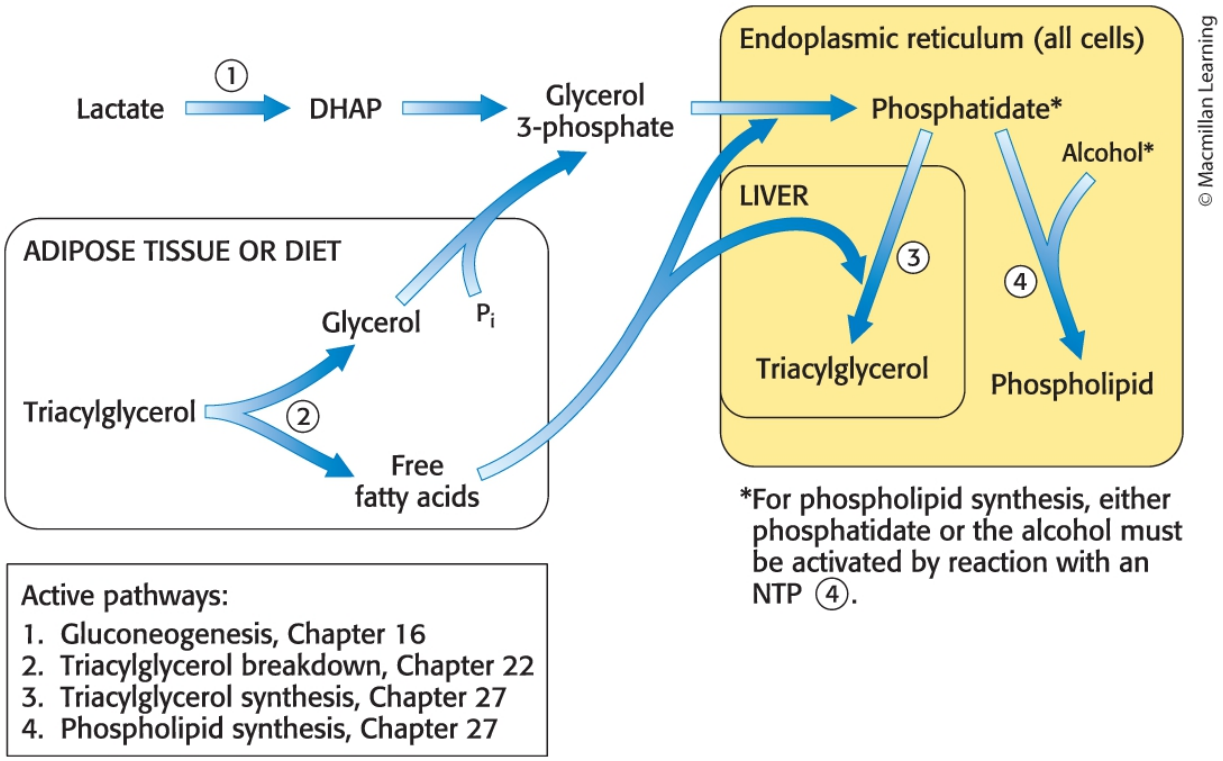
The structure of a compound is as follows: A 4-carbon alkane chain is depicted as a line structure using 3 zigzag lines. C 1 is single bonded to C O O superscript minus on the upper left. C 2 is wedge bonded to C H 3 on the upper left and dash bonded to O H on the upper right. C 4 is double bonded to O above and single bonded to S on the lower right. This S is single bonded to C o A on the upper right.



Three successive downward arrows are shown below the structure. The third arrow points to "Lower cholesterol levels." The first arrow has a cross symbol to depict the inhibitory action of statins.

The photograph shows several medicine packets and tablets. These packets contain the medicines atorvastatin, pravastatin sodium, and

simvastatin and others. Some of the medium packets have the brand name "Lipitor."

Return to Action of statins on cholesterol level and photograph of medicines targeting lipid biosynthesis

Extended description for FIGURE 27.1 Phosphatidate is a key intermediate in lipid biosynthesis

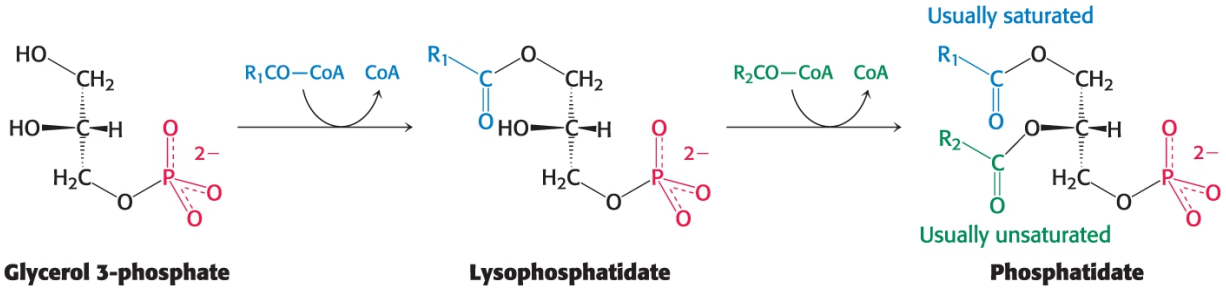
The illustration shows adipose tissue or diet as a rectangle on the lower left. The endoplasmic reticulum of all cells is depicted as a yellow square on the upper right. Inside the endoplasmic reticulum, a smaller square is present and is labeled liver. The process starts with lactate which is present outside the adipose tissue. Lactate is transformed into D H A P which is depicted by a forward arrow numbered 1. D H A P is then converted to glycerol 3-phosphate. Simultaneously, in the adipose tissue triacylglycerol is broken down into glycerol and free fatty acids depicted by a bifurcated arrow numbered 2. Glycerol combines with P subscript i and leaves the adipose tissue to combine with glycerol 3-phosphate outside the adipose tissue. Glycerol 3-phosphate enters into the endoplasmic reticulum of all cells and gets transformed to phosphatidate with an

asterisk. Free fatty acids from the adipose tissue also enter the endoplasmic reticulum of all cells. In the endoplasmic reticulum of all cells, it combines with glycerol 3-phosphate to get transformed to phosphatidate with an asterisk. Phosphatidate with an asterisk has two fates. In the liver, it forms triacylglycerol by combining with free fatty acids from the adipose tissue. This process is depicted by a downward arrow numbered 3. In the endoplasmic reticulum of all cells, it combines with alcohol with an asterisk to form a phospholipid depicted by a downward arrow numbered 4.

A text marked with an asterisk is given below the yellow square. The text reads "For phospholipid synthesis, either phosphatidate or the alcohol must be activated by reaction with an N T P numbered 4."

A key titled active pathways is given below the schematic illustration which lists the following points:

1. Gluconeogenesis, Chapter 16.



2. Triacylglycerol breakdown, Chapter 22.

3. Triacylglycerol synthesis, Chapter 27.

4. Phospholipid synthesis, Chapter 27.

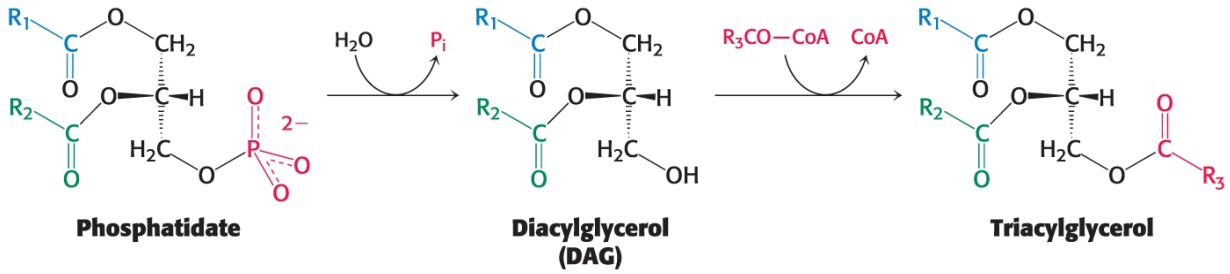
Return to FIGURE 27.1 Phosphatidate is a key intermediate in lipid biosynthesis

Extended description for A reaction depicting the conversion of glycerol 3-phosphate to phosphatidate

In the first irreversible step, glycerol 3-phosphate is converted to lysophosphatidate coupled with the entry of R subscript 1 C O, single bond, C o A, and release of C o A.

The structure of glycerol 3-phosphate is as follows: A central C atom is dash bonded to C H 2 above and C H 2 below. The central C atom is also wedge bonded to O H on the left and H on the right. C H 2 above is single-bonded to O H on the upper left. C H 2 below is single-bonded to O on the lower right. This O atom is single-bonded to P on the upper right. P is partially double-bonded to O above, O on the lower right, and O below. The P O O group has an overall charge of 2 minus.

The structure lysophosphatidate is as follows: A central C atom is dash bonded to C H 2 above and C H 2 below. The central C atom is also wedge bonded to O H on the left and H on the right. C H 2 above is single-bonded to O on the upper left. O is single-bonded to C on the lower left. This C atom is single-bonded to R subscript 1 on the upper left and double-bonded to O below. C H 2 below is single-bonded to O on the lower right. This O atom is single-bonded to P on the upper right. P is partially double-bonded to O above, O on the



lower right, and O below. The P O O group has an overall charge of 2 minus.

In the second irreversible step, lysophosphatidate is converted to phosphatidate coupled with the entry of R subscript 2 C O, single bond, C o A, and release of C o A.

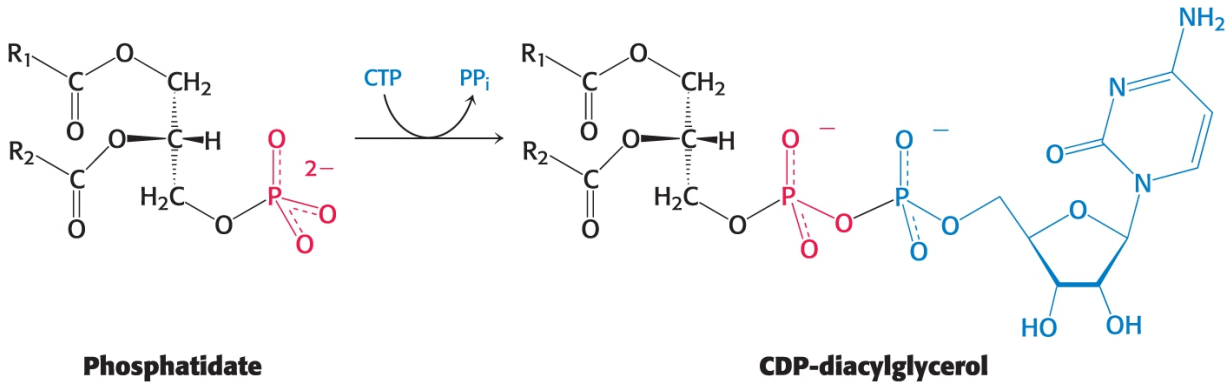
The structure of phosphatidate is as follows: A central C atom is dash bonded to C H 2 above and C H 2 below. The central C atom is also wedge bonded to O on the left and H on the right. C H 2 above is single-bonded to O on the upper left. O is single-bonded to C on the lower left. This C atom is single-bonded to R subscript 1 on the upper left and double-bonded to O below. The left O wedge bonded to the central C atom is single-bonded to C on the lower left. C is single-bonded to R 2 on the upper left and double-bonded to O below. C H 2 dash bonded to the central C atom below is single-bonded to O on the lower right. This O atom is single-bonded to P on the upper right. P is partially double-bonded to O above, O on the lower right, and O below. The P O O group has an overall charge of 2 minus. The R subscript 1 C O group bonded to the upper left O and left O are labeled "Usually saturated."

Return to A reaction depicting the conversion of glycerol 3-phosphate to phosphatidate

Extended description for A reaction depicting the conversion of phosphatidate to triacylglycerol

In the first irreversible step, phosphatidate is converted to diacylglycerol (D A G) coupled with the entry of H 2 O and release of P subscript i.

The structure of phosphatidate is as follows: A central C atom is dash bonded to C H 2 above and C H 2 below. The central C atom is also wedge bonded to O on the left and H on the right. C H 2 above is single-bonded to O on the upper left. O is single-bonded to C on the lower left. This C atom is single-bonded to R subscript 1 on the upper left and double-bonded to O below. The left O wedge bonded to the central C atom is single-bonded to C on the lower left. C is single-bonded to R subscript 2 on the upper left and double-bonded to O below. C H 2 dash bonded to the central C atom below is single-bonded to O on the lower right. This O atom is single-bonded to P on the upper right. P is partially double-bonded to O above, O on the lower right, and O below. The P O O group has an overall charge of 2 minus.



The structure of diacylglycerol (D A G) is as follows: The structure of D A G is the same as phosphatidate except for the absence of the P O O group. The C H 2 that is dash bonded to the central C atom below is single-bonded to O H on the lower right.

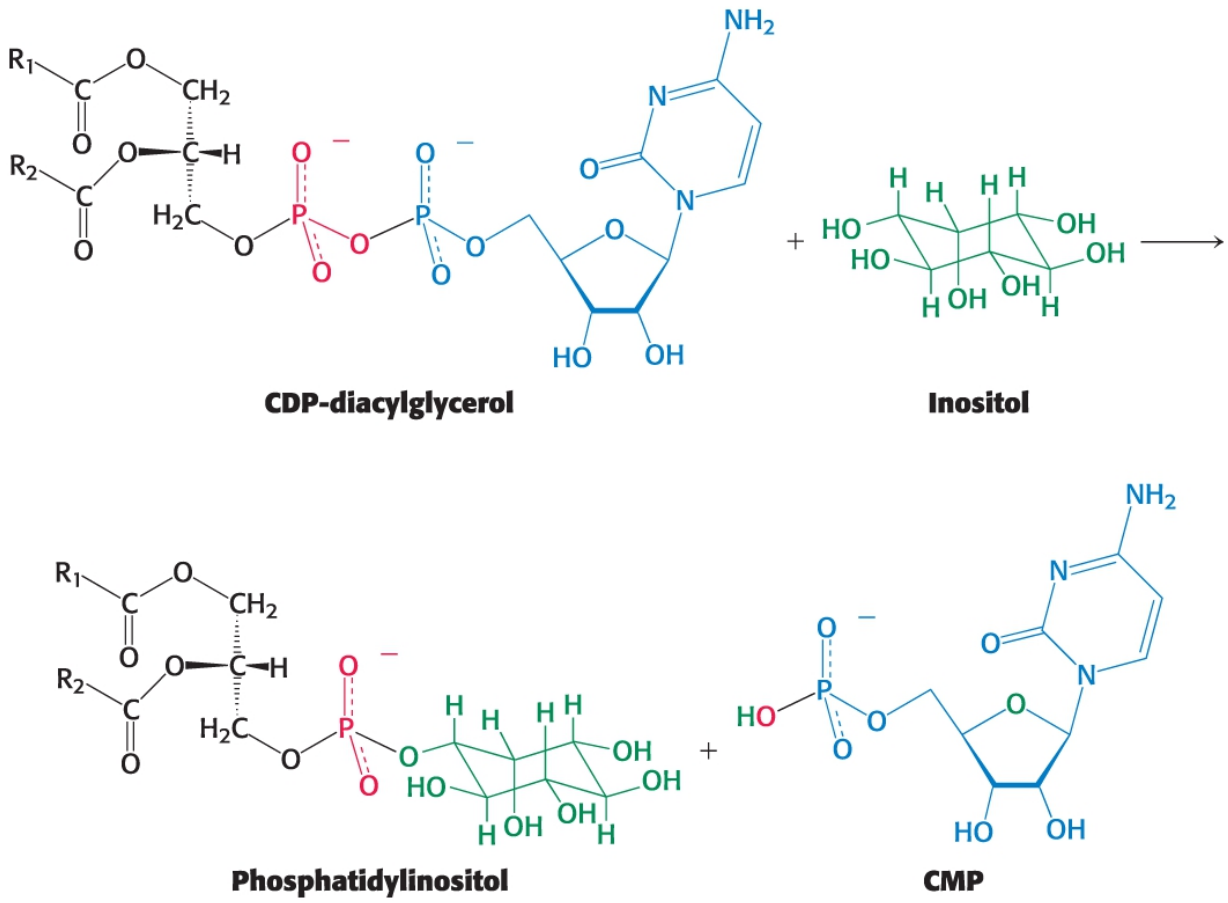
In the second irreversible step, diacylglycerol is converted to triacylglycerol. It is coupled with the entry of R 3 C O, single bond, C o A, and release of C o A.

The structure of triacylglycerol is as follows: The structure of triacylglycerol is the same as D A G except that the C H 2 that is dash bonded to the central C atom below is single-bonded to O on the lower right. This O atom is single-bonded to C on the upper right. C is double-bonded to O above and single-bonded to R subscript 3 on the lower right.

Return to A reaction depicting the conversion of phosphatidate to triacylglycerol

Extended description for Conversion of phosphatidate to C D P diacylglycerol

The conversion of phosphatidate to C D P diacylglycerol is coupled with the entry of C T P and P P subscript i.



The structure of phosphatidate is as follows: A central C atom is dash bonded to C H 2 above and C H 2 below. The central C atom is also wedge bonded to O on the left and H on the right. C H 2 above is single-bonded to O on the upper left. O is single-bonded to C on the lower left. This C atom is single-bonded to R subscript 1 on the upper left and double-bonded to O below. The left O wedge bonded to the central C atom is single-bonded to C on the lower left. C is single-bonded to R subscript 2 on the upper left and double-bonded to O below. C H 2 dash bonded to the central C atom below is single-bonded to O on the lower right. This O atom is single-bonded to P on the upper right. P is partially double-bonded to O above, O on the lower right, and O below. The P O O group has an overall charge of 2 minus.

The structure of C D P diacylglycerol is as follows: The lower right O atom of the P O O group of phosphatidate is single-bonded to another P atom on the upper right. The P atom is partially double-

bonded to O above and O below. P is also single-bonded to O on the lower right. This P O O group has an overall negative charge. The O atom on the lower right is single-bonded to C H 2 on the upper right in the form of a line. This C H 2 is single-bonded to C 4 of a 5-membered heterocyclic pentagonal ring in a vertical orientation with 1 O and 4 C atoms. C 2 and C 3 of the pentagonal ring are each single-bonded to O H. C 1 of the pentagonal ring is single-bonded to N 1 of a 6-membered heterocyclic hexagonal ring in a vertical orientation with 2 N and 4 C atoms. N 1 occupies the first position which is the bottommost vertex and N 2 occupies the third position which is the top left vertex. Double bonds are present between N 2 and C 2 and C 3 and C 4. C 1 is double-bonded to O on the lower left. C 2 is single-bonded to N H 2 above.

Return to Conversion of phosphatidate to C D P diacylglycerol

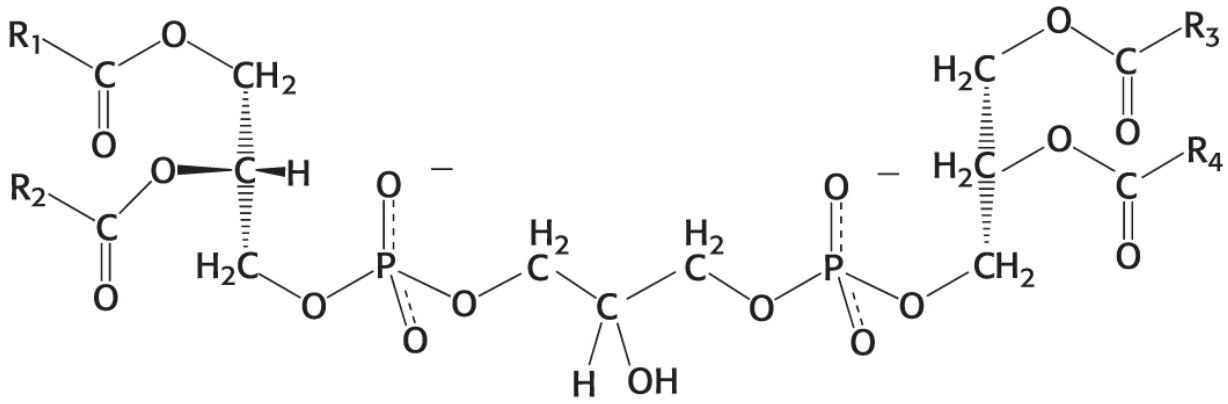
Extended description for Conversion of C D P diacylglycerol to phosphatidylinositol and C M P

C D P diacylglycerol reacts with inositol to produce phosphatidylinositol and C M P.

The structure of C D P diacylglycerol is as follows: A central C atom is dash bonded to C H 2 above and C H 2 below. The central C atom is also wedge bonded to O on the left and H on the right. C H 2 above is single-bonded to O on the upper left. O is single-bonded to C on the lower left. This C atom is single-bonded to R subscript 1 on the upper left and double-bonded to O below. The left O wedge bonded to the central C atom is single-bonded to C on the lower left. C is

single-bonded to R subscript 2 on the upper left and double-bonded to O below. C H 2 dash bonded to the central C atom below is single-bonded to O on the lower right. This O atom is single-bonded to P on the upper right. P is partially double-bonded to O above, O below, and single-bonded to O on the lower right. The P O O group has an overall negative charge. The O atom on the lower right is single-bonded to a P atom on the upper right. The P atom is partially double-bonded to O above and O below. P is also single-bonded to O on the lower right. The P O O group has an overall negative charge. The O atom on the lower right is single-bonded to C H 2 on the upper right in the form of a line. C H 2 is single-bonded to C 4 of a 5-membered heterocyclic pentagonal ring in a vertical orientation with 1 O and 4 C atoms. C 2 and C 3 of the pentagonal ring are each single-bonded to O H. C 1 of the pentagonal ring is single-bonded to N 1 of a 6-membered heterocyclic hexagonal ring in a vertical orientation with 2 N and 4 C atoms. N 1 occupies the first position which is the bottommost vertex and N 2 occupies the third position which is the top left vertex. Double bonds are present between N 2 and C 2 and C 3 and C 4. C 1 is double-bonded to O on the lower left. C 2 is single-bonded to N H 2 above.

The structure of inositol is as follows: A 6-carbon hexagonal ring is in a chair conformation. C 1 occupies the bottom right vertex and C 4 occupies the top left vertex. C 2 and C 5 are close to each other. C 1 is single-bonded to O H on the top right and H below. C 2 is single-bonded to H above and O H on the lower right. C 3 is single-bonded to O H on the top left and H below. C 4 is single-bonded to H above and O H on the lower left. C 5 is single-bonded to H on the top left and O H below. C 6 is single-bonded to H above and O H on the right.



The structure of phosphatidylinositol is as follows: The structure of phosphatidylinositol is the same as C D P diacylglycerol except for the absence of the second P O O group and the addition of inositol.

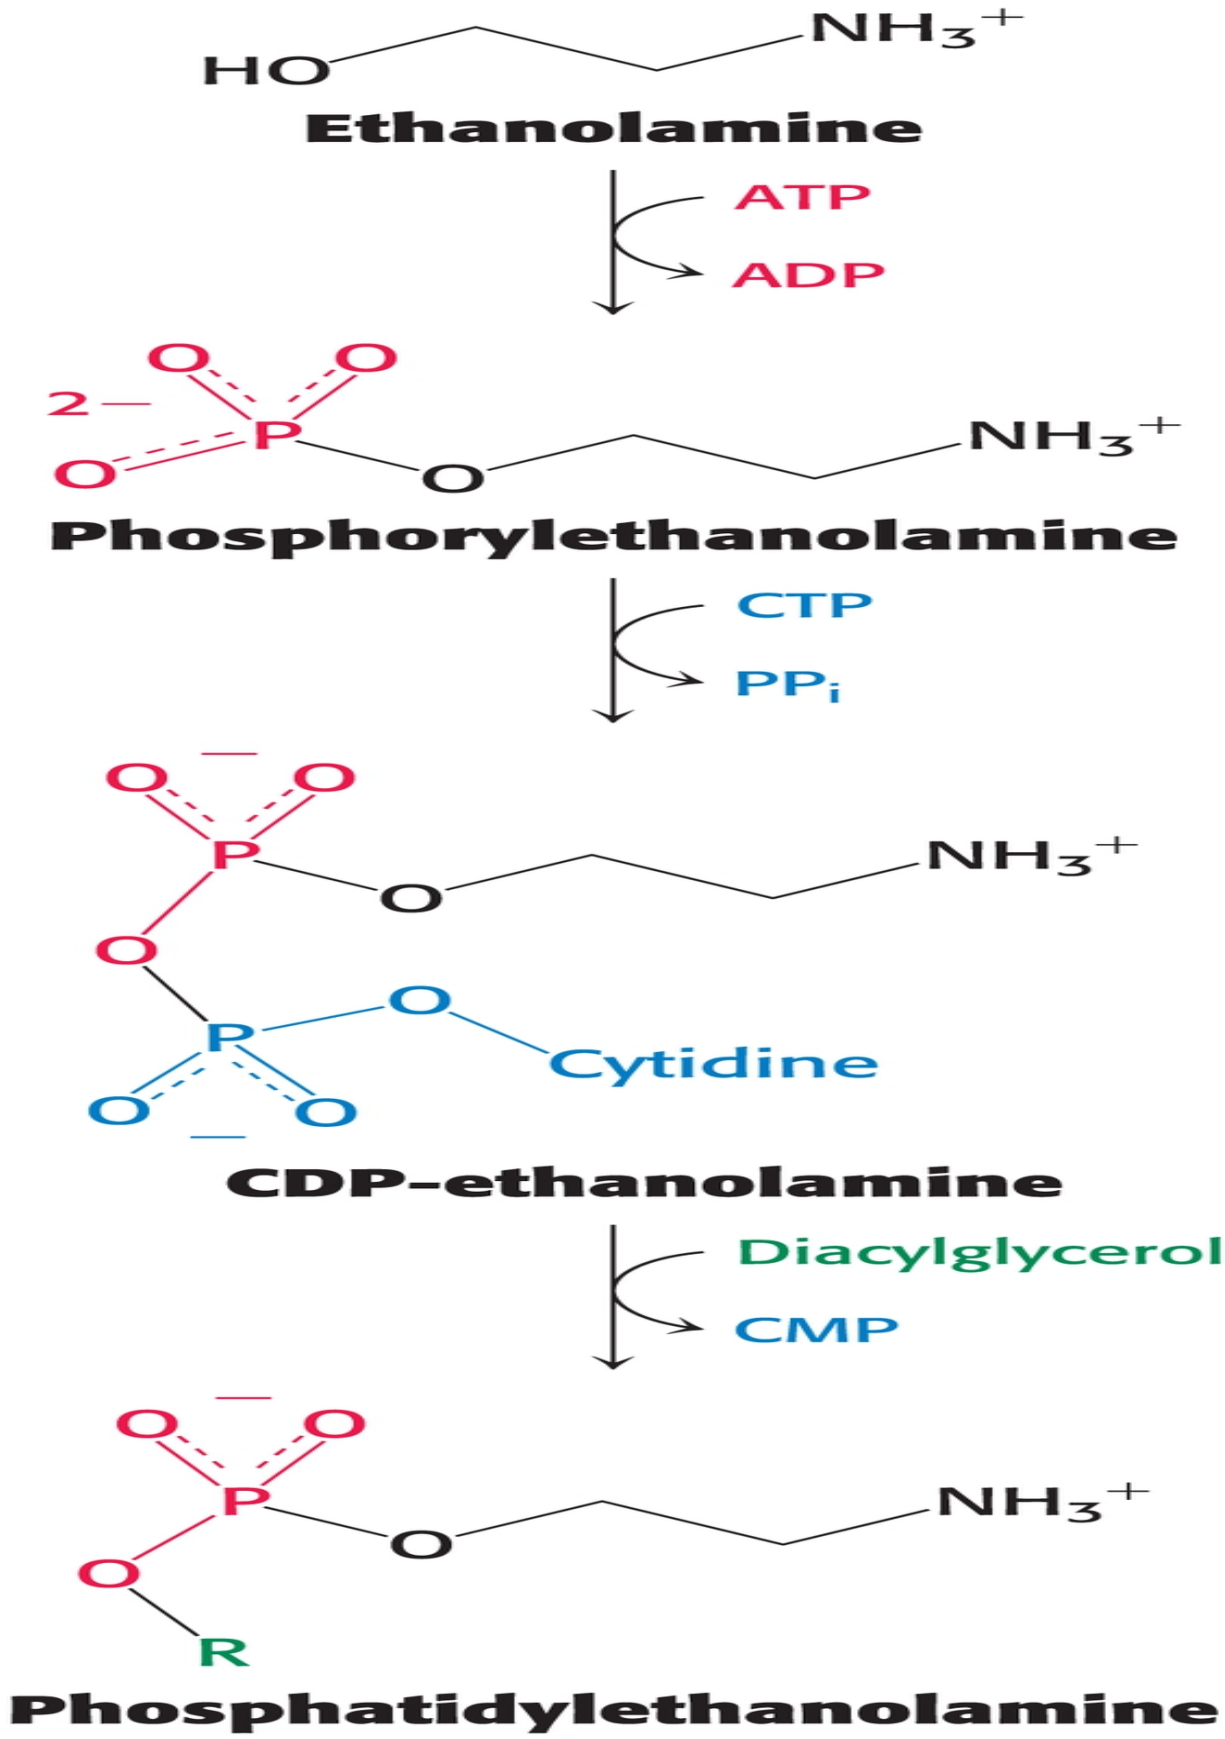
The lower right O atom of the first P O O group is single-bonded to an O atom bonded to C 4 of inositol.

The structure of C M P is as follows: O H atom on the lower left is single-bonded to a P atom on the upper right. The P atom is partially double-bonded to O above and O below. P is also single-bonded to O on the lower right. The P O O group has an overall negative charge. The O atom on the lower right is single-bonded to C H 2 on the upper right in the form of a line. The C H 2 group is single-bonded to C 4 of a 5-membered heterocyclic pentagonal ring in a vertical orientation with 1 O and 4 C atoms. C 2 and C 3 of the pentagonal ring are each single-bonded to O H. C 1 of the pentagonal ring is single-bonded to N 1 of a 6-membered heterocyclic hexagonal ring in a vertical orientation with 2 N and 4 C atoms. N 1 occupies the first position which is the bottommost vertex and N 2 occupies the third position which is the upper left vertex. Double bonds are present between N 2 and C 2 and C 3 and C 4. C 1 is double-bonded to O on the lower left. C 2 is single-bonded to N H 2 above.

Return to Conversion of C D P diacylglycerol to phosphatidylinositol and C M P

Extended description for Structure of diphosphatidylglycerol (cardiolipin)

Diphosphatidylglycerol (Cardiolipin)



The structure of diphosphatidylglycerol (cardiolipin) is as follows: A central C atom is dash bonded to C H 2 above and C H 2 below. The central C atom is also wedge bonded to O on the left and H on the right. C H 2 above is single-bonded to O on the upper left. O is single-bonded to C on the lower left. This C atom is single-bonded to R subscript 1 on the upper left and double-bonded to O below. The left O wedge bonded to the central C atom is single-bonded to C on the lower left. C is single-bonded to R subscript 2 on the upper left and double-bonded to O below. C H 2 dash bonded to the central C atom below is single-bonded to O, single bond, P, single bond, O, single bond, C H 2, single bond, C, single bond, C H 2, single bond, O, single bond, P, single bond, O, single bond, C H 2 in a zigzag pattern. P 1 and P 2 at the second and eighth positions are each partially double-bonded to O above and O on the lower right. Both the P O O groups have a negative charge. C at the fifth position is single-bonded to H on the lower left and O H on the lower right. C H 2 at the tenth position is dash bonded to C H 2 above. This C H 2 is single-bonded on the top right to O, single bond, C, single bond, R subscript 4. C is double-bonded to O below. The C H 2 group that is

dash bonded to C H 2 at the tenth position is further dash bonded to C H 2 above. This C H 2 is single-bonded on the top right to O, single bond, C, single bond, R subscript 3. C is double-bonded to O below.

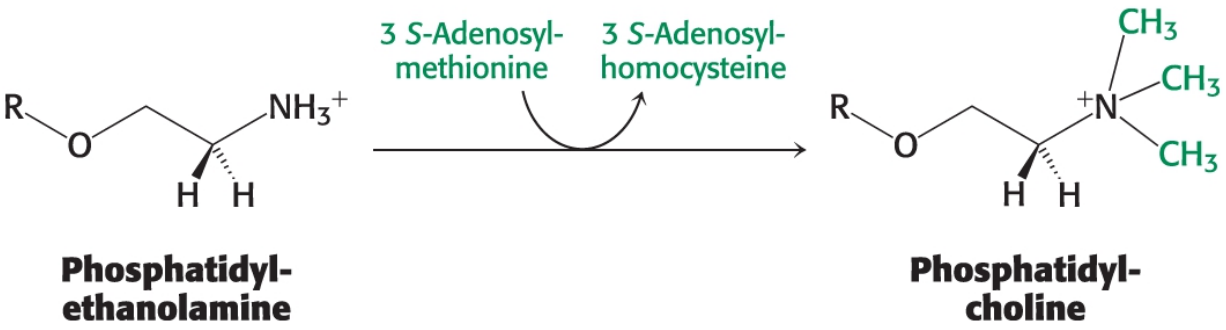
Phosphatidylethanolamine

In the first irreversible step, ethanolamine is converted to phosphorylethanolamine coupled with the breakdown of A T P to A D P.

The structure of ethanolamine is as follows: A 2-carbon alkane chain is depicted using a line. C 1 is single bonded to O H on the lower left. C 4 is single bonded to N H 3 superscript plus on the upper right.

The structure of phosphorylethanolamine is as follows: A 1 O and 2 C heteronuclear alkane is depicted as a line structure using 2 zigzag lines. O occupies the first position and is single-bonded to P on the upper left. P is partially double-bonded to O on the upper right, O on the upper left, and O on the lower left. The P O O group has an overall charge of 2 minus. C 2 is single bonded to N H 3 superscript plus on the upper right.

In the second irreversible step, phosphorylethanolamine is converted to C D P ethanolamine coupled with the entry of C T P and release of P P subscript i.



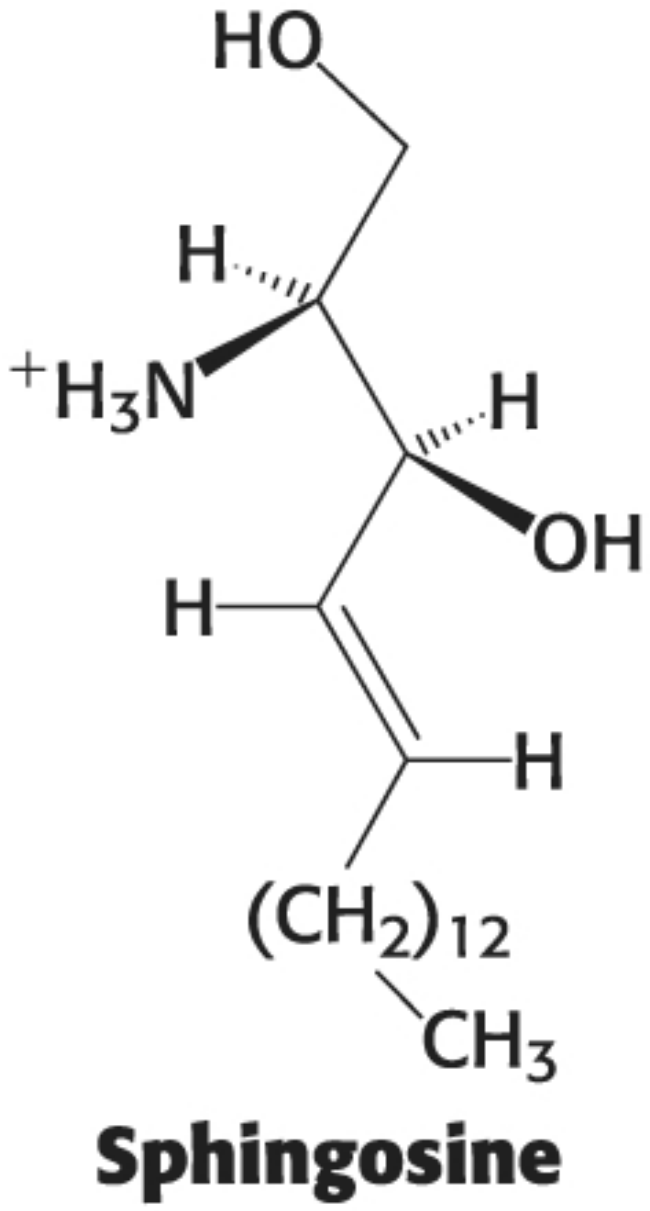
The structure of C D P ethanolamine is as follows: A 1 O and 2 C heteronuclear alkane is depicted as a line structure using 2 zigzag lines. O occupies the first position and is single-bonded to P on the upper left. P is partially double-bonded to O on the upper right, O on the upper left, and single-bonded to O on the lower left. The P O O group has an overall charge of 2 minus. C 2 is single bonded to N H 3 superscript plus on the upper right. The lower left O is single-bonded to another P on the lower right. This P is partially double-bonded to O on the lower left and lower right with an overall negative charge. P is also single-bonded to O on the upper right. The O on the upper right is single-bonded to cytidine on the lower right.

In the third irreversible step, C D P ethanolamine is converted to phosphatidylethanolamine coupled with the entry of diacylglycerol and release of C M P.

The structure of phosphatidylethanolamine is as follows: A 1 O and 2 C heteronuclear alkane is depicted as a line structure using 2 zigzag lines. O occupies the first position and is single-bonded to P on the upper left. P is partially double-bonded to O on the upper right, O on the upper left, and single-bonded to O on the lower left. The P O O group has an overall charge of 2 minus. The lower left O is single-bonded to R on the lower right. C 2 of the alkane chain is single bonded to N H 3 superscript plus on the upper right.

Return to Conversion of ethanolamine to phosphatidylethanolamine

Extended description for Formation of phosphatidylcholine



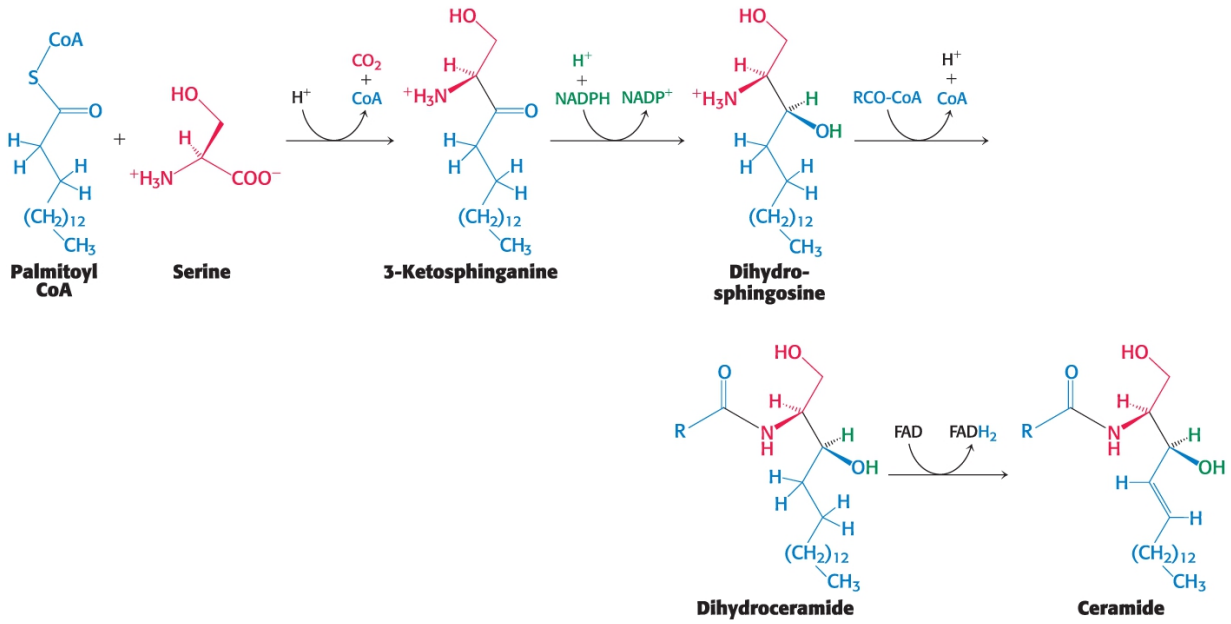
An irreversible reaction depicts the transformation of phosphatidylethanolamine to phosphatidylcholine coupled with the entry of 3 S-adenosyl-methionine and the release of 3 S-adenosyl-homocysteine.

The structure of phosphatidylethanolamine is as follows: A 2-carbon alkane chain is depicted as a line structure using a line. C 1 is single-bonded to O on the lower left. The O atom is single-bonded to R on the upper left. C 2 is single bonded to N H 3 superscript plus on the upper right. C 2 is wedge bonded to H on the lower left and dash bonded to H on the lower right.

The structure of phosphatidylcholine is as follows: A 1 N and 2 C heteronuclear alkane chain is depicted as a line structure using 2 zigzag lines. N superscript plus occupies the third position. C 1 is single-bonded to O on the lower left. The O atom is single-bonded to R on the upper left. C 2 is wedge bonded to H on the lower left and dash bonded to H on the lower right. N superscript plus is single bonded to C H 3 above, C H 3 on the upper right, and C H 3 on the lower right.

Return to Formation of phosphatidylcholine

Extended description for Structure of sphingosine



The structure of sphingosine is as follows: A 5-carbon alkene chain is depicted vertically as a line structure using 4 zigzag lines. A double bond is present between C 4 and C 5. C 1 is single bonded to O H on the upper left. C 2 is dash bonded to H on the upper left and wedge bonded to N H 3 superscript plus on the lower left. C 3 is dash

bonded to H on the upper right and wedge bonded to O H on the lower right. C 4 is single-bonded to H on the left. C 5 is single bonded to H on the right. C 5 is single bonded to open parenthesis C H 2 close parenthesis with subscript 12 on the lower left. Open parenthesis C H 2 close parenthesis with subscript 12 is single bonded to C H 3 on the lower right.

Return to Structure of sphingosine

Extended description for FIGURE 27.2 Biosynthesis of ceramide involves four steps

In the first irreversible step, palmitoyl C o A combines with serine to give rise to 3-ketosphinganine coupled with the entry of H superscript plus ion and release of C O 2 and C o A.

The structure of palmitoyl C o A is as follows: A 3-carbon alkane chain is depicted as a vertical line structure using two zig-zag lines. C 1 is single bonded to S on the upper left and double bonded to O on the right. S is further single bonded to C o A on the upper right. C 2 is single bonded to H on the upper left and H on the lower left. C 3 is single bonded to H on the upper right and H on the lower right. C 3 is also single bonded to open parenthesis C H 2 close parenthesis with subscript 12 on the lower left. Open parenthesis C H 2 close parenthesis 12 is single bonded to C H 3 on the lower right.

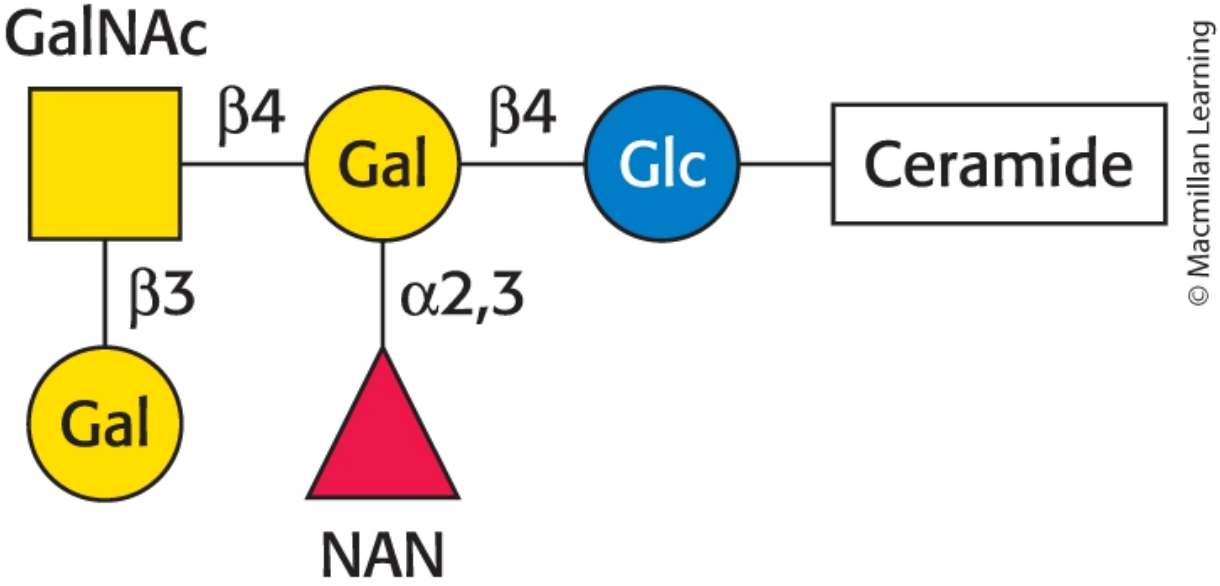
The structure of serine is as follows: A central C atom is single bonded to N H 3 superscript plus on the lower left and C O O superscript minus on the lower right. The central C atom is dash bonded to H on the upper left and wedge bonded to another C atom on the upper right. The upper right C atom is single-bonded to O H on the upper left.

The structure of 3-ketosphinganine is as follows: A 5-carbon alkane chain is depicted as a vertical line structure using 4 zig-zag lines. C 1 is single bonded to O H on the upper left. C 2 is dash bonded to H on the upper left and wedge bonded to N H 3 superscript plus on the lower left. C 3 is double bonded to O on the right. C 4 is single bonded to H on the upper left and H on the lower left. C 5 is single bonded to H on the upper right, H on the lower right, and open parenthesis C H 2 close parenthesis with subscript 12 on the lower left. Open parenthesis C H 2 close parenthesis 12 is single bonded to C H 3 on the lower right.

In the second irreversible step, 3-ketosphinganine is converted to dihydro-sphingosine coupled with oxidation of N A D P H plus H superscript plus to N A D P superscript plus.

The structure of dihydro-sphingosine is as follows: A 5-carbon alkane chain is depicted as a vertical line structure using 4 zigzag lines. C 1 is single bonded to O H on the upper left. C 2 is dash bonded to H on the upper left and wedge bonded to N H 3 superscript plus on the lower left. C 3 is dash bonded to H on the upper right and wedge bonded to O H on the lower right. C 4 is single bonded to H on the upper left and H on the lower left. C 5 is single bonded to H on the upper right, H on the lower right, and single bonded to open parenthesis C H 2 close parenthesis with subscript 12 on the lower left. Open parenthesis C H 2 close parenthesis with subscript 12 is single bonded to C H 3 on the lower right.

In the third irreversible step, dihydro-sphingosine is converted to dihydroceramide coupled with the entry of R C O, single bond, C o A, and release of C o A and H superscript plus.

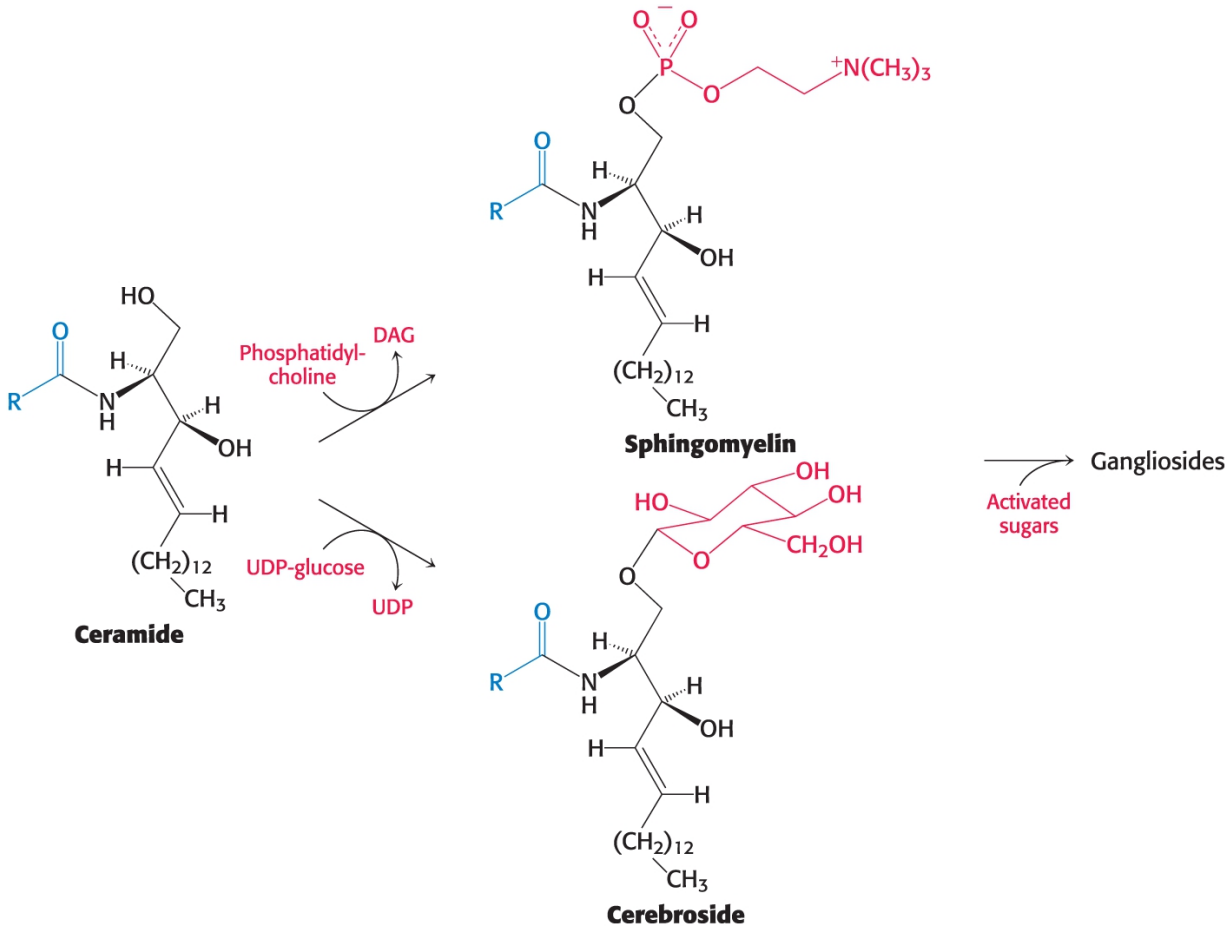


The structure of dihydroceramide is as follows: A 5-carbon alkane chain is depicted as a vertical line structure using 4 zigzag lines. C 1 is single bonded to O H on the upper left. C 2 is dash bonded to H on the upper left and wedge bonded to N H on the lower left. N H is further single-bonded to a central C atom on the upper left. The central C atom is single-bonded to R on the lower left and double-bonded to O above. C 3 of the alkane chain is dash bonded to H on the upper right and wedge bonded to O H on the lower right. C 4 is single bonded to H on the upper left and H on the lower left. C 5 is single bonded to H on the upper right, H on the lower right, and open parenthesis C H 2 close parenthesis with subscript 12 on the lower left. Open parenthesis C H 2 close parenthesis 12 is single bonded to C H 3 on the lower right.

In the fourth irreversible step, dihydroceramide is converted to ceramide coupled with the reduction of F A D to F A D H 2.

The structure of ceramide is as follows: A 5-carbon alkene chain is depicted as a vertical line structure using 4 zigzag lines. A double bond is present between C 4 and C 5. C 1 is single bonded to O H on the upper left. C 2 is dash bonded to H on the upper left and wedge bonded to N H on the lower left. N H is further single-bonded to a central C atom on the upper left. The central C atom is single-bonded to R on the lower left and double-bonded to O above. C 3 of the alkene chain is dash bonded to H on the upper right and wedge bonded to O H on the lower right. C 4 is single-bonded to H on the left. C 5 is single bonded to H on the right and single bonded to open parenthesis C H 2 close parenthesis with subscript 12 on the lower left. Open parenthesis C H 2 close parenthesis with subscript 12 is single bonded to C H 3 on the lower right.

Return to FIGURE 27.2 Biosynthesis of ceramide involves four steps



Extended description for FIGURE 27.3 The ganglioside G subscript M 1 consists of five monosaccharides linked to ceramide

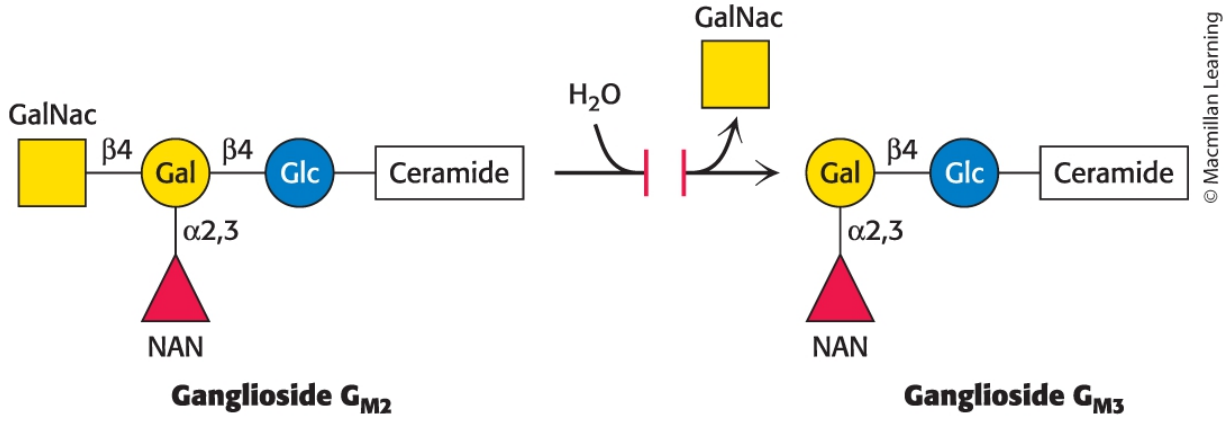
The structure of ganglioside is as follows: A rectangle labeled ceramide is connected to a blue circle on the left. The blue circle is labeled G l c. G l c is connected to a yellow circle on the left by a beta 4 linkage. The yellow circle is labeled G a l. G a l is connected to a yellow square on the left by a beta 4 linkage and a red triangle below by an alpha 2, 3 linkage. The yellow square is labeled G a l N A c and the triangle is labeled N A N. G a l N A c is connected to another yellow circle below by a beta 3 linkage. The yellow circle is labeled G a l.

Return to FIGURE 27.3 The ganglioside G subscript M 1 consists of five monosaccharides linked to ceramide

Extended description for FIGURE 27.4 Ceramide can be converted into sphingomyelin, cerebroside, and gangliosides

Ceramide has two fates. It can either get converted to sphingomyelin or cerebroside. The conversion of ceramide to sphingomyelin is coupled with the entry of phosphatidylcholine and release of D A G. The conversion of ceramide to cerebroside is coupled with the entry of U D P-glucose and release of U D P. Later, sphingomyelin and cerebroside are converted to gangliosides with the addition of activated sugars.

The structure of ceramide is as follows: A 5-carbon alkene chain is depicted as a vertical line structure using 4 zigzag lines. A double bond is present between C 4 and C 5. C 1 is single bonded to O H on the upper left. C 2 is dash bonded to H on the upper left and wedge bonded to N H on the lower left. N H is further single-bonded to a central C atom on the upper left. The central C atom is single-bonded to R on the lower left and double-bonded to O above. C 3 of the alkene chain is dash bonded to H on the upper right and wedge bonded to O H on the lower right. C 4 is single-bonded to H on the left. C 5 is single bonded to H on the right and single bonded to open parenthesis C H 2 close parenthesis with subscript 12 on the lower left. Open parenthesis C H 2 close parenthesis with subscript 12 is single bonded to C H 3 on the lower right.



The structure of sphingomyelin is as follows: A 5-carbon alkene chain is depicted as a vertical line structure using 4 zigzag lines. A double bond is present between C 4 and C 5. C 1 is single-bonded to O on the upper left. This O is single-bonded to P on the upper right. The P atom is partially double-bonded to O on the upper left and O on the upper right. The P O O group has an overall negative charge. The P atom is single-bonded to O on the lower right. The O atom is single-bonded to a 2-carbon alkane chain depicted as a line structure using a line. C 2 of the alkane chain is single bonded to N superscript plus open parenthesis C H 3 close parenthesis with subscript 3. C 2 of the alkene chain is dash bonded to H on the upper left and wedge bonded to N H on the lower left. N H is further single-bonded to a central C atom on the upper left. The central C atom is single-bonded to R on the lower left and double-bonded to O above. C 3 of the alkene chain is dash bonded to H on the upper right and wedge bonded to O H on the lower right. C 4 is single-bonded to H on the left. C 5 is single bonded to H on the right and single bonded to open parenthesis C H 2 close parenthesis with subscript 12 on the lower left. Open parenthesis C H 2 close

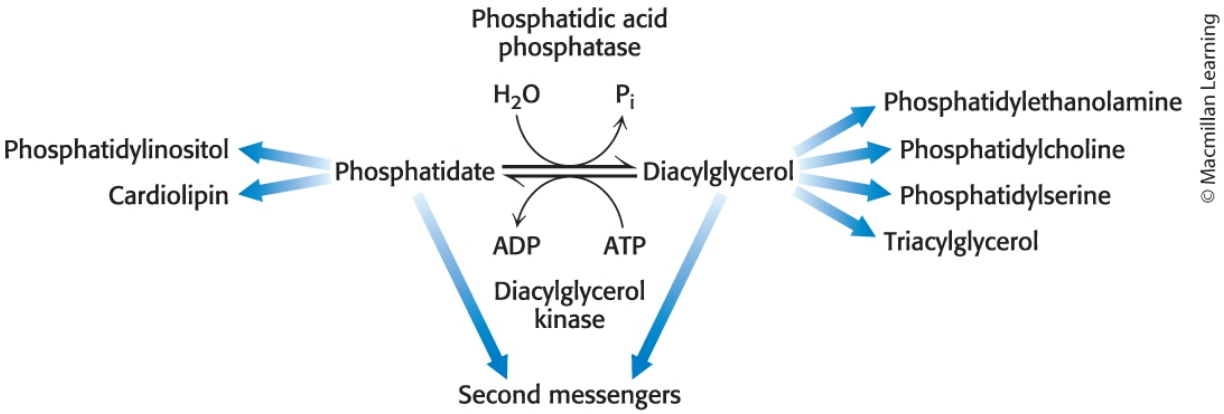
parenthesis with subscript 12 is single bonded to C H 3 on the lower right.

The structure of the cerebroside is as follows: A 5-carbon alkene chain is depicted as a vertical line structure using 4 zigzag lines. A double bond is present between C 4 and C 5. C 2 is dash bonded to H on the upper left and wedge bonded to N H on the lower left. N H is further single-bonded to a central C atom on the upper left. The central C atom is single-bonded to R on the lower left and double-bonded to O above. C 3 of the alkene chain is dash bonded to H on the upper right and wedge bonded to O H on the lower right. C 4 is single-bonded to H on the left. C 5 is single bonded to H on the right and single bonded to open parenthesis C H 2 close parenthesis with subscript 12 on the lower left. Open parenthesis C H 2 close parenthesis with subscript 12 is single bonded to C H 3 on the lower right. C 1 is single-bonded to O on the upper left. The O atom is single-bonded to C 1 of a 6-membered heterocyclic ring in a chair conformation consisting of 1 O and 5 C atoms. The O atom occupies the first position, which is the bottom left vertex. C 2 and C 5 are close to each other. C 2, C 3, and C 4 are each single bonded to O H and C 5 is single bonded to C H 2 O H.

Return to FIGURE 27.4 Ceramide can be converted into sphingomyelin, cerebroside, and gangliosides

Extended description for Conversion of ganglioside G subscript M 2 to ganglioside G subscript M 3

An irreversible reaction depicts the formation of ganglioside G subscript M 3 from ganglioside G subscript M 2 coupled with the entry of H 2 O and release of G a l N a c depicted as a yellow square. Two red parallel lines are shown over the forward arrow pointing from ganglioside G subscript M 2 to ganglioside G subscript M 3.

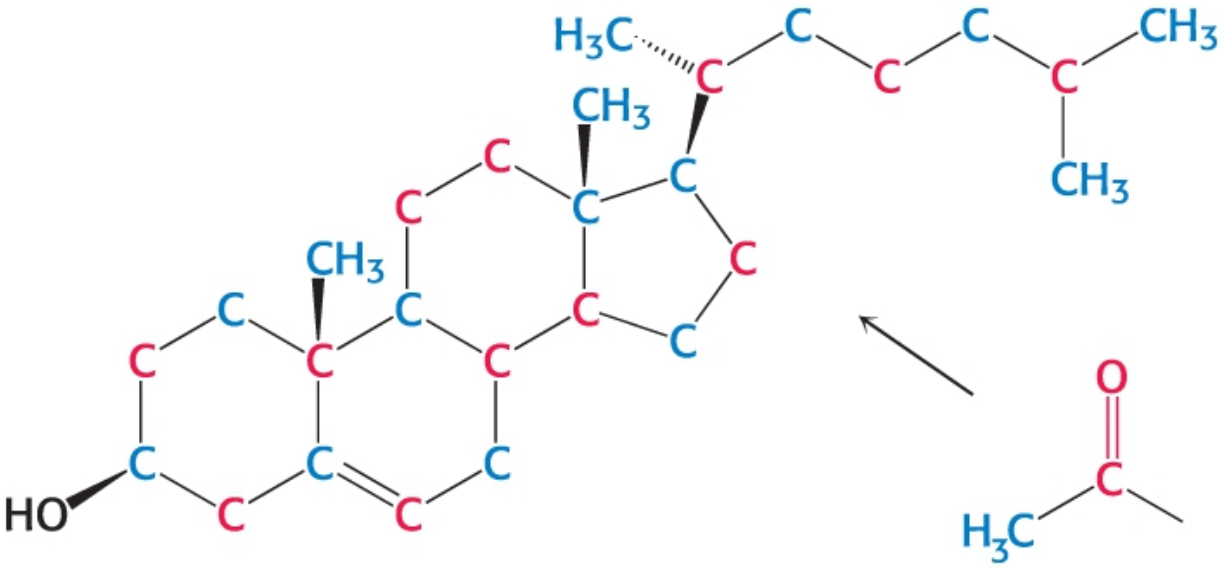


The structure of ganglioside G subscript M 2 is depicted as follows: A rectangle labeled ceramide is connected to a blue circle on the left. The blue circle is labeled G l c. G l c is connected to a yellow circle on the left by a beta 4 linkage. The yellow circle is labeled G a l. G a l is connected to a yellow square on the left by a beta 4 linkage and a red triangle below by an alpha 2, 3 linkage. The yellow square is labeled G a l N A c and the triangle is labeled N A N.

The structure of ganglioside G subscript M 3 is as follows: A rectangle labeled ceramide is connected to a blue circle on the left. The blue circle is labeled G l c. G l c is connected to a yellow circle on the left by a beta 4 linkage. The yellow circle is labeled G a l. G a l

is connected to a red triangle below by an alpha 2, 3 linkage. The triangle is labeled N A N.

Return to Conversion of ganglioside G subscript M 2 to ganglioside G subscript M 3



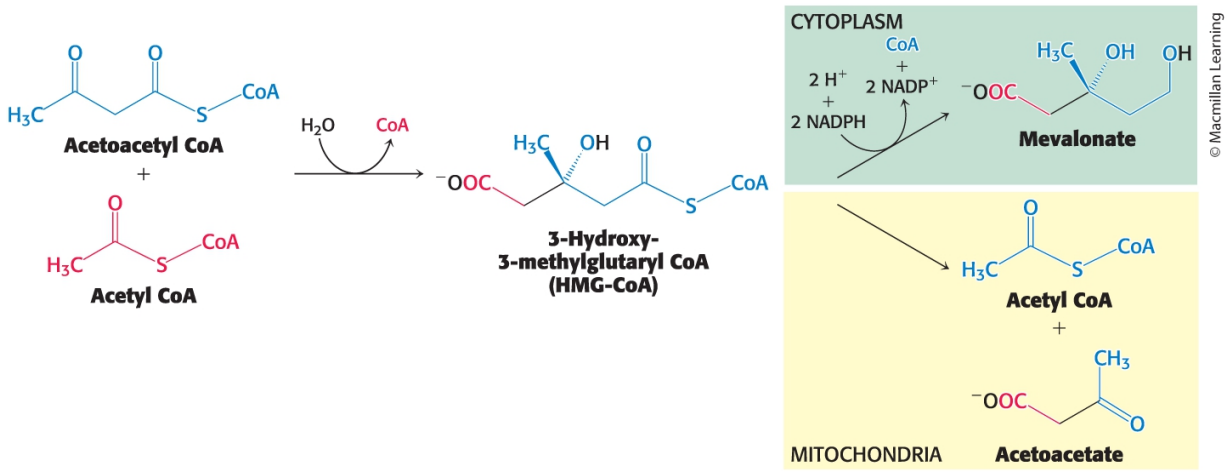
Extended description for FIGURE 27.6 Phosphatidic acid phosphatase is a key regulatory enzyme in lipid synthesis

The figure shows a reversible reaction in which phosphatidate is converted to diacylglycerol by the action of phosphatidic acid phosphatase. It is coupled with the entry of H 2 O and the release of P subscript i. Diacylglycerol can be converted back to phosphatidate by the action of diacylglycerol kinase. It is coupled with the breakdown of A T P to A D P. Phosphatidate gives rise to phosphatidylinositol and cardiolipin. Diacylglycerol gives rise to phosphatidylethanolamine, phosphatidylcholine, phosphatidylserine, and triacylglycerol. Phosphatidate and diacylglycerol are labeled second messengers.

Return to FIGURE 27.6 Phosphatidic acid phosphatase is a key regulatory enzyme in lipid synthesis

Extended description for FIGURE 27.7 Isotope-labeling experiments have revealed the source of carbon atoms in cholesterol synthesized from acetate

Cholesterol has the following structure: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. The second ring has a double bond between C 4 and C 5. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. C 2 of the first ring is wedge bonded to C H 3 above. C 5 of the first ring is wedge bonded to O H on the lower left. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. A 5-membered pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 5 of the pentagonal ring is wedge bonded to C H 3 above. C 1 of the fourth ring is wedge bonded to C 1 of a 5-carbon alkane chain depicted using 4 zigzag lines. C 1 of the alkane chain is dash bonded to C H 3



on the top left. C 5 of the alkane chain is single bonded to C H 3 on the top right and C H 3 below.

The structure of the acetate molecule is shown on the bottom right. An arrow from the acetate molecule points toward the structure of cholesterol. The structure of the acetate molecule is as follows: A central C atom is single bonded to C H 3 on the lower left and double bonded to O above and has an open single bond on the lower right.

In cholesterol, C 1, C 3, and C 5 of the first two rings are highlighted in blue. C H 3 wedge bonded to C 2 of the first ring and C 2 of the third ring are also highlighted in blue. C 2 and C 5 of the third ring are highlighted in blue. C 1, C 3, and C 5 of the fourth ring are highlighted in blue. C 2 and C 4 of the alkane chain are highlighted in blue. C H 3 groups bound to the alkane chain are highlighted in blue. The rest of the C atoms are highlighted in red.

Return to FIGURE 27.7 Isotope-labeling experiments have revealed the source of carbon atoms in cholesterol synthesized from acetate

Extended description for FIGURE 27.8 3-Hydroxy-3-methylglutaryl C o A has different fates

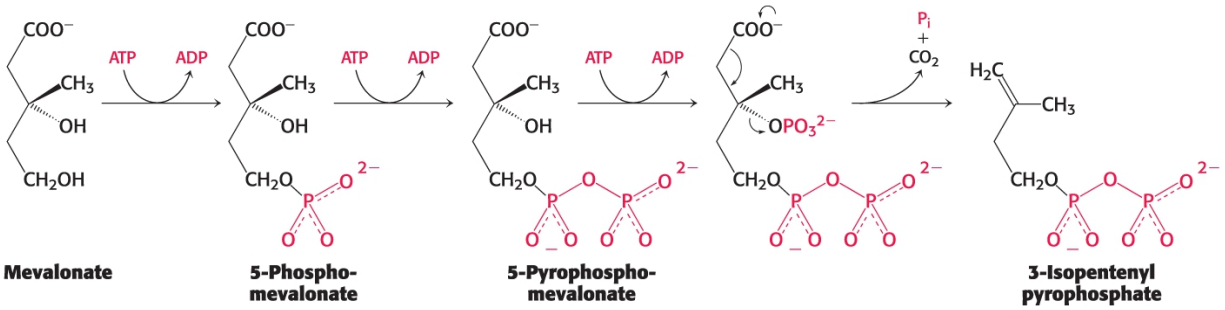
In the first irreversible step, acetoacetyl C o A reacts with acetyl C o A to give rise to 3-hydroxy-3-methylglutaryl C o A coupled with the entry of H 2 O and release of C o A.

The structure of acetoacetyl C o A is as follows: A zigzag chain is composed of C H 3, single bond, C, single bond, C, single bond, C, single bond, S, single bond, C o A. C 1 and C 3 are each double bonded to O above.

The structure of acetyl C o A is as follows: A zigzag chain is composed of C H 3, single bond, C, single bond, S, single bond, C o A. C is double bonded to O above.

The structure of 3-hydroxy-3-methylglutaryl C o A (H M G C o A) is as follows: A zigzag chain is composed of C O O superscript minus, single bond, C, single bond, C, single bond, C, single bond, C, single bond, S, single bond, C o A. C 2 is wedge bonded to C H 3 on the

upper left and dash bonded to O H on the upper right. C 4 is double bonded to O above.



3-hydroxy-3-methylglutaryl C o A (H M G C o A) has two fates. H M G C o A enters the cytoplasm and gets transformed to mevalonate coupled with the entry of 2 H superscript plus and 2 N A D P H and release of 2 N A D P superscript plus and C o A. H M G C o A enters the mitochondria and is transformed to acetyl C o A and acetoacetate.

The structure of mevalonate is as follows: A zigzag chain is composed of C O O superscript minus, single bond, C, single bond, C, single bond, C, single bond, C. C 2 is wedge bonded to C H 3 on the top left and dash bonded to O H on the top right. C 4 is single bonded to O H above.

The structure of acetoacetate is as follows: A zigzag chain is composed of C O O superscript minus, single bond, C, single bond C. C 2 is single bonded to C H 3 on the top and double bonded to O on the lower right.

Return to FIGURE 27.8 3-Hydroxy-3-methylglutaryl C o A has different fates

Extended description for FIGURE 27.9 Mevalonate is converted into isopentenyl pyrophosphate

In the first irreversible step, mevalonate is converted to 5-phospho-mevalonate coupled with the breakdown of A T P to A D P.

The structure of mevalonate is as follows: A 3-carbon alkane chain is depicted vertically as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the upper right. C 2 is wedge bonded to C H 3 on the upper right and dash bonded to O H on the lower right. C 3 is single bonded to C H 2 O H on the lower right.

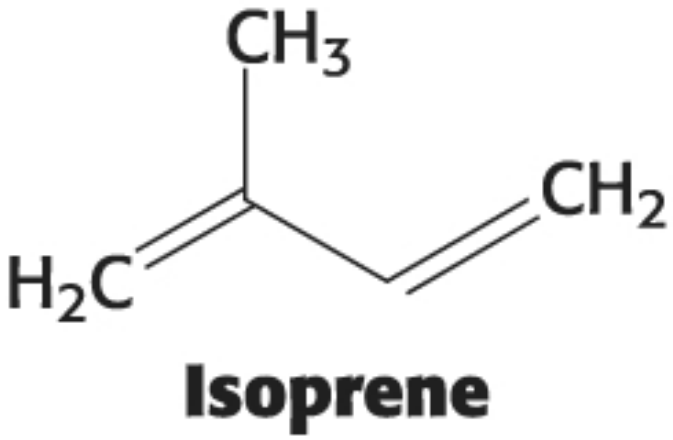
The structure of 5-phospho-mevalonate is as follows: A 3-carbon alkane chain is depicted vertically as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the upper right. C 2 is wedge bonded to C H 3 on the upper right and dash bonded to O H on the lower right. C 3 is single bonded to C H 2 O on the lower right. C H 2 O is single-bonded to P on the lower right. P is partially double-bonded to O on the upper right, O on the lower left, and O on the lower right. The P O O group has an overall charge of 2 minus.

In the second irreversible step, 5-phospho-mevalonate is transformed to 5-pyrophospho-mevalonate coupled with the breakdown of A T P to A D P.

The structure of 5-pyrophospho-mevalonate is as follows: A 3-carbon alkane chain is depicted vertically as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the upper right. C 2 is wedge bonded to C H 3 on the upper right and dash bonded to O H on the lower right. C 3 is single bonded to C H 2 O on the lower right. C H 2 O is single-bonded to P on the lower right. P is single-bonded to O on the upper right. O is single-bonded to P on the lower right. The first P atom is partially double-bonded to O on the lower left, and O on the lower right. The second P atom is partially double-bonded to O on the upper right, O on the lower left, and O on the lower right. The first P O O group has an overall negative charge. The second P O O group has an overall negative charge of 2 minus.

In the third irreversible step, 5-pyrophospho-mevalonate is transformed into an unlabeled intermediate by the breakdown of A T P to A D P.

The structure of the intermediate is as follows: A 3-carbon alkane chain is depicted vertically as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the upper right. C 2 is wedge bonded to C H 3 on the upper right and dash bonded to O P O 3 superscript 2 minus on the lower right. C 3 is single bonded to C H 2 O on the lower right. C H 2 O is single-bonded to P on the lower right. P is single-bonded to O on the upper right. O is single-bonded to P on the lower right. The first P atom is partially double-bonded to O on the lower left, and O on the lower right. The second P atom is partially double-bonded to O on the upper right, O on the lower left, and O on the lower right. The first P O O group has an overall negative charge. The second P O O group has an overall negative



charge of 2 minus. An arrow from superscript minus in C O O superscript minus points toward C O O. An arrow from the single bond between C 1 and C O O superscript minus points to the single bond between C 1 and C 2. An arrow from C 2 points toward O P O 3 superscript 2 minus.

In the fourth irreversible step, the intermediate is transformed to 3-isopentenyl pyrophosphate coupled with the release of P subscript i and C O 2.

The structure of 3-isopentenyl pyrophosphate is as follows: A 2-carbon alkane chain is depicted vertically as a line structure using a line. C 1 is double bonded to C H 2 on the upper left and single bonded to C H 3 on the right. C 2 is single bonded to C H 2 O on the lower right. C H 2 O is single-bonded to P on the lower right. P is single-bonded to O on the upper right. O is single-bonded to P on the lower right. The first P atom is partially double-bonded to O on the lower left, and O on the lower right. The second P atom is partially double-bonded to O on the upper right, O on the lower left, and O on the lower right. The first P O O group has an overall negative charge. The second P O O group has an overall charge of 2 minus.

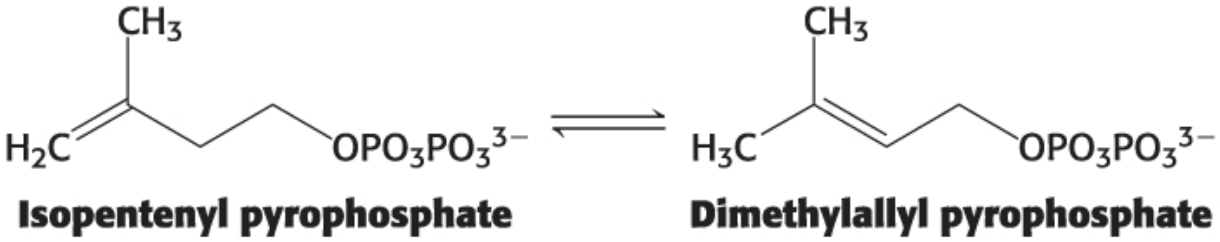
Extended description for Structure of isoprene

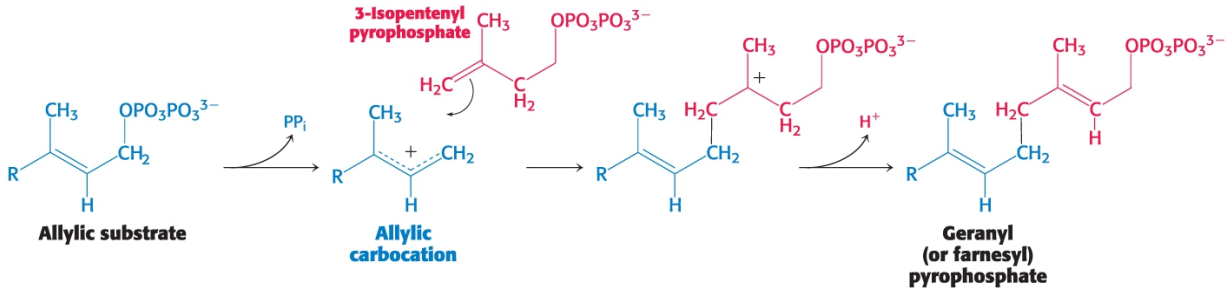


Isoprene

The structure of isoprene is as follows: A 2-carbon alkane chain is depicted as a line structure using a line. C 1 is double bonded to C H 2 on the lower left and single bonded to C H 3 above. C 2 is double bonded to C H 2 on the upper right.

Return to Structure of isoprene

Extended description for Formation of dimethylallyl pyrophosphate from isopentenyl pyrophosphate



The structure of isopentenyl pyrophosphate is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is double bonded to C H 2 on the lower left and single bonded to C H 3 above. C 3 is single bonded to O P O 3 P O 3 superscript 3 minus on the lower right.

The structure of dimethylallyl pyrophosphate is as follows: A 3-carbon alkene chain is depicted as a line structure using 2 zigzag lines. A double bond is present between C 1 and C 2. C 1 is single bonded to C H 3 above and C H 3 on the lower left. C 3 is single bonded to O P O 3 P O 3 superscript 3 minus on the lower right.

Return to Formation of dimethylallyl pyrophosphate from isopentenyl pyrophosphate

Extended description for FIGURE 27.10 Condensation reactions build carbon–carbon bonds that eventually form the cholesterol skeleton

In the first irreversible step, the allylic substrate is transformed to allylic carbocation coupled with the release of P P subscript i.

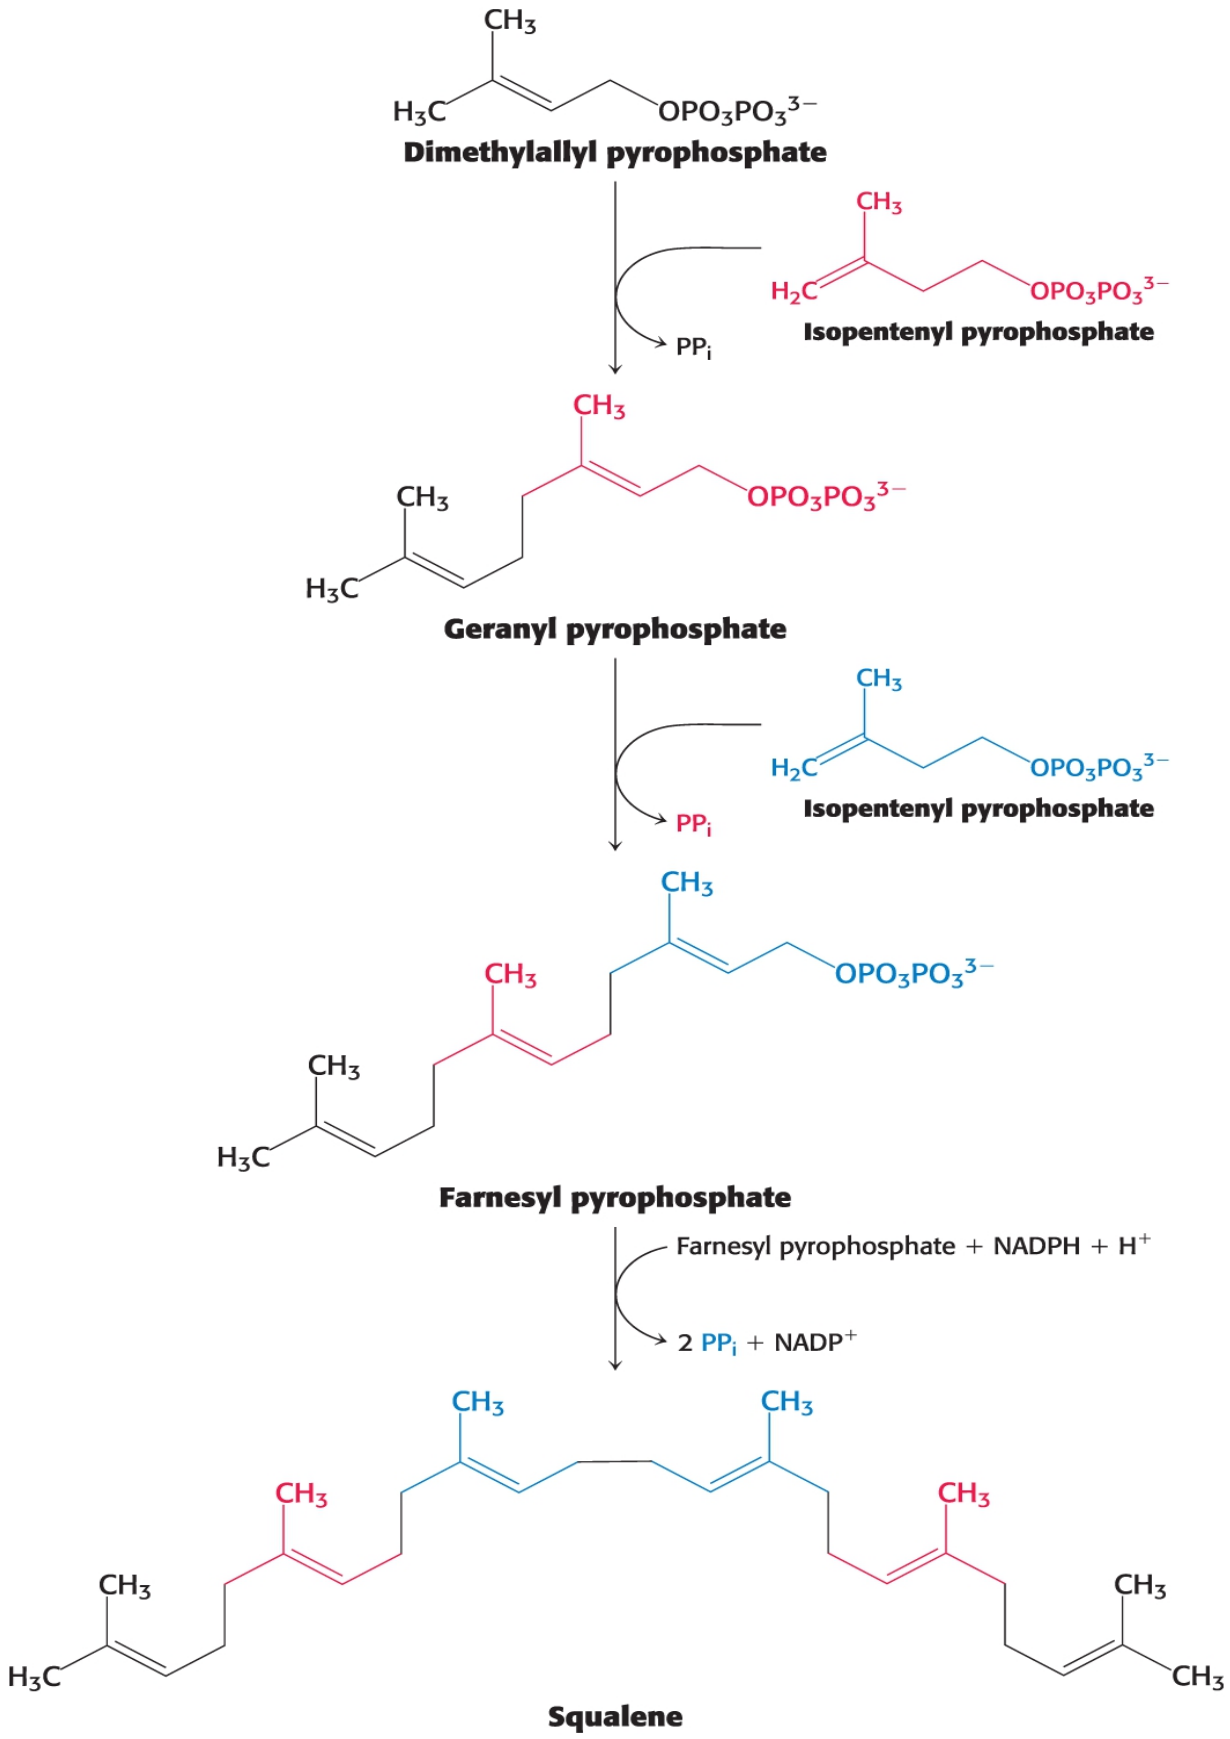
The structure of the allylic substrate is as follows: A 3-carbon alkene chain is depicted as a line structure using 2 zigzag lines. C bound to H 2 occupies the third position. A double bond is present between C 1 and C 2. C 1 is single-bonded to R on the lower left and C H 3 above. C 2 is single bonded to H below. C H 2 is single-bonded to O P O 3 P O 3 superscript 3 minus above.

The structure of allylic carbocation is as follows: A 3-carbon alkene chain is depicted as a line structure using 2 zigzag lines. C bound to H 2 occupies the third position. A partial double bond is present between C 1 and C 2 and C 2 and C 3 along with a positive charge at C 2. C 1 is single-bonded to R on the lower left and C H 3 above. C 2 is single bonded to H below.

In the second irreversible step, 3-isopentenyl pyrophosphate attacks allylic carbocation to give rise to an unlabeled intermediate.

The structure of 3-isopentenyl pyrophosphate is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C H 2 occupies the second position. C 1 is single-bonded to C H 3 above and double-bonded to C H 2 on the lower left. C 3 is single bonded to O P O 3 P O 3 superscript 3 minus above. An arrow from the double bond between C 1 and C H 2 attacks C H 3 of the allylic carbocation.

The structure of the intermediate is as follows: A 3-carbon alkene chain is depicted as a line structure using 2 zigzag lines. C bound to H 2 occupies the third position. A double bond is present between C 1 and C 2. C 1 is single-bonded to R on the lower left and C H 3 above. C 2 is single-bonded to H below. C H 2 is single bonded to C 1 of a 4-carbon alkane chain depicted as a line structure using 3 zigzag lines. C H 2 occupies the first and third positions. C 2 atom has a positive charge. C 2 is single bonded to C H 3 above. C 4 is single bonded to O P O 3 P O 3 superscript 3 minus above.



In the third irreversible step, the intermediate is transformed into geranyl or farnesyl pyrophosphate coupled with the release of H superscript plus ion.

The structure of geranyl or farnesyl pyrophosphate is as follows: A 3-carbon alkene chain is depicted as a line structure using 2 zigzag lines. C H 2 occupies the third position. A double bond is present between C 1 and C 2. C 1 is single bonded to R on the lower left and C H 3 above. C 2 is single bonded to H below. C H 2 is single bonded to C 1 of a 4-carbon alkene chain depicted as a line structure using 3 zigzag lines. C H 2 occupies the first position. A double bond is present between C 2 and C 3. C 2 is single-bonded to C H 3 above. C 3 is single bonded to H below. C 4 is single-bonded to O P O 3 P O 3 superscript 3 minus above.

In the first irreversible step, dimethylallyl pyrophosphate is transformed to geranyl pyrophosphate coupled with the entry of isopentenyl pyrophosphate and the release of P P subscript i.

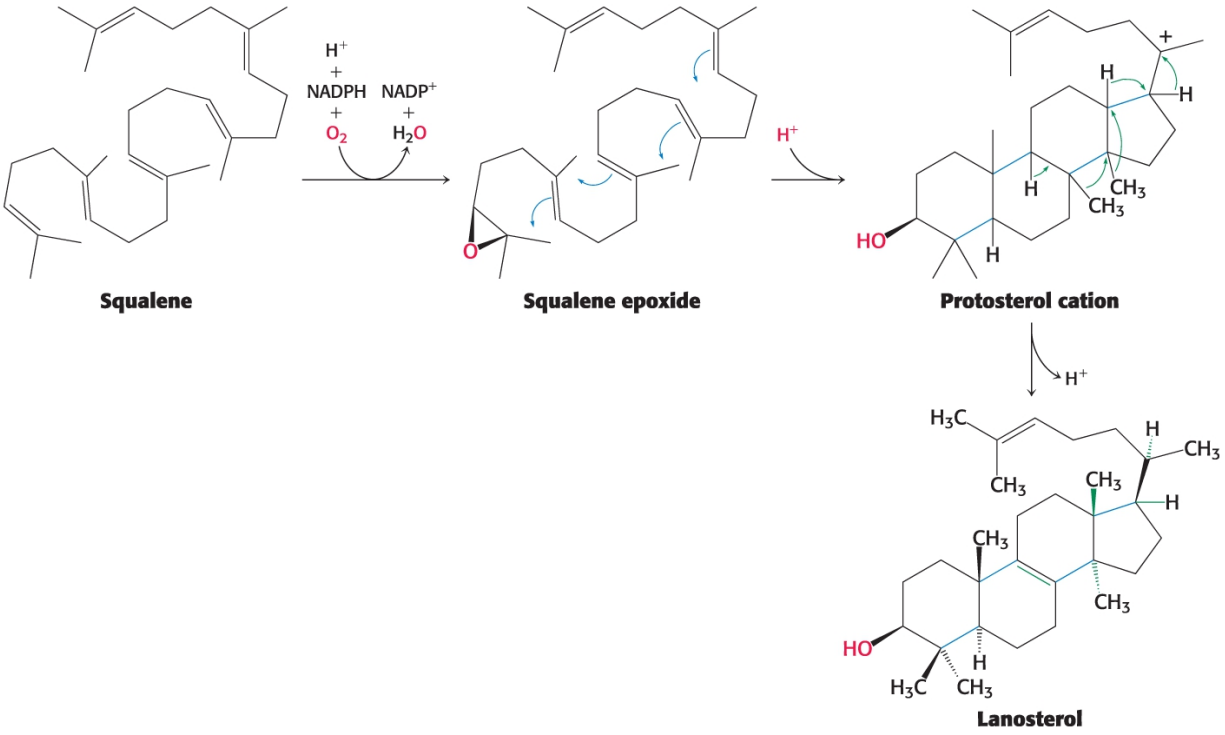
The structure of dimethylallyl pyrophosphate is as follows: A 4-carbon alkene chain is depicted as a line structure using 3 zigzag lines. C H 3 occupies the first position. A double bond is present between C 2 and C 3. C 2 is single bonded to C H 3 above. C 4 is single bonded to O P O 3 P O 3 superscript 3 minus on the lower right.

The structure of isopentenyl pyrophosphate is as follows: A 4-carbon alkene chain is depicted as a line structure using 3 zigzag lines. C H 2 occupies the first position. A double bond is present between C 1 and C 2. C 2 is single bonded to C H 3 above. C 4 is single bonded to O P O 3 P O 3 superscript 2 minus on the lower right.

The structure of geranyl pyrophosphate is as follows: A 4-carbon alkene chain is depicted as a line structure using 3 zigzag lines. C H 3 occupies the first position. A double bond is present between C 2 and C 3. C 2 is single bonded to C H 3 above. C 4 is single bonded to C 1 of a 4-carbon alkene chain depicted as a line structure using 3 zigzag lines. A double bond is present between C 2 and C 3. C 2 is single bonded to C H 3 above. C 4 is single bonded to O P O 3 P O 3 superscript 3 minus.

In the second irreversible step, geranyl pyrophosphate is transformed to farnesyl pyrophosphate coupled with the entry of isopentenyl pyrophosphate and the release of P P subscript i.

The structure of farnesyl pyrophosphate is as follows: A 4-carbon alkene chain is depicted as a line structure using 3 zigzag lines. C H 3 occupies the first position. A double bond is present between C 2



and C 3. C 2 is single bonded to C H 3 above. C 4 is single bonded to C 1 of a 4-carbon alkene chain depicted as a line structure using 3 zigzag lines. A double bond is present between C 2 and C 3. C 2 is single bonded to C H 3 above. C 4 is single bonded to C 1 of another 4-carbon alkene chain depicted as a line structure using 3 zigzag lines. A double bond is present between C 2 and C 3. C 2 is single bonded to C H 3 above. C 4 is single bonded to O P O 3 P O 3 superscript 3 minus.

In the third irreversible step, farnesyl pyrophosphate is transformed to squalene coupled with the entry of farnesyl pyrophosphate, N A D P H plus H superscript plus, and release of 2 P P subscript i and N A D P superscript plus.

The structure of squalene is as follows: A 4-carbon alkene chain is depicted as a line structure using 3 zigzag lines. C H 3 occupies the first position. A double bond is present between C 2 and C 3. C 2 is single bonded to C H 3 above. C 4 is single bonded to C 1 of an alkene chain depicted as a line structure using 3 zigzag lines. A double bond is present between C 2 and C 3. C 2 is single bonded to C H 3 above. C 4 of the alkene chain is single bonded to an 8-carbon alkene chain depicted as a line structure using 7 zigzag lines. A double bond is present between C 2 and C 3 and C 6 and C 7. C 2 and C 7 are each single bonded to C H 3 above. C 8 is single bonded to a 4-carbon alkene chain depicted as a line structure using 3 zigzag lines. A double bond is present between C 2 and C 3. C 3 is single bonded to C H 3 above. C 4 is single bonded to another 4-carbon alkene chain depicted as a line structure using 3 zigzag lines. C H 3 occupies the fourth position. A double bond is present between C 2 and C 3. C 3 is single bonded to C H 3 above.

Return to FIGURE 27.11 Two molecules of farnesyl pyrophosphate are linked to form squalene

Extended description for FIGURE 27.12 Squalene cyclization leads to the steroid skeleton in the form of lanosterol

In the first irreversible step, squalene is transformed to squalene epoxide coupled with the entry of N A D P H plus H superscript plus and O 2 and release of N A D P superscript plus and H 2 O.

The structure of squalene is as follows: A 5-carbon alkene chain is depicted as a line structure using 4 zigzag lines. A double bond is present between C 1 and C 2. C 1 is single bonded to C H 3 on the upper left and C H 3 below in the form of a line. C 5 is single bonded to C H 3 in the form of a line on the upper right and double bonded to C H below. This C H group is single-bonded to a C H 2 group on the lower right in the form of a line. This C H 2 group is single-bonded to C H 2 on the lower left in the form of a line. This C H 2 is

single-bonded to C 1 of a 14-carbon alkene chain on the left depicted as a line structure using 13 zigzag lines. A double bond is present between C 1 and C 2, C 5 and C 6, C 9 and C 10, and C 13 and C 14. C 1 is single-bonded to C H 3 in the form of a line on the lower left. C 6 is single bonded to C H 3 on the lower right in the form of a line. C 10 is single bonded to C H 3 on the upper right in the form of a line. C 14 is single bonded to C H 3 in the form of a line on the lower left and lower right.

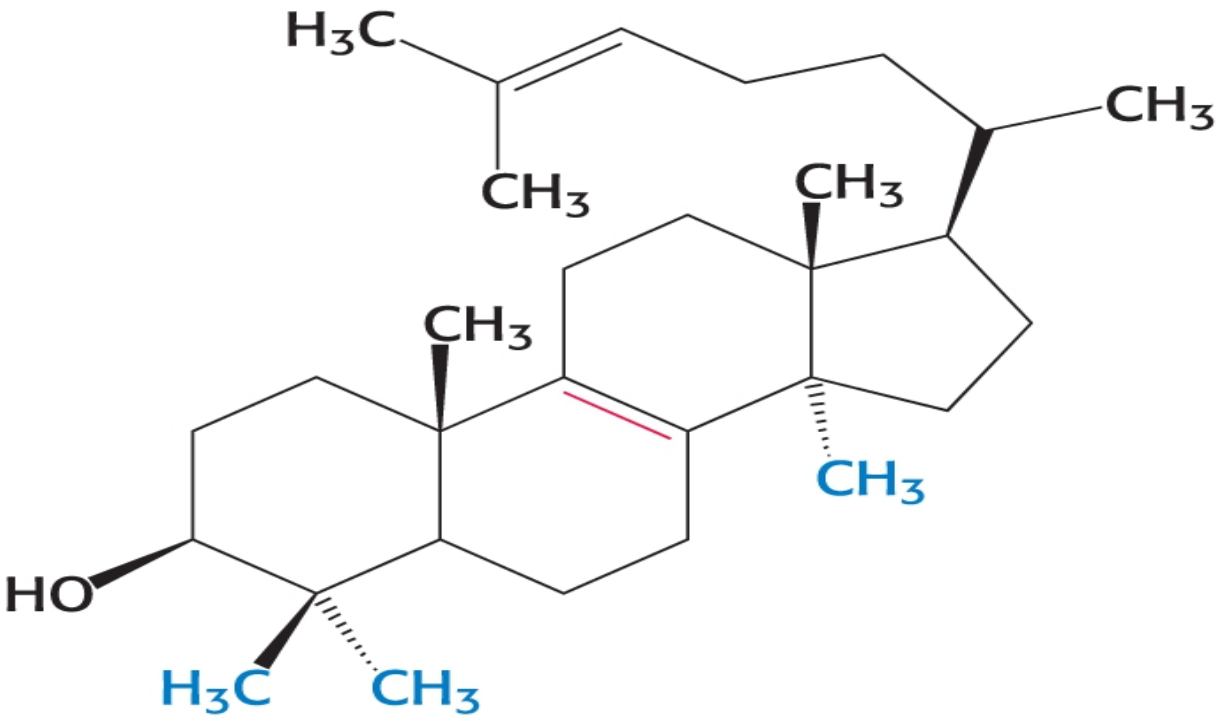
The structure of squalene epoxide is as follows: The structure of squalene epoxide is the same as squalene except C 13 and C 14 are each wedge bonded to a common O atom. An arrow points from the double bond between C 5 of the alkene chain and the C H 2 group points toward C 2 of the 14-carbon alkene chain. An arrow from the double bond between C 1 and C 2 of the 14-carbon alkene chain points toward the C H 3 group single-bonded to C 6 of the 14-carbon alkene chain. An arrow from the double bond between C 5 and C 6 points to C H 3 single bonded to C 10. An arrow from the double bond between C 9 and C 10 points toward C H 3 group single-bonded to C 14.

In the second irreversible step, squalene epoxide is transformed into protosterol cation coupled with the entry of H superscript plus.

The structure of the protosterol cation is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. In the first ring, C 2 is single bonded to C H 3 above in the form of a line, C 3 is single bonded to H below, C 4 is single bonded to C H 3 on the lower left, and C H 3 on the lower right in the form of a line. C 5 is wedge bonded to O H on the lower left. In the second ring, C 1 is single-bonded to H below. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the

second ring are C 5 and C 4 respectively of the third ring. C 2 is single bonded to H above. C 3 and C 4 are each single bonded to C H 3. A 5-membered pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 1 is single bonded to H on the right and single bonded to C 6 of a 7-carbon alkene chain depicted using 6 zigzag lines. A double bond is present between C 2 and C 3. C 6 of the alkene chain has a positive charge. C 2 of the alkane chain is single-bonded to C H 3 below in the form of a line. An arrow from the H atom bonded to C 1 of the second ring points toward the single bond between C 4 and C 5 of the third ring. An arrow from C H 3 bonded to C 4 of the third ring points toward C 3. An arrow from C H 3 bonded to C 3 of the third ring points toward C 2 of the third ring. An arrow from H bonded to C 2 of the third ring points toward C 1 of the fourth ring. An arrow from the H bonded to C 1 of the fourth ring points toward C 6 of the alkene chain.

In the third irreversible step, protosterol cation is converted to lanosterol coupled with the release of H superscript plus ion.

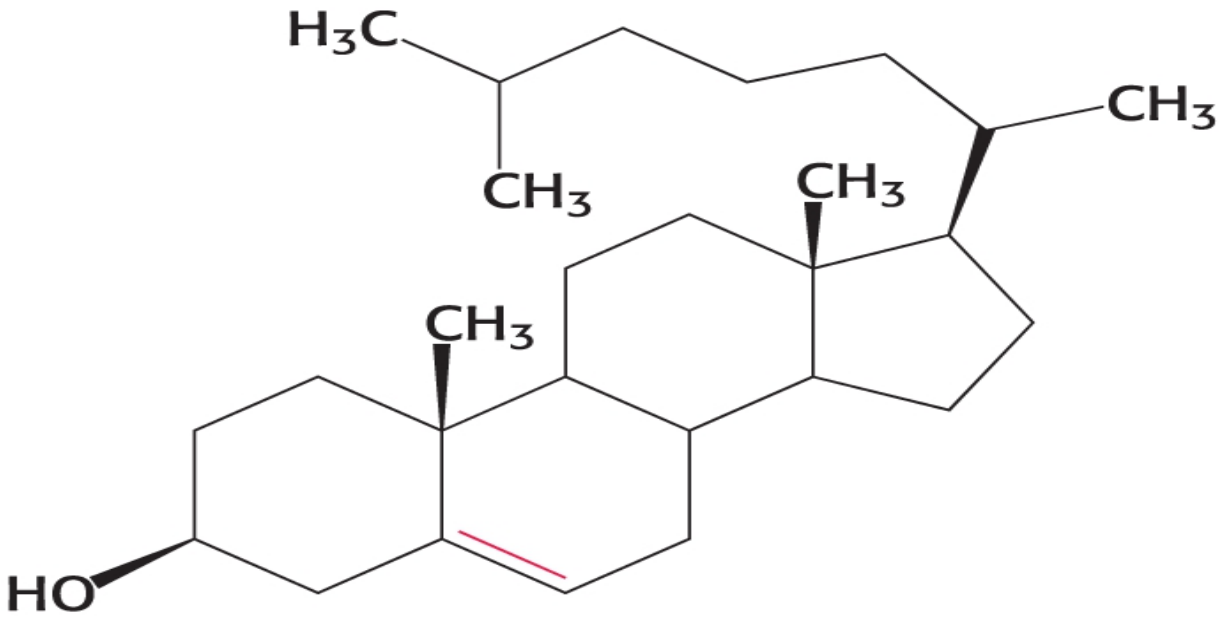


The structure of lanosterol is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. The second ring has a double bond between C 1 and C 2. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. C 2 of the first ring is wedge bonded to C H 3 above. C 3 is dash bonded to H below. C 4 of the first ring is wedge bonded to C H 3 on the lower left and dash bonded to C H 3 on the lower right. C 5 is wedge bonded to O H. A double bond is present between C 1 and C 2 of the second ring. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. A 5-membered pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is fused with the

third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 5 of the pentagonal ring is wedge bonded to C H 3 above and C 4 is dash bonded to C H 3 below. C 1 of the fourth ring is single bonded to H on the right and wedge bonded to C 5 of a 5-carbon alkene chain depicted as a line structure using 4 zigzag lines. A double bond is present between C 1 and C 2. C 1 of the alkene chain is single-bonded to C H 3 on the upper left and C H 3 below. C 5 is single bonded to C H 3 on the top right and dash bonded to H above.

Return to FIGURE 27.12 Squalene cyclization leads to the steroid skeleton in the form of lanosterol

Extended description for FIGURE 27.13 Cholesterol is



formed from lanosterol

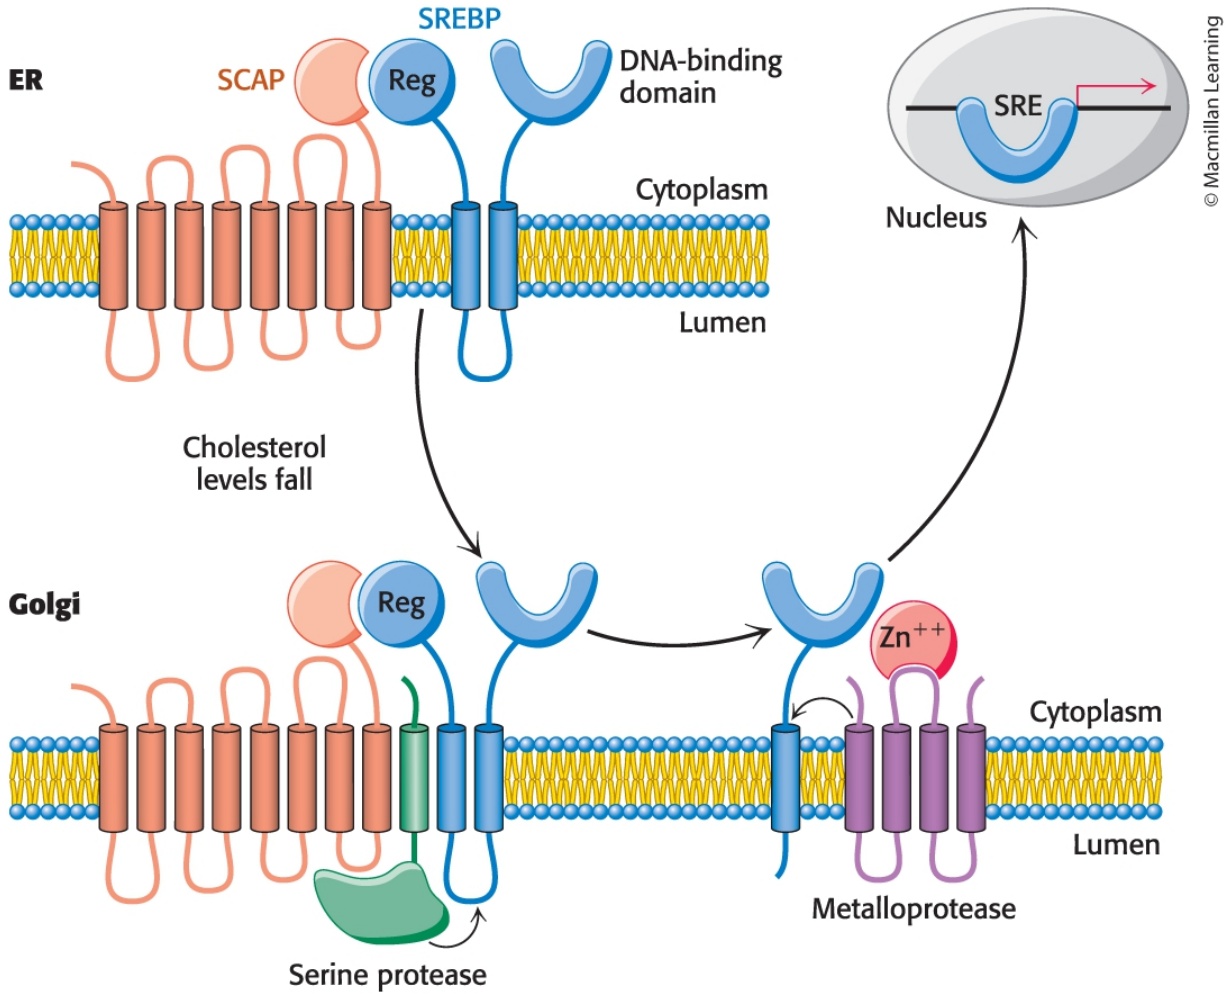
Lanosterol

19 steps

HCOOH + 2 CO_2

Cholesterol

Lanosterol is transformed into cholesterol and this transformation is depicted by a downward arrow labeled 19 steps. It is coupled with the release of H C O O H and 2 C O 2.



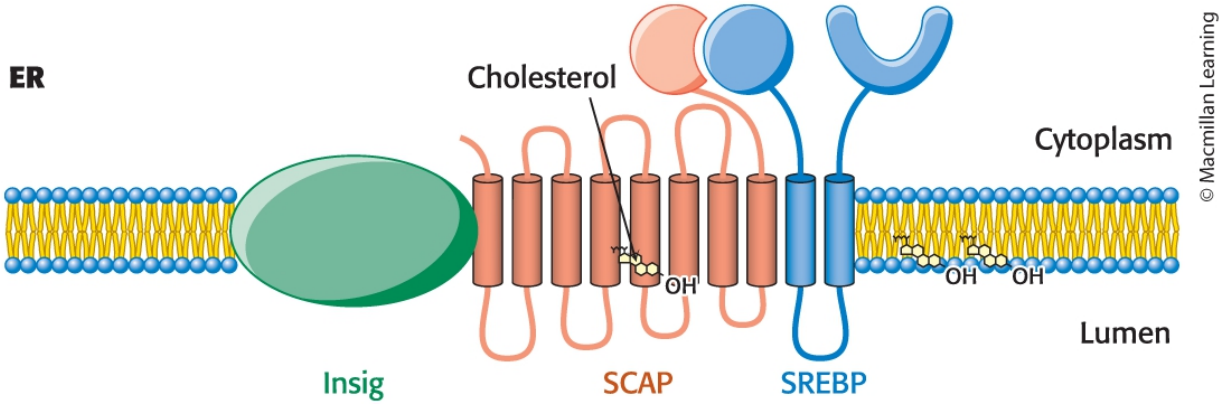
The structure of lanosterol is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. The second ring has a double bond between C 1 and C 2 and is highlighted in red. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. C 2 of the first ring is wedge bonded to C H 3 above. C 4 of the first ring is wedge bonded to C H 3 on the lower left and dash bonded to C H 3 on the lower right. C 5 is wedge bonded to O H. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. A 5-membered pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 5 of the pentagonal ring is wedge bonded to C H 3 above and C 4 is dash bonded to C H 3 below. C 1 of the fourth ring is wedge bonded to C 5 of a 5-carbon alkene chain depicted as a line structure using 4 zigzag lines. A double bond is present between C 1 and C 2. C 1 of the alkene chain is single-bonded to C H 3 on the upper left and C H 3 below. C 5 is single bonded to C H 3 on the top right.

The structure of cholesterol is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. The second ring has a double bond between C 4 and C 5 and is highlighted in red. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. C 2 of the first ring is wedge bonded to C H 3 above. C 5 of the first ring is wedge bonded to O H on the lower left. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third

ring. A 5-membered pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 5 of the pentagonal ring is wedge bonded to C H 3 above. C 1 of the fourth ring is wedge bonded to a C 5 of a 5-carbon alkane chain depicted as a line structure using 4 zigzag lines. C 1 of the alkane chain is single-bonded to C H 3 on the upper left and C H 3 below. C 5 is single bonded to C H 3 on the top right.

Return to FIGURE 27.13 Cholesterol is formed from lanosterol

Extended description for FIGURE 27.14 S R E B P regulates gene expression in response to cholesterol levels

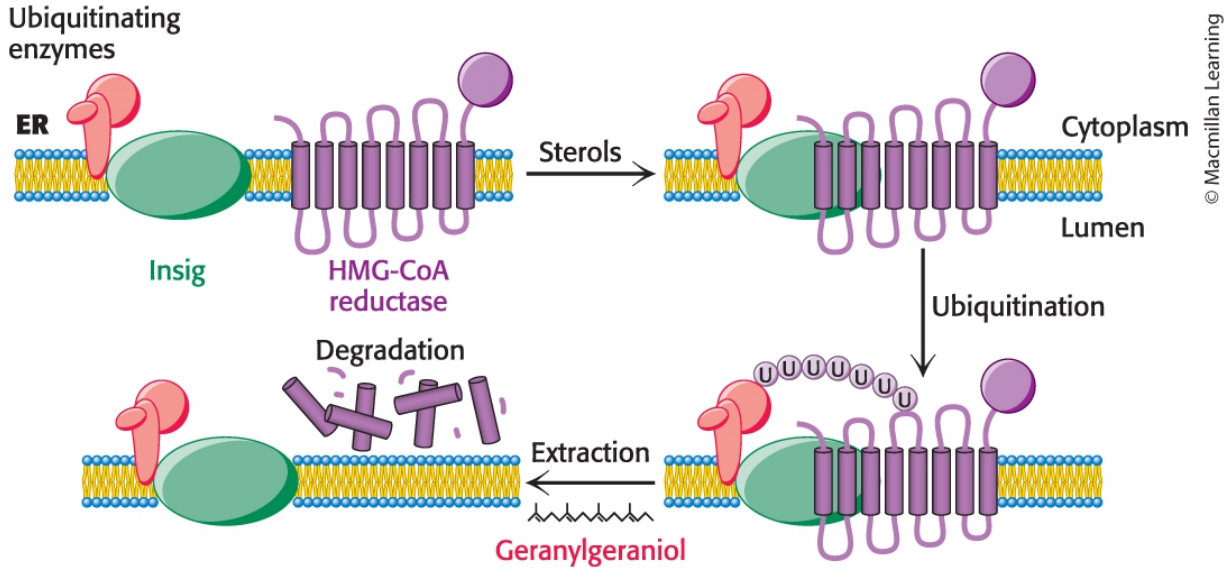


The figure depicts a lipid bilayer of the endoplasmic reticulum. The region above the lipid bilayer is labeled cytoplasm and the region below the lipid bilayer is labeled lumen. The membrane proteins are embedded in the lipid bilayer. The first membrane protein labeled S C A P consists of 8 vertically oriented cylindrical transmembrane domains placed adjacent to each other. The cylindrical domains are connected by thread-like loops at the bottom and top in an

alternating manner. A loop emerging into the cytoplasm from the eighth cylindrical domain is connected to a circular domain with an oval-shaped groove. The second membrane protein labeled S R E B P consists of 2 vertically oriented cylindrical transmembrane domains placed adjacent to each other. A thread-like loop connects the cylindrical domains in the lumen. A loop extending into the cytoplasm from the first cylindrical domain is connected to a circular domain labeled "R e g". A loop extending into the cytoplasm from the second cylindrical domain is connected to a curved elongated structure with a concave groove labeled D N A binding domain. An arrow from the lipid bilayer of the endoplasmic reticulum points to the D N A binding domain of the S R E B P protein embedded in the membrane of the Golgi complex. The membrane lipid bilayer of the Golgi complex consists of an additional membrane protein between S C A P and S R E B P which is labeled serine protease. This membrane protein has an irregular-shaped structure in the lumen. This irregular structure is connected to a single vertically oriented cylindrical transmembrane domain with a loop extending into the cytoplasm. An arrow from serine protease points to S R E B P. An arrow from the D N A binding domain of S R E B P in the Golgi membrane points toward another D N A binding domain on the right connected to a single vertical cylindrical transmembrane domain. Four vertically oriented cylindrical transmembrane domains labeled metalloprotease are connected by thread-like loops at the bottom and top in an alternating manner. The metalloprotease is connected to an oval structure in the cytoplasm. The oval structure is bound to Z n superscript plus plus ion. An arrow from metalloprotease points to the S R E B P. An arrow from the D N A binding domain points to an oval-shaped structure at the top labeled nucleus. The nucleus contains the D N A binding domain of S R E B P bound to S R E. An arrow from S R E points to the right.

Return to FIGURE 27.14 S R E B P regulates gene expression in response to cholesterol levels

Extended description for FIGURE 27.15 Insig regulates S C A P-S R E B P movement



The figure depicts a lipid bilayer of the endoplasmic reticulum. The region above the lipid bilayer is labeled cytoplasm and the region below the lipid bilayer is labeled lumen. The membrane proteins are embedded in the lipid bilayer. The first membrane protein is oval in shape and is labeled Insig. The second membrane protein labeled S C A P consists of 8 vertically oriented cylindrical transmembrane domains placed adjacent to each other. The cylindrical domains are connected by thread-like loops at the bottom and top in an alternating manner. A loop emerging into the cytoplasm from the eighth cylindrical domain is connected to a circular domain with an oval-shaped groove. The third membrane protein labeled S R E B P consists of 2 vertically oriented cylindrical transmembrane domains placed adjacent to each other. A thread-like loop connects the cylindrical domains in the lumen. A loop extending into the cytoplasm from the first cylindrical domain is connected to an oval-shaped domain. A loop extending into the cytoplasm from the second cylindrical domain is connected to a curved elongated structure with a concave center. Two cholesterol molecules are embedded in the lipid bilayer. One cholesterol molecule is bound to

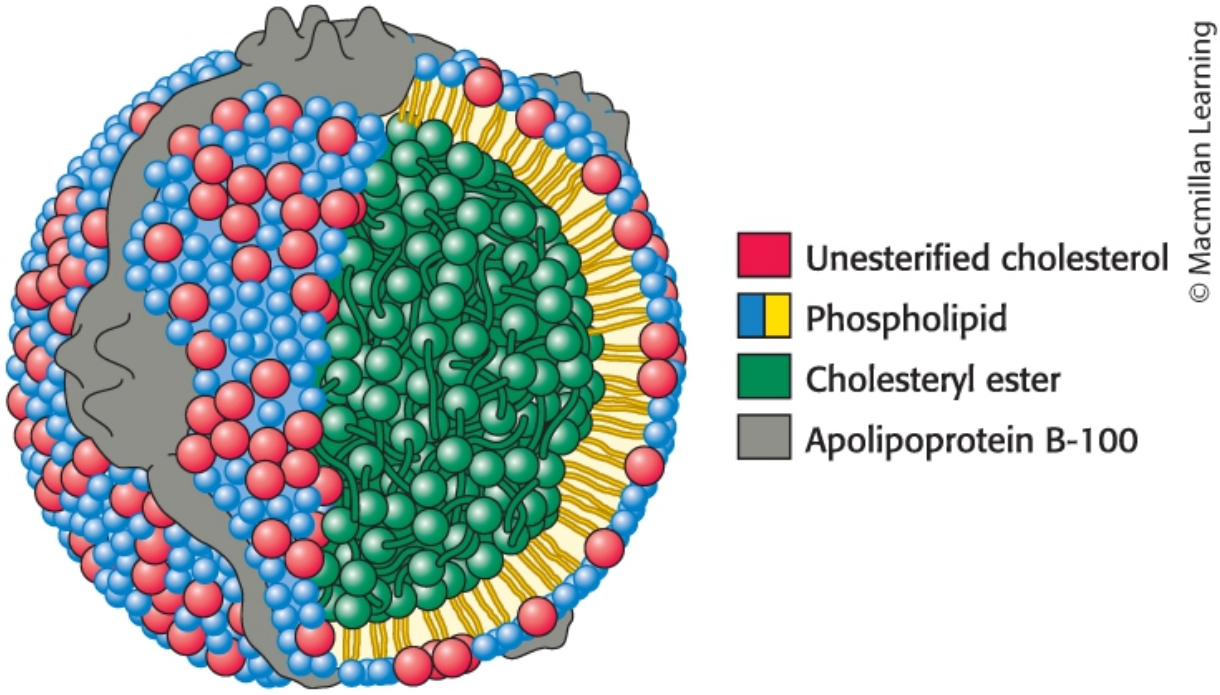
S C A P. The cholesterol molecules are depicted as four-fused rings connected to an O H group.

Return to FIGURE 27.15 Insig regulates S C A P-S R E B P movement

Extended description for FIGURE 27.16 Insig facilitates the degradation of H M G-C o A reductase

The lipid bilayer of the endoplasmic reticulum is shown. The region above the lipid bilayer is labeled cytoplasm and the region below the lipid bilayer is labeled lumen. The membrane proteins are embedded in the lipid bilayer. The first membrane protein has three subunits of which one subunit is embedded into the membrane. This protein is labeled ubiquitinating enzymes. The second membrane protein is oval-shaped and labeled Insig. The third membrane protein labeled H M G C o A reductase consists of 8 vertically oriented cylindrical transmembrane domains placed adjacent to each other. The cylindrical domains are connected by thread-like loops at the bottom and top in an alternating manner. A loop emerging into the cytoplasm from the eighth cylindrical domain is connected to a circular domain.

In the first step, Insig associated with ubiquitinating enzymes binds H M G-C o A reductase in the presence of sterols. Insig directly

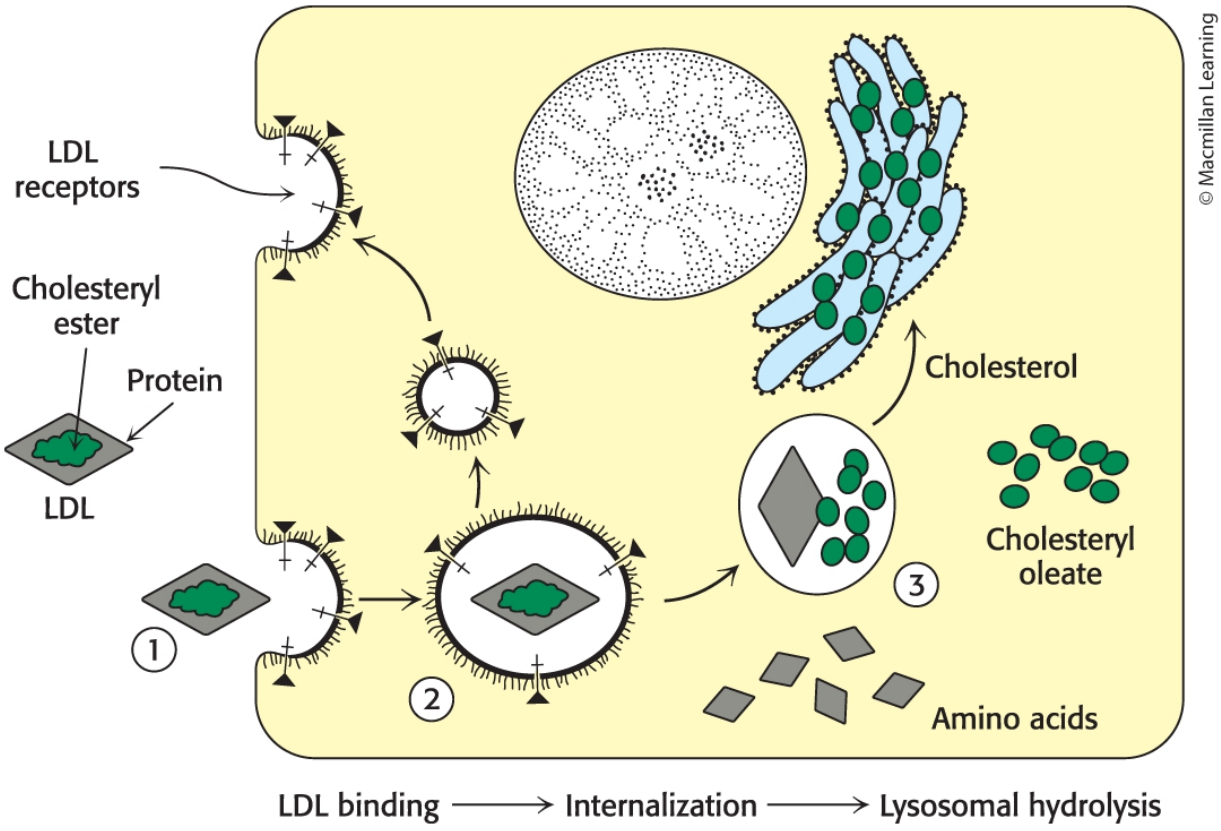


interacts with H M G-C o A reductase.

In the second step, H M G-C o A reductase undergoes ubiquitination. 7 spheres labeled U are connected to each other in the form of a string. This string of U is connected to H M G C o A reductase.

In the third step, ubiquitination and the presence of geranylgeraniol lead to the extraction of the H M G-C o A reductase from the bilayer. Later, the reductase undergoes degradation by the proteasome to release the cylindrical domains into the cytoplasm.

Return to FIGURE 27.16 Insig facilitates the degradation of H M G-C o A reductase

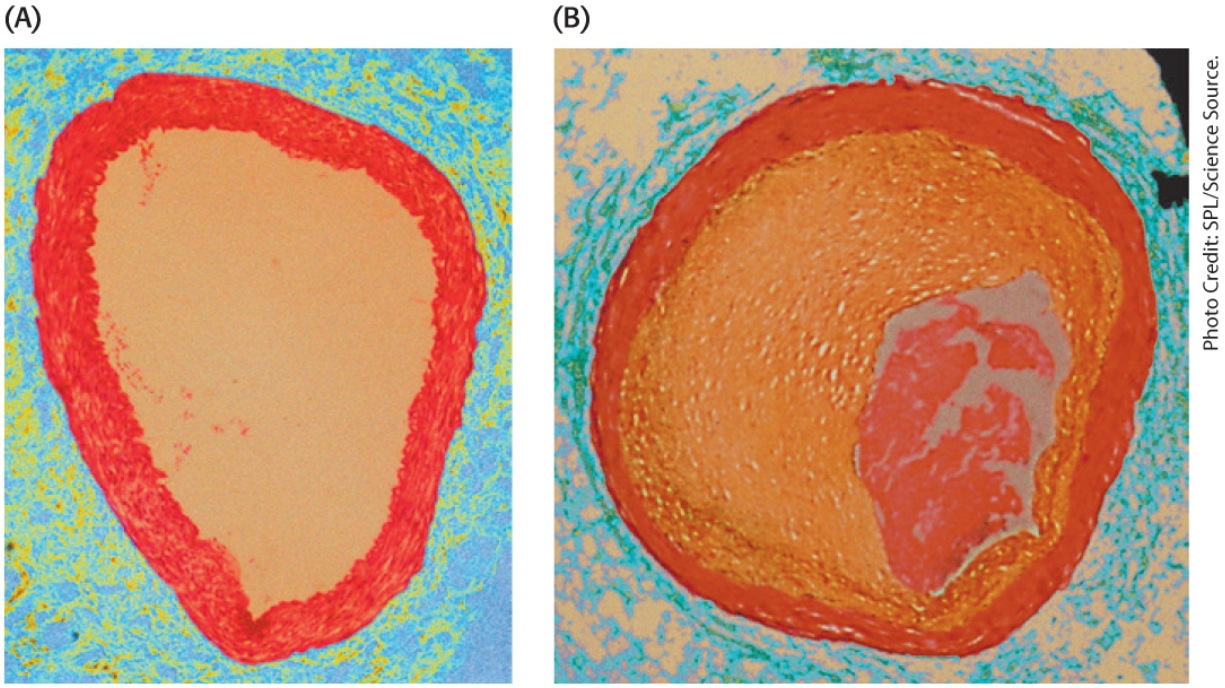


Extended description for FIGURE 27.18 L D L consists of a core of cholesterol esters surrounded by a single molecule of apolipoprotein B-100

The L D L particle is spherical in shape. A part of the L D L particle Is cut open to expose the internal molecules. The core of the L D L particle is composed of green-colored spheres with tail-like structures attached to them. These represent the cholesteryl esters. The cholesteryl esters are surrounded by a layer of phospholipids depicted as blue spheres with two yellow tails. Red spheres embedded in between the blue spheres of the phospholipid represent the unesterified cholesterol. A single grey-colored irregular structure with conical protrusions is embedded in the phospholipid layer of the L D L particle. It represents the apolipoprotein B-100.

Return to FIGURE 27.18 L D L consists of a core of cholesterol esters surrounded by a single molecule of apolipoprotein B-100

Extended description for FIGURE 27.19 L D L enters cells through receptor-mediated endocytosis



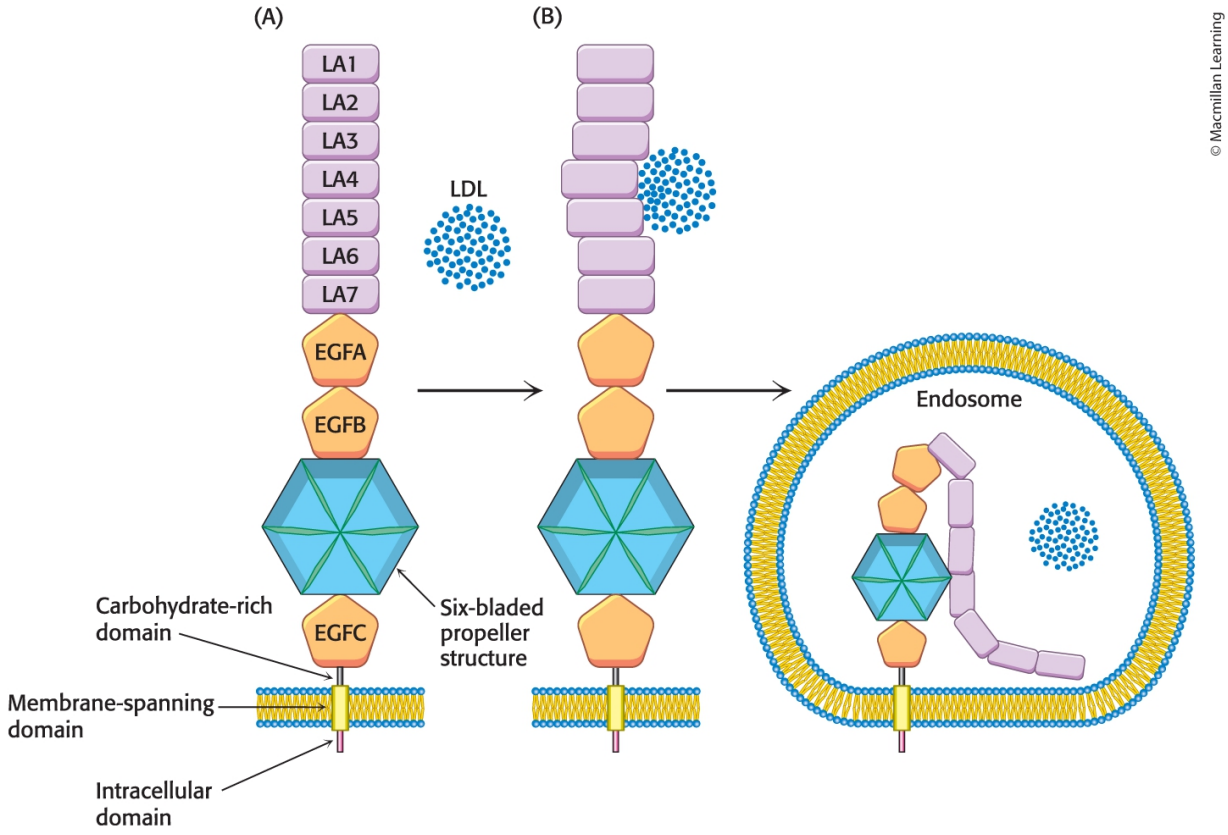
The figure depicts a square-shaped cell with two grooves on the left. The grooves are lined by L D L receptors. Outside the cell, a rhomboid-shaped L D L is present. L D L contains a cloud-like structure inside it labeled cholesteryl ester. In the first step, the L D L binds to the L D L receptors in the second groove. In the second step, the groove containing L D L bound to the L D L receptor undergoes invagination to form an endosome vesicle inside the cell. In the third step, the L D L is separated from the vesicle containing the L D L receptors. The vesicle containing the receptor moves back to the first groove to replenish the pool of L D L receptors in the membrane. Simultaneously, L D L undergoes degradation in

lysosomes to release amino acids, cholesteryl oleate, and cholesterol. The cholesterol and cholesteryl oleate are depicted as tiny green circles and amino acids are depicted as grey diamond-shaped structures. The cholesterol molecules enter into a clump of long sacs-like structures. The remaining molecules are released into the cytoplasm.

A horizontal sequence below the figure shows the process corresponding to each step of L D L processing. This sequence is as follows: L D L binding, forward arrow, internalization, forward arrow, lysosomal hydrolysis.

Return to FIGURE 27.19 L D L enters cells through receptor-mediated endocytosis

Extended description for FIGURE 27.20 Arterial plaques are one of the effects of excess cholesterol



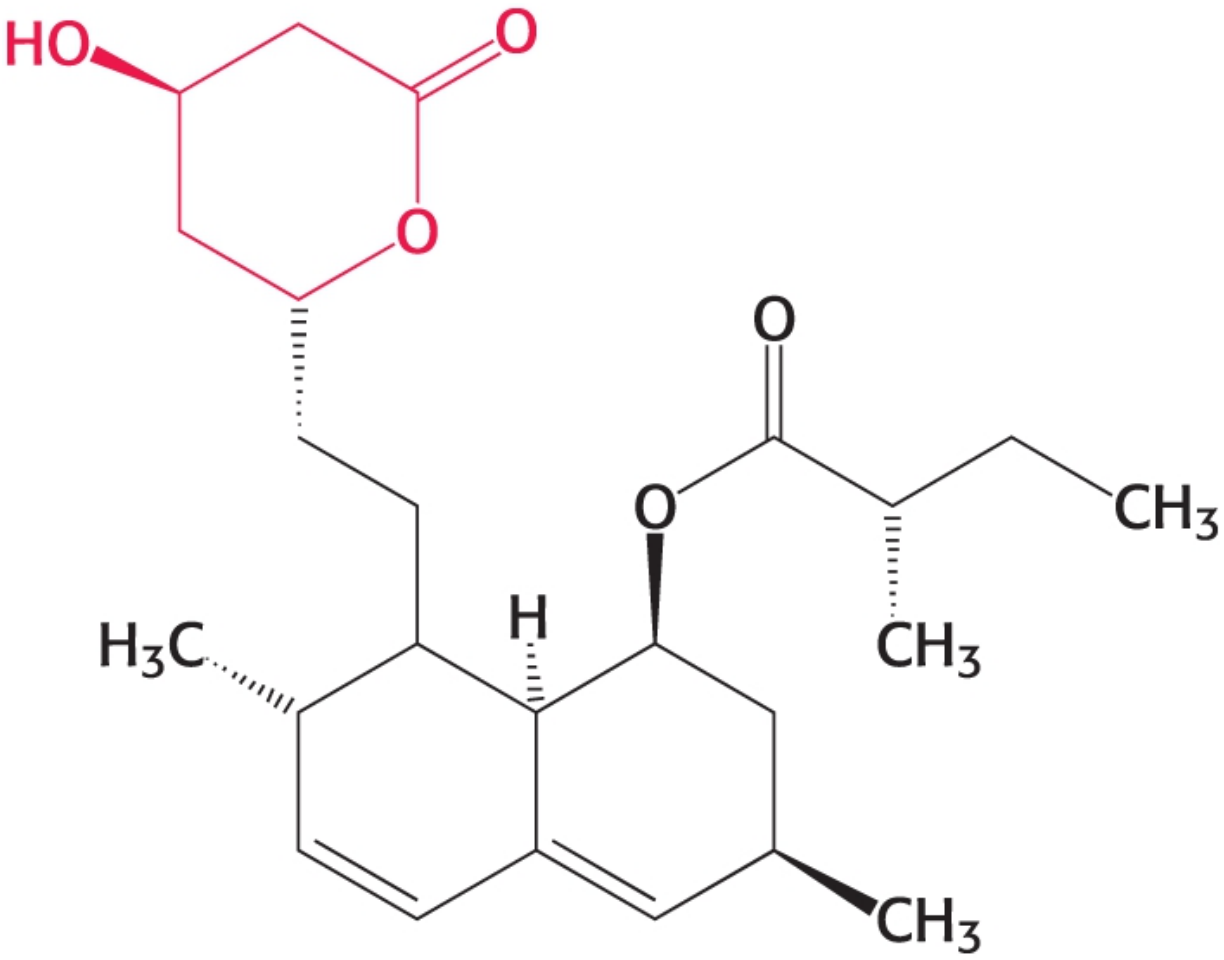
(A): The normal artery is oval-shaped with thick walls. It has a hollow interior.

(B): The blocked artery is circular with thick walls. A plaque is formed due to the deposition of cholesterol in the walls of the artery. The plaque extends into the interior thereby narrowing the hollow region of the artery.

Return to FIGURE 27.20 Arterial plaques are one of the effects of excess cholesterol

Extended description for FIGURE 27.21 The L D L receptor releases L D L in the endosome

© Macmillan Learning



(A): The domain structure of the L D L receptor is shown. The structure consists of a membrane-spanning domain in the lipid bilayer. The membrane-spanning domain is attached to a thin structure in the lumen labeled intracellular domain. In the cytoplasm, the membrane-spanning domain is attached to a short tubular labeled carbohydrate-rich domain. The carbohydrate-rich domain is attached to a pentagonal structure labeled E G F C at the top. E G F C is attached to a six-bladed propeller structure at the top. This is further attached to two pentagonal structures one above the other labeled E G F B and E G F A. E G F A is further attached to 7 blocks labeled from L A 1 to L A 7 from top to bottom. An L D L

molecule depicted as a sphere with small dots is shown on the right side of the L A blocks.

Part (B): The L D L particle attaches to the blocks numbered L A 4 and L A 5 shifting them slightly toward the left. An arrow points toward the L D L receptor inside an endosome. A lipid bilayer lines the circular endosome. The open structure of L D L converts into the closed structure inside the endosome by bending of L A blocks. This leads to the release of L D L in the endosome.

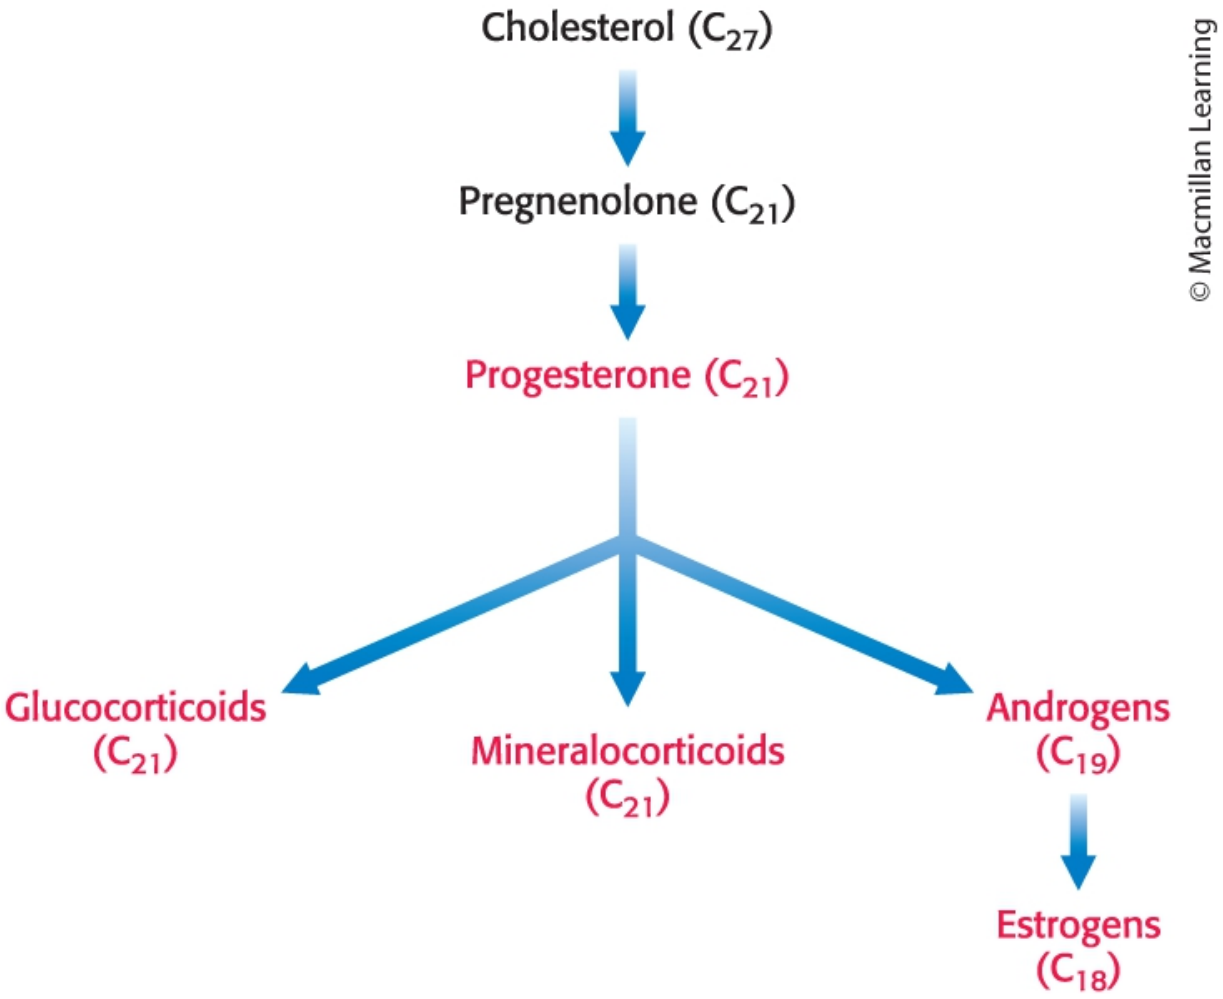
Extended description for FIGURE 27.23 Bile salts are synthesized from cholesterol

The figure shows a bifurcated arrow from cholesterol that points to glycocholate and taurocholate.



The structure of glycocholate is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. C 2 of the first ring is wedge bonded to C H 3 above. C 3 is wedge bonded to H below. C 5 is dash bonded to O H on the lower left. C 3 of the second ring is dash bonded to O H. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. C 1 of this ring is dash bonded to O H above. A 5-membered pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 5 of the pentagonal ring is wedge bonded to C H 3 above. C 1 of the fourth ring is wedge bonded to a C

1 of a 1 N and 5 C heteronuclear alkane chain depicted as a line structure using 5 zigzag lines. N bound to H occupies the fifth position. C 1 is dash bonded to C H 3 on the upper left. C 4 is double bonded to O above. C 5 is single bonded to C O O superscript minus N a superscript plus.

The structure of taurocholate is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. C 2 of the first ring is wedge bonded to C H 3 above. C 3 is wedge bonded to H below. C 5 is dash bonded to O H on the lower left. C 3 of the second ring is dash bonded to O H. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. C 1 of this ring is dash bonded to O H above. A 5-membered pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 5 of the pentagonal ring is wedge bonded to C H 3 above. C 1 of the fourth ring is wedge bonded to C 1 of a 1 N and 6 C heteronuclear alkane chain depicted as a line structure using 6 zigzag lines. N bound to H occupies the fifth position. C 1 is dash bonded to C H 3 on the upper left. C 4 is double bonded to O above. C 6 is single bonded to S O 3 superscript minus N a superscript plus on the upper right.

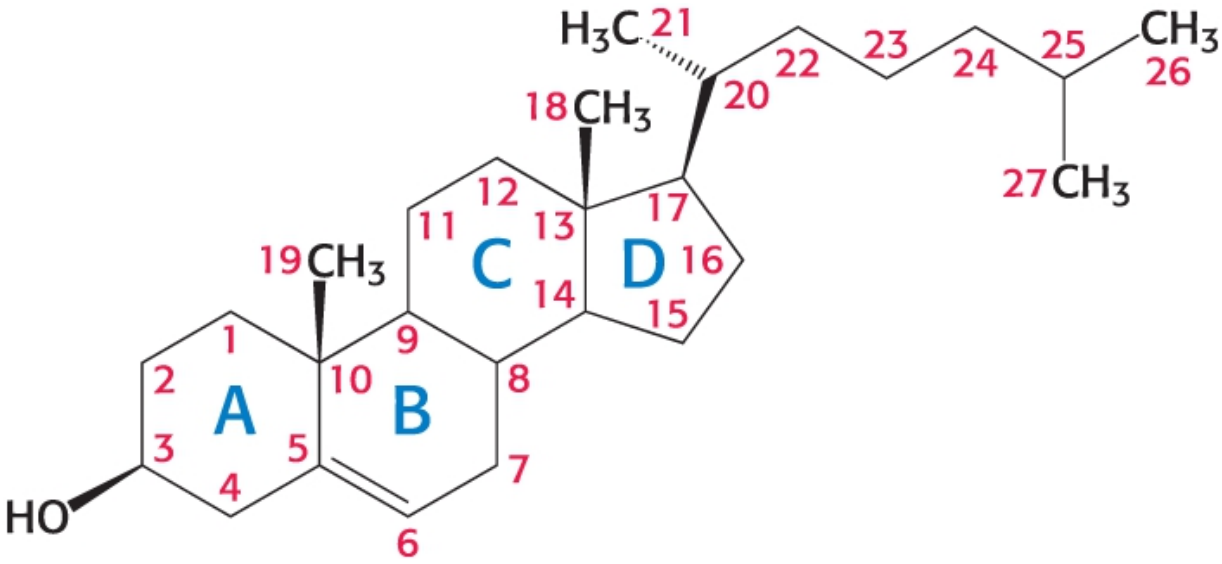
Extended description for FIGURE 27.24 Different classes of steroid hormones are derived from cholesterol

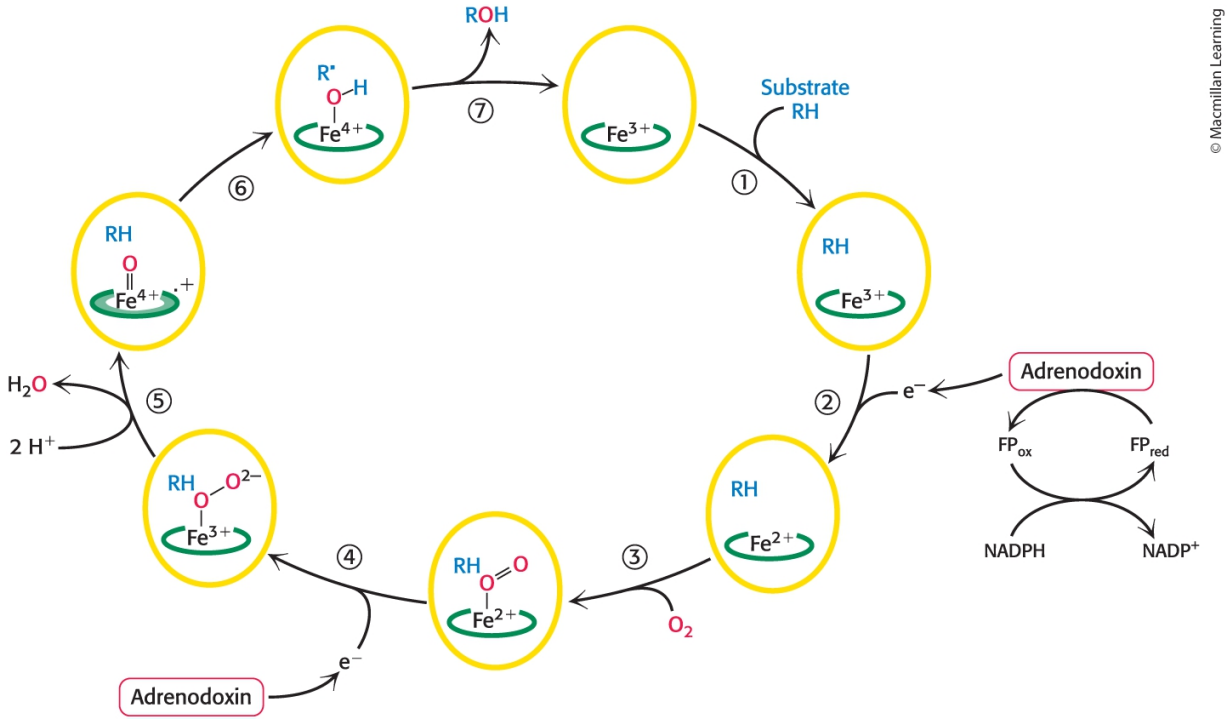


© Macmillan Learning

The schematic illustration starts with cholesterol C 27. A downward arrow from cholesterol C 27 points to pregnenolone C 21. A downward arrow from pregnenolone C 21 leads to progesterone C 21. Three downward arrows from progesterone C 21 lead to glucocorticoids C 21, mineralocorticoids C 21, and androgens C 19. A downward arrow from androgens C 19 leads to estrogens C 18.

Return to FIGURE 27.24 Different classes of steroid hormones are derived from cholesterol

Extended description for FIGURE 27.25 A common numbering system is used for cholesterol and other steroids



The structure of cholesterol is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. The first hexagonal ring is labeled A and the second hexagonal ring is labeled B. The ring labeled B has a double bond between C 4 and C 5. Both the rings are fused such that C 2 and C 3 of ring A are C 6 and C 5 respectively of ring B. C 2 of the first ring is wedge bonded to C H 3 above. C 5 of ring A is wedge bonded to O H on the lower left. Another 6-carbon hexagonal ring in vertical orientation labeled C is fused with ring B such that C 1 and C 2 of ring B are C 5 and C 4 respectively of ring C. A 5-membered pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is labeled D and fused with ring C such that C 2 and C 3 of ring C are C 4 and C 3 respectively of ring D. C 5 of ring D is wedge bonded to C H 3 above. C 1 of ring D is single bonded to C 1 of a 6-carbon alkane chain depicted as a line structure using 5 zigzag lines. C bond to H 3

occupies the sixth position. C 1 is dash bonded to C H 3 on the upper left. C 5 is single bonded to C H 3 below. In the first ring, C 1, C 6, C 5, C 4, and C 3 are numbered from 1 to 5 respectively. In the second ring, C 4, C 3, C 2, C 1, and C 6 are numbered from 6 to 10, respectively. In the third ring, C 6, C 1, C 2, and C 3 are numbered from 11 to 14, respectively. In the fourth ring, C 1, C 2, and C 3 are numbered 17, 16, and 15, respectively. C H 3 bound to C 5 of ring D is numbered 18. C H 3 bound to C 2 of ring A is numbered 19. C 1 of the alkane chain is numbered 20. C H 3 group dash bonded to C 1 of the alkane chain is numbered 21. C 2, C 3, C 4, C 5, and C 6 of the alkane chain are numbered from 22 to 26. C H 3 single bonded to C 5 of the alkane chain is numbered 27.

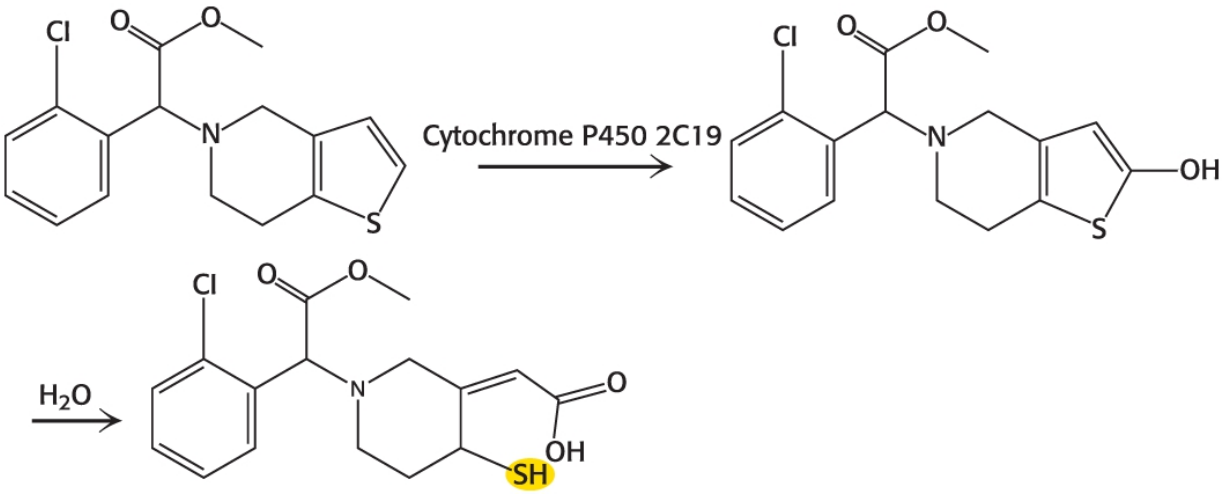
Extended description for FIGURE 27.26 The reaction mechanism for cytochrome P 450 enzymes reveals how oxygen is inserted into R-H bonds

© Macmillan Learning

The figure shows an oval-shaped enzyme with F e superscript 3 plus. In the first step, substrate R H binds to the enzyme.

In the second step, adrenodoxin donates an electron. Simultaneously, adrenodoxin also converts F P reduced to F P oxidized. F P oxidized is converted back to F P reduced, coupled with the oxidation of N A D P H to N A D P superscript plus. The electron is accepted by F e superscript 3 plus to become F e superscript 2 plus. In the third step, O 2 enters the enzyme. This leads to the formation of a single bond between F e superscript 2 plus and O. This O is double-bonded to another O on the top right.

In the fourth step, another adrenodoxin donates an electron. This removes the double bond between the O atoms. The top right O is converted to O superscript 2 minus along with the oxidation of F e superscript 2 plus to F e superscript 3 plus.



In the fifth step, F e superscript 3 plus is further oxidized to F e superscript 4 plus. F e superscript 4 plus is double-bonded to O above. This is coupled with the entry of 2 H superscript plus and release of H 2 O.

In the sixth step, F e superscript 4 plus is single-bonded to O on the top. The H from the R H becomes single-bonded to O on the top right. R with an unpaired electron is shown above it.

In the seventh step, R O H is released from the enzyme to give rise to back the enzyme with F e superscript 3 plus.

Return to FIGURE 27.26 The reaction mechanism for cytochrome P 450 enzymes reveals how oxygen is inserted into R-H bonds

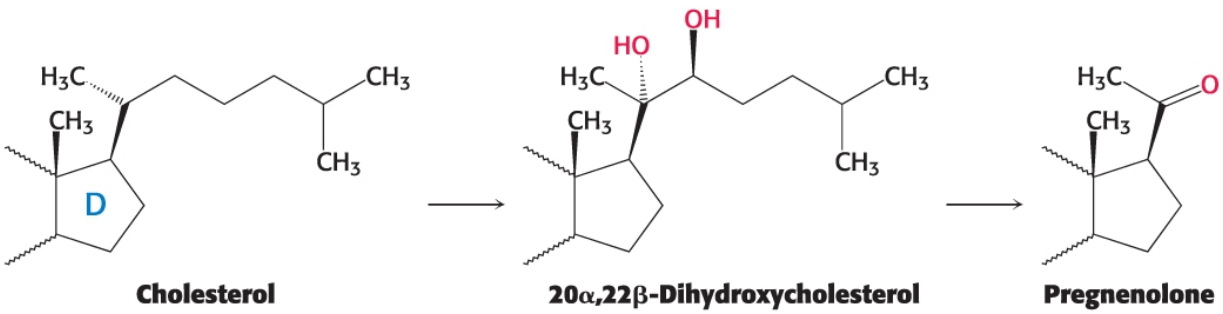
Extended description for FIGURE 27.27 Cytochrome P 450 2 C 19 converts the prodrug clopidogrel to an active form

In the first irreversible step, prodrug clopidogrel is hydroxylated by cytochrome P 450 2 C 19 to form an intermediate.

The structure of prodrug clopidogrel is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to C l above. C 2 is single-bonded to a central C atom on the top right. The central C atom is single-bonded to another C atom above. This C atom is double-bonded to O on the upper left and single-bonded to O on the upper right. The O on the upper right is single-bonded to C H 3 on the lower right in the form of a line. The central C atom is single-bonded to N of a 6-membered heterocyclic hexagonal ring in a vertical orientation with 1 N and 5 C atoms. N occupies the first position which is the top left vertex. This ring is fused with another 5-membered pentagonal ring in a horizontal orientation with 1 S and 4 C atoms. S occupies the first position which is the bottom right

vertex. C 1 occupies the second position, which is the bottom left vertex. Double bonds are present between C 1 and C 2 and C 3 and C 4. The rings are fused such that C 2 and C 3 of the heterocyclic ring are C 2 and C 1 respectively of the pentagonal ring.

The structure of the intermediate is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to C l above. C 2 is single-bonded to a central C atom on the top right. The central C atom is single-bonded to another C atom above. This C atom is double-bonded to O on the upper left and single-bonded to O on the upper right. The O on the upper right is single-bonded to C H 3 on the lower right in the form of a line. The central C atom is single-bonded to N of a 6-membered heterocyclic hexagonal ring in a vertical orientation with 1 N and 5 C atoms. N occupies the first position, which is the top left vertex. This ring is fused with another 5-membered heterocyclic pentagonal ring in a horizontal orientation with 1 S and 4 C atoms. S occupies the first position, which is the bottom right vertex. C 1 occupies the second position, which is the bottom left vertex. Double bonds are present between C 1 and C 2 and C 3 and C 4. C 4 is single bonded to O H on the right. The rings are fused such that C 2 and C 3 of the heterocyclic ring are C 2 and C 1 respectively of the pentagonal ring.



In the second irreversible step, the intermediate product undergoes spontaneous hydrolysis to produce a compound with a reactive thiol group.

The structure of the product is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to C l above. C 2 is single-bonded to a central C atom on the top right. The central C atom is

single-bonded to another C atom above. This C atom is double-bonded to O on the upper left and single-bonded to O on the upper right. The O on the upper right is single-bonded to C H 3 on the lower right in the form of a line. The central C atom is single-bonded to N of a 6-membered heterocyclic hexagonal ring in a vertical orientation with 1 N and 5 C atoms. N occupies the first position, which is the top left vertex. C 2 is double bonded to C H on the upper right. C H is single-bonded to C on the lower right. This C is double bonded to O on the upper right and single bonded to O H below. C 3 is single bonded to S H on the lower right highlighted in yellow.

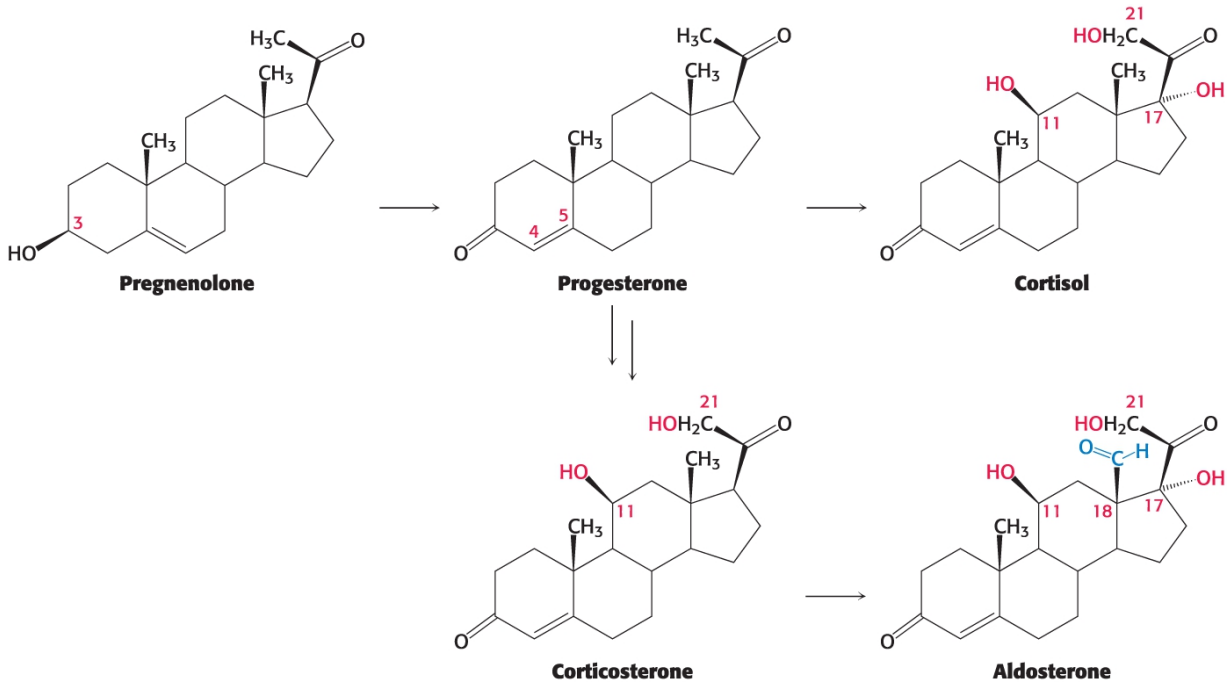
Return to FIGURE 27.27 Cytochrome P 450 2 C 19 converts the prodrug clopidogrel to an active form

Extended description for Conversion of cholesterol to pregnenolone

An irreversible reaction depicts the transformation of cholesterol to 20 alpha, 22 beta-dihydroxycholesterol.

The structure of cholesterol is as follows: A 5-carbon pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is labeled D. C 1 is wedge bonded to a C 1 of a 5-carbon alkane chain depicted as a line structure using 4 zigzag lines. C 1 of the alkane chain is dash bonded to C H 3 on the upper left. C 5 is single bonded to C H 3 on the upper right and C H 3 below. C 4 of the pentagonal ring has an open wiggly line on the lower left. C 5 has a wiggly line on the top left and is wedge bonded to C H 3 on the top.

The structure of 20 alpha, 22 beta-dihydroxycholesterol is as follows: A 5-carbon pentagonal ring is in horizontal orientation with C 1 occupying the top right vertex. C 1 is wedge bonded to a C 1 of a 5-carbon alkane chain depicted as a line structure using 4 zigzag lines. C 1 of the alkane chain is single bonded to C H 3 on the upper left and dash bonded to O H above. C 2 is wedge bonded to O H above. C 5 is single bonded to C H 3 on the upper right and C H 3 below. C 4 of the pentagonal ring has a wiggly line on the lower left. C 5 has a



wiggly line on the upper left and is wedge bonded to C H 3 on the top.

20 alpha, 22 beta-dihydroxycholesterol is irreversibly converted into pregnenolone.

The structure of pregnenolone is as follows: A 5-carbon pentagonal ring is in horizontal orientation with C 1 occupying the top right vertex. C 1 is wedge bonded to a central C atom above. The central C atom is single-bonded to C H 3 on the upper left and double-bonded to O on the upper right. C 4 of the pentagonal ring has a wiggly line on the lower left. C 5 has a wiggly line on the upper left and is wedge bonded to C H 3 on the top.

Return to Conversion of cholesterol to pregnenolone

Extended description for FIGURE 27.28 Pregnenolone is converted into progesterone, cortisol, and aldosterone

In the first irreversible step, pregnenolone is converted to progesterone.

The structure of pregnenolone is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. The second ring has a double bond between C 4 and C 5. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. C 2 of the first ring is wedge bonded to C H 3 above. C 5 numbered 3 is wedge bonded to O H. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. A 5-membered pentagonal ring in horizontal orientation with C 1 occupying the top-right

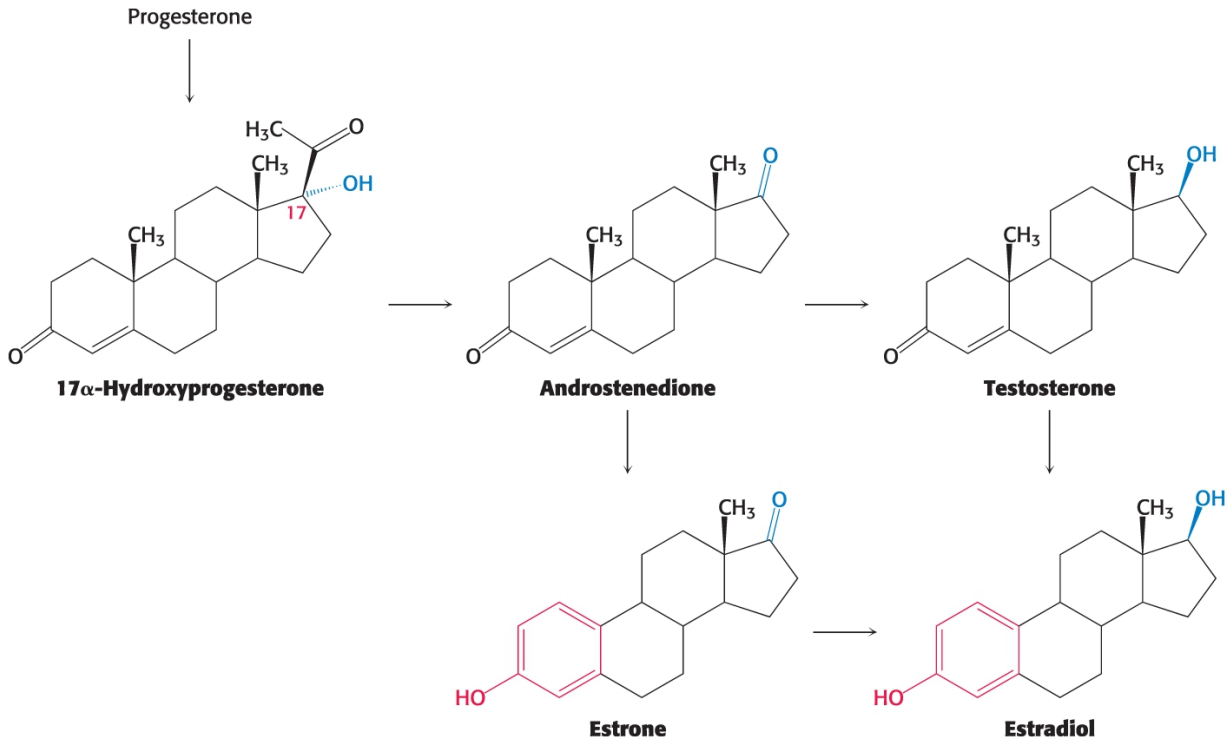
vertex is fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 5 of the pentagonal ring is wedge bonded to C H 3 above. C 1 of the fourth ring is wedge bonded to a central C atom. The central C atom is wedge bonded to C H 3 on the upper left and double-bonded to O on the upper right.

The structure of progesterone is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. The first ring has a double bond between C 3 and C 4. C 3 and C 4 are numbered 5 and 4 respectively. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. C 2 of the first ring is wedge bonded to C H 3 above. C 5 is double bonded to O. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. A 5-membered heterocyclic pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 5 of the pentagonal ring is wedge bonded to C H 3 above. C 1 of the fourth ring is wedge bonded to a central C atom. The central C atom is wedge bonded to C H 3 on the upper left and double-bonded to O on the upper right.

In the second irreversible step, progesterone has two fates, the first being transformation to cortisol and the second being transformation to corticosterone. The conversion of progesterone to corticosterone is depicted using 2 forward arrows.

The structure of cortisol is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. The first ring has a double bond between C 3 and C 4. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. C 2 of the first ring is wedge bonded to C H 3 above.

C 5 is double bonded to O. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. C 6 of the third ring is numbered 11 and wedge bonded to O H. A 5-membered pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 5 of the pentagonal ring is wedge bonded to C H 3 above. C 1 of the fourth ring, numbered 17, is dash bonded to O H on the upper right and wedge bonded to a central C atom above. The central C atom is wedge bonded to C H 2 O H on the upper left and double-bonded to O on the upper right. C H 2 O H is numbered 21.



The structure of corticosterone is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. The first ring has a double bond between C 3 and C 4. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. C 2 of the first ring is wedge bonded to C H 3 above. C 5 is double bonded to O. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. C 6 of the third ring is numbered 11 and wedge bonded to O H. A 5-membered pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 5 of the pentagonal ring is wedge bonded to C H 3 above. C 1 of the fourth ring is wedge bonded to a central C atom above. The central C atom is wedge bonded to C H 2 O H on the upper left and double-bonded to O on the upper right. C H 2 O H is numbered 21.

In the third irreversible step, corticosterone is converted to aldosterone.

The structure of aldosterone is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. The first ring has a double bond between C 3 and C 4. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. C 2 of the first ring is wedge bonded to C H 3 above. C 5 is double bonded to O. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. C 6 of the third ring is numbered 11 and is wedge bonded to O H. C 2 of the third ring is numbered 18. A 5-membered pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 5 of the pentagonal ring is wedge bonded to C above. This C atom is double-bonded to O on the upper left and single-bonded to H on the upper right. C 1 of the fourth ring, numbered 17, is dash bonded to O H on the upper right and wedge bonded to a central C atom above. The central C atom is wedge bonded to C H 2 O H on the upper left and double-bonded to O on the upper right. C H 2 O H is numbered 21.

Return to FIGURE 27.28 Pregnenolone is converted into progesterone, cortisol, and aldosterone

Extended description for FIGURE 27.29 Progesterone is converted into testosterone and estradiol

In the first irreversible step, progesterone is converted to 17 alpha-hydroxyprogesterone.

The structure of 17 alpha-hydroxyprogesterone is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. The first ring has a double bond between C 3 and C 4. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. C 2 of the first ring is wedge bonded to C H 3 above. C 5 is double-bonded to O. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. A 5-membered pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is

fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 5 of the pentagonal ring is wedge bonded to C H 3 above. C 1 of the fourth ring numbered 17 is dash bonded to O H on the upper right and wedge bonded to a central C atom above. The central C atom is single-bonded to C H 3 on the upper left and double-bonded to O on the upper right.

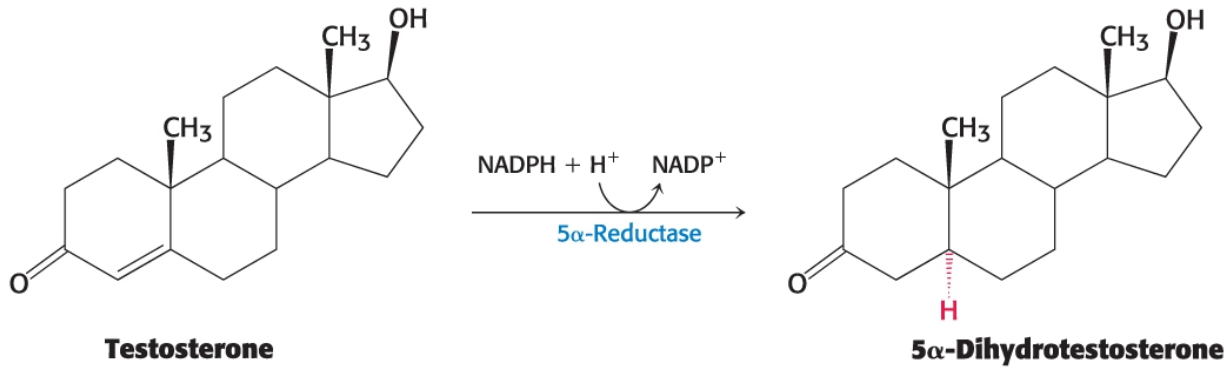
In the second irreversible step, 17 alpha-hydroxyprogesterone is converted to androstenedione. The structure of androstenedione is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. The first ring has a double bond between C 3 and C 4. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. C 2 of the first ring is wedge bonded to C H 3 above. C 5 is double-bonded to O. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. A 5-membered pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 5 of the pentagonal ring is wedge bonded to C H 3 above. C 1 of the fourth ring is double-bonded to O above.

In the third irreversible step, androstenedione has two fates, first is conversion to testosterone and the second is conversion to estrone.

The structure of testosterone is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. A double bond is present between C 3 and C 4 of the first ring. C 2 of the first ring is wedge bonded to C H 3. C 5 of the first ring is double-bonded to O on the lower left. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5

and C 4 respectively of the third ring. A 5-membered pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 5 of the pentagonal ring is wedge bonded to C H 3 above. C 1 of the fourth ring is wedge bonded to O H.

The structure of estrone is as follows: A benzene ring in a vertical orientation consists of double bonds between C 1 and C 2, C 3 and C 4, and C 6 and C 1. C 5 is single bonded to O H. The benzene ring is fused with another 6-membered hexagonal ring in a vertical orientation such that C 2 and C 3 of the benzene ring are C 6 and C 5 of the hexagonal ring. The second hexagonal ring is fused to a third ring hexagonal ring in a vertical orientation such that C 1 and C 2 of the second ring are C 5 and C 4 of the third ring. The third ring is fused with another 5-membered pentagonal ring in a horizontal orientation such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the pentagonal ring. In the pentagonal ring, C 1 occupies the top right vertex. C 1 is double-bonded to O above. C 5 of the pentagonal ring is wedge bonded to C H 3 above.



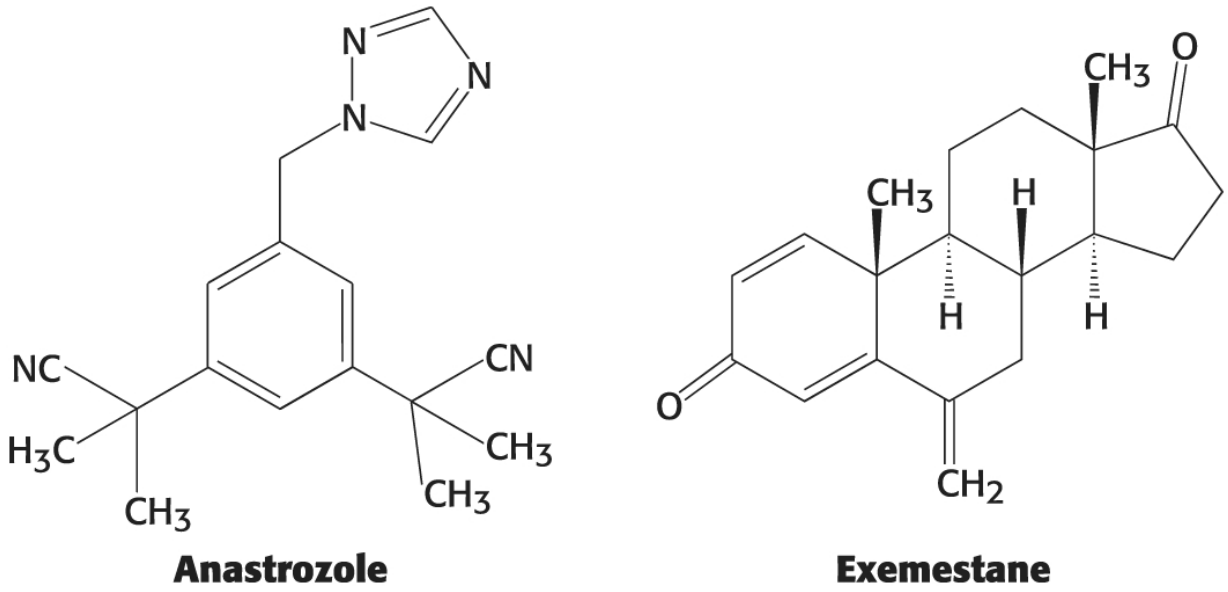
In the fourth irreversible step, testosterone and estrone are both transformed into estradiol.

The structure of estradiol is as follows: A benzene ring in a vertical orientation consists of double bonds between C 1 and C 2, C 3 and C 4, and C 6 and C 1. C 5 is single bonded to O H. The benzene ring is fused with another 6-carbon hexagonal ring in a vertical orientation such that C 2 and C 3 of the benzene ring are C 6 and C 5 respectively of the hexagonal ring. The hexagonal ring is fused to a third ring hexagonal ring in a vertical orientation such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. The third ring is fused with another 5-membered pentagonal ring in a horizontal orientation such that C 2 and C 3 of the third ring are C 5

and C 4 respectively of the pentagonal ring. C 1 of the pentagonal ring is dash bonded to O H above. C 5 of the pentagonal ring is wedge bonded to C H 3 above.

Return to FIGURE 27.29 Progesterone is converted into testosterone and estradiol

Extended description for Formation of 5 alpha-dihydrotestosterone



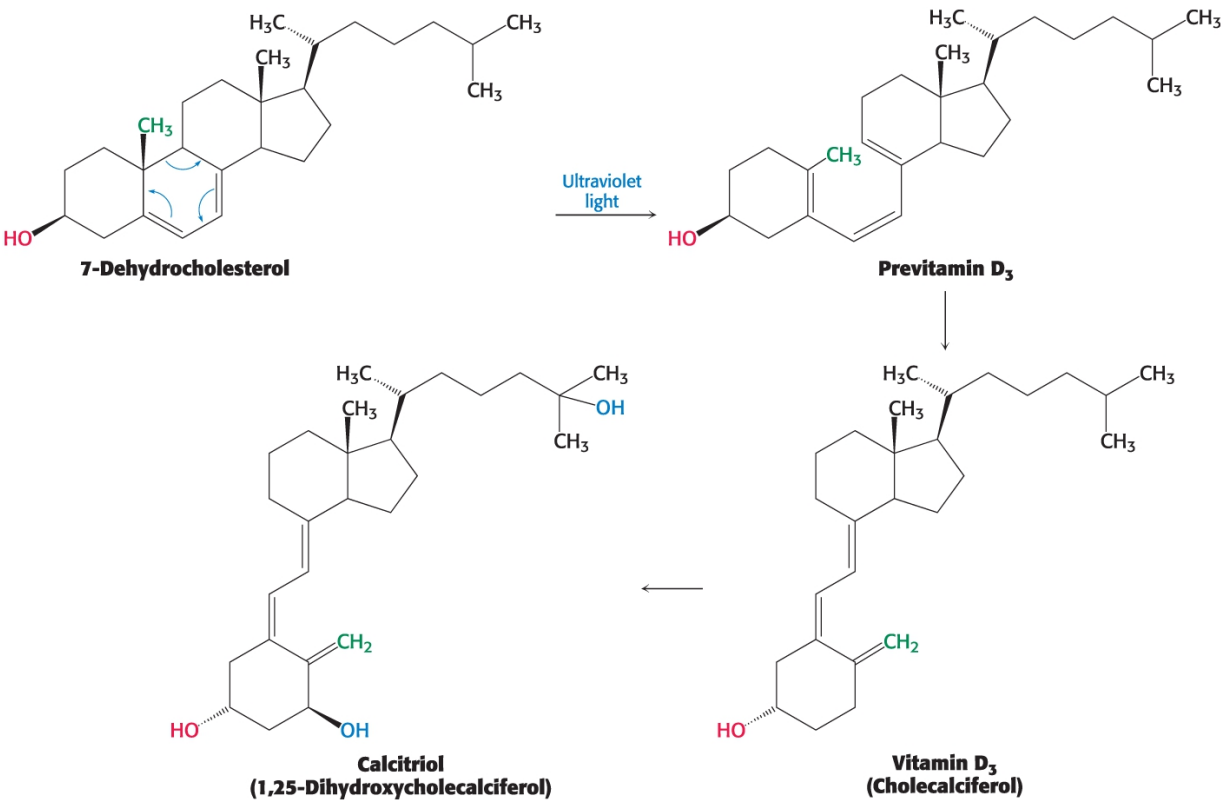
The irreversible reaction depicts the transformation of testosterone to 5 alpha-dihydrotestosterone coupled with the oxidation of N A D P H plus H superscript plus to form N A D P superscript plus. The reaction is catalyzed by 5 alpha-Reductase.

The structure of testosterone is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. The first ring has a double bond between C 3 and C 4. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. C 2 of the first ring is wedge bonded to C H 3. C 5 of the first ring is double bonded to O on the lower left. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. A 5-membered pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 5 of the pentagonal ring is wedge bonded to C H 3 above. C 1 of the fourth ring is wedge bonded to O H.

The structure of 5 alpha-dihydrotestosterone is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. C 2 of the first ring is wedge bonded to C H 3. C 3 is dash bonded to H below. C 5 of the first ring is double bonded to O on the lower left. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. A 5-membered pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 5 of the pentagonal ring is wedge bonded to C H 3 above. C 1 of the fourth ring is wedge bonded to O H.

Return to Formation of 5 alpha-dihydrotestosterone

Extended description for FIGURE 27.30 Structure of anastrozole and exemestane



Anastrozole **Exemestane**

The structure of anastrozole is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single-bonded to a central C atom above. The central C atom is single-bonded to N 1 of a 5-membered heterocyclic pentagonal ring in a horizontal orientation with 2 C and 3 N atoms. N occupies the first, second, and fourth positions respectively. The first N atom occupies the bottom left vertex. Double bonds are present between N 2 and C 1 and N 3 and C 2. C 3 of the benzene ring is single-bonded to a central C atom on the lower right. This C atom is single-bonded to C N on the upper right, C H 3 on the lower right, and C H 3 below. C 5 of the benzene ring is single-bonded to a central C atom on the lower left. This C atom is single-bonded to C N on the upper left, C H 3 on the lower left, and C H 3 below.

The structure of exemestane is as follows: A 6-carbon hexagonal ring is in a vertical orientation with C 1 at the topmost vertex. Double bonds are present between C 3 and C 4 and C 6 and C 1. C 2 is wedge bonded to C H 3 above and C 5 is double bonded to O. The ring is fused with another 6-membered hexagonal ring in a vertical orientation with C 1 at the topmost vertex. C 1 is dash bonded to H below. C 4 is double bonded to C H 2 below. The first ring is fused with the second ring such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. The second ring is fused with the third hexagonal ring in a vertical orientation with C 1 at the topmost vertex. C 2 is wedge bonded to C H 3 above. C 3 is dash bonded to H below. C 4 is wedge bonded to H above. The second and third rings are fused such that C 1 and C 2 of the second ring are C 5 and C 4 of the third ring. The third hexagonal ring is fused with a 5-membered pentagonal ring in a horizontal orientation such that C 2 and C 3 of the hexagonal ring are C 5 and C 4 respectively of the pentagonal ring. C 1 is double bonded to O above.

Return to FIGURE 27.30 Structure of anastrozole and exemestane

Extended description for FIGURE 27.31 Vitamin D is synthesized from 7-dehydrocholesterol in a process initiated by absorption of ultraviolet light

In the first irreversible step, 7-dehydrocholesterol is converted to previtamin D 3 by the action of ultraviolet light.

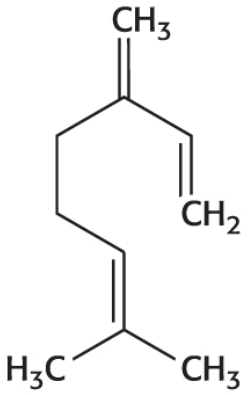
The structure of 7-dehydrocholesterol is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. The second ring has double bonds between C 2 and C 3, and C 4 and C 5. An arrow from the double bond between C 2 and C 3 points toward the single bond between C 3 and C 4. An arrow from the double bond between C 4 and C 5 points to the single bond between C 5 and C 6. An arrow from the single bond between C 6 and C 1 points to the single bond between C 1 and C 2. Both the rings

are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. C 2 of the first ring is wedge bonded to C H 3 above. C 5 of the first ring is wedge bonded to O H on the lower left. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. A 5-carbon pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 5 of the pentagonal ring is wedge bonded to C H 3 above. C 1 of the fourth ring is wedge bonded to a C 1 of a 5-carbon alkane chain depicted as a line structure using 4 zigzag lines. C 1 of the alkane chain is dash bonded to C H 3 on the upper left. C 5 is single-bonded to C H 3 on the upper right and C H 3 below.

The structure of previtamin D 3 is as follows: A 6-carbon hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. C 2 is single bonded to C H 3 on the upper right. C 5 is wedge bonded to O H. A double is present between C 2 and C 3. C 3 is single bonded to C H on the lower right in the form of a line. C H is double bonded to another C H on the upper right. This C H is single bonded to C 4 of a second 6-carbon hexagonal ring in a vertical orientation. In the second ring, a double bond is present between C 4 and C 5. The second ring is fused to a 5-carbon pentagonal ring in a horizontal orientation such that C 2 and C 3 of the second ring are C 5 and C 4 respectively of the pentagonal ring. C 1 of the pentagonal ring is wedge bonded to C 1 of a 5-carbon alkane chain depicted as a line structure using 4 zigzag lines. In the alkane chain, C 1 is dash bonded to C H 3 on the upper left. C 5 is single bonded to C H 3 on the upper right and C H 3 below. C 5 of the pentagonal ring is wedge bonded to C H 3 above.

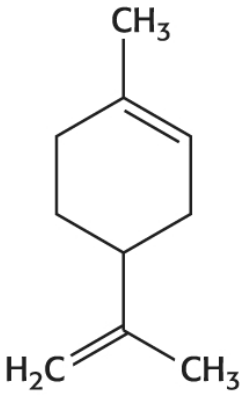
In the second irreversible step, previtamin D 3 is transformed into vitamin D 3 (cholecalciferol).

The structure of vitamin D 3 (cholecalciferol) is as follows: A 6-carbon hexagonal ring in vertical orientation has C 1 occupying the topmost vertex. The hexagonal ring is fused to a 5-membered pentagonal ring in a horizontal orientation with C 1 occupying the top right vertex. The rings are fused such that C 2 and C 3 of the hexagonal ring are C 5 and C 4 respectively of the pentagonal ring. C 5 of the pentagonal ring is wedge bonded to C H 3 above. C 1 of the pentagonal ring is wedge bonded to C 1 of a 5-carbon alkane chain depicted as a line structure using 4 zigzag lines. In the alkane chain, C 1 is dash bonded to C H 3 on the upper left. C 5 is single-bonded to C H 3 on the upper right and C H 3 below. C 4 of the hexagonal ring is double-bonded to a 2-carbon alkane chain depicted as a line structure using a line. C 2 of the alkane chain is double-bonded to C 1 of a 6-carbon hexagonal ring in a vertical orientation. C 2 of the hexagonal ring is double-bonded to C H 2 and C 5 is dash bonded to O H.



In the third irreversible step, vitamin D 3 (cholecalciferol) is converted to calcitriol (1, 25-dihydroxycholecalciferol).

The structure of calcitriol (1, 25-dihydroxycholecalciferol) is as follows: A 6-carbon hexagonal ring in vertical orientation has C 1 occupying the topmost vertex. The hexagonal ring is fused to a 5-membered pentagonal ring in a horizontal orientation with C 1 occupying the top right vertex. The rings are fused such that C 2 and C 3 of the hexagonal ring are C 5 and C 4 respectively of the pentagonal ring. C 5 of the pentagonal ring is wedge bonded to C H 3 above. C 1 of the pentagonal ring is wedge bonded to C 1 of a 5-carbon alkane chain depicted as a line structure using 4 zigzag lines. C 1 is dash bonded to C H 3 on the upper left. C 5 is single-bonded to C H 3 on the upper right, O H on the right, and C H 3 below. C 4 of the hexagonal ring is double-bonded to a 2-carbon alkane chain depicted as a line structure using a line. C 2 of the alkane chain is double-bonded to C 1 of a 6-carbon hexagonal ring in a vertical



orientation. C 2 of the hexagonal ring is double-bonded to C H 2. C 3 is wedge bonded to O H, and C 5 is dash bonded to O H.

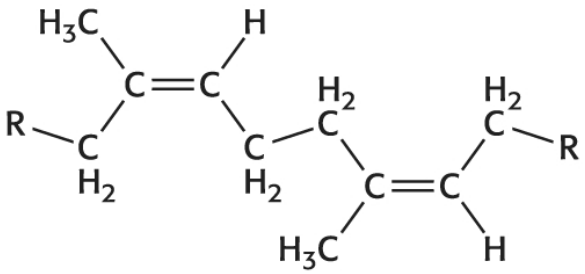
Extended description for FIGURE 27.32 Some terpenes are familiar from everyday life



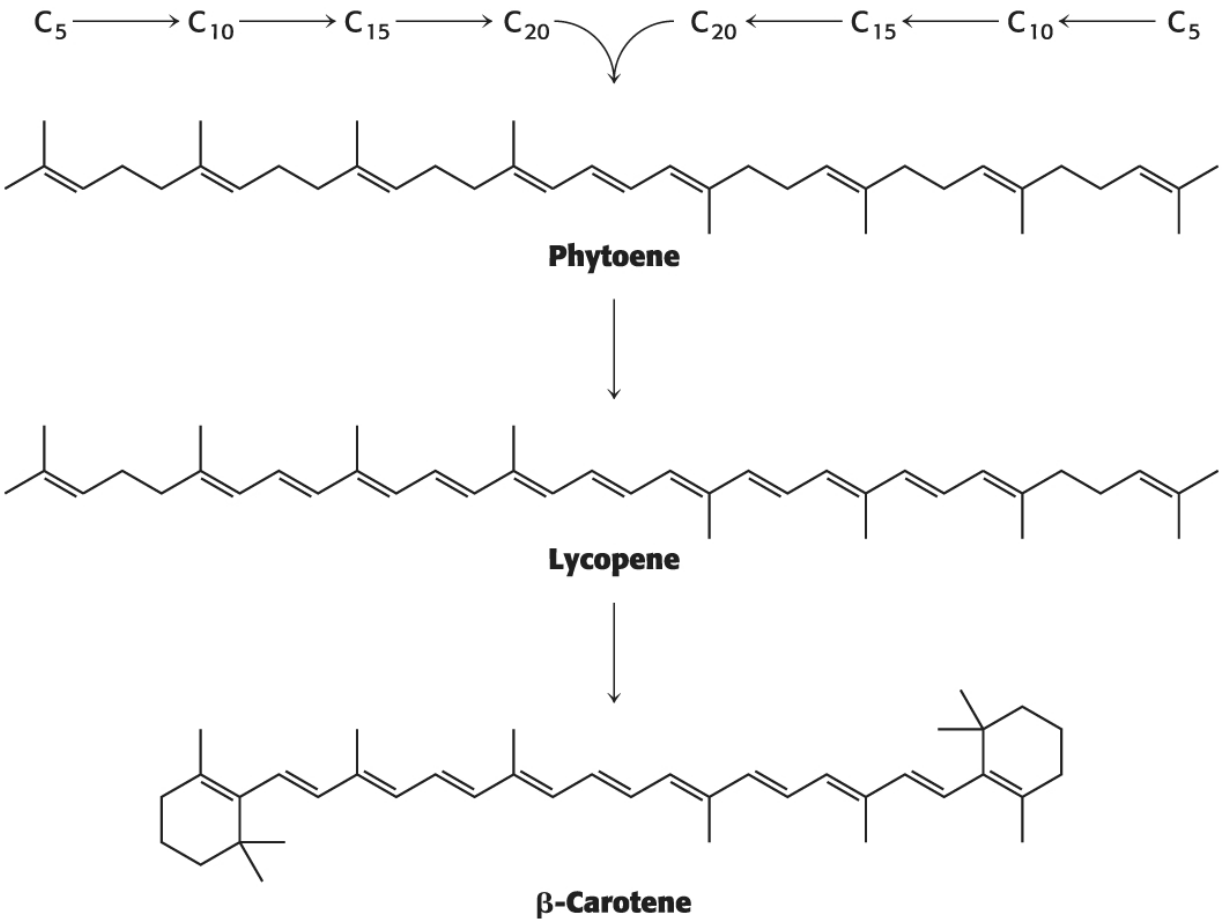
Myrcene
(found in bay leaves, hops, and cannabis)

Limonene
(natural lemon scent)

Zingiberene
(gives ginger its distinct flavor)

***cis*-Polyisoprene**
(natural rubber)

The structure of myrcene (found in bay leaves, hops, and cannabis) is as follows: A 6-carbon alkene chain is depicted as a line structure using 5 zigzag lines. A double bond is present between C 5 and C 6. C 1 is double bonded to C H 2 below. C 2 is double bonded to C H 3 above. C 6 is single bonded to C H 3 on the lower left and C H 3 on the lower right.



The structure of limonene (natural lemon scent) is as follows: A 6-carbon hexagonal ring is in a vertical orientation with C 1 at the topmost vertex. A double bond is present between C 1 and C 2. C 1 is single bonded to C H 3 above. C 4 is single-bonded to a central C atom below. The central C atom is double-bonded to C H 2 on the lower left and single-bonded to C H 3 on the lower right.

The structure of zingiberene that gives ginger its distinct flavor is as follows: A 6-carbon hexagonal ring is in a vertical orientation with C 1 at the topmost vertex. A double bond is present between C 3 and C 4. C 3 is single bonded to C H 3 on the lower right. C 6 is double bonded to a 5-carbon alkene chain depicted as a line structure using 4 zigzag lines. A double bond is present between C 4 and C 5. C 1 is single bonded to C H 3 above. C 5 is single bonded to C H 3 on the lower left and C H 3 on the lower right.

The structure of cis-polyisoprene (natural rubber) is as follows: C, double bond, C. C 1 is single bonded to C H 3 on the upper left and single bonded to C H 2 on the lower left. C H 2 is single bonded to R on the upper left. C 2 is single bonded to H on the upper right and single bonded to C H 2 on the lower right. C H 2 is single-bonded to C H 2 on the upper right. This C H 2 is single bonded to C on the lower right. C is single-bonded to C H 3 on the lower left and double-bonded to another C on the right. The right C is single bonded to C H 2 on the upper right and single bonded to H on the lower right. C H 2 on the upper right is single-bonded to R on the right.

Return to FIGURE 27.32 Some terpenes are familiar from everyday life

Extended description for FIGURE 27.33 Two carotenoids responsible for the color of tomatoes and carrots are large isotrenes

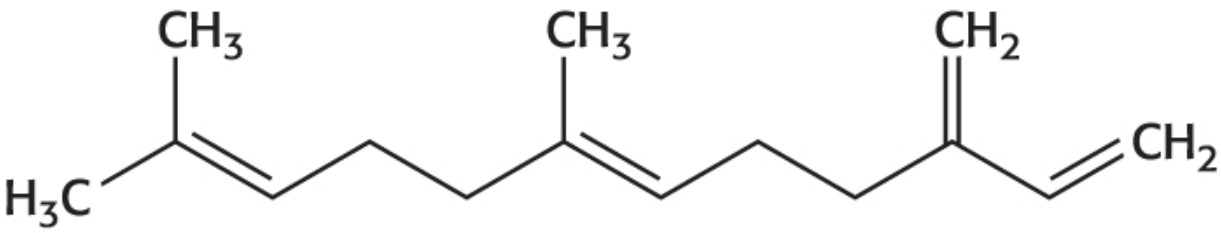
In the first irreversible step, phytoene is transformed into lycopene.

The structure of phytoene is as follows: A 32-carbon alkene chain is depicted as a line structure using 31 zigzag lines. Double bonds are present between C 2 and C 3, C 6 and C 7, C 10 and C 11, C 14 and C 15, C 16 and C 17, C 18 and C 19, C 22 and C 23, C 26 and C 27, and C 30 and C 31. C 2, C 6, C 10, and C 14 are each single bonded to C H 3

above in the form of a line. C 19, C 23, C 27, and C 31 are each single bonded to C H 3 below in the form of a line.

The structure of lycopene is as follows: A 32-carbon alkene chain is depicted as a line structure using 31 zigzag lines. Double bonds are present between C 2 and C 3, C 6 and C 7, C 8 and C 9, C 10 and C 11, C 12 and C 13, C 14 and C 15, C 16 and C 17, C 18 and C 19, C 20 and C 21, C 22 and C 23, C 24 and C 25, C 26 and C 27, and C 30 and C 31. C 2, C 6, C 10, and C 14 are each single bonded to C H 3 above in the form of a line. C 19, C 23, C 27, and C 31 are each single bonded to C H 3 below in the form of a line.

In the second irreversible step, lycopene undergoes cyclization to form beta-carotene.



The structure of beta-carotene is as follows: A 6-carbon hexagonal ring is in a vertical orientation with C 1 at the topmost vertex. A double bond is present between C 1 and C 2. C 1 is single bonded to C H 3 above in the form of a line. C 3 is single bonded to C H 3 on the right and C H 3 on the lower right in the form of a line. C 2 of the hexagonal ring is single-bonded to C 1 of an 18-carbon alkene chain depicted as a line structure using 17 zigzag lines. Double bonds are present between C 1 and C 2, C 3 and C 4, C 5 and C 6, C 7 and C 8, C 9 and C 10, C 11 and C 12, C 13 and C 14, C 15 and C 16, and C 17 and C 18. C 3 and C 7 are each single bonded to C H 3 above in the form of a line. C 12 and C 16 are each single bonded to C H 3 below in the form of a line. C 18 of the alkene chain is single-bonded to C 5 of a hexagonal ring in a vertical orientation with C 1 at the topmost vertex. A double bond is present between C 4 and C 5. C 4 is single bonded to C H 3 below in the form of a line. C 6 is single bonded to C H 3 on the right and C H 3 on the top right in the form of a line.

On the top of phytoene, a flow chart is present horizontally. The flowchart from both sides converges at C 16 of the alkene chain of

phytoene. From left to right the flow chart is as follows: C 5, forward arrow, C 10, forward arrow, C 15, forward arrow, C 20. The flow chart from right to left is C 5, left arrow, C 10, left arrow, C 15, left arrow, C 20. C 20 from the left and right flow chart converges above C 16 of the alkene chain and points downward.

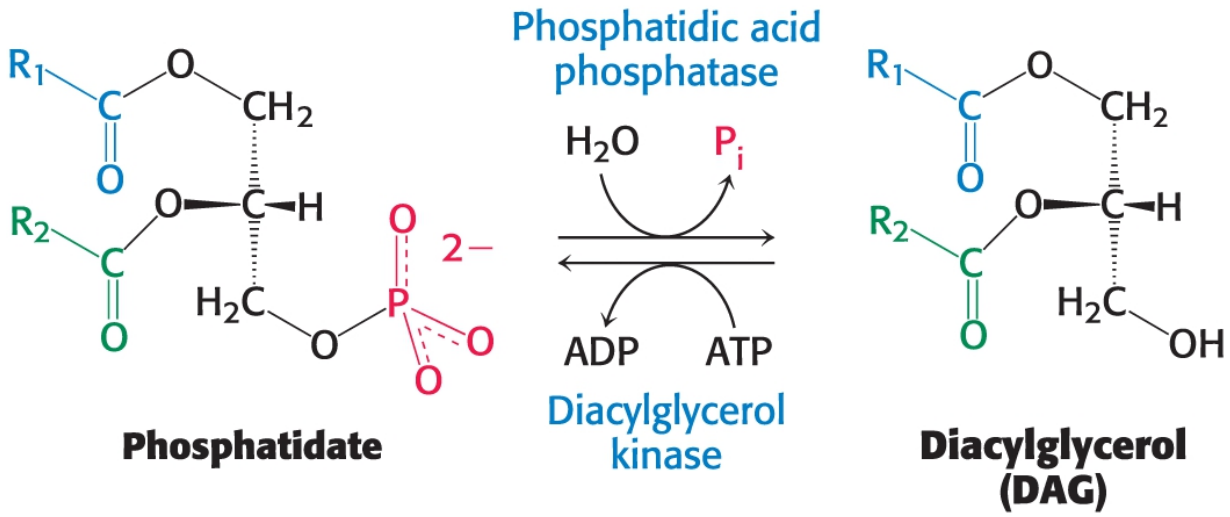
Extended description for Structure of farnesene



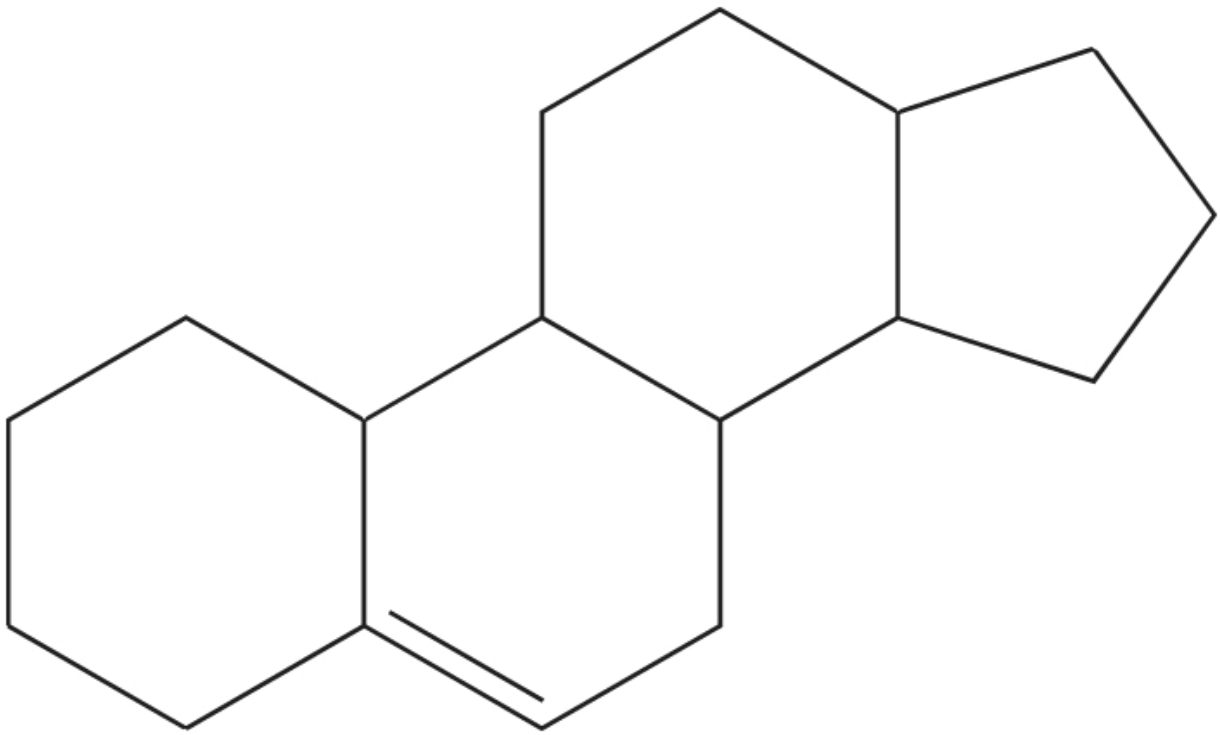
Farnesene

The structure of farnesene is as follows: A 10-carbon alkene chain is depicted as a line structure using 9 zigzag lines. Double bonds are present between C 1 and C 2, and C 5 and C 6. C 1 is single bonded to C H 3 on the lower left and C H 3 above. C 5 is single bonded to C H 3 above. C 9 is double bonded to C H 2 above. C 10 is double bonded to C H 2 on the upper right.

Return to Structure of farnesene

Extended description for Formation of diacylglycerol from phosphatidate

The figure shows a reversible reaction in which phosphatidate is converted to diacylglycerol by the action of phosphatidic acid phosphatase. It is coupled with the entry of H 2 O and the release of P subscript i. Diacylglycerol can be converted back to phosphatidate by the action of diacylglycerol kinase. It is coupled with the breakdown of A T P to A D P.

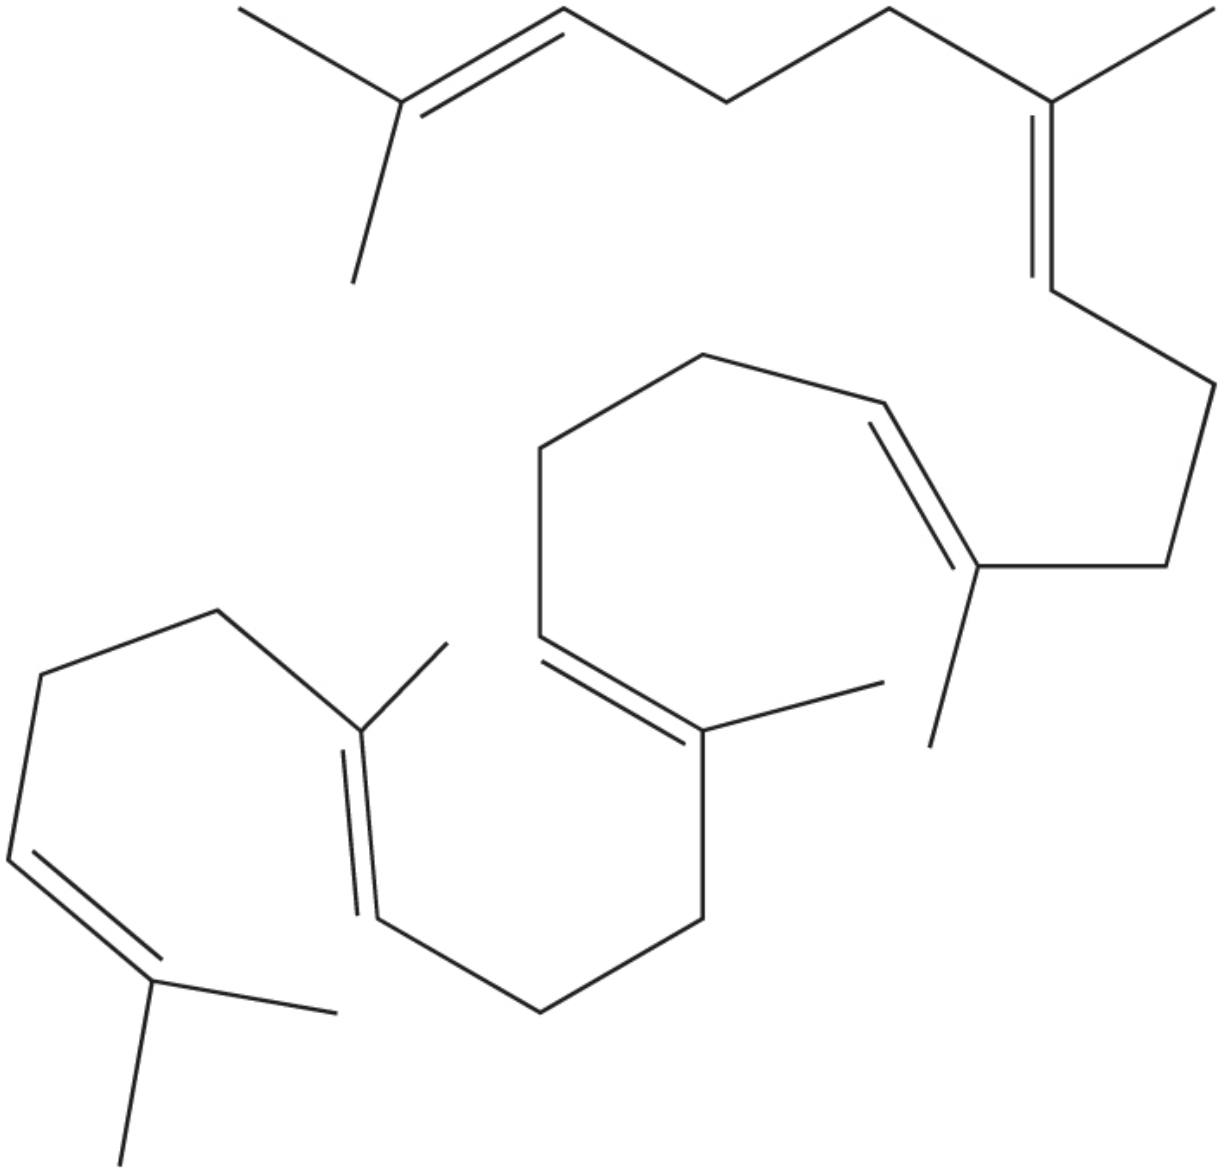


The structure of phosphatidate is as follows: A central C atom is dash bonded to C H 2 above and C H 2 below. The central C atom is also wedge bonded to O on the left and H on the right. C H 2 above is single-bonded to O on the upper left. O is single-bonded to C on the lower left. This C atom is single-bonded to R subscript 1 on the upper left and double-bonded to O below. The left O wedge bonded to the central C atom is single-bonded to C on the lower left. C is single-bonded to R subscript 2 on the upper left and double-bonded to O below. C H 2 dash bonded to the central C atom below is single-bonded to O on the lower right. This O atom is single-bonded to P on

the upper right. P is partially double-bonded to O above, O on the lower right, and O below. The P O O group has an overall charge of 2 minus.

The structure of diacylglycerol (D A G) is as follows: The structure of D A G is the same as phosphatidate except for the absence of the P O O group. The C H 2 that is dash bonded to the central C atom below is single-bonded to O H on the lower right.

Return to Formation of diacylglycerol from phosphatidate

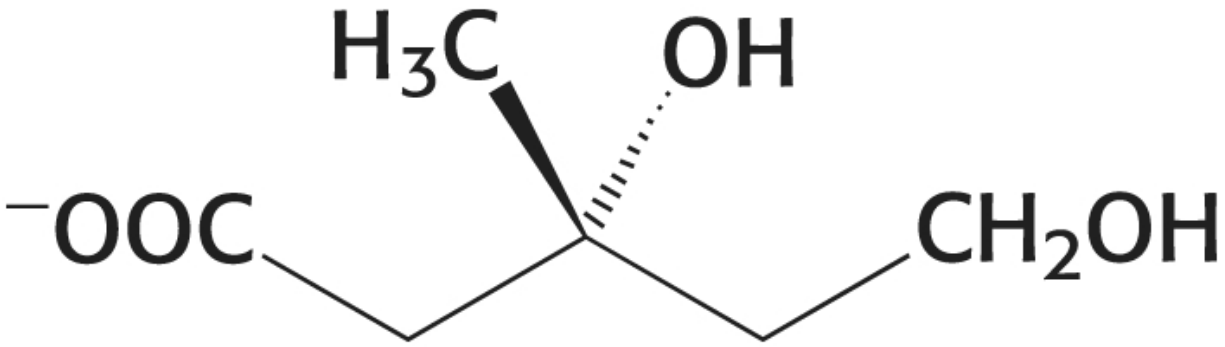


Extended description for Fused-ring core structure of a steroid

The structure is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. The second ring has a double bond between C 4 and C 5. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. A 5-carbon pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring.

Return to Fused-ring core structure of a steroid

Extended description for Structure of a compound



The structure of the compound is as follows: A 5-carbon alkene chain is depicted as a line structure using 4 zigzag lines. A double bond is present between C 1 and C 2. C 1 is single bonded to C H 3 on the upper left and C H 3 below in the form of a line. C 5 is single bonded to C H 3 in the form of a line on the upper right and double bonded to C H below. This C H group is single-bonded to a C H 2

group on the lower right in the form of a line. This C H 2 group is single-bonded to C H 2 on the lower left in the form of a line. This C H 2 is single-bonded to C 1 of a 14-carbon alkene chain on the left depicted as a line structure using 13 zigzag lines. A double bond is present between C 1 and C 2, C 5 and C 6, C 9 and C 10, and C 13 and C 14. C 1 is single-bonded to C H 3 in the form of a line on the lower left. C 6 is single bonded to C H 3 on the lower right in the form of a line. C 10 is single bonded to C H 3 on the upper right in the form of a line. C 14 is single bonded to C H 3 in the form of a line on the lower left and lower right.

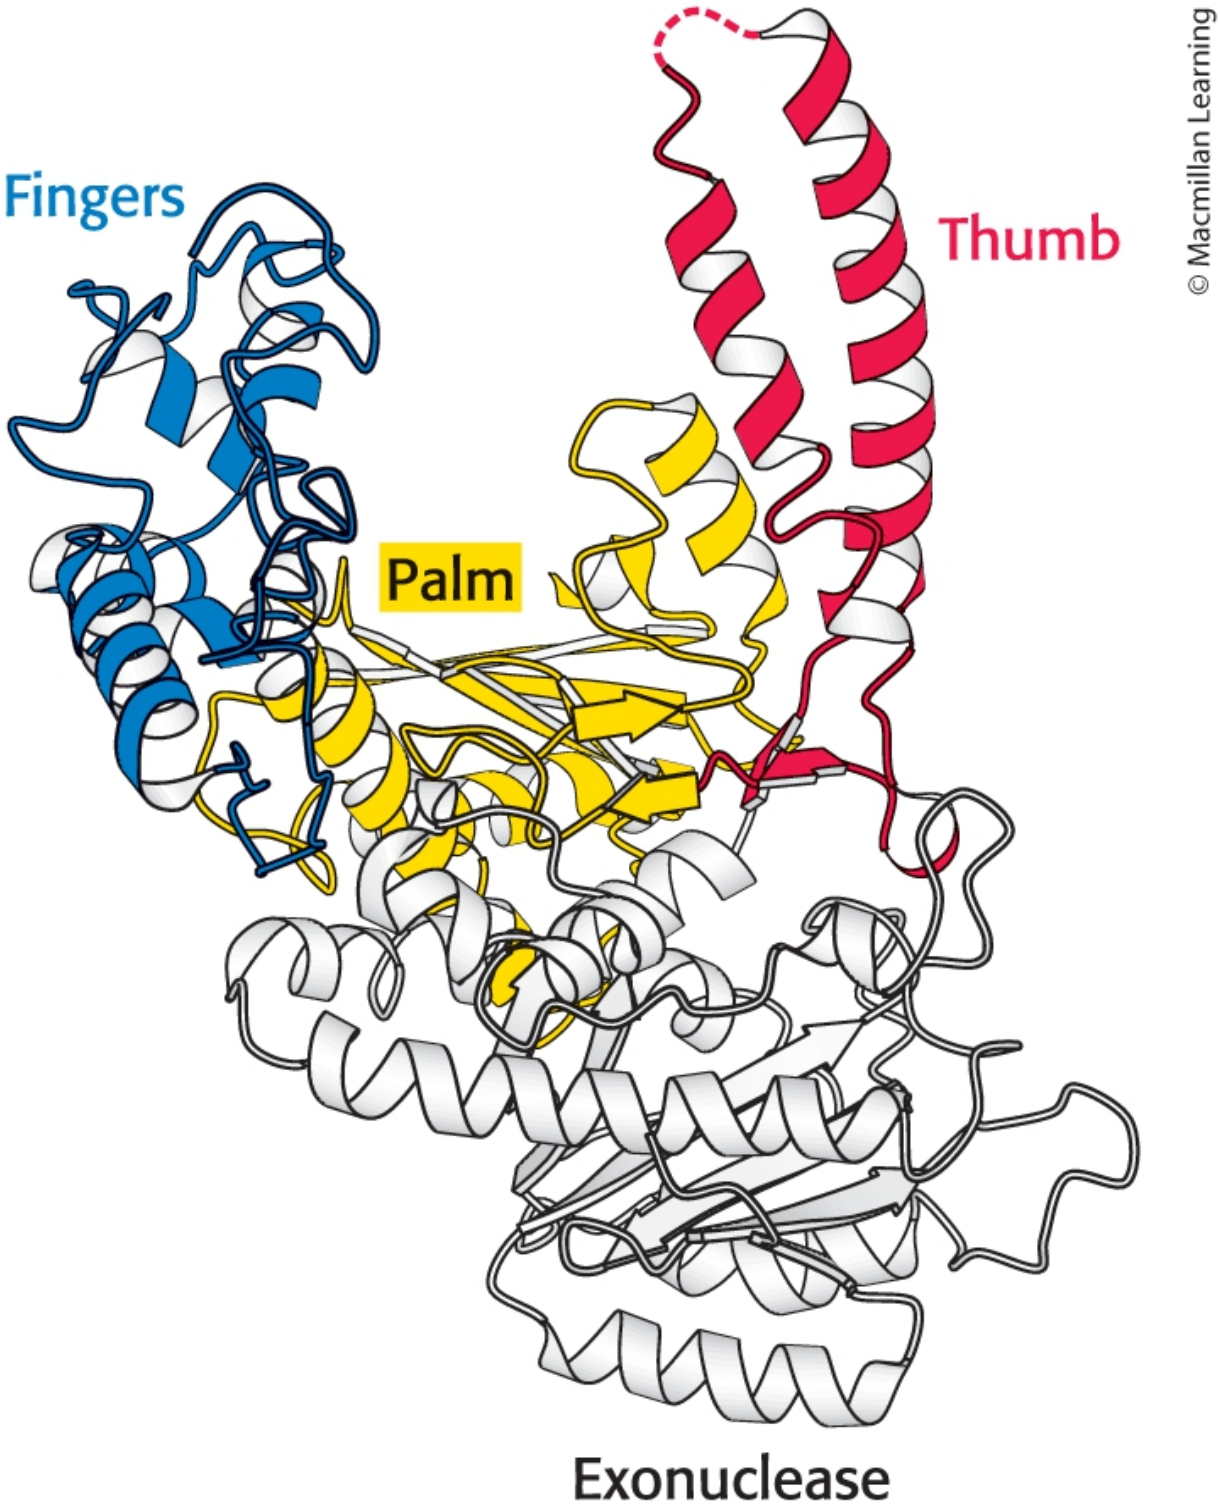
Extended description for Ribbon diagram of D N A polymerase copying D N A



The ribbon diagram of D N A polymerase consists of several alpha-helices and a few beta-strands. A large hollow space is located in the center of the polymerase. A section of a double helix with a single complete turn is shown entering the hollow space of the polymerase. The D N A is composed of red and blue strands. The red strand is labeled template D N A. It extends outside the hollow center. A short blue fragment depicting newly synthesized D N A is shown outside the hollow center.

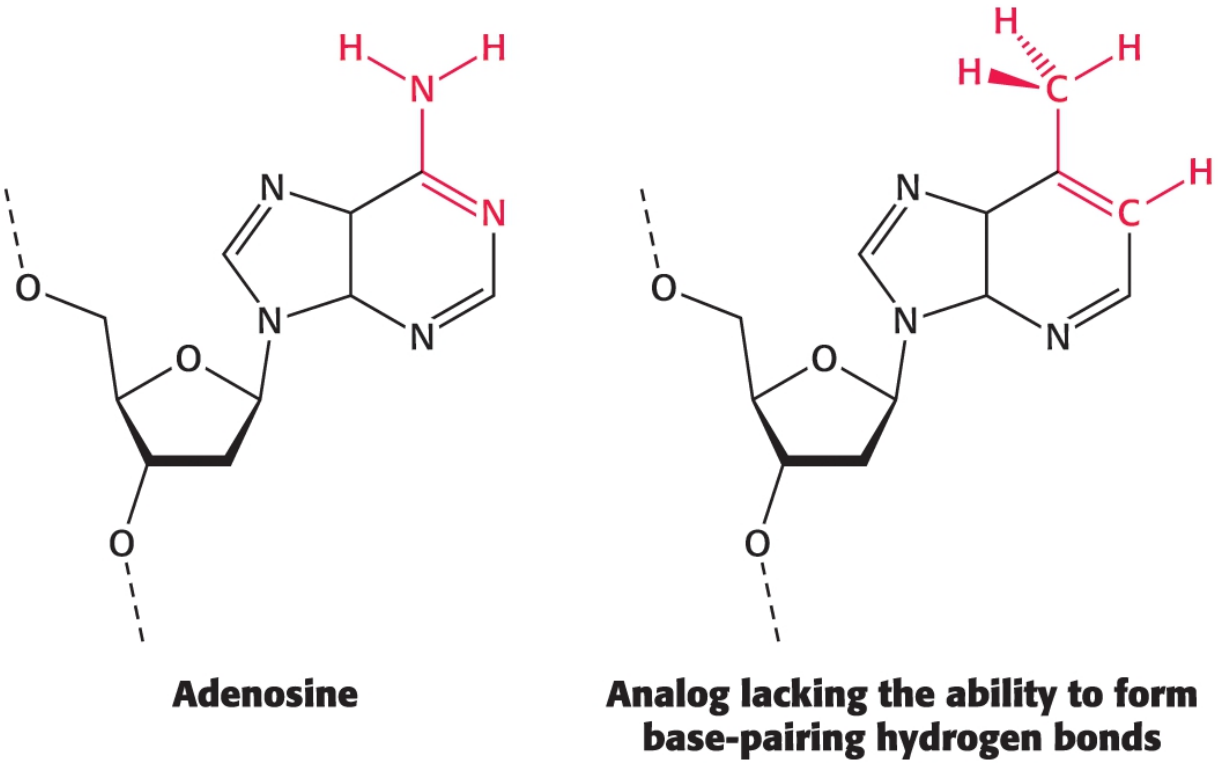
A polymerase reaction

© Macmillan Learning

The metal ions, primer, d N T P, and amino acid residues are depicted as ball-and-stick models. The primer is shown on the top left. It consists of a pentagonal ring in vertical orientation composed of 1 red and 4 black spheres. The red sphere occupies the top left vertex. The topmost black sphere is connected to a 6-membered heterocyclic hexagonal ring. The side view of the hexagonal ring is shown. The ring consists of 2 blue and 4 black spheres. Two of the black spheres are connected to a red sphere. The bottom right black sphere of the pentagonal ring is connected to a red sphere. In the primer, the spheres are connected by blue-colored sticks.

A similar d N T P molecule is shown on the top right. Its structure is the same as a primer, except the bottom left sphere is connected to a chain of 2 red and 3 purple spheres through a black sphere. The red spheres occupy the second and fourth positions. The purple spheres occupy the remaining positions. The first and third purple spheres are connected to 3 red spheres. The second purple sphere is connected to two red spheres. In d N T P, the spheres are connected by red-colored sticks.

The first green sphere depicting M superscript 2 plus ion is located below the pentagonal ring of d N T P. It is connected to the second red sphere of the chain through a dashed line. An arrow from the red sphere connected to the bottom right black sphere of the pentagonal ring of the primer points toward the black sphere connected to the chain of red and purple spheres.



The side chain of glutamic acid, two aspartic acids, and one methionine residue is located below. The glutamic acid side chain consists of a chain of 2 red and 4 black spheres. The aspartic acid side chain consists of 3 black spheres. One of the black spheres is connected to two red spheres. The methionine side chain is composed of a chain of 1 yellow, 1 red, and 5 black spheres.

One red sphere of the two aspartic acid side chains and the methionine side chain is connected to a second central green sphere through a dashed line. One red sphere connected to the first, second, and third purple spheres of the chain is also connected to the second green sphere through a dashed line. The green sphere depicts M superscript 2 plus.

The third green sphere is connected to the red sphere of the glutamic acid side chain, red sphere of the second aspartic acid side chain, and the red sphere connected to the first purple sphere, through a dashed line.

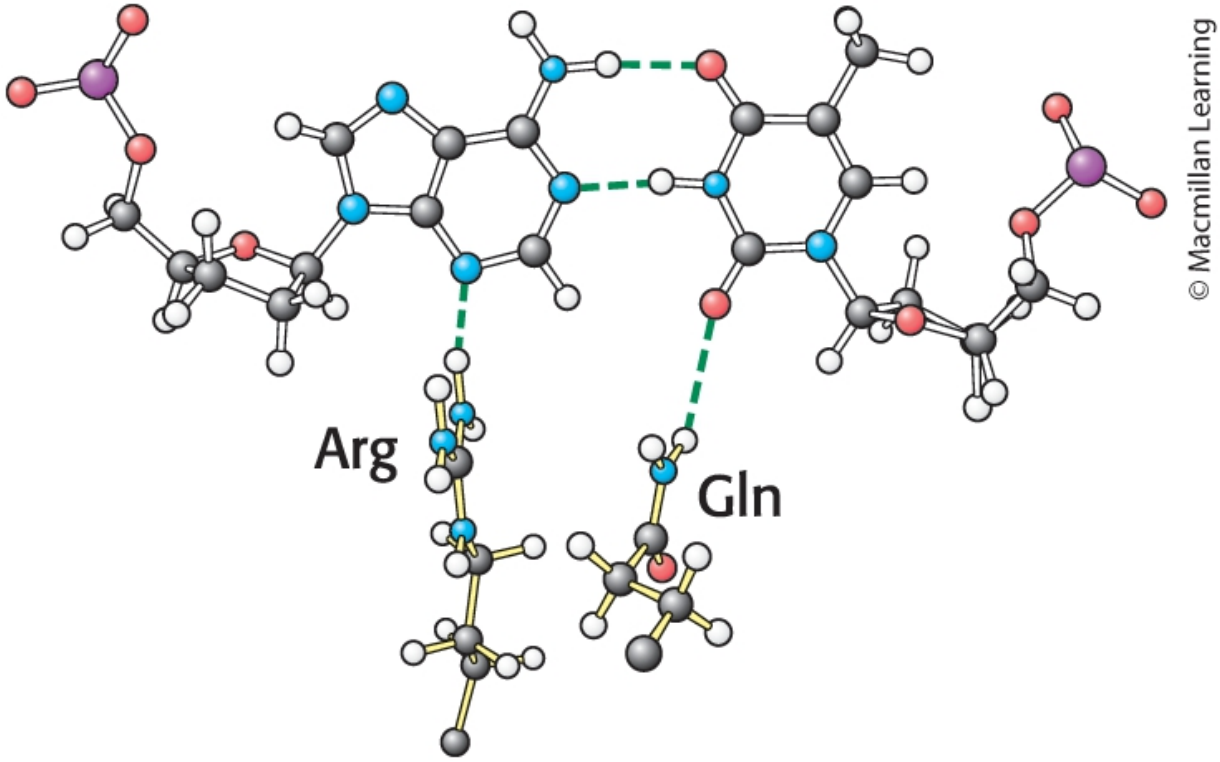
Extended description for FIGURE 28.3 Base analogs that have the same shape as normal bases can participate in D N A replication



The structure of adenosine is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 occupies the top right vertex. C 3 is single bonded to O below, which has a dashed line below. C 4 is single bonded to C H 2 above in the form of a line. C H 2 is single-bonded to O on the upper left. O has a dashed line above. C 1 is single-bonded to N 1 of a 5-membered heterocyclic pentagonal ring in a horizontal orientation. It consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the top left vertex. C 1 occupies the leftmost vertex. A double bond is present between C 1 and N 2. It is fused to a 6-membered

heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. The hexagonal ring is composed of 2 N and 4 C atoms. The first N occupies the top right vertex and the second N occupies the bottom-most vertex. A double bond is present between C 1 and N 2, and C 4 and N 1. C 4 is single bonded to N above. N is single-bonded to H on the upper left and H on the upper right.

The structure of the analog of adenosine is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 occupies the top right vertex. C 3 is single bonded to O below, which has a dashed line below. C 4 is single bonded to C H 2 above in the form of a line. C H 2 is single-bonded to O on the upper left. O has a dashed line above. C 1 is single-bonded to N 1 of a 5-membered heterocyclic pentagonal ring in a horizontal orientation. It consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the top left vertex. C 1 occupies the leftmost vertex. A double bond is present between C 1 and N 2. It is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. The hexagonal ring is composed of 1 N and 5 C atoms. N occupies the bottom-most vertex. A double bond is present between C 3 and C 4, and C 5 and N. C 3 is single bonded to C above. This C is wedge bonded to H on the left, dash bonded to H on the upper left, and single bonded to H on the upper right. C 4 is single bonded to H on the upper right. The text below the analog of adenosine reads "Analog lacking the ability to form base-pairing hydrogen bonds."

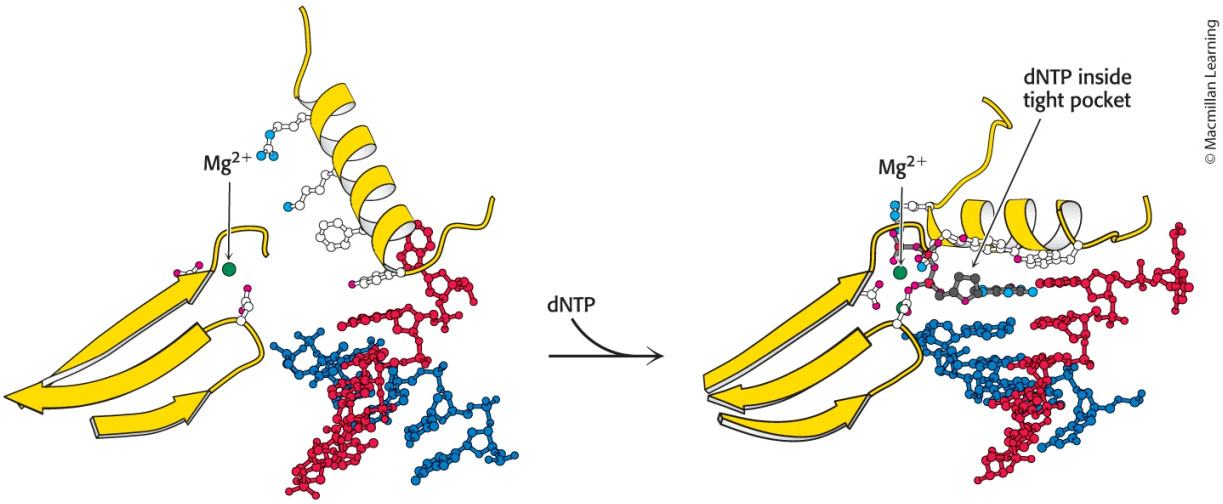
Return to FIGURE 28.3 Base analogs that have the same shape as normal bases can participate in D N A replication

Extended description for FIGURE 28.4 Minor-groove interactions promote the specificity of D N A replication

The ball-and-stick model of the A T base pair is shown. Base A consists of a fused pentagonal and hexagonal ring. The pentagonal ring is composed of 2 blue and 3 black spheres. The top left black sphere is connected to a white sphere. The hexagonal ring is composed of 2 blue and 4 black spheres. The blue sphere of the pentagonal ring is connected to the black sphere of a flat pentagonal ring composed of 1 red and 4 black spheres. The top left black sphere of this ring is connected to a black sphere on the upper left, which is further connected to a red sphere. The black sphere is also connected to two white spheres. The red sphere is connected to a purple sphere on the upper left. The purple sphere is connected to

two different red spheres. The two black spheres of the flat pentagonal ring, facing toward the observer, are connected to two white spheres. The remaining black spheres of this ring are connected to a single white sphere. The topmost black sphere of the hexagonal ring is connected to a blue sphere, which is further connected to two white spheres. The bottom right black sphere is connected to a white sphere. In the hexagonal ring, one white sphere is connected to the topmost black sphere through the blue sphere and the top right blue sphere is connected to a red sphere and the leftmost blue sphere respectively of the base T. This connection is depicted by a dashed green line.

The base T consists of a horizontal hexagonal ring composed of 2 blue and 4 black spheres. The blue sphere occupies the bottom right and leftmost vertex respectively. The remaining positions are occupied by black spheres. The top left black sphere is connected to a red sphere on the upper left. The top right black sphere is connected to a black sphere on the upper right, which is further connected to two white spheres. The rightmost black sphere is connected to a white sphere on the right. The bottom left black sphere is connected to a red sphere. The bottom right blue sphere is connected to a black sphere of a flat pentagonal ring composed of 1 red and 4 black spheres. The red sphere of this ring faces the observer. Two black spheres of the ring are connected to two white spheres. The remaining black spheres are connected to a single white sphere. One of the black spheres of this ring is connected to a black sphere on the upper right. The upper right black sphere is connected to a red sphere above, which is further connected to a purple sphere on the upper right. The purple sphere is connected to two red spheres.



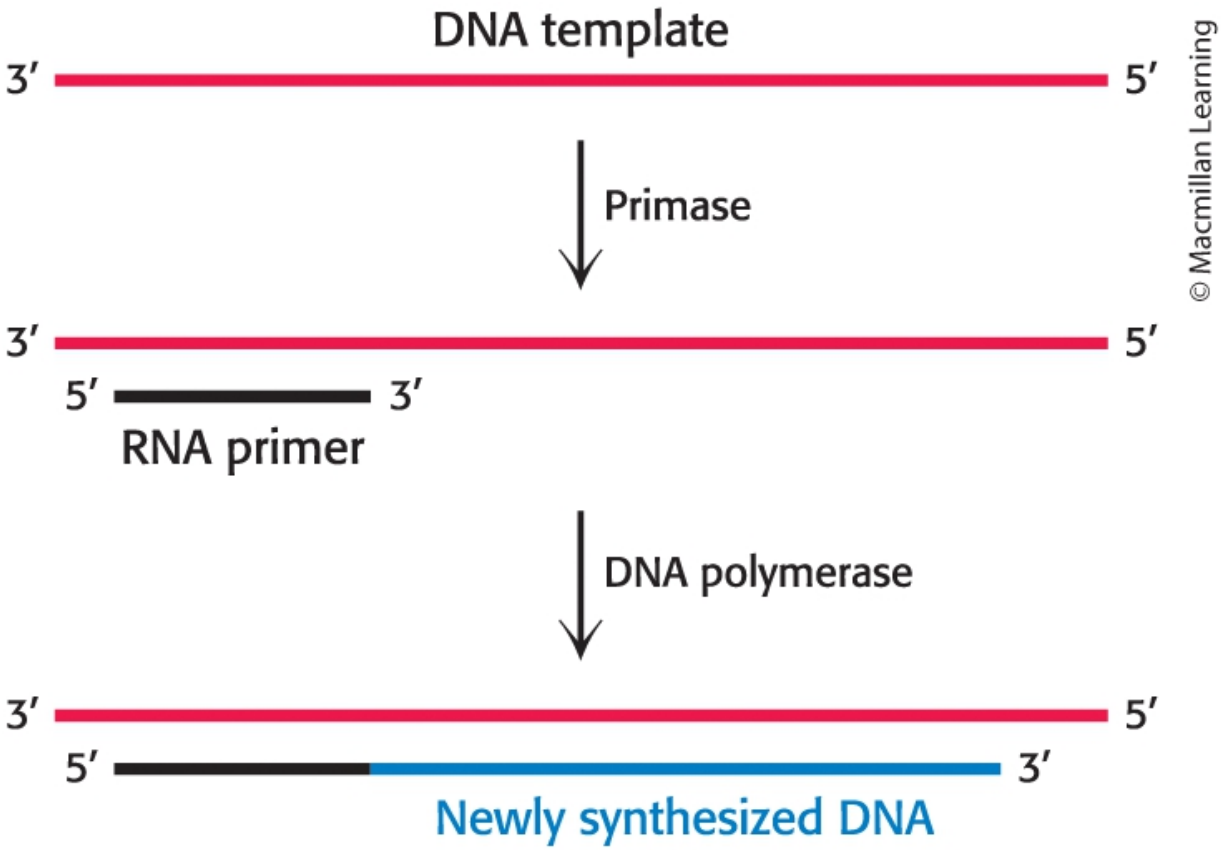
The ball-and-stick models of arginine and glutamine are shown below the A T base pair.

Arginine is located below A and glutamine is located below T. Arginine is composed of a vertical chain of 5 black spheres. The topmost black sphere is connected to two blue spheres. Each of these blue spheres is connected to two white spheres. One of these white spheres is connected to the bottom left blue sphere of the hexagonal ring of base A. The second black sphere from the top is connected to a chain of 1 blue and 1 white sphere, and two different white spheres. The third and fourth black sphere is connected to two white spheres.

Glutamine is composed of a zigzag chain of 4 black spheres. The topmost black sphere is connected to a blue sphere above. This blue sphere is connected to two white spheres. One of these white spheres is connected to a red sphere which in turn is connected to the bottom left black sphere of the hexagonal ring of base T. This connection between the white and red spheres is depicted through a green dashed line. The topmost black sphere of glutamine is also connected to a red sphere. The second and third red spheres of the chain are connected to two white spheres.

Return to FIGURE 28.4 Minor-groove interactions promote the specificity of D N A replication

Extended description for FIGURE 28.5 Shape selectivity promotes the specificity of DNA replication



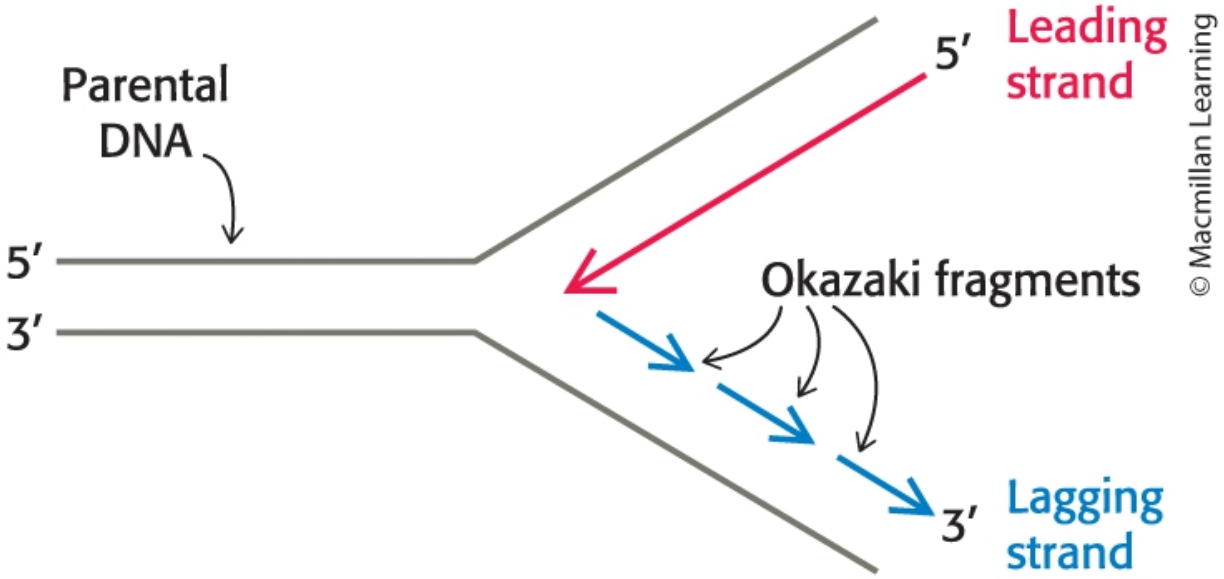
An alpha-helix in diagonal orientation is shown on the top right. Three anti-parallel beta-strands in diagonal orientation are connected by thread-like loops and shown on the bottom right. These secondary structures are separated by a gap. A ball-and-stick model of the D N A double helix is shown below. The different strands of D N A are composed of blue and red spheres. The alpha-helix contains side chains of different amino acids. One of the beta-strand and the loop connecting them also contains a side chain of amino acids. A green sphere labeled M g superscript 2 plus is located above the top-most beta-strand. The D N A strand composed of red spheres extends toward the alpha-helix and is unpaired in this extended region.

A forward arrow shows the conformational change after the addition of d N T P. After the conformational change, the alpha-helix becomes horizontally oriented. The orientation of the beta-strands remains the same. A "d N T P" is shown inside the tight pocket formed after shifting of the position of the helix. This d N T P is

aligned with the unpaired base of the D N A strand composed of red spheres. The location of the M g superscript 2 plus ion is the same.

Return to FIGURE 28.5 Shape selectivity promotes the specificity of DNA replication

Extended description for FIGURE 28.6 D N A polymerases require a primer

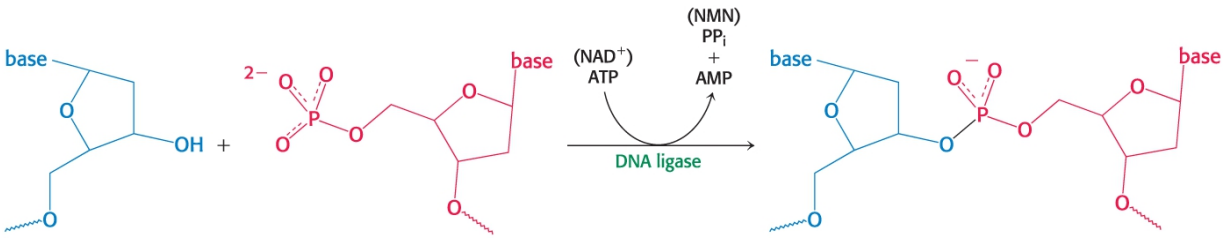


The D N A template is depicted as a horizontal red line. The left end of the D N A template is labeled 3 prime and the right end is labeled 5 prime.

A downward arrow labeled primase is shown below. It shows the attachment of the R N A primer near the 3 prime ends of the D N A template. The R N A primer is depicted as a short horizontal black line. Its left end is labeled 5 prime and the right end is labeled 3 prime. The 5 prime ends of R N A primer is located close to the 3 prime ends.

A downward arrow labeled D N A polymerase is shown below. It shows the synthesis of D N A. A newly synthesized D N A strand is located below the D N A template. It is composed of a short R N A primer at the 5 prime end and the remaining 3 prime region is newly synthesized and shown as a continuous blue line.

Return to FIGURE 28.6 D N A polymerases require a primer



Extended description for FIGURE 28.7 The lagging strand is made in short pieces called Okazaki fragments

A horizontal Y-shaped replication fork is shown. The double-stranded D N A is labeled parental D N A. The 5 prime end of the top D N A strand and 3 prime end of the bottom D N A strand are aligned together. The 3 prime and 5 prime ends of the top and bottom strands are separated to form a Y-shaped structure. The 3 prime end of the top strand is oriented toward the upper right. The 5 prime end of the bottom strand is oriented toward the lower right. A red line parallel to the upper right 3 prime end is labeled leading strand. Its top end is labeled 5 prime and bottom end has an arrowhead pointing toward the replication fork. Three short blue lines separated by short gaps are aligned parallel with the lower right 5 prime end. The bottom end of each blue line has an arrowhead. These short blue lines depict Okazaki fragments. The arrowhead of the terminal Okazaki fragment is labeled 3 prime. These Okazaki fragments are collectively labeled lagging strand.

Return to FIGURE 28.7 The lagging strand is made in short pieces called Okazaki fragments

Extended description for FIGURE 28.8 D N A ligase catalyzes the joining of two D N A strands

The reaction consists of two reactants and one product. It is catalyzed by D N A ligase and coupled with the entry of A T P (N A D superscript plus) and release of A M P plus (N M N) P P subscript i.

The structure of the first reactant is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the leftmost vertex. C 1 is single-bonded to base on the upper right. C 3 is single bonded to O H on the right. C 4 is single bonded to C H 2 on the lower left in the form of a line. C H 2 is single bonded to O below. This O has a wiggly line on the lower left.

The structure of the second reactant is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single-bonded to the base above. C 3 is single bonded to O on the lower left. This O has a wiggly line on the lower right. C 4 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single-bonded to O on the lower left. This O is single-bonded to P on the upper left. P is partially double-bonded to O on the upper left, O on the upper right, and O on the lower left. The P O O group has an overall negative charge of 2 minus.

The structure of the product is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the leftmost vertex. C 1 is single-bonded to base on the upper right. C 3 is single bonded to O on the right. C 4 is single bonded to C H 2 on the lower left in the form of a line. C H 2 is single bonded to O below. This O has a wiggly line on the lower left. The O bonded to C 3 of the ring is further single bonded to P on the upper right. This P is partially double-bonded to O on the upper left and upper right, and single-bonded to O on the lower right. The lower right O is single bonded to C H 2 on the upper right in the form of a line. This C H 2 is single-bonded to C 4 of a 5-membered heterocyclic pentagonal ring in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single-bonded to the base above. C 3 is single bonded to O on the lower left. This O has a wiggly line on the lower right.

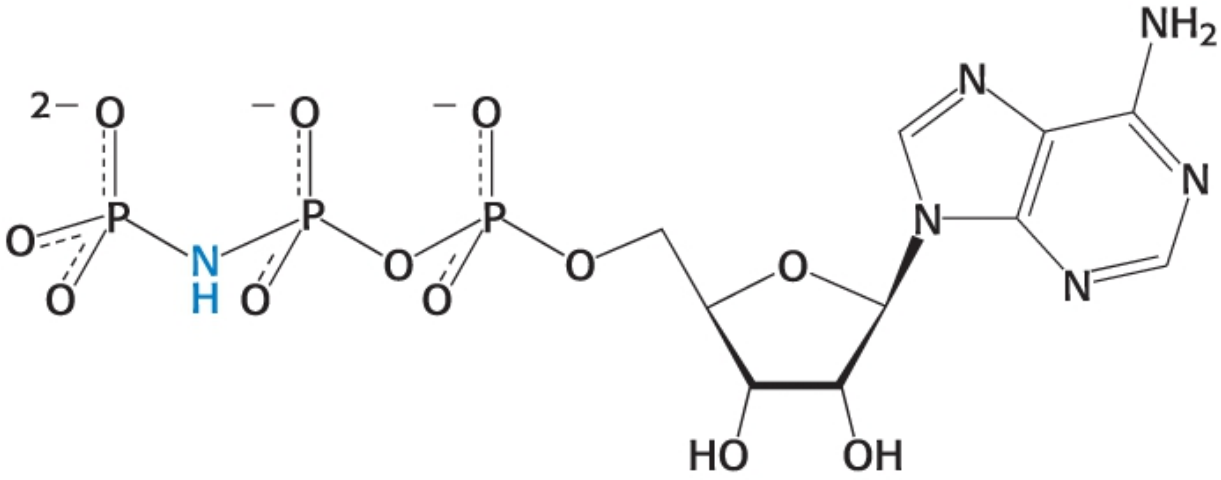
Extended description for FIGURE 28.9 Helicases are hexamers



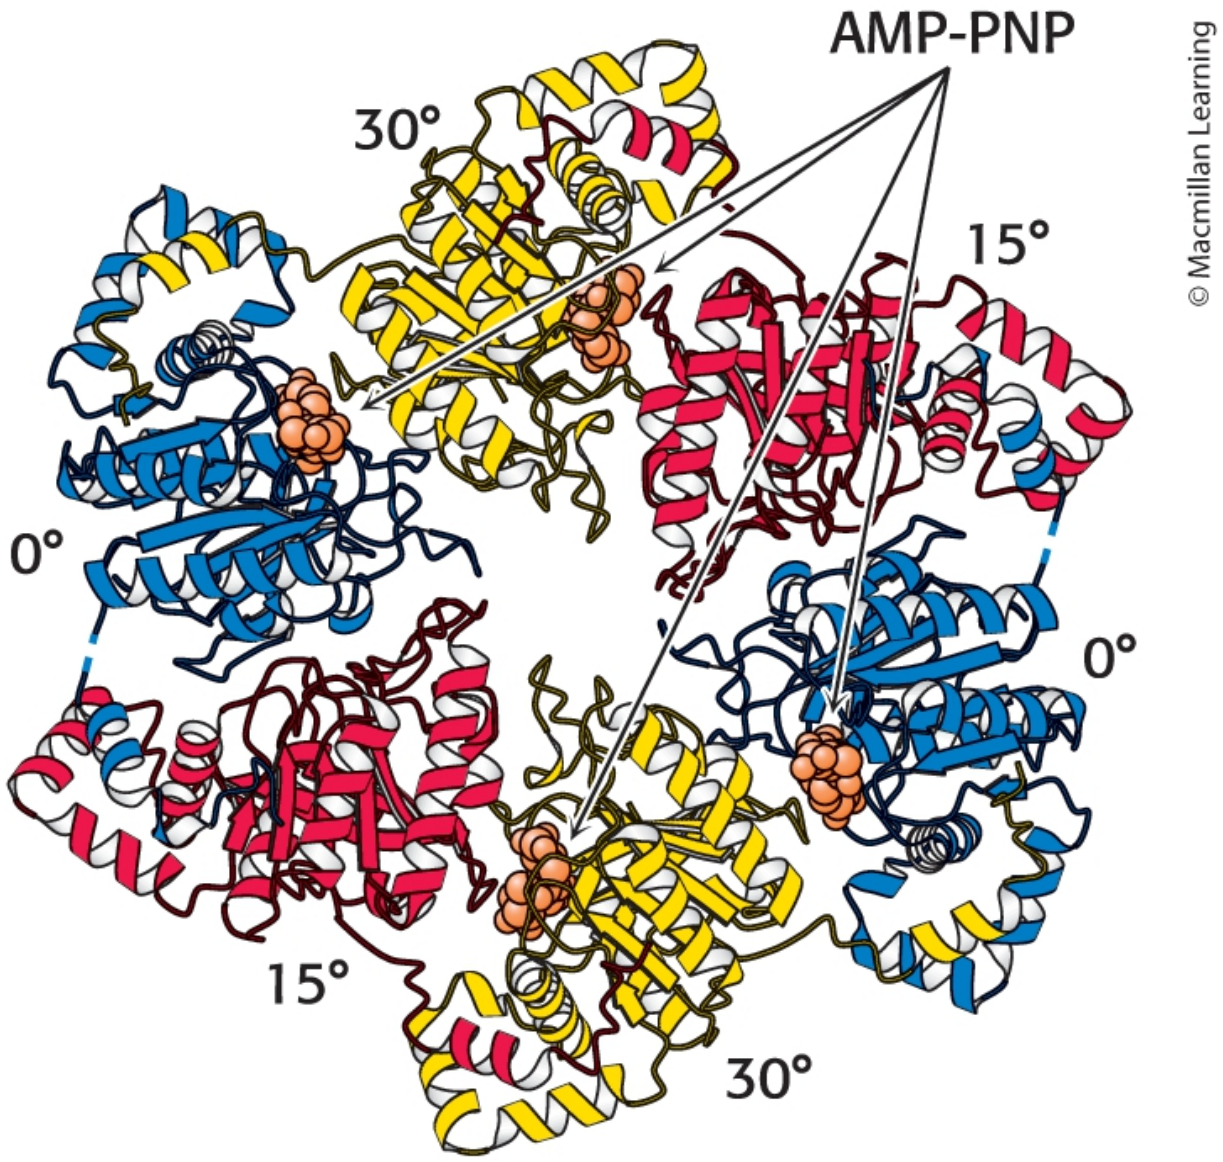
© Macmillan Learning

The helicase is a hexamer composed of 6 subunits. The subunits are arranged in a circular fashion with a hollow center. The subunits are located at the top, bottom, top left, bottom left, top right, and bottom right. Each subunit is composed of several alpha-helices and

a few beta-strands interconnected by loops. Loops from each subunit line the hollow center. The loop of the top subunit is highlighted inside a yellow oval.

Return to FIGURE 28.9 Helicases are hexamers

Extended description for Structure of A M P-P N P



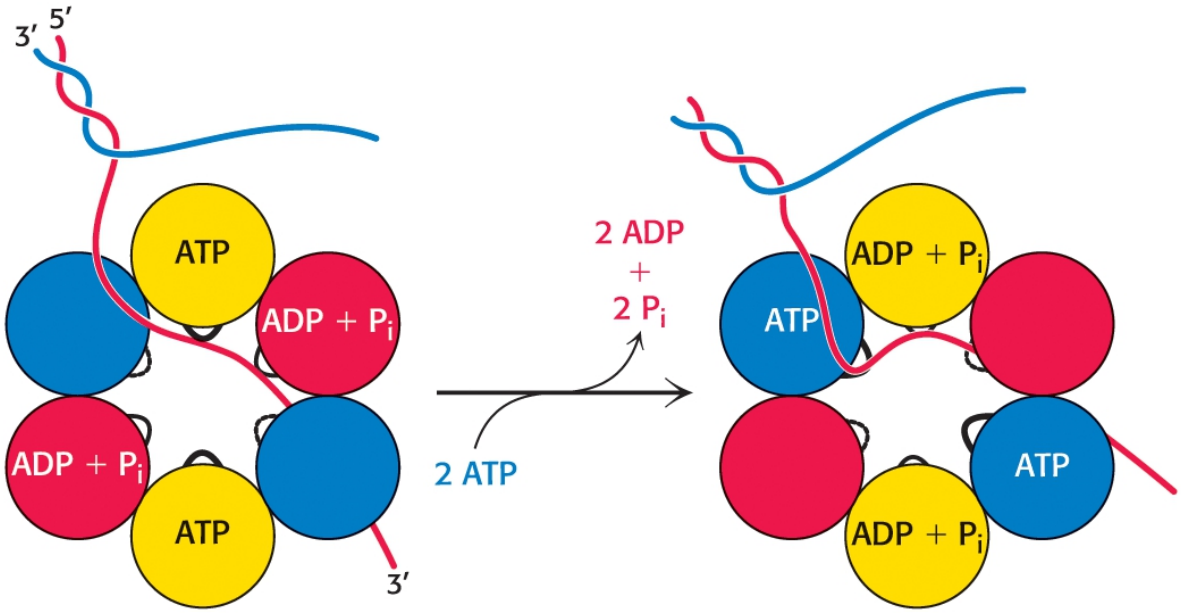
AMP-PNP

The structure of A M P-P N P is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 2 and C 3 are single bonded to O H below. C 4 is single bonded to C H 2 on the upper left in the form of a line. This C H 2 group is single bonded to a zigzag chain composed of O, single bond, P, single bond, O, single bond, P, single bond, N, single bond, P. N atom of this chain is bound to H and both are highlighted in blue. P 1 and P 2 are each partially double bonded to O above and O on the lower left. The top O has an overall negative charge. P 3 is partially double bonded to O above, O on the left, and O on the lower left. These O atoms have an overall charge of 2 minus. C 1 of the ring is wedge bonded to N 1 of a 5-membered heterocyclic pentagonal ring in a horizontal orientation with C 1 occupying the leftmost vertex. The pentagonal ring consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the topmost vertex. A double bond is present between C 1 and N 2. This pentagonal ring is fused with a 6-

membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. In the hexagonal ring, C 1 occupies the bottom right vertex. First N occupies the top right vertex and the second N occupies the bottom-most vertex. A double bond is present between C 1 and N 2, C 2 and C 3, and C 4 and N 1. C 1 is single bonded to N H 2 above.

Return to Structure of A M P-P N P

Extended description for FIGURE 28.10 Helicases have intrinsic asymmetry



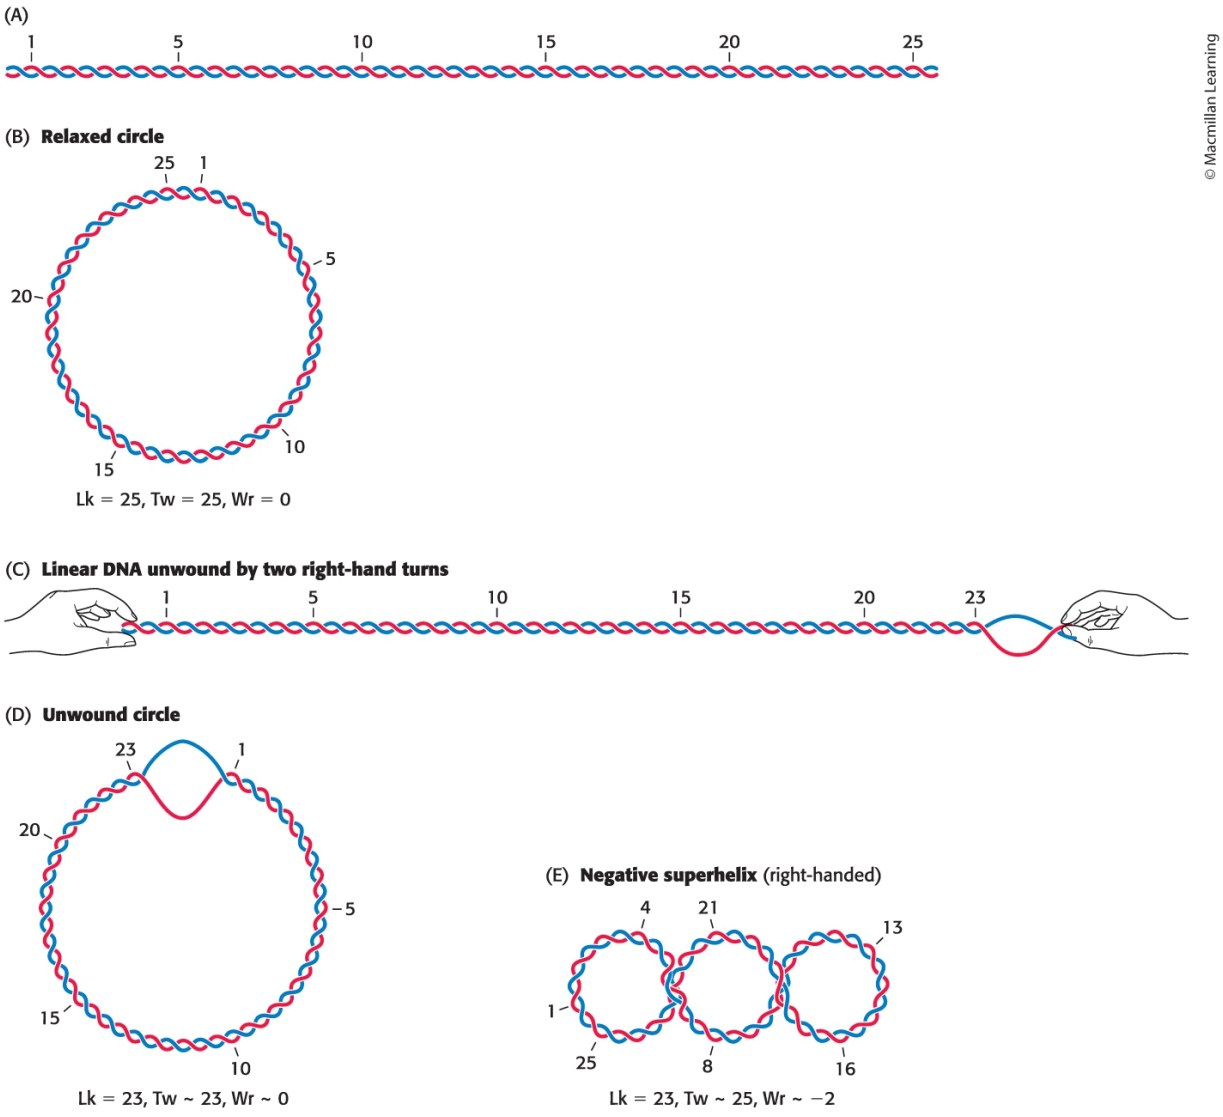
© Macmillan Learning

The helicase is composed of six subunits arranged in a circular fashion. The subunits are located at the top, bottom, top left, bottom left, top right, and bottom right. The top and bottom subunits are shown in yellow. The top left and bottom right subunits are shown in blue. The top right and bottom left subunits are shown in red. The

top and bottom subunits are rotated 30 degrees relative to the plane of the hexamer. The top right and bottom left subunits are rotated 15 degrees relative to the plane of the hexamer. The top left and bottom right subunits are rotated 0 degrees relative to the plane of the hexamer. A cluster of orange spheres depicting A M P-P N P is bound to all the subunits except the top right and bottom left subunits.

Return to FIGURE 28.10 Helicases have intrinsic asymmetry

Extended description for FIGURE 28.11 Helicases unwind D N A



© Macmillan Learning

The helicase is depicted as a ring-like structure composed of 6 subunits depicted as medium-sized circles. It has a hollow interior. The top and bottom circles are yellow colored. The top right and bottom left circles are red colored. The top left and bottom right circles are blue-colored. The top and bottom subunits are bound to A T P. The top right and bottom left subunits are bound to A D P plus P subscript i. A small loop from each circle lines the hollow interior. A "D N A helix" is shown on the top right. It is composed of two strands shown in red and blue. The 3 prime and 5 prime ends of the strands are aligned with each other. The D N A helix is unwound such that the red D N A strands pass through the hollow interior of the helicase. It is attached with the loops of the top yellow and top right red circles. The other end of the red strand that extends outside through the helicase is labeled 3 prime.

A forward arrow shows the conformational change in helicase hexamer after A T P binding to the top left and bottom right blue circles and release of A D P plus P subscript i from the top right and bottom left subunits. In the hexamer, the top and bottom yellow circles are bound to A D P plus P subscript i. The red strand of the helix is pulled through the helicase. It is attached to the loops of the top and top left circles.

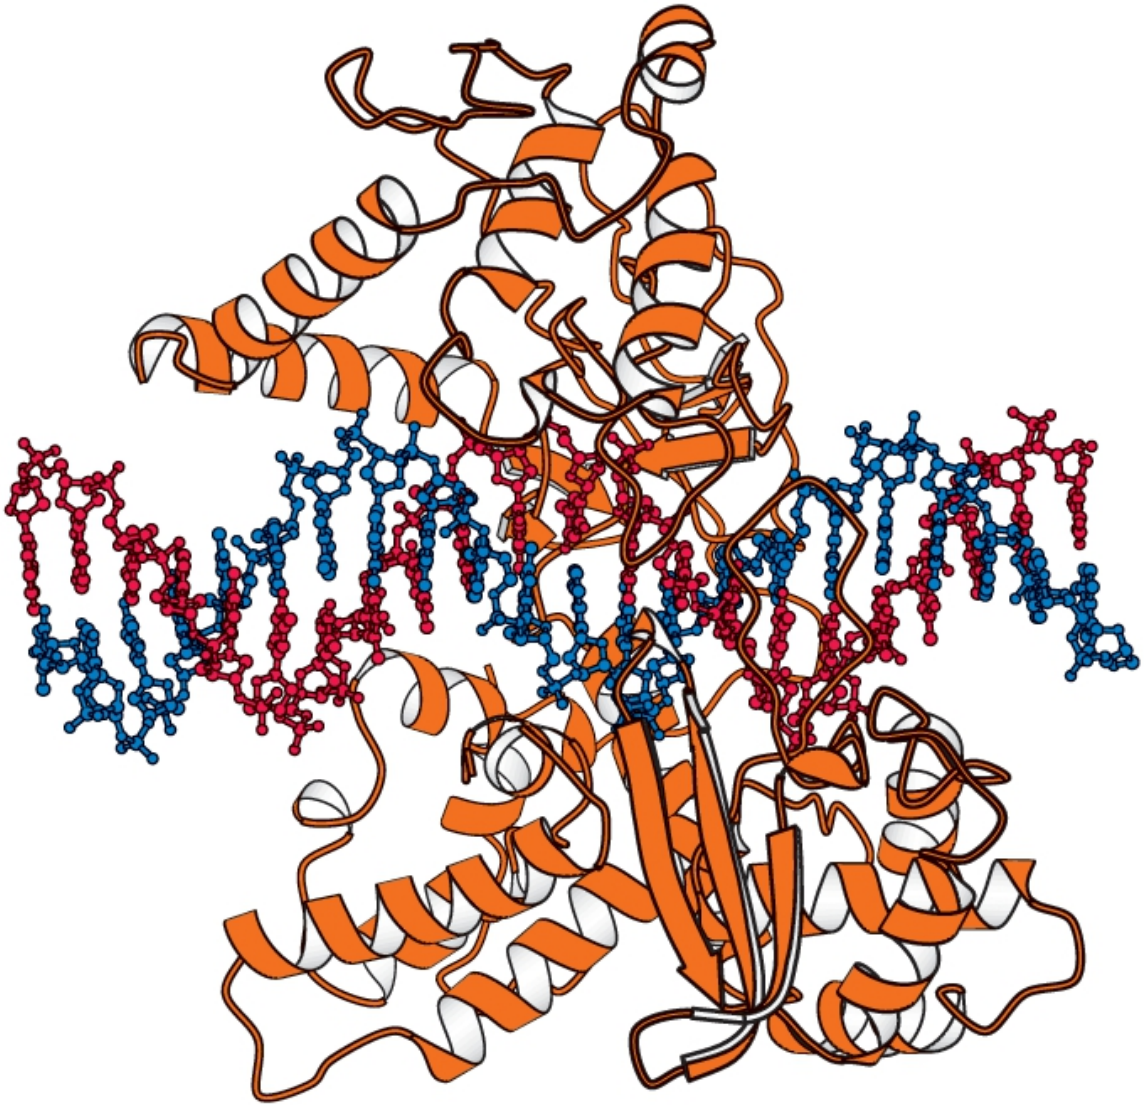
Return to FIGURE 28.11 Helicases unwind D N A

Extended description for FIGURE 28.12 The linking number (L k), twist (T w), and writhe (W r) of circular DNA are related

© Macmillan Learning

Part (A): A linear D N A double helix is shown in horizontal orientation. The first complete turn of the strands around each other is numbered 1. From left to right, the number of complete turns is numbered 1, 5, 10, 15, 20, and 25.

Part (B): A relaxed circular double helical D N A is shown. It is marked 1, 5, 10, 15, 20, and 25 starting from the top in a clockwise direction. The markings depict the number of complete turns. Note: Linking number equals 25, twist equals 25, and writhe equals 0.



Part (C): A linear D N A double helix unwound by two right-hand turns is shown in horizontal orientation. The first complete turn of the strands around each other is numbered 1. From left to right, the number of complete turns is numbered 1, 5, 10, 15, 20, and 23. A hand is holding the left end of the linear D N A. The right end is unwound and another hand is holding the unwound end.

Part (D): An unwound circular double helical D N A is shown. It is marked 1, 5, 10, 15, 20, and 23 starting from the top right in a clockwise direction. The markings depict the number of complete turns. The topmost region of the circular helix is unwound to form a bubble. Note: Linking number equals 23, the twist is approximately 23, and the writhe is approximately 0.

Part (E): It shows a right-handed negative superhelix. The circular D N A double helix is twisted upon itself to form three adjacent and continuous ring-like structures. The left ring is marked 1, 4, and 25 in a clockwise direction starting at the left end. The middle ring is marked 21 and 8 at the top and bottom. The right ring is marked 13 and 16 at the top right and bottom. Note: Linking number equals 23, the twist is approximately 23, and writhe is negative 2.

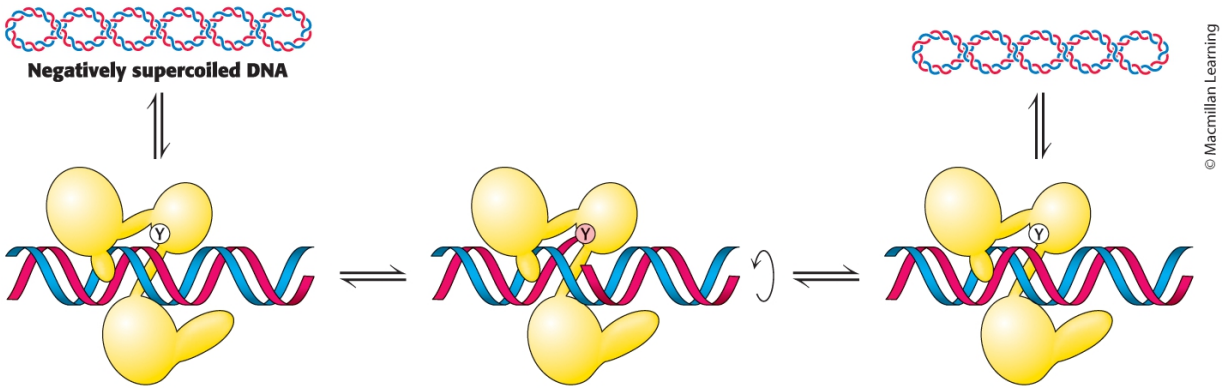
Extended description for FIGURE 28.14 Topoisomerase 1 binds to D N A



© Macmillan Learning

The fragment of human topoisomerase 1 is bound to D N A double helix in horizontal orientation. The strands of the double helix are composed of blue and red spheres. The helix passes through a central cavity in the topoisomerase. Topoisomerase 1 is composed of a cluster of alpha-helices and beta-strands at the top and bottom. These clusters are separated by a small gap or central cavity through

which the D N A helix passes. The clusters are connected by long threads.

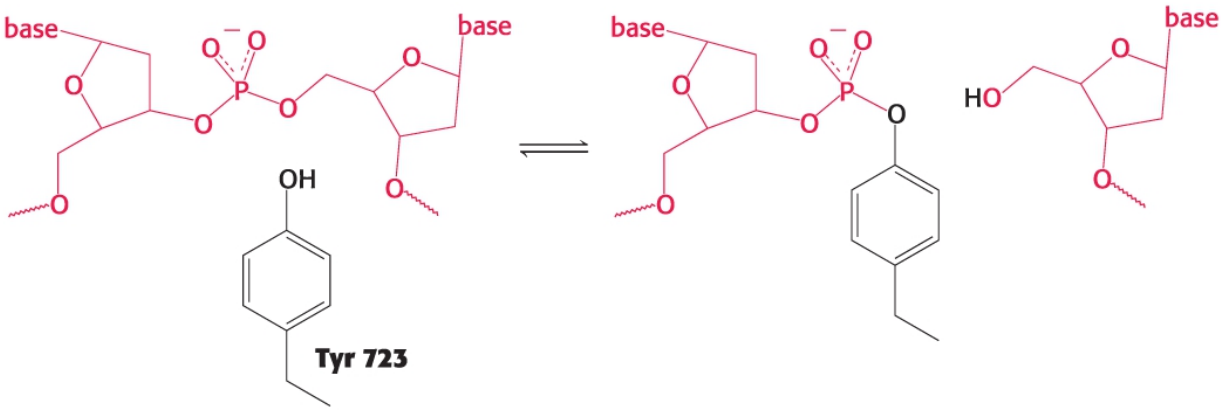
Return to FIGURE 28.14 Topoisomerase 1 binds to D N A

Extended description for FIGURE 28.15 Topoisomerase 1 relaxes supercoiled D N A

© Macmillan Learning

A negatively supercoiled double helical D N A contains six adjacent and continuous ring-like structures. It reversibly binds to topoisomerase 1. A short stretch of D N A double helix in horizontal orientation is bound to topoisomerase 1.

Topoisomerase 1 is composed of 3 spherical structures interconnected by short tubes. Two spherical structures are located above and the third spherical structure is located below the helix. The second spherical structure contains a tyrosine residue depicted as a tiny circle labeled Y.



An irreversible arrow shows the topoisomerase 1 bound to the D N A helix. One of the strands is nicked such that one end of the nicked strand is bound to the tyrosine residue. An anticlockwise arrow depicts the rotation of the cleaved strand.

An irreversible arrow shows the topoisomerase bound to the re-ligated D N A.

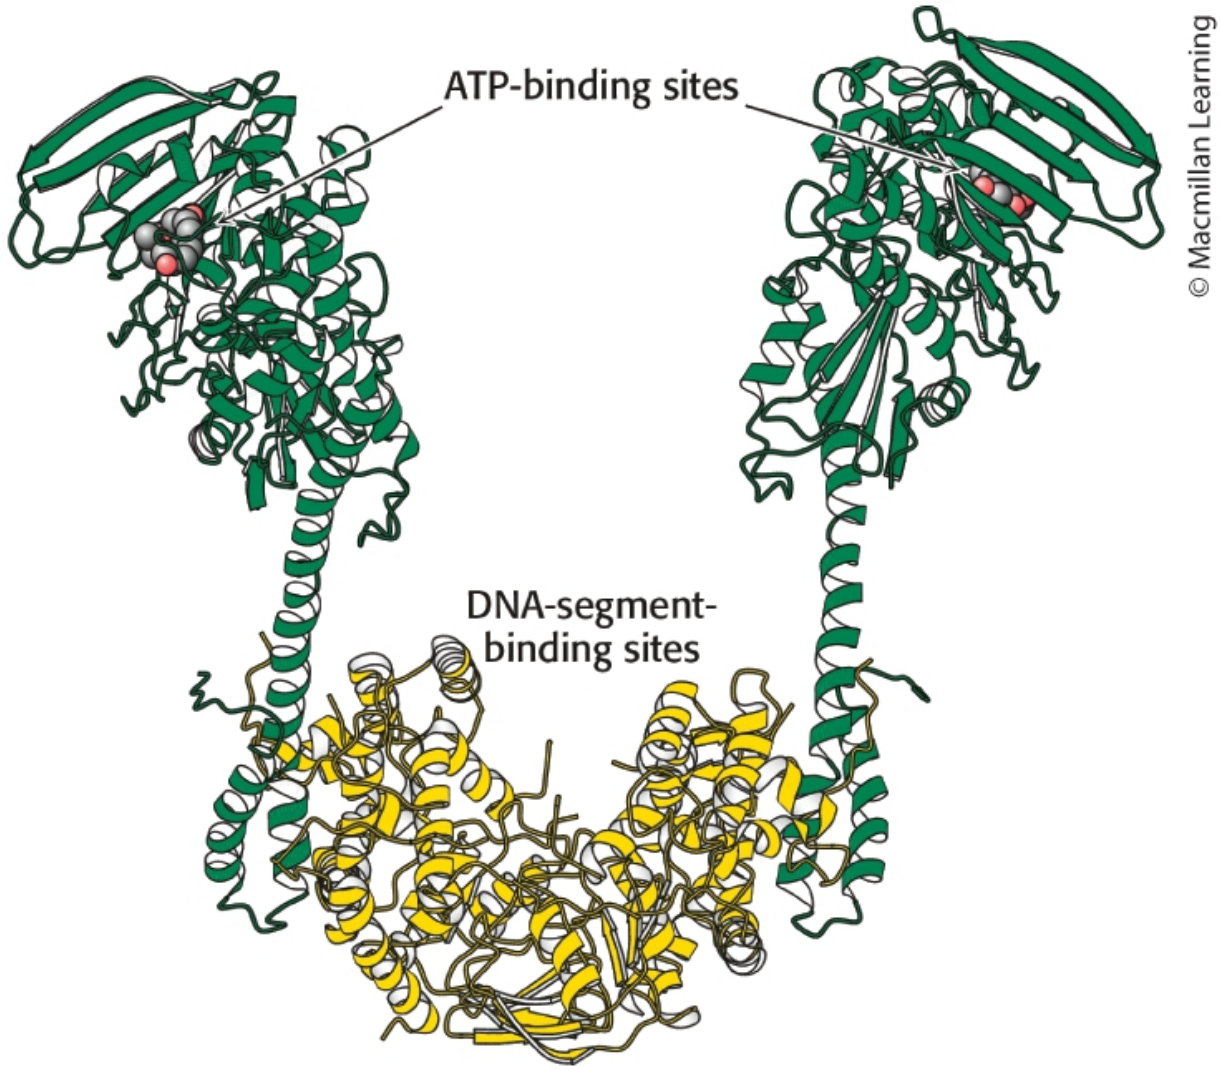
An irreversible arrow shows a coiled double helical D N A composed of five adjacent and continuous ring-like structures.

Return to FIGURE 28.15 Topoisomerase 1 relaxes supercoiled D N A

Extended description for Cleavage of phosphodiester bond by the tyrosine residue of topoisomerase

The reaction includes two reactants and two products.

The structure of the first reactant is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the leftmost vertex. C 1 is single-bonded to base on the upper right. C 3 is single bonded to O on the right. C 4 is single bonded to C H 2 on the lower left in the form of a line. C H 2 is single bonded to O below. This O has a wiggly line on the lower left. The O bonded to C 3 of the ring is further single bonded to P on the upper right. This P is partially double-bonded to O on the upper left and upper right, and single-bonded to O on the lower right. The lower right O is single bonded to C H 2 on the upper right in the form of a line. This C H 2 is single-bonded to C 4 of a 5-membered heterocyclic pentagonal ring in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single-bonded to the base above. C 3 is single bonded to O on the lower left. This O has a wiggly line on the lower right.



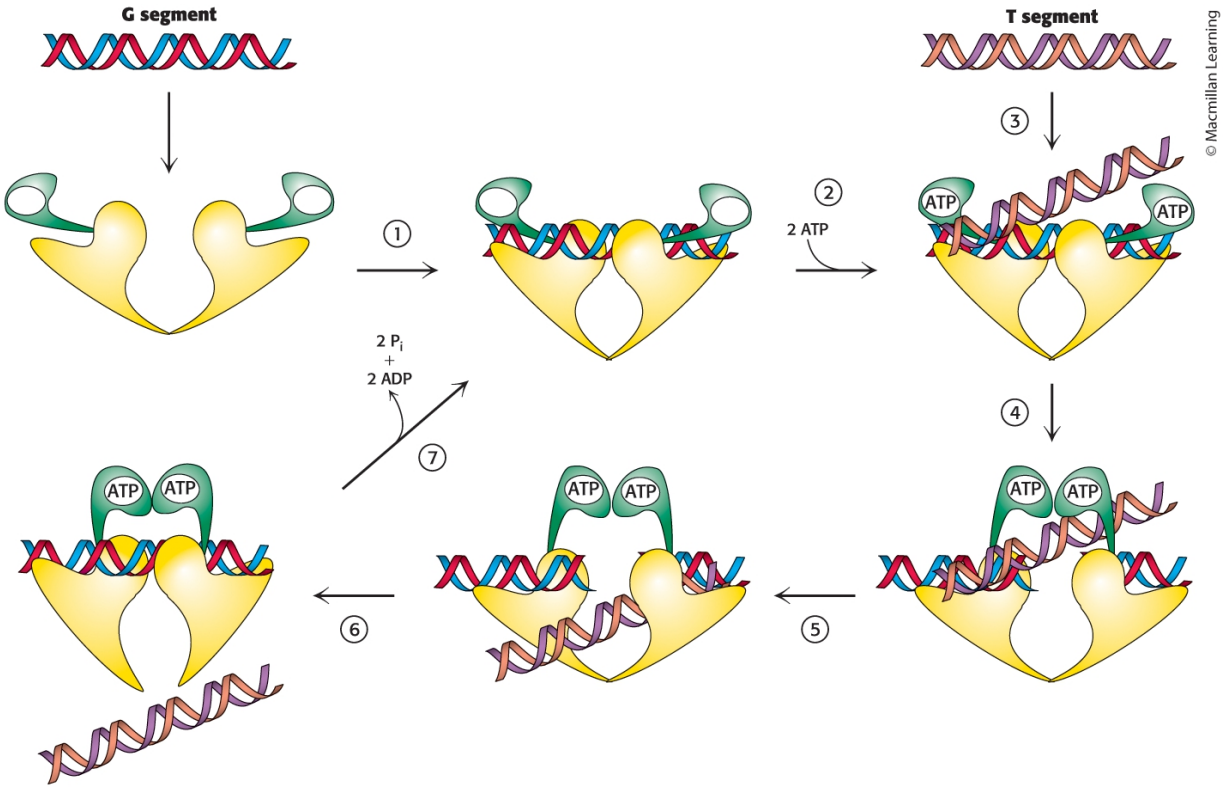
The second reactant is tyrosine 723 whose structure is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 4 is single bonded to C H 2 below in the form of a line. C H 2 has an open single bond on the lower right.

The structure of the first product is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation with C 1 occupying the top right vertex. It consists of 1 O and 4 C atoms. O occupies the leftmost vertex. C 1 is single-bonded to base on the upper right. C 3 is single bonded to O on the right. C 4 is single bonded to C H 2 on the lower left in the form of a line. C H 2 is single bonded to O below. This O has a wiggly line on the lower left. The O bonded to C 3 of the ring is further single bonded to P on the upper right. This P is partially double-bonded to O on the upper left and upper right, and single-bonded to O on the lower right. The lower right O is single-bonded to C 1 of a benzene ring in a vertical orientation. The benzene ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 4 is single bonded to C H 2 below in the form of a line. C H 2 has an open single bond on the lower right.

The structure of the second product is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It contains 1 O and 4 C atoms. O occupies the topmost vertex. C 1 is single-bonded to the base above. C 3 is single bonded to O on the lower left. This O has a wiggly line on the lower right. C 4 is single bonded to C H 2 on the upper left in the form of a line. This C H 2 is single-bonded to O H on the lower left.

Return to Cleavage of phosphodiester bond by the tyrosine residue of topoisomerase

Extended description for FIGURE 28.16 Topoisomerase 2 is a dimer



Topoisomerase 2 is a dimer composed of the left and right subunits. Each subunit has two domains. The bottom domain shown in yellow is small and composed of several alpha-helices. The top domain is shown in green and is composed of a cluster of alpha-helices and beta-strands at the top. A long and vertical alpha-helix extends below the top domain and is connected with another short alpha-

helix. These alpha-helices are associated with the bottom domain. The top cluster of the top domain contains an A T P-binding site bound to a cluster of spheres. The bottom domain contains D N A-segment binding sites.

Return to FIGURE 28.16 Topoisomerase 2 is a dimer

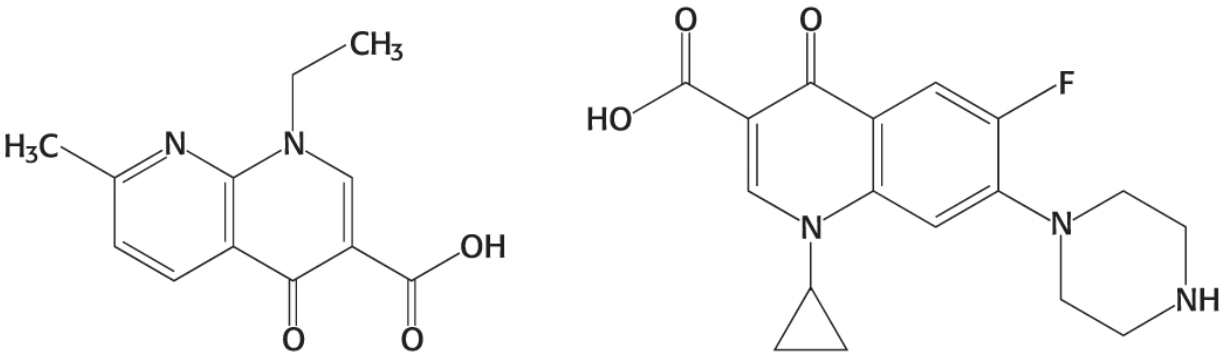
Extended description for FIGURE 28.17 Topoisomerase 2 uses A T P hydrolysis to introduce negative supercoils into D N A

In the first step, a double helical D N A fragment labeled G segment binds to topoisomerase 2. The topoisomerase is depicted as a pair of yellow-colored structures connected at the bottom. The top portion of the yellow structure is broad and the bottom portion is tapered and pointed. In the unbound state, the top portion of the yellow structures is separated. A small green structure is connected to the top of each yellow structure through its pointed tail. The broad portion of each green structure contains an empty site. The G segment is binds to the top portion of the yellow structure. In the D N A bound state, the top portion of the yellow structures is joined.

In the second step, 2 A T P molecules enter the complex. These A T P molecules bind to the empty site of each small green structure.

In the third step, the T segment of D N A binds to the complex of the topoisomerase and G segment. The T segment is in diagonal orientation and bound to the top of the left yellow structure.

In the fourth step, the G segment is cleaved and the top portions of the yellow structures are separated. The small green structures bound to A T P join together to form an arch-shaped structure above the yellow structure. The T segment passes diagonally below the arch-shaped structure.



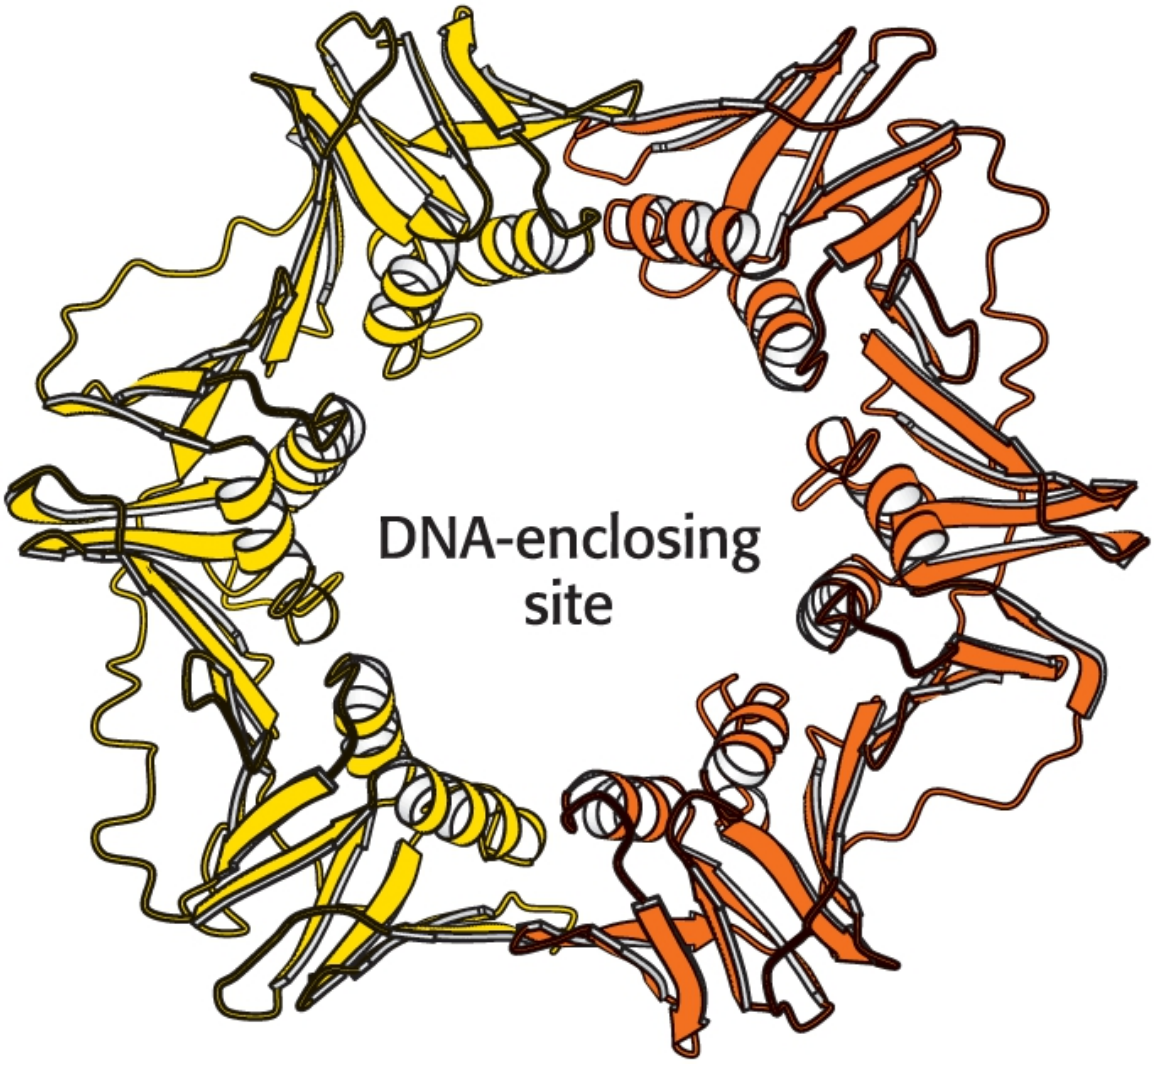
In the fifth step, the T segment is shifted below and it passes diagonally through the hollow cavity between the left and right yellow structures.

In the sixth step, the pointed bottom ends of the yellow structures separate to release the T segment. The G segment is re-ligated.

In the seventh step, 2 A D P plus 2 P subscript i are released from the small green structures due to A T P hydrolysis. The green structures separate from each again and the topoisomerase bound to re-ligated D N A attains the original conformation as observed in step 1.

Return to FIGURE 28.17 Topoisomerase 2 uses A T P hydrolysis to introduce negative supercoils into D N A

Extended description for Structure of nalidixic acid and ciprofloxacin



The structure of nalidixic acid is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the top right vertex. It consists of 1 N and 5 C atoms. N occupies the topmost vertex. A double bond is present between C 1 and C 2, C 3 and C 4, and C 5 and N. C 5 is single bonded to C H 3 on the upper left. This hexagonal ring is fused to a second 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 1 and C 2 of the first ring are C 5 and C 4 respectively of the second ring. The second hexagonal ring consists of 1 N and 5 C atoms. N occupies the topmost vertex. A double bond is present between C 1 and C 2. N is single bonded to C H 2 above in the form of a line, which is further single bonded to C H 3 on the upper right. C 2 is single bonded to C on the lower right. This C is double bonded to O below and single bonded to O H on the upper right. C 3 is double bonded to O below.

The structure of ciprofloxacin is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the bottom left vertex. It contains 1 N and 5 C atoms. N occupies the bottom-most vertex. A double bond is present between

C 1 and C 2. C 2 is single-bonded to C on the upper left. This C is double bonded to O above and single bonded to O H on the lower left. C 3 is double bonded to O above. N is single-bonded to C 1 of a triangular ring. The hexagonal ring is fused to a benzene ring in a vertical orientation such that C 4 and C 5 of the hexagonal ring are C 6 and C 5 respectively of the benzene ring. The benzene ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to F on the upper right. C 3 is single-bonded to N 1 of a 6-membered heterocyclic hexagonal ring in a vertical orientation. This hexagonal ring consists of 2 N and 4 C atoms. First N occupies the top left vertex. The second N bound to H occupies the bottom right vertex.

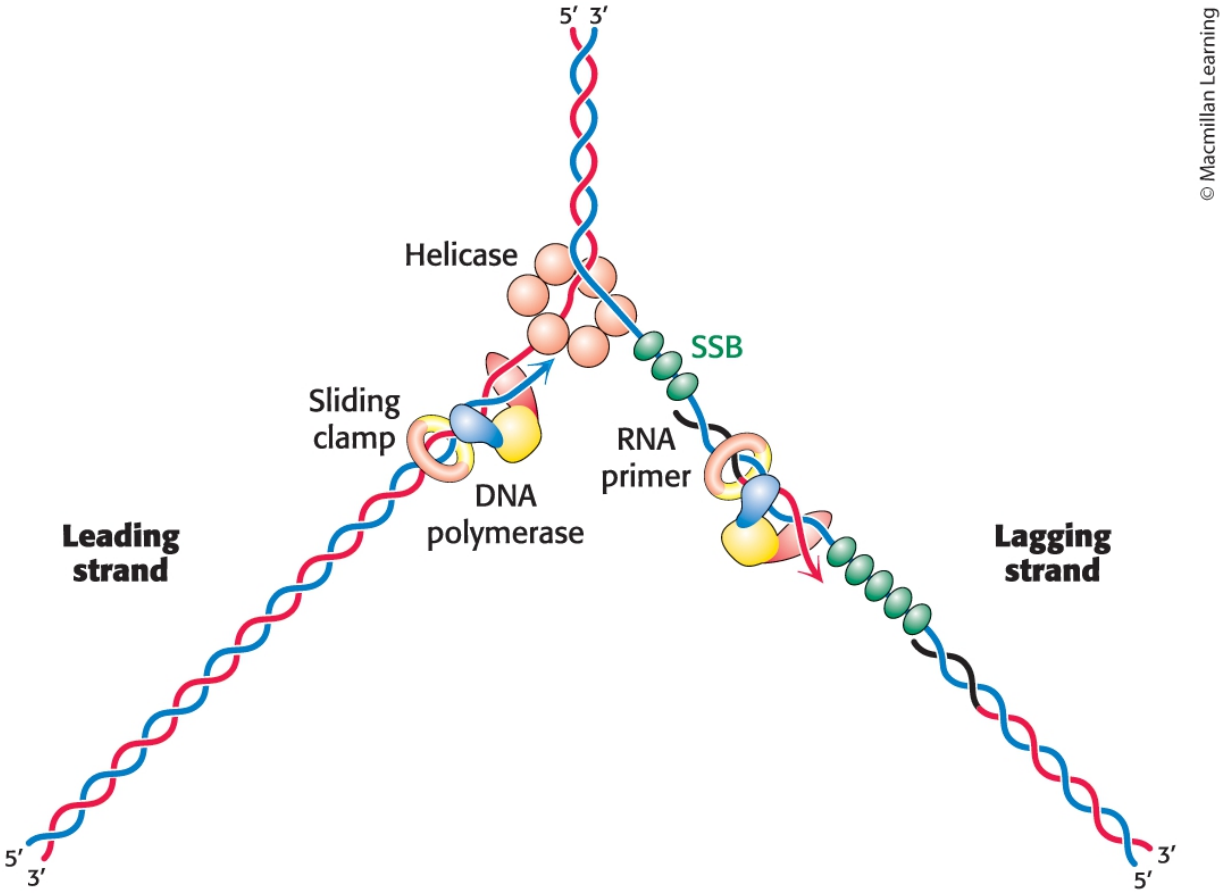
Extended description for FIGURE 28.18 The sliding clamp subunit of D N A polymerase 3 is a dimer



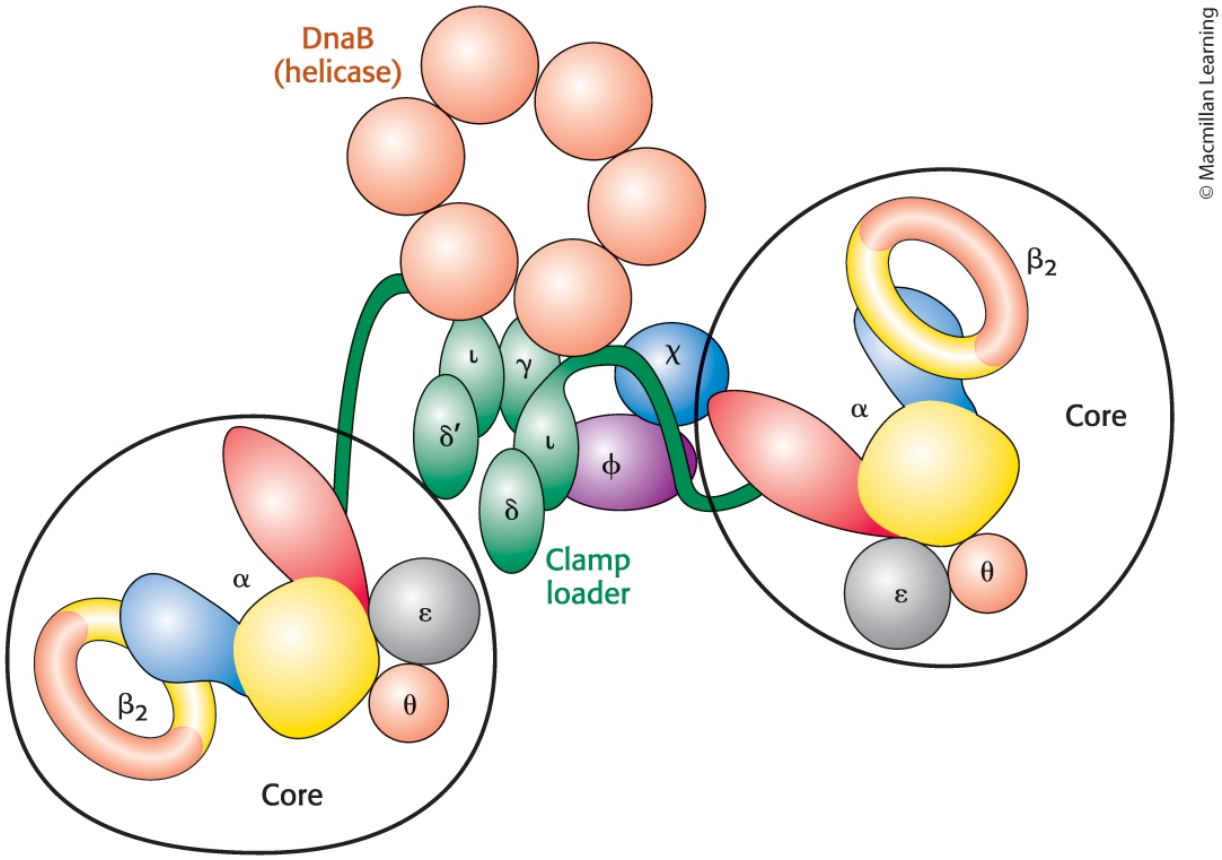
© Macmillan Learning

The sliding clamp subunit is depicted as a hollow ring-like structure. It is a dimer composed of left and right subunits. The left subunit is shown in yellow and the right subunit is shown in orange. Each subunit is composed of three clusters of beta-strands. Each cluster is connected to a few alpha-helices. These alpha-helices line the hollow interior of the ring. The hollow interior is labeled the "D N A-enclosing site."

Return to FIGURE 28.18 The sliding clamp subunit of D N A polymerase 3 is a dimer

Extended description for FIGURE 28.19 D N A synthesis at the replication fork is highly coordinated

© Macmillan Learning



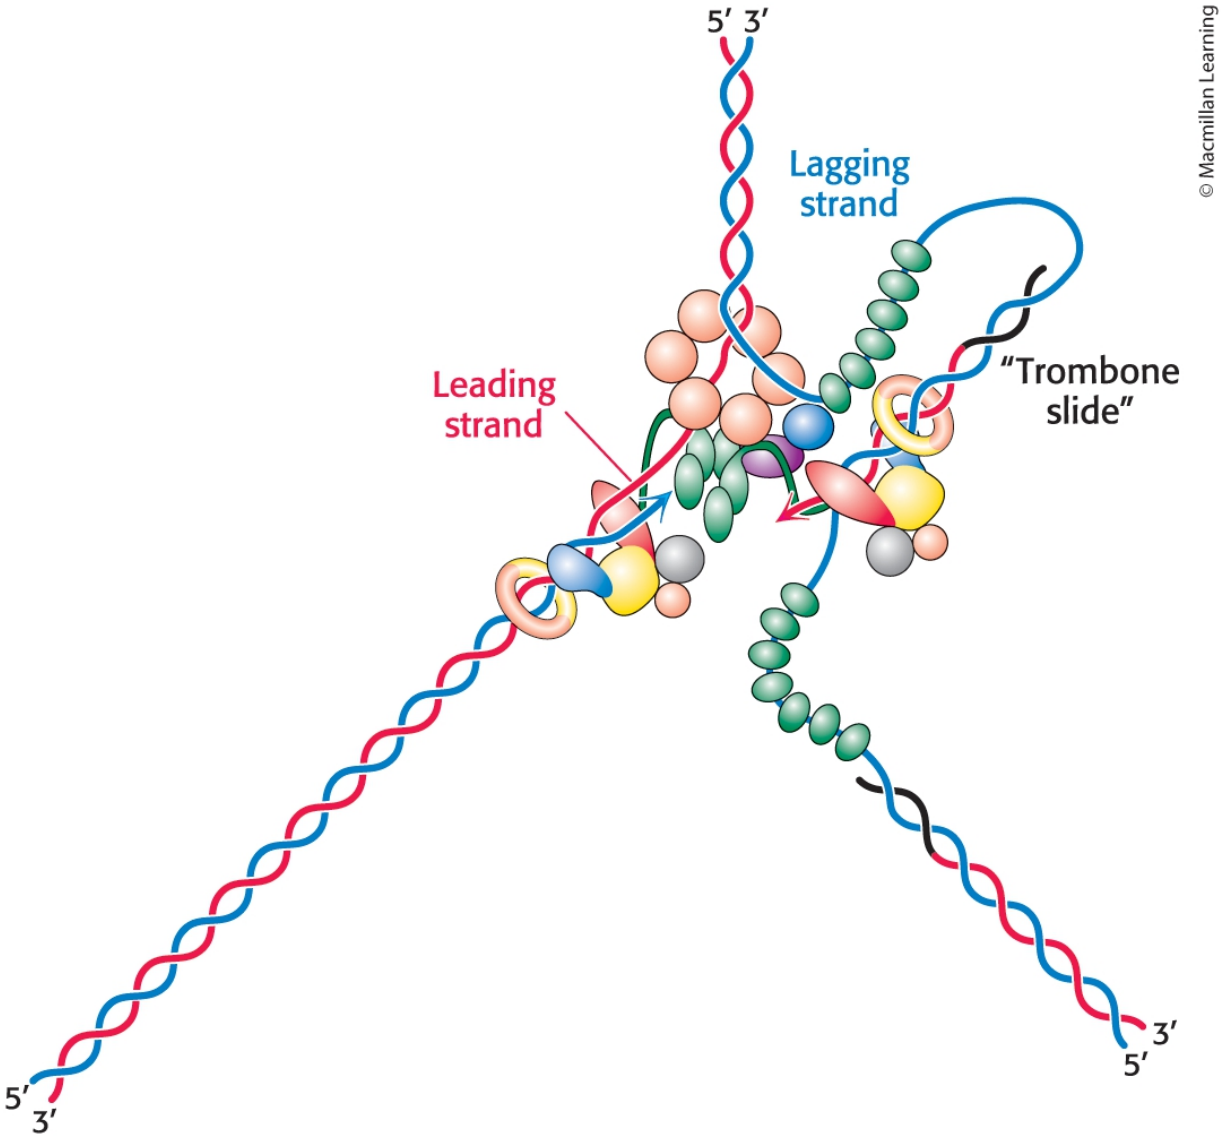
The replication fork is depicted as an inverted Y-shaped structure. The 5 prime and 3 prime ends of the parental D N A are aligned together. The lower left segment is labeled leading strand and the lower right segment is labeled lagging strand. The leading strand is synthesized using the red strand of the parental D N A as the template. It is synthesized in 5 prime to 3 prime direction from the 3 prime end of the parental strand, away from the replication fork. The red parental strand is surrounded by a helicase at the replication fork. The helicase is a hollow ring-like structure composed of 6 spherical subunits. The D N A polymerase is bound at

the 3 prime end of the leading strand, near the replication fork. The hollow ring-like sliding clamp of D N A polymerase allows the passage of a newly formed double helix through it.

The lagging strand is synthesized using the blue strand of the parental D N A ad the template. It is synthesized discontinuously in 5 prime to 3 prime direction from the 3 prime end of the parental strand near the replication fork. Two short Okazaki fragments of the lagging strand are synthesized. Each fragment contains the primer at the 5 prime end. Several S S B depicted as green ovals are bound to the blue parental strand near the replication and between the Okazaki fragments. The D N A polymerase is bound to the 3 prime end of one Okazaki fragment. The newly synthesized double helix passes through the sliding clamp of D N A polymerase.

Return to FIGURE 28.19 D N A synthesis at the replication fork is highly coordinated

Extended description for FIGURE 28.20 The D N A polymerase holoenzyme consists of multiple subunits



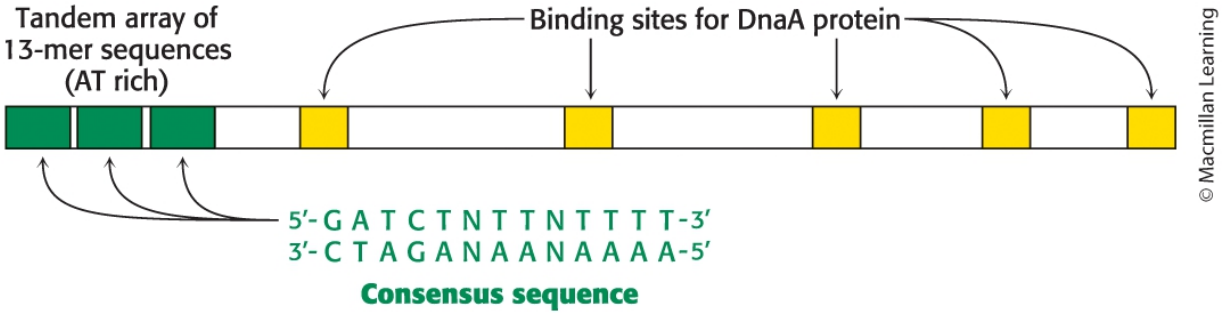
© Macmillan Learning

The D N A polymerase holoenzyme is composed of a central structure connected to two copies of the polymerase core enzyme. Each core enzyme is shown inside a circle with a black outline. It contains an alpha subunit, an epsilon subunit, a theta subunit, and a beta 2 subunit. The alpha subunit is depicted as a round structure connected to two vertical elongated structures on the top left and top right. One of these elongated structures is connected to the hollow ring-like beta 2 subunit. The epsilon and theta subunits are depicted as small round structures.

The central structure is composed of a clamp loader and D n a B (helicase). The helicase is a hollow ring-like structure composed of six circular subunits. It is connected to the elongated structure of the alpha subunit of one of the polymerase core enzymes. The clamp loader is composed of one gamma subunit, two tau subunits, one delta subunit, and one delta prime subunit. These subunits are depicted as green ovals. The other two subunits of the central structure are phi and chi. One of the tau subunits of the clamp loader is connected to the elongated structure of the alpha subunit of the second polymerase core enzyme.

Return to FIGURE 28.20 The D N A polymerase holoenzyme consists of multiple subunits

Extended description for FIGURE 28.21 The trombone model describes the coordination of D N A synthesis at the replication fork



© Macmillan Learning

D N A replication is shown at the replication fork. The model shows the coordination of lagging strand and leading strand replication. The blue parental strand serving as the template of the lagging strand is looped out. It leads to the formation of a trombone slide-

like structure by the looped-out blue strand. D N A polymerase holoenzyme is associated with the replication fork. A polymerase core enzyme is involved in the synthesis of the leading and lagging strands.

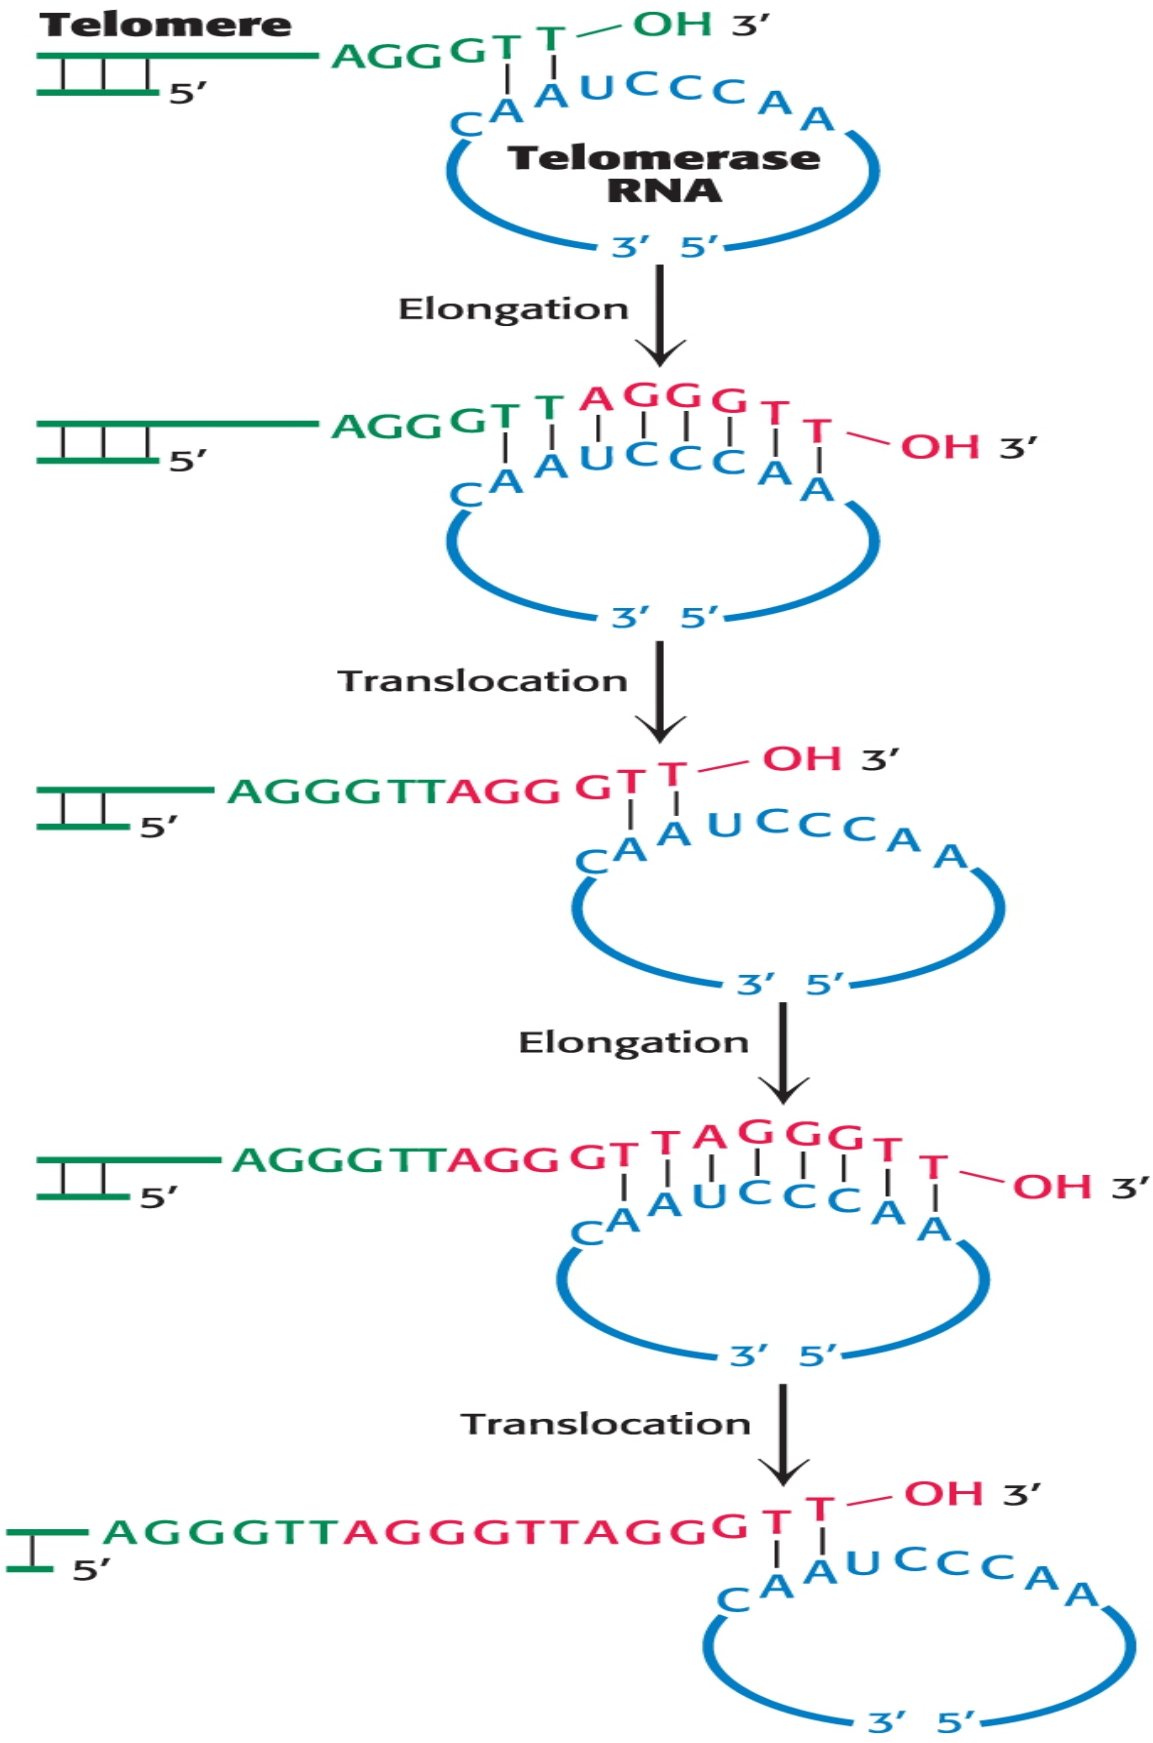
Extended description for FIGURE 28.28 Telomeres may form duplex loops



A G-rich strand is depicted as two parallel lines. The top line is solid red and its right end extends beyond the right end of the bottom blue line. A forward arrow shows the duplex loop formed by the G-rich strand. It shows the folding back of the G-rich strand to form a loop. The extended red line enters into a bubble formed by the red line near its left end.

Return to FIGURE 28.28 Telomeres may form duplex loops

Extended description for FIGURE 28.29 Telomerase uses its R N A template to synthesize the G-rich strand

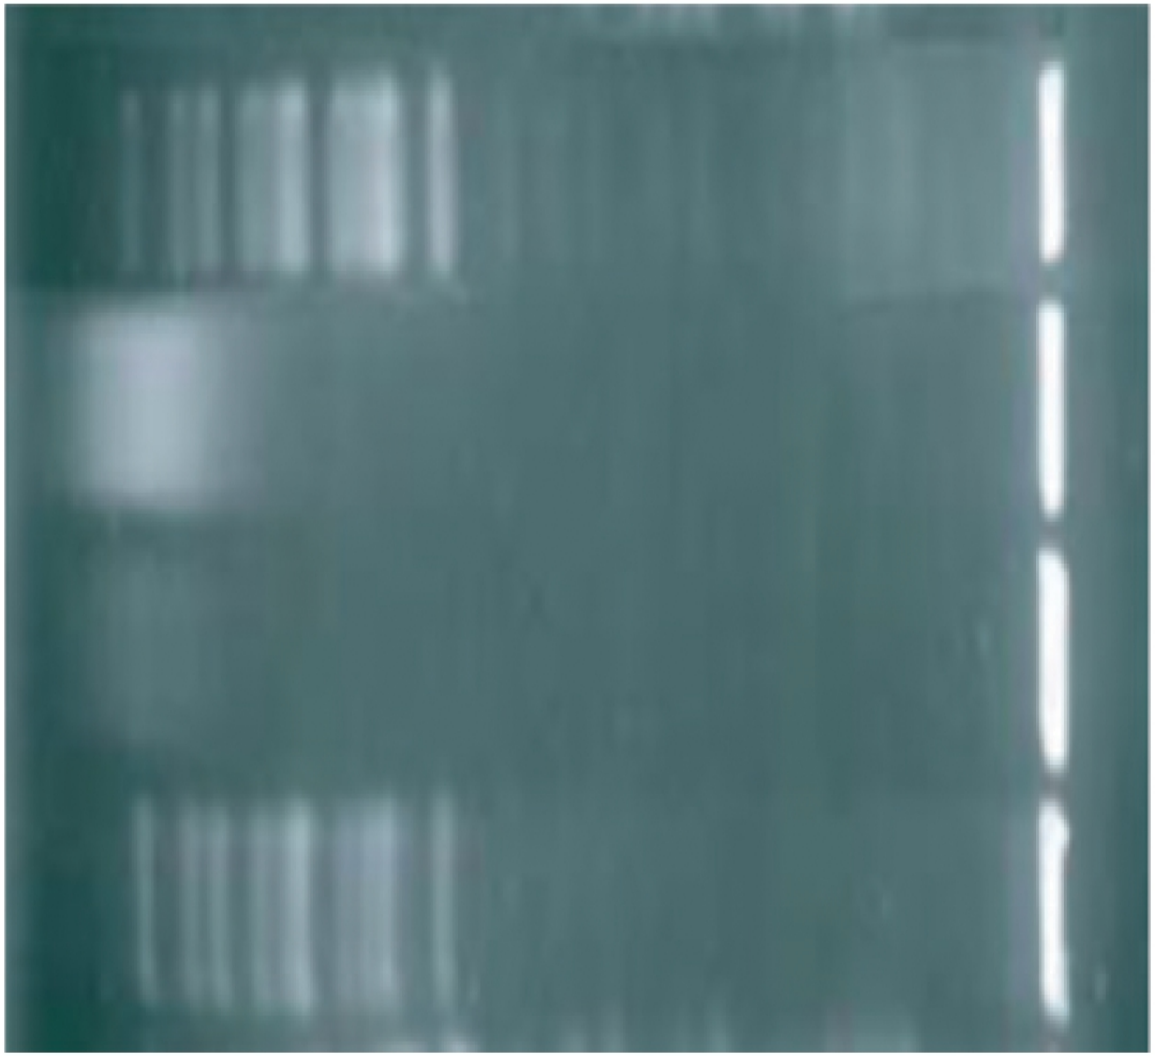
of telomeres

© Macmillan Learning

The telomere is depicted as a double-stranded D N A segment. The right end of the bottom strand is labeled 5 prime. The right end of the top strand is extended and contains the sequence A G G G T T, single bond, O H, 3 prime. The T residues of this sequence are hydrogen bonded to the first and second A residues of the telomerase R N A. The telomerase R N A is depicted as an open circle with the sequence 3 prime C A A U C C C A A 5 prime. The free 3 prime and 5 prime ends are shown at the bottom.

The first step is elongation. The telomerase R N A is used as a template to extend the 3 prime end of the top strand of telomerase. The sequence of the 3 prime end of the top strand of telomere is A G G G T T A G G G T T, single bond, O H, 3 prime. The sequence from the first T to the fourth T is hydrogen bonded with the telomerase R N A.

The second step is translocation. The sequence of the 3 prime end of the top strand of the telomere is translocated toward the left such that only the two terminal T residues are hydrogen bonded to the first and second A residues of telomerase R N A. The remaining bases of the R N A are unpaired.



The third step is elongation. The telomerase R N A is again used as a template to extend the 3 prime end of the top strand of telomerase. The sequence of the 3 prime end of the top strand of the telomere is A G G G T T A G G G T T A G G G T T, single bond, O H, 3 prime. The terminal A G G G T T sequence is hydrogen bonded with the telomerase R N A.

The fourth step is translocation. The sequence of the 3 prime end of the top strand of the telomere is again translocated toward the left such that only the two terminal T residues are hydrogen bonded to the first and second A residues of telomerase R N A. The remaining bases of the R N A are unpaired.

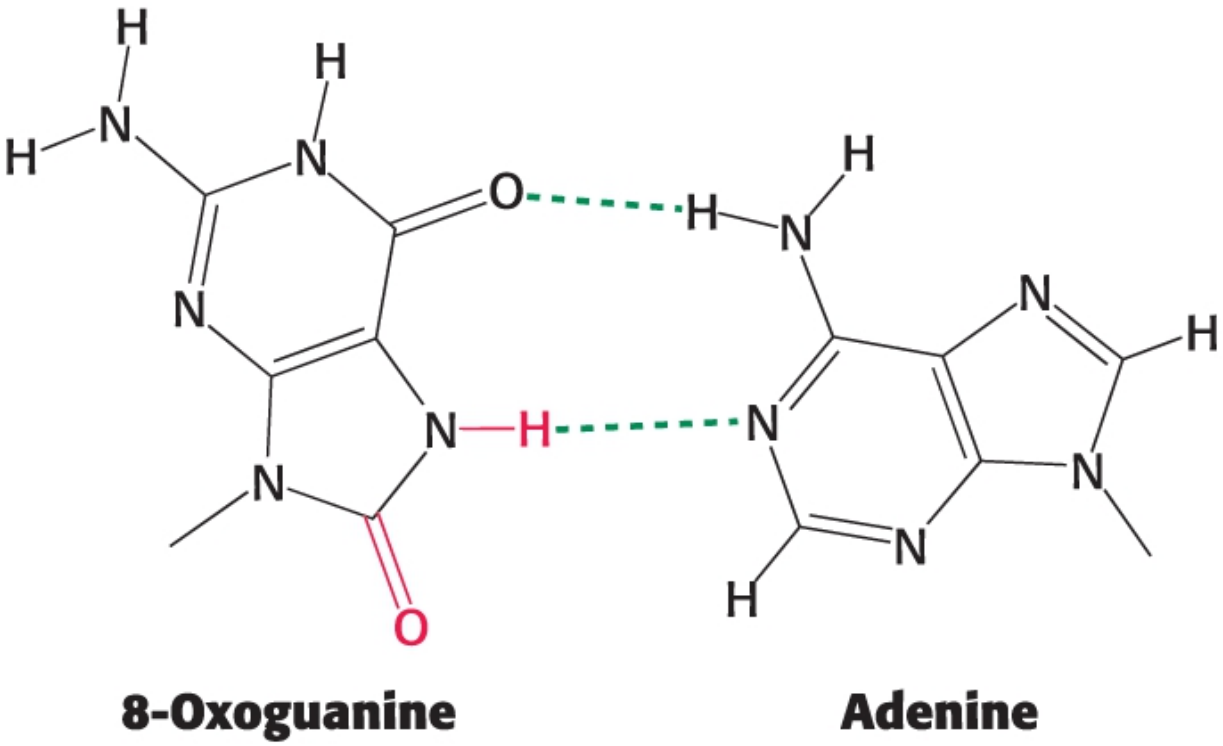
Extended description for FIGURE 28.30 The bacterium

Deinococcus radiodurans repairs DNA damage quickly



Reprinted with permission of Macmillan Publishers Ltd, from Zahradka, K., Slade, D., Bailone, A. et al. Reassembly of shattered chromosomes in Deinococcus radiodurans. Nature 443, 569–573 (2006); permission conveyed through Copyright Clearance Cener, Inc.

The gel contains four lanes. From left to right, the lanes are labeled C, 0 hours, 1.5 hours, and 3 hours. C depicts starting genome, 0 hour depicts the irradiated fragmented genome, and 3 hours depict the spontaneously reassembled genome. In lane C, a thick and bright band is seen at the top which is followed by a series of relatively faint bands near the bottom. In lane 0 hours, a thick and bright band is seen at the top. A thick smear is seen at the bottom of the lane. In lane 1.5, a thick and bright band is seen at the top. A very light and small smear is seen near the bottom of the lane. In lane 3 hours, the banding pattern is almost identical to lane C.

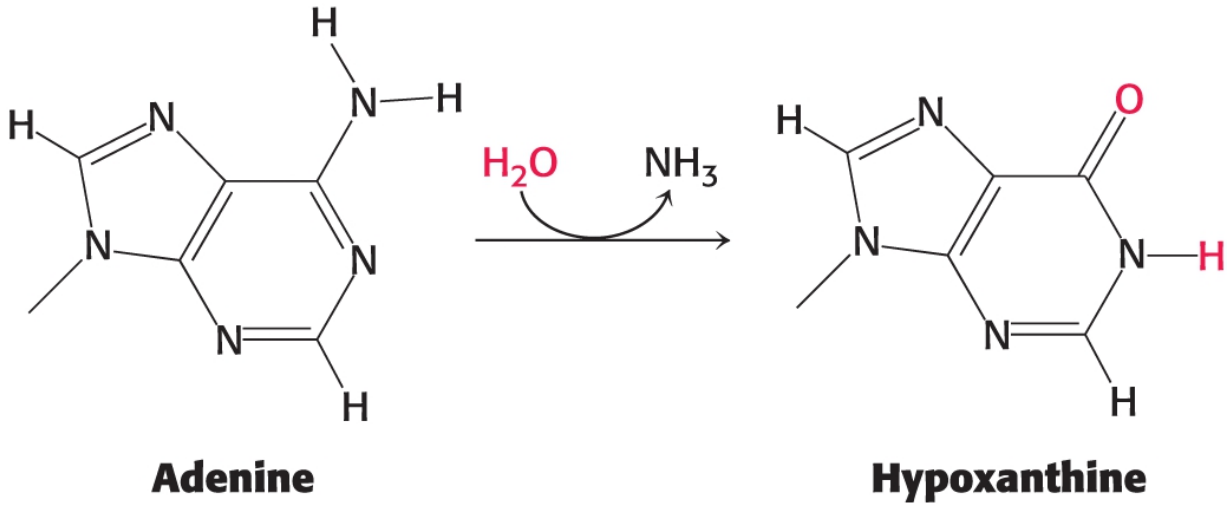
Extended description for FIGURE 28.31 Damaged D N A bases can form base pairs

The structure of 8-oxoguanine is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the top left vertex. It consists of 2 N and 4 C atoms. First N occupies the bottom left vertex and the second N occupies the topmost vertex. A double bond is present between N 1 and C 1, and C 3 and C 4. C 1 is single bonded to N on the upper left. This N is single bonded to H above and H on the lower left. C 2 is single-bonded to O on the upper right. Second N is single bonded to H above. It is fused with a 5-membered heterocyclic pentagonal ring in a horizontal orientation such that C 3 and C 4 of the hexagonal ring are C 3 and C 2 respectively of the pentagonal ring. The pentagonal ring consists of 2 N and 3 C atoms. First N occupies the bottom right vertex and the second N occupies the bottom left vertex. C 1

occupies the bottom-most vertex and is double bonded to O below. N 2 has an open single bond on the lower left. N 1 is single bonded to H on the right.



The structure of adenine is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the bottom left vertex. It consists of 2 N and 4 C atoms. First N occupies the bottom-most vertex and the second N occupies the top left vertex. A double bond is present between N 1 and C 1, N 2 and C 2, and C 3 and C 4. C 1 is single-bonded to H on the lower left. C 2 is single bonded to N above, which is further single bonded to two different H. The hexagonal ring is fused with a 5-membered heterocyclic pentagonal ring such that C 3 and C 4 of the hexagonal ring are C 2 and C 3 respectively of pentagonal ring. The pentagonal ring consists of 2 N and 3 C atoms. First N occupies the top right vertex and the second N occupies the bottom right vertex. C 1 occupies the rightmost vertex. A double bond is present between N 1 and C 1. C 1 is single bonded to H on the right. N 2 has an open single bond below.

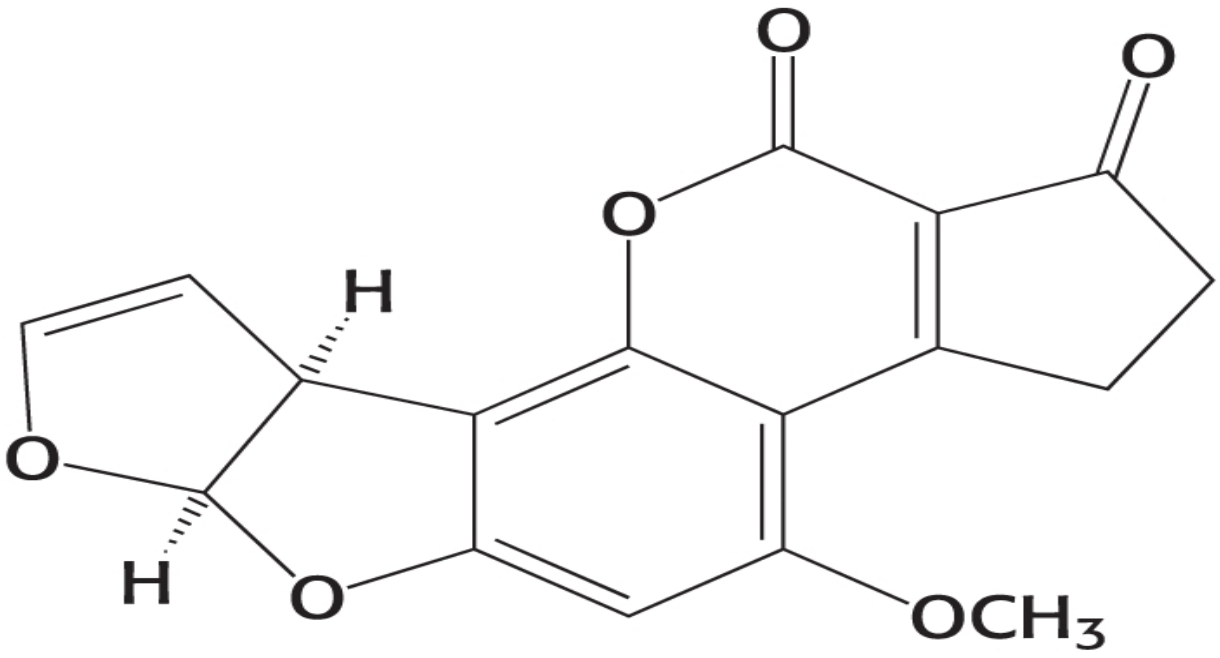
The O atom double bonded to C 2 of the hexagonal ring of 8-oxoguanine is connected to the H atom of the N H 2 group bonded to the hexagonal ring of adenine. This connection is depicted through a green dashed line.

The H atom single bonded to N 1 of the pentagonal ring of 8-oxoguanine is connected to N 2 of the hexagonal ring of adenine. This connection is depicted through a green dashed line.

Return to FIGURE 28.31 Damaged D N A bases can form base pairs

Extended description for FIGURE 28.32 Adenine can be deaminated to form hypoxanthine

The conversion of adenine to hypoxanthine is coupled with the entry of H 2 O and the release of N H 3.



The structure of adenine is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the bottom right vertex. First N occupies the rightmost vertex and the second N occupies the bottom left vertex. A double bond is present between C 1 and N 2, C 2 and C 3, and C 4 and N 1. C 1 is single bonded to H. C 4 is single bonded to N on the upper right, which is further single bonded to H on the upper left and H on the right. The hexagonal ring is fused to a 5-membered heterocyclic pentagonal ring in a vertical orientation such that C 2 and C 3 of the hexagonal ring are C 3 and C 2 respectively of the pentagonal ring. The pentagonal ring consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the topmost vertex. A double bond is present between C 1 and N 2. C 1 is single-bonded to H on the upper left. N 1 has an open single bond on the lower left.

The structure of hypoxanthine is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the bottom right vertex. First N occupies the rightmost vertex and the second N occupies the bottom left vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 1 is single bonded to H. C 4 is double bonded to O on the upper right. N 1 is single bonded to H on the right. The hexagonal ring is fused to a 5-membered heterocyclic pentagonal ring in a vertical orientation such that C 2 and C 3 of the hexagonal ring are C 3 and C 2 respectively of the pentagonal ring. The pentagonal ring consists of 2 N and 3 C atoms. First N occupies the bottom left vertex and the second N occupies the topmost vertex. A double bond is present between C 1 and N 2. C 1 is single-bonded to H on the upper left. N 1 has an open single bond on the lower left.

Extended description for FIGURE 28.33 Aflatoxin can be

activated into a mutagen

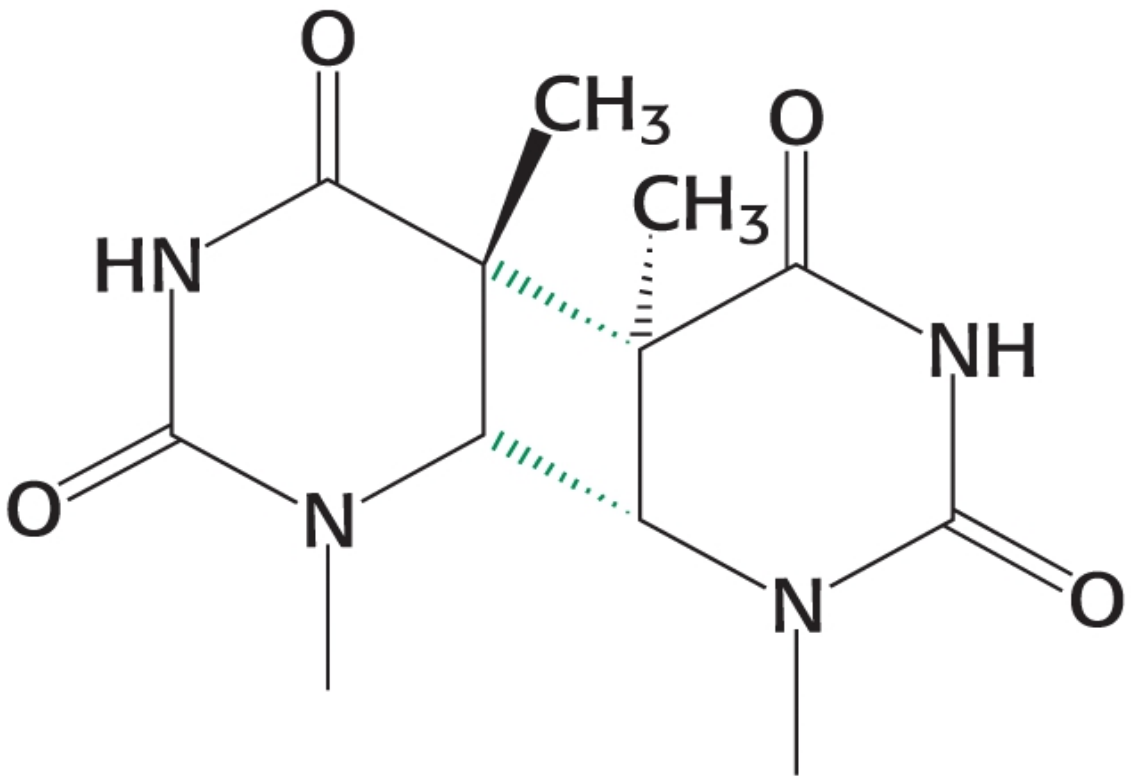
Aflatoxin B_1

Cytochrome P450

Active DNA-modifying agent

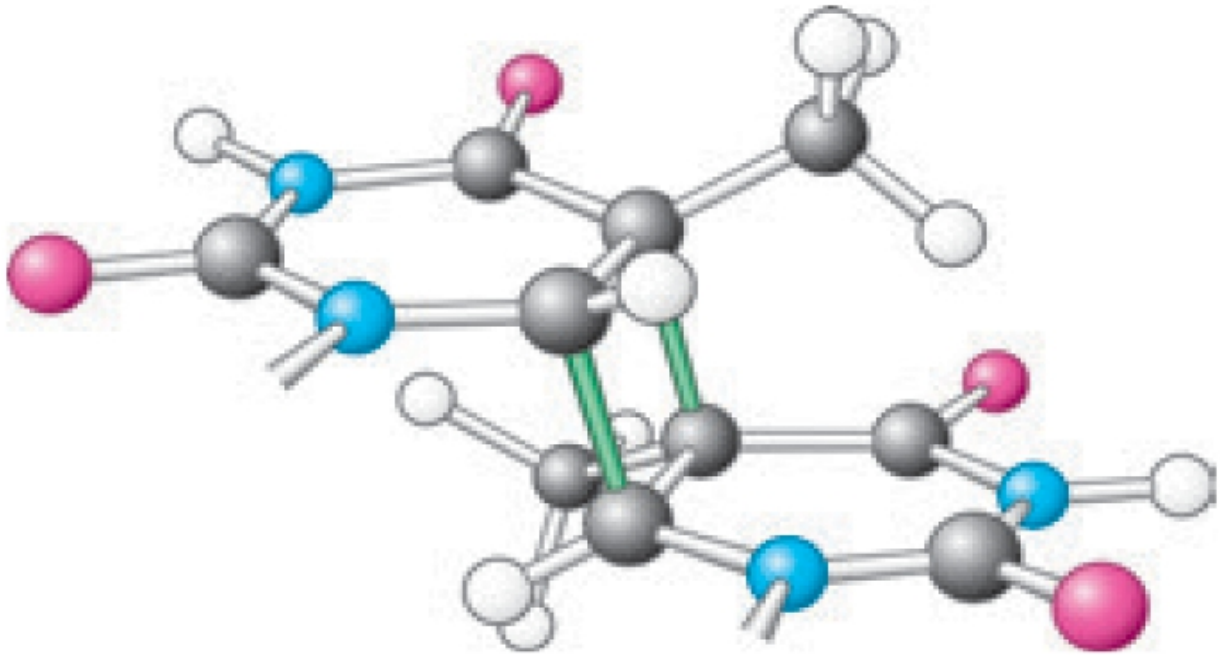
The structure of aflatoxin B 1 is as follows: A 5-membered heterocyclic pentagonal ring is in vertical orientation with C 1 occupying the top left vertex. It consists of 1 O and 4 C atoms. O occupies the bottom left vertex. A double bond is present between C 1 and C 2. It is fused with another 5-membered heterocyclic pentagonal ring in a vertical orientation such that C 3 and C 4 of the first ring are C 2 and C 1 respectively of the pentagonal ring. The pentagonal ring consists of 1 O and 4 C atoms. O occupies the bottom-most vertex. C 1 and C 2 are each dash bonded to H. The second pentagonal ring fused to a benzene ring in vertical orientation such that C 3 and C 4 of the second ring are C 6 and C 5 respectively of the benzene ring. In the benzene ring, alternating double bonds are present between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 3 is single bonded to O C H 3 on the lower right. The benzene ring is fused with a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 1 and C 2 of the benzene ring are C 5 and C 4 respectively of the hexagonal ring. The hexagonal ring consists of 1 O and 5 C atoms. O occupies the top left vertex. C 1 occupies the topmost vertex and is double bonded to O above. A double bond is present between C 2 and C 3. The hexagonal ring is fused with a 5-carbon pentagonal ring in vertical orientation such that C 2 and C 3 of the hexagonal ring are C 5 and C 4 of the pentagonal ring. In the pentagonal ring, C 1 occupies the topmost vertex and is double bonded to O above.

A downward arrow labeled cytochrome P 450 leads to active D N A-modifying agent.



The structure of the active D N A-modifying agent is as follows: A 5-membered heterocyclic pentagonal ring is in vertical orientation with C 1 occupying the top left vertex. It consists of 1 O and 4 C atoms. O occupies the bottom left vertex. C 1 and C 2 are wedge-bonded to a common O atom on the upper left. It is fused with another 5-membered heterocyclic pentagonal ring in a vertical

orientation such that C 3 and C 4 of the first ring are C 2 and C 1 respectively of the pentagonal ring. The pentagonal ring consists of 1 O and 4 C atoms. O occupies the bottom-most vertex. C 1 and C 2 are each dash bonded to H. The second pentagonal ring fused to a benzene ring in vertical orientation such that C 3 and C 4 of the second ring are C 6 and C 5 respectively of the benzene ring. In the benzene ring, alternating double bonds are present between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 3 is single bonded to O C H 3 on the lower right. The benzene ring is fused with a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 1 and C 2 of the benzene ring are C 5 and C 4 respectively of the hexagonal ring. The hexagonal ring consists of 1 O and 5 C atoms. O occupies the top left vertex. C 1 occupies the topmost vertex and is double bonded to O above. A double bond is present between C 2 and C 3. The hexagonal ring is fused with a 5-carbon pentagonal ring in vertical orientation such that C 2 and C 3 of the hexagonal ring are C 5 and C 4 of the pentagonal ring. In the pentagonal ring, C 1 occupies the topmost vertex and is double bonded to O above.



Return to FIGURE 28.33 Aflatoxin can be activated into a mutagen

Extended description for FIGURE 28.34 Chemical

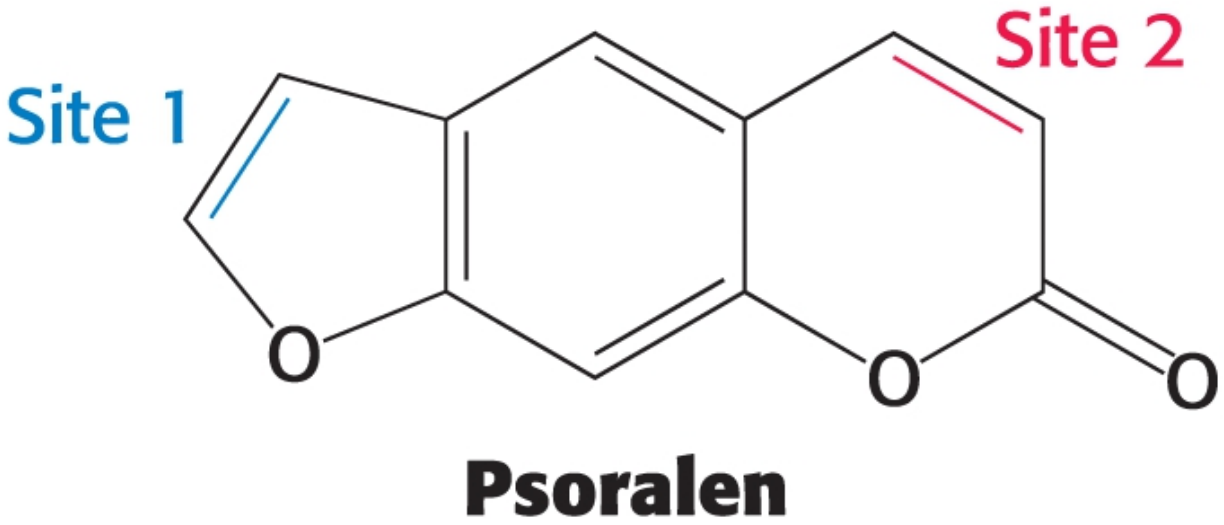
structure and ball-and-stick model of thymine dimer

Thymine dimer

The thymine dimer is composed of two thymine molecules dash bonded to each other.

The structure of the left thymine molecule is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the bottom left vertex. It consists of 2 N and 4 C atoms. First N occupies the bottom-most vertex and the second N bound to H occupies the top-left vertex. N 1 has an open single bond below. C 1 and C 2 are double bonded to O. C 3 is wedge bonded to C H 3 on the upper right.

The structure of the right thymine molecule is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation with C 1 occupying the bottom right vertex. It consists of 2 N and 4 C atoms. The first N bound to H occupies the top right vertex and the second N occupies the bottom-most vertex. N 2 has an open single bond below. C 1 and C 4 are double bonded to O. C 3 is dash bonded to C H 3 above. C 3 of the left thymine molecule is dash bonded to C 3 of the right thymine molecule. C 4 of the left thymine molecule is dash bonded to C 2 of the right thymine molecule.



In the ball-and-stick model, two flat hexagonal rings are shown. Each ring is composed of 2 blue and 4 black spheres. In the top ring, the blue sphere occupies the bottommost and top left vertex. The remaining positions are occupied by black spheres. The top left blue sphere is connected to a white sphere. The bottom left and topmost black spheres are each connected to a pink sphere. The top right black sphere is connected to another black sphere on the upper right, which is further connected to three white spheres. The bottom right black sphere is connected to a white sphere on the upper right.

The bottom ring is the non-superimposable mirror image of the top ring. The top right and bottom right black spheres of the top ring are

connected to the top left and bottom left black spheres respectively of the bottom ring through a green stick.

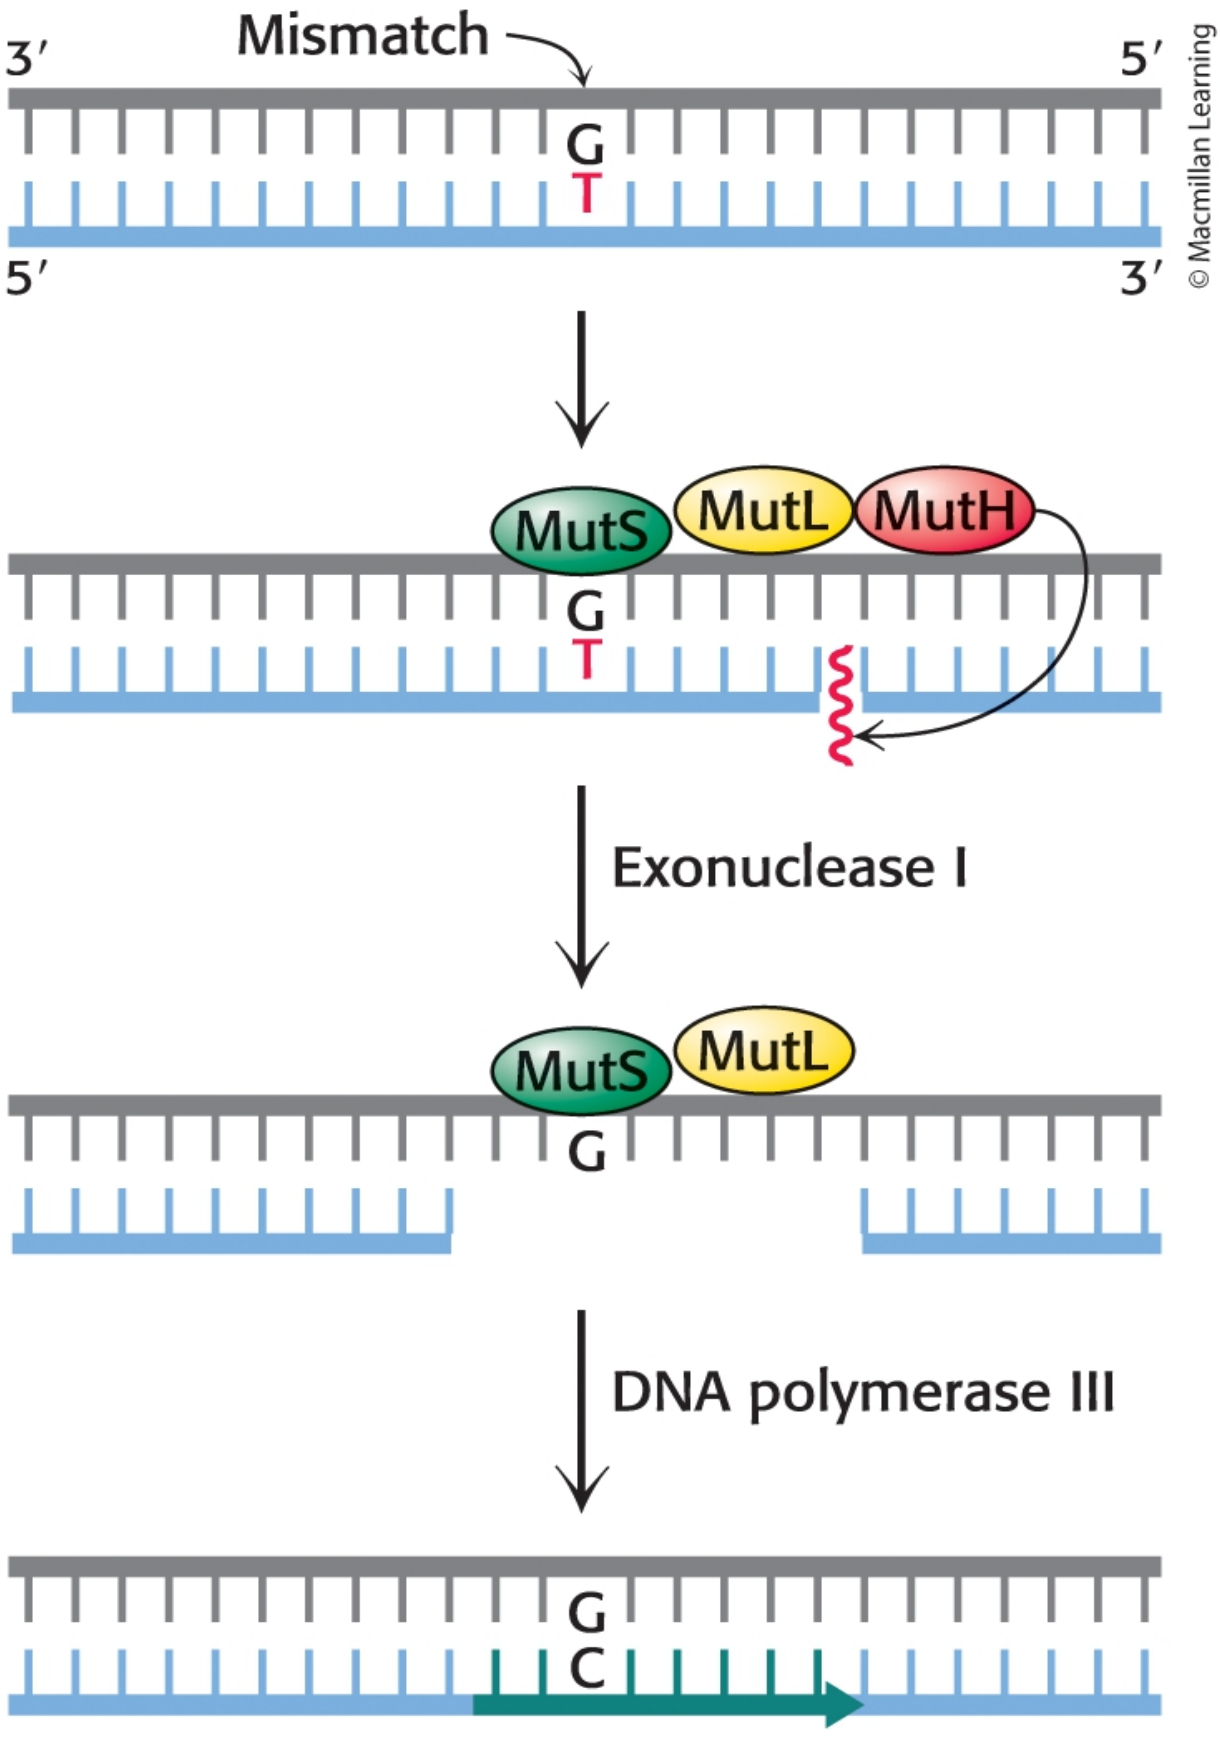
Extended description for FIGURE 28.35 Psoralen is a cross-linking agent

The structure of psoralen is as follows: A 5-membered heterocyclic pentagonal ring is in horizontal orientation with C 1 occupying the leftmost vertex. It consists of 1 O and 4 C atoms. O occupies the bottom-most vertex. A double bond between C 1 and C 2 is highlighted in blue and labeled site 1. It is fused with a benzene ring in a vertical orientation such that C 3 and C 4 of the pentagonal ring are C 6 and C 5 of the benzene ring. In the benzene ring, alternating double bonds are present between C 1 and C 2, C 3 and C 4, and C 5 and C 6. The benzene ring is fused with a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the benzene ring are C 2 and C 1 respectively of the hexagonal ring. The hexagonal ring consists of 1 O and 5 C atoms. O occupies the bottom-most vertex. C 5 is double bonded to O on the lower right. A double bond between C 3 and C 4 is highlighted in red and labeled site 2.

Return to FIGURE 28.35 Psoralen is a cross-linking agent

Extended description for FIGURE 28.36 D N A polymerases have proofreading activities

The D N A polymerase is bound to a replicating double helical D N A. In the helix, the red strand is the template and the blue strand is the replicating strand. The 3 prime end of the blue strand contains a short green block to depict a wrong nucleotide. The D N A polymerase consists of a semi-circular structure at the bottom with an empty exonuclease active site. A horizontally oriented oval-shaped structure is located above it. It has a narrow concave groove at the top center. A blue round subunit is attached to the top left of the oval and an elongated red subunit in vertical orientation is attached to the top right of the oval. The replicating double helix passes through the space between the round and elongated structures.



the first step, the free 3 prime end of replicating blue strand migrates to the exonuclease site. The position of the template strand remains the same.

In the second step, cleavage occurs and the green block along with a short blue stretch is removed from the 3 prime end of the replicating strand. The exonuclease active site becomes empty again.

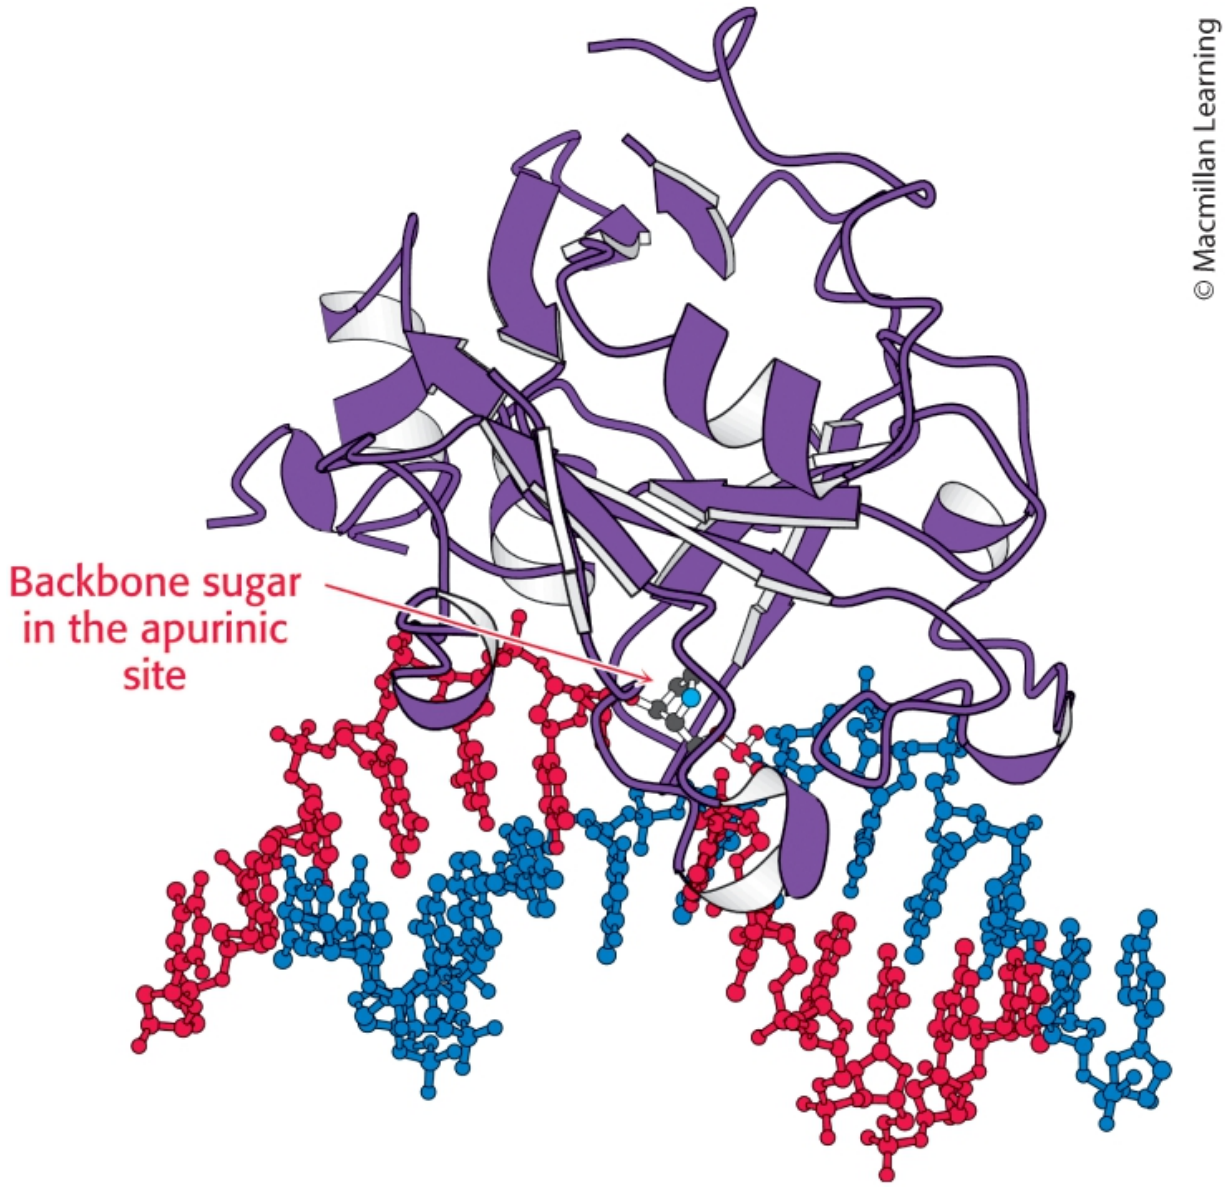
Return to FIGURE 28.36 D N A polymerases have proofreading activities

Extended description for FIGURE 28.37 D N A mismatch

repair in *E. coli* involves multiple proteins

© Macmillan Learning

A double-stranded D N A is shown. The top strand is grey and its left and right ends are labeled 3 prime and 5 prime respectively. The bottom strand is blue and its left and right ends are labeled 5 prime and 3 prime respectively. Short regularly spaced line emerging from the top and bottom strands depicts base pairing. The G base is located in the middle of the top strand corresponding to the T base in the bottom strand. The G T pair depicts a mismatch. T is highlighted in red.



In the second step, Mut S, Mut L, and Mut H are bound to the top strand. Mut S is directly bound to the G T base pair. Mut H creates a nick in the bottom strand five base pairs away from the mismatch. This nick is created toward the right of the mismatch.

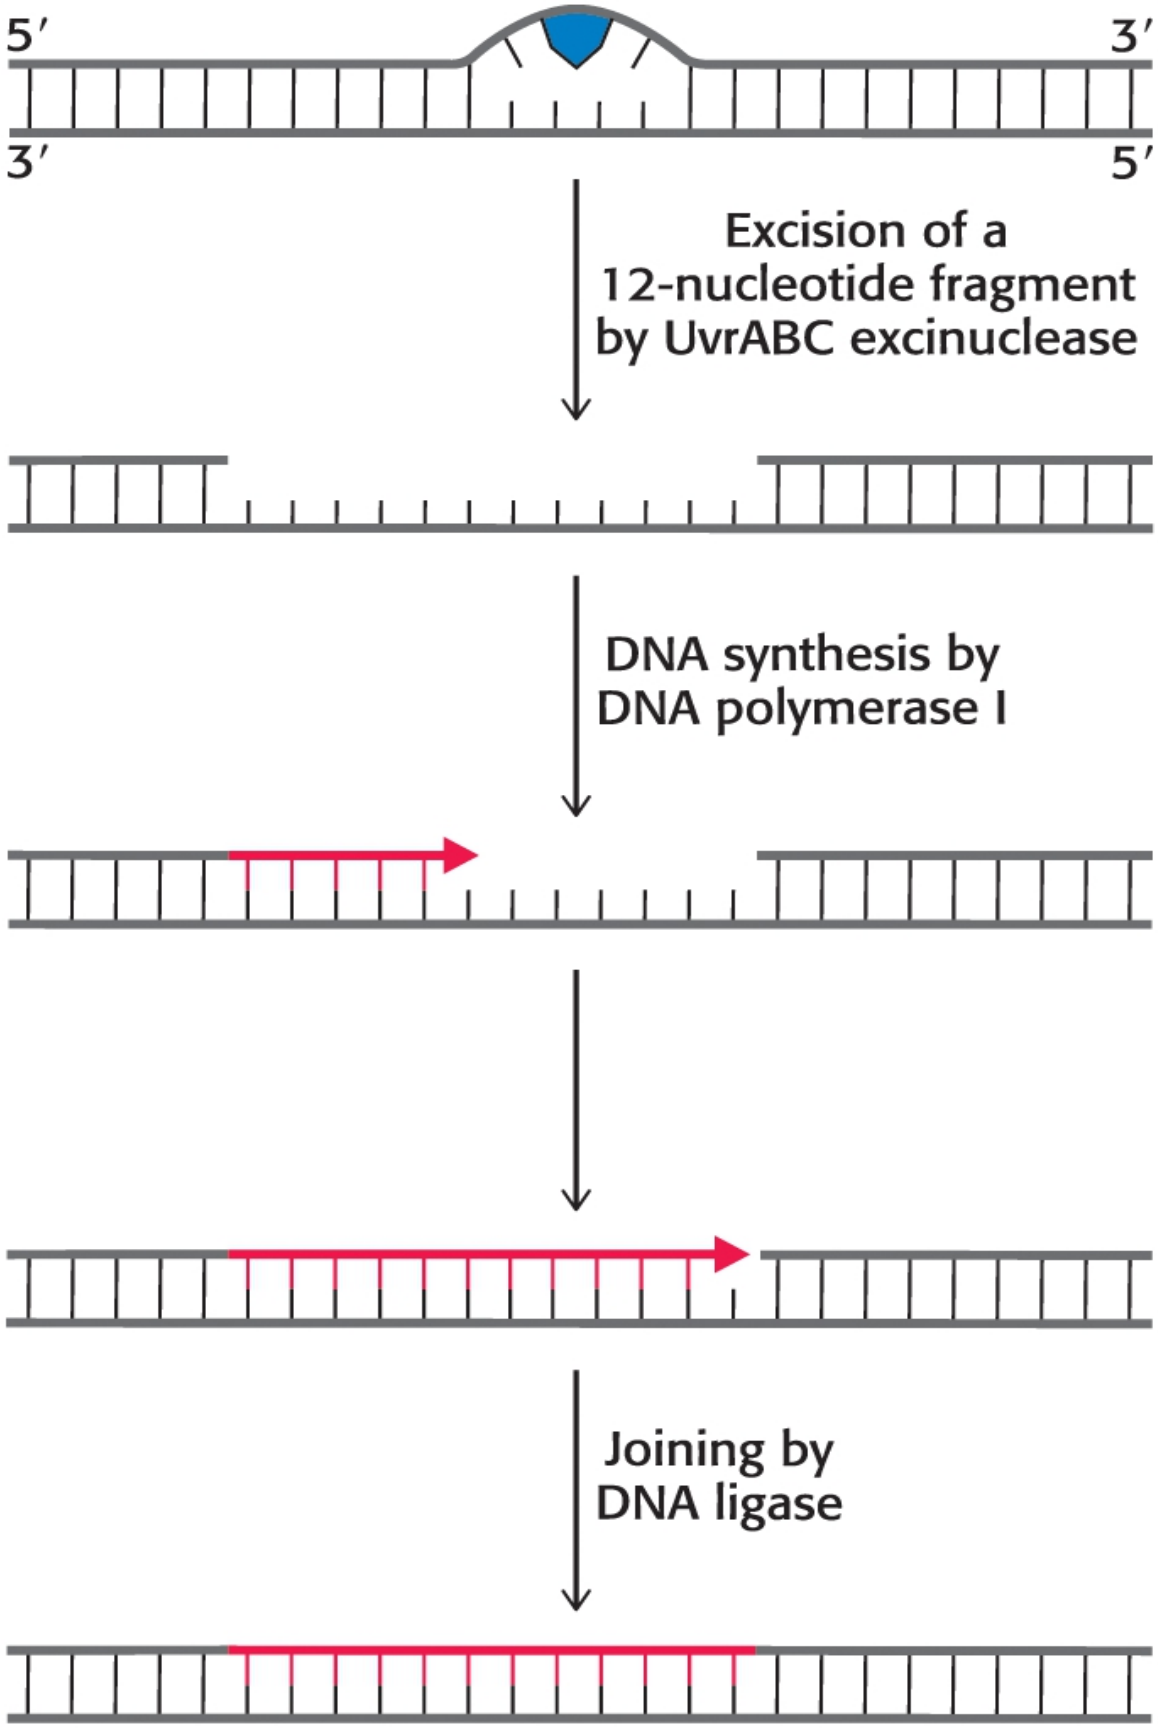
In the third step, exonuclease 1 enters. It cleaves the bottom strand starting from the nick up to 2 base pairs on the left of the mismatch in the 3 prime to 5 prime direction.

In the fourth step, D N A polymerase 3 enters. It re-synthesizes the cleaved bottom strand in the 5 prime to 3 prime direction. The correct base C is added opposite G.

Return to FIGURE 28.37 D N A mismatch repair in *E. coli* involves multiple proteins

Extended description for FIGURE 28.38 Base-excision repair enzymes remove damaged bases

© Macmillan Learning



The D N A double helix is slightly curved. It consists of two strands composed of red and blue spheres. The repair enzyme consists of several beta-strands and a few alpha-helices interconnected by thread-like loops. It is associated with the top groove of the double

helix. The backbone sugar in the apurinic site is flipped out of the helix into the repair enzyme's enzyme active site. The active site is depicted as a small hollow space surrounded by thread-like loops.

Return to FIGURE 28.38 Base-excision repair enzymes remove damaged bases

Extended description for FIGURE 28.39 Nucleotide-excision repair involves the removal of a section of

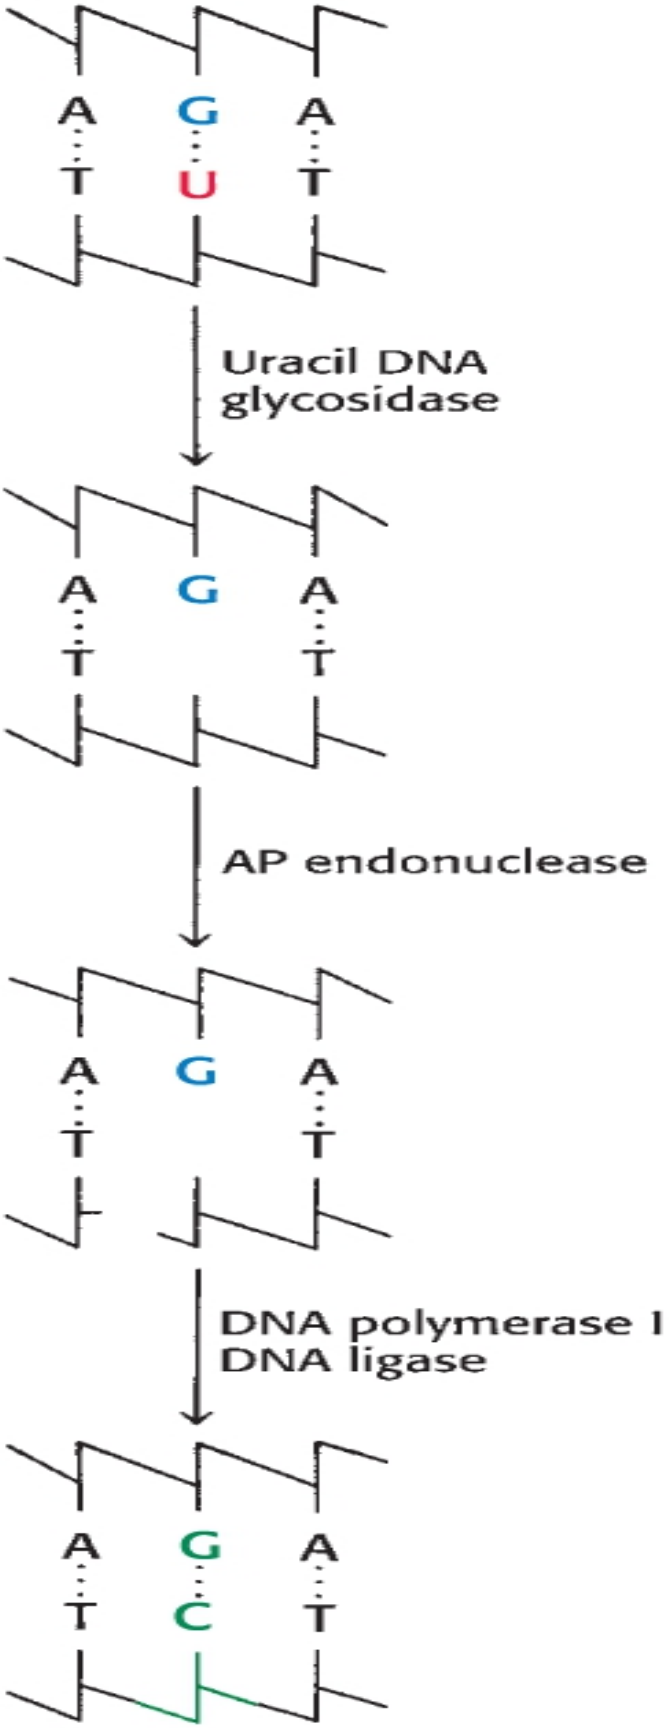
damaged D N A

© Macmillan Learning

A double-stranded D N A is shown. The left and right ends of the top strand are labeled 5 prime and 3 prime respectively. The left and right ends of the bottom strand are labeled 3 prime and 5 prime respectively. A thymine dimer in the middle of the top strand is depicted as a blue block. It causes the bulging out of the top strand.

In the first step, the excision of a 12-nucleotide fragment by U v r A B C excinuclease takes place. In the top strand, a fragment containing the thymine dimer and its flanking region is removed.

In the second step, D N A synthesis by D N A polymerase 1 is initiated. The cleaved region of the top strand is re-filled by the D N A synthesizing activity of D N A polymerase 1. The synthesis takes place in 5 prime to 3 prime direction.



In the third step, D N A synthesis on the top strand is completed. The free 3 prime end of the newly synthesized D N A strand is depicted as an arrowhead pointing toward the right.

In the fourth step, the free 3 prime end of the newly synthesized D N A on the top strand is joined with the free 5 prime end of the adjacent nucleotide by D N A ligase.

Return to FIGURE 28.39 Nucleotide-excision repair involves the removal of a section of damaged D N A

Extended description for FIGURE 28.40 Excision and

replacement of uridine bases in D N A by cytidine

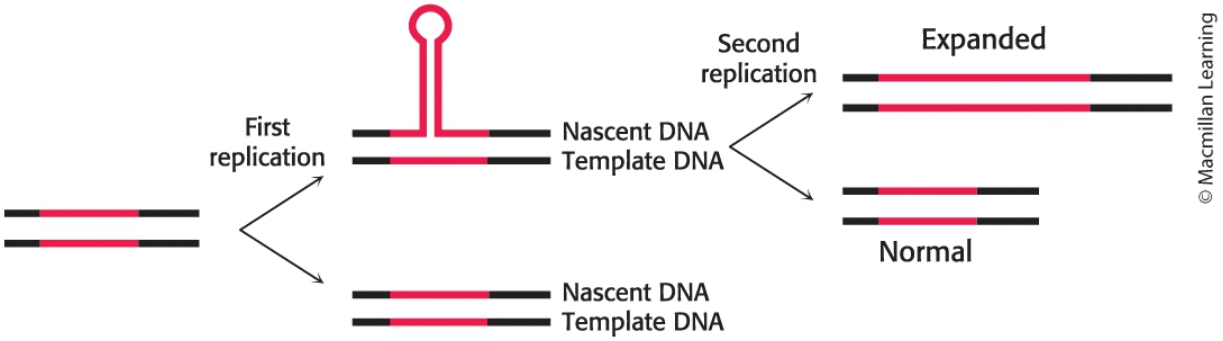
© Macmillan Learning

A section of a double-stranded D N A is shown. The top and bottom strands are depicted as zigzag lines. Short lines from the top and bottom strands are attached to different bases. From left to right, the sequence in these strands is as follows:

Top strand: A G A

Bottom strand: T U T

The complementary bases are connected by hydrogen bonds depicted as a dotted line.



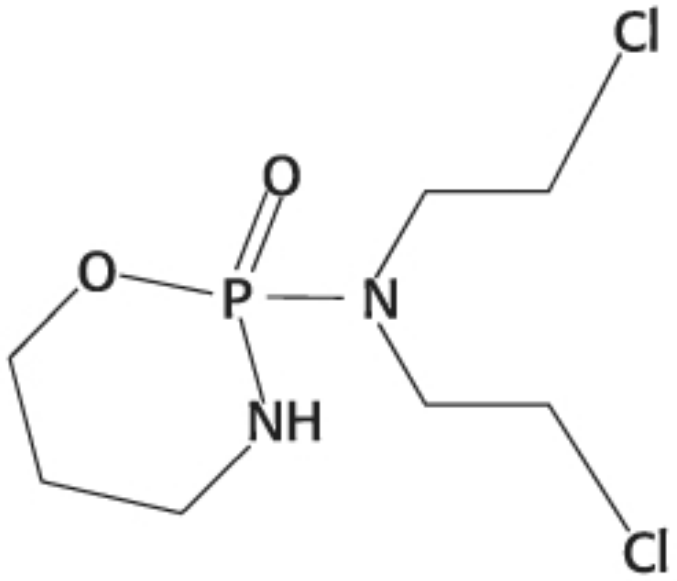
In the first step, uracil D N A glycosidase removes "U" from the bottom strand.

In the second step, A P endonuclease breaks the bond between the apyrimidinic site and the left nucleotide having the base T in the bottom strand.

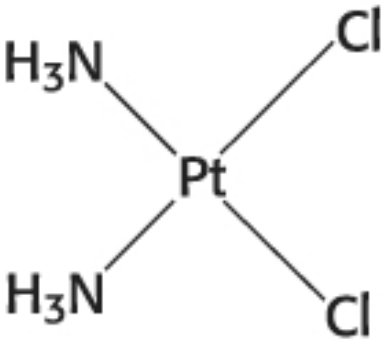
In the third step, the nucleotide in the apyrimidinic site is removed and replaced with a new nucleotide having the base C by D N A polymerase 1. The D N A ligase seals the gap between the newly added nucleotide and its adjacent nucleotides.

Return to FIGURE 28.40 Excision and replacement of uridine bases in D N A by cytidine

Extended description for FIGURE 28.41 Trinucleotide repeats can form structures that lead to their expansion during D N A replication



A double-stranded D N A is depicted as two parallel solid lines. The central large portion of each strand is shown in red and it is flanked by short black stretches. After the first replication round, two daughter D N A molecules are formed. One daughter D N A is linear double-stranded. In this D N A, the top strand is labeled nascent D N A and the bottom strand is labeled template D N A. Another daughter D N A is double-stranded with a hairpin loop. In this D N A, the red region of the nascent D N A strand forms a hairpin loop structure.



After the second replication round in the double-stranded D N A containing the hairpin loop, the red region is expanded in one daughter D N A. However, in the other daughter D N A, the size of the red region is similar to the parental D N A and is labeled normal.

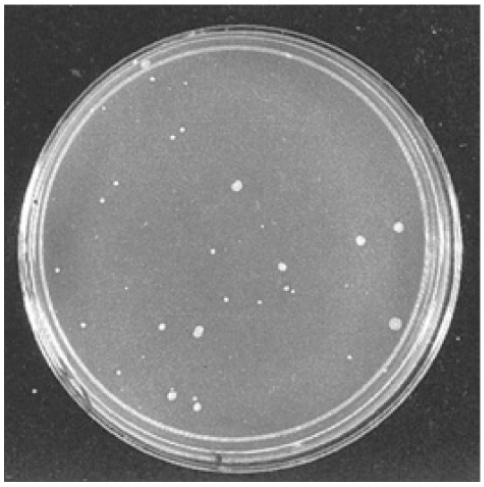
Return to FIGURE 28.41 Trinucleotide repeats can form structures that lead to their expansion during D N A replication

Extended description for Structure of cyclophosphamide and cisplatin

Cyclophosphamide

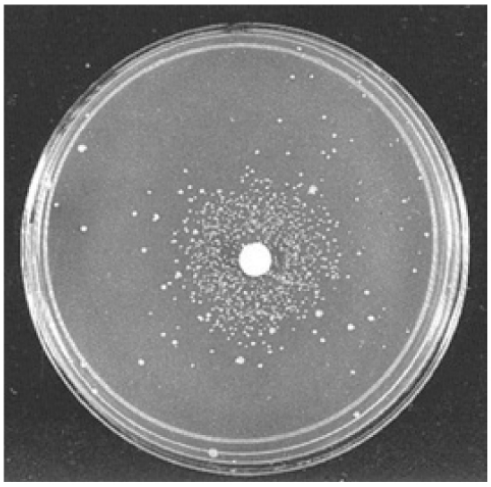
Cisplatin

The structure of cyclophosphamide is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the bottom right vertex. It contains 1 O, 1 P, 1 N, and 3 C



atoms. O occupies the top left vertex. P occupies the top right vertex. N bound to H occupies the rightmost vertex. P is double bonded to O on the upper right. P is single-bonded to N on the right. This N is single-bonded to a 2-carbon alkane chain depicted as a line on the upper right and lower right. C 2 of the upper right alkane chain is single-bonded to C l on the upper right. C 2 of the lower right alkane chain is single bonded to C l on the lower right.

The structure of cisplatin is as follows: A central P t atom is single-bonded to N H 3 on the upper left and N H 3 on the lower left. It is single-bonded to C l on the upper right and C l on the lower right.



Return to Structure of cyclophosphamide and cisplatin

Extended description for FIGURE 28.43 D N A recombination

© Macmillan Learning

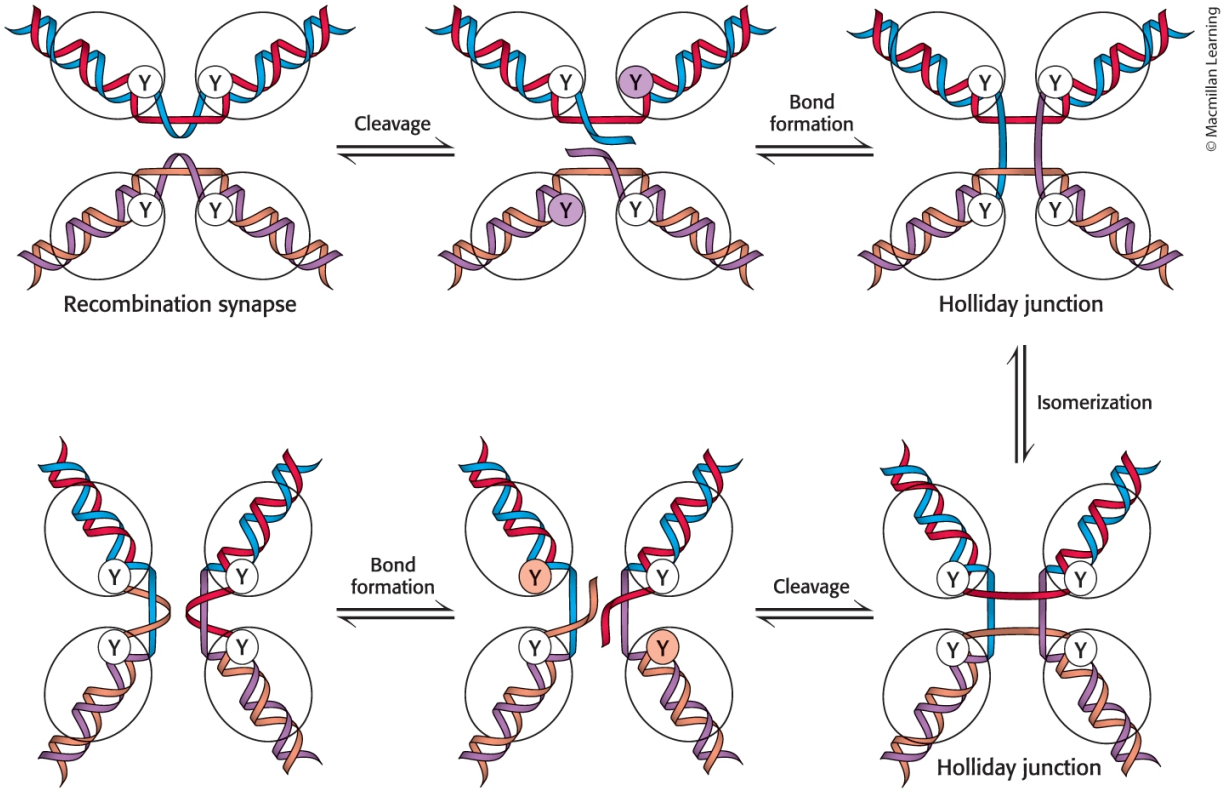
Two double-stranded D N A molecules are depicted as two solid parallel lines. The top D N A molecule contains a red top strand and a blue bottom strand. The bottom D N A molecule contains an orange top strand and a purple bottom strand.

A forward arrow labeled recombination leads to the product of D N A recombination.

In the top D N A molecule, the top strand is half red and half orange, and the bottom strand is half blue and half purple. In the bottom D N A molecule, the top strand is half orange and half red and the bottom strand is half purple and half blue.

Return to FIGURE 28.43 D N A recombination

Extended description for FIGURE 28.44 Strand invasion can initiate recombination



Two double-stranded D N A molecules are depicted as two solid parallel lines. The top D N A molecule is relatively shorter than the bottom D N A molecule. In the top D N A molecule, the bottom strand is relatively longer than the top strand such that its left end extends out. The strands of both D N A molecules are differently colored.

A forward arrow labeled strand invasion shows the formation of a displacement loop in the bottom D N A molecule due to strand invasion.

The left end of the bottom strand of the top D N A molecule enters into the space between the strands of the bottom D N A molecule. As a result, a displacement loop is formed due to the bulging out of the top strand of the bottom D N A molecule.

Return to FIGURE 28.44 Strand invasion can initiate recombination

Extended description for FIGURE 28.45 Holliday junctions are formed and resolved by recombinases

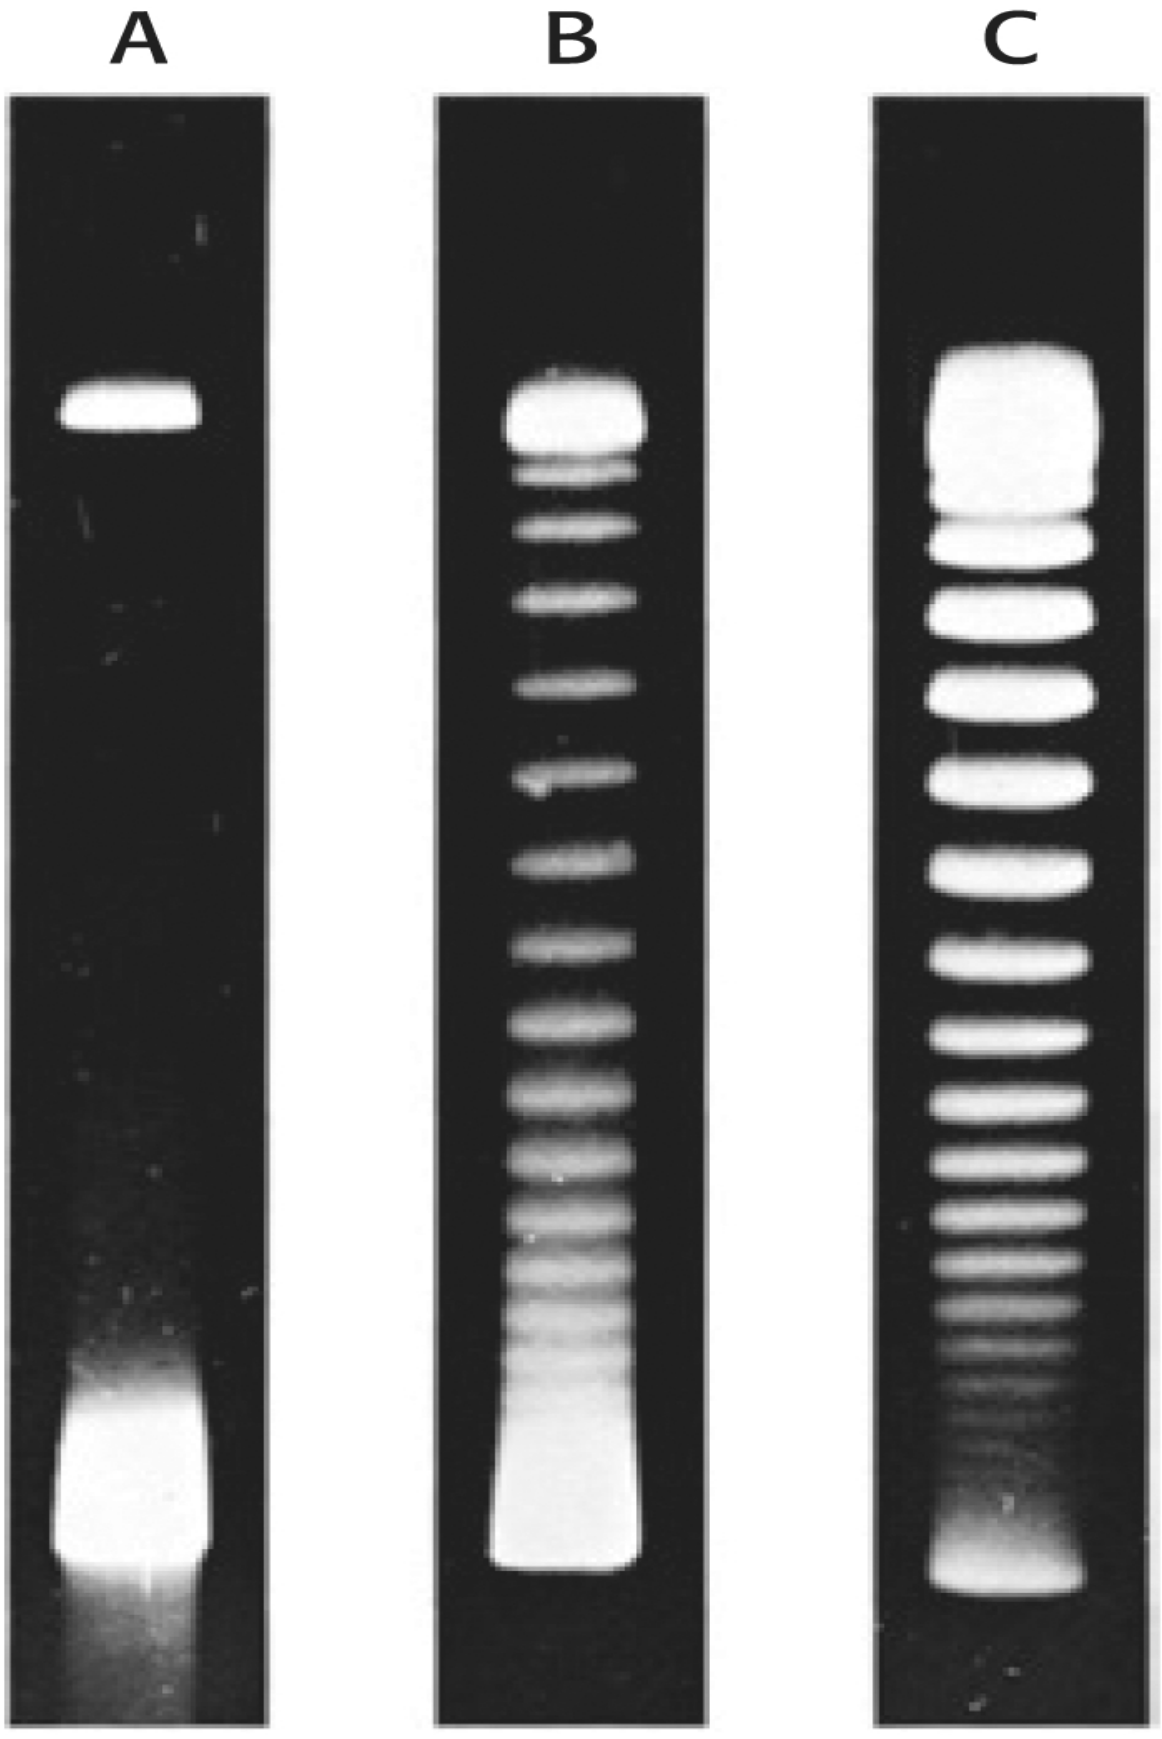
Two double-helical D N A molecules are each bound to two recombinases. The recombinase is depicted as a large white oval. Two recombinases in diagonal orientation are bound to the top helix such that it forms a V-shaped structure. Two recombinases in diagonal orientation are bound to the bottom helix such that it forms an inverted V-shaped structure. Each recombinase contains a tyrosine residue depicted as a tiny circle labeled Y. These residues are located close to the bound helix.

In the first reversible step, cleavage takes place. One strand of the top helix and the bottom helix is cleaved. One end of each cleaved strand is linked to the tyrosine residue of the associated

recombinase. In the top helix, one end of the cleaved strand is linked to the tyrosine of the right recombinase. In the bottom helix, one end of the cleaved strand is linked to the tyrosine of the left recombinase.

In the second reversible step, bond formation takes place leading to the formation of the Holliday junction. The free end of the cleaved strand of the top helix links with the tyrosine residue of the left recombinase of the bottom helix. The free end of the cleaved strand of the bottom helix links with the tyrosine residue of the right recombinase of the top helix. This creates an interlinked D N A having a junction resembling the letter H of the alphabet.

In the third reversible step, isomerization takes place such that the intact strands of both helices are located toward the observer.



In the fourth reversible step, the previously intact strands of both helices are cleaved. One end of the newly cleaved strand of the top helix links with the tyrosine residue of the left recombinase. One end of the newly cleaved strand of the bottom helix links with the tyrosine residue of the right recombinase.

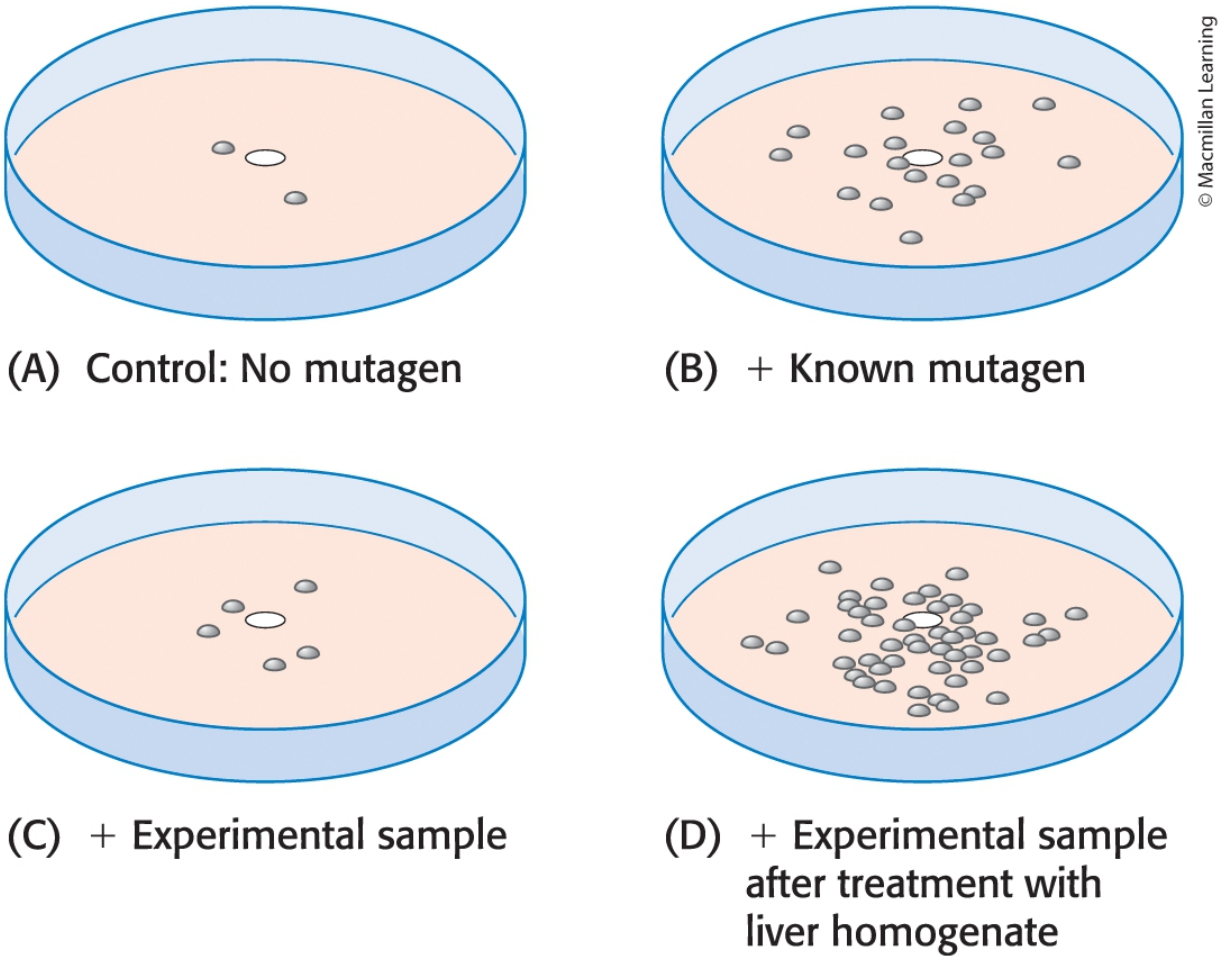
In the fifth reversible step, bond formation takes place. The free end of the cleaved strand of the bottom helix joins with the linked end of the cleaved strand of the top helix. Similarly, the free end of the cleaved strand of the top helix joins with the linked end of the cleaved strand of the bottom helix.

Return to FIGURE 28.45 Holliday junctions are formed and resolved by recombinases

Extended description for D N A banding pattern in

lanes A, B, and C

From W. Keller. PNAS 72(1975):2553.



In lane A, a bright band is present at the top and a thick and bright smear is located at the bottom.

In lane B, a bright band is seen at the top at the same level as the bright band of lane A. It is followed by a series of evenly spaced thin bands from top to bottom. The bottom contains a thick and bright smear.

In lane C, a thick bright band is seen at the top. It is followed by a series of bands whose thickness and intensity decrease from top to bottom. A thin smear is located at the bottom.

Extended description for Electron micrograph and schematic representation of R N A synthesis and splicing respectively

The figure illustrates two images. The first image is an electron micrograph that shows a D N A template from a fruity fly that is being transcribed into R N A. Nascent transcripts, Introns, and D N A are shown with curved arrows on the electron micrograph. The central narrow thread-like D N A has several short threads arising from it labeled nascent transcripts. A loop-like structure at the end of one transcript is labeled introns. The schematic representation depicts the conversion of m R N A precursor into excised intron and m R N A. The m R N A precursor is depicted as a tube-like structure containing three differently colored components shown in red, yellow, and blue. The yellow region forms a loop. The yellow region is cleaved out and labeled excised intron. The blue-colored and red colored components of the m R N A precursor are joined together to form an m R N A.

Extended description for FIGURE 29.1 R N A polymerase structures in prokaryotes and eukaryotes resemble each other

The prokaryotic and eukaryotic R N A polymerase consists of a large dense cluster of several alpha-helices and beta-strands. Each polymerase consists of two subunits shown in dark red and dark blue colors. Both the polymerases have a cleft on the right side. The cleft of the prokaryotic R N A polymerase is relatively deeper and wider than the cleft of the eukaryotic R N A polymerase.

Return to FIGURE 29.1 R N A polymerase structures in prokaryotes and eukaryotes resemble each other

Extended description for R N A synthesis using D N A as a template

The reactant shows a hybrid of R N A and D N A.

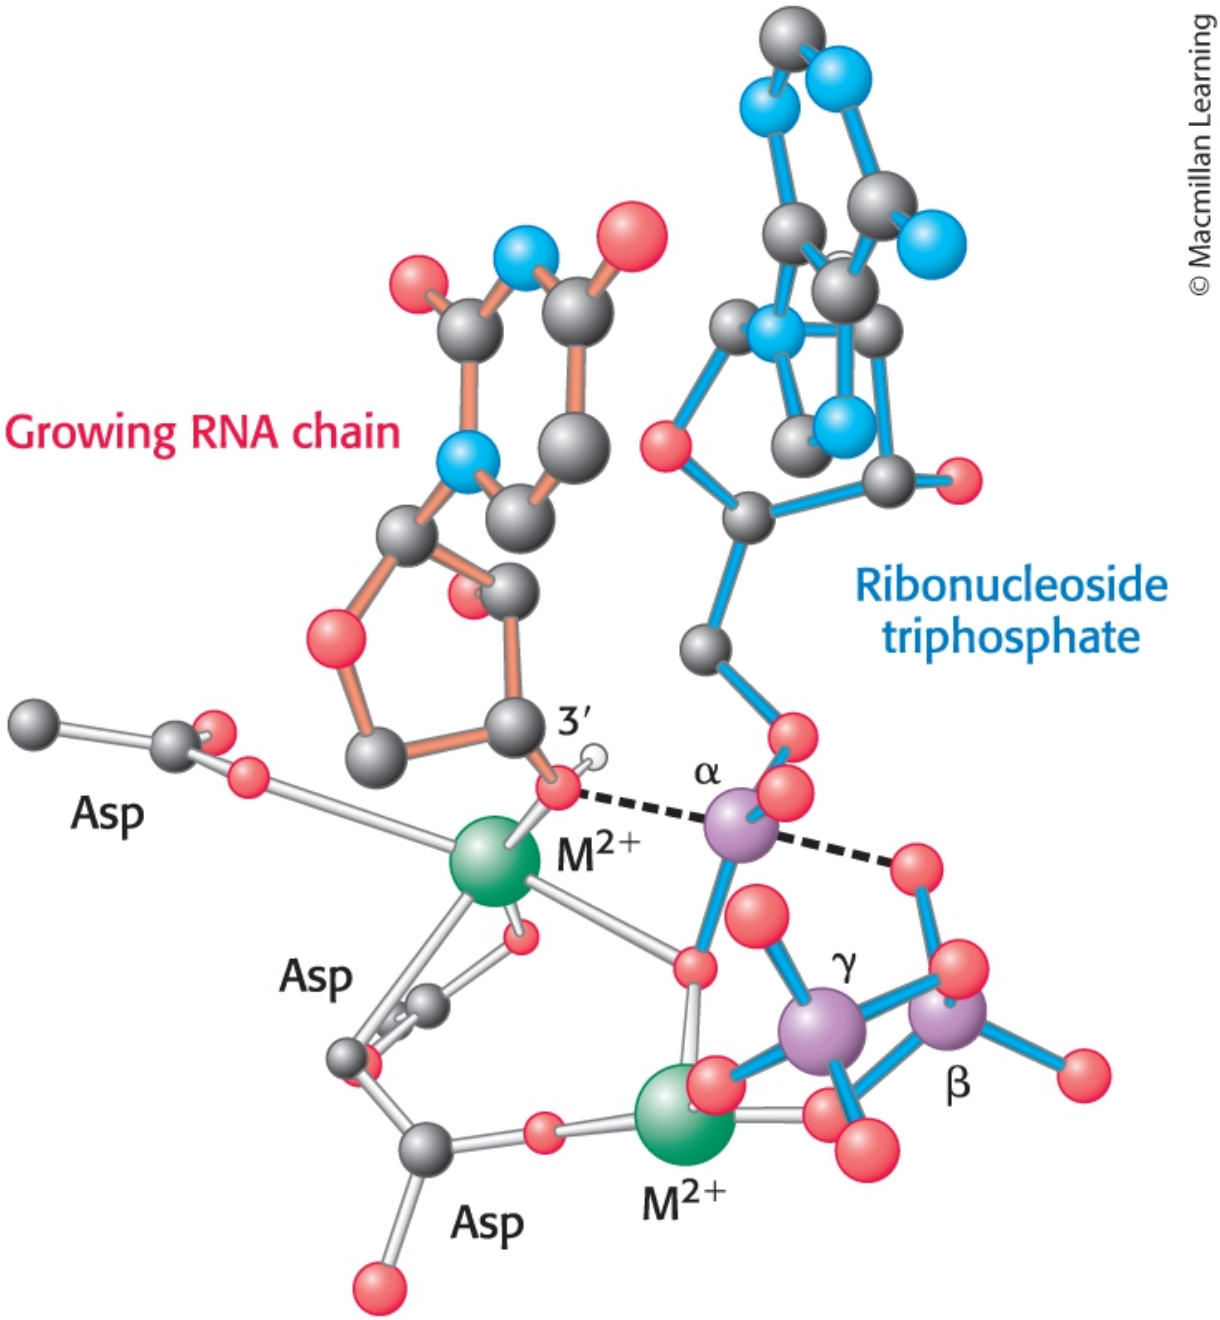
The sequence of D N A is 3 prime, single bond, N, single bond, N, single bond, N, single bond, N, single bond, N, single bond, N, single bond, N, single bond, N, single bond, 5 prime.

The sequence of R N A strand undergoing synthesis is 5 prime, single bond, N, single bond, N, single bond, N, single bond, N, single bond, 3 prime O H.

An incoming nucleoside triphosphate (N T P) is located near the 3 prime end of R N A. The N base of this N T P is aligned opposite to the fifth N base from the 3 prime end of the D N A.

The structure of N T P is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation with C 1 occupying the top left vertex. It consists of 1 O and 4 C atoms. O occupies the leftmost vertex. C 2 and C 3 are each single bonded to H. C 4 is single bonded to N on the lower left. C 1 is single bonded to C H 2 on the upper left in the form of a line. C H 2 is single bonded to O on the

upper right. O is single bonded to a zigzag chain composed of P, single bond, O, single bond, P, single bond, O, single bond, P. P 1 and P 2 are each partially double bonded to two different O. The P O O groups have an overall negative charge. P 3 is partially double bonded to three O. This P O 3 group has an overall negative charge of 2 minus.



An arrow from the 3 prime O H of R N A points toward P 1 of the zigzag chain. Another arrow from the single bond between this P and O 1 points toward O 1.

The first product of the N T P addition includes an R N A and D N A hybrid with a newly added N to the 3 prime end of R N A.

The sequence of D N A is 3 prime, single bond, N, single bond, N, single bond, N, single bond, N, single bond, N, single bond, N, single bond, N, single bond, N, single bond, N, single bond, 5 prime. The sequence of the extended R N A strand is 5 prime, single bond, N, single bond, N, single bond, N, single bond, N, single bond, N. The second product is P P subscript i.

Return to R N A synthesis using D N A as a template

Extended description for FIGURE 29.2 The R N A polymerase active site contains metal ions

The growing R N A chain is shown on the top left and the ribonucleoside triphosphate is shown on the top right. The growing R N A chain consists of a pentagonal ring connected to a hexagonal ring. The pentagonal ring consists of 1 red and 4 black spheres. The hexagonal ring consists of 2 blue and 4 black spheres. The ribonucleoside triphosphate consists of a pentagonal ring connected to a hexagonal ring. The pentagonal ring consists of 1 red and 4 black spheres. The hexagonal ring consists of 2 blue and 4 black spheres. A green sphere depicting M superscript 2 plus is shown below the pentagonal ring of the growing R N A chain. It is connected to the red or black sphere in the side chain of aspartic acid residue on the left, lower left, and bottom. It is also connected to a red sphere on the upper right, which is further connected to a black sphere at the 3 prime position of the pentagonal ring. This red sphere is also connected to a white sphere. A second green sphere depicting M superscript 2 plus is connected to the red sphere of aspartic acid residue on the left, the red sphere of the beta phosphoryl group, the red sphere of gamma phosphoryl group, the red sphere of the alpha-phosphoryl group connected to the pentagonal ring of ribonucleoside triphosphate. This red sphere of the alpha phosphoryl group is also connected to the first green sphere.

The pyrophosphate consists of two purple spheres. Each purple sphere is connected to three red spheres. The purple sphere connected to red spheres depicts beta and gamma phosphoryl groups. The gamma phosphoryl group is located toward the observer. The red sphere of the beta phosphoryl group is connected to the red sphere which is, in turn, connected to the 3 prime position of the pentagonal ring of the growing R N A chain. This connection is represented by a dashed line.

Return to FIGURE 29.2 The R N A polymerase active site contains metal ions

Extended description for FIGURE 29.3 R N A polymerase separates a region of the double helix to form the transcription bubble

© Macmillan Learning

The R N A polymerase is depicted as a large dense cluster composed of several alpha-helices and beta-strands. A ball-and-stick model of D N A double helix passes from the left end of the polymerase to the bottom. The double helix is separated inside the polymerase to form

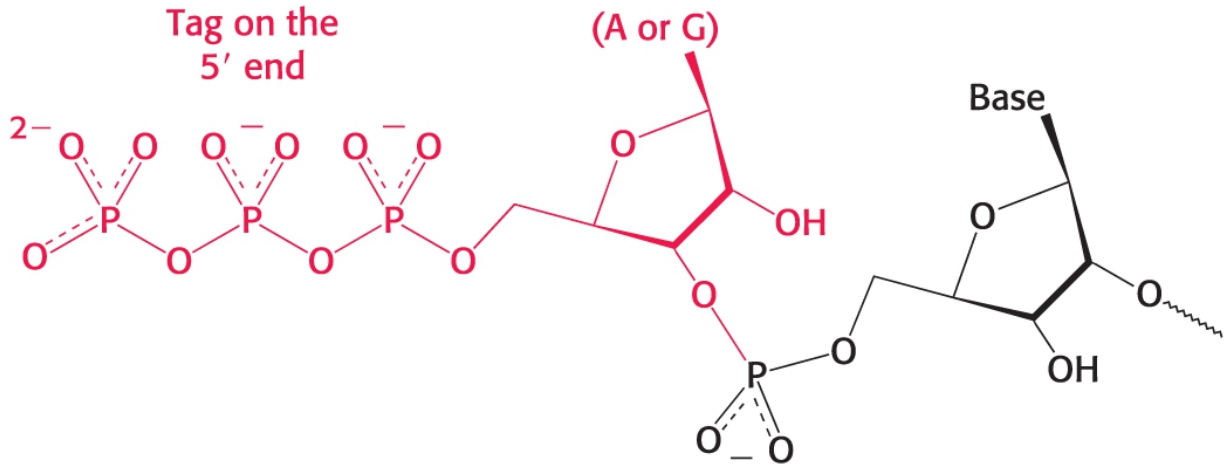
a large transcription bubble. The strands of D N A are composed of red and blue spheres. The strand composed of red spheres depicts the template. A yellow sphere depicting magnesium is located in the center of the polymerase adjacent to the template strand in the bubble. A short R N A strand composed of a green sphere is bonded to the template strand in the bubble.

Return to FIGURE 29.3 R N A polymerase separates a region of the double helix to form the transcription bubble

Extended description for FIGURE 29.4 R N A transcript complementary to the template strand

The sequence of the template or antisense (minus) strand is as follows from left to right: ellipsis, G C A T A C A A C A C A C C T T G C A T C C A G T G T A G, ellipsis.

The sequence of the coding or sense (plus) strand is as follows from left to right: ellipsis, C G T A T G T T G T G T G G A A C G T A G G G T C A C A T C, ellipsis.



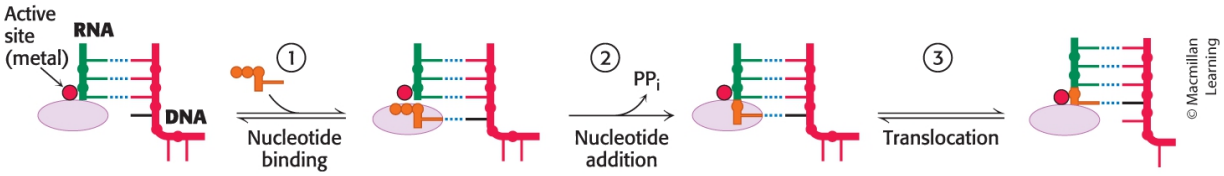
The sequence of R N A transcript complementary to the template strand is as follows from left to right: A A C G U A G G G U C A C A U C, ellipsis.

The first A of R N A corresponds to C at the 14th position of the template. The fourth C of the R N A corresponds to G at the 30th position of the template.

A vertical line passes from the left side of first A in R N A, through the space between C T and G A of the coding strand. The base G on the left of this vertical line in the coding strand is numbered minus 1. The first base A on the right of the vertical line in the coding strand is numbered plus 1. The second A, located on the right of the first A numbered plus 1, is numbered plus 2.

Return to FIGURE 29.4 R N A transcript complementary to the template strand

Extended description for Structure of a molecule



The structure is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. The ring is in a plane perpendicular to the plane of the paper such that O is away from the observer and C 2 and C 3 are toward the observer. C 1 is wedge bonded to (A or G). C 2 is single bonded to O H. C 3 is single-bonded to O. O is single-bonded to a central P atom of the first phosphate group on the lower right. A central P is single-bonded to the first O on the upper right, partially double-bonded to O superscript minus on the lower right, and partially double-bonded to the second O on the lower left. The first O atom of the phosphate group is single-bonded to C H 2 on the upper right in the form of a line. C H 2 is single-bonded to C 4 of the second 5-membered heterocyclic pentagonal ring in a vertical orientation. The 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. The ring is in a plane perpendicular to the plane of the paper such that O is away from the observer and C 2 and C 3 are toward the observer. C 1 is wedge bonded to the base. C 2 is single-bonded to O. O has a wiggly line on

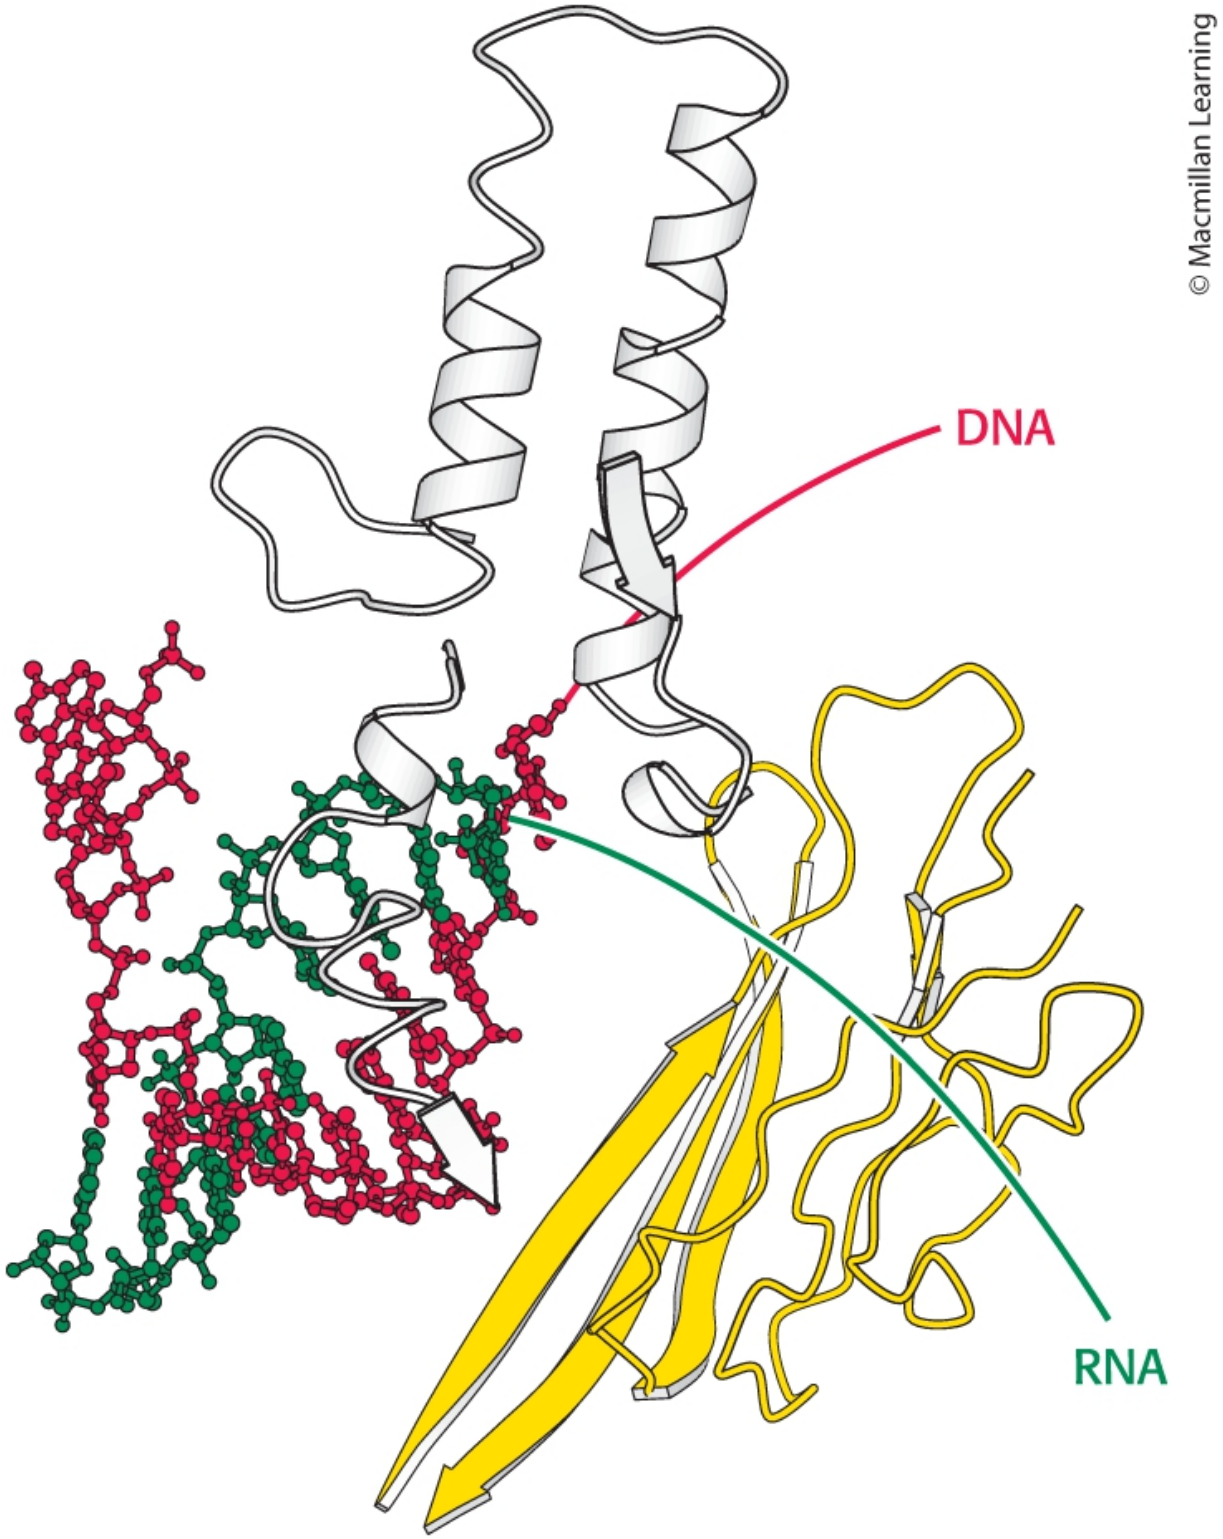
the lower right. C 3 is single-bonded to O H. C 4 of the first pentagonal ring is single-bonded to C H 2 in the form of a line. C H 2 is single-bonded to O on the lower left. O is further single-bonded to a central P atom of the first phosphate group. The central P atom is single-bonded to the first O on the lower left, partially double-bonded to the second O on the upper right, and partially double-bonded to the O superscript minus on the upper left. The first O of the first phosphate group is single-bonded to a central P atom of the second phosphate group. The central P atom is single-bonded to the first O on the lower left, partially double-bonded to the second O on the upper right, and partially double-bonded to the O superscript minus on the upper left. The first O of the second phosphate group is single-bonded to a central P atom of the third phosphate group. The central P atom is partially double-bonded to the first O on the lower left, partially double-bonded to the second O on the upper right, and partially double-bonded to O superscript 2 minus on the upper left. The three phosphate groups are aligned in a zigzag manner. The three phosphate groups in the chain and first pentagonal ring are highlighted in red color and labeled "Tag on the 5 prime end."

Return to Structure of a molecule

Extended description for FIGURE 29.5 The elongation mechanism involves a series of steps

An R N A-D N A hybrid is shown. The R N A is depicted as a solid green vertical line. The D N A is depicted as a solid red vertical line. R N A and D N A molecules are connected by three base pairs. The bottom end of the D N A is curved toward the lower right. It has an unpaired base. A purple oval with a tiny red circle at the top is located at the bottom end of R N A. The red circle is labeled active site (metal).

In the first reversible step, nucleotide binding takes place. The nucleotide is depicted as a short vertical stick with three orange circles at the top left and a short stick on the middle right. It aligns below the bottom end of the R N A inside the purple oval. It forms hydrogen bonds with the free unpaired base of the D N A molecule.



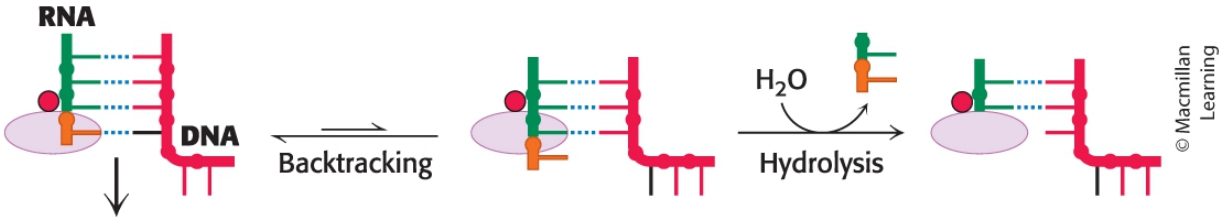
In the second irreversible step, P P subscript i is released and nucleotide addition takes place. The two terminal circles of the nucleotide are removed. The gap between the bottom end of R N A and incoming nucleotide is sealed.

In the third reversible step, translocation takes. The purple oval translocates downward such that it is located opposite the next free unpaired base of D N A.

Return to FIGURE 29.5 The elongation mechanism involves a series of steps

Extended description for FIGURE 29.6 A structure within R N A polymerase forces the separation of the R

N A–D N A hybrid



© Macmillan Learning

A helix-loop-helix is shown at the top. A beta-strand is shown in front of the right helix. Three anti-parallel beta strands in diagonal orientation are shown on the lower right of the helix-loop-helix. The beta strands are connected to several loops on the right. The ball-and-stick model of an R N A-D N A hybrid is located below the helix-loop-helix and on the left of the beta-strands. A short helix connected to a short beta-strand through a long loop passes over the R N A-D N A hybrid. The D N A composed of red spheres forms a U-shaped orientation such that the free end of D N A is located toward the upper left. The R N A composed of green spheres is in a diagonal orientation such that its free end is located toward the lower left, below the D N A.

Return to FIGURE 29.6 A structure within R N A polymerase forces the separation of the R N A–D N A hybrid

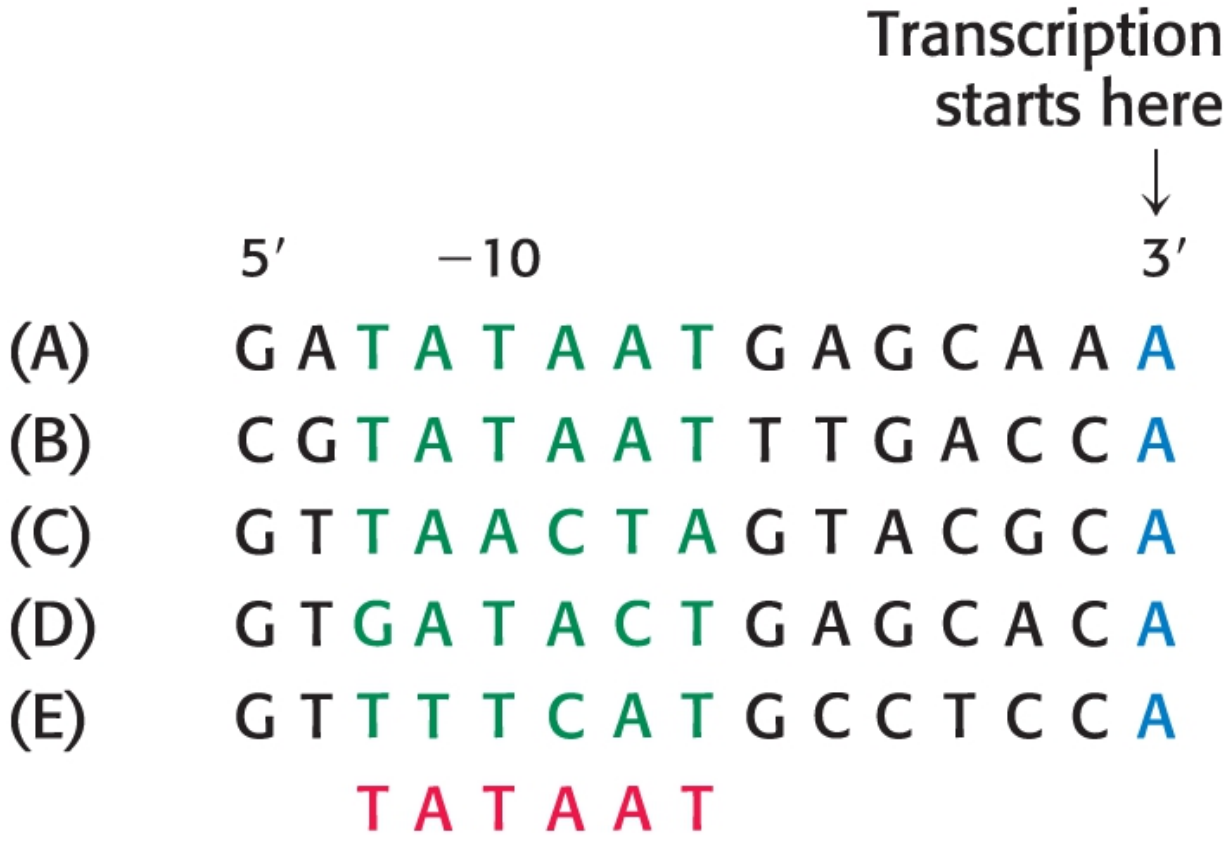
Extended description for FIGURE 29.7 The R N A–D N A hybrid can occasionally backtrack within the R N A polymerase

An R N A-D N A hybrid is shown. The R N A is depicted as a solid green vertical line. The D N A is depicted as a solid red vertical line. R N A and D N A molecules are connected by four base pairs. The bottom end of the D N A is curved toward the lower right. It has two unpaired nucleotides. A purple oval with a tiny red circle at the top is located at the bottom end of R N A. The oval structure encloses the newly added nucleotide depicted in orange color.

In the first reversible step, backtracking takes place. The oval moves upward and encloses the nucleotide located above the orange nucleotide. The base in the D N A previously hydrogen bonded with the orange nucleotide becomes unpaired and moves toward the lower right.

In the second irreversible step, hydrolysis takes place with the entry of H 2 O and removal of dinucleotide from the bottom end of R N A. The released dinucleotide includes the orange nucleotide and the nucleotide located above it. The purple oval is bound to the bottom end of the R N A. In the hybrid, R N A and D N A molecules are connected by two base pairs. The D N A contains three unpaired nucleotides at the lower right.

Return to FIGURE 29.7 The R N A–D N A hybrid can occasionally backtrack within the R N A polymerase



Extended description for Consensus sequence for the core promoter

The consensus sequence deduced from the analyses of the many promoters is as follows: 5 prime, small wiggly line, T T G A C A, large wiggly line, T A T A A T, medium wiggly line, start site. The first and the second sequence are highlighted in red and labeled minus 35 and minus 10 respectively. The start site mentioned at the end of the sequence is labeled plus 1.

Return to Consensus sequence for the core promoter

Extended description for FIGURE 29.8 Bacterial promoters contain conserved sequences

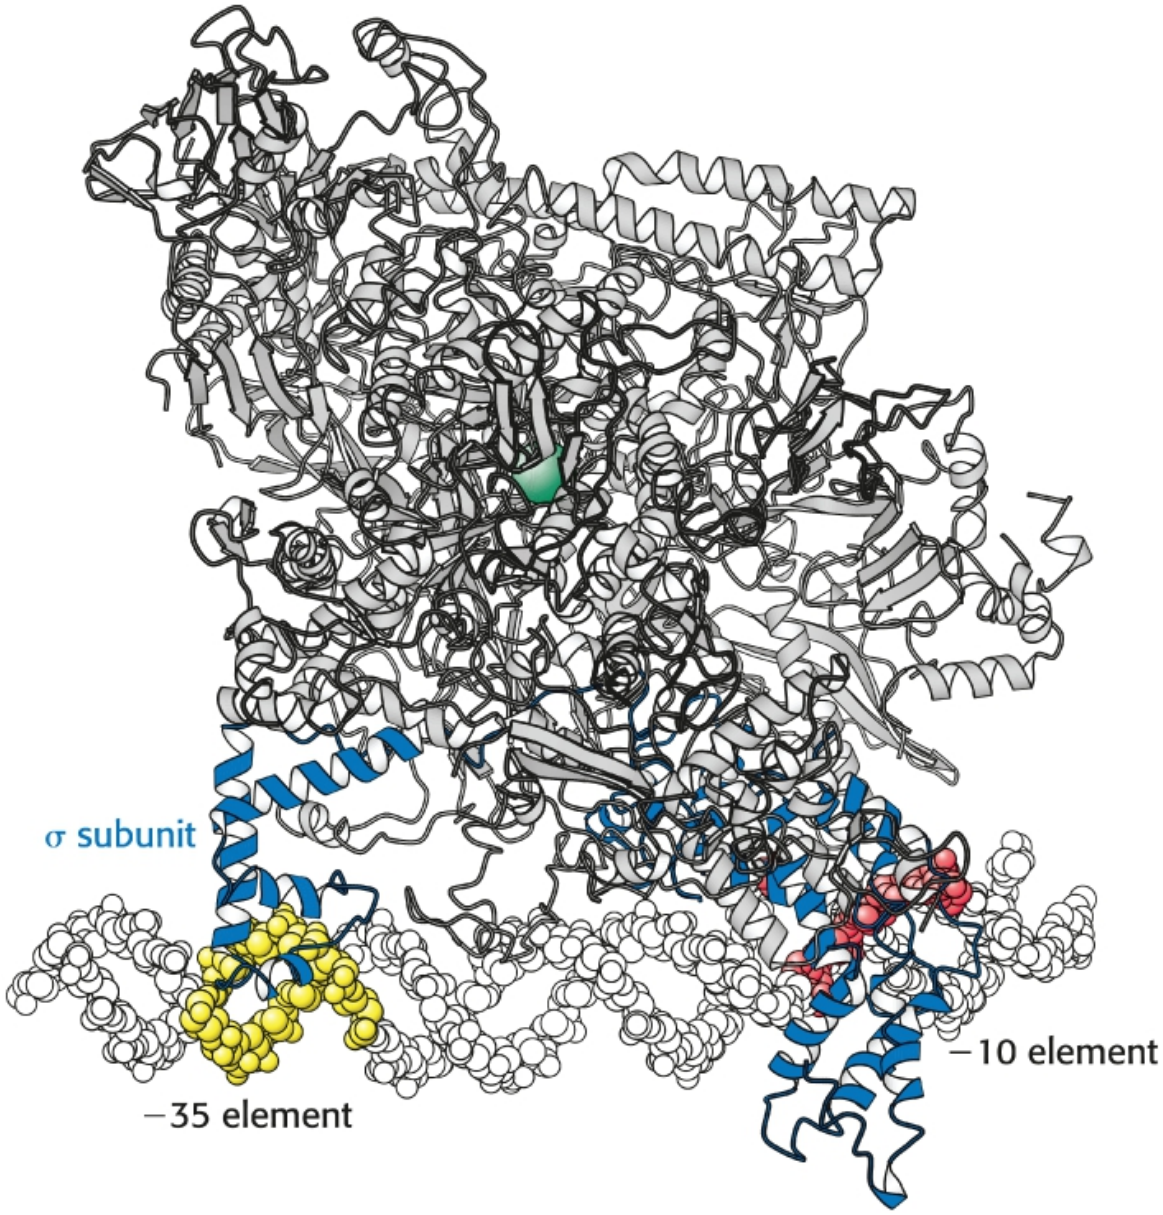
The sequences are labeled (A) to (E).

Sequence (A) reads 5 prime, G A T A T A A T G A G C A A A, 3 prime.

Sequence (B) reads 5 prime, C G T A T A A T T T G A C C A, 3 prime.

Sequence (C) reads 5 prime, G T T A A C T A G T A C G C A, 3 prime.

Sequence (D) reads 5 prime, G T G A T A C T G A G C A C A, 3 prime.



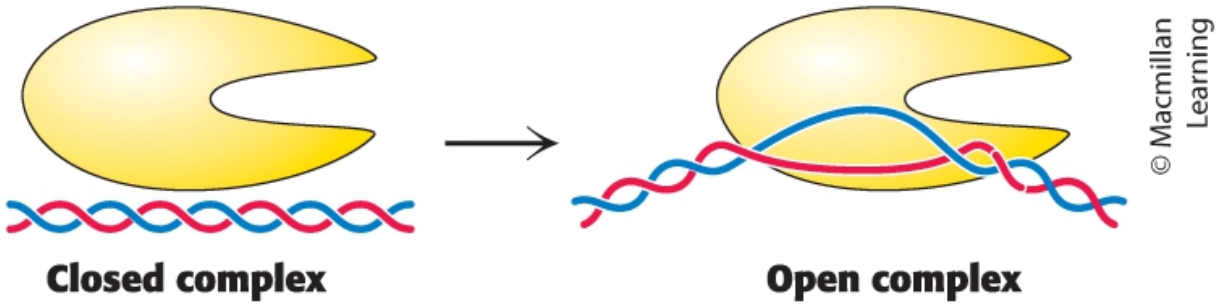
Sequence (E) reads 5 prime, G T T T T C A T G C C T C C A, 3 prime.

The base A at the 3 prime ends is highlighted in blue and labeled "Transcription starts here."

The bases at the fifth position from the 5 prime end in each sequence, occupy the minus 10 position. The sequence T A T A A T highlighted in red corresponds to the consensus sequence at the minus 10 position.

Return to FIGURE 29.8 Bacterial promoters contain conserved sequences

Extended description for FIGURE 29.9 E. coli R N A polymerase holoenzyme complex binds to conserved promoter sequences

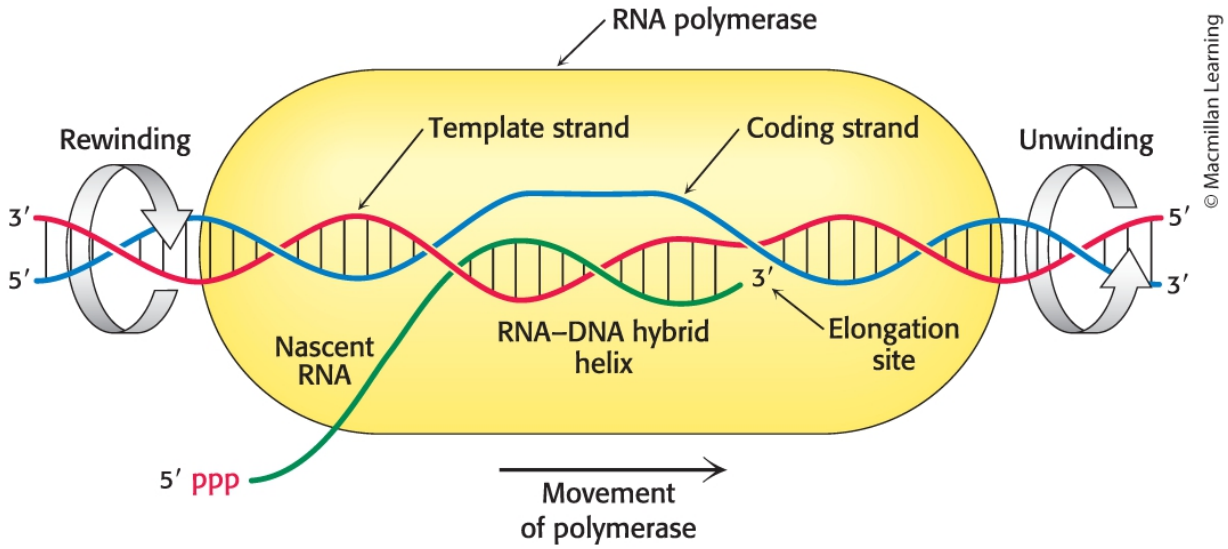


© Macmillan Learning

The R N A polymerase holoenzyme consists of a dense and large cluster of alpha-helices and beta-strands. A few alpha-helices of the

sigma subunit extend from the bottom right and bottom left of the holoenzyme. The alpha-helices on the bottom left are bound to the minus 35 element of D N A. The alpha-helices on the bottom right are bound to the minus 10 element of D N A. D N A double helix in horizontal orientation is depicted as two strands composed of white spheres. The minus 35 element is highlighted in yellow and the minus 10 element is highlighted in red.

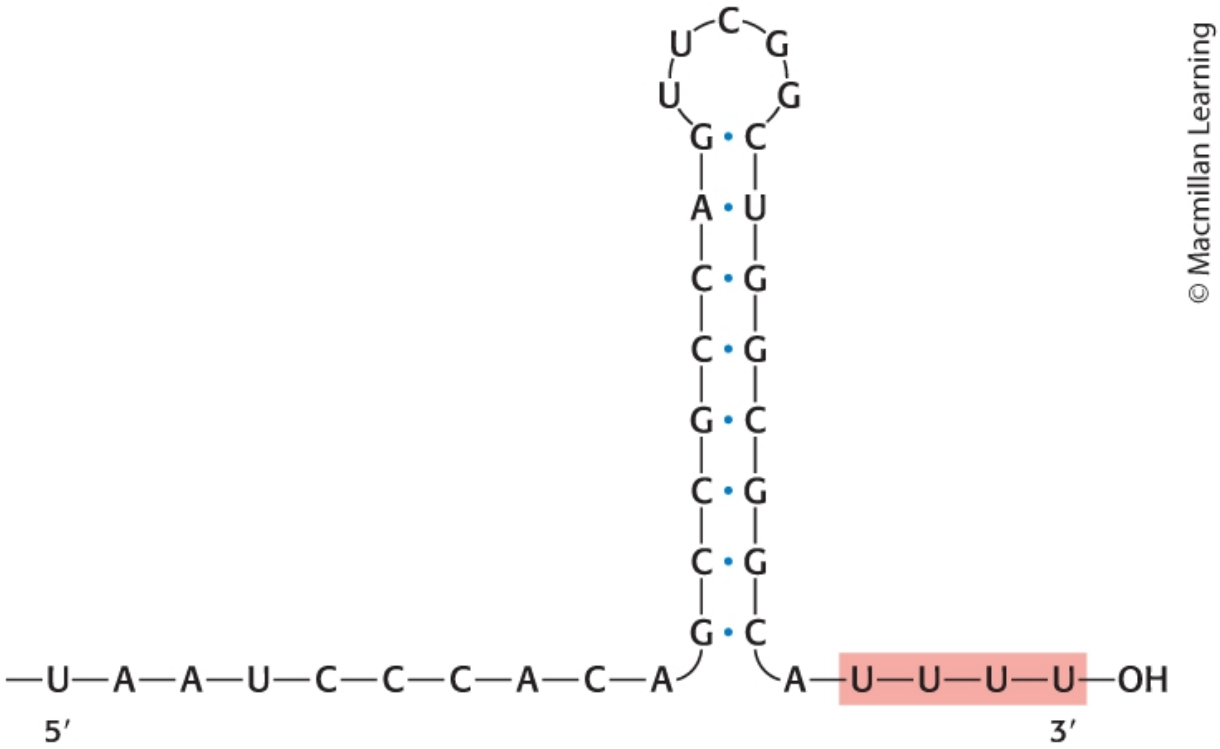
Return to FIGURE 29.9 E. coli R N A polymerase holoenzyme complex binds to conserved promoter sequences



Extended description for FIGURE 29.10 E. coli R N A polymerase binds to a promoter sequence

In the closed complex, R N A polymerase depicted as a yellow oval with a deep cleft on the right is shown above a double helical D N A. A forward arrow leads to the open complex. In the open complex, the D N A is bent downward and its strands are unwound in the middle to form a bubble. The bubble is bound by the polymerase.

Return to FIGURE 29.10 E. coli R N A polymerase binds to a promoter sequence



Extended description for FIGURE 29.11 The transcription bubble moves with the R N A polymerase during elongation

A double-helical D N A is shown in a horizontal orientation. It is composed of a red and a blue strand. The red strand is labeled the template strand. The blue strand is labeled the coding strand. The ends of the D N A double helix are located outside the R N A polymerase. The R N A polymerase is depicted as a large yellow capsule-shaped structure. Rewinding occurs at the left end and is depicted as a clockwise arrow. Unwinding occurs at the right end and is depicted as an anticlockwise arrow. A transcription bubble is formed in the double helix inside the R N A polymerase. A nascent R N A strand is depicted in green. It is bound to the template strand in the bubble to form an R N A-D N A hybrid helix. The nascent R N A exits out of the R N A polymerase and its 5 prime end contains three P. The free 3 prime of the R N A is labeled elongation sites as the polymerase moves in 5 prime to 3 prime direction.

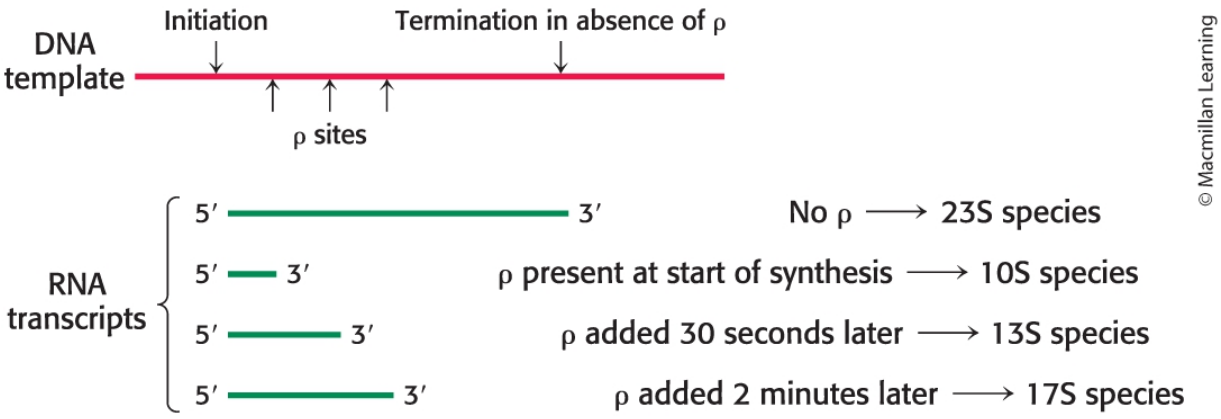
Extended description for FIGURE 29.12 Some genes contain intrinsic termination signals



© Macmillan Learning

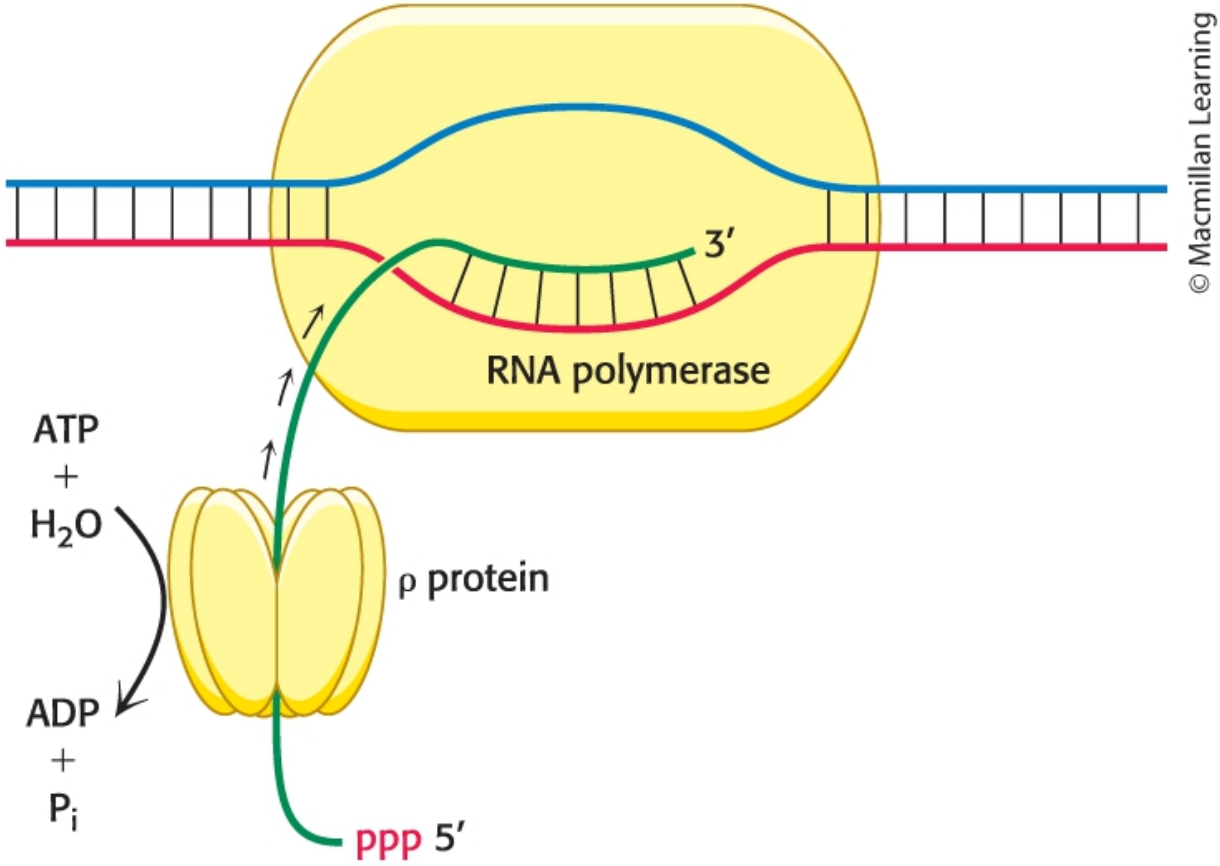
The intrinsic terminal signal consists of a stem-loop structure. The linear 5 prime sequence is U A A U C C C A C A. The stem-loop consists of G C, A U, C G, C G, G C, C G, C G, and G C base pairs from top to bottom of the stem region. The loop region consists of U U C G G in an anti-clockwise orientation starting from the bottom left. The linear 3 prime sequence is A U U U U, single bond, O H. The continuous string of U residues is highlighted inside a pink rectangle.

Return to FIGURE 29.12 Some genes contain intrinsic termination signals

Extended description for FIGURE 29.13 Rho protein promotes the termination of transcription

© Macmillan Learning

The D N A template is depicted as a solid red horizontal line. The initiation site is present near the left end and a site near the right end is labeled "Termination in absence of rho." Three rho sites are present between the initiation and rho-independent sites.



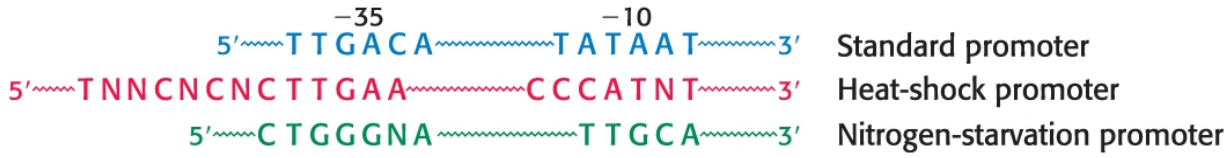
Four R N A transcripts of different lengths are shown below the D N A template. They are depicted as solid green lines. The left end is labeled 5 prime and the right end is labeled 3 prime. The first R N A transcript corresponds to termination in the absence of rho. It has the largest size. A label alongside this transcript reads "No rho, forward arrow, 23 S species."

The second R N A transcript corresponds to termination at the first rho site. It has the smallest size. A label alongside this transcript reads "Rho present at the start of synthesis, forward arrow, 10 S species." The third R N A transcript corresponds to termination at the second rho site. Its size is relatively larger than the second transcript but smaller than the first transcript. A label alongside this transcript reads "Rho added 30 seconds later, forward arrow, 13 S

species." The fourth R N A transcript corresponds to termination at the third rho site. Its size is relatively larger than the third transcript but smaller than the first transcript. A label alongside this transcript reads "Rho added 2 minutes later, forward arrow, 17 S species."

Return to FIGURE 29.13 Rho protein promotes the termination of transcription

Extended description for FIGURE 29.14 Rho protein is an A T P-dependent helicase

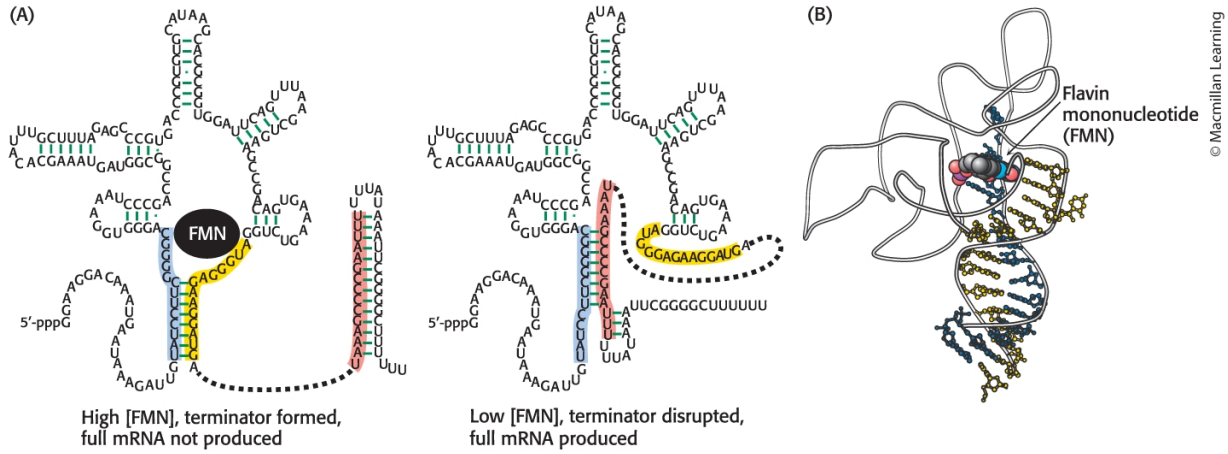


R N A polymerase depicted as a large capsule-shaped structure is bound to the transcription bubble of a double-stranded D N A. An R N A strand is hydrogen bonded to the red strand of the helix in the transcription bubble. The free 3 prime end of the R N A is located inside the polymerase. The 5 prime region of the R N A strand is located outside the polymerase. The 5 prime end contains three P. The rho protein composed of 6 elongated subunits is bound near the 5 prime end of the R N A. The R N A strand passes through the hollow core of the rho protein. Three upward arrows point from the rho protein toward the transcription bubble to depict its movement.

The movement of rho protein is coupled with the hydrolysis of A T P plus H 2 O to A D P plus P subscript i.

Return to FIGURE 29.14 Rho protein is an A T P-dependent helicase

Extended description for FIGURE 29.15 Alternative promoters vary in their consensus sequences at conserved sites



The sequence of a standard promoter is as follows: 5 prime, wiggly line, T T G A C A, wiggly line, T A T A A T, wiggly line, 3 prime. T T G A C A is located at minus 35 position and T A T A A T is located at minus 10 position.

The sequence of heat-shock promoter is as follows: 5 prime, wiggly line, T N N C N C N C T T G A A, wiggly line, C C C A T N T, wiggly line, 3 prime. T N N C N C N C T T G A A is located at minus 35 position and C C C A T N T is located at minus 10 position.

The sequence of nitrogen-starvation promoter is as follows: 5 prime, wiggly line, C T G G G N A, wiggly line, T T G C A, wiggly line, 3 prime. C T G G G N A is located at minus 35 position and T T G C A is located at minus 10 position.

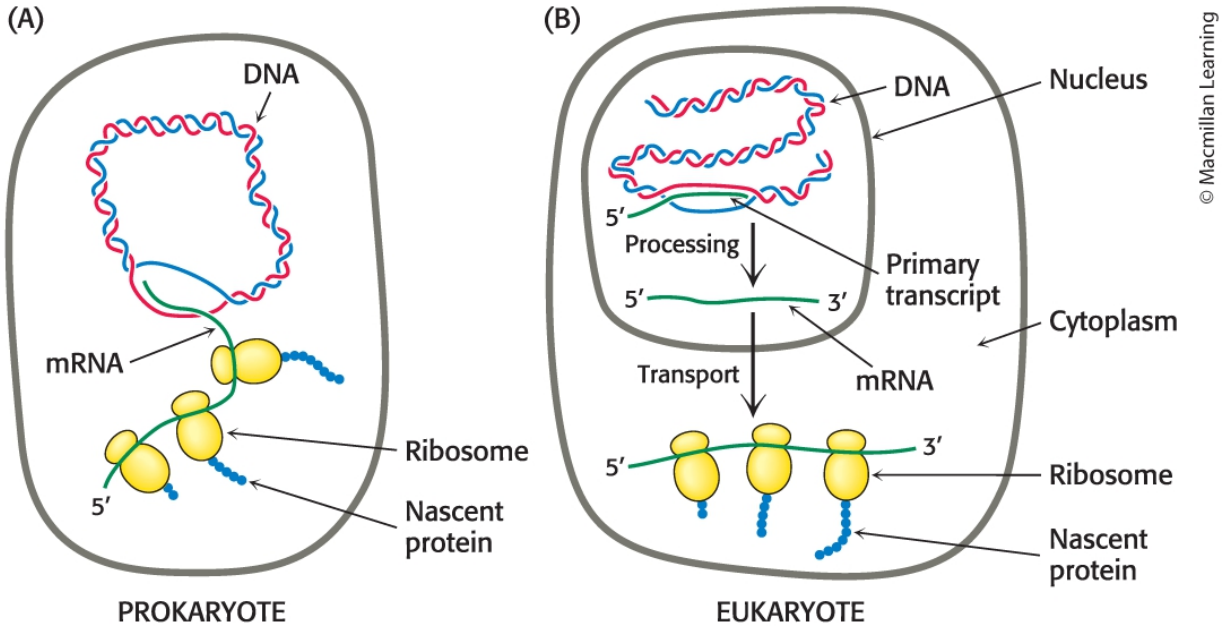
Extended description for FIGURE 29.16 Riboswitches use metabolite concentrations to regulate transcription

Part (A): The first riboswitch is bound to F M N. It has a short 5 prime region followed by stem-loop structures. The loop portion is larger and further contains five stem-loop structures on the bottom left, top left, top, top right, and bottom right. The loop of the main stem-loop is bound to F M N. The main stem-loop is followed by a short linear stretch and a terminator composed of a long stem region and a small loop region. The left side of the stem region of the main stem-loop is highlighted in blue. The right side of the stem region of the main stem-loop is highlighted in yellow. The left side of the stem region of the terminator is highlighted in pink. The text below the riboswitch reads "High concentration of F M N, terminator formed, full m R N A not produced."



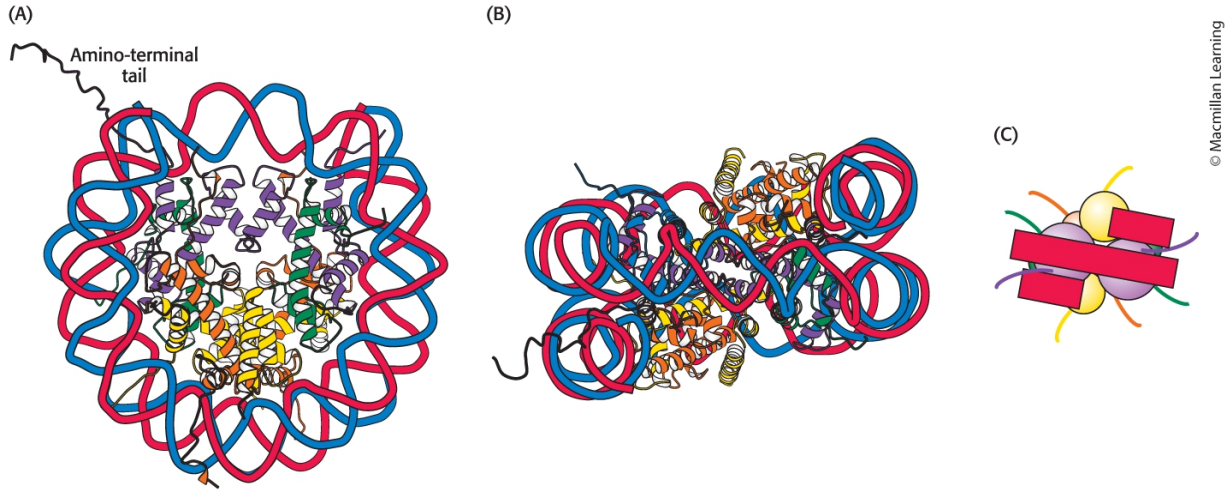
Under low F M N concentration, the terminator is disrupted, and full m R N A is produced. The main stem-loop is also disrupted and the terminator disappears. The blue highlighted sequence partially

base pairs with the pink highlighted sequence to form a stem loop. The yellow sequence is free.

Part (B): A double-helical structure with a complete single turn is shown below. It continues into an irregular wavy structure at the top. A cluster of black, pink, and blue spheres is bound to the top region and labeled "Flavin mononucleotide (F M N)." The helical region contain ball-and-stick models of nucleotide residues. In the bottom half turn, the right side of the helix contains blue highlighted nucleotides and the left side contains yellow highlighted nucleotides. In the top half turn, the right side contains yellow highlighted nucleotides and the left side contains blue highlighted nucleotides.

Return to FIGURE 29.16 Riboswitches use metabolite concentrations to regulate transcription

Extended description for FIGURE 29.17 Transcription and translation are closely coupled in prokaryotes, whereas they are spatially and temporally separate in eukaryotes



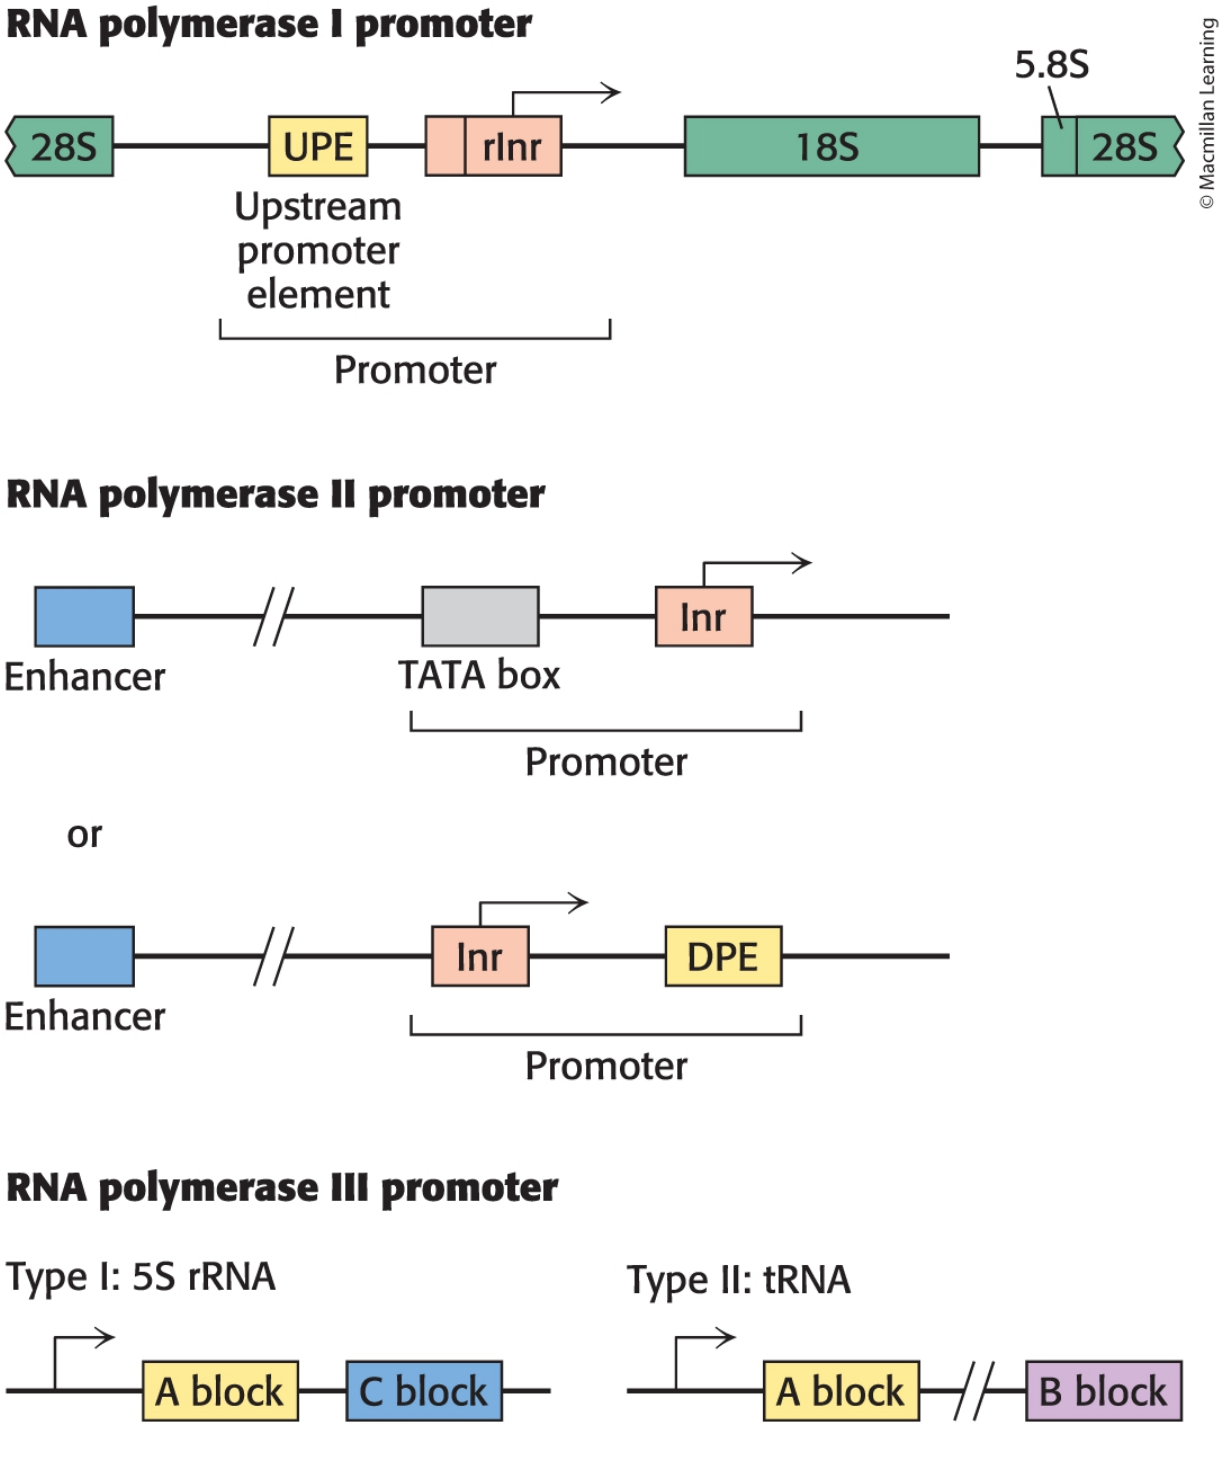
Part (A): In a capsule-shaped prokaryote, D N A depicted as a circular double helix is undergoing transcription to produce m R N A. The newly synthesized m R N A strand binds to ribosomes as it emerges from the transcription bubble. Multiple ribosomes are bound to the free end of the m R N A strand. Each ribosome is producing nascent proteins depicted as chains of tiny blue circles. All the activities are taking place in the cytoplasm.

Part (B): In the nucleus of a eukaryote, a linear D N A molecule is undergoing transcription to produce a primary transcript. The transcript undergoes processing within the nucleus to produce m R N A. The m R N A molecule is transported into the cytoplasm. In the

cytoplasm, m R N A is bound by multiple ribosomes. Each ribosome is producing nascent proteins depicted as chains of tiny blue circles.

Return to FIGURE 29.17 Transcription and translation are closely coupled in prokaryotes, whereas they are spatially and temporally separate in eukaryotes

Extended description for FIGURE 29.19 The structure of the nucleosome consists of eight histone proteins surrounded by D N A



(A): In this view, D N A double helix is circularly wrapped around the histone core. The core consists of the ribbon structures of different histone proteins depicted in different colors. The tails of these histone core proteins are extending outward. One such tail extends out of the double helix and is labeled "Amino-terminal tail."

(B): It shows the 90-degree rotation of the view shown in (A). It shows the side view of a compressed helix with a histone core.

(C): It shows a schematic view consisting of a cluster of purple and yellow spheres. Short tails extend outward from each sphere. Three parallel red bars in diagonal orientation are shown in front of the cluster. The top right and bottom left bars are short. The middle bar is long.

Return to FIGURE 29.19 The structure of the nucleosome consists of eight histone proteins surrounded by D N A

Extended description for FIGURE 29.21 Eukaryotic promoters share common elements

© Macmillan Learning

The R N A polymerase 1 promoter is depicted as follows: A linear stretch contains U P E and r I n r. U P E is the upstream promoter element depicted as a yellow box. The r I n r is a ribosomal initiator depicted as a pink box. U P E and r I n r are located close together and collectively labeled promoter. An arrow pointing toward the right is shown above r I n r. A long rectangular box labeled 18 S is located downstream of the ribosomal initiator. It is followed by 5.8 S and 28 S that are joined together. 28 S is also located upstream of the promoter.

The R N A polymerase 2 promoter is depicted as follows: A linear stretch contains a blue box labeled enhancer at the left end. It is followed by a break depicted as two parallel diagonal lines. On the right side of the break is the T A T A box depicted as a grey rectangle. The T A T A box is followed by the initiator depicted as a pink box labeled "I n r." An arrow pointing toward the right is shown originating from the initiator. T A T A box and initiator are together labeled promoter.

Alternatively, the T A T A box is absent, and the initiator is followed by the downstream promoter element depicted as a yellow box labeled "D P E." The initiator and D P E are together labeled promoter.

The R N A polymerase 3 promoters are depicted as follows: Type 1 promoter is for 5 S r R N A. It consists of a linear stretch composed of two elements downstream of the start site. The start site is depicted as an arrow pointing toward the right. This arrow originates near the left end. The first element is an A block depicted as a yellow rectangle and the second element is a C block depicted as a blue rectangle.

Type 2 promoter is for t R N A. It consists of a linear stretch composed of two elements downstream of the start site. The

elements are separated by a break depicted as two parallel diagonal lines. The start site is depicted as an arrow pointing toward the right. This arrow originates near the left end. The first element is A block depicted as a yellow rectangle and the second element is B block depicted as a purple rectangle.

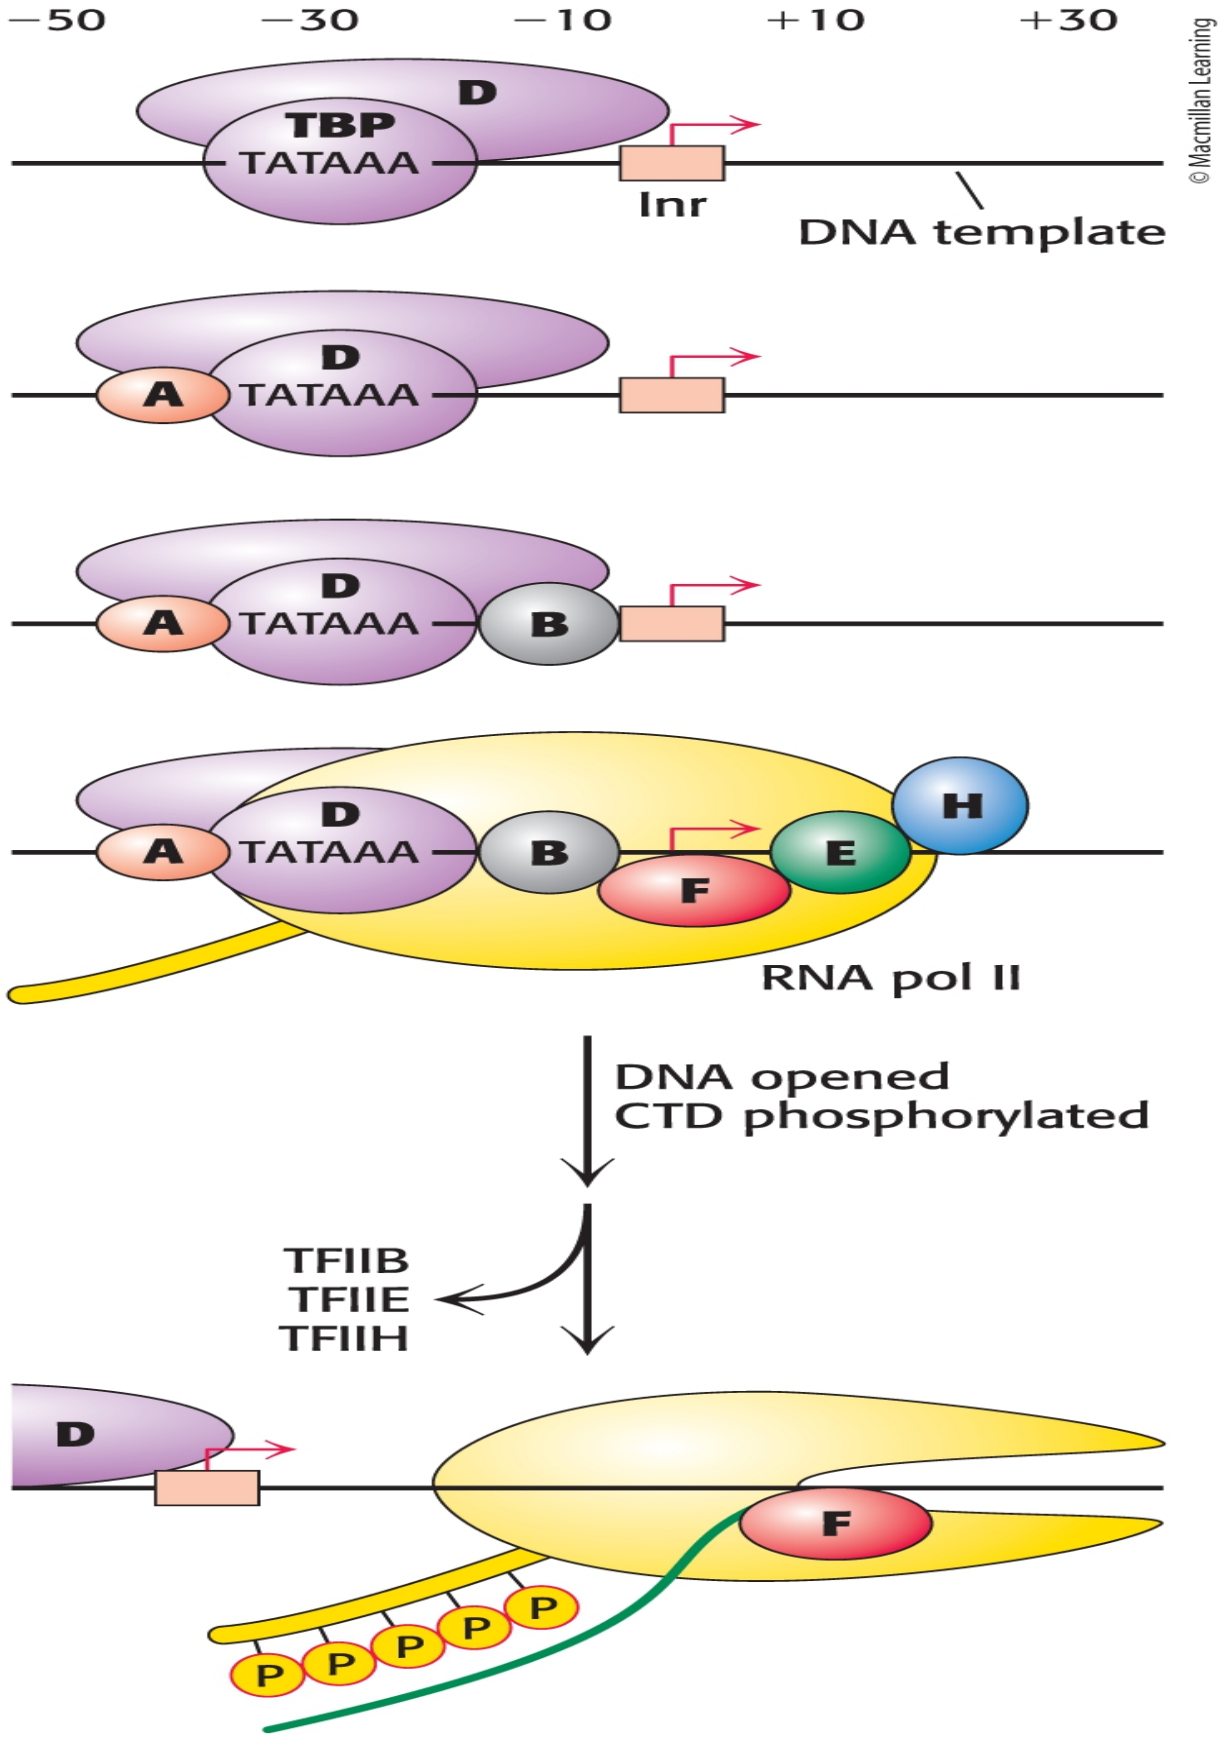
The consensus sequence of the C A A T box in 5 prime to 3 prime direction is as follows: G G N C A A T C T. The C A A T sequence is highlighted in red.

The consensus sequence of the G C box in 5 prime to 3 prime direction is as follows: G G G C G G. The G C sequence in the middle is highlighted in red.

Return to FIGURE 29.23 The sequences of the C A A T box and G C box are also highly conserved

Extended description for FIGURE 29.24 The T A T A-box-binding protein binds to D N A



The T A T A box binding protein is a saddle-shaped protein that sits on the top of the D N A double helix. It consists of two similar domains located on either side of the helix. The protein consists of two long and antiparallel beta-strands crisscrossing each other at the center. On either side of this intersection point, a few short beta-strands and an alpha-helix are located at the bottom and directly attached to the D N A. A slightly curved alpha-helix is located on top of the protein on either side of the intersection point. These

secondary structures are interconnected by thread-like loops. The double helix is curved downward. It is composed of two strands, one composed of red spheres and another one composed of blue spheres.

Return to FIGURE 29.24 The T A T A-box-binding protein binds to D N A

Extended description for FIGURE 29.25 General transcription factors are essential in initiating

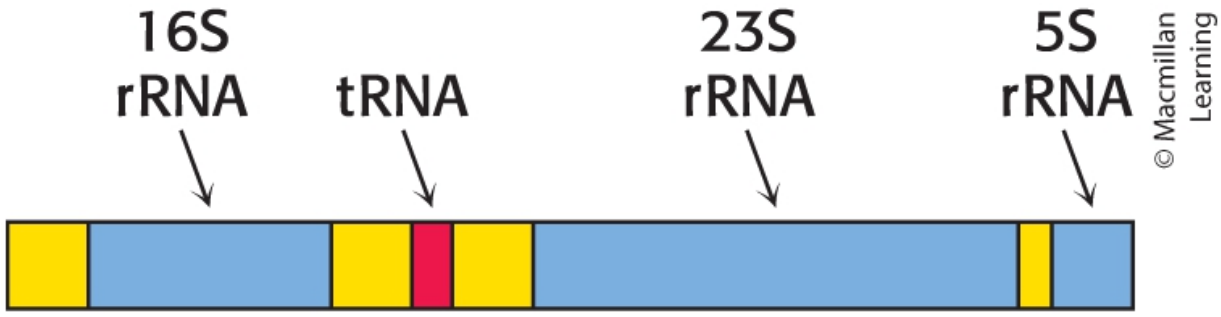
transcription by RNA polymerase 2

© Macmillan Learning

The D N A template is depicted as a solid horizontal line. A pink box labeled "I n r" is shown in the D N A template. An arrow pointing toward the right is shown above the "I n r" box. The region of the D N A template downstream of the I n r box is numbered plus 10 and plus 30. The region of the D N A template upstream of the I n r box is numbered minus 10, minus 30, minus 50. A purple oval in horizontal orientation labeled D, associated with T B P depicted as a sphere, is bound to the T A T A A A sequence located around minus 30 position. T B P is directly bound to the sequence.

In the second step, a small circular orange structure labeled A associates with T B P between minus 30 and minus 50 positions.

In the third step, a small circular grey structure labeled B associates with T B P at minus 10 position.



In the fourth step, R N A polymerase 2 binds to the D N A template between minus 30 and plus 10 positions. The "I n r" box is bound to F. F is further bound to E, which is bound to H. The R N A polymerase has a short tail extending toward the lower left.

Two successive downward arrows are shown below the assembly depicted in the fourth step. The first arrow is labeled "D N A opened C T D phosphorylated." The second arrow shows the release of T F 2 B, T F 2 E, and T F 2 H.

In the last step, initiation occurs which is depicted as the downstream movement of the R N A polymerase. The tail of the polymerase is bonded to 5 different phosphoryl groups depicted as tiny circles labeled P. An R N A strand depicted as a solid green line emerges from the cleft of the polymerase on the right side. F is bound near the cleft of the polymerase.

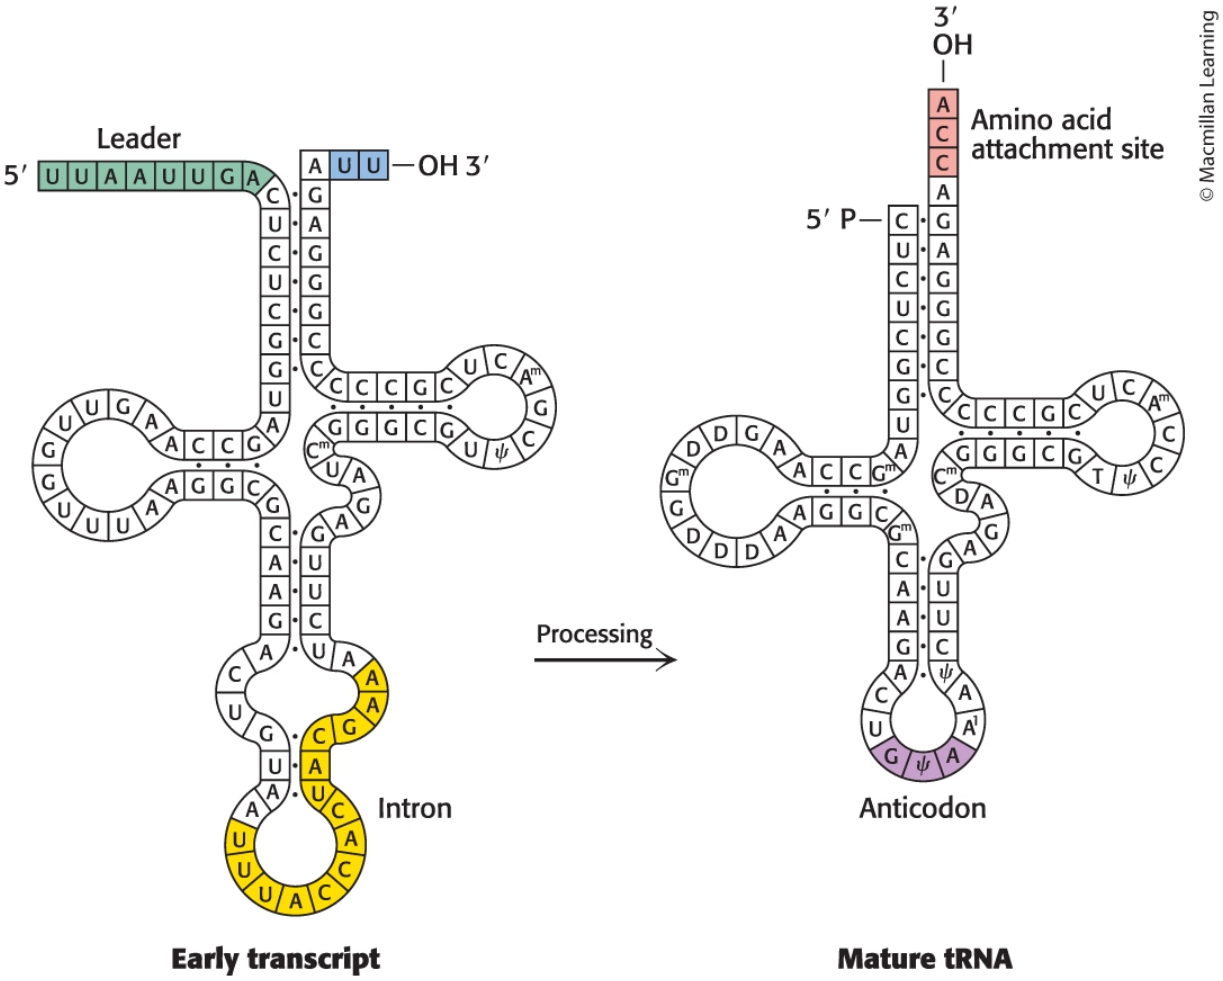
Extended description for FIGURE 29.28 Electron microscopy gives a window into r R N A transcription

and processing in eukaryotes



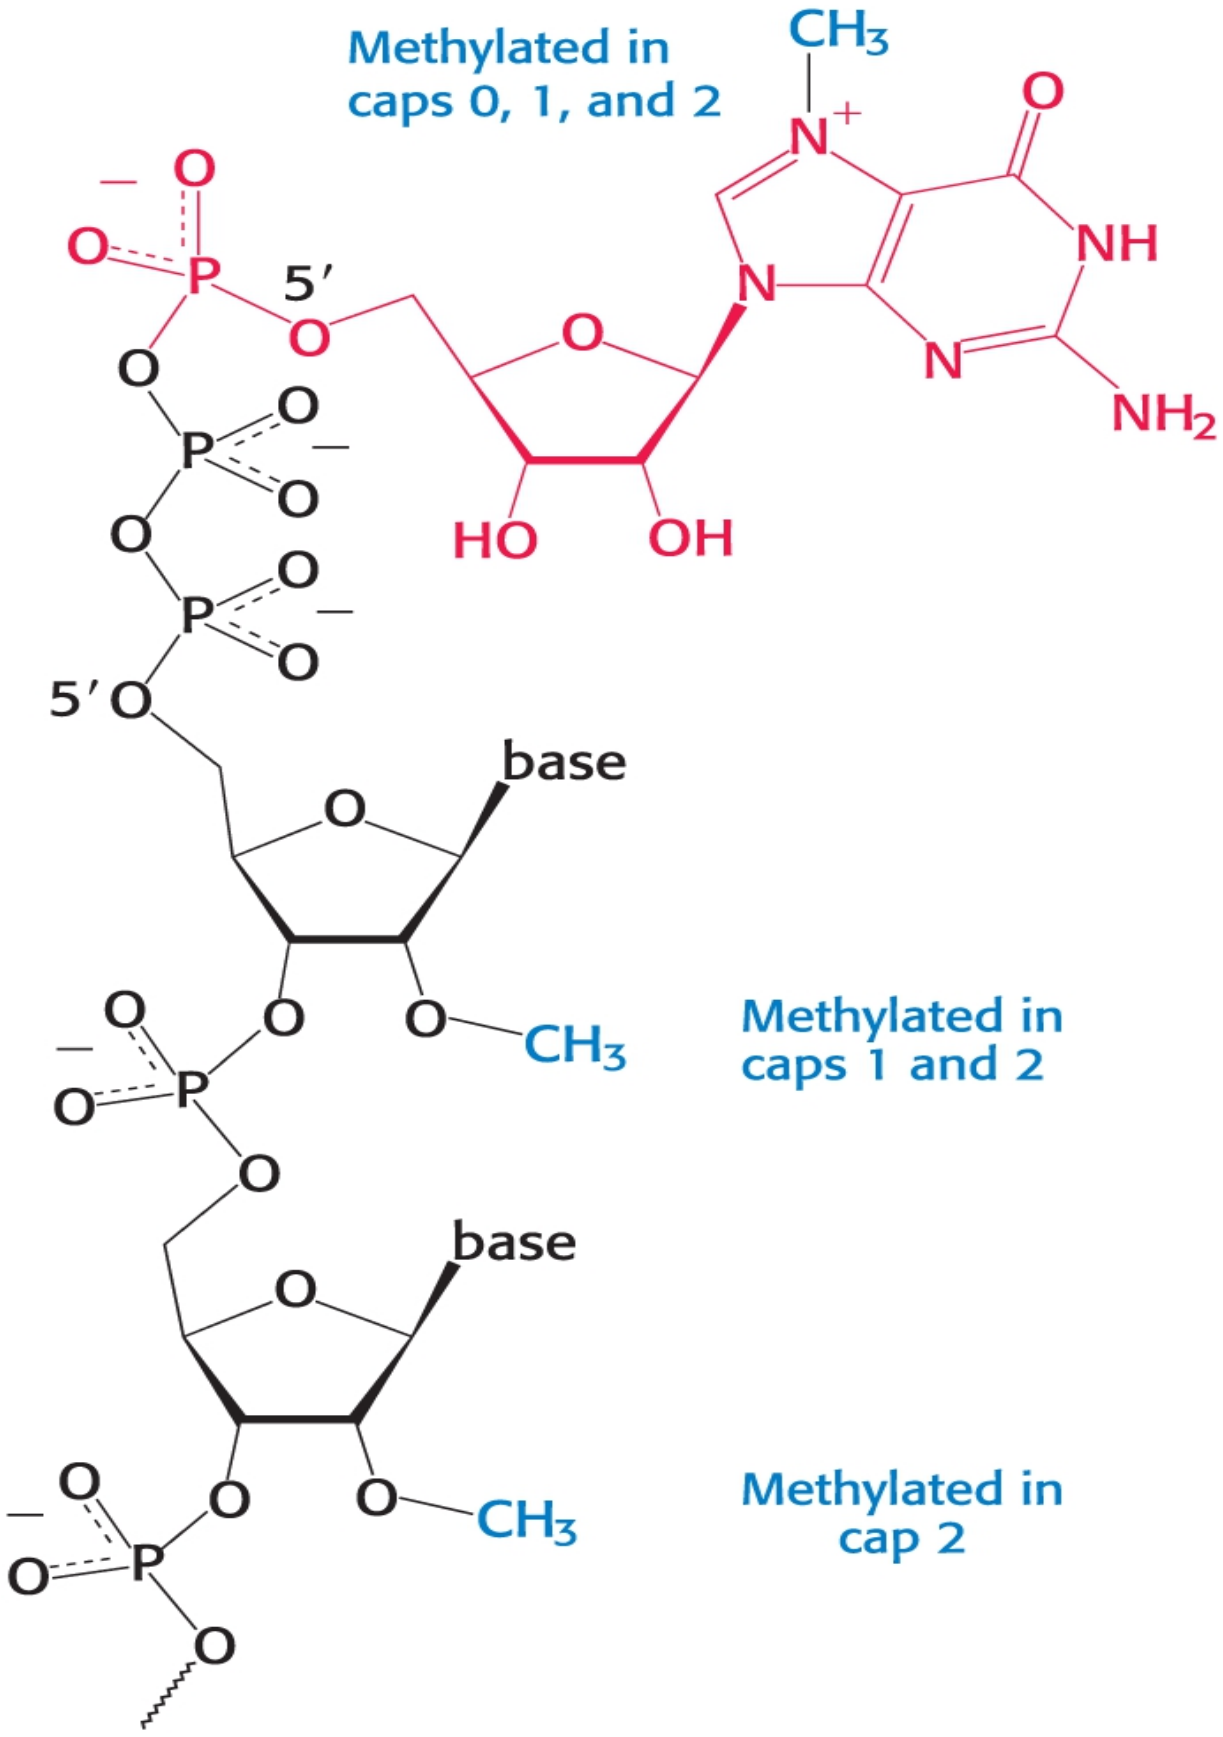
Reprinted by permission from Macmillan Publishers Ltd, from Dragon, F., Gallagher, J., Compagnone-Post, P. et al. A large nucleolar U3 ribonucleoprotein required for 18S ribosomal RNA biogenesis. Nature 417, 967–970 (2002); permission conveyed through Copyright Clearance Center, ltd.

It shows several threads in a vertical orientation. These threads are labeled r D N A. Short horizontal threads originate from either side of the main thread resembling a fir tree. These short threads are labeled pre-r R N A. The length of these threads increases from top to bottom. Most of these threads contain thick knobs at the free end labeled "S S U processome."

Return to FIGURE 29.28 Electron microscopy gives a window into r R N A transcription and processing in eukaryotes

Extended description for FIGURE 29.29 Transfer R N A precursors are processed

The early transcript consists of a linear leader sequence at the 5 prime end followed by several stem loops at the bottom. The stem-loops cause the folding back of the transcript such that 5 prime and 3 prime ends are aligned together at the top. The leader sequence U U A A U U G A is highlighted in green. The 3 prime sequence is A U U, single bond, O H. The last two U residues are highlighted in blue. An intron sequence highlighted in yellow spans through the bottom two loops.



The early transcript undergoes processing to produce the mature t R N A.

The mature t R N A contains a stem-loop on the left, bottom, and right. The 5 prime and 3 prime regions are aligned vertically together at the top of the t R N A. A small bulge is located between the right and bottom stem-loops. The 3 prime end extends above the 5 prime end. The sequence C C A at the 3 prime of the t R N A is highlighted in red and labeled "amino acid attachment site." The 3 prime end contains an O H group. The bottom-most region of the bottom loop contains the sequence G psi A highlighted in purple.

The structure is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. The ring is in a plane perpendicular to the plane of the paper such that O is away from the observer and C 2 and C 3 are toward the observer. C 1 is wedge bonded to the base. C 2 is single bonded to O. O is single bonded to C H 3 on the lower right. C H 3 is highlighted in blue color and labeled "Methylated in Caps 1 and 2." C 3 is single-bonded to O. O is single-bonded to a central P atom of the phosphate group on the lower left. The central P atom is single-bonded to the first O on the lower right, partially double-bonded to the second O on the lower left, and partially double-bonded to the O superscript minus on the upper left. The first O is single bonded to C H 3 on the lower left in the form of the line. C H 3 is single-bonded to C 4 of a second heterocyclic pentagonal ring in a vertical orientation. The second 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. The ring is in a plane perpendicular to the plane of the paper such that O is away from the observer and C 2 and C 3 are toward the observer. C 1 is wedge bonded to the base. C 2 is single bonded to O. O is single bonded to C H 3 on the lower right. C H 3 is highlighted in blue color and labeled "Methylated in cap 2." C 3 of the second pentagonal ring is single-bonded to O. O is single-bonded to a central P atom of the second phosphate group. The central P atom is single-bonded to O on the lower right, partially double-bonded to the second O atom on the lower left, and partially double-bonded to O superscript minus on the upper left. A wiggly line is shown on the lower left of the O atom. C 4 of the first pentagonal ring is single-bonded to C H 2 in the form of a line. C H 2 is single-bonded to O on the upper left. O is labeled 5 prime. O is single-bonded to the first central P atom of the zigzag chain containing three phosphate groups aligned in a zigzag manner. The first central P atom of the first phosphate group is partially double-bonded to O superscript minus on the lower right,

partially double-bonded to O on the upper right, and single-bonded to the second O on the upper left. The second O atom of the first phosphate group is single-bonded to the central P atom of the second phosphate group. The central P atom is partially double-bonded to O superscript minus on the lower right, partially double-bonded to O on the upper right, and single-bonded to the second O on the upper left. The second O atom of the second phosphate group is single-bonded to the central P atom of the third phosphate group. The central P atom is partially double-bonded to the first O atom on the upper left, partially double-bonded to the O superscript minus above, and single-bonded to the second O atom on the lower right. The second O atom of the third phosphate group is labeled 5 prime and single bonded to C H 2 on the upper right in the form of a line. C H 2 is single-bonded to C 4 of a third heterocyclic pentagonal ring in a vertical orientation. The 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. The ring is in a plane perpendicular to the plane of the paper such that O is away from the observer and C 2 and C 3 are toward the observer. C 1 of the third heterocyclic pentagonal ring is single-bonded to the first N of the fourth heterocyclic pentagonal ring in a vertical orientation. The 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 2 N and 3 C atoms. The first N occupies the first position, which is the bottom leftmost vertex and the second N occupies the third position which is the topmost vertex. A double bond is present between C 1 and second N. The second N atom carries a positive charge and is single-bonded to C H 3 above. C H 3 is highlighted in blue and labeled "Methylated in caps 0, 1, and 2." The fourth heterocyclic pentagonal ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the pentagonal ring are C 3 and C 2 respectively of the hexagonal ring. The hexagonal ring consists of 1 N, 1 N bound to H, and 4 C atoms. In the 6-membered heterocyclic hexagonal ring, the first N bound to occupies the first position which is the top right

vertex and the second N occupies the third position which is the top bottom-most vertex. A double bond is present between C 1 and N 2, and C 2 and C 3. C 4 is double bonded to O and C 1 is single bonded to N H 2. C 3 and C 4 of the third pentagonal ring are each single bonded to O H. Third phosphate group, third pentagonal ring, and two fused ring structures are highlighted in red color.

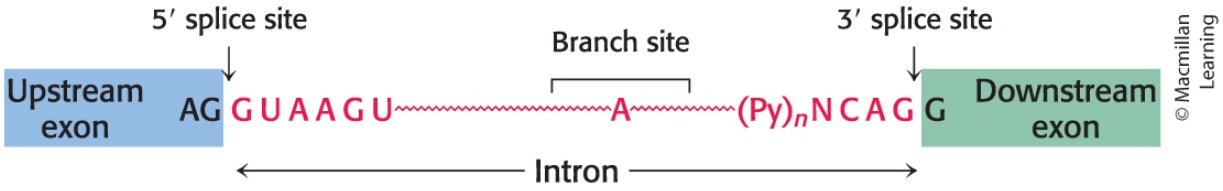
Return to FIGURE 29.30 The 5 prime ends of eukaryotic m R N As are capped

Extended description for FIGURE 29.31 Primary transcripts in eukaryotes are polyadenylated

© Macmillan Learning

A double helical template D N A is bound to a large yellow oval near the right end. The strands of the D N A are unwound to form a transcription bubble inside the oval. A newly synthesized R N A strand emerges out of the transcription bubble. The 5 prime end of the R N A has a cap. It is followed by a cleavage signal sequence A A U A A A near the 3 prime end.

Two downward arrows are shown below.



The first downward arrow is labeled "Cleavage by specific endonuclease." The second downward arrow is labeled "Addition of

tail by poly (A) polymerase. It is coupled with the breakdown of A T P to P P subscript i.

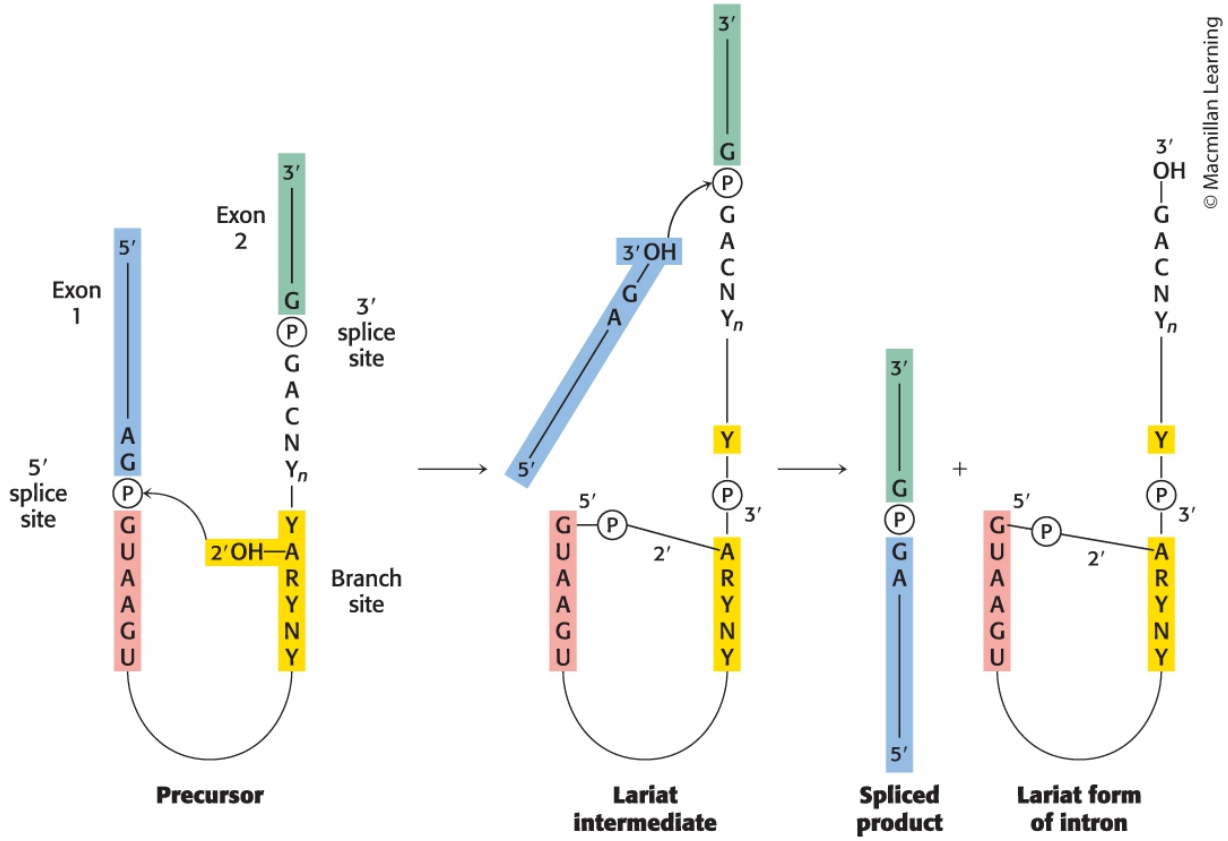
The second arrow leads to a polyadenylated m R N A precursor. The polyadenylated m R N A precursor consists of a 5 prime cap and 3 prime O H group. The sequence A A U A A A is located close to the 3 prime end. It is followed by the sequence A A A A A open parenthesis A close parenthesis with subscript n at the 3 prime end.

Return to FIGURE 29.31 Primary transcripts in eukaryotes are polyadenylated

Extended description for FIGURE 29.32 Splice sites are identified by conserved sequences

The consensus sequence is: A G G U A A G U, a long wiggly line, A, a medium-sized wiggly line, open parenthesis P y close parenthesis with subscript n end subscript N C A G G. The first A and first G from left are enclosed in a blue colored rectangular box labeled upstream exon. A downward-facing arrow labeled 5 prime splice site points toward the sequence A G G U A A G U. The sequence from the second G on the left till the second last G on the right is marked using a horizontal double-headed arrow labeled "Intron." The middle A with wiggly lines on both sides is marked with the square bracket on the top and labeled branch site. The rightmost G at the end of the right sequence is enclosed in a rectangular green-colored box labeled "Downstream exon. The space between the last G and second last G of the right sequence is marked with a downward-facing arrow labeled 3 prime splice site.

Return to FIGURE 29.32 Splice sites are identified by conserved sequences

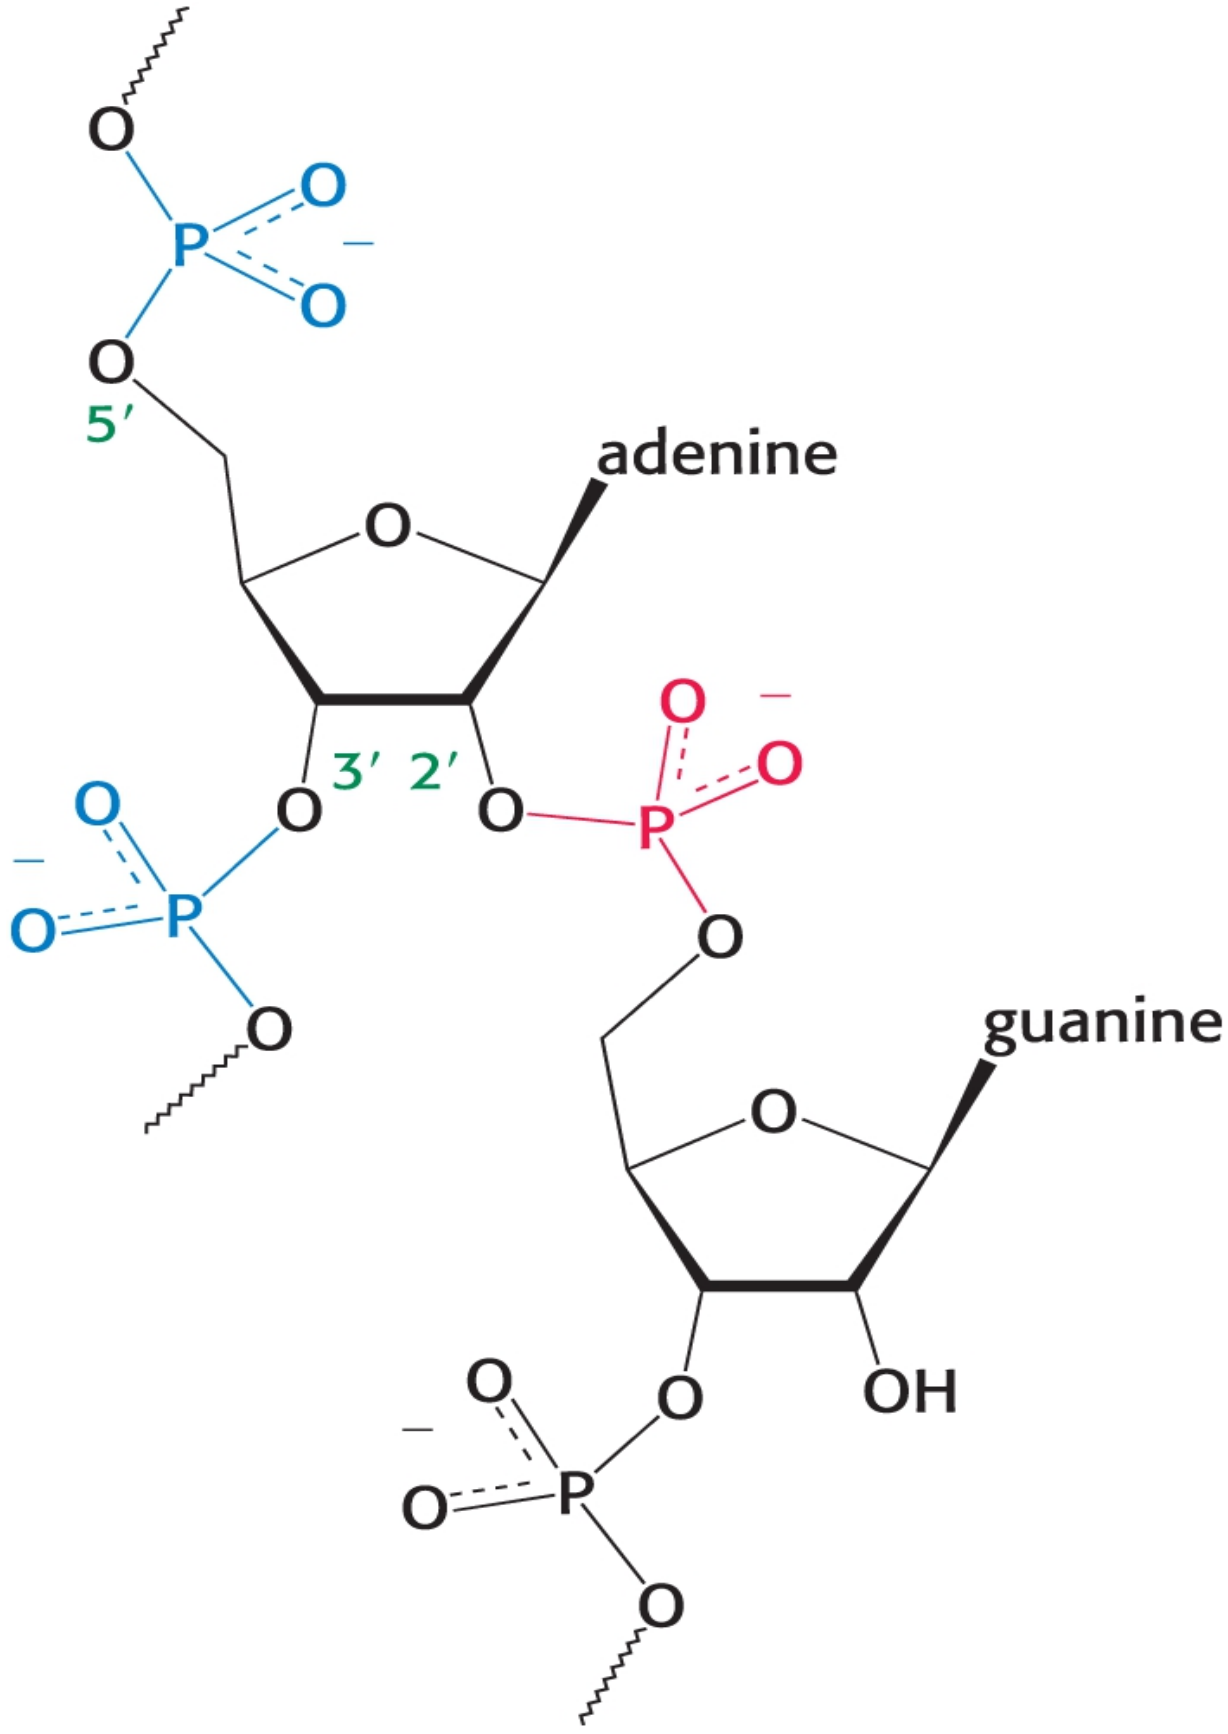


Extended description for Reversible transesterification reaction

The reaction contains two reactants and two products. The reactant has the following structure: A zigzag chain is composed of R 1, single bond, O, single bond, P, single bond, O, single bond, R 2. P is partially double bonded to O on the upper left and O superscript minus on the upper right. The second reactant has the following structure: A zigzag chain is composed of H, single bond, O, single bond, R 3. The first product has the following structure: A zigzag chain is composed of R 1, single bond, O, single bond, P, single bond, O, single bond, R 3. P is partially double bonded to O on the upper left and O superscript minus on the upper right. The second product has the following structure: A zigzag chain is composed of H, single bond, O, single bond, R 2.

Return to Reversible transesterification reaction

Extended description for FIGURE 29.33 The splicing mechanism for m R N A precursors involves a lariat intermediate



The precursor is depicted as a U-shaped structure. Its 5 prime end at the top left contains exon 1 followed by a 5 prime splice site. Its 3 prime end at the top right contains exon 2 followed by 3 prime splice site. The branch site is located below the 3 prime splice sites. The 5 prime splice site is A G G U A A G U. The phosphodiester bond between first G and second G is depicted as a tiny circle labeled P. The initial A G sequence is part of the 3 prime end of exon 1. The 3 prime splice site is G G A C N Y subscript n. The phosphodiester bond between the first and second G is depicted as a tiny circle labeled P. The first G is part of the 5 prime end of exon 2. The

sequence of the branch site is Y N Y R A Y in 5 prime to 3 prime direction. The 2 prime O H of the nucleotide containing base A in the branch site extends into the U-shaped interior of the precursor. An arrow points from 2 prime O H to the phosphodiester linkage between first G and second G in the 5 prime splice site. This attack leads to the formation of a lariat intermediate. The bond between the first G and second G of the 5 prime splice site is broken. This generates a short fragment containing exon 1 and A G at the 3 prime end with a free O H group. The second G of the splice site forms a phosphodiester bond with the 2 prime end of nucleotide containing A in the branch site. The 3 prime O H of the short fragment attacks the 3 prime splice site. It attacks the phosphodiester bond between the first and second G.This leads to the formation of the spliced product containing joined exon 1 and exon 2. The 3 prime end of exon 1 contains A G. The 5 prime end of exon 2 contains G. This G and G of exon 1 are connected by a phosphodiester bond. The second product is a lariat form of intron having a U-shaped formation with 3 prime end extending much above the 5 prime end. The 5 prime end has the sequence G U A A G U in 5 prime to 3 prime direction. The 3 prime end contains the sequence G A C N Y subscript n in 3 prime to 5 prime direction. The 5 prime end is connected to the 2 prime end of A in the branch site.

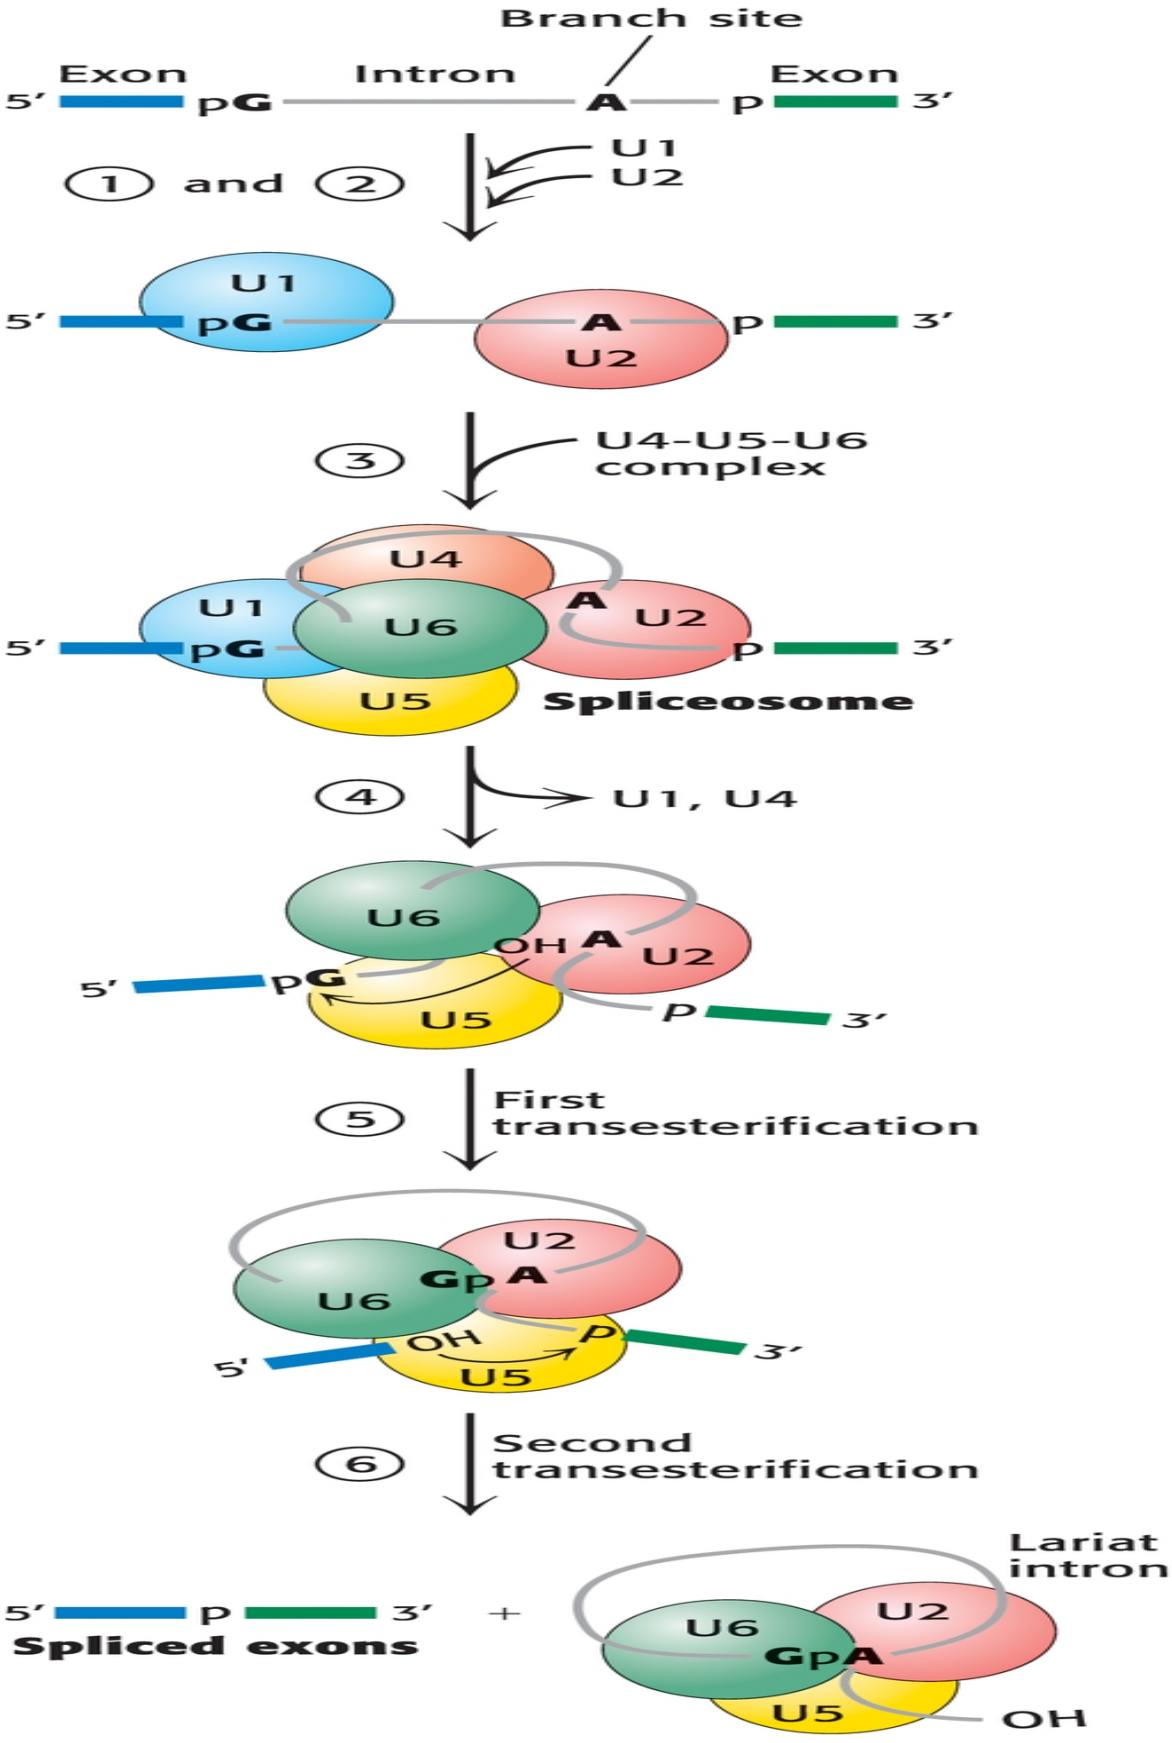
The structure of R N A with splicing branch point is as follows: A 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. The ring is in a plane perpendicular to the plane of the paper such that O is away from the observer and C 2 and C 3 are toward the observer. C 1 is wedge bonded to adenine. C 2 labeled 2 prime is single-bonded to O. O is single-bonded to a central P atom of the first phosphate group on the lower right. A central P is partially double-bonded to the first O on the upper right, partially double-bonded to O superscript minus on the upper right, and single-bonded to the second O on the lower right. The phosphate group is highlighted in red color. The second O atom of the phosphate group is single-bonded to C H 2 on the lower left in the form of a line. C H 2 is single-bonded to C 4 of the second 5-membered heterocyclic pentagonal ring in a vertical orientation. The 5-membered heterocyclic pentagonal ring is in a vertical orientation and consists of 1 O and 4 C atoms. The O atom occupies the first position, which is the topmost vertex. The ring is in a plane perpendicular to the plane of the paper such that O is away from the observer and C 2 and C 3 are toward the observer. C 1 is wedge bonded to guanine. C 2 is single-bonded to O H. C 3 is single-bonded to O. O is single-bonded to a central P atom of the second phosphate group on the lower left. The central P atom is single-bonded to O on the lower right, partially double-bonded to the second O on the lower left, and partially double-bonded to O superscript minus on the upper left. A wiggly line is shown on the lower left of the lower right O atom. C 3 of the first pentagonal ring is labeled 3 prime and single bonded to O below. O is single-bonded to a central P atom of the third phosphate group. The central P atom is single-bonded to O on the lower right, partially double-bonded to the second O on the lower left, and partially double-bonded to O superscript minus on the upper left. A wiggly line is shown on the lower left of the lower right O atom. C 4 of the first pentagonal ring is single-bonded to C H 2 in the form of a line. C H 2 is single-bonded to O on the upper left.

The O is labeled 5 prime. O is single-bonded to a central P atom of the fourth phosphate group. The central P is single-bonded to the first O on the upper left, partially double-bonded to O superscript minus on the lower right, and partially double-bonded to the second O on the upper right. A wiggly line is shown on the upper right of the upper left O atom. The first phosphate group is highlighted in red color, third and fourth phosphate groups are highlighted in blue color.

Return to FIGURE 29.34 The splicing branch point has a unique structure

Extended description for FIGURE 29.35 The spliceosome consists of proteins and R N As

© Macmillan Learning



The structure is a helically coiled ribbon-like structure with folds and loops. The structure consists of three different colored tube-like

structures corresponding to different R N A components. U 2, U 5, and U 6 are shown as red, yellow, and blue tube-like structures.

Return to FIGURE 29.35 The spliceosome consists of proteins and R N As

Extended description for FIGURE 29.36 The

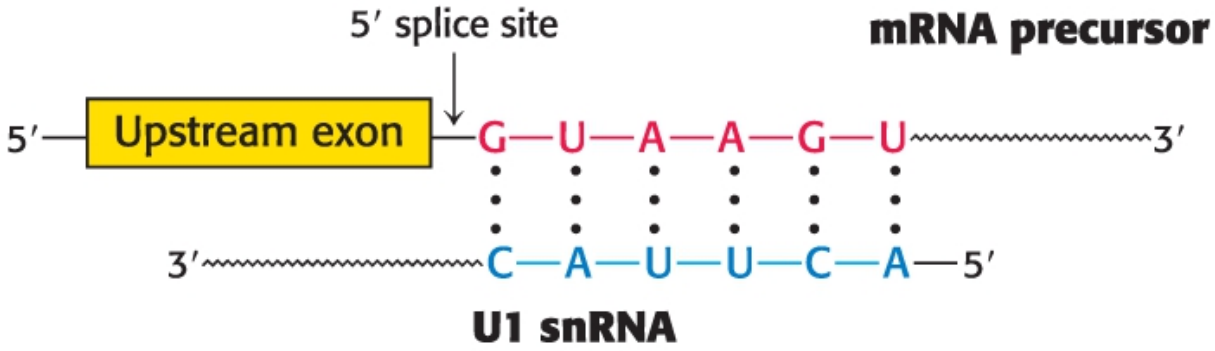
spliceosome promotes the splicing of some genes

© Macmillan Learning

The pre-m R N A exons are located at the 5 prime and 3 prime ends. The exons are separated by an intron. The junction of the upstream exon and the intron contains p G. G is part of the intron. The branch site A is located near the 3 prime end of the intron.

In steps 1 and 2, U 1 and U 2 enter. U 2 binds to p G and U 2 binds to branch site A.

In step 3, U 4-U 5-U 6 complex enters. This complex interacts with U 1 and U 2 to constitute a spliceosome. The spliceosome brings U 1 and U 2 closer to form an intron loop.

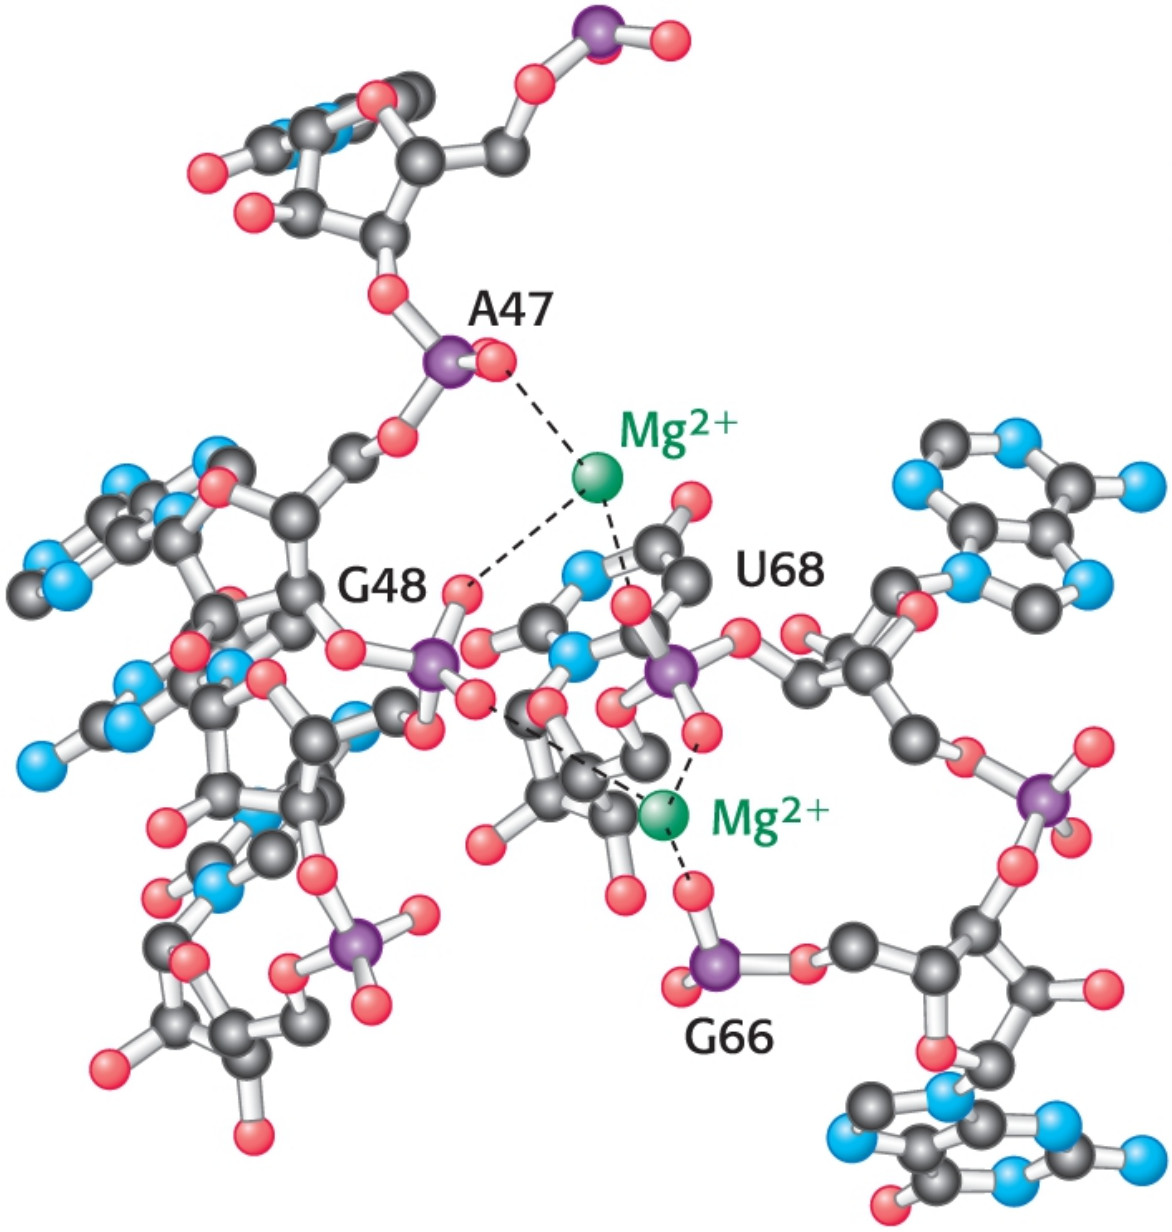


In step 4, U 1 and U 4 are released. The O H group of the branch site A attacks the phosphodiester bond between G and the 3 prime of the first exon.

In step 5, the first transesterification takes place. The first attack by the branch site A cleaves the phosphodiester bond between the first exon and the 5 prime end of the intron. The free 3 prime O H of the first exon attacks the phosphodiester bond between the 3 prime end of the intron and the second intron.

In step 6, the second transesterification takes place leading to the formation of spliced exons and lariat intron. The lariat intron is bound to the U 2, U 5, and U 6 components of the spliceosomes. The 5 prime G of the intron forms a phosphodiester bond with branch site A. The 3 prime region of the intron extends out of the lariat structure.

Return to FIGURE 29.36 The spliceosome promotes the splicing of some genes



Extended description for Base-pairing of the 5 prime splice site of the pre-m R N A with the conserved sequence of U 1 s n R N A

The figure illustrates a strand of the m R N A precursor and U 1 s n R N A. The first strand at the top depicts m R N A precursor. It is labeled 5 prime on the left and 3 prime on the right. A yellow-colored rectangular box labeled "Upstream exon" is placed next to 5 prime end. It is followed by the sequence G, single bond, U, single bond, A, single bond, A, single bond, G, single bond, U, a long wiggly line, 3 prime. The sequence from G to U is highlighted in red color. The second strand for U 1 s n R N A has the following sequence: 3 prime, a long wiggly line, C, single bond, A, single bond, U, single bond, U, single bond, C, single bond, A, a small line 5 prime. Three dots indicating hydrogen bonds are present between the first G of the first sequence and the first C of the second sequence, the first U of the first sequence and the first A of the second sequence, the first A of the first sequence and the first U of the second sequence, second A of the first sequence and second U of the second sequence, second G of the first sequence and second C of the second sequence, and second U of the first sequence and second A of the second sequence.

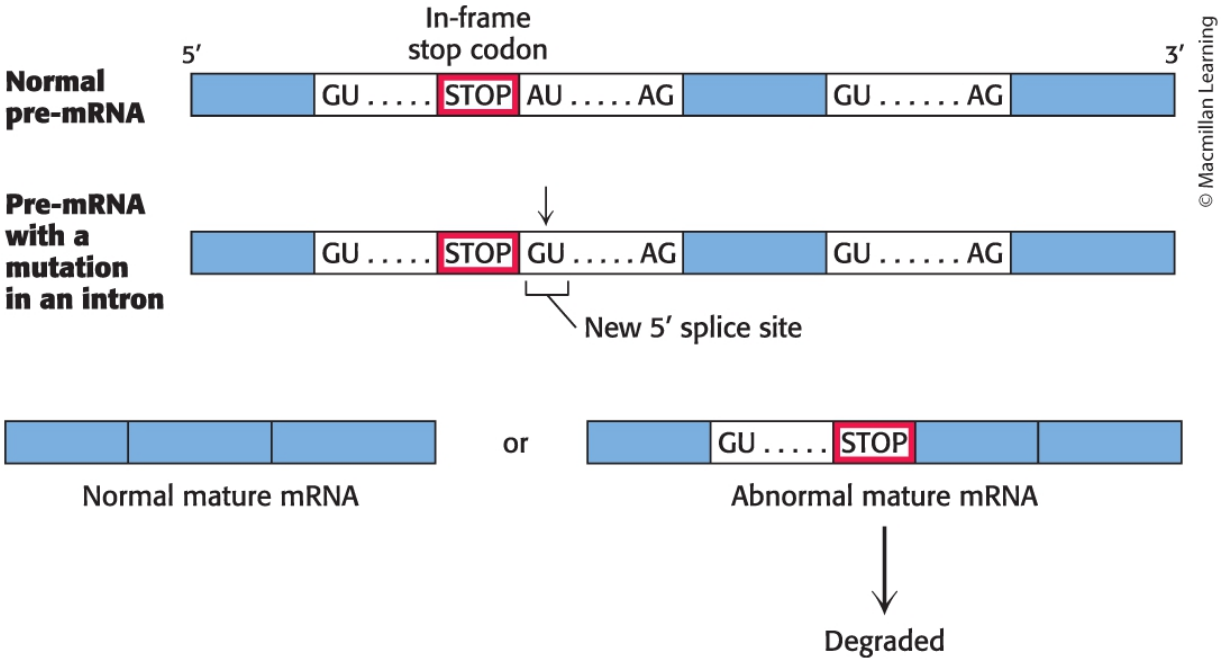
Extended description for FIGURE 29.37 The spliceosome's catalytic center includes two key magnesium ions



© Macmillan Learning

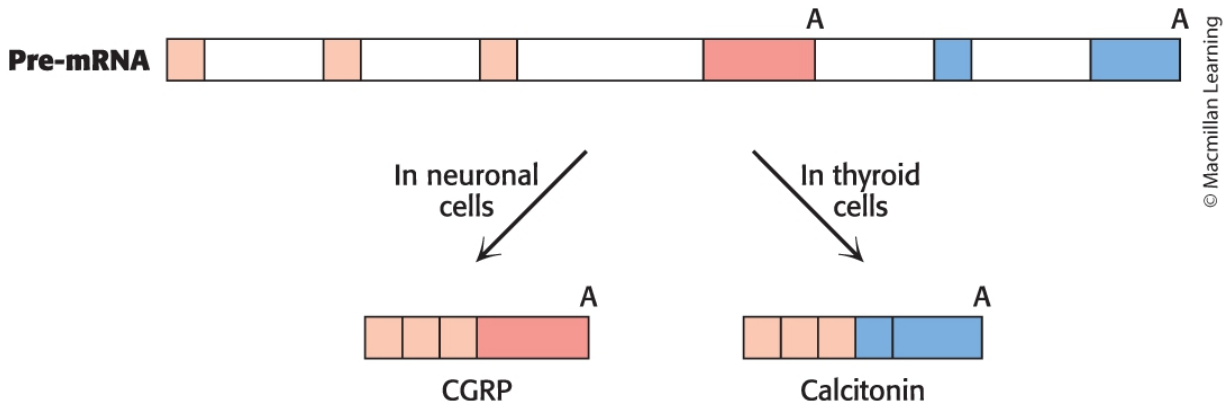
The figure illustrates the ball and stick model of the catalytic center of the spliceosome. It contains black, red, blue, purple, and green

colored small spheres. The size of the black, blue, green, and red colored spheres are similar while the purple colored spheres are slightly bigger than the others. The two green-colored spheres are present at the center of the structure and are labeled M g superscript 2 plus. The first M g superscript 2 plus atom at the top is partially bonded to the three red-colored spheres on the upper left, lower left, and lower right. These red spheres are part of the phosphate groups of A 47, G 48, and U 68 residues. The second green-colored M g superscript 2 plus ion is partially bonded to red-colored spheres on the upper right, lower right, and upper left. These red spheres are part of the phosphate groups of U 68, G 48, and G 66 residues. These phosphate groups are further connected to pentagonal rings composed of 1 red and 4 black spheres. These pentagonal rings are further connected to the fused pentagonal and hexagonal rings or only hexagonal rings in different orientations.

Return to FIGURE 29.37 The spliceosome's catalytic center includes two key magnesium ions

Extended description for FIGURE 29.38 Mutations in splice sites can cause diseases such as thalassemia

The normal pre-m R N A is depicted as a horizontal bar whose left end is labeled 5 prime and right end is labeled 3 prime. The exons are depicted as short blue sections separated by white gaps. There are 3 exons and 2 introns. The first intron contains an in-frame stop codon. The 5 prime end of the first intron contains G U and the 3 prime end contains A G. A stop codon is located in the middle followed by A U. The 5 prime end of the second intron contains G U and the 3 prime end contains A G.



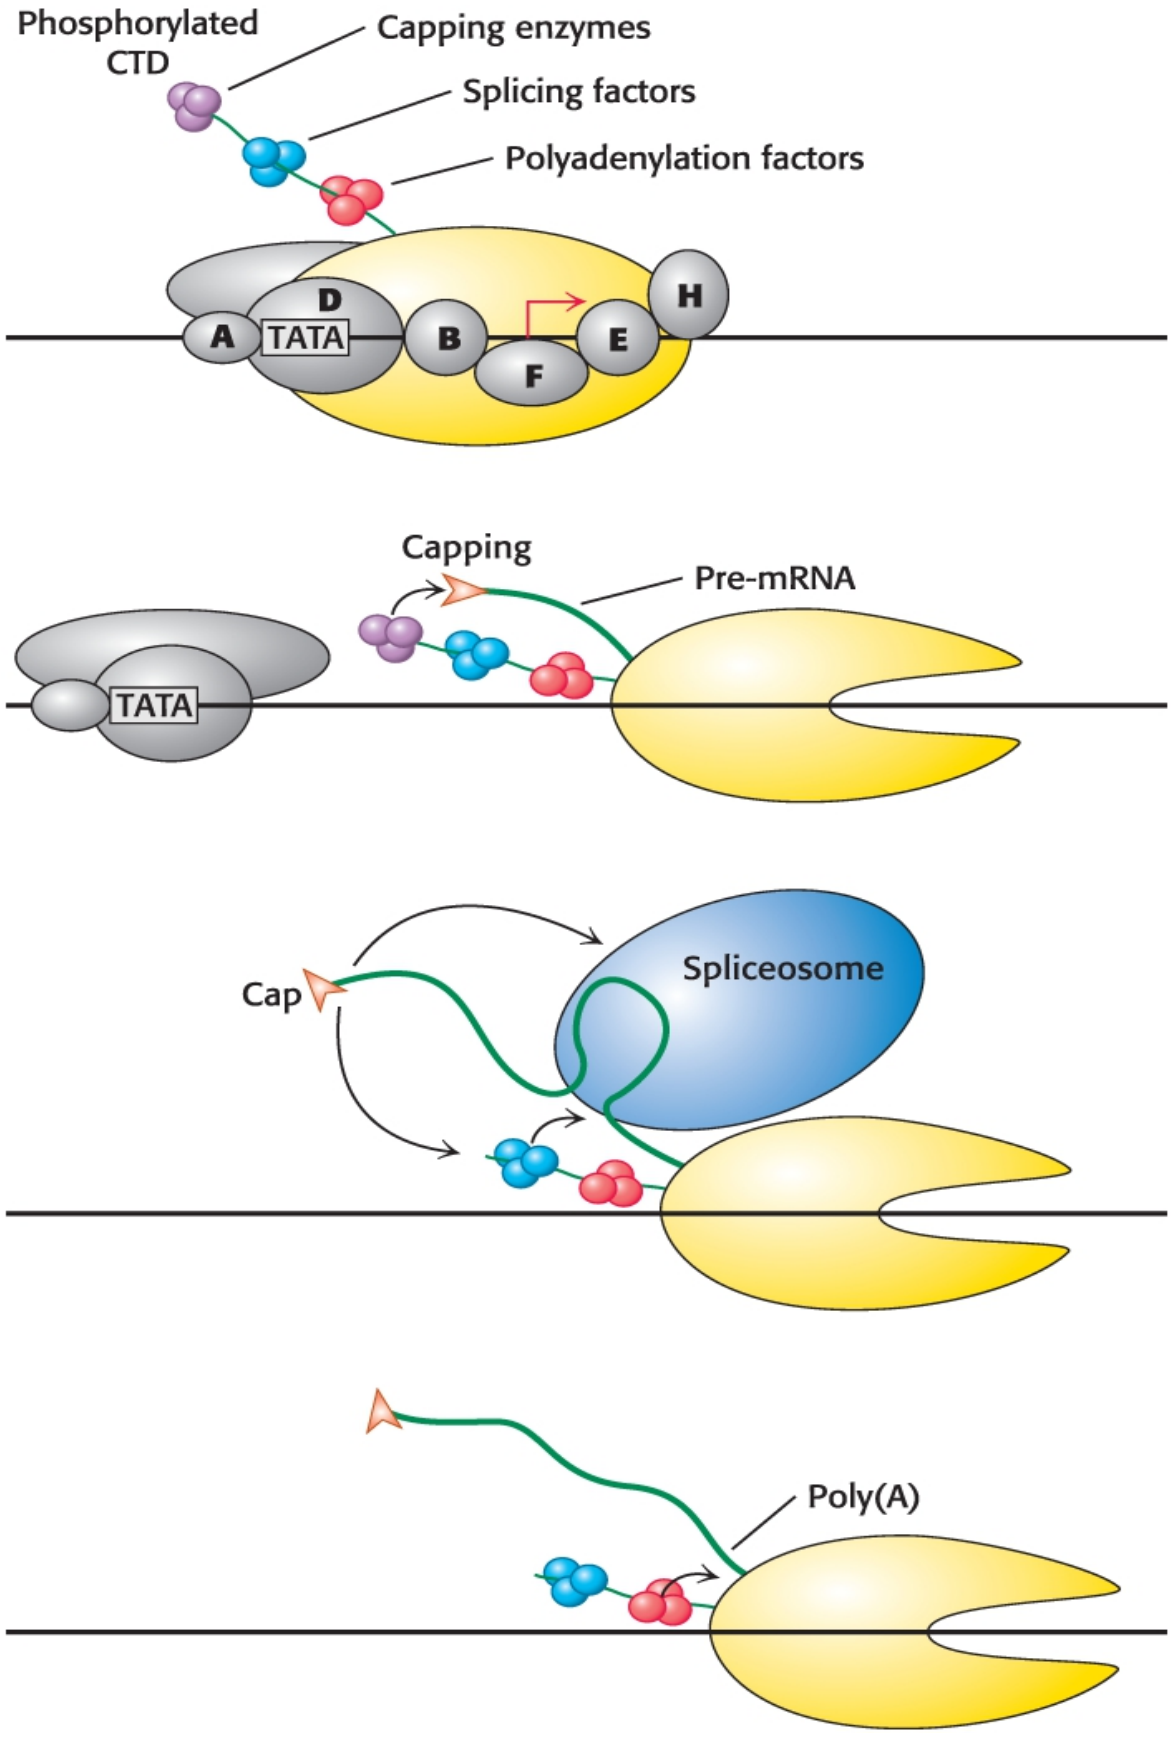
The pre-m R N A with a mutation in an intron is also depicted as a horizontal bar. The exons are depicted as short blue sections separated by white gaps. There are 3 exons and 2 introns. The sequence of the introns are same, except the first intron contains G U instead of A U after the stop codon. This G U is labeled the "New 5 prime splice site."

A normal mature m R N A is shown below. It consists of three short blue sections depicting exons joined together.

Alternatively, an abnormal mature m R N A can be formed due to the mutation. In this m R N A, the 5 prime region of the first intron from G U to the stop codon is retained between the first and second exons. This abnormal mature m R N A is degraded.

Return to FIGURE 29.38 Mutations in splice sites can cause diseases such as thalassemia

Extended description for FIGURE 29.39 Alternative splicing produces different m R N As



The pre-m R N A is depicted as a horizontal bar. It contains three equally spaced small face-colored sections from starting from the left end. It is followed by a relatively larger pink section labeled A, a small blue section, and a blue section labeled A at the right end. The space or gaps between these colored sections is shown in white. In the neuronal cells, the three face-colored sections and the pink section labeled A are joined together from left to right. This segment is labeled C G R P. In the thyroid cells, the three-face-colored sections, the small blue section, and the blue section labeled A are joined together from left to right. This segment is labeled calcitonin.

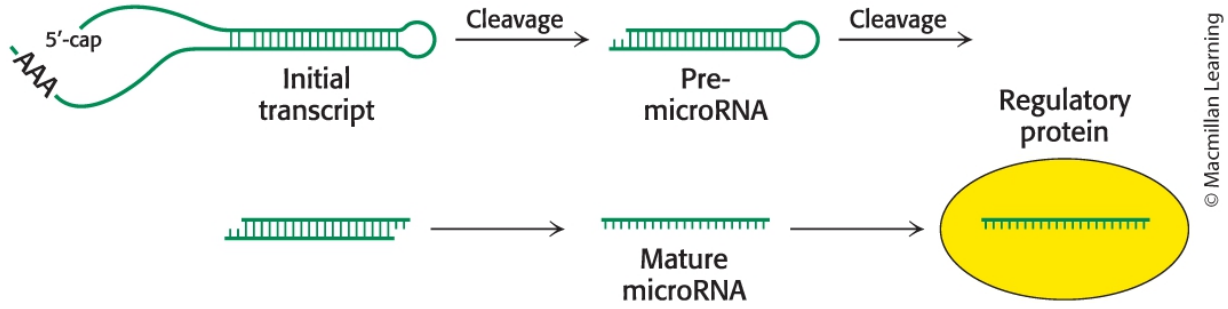
Return to FIGURE 29.39 Alternative splicing produces different m R N As

Extended description for FIGURE 29.40 The C T D

couples transcription to pre-m R N A processing

© Macmillan Learning

A linear D N A is depicted as a solid line. The promoter region of the D N A contains a T A T A box bound to a structure labeled D. The polymerase is associated with the promoter along with other transcription factors labeled A, B, F, E, and H. The tail of the polymerase is labeled phosphorylated C T D. It is bound to capping enzymes, splicing factors, and polyadenylation factors depicted as separate clusters of tiny spheres.



In the first step, the R N A polymerase escapes the promoter and starts the transcription of D N A. The pre-m R N A is depicted as a green strand emerging out of the polymerase as it moves forward. The free end of the pre-m R N A undergoes capping by the capping enzymes bound to the tail.

In the second step, an arrow from the cap at the free end of the pre-m R N A points toward a large oval-shaped structure labeled spliceosome. The spliceosome is bound to the pre-m R N A exiting the polymerase. Another arrow from the cap points toward splicing factors bound to the C T D. An arrow from the splicing factors points toward the spliceosome. The capping enzymes are already released from the C T D.

In the third step, the polyadenylation factors add poly (A) to the m R N A emerging out of the polymerase.

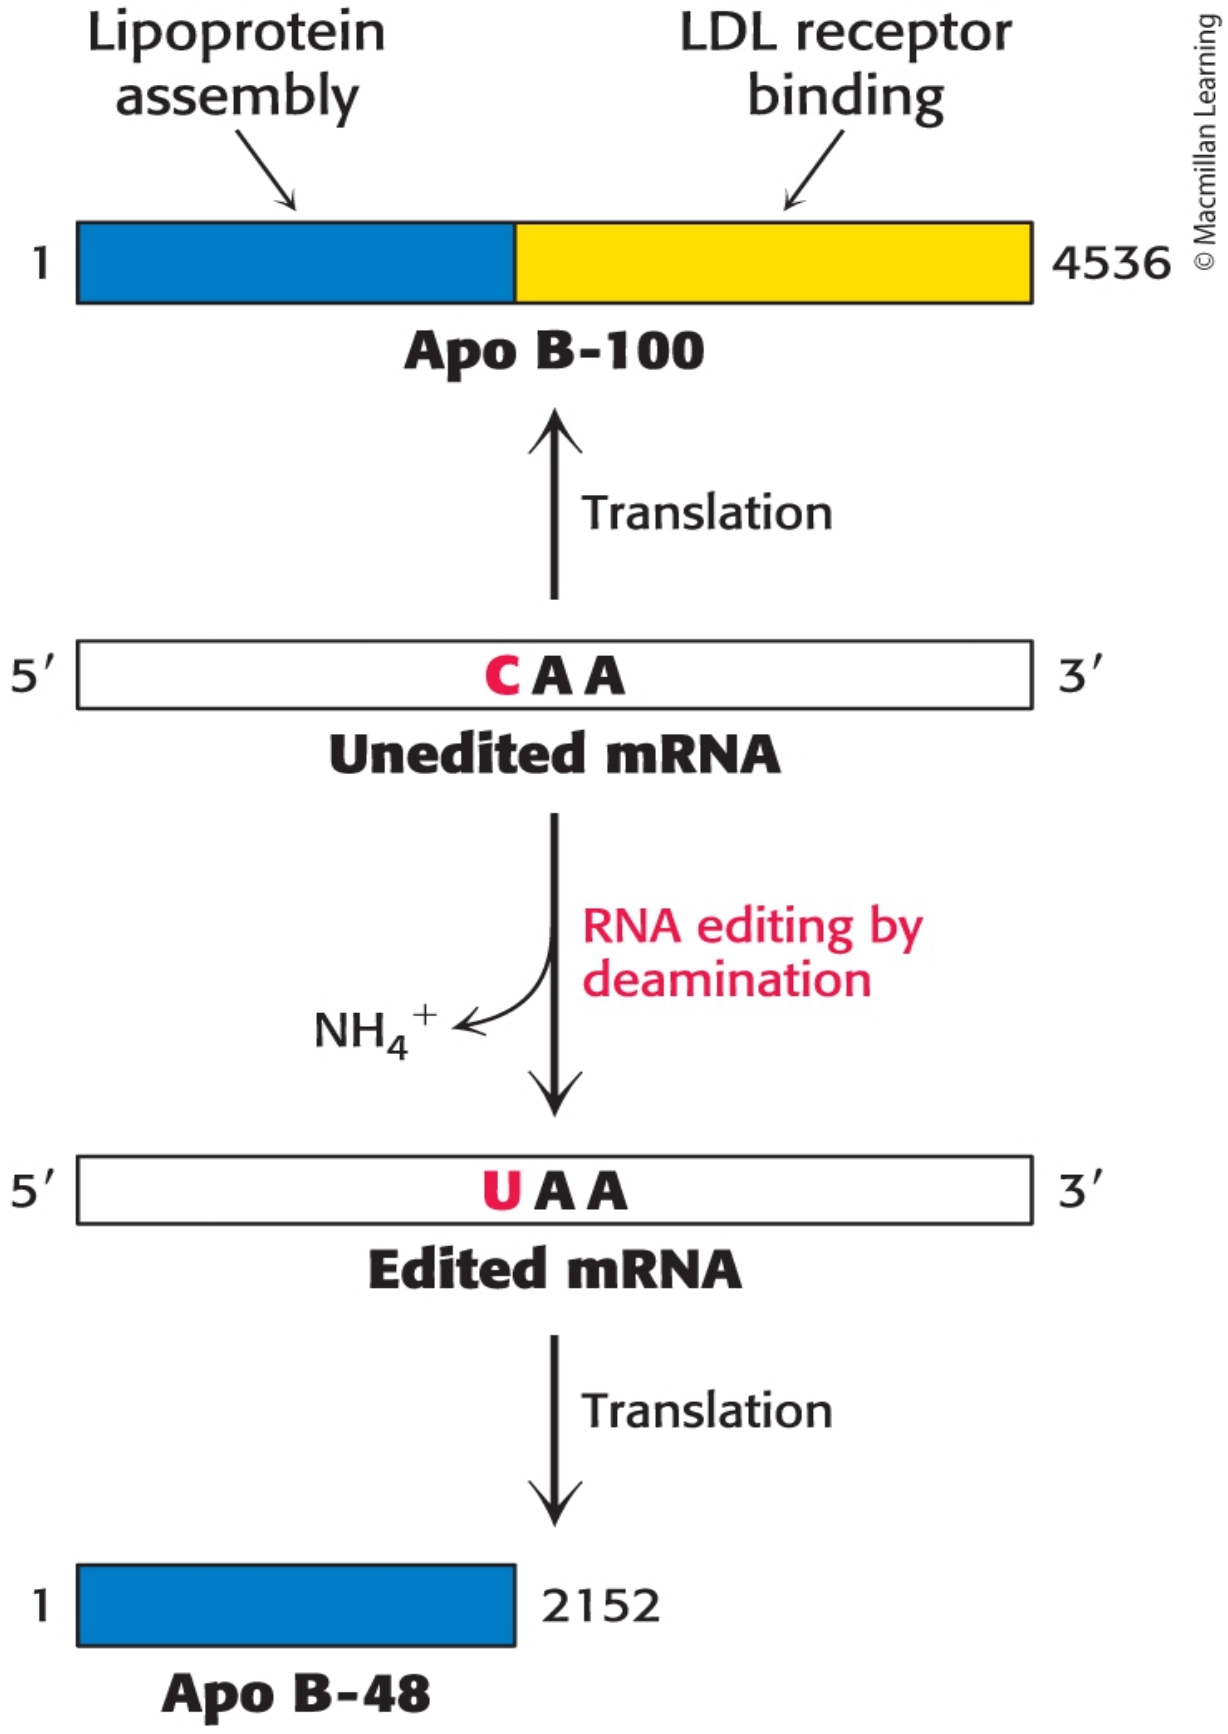
Return to FIGURE 29.40 The C T D couples transcription to pre-m R N A processing

Extended description for FIGURE 29.41 Small regulatory R N As are involved in gene regulation

The initial transcript is depicted as a horizontal stem-loop structure. The 5 prime end contains a cap and the 3 prime end contains three A residues. These ends are free and have a wavy orientation.

In the first step, the initial transcript undergoes cleavage to produce pre-micro R N A. The free 3 prime and 5 prime ends are cleaved such that only the stem-loop structure is left. The top strand of the stem region is cleaved by two extra nucleotides such that the bottom strand of the stem region has an overhang at the 3 prime end.

In the second step, the pre-micro R N A again undergoes cleavage. The loop region is cleaved such that a double-stranded R N A with overhangs of 2 nucleotides is produced.



In the third step, mature micro R N A is produced which is a linear single-stranded R N A.

In the fourth step, it associates with a yellow large circular regulatory protein.

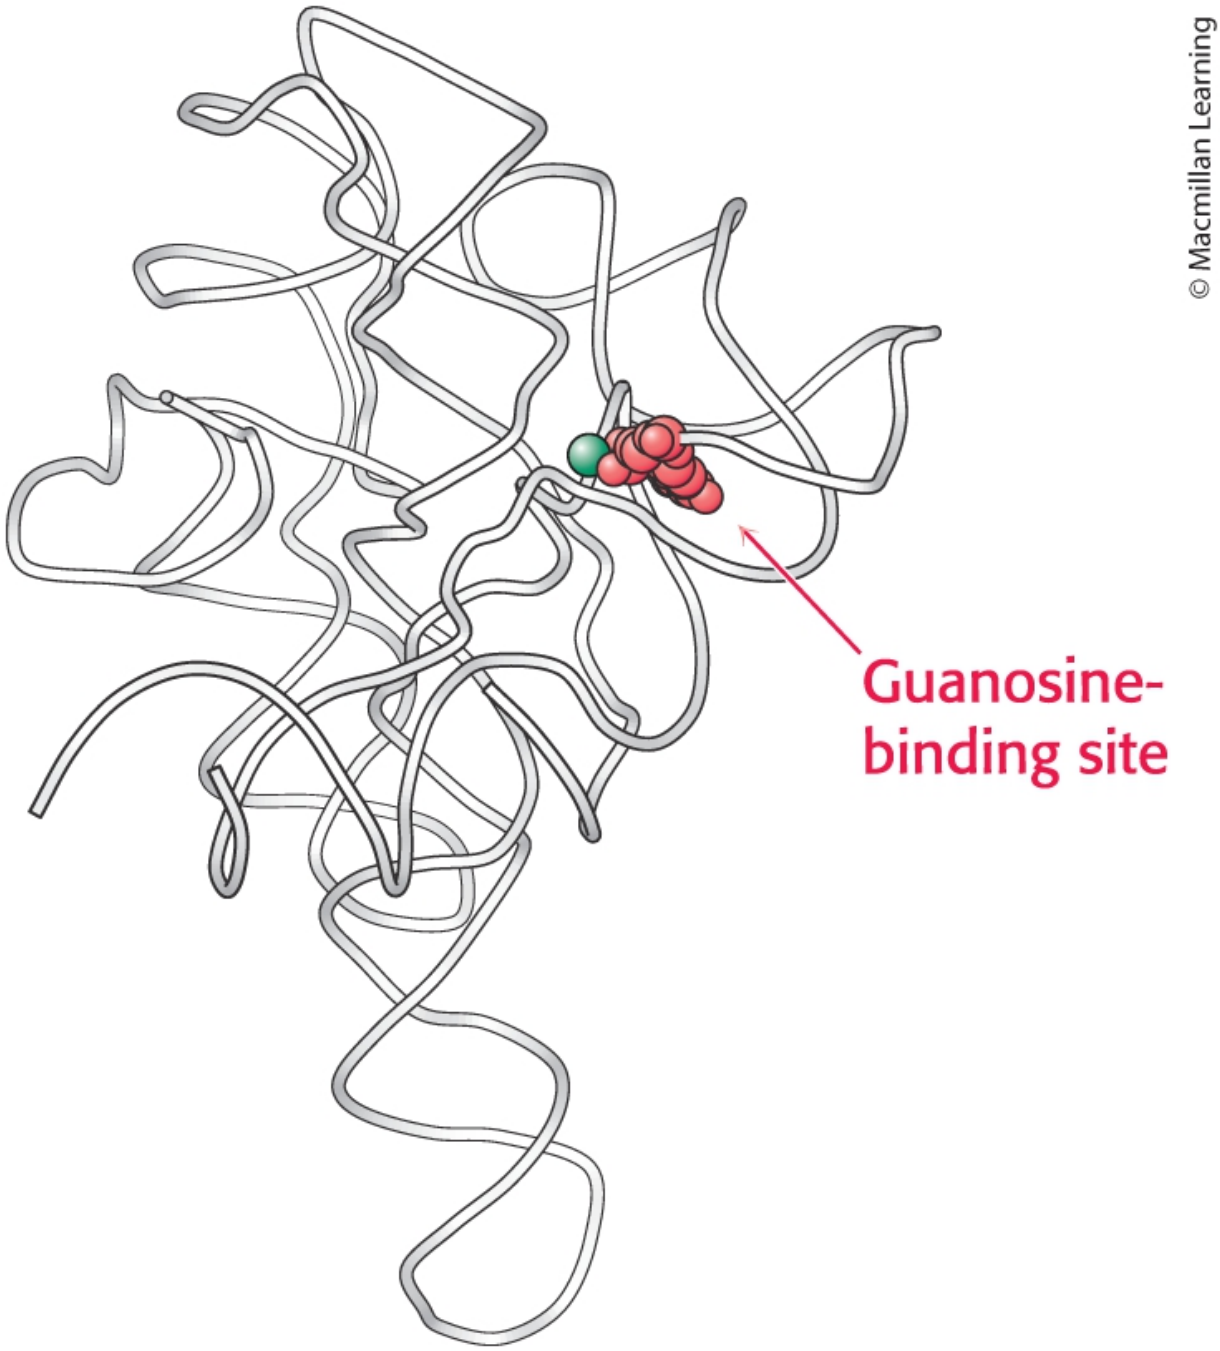
Return to FIGURE 29.41 Small regulatory R N As are involved in gene regulation

Extended description for FIGURE 29.42 R N A editing

alters the coding sequence of m R N As

© Macmillan Learning

A white horizontal bar contains the sequence C A A in the middle. Its left end is 5 prime and the right end is 3 prime end. It depicts the unedited m R N A.



An upward arrow from the unedited m R N A leads to another horizontal bar labeled A p o B-100. Its left part is colored blue and the right part is colored yellow. The blue part is labeled lipoprotein assembly. The yellow part is labeled L D L receptor binding. The left end is numbered 1 and the right end is numbered 4536.

A downward arrow below the unedited m R N A is labeled "R N A editing by deamination." It shows the release of N H 4 superscript plus.

It leads to edited m R N A depicted as a horizontal bar containing the sequence U A A in the middle. The edited m R N A undergoes translation to produce A p o B-48 depicted as a short blue horizontal bar. Its left end is numbered 1 and the right end is numbered 2152.

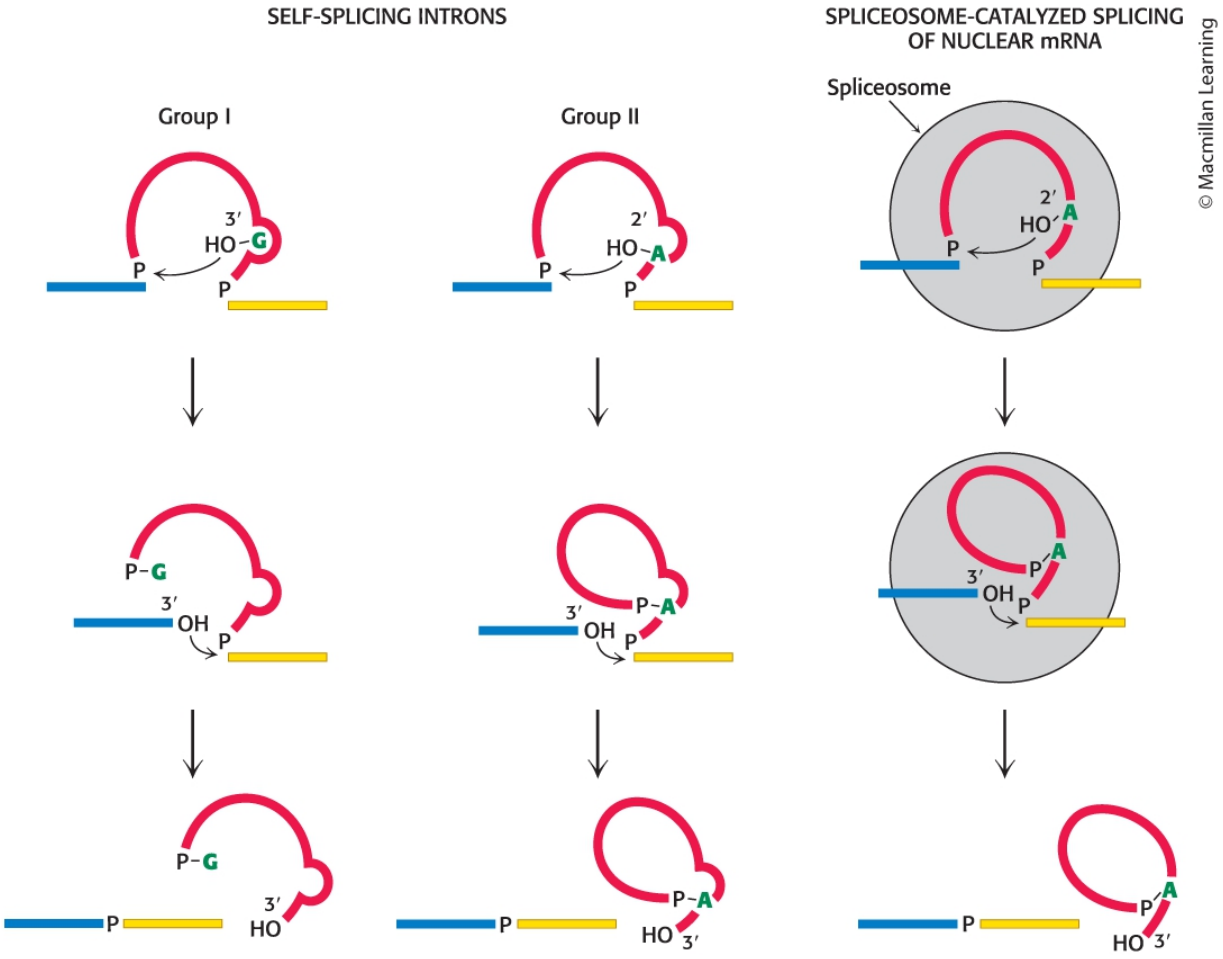
The upstream exon is located at the 5 prime end and the downstream exon is located at the 3 prime end. The long intron between the exons is folded into a structure to bring the exons close to each other. The sequence at the 3 prime end of the upstream exon is C U C U C U. A is present at the 5 prime end of the intron at its junction with the upstream exon. A phosphodiester bond depicted as a tiny circle labeled P is shown between the last U of the upstream exon and A of the intron. The sequence C U C U C U is based paired with the sequence 3 prime G G G A G G 5 prime of the intron. A is located at the 3 prime end of the first G of this sequence labeled "I G S." The 3 prime end of the intron contains G which is connected to 5 prime U of the downstream exon by a phosphodiester bond. The 3 prime end of the intron creates a cleft labeled G-binding site.



In the next step, a G nucleotide with a free O H group binds to its site. This O H group attacks the phosphodiester bond between U and A at the junction of the upstream exon and intron.

In the next step, the phosphodiester bond between U and A is cleaved. G binds to the 5 prime end of the intron. G is followed by A residue. The 3 prime O H of the upstream exon becomes free and attacks the phosphodiester bond between G and U at the 3 prime intron and downstream exon junction.

This attack leads to the formation of a spliced R N A containing the joined exons. The upstream exon is at the 5 prime end and the downstream exon is at the 3 prime end. The sequence at their junction is C U C U C U U. The linear intron is released such that its 3 prime G nucleotide contains a free O H.

Return to FIGURE 29.45 The catalytic mechanism of the group 1 self-splicing intron includes a series of transesterification reactions

Extended description for FIGURE 29.46 In self-splicing mechanisms, the catalytic site is formed by the intron itself

The self-splicing introns are of two types: group 1 and group 2.

In group 1, two exons on either ends are separated by a circular loop-like intron. The intron has a tiny semi-circular groove near its 3 prime end. A "G-nucleotide" with a free 3 prime O H is bound to the groove. O H attacks the phosphodiester bond between the 3 prime end of the upstream exon and the 5 prime end of the intron. In the

next step, the G nucleotide is bound to the free 5 prime end of the intron. The 3 prime O H of the upstream exon also becomes free and attacks the phosphodiester bond between the 3 prime end of the intron and downstream exon.

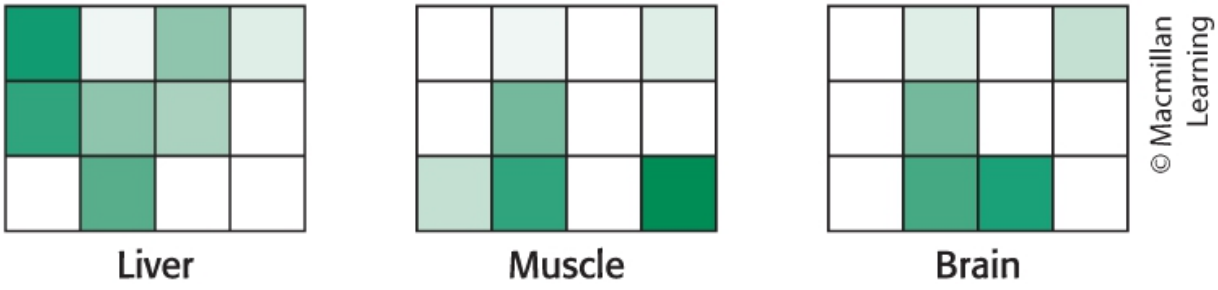
This attacks results in the joining of the two exons and the release of a semi-circular loop like intron. The 5 prime end of the intron contains G nucleotide and its 3 prime end contains a free O H group.

In group 2, An "A nucleotide" is located near the 3 prime end of the intron. It has a free 2 prime O H group. This O H attacks the phosphodiester bond between the upstream exon and the 5 prime end of the intron.

In the next step, the intron circularizes as its 5 prime end becomes bonded with 2 prime O H of A nucleotide near its 3 prime end. The free 3 prime O H of the upstream exon attacks the phosphodiester bond between the 3 prime end of the intron and the downstream exon. This attack results in the joining of the two exons and the release of the intron. The intron is loop-like with the short 3 prime end extending out of the loop.

In the spliceosome-catalyzed splicing of nuclear m R N A, the process is identical to group 2 self-splicing intron. The difference is that the transesterification reaction takes place inside a large spliceosome depicted as a large grey circle.

Return to FIGURE 29.46 In self-splicing mechanisms, the catalytic site is formed by the intron itself



Extended description for Three genes on a double-stranded D N A

Three genes, labeled gene A, gene B, and gene C, are present from left to right between two template strands. The first template strand at the top is blue-colored with 5 prime label at the left end and 3 prime label at the right end. The bottom strand is green colored and labeled 3 prime at the left end and 5 prime at the right end. Gene A is at the left, Gene C is at the right, and Gene B is in the middle of the two genes.

Extended description for FIGURE 30.1 Polypeptides are synthesized by the successive addition of amino acids to the carboxyl terminus

In the first step, an amino acid is converted into a polypeptide. It is coupled with the entry of the second amino acid.

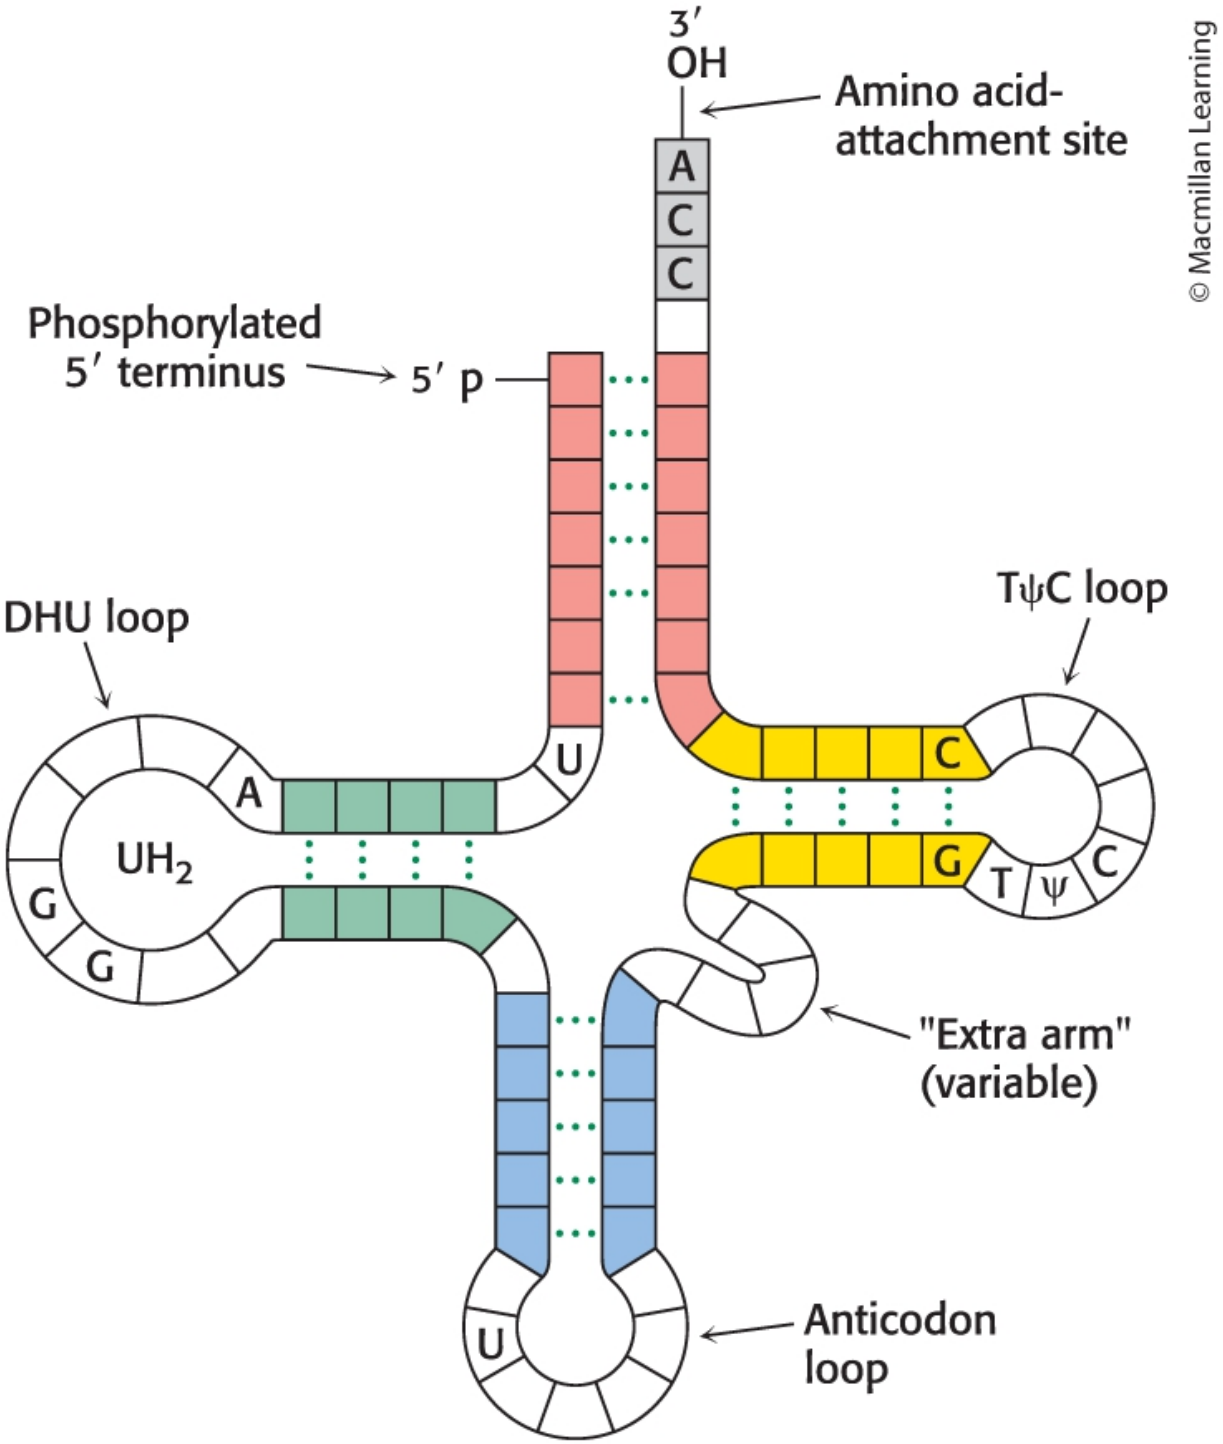
The structure of the amino acid is as follows: A central C atom is double bonded to O on the left and single bonded to a second central C atom in the form of a line. The second central C atom is dash bonded to H on the lower right, wedge bonded to R 1 on the upper right, and single bonded to N H 3 superscript plus on the upper left. This part of the structure is highlighted in red. The first central C atom is single bonded to a second O atom on the lower right. The second O atom is single bonded to t R N A subscript 1 on the lower left.

The structure of the amino acid that is added to the first amino acid is as follows: A central C atom is double bonded to O on the left and single bonded to a second central C atom in the form of a line. The second central C atom is dash bonded to H on the lower right, wedge bonded to R 2 on the upper right, and single bonded to N H 3 superscript plus on the upper left. This part of the structure is highlighted in blue. The first central C atom is single bonded to a second O atom on the lower right. The second O atom is single bonded to t R N A subscript 2 on the lower left.

The structure of the polypeptide formed by the addition of the second amino acid is as follows: A 1 N and 3 C heteronuclear alkane chain is depicted as a line structure using 3 zigzag lines. N bound to H occupies the third position. C 1 is wedge bonded to R 1 on the upper right, dash bonded to H on the lower right, and is single bonded to N H 3 superscript plus on the upper left. C 2 is double bonded to O on the left. C 3 is dash bonded to R 2 on the upper left, wedge bonded to H on the lower left, and is single bonded to a central C atom on the lower right. The central C atom is double bonded to a second O atom on the right and is single bonded to a third O atom on the lower left. The third O atom is single bonded to t R N A subscript 2 on the lower right. In the alkane chain, C 1 to C 2 part of the structure is highlighted in red, and N H to the C atom part of the structure is highlighted in blue.

In the second step, the polypeptide is further transformed to form a longer polypeptide. It is coupled with the entry of the third amino acid.

The structure of the third amino acid is as follows: A central C atom is double bonded to O on the left and single bonded to a second central C atom in the form of a line. The second central C atom is dash bonded to H on the lower right, wedge bonded to R 3 on the upper right, and single bonded to N H 3 superscript plus on the

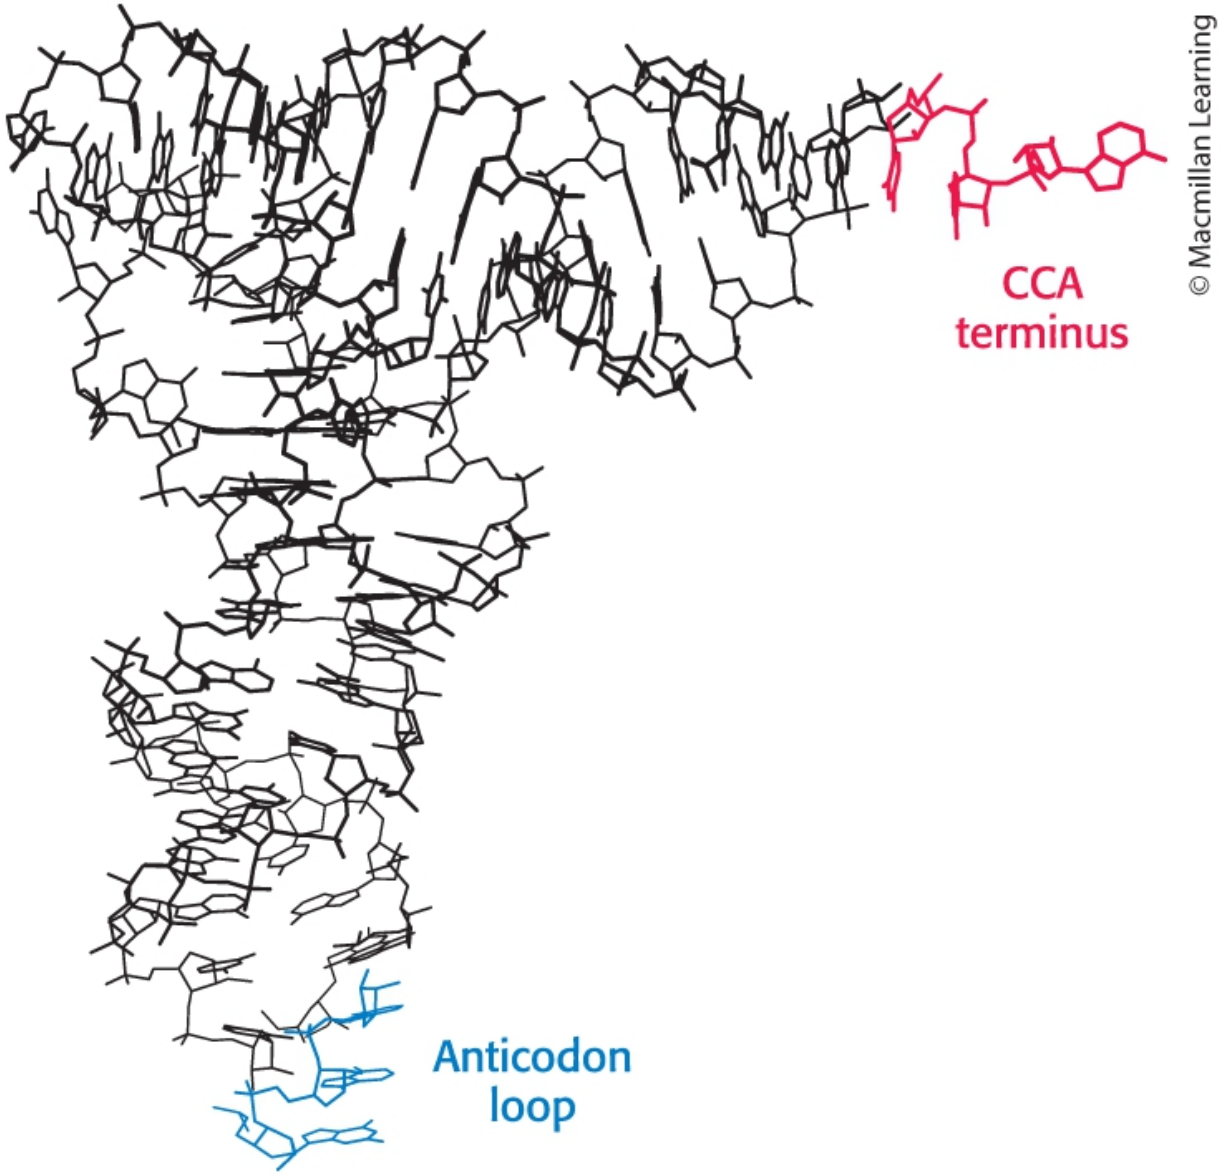


upper left. This part of the structure is highlighted in green. The first central C atom is single bonded to a second O atom on the lower right. The second O atom is single bonded to t R N A subscript 3 on the lower left.

The structure of the polypeptide formed by the addition of the third amino acid is as follows: A 2 N and 3 C heteronuclear alkane chain is depicted as a line structure using 4 zigzag lines. N bound to H occupies the first and the fourth positions. The first N atom is single bonded to a central C atom on the upper right. The central C atom is double bonded to O on the right and is single bonded to a second central C atom on the upper left in the form of a line. The second central C atom is single bonded to N H 3 superscript plus on the upper right, dash bonded to R 1 on the upper left, and is wedge bonded to H on the lower left. C 1 of the alkane chain is wedge bonded to R 2 on the upper right and dash bonded to H on the lower right. C 2 of the alkane chain is double bonded to a second O atom on the left. C 3 of the alkane chain is dash bonded to R 3 on the upper left, wedge bonded to H on the lower left, and is single bonded to a third central C atom on the lower right. The third central C atom is double bonded to a third O atom on the right and is single bonded to a fourth O atom on the lower left. The fourth O atom is single bonded to t R N A subscript 3 on the lower right. In the alkane chain, the first and second central C atoms and the groups attached to them are highlighted in red. In the alkane chain, the first N atom to C 2 part of the chain and groups attached to them is highlighted in blue. In the alkane chain the second N atom to third central C atom part of the chain and groups attached to them is highlighted in green.

Three forward arrows drawn from the product of the second step indicate that the reaction continues.

Return to FIGURE 30.1 Polypeptides are synthesized by the successive addition of amino acids to the carboxyl terminus

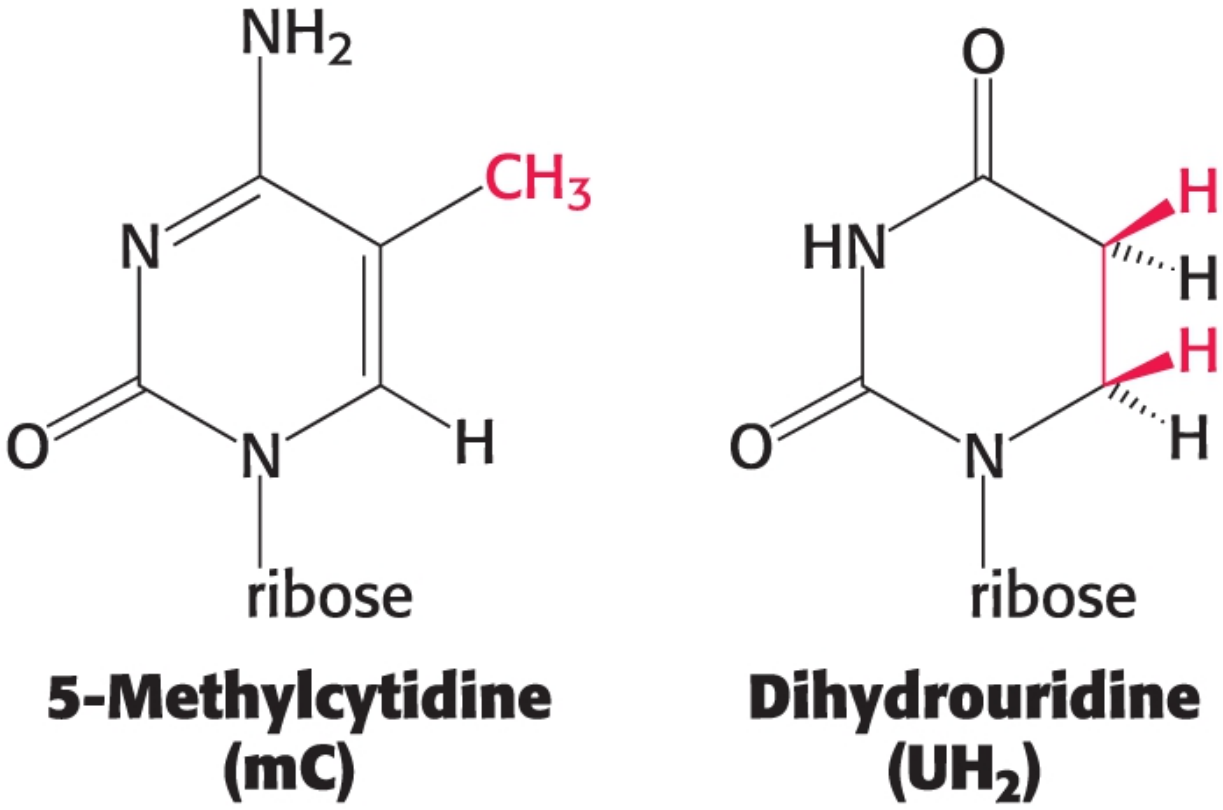


Extended description for FIGURE 30.2 The secondary structure of all transfer R N A s resembles a cloverleaf

The secondary structure of R N A resembles a cloverleaf. A single chain of t R N A is folded to form five arms which results in 3 prime and 5 prime ends that lie adjacent to each other at the top. Each arm consists of a loop and a basal stalk. The 3 prime and 5 prime ends of the t R N A are at the top. They do not form a loop and hence are in the form of two parallel lines. The stalk representing 5 prime terminus is shorter than the 3 prime stalk. The second arm on the right is the T loop and it is labeled T psi C loop. It consists of a bases C, T, and C-G base pair. The third arm at the bottom is labeled the anticodon loop. The loop consists of a base U. The fourth arm on the left is the D loop and it is labeled D H U loop. The center of the loop reads U H 2. The loop consists of bases A, G, and G. G and G are present side by side while A lies away from it. The fifth arm is a short extra arm that lies between the second and third arms. It is labeled extra arm (variable). The 3 prime strand at the top consists of a codon. From top to bottom, the codon reads A C C. The 3 prime end is attached to an O H group at the top. The 5 prime end is single bonded to a phosphate group and is labeled phosphorylated 5 prime terminus. The base pairs in each arm are highlighted in different colors. The base pairs in the free 5 prime and 3 prime ends are highlighted in pink. The base pairs in the stalk of the T loop are highlighted in yellow. The base pairs in the stalk of the anticodon loop are highlighted in blue. The base pairs in the stalk of the D loop are highlighted in green.

Return to FIGURE 30.2 The secondary structure of all transfer R N A s resembles a cloverleaf

Extended description for FIGURE 30.3 Transfer R N A s have an L-shaped tertiary structure

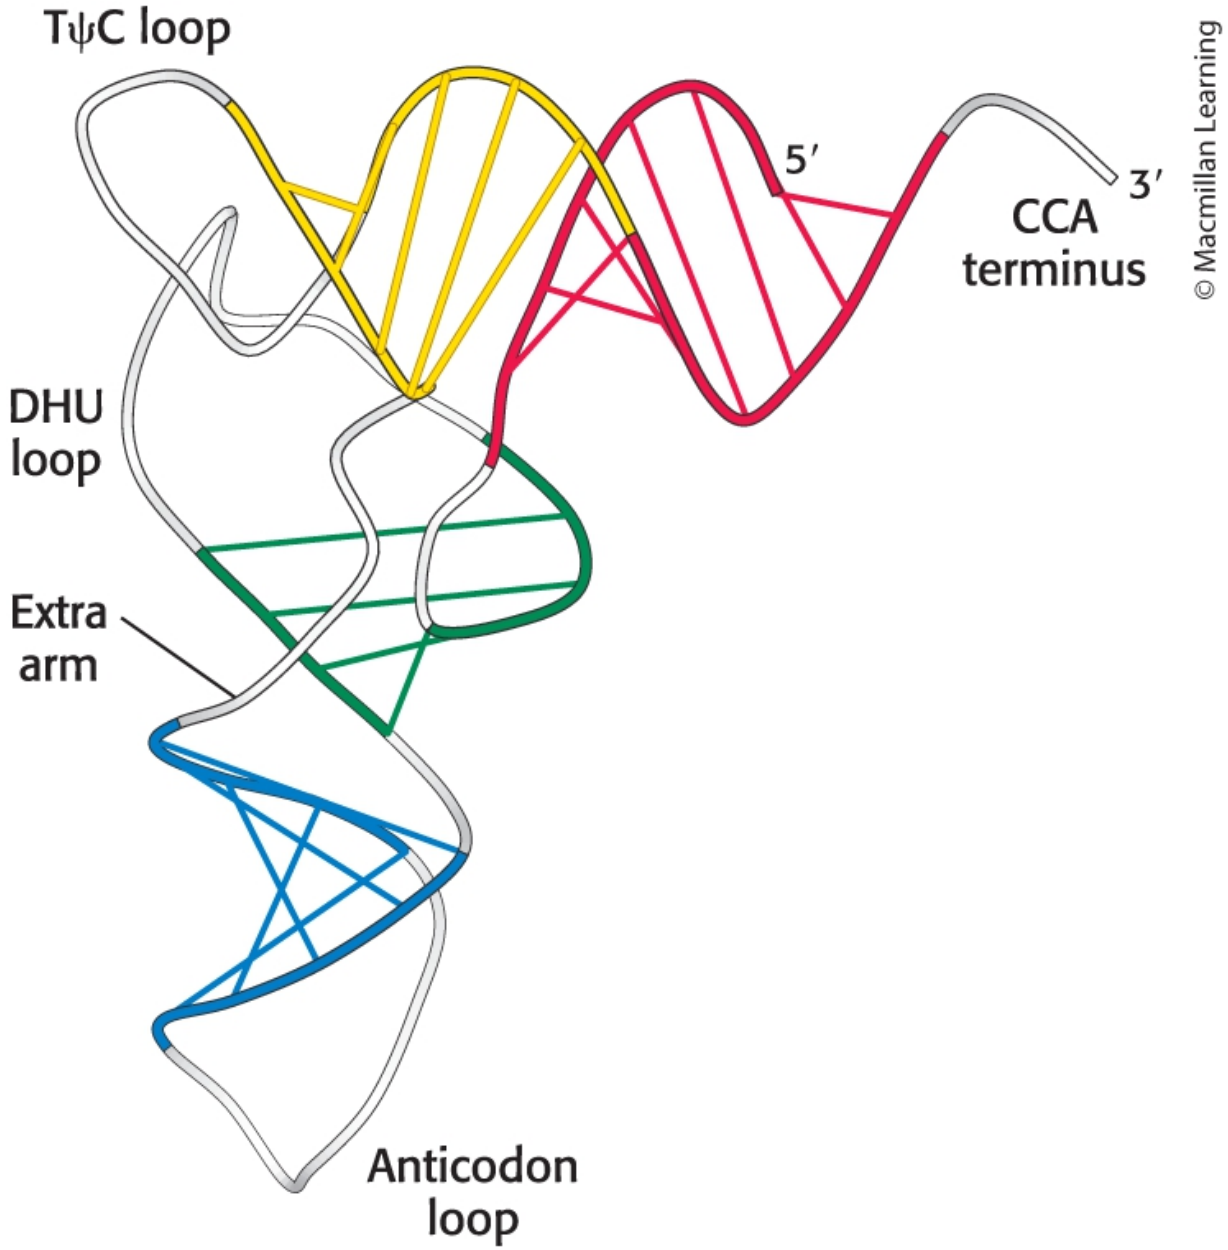


The tertiary structure of t R N A is depicted in the form of an inverted L. The t R N A is composed of ball-and-stick models composed of pentagonal rings attached by sticks to the neighboring pentagonal rings in a haphazard manner. A red-colored ball-and-

stick model attached to the upper right of the t R N A is labeled C C A terminus. A blue-colored ball-and-stick model attached to the lower end of the t R N A is labeled an anticodon loop.

Return to FIGURE 30.3 Transfer R N A s have an L-shaped tertiary structure

Extended description for Structures of 5-methycytidine and dihydrouridine



The structure of 5-methycytidine (m C) is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the bottommost vertex. The second N atom occupies the third position which is the top left vertex. A double bond is present between the second N atom and C 2 and C 3 and C 4. The first N atom is single bonded to ribose. C 1 is double bonded to O. C 2 is single bonded to N H 2. C 3 is single bonded to C H 3. C H 3 is highlighted in red. C 4 is single bonded to H. The structure of dihydrouridine (U H 2) is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 2 N and 4 C atoms. The first N atom occupies the first position, which is the

bottommost vertex. The second N atom bound to H occupies the third position which is the top left vertex. The first N atom is single bonded to ribose. C 1 is double bonded to O. C 2 is double bonded to O. C 3 and C 4 are each wedge bonded to H on the upper right and dash bonded to H on the lower right. The wedge bonded H atoms in both C 3 are C 4 are highlighted in red.

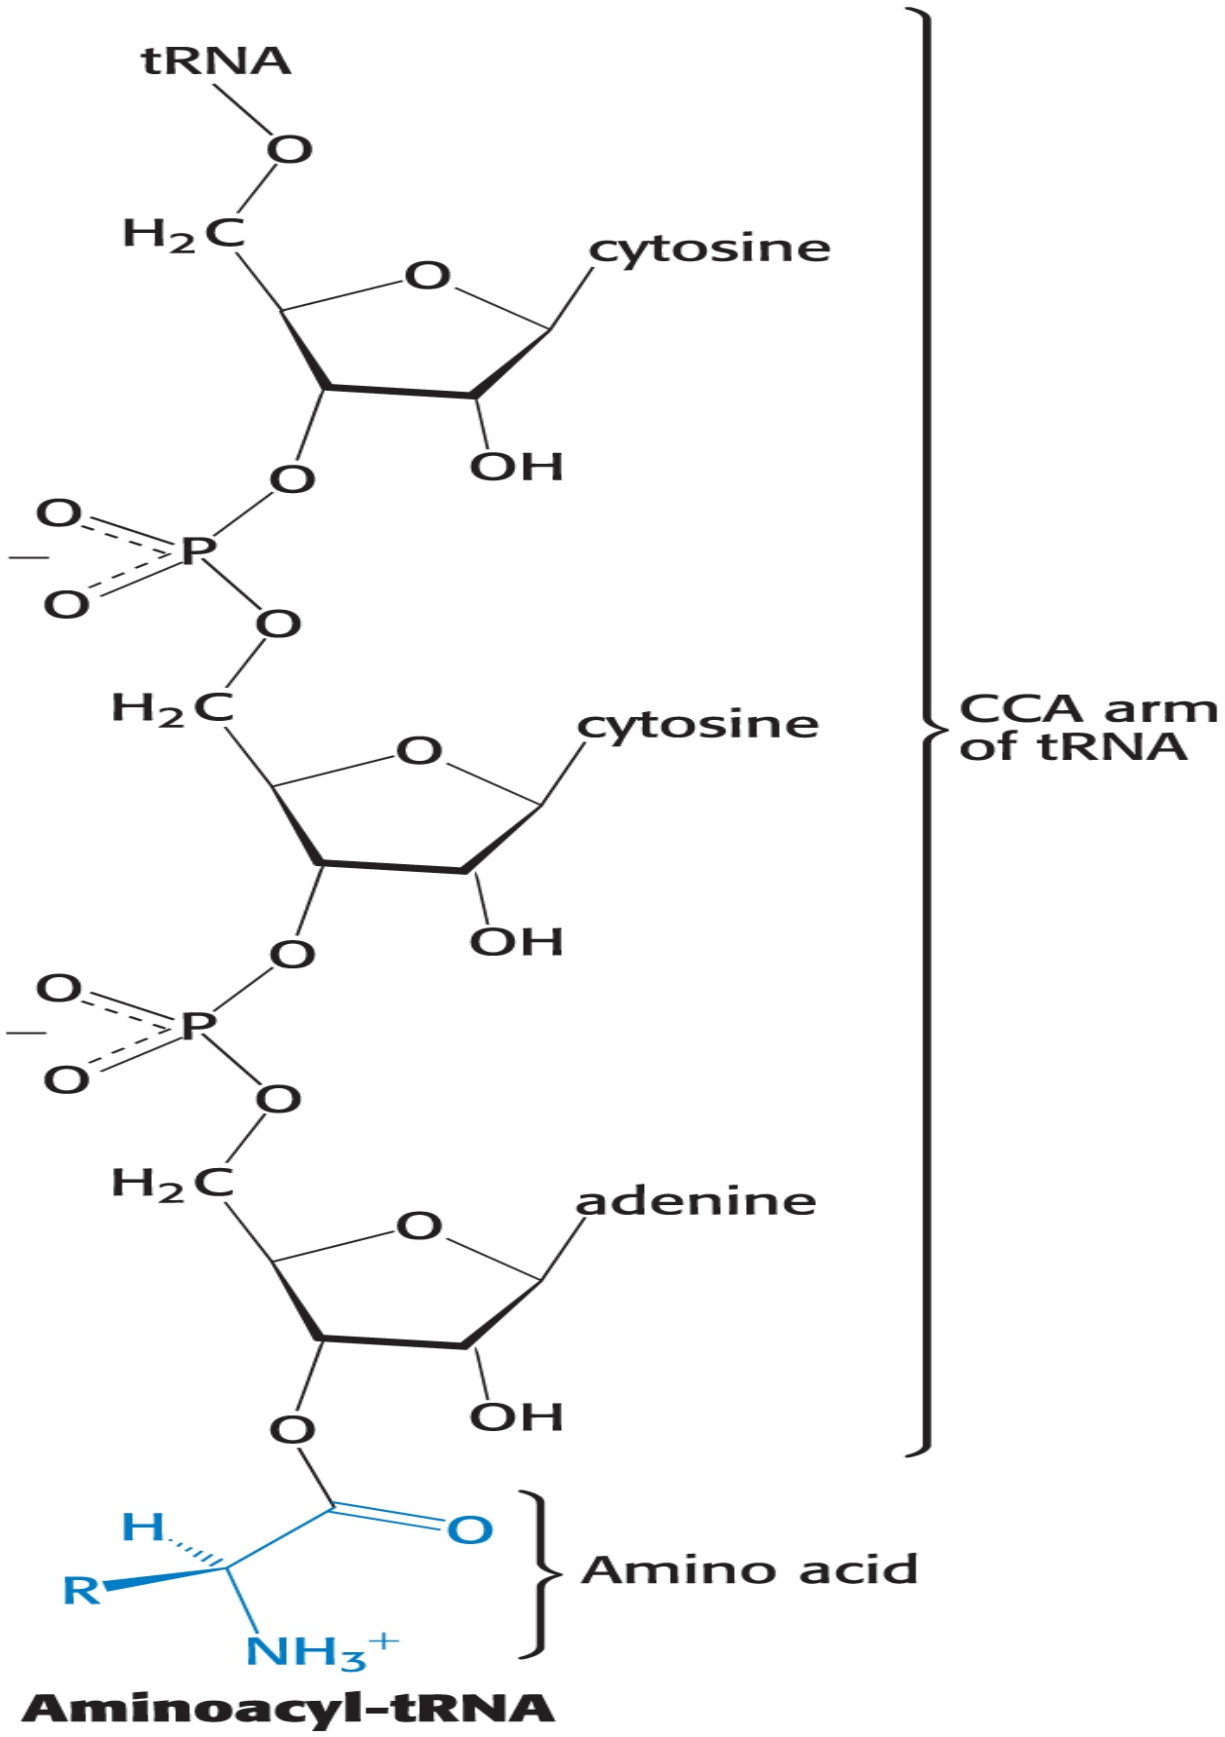
Extended description for FIGURE 30.4 The four double-stranded regions of a t R N A stack to form an L-shaped structure



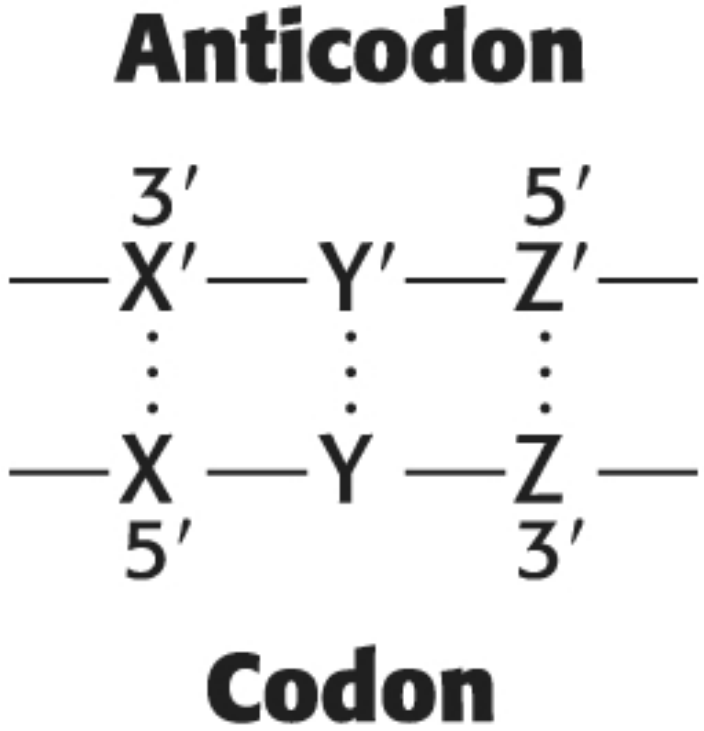
The tertiary structure of t R N A is depicted in the form of an inverted L-shaped structure composed of four double-stranded

regions. These include red, yellow, green, and blue helices. These helices are attached by white helices in between. The helices have 5 prime and 3 prime ends. The region of the helix on the upper right is labeled C C A terminus. The region of the helix on the top left is labeled T psi C loop. The region of the helix at the lower end of the t R N A is labeled the anticodon loop. The region between the T psi loop and anticodon loop consists of the D H U loop and the extra arm.

Return to FIGURE 30.4 The four double-stranded regions of a t R N A stack to form an L-shaped structure

Extended description for FIGURE 30.5 Ester linkages

couple amino acids to t R N A s



Aminoacyl-tRNA

The structure of aminoacyl- t R N A shows an amino acid attached to the C C A arm of t R N A. The structure is as follows: A 5-membered heterocyclic pentagonal ring in a vertical orientation and consists of 1 O and 4 C atoms. O occupies the first position which is the topmost vertex. The ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are toward the observer, and O is away from the observer. C 1 is single bonded to cytosine. C 2 is single bonded to O H. C 4 is single bonded to C H 2. C H 2 is further single bonded to O on the upper right. O on the upper right is single bonded to t R N A on the upper left. C 3 is single bonded to a second O atom. The second O atom is single bonded to a central P atom on the lower left. The central P atom is partially double bonded to a third O atom on the upper left and a fourth O atom on the lower left. The P O O group has an overall negative charge. The central P atom is single bonded to a fifth O atom on the lower right. The fifth O atom is single bonded to a second C H 2 group on the lower left. The second C H 2 group is single bonded to C 4 of a second 5-membered pentagonal ring in a vertical orientation consisting of 1 O and 4 C atoms. In the second ring, O occupies the first position which is the topmost vertex. The second ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are toward the observer, and O is away from the observer. C 1 of the second ring is single bonded to cytosine. C 2 of the second ring is single bonded to O H. C 3 of the second is single bonded to a sixth O atom. The sixth O atom is single bonded to a second central P atom on the lower left. The second central P atom is partially double bonded to a seventh O atom on the upper left and an eighth O atom on the lower left. The P O O group has an overall negative charge. The second central P atom is also single bonded to a ninth O atom on the lower right. The ninth O atom is further single bonded to a third C H 2 group on the lower left. The third C H 2 group is single bonded to C 4 of a third 5-membered pentagonal ring in a vertical orientation consisting of 1 O and 4 C atoms. In the third ring, O occupies the first position which is the topmost vertex. The third ring is in a plane perpendicular to

the plane of the paper such that C 2 and C 3 are toward the observer, and O is away from the observer. C 1 of the third ring is single bonded to adenine. C 2 of the third ring is single bonded to O H. C 3 of the third ring is single bonded to a tenth O atom. The tenth O atom is single bonded to C 2 of a 2-carbon alkane chain depicted as a line structure using 1 line. C 1 of the alkane chain is single bonded to H on the upper left, and N H 3 superscript plus on the lower right and is wedge bonded to R on the left. C 2 of the alkane chain is double bonded to a eleventh O atom on the lower right. The 2-carbon alkane chain and the groups attached to it are highlighted in blue.

Extended description for Anticodon and codon sequence

The anticodon sequence at the top is in the 3 prime to 5 prime direction while the codon sequence below is in the 5 prime to 3 prime direction. The anticodon sequence reads X prime, Y prime, and Z prime from left to right and is connected by bonds. The X and Z on the left and right also have bonds on the left and right, respectively. The codon sequence reads X, Y, and Z from left to right and is connected by bonds. The X and Z on the left and right also have bonds on the left and right, respectively. The anticodons at the top are vertically base paired with the corresponding codons below such that X prime is paired with X, Y prime is paired with Y, and Z prime is paired with Z.

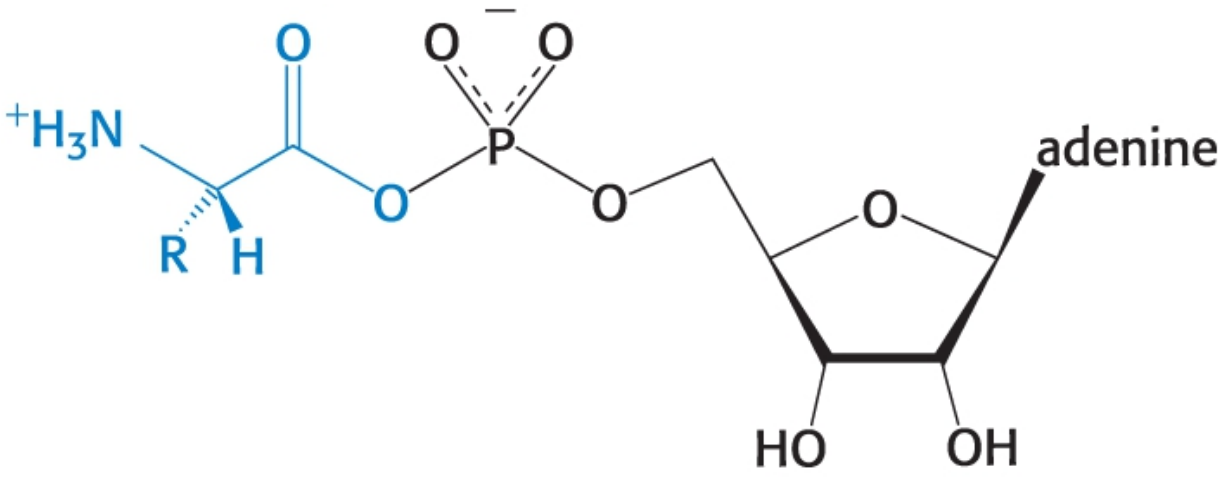
Extended description for FIGURE 30.6 16 S r R N A monitors base-pairing between the codon and the anticodon



© Macmillan Learning

The figure depicts the ball-and-stick model of 16 S r R N A conserved adenine at the top. The ball-and-stick model consists of grey, blue, and red spheres. C atoms are depicted as a grey spheres, N atoms are depicted as a blue spheres, and O atoms are depicted as a red spheres. The ball-and-stick model consists of a 6-membered heterocyclic, hexagonal ring. The hexagonal ring consists of four grey and two blue spheres. A grey sphere on the top left is attached to a blue sphere. The hexagonal ring is fused with a pentagonal ring consisting of 2 blue spheres and three grey spheres. One of the blue spheres in the pentagonal ring is attached to a grey sphere of another pentagonal ring consisting of one red and four grey spheres. One of the grey spheres of the pentagonal ring is attached

to a grey sphere that is further attached to a red sphere. Another grey sphere in the pentagonal ring is attached to a red sphere at the bottom. A blue sphere from the hexagonal ring in the 16 S r R N A is hydrogen bonded to a red sphere in the anticodon base adenine. A red sphere attached to the pentagonal ring in the 16 S r R N A is hydrogen bonded to codon base uracil. The anticodon base adenine consists of five grey spheres attached side by side. The first, fourth, and fifth spheres are each attached to red spheres. The red sphere attached to the fourth grey sphere is the place where the hydrogen bond is formed. The fifth sphere is also attached to a pentagonal ring consisting of two blue and three grey spheres. The pentagonal ring is fused with a hexagonal ring consisting of two blue and three grey spheres. One of the grey spheres is attached to a blue sphere. The codon base uracil consists of a hexagonal ring consisting of four grey and two blue spheres. Two grey spheres are attached to one red sphere each. One of the red spheres directly forms a hydrogen bond with the 16 S r R N A. One of the blue spheres of the hexagonal ring is attached to a pentagonal ring consisting of one red and four grey spheres. One of the grey spheres is attached to a grey sphere at the bottom. This grey sphere is attached to a red sphere. One of the grey spheres at the top is attached to a red sphere. The red sphere forms a hydrogen bond with the 16 S r R N A. Two hydrogen bonds are formed between anticodon base adenine and codon base uracil.

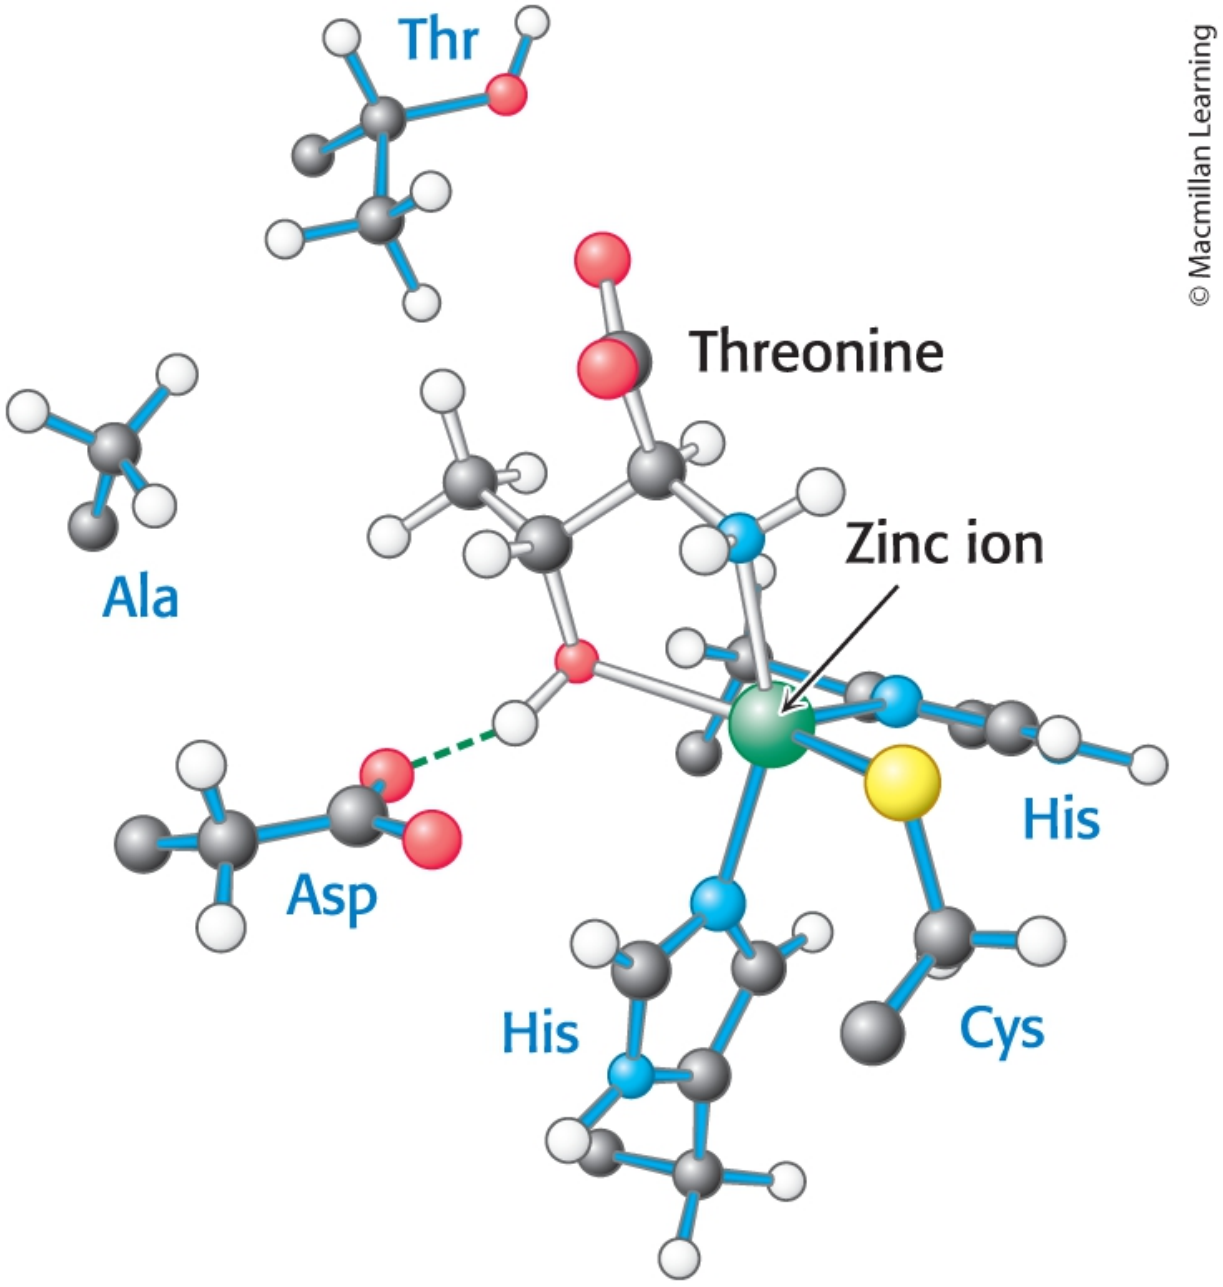
Extended description for Structure of aminoacyl A M P



Aminoacyl-AMP

The structure of aminoacyl A M P is as follows: A 5-membered heterocyclic pentagonal ring in a horizontal orientation consists of 1 O and 4 C atoms. O occupies the first position which is the topmost vertex. C 1 is wedge bonded to adenine. C 2 is single bonded to O H. C 3 is single bonded to O H. C 4 is single bonded to C 3 of a 1 N H 3 superscript plus, 1 P, 2 O, and 3 C heteronuclear alkane chain consisting of depicted as a line structure using 6 zigzag lines. N H 3 superscript plus occupies the first position. The first O atom occupies the fourth position, P occupies the fifth position, and the second O occupies the sixth position. C 1 is dash bonded to R on the lower left and wedge bonded to H on the lower right. C 2 is double bonded to O above. P is partially double bonded to O on the upper left and O on the upper right. The P O O group has an overall negative charge. The structures in the alkane chain upto the fourth position are highlighted in blue.

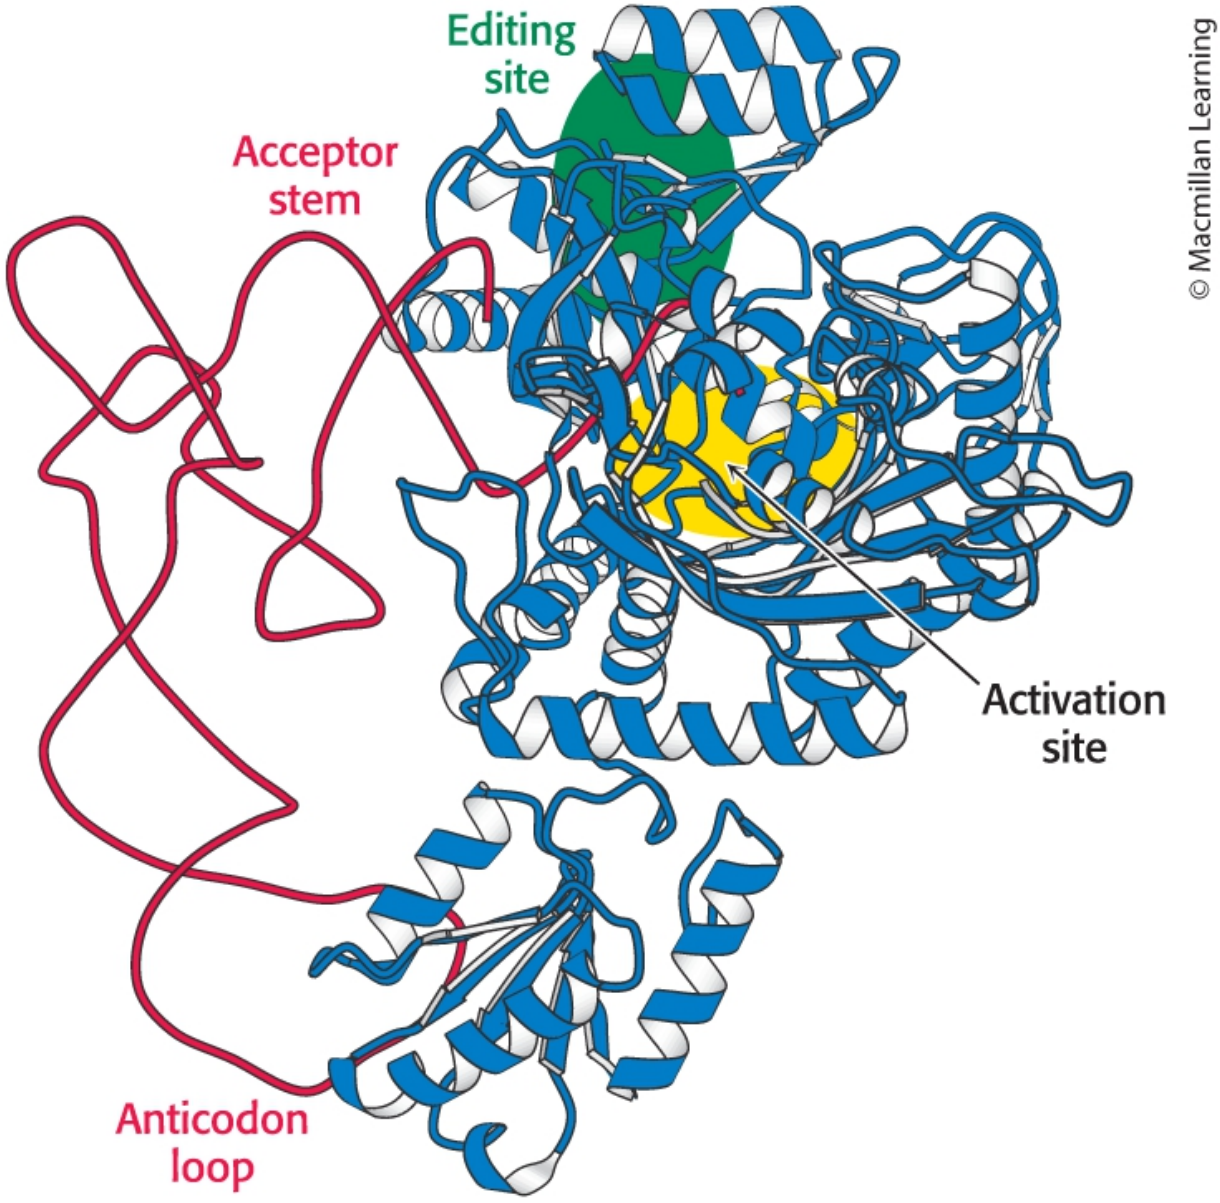
Extended description for FIGURE 30.10 Kinetic proofreading can increase reaction specificity

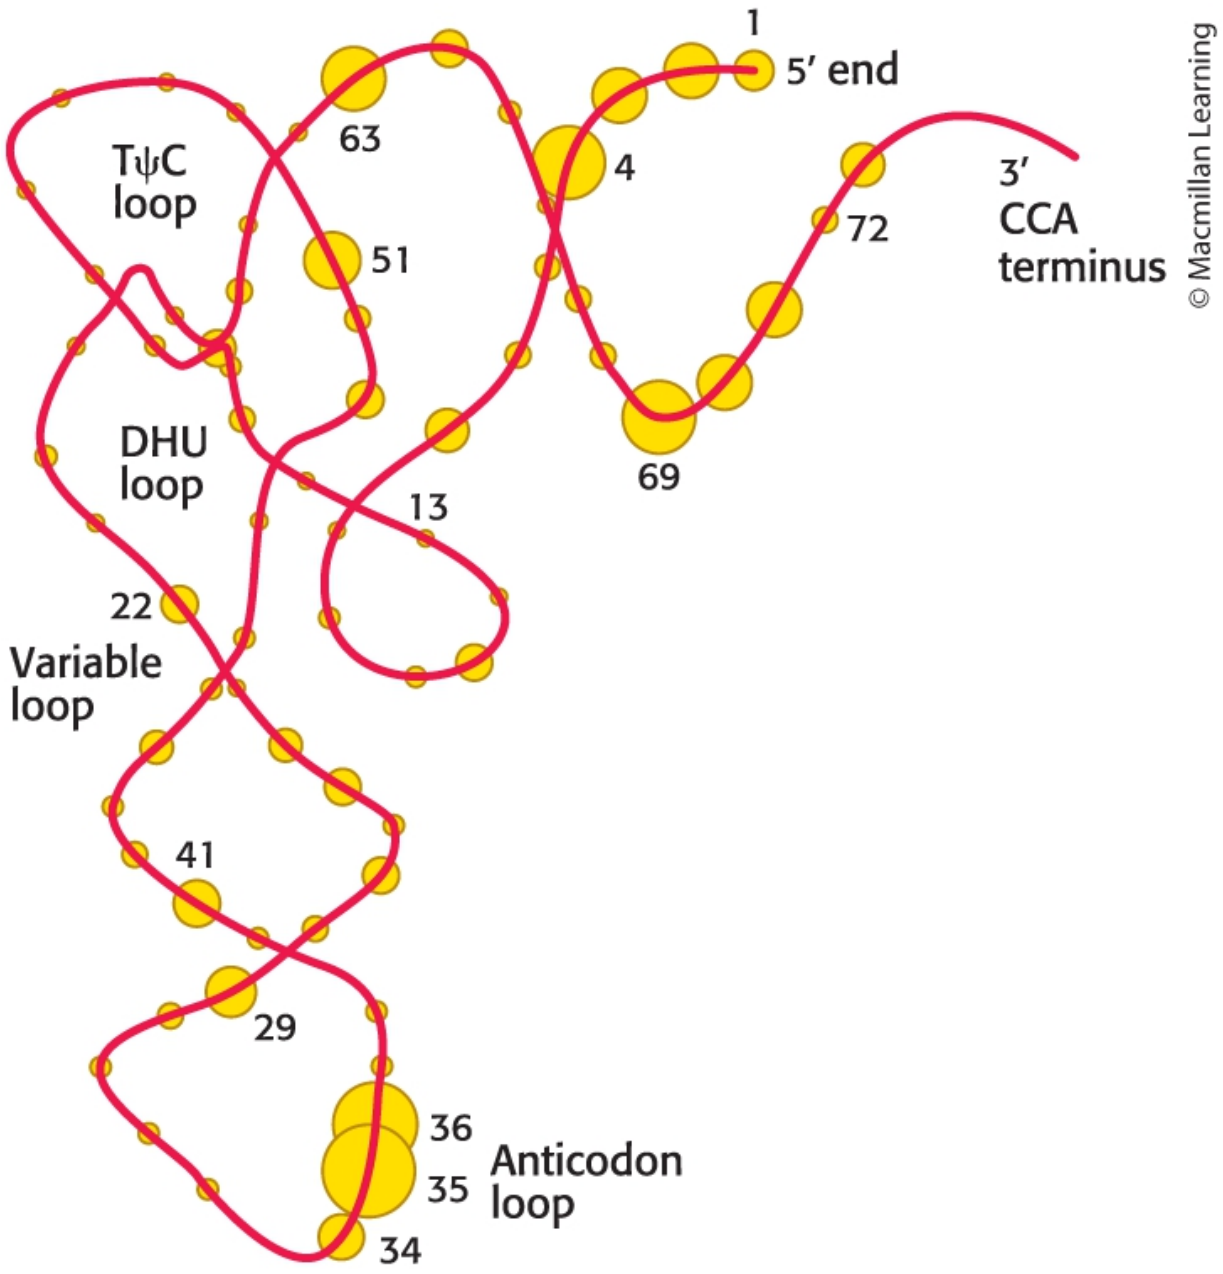


The figure shows two panels, one on the left labeled equilibrium and the other on the right labeled kinetic proofreading. The figure shows a substrate that binds to an enzyme more tightly (curve shown in blue) than an alternate substrate (curve shown in red). The red and blue curves show the simultaneous rise and fall throughout the panels. On the upper region of the equilibrium selection panels, the two curves start from the left, move upward, and slope down, showing a peak between the two panels labeled irreversible step. The curves, then show a dip in the kinetic proofreading panel labeled intermediate. The space between the blue and red curves is slightly larger in the intermediate. A downward arrow from the intermediate shows that it can form a final correct product or the

intermediate shows another peak that gradually slopes down and terminates on the right depicting the formation of wasteful products. The wasteful products are formed faster for the alternate substrate.

Return to FIGURE 30.10 Kinetic proofreading can increase reaction specificity

Extended description for FIGURE 30.11 Aminoacyl- t R N A synthetases bind to both the acceptor stem and the anticodon loop of a t R N A



The ribbon diagram of threonyl- t R N A synthetase is a dimer. Only one subunit of the dimer is depicted in the figure. The subunit roughly has a heart-shaped appearance. It consists of blue-colored

alpha helices and beta strands interconnected by thread-like loops. A green-colored oval structure in the upper region of the subunit is labeled the editing site. A yellow-colored oval structure, slightly above the center of the subunit and below the editing site is labeled activation site. A red-colored double-stranded inverted L-shaped t R N A is present on the left. It consists of an acceptor on the upper right and an anticodon loop on the lower end. Both the acceptor stem and the anticodon loop are bound to the aminoacyl- t R N A synthetase.

Extended description for FIGURE 30.12 t R N A s have multiple recognition sites for aminoacyl- t R N A synthetases

The tertiary structure of t R N A is depicted in the form of an inverted L. The t R N A is composed of a continuous double helix that has free 5 prime and 3 prime ends on the upper right, where the latter is labeled C C A terminus. The region of the helix on the top left is labeled T psi C loop. The region of the helix at the lower end of the t R N A is labeled the anticodon loop. The region between the T psi loop and anticodon loop consists of the D H U loop and the variable arm. The helix consists of yellow-colored circles of different sizes that represent the nucleotides in the base sequence starting from the 5 prime ends of the t R N A molecule. The numbers on the nucleotides represent the positions of the nucleotides in the base sequence. The numbering starts from 1 to 72 between 5 prime and to 3 prime C C A terminus.

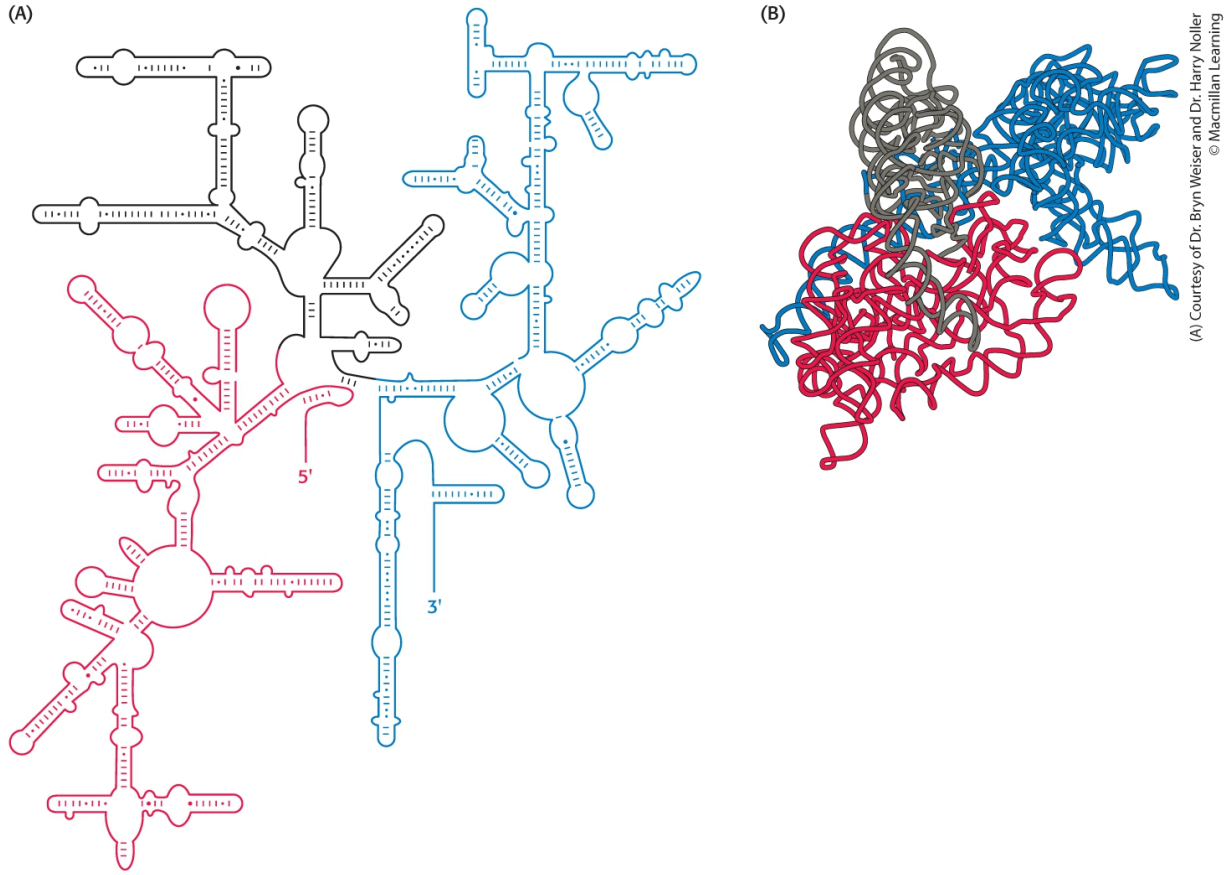
Return to FIGURE 30.13 Class I and class II aminoacyl-t R N A synthetases recognize different faces of the t R N A molecule

Extended description for FIGURE 30.14 The ribosome consists of a large subunit and a small subunit

The figure has three parts.



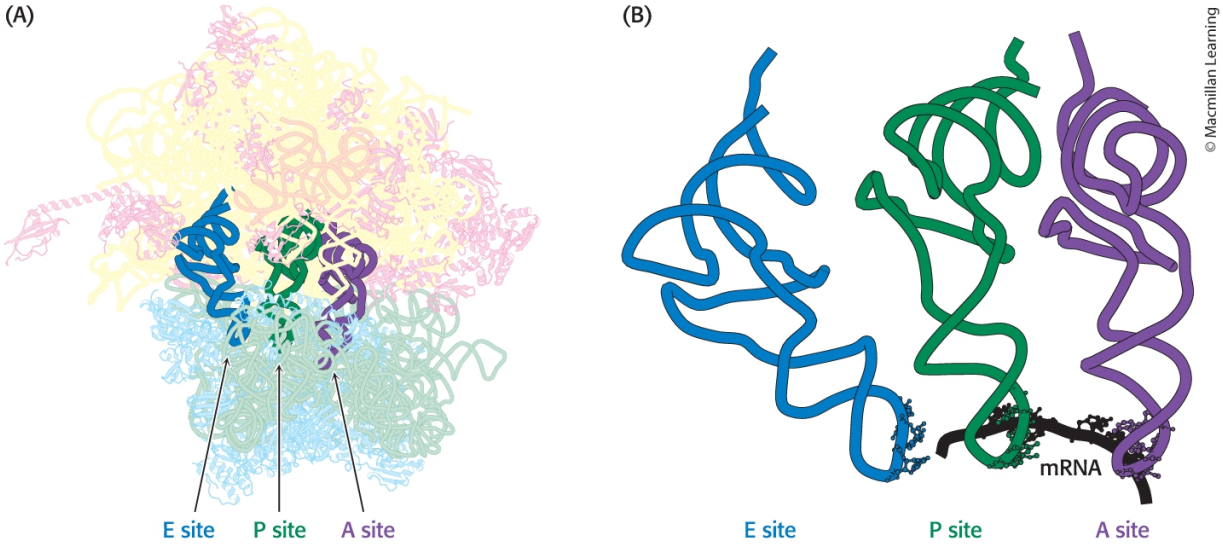
The first part labeled the 50 S subunit shows the view of the part of the 50 S subunit that interacts with the 30 S subunit. It consists of yellow-colored thread-like structures. Red-colored alpha helices and beta strands project from the upper end and lateral sides of the yellow-colored structures. Additionally, orange-colored thread-like structures also project from the upper end. The yellow-colored structures represent the 50 S subunit while the red alpha helices and beta strands represent the 30 S subunit.

The second part labeled 30 S subunit shows the view of the part of the 30 S subunit that interacts with the 50 S subunit. It consists of green-colored thread-like structures. Blue-colored alpha helices and beta strands project from the upper, lower, and lateral sides of the green-colored structures. The green-colored structures represent the 30 S subunit while the blue alpha helices and beta strands represent the 50 S subunit.

The third part labeled 70 S ribosome shows the view of the 70 S ribosome that is rotated with respect to the other two views. It shows two subunits. The subunit at the top consists of yellow-colored thread-like structures. Red-colored alpha helices and beta strands project from the upper end and lateral sides of the yellow-colored structures. Orange-colored thread-like structures emerge from the front. The subunit at the bottom consists of green-colored thread-like structures. Blue-colored alpha helices and beta strands project from the upper, lower, and lateral sides of the green-colored structures. 23 S r R N A are shown in yellow, 5 S r R N A are shown in orange, 16 S r R N A are shown in green, proteins of the 50 S subunit are in red, and proteins of the 30 S subunit are in blue. The interface between the 50 S and the 30 S subunits consists primarily of R N A.

Return to FIGURE 30.14 The ribosome consists of a large subunit and a small subunit

Extended description for FIGURE 30.15 Ribosomal R N A s form intramolecular base pairs



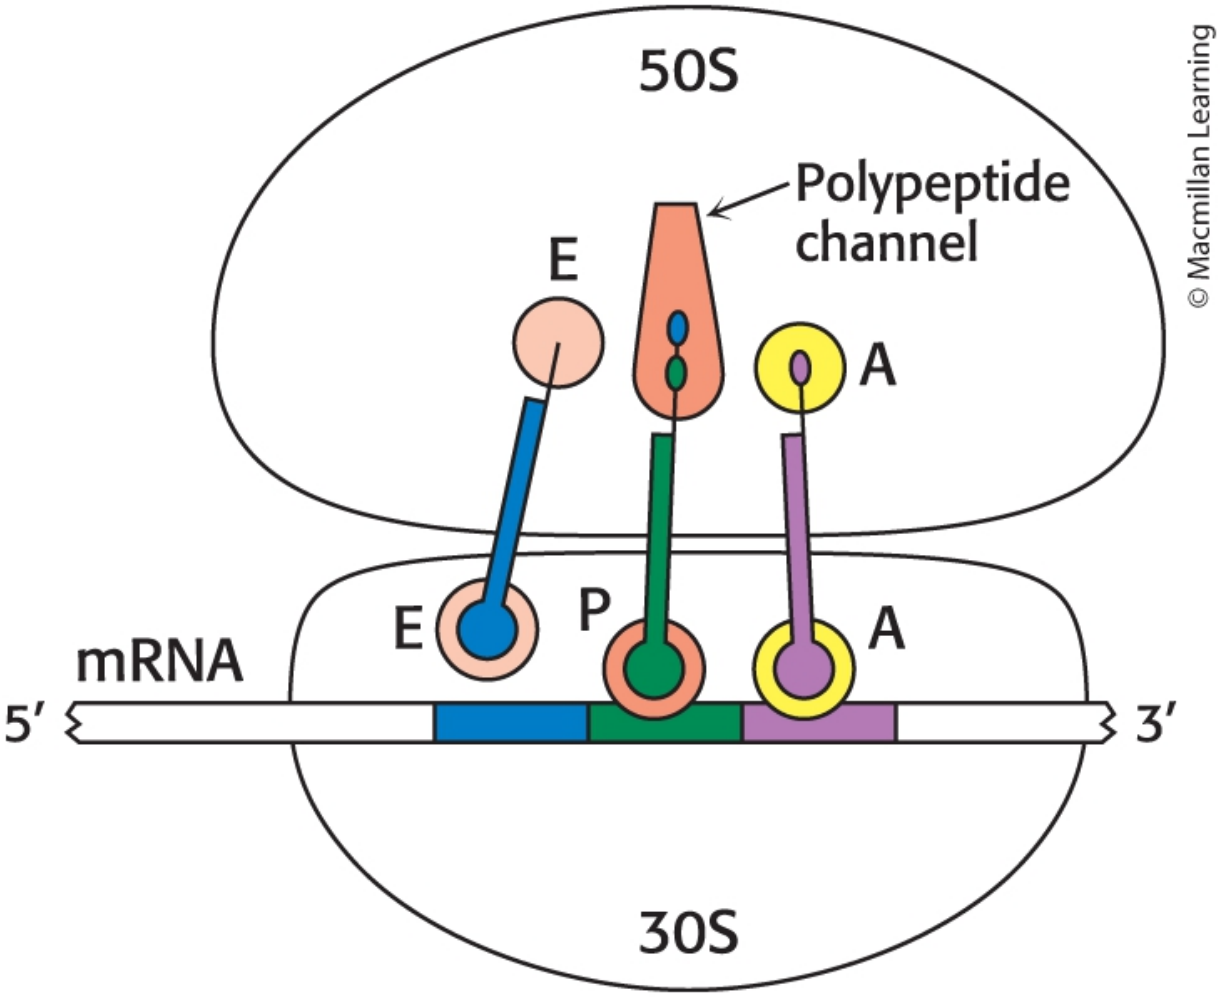
The figure has two parts.

Part A depicts the secondary structure of 16 S r R N A consisting of codon loops that emerge in different directions. The codon loops have 5 prime and 3 prime ends. The codon loops on the top left are black, the codon loops on the top and bottom right are blue, and the codon loops below the black loops at the bottom left position are red. The stem of the codon loops has dashes and dots. Dashes represent standard Watson–Crick base pairs and dots represent non-Watson–Crick base pairs.

Part B depicts the tertiary structure of 16 S r R N A which consists of three types of thread-like structures. Black thread-like structures are present on the top left, blue thread-like structures are present on the top right, and red thread-like structures are present below the black thread-like structures.

Return to FIGURE 30.15 Ribosomal R N A s form intramolecular base pairs

Extended description for FIGURE 30.16 The ribosome has three binding sites for transfer R N A s



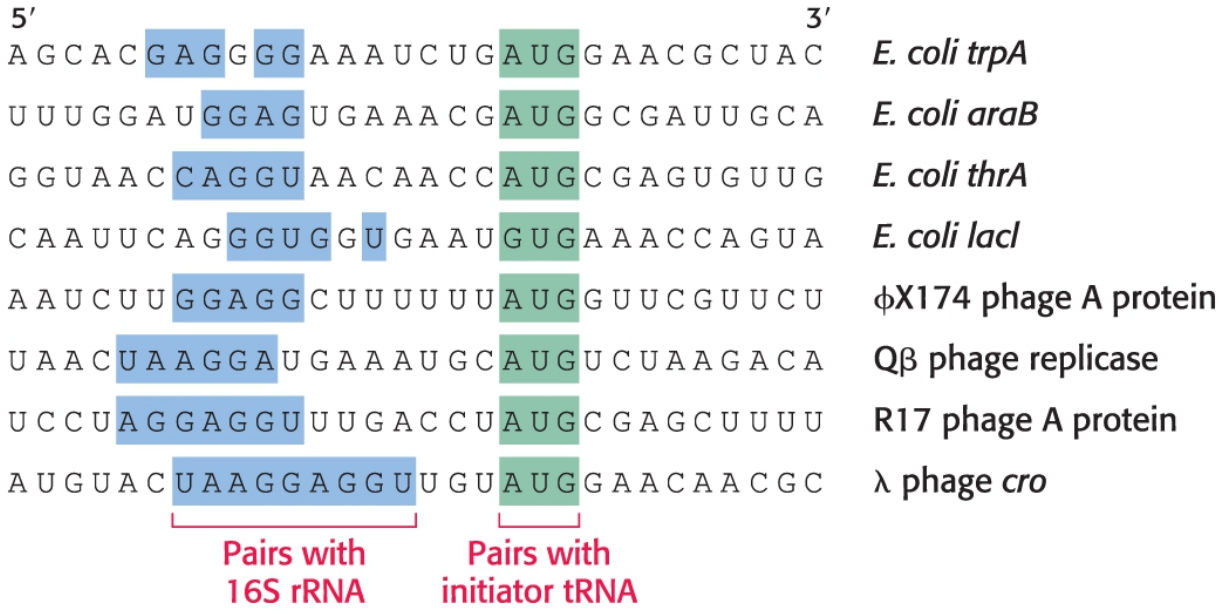
The figure has two parts.

Part A depicts a 70 S ribosome consisting of 30 S and 50 Ssubunits. The 30 S subunit at the top consists of yellow-colored thread-like structures. Pink-colored alpha helices and beta strands project from the upper end and lateral sides of the yellow-colored structures. Additionally, orange-colored thread-like structures also project from the upper end. The 50 Ssubunit at the bottom consists of green-colored thread-like structures. Blue-colored alpha helices and beta strands project from the upper, lower, and lateral sides of the green-colored structures. The three t R N A binding sites of the 70 S ribosome are called the E site, P site, and A site. The t R N A in these sites are depicted as blue, green, and purple double-helix structures that are in the form of an inverted L. The t R N A molecules are connected to the 30 S and 50 S subunits of the 70 S ribosome.

Part B depicts the t R N A molecules isolated from the E, P, and A sites. Each t R N A molecule consists of a ball-and-stick model in the anticodon loop. Each t R N A molecule in sites P and A is base-paired with m R N A. m R N A is depicted as a black continuous strand connected horizontally.

Return to FIGURE 30.16 The ribosome has three binding sites for transfer R N A s

Extended description for FIGURE 30.17 The key components of the translation machinery interact on an active ribosome



The figure has a horizontal m R N A consisting of 5 prime ends on the left and 3 prime ends on the right. A ribosome consisting of two oval-shaped subunits is shown. The smaller 30 S subunit is bound to the m R N A while the larger 50 S m R N A is at the top. The m R N A consists of three segments. The segments from left to right are blue, green, and purple, respectively. These represent the binding sites for t R N A molecules. The blue segment is labeled E site, the green

is labeled P site, and the purple is labeled A site. The 50 S subunit at the top consists of a polypeptide channel that connects the A and P sites from the back end of the ribosome. The t R N A molecules are depicted as stem-loops whose stems are in the 50 S subunit of the ribosome and the loops are in the 30 S subunit. Each t R N A molecule in sites P and A in the 30 S subunit is base-paired with m R N A. The t R N A molecule in site E remains free.

Return to FIGURE 30.17 The key components of the translation machinery interact on an active ribosome

Extended description for FIGURE 30.18 Initiator regions in m R N A determine where protein biosynthesis starts

The figure shows 8 sequences in 5 prime to 3 prime directions.

The first sequence labeled *E. coli t r p A* reads A G C A C G A G G G G A A A U C U G A U G G A A C G C U A C. G A G in the sixth, seventh, and eighth positions and G G in the tenth and eleventh positions are highlighted in blue. A U G in the nineteenth, twentieth, and twenty-first positions is highlighted in green.

The second sequence labeled *E. coli a r a B* reads U U U G G A U G G A G U G A A A C G A U G G C G A U U G C A. G G A G in the eighth, ninth, tenth, and eleventh positions are highlighted in blue. A U G in the nineteenth, twentieth, and twenty-first positions is highlighted in green.

The third sequence labeled *E. coli t h r A* reads G G U A A C C A G G U A A C A A C C A U G C G A G U G U U G. C A G G U in the seventh, eighth, ninth, tenth, and eleventh positions in highlighted in blue. A U G in the nineteenth, twentieth, and twenty-first positions is highlighted in green.

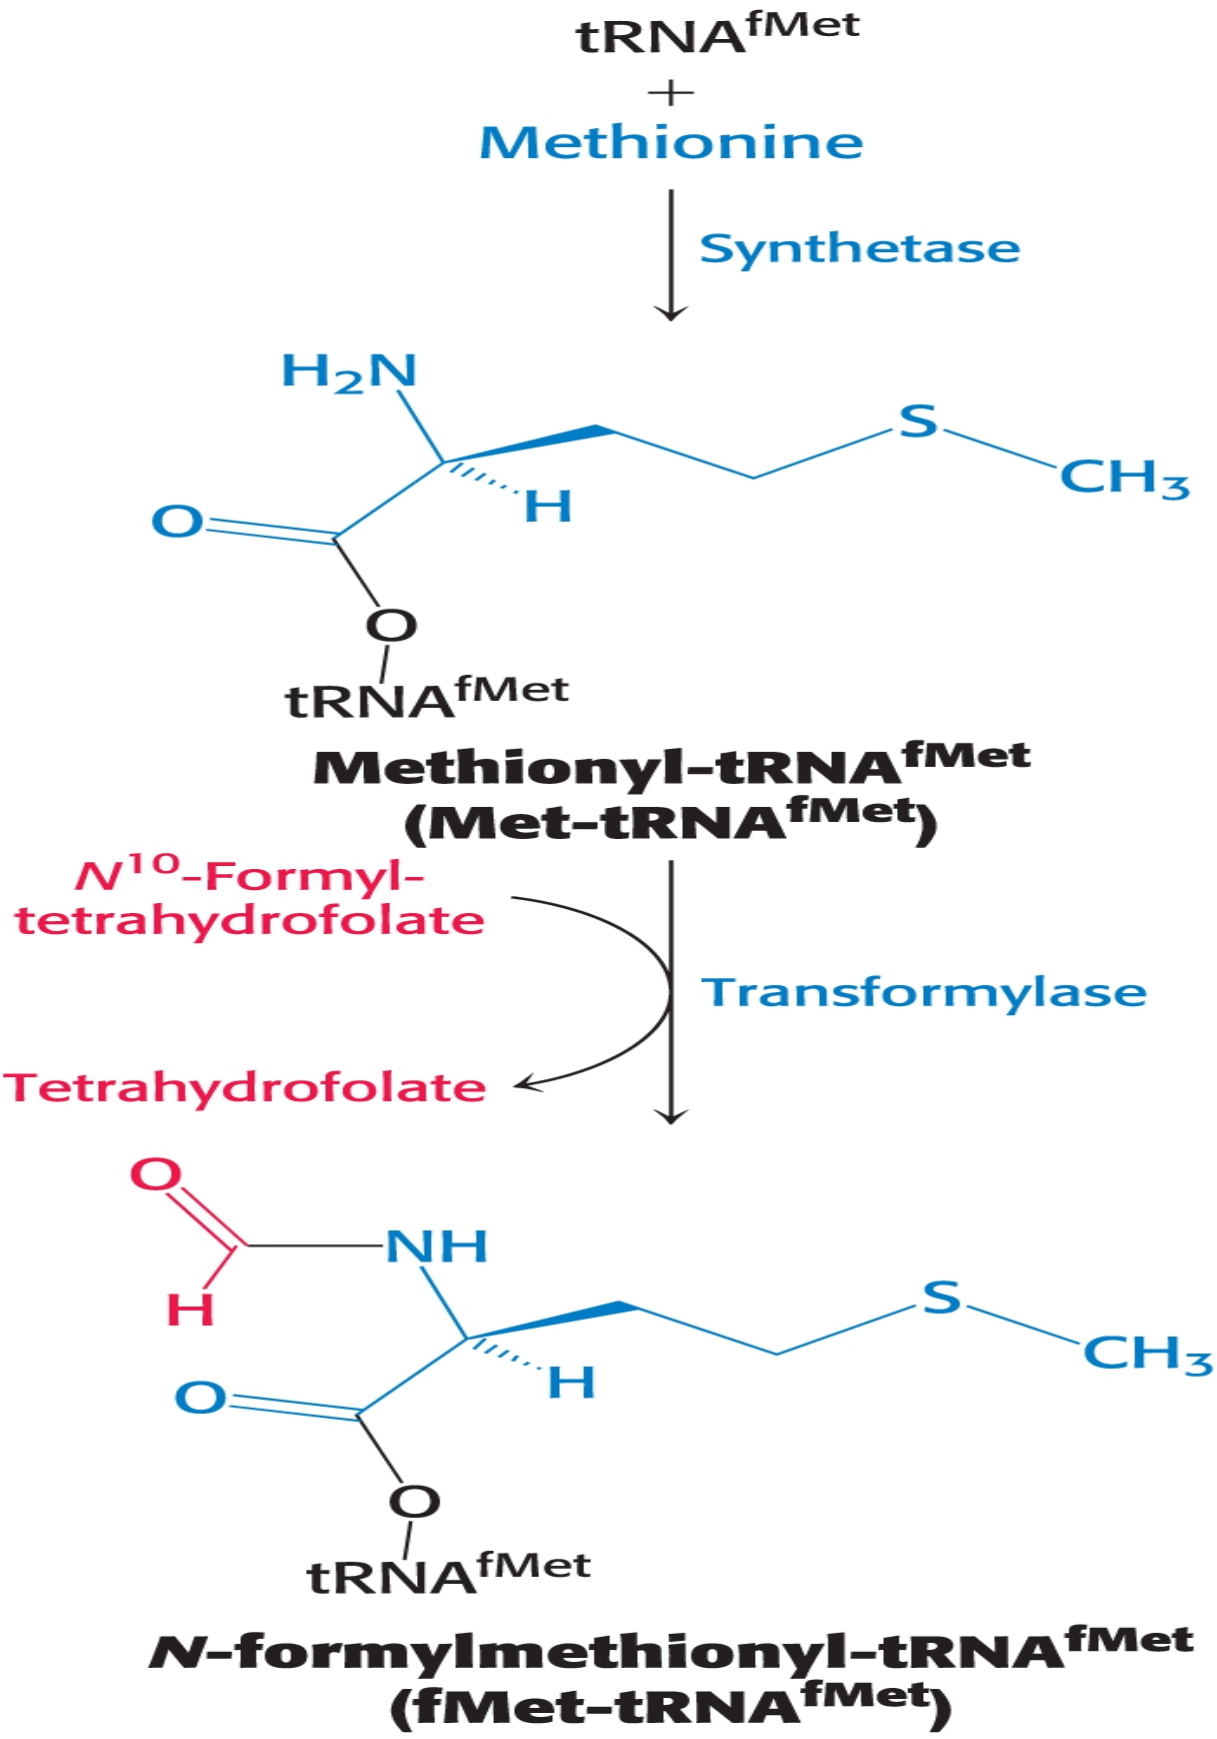
The fourth sequence labeled *E. coli l a d* l reads C A A U U C A G G G U G G U G A A U G U G A A A C C A G U A. G G U G in the ninth, tenth, eleventh, and twelfth positions and U in the fourteenth positions is highlighted in blue. G U G in the nineteenth, twentieth, and twenty-first positions are highlighted in green.

The fifth sequence labeled phi X 174 phage A protein reads A A U C U U G G A G G C U U U U U U A U G G U U C G U U C U. G G A G G in the seventh, eighth, ninth, tenth, and eleventh positions in highlighted in blue. A U G in the nineteenth, twentieth, and twenty-first positions is highlighted in green.

The sixth sequence labeled Q beta phage replicase reads U A A C U A A G G A U G A A A U G C A U G U C U A A G A C A. U A A G G A in the fifth, sixth, seventh, eighth, ninth, and tenth positions is highlighted in blue. A U G in the nineteenth, twentieth, and twenty-first positions is highlighted in green.

The seventh sequence labeled R 17 phage A protein reads U C C U A G G A G G U U U G A C C U A U G C G A G C U U U U. A G G A G G U in the fifth, sixth, seventh, eighth, ninth, tenth, and eleventh positions is highlighted in blue. A U G in the nineteenth, twentieth, and twenty-first positions is highlighted in green.

The eighth sequence labeled lambda phage *cro* reads A U G U A C U A A G G A G G U U G U A U G G A A C A A C G C. U A A G G A G G U in the seventh, eighth, ninth, tenth, eleventh, twelfth, thirteenth,



fourteenth, and fifteenth positions is highlighted in blue. A U G in the nineteenth, twentieth, and twenty-first positions is highlighted in green.

The sequences highlighted in blue are labeled pairs with 16 S r R N A. The sequences highlighted in green are labeled pairs with initiator t R N A.

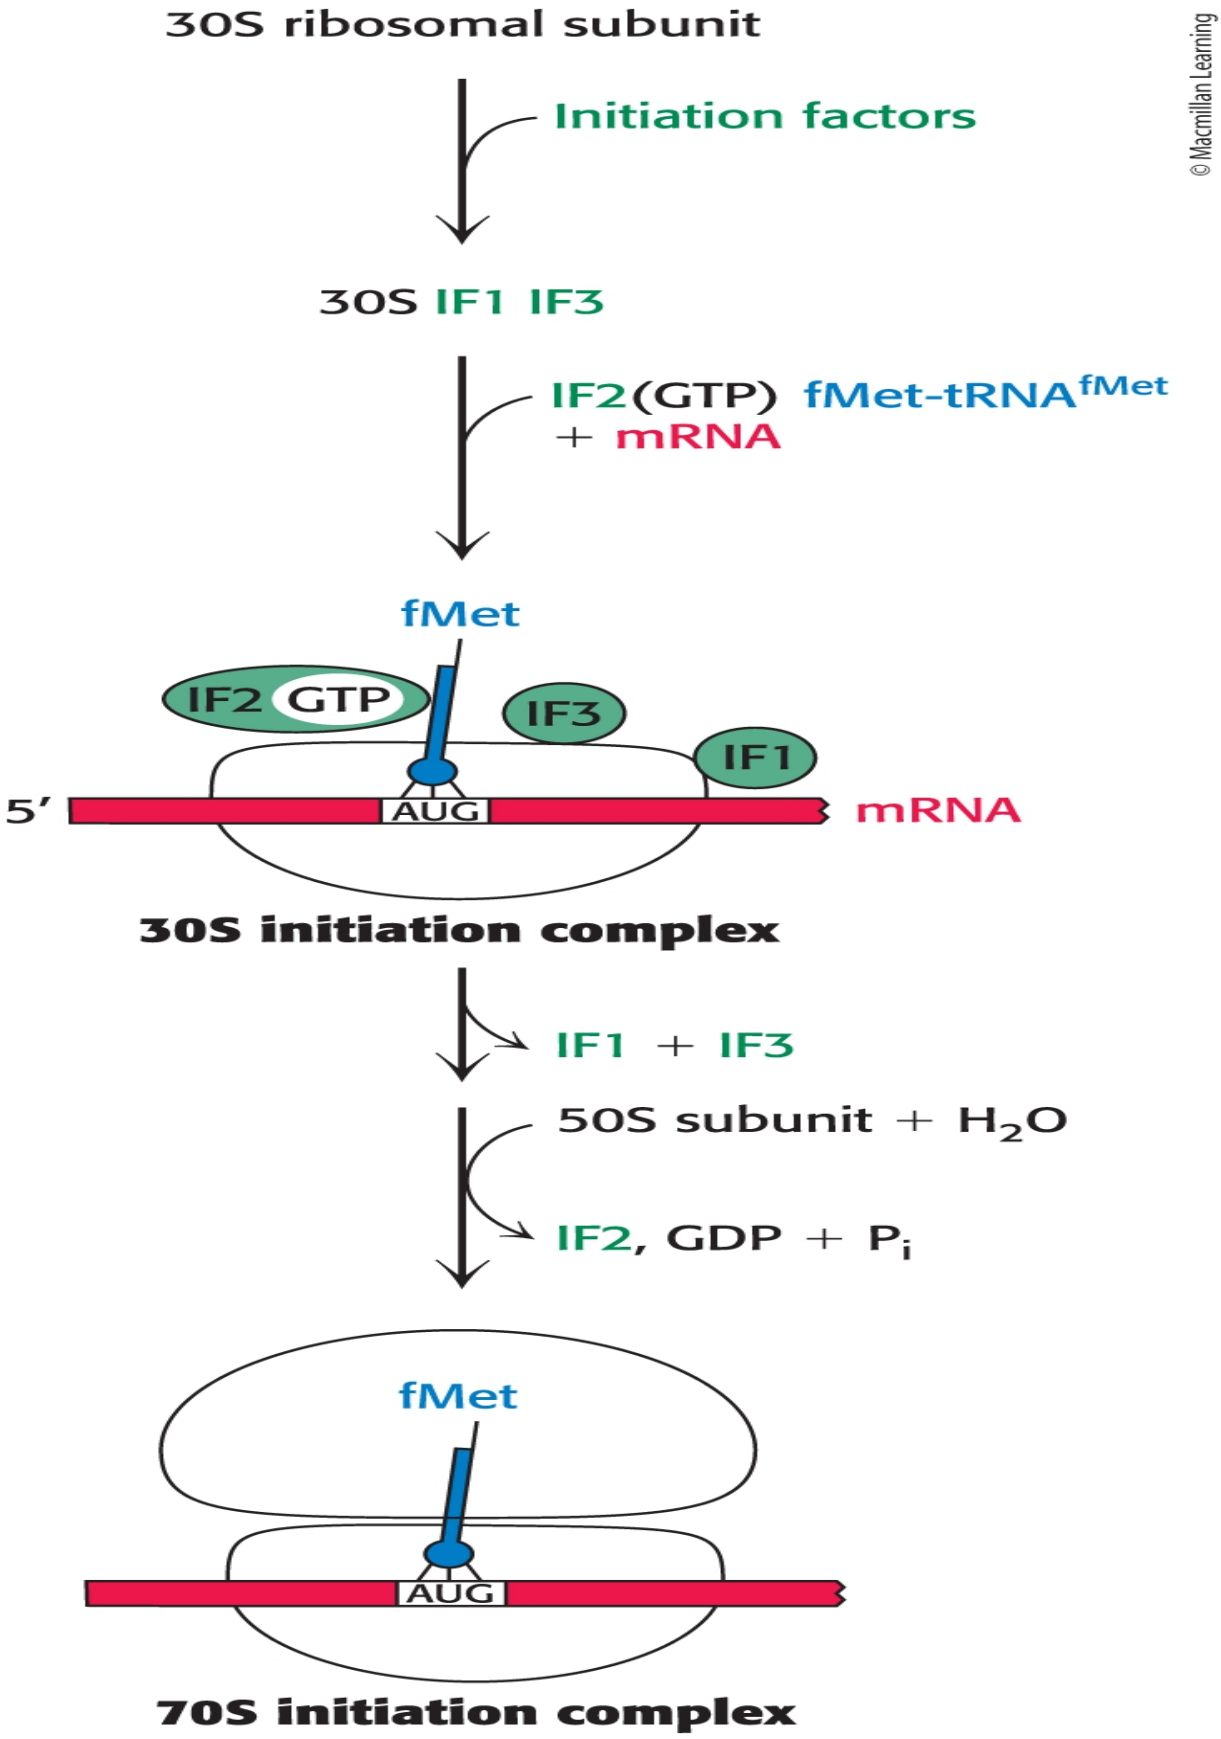
In the first irreversible step, t R N A superscript f Met reacts with methionine in the presence of synthetase to give rise to methionyl t R N A superscript f Met (Met t R N A superscript f Met).



The structure of methionyl t R N A superscript f Met (Met t R N A superscript f Met) is as follows: A 1 S, 1 C H 3, and 2 C heteronuclear alkane chain is depicted as a line structure using 3 zigzag lines. S and C H 3 occupy the third and fourth positions, respectively. C 1 is wedge bonded to C 1 of another 1 N H 2, 1 O, and 2 C heteronuclear alkane chain depicted vertically as a line structure using 3 zigzag lines. N H 2 occupies the first position. O occupies the fourth position. C 1 is dash bonded to H on the lower right. C 2 is double bonded to O on the left. O is single bonded to t R N A superscript f Met below. The O atom and the t R N A is black and the rest of the structure is highlighted in blue. In the second irreversible step, Met (Met t R N A superscript f Met) is transformed to N-formylmethionyl t R N A superscript f Met (f Met t R N A superscript f Met). It is coupled with the entry of N superscript 10 Formyl-tetrahydrofolate and the release of tetrahydrofolate in the presence of transformylase.

The structure of N-formylmethionyl t R N A superscript f Met (f Met t R N A superscript f Met) is as follows: 1 S, 1 C H 3, and 2 C heteronuclear alkane chain is depicted as a line structure using 3 zigzag lines. S and C H 3 occupy the third and fourth positions respectively. C 1 is wedge bonded to C 1 of another 1 N H, 1 O, and 2 C heteronuclear alkane chain depicted vertically as a line structure using 3 zigzag lines. N H occupies the first position. N H is single bonded to a central C on the left. The central C atom is double bonded to O on the upper left and H on the lower left. O occupies the fourth position in the alkane chain. C 1 is dash bonded to H on the lower right. C 2 is double bonded to O on the left. O is single bonded to t R N A superscript f Met below. The central C atom and the structures attached to it on the left are highlighted in red.

Return to FIGURE 30.19 Methionyl-t R N A is formylated to create a modified amino acid

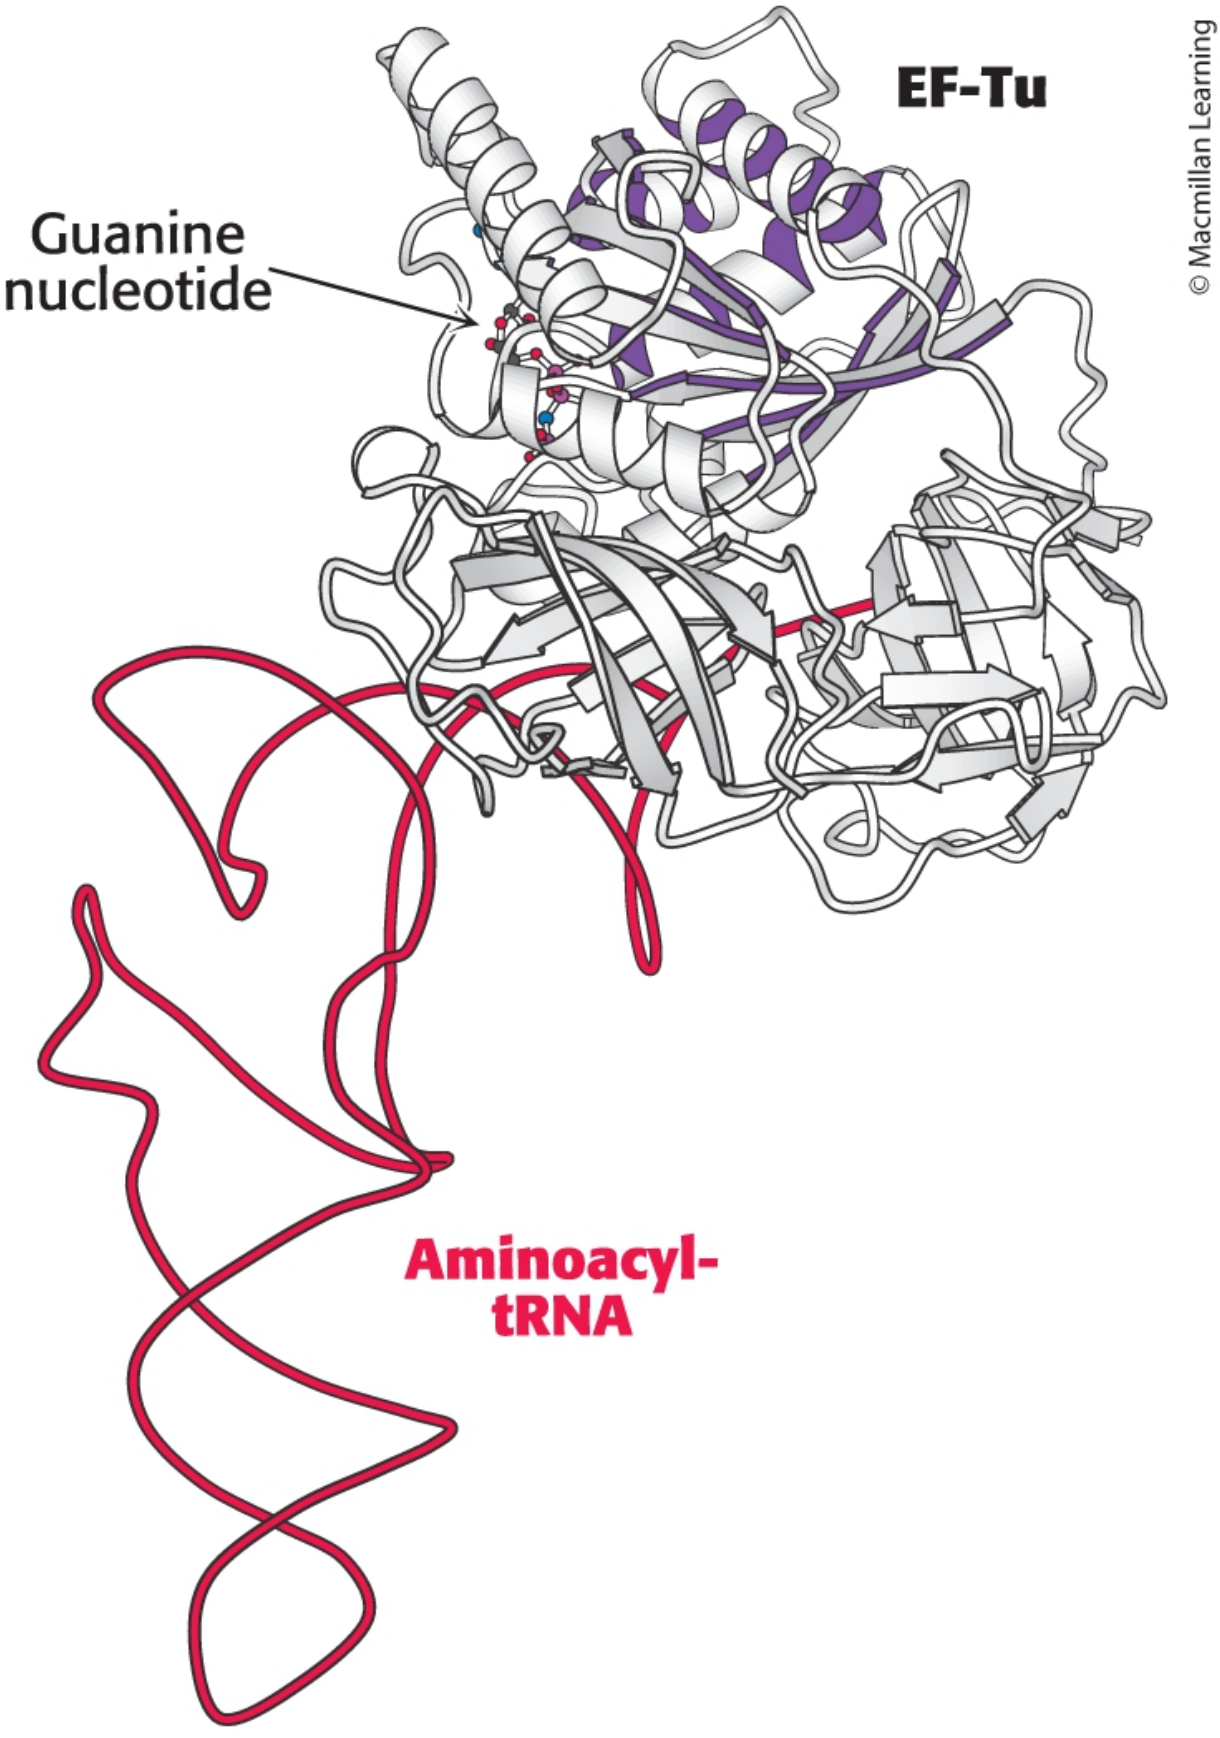
Extended description for FIGURE 30.20 Prokaryotic initiation factors aid the assembly of initiation

complexes

© Macmillan Learning

In the first irreversible step, the 30 S ribosomal subunit is transformed to 30 S I F 1 I F 3 coupled with the entry of initiation factors. Initiation factors are highlighted in green. In the second irreversible step, 30 S I F 1 I F 3 is transformed into a 30 S initiation complex coupled with the entry of I F 2 (G T P) f met t R N A superscript f Met and m R N A. I F 1 I F 3 are highighted in green m R N A is highlighted in red. f met t R N A superscript f Met is highlighted in blue.

The 30 S initiation complex shows the 30 S ribosomal subunit bound to m R N A. The m R N A is in 5 prime to 3 prime direction. The m R N A has a codon at the center that reads A U G. The f Met t R N A is depicted as a stem-loop with the loop embedded in the 30 S ribosome and the stem lies outside. The loop of the t R N A is base paired with the A U G codon in the m R N A. The ribosome is attached to three spheres at the top labeled I F 2 (G T P), I F 3, and I F 1. I F 1 bind near the A site and prevents any t R N A from binding with the m R N A.



In the third irreversible step, the 50 S t R N A interacts with the 30 S t R N A to form the 70 S initiation complex. It is coupled with the release of I F 1 and I F 3. It is also coupled with the entry of 50 S subunit and H 2 O and release of I F 2, G D P, and P subscript i.

The 50 S ribosomal subunit binds with the 30 S subunit from the top. The 50 S subunit is larger than the 30 S subunit. The stem of the f Met t R N A lies in the 50 S subunit while its loop is base paired with the A U G codon in the m R N A.

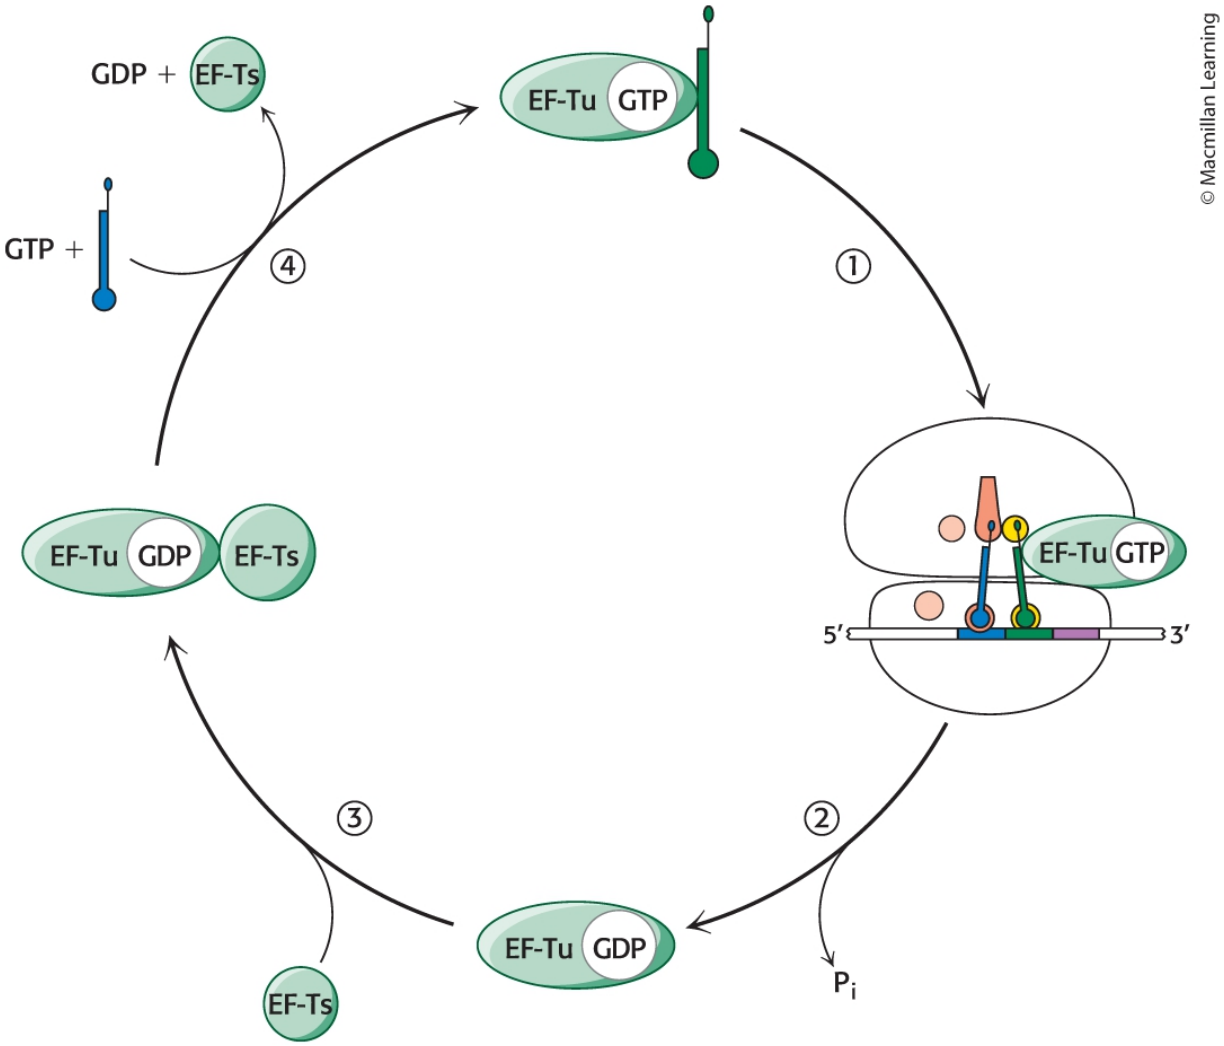
Extended description for FIGURE 30.21 The structure of elongation factor T u (E F-T u) and an aminoacyl-t R N A

resembles those of other G proteins



© Macmillan Learning

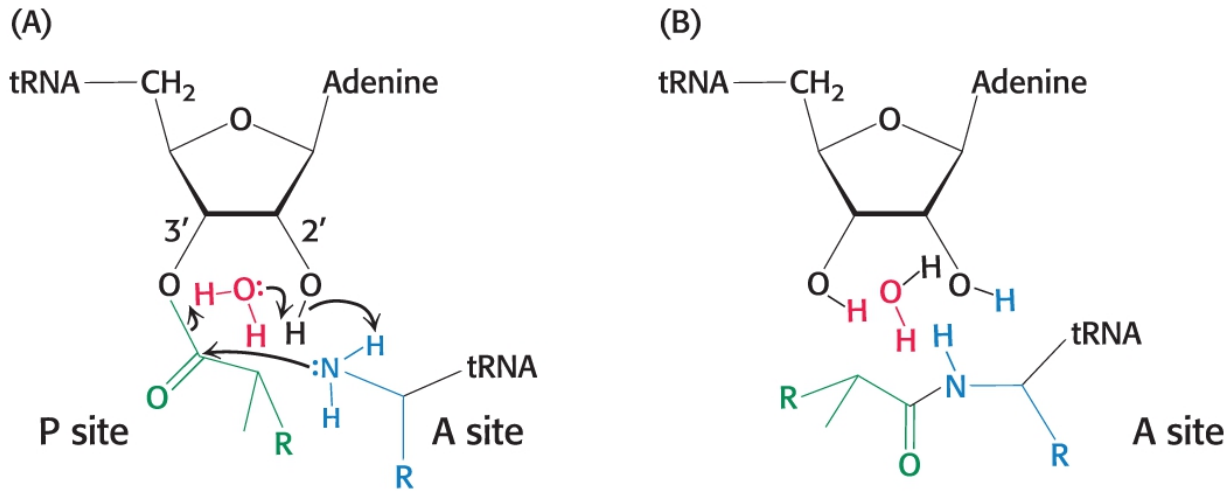
A red-colored double-stranded inverted L-shaped t R N A is present on the bottom left. It consists of an acceptor on the upper right and an anticodon loop on the lower end. The acceptor on the upper right is bound to E F T u consisting of white-colored alpha helices and beta strands interconnected by thread-like structures. The amino-terminal end of E F T u on the upper end highlighted in purple represents the P loop N T Pase domain. The E F T u consists of a ball-and-stick model on the top left labeled guanine nucleotide.

Return to FIGURE 30.21 The structure of elongation factor T u (E F-T u) and an aminoacyl-t R N A resembles those of other G proteins

Extended description for FIGURE 30.22 The G T P ase E F T u binds aminoacyl t R N A only in its G T P form

The cycle has four steps. In the first step, an oval-shaped E F T u along with the G T P binds with a green t R N A that is depicted by a stem loop with the stem at the top and a loop at the bottom. The E F T u G T P binds aminoacyl t R N A and delivers it to the A site of the ribosome.

The ribosome consists of two oval-shaped subunits. The smaller 30 S subunit is bound to the m R N A while the larger 50 S m R N A is at the top. The m R N A consists of three segments. The segments from left to right are blue, green, and purple, respectively. These represent the binding sites for t R N A molecules. The blue segment is labeled E site, green is labeled P site, and purple is labeled A site. The 50 S subunit at the top consists of a polypeptide channel that connects the A and P sites from the back end of the ribosome. The t R N A molecules are depicted as stem loops whose stems are in the 50 S subunit of the ribosome and the loops are in the 30 S subunit. Each t R N A molecule in sites E and P in the 30 S subunit are base-paired with m R N A. The t R N A molecule in site A remains free. The sphere E F T u G T P binds to the 50 S ribosome.



In the second step, the G T P from the E F T u G T P is converted to G D P coupled with the release of P subscript i.

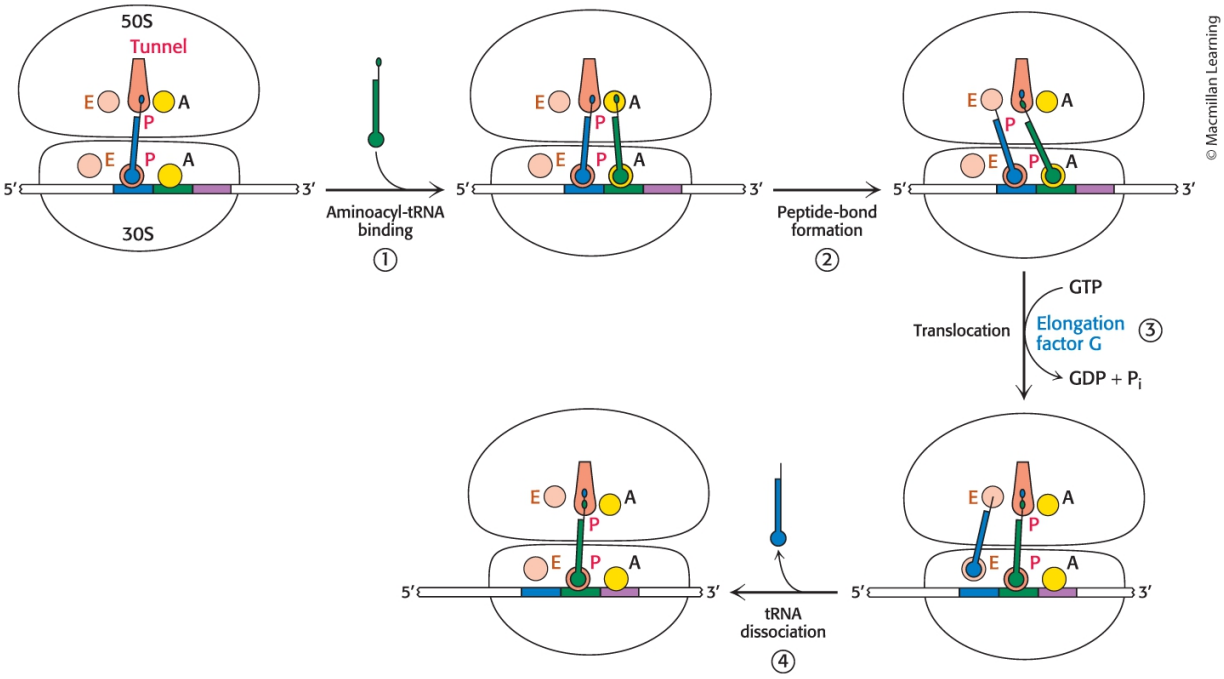
In the third step, the oval E F T u G D P is attached to a sphere E F T s. It is coupled with the entry of E F T s.

In the fourth step, the oval and sphere are transformed to E F T u G T P with a t R N A attached to it. It is coupled with the entry of G T P and a blue t R N A and the release of G D P and E F T s.

Return to FIGURE 30.22 The G T P ase E F T u binds aminoacyl t R N A only in its G T P form

Extended description for FIGURE 30.23 Peptide-bond formation links amino acids

Part A shows a 5-membered heterocyclic pentagonal ring in a vertical orientation consisting of 1 O and 4 C atoms. O occupies the first position which is the topmost vertex. C 1 is single bonded to adenine. C 2 and C 3 are each single bonded to O and they are labeled 2 prime and 3 prime, respectively. C 4 is single bonded to C H 2. C H 2 is further single bonded to t R N A on the left. O bound to C 2 is single bonded to H. O bound to C 3 is single bonded to C 1 of a 2 C alkane chain depicted as a line structure using a line. C 1 is double bonded to O on the lower left. C 2 is single bonded to C H 3 on the lower left and R on the lower right. The alkane chain is labeled P site. An aminoacyl t R N A with an A site is depicted on the right. The A site consists of a central C atom that is single bonded to t R N A on the upper right, single bonded to R below, and single bonded to N on the upper left. N carries a pair of electrons. It is single bonded to H on the upper right and H below. The amino group of the A site attacks the carbonyl group of the P site. A water molecule is added in the next step. The water molecule consists of an O atom with a pair of electrons. The O atom is attached to two H



atoms. The water molecule attacks the O atom attached to C 3 and C 4 of the pentagonal ring simultaneously. The O atom attached to C 2 attacks the A site.

Part B shows a 5-membered heterocyclic pentagonal ring in a vertical orientation consisting of 1 O and 4 C atoms. O occupies the first position which is the topmost vertex. C 1 is single bonded to adenine. C 2 and C 3 are each single bonded to O. C 4 is single bonded to C H 2. C H 2 is single bonded to t R N A on the left. O bound to C 2 and C 3 are each single bonded to H. The transition results in the formation of the peptide bond and the release of deacylated t R N A. The water molecule is free and consists of an O atom bound to 2 H atoms.

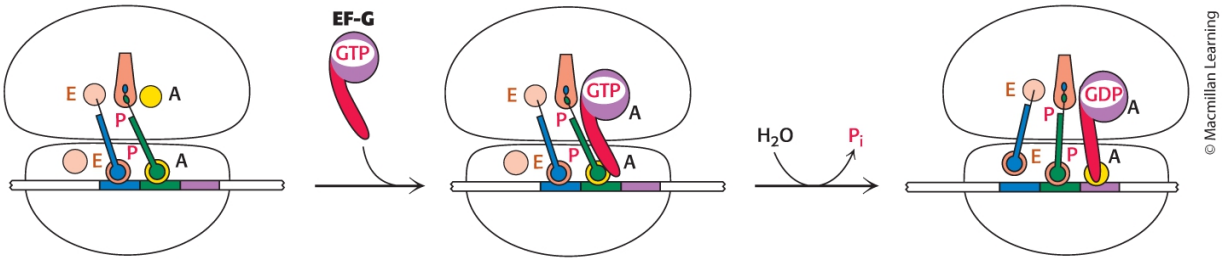
The deacylated t R N A that is released consists of a 1 N and 3 C heteronuclear alkane chain depicted as a line structure using 3 zigzag lines. N occupies the third position. C 1 is single bonded to R on the left and C H 3 on the lower left. C 2 is double bonded to O below. N is single bonded to H. C 3 is single bonded to t R N A on the upper right and R on the lower right.

Return to FIGURE 30.23 Peptide-bond formation links amino acids

Extended description for FIGURE 30.24 Protein biosynthesis is a cyclical process

The cycle has four steps. The cycle begins with peptidyl t R N A in the P site. The figure has a horizontal m R N A consisting of 5 prime end on the left and 3 prime end on the right. A ribosome consisting of two oval-shaped subunits is shown. The smaller 30 S subunit is bound to the m R N A while the larger 50 S m R N A is at the top. The m R N A consists of three segments. The segments from left to right are blue, green, and purple, respectively. These represent the binding sites for t R N A molecules. The blue segment is labeled E site, the green is labeled P site, and the purple is labeled A site. The 50 S subunit at the top consists of a polypeptide tunnel. The t R N A molecule is depicted as a stem-loop whose stem is in the 50 S subunit of the ribosome and the loop is in the 30 S subunit. The t R N A molecule in site P in the 30 S subunit is base-paired with m R N A. There are no t R N A molecules in sites E and A.

In the first step, an aminoacyl t R N A molecule in site A in the 30 S subunit is base-paired with m R N A.



In the second step, peptide-bond formation takes place. When both the sites are occupied a peptide bond is formed in the tunnel in the 50 S subunit where the stem of the t R N A is attached.

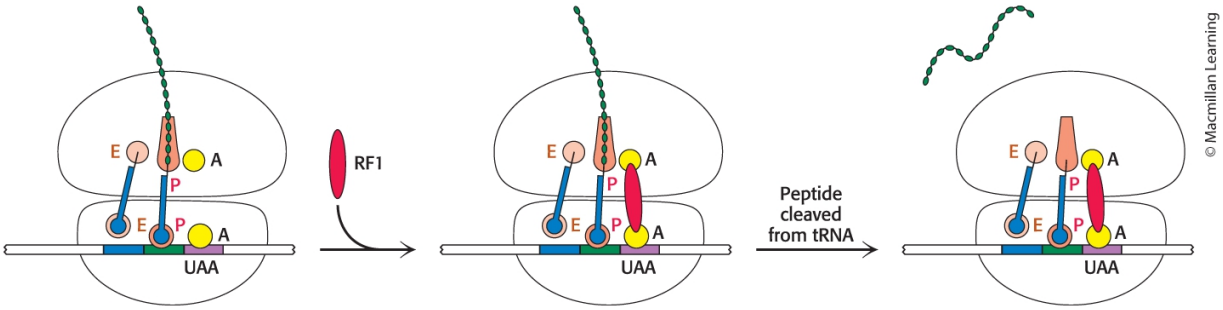
In the third step, the translocation of the t R N A s and the m R N A occurs through the action of elongation factor G. This is coupled with the entry of G T P and release of G D P and P subscript i. In this step, the deacylated t R N A moves to the E site.

In the fourth step t R N A dissociation occurs due to the release of the t R N A from the E site.

Return to FIGURE 30.24 Protein biosynthesis is a cyclical process

Extended description for FIGURE 30.25 Translocation repositions t R N A s and m R N A with respect to the ribosome

The figure has three steps.



In the first step, a horizontal m R N A consists of 5 prime end on the left and 3 prime end on the right. A ribosome consisting of two oval-shaped subunits is shown. The smaller 30 S subunit is bound to the m R N A while the larger 50 S m R N A is at the top. The m R N A consists of three segments. The segments from left to right are blue, green, and purple, respectively. These represent the binding sites for t R N A molecules. The blue segment is labeled E site, the green is labeled P site, and the purple is labeled A site. The 50 S subunit at the top consists of a polypeptide channel that connects the A and P sites from the back end of the ribosome. The t R N A molecules are depicted as stem-loops whose stems are in the 50 S subunit of the ribosome and the loops are in the 30 S subunit. Each t R N A molecule in sites E and P in the 30 S subunit are base-paired with m R N A. There is no t R N A in site A.

In the second step, the E F G in the G T P form binds to the A site of the 50 S subunit.

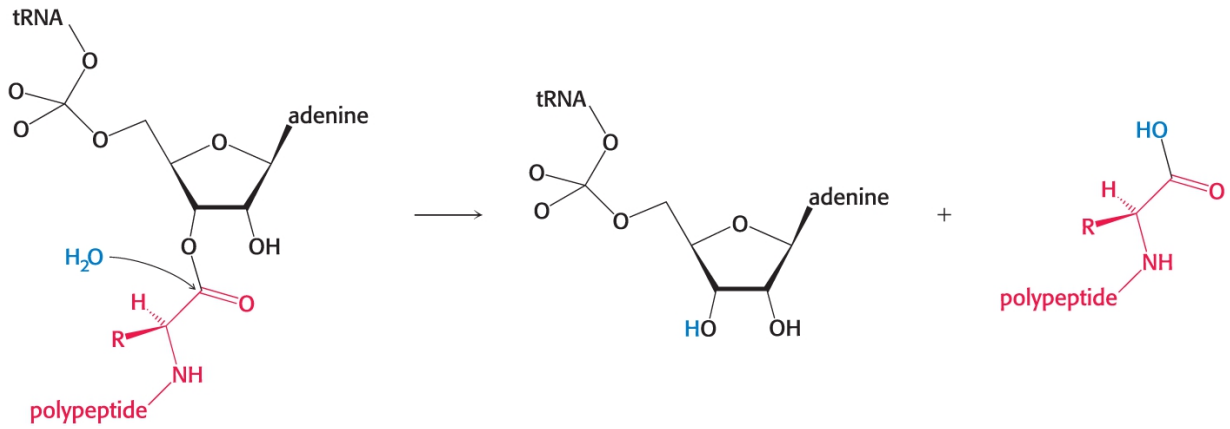
In the third step, the G T P bound to the 50 S subunit is converted to G D P, and the E F G is attached to the A site of the m R N A in the 30 S subunit. This is coupled with the entry of H 2 O and the release of P subscript i.

Return to FIGURE 30.25 Translocation repositions t R N A s and m R N A with respect to the ribosome

Extended description for FIGURE 30.27 Release factors facilitate the termination of protein biosynthesis

The figure has three steps.

In the first step, a horizontal m R N A consists of 5 prime end on the left and 3 prime end on the right. A ribosome consisting of two oval-shaped subunits is shown. The smaller 30 S subunit is bound to the m R N A while the larger 50 S m R N A is at the top. The m R N A consists of three segments. The segments from left to right are blue, green, and purple, respectively. These represent the binding sites for t R N A molecules. The blue segment is labeled E site, the green is labeled P site, and the purple is labeled A site. The A site has a codon U A A. The 50 S subunit at the top consists of a polypeptide channel that connects the A and P sites from the back end of the ribosome. A polypeptide chain emerges from the polypeptide channel that resembles a beaded string. The t R N A molecules are depicted as stem-loops whose stems are in the 50 S subunit of the ribosome and the loops are in the 30 S subunit. The t R N A in the E site in the 30 S subunit is free while the t R N A in the P site is base-paired with m R N A. There is no t R N A in site A.



In the second step, the entry of R F 1 causes the R F 1 to bind to the A site of the 50 S and 30 S subunits of the ribosome. The R F 1

recognizes the stop codon in the A site.

In the third step, the R F 1 stimulates the release of the peptide from the peptide channel. The peptide channel is depicted as a free-beaded structure at the top.

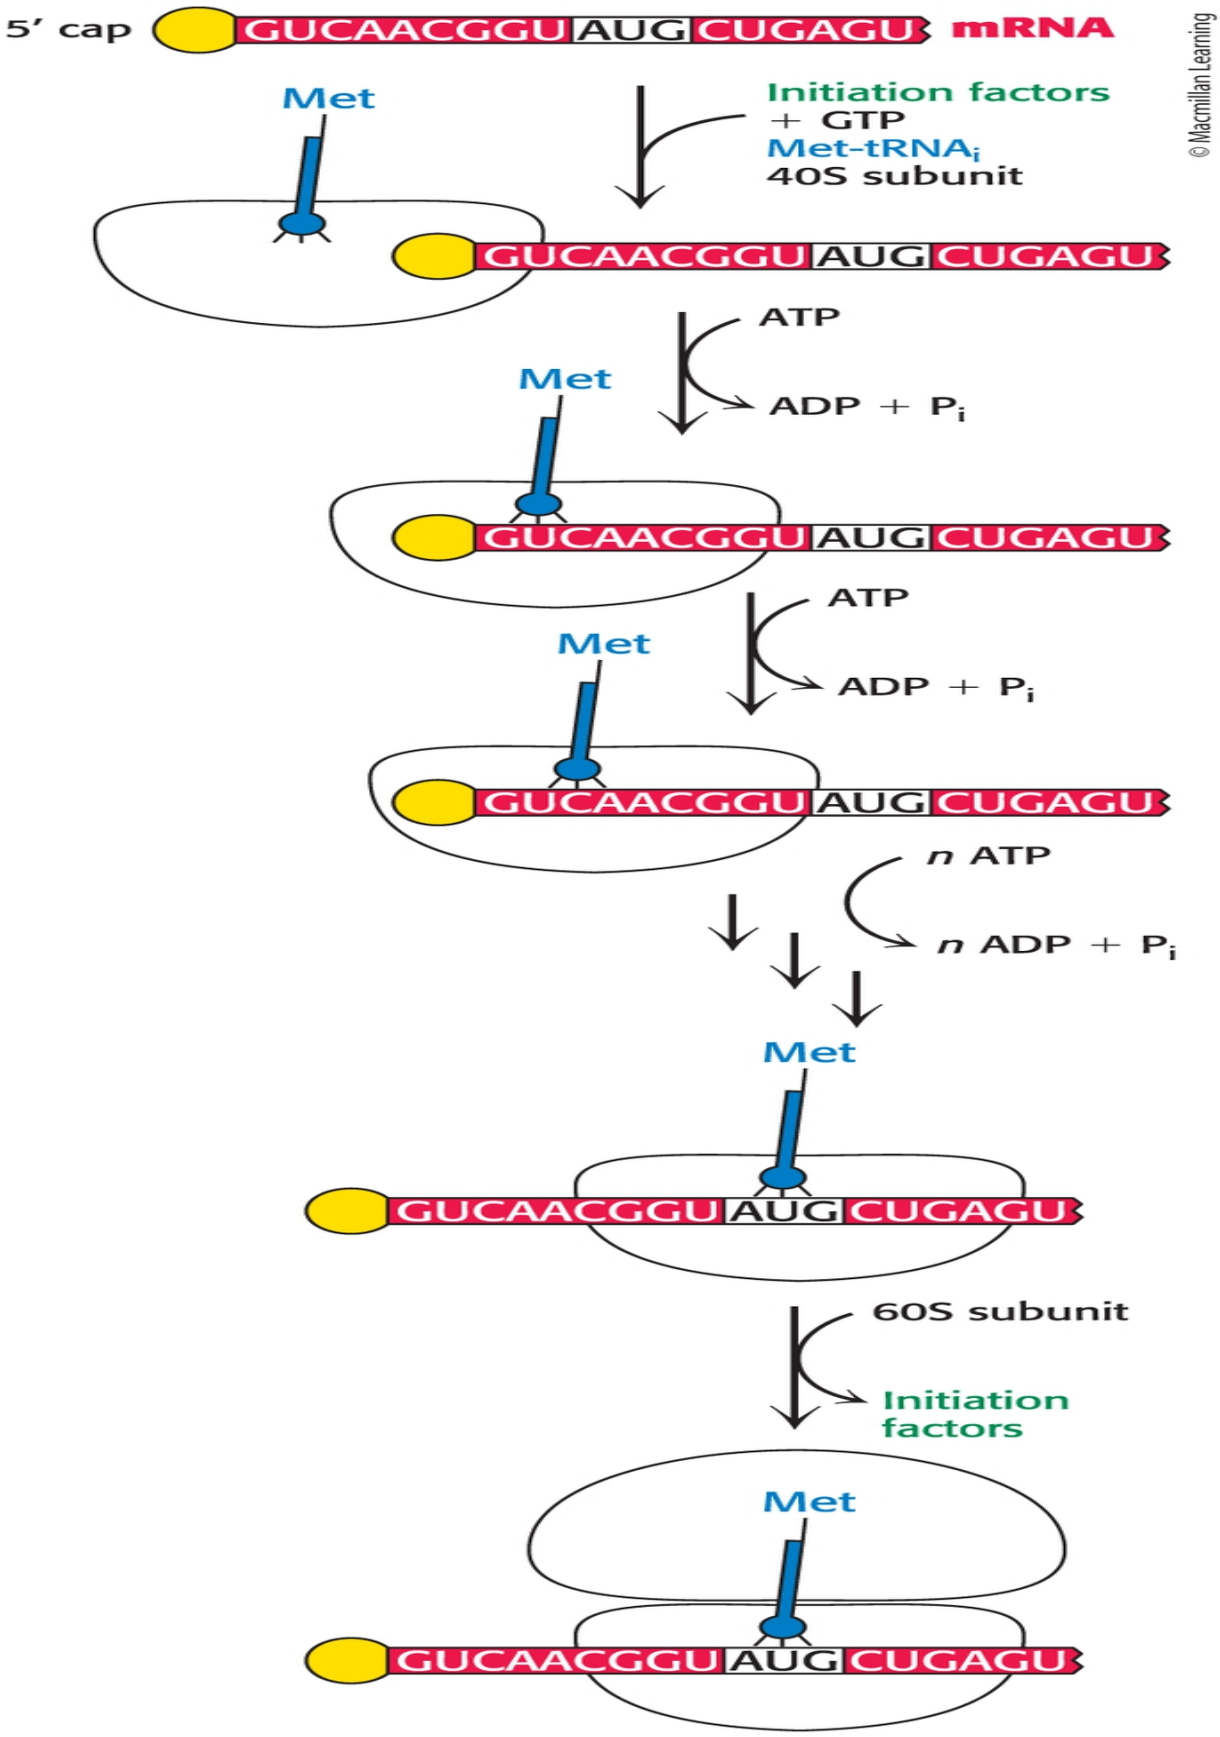
Return to FIGURE 30.27 Release factors facilitate the termination of protein biosynthesis

Extended description for Release of complete protein from t R N A

The reactant undergoes cleavage to form two products.

The structure of the reactant is as follows: A 5-membered heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. O occupies the first position which is the topmost vertex. C 1 is wedge bonded to adenine. C 2 is single bonded to O H. C 3 is single bonded to O of a 1 O, 1 N, and 2 C heteronuclear alkane chain depicted as a line structure vertically using 3 zigzag lines. O occupies the first position. N bound to H occupies the fourth position. C 1 is double bonded to O on the lower right. C 2 is dash bonded to H on the upper left and wedge bonded to R on the lower left. N H is single bonded to a polypeptide on the lower left. A H 2 O molecule attacks C 1 of the alkane chain. The structures from C 1 upto the polypeptide are highlighted in red. C 4 of the pentagonal ring is single bonded to a central C atom on the upper left. The central C atom is single bonded to O on the lower left. This O is further single bonded to a second C atom on the upper left. The second C atom is single bonded to a second O on the lower left, third

O on the upper left, and fourth O on the upper right. The fourth O atom is single bonded to t R N A on the upper left.



The structure of the first product is as follows: A 5-membered heterocyclic pentagonal ring in a horizontal orientation consists of 1 O and 4 C atoms. O occupies the first position which is the topmost vertex. C 1 is wedge bonded to adenine. C 2 is single bonded to O H. C 3 is single bonded to O H. H from the O H is highlighted in blue. C 4 is single bonded to a central C atom on the upper left. The central C atom is single bonded to O on the lower left. This O is further single bonded to a second C atom on the upper left. The second C atom is single bonded to a second O on the lower left, third O on the upper left, and fourth O on the upper right. The fourth O atom is single bonded to t R N A on the upper left.

The structure of the second product is as follows: A 1 O H, 1 N, and 2 C heteronuclear alkane chain is depicted as a line structure vertically using 3 zigzag lines. O H occupies the first position. N H occupies the fourth position. C 1 is double bonded to O on the lower right. C 2 is dash bonded to H on the upper left and wedge bonded to R on the lower left. N H is single bonded to a polypeptide on the lower left. O H in the first position is highlighted in blue and the rest of the structures are highlighted in red.

Return to Release of complete protein from t R N A

Extended description for FIGURE 30.28 Translation initiation differs in eukaryotes as compared with

prokaryotes

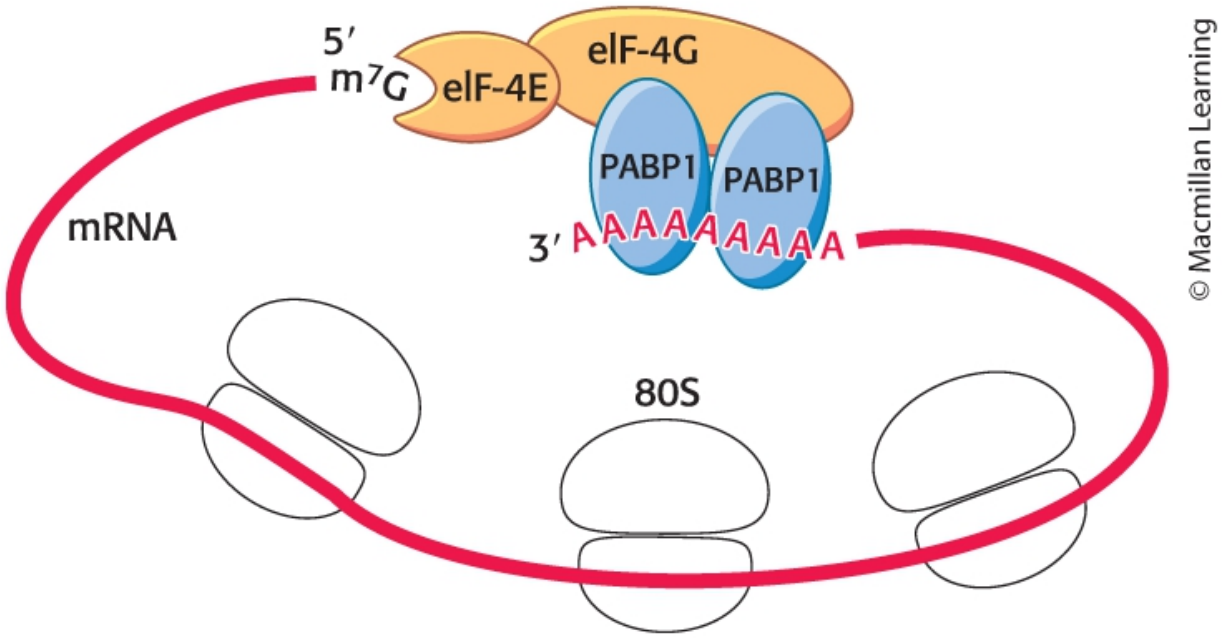
© Macmillan Learning

The figure has five steps. In all steps, the codon A U G is highlighted.

In the first step, the m R N A strand is depicted as a horizontal bar with a yellow sphere on the left which has the following sequence G U C A A C G G U A U G C U G A G U. A 40 S ribosomal subunit binds with the m R N A. A downward arrow depicts the entry of initiation factors plus G T P, Met t R N A, and 40 S subunit.

In the first step, a 40 S ribosomal subunit with a met t R N A binds to the left side of the m R N A such that the ribosome does not fully overlap with the m R N A. The Met t R N A is depicted as a stem-loop with the stem facing up and the loop embedded in the subunit.

In the second step, the ribosome completely overlaps with the m R N A. This is coupled with the entry of A T P and release of A D P and P subscript i. The Met t R N A is base paired with G U C of the m R N A.



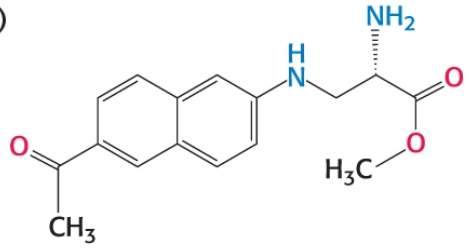
In the third step, the ribosome moves slightly to the right. This is coupled with the entry of A T P and release of A D P and P subscript i. The Met t R N A base pairing slightly shifts to the right. Now it is base paired with U C A.

In the fourth step, the ribosome moves to the right. This is coupled with the entry of n A T P and release of n A D P and P subscript i. This indicates that the shift is continuous. The Met t R N A is now base paired with the codon A U G in the m R N A.

In the fifth step, the 60 S ribosome binds with the 40 S subunit at the top. This is coupled with the entry of 60 S ribosome and the release of initiation factors. The Met t R N A remains attached to the A U G codon in the m R N A.

Return to FIGURE 30.28 Translation initiation differs in eukaryotes as compared with prokaryotes

Extended description for FIGURE 30.29 Protein interactions circularize eukaryotic m R N A



The figure shows a single-stranded m R N A that forms a circular loop such that the 5 prime and 3 prime ends of the loop are at the top. An oval structure with a groove on the left is labeled e l F 4 E. The groove on the left side of e l F 4 E is labeled m 7 G. This e l F 4 E binds with the 5 prime end of the m R N A. Another oval labeled e l F 4 G is attached to the right side of e l F 4 E. Two oval-shaped structures attached to one another are labeled P A B P 1. P A B P 1 overlap with e l F 4 G. The 3 prime end of the m R N A with sequence A A A A A A A A A overlap the P A B P 1. The lower end of the loop of m R N A consists of three ribosomal subunits. The smaller subunits are bound to the m R N A while the larger subunits are at the top. One of the larger subunits is labeled 80 S.

Extended description for FIGURE 30.30 Unnatural amino acids can be incorporated into proteins

(A)

(2S)-3-[(6-Acetylnaphthalen-2-yl)amino]-2-aminopropanoic acid (L-ANAP)

(B)

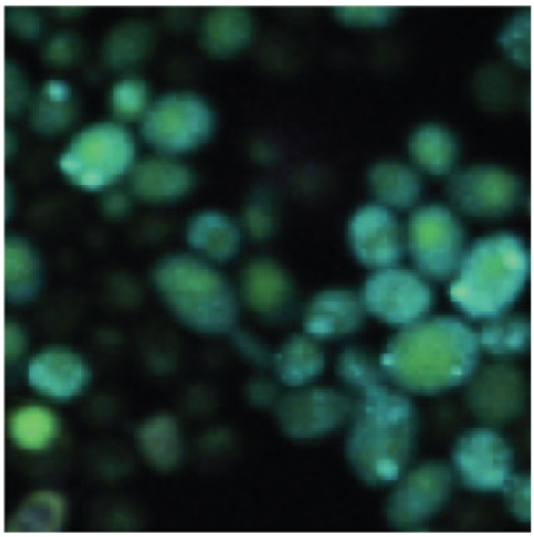

Image from Hsieh et al. 2014. Monitoring Protein Misfolding by Site-Specific Labeling of Proteins In Vivo. PLoS ONE 9:e99395, 10.1371/journal.pone.0099395.

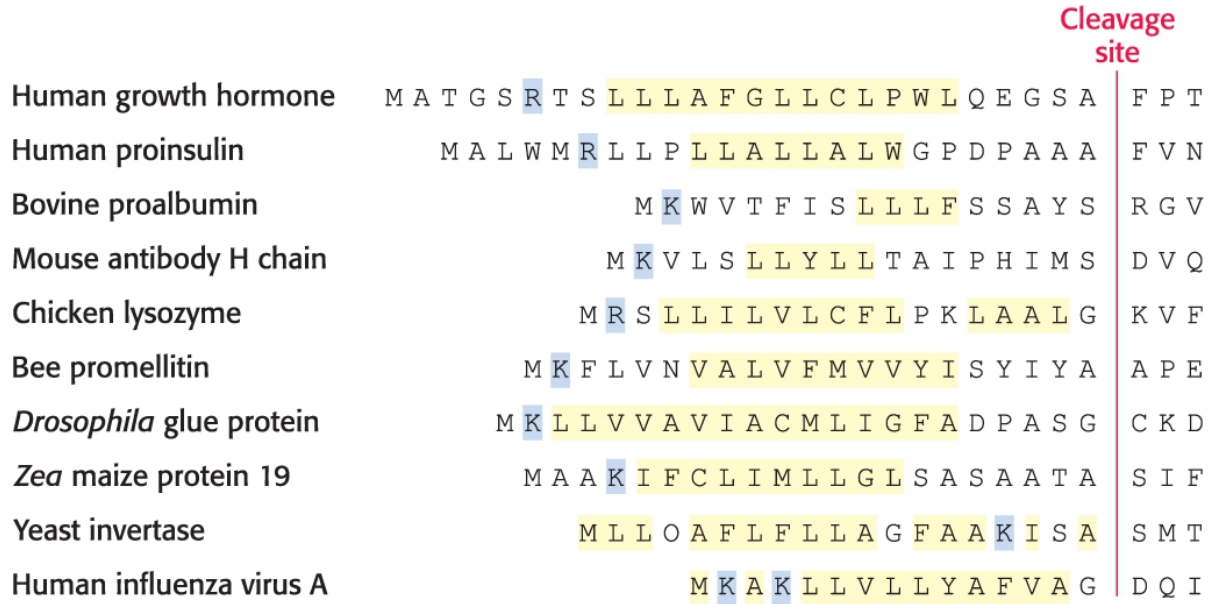
The figure has two parts.



The first part depicts the structure of L A N A P ((2 S)-3-[(6-Acetylnaphthalen-2-y l)amino]-2-aminopropanoic acid), a fluorescent unnatural amino acid. The structure is as follows: A 6-carbon hexagonal ring in a vertical orientation with C 1 occupying the topmost vertex. A double bond is present between C 4 and C 5 and C 6 and C 1. C 5 is single bonded to a central C atom. The central C atom is double bonded to O on the upper left and single bonded to C H 3 below. This ring is fused to a benzene ring in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 2 and C 3, C 4 and C5, and C 6 and C 1. The two rings are fused to each other such that C 2 and C 3 of the 6-carbon hexagonal ring are the C 6 and C 5 of the benzene ring, respectively. C 2 of the benzene ring is single bonded to N of a 1 N and 3 C heteronuclear alkane chain depicted as a line

structure using 3 zigzag lines. N bound to H occupies the first position. C 2 is dash bonded to N H 2 above. C 3 is double bonded to O on the upper right and single bonded to O below. O is further single bonded to C H 3 on the lower left.

The second part depicts a photomicrograph of yeast cells with green fluorescence due to the presence of protein L A N A P.

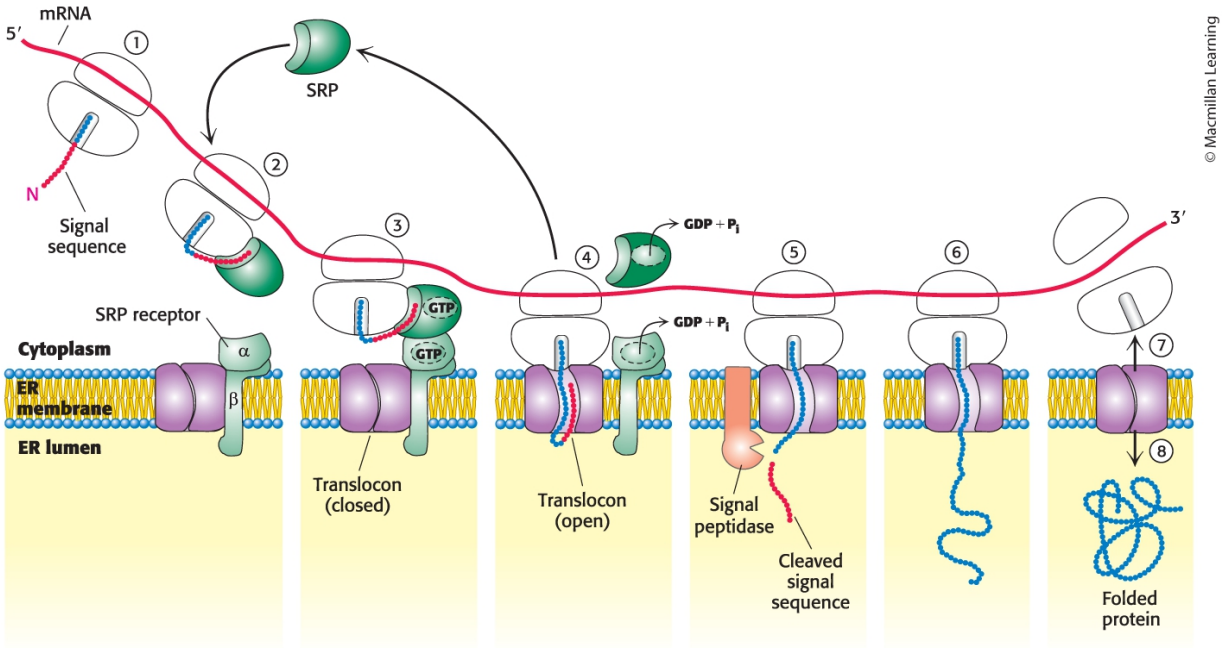
Return to FIGURE 30.32 The signal sequences of eukaryotic secretory and plasma membrane proteins contain hydrophobic residues

Extended description for FIGURE 30.33 The signal-recognition particle (S R P) consists of six proteins and



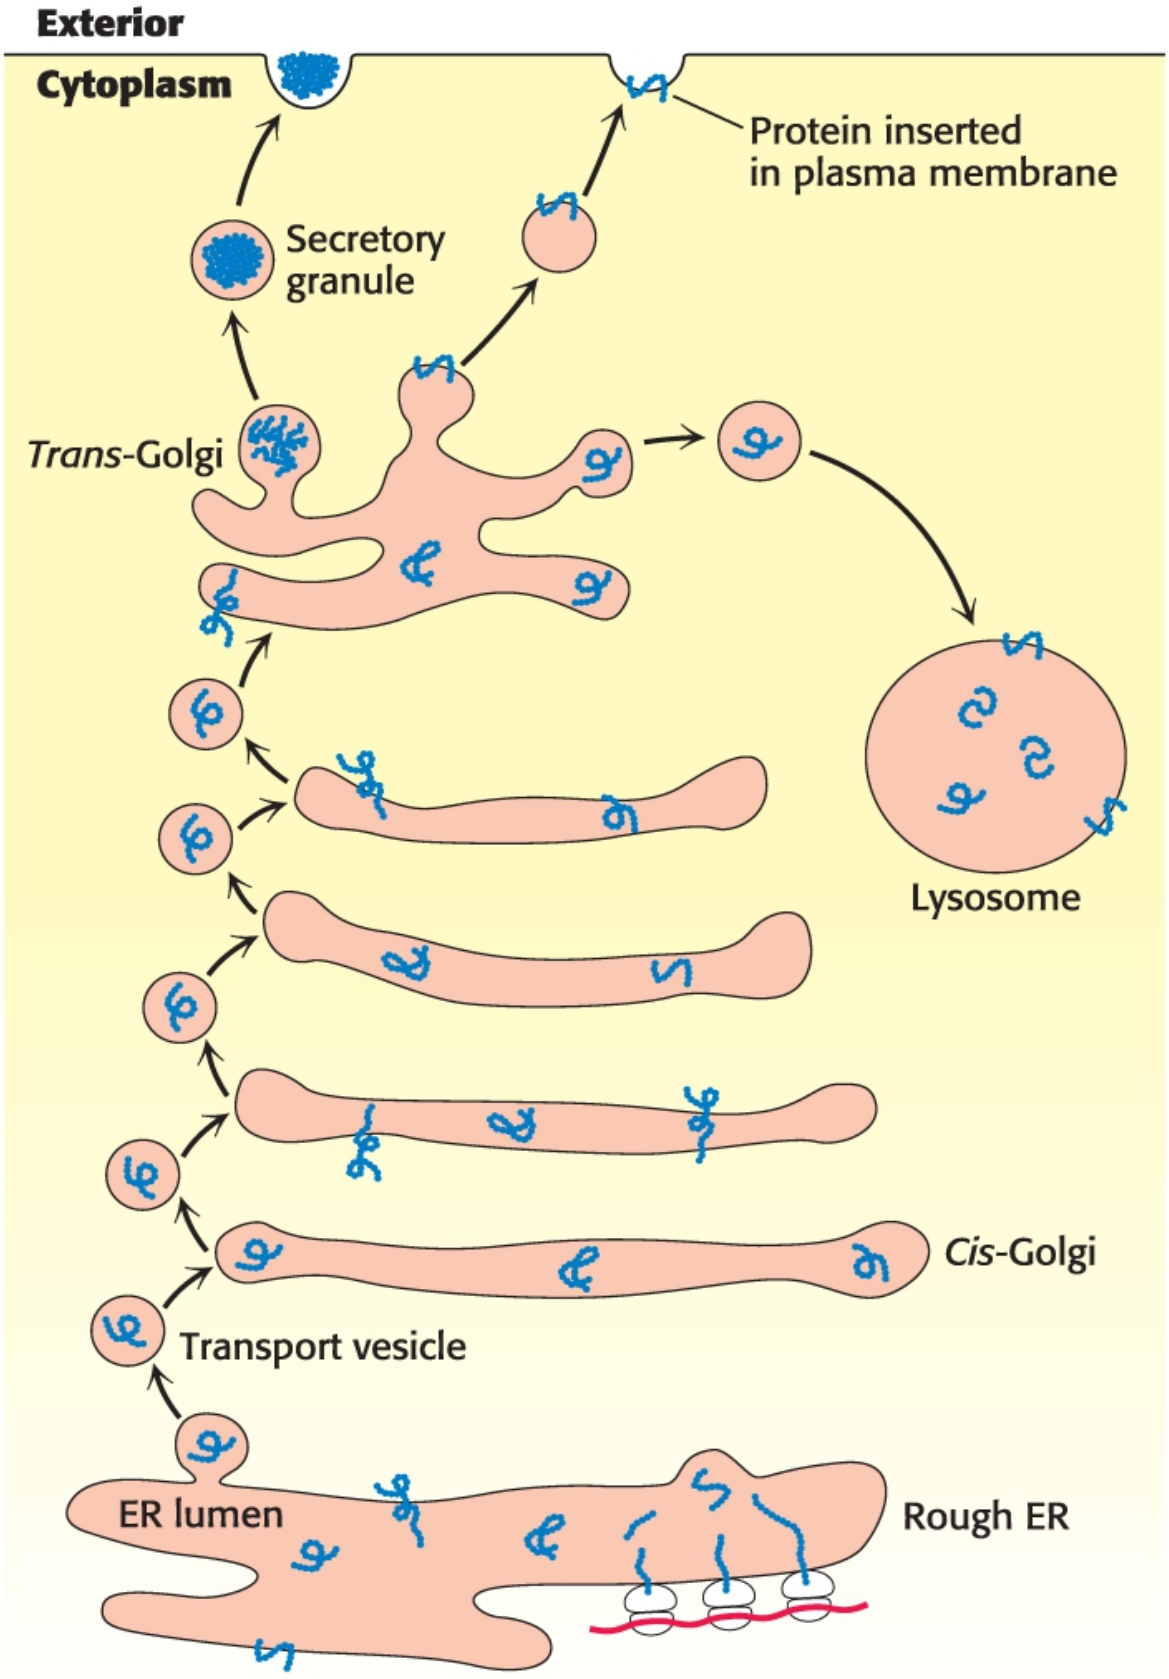
one 300-nucleotide R N A

A figure depicts the structure of R N A consisting of codon loops and stem-like extensions. The stems have horizontal lines on them. The loops on the R N A vary in size. The S R P is composed of six proteins and a 300 nucleotide R N A. The first protein on the upper left is labeled S R P 54. A callout from this protein reads "binds E R signal sequence." The next protein that is present on the right side of the S R P 54 has a dumbbell-shaped appearance and is labeled S R P 19. The next set of proteins is found in pairs which are oval-shaped structures attached side by side. They are labeled S R P 68 or S R P 72. The next set of proteins is also found in pairs with two oval-shaped structures attached one below the other. These proteins are not attached to the previous pair of proteins but are found at a distance and are labeled S R P 9 or S R P 14. The codon loop of R N A start from the bottom and moves upward attaches with the S R P or S R P 14 proteins on the left, takes a left turn overlaps the S R P 68 or S R P 72 proteins. It finally branches into two separate codon loops and terminates in the S R P 19.

Return to FIGURE 30.33 The signal-recognition particle (S R P) consists of six proteins and one 300-nucleotide R N A

Extended description for FIGURE 30.34 The S R P targeting cycle delivers nascent proteins containing a signal sequence to the E R

© Macmillan Learning



The figure depicts a lipid bilayer of the E R membrane with the cytoplasm at the top and the lumen at the bottom. The E R membrane consists of a translocon that has two subunits. The translocon opens and closes as per requirement. The translocon is attached to a green-colored S R P receptor consisting of alpha and beta subunits. The beta subunit is embedded in the E R membrane while the alpha subunit is in the cytoplasm. The series of events consists of eight steps. These steps are shown subsequently in eight parts. An m R N A in 5 prime to 3 prime direction bound to a ribosome is shown at the top in the first step. The larger subunit of the m R N A is at the bottom and the smaller subunit is at the top. The larger subunit consists of a polypeptide channel through which a beaded string-like structure emerges. The beaded structure

represents a protein. The beaded structure within the ribosome is blue and that emerging out chain is red and is labeled signal sequence. In the second step, a green-colored S R P binds with the larger subunit of the ribosome. This leads to the bending of the signal sequence into the S R P. In the third step, the S R P bound with the ribosome binds with the S R P receptor. Both S R P and S R P receptors consist of G T P. In the fourth step, the S R P is released along with the hydrolysis of G T P in the S R P and S R P receptors. Simultaneously, the ribosome now binds with the translocon. The translocon now opens to allow the entry of the signal sequence. In the fifth step, a membrane protein labeled signal peptidase removes the signal sequence from the peptide channel. The peptide sequence enters the lumen of the E R and is labeled cleaved signal sequence. In the sixth step, the protein biosynthesis continues directly into the E R. In the seventh step, the ribosomes are released. In the eighth step, the translocon closes and the peptide sequence is shown in a uniquely folded condition.

The figure depicts the organelles Golgi body and rough E R within a cell. The interior of the cell is labeled cytoplasm and the outer region of the cell is labeled exterior. The cell interior consists of a two-dimensional array of flattened sacs that extend across the cytoplasm labeled rough E R. The inner region of the E R is labeled E R lumen. Above the E R, the Golgi apparatus is depicted as a series of stacked flat cisternae with two distinct faces called the trans-Golgi and cis-Golgi. The trans-Golgi is at the top and the cis-Golgi is at the bottom near the rough E R. An m R N A with three ribosomes is attached to the lower side of the rough E R. The proteins synthesized by the ribosomes are released into the E R lumen. The protein from the E R lumen pinches off as a vesicle labeled transport vesicle. The transport vesicle enters the cis side of the Golgi. The proteins go through a series of modifications as they move from the cis side of the Golgi to the trans side. On the trans side, these proteins are packaged properly. The proteins are released into the cytoplasm in the form of a secretory granule. The secretory granule is then sent to the exterior. On the other hand, one of the proteins is shown inserted into the plasma membrane. The rest of the proteins are sent to the lysosome in the cytoplasm.

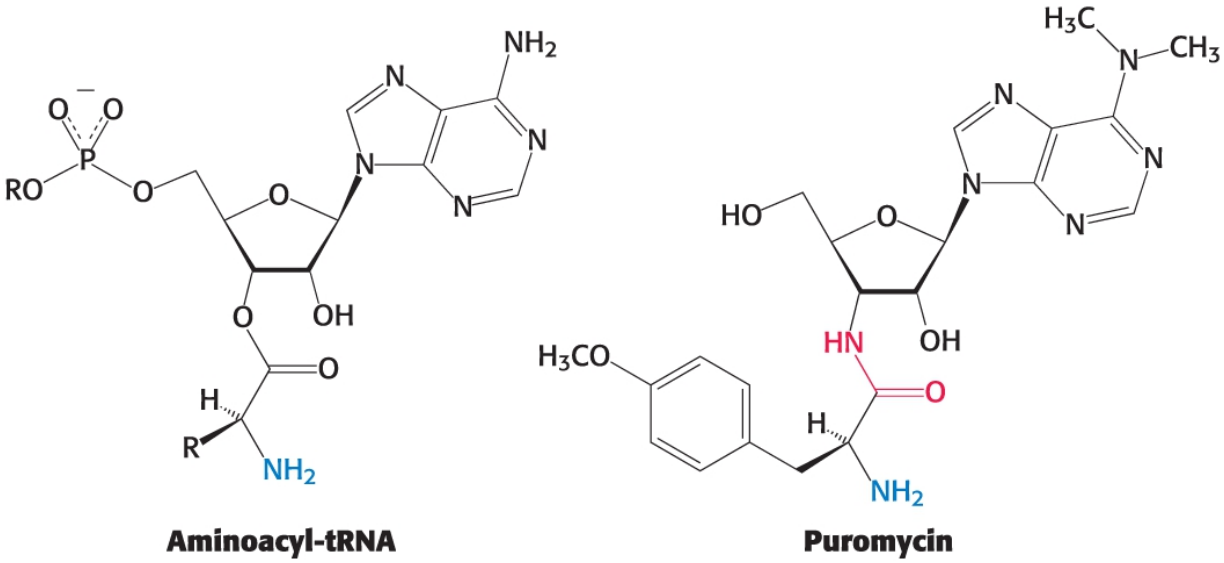
Extended description for Structure of streptomycin



Streptomycin

A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. The ring is in a plane perpendicular to the plane of the paper such that C 5 and O are away from the observer and C 2 and C 3 are towards the observer. C 2 is single bonded to C H 3 N H. N in C H 3 N H is highlighted in blue. C 3 is single bonded to O H below. O in the O H is higlighted in red. C 4 is single bonded to O H above. O in the O H is higlighted in red. C 5 is single bonded to C H 2 O H below. O in the C H 2 O H is higlighted in red. C 1 is single bonded to O on the upper right. The O is highlighted in red. The O atom single bonded to C 2 of the 5-membered heterocyclic pentagonal ring in a vertical orientation and consists of 1 O and 4 C atoms. The O atom is at the topmost vertex. The ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are towards the observer and O is away from the observer. C 3 is single bonded to C H O above and O H below. The O in both C H O and O H are highlighted in red. C 4 is single bonded to C H 3 below. C 1 is single bonded to O above and is highlighted in red. The O atom is single bonded to C 3 of a 6-carbon hexagonal ring in a horizontal orientation with C 1 occupying the rightmost vertex. The ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are towards the observer and C 5 and C 6 are away from the observer. C 1 and C 5 are each single bonded to O H below. C 2 is single bonded to O H above. O in the O H are highlighted in red. C 4 of the hexagonal ring is single bonded to N H above. N H is single bonded to a central C atom on the upper left. The central C atom is partially double bonded to N H 2 above and N H 2 on the lower left. The N H 2 atoms have an overall positive charge. C 6 of the hexagonal ring is single bonded to N H above. N H is single bonded to a central C atom on the upper right. The central C atom is partially double bonded to N H 2 above and N H 2 on the lower right. The N H 2 atoms have an overall positive charge. The N in the N H and N H 2 atoms are highlighted in blue.

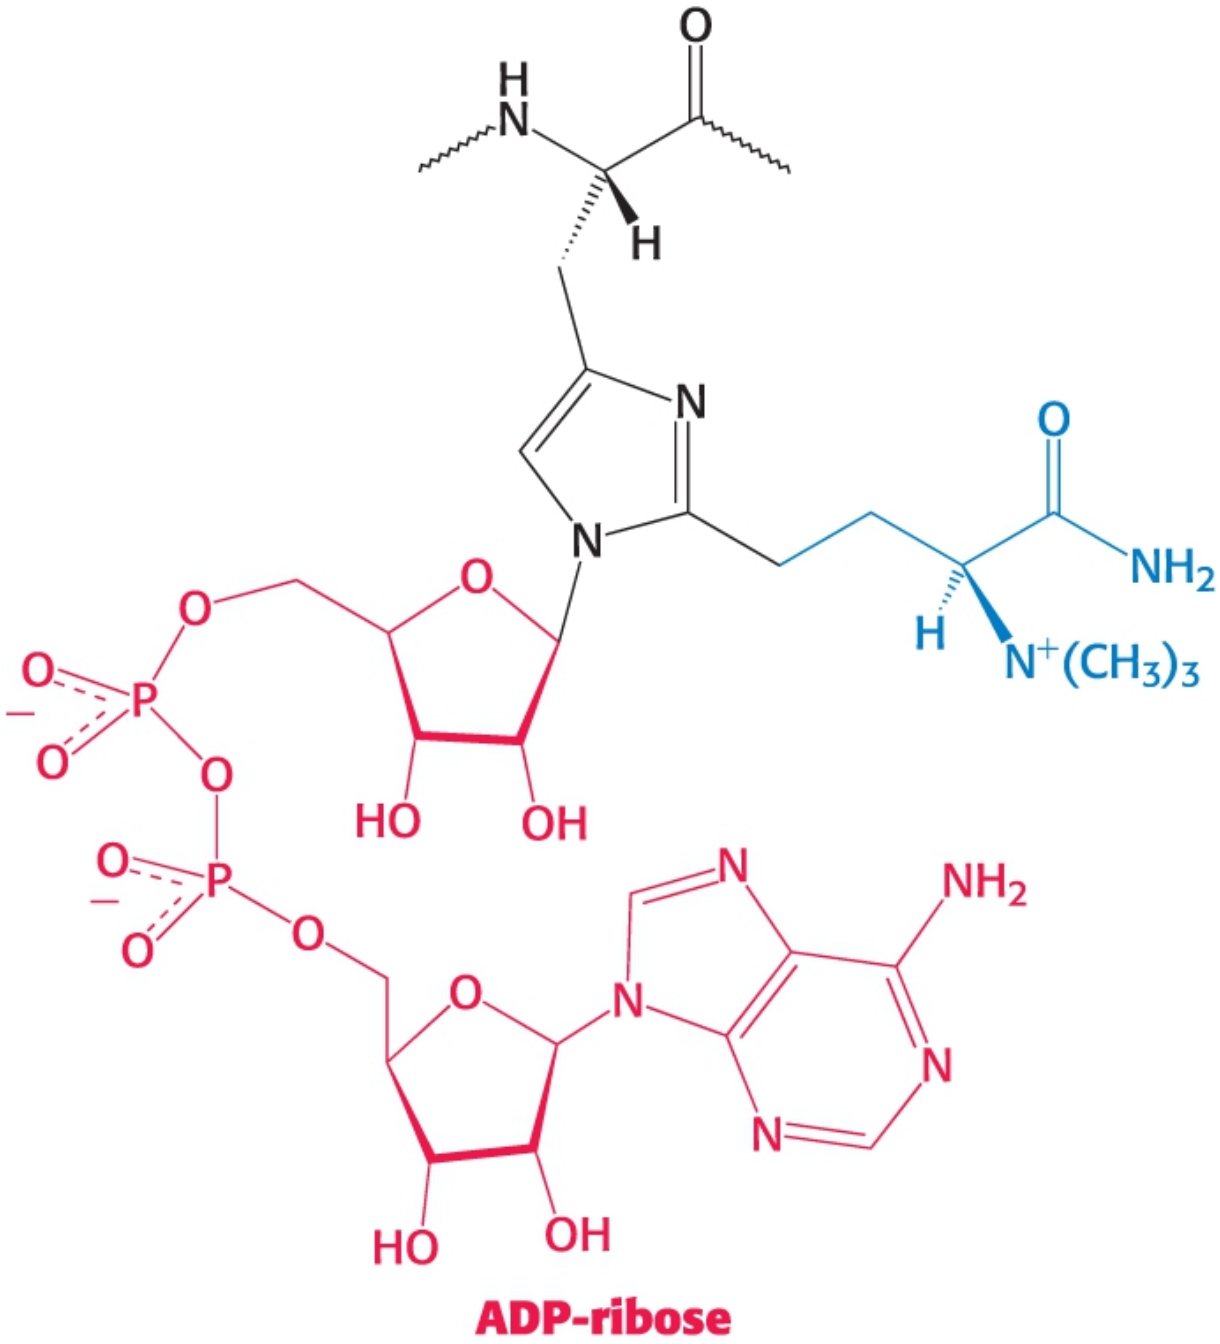
Extended description for FIGURE 30.36 The antibiotic puromycin resembles the aminoacyl terminus of an aminoacyl-t R N A

The structure of aminoacyl- t R N A is as follows: A 5-membered heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. O occupies the first position which is the topmost vertex. C 2 is single bonded to O H. C 3 is single bonded to O of a 1 O and 2 C heteronuclear alkane chain depicted as a line structure vertically using 2 zigzag lines. O ccupies the first position C 1 is double bonded to O on the right. C 2 is dash bonded to H on the upper left, wedge bonded to R on the lower left, and single bonded to N H 2 on the lower right. N H 2 is highlighted in blue. C 4 of the pentagonal ring is single bonded to a central C atom. The central C atom is further single bonded to O on the lower left. This O is further single bonded to a central P on the upper left. The central P atom is single bonded to O R on the lower left and partially double bonded to O on the upper left and O on the upper right. The P O O group has an overall negative charge. C 1 of the pentagonal ring is



single bonded to the first N atom of a 5-membered heterocyclic pentagonal ring is in a vertical orientation consisting of 2 N and 3 C atoms. The first N atom occupies the first position, which is the bottom left vertex. The second N atom occupies the third position which is the topmost vertex. A double bond is present between C 1 and the second N atom. The 5-membered ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 2 N and 4 C atoms. In the 6-membered ring, the first N atom occupies the first position, which is the top right vertex. The second N atom occupies the third position which is the bottommost vertex. The 6-membered ring contains double bonded between C 1 and the second N atom, C 2 and C 3, and C 4 and the second N atom. C 4 is single bonded to N H 2 above. The two rings are fused to each other such that C 2 and C 3 of the 5-membered ring are the C 3 and C 2 of the 6-membered ring, respectively.

The structure of puromycin is as follows: A 5-membered heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. O occupies the first position which is the topmost vertex. C 2 is single bonded to O H. C 3 is single bonded to N H of a 1 N H and 2 C heteronuclear alkane chain depicted as a line structure vertically using 2 zigzag lines. N H occupies the first position. C 1 is double bonded to O on the right. These structures of the alkane chain are highlighted in red. C 2 is dash bonded to H on the upper left, wedge bonded to a central C atom on the lower left, and single bonded to N H 2 on the lower right. N H 2 is highlighted in blue. The central C atom is further single bonded to C 3 of a benzene ring in vertical orientation with C 1 occupying the topmost vertex. Double bonds are present between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 6 is single bonded to O C H 3. C 4 of the pentagonal ring is single bonded to a central C atom. The central C atom is further single bonded to O H on the lower left. C 1 of the pentagonal ring is single bonded to the first N atom of a 5-membered heterocyclic pentagonal ring and in a vertical orientation consisting of 2 N and 3 C atoms.

The first N atom occupies the first position, which is the bottom left vertex. The second N atom occupies the third position which is the topmost vertex. A double bond is present between C 1 and the second N atom. The 5-membered ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 2 N and 4 C atoms. In the 6-membered ring, the first N atom occupies the first position, which is the top right vertex. The second N atom occupies the third position which is the bottommost vertex. The 6-membered ring contains double bonded between C 1 and the second N atom, C 2 and C 3, and C 4 and the first N atom. C 4 is single bonded to N above. This N is further single bonded to C H 3 on the upper left and C H 3 on the upper right. The two rings are fused to each other such that C 2 and C 3 of the 5-membered ring are the C 3 and C 2 of the 6-membered ring, respectively.

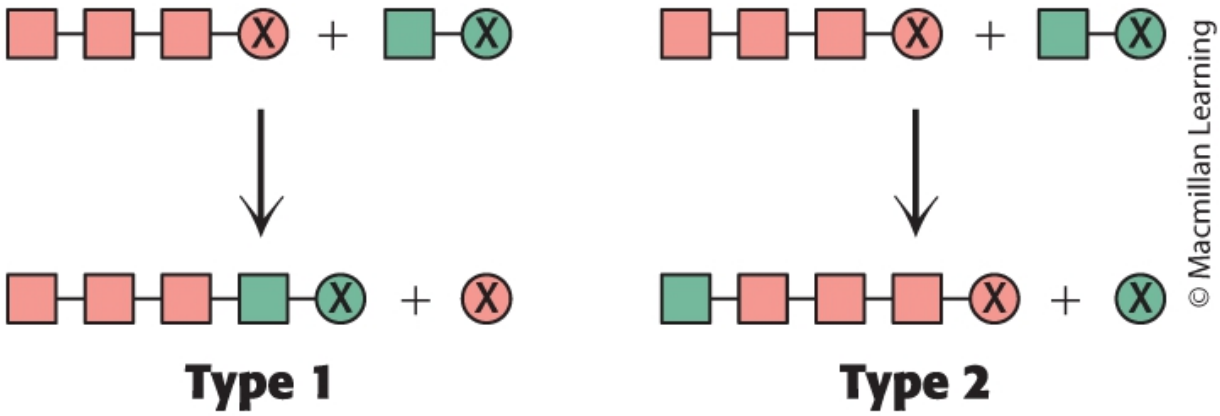
Extended description for FIGURE 30.37 Diphtheria toxin inhibits protein biosynthesis in eukaryotes



The structure of diphtheria toxin is as follows: A 5-membered heterocyclic pentagonal ring in a vertical orientation consists of 1 O and 4 C atoms. O occupies the first position which is the topmost vertex. C 2 and C 3 are each single bonded to O H. C 1 of the pentagonal ring is single bonded to the first N atom of a 5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 2 N and 3 C atoms. The first N atom occupies the first position, which is the bottom left vertex. The second N atom occupies the third position which is the top right vertex. A double bond is present between C 1 and the second N atom. The 5-membered ring is fused to a 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 2 N and 4 C atoms. In the 6-membered ring, the first N atom occupies the first position, which is the rightmost vertex. The second N atom occupies the third position which is the bottom left vertex. The 6-membered ring contains double bonded between C 1 and the second N atom, C 2 and C 3, and C 4 and the first N atom. C 4 is single bonded to N H 2 above. The two rings are fused to each other such that C 2 and C 3 of the 5-membered ring are the C 3 and C 2 of the 6-membered ring, respectively. C 4 of the first heterocyclic pentagonal ring is single bonded to a central C atom above. The central C atom is further single bonded to O on the upper left. This O is further single bonded to a central P on the upper left. The central P atom is single bonded to O above and partially double bonded to O on the upper left and O on the lower left. The P O O group has an overall negative charge. O that is single bonded to P above is further single bonded to a second P atom on the upper left. The second P atom is partially double bonded to O on the upper left and O on the lower left. The P O O group has an overall negative charge. P is also single bonded to O on the upper right. O is single bonded to a central C atom. The central C atom is single bonded to C 4 of a 5-membered heterocyclic pentagonal ring in a vertical orientation consisting of 1 O and 4 C atoms. O occupies the first position which is the topmost vertex. C 2 and C 3 are each single bonded to O H. The structures upto this

pentagonal ring are highlighted in red. C 1 of the pentagonal ring is single bonded to the first N atom of a 5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 2 N and 3 C atoms. The first N atom occupies the first position, which is the bottom left vertex. The second N atom occupies the fourth position which is the top right vertex. A double bond is present between C 1 and C 2 and the second N atom and C 3. C 2 is single bonded to a central C atom above. The central C atom is dash bonded to C 1 of a 1 N and 2 C heteronuclear alkane chain depicted as a line structure using 2 zigzag lines. N bound to H occupies the first position. C 1 is wedge bonded to H on the lower right. C 2 is double bonded to O above. N bound to H has a wiggly bond on the lower left. C 2 has a wiggly bond on the lower right The pentagonal ring and the alkane chain are highlighted in black. C 3 of the 5-membered ring is single bonded to a 1 N H 2 and 4 C heteronuclear alkane chain depicted as a line structure using 4 zigzag lines. N H 2 occupies the fifth position. C 3 is dash bonded to H on the lower left and wedge bonded to N superscript plus open parenthesis C H 3 close parenthesis subscript 3. C 4 is double bonded to O above. This alkane chain is highlighted in blue.

Extended description for The two basic mechanisms for the elongation of biomolecules are represented in the adjoining illustration

In the first mechanism labeled type 1, two biomolecules, each with an activating group is depicted. These biomolecules are separated by a plus sign. The first biomolecule is pink and consists of three squares connected by single bonds from left to right. The third square on the right is single-bonded to a circle marked with an X. The X mark represents the activating group of the biomolecule. The second biomolecule in green consists of one square connected to a circle marked with an X on the right. When the reaction proceeds, the activating group from the first biomolecule is released and the second biomolecule with its activating group is added to the right side of the first biomolecule.

The secondary structure of R N A resembles a cloverleaf. A single chain of t R N A is folded to form five arms which results in 3 prime and 5 prime ends that lie adjacent to each other at the top. Each arm consists of a loop and a basal stalk. The 3 prime and 5 prime ends of the t R N A are at the top. They do not form a loop and hence are in the form of two parallel lines. The stalk representing 5 prime terminus is shorter than the 3 prime stalk. The 3 prime stalk is attached to O, single bond, C, single bond, C, single bond, C H 3. C 1 is double bonded to O below. C 2 is single bonded to H above and N H 3 superscript plus below. The R N A consists of bases that are based paired with complementary bases.

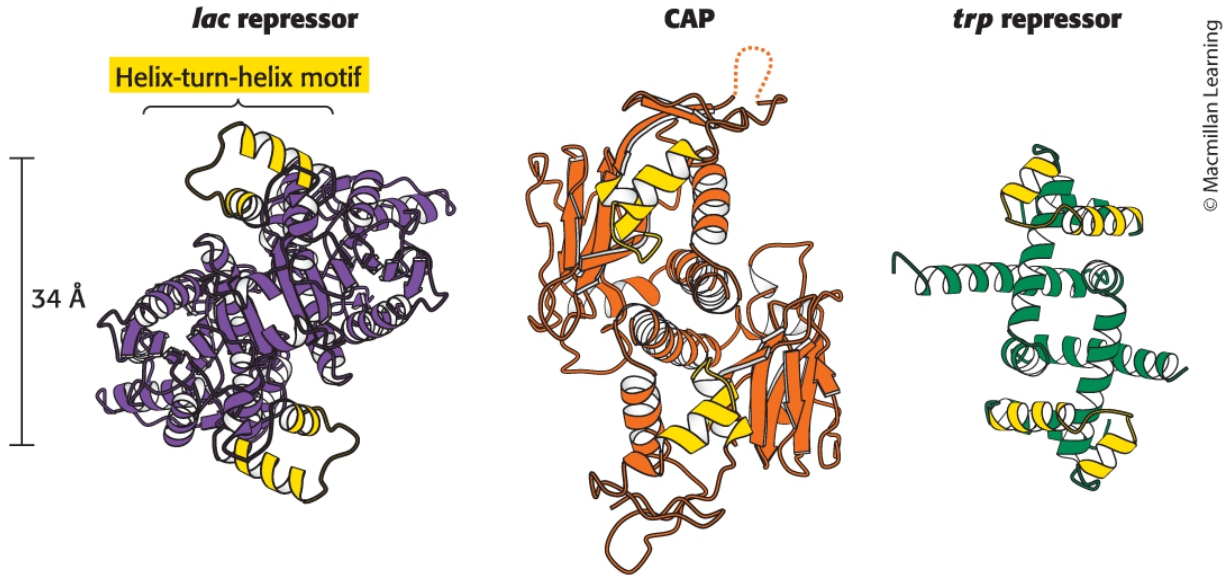
Extended description for FIGURE 31.1 The sequence of the lac regulatory site is a nearly perfect inverted repeat

The sequence of the top strand of the regulatory site in 5 prime to 3 prime direction reads T G T G T G G A A T T G T G A G C G G A T A A C A A T T T C A C A C A. The sequence of the bottom strand in 3 prime to 5 prime direction reads A C A C A C C T T A A C A C T C G C C T A T T G T T A A A G T G T G T. The base G at the eighteenth position of the top strand is paired with C at the eighteenth position of the bottom strand. The bases from positions 1 to 6 and 30 to 35 in the top and bottom strands are highlighted in blue. The bases at the seventh, fourteenth, sixteenth, eighteenth, twentieth, twenty-second, and twenty-ninth positions in the top and bottom strands are highlighted in black. The bases from positions 8 to 13 and 23 to 28 in the top and bottom strands are highlighted in red. The bases at the fifteenth and twenty-first positions in the top and bottom strands are highlighted in purple.

Return to FIGURE 31.1 The sequence of the lac regulatory site is a nearly perfect inverted repeat

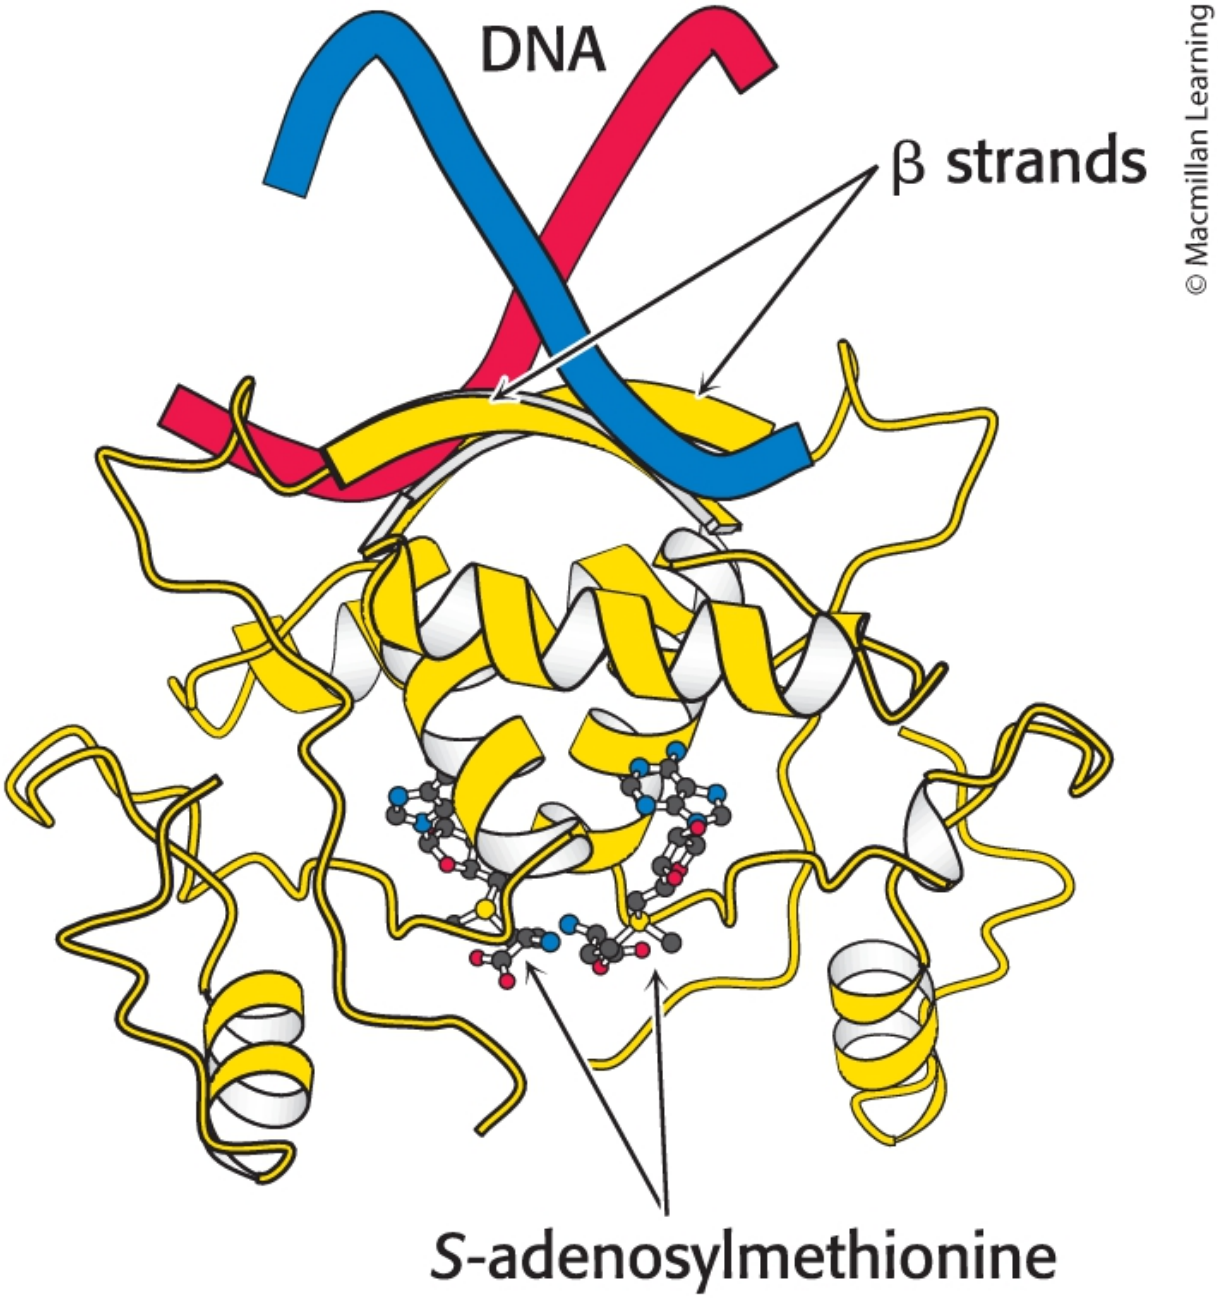
Extended description for FIGURE 31.2 The lac repressor binds to operator D N A



The figure shows a ribbon diagram of the D N A-binding subunit of the lac repressor. It is a dimer composed of two subunits. Each subunit is composed of 3 alpha helices. The subunits are bound to a ball-and-stick model of an operator D N A that consists of blue and orange spheres. One alpha-helix of each repressor extends into the major groove of the operator D N A. A zoomed-in view shows the interaction between the G-C pair of operator D N A and the arginine residue of the repressor. The base G on the left has the following structure: A 6-membered heterocyclic hexagonal ring in a horizontal orientation consists of three grey and two blue spheres. The blue spheres occupy the top left and the rightmost vertices which are the first and third positions, respectively. The first grey sphere is single bonded to a central blue sphere which is further single bonded to a white sphere on the right and a white sphere on the upper left. The second grey sphere of the ring is single bonded to a red sphere. The ring is fused to a 5-membered heterocyclic pentagonal ring in a vertical orientation consisting of 2 blue and three grey spheres. In the pentagonal ring, the blue spheres occupy the bottommost and the top left vertices which are the first and third positions,

respectively. The two rings are fused to each other such that the third and the fourth grey spheres of the hexagonal ring are the third and the second grey spheres of the pentagonal ring, respectively. An open single bond is shown on the upper left of the second blue sphere of the pentagonal ring. The base C on the right has the following structure: A 6-membered heterocyclic hexagonal ring in a horizontal orientation consists of three grey and two blue spheres. The blue spheres occupy the leftmost and the top right vertices which are the first and third positions, respectively. The first grey sphere is single bonded to a red sphere. The fourth grey sphere is single bonded to a central blue sphere which is further single bonded to a white sphere on the left and a white sphere on the lower right. The second blue sphere has an open single bond on the upper right. The second and third grey spheres are each single bonded to a white sphere. The arginine residue has the following structure: A zigzag chain consists of four grey spheres and one blue sphere with the blue sphere occupying the fourth position. The first, second, and third grey spheres are each single bonded to two white spheres. The blue sphere is single bonded to a white sphere. The fourth grey sphere is single bonded to a second blue sphere on the upper right and a third blue sphere on the upper left. Each of the second and third blue spheres are single bonded to two white spheres. The interaction between the spheres of one molecule with that of the other molecule is depicted by dotted lines. In the guanine structure, the white sphere attached to the central blue sphere, the second blue sphere of the hexagonal ring, and the red sphere interact with the red sphere, the first blue sphere, and the white sphere attached to the central blue sphere in the cytosine structure, respectively. In the guanine structure, the first blue sphere of the pentagonal ring and the red sphere interacts with the white spheres attached to the third and second blue spheres of the arginine residue, respectively.

Return to FIGURE 31.2 The lac repressor binds to operator D N A



Extended description for FIGURE 31.3 Sequence-specific D N A-binding proteins interact with D N A through a helix-turn-helix motif

The figure shows the ribbon diagrams of the lac repressor, C A P, and t r p repressor. The ribbon diagram of the lac repressor consists of purple-colored alpha helices and beta strands that are coiled together to form two clusters. Each cluster consists of two yellow-colored alpha-helices interconnected by a short loop. These are present at the top and bottom edges of the lac repressor and labeled helix-turn-helix motif. These motifs range about 34 Angstrom. The ribbon diagram of C A P consists of orange-colored alpha helices and beta strands that are coiled together to form two clusters. Each cluster consists of two yellow-colored alpha-helices interconnected by a short loop. The ribbon diagram of the t r p repressor consists of green-colored alpha helices. The alpha helices are attached to yellow-colored alpha helices.

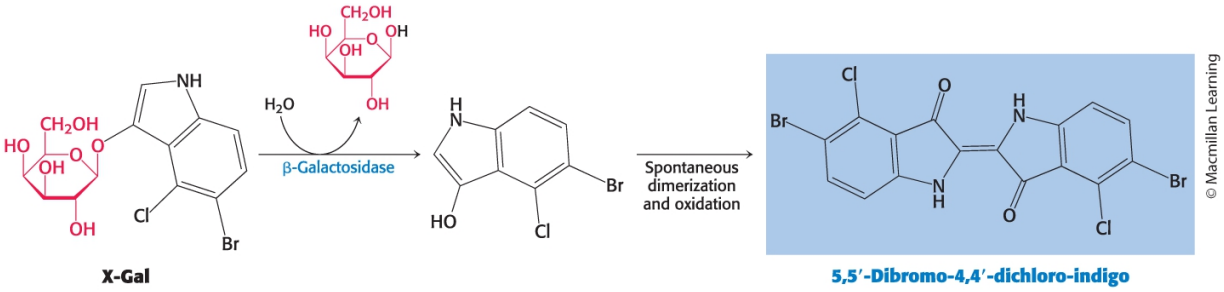
Extended description for Formation of galactose and glucose

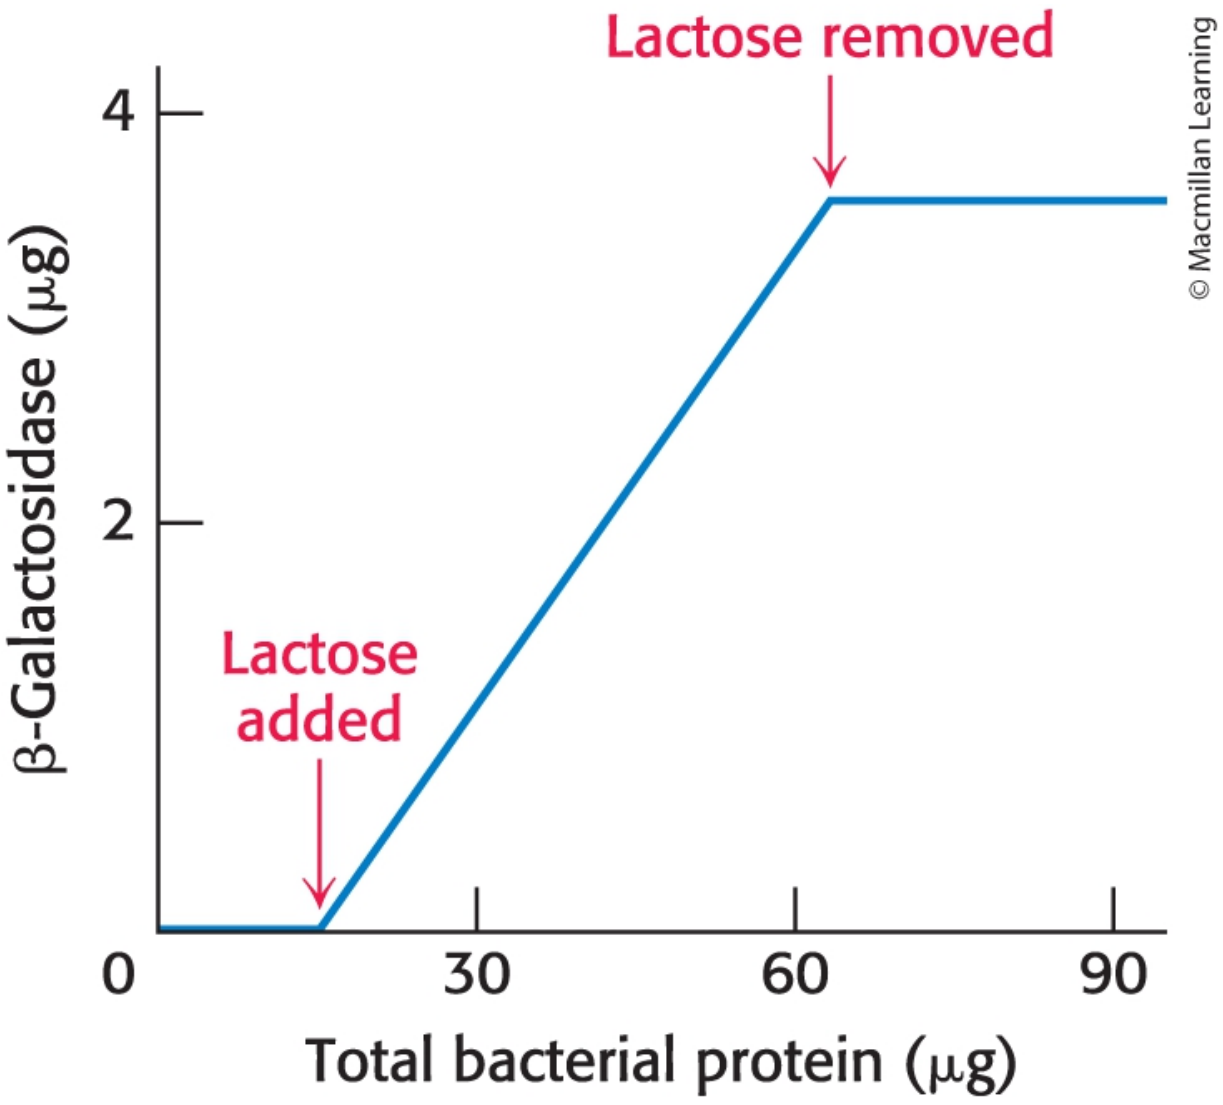


Lactose undergoes hydrolysis in the presence of beta-galactosidase to give rise to galactose and glucose. The structure of lactose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. The ring is in a plane perpendicular to the plane of the observer such that C 5 and O are away from the observer and C 2 and C 3 are toward the observer. C 2 is single-bonded to O H below. C 3 and C 4 are each single-bonded to O H above. C 5 is single-bonded to C H 2 O H above. C 1 is single-bonded to O on the right. The ring and its attached groups are highlighted in red. The O attached to C 1 is single-bonded to C 4 of a second 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 1 O and 5 C atoms. In the second ring, the O atom occupies the first position, which is the top right vertex. The second ring is in a plane perpendicular to the plane of the observer such that C 5 and O are away from the observer and C 2 and C 3 are toward the observer. In the second ring, C 1 and C 2 are each single bonded to O H below, C 3 is single bonded to O H above, and C 5 is single-bonded to C H 2 O H above. The second ring and its attached groups are highlighted in blue. The structure of galactose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies

the top right vertex. The ring is in a plane perpendicular to the plane of the observer such that C 5 and O are away from the observer and C 2 and C 3 are toward the observer. C 1, C 3, and C 4 are each single bonded to O H above. C 2 is single-bonded to O H below. C 5 is single-bonded to C H 2 O H above. The ring and all its attached groups except for O H attached to C 1 are highlighted in red. The structure of glucose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the top right vertex. The ring is in a plane perpendicular to the plane of the observer such that C 5 and O are away from the observer and C 2 and C 3 are toward the observer. C 1, C 2, and C 4 are each single-bonded to O H below. C 3 is single-bonded to O H above. C 5 is single-bonded to C H 2 O H above.

Return to Formation of galactose and glucose

Extended description for FIGURE 31.5 The Beta-galactosidase reaction can be monitored using a colored indicator.



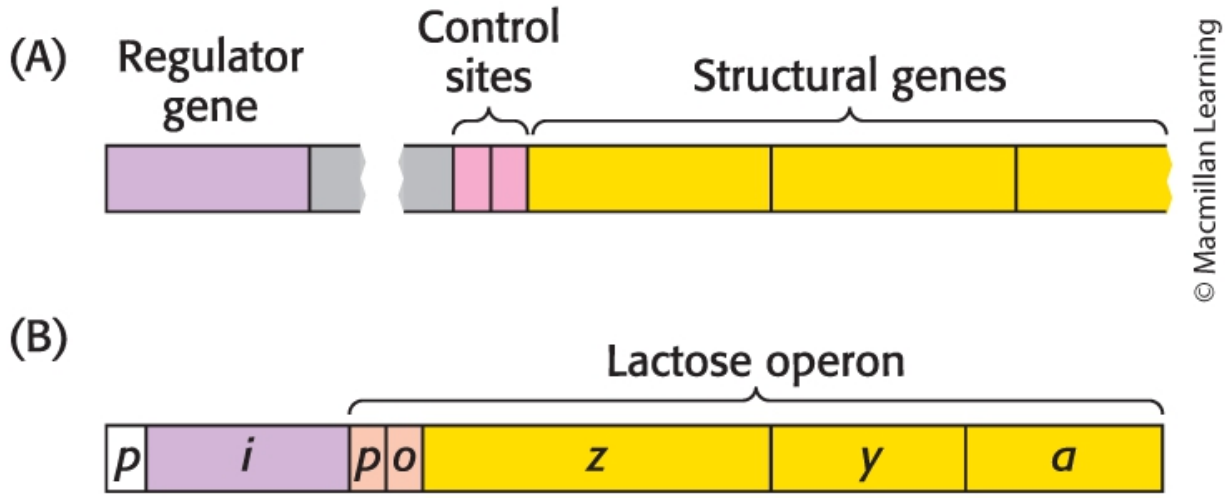
The coupled reaction consists of two steps and contains one reactant, one intermediate, and one product. In the first step, X-Gal is transformed to an intermediate by the action of betagalactosidase. This is coupled with the entry of H 2 O and release of galactose. The structure of X-Gal is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 1 N and 4 C atoms. N bound to H occupies the first position, which is the top right vertex. A double bond is present between C 3 and C 4. This ring is fused to a benzene ring in a vertical orientation with C 1 occupying the topmost vertex. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. The two rings are fused to each other such that C 1 and C 2 of the 5-membered ring are the C 1 and C 6 of the benzene ring, respectively. In the benzene ring, C 4 is single bonded to B r and C 5 is single bonded to C l. C 3 of the 5-membered ring is single-bonded to O on the lower left. O is single bonded to C 1 of a 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 1 O and 5 C atoms. In the hexagonal ring, the O atom occupies the first position, which is the top right vertex. The hexagonal ring is in a plane perpendicular to the plane of the paper such that C 5 and O are away from the observer and C 2 and C 3 are toward the observer.

In the hexagonal ring, C 2 is single bonded to O H below, C 3 and C 4 are each single bonded to O H above, and C 5 is single bonded to C H 2 O H above. The hexagonal ring and its attached groups are highlighted in red. The structure of Galactose is as follows: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation consisting of 1 O and 5 C atoms. The O atom occupies the first position, which is the top right vertex. The ring is in a plane perpendicular to the plane of the paper such that C 5 and O are away from the observer and C 2 and C 3 are towards the observer. C 1 is single bonded to O H above. C 2 is single bonded to O H below. C 3 and C 4 are each single bonded to O H above. C 5 is single bonded to C H 2 O H above. The ring is highlighted in red with the exception of H of O H single bonded to C 1. The structure of the intermediate is as follows: A 5-membered heterocyclic pentagonal ring is in a horizontal orientation and consists of 1 N and 4 C atoms. N bound to H occupies the first position, which is the top left vertex. A double bond is present between C 3 and C 4. C 3 is single bonded to O H. This ring is fused to a benzene ring in a vertical orientation with C 1 occupying the topmost vertex. The two rings are fused to each other such that C 1 and C 2 of the pentagonal ring are the C 6 and C 5 of the benzene ring, respectively. In the benzene ring, double bonds are present between C 1 and C 2, C 3 and C 4, and C 5 and C 6. In the benzene ring, C 3 is single bonded to B r and C 4 is single bonded to C l. In the second step, the intermediate is transformed to 5, 5 prime Dibromo-4, 4 prime dichloro indigo through spontaneous dimerization and oxidation. The structure of 5, 5 prime Dibromo-4, 4 prime dichloro indigo is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to C l and C 6 is single bonded to B r. The benzene ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation with 1 N and 4 C atoms. In the pentagonal ring, N bound to H occupies the first position which is the bottom right vertex. The two rings are fused such that C

2 and C 3 of the benzene ring are C 2 and C 1 of the 5-membered ring, respectively. In the pentagonal ring, C 3 is double bonded to O. C 4 of the 5-membered ring is double bonded to C 4 of a second 5-membered heterocyclic pentagonal ring in horizontal orientation with 1 N and 4 C atoms. In the second pentagonal ring, N bound to H occupies the top left vertex. In the second pentagonal ring, C 3 is double bonded to O. The second 5-membered ring is fused to a second benzene ring in a vertical orientation with C 1 occupying the topmost vertex. In the second benzene ring, double bonds are present between C 1 and C 2, C 3 and C 4, and C 5 and C 6. The two rings are fused such that C 1 and C 2 of the second 5-membered ring are the C 6 and C 5 of the second benzene ring, respectively. In the second benzene ring, C 3 is single bonded to B r and C 4 is single bonded to C l.

Return to FIGURE 31.5 The Beta-galactosidase reaction can be monitored using a colored indicator.

Extended description for FIGURE 31.6 The production of β-galactosidase can be increased by the addition of lactose



The horizontal axis, labeled total bacterial protein in micrograms, has markings ranging from 0 to 90 in increments of 30 units. The vertical axis, labeled beta-galactosidase in micrograms, has markings ranging from 0 to 4 in increments of 2 units. The graph starts from (18, 0), moves linearly to the upper right to (60, 3.5),

moves to the right, and terminates at (90, 3.5). The coordinate (18, 0) is labeled lactose added and the coordinate (60, 3.5) is labeled lactose removed. All values are approximated.

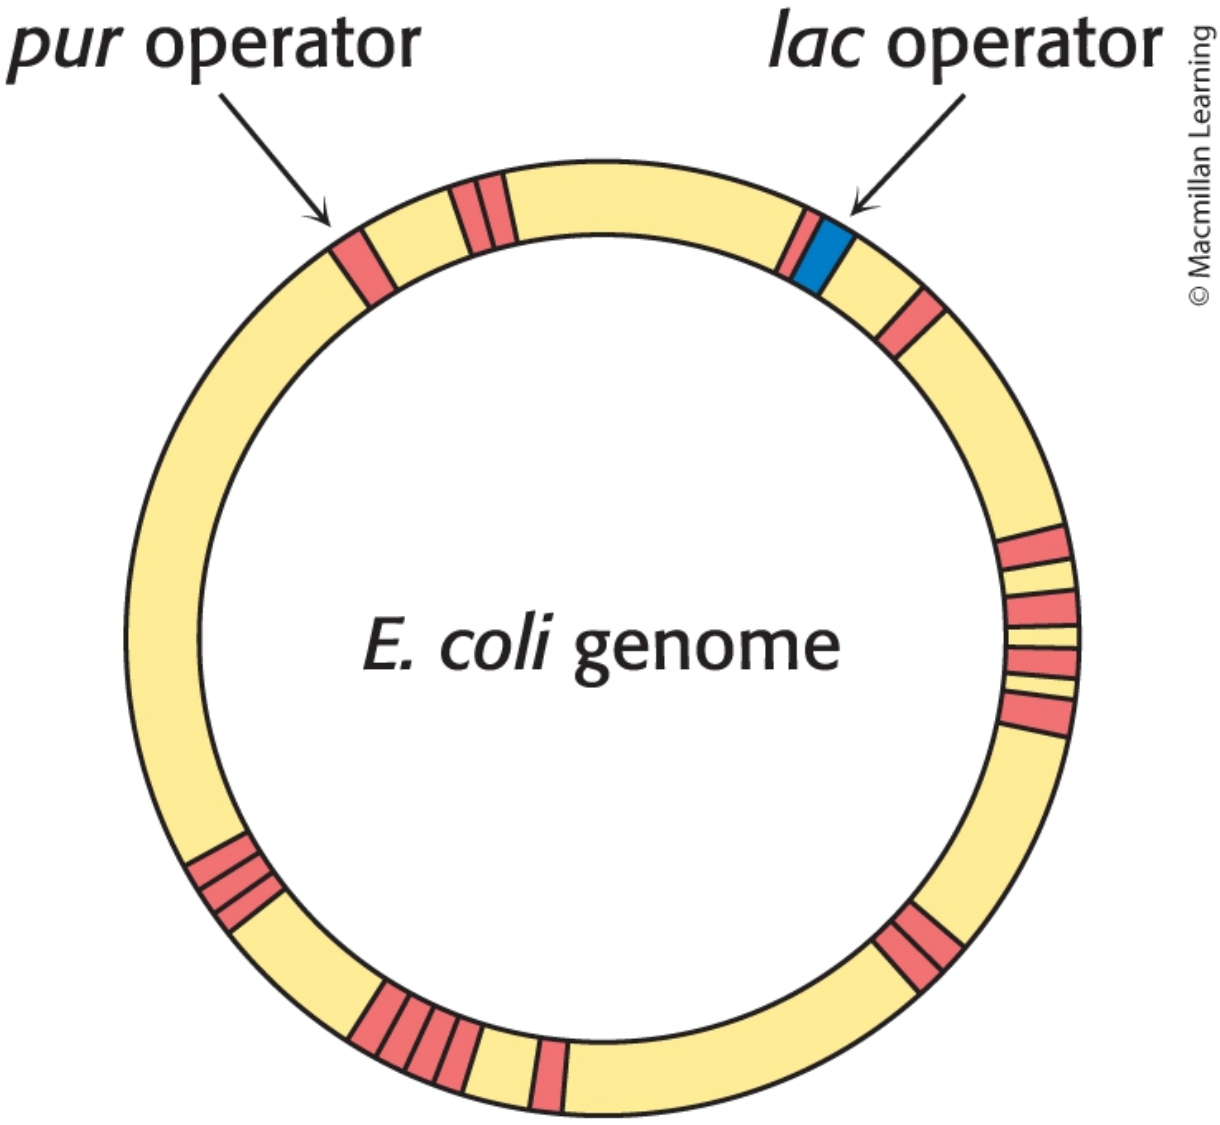
The figure has two parts.



Part A: The figure shows a horizontal bar with a regulator gene attached to the lactose operon. The regulator gene is divided into two parts and is labeled p and i. The lactose operon has two control sites depicted in pink labeled p and o and three structural genes depicted in yellow labeled z, y, and a. Below the regulator gene a right wavy arrow labeled i m R N A is present. A downward arrow

from i m R N A points to two spheres attached side by side. The spheres represent the repressor. An arrow from the repressor points to the operator site on the horizontal bar. The arrow reads the repressor bound to the operator site and prevents transcription of z, y, and a.

Part B: The figure shows a horizontal bar with a regulator gene attached to the lactose operon. The regulator gene is divided into two parts and is labeled p and i. The lactose operon has two control sites depicted in pink labeled p and o and three structural genes depicted in yellow labeled z, y, and a. Below the regulator gene a right wavy arrow labeled i m R N A is present. A downward arrow from i m R N A points to two spheres attached side by side. The spheres represent the repressor. Small pink-colored structures labeled inducer bind to the repressor. The text below the repressor bound to the inducer reads repressor-inducer complex does not bind to D N A. A right wavy arrow below the lactose operon region of the horizontal bar is labeled lac m R N A. Three downward arrows from the z, y, and a point down to three yellow spheres at the bottom. The yellow spheres are labeled beta-galactosidase, permease, and transacetylase, respectively.

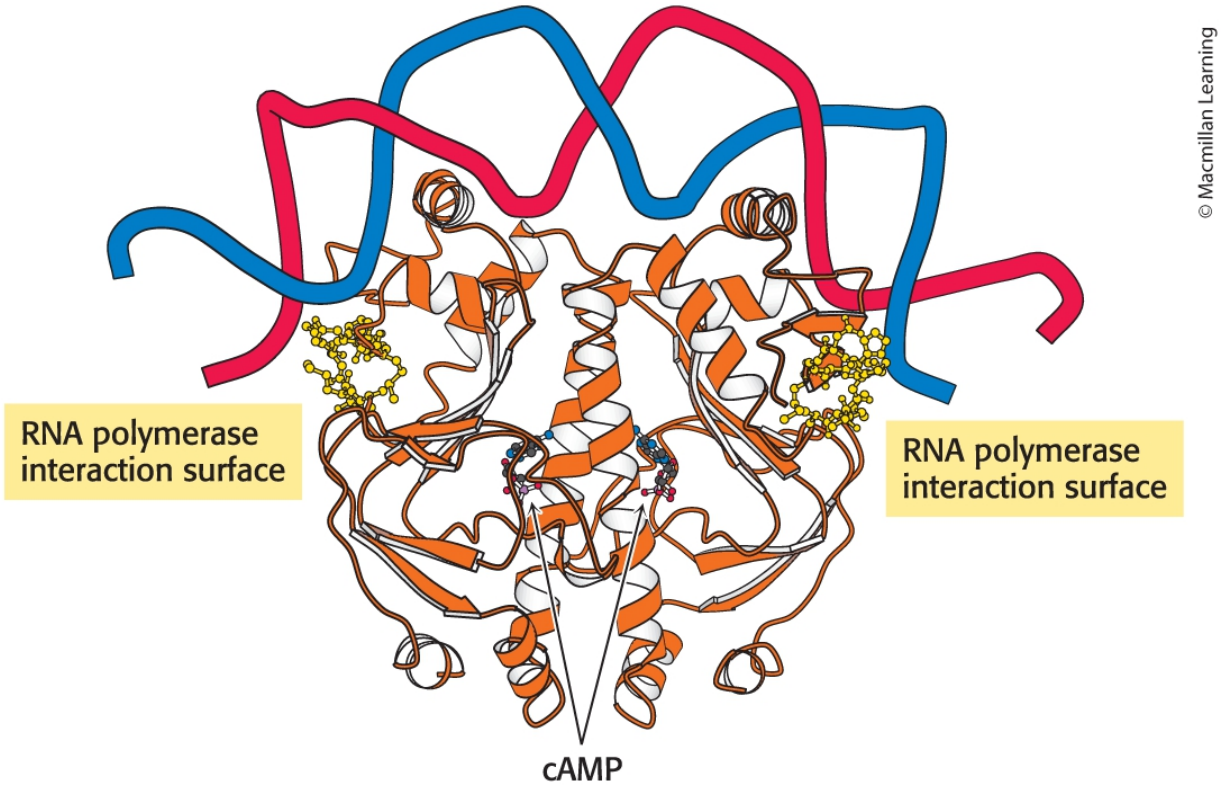
activator protein (CAP) binds to DNA as a dimer

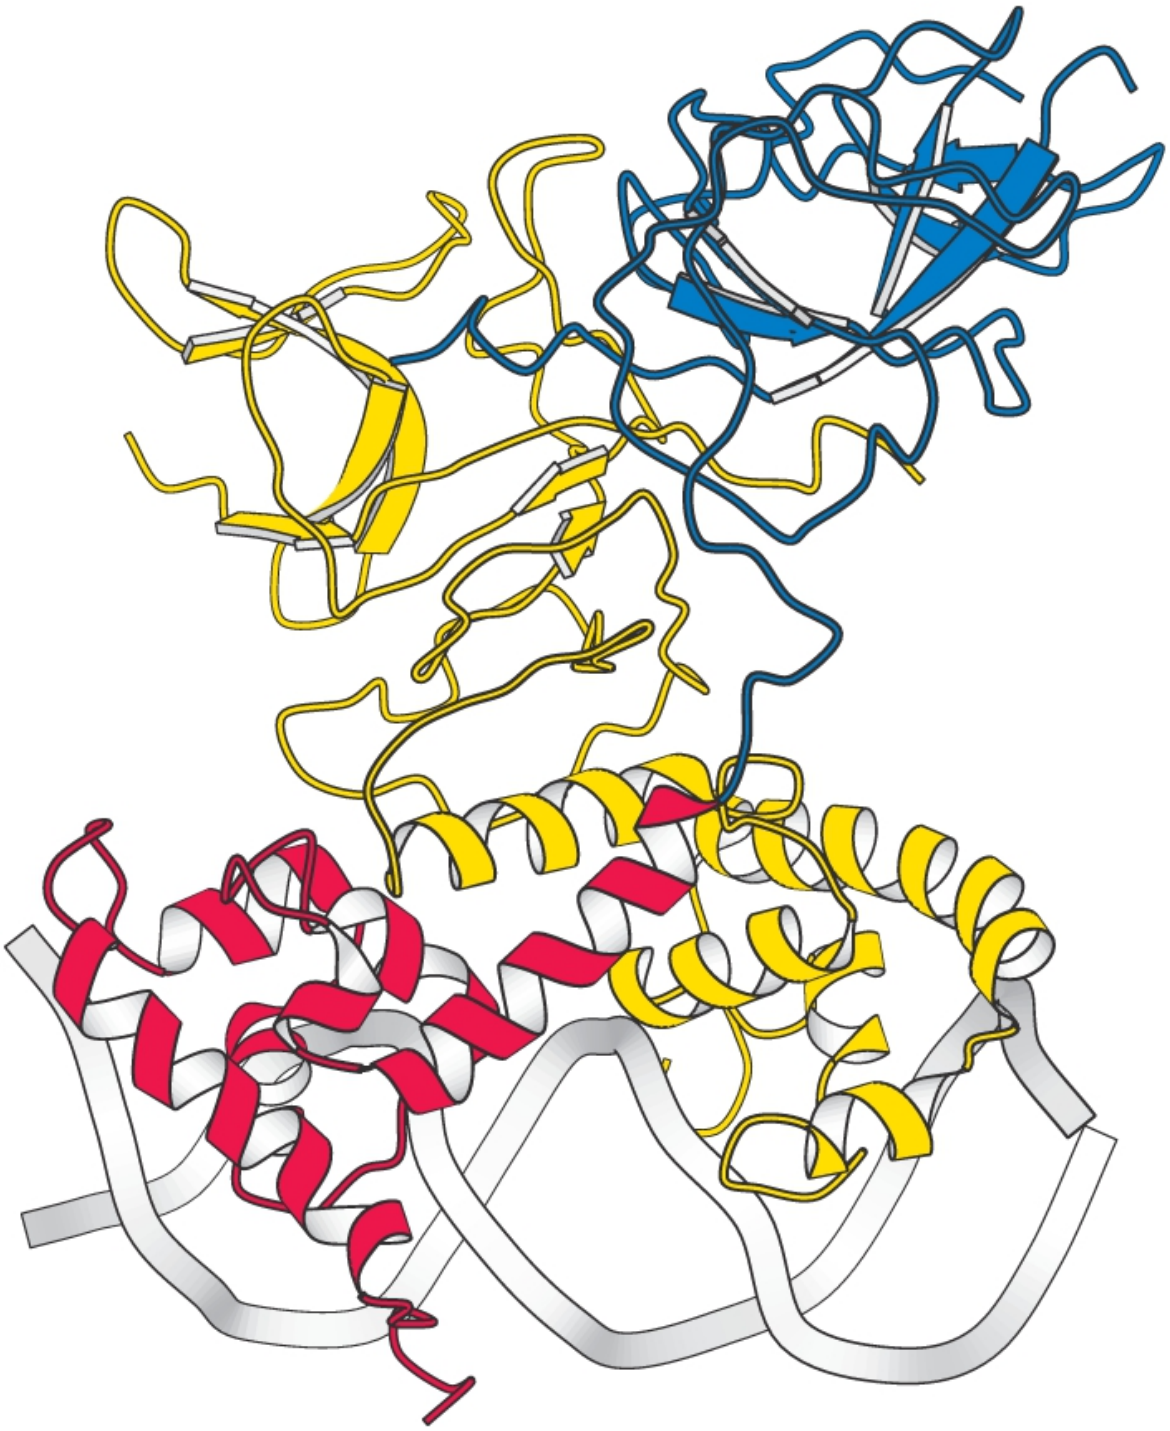


© Macmillan Learning

The figure shows a vertical double helix consisting of red and blue strands wrapped around each other. The upper end of the double helix is attached to two c A M P receptor proteins. c A M P is bound to CAP. R N A polymerase binds to the double helix below the c A M P and it is the site where the transcription starts.

Return to FIGURE 31.12 The catabolite activator protein (CAP) binds to DNA as a dimer

Extended description for The CAP dimer binds to D N A and to R N A polymerase

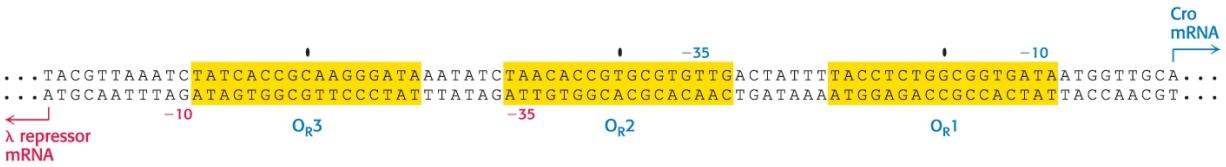


© Macmillan Learning

The figure shows a D N A double helix consisting of red and blue flat-ribbon-like structures at the top. The D N A binds to a CAP dimer at the bottom. The CAP dimer is formed by two CAP monomers. The CAP dimer consists of alpha helices and beta strands. The alpha helices of each monomer consisting of a ball-and-stick model. The region of attachment of the space-filling ball-and stick-model to the alpha helices is labeled R N A polymerase interaction surface. The core of each CAP monomer consists of a space-filling ball-and-stick model with blue and red spheres. These space-filling models are labeled c A M P.

Return to The CAP dimer binds to D N A and to R N A polymerase

Extended description for FIGURE 31.14 The lambda repressor binds to D N A as a dimer



© Macmillan Learning

The figure shows a double-stranded grey-colored D N A in a horizontal orientation. Red and yellow ribbon structures with alpha helices and beta strands are attached to the major groove of the D N A from the top. The red and yellow ribbon structures represent the two subunits of the amino-terminal domain. The alpha helices of the two subunits extend upward and attach to the ribbon diagram with beta strands shown in blue and yellow at the top via loops and turns. The blue and yellow beta strands and the loops represent the carboxyl-terminal domain.

Return to FIGURE 31.14 The lambda repressor binds to D N A as a dimer

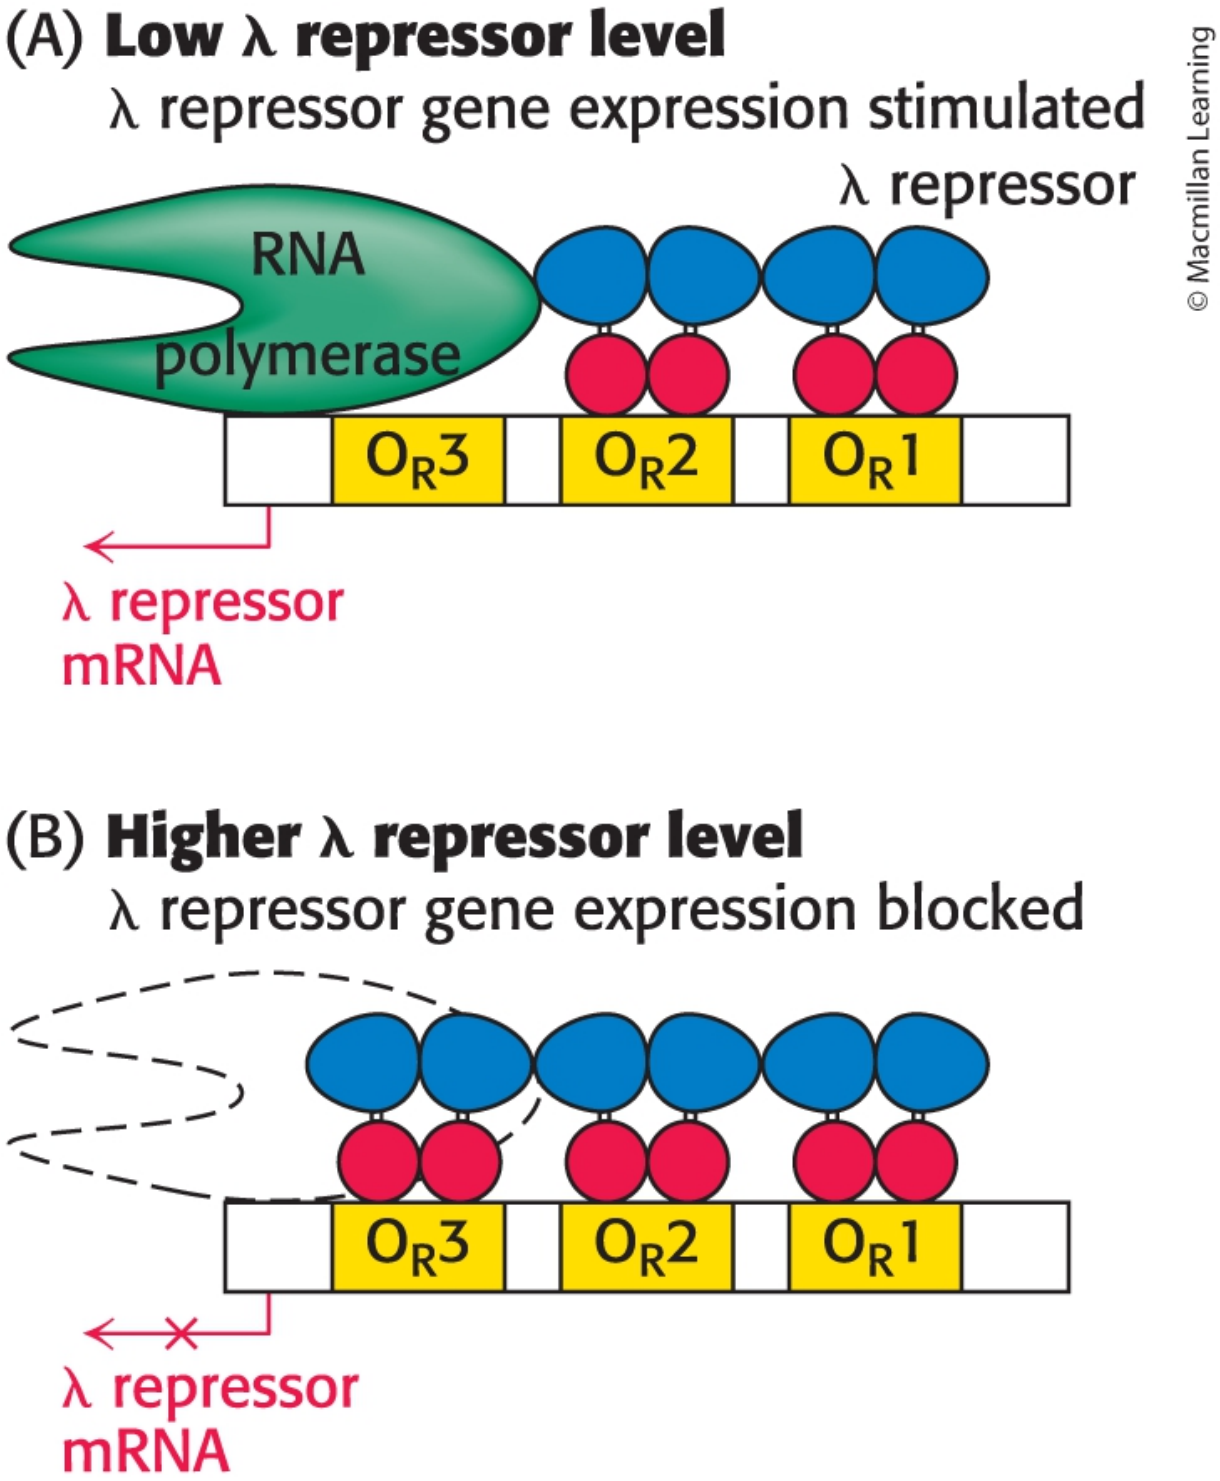
Extended description for FIGURE 31.15 The sequence of the lambda right operator is a binding target for regulatory proteins

The figure shows two sequences.

The sequence of the top strand reads ellipses A T A C G T T A A A T C T A T C A C C G C A A G G G A T A A A T A T C T A A C A C C G T G C G T G T T G A C T A T T T T A C C T C T G G C G G T G A T A A T G G T T G C A ellipses. An arrow from the top strand points toward the right. The arrow is labeled Cro m R N A.

The sequence of the bottom strand reads ellipses A T G C A A T T T A G A T A G T G G C G T T C C C T A T T T A T A G A T T G T G G C A C G C A C A A C T G A T A A A A T G G A G A C C G C C A C T A T T A C C A A C G T ellipses. An arrow from the bottom strand points toward the left. The arrow is labeled lambda repressor m R N A.

The bases from the twelfth position to the twenty-eighth position of both strands are highlighted in yellow and labeled O R 3. The bases from the thirty-fourth position to the fiftieth position of both strands are highlighted in yellow and labeled O R 2. The bases from the fifty-eighth position to the seventy-fourth position of both strands are highlighted in yellow and labeled O R 1.



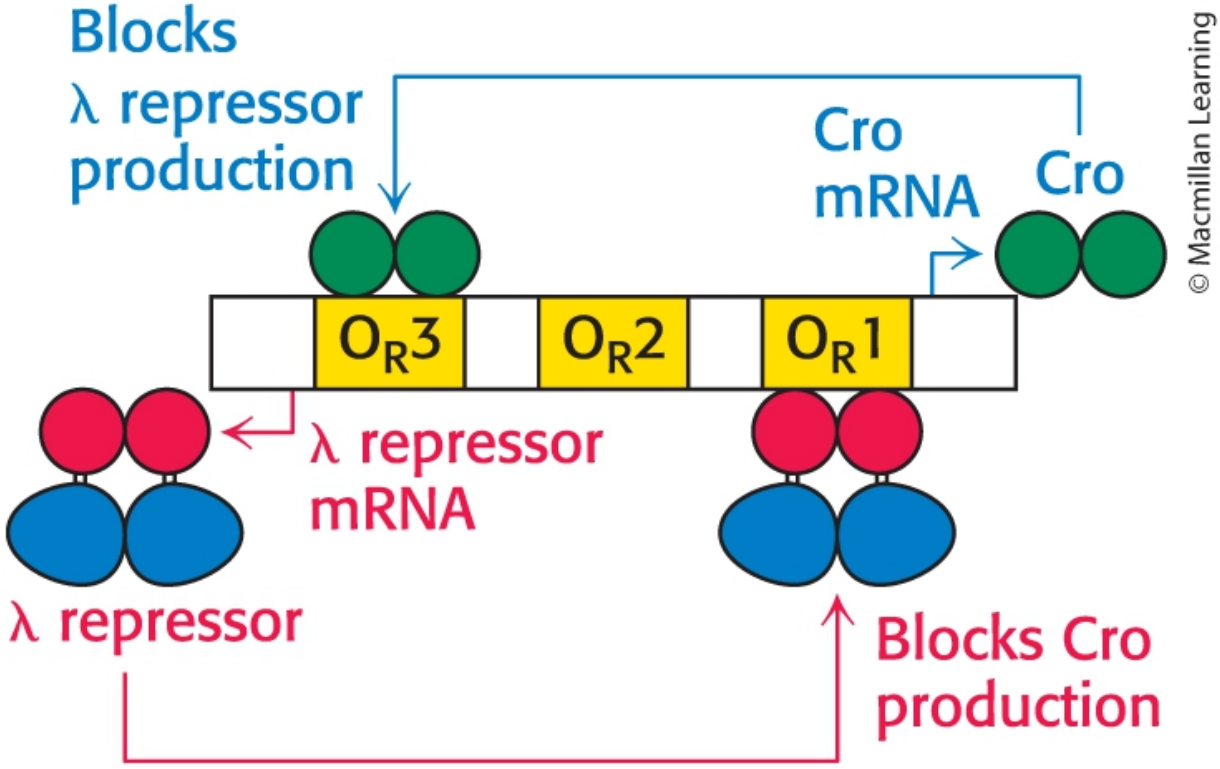
O R 1, O R 2, and O R 3 represent the operator sites. The centers of each of the operator sites are indicated by a small stroke at the top.

The right side of the O R 2 and O R 1 regions of the top strand is labeled negative 35 and negative 10, respectively. The left side of O R 3 and O R 2 regions of the bottom strand are labeled negative 10 and negative 35, respectively.

Return to FIGURE 31.15 The sequence of the lambda right operator is a binding target for regulatory proteins

Extended description for FIGURE 31.16 The lambda

repressor controls its own synthesis



© Macmillan Learning

Part A: Low lambda repressor level: A figure depicts a repressor strand with sequence O R 3-O R 2-O R 1 each depicted as a yellow box in a horizontal set of boxes. A green-colored oval structure with a groove on the left labeled R N A polymerase binds to the site O R 3 at the top. A lambda repressor binds to O R 2 and O R 1. Lambda repressor consists of two red spheres attached to two blue oval-shaped structures at the top. An arrow from the repressor strand pointing toward the left is labeled lambda repressor m R N A. A text at the top reads lambda repressor gene expression stimulated.

Part B: Higher lambda repressor level: The figure shows a repressor strand with sequence O R 3-O R 2-O R 1 each depicted as a yellow box in a horizontal set of boxes. A dotted oval structure with a groove on the left labeled R N A polymerase binds to the site O R 3 at the top. A lambda repressor binds to each O R 3, O R 2, and O R 1 at the top. An arrow from the repressor strand pointing toward the left is cross marked and is labeled lambda repressor m R N A. A text at the top reads lambda repressor gene expression blocked.

Return to FIGURE 31.16 The lambda repressor controls its own synthesis

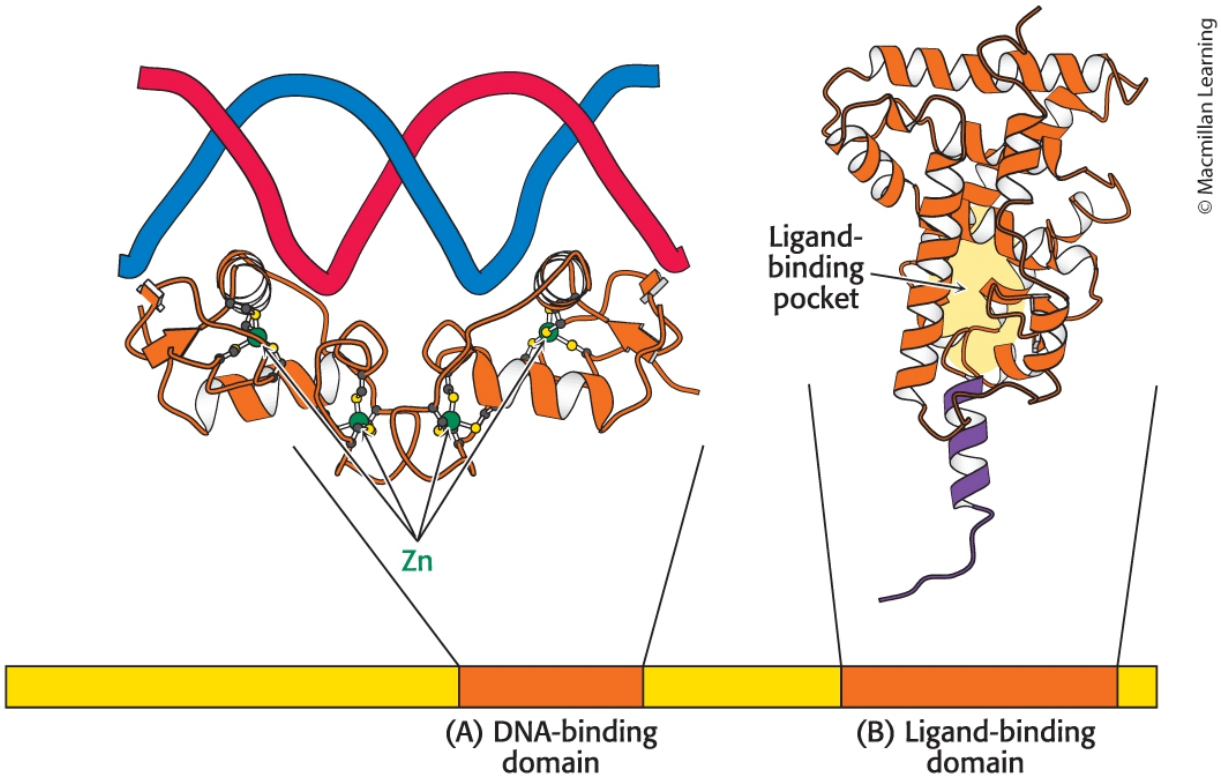
Extended description for Structure of all-trans-retinoic acid (a retinoid) and thyroxine (L-3,5,39,59-tetraiodothyronine) (a thyroid hormone)

All-*trans*-retinoic acid
(a retinoid)



Thyroxine
(L-3,5,3′,5′-Tetraiodothyronine)
(a thyroid hormone)

The structure of the retinoid is as follows: A 6-carbon hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. A double bond is present between C 2 and C 3. C 1 is single bonded to C H 3 on the upper left and C H 3 on the upper right. C 3 is single bonded to C H 3. C 2 is single bonded to C 1 of a 9-carbon alkene chain depicted as a line structure using 8 zigzag lines. In the alkene chain, double bonds are present between C 1 and C 2, C 3 and C 4, C 5 and C 6, and C 7 and C 8. In the alkene chain, C 3 and C 7 are each single bonded to C H 3 above. In the alkene chain, C 9 is double bonded to O above and single bonded to O H on the lower right. The structure of thyroid hormone is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 1 and C 3 are each single bonded to I. C 5 is single bonded to C 1 of a 2-carbon alkane chain depicted as a line structure using 1 wedged line. C 2 of the 2-carbon alkene chain is single bonded to N H 3 superscript plus on the upper left, C O O superscript minus on the lower left, and dash bonded to H on the upper right. C 2 of the benzene ring is single bonded to O. The O

atom is single bonded to C 6 of a second benzene ring in a vertical orientation with C 1 occupying the topmost vertex. The second benzene ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. In the second benzene ring, C 2 and C 4 are each single bonded to I and C 3 is single bonded to O H.

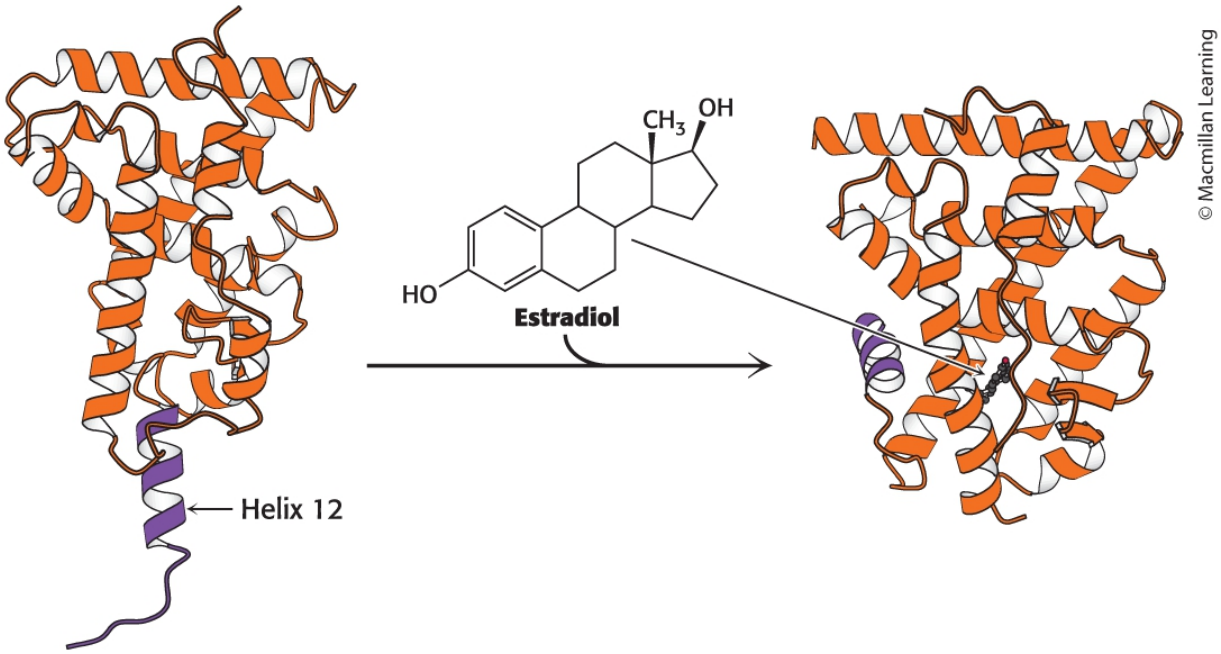
Extended description for FIGURE 31.24 Nuclear hormone receptors contain two important conserved domains

© Macmillan Learning

The figure depicts a nuclear hormone receptor depicted in the form of a horizontal bar. The bar consists of two conserved domains highlighted in orange. The first domain lies toward the center of the horizontal bar while the second domain lies on the right. The first domain is labeled D N A binding domain and the second domain is labeled ligand-binding domain.



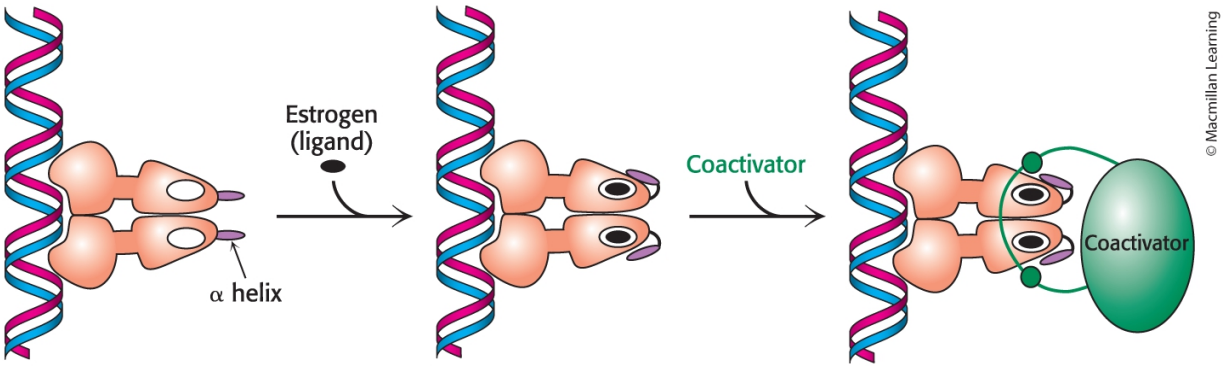
A zoomed-in view from the D N A binding domain on the top shows an orange-colored ribbon structure consisting of alpha helices and beta strands. The ribbon structure is accompanied by a D N A double-helix in a horizontal orientation. The D N A double helix

consists of red and blue flat ribbon-like structures. The ribbon structure is bound to four space-filling ball-and-stick models. Each ball-and-stick model consists of a green sphere along with a few grey and yellow spheres. The green sphere is labeled zinc.

A zoomed-in view from the ligand-binding domain on the top shows two alpha helices. A circular hydrophobic pocket is present at the center of the helices.

Return to FIGURE 31.24 Nuclear hormone receptors contain two important conserved domains

Extended description for FIGURE 31.25 Nuclear hormone receptors interact with ligands



The figure shows an unbound ligand-binding domain of the left. An arrow from the ligand binding domain points to the right to a ligand binding domain bound to an estradiol molecule. The structure of estradiol molecule is shown entering the reaction. In the unbound state, the figure shows two ribbon structures. One ribbon structure consists of orange-colored alpha helices and beta strands while the second ribbon structure consists of a purple colored alpha helix and beta strand. The purple colored alpha helix labeled helix 12 is attached at the bottom. The structure of estradiol is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 5 is single bonded to O H. The benzene ring is fused to a 6-carbon hexagonal ring in a vertical orientation with C 1 occupying the topmost vertex. The two rings are fused such that C 2 and C 3 of the benzene ring are C 6 and C 5 of the

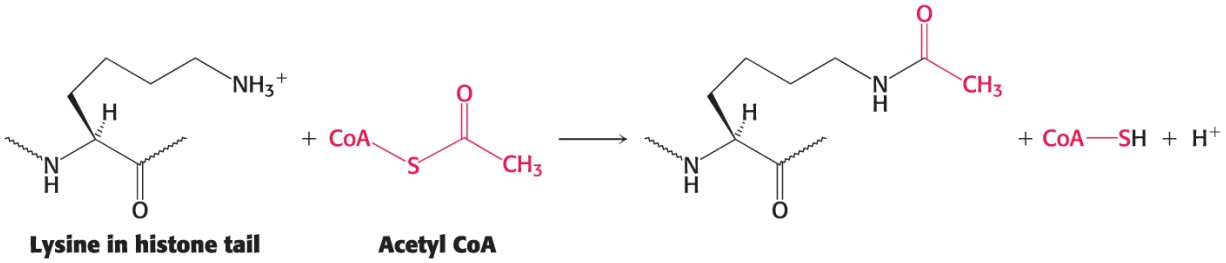
6-carbon hexagonal ring, respectively. In the second 6-carbon ring, C 2 is wedge bonded to O H above. The 6-carbon hexagonal ring is fused to a second 6-carbon hexagonal ring in a vertical orientation with C 1 occupying the topmost vertex. In the second hexagonal ring, C 2 is wedge bonded to C H 3 above The two rings are fused such that C 1 and C 2 of the first 6-carbon ring are C 5 and C 4 of the second 6-carbon ring, respectively. The second 6-carbon ring is fused to a five-membered pentagonal ring in a horizontal orientation with C 1 occupying the rightmost vertex. The two rings are fused such that C 2 and C 3 of the second hexagonal ring are the C 4 and C 3 of the pentagonal ring, respectively. In the pentagonal ring, C 5 is wedge bonded to O H. On the right, an estradiol molecule is bound to the ligand binding domain. In the bound state, the figure shows an estradiol molecule bound to two ribbon structures. One ribbon structure consists of orange-colored alpha helices and beta strands while the second ribbon structure consists of a purple colored alpha helix and beta strand. The purple colored alpha helix labeled helix 12 is attached to the left of the orange-colored alpha helices. A space-filling model of estradiol is attached to the core of the ribbon structure.

Return to FIGURE 31.25 Nuclear hormone receptors interact with ligands

Extended description for FIGURE 31.26 Nuclear hormone receptors recruit coactivators upon ligand binding

© Macmillan Learning

The process is given in a series of three sequential steps. In the first step, a vertical double helix consists of red and blue flat ribbon-like structures wrapped around each other. The vertical double helix consists of two receptors on the right. Each receptor consists of an irregularly oval structure on the left that continues on the right as a triangular head with a constriction. The triangular head consists of an oval-shaped ligand binding site. Each receptor is attached to a short oval-shaped structure on the right labeled alpha helix.



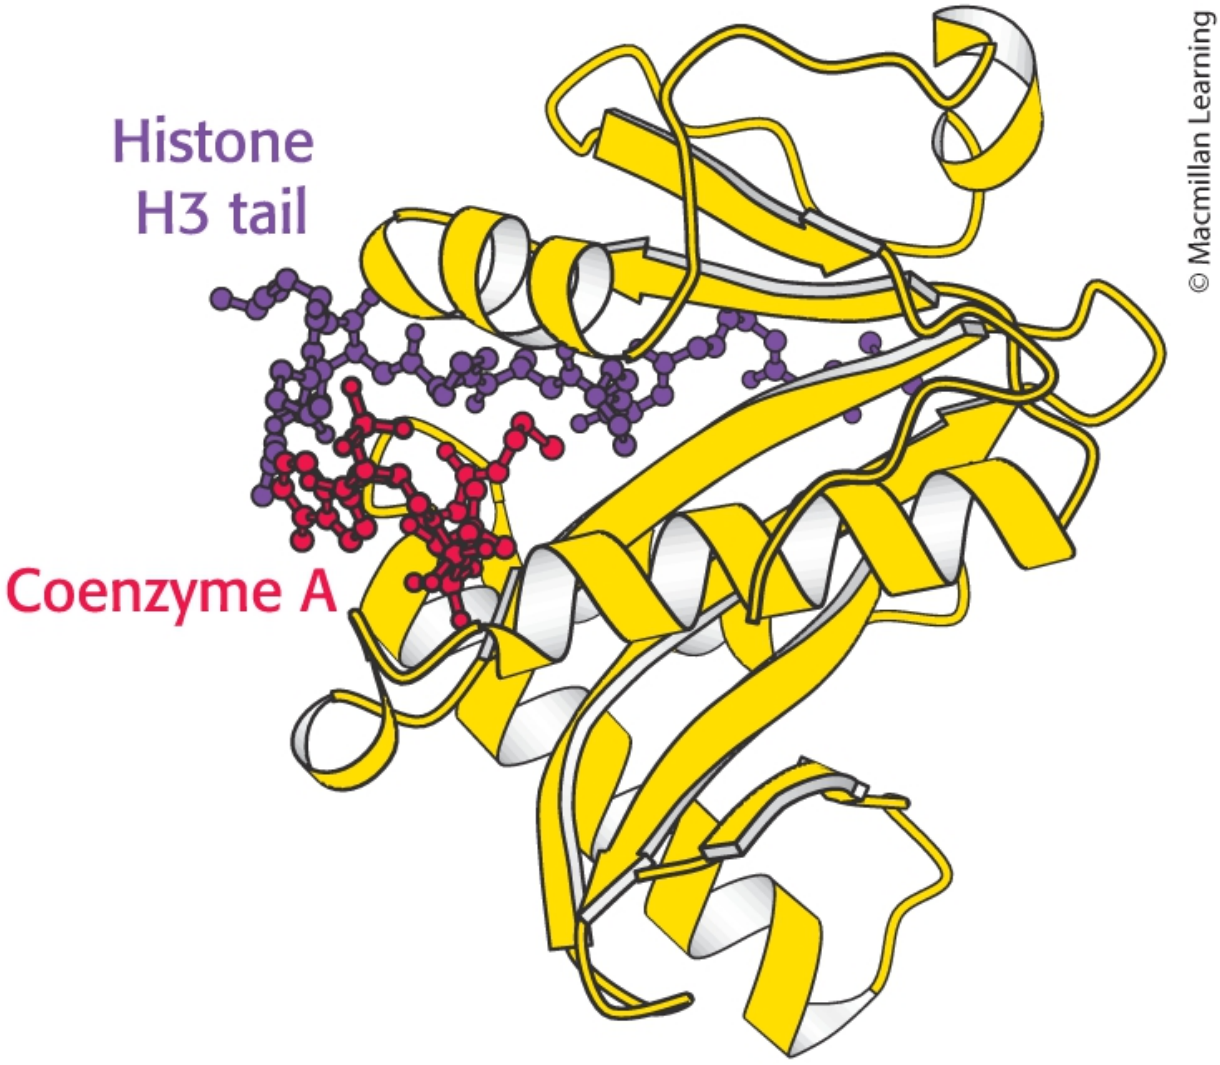
An arrow from the first step points to the second step. The arrow depicts the entry of an oval-shaped structure labeled estrogen or ligand.

In the second step, the estrogen binds to the ligand-binding site of the receptor. This induces a conformational change in the alpha helix. The alpha helix bends and attaches to the sides of the triangular heads.

An arrow from the second step points to the third step. The arrow depicts the binding of the coactivator to the receptors. In the third step, an oval-shaped structure labeled coactivator is present on the right side of the receptor. A loop-like structure from the coactivator attaches to the receptor. The loop consists of two bead-like structures.

Return to FIGURE 31.26 Nuclear hormone receptors recruit coactivators upon ligand binding

Extended description for A chemical reaction



Lysine in histone tail Acetyl CoA

Lysine in histone tail reacts with acetyl C o A to give rise to three products. The structure of lysine in histone tail is as follows: A 4-carbon alkane chain is depicted as line structure using 3 zigzag lines. C 4 is single bonded to N H 3 superscript minus on the lower right. C 1 is wedge bonded to C 1 of a 2-carbon alkane chain depicted as a line structure using a line. C 1 of the second alkane chain is dash bonded to H on the upper right and single bonded to N H on the lower left. This N H has an open wavy bond on the upper left. C 2 is double bonded to O below and has an open wavy bond on the upper right. The structure of acetyl C o A highlighted in red is as follows: A central C atom is double bonded to O above. C is single bonded to C H 3 on the lower right and S on the lower left. S is further single bonded to C o A on the upper left. The structure of the first product is as follows: A 1 N and 5 C heteronuclear alkane chain is depicted as a line structure using 5 zigzag lines. N bound to H occupies the fifth position. C 5 is double bonded to O above and single bonded to C H 3 on the lower right, both of which are highlighted in red. C 1 is wedge bonded to C 1 of a 2-carbon alkane chain depicted as a line structure using a line. C 1 of the second alkane chain is dash bonded to H on the upper right and single bonded to N H on the lower left. This N H has an open wavy bond on the upper left. In the second alkane chain, C 2 is double bonded to O below and has an open wavy bond on the upper right. The second

product is C o A, single bond, S H, in which except for H the rest are highlighted in red. The third product is H superscript plus.

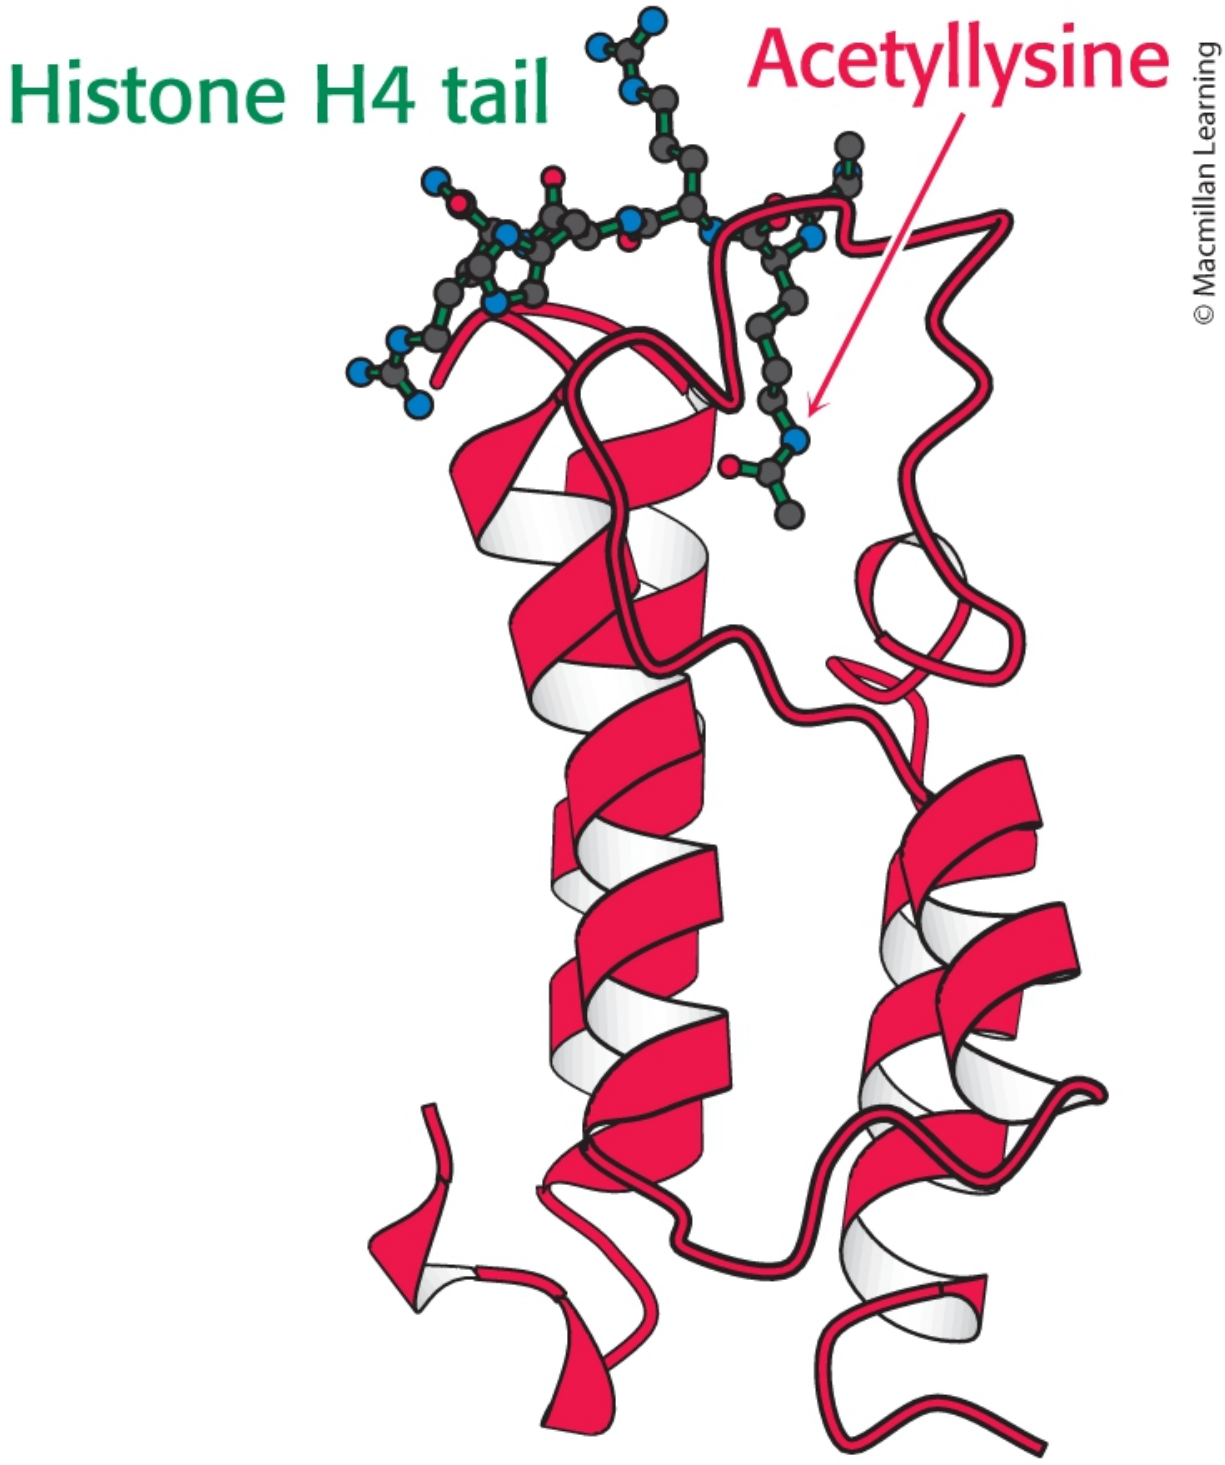
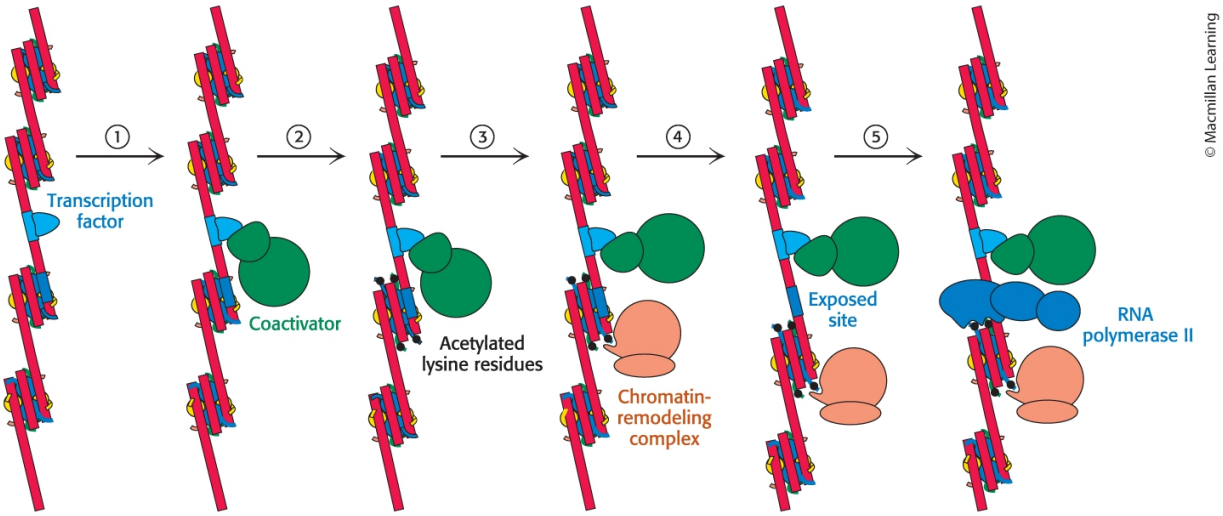
Extended description for FIGURE 31.27 Histone acetyltransferase modifies histone tails



© Macmillan Learning

The ribbon structure consists of three alpha helices and beta strands interconnected by thread-like structures. A ball-and-stick model of purple-colored histone H 3 tail is attached to the amino-terminal domain of the histone acetyltransferase. The ball-and-stick model of the histone H 3 tail is attached to another space-filling ball-and-stick model of red-colored coenzyme A.

Return to FIGURE 31.27 Histone acetyltransferase modifies histone tails



Extended description for FIGURE 31.28 Bromodomains interact with acetyllysine

The ribbon structure consists of four vertical alpha helix bundles interconnected by thread-like structures of loops and turns. The upper end of the helix bundles is attached to ball-and-stick models of histone H 4 tail and acetyllysine.

Return to FIGURE 31.28 Bromodomains interact with acetyllysine

Extended description for FIGURE 31.29 Gene regulation can involve chromatin remodeling

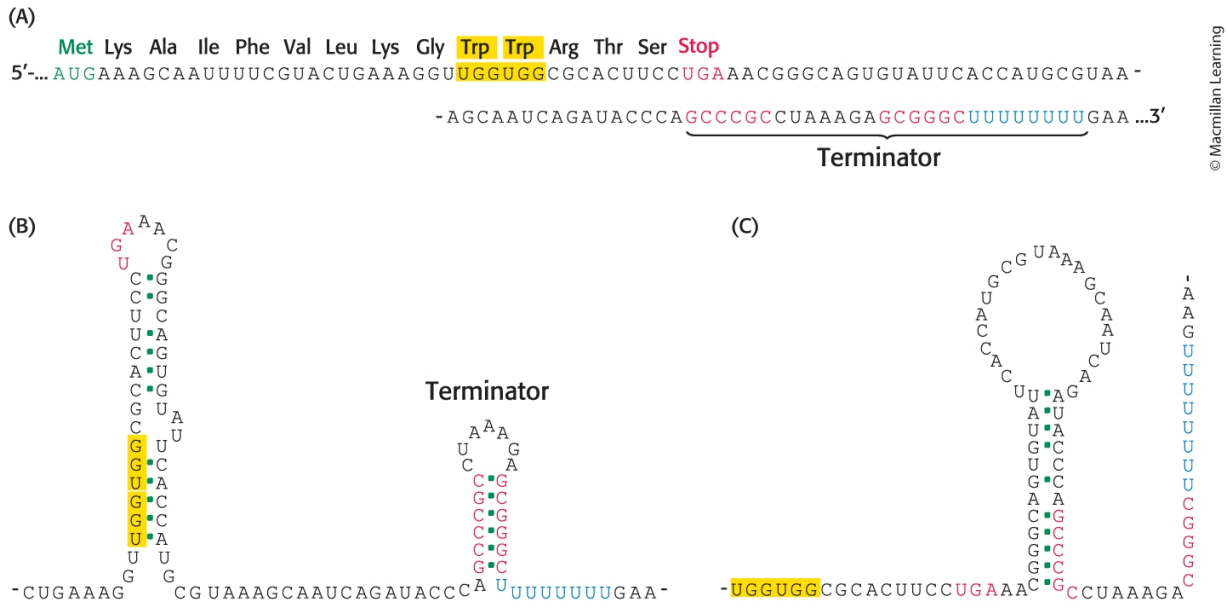
In the first step, chromatin strands are packaged in such a way that it appears vertically with four monomeric nucleotides arranged in vertical series. Each unit is composed of 2 small blue spheres combined with two yellow spheres without any protrusions. From top to bottom between the second and third monomeric unit, an irregular triangular structure is attached and is labeled transcription factor. An arrow numbered 1, from the first step, points to the second step.

In the second step, two green-colored spheres are attached to the transcription factor. One sphere is smaller than the other. These spheres represent the coactivator.

An arrow numbered 2, from the second step, points to the third step.

In the third step, black spherical protrusions are seen in the third monomeric unit. These black spheres represent the acetylated lysine residues.

An arrow numbered 3, from the third step, points to the fourth step.



In the fourth step, two subunits consisting of two spheres are attached to the third monomeric unit. The first subunit is larger than the second one. The subunits are labeled chromatin-remodeling complex.

An arrow numbered 4, from the fourth step, points to the fifth step.

In the fifth step, a short fragment from the chromatin between the second and third monomeric units is exposed. This fragment is labeled exposed site. An arrow numbered 5, from the fifth step, points to the sixth step. In the sixth step, R N A polymerase roman numeral I I is attached to the exposed site. R N A polymerase roman numeral I I consists of three irregular spherical subunits.

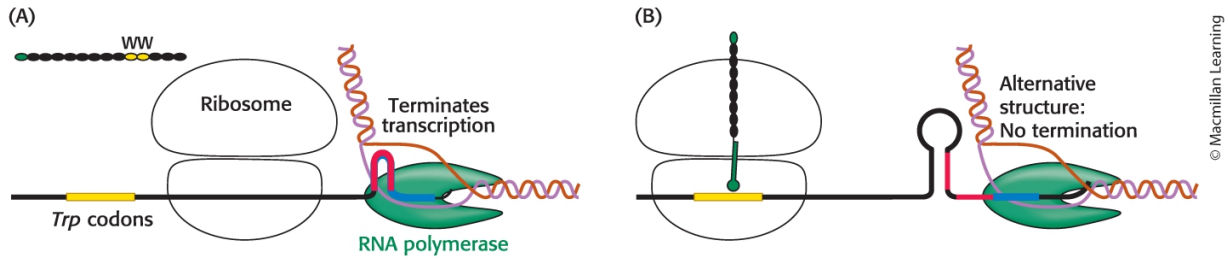
Part A shows a nucleotide sequence in 5 prime to 3 prime direction. The nucleotide sequence reads A U G A A A G C A A U U U U C G U A C U G A A A G G U U G G U G G C G C A C U U C C U G A A A C G G G C A G U G U A U U C A C C A U G C G U A A A G C A A U C A G A U A C C C A G C C C G C C U A A A G A G C G G G C U U U U U U U U U G A A. The nucleotide sequence of the 5 prime ends of t r p m R N A encodes a peptide comprising 14 amino acids which include methionine, lysine, alanine, isoleucine, phenylalanine, valine, leucine, lysine, glycine, tryptophan, tryptophan, arginine, threonine, and serine followed by a stop codon which is U G A. The part of the sequence A G C A A U C A G A U A C C C A G C C C G C C U A A A G A G C G G G C U U U U U U U U U is labeled terminator.



Part B shows the formation of two stem loops in the attenuator region. The first stem-loop is formed from the peptide comprising the 14 amino acid sequences such that the stop codon forms the

peak of the stem loop. The loop then moves down becomes horizontal and again shows a smaller stem loop that is formed from the terminator sequence. The loop again moves down and becomes horizontal in the U U U U U U U U sequence.

Part C shows the formation of a single stem loop. The nucleotide sequence remains horizontal up to the stop codon, rises upward to form the stem-loop, moves down at the terminator nucleotide becomes horizontal for about 8 bases and again rises upward and terminates on the top right.

Return to FIGURE 31.30 The leader region of t r p m R N A includes tryptophan codons

Extended description for FIGURE 31.31 Attenuation regulates transcription

Part A shows a horizontal nucleotide consisting of t r p codons on the left and a stem loop on the right. A ribosome consisting of two oval-shaped subunits is present between the t r p codons and the stem loop. The lower subunit lies on the nucleotide sequence. On the right side of the stem loop, R N A polymerase is present. The R N A polymerase is an oval-shaped structure with a groove on the right. A double helix starts from the region above the stem loop, moves down, makes a larger loop, and terminates on the right side of the R N A polymerase. A text above the nucleotide reads terminates transcription. A horizontal beaded strand with 14 beads is present above the t r p codons. The first bead is green, the eleventh and twelfth beads are yellow, and the rest of the beads are green. The yellow beads are labeled W W.

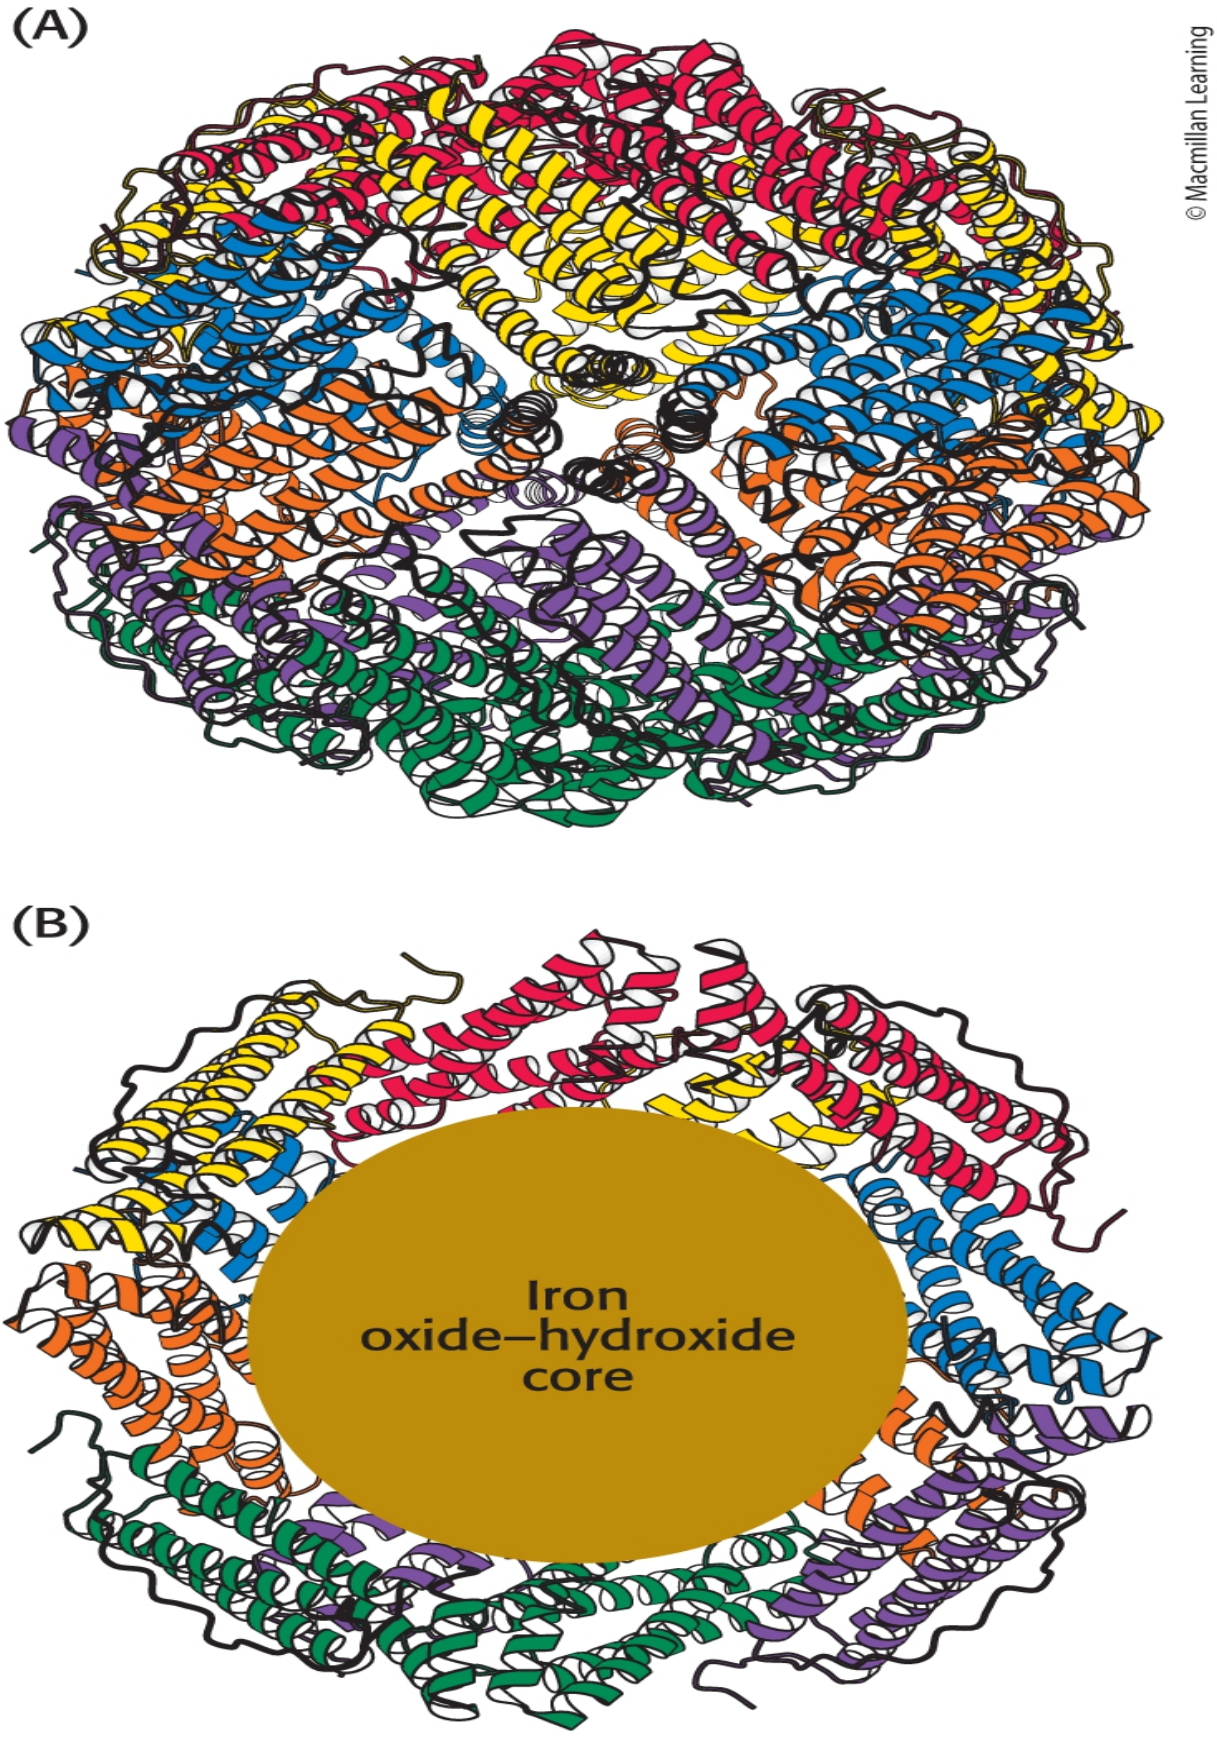
Part B shows a vertical beaded structure above the t r p codons. A ribosome is found occupying the t r p codons site. A green bead with a long tubular extension above is in contact with the lower subunit of the ribosome and about 10 beaded structures are arranged along the length of the large subunit of the ribosome. Out of 10, 9 are black beads, and the tenth bead is green which is located outside the larger subunit of the ribosome. At the right end, a stem-loop is seen where the right half of the loop is seen with alternating pink strands, post which R N A polymerase is seen bound to. The R N A

polymerase is an oval-shaped structure with a groove on the right. A double helix starts from the region above the stem loop, moves down, makes a larger loop, and terminates on the right side of the R N A polymerase. A text above the nucleotide reads alternative structure: no termination.

Return to FIGURE 31.31 Attenuation regulates transcription

Extended description for FIGURE 31.32 The leader sequences of several operons contain codons for the specific amino acid that they regulate

Part A shows the leader sequence of the threonine operon. The nucleotide sequence of threonine operon in 5 prime to 3 prime direction reads A U G A A A C G C A U U A G C A C C A C C A U U A C C A C C A C C A U C A C C A U U A C C A C A. The nucleotide sequence codes for the following amino acids: methionine, lysine, arginine, isoleucine, serine, threonine, threonine, isoleucine, threonine, threonine, threonine, isoleucine, threonine, isoleucine, threonine, and threonine.



Part B shows the leader sequence of the phenylalanine operon. The nucleotide sequence of phenylalanine operon in 5 prime to 3 prime direction reads A U G A A A C A C A U A C C G U U U U U U C G C A U U C U U U U U U U A C C U U C C C C U G A. The nucleotide sequence codes for the following amino acids: methionine, lysine, histidine, isoleucine, proline, phenylalanine, phenylalanine, phenylalanine, alanine, phenylalanine, phenylalanine, phenylalanine, threonine, phenylalanine, proline, followed by a stop codon.

Part C shows the nucleotide sequence of the histidine operon. The nucleotide sequence of histidine operon in 5 prime to 3 prime direction reads A U G A C A C G C G U U C A A U U U A A A C A C C A C C A U C A U C A C C A U C A U C C U G A C. The nucleotide sequence codes for the following amino acids: methionine, threonine, arginine, valine, glutamine, phenylalanine, lysine, histidine, histidine, histidine, histidine, histidine, histidine, histidine, proline, and aspartic acid.

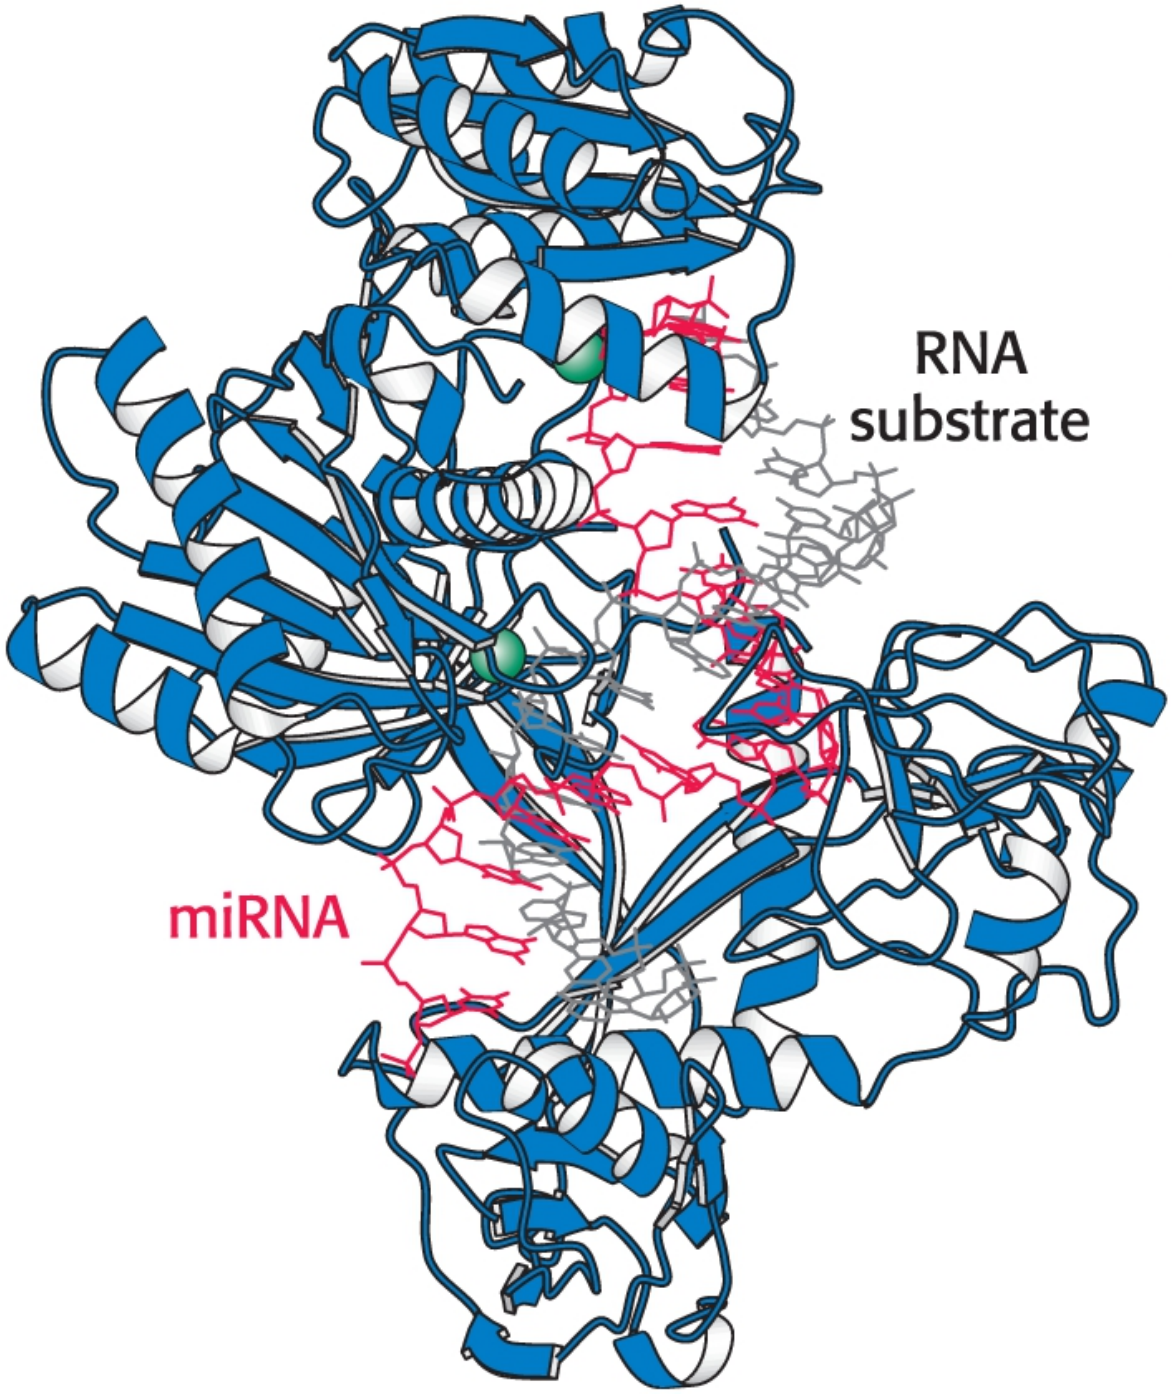
Extended description for FIGURE 31.36 The I R P is an aconitase

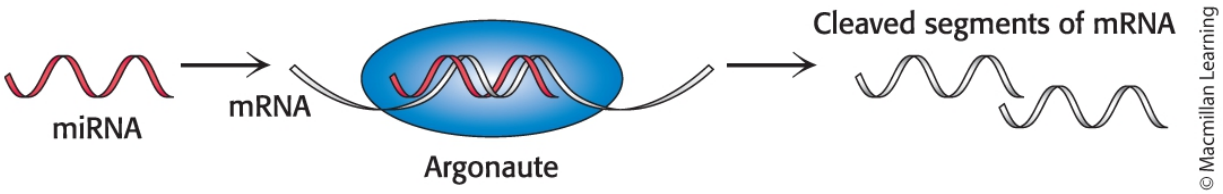


Part A shows a ribbon structure forming a cluster of alpha helices and beta strands. The core of the ribbon structure consists of a ball-and-stick model of 4 F e to 4 S cluster.

Part B shows the binding and dissociation of 4 F e 4 S clusters to aconitase under high and low iron conditions. Aconitase is depicted as a bean-shaped structure with a concavity on the left. Under high-iron conditions, a 4 F e 4 S cluster attaches to the concave side of the aconitase. Under low-iron conditions, a ribbon-like structure attaches to the concave side of the aconitase.

Return to FIGURE 31.36 The I R P is an aconitase

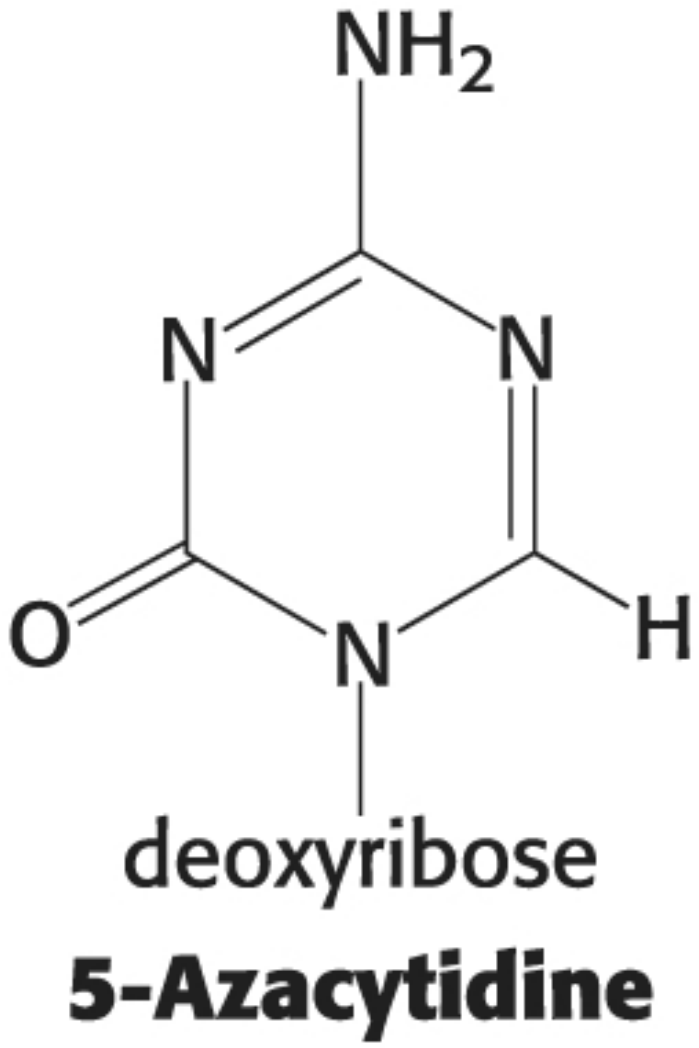
Extended description for FIGURE 31.37 Micro R N A s bind to the Argonaute complex



© Macmillan Learning

The figure shows a ribbon structure of an argonaute complex forming two clusters. The clusters are composed of alpha helices and beta strands joined by loops and turns. Thin ribbon strands representing m i R N A are shown in red and R N A substrate is shown in grey along with two magnesium ions. The magnesium ions are represented as green spheres found bound to the argonaute complex.

Return to FIGURE 31.37 Micro R N A s bind to the Argonaute complex



Extended description for FIGURE 31.38 Micro R N A–Argonaute complexes target specific m R N A molecules for cleavage

In the first step, a red-colored single-stranded, coiled, ribbon-like structure labeled m i R N A is shown. An arrow from the first step points to the second step. In the second step, an oval-shaped structure with the m i R N A from the first step is labeled argonaute. Argonaute consists of a white-colored single-stranded ribbon-like structure protruding outside from either side. The white-colored ribbon-like structure is labeled m R N A. The m i R N A binds to the m R N A inside the Argonaute. An arrow from the second step points to the third step. In the third step, two cleaved segments of m R N A are shown as small fragments of two white-coiled, single strands.

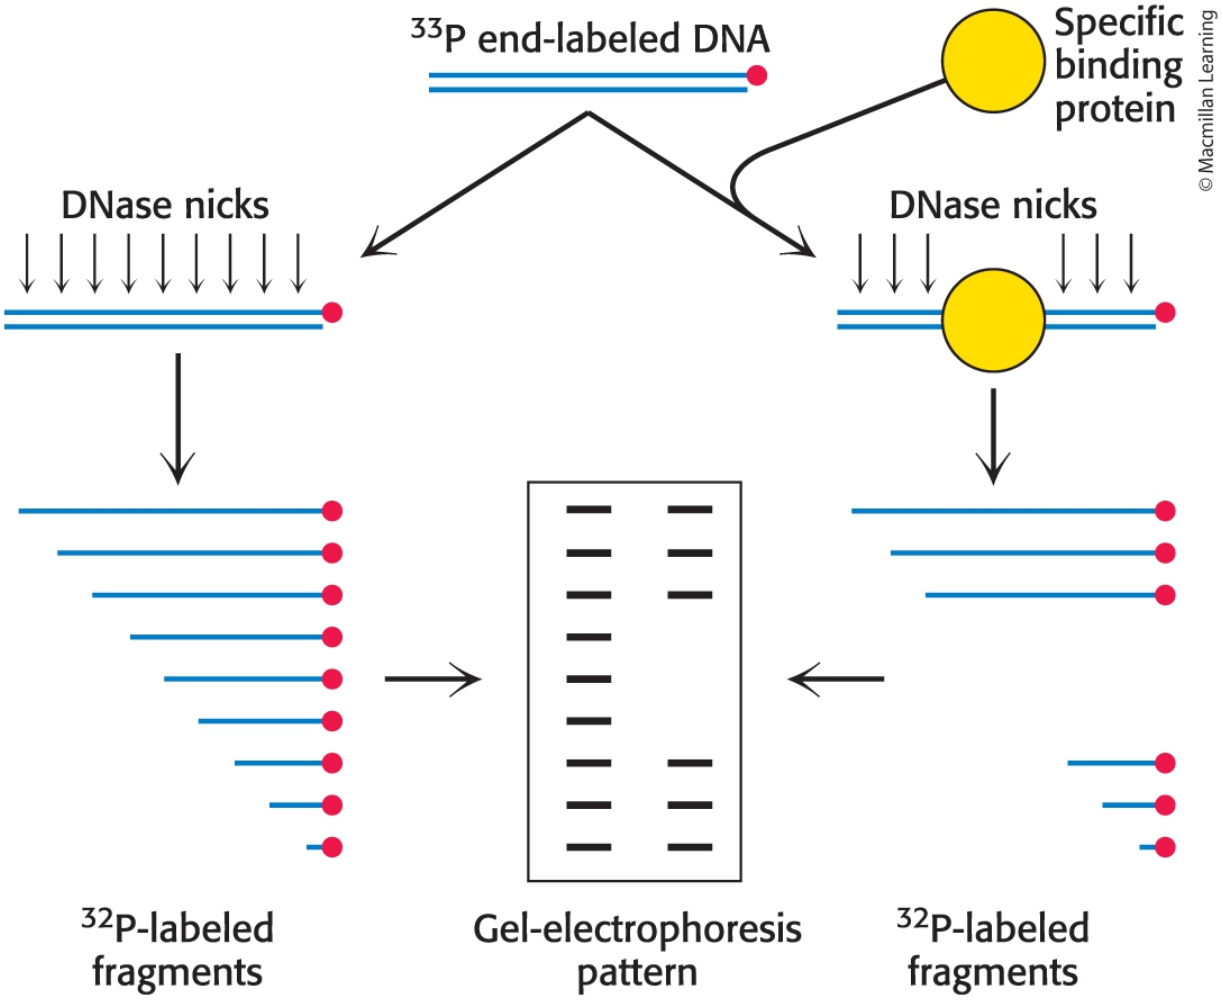
Extended description for Structure of 5-azacytidine



The structure of 5-azacytidine is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation and consists of 3 N and 3 C atoms. The first N atom occupies the first position which is the bottommost vertex, the second N atom occupies the third position which is the top left vertex, and the third N atom occupies the fifth position which is the top right vertex. Double bonds are present between the second N atom and C 2, and the third N atom and C 3. C 2 is single bonded to N H 2, C 3 is single bonded to

H, and C 1 is double bonded to O. The first N atom is single bonded to deoxyribose below.

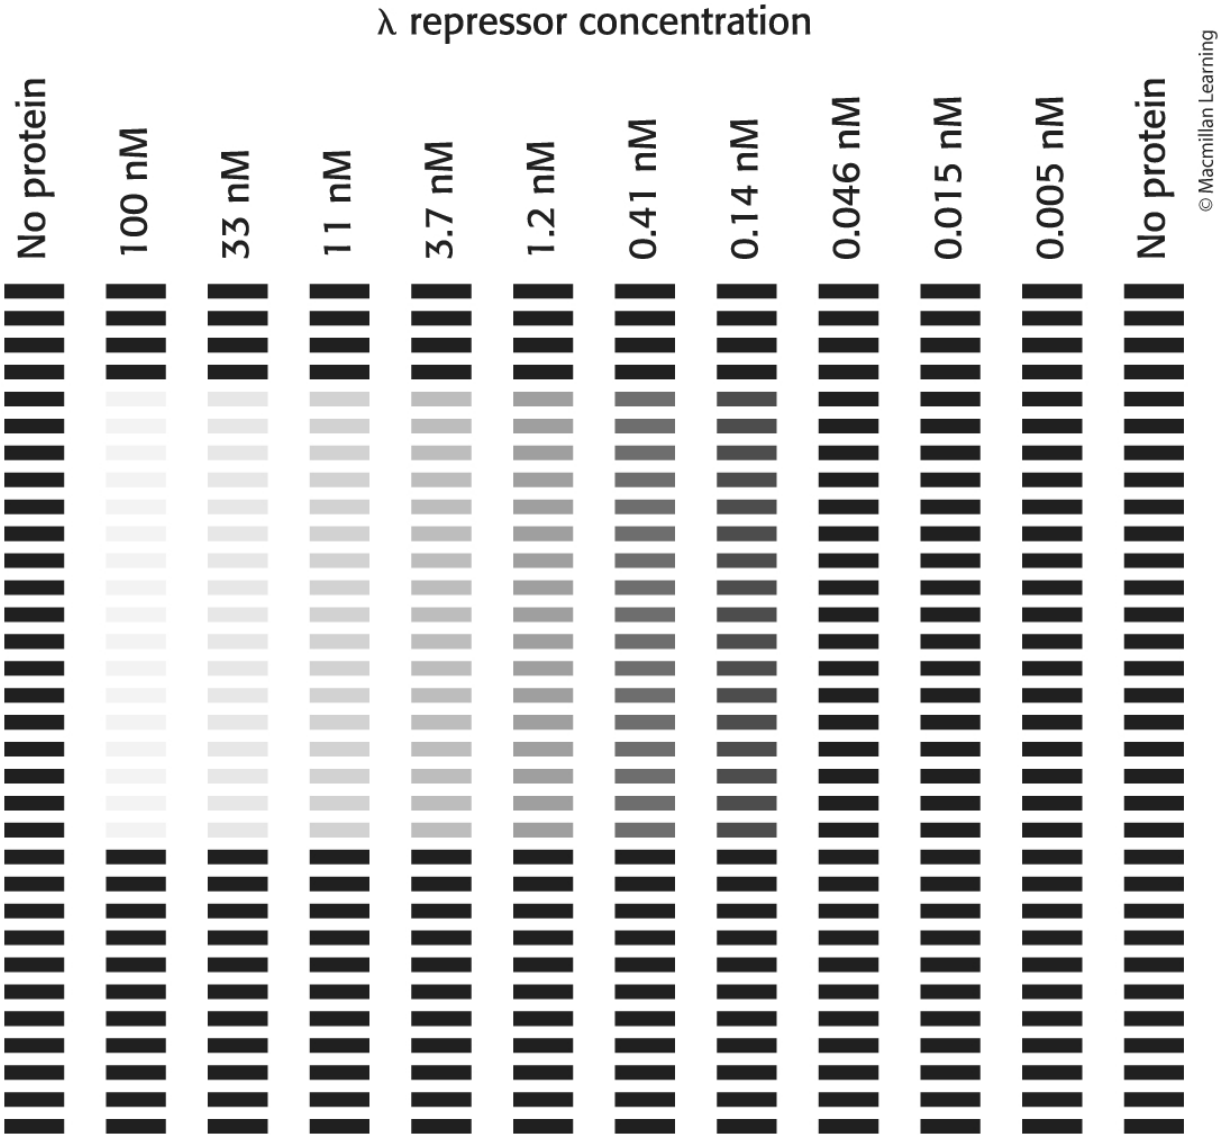
Extended description for Patterns of D N A fragments in Gel electrophoresis



The figure depicts a double-stranded D N A labeled superscript 33 baseline uppercase P end-labeled D N A. The strand at the top is attached to a red sphere on the right. The bottom strand does not have any sphere. A bifurcated arrow from the double-stranded D N A points down. On the left, the top strand of D N A is subjected to nicks by the enzyme D N ase in the absence of proteins. On the right, the bottom strand of D N A is subjected to nicks by the enzyme D N ase in the presence of a specific binding protein. In the absence

of proteins, the top strand of D N A is broken down into 9 fragments labeled superscript 32 baseline uppercase P- labeled fragments. The fragments are depicted as horizontal lines from top to bottom. The fragment size decreases from top to bottom such that the first strand is the longest and the ninth strand is the shortest. Each fragment is attached to a red sphere on the right. In the presence of a specific binding protein, the top strand of D N A is broken down into 6 fragments labeled superscript 32 baseline uppercase P- labeled fragments. The fragments are depicted as horizontal lines from top to bottom. The fragment size decreases from top to bottom such that the first strand is the longest and the sixth strand is the shortest. Each strand is attached to a red sphere on the right. The cleaved D N A fragments are subjected to gel electrophoresis. The gel electrophoresis plate has two lanes. The first lane consists of 9 fragments placed one below the other continuously. The second lane consists of 6 fragments. The first three fragments are present at the top and the other three fragments are present at the bottom.

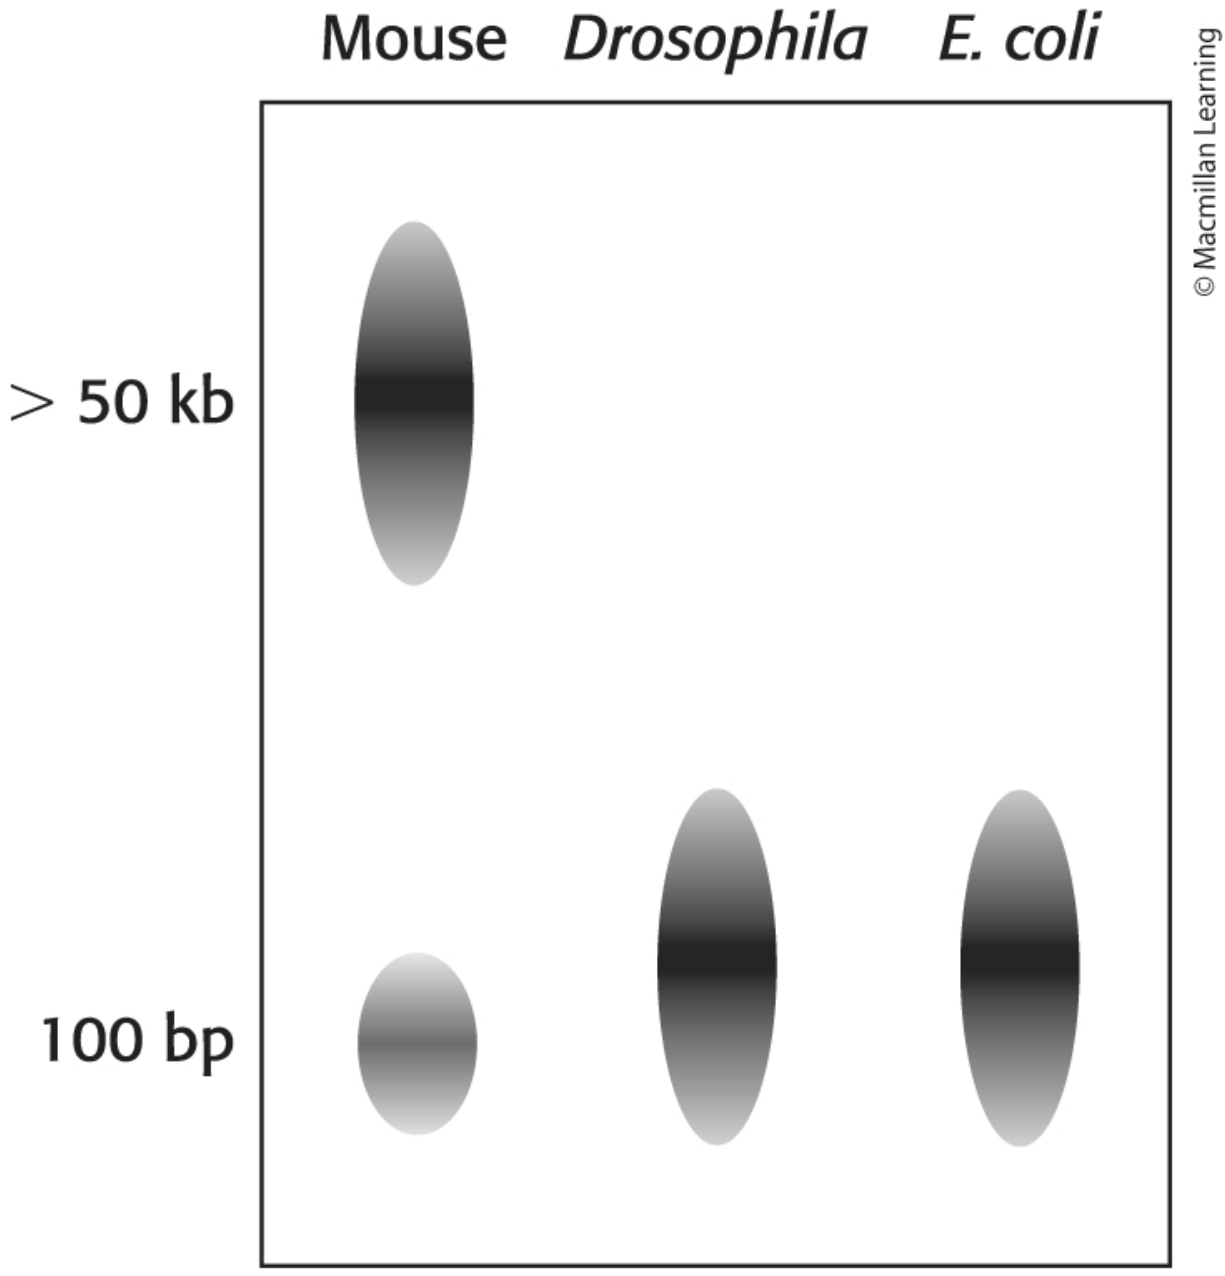
Extended description for Autoradiograph of lambda repressor concentration



The autoradiograph shows twelve columns and thirty-two rows. The column headings from left to right are no protein, 100 n M, 33 n M, 11 n M, 3.7 n M, 1.2 n M, 0.41 n M, 0.14 n M, 0.046 n M, 0.015 n M, 0.005 n M, and no protein. The column headings have a common title as lambda repressor concentration. Each column consists of 32

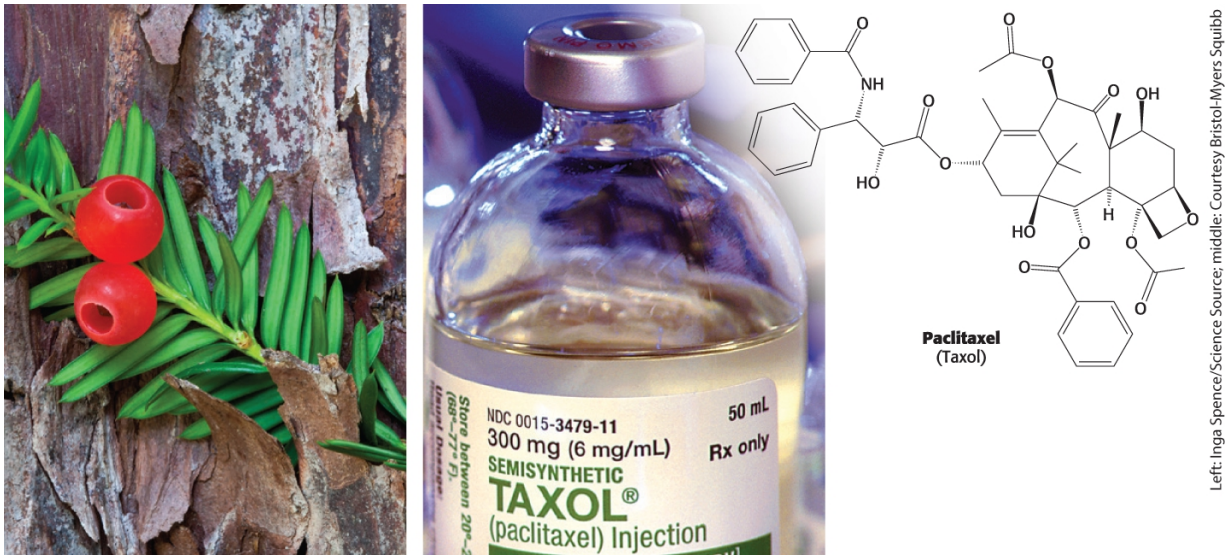
fragments. The second, third, fourth, fifth, sixth, and seventh columns have light-colored bands between rows five to twenty-one. The rest of the bands in all other rows have dark fragments.

Return to Autoradiograph of lambda repressor concentration

Extended description for Gel electrophoresis showing results of D N A from different organisms treated with H p a 2

The gel electrophoresis consists of three lanes. The first lane is labeled mouse, the second lane is labeled *Drosophila*, and the third lane is labeled *E. coli*. The gel electrophoresis plate shows two rows. The first row is labeled greater than 50 k b and the second row is labeled 100 b p.

The row entries are as follows.



Row Lesser than 50 k b: Mouse lane: A thick horizontal fragment inside a sphere. *Drosophila* and *E. coli* lanes are blank.

Row 100 b p: Mouse lane: A small sphere has a thin horizontal fragment inside.

Drosophila lane: A large sphere has a thick horizontal fragment inside. *E. coli* lane: A large sphere has a thick horizontal fragment inside.

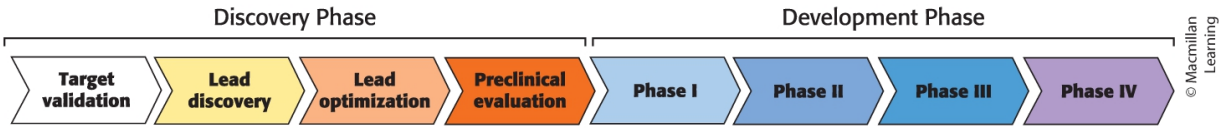
Extended description for Structure of Paclitaxel



The structure is as follows: A benzene ring is in a vertical orientation with C 1 occupying the rightmost vertex. The ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 is single bonded to C 1 of a 1 N and 4 C heteronuclear alkane chain is depicted as a line structure using 4 zigzag lines. In the alkane chain, N bound to H occupies the second position. In the alkane chain, a dash bond is present between N H and C 2. C 1 of the alkane chain is double bonded to O on the upper right. C 2 of the alkane chain is single bonded on the lower left to C 2 of a second ring in a vertical orientation with C 1 occupying the topmost vertex. The second benzene ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 3 of the alkane chain is dash bonded to O H on the lower left. C 4 of the alkane chain is double bonded to a second O atom on the upper right and is single bonded to a third O atom on the lower right. The third O atom is dash bonded on the right to C 4 of a 6-carbon hexagonal ring in a horizontal orientation with C 1 occupying the rightmost vertex. In the 6-carbon ring, a double bond is present

between C 5 and C 6. C 5 of the 6-carbon ring is single bonded to C H 3 in the form of a line. C 1 of the 6-carbon ring is single bonded to C H 3 on the upper right and C H 3 on the lower right, each in the form of a line. C 2 of the 6-carbon ring is wedge bonded to O H on the lower left and is single bonded to a central C atom on the lower right in the form of a line. The central C atom is dash bonded to a fourth O atom on the lower right. The fourth O atom is single bonded to a second central C atom on the lower left in the form of a line. The second central C atom is double bonded to a fifth O atom on the upper left and is single bonded on the lower right to C 5 of a third benzene ring in a horizontal orientation with C 1 occupying the rightmost vertex. The third benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. The first central C atom is single bonded on the upper right to C 5 of a second 6-carbon hexagonal ring in a vertical orientation with C 1 occupying the topmost vertex. C 1 of the second 6-carbon ring is wedge bonded to O H. C 5 of the second 6-carbon ring is dash bonded to H below. C 6 of the second 6-carbon ring is wedge bonded to C H 3 on the upper right in the form of a wedged line. C 4 of the second 6-carbon ring is dash bonded on the lower left to a sixth O atom. The sixth O atom is single bonded on the lower right to a third central C atom in the form of a line. The third central C atom is double bonded to a seventh O atom on the lower left and is single bonded to C H 3 on the upper right in the form of a line. The second 6-carbon ring is fused to a 4-membered heterocyclic square ring in a vertical orientation consisting of 1 O and 3 C atoms. In the square ring, O occupies the first position which is the rightmost vertex. The two rings are fused to each other such that C 3 and C 4 of the second 6-carbon ring are the C 3 and C 2 of the square ring, respectively. In the square ring, a wedge bond is present between C 1 and C 2, and C 3 and O. C 6 of the second 6-carbon ring is single bonded on the upper left to C 2 of a 2-carbon alkane chain depicted as a line structure using 1 line. C 2 of the 2-carbon alkane chain is double bonded to an eighth O atom on the upper right. C 1 of the 2-carbon

alkane chain is single bonded o the lower left to C 6 of the first 6-carbon ring and is wedge bonded on the upper left to a ninth O atom. The ninth O atom is single bonded on the upper left to a fourth central C atom in the form of a line. The fourth central C atom is double bonded to a tenth O atom above and is single bonded on the lower left to C H 3 in the form of a line.

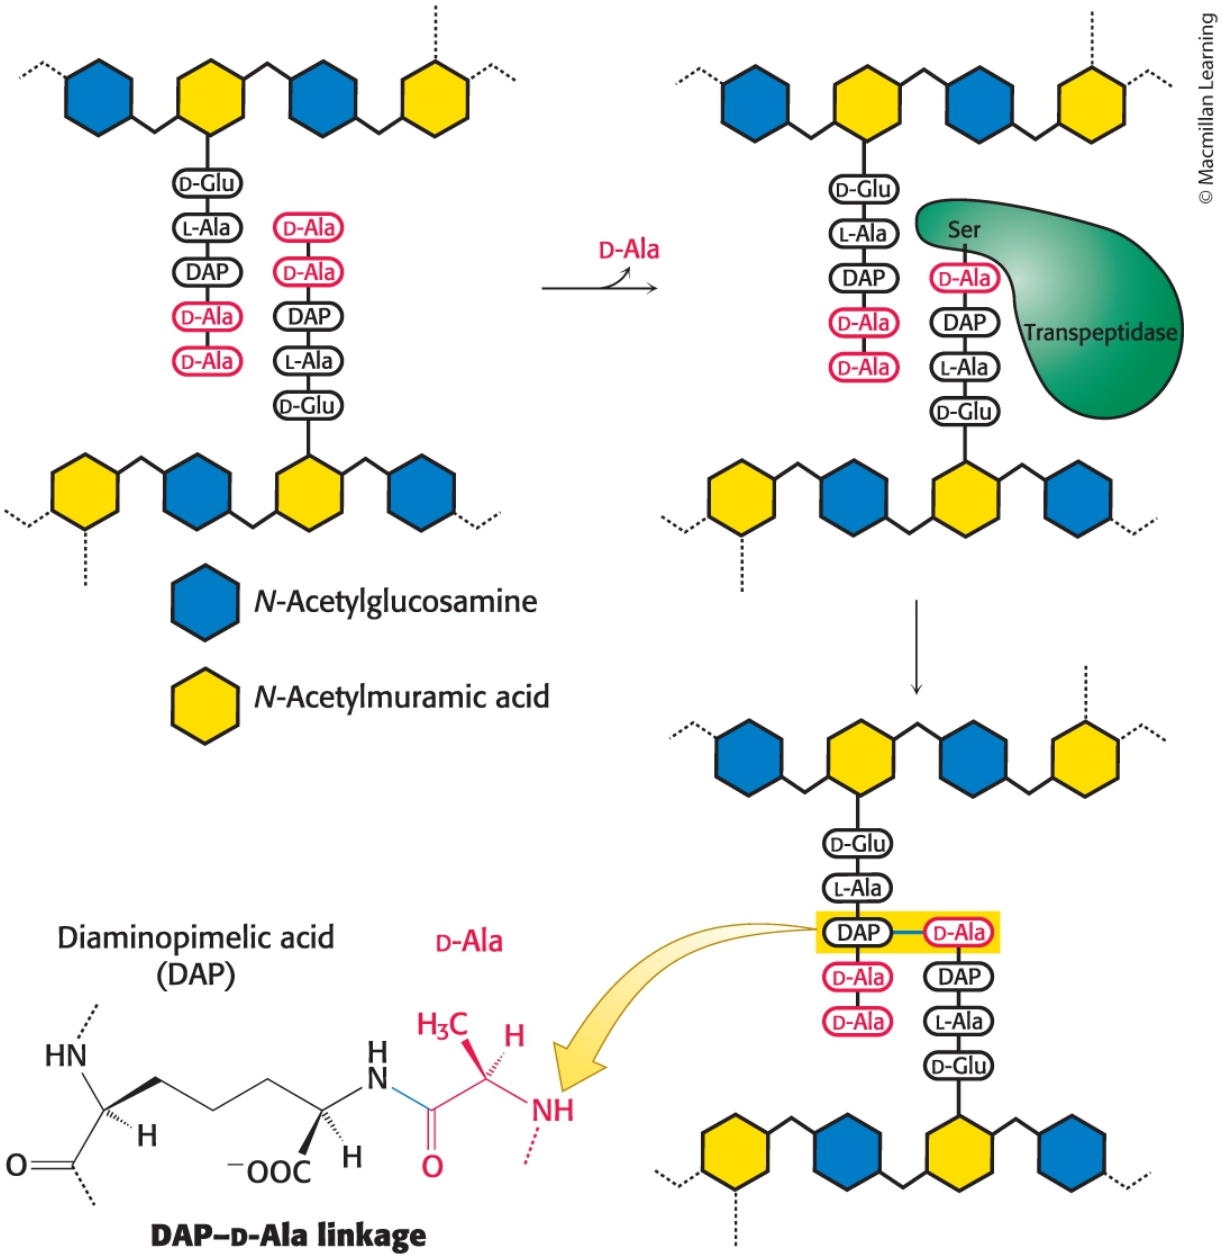
Extended description for Structure of Penicillin

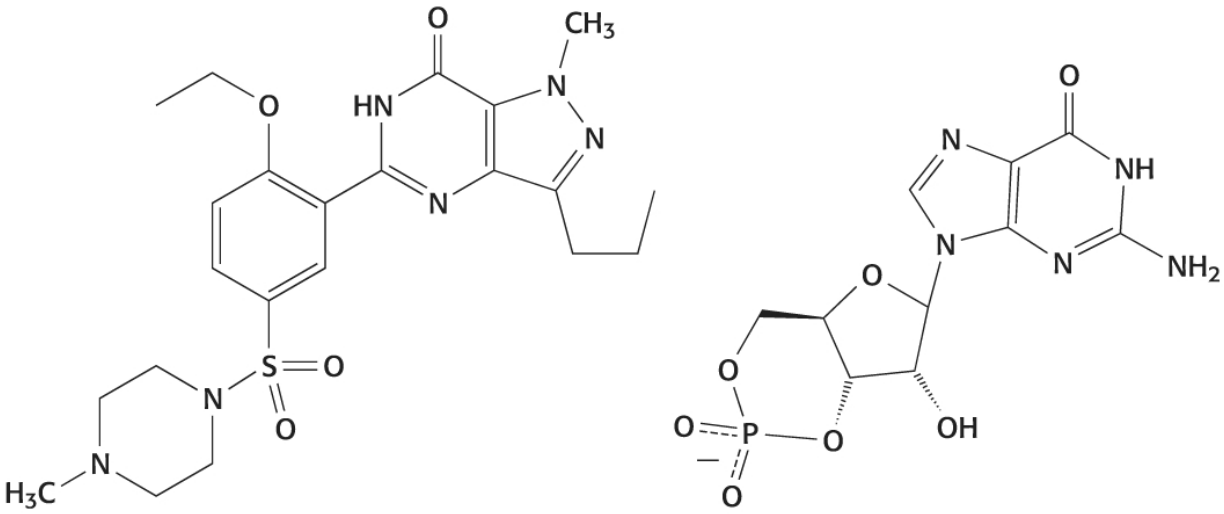


A 4-membered heterocyclic square ring labeled Beta-Lactam ring is in a horizontal orientation consisting of 1 N and 3 C atoms. N occupies the first position which is the bottom right vertex. C 1 is double bonded to O. C 3 is dash bonded to H above. C 2 is wedge bonded to N H. N H is single bonded to a central C atom on the upper left in the form of a line. The central C atom is double bonded to a second O atom on the upper right and single bonded to R on the left. The ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 1 N, 1 S, and 3 C atoms. In the pentagonal ring, N occupies the first position which is the

bottom left vertex, and S occupies the third position which is the top right vertex. The two rings are fused to each other such that C 3 and N of the square ring are the C 1 and N of the pentagonal ring, respectively. C 2 of the pentagonal ring is wedge bonded to C H 3 on the upper right and dash bonded to C H 3 on the lower right. C 3 of the pentagonal ring is dash bonded to C O O superscript minus.

Return to Structure of Penicillin

Extended description for FIGURE 32.3 Penicillin disrupts the biosynthesis of the bacterial cell wall



The reaction consists of two steps. In the first step two peptidoglycan groups are shown. The peptidoglycan group has the following structure: Four hexagonal rings each in a vertical

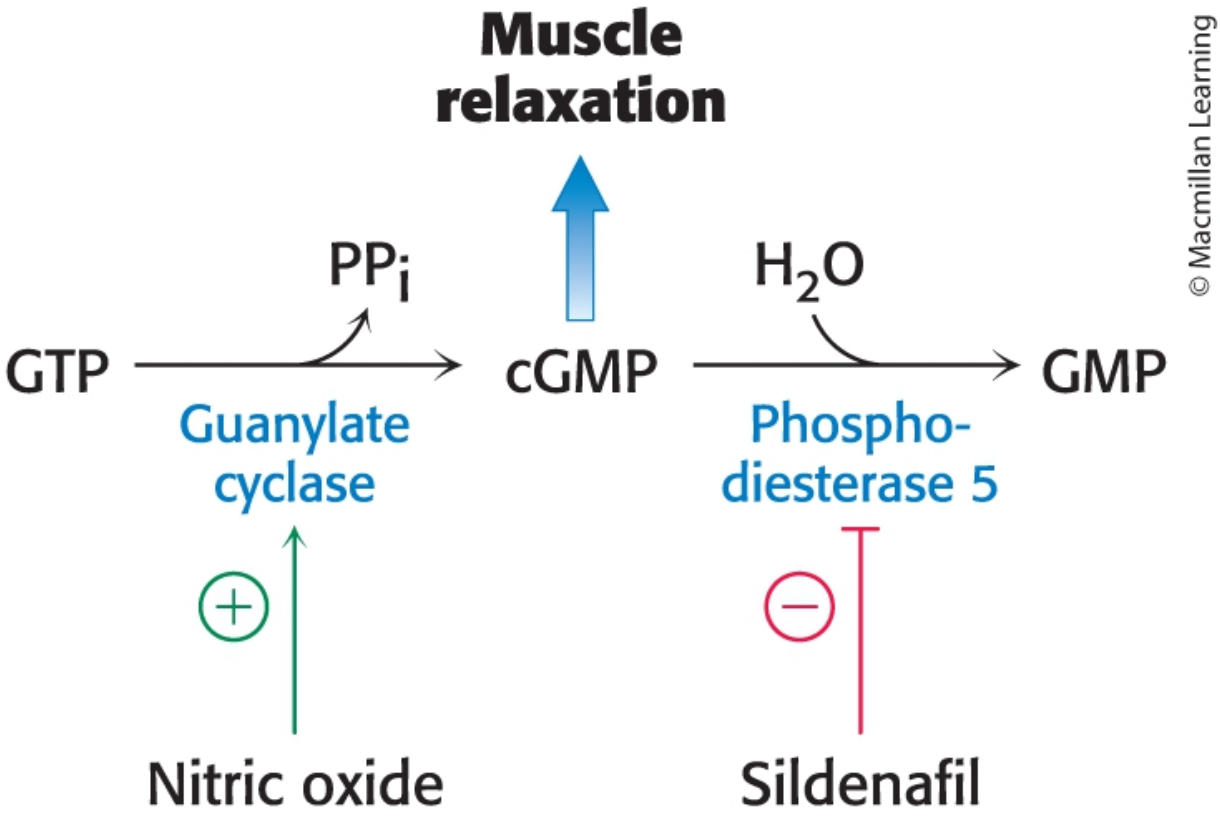
orientation are bonded together in a chain. From the left to the right, the first and the third hexagonal rings are shaded blue and represent N-Acetylglucosamine, and the second and fourth hexagonal rings are shaded yellow and represent N-Acetylmuramic acid. C 3 of each of the first and third hexagonal rings are single bonded to a C H group in the form of a line, which is single bonded on the upper right to C 5 of each of the second and fourth hexagonal rings. C 2 of the second hexagonal ring is single bonded to a C H 2 group which is single bonded on the lower right to C 6 of the third hexagonal ring. Open bonds are present at C 6 of the first hexagonal ring, C 1 and C 2 of the fourth hexagonal ring. C 4 of the second hexagonal ring is single bonded to D-G l u of the following vertical chain: D-G l u, single bond, L-A l a, single bond, D A P, single bond, D-A l a, single bond, D-A l a. In each of the peptidoglycan groups, the D-A l a molecules are highlighted in red. The second D-A l a molecule of the second peptidoglycan group is released and the first D-A l a molecule of the second peptidoglycan group is single bonded to S e r contained in Transpeptidase depicted as an irregular shaped green structure. In the second step, D A P of the first peptidoglycan group forms a linkage with D-A l a of the second peptidoglycan group. The structure of the linkage is as follows: A 2 N and 8 C heteronuclear alkane chain is depicted as a line structure using 9 zigzag lines. N bound to H occupies the seventh and tenth positions. A wedge bond is present between C 2 and C 3. C 1 is double bonded to O on the left and has an open single bond on the lower right. C 2 is dash bonded to H on the lower right and is single bonded to N H on the upper left which has an open single bond on the upper right. C 6 is dash bonded to H on the lower right and is wedge bonded to C O O superscript minus on the lower left. C 7 is double bonded to a second O atom below. C 8 is wedge bonded to C H 3 on the upper left, and dash bonded to H on the upper right. The second N atom has an open single bond on the lower left. C 1 to the first N atom part of the chain is in black and labeled Diaminopimelic acid (D A P)

and the first N atom to the second N atom part of the chain is in red and labeled D-A l a.

Return to FIGURE 32.3 Penicillin disrupts the biosynthesis of the bacterial cell wall

Extended description for FIGURE 32.4 Structures of Sildenafil and c G M P

Sildenafil has the following structure: A 6-membered heterocyclic hexagonal ring is in a vertical orientation consisting of 2 N and 4 C atoms. The first N atom is in the first position which is the top right vertex. The second N atom is in the fourth position which is the bottom left vertex. The second N atom is single bonded to C H 3. The first N atom is single bonded to a central S atom. The central S atom is double bonded to O on the right and a second O atom on the lower right, and single bonded above to C 4 of a benzene ring in a vertical orientation with C 1 occupying the topmost vertex. The benzene ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 1 of the benzene ring is single bonded to a third O atom. The third O atom is single bonded on the upper left to C 2 of a 2-carbon alkane chain depicted as a line structure using 1 line. C 2 of the benzene ring is single bonded to C 1 of a second 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 2 N and 4 C atoms. In the second 6-membered ring, the first N atom occupies the first position which is the bottommost



vertex, and the second N atom bound to H occupies the third position which is the top left vertex. In the second 6-membered ring, a double bond is present between the first N atom and C 1, and C 3 and C 4. C 2 of the second 6-membered ring is double bonded to a fourth O atom. The second 6-membered ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 2 N and 3 C atoms. In the pentagonal ring, the first N atom occupies the first position which is the top right vertex, and the second N atom occupies the second position which is the rightmost vertex. In the pentagonal ring, a double bond is present between the second N atom and C 1. The first N atom of the pentagonal ring is single bonded to C H 3. C 1 of the pentagonal ring is single bonded to C 1 of a 3-carbon alkane chain depicted as a line structure using 2 zigzag lines.

c G M P has the following structure: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation consisting of 2 O, 1 P, and 3 C atoms. The first O atom occupies the first position which is the bottom right vertex, P occupies the second position which is the bottom left vertex, and the third O atom occupies the third position which is the leftmost vertex. A wedge bond is present between C 1 and C 2, and a dash bond is present between C 3 and O. P carries a negative charge and is partially double bonded to O on the lower left and a second O atom on the upper left. The ring is fused to a 5-membered heterocyclic pentagonal ring in a vertical orientation consisting of 1 O and 4 C atoms. In the pentagonal ring, O occupies the first position which is the topmost vertex. The two rings are fused to each other such that C 2 and C 3 of the hexagonal ring are the C 4 and C 3 of the 5-membered ring, respectively. C 2 of the pentagonal ring is dash bonded to O H. C 1 of the pentagonal ring is single bonded to the first N atom of a second 5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 2 N and 3 C atoms. In the second pentagonal ring, the first N atom occupies the first position which is the bottom left vertex and the

second N atom occupies the third position which is the top left vertex. In the second pentagonal ring, a double bond is present between C 1 and the second N atom. The second pentagonal ring is fused to a second 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 2 N and 4 C atoms. In the second hexagonal ring, the first N atom bound to H occupies the first position which is the top right vertex, and the second N atom occupies the third position which is the bottommost vertex. The two rings are fused to each other such that C 2 and C 3 of the second pentagonal ring are the C 3 and C 2 of the second hexagonal ring, respectively. In the second hexagonal ring, a double bond is present between C 1 and the second N atom, and C 2 and C 3. C 1 of the second hexagonal ring is single bonded to N H 2. C 4 of the second hexagonal ring is double bonded to a third O atom.

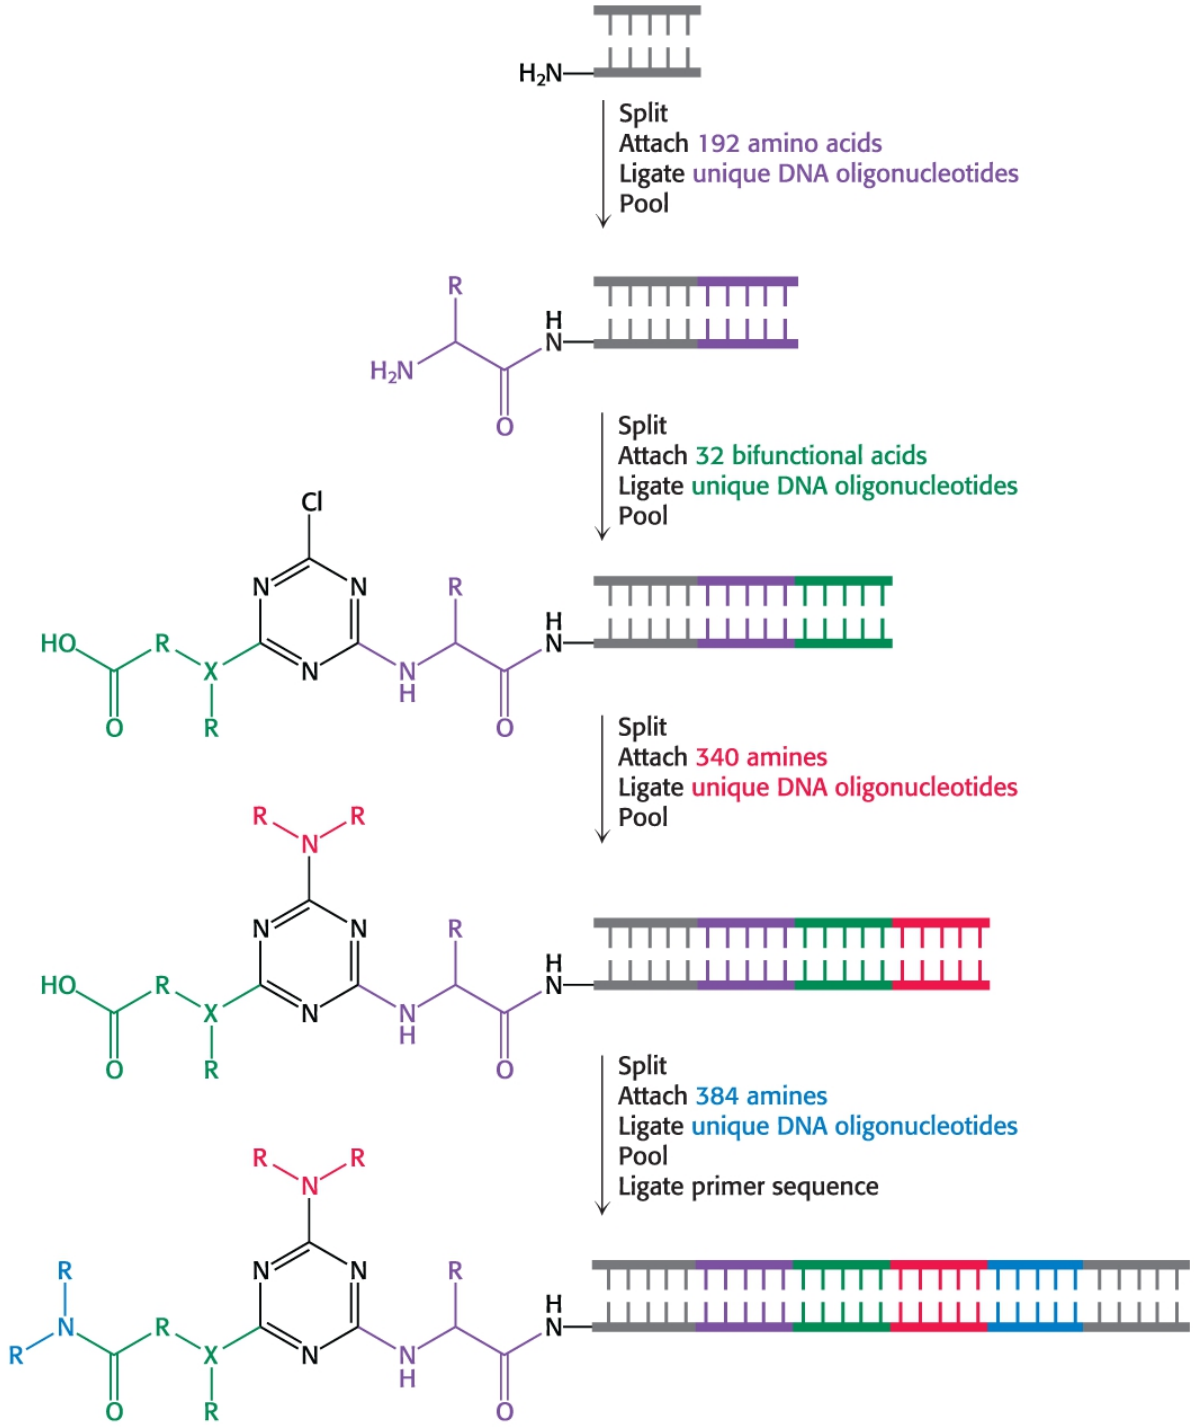
Extended description for FIGURE 32.8 Compound

libraries can be generated by split-pool synthesis



© Macmillan Learning

Each set of compounds consists of three beads shown in gray. Each bead contains an initial structural scaffold depicted as three white arrows attached to the circumference of the bead and tangent to it. In the first step, three set of compounds are shown. Each of the compound set reacts with the first reactant set. The first compound set reacts with a green oval-shaped reactant, the second compound set reacts with a blue oval-shaped reactant, and the third compound reacts with a yellow oval-shaped reactant. Each of these reactions produce a compound set with three beads with the corresponding reactant attached to each arrow of the scaffold structure of the bead. In the second step, the three compound sets are mixed in a box labeled Pool. Three arrows from the pool show the new three compound sets. In each of the new compound sets, the three arrows on each bead are attached with the blue, green and yellow reactants, respectively. In the third step, each of the three new compound sets react with the second reactant set. The first new compound set reacts with a red oval-shaped reactant, the second new compound set reacts with a purple oval-shaped reactant, and the third new compound set reacts with a yellow oval-shaped reactant. Each of these reactions produce a compound set with three beads with the corresponding reactant attached to each arrow of the scaffold structure of the bead.

DNA-encoded library containing 802,160,640 unique molecules

The process shows the initial four steps in the synthesis. In the first step, a short D N A strand is shown with the main bottom strand and the complementary top strand each consisting of 5 bases colored gray. The bottom strand is single bonded to N H 2 on the left. The D N A strand undergoes the following process: Split, Attach, 192 amino acids, Ligate unique D N A oligonucleotides, and pool. The resulting D N A strand shows a new strand consisting of 5 bases colored purple attached on the right of the original D N A strand. N H is single bonded on the lower left to C 2 of a 2-carbon alkane chain depicted as a line structure using 1 line. C 1 of the alkane chain is single bonded to R above and N H 2 on the lower left. C 2 is double bonded to O below. The structure is colored purple. In the second step, the resulting D N A strand of the first step undergoes the following process: Split, Attach, 32 bifunctional acids, Ligate unique D N A oligonucleotides, and pool. The resulting D N A strand shows a new strand consisting of 5 bases colored green attached on the right of the resulting D N A strand of the first step. C 1 of the alkane chain is single bonded to R above and N H on the lower left instead of N H 2. This part is colored purple. N H is single bonded on the upper left to C 1 of a 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 3 N and 3 C atoms. In the hexagonal ring, the first N atom occupies the first position which is the top right vertex, the second N atom occupies the third position which is the bottommost vertex, and the third N atom occupies the fifth position which is the top left vertex. In the hexagonal ring, a double bond is present between the first N atom and C 1, the second N atom and C 2, and the third N atom and C 3. C 3 of the hexagonal ring is single bonded to C l. C 2 of the hexagonal ring is single bonded to X on the lower left. X is single bonded to R below and a second R group on the upper left. The second R group is single bonded to a central C atom on the lower left in the form of a line. The central C atom is double bonded to a second O atom below and single bonded to O H on the upper left. The X to central C atom part of the structure with its attached groups is highlighted in green. In

the third step, the resulting D N A strand of the second step undergoes the following process: Split, Attach, 34 amines, Ligate unique D N A oligonucleotides, and pool. The resulting D N A strand shows a new strand consisting of 5 bases colored red attached on the right of the resulting D N A strand of the second step. C 3 of the hexagonal ring is single bonded to a central N atom instead of C l. The central N atom is single bonded to a third R group on the upper right and a fourth R group on the upper left. The central N atom and its attached groups is highlighted in red. In the fourth step, the resulting D N A strand of the third step undergoes the following process: Split, Attach, 384 amines, Ligate unique D N A oligonucleotides, pool, and ligate primer sequence. The resulting D N A strand shows a new strand consisting of 10 bases, with the first 5 colored blue and the next 5 colored gray attached on the right of the resulting D N A strand of the third step. The central C atom is single bonded to a second central N atom instead of O H on the upper left. The second central N atom is single bonded to a fourth R group above and a fifth R group on the lower left. The second central N atom and its attached groups is highlighted in blue.

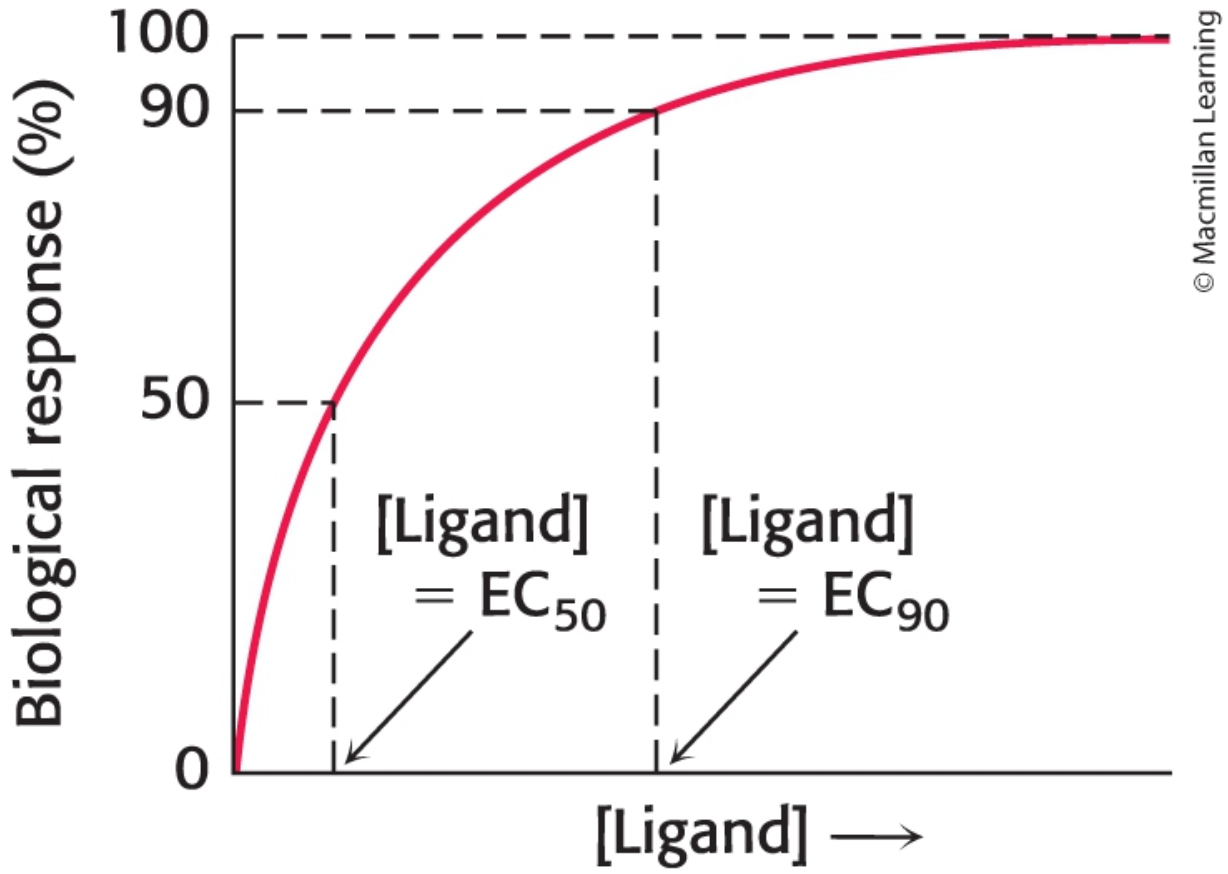
Extended description for FIGURE 32.12 Simple ligand binding results in a hyperbolic curve

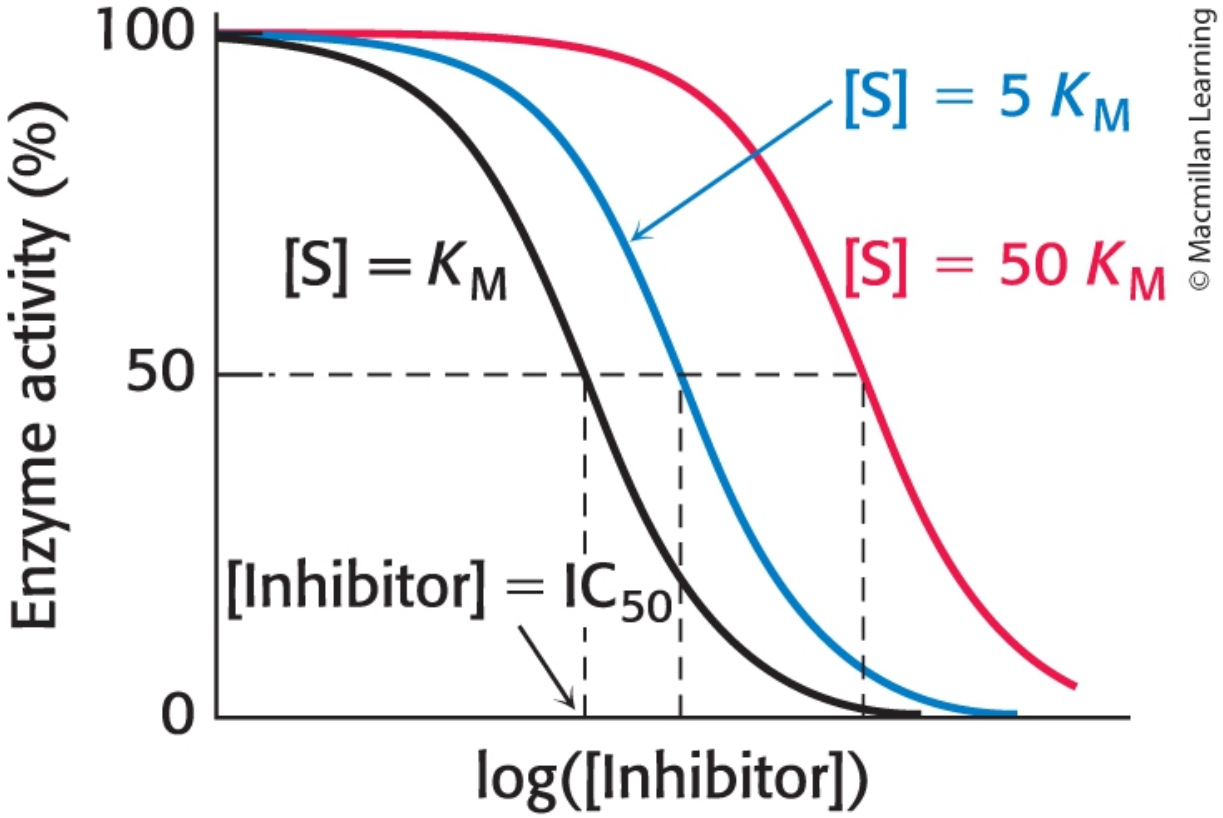


The horizontal axis is labeled open square bracket Ligand close square bracket indicated by a rightward arrow. The vertical axis is labeled Fraction of receptors bound and ranges from 0 to 1.0 in increments of 0.5 units. The two axes intersect at the bottom left. A black hyperbolic curve starts at the intersection of the axes, rises to the upper right with a decreasing slope up to 0.75 value on the vertical axis, and moves almost horizontally to the right to 0.9 value on the vertical axis. A point on the black curve is shown with coordinates (open square bracket Ligand close square bracket

equals K subscript d Baseline, 0.5). A vertical dotted line and a horizontal dotted line are drawn from the point to the horizontal and vertical axes, respectively.

Return to FIGURE 32.12 Simple ligand binding results in a hyperbolic curve

Extended description for FIGURE 32.13 Effective concentration (E C) describes the amount of compound required to elicit a particular biological response

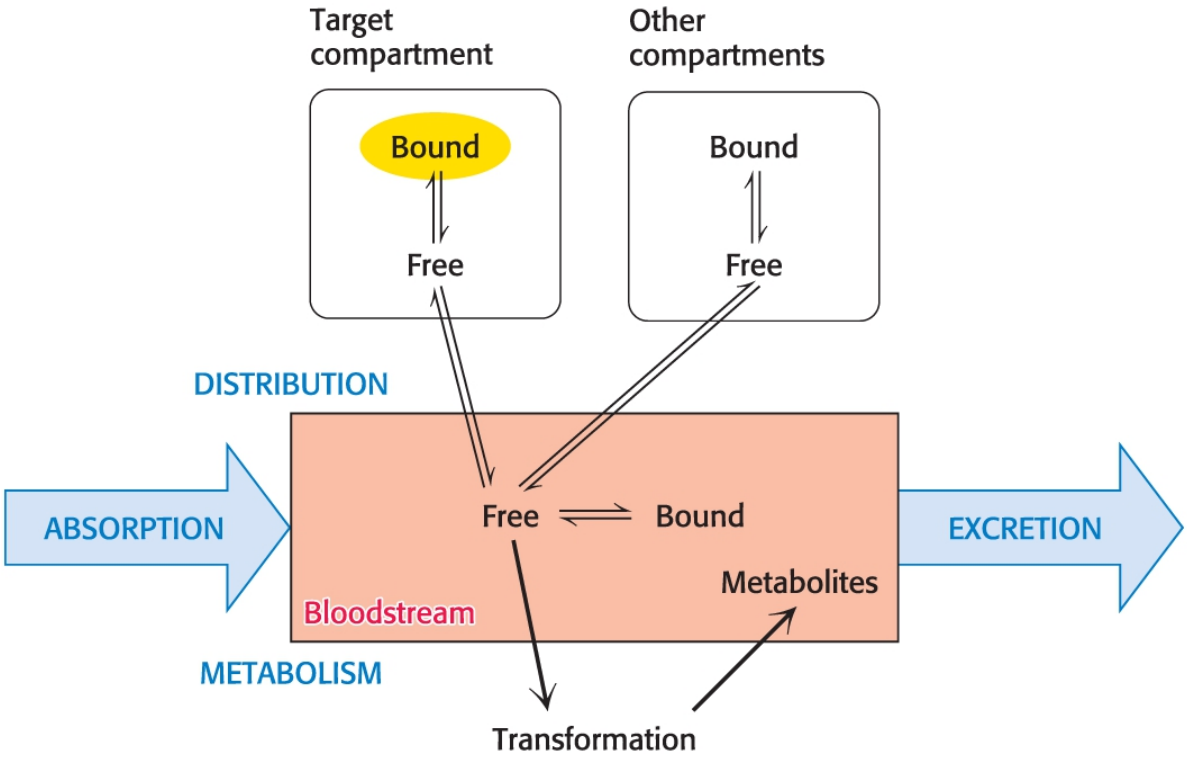


The horizontal axis is labeled open square bracket Ligand close square bracket indicated by a rightward arrow. The vertical axis is labeled Biological response (percent) and has the markings 0, 50, 90, and 100 from the bottom to the top. The two axes intersect at the bottom left. A red curve starts at the intersection of the axes and rises to the upper right with a decreasing slope passing through points (open square bracket Ligand close square bracket equals E C subscript 50 Baseline, 50) and (open square bracket Ligand close square bracket equals E C subscript 90 Baseline, 90), and moves

almost horizontally to the right to 100 value on the vertical axis. Vertical dotted lines and horizontal dotted lines are drawn from the points to the horizontal and vertical axes, respectively.

Return to FIGURE 32.13 Effective concentration (E C) describes the amount of compound required to elicit a particular biological response

Extended description for FIGURE 32.14 Inhibitors compete with substrates for enzyme active sites



The horizontal axis is labeled log (open square bracket inhibitor close square bracket). The vertical axis is labeled Enzyme activity (percent) and ranges from 0 to 100 in increments of 50 units. A black curve for concentration of S equals K subscript M Baseline starts from 100 on the vertical axis, and falls with an increasing slope concave down up to 50 units value on the vertical axis, falls further with a decreasing slope concave up to intersect the horizontal axis. A blue curve for concentration of S equals 5 K subscript M Baseline starts from 100 on the vertical axis, falls with an increasing slope concave down up to 50 units value on the vertical axis to the right of the black curve, and falls further with a decreasing slope concave up to intersect the horizontal axis to the right of the end point of the

black curve. A red curve for concentration of S equals 50 K subscript M Baseline starts from 100 on the vertical axis, falls with an increasing slope concave down up to 50 units value on the vertical axis to the right of the blue curve, and falls further with a decreasing slope concave up to intersect the horizontal axis to the right of the end point of the blue curve. A horizontal dotted line is drawn from 50 units value on the vertical axis. Three vertical dotted lines are drawn from each point of the three curves at 50 units value on the vertical axis. The vertical dotted line from the point on the black curve at 50 units value on the vertical axis intersects the horizontal axis at (open square bracket Inhibitor close square bracket) equals I C subscript 50 Baseline.

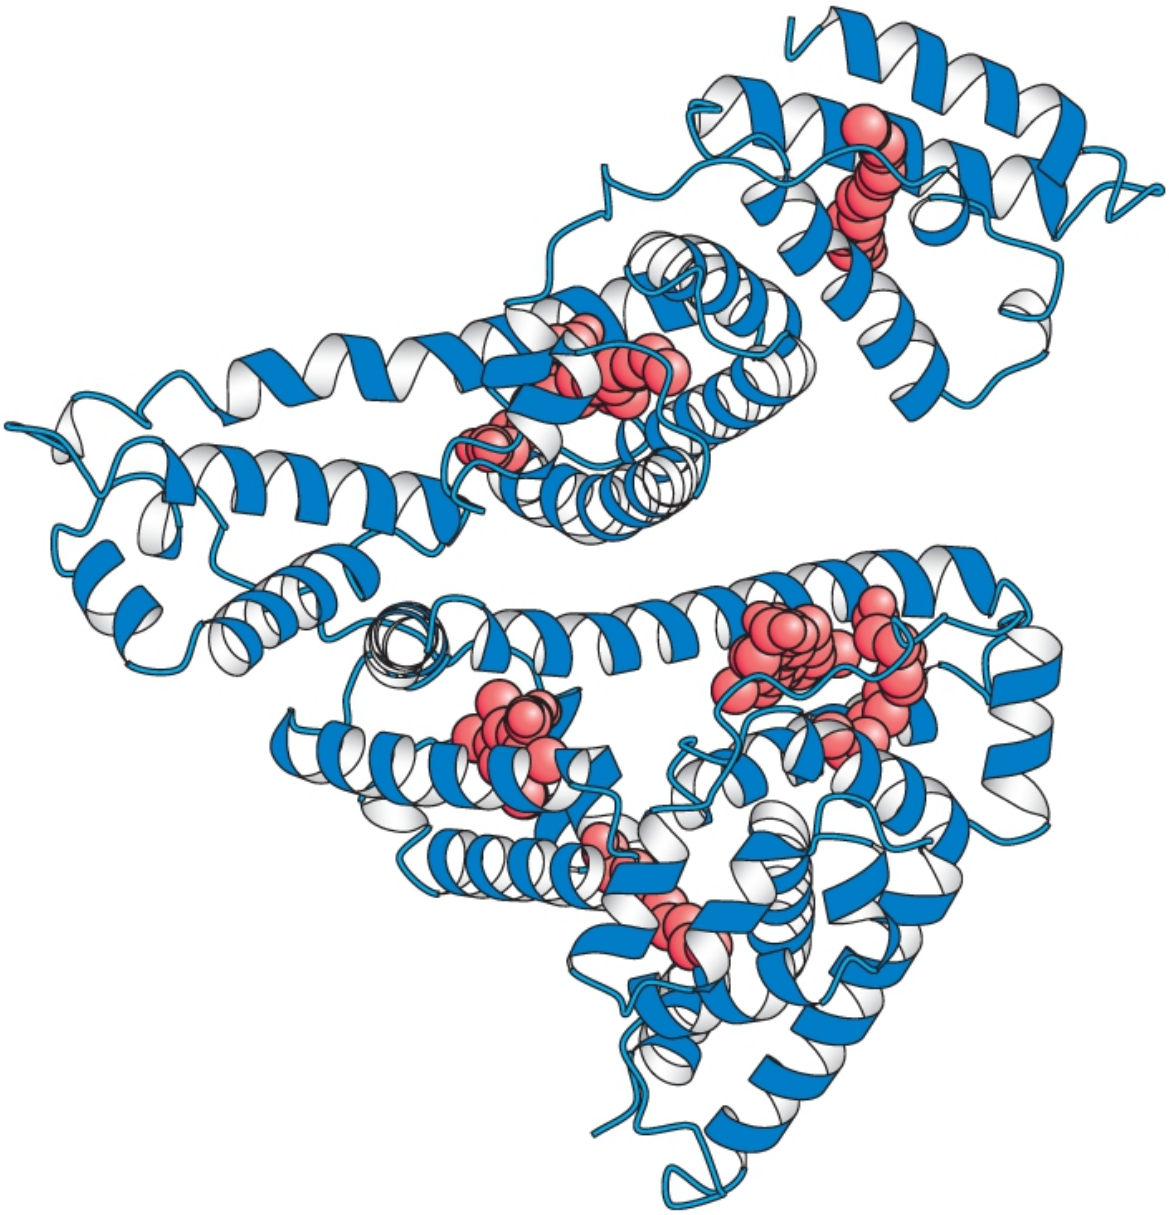
Extended description for FIGURE 32.16 Lipinski's rules serve as a guide to predict oral bioavailability



A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 6 of the benzene ring is single bonded to O H. The benzene ring is fused to a bridged bicyclic ring which is as follows: A non-planar cyclic heterocyclic ring consisting of 1 N and 7 C atoms is shown. N occupies the first

position. N is single bonded to C 1 on the upper left. C 1 is single bonded to C 2 on the lower left. C 2 is wedge bonded to C 3 on the lower left. C 3 is single bonded to C 4 above. C 4 is single bonded to C 5 on the upper right. C 5 is single bonded to C 6 on the lower right. C 6 is single bonded to C 7 below. C 7 is wedge bonded to N on the upper right, completing the ring. C 3 and C 7 are each single bonded to a common C 8 below the ring. The benzene ring and the bridged bicyclic ring are fused to each other such that C 3 and C 4 of the benzene ring are the C 5 and C 4 of the bridged bicyclic ring, respectively. N of the bridged bicyclic ring is single bonded to C H 3 above. C 7 of the bridged bicyclic ring is dash bonded to H on the lower right. C 8 of the bridged bicyclic ring is wedge bonded to H above. The bridged bicyclic ring is fused to a 6-carbon hexagonal ring in a vertical orientation with C 1 occupying the topmost vertex. The two rings are fused to each other such that C 3 and C 8 of the bridged bicyclic ring are the C 1 and C 2 of the 6-carbon hexagonal ring, respectively. In the 6-carbon hexagonal ring, a double bond is present between C 3 and C 4. C 5 of the 6-carbon hexagonal ring is dash bonded to O H. The 6-carbon hexagonal ring, the bridged bicyclic ring, and the benzene ring are fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 1 O and 4 C atoms. In the pentagonal ring, O occupies the first position which is the leftmost vertex. The 6-carbon hexagonal ring and the pentagonal ring are fused to each other such that C 6 and C 1 of the 6-carbon hexagonal ring are the C 4 and C 3 of the pentagonal ring, respectively. The bridged bicyclic ring and the pentagonal ring are fused to each other such that C 3 and C 4 of the bridged bicyclic ring are the C 3 and C 2 of the pentagonal ring, respectively. The benzene ring and the pentagonal ring are fused to each other such that C 4 and C 5 of the benzene ring are the C 2 and C 1 of the pentagonal ring, respectively. O of the O H groups, O of the pentagonal ring, and N of the bridged bicyclic ring are highlighted in red and are the four hydrogen-bond receptors. H of the O H

groups are the two hydrogen-bond donors. Note: Molecular weight equals 285. Log of (P) equals 1.27.

The composite P E T scanned image shows the distribution of fluconazole labeled with the positron-emitting isotope superscript 18 F into the following target compartments: Brain, Heart, Liver, spleen, Kidney, and Muscle. A color gradient scale is shown on the right ranging from a concentration of 0.0 to 60 micrograms per milliliter in increments of 12 micrograms per milliliter. 0 to 12 micrograms per milliliter represent purple. 12 to 20 micrograms per milliliter represent blue. 20 to 28 micrograms per milliliter represent green. 24 to 36 micrograms per milliliter represent yellow. 36 to 48 orange. 48 to 54 micrograms per milliliter represent pink. 54 to 60 micrograms per milliliter represent white. First target compartment Brain: The distribution of fluconazole all over the

brain ranges from approximately 0 to 10 micrograms per milliliter. Second target compartment Heart: The distribution of fluconazole in the heart ranges from approximately 12 to 18 micrograms per milliliter in the center and the lower right regions lightly and the remaining area has 0 to 10 micrograms per milliliter predominantly. Third target compartment Liver on the upper right and spleen on the lower left: The distribution of fluconazole in the liver ranges from approximately 12 to 18 micrograms per milliliter dispersing from the center to the upper right and the lower right regions predominantly and the remaining outlining area has a concentration of 0 to 10 micrograms per milliliter. The distribution of fluconazole in the spleen ranges from approximately 48 to 52 micrograms per milliliter concentrated at the core, surrounded by 30 to 36 micrograms per milliliter at the center-left, 12 to 18 micrograms per milliliter dispersing toward lower left regions and the remaining are has a concentration of 0 to 10 micrograms per milliliter. Fourth target compartment kidney. The distribution of fluconazole in the kidney ranges from approximately 12 to 18 micrograms per milliliter predominantly and feeble concentration of 12 to 18 micrograms per milliliter in the lower left and the lower right regions, and minute concentration of 36 to 52 micrograms per milliliter in the lower left region. Fifth target compartment muscle. The distribution of fluconazole in the muscle ranges from approximately 0 to 10 micrograms per milliliter predominantly and a minute concentration of 12 to 18 micrograms per milliliter on the upper left and lower right regions.

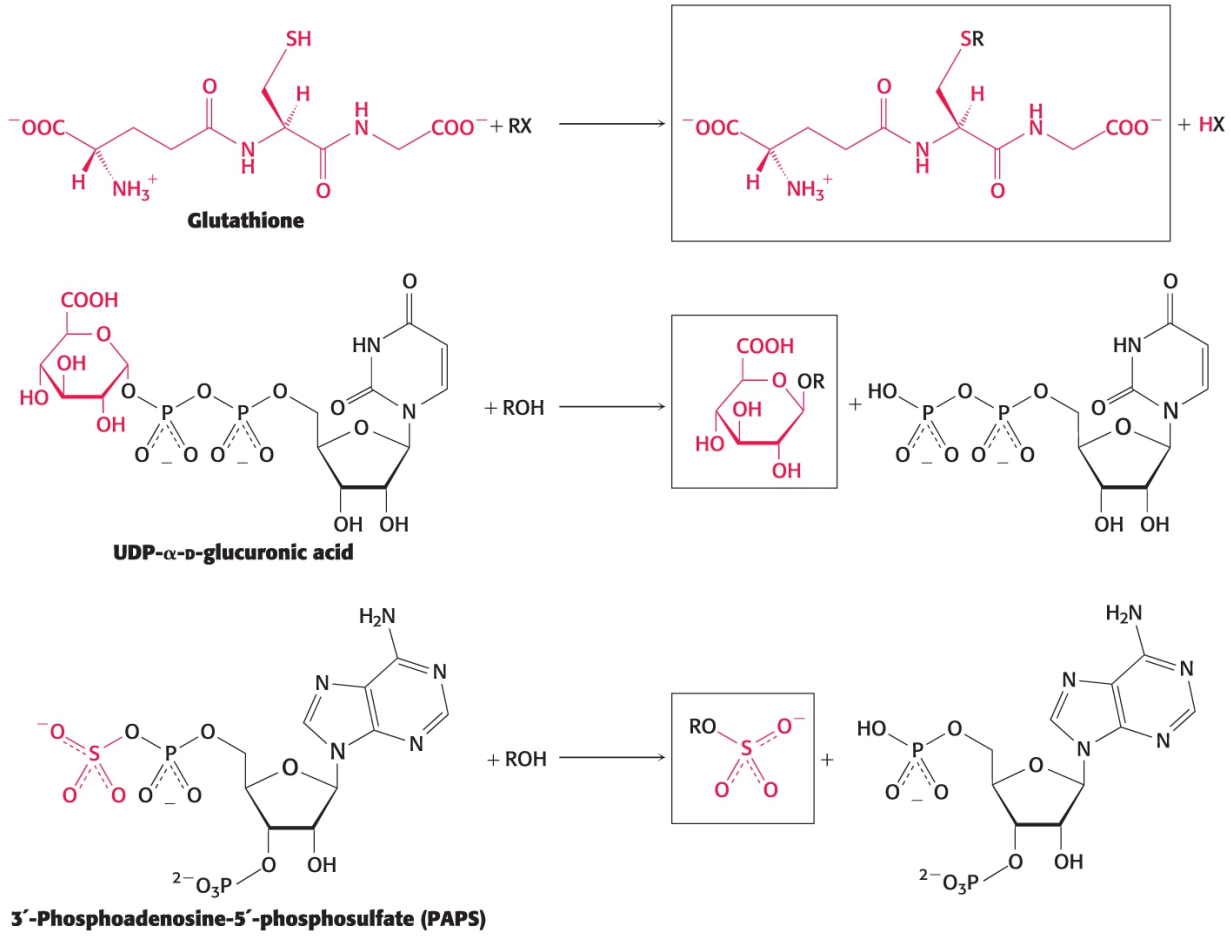
Extended description for FIGURE 32.19 Cytochrome P450 isozymes catalyze xenobiotic metabolic reactions such as hydroxylation



The reaction contains four reactants and three products. The first reactant is N A D P H. The second reactant is H superscript plus. The third reactant is O 2 highlighted in red. The fourth reactant is labeled Ibuprofen and has the following structure: A benzene ring is in a horizontal orientation with C 1 occupying the rightmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 1 is single bonded to a central C atom in the form of a line. The central C atom is single bonded to H on the upper left, C H 3 on the upper right, and C O O H on the lower right. C 4 of the benzene ring is single bonded to C 2 of a 2-carbon alkane chain depicted as a line structure using 1 line. C 1 of the alkane chain is single bonded to H on the upper left, C H 3 on the lower left, and C H 3 on the lower right. The first product is N A D P superscript plus. The second product is H 2 O of which O is highlighted in red. The third product has the following structure: A benzene ring is in a horizontal orientation with C 1 occupying the rightmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 1 is single bonded to a central C atom in the form of a line. The central C atom is single bonded to H on the upper left, C H 3 on the upper right, and C O O H on the lower right. C 4 of the benzene ring is single bonded to C 2 of a 2-carbon alkane chain depicted as a line structure using 1 line. C 1 of the alkane

chain is single bonded to C H 3 on the lower left, C H 3 on the lower right, and O H on the upper left of which O is highlighted in red.

Return to FIGURE 32.19 Cytochrome P450 isozymes catalyze xenobiotic metabolic reactions such as hydroxylation

Extended description for FIGURE 32.20 Compounds that have certain functional groups are often modified by conjugation reactions

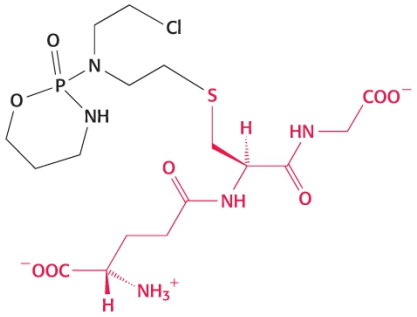
The first reaction contains two reactants and two products. The first reactant labeled Glutathione and highlighted in red has the following structure: A 2 N and 7 C heteronuclear alkane chain is depicted as a line structure using 8 zigzag lines. N bound to H occupies the fifth and the eighth positions. C 1 is single bonded to C O O superscript minus on the upper left, wedge bonded to H on the lower left, and dash bonded to N H 3 superscript plus on the lower right. C 4 is double bonded to O above. C 5 is dash bonded to H on

the upper right and wedge bonded to a central C H 2 group on the upper left. The central C H 2 group is single bonded to S H on the upper right. C 6 is double bonded to a second O atom below. C 7 is single bonded to C O O superscript minus on the upper right. The second reactant is R X. The first product enclosed in a box has the following structure: A 2 N and 7 C heteronuclear alkane chain is depicted as a line structure using 8 zigzag lines. N bound to H occupies the fifth and the eighth positions. C 1 is single bonded to C O O superscript minus on the upper left, wedge bonded to H on the lower left, and dash bonded to N H 3 superscript plus on the lower right. C 4 is double bonded to O above. C 5 is dash bonded to H on the upper right and wedge bonded to a central C H 2 group on the upper left. The central C H 2 group is single bonded to S R on the upper right. C 6 is double bonded to a second O atom below. C 7 is single bonded to C O O superscript minus on the upper right. The entire structure except for R of S R is highlighted in red. The second reactant is H X of which H is highlighted in red.

The second reaction contains two reactants and two products. The first reactant labeled U D P-alpha-D-glucuronic acid has the following structure: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation consisting of 1 O and 5 C atoms. O occupies the first position which is the top right vertex. The ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are toward the observer, and C 5 and O are away from the observer. C 2 and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C O O H above. The ring is highlighted in red. C 1 is single bonded below to the first O atom of the following horizontal zigzag chain: O, single bond, P, single bond, O, single bond, P, single bond, O. Each P atom of the horizontal zigzag chain carries a negative charge and is partially double bonded to an O atom on the lower right and an O atom on the lower left. The third O atom of the main horizontal zigzag chain is single bonded to a central C H 2 group on the lower right in the form of a line. The

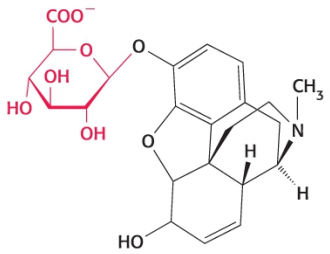
central C H 2 group is single bonded below to C 4 of a 5-membered heterocyclic pentagonal ring in a vertical orientation consisting of 1 O and 4 C atoms. In the pentagonal ring, O occupies the first position which is the topmost vertex. The pentagonal ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are toward the observer, and O is away from the observer. In the pentagonal ring, C 2 and C 3 are each single bonded to O H below. C 1 of the pentagonal ring is single bonded to the first N atom of a second 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 2 N and 4 C atoms. In the second 6-membered ring, the first N atom occupies the first position which is the bottommost vertex and the second N atom bound to H occupies the third position which is the top left vertex. In the second 6-membered ring, a double bond is present between C 3 and C 4. In the second 6-membered ring, C 1 and C 2 are each double bonded to O. The second reactant is R O H. The first product is enclosed in a box and has the following structure: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation consisting of 1 O and 5 C atoms. O occupies the first position which is the top right vertex. The ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are toward the observer, and C 5 and O are away from the observer. C 2 and C 4 are each single bonded to O H below. C 3 is single bonded to O H above. C 5 is single bonded to C O O H above. The ring is highlighted in red. C 1 is single bonded to O R above. The second product has the following structure: A horizontal zigzag chain is illustrated by: H O, single bond, P, single bond, O, single bond, P, single bond, O. Each P atom of the horizontal zigzag chain carries a negative charge and is partially double bonded to an O atom on the lower right and an O atom on the lower left. The second O atom of the main horizontal zigzag chain is single bonded to a central C H 2 group on the lower right in the form of a line. The central C H 2 group is single bonded below to C 4 of a 5-membered heterocyclic pentagonal ring in a vertical orientation consisting of 1 O and 4 C atoms. In the pentagonal ring, O occupies the first

position which is the topmost vertex. The pentagonal ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are toward the observer, and O is away from the observer. In the pentagonal ring, C 2 and C 3 are each single bonded to O H below. C 1 of the pentagonal ring is single bonded to the first N atom of a second 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 2 N and 4 C atoms. In the second 6-membered ring, the first N atom occupies the first position which is the bottommost vertex and the second N atom bound to H occupies the third position which is the top left vertex. In the second 6-membered ring, a double bond is present between C 3 and C 4. In the second 6-membered ring, C 1 and C 2 are each double bonded to O.



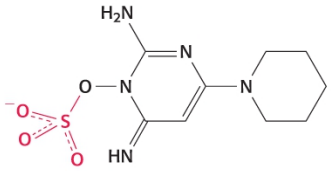
The third reaction contains two reactants and two products. The first reactant labeled 3 prime-Phosphoadenosine-5 prime-phosphosulfate (P A P S) has the following structure: A horizontal zigzag chain is illustrated by: O superscript minus, single bond, S, single bond, O, single bond, P, single bond, O. The P atom carries a negative charge. The S and the P atoms are each partially double bonded to an O atom on the lower right and an O atom on the lower left. O superscript minus, the S atom and the groups attached to it are highlighted in red. The second O atom of the main horizontal zigzag chain is single bonded to a central C H 2 group on the lower right in the form of a line. The central C H 2 group is single bonded below to C 4 of a 5-membered heterocyclic pentagonal ring in a vertical orientation consisting of 1 O and 4 C atoms. In the pentagonal ring, O occupies the first position which is the topmost vertex. The pentagonal ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are toward the observer, and O is away from the observer. In the pentagonal ring, C 2 is single bonded to O H below. C 3 of the pentagonal ring is single bonded to O below which is further single bonded to P O 3 superscript 2 minus. C 1 of the pentagonal ring is single bonded to the first N atom of a second

5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 2 N and 3 C atoms. In the second pentagonal ring, the first N atom occupies the first position which is the bottom left vertex and the second N atom occupies the third position which is the top left vertex. In the second pentagonal ring, a double bond is present between C 1 and the second N atom. The second pentagonal ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 2 N and 4 C atoms. In the 6-membered ring, the first N atom occupies the first position which is the top right vertex and the second N atom occupies the third position which is the bottommost vertex. The two rings are fused to each other such that C 2 and C 3 of the second pentagonal ring are the C 3 and C 2 of the 6-membered ring, respectively. In the 6-membered ring, a double bond is present between C 1 and the second N atom, C 2 and C 3, and C 4 and the first N atom. In the second 6-membered ring, C 4 is single bonded to N H 2. The second reactant is R O H. The first product enclosed in a box has the following structure: A central S atom is partially double bonded to O superscript minus on the upper right, O on the lower right, and a second O atom on the lower left. This part is highlighted in red. The central S atom is single bonded to O R on the upper left. The second product has the following structure: A horizontal zigzag chain is illustrated by: O H, single bond, P, single bond, O. The P atom carries a negative charge and is partially double bonded to an O atom on the lower right and an O atom on the lower left. O of the main horizontal zigzag chain is single bonded to a central C H 2 group on the lower right in the form of a line. The central C H 2 group is single bonded below to C 4 of a 5-membered heterocyclic pentagonal ring in a vertical orientation consisting of 1 O and 4 C atoms. In the pentagonal ring, O occupies the first position which is the topmost vertex. The pentagonal ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are toward the observer, and O is away from the observer. In the pentagonal ring, C 2 is single bonded to O H below. C 3 of the pentagonal ring is single



bonded to O below which is further single bonded to P O 3 superscript 2 minus. C 1 of the pentagonal ring is single bonded to the first N atom of a second 5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 2 N and 3 C atoms. In the second pentagonal ring, the first N atom occupies the first position which is the bottom left vertex and the second N atom occupies the third position which is the top left vertex. In the second pentagonal ring, a double bond is present between C 1 and the second N atom. The second pentagonal ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 2 N and 4 C atoms. In the 6-membered ring, the first N atom occupies the first position which is the top right vertex and the second N atom occupies the third position which is the bottommost vertex. The two rings are fused to each other such that C 2 and C 3 of the second pentagonal ring are the C 3 and C 2 of the 6-membered ring, respectively. In the 6-membered ring, a double bond is present between C 1 and the second N atom, C 2 and C 3, and C 4 and the first N atom. In the second 6-membered ring, C 4 is single bonded to N H 2.

Return to FIGURE 32.20 Compounds that have certain functional groups are often modified by conjugation reactions



Extended description for Structures of Cyclophosphamide-glutathione conjugate, Morphine glucuronidate, and Minoxidil sulfate

Cyclophosphamide-glutathione conjugate

Morphine glucuronidate

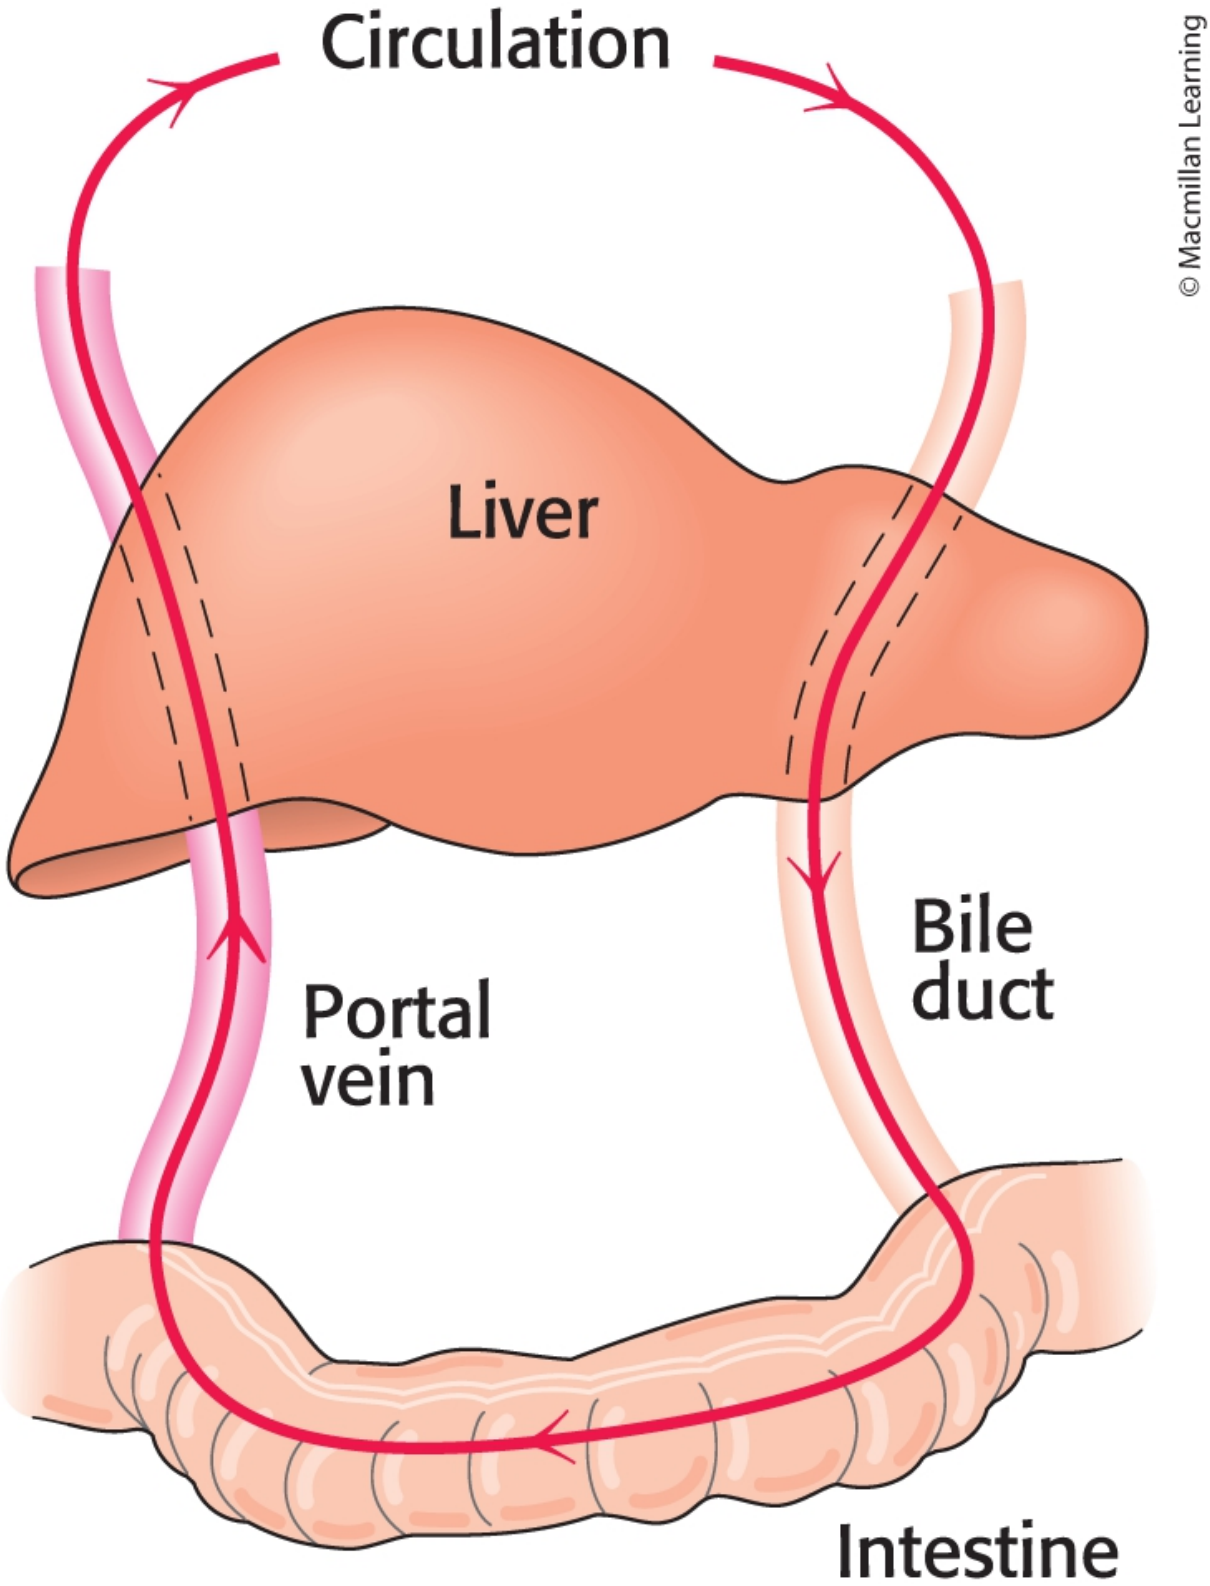
Minoxidil sulfate

Cyclophosphamide-glutathione conjugate has the following structure: A 6-membered heterocyclic hexagonal ring is in a vertical orientation consisting of 1 O 1 P, 1 N, and 3 C atoms. O occupies the first position which is the top left vertex. P occupies the second position which is the topmost vertex. N bound to H occupies the third position which is the top right vertex. P is double bonded to a second O atom on the upper left and is single bonded on the upper right to N of 1 N and 4 C heteronuclear alkane chain depicted as a line structure using 4 zigzag lines. In the alkane chain, N occupies the third position. C 1 of the alkane chain is single bonded to C l on the lower right. C 4 of the alkane chain is single bonded to S on the lower right. S is single bonded to a central C H 2 group below in the form of a line. The central C H 2 group is wedge bonded on the lower right to C 5 of a 2 N and 6 C heteronuclear alkane chain depicted as a line structure using 6 zigzag lines. In the 2 N and 6 C heteronuclear alkane chain, N bound to H occupies the fifth and the eighth positions. C 1 of the 2 N and 6 C heteronuclear alkane chain, is dash bonded to N H 3 superscript plus on the lower right, wedge bonded to H below, and single bonded to C O O superscript minus

on the left. C 4 is double bonded to a third O atom on the upper left. C 5 is dash bonded to H above. C 6 is double bonded to a fourth O atom on the lower right. C 6 is single bonded to C O O superscript minus on the upper right. The S atom and the 2 N and 6 C heteronuclear alkane chain along with its attached groups is highlighted in red.

Morphine glucuronidate has the following structure: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation and consists of 1 O and 5 C atoms. O occupies the first position which is the top right vertex. The ring is in a plane perpendicular to the plane of the paper such that C 2 and C 3 are toward the observer, and C 5 and O are away from the observer. C 2 is single bonded to O H below. C 3 is single bonded to O H above. C 4 is single bonded to O H on the lower left. C 5 is single bonded to C O O superscript minus. The ring and the groups attached to the vertices are highlighted in red. C 1 is single bonded to a second O atom on the upper right. The second O atom is single bonded on the lower right to C 5 of a benzene ring in a vertical orientation with C 1 occupying the topmost vertex. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. The benzene ring is fused to a bridged bicyclic ring which is as follows: A non-planar cyclic heterocyclic ring consisting of 1 N and 7 C atoms is shown. N occupies the first position. N is single bonded to C 1 on the upper left. C 1 is single bonded to C 2 on the lower left. C 2 is wedge bonded to C 3 on the lower left. C 3 is single bonded to C 4 above. C 4 is single bonded to C 5 on the upper right. C 5 is single bonded to C 6 on the lower right. C 6 is single bonded to C 7 below. C 7 is wedge bonded to N on the upper right, completing the ring. C 3 and C 7 are each single bonded to a common C 8 below the ring. The benzene ring and the bridged bicyclic ring are fused to each other such that C 3 and C 4 of the benzene ring are the C 5 and C 4 of the bridged bicyclic ring, respectively. N of the bridged bicyclic ring is single bonded to C H 3 above. C 7 of the bridged bicyclic ring is dash

bonded to H on the lower right. C 8 of the bridged bicyclic ring is wedge bonded to H above. The bridged bicyclic ring is fused to a 6-carbon hexagonal ring in a vertical orientation with C 1 occupying the topmost vertex. The two rings are fused to each other such that C 3 and C 8 of the bridged bicyclic ring are the C 1 and C 2 of the 6-carbon hexagonal ring, respectively. In the 6-carbon hexagonal ring, a double bond is present between C 3 and C 4. C 5 of the 6-carbon hexagonal ring is dash bonded to O H. The 6-carbon hexagonal ring, the bridged bicyclic ring, and the benzene ring are fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 1 O and 4 C atoms. In the pentagonal ring, O occupies the first position which is the leftmost vertex. The 6-carbon hexagonal ring and the pentagonal ring are fused to each other such that C 6 and C 1 of the 6-carbon hexagonal ring are the C 4 and C 3 of the pentagonal ring, respectively. The bridged bicyclic ring and the pentagonal ring are fused to each other such that C 3 and C 4 of the bridged bicyclic ring are the C 3 and C 2 of the pentagonal ring, respectively. The benzene ring and the pentagonal ring are fused to each other such that C 4 and C 5 of the benzene ring are the C 2 and C 1 of the pentagonal ring, respectively.



Minoxidil sulfate has the following structure: A 6-membered heterocyclic hexagonal ring is in a horizontal orientation consisting of 2 N and 4 C atoms. The first N atom occupies the first position which is the leftmost vertex. The second N atom occupies the third position which is the top right vertex. A double bond is present between C 1 and the second N atom, and C 2 and C 3. C 1 is single bonded to N H 2. C 4 is double bonded to N H. C 2 is single bonded to N of a second 6-membered heterocyclic hexagonal ring in a horizontal orientation consisting of 1 N and 5 C atoms. In the second ring, N occupies the first position which is the leftmost vertex. The first N atom of the first ring is single bonded to O. O is single bonded to a central S atom on the lower left. The central S atom is partially double bonded to O on the lower right, a second O atom on the

lower left, and O superscript minus on the upper left. The central S atom and the groups attached to it are highlighted in red.

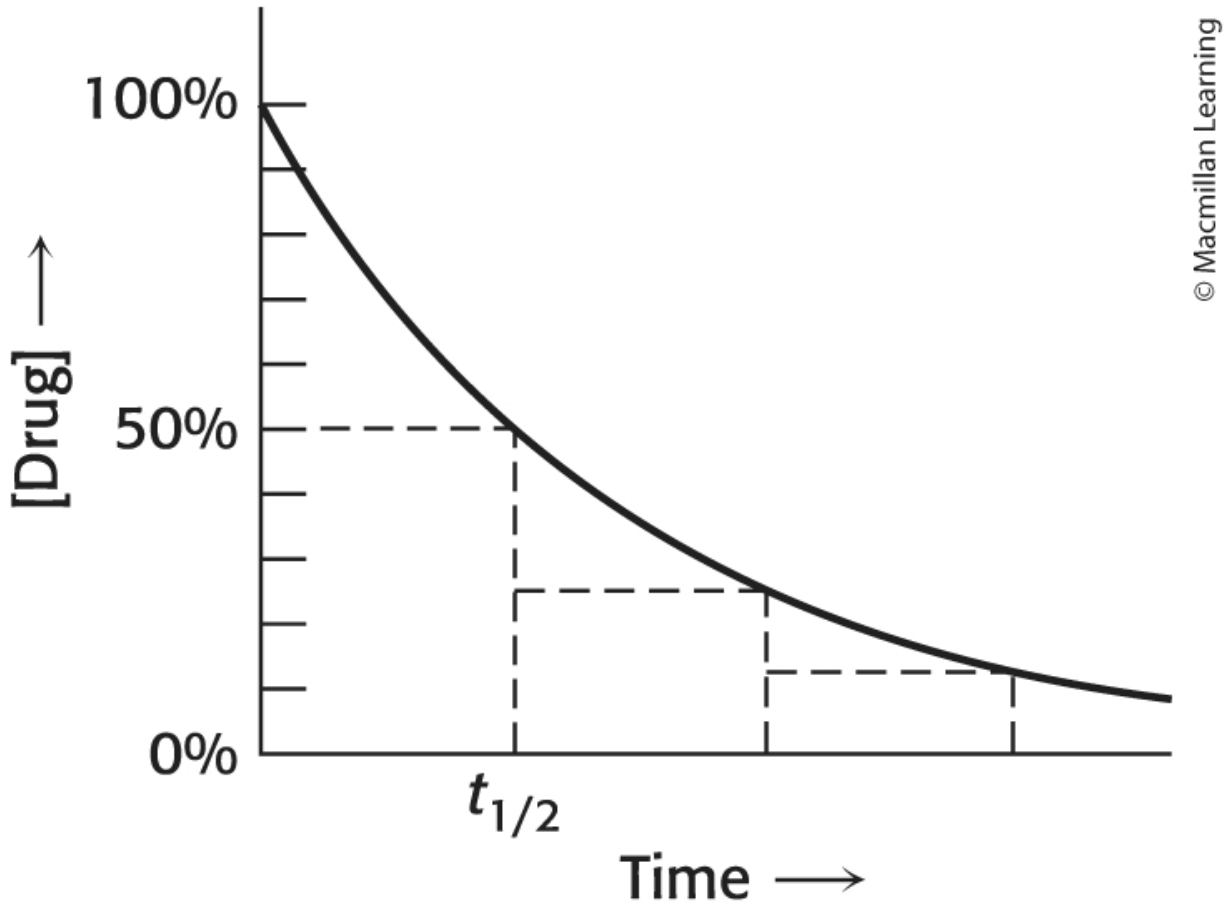
Extended description for FIGURE 32.21 Drugs can move between the intestine and the circulation via



enterohepatic cycling

The illustration shows the cone-shaped muscular organ liver and the long horizontal muscular tube of the intestine with numerous folds running at the bottom. The liver is connected to the intestine by two thin tubular structures: the bile duct on the right and the portal vein on the left. The enterohepatic drug circulation indicated by arrows is shown from the liver to the intestine via the bile duct and back to the liver via the portal vein.

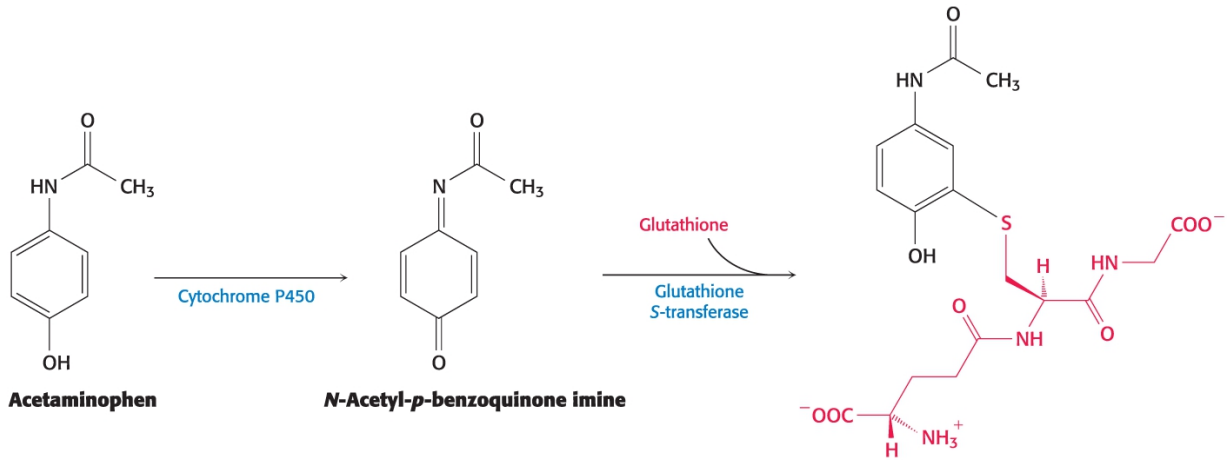
Extended description for FIGURE 32.22 Drug excretion may be measured by its half-life



© Macmillan Learning

The horizontal axis is labeled time indicated by a rightward arrow. The vertical axis is labeled concentration of drug indicated by an upward arrow and ranges from 0 to 100 percent in increments of 50 percent. A black elliptical curve starts at 100 percent on the vertical axis, and falls to the lower right concave up till it almost becomes parallel to the horizontal axis. A point is shown on the curve at 50 percent ordinate with an abscissa of t subscript one-half Baseline. Vertical dashed lines and horizontal dashed lines are drawn from this point and two other points on the lower half of the curve to the horizontal and the vertical axes, respectively.

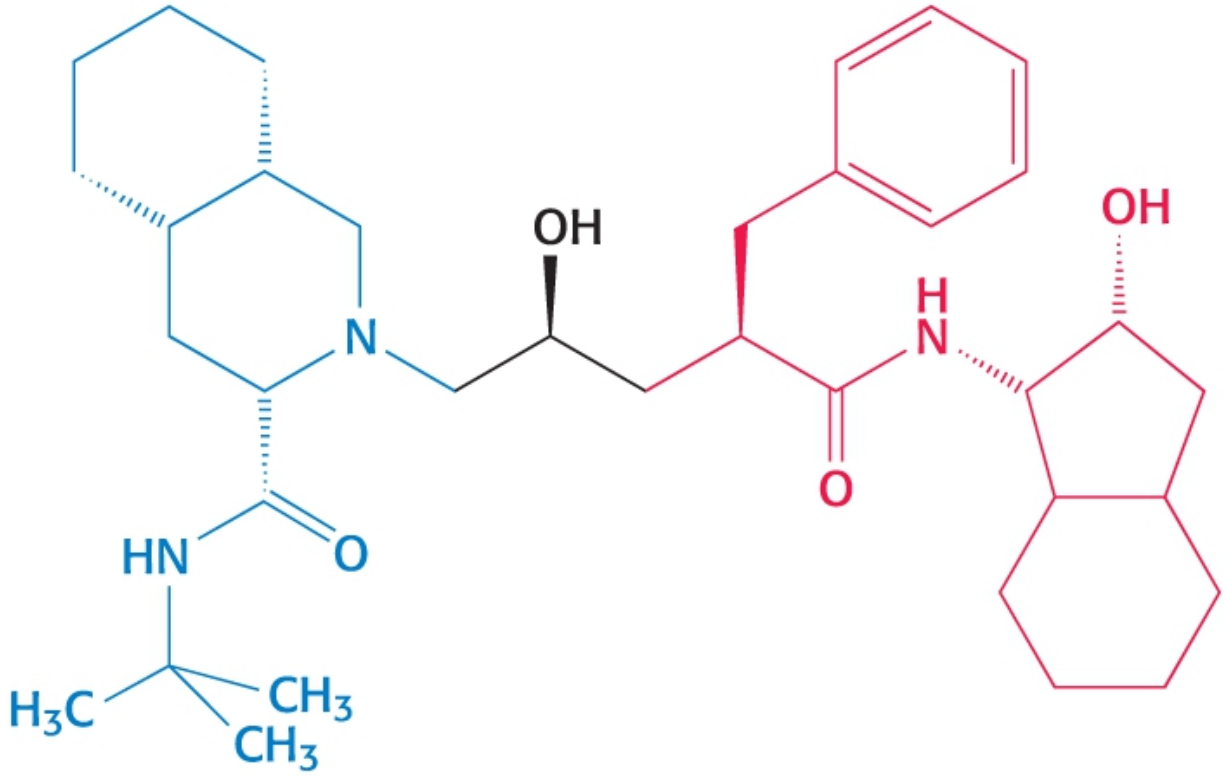
Extended description for FIGURE 32.23 Acetaminophen metabolism results in its toxicity

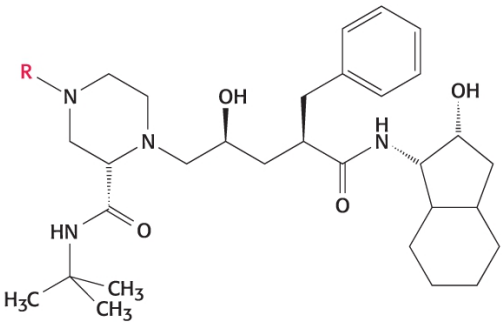


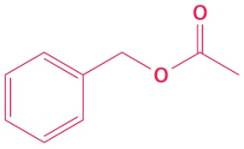
A two-step reaction contains two reactants, one intermediate, and one product. In the first step, the first reactant converts to the intermediate in the presence of Cytochrome P 450 which is highlighted in blue. The first reactant labeled Acetaminophen has the following structure: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 4 is single bonded to O H. C 1 is single bonded to N H. N H is single bonded to a central C atom on the upper right in the form of a line. The central C atom is double bonded to O above and is single bonded to C H 3 on the lower right. The intermediate labeled N-Acetyl-p-benzoquinone imine has the following structure: A 6-carbon hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. A double bond is present between C 2 and C 3, and C 5 and C 6. C 4 is double bonded to O. C 1 is double bonded to N. N is single bonded to a central C atom on the upper right in the form of a line. The central C atom is double bonded to O above and is single bonded to C H 3 on the lower right. In the second step, the second reactant Glutathione highlighted in red, reacts with the

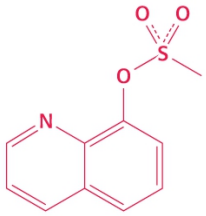
intermediate in the presence of Glutathione 5-transferase highlighted in blue. The product has the following structure: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 4 is single bonded to O H. C 1 is single bonded to N H. N H is single bonded to a central C atom on the upper right in the form of a line. The central C atom is double bonded to O above and is single bonded to C H 3 on the lower right. C 3 is single bonded to S. S is single bonded to a central C H 2 group below in the form of a line. The central C H 2 group is wedge bonded on the lower right to C 5 of a 2 N and 6 C heteronuclear alkane chain depicted as a line structure using 6 zigzag lines. In the 2 N and 6 C heteronuclear alkane chain, N bound to H occupies the fifth and the eighth positions. C 1 of the 2 N and 6 C heteronuclear alkane chain, is dash bonded to N H 3 superscript plus on the lower right, wedge bonded to H below, and single bonded to C O O superscript minus on the left. C 4 is double bonded to a second O atom on the upper left. C 5 is dash bonded to H above. C 6 is double bonded to a third O atom on the lower right. C 6 is single bonded to C O O superscript minus on the upper right. The S atom and the 2 N and 6 C heteronuclear alkane chain along with its attached groups is highlighted in red.

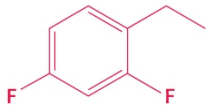
Return to FIGURE 32.23 Acetaminophen metabolism results in its toxicity

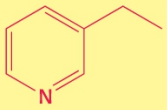
Extended description for FIGURE 32.24 Structural information led to the initial design of an H I V protease inhibitor











The molecule has the following structure: A 6-carbon hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. A dash bond is present between C 2 and C 3, and C 4 and C 5. The ring is fused to a 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 1 N and 5 C atoms. In the 6-membered ring, N occupies the first position which is the bottom right vertex. The two rings are fused to each other such that C 3 and C 4 of the 6-carbon ring are the C 4 and C 3 of the 6-membered ring, respectively. C 3 of the 6-membered ring is dash bonded to a central C atom in the form of a dashed line. The central C atom is double bonded to O on the lower right and single bonded to N H on the

lower left. N H is single bonded to a second central C atom below in the form of a line. The second central C atom is single bonded to C H 3 on the right, C H 3 on the lower right, and C H 3 on the lower left. The structures until this point is highlighted in blue. The second N atom of the 6-membered ring is single bonded on the lower right to C 1 of a 5-carbon alkane chain depicted as a line structure using 4 zigzag lines. C 2 of the alkane chain is wedge bonded to O H above. C 4 of the alkane chain is wedge bonded to a C H 2 group in the form of a wedged line. The C H 2 group is single bonded on the upper right to C 4 of a benzene ring in a vertical orientation with C 1 occupying the topmost vertex. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 5 of the alkane chain is double bonded to O below and single bonded to N H on the upper right. N H is dash bonded on the lower right to C 5 of a 5-carbon pentagonal ring in a vertical orientation with C 1 occupying the topmost vertex. C 1 of the pentagonal ring is dash bonded to O H. The pentagonal ring is fused to a second 6-carbon hexagonal ring in a horizontal orientation with C 1 occupying the rightmost vertex. The two rings are fused to each other such that C 3 and C 4 of the pentagonal ring are the C 6 and C 5 of the second 6-carbon ring, respectively. The part of the structure from C 3 of the 5-carbon alkane chain onwards is highlighted in red.

Return to FIGURE 32.24 Structural information led to the initial design of an H I V protease inhibitor

Extended description for FIGURE 32.25. Optimizing lead molecules requires the balancing of multiple compound properties

R group	IC_{50} (nM)	log(*P*)	c_{max} (μM)
	0.4	4.67	< 0.1
	0.01	3.70	< 0.1
	0.3	3.69	0.7
	0.6	2.92	11

The base structure of a drug compound is as follows: A 6-membered heterocyclic hexagonal ring is in a vertical orientation consisting of 2 N and 4 C atoms. The first N atom occupies the first position which is the top left vertex and the second N atom occupies the third position which is the bottom right vertex. The first N atom is single bonded to R which is highlighted in red. C 3 is dash bonded to a central C atom in the form of a dashed line. The central C atom is double bonded to O on the lower right and single bonded to N H on the lower left. N H is single bonded to a second central C atom below in the form of a line. The second central C atom is single bonded to C H 3 on the right, C H 3 on the lower right, and C H 3 on the lower left. The second N atom of the ring is single bonded on the

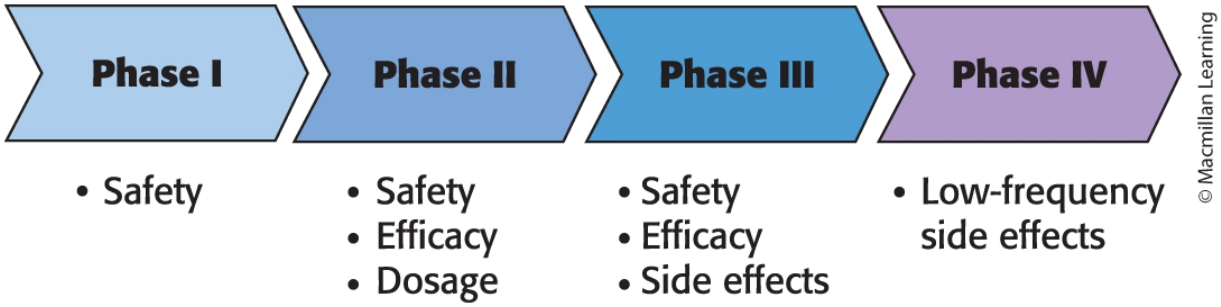
lower right to C 1 of a 5-carbon alkane chain depicted as a line structure using 4 zigzag lines. C 2 of the alkane chain is wedge bonded to O H above. C 4 of the alkane chain is wedge bonded to a C H 2 group in the form of a wedged line. The C H 2 group is single bonded on the upper right to C 4 of a benzene ring in a vertical orientation with C 1 occupying the topmost vertex. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 5 of the alkane chain is double bonded to O below and single bonded to N H on the upper right. N H is wedge bonded on the lower right to C 5 of a 5-carbon pentagonal ring in a vertical orientation with C 1 occupying the topmost vertex. C 1 of the pentagonal ring is wedge bonded to O H. The pentagonal ring is fused to a 6-carbon hexagonal ring in a horizontal orientation with C 1 occupying the rightmost vertex. The two rings are fused to each other such that C 3 and C 4 of the pentagonal ring are the C 6 and C 5 of the 6-carbon ring, respectively.

The table consists of 4 columns and 4 rows. The column headers are as follows: R group, I C subscript 50 Baseline (nanoMolars), log of (P), and c subscript maximum Baseline (microMolars). The row entries are as follows:

Row 1: R group, A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 2 is single bonded to C 1 of a 1 O and 2 C heteronuclear alkane chain depicted as a line structure using 2 zigzag lines. In the alkane chain, O occupies the second position. C 2 is double bonded to a second O atom above and has an open single bond on the lower right. I C subscript 50 Baseline (nanoMolars), 0.4. log of (P), 4.67. c subscript maximum Baseline (microMolars), less than 0.1.

Row 2: R group, A 6-membered heterocyclic hexagonal ring is in a vertical orientation consisting of 1 N and 5 C atoms. N occupies the

first position which is the topmost vertex. A double bond is present between C 3 and C 4, and C 5 and N. The ring is fused to a benzene ring in a vertical orientation with C 1 occupying the topmost vertex. The two rings are fused to each other such that C 1 and C 2 of the 6-membered ring are the C 6 and C 5 of the benzene ring, respectively. The benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 1 of the benzene ring is single bonded to O. O is single bonded to a central S atom on the upper right. The central S atom is partially double bonded to a second O atom on the upper right, a third O atom on the upper left and has an open single bond on the lower right. I C subscript 50 Baseline (nanoMolars), 0.01. log of (P), 3.70. c subscript maximum Baseline (microMolars), less than 0.1.



Row 3: R group, A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. C 3 and C 5 are each single bonded to F. C 2 is single bonded to a central C H 2 group in the form of a line. The central C H 2 group has an open bond on the lower right. I C subscript 50 Baseline (nanoMolars), 0.3. log of (P), 3.69. c subscript maximum Baseline (microMolars), 0.7.

Row 4: R group, A 6-membered heterocyclic hexagonal ring is in a vertical orientation consisting of 1 N and 5 C atoms. N occupies the first position which is the bottommost vertex. A double bond is present between C 1 and C 2, C 3 and C 4, and C 5 and N. C 4 is single bonded to a central C H 2 group in the form of a line. The central C H 2 group has an open single bond on the lower right. I C subscript 50 Baseline (nanoMolars), 0.6. log of (P), 2.92. c subscript maximum Baseline (microMolars), 11.

The R group column structures are highlighted in red and Row 4 is highlighted in yellow.

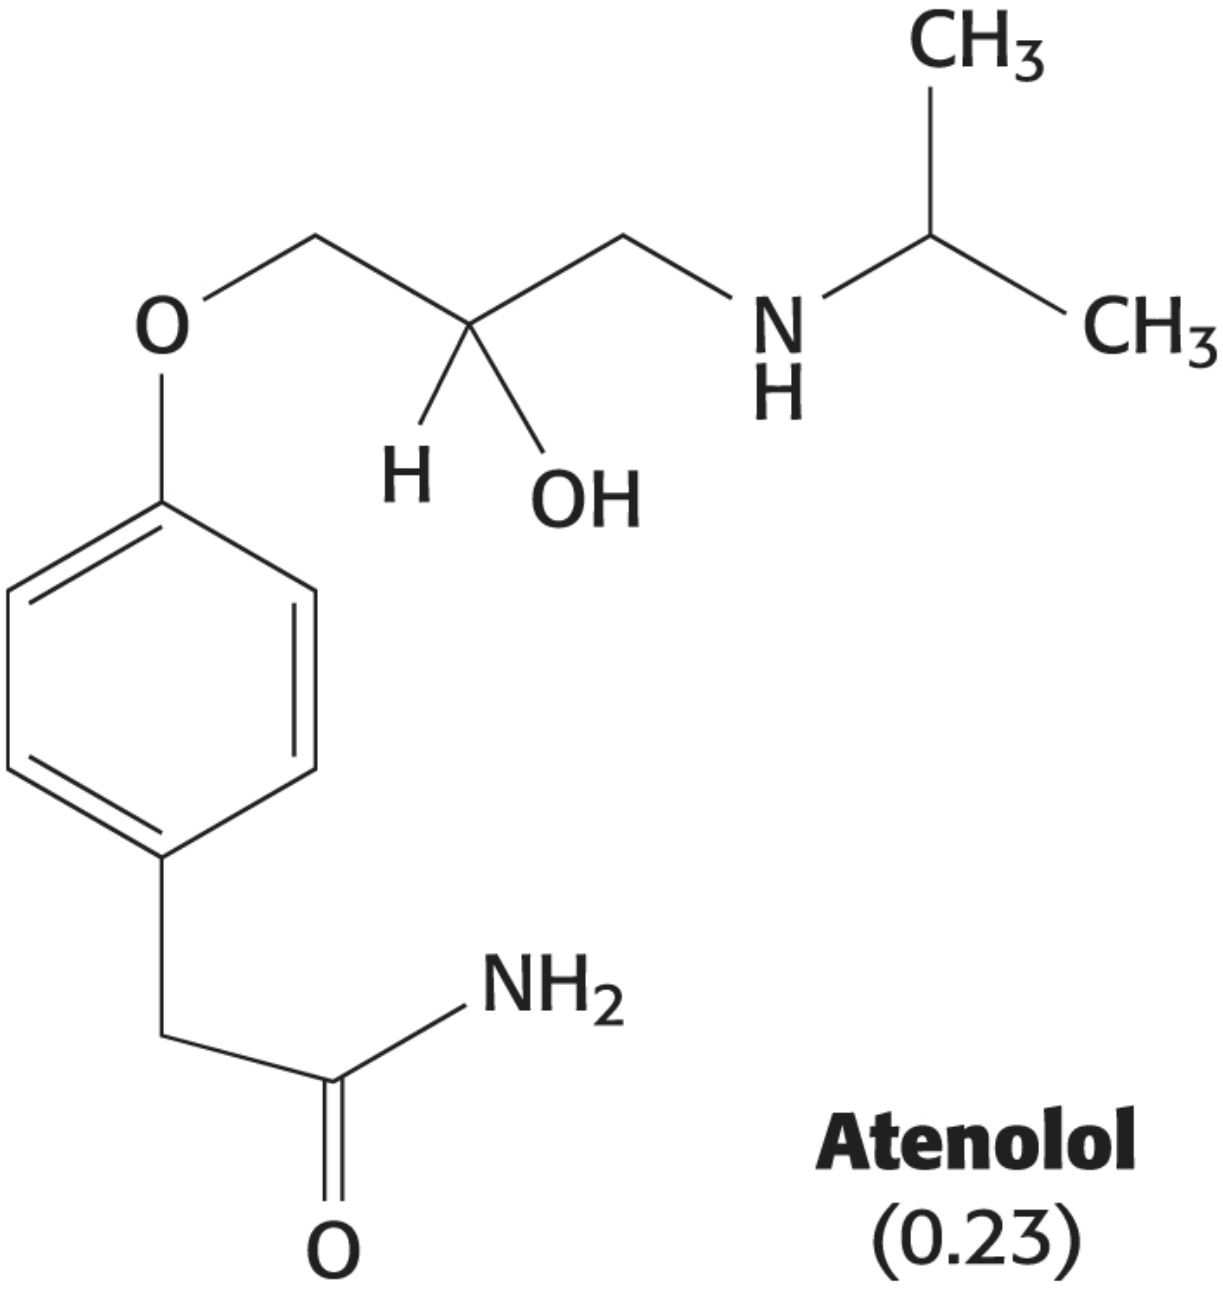
Extended description for Hydrolyzation of penicillin by Beta-Lactamase



Penicillin

The reversible reaction contains two reactants and one product. The first reactant labeled Penicillin has the following structure: A 4-membered heterocyclic square ring is in a horizontal orientation consisting of 1 N and 3 C atoms. N occupies the first position which is the bottom right vertex. C 1 is double bonded to O. C 3 is dash bonded to H above. C 2 is wedge bonded to N H. N H is single bonded to a central C atom on the upper left in the form of a line. The central C atom is double bonded to a second O atom on the upper right and single bonded to R on the left. The ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 1 N, 1 S, and 3 C atoms. In the pentagonal ring, N occupies the first position which is the bottom left vertex, and S occupies the third position which is the top right vertex. The two rings are fused to each other such that C 3 and N of the square ring are the C 1 and N of the pentagonal ring, respectively. C 2 of the pentagonal ring is wedge bonded to C H 3 on the upper right and dash bonded to C H 3 on the lower right. C 3 of the pentagonal ring is dash bonded to C O O superscript minus. The second reactant is H 2 O highlighted in red. The reaction takes place in the presence of Beta-Lactamase highlighted in blue and written over the reversible

reaction arrow. The product has the following structure: A 1 N and 3 C heteronuclear alkane chain is depicted as a line structure using 3 zigzag lines. N bound to H occupies the second position. A wedge bond is present between N H and C 2. C 1 is double bonded to O on the upper right and is single bonded to R on the left. C 3 is double bonded to a second O atom on the left and is single bonded to O H on the lower right. O H is highlighted in red. C 2 is single bonded on the right to C 1 of a 5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 1 N, 1 S, and 3 C atoms. In the pentagonal ring, N occupies the first position which is the bottom left vertex, and S occupies the third position which is the top right vertex. H of N H of the pentagonal ring is highlighted in red. C 1 of the pentagonal ring is dash bonded to H above. C 2 of the pentagonal ring is wedge bonded to C H 3 on the upper right and dash bonded to C H 3 on the lower right. C 3 of the pentagonal ring is dash bonded to C O O superscript minus.

Sildenafil
(3.18)

A 6-membered heterocyclic hexagonal ring is in a vertical orientation consisting of 2 N and 4 C atoms. The first N atom is in the first position which is the top right vertex. The second N atom is in the fourth position which is the bottom left vertex. The second N atom is single bonded to C H 3. The first N atom is single bonded to a central S atom. The central S atom is double bonded to O on the right and a second O atom on the lower right, and single bonded above to C 4 of a benzene ring in a vertical orientation with C 1 occupying the topmost vertex. The benzene ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5

and C 6. C 1 of the benzene ring is single bonded to a third O atom. The third O atom is single bonded on the upper left to C 2 of a 2-carbon alkane chain depicted as a line structure using 1 line. C 2 of the benzene ring is single bonded to C 1 of a second 6-membered heterocyclic hexagonal ring in a vertical orientation consisting of 2 N and 4 C atoms. In the second 6-membered ring, the first N atom occupies the first position which is the bottommost vertex, and the second N atom bound to H occupies the third position which is the top left vertex. In the second 6-membered ring, a double bond is present between the first N atom and C 1, and C 3 and C 4. C 2 of the second 6-membered ring is double bonded to a fourth O atom. The second 6-membered ring is fused to a 5-membered heterocyclic pentagonal ring in a horizontal orientation consisting of 2 N and 3 C atoms. In the pentagonal ring, the first N atom occupies the first position which is the top right vertex, and the second N atom occupies the second position which is the rightmost vertex. In the pentagonal ring, a double bond is present between the second N atom and C 1. The first N atom of the pentagonal ring is single bonded to C H 3. C 1 of the pentagonal ring is single bonded to C 1 of a 3-carbon alkane chain depicted as a line structure using 2 zigzag lines.

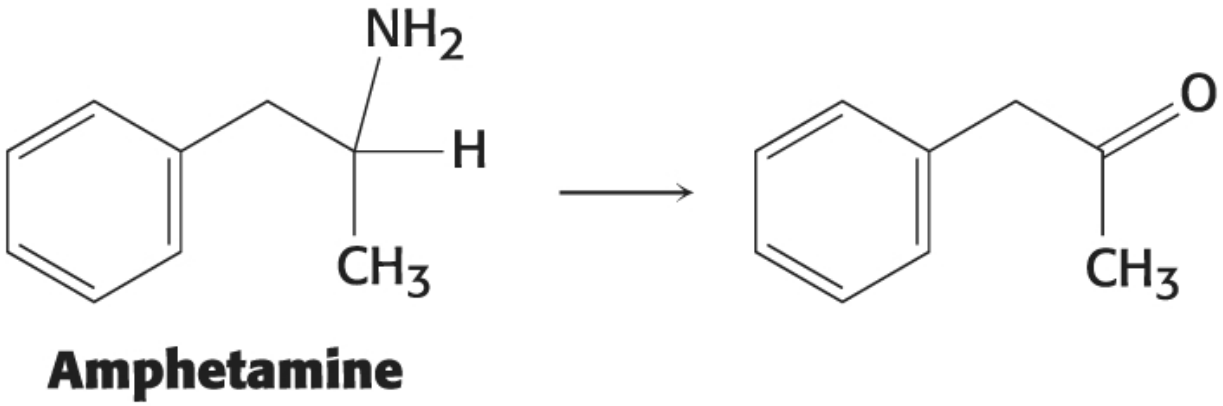
Extended description for Structure of Compound A



Compound A

A 7-membered heterocyclic heptagonal ring is in a vertical orientation and consists of 2 N and 5 C atoms. The first N atom is in the first position which occupies the top left vertex. The second N atom is in the third position which occupies the top right vertex. C 1 is double bonded to O. C 3 is dash bonded to O H. C 4 is wedge bonded to O H. The first N atom is single bonded to a central C H 2 group in the form of a line. The central C H 2 group is single bonded on the lower left to C 2 of a benzene ring in a vertical orientation with C 1 occupying the topmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and C 4, and C 5 and C 6. The ring is fused to a 6-carbon hexagonal ring in a vertical orientation with C 1 occupying the topmost vertex. The two rings are fused to each other such that C 5 and C 6 of the benzene ring are the C 3 and C 2 of the 6-carbon hexagonal ring in a orientation with C 1 occupying the vertex ring, respectively. In the 6-carbon ring, a double bond is present between C 4 and C 5, and C 6 and C 1. The

second N atom of the heptagonal ring is single bonded to a second central C H 2 group in the form of a line. The second central C H 2 group is single bonded on the lower right to C 6 of a second benzene ring in a vertical orientation with C 1 occupying the topmost vertex. The second benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. The second benzene ring is fused to a second 6-carbon hexagonal ring in a vertical orientation with C 1 occupying the topmost vertex. The two rings are fused to each other such that C 2 and C 3 of the second benzene ring are the C 6 and C 5 of the second 6-carbon ring, respectively. C 2 of the heptagonal ring is dash bonded to a third central C H 2 group in the form of a dashed line. The third central C H 2 group is single bonded to C 5 of a third benzene ring in a horizontal orientation with C 1 occupying the rightmost vertex. The third benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 5 of the heptagonal ring is wedge bonded to a fourth central C H 2 group in the form of a wedged line. The fourth central C H 2 group is single bonded to C 1 of a fourth benzene ring in a vertical orientation with C 1 occupying the topmost vertex. The fourth benzene ring contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1.

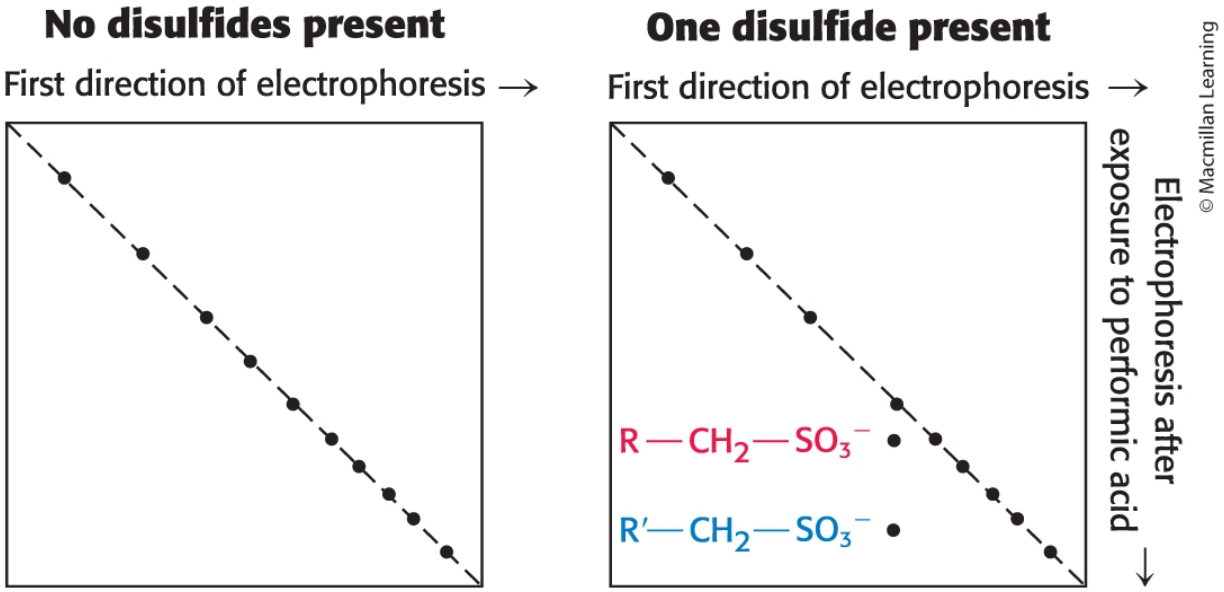
Extended description for Relationship between concentration and p H

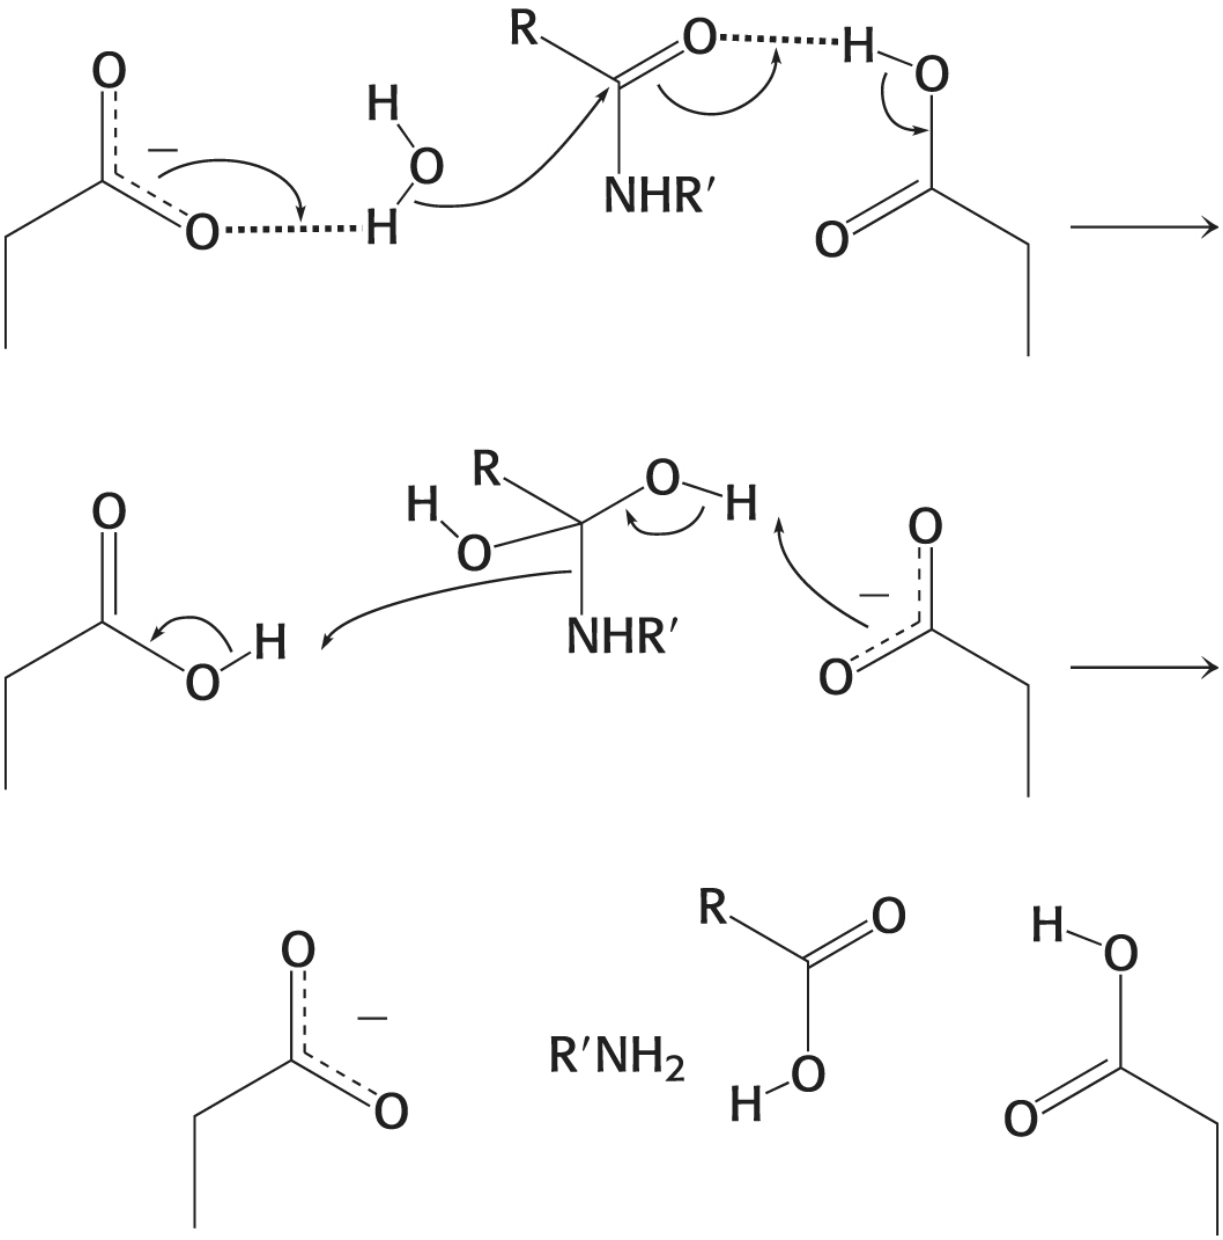


The horizontal axis is labeled p H. It has markings ranging from 0 to 14 in increments of 2 units. The vertical axis is labeled concentration. The graph contains three curves depicted in red, blue, and green colors. The first red curve starts at the highest concentration, moves horizontally till p H 1.2, and then gradually declines to reach p H 5 on the horizontal axis. The second blue curve is a bell-shaped curve with a broad and flat peak. It starts at the lowest concentration at p H 0, moves horizontally till p H 0. 8, and then rises toward the upper right to reach the highest concentration at p H 4. The curves then move horizontally toward the right till p H 8 and then fall gradually to reach p H 12 on the horizontal axis. The point of the intersection of the downward slope of the red curve and the upward slope of the blue curve at an average concentration and p H of 2.2 is labeled p K subscript 1. A dashed vertical line originates from p H 5.8 on the horizontal axis and touches the horizontal part of the blue curve. The third green starts at p H 6.9 on the horizontal

axis, moves horizontally till p H 7.5, and then rises gradually toward the upper right to reach the highest concentration at p H 11.5. The curve continues moving horizontally toward the right. The point of intersection between the downward slope of the blue curve and the upward slope of the green curve at an average concentration and p H of 9.7 is labeled p K subscript 2. All values are estimated.

Return to Relationship between concentration and p H

Extended description for Electrophoretic mobility of a protein with no disulfide bond or one disulfide bond



The first square-shaped chromatography paper depicts the mobility of protein with no disulfides present. The top of the paper is labeled "First direction of electrophoresis" which is from left to right. The right side is labeled "Electrophoresis after exposure to performic acid." Its direction is from top to bottom. The paper contains a diagonal dashed line from the top left to the bottom right vertex. A series of dots are placed across the diagonal line.

The second chromatography paper depicts the mobility of protein with one disulfide present. It contains a diagonal dashed line from the top left to the bottom right vertex. A series of dots are placed across the diagonal line. Two dots are located on the bottom left side of the diagonal line. The top dot is for R, single bond, C H 2, single bond, S O 3 superscript minus. The bottom dot is for R dash, single bond, C H 2, single bond, S O 3 superscript minus.

Return to Electrophoretic mobility of a protein with no disulfide bond or one disulfide bond

Extended description for Reaction mechanism of aspartyl protease

A 2-carbon alkane chain is depicted as a vertical line. C 2 is single-bonded to C on the upper right. This C is partially double bonded to O above and O on the lower right. The C O O group has an overall

negative charge. An arrow from the partial double bond between C and lower right O points toward a dashed line connecting the lower right O with H of H 2 O. H 2 O consists of a central O single bonded to H on the upper left and lower left. An arrow from the single bond between O and lower left H of H 2 O points toward a central C atom of a compound. This C is single bonded to R on the upper left, single bonded to N H R dash, and double bonded to O on the upper right. The upper right O of this compound is connected to the H of another compound through a dashed line. H is single-bonded to O on the lower right. This O is single-bonded to a central C below. This C is double bonded to O on the lower left and C 1 of a 2-carbon alkane chain is depicted as a vertical line. An arrow from the single bond between H and O of this compound points toward the single bond between O and C.

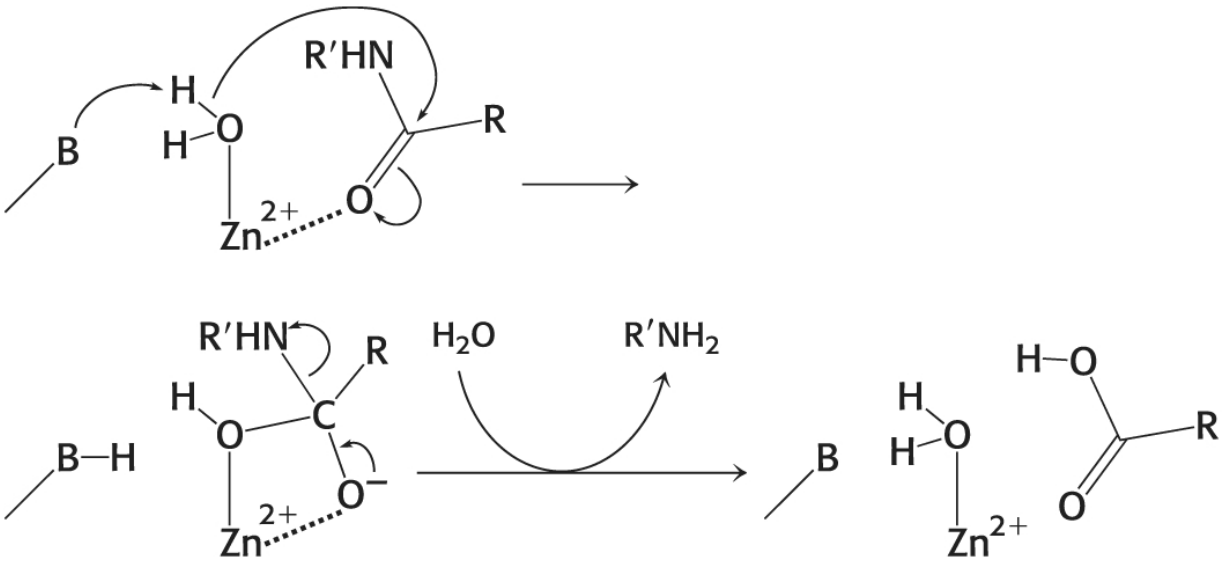
In the next step, a 2-carbon alkane chain is depicted as a vertical line. C 2 is single-bonded to C on the upper right. This C is double bonded to O above and single bonded to O, single bond, H on the lower right. An arrow from the single bond between O and H points toward the single bond between C and O.

A compound located on the right has the following structure: A central C atom is single bonded to R on the upper left, single bonded to O on the lower left, single bonded to N H R dash below, and single bonded to O on the upper right. Both the O atoms are single-bonded to H.

An arrow from the single bond between upper right O and H points toward the single bond between O and C. An arrow from the single bond between N H R dash and C points toward the H atom of the first alkane chain.

A second 2-carbon alkane chain is depicted as a vertical line on the right. C 1 of this chain is single-bonded to C on the upper left. This C

is partially double-bonded to O above and partially double-bonded to O on the lower left. The C O O group has a negative charge. An arrow from the partial double bond between C and the lower left O of the C O O group points toward H of the compound in the middle.



In the final step, two products are formed. The first product is R dash N H 2. The structure of the second product is as follows: A central C is single bonded to R on the upper left, double bonded to O on the upper right, single bonded to O below. The O atom below is single-bonded to H on the lower left.

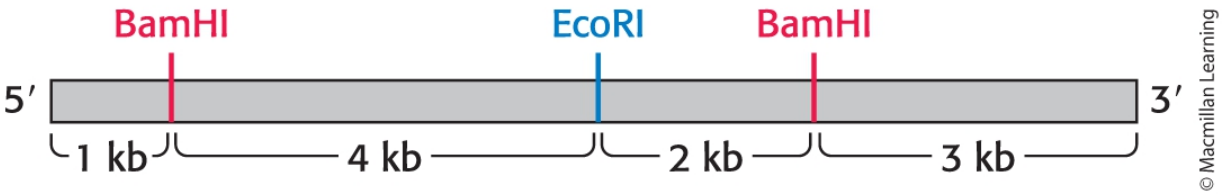
A 2-carbon alkane chain is depicted as a vertical line on the right. C 1 of this chain is single-bonded to C on the upper left. This C is partially double-bonded to O above and partially double-bonded to O on the lower left. The C O O group has a negative charge.

A 2-carbon alkane chain is depicted as a vertical line on the left. C 1 of this chain is single-bonded to C on the upper left. This C is single bonded O, single bond, H above, and double bonded to O on the lower left.

Return to Reaction mechanism of aspartyl protease

Extended description for Reaction mechanism of metalloprotease

In the first step, a central Z n superscript 2 plus atom is shown below. It is single-bonded to O above. This O is single-bonded to H on the upper left and lower left. A dashed line connects the Z n superscript plus atom with the O atom of another compound. This compound consists of a central C atom double bonded to O on the lower left, single bonded to R dash H N on the upper left, and single bonded to R on the upper right. B with an open single bond on the lower left attacks the upper left H of H 2 O. An arrow from the single bond between this H and O of H 2 O points toward the central C atom. An arrow from the double bond between the central C atom and the lower left O points toward O.

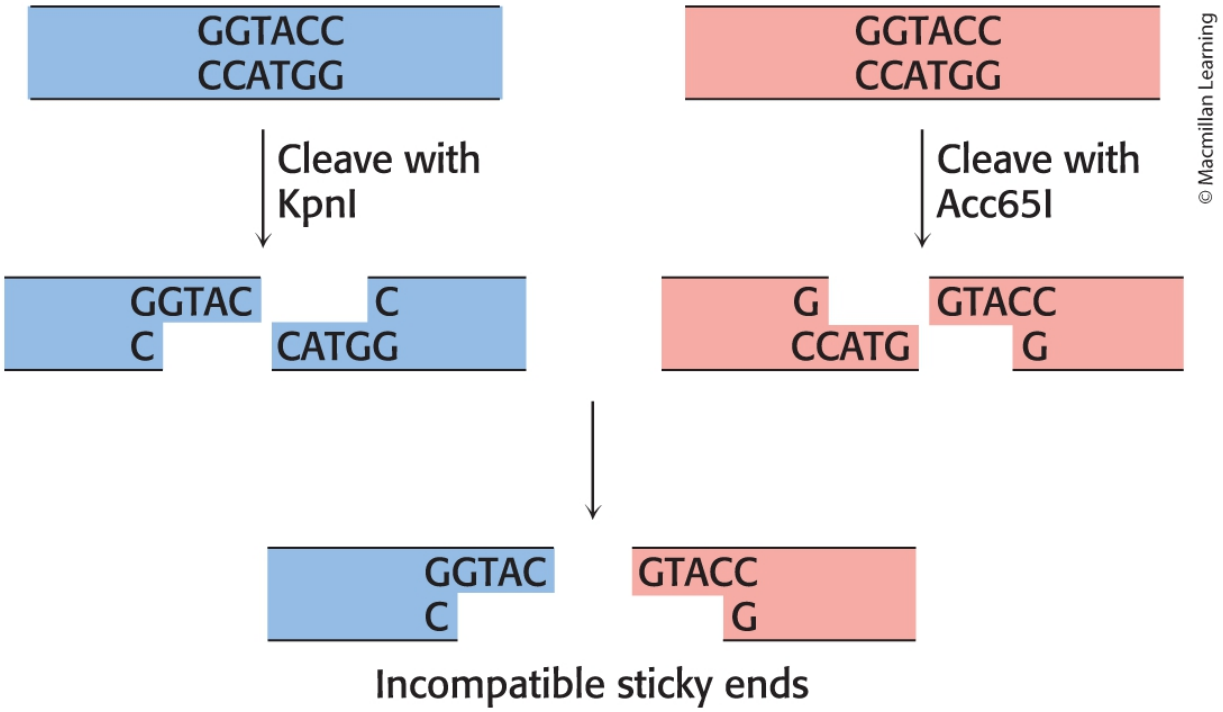


In the second step, B with an open single bond is single-bonded to H on the right. Z n superscript 2 plus is single bonded to O above, which is further single bonded to H on the upper left. This O is also single-bonded to C on the right. C is single bonded to N H R dash on the upper left, single bonded to R on the upper right, and single

bonded to O superscript minus on the lower left. A dashed line connects O superscript minus with Z n superscript 2 plus. An arrow from O superscript minus points toward its single bond with the C atom. An arrow from the single bond between this C and N H R dash points toward the N H R dash.

In the third step, H 2 O enters, and R dash N H 2 leaves. B with an open single bond is located on the left. A central O single bonded to Z n superscript 2 plus below, single bonded to H on the upper left and lower left is shown in the middle. The third compound consists of a central C atom double bonded to O on the lower left, single bonded to R on the right, and single bonded to O above. This O is single-bonded to H on the left.

Return to Reaction mechanism of metalloprotease



Extended description for Restriction map of a linear D N A

The D N A is depicted as a horizontal bar with its left end labeled 5 prime and right end labeled 3 prime. It contains two B a m H 1 sites and one Eco R 1 site. The first B a m H 1 site is located near the 5 prime end and the second site is located close to the 3 prime end. The Eco R 1 site is located in the middle of the D N A. The distance between the 5 prime end and the first B a m H 1 site is 1 k b. The distance between the second B a m H 1 site and the 3 prime end is 3 k b. The distance between the first B a m H 1 and Eco R 1 site is 4 k b. The distance between the Eco R 1 site and the second B a m H 1 site is 2 k b.

Return to Restriction map of a linear D N A

Extended description for Formation of incompatible sticky ends

A short blue horizontal bar depicts a D N A segment containing the sequence G G T A C C. G G T A C C is base paired with C C A T G G. This D N A is cleaved with K p n roman number 1. The bond between the first C and second C of the top sequence and the first C and second C of the bottom sequence is cleaved. This creates an overhang sequence containing G G T A C at the top and C at the bottom. The first G of the top sequence is base paired with C.

A short pink horizontal bar depicts a D N A segment containing the sequence G G T A C C. G G T A C C is base paired with C C A T G G. The D N A segment is cleaved with A c c 65 roman number 1. The bond between the first and second G of the top sequence and the first G and second G of the bottom sequence is cleaved. This creates

an overhang sequence containing G T A C C at the top and G at the bottom. The second C of the top sequence is base paired with G.

These overhang sequences produced from the two different D N A segments are labeled "incompatible sticky ends."

Return to Formation of incompatible sticky ends

Extended description for Three pairs of aligned protein sequences

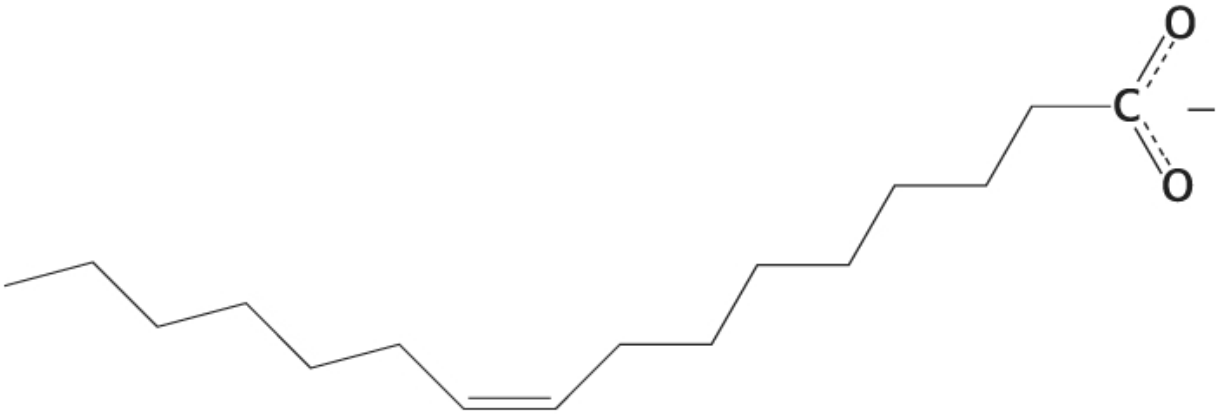
In the first pair, the aligned sequences are as follows:

The first sequence is as follows: W Y L G K I T R M D A E V L L K K P T V R D G H F L V T Q C E S S P G E F.

The second sequence is as follows: W Y F G K I T R R E S E R L L L N P E N P R G T F L V R E S E T T K G A Y.

In the second pair, the aligned sequences are as follows:

The first sequence is as follows: S I S V R F G D S V Q, five dashes, H F K V L R D Q N G K Y Y L W A V K, single dash, F N. The second sequence is as follows: C L S V S D F D N A K G L N V K H Y K I R K L D S G G F Y I T S R T Q F S.

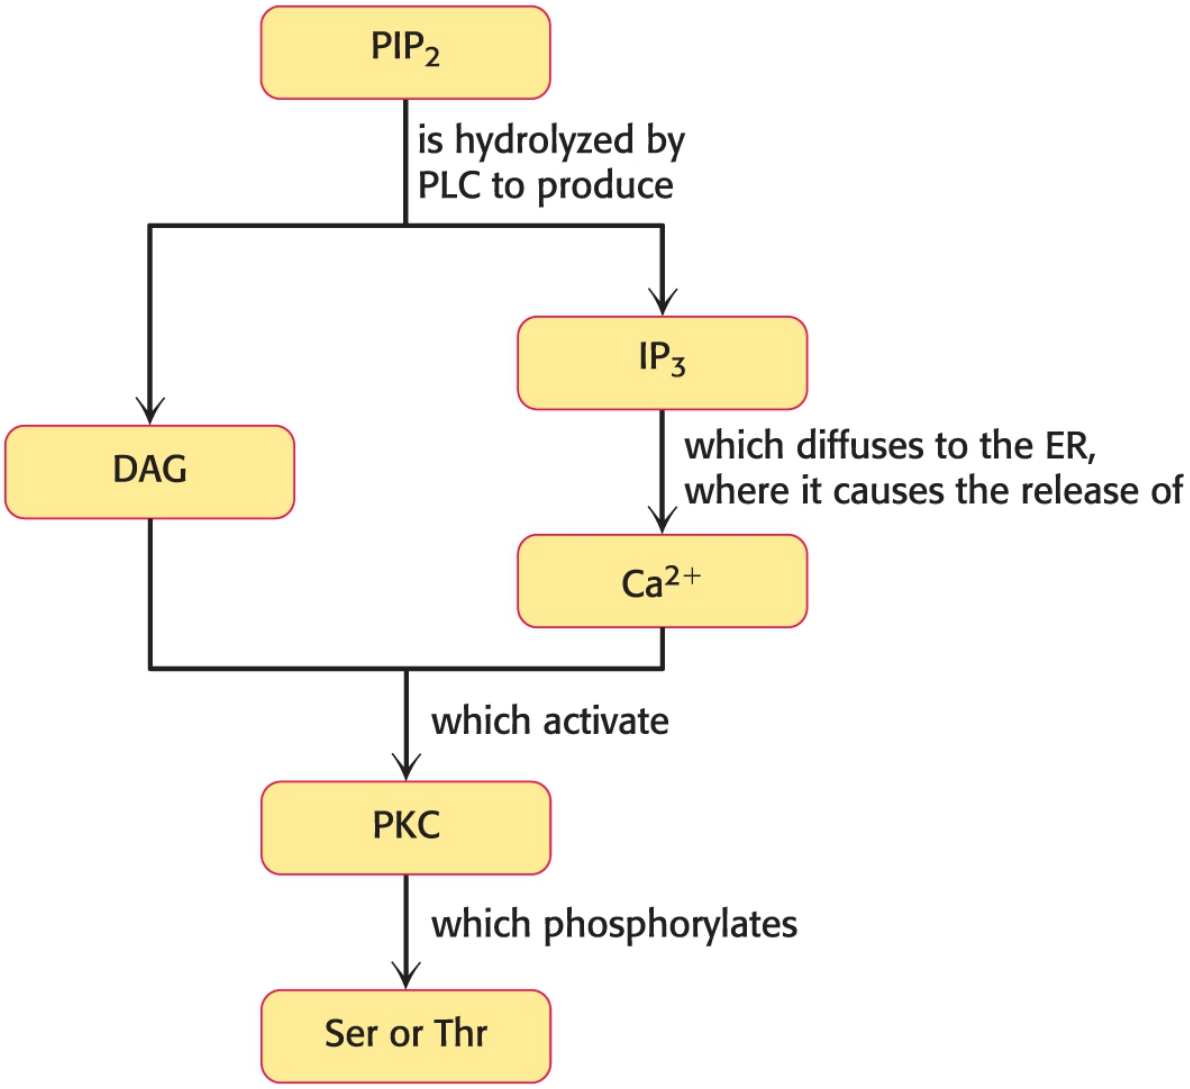


In the third pair, the aligned sequences are as follows: The first sequence is as follows: S L N E L V A Y H R T A S V S R T H T I L L S D M N V.

The second sequence is as follows: S S L Q Q L V A Y Y S K H A D G L C H R L T N V.

The identical amino acid residues in the aligned pairs are highlighted in yellow.

Return to Three pairs of aligned protein sequences



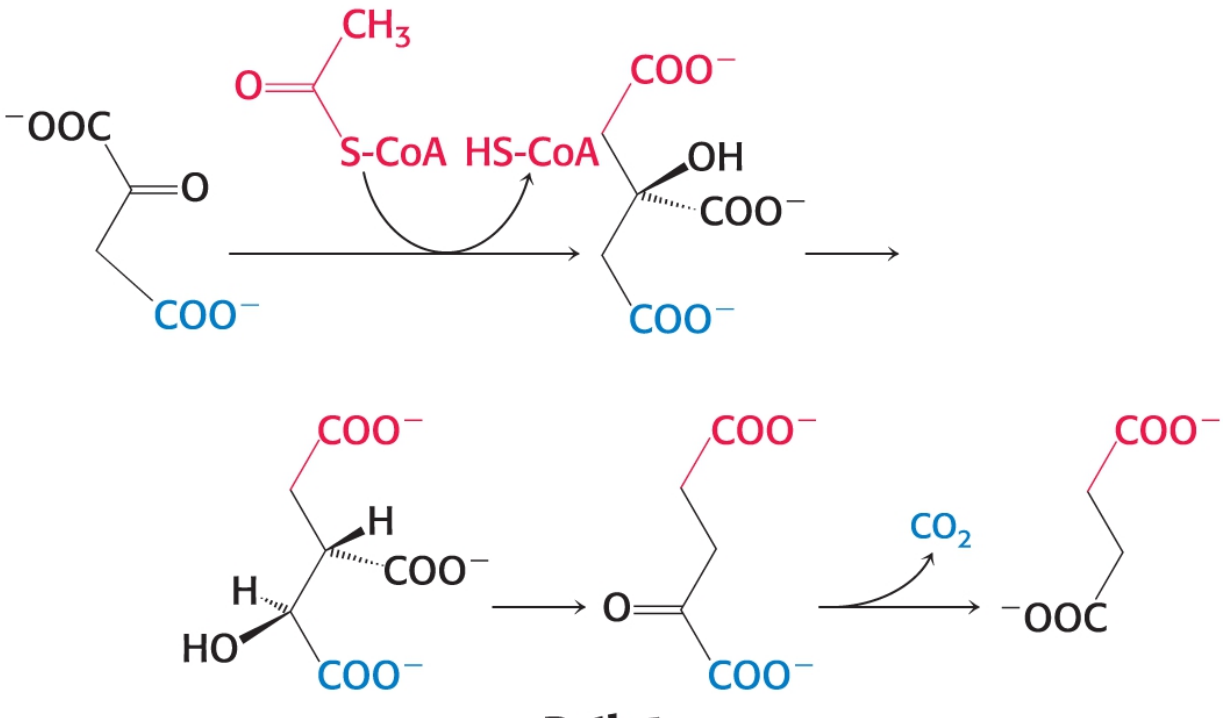
Extended description for Chemical structure

The chemical structure is depicted as follows: A 15-carbon alkene chain is depicted as a line structure using 14 zigzag lines. A double bond is present between C 7 and C 8. C 15 is single bonded to C on the right. This C is partially double-bonded to O on the upper right and O on the lower right. The C O O group has an overall negative charge.

Return to Chemical structure

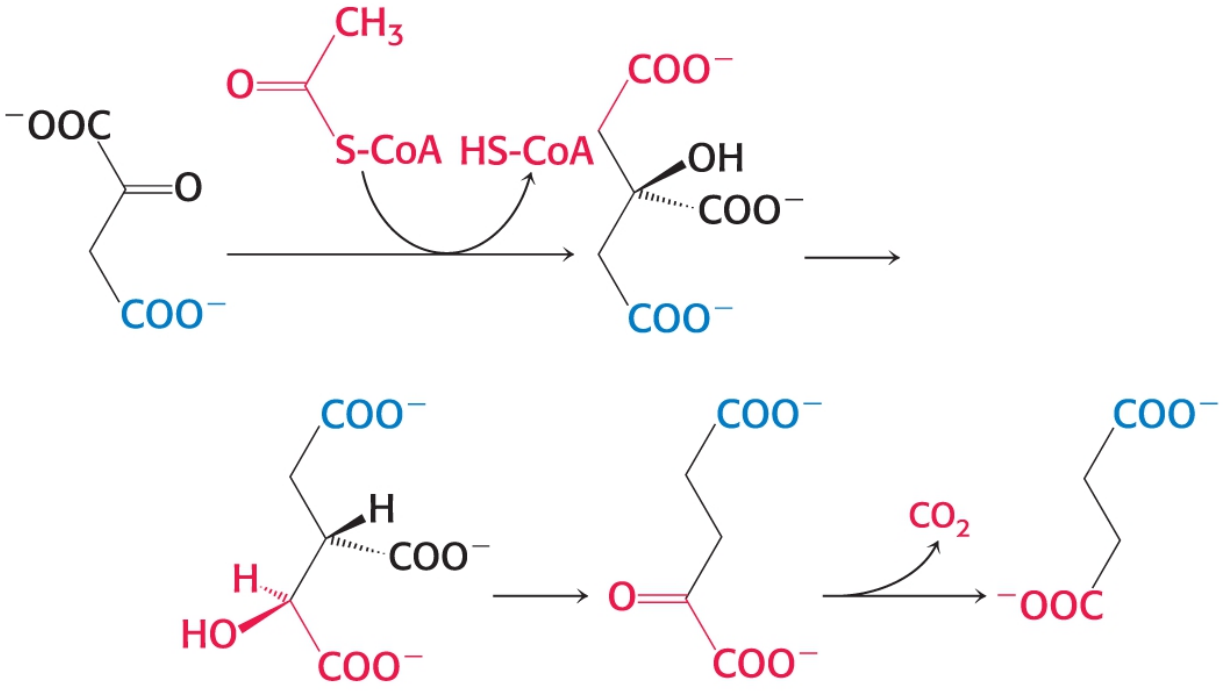
Extended description for Flowchart depicts a signaling pathway

© Macmillan Learning



A rectangular yellow box labeled P I P 2 is shown at the top. A line below this box is labeled "is hydrolyzed by P L C to produce." The line bifurcates into two downward arrows. The left arrow leads to a yellow box labeled D A G. The right arrow leads to a box labeled I P 3. A downward arrow labeled "which diffuses to the E R, where it causes the release of." leads to a yellow box labeled C a superscript 2

plus. Lines from D A G and C a superscript 2 plus combine into a single downward arrow labeled "which activate." This arrow leads to a yellow box labeled P K C. A downward arrow below P K C is labeled "which phosphorylates" and it leads to a box labeled serine or threonine.



Return to Flowchart depicts a signaling pathway

Extended description for Citrate molecule undergoing

a series of reactions

Path 1

Path 2 (does not occur)

Path 1 is depicted as follows:

In the first irreversible, there is one reactant and one product. It is coupled with the entry of acetyl-C o A and release of H S, single bond, C o A.

The structure of the reactant is as follows: A central C atom is single bonded to C H 2 on the lower left in the form of a line, double bonded to O on the right, and single bonded to C O O superscript minus on the upper left. C H 2 is single bonded to C O O superscript minus on the lower right.

The structure of acetyl C o A is as follows: A central C atom is double bonded to O on the left, single bonded to C H 3 on the upper right, and single bonded to S, single bond, C o A on the lower right.

The structure of the product is as follows: A 3-carbon alkane chain is depicted as a vertical line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the upper right. C 2 is wedge bonded to O H on the upper right and dash bonded to C O O superscript minus on the lower right. C 3 is single bonded to C O O superscript minus on the lower right.

In the second irreversible step, the product of the first step serves as the reactant and is converted into another product.

The structure of the product is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the upper right. The C O O group is highlighted in red. C 2 is wedge bonded to H on the upper right and dash bonded to C O O superscript minus on the right. C 3 is dash bonded to H on the left, wedge bonded to O H on the lower left, and

single bonded to C O O superscript minus on the lower right. The C O O group is highlighted in blue.

In the third irreversible step, the product of the second step is converted into another product.

The structure of the product is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the upper right. C 3 is double bonded to O on the left and single bonded to C O O superscript on the lower right.

In the fourth irreversible step, C O 2 is released and the product of the third step is converted into the final product. C O 2 is highlighted in blue.

The structure of the final product is as follows: A 2-carbon alkane chain is depicted as a diagonal line. C 1 is single bonded to C O O superscript minus on the upper right and single bonded to C O O superscript minus on the lower left. The upper right C O O group is highlighted in red.

Path 2 is depicted as follows:

In the first irreversible, there is one reactant and one product. It is coupled with the entry of acetyl-C o A and release of H S, single bond, C o A.

The structure of the reactant is as follows: A central C atom is single bonded to C H 2 on the lower left in the form of a line, double bonded to O on the right, and single bonded to C O O superscript minus on the upper left. C H 2 is single bonded to C O O superscript minus on the lower right.

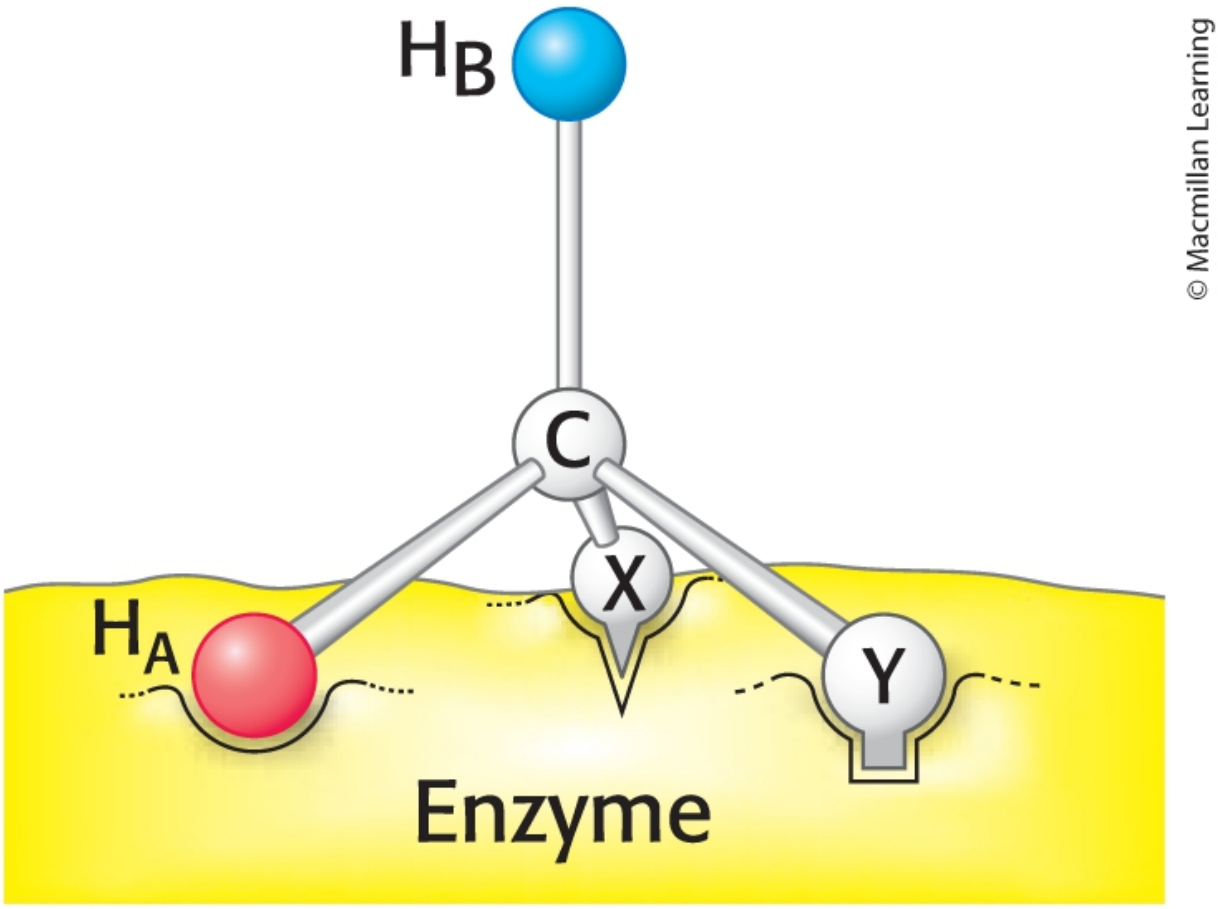
The structure of acetyl C o A is as follows: A central C atom is double bonded to O on the left, single bonded to C H 3 on the upper right, and single bonded to S, single bond, C o A on the lower right.

The structure of the product is as follows: A 3-carbon alkane chain is depicted as a vertical line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the upper right. C 2 is wedge bonded to O H on the upper right and dash bonded to C O O superscript minus on the lower right. C 3 is single bonded to C O O superscript minus on the lower right. In the second irreversible step, the product of the first step serves as the reactant and is converted into another product.

The structure of the product is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the upper right. The C O O group is highlighted in blue. C 2 is wedge bonded to H on the upper right and dash bonded to C O O superscript minus on the right. C 3 is dash bonded to H on the left, wedge bonded to O H on the lower left, and single bonded to C O O superscript minus on the lower right. The substituents of C 3 are highlighted in red.

In the third irreversible step, the product of the second step is converted into another product.

The structure of the product is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the upper right highlighted in blue. C 3 is double bonded to O on the left and single bonded to C O O superscript on the lower right. Both O and C O O superscript minus are highlighted in red.



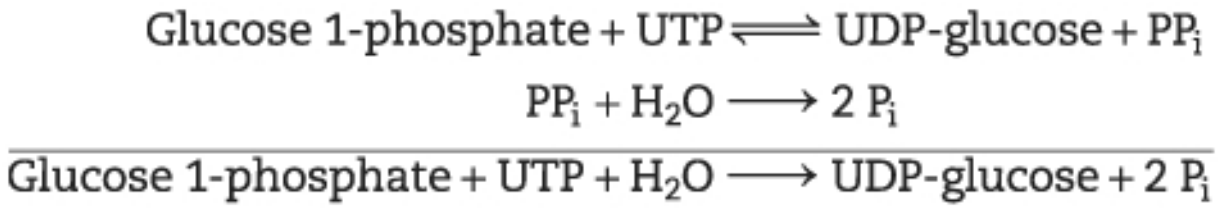
In the fourth irreversible step, C O 2 is released and the product of the third step is converted into the final product. C O 2 is highlighted in red.

The structure of the final product is as follows: A 2-carbon alkane chain is depicted as a diagonal line. C 1 is single bonded to C O O superscript minus on the upper right and single bonded to C O O superscript minus on the lower left. The upper right C O O group is highlighted in blue and the lower left C O O group is highlighted in red.

Note: Path 2 does not occur.

Return to Citrate molecule undergoing a series of reactions

Extended description for Illustration of an enzyme bound to a substrate



© Macmillan Learning

The top surface of the enzyme is shown. The substrate is depicted in a ball-and-stick model. It consists of a central white sphere depicting C connected to a blue sphere above, a red sphere on the lower left, a white sphere labeled Y on the lower right, and a small white sphere labeled X below. The blue sphere is labeled H subscript B and the red sphere is labeled H subscript A. The red sphere and the white sphere labeled Y are located toward the observer. Both these spheres are bound to a cleft on the top surface of the enzyme. The sphere labeled Y has a small rectangular portion that fits inside a rectangular groove. The white sphere labeled X has a conical

protrusion at the bottom that fits inside a complementary groove on the top surface of the enzyme.

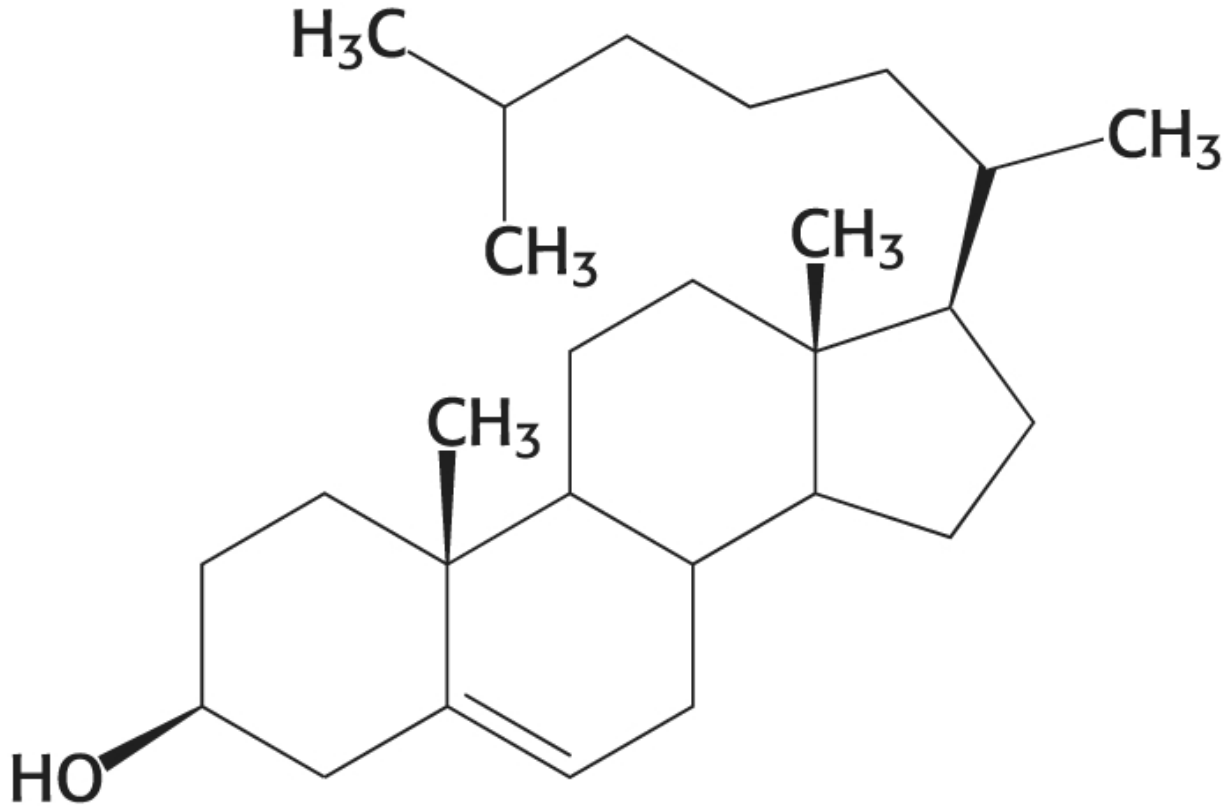
Extended description for Structure of alpha-ketoglutarate

The structure of alpha-ketoglutarate is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus on the lower left. C 3 is double bonded to O above and single bonded to C O O superscript minus on the lower right.

Return to Structure of alpha-ketoglutarate

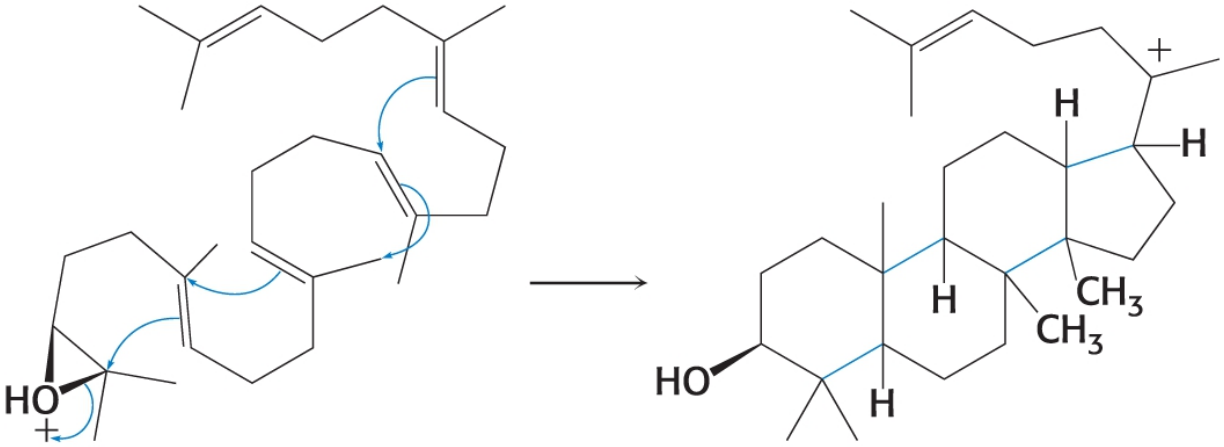


Extended description for Structure of pipecolate

A 6-membered heterocyclic hexagonal ring is in a horizontal orientation with C 1 occupying the bottom left vertex. It consists of 1 N and 5 C atoms. N with a positive charge occupies the bottom right vertex and is bound to H 2. C 5 is wedge bonded to C 4. C 5 is dash bonded to H on the upper right and single bonded to C O O superscript minus on the lower right.

Return to Structure of pipecolate

Extended description for Chemical structure of four fused rings



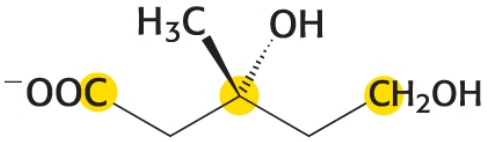
The structure is as follows: A 6-carbon homocyclic hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. C 5 is wedge bonded to O H on the lower left. It is fused to a second 6-carbon homocyclic hexagonal ring in a vertical orientation such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. In the second ring, C 6 is wedge bonded to C H 3 above. A double bond is present between C 4 and C 5. The second ring is fused to a third 6-carbon homocyclic hexagonal ring in a vertical orientation such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. The third ring is fused to a 5-carbon homocyclic pentagonal ring in a horizontal orientation such that C 2 and C 3 of the third ring are C 4 and C 3 respectively of the

pentagonal ring. C 4 is wedge bonded to C H 3 above. C 5 is wedge bonded to C 5 of a 5 carbon alkane chain depicted as a line structure using 4 zigzag lines. C 1 of the alkane chain is single bonded to C H 3 on the upper right and C H 3 below. C 5 is single bonded to C H 3 on the upper left.

Return to Chemical structure of four fused rings

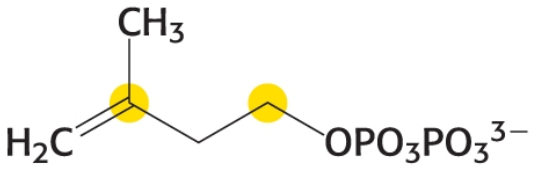
Extended description for Formation of protosterol cation

Protosterol cation



The structure of the reactant is as follows: A 5-carbon alkene chain is depicted as a line structure using 4 zigzag lines. A double bond is present between C 1 and C 2. C 1 is single bonded to C H 3 on the upper left and C H 3 below in the form of a line. C 5 is single bonded to C H 3 in the form of a line on the upper right and double bonded to C H below. This C H group is single-bonded to a C H 2 group on the lower right in the form of a line. This C H 2 group is single-bonded to C H 2 on the lower left in the form of a line. This C H 2 is single-bonded to C 1 of a 14-carbon alkene chain on the left depicted as a line structure using 13 zigzag lines. A double bond is present between C 1 and C 2, C 5 and C 6, and C 9 and C 10. C 1 is single-bonded to C H 3 in the form of a line on the lower left. C 6 is single bonded to C H 3 on the lower right in the form of a line. C 10 is single bonded to C H 3 on the upper right in the form of a line. C 13 and C 14 are each wedge bonded to a common O H superscript plus group atom. C 14 is single bonded to C H 3 on the lower right and lower left in the formation of a line. An arrow from the double bond between C 5 of the alkene chain and the C H group points toward C 2

of the 14-carbon alkene chain. An arrow from the double bond between C 1 and C 2 of the 14-carbon alkene chain points toward the C H 3 group single-bonded to C 6 of the 14-carbon alkene chain. An arrow from the double bond between C 5 and C 6 points to C H 3 single bonded to C 10. An arrow from the double bond between C 9 and C 10 points toward C H 3 group single-bonded to C 14.

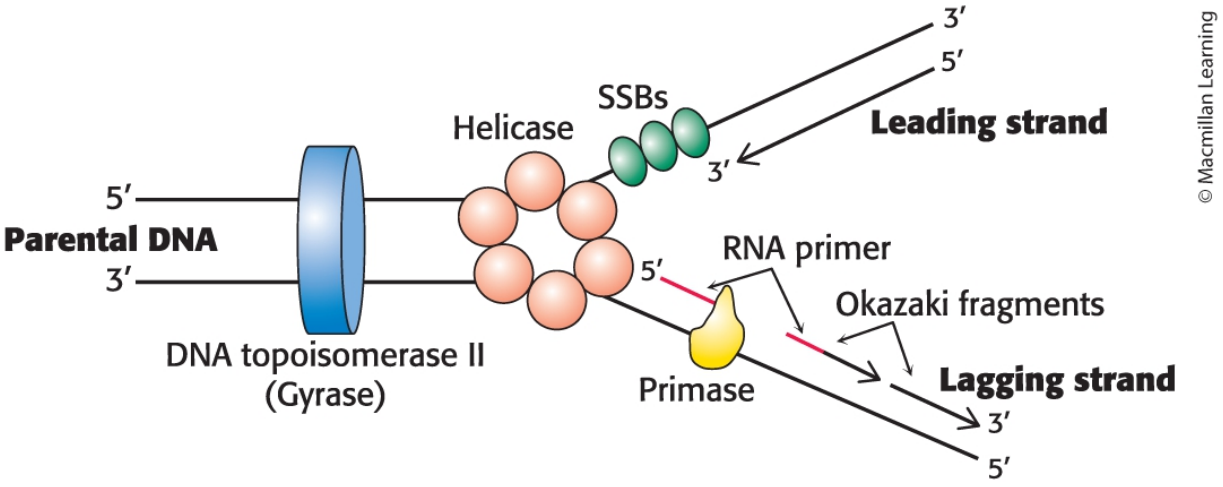


The product is a protosterol cation whose structure is as follows: Two 6-carbon hexagonal rings in vertical orientation have C 1 at the topmost vertex. Both the rings are fused such that C 2 and C 3 of the first ring are C 6 and C 5 respectively of the second ring. In the first ring, C 2 is single bonded to C H 3 above in the form of a line, C 3 is single bonded to H below, C 4 is single bonded to C H 3 on the lower left, and C H 3 on the lower right in the form of a line. C 5 is wedge bonded to O H on the lower left. In the second ring, C 1 is single-bonded to H below. Another 6-carbon hexagonal ring in vertical orientation is fused with the second ring such that C 1 and C 2 of the second ring are C 5 and C 4 respectively of the third ring. C 2 is single bonded to H above. C 3 and C 4 are each single bonded to C H 3. A 5-membered pentagonal ring in horizontal orientation with C 1 occupying the top right vertex is fused with the third ring such that C 2 and C 3 of the third ring are C 5 and C 4 respectively of the fourth ring. C 1 is single bonded to H on the right and single bonded to C 6 of a 7-carbon alkene chain depicted using 6 zigzag lines. In the alkane chain, a double bond is present between C 2 and C 3. C 6 of the alkene chain has a positive charge. C 2 of the alkane chain is single-bonded to C H 3 below in the form of a line.

Return to Formation of protosterol cation

Extended description for Structure of labeled mevalonate and labeled isopentenyl pyrophosphate

Labeled mevalonate



Labeled isopentenyl pyrophosphate

The structure of labeled mevalonate is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 is single bonded to C O O superscript minus. The C atom of the C O O group is highlighted in yellow. C 2 highlighted in yellow is wedge bonded to C H 3 on the upper left and dash bonded to O H on the upper right. C 3 is single bonded to C H 2 O H on the upper right. The C atom of the C H 2 O H group is highlighted in yellow.

The structure of labeled isopentenyl pyrophosphate is as follows: A 3-carbon alkane chain is depicted as a line structure using 2 zigzag lines. C 1 and C 3 are highlighted in yellow. C 1 is double bonded to C H 2 on the lower left and single bonded to C H 3 above. C 3 is single bonded to O P O 3 P O 3 superscript 3 minus on the lower right.

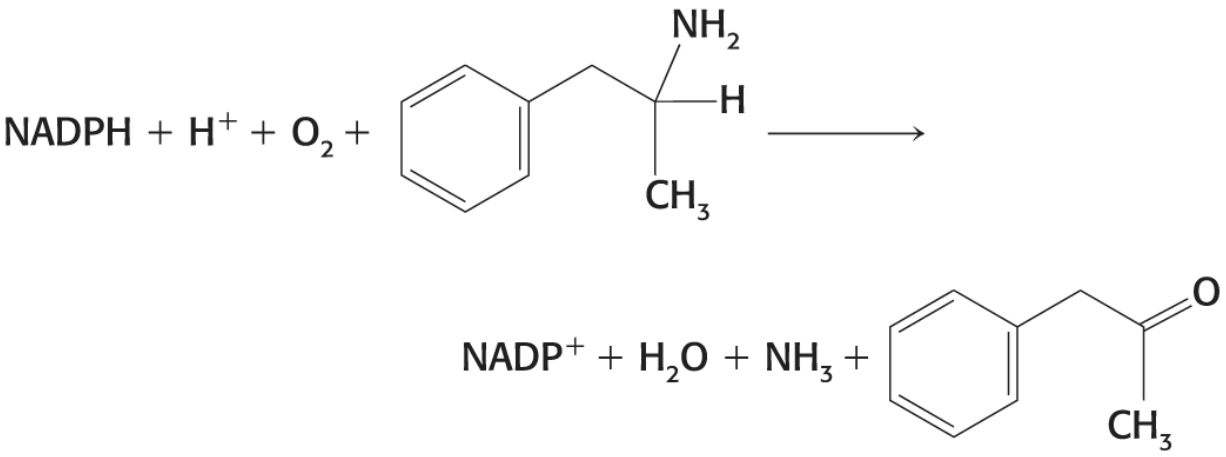
Extended description for Illustration of the replication fork



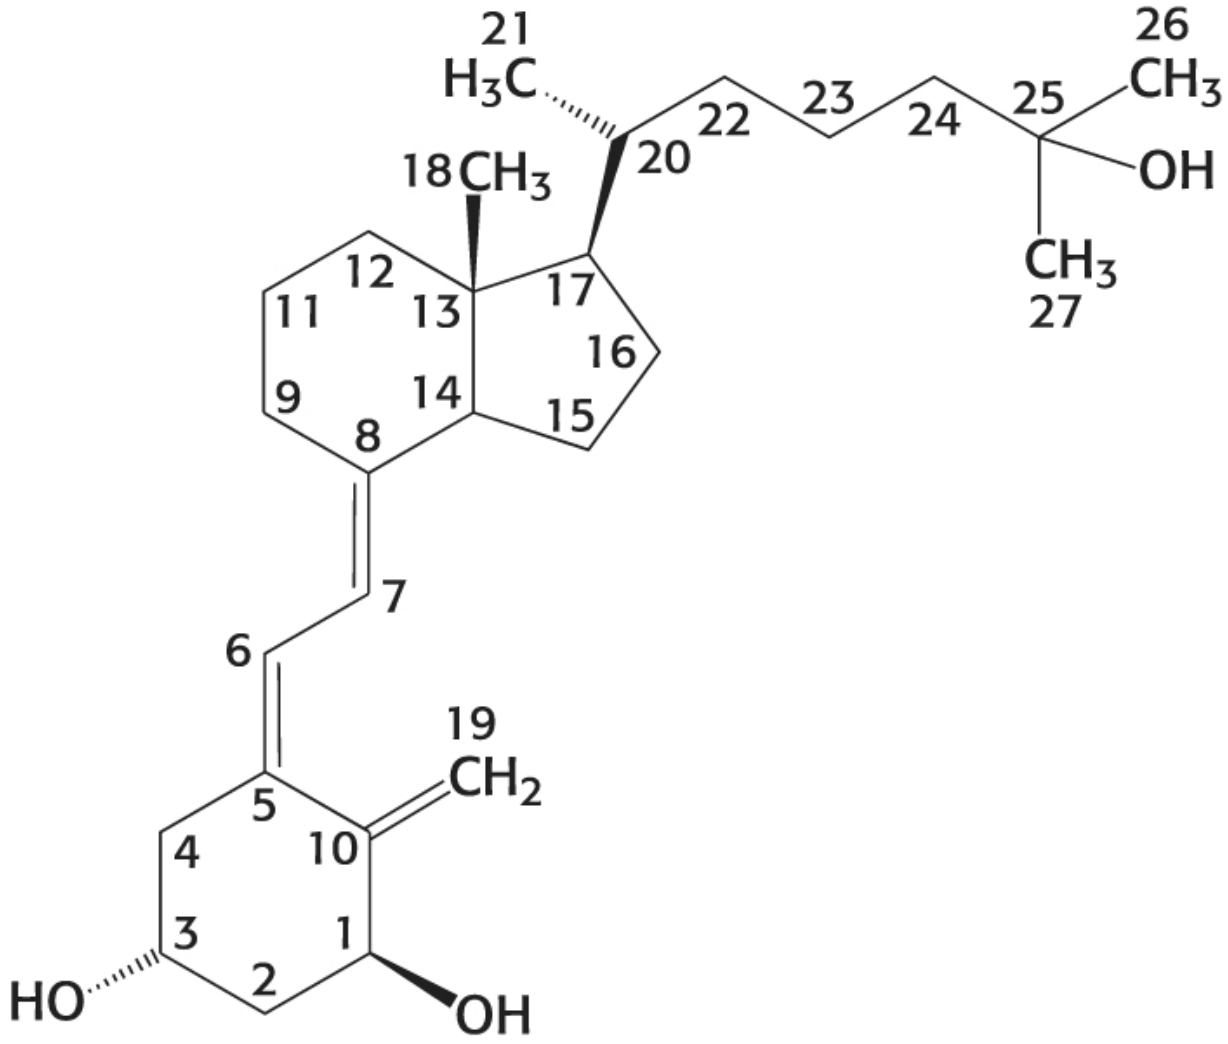
© Macmillan Learning

A horizontal Y-shaped replication fork is shown. The double-stranded D N A is labeled parental D N A. It is bound by a D N A topoisomerase 2 (gyrase) depicted as a thick circular disc. The side view of the disc is visible to the observer. The 5 prime end of the top D N A strand and 3 prime end of the bottom D N A strand are aligned together. The 3 prime and 5 prime ends of the top and bottom strands are separated to form a Y-shaped structure. The 3 prime end of the top strand is oriented toward the upper right. The 5 prime end of the bottom strand is oriented toward the lower right. A line parallel to the upper right 3 prime end is labeled leading strand. Its top end is labeled 5 prime and the bottom end has an arrowhead pointing toward the replication fork. The arrowhead end is labeled 3 prime. Two short lines separated by short gaps are aligned parallel with the lower right 5 prime end. The bottom end of each line has an arrowhead. These short lines depict Okazaki fragments. The arrowhead of the terminal Okazaki fragment is labeled 3 prime. These Okazaki fragments are collectively labeled lagging strand. The Okazaki fragment closer to the fork contains an R N A primer

depicted as a short red stretch. A primase is bound to the lagging strand template near the replication fork. It is engaged in the synthesis of a R N A primer. A helicase depicted as a hollow ring-like structure composed of 6 small spherical structures is bound to the replication fork. The single-stranded region of the leading strand template is bound by S S Bs depicted as small green ovals.

Return to Illustration of the replication fork

Extended description for Oxidative deamination reaction

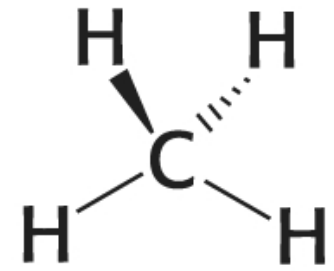


The reaction consists of three reactants and four products. The first reactant is N A D P H plus H superscript plus. The second reactant is O 2. The structure of the third reactant is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 2 is single bonded to C H 2 on the upper right in the form of a line. This C H 2 is single bonded to C on the lower right. The C atom is single-bonded to N H 2 on the upper right, H on the right, and C H 3 below.

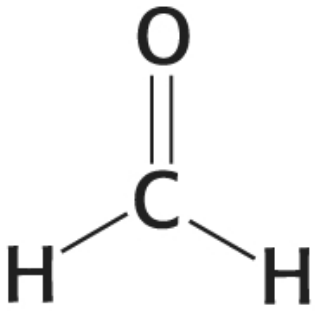
The first product is N A D P superscript plus. The second product is H 2 O. The third product is N H 3. The structure of the fourth product is as follows: A benzene ring is in a vertical orientation with C 1 occupying the topmost vertex. It contains alternating double bonds between C 2 and C 3, C 4 and C 5, and C 6 and C 1. C 2 is single bonded to C H 2 on the upper right in the form of a line. This C H 2 is single bonded to C on the lower right. The C atom is double-bonded to O on the upper right and single-bonded to C H 3.

Return to Oxidative deamination reaction

Extended description for Chemical structure



The structure is as follows: A 6-carbon hexagonal ring is in a vertical orientation with C 1 occupying the topmost vertex. C 2 is double bonded to C H 2 on the upper right, numbered 19. C 3 is wedge bonded to O H on the lower right. C 5 is dash bonded to O H on the lower left. C 3, C 4, C 5, C 6, C 1, and C 2 of this ring are numbered 1, 2, 3, 4, 5, and 10 respectively. C 1 is double bonded to C H above, numbered 6. C H is single bonded to C H on the upper right, numbered 7. This C H is double bonded to C 4 of a 6-carbon



hexagonal ring in a vertical orientation with C 1 occupying the topmost vertex. C 4, C 5, C 6, C 1, C 2, and C 3 of this ring are numbered 8, 9, 11, 12, 13, and 14 respectively. The hexagonal ring is fused with a 5-carbon pentagonal ring in a horizontal orientation such that C 2 and C 3 of the hexagonal ring are C 4 and C 3 respectively of the pentagonal ring. C 4 of the pentagonal ring is wedge bonded to C H 3 above, numbered 18. C 2, C 1, and C 5 of this ring are numbered 15, 16, and 17 respectively. C 5 is wedge bonded to C 1 of a 5-carbon alkane chain depicted as a line structure using 4 zigzag lines. C 1 is dash bonded to C H 3 on the upper left, numbered 21. C 5 is single bonded to C H 3 on the upper right, numbered 26, O H on the lower right, and C H 3 below numbered 27. C 1, C 2, C 3, C 4, and C 5 are numbered 20, 22, 23, 24, and 25 respectively.

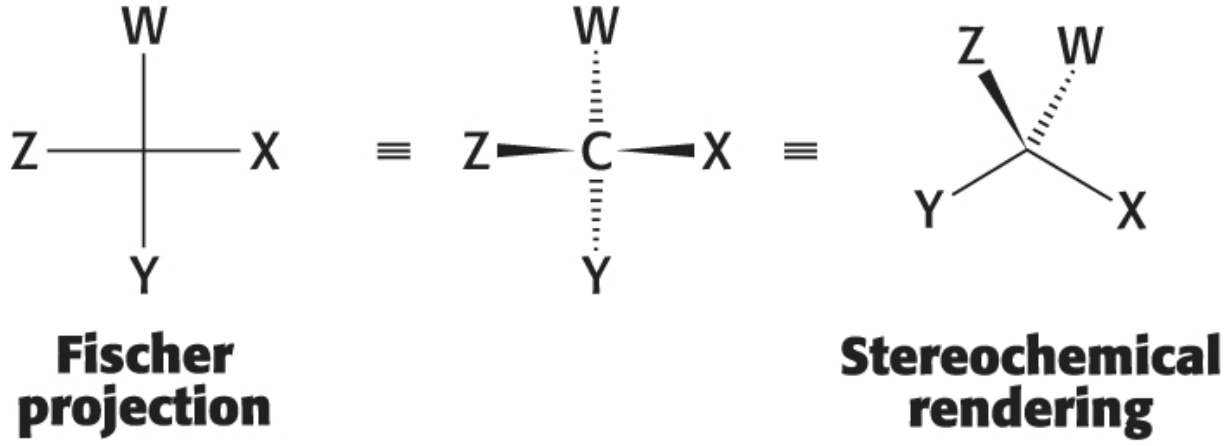
Extended description for Structure of methane and formaldehyde

Methane



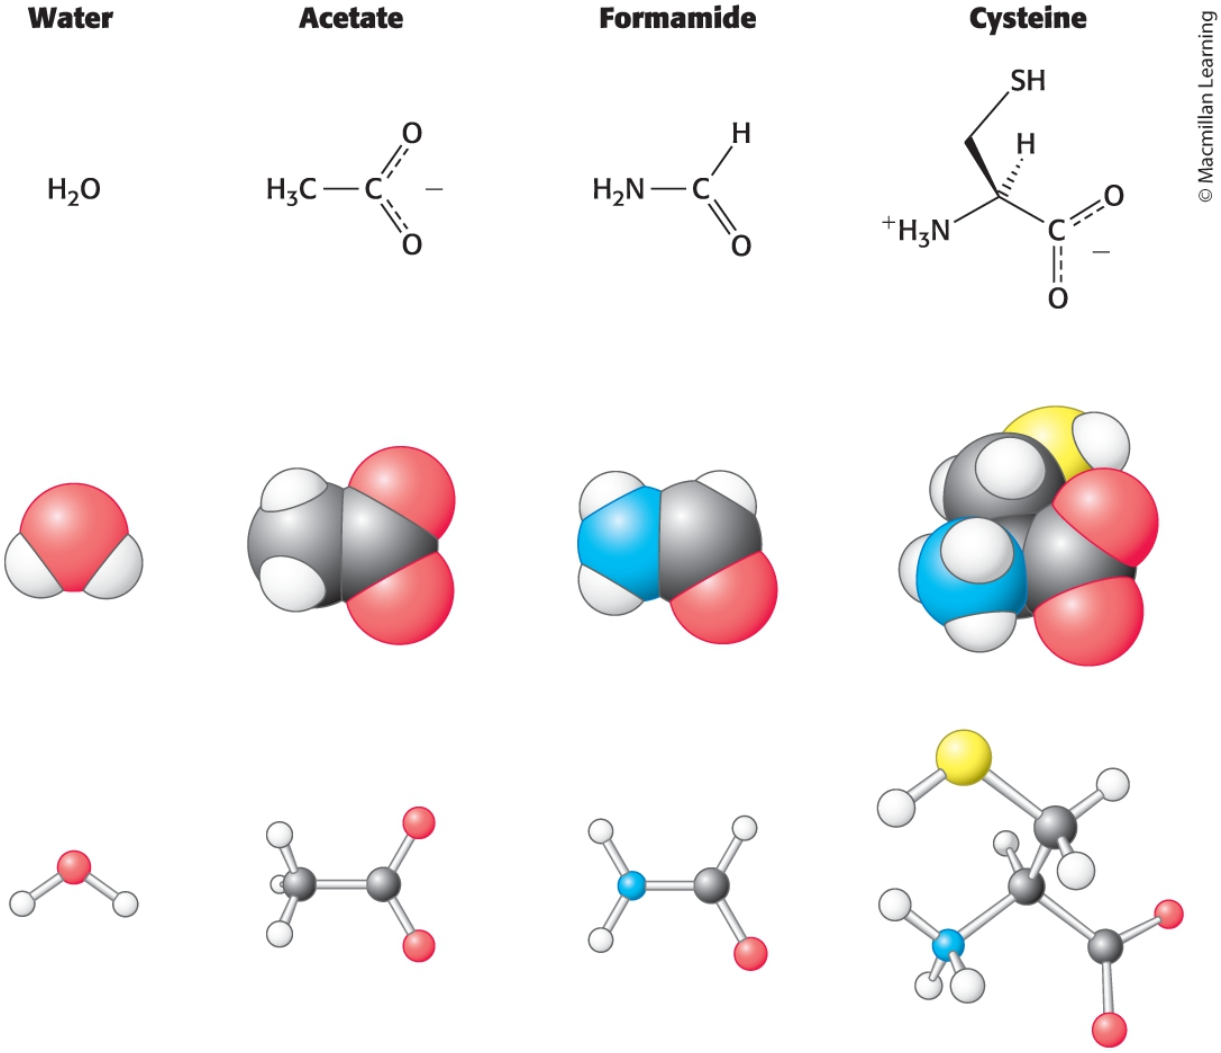
Formaldehyde

Methane has the following structure: A central C atom is dash bonded to H on the upper right, single bonded to H on the lower right and H on the lower left, and is wedge bonded to H on the upper left.

Formaldehyde has the following structure: A central C atom is double bonded to O above and is single bonded to H on the lower right and H on the lower left.

Return to Structure of methane and formaldehyde

Extended description for Structure of a molecule with its Fischer projection and stereochemical rendering



The molecule has the following structure: A central C atom is dash bonded to W above, wedge bonded to X on the right, dash bonded to Y below, and wedge bonded to Z on the left.

The Fischer projection consists of a central C atom depicted as a dot with a vertical line passing through it with W at the top and Y at the bottom, and a horizontal line passing through it with X on the right and Z on the left.

The stereochemical rendering shows a central C atom dash bonded to W on the upper right, single bonded to X on the lower right and Y on the lower left, and wedge bonded to Z on the upper left.

In each space-filling and ball-and-stick model, an H atom is depicted as a small white sphere, an O atom is depicted as a red sphere, a C atom is depicted as a black sphere, an N atom is depicted as a blue sphere, and an S atom is depicted as a large yellow sphere.

Water: Structural formula: H 2 O.

Space-filling model: A large central red sphere is fused to a white sphere on the lower right and a white sphere on the lower left.

Ball-and-stick model: A central red sphere is single bonded to a white sphere on the lower right and a white sphere on the lower left.

Acetate: Structural formula: A central C atom carrying a negative charge is partially double bonded to O on the upper right, partially double bonded to a second O atom on the lower right, and is single bonded to C H 3 on the left.

Space-filling model: Two black spheres are fused horizontally. The first black sphere on the left is fused to a white sphere on the upper left toward the observer, a white sphere on the lower left toward the observer, and a white sphere on the left away from the observer. The second black sphere on the right is fused to a red sphere on the upper right toward the observer and a second red sphere on the lower right toward the observer.

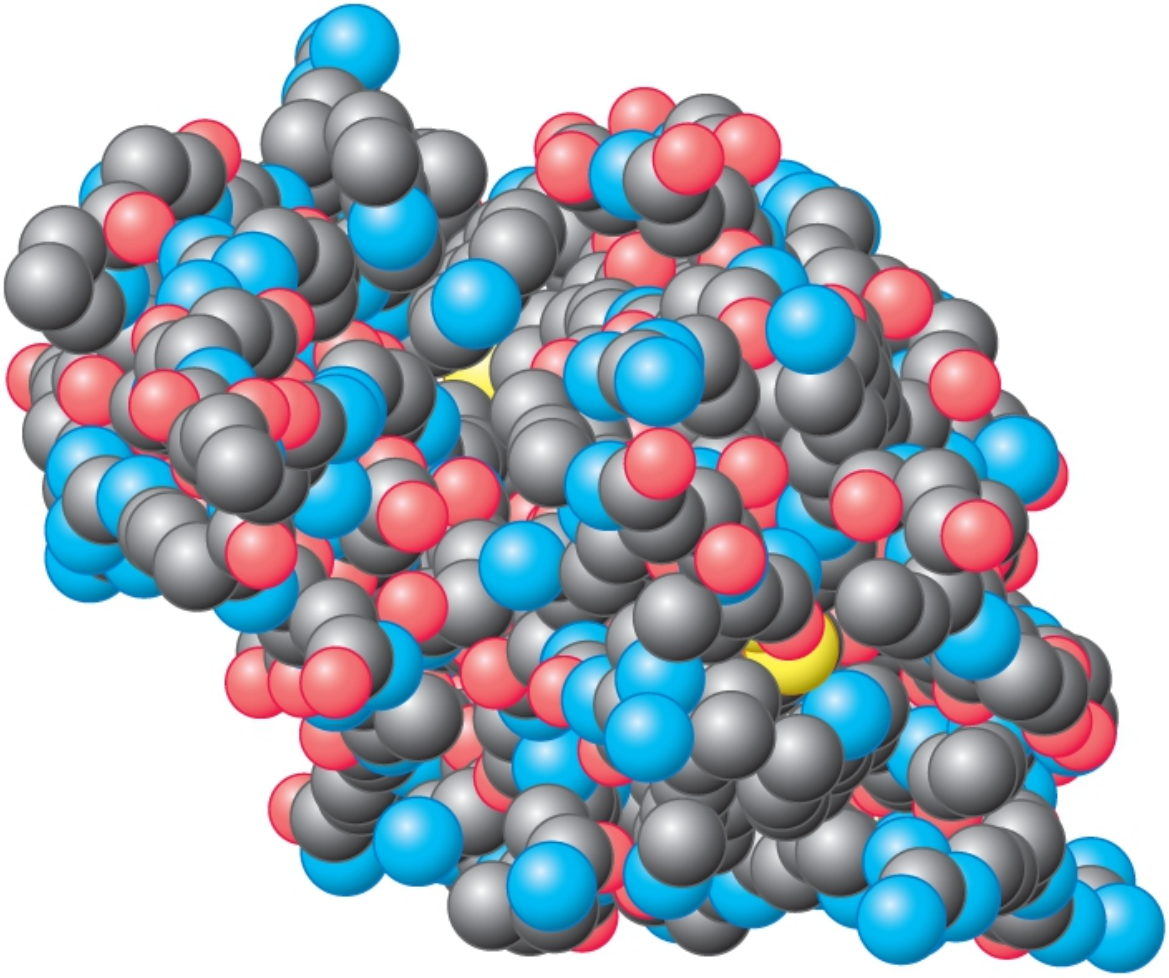
Ball-and-stick model: Two black spheres are single bonded to each other. The first black sphere on the left is single bonded to a white sphere on the upper left toward the observer, a white sphere on the lower left toward the observer, and a white sphere on the left away from the observer. The second black sphere on the right is single bonded to a red sphere on the upper right toward the observer and a second red sphere on the lower right toward the observer.

Formamide: Structural Formula: A central C atom is single bonded to H on the upper right, double bonded to O on the lower right, and single bonded to N H 2 on the left.

Space-filling model: A blue sphere is fused to a black sphere on the right. The blue sphere is fused to a white sphere on the upper left

toward the observer, and a white sphere on the lower left toward the observer. The black sphere is fused to a white sphere on the upper right toward the observer and a red sphere on the lower right toward the observer.

Ball-and-stick model: A blue sphere is single bonded to a black sphere on the right. The blue sphere is single bonded to a white sphere on the upper left toward the observer, and a white sphere on the lower left toward the observer. The black sphere is single bonded to a white sphere on the upper right toward the observer and is double bonded to a red sphere on the lower right toward the observer.



Cysteine: Structural Formula: A 2-carbon alkane chain is depicted as a line structure using 1 wedged line. C 1 is single bonded to S H on the upper right. C 2 is dash bonded to H on the upper right, single bonded to N H 3 superscript plus on the lower left, and is single bonded to a central C atom carrying a negative charge on the lower right. The central C atom is partially double bonded to O on the upper right and a second O atom below.

Space-filling model: A central black sphere is fused to a second black sphere on the upper left away from the observer, a third black sphere on the upper right toward the observer, a blue sphere on the lower left toward the observer, and a white sphere not visible to the observer. The second black sphere is fused to a white sphere on the upper right toward the observer, a white sphere on the upper left away from the observer, and a yellow sphere on the upper right away from the observer. The yellow sphere is fused to a white sphere on the upper right away from the observer. The second black sphere is fused to a red sphere on the upper right and a second red sphere on the lower right. The blue sphere is fused to a white sphere on the upper right toward the observer, a white sphere below, and a white sphere on the upper left away from the observer.

Ball-and-stick model: A central black sphere is single bonded to a white sphere on the upper left away from the observer, a second black sphere on the upper right toward the observer, a third black sphere on the lower right, and a blue sphere on the lower left. The second black sphere is single bonded to a white sphere on the upper right away from the observer, a white sphere on the lower right toward the observer, and a yellow sphere on the upper left. The yellow sphere is single bonded to a white sphere on the lower left toward the observer. The third black sphere is single bonded to a red sphere on the upper right away from the observer, and a second red sphere below. The blue sphere is single bonded to a white sphere on the lower right toward the observer, a white sphere on the lower left away from the observer, and a white sphere on the upper left toward the observer.

© Macmillan Learning

In the space-filling model, an O atom is depicted as a red sphere, a C atom is depicted as a black sphere, an N atom is depicted as a blue sphere, and an S atom is depicted as a large yellow sphere. The model shows a large number of red, blue, and black spheres and one yellow sphere fused together forming an aggregated cluster.

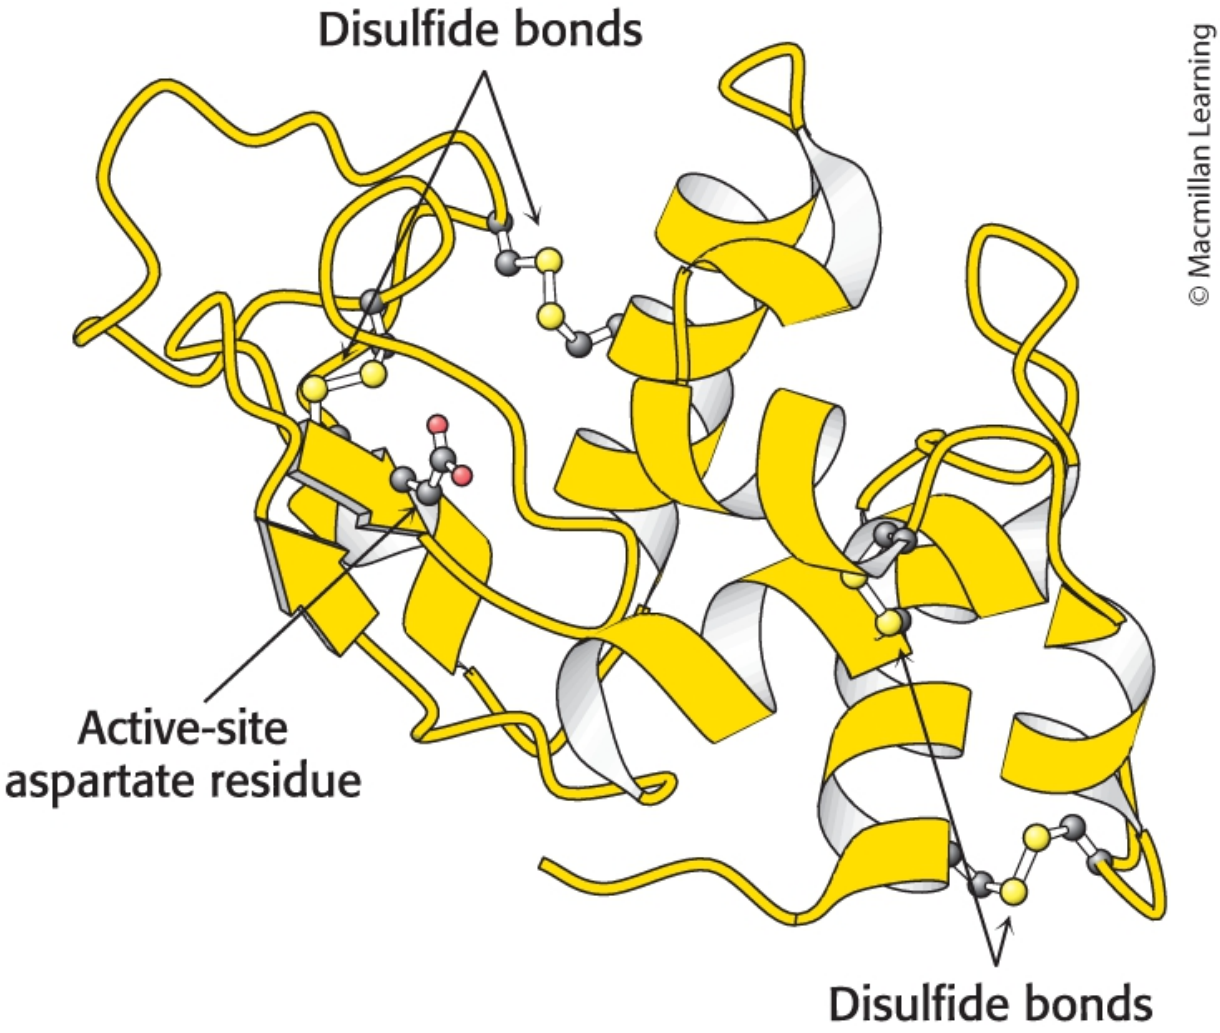
Extended description for FIGURE 5 In a simple ribbon diagram, the *α* helices are shown as coiled ribbons and a strands are depicted as arrows

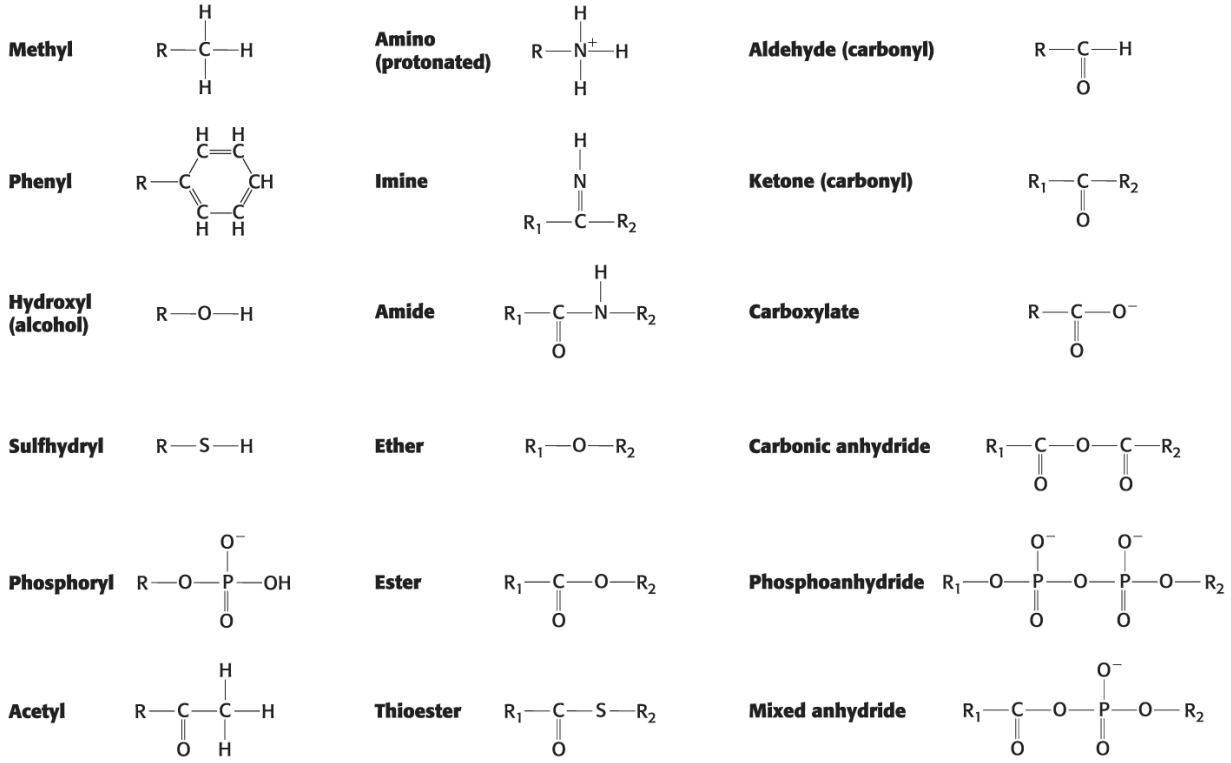


© Macmillan Learning

In the simple ribbon diagram, three alpha helices depicted as coiled yellow ribbons are shown on the right connected by thin thread-like loops. Two antiparallel beta strands are shown on the lower left depicted as arrows pointing toward the upper left and lower right, respectively.

Return to FIGURE 5 In a simple ribbon diagram, the *α* helices are shown as coiled ribbons and a strands are depicted as arrows

Extended description for FIGURE 6 An enhanced ribbon diagram may show functionally important areas using ball-and-stick



In the enhanced ribbon diagram, three alpha helices depicted as coiled yellow ribbons are shown on the right connected by thin thread-like loops. Two antiparallel beta strands are shown on the lower left depicted as arrows pointing toward the upper left and lower right, respectively. Five ball-and-stick models are shown in which an O atom is depicted as a red sphere, a C atom is depicted as

a black sphere, and an S atom is depicted as a large yellow sphere. A disulfide bond consists of a zigzag chain of four black spheres and two yellow spheres, in which the yellow spheres occupy the third and fourth positions. Two disulfide bonds are present on the upper left, one on the center right, and one on the lower right. An active-site aspartate residue shown on the lower left, consists of a zigzag chain of three black spheres. The third black sphere is double bonded to a red sphere above and is single bonded to a second red sphere on the lower right.

Extended description for FIGURE 7 Structures of various functional groups

Methyl: A central C atom is single bonded to H above, H on the right, H below, and R on the left.

Amino (protonated): A central N atom carrying a positive charge is single bonded to H above, H on the right, H below, and R on the left.

Aldehyde (carbonyl): A central C atom is single bonded to H on the right, double bonded to O below, and single bonded to R on the left.

Phenyl: A benzene ring is in a horizontal orientation with a C atom occupying each vertex and C 1 occupying the rightmost vertex. The ring contains alternating double bonds between C 1 and C 2, C 3 and

C 4, and C 5 and C 6. C 1 to C 3, C 5, and C 6 are each bound to H. C 4 is single bonded to R.

Imine: A vertical chain is illustrated by H, single bond, N, double bond, C. C is single bonded to R 1 on the left and R 2 on the right.

Ketone (carbonyl): A central C atom is double bonded to O below, and single bonded to R 1 on the left and R 2 on the right.

Hydroxyl (alcohol): A central O atom is single bonded to H on the right, and R on the left.

Amide: R 1, single bond, C, single bond, N, single bond, R 2. C is double bonded to O below. N is single bonded to H above.

Carboxylate: A central C atom is single bonded to O superscript minus on the right, double bonded to O below, and is single bonded to R on the left.

Sulfhydryl: A central S atom is single bonded to H on the right and R on the left.

Ether: A central O atom is single bonded to R 1 on the left and R 2 on the right.

Carbonic anhydride: R 1, single bond, C, single bond, O, single bond, C, single bond, R 2. C 1 and C 2 are each double bonded to O below.

Phosphoryl: R, single bond, O, single bond, P, single bond, O H. P is single bonded to O superscript minus above and is double bonded to a second O atom below.

Ester: R 1, single bond, C, single bond, O, single bond, R 2. C is double bonded to a second O atom below. Phosphoanhydride: R 1, single bond, O, single bond, P, single bond, O, single bond, P, single bond, O, single bond, R 2. Each P atom is single bonded to O superscript minus above and is double bonded to an O atom below.

Acetyl: R, single bond, C, single bond, C, single bond, H. C 1 is double bonded to O below. C 2 is single bonded to H above and H below.

Thioester: R 1, single bond, C, single bond, S, single bond, R 2. C is double bonded to a second O atom below.

Mixed anhydride: R 1, single bond, C, single bond, O, single bond, P, single bond, O, single bond, R 2. C is double bonded to a third O atom below. P is single bonded to O superscript minus above and is double bonded to a fourth O atom below.

Extended description for Reaction between ammonia, N H 3, and methyl iodide, H 3 C, single bond, I and its mechanism

The reaction contains two reactants and two products. The first reactant is H 3 N in which N has a lone pair of electrons. The second reactant is H 3 C, single bond, I. A curved arrow from the lone pair of electrons in the first reactant points to C of H 3 C in the second reactant. A second curved arrow from the single bond in the second reactant between H 3 C and I points to I. The first product is H 3 N superscript plus, single bond, C H 3. The second product is I superscript minus.
